Abstract. This paper deals with state-constrained optimal control problems governed by semilinear parabolic equations. We establish a minimum principle of Pontryagin's type. To deal with the state constraints, we introduce a penalty problem by using Ekeland's principle. The key tool for the proof is the use of a special kind of spike perturbations distributed in the domain where the controls are defined. Conditions for normality of optimality conditions are given.

Key words. Pontryagin principle, boundary control, semilinear parabolic equations, optimality conditions, state constraints

1. Introduction.

In the last years, some proofs of minimum principles of Pontryagin's type have appeared. For long time, the optimality conditions for control problems governed by partial differential equations (PDEs) have been given in an integral form, assuming the convexity of the control set and the differentiability with respect to the control and state of all functions involved in the problem. This makes a big difference with the control theory for problems governed by ordinary differential equations (ODEs), where a Pontryagin principle is derived without the previous assumptions. In my opinion, the reason for this difference is the difficulty of extending the methods used for ODEs to infinite-dimensional systems. In particular, the classical spike perturbations of the controls localized around a point do not work properly for PDEs because they lead to some equations with Dirac measures as data, which produce noncontinuous solutions. This makes it difficult to treat the state constraints, especially the pointwise state constraints.

A new type of spike perturbation was developed by a group of mathematicians from Fudan University; see Li [25], Li and Yao [26], and Li and Yong [27]. They used these perturbations to study control problems of evolution equations. The spike perturbations were defined by using the representation of the state given by the corresponding semigroup. This idea was also followed by Fattorini [17], [18]; Fattorini and Frankowska [19]; and Fattorini and Murphy [20], [21]. Later Yong [33] and Casas and Yong [14] built a similar kind of spike perturbations for elliptic equations by using the representation of the solution with the aid of the Green function. Afterwards, Casas suggested a new construction of the set where the perturbations were localized; see Casas [11] and Bei Hu and Yong [22]. This construction was independent of the equation. For a different viewpoint explaining the true nature of this new type of spike perturbations, the reader is referred to Casas [12], where the boundary control of a quasi-linear elliptic equation was considered.

Bonnans and Casas [5], [6] followed a different approach to derive Pontryagin's principle that did not use this type of spike perturbations. However, it was necessary

to assume a stability condition of the optimal cost functional with respect to small perturbation of the feasible state set.

In this paper, we consider a boundary control problem governed by a parabolic semilinear equation. General state constraints are included in the formulation of the problem. The idea developed in [12] is used here. To deal with the state constraints we penalize them. The lack of convexity of the control set and the noncontinuity with respect to the control of the functions involved in the control problem make it difficult to formulate a penalty problem having a solution converging to the optimal control of the original problem, however. Ekeland's variational principle is the key to obtaining the suitable penalization.

Pontryagin's principle is often established in a nonqualified form, which implies that the cost functional does not appear in the conditions for optimality. In the absence of equality state constraints, we give a condition that leads to a qualified optimality system. This condition was introduced by Bonnans [4] and Bonnans and Casas [6]. It consists of assuming a certain kind of Lipschitz dependence of the optimal cost functional with respect to small perturbations of the state constraint. It is proved that this condition is satisfied "almost everywhere (a.e.)." We will distinguish strong and weak Pontryagin principles, depending on whether the optimality system is qualified or not. To prove the strong principle we make an exact penalization of the state contraints.

One of the difficulties found in the optimality system is the adjoint state equation. This equation can have measures as data in the domain, on the boundary, and as a final condition. There are not many papers written about parabolic equations involving measures. For these equations the reader is referred to Barbu and Precupanu [1], Lasiecka [24], Tröltzsch [32], and Boccardo and Gallouët [3], the last one dealing with quasi-linear equations. Here we use the transposition method to derive a general result of existence and "uniqueness" of solution. Since we do not assume continuity of the coefficients of the state equation, we need to be precise in which sense the solution is unique; see Serrin [30] for a nonuniqueness result in $W_0^{1,p}(\Omega)$ $(p < 2)$ of an elliptic problem well posed in $H^1(\Omega)$.

The paper is organized as follows. In the next section, the control problem is formulated. The state constraints are presented in an abstract framework. We show through some examples how the usual state constraints are included in the abstract formulation. The weak and strong Pontryagin principles are formulated in sections 3 and 4, respectively. In section 5, the state equation is studied and the spike perturbations are defined. The linear parabolic equations involving measures are analyzed in section 6. All the mentioned papers dealing with control of evolution equations, except [22], followed the semigroup approach to analyze the state and adjoint state equations. Here we will follow the variational approach, which allows us to obtain some pointwise information of the solutions of the PDEs. This information is very important for studying the control problems with pointwise state constraints. Finally, the proofs of weak and strong principles are given in section 7.

2. Setting of the control problem. Let $\Omega \subset \mathbb{R}^n$, $n \geq 1$, be an open and bounded set, with Lipschitz boundary Γ. Given $0 < T < +\infty$, we set $\Omega_T = \Omega \times (0,T)$ and $\Sigma_T = \Gamma \times (0,T)$. Let $(\mathcal{K}, d)$ be a metric space and let us consider a function $f : \Sigma_T \times \mathbb{R} \times \mathcal{K} \longrightarrow \mathbb{R}$ of class C^1 with respect to the second variable and satisfying the following assumptions:

$$\frac{\partial f}{\partial y}(x,t,y,u) \leq 0 \quad \forall (x,t,y,u) \in \Sigma_T \times \mathbb{R} \times \mathcal{K}; \tag{2.1}$$

$$\text{(2.2)}\qquad \begin{cases} \forall M>0\ \exists C_M>0 \text{ such that } \forall (x,t,u)\in \Sigma_T\times\mathcal{K} \text{ and } |y|\le M, \\ |f(x,t,0,u)|+\left|\dfrac{\partial f}{\partial y}(x,t,y,u)\right|\le C_M. \end{cases}$$

The state equation is as follows:

$$\text{(2.3)}\qquad \begin{cases} \dfrac{\partial y}{\partial t}(x,t)+Ay(x,t)+a_0(x,t,y(x,t))=0 & \text{in } \Omega_T, \\ \partial_{\nu_A}y(x,t)=f(x,t,y(x,t),u(x,t)) & \text{on } \Sigma_T, \\ y(x,0)=y_0(x) & \text{in } \Omega, \end{cases}$$

where $y_0\in C(\bar\Omega)$, A is the linear operator

$$\text{(2.4)}\qquad \begin{aligned} Ay= & -\sum_{j=1}^n \partial_{x_j}\left\{\sum_{i=1}^n [a_{ij}(x,t)\partial_{x_i}y(x,t)]+b_j(x,t)y(x,t)\right\} \\ & +\sum_{j=1}^n d_j(x,t)\partial_{x_j}y(x,t)+c(x,t)y(x,t), \end{aligned}$$

and

$$\text{(2.5)}\qquad \partial_{\nu_A}y(x,t)=\sum_{j=1}^n\left\{\sum_{i=1}^n [a_{ij}(x,t)\partial_{x_i}y(x,t)]+b_j(x,t)y(x,t)\right\}\nu_j(x),$$

$\nu(x)$ being the outward unit normal vector to Γ at the point x; see Casas [9] or Casas and Fernández [13] for an interpretation of this Neumann condition in a trace sense. Function $a_0:\Omega_T\times\mathbb{R}\longrightarrow\mathbb{R}$ is a Carathéodory function of class C^1 with respect to the second variable and satisfies the following assumptions:

$$\text{(2.6)}\qquad \begin{cases} \exists \psi_0\in L^{\hat p}([0,T],L^{\hat q}(\Omega)) \text{ and } C_1>0 \text{ such that} \\ a_0(x,t,y)y\ge \psi_0(x,t)-C_1y^2 \quad \forall (x,t,y)\in\Omega_T\times\mathbb{R}; \end{cases}$$

$$\text{(2.7)}\qquad \begin{cases} a_0(\cdot,\cdot,0)\in L^{\hat p}([0,T],L^{\hat q}(\Omega)) \text{ and } \forall M>0\ \exists C_M>0 \text{ such that} \\ \left|\dfrac{\partial a_0}{\partial y}(x,t,y)\right|\le C_M\ \forall (x,t)\in\Omega_T, |y|\le M; \end{cases}$$

where $\hat q,\hat p\in[1,+\infty]$ and $1/\hat p+n/2\hat q<1$.

As usual, we assume the following hypotheses on A:

$$\text{(2.8)}\qquad \begin{cases} a_{ij},b_j,d_j,c\in L^\infty(\Omega_T)\quad \forall i,j=1,\dots,n; \\ \displaystyle\sum_{i.j=1}^n a_{ij}(x,t)\xi_i\xi_j\ge\Lambda|\xi|^2\quad \forall\xi\in\mathbb{R}^n \text{ a.e. } (x,t)\in\Omega_T, \text{ with } \Lambda>0. \end{cases}$$

Once given the state equation, we introduce the cost functional

$$J(u)=\int_{\Omega_T}L(x,t,y_u(x,t))dxdt+\int_{\Sigma_T}l(x,t,y_u(x,t),u(x,t))d\sigma(x)dt,$$

where y_u is the solution of (2.3) associated with u; σ denotes the usual $(n-1)$-dimensional measure on Γ induced by the parametrization (remember that Γ is a Lipschitz manifold); and $L : \Omega_T \times \mathbb{R} \longrightarrow \mathbb{R}$ and $l : \Sigma_T \times \mathbb{R} \times \mathcal{K} \longrightarrow \mathbb{R}$ are of class C^1 with respect to the second variable, L being measurable with respect to the first one, satisfying

$$\begin{cases} \forall M > 0\ \exists \psi_{dM} \in L^1(\Omega_T) \text{ such that } \forall (x,t) \in \Omega_T, |y| \le M, \\ |L(x,t,0)| + \left| \dfrac{\partial L}{\partial y}(x,t,y) \right| \le \psi_{dM}(x,t) \end{cases} \tag{2.9}$$

and

$$\begin{cases} \forall M > 0\ \exists \psi_{bM} \in L^1(\Sigma_T) \text{ such that } \forall (x,t,u) \in \Sigma_T \times \mathcal{K}, |y| \le M, \\ |l(x,t,0,u)| + \left| \dfrac{\partial l}{\partial y}(x,t,y,u) \right| \le \psi_{bM}(x,t). \end{cases} \tag{2.10}$$

The space of controls $\mathcal{U}$ is formed by the measurable functions $u : \Sigma_T \longrightarrow \mathcal{K}$ such that the mapping

$$(x,t) \in \Sigma_T \longrightarrow (f(x,t,y,u(x,t)), l(x,t,y,u(x,t))) \in \mathbb{R}^2$$

is measurable for every $y \in \mathbb{R}$. In section 5 we will prove that there exists a unique solution of (2.3) in the space $Y = C(\bar{\Omega}_T) \cap L^2([0,T], H^1(\Omega))$ for every $u \in \mathcal{U}$, so that functional $J : \mathcal{U} \longrightarrow \mathbb{R}$ is well defined.

Finally we introduce the state constraints. Let Z be a separable Banach space and $Q \subset Z$ a closed convex subset with nonempty interior. Given two mappings of class C^1, $G : Y \longrightarrow Z$ and $F : C(\bar{\Omega}_T) \longrightarrow \mathbb{R}^s$, $s \ge 1$, we formulate the optimal control problem as follows:

$$\text{Minimize } \{J(u) : u \in \mathcal{U}, G(y_u) \in Q, F(y_u) = 0\}. \tag{P}$$

Let us show how the usual examples of state constraints can be handled with this formulation.

Example 2.1. Given a continuous function $g : \bar{\Omega}_T \times \mathbb{R} \longrightarrow \mathbb{R}$ of class C^1 in respect to the second variable, the constraint $g(x,t,y_u(x,t)) \le \delta$ for all $(x,t) \in \bar{\Omega}_T$, with $\delta > 0$ being a given number, can be written in the above framework by putting $Z = C(\bar{\Omega}_T)$, $G : Y \longrightarrow C(\bar{\Omega}_T)$, defined by $G(y) = g(\cdot, y(\cdot))$, and

$$Q = \{z \in C(\bar{\Omega}_T) : z(x,t) \le \delta \quad \forall (x,t) \in \bar{\Omega}_T\}.$$

Example 2.2. Let $\{(x_j,t_j)\}_{j=1}^s \subset \bar{\Omega}_T$; then we can include the equality constraints $y_u(x_j,t_j) = \delta_j$, $1 \le j \le s$, in the above formulation. Indeed, it is enough to define the functions $F_j : C(\bar{\Omega}_T) \longrightarrow \mathbb{R}$ given by $F_j(y) = y(x_j) - \delta_j$ and to take $F = (F_1, \dots, F_s)^T$. Then F is of class C^1.

Example 2.3. Let $g : \Omega \times [0,T] \times \mathbb{R} \longrightarrow \mathbb{R}$ be a function measurable with respect to the first variable, continuous with respect to the second, of class C^1 with respect to the third, and such that $\partial g/\partial y$ is also continuous in the last two variables. Moreover, it is assumed that for every $M > 0$ there exists a function $\psi_M \in L^1(\Omega)$ such that

$$|g(x,t,0)| + \left| \frac{\partial g}{\partial y}(x,t,y) \right| \le \psi_M(x) \quad \text{a.e. } x \in \Omega \ \ \forall t \in [0,T] \text{ and } |y| \le M.$$

Then the constraint

$$\int_\Omega g(x,t,y_u(x,t))dx \le \delta \quad \forall t \in [0,T]$$

is included in the above formulation by taking $Z = C[0,T]$,

$$Q = \{z \in C[0,T] : z(t) \le \delta \quad \forall t \in [0,T]\},$$

and $G : Y \longrightarrow C[0,T]$ given by

$$G(y) = \int_\Omega g(x,\cdot,y(x,\cdot))dx.$$

Example 2.4. The constraint

$$\int_{\Omega_T} |y_u(x,t)|dxdt \le \delta$$

is considered by taking $Z = L^1(\Omega_T)$, $G : Y \longrightarrow L^1(\Omega)$, with $G(y) = y$, and Q the closed ball in $L^1(\Omega)$ of center at 0 and radius δ.

Example 2.5. For every $1 \le j \le k$ let $g_j : \Omega_T \times \mathbb{R} \longrightarrow \mathbb{R}$ be a measurable function of class C^1 with respect to the second variable such that for each $M > 0$ there exists a function $\eta_M^j \in L^1(\Omega_T)$ satisfying

$$|g_j(x,t,0)| + \left|\frac{\partial g_j}{\partial y}(x,t,y)\right| \le \eta_M^j(x,t) \quad \text{a.e. } (x,t) \in \Omega_T \ \ \forall |y| \le M.$$

Then the constraints

$$\int_\Omega g_j(x,t,y_u(x,t))dxdt \le \delta_j, \quad 1 \le j \le k,$$

are included in the formulation of (P) by choosing $G = (G_1,\dots,G_k)^T$, with

$$G_j(y) = \int_\Omega g_j(x,t,y(x,t))dxdt,$$

$Z = \mathbb{R}^k$, and $Q = (-\infty,\delta_1] \times \cdots \times (-\infty,\delta_k]$.

Example 2.6. The equality constraints

$$\int_\Omega f_j(x,t,y_u(x,t))dx = \delta_j, \quad 1 \le j \le l,$$

can also be included in problem (P) in the obvious way by assuming the same hypotheses as in Example 2.5.

Example 2.7. Integral constraints on the gradient of the state can be considered within our formulation of problem (P):

$$G(y_u) = \int_0^T \int_\Omega |\nabla_x y_u(x,t)|^2 dxdt \le \delta.$$

In this case we can take $Z = \mathbb{R}$ and $Q = (-\infty,\delta]$.

3. The weak Pontryagin principle. Before formulating the weak Pontryagin principle, we introduce some notation. Given $\alpha \geq 0$, we define the Hamiltonian $H_\alpha : \Sigma_T \times \mathbb{R} \times \mathcal{K} \times \mathbb{R} \longrightarrow \mathbb{R}$ as follows:

$$H_\alpha(x,t,y,u,\varphi) = \alpha l(x,t,y,u) + \varphi f(x,t,y,u).$$

Now we can establish Pontryagin's principle.

THEOREM 3.1. *If $\bar{u} \in \mathcal{U}$ is a solution of (P), then there exist $\bar{\alpha} \geq 0$, $\bar{y} \in C(\bar{\Omega}_T) \cap L^2([0,T], H^1(\Omega))$, and $\bar{\varphi} \in L^r([0,T], W^{1,p}(\Omega))$ for all $p, r \in [1,2)$ with $(2/r)+(n/p) > n+1$, $\bar{\mu} \in Z'$ and $\bar{\lambda} \in R^s$ such that*

$$\bar{\alpha} + \|\bar{\mu}\|_{Z'} + |\bar{\lambda}| > 0; \tag{3.1}$$

$$\begin{cases} \dfrac{\partial \bar{y}}{\partial t} + A\bar{y} + a_0(x,t,\bar{y}(x,t)) = 0 \quad \text{in } \Omega_T, \\ \partial_{\nu_A} \bar{y}(x,t) = f(x,t,\bar{y}(x,t),\bar{u}(x,t)) \text{ on } \Sigma_T, \\ \bar{y}(0) = y_0 \quad \text{in } \Omega; \end{cases} \tag{3.2}$$

$$\begin{cases} -\dfrac{\partial \bar{\varphi}}{\partial t} + A^*\bar{\varphi} + \dfrac{\partial a_0}{\partial y}(x,t,\bar{y})\bar{\varphi} = \bar{\alpha}\dfrac{\partial L}{\partial y}(x,t,\bar{y}) \\ \qquad\qquad + [DG(\bar{y})^*\bar{\mu}]|_{\Omega_T} + [DF(\bar{y})^*\bar{\lambda}]|_{\Omega_T} \quad \text{in } \Omega_T, \\ \partial_{\nu_{A^*}}\bar{\varphi} = \dfrac{\partial f}{\partial y}(x,t,\bar{y},\bar{u})\bar{\varphi} + \bar{\alpha}\dfrac{\partial l}{\partial y}(x,t,\bar{y},\bar{u}) \\ \qquad\qquad + [DG(\bar{y})^*\bar{\mu}]|_{\Sigma_T} + [DF(\bar{y})^*\bar{\lambda}]|_{\Sigma_T} \text{ on } \Sigma_T, \\ \bar{\varphi}(T) = [DG(\bar{y})^*\bar{\mu}]|_{\bar{\Omega}\times\{T\}} + [DF(\bar{y})^*\bar{\lambda}]|_{\bar{\Omega}\times\{T\}} \text{ in } \bar{\Omega}; \end{cases} \tag{3.3}$$

$$\langle \bar{\mu}, z - G(\bar{y}) \rangle \leq 0 \quad \forall z \in Q; \tag{3.4}$$

$$\begin{aligned} &\int_{\Sigma_T} H_{\bar{\alpha}}(x,t,\bar{y}(x,t),\bar{u}(x,t),\bar{\varphi}(x,t))d\sigma(x)dt \\ &= \min_{u\in\mathcal{U}} \int_{\Sigma_T} H_{\bar{\alpha}}(x,t,\bar{y}(x,t),u(x,t),\bar{\varphi}(x,t))d\sigma(x)dt; \end{aligned} \tag{3.5}$$

where A^* denotes the formal adjoint operator of A. Moreover, if one of the following assumptions is satisfied,

(A1) *Functions f and l are continuous with respect to the third variable on $(\mathcal{K}, d)$ and this space is separable;*

(A2) *There exists a set $\Sigma_T^0 \subset \Sigma_T$, with $m_{\Sigma_T}(\Sigma_T^0) = m_{\Sigma_T}(\Sigma_T)$, such that the function*

$$(x,t) \in \Sigma_T \longrightarrow (f(x,t,y,u), l(x,t,y,u)) \in \mathbb{R}^2$$

is continuous in Σ_T^0 for every $(y,u) \in \mathbb{R} \times \mathcal{K}$,
then the following pointwise relation holds:

$$\begin{aligned} &H_{\bar{\alpha}}(x,t,\bar{y}(x,t),\bar{u}(x,t),\bar{\varphi}(x,t)) \\ &= \min_{u\in\mathcal{K}} H_{\bar{\alpha}}(x,t,\bar{y}(x,t),u,\bar{\varphi}(x,t)) \quad \text{a.e.}[\sigma]\ x \in \Gamma \text{ and a.e. } t \in [0,T]. \end{aligned} \tag{3.6}$$

Remark 3.2. In the previous theorem, $[DG(\bar{y})]^*\bar{\mu}$ and $[DF(\bar{y})]^*\bar{\lambda}$ are elements of

$$Y' = C(\bar{\Omega}_T)' + L^2([0,T], H^1(\Omega))' = M(\bar{\Omega}_T) + L^2([0,T], H^1(\Omega)'),$$

where $M(\bar{\Omega}_T)$ is the space of the real and regular Borel measures in $\bar{\Omega}_T$. Let us assume that $[DG(\bar{y})]^*\bar{\mu} = \bar{\phi} + \bar{\nu}$, with $\bar{\phi} \in L^2([0,T], H^1(\Omega)')$ and $\bar{\nu} \in M(\bar{\Omega}_T)$, then we can write

$$[DG(\bar{y})]^*\bar{\mu}|_{\Omega_T} = \bar{\phi} + \bar{\nu}|_{\Omega_T}, \quad [DG(\bar{y})]^*\bar{\mu}|_{\Sigma_T} = \bar{\nu}|_{\Sigma_T}, \text{ and } [DG(\bar{y})]^*\bar{\mu}|_{\bar{\Omega}\times\{T\}} = \bar{\nu}|_{\bar{\Omega}\times\{T\}}.$$

Analogous considerations can be made for $[DF(\bar{y})]^*\bar{\lambda}$.

Let us apply the above principle to the examples given in section 2.

Example 3.3. In Example 2.1, $Z = C(\bar{\Omega}_T)$; therefore, the Lagrange multiplier $\bar{\mu}$ whose existence is established in Theorem 3.1 is a measure in $\bar{\Omega}_T$. In this case the transversality condition (3.4) is written as follows:

$$\int_{\bar{\Omega}_T} (z(x,t) - g(x,t,\bar{y}(x,t)))d\bar{\mu}(x,t) \le 0 \quad \forall z \in C(\bar{\Omega}_T) \text{ with } z(x,t) \le \delta.$$

From this relation we can deduce that $\bar{\mu}$ is a positive measure concentrated in the set of points $(x,t) \in \bar{\Omega}_T$, where $g(x,t,\bar{y}(x,t)) = \delta$. In particular, it could be a Dirac measure or a combination of Dirac measures; see Casas [7].

The adjoint state equation (3.2) now becomes

$$\begin{cases} -\dfrac{\partial\bar{\varphi}}{\partial t} + A^*\bar{\varphi} + \dfrac{\partial a_0}{\partial y}(x,t,\bar{y})\bar{\varphi} = \bar{\alpha}\dfrac{\partial L}{\partial y}(x,t,\bar{y}) + \dfrac{\partial g}{\partial y}(x,t,\bar{y})\bar{\mu}|_{\Omega_T} & \text{in } \Omega_T, \\ \partial_{\nu_{A^*}}\bar{\varphi} = \dfrac{\partial f}{\partial y}(x,t,\bar{y},\bar{u})\bar{\varphi} + \bar{\alpha}\dfrac{\partial l}{\partial y}(x,t,\bar{y},\bar{u}) + \dfrac{\partial g}{\partial y}(x,t,\bar{y})\bar{\mu}|_{\Sigma_T} & \text{on } \Sigma_T, \\ \bar{\varphi}(T) = \dfrac{\partial g}{\partial y}(x,T,\bar{y}(x,T))\bar{\mu}|_{\bar{\Omega}\times\{T\}} & \text{in } \bar{\Omega}. \end{cases}$$

Since $\partial g/\partial y$ is a continuous function in $\bar{\Omega}_T$, then the product $(\partial g/\partial y)\bar{\mu}$ is well defined and can be identified again with a measure.

Example 3.4. In Example 2.2

$$[DF(\bar{y})]^*\bar{\lambda} = \sum_{j=1}^{l} \bar{\lambda}_j \delta_{(x_j,t_j)}.$$

If the points (x_j,t_j) are all of them included in Ω_T, then the adjoint state equation is

$$\begin{cases} -\dfrac{\partial\bar{\varphi}}{\partial t} + A^*\bar{\varphi} + \dfrac{\partial a_0}{\partial y}(x,\bar{y}(x))\bar{\varphi} = \bar{\alpha}\dfrac{\partial L}{\partial y}(x,\bar{y}(x)) + \displaystyle\sum_{j=1}^{l} \bar{\lambda}_j\delta_{(x_j,t_j)} & \text{in } \Omega_T, \\ \partial_{\nu_{A^*}}\bar{\varphi} = \dfrac{\partial f}{\partial y}(x,t,\bar{y},\bar{u})\bar{\varphi} + \bar{\alpha}\dfrac{\partial l}{\partial y}(x,t,\bar{y},\bar{u}) & \text{on } \Sigma_T, \\ \bar{\varphi}(T) = 0 & \text{in } \Omega. \end{cases}$$

If some points x_j are in Γ, then the corresponding term $\bar{\lambda}_j\delta_{(x_j,t_j)}$ should appear on the Neumann condition. Analogously, if $t_j = T$ for some index j, then $\bar{\lambda}\delta_{(x_j,T)}$ should be included in the final condition.

Example 3.5. In Example 2.3, the Lagrange multiplier $\bar\mu$ is a positive Borel measure in $[0,T]$ concentrated in the set of points t where the state constraint is active and

$$DG(\bar y)^*\bar\mu = \frac{\partial g}{\partial y}(x,t,\bar y(x,t))\bar\mu(t).$$

Then we have the following equation for $\bar\varphi$:

$$\begin{cases} -\dfrac{\partial\bar\varphi}{\partial t} + A^*\bar\varphi + \dfrac{\partial a_0}{\partial y}(x,t,\bar y)\bar\varphi = \bar\alpha\dfrac{\partial L}{\partial y}(x,t,\bar y) + \dfrac{\partial g}{\partial y}(x,t,\bar y)\bar\mu|_{(0,T)} \ \text{ in } \Omega_T, \\ \partial_{\nu_{A^*}}\bar\varphi = \dfrac{\partial f}{\partial y}(x,t,\bar y,\bar u)\bar\varphi + \bar\alpha\dfrac{\partial l}{\partial y}(x,t,\bar y,\bar u) \text{ on } \Sigma_T, \\ \bar\varphi(T) = \dfrac{\partial g}{\partial y}(x,T,\bar y(x,T))\bar\mu(\{T\}) \text{ in } \Omega. \end{cases}$$

So, in particular, we have that $\bar\varphi(T) = 0$ if the state constraint is not active in T. This type of state constraints has been studied by many authors; see Barbu and Precupanu [1], Lasiecka [24], and Tröltzsch [32]. All of them consider the semigroup theory approach to deal with the state and adjoint state equations. They prove some regularity of the adjoint state $\bar\varphi$; see section 6.

Example 3.6. In Example 2.4, the Lagrange multiplier $\bar\mu$ is an element of $Z' = L^\infty(\Omega_T)$; therefore, (3.2) reduces in this case to

$$\begin{cases} -\dfrac{\partial\bar\varphi}{\partial t} + A^*\bar\varphi + \dfrac{\partial a_0}{\partial y}(x,t,\bar y)\bar\varphi = \bar\alpha\dfrac{\partial L}{\partial y}(x,t,\bar y) + \bar\mu \ \text{ in } \Omega_T, \\ \partial_{\nu_{A^*}}\bar\varphi = \dfrac{\partial f}{\partial y}(x,t,\bar y,\bar u)\bar\varphi + \bar\alpha\dfrac{\partial l}{\partial y}(x,t,\bar y,\bar u) \text{ on } \Sigma_T, \\ \bar\varphi(T) = 0 \text{ in } \Omega. \end{cases}$$

In this case, assuming more regularity for the functions ψ_{dM} and ψ_{bM} given in (2.8)–(2.9), we can obtain additional regularity for $\bar\varphi$. For instance, if we take function $\psi_{bM} \in L^{\hat p}([0,T], L^{\hat q}(\Omega))$, then $\bar\varphi \in Y$. $H^{2,1}(\Omega)$-regularity is also obtained provided that Γ is of class C^2 and the coefficients a_{ij} of A are Lipschitz in the variable x.

Example 3.7. The Lagrange multipliers in Example 2.5 are positive real numbers $\{\bar\mu_j\}_{j=1}^k$. The positivity is a consequence of the transversality condition (3.3). The adjoint state equation can be written as follows:

$$\begin{cases} -\dfrac{\partial\bar\varphi}{\partial t} + A^*\bar\varphi + \dfrac{\partial a_0}{\partial y}(x,t,\bar y)\bar\varphi = \bar\alpha\dfrac{\partial L}{\partial y}(x,t,\bar y) + \displaystyle\sum_{j=1}^k \bar\mu_j\frac{\partial g_j}{\partial y}(x,t,\bar y) \ \text{ in } \Omega_T, \\ \partial_{\nu_{A^*}}\bar\varphi = \dfrac{\partial f}{\partial y}(x,t,\bar y,\bar u)\bar\varphi + \bar\alpha\dfrac{\partial l}{\partial y}(x,t,\bar y,\bar u) \text{ on } \Sigma_T, \\ \bar\varphi(T) = 0 \text{ in } \Omega. \end{cases}$$

By increasing the regularity of functions η_j, we can improve the regularity of $\bar\varphi$ such as it was described in Example 3.6.

For the equality constraints considered in Example 2.6 the adjoint state equation is similar to the above one. The only difference is that the Lagrange multipliers can be negative.

Example 3.8. In Example 2.7, the Lagrange multiplier $\bar{\mu}$ is a nonnegative real number, $\bar{\varphi} \in Y$, and the adjoint state equation is

$$\begin{cases} -\dfrac{\partial \bar{\varphi}}{\partial t} + A^*\bar{\varphi} + \dfrac{\partial a_0}{\partial y}(x,t,\bar{y})\bar{\varphi} = \bar{\alpha}\dfrac{\partial L}{\partial y}(x,t,\bar{y}) + 2\bar{\mu}\nabla^*\nabla_x y(x,t) \ \text{ in } \Omega_T, \\ \partial_{\nu_{A^*}}\bar{\varphi} = \dfrac{\partial f}{\partial y}(x,t,\bar{y},\bar{u})\bar{\varphi} + \bar{\alpha}\dfrac{\partial l}{\partial y}(x,t,\bar{y},\bar{u}) \text{ on } \Sigma_T, \\ \bar{\varphi}(T) = 0 \text{ in } \Omega, \end{cases}$$

where $\nabla^*\nabla_x y \in L^2([0,T], H^1(\Omega)')$ is given by

$$\langle \nabla^*\nabla_x y, z\rangle = \int_{\Omega_T} \nabla_x y(x,t)\nabla_x z(x,t)dxdt.$$

The restriction of $\nabla^*\nabla_x y$ to $L^2([0,T], H_0^1(\Omega))$ is equal to $-\Delta_x y$.

4. The strong Pontryagin principle. In this section we will prove that, in the absence of equality constraints, Theorem 3.1 holds with $\bar{\alpha} = 1$ for "almost all" control problems. We will be precise about this term later. The key to achieving this result is the introduction of a stability assumption of the optimal cost functional with respect to small perturbations of the set of feasible controls. This stability allows us to accomplish an exact penalization of the state constraints. First of all let us formulate the following control problem:

$$(\mathrm{P}_\delta) \begin{cases} \text{Minimize } J(u), \\ u \in \mathcal{U},\ G(y_u) \in Q_\delta \end{cases}$$

with the same notation and assumptions of section 2 and setting $Q_\delta = Q + \bar{B}_\delta(0)$ for every $\delta > 0$.

DEFINITION 4.1. *We say that* (P_δ) *is strongly stable if there exist* $\epsilon > 0$ *and* $C > 0$ *such that*

$$\inf(\mathrm{P}_\delta) - \inf(\mathrm{P}_{\delta'}) \le C(\delta' - \delta) \quad \forall \delta' \in [\delta, \delta + \epsilon]. \tag{4.1}$$

This concept was first introduced in relation with optimal control problems by Bonnans [4]; see also Bonnans and Casas [6]. A weaker stability concept was used by Casas [8] to analyze the convergence of the numerical discretizations of optimal control problems. The following proposition states that almost all problems (P_δ) are strongly stable.

PROPOSITION 4.2. *Let* $\delta_0 \ge 0$ *be the smallest number such that* (P_δ) *has feasible controls for every* $\delta > \delta_0$. *Then* (P_δ) *is strongly stable for all* $\delta > \delta_0$ *except at most a zero Lebesgue measure set.*

Proof. It is enough to consider the function $h : (\delta_0, +\infty) \longrightarrow \mathbb{R}$ defined by

$$h(\delta) = \inf(\mathrm{P}_\delta)$$

and remark that it is a nonincreasing monotone function and, consequently, differentiable at every point of $(\delta_0, +\infty)$ except at a zero measure set. Now it is obvious to check that (P_δ) is strongly stable at every point where h is differentiable. ∎

Now we state the strong Pontryagin principle.

THEOREM 4.3. *If* (P_δ) *is strongly stable and* $\bar{u}$ *is a solution of this problem, then Theorem* 3.1 *remains to be true with* $\bar{\alpha} = 1$.

The proof of this theorem is postponed until section 7.

5. Analysis of the state equation. In this section we will see that (2.3) is well posed in $Y = C(\bar{\Omega}_T) \cap L^2([0,T], H^1(\Omega))$ for every control $u \in \mathcal{U}$. Also we will study the variations of the state with respect to some pointwise perturbations of the control which are the crucial point in the proof of Pontryagin's principle. In $\mathcal{U}$ we consider Ekeland's distance

$$d_E(u,v) = m_{\Sigma_T}\left(\{(x,t) \in \Sigma_T : u(x,t) \neq v(x,t)\}\right), \tag{5.1}$$

where m_{Σ_T} is the measure on Σ_T obtained as the product of σ and the Lebesgue measure in the interval $(0,T)$. It is easy to check that $(\mathcal{U}, d_E)$ is a complete metric space. Indeed the proof given by Ekeland [16] can be repeated in this framework.

THEOREM 5.1. *Under assumptions* (2.1)–(2.8), *problem* (2.3) *has a unique solution in* $Y = C(\bar{\Omega}_T) \cap L^2([0,T], H^1(\Omega))$ *for every control* $u \in \mathcal{U}$. *Moreover, there exists a constant* $M > 0$ *such that*

$$\|y_u\|_\infty + \|y_u\|_{L^2([0,T],H^1(\Omega))} \leq M \quad \forall u \in \mathcal{U}. \tag{5.2}$$

Finally, if $\{u_k\}_{k=1}^\infty \subset \mathcal{U}$ *is a sequence converging to* u *in* $\mathcal{U}$, *i.e.* $d_E(u_k, u) \to 0$, *then* $\{y_{u_k}\}_{k=1}^\infty$ *converges to* y_u *strongly in* Y.

Proof. The uniqueness of the solution in Y can be proved by using the Gronwall inequality in the standard way along with the monotonicity of the nonlinear terms. Let us prove the existence.

If a_0 and f are bounded functions, then the existence and uniqueness of a solution in $L^\infty([0,T], L^2(\Omega)) \cap L^2([0,T], H^1(\Omega))$ is a consequence of the monotonicity of f imposed in (2.1) and the condition on a_0 given in (2.6); see Lions [29] or Ladyzhenskaya, Solonnikov, and Ural'tseva [23] for a proof based in Galerkin's approximation of the problem. If f is not bounded, we can consider the usual truncation of the function

$$f_m(x,t,y,u) = \begin{cases} f(x,t,y,u) & \text{if } |y| \leq m, \\ f(x,t,m,u) & \text{if } y > m, \\ f(x,t,m,u) & \text{if } y < -m. \end{cases}$$

Thus hypothesis (2.2) implies the boundedness of f_m.

An analogous modification can be made on a_0. Then we deduce the existence and uniqueness of a solution $y_m \in L^\infty([0,T], L^2(\Omega)) \cap L^2([0,T], H^1(\Omega))$ for problem (2.3) with a_0 and f replaced by a_{0m} and f_m, respectively. Now thanks to the assumptions (2.1)–(2.8), we can apply the procedure of Ladyzhenskaya, Solonnikov, and Ural'tseva [23] to deduce the existence of a constant $M > 0$ independent of m and $u \in \mathcal{U}$ such that (5.2) holds for y_u replaced by y_m. This implies that

$$a_m(x,t,y_m(x,t)) = a(x,t,y_m(x,t)) \ \ \forall m \geq M$$

and

$$f_m(x,t,y_m(x,t),u(x,t)) = f(x,t,y_m(x,t),u(x,t)) \ \ \forall m \geq M.$$

Consequently, the uniqueness of a solution of (2.3) lets us obtain the identity $y_m = y_u$ and the inequality (5.2).

In order to prove the continuity of y_u, we first suppose that $y_0 \in C^\theta(\bar{\Omega}_T)$ for some constant $\theta \in (0,1]$. Then, by applying the results of di Benedetto [2], we deduce

that $y_u \in C^{\beta,\beta/2}(\bar{\Omega}_T)$ for some $\beta \in (0,\theta]$. When y_0 is not a Hölder function, we can take a sequence $\{y_{0k}\}_{k=1}^{\infty} \subset C^{\theta}(\bar{\Omega}_T)$ converging uniformly to y_0 in $\bar{\Omega}_T$. Then the corresponding solutions of (2.3), denoted by y_k, are Hölder functions. Now, by applying the methods of [23] is easy to deduce the convergence $y_k \to y_u$ in $L^{\infty}(\Omega_T)$, which proves the continuity of y_u.

Finally, the convergence $y_{u_k} \to y_u$ in $L^2([0,T],H^1(\Omega))$ when $d_E(u_k,u) \to 0$ is easily derived. The uniform convergence is obtained again by using the arguments of [23]. □

The rest of the section is devoted to the proof of the following theorem

THEOREM 5.2. *Let $u,v \in \mathcal{U}$. Given $\rho \in (0,1)$, there exist m_{Σ_T}-measurable sets $E_\rho \subset \Sigma_T$, with $m_{\Sigma_T}(E_\rho) = \rho m_{\Sigma_T}(\Sigma_T)$, such that if we define*

$$u_\rho(x,t) = \begin{cases} u(x,t) & \text{if } (x,t) \in \Sigma_T \setminus E_\rho, \\ v(x,t) & \text{if } (x,t) \in E_\rho, \end{cases}$$

and if we denote by y_ρ and y the states corresponding to u_ρ and u, respectively, then the following equalities hold:

$$y_\rho = y + \rho z + r_\rho, \quad \lim_{\rho \to 0} \frac{1}{\rho} \|r_\rho\|_Y = 0, \tag{5.3}$$

and

$$J(u_\rho) = J(u) + \rho z^0 + r_\rho^0, \quad \lim_{\rho \to 0} \frac{1}{\rho} r_\rho^0 = 0, \tag{5.4}$$

where $z \in Y$ satisfies

$$\begin{cases} \dfrac{\partial z}{\partial t} + Az + \dfrac{\partial a_0}{\partial y}(x,t,y(x,t))z = 0 \quad \text{in } \Omega_T, \\ \partial_{\nu_A} z = \dfrac{\partial f}{\partial y}(x,t,y(x,t),u(x,t))z \\ +f(x,t,y(x,t),v(x,t)) - f(x,t,y(x,t),u(x,t)) \text{ on } \Sigma_T, \\ z(x,0) = 0 \text{ in } \Omega \end{cases} \tag{5.5}$$

and

$$\begin{aligned} z^0 = &\int_{\Omega_T} \frac{\partial L}{\partial y}(x,t,y(x,t))z(x,t)dxdt + \int_{\Sigma_T} \frac{\partial l}{\partial y}(x,t,y(x,t),u(x,t))z(x,t)d\sigma(x)dt \\ &+ \int_{\Sigma_T} [l(x,t,y(x,t),v(x,t)) - l(x,t,y(x,t),u(x,t))]d\sigma(x)dt. \end{aligned} \tag{5.6}$$

The first step is the proof of the following result

PROPOSITION 5.3. *For every $0 < \rho < 1$ there exists a sequence of m_{Σ_T}-measurable sets $\{E_k\}_{k=1}^{\infty}$ satisfying*

(1) *$E_k = E_\Gamma^k \times J^k$, with $E_k \subset \Gamma$ and $J^k \subset (0,T)$, $\sigma(E_\Gamma^k) = \sqrt{\rho}\sigma(\Gamma)$, and $|J^k| = \sqrt{\rho}T$.*
(2) *$(1/\sqrt{\rho})\chi_{E_\Gamma^k} \to 1$ *weakly in $L^{\infty}(\Gamma)$; $(1/\sqrt{\rho})\chi_{J^k} \to 1$ *weakly in $L^{\infty}(0,T)$; and $(1/\rho)\chi_{E_k} \to 1$ *weakly in $L^{\infty}(\Sigma_T)$.*

Proof. We divide the proof into several steps.

Step 1. *The sets* E_Γ^k.

Let us construct the sets E_Γ^k. Since Ω is bounded and Γ is a Lipschitz manifold, we can obtain a finite collection of σ-measurable sets $\{\Gamma_r\}_{r=1}^d$ and functions $\{a_r\}_{r=1}^d$ satisfying

(i) $\bigcup_{r=1}^d \Gamma_r = \Gamma$, $\overset{o}{\Gamma}_i \bigcap \overset{o}{\Gamma}_j = \emptyset$ if $i \neq j$ and $\sigma(\Gamma) = \sum_{r=1}^d \sigma(\overset{o}{\Gamma}_r)$.

(ii) The functions $a_r : (-\Lambda_\Gamma, +\Lambda_\Gamma)^{n-1} \longrightarrow \mathbb{R}$ are Lipschitz, and for some coordinate system $(x_r', x_{r,n}) = (x_{r,1}, \dots, x_{r,n})$ in $\mathbb{R}^n$ we have that

$$\overset{o}{\Gamma}_r = \{(x_r', a_r(x_r')) : x_r' \in (-\Lambda_\Gamma, +\Lambda_\Gamma)^{n-1}\}$$

and for every set $E = \{(x_r', a_r(x_r')) : x_r' \in F\}$, with $F \subset (-\Lambda_\Gamma, +\Lambda_\Gamma)^{n-1}$ Lebesgue measurable, the following identity holds:

$$\sigma(E) = \int_F \sqrt{1 + \sum_{i=1}^{n-1} \left| \frac{\partial a_r}{\partial x_{r,i}}(x_r') \right|^2}\, dx_r'.$$

For every $k \in \mathbb{N}$ we decompose the interval $[-\Lambda_\Gamma, +\Lambda_\Gamma]$ into k closed subintervals of length $2\Lambda_\Gamma/k$ and disjoint interiors. Now we make all possible Cartesian products of these subintervals and obtain a family of cubes $\{Q_{k,i}\}_{i=1}^{k^{n-1}}$ of equal Lebesgue measure, covering $[-\Lambda_\Gamma, +\Lambda_\Gamma]^{n-1}$ and with disjoint interiors. For every $r = 1, \dots, d$ and every cube we take a measurable set $F_{k,j}^r \subset \overset{o}{Q}_{k,j}$ such that

$$\int_{F_{k,j}^r} \sqrt{1 + \sum_{i=1}^{n-1} \left| \frac{\partial a_r}{\partial x_{r,i}}(x_r') \right|^2}\, dx_r' = \sqrt{\rho} \int_{Q_{k,j}} \sqrt{1 + \sum_{i=1}^{n-1} \left| \frac{\partial a_r}{\partial x_{r,i}}(x_r') \right|^2}\, dx_r'.$$

Let us see that such an $F_{k,j}^r$ exists. For every $t \in [0,1]$ we define $Q_{k,j}(t)$ as the cube with the same center as $Q_{k,j}$ and the length of each side being equal to t times the length of the sides of $Q_{k,j}$. So $Q_{k,j}(1) = Q_{k,j}$ and $Q_{k,j}(0)$ is reduced to one point: the center of $Q_{k,j}$. Let us consider the function $g : [0,1] \longrightarrow \mathbb{R}$ defined by

$$g(t) = \int_{Q_{k,j}(t)} \sqrt{1 + \sum_{i=1}^{n-1} \left| \frac{\partial a_r}{\partial x_{r,i}}(x_r') \right|^2}\, dx_r'.$$

Then it is obvious that g is continuous and

$$0 = g(0) < \sqrt{\rho} \int_{Q_{k,j}} \sqrt{1 + \sum_{i=1}^{n-1} \left| \frac{\partial a_r}{\partial x_{r,i}}(x_r') \right|^2}\, dx_r' < g(1).$$

Therefore there exists $0 < t_0 < 1$ such that

$$g(t_0) = \sqrt{\rho} \int_{Q_{k,j}} \sqrt{1 + \sum_{i=1}^{n-1} \left| \frac{\partial a_r}{\partial x_{r,i}}(x_r') \right|^2}\, dx_r'.$$

Thus we can choose $F_{k,j}^r = Q_{k,j}(t_0)$.

Now we set

$$F_k^r = \bigcup_{i=1}^{k^{n-1}} F_{k,i}^r, \quad E_k^r = \{(x_r', a_r(x_r')) : x_r' \in F_k^r\} \subset \overset{o}{\Gamma}_r, \quad E_\Gamma^k = \bigcup_{r=1}^d E_k^r.$$

Then

$$\sigma(E_\Gamma^k)=\sum_{r=1}^d\sigma(E_k^r)=\sum_{r=1}^d\int_{F_k^r}\sqrt{1+\sum_{i=1}^{n-1}\left|\frac{\partial a_r}{\partial x_{r,i}}(x_r')\right|^2}\,dx_r'$$

$$=\sqrt{\rho}\sum_{r=1}^d\int_{[-\Lambda_\Gamma,+\Lambda_\Gamma]^{n-1}}\sqrt{1+\sum_{i=1}^{n-1}\left|\frac{\partial a_r}{\partial x_{r,i}}(x_r')\right|^2}\,dx_r'=\sqrt{\rho}\sum_{r=1}^d\sigma(\overset{o}{\Gamma}_r)=\sqrt{\rho}\sigma(\Gamma).$$

We are going to prove that

$$\frac{1}{\sqrt{\rho}}\lim_{k\to\infty}\sigma(A\cap E_\Gamma^k)=\sigma(A)\quad\forall A\subset\Gamma\ \sigma\text{ measurable.}\tag{5.7}$$

Once this is proved, the convergence $(1/\sqrt{\rho})\chi_{E_\Gamma^k}\to 1$ *weakly in $L^\infty(\Gamma)$ follows from the density of the simple functions in $L^1(\Gamma)$.

First, let us assume that $A\subset\overset{o}{\Gamma}_r$ is an open set. Let us take the open set $B\subset(-\Lambda_\Gamma,+\Lambda_\Gamma)^{n-1}$ such that $A=\{(x_r',a_r(x_r')):x_r'\in B\}$. Then, from Lemma 5.4 proved below, we deduce

$$\sigma(A)=\int_B\sqrt{1+\sum_{i=1}^{n-1}\left|\frac{\partial a_r}{\partial x_{r,i}}(x_r')\right|^2}\,dx_r'$$

$$=\frac{1}{\sqrt{\rho}}\lim_{k\to\infty}\int_{B\cap F_k^r}\sqrt{1+\sum_{i=1}^{n-1}\left|\frac{\partial a_r}{\partial x_{r,i}}(x_r')\right|^2}\,dx_r'$$

$$=\frac{1}{\sqrt{\rho}}\lim_{k\to\infty}\sigma(A\cap E_k^r)=\frac{1}{\sqrt{\rho}}\lim_{k\to\infty}\sigma(A\cap E_\Gamma^k).$$

If $A\subset\Gamma$ is an open set, then

$$\sigma(A)=\sum_{r=1}^d\sigma(A\cap\overset{0}{\Gamma}_r)=\sum_{r=1}^d\frac{1}{\sqrt{\rho}}\lim_{k\to\infty}\sigma(A\cap\overset{0}{\Gamma}_r\cap E_\Gamma^k)=\frac{1}{\sqrt{\rho}}\lim_{k\to\infty}\sigma(A\cap E_\Gamma^k).$$

Thus (5.7) holds for every open subset of Γ. Let us take a closed set $K\subset\Gamma$,

$$\sigma(K)=\sigma(\Gamma)-\sigma(\Gamma\setminus K)=\sigma(\Gamma)-\frac{1}{\sqrt{\rho}}\lim_{k\to\infty}\sigma([\Gamma\setminus K]\cap E_\Gamma^k)$$

$$=\sigma(\Gamma)-\frac{1}{\sqrt{\rho}}\lim_{k\to\infty}\left\{\sigma(E_\Gamma^k)-\sigma(K\cap E_\Gamma^k)\right\}=\frac{1}{\sqrt{\rho}}\lim_{k\to\infty}\sigma(K\cap E_\Gamma^k).$$

Finally, let $A\subset\Gamma$ be a σ-measurable set. Given $\epsilon>0$ arbitrary, we can take $K\subset\Gamma$ closed and $V\subset\Gamma$ open such that $K\subset A\subset V$ and

$$\sigma(A)-\epsilon\le\sigma(K)\le\sigma(V)\le\sigma(A)+\epsilon.$$

Then

$$\sigma(A)-\epsilon\le\sigma(K)\le\frac{1}{\sqrt{\rho}}\lim_{k\to\infty}\sigma(K\cap E_\Gamma^k)\le\frac{1}{\sqrt{\rho}}\liminf_{k\to\infty}\sigma(A\cap E_\Gamma^k)$$
$$\le\frac{1}{\sqrt{\rho}}\limsup_{k\to\infty}\sigma(A\cap E_\Gamma^k)\le\frac{1}{\sqrt{\rho}}\lim_{k\to\infty}\sigma(V\cap E_\Gamma^k)=\sigma(V)\le\sigma(A)+\epsilon,$$

which concludes the proof of (5.7).

Step 2. *The sets* J^k.

To construct the sets J^k, we decompose the interval $[0,T]$ into k closed intervals I_j^k of length T/k and disjoint interiors. For each $j=1,\dots,k$ we take a subinterval $J_j^k\subset\overset{0}{I}{}_j^k$ of length $\sqrt{\rho}T/k$ and the same center as I_j^k. Finally, we define J^k as the union of the intervals $\{J_j^k\}_{j=1}^k$. Then $|J^k|=\sqrt{\rho}T$ and the convergence $(1/\sqrt{\rho})\chi_{J^k}\to 1$ *weakly in $L^\infty(0,T)$ can be proved following the same ideas as in the previous step.

Step 3. *The sets* E_k.

Taking $E_k=E_\Gamma^k\times J^k$, it remains to prove the convergence $(1/\rho)\chi_{E_k}\to 1$ *weakly in $L^\infty(\Sigma_T)$. Given $f\in L^1(\Gamma)$ and $h\in L^1(0,T)$, we get from Steps 1 and 2 that

$$\lim_{k\to\infty}\int_{\Sigma_T}\frac{1}{\rho}\chi_{E_k}(x,t)f(x)h(t)dm_{\Sigma_T}(x,t)$$
$$=\left(\lim_{k\to\infty}\int_\Gamma\frac{1}{\sqrt{\rho}}\chi_{E_\Gamma^k}(x)f(x)d\sigma(x)\right)\left(\lim_{k\to\infty}\int_0^T\frac{1}{\sqrt{\rho}}\chi_{J^k}(t)h(t)dt\right)$$
$$=\int_{\Sigma_T}f(x)h(t)dm_{\Sigma_T}(x,t).$$

Since the functions $f(x)h(t)$, with $f\in L^1(\Gamma)$ and $h\in L^1(0,T)$, expand a subspace dense in $L^1(\Sigma_T)$, we conclude the proof. □

LEMMA 5.4. *With the notations of the above proof, the following identity holds for all open sets* $B\subset(-\Lambda_\Gamma,+\Lambda_\Gamma)^{n-1}$*:*

$$\int_B\sqrt{1+\sum_{i=1}^{n-1}\left|\frac{\partial a_r}{\partial x_{r,i}}(x_r')\right|^2}\,dx_r'=\frac{1}{\sqrt{\rho}}\lim_{k\to\infty}\int_{B\cap F_k^r}\sqrt{1+\sum_{i=1}^{n-1}\left|\frac{\partial a_r}{\partial x_{r,i}}(x_r')\right|^2}\,dx_r'\tag{5.8}$$

for every $r=1,\dots,d$.

Proof. Let us take a sequence $\{C_k\}_{k=1}^\infty$ of closed cubes with sides parallel to the axes and $\overset{o}{C}{}_k\cap\overset{o}{C}{}_i=\emptyset$ if $i\ne k$, so that $B=\bigcup_{k=1}^\infty C_k$; see Stein [31, pp. 167–170].

Fixed r, for each cube C_l, it is obvious that

$$\int_{C_l}\sqrt{1+\sum_{i=1}^{n-1}\left|\frac{\partial a_r}{\partial x_{r,i}}(x_r')\right|^2}\,dx_r'=\lim_{k\to\infty}\sum_{Q_{k,j}\subset C_l}\int_{Q_{k,j}}\sqrt{1+\sum_{i=1}^{n-1}\left|\frac{\partial a_r}{\partial x_{r,i}}(x_r')\right|^2}\,dx_r'$$
$$=\frac{1}{\sqrt{\rho}}\lim_{k\to\infty}\sum_{Q_{k,j}\subset C_l}\int_{F_{k,j}^r}\sqrt{1+\sum_{i=1}^{n-1}\left|\frac{\partial a_r}{\partial x_{r,i}}(x_r')\right|^2}\,dx_r'$$
$$=\frac{1}{\sqrt{\rho}}\lim_{k\to\infty}\int_{C_l\cap F_k^r}\sqrt{1+\sum_{i=1}^{n-1}\left|\frac{\partial a_r}{\partial x_{r,i}}(x_r')\right|^2}\,dx_r'.$$

Now, given $\epsilon > 0$ there exists $k_\epsilon \in \mathbb{N}$ such that

$$\left| \int_B \sqrt{1 + \sum_{i=1}^{n-1} \left| \frac{\partial a_r}{\partial x_{r,i}}(x'_r) \right|^2} dx'_r - \sum_{l=1}^{k_\epsilon} \int_{C_l} \sqrt{1 + \sum_{i=1}^{n-1} \left| \frac{\partial a_r}{\partial x_{r,i}}(x'_r) \right|^2} dx'_r \right| < \epsilon.$$

From here it follows

$$\int_B \sqrt{1 + \sum_{i=1}^{n-1} \left| \frac{\partial a_r}{\partial x_{r,i}}(x'_r) \right|^2} dx'_r - \epsilon$$

$$\leq \sum_{l=1}^{k_\epsilon} \int_{C_l} \sqrt{1 + \sum_{i=1}^{n-1} \left| \frac{\partial a_r}{\partial x_{r,i}}(x'_r) \right|^2} dx'_r$$

$$= \lim_{k\to\infty} \frac{1}{\sqrt{\rho}} \sum_{l=1}^{k_\epsilon} \int_{C_l \cap F_k^r} \sqrt{1 + \sum_{i=1}^{n-1} \left| \frac{\partial a_r}{\partial x_{r,i}}(x'_r) \right|^2} dx'_r$$

$$\leq \liminf_{k\to\infty} \frac{1}{\sqrt{\rho}} \int_{B \cap F_k^r} \sqrt{1 + \sum_{i=1}^{n-1} \left| \frac{\partial a_r}{\partial x_{r,i}}(x'_r) \right|^2} dx'_r \leq$$

$$\limsup_{k\to\infty} \frac{1}{\sqrt{\rho}} \int_{B \cap F_k^r} \sqrt{1 + \sum_{i=1}^{n-1} \left| \frac{\partial a_r}{\partial x_{r,i}}(x'_r) \right|^2} dx'_r$$

$$\leq \limsup_{k\to\infty} \frac{1}{\sqrt{\rho}} \sum_{l=1}^{k_\epsilon} \int_{C_l \cap F_k^r} \sqrt{1 + \sum_{i=1}^{n-1} \left| \frac{\partial a_r}{\partial x_{r,i}}(x'_r) \right|^2} dx'_r + \frac{\epsilon}{\sqrt{\rho}}$$

$$= \sum_{l=1}^{k_\epsilon} \int_{C_l} \sqrt{1 + \sum_{i=1}^{n-1} \left| \frac{\partial a_r}{\partial x_{r,i}}(x'_r) \right|^2} dx'_r + \frac{\epsilon}{\sqrt{\rho}}$$

$$\leq \int_B \sqrt{1 + \sum_{i=1}^{n-1} \left| \frac{\partial a_r}{\partial x_{r,i}}(x'_r) \right|^2} dx'_r + \left(1 + \frac{1}{\sqrt{\rho}}\right) \epsilon.$$

Since $\epsilon > 0$ is arbitrary, the previous relations conclude the proof. □

Finally, we are ready to prove Theorem 5.2.

Proof of Theorem 5.2. Let $\rho \in (0,1)$ be fixed. Applying Proposition 5.3, we deduce the existence of measurable sets $\{E_k\}_{k=1}^\infty$ such that $m_{\Sigma_T}(E_k) = \rho m_{\Sigma_T}(\Sigma_T)$ and $(1/\rho)\chi_{E_k} \to 1$ *weakly in $L^\infty(\Sigma_T)$. For every $k \in \mathbb{N}$, we set

$$u_k(x,t) = \begin{cases} u(x,t) & \text{if } (x,t) \in \Sigma_T \setminus E_k, \\ v(x,t) & \text{if } (x,t) \in E_k, \end{cases}$$

and we denote by y_k and y the states corresponding to u_k and u, respectively. Now, subtracting the equations satisfied by y_k and y, and putting $z_k = (y_k - y)/\rho$ we obtain

$$\begin{cases} \dfrac{\partial z_k}{\partial t} + Az_k + c_k(x,t)z_k = 0 \quad \text{in } \Omega_T, \\ \partial_{\nu_A} z_k = b_k(x,t)z_k + h(x,t)\dfrac{1}{\rho}\chi_{E_k} \text{ on } \Sigma_T, \\ z(x,0) = 0 \text{ in } \Omega, \end{cases} \tag{5.9}$$

where

$$c_k(x,t) = \int_0^1 \frac{\partial a_0}{\partial y}(x,t,y(x,t) + \tau[y_k(x,t) - y(x,t)])d\tau,$$

$$b_k(x,t) = \int_0^1 \frac{\partial f}{\partial y}(x,t,y(x,t) + \tau[y_k(x,t) - y(x,t)], u_k(x,t))d\tau,$$

and

$$h(x,t) = f(x,t,y(x,t),v(x,t)) - f(x,t,y(x,t),u(x,t)).$$

By subtracting (5.9) and (5.5) and writing $\zeta_k = z_k - z$, we deduce

$$\begin{cases} \dfrac{\partial \zeta_k}{\partial t} + A\zeta_k + c_k(x,t)\zeta_k = \left[\dfrac{\partial a_0}{\partial y}(x,t,y(x,t)) - c_k(x,t)\right] z \quad \text{in } \Omega_T, \\ \partial_{\nu_A}\zeta_k = b_k(x,t)\zeta_k + \left[b_k(x,t) - \dfrac{\partial f}{\partial y}(x,t,y(x,t),u(x,t))\right] z \\ + h(x,t)\left(\dfrac{1}{\rho}\chi_{E_k} - 1\right) \text{ on } \Sigma_T, \\ \zeta_k(x,0) = 0 \text{ in } \Omega. \end{cases} \tag{5.10}$$

Now we decompose $\zeta_k = \zeta_k^1 + \zeta_k^2$, with

$$\begin{cases} \dfrac{\partial \zeta_k^1}{\partial t} + A\zeta_k^1 + c_k(x,t)\zeta_k^1 = \left[\dfrac{\partial a_0}{\partial y}(x,t,y(x,t)) - c_k(x,t)\right] z \quad \text{in } \Omega_T, \\ \partial_{\nu_A}\zeta_k^1 = b_k(x,t)\zeta_k^1 + \left[b_k(x,t) - \dfrac{\partial f}{\partial y}(x,t,y(x,t),u(x,t))\right] z \text{ on } \Sigma_T, \\ \zeta_k^1(x,0) = 0 \text{ in } \Omega \end{cases} \tag{5.11}$$

and

$$\begin{cases} \dfrac{\partial \zeta_k^2}{\partial t} + A\zeta_k^2 + c_k(x,t)\zeta_k^2 = 0 \quad \text{in } \Omega_T, \\ \partial_{\nu_A}\zeta_k^2 = b_k(x,t)\zeta_k^2 + h(x,t)\left(\dfrac{1}{\rho}\chi_{E_k} - 1\right) \text{ on } \Sigma_T, \\ \zeta_k^2(x,0) = 0 \text{ in } \Omega. \end{cases} \tag{5.12}$$

Taking into account (5.2) and (2.1)–(2.8), multiplying equation (5.12) by the function $\exp(-\omega t)\zeta_k^2$, with $\omega > 0$ large enough, and integrating by parts, we deduce

$$C\left(\|\zeta_k^2\|^2_{L^2(\Omega_T)} + \|\zeta_k^2\|^2_{L^2([0,T],H^1(\Omega))}\right)$$

$$\leq \frac{\exp(-\omega T)}{2}\|\zeta_k^2(T)\|^2_{L^2(\Omega)} + \frac{\omega}{2}\int_0^T \exp(-\omega t)\int_\Omega |\zeta_k^2(x,t)|^2 dxdt$$

$$+\int_0^T \exp(-\omega t)\langle A\zeta_k^2, \zeta_k^2\rangle dt + \int_0^T \exp(-\omega t)\int_\Omega c_k(x,t)|\zeta_k^2(x,t)|^2 dxdt$$

$$= \int_0^T\int_\Gamma \exp(-\omega t) b_k(x,t)|\zeta_k^2(x,t)|^2 d\sigma(x)dt$$

$$+\int_0^T\int_\Gamma \exp(-\omega t)h(x,t)\left(\frac{1}{\rho}\chi_{E_k}(x,t)-1\right)\zeta_k^2(x,t)d\sigma(x)dt$$

$$\leq \int_0^T\int_\Gamma \exp(-\omega t)h(x,t)\left(\frac{1}{\rho}\chi_{E_k}(x,t)-1\right)\zeta_k^2(x,t)d\sigma(x)dt. \tag{5.13}$$

From here it follows that

$$\|\zeta_k^2\|^2_{L^2(\Omega_T)} \leq C'\left\|h\left(\frac{1}{\rho}\chi_{E_k}-1\right)\right\|_{C^{\beta,\beta/2}(\bar\Omega_T)'}\|\zeta_k^2\|_{C^{\beta,\beta/2}(\bar\Omega_T)} \tag{5.14}$$

for some $\beta \in (0,1]$. The Hölder regularity of ζ_k^2 follows from the assumptions (2.1)–(2.8) and the results of di Benedetto [2].

On the other hand, for $\theta \in (0,\beta)$, the inclusions

$$C^{\beta,\beta/2}(\bar\Omega_T) \subset C^{\theta,\theta/2}(\bar\Omega_T) \subset L^2(\Omega_T)$$

are compact. Then we can apply the Lions lemma [28] to obtain

$$\|\zeta_k^2\|_{C^{\theta,\theta/2}(\bar\Omega_T)} \leq \epsilon\|\zeta_k^2\|_{C^{\beta,\beta/2}(\bar\Omega_T)} + C_\epsilon\|\zeta_k^2\|_{L^2(\Omega_T)}. \tag{5.15}$$

Since y, y_k, and h are uniformly bounded, the Hölder estimate of ζ_k^2 can be chosen depending only on ρ:

$$\|\zeta_k^2\|_{C^{\beta,\beta/2}(\bar\Omega_T)} \leq C_\rho \quad \forall k \in \mathbb{N}. \tag{5.16}$$

Taking $\epsilon = \rho/(2[1+C_\rho])$ in (5.15) and using (5.14) and (5.16), it follows

$$\|\zeta_k^2\|_{C^{\theta,\theta/2}(\bar\Omega_T)} \leq \frac{\rho}{2} + C_\epsilon\left\{C'\left\|h\left(\frac{1}{\rho}\chi_{E_k}-1\right)\right\|_{C^{\beta,\beta/2}(\bar\Omega_T)'}C_\rho\right\}^{1/2}$$

$$= \frac{\rho}{2} + C'_\rho\left\|h\left(\frac{1}{\rho}\chi_{E_k}-1\right)\right\|^{1/2}_{C^{\beta,\beta/2}(\bar\Omega_T)'}. \tag{5.17}$$

Then, for ρ fixed, the convergence $(1/\rho)\chi_{E_k} \to 1$ *weakly in $L^\infty(\Sigma_T)$, the boundedness of h, and the compactness of the inclusion $L^\infty(\Sigma_T) \subset C^{\beta,\beta/2}(\bar\Omega_T)'$ implies strong convergence $(1/\rho)h\chi_{E_k} \to h$ in $C^{\beta,\beta/2}(\bar\Omega_T)'$. Therefore we can take $k_\rho \in \mathbb{N}$ large enough in such a way that

$$\left|\int_{\Sigma_T} h_0(x,t)\left(\frac{1}{\rho}\chi_{E_k}-1\right)d\sigma(x)dt\right| + \left\|h(x,t)\left(\frac{1}{\rho}\chi_{E_k}-1\right)\right\|_{C^{\beta,\beta/2}(\bar\Omega_T)'}$$

$$< \frac{\rho^2}{4(1+C'_\rho)^2} \quad \forall k \ge k_\rho, \tag{5.18}$$

where

$$h_0(x,t) = l(x,t,y(x,t),v(x,t)) - l(x,t,y(x,t),u(x,t)).$$

Let us set $E_\rho = E_{k_\rho}$, $u_\rho = u_{k_\rho}$, and the analogous changes for y_ρ, ζ_ρ, ζ^i_ρ, $i = 1, 2$. It is obvious that $d_E(u_\rho, u) \to 0$ when $\rho \to 0$. Hence Theorem 5.1 implies that $y_\rho \to y$ in Y. This convergence along with the estimates of di Benedetto [2] allow us to deduce from (5.11) the strong convergence $\zeta^1_\rho \to 0$ in Y when $\rho \to 0$. Combining this with (5.13), (5.17), and (5.18), it is easy to derive the strong convergence $\zeta_\rho \to 0$ in Y, which proves (5.3).

To conclude the proof it is enough to note that

$$\frac{J(u_\rho)-J(u)}{\rho} - z^0$$

$$= \int_{\Omega_T}\left\{\frac{L(x,t,y_\rho(x,t))-L(x,t,y(x,t))}{\rho} - \frac{\partial L}{\partial y}(x,t,y(x,t))z(x,t)\right\}dxdt$$

$$\int_{\Sigma_T}\left\{\frac{l(x,t,y_\rho(x,t),u_\rho(x,t))-l(x,t,y(x,t),u_\rho(x,t))}{\rho}\right.$$

$$\left.-\frac{\partial l}{\partial y}(x,t,y(x,t),u(x,t))z(x,t)\right\}d\sigma(x)dt$$

$$+\int_{\Sigma_T} h_0(x,t)\left(\frac{1}{\rho}\chi_{E_\rho}(x,t)-1\right)d\sigma(x)dt$$

and to take into account the convergences previously established and (5.18). □

6. Linear parabolic equations involving measure data. Let μ be a regular Borel measure in $\bar\Omega_T$. We can write $\mu = \mu_{\Omega_T} + \mu_{\Sigma_T} + \mu_T + \mu_0$, where $\mu_{\Omega_T} = \mu|_{\Omega_T}$, $\mu_{\Sigma_T} = \mu|_{\Sigma_T}$, $\mu_T = \mu|_{\bar\Omega\times\{T\}}$, and $\mu_0 = \mu|_{\bar\Omega\times\{0\}}$. The aim of this section is the study of the following problem:

$$\begin{cases} -\dfrac{\partial\varphi}{\partial t} + A^*\varphi = \mu_{\Omega_T} \text{ in } \Omega_T, \\ \partial_{\nu_{A^*}}\varphi = \mu_{\Sigma_T} \text{ on } \Sigma_T, \\ \varphi(T) = \mu_T \text{ in } \bar\Omega. \end{cases} \tag{6.1}$$

The reader is referred to Boccardo and Gallouët [3] for the study of a quasi-linear parabolic equation with a measure in Ω_T as a datum. Here we improve the results of [3] by exploiting the linearity of the equation.

Let us denote

$$Y_0 = \{y \in Y : y(x,0) = 0 \ \forall x \in \Omega\}.$$

DEFINITION 6.1. *Given $p, r \in [1,2)$, with $(2/r) + (n/p) > n+1$, we will say that a function $\varphi \in L^r([0,T], W^{1,p}(\Omega))$ is a solution of (6.1) if for every $y \in Y_0 \cap C^1(\bar{\Omega}_T)$*

$$\int_{\Omega_T} \left\{ \frac{\partial y}{\partial t}\varphi + \sum_{j=1}^{n} \left[\sum_{i=1}^{n} a_{ij} \partial_{x_i} y \partial_{x_j} \varphi + b_j y \partial_{x_j} \varphi + d_j \partial_{x_j} y \varphi \right] + cy\varphi \right\} dxdt$$

$$= \int_{\bar{\Omega}_T} y d\mu(x,t) = \int_{\Omega_T} y d\mu_{\Omega_T}(x,t) + \int_{\Sigma_T} y d\mu_{\Sigma_T}(x,t) + \int_{\bar{\Omega}} y(x,T) d\mu_T(x). \tag{6.2}$$

Let us note that (6.2) implies that $-(\partial\varphi/\partial t) + A^*\varphi = \mu_{\Omega_T}$ in the distribution sense in Ω_T. Let us take $\vec{w} = (w_1, \ldots, w_{n+1})$, with

$$w_i = \sum_{j=1}^{n} a_{ij} \partial_{x_j} \varphi + d_i \varphi, \ 1 \le i \le n, \text{ and } \ w_{n+1} = \varphi.$$

Then $\vec{w} \in L^q(\Omega_T)^{n+1}$, $q = \min\{r,p\} < (n+1)/n$, and

$$\operatorname{div}_{(x,t)} \vec{w} = \frac{\partial \varphi}{\partial t} + \sum_{i=1}^{n} \partial_{x_i} \left[\sum_{j=1}^{n} a_{ij} \partial_{x_j} \varphi + d_i \varphi \right] = \frac{\partial \varphi}{\partial t} - A^*\varphi + \sum_{i=1}^{n} b_i \partial_{x_i} \varphi + c\varphi$$

$$= -\mu_{\Omega_T} + \sum_{i=1}^{n} b_i \partial_{x_i} \varphi + c\varphi \in M(\Omega_T). \tag{6.3}$$

Thus we have $\vec{w} \in V^q(\Omega_T)$,

$$V^q(\Omega_T) = \{\vec{w} \in L^q(\Omega_T)^{n+1} : \operatorname{div}_{(x,t)} \vec{w} \in M(\Omega_T)\}.$$

This space, endowed with the graph norm, is a Banach space. We have the following result.

THEOREM 6.2 (see Casas [10]). *Given $q \in (1, (n+1)/n)$, there exists a unique continuous linear mapping $\gamma_{\nu_T} : V^q(\Omega_T) \longrightarrow W^{-1/q,q}(\partial\Omega_T)$ satisfying*

$$\gamma_{\nu_T}(\vec{w}) = \vec{w} \cdot \vec{\nu}_T \quad \forall \vec{w} \in C^1(\bar{\Omega}_T) \tag{6.4}$$

and

$$\int_{\Omega_T} \vec{w} \cdot \nabla_{(x,t)} \phi dxdt + \langle \operatorname{div}_{(x,t)} \vec{w}, \phi \rangle_{M(\Omega_T), C_b(\Omega_T)}$$

$$= \langle \gamma_{\nu_T}(\vec{w}), \gamma(\phi) \rangle_{W^{-1/q,q}(\partial\Omega_T), W^{1/q,q'}(\partial\Omega_T)} \quad \forall \phi \in W^{1,q'}(\Omega_T), \tag{6.5}$$

where $C_b(\Omega_T)$ is the space of bounded and continuous functions in Ω_T and $\vec{\nu}_T(x,t)$ is the outward unit normal vector to $\partial\Omega_T$ at the point (x,t).

By applying this theorem to the function $\vec{w}$ defined above and using (6.2) and (6.3), we have for all $y \in Y_0 \cap C^1(\bar{\Omega}_T)$

$$\langle \gamma_{\nu_T}(\vec{w}), \gamma(y) \rangle_{W^{-1/q,q}(\partial\Omega_T), W^{1/q,q'}(\partial\Omega_T)}$$

$$= \int_{\Omega_T} \vec{w} \cdot \nabla_{(x,t)} y dx dt + \langle \mathrm{div}_{(x,t)} \vec{w}, y \rangle_{M(\Omega_T), C_b(\Omega_T)}$$

$$= \int_{\Omega_T} \left\{ \frac{\partial y}{\partial t}\varphi + \sum_{i=1}^n \left[\sum_{j=1}^n a_{ij} \partial_{x_i} y \partial_{x_j} \varphi + b_i y \partial_{x_i} \varphi + d_i \partial_{x_i} y \varphi \right] + cy\varphi \right\} dx dt$$

$$- \int_{\Omega_T} y d\mu_{\Omega_T} = \int_0^T \int_\Gamma y d\mu_{\Sigma_T}(x,t) + \int_\Omega y(x,T) d\mu_T(x).$$

From the identity

$$\langle \gamma_{\nu_T}(\vec{w}), \gamma(y) \rangle_{W^{-1/q,q}(\partial\Omega_T), W^{1/q,q'}(\partial\Omega_T)} = \int_0^T \int_\Gamma y d\mu_{\Sigma_T}(x,t) + \int_\Omega y(x,T) d\mu_T(x)$$

and taking into account that

$$\vec{\nu}_T(x,t) = \begin{pmatrix} \vec{\nu}(x) \\ 0 \end{pmatrix} \quad \forall (x,t) \in \Sigma_T \quad \text{and} \quad \vec{\nu}_T(x,T) = \begin{pmatrix} \vec{0} \\ 1 \end{pmatrix} \quad \forall x \in \Omega,$$

we can identify

$$\partial_{\nu_{A^*}} \varphi = \gamma_{\nu_T}(\vec{\omega})|_{\Sigma_T} = \mu_{\Sigma_T} \quad \text{and} \quad \varphi(x,T) = \gamma_{\nu_T}(\vec{\omega})|_{\bar{\Omega}\times\{T\}} = \mu_T.$$

Now we have the following result of existence and uniqueness of solution for problem (6.1).

THEOREM 6.3. *There exists a unique function $\varphi \in L^r([0,T], W^{1,p}(\Omega))$ $\forall r,p \in [1,2)$ with $(2/r) + (n/p) > n+1$ such that it is a solution of* (6.1) *and*

$$\int_{\Omega_T} \left(\frac{\partial y}{\partial t} + Ay \right) \varphi dx dt + \int_{\Sigma_T} \partial_{\nu_A} y \varphi d\sigma(x) dt = \int_{\bar{\Omega}_T} y d\mu(x,t) \quad \forall y \in Y_0^\infty, \tag{6.6}$$

with

$$Y_0^\infty = \left\{ y \in Y_0 : \frac{\partial y}{\partial t} + Ay \in L^\infty(\Omega_T) \quad \textit{and} \quad \partial_{\nu_A} y \in L^\infty(\Sigma_T) \right\}.$$

Moreover, there exists a constant $C_{r,p} > 0$ independent of μ such that

$$\|\varphi\|_{L^r([0,T],W^{1,p}(\Omega))} \le C_{r,p} \|\mu\|_{M(\bar{\Omega}_T)}. \tag{6.7}$$

Proof. Let $\{f_k\}_k \subset C(\bar{\Omega}_T)$, $\{g_k\}_k \subset C(\Gamma \times [0,T])$ and $\{h_k\}_k \subset C(\bar{\Omega})$ such that $f_k \to \mu_{\Omega_T}$, $g_k \to \mu_{\Sigma_T}$, and $h_k \to \mu_T$ *weakly in $M(\Omega_T)$, $M(\Sigma_T)$, and $M(\bar{\Omega})$, respectively. Moreover, we can assume that

$$\|f_k\|_{L^1(\Omega_T)} \le \|\mu_{\Omega_T}\|_{M(\Omega_T)}, \quad \|g_k\|_{L^1(\Sigma_T)} \le \|\mu_{\Sigma_T}\|_{M(\Sigma_T)}, \text{ and } \|h_k\|_{L^1(\Omega)} \le \|\mu_T\|_{M(\bar{\Omega})}.$$

Let us take $\varphi_k \in Y$ such that

$$\begin{cases} -\dfrac{\partial \varphi_k}{\partial t} + A^*\varphi_k = f_k \text{ in } \Omega_T, \\ \partial_{\nu_{A^*}} \varphi_k = g_k \text{ on } \Sigma_T, \\ \varphi_k(T) = h_k \text{ in } \Omega. \end{cases} \tag{6.8}$$

Now for every $\psi = (\psi_0, \psi_1, \ldots, \psi_n) \in \mathcal{D}(\Omega_T)^{n+1}$, we denote by y_ψ the solution in Y of

$$\begin{cases} \dfrac{\partial y}{\partial t} + Ay = \psi_0 - \displaystyle\sum_{j=1}^{n} \partial_{x_j} \psi_j \text{ in } \Omega_T, \\ \partial_{\nu_A} y = 0 \text{ on } \Sigma_T, \\ y(0) = 0 \text{ in } \Omega. \end{cases} \tag{6.9}$$

Then

$$\int_{\Omega_T} \left(\psi_0 \varphi_k + \sum_{j=1}^{n} \psi_j \partial_{x_j} \varphi_k \right) dxdt = \int_{\Omega_T} \left(\frac{\partial y_\psi}{\partial t} + A y_\psi \right) \varphi_k dxdt$$

$$= \int_{\Omega_T} \left(-\frac{\partial \varphi_k}{\partial t} + A^*\varphi_k \right) y_\psi dxdt + \int_{\Sigma_T} \partial_{\nu_{A^*}} \varphi_k y_\psi d\sigma(x)dt + \int_{\Omega} \varphi_k(T) y_\psi(T) dx. \tag{6.10}$$

Using (6.8) and the properties of f_k, g_k, and h_k, we deduce from (6.8)

$$\int_{\Omega_T} \left(\psi_0 \varphi_k + \sum_{j=1}^{n} \psi_j \partial_{x_j} \varphi_k \right) dxdt$$

$$\leq \|\mu\|_{M(\bar{\Omega}_T)} \|y_\psi\|_{C(\bar{\Omega}_T)} \leq C_{r,p} \|\mu\|_{M(\bar{\Omega}_T)} \sum_{j=0}^{n} \|\psi_j\|_{L^{r'}([0,T], L^{p'}(\Omega))}, \tag{6.11}$$

the last inequality being a consequence of the estimates for the solution of (6.9); see di Benedetto [2] and Ladyzhenskaya, Solonnikov, and Ural'tseva [23]. From the density of the space $\{\psi_0 - \sum_{j=1}^{n} \partial_{x_j} \psi_j : \psi \in \mathcal{D}(\Omega_T)^{n+1}\}$ in $L^{r'}([0,T], W^{1,p}(\Omega)')$ and estimate (6.11) follows the boundedness of $\{\varphi_k\}_k$ in the space $L^r([0,T], W^{1,p}(\Omega))$. Moreover, by taking a subsequence if necessary, we can assume that $\varphi_k \to \varphi$ weakly in $L^r([0,T], W^{1,p}(\Omega))$ and (6.7) is satisfied.

Let us prove that φ does not depend on r and p. Indeed, passing to the limit in (6.10) and remembering that $y_\psi(0) = 0$, we get

$$\int_{\Omega_T} \left(\psi_0 \varphi + \sum_{j=1}^{n} \psi_j \partial_{x_j} \varphi \right) dxdt = \int_{\bar{\Omega}_T} y_\psi d\mu \quad \forall \psi \in \mathcal{D}(\Omega_T)^{n+1}. \tag{6.12}$$

It is obvious that there is at most one function φ in $L^1([0,T], W^{1,1}(\Omega))$ satisfying (6.12), which proves that φ is independent of r and p.

Given $y \in Y_0 \cap C^1(\bar{\Omega}_T)$, multiplying (6.8) by y and integrating by parts, it follows that

$$\int_{\Omega_T} \left\{ \frac{\partial y}{\partial t}\varphi_k + \sum_{j=1}^{n} \left[\sum_{i=1}^{n} a_{ij}\partial_{x_i} y \partial_{x_j}\varphi_k + b_j y \partial_{x_j}\varphi_k + d_j \partial_{x_j} y \varphi_k \right] + cy\varphi_k \right\} dxdt$$
$$= \int_{\Omega_T} f_k y dxdt + \int_{\Sigma_T} g_k y d\sigma(x)dt + \int_{\Omega} h_k y(T)dx.$$

Now passing to the limit we deduce (6.2) and consequently φ is a solution of (6.1).

Let us prove (6.6). Given $y \in Y_0^\infty$, multiplying (6.8) by y and integrating by parts, we deduce

$$\int_{\Omega_T} f_k y dxdt + \int_{\Sigma_T} g_k y d\sigma(x)dt + \int_{\Omega} h_k y(T)dx$$
$$= \int_{\Omega_T} \left(\frac{\partial y}{\partial t} + Ay \right) \varphi_k dxdt + \int_{\Sigma_T} \partial_{\nu_A} y \varphi_k d\sigma(x)dt.$$

Now (6.6) is obtained by passing to the limit.

Finally, the uniqueness of φ follows from (6.6). Indeed, the regularity results for the Neumann problem associated with the operator $(\partial/\partial t) + A$ (see [2] or [23]) prove the surjectivity of the mapping

$$y \in Y_0^\infty \longrightarrow \left(\frac{\partial y}{\partial t} + Ay, \partial_{\nu_A} y \right) \in L^\infty(\Omega_T) \times L^\infty(\Sigma_T).$$

This along with (6.6) implies that the zero function of $L^r([0,T], W^{1,p}(\Omega))$ is the only one satisfying

$$\int_{\Omega_T} \left(\frac{\partial y}{\partial t} + Ay \right) \varphi dxdt + \int_{\Sigma_T} \partial_{\nu_A} y \varphi d\sigma(x)dt = 0 \quad \forall y \in Y_0^\infty.$$

This shows the uniqueness of φ. □

An interesting case arises when $\mu = g\omega$, with $g \in C([0,T], L^2(\Omega))$ and $\omega \in M[0,T]$

$$\int_{\bar{\Omega}_T} z d\mu = \int_0^T \left(\int_\Omega z(x,t)g(x,t)dx \right) d\omega(t) \quad \forall z \in C([0,T], L^2(\Omega));$$

see Example 3.5. In this particular case we have the following result.

THEOREM 6.4. *With the above notation, there exists a unique function φ in the space $L^2([0,T], H^1(\Omega)) \cap L^\infty([0,T], L^2(\Omega))$ solution of the problem*

$$\begin{cases} -\dfrac{\partial \varphi}{\partial t} + A^*\varphi = g\omega \text{ in } \Omega_T, \\ \partial_{\nu_{A^*}} \varphi = 0 \text{ on } \Sigma_T, \\ \varphi(T) = g(T)\omega(\{T\}) \text{ in } \Omega. \end{cases} \tag{6.13}$$

Proof. Uniqueness can be obtained in the standard way. For the proof of the existence we take a sequence $\{\omega_k\}_k \subset C[0,T]$ converging *weakly to ω in $M[0,T]$ and satisfying

$$\|\omega_k\|_{L^1(\Omega_T)} \le \|\omega\|_{M[0,T]}.$$

Let us take $\varphi_k \in Y$ such that

$$\begin{cases} -\dfrac{\partial \varphi_k}{\partial t} + A^*\varphi_k = g\omega_k \text{ in } \Omega_T, \\ \partial_{\nu_{A^*}}\varphi_k = 0 \text{ on } \Sigma_T, \\ \varphi_k(T) = g(T)\omega(\{T\}) \text{ in } \Omega. \end{cases} \tag{6.14}$$

Given $f \in \mathcal{D}(\Omega_T)$, let us denote by y_f the solution in Y of the problem

$$\begin{cases} \dfrac{\partial y}{\partial t} + Ay = f \text{ in } \Omega_T, \\ \partial_{\nu_A} y = 0 \text{ on } \Sigma_T, \\ y(0) = 0 \text{ in } \Omega. \end{cases} \tag{6.15}$$

Then

$$\int_{\Omega_T} f\varphi_k dxdt = \int_{\Omega_T} \left(\frac{\partial y}{\partial t} + Ay\right)\varphi_k dxdt = \int_{\Omega_T} g\omega_k y dxdt + \int_{\Omega} \omega(\{T\})g(T)y(T)dx$$

$$\leq \|g\|_{C([0,T],L^2(\Omega))}\|\omega\|_{M[0,T]}\|y\|_{C([0,T],L^2(\Omega))}. \tag{6.16}$$

From (6.15) it follows by using the classical arguments that

$$\|y\|_{C([0,T],L^2(\Omega))} \leq C_1\|f\|_{L^1([0,T],L^2(\Omega))} \text{ and } \|y\|_{C([0,T],L^2(\Omega))} \leq C_2\|f\|_{L^2([0,T],H^1(\Omega)')}.$$

From the first inequality and (6.16) we deduce the boundedness of the sequence $\{\varphi_k\}_k$ in the space $L^\infty([0,T],L^2(\Omega))$. The second inequality leads to the boundedness of the same sequence in $L^2([0,T],H^1(\Omega))$. The rest of the proof is easy. □

As mentioned in section 3, problems of type (6.13) have been studied by Barbu and Precupanu [1], Lasiecka [24], and Tröltzsch [32].

In the case of a measure $\mu = g\omega$, with $g \in L^1[0,T]$ and $\omega \in \mathcal{M}(\bar{\Omega})$, we deduce from Theorem 6.3 and the inclusion $W^{1,p}(\Omega) \subset \mathcal{M}(\bar{\Omega}) \subset W^{1,p'}(\Omega)'$the existence of a solution $\varphi \in L^1([0,T],W^{1,p}(\Omega))$ for all $p \in [1, n/(n-1))$ and such that $\partial\varphi/\partial t \in L^1([0,T],W^{1,p'}(\Omega)')$. Hence we deduce that $\varphi \in C([0,T],W^{1,p'}(\Omega)')$ after a modification on a set of zero measure.

7. Proof of Pontryagin principle. In this section we prove Theorems 3.1 and 4.3. A crucial point in the proofs is the use of Ekeland's variational principle that we state now.

LEMMA 7.1 (see Ekeland [16]). *Let (E,d) be a complete metric space and $F : E \longrightarrow \mathbb{R} \cup \{+\infty\}$ a lower semicontinuous function, and let $e_\epsilon \in E$ satisfy*

$$F(e_\epsilon) \leq \inf_{e\in E} F(e) + \epsilon.$$

Then there exists an element $\bar{e}_\epsilon \in E$ such that

$$F(\bar{e}_\epsilon) \leq F(e_\epsilon), \quad d(\bar{e}_\epsilon, e_\epsilon) \leq \sqrt{\epsilon},$$

and

$$F(\bar{e}_\epsilon) \leq F(e) + \sqrt{\epsilon}d(e,\bar{e}_\epsilon) \quad \forall e \in E.$$

Proof of Theorem 3.1. Since Z is separable, we can take in Z a norm $\|\cdot\|_Z$ such that Z' endowed with the dual norm $\|\cdot\|_{Z'}$ is strictly convex. Then the function

$$d_Q : (Z, \|\cdot\|_Z) \longrightarrow \mathbb{R},$$

$$d_Q(z) = \inf_{y\in Q} \|y - z\|_Z$$

is convex, Lipschitz and Gâteaux differentiable at every point $z \notin Q$, with $\partial d_Q(z) = \{\nabla d_Q(z)\}$, where the Clarke's generalized gradient and the subdifferential in the sense of the convex analysis coincide for this function. Therefore, given $\xi \in \partial d_Q(y)$, we have that

$$\langle \xi, z - y\rangle + d_Q(y) \le d_Q(z) \quad \forall z \in Z. \tag{7.1}$$

Moreover, $\|\nabla d_Q(z)\|_{Z'} = 1$ for every $z \notin Q$; see Clarke [15] and Casas and Yong [14].

Let us take $J_\epsilon : \mathcal{U} \longrightarrow \mathbb{R}$ defined by

$$J_\epsilon(u) = \left\{[(J(u) - J(\bar u) + \epsilon)^+]^2 + d_Q(G(y_u))^2 + |F(y_u)|^2\right\}^{1/2}.$$

It is obvious that $J_\epsilon(u) > 0$ for every $u \in \mathcal{U}$ and $J_\epsilon(\bar u) = \epsilon$. On the other hand, thanks to Theorem 5.1 we have that J_ϵ is continuous in $(\mathcal{U}, d_E)$, with d_E defined by (5.1). Therefore we can apply Ekeland's variational principle and deduce the existence of $u^\epsilon \in \mathcal{U}$ such that

$$d_E(u^\epsilon, \bar u) \le \sqrt{\epsilon} \quad \text{and} \quad 0 < J_\epsilon(u^\epsilon) \le J_\epsilon(u) + \sqrt{\epsilon} d_E(u^\epsilon, u) \ \ \forall u \in \mathcal{U}. \tag{7.2}$$

Given $v \in \mathcal{U}$ arbitrary, let us take E_ρ and u^ϵ_ρ as in Theorem 5.2,

$$u^\epsilon_\rho(x) = \begin{cases} u^\epsilon(x) & \text{if } x \in \Sigma_T \setminus E_\rho, \\ v(x) & \text{if } x \in E_\rho. \end{cases}$$

Then with the help of (5.3) and (5.4) we get

$$\begin{aligned} -\sqrt{\epsilon} m_{\Sigma_T}(\Sigma) \le \frac{J_\epsilon(u^\epsilon_\rho) - J_\epsilon(u^\epsilon)}{\rho} &= \frac{[(J(u^\epsilon_\rho) - J(\bar u) + \epsilon)^+]^2 - [(J(u^\epsilon) - J(\bar u) + \epsilon)^+]^2}{\rho[J_\epsilon(u^\epsilon_\rho) + J_\epsilon(u^\epsilon)]} \\ &+ \frac{d_Q(G(y^\epsilon_\rho))^2 - d_Q(G(y^\epsilon))^2 + |F(y^\epsilon_\rho)|^2 - |F(y^\epsilon)|^2}{\rho[J_\epsilon(u^\epsilon_\rho) + J_\epsilon(u^\epsilon)]} \\ \xrightarrow{\rho\to 0} \left\{(J(u^\epsilon) - J(\bar u) + \epsilon)^+ z^{0,\epsilon} + \langle \xi^\epsilon, DG(y^\epsilon)z^\epsilon\rangle + \langle F(y^\epsilon), DF(y^\epsilon)z^\epsilon\rangle\right\} &/ J_\epsilon(u^\epsilon) \\ = \alpha_\epsilon z^{0,\epsilon} + \langle [DG(y^\epsilon)]^* \mu^\epsilon, z^\epsilon\rangle + \langle [DF(y^\epsilon)]^* \lambda^\epsilon, z^\epsilon\rangle, & \end{aligned} \tag{7.3}$$

where y^ϵ and y^ϵ_ρ are the states associated with u^ϵ and u^ϵ_ρ, respectively, and $z^\epsilon \in Y$ satisfies

$$\begin{cases} \dfrac{\partial z^\epsilon}{\partial t} + Az^\epsilon + \dfrac{\partial a_0}{\partial y}(x, t, y^\epsilon(x))z^\epsilon = 0 \quad \text{in } \Omega_T, \\ \partial_{\nu_A} z^\epsilon = \dfrac{\partial f}{\partial y}(x, t, y^\epsilon(x,t), u^\epsilon(x,t))z^\epsilon \\ + f(x, t, y^\epsilon(x,t), v(x,t)) - f(x, t, y^\epsilon(x,t), u^\epsilon(x,t)) \text{ on } \Sigma_T, \\ z^\epsilon(x, 0) = 0 \text{ in } \Omega, \end{cases} \tag{7.4}$$

$$z^{0,\epsilon} = \int_{\Omega_T} \frac{\partial L}{\partial y}(x,t,y^\epsilon(x,t))z^\epsilon(x,t)dxdt + \int_{\Sigma_T} \frac{\partial l}{\partial y}(x,t,y^\epsilon(x,t),u^\epsilon(x,t))z^\epsilon(x,t)d\sigma(x)dt$$

$$+ \int_{\Sigma_T} [l(x,t,y^\epsilon(x,t),v(x,t)) - l(x,t,y^\epsilon(x,t),u(x,t))]d\sigma(x)dt, \tag{7.5}$$

$$\alpha_\epsilon = \frac{(J(u^\epsilon) - J(\bar{u}) + \epsilon)^+}{J_\epsilon(u^\epsilon)}, \quad \mu^\epsilon = \frac{\xi^\epsilon}{J_\epsilon(u^\epsilon)}, \quad \lambda^\epsilon = \frac{F(y^\epsilon)}{J_\epsilon(u^\epsilon)}, \tag{7.6}$$

$$\xi^\epsilon = \begin{cases} d_Q(G(y^\epsilon))\nabla d_Q G(y^\epsilon)) & \text{if } G(y^\epsilon) \notin Q, \\ 0 & \text{otherwise.} \end{cases} \tag{7.7}$$

By using Theorem 6.3, we can take a function $\varphi^\epsilon \in L^r([0,T],W^{1,p}(\Omega))$ $\forall r,p \in [1,2)$ with $(2/r)+(n/p) > n+1$ such that

$$\begin{cases} -\dfrac{\partial \varphi^\epsilon}{\partial t} + A^*\varphi^\epsilon + \dfrac{\partial a_0}{\partial y}(x,t,y^\epsilon)\varphi^\epsilon = \alpha_\epsilon \dfrac{\partial L}{\partial y}(x,t,y^\epsilon) \\ \qquad\qquad +[DG(y^\epsilon)^*\mu_\epsilon]|_{\Omega_T} + [DF(y^\epsilon)^*\lambda_\epsilon]|_{\Omega_T} \quad \text{in } \Omega_T, \\ \partial_{\nu_{A^*}}\varphi^\epsilon = \dfrac{\partial f}{\partial y}(x,t,y^\epsilon,u^\epsilon)\varphi^\epsilon + \alpha_\epsilon \dfrac{\partial l}{\partial y}(x,t,y^\epsilon,u^\epsilon) \\ \qquad\qquad +[DG(y^\epsilon)^*\mu_\epsilon]|_{\Sigma_T} + [DF(y^\epsilon)^*\lambda_\epsilon]|_{\Sigma_T} \text{ on } \Sigma_T, \\ \varphi^\epsilon(T) = [DG(y^\epsilon)^*\mu_\epsilon]|_{\Omega\times\{T\}} + [DF(y^\epsilon)^*\lambda_\epsilon]|_{\Omega\times\{T\}} \text{ in } \Omega. \end{cases} \tag{7.8}$$

Thanks to the assumptions (2.2) and (2.7), we have that $z^\epsilon \in Y_0^\infty$. Then we can apply (6.6) with $y = z^\epsilon$ and deduce from (7.3)–(7.5) and the definition of H_α given in section 3 the inequality

$$\int_{\Sigma_T} H_{\alpha_\epsilon}(x,t,y^\epsilon(x,t),u^\epsilon(x,t),\varphi^\epsilon(x,t))d\sigma(x)dt$$

$$\leq \int_{\Sigma_T} H_{\alpha_\epsilon}(x,t,y^\epsilon(x,t),v(x,t),\varphi^\epsilon(x,t))d\sigma(x)dt + \sqrt{\epsilon}m_{\Sigma_T}(\Sigma_T) \quad \forall v \in \mathcal{U}. \tag{7.9}$$

Now we pass to the limit when $\epsilon \to 0$. To do this, let us remark that

$$\alpha_\epsilon^2 + \|\mu^\epsilon\|_{Z'}^2 + |\lambda^\epsilon|^2 = 1. \tag{7.10}$$

Then we take subsequences, denoted in the same way, satisfying

$$\begin{cases} \alpha_\epsilon \to \bar{\alpha} \ \text{ in } \mathbb{R}, \quad \lambda^\epsilon \to \bar{\lambda} \ \text{ in } \mathbb{R}^n, \\ \mu^\epsilon \to \bar{\mu} \ \text{ in the } {}^*\text{weak topology of } Z'. \end{cases} \tag{7.11}$$

On the other hand, the convergence $y^\epsilon \to \bar{y}$ in Y follows from Theorem 5.1. The boundedness of $\{\varphi^\epsilon\}$ in $L^r([0,T],W^{1,p}(\Omega))$ follows from (6.7) and (7.10). Then, using (7.11), it is easy to pass to the limit in (7.8) and (7.9) and to deduce (3.3) and (3.5). Now remembering the definition of μ^ϵ and ξ^ϵ and (7.1), we deduce

$$\langle \mu^\epsilon, z - G(y^\epsilon)\rangle \leq 0 \quad \forall z \in Q. \tag{7.12}$$

Passing to the limit in this expression we obtain (3.4). Let us prove (3.1). To do this, let us suppose that $\bar{\alpha} = |\bar{\lambda}| = 0$; then from (7.10) it follows $\|\mu^\epsilon\|_{Z'} \to 1$ as $\epsilon \to 0$. Let us take $z_0 \in \overset{o}{Q}$ and $\rho > 0$ such that $\bar{B}_\rho(z_0) \subset \overset{o}{Q}$. Then (7.12) implies that

$$\langle \mu^\epsilon, z + z_0 - G(y^\epsilon)\rangle \leq 0 \quad \forall z \in \bar{B}_\rho(0).$$

Hence

$$\rho\|\mu^\epsilon\|_{Z'} = \sup_{z\in\bar B_\rho(0)} \langle\mu^\epsilon, z\rangle \le \langle\mu^\epsilon, G(y^\epsilon) - z_0\rangle.$$

Passing to the limit

$$0 < \rho \le \lim_{\epsilon\to 0}\langle\mu^\epsilon, G(y^\epsilon) - z_0\rangle = \langle\bar\mu, G(\bar y) - z_0\rangle,$$

which proves that $\bar\mu \neq 0$.

It remains to prove (3.6); see Bonnans and Casas [5] or Casas [11] for the study of analogous situations. To do this we consider the coordinate system $\{(\Gamma_r, a_r)\}_{r=1}^d$ of Γ introduced in the proof of Proposition 5.3. Given a point $x_0 \in \overset{o}{\Gamma}_r$ for some $1 \le r \le d$ we denote for each $\epsilon > 0$ small enough

$$\Gamma_\epsilon(x_0) = \{x = (x'_r, a_r(x'_r)) : x'_r \in B_\epsilon(x'_{0r}) \subset (0,1)^{n-1}\},$$

where $B_\epsilon(x'_{0r})$ is the ball in $\mathbb{R}^{n-1}$ centered at x'_{0r} and having radius ϵ. Now given $0 < t_0 < T$, we set

$$\Sigma_T^\epsilon(x_0, t_0) = \Gamma_\epsilon(x_0) \times (t_0 - \epsilon, t_0 + \epsilon).$$

The following lemma is used in this proof.

LEMMA 7.2. *Given $f \in L^1(\Sigma_T)$, there exists a m_{Σ_T}-measurable set $S \subset \bigcup_{r=1}^d \overset{o}{\Gamma}_r \times(0,T)$, with $m_{\Sigma_T}(S) = m_{\Sigma_T}(\Sigma_T)$, such that for every $(x_0, t_0) \in S$ we have*

$$\lim_{\epsilon\to 0} \frac{1}{m_{\Sigma_T}(\Sigma_T^\epsilon(x_0,t_0))} \int_{\Sigma_T^\epsilon(x_0,t_0)} |f(x,t) - f(x_0,t_0)| dm_{\Sigma_T}(x,t) = 0. \tag{7.13}$$

Proof. Let us denote for all $(x'_r, t) \in (0,1)^{n-1} \times (0,T)$

$$\omega_r(x'_r) = \sqrt{1 + \sum_{i=1}^{n-1} \left|\frac{\partial a_r}{\partial x_i}(x'_r)\right|^2} \quad \text{and} \quad f_r(x'_r, t) = \omega_j(x'_r) f(x'_r, a_r(x'_r), t).$$

Since ω_r and f_r are Lebesgue integrable functions in $(0,1)^{n-1}$ and $(0,1)^{n-1}\times(0,T)$, respectively, we know that the set of Lebesgue points of these functions U_r and V_r, respectively, have measure equal to 1 and T, respectively. Let us define

$$S_r = \{(x,t) \in V_r = (x'_r, a_r(x'_r), t) : x'_r \in U_r\} \quad \text{and} \quad S = \bigcap_{r=1}^d S_r.$$

Then $m_{\Sigma_T}(S) = m_{\Sigma_T}(\Sigma_T)$ and $S_r \subset \overset{o}{\Gamma}_r \times(0,T)$, $1 \le r \le d$.

Let us take $(x_0, t_0) = (x'_{0r}, a(x'_{0r}), t_0) \in S_r$. Then x'_{0j} and (x_0, t_0) are Lebesgue points of ω_r and f_r; consequently,

$$\lim_{\epsilon\to 0} \frac{1}{m_{\Sigma_T}(\Sigma_T^\epsilon(x_0,t_0))} \int_{\Sigma_T^\epsilon(x_0,t_0)} |f(x,t) - f(x_0,t_0)| dm_{\Sigma_T}(x,t)$$

$$= \lim_{\epsilon\to 0} \left(\frac{1}{2\epsilon|B_\epsilon(x'_{0r})|} \int_{t_0-\epsilon}^{t_0+\epsilon} \int_{B_\epsilon(x'_{0r})} |f_r(x'_r,t) - f_r(x'_{0r},t)| dx'_r dt \right),$$

$$\lim_{\epsilon\to 0}\left(\frac{1}{|B_\epsilon(x'_{0r})|}\int_{B_\epsilon(x'_{0r})}\omega_r(x'_r)dx'_r\right)^{-1}$$

$$= f_r(x'_{0r},t_0)/\omega_r(x'_{0r}) = f(x_0,t_0),$$

where $|B_\epsilon(x'_{0r})|$ denotes the $(n-1)$-measure of $B_\epsilon(x'_{0r})$. □

The set points of S will be called the Lebesgue points of f. This set depends on the system of coordinates $\{(\Gamma_r,a_r)\}_{r=1}^d$, but this dependence only affects a set of σ-measure equal to zero.

We return to the proof of (3.6). Assume first that (A1) holds. Let us take a numerable dense subset $\{v_r\}_{j=1}^\infty$ of $\mathcal{K}$. Let F and $\{F_r\}_{j=1}^\infty$ be measurable subsets of Ω, with $m_{\Sigma_T}(F) = m_{\Sigma_T}(\Sigma_T) = m_{\Sigma_T}(F_r)$ for every j, such that the Lebesgue point sets of functions $(x,t)\in\Sigma_T \longrightarrow H_{\bar\alpha}(x,t,\bar y(x,t),\bar u(x,t),\bar\varphi(x,t))$ and $(x,t)\in\Omega\longrightarrow H_{\bar\alpha}(x,t,\bar y(x,t),v_j,\bar\varphi(x,t))$ are F and F_j, respectively. Let us set $F_0 = F\cap[\cap_{j=1}^\infty F_j]$. Then we have $m_{\Sigma_T}(F_0) = m_{\Sigma_T}(\Sigma_T)$. Now given $(x_0,t_0)\in F_0$ arbitrary, for every $\epsilon>0$ small enough and $j\ge 1$ we define the admissible controls

$$u_j^\epsilon(x,t) = \begin{cases} \bar u(x,t) & \text{if } (x,t)\notin\Sigma_T^\epsilon(x_0,t_0),\\ v_j & \text{otherwise.}\end{cases}$$

Then from (3.5) we deduce

$$\frac{1}{m_{\Sigma_T}(\Sigma_T^\epsilon(x_0,t_0))}\int_{\Sigma_T^\epsilon(x_0,t_0)} H_{\bar\alpha}(x,t,\bar y(x,t),\bar u(x,t),\bar\varphi(x,t))d\sigma(x)dt$$

$$\le \frac{1}{m_{\Sigma_T}(\Sigma_T^\epsilon(x_0,t_0))}\int_{\Sigma_T^\epsilon(x_0,t_0)} H_{\bar\alpha}(x,t,\bar y(x,t),v_j,\bar\varphi(x,t))d\sigma(x)dt,\quad 1\le j.$$

Passing to the limit where $\epsilon\to 0$, with the help of Lemma 7.2 we get

$$H_{\bar\alpha}(x_0,t_0,\bar y(x_0,t_0),\bar u(x_0,t_0),\bar\varphi(x_0,t_0)) \le H_{\bar\alpha}(x_0,t_0,\bar y(x_0,t_0),v_j,\bar\varphi(x_0,t_0))$$

for every $(x_0,t_0)\in F_0$ and $j\ge 1$. Taking into account that function

$$v\longrightarrow H_{\bar\alpha}(x_0,t_0,\bar y(x_0,t_0),v,\bar\varphi(x_0,t_0))$$

is continuous and that $\{v_j\}_{j=1}^\infty$ is dense in $\mathcal{K}$, (3.6) follows from the above inequality.

Now let us suppose that assumption (A2) holds. Let $F_{\bar\varphi}$ be a measurable subset of Σ_T such that for every $(x_0,t_0)\in F_{\bar\varphi}$

$$\lim_{\epsilon\to 0}\frac{1}{m_{\Sigma_T}(\Sigma_T^\epsilon(x_0,t_0))}\int_{\Sigma_T^\epsilon(x_0,t_0)}|\bar\varphi(x,t)-\bar\varphi(x_0,t_0)|d\sigma(x)dt = 0. \tag{7.14}$$

Let $F_0 = F_{\bar\varphi}\cap\Sigma_T^0\cap F$, where F is taken as above. Thus we have that $m_{\Sigma_T}(F_0) = m_{\Sigma_T}(\Sigma_T)$, and taking spike perturbations as before we deduce

$$\frac{1}{m_{\Sigma_T}(\Sigma_T^\epsilon(x_0,t_0))}\int_{\Sigma_T^\epsilon(x_0,t_0)} H_{\bar\alpha}(x,t,\bar y(x,t),\bar u(x,t),\bar\varphi(x,t))d\sigma(x)dt$$

$$\le \frac{1}{m_{\Sigma_T}(\Sigma_T^\epsilon(x_0,t_0))}\int_{\Sigma_T^\epsilon(x_0,t_0)} H_{\bar\alpha}(x,t,\bar y(x,t),v,\bar\varphi(x,t))d\sigma(x)dt$$

for every $(x_0,t_0)\in F_0$ and $v\in\mathcal{K}$. Since $(x_0,t_0)\in F$, we can pass to the limit on the left-hand side of the inequality. Let us study the right-hand side:

$$\begin{aligned}
&\frac{1}{m_{\Sigma_T}(\Sigma_T^\epsilon(x_0,t_0))}\int_{\Sigma_T^\epsilon(x_0,t_0)} H_{\bar\alpha}(x,t,\bar y(x,t),v,\bar\varphi(x,t))d\sigma(x)dt\\
&\quad=\frac{1}{m_{\Sigma_T}(\Sigma_T^\epsilon(x_0,t_0))}\int_{\Sigma_T^\epsilon(x_0,t_0)}\bar\alpha l(x,t,\bar y(x,t),v)d\sigma(x)dt\\
&\quad+\frac{1}{m_{\Sigma_T}(\Sigma_T^\epsilon(x_0,t_0))}\int_{\Sigma_T^\epsilon(x_0,t_0)} f(x,t,\bar y(x,t),v)d\sigma(x)dt\bar\varphi(x_0,t_0)\\
&+\frac{1}{m_{\Sigma_T}(\Sigma_T^\epsilon(x_0,t_0))}\int_{\Sigma_T^\epsilon(x_0,t_0)}[\bar\varphi(x,t)-\bar\varphi(x_0,t_0)]f(x,t,\bar y(x,t),v)d\sigma(x)dt.
\end{aligned}$$

The first two terms converge to $H_{\bar\alpha}(x_0,t_0,\bar y(x_0,t_0),v,\bar\varphi(x_0,t_0))$ because of the continuity of the integrands in $(x_0,t_0)\in\Sigma_T^0$. Let us prove that the last term goes to zero.

$$\begin{aligned}
&\left|\frac{1}{m_{\Sigma_T}(\Sigma_T^\epsilon(x_0,t_0))}\int_{\Sigma_T^\epsilon(x_0,t_0)}[\bar\varphi(x,t)-\bar\varphi(x_0,t_0)]f(x,t,\bar y(x,t),v)d\sigma(x)dt\right|\\
&\quad\le C\frac{1}{m_{\Sigma_T}(\Sigma_T^\epsilon(x_0,t_0))}\int_{\Sigma_T^\epsilon(x_0,t_0)}|\bar\varphi(x,t)-\bar\varphi(x_0,t_0)|d\sigma(x)dt\longrightarrow 0,
\end{aligned}$$

thanks to (7.14) and the fact that $(x,t)\to f(x,t,\bar y(x,t),v)$ is bounded in Σ_T because of the assumption (2.2) and the boundedness of $\bar y$. ∎

Now we will prove Theorem 4.3. The key to achieving this result is to carry out an exact penalization of the state constraint. To do this, we will use the distance function d_{Q_δ} associated with the set Q_δ and defined in the same way as in the proof of Theorem 4.3.

PROPOSITION 7.3. *If (P_δ) is strongly stable and $\bar u$ is a solution of this problem, then there exists $q_0>0$ such that $\bar u$ is also a solution of*

$$\inf_{u\in\mathcal{U}} J_q(u)=J(u)+qd_{Q_\delta}(G(y_u)) \tag{7.15}$$

for every $q\ge q_0$.

Proof. Let us suppose that it is false. Then there exists a sequence $\{q_k\}_{k=1}^\infty$ of real numbers, with $q_k\to+\infty$ and elements $\{u_k\}_{k=1}^\infty\subset\mathcal{U}$ such that

$$J(u_k)+q_kd_{Q_\delta}(G(y_k))<J(\bar u)\quad\forall k\ge 1,$$

where y_k is the state corresponding to u_k. From here we obtain that

$$d_{Q_\delta}(G(y_k))<\frac{J(\bar u)-J(u_k)}{q_k}\longrightarrow 0\quad\text{when } k\to+\infty$$

and $G(y_k)\notin Q_\delta$. Let $\delta_k>\delta$ be the smallest number such that $G(y_k)\in Q_{\delta_k}$. Since $\delta_k\to\delta$, we can use (4.1) to deduce

$$\begin{aligned}
C(\delta_k-\delta)&\ge\inf(\mathrm{P}_\delta)-\inf(\mathrm{P}_{\delta_k})\ge J(\bar u)-J(u_k)\\
&>q_kd_{Q_\delta}(G(y_k))=q_k(\delta_k-\delta)\quad\forall k\ge k_\epsilon,
\end{aligned}$$

which is not possible. ∎

Since J_q is not Gâteaux differentiable on Q_δ, we are going to modify slightly this functional to attain the differentiability necessary for the proof.

PROPOSITION 7.4. *Let us take $q \geq q_0$ and for every $\epsilon > 0$ let us consider the problem*

$$(P_{\delta,\epsilon}) \quad \inf_{u\in\mathcal{U}} J_{q,\epsilon}(u) = J(u) + q\left\{d_{Q_\delta}(G(y_u))^2 + \epsilon^2\right\}^{1/2}.$$

Then $\inf(P_{\delta,\epsilon}) \to \inf(P_\delta)$ *when* $\epsilon \to 0$.

Proof. It is an immediate consequence of the inequality

$$J_q(u) \leq J_{q,\epsilon}(u) \leq J_q(u) + q\epsilon \quad \forall u \in \mathcal{U}. \qquad \square$$

Finally we are ready to prove the strong Pontryagin principle.

Proof of Theorem 4.3. Propositions 7.3 and 7.4 imply that $\bar{u}$ is a σ_ϵ^2–solution of $(\mathrm{P}_{\delta,\epsilon})$, with $\sigma_\epsilon \to 0$ when $\epsilon \to 0$; i.e.

$$J_{q,\epsilon}(\bar{u}) \leq \inf(\mathrm{P}_{\delta,\epsilon}) + \sigma_\epsilon^2.$$

Then we can apply again Ekeland's principle and deduce the existence of an element $u^\epsilon \in \mathcal{U}$ such that

$$d(u^\epsilon, \bar{u}) \leq \sigma_\epsilon, \quad J_{q,\epsilon}(u^\epsilon) \leq J_{q,\epsilon}(\bar{u}),$$

and

$$J_{q,\epsilon}(u^\epsilon) \leq J_{q,\epsilon}(u) + \sigma_\epsilon d_E(u^\epsilon, u) \quad \forall u \in \mathcal{U}.$$

Now we argue as in the proof of Theorem 3.1 and replace (7.3) by

$$-\sigma_\epsilon m_{\Sigma_T}(\Sigma_T) \leq \lim_{\rho\to 0} \frac{J_{q,\epsilon}(u_\rho^\epsilon) - J_{q,\epsilon}(u^\epsilon)}{\rho} = z^{0,\epsilon} + \langle \mu^\epsilon, DG(y^\epsilon)z^\epsilon\rangle,$$

where $\mu^\epsilon \in Z'$ is given by

$$\mu^\epsilon = \begin{cases} \dfrac{q d_{Q_\delta}(G(y^\epsilon))}{\{d_{Q_\delta}(G(y^\epsilon))^2 + \epsilon^2\}^{1/2}} \nabla d_{Q_\delta}(G(y^\epsilon)) & \text{if } G(y^\epsilon) \notin Q_\delta, \\ 0 & \text{otherwise.} \end{cases}$$

Therefore we have $\|\mu^\epsilon\|_{Z'} \leq q$ for every $\epsilon > 0$. Now we can take a subsequence that converges weakly* to an element $\bar{\mu} \in Z'$. The rest is as in the proof of Theorem 3.1, taking $\alpha_\epsilon = 1$. $\square$

AN APPROXIMATION ALGORITHM FOR NONHOLONOMIC SYSTEMS*

WENSHENG LIU†

Abstract. In [*SIAM J. Control Optim.*, 37 (1997), to appear], [*Limiting process of control-affine systems with Hölder continuous inputs*, submitted], we have studied the limiting behavior of trajectories of control affine systems $\Sigma : \dot{x} = \sum_{k=1}^{m} u_k f_k(x)$ generated by a sequence $\{u^j\} \subseteq L^1([0,T],\mathbb{R}^m)$, where the f_k are smooth vector fields on a smooth manifold M. We have shown that under very general conditions the trajectories of Σ generated by the u^j converge to trajectories of an *extended system* of Σ of the form $\Sigma_{ext} : \dot{x} = \sum_{k=1}^{r} v_k f_k(x)$, where $f_k, k = 1,\dots,m$, are the same as in Σ and $f_{m+1},\dots,f_r$ are Lie brackets of $f_1,\dots,f_m$. In this paper, we will apply these convergence results to solve the *inverse* problem; i.e., given any trajectory γ of an extended system Σ_{ext}, find trajectories of Σ that converge to γ uniformly. This is done by means of a universal construction that only involves the knowledge of the $v_k, k = 1,\dots,r$, and the structure of the Lie brackets in Σ_{ext} but does not depend on the manifold M and the vector fields $f_1,\dots,f_m$. These results can be applied to approximately track an arbitrary smooth path in M for controllable systems Σ, which in particular gives an alternative approach to the motion planning problem for nonholonomic systems.

Key words. control affine systems, extended inputs, free associative algebras, free Lie algebras, Chen–Fliess series, nonholonomic motion planning

1. Introduction.

The purpose of this paper is to study the relation between trajectories of control affine systems

$$\dot{x} = \sum_{k=1}^{m} u_k(t) f_k(x), \tag{1}$$

where $f_1,\dots,f_m$ are smooth vector fields on a smooth manifold M, and those of a "Lie bracket extension" of (1), which will be called an *extended system*, given by

$$\dot{x} = \sum_{k=1}^{r} v_k(t) f_k(x), \tag{2}$$

where the first m vector fields $f_1,\dots,f_m$ are the same as in (1) and the new admissible directions of motion $f_{m+1},\dots,f_r$ are Lie brackets of the f_k, $k \in \{1,\dots,m\}$.

Using averaging techniques and developing proper algebraic formalisms, in [19] and [20] we have studied the limiting behavior of trajectories of (1). We have shown that under very general conditions trajectories of (1) generated by a sequence $\{u^j\} \subseteq L^1([0,T],\mathbb{R}^m)$ converge to trajectories of (2). In this paper we will apply these convergence results to solve the *inverse* problem, i.e., to find a sequence of trajectories of (1) approximating a given trajectory of (2).

*Received by the editors December 21, 1993; accepted for publication (in revised form) May 21, 1996. This research was supported in part by National Science Foundation grant DMS92-02554.

It was proved by Haynes and Hermes in [6] that if system (1) satisfies the *Lie algebra rank condition*[1] (LARC), every trajectory of (2) can be uniformly approximated by trajectories of (1). However, their proof does not easily lead to an explicit constructive procedure for producing such a sequence. Here we present a different approach. Based on the convergence results described in [19], we give an algorithm that, for each extended system (2), produces a sequence $\{u^j\}$ of inputs that explicitly generates trajectories for (1) converging to those of (2). This is done in a universal way in the sense that the construction of the u^j only involves the knowledge of the $v_k, k = 1, \ldots, r$ and the structure of the Lie brackets in (2) but does not depend on the manifold M and the vector fields $f_1, \ldots, f_m$.

The motivation for our interest in an explicit construction of trajectories of (1) that converge to a prescribed trajectory of (2) is the *motion planning problem* (MPP) for nonholonomic systems.[2] The extended system (2) clearly has more trajectories than (1). So, if we want to construct paths that satisfy some extra conditions (e.g., the solution of MPP), it is easier to do it for (2) than for (1). In the extreme case when system (1) satisfies the LARC, every smooth curve $\gamma : [0, T] \to M$ is a trajectory of a suitably chosen extended system (2). (To see this, take any compact subset K of M that contains γ in its interior. Then, by the LARC, in principle we can take r large enough such that the set of admissible directions $\{f_1, \ldots, f_r\}$ at each point $x \in K$ is simply the set of all possible directions. Then by the span condition, $\dot{\gamma}(t)$ can be written as a linear combination of $f_1(\gamma(t)), \ldots, f_r(\gamma(t))$.) If we could somehow produce for any given trajectory γ of (2) a sequence $\{\gamma^j\}$ of trajectories of (1) that converges to γ uniformly as $j \to \infty$, then we would have solved (for systems satisfying the LARC) the problem of approximating any given smooth curve by admissible trajectories. On the other hand, the LARC is a natural condition for these kinds of problems. For example, if system (1) is analytic and M is connected, the LARC is equivalent to the notion of *complete controllability*, which is the property that any two points in M can be joined by a trajectory of (1). Suppose that, in addition, M is such that it is easy to find a smooth curve in M that joins any two given points p, q. (This happens, for instance, if M is Euclidean space $\mathbb{R}^n$—in which case we can always use a straight-line segment—or if $M = \mathbb{R}^n - C$, where the "obstacle" C is a closed set, provided that we can somehow solve the problem of "path finding with obstacle avoidance," i.e., that we can find for any two points p, q a path that goes from p to q and avoids C.) In that case we will have solved the problem of producing an admissible trajectory that approximately steers p to q. This leads to an alternative approach to the MPP for nonholonomic systems studied by many authors, e.g., Brockett and Dai [2]; Fernandes, Gurvits, and Li [4]; Gurvits and Li [5]; Lafferriere and Sussmann [8]; Jacobs and Canny [7]; Laumond [9]; Murray and Sastry [12], [11]; Sastry and Li [14]; and Sussmann and Liu [17].

Our strategy for constructing the approximation sequences relies on the algebraic formalisms and the convergence results given in [19]. The key point for the algebraic formulations in [19] is the reformulation of the problem of convergence of trajectories in terms of convergence of inputs. This is done by introducing the concept of extended inputs. More precisely, let $X_1, \ldots, X_m$ be noncommuting *in-*

[1]System (1) is said to satisfy the Lie algebra rank condition if for every $x \in M$ we have $\Lambda(x) = T_xM$, where Λ is the Lie algebra of vector fields generated by the f_k, $\Lambda(x) = \{X(x) : X \in \Lambda\}$, and T_xM is the tangent space of M at x.

[2]The MPP for system (1) is the problem of finding an input $u \in L^1([0, T], \mathbb{R}^m)$ that steers p to q for any prescribed points p and q in the state space.

determinates. We define an *extended input* to be an integrable function on $[0,T]$ whose values are linear combinations of $X_1,\dots,X_m$ and various Lie brackets such as $[X_1,X_2]$, $[X_1,\,[X_1,X_2]]$, etc. For example, an expression (for $m=2$) like $v = v_1X_1 + v_2X_2 + v_3[X_1,X_2] + v_4[X_2,[X_1,X_2]]$ with integrable coefficients v_k on $[0,T]$ is an extended input. Clearly an ordinary input $u=(u_1,\dots,u_m)$ can be regarded as an extended input by identifying it with $u = u_1X_1 + \cdots + u_mX_m$, i.e., a linear combination of $X_1,\dots,X_m$ only without higher-order Lie brackets. The point is that extended inputs can be plugged into any system (1) exactly the same as ordinary inputs can, giving rise to ordinary differential equations. (This requires only that the vector fields $f_1,\dots,f_m$ be smooth enough so that the various Lie brackets exist.) For example, the extended input above gives rise to the following differential equation: $\dot{x} = v_1(t)f_1(x) + v_2(t)f_2(x) + v_3(t)[f_1,f_2](x) + v_4(t)[f_2,[f_1,f_2]](x)$. Therefore, we can talk about trajectories of extended inputs once the vector fields $f_1,\dots,f_m$ are known. We say that a sequence $\{u^j\}$ of ordinary inputs converges to an extended input u^∞ if for every initial condition $x(0)=p$, every choice of sufficiently smooth vector fields $f_1,\dots,f_m$, the trajectories x^j generated by the u^j converge uniformly to the trajectory x^∞ generated by u^∞. In [19] we have presented various sufficient conditions for a sequence of ordinary inputs to converge to an extended input. In this paper we show how to use those conditions to solve the inverse problem of producing, for a given extended input v, a sequence $\{u^j\}$ of ordinary inputs that converges to v.

The basic idea for solving the inverse problem is to use *highly oscillatory sequences*. (For short, HOSs. The precise definition of HOSs will be given later.) Applying the convergence results in [19], we can explicitly compute the limiting extended inputs of certain HOSs. An HOS used in our approximation algorithm involves several arbitrary functions η_ω, and the limiting extended input turns out to be given by an explicit formula in terms of these η_ω. We then show that this formula implies that any prescribed extended input can be achieved by a suitable choice of the η_ω.

An outline of this paper is as follows. Section 2 introduces some algebraic machinery that is needed throughout this paper. We start by reviewing the algebraic formalism developed in [19] and making it more appropriate for our needs here. We then state a convergence theorem proved in [19] which will be used to establish the approximation algorithm. Beginning in section 3, we proceed to solve the problem of finding a sequence of ordinary inputs that converges to a prescribed extended input. We first examine the limiting behavior of some special sequences of ordinary inputs. This leads naturally to the definition of some functions associated with brackets in a *P. Hall basis* of a free Lie algebra. These functions have nice algebraic properties and are naturally related to the *Chen–Fliess* product expansions of formal trajectories of some HOSs. The approximation algorithm is described in section 5, and its proof is given in sections 6 and 7. In section 8, we first present some examples that show how the algorithm is applied and then discuss briefly the feedback control laws and the case in which systems have a drift term.

2. Algebraic preliminaries and a convergence result. In this section we present briefly some algebraic preliminaries and state a convergence result that is needed later. For a more detailed treatment of the materials presented in this section, we refer to [19]. We follow the notations and definitions in [19].

2.1. Algebraic preliminaries. As in [19], let $\mathbf{X} = \{X_1,\dots,X_m\}$ be a finite sequence of objects that will be called *indeterminates*. We let $A(\mathbf{X})$ denote the free associative algebra generated over $\mathbb{R}$ by $\mathbf{X}$. For any multi-index $I=(i_1,\dots,i_k)$ with $i_1,\dots,i_k \in \{1,\dots,m\}$, we let $X_I = X_{i_1}\cdots X_{i_k}$. (There is a special multi-index $I=\emptyset$.

It is understood that $X_\emptyset = 1$.) Then $A(\mathbf{X})$ is the set of all sums $\sum_I a_I X_I$, where the coefficients a_I are real numbers, the summation runs over all possible multi-indices I, and all but finitely many a_I vanish. Therefore, the *monomials* X_I form a basis of $A(\mathbf{X})$, and every element of $A(\mathbf{X})$ is a finite linear combination of the X_I.

We also consider the algebra $\hat{A}(\mathbf{X})$ of all formal power series in $\mathbf{X}$. The elements of $\hat{A}(\mathbf{X})$ are the formal sums $\sum_I a_I X_I$, where I ranges over all multi-indices. This is the sum as above except that the a_I are no longer required to vanish for all but finitely many I. In both $A(\mathbf{X})$ and $\hat{A}(\mathbf{X})$, addition is done componentwise, and multiplication is carried out using the formula $X_I X_J = X_{IJ}$, where IJ is the concatenation of I and J, namely the multi-index obtained by writing, in order, first the components of I and then those of J.

For any integer $r \geq 0$, we use $A^r(\mathbf{X})$ to denote the *free nilpotent associative algebra of step* $r+1$ in the indeterminates $\mathbf{X}$. Therefore, $A^r(\mathbf{X})$ is defined like $\hat{A}(\mathbf{X})$, except that now all the monomials X_I with $|I| > r$ are set equal to zero. (Here $|I|$ is the length of I, i.e., $|I| = k$ if $I = (i_1, \ldots, i_k)$.) Clearly $A^r(\mathbf{X})$ can be thought of as the quotient of $A(\mathbf{X})$ or $\hat{A}(\mathbf{X})$ modulo the two side ideal of all sums of monomials of degree strictly larger than r. (The degree of a monomial X_I is $|I|$.) The canonical projection $\mathbf{Tr}(r)$ from $\hat{A}(\mathbf{X})$ to $A^r(\mathbf{X})$ is the operator that assigns to each series $S \in \hat{A}(\mathbf{X})$ the finite series $\mathbf{Tr}(r)(S)$ obtained from S by deleting all the terms of degree $> r$. (The symbol **Tr** comes from the word "truncation." It is used to indicate that the map $\mathbf{Tr}(r) : \hat{A}(\mathbf{X}) \to A^r(\mathbf{X})$ is in essence a truncation map, i.e., for any $S \in \hat{A}(\mathbf{X})$, $\mathbf{Tr}(r)(S)$ is the truncation of S "up to order r.") The kernel of $\mathbf{Tr}(r)$ is denoted by $\hat{A}_r(\mathbf{X})$. In particular, $\hat{A}_0(\mathbf{X})$ is the set of all formal power series $\sum_I a_I X_I$ for which $a_\emptyset = 0$. The exponential map is a well-defined bijection $\exp : \hat{A}_0(\mathbf{X}) \to 1 + \hat{A}_0(\mathbf{X})$, whose inverse is a map from $1+\hat{A}_0(\mathbf{X})$ to $\hat{A}_0(\mathbf{X})$ denoted by "log." (Here $1+\hat{A}_0(\mathbf{X})$ is the subset of $\hat{A}(\mathbf{X})$ that contains all the elements S such that $S-1 \in \hat{A}_0(\mathbf{X})$.) If $S \in \hat{A}_0(\mathbf{X})$, then $\exp(S)$ and $\log(1+S)$ are given by the usual series $\exp(S) = \sum_{n=0}^{\infty} \frac{S^n}{n!}$, $\log(1+S) = \sum_{n=1}^{\infty} \frac{(-1)^{(n-1)} S^n}{n}$. The algebras $A(\mathbf{X}), \hat{A}(\mathbf{X}), A^r(\mathbf{X})$ are Lie algebras in the usual way. We let $L(\mathbf{X})$ denote the Lie subalgebra of $A(\mathbf{X})$ generated by the indeterminates $X_1, \ldots, X_m$. An element S of $A(\mathbf{X})$ will be said to be a *Lie element* if $S \in L(\mathbf{X})$. It is clear that an $S \in A(\mathbf{X})$ is a Lie element iff all the *homogeneous* components of S are Lie elements. (An $S \in \hat{A}(\mathbf{X})$ is homogeneous if it is a linear combination of monomials with equal degree.)

For $\mathbf{X} = \{X_1, \ldots, X_m\}$, we let $\mathcal{FB}r(\mathbf{X})$ denote the set of *formal brackets*. The elements of $\mathcal{FB}r(\mathbf{X})$ are purely formal expressions in the indeterminates X_i, the left and the right brackets, and the commas. Precisely, cf. [16], let $\mathcal{A}$ be the alphabet that consists of the X_i, the left and the right brackets, and the commas. Then $\mathcal{FB}r(\mathbf{X})$ is the smallest set Ω of words in $\mathcal{A}$ that contains $X_1, \ldots, X_m$ and has the property that whenever α, β are two words that belong to Ω, then the word "$[\alpha, \beta]$" also belongs to Ω. Every formal bracket $B \in \mathcal{FB}r(\mathbf{X})$ has a well-defined *degree* $\delta(B)$, which is an integer ≥ 1. (The degree $\delta(B)$ of $B \in \mathcal{FB}r(\mathbf{X})$ is inductively defined as follows: $\delta(X_i) = 1, i = 1, \ldots, m$, and $\delta([\alpha, \beta]) = \delta(\alpha) + \delta(\beta)$.) If degree $\delta(B) > 1$, then B can be written in a unique way as $[B_1, B_2]$ with $B_1, B_2 \in \mathcal{FB}r(\mathbf{X})$. The formal brackets B_1, B_2 are called the *left* and the *right* factors of B, respectively. There is a natural mapping μ which associates with each $B \in \mathcal{FB}r(\mathbf{X})$ an element of $L(\mathbf{X})$. The elements of $L(\mathbf{X})$ of the form $\mu(B), B \in \mathcal{FB}r(\mathbf{X})$, are called *Lie monomials*. They will also be referred to as Lie brackets in $L(\mathbf{X})$ in the indeterminates $X_1, \ldots, X_m$. The Lie algebra $L(\mathbf{X})$ is spanned by all the Lie brackets of $X_1, \ldots, X_m$. Naturally Lie brackets in the indeterminates $X_1, \ldots, X_m$ are not linearly independent. There are

several systematic procedures for singling out a basis of $L(\mathbf{X})$. We will come back to this later.

Remark 2.1. In the following we will use $\mathcal{B}r(\mathbf{X})$ to denote the set of Lie monomials in $L(\mathbf{X})$, i.e., the set $\{\mu(B) \ : \ B \in \mathcal{FB}r(\mathbf{X})\}$ in $L(\mathbf{X})$. For simplicity, we will drop the symbol μ and just use B to denote a Lie bracket in $\mathcal{B}r(\mathbf{X})$. Each bracket $B \in \mathcal{B}r(\mathbf{X})$ has a well-defined *degree* $\delta(B)$. For later use, we let $\delta_i(B), i = 1, \ldots, m$, be the *degree* of B in X_i, so $\delta_1(B) + \cdots + \delta_m(B) = \delta(B)$. For example if $B = [X_1, [X_1, X_2]]$, then $\delta_1(B) = 2, \delta_2(B) = 1$, and $\delta(B) = 3$.

We define $\hat{L}(\mathbf{X})$ to be the set of all those elements of $\hat{A}(\mathbf{X})$ whose components are Lie elements. The elements of $\hat{L}(\mathbf{X})$ are called a *Lie series* in $X_1, \ldots, X_m$. Let $\hat{G}(\mathbf{X}) = \{\exp(Z), Z \in \hat{L}(\mathbf{X})\}$, the set of exponentials of the elements of $\hat{L}(\mathbf{X})$. The Campbell–Hausdorff formula implies (cf., e.g., [1]) that $\hat{G}(\mathbf{X})$ is a group under the operation of multiplication in $\hat{A}(\mathbf{X})$. The elements of $\hat{G}(\mathbf{X})$ are called an *exponential Lie series*. If we let $L^r(\mathbf{X})$ be the Lie subalgebra of $A^r(\mathbf{X})$ generated by the $\mathbf{X}$ and define $G^r(\mathbf{X})$ to be the subset of $A^r(\mathbf{X})$ consisting of all the exponentials of elements of $L^r(\mathbf{X})$, then $L^r(\mathbf{X})$ is a finite-dimensional Lie algebra and $G^r(\mathbf{X})$ is its corresponding simply connected Lie group.

Let $v(t) = \sum_I v_I(t) X_I$ be a function on $[0, T]$ with values in $\hat{A}(\mathbf{X})$. We say that v is *integrable* if all the functions v_I are in $L^1[0, T]$. A *polynomial input* is an integrable function $\mathbf{v}$ on an interval $[0, T]$ with values in $\hat{A}_0(\mathbf{X})$. An *extended input* is a polynomial input which is $\hat{L}(\mathbf{X})$ valued. An ordinary input $u = (u_1, \ldots, u_m) \in L^1([0, T], \mathbb{R}^m)$ can be regarded as a polynomial input by identifying it with the function $\mathbf{u} = u_1 X_1 + \cdots + u_m X_m$. It is an extended input in fact by the above definition. In most cases we will make no difference between $u = (u_1, \ldots, u_m)$ and $\mathbf{u} = u_1 X_1 + \cdots + u_m X_m$ and call both ordinary inputs.

To each polynomial input $\mathbf{v}$, the *Chen–Fliess series* $S_{\mathbf{v}}$ determined by $\mathbf{v}$ is the absolutely continuous $\hat{A}(\mathbf{X})$-valued function on $[0, T]$ that satisfies

$$\dot{S} = S\mathbf{v}, \quad S(0) = 1, \quad S(t) \in \hat{A}(\mathbf{X}). \tag{3}$$

So if $S_{\mathbf{v}}$ is the solution of (3), then it is clear that

$$S_{\mathbf{v}} = 1 + \sum_{k=1}^{\infty} \int_0^t \int_0^{t_1} \cdots \int_0^{t_{k-1}} \mathbf{v}(t_k)\mathbf{v}(t_{k-1}) \cdots \mathbf{v}(t_1)\, dt_k \cdots dt_1.$$

The Chen–Fliess series $S_{\mathbf{v}}$ will be called the *formal trajectory* of $\mathbf{v}$.

By definition, the function $t \to S_{\mathbf{v}}(t)$ is an absolutely continuous $\hat{A}(\mathbf{X})$-valued function. It is in fact $1 + \hat{A}_0(\mathbf{X})$-valued. Conversely, define a *formal trajectory* to be an absolutely continuous $1 + \hat{A}_0(\mathbf{X})$-valued function S on $[0, T]$. Then every formal trajectory S is the formal trajectory of a polynomial input $\mathbf{v}$ given by $\mathbf{v} = S^{-1}\dot{S}$. Therefore the map $\mathbf{v} \to S_{\mathbf{v}}$ is a one-to-one correspondence between the set of polynomial inputs and that of formal trajectories whose inverse is given by $\mathbf{v} = S_{\mathbf{v}}^{-1}\dot{S}_{\mathbf{v}}$.

The polynomial input $\mathbf{v}$ can be computed from $S_{\mathbf{v}}$ using standard algebraic tools. If $S_{\mathbf{v}} = 1 + \sum_{|I|>0} H_I X_I$, then we know that

$$S_{\mathbf{v}}^{-1} = 1 + \sum_{|I|>0} \left(\sum_{k=1}^{\infty} (-1)^k \sum_{J_1 \ldots J_k = I} H_{J_1} \cdots H_{J_k} \right) X_I.$$

We have

$$S_{\mathbf{v}}^{-1}\dot{S}_{\mathbf{v}} = \sum_{|I|>0}\left(\dot{H}_I + \sum_{k=1}^{\infty}(-1)^k \sum_{J_1\dots J_k J_{k+1}=I} H_{J_1}\cdots H_{J_k}\dot{H}_{J_{k+1}}\right) X_I,$$

where the inner summation above runs over all ways of expressing the multi-index I as a concatenation $J_1\cdots J_kJ_{k+1}$ of $k+1$ indices. So, if we let $\mathbf{v} = S_{\mathbf{v}}^{-1}\dot{S}_{\mathbf{v}} = \sum_{|I|>0} v_I X_I$, then the v_I are given by

$$v_I = \dot{H}_I + \sum_{k=1}^{\infty}(-1)^k \sum_{J_1\cdots J_k J_{k+1}=I} H_{J_1}H_{J_2}\cdots H_{J_k}\dot{H}_{J_{k+1}}. \tag{4}$$

Remark 2.2. It follows from [15] that $S_{\mathbf{v}}$ is $\hat{G}(\mathbf{X})$-valued if $\mathbf{v}$ is an extended input. The converse of this is also true; i.e., if S is a $\hat{G}(\mathbf{X})$-valued formal trajectory, then $\mathbf{v} = S^{-1}\dot{S}$ is an extended input. To see this, it suffices to prove that in this case the function $S^{-1}\dot{S}$ is $\hat{L}(\mathbf{X})$ valued. Notice that $S^{-1}(t)\dot{S}(t) = \lim_{h\to 0}\frac{1}{h}S^{-1}(t)(S(t+h) - S(t)) = \lim_{h\to 0}\frac{1}{h}(S^{-1}(t)S(t+h) - 1)$. Using the Campbell–Hausdorff formula we conclude that $S^{-1}(t)S(t+h) = e^{\Lambda(t,h)}$, where $\Lambda(t,h)$ is a Lie series that goes to zero as $h\to 0$. So $S^{-1}(t)\dot{S}(t) = \lim_{h\to 0}\frac{1}{h}(\Lambda(t,h) + \frac{1}{2}\Lambda(t,h)^2 + \cdots) = \lim_{h\to 0}\frac{\Lambda(t,h)}{h}$, which implies that $S^{-1}\dot{S}$ is Lie series valued.

Let π be the linear map of $A(\mathbf{X})$ onto $L(\mathbf{X})$ defined by $\pi(X_I) = \frac{1}{|I|}[X_I]$ for $|I| > 0$, where if $I = (i_1,\cdots,i_k)$, then $[X_I] \stackrel{\text{def}}{=} [X_{i_1},[X_{i_2},\dots,[X_{i_{k-1}},X_{i_k}]\cdots]]$. It is well known, cf., e.g., [1], that the restriction of π to $L(\mathbf{X})$ is the identity map; i.e., π is a projector of $A(\mathbf{X})$ onto $L(\mathbf{X})$. Let $\hat{\pi}$ be the linear projection map from $\hat{A}(\mathbf{X})$ to $\hat{L}(\mathbf{X})$ that extends π. From Remark 2.2 we know that if $S = 1 + \sum_{|I|>0} H_I X_I$ is a $\hat{G}(\mathbf{X})$-valued formal trajectory, $\mathbf{v} = S^{-1}\dot{S}$ is an extended input. In that case we have $\hat{\pi}(\mathbf{v}) = \mathbf{v}$, so

$$\mathbf{v} = \sum_{|I|>0}\frac{1}{|I|}v_I[X_I], \tag{5}$$

where the v_I are given by (4).

In the particular case where $\mathbf{v}$ is an ordinary input $\mathbf{u} = u_1X_1 + \cdots + u_mX_m$, the Chen–Fliess series $S_{\mathbf{u}}$ is given by the formula $S_{\mathbf{u}}(t) = 1 + \sum_{|I|>0} U_I(t)X_I$, where if $I = (i_1,\dots,i_k)$, then U_I is the iterated integral defined by

$$U_I(t) \stackrel{\text{def}}{=} \int_0^t u_{i_k}(t_k)\int_0^{t_k} u_{i_{k-1}}(t_{k-1})\cdots\int_0^{t_2} u_{i_1}(t_1)\,dt_1\cdots dt_k. \tag{6}$$

Let $\mathbf{u}$ be an ordinary input and $\mathbf{v}$ be a polynomial input. We define a *generalized difference* of $\mathbf{u}$ and $\mathbf{v}$ to be an absolutely continuous $\hat{A}_0(\mathbf{X})$-valued function W on $[0,T]$ that satisfies

$$\dot{W} = -\mathbf{u}W + \mathbf{v} - \mathbf{u}, \quad W(t)\in\hat{A}_0(\mathbf{X}). \tag{7}$$

Clearly a solution W of (7) is uniquely determined by its initial value $W(0)$.

Let W be a solution of (7) with initial condition $W(0) = W_0 \in \hat{A}_0(\mathbf{X})$. Then W satisfies the integral equation

$$W(t) = W_0 - \int_0^t \mathbf{u}(s)W(s)ds + \int_0^t (\mathbf{v}(s) - \mathbf{u}(s))\,ds. \tag{8}$$

If $\mathbf{u} = u_1X_1+\cdots+u_mX_m$ and $\mathbf{v} = \sum_{|I|>0} v_IX_I$, letting $(\mathbf{u} \overset{\text{g.d.}}{-} \mathbf{v})(t) = \sum_{|I|>0} \widetilde{UV}_I(t)X_I$ be a generalized difference of $\mathbf{u}$ and $\mathbf{v}$ with initial value $(\mathbf{u} \overset{\text{g.d.}}{-} \mathbf{v})(0) = \sum_{|I|>0} \hat{W}_IX_I$, then from (8) we have the recursive formulas

$$\widetilde{UV}_i(t) = \hat{W}_i + \int_0^t v_i(s)ds - \int_0^t u_i(s)ds, \tag{9}$$

$$\widetilde{UV}_{i_1,\dots,i_k}(t) = \hat{W}_{i_1,\dots,i_k} + \int_0^t v_{i_1,\dots,i_k}(s) - \int_0^t u_{i_1}(s)\widetilde{UV}_{i_2,\dots,i_k}(s)ds. \tag{10}$$

If we let $\widetilde{uv}_I = \dot{\widetilde{UV}}_I$, from the above we see that the $\widetilde{uv}_I$ satisfy $\widetilde{uv}_i(t) = v_i(t) - u_i(t)$ and $\widetilde{uv}_{i_1,\dots,i_k}(t) = v_{i_1,\dots,i_k}(t) - u_{i_1}(t)\widetilde{UV}_{i_2,\dots,i_k}(t)$.

The concepts of polynomial inputs, extended inputs, formal trajectories, generalized differences, etc., have truncated analogues. Let us say that a polynomial input $\mathbf{v}$ has *order* $\le r$ if the values of $\mathbf{v}$ are linear combinations of monomials of degree $\le r$. The smallest such r is called the *order* of $\mathbf{v}$. We say that $\mathbf{v}$ is of *finite order* if it has order r for some integer $r > 0$.

If $\mathbf{v}$ is a polynomial input of order $\le r$, we can regard $\mathbf{v}$ as an $A_0^r(\mathbf{X})$-valued rather than $\hat{A}_0(\mathbf{X})$-valued function, and we define the *rth-order truncated formal trajectory* determined by $\mathbf{v}$ to be the solution of the initial value problem $\dot{S} = S\mathbf{v}$, $S(0) = 1$, $S(t) \in A^r(\mathbf{X})$ on $[0,T]$ (here $A_0^r(\mathbf{X}) = A^r(\mathbf{X}) \cap A_0(\mathbf{X})$). We will use $S_{\mathbf{v}}^r$ to denote the rth-order truncated formal trajectory determined by $\mathbf{v}$ in $A^r(\mathbf{X})$.

If $\mathbf{u}$ is an ordinary input and $\mathbf{v}$ is a polynomial input of order $\le r$, we can also define an *rth-order truncated generalized difference* of $\mathbf{u}$ and $\mathbf{v}$, which is an absolutely continuous $A_0^r(\mathbf{X})$-valued function on $[0,T]$ that satisfies

$$\dot{W} = -\mathbf{u}W + \mathbf{v} - \mathbf{u}, \quad W(t) \in A_0^r(\mathbf{X}). \tag{11}$$

We will use the notation $(\mathbf{u} \overset{\text{g.d.(r)}}{-} \mathbf{v})$ to denote an rth-order truncated generalized difference of $\mathbf{u}$ and $\mathbf{v}$. It is uniquely determined by $(\mathbf{u} \overset{\text{g.d.(r)}}{-} \mathbf{v})(0)$. Let $\mathbf{u} = u_1X_1 + \cdots + u_mX_m$ and $\mathbf{v} = \sum_{0<|I|\le r} v_IX_I$. Let $(\mathbf{u} \overset{\text{g.d.(r)}}{-} \mathbf{v})(t) = \sum_{0<|I|\le r} \widetilde{UV}_I(t)X_I$ be an rth-order truncated generalized difference of $\mathbf{u}$ and $\mathbf{v}$. Then the $\widetilde{UV}_I, 0 < |I| \le r$, can still be calculated by (9) and (10) once the initial values $\widetilde{UV}_I(0)$ are known.

For more general results and some of the generalizations, we refer to [20], [21].

2.2. A convergence theorem. Now we state a convergence theorem from [19] that is needed later.

Let $\mathbf{v} = \sum_{0<|I|\le r} v_IX_I$ be an extended input of order $\le r$. Then we know that $\mathbf{v} = \sum_{0<|I|\le r} \frac{v_I}{|I|}[X_I]$. As was said in the introduction, $\mathbf{v}$ can be plugged into any system (1) if the vector fields $f_1,\dots,f_m$ are of class C^{r-1}. The result is a time-varying ordinary differential equation $\dot{x} = \sum_{0<|I|\le r} \frac{v_I(t)}{|I|}[f_I](x)$, where we write $[f_I] \overset{\text{def}}{=} [f_{i_1},[f_{i_2},[\cdots,[f_{i_{k-1}},f_{i_k}]\cdots]]]$ for $I = (i_1,\dots,i_k)$.

Let $\mathbf{v} = \sum_{0<|I|\le r} v_IX_I$ be an extended input of order $\le r$. A sequence $\{\mathbf{u}^j\}$ of ordinary inputs *EI(r)-converges* to $\mathbf{v}$ if the following condition is satisfied:

For every integer $n > 0$, every point $p \in \mathbb{R}^n$, any sequence $\{p^j\} \subseteq \mathbb{R}^n$ that converges to p, and any vector fields $f_1,\dots,f_m$ of class C^{r-1} on $\mathbb{R}^n$, if the initial

value problem

$$\dot{x} = \sum_{0<|I|\le r} \frac{v_I(t)}{|I|}[f_I](x),\ x(0) = p,$$

has a unique solution x^∞ which is defined on $[0,T]$ and if x^j is a maximal solution of the initial value problem

$$\dot{x} = \sum_{k=1}^{m} u_k^j(t) f_k(x),\ x(0) = p^j,$$

then the x^j are defined on $[0,T]$ for j large enough and converge uniformly to x^∞ on $[0,T]$ as $j \to \infty$.

With these preliminaries, we have the following convergence theorem from [19].

THEOREM 2.1. *Let r be a positive integer. Let $\{\mathbf{u}^j = (u_1^j, \dots, u_m^j)\} \subseteq L^1([0,T], \mathbb{R}^m)$ be a sequence of ordinary inputs. Let $\mathbf{v} = \sum_{0<|I|\le r} v_I X_I$ be a polynomial input of order $\le r$. Assume that there exist a sequence $\{\mathbf{v}^j = \sum_{0<|I|\le r} v_I^j X_I\}$ of polynomial inputs of order $\le r$ and rth-order truncated generalized differences $(\mathbf{u}^j \overset{\text{g.d.(r)}}{-} \mathbf{v}^j) = \sum_{0<|I|\le r} \widetilde{UV}_I^j X_I$ of $\mathbf{u}^j$ and $\mathbf{v}^j$ such that*

c1(r). *the indefinite integrals $\int_0^t v_I^j(s)ds$ converge to $\int_0^t v_I(s)ds$ uniformly on $[0,T]$ as $j \to \infty$ for all $0 < |I| \le r$,*

c2(r). *the $\widetilde{UV}_I^j$ converge to 0 uniformly as $j \to \infty$ for $0 < |I| \le r$,*

c3(r). *the L^1 norms of the $\widetilde{uv}_I^j = \dot{\widetilde{UV}}_I^j$ for $|I| = r$ and of the v_I^j for $0 < |I| \le r$ are uniformly bounded.*

Then

C1. $\mathbf{v}$ *is an extended input of order $\le r$;*

C2. *the $\mathbf{u}^j$ EI(r)-converge to $\mathbf{v}$.*

Remark 2.3. It is shown in [19] that if a sequence $\{\mathbf{u}^j\}$ of ordinary inputs EI(r)-converges to an extended input $\mathbf{v}$ of order r, then the $S^r_{\mathbf{u}^j}$ converge to $S^r_{\mathbf{v}}$ uniformly; i.e., if we write $S^r_{\mathbf{u}^j} = 1 + \sum_{0<|I|\le r} U_I^j X_I$ and $S^r_{\mathbf{v}} = 1 + \sum_{0<|I|\le r} H_I V_I$, then the U_I^j converge to H_I uniformly for all $0 < |I| \le r$.

Remark 2.4. In practice, we just know the sequence $\{\mathbf{u}^j\}$. We do not know a priori if it is convergent or what its limit $\mathbf{v}$ is even if it converges. We have to find sequences $\{\mathbf{v}^j\}$ and $(\mathbf{u}^j \overset{\text{g.d.(r)}}{-} \mathbf{v}^j)$ so that c1(r), c2(r), and c3(r) are satisfied for some r. From (9) and (10) we see that

$$\widetilde{UV}_i^j(t) = \widetilde{UV}_i^j(0) + \int_0^t v_i^j(s)ds - \int_0^t u_i^j(s)ds,$$

$$\widetilde{UV}_{i_1,\dots,i_k}^j(t) = \widetilde{UV}_{i_1,\dots,i_k}^j(0) + \int_0^t v_{i_1,\dots,i_k}^j(s) - \int_0^t u_{i_1}^j(s)\widetilde{UV}_{i_2,\dots,i_k}^j(s)ds.$$

If we let $V_I^j(t) = \widetilde{UV}_I^j(0) + \int_0^t v_I^j(s)ds$, then we can rewrite the above as

$$\widetilde{UV}_i^j(t) = V_i^j(t) - \int_0^t u_i^j(s)ds, \tag{12}$$

$$\widetilde{UV}_{i_1,\dots,i_k}^j(t) = V_{i_1,\dots,i_k}^j(t) - \int_0^t u_{i_1}^j(s)\widetilde{UV}_{i_2,\dots,i_k}^j(s)ds. \tag{13}$$

If we can find absolutely continuous functions V_I^j for $0 < |I| \le r$ such that

c1′(r). the V_I^j converge to absolutely continuous functions V_I uniformly for all $0 < |I| \le r$,

c2′(r). the $\widetilde{UV}_I^j$ determined by (12) and (13) converge to 0 uniformly for $0 < |I| \le r$,

c3′(r). the L^1 norms of the $\dot{\widetilde{UV}}_I^j$ for $|I| = r$ and of the $\dot{V}_I^j$ for $0 < |I| \le r$ are uniformly bounded,

then the conclusions C1 and C2 in Theorem 2.1 hold, and the EI(r)-limit of the $\mathbf{u}^j$ is equal to $\mathbf{v} = \sum_{0<|I|\le r} \dot{V}_I(t) X_I$.

To see an explicit example of how Theorem 2.1 is used, see Example 3.1 in the next section.

3. Approximate tracking: A simple example. Theorem 2.1 can be applied to the problem of approximating a given trajectory of an extended system. Our final goal is, for any given extended input $\mathbf{v}$ of finite order, find a sequence $\{\mathbf{u}^j\}$ of ordinary inputs that converges to $\mathbf{v}$. Before we describe how this can be done, we present some simple examples to show the basic ideas of how Theorem 2.1 can be applied to compute the limit of sequences of some highly oscillatory ordinary inputs.

Example 3.1. Let

$$u_1^j(t) = \eta_1(t) + j^{\frac{2}{3}} \cos \omega_1 jt, \qquad u_2^j(t) = \eta_2(t) + j^{\frac{2}{3}} \eta_3(t) \cos \omega_2 jt,$$

where η_i are functions of class C^1 on $[0, T]$, ω_1, ω_2 are nonzero numbers such that $2\omega_1 + \omega_2 = 0$. Using Theorem 2.1 we can show that $\{\mathbf{u}^j\}$ is convergent to some $\mathbf{v}$, and we can find $\mathbf{v}$ explicitly.

As the first step, we let

$$U_1^j(t) = \int_0^t u_1^j(s)ds = \int_0^t \eta_1(s)\, ds + \frac{j^{-\frac{1}{3}}}{\omega_1} \sin \omega_1 jt,$$
$$U_2^j(t) = \int_0^t u_2^j(s)ds = \int_0^t \eta_2(s)\, ds + \frac{j^{-\frac{1}{3}}}{\omega_2} \eta_3(t) \sin \omega_2 jt - \frac{j^{-\frac{1}{3}}}{\omega_2} \int_0^t \eta_3'(s) \sin \omega_2 js\, ds.$$

Letting

$$V_1^j(t) = \int_0^t \eta_1(s)\, ds, \qquad V_2^j(t) = \int_0^t \eta_2(s)\, ds - \frac{j^{-\frac{1}{3}}}{\omega_2} \int_0^t \eta_3'(s) \sin \omega_2 js\, ds,$$

we get

$$\widetilde{UV}_1^j(t) = -\frac{j^{-\frac{1}{3}}}{\omega_1} \sin \omega_1 jt, \qquad \widetilde{UV}_2^j(t) = -\frac{j^{-\frac{1}{3}}}{\omega_2} \eta_3(t) \sin \omega_2 jt.$$

Now it is easily computed that

$$\int_0^t u_1^j(s) \widetilde{UV}_1^j(s)\, ds = \int_0^t \eta_1(s) \widetilde{UV}_1^j(s) ds + \frac{j^{-\frac{2}{3}}}{4\omega_1^2} \left[\cos 2\omega_1 jt - 1\right],$$
$$\int_0^t u_1^j(s) \widetilde{UV}_2^j(s)\, ds = \int_0^t \eta_1(s) \widetilde{UV}_2^j(s) ds + \frac{j^{-\frac{2}{3}} \eta_3(t)}{2\omega_2} \left[\frac{\cos(\omega_1 + \omega_2)jt}{\omega_1 + \omega_2} + \frac{\cos(\omega_2 - \omega_1)jt}{\omega_2 - \omega_1}\right]$$

$$- \frac{j^{-\frac{2}{3}} \eta_3(0)}{2\omega_2} \left[\frac{1}{\omega_1 + \omega_2} + \frac{1}{\omega_2 - \omega_1}\right] - \frac{j^{-\frac{2}{3}}}{2\omega_2} \int_0^t \eta_3'(s) \left[\frac{\cos(\omega_1 + \omega_2)js}{\omega_1 + \omega_2} + \frac{\cos(\omega_2 - \omega_1)js}{\omega_2 - \omega_1}\right] ds,$$

$$\int_0^t u_2^j(s)\widetilde{UV}_1^j(s)\,ds = \int_0^t \eta_2(s)\widetilde{UV}_1^j(s)ds + \frac{j^{-\frac{2}{3}}\eta_3(t)}{2\omega_1}\left[\frac{\cos(\omega_1+\omega_2)jt}{\omega_1+\omega_2} + \frac{\cos(\omega_1-\omega_2)jt}{\omega_1-\omega_2}\right]$$

$$-\frac{j^{-\frac{2}{3}}\eta_3(0)}{2\omega_1}\left[\frac{1}{\omega_1+\omega_2} + \frac{1}{\omega_1-\omega_2}\right] - \frac{j^{-\frac{2}{3}}}{2\omega_1}\int_0^t \eta_3'(s)\left[\frac{\cos(\omega_1+\omega_2)js}{\omega_1+\omega_2} + \frac{\cos(\omega_1-\omega_2)js}{\omega_1-\omega_2}\right] ds,$$

$$\int_0^t u_2^j(s)\widetilde{UV}_2^j(s)\,ds = \int_0^t \eta_2(s)\widetilde{UV}_2^j(s)ds + \frac{j^{-\frac{2}{3}}}{4\omega_2^2}\left[\eta_3^2(t)\cos 2\omega_2 jt - \eta_3^2(0)\right]$$

$$-\frac{j^{-\frac{2}{3}}}{2\omega_2^2}\int_0^t \eta_3(s)\eta_3'(s)\cos 2\omega_2 js\,ds.$$

So if we let

$$\begin{aligned}
V_{1,1}^j(t) &= \int_0^t \eta_1(s)\widetilde{UV}_1^j(s)ds - \frac{j^{-\frac{2}{3}}}{4\omega_1^2},\\
V_{1,2}^j(t) &= \int_0^t \eta_1(s)\widetilde{UV}_2^j(s)ds - \frac{j^{-\frac{2}{3}}\eta_3(0)}{2\omega_2}\left[\frac{1}{\omega_1+\omega_2} + \frac{1}{\omega_2-\omega_1}\right]\\
&\quad -\frac{j^{-\frac{2}{3}}}{2\omega_2}\int_0^t \eta_3'(s)\left[\frac{\cos(\omega_1+\omega_2)js}{\omega_1+\omega_2} + \frac{\cos(\omega_2-\omega_1)js}{\omega_2-\omega_1}\right] ds,\\
V_{2,1}^j(t) &= \int_0^t \eta_2(s)\widetilde{UV}_1^j(s)ds - \frac{j^{-\frac{2}{3}}\eta_3(0)}{2\omega_1}\left[\frac{1}{\omega_1+\omega_2} + \frac{1}{\omega_1-\omega_2}\right]\\
&\quad -\frac{j^{-\frac{2}{3}}}{2\omega_1}\int_0^t \eta_3'(s)\left[\frac{\cos(\omega_1+\omega_2)js}{\omega_1+\omega_2} + \frac{\cos(\omega_1-\omega_2)js}{\omega_1-\omega_2}\right] ds,\\
V_{2,2}^j(t) &= \int_0^t \eta_2(s)\widetilde{UV}_2^j(s)ds - \frac{j^{-\frac{2}{3}}\eta_3^2(0)}{4\omega_2^2} - \frac{j^{-\frac{2}{3}}}{2\omega_2^2}\int_0^t \eta_3(s)\eta_3'(s)\cos 2\omega_2 js\,ds,
\end{aligned}$$

then we get

$$\begin{aligned}
\widetilde{UV}_{1,1}^j(t) &= -\frac{j^{-\frac{2}{3}}}{4\omega_1^2}\cos 2\omega_1 jt,\\
\widetilde{UV}_{1,2}^j(t) &= -\frac{j^{-\frac{2}{3}}\eta_3(t)}{2\omega_2}\left[\frac{\cos(\omega_1+\omega_2)jt}{\omega_1+\omega_2} + \frac{\cos(\omega_2-\omega_1)jt}{\omega_2-\omega_1}\right],\\
\widetilde{UV}_{2,1}^j(t) &= -\frac{j^{-\frac{2}{3}}\eta_3(t)}{2\omega_1}\left[\frac{\cos(\omega_1+\omega_2)jt}{\omega_1+\omega_2} + \frac{\cos(\omega_1-\omega_2)jt}{\omega_1-\omega_2}\right],\\
\widetilde{UV}_{2,2}^j(t) &= -\frac{j^{-\frac{2}{3}}\eta_3^2(t)}{4\omega_2^2}\cos 2\omega_2 jt.
\end{aligned}$$

There are eight indices of degree 3, namely, $(1,1,1)$, $(1,1,2)$, $(1,2,1)$, $(1,2,2)$, $(2,1,1)$, $(2,1,2)$, $(2,2,1)$, $(2,2,2)$. We simply let $V_{i_1,i_2,i_3}^j(t) = \int_0^t u_{i_1}^j(s)\widetilde{UV}_{i_2,i_3}^j(s)ds$, so that $\widetilde{UV}_{i_1,i_2,i_3}^j(t) \equiv 0$. The V_{i_1,i_2,i_3}^j can be computed explicitly. We just compute $V_{1,1,2}^j$.

By definition we have

$$\begin{aligned} V^j_{1,1,2}(t) &= \int_0^t \eta_1(s)\widetilde{UV}^j_{1,2}(s) \\ &\quad - \int_0^t \eta_3(s)\left[\frac{\cos\omega_1 js\cos(\omega_1+\omega_2)js}{2\omega_2(\omega_1+\omega_2)} + \frac{\cos\omega_1 js\cos(\omega_2-\omega_1)js}{2\omega_2(\omega_2-\omega_1)}\right]ds \\ &= -\int_0^t \frac{\eta_3(s)}{4\omega_2(\omega_1+\omega_2)}ds + o(1). \end{aligned}$$

In the above $o(1)$ denotes the terms that converge to 0 uniformly as $j\to\infty$. Also we have used the fact $2\omega_1+\omega_2=0$ to get the first term, since

$$\cos\omega_1 js\cos(\omega_1+\omega_2)js = \frac{1}{2}[\cos(2\omega_1+\omega_2)js + \cos(\omega_1-\omega_1-\omega_2)js] = \frac{1}{2}[1+\cos\omega_2 js].$$

Similarly, one can compute all the other $V^j_{i_1,i_2,i_3}$.

From the definition of the V^j_I we can get that

$$\lim_{j\to\infty} V^j_1(t) = \int_0^t \eta_1(s)\,ds, \quad \lim_{j\to\infty} V^j_2(t) = \int_0^t \eta_2(s)\,ds,$$

$$\lim_{j\to\infty} V^j_{1,1,2}(t) = -\int_0^t \frac{\eta_3(s)}{4\omega_2(\omega_1+\omega_2)}ds,$$

$$\lim_{j\to\infty} V^j_{1,2,1}(t) = -\int_0^t \frac{\eta_3(s)}{4\omega_1(\omega_1+\omega_2)}ds,$$

$$\lim_{j\to\infty} V^j_{2,1,1}(t) = -\int_0^t \frac{\eta_3(s)}{8\omega_1^2}ds,$$

and all the other V^j_I converge to 0 uniformly. It is also clear that if we let $v^j_I = \dot V^j_I$, then the $\|v^j_I\|_{L^1[0,T]}$ are uniformly bounded. Therefore if we let

$$\mathbf{v} = \eta_1(t)X_1 + \eta_2(t)X_2 - \frac{\eta_3(t)}{4\omega_2(\omega_1+\omega_2)}X_1X_1X_2 - \frac{\eta_3(t)}{4\omega_1(\omega_1+\omega_2)}X_1X_2X_1 - \frac{\eta_3(t)}{8\omega_1^2}X_2X_1X_1,$$

using the fact that $\omega_2=-2\omega_1$, and $[X_1,[X_1,X_2]] = X_1X_1X_2 - 2X_1X_2X_1 + X_2X_1X_1$, we get that $\mathbf{v} = \eta_1(t)X_1 + \eta_2(t)X_2 - \frac{\eta_3(t)}{8\omega_1^2}[X_1,[X_1,X_2]]$. From Theorem 2.1 we can conclude that the $\mathbf{u}^j$ EI(3)-converge to $\mathbf{v}$.

4. Some definitions and a special sequence of ordinary inputs. In this section we do some preliminary work for the general approximate tracking algorithm. We first introduce a number of new definitions and review some known facts about the free Lie algebra $L(\mathbf{X})$ generated by the indeterminates $\{X_1,\dots,X_m\}$ and about the *Chen–Fliess* product expansion of formal trajectories. Then we analyze one special sequence $\{u^j = (j^{\frac{m-1}{m}}e^{ij\omega_1 t},\dots,j^{\frac{m-1}{m}}e^{ij\omega_m t})\}$ of ordinary inputs in detail and show that $\{u^j\}$ is convergent to some extended input of finite order (here the ω_k are constants, $i=\sqrt{-1}$). The sequences of this form will be generalized later, and they play a crucial rule in our approximate tracking algorithm described in the next section.

4.1. P. Hall basis and Chen–Fliess product expansions of formal trajectories. Suppose that $\mathbf{v}$ is an rth-order extended input with coefficients of class C^1. Our goal is to write an explicit formula for a sequence of ordinary inputs that converges to $\mathbf{v}$. The basic idea for solving this problem is to use highly oscillatory inputs as was done in the example of section 3. The HOSs used in our general approximation algorithm involve a finite set of frequencies ω chosen so as to satisfy some special resonance conditions. We proceed by trying to handle each bracket in $\mathbf{v}$ separately. Let $L(\mathbf{X})_{\nu_1,\dots,\nu_m}$ denote the linear span of all the brackets $B \in \mathcal{B}r(\mathbf{X})$ such that $\delta_k(B) = \nu_k, k = 1,\dots,m$. Then $L(\mathbf{X})$ is the direct sum of the spaces $L(\mathbf{X})_{\nu_1,\dots,\nu_m}$. In particular an extended input $\mathbf{v}$ of finite order has a unique decomposition into a sum $\sum_{\nu_1,\dots,\nu_m} \mathbf{v}_{\nu_1,\dots,\nu_m}$, where each $\mathbf{v}_{\nu_1,\dots,\nu_m}$ is $L(\mathbf{X})_{\nu_1,\dots,\nu_m}$ valued. We try to produce, for each $\mathbf{v}_{\nu_1,\dots,\nu_m}$, an HOS $\{u^j_{\nu_1,\dots,\nu_m}\}$ that converges to $\mathbf{v}_{\nu_1,\dots,\nu_m}$. We then let $u^j = \sum_{\nu_1,\dots,\nu_m} u^j_{\nu_1,\dots,\nu_m}$ and hope that this will work. It turns out that even though the "input-to-trajectory" map is highly nonlinear a kind of "high frequency superposition principle" holds, and the u^j converge to $\mathbf{v}$, *provided that the frequencies associated to the various components* $\mathbf{v}_{\nu_1,\dots,\nu_m}$ *are independent* in a sense that will be made precise below.

If B is a Lie bracket in $L(\mathbf{X})$, $\delta_k(B) = \nu_k, k = 1,\dots,m$, then we define the *multiplicity* of B to be the dimension of $L(\mathbf{X})_{\nu_1,\dots,\nu_m}$.

In order to carry out the above program, one has to take into account the fact that it is not obvious how to decompose an extended input into parts in a canonical way (although there is a unique decomposition of $\mathbf{v}$ into a sum $\sum_{\nu_1,\dots,\nu_m} \mathbf{v}_{\nu_1,\dots,\nu_m}$). The general expression for an extended input obtained in (5) is not suitable because the brackets $[X_I]$ are not independent. What is needed is to write in an explicit way a *basis* of $L(\mathbf{X})$. One way of doing that is by using a *P. Hall basis*. (Cf. [1]. For an explanation of the reason why this is the right kind of basis for our problem, cf. [15].)

We recall that a *P. Hall set* $\mathcal{B}$ of formal brackets is a subset of $\mathcal{FB}r(\mathbf{X})$, endowed with a total ordering $\preceq$, that satisfies the following:

PH1. If $B, B' \in \mathcal{B}$ and $\delta(B) < \delta(B')$, then $B \preceq B'$;

PH2. Every X_k is in $\mathcal{B}$;

PH3. If B is a formal bracket and $\delta(B) > 1$, so that B can be written in a unique way as $[B_1, B_2]$, then $B \in \mathcal{B}$ iff (i) $B_1 \in \mathcal{B}$, (ii) $B_2 \in \mathcal{B}$, (iii) $B_1 \preceq B_2$, and (iv) either $\delta(B_2) = 1$ or $B_2 = [B_3, B_4]$ and $B_3 \preceq B_1$.

We will impose the additional requirement (which is not usually included in the definition of a P. Hall set) that

PH4. $X_{k_1} \preceq X_{k_2}$ iff $k_1 < k_2$.

The canonical map μ from $\mathcal{FB}r(\mathbf{X})$ to $L(\mathbf{X})$ is not one to one as shown by the example $B_1 = [X_1, [X_1, X_2]], B_2 = [[X_2, X_1], X_1]$, which are different as formal brackets, but $B_1 = B_2$ in $L(\mathbf{X})$. If we restrict μ to $\mathcal{B}$, then μ is one to one, and it turns out that $\mu(\mathcal{B})$ is a basis of $L(\mathbf{X})$, cf., e.g., [1]. Later on, we will make no difference between $\mathcal{B}$ and $\mu(\mathcal{B})$ and use $(\mathcal{B}, \preceq)$ to denote a basis of $L(\mathbf{X})$. A basis $(\mathcal{B}, \preceq)$ coming from this way is called a *P. Hall basis* of $L(\mathbf{X})$.

We remark for future use that every $B \in \mathcal{B}$ such that $\delta(B) > 1$ can be written in a unique way as $\mathrm{ad}^{\kappa}_{B_1}(B_2)$, where $B_1 \preceq B_2$ and either $\delta(B_2) = 1$ or the left factor B_3 of B_2 satisfies $B_3 \preceq B_1$. (Here we are using the standard notation ad_B to denote the operator $Z \to [B, Z]$.) From now on we fix a choice of P. Hall basis $(\mathcal{B}, \preceq)$ of $L(\mathbf{X})$ for which PH4 holds. We let $\mathcal{B}_n$ be the set of members of $\mathcal{B}$ that are of degree n.

Next we define the *Chen–Fliess product coefficients* associated with functions $u \in L^1([0,T],\mathbb{R}^m)$ and brackets $B \in \mathcal{B}$. We follow the notations in [15].

Associate with each bracket $B \in \mathcal{B}$ and each $u = (u_1,\dots,u_m) \in L^1([0,T],\mathbb{R}^m)$, two functions $c_B(u), C_B(u)$, defined on the interval $[0,T]$. The functions $c_B(u)$ will be in $L^1([0,T],\mathbb{R})$, and then $C_B(u)$ will be given by

$$C_B(u)(t) = \int_0^t c_B(s)\,ds. \tag{14}$$

The $c_B(u), C_B(u)$ are defined recursively as follows. For $B = X_k$, we let $c_B(u)(t) = u_k(t), 0 \le t \le T$, and then define $C_B(u)(t)$ by (14). Assume that $c_B(u), C_B(u)$ have been defined for all $B \in \mathcal{B}$ of degree $\le n$, and let $B \in \mathcal{B}_{n+1}$. Then B can be written in a unique way as $\mathrm{ad}^{\kappa}_{B_1}(B_2)$, where either $\delta(B_2) = 1$ or the left factor B_3 of B_2 satisfies $B_3 \preceq B_1$. We then define $c_B(u) = \frac{1}{\kappa!}(C_{B_1}(u))^{\kappa} c_{B_2}(u)$ and again define $C_B(u)$ by (14). This completes the recursive definition of the functions $c_B(u), C_B(u)$.

For each $u = (u_1,\dots,u_m) \in L^1([0,T],\mathbb{R}^m)$, let $S_{\mathbf{u}}$ be the formal trajectory determined by $\mathbf{u} = u_1X_1 + \cdots + u_mX_m$. We will simply say that $S_{\mathbf{u}}$ is the formal trajectory determined by u. It is proved in [15] that with the $C_B(u)$ defined as above, the formal trajectory $S_{\mathbf{u}}$ determined by u can be written as $S_{\mathbf{u}}(t) = \overleftarrow{\prod}_{B\in\mathcal{B}} \exp(C_B(u)(t)\,B)$, where "$\leftarrow$" means that the product is taken from left to right according to the total ordering $\preceq$ in $\mathcal{B}$. The above formula is the Chen–Fliess product expansion of $S_{\mathbf{u}}$, cf. [15].

4.2. A special sequence of ordinary inputs. For any finite set of real numbers F, let us write $|F|$ to denote the number of elements of F. Call a finite set $F \subseteq \mathbb{R} - \{0\}$ *canceling* if the sum of all the members of F is equal to 0. Call F *properly noncanceling* (PNC) if no proper subset of F is canceling. Call F *minimally canceling* (MC) if the only linear combinations $\sum_{\omega\in F} a_\omega\omega$ that are equal to zero and have integer coefficients such that $\sum_{\omega\in F}|a_\omega| \le |F|$ are those for which the a_ω are all equal (in which case, of course, they all have to be equal to 0, 1 or -1). It is clear that every MC set is PNC.

LEMMA 4.1. *Let $\{\omega_1,\dots,\omega_m\} \subseteq \mathbb{R} - \{0\}$ be MC. Let $\{u^j = (u_1^j,\dots,u_m^j)\}$, with $u_k^j(t) = j^{\frac{m-1}{m}} e^{ij\omega_k t}$, be a sequence of inputs. Then the u^j EI(m)-converge to*

$$\begin{aligned}\mathbf{u}^\infty &= \sum_{\ell_1\ne\ell_2\ne\cdots\ne\ell_m} \frac{1}{i^{m-1}\omega_{\ell_1}(\omega_{\ell_1}+\omega_{\ell_2})\cdots(\omega_{\ell_1}+\cdots+\omega_{\ell_{m-1}})} X_{\ell_1}\cdots X_{\ell_m}\\ &= \sum_{\ell_1\ne\ell_2\ne\cdots\ne\ell_m} \frac{1}{i^{m-1}m\,\omega_{\ell_1}(\omega_{\ell_1}+\omega_{\ell_2})\cdots(\omega_{\ell_1}+\cdots+\omega_{\ell_{m-1}})} [X_{\ell_1,\dots,\ell_m}].\end{aligned}$$

The proof follows from a direct verification that the conditions of Theorem 2.1 are satisfied with u^j and $\mathbf{u}^\infty$. We show how this is done by an example.

Example 4.1. Let $m = 3$, $\{\omega_1,\omega_2,\omega_3\} \subseteq \mathbb{R} - \{0\}$ be MC, and $u^j = (u_1^j, u_2^j, u_3^j)$ with $u_k^j(t) = j^{\frac{2}{3}} e^{ij\omega_k t}$. As in Example 3.1, we let $U_\ell^j(t) = \int_0^t u_\ell^j(s)\,ds = \frac{j^{-\frac{1}{3}}}{i\omega_\ell}[e^{ij\omega_\ell t} - 1]$. So if we let $V_\ell^j(t) = -\frac{j^{-\frac{1}{3}}}{i\omega_\ell}$, we get $\widetilde{UV}_\ell^j(t) = -\frac{j^{-\frac{1}{3}}}{i\omega_\ell} e^{ij\omega_\ell t}$. Then $\int_0^t u_{\ell_1}^j(s)\widetilde{UV}_{\ell_2}^j(s)ds = -\frac{j^{-\frac{2}{3}}}{i^2\omega_{\ell_2}(\omega_{\ell_1}+\omega_{\ell_2})}[e^{ij(\omega_{\ell_1}+\omega_{\ell_2})t} - 1]$. Letting $V_{\ell_1,\ell_2}^j(t) = \frac{j^{-\frac{2}{3}}}{i^2\omega_{\ell_2}(\omega_{\ell_1}+\omega_{\ell_2})}$, we have $\widetilde{UV}_{\ell_1,\ell_2}^j(t)$ $= \frac{j^{-\frac{2}{3}}}{i^2\omega_{\ell_2}(\omega_{\ell_1}+\omega_{\ell_2})} e^{ij(\omega_{\ell_1}+\omega_{\ell_2})t}$. Finally we simply let

$$V^j_{\ell_1,\ell_2,\ell_3}(t) = \int_0^t u^j_{\ell_1}(s)\widetilde{UV}^j_{\ell_2,\ell_3}(s)\,ds = \frac{1}{i^2\omega_{\ell_3}(\omega_{\ell_3}+\omega_{\ell_2})}\int_0^t e^{ij(\omega_{\ell_1}+\omega_{\ell_2}+\omega_{\ell_3})s}\,ds$$
$$= \begin{cases} \frac{t}{i^2\omega_{\ell_3}(\omega_{\ell_3}+\omega_{\ell_2})} & \text{if } \ell_1\neq\ell_2\neq\ell_3,\\ \frac{1}{i^3 j\omega_{\ell_3}(\omega_{\ell_3}+\omega_{\ell_2})(\omega_{\ell_3}+\omega_{\ell_2}+\omega_{\ell_1})}\left[e^{ij(\omega_{\ell_1}+\omega_{\ell_2}+\omega_{\ell_3})t}-1\right] & \text{otherwise.}\end{cases}$$

Then we have $\widetilde{UV}^j_{\ell_1,\ell_2,\ell_3}(t)\equiv 0$. Clearly the conditions of Theorem 2.1 are satisfied and the u^j EI(3)-converge to $\mathbf{u}^\infty = \sum_{\ell_1\neq\ell_2\neq\ell_3}\frac{1}{i^2\omega_{\ell_3}(\omega_{\ell_3}+\omega_{\ell_2})}X_{\ell_1}X_{\ell_2}X_{\ell_3}$. Since $\omega_1+\omega_2+\omega_3=0$, we have $\mathbf{u}^\infty = \sum_{\ell_1\neq\ell_2\neq\ell_3}\frac{1}{i^2\omega_{\ell_1}(\omega_{\ell_1}+\omega_{\ell_2})}X_{\ell_1}X_{\ell_2}X_{\ell_3}$, which is as claimed in Lemma 4.1.

Now come back to Lemma 4.1. Since $\mathcal{B}$ is a basis of $L(\mathbf{X})$, we can write each $[X_{\ell_1,\dots,\ell_m}]$ as a linear combination of brackets $B\in\mathcal{B}_m$. Then we get $\mathbf{u}^\infty = \sum_{B\in E^m} i^{1-m}g_B(\omega_1,\dots,\omega_m)B$, where E^m is the subset of $\mathcal{B}_m$ that contains all the brackets B such that $\delta_k(B)=1, k=1,\dots,m$, and $g_B(\omega_1,\dots,\omega_m)$ denote the coefficients of $B\in E^m$. Let $S^m_{\mathbf{u}^j}$ be the mth-order truncated formal trajectory determined by $\mathbf{u}^j$. By the Chen–Fliess product expansion, we get that $S^m_{\mathbf{u}^j}(t) = \mathbf{Tr}(m)(\prod^{\leftarrow}_{B\in\mathcal{B}}\exp(C_B(u^j)(t)\,B))$ in $A^m(\mathbf{X})$. It is clear also that in $A^m(\mathbf{X})$, $S^m_{\mathbf{u}^\infty}(t) = 1+\int_0^t \mathbf{u}^\infty(s)\,ds = 1+\sum_{B\in E^m} i^{1-m}g_B(\omega_1,\dots,\omega_m)t\,B$. Since $S^m_{\mathbf{u}^j}\to S^m_{\mathbf{u}^\infty}$ uniformly, cf. Remark 2.3, we see that $C_B(u^j)\to 0$ if $B\in\cup_{k=1}^m\mathcal{B}_k - E^m$ and $C_B(u^j)(t)\to i^{1-m}g_B(\omega_1,\dots,\omega_m)t$ if $B\in E^m$. So $g_B(\omega_1,\dots,\omega_m) = \frac{i^{m-1}}{t}\lim_{j\to\infty}C_B(u^j)(t)$ for $B\in E^m$.

Next we generalize this to an arbitrary bracket $B\in\mathcal{B}$. Let $\bar B\in\mathcal{B}$ be a bracket of degree $\delta(\bar B)=n>1$. Let $\{\omega_1,\dots,\omega_n\}$ be MC. We define a sequence $\{u^j\}$ of ordinary inputs associated to $\bar B$ by the following

$$u^j_k(t) = j^{\frac{n-1}{n}}\sum_{\ell=\delta_1(\bar B)+\cdots+\delta_{k-1}(\bar B)+1}^{\delta_1(\bar B)+\cdots+\delta_k(\bar B)} e^{ij\omega_\ell t},\quad k=1,\dots,m. \tag{15}$$

(Note that if $\delta_k(\bar B)=0$ we just let $u^j_k(t)=0$.) Then it is easy to see that the u^j EI(n)-converge to some extended input $\mathbf{u}^\infty$ of order n and $\mathbf{u}^\infty$ can be written as $\mathbf{u}^\infty = \sum_{B\in E(\bar B)} i^{1-n}g_B(\omega_1,\dots,\omega_n)\,B$ for some constants $g_B(\omega_1,\dots,\omega_n)$ determined by $(\omega_1,\dots,\omega_n)$ and B, where $E(\bar B)$ denotes the set of the brackets $B\in\mathcal{B}_n$ which are *equivalent* to $\bar B$ in the sense that $B\in E(\bar B)$ iff $\delta_k(B)=\delta_k(\bar B)$ for $k=1,\dots,m$. It follows from the Chen–Fliess product expansion that the $g_B(\omega_1,\dots,\omega_n)$ are equal to $g_B(\omega_1,\dots,\omega_n) = \frac{i^{n-1}}{t}\lim_{j\to\infty}C_B(u^j)(t)$, which in fact do not depend on t. In particular this is true for $\bar B\in E(\bar B)$.

Remark 4.1. An alternative way of getting the general g_B is as follows. Let $\bar B\in\mathcal{B}$ be a bracket of degree $\delta(\bar B)=n$. Take another set $\mathbf{Y}=\{Y_1,\dots,Y_n\}$ of indeterminates. Fix a choice of a P. Hall basis $\mathcal{B}^{\mathbf{Y}}$ of $L(\mathbf{Y})$. Let $\{\omega_1,\dots,\omega_n\}$ be MC. Consider the sequence $\bar u^j = (\bar u^j_1\ \dots,\bar u^j_n)$ with $\bar u^j_k(t) = j^{\frac{n-1}{n}}\exp(ij\omega_k t)$, $k=1,\dots,n$. Let $\bar{\mathbf{u}}^j = \bar u^j_1 Y_1+\cdots+\bar u^j_n Y_n$. From Lemma 4.1 we know that the $\bar{\mathbf{u}}^j$ EI(n)-converge to

$$\bar{\mathbf{u}}^\infty_{\mathbf{Y}} = \sum_{B^{\mathbf{Y}}\in E^{\mathbf{Y}}} i^{1-n}g_{B^{\mathbf{Y}}}(\omega_1,\dots,\omega_n)\,B^{\mathbf{Y}}, \tag{16}$$

where $E^{\mathbf{Y}}$ denotes the set of brackets $B^{\mathbf{Y}}\in\mathcal{B}^{\mathbf{Y}}$ such that $\delta_k(B^{\mathbf{Y}})=1, k=1,\dots,n$, and

$$g_{B^{\mathbf{Y}}}(\omega_1,\dots,\omega_n) = \frac{i^{n-1}}{t}\lim_{j\to\infty}C_{B^{\mathbf{Y}}}(\bar u^j)(t).$$

Now let $\theta_{\bar{B}}$ be the algebra homomorphism from $\hat{A}(\mathbf{Y})$ to $\hat{A}(\mathbf{X})$ defined by

$$\theta_{\bar{B}}(Y_k) = X_\ell, \text{ for } k = \delta_1(\bar{B}) + \cdots + \delta_{\ell-1}(\bar{B}) + 1, \ldots, \delta_1(\bar{B}) + \cdots + \delta_\ell(\bar{B}).$$

Letting $\theta_{\bar{B}}$ act on (16) we get an $L(\mathbf{X})$-valued function $\bar{\mathbf{u}}^\infty$. This $\bar{\mathbf{u}}^\infty$ is clearly equal to $\mathbf{u}^\infty$, which is the limit of the u^j associated to $\bar{B}$ in (15). If we write the brackets in $\bar{\mathbf{u}}^\infty$ into linear combinations of brackets in $\mathcal{B}$ we see that the $g_B(\omega_1, \ldots, \omega_n), B \in E(\bar{B})$, are linear combinations of the $g_{B^{\mathbf{Y}}}(\omega_1, \ldots, \omega_n)$ for $B^{\mathbf{Y}} \in E^{\mathbf{Y}}$. This observation will be used later.

So we have associated with each bracket $B \in \mathcal{B}$, $\delta(B) > 1$, each MC set $\{\omega_1, \ldots, \omega_{\delta(B)}\}$, a number $g_B(\omega_1, \ldots, \omega_{\delta(B)})$. We will think of these $g_B(\omega_1, \ldots, \omega_{\delta(B)})$ thus defined as functions in $\delta(B)$ variables $(\omega_1, \ldots, \omega_{\delta(B)})$. (For $B = X_k$, we define $g_{X_k}(\omega) = 1$.) Although they are only defined for $(\omega_1, \ldots, \omega_{\delta(B)})$ with $\{\omega_1, \ldots, \omega_{\delta(B)}\}$ being MC, as rational functions, they are completely determined.

4.3. An alternative definition. The definition of $g_B(\omega_1, \ldots, \omega_{\delta(B)})$ given in the previous section as limits of the Chen–Fliess product coefficients of some sequences of ordinary inputs is good for analyzing their structures. Next we give an alternative definition of g_B which is good for explicit calculations. First we need some definitions.

Any set M equipped with a map $M \times M \to M$ denoted by $(a, b) \to ab$ is called a *magma*.

Example 4.2. For any two functions $f, g \in L^1[0, T]$, we let $(f, g) \to f\#g$ be defined by $(f\#g)(t) = \int_0^t f(s)dsg(t)$. Then $(L^1[0, T], \#)$ is a magma.

Example 4.3. Let $AC[0, T]$ be the set of real-valued absolutely continuous functions on $[0, T]$. We define a product $* : AC[0, T] \times AC[0, T] \to AC[0, T]$ by $(U * V)(t) = \int_0^t U(s)\dot{V}(s)ds$. Then $(AC[0, T], *)$ is a magma.

Example 4.4. Let RF_n be the set of all real-valued rational functions on $\mathbb{R}^n$. Let $\mathrm{RF} = \cup_{n=1}^\infty \mathrm{RF}_n$ with the product $\tilde{\#} : \mathrm{RF}_p \times \mathrm{RF}_q \to \mathrm{RF}_{p+q}$ given by

$$(f\tilde{\#}g)(x_1, \ldots, x_p, y_1, \ldots, y_q) = \frac{f(x_1, \ldots, x_p)}{x_1 + \cdots + x_p} g(y_1, \ldots, y_q).$$

Then $(\mathrm{RF}, \tilde{\#})$ is a magma.

Example 4.5. Let $AC([0, T], \mathbb{R}^n)$ be the set of absolutely continuous $\mathbb{R}^n$-valued functions on $[0, T]$. Let $\mathcal{FL}_n$ be the set of all maps from $AC([0, T], \mathbb{R}^n)$ to $AC[0, T]$. Let $\mathcal{FL} = \cup_{n=1}^\infty \mathcal{FL}_n$. For any $h_1 \in \mathcal{FL}_p, h_2 \in \mathcal{FL}_q$, we define the product $(h_1, h_2) \to h_1.h_2 \in \mathcal{FL}_{p+q}$ by

$$(h_1.h_2)(U_1, \ldots, U_p, V_1, \ldots, V_q)(t) = (h_1(U_1, \ldots, U_p) * h_2(V_1, \ldots, V_q))(t).$$

Then with this product $\mathcal{FL}$ is a magma.

Equipped with the bracket product, i.e., $\mathcal{FB}r(\mathbf{X}) \times \mathcal{FB}r(\mathbf{X}) \ni (B_1, B_2) \to [B_1, B_2] \in \mathcal{FB}r(\mathbf{X})$, $(\mathcal{FB}r(\mathbf{X}), [\cdot, \cdot])$ is a magma. This magma is *isomorphic* to the free magma generated by $\mathbf{X}$ (for the definition of a free magma generated by $\mathbf{X}$, cf. [1]) and has the following property: let N be any magma; then every mapping of $\mathbf{X}$ into N can be uniquely extended to a *magma homomorphism* of $\mathcal{FB}r(\mathbf{X})$ into N. (A magma homomorphism $\nu : M \to N$ is a map from $M \to N$ that satisfies $\nu(ab) = \nu(a)\nu(b)$. It is an isomorphism if it is also $1 - 1$ and onto.)

Now let $u = (u_1, \ldots, u_m)$ be a function in $L^1([0, T], \mathbb{R}^m)$. We define $\phi(u) : \mathbf{X} \to (L^1[0, T], \#)$ by

$$X_k \to \phi_{X_k}(u)(t) = u_k(t),\ k = 1, \ldots, m.$$

Then we have a unique extension of $\phi(u)$ (still denoted by $\phi(u)$) from $\mathcal{FB}r(\mathbf{X}) \to (L^1[0,T],\#)$ satisfying $\phi_{[B_1,B_2]}(u)(t) = (\phi_{B_1}(u)\#\phi_{B_2}(u))(t)$.

Define a map Θ from $\mathbf{X}$ to $\mathcal{FL}_1 \subset \mathcal{FL}$ by $\Theta_{X_k}(U)(t) = U(t)$ for $U \in AC[0,T]$ and extend Θ to a unique map (denoted by Θ again) $\Theta : \mathcal{FB}r(\mathbf{X}) \to \mathcal{FL}$. Let $B = [B_1, B_2]$. Then Θ satisfies

$$\Theta_B(U_1,\dots,U_{\delta(B)})(t) = \left(\Theta_{B_1}(U_1,\dots,U_{\delta(B_1)}) * \Theta_{B_2}(U_{\delta(B_1)+1},\dots,U_{\delta(B)})\right)(t).$$

For each fixed $B \in \mathcal{FB}r(\mathbf{X}), \delta(B) = n$, it is clear that $\Theta_B : AC([0,T],\mathbb{R}^n) \to AC[0,T]$ is multiple linear in $(U_1,\dots,U_n)$; i.e., if $U_k = \sum_{\ell\in\Omega(k)} U_k^\ell(t),\ k = 1,\dots,n$, where $\Omega(k)$ are some finite index sets and $U_k^\ell \in AC[0,T]$ for $\ell \in \Omega(k)$, then

$$\Theta_B(U_1,\dots,U_n)(t) = \sum_{(\ell_1,\dots,\ell_n)\in\Omega} \Theta_B(U_1^{\ell_1},\dots,U_n^{\ell_n})(t),$$

where $\Omega = \Omega(1)\times\Omega(2)\times\cdots\times\Omega(n)$.

Let $\Psi : \mathbf{X} \to \mathbb{RF}_1 \subset \mathbb{RF}$ be defined as follows: $\Psi_{X_k}(\omega) = 1$ for $k = 1,\dots,m$. Then extend this to a homomorphism $\Psi : \mathcal{FB}r(\mathbf{X}) \to \mathbb{RF}$. So if $B = [B_1, B_2]$, Ψ_B is a rational function in $\delta(B)$ variables satisfying

$$\begin{aligned}\Psi_B(\omega_1,\dots,\omega_{\delta(B)}) &= \Psi_{B_1}(\omega_1,\dots,\omega_{\delta(B_1)})\tilde{\#}\Psi_{B_2}(\omega_{\delta(B_1)+1},\dots,\omega_{\delta(B)}) \\ &= \frac{\Psi_{B_1}(\omega_1,\dots,\omega_{\delta(B_1)})\Psi_{B_2}(\omega_{\delta(B_1)+1},\dots,\omega_{\delta(B)})}{\omega_1+\cdots+\omega_{\delta(B_1)}}.\end{aligned}$$

Since the map $\mu : \mathcal{FB}r(\mathbf{X}) \to L(\mathbf{X})$ is one-to-one restricted to any P. Hall set in $\mathcal{FB}r(\mathbf{X})$, the maps ϕ, Θ, Ψ are well defined on any P. Hall basis of $L(\mathbf{X})$.

Let $\mathcal{B}$ be a fixed P. Hall basis of $L(\mathbf{X})$. Let $u = (u_1,\dots,u_m)$ be an ordinary input. From the definition of the $c_B(u)$ and $\phi_B(u)$ we see that $c_B(u)(t) = æ_B\phi_B(u)(t)$ for some constant $æ_B$. Clearly $æ_{X_k} = 1$. If $\delta(B) = n > 1$, write B into the unique decomposition of $ad^\kappa_{B_1}(B_2)$, where $B_1, B_2 \in \mathcal{B}$ and either $\delta(B_2) = 1$ or the left factor of B_2 is not equal to B_1. We see that $æ_B = \frac{1}{\kappa!}æ^\kappa_{B_1}æ_{B_2}$.

For any $B \in \mathcal{B}$, we define a rational function $\hat{g}_B$, depending on $\delta(B)$ variables, by

$$\hat{g}_B(\omega_1,\dots,\omega_{\delta(B)}) = æ_B\Psi_B(\omega_1,\dots,\omega_{\delta(B)}). \tag{17}$$

It is clear that $\hat{g}_{X_k}(\omega) = 1$. Let $B \in \mathcal{B}_n, n > 1$. Write the unique decomposition $B = ad^\kappa_{B_1}(B_2)$, where $B_1, B_2 \in \mathcal{B}$ and either $\delta(B_2) = 1$ or the left factor of B_2 is not equal to B_1. Let n_1, n_2 be the degrees of B_1, B_2, so that $\kappa n_1 + n_2 = n$. Then formula (17) implies

$$\begin{aligned}&\hat{g}_B(\omega_1,\dots,\omega_n) \\ &\quad= \frac{1}{\kappa!}\prod_{q=1}^{\kappa}\left(\frac{\hat{g}_{B_1}(\omega_{(q-1)n_1+1},\omega_{(q-1)n_1+2},\dots,\omega_{qn_1})}{\omega_{(q-1)n_1+1}+\omega_{(q-1)n_1+2}+\ldots+\omega_{qn_1}}\right)\hat{g}_{B_2}(\omega_{\kappa n_1+1},\omega_{\kappa n_1+2},\dots,\omega_n).\end{aligned} \tag{18}$$

Our purpose is to define g_B in terms of $\hat{g}_B$. It is clear that in order to get g_B from $\hat{g}_B$, we need to take a symmetrization procedure. To each $B \in \mathcal{B}$, associate the sequence Σ_B of indeterminates obtained by just deleting all the brackets and commas, so that, for instance, if $B = [X_1,[X_1,X_2]]$, we associate the sequence $\Sigma_B = X_1X_1X_2$. We then define a map $\theta_B : \{1,\dots,\delta(B)\} \to \{1,\dots,m\}$ by letting $\theta_B(s) = k$ if the

indeterminate in the sth place of Σ_B is X_k. Next let P_B be the set of all permutations of the set $\{1,2,\dots,\delta(B)\}$ that map the set $\{s:\theta_B(s)=k\}$ for each $k\in\{1,\dots,m\}$ to the interval $\mathcal{I}_{B,k}=\{\delta_1(B)+\cdots+\delta_{k-1}(B)+1,\dots,\delta_1(B)+\cdots+\delta_k(B)\}$. We then define $g_B(\omega_1,\dots,\omega_{\delta(B)})$ by

$$g_B(\omega_1,\dots,\omega_{\delta(B)})=\sum_{\pi\in P_B}\hat{g}_B(\omega_{\pi(1)},\dots,\omega_{\pi(\delta(B))}). \tag{19}$$

Next we prove that the functions g_B thus defined from the symmetrization of the $\hat{g}_B$ are the same as those defined to be the limits of the Chen–Fliess product coefficients $C_B(u^j)$ of some sequences $\{u^j\}$ defined in section 4.2. First we need an auxiliary result. Let $\hat{\omega}=(\omega_1,\dots,\omega_n)$ be an $n$tuple of real numbers. Then we say that $\hat{\omega}$ is *essentially noncanceling* (ENC) if $\sum_{\ell\in\Omega}\omega_\ell\neq 0$ for any proper subset Ω of $\{1,\dots,n\}$. (Note that in the definition of ENC, the entries ω_k of $(\omega_1,\dots,\omega_n)$ are allowed to be equal.) Clearly if $\Omega=\{\omega_1,\dots,\omega_n\}$ is MC, then for any $\tilde{\omega}_i\in\Omega$, $(\tilde{\omega}_1,\dots,\tilde{\omega}_n)\in\Omega\times\cdots\times\Omega$ is ENC.

LEMMA 4.2. *Let $B\in\mathcal{B}$ be a bracket of degree n. Let $\hat{\omega}=(\omega_1,\dots,\omega_n)$ be ENC. Let $\{U^j=(U_1^j,\dots,U_n^j)\}$ be a sequence of $\mathbb{R}^n$-valued functions on $[0,T]$ defined by $U_k^j(t)=j^{\frac{n-1}{n}}\int_0^t e^{ij\omega_k s}\,ds$, $k=1,\dots,n$. Then for $j=1,2,\dots$, and $t\in[0,T]$, we have*

$$i^{n-1}\Theta_B(U_1^j,\dots,U_n^j)(t)=\int_0^t\Psi_B(\omega_1,\dots,\omega_n)e^{ij(\omega_1+\cdots+\omega_n)s}\,ds+R_B^j(t), \tag{20}$$

where the R_B^j are finite linear combinations of integrals of the form $\int_0^t h_\xi e^{ij\sum_{\ell\in\Omega(\xi)}\omega_\ell s}\,ds$, where h_ξ are some constants and $\Omega(\xi)$ are some proper subsets of $\{1,2,\dots,n\}$.

Proof. We use induction on n to prove the lemma. Obviously (20) is true if $B=X_k$. Assume that (20) is true for all $B\in\mathcal{B}$ of degree $\le n-1$. Let $B\in\mathcal{B}_n$, $n>1$. Write $B=[B_1,B_2]$ with $B_1,B_2\in\mathcal{B}$, $B_1\preceq B_2$. Assume that $\delta(B_1)=n_1,\delta(B_2)=n_2$, so $n_1+n_2=n$. Let $(\omega_1,\dots,\omega_n)$ be ENC. Then both $(\omega_1,\dots,\omega_{n_1})$ and $(\omega_{n_1+1},\dots,\omega_n)$ are ENC. Let $\bar{U}_k^j(t)=j^{\frac{n_1-1}{n_1}}\int_0^t e^{ij\omega_k s}ds$ for $k=1,\dots,n_1$, $\bar{U}_k^j(t)=j^{\frac{n_2-1}{n_2}}\int_0^t e^{ij\omega_k s}ds$ for $k=n_1+1,\dots,n$. So $U_k^j(t)=j^{\frac{n-1}{n}-\frac{n_1-1}{n_1}}\bar{U}_k^j(t)$ for $k=1,\dots,n_1$, $U_k^j(t)=j^{\frac{n-1}{n}-\frac{n_2-1}{n_2}}\bar{U}_k^j(t)$ for $k=n_1+1,\dots,n$. By induction we know that

$$i^{n_1-1}\Theta_{B_1}(\bar{U}_1^j,\dots,\bar{U}_{n_1}^j)(t)=\int_0^t\Psi_{B_1}(\omega_1,\dots,\omega_{n_1})e^{ij(\omega_1+\cdots+\omega_{n_1})s}\,ds+R_{B_1}^j(t),$$

$$i^{n_2-1}\Theta_{B_2}(\bar{U}_{n_1+1}^j,\dots,\bar{U}_n^j)(t)=\int_0^t\Psi_{B_2}(\omega_{n_1+1},\dots,\omega_n)e^{ij(\omega_{n_1+1}+\cdots+\omega_n)s}\,ds+R_{B_2}^j(t),$$

with $R_{B_1}^j,R_{B_2}^j$ satisfying the induction assumptions. We have

$$\begin{aligned}
i^{n-1}\Theta_B(U_1^j,\dots,U_n^j)(t)&=ij((i^{n_1-1}\Theta_{B_1}(\bar{U}_1^j,\dots,\bar{U}_{n_1}^j))*(i^{n_2-1}\Theta_{B_2}(\bar{U}_{n_1+1}^j,\dots,\bar{U}_n^j)))(t)\\
&=ij\int_0^t\left\{\left(\int_0^s\Psi_{B_1}(\omega_1,\dots,\omega_{n_1})e^{ij(\omega_1+\cdots+\omega_{n_1})\tau}\,d\tau+R_{B_1}^j(s)\right)\right.\\
&\qquad\left.\times\,\Psi_{B_2}(\omega_{n_1+1},\dots,\omega_n)e^{ij(\omega_{n_1+1}+\cdots+\omega_n)s}+\dot{R}_{B_2}^j(s)\right\}ds\\
&=\int_0^t\Psi_B(\omega_1,\dots,\omega_n)e^{ij(\omega_1+\cdots+\omega_n)s}\,ds+R_B^j(t),
\end{aligned}$$

where

$$R_B^j(t) = ij\int_0^t \Big\{ R_{B_1}^j(s)\Psi_{B_2}(\omega_{n_1+1},\dots,\omega_n)e^{ij(\omega_{n_1+1}+\cdots+\omega_n)s} + \dot{R}_{B_2}^j(s)\int_0^s \Psi_{B_1}(\omega_1,\dots,\omega_{n_1})e^{ij(\omega_1+\cdots+\omega_{n_1})\tau}\,d\tau + R_{B_1}^j(s)\dot{R}_{B_2}^j(s)\Big\}\,ds - \int_0^t \frac{\Psi_{B_1}(\omega_1,\dots,\omega_{n_1})\Psi_{B_2}(\omega_{n_1+1},\dots,\omega_n)e^{ij(\omega_{n_1+1}+\cdots+\omega_n)s}}{\omega_1+\cdots+\omega_{n_1}}\,ds.$$

It is clear that R_B^j satisfies the induction assumption. This finishes the proof of the lemma.

Now we are ready to show that the two definitions of the g_B give rise to the same functions. Let $B \in \mathcal{B}_n$ with $\Sigma_B = X_{\ell_1}\cdots X_{\ell_n}$. Let $u \in L^1([0,T],\mathbb{R}^m)$ be a function and $U(t) = \int_0^t u(s)ds$. Using induction, we can easily show that $\int_0^t \phi_B(u)(s)ds = \Theta_B(U_{\ell_1},\dots,U_{\ell_n})(t)$. Let $\{\omega_1,\dots,\omega_n\}$ be MC. Recall that $g_B(\omega_1,\dots,\omega_n)$ is the limit of $\frac{i^{n-1}}{t}C_B(u^j)(t) = \frac{i^{n-1}\text{æ}_B}{t}\int_0^t \phi_B(u^j)(s)ds$, where the u^j are defined by

$$u_k^j(t) = j^{\frac{n-1}{n}} \sum_{\ell=\delta_1(B)+\cdots+\delta_{k-1}(B)+1}^{\delta_1(B)+\cdots+\delta_k(B)} e^{ij\omega_\ell t}. \tag{21}$$

Let $U^j(t) = \int_0^t u^j(s)ds$. We have

$$\frac{i^{n-1}\text{æ}_B}{t}\int_0^t \phi_B(u^j)(s)ds = \frac{i^{n-1}\text{æ}_B}{t}\Theta_B(U_{\ell_1}^j,\dots,U_{\ell_n}^j)(t) = \frac{i^{n-1}\text{æ}_B}{t}\sum_{\pi\in Q_B}\Theta_B(\bar{U}_{\pi(1)}^j,\dots,\bar{U}_{\pi(n)}^j)(t),$$

where (1) $Q_B = \mathcal{I}_{B,\ell_1}\times\mathcal{I}_{B,\ell_2}\times\cdots\times\mathcal{I}_{B,\ell_n}$, $\pi = (\pi(1),\dots,\pi(n)) \in Q_B$; (2) $\bar{U}_{\pi(l)}^j(t) = j^{\frac{n-1}{n}}\int_0^t e^{ij\omega_{\pi(l)}s}ds$. Clearly $P_B \subset Q_B$. Now from the requirement that $\{\omega_1,\dots,\omega_n\}$ be MC, using Lemma 4.2 and the definition of $\hat{g}_B$, we have

$$i^{n-1}\text{æ}_B\Theta_B(\bar{U}_{\pi(1)}^j,\dots,\bar{U}_{\pi(n)}^j)(t) = \int_0^t \hat{g}_B(\omega_{\pi(1)},\dots,\omega_{\pi(n)})e^{ij(\omega_{\pi(1)}+\cdots+\omega_{\pi(n)})s}\,ds + \text{æ}_B R_B^j(t),$$

where the R_B^j converge to 0 as $j\to\infty$. So if $\omega_{\pi(1)}+\cdots+\omega_{\pi(n)} \neq 0$, then $\Theta_B(\bar{U}_{\pi(1)}^j,\dots,\bar{U}_{\pi(n)}^j)(t) \to 0$. By the minimally canceling property of the $\{\omega_1,\dots,\omega_n\}$, $\omega_{\pi(1)}+\cdots+\omega_{\pi(n)} = 0$ iff π is a permutation of $(1,\dots,n)$, i.e., $\pi \in P_B$. In that case we get

$$\lim_{j\to\infty} i^{n-1}\text{æ}_B\Theta_B(\bar{U}_{\pi(1)}^j,\dots,\bar{U}_{\pi(n)}^j)(t) = \hat{g}_B(\omega_{\pi(1)},\dots,\omega_{\pi(n)})t.$$

So we conclude that

$$\lim_{j\to\infty}\frac{i^{n-1}\text{æ}_B}{t}\Phi_B(U^j)(t) = \lim_{j\to\infty}\frac{i^{n-1}\text{æ}_B}{t}\Theta_B(U_{\ell_1}^j,\dots,U_{\ell_m}^j)(t) = \sum_{\pi\in P_B}\hat{g}_B(\omega_{\pi(1)},\dots,\omega_{\pi(n)}).$$

This shows that the functions g_B defined to be the limits of the Chen–Fliess product coefficients of some control sequences $\{u^j\}$ in (21) coincide with the functions obtained from the symmetrization of the $\hat{g}_B$ on the set $\{(\omega_1, \ldots, \omega_n) \mid \{\omega_1, \ldots, \omega_n\} \text{ is MC}\}$. So they coincide as rational functions.

5. Approximate tracking: The general case. We now describe the algorithm of approximating an arbitrary rth-order extended input by ordinary inputs. We will limit ourselves to the presentation of the algorithm in this section. The proof that it actually works will be given in the next two sections.

Let's fix a choice of P. Hall basis $(\mathcal{B}, \preceq)$ of $L(\mathbf{X})$ for which PH4 holds. We express our extended input $\mathbf{v}$ as a sum $\mathbf{v}(t) = \sum_{n=1}^{r} \sum_{B \in \mathcal{B}_n} v_B(t) B$, where the v_B are functions of class C^1 on $[0, T]$.

We take our approximating sequence to be of the form

$$u_k^j(t) = \eta_{k,0}(t) + j^{\frac{1}{2}} \sum_{\omega \in \Omega(2,k)} \eta_{\omega,k}(t) \mathrm{e}^{ij\omega t} + \sum_{n=3}^{r} j^{\frac{n-1}{n}} \sum_{\omega \in \Omega(n,k)} \eta_{\omega}(t) \mathrm{e}^{ij\omega t}. \tag{22}$$

Here

(1) the $\Omega(n,k)$ for $(n,k) \in \{2, \ldots, r\} \times \{1, \ldots, m\}$ are pairwise disjoint finite subsets of $\mathbb{R} - \{0\}$.

(2) each $\Omega(n,k)$ is symmetric; i.e., $\omega \in \Omega(n,k)$ implies $-\omega \in \Omega(n,k)$.

(3) the $\eta_{k,0}$, $\eta_{\omega,k}$, η_{ω} are complex-valued functions of class C^1 on $[0,T]$.

(4) the $\eta_{k,0}$ are in fact real valued.

(5) the identity $\eta_{-\omega} = \overline{\eta_{\omega}}$ holds for each $\omega \in \cup_{n=3}^{r} \cup_{k=1}^{m} \Omega(n,k)$, and the functions $\eta_{\omega,k}$ satisfy $\eta_{-\omega,k} = \overline{\eta_{\omega,k}}$ for $\omega \in \Omega(2,k)$.

(Here $\bar{z}$ denotes the complex conjugate of z.) Notice that the various terms of (22) are in principle complex, but conditions (4) and (5) imply that the u_k^j are real.

We now describe in detail how the sets $\Omega(n,k)$ are chosen. Let us call F *symmetrically minimally canceling* (SMC) if it is symmetric (i.e., $\omega \in F$ implies $-\omega \in F$) and contains an MC subset of cardinality $\frac{1}{2}|F|$. (In that case, it is easy to see that F has exactly two such subsets F_1, F_2, and these subsets are disjoint and satisfy $\omega \in F_1$ iff $-\omega \in F_2$.)

At this point we have to take care of an additional technical issue. The "nonlinear superposition principle" that was referred to in section 4 only makes it possible to separate brackets in $B \in \mathcal{B}$ *as long as not all their degrees* $\delta_k(B)$ *are equal.* (So, for instance, the brackets $[X_2, [X_1, [X_1, [X_1, X_2]]]]$ and $[[X_1, X_2], [X_1, [X_1, X_2]]]$, both of which are in $\mathcal{B}$, cannot be separated.) This requires that we group brackets in $\mathcal{B}$ into classes, separate the classes rather than the individual brackets, and handle the problem of fitting the coefficients of the individual brackets by a different procedure.

Divide each $\mathcal{B}_n$ into equivalence classes by declaring two members B_1, B_2 of $\mathcal{B}_n$ to be equivalent if $\delta_k(B_1) = \delta_k(B_2)$ for $k = 1, \ldots, m$. Let $\mathcal{E}_n$ be the set of equivalence classes of $\mathcal{B}_n$. For each $E \in \mathcal{E}_n$, we can define $\delta_k(E)$, $\delta(E)$ to be $\delta_k(B)$, $\delta(B)$ for any $B \in E$. Clearly the cardinality $|E|$ of E is equal to the multiplicity of the brackets $B \in E$.

For $n \geq 2$, $E \in \mathcal{E}_n$, $k \in \{1, \ldots, m\}$, choose $|E|$ sets $\Omega_{E,\rho,k}$, $\rho = 1, \ldots, |E|$ of $\mathbb{R} - \{0\}$ such that

(6) each $\Omega_{E,\rho,k}$, for $E \in \cup_{n=2}^{r} \mathcal{E}_n$, $\rho \in \{1, \ldots, |E|\}$, $k \in \{1, \ldots, m\}$, is a symmetric subset of $\mathbb{R} - \{0\}$ of cardinality $|\Omega_{E,\rho,k}| = 2\delta_k(E)$.

About the sets $\Omega_{E,\rho,k}$ for $n \geq 3$, assume

(7) for each $E \in \cup_{n=3}^{r} \mathcal{E}_n$, $\rho \in \{1, \dots, |E|\}$, the sets $\Omega_{E,\rho,k}$, $k \in \{1, \dots, m\}$, are pairwise disjoint.

For $n = 2$ we make a different assumption. We first observe that every $E \in \mathcal{E}_2$ consists of exactly one bracket which is of the form $[X_{k_1}, X_{k_2}]$ with $k_1 < k_2$. (And, conversely, every such bracket gives rise to an $E \in \mathcal{E}_2$.) We take $\Omega_{E,\rho,k_1} = \Omega_{E,\rho,k_2}$ and let $\Omega_{E,\rho,k} = \emptyset$ if $k \notin \{k_1, k_2\}$. So

(8) for each $E \in \mathcal{E}_2$, $E = [X_{k_1}, X_{k_2}]$, we have $\Omega_{E,1,k_1} = \Omega_{E,1,k_2}$.

We then let $\Omega_{E,\rho} = \bigcup_{k=1}^{m} \Omega_{E,\rho,k}$, so that $|\Omega_{E,\rho}| = 2\delta(E)$ if $\delta(E) > 2$, and $|\Omega_{E,\rho}| = 2$ if $\delta(E) = 2$. We assume

(9) each $\Omega_{E,\rho}$, for $E \in \cup_{n=3}^{r} \mathcal{E}_n$, $\rho \in \{1, \dots, |E|\}$, is SMC.

Next define $\Omega(n,k)$ by $\Omega(n,k) = \bigcup_{E \in \mathcal{E}_n} \bigcup_{\rho=1}^{|E|} \Omega_{E,\rho,k}$. Since the sets $\Omega_{E,\rho}$ are SMC, each $\Omega_{E,\rho}$ has exactly two MC subsets, and these subsets are disjoint and have cardinality $\frac{1}{2}|\Omega_{E,\rho}|$. Let $Q_{E,\rho}$ be the set whose two elements are these two MC subsets of $\Omega_{E,\rho}$.

There are two further conditions that have to be imposed on the sets $\Omega_{E,\rho}$. Let us call a finite collection $\{S_\lambda\}_{\lambda \in \Lambda}$ of finite subsets of $\mathbb{R}$ *independent* with respect to r if the sets S_λ are pairwise disjoint and, whenever a linear combination $\sum_{\lambda \in \Lambda} \sum_{s \in S_\lambda} a_s s$ vanishes, and the a_s are integers such that $\sum_{\lambda \in \Lambda} \sum_{s \in S_\lambda} |a_s| \le r$, it follows that each of the sums $\sum_{s \in S_\lambda} a_s s$ vanishes. (In other words, there should not be any integral relations among the members of $\cup_\lambda S_\lambda$ other than those that come from the S_λ themselves.)

We then require

(10) that the $\Omega_{E,\rho}$, as (E,ρ) ranges over all pairs such that $E \in \cup_{n=2}^{r} \mathcal{E}_n$, $\rho \in \{1, \dots, |E|\}$, are independent with respect to r.

In the special case when $\delta(E) = 2$, each E is of the form $\{[X_{k_1}, X_{k_2}]\}$, where $k_1 < k_2$. In that case, the set $\Omega_{E,1} = \Omega_{E,1,k_1} = \Omega_{E,1,k_2}$ consists of a frequency $\omega_{k_1,k_2} > 0$ together with its negative.

We then have the following.

THEOREM 5.1. *Let m, r be positive integers. Let $\{u^j\}_{j=1}^{\infty}$ be the sequence of input functions defined by* (22)*, where the functions $\eta_{0,k}$, $\eta_{\omega,k}$, η_ω and the sets $\Omega(n,k)$, $\Omega_{E,\rho}$, $\Omega_{E,\rho,k}$ satisfy conditions* (1)–(10)*. Then the sequence $\{u^j\}$ EI(r)-converges to the extended input*

$$\begin{aligned} \mathbf{u}^\infty(t) = &\sum_{k=1}^{m} \eta_{0,k}(t) X_k + \sum_{1 \le k_1 < k_2 \le m} \frac{1}{i\omega_{k_1,k_2}} \xi_{k_1,k_2}(t) [X_{k_1}, X_{k_2}] \\ &+ \sum_{n=3}^{r} \sum_{E \in \mathcal{E}_n} \sum_{B \in E} \sum_{\rho=1}^{|E|} \left(\sum_{F \in Q_{E,\rho}} i^{1-\delta(E)} \xi_{B,\rho}^{F} \prod_{\omega \in F} \eta_\omega(t) \right) B, \end{aligned} \tag{23}$$

where $\xi_{k_1,k_2}(t) = \eta_{\omega_{k_1,k_2},k_1} \eta_{-\omega_{k_1,k_2},k_2} - \eta_{-\omega_{k_1,k_2},k_1} \eta_{\omega_{k_1,k_2},k_2}$.

It is now easy to see how to choose the η_ω so that the limiting extended input $\mathbf{u}^\infty$ has a desired value. Fix an E and a ρ.

CH1. Assume first that $\delta(E)$ is odd and $\delta(E) > 1$. Then the numbers $\xi_{B,\rho}^{F}$ for the two members of $Q_{E,\rho}$ are equal. Call their common value $\xi_{B,\rho}$. Also, $i^{1-\delta(E)} = \pm 1$. Let $\hat{\xi}_{B,\rho} = \xi_{B,\rho}$. Pick all the η_ω for $\omega \in \Omega_{E,\rho}$ to be equal to 1, except for one pair $\{\omega, -\omega\}$ of members of $\Omega_{E,\rho}$, for which we pick $\eta_\omega = \eta_{-\omega} = \frac{i^{1-\delta(E)}}{2} \zeta_{E,\rho}$, where $\zeta_{E,\rho} \in C^1([0,T], \mathbb{R})$.

CH2. Assume that $\delta(E)$ is even and $\delta(E) > 2$. Then the numbers $\xi_{B,\rho}^{F}$, for the two members of $Q_{E,\rho}$, are negatives of each other. Pick one of the two members of

$Q_{E,\rho}$ and call it $F_{E,\rho}$. Also, $i^{1-\delta(E)} = \pm i$. Let $\hat{\xi}_{B,\rho} = \xi_{B,\rho}^{F_{E,\rho}}$. Pick all the η_ω for $\omega \in \Omega_{E,\rho}$ to be equal to 1, except for one pair $\{\omega, -\omega\}$ of members of $\Omega_{E,\rho}$ such that $\omega \in F_{E,\rho}$. Then pick $\eta_\omega = -\frac{i^{1-\delta(E)}}{2}\zeta_{E,\rho}$, where $\zeta_{E,\rho} \in C^1([0,T],\mathbb{R})$, and let $\eta_{-\omega} = -\eta_\omega = \overline{\eta_\omega}$.

CH3. Assume that $\delta(E) = 2$. Let $E = \{[X_{k_1}, X_{k_2}]\}$, $k_1 < k_2$. We pick $\eta_{\omega_{k_1,k_2},k_2} = \eta_{-\omega_{k_1,k_2},k_2} = 1$, and $\eta_{\omega_{k_1,k_2},k_1} = -\eta_{-\omega_{k_1,k_2},k_1} = \frac{i\omega_{k_1,k_2}}{2}\zeta_{k_1,k_2}$, where $\zeta_{k_1,k_2} \in C^1([0,T],\mathbb{R})$. If $k_1 \neq k \neq k_2$, we let $\eta_{\omega_{k_1,k_2},k} = \eta_{-\omega_{k_1,k_2},k} = 0$.

CH4. Choose $\eta_{k,0} = \zeta_{0,k} \in C^1([0,T],\mathbb{R})$.

With these choices, we have

$$\mathbf{u}^\infty(t) = \sum_{k=1}^{m} \zeta_{k,0}(t)X_k + \sum_{1\le k_1<k_2\le m} \zeta_{k_1,k_2}(t)[X_{k_1},X_{k_2}] + \sum_{n=3}^{r}\sum_{E\in\mathcal{E}_n}\sum_{B\in E}\sum_{\rho=1}^{|E|}(\hat{\xi}_{B,\rho}\zeta_{E,\rho}(t))B. \tag{24}$$

In order to get $\mathbf{u}^\infty$ to be equal to $\mathbf{v}$, we need to choose

$$\zeta_{0,k} = v_{X_k}, \qquad \zeta_{k_1,k_2} = v_{[X_{k_1},X_{k_2}]} \tag{25}$$

and to let the $\zeta_{E,\rho}$ be solutions of

$$\sum_{\rho=1}^{|E|} \hat{\xi}_{B,\rho}\zeta_{E,\rho}(t) = v_B(t) \text{ for each } E \in \mathcal{E}_n,\ n > 2. \tag{26}$$

The possibility of solving (26) is guaranteed if the frequency sets $\Omega_{E,\rho,k}$ are chosen so that

(11) the square matrix $\{\hat{\xi}_{B,\rho}\}_{B\in E,\,1\le\rho\le|E|}$ is invertible for each $E \in \cup_{n=3}^{r}\mathcal{E}_n$. It turns out that

(A) it is always possible to choose frequencies so that conditions (1), (2), (6), (7), (8), (9), (10), (11) hold;

(B) if the frequencies are chosen so that conditions (1), (2), (6), (7), (8), (9), (10), (11) hold, and if the η's are chosen according to CH1, CH2, CH3, CH4 (so that, in particular, (3), (4), (5) hold), where the ζ's satisfy (25) and (26), then the u^j EI(r)-converge to $\mathbf{v}$.

This completes the description of the algorithm. Its justification requires, of course, that we prove Theorem 5.1 and statement A. The proofs are given in the next two sections.

6. Proof of Theorem 5.1**.** Now we prove Theorem 5.1. In order to justify the algorithm we still need to prove that it is always possible to choose the frequency sets so that condition (11) holds in addition to the other requirements. This will be done in the next section.

Proof of Theorem 5.1. We will apply Theorem 2.1. For this we need to find a sequence $\{\mathbf{v}^j = \sum_{0<|I|\le r} v_I^j X_I\}$ of polynomial inputs of order $\le r$ and rth-order truncated generalized differences $(\mathbf{u}^j \overset{\text{g.d.(r)}}{-} \mathbf{v}^j) = \sum_{0<|I|\le r} \widetilde{UV}_I^j X_I$ of $\mathbf{u}^j$ and $\mathbf{v}^j$ such that $\{\mathbf{v}^j\}$, $\mathbf{u}^\infty$, and $\{(\mathbf{u}^j \overset{\text{g.d.(r)}}{-} \mathbf{v}^j)\}$ satisfy the conditions of Theorem 2.1.

We define absolutely continuous functions V_I^j and $\widetilde{UV}_I^j$ for $0 < |I| \le r$ such that (12) and (13) hold and conditions c1′(r), c2′(r), c3′(r) are satisfied; cf. Remark 2.4. For this, we use induction to define V_I^j and $\widetilde{UV}_I^j$ such that

(A) the V_I^j have the form $V_I^j = V_I + R_I^j$, where
(i)

$$V_\ell(t) = \int_0^t \eta_{\ell,0}(s)\,ds, \tag{27}$$

$$V_{\ell_1,\ell_2}(t) = -\sum_{\substack{(\omega_1,\omega_2)\in\Omega(2,\ell_1)\times\Omega(2,\ell_2)\\ \omega_1+\omega_2=0}} \int_0^t \frac{\eta_{\omega_1,\ell_1}(s)\eta_{\omega_2,\ell_2}(s)}{i\omega_2}\,ds, \tag{28}$$

$$V_I(t) = (-1)^{k-1}\sum_{\hat\omega\in\Omega(I)}\int_0^t \frac{\eta_{\hat\omega}(s)}{i^{k-1}\omega_k(\omega_k+\omega_{k-1})\cdots(\omega_k+\cdots+\omega_2)}\,ds \tag{29}$$

for $I = (\ell_1,\dots,\ell_k), 3 \le k \le r$, where $\hat\omega = (\omega_1,\dots,\omega_k)$, $\eta_{\hat\omega}(t) = \eta_{\omega_1}(t)\cdots\eta_{\omega_k}(t)$, and $\Omega(I)$ is the subset of $\Omega(k,\ell_1)\times\cdots\times\Omega(k,\ell_k)$ such that $\hat\omega = (\omega_1,\dots,\omega_k)$ belongs to $\Omega(I)$ iff the set $\{\omega_1,\dots,\omega_k\} \in Q_{E,\rho}$ for some $E \in \mathcal{E}_k, \rho \in \{1,\dots,|E|\}$;

(ii) the R_I^j converge to 0 uniformly as $j \to \infty$ and the $\|\dot R_I^j\|_{L^1}$ are uniformly bounded;

(B) for $I = (\ell_1,\dots,\ell_k)$, the $\widetilde{UV}_I^j$ can be written as

$$\widetilde{UV}_I^j(t) = (-1)^k \sum_{\hat n\in\Omega_1(k)} j^{-\alpha_{\hat n}} \sum_{\hat\omega\in\Omega(\hat n,I)} \frac{\eta_{\hat\omega}(t)e^{ij\sum\hat\omega t}}{i^k\omega_k(\omega_k+\omega_{k-1})\cdots(\omega_k+\cdots+\omega_1)}$$

$$+(-1)^k \sum_{\hat n\in\Omega_2(k)} j^{-\alpha_{\hat n}} \sum_{\hat\omega\in\Omega(\hat n,I)} \frac{\eta_{\hat\omega}(t)e^{ij\sum\hat\omega t}}{i^k\omega_k(\omega_k+\omega_{k-1})\cdots(\omega_k+\cdots+\omega_1)}. \tag{30}$$

Here
(1) we write $\hat n = (n_1,\dots,n_k)$, $\alpha_{\hat n} = \frac{1}{n_1}+\cdots+\frac{1}{n_k}$, $\sum\hat\omega = \omega_1+\cdots+\omega_k$;
(2) $\Omega_1(k)$ is a subset of

$$\overbrace{\{2,\dots,r\}\times\{2,\dots,r\}\times\cdots\times\{2,\dots,r\}}^{k}$$

and $\Omega_2(k)$ is a subset of

$$\overbrace{\{3,\dots,r\}\times\{3,\dots,r\}\times\cdots\times\{3,\dots,r\}}^{k}$$

such that
(a) $\hat n = (n_1,\dots,n_k) \in \Omega_2(k)$ iff $\alpha_{\hat n} < 1$;
(b) $\hat n = (n_1,\dots,n_k) \in \Omega_1(k)$ iff one of $n_1,\dots,n_k$, say n_τ, is equal to 2 and the others are between 3 and r; or $\alpha_{\hat n} < 1$;
(3) for each $\hat n = (n_1,\dots,n_k)$, $\Omega(\hat n, I)$ is a subset of $\Omega(n_1,\ell_1)\times\cdots\times\Omega(n_k,\ell_k)$ such that $\hat\omega = (\omega_1,\dots,\omega_k) \in \Omega(\hat n, I)$ iff $\omega_k(\omega_k+\omega_{k-1})\cdots(\omega_k+\cdots+\omega_1) \ne 0$;
(4) if $\hat n \in \Omega_2(k)$, for each $\hat\omega = (\omega_1,\dots,\omega_k) \in \Omega(\hat n, I)$ we write $\eta_{\hat\omega}(t) = \eta_{\omega_1}(t)\cdots\eta_{\omega_k}(t)$. If $\hat n = (n_1,\dots,n_k) \in \Omega_1(k)$ with $n_\tau = 2$, for each $\hat\omega = (\omega_1,\dots,\omega_k) \in \Omega(\hat n, I)$, we write $\eta_{\hat\omega}(t) = \eta_{\omega_1}(t)\cdots\eta_{\omega_\tau,\ell_\tau}(t)\cdots\eta_{\omega_k}(t)$.

Using integration by parts we get

$$\begin{aligned}
U_\ell^j(t) &= \int_0^t \eta_{\ell,0}(s)\,ds + j^{\frac{1}{2}} \sum_{\omega\in\Omega(2,\ell)} \int_0^t \eta_{\omega,\ell}(s) e^{ij\omega s}\,ds \\
&\quad + \int_0^t \sum_{n=3}^{r} j^{\frac{n-1}{n}} \sum_{\omega\in\Omega(n,\ell)} \eta_\omega(s) e^{ij\omega s}\,ds \\
&= \int_0^t \eta_{\ell,0}(s)\,ds + j^{-\frac{1}{2}} \sum_{\omega\in\Omega(2,\ell)} \left\{ \frac{\eta_{\omega,\ell}(t)e^{ij\omega t}}{i\omega} - \frac{\eta_{\omega,\ell}(0)}{i\omega} - \int_0^t \frac{\eta'_{\omega,\ell}(s)e^{ij\omega s}}{i\omega}\,ds \right\} \\
&\quad + \sum_{n=3}^{r} j^{-\frac{1}{n}} \sum_{\omega\in\Omega(n,\ell)} \left\{ \frac{\eta_\omega(t)e^{ij\omega t}}{i\omega} - \frac{\eta_\omega(0)}{i\omega} - \int_0^t \frac{\eta'_\omega(s)e^{ij\omega s}}{i\omega}\,ds \right\}.
\end{aligned}$$

We then let

$$\begin{aligned}
V_\ell(t) &= \int_0^t \eta_{\ell,0}(s)\,ds, \\
R_\ell^j(t) &= -j^{-\frac{1}{2}} \sum_{\omega\in\Omega(2,\ell)} \left\{ \frac{\eta_{\omega,\ell}(0)}{i\omega} + \int_0^t \frac{\eta'_{\omega,\ell}(s)}{i\omega} e^{ij\omega s}\,ds \right\} \\
&\quad - \sum_{n=3}^{r} j^{-\frac{1}{n}} \sum_{\omega\in\Omega(n,\ell)} \left\{ \frac{\eta_\omega(0)}{i\omega} + \int_0^t \frac{\eta'_\omega(s)}{i\omega} e^{ij\omega s}\,ds \right\}, \\
V_\ell^j(t) &= V_\ell(t) + R_\ell^j(t)
\end{aligned}$$

and define

$$\widetilde{UV}_\ell^j(t) = V_\ell^j(t) - U_\ell^j(t) = -j^{-\frac{1}{2}} \sum_{\omega\in\Omega(2,\ell)} \frac{\eta_{\omega,\ell}(t)}{i\omega} e^{ij\omega t} - \sum_{n=3}^{r} j^{-\frac{1}{n}} \sum_{\omega\in\Omega(n,\ell)} \frac{\eta_\omega(t)}{i\omega} e^{ij\omega t}.$$

Now in order to show the idea of how the general V_I^j and $\widetilde{UV}_I^j$ are defined, let us proceed one more step and write down V_{ℓ_1,ℓ_2}^j and $\widetilde{UV}_{\ell_1,\ell_2}^j$ explicitly. If we multiply $\widetilde{UV}_{\ell_2}^j(t)$ by $u_{\ell_1}^j(t)$ and integrate we get

$$\int_0^t u_{\ell_1}^j(s)\widetilde{UV}_{\ell_2}^j(s)\,ds = A_{\ell_1,\ell_2}^j + B_{\ell_1,\ell_2}^j + C_{\ell_1,\ell_2}^j,$$

where

$$\begin{aligned}
A_{\ell_1,\ell_2}^j &= -j^{-\frac{1}{2}} \sum_{\omega\in\Omega(2,\ell_2)} \int_0^t \frac{\eta_{\ell_1,0}(s)\eta_{\omega,\ell_2}(s)}{i\omega} e^{ij\omega s}\,ds \\
&\quad - \sum_{n=3}^{r} j^{-\frac{1}{n}} \sum_{\omega\in\Omega(n,\ell_2)} \int_0^t \frac{\eta_{\ell_1,0}(s)\eta_\omega(s)}{i\omega} e^{ij\omega s}\,ds, \\
B_{\ell_1,\ell_2}^j &= - \sum_{(\omega_1,\omega_2)\in\Omega(2,\ell_1)\times\Omega(2,\ell_2)} \int_0^t \frac{\eta_{\omega_1,\ell_1}(s)\eta_{\omega_2,\ell_2}(s)}{i\omega_2} e^{ij(\omega_1+\omega_2)s}\,ds, \\
C_{\ell_1,\ell_2}^j &= - \sum_{n=3}^{r} j^{\frac{1}{2}-\frac{1}{n}} \sum_{(\omega_1,\omega_2)\in\Omega(2,\ell_1)\times\Omega(n,\ell_2)} \int_0^t \frac{\eta_{\omega_1,\ell_1}(s)\eta_{\omega_2}(s)}{i\omega_2} e^{ij(\omega_1+\omega_2)s}\,ds
\end{aligned}$$

$$-\sum_{n=3}^{r} j^{\frac{1}{2}-\frac{1}{n}} \sum_{(\omega_1,\omega_2)\in\Omega(n,\ell_1)\times\Omega(2,\ell_2)} \int_0^t \frac{\eta_{\omega_1}(s)\eta_{\omega_2,\ell_2}(s)}{i\omega_2} e^{ij(\omega_1+\omega_2)s}\,ds$$

$$-\sum_{n_1,n_2=3}^{r} j^{1-\frac{1}{n_1}-\frac{1}{n_2}} \sum_{(\omega_1,\omega_2)\in\Omega(n_1,\ell_1)\times\Omega(n_2,\ell_2)} \int_0^t \frac{\eta_{\omega_1}(s)\eta_{\omega_2}(s)}{i\omega_2} e^{ij(\omega_1+\omega_2)s}\,ds.$$

Clearly, the $A^j_{\ell_1,\ell_2}$ converge to 0 uniformly and have uniformly bounded derivatives in j. In $B^j_{\ell_1,\ell_2}$, the terms with $\omega_1+\omega_2\neq 0$ go to 0 uniformly and have uniformly bounded derivatives. These terms will be moved to $R^j_{\ell_1,\ell_2}$. The terms in $B^j_{\ell_1,\ell_2}$ that correspond to $\omega_1+\omega_2=0$ give rise to V_{ℓ_1,ℓ_2}. Precisely, we let

$$V_{\ell_1,\ell_2}(t) = -\sum_{\substack{(\omega_1,\omega_2)\in\Omega(2,\ell_1)\times\Omega(2,\ell_2)\\ \omega_1+\omega_2=0}} \int_0^t \frac{\eta_{\omega_1,\ell_1}(s)\eta_{\omega_2,\ell_2}(s)}{i\omega_2}\,ds.$$

In $C^j_{\ell_1,\ell_2}$ for those terms with $\omega_1+\omega_2\neq 0$, we can use integration by parts to bring a factor j^{-1}. We then move the terms coming from the integration by parts that converge to 0 uniformly and have uniformly bounded derivatives in L^1 to $R^j_{\ell_1,\ell_2}$. For example, for the terms

$$j^{\frac{1}{2}-\frac{1}{n}} \int_0^t \frac{\eta_{\omega_1,\ell_1}(s)\eta_{\omega_2}(s)}{i\omega_2} e^{ij(\omega_1+\omega_2)s}\,ds$$

in the first summation in the right-hand side of $C^j_{\ell_1,\ell_2}$, we know that $\omega_1+\omega_2\neq 0$. Via integration by parts we get

$$j^{\frac{1}{2}-\frac{1}{n}} \int_0^t \frac{\eta_{\omega_1,\ell_1}(s)\eta_{\omega_2}(s)}{i\omega_2} e^{ij(\omega_1+\omega_2)s}\,ds = j^{-\frac{1}{2}-\frac{1}{n}} \frac{\eta_{\omega_1,\ell_1}(t)\eta_{\omega_2}(t)}{i^2\omega_2(\omega_1+\omega_2)} e^{ij(\omega_1+\omega_2)t} + D^j_{\omega_1,\omega_2},$$

where

$$D^j_{\omega_1,\omega_2} = -j^{-\frac{1}{2}-\frac{1}{n}} \frac{\eta_{\omega_1,\ell_1}(0)\eta_{\omega_2}(0)}{i^2\omega_2(\omega_1+\omega_2)} - j^{-\frac{1}{2}-\frac{1}{n}} \int_0^t \frac{(\eta_{\omega_1,\ell_1}(s)\eta_{\omega_2}(s))'}{i^2\omega_2(\omega_1+\omega_2)} e^{ij(\omega_1+\omega_2)s}\,ds.$$

The $D^j_{\omega_1,\omega_2}$ go to zero uniformly and have uniformly bounded derivatives. We then move them to $R^j_{\ell_1,\ell_2}$. Similarly, we can take care of the terms in the second summation and the terms with $\omega_1+\omega_2\neq 0$ in the third summation in the right-hand side of $C^j_{\ell_1,\ell_2}$. The terms in $C^j_{\ell_1,\ell_2}$ that correspond to $\omega_1+\omega_2=0$ add up to 0. Precisely,

$$\sum_{n_1,n_2=3}^{r} j^{1-\frac{1}{n_1}-\frac{1}{n_2}} \sum_{\substack{(\omega_1,\omega_2)\in\Omega(n_1,\ell_1)\times\Omega(n_2,\ell_2)\\ \omega_1+\omega_2=0}} \int_0^t \frac{\eta_{\omega_1}(s)\eta_{\omega_2}(s)}{i\omega_2}\,ds = 0.$$

This is because, by the symmetry of $\Omega(n,k)$, if $\frac{\eta_{\omega_1}\eta_{-\omega_1}}{i\omega_1} = \frac{|\eta_{\omega_1}|^2}{i\omega_1}$ is in the summation, then $\frac{\eta_{-\omega_1}\eta_{\omega_1}}{-i\omega_1} = -\frac{|\eta_{\omega_1}|^2}{i\omega_1}$ is also in the summation. So they add up to 0. We then let

$$R^j_{\ell_1,\ell_2}(t) = A^j_{\ell_1,\ell_2} - \sum_{\substack{(\omega_1,\omega_2)\in\Omega(2,\ell_1)\times\Omega(2,\ell_2)\\ \omega_1+\omega_2\neq 0}} \int_0^t \frac{\eta_{\omega_1,\ell_1}(s)\eta_{\omega_2,\ell_2}(s)}{i\omega_2} e^{ij(\omega_1+\omega_2)s}\,ds$$

$$+\sum_{n=3}^{r} j^{-\frac{1}{2}-\frac{1}{n}} \sum_{(\omega_1,\omega_2)\in\Omega(2,\ell_1)\times\Omega(n,\ell_2)} \left\{ \frac{\eta_{\omega_1,\ell_1}(0)\eta_{\omega_2}(0)}{i^2\omega_2(\omega_2+\omega_1)} + \int_0^t \frac{(\eta_{\omega_1,\ell_1}(s)\eta_{\omega_2}(s))'}{i^2\omega_2(\omega_2+\omega_1)} e^{ij(\omega_1+\omega_2)s} ds \right\}$$

$$+\sum_{n=3}^{r} j^{-\frac{1}{2}-\frac{1}{n}} \sum_{(\omega_1,\omega_2)\in\Omega(n,\ell_1)\times\Omega(2,\ell_2)} \left\{ \frac{\eta_{\omega_1}(0)\eta_{\omega_2,\ell_2}(0)}{i^2\omega_2(\omega_2+\omega_1)} + \int_0^t \frac{(\eta_{\omega_1}(s)\eta_{\omega_2,\ell_2}(s))'}{i^2\omega_2(\omega_2+\omega_1)} e^{ij(\omega_1+\omega_2)s} ds \right\}$$

$$+ \sum_{n_1,n_2=3}^{r} j^{-\frac{1}{n_1}-\frac{1}{n_2}} \sum_{\substack{(\omega_1,\omega_2)\in\Omega(n_1,\ell_1)\times\Omega(n_2,\ell_2)\\ \omega_1+\omega_2\neq 0}} \left\{ \frac{\eta_{\omega_1}(0)\eta_{\omega_2}(0)}{i^2\omega_2(\omega_2+\omega_1)} + \int_0^t \frac{(\eta_{\omega_1}(s)\eta_{\omega_2}(s))'}{i^2\omega_2(\omega_2+\omega_1)} e^{ij(\omega_1+\omega_2)s}\, ds \right\},$$

$V^j_{\ell_1,\ell_2}(t) = V_{\ell_1,\ell_2}(t) + R^j_{\ell_1,\ell_2}(t)$.

So we define

$$\begin{aligned}
\widetilde{UV}^j_{\ell_1,\ell_2}(t) &= V^j_{\ell_1,\ell_2}(t) - \int_0^t u^j_{\ell_1}(s)\widetilde{UV}^j_{\ell_2}(s)\, ds \\
&= \sum_{n=3}^{r} j^{-\frac{1}{2}-\frac{1}{n}} \sum_{(\omega_1,\omega_2)\in\Omega(2,\ell_1)\times\Omega(n,\ell_2)} \frac{\eta_{\omega_1,\ell_1}(t)\eta_{\omega_2}(t)}{i^2\omega_2(\omega_2+\omega_1)} e^{ij(\omega_1+\omega_2)t} \\
&\quad + \sum_{n=3}^{r} j^{-\frac{1}{2}-\frac{1}{n}} \sum_{(\omega_1,\omega_2)\in\Omega(n,\ell_1)\times\Omega(2,\ell_2)} \frac{\eta_{\omega_1}(t)\eta_{\omega_2,\ell_2}(t)}{i^2\omega_2(\omega_2+\omega_1)} e^{ij(\omega_1+\omega_2)t} \\
&\quad + \sum_{n_1,n_2=3}^{r} j^{-\frac{1}{n_1}-\frac{1}{n_2}} \sum_{\substack{(\omega_1,\omega_2)\in\Omega(n_1,\ell_1)\times\Omega(n_2,\ell_2)\\ \omega_1+\omega_2\neq 0}} \frac{\eta_{\omega_1}(t)\eta_{\omega_2}(t)}{i^2\omega_2(\omega_2+\omega_1)} e^{ij(\omega_1+\omega_2)t}.
\end{aligned}$$

Clearly the $\widetilde{UV}^j_{\ell_1,\ell_2}(t)$ are of the form (30).

Assume that we have defined $V^j_I, \widetilde{UV}^j_I$ such that $V^j_I, \widetilde{UV}^j_I$ are as in (29) and (30) for $|I|$ up to $|I| \le k-1, 3 \le k \le r$. Let $I = (\ell_1, \dots, \ell_k)$. For simplicity we introduce the following notations:

$$\begin{aligned}
\bar{I} &= (\ell_2, \dots, \ell_k), \\
h(\hat{\omega}) &= \omega_k(\omega_k+\omega_{k-1})\cdots(\omega_k+\cdots+\omega_1) \quad \text{if} \quad \hat{\omega} = (\omega_1, \dots, \omega_k).
\end{aligned}$$

Multiplying $u^j_{\ell_1}$ by $\widetilde{UV}^j_{\bar{I}}$ and integrating we get

$$\int_0^t u^j_{\ell_1}(s)\widetilde{UV}^j_{\bar{I}}(s)\, ds = \int_0^t \eta_{\ell_1,0}(s)\widetilde{UV}^j_{\bar{I}}(s)\, ds + A^j_I + B^j_I + C^j_I + D^j_I.$$

Here

$$A_I^j = (-1)^{k-1} \sum_{\hat{n}\in\Omega_1(k-1)} j^{\frac{1}{2}-\alpha_{\hat{n}}} \sum_{(\omega_1,\hat{\omega})\in\Omega(2,\ell_1)\times\Omega(\hat{n},\bar{I})} \int_0^t \frac{\eta_{\hat{\omega}}(s)\eta_{\omega_1,\ell_1}(s)e^{ij(\omega_1+\sum\hat{\omega})s}}{i^{k-1}h(\hat{\omega})} ds,$$

$$B_I^j = (-1)^{k-1} \sum_{\hat{n}\in\Omega_2(k-1)} j^{\frac{1}{2}-\alpha_{\hat{n}}} \sum_{(\omega_1,\hat{\omega})\in\Omega(2,\ell_1)\times\Omega(\hat{n},\bar{I})} \int_0^t \frac{\eta_{\hat{\omega}}(s)\eta_{\omega_1,\ell_1}(s)e^{ij(\omega_1+\sum\hat{\omega})s}}{i^{k-1}h(\hat{\omega})} ds,$$

$$C_I^j = (-1)^{k-1} \sum_{n_1=3}^{r} \sum_{\hat{n}\in\Omega_1(k-1)} j^{1-\frac{1}{n_1}-\alpha_{\hat{n}}} \sum_{(\omega_1,\hat{\omega})\in\Omega(n_1,\ell_1)\times\Omega(\hat{n},\bar{I})} \int_0^t \frac{\eta_{\hat{\omega}}(s)\eta_{\omega_1}(s)e^{ij(\omega_1+\sum\hat{\omega})s}}{i^{k-1}h(\hat{\omega})} ds,$$

$$D_I^j = (-1)^{k-1} \sum_{n_1=3}^{r} \sum_{\hat{n}\in\Omega_2(k-1)} j^{1-\frac{1}{n_1}-\alpha_{\hat{n}}} \sum_{(\omega_1,\hat{\omega})\in\Omega(n_1,\ell_1)\times\Omega(\hat{n},\bar{I})} \int_0^t \frac{\eta_{\omega_1}(s)\eta_{\hat{\omega}}(s)e^{ij(\omega_1+\sum\hat{\omega})s}}{i^{k-1}h(\hat{\omega})} ds.$$

Notice that for the terms in A_I^j, we know that $\frac{1}{2}-\alpha_{\hat{n}} < 0$. So the A_I^j converge to 0 and have uniformly bounded derivatives. For all the terms in B_I^j, by the independence of the sets $\Omega_{E,\rho}$, we know that $\omega_1+\sum\hat{\omega} \neq 0$. So in B_I^j, if $\frac{1}{2}-\alpha_{\hat{n}} \leq 0$, the corresponding terms converge to 0 uniformly and have uniformly bounded derivatives already. For the terms with $\frac{1}{2}-\alpha_{\hat{n}}$ positive, we apply integration by parts to get a j^{-1}. We then move those terms coming from the integration by parts that converge to 0 and have uniformly bounded derivatives to R_I^j. This is done in exactly the same way as we take care of the terms in the first two summations in the right hand of C_{ℓ_1,ℓ_2}^j. The C_I^j are taken care of in exactly the same way as for B_I^j. Finally we take care of the terms in D_I^j by the following:

(i) We move all the terms in D_I^j whose j powers are negative or equal 0 but $\omega_1+\hat{\omega} \neq 0$ to R_I^j.

(ii) For the terms with j powers positive and $\omega_1+\hat{\omega} \neq 0$, we apply integration by parts and then move all the terms coming from the integration by parts that go to 0 and have uniformly bounded derivatives to R_I^j.

This takes care of the terms in D_I^j with $\omega_1+\sum\hat{\omega} \neq 0$ and those with j powers negative. For the terms in D_I^j with $\omega_1+\sum\hat{\omega}=0$ and j powers ≥ 0, there are two possibilities:

(iii) $\omega_1+\sum\hat{\omega}=0$ and the j powers $1-\frac{1}{n_1}-\alpha_{\hat{n}}=0$. These terms give rise to the V_I; i.e., we let

$$V_I(t) = (-1)^{k-1} \sum_{n_1=3}^{r} \sum_{\hat{n}\in\Omega_2(k-1)} \sum_{\substack{(\omega_1,\hat{\omega})\in\Omega(n_1,\ell_1)\times\Omega(\hat{n},\bar{I}) \\ \omega_1+\sum\hat{\omega}=0 \\ 1-\frac{1}{n_1}-\alpha_{\hat{n}}=0}} \int_0^t \frac{\eta_{\omega_1}(s)\eta_{\hat{\omega}}(s)}{i^{k-1}h(\hat{\omega})} ds\,;$$

(iv) $\omega_1+\sum\hat{\omega}=0$ and the j powers $1-\frac{1}{n_1}-\alpha_{\hat{n}}>0$.

In order to take care of the terms in (iv), we first notice the following fact. Let $(\omega_1,\ldots,\omega_k)$ be a k tuple of numbers with $\{\omega_1,\ldots,\omega_k\} \subset \cup_{\ell=1}^{m}\cup_{n=2}^{r}\Omega(n,\ell)$. Because of the linear independence of the $\Omega_{E,\rho}$ and the minimal cancelation requirement of each $F\in Q_{E,\rho}$, $\omega_1+\cdots+\omega_k=0$ is possible only in the following cases:

(a) k is even and each ω_ℓ is canceled out by its negative $-\omega_\ell$. This case will be referred to as *pure cancelation by pairs*;

(b) $\omega_1 + \cdots + \omega_k = 0$ because the set $\{\omega_1, \ldots, \omega_k\}$ is equal to some $F \in Q_{E,\rho}$ for some E and ρ. (Note that each $F \in Q_{E,\rho}$ is canceling.) This case will be referred to as *pure cancelation by F*;

(c) *mixed cancelation*; i.e., some of the ω_ℓ are canceled out by $-\omega_\ell$, some others are canceled out because the set of them is equal to some $F \in Q_{E,\rho}$.

Let $\bar{D}_I^j$ denote the sum of the terms in D_I^j for which (iv) happens; i.e., let

$$\bar{D}_I^j = (-1)^{k-1} \sum_{n_1=3}^{r} \sum_{\hat{n} \in \Omega_2(k-1)} j^{1-\frac{1}{n_1}-\alpha_{\hat{n}}} \sum_{\substack{(\omega_1,\hat{\omega}) \in \Omega(n_1,\ell_1)\times\Omega(\hat{n},\bar{I}) \\ \omega_1+\sum\hat{\omega}=0 \\ 1-\frac{1}{n_1}-\alpha_{\hat{n}}>0}} \int_0^t \frac{\eta_{\omega_1}(s)\eta_{\hat{\omega}}(s)}{i^{k-1}h(\hat{\omega})}\, ds.$$

Now the two conditions $1-\frac{1}{n_1}-\alpha_{\hat{n}} > 0$, $\omega_1+\sum\hat{\omega} = 0$ imply that the $(\omega_1, \hat{\omega})$ is canceled out purely by pairs. (Notice that if the $(\omega_1, \hat{\omega}) \in \Omega(n_1, \ell_1) \times \Omega(\hat{n}, \bar{I})$ is canceled by an $F \in Q_{E,\rho}$, then $1 - \frac{1}{n_1} - \alpha_{\hat{n}} \le 0$. Similarly, since we require that the $\alpha_{\hat{n}}$ be less than 1, the mixed cancelations cannot occur too.) In particular $|I| = k$ has to be even. But now, by the symmetry of the $\Omega(\hat{n}, \bar{I})$ and $\Omega(n_1, \ell_1)$, we know that if $\int_0^t \frac{\eta_{\omega_1}(s)\eta_{\hat{\omega}}(s)}{i^{k-1}h(\hat{\omega})}\, ds$ is in $\bar{D}_I^j$, then, since $\eta_{-\omega_1}\eta_{-\hat{\omega}} = \eta_{\omega_1}\eta_{\hat{\omega}}, h(-\hat{\omega}) = (-1)^{k-1}h(\hat{\omega}) = -h(\hat{\omega})$, the integral

$$\int_0^t \frac{\eta_{-\omega_1}\eta_{-\hat{\omega}}(s)}{i^{k-1}h(-\hat{\omega})}\, ds = -\int_0^t \frac{\eta_{\omega_1}(s)\eta_{\hat{\omega}}(s)}{i^{k-1}h(\hat{\omega})}\, ds$$

is also in $\bar{D}_I^j$. So they add up to 0; i.e. the contribution of each term and that of its negative cancel. So we get that $\bar{D}_I^j = 0$. Summarizing the above we define

$$\begin{aligned}
R_I^j(t) &= \int_0^t \eta_{\ell_1,0}(s)\widetilde{UV}_{\bar{I}}^j(s)\, ds + A_I^j \\
&+(-1)^{k-1} \sum_{\hat{n} \in \Omega_2(k-1)} j^{\frac{1}{2}-\alpha_{\hat{n}}} \sum_{\substack{(\omega_1,\hat{\omega}) \in \Omega(2,\ell_1)\times\Omega(\hat{n},\bar{I}) \\ \frac{1}{2}-\alpha_{\hat{n}} \le 0}} \int_0^t \frac{\eta_{\omega_1,\ell_1}(s)\eta_{\hat{\omega}}(s)e^{ij(\omega_1+\sum\hat{\omega})s}}{i^{k-1}h(\hat{\omega})}\, ds \\
&+(-1)^{k} \sum_{\hat{n} \in \Omega_2(k-1)} j^{-\frac{1}{2}-\alpha_{\hat{n}}} \sum_{\substack{(\omega_1,\hat{\omega}) \in \Omega(2,\ell_1)\times\Omega(\hat{n},\bar{I}) \\ \frac{1}{2}-\alpha_{\hat{n}} > 0}} \left\{ \frac{\eta_{\omega_1,\ell_1}(0)\eta_{\hat{\omega}}(0)}{i^k(\omega_1+\sum\hat{\omega})h(\hat{\omega})} \right. \\
&\qquad \left. + \int_0^t \frac{(\eta_{\omega_1,\ell_1}(s)\eta_{\hat{\omega}}(s))' e^{ij(\omega_1+\sum\hat{\omega})s}}{i^k(\omega_1+\sum\hat{\omega})h(\hat{\omega})}\, ds \right\} \\
&+(-1)^{k-1} \sum_{n_1=3}^{r} \sum_{\hat{n} \in \Omega_1(k-1)} j^{\frac{n_1-1}{n_1}-\alpha_{\hat{n}}} \sum_{\substack{(\omega_1,\hat{\omega}) \in \Omega(n_1,\ell_1)\times\Omega(\hat{n},\bar{I}) \\ 1-\frac{1}{n_1}-\alpha_{\hat{n}} \le 0}} \int_0^t \frac{\eta_{\omega_1}(s)\eta_{\hat{\omega}}(s)e^{ij(\omega_1+\sum\hat{\omega})s}}{i^{k-1}h(\hat{\omega})}\, ds
\end{aligned}$$

$$+(-1)^k \sum_{n_1=3}^{r} \sum_{\hat{n}\in\Omega_1(k-1)} j^{-\frac{1}{n_1}-\alpha_{\hat{n}}} \sum_{\substack{(\omega_1,\hat{\omega})\in\Omega(n_1,\ell_1)\times\Omega(\hat{n},\bar{I})\\ 1-\frac{1}{n_1}-\alpha_{\hat{n}}>0}} \left\{ \frac{\eta_{\omega_1}(0)\eta_{\hat{\omega}}(0)}{i^k(\omega_1+\sum\hat{\omega})h(\hat{\omega})} \right.$$

$$\left. + \int_0^t \frac{(\eta_{\omega_1}(s)\eta_{\hat{\omega}}(s))' e^{ij(\omega_1+\sum\hat{\omega})s}}{i^k(\omega_1+\sum\hat{\omega})h(\hat{\omega})}\, ds \right\}$$

$$+(-1)^k \sum_{n_1=3}^{r} \sum_{\hat{n}\in\Omega_2(k-1)} j^{-\frac{1}{n_1}-\alpha_{\hat{n}}} \sum_{\substack{(\omega_1,\hat{\omega})\in\Omega(n_1,\ell_1)\times\Omega(\hat{n},\bar{I})\\ \omega_1+\sum\hat{\omega}\neq 0\\ 1-\frac{1}{n_1}-\alpha_{\hat{n}}>0}} \left\{ \frac{\eta_{\omega_1}(0)\eta_{\hat{\omega}}(0)}{i^k(\omega_1+\sum\hat{\omega})h(\hat{\omega})} \right.$$

$$\left. + \int_0^t \frac{(\eta_{\omega_1}(s)\eta_{\hat{\omega}}(s))' e^{ij(\omega_1+\sum\hat{\omega})s}}{i^k(\omega_1+\sum\hat{\omega})h(\hat{\omega})}\, ds \right\}$$

$$+(-1)^{k-1} \sum_{n_1=3}^{r} \sum_{\hat{n}\in\Omega_2(k-1)} \sum_{\substack{(\omega_1,\hat{\omega})\in\Omega(n_1,\ell_1)\times\Omega(\hat{n},\bar{I})\\ \omega_1+\sum\hat{\omega}\neq 0\\ 1-\frac{1}{n_1}-\alpha_{\hat{n}}=0}} \int_0^t \frac{\eta_{\omega_1}(s)\eta_{\hat{\omega}}(s)e^{ij(\omega_1+\sum\hat{\omega})s}}{i^{k-1}h(\hat{\omega})}\, ds$$

$$+(-1)^{k-1} \sum_{n_1=3}^{r} \sum_{\hat{n}\in\Omega_2(k-1)} j^{1-\frac{1}{n_1}-\alpha_{\hat{n}}} \sum_{\substack{(\omega_1,\hat{\omega})\in\Omega(n_1,\ell_1)\times\Omega(\hat{n},\bar{I})\\ 1-\frac{1}{n_1}-\alpha_{\hat{n}}<0}} \int_0^t \frac{\eta_{\omega_1}(s)\eta_{\hat{\omega}}(s)e^{ij(\omega_1+\sum\hat{\omega})s}}{i^{k-1}h(\hat{\omega})}\, ds.$$

We then define $V_I^j = V_I + R_I^j$. So we have

$$\widetilde{UV}_I^j(t) = V_I^j(t) - \int_0^t u_{\ell_1}^j(s)\widetilde{UV}_{\bar{I}}^j(s)\, ds$$

$$= (-1)^k \sum_{\hat{n}\in\Omega_2(k-1)} j^{-\frac{1}{2}-\alpha_{\hat{n}}} \sum_{\substack{(\omega_1,\hat{\omega})\in\Omega(2,\ell_1)\times\Omega(\hat{n},\bar{I})\\ \frac{1}{2}-\alpha_{\hat{n}}>0}} \frac{\eta_{\omega_1,\ell_1}(t)\eta_{\hat{\omega}}(t)e^{ij(\omega_1+\sum\hat{\omega})t}}{i^k(\omega_1+\sum\hat{\omega})h(\hat{\omega})}$$

$$+(-1)^k \sum_{n_1=3}^{r} \sum_{\hat{n}\in\Omega_1(k-1)} j^{-\frac{1}{n_1}-\alpha_{\hat{n}}} \sum_{\substack{(\omega_1,\hat{\omega})\in\Omega(n_1,\ell_1)\times\Omega(\hat{n},\bar{I})\\ 1-\frac{1}{n_1}-\alpha_{\hat{n}}>0}} \frac{\eta_{\omega_1}(t)\eta_{\hat{\omega}}(t)e^{ij(\omega_1+\sum\hat{\omega})t}}{i^k(\omega_1+\sum\hat{\omega})h(\hat{\omega})}$$

$$+(-1)^k \sum_{n_1=3}^{r} \sum_{\hat{n}\in\Omega_2(k-1)} j^{-\frac{1}{n_1}-\alpha_{\hat{n}}} \sum_{\substack{(\omega_1,\hat{\omega})\in\Omega(n_1,\ell_1)\times\Omega(\hat{n},\bar{I})\\ 1-\frac{1}{n_1}-\alpha_{\hat{n}}>0\\ \omega_1+\sum\hat{\omega}\neq 0}} \frac{\eta_{\omega_1}(t)\eta_{\hat{\omega}}(t)e^{ij(\omega_1+\sum\hat{\omega})t}}{i^k(\omega_1+\sum\hat{\omega})h(\hat{\omega})}.$$

The $\widetilde{UV}_I^j$ are clearly of the form (30).

To finish the inductive step, we have to show that the V_I defined above have the form (29). Since

$$V_I(t) = (-1)^{k-1} \sum_{n_1=3}^{r} \sum_{\hat{n}\in\Omega_2(k-1)} \sum_{\substack{(\omega_1,\hat{\omega})\in\Omega(n_1,\ell_1)\times\Omega(\hat{n},\bar{I}) \\ \omega_1+\sum\hat{\omega}=0 \\ 1-\frac{1}{n_1}-\alpha_{\hat{n}}=0}} \int_0^t \frac{\eta_{\omega_1}(s)\eta_{\hat{\omega}}(s)}{i^{k-1}h(\hat{\omega})}\,ds,$$

for exactly the same reason as above, the two equalities $1-\frac{1}{n_1}-\alpha_{\hat{n}}=0$, $\omega_1+\sum\hat{\omega}=0$ imply that each $(\omega_1,\hat{\omega})$ is canceled out either purely by pairs or purely by some F. The mixed cancelation cannot happen. If the $(\omega_1,\hat{\omega})$ in the summation is canceled out purely by pairs, then k must be even and $(-\omega_1,-\hat{\omega})$ is also in the summation, so they add up to zero. So only those terms whose frequencies are canceled out purely by F will contribute to V_I. Moreover, if the frequencies are canceled purely by an $F\in Q_{E,\rho}$, then $\delta(E)$ must be equal to $|I|=k$. Precisely for $I=(\ell_1,\dots,\ell_k)$, V_I is given by

$$V_I = (-1)^{k-1} \sum_{E\in\mathcal{E}_k} \sum_{\rho=1}^{|E|} \sum_{F\in Q_{E,\rho}} \sum_{\hat{\omega}\in\Omega(F,I)} \int_0^t \frac{\eta_{\hat{\omega}}(s)}{i^{k-1}\omega_k(\omega_k+\omega_{k-1})\cdots(\omega_k+\cdots+\omega_2)}\,ds, \tag{31}$$

where $\Omega(F,I)$ is a subset of $\Omega(k,\ell_1)\times\cdots\times\Omega(k,\ell_k)$ such that $\hat{\omega}=(\omega_1,\dots,\omega_k)\in\Omega(F,I)$ iff as a set $\{\omega_1,\dots,\omega_k\}=F$, so, V_I can be written in form (29) for $3\le|I|\le r$. This finishes the recursive definition of V_I^j and $\widetilde{UV}_I^j$.

Clearly (A) and (B) imply that the $\mathbf{u}^j$ EI(r)-converge to $\mathbf{v}^\infty=\sum_{0<|I|\le r} v_I X_I$, where $v_I=\dot{V}_I$. To finish the proof of Theorem 5.1, we need to show that $\mathbf{u}^\infty=\mathbf{v}^\infty$. For each I and F, let $g(F,I)$ be the number $g(F,I)=\sum_{\hat{\omega}\in\Omega(F,I)}\frac{1}{\omega_k(\omega_k+\omega_{k-1})\dots(\omega_k+\cdots+\omega_2)}$. Then we have

$$v_I = (-1)^{k-1} \sum_{E\in\mathcal{E}_k} \sum_{\rho=1}^{|E|} \sum_{F\in Q_{E,\rho}} \frac{g(F,I)}{i^{k-1}} \prod_{\omega\in F} \eta_\omega(t). \tag{32}$$

In order to get $\mathbf{v}^\infty$ explicitly we need to determine the constants $g(F,I)$. From the expression of V_I in (31) we notice that the contributions to $\mathbf{v}^\infty$ from the terms in u_k^j with frequencies in different $F\in Q_{E,\rho}$ are *independent*. Precisely, for $\delta(E)\ge 3, F\in Q_{E,\rho}$, let

$$u_{k,F,E,\rho}^j(t) = j^{\frac{\delta(E)-1}{\delta(E)}} \sum_{\omega\in F\cap\Omega_{E,\rho,k}} \eta_\omega(t) e^{ij\omega t}, \qquad k=1,\dots,m,$$
$$u_{F,E,\rho}^j = (u_{1,F,E,\rho}^j,\dots,u_{m,F,E,\rho}^j),$$

and for $\delta(E)=2$, let $u_{k,E}^j(t)=j^{\frac{1}{2}}\sum_{\omega\in\Omega_{E,1,k}}\eta_{\omega,k}(t)e^{ij\omega t}, k=1,\dots,m$, $u_E^j=(u_{1,E}^j,\dots,u_{m,E}^j)$. Let $\mathbf{v}_{F,E,\rho}^\infty$ and $\mathbf{v}_E^\infty$ be the limiting extended inputs of the $u_{F,E,\rho}^j$ and u_E^j, respectively. We have

$$\mathbf{v}^\infty(t) = \sum_{\ell=1}^{m} \eta_{\ell,0}(t)\,X_\ell + \sum_{E\in\mathcal{E}_2} \mathbf{v}_E^\infty(t) + \sum_{n=3}^{r} \sum_{E\in\mathcal{E}_n} \sum_{\rho=1}^{|E|} \sum_{F\in Q_{E,\rho}} \mathbf{v}_{F,E,\rho}^\infty(t).$$

This is the high-frequency superposition principle we mentioned in the beginning of section 4. So in order to figure out the explicit formula of $\mathbf{v}^\infty$, we need only find out each $\mathbf{v}^\infty_{F,E,\rho}$ and $\mathbf{v}^\infty_E$.

For $\delta(E)=2$ we have $\mathbf{v}^\infty_E = -v_{\ell_1,\ell_2}\ X_{\ell_1}X_{\ell_2} - v_{\ell_2,\ell_1}\ X_{\ell_2}X_{\ell_1}$, if $E=[X_{\ell_1},X_{\ell_2}]$. Since

$$v_{\ell_1,\ell_2}(t) = -\sum_{\substack{(\omega_1,\omega_2)\in\Omega(2,\ell_1)\times\Omega(2,\ell_2)\\ \omega_1+\omega_2=0}} \frac{\eta_{\omega_1,\ell_1}(t)\eta_{\omega_2,\ell_2}(t)}{i\omega_2},$$

we see that

$$\mathbf{v}^\infty_{[X_{\ell_1},X_{\ell_2}]}(t) = v_{[X_{\ell_1},X_{\ell_2}]}(t)[X_{\ell_1},X_{\ell_2}], \tag{33}$$

where

$$v_{[X_{\ell_1},X_{\ell_2}]}(t) = \frac{1}{i\omega_{\ell_1,\ell_2}}\left(\eta_{\omega_{\ell_1,\ell_2},\ell_1}(t)\eta_{-\omega_{\ell_1,\ell_2},\ell_2}(t) - \eta_{-\omega_{\ell_1,\ell_2},\ell_1}(t)\eta_{\omega_{\ell_1,\ell_2},\ell_2}(t)\right).$$

For $F\in Q_{E,\rho}$, $\delta(E)\ge 3$, from (32) we have

$$\mathbf{v}^\infty_{F,E,\rho} = (-1)^{\delta(E)-1}\sum_{0<|I|\le r}\frac{g(F,I)}{i^{|I|-1}}\prod_{\omega\in F}\eta_\omega(t)\,X_I.$$

It is easy to see that for each $F\in Q_{E,\rho}$ all the $g(F,I)=0$ except for $I\in\Omega(E)$, where $\Omega(E)$ is the set of multi-indices I such that $\delta_k(I)=\delta_k(E)$ for $k=1,\dots,m$ (here $\delta_k(I)$ denotes the number of occurrence of k in I). (For $F\in Q_{E,\rho}$, if $I\notin\Omega(E)$, then $\Omega(F,I)$ is empty.) Let us write

$$\mathbf{v}^\infty_{F,E,\rho} = (-1)^{\delta(E)-1}\sum_{I\in\Omega(E)}\frac{g(F,I)}{i^{|I|-1}}\prod_{\omega\in F}\eta_\omega(t)\ X_I\ = \sum_{B\in E}\left(v_B^{F,E,\rho}\prod_{\omega\in F}\eta_\omega(t)\right)\ B.$$

In order to figure out the limit $\mathbf{v}^\infty_{F,E,\rho}$ of the $u^j_{F,E,\rho}$ for $\delta(E)>2$, we need only figure out $v_B^{F,E,\rho}$, so we may assume that $\eta_\omega=1$. Namely, we need only find out the limit of $\bar u^j_{F,E,\rho}(t)$, where $\bar u^j_{F,E,\rho}=(\bar u^j_{1,F,E,\rho},\dots,\bar u^j_{m,F,E,\rho})$ are given by $\bar u^j_{k,F,E,\rho}(t) = j^{\frac{\delta(E)-1}{\delta(E)}}\sum_{\omega\in F\cap\Omega_{E,\rho,k}}e^{ij\omega t}$, $\delta(E)\ge 3$. From the discussion of the limit of (15) defined in section 4 we know that, if we let $\xi^F_{B,\rho}=g_B(F\cap\Omega_{E,\rho,1},F\cap\Omega_{E,\rho,2},\dots,F\cap\Omega_{E,\rho,m})$, then $v_B^{F,E,\rho}=i^{1-\delta(E)}\xi^F_{B,\rho}$ for $B\in E$. So we get

$$\mathbf{v}^\infty_{F,E,\rho}(t) = \sum_{B\in E} i^{1-\delta(E)}\xi^F_{B,\rho}\prod_{\omega\in F}\eta_\omega(t)\,B. \tag{34}$$

Combining (33) and (34) we get

$$\begin{aligned}\mathbf{v}^\infty(t) = &\sum_{k=1}^m \eta_{k,0}(t)\ X_k + \sum_{\ell_1<\ell_2}\frac{1}{i\omega_{\ell_1,\ell_2}}\xi_{\ell_1,\ell_2}(t)\ [X_{\ell_1},X_{\ell_2}]\\ &+\sum_{n=3}^r\sum_{E\in\mathcal{E}_n}\sum_{B\in E}\sum_{\rho=1}^{|E|}\sum_{F\in Q_{E,\rho}} i^{1-\delta(E)}\xi^F_{B,\rho}\prod_{\omega\in F}\eta_\omega(t)\ B,\end{aligned}$$

where $\xi_{\ell_1,\ell_2}=\eta_{\omega_{\ell_1,\ell_2},\ell_1}\eta_{-\omega_{\ell_1,\ell_2},\ell_2}-\eta_{\omega_{-\ell_1,\ell_2},\ell_1}\eta_{\omega_{\ell_1,\ell_2},\ell_2}$. So $\mathbf{u}^\infty=\mathbf{v}^\infty$. Now the proof of Theorem 5.1 is complete.

7. The linear independence of g_B. In the previous section we proved Theorem 5.1. In order to justify the algorithm we need to show that it is always possible to choose the frequency sets so that condition (11) holds in addition to the other conditions. If $E \in \mathcal{E}_2$, this is obvious. Take an $E \in \cup_{n=3}^{r}\mathcal{E}_n$. Assume that $\delta(E) = n$, $|E| = N$, and $E = \{B_1, \dots, B_N\}$. By definition we know that each $\hat{\xi}_{B,\rho}$ is equal to $\xi^F_{B,\rho} = g_B(F \cap \Omega_{E,\rho,1}, \dots, F \cap \Omega_{E,\rho,m})$ for some fixed $F \in Q_{E,\rho}$. For each $Q_{E,\rho}$, assume that the fixed set $F \in Q_{E,\rho}$ contains the numbers $\omega_1^{E,\rho}, \dots, \omega_n^{E,\rho}$. Assume also that we have listed the $\omega_1^{E,\rho}, \dots, \omega_n^{E,\rho}$ such that

$$\{\omega_1^{E,\rho}, \dots, \omega_{\delta_1(E)}^{E,\rho}\} = F \cap \Omega_{E,\rho,1}, \dots, \{\omega^{E,\rho}_{\delta_1(E)+\cdots+\delta_{m-1}(E)+1}, \dots, \omega_n^{E,\rho}\} = F \cap \Omega_{E,\rho,m}.$$

Now if we think of $\omega^{E,\rho} = (\omega_1^{E,\rho}, \dots, \omega_n^{E,\rho})$ as a point in $\mathbb{R}^n$, we see that $\xi^F_{B,\rho} = g_B(\omega_1^{E,\rho}, \dots, \omega_n^{E,\rho})$. Take any N points $w^k = (w_1^k, \dots, w_n^k), k = 1, \dots, N$, in $\mathbb{R}^n$. Let $M(w^1, \dots, w^n)$ be the matrix $M(w^1, \dots, w^N) = (g_B(w^\rho))_{B\in E, 1\le\rho\le N}$. We will think of M as a matrix-valued function depending on nN variables $(w^1, \dots, w^N)$, i.e., as a matrix-valued function on $\mathbb{R}^{nN}$. Now let H be the subset of $\mathbb{R}^{nN}$ consisting of the points $(w^1, \dots, w^N)$ such that $w_1^k + \cdots + w_n^k = 0, k = 1, \dots, N$. Then $\det(\hat{\xi}^F_{B,\rho}) \neq 0$ just means that we need to take the point $(\omega^{E,1}, \dots, \omega^{E,N}) \in H$ to be not on the surface $\{\det(M) = 0\} \bigcap H$. If we can show that the determinant $\det(M)$ of M, as a rational function of nN variables, is not identically 0 on H, then $\det(M)$ is not zero on a relatively open dense subset of H. With this fact, if we think of the frequencies as taking from one very large dimensional Euclidean space $\mathbb{R}^\kappa$, then we can regard the conditions such as $Q_{E,\rho}$ being SMC, independent, the invertibility of each matrix $(\hat{\xi}_{B,\rho})_{B\in E, 1\le\rho\le|E|}$, etc., as taken some points in $\mathbb{R}^\kappa$ that are not on some finite number of surfaces which have measure 0 in $\mathbb{R}^\kappa$, so it is possible to choose the sets $\Omega(n,k)$ such that all the conditions 1, 2, 6, 7, 8, 9, 10, 11 hold simultaneously.

So all that is needed is to prove that $\det(M) \not\equiv 0$ on the set H. For a matrix-valued function like $M = (g_B(w^\rho))_{B\in E, 1\le\rho\le N}$, $\det(M) \not\equiv 0$ on H iff the functions $g_B(w), B \in E$, are linearly independent on the subset $\{(w_1, \dots, w_n) \mid w_1 + \cdots + w_n = 0\}$ of $\mathbb{R}^n$. (In the following we will simply call this the subset $w_1 + \cdots + w_n = 0$.) From the observation made about g_B in Remark 4.1 we know that each g_B is a linear combination of some $g_{B^{\mathbf{Y}}}$ with $B^{\mathbf{Y}} \in E^{\mathbf{Y}} = \{B^{\mathbf{Y}} \in \mathcal{B}^{\mathbf{Y}}, \delta_k(B^{\mathbf{Y}}) = 1, k = 1, \dots, n\}$. In order to show that the $g_B, B \in E$, are linearly independent on the set $w_1 + \cdots + w_n = 0$, we first show that the functions $g_B, B \in E^m$, are linearly independent on the set $w_1 + \cdots + w_m = 0$, where $E^m = \{B \in \mathcal{B}_m, \delta_k(B) = 1, k = 1, \dots, m\}$.

We recall that two brackets $B_1, B_2 \in \mathcal{B}$ are equivalent if $\delta_k(B_1) = \delta_k(B_2), k = 1, \dots, m$. We will write $B_1 \simeq B_2$ if B_1 is equivalent to B_2. Let $\mathcal{E}$ be the set of equivalence classes. For $k = 1, \dots, m$, let $\mathcal{E}^k$ be the subset of $\mathcal{E}$ such that $E \in \mathcal{E}^k$ iff $\delta(E) = k, \delta_\ell(E) \le 1, \ell = 1, \dots, m$. In particular, $\mathcal{E}^m$ has only one element, namely E^m. Let $\bar{\mathcal{E}} = \cup_{k=2}^m \mathcal{E}^k$. Let $\mathcal{B}^m$ be the subset of $\mathcal{B}$ that contains all the $B \in \mathcal{B}$ of degree $\delta(B) \le m$ with $\delta_k(B) \le 1, k = 1, \dots, m$. If $B \in \mathcal{B}^m$ is a bracket with $\Sigma_B = X_{\ell_1} \dots X_{\ell_k}$, and $w = (w_1, \dots, w_m) \in \mathbb{R}^m$ is a point, for simplicity, we introduce the following notations: $w_B = (w_{\ell_1}, \dots, w_{\ell_k})$, $\sum w_B = w_{\ell_1} + \cdots + w_{\ell_k}$, $\hat{g}_B(w_B) = \hat{g}_B(w_{\ell_1}, \dots, w_{\ell_k})$. We let Σ_E^0 denote the set $\{w_B \mid \sum w_B = 0\}$ of $\delta(E)$-tuples of numbers. It is clear that the set Σ_E^0 depends only on E and can be identified with the subset $\{(w_1, \dots, w_{\delta(E)}) \mid w_1 + \cdots + w_{\delta(E)} = 0\}$ of $\mathbb{R}^{\delta(E)}$.

Now for each $B \in E^m$, by definition we know that $g_B(w_1, \dots, w_m) = \hat{g}_B(w_B)$. So in order to show that the functions $g_B, B \in E^m$, are linearly independent on the

set $w_1 + \cdots + w_m = 0$, we need only prove that the $\hat{g}_B(w_B), B \in E^m$, are linearly independent on $\Sigma^0_{E^m}$. We will show the following:

(IND) For any $E \in \bar{\mathcal{E}}$, the functions $\hat{g}_B(w_B), B \in E$, are linearly independent on the set Σ^0_E.

For each $B \in \mathcal{B}$ of degree $\delta(B) > 1$, B can be written uniquely as $[B_1, B^2]$, where $B_1, B^2 \in \mathcal{B}$, $B_1 \preceq B^2$. We will call B_1, B^2 the *left* and the *right* factors of B and use $\lambda(B)$ and $\rho(B)$ to denote them, i.e., $B = [\lambda(B), \rho(B)]$. (The left and right factors have been defined for formal brackets, cf. section 2.) If $\delta(B^2) > 1$, then we can write the unique decomposition $B^2 = [B_2, B^3]$, $B_2, B^3 \in \mathcal{B}, B_2 \preceq B^3$. Continuing this way, each $B \in \mathcal{B}^m$ can be written uniquely as $B = [B_1, [B_2, \ldots, [B_{s_B}, B^{s_B+1}] \cdots]$, where $B_1, B_2, \ldots, B_{s_B}, B^{s_B+1} \in \mathcal{B}$, $B_1 \succeq B_2 \succeq \cdots \succeq B_{s_B}, B^{s_B+1} \in \{X_1, \ldots, X_m\}$. So we have associated with each $B \in \mathcal{B}$ an ordered set $\{B_1, \ldots, B_{s_B}\}$. Each of the brackets $B_1, \ldots, B_{s_B}$ is called a *principal L-factor* of B. For each $B \in \mathcal{B}$ with $B = [B_1, [B_2, \ldots, [B_{s_B}, B^{s_B+1}] \cdots]$, we will write $B^\ell = [B_\ell, [B_{\ell+1}, \ldots, [B_{s_B}, B^{s_B+1}] \cdots]$ for $\ell = 1, \ldots, s_B$, so $B = [B_1, [B_2, \ldots, [B_{\ell-1}, B^\ell] \cdots]$. Let $B \in \mathcal{B}$ be a bracket of degree $\delta(B) > 1$. We define $LF(B)$, the set of *L-factors* of B, recursively as follows. If $B = [X_{k_1}, X_{k_2}]$, then $LF(B)$ contains only one element X_{k_1}. If $\delta(B) > 2$, write the unique decomposition $B = [B_1, B_2], B_1, B_2 \in \mathcal{B}, B_1 \preceq B_2$. If $\delta(B_1) = 1$, we define $LF(B) = \{B_1\} \cup LF(B_2)$. If $\delta(B_1) > 1$, we define $LF(B) = \{B_1\} \cup LF(B_1) \cup LF(B_2)$. The elements of $LF(B)$ are called the L-factors of B.

Now we prove (IND). We use induction on $\delta(E)$ to prove it. If $E \in \bar{\mathcal{E}}$, $\delta(E) = 2$, then E has only one element, i.e., $[X_{k_1}, X_{k_2}]$ for some $k_1 < k_2$. Then by definition $\hat{g}_{[X_{k_1}, X_{k_2}]}(w_{k_1}, w_{k_2}) = 1/w_{k_1}$ which is not identically 0 on the set $w_{k_1} + w_{k_2} = 0$. Assume that (IND) is true for all $E \in \bar{\mathcal{E}}$ with $\delta(E) \le k-1$, $3 \le k \le r$. Let $E \in \mathcal{E}^k$. Assume that the functions $\hat{g}_B(w_B), B \in E$, are linearly dependent on Σ^0_E. Then there exist constants l_B such that $\sum_{B \in E} l_B \hat{g}_B(w_B) \equiv 0$ on Σ^0_E. Let $\bar{E}$ be the subset of E that contains all the $B \in E$ with $l_B \neq 0$. Then

$$\sum_{B \in \bar{E}} l_B \hat{g}_B(w_B) \equiv 0 \quad \text{on } \Sigma^0_E. \tag{35}$$

Note that the set $\{\lambda(B), B \in \bar{E}\}$ is an ordered set. Let $\bar{B} \in \bar{E}$ be a bracket such that $\lambda(\bar{B}) \succeq \lambda(B)$ for all $B \in \bar{E}$. Let $\bar{B}_1 = \lambda(\bar{B}), \bar{B}_2 = \rho(\bar{B})$. Let $E_{\bar{B}}$ be the subset of $\bar{E}$ such that $B \in E_{\bar{B}}$ iff there is an L-factor of B, denoted by B', that is either equivalent to $\bar{B}_1$ or equivalent to $\bar{B}_2$. (It is obvious that if such an L-factor exists, it is unique.) For each $B \in E_{\bar{B}}$, if B' is the L-factor of B that is either equivalent to $\bar{B}_1$ or equivalent to $\bar{B}_2$, then B' has to be a principal L-factor of B. Write the unique decomposition $B = [B_1, [B_2, \ldots, [B_{\kappa-1}, [B', B^{\kappa+1}] \cdots]]]$. We let $\tilde{B}$ be the bracket $\tilde{B} = [B_1, [B_2, \ldots, [B_{\kappa-1}, B^{\kappa+1}] \cdots]]$ and define

$$\hat{g}_{\tilde{B}}(w_{\tilde{B}}) = \frac{\hat{g}_{B_1}(w_{B_1})}{\sum w_{B_1}} \frac{\hat{g}_{B_2}(w_{B_2})}{\sum w_{B_2}} \cdots \frac{\hat{g}_{B_{\kappa-1}}(w_{B_{\kappa-1}})}{\sum w_{B_{\kappa-1}}} \hat{g}_{B^{\kappa+1}}(w_{B^{\kappa+1}}),$$

where, if as a formal bracket, $\Sigma_{\tilde{B}} = X_{\ell_1} \ldots X_{\ell_s}$, we write $w_{\tilde{B}} = (w_{\ell_1}, \ldots, w_{\ell_s})$. So we get

$$\hat{g}_B(w_B) = \frac{\hat{g}_{\tilde{B}}(w_{\tilde{B}}) \hat{g}_{B'}(w_{B'})}{\sum w_{B'}}.$$

Now it is clear that for each $B \in \bar{E} - E_{\bar{B}}$, $\hat{g}_B(w_B)$ does not contain the factors $\frac{1}{\sum w_{\bar{B}_1}}$ or $\frac{1}{\sum w_{\bar{B}_2}}$. (By this we mean that the multivariable polynomial $\frac{1}{\hat{g}_B(w_B)}$ does

not contain the factors $\sum w_{\bar{B}_1}$ or $\sum w_{\bar{B}_2}$.) From (35) we get

$$\sum_{B\in E_{\bar{B}}} \frac{l_B \hat{g}_{\tilde{B}}(w_{\tilde{B}})\hat{g}_{B'}(w_{B'})}{\sum w_{B'}} + \sum_{B\in \bar{E}-E_{\bar{B}}} l_B \hat{g}_B(w_B) \equiv 0 \text{ on } \Sigma^0_E. \tag{36}$$

Now on Σ^0_E, for any $B \in E_{\bar{B}}$, we have either $\sum w_{B'} = \sum w_{\bar{B}_1}$ or $\sum w_{B'} = \sum w_{\bar{B}_2} = -\sum w_{\bar{B}_1}$ (according to whether B' is equivalent to $\bar{B}_1$ or $\bar{B}_2$). Let $q_B = 1$ if $B' \simeq \bar{B}_1$ and $q_B = -1$ if $B' \simeq \bar{B}_2$. From (36) we have

$$\sum_{B\in E_{\bar{B}}} l_B q_B \hat{g}_{\tilde{B}}(w_{\tilde{B}})\hat{g}_{B'}(w_{B'}) \equiv 0 \tag{37}$$

if $\sum w_{B'} = 0$, $\sum w_{\tilde{B}} = 0$. Note that for any $B \in E_{\bar{B}}$, if B' is equivalent to $\bar{B}_2$, then $B' = \lambda(B)$, so $\rho(B) = \tilde{B}$ is equivalent to $\bar{B}_1$. (By the definition of $\bar{B}_1$ and $\bar{B}_2$ we know that $\bar{B}_1 \preceq \bar{B}_2$, $\bar{B}_1 \succeq \lambda(B)$ for all $B \in \bar{E}$. If there is a $B \in E_{\bar{B}}$ such that $B' \simeq \bar{B}_2$, then $\delta(\bar{B}_1) = \delta(\bar{B}_2)$. It follows from this that if B' is equivalent to $\bar{B}_2$, then $\rho(B)$ must be equivalent to $\bar{B}_1$.) Let $E(\bar{B}_1)$, $E(\bar{B}_2)$ be the equivalence classes determined by $\bar{B}_1$ and $\bar{B}_2$, respectively. Then $E(\bar{B}_2) \in \bar{\mathcal{E}}$ and either $\delta(\bar{B}_1) = 1$ or $E(\bar{B}_1) \in \bar{\mathcal{E}}$. Let us assume first that $\delta(\bar{B}_1) > 1$. Let $E^1_{\bar{B}} = \{B \in E_{\bar{B}} \mid B' \simeq \bar{B}_1\}$ and $E^2_{\bar{B}} = \{B \in E_{\bar{B}} \mid B' \simeq \bar{B}_2\}$. Then $\{B'\}_{B\in E^1_{\bar{B}}} \cup \{\tilde{B}\}_{B\in E^2_{\bar{B}}} \subset E(\bar{B}_1)$. (Here $\tilde{B} = \rho(B)$ for $B \in E^2_{\bar{B}}$.) Now (37) can be rewritten as

$$\sum_{B\in E^1_{\bar{B}}} \left(l_B q_B \hat{g}_{\tilde{B}}(w_{\tilde{B}})\right) \hat{g}_{B'}(w_{B'}) + \sum_{B\in E^2_{\bar{B}}} \left(l_B q_B \hat{g}_{B'}(w_{B'})\right) \hat{g}_{\tilde{B}}(w_{\tilde{B}}) \equiv 0. \tag{38}$$

The left-hand side of (38) is a linear combination of $\hat{g}_B, B \in E(\bar{B}_1)$. From the linear independence of the $\hat{g}_B(w_B), B \in E(\bar{B}_1)$, on $\Sigma^0_{E(\bar{B}_1)}$, we see that in particular the coefficient of $\hat{g}_{\bar{B}_1}(w_{\bar{B}_1})$ in the left-hand side of (38) is zero. Let $\bar{E}'$ be the subset of $\bar{E}$ that contains the brackets $B \in \bar{E}$ such that either $\lambda(B) = \bar{B}_1$ or $\rho(B) = \bar{B}_1$. Then the coefficient of $\hat{g}_{\bar{B}_1}(w_{\bar{B}_1})$ in the left-hand side of (38) is equal to

$$\sum_{B\in \bar{E}'\cap E^1_{\bar{B}}} l_B q_B \hat{g}_{\tilde{B}}(w_{\tilde{B}}) + \sum_{B\in \bar{E}'\cap E^2_{\bar{B}}} l_B q_B \hat{g}_{B'}(w_{B'}).$$

So we get

$$\sum_{B\in \bar{E}'\cap E^1_{\bar{B}}} l_B q_B \hat{g}_{\tilde{B}}(w_{\tilde{B}}) + \sum_{B\in \bar{E}'\cap E^2_{\bar{B}}} l_B q_B \hat{g}_{B'}(w_{B'}) \equiv 0 \tag{39}$$

on $\Sigma^0_{E(\bar{B}_2)}$. Notice that for $B \in \bar{E}' \cap E^1_{\bar{B}}$, the brackets $\tilde{B}$ are in $E(\bar{B}_2)$ (since $\tilde{B} = \rho(B) \simeq \bar{B}_2$). By the linear independence of the $\hat{g}_B(w_B), B \in E(\bar{B}_2)$, on $\Sigma^0_{E(\bar{B}_2)}$ we get that all the coefficients $q_B l_B$ in the summations in the left-hand side of (39) are 0. Therefore we get $l_{\bar{B}} = 0$, which is a contradiction. If $\delta(\bar{B}_1) = 1$, assume that $\bar{B}_1 = X_\ell$. Then by the definition of $\bar{B}$, $E_{\bar{B}} = E^1_{\bar{B}} = \{B \in \bar{E} \mid \lambda(B) = X_\ell\}$. In this case $l_{\bar{B}} = 0$ follows from the linear independence of the $\hat{g}_B(w_B), B \in E(\bar{B}_2)$, on $\Sigma^0_{E(\bar{B}_2)}$, which still contradicts with $l_{\bar{B}} \neq 0$. This finishes the proof of (IND). In particular, we get that the $g_B(w_1, \ldots, w_m), B \in E^m$, are linearly independent on the hyperplane $w_1 + \cdots + w_m = 0$ in $\mathbb{R}^m$.

In the general case, we fix an $E \in \mathcal{E}_n$. Take another group of indeterminates $\mathbf{Y} = \{Y_1, \ldots, Y_n\}$. Let us fix a choice of a P. Hall basis $\mathcal{B}^{\mathbf{Y}}$ of $L(\mathbf{Y})$. We know

that each $g_B, B \in E$, is a linear combination of some $g_{B^{\mathbf{Y}}}$ with $B^{\mathbf{Y}} \in E^{\mathbf{Y}} = \{B^{\mathbf{Y}} \in \mathcal{B}^{\mathbf{Y}}, \delta_k(B^{\mathbf{Y}}) = 1, k = 1, \dots, n\}$. Let θ_E be the algebra homomorphism from $A(\mathbf{Y})$ to $A(\mathbf{X})$, cf. Remark 4.1, defined by $\theta_E(Y_k) = X_\ell$ if $\delta_1(E) + \cdots + \delta_{\ell-1}(E) + 1 \le k \le \delta_1(E) + \cdots + \delta_\ell(E)$. Let $L_E(\mathbf{X})$, $L_{E^{\mathbf{Y}}}(\mathbf{Y})$ be the subsets of $L(\mathbf{X})$ and $L(\mathbf{Y})$, respectively, that are linearly spanned by the brackets $B \in E$ and $B^{\mathbf{Y}} \in E^{\mathbf{Y}}$. Let us use $\mathcal{I}$ to denote a multi-index $\mathcal{I} = (\ell_1, \dots, \ell_k)$ with entries $1 \le \ell_s \le n$. Then $L_E(\mathbf{X})$ is the subset of $L(\mathbf{X})$ linearly spanned by the brackets $[X_I]$ with $\delta_k(X_I) = \delta_k(E), k = 1, \dots, m$, and $L_{E^{\mathbf{Y}}}(\mathbf{Y})$ is the subset of $L(\mathbf{Y})$ spanned by the $[Y_{\mathcal{I}}]$ with $\delta_k(Y_{\mathcal{I}}) = 1, k = 1, \dots, n$. (Here $\delta_k(X_I)$ denotes the degree of X_k in X_I and $\delta_k(Y_{\mathcal{I}})$ denotes the degree of Y_k in $Y_{\mathcal{I}}$.) Clearly the restriction of θ_E to $L_{E^{\mathbf{Y}}}(\mathbf{Y})$ maps $L_{E^{\mathbf{Y}}}(\mathbf{Y})$ onto $L_E(\mathbf{X})$. Let us still use θ_E to denote the restriction of θ_E to $L_{E^{\mathbf{Y}}}(\mathbf{Y})$. The $L_E(\mathbf{X})$, $L_{E^{\mathbf{Y}}}(\mathbf{Y})$ can be regarded as vector spaces over $\mathbb{R}$. It is obvious that E is a basis of $L_E(\mathbf{X})$ and $E^{\mathbf{Y}}$ spans $L_{E^{\mathbf{Y}}}(\mathbf{Y})$. Assume $|E| = N$, $|E^{\mathbf{Y}}| = \bar{N}$, $E = \{B_1, \dots, B_N\}$, and $E^{\mathbf{Y}} = \{B_1^{\mathbf{Y}}, \dots, B_{\bar{N}}^{\mathbf{Y}}\}$. Let $M = (\alpha_{\ell,k})_{1 \le \ell \le \bar{N}, 1 \le k \le N}$ be the matrix with $\alpha_{\ell,k}$ determined by $\theta_E(B_\ell^{\mathbf{Y}}) = \sum_{k=1}^N \alpha_{\ell,k} B_k$, $\ell = 1, \dots, \bar{N}$. Because the map $\theta_E : L_{E^{\mathbf{Y}}}(\mathbf{Y}) \to L_E(\mathbf{X})$ is onto, the matrix has rank N. From Remark 4.1 we know that each of the $g_B, B \in E$, is a linear combination of some $g_{B^{\mathbf{Y}}}$ with $B^{\mathbf{Y}} \in E^{\mathbf{Y}}$. More precisely, we have the following $g_{B_k}(w_1, \dots, w_n) = \sum_{\ell=1}^{\bar{N}} \alpha_{\ell,k} g_{B_\ell^{\mathbf{Y}}}(w_1, \dots, w_n)$ for all $(w_1, \dots, w_n) \in \mathbb{R}^n$, i.e., $(g_{B_1}, \dots, g_{B_N}) = (g_{B_1^{\mathbf{Y}}}, \dots, g_{B_{\bar{N}}^{\mathbf{Y}}})M$. From this it follows that the linear independence of the $g_{B^{\mathbf{Y}}}, B^{\mathbf{Y}} \in E^{\mathbf{Y}}$, on the set $w_1 + \cdots + w_n = 0$ implies that the $g_B, B \in E$, are linearly independent on that set too. Now the judgment of the approximation algorithm is complete.

8. Some examples and variations. We give some examples and variations of the approximation algorithm. From conditions CH1, CH2, CH3 we know that the u_k^j in (22) are linear combinations of $j^\alpha \eta_\omega(t)\cos(\omega j t)$ and $j^\alpha \eta_\omega(t)\sin(\omega j t)$. From the proof of Theorem 5.1 we see that, for the control sequence defined in (22), the limiting extended input has form (23) mainly because of the fact that the frequencies are MC and independent. If we require that the frequencies satisfy some other kind of MC properties (this will be clear in the example below) and the frequencies associated with each part in the extended input be independent, then the limiting extended input can also be calculated explicitly and can be made equal to any prescribed extended input of finite order if the frequencies satisfy some additional conditions like the invertibility of the matrices $\{\hat{\xi}_{B,\rho}\}$, etc.

Example 8.1. Let us consider the case of a two-input system in $\mathbb{R}^5$; i.e., a system

$$\dot{x}(t) = u_1(t) f_1(x(t)) + u_2(t) f_2(x(t)),$$

where f_1, f_2 are smooth vector fields on $\mathbb{R}^5$. Assume that the vectors

$$f_1(x), f_2(x), [f_1, f_2](x), [f_1, [f_1, f_2]](x), [f_2, [f_1, f_2]](x)$$

span $\mathbb{R}^5$ everywhere. Let $t \to \gamma(t) \in \mathbb{R}^5$ on $[0, 1]$ be a smooth curve. Then, by the span condition, there exist smooth functions $v_1, \dots, v_5$ on $[0, 1]$ such that $t \to \gamma(t)$ is a solution of the equation

$$\dot{x} = v_1(t) f_1(x) + v_2(t) f_2(x) + v_3(t)[f_1, f_2](x) + v_4(t)[f_1, [f_1, f_2]](x) + v_5(t)[f_2, [f_1, f_2]](x)$$

with initial condition $x(0) = \gamma(0)$.

In this case the extended input $\mathbf{v}$ that we want to approximate is given by

$$\mathbf{v} = v_1 X_1 + v_2 X_2 + v_3[X_1, X_2] + v_4[X_1, [X_1, X2]] + v_5[X_2, [X_1, X_2]]. \tag{40}$$

Take three groups $\Omega_1 = \{\omega_{1,1}, \omega_{1,2}\}$, $\Omega_k = \{\omega_{k,1}, \omega_{k,2}, \omega_{k,3}\}$, $k = 2, 3$ of real numbers. Assume that (1) each Ω_k is MC; (2) the sets $\Omega_1, \Omega_2, \Omega_3$ are independent with respect to 3.

For any C^1 functions $\eta_1, \eta_2, \eta_{\omega_{1,1}}, \eta_{\omega_{1,2}}$, $\eta_{\omega_{k,l}}, k = 2, 3, l = 1, 2, 3$, on $[0, 1]$, let

$$\begin{aligned} u_1^j(t) &= \eta_1(t) + j^{\frac{1}{2}}\eta_{\omega_{1,1}}(t)\cos\omega_{1,1}jt + j^{\frac{2}{3}}\eta_{\omega_{2,1}}(t)\cos\omega_{2,1}jt \\ &\quad + j^{\frac{2}{3}}\eta_{\omega_{2,2}}(t)\cos\omega_{2,2}jt + j^{\frac{2}{3}}\eta_{\omega_{3,1}}(t)\cos\omega_{3,1}jt, \\ u_2^j(t) &= \eta_2(t) + j^{\frac{1}{2}}\eta_{\omega_{1,2}}(t)\sin\omega_{1,2}jt + j^{\frac{2}{3}}\eta_{\omega_{2,3}}(t)\cos\omega_{2,3}jt \\ &\quad + j^{\frac{2}{3}}\eta_{\omega_{3,2}}(t)\cos\omega_{3,2}jt + j^{\frac{2}{3}}\eta_{\omega_{3,3}}(t)\cos\omega_{3,3}jt. \end{aligned}$$

From Theorem 5.1 we have the following.

PROPOSITION 8.1. *The sequence* $\{u^j = (u_1^j, u_2^j)\}$ *of inputs defined above EI*(3)*-converges to*

$$\mathbf{u}^\infty(t) = \eta_1(t)X_1 + \eta_2(t)X_2 - \frac{\eta_{\omega_{1,1}}(t)\eta_{\omega_{1,2}}(t)}{2\omega_{1,1}}[X_1, X_2]$$

$$-\frac{\eta_{\omega_{2,1}}(t)\eta_{\omega_{2,2}}(t)\eta_{\omega_{2,3}}(t)}{4\omega_{2,1}\omega_{2,2}}[X_1, [X_1, X_2]] + \frac{\eta_{\omega_{3,1}}(t)\eta_{\omega_{3,2}}(t)\eta_{\omega_{3,3}}(t)}{4\omega_{3,2}\omega_{3,3}}[X_2, [X_1, X_2]].$$

Now it is easy to see that in order to get $\mathbf{u}^\infty$ to be equal to $\mathbf{v}$ we can simply let $\eta_1 = v_1$, $\eta_2 = v_2$, $\eta_{\omega_{1,1}} = 1$, $\eta_{\omega_{1,2}} = -2\omega_{1,1}v_3$, $\eta_{\omega_{2,1}} = 1$, $\eta_{\omega_{2,2}} = 1$, $\eta_{\omega_{2,3}} = -4\omega_{2,1}\omega_{2,2}v_4$, $\eta_{\omega_{3,1}} = 1$, $\eta_{\omega_{3,2}} = 1$, $\eta_{\omega_{3,3}} = 4\omega_{3,2}\omega_{3,3}v_5$. There are five terms in u_1^j and u_2^j, respectively. Next we give another control sequence which has fewer terms in u_1^j and u_2^j. Take three groups $\Omega_k = \{\omega_{k,1}, \omega_{k,2}\}$, $k = 1, 2, 3$ of nonzero frequencies. Assume that the $\omega_{k,l}$ satisfy (1) $\omega_{1,1} + \omega_{1,2} = 0$, $2\omega_{2,1} + \omega_{2,2} = 0$, $\omega_{3,1} + 2\omega_{3,2} = 0$ and that (2) $\Omega_1, \Omega_2, \Omega_3$ are independent with respect to 3.

For any functions $\eta_1, \eta_2, \eta_{\omega_{k,l}}, k = 1, 2, 3, l = 1, 2$, of class C^1 on $[0, 1]$, let

$$\begin{aligned} u_1^j(t) &= \eta_1(t) + j^{\frac{1}{2}}\eta_{\omega_{1,1}}(t)\cos\omega_{1,1}jt + j^{\frac{2}{3}}\eta_{\omega_{2,1}}(t)\cos\omega_{2,1}jt + j^{\frac{2}{3}}\eta_{\omega_{3,1}}(t)\cos\omega_{3,1}jt, \\ u_2^j(t) &= \eta_2(t) + j^{\frac{1}{2}}\eta_{\omega_{1,2}}(t)\sin\omega_{1,2}jt + j^{\frac{2}{3}}\eta_{\omega_{2,2}}(t)\cos\omega_{2,2}jt + j^{\frac{2}{3}}\eta_{\omega_{3,2}}(t)\cos\omega_{3,2}jt. \end{aligned}$$

Then we have the following.

PROPOSITION 8.2. *For any frequencies* $\omega_{k,l}, k = 1, 2, 3, l = 1, 2$, *satisfying* (1) *and* (2) *and any functions* $\eta_1, \eta_2, \eta_{\omega_{k,l}}, k = 1, 2, 3, l = 1, 2$, *of class* C^1 *on* $[0, 1]$, *the* $u^j = (u_1^j, u_2^j)$ *EI*(3)*-converge to*

$$\begin{aligned} \mathbf{u}^\infty = \eta_1 X_1 + \eta_2 X_2 &- \frac{\eta_{\omega_{1,1}}\eta_{\omega_{1,2}}}{2\omega_{1,1}}[X_1, X_2] - \frac{\eta_{\omega_{2,1}}^2\eta_{\omega_{2,2}}}{8\omega_{2,1}^2}[X_1, [X_1, X_2]] \\ &- \frac{\eta_{\omega_{3,1}}\eta_{\omega_{3,2}}^2}{4\omega_{3,1}\omega_{3,2}}[X_2, [X_1, X_2]]. \end{aligned}$$

Again, if we want $\mathbf{u}^\infty = \mathbf{v}$ we can let $\eta_1 = v_1$, $\eta_2 = v_2$, $\eta_{\omega_{1,1}} = 1$, $\eta_{\omega_{1,2}} = -2\omega_{1,1}v_3$, $\eta_{\omega_{2,1}} = 1$, $\eta_{\omega_{2,2}} = -8\omega_{2,1}^2 v_4$, $\eta_{\omega_{3,1}} = -4\omega_{3,1}\omega_{3,2}v_5$, $\eta_{\omega_{3,2}} = 1$.

The Lie brackets in the above example are of multiplicity 1. For a simple example with brackets of > 1, cf. [18].

Next we give some remarks about the approximation algorithm. First, using Theorem 6 in [20], we have the following.

THEOREM 8.1. *Let r be a positive integer. Let $\{u^j\}_{j=1}^{\infty}$ be the sequence defined in (22), where the functions $\eta_{0,k}$, η_ω and the sets $\Omega(n,k)$, $\Omega_{E,\rho}$, $\Omega_{E,\rho,k}$ satisfy conditions (1)–(10). Let $f_k : \mathbb{R}^n \times [0,T] \to \mathbb{R}^n$, $k = 1,\dots,m$ be time-varying vector fields on $\mathbb{R}^n$. Assume that $f_1,\dots,f_m$ are of class C^{r-1} in x and of class C^1 jointly in (x,t). Let $f_0 : \mathbb{R}^n \times [0,T] \to \mathbb{R}^n$ be continuous. Let $x_0 \in \mathbb{R}^n$ be a point and let x^j be maximal solutions of*

$$\dot{x} = f_0(x,t) + \sum_{k=1}^{m} u_k^j(t) f_k(x,t),\ x(0) = x_0.$$

Assume that the initial value problem

$$\begin{aligned}\dot{x}(t) = {} & f_0(x,t) + \sum_{k=1}^{m} \eta_{0,k}(t) f_k(x,t) + \sum_{1\le k_1<k_2\le m} \frac{1}{i\omega_{k_1,k_2}} \zeta_{k_1,k_2}[f_{k_1},f_{k_2}](x,t) \\ & + \sum_{n=3}^{r} \sum_{E\in\mathcal{E}_n} \sum_{B\in E} \sum_{\rho=1}^{|E|} \left(\sum_{F\in Q_{E,\rho}} i^{1-\delta(E)} \xi_{B,\rho}^{F} \prod_{\omega\in F} \eta_\omega(t) \right) \mathrm{Ev}(\mathbf{f})(B)(x,t), \\ x(0) = {} & x_0,\end{aligned}$$

where $\zeta_{k_1,k_2} = (\eta_{\omega_{k_1,k_2},k_1}\eta_{-\omega_{k_1,k_2},k_2} - \eta_{-\omega_{k_1,k_2},k_1}\eta_{\omega_{k_1,k_2},k_2})$, has a unique solution x^∞ which is defined on the whole interval $[0,T]$. (Here for each B, $\mathrm{Ev}(\mathbf{f})(B)$ is the vector field obtained by plugging in the vector field f_k for X_k in B.) Then the x^j are defined on $[0,T]$ for j large enough and converge to x^∞ uniformly on $[0,T]$ as $j \to \infty$.

From this theorem we see that exactly the same algorithm works for the time-varying vector field case even with a drift term. But we note that the vector fields $\mathrm{Ev}(\mathbf{f})(B)$ are Lie brackets of f_k for $k = 1,\dots,m$ only.

As suggested to us by Gurvits, it would be nicer if the approximation algorithm could be used to produce *feedback controls*. Suppose that for a suitable Lie bracket extension $\dot{x} = f_0(x,t) + \sum_{k=1}^{r} v_k f_k(x,t)$ of

$$\dot{x} = f_0(x,t) + \sum_{k=1}^{m} u_k f_k(x,t), \tag{41}$$

there exists a time-dependent feedback law $v_k = v_k(x,t)$, $k = 1,\dots,r$, such that the closed loop system

$$\dot{x} = f_0(x,t) + \sum_{k=1}^{r} v_k(x,t) f_k(x,t) \tag{42}$$

has some desired properties. Then one may try to produce time-dependent feedback controls $u_k^j = u_k^j(x,t)$ that generate trajectories of (41) that, as $j \to \infty$, converge to those of the closed loop system (42), at least on some fixed time interval $[0,T]$. It is easy to see that this problem can be reduced to a special case of Theorem 8.1. Our algorithm makes it possible to produce such an approximation as follows. Assume that the functions v_k are sufficiently smooth. Then, by introducing some new vector fields $g_1,\dots,g_\rho$, we can rewrite system (42) into a new system of the form

$$\dot{x} = f_0(x,t) + \sum_{k=1}^{\tau} g_k(x,t) + \sum_{k=\tau+1}^{\rho} g_k(x,t), \tag{43}$$

where the first τ functions $g_1, \ldots, g_\tau$ are linear combinations of $f_1, \ldots, f_m$ with sufficiently smooth coefficients, and the $g_k, k = \tau + 1, \ldots, \rho$, are Lie brackets of the $g_k, k \in \{1, \ldots, \tau\}$. So system (43) can be viewed as a special Lie bracket extension of

$$\dot{x} = f_0(x,t) + \sum_{k=1}^{\tau} w_k g_k(x,t), \tag{44}$$

with constant coefficients (0, or 1, cf. the example below). We then apply our algorithm to system (44) to get a control sequence $\{w^j = (w_1^j, \ldots, w_\tau^j)\}$ that generates trajectories converging to solutions of (43). To see how this can be done, let us examine the following example.

Example 8.2. Suppose $m = 2$ and (42) is given by

$$\dot{x} = f_0(x,t) + v_1(x,t)f_1(x,t) + v_2(x,t)f_2(x,t) + v_3(x,t)[f_1, f_2](x,t). \tag{45}$$

We rewrite $v_3[f_1, f_2] = [f_1, v_3 f_2] - (L_{f_1} v_3) f_2$ and let $g_1 = v_1 f_1, g_2 = v_2 f_2$, $g_3 = -(L_{f_1} v_3) f_2, g_4 = f_1, g_5 = v_3 f_2$. Then system (45) can be rewritten as $\dot{x} = f_0(x,t) + g_1(x,t) + g_2(x,t) + g_3(x,t) + [g_4, g_5](x,t)$, which arises from the extension $\dot{x} = f_0(x,t) + \sum_{k=1}^{5} \bar{w}_k g_k(x,t) + \bar{w}_6 [g_4, g_5](x,t)$ of

$$\dot{x} = f_0(x,t) + \sum_{k=1}^{5} w_k g_k(x,t) \tag{46}$$

by specializing the controls $\bar{w}_4 = \bar{w}_5 = 0$, $\bar{w}_1 = \bar{w}_2 = \bar{w}_3 = \bar{w}_6 = 1$. If we apply our algorithm to produce a control sequence $\{w^j\}$ for (46) that EI(2)-converges to the extended input $\mathbf{v} = X_1 + X_2 + X_3 + [X_4, X_5]$, then the time-dependent feedbacks $u_1^j(x,t) = w_1^j(t) v_1(x,t) + w_4^j(t)$, $u_2^j(x,t) = w_2^j(t) v_2(x,t) - w_3^j(t)(L_{f_1} v_3)(x,t) + w_5^j(x,t) v_3(x,t)$ have the desired properties.

We conclude this section by giving an estimate for the rate of how fast the trajectories generated by the u^j in (22) converge to trajectories generated by $\mathbf{u}^\infty$ in (23).

PROPOSITION 8.3. *Let $\mathbf{f} = (f_1, \ldots, f_m)$ be an $m$tuple of vector fields of class C^r on $\mathbb{R}^n$. Let x_0 be a point in $\mathbb{R}^n$. Let $\{u^j\}$ and $\mathbf{u}^\infty$ be defined in* (22) *and* (23)*, respectively, with the functions $\eta_\omega's$ and the frequency sets $\Omega(n,k)$ satisfying conditions* (1)–(10)*. Assume that the solution x^∞ generated by $\mathbf{u}^\infty$ and $\mathbf{f}$ with initial condition $x(0) = x_0$ is defined on $[0,T]$. Then there exists a constant K such that the solutions x^j with initial condition $x(0) = x_0$, generated by the u^j and $\mathbf{f}$, are defined on $[0,T]$ for j large enough and $\|x^j - x^\infty\|_{\sup} \le K j^{-\frac{1}{r}}$. Let Δ be a compact set in $\mathbb{R}^n$ that contains x^∞ in its interior. Then the constant K depends on $\mathbf{f}$ restricted on Δ, the ω, and the η_ω.*

Acknowledgment. The author would like to thank Professor H. J. Sussmann for proposing to him the topic and for his help and many fruitful discussions.

REGULARITY PROPERTIES OF THE PHASE FOR MULTIVARIABLE SYSTEMS*

KEVIN A. GRASSE† AND JONATHAN R. BAR-ON‡

Abstract. For multivariable, input-output systems that are represented as rational, transfer-function matrices, the most frequently used measures of relative stability are gain based. However, there are a number of important physical applications where the phase of a perturbation can also have a significant effect on relative stability. Such applications led J. R. Bar-on and E. A. Jonckheere [J. R. Bar-on, *Phase and Gain Margins for Multivariable Control Systems*, Ph.D. thesis, University of Southern California, 1990; J. R. Bar-on and E. A. Jonckheere, *Internat. J. Control*, 52 (1990), pp. 485–498] to define precisely the notions of phase, minimum-phase mapping, and phase margin for multivariable systems. The objective of this paper is to establish conditions under which the phase and minimum-phase mappings have certain desired regularity properties (e.g., continuity or differentiability). After a review of the definitions of the phase concepts under consideration, we collect a few well-known results about set-valued maps that have direct applications to parametrized families of constrained optimization problems. Using these results we show that, under very mild conditions, the minimum-phase mapping is lower semicontinuous as a function of frequency; as a consequence, the phase margin (initially defined as the infimum of the phase of all destabilizing unitary perturbations in the range of frequencies where destabilizing perturbations can occur) is achieved as the phase of a specific destabilizing unitary perturbation. We then establish sufficient conditions of gradually increasing strength for the minimum-phase mapping to be continuous and real analytic as a function of frequency. The proof of the real analyticity of the minimum-phase mapping relies on the implicit function theorem and the Lagrange multiplier theorem.

Key words. multivariable system, robust stability, unitary matrix, phase margin, parametric optimization problem, value function, marginal function

1. Introduction.

A desirable feature of a multivariable control system is its ability to maintain stability in the presence of unknown perturbations. Such perturbations can be attributed to modeling errors (i.e., linearization or the neglect of high-frequency terms) as well as to external environmental factors that may impact the system. Consequently, it is important to have quantitative measurements of relative stability, or robustness, of control systems. For multi-input, multioutput (MIMO) control systems there currently exist a number of different measurements of relative stability. Most of these measurements are *gain* based; i.e., they focus only on the modulus (size) of the perturbation (see [9, 11, 12, 18, 19, 21]). However, the *phase* (or "angle of rotation") of the perturbation can also have a significant effect in some systems (see [3, 4, 7] for a more detailed discussion), and such effects are essentially ignored by gain-based stability measurements. These considerations motivated J. R. Bar-on and E. A. Jonckheere to define the notions of the *phase*, *minimum-phase mapping*, and *phase margin* for multivariable control systems [3, 4, 5]. We review the precise mathematical definitions of these terms in the next section.

Our objective here is to establish some important mathematical properties of these phase-related concepts, which should further enhance their usefulness. For input-output systems that are representable as transfer-function matrices $L(s)$ and are closed-loop stable, we will consider the effect of unitary (pure phase) perturbations on their stability. In generic situations, there is a specific set of frequencies at which it is possible to destabilize the system via unitary perturbations; the set of these frequencies is called the *gain-crossover region*. To each frequency in the gain-crossover region one can assign the minimum value of the phase for the unitary perturbations that destabilize the system at that frequency. This results in the what is called the *minimum-phase mapping* of the system. The *phase margin* of the system is by definition the minimum value of the minimum-phase mapping as it ranges over all frequencies in the gain-crossover region. In order to ensure that the minimum is achieved, it is necessary that the minimum-phase mapping be at least lower semicontinuous, and we prove that this is always the case under very mild conditions on the transfer function $L(s)$. However, there is ample numerical evidence that the minimum-phase mapping is far better than merely lower semicontinuous. Thus we will also state specific sufficient conditions for the minimum-phase mapping to be continuous, differentiable, and even real analytic as a function of the frequency. The continuity results will be obtained from standard results on parametrized optimization problems. The differentiability results will follow from the Lagrange multiplier theorem and the implicit function theorem.

The fact that the minimum-phase mapping is (under reasonable assumptions) a differentiable function of frequency is important for at least two reasons. First, as we will see, the values of the minimum-phase mapping are computed as the solutions of a family of constrained optimization problems parametrized by frequency. For a general parametrized optimization problem one cannot even expect continuous dependence of the optimal value on the parameter, to say nothing of differentiable dependence. There is ample numerical evidence to suggest that the minimum-phase mapping is smooth in generic cases, and this poses a purely mathematical question of why it should be so. Second, it turns out that the regularity of the minimum-phase mapping is closely tied to the stability of the numerical methods that are employed to compute the phase margin. We will return to this point at the end of the next section.

The remainder of the paper is organized as follows. In section 2 we review the definitions of the phase, minimum-phase mapping, and phase margin as given by Bar-on and Jonckheere [3, 4, 5]. We also review Bar-on's formulation of the computation of the minimum-phase mapping as the minimum value of a constrained optimization problem, since this formulation is very useful in the theoretical development. Section 3 presents a concise review of a few well-known results in parametrized optimization problems. These results are applied in section 4 to show that the phase and, under appropriate conditions, the minimum-phase mapping are continuous on their domains. Finally, differentiability of the minimum-phase mapping is discussed in section 5.

2. Phase concepts for multivariable systems. We begin with a review of phase concepts for multivariable systems. To do this, we adopt the frequency domain approach and view a control system as a transfer function $L(s)$. More precisely, $L(s)$ denotes an $n \times n$ matrix function of $s \in \mathbb{C}$ whose entries are in the field of rational functions of s with real coefficients. Here $\mathbb{C}$ denotes the field of complex numbers, and we let $j \in \mathbb{C}$ denote the imaginary unit. It is assumed throughout that $n \geq 2$ since we wish to focus on multivariable systems. The assumption that $L(s)$ is square means that the number of system inputs equals the number of system outputs, which

is typical for feedback systems. We always assume that $L(s)$ has no poles on the imaginary axis $s = j\omega$ and is *proper*; i.e., $\lim_{s\to\infty} L(s) = L_\infty$, where L_∞ is a real $n \times n$ constant matrix. If $L_\infty = 0$, then we call $L(s)$ *strictly proper*. Since $L(s)$ is assumed to be proper, we can extend the continuous mapping $\omega \mapsto L(j\omega)$ of $\mathbb{R}$ into $\mathbb{C}^{n\times n}$ (the set of all $n \times n$ matrices with entries in $\mathbb{C}$) to a continuous mapping defined on the extended real numbers $\overline{\mathbb{R}} = \mathbb{R} \cup \{\infty\}$ (recall that $\overline{\mathbb{R}}$ is the one-point compactification of $\mathbb{R}$ and is homeomorphic to the unit circle $S^1 \subseteq \mathbb{C}$).

The multivariable Nyquist criterion [8, 10] states that $L(s)$ is closed-loop stable (in the sense that $L(s)(I + L(s))^{-1}$ is stable) if and only if

(N1) $\det(I + L(j\omega)) \neq 0 \ \forall\ \omega \in \overline{\mathbb{R}}$;

(N2) the number of counterclockwise encirclements of the origin by the curve $\gamma : \overline{\mathbb{R}} \to \mathbb{C}$ given by $\gamma(\omega) = \det(I + L(j\omega))$ equals the number of right-half-plane poles of $L(s)$ (here I denotes the $n \times n$ identity matrix and the curve γ is given the orientation induced from the standard positive orientation on $\overline{\mathbb{R}}$).

In addition to being proper and having no poles on the imaginary axis, we shall always assume that $L(s)$ is closed-loop stable in the sense of (N1) and (N2).

The perturbations that act on the system will be assumed to occur in the feedback path as discussed in [3, 4]. Since we wish to focus on the phase of such perturbations, it will also be assumed that the perturbations come from the group $U(n, \mathbb{C})$ of complex unitary $n \times n$ matrices defined by

$$U(n, \mathbb{C}) = \{\Delta \in \mathbb{C}^{n\times n} \mid \Delta^* = \Delta^{-1}\},$$

where the $*$ denotes the complex-conjugate transpose. If we give $U(n, \mathbb{C})$ the topology that it inherits as a subspace of the complex vector space $\mathbb{C}^{n\times n}$, then $U(n, \mathbb{C})$ is compact. The *phase* of a unitary matrix $\Delta \in U(n, \mathbb{C})$ is defined as

$$\Pi(\Delta) = \max\{|\arg(\lambda)| : \lambda \text{ is an eigenvalue of } \Delta\},$$

where the argument of a complex number $s \in \mathbb{C}$ is chosen to satisfy $-\pi < \arg(s) \leq \pi$. We recall that since Δ is unitary, every eigenvalue λ of Δ satisfies $|\lambda| = 1$. An equivalent definition of the phase (see [3, 4]) is given by

$$\Pi(\Delta) = \max\{\cos^{-1}(\mathrm{Re}(z^*\Delta z)) \mid z \in \mathbb{C}^n \text{ and } z^*z = 1\}, \tag{1}$$

where Re denotes the real part of a complex number and we select the branch of $\cos^{-1}$ that returns angles in the interval $[0, \pi]$. In section 4 we give a short proof that the function $\Pi : U(n, \mathbb{C}) \to [0, \pi]$ is continuous. Suppose now that the system is affected by perturbations $\Delta \in U(n, \mathbb{C})$ in the feedback path as indicated previously. The *stability set* $\mathcal{S}$ is by definition the set of $\Delta \in U(n, \mathbb{C})$ such that the perturbed system is closed-loop stable. Using the Nyquist criterion, we see that $\Delta \in \mathcal{S}$ if and only if (N1) and (N2) are satisfied with $L(j\omega)$ replaced by $L(j\omega)\Delta$. From this characterization of $\mathcal{S}$ it follows that $\mathcal{S}$ is an open subset of $U(n, \mathbb{C})$. Moreover, $\mathcal{S}$ is nonempty since $I \in \mathcal{S}$ by the assumed closed-loop stability of the unperturbed system.

Let $g : \mathbb{R} \times U(n, \mathbb{C}) \to \mathbb{C}$ denote the mapping given by

$$g(\omega, \Delta) = \det(I + L(j\omega)\Delta).$$

Since $L(s)$ is assumed to be proper, we can extend g to a mapping defined on $\overline{\mathbb{R}} \times U(n, \mathbb{C})$. The preimage $g^{-1}(0)$ will be of fundamental importance in our work. This preimage is a closed (hence compact) subset of $\overline{\mathbb{R}} \times U(n, \mathbb{C})$. Furthermore, if $\det(I +$

$L_\infty\Delta) \neq 0$ for every $\Delta \in U(n,\mathbb{C})$, then it is easy to see that $g^{-1}(0)$ is actually compact as a subset of $\mathbb{R} \times U(n,\mathbb{C})$. We will call such transfer functions *nicely proper*. This is the case, for example, if $||L_\infty|| < 1$ (the norm is the standard matrix norm).

From the Nyquist criterion, it is easy to see that the boundary of the stability set, $\partial\mathcal{S}$, is contained in the set

$$D = \{\Delta \in U(n,\mathbb{C}) \mid \exists\, \omega \in \overline{\mathbb{R}} \text{ such that } g(\omega,\Delta) = 0\}.$$

We also define the *gain-crossover region* by

$$\Omega = \{\omega \in \overline{\mathbb{R}} \mid \exists\, \Delta \in U(n,\mathbb{C}) \text{ such that } g(\omega,\Delta) = 0\}.$$

It is evident that D is compact (hence closed) in $U(n,\mathbb{C})$ and Ω is compact in $\overline{\mathbb{R}}$; furthermore, if $L(s)$ is nicely proper, then Ω is actually a compact subset of $\mathbb{R}$. If D is empty, then we are in the pleasant situation where no unitary perturbation destabilizes the system. On the other hand, if D is nonempty, then we define the *phase margin* of the system $L(s)$ by

$$\mathrm{PM}(L) = \min\{\Pi(\Delta) \mid \Delta \in D\}. \tag{2}$$

Observe that the minimum is attained since D is compact and, as we will see, the phase is a continuous function of its matrix argument. Consequently, closed-loop stability of the perturbed system is guaranteed if the perturbation Δ satisfies $\Pi(\Delta) < \mathrm{PM}(L)$. For computational purposes, it is convenient to redefine the phase margin in the following manner. Let $\mu\colon\Omega \to [0,\pi]$ be given by

$$\mu(\omega) = \min\{\Pi(\Delta) | \Delta \in U(n,\mathbb{C}) \text{ and } g(\omega,\Delta) = 0\}. \tag{3}$$

We will call μ the *minimum-phase mapping* of the system $L(s)$. Clearly the minimum-phase mapping and phase margin are related by

$$\mathrm{PM}(L) = \inf\{\mu(\omega) \mid \omega \in \Omega\}. \tag{4}$$

We will see later in section 4 that μ is always lower semicontinuous, so the compactness of $\Omega \subseteq \overline{\mathbb{R}}$ allows us to replace "inf" by "min" (see [13, p. 277]).

An effective means of computing the values of the minimum-phase mapping at a particular frequency ω in the gain crossover region Ω has been developed by J. R. Bar-on and E. A. Jonckheere in [3, 4]. They show that for $\omega \in \Omega$

$$\mu(\omega) = \cos^{-1}\left(-\frac{1}{2}\phi(\omega)\right), \tag{5}$$

where $\phi(\omega)$ is the minimum value of the constrained optimization problem:

$$\text{(CMP}\omega\text{)} \qquad \begin{array}{ll} \text{minimize} & z^*(L(j\omega)^* + L(j\omega))z, \quad z \in \mathbb{C}^n \quad (\omega \in \Omega \text{ fixed}) \\ \text{subject to} & \begin{cases} z^*z = 1, \\ z^*L(j\omega)^*L(j\omega)z = 1. \end{cases} \end{array}$$

Observe that the constraint set is always closed and bounded (hence compact) in $\mathbb{C}^n$. The continuity of the functional being minimized ensures a solution to the problem if the constraint set is nonempty. Thus the existence of solutions of CMPω depends on the feasibility of the constraints, which in turn is governed by the magnitude of

the (real) eigenvalues of the nonnegative definite (Hermitian) matrix $L(j\omega)^* L(j\omega)$; the nonnegative square roots of these eigenvalues are precisely the *singular values* of $L(j\omega)$. Specifically, letting $\overline{\sigma}(L(j\omega))$ (resp., $\underline{\sigma}(L(j\omega))$) denote the maximum (resp., minimum) singular value of $L(j\omega)$, we see that the constraint set in CMPω will be empty if and only if either $\overline{\sigma}(L(j\omega)) < 1$ or $\underline{\sigma}(L(j\omega)) > 1$. Consequently, the constraint set of CMPω is nonempty if and only if $\underline{\sigma}(L(j\omega)) \leq 1 \leq \overline{\sigma}(L(j\omega))$, in which case we say that the singular values of $L(j\omega)$ are "spread across one." It is shown in [3, 4] that the frequencies $\omega \in \overline{\mathbb{R}}$ for which the singular values of $L(j\omega)$ are spread across one coincide with the frequencies in the gain crossover region Ω; i.e.,

$$\Omega = \{\omega \in \overline{\mathbb{R}} \mid \underline{\sigma}(L(j\omega)) \leq 1 \leq \overline{\sigma}(L(j\omega))\}. \tag{6}$$

The continuity of the singular values as a function of the matrix (see, e.g., [20, p. 330]) gives an alternative proof of the fact that Ω is a closed (hence compact) subset of $\overline{\mathbb{R}}$ (and is a compact subset of $\mathbb{R}$ if $L(s)$ is nicely proper).

The problem CMPω is well suited to numerical computation because, after conversion to an equivalent real problem via a standard "decomplexification" process, it is a purely quadratic minimization problem whose global minima admit a precise characterization (we will have more to say on this in section 5). The phase margin can be effectively approximated by computing $\mu(\omega)$ on a suitably fine discrete subset of Ω and then selecting the smallest value of μ so obtained. While this method works well in practice, its success requires that μ be continuous as a function of ω. However, stronger regularity of μ yields additional desirable features of the numerical scheme by which PM(L) is computed. Specifically, conditions which guarantee the differentiability of μ coincide with conditions which guarantee the appropriate nonsingularity of the Jacobian when one attempts to solve CMPω (or its decomplexified equivalent) via the Lagrange multiplier technique and Newton's method, so one can interpret the differentiability of μ as a guarantee of the numerical stability of the routines by which PM(L) is computed. These considerations form the primary motivation for our study of the regularity properties of the minimum-phase mapping.

3. Generalities on parametrized optimization problems. The phase of a unitary matrix $\Delta \in U(n, \mathbb{C})$ is the maximum value of a constrained optimization problem in which the matrix Δ appears as a parameter (cf. equation (1)). Likewise, the value of the minimum-phase mapping at a specific frequency ω in the gain-crossover region ω is the minimum value of a constrained optimization problem CMPω in which the frequency ω appears as a parameter. Thus, the study of the regularity properties of the phase and the study of the regularity properties of the minimum-phase mapping are both special cases of the study of regularity properties of the "value function" for a parametrized family of constrained optimization problems. In this section we will state for future reference two results about the behavior of the value function for a certain class of parametrized constrained optimization problems.

Notation 3.1. Given a metric space X with metric d, we let $\mathcal{C}(X)$ denote the family of all nonempty compact subsets of X. For metric spaces X, Y, we recall that a *set-valued* function on Y is map $G : Y \to \mathcal{C}(X)$. As with single-valued functions, one can make precise what it means for a set-valued function to be continuous, upper semicontinuous (usc), and lower semicontinuous (lsc). We assume that these notions are familiar to the reader (see, e.g., [1, Chap. 1] and [13, Chap. 3] for details).

We will have occasion to refer to the following well-known proposition (see, e.g., [17]), which gives a simple sufficient condition for the lower semicontinuity of a set-valued function.

PROPOSITION 3.2. *Let X, Y be metric spaces, let $G: Y \to \mathcal{C}(X)$ be a set-valued function, and let $y_0 \in Y$ be such that for every $x \in G(y_0)$ there exist an open neighborhood U_0 of y_0 and a continuous function $\alpha_x : U_0 \to X$ such that $\alpha_x(y_0) = x$ and $\alpha_x(y) \in G(y)$ for every $y \in U_0$. Then G is lsc at y_0.*

The subsequent theorem and its corollary summarize the specific results that we will need concerning the continuity properties of the value function for parametrized constrained optimization problems. For the proofs, we refer the reader to [1, section 1.2] or [2, section 1.4]. (Note that in these references the value function is referred to as the "marginal function.")

THEOREM 3.3. *Let X, Y be metric spaces, let $f: X \times Y \to \mathbb{R}$ be continuous, let $G: Y \to \mathcal{C}(X)$ be a set-valued function, and define $\phi: Y \to \mathbb{R}$ by*

$$\phi(y) = \min \{f(x, y) \mid x \in G(y)\}.$$

Then

(a) *G usc $\Rightarrow$ ϕ lsc;*

(b) *G lsc $\Rightarrow$ ϕ usc;*

(c) *if G is continuous, then ϕ is continuous.*

COROLLARY 3.4. *Let X, Y, Z be metric spaces with X and Y compact, and let $\bar{z} \in Z$ be a fixed element. Let $f: X \times Y \to \mathbb{R}$ and $g: X \times Y \to Z$ be continuous mappings, and suppose that g has the additional property that for every $y \in Y$ there exists $x \in X$ such that $g(x, y) = \bar{z}$. Then for each fixed $y \in Y$ the constrained minimization problem*

$$\begin{array}{ll} \textit{minimize} & f(x, y) \quad x \in X \ (y \in Y \textit{ fixed}) \\ \textit{subject to} & g(x, y) = \bar{z} \end{array}$$

has a solution. Furthermore, if $\phi(y)$ denotes the constrained minimum value, then the mapping $\phi: Y \to \mathbb{R}$ is lower semicontinuous. In particular, there exists $\tilde{y} \in Y$ such that $\phi(\tilde{y}) \leq \phi(y)$ for every $y \in Y$, so $\min \{\phi(y) \mid y \in Y\}$ exists.

Proof. Define $G: Y \to \mathcal{C}(X)$ by $G(y) = \{x \in X \mid g(x, y) = \bar{z}\}$, verify G is usc, and apply the theorem. ∎

4. Continuity of the phase and minimum-phase mappings. The results of the previous section will now be applied to the study of the continuity properties of the phase and minimum-phase mappings. First we will show that phase of a unitary matrix, as defined in (1), is a continuous function of its matrix argument. Next we will consider the minimum-phase mapping (3) and show that, under very general conditions, it is an lsc function of frequency. A useful consequence of this lower semicontinuity is that we can replace "inf" by "min" in the definition (4) of the phase margin. We then formulate slightly more restrictive conditions which guarantee that the minimum-phase mapping is a continuous function of frequency.

PROPOSITION 4.1. *The phase mapping $\Pi: U(n, \mathbb{C}) \to [0, \pi]$ is continuous.*

Proof. The function $\cos^{-1}: [-1, 1] \to [0, \pi]$ is decreasing, so for each $\Delta \in U(n, \mathbb{C})$ we have

$$\Pi(\Delta) = \max \{\cos^{-1}(\mathrm{Re}(z^* \Delta z)) \mid z \in \mathbb{C}^n \text{ and } z^* z = 1\} = \cos^{-1}(\phi(\Delta)),$$

where $\phi: U(n, \mathbb{C}) \to \mathbb{R}$ is defined by

$$\phi(\Delta) = \min \{\mathrm{Re}(z^* \Delta z) \mid z \in \mathbb{C}^n \text{ and } z^* z = 1\}.$$

Thus to show that Π is continuous, it suffices to show that ϕ is continuous. Define mappings $f : \mathbb{C}^n \times U(n,\mathbb{C}) \to \mathbb{R}$ by $f(z,\Delta) = \mathrm{Re}(z^*\Delta z)$ and $G : U(n,\mathbb{C}) \to \mathcal{C}(\mathbb{C}^n)$ by $G(\Delta) = \{z \in \mathbb{C}^n \mid z^*z = 1\}$. It is clear that f is continuous. In addition, G is a constant set-valued function and is obviously continuous. With the above definitions we have

$$\phi(\Delta) = \min\{f(z,\Delta) \mid z \in G(\Delta)\},$$

so the continuity of ϕ is an immediate consequence of Theorem 3.3(c). ∎

THEOREM 4.2. *Let $L(s)$ be a $n \times n$ matrix function of $s \in \mathbb{C}$ whose entries are in the field of rational functions of s with real coefficients and assume that $L(s)$ satisfies the following conditions:*

(i) *$L(s)$ has no poles on the $j\omega$ axis;*

(ii) *$L(s)$ is proper in the sense that $\lim_{s\to\infty} L(s) = L_\infty$, where L_∞ is a real $n \times n$ matrix satisfying $\det(I + L_\infty) \neq 0$;*

(iii) *the gain-crossover region*

$$\Omega = \{\omega \in \overline{\mathbb{R}} \mid \exists \Delta \in U(n,\mathbb{C}) \text{ such that } \det(I + L(j\omega)\Delta) = 0\}$$

is nonempty. Then the minimum-phase mapping $\mu : \Omega \to [0,\pi]$ defined by

$$\mu(\omega) = \min\{\Pi(\Delta) \mid \Delta \in U(n,\mathbb{C}),\ \det(I + L(j\omega)\Delta) = 0\}$$

is lsc.

Proof. Let $g : U(n,\mathbb{C}) \times \Omega \to \mathbb{C}$ be defined by

$$g(\Delta,\omega) = \det(I + L(j\omega)\Delta),$$

where it is understood that we set $g(\Delta,\infty) = \det(I + L_\infty\Delta)$ in case $\infty \in \Omega$. Assumption (ii) ensures that g is continuous on its domain $U(n,\mathbb{C}) \times \Omega$, and this domain is obviously compact. The definition of Ω guarantees that for each $\omega \in \Omega$ there exists a $\Delta \in U(n,\mathbb{C})$ such that $g(\Delta,\Omega) = 0$. Moreover, the map $f : U(n,\mathbb{C}) \times \Omega \to [0,\pi]$ defined by $f(\Delta,\omega) = \Pi(\Delta)$ is continuous by Proposition 4.1. For each $\omega \in \Omega$ our definitions imply that $\mu(\omega)$ is the minimum value of the constrained optimization problem

$$\begin{aligned} &\text{minimize} && f(\Delta,\omega), \quad \Delta \in U(n,\mathbb{C}) \ (\omega \in \Omega \text{ fixed}), \\ &\text{subject to} && g(\Delta,\omega) = 0. \end{aligned}$$

Hence $\mu : \Omega \to [0,\pi]$ is lsc by Corollary 3.4. ∎

We next develop conditions under which the minimum-phase mapping is actually continuous as a function of frequency. These conditions involve a more subtle analysis of the singular values of $L(j\omega)$.

Remark 4.3. Let $L(s)$ be an $n \times n$ transfer-function matrix that satisfies the conditions of Theorem 4.2. By assumption, $L(s)$ has no poles on the $j\omega$-axis, so the matrix function $T(s) = L(-js)^T L(js)$ is holomorphic on a domain containing the real axis $s = \omega$. Furthermore, since the coefficients of the rational entries of $L(s)$ are real, it is clear that $T(s)$ is Hermitian for real s; i.e., $T(\omega)^* = T(\omega)$ for every $\omega \in \mathbb{R}$. From [14, Thm. S6.3] or [15, Chap. 2] we infer that there exists an $n \times n$ matrix function $P(s)$ which is holomorphic on a domain containing the real axis $s = \omega$, unitary on the real axis (i.e., $P(\omega)^* = P(\omega)^{-1}$ for $\omega \in \mathbb{R}$) and satisfies

$$P(\omega)^* T(\omega) P(\omega) = \mathrm{diag}\,[\lambda_1(\omega), \ldots, \lambda_n(\omega)] \tag{7}$$

for every $\omega \in \mathbb{R}$. In particular, (7) exhibits the (real and nonnegative) eigenvalues, $\lambda_i(\omega), i = 1, \ldots, n$, of $T(\omega)$ as real-analytic functions of ω. (Note, however, that no ordering of the eigenvalues is implied by the indexing.) We adopt the usual conventions regarding real analyticity at $\omega = \infty$: $\lambda_i(\omega)$ is real analytic at $\omega = \infty$ if and only if $\lambda_i(1/\omega)$ is real analytic at $\omega = 0$. Since $T(\omega)$ is nonnegative definite, we have $\lambda_i(\omega) \geq 0$ for each $i = 1, \ldots, n$. The singular values of $L(j\omega)$ are given by $\sigma_i(\omega) = \sqrt{\lambda_i(\omega)}, i = 1, \ldots, n$ (note that these too are not necessarily ordered); consequently, the singular values are real analytic on the open set where they are positive. It is clear that $\sigma_i(\omega) < 1 \iff \lambda_i(\omega) < 1$ and $\sigma_i(\omega) > 1 \iff \lambda_i(\omega) > 1$.

DEFINITION 4.4. *Let $L(s)$ be an $n \times n$ transfer-function matrix having the properties listed in Theorem* 4.2*, and let $\Omega \subseteq \overline{\mathbb{R}}$ denote its gain-crossover region. A frequency point $\omega_0 \in \Omega$ is said to be*

(a) Type I *if there exist $i, k \in \{1, \ldots, n\}$ such that $\sigma_i(\omega_0) < 1 < \sigma_k(\omega_0)$;*

(b) Type II *if it is not of Type* I*, the set of indices $I_1 = \{i \in \{1, \ldots, n\} \mid \sigma_i(\omega_0) = 1\}$ is a proper subset of $\{1, \ldots, n\}$, and one of the following conditions holds.*

(C1) $\overline{\sigma}(L(j\omega_0)) > 1$ *and there exists $\delta > 0$ such that $\sigma_i(\omega) \leq 1$ for every $i \in I_1$ and $\omega \in (\omega_0 - \delta, \omega_0 + \delta) \cap \Omega$.*

(C2) $\underline{\sigma}(L(j\omega_0)) < 1$ *and there exists $\delta > 0$ such that $\sigma_i(\omega) \geq 1$ for every $i \in I_1$ and $\omega \in (\omega_0 - \delta, \omega_0 + \delta) \cap \Omega$.*

Remark 4.5. (a) A frequency point $\omega_0 \in \Omega$ is Type I if and only if the singular values of $L(j\omega_0)$ are *strictly* spread across one in the sense that $\underline{\sigma}(L(j\omega_0)) < 1 < \overline{\sigma}(L(j\omega_0))$. Thus, the continuity of the maximum and minimum singular values as functions of frequency implies that a Type I frequency point $\omega_0 \in \Omega$ is an interior point of Ω. However, it can also be the case that Type II frequency points are interior points of Ω.

(b) If $\omega_0 \in \Omega$ is not Type I, then the set of indices I_1 is necessarily nonempty. This follows directly from the fact that $\omega_0 \in \Omega \iff \underline{\sigma}(L(j\omega_0)) \leq 1 \leq \overline{\sigma}(L(j\omega_0))$.

(c) If the transfer function $L(j\omega)$ has the property that for each $\omega \in \Omega$ at most one singular value is equal to one, then every $\omega \in \Omega$ that is not Type I will automatically be Type II.

(d) We refer the reader to Example 4.7 for an example of a transfer function whose gain-crossover region has an interior point that is neither Type I nor Type II.

THEOREM 4.6. *Let $L(s)$ be an $n \times n$ matrix function of $s \in \mathbb{C}$ whose entries are in the field of rational functions of s with real coefficients. Assume that $L(s)$ satisfies conditions* (i)*,* (ii)*, and* (iii) *of Theorem* 4.2 *and in addition has the property that every frequency ω in the gain-crossover region Ω is either Type* I *or Type* II*. Then the minimum-phase mapping $\mu : \Omega \to [0, \pi]$ is continuous.*

Proof. In light of Theorem 4.2 it suffices to prove that μ is usc. Recall that for $\omega \in \Omega$ the minimum-phase mapping $\mu(\omega)$ is given by (5), where $\phi(\omega)$ is the solution of the constrained minimization problem CMPω. Since $\cos^{-1} : [-1, 1] \to [0, \pi]$ is continuous and decreasing, it is easy to see that μ is usc if and only if ϕ is usc, so we will focus on proving the upper semicontinuity of ϕ on Ω. Let $X = \{z \in \mathbb{C}^n \mid z^* z = 1\}$ and define maps $\tilde{f}, \tilde{g} : X \times \Omega \to \mathbb{R}$ by

$$\tilde{f}(\zeta, \omega) = \zeta^* \big(L(j\omega)^* + L(j\omega)\big)\zeta,$$
$$\tilde{g}(\zeta, \omega) = \zeta^* L(j\omega)^* L(j\omega)\zeta.$$

Referring back to CMPω, we see that the first constraint is incorporated in the definition of X. Thus, for $\omega \in \Omega$ we have

$$\phi(\omega) = \min \{\tilde{f}(\zeta, \omega) \mid \zeta \in X \text{ and } \tilde{g}(\zeta, \omega) = 1\}.$$

As in Remark 4.3, we let $T(s) = L(-js)^T L(js)$, and we choose an $n \times n$ matrix function $P(s)$ which is holomorphic on a domain containing the real axis $s = \omega$, unitary on the real axis (i.e., $P(\omega)^* = P(\omega)^{-1}$ for $\omega \in \mathbb{R}$) and satisfies (7) for every $\omega \in \mathbb{R}$. Next we define maps $f, g : X \times \Omega \to \mathbb{R}$ by

$$\begin{aligned} f(z,\omega) &= \tilde{f}(P(\omega)z, \omega), \\ g(z,\omega) &= \tilde{g}(P(\omega)z, \omega) = z^* P(\omega)^* T(\omega) P(\omega) z. \end{aligned}$$

Observe that since $P(\omega)$ diagonalizes $T(\omega)$ we can rewrite $g(z,\omega)$ as

$$g(z,\omega) = \sum_{i=1}^{n} \lambda_i(\omega) |z_i|^2,$$

where $z_1, \ldots, z_n$ are the coordinates of z in $\mathbb{C}^n$. Since for each $\omega \in \Omega$ the unitary matrix $P(\omega)$ is an isometric bijection of the unit sphere X in $\mathbb{C}^n$ with itself, it is easy to see that

$$\phi(\omega) = \min\{f(z,\omega) \mid z \in X \text{ and } g(z,\omega) = 1\} = \min\{f(z,\omega) \mid z \in G(\omega)\},$$

where $G : \Omega \to \mathcal{C}(X)$ is the set-valued function given by

$$G(\omega) = \{z \in X \mid g(z,\omega) = 1\}.$$

By Theorem 3.3(b) to show that ϕ is usc, it suffices to show that G is lsc, and for this we will appeal to the criterion for lower semicontinuity given in Proposition 3.2.

Let ω_0 be an arbitrary frequency in Ω and let z_0 be an arbitrary point in $G(\omega_0)$. We must show that there exist a $\delta > 0$ and a continuous function $\alpha : (\omega_0 - \delta, \omega_0 + \delta) \cap \Omega \to X$ such that $\alpha(\omega_0) = z_0$ and $\alpha(\omega) \in G(\omega)$ for every $\omega \in (\omega_0 - \delta, \omega_0 + \delta) \cap \Omega$. Let $z_0 = (z_{01}, \ldots, z_{0n}) \in X \subseteq \mathbb{C}^n$ and note that

$$z_0 \in G(\omega_0) \iff g(z_0, \omega_0) = 1 \iff \sum_{i=1}^{n} (\lambda_i(\omega_0) - 1)|z_{0i}|^2 = 0. \tag{8}$$

(We have used the fact that $\sum_{i=1}^{n} |z_{0i}|^2 = (z_0)^* z_0 = 1$.) First let us suppose that there exists an index $k \in \{1, \ldots, n\}$ such that $\lambda_k(\omega_0) - 1 \neq 0$ and $z_{0k} \neq 0$. Then (8) yields

$$(\lambda_k(\omega_0) - 1)|z_{0k}|^2 = -\sum_{i \neq k} (\lambda_i(\omega_0) - 1)|z_{0i}|^2,$$

from which we obtain

$$|z_{0k}|^2 = -\sum_{i \neq k} \frac{\lambda_i(\omega_0) - 1}{\lambda_k(\omega_0) - 1} |z_{0i}|^2 > 0. \tag{9}$$

Choose $\delta > 0$ small enough so that for $\omega \in (\omega_0 - \delta, \omega_0 + \delta) \cap \Omega$ the function

$$\Lambda(\omega) = -\sum_{i \neq k} \frac{\lambda_i(\omega) - 1}{\lambda_k(\omega) - 1} |z_{0i}|^2$$

is defined and positive. The existence of such a δ follows from (9) and the continuity of the functions $\lambda_i(\omega),\ i = 1, \ldots, n$ with respect to ω. In particular, $\Lambda(\omega)$ is continuous

for $\omega \in (\omega_0 - \delta, \omega_0 + \delta)$. Choose $\theta_0 \in (-\pi, \pi]$ such that $z_{0k} = e^{j\theta_0}|z_{0k}|$ and for $\omega \in (\omega_0 - \delta, \omega_0 + \delta) \cap \Omega$ and $i \in \{1, \dots, n\}$ define complex-valued functions $z_i(\omega)$ by

$$z_i(\omega) = \begin{cases} z_{0i}, & i \neq k, \\ e^{j\theta_0}\sqrt{\Lambda(\omega)}, & i = k. \end{cases}$$

Observe that the function $z_k(\omega)$ is defined and continuous for $\omega \in (\omega_0 - \delta, \omega_0 + \delta) \cap \Omega$ since $\Lambda(\omega) > 0$ for these values of ω. The functions $z_i(\omega)$ for $i \neq k$ are obviously continuous since they are constant. Hence it is easy to see that the function α: $(\omega_0 - \delta, \omega_0 + \delta) \cap \Omega \to X$ defined by

$$\alpha(\omega) = \frac{1}{\sqrt{z(\omega)^* z(\omega)}} z(\omega), \quad z(\omega) = (z_1(\omega), \dots, z_n(\omega)), \tag{10}$$

is continuous and satisfies $\alpha(\omega_0) = z_0$ and $g(\alpha(\omega), \omega) = 1$ (or equivalently $\alpha(\omega) \in G(\omega)$) for $\omega \in (\omega_0 - \delta, \omega_0 + \delta)$. This completes the proof of the lower semicontinuity of G at the frequency ω_0 under the assumption that there exists an index $k \in \{1, \dots, n\}$ such that $\lambda_k(\omega_0) - 1 \neq 0$ and $z_{0k} \neq 0$. The reader will note that we have not yet made use of the assumption that every frequency point in the gain-crossover region is of Type I or II.

It remains to consider the case where for each $i \in \{1, \dots, n\}$ either $\lambda_i(\omega_0) - 1 = 0$ or $z_{0i} = 0$. In this case each term in the summation in (8) is zero. We set

$$I_1 = \big\{ i \in \{1, \dots, n\} \mid \lambda_i(\omega_0) - 1 = 0 \big\}, \quad I_2 = \{1, \dots, n\} \setminus I_1.$$

Observe that since $z_0 \in X \subseteq \mathbb{C}^n \setminus \{0\}$, not all of the coordinates z_{0i} can be zero; thus $I_1 \neq \emptyset$. On the other hand, the assumption that ω_0 is either of Type I or Type II forces $I_2 \neq \emptyset$. Moreover for $i \in I_2$ we have $z_{0i} = 0$. Equation (8) can be rewritten as

$$\sum_{i \in I_1} (\lambda_i(\omega_0) - 1)|z_{0i}|^2 + \sum_{i \in I_2} (\lambda_i(\omega_0) - 1)|z_{0i}|^2 = 0,$$

and this suggests that we define a real-analytic function $h(\omega)$ by

$$h(\omega) = \sum_{i \in I_1} (\lambda_i(\omega) - 1)|z_{0i}|^2. \tag{11}$$

Clearly $h(\omega_0) = 0$, so the real analyticity of h implies either that ω_0 is an isolated zero of h or that h is identically zero for all $\omega \in \mathbb{R}$. In either case there exists $\delta_0 > 0$ such that h does not change sign on the intervals $(\omega_0 - \delta_0, \omega_0]$ and $[\omega_0, \omega_0 + \delta_0)$; i.e., either $h(\omega) \leq 0$ for every $\omega \in (\omega_0 - \delta_0, \omega_0]$ or $h(\omega) \geq 0$ for every $\omega \in (\omega_0 - \delta_0, \omega_0]$, with a similar statement for the interval $[\omega_0, \omega_0 + \delta_0)$.

If ω_0 is of Type I, then let $i, k \in I_2$ be such that $\sigma_i(\omega_0) < 1 < \sigma_k(\omega_0)$. The continuity of the singular values yields a $\delta > 0$ such that $\delta \leq \delta_0$ and $\omega \in (\omega_0 - \delta, \omega_0 + \delta) \Rightarrow \sigma_i(\omega) < 1 < \sigma_k(\omega)$; in particular $(\omega_0 - \delta, \omega_0 + \delta) \subseteq \Omega$ and $\lambda_i(\omega) - 1 < 0 < \lambda_k(\omega) - 1$ for $\omega \in (\omega_0 - \delta, \omega_0 + \delta)$. Since h has constant sign on the interval $(\omega_0 - \delta, \omega_0]$, we can select an index $\ell \in I_2$ for which

$$\frac{1}{\lambda_\ell(\omega) - 1} h(\omega) \leq 0 \quad \forall\, \omega \in (\omega_0 - \delta, \omega_0]. \tag{12}$$

For $\omega \in (\omega_0 - \delta, \omega_0] \subseteq \Omega$ and $i \in \{1, \dots, n\}$ we then define complex-valued functions $z_i^-(\omega)$ by

$$z_i^-(\omega) = \begin{cases} z_{0i}, & i \in I_1, \\ 0, & i \in I_2, i \neq \ell, \\ \sqrt{-\frac{1}{\lambda_\ell(\omega) - 1} h(\omega)}, & i = \ell. \end{cases} \tag{13}$$

Observe that $z_\ell^-(\omega)$ is defined and continuous and has nonnegative real values by (12) (note, however, that $z_\ell^-(\omega)$ fails to have a one-sided derivative at ω_0 since $h(\omega_0) = 0$). The remaining functions $z_i^-(\omega)$ for $i \neq \ell$ are constant and thus obviously continuous. If we define $\alpha^- : (\omega_0 - \delta, \omega_0] \to X$ by the formula in (10) with the functions $z_i(\omega) = z_i^-(\omega)$ defined in (13), then it is easy to see that α^- is continuous and satisfies $\alpha^-(\omega_0) = z_0$ and $g(\alpha^-(\omega), \omega) = 1$. Since h also has constant sign on the interval $[\omega_0, \omega_0 + \delta)$, a similar argument yields a continuous map $\alpha^+ : \Omega \cap [\omega_0, \omega_0 + \delta) \to X$ such that $\alpha^+(\omega_0) = z_0$ and $g(\alpha^+(\omega), \omega) = 1$. We can then define $\alpha : (\omega_0 - \delta, \omega_0 + \delta) \to X$ by

$$\alpha(\omega) = \begin{cases} \alpha^-(\omega), & \omega_0 - \delta < \omega \leq \omega_0, \\ \alpha^+(\omega), & \omega_0 \leq \omega < \omega_0 + \delta. \end{cases}$$

It is evident that α is continuous, $\alpha(\omega_0) = z_0$, and $g(\alpha(\omega), \omega) = 1$ (or equivalently $\alpha(\omega) \in G(\omega)$) for every $\omega \in (\omega_0 - \delta, \omega_0 + \delta) \subseteq \Omega$. Consequently, G is lsc at ω_0 if ω_0 is of Type I.

The last case to consider is when ω_0 is of Type II. Then one of conditions C1 or C2 in Definition 4.4(b) holds. For concreteness we will carry out the remainder of the proof under the assumption that C1 holds (the proof when C2 holds is entirely analogous). For $\delta > 0$ as given in C1 and for $\omega \in (\omega_0 - \delta, \omega_0 + \delta) \cap \Omega$ the function h defined in (11) satisfies $h(\omega) \leq 0$. Furthermore, C1 yields an $\ell \in I_2$ such that $\sigma_\ell(\omega_0) > 1$ (in fact just choose ℓ so that $\sigma_\ell(\omega_0) = \overline{\sigma}(L(j\omega_0))$), which implies $\lambda_\ell(\omega_0) - 1 > 0$. The continuity of λ_ℓ enables us to shrink $\delta > 0$ if necessary so as to obtain $\lambda_\ell(\omega) - 1 > 0$ for every $\omega \in (\omega_0 - \delta, \omega_0 + \delta) \cap \Omega$. If we define $\alpha : (\omega_0 - \delta, \omega_0 + \delta) \cap \Omega \to X$ by the formula in (10), where the functions $z_i(\omega) = z_i^-(\omega)$ are as defined in (13), then once again α is continuous, $\alpha(\omega_0) = z_0$, and $g(\alpha(\omega), \omega) = 1$; equivalently, $\alpha(\omega) \in G(\omega)$ for every $\omega \in (\omega_0 - \delta, \omega_0 + \delta) \cap \Omega$. Consequently, G is lsc at ω_0 if ω_0 is of Type II and the proof is complete. □

Examples of systems with a continuous minimum-phase mapping are quite common; see, e.g., [4, section 7]. The graph of the minimum-phase mapping exhibited in the indicated reference gives numerical evidence of its continuity. However, continuity can also be deduced a priori via Theorem 4.6, since this example satisfies the conditions of Remark 4.5(c).

Example 4.7. For an example where the minimum-phase mapping fails to be continuous throughout the gain-crossover region, we consider the 3×3 transfer function

$$L(s) = \begin{bmatrix} \frac{80\kappa(s+9)(s+55)}{495(s+1)(s+80)} & 0 & 0 \\ 0 & \frac{\omega_n^2}{m_r(s^2+2\zeta\omega_n s+\omega_n^2)} & 0 \\ 0 & 0 & \frac{0.3(s+40)}{(s+20)} \end{bmatrix},$$

where $\kappa = 8.0953\ldots, \omega_r = 27.6002\ldots$ (the values are approximate), $\zeta = .05$, and

$$\omega_n = \frac{\omega_r}{\sqrt{1-2\zeta^2}}, \qquad m_r = \frac{1}{2\zeta\sqrt{1-\zeta^2}}.$$

Plots of the singular values of $L(j\omega)$ and the minimum-phase mapping $\mu(\omega)$ over the frequency range $0 \leq \omega \leq 60$ are shown in Figs. 1 and 2, respectively. Observe that although μ is an lsc function of ω as predicted by Theorem 4.2, μ has a discontinuity at $\omega = \omega_r = 27.6002\ldots$. An examination of the graph of the singular values of $L(j\omega)$ shows that the frequency ω_r is neither Type I nor Type II as specified in Definition 4.4; note that $\underline{\sigma}(L(j\omega_r)) < 1$, but it is not the case that both of the remaining singular

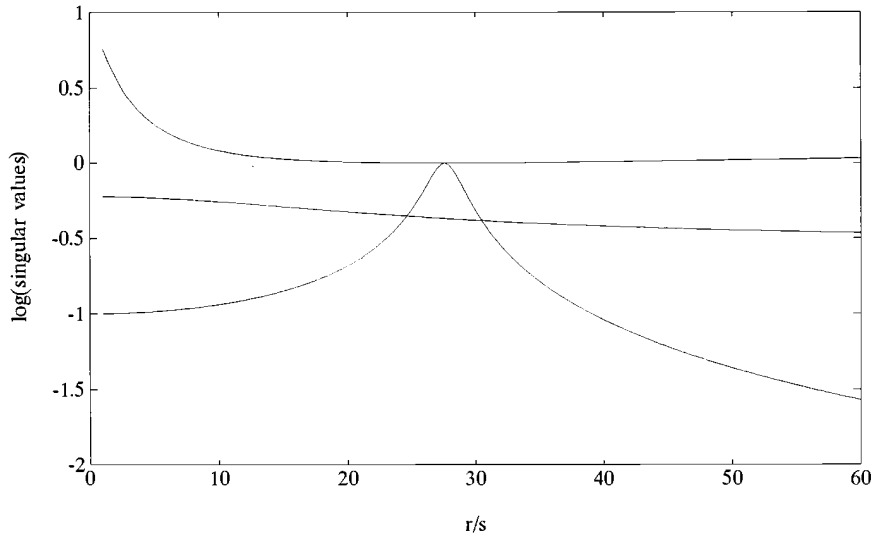

FIG. 1. *Plot of the* (*base* 10) *logarithm of the singular values against frequency for the transfer function in Example* 4.7.

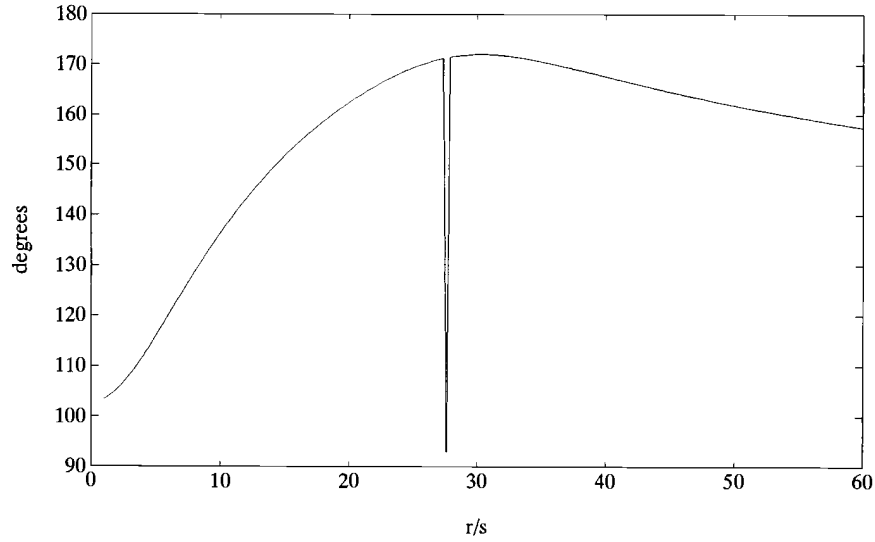

FIG. 2. *Plot of* $\mu(\omega)$ *for the transfer function in Example* 4.7.

values are ≥ 1 on an open interval containing ω_r, so C2 is violated. While simpler examples of such transfer functions could be constructed, the above example has the additional property of being closed-loop stable (and thus conforms to our standing assumptions).

5. Differentiability of the minimum-phase mapping. We next take up the question of the differentiability of the minimum-phase mapping $\mu : \Omega \to [0, \pi]$. As with the continuity question discussed in the previous section, it is convenient to express the minimum-phase mapping in terms of the value function of a parametrized family

of constrained optimization problems (see equation (5) and CMPω). However, the constrained optimization problem CMPω is not well suited to handling differentiability questions, since neither the functional nor the constraints are holomorphic functions of z or ω. Thus, we resort to the standard technique of converting CMPω to an equivalent real constrained optimization problem by the process of "decomplexification," which makes use of a canonical isomorphism between $\mathbb{C}^n$ and $\mathbb{R}^{2n}$. This process is described in [3], but it will also be reviewed here as there are specific aspects of the structure of the matrices obtained in the decomplexification process that are essential for our results. For other results on the differentiability of the value function of parametrized constrained optimization problems, the reader is referred to [16].

A (column) vector $z \in \mathbb{C}^n$ has a unique expression as $z = u + jv$, where u, v are (column) vectors in $\mathbb{R}^n$. This enables us to define a bijection

$$\Theta : \mathbb{C}^n \to \mathbb{R}^{2n}, \qquad \Theta(z) = \begin{bmatrix} u \\ v \end{bmatrix} \quad (\text{where } z = u + jv).$$

Indeed, if we view $\mathbb{C}^n$ as a real vector space, then Θ is an $\mathbb{R}$-linear isomorphism. Observe that if $x = \Theta(z)$, then $z^* z = x^T x$, where we view $x \in \mathbb{R}^{2n}$ as a $2n$-dimensional column vector and the superscript T denotes transpose. As is the case with vectors, a complex matrix $M \in \mathbb{C}^{n \times n}$ has a unique expression as $M = R + jS$, where $R, S \in \mathbb{R}^{n \times n}$. The linear mapping $M = R + jS$ from $\mathbb{C}^n$ into $\mathbb{C}^n$ and the bijection Θ together induce a linear mapping from $\mathbb{R}^{2n}$ into $\mathbb{R}^{2n}$, which is represented by the matrix

$$M_\Theta = \begin{bmatrix} R & -S \\ S & R \end{bmatrix} \in \mathbb{R}^{2n \times 2n}. \tag{14}$$

It will be convenient to let $\mathbb{R}_\Theta^{2n \times 2n}$ denote the subset of $\mathbb{R}^{2n \times 2n}$ consisting of those matrices $\mathcal{M}$ such that $\mathcal{M} = M_\Theta$ for some $M \in \mathbb{C}^{n \times n}$. One easily checks that the correspondence $M \mapsto M_\Theta$ of $\mathbb{C}^{n \times n}$ into $\mathbb{R}_\Theta^{2n \times 2n}$ is an isomorphism which preserves matrix sums and products. Of special interest is the matrix

$$\mathcal{J} = \begin{bmatrix} 0 & -I_n \\ I_n & 0 \end{bmatrix} \in \mathbb{R}^{2n \times 2n}$$

(I_n is the $n \times n$ identity matrix), which corresponds to the matrix $jI_n \in \mathbb{C}^{n \times n}$. It is clear that $\mathcal{J}^T = -\mathcal{J}$ and $\mathcal{J}^2 = -I_{2n}$. Moreover, $\mathcal{M}\mathcal{J} = \mathcal{J}\mathcal{M}$ for every matrix $\mathcal{M} \in \mathbb{R}_\Theta^{2n \times 2n}$ (in fact $\mathcal{M} \in \mathbb{R}^{2n \times 2n}$ is in $\mathbb{R}_\Theta^{2n \times 2n}$ if and only if $\mathcal{M}$ commutes with $\mathcal{J}$). It is also evident that $M \in \mathbb{C}^{n \times n}$ is Hermitian if and only if its associated matrix $M_\Theta \in \mathbb{R}_\Theta^{2n \times 2n}$ is symmetric. We use $\mathbb{R}_{\Theta,\mathrm{sym}}^{2n \times 2n}$ to denote the set of symmetric matrices in $\mathbb{R}_\Theta^{2n \times 2n}$.

Another useful fact about matrices in $\mathbb{R}_\Theta^{2n \times 2n}$ is the following. If λ is a real eigenvalue of a complex matrix $M = R + jS \in \mathbb{C}^{n \times n}$, then λ is also an eigenvalue of the corresponding matrix M_Θ. Moreover, if $x \in \mathbb{R}^{2n}$ is a (nonzero) eigenvector of M_Θ corresponding to λ, then it is easy to see that $\mathcal{J}x$ is also an eigenvector of M_Θ corresponding to λ and $\mathcal{J}x$ is orthogonal to x; i.e., $x^T \mathcal{J}\, x = 0$. It follows that every real eigenvalue of a matrix $\mathcal{M} \in \mathbb{R}_\Theta^{2n \times 2n}$ must have algebraic multiplicity greater than one. A more precise argument shows that every real eigenvalue has even multiplicity.

It is now a routine matter to reformulate the complex constrained optimization problem CMPω as a real constrained optimization problem. For each frequency ω in the gain-crossover region Ω we let

$$\mathcal{A}(\omega) = \big(L(j\omega)^* + L(j\omega)\big)_\Theta \in \mathbb{R}_{\Theta,\mathrm{sym}}^{2n \times 2n}, \qquad \mathcal{B}(\omega) = \big(L(j\omega)^* L(j\omega)\big)_\Theta \in \mathbb{R}_{\Theta,\mathrm{sym}}^{2n \times 2n} \tag{15}$$

denote the real symmetric matrices induced by the isomorphism Θ. Observe that $\mathcal{B}(\omega)$ is positive semidefinite, its eigenvalues coincide with those of $L(j\omega)^*L(j\omega)$, and the multiplicity of each eigenvalue of $\mathcal{B}(\omega)$ is twice that of the multiplicity of the corresponding eigenvalue of $L(j\omega)^*L(j\omega)$. In particular, the eigenvalues of $\mathcal{B}(\omega)$ are precisely the squares of the singular values of $L(j\omega)$, and consequently the eigenvalues of $\mathcal{B}(\omega)$ are spread across one if and only if the singular values of $L(j\omega)$ are spread across one. Since the entries of $L(s)$ are rational functions of s and, by assumption, have no poles on the $j\omega$-axis, the entries of $\mathcal{A}(\omega)$ and $\mathcal{B}(\omega)$ will be everywhere defined, rational functions of ω (i.e., all of their poles are complex). In particular, the entries of $\mathcal{A}(\omega)$ and $\mathcal{B}(\omega)$ are globally defined, real-analytic functions of $\omega \in \mathbb{R}$.

The real constrained optimization problem equivalent to CMPω then takes the form

$$\text{(RCMP}\omega\text{)} \qquad \begin{array}{ll} \text{minimize} & x^T\mathcal{A}(\omega)x, \quad x \in \mathbb{R}^{2n} \quad (\omega \in \Omega \text{ fixed}) \\ \text{subject to} & \begin{cases} x^Tx = 1, \\ x^T\mathcal{B}(\omega)x = 1. \end{cases} \end{array}$$

It is evident that the minimum value $\phi(\omega)$ of RCMPω coincides with the minimum value of CMPω, so we still have the formula (5) for the minimum-phase mapping. Thus, μ will be differentiable at every interior point ω_0 of the gain-crossover region Ω where $\phi'(\omega_0)$ exists and $|\phi(\omega_0)| < 2$. These considerations motivate us to first take up the differentiability with respect to ω of the minimum value $\phi(\omega)$ of the constrained optimization problem RCMPω.

Our main theorem on the differentiability of the minimum value $\phi(\omega)$ of RCMPω can be stated for slightly more general situations than described above. Specifically, it is not necessary to assume that the matrix functions $\mathcal{A}(\omega)$ and $\mathcal{B}(\omega)$ in $\mathbb{R}^{2n\times 2n}_{\Theta,\mathrm{sym}}$ are directly related to a transfer function $L(s)$ via the decomplexification process. Thus the differentiability theorem itself will not make any reference to transfer functions, but its relevance to transfer functions will be explained in Corollary 5.5. Furthermore, to make the assumptions in the differentiability theorem palatable, we will first make a few comments about the necessary conditions that apply to the constrained optimization problem RCMPω.

Fix ω_0 in the gain-crossover region Ω and let $\phi(\omega_0)$ be the solution to RCMPω_0; that is, let

$$\phi(\omega_0) = \min\{x^T\mathcal{A}(\omega_0)x \mid x^Tx = 1, x^T\mathcal{B}(\omega_0)x = 1\}.$$

Since the minimum is achieved, there exists $x_0 \in \mathbb{R}^{2n}$ such that $\phi(\omega_0) = (x_0)^T\mathcal{A}(\omega_0)x_0$ and $(x_0)^Tx_0 = (x_0)^T\mathcal{B}(\omega_0)x_0 = 1$. If the constraints are independent in the sense that the vectors x_0 and $\mathcal{B}(\omega_0)x_0$ are linearly independent, then the Lagrange multiplier theorem implies that there exist real numbers ξ_0, η_0 such that both the first-order condition

$$\text{(FO)} \qquad \big(\mathcal{A}(\omega_0) - \xi_0 I - \eta_0\mathcal{B}(\omega_0)\big)x_0 = 0$$

(I denotes the $2n \times 2n$ identity matrix) and the second-order condition

$$\text{(SO)} \quad x^T\big(\mathcal{A}(\omega_0) - \xi_0 I - \eta_0\mathcal{B}(\omega_0)\big)x \geq 0 \quad \forall\, x \in \mathbb{R}^{2n} \text{ such that } x^Tx_0 = x^T\mathcal{B}(\omega_0)x_0 = 0$$

are satisfied. Furthermore, under these assumptions the authors have shown in [6] that the strengthened version of the second-order condition

$$\text{(SSO)} \qquad x^T\big(\mathcal{A}(\omega_0) - \xi_0 I - \eta_0\mathcal{B}(\omega_0)\big)x \geq 0 \quad \forall\, x \in \mathbb{R}^{2n}$$

must hold for this problem. Conversely, if x_0 and $\mathcal{B}(\omega_0)x_0$ are linearly independent vectors that satisfy $(x_0)^T x_0 = (x_0)^T \mathcal{B}(\omega_0) x_0 = 1$ and if ξ_0 and η_0 are real numbers such that (FO) and (SSO) hold, then it is easy to see that $\phi(\omega_0) = \xi_0 + \eta_0$.

The following technical lemma will be used in the proof of the differentiability theorem. The proof of the lemma is straightforward and thus is omitted (a simple proof can be built around Corollary 3.4).

LEMMA 5.1. *Let $(\alpha, \beta) \subseteq \mathbb{R}$ be an open interval, and let $\eta, \nu : (\alpha, \beta) \to \mathbb{R}^q$ and $P : (\alpha, \beta) \to \mathbb{R}^{q \times q}$ be continuous maps. Suppose that for some $\omega_0 \in (\alpha, \beta)$ we have*

$$x^T P(\omega_0) x > 0 \quad \forall\, x \in \mathbb{R}^q \setminus \{0\} \text{ such that } x^T \eta(\omega_0) = x^T \nu(\omega_0) = 0.$$

Then there exists $\delta > 0$ such that $(\omega_0 - \delta, \omega_0 + \delta) \subseteq (\alpha, \beta)$ and for every $\omega \in (\omega_0 - \delta, \omega_0 + \delta)$ we have

$$x^T P(\omega) x > 0 \quad \forall\, x \in \mathbb{R}^q \setminus \{0\} \text{ such that } x^T \eta(\omega) = x^T \nu(\omega) = 0.$$

THEOREM 5.2. *Let $(\alpha, \beta) \subseteq \mathbb{R}$ be an open interval, and let*

$$\mathcal{A}, \mathcal{B} : (\alpha, \beta) \to \mathbb{R}^{2n \times 2n}_{\Theta,\mathrm{sym}}$$

be C^k, $1 \le k \le \infty$, (resp., real-analytic) functions such that $\mathcal{B}(\omega)$ is positive semidefinite and its eigenvalues are spread across one for each $\omega \in (\alpha, \beta)$. Define $\phi : (\alpha, \beta) \to \mathbb{R}$ by

$$\phi(\omega) = \min \{ x^T \mathcal{A}(\omega) x \mid x^T x = x^T \mathcal{B}(\omega) x = 1 \}.$$

Let $\omega_0 \in (\alpha, \beta)$ be such that there exists $x_0 \in \mathbb{R}^{2n}$ satisfying

(i) $(x_0)^T x_0 = (x_0)^T \mathcal{B}(\omega_0) x_0 = 1$;

(ii) *x_0 and $\mathcal{B}(\omega_0)x_0$ are linearly independent in $\mathbb{R}^{2n}$;*

(iii) *there exist real numbers ξ_0 and η_0 such that* (FO) *is satisfied and*

$$x^T \big(\mathcal{A}(\omega_0) - \xi_0 I - \eta_0 \mathcal{B}(\omega_0) \big) x > 0 \quad \forall\, x \in \mathbb{R}^{2n} \setminus \{0\} \text{ such that } x^T x_0 = x^T \mathcal{J}\, x_0 = 0.$$

Then $\phi(\omega_0) = (x_0)^T \mathcal{A}(\omega_0) x_0 = \xi_0 + \eta_0$ and ϕ is C^k (resp., real analytic) in a neighborhood of ω_0.

Remark 5.3. The hypotheses of Theorem 5.2 are quite reasonable in the sense that if $x_0 \in \mathbb{R}^{2n}$ is such that $\phi(\omega_0) = (x_0)^T \mathcal{A}(\omega_0) x_0$ and assumptions (i) and (ii) are satisfied, then by the discussion preceding Lemma 5.1 there will necessarily exist scalars ξ_0, η_0 such that the necessary conditions (FO) and (SSO) hold, so in particular the matrix

$$\mathcal{A}(\omega_0) - \xi_0 I - \eta_0 \mathcal{B}(\omega_0) \tag{16}$$

is positive semidefinite. Assumption (iii) demands more than (SSO) as it requires that the matrix (16) has a nontrivial null space of dimension 2 and is positive definite on the orthogonal complement of its null space. As was noted previously, the minimum positive dimension of the null space of (16) is 2 (the algebraic and geometric multiplicities of the eigenvalue 0 coincide since (16) is real symmetric).

Proof of Theorem 5.2. Define a mapping $F : \mathbb{R}^{2n} \times \mathbb{R} \times \mathbb{R} \times \mathbb{R} \times (\alpha, \beta) \to \mathbb{R}^{2n} \times \mathbb{R} \times \mathbb{R} \times \mathbb{R}$ by

$$F(x, \xi, \eta, \zeta, \omega) = \big((\mathcal{A}(\omega) - \xi I - \eta \mathcal{B}(\omega) - \zeta \mathcal{J}\,) x, x^T x, x^T \mathcal{B}(\omega) x, x_0^T \mathcal{J}\, x \big).$$

It is clear that F is C^k (resp., real analytic) with respect to the group of variables $x, \xi, \eta, \zeta, \omega$, and we have

$$F(x_0, \xi_0, \eta_0, 0, \omega_0) = (0, 1, 1, 0).$$

(Note that $(x_0)^T \mathcal{J} x_0 = 0$ by the skew symmetry of $\mathcal{J}$.) If we fix ω at the value ω_0 and let

$$\overline{D}F(x_0, \xi_0, \eta_0, 0, \omega_0) : \mathbb{R}^{2n+3} \to \mathbb{R}^{2n+3}$$

denote the Fréchet derivative of the map

$$(x, \xi, \eta, \zeta) \mapsto F(x, \xi, \eta, \zeta, \omega_0)$$

at $(x_0, \xi_0, \eta_0, 0)$, then this Fréchet derivative has a representation as a $(2n+3)\times(2n+3)$ matrix of the form

$$\overline{D}F(x_0, \xi_0, \eta_0, 0, \omega_0) = \begin{bmatrix} \mathcal{A}(\omega_0) - \xi_0 I - \eta_0 \mathcal{B}(\omega_0) & -x_0 & -\mathcal{B}(\omega_0) x_0 & -\mathcal{J}\, x_0 \\ 2(x_0)^T & 0 & 0 & 0 \\ 2(x_0)^T \mathcal{B}(\omega_0) & 0 & 0 & 0 \\ x_0^T \mathcal{J} & 0 & 0 & 0 \end{bmatrix}. \tag{17}$$

(We use the convention that vectors $x \in \mathbb{R}^{2n}$ are viewed as $2n$-dimensional column vectors in the matrix representation.) We claim that the linear map $\overline{D}F(x_0, \xi_0, \eta_0, 0, \omega_0)$ is a linear isomorphism of $\mathbb{R}^{2n+3}$ with itself. To prove this it suffices to prove that $\overline{D}F(x_0, \xi_0, \eta_0, 0, \omega_0)$ is one to one. Indeed, if $[x, \xi, \eta, \zeta]^T \in \mathbb{R}^{2n+3}$ is in the null space of the matrix (17), then

$$\begin{aligned} &\big(\mathcal{A}(\omega_0) - \xi_0 I - \eta_0 \mathcal{B}(\omega_0)\big) x - \xi x_0 - \eta \mathcal{B}(\omega_0) x_0 - \zeta \mathcal{J}\, x_0 = 0, \\ &(x_0)^T x = 0, \quad (x_0)^T \mathcal{B}(\omega_0) x = 0, \quad (x_0)^T \mathcal{J}\, x = 0. \end{aligned} \tag{18}$$

Multiply the first equation on the left by x^T and use the remaining equations, along with the symmetry of $\mathcal{B}(\omega_0)$ and the skew symmetry of $\mathcal{J}$, to obtain

$$x^T \big(\mathcal{A}(\omega_0) - \xi_0 I - \eta_0 \mathcal{B}(\omega_0)\big) x = 0.$$

Since $x^T x_0 = x^T \mathcal{J}\, x_0 = 0$, assumption (iii) implies that $x = 0$. Using this in the first of the equations (18), we obtain

$$\xi x_0 + \eta \mathcal{B}(\omega_0) x_0 + \zeta \mathcal{J}\, x_0 = 0. \tag{19}$$

Multiplication of (19) on the right by $x_0^T \mathcal{J}^{\,T} = -x_0^T \mathcal{J}$ results in

$$-\xi x_0^T \mathcal{J}\, x_0 - \eta x_0^T \mathcal{J} \mathcal{B}(\omega_0) x_0 - \zeta x_0^T \mathcal{J}^{\,2} x_0 = 0. \tag{20}$$

It has already been pointed out that $\mathcal{J}$ is skew symmetric, and we note in addition that $\mathcal{J}\mathcal{B}(\omega_0)$ is skew symmetric, since $\mathcal{B}(\omega_0)$ is symmetric and commutes with $\mathcal{J}$. The skew symmetry of these matrices yields $x_0^T \mathcal{J}\, x_0 = x_0^T \mathcal{J} \mathcal{B}(\omega_0) x_0 = 0$, so (20) becomes

$$0 = -\zeta x_0^T \mathcal{J}^{\,2} x_0 = \zeta x_0^T x_0 = \zeta,$$

since $\mathcal{J}^{\,2} = -I_{2n}$ and x_0 satisfies the constraint (i). Put $\zeta = 0$ in (19) and use the assumed linear independence of x_0 and $\mathcal{B}(\omega_0) x_0$ to conclude that $\xi = \eta = 0$. Hence the derivative $\overline{D}F(x_0, \xi_0, \eta_0, 0, \omega_0)$ is a linear isomorphism of $\mathbb{R}^{2n+3}$ with itself. By

the implicit function theorem, there exists $\delta_1 > 0$ such that $(\omega_0 - \delta_1, \omega_0 + \delta_1) \subseteq (\alpha, \beta)$ and there exist C^k (resp., real-analytic) functions

$$\sigma : (\omega_0 - \delta_1, \omega_0 + \delta_1) \to \mathbb{R}^{2n}, \qquad \xi, \eta, \zeta : (\omega_0 - \delta_1, \omega_0 + \delta_1) \to \mathbb{R},$$

which satisfy $\sigma(\omega_0) = x_0, \xi(\omega_0) = \xi_0, \eta(\omega_0) = \eta_0, \zeta(\omega_0) = 0$ and

$$F(\sigma(\omega), \xi(\omega), \eta(\omega), \zeta(\omega), \omega) = (0, 1, 1, 0) \quad \forall\, \omega \in (\omega_0 - \delta_1, \omega_0 + \delta_1). \tag{21}$$

For fixed $\omega \in (\omega_0 - \delta, \omega_0 + \delta)$ equation (21) yields

$$\big(\mathcal{A}(\omega) - \xi(\omega) I - \eta(\omega)\mathcal{B}(\omega) - \zeta(\omega)\mathcal{J}\,\big)\sigma(\omega) = 0, \tag{22a}$$

$$\sigma(\omega)^T \sigma(\omega) = 1, \tag{22b}$$

$$\sigma(\omega)^T \mathcal{B}(\omega)\sigma(\omega) = 1. \tag{22c}$$

We claim that $\zeta(\omega) = 0$ for every $\omega \in (\omega_0 - \delta_1, \omega_0 + \delta_1)$. To see this note that equation (22a) yields

$$\big(\mathcal{A}(\omega) - \xi(\omega) I - \eta(\omega)\mathcal{B}(\omega)\big)\sigma(\omega) = \zeta(\omega)\mathcal{J}\,\sigma(\omega). \tag{23}$$

Apply $\sigma(\omega)^T \mathcal{J}^{\,T}$ to both sides of (23) to get

$$\sigma(\omega)^T \mathcal{J}^{\,T} \big(\mathcal{A}(\omega) - \xi(\omega) I - \eta(\omega)\mathcal{B}(\omega)\big)\sigma(\omega) = \zeta(\omega)\sigma(\omega)^T \mathcal{J}^{\,T} \mathcal{J}\,\sigma(\omega). \tag{24}$$

Since $||\mathcal{J}\,\sigma(\omega)|| = ||\sigma(\omega)|| = 1$, the right-hand side of (24) clearly equals $\zeta(\omega)$. Furthermore, since $\mathcal{J}$ is skew symmetric and commutes with the real-symmetric matrix

$$\mathcal{A}(\omega) - \xi(\omega) I - \eta(\omega)\mathcal{B}(\omega), \tag{25}$$

it follows that $\mathcal{J}^{\,T}(\mathcal{A}(\omega) - \xi(\omega) I - \eta(\omega)\mathcal{B}(\omega))$ is skew symmetric, whence the left-hand side of (24) is 0. Thus $\zeta(\omega) = 0$. Equation (23) now takes the form

$$\big(\mathcal{A}(\omega) - \xi(\omega) I - \eta(\omega)\mathcal{B}(\omega)\big)\sigma(\omega) = 0. \tag{26}$$

Multiplying (26) by $\mathcal{J}$ and using the fact that $\mathcal{J}$ commutes with (25), we also obtain

$$\big(\mathcal{A}(\omega) - \xi(\omega) I - \eta(\omega)\mathcal{B}(\omega)\big)\mathcal{J}\,\sigma(\omega) = 0. \tag{27}$$

By assumption (iii) and Lemma 5.1 there exists $\delta_2 > 0$ such that $(\omega_0 - \delta_2, \omega_0 + \delta_2) \subseteq (\alpha, \beta)$ and for $\omega \in (\omega_0 - \delta_2, \omega_0 + \delta_2)$ we have

$$x^T \big(\mathcal{A}(\omega) - \xi(\omega) I - \eta(\omega)\mathcal{B}(\omega)\big)x > 0 \quad \forall\, x \in \mathbb{R}^{2n} \setminus \{0\} \text{ such that } x^T \sigma(\omega) = x^T \mathcal{J}\,\sigma(\omega) = 0. \tag{28}$$

For $\delta = \min\{\delta_1, \delta_2\}$ and for $\omega \in (\omega_0 - \delta, \omega_0 + \delta)$, equations (26) and (27) show that zero is an eigenvalue of the real-symmetric matrix (25) and $\sigma(\omega), \mathcal{J}\,\sigma(\omega)$ are corresponding orthogonal, unit-length eigenvectors. If we extend the set $\{\sigma(\omega), \mathcal{J}\,\sigma(\omega)\}$ to an orthonormal basis of $\mathbb{R}^{2n}$ consisting of eigenvectors of the matrix (25), then (28) implies that the remaining $2n-2$ eigenvalues of (25) (each eigenvalue listed as often as its multiplicity indicates) are positive. We conclude that for every $\omega \in (\omega_0 - \delta, \omega_0 + \delta)$

$$x^T \big(\mathcal{A}(\omega) - \xi(\omega) I - \eta(\omega)\mathcal{B}(\omega)\big)x \geq 0 \quad \forall\, x \in \mathbb{R}^{2n},$$

or equivalently

$$x^T\mathcal{A}(\omega)x \geq \xi(\omega)x^Tx + \eta(\omega)x^T\mathcal{B}(\omega)x \quad \forall x \in \mathbb{R}^{2n}. \tag{29}$$

In particular, if $x \in \mathbb{R}^{2n}$ satisfies $x^Tx = x^T\mathcal{B}(\omega)x = 1$, then (29) yields

$$x^T\mathcal{A}(\omega)x \geq \xi(\omega) + \eta(\omega). \tag{30}$$

Furthermore, if we multiply equation (26) on the right by $\sigma(\omega)^T$ and make use of (22b) and (22c), we obtain

$$\sigma(\omega)^T\mathcal{A}(\omega)\sigma(\omega) = \xi(\omega) + \eta(\omega). \tag{31}$$

From (30) and (31) we infer that

$$\phi(\omega) = \min\{x^T\mathcal{A}(\omega)x \mid x^Tx = x^T\mathcal{B}(\omega)x = 1\} = \xi(\omega) + \eta(\omega).$$

Consequently, $\phi : (\omega_0 - \delta, \omega_0 + \delta) \to \mathbb{R}$ is C^k (resp., real analytic), since the same is true of the functions ξ and η. This completes the proof. ∎

The following example demonstrates that we need some sort of strengthening of the basic necessary conditions (FO) and (SSO), such as assumption (iii) of Theorem 5.2, if we are to expect differentiability of ϕ.

Example 5.4. Consider the parametrized constrained optimization problem

$$\text{minimize} \quad 2\omega(x_1x_3 + x_4x_6) = x^T\mathcal{A}(\omega)x,$$

where $\omega \in \mathbb{R}$, $x = \operatorname{col}[x_1, x_2, x_3, x_4, x_5, x_6] \in \mathbb{R}^6$ and

$$\mathcal{A}(\omega) = \begin{bmatrix} A(\omega) & 0_{3\times 3} \\ 0_{3\times 3} & A(\omega) \end{bmatrix} \quad \text{with} \quad A(\omega) = \begin{bmatrix} 0 & 0 & \omega \\ 0 & 0 & 0 \\ \omega & 0 & 0 \end{bmatrix}$$

subject to the constraints $x^Tx = x^T\mathcal{B}(\omega)x = 1$, where $\mathcal{B}(\omega)$ is the constant 6×6 diagonal matrix

$$\mathcal{B}(\omega) = \operatorname{diag}[2, 1, 0, 2, 1, 0].$$

The matrix functions $\mathcal{A}(\omega)$ and $\mathcal{B}(\omega)$ are evidently real analytic and take values in $\mathbb{R}^{6\times 6}_{\Theta,\mathrm{sym}}$. Elementary computations show that

$$\phi(\omega) = \min\{x^T\mathcal{A}(\omega)x \mid x^Tx = x^T\mathcal{B}(\omega)x = 1\} = -|\omega|,$$

so ϕ fails to be differentiable at $\omega = 0$. One can readily see that this example fails to satisfy condition (iii) of Theorem 5.2.

We conclude by applying Theorem 5.2 to the specific case of the minimum-phase mapping of a multivariable control system.

COROLLARY 5.5. *Let $L(s)$ be an $n \times n$ matrix function of $s \in \mathbb{C}$ whose entries are in the field of rational functions of s with real coefficients. Assume that $L(s)$ satisfies conditions* (i), (ii), *and* (iii) *of Theorem* 4.2, *and let ω_0 be a frequency in the gain-crossover region Ω such that*

(i) *$I - L(j\omega_0)^*L(j\omega_0)$ is invertible (equivalently, one is not an eigenvalue of $L(j\omega_0)^*L(j\omega_0)$),*

(ii) *all of the eigenvalues of the matrix*

$$\big(L(j\omega_0)^* + L(j\omega_0) - \phi(\omega_0)L(j\omega_0)^*L(j\omega_0)\big)\big(I - L(j\omega_0)^*L(j\omega_0)\big)^{-1} \tag{32}$$

have multiplicity one, where $\phi(\omega_0)$ *is the minimum value of the constrained optimization problem* CMPω *(or, equivalently,* RCMPω*) with* $\omega = \omega_0$.

Then ω_0 *is an interior point of* Ω *and the minimum-phase mapping* $\mu : \Omega \to [0, \pi]$ *is real analytic on some open subinterval of* Ω *containing* ω_0.

Proof. Observe that (i) forces the singular values of $L(j\omega_0)$ to be strictly spread across one, so ω_0 is a Type I frequency point as specified in Definition 4.4.(a). Thus ω_0 is an interior point of Ω (cf. Remark 4.5.(a)), and continuity of μ in a neighborhood of ω_0 is assured by Theorem 4.6. Let $\mathcal{A}(\omega)$ and $\mathcal{B}(\omega)$ be as defined in (15) and for $\omega \in \Omega$ let $\phi(\omega)$ be the common minimum value of the associated constrained optimization problems CMPω and RCMPω. The eigenvalues of $\mathcal{B}(\omega)$ are real and nonnegative, and coincide with the eigenvalues of $L(j\omega)^*L(j\omega)$. Note, however, that the algebraic multiplicity of each eigenvalue of $\mathcal{B}(\omega)$ is twice that of the corresponding eigenvalue of $L(j\omega)^*L(j\omega)$. In particular, one is not an eigenvalue of $\mathcal{B}(\omega_0)$. By continuity of the maximum and minimum eigenvalues of $\mathcal{B}(\omega)$ as functions of ω, we can find an open interval $(\alpha, \beta) \subseteq \Omega$ such that $\omega_0 \in (\alpha, \beta)$ and the eigenvalues of $\mathcal{B}(\omega)$ are spread across one for every $\omega \in (\alpha, \beta)$.

Choose $x_0 \in \mathbb{R}^{2n}$ such that $x_0^T x_0 = x_0^T \mathcal{B}(\omega_0) x_0 = 1$ and $\phi(\omega_0) = x_0^T \mathcal{A}(\omega_0) x_0$. The existence of x_0 is guaranteed because the minimum value of RCMPω_0 is achieved on the constraint set. We claim that vectors x_0 and $\mathcal{B}(\omega_0)x_0$ must be linearly independent. For otherwise, there exists a real scalar λ such that $\mathcal{B}(\omega_0)x_0 = \lambda x_0$ (i.e., λ is an eigenvalue of $\mathcal{B}(\omega_0)$). But then the constraints on x_0 yield

$$1 = x_0^T \mathcal{B}(\omega_0) x_0 = x_0^T (\lambda x_0) = \lambda x_0^T x_0 = \lambda,$$

which contradicts the fact that one is not an eigenvalue of $\mathcal{B}(\omega_0)$.

Since x_0 and $\mathcal{B}(\omega_0)x_0$ are linearly independent, we can invoke the standard necessary conditions for RCMPω_0 discussed just prior to the statement of Lemma 5.1. Thus, there exist real numbers ξ_0, η_0 such that (FO) and (SSO) are satisfied. Furthermore $\phi(\omega_0) = \xi_0 + \eta_0$. Condition (FO) says that zero is an eigenvalue of the matrix

$$\mathcal{A}(\omega_0) - \xi_0 I - \eta_0 \mathcal{B}(\omega_0), \tag{33}$$

and from the structure of this matrix we know that the algebraic multiplicity of the eigenvalue zero must be even. Moreover, $\mathcal{J} x_0$ is a second linearly independent eigenvector of (33) corresponding to zero.

Let $N_0 \subseteq \mathbb{R}^{2n}$ denote the null space of the matrix (33). Then $\{x_0, \mathcal{J}x_0\} \subseteq N_0$, and we claim that

$$N_0 = \operatorname{span}\{x_0, \mathcal{J}x_0\}. \tag{34}$$

Since $\dim N_0 \geq 2$, to show (34) it suffices to show that $\dim N_0 \leq 2$. Using the equation $\phi(\omega_0) = \xi_0 + \eta_0$, we obtain

$$\begin{aligned} x \in N_0 &\Leftrightarrow \big(\mathcal{A}(\omega_0) - \xi_0 I - (\phi(\omega_0) - \xi_0)\mathcal{B}(\omega_0)\big)x = 0 \\ &\Leftrightarrow \big(\mathcal{A}(\omega_0) - \phi(\omega_0)\mathcal{B}(\omega_0) - \xi_0(I - \mathcal{B}(\omega_0))\big)x = 0 \\ &\Leftrightarrow \big[\big(\mathcal{A}(\omega_0) - \phi(\omega_0)\mathcal{B}(\omega_0)\big)(I - \mathcal{B}(\omega_0))^{-1} - \xi_0 I\big](I - \mathcal{B}(\omega_0))x = 0. \end{aligned}$$

Observe that $I - \mathcal{B}(\omega_0)$ is invertible since one is not an eigenvalue of $\mathcal{B}(\omega_0)$ by assumption. It follows that ξ_0 is an eigenvalue of the matrix

$$\big(\mathcal{A}(\omega_0) - \phi(\omega_0)\mathcal{B}(\omega_0)\big)(I - \mathcal{B}(\omega_0))^{-1} \tag{35}$$

and $I - \mathcal{B}(\omega_0)$ sets up a linear isomorphism between N_0 and the eigenspace of (35) corresponding to the eigenvalue ξ_0. From the formulas in (15) it is clear that the matrix (35) corresponds to the matrix (32) under the decomplexification isomorphism Θ. Since the eigenvalues of (32) are all of (algebraic) multiplicity 1 by assumption, we infer from that all real eigenvalues of (35) have algebraic multiplicity 2. Hence the dimension of eigenspace of (35) corresponding to ξ_0, also known as the geometric multiplicity of ξ_0, is at most two. Consequently, $\dim N_0 \leq 2$ and we obtain (34).

From (SSO) and (34), we deduce that any eigenvalue of (33) that corresponds to an eigenvector orthogonal to N_0 must be positive, and thus (33) is positive definite on the orthogonal complement of N_0. Theorem 5.2 then implies that ϕ is real analytic in some open subinterval of Ω containing ω_0.

The formula (5) will immediately yield the real analyticity of the minimum-phase mapping μ in a neighborhood of ω_0 once we know that $|\phi(\omega_0)| < 2$ (since $\cos^{-1}$ is real analytic on the open interval $(-1, 1)$). Let $z_0 \in \mathbb{C}^n$ be such that $\Theta(z_0) = x_0$. Then

$$\phi(\omega_0) = x_0^T \mathcal{A}(\omega_0) x_0 \Rightarrow \phi(\omega_0) = (z_0)^* L(j\omega_0)^* z_0 + (z_0)^* L(j\omega_0) z_0$$

and

$$x_0^T x_0 = x_0^T \mathcal{B}(\omega_0) x_0 = 1 \Rightarrow (z_0)^* z_0 = (z_0)^* L(j\omega_0)^* L(j\omega_0) z_0 = 1,$$

so that $\|z_0\| = \|L(j\omega_0)z_0\| = 1$. The Cauchy–Schwarz inequality yields

$$|(z_0)^* L(j\omega_0) z_0| \leq \|z_0\| \, \|L(j\omega_0)z_0\| = 1,$$

so it follows that $|\phi(\omega_0)| = 2$ if and only if equality holds in the Cauchy–Schwarz inequality. This in turn will hold if and only if both $L(j\omega_0)z_0$ and $L(j\omega_0)^* z_0$ are multiples of z_0; i.e., $L(j\omega_0)z_0 = \lambda z_0$ and $L(j\omega_0)^* z_0 = \rho z_0$ for some $\lambda, \rho \in \mathbb{C}$. However, this would give

$$1 = (z_0)^* L(j\omega_0)^* L(j\omega_0) z_0 = (\lambda z_0)^* (\lambda z_0) = |\lambda|^2 (z_0)^* z_0 = |\lambda|^2,$$

so $|\lambda| = 1$. Similarly, $|\rho| = 1$. We infer that

$$L(j\omega_0)^* L(j\omega_0) z_0 = L(j\omega_0)^* (\lambda z_0) = \lambda\rho z_0,$$

so $\lambda\rho$ is a eigenvalue of $L(j\omega_0)^* L(j\omega_0)$ of modulus 1. Since all eigenvalues of the matrix $L(j\omega_0)^* L(j\omega_0)$ are real and nonnegative, we obtain $\lambda\rho = 1$, which contradicts the assumption that one is not an eigenvalue of $L(j\omega_0)^* L(j\omega_0)$. Thus $|\phi(\omega_0)| < 2$ and the proof of the corollary is complete. ∎

A GENERAL STOCHASTIC OUTER APPROXIMATIONS METHOD*

Y. V. VOLKOV† AND S. K. ZAVRIEV†

Abstract. Optimization problems involving an infinite number of constraints are considered. This paper presents a general stochastic outer approximations method which incorporates mechanisms for active search of relevant constraints and for dropping of irrelevant constraints. The method extracts the characteristic features of several stochastic outer approximations algorithms suggested by Wardi [*J. Optim. Theory Appl.*, 56 (1988), pp. 285–311; *J. Optim. Theory Appl.*, 64 (1990), pp. 615–640] and furthermore develops the approach to get advantages of the Eaves–Zangwill scheme. Similarly to Gonzaga and Polak [*SIAM J. Control Optim.*, 17 (1979), pp. 477–493] the method is based on the use of quasi-optimality functions satisfying some general unrestricted assumptions. These functions are usually employed in the stopping criteria of numerical techniques for solving simpler problems. It is shown that the method's trajectories almost surely converge to the quasi-optimal set. Following the proposed approach a stochastic algorithm for solving the approximation problem is constructed and studied.

The proposed general method can be considered as a developed Eaves–Zangwill method applying the multistart technique at each iteration for the search of relevant constraints' parameters.

1. Introduction.

Optimization problems involving continua of constraints appear in different areas of applications (see, for example, the conference proceedings edited by Hettich [9] and Fiacco and Kortanek [7]). A typical problem with an infinite number of constraints is the semi-infinite programming problem

$$\text{sip:} \qquad f(x) \to \min_x$$
$$\text{such that (s.t.) } g(x,y) \le 0 \quad \forall y \in Y^0,$$
$$x \in X^0,$$

where $f(\cdot)$ and $g(\cdot,\cdot)$ are assumed to be continuously differentiable on a neighborhood of $X^0 \times Y^0$, $X^0 \subset \Re^k$ and $Y^0 \subset \Re^l$ are convex and compact and $\Re^k$ is the k-dimensional real space.

There are various numerical techniques for solving problems with continua of constraints (see, for instance, [9, 10, 8, 17, 4, 26, 27, 28]; among them outer approximations methods are of great importance.

The outer approximations methods are intended to solve a problem

$$\mathcal{P}^0: \qquad \text{find } x \in \mathcal{X}^0_{opt},$$

where $\mathcal{X}^0_{opt}$ has a very complicated description, e.g., for the semi-infinite programming

problem $\mathcal{X}^0_{opt} = \{x \in \mathcal{X}^0 \mid f(x) = \min_{x' \in \mathcal{X}^0} f(x')\}$, where the feasible set $\mathcal{X}^0$ is as follows:

$$\mathcal{X}^0 = \{x \in X^0 \mid g(x,y) \le 0 \ \forall y \in Y^0\}.$$

The approach is to substitute for $\mathcal{P}^0$ a sequence $\mathcal{P}_n$ of approximating problems

$$\mathcal{P}_n : \qquad \text{find } x \in \mathcal{X}^n_{opt},$$

where $\mathcal{X}^n_{opt}$ has relatively simple descriptions, e.g., for the semi-infinite programming problem

$$\text{sip.}\mathcal{P}_n: \qquad \text{find } x \in \mathcal{X}^n_{opt},$$

$$\mathcal{X}^n_{opt} = \{x \in \mathcal{X}_n \mid f(x) = \min_{x' \in \mathcal{X}_n} f(x')\},$$

where the feasible set $\mathcal{X}_n$ is defined by a finite set of inequalities, i.e.,

$$\mathcal{X}_n = \{x \in X^0 \mid g(x,y) \le 0 \ \forall y \in Y_n\}, \ \ \mid Y_n \mid < +\infty$$

($\mid Y_n \mid$ denotes the cardinality of Y_n), $n = 1, 2, \ldots$. Consequently solving the problems $\mathcal{P}_n, n = 1, 2, \ldots$, we get a trajectory $\{x^n\}$ which is intended to converge to the optimal set of the original problem $\mathcal{P}^0$.

The pioneer works in the outer approximations methods [2, 14, 15], provided the monotonic growth of the descriptions of $\mathcal{X}^n_{opt}, \ n = 1, 2, \ldots$ (e.g., for sip $Y_1 \subset Y_2 \subset \cdots$). And unfortunately in all these algorithms the complexity of the description of $\mathcal{X}^n_{opt}$ (i.e., $\mid Y_n \mid$) grew rapidly with n, and quite quickly the problems $\mathcal{P}_n, \ n = 1, 2, \ldots,$ become almost as difficult as the original problem $\mathcal{P}^0$. To avoid this disadvantage Topkis [24] and Eaves and Zangwill [5] proposed special adaptive rules for forming $\mathcal{X}^n_{opt}, \ n = 1, 2, \ldots,$ involving constraints-dropping schemes which broke the monotonic growth of the descriptions of $\mathcal{X}^n_{opt}, \ n = 1, 2, \ldots$. This approach has been developed by Hogan [13] and Gonzaga and Polak [8]. Heunis [12] suggested employing Monte Carlo simulations for forming simpler problems; this idea later was refined by Wardi [26, 27] via constraints-dropping schemes for reducing the size of the constraint set.

In application to the semi-infinite programming problem the main points of adaptive rules for forming Y_{n+1} at the nth iteration of an outer approximations method are as follows.

Adding of Relevant Constraints.

Obtain $y^n_1, \ldots, y^n_{S_n} \in Y^0$ such that x^n does not approach the optimal set of the problem

$$\text{sip.}\overline{\mathcal{P}}_n : \qquad f(x) \to \min_x$$

$$s.t. \ \ g(x,y) \le 0 \ \ \forall y \in Y_n \ \cup \ \{y^n_1, \ldots, y^n_{S_n}\}.$$

Add $y^n_1, \ldots, y^n_{S_n}$ to Y_n to form $\overline{Y}_n$.

Dropping of Irrelevant Constraints.

Drop some points from $\overline{Y}_n$ to extract a subset $\Delta Y_n \subset \overline{Y}_n$ such that the constraints

$$g(x,y) \le 0 \ \forall y \in \Delta Y_n$$

are relevant at x^n with respect to the problem sip.$\overline{\mathcal{P}}_n$.

Then drop some sets from $\{\Delta Y_i,\ i = 1, \dots, n\}$ *to form*

$$Y_{n+1} = \bigcup_{j \in J_n} \Delta Y_j,\ J_n \subset \{1, \dots, n\}.$$

The following are approaches to the search of relevant constraints.

SCHEME AS (active search [5, 8]).

Compute y_1^n *as an approximate solution of the inner maximization problem*

$$\text{sip.}\mathcal{JP}_n : \qquad g(x^n, y) \to \max_{y \in Y}.$$

(Then $y_2^n, \dots, y_{S_n}^n$ *may be chosen arbitrarily.)*

SCHEME RS (passive random search [26, 27]).

Step 1. *Set* $i := 0$.

Step 2. *Set* $i := i + 1$.

Step 3. *Determine* y_i^n *by using the uniform probability distribution on* Y^0.

If an optimality condition of the problem

$$f(x) \to \min_x$$
$$s.t.\ \ g(x, y) \le 0 \ \ \forall y \in Y_n \ \cup \ \{y_1^n, \dots, y_i^n\}$$

is not sufficiently violated at x^n*, then go to Step* 2.

Else go to Step 4.

Step 4. *Set*

$$S_n := i,$$
$$\overline{Y}_n := Y_n \ \cup \ \{y_1^n, \dots, y_{S_n}^n\},$$

and exit.

Scheme AS is quite effective in the case when the inner problems are unimodal, but if they are not, there exist only effective descent algorithms to obtain a local maximum (or a stationary point) of $\text{sip.}\mathcal{JP}_n$. Thus, the execution of an outer approximations method using Scheme AS needs to apply a global optimization technique at each iteration and becomes too laborious. On the other hand it is evident that if the dimension of Y^0 is not very small, methods using Scheme RS cannot be effective because the parameters drawn by the uniform probability distribution on Y^0 are not essentially relevant. To achieve a balance between simplicity of the execution and the relevance of the outget constraints we extend Wardi's scheme as follows.

SCHEME RS.ACTIV (activated random search).

Step 1. *Set* $i := 0$.

Step 2. *Set* $i := i + 1$.

Step 3. *Determine* y_i^n *by using the uniform probability distribution on* Y^0.

Apply a local descent method starting with y_i^n *to obtain a local maximum* $y_i^{n,*}$ *of* $\text{sip.}\mathcal{JP}_n$.

If an optimality condition of the problem

$$f(x) \to \min_x$$
$$s.t.\ \ g(x, y) \le 0 \ \ \forall y \in Y_n \ \cup \ \{y_1^n, y_1^{n,*}, \dots, y_i^n, y_i^{n,*}\}$$

is not sufficiently violated at x^n*, then go to Step* 2.

Else go to Step 4.

Step 4. *Set*

$$S_n := i,$$

$$\overline{Y}_n := Y_n \ \cup \ \{y_1^n, y_1^{n,*}, \ldots, y_{S_n}^n, y_{S_n}^{n,*}\}$$

and exit.

In the present paper we consider an outer approximations method using Scheme RS.ACTIV for the search of relevant parameters to form approximative problems $\mathcal{P}_n,\ n = 1, 2, \ldots$. The constructed method possesses the guaranteed convergence properties of Wardi's algorithms (i.e., of the algorithms based on Scheme RS), and the method's computational efforts needed to obtain $x^n,\ n = 1, 2, \ldots$, are relatively inexpensive. At the same time the practical convergence rate of our method often appears to be similar to the rates of the methods based on Scheme AS which compute trajectories $\{x^n\}$ in a much more laborious way.

In section 2 the master method for solving the general problem $\mathcal{P}^0$ is constructed. The method employs the activated random search scheme RS.ACTIV for forming approximative problems $\mathcal{P}_n,\ n = 1, 2, \ldots$, and it analyzes these problems with the use of a quasi-optimality function which is supposed to satisfy some general unrestricted assumptions. Examples of appropriate quasi-optimality functions for the semi-infinite programming problem and the problem of solving a system with continuum of inequalities are considered in section 3.

We call the proposed master method (using Scheme RS.ACTIV) *the activated method*, in contrast to the similar method using the nonactivated Scheme RS, which is called *the standard method*. (Note that the standard method directly generalizes Wardi's algorithms.) The efficiency of the activation is explored in section 4, where we consider realizations of these methods for solving the global optimization problem. It appears that in this case the standard method becomes the pure random search global optimization algorithm and the activated method is an algorithm of the well-known multistart method. The advantages of the multistart method over the pure random search are evident.

In sections 5 and 6 the convergence theorem is proven. It is shown that trajectories of the master method almost surely converge to the quasi-optimal set of the considered general problem $\mathcal{P}^0$.

In section 7 a version of the master method for solving the approximation problem is constructed and studied. Numerical examples are presented in section 8.

For the reader's convenience we provide a list of notation.

Let

$$\mathbf{N} := \{1, 2, \ldots\},$$

$$\Re^1_+ = \{x \in \Re^1 \mid x \geq 0\},$$

$$B_\delta(x) = \{x' \in \Re^k \mid\mid\mid x' - x \mid\mid\mid < \delta\},\ \delta > 0.$$

We denote by $\mathfrak{M}(Y^0)$ the set of all subsets of $Y^0 \subset \Re^k$; $\mathfrak{M}_c(Y^0)$ and $\mathfrak{M}_f(Y^0)$ denote the set of all compact subsets and the set of all finite subsets, respectively. It is obvious that

$$\mathfrak{M}_f(Y^0) \subset \mathfrak{M}_c(Y^0) \subset \mathfrak{M}(Y^0).$$

For any $Y, Y' \in \mathfrak{M}_c(Y^0)$ define

$$\rho(Y, Y') := \max_{y \in Y} \min_{y \in Y'} \| y - y' \|,$$

$$h(Y, Y') := \max(\rho(Y, Y'),\ \rho(Y', Y)).$$

$h(Y, Y')$ is said to be the *Hausdorff distance between* Y *and* Y'.

Let $\{x_n\}$ be a bounded sequence, $x_n \in \Re^k,\ n = 1, 2, \ldots$, the set of all limit points of $\{x_n\}$ is denoted by $\overline{lt}\{x_n\}$. We say that $\{x_n\}$ converges to $C \subset \Re^k$ if

$$\overline{lt}\{x_n\} \subset C.$$

For a set $C \subset \Re^k$ we denote by $K_C(x)$ the tangent cone at a point $x \in C$; let *conv* C and C^* denote the convex hull and the polar of C, respectively.

Consider the constrained optimization problem

$$\text{opt:} \qquad f(x) \to \min$$

$$\text{s.t.} \quad g_i(x) \le 0,\ i = 1, \ldots, m,$$

$$x \in X^0,$$

where $f(\cdot)$, $g_i(\cdot)$, $i = 1, \ldots, m$, are assumed to be locally Lipschitz continuous on $\Re^k$, the optimal set X_{opt} is assumed to be nonempty, and $X^0 \in \Re^k$ is closed and convex.

Let $\partial f(x)$ denote the set of all generalized gradients (in the sense of Clarke [3]) of $f(\cdot)$ at $x \in \Re^k$.

It is known [3] that for every $x \in X_{opt}$ satisfying the constraints qualification

$$conv \bigcup_{i:\ g_i(x)=0} \partial g_i(x) + K^*_{X^0}(x) \ni \mathbf{0}$$

(when $g_i(x) \ne 0$, $i = 1, \ldots, m$, we formally suppose that this constraints qualification holds) the following optimality conditions hold:

$$\text{there exist } \lambda_1, \ldots, \lambda_s \ge 0,\ s \le k+1,\ \text{s.t.}$$

$$\partial f(x) + \sum_{i=1}^{s} \lambda_i\ \partial g_i(x) + K^*_{X^0} \ni \mathbf{0}, \tag{1.1}$$

$$\lambda_i\ g_i(x) = 0,\ i = 1, \ldots, s.$$

This fact provides a number of corollaries on the first-order necessary optimality conditions for various optimization problems, e.g., for the semi-infinite programming problem, the minimax problem, the problem of solving a system of inequalities, etc. (See [18, 6, 3].) In the course of the present paper we shall use some of these results without specially referring to the sources.

For any $f(\cdot) :\ X \to \Re^1$ we denote

$$\operatorname{Arg\,min}_{x \in X} f(x) := \{x \in X \mid f(x) = \min_{x' \in X} f(x')\};$$

$\arg\min_{x \in X} f(x)$ denotes an arbitrary element of the set $\operatorname{Arg\,min}_{x \in X} f(x)$. Similarly we define $\operatorname{Arg\,max}_{x \in X} f(x)$ and $\arg\max_{x \in X} f(x)$.

For a convex and closed $X \subset \Re^k$ the orthogonal projector on X, $pr_X(\cdot) : \Re^k \to X$, is given by

$$pr_X(x) := \arg\min_{x' \in X} \| x - x' \| .$$

Note that for the problem

$$f(x) \to \min,\ x \in X^0,$$

where $f(\cdot)$ is assumed to be differentiable on a neighborhood of $x \in X_{opt}$, the optimality condition (1.1) can be rewritten in the following form:

$$pr_{X^0}(x - \nabla f(x)) - x = 0.$$

2. The master method. Let us consider our problem in the most general form:

$$\mathcal{P}^0 : \qquad \text{find}\ \ x \in \mathcal{X}_{opt},$$

where $\mathcal{X}_{opt} \subset X^0,\ X^0 \subset \Re^k$ is compact, and the description of $\mathcal{X}_{opt}$ involves an infinite number of parameters $y \in Y^0,\ Y^0 \subset \Re^l$ is compact. To show the dependence of $\mathcal{P}^0$ upon the parameter set Y^0, we shall also denote $\mathcal{P}^0$ by $\mathcal{P}[Y^0]$.

To construct an outer approximations method we consider simpler problems of the same type as $\mathcal{P}^0$. Let for any $Y \in \mathfrak{M}_c(Y^0)$ the problem $\mathcal{P}[Y]$ be defined similarly to $\mathcal{P}^0$ but subject to the smaller parameter set Y; i.e., the description of $\mathcal{P}[Y]$ involves only parameters $y \in Y$. The presented general stochastic outer approximation method provides the sequential solving of problems $\mathcal{P}[Y_n],\ n = 1, 2, \ldots$, where each problem $\mathcal{P}[Y_n]$ depends upon only a finite number $\mid Y_n \mid$ of parameters, $Y_n \in \mathfrak{M}_f(Y^0),\ n = 1, 2, \ldots$.

Let us introduce a quasi-optimality function, i.e., a scalar nonnegative criterion $\Theta(\cdot, \cdot) : X^0 \times \mathfrak{M}_c(Y^0) \to \Re^1_+$ s.t. for any compact $Y \subset Y^0$ and $x \in X^0$ the value $\Theta(x, Y)$ estimates the quality of x as an approximate local solution of the problem $\mathcal{P}[Y]$. In particular, we suppose that

$$x \in \mathcal{X}_{opt} \ \Rightarrow\ \Theta(x, Y^0) = 0. \tag{2.1}$$

Usually the inequality

$$\Theta(x, Y) \le \varepsilon \tag{2.2}$$

can be employed as a stopping criterion for an effective local descent technique for solving $\mathcal{P}[Y]$ and, thus, when $\mid Y \mid$ is not large, we can effectively solve (2.2) even for small $\varepsilon > 0$.

We define the $\Theta(\cdot, \cdot)$–quasi-optimal set of the problem $\mathcal{P}[Y]$ as follows:

$$\mathcal{X}_{qopt}[Y] := \{x \in X^0 \mid \Theta(x, Y) = 0\},\ Y \in \mathfrak{M}_c(Y^0).$$

Note that by (2.1)

$$\mathcal{X}_{opt} \subset \mathcal{X}^0_{qopt},$$

where $\mathcal{X}^0_{qopt} := \mathcal{X}_{qopt}[Y^0] = \{x \in X^0 \mid \Theta(x, Y^0) = 0\}$.

Let the following assumptions hold.

Assumption A1. Let

$$\mathcal{X}_{qopt}[Y] \neq \emptyset \ \forall Y \in \mathfrak{M}_c(Y^0). \qquad \square$$

Assumption A2. For every $x \in X^0$ and $Y \in \mathfrak{M}_c(Y^0)$ let the following properties hold:

(i) If $\Theta(x, Y) > 0$, then there exist $\theta, \delta > 0$ such that

$$\Theta(x', Y') \geq \theta > 0$$

for every $x' \in B_\delta(x) \bigcap X^0$ and $Y' \in \mathfrak{M}_c(Y^0),\ h(Y, Y') < \delta$.

(ii) If $\Theta(x, Y) = 0$, then for every $\varepsilon > 0$ there exists $\delta > 0$ such that

$$\Theta(x', Y') < \varepsilon$$

for every $x' \in B_\delta(x) \bigcap X^0$ and $Y' \in \mathfrak{M}_c(Y^0),\ h(Y, Y') < \delta$. $\square$

For any $x \in X^0$ and $Y \in \mathfrak{M}_c(Y^0)$ a finite set $A,\ A \in Y^0$ is called an *active parameters set at* (x, Y) *with respect to the quasi-optimality function* $\Theta(\cdot, \cdot)$ if

$$\Theta(x, A) = \Theta(x, Y') = \Theta(x, Y) \ \ \forall Y' \in \mathfrak{M}_c(Y) :\ A \subset Y' \subset Y$$

and, moreover, there are no $A' \subset A,\ A' \neq A$, satisfying the same property. Let $\mathcal{A}(x, Y)$ denote the set of all active parameters sets at (x, Y) with respect to $\Theta(\cdot, \cdot)$. For $\Delta Y \subset Y$ we denote

$$\Delta Y \succeq \mathcal{A}(x, Y)$$

if there exists $A \in \mathcal{A}(x, Y)$ such that $\Delta Y \supset A$.

Now we construct a general stochastic iterative method converging almost surely (a.s.) to the set $\mathcal{X}_{qopt}[Y^0]$ (note that $\mathcal{X}_{opt} \subset \mathcal{X}_{qopt}[Y^0]$). The method suggests solving (2.2) with $Y = Y_n$ and $\varepsilon = \varepsilon_n$ for $n = 1, 2, \ldots$, where $\{Y_n\}$ is a sequence of finite subsets of Y^0 and $\varepsilon_n > 0,\ n = 1, 2, \ldots,\ \varepsilon_n \searrow 0$, are the corresponding precision levels; it uses special mechanisms for limiting the growth of $\mid Y_n \mid$: an *activated random search mechanism* for choosing relevant parameters to include in Y_n and *a dropping mechanism* to exclude irrelevant parameters from Y_n. The method refines the Wardi's stochastic algorithms (see [26, 27]) and, furthermore, develops this approach getting features of the Eaves–Zangwill method.

The main points of the method are focused in the following iterative stochastic procedure.

Procedure SPROC.ACTIV.

Input. $x \in X,\ Y \in \mathfrak{M}_f(Y^0)$.

Output. $\theta \in \Re^1_+,\ \Delta Y \in \mathfrak{M}_f(Y^0),\ \overline{Y} \in \mathfrak{M}_f(Y^0),$ *and* $S \in \mathbf{N}$.

Parameter. $\gamma > 0$.

Step 0 (*initial step*). *Set*

$$\overline{Y}_1 := Y,$$

$$i := 1.$$

Step 1 (*passive search of a relevant parameter*).

Determine a point $y_i \in Y$ *by using the uniform probability distribution on* Y.

Include y_i *in* $\overline{Y}_i$.

Step 1.ACTIV (*activated search of a relevant parameter*).
Searching on Y *obtain a point* $y_i^* = y_i^*(x, \overline{Y}_i, y_i)$ (*e.g., using a local search algorithm starting with* y_i *at an inner problem* $\mathcal{JP}(x, Y)$).
Include y_i^* *in* $\overline{Y}_i$.
Step 2. *Set* $\theta_i = \Theta(x, \overline{Y}_i)$.
Step 3 (*control step*). *If*

$$i\ \theta_i \le \gamma, \tag{2.3}$$

then set $i := i + 1$ *and go to Step* 1.
Step 4. *Set*

$$\overline{Y} := \overline{Y}_i,$$

$$\theta := \theta_i,$$

$$S := i.$$

Step 5 (*dropping*). *Analyzing* $\Theta(x, \overline{Y})$ *obtain*

$$\Delta Y \succeq \mathcal{A}(x, \overline{Y}).$$

Then exit.

The procedure without Step 1.ACTIV (with $y_i^* = y_i,\ i = 1, \dots, S$) is similar to the original Wardi's procedures and will be denoted SPROC. We call SPROC and SPROC.ACTIV *the standard procedure* and *the activated procedure*, respectively.

Now we present the master method.
Method SMETH.ACTIV.
Data. $x^1 \in X$.
Parameters. *Sequences* $\{\varepsilon_n\},\ \{\sigma_n\}$,

$$\varepsilon_n,\ \sigma_n > 0,\ n = 1, 2, \dots,\ \ \varepsilon_n,\ \sigma_n \searrow 0. \tag{2.4}$$

Stage 0 (*initial step*). *Set*

$$n := 1,$$

$$Y_1 := \emptyset.$$

Stage 1. *Enter* SPROC.ACTIV *with input* x^n *and* Y_n. *Denote the outputs by* Θ_n, ΔY_n, $\overline{Y}_n$, S_n.
Stage 2. *Set*

$$Y_{n+1} := \Delta Y_n \cup \bigcup_{\substack{j:\theta_j > \sigma_j, \\ 1 \le j \le n-1}} \Delta Y_j.$$

Stage 3. *Find* $x^{n+1} \in X$ *satisfying*

$$\Theta(x^{n+1}, Y_{n+1}) < \varepsilon_{n+1}.$$

Stage 4. *Set*

$$n =: n + 1.$$

Go to Step 1.

The method using SPROC instead of SPROC.ACTIV will be denoted SMETH. The methods SMETH and SMETH.ACTIV are said to be *the standard method* and *the activated method*, respectively.

The constructed general stochastic outer approximations method possesses the following property.

PROPOSITION. *Every trajectory* $\{x^n\}$ *of SMETH.ACTIV a.s. converges to* $\mathcal{X}_{qopt}[Y^0]$.

The formal statement and the proof of the proposition will be given below (see Theorem 6.1).

3. Examples of quasi-optimality functions. Now we present some examples of appropriate quasi-optimality functions for several classes of optimization problems with continua of inequalities, and we consider the corresponding mechanisms for active search of relevant constraints.

Example 3.1. Consider the problem of solving a system with continuum of inequalities:

$$\text{ineq.}\mathcal{P}^0: \qquad \text{to find } x \in \mathcal{X}^0_{opt},$$

$$\mathcal{X}^0_{opt} = \{x \in X^0 \mid g(x,y) \le 0 \ \forall y \in Y^0\},$$

where $g(\cdot,\cdot)$ is assumed to be continuously differentiable on a neighborhood of $X^0 \times Y^0$ and $X^0 \subset \Re^k$, $Y^0 \subset \Re^l$ are convex and compact.

We define the simpler problems ineq.$\mathcal{P}[Y]$, $Y \in \mathfrak{M}_c(Y^0)$, as follows:

$$\text{ineq.}\mathcal{P}[Y]: \qquad \text{to find} \quad x \in \mathcal{X}_{opt}[Y],$$

$$\mathcal{X}_{opt}[Y] = \{x \in X^0 \mid g(x,y) \le 0 \ \forall y \in Y\},$$

it is clear that $\mathcal{X}_{opt}[Y^0] = \mathcal{X}^0_{opt}$.

Let us define a quasi-optimality function $\Theta(\cdot,\cdot): \ X^0 \times \mathfrak{M}_c(Y^0) \ \to \ \Re^1_+$ by

$$\Theta(x,Y) := \max(0; \ \max_{y' \in Y} g(x,y')).$$

Obviously, Assumptions A1 and A2 hold and

$$\mathcal{X}^0_{opt} = \mathcal{X}_{qopt}[Y^0].$$

Note that for any $A \subset Y$ satisfying

$$A \subset \begin{cases} \operatorname{Arg}\max_{y' \in Y} \ g(x,y') & \text{if } \Theta(x,Y) > 0, \\ Y & \text{if } \Theta(x,Y) = 0, \end{cases}$$

the following equalities hold:

$$\Theta(x,A) = \Theta(x,Y') = \Theta(x,Y) \ \ \forall Y' : A \subset Y' \subset Y.$$

Therefore, for the considered quasi-optimality function $\Theta(\cdot,\cdot)$ the active parameters sets are singletons and

$$\mathcal{A}(x,Y) := \begin{cases} \operatorname{Arg} \ \max_{y' \in Y} \ g(x,y') & \text{if } \Theta(x,Y) > 0, \\ Y & \text{if } \Theta(x,Y) = 0. \end{cases}$$

In particular, if $\Theta(x, Y) > 0$ then for any $\Delta Y \subset Y$ we have

$$\Delta Y \succeq \mathcal{A}(x, Y) \;\Leftrightarrow \Delta Y \cap \mathrm{Arg} \max_{y' \in Y} g(x, y') \neq \emptyset.$$

Thus, the criterion $\Theta(\cdot, \cdot)$ can be employed in the stochastic outer approximations method SMETH.ACTIV for solving ineq.$\mathcal{P}^0$; we shall denote by SMETH.ACTIV.ineq and SPROC.ACTIV.ineq, respectively, the corresponding versions of the master method SMETH.ACTIV and of the procedure SPROC.ACTIV.

Let us introduce some notions to construct a mechanism of the activated random search of a relevant parameter y_i^* within the procedure SPROC.ACTIV for the problem ineq.$\mathcal{P}^0$.

Consider the inner problem

ineq.$\mathcal{JP}(x)$: $$g(x, y) \to \max$$

$$\text{s.t.} \;\; y \in Y^0,$$

and define the stationary set (the set of all points satisfying the first-order necessary optimality conditions) of ineq.$\mathcal{JP}(x)$ by

$$Y_{stat}(x) := \{y \in Y^0 \mid \nabla_y g(x, y) - K^*_{Y^0}(y) \ni \mathbf{0}\}.$$

We also define the ε-stationary set $Y^{\varepsilon}_{stat}(x)$ of the problem ineq.$\mathcal{JP}(x)$ by

$$Y^{\varepsilon}_{stat}(x) := \{y \in Y^0 \mid \;\; \| \, pr_{Y^0}(y + \nabla_y g(x, y)) - y \, \| \leq \varepsilon\}, \;\; \varepsilon \geq 0;$$

it is clear that $Y^0_{stat}(x) = Y_{stat}(x)$.

We suggest the following mechanism for activation of a parameter y_i generated by a random experiment within the procedure SPROC.ACTIV.ineq (at Step 1).

Step 1.ACTIV.ineq.

Apply a local descent technique for solving ineq.$\mathcal{JP}(x)$ *(for instance, the gradient projection method) starting with* y_i *to obtain* $y_i^* \in Y$ *such that*

$$y_i^* \in Y^{\varepsilon}_{stat}(x), \;\; g(x, y_i) \leq g(x, y_i^*).$$

Here $\varepsilon > 0$ *is a parameter.*

Example 3.2. Consider the semi-infinite programming problem sip, which we present in the form $\mathcal{P}^0$:

sip.$\mathcal{P}^0$: $$find \; x \in \mathcal{X}^0_{opt},$$

$$\mathcal{X}^0_{opt} = \{x \in \mathcal{X}^0 \mid f(x) = \min_{x' \in \mathcal{X}^0} f(x')\},$$

$$\mathcal{X}^0 = \{x \in X^0 \mid g(x, y) \leq 0 \;\; \forall y \in Y^0\},$$

where $f(\cdot)$, $g(\cdot, \cdot)$ are assumed to be continuously differentiable on a neighborhood of $X^0 \times Y^0$; $\nabla f(\cdot)$, $\nabla g(\cdot) \in \mathbf{C}_{Lip}(X^0 \times Y^0, L)$, $L > 0$, $X^0 \subset \Re^k$, $Y^0 \subset \Re^l$ are convex and compact. Let us also suppose that the Slater constraints qualification holds; i.e., $g(\cdot, y)$ is convex on X for every $y \in Y$ and there exists $x^* \in X$ such that

$$g(x^*, y) < 0 \;\; \forall y \in Y^0.$$

Define

$$\mathcal{X}^0_{stat} = \Big\{ x \in X^0 \mid \text{ there exist } \lambda_1, \dots, \lambda_s \geq 0$$

$$\text{and } y_1, \dots, y_s \in Y^0,\ s \leq k+1, \text{s.t.}$$

$$\nabla f(x) + \sum_{i=1}^{s} \lambda_i\ \nabla_x g(x, y_i) + K^*_{X^0}(x) \ni \mathbf{0};$$

$$\lambda_i\ g(x, y_i) = 0,\ i = 1, \dots, s \Big\},$$

$\mathcal{X}^0_{stat}$ is the stationary set (the set of all points satisfying the first-order necessary optimality conditions) of the problem sip.$\mathcal{P}^0$.

To construct an outer approximations technique for solving sip.$\mathcal{P}^0$ consider the following simpler problems:

sip.$\mathcal{P}[Y]$: find $x \in \mathcal{X}_{opt}[Y]$,

$$\mathcal{X}_{opt}[Y] = \{x \in \mathcal{X}[Y] \mid f(x) = \min_{x' \in \mathcal{X}[Y]} f(x')\},$$

$$\mathcal{X}[Y] = \{x \in X^0 \mid g(x, y) \leq 0\ \ \forall y \in Y\},$$

where $Y \in \mathfrak{M}_c(Y^0)$. It is obvious that sip.$\mathcal{P}[Y^0]$ is the original problem sip.$\mathcal{P}^0$.

The following quadratic subproblem proves to be useful in both theoretical and numerical analysis of constrained optimization problems (see [1, 19]):

sip.$\mathcal{QP}(x, Y)$: $\langle \nabla f(x), p \rangle + \frac{1}{2} \parallel p \parallel^2 \to \min$

$$\text{s.t. } g(x, y) + \langle \nabla_x g(x, y), p \rangle \leq 0\ \ \forall y \in Y,$$

$$x + p \in X,$$

where $Y \in \mathfrak{M}_c(Y^0)$, $x \in X$. It is easy to see that for every $x \in X$, $Y \in \mathfrak{M}_c(Y^0)$ the feasible set of sip.$\mathcal{QP}(x, Y)$ is not empty. Actually, for $p^* = x^* - x$ we have

$$g(x, y) + \langle \nabla_x g(x, y), p^* \rangle = g(x, y) + \langle \nabla_x g(x, y), x^* - x \rangle$$

$$\leq g(x, y) + g(x^*, y) - g(x, y) = g(x^*, y) < 0\ \forall y \in Y^0,$$

$$x + p^* = x^* \in X.$$

Therefore, for every $x \in X^0$, $Y \in \mathfrak{M}_c(Y^0)$ there exists the unique solution $p_0(x, Y)$ of the problem sip.$\mathcal{QP}(x, Y)$. Moreover, the following optimality criterion holds.

LEMMA 3.1. *For every $x \in X^0$ and $Y \in \mathfrak{M}_c(Y^0)$ a vector $p \in \Re^k$ is the solution of* sip.$\mathcal{QP}(x, Y)$ *if and only if there exist $\lambda_1, \dots, \lambda_s \geq 0$ and $y_1, \dots, y_s \in Y$, $s \leq k+1$ such that the following properties hold:*

$$p + \nabla f(x) + \sum_{i=1}^{s} \lambda_i\ \nabla_x g(x, y_i) + K^*_{X^0}(x + p) \ni \mathbf{0}, \tag{3.1}$$

$$\lambda_i\ (g(x, y_i) + \langle \nabla_x g(x, y), p \rangle) = 0,\ i = 1, \dots, s, \tag{3.2}$$

$$g(x,y) + \langle \nabla_x g(x,y), p \rangle \le 0 \ \forall y \in Y, \tag{3.3}$$

$$x + p \in X^0. \tag{3.4}$$

From Lemma 3.1 we get immediately the following important corollaries. Let $\mathcal{X}_{stat}[Y]$ denote the stationary set of sip.$\mathcal{P}[Y]$, $Y \in \mathfrak{M}_c(Y^0)$.

COROLLARY 3.1. *For every $x \in X^0$ and $Y \in \mathfrak{M}_c(Y^0)$ the vector $p_0(x,Y) = 0$ if and only if $x \in \mathcal{X}_{stat}[Y]$.*

COROLLARY 3.2. *For every $x \in X^0$, $Y \in \mathfrak{M}_c(Y^0)$, and sequences $\{x_n\}$, $\{Y_n\}$ satisfying*

$$x_n \in X^0, \ n = 1,2,\ldots, \ \lim_{n\to\infty} x_n = x,$$

$$Y_n \in \mathfrak{M}_c(Y^0), \ n = 1,2,\ldots, \ \lim_{n\to\infty} h(Y_n, Y) = 0,$$

the following property holds:

$$\lim_{n\to\infty} p_0(x_n, Y_n) = p_0(x,Y).$$

Let us define a quasi-optimality function $\Theta(\cdot,\cdot) : \ X^0 \times \mathfrak{M}_c(Y^0) \to \Re^1_+$ as follows:

$$\Theta(x,Y) = \| \ p_0(x,Y) \ \|, \ x \in X, \ Y \in \mathfrak{M}_c(Y^0).$$

Applying Corollaries 3.1 and 3.2, we obtain that Assumptions A1 and A2 hold and

$$\mathcal{X}_{qopt}[Y] = \mathcal{X}_{stat}[Y] \ \ \forall Y \in \mathfrak{M}_c(Y^0),$$

$$\mathcal{X}^0_{opt} \subset \mathcal{X}^0_{stat} = \mathcal{X}_{qopt}[Y^0].$$

For any $x \in X^0$ and $Y \subset Y^0$ denote

$$\mathfrak{Y}(x,Y) := \big\{ \{y_1,\ldots,y_s\} \in \mathfrak{M}_f(Y) \mid \ s \le k+1 \text{ and there exist } \lambda_1,\ldots,\lambda_s \ge 0$$

$$\text{s.t. (3.1), (3.2), (3.3), and (3.4) hold for } p = p_0(x,Y) \big\}.$$

It is clear that for the considered quasi-optimality function $\Theta(\cdot,\cdot)$ the set of all active parameters sets is as follows:

$$\mathcal{A}(x,Y) = \{ Y' \in \mathfrak{Y}(x,Y) \mid \text{ there does not exist } Y'' \in \mathfrak{Y}(x,Y)$$

$$\text{s.t. } Y'' \subset Y', \ Y'' \ne Y' \}.$$

Obviously,

$$\Delta Y \in \mathfrak{Y}(x,Y) \Rightarrow \ \Delta Y \succeq \mathcal{A}(x,Y).$$

We see that $\Theta(\cdot,\cdot)$ can be employed in the stochastic outer approximations method SMETH.ACTIV for solving sip.$\mathcal{P}^0$. The mechanism for active search of relevant constraints within the corresponding procedure SPROC.ACTIV.sip (i.e., Step 1.ACTIV.sip) can be similar to Step 1.ACTIV.ineq.

Note that we may also employ various quasi-optimality functions from [8, 26, 27].

4. Comparative efficiency of the activated and the standard versions of the method. Due to the active search modification at Step 1.ACTIV in the procedure PROC, the efficiency of the standard method can be essentially improved. To clarify the advantages of the activation we consider the following important example.

Consider the global optimization problem

$$\text{glob:} \qquad F(x) \to \min\limits_{x \in X^0},$$

where the objective function $F(\cdot)$ is assumed to be continuously differentiable on $X^0 \subset \Re^k$, $\nabla F(\cdot) \in \mathbf{C}_{Lip}(X^0, L)$, X^0 is convex and compact. Let us denote

$$X^0_{opt} := \{x \in X^0 \mid F(x) = \min\limits_{x' \in X^0} F(x')\},$$

$$X^{\varepsilon}_{stat} := \{x \in X^0 \mid\mid pr_{X^0}(x - \nabla F(x)) - x \mid\mid \leq \varepsilon\}, \varepsilon \geq 0,$$

X^0_{opt} and X^{ε}_{stat} are the optimal set and the ε-stationary set of the considered problem, respectively. Obviously, the problem can be rewritten in the form of a problem with an infinite number of constraints as follows:

$$\text{glob.}\mathcal{P}^0: \qquad \text{find } x \in \mathcal{X}_{opt},$$

$$\mathcal{X}_{opt} := \{x \in X^0 \mid F(x) - F(y) \leq 0 \ \forall y \in X^0\}.$$

Following the proposed general scheme we construct a stochastic outer approximations method for solving the problem glob.$\mathcal{P}^0$. First define approximative problems glob.$\mathcal{P}[X]$, $X \subset \mathfrak{M}_c(X^0)$, by

$$\text{glob.}\mathcal{P}[X]: \qquad \text{find } x \in \mathcal{X}_{opt}[X],$$

$$\mathcal{X}_{opt}[X] := \{x \in X^0 \mid F(x) \leq F(y) \ \ \forall y \in X\};$$

clearly,

$$\mathcal{X}_{opt}[X] := \{x \in X^0 \mid F(x) \leq \min\limits_{y \in X} F(y)\} \ \ \forall X \in \mathfrak{M}_c(X^0).$$

We also define the quasi-optimality function $\Theta(\cdot, X) : X^0 \to \Re^1_+$ by

$$\Theta(x, X) := \max(0; F(x) - \min\limits_{y \in X} F(y)), \ x \in X^0.$$

It is easily seen that

$$\mathcal{X}_{qopt}[X] := \{x \in X^0 \mid \Theta(x, X) = 0\} = \mathcal{X}_{opt}[X] \ \ \forall X \in \mathfrak{M}_c(X^0),$$

$$\mathcal{X}^0_{qopt} := \mathcal{X}_{qopt}[X^0] = \mathcal{X}^0_{opt},$$

and, moreover, Assumptions A1 and A2 hold.

Note that every active parameters set at (x, X) with respect to the considered quasi-optimality function $\Theta(\cdot, \cdot)$ is a singleton and

$$\mathcal{A}(x, X) = \{x \in X^0 \mid F(x) \leq \min\limits_{y \in X} F(y)\}. \tag{4.1}$$

After some straightforward simplifications based on the specificity of the considered problems glob.$\mathcal{P}[X]$ and the quasi-optimality function $\Theta(\cdot, X)$, $X \in \mathfrak{M}_f(X^0)$, the standard procedure SPROC (for simplicity we set $\gamma = 0$) adapted for glob.$\mathcal{P}[X]$ takes the following form:

PROCEDURE SPROC.glob.

Input. $x \in X^0$, $X \in \mathfrak{M}_f(X^0)$ $(x = \arg\min_{y \in X} F(y))$.

Output. $\Delta X = \{\overline{x}\}$, $\overline{X} = X \cup \{\overline{x}\}$.

Step 0. *Set* $i := 1$.

Step 1. *Determine a point* $x_i \in X^0$ *by using the uniform probability distribution on* X^0.

Step 2-3-4-5. *If*

$$F(x_i) \geq \min_{y \in X} F(y),$$

then $i := i + 1$ *and go to Step* 1. *Else set*

$$\overline{x} := x_i;\ \overline{X} := X \cup \{\overline{x}\};$$
$$\Delta\overline{X} := \{\overline{x}\}$$

(*note that by* (4.1) $\Delta\overline{X} \in \mathcal{A}(x, X)$).

Then exit.

Activating the standard procedure SPROC.glob by the use of a local descent technique for solving the problem

glob.$\mathcal{JP}$: $$F(y) \to \min_{y \in X^0},$$

we arrive at the procedure SPROC.ACTIV in the following form:

PROCEDURE SPROC.ACTIV.glob.

Input. $x \in X^0$, $X \in \mathfrak{M}_f(X^0)$ $(x = \arg\min_{y \in X} F(y))$.

Output. $\Delta X = \{\overline{x}\}$, $\overline{X} = X \cup \{\overline{x}\}$.

Step 0. *Set* $i := 1$.

Step 1. *Determine a point* $x_i \in X^0$ *by using the uniform probability distribution on* X^0.

Step 1.ACTIV. *Using a local descent technique (for instance, the gradient projection method) for solving the problem glob.*$\mathcal{JP}$, *starting with* x_i, *obtain* x_i^*,

$$x_i^* \in X^{\varepsilon}_{stat},\ F(x_i^*) \leq F(x_i).$$

Step 2-3-4-5. *If*

$$F(x_i^*) \geq \min_{y \in X} F(y),$$

then $i := i + 1$ *and go to Step* 1. *Else set*

$$\overline{x} := x_i^*,\ \overline{X} := X \cup \{\overline{x}\},$$
$$\Delta\overline{X} := \{\overline{x}\}.$$

Then exit.

Here $\varepsilon > 0$ is a parameter.

Taking into account that in the considered case the run of the master method does not depend upon $\{\varepsilon_n\}$ and $\{\sigma_n\}$ and making some further simplifications we obtain the following versions of the standard and the activated stochastic outer approximations methods.

METHOD SMETH.glob.

Data. $x^1 \in X^0$.

Stage 0. *Set* $n := 1$.

Stage 1.

Step 0. *Set* $i := 1$.

Step 1. *Determine a point* $x_i^n \in X^0$ *by using the uniform probability distribution on* X^0.

Step 2. *If*

$$F(x_i^n) \geq F(x^n),$$

then $i := i + 1$ *and go to Step* 1. *Else set*

$$\overline{x}^n := x_i^n.$$

Stage 3. Set

$$x^{n+1} := \overline{x}^n,$$
$$n := n + 1.$$

Go to Stage 1.

The activated stochastic outer approximations method for solving the global optimization problem is as follows:

METHOD SMETH.ACTIV.glob.

Data. $x^1 \in X^0$.

Stage 0. *Set* $n := 1$.

Stage 1.

Step 0. *Set* $i := 1$.

Step 1. *Determine a point* $x_i^n \in X^0$ *by using the uniform probability distribution on* X^0.

Step 1.ACTIV. *Using a local descent technique, starting with* x_i^n, *obtain* $x_i^{n,*}$,

$$x_i^{n,*} \in X_{stat}^{\varepsilon},\ F(x_i^{n,*}) \leq F(x_i^n).$$

Step 2. *If*

$$F(x_i^{n,*}) \geq F(x^n),$$

then $i := i + 1$ *and go to Step* 1. *Else set*

$$\overline{x}^n := x_i^{n,*}.$$

Stage 3. *Set*

$$x^{n+1} := \overline{x}^n,$$
$$n := n + 1.$$

Go to Stage 1.

Now it is obvious that the standard method SMETH.glob is the classical pure random search technique for global optimization and the activated method SMETH. ACTIV.glob is a version of the well-known multistart method (see [22]). The practical advantages of the multistart method over the pure random search are evident.

5. The basic property of the method. Let us introduce some necessary notation.

Let $(Y^0, \mathfrak{B}, \mu)$ be the probability space, where $\mathfrak{B}$ is the σ-algebra of Borel subsets of Y^0 and μ is the Borel measure on Y, normalized in such a way that $\mu(Y) = 1$. Set

$$\mathfrak{B}_n = \overset{n}{\underset{i=1}{\otimes}} \mathfrak{B},\ P_n = \overset{n}{\underset{i=1}{\otimes}} \mu,\ n = 1, 2, \ldots,$$

$$\Omega = \overset{\infty}{\underset{i=1}{\otimes}} Y^0,\ \mathfrak{A} = \overset{\infty}{\underset{i=1}{\otimes}} \mathfrak{B},\ P = \overset{\infty}{\underset{i=1}{\otimes}} \mu.$$

(Note that the existence of the countable product $(\Omega, \mathfrak{A}, P)$ of $(Y^0, \mathfrak{B}, \mu)$ follows from [16, Thm. III.3].) We shall denote by $\omega = (y_1, \ldots, y_n, \ldots)$ a typical element of Ω.

By the definition of the countable product of probability spaces for every $\Omega' \in \mathfrak{A}$, $B_1 \in \mathfrak{B}_{n_1}$, and $B_2 \in \mathfrak{B}_{n_2}$ satisfying the property

$$\forall \omega = (y_1, \ldots, y_n, \ldots) \in \Omega'$$

$$\Rightarrow (y_1, \ldots, y_{n_1}) \in B_1 \ \wedge\ (y_{n_1+1}, \ldots, y_{n_1+n_2}) \in B_2$$

the following estimation holds:

$$P(\Omega') \le P_{n_1}(B_1) \times P_{n_2}(B_2)$$

$$= P(\overline{B}_1) P_{n_2}(B_2), \tag{5.1}$$

where $\overline{B}_1 = B_1 \times \otimes_{i=n_1+1}^{\infty} Y^0 \in \mathfrak{A}$.

The following lemma proves useful.

LEMMA 5.1. *For any $\varepsilon,\ \eta > 0$ there exist $\tilde{S} = \tilde{S}(\varepsilon, \eta) \in \mathbf{N}$ and $\tilde{B} = \tilde{B}(\varepsilon, \eta) \in \mathfrak{B}_{\tilde{S}}$, $P_{\tilde{S}}(\tilde{B}) < \varepsilon$, such that*

$$h(\{y_1, \ldots, y_{\tilde{S}}\}, Y^0) \ge \eta$$

$$\Rightarrow (y_1, \ldots, y_{\tilde{S}}) \in \tilde{B}, \tag{5.2}$$

where $(y_1, \ldots, y_{\tilde{S}}) \in \otimes_{i=1}^{\tilde{S}} Y^0$.

For any $\omega = (y_1, \ldots, y_n, \ldots) \in \Omega$ and $n, s \in \mathbf{N}$ denote

$$Y_n^s(\omega) := \{y_{n+1}, \ldots, y_{n+s}\} \subset Y^0.$$

LEMMA 5.2. *There exists $\Omega^{(1)} \subset \Omega$, $P(\Omega^{(1)}) = 0$, such that*

$$\lim_{s \to \infty} h(Y_n^s(\omega), Y^0) = 0,\ n = 1, 2, \ldots,$$

for every $\omega \in \Omega \setminus \Omega^{(1)}$.

Proof. Fix an arbitrary $\varepsilon,\ 0 < \varepsilon < 1$, and a sequence $\eta_m > 0$, $m = 1, 2, \ldots,\ \eta_m \searrow 0$. Let $S_m = \tilde{S}(\varepsilon, \eta_m)$ and $\tilde{B}_m = \tilde{B}(\varepsilon, \eta_m) \subset \mathfrak{B}_{S_m}$ be defined by Lemma 5.1 for every $m = 1, 2, \ldots$. Set

$$\tilde{\Omega}_{n,m} := \underbrace{Y^0 \times \cdots \times Y^0}_{n\text{-}times} \times \tilde{B}_m \times \tilde{B}_m \times \cdots,$$

$$\tilde{\Omega}_n := \bigcup_{m=1}^{\infty} \tilde{\Omega}_{n,m},$$

$$\Omega^{(1)} := \bigcup_{n=1}^{\infty} \tilde{\Omega}_n.$$

Since obviously $P(\tilde{\Omega}_{n,m}) = 0$ for every $n, m = 1, 2, \ldots$, then

$$P(\Omega^{(1)}) = 0.$$

Let us fix an arbitrary ω,

$$\omega = (y_1, \ldots, y_n, \ldots) \in \Omega \setminus \Omega^{(1)}, \tag{5.3}$$

and suppose that for some $n \in \mathbf{N}$

$$\lim_{s \to \infty} h(Y_n^s(\omega), Y^0) \neq 0. \tag{5.4}$$

Since

$$Y_n^s(\omega) \subset Y_n^{s+1}(\omega) \subset Y^0,\ s = 1, 2, \ldots,$$

the sequence $\{h(Y_n^s(\omega), Y^0),\ s = 1, 2, \ldots\}$ is convergent and by (5.4)

$$h(Y_n^s(\omega), Y^0) \geq \lim_{s \to \infty} h(Y_n^s(\omega), Y^0) = \eta_0 > 0,\ s = 1, 2, \ldots.$$

It is easily seen that for every $s = 1, 2, \ldots$

$$Y_{n'}^s(\omega) \subset Y_n^{s+(n'-n)}(\omega) \subset Y^0,\ n' = n, n+1, \ldots;$$

hence,

$$h(Y_{n'}^s(\omega), Y^0) \geq h(Y_n^{s+(n'-n)}(\omega), Y^0),\ n' = n, n+1, \ldots.$$

Thus, we get

$$h(Y_{n'}^s(\omega), Y^0) \geq \eta_0 > 0,\ n' = n, n+1, \ldots,\ s = 1, 2, \ldots. \tag{5.5}$$

Choose an arbitrary m satisfying

$$\eta_m < \eta_0.$$

By (5.5) we have

$$h(Y_{n+iS_m}^{S_m}(\omega), Y) \geq \eta_0 > \eta_m,\ i = 0, 1, 2, \ldots.$$

Therefore by the definition of S_m and $\tilde{B}_m$ obtain

$$(y_{n+iS_m+1}, \ldots, y_{n+iS_m+S_m}) \in \tilde{B}_m,\ i = 0, 1, 2, \ldots.$$

Hence,

$$\omega = (y_1, \ldots, y_n, y_{n+1}, \ldots, y_{n+S_m}, y_{n+S_m+1}, \ldots)$$

$$\in \underbrace{Y \times \cdots \times Y}_{n\text{-}times} \times \overset{\infty}{\underset{i=0}{\otimes}} \tilde{B}_m = \tilde{\Omega}_n \subset \Omega^{(1)},$$

which contradicts with (5.3). Thus, the supposition (5.4) is not valid.

The lemma is proven. □

Every trajectory $\{x^n\}$ generated by SMETH.ACTIV depends upon outcomes of random experiments $y_1, \ldots, y_n, \ldots$ and hence $\{x^n\}$ is $\omega = (y_1, \ldots, y_n, \ldots)$-dependent, $\{x^n = x^n(\omega),\ n = 1, 2, \ldots\}$. Let us consider outcomes $\{x^n(\omega),\ n = 1, 2, \ldots\}$, $\omega \in \Omega$, of the method's run. We assume that the mappings $x^n(\cdot)$, $n = 1, 2, \ldots$, are measurable. Thus, $\{x^n\}$ is a sequence of random vectors on the probability space $(\Omega, \mathfrak{A}, P)$, and we shall study P-almost surely (P-a.s.) convergence properties of $\{x^n\}$.

For any $\omega = (y_1, y_2, \ldots) \in \Omega$ consider the corresponding trajectory $\{x^n\}$ of the method SMETH.ACTIV. Let $R_n(\omega)$ denote the number of random experiment executed to obtain $x^1(\omega), \ldots, x^n(\omega)$, i.e.,

$$x^n(\omega) = x^n(y_1, y_2, \ldots) = x^n(y_1, y_2, \ldots, y_{R_n}),\ n = 2, 3, \ldots.$$

(It is clear that $R_1(\omega) = 0$.)

By the definition of the method $S_n(\omega)$ is the number of random experiment executed at the nth iteration of SMETH.ACTIV to obtain $x^{n+1}(\omega)$; hence

$$R_{n+1}(\omega) = R_n(\omega) + S_n(\omega),\ n = 1, 2, \ldots.$$

It is possible that at the n_0th iteration of SMETH.ACTIV the inequality (2.3) in the procedure SPROC.ACTIV does not hold for every $i = 1, 2, \ldots$. Thus, the method generates a finite trajectory $x^1(\omega), \ldots, x^{n_0}(\omega)$. In this case we set

$$S_{n_0}(\omega) = +\infty,\ S_n(\omega) = 0,\ n = n_0 + 1, n_0 + 2, \ldots$$

and

$$N_{stop}(\omega) = n_0;$$

otherwise, $S_n(\omega) < +\infty,\ n = 1, 2, \ldots$, and

$$N_{stop}(\omega) = +\infty.$$

For a subset D of X^0 and $s \in \mathbf{N}$ consider the sets

$$\{1 \le n \le s \mid x^n(\omega) \in D\},\ s = 1, 2, \ldots;$$

obviously,

$$\{n \in \mathbf{N} \mid x^n(\omega) \in D\} = \bigcup_{s=1}^{\infty} \{1 \le n \le s \mid x^n(\omega) \in D\}.$$

Let us define

$$\mathcal{N}(D, s \mid \omega) :=\mid \{1 \le n \le s \mid x^n(\omega) \in D\} \mid,\ s = 1, 2, \ldots,$$

$$\mathcal{N}(D, \infty \mid \omega) :=\mid \{n \in \mathbf{N} \mid x^n(\omega) \in D\} \mid,$$

and

$$m_n(D \mid \omega) := \min\{s \in \mathbf{N} \mid \mathcal{N}(D, s \mid \omega) = n\};$$

when $\{s \in \mathbf{N} \mid \mathcal{N}(D, s \mid \omega) = n\} = \emptyset$ (i.e., $\mathcal{N}(D, \infty \mid \omega) < n$), we set $m_n(D \mid \omega) := +\infty$. It is clear that $m_{n_0}(D \mid \omega) = n^*$ means that the inclusion

$$x^n(\omega) \in D$$

holds for exactly n_0 of the first n^* elements of the trajectory $\{x^n(\omega),\ n = 1, 2, \ldots\}$ and, moreover, it holds for $n = n^*$; i.e., there exist $j_1, \ldots, j_{n_0},\ 1 \le j_1 \le \cdots \le j_{n_0} = n^*$, such that

$$x^j(\omega) \in D \quad \forall j \in \{j_1, \ldots, j_{n_0}\}$$

and

$$x^j(\omega) \notin D \quad \forall j \notin \{j_1, \ldots, j_{n_0}\},\ 1 \le j \le n^*.$$

Let us denote

$$\overline{\Omega}(D) := \{\omega \in \Omega \mid m_n(D \mid \omega) < +\infty \quad \forall n = 1, 2, \ldots\}.$$

It follows from the definition of $m_n(D \mid \omega)$ that

$$\omega \in \overline{\Omega}(D) \Leftrightarrow x^n(\omega) \in D \text{ for an infinite number of } n \in \mathbf{N}.$$

Set

$$\overline{\Omega}_\infty = \{\omega \in \Omega \mid N_{stop}(\omega) < +\infty\},$$

$$\Omega_\infty = \Omega \setminus \overline{\Omega}_\infty = \{\omega \in \Omega \mid \{x^n(\omega)\} \text{ is infinite}\}.$$

Note that, for every $D \subset X^0$,

$$\overline{\Omega}(D) \subset \Omega_\infty.$$

Now we establish the basic property of the considered outer approximations scheme.

LEMMA 5.3. *For every $\omega \in \Omega_\infty$ the following property holds:*

$$\lim_{n \to \infty} S_n(\omega) = +\infty.$$

Proof. Let us fix an arbitrary $\omega \in \Omega_\infty$ and consider the corresponding outcome sequences $\{x^n(\omega)\}$, $\{S_n(\omega)\}$, $\{Y_n(\omega)\}$, $\{\Delta Y_n(\omega)\}$, $\{\overline{Y}_n(\omega)\}$, $\{\theta_n(\omega)\}$; for simplicity we shall denote them by $\{x^n\}$, $\{S_n\}$, $\{Y_n\}$, $\{\Delta Y_n\}$, $\{\overline{Y}_n\}$, and $\{\theta_n\}$. Note that by (2.4), (2.5)

$$Y_n \subset Y_{n+1},\ n = 1, 2, \ldots. \tag{5.6}$$

Suppose that

$$\lim_{n\to\infty} S_n(\omega) \neq +\infty. \tag{5.7}$$

Therefore, there exist a subsequence $\{x^{t_n}\}$ of $\{x^n\}$ and $S_0 \in \mathbf{N}$ such that

$$\lim_{n\to\infty} x^{t_n} = x_0, \tag{5.8}$$

$$S_{t_n} \leq S_0,\ n = 1, 2, \ldots.$$

It follows from the definition of SPROC.ACTIV that

$$\theta_{t_n} = \Theta(x^{t_n}, \overline{Y}_{t_n}) > \gamma/S_{t_n} > \gamma/S_0 > 0,\ n = 1, 2, \ldots. \tag{5.9}$$

By (2.4) there exists $N \in \mathbf{N}$ such that

$$\sigma_n < \gamma/S_0,\ n = N, N+1, \ldots;$$

and without loss of generality we assume that

$$\theta_{t_n} > \sigma_{t_n},\ n = 1, 2, \ldots.$$

Hence by the construction of SMETH.ACTIV we have

$$Y_n \supset \Delta Y_{t_i}\ \ \forall i :\ t_i \leq n$$

for every $n \geq t_1$.

Therefore

$$Y_{t_n} \supset \Delta Y_{t_{n'}}\ \ \forall n, n',\ n \geq n'. \tag{5.10}$$

Let us define a sequence $\{U_n\}$ by the following rule:

$$U_1 = Y_{t_1},\ U_2 = Y_{t_1} \cup \Delta Y_{t_1}, \ldots,$$

$$U_{2n-1} = Y_{t_n},\ U_{2n} = Y_{t_n} \cup \Delta Y_{t_n}, \ldots.$$

It follows from (5.6) and (5.10) that

$$U_{2n} = Y_{t_n} \cup \Delta Y_{t_n} \subset Y_{t_{n+1}} = U_{2n+1},\ n = 1, 2, \ldots;$$

thus,

$$U_n \subset U_{n+1},\ n = 1, 2, \ldots.$$

Set

$$U_0 = \bigcup_{n=1}^{\infty} U_n.$$

By the monotonicity of $\{U_n\}$ we obtain

$$\lim_{n\to\infty} h(U_n, U_0) = 0. \tag{5.11}$$

By (2.6) we get

$$\Theta(x^{t_n}, Y_{t_n}) = \Theta(x^{t_n}, U_{2n-1}) \le \varepsilon_{t_n},\ n = 1, 2, \dots;$$

hence

$$\lim_{n\to\infty} \inf \Theta(x^{t_n}, U_{2n-1}) = 0.$$

Therefore from (5.8), (5.11), and Assumption A2(i) we obtain

$$\Theta(x_0, U_0) = 0$$

and, furthermore, by Assumption A2(ii)

$$\lim_{n\to\infty} \Theta(x^{t_n}, U_{2n}) = 0. \tag{5.12}$$

It follows from the definition of SPROC.ACTIV (see the dropping step) that

$$\Delta Y_n \succeq \mathcal{A}(x^n, \overline{Y}_n),$$

$$\Delta Y_n \subset Y_n \cup \Delta Y_n \subset \overline{Y}_n,\ n = 1, 2, \dots;$$

thus,

$$\Theta(x^n, \Delta Y_n) = \Theta(x^n, Y_n \cup \Delta Y_n) = \Theta(x^n, \overline{Y}_n),\ n = 1, 2, \dots.$$

Applying (5.9) we obtain

$$\Theta(x^{t_n}, U_{2n}) = \Theta(x^{t_n}, Y_{t_n} \cup \Delta Y_{t_n}) = \Theta(x^{t_n}, \overline{Y}_{t_n}) \ge \gamma/S_0 > 0,\ n = 1, 2, \dots;$$

hence

$$\lim_{n\to\infty} \sup \Theta(x^{t_n}, U_{2n}) > 0,$$

which contradicts with (5.12).

Thus, (5.6) does not hold.

The lemma is proven. □

6. Convergence theorem. The following lemma plays the important role in the convergence analysis of the method SMETH.ACTIV.

LEMMA 6.1. *For every $x \notin X^0_{qopt}$ there exist $\delta_* = \delta_*(x) > 0$,*

$$B_{\delta_*}(x) \cap X^0 \subset X^0 \setminus X^0_{qopt}, \tag{6.1}$$

and $\Omega^* = \Omega^*(x) \subset \Omega_\infty$, $P(\Omega^*) = 0$, such that the following property holds:

$$\overline{lt}\{x^n(\omega)\} \cap B_{\delta_*}(x) = \emptyset \quad \forall \omega \in \Omega_\infty \setminus \Omega^*.$$

Proof. Let us fix an arbitrary $x \notin X^0_{qopt}$. By the definition of X^0_{qopt} we have

$$\Theta(x, Y^0) > 0;$$

hence by Assumption A2(i) there exist $\delta_* > 0$ satisfying (6.1) and $\eta_*,\ d_* > 0$ such that

$$\Theta(x', U) \ge d_* > 0 \tag{6.2}$$

for every $x' \in B_{\delta_*}(x) \cap X^0$ and $U \subset Y^0,\ h(U, Y^0) < \eta_*$.

Set

$$\Omega^* = \overline{\Omega}(D),\ D = B_{\delta_*}(x).$$

It is obvious that $\Omega^* \subset \Omega_\infty$.

Let us fix an arbitrary $\varepsilon > 0$ and show that

$$P(\Omega^*) \le \varepsilon.$$

By Lemma 5.1 there exist $\tilde{S} \in \mathbf{N}$,

$$\tilde{S} > \gamma/d_*, \tag{6.3}$$

and $\tilde{B} \in \mathfrak{B}_S$, $P_S(\tilde{B}) < \varepsilon$, such that (5.2) holds.

It follows from Lemma 5.3 that for every $\omega \in \Omega^*$

$$\lim_{n\to\infty} S_{m_n(D|\omega)}(\omega) = +\infty;$$

hence,

$$\Omega^* = \bigcup_{l=1}^{\infty} \Omega_l,$$
$$\Omega_l = \{\omega \in \Omega^* \mid S_{m_n(D|\omega)}(\omega) \ge S+1,$$
$$n = l, l+1, \ldots\}.$$

It is clear that

$$\Omega_l \subset \Omega_{l+1},\ l = 1, 2, \ldots;$$

therefore,

$$P(\Omega^*) = \lim_{l\to\infty} P(\Omega_l). \tag{6.4}$$

Let us fix an arbitrary $l \in \mathbf{N}$ and set

$$\Omega^i = \{\omega \in \Omega \mid R_{m_l(D|\omega)}(\omega) = i\},\ i = 1, 2, \ldots;$$

it is easy to see that there exist $B_i \in \mathfrak{B}_i$, $i = 1, 2, \ldots$, such that

$$\Omega^i = B_i \times \bigotimes_{j=i+1}^{\infty} Y,\ i = 1, 2, \ldots. \tag{6.5}$$

Note that

$$\Omega^i \cap \Omega^{i'} = \emptyset\ \ \forall i \ne i',\ i, i' = 1, 2, \ldots,$$
$$\Omega_l \subset \bigcup_{i=1}^{\infty} \Omega^i.$$

Set

$$\Omega_l^i = \Omega_l \cap \Omega^i,\ i = 1, 2, \ldots.$$

Then obtain

$$\Omega_l^{i'} \cap \Omega_l^{i''} = \emptyset\ \ \forall i' \ne i'',\ i', i'' = 1, 2, \ldots,$$
$$\Omega_l = \bigcup_{i=1}^{\infty} \Omega_l^i,$$

and hence

$$P(\Omega_l) = \sum_{i=1}^{\infty} P(\Omega_l^i). \tag{6.6}$$

Consider an arbitrary Ω_l^i.

For every $\omega \in \Omega_l^i$ we have

$$R_{m_l(D|\omega)}(\omega) = i,$$

$$x^{m_l(D|\omega)} \in D \cap X^0 = B_{\delta_*}(x) \cap X^0, \tag{6.7}$$

$$S_{m_l(D|\omega)}(\omega) \geq S + 1.$$

(For simplicity we shall use m_l instead of $m_l(D \mid \omega)$.) Therefore,

$$x^{m_l}(\omega) = x^{m_l}(y_1, \ldots, y_i),$$

$$\tilde{S}\ \Theta(x^{m_l}(\omega), Y_{m_l} \cup \{y_{i+1}, y_{i+1}^*, \ldots, y_{i+s}, y_{i+s}^*\}) \leq \gamma,$$

and, furthermore, by (6.3)

$$\Theta(x^{m_l}(\omega), Y_{m_l} \cup \{y_{i+1}, y_{i+1}^*, \ldots, y_{i+s}, y_{i+s}^*\}) \leq d_*.$$

Thus, by (6.2) and (6.7) we obtain

$$h((Y_{m_l} \cup \{y_{i+1}, y_{i+1}^*, \ldots, y_{i+s}, y_{i+s}^*\}), Y^0) \geq \eta_*,$$

and hence

$$h(\{y_{i+1}, \ldots, y_{i+s}\}, Y^0) \geq \eta_*.$$

Since by the choice of $\tilde{S}$ the property (4.2) holds,

$$(y_{i+1}, \ldots, y_{i+s}) \in \tilde{B} \in \mathfrak{B}_{\tilde{S}},\ P_{\tilde{S}}(\tilde{B}) < \varepsilon.$$

Taking into account (6.5) and applying (5.1) we get

$$P(\Omega_l^i) \leq P(\Omega^i) P_{\tilde{S}}(\tilde{B}) \leq \varepsilon P(\Omega^i),\ i = 1, 2, \ldots.$$

Turning back to (6.6) we obtain

$$P(\Omega_l) = \sum_{i=1}^{\infty} P(\Omega_l^i) \leq \varepsilon \sum_{i=1}^{\infty} P(\Omega^i) \leq \varepsilon,\ l = 1, 2, \ldots;$$

therefore by (6.4)

$$P(\Omega^*) \leq \varepsilon.$$

Since in this estimation ε is an arbitrary positive number,

$$P(\Omega^*) = 0.$$

By the definition of $\Omega^* = \overline{\Omega}(B_{\delta_*}(x))$ for every $\omega \in \Omega_\infty \setminus \Omega^*$ the inclusion

$$x^n(\omega) \in B_{\delta_*}(x)$$

holds only for a finite number of $n \in \mathbf{N}$.

Thus,

$$\overline{lt}\{x^n(\omega)\} \cap B_{\delta_*}(x) = \emptyset \quad \forall \omega \in \Omega_\infty \setminus \Omega^*.$$

The lemma is proven. □

We also need the property of finite trajectories of SMETH.ACTIV.

LEMMA 6.2. *For every* $\omega \in \overline{\Omega}_\infty \setminus \Omega^{(1)}$, $P(\Omega^{(1)}) = 0$, *the following property holds:*

$$x^{N_{stop}}(\omega) \in X^0_{qopt},$$

where $\Omega^{(1)}$ *is defined in Lemma* 5.2.

Proof. The desired result follows immediately from Assumption A2(i) and Lemma 5.2. □

THEOREM 6.1. *There exists* $\Omega^{(0)} \subset \Omega$, $P(\Omega^{(0)}) = 0$, *such that for every* $\omega \in \Omega \setminus \Omega^{(0)}$ *the trajectory* $\{x^n(\omega)\}$ *of SMETH.ACTIV satisfies one of the following properties:*

(i) $N_{stop} < +\infty$ and $x^{N_{stop}}(\omega) \in X^0_{qopt}$;

(ii) $N_{stop} = +\infty$ and $\{x^n(\omega)\}$ converges to X^0_{qopt}.

Proof. Let us fix an arbitrary sequence $\zeta_j \searrow 0$ and consider the following sets:

$$Z_j = X^0 \setminus B_{\zeta_j}(X^0_{qopt}),\ j = 1, 2, \ldots.$$

It is clear that $Z_j,\ j = 1, 2, \ldots$, are compact and

$$\bigcup_{j=1}^{\infty} Z_j = X^0 \setminus X^0_{qopt}. \tag{6.8}$$

For any $j = 1, 2, \ldots$ it follows from (6.1) that

$$X \setminus X_{qopt} \supset \bigcup_{x \in Z_j} B_{\delta_*(x)}(x) \supset Z_j,$$

where $\delta_*(x) > 0$ is defined in Lemma 6.1.

Since Z_j is compact, there is a finite set of points $x_{i,j},\ i = 1, 2, \ldots, I_j$, such that

$$X^0 \setminus X^0_{qopt} \supset \bigcup_{i=1}^{I_j} B_{\delta_*(x_{i,j})}(x_{i,j}) \supset Z_j,$$

for every $j = 1, 2, \ldots$.

Hence, by (6.8)

$$X^0 \setminus X^0_{qopt} = \bigcup_{j=1}^{\infty} \bigcup_{i=1}^{I_j} B_{\delta_*(x_{i,j})}(x_{i,j}). \tag{6.9}$$

Define

$$\Omega^*_j = \bigcup_{i=1}^{I_j} \Omega^*(x_{i,j}), \quad \Omega^{(2)} = \bigcup_{j=1}^{\infty} \Omega^*_j,$$

where $\Omega^*(x) \subset \Omega$, $P(\Omega^*(x)) = 0$, is defined in Lemma 6.1. It is obvious that

$$P(\Omega^{(2)}) = 0.$$

Set

$$\Omega^{(0)} = \Omega^{(1)} \cup \Omega^{(2)},\ P(\Omega^{(0)}) = 0,$$

where $\Omega^{(1)} \subset \Omega$, $P(\Omega^{(1)}) = 0$, is defined in Lemma 5.2 (see also Lemma 6.2).

Let us fix an arbitrary $\omega \in \Omega \setminus \Omega^{(0)}$.

If $\omega \in \overline{\Omega}_\infty$, then $\omega \in \overline{\Omega}_\infty \setminus \Omega^{(1)}$ and by Lemma 6.2 the trajectory $\{x^n\}$ satisfies the property:

$$N_{stop}(\omega) < \infty, \quad x^{N_{stop}}(\omega) \in X^0_{qopt}.$$

If $\omega \in \Omega_\infty$, then

$$\omega \in \Omega_\infty \setminus \Omega^*(x_{i,j}),\ i = 1, \ldots, I_j,\ j = 1, 2, \ldots$$

Therefore, from Lemma 6.1 we have

$$\overline{lt}\{x^n(\omega)\} \cap B_{\delta_*(x_{i,j})}(x_{i,j}) = \emptyset,\ i = 1, \ldots, I_j,\ j = 1, 2, \ldots,$$

i.e.,

$$\overline{lt}\{x^n(\omega)\} \cap \bigcup_{j=1}^{\infty} \bigcup_{i=1}^{I_j} B_{\delta_*(x_{i,j})}(x_{i,j}) = \emptyset;$$

and hence by (6.9) we obtain

$$\overline{lt}\{x^n(\omega)\} \cap (X^0 \setminus X^0_{qopt}) = \emptyset.$$

Thus,

$$\overline{lt}\{x^n(\omega)\} \subset X^0_{qopt}.$$

The theorem is proven. □

7. Stochastic algorithm for solving the approximation problem. Consider the following approximation problem:

apprx.$\mathcal{P}^0$: find $x \in \mathcal{X}^0_{opt}$,

$$\mathcal{X}^0_{opt} = \{x \in X^0 \mid \max_{y \in Y^0} \mid \Phi(x, y) - F(y) \mid = v^0_{opt}\},$$

$$v^0_{opt} = \min_{x \in X^0} \max_{y \in Y^0} \mid \Phi(x, y) - F(y) \mid,$$

where the functions $\Phi(\cdot, \cdot)$, $F(\cdot)$ are assumed to be continuous and continuously differentiable on $X^0 \times Y^0$, $\nabla\Phi(\cdot) = (\nabla_x\Phi(\cdot, \cdot), \nabla_y\Phi(\cdot, \cdot)) \in \mathbf{C}_{Lip}(X^0 \times Y^0, L)$, $\nabla F(\cdot) \in \mathbf{C}_{Lip}(Y^0, L)$, $L > 0$, $X^0 \subset \Re^k$ is polyhedral and compact, and $Y^0 \subset \Re^l$ is convex and compact.

To demonstrate a practical embodiment of the proposed activated random search technique for forming relevant parameter sets within the outer approximations method we consider a stochastic algorithm for solving the problem apprx.$\mathcal{P}^0$. The algorithm is constructed as a version of the general method SMETH.ACTIV specially adapted for apprx.$\mathcal{P}^0$.

We also introduce the stationary set $\mathcal{X}^0_{stat}$ of the problem apprx.$\mathcal{P}^0$, i.e., the set of all points satisfying the first-order necessary optimality conditions. For $x \in X^0$ denote

$$R^0(x) := \{y \in Y^0 \mid \ \mid \Phi(x,y) - F(y) \mid \ = \max_{y \in Y^0} \mid \Phi(x,y) - F(y) \mid\}.$$

The stationary set $\mathcal{X}^0_{stat}$ is given by

$$\begin{aligned}\mathcal{X}^0_{stat} := \{x \in X^0 \mid &\text{there exist } y_1, \dots, y_s \in R^0(x)\\ &\text{and } \lambda_1, \dots, \lambda_s \in \Re^1,\ \sum_{i=1}^{s} \mid \lambda_i \mid = 1,\ s \le k+1, \text{s.t.}\\ &\sum_{i=1}^{s} \lambda_i \nabla_x \Phi(x, y_i) + K_{X^0}(x) \ni \mathbf{0},\\ &\lambda_i(\Phi(x, y_i) - F(y_i)) \ge 0,\ i = 1, \dots, s\}.\end{aligned}$$

Note that if the function $\Phi(x,y)$ is linear with respect to x for every $y \in Y^0$, i.e.,

$$\Phi(x,y) = \langle a(y), x\rangle + b(y) \quad \forall x \in X^0,\ a(y) \in \Re^k,\ b(y) \in \Re^1,\ y \in Y^0, \tag{7.1}$$

then the objective function

$$\varphi(x) = \max_{y \in Y^0} \mid \Phi(x,y) - F(y) \mid$$

of the problem apprx.$\mathcal{P}^0$ is convex on X^0 and

$$\mathcal{X}^0_{stat} = \mathcal{X}^0_{opt}.$$

To construct the outer approximations algorithm for solving apprx.$\mathcal{P}^0$ we define the simpler problems apprx.$\mathcal{P}[Y]$, $Y \in \mathfrak{M}_c(Y^0)$, by

apprx.$\mathcal{P}[Y]$: to find $x \in \mathcal{X}_{opt}[Y]$,

$$\mathcal{X}_{opt}[Y] := \{x \in X^0 \mid \ \max_{y \in Y} \mid \Phi(x,y) - F(y) \mid = v_{opt}[Y]\},$$

$$v_{opt}[Y] := \min_{x \in X^0} \max_{y \in Y} \mid \Phi(x,y) - F(y) \mid .$$

It is clear that the problem apprx.$\mathcal{P}[Y^0]$ is the initial problem apprx.$\mathcal{P}^0$ and $\mathcal{X}_{opt}[Y^0] = \mathcal{X}^0_{opt}$. For $x \in X^0$ and $Y \in \mathfrak{M}_c(Y^0)$ denote

$$R(x,Y) := \{y \in Y \mid \ \mid \Phi(x,y) - F(y) \mid \ = \max_{y \in Y} \mid \Phi(x,y) - F(y) \mid\};$$

obviously $R(x, Y^0) = R^0(x)$. The stationary set $\mathcal{X}_{stat}[Y]$ of the problem apprx.$\mathcal{P}[Y]$ is as follows:

$$\begin{aligned}\mathcal{X}_{stat}[Y] := \Big\{ x \in X^0 \mid &\text{ there exist } y_1, \dots, y_s \in R(x,Y)\\ &\text{and } \lambda_1, \dots, \lambda_s \in \Re^1,\ \textstyle\sum_{i=1}^{s} \mid \lambda_i \mid = 1,\ s \le k+1, \text{s.t.}\\ &\sum_{i=1}^{s} \lambda_i \nabla_x \Phi(x, y_i) + K^*_{X^0}(x) \ni \mathbf{0},\\ &\lambda_i(\Phi(x, y_i) - F(y_i)) \ge 0,\ i = 1, \dots, s\Big\}.\end{aligned}$$

Let $V \subset \Re^1$ be a line segment, $V = [\underline{v}, \overline{v}]$, where

$$\underline{v} < 0, \ \max_{x \in X^0} \max_{y \in Y^0} \mid \Phi(x,y) - F(y) \mid + L \text{ diam } X^0 < \overline{v}.$$

It is clear that for every $Y \in \mathfrak{M}_c(Y^0)$ the problem apprx.$\mathcal{P}[Y]$ can be rewritten in the following form:

apprx.$\mathcal{P}[Y]'$:
$$v \to \min_{x,v}$$
$$\text{s.t. } \Phi(x,y) - F(y) - v \le 0 \ \ \forall y \in Y,$$
$$-\Phi(x,y) + F(y) - v \le 0 \ \ \forall y \in Y,$$
$$x \in X^0, \ v \in V;$$

i.e., the solution set of apprx.$\mathcal{P}[Y]'$ is equal to $\mathcal{X}_{opt}[Y] \times \{v_{opt}[Y]\}$.

Similarly to Example 3.2 we define the auxiliary quadratic programming problem:

apprx.$\mathcal{QP}(x, Y)$:
$$v + \frac{1}{2} \parallel p \parallel^2 \to \min_{p,v}$$
$$\text{s.t. } \Phi(x,y) + \langle \nabla_x \Phi(x,y), p \rangle - F(x) - v \le 0 \ \ \forall y \in Y,$$
$$-\Phi(x,y) - \langle \nabla_x \Phi(x,y), p \rangle + F(x) - v \le 0 \ \ \forall y \in Y,$$
$$x + p \in X^0, \ v \in V.$$

It is easy to show that for every $x \in X^0$ and $Y \in \mathfrak{M}_f(Y^0)$ there exists the unique solution $(p_0(x,Y), v_0(x,Y))$ of apprx.$\mathcal{QP}(x,Y)$ and, moreover,

$$v_0(x,Y) = \max_{y \in Y} \mid \Phi(x,y) + \langle \nabla_x \Phi(x,y), p_0(x,Y) \rangle - F(x) \mid .$$

Furthermore, the following optimality criterion holds.

LEMMA 7.1. *For every $x \in X^0$ and $Y \in \mathfrak{M}_c(Y^0)$ a vector $(p,v) \in \Re^k \times \Re^1$ is the solution of* apprx.$\mathcal{QP}(x,Y)$ *if and only if there exist $y_1, \dots, y_s \in Y$ and $\lambda_1, \dots, \lambda_s \in \Re^1$, $\sum_{i=1}^s \mid \lambda_i \mid = 1$, $s \le k+1$, such that the following properties hold:*

$$p + \sum_{i=1}^{s} \lambda_i \nabla_x \Phi(x, y_i) + K^*_{X^0}(x+p) \ni \mathbf{0}, \tag{7.2}$$

$$v = \max_{y \in Y} \mid \Phi(x,y) + \langle \nabla_x \Phi(x,y), p \rangle - F(x) \mid, \tag{7.3}$$

$$\mid \Phi(x, y_i) + \langle \nabla_x \Phi(x, y_i), p \rangle - F(x) \mid = v, \ i = 1, \dots, s, \tag{7.4}$$

$$\lambda_i (\Phi(x,y) + \langle \nabla_x \Phi(x,y), p \rangle - F(x)) \ge 0, \ i = 1, \dots, s, \tag{7.5}$$

$$x + p \in X. \tag{7.6}$$

From Lemma 7.1 we get immediately the following corollaries.

COROLLARY 7.1. *For every* $x \in X^0$ *and* $Y \in \mathfrak{M}_c(Y^0)$ *the following property holds:*

$$p_0(x, Y) = 0 \Leftrightarrow x \in \mathcal{X}_{stat}(Y).$$

COROLLARY 7.2. *For every* $x \in X^0$, $Y \in \mathfrak{M}_c(Y^0)$, *and sequences* $\{x_n\}$, $\{Y_n\}$ *satisfying*

$$x_n \in X^0,\ n = 1, 2, \ldots,\ \lim_{n\to\infty} x_n = x,$$

$$Y_n \in \mathfrak{M}_c(Y^0),\ n = 1, 2, \ldots,\ \lim_{n\to\infty} h(Y_n, Y) = 0,$$

the following property holds:

$$\lim_{n\to\infty} p_0(x_n, Y_n) = p_0(x, Y).$$

Let us define a quasi-optimality function $\Theta(\cdot,\cdot) :\ X^0 \times \mathfrak{M}_c(Y^0)\ \to \Re^1_+$ by

$$\Theta(x, Y) :=\| p_0(x, Y) \|,\ x \in X^0,\ Y \in \mathfrak{M}_c(Y^0).$$

Applying Corollary 7.1 we obtain that

$$\mathcal{X}_{qopt}[Y] = \mathcal{X}_{stat}[Y]\ \ \forall Y \in \mathfrak{M}_c(Y^0)$$

and, in particular,

$$\mathcal{X}_{qopt}[Y^0] = \mathcal{X}^0_{stat} \supset \mathcal{X}^0_{opt}. \tag{7.7}$$

From Corollary 7.2 and (7.7) we deduce the following important result.

LEMMA 7.2. *The considered quasi-optimality function* $\Theta(\cdot,\cdot)$ *satisfies Assumptions* A1 *and* A2 *and*

$$\mathcal{X}_{qopt}[Y^0] = \mathcal{X}^0_{stat}.$$

Moreover, if (7.1) *holds, then*

$$\mathcal{X}_{qopt}[Y^0] = \mathcal{X}^0_{opt}.$$

For any $x \in X^0$ and $Y \in \mathfrak{M}_c(Y^0)$ denote

$$\mathfrak{Y}(x, Y) = \Big\{ \{y_1, \ldots, y_s\} \in \mathfrak{M}_f(Y) \mid s \le k+1 \text{ and there exist}$$

$$\lambda_1, \ldots, \lambda_s \ge 0,\ \sum_{i=1}^{s} \mid \lambda_i \mid = 1, \text{s.t. (7.2), (7.3), (7.4),}$$

$$\text{(7.5), and (7.6) hold for } p = p_0(x, Y) \text{ and } v = v_0(x, Y)\Big\}.$$

It is clear that for the considered quasi-optimality function $\Theta(\cdot,\cdot)$ the set of all active parameter sets is as follows:

$$\mathcal{A}(x, Y) = \{Y' \in \mathfrak{Y}(x, Y) \mid \text{ there does not exist } Y'' \in \mathfrak{Y}(x, Y)$$

$$\text{s.t. } Y'' \subset Y', Y'' \ne Y'\}.$$

Hence, we have

$$\forall \Delta Y \in \mathfrak{Y}(x, Y) \Rightarrow \Delta Y \succeq \mathcal{A}(x, Y). \tag{7.8}$$

Note that for any $x \in X^0$ and $Y \in \mathfrak{M}_f(Y^0)$ calculating $\Theta(x, Y)$ (i.e., solving the problem apprx.$\mathcal{QP}(x, Y)$) with the use of the conjugate gradient method (see [19]) we obtain $p_0(x, Y)$ together with a finite set $\mathcal{Y}_0(x, Y) = \{y_1, \ldots, y_s\} \subset Y$, $s \leq k + 1$, such that

$$p_0(x, Y) = -\sum_{i=1}^{s} \lambda_i \nabla_x \Phi(x, y_i) - \eta,\ \eta \in K^*_{X^0}(x + p_0(x, Y)), \tag{7.9}$$

$$\mathcal{Y}_0(x, Y) = \{y_1, \ldots, y_s\} \in \mathfrak{Y}(x, Y), \tag{7.10}$$

and by (7.8)

$$\mathcal{Y}_0(x, Y) \succeq \mathcal{A}(x, Y). \tag{7.11}$$

Now we construct an activation mechanism for the search of relevant parameters. Let us fix an arbitrary $x \in X^0$ and consider the inner problem

apprx.$\mathcal{JP}(x)$:
$$\mid \Phi(x, y) - F(y) \mid \rightarrow \max_y$$
$$\text{s.t. } y \in Y^0;$$

for simplicity we denote

$$f(y \mid x) := \mid \Phi(x, y) - F(y) \mid .$$

For every $y \in Y^0$, $f(y \mid x) \neq 0$, define

$$h(y \mid x) := pr_{Y^0}(y + \ \text{sign}(\Phi(x, y) - F(y))(\nabla_y \Phi(x, y) - \nabla F(y))) - y$$

$$= pr_{Y^0}(y + \nabla_y f(y \mid x)) - y.$$

When $f(y \mid x) = 0$ we set

$$h(y \mid x) := \arg \max_{\overline{h} \in \overline{H}} \parallel \overline{h} \parallel,$$

$$\overline{H} = \{pr_{Y^0}(y + (\nabla_y \Phi(x, y) - \nabla F(y))) - y,$$

$$pr_{Y^0}(y - (\nabla_y \Phi(x, y) - \nabla F(y))) - y\}.$$

The ε-stationary set $Y^{\varepsilon}_{stat}(x)$ of the problem apprx.$\mathcal{JP}(x)$ is given by

$$Y^{\varepsilon}_{stat}(x) := \{y \in Y^0 \mid\mid\mid h(y \mid x) \parallel \leq \varepsilon\},\ \varepsilon \geq 0.$$

Obviously, $Y^0_{stat}(x)$ is the set of all points satisfying the standard first-order necessary optimality conditions for apprx.$\mathcal{JP}(x)$; in particular, if

$$\min_{y \in Y^0} f(y \mid x) > 0,$$

then we have

$$Y^0_{stat}(x) = \{y \in Y^0 \mid -\nabla_y f(y \mid x) + K^*_{Y^0}(y) \ni \mathbf{0}\}.$$

The gradient projection method for the local search in apprx.$\mathcal{JP}(x)$ is as follows:

$$\text{GPM}(x): \qquad y_{n+1} = y_n + a_n h(y_n \mid x),\ n = 1, 2, \ldots,\ y_1 \in Y^0,$$

where stepsizes $a_n \geq 0$, $n = 1, 2, \ldots$, can be chosen, for instance, by Armijo's rule:

$$a_n = \eta^{i_n},$$

$$i_n := \min\{i \in \{0, 1, 2, \ldots\} \mid f(y_n + \eta^i h(y_n \mid x) \mid x) - f(y_n \mid x)$$

$$\geq \kappa\eta^i \parallel h(y_n \mid x) \parallel^2\},$$

$0 < \eta$, $\kappa < 1$ are parameters; $y_1 \in Y^0$ is a starting point.

Based on the convergence properties of the gradient projection method we obtain the following result.

LEMMA 7.3. *Every trajectory* $\{y_n\}$ *of* GPM(x) *converges to* $Y^0_{stat}(x)$, *and for every* $\varepsilon > 0$ *there exists* $N \in \mathbf{N}$ *such that*

$$f(y_1 \mid x) \leq f(y_N \mid x),\ y_N \in Y^{\varepsilon}_{stat}.$$

Now following the proposed general approach we construct a stochastic algorithm for solving the approximation problem apprx.$\mathcal{P}^0$.

METHOD SMETH.ACTIV.apprx.

Data. $x^1 \in X^0$.

Parameters. $\gamma, \varepsilon > 0$, $0 < \eta$, $\kappa < 1$, *and sequences* $\{\varepsilon_n\}$, $\{\sigma_n\}$, $\varepsilon_n, \sigma_n > 0$, $n = 1, 2, \ldots$, $\varepsilon_n, \sigma_n \searrow 0$.

Stage 0. *Set*

$$n := 1,$$

$$Y_1 := \emptyset.$$

Stage 1.

Step 0. *Set*

$$i := 1,$$

$$\overline{Y_n} := Y_n.$$

Step 1. *Determine a point* $y^n_i \in Y^0$ *by using the uniform probability distribution on* Y^0. *Set*

$$\overline{Y_n} := \overline{Y_n} \cup \{y^n_i\}.$$

Step 1.ACTIV. *Applying* GPM(x^n) *(with parameters* η *and* κ*), starting with* y^n_i, *obtain* $y^{n,*}_i \in Y^0$ *satisfying*

$$\mid \Phi(x^n, y^{n,*}_i) - F(y^{n,*}_i) \mid \geq \mid \Phi(x^n, y^n_i) - F(y^n_i) \mid,$$

$$y^{n,*}_i \in Y^{\varepsilon}_{stat}(x^n).$$

Set

$$\overline{Y}_n := \overline{Y}_n \cup \{y_i^{n,*}\}.$$

Step 2. *Solving the quadratic problem* apprx.$\mathcal{QP}(x^n, \overline{Y_n})$, *obtain* $p_0(x^n, \overline{Y_n})$ *and* $\mathcal{Y}_0(x^n, \overline{Y_n}) \subset \overline{Y_n}$, $\mid \mathcal{Y}_0(x^n, \overline{Y_n}) \mid \leq k+1$ (*see* (7.9), (7.10)).
Set

$$\theta_n^i := \| \, h(x^n, \overline{Y}_n) \, \| \, .$$

Step 3. *If*

$$i\theta_n^i \leq \gamma,$$

then set

$$i := i + 1$$

and go to Step 1.

Step 4. *Set*

$$\theta_n := \theta_n^i,$$

$$S_n := i,$$

$$\Delta Y_n := \mathcal{Y}_0(x^n, \overline{Y_n}).$$

Go to Stage 2.

Stage 2. *Set*

$$Y_{n+1} := \Delta Y_n \cup \bigcup_{\substack{j:\theta_j > \sigma_j, \\ 1 \leq j \leq n-1}} \Delta Y_j.$$

Stage 3. *Solving the problem* apprx.$\mathcal{P}[Y_{n+1}]$ *(for instance, by Pschenichny's linearization method), find* $x^{n+1} \in X^0$ *satisfying*

$$\Theta(x^{n+1}, Y_{n+1}) \leq \varepsilon_{n+1}.$$

Stage 4. *Set*

$$n := n + 1.$$

Go to Stage 1.

Obviously, for every $x^1 \in X^0$ the method SMETH.ACTIV.apprx generates a sequence of random vectors $\{x^n(\omega)\}$ on the probability space $(\Omega, \mathfrak{A}, P)$ (see section 5). And it is possible that for some $\omega \in \Omega$ the trajectory $\{x^n(\omega)\}$ is finite, i.e., we get $x^1, x^2(\omega), \ldots, x^{N_{stop}}(\omega)$, $N_{stop}(\omega) < +\infty$; in this case setting

$$x^n(\omega) := x^{N_{stop}}(\omega), \; n = N_{stop}, N_{stop}+1, \ldots,$$

we shall formally consider $\{x^n(\omega)\}$ as an infinite trajectory.

Applying Theorem 6.1, Lemmas 7.2 and 7.3, and (7.11) we obtain the following result.

THEOREM 7.1. *Every trajectory* $\{x_n\}$ *of the method SMETH.ACTIV.apprx P-a.s. converges to the stationary set* $\mathcal{X}^0_{stat}$ *of the problem* apprx.$\mathcal{P}^0$.

Moreover, under the assumption (7.1) $\{x^n\}$ *P-a.s. converges to the optimal set* $\mathcal{X}^0_{opt}$.

Remark 7.1. Under assumption (7.1), for every $Y \in \mathfrak{M}_f(Y^0)$ we have that apprx.$\mathcal{P}[Y]$ is a linear programming problem (see its form apprx.$\mathcal{P}[Y]'$). Thus, at Stage 3 in the method SMETH.ACTIV.apprx linear programming techniques can be effectively employed to find $x^{n+1} \in X^0$,

$$\Theta(x^{n+1}, Y_{n+1}) = 0.$$

Remark 7.2. To simplify problems apprx.$\mathcal{P}[Y_n]$, $n = 1, 2, \ldots$ (i.e., to increase practical convergence properties of SMETH.ACTIV.apprx) it turns out to be useful to cluster elements in Y_n under the condition

$$| y' - y'' | < \varepsilon \ \Rightarrow y'' := y', \ y', y'' \in Y_n.$$

8. Numerical experiments for the Chebyshev approximation problem. Let us consider the linear Chebyshev approximation problem

$$\max_{y \in Y^0} \left| F(y) - \sum_{i=1}^{k} x_i z_i(y) \right| \to \min_{x \in \Re^k},$$

where Y^0 is an l-dimensional box. For the case $\dim Y^0 = 2$, we choose $z_i(\cdot)$, $i = 1, \ldots, k$, to be $k(d)$ functions

$$x_1^{i_1} x_2^{i_2}, \ i_1 + i_2 \le d, \tag{8.1}$$

or alternatively, the $k(t)$ functions

$$x_1^{i_1} x_2^{i_2}, \ 0 \le i_1, i_2 \le t. \tag{8.2}$$

For better presentation we employ the following definitions:

N: the number of iterations = number of solved problems apprx.$\mathcal{P}[Y_n]$, $n = 1, 2, \ldots, N$;

M: the number of elements in apprx.$\mathcal{P}[Y_N]$;

C: the number of elements in $\overline{Y}_n$;

v^*: $v^* := \max_{y \in Y^*} | \Phi(x^N, y) - F(y) |$, where Y^* is an equispace grid, $Y^* \subset Y^0$;

v: $v := \max_{y \in Y_N} | \Phi(x^N, y) - F(y) |$.

We consider the following examples (see [11, 20, 21]).

Example 8.1.

Data: $F(y_1, y_2) = \log(y_1 + y_2) \sin y_1$,
$Y^0 = [0, 1] \times [1, 2.5]$,
$z_i(\cdot)$ as in (8.1).

Parameters: $\gamma = 0.1$,
$\varepsilon = 0.01$, $\kappa = 0.3$, $\eta = 0.7$,
$\varepsilon_n = \max(\varepsilon_0 (1.2)^{-n}, 10^{-3})$, $n = 1, 2, \ldots$,
$\sigma_n = \varepsilon_0 (1.2)^{-n}$, $n = 1, 2, \ldots$,
$\varepsilon_0 = 2$.

Results: See Tables 8.1 and 8.2 ($| Y^* | = 10000$).

TABLE 8.1
Example 8.2, $d = 2$.

Method	N	M	C	v	v^*
SMETH.ACTIV.apprx	10	12	224	0.012091	0.012094
Nonactivated SMETH.apprx	205	218	499	0.016666	0.014092

TABLE 8.2

Example	N	M	C	v	v^*
8.2, $d = 2$	10	12	224	0.012091	0.012094
8.2, $d = 3$	14	13	226	0.001437	0.001701
8.3, $d = 2$	25	22	74	0.177449	0.178742
8.3, $d = 3$	16	15	58	0.036201	0.036202
8.4, $d = 2$	14	30	72	0.265867	0.263526

Example 8.2.
Data: $F(y_1, y_2) = (1 + y_1)^{y_2}$,
$Y^0 = [0, 1] \times [1, 2.5]$,
$z_i(\cdot)$ as in (8.1).
Parameters: See Example 8.1.
Results: See Table 8.2 ($\mid Y^* \mid = 10000$).
Example 8.3.
Data: $F(y_1, y_2, y_3) = \cos(y_3)(1 + y_1)^{y_2}$,
$Y^0 = [0, 1] \times [1, 2.5] \times [0, 1]$,
$z_i(\cdot)$ as in (8.1).
Parameters: See Example 8.1.
Results: See Table 8.2 ($\mid Y^* \mid = 1000000$).

Now we can provide some comparisons between SMETH.ACTIV.apprx and existing outer approximations methods.

Regarding methods based on passive random search procedures for finding relevant parameters we can note that the nonactivated SMETH.apprx does not work effectively even on the simplest test problem from Example 8.1. Certainly, advantages of SMETH.ACTIV.apprx over the nonactivated SMETH.ACTIV.apprx are already clear after the considerations of section 4.

Regarding methods based on active search procedures we consider results of numerical experiments reported in [21]. Recall that Reemtsen's method involves a refined active search of relevant parameters and at the nth iteration to form a simpler linear problem apprx.$\mathcal{P}[Y_{n+1}]$ it solves the following discrete inner maximization problem:

$$\mid \Phi(x^n, y) - F(y) \mid \rightarrow \max_{y \in \tilde{Y}_n},$$

where $\tilde{Y}_n$ is an equispace grid, $\tilde{Y}_n \subset Y^0$.

To present results from [21] we introduce the following definitions:

N: the number of iterations = number of solved problems $\mathcal{P}[Y_n],\ n = 1, 2, \ldots, N$ (for a run of Reemtsen's method);

M: average number of elements in $\mathcal{P}[Y_n],\ n = 1, 2, \ldots, N$ (for a run of Reemtsen's method);

v^*: $v^* := \max_{y \in \tilde{Y}} \mid \Phi(x^N, y) - F(y) \mid$, where $\tilde{Y}$ is an equispace grid, $\tilde{Y} \subset Y^0$.

TABLE 8.3

Example	Method	N	M	C	v
8.2, $d=2$	SMETH.ACTIV.apprx	10	12	224	0.012091
	Reemtsen's method	4	21	>32761	0.0280626
8.2, $d=3$	SMETH.ACTIV.apprx	14	13	226	0.001437
	Reemtsen's method	6	22	>32761	0.0034744
8.3, $d=2$	SMETH.ACTIV.apprx	25	22	74	0.177449
	Reemtsen's method	4	24	>32761	0.1776570
8.3, $d=3$	SMETH.ACTIV.apprx	16	15	58	0.036201
	Reemtsen's method	5	23	>32761	0.0365746
8.4, $d=2$	SMETH.ACTIV.apprx	14	30	72	0.265867
	Reemtsen's method	4	24	>68921	0.1524860

In the reported results

$$\mid \tilde{Y} \mid = \begin{cases} 32761 & \text{for Example 8.2,} \\ 32761 & \text{for Example 8.3,} \\ 68921 & \text{for Example 8.4} \end{cases}$$

(see [21]).
Then we set

$$\mid C \mid := \begin{cases} \mid \overline{Y}_N \mid & \text{for a run of SMETH.ACTIV.apprx,} \\ \mid \tilde{Y}_N \mid & \text{for a run of Reemtsen's method.} \end{cases}$$

The results of the comparison are presented in Table 8.3. We can see that SMETH.ACTIV.apprx was used to solve several times more simpler linear problems than Reemtsen's method (and these problems apprx.$\mathcal{P}[Y_n]$, $n = 1, 2, \ldots, N$, are somewhat more complicated for SMETH.ACTIV.apprx), but the overall efficiency of SMETH.ACTIV.apprx seems to be better due to less computational efforts paid at each iteration (note that $\mid \overline{Y}_n \mid << \mid \tilde{Y}_n \mid$, $n = 1, 2, \ldots, N$).

9. Conclusion. We suggest that important advantages of the proposed general stochastic outer approximations method consist of the following.

First, the method has been constructed for the general problem $\mathcal{P}^0$, but it can be easily essentially adapted for any special class of optimization problems involving an infinite number of constraints. Note that, for instance, SMETH.ACTIV.glob and SMETH.ACTIV.apprx (see also Remark 7.1) are specific such versions of the general method SMETH.ACTIV. Moreover, for any special class of problems some new effective optimization techniques for solving simpler problems or inner problems can be instantly employed within SMETH.ACTIV's scheme.

In forthcoming papers we intend to present versions of the general method SMETH.ACTIV for solving semi-infinite programming problems and minimax optimization problems.

Second, the construction of SMETH.ACTIV is open for further developments. Thus, since the method SMETH.ACTIV can be considered as a developed Eaves–Zangwill method applying at each iteration the multistart scheme for the search of relevant parameters (note that if the inner problems $\mathcal{JP}(x^n)$, $n = 1, 2, \ldots$, are unimodal, SMETH.ACTIV appears to be similar to the Eaves–Zangwill method), some recent advanced techniques of the multistart method can be employed to develop SMETH.ACTIV. We shall point out some of these possible refinements:

(i) To limit the growth of the descriptions of problems $\mathcal{P}[Y_n]$, $n = 1, 2, \ldots$, we can apply clustering techniques (see, for instance, [25]) in forming relevant parameter sets Y_n, $n = 1, 2, \ldots$.

(ii) To improve the efficiency of the active search of relevant parameters (see Step 1.ACTIV of SPROC.ACTIV) we can apply local descent techniques specially developed for use within the multistart method (see, for instance, [23, 29]).

A REMARK ON EXISTENCE OF SOLUTIONS OF INFINITE-DIMENSIONAL NONCOMPACT OPTIMAL CONTROL PROBLEMS*

H. O. FATTORINI†

Abstract. Without compactness of the semigroup, optimal controls for semilinear infinite dimensional control problems may not exist even under the usual convexity–lower semicontinuity assumptions. This is shown with two counterexamples, and two fixes for nonexistence are discussed.

Key words. distributed parameter systems, maximum principle

1. Introduction. Let A be the infinitesimal generator of a strongly continuous semigroup $S(t)$ in a Banach space E. It is well known that existence theorems for the semilinear control system

$$y'(t) = Ay(t) + f(t, y(t), u(t)), \qquad y(0) = \zeta, \tag{1.1}$$

with cost functional

$$y_0(t, u) = \int_0^t f_0(\tau, y(\tau), u(\tau))d\tau \tag{1.2}$$

require assumptions of two types: (a) compactness of the semigroup $S(\cdot)$ and (b) some condition such as convexity and closedness of

$$\{(z_0, z) \in \mathbb{R} \times E;\ z_0 \geq f_0(t, y, u),\ z = f(t, y, u)\ \ (u \in U)\} \tag{1.3}$$

for every t, y, where U is the control set (see [12]). Lack of convexity or closedness of (1.3) can be "repaired" using relaxed controls [4], [5], but lack of compactness of the semigroup cannot, as we show in two examples in section 2. This motivates an extension of the definition of solution discussed in section 3, a revival of Gamkrelidze's *sliding optimal states* [7]. As shown in section 4, sliding optimal states can be interpreted using measure-valued solutions of (1.1).

2. Two counterexamples. The systems are of the form

$$y'(t) = Ay(t) + f(t, y(t)) + u(t)\,, \qquad y(0) = \zeta, \tag{2.1}$$

in a separable Hilbert space H. The control set U is the unit ball of H, and the space $C_{\rm ad}(0, \bar{t}; U)$ of admissible controls consists of all strongly measurable U-valued functions defined in $0 \leq t \leq \bar{t}$. A *solution* $y(t, u) = y(t, u(\cdot))$ of (2.1) is a function in the space $C(0, \bar{t}; H)$ of H-valued continuous functions in $0 \leq t \leq \bar{t}$ satisfying the integral equation

$$y(t) = S(t)\zeta + \int_0^t S(t - \tau)\{f(\tau, y(\tau)) + u(\tau)\}d\tau. \tag{2.2}$$

(The definition includes the requirement that $\tau \to f(\tau, y(\tau))$ belong to $L^1(0, \bar{t}; H)$.) In the two examples, $y(t, u)$ exists globally and is unique for every $u(\cdot) \in C_{ad}(0, \bar{t}; U)$.

A cost functional $y_0(t, u)$ (not necessarily of the form (1.2)) is *weakly lower semicontinuous* if, for every sequence $\{u_n(\cdot)\} \subseteq C_{\mathrm{ad}}(0, \bar{t}; U)$ such that

$$u_n(\cdot) \to \bar{u}(\cdot) \in C_{\mathrm{ad}}(0, \bar{t}; U) \quad L^1(0, \bar{t}; H) \text{ -weakly} \quad \text{in } L^\infty(0, \bar{t}; H) \tag{2.3}$$

and such that $y(t, u_n)$ exists in $0 \le t \le \bar{t}$ and

$$y(\cdot, u_n) \to y(\cdot) \quad \text{in} \quad C(0, \bar{t}; H), \tag{2.4}$$

we have

$$y_0(\bar{t}, \bar{u}) \le \limsup_{n \to \infty} y_0(\bar{t}, u_n)\,. \tag{2.5}$$

Example 2.1. Consider the linear control system

$$y'(t) = Ay(t) + u(t), \quad y(0) = 0, \tag{2.6}$$

in the space $H = L^2(0, 2\pi)$. The semigroup is $S(t)y(x) = y(x + t)$ ($y(\cdot)$ continued 2π-periodically outside of $(0, 2\pi)$). This semigroup has the infinitesimal generator $Ay(x) = y'(x)$, with domain consisting of all $y(\cdot) \in H$ absolutely continuous, with square integrable derivative and $y(0) = y(2\pi)$. The operator A is skew-adjoint, and $S(t)$ is a unitary group: $S(t)^* = S(-t)$. In particular, $\|S(t)y\| = \|y\|$ for all $y \in H$. The (fixed) control interval is $0 \le t \le \pi$, there are no state constraints or target condition, and the cost functional is

$$y_0(\pi, u) = \int_0^\pi \{(S(-t)\eta, y(t, u))^2 + (t^2 - \|y(t, u)\|^2)^2\} dt, \tag{2.7}$$

where η is a fixed element of H. Weak lower semicontinuity of this functional is obvious. (In fact, (2.5) holds with equality and lim instead of lim sup.)

We construct a minimizing sequence $\{u^n(\cdot)\}$. Let

$$u^n(t) = S(t)y_n\,, \qquad y_n(x) = \frac{1}{\sqrt{\pi}} \cos nx\,. \tag{2.8}$$

Trajectories of the system are

$$y(t, u) = \int_0^t S(t - \tau)u(\tau) d\tau \tag{2.9}$$

so that

$$y(t, u^n) = tS(t)y_n\,. \tag{2.10}$$

Since $y_n \to 0$ in H weakly, the same is true of $y(t, u^n)$ for all t. On the other hand, $\|y(t, u^n)\| = t$ so that the integrand of $y_0(\pi, u_n)$ tends to zero almost everywhere (a.e.). Thus $y_0(\pi, u^n) \to 0$ by the dominated convergence theorem. Since the functional is nonnegative, $\{u^n\}$ is a minimizing sequence. However, we show below that if

$$\eta(x) = \sum_{n=0}^{\infty} e^{-n^2} \cos nx, \tag{2.11}$$

there is no optimal control.

LEMMA 2.2. *Let H be a Hilbert space and $f(\tau)$ a strongly measurable H-valued function in a measurable set e with $\|f(\tau)\| \leq 1$. Assume that*

$$\left\| \int_e f(\tau) d\tau \right\| = |e| < \infty$$

($|\cdot|$ = Lebesgue measure). Then there exists a one-dimensional subspace H_0 of H such that $f(t) \in H_0$ a.e. in e.

Proof. If this is not true and $y \neq 0$ is arbitrary, we can write

$$f(\tau) = f_0(\tau) y + g(\tau), \tag{2.12}$$

where $g(\tau)$ belongs to the orthogonal complement of the subspace generated by y and $g(t) \neq 0$ in a subset of e of positive measure. We apply (2.12) to $y = \int_e f(\tau) d\tau$. Then $(y, f(\tau)) = (y, y) f_0(\tau)$ so that $|e|^2 = (y, y) = (y, y) \int_e f_0(\tau) d\tau$. It follows that $f_0(\tau) = 1$ a.e. in e, hence $g(\tau) = 0$ a.e. in e, absurd. This ends the proof.

Assume that there is an optimal control $\bar{u}(\cdot)$. Then we must have $\|y(t, \bar{u})\| = t$, in particular $\|y(\pi, \bar{u})\| = \pi$. Since $\|S(t - \tau)\bar{u}(\tau)\| \leq 1$, we may apply Lemma 2.2 to the integral (2.9) in $e = [0, 2\pi]$ and obtain that $S(\pi - \tau)\bar{u}(\tau) = \rho(\tau) y$, where $\|y\| = 1$ and $\rho(\cdot)$ is a scalar function with $|\rho(\tau)| = 1$ a.e.; a fortiori, $\bar{u}(\tau) = S(\tau - \pi)\rho(\tau) y$. It then follows that

$$y(t, \bar{u}) = S(t - \pi) y \int_0^t \rho(\tau) d\tau \, .$$

Since $\|y(t, \bar{u})\| = t$, we must have $\rho(\tau) \equiv 1$ or $\rho(\tau) \equiv -1$. Hence

$$y(t, \bar{u}) = t S(t) z \tag{2.13}$$

with $\|z\| = 1$. Replacing in the cost functional,

$$0 = y_0(\pi, \bar{u}) = \int_0^\pi t^2 (S(-t)\eta, S(t)z)^2 dt = \int_0^\pi t^2 (S(-2t)\eta, z)^2 dt$$

so that

$$(S(-2t)\eta, z) = 0 \qquad (0 \leq t \leq \pi) \, . \tag{2.14}$$

We have $S(-2t)(\cos nx) = \cos n(x - 2t) = \cos nx \cos 2nt + \sin nx \sin 2nt$; hence (2.14) is

$$\phi(t) = \sum_{n=0}^{\infty} e^{-n^2} \left(\cos 2nt \int_0^{2\pi} z(x) \cos nx dx - \sin 2nt \int_0^{2\pi} z(x) \sin nx dx \right) = 0$$

in $0 \leq t \leq \pi$. The function $\phi(t/2)$ is then identically zero in $0 \leq t \leq 2\pi$. It has a uniformly convergent Fourier series; thus all of its Fourier coefficients must be zero, and we have

$$\int_0^{2\pi} z(x) \cos nx \; dx = \int_0^{2\pi} z(x) \sin nx \; dx = 0$$

for $n = 1, 2, \ldots$, which implies that $z(x) = 0$ a.e., a contradiction since $\|z\| = 1$.

What fails in this example is not the functional, which is weakly lower semicontinuous; the problem is that (2.4) does not hold because of lack of compactness of

the semigroup. In fact, (2.3) is trivially satisfied. (Note also that (1.3) is convex and closed for every t, y.)

Example 2.1 raises the idea of weakening the definition of weak lower semicontinuity in such a way that *weak* rather than *strong* convergence is required in (2.4). We assume below a cost functional of the form $y_0(t, y, u)$ defined for $u(\cdot) \in C_{\rm ad}(0, T; U)$ and $y(\cdot) \in C(0, T; E)$. What makes it different from the cost functionals at play until now is that $y(\cdot)$ is not necessarily the trajectory $y(\cdot, u)$. We call $y_0(t, y, u)$ *weakly-weakly lower semicontinuous* if, for every sequence $\{u_n(\cdot)\} \subseteq C_{\rm ad}(0, \bar{t}; U)$ such that (2.3) holds, $y(t, u_n)$ exists in $0 \le t \le \bar{t}$, the $y(t, u_n)$ are uniformly bounded, and

$$(y, y(t, u_n)) \to (y, \bar{y}(t)) \quad (0 \le t \le \bar{t},\ y \in H) \tag{2.15}$$

for some $\bar{y}(\cdot) \in C(0, \bar{t}; U)$, we have the inequality corresponding to (2.5):

$$y_0(\bar{t}, \bar{y}, \bar{u}) \le \limsup_{n \to \infty} y(\bar{t}, y(u_n), u_n).$$

(The definition can be generalized to a Banach space E taking $y \in E^*$.) Under this new definition, we can show an existence result for optimal problems for a linear system

$$y'(t) = Ay(t) + Bu(t)\,, \tag{2.16}$$

with A the infinitesimal generator of a strongly continuous semigroup $S(\cdot)$ in an arbitrary Banach space E. We take $B : X^* \to E$, where X is another Banach space with X^* separable, so that $L^\infty(0, T; X^*) = L^1(0, T; X)^*$ (see Remark 4.5) and assume that $B^* : E^* \to X$ and that $U \subseteq X^*$ is such that $C_{ad}(0, T; U)$ is $L^1(0, T; X)$-weakly compact in $L^\infty(0, T; X^*)$. If $\{u^n(\cdot)\}$ is a minimizing sequence, we may always assume that $\{u^n(\cdot)\}$ is $L^1(0, \bar{t}; X)$-weakly convergent in $L^\infty(0, \bar{t}; X^*)$ so that if $y^* \in E^*$ we have

$$\langle y^*, y(t, u^n)\rangle = \langle y^*, S(t)\zeta\rangle + \int_0^{\bar{t}} \langle B^* S(t - \tau)^* y^*, u^n(\tau)\rangle d\tau\,. \tag{2.17}$$

It follows that (2.15) holds; hence we can take lim sup in the cost functional. The argument is much the same as that of Lemma 1.1 in [2] for the time-optimal problem. However, the result is not generalizable to nonlinear systems, as the following example shows.

Example 2.3. Consider the control system

$$y'(t) = Ay(t) + \phi(t^2 - \|y(t)\|^2)\xi + u(t)\,, \quad y(0) = 0, \tag{2.18}$$

with the same space H, operator A, and admissible control space $C_{ad}(0, \bar{t}; U)$ as in Example 2.1. The function $\phi(s)$ is infinitely differentiable, bounded, positive for $s \ne 0$ and $\phi(0) = 0$ (for instance, $\phi(s) = s^2/(1 + s^2)$), and ξ is an arbitrary nonzero element of H. It is well known that under these assumptions solutions exist globally and are uniformly bounded for $u(\cdot) \in C_{ad}(0, T; U)$.

We consider the optimal control problem in the fixed interval $0 \le t \le 2\pi$ with cost functional

$$y_0(2\pi, u) = \int_0^{2\pi} \{(S(-t)\eta, y(t, u))^2 + (S(t)\eta, y(t, u))^2 + (S(t)\eta, u(t))^2\} dt\,, \tag{2.19}$$

and no target condition or state constraints: $\eta \in H$ is again given by (2.11). The functional $y_0(2\pi, u)$ is weakly-weakly lower semicontinuous. That this is true for the first two terms is a consequence of the dominated convergence theorem. For the third term, we note that if $\{u_n(\cdot)\}$ is a sequence in $L^\infty(0,\bar t; H)$ such that $u_n(\cdot) \to \bar u(\cdot)$ $L^1(0,\bar t; H)$-weakly in $L^\infty(0,\bar t; H)$, then $(S(\cdot)\eta, u_n(\cdot)) \to (S(\cdot)\eta, \bar u(\cdot))$ $L^1(0,\bar t)$-weakly in $L^\infty(0,\bar t)$. A fortiori, $(S(\cdot)\eta, u_n(\cdot)) \to (S(\cdot)\eta, \bar u(\cdot))$ $L^2(0,\bar t)$-weakly in $L^2(0,\bar t)$; hence,

$$\int_0^{\bar t} (S(\tau)\eta, \bar u(\tau))^2 d\tau \le \limsup_{n\to\infty} \int_0^{\bar t} (S(\tau)\eta, u_n(\tau))^2 d\tau\,.$$

The sequence (2.8) is a minimizing sequence also for this problem, that is,

$$y_0(2\pi, u_n) \to 0 \qquad \text{as} \quad n \to \infty\,. \tag{2.20}$$

That this is true for the first two terms follows from (2.13) (we have $\|y(t,u^n)\| = t^2$ for the function defined by (2.9) so that $y(t,u^n)$ solves (2.6) as well as (2.18)), the fact that $y_n \to 0$ weakly, and the dominated convergence theorem. For the third, we note that $(S(t)\eta, u^n(t)) = (S(t)\eta, S(t)y_n) = (\eta, y_n)$. These observations are of course independent of ξ.

We show below that there are no optimal controls. In fact, assume $\bar u(\cdot)$ is optimal. Then we must have

$$(S(-t)\eta, y(t,\bar u)) = (S(t)\eta, y(t,\bar u)) = (S(t)\eta, \bar u(t)) = 0 \qquad (0 \le t \le 2\pi)\,. \tag{2.21}$$

Thus

$$\begin{aligned} 0 = (S(t)\eta, y(t,\bar u)) &= \left(S(t)\eta, \int_0^t S(t-\tau)\{\phi(\tau^2 - \|y(\tau,\bar u)\|^2)\xi + \bar u(\tau)\}d\tau\right) \\ &= \int_0^t (S(t)\eta, S(t-\tau)\xi)\phi(\tau^2 - \|y(\tau,\bar u)\|^2)d\tau + \int_0^t (S(t)\eta, S(t-\tau)\bar u(\tau))d\tau \\ &= \int_0^t (S(\tau)\eta, \xi)\phi(\tau^2 - \|y(\tau,\bar u)\|^2)d\tau + \int_0^t (S(\tau)\eta, \bar u(\tau))d\tau \\ &= \int_0^t (S(\tau)\eta, \xi)\phi(\tau^2 - \|y(\tau,\bar u)\|^2)d\tau \qquad (0 \le t \le 2\pi), \end{aligned} \tag{2.22}$$

where the second integral drops out in view of the third equality (2.21). We deduce that

$$(S(t)\eta, \xi)\phi(t^2 - \|y(t,\bar u)\|^2) = 0 \qquad (0 \le t \le 2\pi). \tag{2.23}$$

Assume that

$$(S(t)\eta, \xi) = 0 \qquad (0 \le t \le 2\pi)\,. \tag{2.24}$$

Then the argument following (2.14), this time applied to ξ, reveals that $\xi = 0$, a contradiction. On the other hand, assume that (2.24) is false. Then, since the function $(S(\cdot)\eta, \xi)$ is analytic, we must have $(S(\tau)\eta, \xi) \ne 0$ a.e.; hence (2.23) and the fact that $\phi(s) > 0$ for $s \ne 0$ imply that $\|y(t,\bar u)\| = t$ a.e. By continuity, $\|y(t,\bar u)\| = t$ in $0 \le t \le 2\pi$. It follows that for the optimal control $\bar u(\cdot)$, (2.18) reduces to the linear equation (2.6) so that the trajectory corresponding to $\bar u(\cdot)$ is given by (2.13):

$y(t,\bar{u}) = tS(t)z$ with $\|z\| = 1$. The first equality (2.21) then yields $(S(-2t)\eta, z) = 0$ $(0 \le t \le 2\pi)$; we apply once again the argument after (2.14) to conclude that $z = 0$, again a contradiction.

This time, nonexistence of optimal controls is caused by the fact that the weak limit of the sequence $\{y(\cdot, u^n)\}$ is *not* the solution $y(\cdot,\bar{u})$ of (2.18), a phenomenon typical in nonlinear equations. Note that the function $u \to (y,u)^2$ is continuous and convex so that the set (1.3) is closed and convex for every t, y.

3. Sliding trajectories. Paying heed to a celebrated dictum of Hilbert [8] (in the very free translation of [14]) such problems as those in Example 2.1 and 2.3 should have a solution if "solution" is suitably defined. One way to a suitable definition is to generalize Gamkrelidze's finite-dimensional definition of "sliding optimal states" in [7]. We do this for the system (2.1) in a reflexive, separable space E with a control set $U \subseteq E$. The admissible control space $C_{ad}(0,T;U)$ is the subspace of $L^\infty(0,T;E) = L^1(0,T;E^*)^*$ (see Remark 4.5) defined by $u(t) \in U$ a.e., and we assume that $C_{ad}(0,T;U)$ is $L^1(0,T;E^*)$-weakly compact in $L^\infty(0,T;E)$; this implies, among other things, that U must be closed and bounded. (All assumptions on the control space are satisfied, for instance, if $U =$ unit ball of E.) Finally, we assume that $f(t,y)$ is continuous in y for t fixed, strongly measurable in t for y fixed and that for every $r > 0$ there exists a constant $K(r)$ such that

$$\|f(t,y)\| \le K(r) \qquad (0 \le t \le T,\ \|y\| \le r). \tag{3.1}$$

This is enough to define solutions by (2.2), although it does not guarantee even local existence or uniqueness. In this situation, $y(t,u)$ means one of the solutions of (2.1) corresponding to $u(\cdot)$ if any exist. We assume a cost functional of the form $y_0(t,y,u)$, where $u = u(\cdot) \in C_{ad}(0,\bar{t};U)$ and $y(\cdot) \in C(0,\bar{t};E)$. The definition of weak-weak lower semicontinuity is the same in section 2.

A *sliding trajectory* of (2.1) in $0 \le t \le \bar{t}$ is any E-valued continuous function $y(t)$ such that there exists a sequence $\{u^n(\cdot)\} \subseteq C_{ad}(0,\bar{t};U)$ with $y(t,u^n)$ defined in $0 \le t \le \bar{t}$, the trajectories $\{y(\cdot,u^n)\}$ are uniformly bounded, and

$$y(t) = \lim_{n\to\infty} y(t,u^n) \tag{3.2}$$

E^*-weakly in $0 \le t \le \bar{t}$. If $y_0(\bar{t},u^n)$ approaches the minimum value m of the functional, we have a *sliding optimal trajectory*, not necessarily the trajectory corresponding to any admissible control (as is the case in Examples 2.1 and 2.3). To give interest to such a definition, one should be able (i) to define the cost functional for sliding trajectories and show these provide minimizing elements in cases where ordinary trajectories fail and (ii) to prove some version of Pontryagin's maximum principle for the elements $\{u^n(\cdot)\}$ of the minimizing sequence defining the sliding optimal trajectory. We do (i) in Theorem 3.1 below and (ii) (for a particular optimal problem) in Example 3.2. In part (b) of the result below, the optimal problem may include a target condition $y(\bar{t},u) \in Y$ or state constraints $y(t,u) \in M(t)$ $(0 \le t \le \bar{t})$ as long as Y and the $M(t)$ are E^*-weakly closed. Finally, we assume that $m > -\infty$.

THEOREM 3.1. (a) *Let $\{u^n(\cdot)\}$ be an arbitrary sequence in $C_{ad}(0,\bar{t};U)$ with $\{y(t,u^n)\}$ uniformly bounded in $0 \le t \le \bar{t}$. Then, if necessary passing to a subsequence,*

$$y(t,u^n) \to \bar{y}(t)\ E^*\text{-weakly in } 0 \le t \le \bar{t} \tag{3.3}$$

where $\bar{y}(t)$ is a sliding trajectory.

(b) *If* $\{u^n(\cdot)\} \subseteq C_{ad}(0,\bar{t};U)$ *is in addition a minimizing sequence, there exists* $\bar{u}(\cdot) \in C_{ad}(0,\bar{t};U)$ *such that* $\bar{u}(\cdot)$ *is the* $L^1(0,\bar{t};E^*)$*-weak limit of (a subsequence of)* $\{u^n(\cdot)\}$ *and*

$$y_0(\bar{t},\bar{y},\bar{u}) = m \tag{3.4}$$

so that $\bar{y}(\cdot)$ *is an optimal sliding trajectory.*

Proof. Selecting a subsequence and using (3.1) we may take for granted that $\{u^n(\cdot)\}$ is $L^1(0,\bar{t};E^*)$-weakly convergent to $\bar{u}(\cdot) \in C_{ad}(0,\bar{t};U)$ and that $\{f(\cdot,y(\cdot,u^n))\}$ is $L^1(0,\bar{t};E^*)$-weakly convergent to $\Phi(\cdot) \in L^\infty(0,\bar{t};E)$. We write (2.2) for each $u^n(t)$ and each $y(t,u^n)$, apply a functional $y^* \in E^*$ to both sides, and take limits. We deduce that $y(t,u^n) \to \bar{y}(t)$ E^*-weakly for $0 \le t \le \bar{t}$, $\bar{y}(t)$ given by

$$\bar{y}(t) = S(t)\zeta + \int_0^t S(t-\tau)\Phi(\tau)d\tau \tag{3.5}$$

and thus continuous. That (3.4) holds is obvious from the definitions.

Example 3.2. We consider the time-optimal problem for (2.1) with A the infinitesimal generator of a group $S(t)$ in a Hilbert space H. The nonlinear term is strongly measurable in t for y fixed and has a Fréchet derivative $\partial_y f(t,y) \in (H,H)$ with respect to y such that $\partial_y f(t,y)z$ is strongly measurable with respect to t for y,z fixed and continuous in y for t,z fixed. Finally, for every $r>0$ there exists constants $K(r)$, $L(r)$ such that

$$\|f(t,y)\|_H \le K(r), \quad \|\partial_y f(t,y)\|_{(H,H)} \le L(r) \quad (0 \le t \le T,\ \|y\| \le r). \tag{3.6}$$

((H,H) is the space of all linear bounded operators from H into itself equipped with the operator norm.) The target condition is $y(\bar{t},u) \in Y$, $Y \subseteq E$ closed, and there are no state constraints. We assume the existence of a minimizing sequence $\{u^n(\cdot)\}$ such that

$$\operatorname{dist}(y(t_n,u^n),Y) = \varepsilon_n \to 0 \qquad \text{as} \quad n \to \infty \tag{3.7}$$

with $t_n < \bar{t}$ = optimal time, and

$$\|y(t,u^n)\| \le C \qquad (0 \le t \le t_n)\,. \tag{3.8}$$

Using Theorem 5.2 in [6] we obtain a sequence $\{\tilde{u}^n\}$, $\tilde{u}^n \in C_{\mathrm{ad}}(0,t_n;U)$ with

$$d_n(u^n,\tilde{u}^n) = |\{t \in [0,t_n]; u^n(t) \ne \tilde{u}^n(t)\}| \le \sqrt{\varepsilon}_n \tag{3.9}$$

and sequences $\{\tilde{y}^n\} \subseteq Y, \{z_n\} \subseteq E$ such that

$$\|z_n\| = 1\,, (z_n, \xi^n - w^n) \le \sqrt{\varepsilon}_n(1 + \|w^n\|) \tag{3.10}$$

for w^n in the contingent cone $K_Y(\tilde{y}^n)$ and

$$\xi^n = \lim_{h \to 0+} \frac{1}{h}(y(\bar{t},\tilde{u}^n_{s,h,v}) - y(\bar{t}))$$

for s in a set of full measure of $[0,\bar{t}]$, where $u_{s,h,v}(t)$ is the spike perturbation $u_{s,h,v}(t) = v \in U$ $(s-h < t \le s), u_{s,h,v}(t) = u(t)$ elsewhere. Going to a subsequence we may assume that $\{z_n\}$ is weakly convergent, and we have

$$z = \text{weak} \lim_{n \to \infty} z_n \ne 0 \tag{3.11}$$

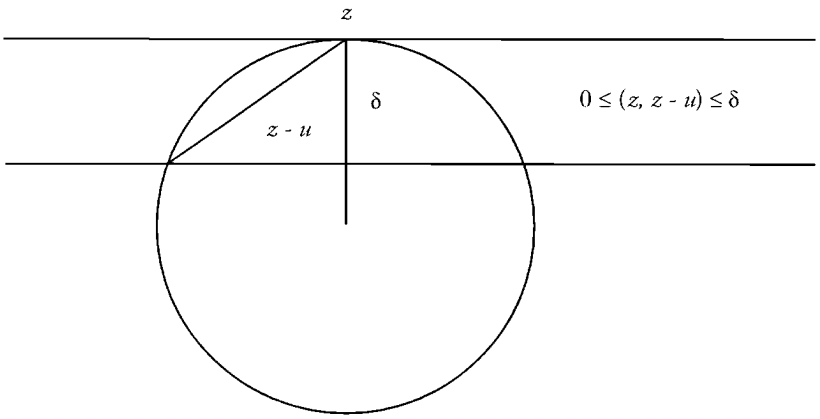

FIG. 1.

(see [3], [6]). Assumption (3.8) on global boundedness of $y(t, u^n)$, (3.9), and a simple application of Gronwall's lemma imply that the trajectories $y(t, \tilde{u}^n)$ exist globally and are uniformly bounded:

$$\|y(t, \tilde{u}^n)\| \le C \qquad (0 \le t \le t_n)\,. \tag{3.12}$$

Computing ξ^n as in [3], [6] and setting $w^n = 0$ in (3.10) we obtain

$$(S(t_n, s; \tilde{u}^n)^* z_n\,, v - \tilde{u}^n(s)) \le \sqrt{\varepsilon}_n \qquad (\|v\| \le 1) \tag{3.13}$$

a.e. in $0 \le t \le \bar{t}$, where $S(t, s; u)$ is the solution operator of the variational equation $z'(t) = \{A + \partial_y f(t, y(t, u))\}z(t)$. This inequality is exploited through the following result.

LEMMA 3.3. *Let* $\|z\| = 1$, $\|u\| \le 1$, $0 < \delta < 1$,

$$(z, v - u) \le \delta \qquad (\|v\| \le 1)\,. \tag{3.14}$$

Then

$$\|u - z\| \le \sqrt{2\delta} \tag{3.15}$$

Proof. Inequality (3.14) implies $(z, z - u) \le \delta$, while we have $(z, z - u) \ge 0$, so the proof can be read from Figure 1 and the fact that $1 - (1 - \delta)^2 + \delta^2 = 2\delta$.

We continue with Example 3.2. Since $S(t)$ is a group, the solution operator $S(t, s; u)$ is defined for $s \le t$ as well as for $s \ge t$. Moreover (3.12) implies that

$$\|S(t, s; \tilde{u}^n)\| \le C \qquad (0 \le s, t \le t_n)$$

and $S(t, s; \tilde{u}^n)^{-1} = S(s, t; \tilde{u}^n)$, thus the inverses are uniformly bounded as well. The same statements apply to the adjoint operator $S(t, s; \tilde{u}^n)^*$, so $\|S(t, s; \tilde{u}^n)^* z\| \ge c\|z\|$ $(0 \le s, t \le t_n)$ with $c > 0$. It follows from (3.10) that $\|z_n\|$ is bounded away from zero, hence

$$\|S(t_n, s; \tilde{u}^n)^* z_n\| \ge \rho > 0 \tag{3.16}$$

for n large enough.

We deduce from (3.13) divided by $\|S(t_n, s; \tilde{u}^n)^* z_n\|$, from (3.16), and from Lemma 3.3 that if we define

$$\bar{u}^n(s) = \frac{S(t_n, s; \tilde{u}^n)^* z_n}{\|S(t_n, s; \tilde{u}^n)^* z_n\|} \qquad (0 \le t \le t_n), \tag{3.17}$$

then

$$\|\tilde{u}^n(t) - \bar{u}^n(t)\| \to 0 \tag{3.18}$$

uniformly in $0 \le t \le t_n$ so that $\bar{u}^n(\cdot)$ is a minimizing sequence as well due to continuous dependence of the solution of (2.1) on the control. It finally results that although the time-optimal control problem for (2.1) may not have a solution, there exists a sequence $\{z_n\}$ with $\|z_n\| = 1$ and weak $\lim z_n \neq 0$ and such that (3.17) is a minimizing sequence; moreover, combining (3.9) with (3.18) we obtain

$$\|u^n - \bar{u}^n\|_{L^p(0,t_n)} \to 0 \tag{3.19}$$

for $p < \infty$. This may be considered "almost as good" as the maximum principle. Note, however, that the existence of a minimizing sequence with $t_n <$ optimal time is a serious restriction. Note also that it does not seem possible to extend (3.17) to $\bar{u}(s)$, the weak limit of the $u^n(s)$ in Theorem 3.1. In fact, to do this, one would have to take limits in (3.13). Weak convergence of $\{\tilde{u}^n(\cdot)\}$ could be exploited integrating against L^1 functions, but convergence of $S(t_n, s; \tilde{u}^n)^* z_n$ seems dubious in any sense.

Results for cost functionals other than time can be obtained by using the corresponding "approximate maximum principles" in [3], [6].

Applied to the systems in Examples 2.1 and 2.3 and to the minimizing sequence (2.8), the optimal sliding trajectory turns out to be $y(t) \equiv 0$ (the sequence (2.10) converges weakly to zero for all t).

4. Sliding trajectories as relaxed trajectories. In an equation like (2.1), measure-valued controls are not necessary, since the control appears linearly; what must be relaxed are the trajectories. This will be done averaging with time-dependent probability measures in accordance with the general idea of Young measures [13].

Let X be an arbitrary Banach space. $L^\infty_w(0, T; X^*)$ is the space of all X-weakly measurable X^*-valued functions $g(t)$ endowed with the norm $\|g\| =$ least c with $\langle y, g(t)\rangle \le c\|y\|$ a.e. in $0 \le t \le T$ for $y \in X$ ("a.e." depends on y). We have

$$L^1(0, T; X)^* = L^\infty_w(0, T; X^*) \tag{4.1}$$

with duality $\langle f(\cdot), g(\cdot)\rangle = \int \langle f(t), g(t)\rangle dt$. For more on the space $L^\infty_w(0, T; X^*)$ and on more general spaces see [9, p. 78]; the proof of (4.1) and more details on the duality are in [9, p. 94]. See also Remark 4.5 below, and [4], [5] for other control applications of $L^\infty_w(0, T; X^*)$.

Let B_r be the ball of center 0 and radius r in a Banach space E, and consider the space $BC(B_r)$ of bounded continuous functions in B_r equipped with the supremum norm and its dual $\Sigma_{rba}(B_r, \Phi_c)$ of all bounded, finitely additive regular measures $\mu = \mu(d\xi)$ defined in the field Φ_c generated by the closed subsets of B_r; $\Sigma_{rba}(B_r, \Phi_c)$ is furnished with the total variation norm. The duality map is $\langle f, \mu\rangle = \int_{B_r} f(\xi)\mu(d\xi)$. Applied to these spaces, (4.1) gives

$$L^1(0, T; BC(B_r))^* = L^\infty_w(0, T; \Sigma_{rba}(B_r, \Phi_c))\,. \tag{4.2}$$

Finally, let $\Pi_{rba}(B_r, \Phi_c)$ be the set of all probability measures η in $\Sigma_{rba}(B_r, \Phi_c)$ (that is, the set of measures satisfying $\eta \geq 0,\ \eta(B_r) = 1$), and let $L^\infty_w(0,T;\Pi_{rba}(B_r,\Phi_c))$ be the subspace of $L^\infty_w(0,T;\Sigma_{rba}(B_r,\Phi_c))$ consisting of all $\eta(\cdot)$ such that there exists an element $\mu(\cdot)$ in the equivalence class of $\eta(\cdot)$ in $L^\infty_w(0,T;\Sigma_{rba}(B_r,\Phi_c))$ with $\mu(t) \in \Pi_{rba}(B_r,\Phi_c)$ a.e. (For the technicalities associated with this definition see [9], [4], [5].)

We install the relaxed trajectories in (2.1) assuming that $t \to \langle y^*, f(t,\cdot)\rangle$ is a strongly measurable $BC(B_r)$-valued function for every $y^* \in E^*$ and satisfies (3.1). Below, $\eta(t, d\xi, u) = \eta(t, d\xi, u(\cdot))$ denotes an element of the space $\Pi_{rba}(B_r,\Phi_c)$ depending on $t \in [0,T]$ and $u = u(\cdot) \in C_{ad}(0,T;U)$.

Let $u = u(\cdot) \in C_{ad}(0,\bar t;U)$. Call $\eta(\cdot,u) = \eta(\cdot, d\xi, u) \in L^\infty_w(0,\bar t;\Pi_{rba}(B_r,\Phi_c))$ a *measure solution* of (2.1) in $0 \leq t \leq \bar t$ if

$$\begin{aligned}\int_{B_r} \langle y^*, \xi\rangle \eta(t, d\xi, u) &= \langle y^*, S(t)\zeta\rangle \\ &+ \int_0^t \int_{B_r} \langle S(t-\tau)^* y^*,\ f(\tau,\xi)\rangle \eta(\tau, d\xi, u) d\tau + \int_0^t \langle y^*, u(\tau)\rangle d\tau\end{aligned} \tag{4.3}$$

for all $y^* \in E^*$, $0 \leq t \leq \bar t$; for this definition to make sense, we need only the function $\tau \to \langle S(t-\tau)^* y^*, f(\tau,\xi)\rangle$ to belong to $L^1(0,t;BC(B_r))$, which follows from the hypotheses, strong continuity of the adjoint semigroup, and a simple approximation argument. The notation $\eta(t, d\xi, u)$ does not imply that, given $u(\cdot)$, there exists a unique measure solution satisfying (4.3); it indicates only the association of η and $u = u(\cdot)$ in the integral equation (4.3). The *relaxed trajectory* $y(t,\eta(u))$ corresponding to the measure solution $\eta(u) = \eta(\cdot\,, u) = \eta(\cdot, d\xi, u)$ is the E-valued function $y(t,\eta(u))$ defined by

$$\langle y^*, y(t,\eta(u))\rangle = \int_{B_r} \langle y^*, \xi\rangle \eta(t, d\xi, u) \tag{4.4}$$

for $y^* \in E^*$, $0 \leq t \leq \bar t$. Since $t \to \langle y^*, \cdot\rangle$ trivially belongs to $L^1(0,T;BC(B_r))$, $y(t,\eta(u))$ is E^*-weakly measurable and thus strongly measurable. (In fact, relaxed trajectories are continuous; see Remark 4.3.) We also have $|\langle y^*, y(t,\eta(u))\rangle| \leq r\|y^*\|$ since η is a probability measure, so that

$$\|y(t,\eta(u))\| \leq r \qquad (0 \leq t \leq \bar t)\,. \tag{4.5}$$

Usual solutions $y(t,u)$ of (2.1) with $\|y(t,u)\| \leq r$ correspond to measure solutions

$$\eta(t, d\xi, u) = \delta_{y(t,u)}(d\xi)\,. \tag{4.6}$$

The assumptions on the cost functional and the target set Y are the same in section 3; in particular, $m > -\infty$. We limit ourselves below to show that sliding trajectories are relaxed trajectories.

THEOREM 4.1. *Let $\bar y(t) = \lim y(t,u^n)$ be one of the sliding trajectories in Theorem 3.1. Then there exists a control $\bar u(\cdot)$ and a measure-valued solution $\eta(\cdot,\bar u)$ such that*

$$\bar y(t) = y(t,\eta(\bar u)).$$

Proof. Let $\eta(t, d\xi, u^n) = \delta_{y(t,u^n)}(d\xi)$. Using Alaoglu's theorem, select a (generalized) subsequence $\{u^k(\cdot), \eta(\cdot, u^k)\}$ such that

$$u^k(\cdot) \to \bar u(\cdot) \qquad L^1(0,\bar t;E^*)\text{-weakly} \quad \text{in} \quad L^\infty(0,T;E)\,, \tag{4.7}$$

$$\eta(\cdot,u^k) \to \bar\eta(\cdot) \quad L^1(0,T;BC(B_r))\text{-weakly} \quad \text{in} \quad L^\infty_w(0,T;\Sigma_{rba}(B_r,\Phi_c))\,, \tag{4.8}$$

where $\bar{\eta} \in L^\infty_w(0,T;\Pi_{rba}(B_r,\Phi_c))$; see [4]. Write (4.3) for $\eta(\cdot,u^k), u^k(\cdot)$. Convergence of the first (resp., the second) integral in (4.3) follows from (4.8) (resp., (4.7)), and we deduce that $\bar{u}(\cdot)$ and $\bar{\eta}(\cdot)$ satisfy (4.3), so $\eta(\cdot) = \eta(\cdot,\bar{u})$. This ends the proof.

Remark 4.2. The functional equation (4.3) is in some sense simpler than the original equation (2.1) (for instance, it is linear in η when $u = 0$), and the definition of solution is weaker; thus it would seem to be interesting (independently of control theory) to put conditions on $f(t,y)$ that would guarantee existence of measure-valued solutions, although perhaps not of ordinary solutions. We don't know of any such results; in fact, under the usual assumptions in control theory (those of Example 3.2) usual solutions exist and are unique (locally); measure-valued solutions only make their appearance to provide missing minima in certain problems lacking compactness (such as those in Examples 3.1 and 3.2).

Remark 4.3. Let $\varphi(\xi)$ be an E-valued function defined in B_r and such that $\langle y^*, \varphi(\xi)\rangle \in BC(B_r)$, and let $\eta(d\xi) \in \Pi_{rba}(B_r,\Phi_c)$. Define $\Phi = \int_{B_r} \varphi(\xi)\eta(d\xi) \in E$ as the only element of E satisfying

$$\langle y^*, \Phi\rangle = \int_{B_r} \langle y^*, \varphi(\xi)\rangle \eta(d\xi). \tag{4.9}$$

Then

$$\Phi = \int_{B_r} \varphi(\xi)\eta(d\xi) \in \overline{\text{conv}}(\varphi(B_r)), \tag{4.10}$$

where $\overline{\text{conv}}$ = closed convex hull (see [5]). Let

$$\Phi(\tau,u) = \int_{B_r} f(\tau,\xi)\eta(\tau,d\xi,u) \tag{4.11}$$

(the integral defined as in (4.9)). If $y^* \in E^*$, then $\tau \to \langle y^*, f(\tau,\cdot)\rangle$ belongs to $L^1(0,\bar{t};BC(B_r))$, so that $\Phi(t,u)$ is E^*-weakly measurable, hence (under the present assumptions on E) strongly measurable; moreover, $\|\Phi(\tau,u)\| \le K(r)$. It follows that y^* can be "simplified from" the integral equation (4.3) defining measure solutions; in other words, the integral equation can be written

$$y(t,\eta(u)) = S(t)\zeta + \int_0^t \{S(t-\tau)\Phi(\tau,u) + u(\tau)\}d\tau \tag{4.12}$$

and, in view of (4.10),

$$\Phi(\tau,u) \in \overline{\text{conv}}(f(\tau,B_r)) \tag{4.13}$$

a.e. in $0 \le t \le \bar{t}$ so that the role of the measure $\eta(\tau,d\xi,u)$ in the integral equation (4.3) is that of providing a (time-dependent) average of the values of $f(\tau,y)$. Not also that (4.12) shows that relaxed trajectories are continuous.

Remark 4.4. It is apparently unknown whether the relaxed trajectory corresponding to a measure-valued solution is a sliding trajectory, that is, whether it can be approximated weakly for all t by an uniformly bounded sequence of ordinary trajectories. A result of this type would be a "trajectory analogue" of the *relaxation theorems* (see [11] for finite-dimensional systems, [5] for infinite-dimensional generalizations) stating that trajectories driven by relaxed controls can be approximated by ordinary trajectories.

Remark 4.5. The space $L^\infty_w(0,T;X^*)$ has rather nonstandard properties when X is not separable; its elements $g(\cdot)$ may not be strongly measurable, even the norm function $t \to \|g(\cdot)\|$ may not be measurable, there are equivalent elements that do not coincide a.e., and the norm of $L^\infty_w(0,T;X^*)$ is not the same as the essential supremum norm. Even when X is separable, we may have $L^\infty_w(0,T;X^*) \neq L^\infty(0,T;X^*)$ (this happens for $X = C(U)$, the space of all continuous functions on a compact metric space U; the spaces $L^\infty_w(0,T;C(U)^*)$ are the basic spaces of relaxed controls in [10]). When X is separable, however, the norm function $t \to \|g(\cdot)\|$ is measurable and the essential supremum norm coincides with the norm of $L^\infty_w(0,T;X^*)$. We have $L^\infty_w(0,T;X^*) = L^\infty(0,T;X^*)$ when and only when X^* has the Radon−Nikodým property [1, Theorem 1, p. 98]; this happens for instance if X^* is separable [1, Theorem 1, p. 79] or if X is reflexive [1, Corollary 13, p. 76]. None of these "simplifications" applies here, since the space $\Pi_{rba}(B_r,\Phi_c)$ is not separable or reflexive, or even possesses the Radon−Nikodým property. Generally speaking, a space of finitely additive measures like $L^\infty_w(0,T;\Pi_{rba}(B_r,\Phi_c))$ is uncomfortably large and contains weird elements. For particular partial differential equations (rather than abstract differential equations like (2.1)), spaces of countably additive measures parameterized not only by time but by the space variables may be more suitable.

Acknowledgments. The author is most grateful to two anonymous referees for their constructive criticism, which resulted in substantial improvements to this paper.

SEQUENTIAL CONVEX SUBDIFFERENTIAL CALCULUS AND SEQUENTIAL LAGRANGE MULTIPLIERS*

LIONEL THIBAULT†

Abstract. The aim of this paper is to establish formulas for the subdifferentials of the sum and the composition of convex functions in terms of the subdifferentials of the data functions at nearby points. Applications to general optimization problems lead to a new notion of sequential Lagrange multipliers.

Key words. ε-subdifferential, sequential subdifferential calculus, sequential Lagrange multipliers

Introduction. This paper has been motivated by the two important recent contributions by Hiriart-Urruty and Phelps [10] and Attouch, Baillon, and Théra [1] to the theory of subdifferential calculus of convex functions. In [10] a general formula has been established without any qualification condition for the sum of two proper convex lower semicontinuous functions over a locally convex topological vector space X. This formula is in terms of ε-approximate subdifferentials of the functions at the fixed point. As a consequence of the study undertaken about the variational sum of maximal monotone operators another formula has been obtained in [1] in terms of exact subdifferentials at nearby points but for Hilbert spaces. This latter formula also does not require any qualification condition.

The aim of this work is twofold. First we will show how the formula by Hiriart-Urruty and Phelps can be used to get a formula in terms of exact subdifferentials at nearby points. Second, with this formula at hand, we will consider a new notion of Lagrange multipliers and we will establish existence of multipliers in this sense for general constrained convex optimization problems where no constraint qualification is assumed. These generalized multipliers appear as sequences of multipliers at nearby points and the optimality conditions that they provide are both necessary and sufficient whenever all the data of the optimization problem are convex. Note that Hanson [9] has recently showed that the existence of a similar sequence of multipliers is a sufficient condition for a point to be optimal for minimization problems with differentiable *invex* functions defined on finite-dimensional spaces. However, he did not prove at all that this condition is necessary; that is, he did not show that such a sequence of multipliers does exist at any optimal solution which does not satisfy any constraint qualification.

In section 1 we will recall the formula by Hiriart-Urruty and Phelps, and we will establish some preliminary results. Section 2 is devoted to proving our sequential formula relative to the sum of convex functions. We will also show how the already known general formulas under general qualification conditions can be derived. The composition with a vector-valued convex mapping is considered in section 3. The formula obtained for such a composition allows us to derive in section 4 the existence

†Laboratoire d'Analyse Convexe, Case Courrier 051, Université Montpellier II, 34095 Montpellier, France (thibault@math.univ-montp2.fr).

of sequential Lagrange multipliers for any general constrained convex optimization problem without any constraint qualification. We have chosen in this article to avoid the use of nets and subnets and hence all the results will be established for reflexive Banach spaces. The more general spaces will be treated in other papers.

1. Preliminary results. In this section we are going to recall the main result of Hiriart-Urruty and Phelps [10], and we will give a new version of the Brøndsted–Rockafellar theorem which will be used in section 2.

Before stating the theorem by Hiriart-Urruty and Phelps let us recall that, for any convex function f from a topological vector space X into $\mathbb{R}\cup\{+\infty\}$ and for any real number $\varepsilon \geq 0$, the ε-subdifferential of f at any point $x \in \operatorname{dom} f := \{u \in X : f(u) < \infty\}$ is defined by

$$\partial_\varepsilon f(x) = \{x^* \in X^* : \langle x^*, u - x\rangle \leq f(u) - f(x) + \varepsilon \quad \text{for all } u \in X\}.$$

If $\varepsilon = 0$ one writes $\partial f(x)$, which is then called the subdifferential of f at x. When $\operatorname{dom} f \neq \emptyset$ one says that f is proper and for $x \notin \operatorname{dom} f$ one puts $\partial_\varepsilon f(x) = \emptyset$.

THEOREM 1.1 (see Hiriart-Urruty and Phelps [10]). *Let X be a locally convex vector space and $f_1, f_2 : X \longrightarrow \mathbb{R}\cup\{+\infty\}$ be two proper lower semicontinuous convex functions. Then for any $\overline{x} \in \operatorname{dom} f_1 \cap \operatorname{dom} f_2$, one has*

$$\partial(f_1 + f_2)(\overline{x}) = \bigcap_{\varepsilon>0} \operatorname{cl}_{w^*}(\partial_\varepsilon f_1(\overline{x}) + \partial_\varepsilon f_2(\overline{x})),$$

where cl_{w^*} denotes the closure with respect to the weak-star topology of X^*.

The version in Theorem 1.3 of the Brøndsted–Rockafellar theorem (which we have not found in the form given below in the literature, although the main idea of the proof was already used in Borwein [4]) will be needed in the next section. Note that it could be proved by the result of the version of Brøndsted–Rockafellar theorem by Borwein but the proof below is simple. It will be one of the keys of the proof of Theorem 2.1. Recall first the following form of the Ekeland variational principle.

THEOREM 1.2 (see Ekeland [8]). *Let (X, d) be a complete metric space and $f : X \longrightarrow \mathbb{R}\cup\{+\infty\}$ be a lower semicontinuous function. Let $\varepsilon > 0$ and $\overline{x} \in X$ such that*

$$f(\overline{x}) \leq \inf_X f + \varepsilon.$$

Then for any $\lambda > 0$ there exists $z \in X$ such that

$$d(z, \overline{x}) \leq \lambda, \qquad |f(z) - f(\overline{x})| \leq \varepsilon,$$

$f(z) < f(x) + \lambda^{-1}\varepsilon\, d(x, z)$ for all $x \neq z$ in X.

In the proof below and in what follows we will denote by $\mathbb{B}_X$ the closed unit ball centered at zero of a Banach space X.

THEOREM 1.3 (A version of the Brøndsted–Rockafellar theorem). *Let X be a Banach space and $f : X \longrightarrow \mathbb{R}\cup\{+\infty\}$ be a proper lower semicontinuous convex function. Then for any real number $\varepsilon > 0$ and any $x^* \in \partial_\varepsilon f(\overline{x})$ there exists $(x_\varepsilon, x^*_\varepsilon) \in X \times X^*$ such that*

$$\|x_\varepsilon - \overline{x}\| \leq \sqrt{\varepsilon},\ \|x^*_\varepsilon - x^*\| \leq \sqrt{\varepsilon}, \qquad |f(x_\varepsilon) - \langle x^*_\varepsilon, x_\varepsilon - \overline{x}\rangle - f(\overline{x})| \leq 2\varepsilon,$$

and

$$x^*_\varepsilon \in \partial f(x_\varepsilon).$$

Proof. By definition we have for all $x \in X$

$$\langle x^*, x - \overline{x}\rangle \leq f(x) - f(\overline{x}) + \varepsilon$$

and hence

$$f(\overline{x}) - \langle x^*, \overline{x}\rangle \leq f(x) - \langle x^*, x\rangle + \varepsilon.$$

By the Ekeland variational principle (see Theorem 1.2) applied to the function $f - \langle x^*, .\rangle$ (with $\lambda = \sqrt{\varepsilon}$) there exists an element $x_\varepsilon \in \overline{x} + \sqrt{\varepsilon}\ \mathbb{B}_X$ such that

$$|f(x_\varepsilon) - \langle x^*, x_\varepsilon\rangle - f(\overline{x}) + \langle x^*, \overline{x}\rangle| \leq \varepsilon \tag{1.1}$$

and

$$f(x_\varepsilon) - \langle x^*, x_\varepsilon\rangle \leq f(x) - \langle x^*, x\rangle + \sqrt{\varepsilon}\ \ \|x - x_\varepsilon\|$$

for all $x \in X$. Then

$$x^* \in \partial(f + \sqrt{\varepsilon}\ \|. - x_\varepsilon\|)(x_\varepsilon) = \partial f(x_\varepsilon) + \sqrt{\varepsilon}\ \mathbb{B}_{X^*}$$

and hence there exists $x^*_\varepsilon \in \partial f(x_\varepsilon)$ satisfying $\|x^*_\varepsilon - x^*\| \leq \sqrt{\varepsilon}$. It then follows from (1.1) that

$$|f(x_\varepsilon) - \langle x^*_\varepsilon, x_\varepsilon - \overline{x}\rangle - f(\overline{x})| \leq \varepsilon + |\langle x^*_\varepsilon - x^*, x_\varepsilon - \overline{x}\rangle| \leq 2\varepsilon$$

which completes the proof. □

Remark. The usual versions of the Brøndsted–Rockafellar theorem are given without the third inequality of the above theorem. As we will see later, this inequality will be used in force in the proof of Theorem 2.1.

2. Sequential calculus for sums of convex functions. If f_1 and f_2 are two convex functions from a Banach space X into $\mathbb{R} \cup \{+\infty\}$ and if $\overline{x} \in \operatorname{dom} f_1 \cap \operatorname{dom} f_2$, we will denote by $\|\quad\| - \limsup_{u_i \overset{f_i}{\longrightarrow} \overline{x}} [\partial f_1(u_1) + \partial f_2(u_2)]$ the set all limits $\|\quad\| - \lim_{n\longrightarrow\infty}(x^*_{1,n} + x^*_{2,n})$ for which there exists $x_{i,n} \xrightarrow[n\to\infty]{\|\ \|} \overline{x}$ such that $x^*_{i,n} \in \partial f_i(x_{i,n})$ and $f_i(x_{i,n}) - \langle x^*_{i,n}, x_{i,n} - \overline{x}\rangle \underset{n\longrightarrow\infty}{\longrightarrow} f_i(\overline{x})$.

In order to avoid the use of nets we will restrict ourselves to reflexive Banach spaces. The general case will considered in another paper.

THEOREM 2.1. *Let X be a reflexive Banach space and let $f_1, f_2 : X \longrightarrow \mathbb{R}\cup\{+\infty\}$ be two proper lower semicontinuous convex functions. Then for any $\overline{x} \in \operatorname{dom} f_1 \cap \operatorname{dom} f_2$*

$$\begin{aligned}
\partial(f_1 + f_2)(\overline{x}) &= \|\quad\| - \limsup_{u_i \overset{f_i}{\longrightarrow} \overline{x}} [\partial f_1(u_1) + \partial f_2(u_2)] \\
&= w^* - \limsup_{u_i \overset{f_i}{\longrightarrow} \overline{x}} [\partial f_1(u_1) + \partial f_2(u_2)] \\
&= \big\{\|\quad\| - \lim_n (x^*_{1,n} + x^*_{2,n}) : x^*_{i,n} \in \partial f_i(x_{i,n}), x_{i,n} \xrightarrow{\|\ \|} \overline{x}, \\
&\qquad \liminf_n \gamma(x_{1,n}, x_{2,n}, x^*_{1,n}, x^*_{2,n}) \leq 0\big\} \\
&= \big\{w^* - \lim_n (x^*_{1,n} + x^*_{2,n}) : x^*_{i,n} \in \partial f_i(x_{i,n}), x_{i,n} \xrightarrow{\|\ \|} \overline{x}, \\
&\qquad \liminf_n \gamma(x_{1,n}, x_{2,n}, x^*_{1,n}, x^*_{2,n}) \leq 0\big\},
\end{aligned}$$

where $\gamma(x, y, x^*, y^*) := f_1(\overline{x}) + f_2(\overline{x}) - f_1(x) - f_2(y) + \langle x^*, x - \overline{x}\rangle + \langle y^*, y - \overline{x}\rangle$.

Proof. (1) Let us prove that the first member is included in the second one. Fix any $x^* \in \partial(f_1 + f_2)(\overline{x})$. Since X is reflexive it follows from the theorem by

Hiriart-Urruty and Phelps (see section 1) that (for $\mathbb{N}^* := \mathbb{N} \setminus \{0\}$)

$$x^* \in \bigcap_{n\in\mathbb{N}^*} \operatorname{cl}_{w^*}\left[\partial_{1/n} f_1(\overline{x}) + \partial_{1/n} f_2(\overline{x})\right] = \bigcap_{n\in\mathbb{N}^*} \operatorname{cl}_{\|\ \|}\left[\partial_{1/n}\, f_1(\overline{x}) + \partial_{1/n}\, f_2(\overline{x})\right].$$

Therefore for each $n \in \mathbb{N}^*$ we have

$$x^* \in \partial_{1,n} f_1(\overline{x}) + \partial_{1/n} f_2(\overline{x}) + \frac{1}{n}\ \mathbb{B}_{X^*}$$

and hence there exist $u^*_{i,n} \in \partial_{1/n}\, f_i(\overline{x})$ and $b^*_n \in \mathbb{B}_{X^*}$ such that

$$x^* = u^*_{1,n} + u^*_{2,n} + \frac{1}{n}\ b^*_n. \tag{2.1}$$

By the Brøndsted–Rockafellar theorem in section 1 there exists $(x_{i,n}, x^*_{i,n}) \in \operatorname{graph} \partial f$ such that

$$\|x_{i,n} - \overline{x}\| \le \frac{1}{\sqrt{n}}, \qquad \|x^*_{i,n} - u^*_{i,n}\| \le \frac{1}{\sqrt{n}},$$

and

$$|f_i(x_{i,n}) - \langle x^*_{i,n}, x_{i,n} - \overline{x}\rangle - f_i(\overline{x})| \le \frac{2}{n}.$$

We may choose $b^*_{i,n} \in \mathbb{B}_{X^*}$ satisfying $u^*_{i,n} = x^*_{i,n} + \frac{1}{\sqrt{n}} b^*_{i,n}$.

It then follows from (2.1) that

$$x^* = x^*_{1,n} + x^*_{2,n} + \frac{1}{\sqrt{n}}\left(\frac{1}{\sqrt{n}} b^*_n + b^*_{1,n} + b^*_{2,n}\right)$$

and hence $x^* = \|\ \| - \lim_n (x^*_{1,n} + x^*_{2,n})$, which completes the proof of the first inclusion.

(2) Obviously the second member is included in the third and fourth ones and the third and fourth ones are included in the fifth one. So it remains to prove that the fifth member is included in the first one. Fix any x^* in the fifth member. There exist $x_{i,n} \xrightarrow[n\to\infty]{\|\ \|} \overline{x}$, $x^*_{i,n} \in \partial\, f_i(x_{i,n})$ such that $x^* = w^* - \lim(x^*_{1,n} + x^*_{2,n})$ and $\liminf \gamma_n \le 0$, where

$$\gamma_n := f_1(\overline{x}) + f_2(\overline{x}) - f_1(x_{1,n}) - f_2(x_{2,n}) + \langle x^*_{1,n}, x_{1,n} - \overline{x}\rangle + \langle x^*_{2,n}, x_{2,n} - \overline{x}\rangle.$$

Fix any $x \in X$. Then

$$\begin{aligned}\langle x^*_{i,n}, x - \overline{x}\rangle &= \langle x^*_{i,n}, x_{i,n} - \overline{x}\rangle + \langle x^*_{i,n} x - x_{i,n}\rangle \\ &\le \langle x^*_{i,n}, x_{i,n} - \overline{x}\rangle + f_i(x) - f_i(x_{i,n})\end{aligned}$$

and hence

$$\langle x^*_{1,n} + x^*_{2,n}, x - \overline{x}\rangle \le f_1(x) + f_2(x) - f_1(\overline{x}) - f_2(\overline{x}) + \gamma_n.$$

Taking the limit inferior of both members we get

$$\langle x^*, x - \overline{x}\rangle \le (f_1 + f_2)(x) - (f_1 + f_2)(\overline{x})$$

and hence $x^* \in \partial(f_1 + f_2)(\overline{x})$. So the proof of the theorem is complete. □

A similar result has been proved by Attouch, Baillon, and Théra (see Theorem 7.3 in [1]), where it is assumed that X is a Hilbert space. Their method is completely

different and depends heavily on the use of the theory of maximal monotone set-valued operators and of the Moreau–Yosida approximations of convex functions. In a subsequent paper we will show how one can obtain a formula where instead of

$$f_i(x_{i,n}) - \langle x^*_{i,n}, x_{i,n} - \overline{x}\rangle \underset{n\to\infty}{\longrightarrow} f_i(\overline{x})$$

one requires the stronger conditions

$$f_i(x_{i,n}) \underset{n\to\infty}{\longrightarrow} f_i(\overline{x}) \quad \text{and} \quad \langle x^*_{i,n}, x_{i,n} - \overline{x}\rangle \underset{n\to\infty}{\longrightarrow} 0. \tag{2.2}$$

With this we will extend the formula as given by Attouch, Baillon, and Théra [1] to reflexive Banach spaces. We also have to mention that this will inspire us to derive from Borwein and Ioffe [5], for example, similar formulas in equality form for nonconvex functions under some regularity assumptions.

Now we are going to show how the famous sum formula under the general Robinson qualification condition can be deduced from Theorem 2.1. Here we will restrict ourselves to the reflexive case. The general nonreflexive case will be treated elsewhere. The method below may also be applied to derive directly from Hiriart-Urruty and Phelps's formula, under any known qualification condition, the exact subdifferential calculus formula. This will appear elsewhere and will also be done for many other formulas.

Recall first that a point x is in the core of a convex subset C of X if for any $y \in X$ there exists a real number $t > 0$ such that $ty + (1-t)x \in C$. This is equivalent to $\mathbb{R}_+(C - x) = X$.

We can now prove the following corollary of Theorem 2.1. It has been proved for the first time by Rockafellar [18] for reflexive spaces, and then, for any Banach space, it was a consequence of the method of Rockafellar [18] and of Corollary 1 in Robinson [17]. Another proof has also been given in Aubin and Ekeland [3].

COROLLARY 2.2. *Let X be a reflexive Banach space and $f_1, f_2 : X \longrightarrow \mathbb{R}\cup\{+\infty\}$ be two proper lower semicontinuous convex functions. If*

$$0 \in \operatorname{core}(\operatorname{dom} f_1 - \operatorname{dom} f_2),$$

then for any $\overline{x} \in X$

$$\partial\,(f_1 + f_2)(\overline{x}) = \partial\, f_1(\overline{x}) + \partial\, f_2(\overline{x}).$$

Proof. We may obviously suppose that $\overline{x} \in \operatorname{dom} f_1 \cap \operatorname{dom} f_2$. We only have to prove that the first member is included in the second one. Fix any $x^* \in \partial(f_1+f_2)(\overline{x})$. By Theorem 2.1 there exist $x_{i,n} \xrightarrow[n\to\infty]{\|\ \|} \overline{x}$, $x^*_{i,n} \in \partial\, f_i(x_{i,n})$ such that

$$x^* = \lim_n (x^*_{1,n} + x^*_{2,n}) \quad \text{and} \quad \gamma_{i,n} := f_i(x_{i,n}) - \langle x^*_{i,n}, x_{i,n} - \overline{x}\rangle \underset{n\to\infty}{\longrightarrow} f_i(\overline{x}).$$

Consider any nonzero $v \in X$ and choose $s > 0$ and $u_i \in \operatorname{dom} f_i$ such that $sv = u_1 - u_2$. Then for $x^*_n := x^*_{1,n} + x^*_{2,n}$ we have

$$\begin{aligned}
\langle x^*_{1,n}, sv\rangle &= \langle x^*_{1,n}, u_1 - \overline{x}\rangle + \langle x^*_{1,n}, \overline{x} - u_2\rangle \\
&= \langle x^*_{1,n}, u_1 - x_{1,n}\rangle + \langle x^*_{1,n}, x_{1,n} - \overline{x}\rangle + \langle x^*_{1,n}, \overline{x} - u_2\rangle \\
&\le f_1(u_1) - f_1(x_{1,n}) + \langle x^*_{1,n}, x_{1,n} - \overline{x}\rangle + \langle x^*_{1,n}, \overline{x} - u_2\rangle \\
&\le f_1(u_1) - \gamma_{1,n} + \langle x^*_n, \overline{x} - u_2\rangle + \langle x^*_{2,n}, u_2 - x_{2,n}\rangle + \langle x^*_{2,n}, x_{2,n} - \overline{x}\rangle \\
&\le f_1(u_1) - \gamma_{1,n} + \langle x^*_n, \overline{x} - u_2\rangle + f_2(u_2) - f_2(x_{2,n}) + \langle x^*_{2,n}, x_{2,n} - \overline{x}\rangle \\
&= (f_1(u_1) - \gamma_{1,n}) + (f_2(u_2) - \gamma_{2,n}) + \langle x^*_n, \overline{x} - u_2\rangle.
\end{aligned}$$

It follows that the sequence $(x^*_{1,n})_n$ is w^*-bounded. Since $x^* = \lim_n (x^*_{1,n} + x^*_{2,n})$ and X is reflexive, we may suppose (extracting subsequences) that $x^*_{i,n} \xrightarrow[n\to\infty]{}^{w^*} x^*_i$, which ensures that $x^* = x^*_1 + x^*_2$. Moreover, as the graph of ∂f_i is sequentially $\| \ \| \times w^*$-closed, we have $x^*_i \in \partial f_i(\overline{x})$. So we have proved the inclusion $\partial (f_1 + f_2)(\overline{x}) \subset \partial f_1(\overline{x}) + \partial f_2(\overline{x})$ and hence the proof is complete. □

The formula could also be derived under the Attouch and Brézis [2] qualification condition or under the general condition in Rubinov [19] and Kutateladze [14] of general position of the domains.

3. Composition of convex functions. Let Y be a Banach space and Y_+ a convex cone of Y inducing a preorder $\leq_Y$ on Y defined by $y_1 \leq_Y y_2$ if and only if $y_2 - y_1 \in Y_+$. Let $+\infty$ be an abstract maximal element adjoined to Y.

Recall that a mapping $F : X \longrightarrow Y \cup \{+\infty\}$ is convex if for all $x, x' \in X$, and $t \in]0,1[$ one has

$$F(tx + (1-t)\,x') \leq_Y t\,F(x) + (1-t)\,F(x').$$

The set dom $F := \{x \in X : F(x) \in Y\}$ is the effective domain of F, $\mathrm{Im}F := F(X)$ the effective image of F and epi $F := \{(x,y) \in X \times Y : F(x) \leq_Y y\}$ the epigraph of F.

A function $f : Y \longrightarrow \mathbb{R} \cup \{+\infty\}$ is Y_+-nondecreasing on a subset S of Y if $f(y_1) \leq f(y_2)$ for all $y_1, y_2 \in S$ satisfying $y_1 \leq_Y y_2$. By convention one puts $f(+\infty) = +\infty$. If f is convex and Y_+-nondecreasing over $\mathrm{Im}F + Y_+$, then $f \circ F$ is convex.

THEOREM 3.1. *Let X, Y be two reflexive Banach spaces and Y_+ be a convex cone of Y. Suppose that $F : X \longrightarrow Y \cup \{+\infty\}$ is a convex mapping with closed epigraph and that $f : Y \longrightarrow \mathbb{R} \cup \{+\infty\}$ is a proper convex lower semicontinuous function which is nondecreasing over* $\mathrm{Im}(F) + Y_+$. *Then for $\overline{y} := F(\overline{x}) \in \mathrm{dom}\, f$ one has $x^* \in \partial(f \circ F)(\overline{x})$ if and only if there exist $x_n \xrightarrow{\| \ \|} \overline{x}$, $y_n \xrightarrow{\| \ \|} \overline{y}$, $x^*_n \xrightarrow{\| \ \|} x^*$, $e^*_n \xrightarrow{\| \ \|} 0$, $y'_n \in F(x_n) + Y_+$ with $y'_n \xrightarrow{\| \ \|} F(\overline{x})$ and $y^*_n \in Y^*_+ := \{y^* \in Y^* : \langle y^*, y\rangle \geq 0$ for all $y \in Y_+\}$ such that*

$$y^*_n + e^*_n \in \partial\, f(y_n),\ x^*_n \in \partial\,(y^*_n \circ F)(x_n),\ \langle y^*_n, y'_n\rangle = \langle y^*_n, F(x_n)\rangle$$

and

$$f(y_n) - \langle y^*_n, y_n - \overline{y}\rangle \longrightarrow f(\overline{y}) \quad \text{and} \quad \langle y^*_n, F(x_n) - \overline{y}\rangle \longrightarrow 0.$$

Proof. Put $f_1(x,y) := f(y)$ and $f_2(x,y) := \psi(x, y\,|\mathrm{epi}\, F)$ (the indicator function of epi F). One can easily verify that $x^* \in \partial\,(f \circ F)(\overline{x})$ if and only if $(x^*, 0) \in \partial\,(f_1 + f_2)(\overline{x}, \overline{y})$ and hence if and only if there exist

$$(0, y^*_n + e^*_n) + (x^*_n, -y^*_n) \xrightarrow{\| \ \|} (x^*, 0)$$

with

$$y^*_n + e^*_n \in \partial\, f(y_n),\ (x^*_n, -y^*_n) \in \partial\, \psi(.|\mathrm{epi}\, F)(x_n, y'_n),$$

$$y_n \xrightarrow{\| \ \|} \overline{y},\ (x_n, y'_n) \xrightarrow{\| \ \|} (\overline{x}, \overline{y}),$$

$$f(y_n) - \langle y^*_n + e^*_n, y_n - \overline{y}\rangle \longrightarrow f(\overline{y}), \tag{3.1}$$

$$f_2(x_n, y'_n) + \langle y^*_n, y'_n - \overline{y}\rangle - \langle x^*_n, x_n - \overline{x}\rangle \longrightarrow f_2(\overline{x}, \overline{y}) = 0. \tag{3.2}$$

Note that (3.2) is equivalent to

$$\langle y_n^*, y_n' - \overline{y}\rangle \longrightarrow 0 \tag{3.3}$$

since $x_n^* \xrightarrow{\|\ \|} x^*$, $x_n \xrightarrow{\|\ \|} \overline{x}$, and $f_2(x_n, y_n') = 0$. Note also that $(x_n^*, -y_n^*) \in \partial\,\psi(.\,|\,\mathrm{epi}\,F)(x_n, y_n')$ means that

$$\langle x_n^*, x - x_n\rangle - \langle y_n^*, y - y_n'\rangle \leq 0 \quad \text{for all } (x,y) \in \mathrm{epi}\,F. \tag{3.4}$$

On the one hand, taking for any $y' \in Y_+$, $x = x_n$, and $y = y_n' + y'$ in (3.4) we obtain $\langle y_n^*, y'\rangle \geq 0$ and hence $y_n^* \in Y_+^*$. On the other hand taking $x = x_n$ and $y = F(x_n)$ in (3.4) we obtain $\langle y_n^*, y_n' - F(x_n)\rangle \leq 0$ and hence $\langle y_n^*, y_n' - F(x_n)\rangle = 0$ since $y_n^* \in Y_+^*$ and $y_n' - F(x_n) \in Y_+$. Then (3.4) is equivalent to

$$\langle x_n^*, x - x_n\rangle \leq \langle y_n^*, y\rangle - \langle y_n^*, F(x_n)\rangle \quad \text{for all } (x,y) \in \mathrm{epi}\,F,$$

which is equivalent to

$$\langle x_n^*, x - x_n\rangle \leq y_n^* \circ F(x) - y_n^* \circ F(x_n) \quad \text{for all } x \in \mathrm{dom}\,F,$$

since $y_n^* \in Y_+^*$. As $y_n^* \circ F$ is convex (since $y_n^* \in Y_+^*$) (3.4) is then equivalent to $x_n^* \in \partial\,(y_n^* \circ F)(x_n)$. It also follows from the equality $\langle y_n^*, y_n' - F(x_n)\rangle = 0$ that (3.3) can be rewritten as

$$\langle y_n^*, F(x_n) - \overline{y}\rangle \longrightarrow 0.$$

Finally, since $e_n^* \xrightarrow{\|\ \|} 0$ and $y_n \xrightarrow{\|\ \|} \overline{y}$, (3.1) is equivalent to

$$f(y_n) - \langle y_n^*, y_n - \overline{y}\rangle \longrightarrow f(\overline{y})$$

and hence the proof is complete. □

In case the convex mapping F is assumed to be continuous, we have the following corollary. It generalizes the result proved by Levin in [15] and also that of [7].

COROLLARY 3.2. *Let X and Y be two reflexive Banach spaces and Y_+ be a closed convex cone in Y which is normal (see [16]). Suppose that $F : X \to Y$ is a continuous convex mapping and $f : Y \longrightarrow \mathbb{R} \cup \{+\infty\}$ is a proper convex lower semicontinuous function which is nondecreasing over $\mathrm{Im}(F) + Y_+$. Then for $\overline{y} := F(\overline{x}) \in \mathrm{dom}\,f$ one has $x^* \in \partial\,(f \circ F)(\overline{x})$ if and only if there exist*

$$y_n^* \in \partial\, f(y_n) \quad \text{and} \quad x_n^* \in \partial\,(y_n^* \circ F)(x_n),$$

with

$$x_n \xrightarrow{\|\ \|} \overline{x}, \quad y_n \xrightarrow{\|\ \|} F(\overline{x}), \quad x_n^* \xrightarrow{\|\ \|} x^*,$$

$$f(y_n) - \langle y_n^*, y_n - \overline{y}\rangle \to f(\overline{y}) \quad \text{and} \quad \langle y_n^*, F(x_n) - \overline{y}\rangle \longrightarrow 0.$$

Proof. Consider $x^* \in \partial\,(f \circ F)(\overline{x})$. Let x_n, y_n, x_n^*, e_n^*, y_n', and y_n^* be given by Theorem 3.1. Put $z_n^* := y_n^* + e_n^*$ and note that

$$x_n^* \in \partial\,(y_n^* \circ F)(x_n) \quad \text{and} \quad y_n^* \circ F = z_n^* \circ F + (y_n^* - z_n^*) \circ F$$

with $y_n^* - z_n^* = -e_n^* \xrightarrow{\|\ \|} 0$. Since Y_+ is normal, then F is k-Lipschitzian (for some real number $k \geq 0$) on a neighborhood V of $\overline{x}$ (see Theorem 5 in [17], for example),

and hence $(y_n^* - z_n^*) \circ F$ is $k\|y_n^* - z_n^*\|$-Lipschitzian on V. So there exists $v_n^* \xrightarrow{\|\ \|} 0$ with $u_n^* := x_n^* + v_n^* \in \partial\,(z_n^* \circ F)(x_n)$. Moreover $u_n^* \xrightarrow{\|\ \|} x^*$, $z_n^* \in \partial\, f(y_n)$, $\langle z_n^*, F(x_n) - \overline{y}\rangle \longrightarrow 0$, and

$$f(y_n) - \langle z_n^*, y_n - \overline{y}\rangle \longrightarrow f(\overline{y}).$$

Since it is not difficult to see that the converse also holds, the proof is complete. □

Remark. With the help of (2.2) another form will be established elsewhere.

In the following corollary, F is assumed to be a continuous linear mapping A.

COROLLARY 3.3. *Let X and Y be two reflexive Banach spaces and $A : X \longrightarrow Y$ be a continuous linear mapping. Suppose that $f : Y \longrightarrow \mathbb{R} \cup \{+\infty\}$ is a proper convex lower semicontinuous function. Then for $A\,\overline{x} \in \operatorname{dom} f$ one has $x^* \in \partial\,(f \circ A)(\overline{x})$ if and only if there exist*

$$y_n^* \in \partial\, f(y_n) \quad \text{with} \quad y_n^* \circ A \xrightarrow{\|\ \|} x^*,$$

$$y_n \xrightarrow{\|\ \|} A\,\overline{x} \quad \text{and} \quad f(y_n) - \langle y_n^*, y_n - \overline{y}\rangle \longrightarrow f(A\,\overline{x}),$$

which we will translate by

$$\partial\,(f \circ A)(\overline{x}) = \|\ \| - \limsup_{y \xrightarrow{f - \langle\,,\,\rangle} A\,\overline{x}} \big[\partial\, f(y) \circ A\big].$$

Proof. Consider the sequences given by Corollary 3.2 for $Y_+ = \{0\}$. Then

$$x_n^* \in \partial\,(y_n^* \circ A)(\overline{x}) = y_n^* \circ A \quad \text{and} \quad \langle y_n^*, A\,x_n - \overline{y}\rangle = \langle y_n^* \circ A, x_n - \overline{x}\rangle,$$

and hence the condition $\langle y_n^*, A\,x_n - \overline{y}\rangle \longrightarrow 0$ is superfluous. So the proof is complete. □

A mean-value result in the spirit of Zagrodny's mean value theorem (see [22]) can be deduced from the above corollary. An equality form (instead of the inequality one in [22]) can be reached here because of the convexity assumption. This form has been proved much earlier by Borwein [4] by another method.

COROLLARY 3.4. *Let X be a reflexive Banach space and $f : X \longrightarrow \mathbb{R} \cup \{+\infty\}$ be a proper convex lower semicontinuous function. Suppose that a and b are two different points of* $\operatorname{dom} f$. *Then there exists some c in the open line segment (a, b), (c_n) in X converging to c and $x_n^* \in \partial\, f(c_n)$ such that*

$$f(b) - f(a) = \lim_{n\to\infty} \langle x_n^*, b - a\rangle.$$

Proof. Consider the classical function g defined on $\mathbb{R}$ by

$$g(t) := f(a + t(b - a)) + t(f(a) - f(b)).$$

This convex function g is lower semicontinuous on [0,1] with $g(0) = g(1)$ and hence attains its minimum on [0,1] at some point $r \in]0, 1[$. This ensures that $O \in \partial\, g(r)$, which can be rewritten as

$$f(b) - f(a) \in \partial\,(h \circ A)(r),$$

where $h(x) := f(a + x)$ and $A(t) := t(b - a)$. By Corollary 3.3 one easily sees that there exists (c_n) in X converging to $c := a + r(b - a)$ and $x_n^* \in \partial\, f(c_n)$ such that

$$f(b) - f(a) = \lim_{n\to\infty} \langle x_n^*, b - a\rangle. \qquad \square$$

4. Sequential Lagrange multipliers. In all of what follows, X and Y are two reflexive Banach spaces, K a closed convex normal cone of Y, and C a closed convex subset of X. Consider the constrained minimization problem

$$(\mathcal{P}) \qquad \text{minimize } f(x) \quad \text{subject to } x \in C \quad \text{and } F(x) \in -K,$$

where f, F are mappings from X into $\mathbb{R}$ and Y, respectively.

Generally, under some constraint qualification, for example,

$$\mathbb{R}_+[K + F(C)] \text{ is a closed vector subspace of } Y, \tag{4.1}$$

one can prove (see [7]) that there exist a real number $\lambda > 0$, $y^* \in Y^*$ with $\langle y^*, y\rangle \geq 0$ for all $y \in K$ and $\langle y^*, F(\overline{x})\rangle = 0$ such that

$$0 \in \partial\,(\lambda f + y^* \circ F + \psi(., C))(\overline{x}) \tag{4.2}$$

whenever $\overline{x}$ is a solution of $(\mathcal{P})$ and f and F are continuous (or more generally lower semicontinuous) and convex. Note that the qualification condition (4.1) is much less stringent than the classical Slater condition ($F(x_0) \in -\operatorname{int} K$ for some $x_0 \in C$) which requires the nonemptiness of the topological interior of the cone K. However, even in finite-dimensional settings, when any constraint qualification is not satisfied, one only generally proved (up to now) the necessary optimality condition corresponding to (4.2) with $\lambda = 0$; that is,

$$0 \in \partial\,(y^* \circ F + \psi(., C))(\overline{x}). \tag{4.3}$$

This condition is not sufficient at all to ensure that $\overline{x}$ is a solution of $(\mathcal{P})$, and it does not take into account the objective function f. Moreover, when the space Y is not finite dimensional (i.e., infinitely many inequality and equality constraints are considered) one generally needs some extra (or compactness-like) condition on the mapping F or the cone K (see [21]) to obtain (4.3).

In this section we are going to show how the sequential subdifferential calculus can be used to establish new necessary and sufficient optimality conditions for the problem $(\mathcal{P})$. These conditions will make appear a new form of Lagrange multipliers that we call *sequential Lagrange multipliers*. We also have to mention that Hanson has proved very recently in [9] that a certain form of sequential Lagrange multipliers is a sufficient optimality condition whenever f and F are convex (more generally invex) differentiable functions and X and Y are finite dimensional. However, Hanson did not show that there exist sequential Lagrange multipliers for the solution points. So he did not establish any sequential Lagrange necessary optimality condition.

To prove the result we will employ a method that Jourani and the author have introduced (to our knowledge for the first time in optimization) in a common work which is the last chapter of the thesis [12].

This work, whose main result has been stated in [20], has constituted the article [13]. The method consisted of reducing a constrained optimization problem to the unconstrained minimization of a composition function and to apply an appropriate formula estimating the approximate subdifferential of a composition when the data nonlinear mappings are compactly Lipschitzian. There we used the distance function in the reduction procedure. In the proof below we will use a similar reduction procedure but with the indicator function.

THEOREM 4.1. *Assume that f and F are convex and continuous. Then a point $\overline{x} \in C \cap F^{-1}(-K)$ is a solution of the minimization problem $(\mathcal{P})$ if and only if there*

exist $x_n \longrightarrow \overline{x}$, $w_n \longrightarrow \overline{x}$, $y_n \longrightarrow F(\overline{x})$, $y_n^* \in Y^*$, $u_n^* \in \partial f(x_n)$, $v_n^* \in \partial (y_n^* \circ F)(x_n)$, *and* $w_n^* \in \partial \psi(., C)(w_n)$ *such that*

(i) $\langle y_n^*, y\rangle \geq 0$ *for all* $y \in K$ *and* $\langle y_n^*, y_n\rangle = 0$,

(ii) $0 = \| \ \| - \lim_{n\to\infty}(u_n^* + v_n^* + w_n^*)$,

(iii) $\langle y_n^*, y_n - F(\overline{x})\rangle + \langle w_n^*, w_n - \overline{x}\rangle \longrightarrow 0$ *and* $\langle y_n^*, F(x_n) - F(\overline{x})\rangle + \langle w_n^*, x_n - \overline{x}\rangle \longrightarrow 0$.

Proof. It is easily seen that $\overline{x}$ is a solution of the problem $(\mathcal{P})$ if and only if $\overline{x}$ minimizes the unconstrained function

$$f + \psi(., -K) \circ F + \psi(., C) := g \circ G,$$

where $G : X \longrightarrow \mathbb{R} \times Y \times X$ and $g : \mathbb{R} \times Y \times X \longrightarrow \mathbb{R}$ are defined via

$$G(x) = (f(x), F(x), x) \text{ and } g(r, y, x) = r + \psi(y, -K) + \psi(x, C),$$

and $\psi(., C)$ is the indicator function of C. Denote by Q the closed convex normal cone $[0, \infty[\times K \times \{0_X\}$ of $\mathbb{R} \times Y \times X$. Obviously g is convex lower semicontinuous and Q-nondecreasing and G is Q-convex and continuous. Then $\overline{x}$ is a solution of $(\mathcal{P})$ if and only if $0 \in \partial g \circ G(\overline{x})$, and hence if and only if (by Corollary 3.2) there exist

$$x_n \longrightarrow \overline{x}, \ (r_n, y_n, w_n) \longrightarrow (f(\overline{x}), F(\overline{x}), \overline{x}),$$

$$(y_n^*, w_n^*) \in \partial \psi(., -K)(y_n) \times \partial \psi(., C)(w_n),$$

$$x_n^* \in \partial (f + y_n^* \circ F + \langle w_n^*, .\rangle)(x_n) = \partial f(x_n) + \partial (y_n^* \circ F)(x_n) + w_n^*$$

(that is, $x_n^* = u_n^* + v_n^* + w_n^*$ for some $u_n^* \in \partial f(x_n)$ and $v_n^* \in \partial (y_n^* \circ F)(x_n)$) such that

$$\|x_n^*\| \longrightarrow 0, \ g(r_n, y_n, w_n) - (r_n - f(\overline{x})) - \langle y_n^*, y_n - F(\overline{x})\rangle - \langle w_n^*, w_n - \overline{x}\rangle \longrightarrow g(G(\overline{x}))$$

and

$$(f(x_n) - f(\overline{x})) + \langle y_n^*, F(x_n) - F(\overline{x})\rangle + \langle w_n^*, x_n - \overline{x}\rangle \longrightarrow 0.$$

The three last relations can be rephrased, respectively, as

$$\langle y_n^*, y_n - F(\overline{x})\rangle + \langle w_n^*, w_n - \overline{x}\rangle \longrightarrow 0$$

and

$$\langle y_n^*, F(x_n) - F(\overline{x})\rangle + \langle w_n^*, x_n - \overline{x}\rangle \longrightarrow 0.$$

So $\overline{x}$ is a solution of $(\mathcal{P})$ if and only if there exist (x_n) and (w_n) converging to $\overline{x}$, $y_n \xrightarrow{\| \ \|} F(\overline{x})$, $y_n^* \in \partial \psi(., -K)(y_n)$, $w_n^* \in \partial \psi(, C)(w_n)$, $u_n^* \in \partial f(x_n)$ and $v_n^* \in \partial (y_n^* \circ F)(x_n)$ such that

$$0 = \| \ \| - \lim(u_n^* + v_n^* + w_n^*)$$

and

$$\langle y_n^*, y_n - F(\overline{x})\rangle + \langle w_n^*, w_n - \overline{x}\rangle \longrightarrow 0 \text{ and } \langle y_n^*, F(x_n) - F(\overline{x})\rangle + \langle w_n^*, x_n - \overline{x}\rangle \longrightarrow 0.$$

So the proof is complete. □

The theorem makes clear that the sequence (y_n^*) may be considered as a generalized Lagrange multiplier. It is what we call a sequential Lagrange multiplier. It does not require any constraint qualification. Moreover, its applicability does not depend on the analytical forms of the mappings defining the constraints, whereas this may often be the case with the use of constraint qualifications (see comments and examples in [9]).

WEIGHTED SENSITIVITY MINIMIZATION IN SYSTEMS WITH A SINGLE INPUT DELAY: A STATE SPACE SOLUTION*

GILEAD TADMOR†

Abstract. A differential/algebraic matrix Riccati equation–based design method is developed. The solution is reached via a parallel, two-way analysis of an underlying differential game: in the framework of both the finite order delay system and a distributed parameter, ordinary evolution model.

Key words. input delay, Nehari problem, state space solutions, matrix Riccati equations

AMS subject classifications. 49K25, 93B36, 93D21

PII. S0363012995279651

1. Introduction.

This note concerns the weighted sensitivity minimization problem when the underlying plant has a single input lag. The usual solution approach is to reduce this control design problem to a model-matching Nehari problem [16]. An account of this reduction, of the subsequent state space solution, and of relevant references in the ordinary linear, time invariant (LTI) case can be found in [9]. Extensions to ordinary linear, time varying (LTV) systems are provided in [12, 32]. This note concerns the LTI problem when an ordinary plant is cascaded with the pure delay operator. The weight function is restricted to being rational. The LTI case is selected for simplicity; LTV extensions, following the ideas outlined in [12, 32], could be readily achieved.

Transform-based solutions of the (SISO) weighted sensitivity minimization problem in delay systems were obtained during the 1980s [7, 8, 36], including extensions to the case of multiple commensurate input lags [25] and a rather restricted class of distributed input delays [24]. The main tool in these solutions is the commutant lifting theorem which is described in [22, 23]. More general frameworks for the solution of distributed parameter H_∞problems include the skew Toeplitz approach and a state space approach in which abstract evolution models are used. Sample presentations of the two approaches are, respectively, [17] and [28, 33].

A drawback of state space solutions of distributed parameter linear-quadratic (LQ) optimization problems (LQR, LQG, H_∞, etc.) is that they require the often difficult solution of operator Riccati equations. A main contribution of this note is the reduction of the operator Riccati equations that arise in the context of the weighted sensitivity minimization problem to a set of algebraic and differential matrix Riccati equations. Similar results have been previously reported in [15], which inspired the current developments. The key idea in [15] is the use of a "lifting" technique and a reduction to a finite state space discrete time model with distributed inputs and outputs. [15] provides periodic solutions to a variety of delayed H_∞problems. The advantage of the method suggested here is that the generic design in the LTI case is LTI. The approach described here has been applied in [30, 29], with a similar type

of result, to a variant of the *standard H_∞ problem* and to the problem of robustness optimization in the *gap* metric in systems that involve a pure input lag.

2. Notation. Prime will denote an adjoint of a matrix or an operator. The notation of an "$L_2[a,b]$" space will include an indication of the value space of the functions considered (e.g., $L_2([a,b],\mathbb{R}^l)$) only when ambiguous. $W_2^1[a,b]$ stands for the usual Sobolev space of absolutely continuous $L_2[a,b]$ functions with $L_2[a,b]$ derivatives. The subscript "*loc*" will have the usual "local" meaning, e.g., $-L_{2\ loc}[0,\infty)=\cap_{t>0}L_2[0,t)$. The subscript "2" will indicate the $L_2[0,\infty)$ norm. In other cases inner products and norms will be distinguished by a subscript indicating the relevant space (e.g., $\|\phi\|_{L_2[-1,0]}$). The subscript "e" will indicate the Euclidean inner product and norm. H_∞ will stand for the Hardy space of uniformly bounded, analytic functions in the right half-plane with the $L_\infty(\jmath\mathbb{R})$ norm. The spectral radius of a matrix M will be denoted $\rho(M)$. The standard notation of "u_t" will be used in reference to the single-time unit history of the trajectory at the time t: $u_t(\theta)=u(t+\theta)$, $\theta\in[-1,0]$.

3. The problem. Consider a multivariable LTI system with a transfer function $G(s)=G_0(s)e^{-s}$ and a weight function $W(s)$, where $G_0(s)$ and $W(s)$ are rational. The weighted sensitivity minimization problem concerns a search for a selection of a stabilizing compensator C (i.e., such that $S=(I+GC)^{-1}\in H_\infty$) that minimizes the H_∞ norm $\|WS\|_\infty$. In the commonly treated suboptimal version of this problem, one seeks a characterization of suboptimal values $\gamma>\gamma_0$, where

$$\gamma_0=\inf\left\{\|WS\|_\infty\ :\ S\in H_\infty\right\}, \tag{1}$$

and a parameterization of the suboptimal set,

$$\mathbf{C}_\gamma=\left\{C\ :\ S\in H_\infty \text{ and } \|WS\|_\infty<\gamma\right\}. \tag{2}$$

A standard step is the reduction of the suboptimal weighted sensitivity minimization problem to an equivalent (or close to equivalent) Nehari problem. Details of the reduction, which remains valid in the presence of an input delay in $G(s)$, can be found in [9]. Consequently, the problem addressed is stated in the following form: given a rational transfer function $\Upsilon(s)\in L_\infty(\jmath\mathbb{R})$, characterize the optimal value

$$\gamma_0=\inf\left\{\|\Upsilon(s)-e^{-s}\Theta(s)\|_{L_\infty(\jmath\mathbb{R})}\ :\ \Theta\in H_\infty\right\} \tag{3}$$

and, given $\gamma>\gamma_0$, parameterize the suboptimal set

$$\mathbf{\Theta}_\gamma=\left\{\Theta\in H_\infty\ :\ \|\Upsilon(s)-e^{-s}\Theta(s)\|_{L_\infty(\jmath)}<\gamma\right\}. \tag{4}$$

Given the focus of this note on delay systems we shall limit our attention here to choices of Θ in the class of well-posed, neutral functional differential equations (FDEs).[1] This class has been identified [31] as containing all well-posed finite memory, Euclidean space evolutions, and the restriction is made merely for convenience and cohesion in the presentation. This restriction can be easily replaced by other classes of distributed parameter systems for certain closed-loop well-posedness properties to be assured, and, in particular, it effects neither the characterization of the optimal value γ_0 nor the form of the "central compensator" in this note's main result, Theorem 4.1.

[1] The issue of well-posedness of neutral FDEs is quite involved. For the purpose of this discussion well-posedness may be interpreted as the existence of an integral, variations-of-parameters solution formula, as described in [31, Cor. E].

Let $\Upsilon = [A, B, C, D]$ be a minimal realization over the state space $\mathbb{R}^n$. In view of the assumption that $\Upsilon(s)$ has no purely imaginary poles there exists a partition of the state space as the direct sum of a stable component and an antistable component:

$$\mathbb{R}^n = X_{st} \oplus X_{as}. \tag{5}$$

Associated with this partition are block structures of the coefficients A, B, C, and D:

$$A = \begin{bmatrix} A_{st} & 0 \\ 0 & A_{as} \end{bmatrix}, \quad B = \begin{bmatrix} B_{st} \\ B_{as} \end{bmatrix}, \quad \text{and} \quad C = [C_{st} \;\; C_{as}],$$

such that $\Upsilon = \Upsilon_{st} + \Upsilon_{as}$ with $\Upsilon_{st} = [A_{st}, B_{st}, C_{st}, D]$ stable and $\Upsilon_{as} = [A_{as}, B_{as}, C_{as}, 0]$ antistable.

Let X_{as} and Y_{as} be the positive definite, infinite time, controllability and observability Gramians of the antistable component, solving

$$A_{as}X_{as} + X_{as}A_{as}' = B_{as}B_{as}' \quad \text{and} \quad Y_{as}A_{as} + A_{as}'Y_{as} = C_{as}'C_{as}. \tag{6}$$

Denote

$$P = \begin{bmatrix} 0 & 0 \\ 0 & X_{as}^{-1} \end{bmatrix} \quad \text{and} \quad Q = \begin{bmatrix} 0 & 0 \\ 0 & Y_{as}^{-1} \end{bmatrix}.$$

It is a standard observation that P and Q are positive semidefinite, stabilizing solutions of the following deficient algebraic Riccati equations (AREs):

$$PA + A'P - PBB'P = 0 \quad \text{and} \quad AQ + QA' - QC'CQ = 0. \tag{7}$$

Left and right, stable co-prime factorizations of Υ with isometric denominators are provided in terms of these solutions: $\Upsilon = {M_l}^{-1}N_l = N_r{M_r}^{-1}$, where $N_l = [A - QC'C, B - QC'D, C, D]$, $M_l = [A - QC'C, -QC', C, I]$, $N_r = [A - BB'P, B, C - DB'P, D]$, and $M_r = [A - BB'P, B, -B'P, I]$. The following expressions for γ_0 and the set $\mathbf{\Theta}_\gamma$ are written in terms of N_l and M_l:

$$\gamma_0 = \inf\left\{\|N_l(s) - M_l(s)e^{-s}\Theta(s)\|_\infty \;:\; \Theta \in H_\infty\right\} \tag{8}$$

and

$$\mathbf{\Theta}_\gamma = \left\{\Theta \in H_\infty \;:\; \|N_l(s) - M_l(s)e^{-s}\Theta(s)\|_\infty < \gamma\right\}. \tag{9}$$

4. The main result. The following abbreviations and notations are used in the statement of the main result of this note, Theorem 4.1 below. They include the notation of "ρ_0" and are well defined for $\gamma^2 > \rho_0$.

$$\begin{aligned}
\rho_0 &= \max\left\{\rho(X_{as}Y_{as}),\ \rho(D'D)\right\}, & Z_{as} &= Y_{as}^{-1} - \tfrac{1}{\gamma^2}X_{as}, \\
R &= \begin{bmatrix} 0 & 0 \\ 0 & Z_{as}^{-1} \end{bmatrix}, & E_{22} &= -(\gamma^2 I - D'D)^{-1}D', \\
E_{12} &= -\gamma(\gamma^2 I - DD')^{-\frac{1}{2}}, & E_{21} &= (\gamma^2 I - D'D)^{-\frac{1}{2}}, \\
H_1 &= \gamma(\gamma^2 I - DD')^{-\frac{1}{2}}C, & H_2 &= (\gamma^2 I - D'D)^{-1}D'C, \\
G_1 &= (B - QC'D)(\gamma^2 - D'D)^{-\frac{1}{2}}, & G_2 &= (\gamma^2 QC' - BD')(\gamma^2 I - DD')^{-1},
\end{aligned} \tag{10}$$

where the block structure of R is consistent with the state space partition (5).

THEOREM 4.1. *$\gamma > \gamma_0$ if and only if the following two conditions hold.* (a) $\gamma^2 > \rho_0$. (b) *There exists a positive semidefinite, uniformly bounded solution of the following differential Riccati equation over the interval* $[0,1]$:

$$\dot{R}_0 + R_0(A - G_2C) + (A - G_2C)'R_0 + R_0G_1G_1'R_0 + H_1'H_1 = 0, \qquad R_0(1) = R. \tag{11}$$

Suppose that, indeed, $\gamma > \gamma_0$. Then a complete parameterization of the family $\mathbf{\Theta}_\gamma$ is provided in terms of the following realization of the mapping $u = \Theta w$ in members $\Theta \in \mathbf{\Theta}_\gamma$:

$$\begin{aligned} \dot{x}_c(t) &= A_c x_c(t) + B_{c1} w(t) + B_{c2} u(t-1), \\ u(t) &= C_{c1} x_c(t) + D_{c12}\phi(t) + D_{c13} u_t, \\ \psi(t) &= C_{c2} x_c(t) + D_{c21} w(t) + D_{c22} u(t-1) + D_{c23} u_t, \qquad \phi = \Theta_0 \psi, \end{aligned} \tag{12}$$

where the coefficients are as defined below and where the design parameter is the mapping Θ_0 that is defined as the I/O mapping in a stable, neutral FDE and is selected subject to the induced norm constraint $\|\Theta_0\| < 1$.

The following instructions concern the definition of the coefficients of (12). *Given the solution $R_0(t)$ of* (11), *define $A_0(t) = A - G_2C + G_1G_1'R_0(t)$, and let $\Phi_0(t,s)$ be the transition matrix generated by $A_0(t)$. In these terms define the matrices A_c, B_{c1}, B_{c2}, C_{c1}, D_{c12}, C_{c2}, D_{c21}, and D_{c22} via*

$$\begin{aligned} A_c &= A - QC'C, & B_{c1} &= B - QC'D, \\ B_{c2} &= QC', & C_{c1} &= \left(C(I - QR) + \tfrac{1}{\gamma^2} DB'R\right)\Phi_0(1,0), \\ D_{c12} &= (2E_{12}'E_{12})^{-\frac{1}{2}}, & C_{c2} &= -G_1'R_0(0) - \tfrac{1}{\gamma} D'H_1, \\ D_{c21} &= E_{21}^{-1}, & D_{c22} &= -\tfrac{1}{\gamma} D'E_{12}. \end{aligned} \tag{13}$$

Define a matrix-valued function

$$\Xi(r) = \int_0^r \Phi_0(r,s) G_1 G_1' \Phi_0(r,s)' ds, \tag{14}$$

and let D_{c13} and D_{c23} be the following finite rank operators over $L_2[-1,0]$:

$$\begin{aligned} D_{c13}u_t &= (C(I - QR) + \tfrac{1}{\gamma^2} DB'R) \\ &\quad \cdot \int_{-1}^0 \Phi_0(1, s+1)((I + \Xi(s+1)R_0(s+1)G_2 + \Xi(s+1)H_1'E_{12})u_t(s) ds, \\ D_{c23}u_t &= -G_1' \int_{-1}^0 \Phi_0(s+1,0)'(R_0(s+1)G_2 + H_1'E_{12})u_t(s) ds. \end{aligned} \tag{15}$$

The "central" solution that generates the suboptimal family $\mathbf{\Theta}_\gamma$ in (12) is a delay system, involving both discrete and distributed delay effects in the control function. The internal dynamics in (12) are governed by *both* the differential equation in $x_c(t)$ (the first equation) and the recursion formula for $u(t)$ (the second equation). As will become clear from the proof, this structure of the central solution fits into the general

framework of a neutral FDE, but it arises *regardless* of the explicit requirement that compensators be defined by neutral FDEs. That requirement, made merely to avoid issues of well-posedness, affects only the selection of Θ_0. It is noted that this form adheres to the pattern of other previously obtained solutions of the delayed Nehari problem.

5. The proof. For any selection of $\Theta \in H_\infty$, the transfer function $N_l(s) - M_l(s)e^{-s}\Theta(s)$ has the following stable realization:

$$\begin{aligned} \dot{x}(t) &= (A - QC'C)x(t) + (B - QC'D)w(t) + QC'u(t-1), \\ z(t) &= Cx(t) + Dw(t) - u(t-1), \\ y(t) &= w(t), \qquad u = \Theta y, \end{aligned} \tag{16}$$

which, ignoring the control delay, adheres to the form of a "standard H_∞problem," with Θ being the sought controller. As is well known, due to the input delay, initial data that are needed at any given time in order to determine the solution of (16) comprise both the momentary value of the trajectory x and the single time unit history of the control input. In that sense, the true state of (16) at the time t comprises the pair $(x(t), u_t)$. Focusing on the Euclidean and the L_2 topologies, these data will be embedded with the structure of the product Hilbert space $M_2 = \mathbb{R}^n \times L_2[-1, 0]$.

5.1. A differential game. Following an approach that became standard in the treatment of H_∞ optimization problems, the test of suboptimal model matching is reduced to an equivalent differential game. The following is the basic observation.

LEMMA 5.1. *If $\gamma > \gamma_0$, then there exists a unique solution to the following differential game, given any initial data $(x(0), u_0) \in M_2$ in* (16)*:*

$$\inf_{w \in L_2[0,\infty)} \left\{ \gamma^2 \|w\|_2^2 - \inf_{u \in L_2[0,\infty)} \|z\|_2^2 \right\}, \tag{17}$$

where the data for the internal optimization problem (over u) comprises both the initial data $(x(0), u_0)$ and the selection of w.

A brief outline of the proof. The basic ideas are the same as in the ordinary case. Details can be found in [27, 28]. The statement $\gamma > \gamma_0$ is equivalent to the existence of $\Theta \in H_\infty$ such that $\|N_l - M_l e^{-s}\Theta\|_\infty < \gamma$. This bound holds, in turn, if and only if there exists $\lambda > 0$ such that

$$\gamma^2 \|w\|_2^2 - \|z\|_2^2 \geq \lambda^2 \|w\|_2^2 \tag{18}$$

for any $w \in L_2[0, \infty)$, $u = \Theta w$, and with the zero initial data in (16). Assuming that $\gamma > \gamma_0$, the validity of (18) with $u = \Theta w$ (for some choice of Θ) leads to the following stronger, open-loop inequality:

$$\gamma^2 \|w\|_2^2 - \inf_{u \in L_2[0,\infty)} \|z\|_2^2 \geq \lambda^2 \|w\|_2^2. \tag{19}$$

As can be easily seen, the delay in u does not affect the solvability of the optimization problem in (19) and thus the arguments in [27, 28]. In particular, one can use (19) to show that the assumption "$\gamma > \gamma_0$" leads to existence and uniqueness of a solution of (17). □

Notice that in the open-loop context of (17), there is no requirement of causality in the dependence of the optimal selection of u on w.

5.2. Explicit solution of the differential game problem. The differential game (17) will be divided into two subproblems. One subproblem concerns input effects on $z(t)$ prior to $t = 1$. The other subproblem concerns such effects for $t > 1$.

It is observed that the selection of $u(t)$, $t \geq 0$, has no effect on the values of $z(t)$, $t \leq 1$. Once the initial data and $w(t)$, $t \in [0, 1]$, are fixed, the component of (17) that is determined by the selection of $w(t)$, $t > 1$, and of $u(t)$, $t > 0$, reduces to an equivalent problem that does not involve control delay, as follows. Denote $\tilde{u}(t) = u(t-1)$. Then, over the positive ray $t > 1$, there holds

$$\begin{array}{rcccccc} \dot{x} & = & (A - QC'C)x & + & (B - QC'D)w & + & QC'\tilde{u}, \\ z & = & Cx & + & Dw & - & \tilde{u}. \end{array} \tag{20}$$

The important fact is that the only constraint in (20) is the initial value of $x(1)$, as determined by $x(0)$, u_0, and the restriction of $w(t)$ to the interval $[0, 1]$. With (20) as the underlying system and given $x(1)$, the solution of (17) must define a solution of the following min-max problem:

$$\inf_{w \in L_2[1,\infty)} \left\{ \gamma^2 \|w\|^2_{L_2[1,\infty)} - \inf_{\tilde{u} \in L_2[1,\infty)} \|z\|^2_{L_2[1,\infty)} \right\}. \tag{21}$$

Problem (21) can be considered over the following alternative state space realization, where z is considered as the "control input":

$$\dot{x} = Ax + Bw - QC'z. \tag{22}$$

In this setting the optimal selection of $\tilde{u} \in L_2[1, \infty)$ is replaced by an optimal selection of $z \in L_2[1, \infty)$, subject to the additional qualitative requirement that the associated state of (22) be a member of $L_2[1, \infty)$.

This is precisely the framework to which one can reduce the ordinary version of the model-matching problem $\|N_l - M_l Q\|_\infty < \gamma$. Detailed analysis can be found, e.g., in [32]. The conclusions are summarized as follows.

THEOREM 5.2. *The infimum of values of γ for which the problem* (21) *has a finite solution is $\hat{\gamma} = \rho(X_{as}Y_{as})$. Given $\gamma > \hat{\gamma}$, define R as in* (10). *Then R is the unique, positive semidefinite solution of the deficient ARE,*

$$RA + A'R + R\left(\frac{1}{\gamma^2}B'B - QC'CQ\right)R = 0, \tag{23}$$

with the property that $A_1 = A + (\frac{1}{\gamma^2}B'B - QC'CQ)R$ is stable. Equivalently, $\gamma > \hat{\gamma}$ if and only if there exists a unique, $L_2[1, \infty)$ norm bounded solution to the following Hamilton–Jacobi–Bellman problem:

$$\begin{array}{rcccc} \dot{x} & = & Ax & + & \left(\frac{1}{\gamma^2}B'B - QC'CQ\right)p, \\ \dot{p} & = & & & -A'p \end{array} \tag{24}$$

given any specified initial value $x(1) \in \mathbb{R}^n$. That solution is characterized by the relation $p(t) = Rx(t)$, $t \geq 1$. A complete parameterization of the suboptimal set $\{\Theta \in H_\infty \ : \ \|N_l - M_l\Theta\|_\infty < \gamma\}$ is provided by the following realization:

$$\begin{array}{rcccccccc} \dot{x}_c & = & (A - QC'CQR)x_c & + & Bw & - & QC'\phi, & & \\ \tilde{u} & = & C(I - QR)x_c & + & Dw & - & \phi, & & \\ \psi & = & -\frac{1}{\gamma^2}B'Rx_c & + & w, & & & \phi = \Theta_0\psi, \end{array} \tag{25}$$

where the free design parameter, the stable system Θ_0*, is selected subject to the induced* L_2 *norm bound* $\|\Theta_0\| < \gamma$*. Moreover, given any selections* $w, \tilde{u} \in L_{2,loc}[1,\infty)$ *and* $t > r \geq 1$*, there holds*

$$\gamma^2\|w\|^2_{L_2[r,t]} - \|z\|^2_{L_2[r,t]} = \langle x(\alpha), Rx(\alpha)\rangle_e \Big|_{\alpha=r}^{\alpha=t} + \gamma^2\|w^{\triangle}\|^2_{L_2[r,t]} - \|\tilde{u}^{\triangle}\|^2_{L_2[r,t]}, \tag{26}$$

where, given the associated state x *in* (20)*, the trajectories* $w^{\triangle}$ *and* $\tilde{u}^{\triangle}$ *are defined as*

$$w^{\triangle} = w - \frac{1}{\gamma^2}B'Rx \qquad \text{and} \qquad \tilde{u}^{\triangle} = C(I-QR)x + Dw - \tilde{u}. \tag{27}$$

The solution to the open loop min-max game (21) *is given by the optimal selections* $w^{\triangle} = 0$ *and* $\tilde{u}^{\triangle} = 0$*; namely,*

$$w(t) = \frac{1}{\gamma^2}B'Rx(t) \quad \text{and} \quad u(t-1) = \tilde{u}(t) = \left(C(I-QR) + \frac{1}{\gamma^2}DB'R\right)x(t), \tag{28}$$

and the optimal value of the game is $-\langle x(1), Rx(1)\rangle_e$*.*

Obviously, the infimal value of γ for which a solution exists in (17) is at least the infimal value $\hat{\gamma}$ from (21). That is, $\gamma_0 \geq \hat{\gamma}$. Substituting $-\langle x(1), Rx(1)\rangle_e$ for the optimal value of the game (21) in (17), the original differential game (17) reduces to the following finite time optimization problem with the data $(x(0), u_0) \in M_2$:

$$\inf_{w\in L_2[0,1]} \left\{\gamma^2\|w\|^2_{L_2[0,1]} - \|z\|^2_{L_2[0,1]} - \langle x(1), Rx(1)\rangle_e\right\}. \tag{29}$$

When $\gamma > \rho_0$, the following equality is obtained by direct completion-of-squares computation and is used to simplify notation later on. There holds

$$\gamma^2\|w\|^2_{L_2[0,1]} - \|z\|^2_{L_2[0,1]} - \langle x(1), Rx(1)\rangle_e = \|\bar{w}\|^2_{L_2[0,1]} - \|\bar{z}\|^2_{L_2[0,1]} - \langle x(1), Rx(1)\rangle_e, \tag{30}$$

where

$$\bar{z}(t) = H_1x(t) + E_{12}u(t-1) \qquad \text{and} \qquad \bar{w}(t) = E_{21}^{-1}w(t) - \frac{1}{\gamma}D'\bar{z}(t). \tag{31}$$

Subject to these definitions, (16) becomes

$$\begin{array}{rcccccccc} \dot{x}(t) & = & (A-G_2C)x(t) & + & G_1\bar{w}(t) & + & G_2u(t-1), & & \\ \bar{z}(t) & = & H_1x(t) & + & & + & E_{12}u(t-1), & & \\ y(t) & = & H_2x(t) & + & E_{21}\bar{w}(t) & + & E_{22}u(t-1), & u = \Theta y, & \end{array} \tag{32}$$

where the abbreviated notation of (10) is used. Problem (29) can then be stated, equivalently, in the following form:

$$\inf_{\bar{w}\in L_2[0,1]} \left\{\|\bar{w}\|^2_{L_2[0,1]} - \|\bar{z}\|^2_{L_2[0,1]} - \langle x(1), Rx(1)\rangle_e\right\}. \tag{33}$$

Theorem 5.3, below, is based on results from [14, 26].

THEOREM 5.3. *Let* $\gamma > \hat{\gamma}$*. Then there exists a unique solution of the differential game* (17) *and, consequently, of the optimization problem* (29)*, given any data pair* $(x(0), u_0) \in M_2$*, if and only if conditions* (a) *and* (b) *in the statement of Theorem* 4.1 *are satisfied. Assume that to be the case. Then, for any initial data* $(x(0), u_0) \in M_2$*, there exists a unique* $L_2[0,1]$ *solution for the following Hamilton–Jacobi–Bellman problem:*

$$\begin{array}{rcccccc} \dot{x}(t) & = & (A-G_2C)x(t) & + & G_1G_1'p(t) & + & G_2u(t-1), \\ \dot{p}(t) & = & -H_1'H_1x(t) & - & (A-G_2C)'p(t) & - & H_1'E_{12}u(t-1) \end{array} \tag{34}$$

subject to the terminal constraint $p(1) = Rx(1)$. *In the particular case where* $u_0 = 0$, *the state and co-state of* (34) *are related via* $p(t) = R_0(t)x(t)$, *where* R_0 *is the solution of* (11). *The optimal selection of* w *in the problem* (29), *and the corresponding optimal selection of* $\bar{w}$ *in the problem* (33), *are then*

$$\bar{w}(t) = G_1'p(t) \qquad \textit{and} \qquad w(t) = H_2x(t) + E_{21}G_1'p(t) + E_{22}u(t-1). \tag{35}$$

The proof of necessity in Theorem 4.1 will be complete once the necessity claim in Theorem 5.3 is established. The detailed characterization of the solution of (29) is provided in preparation for the proof of the sufficiency claim in Theorem 4.1.

Proof. In the proof of necessity of the conditions (a) and (b) of Theorem 4.1 for solvability of (29), it certainly suffices to establish the same for the particular case of $u_0 = 0$. Referring to that case, it has been established in [14, 26] that a solution of (29) exists if and only if the induced norm of the mapping $\bar{w} \mapsto (R^{\frac{1}{2}}x(1), \bar{z})$: $L_2[0,1] \mapsto \mathbb{R}^n \times L_2[0,1]$ is smaller than 1, which, in turn, holds if and only if $\gamma^2 > \rho(D'D)$ and the differential Riccati equation (11) has a bounded solution. It is also a standard observation, used in [14, 26], that the state and co-state of the homogeneous (34) are related via $p = R_0x$ (when R_0 exists). The proof of necessity is therefore complete.

The fact that all solutions of (29) (hence, eventually, of (17)), should they exist, are characterized by (34) via (35), is a standard observation which can be established following the arguments in [14, 26] (or any other variant argument of the "Lagrange multiplier" type). Similarly, should a solution of (34) exist, it is a basic fact from optimal control theory that such a solution defines a solution of (29), as explained above. It remains to show that if $\gamma > \rho_0$ and a solution of (11) exists, then there also exists a unique solution of the inhomogeneous (34), given any initial data $(x(0), u_0) \in M_2$.

Indeed, let the definitions of the matrix function $A_0(t)$, and of the transition matrix $\Phi_0(t,s)$ that is generated by A_0, stand, as made in the statement of Theorem 4.1. Then let x and q be defined by the following boundary value problem:

$$\begin{array}{rcccccc} \dot{x}(t) & = & A_0(t)x(t) & - & G_1G_1'q(t) & + & G_2u(t-1), \\ \dot{q}(t) & = & & - & A_0(t)'q(t) & + & (R_0(t)G_2 + H_1'E_{12})u(t-1) \end{array} \tag{36}$$

subject to the specified initial value $x(0)$ and the terminal value $q(1) = 0$. Existence, uniqueness, and boundedness of the solution are guaranteed in (36) due to the fact that the second equation is independent of the first. All that remains is to observe that solutions of (34) and those of (36) are related by the equality $p = R_0x - q$. The proof is complete. □

This completes the proof of necessity of conditions (a) and (b) in Theorem 4.1 for γ to be a suboptimal value. From this point on the discussion continues under the assumption that conditions (a) and (b) in Theorem 4.1 are satisfied by a specified γ. In particular, solvability of both (23) and (11), of the differential game (17), and of the allied optimization problem (29) is assumed. The explicit goal of the ensuing analysis will be to establish the validity of the parameterization (12) of the suboptimal class $\mathbf{\Theta}_\gamma$, and thus, constructively, the sufficiency of the stated conditions for the inequality $\gamma > \gamma_0$.

LEMMA 5.4. *Fix* γ *satisfying conditions* (a) *and* (b) *in Theorem* 4.1, *and let the definitions made heretofore stand. Let* x, w, *and* u *be the optimal trajectories in the solution of* (17) *along* $[0,\infty)$; *let* p *be defined as the co-state trajectory in* (34), *along* $[0,1]$, *continued by the co-state trajectory of* (24) *along* $(1,\infty)$; *and let* $\bar{w}$ *be the*

allied trajectory, as defined in (31). *Then the following hold.* (a) *The co-state* $p(t)$ *is continuous.* (b) *The pair* (x,p) *satisfies the Hamilton–Jacobi–Bellman boundary value problem* (34) *when shifted from* $[0,1]$ *to any interval* $[t,t+1]$, $t>0$. (c) *At any given time* $t\geq 0$, *the values of* $p(t)$, $\bar{w}(t)$, *and* $u(t)$ *are determined by the pair* $(x(t),u_t)\in M_2$ *via*

$$p(t)=R_0(0)x(t)+\int_0^1\Phi_0(r,0)'(R_0(r)G_2+H_1'E_{12})u_t(r-1)dr, \tag{37}$$

$$\bar{w}(t)=G_1'\left(R_0(0)x(t)+\int_0^1\Phi_0(r,0)'(R_0(r)G_2+H_1'E_{12})u_t(r-1)dr\right), \tag{38}$$

$$\begin{aligned}u(t)=\left(C(I-QR)+\frac{1}{\gamma^2}DB'R\right)\cdot\Bigg(&\Phi_0(1,0)x(t)\\&+\int_0^1\Phi_0(1,r)((I+\Xi(r)R_0(r))G_2+\Xi(r)H_1'E_{12})u_t(r-1)dr\Bigg),\end{aligned} \tag{39}$$

where $\Xi(t)$ *is as defined in* (14). *For future reference we introduce the notations of matrices* K^0 *and* L^0 *and operators* K^1 *and* L^1 *over* $L_2[-1,0]$ *such that* (38) *and* (39) *are abbreviated as*

$$\begin{aligned}&\bar{w}(t)=L^0x(t)+L^1u_t,\qquad w(t)=(H_2+E_{21}L^0)x(t)+E_{21}L^1u_t+E_{22}u(t-1),\\&\qquad\qquad\qquad\qquad\text{and}\quad u(t)=K^0x(t)+K^1u_t.\end{aligned} \tag{40}$$

(d) *Combined, the complete state feedback expressions* (38) *and* (39) *are defining a stabilizing feedback policy in* (32) *and provide for exponential decay of the complete state*

$$\|f(t)\|_{M_2}\leq\alpha e^{-\beta t}\|f(0)\|_{M_2}, \tag{41}$$

where $f(t)=(x(t),u_t)$ *and where* $\alpha>0$ *and* $\beta>0$ *are appropriately selected and fixed constants.* (e) *The optimal value of* (17)–(29) *is given by the quadratic form* $-\langle f(0),\mathcal{R}f(0)\rangle_{M_2}$, *where* $f(0)=(x(0),u_0)$ *comprises the specified initial data and where* $\mathcal{R}$ *is the bounded, positive semidefinite operator on* M_2 *that is defined in terms of the solution of* (34), *as* $\mathcal{R}(x(0),u_0)=(p(0),\ E_{12}'(H_1x(\cdot+1)+E_{12}u_0(\cdot))+G_2'p(\cdot+1))$.

Proof. We have already established that the optimal state trajectory of (16) coincides with the state of (24) along $[1,\infty)$ and with the state of (34) along the ray $[0,1]$. The co-state in (24) is related to the state via $p=Rx$, and in (34) it is required to satisfy the terminal condition $p(1)=Rx(1)$. Hence the continuity of p, which is claim (a) in the statement of Lemma 5.4.

The purpose of the following observations is to show that the optimal trajectories x, u, and the associated p satisfy (34) when shifted to any interval $[t,t+1]$. First, using (31), the optimal selections in (28) translate to $\bar{w}(t)=G_1'Rx(t)$, $t\geq 1$. Thus the expression (35) for the optimal $\bar{w}$ is valid for all $t\geq 0$.

Second, using the expression in (28) for $u(t-1)$, substituting Rx for p, and taking into account the precise definitions of G_1 and G_2 in (10), the state equation in (34) becomes a stable, homogeneous ODE

$$\dot{x}=A_1x, \tag{42}$$

where $A_1 = A - (\frac{1}{\gamma^2}B'B - QC'CQ)R$, as defined in the statement of Theorem 5.2. Now substitute p for Rx in (42); this equation takes the shape of the state equation in (24). In short, we have established that the triplet x, p, and u satisfies the state equation in (34) throughout the positive ray $t \geq 0$.

Third, the combination of the expression (28) for $u(t-1)$ and of $p = Rx$ provides for the equality $C'G_2'p(t) - H_1'(H_1x(t) + E_{12}u(t-1)) = 0$, for all $t \geq 1$. Thus the co-state equation of (34) reduces to the co-state equation in (24). In particular, the triplet x, p, and u satisfies the co-state equation in (34) throughout the positive ray $t \geq 0$. This completes the proof of claim (b) in Lemma 5.4.

We shall now provide explicit expressions for the solution of (34), shifted to the interval $[t, t+1]$, in terms of the data $(x(t), u_t)$. These expressions are obtained by a straightforward manipulation of the variations-of-parameters formula, beginning with the second equation in (36), continuing with the first equation in the same system, and then substituting $p = R_0x - q$:

$$q(t+r) = -\int_r^1 \Phi_0(s,r)'(s)(R_0(s)G_2 + H_1'E_{12})u_t(s-1)ds, \tag{43}$$

$$\begin{aligned} x(t+r) = \Phi_0(r,0)x(t) &+ \int_0^r \Phi_0(r,s)((I + \Xi(s)R_0(s))G_2 + \Xi(s)H_1'E_{12})u_t(s-1)ds \\ &+ \ \Xi(r)\int_r^1 \Phi_0(s,r)'(R_0(s)G_2 + H_1'E_{12})u_t(s-1)ds, \end{aligned} \tag{44}$$

$$\begin{aligned} p(t+r) = R_0(r)\Phi_0(r,0)x(t) &\\ &+ \ R_0(r)\int_0^r \Phi_0(r,s)((I + \Xi(s)R_0(s))G_2 + \Xi(s)H_1'E_{12})u_t(s-1)ds \\ &+ \ (I + R_0(r)\Xi(r))\int_r^1 \Phi_0(s,r)'(R_0(s)G_2 + H_1'E_{12})u_t(s-1)ds. \end{aligned} \tag{45}$$

Substituting $r = 0$ in (45) one obtains the expression (37) for $p(t)$. The expression (38) is then a consequence of the relation $\bar{w} = G_1'p$. The expression (39) is obtained by substituting $r = 1$ in (44) and then using (28) to characterize $u(t)$ in terms of $x(t+1)$. This completes the proof of claim (c) in Lemma 5.4.

To establish the stability claim we first make note of the fact that the coupling of the complete state feedback expressions (38) and (39) with the state equation of (32) forms a well-posed integrodifferential equation. The uniqueness of its solution forces it to coincide with the trajectories that are associated with the solution of (17), as discussed above. Once again, it is also noticed that for $t \geq 1$ the trajectory of the optimal $x(t)$ is governed by the homogeneous, stable ODE (42). Invoking (28), there must exist positive α and β such that, for all $t \geq 1$, the following holds:

$$\|u(t-1)\|_e, \ \|x(t)\|_e \leq \alpha e^{-\beta(t-1)}\|x(1)\|_e. \tag{46}$$

Continuity of the mapping $(x(0), u_0) \mapsto (x(1), x(\cdot), u(\cdot)) : M_2 \mapsto \mathbb{R}^n \times L_2[0,1] \times L_2[0,1]$ is obvious from (44) and (39). Thus (with a possible need for a modification of α), the expression (46) leads to (41), and part (d) of Lemma 5.4 is established.

To compute the optimal value in (17)–(29) we first introduce notations of operators $\mathcal{M}$, $\mathcal{N}$, and $\mathcal{J}$. The definition $\mathcal{M}(x(0), p(0), u_0) = (x(1), x(\cdot), p(\cdot), u_0(\cdot + 1))$ is

made where the pair (x,p) defines the solution of (34), viewed as a causal initial value problem with the data $(x(0),p(0),u_0)$. The mapping $\mathcal{N}(x(0),u_0)=(x(0),p(0),u_0)$ translates the original data for the boundary value problem (34) to initial data, using (37) with $t=0$. The operator $\mathcal{J}$ is represented by the matrix

$$\mathcal{J}=\begin{bmatrix} R & 0 & 0 & 0\\ 0 & H_1'H_1 & 0 & H_1'E_{12}\\ 0 & 0 & -G_1'G_1 & 0\\ 0 & E_{12}'H_1 & 0 & E_{12}'E_{12}\end{bmatrix}. \tag{47}$$

In these terms the solution (x,p) of the boundary value problem (34) is satisfying $\mathcal{MN}(x(0),u_0)=(x(1),x(\cdot),p(\cdot),u_0(\cdot+1))$ and there holds $\mathcal{JMN}(x(0),u_0)=(Rx(1),H_1'\bar{z},-G_1'\bar{w},E_{12}'\bar{z})$, where $\bar{z}(t)=H_1x(t)+E_{12}u(t-1)$ and $\bar{w}(t)=G_1'p(t)$. It is a summary of our results heretofore that the optimal value of the cost functional in (33), hence in (29), is $-\langle\mathcal{MN}f(0),\,\mathcal{JMN}f(0)\rangle_{M_2}$. We thus denote $\mathcal{R}=\mathcal{N}'\mathcal{M}'\mathcal{JMN}$ and continue to show that $\mathcal{R}$ is realized by the solution of (34), as stated in the theorem. The following observations are made to that end.

The computation of the conjugate of the I/O operator that is defined in terms of a causal system is straightforward. In the case of $\mathcal{M}$, the relation $(\phi^1,\phi^2,\phi^3)=\mathcal{M}'(\psi^1,\psi^2,\psi^3,\psi^4)$ is characterized by $\phi^1=p_1(0)$, $\phi^2=-x_1(0)$, $\phi^3(\cdot)=E_{12}'H_1x_1(\cdot)+G_2'p_1(\cdot)+\psi^4(\cdot+1)$, where the pair (x_1,p_1) provides a solution of the following variant of (34):

$$\begin{aligned}\dot{x}_1 &= (A-G_2C)x_1 + G_1G_1'p_1 + \psi^3,\\ \dot{p}_1 &= -H_1'H_1x_1 - (A-G_2C)'p_1 - \psi^2,\end{aligned} \tag{48}$$

subject to the terminal conditions $x_1(1)=0$ and $p_1(1)=\psi^1$. In particular, when $(\psi^1,\psi^2,\psi^3,\psi^4)=\mathcal{JMN}(x(0),u_0)$, the pair (x_1,p_1) is defined in terms of the following system:

$$\begin{aligned}\dot{x}_1(t) &= (A-G_2C)x_1(t) + G_1G_1'(p_1-p)(t),\\ \dot{p}_1(t) &= -H_1'H_1(x+x_1)(t) - (A-G_2C)'p_1(t) - H_1'E_{12}u(t-1),\end{aligned} \tag{49}$$

with (x,p) from the original solution of (34), $x_1(1)=0$, and $p_1(1)=Rx(1)$. Denoting $x_2(t)=x(t)+x_1(t)-\Phi_0(t,0)x_1(0)$ and $p_2(t)=p_1(t)-R_0(t)\Phi_0(t,0)x_1(0)$ and taking derivatives, one observes that the pair (x_2,p_2) satisfies (34) with the same data and boundary conditions as (x,p). Following from the established uniqueness of the solution, $x_2=x$ and $p_2=p$.

Given $(\phi^1,\phi^2,\phi^3)\in\mathbb{R}^n\times\mathbb{R}^n\times L_2[-1,0]$, it follows directly from the definition of $\mathcal{N}$ that $\mathcal{N}'(\phi^1,\phi^2,\phi^3)=(\phi^1+R_0(0)\phi^2,\ (E_{12}'H_1+G_2'R_0(\cdot+1))\Phi_0(\cdot+1,0)\phi^2+\phi^3(\cdot))$. In particular, when $(\phi^1,\phi^2,\phi^3)=\mathcal{M}'\mathcal{JMN}(x(0),u_0)$, the value of $\mathcal{R}(x(0),u_0)=\mathcal{N}'\mathcal{M}'\mathcal{JMN}(x(0),u_0)$, as stated in the statement of part (e) of Lemma 5.4, is obtained. The proof of the lemma is complete. ∎

5.3. The abstract model. As mentioned earlier, the complete state of the process that is described by the delay differential equations (16)–(32) must include an account of the history of the control input, as provided by $f(t)=(f^0(t),f^1(t,s))=(x(t),u_t(s))\in M_2$. This section concerns a brief account of an abstract evolution model for the dynamics of the complete state $f(t)$. General background on c_0-semigroups and on distributed parameter systems can be found, e.g., in [4, 5, 10,

13, 18]. Abstract models for delay systems over the state space M_2 (and related spaces) have been studied extensively, and a sample of relevant sources and leads is [1, 2, 3, 6, 11, 19, 20, 21, 31, 34, 35]. As compared with most of these references, our system, and accordingly, the model we use, is relatively simple and dates back to the 1970s (see, e.g., [11]). We shall thus be content with a brief explanation of the model and refer the interested reader to existing literature for more details.

Starting with formal definitions, the abstract model for the complete state dynamics, input, and output in (16) will be written as follows:

$$\begin{array}{rcccccl} \dot f & = & \mathcal{A}f & + & \mathcal{B}_1 w & + & \mathcal{B}_2 u, \\ z & = & \mathcal{C}_1 f & + & \mathcal{D}_{11} w, & & \\ y & = & & & w, & & u = \Theta y, \end{array} \tag{50}$$

with the coefficients

$$\begin{array}{rclcrcl} \mathcal{A}f & = & \left((A-QC'C)f^0 + QC'f^1(-1), \frac{d}{ds}f^1\right), & & & & \\ \mathcal{B}_1 w & = & ((B-QC'D)w, 0), & & \mathcal{B}_2 u & = & (0, \delta_0 u), \\ \mathcal{C}_1 f & = & Cf^0 - f^1(-1), & & \mathcal{D}_{11} w & = & Dw, \end{array} \tag{51}$$

where δ_0 is the usual Dirac function, centered at the origin, and where the domain of the infinitesimal generator is

$$\mathcal{D}(\mathcal{A}) = \left\{ f \in M_2 \ : \ f^1 \in W_2^1[-1,0],\ f^1(0) = 0 \right\}. \tag{52}$$

The meaning of this model will be explained via the following series of observations.

LEMMA 5.5. *Let $\mathcal{S}(t)$ be the family of linear operators over M_2, as defined by the homogeneous dynamics in* (16) *(that is, with $w(t) = 0$ and $u(t) = 0$, $t > 0$) and the relation $(x(t), u_t) = \mathcal{S}(t)(x(0), u_0)$. Then $\mathcal{S}(t)$ is a c_0-semigroup, generated by $\mathcal{A}$, as defined above.*

Outline of the proof. The fact that the family $\mathcal{S}(t)$ adheres to the axioms of a c_0-semigroup ($\mathcal{S}(0) = \mathcal{I}$, $\mathcal{S}(t+s) = \mathcal{S}(t)\mathcal{S}(s)$ and strong continuity in t [10]) is clear. The stated forms of $\mathcal{A}$ and of its domain can be motivated by formal differentiation of $f(t) = (x(t), u_t)$ and by the fact that, in the homogeneous dynamics, $u_t(s) = 0$ for $t + s > 0$. A complete and rigorous proof of the validity of the stated forms of $\mathcal{A}$ and of its domain can be obtained, e.g., by adaptations of the arguments used in one of the following proofs: [5, Thm. 2.4.6], [3, Thm. 2.3], or [31, Thms. A and B].

The following remarks concern the adaptation of the frameworks of [3, 31], which originally concern neutral FDEs of the form

$$\frac{d}{dt}\mathcal{E}z_t = \mathcal{F}z_t, \qquad t > 0. \tag{53}$$

The current setting can be brought to this form with $z = (x, u)$, $\mathcal{E}(z_t) = z_t(0) = z(t)$, and $\mathcal{F}(x_t, u_t) = ((A - QC'C)x_t(0) + QC'u_t(-1),\ 0)$. In the framework of the cited papers this would have called for the use of the higher-dimensional "M_2" state space $\mathbb{R}^{n+l} \times L_2([-1,0], \mathbb{R}^{n+l})$ (where $C \in \mathbb{R}^{l \times n}$), with the complete state $(\mathcal{E}z_t, z_t)$. The current simplification is due to the following two facts. (a) The last l entries of $\mathcal{F}z_t$ vanish, making the subspace where the last l entries of $\mathcal{E}(x_t, u_t)$ are zero, an invariant subspace under the evolution of (53). Focusing on that subspace, the last l entries of $\mathcal{E}z_t = \mathcal{E}(x_t, u_t)$ can be removed from the state $(\mathcal{E}z_t, z_t)$. (b) The dependence on

x_t in both $\mathcal{E}z_t$ and $\mathcal{F}z_t$ is restricted to the value of $x(t) = x_t(0)$. Thus, no needed information is lost when the state component $x_t \in L_2[-1, 0]$ is replaced by $x(t) \in \mathbb{R}^n$ and the definitions of $\mathcal{E}$ and $\mathcal{F}$ are modified accordingly. Following these modifications, the current state choice of $f(t) = (x(t), u_t)$ is obtained, while the arguments in the cited articles concerning the form of the domain of the infinitesimal generator remain valid. □

In what follows, we shall encounter several other semigroups over M_2 and provide, without proof, the forms of their generators and their respective domains. Indeed, in each of these cases, one will be able to draw on arguments from [3, 31] to verify the association of the semigroup and the generator. In particular, in each of these cases, the dynamics under consideration will be generated by a neutral FDE of the form (53), to which the comments in the outline of the proof of Lemma 5.5 apply. This association will be key to our ability to fairly freely consider perturbations of $\mathcal{S}(t)$, an issue that is quite delicate in the general framework of c_0-semigroup theory.

For later reference we write down the explicit form of the relationship $f(t) = \mathcal{S}(t)f(0)$, as derived from the variation-of-parameters formula in (16):

$$
\begin{aligned}
f^0(t) &= e^{(A-QC'C)t}f^0(0) + \int_0^{\min(t,1)} e^{(A-QC'C)(t-s)}QC'f^1(0,\ s-1)ds, \\
f^1(t,\theta) &= \begin{cases} f^1(0, t+\theta) & -1 \le \theta \le -t, \quad 0 \le t < 1, \\ 0 & \text{else.} \end{cases}
\end{aligned} \tag{54}
$$

As is well known, a restriction of $\mathcal{S}(t)$ to the dense subspace $\mathcal{D}(\mathcal{A}) \subset M_2$ defines a c_0-semigroup over $\mathcal{D}(\mathcal{A})$ relative to the stronger graph($\mathcal{A}$) topology. Also, the definition of $\mathcal{S}(t)$ extends, by dense injection, to a c_0-semigroup over the larger space $\mathcal{D}(\mathcal{A}')' \supset M_2$. Such extensions and restrictions are used extensively, e.g., in the much more general discussions in [21, 19]. The definition of the restriction to $\mathcal{D}(\mathcal{A})$ is obvious. The following details concern the extension to $\mathcal{D}(\mathcal{A}')'$.

By direct computation one finds the form of $\mathcal{A}'$,

$$
\mathcal{A}'g = \left((A - QC'C)'g^0,\ -\ \frac{d}{ds}g^1 \right), \tag{55}
$$

and the domain,

$$
\mathcal{D}(\mathcal{A}') = \left\{ g \in M_2 \ :\ g^1 \in W_2^1[-1, 0],\ \ g^1(-1) = CQg^0 \right\}. \tag{56}
$$

Integration by parts and (56) yield the following equality for any $f \in M_2$ and $g \in \mathcal{D}(\mathcal{A}')$:

$$
\langle f, g \rangle_{M_2} = \left\langle \left(f^0 + QC' \int_{-1}^0 f^1(r)dr, \int_s^0 f^1(r)dr \right),\ \left(g^0, \frac{d}{ds}g^1(s) \right) \right\rangle_{M_2}. \tag{57}
$$

The emerging representation of elements $g \in \mathcal{D}(\mathcal{A}')$ by the associated pairs $(g^0, \frac{d}{ds}g^1) \in M_2$ defines an isomorphism between $\mathcal{D}(\mathcal{A}')$ and M_2, and the definition of a norm $\|g\|_{\mathcal{D}(\mathcal{A}')} = \|(g^0, \frac{d}{ds}g^1)\|_{M_2}$ is consistent with the graph($\mathcal{A}$) topology in $\mathcal{D}(\mathcal{A}')$. Using this representation, an element $h \in \mathcal{D}(\mathcal{A}')'$ must be determined by an associated element $(h^0, h^1) \in M_2$, via the pairing

$$
\langle h, g \rangle_{\mathcal{D}(\mathcal{A}')'}, \mathcal{D}(\mathcal{A}') = \left\langle (h^0, h^1)\ ,\ \left(g^0, \frac{d}{ds}g^1(s) \right) \right\rangle_{M_2}. \tag{58}
$$

Thus, the definition of a norm $\|h\|_{\mathcal{D}(\mathcal{A}')'} = \|(h^0, h^1)\|_{M_2}$ is consistent with the adjoint space topology of $\mathcal{D}(\mathcal{A}')'$.

Referring to the representation of elements of $\mathcal{D}(\mathcal{A}')$ and of $\mathcal{D}(\mathcal{A}')'$ by M_2 pairs, as explained above, one defines the following continuous injection $\imath : M_2 \mapsto \mathcal{D}(\mathcal{A}')'$, its unbounded inverse $\pi : \mathcal{D}(\mathcal{A}')' \mapsto M_2$, and their adjoints:

$$
\begin{aligned}
\imath(f) &= \left(f^0 + QC' \int_{-1}^{0} f^1(r)dr \ , \ \int_s^0 f^1(r)dr \right), \\
\pi(h) &= \left(h^0 - QC'h^1(-1) \ , \ -\frac{d}{ds}h^1(s) \right), \\
\imath'(\phi) &= \left(\phi^0 \ , \ CQ\phi^0 + \int_{-1}^{s} \phi^1(r)dr \right), \\
\pi'(\psi) &= \left(\psi^0 \ , \ \frac{d}{ds}\psi(s) \right).
\end{aligned}
\tag{59}
$$

The extended semigroup is defined as a continuous continuation of $\imath \circ \mathcal{S}(t) \circ \pi$ from the dense submanifold $\imath(M_2)$ to the entire $\mathcal{D}(\mathcal{A}')'$. For simplicity in what follows, we shall use the same notation for the original semigroup $\mathcal{S}(t)$ and for its extension. (The same notational policy will be applied to other semigroups that will be encountered later on.) The following expression for the relation $h(t) = \mathcal{S}(t)h(0)$, $h(0) \in \mathcal{D}(\mathcal{A}')'$, in the extended semigroup, is easily obtained, appealing to the original definition of $\mathcal{S}(t)$ over M_2 and to the definition of its extension:

$$
h^0(t) = e^{(A-QC'C)t}h^0(0) - \int_0^{\min(t,1)} e^{(A-QC'C)(t-s)}(A - QC'C)QC'h^1(0, s-1)ds,
$$

$$
h^1(t,\theta) = \begin{cases} h^1(0, t+\theta), & -1 \le \theta \le -t, \quad 0 \le t < 1, \\ \\ 0 & \text{otherwise.} \end{cases}
\tag{60}
$$

The input operator $\mathcal{B}_1$ takes values in M_2. The value $h = \mathcal{B}_1 w$ is interpreted as a member of the extended state space $\mathcal{D}(\mathcal{A}')'$ via the injection $\imath$. That is, $h = ((B - QC'D)w, 0)$. As defined, the operator $\mathcal{B}_2$ takes values in $\mathcal{D}(\mathcal{A}')'$. With the M_2 representation of elements of $\mathcal{D}(\mathcal{A}')'$, as described above, $h = \mathcal{B}_2 u$ is identified with the pair $h = (QC'u, \ 1(s)u)$, where "$1(s)$" is the $L_2[-1, 0]$ function that takes the unit value throughout. Thus interpreted, $\mathcal{B}_2$ is a bounded operator as well. The state response of the inhomogeneous (50) is defined in terms of "mild solutions"; that is, it is defined in terms of the variations-of-parameters formula, which is well defined over the extended state space $\mathcal{D}(\mathcal{A}')'$:

$$
h(t) = \mathcal{S}(t)h(0) + \int_0^t \mathcal{S}(t-r)(\mathcal{B}_1 w(r) + \mathcal{B}_2 u(r))dr.
\tag{61}
$$

LEMMA 5.6. *Given any initial data $f(0) = (x(0), u_0) \in M_2$, $h(0) = \imath(f(0)) \in \mathcal{D}(\mathcal{A}')'$, and inputs $w, u \in L_{2\ loc}[0, \infty)$, let $h(t)$ be the response of* (61) *and let $f(t) = (x(t), u_t)$ be defined in terms of the response of* (16). *Then $h(t) = \imath(f(t))$ throughout.*

Proof. The fact that the contribution of the initial data is as stated follows from the original definition of the semigroup $\mathcal{S}(t)$ over M_2 and its extension to $\mathcal{D}(\mathcal{A}')'$. As follows from the definition of $\mathcal{S}(t)$ and of $\mathcal{B}_1$, the term $\mathcal{S}(t-r)\mathcal{B}_1 w(r)$ has a

zero $L_2[-1,0]$ component, and the $\mathbb{R}^n$ component is identical to the one from the variations-of-parameters formula in (16). So the claim concerning the contribution of w is clear as well. Assuming $w=0$ and $f(0)=0$, we thus focus on the contribution of u.

As follows from (60), the $L_2[-1,0]$ component of $\mathcal{S}(t-r)\mathcal{B}_2u(r)$, denoted $\phi^1(t,r,\theta)$, is

$$\phi^1(t,r,\theta)=\begin{cases} u(r), & \max(0,t+\theta)\le r\le t,\quad \theta\in[-1,0],\\ 0, & \text{else,}\end{cases} \tag{62}$$

and the $\mathbb{R}^n$ component, denoted $\phi^0(t,r)$, is

$$\begin{aligned}\phi^0(t,r)&=\left(e^{(A-QC'C)(t-r)}-\int_0^{\min(t-r,1)}e^{(A-QC'C)(t-r-s)}(A-QC'C)ds\right)QC'u(r),\\ &=\begin{cases} QC'u(r), & \max(t-1,0)\le r\le t,\\ e^{A(t-r-1)}QC'u(r), & \text{else.}\end{cases}\end{aligned} \tag{63}$$

Integrating over the interval $r\in[0,t]$, we thus get

$$\begin{aligned}h^0(t)&=\int_0^{\max(t-1,0)}e^{(A-QC'C)(t-r-1)}QC'u(r)dr+QC'\int_{\max(t-1,0)}^t u(r)dr\\ &=\int_{\min(1,t)}^t e^{(A-QC'C)(t-r)}QC'u(r-1)dr+QC'\int_{\max(-1,-t)}^0 u_t(r)dr,\\ h^1(t,\theta)&=\int_{\max(0,t+\theta)}^t u(r)dr=\int_{\max(-t,\theta)}^0 u_t(r)dr.\end{aligned} \tag{64}$$

Comparing with the definition of $f(t)$ by the variations-of-parameters formula in (16) (with $x(0)=0$,$u_0=0$, and $w(t)=0$, $t>0$) and the definition of the injection $\imath$, it is obvious that, here too, $h(t)=\imath(f(t))$. □

It is noticed that while $\mathcal{C}_1$ is unbounded over M_2, it does define a bounded operator when restricted to the dense submanifold $M_2^1=\mathbb{R}^n\times W_2^1[-1,0]$. Following from the previous lemma, when $u\in W_{2\ loc}^1[-1,\infty)$, the state response in (50), as defined via (61), is $f(t)=(x(t),u_t)\in M_2^1$. Thus, $z(t)=\mathcal{C}_1f(t)+\mathcal{D}_{11}w(t)$ is a well-defined trajectory, coinciding with the value of the controlled output trajectory in (16). Furthermore, embedding trajectories of z with the $L_{2\ loc}[0,\infty)$ topology, the mapping $(f(0),u,w)\mapsto z$ extends to a continuous mapping over the entire $M_2\times L_{2\ loc}[0,\infty)\times L_{2\ loc}[0,\infty)$. The output equation in (50), as well as in other abstract models that will be considered hereafter, are to be understood in this sense. Similarly, for notational convenience, we shall identify the left-hand side of the following equality (and similar equalities that will be encountered) with the well-defined right-hand side (and its appropriate counterparts),

$$\left\langle f\ ,\ \int_0^t \mathcal{S}(r)'\mathcal{C}_1'\mathcal{C}_1\mathcal{S}(r)dr\ f\right\rangle_{M_2}=\int_0^t\langle\mathcal{C}_1\mathcal{S}(r)f\ ,\ \mathcal{C}_1\mathcal{S}(r)f\rangle_{M_2}dr.$$

5.4. Solution of the differential game: A complete state space description. The following two lemmas set the groundwork for the completion of the proof of Theorem 4.1.

LEMMA 5.7. *Assume that conditions* (a) *and* (b) *in Theorem* 4.1 *are satisfied, whereby a unique solution of the differential game* (17) *does exist, as shown above. Let a family of mappings* $f(t) = \mathcal{S}_1(t)f(0)$, $t \geq 0$, *be defined by shifts along solutions of* (17). *That is,* $f(t) = (x(t), u_t)$, *where* x *and* u *are the optimal trajectory and control in* (17), *given the initial data* $f(0) = (x(0), u_0) \in M_2$. *Then* $\mathcal{S}_1$ *defines an exponentially stable* c_0*-semigroup over* M_2, *generated by*

$$\mathcal{A}_1 f = \left((A - G_2C + G_1L^0)f^0 + G_1L^1f^1 + G_2f^1(-1),\ \frac{d}{ds}f^1 \right) \tag{65}$$

as defined over the domain

$$\mathcal{D}(\mathcal{A}_1) = \left\{ f \in M_2\ :\ f^1 \in W_2^1[-1,0],\quad f^1(0) = K^0f^0 + K^1f^1 \right\}, \tag{66}$$

where the notation of (40) *is used.*

Proof. The following facts imply that, indeed, $\mathcal{S}_1$ is a well-defined, exponentially stable c_0-semigroup. (a) The solution of (17) is unique, given the initial data. (b) The restriction of the solution of (17) to any positive ray $[t, \infty)$ must coincide with the solution of the restriction of (17) to that ray, with the initial data $f(t) = (x(t), u_t)$. (This follows from the observation in part (b) of Lemma 5.4.) (c) The stability observation in part (d) in Lemma 5.4.

An intuitive motivation of (65)–(66) as the correct form of the generator of $\mathcal{S}(t)$ and of its domain can be motivated by formal differentiation. Here too, an adaptation of the more general arguments concerning semigroup representations of neutral FDEs in [3, 31] will provide a complete and rigorous proof. The following are counterparts of the similar remarks in the outlined proof of Lemma 5.5, concerning that adaptation. As was established in Lemma 5.4, the optimal inputs in the solution of (17) are given by (40). Thus the evolution of the optimal trajectory $(x(t), u_t)$ is governed by the unique solution of the integrodifferential equation, coupling (16) and (40). The coupled system can be brought to the neutral FDE form of (53) with $z = (x, u)$ and with

$$\begin{aligned}
\mathcal{F}(x_t, u_t) &= ((A - G_2C + G_1L^0)x_t(0) + G_1L^1u_t + G_2u_t(-1),\ 0),\\
\mathcal{E}(x_t, u_t) &= (x_t(0),\ u_t(0) - K^0x_t(0) - K^1u_t).
\end{aligned}$$

As we focus on the invariant subspace where the last l entries of $\mathcal{E}(x_t, u_t)$ vanish, the definitions of the operators $\mathcal{E}$ and $\mathcal{F}$ allow us to simplify the state from the standard choice of $(\mathcal{E}z_t, z_t)$ to $f(t)$ and yet maintain the validity of the arguments from [3, 31]. ∎

With any initial state $f(0) = (x(0), u_0) \in M_2$, inputs $w, u \in L_{2\ loc}[0, \infty)$, and the associated response in (16), we associate trajectories

$$w^\nabla(t) = \bar{w}(t) - L^0x(t) - L^1u_t \quad \text{and} \quad u^\nabla(t) = (2E_{12}'E_{12})^{\frac{1}{2}}(u(t) - K^0x(t) - K^1u_t). \tag{67}$$

The state dynamics and the output of (16)–(50) can be represented by the following abstract equation:

$$\begin{aligned}
\dot{f} &= \mathcal{A}_1 f \quad + \quad \bar{\mathcal{B}}_1 w^\nabla \quad + \quad \bar{\mathcal{B}}_2 u^\nabla,\\
\bar{z} &= \bar{\mathcal{C}}_1 f,
\end{aligned} \tag{68}$$

where

$$\bar{\mathcal{B}}_1 w^\nabla = (G_1 w^\nabla, 0), \quad \bar{\mathcal{B}}_2 u^\nabla = (2E_{12}'E_{12})^{-\frac{1}{2}}\mathcal{B}_2 u^\nabla, \quad \bar{\mathcal{C}}_1 f = H_1 f^0 + E_{12} f^1(-1). \tag{69}$$

Here, again, the state equation is to be understood in the "mild" sense, in terms of the variations-of-parameters formula:

$$f(t) = \mathcal{S}_1(t)f(0) + \int_0^t \mathcal{S}_1(t-r)(\bar{\mathcal{B}}_1 w^\nabla(r) + \bar{\mathcal{B}}_2 u^\nabla(r))dr. \tag{70}$$

In complete analogy to Lemma 5.6 it is observed that the state $f(t)$ in (70) coincides with $(x(t), u_t)$ in the solution of (32) with $\bar{w}(t) = w^\nabla(t) + L^0x(t) + L^1u_t$ and with $u(t) = (2E_{12}'E_{12})^{-\frac{1}{2}}u^\nabla(t) + K^0x(t) + K^1u_t$. Using the notation of (69) and the explicit expression for $\mathcal{R}$ in part (e) of Lemma 5.4, it is useful to note that there holds

$$w^\nabla(t) = \bar{w}(t) - \bar{\mathcal{B}}_1'\mathcal{R}f(t) \qquad \text{and} \qquad u^\nabla(t) = 2\bar{\mathcal{B}}_2'\mathcal{R}f(t). \tag{71}$$

LEMMA 5.8. *Let the hypotheses of Lemma* 5.7 *stand. Then the following hold.* (a) *The operator* $\mathcal{R}$*, as defined in Lemma* 5.4*, satisfies the following operator Riccati equation, for each* $f \in M_2$*:*

$$\langle f, \mathcal{R}f\rangle_{M_2} = \int_0^\infty \langle f,\ \mathcal{S}_1(t)'\left(\bar{\mathcal{C}}_1'\bar{C}_1 - \mathcal{R}\bar{\mathcal{B}}_1\bar{\mathcal{B}}_1'\mathcal{R}\right)\mathcal{S}_1(t)f\rangle_{M_2}dt. \tag{72}$$

(b) *The following equality is satisfied over any finite time interval:*

$$\|\bar{w}\|^2_{L_2[0,t]} - \|\bar{z}\|^2_{L_2[0,t]} - \langle f(t), \mathcal{R}f(t)\rangle_{M_2} = \|w^\nabla\|^2_{L_2[0,t]} - \|u^\nabla\|^2_{L_2[0,t]} - \langle f(0), \mathcal{R}f(0)\rangle_{M_2}. \tag{73}$$

Proof. It will be convenient to use the abbreviation $\Delta = \mathcal{R}\bar{\mathcal{B}}_1\bar{\mathcal{B}}_1'\mathcal{R} - \bar{\mathcal{C}}_1'\bar{\mathcal{C}}_1$. Two facts are used in establishing (72). First, following from (71), the feedback expression for $\bar{w}$ in (40) is equivalent to $\bar{w} = \bar{\mathcal{B}}_1'\mathcal{R}f$. Second, by part (e) of Lemma 5.4, the optimal cost in (17) is $-\langle f(0), \mathcal{R}f(0)\rangle_{M_2}$. Combining these observations with the definition of $\mathcal{S}_1(t)$, we have

$$\begin{aligned} -\langle f(0), \mathcal{R}f(0)\rangle_{M_2} &= \|\bar{w}\|_2^2 - \|\bar{z}\|_2^2 \\ &= \|\bar{\mathcal{B}}_1'\mathcal{R}f\|_2^2 - \|\bar{\mathcal{C}}_1 f\|_2^2 = \textstyle\int_0^\infty \langle f(0), \mathcal{S}_1(t)'\Delta\mathcal{S}_1(t)f(0)\rangle_{M_2}dt, \end{aligned} \tag{74}$$

which is (72).

The following fact is an immediate consequence of (72):

$$\langle f, \mathcal{R}f\rangle_{M_2} - \langle f, \mathcal{S}_1(t)'\mathcal{R}\mathcal{S}_1(t)f\rangle_{M_2} + \int_0^t \langle f\ ,\ \mathcal{S}_1(r)'\Delta\mathcal{S}_1(r)f\rangle_{M_2}dt = 0, \tag{75}$$

holding for any $t > 0$ and $f \in M_2$. This fact will be used in these next derivations of (73):

$$\begin{aligned} &\|\bar{w}\|^2_{L_2[0,t]} - \|\bar{z}\|^2_{L_2[0,t]} - \langle f(t), \mathcal{R}f(t)\rangle_{M_2} + \langle f(0), \mathcal{R}f(0)\rangle_{M_2} \\ &\quad = \|w^\nabla + \bar{\mathcal{B}}_1'\mathcal{R}f\|^2_{L_2[0,t]} - \|\bar{\mathcal{C}}_1 f\|^2_{L_2[0,t]} - \langle f(t), \mathcal{R}f(t)\rangle_{M_2} + \langle f(0), \mathcal{R}f(0)\rangle_{M_2} \\ &\quad = \int_0^t \left\langle \left(\mathcal{S}_1(r)f(0) + \int_0^r \mathcal{S}_1(r-s)(\bar{\mathcal{B}}_1 w^\nabla(s) + \bar{\mathcal{B}}_2 u^\nabla(s))ds\right), \right. \end{aligned}$$

$$
\begin{aligned}

which establish the validity of (73) and complete the proof of Lemma 5.8. □

LEMMA 5.9. *The family of admissible, strictly γ suboptimal selections of the system Θ comprises those systems that can be realized by the following abstract models:*

$$
\begin{aligned}
\dot{f}_c &= \mathcal{A}_c f_c + \mathcal{B}_{c1} w + \mathcal{B}_{c2}\phi, \\
u &= \mathcal{C}_{c1} f_c + \mathcal{D}_{c12}\phi, \qquad (77)\\
\psi &= \mathcal{C}_{c2} f_c + \mathcal{D}_{c21} w, \qquad \phi = \Theta_0\psi,
\end{aligned}
$$

where the coefficients are defined as follows:

$$
\begin{aligned}
\mathcal{A}_c f_c &= \left((A - QC'C)f_c^0 + QC' f_c^1(-1)\ ,\ \frac{d}{ds}f_c^1\right), \\
\mathcal{B}_{c1} &= \mathcal{B}_1, & \mathcal{B}_{c2} &= \bar{\mathcal{B}}_2, \\
\mathcal{C}_{c1} f_c &= K^0 f_c^0 + K^1 f_c^1, & \mathcal{D}_{c12} &= (2E_{12}'E_{12})^{-\frac{1}{2}}, \\
\mathcal{C}_{c2} f_c &= -\left(L^0 + \frac{1}{\gamma}D'H_1\right)f_c^0 - L^1 f_c^1 - \frac{1}{\gamma}D'E_{12}f_c^1(-1), & \mathcal{D}_{c21} &= E_{21}^{-1},
\end{aligned} \qquad (78)
$$

where

$$
\mathcal{D}(\mathcal{A}_c) = \left\{f_c \in M_2\ :\ f_c^1 \in W_2^1[-1,0],\quad f_c^1(0) = K^0 f_c^0 + K^1 f_c^1\right\} \qquad (79)
$$

and where the free design parameter, the mapping Θ_0, is defined by the I/O mapping in a stable, neutral FDE with the $L_2[0,\infty)$ induced norm bound $\|\Theta_0\| < 1$.

Proof. The arguments are essentially the same as in the proof of a counterpart statement in the finite-dimensional framework of [32], where the equality (73) is playing the key role. For completeness, we shall outline the arguments in the current distributed parameter framework. These arguments are broken into several steps.

Step 1. *Well-Posedness and a Neutral FDE Interpretation of* (77). Again we draw on observations, similar to those made in section 5.3, concerning neutral FDEs and associated semigroups. Following from the definition of $\mathcal{A}_c$ (and of the rest of the coefficients) it is noted that (77) is defined in terms of a closed-loop interconnection of two well-posed, inhomogeneous neutral FDEs. The first subsystem is the stable neutral FDE that defines Θ_0. The second neutral FDE is defined in terms of the explicit state space formulas with Θ_0 removed. A close look reveals that this abstract model is a realization of an integrodifferential equation where the homogeneous part couples (16), say, with the state "x_c" and the regression $u(t) = K^0 x_c(t) + K^1 u_t$. The neutral FDE interpretation of this equation is similar to the one provided in the proof of Lemma 5.4 in the context of $\mathcal{S}_1(t)$, omitting the terms in L^0 and L^1. The inhomogeneous system includes the added input $(2E_{12}'E_{12})^{-\frac{1}{2}}\phi(t)$ in the regression for $u(t)$, and thus creates a well-posed inhomogeneous neutral FDE. (Details on inhomogeneous neutral FDEs can be found in [31].) Removing Θ_0, the open-loop mapping $\phi \mapsto \psi$ is strictly proper, whereby the interconnection results in a well-posed neutral FDE. (Indeed, the restriction of Θ_0 to the class of neutral FDEs is made expressly for this purpose, and the class of admissible "Θ_0" could easily be extended to any distributed parameter systems class that will provide for a meaningful well-posedness and state space realizability of (77).)

Since the state is defined in terms of trajectories of (16), the equality (73) remains valid, where f_c substitute for f throughout. In particular, it is noted that, with respect to the state f_c, $w^\nabla = \psi$, $u^\nabla = \phi$ and a counterpart $\bar{z}_c$ of $\bar{z}$ is defined as $\bar{\mathcal{C}}_1 f_c$. These observations will be our main tools in what follows.

Step 2. *Stability of* (77). Without reference to the detailed model, we shall use the notation f_0 in reference to the state of a stable abstract model of Θ_0. The bounded mapping from the initial state to the output, in that system, will be denoted $\Upsilon_0 \ : f_0 \mapsto \psi : M_2 \mapsto L_2[0,\infty)$. The associated I/O mapping will be denoted simply $\Theta_0 : \psi \mapsto \phi : L_2[0,\infty) \mapsto L_2[0,\infty)$. Thus, having started at a nonzero state, $\phi = \Upsilon_0 f_0(0) + \Theta_0 \psi$. The induced norm bound $\|\Theta_0\| < 1$ allows us to denote $\lambda^2 = 1 - \|\Theta_0\|^2$.

To establish internal stability one considers the case where an arbitrary, combined initial state $(f_c(0), f_0(0))$ is in place and where the external input is $w = 0$, whereby $w^\nabla = \psi = \mathcal{C}_{c2} f_c$. Invoking (73), then for each $t > 0$ there holds

$$
\begin{aligned}
0 &= \langle f_c(0), \mathcal{R} f_c(0)\rangle_{M_2} - \|\bar{z}_c\|^2_{L_2[0,t]} - \|\psi\|^2_{L_2[0,t]} + \|\phi\|^2_{L_2[0,t]} \\
&\le \langle f_c(0), \mathcal{R} f_c(0)\rangle_{M_2} - \|\psi\|^2_{L_2[0,t]} + \|\Theta_0\psi + \Upsilon_0 f_0(0)\|\|^2_{L_2[0,t]} \\
&\le \langle f_c(0), \mathcal{R} f_c(0)\rangle_{M_2} - \|\psi\|^2_{L_2[0,t]} + \big(\|\Theta_0\|\|\psi\|_{L_2[0,t]} + \|\Upsilon_0\|\|f_0\|_{M_2}\big)^2 \\
&= \langle f_c(0), \mathcal{R} f_c(0)\rangle_{M_2} + \|\Upsilon_0\|^2\|f_0\|^2_{M_2} + 2\|\Theta_0\|\|\Upsilon_0\|\|f_0\|_{M_2}\|\psi\|_{L_2[0,t]} - \lambda^2\|\psi\|^2_{L_2[0,t]}.
\end{aligned}
\tag{80}
$$

Viewing the rightmost term in (80) as a quadratic polynomial with a negative leading coefficient in the variable $\|\psi\|_{L_2[0,t]}$, the inequality forces $\|\psi\|_{L_2[0,t]}$ to take values between the two zeros of the polynomial. This leads to the following bound:

$$
\|\psi\|_{L_2[0,t]} \le \|\Theta_0\|\|\Upsilon_0\|\|f_0\|_{M_2} + \Big(\big(\|\Theta_0\|^2 + \lambda^2\big)\|\Upsilon_0\|^2\|f_0\|^2_{M_2} + \lambda^2\langle f_c(0), \mathcal{R} f_c(0)\rangle_{M_2}\Big)^{\frac{1}{2}},
\tag{81}
$$

which holds for each t. It thus extends to a similar bound, as $t \to \infty$, and can be abbreviated in the form

$$\|\psi\|_2 < \alpha \|(f_0(0), f_c(0))\|_{M_2 \times M_2}, \tag{82}$$

with some fixed $\alpha > 0$ and all initial data. Since Θ_0 is defined by a stable system, the mapping $(f_0(0), \psi) \mapsto (f_0, \phi) : M_2 \times L_2[0,\infty) \mapsto L_2[0,\infty) \times L_2[0,\infty)$ is bounded. Thus, with a possible modification of α, (82) translates into

$$\|\phi\|_2,\ \|f_0\|_2 < \alpha \|(f_0(0), f_c(0))\|_{M_2 \times M_2}. \tag{83}$$

We now use, once again, the observation that $f_c(t) = (x_c(t), u_t)$, ψ, and ϕ play in (16) the precise counterpart roles that $f = (x(t), u_t)$, w^∇, and u^∇, respectively, play, with x_c substituting for x. In particular, the following counterpart of the state equation from (68) is satisfied:

$$\dot{f}_c = \mathcal{A}_1 f_c + \bar{\mathcal{B}}_1 \psi + \bar{\mathcal{B}}_2 \phi. \tag{84}$$

The stability of $\mathcal{A}_1$ implies boundedness of the mapping $(f_c(0), \psi, \phi) \mapsto f_c : M_2 \times L_2[0,\infty) \times L_2[0,\infty) \mapsto L_2[0,\infty)$. Coupling this fact with (82) and (83) it turns out that, with the possible need to modify α, we have

$$\|(f_c, f_0)\|_2 < \alpha \|(f_0(0), f_c(0))\|_{M_2 \times M_2}. \tag{85}$$

It is a standard observation (see, e.g., [5, Lem. 5.1.2]) that the bound (85) implies uniform exponential stability in the combined system (77).

Step 3. *Strict γ Suboptimality.* We now consider the case where Θ is of the form (77), $w \neq 0$ in (16)–(50) and in (77), and where the initial data are all zero. Namely, $f(0) = 0 = f_c(0)$ and $f_0(0) = 0$. As noted above, then both $f(t) = (x(t), u_t)$ and $f_c(t) = (x_c(t), u_t)$ correspond to solutions of (16) with the same inputs u and w and the zero initial data, and with the $\mathbb{R}^n$ "states" $x(t)$ and $x_c(t)$. The uniqueness of the solution of (16) implies that $x(t) = x_c(t)$ throughout, whereby $f(t) = f_c(t)$ throughout. In particular, then $w^\nabla = \psi$ and $u^\nabla = \phi = \Theta_0 w^\nabla$. Using the established stability of (77), we can then let $t \to \infty$ in (73) and obtain

$$\gamma^2 \|w\|_2^2 - \|z\|_2^2 = \|w^\nabla\|_2^2 - \|\Theta_0 w^\nabla\|_2^2 \geq \lambda^2 \|w^\nabla\|_2^2. \tag{86}$$

The signals w and w^∇ are now related by a stable system, combining the state equation (68) (with the zero initial data), the relation $u^\nabla = \Theta_0 w^\nabla$, and the output equation

$$w = \mathcal{D}_{c21}^{-1}(w^\nabla - \mathcal{C}_{c2} f). \tag{87}$$

Thus defined, the mapping $w^\nabla \mapsto w$ is a bounded operator over $L_2[0,\infty)$ and $\lambda^2 \|w^\nabla\|_2^2$ can be bounded below by $\mu^2 \|w\|_2^2$, with some fixed positive μ. Substituting this lower bound in (86), it follows that the closed-loop induced norm of the mapping $w \mapsto z$ is, at most, $\sqrt{\gamma^2 - \mu^2}$.

This completes the proof of the fact that each selection of Θ via the parameterization (77) is indeed a stable and a strictly γ suboptimal selection. In particular, the family of these selections is nonempty, and the proof of the sufficiency claim in Theorem 4.1 is complete.

Step 4. *Completeness of the Parameterization* (77). Let Θ be any strictly γ suboptimal, stable neutral FDE. The fact that Θ is strictly γ suboptimal means that (with the zero initial data) there holds

$$\gamma^2\|w\|_2^2 - \|z\|_2^2 > \mu^2\|w\|_2^2 \tag{88}$$

in the closed-loop system, with any $w \in L_2[0,\infty)$ and some fixed $\mu > 0$. The system that combines (16) and Θ is defined in terms of a stable neutral FDE. Associating the state equation in this system with the second output mapping of (77),

$$w^\nabla = \mathcal{C}_{c2} f + \mathcal{D}_{c21} w, \tag{89}$$

one thus obtains a stable realization of the mapping $w \mapsto w^\nabla$ in the closed-loop system. In particular, with the zero initial state, $\mu^2\|w\|_2^2$ can be bounded below by $\lambda^2\|w^\nabla\|_2^2$, with some fixed, positive λ. Invoking (73) with the zero initial data and with $t \to \infty$, the following closed-loop inequality emerges:

$$\|w^\nabla\|_2^2 - \|u^\nabla\|_2^2 > \lambda^2\|w^\nabla\|_2^2, \tag{90}$$

indicating that the induced norm of the closed-loop mapping $w^\nabla \mapsto u^\nabla$ is smaller than 1.

It has to be verified that this mapping is realized by a stable system. The following is an abstract model for that mapping:

$$\begin{array}{rcl} \dot{f}_\nabla &=& \mathcal{A}_\nabla f_\nabla + \mathcal{B}_{\nabla 1} w^\nabla + \mathcal{B}_{\nabla 2} u, \\ u^\nabla &=& \mathcal{C}_{\nabla 1} f_\nabla + \mathcal{D}_{\nabla 12} u, \\ w &=& \mathcal{C}_{\nabla 2} f_\nabla + \mathcal{D}_{\nabla 21} w^\nabla, \qquad u = \Theta w, \end{array} \tag{91}$$

where the coefficients are defined as follows:

$$\begin{array}{ll} \mathcal{A}_\nabla f_\nabla = \left((A - G_2 C + G_1 L^0) f_\nabla^0 + G_1 L^1 u_t + G_2 f_\nabla^1(-1)\ ,\ \dfrac{d}{ds} f^1 \right), & \\ \mathcal{B}_{\nabla 1} = \bar{\mathcal{B}}_1, & \mathcal{B}_{\nabla 2} = \mathcal{B}_2, \\ \mathcal{C}_{\nabla 1} f_\nabla = -(2E_{12}' E_{12})^{\frac{1}{2}} (K^0 f_\nabla^0 + K^1 f_\nabla^1), & \mathcal{D}_{\nabla 12} = (2E_{12}' E12)^{\frac{1}{2}}, \\ \mathcal{C}_{\nabla 2} = -\mathcal{D}_{c21}^{-1} \mathcal{C}_{c2}, & \mathcal{D}_{c21} = \mathcal{D}_{c21}^{-1}, \end{array} \tag{92}$$

where

$$\mathcal{D}(\mathcal{A}_\nabla) = \mathcal{D}(\mathcal{A}) = \left\{ f_\nabla \in M_2 \ :\ f_\nabla^1 \in W_2^1[-1,0],\quad f_\nabla^1(0) = 0 \right\}. \tag{93}$$

As all other models encountered heretofore, this model too is associated with (16) (with the $\mathbb{R}^n$ "state" $x_\nabla(t)$) via $f_\nabla(t) = (x_\nabla(t), u_t)$, and subject to the input lows $w = \mathcal{C}_{\nabla 2} f_\nabla + \mathcal{D}_{\nabla 21} w^\nabla$ and $u = \Theta w$. Without specifying the details of the stable dynamic equations by which Θ is defined, we shall refer to the complete state of such a realization with the notation f_1. The proof of closed-loop stability follows the pattern of similar arguments in [27, 28, 32] and is now outlined for completeness.

Indeed, in contradiction, suppose that the closed-loop system in (92) is not uniformly exponentially stable and consider that system with the zero external input, $w^\nabla = 0$ (hence with $w = \mathcal{C}_{\nabla 2} f_\nabla$). We argue that this must imply that the ratios

$$\frac{\|w\|_{L_2[0,t]}}{\|(f_\nabla(0), f_1(0))\|_{M_2 \times M_2}} \tag{94}$$

are not uniformly bounded over all possible selections of the combined initial data and of $t > 0$. For suppose those ratios were uniformly bounded, whereby the closed-loop mapping $(f_\nabla(0), f_1(0)) \mapsto w = \mathcal{C}_{\nabla 2} f_\nabla : M_2 \times M_2 \mapsto L_2[0,\infty)$ were a bounded operator. To see that this is impossible (under the contradiction assumption), note that the closed loop (16) is stable anyway, whereby the mapping $(w, f_\nabla(0), f_1(0)) \mapsto (f_\nabla, f_1)$: $L_2[0,\infty) \times M_2 \times M_2 \mapsto L_2[0,\infty)$ defines a bounded operator. Combining these two facts we would have then concluded that the closed-loop mapping $(f_\nabla(0), f_1(0)) \mapsto (f_\nabla, f_1) :\ M_2 \times M_2 \mapsto L_2[0,\infty)$ is bounded. Yet this latter mapping is defined, by our assumption, in an unstable system, and by [5, Lem. 5.1.2], cannot be bounded.

Having selected t and the combined initial data, let the dynamics under consideration be determined over $[0,t]$ by the closed loop (91) with $w^\nabla = 0$, as above, and by the combined rules $w^\nabla = 0$ and $u^\nabla = 0$, over (t,∞). Over the latter ray the dynamics of f_∇ is generated by the stable $\mathcal{A}_1$. Let the definition $w = \mathcal{C}_{\nabla 2} f$ prevail throughout and let z be the associated output of (16), with x_∇ substituting for x.

Let κ be a uniform induced norm bound over the closed-loop mapping $(f(0), f_1(0)) \mapsto z : M_2 \times M_2 \mapsto L_2[0,\infty)$ in the stable closed-loop system (16). The same bound applies when f_∇ substitutes for f. We recall that $\sqrt{\gamma^2 - \mu^2}$ is an induced norm bound over the closed-loop mapping $w \mapsto z : L_2[0,\infty) \mapsto L_2[0,\infty)$, in (16). Applying (73) to the trajectories that were constructed above, we get

$$\begin{aligned}
&\langle f_\nabla(0), \mathcal{R} f_\nabla(0)\rangle_{M_2} + \|u^\nabla\|^2_{L_2[0,t]} = \|z\|_2^2 - \gamma^2 \|w\|_2^2 \\
&\quad \le \left(\sqrt{\gamma^2 - \mu^2}\|w\|_2 + \kappa \|(f_\nabla(0), f_1(0))\|_{M_2 \times M_2}\right)^2 - \gamma^2 \|w\|_2^2 \\
&\quad = -\mu^2 \|w\|_2^2 \left(1 - 2\tfrac{\kappa\sqrt{\gamma^2-\mu^2}}{\mu^2} \tfrac{\|(f_\nabla(0), f_1(0))\|_{M_2\times M_2}}{\|w\|_2} - \tfrac{\kappa^2}{\mu^2} \tfrac{\|(f_\nabla(0), f_1(0))\|^2_{M_2\times M_2}}{\|w\|_2^2}\right).
\end{aligned} \tag{95}$$

If indeed it were possible for the ratios (94) to be made arbitrarily large by a selection of t and of the combined initial state, then it would be possible to make the rightmost expression in (95) arbitrarily close to the negative value $-\mu^2\|w\|_2^2$. Yet, the leftmost expression of the same inequality is nonnegative, which is a contradiction. Thus the closed-loop system (91), governing the closed-loop mapping $\Theta_0 : w^\nabla \mapsto u^\nabla$, must be stable. We have already established that its induced norm is strictly smaller than unity. The fact that (77) is a realization of the mapping $w \mapsto u$ in terms of the mapping $w^\nabla \mapsto u^\nabla$ is clear.

This completes the proof of Lemma 5.9. ∎

As noted above, the abstract model (77) is a representation of a system, coupling (16), with $x_c(t)$ substituting for $x(t)$, the control selection that couples the regression formula $u(t) = K^0 x_c(t) + K^1 u_t + (2E_{12}' E12)^{-\frac{1}{2}} \phi(t)$, the feedback rule $\phi = \Theta_0 \psi$, and the output $\psi(t) = -(L^0 + \frac{1}{\gamma} D' H_1) x_c(t) - L^1 u_t - \frac{1}{\gamma} D' E_{12} u(t-1) + E_{21}^{-1} w(t)$. These facts are precisely those that are captured in the parameterization (12), in the statement of Theorem 4.1. The proof of the theorem is thus complete. ∎

ON THE TIME-DISCRETIZATION OF CONTROL SYSTEMS*

VLADIMIR VELIOV†

Abstract. This paper develops an approach for obtaining discrete approximations to nonlinear (affine) control systems that are of higher than first order of accuracy with respect to the discretization step h. The approach consists of two parts: first the set $\mathcal{U}$ of measurable admissible controls is replaced by an appropriate finite-dimensional subset $\mathcal{U}_N$; then the differential equations corresponding to controls from $\mathcal{U}_N$ (which are in a reasonable sense "regular") are discretized by single step discretization methods. The main result estimates the accuracy in the first part, measured in terms of a prescribed collection of performance indexes. The result can be interpreted both in the context of approximation of optimal control problems and in the context of approximation of the reachable set. In the first case, accuracy $O(h^2)$ is proven for appropriate Runge–Kutta-type discretization methods, without explicitly or implicitly requiring any regularity of the optimal solutions. In the case of a convex reachable set we obtain $O(h^2)$ approximation with respect to the Hausdorff distance and $O(h^{1.5})$ accuracy in the nonconvex case. An application to the time-aggregation of discrete-time control systems is also presented.

Key words. control systems, differential inclusion, reachable set, discrete approximation, Runge–Kutta scheme, optimal control

1. Introduction.

In this paper we consider a control system

$$\dot{x} = f(t,x,u), \quad x(t_0) = x_0,\ u(\cdot) \in \mathcal{U},\ x \in \mathbf{R}^n,\ t \in [t_0,T], \tag{1}$$

with a given set $\mathcal{U}$ of admissible control functions $u(\cdot) : [t_0,T] \mapsto \mathbf{R}^r$ and fixed x_0, t_0, and T. In fact, the system under consideration will be linear with respect to u, but for notational convenience, we discuss the general case in the introduction.

For a prescribed collection of functions (performance indexes) $\mathcal{G} = \{g(\cdot)\,;\ g : \mathbf{R}^n \mapsto \mathbf{R}\}$, the set of real numbers

$$\{\inf_{x(\cdot)} g(x(T))\,;\ g(\cdot) \in \mathcal{G}\}$$

will be considered as a characterization of the performance of the system. Accordingly, if

$$\dot{y} = \tilde{f}(t,y,v), \quad y(t_0) = x_0,\ v(\cdot) \in \mathcal{V},\ y \in \mathbf{R}^n,\ t \in [t_0,T], \tag{2}$$

is another system, then

$$\varepsilon^-((2),(1)) = \sup_{g\in\mathcal{G}} \left\{ \inf_{y(\cdot)} g(y(T)) - \inf_{x(\cdot)} g(x(T)) \right\}$$

is a measure of the "disadvantage," with respect to the performance, of system (2) compared with (1). In particular, if $\tilde{f} = f$ and only the admissible control sets differ, $\varepsilon^-((2),(1))$ (which will be denoted in this case by $\varepsilon^-(\mathcal{V},\mathcal{U})$) is a measure of the "loss"

of performance when the set $\mathcal{U}$ of admissible controls is replaced by $\mathcal{V}$. The principle result of the paper is an estimation of the last quantity in the case when

$$\mathcal{U} = \{u(\cdot)\,;\ u(\cdot) \in L_1^r[t_0, T],\ u(t) \in U \text{ for a.e. } t\}, \tag{3}$$

where $U \subset \mathbf{R}^r$ is a convex and compact set and

$$\mathcal{V} = \mathcal{U}_N \stackrel{def}{=} \{u(\cdot) \in \mathcal{U}\,;\ u(\cdot) \text{ is constant on } (t_i, t_{i+1}),\ i = 0, \ldots, N-1\}, \tag{4}$$

where N is a natural number (of jumps) and $t_i = t_0 + ih$, $h = (T - t_0)/N$. From Dontchev and Farkhi [8] or Wolenski [23], it follows that under mild conditions

$$\varepsilon^-(\mathcal{U}_N, \mathcal{U}) \leq C/N. \tag{5}$$

The problem of estimating $\varepsilon^-(\mathcal{U}_N, \mathcal{U})$ can be considered from the general point of view of the sensitivity analysis of extremal problems. It has been know since the 17th Century that a smooth function deviates from its value at an *extreme* point proportionally to the square of the distance of its argument to this point. This observation (of J. Kepler, in 1615) also has a counterpart for constrained optimization problems in normed spaces. In our case the extreme point in question is a minimizing control function $\hat{u}(\cdot)$ (subject to infinitely many linear constraints in $L_2^r(0, T)$, corresponding to the constraint $u(t) \in U$) for a particular performance index $g(\cdot) \in \mathcal{G}$. The general analysis, however, fails in this case, since the Hausdorff distance, with respect to any L_p-norm, between the sets $\mathcal{U}_N$ and $\mathcal{U}$ does not even tend to zero when $N \longrightarrow +\infty$. A more specific analysis is needed, in this sense, even for the above-mentioned first-order estimation (5).

On the other hand, the papers [22, 20] imply that a second-order estimation

$$\varepsilon^-(\mathcal{U}_N, \mathcal{U}) \leq C/N^2 \tag{6}$$

holds in two rather different cases (supposing, however, that the functions $g \in \mathcal{G}$ have equi-Lipschitz-continuous derivatives): in the case when system (1) is linear and in the case of system (1) for which $f(t, x, U)$ is a uniformly strongly convex set. The main result in the present paper, presented in section 2, extends the second-order estimation (6) to the case of nonlinear systems that are affine with respect to u and satisfy an additional structural condition. The subsequent sections present some applications. (The problem considered here can also be interpreted within the issue of approximation of differential inclusions by collections of differential equations that are finite-dimensionally parametrizable or finite; cf. [11]).

In section 3 the main result is applied for obtaining appropriate Runge–Kutta-type discrete approximations to nonlinear optimal control problems that ensure second-order approximation (relative to the discretization step) with respect to the performance value. In contrast to the known results this estimation is not based on any regularity assumptions for the optimal solution, and even the constant C in the estimation corresponding to (6) is in a reasonable sense *robust* with respect to the data. In particular, the cases of an optimal control function that is of unbounded variation, or one that is nonintegrable in the Riemann sense, are not excluded by the suppositions under which the second-order estimation holds.

Section 4 is devoted to the issue of discrete approximations of the reachable set of (1), (3). The main result, together with a duality argument, implies (under an appropriate convexity assumption) second-order error estimation in the Hausdorff

metric for certain *set-valued* Runge–Kutta-type discretization schemes. Notice that, according to [22], Runge–Kutta schemes of higher order of accuracy exist in the set-valued case only under conditions that are rather restrictive in the context of control theory (cf. [4]). For an extended bibliography concerning the issue of discretization of control systems and differential inclusions, see [6, 10, 15].

Section 5 concerns the following issue with obvious practical motivation: what is the "loss of performance" of a given N-stage discrete-time control system if the control value is allowed to change only at the stages kM, $k = 1, \dots, N/M$, rather than at each stage? The performance is defined as above, by a collection of indexes. The main result is used to obtain an exact estimation, as well as a constructive way of defining corresponding N/M-stage time-aggregated discrete-time systems.

2. Main result. It is supposed further that system (1) has the form

$$\dot{x} = f_0(t,x) + F(t,x)u, \quad x(t_0) = x_0, \tag{7}$$

where $f_0 : [t_0, T] \times \mathbf{R}^n \to \mathbf{R}^n$, $F : [t_0, T] \times \mathbf{R}^n \to \mathbf{R}^n \times \mathbf{R}^r$. The set $\mathcal{U}$ of admissible control functions is defined as in (3), where $U \subset \mathbf{R}^r$ is a convex and compact set.

The next theorem estimates the "loss of performance" of system (7) when the rN-dimensional control set $\mathcal{U}_N$ defined by (4) is used instead of the infinite-dimensional (in general) control set $\mathcal{U}$.

Denote by $R(\tau)$ the reachable set of (7) on $[t_0, \tau]$, that is, $x \in R(\tau)$ if and only if there is a $u(\cdot) \in \mathcal{U}$ such that a corresponding trajectory $x(\cdot)$ of (7) exists on $[t_0, \tau]$ and $x(\tau) = x$.

Assumption 1. There is a convex compact set $S \subset \mathbf{R}^n$ such that $R(t) \subset \operatorname{int} S$ for every $t \in [t_0, T]$.

Assumption 2. The components of f_0 and F are differentiable with respect to t and x, and all the first derivatives are Lipschitz continuous with respect to $(t,x) \in [t_0, T] \times S$.

Assumption 3 (structural condition). The columns $f_1(t,x), \dots, f_r(t,x)$ of $F(t,x)$ satisfy the relations

$$[f_i, f_j]_x(t,x) \stackrel{def}{=} \left(\frac{\partial f_i}{\partial x} f_j - \frac{\partial f_j}{\partial x} f_i \right)(t,x) = 0$$

for every $i, j = 1, \dots, r$ and $(t,x) \in [t_0, T] \times S$.

Assumption 4. There are constants L_g and L'_g such that each function $g \in \mathcal{G}$ is differentiable in the interior of S, and $\partial g / \partial x$ is bounded by L_g and is Lipschitz continuous at each point of $R(T)$ with Lipschitz constant L'_g.

We mention that Assumption 3 for the Lie brackets of the vector fields f_j is always fulfilled if F is independent of x, or $\dim u = 1$. Otherwise it poses a restriction on the interaction between the different control components. It is an open problem whether Assumption 3 is essential for the claim of Theorem 2.1 below. The author has some reason to expect that the answer might be (in general) affirmative, but a counterexample is not available.

Remark 1. The constant in the estimation (8) below does not depend directly on the particular function $f = f_0 + Fu$. Rather, it depends (and can be evaluated following the proof) on certain constants associated with f:

—the Lipschitz constants L_0, L_F, L'_0, and L'_F of f_0, and the columns of F and their first derivatives in the set $[t_0, T] \times S$ (denoted further briefly as L);

—the maximum M_0 and M_F of $|f_0(t,x)|$ and $|F(t,x)|$ in $[t_0, T] \times S$ and the maximum M'_0 and M'_F of the norms of the derivatives with respect to x of f_0 and the

columns of F in $[t_0, T] \times S$ (everywhere, the operator matrix norm is meant); these constants will be succinctly symbolized by M.

THEOREM 2.1. *Let Assumptions* 1–4 *be fulfilled. Then there exists a constant* C *depending only on* L, M, L_g, L'_g, $|U|$, *and* $T - t_0$, *such that for every natural number* N

$$\varepsilon^-(\mathcal{U}_N, \mathcal{U}) \stackrel{def}{=} \sup_{g \in \mathcal{G}} \left\{ \inf_{v(\cdot) \in \mathcal{U}_N} g(y(T)) - \inf_{u(\cdot) \in \mathcal{U}} g(x(T)) \right\} \leq \frac{C}{N^2}. \tag{8}$$

(Here $y(\cdot)$ *is the trajectory corresponding to* $v(\cdot)$, *and* $x(\cdot)$ *is the trajectory corresponding to* $u(\cdot)$, *according to* (7)*).*

This theorem is a direct consequence of the following one (corresponding to the case of a set $\mathcal{G}$ consisting of a single function g). For a particular $g(\cdot) \in \mathcal{G}$, consider the following terminal optimal control problem for system (7):

$$g(x(T)) \longrightarrow \min, \tag{9}$$

Assumptions 1–4 ensure existence of a solution in both class $\mathcal{U}$ and $\mathcal{U}_N$ of admissible control functions. The corresponding optimal values will be denoted by $\hat{g}$ and $\hat{g}_N$.

THEOREM 2.2. *Let Assumptions* 1–4 *be fulfilled. Then there exist constants* C_1 *and* C_2 *depending only on* L, M, $|U|$, *and* $T - t_0$ *such that for every natural number* N

$$0 \leq \hat{g}_N - \hat{g} \leq \frac{C_1 L_g + C_2 L'_g}{N^2}. \tag{10}$$

Notice that C_1 and C_2 do not depend on the properties of the optimal control, which can be even of unbounded variation, nonintegrable in the Riemann sense, or even discontinuous almost everywhere (Assumptions 1–4 do not exclude these possibilities; see Silin [19]).

The proof will be preceded by some auxiliary results.

Let $l(\cdot) : [t_0, T] \mapsto \mathbf{R}^n$ satisfy the conditions

(i) $l(\cdot)$ is Lipschitz continuous with constant L_l;

(ii) $\dot{l}(\cdot)$ is of bounded variation.

The following result, playing a crucial role in the forthcoming analysis, is a consequence of [5, Prop. 2].

PROPOSITION 2.3. *The function*

$$\hat{l}(t) = \sup_{u \in U} \langle l(t), u \rangle$$

is Lipschitz continuous and

$$\bigvee_{t_0}^{T} \dot{\hat{l}}(\cdot) \leq 2L_l + 2|U| \bigvee_{t_0}^{T} \dot{l}(\cdot).$$

The precise (natural) meaning of the variations of $\dot{l}$ and $\dot{\hat{l}}$—these functions are defined almost everywhere—is also given in [5].

By [2, Thm. 8.2.8] the set-valued mapping

$$\hat{U}(t) = \{u \in U \,;\, \langle l(t), u \rangle = \hat{l}(t)\}$$

is measurable. Let $\hat{u}(\cdot)$ be an arbitrary measurable selection of $\hat{U}(\cdot)$.

The proof of the following lemma is standard.

LEMMA 2.4. *If $\dot{l}(t)$ and $\hat{\dot{l}}(t)$ exist for some $t \in [t_0, T]$, then*

$$\dot{\hat{l}}(t) = \langle \dot{l}(t), \hat{u}(t) \rangle.$$

For the fixed selection $\hat{u}(\cdot)$ of $\hat{U}(\cdot)$ define

$$u_N^i = \frac{1}{h} \int_{t_i}^{t_{i+1}} \hat{u}(t)\, dt \tag{11}$$

and

$$u_N(t) = u_N^i \quad \text{for} \quad t \in [t_i, t_{i+1}),\ i = 0, \dots, N-1. \tag{12}$$

LEMMA 2.5.

$$0 \le \int_{t_0}^{T} \langle l(t), \hat{u}(t) - u_N(t) \rangle\, dt \le \left(2L_l + 3|U| \bigvee_{t_0}^{T} \dot{l}(\cdot) \right) h^2.$$

Proof. By definition, and using Lemma 2.4, we estimate

$$0 \le \int_{t_0}^{T} \langle l(t), \hat{u}(t) - u_N(t) \rangle\, dt = \frac{1}{h} \sum_{i=0}^{N-1} \int_{t_i}^{t_{i+1}} \int_{t_i}^{t_{i+1}} \langle l(t), \hat{u}(t) - \hat{u}(s) \rangle\, ds\, dt$$

$$= \frac{1}{h} \sum_{i=0}^{N-1} \int_{t_i}^{t_{i+1}} \int_{t_i}^{t_{i+1}} [\langle l(t), \hat{u}(t) \rangle - \langle l(s), \hat{u}(s) \rangle + \langle l(s) - l(t), \hat{u}(s) \rangle]\, ds\, dt$$

$$= \frac{1}{h} \sum_{i=0}^{N-1} \int_{t_i}^{t_{i+1}} \int_{t_i}^{t_{i+1}} \left[\int_s^t \dot{\hat{l}}(\tau)\, d\tau - \left\langle \int_s^t \dot{l}(\tau)\, d\tau, \hat{u}(s) \right\rangle \right] ds\, dt$$

$$= \frac{1}{h} \sum_{i=0}^{N-1} \int_{t_i}^{t_{i+1}} \int_{t_i}^{t_{i+1}} \int_s^t [\dot{\hat{l}}(\tau) - \langle \dot{l}(\tau), \hat{u}(s) \rangle]\, d\tau\, ds\, dt$$

$$= \frac{1}{h} \sum_{i=0}^{N-1} \int_{t_i}^{t_{i+1}} \int_{t_i}^{t_{i+1}} \int_s^t [\dot{\hat{l}}(\tau) - \dot{\hat{l}}(s) + \langle \dot{l}(s) - \dot{l}(\tau), \hat{u}(s) \rangle]\, d\tau\, ds\, dt$$

$$\le \left(\bigvee_{t_0}^{T} \dot{\hat{l}}(\cdot) + |U| \bigvee_{t_0}^{T} \dot{l}(\cdot) \right) h^2 \le \left(2L_l + 3|U| \bigvee_{t_0}^{T} \dot{l}(\cdot) \right) h^2,$$

where the last estimation is based on Proposition 2.3. ∎

Further, we denote for brevity

$$L_f = L_0 + |U| L_F, \quad M_f = M_0 + |U| M_F, \quad M_f' = M_0' + |U| M_F'.$$

A standard application of the Gronwall inequality gives the following estimation.

LEMMA 2.6. *Let $\hat{u}(\cdot) \in \mathcal{U}$ be arbitrary and let $\hat{x}(\cdot)$ be the corresponding solution of* (7). *Define $u_N(\cdot)$ as in* (11), (12), *and let $x_N(\cdot)$ be the trajectory of* (7) *corresponding to $u_N(\cdot)$. Then*

$$\|\hat{x}(\cdot) - x_N(\cdot)\| \le e^{L_f(T-t_0)} (T - t_0) L_F (1 + M_F) |U| h.$$

The proof of the following lemma goes along the line of the direct proof of the maximum principle for the problem (9) and therefore is omitted.

LEMMA 2.7. *Let $\hat{u}(\cdot) \in \mathcal{U}$ be an arbitrary optimal control of* (9) *and let $u(\cdot) \in \mathcal{U}$ be another admissible control. Let $\hat{x}(\cdot)$, $\hat{g}$ and $x(\cdot)$, g be the corresponding trajectories and values of the objective function. Denote by $\hat{\psi}(\cdot)$ the solution of the adjoined system*

$$\dot{\hat{\psi}} = -\frac{\partial f^*}{\partial x}(t, \hat{x}(t), \hat{u}(t))\hat{\psi}, \quad \hat{\psi}(T) = -\frac{\partial g}{\partial x}(\hat{x}(T)), \tag{13}$$

where $f(t,x,u) = f_0(t,x) + F(t,x)u$ and * denotes transposition. Then

$$0 \le g - \hat{g} \le \int_{t_0}^{T} \langle \hat{\psi}(t), F(t, \hat{x}(t))(\hat{u}(t) - u(t)) \rangle \, dt$$

$$+ \int_{t_0}^{T} \left\langle \hat{\psi}(t), \sum_{k=1}^{r} (\hat{u}^k(t) - u^k(t)) \frac{\partial f_k}{\partial x}(t, \hat{x}(t))(x(t) - \hat{x}(t)) \right\rangle dt$$

$$+ L'_g |\hat{x}(T) - x(T)|^2 + (L'_0 + L'_F|U|)\|\hat{\psi}\|_C \|\hat{x} - x\|_L^2,$$

where u^i is the ith component of u and the constants in the above expression are defined in Remark 1.

LEMMA 2.8. *Let $\hat{u}(\cdot)$, $\hat{x}(\cdot)$, and $\hat{\psi}(\cdot)$ be as in Lemma* 2.7. *Then the function*

$$l(t) = F^*(t, \hat{x}(t))\hat{\psi}(t) \tag{14}$$

satisfies conditions (i) *and* (ii) *above. Moreover, both the Lipschitz constant of $l(\cdot)$ and the variation of $\dot{l}(\cdot)$ can be estimated by CL_g, where C depends only on L, M, $|U|$, and $T - t_0$.*

Proof. A straightforward estimation of the Lipschitz constant L_l of $l(\cdot)$ gives

$$L_l \le L_F(1 + M_f)M_\psi + M_F L_\psi,$$

where M_ψ and L_ψ are the maximum of the norm and the Lipschitz constant of $\psi(\cdot)$, respectively. Moreover, having in mind (13), we can estimate

$$M_\psi \le e^{M'_f(T-t_0)} L_g, \qquad L_\psi \le e^{M'_f(T-t_0)} M'_f L_g = C' L_g, \tag{15}$$

where C' depends on the constants listed in the formulation of the lemma.

Let us estimate the variation of $\dot{l}(\cdot)$. Direct calculation shows that the derivative of the ith component of $l(\cdot)$ is

$$\dot{l}_i = \left\langle \hat{\psi}, \frac{\partial f_i}{\partial t} + [f_i, f_0] + \sum_{j=1}^{r} \hat{u}_j [f_i, f_j] \right\rangle,$$

where all the arguments in the above expression are either t or (where appropriate) $(t, \hat{x}(t))$. The last term, however, is zero, according to Assumption 3. Therefore, $\dot{l}(\cdot)$ turns out to be even Lipschitz continuous, and its Lipschitz constant can be explicitly estimated by $C'' L_g$, where C'' depends only on the constants listed in the formulation of the lemma. The same applies, therefore, to the variation of $\dot{l}(\cdot)$. ∎

Now we are ready to proceed with the proof of the theorem.

Proof of Theorem 2.2. All numbers c_1, $c_2, \dots$ appearing in the subsequent proof depend only on the constants listed in Theorem 2.2.

Let $\hat{u}(\cdot) \in \mathcal{U}$ be an arbitrary optimal control, $\hat{x}(\cdot)$ be the corresponding trajectory of (7) and $\hat{\psi}(\cdot)$ be the corresponding solution of the adjoined equation (13).

Define the control function $u_N(\cdot) \in \mathcal{U}_N$ as

$$u_N(t) = \frac{1}{h} \int_{t_i}^{t_{i+1}} \hat{u}(s)\, ds \ \text{ for } \ t \in [t_i, t_{i+1}),\ i = 0, \dots, N-1,$$

and let $x_N(\cdot)$ be the corresponding trajectory of (7). According to Lemma 2.7

$$0 \le \hat{g}_N - \hat{g} \le g(x_N(T)) - g(\hat{x}(T)) \le \int_{t_0}^{T} \langle l(t), \hat{u}(t) - u_N(t) \rangle\, dt \tag{16}$$

$$+ \sum_{k=1}^{r} \int_{t_0}^{T} \langle B_k(t), x_N(t) - \hat{x}(t) \rangle (\hat{u}^k(t) - u_N^k(t))\, dt + e \|\hat{x} - x_N\|_C^2,$$

where $l(t)$ is defined by (14),

$$B_k(t) = \frac{\partial f_k^*}{\partial x}(\hat{x}(t), t) \hat{\psi}(t),$$

and $e = L_g' + L_f' M_\psi \le L_g' + c_1 L_g$ (see (15)).

Denote $\Delta(t) = x_N(t) - \hat{x}(t)$. According to Lemma 2.6, $|\Delta(t)| \le c_2 h$. Since $\hat{u}(\cdot)$ is an optimal control to problem (9), (7), (3) and, therefore, satisfies the maximum principle, we have that

$$\langle l(t), \hat{u}(t) \rangle = \max_{u \in U} \langle l(t), u \rangle = \hat{l}(t).$$

Applying Lemmas 2.5 and 2.8, we obtain the inequality

$$0 \le \hat{g}_N - \hat{g} \le \sum_{k=1}^{r} \int_{t_0}^{T} \langle B_k(t), x_N(t) - \hat{x}(t) \rangle (\hat{u}^k(t) - u_N^k(t))\, dt + \frac{c_3 L_g + c_4 L_g'}{N^2}.$$

The first term in the right-hand side can be represented as

$$\delta = \frac{1}{h} \sum_{k=1}^{r} \sum_{i=0}^{N-1} \int_{t_i}^{t_{i+1}} \int_{t_i}^{t_{i+1}} \langle B_k(t), \Delta(t) \rangle (\hat{u}^k(t) - \hat{u}^k(s))\, ds\, dt.$$

Because of the Lipschitz continuity of $B_k(\cdot)$ (see (15)) and the estimation of $\Delta(\cdot)$ in Lemma 2.6 we have

$$\delta \le \frac{1}{h} \sum_{k=1}^{r} \sum_{i=0}^{N-1} \int_{t_i}^{t_{i+1}} \int_{t_i}^{t_{i+1}} \langle B_k(t_i), \Delta(t) \rangle (\hat{u}^k(t) - \hat{u}^k(s))\, ds\, dt + (c_5 L_g + c_6 L_g')/N^2.$$

Using the fact that the double integral of $\hat{u}^k(t) - \hat{u}^k(s)$ equals zero, we obtain

$$\delta \le \frac{1}{h} \sum_{k=1}^{r} \sum_{i=0}^{N-1} \int_{t_i}^{t_{i+1}} \int_{t_i}^{t_{i+1}} \langle B_k(t_i), \Delta(t) - \Delta(t_i) \rangle (\hat{u}^k(t) - \hat{u}^k(s))\, ds\, dt + (c_5 L_g + c_6 L_g')/N^2.$$

Thanks to Lemma 2.6, we have for $t \in [t_i, t_{i+1}]$

$$\Delta(t) - \Delta(t_i) = \int_{t_i}^{t} \dot{\Delta}(\tau)\, d\tau = \int_{t_i}^{t} (f_0(x_N(\tau),\tau) - f_0(\hat{x}(\tau),\tau))\, d\tau$$

$$+ \int_{t_i}^{t} \sum_{j=1}^{r} (f_j(x_N(\tau),\tau)u_N^j(\tau) - f_j(\hat{x}(\tau),\tau)\hat{u}^j(\tau))\, d\tau$$

$$= \int_{t_i}^{t} \sum_{j=1}^{r} \hat{f}_j(t_i)(u_N^j(\tau) - \hat{u}^j(\tau))\, d\tau + O(h^2),$$

where $\hat{f}_j(t) = f_j(\hat{x}(t), t)$ (further, we use similar notation for the derivative) and $O(h^2) \le c_7/N^2$. Hence,

$$\delta \le \frac{1}{h} \sum_{k=1}^{r} \sum_{i=0}^{N-1} \sum_{j=1}^{r} \int_{t_i}^{t_{i+1}} \int_{t_i}^{t_{i+1}} \int_{t_i}^{t} \left\langle \hat{\psi}(t_i), \frac{\partial \hat{f}_k}{\partial x} \hat{f}_j(t_i) \right\rangle$$

$$\times (u_N^j(\tau) - \hat{u}^j(\tau))(\hat{u}^k(t) - \hat{u}^k(s))\, d\tau\, ds\, dt + (c_7 L_g + c_8 L_g')/N^2$$

$$= \frac{1}{h^2} \sum_{i=0}^{N-1} \sum_{j=1}^{r} \sum_{k=1}^{r} \left\langle \hat{\psi}(t_i), \frac{\partial \hat{f}_k}{\partial x} \hat{f}_j(t_i) \right\rangle \int_{t_i}^{t_{i+1}} \int_{t_i}^{t_{i+1}} \int_{t_i}^{t_{i+1}} \int_{t_i}^{t}$$

$$\times (\hat{u}^j(\theta) - \hat{u}^j(\tau))(\hat{u}^k(t) - \hat{u}^k(s))\, d\tau\, d\theta\, ds\, dt + (c_8 L_g + c_9 L_g')/N^2.$$

Using Assumption 3 one can rewrite the above sums as

$$\frac{1}{h^2} \sum_{i=0}^{N-1} \sum_{k=1}^{r} \left\langle \hat{\psi}(t_i), \frac{\partial \hat{f}_k}{\partial x} \hat{f}_k(t_i) \right\rangle \int_{t_i}^{t_{i+1}} \int_{t_i}^{t_{i+1}} \int_{t_i}^{t_{i+1}} \int_{t_i}^{t} (\hat{u}^k(\theta) - \hat{u}^k(\tau))(\hat{u}^k(t) - \hat{u}^k(s))\, d\tau\, d\theta\, ds\, dt$$

$$+ \frac{1}{h^2} \sum_{i=0}^{N-1} \sum_{1 \le j < k \le r} \left\langle \hat{\psi}(t_i), \frac{\partial \hat{f}_k}{\partial x} \hat{f}_j(t_i) \right\rangle \int_{t_i}^{t_{i+1}} \int_{t_i}^{t_{i+1}} \int_{t_i}^{t_{i+1}} \int_{t_i}^{t} [(\hat{u}^j(\theta) - \hat{u}^j(\tau))(\hat{u}^k(t) - \hat{u}^k(s))$$

$$+ (\hat{u}^k(\theta) - \hat{u}^k(\tau))(\hat{u}^j(t) - \hat{u}^j(s))]\, d\tau\, d\theta\, ds\, dt.$$

It can be shown that each of the above fourtuple integrals equals zero, which completes the proof of the theorem. □

3. Discretization of optimal control problems. Theorem 2.2 provides a basis for obtaining discrete approximations of second-order accuracy (with respect to the length of the discretization step) to optimal control problems. The underlying idea is that thanks to Theorem 2.2 one can first restrict the consideration to control functions that are constant between each of two neighboring grid points t_i, t_{i+1}, sacrificing only the $O(h^2)$ value of the objective function. For any fixed control function from this class, one can then discretize the corresponding differential equation (7) by means of any *single-step* discretization scheme that provides at least $O(h^3)$ local accuracy. According to our smoothness assumptions and the fact that the control is constant in any particular subinterval $[t_i, t_{i+1})$, such schemes exist. In this way one

can obtain a variety of discrete-time problems, each of which provides an approximation of second-order accuracy (in the sense described in the next lines) to the original problem. To illustrate the approach we take a second-order symmetric Runge–Kutta scheme (known as Euler–Cauchy method).

The approach is directly applicable to terminal-type optimal control problems, but the well-known trick used below allows us to consider the following more general problem (where the criterion is nonlinear in u):

$$g(x(T)) + \int_{t_0}^{T} [e_0(t, x(t)) + \langle e(t, x(t)), \varphi(u(t))\rangle]\, dt \longrightarrow \min, \tag{17}$$

$$\dot{x} = f_0(t, x) + F(t, x)u, \quad x(t_0) \in X_0, \tag{18}$$

$$u(t) \in U \tag{19}$$

on the fixed time-interval $[t_0, T]$. Here $e_0(t, x)$, $e(t, x) = (e_1(t, x), \dots, e_p(t, x))$, and $\varphi(u) = (\varphi_1(u), \dots, \varphi_p(u))$ are given functions. Let $\hat{J}$ be the optimal value of the objective function. Given the natural number N we find below an N-stage discrete-time optimal control problem $\mathcal{P}_N$ such that for any optimal control $u_N = (u_N^0, \dots, u_N^{N-1})$ of $\mathcal{P}_N$, if $u_N(\cdot) \in \mathcal{U}$ is defined as $u_N(t) = u_N^k$ for $t \in [t_k, t_{k+1})$, then the corresponding performance value $J(u_N(\cdot))$ of (17), (18) satisfies

$$J(u_N(\cdot)) \le \hat{J} + \text{const}/N^2.$$

Thus, the meaning of accuracy that we employ does not imply any relation between the optimal controls or trajectories of the two problems; rather, it ensures that the control function for the continuous-time problem that we construct by solving the discrete-time one is $O(1/N^2)$-optimal. We refer to Dontchev [6, 7], Mordukhovich [17], and the papers quoted in [6, 7] for results concerning (first-order) approximation of the optimal control function via discretization of problem (17), (18), (19).

A number of papers explicitly or implicitly prove accuracy $O(1/N)$ of approximation if the discrete-time problem is obtained by formal application of the Euler or other discretization schemes to the differential equation and the integral involved in (17), (18) (see [6, 7] for a comprehensive bibliography). The known results for higher order accuracy (cf. [12, 18]), however, are based on certain regularity requirements for the optimal controls of (17), (18), (19), which are by no means implied by our suppositions below. On the contrary, it might happen that all optimal controls are of unbounded variation, nonintegrable in Riemann sense, or even discontinuous almost everywhere (cf. [19]). Nevertheless, we prove second-order accuracy, even with a constant (multiplying h^2 in the estimation) that is not "sensitive" with respect to the data, supposing, however, that a certain additional structural condition (corresponding to Assumption 3) is satisfied.

The next result extends the one obtained for linear systems in [22] (accuracy $O(h^2)$) and the one from [21], where accuracy $O(1/N^{1.5})$ is proven under similar suppositions.

Define the following discrete-time optimal control problem.

Minimize

$$g(x_N) + \frac{h}{2} \sum_{k=0}^{N-1} [e_0(t_k, x_k) + e_0(t_{k+1}, x_{k+1}) + \langle e(t_k, x_k) + e(t_{k+1}, x_{k+1}), \varphi(u_k)\rangle] \tag{20}$$

subject to

$$x_{k+1} = x_k + 0.5h[f(t_k, x_k, u_k) + f(t_{k+1}, x_k + hf(t_k, x_k, u_k), u_k)], \tag{21}$$

$$u_k \in U, \quad k = 0, \dots, N-1, \tag{22}$$

where, as in the previous section, $f(t, x, u) = f(t, x) + F(t, x)u$.

THEOREM 3.1. *Let Assumptions* 1–4 *from section* 2 *be fulfilled (for* $\mathcal{G} = \{g\}$*). Let, in addition, the functions* φ_j *be convex and continuous, the functions* e_j *satisfy the same differentiability conditions as* f_i*, and* $e_j(x, t) \geq 0$ *for every* (t, x)*,* $j = 1, \dots, p$*. Let, moreover,* $\langle \frac{\partial e_j}{\partial x}, f_i \rangle(t, x) = 0$ *for* $i = 1, \dots, r$*,* $j = 1, \dots, p$*, and* $(t, x) \in [t_0, T] \times \mathbf{R}^n$*. Then there are constants* C_1 *and* C_2 *such that for every natural number* N *and for every* ε*-optimal control* $(u_0, u_1, \dots, u_{N-1})$ *of problem* (20)–(22) *with corresponding performance value* J_N

(1)

$$|\hat{J} - J_N| \leq C_1/N^2 + \varepsilon; \tag{23}$$

(2) *the control function* $u_N(\cdot)$ *defined as* $u_N(t) = u_k$ *for* $t \in [t_k, t_{k+1})$*,* $k = 0, \dots, N-1$*, when applied to* (17), (18) *gives value* $J(u_N(\cdot))$ *of the objective function, that satisfies*

$$J(u_N(\cdot)) \leq \hat{J} + C_2/N^2 + \varepsilon.$$

("ε-optimal" in the above formulation means that $J_N \leq \hat{J}_N + \varepsilon$, where $\hat{J}_N$ is the optimal value in the problem (20)–(22).)

Remark 2. The constants C_1 and C_2 in the above theorem do not depend on the particular data. Rather, they depend on certain constants associated with the data, as in Theorem 2.2 (with $e_0(\cdot)$ and $e(\cdot)$ treated similarly as $f_0(\cdot)$ and $F(\cdot)$). In this sense C_1 and C_2 are not sensitive with respect to the data, nor to the properties of the optimal control.

Proof. One can reformulate problem (17), (18), (19) as follows:

$$g(x(T)) + x^0(T) \longrightarrow \min, \tag{24}$$

$$\dot{x}^0 = e_0(t, x) + \langle e(t, x), v \rangle, \quad x^0(t_0) = 0, \tag{25}$$

$$\dot{x} = f_0(t, x) + \sum_{i=1}^{p} f_i(t, x)u^i, \quad x(t_0) = x_0, \tag{26}$$

$$(u(t), v(t)) \in W, \tag{27}$$

where

$$W = \{(u, v)\,;\ u \in U,\ \varphi_j(u) \leq v^j \leq \bar{M},\ j = 1, \dots, p\}$$

is apparently convex and compact and the constant $\bar{M}$ is chosen so that

$$\bar{M} \geq \max\{\varphi_j(u)\,;\ u \in U,\ j = 1, \dots, p\}.$$

Thanks to the nonnegativity of $e_i(\cdot)$ it is easy to verify that the optimal values of problems (17), (18), (19) and (24)–(27) coincide. Moreover, if $\hat{u}(\cdot)$ is an optimal control of the former problem, then $(\hat{u}(\cdot), \varphi(\hat{u}(\cdot))$ is an optimal control to the latter. The same applies also to the pair consisting of the discrete-time problem (20), (21), (22) and the following one:

$$g(x_N) + x_N^0 \longrightarrow \min, \tag{28}$$

$$x_{k+1}^0 = 0.5h \sum_{k=0}^{N-1} [e_0(t_k, x_k) + e_0(t_{k+1}, x_{k+1}) + \langle e(t_k, x_k) + e(t_{k+1}, x_{k+1}), v_k \rangle], \tag{29}$$

$$x_{k+1} = x_k + 0.5h[f(t_k, x_k, u_k) + f(t_{k+1}, x_k + hf(t_k, x_k, u_k), u_k)], \tag{30}$$

$$(u_k, v_k) \in W, \quad k = 0, \dots, N-1. \tag{31}$$

Let $\hat{u}(\cdot)$ be an optimal control of (17), (18), (19). Since $(\hat{u}(\cdot), \hat{v}(\cdot)) = \varphi(\hat{u}(\cdot))$ is an optimal control of (24)–(27), we can apply Theorem 2.2. Notice that the condition $\langle \frac{\partial e_j}{\partial x}, f_i \rangle = 0$ implies that Assumption 3 of Theorem 2.1 is fulfilled for the extended system (29), (30). Hence,

$$J(\hat{u}_N(\cdot), \hat{v}_N(\cdot)) \le \hat{J} + \frac{C}{N^2}, \tag{32}$$

where $J(u, v)$ is the performance value of (24)–(27) corresponding to the control function (u, v), and $\hat{u}_N, \hat{v}_N$ is the piecewise constant control with jumps only at the grid points $t_1, \dots, t_{N-1}$, obtained by local averaging of (u, v), as in (11), (12). Discretizing equations (25), (26) by using the chosen Runge–Kutta scheme (and the fact that the control is constant in each subinterval $[t_i, t_{i+1})$) and thanks to the equivalence of problems (20), (21), (22) and (28)–(31), we obtain the estimation

$$\hat{J}_N \le \hat{J} + \frac{C_1}{N^2}. \tag{33}$$

Now let $(\tilde{u}_0, \dots, \tilde{u}_{N-1})$ be an ε-optimal control in problem (20)–(22). Then $((\tilde{u}_0), \dots, \tilde{u}_{N-1}, \tilde{v}_0 = \varphi(\tilde{u}_0), \dots, \tilde{v}_{N-1} = \varphi(\tilde{u}_{N-1}))$ is an ε-optimal control to problem (28)–(31). Therefore, the continuous-time control

$$\tilde{u}(t) = \tilde{u}_k, \quad \tilde{v}(t) = \tilde{v}_k, \quad t \in [t_k, t_{k+1})$$

gives the value

$$J(\tilde{u}, \tilde{v}) \le \hat{J}_N + \varepsilon + \frac{C_2}{N^2};$$

therefore,

$$J(\tilde{u}) \le \hat{J}_N + \varepsilon + \frac{C_2}{N^2}.$$

This, together with (33), gives on one hand

$$\hat{J} \le \hat{J}_N + \varepsilon + \frac{C_2}{N^2},$$

and on the other hand

$$J(\tilde{u}) \le \hat{J} + \varepsilon + \frac{C_1 + C_2}{N^2}.$$

The constants C_1 and C_2 result from the constants in Theorem 2.2 and from the constant in the local $O(h^3)$-error of the Runge–Kutta scheme, which can also be estimated by the quantities mentioned in Remark 2. □

Finally we mention that, as it is shown in [22], formal application of higher order Runge–Kutta schemes (even to time-invariant linear optimal control problems) does not provide better than $O(h^2)$ estimation in (23), excepting some "special" cases.

4. Approximation of the reachable set. The issue of approximation of the reachable set of a control system (or differential inclusion) is treated in many papers, but wherever discretization schemes are employed, typically at most first-order estimation of the error is obtained (cf. [8, 14, 11, 9, 1]). The paper [22] develops a second-order approximation scheme applicable to linear control systems. Below, we extend this result, as an application of Theorem 2.1.

For two compact sets $P, Q \subset \mathbf{R}^n$ the Hausdorff semidistance from P to Q is defined as

$$H^+(P,Q) = \inf\{\alpha \ge 0\,;\ P \subset Q + \alpha\mathbf{B}\}$$

($\mathbf{B}$ is the unit ball in $\mathbf{R}^n$), and the Hausdorff distance is

$$H(P,Q) = \max\{H^+(P,Q), H^+(Q,P)\}.$$

If the set Q is convex, then one can represent

$$H^+(P,Q) = \sup_{|l|=1}\{0, \inf_{x\in Q}\langle l,x\rangle - \inf_{x\in P}\langle l,x\rangle\}. \tag{34}$$

The above relation will be applied in the cases $P = R(T)$ (the reachable set of (7) in the set $\mathcal{U}$ of admissible controls) and $Q = R_N(T)$ (the reachable set of (7) in the set $\mathcal{U}_N$ of admissible controls). If $R_N(T)$ happens to be convex, then in view of (34), one can choose the collection of performance indexes

$$\mathcal{G} = \{g(\cdot) = \langle l, \cdot\rangle\,;\ |l| = 1\},$$

which obviously fulfills Assumption 4 with $L_g = 1$ and $L'_g = 0$. Supposing that Assumptions 1–3 are also fulfilled, one can apply Theorem 2.1 to get the estimation

$$H(R_N(T), R(T)) \le \frac{C}{N^2},$$

where C is as in Theorem 2.2. Then a similar argument as in section 3 leads to a *set-valued* version of any single-step discretization scheme for ordinary differential equations. The approach is illustrated by the next theorem, which corresponds to the Runge–Kutta scheme used in section 3. The same scheme, but interpreted in a different way in the set-valued case, is employed by Lempio [16].

THEOREM 4.1. *Let Assumptions* 1–3 *from section* 2 *be fulfilled. Given* N*, define the sequence of sets* X_k^N *by*

$$X_{k+1}^N = \bigcup_{x\in X_k^N}\{x + 0.5h\tilde{f}_h(k,x,U)\}, \quad X_0^N = \{x_0\},\ \ k = 0,\dots,N-1, \tag{35}$$

where

$$\tilde{f}_h(k,x,u) = f(t_k,x,u) + f(t_{k+1}, x + hf(t_k,x,u), u).$$

Then there exists a constant C (*as in Theorem* 2.2) *such that for any* N *for which* X_N^N *is convex*

$$H(X_N^N, R(T)) \le \frac{C}{N^2}.$$

In the case of a linear system (7), the set-valued dynamical system (35) has the form

$$X_{k+1}^N = A_k X_k^N + B_k U$$

(cf. [22], where A_k and B_k are given explicitly), and X_N^N is apparently convex. Computer implementations of (35) are described in [13, 3].

If the convexity assumption for $R_N(T)$ is not satisfied (or cannot be verified), then nonlinear functions $g(\cdot)$ should be involved in a dual representation like (34). However, Theorem 2.1 imposes restrictions on the set of "test" functions $\mathcal{G}$, namely, uniform boundedness of the Lipschitz constant of the derivative. This restriction results in specific geometric requirements for the set $Q = R_N(T)$, necessary to ensure that the separation argument (needed in the proof of the nonconvex/nonlinear version of (34)) still works. Here we skip this analysis, quoting only a result from [21] that is independent of the geometry of $R_N(T)$, but the order of the estimation is worse.

THEOREM 4.2. *Let Assumptions* 1–3 *be fulfilled. Then there exists a constant* C (*as in Theorem* 2.2) *such that for any* N,

$$H(X_N^N, R(T)) \le \frac{C}{N^{1.5}},$$

where X_N^N *is the end state of the set-valued dynamic system* (35).

5. Time-step aggregation of discrete-time control systems. In this section we apply Theorem 2.1 to the following problem with obvious practical motivation. Consider a discrete-time control system

$$x_{i+1} = \mathcal{F}(i, x_i, u_i), \quad i = 0, \dots, N-1, \;\; x_0 \text{ given}, \tag{36}$$

where $x_i \in \mathbf{R}^n$, $u_i \in U \subset \mathbf{R}^r$. Generally speaking, we shall discuss the issue of approximation of (36) by another discrete-time system with significantly smaller number of steps, eventually sacrificing performance value. A natural way to do this is to keep the input vector u_i constant on M successive steps, changing its value only at the "moments" $i = kM$. Presumably $N = KM$, so that from a control point of view, system (36) becomes a K-step system (and can be explicitly approximately rewritten as such, as shown at the end of the section). However, the main point will be the analysis of the loss of performance, resulting from the aggregation of the input values.

The function $\mathcal{F}$ is supposed to be in the form

$$\mathcal{F}(i,x,u) = x + h(p_0(i,x) + P(i,x)u), \tag{37}$$

where $p_0(i,\cdot) : \mathbf{R}^n \mapsto \mathbf{R}^n$, $P(i,\cdot) = [p_1(i,\cdot), \dots, p_r(i,\cdot)] : \mathbf{R}^n \mapsto \mathbf{R}^{n\times r}$. The increment factor h is supposed to be "small," while the number of steps N is "large," so that $T = hN$ is a "finite" number.

The time-aggregated system has the form

$$y_{k+1} = \mathcal{F}_M(k, y_k, v_k), \quad k = 0, \dots, K-1, \quad y_0 = x_0, \tag{38}$$

where

$$\mathcal{F}_M(k, y, v) = \mathcal{F}((k+1)M - 1, \cdot, v) \circ \cdots \circ \mathcal{F}(kM, \cdot, v)(y) \tag{39}$$

is the M-times iterated value of y with fixed v.

For any sequence $u_0, \dots, u_{N-1}$, $u_i \in U$, the corresponding (according to (36)) sequence $x_0, \dots, x_N$ is called a trajectory of (36). Similarly, for any sequence $v_0, \dots, v_{K-1}$, $v_i \in U$, the corresponding (according to (38)) sequence $y_0, \dots, y_K$ is a trajectory of (38). In order to compare the two sets of trajectories (denoted further by X_N and Y_K, respectively), we define the following criterion, as in section 1. Let $\mathcal{G} = \{g(\cdot)\}$ be a prescribed collection of functions $g : \mathbf{R}^n \mapsto \mathbf{R}$, which are Lipschitz continuous together with their first derivatives, with a common Lipschitz constant L_g. The value

$$\delta(N, K) = \sup_{g \in \mathcal{G}} \{ \inf_{(y_0, \dots, y_K) \in Y_K} g(y_K) - \inf_{(x_0, \dots, x_N) \in X_N} g(x_N) \}$$

will be considered as a measure of the loss of performance when passing from (36) to (38). In particular, if $\mathcal{G}$ consists of a single function g, then $\delta(N, K)$ is the difference between the optimal values of the problems $\min g(y_K)$ and $\min g(x_N)$ subject to (38) and (36), respectively. If $\mathcal{G}$ consists of all linear functionals with unit norm and the reachable sets of (36) and (38) are convex, then $\delta(N, K)$ is just the Hausdorff distance between the reachable sets.

Under the assumptions listed below, one can obtain in a standard way that for each $M > 1$

$$\delta(N, K) \leq \text{const} \frac{1}{K}. \tag{40}$$

Below we obtain the estimation

$$\delta(N, K) \leq C \left(\frac{1}{N} + \frac{1}{K^2} \right), \tag{41}$$

which is essentially better than (40). In particular, for the reasonable choice $K = M = \sqrt{N}$ we obtain estimation Ch, while (40) gives $C\sqrt{h}$. Moreover, the proof allows us to explicitly obtain aggregated systems of the type shown in (38) (without iterating the operator $\mathcal{F}$ as in (39)), for which (41) is satisfied.

We suppose the following.

Assumption $1'$. There is a constant R such that

$$|p_j(i, x)| \leq R(1 + |x|) \tag{42}$$

for every $x \in \mathbf{R}^n$, $j = 0, \dots, r$, $i = 0, \dots, N-1$.

Denote by S the unit ball in $\mathbf{R}^n$ centered at the origin and with the following radius: $(1 + |x_0|) \exp(3R(1 + r|U|))$.

Assumption $2'$. The components of $p_0(i, \cdot)$ and $P(i, \cdot)$ and all their first derivatives are Lipschitz continuous (with a constant $L_{\mathcal{F}}$) in the set S. Moreover, there are constants d_0 and d_1 such that

$$|p_j(i+1, x) - p_j(i, x)| \leq h d_0, \quad i = 0, \dots, N-1, \tag{43}$$

$$|p_j(i+1,x) - 2p_j(i,x) + p_j(i-1,x)| \le 2h^2 d_1, \quad i = 1,\dots,N-1, \tag{44}$$

for any $x \in S$ and $j = 0,\dots,r$.

Assumption 3′.

$$[p_\alpha(i,\cdot), p_\beta(j,\cdot)](x) = 0$$

for every $x \in S$, $\alpha,\beta = 1,\dots,r$ and for those $i,j \in \{0,\dots N-1\}$ for which $|i-j| \le 4$.

The growth condition (42) replaces the more general boundedness condition in Assumption 1 just for technical convenience. Obviously, Assumption 3′ is automatically fulfilled if P is independent of x or if $r = \dim u = 1$. Conditions (43) and (44) are the discrete analogs of the differentiability conditions with respect to t in Assumption 2.

THEOREM 5.1. *Let the right-hand side of* (36) *have the form of* (37). *Then there exists a constant C depending only on R, L_g, $L_{\mathcal{F}}$, M, d_0, d_1, $|U|$, and T, such that* (41) *is satisfied for any N, M (for which $K = N/M$ is natural), for any functions p_0 and P for which Assumptions* 1′–3′ *are fulfilled, and for any $h \le T/N$.*

In the proof we use the following spline interpolation lemma, which can be verified by direct inspection.

LEMMA 5.2. *Let $\xi_0,\dots,\xi_N \in \mathbf{R}^n$ be given, $t_i = ih$, $h = T/N$. Denote*

$$\Delta_1(i) = \frac{\xi_{i+1} - \xi_{i-1}}{2h},$$

$$\Delta_2(i) = \frac{\xi_{i+1} - 2\xi_i + \xi_{i-1}}{2h^2}, \quad i = 1,\dots,N-1$$

(by definition, $\Delta_2(0) = \Delta_2(N) = 0$, $\Delta_1(0) = (\xi_1 - \xi_0)/h$, $\Delta_1(N) = (\xi_N - \xi_{N-1})/h$). Assume that $|\Delta_1(i)| \le d_0$, $|\Delta_2(i)| \le d_1$. Then the function

$$\xi(t) = \begin{cases} \xi_i + (t-t_i)\Delta_1(i) + \frac{(t-t_i)^2}{2}(3\Delta_2(i) - \Delta_2(i+1)) \ \text{ for } \ t \in [t_i, t_i + \frac{h}{2}], \\ \xi_{i+1} + (t-t_{i+1})\Delta_1(i+1) + \frac{(t-t_{i+1})^2}{2}(3\Delta_2(i+1) - \Delta_2(i)), \quad t \in (t_i + \frac{h}{2}, t_{i+1}) \end{cases}$$

has the following properties:

(1) *$\xi(t_i) = \xi_i$, $i = 0,\dots,N$;*

(2) *$\xi(\cdot)$ is Lipschitz continuous with constant $d_0 + 2hd_1$;*

(3) *$\xi(\cdot)$ is Lipschitz continuous with constant $4d_1$;*

(4) *$t_0,\dots,t_N$ being fixed, for $t \in [t_i, t_{i+1})$ the value $\xi(t)$ depends only on ξ_{i-1}, ξ_i, ξ_{i+1}, ξ_{i+2}; the dependence is linear, with coefficients that depend only on $\Delta_0(i)$ and $\Delta_1(i)$;*

(5) *$|\xi(t)| \le 2.5 \max\{|\xi_0|,\dots,|\xi_N|\}$.*

Proof of Theorem 5.1. For each $j = 0,\dots,r$ we apply Lemma 5.2 for $\xi_i = p_j(i,x)$, where x is considered as a parameter. The suppositions of the lemma are satisfied according to (43) and (44) with the same d_0 and d_1. Denote by $f_j(\cdot,x)$ the resulting interpolation spline $\xi(\cdot)$. Thanks to property (4) of $\xi(\cdot)$ in Lemma 5.2 the function $f_j(t,\cdot)$ is differentiable with a Lipschitz continuous derivative whose Lipschitz constant can be estimated by d_0 and d_1. The same applies to $f_j(\cdot,x)$ for any $x \in S$, because of properties (2) and (3) of $\xi(\cdot)$. Thus, Assumption 2 from section 2 is fulfilled for f_0 and $F = (f_1,\dots,f_r)$. Assumption 3 is also satisfied because of Assumption 3′ and the property (4) of $\xi(\cdot)$.

Now consider the control system

$$\dot{x} = f_0(t,x) + F(t,x)u, \quad x(0) = x_0, \quad u \in U. \tag{45}$$

According to property (5) in Lemma 5.2, each $f_j(t,\cdot)$ satisfies the growth condition (42) with constant $3R$ instead of R. Therefore, Assumption 1 from section 2 is also fulfilled with S defined above in the present section.

Because of property (1) in Lemma 5.2, system (36), (37) can be viewed as an Euler discretization of (45) with step length h.

From [8] we obtain the following estimation of the Hausdorff distance between the reachable set $R(T)$ of (45) on $[0,T]$ and the reachable set R_N of (36):

$$H(R_N, R(T)) \le \frac{C_1}{N}, \tag{46}$$

where C_1 depends only on the constants listed in the formulation of the theorem (see also the first paragraph of the proof). Because of the equi-Lipschitz continuity of the functions $g \in \mathcal{G}$ we obtain

$$\sup_{g\in\mathcal{G}} \left| \inf_{x_N \in R_N} g(x_N) - \inf_{x(T)\in R(T)} g(x(T)) \right| \le \frac{C_1 L_g}{N}. \tag{47}$$

On the other hand, since Assumptions 1–4 are fulfilled by system (45), we can apply Theorem 2.1 for K (instead of N) subintervals of constant control. If $R_K(T)$ is the corresponding reachable set of (45) in the set $\mathcal{U}_K$ of admissible controls, we obtain the estimation

$$\sup_{g\in\mathcal{G}} \left| \inf_{x_K(T)\in R_K(T)} g(x_K(T)) - \inf_{x(T)\in R(T)} g(x(T)) \right| \le \frac{C_2}{K^2}. \tag{48}$$

For any $u(\cdot) \in \mathcal{U}_K$ one can discretize (45) by the Euler scheme with step h and come back to the discrete system (36), but with $u_{kM} = u_{kM+1} = \cdots = u_{(k+1)M-1}$. The accuracy with respect to the performance $\mathcal{G}$ is as in (46), which together with (47), (48) completes the proof. □

If instead of the Euler discretization scheme we apply in the last step of the proof the Euler–Cauchy scheme (or some other Runge–Kutta one) with step $\tau = T/K = Mh$, we obtain

$$x_{k+1} = x_k + 0.5\tau(f(t_k,x_k,u_k) + f(t_{k+1}, x_k + \tau f(t_k,x_k,u_k), u_k)), \quad k = 0,\dots,K-1,$$

where $f = f_0 + Fu$, $t_k = k\tau$, and u_k is the value of $u(\cdot)$ in (t_k, t_{k+1}). It is well known that

$$|x(T) - x_N| \le C_3/K^2.$$

Hence, denoting for $k = 0,\dots,K-1$

$$\mathcal{F}_M(k,y,v) = y + 0.5\tau(\mathcal{F}(kM,y,v) + \mathcal{F}((k+1)M, y + \tau\mathcal{F}(k,y,v), v)), \tag{49}$$

we obtain for the reachable set $\tilde{R}_K$ of the corresponding system (38) the estimation

$$H(\tilde{R}_K, R_K(T)) \le \frac{C_3}{K^2}.$$

Combining this with (47) and (48) we get

$$\sup_{g\in\mathcal{G}} \left| \inf_{y_K\in\tilde{R}_K} g(y_K) - \inf_{x_N\in R_N} g(x_N) \right| \le \frac{C_1 L_G}{N} + \frac{C_2 + C_3 L_G}{K^2} = C\left(\frac{1}{N} + \frac{1}{K^2}\right).$$

The right-hand side of the K-stage system (38) is here defined by (49) instead of (39), but the estimation (41) still holds. In fact, (49) is an approximation of (39), which avoids the iteration in (39).

TRACKING FAST TRAJECTORIES ALONG A SLOW DYNAMICS: A SINGULAR PERTURBATIONS APPROACH*

ZVI ARTSTEIN† AND VLADIMIR GAITSGORY‡

Abstract. Controlled coupled slow and fast motions are examined in a singular perturbations setting. The objective is to minimize a cost functional that takes into account both the fast motion, supposing, say, tracking a fast target, and the slow dynamics. A method is offered to cope with the possibility that the fast flow has nonstationary limits. Invariant measures of the fast motion are then the controlled objects on the infinitesimal scale. Optimal amalgamation of them on the slow scale induces the variational limit, whose solutions are near optimal solutions of the perturbed system.

Key words. singular perturbations, chattering systems, tracking, invariant measures

1. Introduction.

This paper examines systems where a control policy $u(t)$ determines simultaneously two moving states. One—say, $x(t)$—moves at an ordinary pace, while the second—say, $y(t)$—progresses much faster. An example that motivates our analysis is the case where $y(t)$ is supposed to track a prescribed target $\Gamma(t)$, which also progresses very fast and whose characteristics may depend on the slow moving state. The controller's goal is to minimize a cost functional that takes into account both the success in tracking and the performance of the relatively slow motion. As it is assumed that both $y(t)$ and $\Gamma(t)$ evolve considerably faster than $x(t)$, their motion could be modeled as a singular perturbation relative to the slow time scale.

Indeed, we address a singularly perturbed model, where the small parameter ϵ reflects the speed ratio of the slow and fast movements. As customary, we look for a control rule associated with the limit optimization problem as $\epsilon \to 0$, and hope that it will generate a near optimal policy for $\epsilon > 0$ small. To this end, it is useful to identify a nominal control problem associated with the limit case. This nominal problem should be such that the case $\epsilon > 0$ small can be regarded as a small perturbation.

In many control and optimal control of singular perturbations problems, the reduced-order system (where ϵ is actually set to be equal to 0) serves as an appropriate nominal problem. For a partial list of successful applications of this approach, consult Kokotovic, Khalil, and O'Reilly [13]; Kokotovic and Sannuti [15]; Chow and Kokotovic [8]; Kokotovic, O'Malley, and Sannuti [14]; Saksena, O'Reilly, and Kokotovic [20]; and Kokotovic [11]. The reduced-order approach, however, may not be adequate for the analysis of the fast tracking. Indeed, the technique assumes that the fast dynamics converges on the fast scale to an equilibrium (that may vary on the slow scale). Such a consideration may not apply to optimal tracking of a fast moving target, which may exhibit nontrivial dynamics even relative to the fast time scale.

The present paper offers a nominal limit problem which is able to analyze dynamic limits. It is based on ideas rooted in earlier works of the authors; see [1], [3], [9], [10], and references therein and also Vigodner [21], where the case of slowly varying

controls is considered. The essence of our approach is that the controller solves on an infinitesimal scale dynamic control problems associated with the fast motion, and integrates their solutions on the slow scale. The integrated control policy is, under appropriate conditions, a near optimal policy for the original singular perturbations problem. In this paper we do not investigate thoroughly mathematical aspects such as finding general conditions under which the procedure works. Rather, we do not hesitate to assume that the solution to the limit problem exists, and we prove that it is near optimal. In the closing section of the paper we display a broad class of tracking problems for which the solution can be exhibited.

The paper is organized as follows. Sections 2 to 9 are devoted to the general theory, while in the last two sections of the paper we address applications. The model is set in section 2. Some preliminaries on invariant measures are given in section 3. The notion of near optimal solutions is defined in section 4. Sections 5 and 6 introduce and analyze control policies operating on the infinitesimal and global time scales, respectively. These are related to the limit problem as $\epsilon \to 0$, and the stability of them with respect to the singular perturbations is checked in section 7. In sections 8 and 9 we formulate the limit problem and verify when solutions of it are indeed near optimal solutions.

2. Setting the model. In what follows, x, which represents the slow state, is an element in R^n, the n-dimensional Euclidean space. The fast state y is in R^m. The admissible controls are Borel-measurable functions into a prescribed constraint set $U \subset R^k$. The time variable is t. We use interchangeably the notations $\frac{dx}{dt}$ and $\dot{x}$ to denote derivation with respect to time.

The cost function is generated by a function

$$c(x, y, u) : R^n \times R^m \times U \to R. \tag{2.1}$$

The underlying problem is then as follows. (SP stands for singular perturbations.)

SP Problem 2.1.

$$\text{minimize} \quad \int_0^1 c(x(t), y(t), u(t))dt \tag{2.2}$$

subject to

$$\begin{aligned} \frac{dx}{dt} &= f(x, y, u), \\ \epsilon\frac{dy}{dt} &= g(x, y, u) \end{aligned} \tag{2.3}$$

with initial conditions

$$x(0) = \overline{x}, \quad y(0) = \overline{y} \tag{2.4}$$

and where the minimization is over all admissible controls $u(t) : [0, 1] \to U$. The infimal value, as well as the optimal policies, may depend on ϵ. By

$$\text{val}(\epsilon) \tag{2.5}$$

we denote the infimal value of the problem for $\epsilon > 0$ fixed.

Remark 2.2. This is an important remark. We did not include explicit dependence of the equations on the slow time t. This was done only for the sake of clarity. The

state x could include the time t, with an additional equation added, namely, $\dot{t} = 1$, to the slow part of the equation. The time t could also be a variable in the cost c, given in (2.1) and (2.2).

We collect here some technical assumptions of the model that are assumed throughout the paper.

Assumption 2.3. The functions $c(x, y, u)$, $f(x, y, u)$, and $g(x, y, u)$ are continuous on their respective domains.

Assumption 2.4. For every x fixed and an admissible control $u(t) : [0, \infty) \to U$, if there exists a solution to the equation $\dot{y} = g(x, y, u(t))$, $y(0) = y_0$, then it is unique.

The standing assumptions are not strong. This is possible as in later developments the existence of solutions with prescribed properties is assumed or checked directly rather than derived from the underlying assumptions (see the introduction). Note, however, that we assume that the functions f, g, and c are defined globally. This can be clearly relaxed by introducing partial domains. We leave out the details.

3. Invariant measures. For the convenience of the reader, we briefly recall here the notion of invariant measure. It plays a major role in our definition of a near optimal control. For background information consult Nemytskii and Stepanov [18, Chapter VI.9] or [3].

A probability measure—say, μ—on a closed subset S of R^d is a countably additive map defined on the Borel subset of S, with values in [0,1] and $\mu(S) = 1$. Let $\dot{\sigma} = L(\sigma)$ be a differential equation on R^d. Suppose that for each $\sigma_0 \in S$ there exists a unique solution $\varphi(t, \sigma_0)$ satisfying $\varphi(0, \sigma_0) = \sigma_0$ of the differential equation and $\varphi(t, \sigma_0) \in S$ for $t \geq 0$. A probability measure μ on S is invariant with respect to $\dot{\sigma} = L(\sigma)$ if

$$\mu(C) = \mu(\varphi(t, C)) \tag{3.1}$$

for all $C \subset S$ closed and all $t \geq 0$ (here $\varphi(t, C) = \{\varphi(t, c) : c \in C\}$).

The support of a measure μ, denoted supp μ, is the smallest closed set C such that $\mu(C) = 1$. It is easy to see that if $\sigma_0 \in$ supp μ, then $\varphi(t, \sigma_0) \in$ supp μ for all t; hence (3.1) holds actually for all $t \in R$.

If S is compact, then an invariant measure of $\dot{\sigma} = L(\sigma)$ exists. If there exists a unique invariant probability measure μ, then any solution $\sigma(t)$ which is bounded for $t \geq 0$ converges in distribution to μ in the following sense. If ν_T is the measure on S given by

$$\nu_T(C) = \frac{1}{T}\lambda\{t : 0 \leq t \leq T, \sigma(t) \in C\}, \tag{3.2}$$

where λ is the Lebesgue measure, then ν_T converge weakly to μ (see the following paragraph). This means in particular that the asymptotic statistics of the values of $\sigma(\cdot)$ is governed by the unique invariant measure, namely,

$$\frac{1}{T}\int_0^T h(\sigma(\tau))d\tau \to \int_{R^d} h(z)\mu(dz) \tag{3.3}$$

for all $h : R^d \to R$ bounded and continuous.

The previous claim follows directly from the definition of weak convergence. The sequence μ_k of probability measures on R^d converges weakly to μ_0 if

$$\int_{R^d} h(z)\mu_k(dz) \to \int_{R^d} h(z)\mu_0(dz) \tag{3.4}$$

for every bounded and continuous function $h : R^d \to R$. See, e.g., [5].

4. Near optimal solutions. The notion of near optimality is formally introduced in this section. In essence it does not differ from the standard considerations of singularly perturbed problems—say, for the reduced order form (see, e.g., Chow and Kokotovic [8]). The novelty in the dynamic limit form is that we allow feedback of a clock variable as follows.

DEFINITION 4.1. *Let $S \subset R^\ell$ be bounded. A differential equation $\dot\sigma = L(\sigma)$ defined for $\sigma \in S$ is called a* clock *if for every $\sigma_0 \in S$ there exists a unique solution $\sigma(t)$ satisfying $\sigma(0) = \sigma_0$ and $\sigma(t) \in S$ for $t \geq 0$. A clock is called a* proper clock *if the equation has a unique invariant measure and every solution $\sigma(t)$ converges to it in distribution (see previous section). We shall also consider a* parametrized proper clock*, namely, an equation $\dot\sigma = L(x, \sigma)$ for $\sigma \in S$, which is a proper clock for each fixed x.*

The controls $\mathbf{u}$ that we consider as candidates for solving the singular perturbation problem 2.1 have the form

$$u(x, y, \sigma, t) : R^n \times R^m \times S \times [0, 1] \to U, \tag{4.1}$$

where $\sigma = \sigma(t)$ is a solution of

$$\epsilon \frac{d\sigma}{dt} = L(x, \sigma), \quad \sigma(0) = \sigma_0, \tag{4.2}$$

with $\dot\sigma = L(x, \sigma)$ being a parametrized proper clock on a set $S \subset R^\ell$; namely, we allow feedback of the slow and fast moving states, the clock variable and the time.

Remark 4.2. Although we have stated in Remark 2.2 that the slow state x may include the variable t and thus no explicit dependence on t is needed, we choose to have t as an explicit variable in (4.1). This is done to emphasize that, even if the state equations are time-invariant, an optimal control may be time-varying.

When the control $\mathbf{u}$ of (4.1) is inserted into the system (2.4)–(2.5) and (4.2), it yields (under standard assumptions) a solution which depends of course on ϵ. We denote it by

$$(x_\epsilon(t), y_\epsilon(t), \sigma_\epsilon(t)). \tag{4.3}$$

Note that although the clock equation in (4.2) is not affected by the control, there is an indirect dependence through the x variable.

We do not demand that the solution (4.3) be the unique solution of the control equation, although in most cases it is. The reason is that our results hold without the uniqueness assumption. (We shall need uniqueness for the limit problem, though.) But, in order to simplify notations, we suppress the dependence on the triplet (4.3) when defining $c_\epsilon(\mathbf{u})$, the cost of $\mathbf{u}$, as follows:

$$c_\epsilon(\mathbf{u}) = \int_0^1 c(x_\epsilon(t), y_\epsilon(t), u(x_\epsilon(t), y_\epsilon(t), \sigma_\epsilon(t), t))dt; \tag{4.4}$$

namely, $c_\epsilon(\mathbf{u})$ is the cost when applying $\mathbf{u}$ to Problem 2.1 with ϵ given. Note, however, that when applying the control $\mathbf{u}$, the precise value of ϵ need not be available. Instead, the control employs the variable σ, which is affected by ϵ through (4.2).

DEFINITION 4.3. *The control policy $\mathbf{u}$ is near optimal if*

$$c_\epsilon(\mathbf{u}) - \mathrm{val}(\epsilon) \to 0 \tag{4.5}$$

as $\epsilon \to 0$.

A motivation to consider a control function that depends on the auxiliary clock variable σ is as follows. Consider the case where the fast variable $y(t)$ has to track a fast target, with dynamical characteristics such as periodicity, almost periodicity, recurrence, etc., which could vary with the slow dynamics. A reasonable description for such a target is $\Gamma(x, \sigma(t))$, with $\sigma(t)$ a clock variable which solves an equation of the form (4.2).

For instance, the equation $\dot{\sigma} = 1 - \sigma$ is a proper clock on $[0, 2]$. The corresponding motion of a target $\Gamma(\sigma(t))$ exhibits a convergence to the stationary point $\Gamma(1)$. The convergence becomes faster when a small ϵ multiplies the derivative. A clock that models a periodic motion is obtained by setting $S = S^1$, the unit sphere $\{(\xi, \eta) : \xi^2 + \eta^2 = 1\}$ in R^2, and letting $\sigma = (\xi, \eta)$ be parametrized by $\arg(\xi + i\eta)$; namely, σ is the angle in the polar coordinates. Then setting $\dot{\sigma} = 1$ induces a periodic motion $\Gamma(\sigma(t))$ of the target. If $\dot{\sigma} = L(x)$ with $L(x) > 0$, then the induced target $\Gamma(x, \sigma(t))$ exhibits periodicity in time, with period and location depending on the slow state. A target whose movement is generated by two incommensurable periods—say, α and β—can be modeled by a clock on $S^1 \times S^1$, with (σ_1, σ_2) being the clock variable, and the differential system $\dot{\sigma}_1 = 2\pi\alpha^{-1}$, $\dot{\sigma}_2 = 2\pi\beta^{-1}$. In these examples there is clearly a unique invariant measure on S.

This general class of problems has the form

$$\text{minimize} \int_0^1 c(x(t), y(t), u(t), \Gamma(x(t), \sigma(t)))dt \tag{4.6}$$

subject to

$$\begin{aligned} \frac{dx}{dt} &= f(x, y, u), \\ \epsilon\frac{dy}{dt} &= g(x, y, u), \\ \epsilon\frac{d\sigma}{dt} &= L(x, \sigma), \end{aligned} \tag{4.7}$$

which is a particular case of (2.2)–(2.3), namely, with (y, σ) being the fast dynamics. It is then reasonable that the near optimal controls will employ the clock variable which induces the target. A concrete example is solved in the closing section.

5. Infinitesimal control policies. In the present and the next section we identify a class of control policies, among which we shall find the near optimal solutions. In this section we study their infinitesimal properties. In the next section we examine their global structure.

DEFINITION 5.1. *Let x be fixed. (x could incorporate an instant t of the slow time; see Remark* 2.2.*) Let $\dot{\sigma} = L(x, \sigma)$ be a parametrized proper clock on $S \subset R^\ell$. The control function*

$$u(x, y, \sigma) : R^n \times R^m \times S \to U \tag{5.1}$$

is called proper *if the following hold.*

(i) *$u(x, y, \sigma)$ is continuous, and for every $(y_0, \sigma_0) \in R^m \times S$, the system*

$$\begin{aligned} \frac{dy}{d\tau} &= g(x, y, u(x, y, \sigma)), \\ \frac{d\sigma}{d\tau} &= L(x, \sigma) \end{aligned} \tag{5.2}$$

with initial conditions $y(0) = y_0$, $\sigma(0) = \sigma_0$ *has a unique solution* $(y(\tau), \sigma(\tau))$, *which is defined and bounded on* $[0, \infty)$, *and*

(ii) *There is a unique invariant probability measure of* (5.2) *on* $R^m \times S$, *and it is with compact support.*

Remark 5.2. Condition (ii) may need an explanation. Recall that the clock equation $\dot{\sigma} = L(x, \sigma)$ is assumed to have a unique invariant measure; see Definition 4.1. Thus, the asymptotic statistics of $\sigma(\tau)$, for x fixed, is determined by this invariant measure. It is therefore plausible that the trajectory $y(\tau)$, which, say, tracks $\Gamma(x, \sigma(\tau))$, will also inherit this dynamical characteristic. This is indeed the case in the available tracking examples; see, e.g., [2] for the periodic case. The example treated in the closing section is of such nature.

PROPOSITION 5.3. *Let* $u(x, y, \sigma)$ *be a proper control function, and let* ν *be the invariant probability measure on* $R^m \times S$ *associated with it. Let* $(y(\tau), \sigma(\tau))$ *be the solution of* (5.2) *with initial conditions* (y_0, σ_0). *Then the limit*

$$\lim_{T\to\infty} \frac{1}{T} \int_0^T f(x, y(\tau), u(x, y(\tau), \sigma(\tau)))d\tau \tag{5.3}$$

exists, and regardless of (y_0, σ_0), *it is equal to*

$$\int_{R^m\times S} f(x, y, u(x, y, \sigma))\nu(dy \times d\sigma). \tag{5.4}$$

Likewise, the limit

$$\lim_{T\to\infty} \frac{1}{T} \int_0^T c(x, y(\tau), u(x, y(\tau), \sigma(\tau)))d\tau \tag{5.5}$$

exists and is equal to

$$\int_{R^m\times S} c(x, y, u(x, y, \sigma))\nu(dy \times d\sigma) \tag{5.6}$$

independently of (y_0, σ_0).

Proof. This is a version of the ergodic theorem. What follows is the argument in brief (see also the background in section 3). The probability measures ν_T induced on $R^m \times S$ by $(y(\tau), \sigma(\tau)) : [0, T] \to R^m \times S$ (see (3.2)) converge weakly to ν as $T \to \infty$. Since both functions $f(x, y, u)$ and $c(x, y, u)$ are assumed continuous and since $u(x, y, \sigma)$ is assumed continuous, it follows that the integrands in (5.4) and (5.6) are continuous in (y, σ). They are also bounded on the support of ν and the range of $(y(\tau), \sigma(\tau))$. Hence the weak convergence of ν_T to ν implies the respective convergences. □

Remark 5.4. The interpretation we give to the expressions (5.3)–(5.6) is as follows. If on an infinitesimal period, where the slow state x stays put, the fast state and clock solve (5.2) on an unbounded interval, then the limit in (5.3) constitutes the right-hand side of the slow equation. We say then that (5.4) is a velocity at x, infinitesimally generated by the control. Likewise, (5.5) represents the limit of the average cost of the operation on $[0, T]$. Thus (5.6) is the cost of infinitesimally generating (5.4) at x by using the control u.

Next, we extend the definition of a proper control function and consider dependence on v. We use the same adjective, namely, proper, but no confusion should arise, since the context dictates which version is applicable.

Convention 5.5. In what follows, we refer to domains D of the form

$$D \subset R^n \times R^m \times S \times R^n.$$

We then agree that if $(x, y, \sigma, v) \in D$, then $(x, y', \sigma', v) \in D$ for all $(y', \sigma') \in R^m \times S$. This is done for convenience only; see the comment closing section 2. Then we may say that (x, v) is in D, meaning that $\{x\} \times R^m \times S \times \{v\}$ is a subset of D.

DEFINITION 5.6. *Let* $\mathbf{u}$ *be given as*

$$u(x, y, \sigma, v) : D \to U$$

with domain $D \subset R^n \times R^m \times S \times R^n$. *We say that* $\mathbf{u}$ *is a* proper control policy *if the following hold:*

(iii) $\mathbf{u}$ *is continuous on* D.

(iv) *For each* (x, v) *fixed in* D, *the function* $\mathbf{u}$ *is a proper control function.*

(v) *For each* (x, v) *fixed in* D, *the control* $\mathbf{u}$ *infinitesimally generates* v *at* x, *namely,*

$$v = \int_{R^m \times S} f(x, y, u(x, y, \sigma, v)) \nu_{x,v}(dy \times d\sigma), \tag{5.7}$$

where $\nu_{x,v}$ *is the invariant probability measure associated with* $\mathbf{u}$ *for* (x, v) *fixed.*

(vi) *For* $K \subset R^n \times R^n$ *a bounded set in the domain* D, *all the invariant probability measures* $\nu_{x,v}$ *associated with* $\mathbf{u}$ *for* $(x, v) \in K$, *are supported in a common bounded subset of* $R^m \times S$.

PROPOSITION 5.7. *Let* $\mathbf{u}$ *be a proper control policy. The cost of generating* v *at* x *by* $\mathbf{u}$, *namely,*

$$\text{cost}(\mathbf{u}, x, v) = \int_{R^m \times S} c(x, y, u(x, y, \sigma, v)) \nu_{x,v}(dy \times d\sigma), \tag{5.8}$$

is a continuous function of (x, v) *in the domain of* $\mathbf{u}$.

Proof. The continuity of the functions $\mathbf{u}$ and c implies that the integrand in (5.8) is uniformly continuous on bounded sets in $R^m \times S$. Applying this to the common support of $\nu_{x,v}$ for (x, v) in a bounded set (see condition (vi)) would imply the desired continuity, provided that $\nu_{x,v}$ is weakly continuous as a function of (x, v). The weak continuity follows from the uniqueness; see [3, Proposition 3.2, Remark 3.3]. Thus the proof is complete. ∎

6. Global control policies. A proper control policy, as introduced in the previous section, generates the velocity v at x. This provides the option that the derivative of the slow motion at x will be v. But the infinitesimal policy by itself does not suffice to induce the slow motion $x(t)$. To this end we need to combine it with a policy on the slow scale. This is achieved as follows.

DEFINITION 6.1. *Let* $\mathbf{v}$ *be a function*

$$v(x, t) : R^n \times [0, 1] \to R^n \tag{6.1}$$

continuous in (x, t) *and such that for every initial condition* $x(0) = \overline{x}$, *the solution* $x(t)$ *of the differential equation*

$$\frac{dx}{dt} = v(x, t), \quad x(0) = \overline{x} \tag{6.2}$$

is determined uniquely. (*We allow* $\mathbf{v}$ *to be defined on a subset of* $R^n \times [0,1]$.) *Let* $\mathbf{u}$ *be a proper control policy. The pair* $(\mathbf{u}, \mathbf{v})$ *is called a* proper global control policy. *We say that* $(\mathbf{u}, \mathbf{v})$ *generates the solution* $x(\cdot)$ *of* (6.2) *if for all* $t \in [0,1]$, *the pair* $(x(t), v(x(t),t))$ *is in the domain of* $\mathbf{u}$.

Remark 6.2. In the following discussion we may consider $v(x,t)$, which is defined globally, but this would be done for convenience only; see the closing comment in section 2. The explicit dependence of v on t is done for the reason mentioned in Remark 4.2.

Remark 6.3. The reasoning behind Definition 6.1 is that $\mathbf{v}$ determines the slow evolution on the slow time scale, while $\mathbf{u}$ determines the desired velocities on the infinitesimal scale. The differential equation (6.2) then becomes a chattering equation (see [1], [3]), namely,

$$\frac{dx}{dt} = \int_{R^m \times S} f(x, y, u(x, y, \sigma, v(x,t)) \nu_{x, v(x,t)}(dy \times d\sigma), \tag{6.3}$$

where $\nu_{x,v}$ is the invariant probability measure associated with $\mathbf{u}$ at (x,v). It is in this sense that the pair $(\mathbf{u}, \mathbf{v})$ generates the trajectory $x(t)$ as a solution of (6.3). Indeed, (6.3) is defined only for (x,t) such that $(x, v(x,t))$ is in the domain of $\mathbf{u}$. Note that in this domain we require that solutions of (6.3) be uniquely determined by the initial conditions.

We now identify the cost of generating a trajectory $x(t)$ by $(\mathbf{u}, \mathbf{v})$. It will, naturally, be the accumulation of the infinitesimal costs, as follows.

DEFINITION 6.4. *Let* $(\mathbf{u}, \mathbf{v})$ *be a proper global control policy which generates* $x(t)$ *on* $[0,1]$. *The cost of generating the trajectory is given by*

$$\text{cost}(\mathbf{u}, \mathbf{v}) = \int_0^1 \text{cost}(\mathbf{u}, x(t), v(x(t),t)) dt, \tag{6.4}$$

with $\text{cost}(\mathbf{u}, x, v)$ *given in* (5.8). *Notice that denoting the cost by* $\text{cost}(\mathbf{u}, \mathbf{v})$ *suppresses the dependence on the initial condition* $x(0)$, *which later is assumed to be prescribed.*

7. Stability. The proper global control policies $(\mathbf{u}, \mathbf{v})$ are obtained as combinations of a policy $\mathbf{v}$ on the slow scale and a control $\mathbf{u}$ on the fast scale. The outcome is a chattering equation (6.3). But the composed control policy, given by

$$u(x, y, \sigma, v(x,t)),$$

is of the type described in section 4 and can in particular be applied to the singular perturbation Problem 2.1. For a given $\epsilon > 0$, applying $(\mathbf{u}, \mathbf{v})$ in this manner results in the equations

$$\begin{aligned} \frac{dx}{dt} &= f(x, y, u(x, y, \sigma, v(x,t)), \\ \epsilon \frac{dy}{dt} &= g(x, y, u(x, y, \sigma, v(x,t)), \\ \epsilon \frac{d\sigma}{dt} &= L(x, \sigma), \end{aligned} \tag{7.1}$$

with initial conditions (2.4). A solution $(x_\epsilon(t), y_\epsilon(t), \sigma_\epsilon(t))$ then gives rise to the cost

$$\int_0^1 c(x_\epsilon(t), y_\epsilon(t), u(x_\epsilon(t), y_\epsilon(t), \sigma_\epsilon(t), v(x_\epsilon(t),t))) dt, \tag{7.2}$$

which we denote by $c_\epsilon(\mathbf{u},\mathbf{v})$, suppressing the dependence on the specific solution; see the discussion concerning (4.4).

The stability result that follows employs the notions of a direct integral of probability measures, and of statistical convergence. These concepts are examined in detail in [3]. We briefly recall the definitions here in the framework of the theorem. Consider a function $(y_\epsilon(t),\sigma_\epsilon(t))$ defined on $[0,1]$ with values in $R^m \times S$. With this function we associate a measure ν_ϵ defined on $R^m \times S \times [0,1]$ and given by

$$\nu_\epsilon(D) = \lambda\{t : (y_\epsilon(t),\sigma_\epsilon(t),t) \in D\}, \tag{7.3}$$

where λ is the Lebesgue measure. We say that $(y_\epsilon(t),\sigma_\epsilon(t))$ converge statistically, as $\epsilon \to 0$, to a measure ν, if ν_ϵ given in (7.3) converges weakly to ν. The motivation is that ν, which is defined on $R^m \times S \times [0,1]$, dominates the asymptotic distribution of the graph of $(y_\epsilon(t),\sigma_\epsilon(t))$.

Next consider the probability measures ν_t defined on $R^m \times S$, for $t \in [0,1]$. The direct integral of ν_t is the measure ν on $R^m \times S \times [0,1]$ determined by

$$\nu(C \times E) = \int_E \nu_t(C)dt \tag{7.4}$$

for $C \subset R^m \times S$ and $E \subset [0,1]$ measurable. On the entire Borel field of $R^m \times S \times [0,1]$ the measure ν is obtained by a standard extension.

We now state and prove the stability of applying a proper global control policy to the singular perturbations problem.

THEOREM 7.1. *Let $(\mathbf{u},\mathbf{v})$ be a proper global control policy that generates the trajectory $x(t)$, with $x(0) = \overline{x}$. Suppose also that the domain of $\mathbf{u}$ contains an open neighborhood of the graph of $(x(t),v(x(t),t))$ in $R^n \times R^n$. Let $(x_\epsilon(t),y_\epsilon(t),\sigma_\epsilon(t))$ be a solution of (7.1) for $\epsilon > 0$ fixed. Then, as $\epsilon \to 0$,*

(a) *$c_\epsilon(\mathbf{u},\mathbf{v})$ converge to $\mathrm{cost}(\mathbf{u},\mathbf{v})$;*

(b) *$x_\epsilon(t)$ converge uniformly on $[0,1]$ to $x(t)$;*

(c) *the trajectories $(y_\epsilon(t),\sigma_\epsilon(t))$ converge statistically to the direct integral of $\nu_{x(t),v(x(t),t)}$, where $\nu_{x,v}$ is the invariant probability measure associated with $\mathbf{u}$ for (x,v).*

Proof. Notice that once $(\mathbf{u},\mathbf{v})$ is inserted into the control equations of Problem 2.1, the resulting system (7.1) is a standard system of ordinary differential equations, some of them singularly perturbed. Claims (b) and (c) then follow from Theorem 2.5 in [3]. Indeed, the conditions in the latter paper are easily implied by the definition of a proper global control policy, and the chattering equation (6.3) is the chattering limit that governs the uniform limit of $x_\epsilon(t)$ and the statistical limit of the singularly perturbed part as $\epsilon \to 0$.

To verify claim (a), we use claims (b) and (c) as follows. The expression (6.4) for $\mathrm{cost}(\mathbf{u},\mathbf{v})$ can also be written as

$$\int_{R^m \times S \times [0,1]} c(x(t),y,u(x(t),y,\sigma,v(x(t),t))\nu(dy \times d\sigma \times dt), \tag{7.5}$$

with ν being the direct integral of $\nu_{x(t),v(x(t),t)}$ (see (7.4)). This is an extension of Fubini's theorem; see, e.g., [6]. The cost $c_\epsilon(\mathbf{u},\mathbf{v})$ given in (7.2) can in turn be expressed in the form

$$\int_{R^m \times S \times [0,1]} c(x_\epsilon(t),y,u(x_\epsilon(t),y,\sigma,v(x_\epsilon(t),t)))\nu_\epsilon(dy \times d\sigma \times dt), \tag{7.6}$$

where ν_ϵ is the measure obtained as the distribution of $(y_\epsilon(t), \sigma_\epsilon(t), t)$ on $R^m \times S \times [0,1]$ (see (7.3)). This expression is obtained from (7.2) by a change of notation only. Claim (b) guarantees that $x_\epsilon(t)$ converge uniformly to $x(t)$, and claim (c) implies that ν_ϵ converges weakly to ν. Hence the desired convergence of (7.6) to (7.5) as $\epsilon \to 0$ follows from the continuity of c, $\mathbf{u}$, and $\mathbf{v}$ and from their boundedness on the common supports of ν_ϵ and ν. This completes the proof. ∎

8. Infinitesimally generated velocities. As a step toward optimality considerations, in this section we broaden the notion of infinitesimal generation of velocities. The motivation is the same as the one displayed in Remark 5.4. The extension is needed for variational considerations.

DEFINITION 8.1. *Let $x \in R^n$ be fixed. Let $B \subset R^m$ be fixed. We say that the velocity vector $v \in R^n$ is* infinitesimally generated *at x using the base B if the following holds. There exist a sequence $T_k \to \infty$ and a sequence of admissible controls $u_k(\tau) : [0, T_k] \to U$ such that*

$$v = \lim_{k\to\infty} \frac{1}{T_k} \int_0^{T_k} f(x_k(\tau), y_k(\tau), u_k(\tau)) d\tau, \tag{8.1}$$

where $y_k(\tau)$ is a solution on $[0, T_k]$ of

$$\frac{dy}{d\tau} = g(x_k(\tau), y, u_k(\tau)) \tag{8.2}$$

and where $y_k(\tau) \in B$ for all k and all $\tau \in [0, T_k]$, and $\sup\{|x_k(\tau) - x| : \tau \in [0, T_k]\}$ converge to 0 as $k \to \infty$. The set of velocities that are infinitesimally generated at x from the base B is denoted by $V_B(x)$.

PROPOSITION 8.2. *For a fixed B, the set $V_B(x)$ is closed in R^n, and the mapping $x \to V_B(x)$ has a closed graph.*

Proof. The claims follow from the definition by using a diagonal argument. ∎

As mentioned, the set $V_B(x)$ represents the limit directions that the slow dynamics could move in, in a given instant, if the fast dynamics is confined to the set B. We consider a varying state $x_k(\tau)$ in the generation of v and a sequence of controls, since v is indeed the result of a limit process. Next we consider a more restrictive notion.

DEFINITION 8.3. *Let x and $B \subset R^m$ be fixed. We say that $v \in V_B(x)$ is properly generated if there exist a control $u(\tau) : [0, \infty) \to U$ and $y_0 \in B$ such that*

$$v = \lim_{T\to\infty} \frac{1}{T} \int_0^{T} f(x, y(\tau), u(\tau)) d\tau, \tag{8.3}$$

where $y(\cdot)$ is the solution of $\dot{y} = g(x, y, u(\tau))$, $y(0) = y_0$, and $y(\tau) \in B$ for $\tau \in [0, \infty)$.

Note that if (x, v) is in the domain of the proper control policy $\mathbf{u}$ and the trajectory $y(\tau)$ resulting from (5.2) is in B, then $v \in V_B(x)$, and it is properly generated.

9. Optimality. We are about to introduce two optimization problems, one on the infinitesimal (fast) scale, the other on the global (slow) time scale. A composition of their solutions would constitute a near optimal solution.

The infinitesimal problem depends on three parameters, $x \in R^n$, $B \subset R^m$, and $v \in V_B(x)$, as follows. (IG stands for infinitesimally generating.)

IG(x, v, B) Problem 9.1.

$$\text{minimize } \lim_{k\to\infty} \frac{1}{T_k} \int_0^{T_k} c(x_k(\tau), y_k(\tau), u_k(\tau)) d\tau, \tag{9.1}$$

with the minimization being over all sequences $T_k \to \infty$, admissible controls $u_k(\tau) : [0, T_k] \to U$, and functions $x_k(\tau) : [0, T_k] \to R^n$ satisfying $\sup\{|x_k(\tau) - x| : 0 \le \tau \le T_k\}$ converge to 0 as $k \to \infty$, and where $y_k(\tau)$ solve on $[0, T_k]$ the equation

$$\frac{dy}{d\tau} = g(x_k(\tau), y, u_k(\tau)) \tag{9.2}$$

and $y_k(\tau) \in B$ for $\tau \in [0, T_k]$. In addition, it is demanded that

$$v = \lim_{k\to\infty} \frac{1}{T_k} \int_0^{T_k} f(x_k(\tau), y_k(\tau), u_k(\tau))d\tau. \tag{9.3}$$

We denote by $\Phi_B(x, v)$ the infimal value in (9.1). It is clear that the IG(x, v, B) problem is simply the problem of infinitesimally generating the velocity v at x using the base B (see Definition 8.1) with a minimal averaged cost. The value $\Phi_B(x, v)$ could be equal to $+\infty$, and in fact we set $\Phi_B(x, v) = \infty$ if $v \notin V_B(x)$.

PROPOSITION 9.2. *For $B \subset R^m$ fixed, the function $\Phi_B(x, v)$ is lower semicontinuous, namely, $(x_k, v_k) \to (x_0, v_0)$ implies $\liminf \Phi_B(x_k, v_k) \ge \Phi_B(x_0, v_0)$.*

Proof. It follows from a simple diagonal argument. □

Our next step is the global problem. It depends on a parameter $B \subset R^m$ and also refers to the initial condition $x(0) = \overline{x}$ (see (2.4)) of the original singular perturbations problem, as follows. (GO stands for global optimization.)

GO(B) Problem 9.3.

$$\text{minimize} \int_0^1 \Phi_B(x(t), v(x(t), t))dt \tag{9.4}$$

subject to

$$\frac{dx}{dt} = v(x, t), \quad x(0) = \overline{x} \tag{9.5}$$

and the constraint

$$v(x, t) \in V_B(x). \tag{9.6}$$

A solution to the problem is a pair $(x(\cdot), v(\cdot, \cdot))$ such that $x(t)$ is absolutely continuous; $v(x, t)$ is continuous in x and measurable in t, defined on a subset of $R^n \times [0, 1]$; and (9.5) produces $x(t)$ as its unique solution.

Remark 9.4. The GO(B) problem is actually a standard Bolza problem of minimizing $\int_0^1 \Phi_B(x, \dot{x})dt$ subject to $x(0) = \overline{x}$ and $\dot{x} \in V_B(x)$. Indeed, we allow in our formulation $v(x, t)$ to be defined on the graph of $x(t)$ only, namely $v(x, t) = \dot{x}(t)$. We prefer the formulation with the function $v(x, t)$, for two reasons. The first one is to make transparent the fact that in the singular perturbations setting, the velocity $v(x, t)$ is infinitesimally generated. The second one is that in many problems that arise in applications, the solution is indeed given in a feedback form, generating a differential equation on a domain larger than the optimal trajectory. It is this property that enables us to derive the near optimal solutions for the fast tracking.

The mathematical characteristics of the two problems, 9.1 and 9.3, are of course of interest. An avenue to a systematic treatment of them is the concept of overtaking solutions; see, e.g., Carlson, Haurie, and Leizarowitz [7] and the recent contribution of Zaslawski [23]. As mentioned earlier, in this paper we do not pursue these problems.

Rather, we go ahead, assume that the two problems have solutions, and show that under some conditions, the composition of the solutions is near optimal for the SP Problem 2.1.

The main result is proven under a coercivity condition described in the following definition. In the formulation we refer to control functions $u_\epsilon(t)$ that, when applied to equations (2.3)–(2.4) and (4.2), produce trajectories $(x_\epsilon(t), y_\epsilon(t), \sigma_\epsilon(t))$. The resulting cost is given by

$$\text{cost } (u_\epsilon) = \int_0^1 c(x_\epsilon(t), y_\epsilon(t), u_\epsilon(t))dt. \tag{9.7}$$

Compare with (2.2). We shall write $c_\epsilon(t)$ for the integrand in (9.7). Recall that $\text{val}(\epsilon)$ is the infimal cost.

DEFINITION 9.5. *The singular perturbations problem is called* coercive *if, whenever $u_\epsilon(t)$ are control functions satisfying $\text{cost}(u_\epsilon) - \text{val}(\epsilon) \to 0$ as $\epsilon \to 0$, then for ϵ small enough (say, $0 < \epsilon \le \epsilon_0$) the trajectories $(x_\epsilon(t), y_\epsilon(t))$ are contained in one compact subset of $R^n \times R^m$ (say, $C \times B$) and $\dot{x}_\epsilon(t)$ and $c(t)$ share a common L_2-bound, namely, $\int_0^1 |\dot{x}_\epsilon(t)|^2 dt$, and $\int_0^1 |c_\epsilon(t)|^2 dt$ have a bound independent of ϵ.*

Coercivity is very common in optimal control problems; we do not elaborate on this concept here.

THEOREM 9.6. *Suppose that the singular perturbations problem is coercive, and let $C \times B$ be the compact subset of $R^n \times R^m$ provided by the coercivity. Let $(x(t), v(x(t), t))$ be a solution of the GO(B) Problem 9.3 and such that $\mathbf{v} = v(x, t)$ is defined and continuous on a neighborhood of the graph $\{(x(t), t) : 0 \le t \le 1\}$ in $R^n \times [0, 1]$. Let $\mathbf{u} = u(x, y, \sigma, v)$ be a proper control policy whose domain contains a neighborhood of the graph of $(x(\cdot), \dot{x}(\cdot))$, and furthermore assume that $\text{cost}(\mathbf{u}, x, v) = \Phi_B(x, v)$. Then the composition*

$$u(x, y, \sigma, t) = u(x, y, \sigma, v(x, t))$$

is a near optimal solution of the singular perturbations problem.

Proof. We shall denote by $c_\epsilon(\mathbf{u})$ the cost of applying the displayed composition of $\mathbf{u}$ and $\mathbf{v}$ to the problem with $\epsilon > 0$ fixed. See (4.4).

It is clear that the pair $(\mathbf{u}, \mathbf{v})$ is a proper global control policy that generates the trajectory $x(t)$. By the stability result, Theorem 7.1, the convergence $c_\epsilon(\mathbf{u}) = c_\epsilon(\mathbf{u}, \mathbf{v})$ to $\text{cost}(\mathbf{u}, \mathbf{v})$ holds. The latter, in turn, is equal (by (6.4) and the assumption of the present result) to the optimal value of the GO(B) problem. Hence we deduce that

$$c_\epsilon(\mathbf{u}) - \int_0^1 \Phi_B(x(t), v(x(t), t))dt \to 0 \tag{9.8}$$

as $\epsilon \to 0$.

Next we show that

$$\int_0^1 \Phi_B(x(t), v(x(t), t))dt - \text{val}(\epsilon) \to 0 \tag{9.9}$$

as $\epsilon \to 0$. To this end, let $u_\epsilon(t)$ be admissible control functions, generating the solutions $(x_\epsilon(t), y_\epsilon(t), \sigma_\epsilon(t))$ of (2.3)–(2.4) and (4.2), with $\epsilon > 0$ fixed, and such that $c(u_\epsilon) - \text{val}(\epsilon) \to 0$ as $\epsilon \to 0$ (namely, $u_\epsilon(\cdot)$ provides an approximately optimal solution). By the coercivity, there exists a subsequence ϵ_i, with $\epsilon_i \to 0$, such that (and we write $x_i(t)$ for $x_{\epsilon_i}(t)$, etc.)

(1) $x_i(t)$ converge uniformly on $[0,1]$, say, to $x_0(t)$,
(2) $\dot{x}_i(t) = f(x_i(t), y_i(t), u_i(t))$ converge weakly in L_2 to $\dot{x}_0(t)$,
(3) $c_i(t) = c(x_i(t), y_i(t), u_i(t))$ converge weakly in L_2, say, to $c_0(t)$.

For a fixed $h > 0$, consider a time $t \in [0, 1-h]$. The vector

$$v_h(t) = \frac{x_0(t+h) - x_0(t)}{h} \tag{9.10}$$

is the limit as $\epsilon_i \to 0$ of

$$\frac{1}{h}(x_i(t+h) - x_i(t)) = \frac{1}{h}\int_t^{t+h} f(x_i(s), y_i(s), u_i(s))ds,$$

which after the change of variables $\tau = \epsilon_i^{-1}(s-t)$ is written as

$$\frac{\epsilon_i}{h}\int_0^{h/\epsilon_i} f(x_i(\tau), y_i(\tau), u_i(\tau))d\tau. \tag{9.11}$$

Likewise, the average

$$c_h(t) = \frac{1}{h}\int_t^{t+h} c_0(s)ds$$

is the limit as $\epsilon_i \to 0$ of

$$\frac{1}{h}\int_t^{t+h} c_i(s)ds = \frac{\epsilon_i}{h}\int_0^{h/\epsilon_i} c(x_i(\tau), y_i(\tau), u_i(\tau))d\tau. \tag{9.12}$$

Since $(y_i(\tau), \sigma_i(\tau))$ on $[0, h/\epsilon_i]$ solve (9.2) with $x_i(\tau)$ the parameter, and since $x_i(\tau)$ on $[0, h/\epsilon_i]$ is near $x(t)$ if h is small, it follows that if we take a diagonal subsequence i_j associated with a sequence $h_j \to 0$, any cluster point $v(t)$ of $v_h(t)$ is in $V_B(x_0(t))$ and any cluster point $c(t)$ of $c_h(t)$ satisfies $c(t) \geq \Phi_B(x_0(t), v(t))$. This occurs by Definition 8.1 and the definition of $\Phi_B(x,v)$ in Problem 9.1.

But $v_h(t)$ converges almost everywhere to $\dot{x}_0(t)$, and $c_h(t)$ converges almost everywhere to $c_0(t)$. We therefore conclude that

$$\int_0^1 c_0(t)dt \geq \int_0^1 \Phi_B(x_0(t), \dot{x}_0(t))dt. \tag{9.13}$$

Since the left-hand side of (9.13) is the limit of $\int_0^1 c_i(t)dt$, and since $\mathbf{v}$ was the solution of the GO(B) problem, we conclude that

$$\lim \int_0^1 c_i(t)dt \geq \int_0^1 \Phi_B(x_0(t), \dot{x}_0(t))dt \geq \int_0^1 \Phi_B(x(t), v(x(t), t))dt, \tag{9.14}$$

or in other words, $\lim \operatorname{val}(\epsilon_i)$ exists, and it is bigger or equal to the right-hand side term of the displayed inequalities. But since $c_\epsilon(\mathbf{u}) \geq \operatorname{val}(\epsilon)$, it actually follows from the stability part, in particular from (9.8), that

$$\lim_{\epsilon_i \to 0} \operatorname{val}(\epsilon_i) = \int_0^1 \Phi_B(x(t), t))dt. \tag{9.15}$$

Since ϵ_i was an arbitrary subsequence for which the weak convergence holds, and since the coercivity implies weak-L_2 compactness, the limit in (9.15) holds for all $\epsilon \to 0$. This is the desired conclusion. ∎

Remark 9.7. Since $B_1 \subset B_2$ implies $\Phi_{B_2}(x,v) \le \Phi_{B_1}(x,v)$, it clearly follows that any domain containing the one given by the coercivity can be used in the calculation of the optimal proper policy. In particular, we can use $B = R^m$. The coercivity, however, is needed in the proof of the near optimality.

Remark 9.8. The proper controls $\mathbf{u}$ in the main result, Theorem 9.6, were assumed to generate a unique invariant measure $\nu_{x,v}$, with cost (given by (5.8)) equal to $\Phi_B(x,v)$. The result would hold even if the uniqueness of the invariant measure is dropped, provided that the expression (5.8) is equal to $\Phi_B(x,v)$ for every invariant measure $\nu_{x,v}$. The only change in the proof would be to refer in the stability part to Theorem 2.2 (rather than Theorem 2.5) in [3].

10. Comments. We display two examples whose formulation does not include a fast clock variable but which still cannot be solved with the order reduction method (see the introduction). We show how the reasoning of the present paper applies.

Note first that the structure of the solutions suggested by the reduced-order approach is a particular case of those offered in this paper. Indeed, equating $\epsilon = 0$ in (2.3) and providing $u(x,y)$, which makes the equation $\dot y = g(x,y,u(x,y))$ asymptotically stable around, say, $y_0(x)$, are equivalent to proper generation of the velocity $f(x,y_0(x),u(x,y_0(x)))$ at x, with a proper control that has a special type of invariant measure, namely, a measure supported at the equilibrium $y_0(x)$. So, in case our infinitesimal optimization step can be achieved with an invariant measure supported at a stable point, we get back the reduced-order procedure.

Here are the promised examples.

Example 10.1. Consider the problem with scalar variables

$$\text{minimize} \int_0^1 (x^2(t) + (y_1^2(t) + y_2^2(t) - 1)^2 + u^2(t))dt \tag{10.1}$$

subject to

$$\begin{aligned} \frac{dx}{dt} &= y_1 + y_2, \\ \epsilon \begin{pmatrix} \dot y_1 \\ \dot y_2 \end{pmatrix} &= \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} \begin{pmatrix} y_1 \\ y_2 \end{pmatrix} + \begin{pmatrix} 0 \\ 1 \end{pmatrix} u, \\ x(0) = 0, \quad y_1(0) &= \overline{y}_1, \quad y_2(0) = \overline{y}_2. \end{aligned} \tag{10.2}$$

A direct inspection reveals that the limit of the minimal cost as $\epsilon \to 0$ is 0. A near optimal solution can be constructed by examining the fast equation

$$\frac{dy_1}{d\tau} = y_2, \quad \frac{dy_2}{d\tau} = -y_1 + u \tag{10.3}$$

and devising a feedback control $u = u(y_1, y_2)$ which stabilizes the solution of (10.3) around a periodic solution of the form $(\cos(\varphi + \tau), \sin(\varphi + \tau))$, while $u = 0$ on the limit trajectory. This can be achieved easily. Note that there is no need to employ an auxiliary clock variable; note also that setting $\epsilon = 0$ in (10.2) will not lead to a near optimal solution.

Example 10.2. In this example a nontrivial clock example is employed. Consider the system with scalar variables

$$\text{minimize} \int_0^1 (x^2(t) + y_1^2(t) + y_2^2(t) + (u_1^2(t) + u_2^2(t) - 1)^2)dt$$

subject to

$$\begin{aligned} \frac{dx}{dt} &= u_1 + u_2, \\ \epsilon\frac{dy_1}{dt} &= u_1, \\ \epsilon\frac{dy_2}{dt} &= u_2, \\ x(0) = 0, \quad y_1(0) &= \overline{y}_1, \quad y_2(0) = \overline{y}_2. \end{aligned} \tag{10.4}$$

A direct inspection reveals that the limit of the minimal value as $\epsilon \to 0$ is 0. A near optimal solution can be constructed using the clock equation $\epsilon\dot{\sigma} = 1$, with $\sigma \in S^1$ (namely, $\sigma = \arg(\xi + i\eta)$ on the unit circle in R^2). Then

$$u_1 = -y_1 + \sin\sigma, \quad u_2 = -y_2 + \cos\sigma \tag{10.5}$$

is a near optimal solution.

11. A linear-quadratic tracking. The technique offered in the previous sections is applied in this section to a system with linear state equations and a quadratic cost criterion. The target is assumed to be periodic. Note that the corresponding regulator problem was analyzed in the literature; see Kokotovic and Yackel [16], O'Malley [19], and Chow and Kokotovic [8].

In what follows, a prime over a matrix—say, A'—denotes the transposed matrix; for vectors y we use y' to denote the row version. For a matrix Q symmetric and positive semidefinite, we denote by $\|x\|_Q^2$ the quadratic form $x'Qx$.

The target to be tracked is given by

$$\Gamma(x, \sigma) : R^n \times R \to R^m, \tag{11.1}$$

assuming that $\Gamma(x, \sigma)$ is continuous and periodic in σ, with period $T(x) > 0$ (not necessarily the minimal one) continuous in x.

The tracking problem is as follows. (SP-LQPT stands for singularly perturbed linear quadratic periodic tracking.)

SP-LQPT Problem 11.1.

$$\text{minimize} \int_0^1 (\|x(t)\|_Q^2 + \|y(t) - \Gamma(x(t), \sigma(t))\|_W^2 + \|u(t)\|_R^2)dt \tag{11.2}$$

subject to

$$\begin{aligned} \frac{dx}{dt} &= Fx + Gy + Hu, \\ \epsilon\frac{dy}{dt} &= Cx + Ay + Bu, \\ \epsilon\frac{d\sigma}{dt} &= 1, \end{aligned} \tag{11.3}$$

with initial conditions

$$x(0) = \overline{x}, \quad y(0) = \overline{y}, \quad \sigma(0) = \overline{\sigma}, \tag{11.4}$$

and where the matrices appearing in (11.2)–(11.3) are constant and have the appropriate dimensions. Compare with (4.6)–(4.7).

The following assumption is standard in the linear-quadratic trait; it is employed throughout.

Assumption 11.2. The matrices Q and W are symmetric and positive semidefinite; the matrix R is symmetric and positive definite. The pair (A, B) is controllable and (A, W) is observable.

Remark 11.3. The form in which the SP-LQPT problem is presented is with the fast time σ being in R and with our stating explicitly that $\Gamma(x, \cdot)$ is $T(x)$-periodic. This deviates from the clock description of Definition 4.1. The latter would consider σ in S^1. We find (11.3) a bit more convenient in the purely periodic case. It is clear that the two forms are equivalent.

The analysis of the SP-LQPT problem will follow several steps.

Note first that the positive definiteness of R implies that the problem (11.2)–(11.3) is coercive (see Definition 9.5). Hence the base set appearing in Problems 9.1 and 9.3 can be taken as any large enough bounded set in R^n. A reference to it is therefore suppressed in the formulas that follow.

Step I. Determination of the infinitesimally generated velocities.

For each $x \in R^n$ we have to determine the set $V(x)$ of velocities that can be infinitesimally generated at x; see Definition 8.1. To this end, consider the $m \times (m+k)$ matrix $[A, B]$, operating on pairs (y, u) in $R^m \times R^k$ and with values in R^m. The controllability of (A, B) implies that $[A, B]$ has a full range. Therefore the $m \times m$ matrix

$$M = [A, B] \begin{bmatrix} A' \\ B' \end{bmatrix} \tag{11.5}$$

is invertible. Denote by $\ker[A, B]$ the kernel of $[A, B]$, namely, the family of pairs (y, u) such that $Ay + Bu = 0$. Finally, let

$$V = \{Gy + Hu : (y, u) \in \ker[A, B]\}. \tag{11.6}$$

It is clear that V is a linear subspace of R^n.

PROPOSITION 11.4. *The infinitesimally generated velocities at x form a translation of a linear space, given by*

$$V(x) = \left(F - [G, H] \begin{bmatrix} A' \\ B' \end{bmatrix} M^{-1} C \right) x + V \tag{11.7}$$

(*with M and V given in* (11.5)–(11.6)).

Proof. An infinitesimally generated velocity has the form

$$\lim_{k \to \infty} \frac{1}{T_k} \int_0^{T_k} (Fx_k(\tau) + Gy_k(\tau) + Hu_k(\tau)) d\tau, \tag{11.8}$$

with constraints as described in Definition 8.1 and in particular when $(y_k(\cdot), u_k(\cdot))$ satisfy

$$\frac{dy_k}{d\tau}(\tau) = Ay_k(\tau) + Bu_k(\tau) + Cx_k(\tau) \tag{11.9}$$

and $y_k(\tau)$ are uniformly bounded. Taking averages on $[0, T_k]$ and using the fact that $y_k(\tau)$ are bounded (and $x_k(\tau) \to x$) imply that the limit in (11.8) has the form

$$Fx + Gy + Hu \tag{11.10}$$

under the constraint

$$Ay + Bu + Cx = 0, \tag{11.11}$$

and the controllability clearly implies that any element obtained in this way is a limit of the form (11.8) (in fact with $x_k(\tau) = x$). The passage from the formulation (11.10)–(11.11) to the representation (11.7) follows simple linear algebra considerations. ∎

Step II. An auxiliary problem.

The periodicity in σ of the target $\Gamma(x, \sigma)$ suggests that the infinitesimal generation problem (i.e., IG(x, v) problem 9.1) could be solved with a proper control policy that induces an invariant measure supported on a periodic orbit. We shall see later that this is indeed the case. At present we formulate a variational problem that determines, as we shall see, the limit trajectory.

In what follows, $\Gamma(\tau)$ is T-periodic, with $T > 0$, $c \in R^m$, and $q \in R^n$ (with a constraint on q displayed later). The rest of the data are taken from Problem 11.1. (LQPBVT stands for linear-quadratic periodic boundary value tracking.)

LQPBVT$(\Gamma(\cdot), c, q)$ *Problem* 11.5.

$$\text{minimize } \frac{1}{T}\int_0^T (\|y(\tau) - \Gamma(\tau)\|_W^2 + \|u(\tau)\|_R^2)d\tau \tag{11.12}$$

subject to

$$\begin{aligned} \frac{dy}{d\tau} &= Ay + Bu + c, \\ \frac{dz}{d\tau} &= Gy + Hu, \end{aligned} \tag{11.13}$$

with the boundary condition

$$\begin{aligned} y(T) &= y(0), \\ z(T) &= z(0) + Tq, \end{aligned} \tag{11.14}$$

where q belongs to a translation of a subspace, namely, to

$$-[G, H]\begin{bmatrix} A' \\ B' \end{bmatrix} M^{-1}c + V, \tag{11.15}$$

with V the subspace given in (11.6). Clearly, a solution is a pair $(y(\tau), u(\tau))$ defined on $[0, T]$.

In what follows, we consider the varying data $\Gamma(\cdot)$, c, and q, where the period T may vary as well. When we say that $\Gamma_j(\cdot)$ converge to $\Gamma_0(\cdot)$, we mean that the periods converge and the periodic continuations converge uniformly on compact intervals.

PROPOSITION 11.6. *The problem LQPBVT* (Γ, c, q) *has a unique optimal solution* $(y^*(\tau), u^*(\tau))$. *It satisfies* $u^*(0) = u^*(T)$, *and its periodic continuation is uniformly continuous on compact intervals with respect to the parameters* $(\Gamma(\cdot), c, q)$.

Proof. First we note that a feasible pair $(y(\tau), u(\tau))$, namely, one that satisfies the constraints, exists. In fact, there is a constant pair (y, u) which is feasible. Indeed, if

$$q = \frac{1}{T}\left(-[G, H]\begin{bmatrix} A' \\ B' \end{bmatrix} M^{-1}c + Gy_0 + Hu_0\right) \tag{11.16}$$

with $(y_0, u_0) \in \ker[A, B]$, take

$$(y, u) = -\begin{bmatrix} A' \\ B' \end{bmatrix} M^{-1}c + (y_0, u_0) \tag{11.17}$$

(see also Remark 11.7). The constant feasible control may not be an optimal one. Existence and uniqueness of an optimal control follow standard arguments; see, for instance, Lee and Markus [17, Chapters 2 and 3].

Next we verify the claim that the optimal control $u^*(\tau)$ is continuous and periodic. Applying to (11.12)–(11.13) the standard necessary and sufficient conditions for extrema in linear-quadratic systems (see, e.g., Lee and Markus [17, pp. 180, 191]), we get that the control $u^*(\tau)$ is of the form

$$u^*(\tau) = R^{-1}[B, H] \begin{bmatrix} \eta^*(\tau) \\ \zeta^*(\tau) \end{bmatrix}, \tag{11.18}$$

where $(y^*(\tau), z^*(\tau), \eta^*(\tau), \zeta^*(\tau))$ satisfy the equations

$$\frac{d}{d\tau} \begin{pmatrix} y \\ z \\ \eta \\ \zeta \end{pmatrix} = \begin{pmatrix} A & 0 & BR^{-1}B' & BR^{-1}H' \\ G & 0 & HR^{-1}B' & HR^{-1}H' \\ W & 0 & -A' & -G' \\ 0 & 0 & 0 & 0 \end{pmatrix} \begin{pmatrix} y \\ z \\ \eta \\ \zeta \end{pmatrix} + \begin{pmatrix} c \\ 0 \\ -W\Gamma(\tau) \\ 0 \end{pmatrix}. \tag{11.19}$$

We see right away that $u^*(\tau)$ must be continuous. Since the dual variable $\zeta^*(\tau)$ is constant, it follows that $\eta^*(\tau)$ must be periodic (by the periodicity of $y(\tau)$ and $\Gamma(\tau)$ and by the transversality conditions); hence from (11.18) it follows that $u^*(\tau)$ is indeed periodic. (Another argument for the periodicity is that, by solving the problem on $[0, 2T]$, we should get on $[T, 2T]$ a replica of the solution on $[0, T]$; otherwise the uniqueness is violated.) (Note that (11.18)–(11.19) can be used to compute the optimal trajectory and control.)

Finally we note that indeed $(y^*(\tau), u^*(\tau))$ depends continuously on the data. This follows easily from continuous dependence arguments and the uniqueness. This completes the proof of the proposition. □

Remark 11.7. We showed that if q satisfies the constraint (11.15), then there is a constant feasible pair (y, u). Note that satisfying (11.15) is a necessary condition for the existence of any feasible control $(y(\tau), u(\tau))$. This follows from the considerations of Proposition 11.4.

Step III. The infinitesimal generation problem.

Fix $x \in R^n$ and $v \in V(x)$ (see Proposition 11.4). We consider the IG(x, v) Problem 9.1. It is shown in this step that a solution is essentially provided by applying the solution of Problem 11.5 periodically (and where q and v are related by $v = Fx+q$; see (11.7) and (11.15)), and $c = Cx$.

The linearity, which is reflected by the separation of x and (y, u), and the required boundedness of $y(t)$ imply that the infinitesimal generation problems with data (x, v) take the form as follows. (Compare with (9.1)–(9.3); note that here proper generation, in particular x fixed, suffices.)

IG(x, v) *Problem* 11.8.

$$\text{minimize } \lim_{T\to\infty} \frac{1}{T} \int_0^T (\|x\|_Q^2 + \|y(\tau) - \Gamma(x, \tau)\|_W^2 + \|u(\tau)\|_R^2) d\tau \tag{11.20}$$

subject to

$$\frac{dy}{d\tau} = Ay + Bu + Cx \tag{11.21}$$

and

$$v = \lim_{T\to\infty} \frac{1}{T} \int_0^T (Fx + Gy(\tau) + Hu(\tau)) d\tau. \tag{11.22}$$

Associated with Problem 11.8, consider the periodic-boundary value problem LQPBVT $(\Gamma(\cdot), c, q)$ Problem 11.5 with $\Gamma(t) = \Gamma(x,t)$, $c = Cx$, and $q = v - Fx$. For the latter problem, we have determined an optimal pair $(y^*(\tau), u^*(\tau))$, which we now denote by

$$(y^*(\tau, x, v), u^*(\tau, x, v)), \tag{11.23}$$

and furthermore, the periodicity allows us to extend the functions periodically to the entire line.

PROPOSITION 11.9. *$(y^*(\tau,x,v), u^*(\tau,x,v))$ is an optimal solution of the IG(x,v) Problem* 11.8*, and consequently the minimal value of the problem is given by*

$$\Phi(x,v) = \frac{1}{T(x)} \int_0^{T(x)} (\|x\|_Q^2 + \|y^*(\tau,x,v) - \Gamma(x,\tau)\|_W^2 + \|u^*(\tau,x,v\|_R^2) d\tau. \tag{11.24}$$

Proof. Let $(y(\tau), y(\tau))$ be any pair which satisfies the constraint (11.22). Take $T = kT(x)$ with k large enough, such that the average

$$\frac{1}{T} \int_0^T (Fx + Gy(\tau) + Hu(\tau)) d\tau \tag{11.25}$$

is very close to v. The controllability of (A, B) implies that we can make $u(T) = u(0)$ and $y(T) = y(0)$ without changing much the value in (11.25). Averaging of the k translation $u_j(\tau) = u(\tau + jT(x))$, $y_j(\tau) = y(\tau + jT(x))$, with $j = 0, \ldots, k-1$ (and interpreting $(u(\cdot), y(\cdot))$ as periodic, with $kT(x)$ being the period) induces a $T(x)$-periodic pair, with cost smaller than or equal to the cost associated with $(u(\cdot), y(\cdot))$; this by the convexity. Still, the cost of the generated periodic pair is greater than or equal to that of $(u^*(\tau), y^*(\tau))$, the latter being the optimal periodic one. ∎

Step IV. Stabilization and proper control policies.

We already know that the periodic pair $(y^*(\tau,x,v), u^*(\tau,x,v))$ forms an optimal trajectory for the generation of v at x. But we wish to construct a control $\mathbf{u} = u(x,y,\tau,v)$ which would be proper (see Definition 5.6, but note that we work with periodic functions on R (see Remark 11.3)) and for (x,v) fixed would solve the infinitesimal generation problem. What we do is simply find a feedback control that, for (x,v) fixed, stabilizes the linear equation around $y^*(\tau,x,v)$ as follows.

Let K be the unique positive definite symmetric solution of the Riccati equation

$$-KA - A'K + KBR^{-1}B'K - W = 0. \tag{11.26}$$

Then it is well known that the controllability of (A,B) and the observability of (A,W) imply that such a K exists and is unique, and furthermore, it is known that $G = A - BR^{-1}B'K$ is a stable matrix; see, e.g., Athans and Falb [4, p. 773].

PROPOSITION 11.10. *Consider the control*

$$u(x,y,\tau,v) = -R^{-1}B'K(y - y^*(\tau,x,v)) + u^*(\tau,x,v). \tag{11.27}$$

Then it is a periodic control, continuous in all its variables, and for each (x,v) fixed, the solutions of

$$\frac{dy}{d\tau} = Ay + Bu + Cx$$

converge uniformly to $y^*(\tau,x,v)$.

Proof. The periodicity and continuity follow from the corresponding properties of $y^*(\tau)$ and $u^*(\tau)$, namely, Proposition 11.6. The stabilization is standard. ∎

COROLLARY 11.11. *For* $\mathbf{u}$ *given in* (11.27), $\mathrm{cost}(\mathbf{u}, x, v) = \Phi(x, v)$, *where* $\Phi(x, v)$ *is the infimal cost of generating* v *at* x.

Proof. It follows directly from the stabilization statement of Proposition 11.10 and the form (11.24) for $\Phi(x, v)$. ∎

Step V. The global problem.

Once the cost $\Phi(x, v)$ of optimally generating the velocity v at x is determined (see (11.24)), the global problem $GO(R^n)$ can be formed; see Problem 9.3. In the tracking case we study, it can be presented in the following form:

$$\text{minimize} \int_0^1 (\|x(t)\|_Q^2 + \Psi(x(t), w(t)))dt \tag{11.28}$$

subject to

$$\begin{aligned} \frac{dx}{dt} &= \left(F - [G, H]\begin{bmatrix} A' \\ B' \end{bmatrix} M^{-1}C\right)x + w, \\ x(0) &= \overline{x}, \\ w &\in V, \end{aligned} \tag{11.29}$$

with V given in (11.6) and the vectors v and w related by

$$v = w - [G, H]\begin{bmatrix} A' \\ B' \end{bmatrix} M^{-1}Cx \tag{11.30}$$

and where $\Psi(x, w)$ is related to $\Phi(x, v)$ by $\Phi(x, v) = \Psi(x, w) + \|x\|_Q^2$, namely, (by (11.24)) $\Psi(x, w)$ is given by

$$\Psi(x, w) = \frac{1}{T(x)} \int_0^{T(x)} (\|y^*(\tau, x, v) - \Gamma(x, \tau)\|_W^2 + \|u^*(\tau, x, v)\|_R^2)d\tau. \tag{11.31}$$

Note that the state equation for the global optimization is linear in x, with coefficients easily calculable from the data. The cost $\Psi(x, w)$ is not separable in general. (When $C = 0$ and Γ is independent of x, then $\Psi(x, w)$ is independent of x.)

PROPOSITION 11.12. *The cost* $\Psi(x, w)$ *is continuous in* (x, w), *it tends to* $+\infty$ *as* $|w| \to \infty$, *and it is a convex function of the variable* w.

Proof. The continuity follows from the relations (11.31) and (11.30) together with the continuous dependence statement in Proposition 11.6. The growth to $+\infty$ follows directly from the positive definiteness of R and the boundary condition (11.14). The convexity in the variable w follows as pairs $(y^*(\tau, x, v_i), u^*(\tau, x, v_i))$ for $i = 1, 2$ can be averaged, producing a feasible pair for the averaged v_i (by the linearity) with cost greater than or equal to the infimal one. The convexity of the quadratic cost concludes the argument. ∎

Step VI. The near optimal solution.

We conclude by writing down explicitly the near optimal solution to the SP-LQPT Problem 11.1. The construction (which includes an existence statement) is as follows:

For each $w \in V$ the cost $\Psi(x, w)$ is determined by (11.31), with $y^*(\tau, x, v)$ and $u^*(\tau, x, v)$ being the solution of the associated periodic boundary value, linear-quadratic tracking. Once a solution $w(x, t)$ to the global problem (11.28)–(11.29) is found, we write

$$v(x, t) = w(x, t) - [G, H]\begin{bmatrix} A' \\ B' \end{bmatrix} M^{-1}Cx,$$

and then a near optimal solution to the original singular perturbations tracking is given by

$$u(x,y,\sigma,t) = -R^{-1}B'K(y - y^*(\sigma, x, v(x,t))) + u^*(\sigma, x, v(x,t)). \tag{11.32}$$

The near optimality of this feedback control is guaranteed by the main result, Theorem 9.6. Note that indeed the near optimal solution does not employ the parameter ϵ. It is a feedback, though, of the fast time σ. Note that the near optimal solution (11.32) for the linear-quadratic tracking example is explicit in terms of solutions of the explicitly given two problems on finite intervals.

A HOMEOMORPHIC CHARACTERIZATION OF MINIMAL SPECTRAL FACTORS*

AUGUSTO FERRANTE†

Abstract. In this paper a new characterization of the class of all minimal square spectral factors of a given rational spectral density is presented. This characterization, which is established without assumptions on poles and zeroes of the spectral density, extends a result presented in [A. Ferrante, *IEEE Trans. Automat. Control*, 39 (1994), pp. 2122–2126]. The characterization consists of two bijective maps which relate the set of minimal square spectral factors to a set of invariant subspaces of a certain matrix and to a set of symmetric solutions of an algebraic Riccati equation (ARE). In the second part of the paper it is proven that these two maps are homeomorphisms. This result extends and applies to spectral factorization theory recent results of H. Wimmer [*Integral Equations Operator Theory*, 21 (1995), pp. 362–375], where it is proven that the well-known relation between solutions of ARE and invariant subspaces of a certain matrix is, in fact, a homeomorphism.

1. Introduction.

The spectral factorization problem is a cornerstone of many areas of systems and control theory, circuit theory, and prediction theory. Indeed, this problem is crucial in both linear quadratic optimal control and optimal filtering [16], [10]. In recent years, we have witnessed an increasing interest in *acausal* spectral factors, i.e., spectral factors whose poles and zeroes need not be in the left half complex plane [14], [15], [13], [4], [2], [3], [6], [7], [11]. These spectral factors are employed in problems of estimation in which the available information is not organized in a causal structure. For example, in [12, sect. 8] a noncausal estimation problem is considered, and the solution is given (in the spectral domain) in terms of an acausal spectral factor.

Also, great effort has been made to understand the relation between solutions of the spectral factorization problem and solutions of the ARE: since the first works in the late 1960s, the spectral factorization problem has been related to the Kalman–Popov–Yacubovich positive-real lemma, and this, in turn, to linear matrix inequality (see, for example, [16]) and to the ARE. In [14] and [15], the set of minimal spectral factors with given structure of poles or zeroes was characterized in terms of solutions of a homogeneous ARE. In [4] and [2], a characterization of the set of all minimal square spectral factors was provided for a class (a certain condition on sets of poles and zeroes of the spectral density was assumed) of multivariate rational spectral densities, in terms of a homogeneous ARE of double dimension with respect to that of [14] and [15]. In [6], a different characterization of all minimal spectral factors was given, without any assumption on the zeroes and poles of the spectral density. In the first part of this paper we obtain a characterization alternative, but equivalent, to that of [6] extending the results presented in [4] and [2] to an arbitrary rational coercive spectral density. More precisely, we show that, given a rational coercive spectral

density $\Phi(s)$, there is a one-to-one correspondence between the set of its minimal spectral factors and a class of symmetric solutions of an homogeneous ARE. This class, in turn, is in one-to-one correspondence with a set of invariant subspaces of a certain matrix Z which contains all the information about poles and zeroes of the spectral density. This matrix can be computed directly from the spectral density $\Phi(s)$. The correspondence between the set of invariant subspaces of Z and the set of solutions of the ARE has been extensively studied, and it is given by a standard procedure; see [19], [17], [20], and references therein.

In the second part of this paper we address the issue of the continuity of the maps which relate invariant subspaces of the above-mentioned matrix Z, solutions of the ARE, and minimal spectral factors. In the cases in which the ARE—and the related spectral factorization problem—have a finite number of solutions, the map which assigns a minimal spectral factor to a solution of the ARE is clearly continuous when we endow the domain and the image of the map with any reasonable topology. The same is true for the map relating invariant subspaces of the matrix Z and solutions of the ARE. However, when the ARE—and the related spectral factorization problem—have a continuum of solutions, the issue of continuity becomes more interesting. Indeed, in recent literature we find a relevant amount of work studying topological properties of solutions of the ARE; see, for instance, [8], [18], [19]. In particular, in [19] the problem of the continuity of the map which relates invariant subspaces of Z and solutions of the ARE has been investigated. In that paper it was shown that the function which maps an invariant subspace into a solution of the ARE is a homeomorphism when we endow the set of subspaces of $\mathbb{R}^n$ with the topology induced by the *gap metric*. In this paper we show that also the map which relates solutions of the ARE to minimal spectral factors is a homeomorphism when we endow the set of spectral factors of $\Phi(s)$ with the topology induced by the $\mathcal{L}^\infty$ norm. By composition, we have that also the map relating invariant subspaces of Z and minimal spectral factors is a homeomorphism.

Moreover we show that the map which assigns a minimal spectral factor to a solution of the ARE, and its inverse, are *Lipschitz continuous*, and we provide an upper-bound for the Lipschitz constant. This fact may be interesting in numerical solutions of the spectral factorization problem where a minimal spectral factor is computed starting from a numerical approximation of a fixed solution of the ARE. The Lipschitz continuity is interesting also in the case when the ARE has a finite number of solutions because it provides a bound on the distance of two minimal spectral factors given the distance of the corresponding solutions of the ARE.

2. Mathematical preliminaries and definitions. In this paper we deal with multivariate *real rational coercive spectral densities*, i.e., $m \times m$ matrix-valued rational functions $\Phi(s)$ with real coefficients and such that (s.t.) the following properties hold:

(i) $\Phi(s) = \Phi(-s)^T$.

(ii) $\Phi(s)$ is analytic on an open strip including the imaginary axis.

(iii) $\exists\ c \in \mathbb{R}_+$ s.t. $\Phi(i\omega) > cI > 0 \quad \forall \omega \in \mathbb{R}$.

Note that property (iii) implies that $R := \Phi(i\infty)$ is a symmetric positive definite matrix.

A matrix function $W(s)$ of dimensions $(m \times p)$ is called a *spectral factor* of $\Phi(s)$ if

$$W(s)W(-s)^T = \Phi(s). \tag{2.1}$$

Condition (iii) implies that $p \geq m$; if $p = m$, we have a *square* spectral factor. $W(s)$ is said to be *minimal* if it has least possible McMillan degree. In this paper we are

interested in minimal square spectral factors. Therefore in the following we shall say that a minimal square spectral factor is a solution of the spectral factorization problem for $\Phi(s)$. Clearly if $W(s)$ is a minimal spectral factors and O is a constant orthogonal matrix, then also $W_O(s) := W(s)O$ is a minimal spectral factor. However, $W(s)$ and $W_O(s)$, considered as transfer functions of linear systems, correspond to the same dynamics, and they differ only for a change of basis on the input space. For this reason we shall identify spectral factors which differ by multiplication on the right by a constant orthogonal matrix. Hence, without loss of generality, we shall suppose that $W(i\infty) = \Phi(i\infty)^{1/2} = R^{1/2}$.

Given a minimal realization

$$W(s) = R^{1/2} + C(sI - A)^{-1}B \tag{2.2}$$

of a spectral factor, we define the *pole structure* of $W(s)$ to be the Jordan structure of the *state matrix* A. We define the *zero structure* of $W(s)$ to be the Jordan structure of the *zero matrix* $\Gamma := A - BR^{-1/2}C$. It is immediate to see that the zero matrix Γ is the state matrix of a minimal realization of $W(s)^{-1}$. The eigenvalues of A and Γ will be called *poles* and *zeroes* of $W(s)$, respectively. The pole and zero structures of $W(s)$ are well defined since the Jordan forms of A and Γ do not depend on the realization (2.2).

It is well known (see, for instance, [10]) that, given a spectral density, there exists a minimal spectral factor $\overline{W}_-(s)$ which is *antistable* and *minimum phase*; i.e., all the poles of $\overline{W}_-(s)$ are in the open right half plane, and all the zeroes of $\overline{W}_-(s)$ are on the open left half plane. This spectral factor, which may be computed from $\Phi(s)$ via various algorithms [1], [15], will play a crucial role in this paper since it will be taken as the reference spectral factor.

3. Characterization of minimal square spectral factors. Let $\Phi(s)$ be a rational coercive spectral density and

$$\overline{W}_-(s) = R^{1/2} + C(sI + A^T)^{-1}B \tag{3.1}$$

be a minimal realization of its minimal spectral factor $\overline{W}_-(s)$. Define

$$\Gamma := -A^T - BR^{-1/2}C \tag{3.2}$$

to be the zero matrix of $\overline{W}_-(s)$. In what follows, A, B, and C will be matrices of dimensions $n \times n$, $n \times m$, and $m \times n$, respectively. Clearly Γ is an $n \times n$ matrix. Notice that, since both A and Γ are stability matrices, their spectra $\sigma(A)$ and $\sigma(\Gamma)$ are unmixed; i.e.,

$$\sigma(A) \cap \sigma(-A) = \emptyset, \tag{3.3}$$

$$\sigma(\Gamma) \cap \sigma(-\Gamma) = \emptyset. \tag{3.4}$$

Let $\mathcal{S}_A$ and $\mathcal{S}_\Gamma$ be the sets of invariant subspaces of A^T and Γ^T, respectively, and let $\mathcal{S}$ be the set defined by

$$\mathcal{S} := \{(S_A, S_\Gamma) : \quad S_A \in \mathcal{S}_A, \quad S_\Gamma \in \mathcal{S}_\Gamma\}. \tag{3.5}$$

$\mathcal{S}$ is the set of pairs of subspaces, one invariant for A^T and the other for Γ^T.

The following lemma gives a first characterization of the set of minimal square spectral factors.

LEMMA 3.1. *There exists a one-to-one correspondence between the set $\mathcal{W}$ of the minimal square spectral factors of $\Phi(s)$ and the set $\mathcal{S}$ defined above.*

Proof. Let $S := (S_A, S_\Gamma)$ be an element of $\mathcal{S}$. The first step of the proof is to compute a spectral factor $W(s) \in \mathcal{W}$ corresponding to such S.

Consider the following homogeneous ARE:

$$AQ + QA^T + QBB^TQ = 0. \tag{3.6}$$

Since A has unmixed spectrum, there is a one-to-one correspondence between symmetric solutions of (3.6) and invariant subspaces of A^T: this correspondence is given by the map which assigns to each solution $\bar{Q}$ the A^T-invariant subspace $\bar{S} := \ker \bar{Q}$; see, for instance, [14], [15], or [17]. Then let Q_{S_A} be the (unique) symmetric solution of (3.6) whose kernel is S_A, and let

$$H := C - R^{1/2}B^TQ_{S_A}. \tag{3.7}$$

Now let P_{S_Γ} be the (unique) symmetric solution of the ARE

$$\Gamma P + P\Gamma^T + PH^TR^{-1}HP = 0, \tag{3.8}$$

whose kernel is S_Γ. Again the existence and uniqueness of such solution is guaranteed since Γ has unmixed spectrum [14].

Now define the all-pass functions

$$K(s) := I - B^T(sI - A)^{-1}Q_{S_A}B \tag{3.9}$$

and

$$Q(s) := I - R^{-1/2}H(sI - \Gamma)^{-1}P_{S_\Gamma}H^TR^{-1/2}. \tag{3.10}$$

Computing the product $\overline{W}_-(s)K(s)Q(s)$ we get

$$W_S(s) := \overline{W}_-(s)K(s)Q(s) \tag{3.11}$$

$$= [R^{1/2} + C(sI + A^T)^{-1}B][I - B^T(sI - A)^{-1}Q_{S_A}B]Q(s) \tag{3.12}$$

$$= [R^{1/2} + (C - R^{1/2}B^TQ_{S_A})(sI + A^T + BB^TQ_{S_A})^{-1}B]$$

$$\times [I - R^{-1/2}H(sI - \Gamma)^{-1}P_{S_\Gamma}H^TR^{-1/2}] \tag{3.13}$$

$$= R^{1/2} + (C - R^{1/2}B^TQ_{S_A})(sI + A^T + BB^TQ_{S_A})^{-1}(B - P_{S_\Gamma}C^TR^{-1/2}), \tag{3.14}$$

and hence $W_S(s)$ is clearly a minimal spectral factor.

Conversely, given any minimal spectral factor $W_1(s)$, the all-pass function defined by $U_1(s) := \overline{W}_-(s)^{-1}W_1(s)$ is an inner function that admits the inner factorization $U_1(s) = K(s)Q(s)$, where $K(s)$ is such that $\overline{W}_-(s)$ and $W_{1,-}(s) := \overline{W}_-(s)K(s)$ have the same zero structure and $Q(s)$ is such that $W_{1,-}(s)$ and $W_1(s) = W_{1,-}(s)Q(s)$ have the same pole structure [4, Lemma 3.6]. From this fact, using Theorems 3.1 and 3.2 in [14], we can conclude that $K(s)$ has a realization of the form (3.9) and $Q(s)$ has a realization of the form (3.10) for a certain couple Q_{S_A} and P_{S_Γ} of solutions of (3.6) and (3.8), respectively. To the pair (Q_{S_A}, P_{S_Γ}), there corresponds the couple of subspaces $S_A := \ker Q_{S_A}$ and $S_\Gamma := \ker P_{S_\Gamma}$, invariant for A^T and Γ^T, respectively.

It remains to show that the map assigning a minimal spectral factor to each $S \in \mathcal{S}$ is injective. From equation (3.14) we see that the state matrix of a minimal

realization of $W_S(s)$ is given by $F := -A^T - BB^T Q_{S_A}$, where Q_{S_A} is the unique solution of equation (3.6) s.t. its kernel is S_A. Since the subspace S_A is A^T-invariant, we have that, in a basis where the first vectors form a basis for S_A and the remaining vectors form a basis for $(S_A)^\perp$, A^T has the structure $A^T = \left[\begin{smallmatrix} A_{11} & A_{12} \\ 0 & A_{22} \end{smallmatrix}\right]$. In this basis, the matrix Q_{S_A} has the structure $Q_{S_A} = \left[\begin{smallmatrix} 0 & 0 \\ 0 & Q_R \end{smallmatrix}\right]$, where Q_R is a nonsingular matrix. In fact Q_{S_A} is a symmetric matrix whose kernel is S_A. Moreover, denoting by M the lower right block of the matrix BB^T partitioned conforming with A^T, Q_R is the unique nonsingular solution of the following reduced-order ARE:

$$A_{22}^T X + X A_{22} + X M X = 0. \tag{3.15}$$

Hence the state matrix F of $W_S(s)$ can be written as

$$F = -A^T - BB^T Q_{S_A} = \begin{bmatrix} -A_{11} & -A_{12} \\ 0 & -A_{22} \end{bmatrix} - \begin{bmatrix} 0 & * \\ 0 & MQ_R \end{bmatrix} \tag{3.16}$$

$$= \begin{bmatrix} -A_{11} & ** \\ 0 & -A_{22} - MQ_R \end{bmatrix} = \begin{bmatrix} -A_{11} & ** \\ 0 & Q_R^{-1} A_{22}^T Q_R \end{bmatrix}, \tag{3.17}$$

where the values of the blocks $*$ and $**$ have no influence on the argument. Since A has the structure

$$A = \begin{bmatrix} A_{11}^T & 0 \\ A_{12}^T & A_{22}^T \end{bmatrix},$$

we can conclude that the restriction of F to S_A coincides with the restriction of $-A^T$ to S_A, and the map induced by F in the quotient space $\mathbb{R}^n/S_A$ is similar to the map induced by A in the same quotient space. Since A has unmixed spectrum, this implies that to different A^T-invariant subspaces there correspond spectral factors with different pole structure which are therefore necessarily different.

A similar argument shows that to different Γ^T-invariant subspaces there correspond different spectral factors. □

The following corollary characterizes the state and zero dynamics of the spectral factor $W_S(s)$ corresponding to the pair $S = (S_A,\ S_\Gamma)$.

COROLLARY 3.2. *The minimal spectral factor $W_S(s)$ has a minimal realization where the state and the zero matrices F and Λ are s.t.*

1. *the restriction of F to S_A coincides with the restriction of $-A^T$ to S_A.*
2. *the map induced by F in the quotient space $\mathbb{R}^n/S_A$ is similar to the map induced by A in the same quotient space.*
3. *the restriction of Λ to S_Γ coincides with the restriction of Γ to S_Γ.*
4. *the map induced by Λ in the quotient space $\mathbb{R}^n/S_\Gamma$ is similar to the map induced by $-\Gamma^T$ in the same quotient space.*

Proof. The first two points of the corollary are proven by equation (3.16). The proof of points (3) and (4) is similar. □

Remark 3.3. We notice that, in Lemma 3.1, the choice of $\overline{W}_-(s)$ as the reference spectral factor has been made just for the sake of simplicity. In fact, from the proof of that lemma, we see that its validity is independent on this assumption, and it remains true starting from any minimal spectral factor $W(s)$ such that the corresponding state and zero matrices A and Γ satisfies conditions (3.3). For example, a spectral factor (different from $\overline{W}_-(s)$) which satisfies condition (3.3) is $W_+(s)$, the unique minimal stable spectral factor whose inverse is antistable.

We now give an explicit and direct characterization of the set $\mathcal{W}$ in term of a set of solutions of a unique ARE of dimension $2n$. To this aim we define the two matrices L and Z in the following way:

$$L := [-B^T \mid R^{-1/2}C], \qquad Z := \begin{bmatrix} A & 0 \\ 0 & \Gamma \end{bmatrix}. \tag{3.18}$$

Notice that, since both A and Γ are stability matrices, also the spectrum $\sigma(Z)$ of Z is unmixed, i.e.,

$$\sigma(Z) \cap \sigma(-Z) = \emptyset. \tag{3.19}$$

For compactness of notation we shall represent each element $S = (S_A, S_\Gamma) \in \mathcal{S}$ as a subspace of $\mathbb{R}^{2n}$. More precisely,

$$\mathcal{S} := \left\{ S = \left\{ z = \begin{bmatrix} x \\ 0 \end{bmatrix} + \begin{bmatrix} 0 \\ y \end{bmatrix} : \quad x \in S_A,\ y \in S_\Gamma \right\} : \quad S_A \in \mathcal{S}_A, \quad S_\Gamma \in \mathcal{S}_\Gamma \right\}.$$

Clearly each $S \in \mathcal{S}$ is an invariant subspace of Z. The converse is true if and only if A and Γ have disjoint spectra:

$$\sigma(A) \cap \sigma(\Gamma) = \emptyset. \tag{3.20}$$

Consider the following ARE whose solutions are in one-to-one correspondence with the set of invariant subspaces of Z^T:

$$Z\Delta + \Delta Z^T + \Delta L^T L \Delta = 0. \tag{3.21}$$

In view of such correspondence, with each $S \in \mathcal{S}$ we can associate a symmetric solution of equation (3.21): we shall denote by Δ_S such solution. Let $\mathcal{D}_\mathcal{S}$ be the set of solution of (3.21) corresponding to $\mathcal{S}$:

$$\mathcal{D}_\mathcal{S} := \{\Delta_S : \quad S \in \mathcal{S}\}. \tag{3.22}$$

We observe that, in the case when A and Γ have disjoint spectra, $\mathcal{D}_\mathcal{S}$ is the set of all symmetric solutions of (3.21). Also, notice that, given the subspace $S \in \mathcal{S}$, the solution Δ_S may be computed by employing a standard procedure.

In the following proposition we provide an explicit characterization of the set $\mathcal{W}$ in terms of the elements of $\mathcal{D}_\mathcal{S}$.

PROPOSITION 3.4. *There exists a one-to-one correspondence between the set $\mathcal{W}$ of the minimal square spectral factors of $\Phi(s)$ and the set $\mathcal{D}_\mathcal{S}$ above defined. More precisely, we have*

$$\mathcal{W} = \{\overline{W}_-(s)[I - L(sI - Z)^{-1}\Delta L^T] \ : \quad \Delta \in \mathcal{D}_\mathcal{S}\ \}. \tag{3.23}$$

Proof. Let $S = \left\{ \left[\begin{smallmatrix} x \\ 0 \end{smallmatrix} \right] + \left[\begin{smallmatrix} 0 \\ y \end{smallmatrix} \right] : x \in S_A,\ y \in S_\Gamma \right\} \in \mathcal{S}$, and denote by Q_{S_A}, P_{S_Γ}, and Δ_S the solutions of (3.6), (3.8), and (3.21) corresponding to S_A, S_Γ, and S, respectively. Moreover, set

$$\Delta := \begin{bmatrix} Q_{S_A}P_{S_\Gamma}Q_{S_A} + Q_{S_A} & Q_{S_A}P_{S_\Gamma} \\ P_{S_\Gamma}Q_{S_A} & P_{S_\Gamma} \end{bmatrix}. \tag{3.24}$$

We now show that

$$\Delta_S = \Delta. \tag{3.25}$$

To this aim, it is sufficient to prove that the matrix Δ given by (3.24) solves equation (3.21) and that $\ker \Delta = S$. The first of these two facts may be checked by plugging the left-hand side of (3.24) into equation (3.21) and analyzing the resulting equation block by block. The upper left block is given by

$$\begin{aligned}
&AQ_{S_A} + Q_{S_A}A^T + Q_{S_A}BB^TQ_{S_A} \\
&+ (Q_{S_A}BB^TQ_{S_A} + AQ_{S_A} - Q_{S_A}BR^{-1/2}C)P_{S_\Gamma}Q_{S_A} \\
&+ Q_{S_A}P_{S_\Gamma}(Q_{S_A}BB^TQ_{S_A} + Q_{S_A}A^T - C^TR^{-1/2}B^TQ_{S_A}) \\
&+ Q_{S_A}P_{S_\Gamma}(Q_{S_A}BB^TQ_{S_A} - C^TR^{-1/2}B^TQ_{S_A} - Q_{S_A}BR^{-1/2}C + C^TR^{-1}C)P_{S_\Gamma}Q_{S_A}.
\end{aligned} \tag{3.26}$$

The sum of the first three terms vanishes in view of equation (3.6). Again, in view of equation (3.6) and using the definition of Γ, the terms in the first parenthesis reduce to $Q_{S_A}\Gamma$. Symmetrically the second parenthesis reduces to $\Gamma^TQ_{S_A}$. Finally, it is easy to see that the terms in the last parenthesis add up to $HR^{-1}H$, where H is defined in (3.7). The upper left block is therefore $Q_{S_A}(\Gamma P_{S_\Gamma} + P_{S_\Gamma}\Gamma^T + P_{S_\Gamma}C_1R^{-1}C_1P_{S_\Gamma})Q_{S_A}$, and this clearly vanishes since P_{S_Γ} solves (3.8). Similarly one can check that the other blocks are equal to zero. Therefore Δ is a symmetric solution of (3.21).

The fact that $\ker \Delta = S$ follows from the identity

$$\begin{bmatrix} Q_{S_A}P_{S_\Gamma}Q_{S_A} + Q_{S_A} & Q_{S_A}P_{S_\Gamma} \\ P_{S_\Gamma}Q_{S_A} & P_{S_\Gamma} \end{bmatrix} = \begin{bmatrix} I & Q_{S_A} \\ 0 & I \end{bmatrix} \begin{bmatrix} Q_{S_A} & 0 \\ P_{S_\Gamma}Q_{S_A} & P_{S_\Gamma} \end{bmatrix}, \tag{3.27}$$

which implies

$$\begin{aligned}
\ker \Delta &= \ker \begin{bmatrix} Q_{S_A} & 0 \\ P_{S_\Gamma}Q_{S_A} & P_{S_\Gamma} \end{bmatrix} \\
&= \left\{ \begin{bmatrix} x \\ y \end{bmatrix} \ : \ Q_{S_A}x = 0, \ \ P_{S_\Gamma}Q_{S_A}x + P_{S_\Gamma}y = 0 \right\} \qquad (3.28) \\
&= \left\{ \begin{bmatrix} x \\ y \end{bmatrix} \ : \ x \in \ker Q_{S_A}, \ \ y \in \ker P_{S_\Gamma} \right\} = S.
\end{aligned}$$

In this way equation (3.25) remains proven.

Now we show that

$$I - L(sI - Z)^{-1}\Delta_S L^T = K(s)Q(s), \tag{3.29}$$

where $K(s)$ and $Q(s)$ are defined by (3.9) and (3.10). Taking into account that

$$\begin{aligned}
Q_{S_A}BR^{-1/2}H &= Q_{S_A}BR^{-1/2}C - Q_{S_A}BB^TQ_{S_A} \\
&= -Q_{S_A}A^T - Q_{S_A}\Gamma - Q_{S_A}BB^TQ_{S_A} \qquad (3.30) \\
&= AQ_{S_A} - Q_{S_A}\Gamma = Q_{S_A}(sI - \Gamma) - (sI - A)Q_{S_A}, \qquad (3.31)
\end{aligned}$$

where the first equality follows from the definition (3.7) of H, the second from the definition of Γ, and the third from (3.6), we get

$$K(s)Q(s) = B^T(sI - A)^{-1}Q_{S_A}(P_{S_\Gamma}H^TR^{-1/2} - B) - (R^{-1/2}H + B^TQ_{S_A})(sI - \Gamma)^{-1}P_{S_\Gamma}H^TR^{-1/2} + I. \tag{3.32}$$

From this equation, using again the definition (3.7) of H we immediately get equation (3.29).

The previous argument, together with equation (3.11) and Lemma 3.1, proves equation (3.23). □

Remark 3.5. Proposition 3.4 extends a result presented in [4], where the assumption (3.20) was made, to arbitrary coercive spectral densities. In particular, as was pointed out in [2], if condition (3.20) fails, then there exist solutions of equation (3.21) corresponding to nonminimal spectral factors: Proposition 3.4 characterizes the set $\mathcal{D}_\mathcal{S}$ of the solutions of (3.21) corresponding to minimal spectral factors.

Remark 3.6. In [6] a characterization of minimal spectral factors in terms of the solutions of a pair of n-dimensional ARE was presented. Proposition 3.4 gives a characterization of minimal spectral factors *at once* in terms of the solutions of a unique $2n$-dimensional ARE. The advantage of such characterization is that of representing the class of minimal spectral factors in terms of a unique parameter $\Delta \in \mathcal{D}_\mathcal{S}$, as shown by equation (3.23). In this way, the comparison of different spectral factors is more direct as is shown, for example, in the next section, where the difference of minimal spectral factors is considered. Also, such a representation of the class $\mathcal{W}$ in terms of a unique parameter Δ seems to be very natural when one minimal spectral factor has to be selected in the class $\mathcal{W}$ by minimizing a certain cost function. Finally, from the numerical point of view, the $2n$-dimensional ARE (3.21) is not more complex than a pair of n-dimensional AREs. In fact, since the matrix Z is block-diagonal, equation (3.21) may be easily decoupled.

Remark 3.7. Let Δ be an element of $\mathcal{D}_\mathcal{S}$ partitioned into four $n \times n$ blocks:

$$\Delta = \begin{bmatrix} \Delta_{11} & \Delta_{12} \\ \Delta_{21} & \Delta_{22} \end{bmatrix}. \tag{3.33}$$

As we have shown in the proof of the previous proposition, Δ has the form (3.24). Hence we have[1]

$$\begin{cases} P_{S_\Gamma} = \Delta_{22}, \\ P_{S_A} = \Delta_{11} - \Delta_{12}\Delta_{22}^\sharp\Delta_{21}. \end{cases} \tag{3.34}$$

This observation and equations (3.11) provide a minimal realization of the spectral factor $W_\Delta(s)$ directly in terms of A, B, C, R, and the solution Δ.

[1] In this paper, if Δ is a matrix, $\Delta^\sharp$ will denote the Moore–Penrose pseudoinverse of Δ, i.e., the unique matrix s.t.
(1) $\Delta\Delta^\sharp\Delta = \Delta$,
(2) $\Delta^\sharp\Delta\Delta^\sharp = \Delta^\sharp$,
(3) $(\Delta\Delta^\sharp)^T = \Delta\Delta^\sharp$,
(4) $(\Delta^\sharp\Delta)^T = \Delta^\sharp\Delta$.

4. Continuity. In this section we investigate the properties of continuity of the function Θ, which associates a solution $\Delta_S \in \mathcal{D}_{\mathcal{S}}$ with the Z^T-invariant subspace $S \in \mathcal{S}$, and of the function Ξ, which associates a minimal spectral factor $W_\Delta(s) \in \mathcal{W}$ to $\Delta \in \mathcal{D}_{\mathcal{S}}$. To this aim, we specify a metric for each of the three sets $\mathcal{S}$, $\mathcal{D}_{\mathcal{S}}$, and $\mathcal{W}$. We endow the vector space $\mathbb{C}^n$ ($n \in \mathbb{N}$) with the usual Euclidean norm; i.e., for $x \in \mathbb{C}^n$, $\|x\|_e := (x^*x)^{1/2}$ (with the symbol x^* we denote the conjugate transpose of x). We define, as usual, $\|Y\| := \max\{\|Yx\|_e : \ x \in \mathbb{C}^n, \|x\|_e = 1\}$ to be the norm of a matrix $Y \in \mathbb{C}^{m\times n}$. It is well known that $\|Y\|$ equals the largest singular value of the matrix Y, i.e., the square root of the largest eigenvalue of Y^*Y. Since $\mathcal{D}_{\mathcal{S}} \subset \mathbb{C}^{n\times n}$, the norm $\|\cdot\|$ defined above induces a metric in the set $\mathcal{D}_{\mathcal{S}}$.

Since $\Phi(s)$ is a spectral density, it is analytic on an open strip including the imaginary axis. Then any minimal spectral factor $W(s) \in \mathcal{W}$ is analytic in the same strip, and this implies that the matrix norm of $W(i\omega)$ is a bounded function of $\omega \in \mathbb{R}$, or, more compactly, $W(s) \in \mathcal{L}^\infty_{m\times m}(\mathbb{I})$. Hence, we endow the set $\mathcal{W}$ with the metric induced by the $\mathcal{L}^\infty_{m\times m}(\mathbb{I})$ norm; i.e., if $W(s) \in \mathcal{W}$, $\|W(s)\|_\infty := \sup_{\omega\in\mathbb{R}} \|W(i\omega)\|$, where by $\|W(i\omega)\|$ we intend the norm of the matrix $W(i\omega)$ as defined above. Finally we endow the set $\mathcal{S}$ with the *gap metric*. This is defined as follows: Let $S_1, S_2 \in \mathcal{S}$, and define

$$
\begin{array}{rccl}
d: & \mathcal{S}\times\mathcal{S} & \longrightarrow & \mathbb{R}_+, \\
 & S_1 \times S_2 & \mapsto & d(S_1,S_2) := ||P_{S_1} - P_{S_2}||,
\end{array}
\tag{4.1}
$$

where P_{S_i}, $i = 1, 2$, is the (linear) operator of orthogonal projection onto the space S_i. (This function d defines a metric in the set of subspaces of $\mathbb{R}^{2n}$). Next we recall some well-known facts. Let $\mathcal{L}^2_m[a, b]$ be the space of m-dimensional vector-valued functions $v(t)$ such that $\int_a^b v^T(t)v(t)dt < +\infty$. The number $\int_a^b v^T(t)v(t)dt$ is the $\mathcal{L}^2_m[a, b]$-norm of $v(t)$, and it is denoted by $\|v\|_2$. As a standard application of Parseval equality and the Bochner theorem (see, e.g., [5]) we have that if

$$
\begin{cases}
\dot{x}(t) = Ax(t) + Bu(t), \\
y(t) = Cx(t) + Du(t)
\end{cases}
\tag{4.2}
$$

is a linear system where $A \in \mathbb{R}^{n\times n}$ is a stability matrix, $B \in \mathbb{R}^{n\times m}$, and $C \in \mathbb{R}^{p\times n}$, then the transfer function $G(s) = C(sI - A)^{-1}B + D$ is in $\mathcal{L}^\infty_{p\times m}(\mathbb{I})$ and its norm is given by

$$
\|G(s)\|_\infty = \sup\{\|y_u(t)\|_2 : \ u \in \mathcal{L}^2_m[0,\infty], \ \|u(t)\|_2 = 1\},
\tag{4.3}
$$

where $y_u(t)$ is the forced response of system (4.2) to the input $u(t)$. The function $G(s)$ is in fact in $H^\infty_{p\times m}$ [5], and (4.3) is also the H^∞ norm of $G(s)$.

To prove our result on the continuity properties of Θ, Ξ, we need some preliminary results. First, we recall from [9] that, given two matrices $A \in \mathbb{R}^{n\times n}$ and $B \in \mathbb{R}^{n\times m}$ and denoting by $\lambda_m(A)$ the smallest singular value of A, the following inequality holds:

$$
\|AB\| \geq \lambda_m(A)\|B\|.
\tag{4.4}
$$

The next two lemmas collect some results that will be useful in what follows.

LEMMA 4.1. *The pair* (L, Z) *defined by equation* (3.18) *is observable.*

Proof. Since equation (3.1) is a minimal realization of a minimal spectral factor, the spectral density $\Phi(s) = \overline{W}_-(s)\overline{W}_-^T(-s)$ has McMillan degree $2n$ (where n is the dimension of the square matrix A). Using the realization (3.1) we get

$$\begin{aligned}\Phi(s) &= \overline{W}_-(s)\overline{W}_-^T(-s)\\ &= R + C(sI + A^T)^{-1}BR^{1/2}\\ &\quad - R^{1/2}B^T(sI - A)^{-1}C^T - C(sI + A^T)^{-1}BB^T(sI - A)^{-1}C^T.\end{aligned} \tag{4.5}$$

We now define N to be the unique solution of the following Lyapunov equation:

$$BB^T = A^TN + NA. \tag{4.6}$$

The existence and uniqueness of such N are due to the stability of A. Equation (4.6) yields immediately $BB^T = (sI + A^T)N - N(sI - A)$. Plugging this expression of BB^T in equation (4.5) we get

$$\begin{aligned}\Phi(s) = &\begin{bmatrix} -CN - R^{1/2}B^T & C \end{bmatrix} \begin{bmatrix} sI - A & 0 \\ 0 & sI + A^T \end{bmatrix}^{-1}\\ &\times \begin{bmatrix} C^T \\ BR^{1/2} + NC^T \end{bmatrix} + R.\end{aligned} \tag{4.7}$$

Since $\Phi(s)$ has McMillan degree $2n$, its realization (4.7) is minimal and hence observable. Therefore, using the celebrated Popov–Bielevich–Hautus test, we have

$$\text{Rank} \begin{bmatrix} \lambda I - A & 0 \\ 0 & \lambda I + A^T \\ -CN - R^{1/2}B^T & C \end{bmatrix} = 2n \qquad \forall \lambda \in \mathbb{C}. \tag{4.8}$$

This immediately implies

$$2n = \text{Rank} \begin{bmatrix} \lambda I - A & 0 \\ 0 & \lambda I + A^T \\ -CN - R^{1/2}B^T & C \end{bmatrix} \tag{4.9}$$

$$\begin{aligned}= \text{Rank} \Bigg(&\begin{bmatrix} I & 0 & 0 \\ -N & I & 0 \\ 0 & 0 & I \end{bmatrix} \begin{bmatrix} I & 0 & 0 \\ 0 & I & BR^{-1/2} \\ 0 & 0 & R^{-1/2} \end{bmatrix}\\ &\times \begin{bmatrix} \lambda I - A & 0 \\ 0 & \lambda I + A^T \\ -CN - R^{1/2}B^T & C \end{bmatrix} \begin{bmatrix} I & 0 \\ N & I \end{bmatrix} \Bigg)\end{aligned} \tag{4.10}$$

$$= \text{Rank} \begin{bmatrix} \lambda I - Z \\ L \end{bmatrix} \qquad \forall \lambda \in \mathbb{C}. \tag{4.11}$$

This concludes the proof. ∎

Before introducing the next lemma we give a definition and recall some well-known results. Given a pair of matrices $Z \in \mathbb{R}^{n\times n}$ and $G \in \mathbb{R}^{n\times m}$, we define $\mathcal{R}_{[0.T]}^{(Z,G)}$ as the following reachability operator:

$$\begin{aligned}\mathcal{R}_{[0.T]}^{(Z,G)}: \quad \mathcal{L}_m^2[0,T] &\longrightarrow \mathbb{R}^n,\\ u(\cdot) &\mapsto \mathcal{R}_{[0.T]}^{(Z,G)}(u) := \int_0^T e^{Zt}Gu(t)dt.\end{aligned} \tag{4.12}$$

For simplicity of notation, from now on, we shall drop the (Z, G) and simply write $\mathcal{R}_{[0,T]}$. We define the norm $\|\mathcal{R}_{[0,T]}\|_o$ as the operator norm induced on $\mathcal{R}_{[0,T]}$ by the usual norms $\|\cdot\|_2$ and $\|\cdot\|_e$ on $\mathcal{L}^2_m[0,T]$ and $\mathbb{R}^n$, respectively. Precisely,

$$\|\mathcal{R}_{[0,T]}\|_o = \sup\{\|\mathcal{R}_{[0,T]}(u)\|_e : \ u \in \mathcal{L}^2_m[0,T], \ \|u(t)\|_2 = 1\}. \tag{4.13}$$

It is easy to see that

$$\|\mathcal{R}_{[0,T]}\|_o = \left\| \int_0^T e^{Zt} G G^T e^{Z^T t} dt \right\|^{1/2}. \tag{4.14}$$

In fact $\mathcal{R}_{[0,T]}$ is a linear operator on Hilbert spaces, and hence the well-known relation

$$\|\mathcal{R}_{[0,T]}\|_o = \|\mathcal{R}^*_{[0,T]} \mathcal{R}_{[0,T]}\|_o^{1/2}, \tag{4.15}$$

where $\mathcal{R}^*_{[0,T]}$ is the adjoint of $\mathcal{R}_{[0,T]}$, holds.

LEMMA 4.2. *Let $Z \in \mathbb{R}^{n\times n}$ be a matrix with no eigenvalues on the imaginary axis, $G \in \mathbb{R}^{n\times m}$, and $\mathcal{R}_{[0,1]}$ be the corresponding reachability operator defined in* (4.12). *Then, there exist a real constant $k > 0$ independent of G and a function $\bar{u} \in \mathcal{L}^2_m[0,1]$ s.t. $\|\bar{u}\|_2 = 1$ and*

$$\|\mathcal{R}_{[0,1]}\|_o \geq \|\mathcal{R}_{[0,1]}(\bar{u})\|_e \geq k\|G\|. \tag{4.16}$$

Proof. By definition we have $\|G\| = \max_{\|u\|_e=1} \|Gu\|_e$. Then, denoting by u_m the vector $u_m := \arg\max_{\|u\|_e=1} \ \|Gu\|_e$ and by g the vector $g := Gu_m$ we have

$$\|G\| = \|g\|_e. \tag{4.17}$$

Set $\bar{u}(t) := u_m$, $t \in [0,1]$. Clearly, $\bar{u} \in \mathcal{L}^2_m[0,1]$ and $\|\bar{u}\|_2 = 1$.

Since Z has no eigenvalues on the imaginary axis, it is nonsingular, and hence we can write

$$\|\mathcal{R}_{[0,1]}\|_o \geq \|\mathcal{R}_{[0,1]}(\bar{u})\|_e = \left\| \int_0^1 e^{Zt} G u_m dt \right\|_e \tag{4.18}$$

$$= \left\| \int_0^1 e^{Zt} dt g \right\|_e = \|Z^{-1}(e^Z - I)g\|_e \tag{4.19}$$

$$\geq \lambda_m(Z^{-1}(e^Z - I))\|g\|_e \tag{4.20}$$

$$= k\|G\|, \tag{4.21}$$

where $k := \lambda_m(Z^{-1}(e^Z - I))$ is the smallest singular value of $Z^{-1}(e^Z - I)$ and (4.20) is obtained in view of equation (4.4). We now observe that Z has no eigenvalues on the imaginary axis, and hence $e^Z - I$ is nonsingular. Then, so is $Z^{-1}(e^Z - I)$, and therefore k, the smallest singular value of $Z^{-1}(e^Z - I)$, is strictly positive. ∎

The following theorem, which is our main result, establishes the continuity of functions Θ and Ξ and their inverses.

THEOREM 4.3. *The maps*

$$\begin{array}{rccc} \Theta : & \mathcal{S} & \longrightarrow & \mathcal{D}_{\mathcal{S}}, \\ & S & \mapsto & \Delta_S \end{array} \tag{4.22}$$

and

$$\begin{array}{rccc} \Xi: & \mathcal{D}_{\mathcal{S}} & \longrightarrow & \mathcal{W}, \\ & \Delta & \mapsto & W_{\Delta}(s) \end{array} \tag{4.23}$$

are homeomorphisms.

Proof. The proof for the map Θ can be obtained with trivial modifications from [19, Theorem 4.3].

We now prove the continuity of the map Ξ. Let $\mu := \|\overline{W}_-(s)\|_\infty$ and $\nu := \|L(sI - Z)^{-1}\|_\infty$. Since A and Z are stability matrices, they have no eigenvalues on the imaginary axis. Hence μ and ν are finite nonnegative real numbers. Now let $\Delta, \Delta_1 \in \mathcal{D}_{\mathcal{S}}$. In view of Proposition 3.4, we have

$$\|\Xi(\Delta) - \Xi(\Delta_1)\|_\infty = \|\overline{W}_-(s)[L(sI - Z)^{-1}(\Delta - \Delta_1)L^T]\|_\infty. \tag{4.24}$$

Now recall that if $U(s) \in \mathcal{L}^\infty_{p\times q}$, $V(s) \in \mathcal{L}^\infty_{q\times r}$, then $\|U(s)V(s)\|_\infty \le \|U(s)\|_\infty \|V(s)\|_\infty$. Then from equation (4.24) it follows that

$$\|\Xi(\Delta) - \Xi(\Delta_1)\|_\infty \le \mu\nu\|L\|\|\Delta - \Delta_1\|, \tag{4.25}$$

and this immediately yields

$$\|\Xi(\Delta) - \Xi(\Delta_1)\|_\infty \xrightarrow{\|\Delta-\Delta_1\|\to 0} 0. \tag{4.26}$$

It remains to prove continuity of the map Ξ^{-1}. Assume that $W(s)$ and $W_1(s)$ are two minimal spectral factors and Δ and Δ_1 are the corresponding solutions of equation (3.21).

Since the spectral density $\Phi(s)$ is, by assumption, coercive, the smallest singular value $\lambda_m(\overline{W}_-(i\omega))$ of $\overline{W}_-(i\omega)$, is, as a function of ω, bounded away from zero, i.e.,

$$\inf_\omega \lambda_m(\overline{W}_-(i\omega)) = c > 0. \tag{4.27}$$

Thus, in view of equation (4.4), we have

$$\|\Xi(\Delta) - \Xi(\Delta_1)\|_\infty \tag{4.28}$$

$$= \|\overline{W}_-(s)L(sI - Z)^{-1}(\Delta - \Delta_1)L^T\|_\infty \tag{4.29}$$

$$= \sup_\omega \|\overline{W}_-(i\omega)L(i\omega I - Z)^{-1}(\Delta - \Delta_1)L^T\| \tag{4.30}$$

$$\ge \sup_\omega [\lambda_m(\overline{W}_-(i\omega))\|L(i\omega I - Z)^{-1}(\Delta - \Delta_1)L^T\|] \tag{4.31}$$

$$\ge \inf_\omega [\lambda_m(\overline{W}_-(i\omega))] \sup_\omega \|L(i\omega I - Z)^{-1}(\Delta - \Delta_1)L^T\| \tag{4.32}$$

$$= c\|L(sI - Z)^{-1}(\Delta - \Delta_1)L^T\|_\infty. \tag{4.33}$$

Since $c > 0$, the comparison of equations (4.33) and (4.28) proves that

$$\|L(sI - Z)^{-1}(\Delta - \Delta_1)L^T\|_\infty \xrightarrow{\|\Xi(\Delta)-\Xi(\Delta_1)\|_\infty\to 0} 0. \tag{4.34}$$

We now use Lemmas 4.2 and 4.1 to prove that if $\|L(sI-Z)^{-1}(\Delta-\Delta_1)L^T\|_\infty \to 0$, then also

$$\|(\Delta - \Delta_1)L^T\| \to 0. \tag{4.35}$$

Define $G := (\Delta - \Delta_1)L^T$. Since Z is a stability matrix, as we have recalled in (4.3), the norm $\|L(sI - Z)^{-1}G\|_\infty$ is given by

$$\|L(sI - Z)^{-1}G\|_\infty = \sup_{\substack{u \in \mathcal{L}^2_m[0,+\infty) \\ \|u\|_2 = 1}} \|y_u(\cdot)\|_2, \tag{4.36}$$

where $y_u(\cdot)$ is defined by

$$y_u(t) := \int_0^t Le^{Z(t-\sigma)}Gu(\sigma)d\sigma. \tag{4.37}$$

From (4.36) we easily get

$$\|L(sI - Z)^{-1}G\|_\infty \geq \sup_{\substack{u \in \mathcal{L}^2_m[0,1] \\ \|u\|_2 = 1}} \|y_u(\cdot)\|_2. \tag{4.38}$$

We observe that if $u \in \mathcal{L}^2_m[0,1]$, then $y_u(t)$ is, for $t \geq 1$, the free response the system (G, Z, L) corresponding to the initial state $x(1) = \mathcal{R}_{[0,1]}(u)$, where $\mathcal{R}_{[0,1]}$ is the operator defined in (4.12). Also, it is obvious that $\int_0^{+\infty} \|y(t)\|_e^2 dt \geq \int_1^{+\infty} \|y(t)\|_e^2 dt$, and hence we can write

$$\sup_{\substack{u \in \mathcal{L}^2_m[0,1] \\ \|u\|_2 = 1}} \|y_u(\cdot)\|_2 \geq \sup_{\substack{u \in \mathcal{L}^2_m[0,1] \\ \|u\|_2 = 1}} \left(\int_1^{\infty} \|y_u(t)\|_e^2 dt \right)^{1/2} \tag{4.39}$$

$$= \sup_{\substack{u \in \mathcal{L}^2_m[0,1] \\ \|u\|_2 = 1}} \left(\int_1^{+\infty} \|Le^{Z(t-1)}\mathcal{R}_{[0,1]}(u)\|_e^2 dt \right)^{1/2} \tag{4.40}$$

$$= \sup_{\substack{u \in \mathcal{L}^2_m[0,1] \\ \|u\|_2 = 1}} \left(\int_0^{+\infty} \|Le^{Zt}\mathcal{R}_{[0,1]}(u)\|_e^2 dt \right)^{1/2}, \tag{4.41}$$

where the derivation of equation (4.41) is immediate.

Since Z is a stability matrix, it has no eigenvalues on the imaginary axis. Thus, we can employ Lemma 4.2, which proves the existence of an $\mathcal{L}^2_m[0,1]$ function $\bar{u}$ with unitary norm and of a positive constant k independent of G s.t., defining $\bar{x} := \mathcal{R}_{[0,1]}(\bar{u})$, we have

$$\|\bar{x}\|_e \geq k\|G\|. \tag{4.42}$$

From the latter equation and equations (4.36), (4.38), and (4.39) we get

$$\|L(sI - Z)^{-1}G\|_\infty \geq \left(\int_0^{+\infty} \|Le^{Zt}\bar{x}\|_e^2 dt \right)^{1/2} = \left(\bar{x}^T \mathcal{O} \bar{x}\right)^{1/2}, \tag{4.43}$$

where $\mathcal{O}$ is the observability Gramian of the pair (Z, L). Since, as we proved in Lemma 4.1, the pair (Z, L) is observable, the matrix $\mathcal{O}$ is positive definite and hence it may be factored as $\mathcal{O} = V^T V$, where V is nonsingular. Thus, the smallest singular value $\lambda_m(V)$ of V is strictly positive. Therefore, employing equation (4.4), we get

$$\|L(sI - Z)^{-1}G\|_\infty \geq \|V\bar{x}\| \geq \lambda_m(V)\|\bar{x}\|_e \geq k_1\|G\|, \tag{4.44}$$

where $k_1 := k\lambda_m(V)$ is strictly positive. We can then conclude that if $\|L(sI - Z)^{-1}(\Delta - \Delta_1)L^T\|_\infty \to 0$, then also $\|(\Delta - \Delta_1)L^T\| = \|G\| \to 0$. This clearly implies that

$$\|\Delta L^T L\Delta - \Delta_1 L^T L\Delta_1\| \to 0. \tag{4.45}$$

In fact, defining $X := \Delta L^T$ and $X_1 := \Delta_1 L^T$, we have

$$\|\Delta L^T - \Delta_1 L^T\| = \|X - X_1\| \tag{4.46}$$

$$\geq \frac{1}{2\|X_m\|}[\|X - X_1\|\|X_1^T\| + \|X\|\|X^T - X_1^T\|] \tag{4.47}$$

$$\geq \frac{1}{2\|X_m\|}\|X_1X_1^T - XX^T\| \tag{4.48}$$

$$= k_2\|\Delta L^T L\Delta - \Delta_1 L^T L\Delta_1\|, \tag{4.49}$$

with $k_2 := \frac{1}{2\|X_m\|} > 0$ and $X_m := \Delta_m L^T$, where Δ_m is the solution of (3.21) which maximizes the norm $\|\Delta_m L^T\|$. (Such solution exists since the set of solutions of (3.21) is compact.)

Since both Δ and Δ_1 solve (3.21), equations (4.46) to (4.49) may be rewritten as

$$\|\Delta L^T - \Delta_1 L^T\| \geq k_2\|Z(\Delta - \Delta_1) + (\Delta - \Delta_1)Z^T\|, \tag{4.50}$$

where k_2 is strictly positive. This clearly implies that if $\|(\Delta - \Delta_1)L^T\| \to 0$ then also

$$\|Z(\Delta - \Delta_1) + (\Delta - \Delta_1)Z^T\| \to 0. \tag{4.51}$$

Finally we have to prove that (4.51) implies

$$\|\Delta - \Delta_1\| \to 0. \tag{4.52}$$

To see this define $Y := \Delta - \Delta_1$ and $W := Z(\Delta - \Delta_1) + (\Delta - \Delta_1)Z^T$. Since Z is a stability matrix, the Lyapunov equation

$$ZY + YZ^T = W \tag{4.53}$$

has the unique solution

$$Y = \Delta - \Delta_1 = \int_0^\infty e^{Zt}We^{Z^Tt}dt, \tag{4.54}$$

and then we have

$$\|\Delta - \Delta_1\| = \left\|\int_0^\infty e^{Zt}We^{Z^Tt}dt\right\| \tag{4.55}$$

$$\leq \int_0^\infty \|e^{Zt}We^{Z^Tt}\|dt \tag{4.56}$$

$$\leq \int_0^\infty \|e^{Zt}\|^2dt\|W\| \tag{4.57}$$

$$= k_3\|W\|, \tag{4.58}$$

where $k_3 := \int_0^\infty \|e^{Zt}\|^2 dt$ is finite since Z is a stability matrix. This proves formula (4.52) and concludes the proof. □

COROLLARY 4.4. *The map Ξ and its inverse are Lipschitz continuous.*

Proof. From the first part of the proof of Theorem 4.3, it immediately follows that if Δ and Δ_1 are elements of $\mathcal{D}_\mathcal{S}$, then

$$\|\Xi(\Delta) - \Xi(\Delta_1)\|_\infty \leq K\|\Delta - \Delta_1\|, \tag{4.59}$$

where K is given by

$$K = \|\overline{W}_-(s)\|_\infty \|L\| \cdot \|L(sI - Z)^{-1}\|_\infty. \tag{4.60}$$

On the other hand, comparing inequalities (4.28)–(4.33), (4.44), (4.50), and (4.55)–(4.58) we get

$$\|\Delta - \Delta_1\| \leq \bar{K}\|\Xi(\Delta) - \Xi(\Delta_1)\|_\infty, \tag{4.61}$$

where $\bar{K} := \frac{k_3}{ck_1k_2}$ is finite since k_3 is finite and c, k_1, and k_2 are strictly positive. (See the definitions of c, k_1, k_2, and k_3, in (4.33), (4.44), (4.50), and (4.58), respectively.) □

Remark 4.5. It is worth noting that equations (4.59) and (4.60) give

$$\frac{\|W_\Delta(s) - W_{\Delta_1}(s)\|_\infty}{\|\overline{W}_-(s)\|_\infty} \leq k\|\Delta - \Delta_1\|, \tag{4.62}$$

where $k = \|L\| \cdot \|L(sI - Z)^{-1}\|_\infty$. We observe that for all spectral factors $W(s)$ of $\Phi(s)$ we have $\|\overline{W}_-(s)\|_\infty = \|W(s)\|_\infty = \|\Phi(s)\|_\infty^{1/2}$. Then the denominator of the left-hand side of (4.62) is a constant depending only on $\Phi(s)$, and thus the left-hand side of (4.62) has the meaning of relative error on determination of the spectral factor given an error $\|\Delta - \Delta_1\|$ on the solution of the ARE (3.21). From equation (4.62) we see that given a spectral density corresponding to a *small* k, if Δ_1 is *close* to Δ, then the relative error on $W_{\Delta_1}(s)$ (with respect to $W_\Delta(s)$) is *small*. On the contrary, for spectral density corresponding to a *large* k, this is not guaranteed.

The value of k depends on L and Z, which depend only on the data of the problem. Roughly speaking, once the matrix L has been fixed, the value of k depends on the stability margin of Z and hence on the stability margin of A and Γ. Thus for spectral factors with zeros and poles *far* from the imaginary axis, the relative error on the spectral factor is not much larger of the error on the solution of the ARE (3.21).

AUGMENTED LAGRANGIAN TECHNIQUES FOR ELLIPTIC STATE CONSTRAINED OPTIMAL CONTROL PROBLEMS*

MAÏTINE BERGOUNIOUX† AND KARL KUNISCH‡

Abstract. We propose augmented Lagrangian methods to solve state and control constrained optimal control problems. The approach is based on the Lagrangian formulation of nonsmooth convex optimization in Hilbert spaces developed in [K. Ito and K. Kunisch, *Augmented Lagrangian Methods for Nonsmooth Convex Optimization in Hilbert Spaces*, preprint, 1994]. We investigate a linear optimal control problem with a boundary control function as in [M. Bergounioux, *Numer. Funct. Anal. Optim.*, 14 (1993), pp. 515–543]. Both the equation and the constraints are augmented. The proposed methods are general and can be adapted to a much wider class of problems.

Key words. state and control constrained optimal control problems, augmented Lagrangian, elliptic equations

1. Setting of the problem. Let Ω be an open, bounded subset of $\mathbb{R}^n$, $n \leq 3$, with a smooth boundary Γ. We consider the following optimal control problem:

$$(\mathcal{P}) \qquad \min \quad J(y,u) = \frac{1}{2}\int_\Omega (y - z_d)^2 \, dx + \frac{\alpha}{2}\int_\Gamma (u - u_d)^2 \, d\sigma,$$

$$Ay = f \text{ in } \Omega, \quad y = u \quad \text{on } \Gamma, \tag{1.1}$$

$$\Lambda_1 y \in K, \ u \in U, \tag{1.2}$$

where

- $f,\ z_d \in L^2(\Omega),\ u,\ u_d \in L^2(\Gamma)$, and either $\alpha > 0$ or U_{ad} is bounded in $L^2(\Gamma)$;
- A is an elliptic operator defined by

$$\begin{cases} Ay = -\displaystyle\sum_{i,j=1}^{n} \partial_{x_i}(a_{ij}(x)\partial_{x_j} y) + a_0(x)y \ \text{ with} \\ a_{ij}, a_0 \in \mathcal{C}^2(\bar{\Omega}) \text{ for } i,j = 1,\dots,n, \ \inf\ \{a_0(x) \mid x \in \bar{\Omega}\} > 0, \\ \displaystyle\sum_{ij=1}^{n} a_{ij}(x)\xi_i\xi_j \geq \delta \sum_{i=1}^{n} \xi_i^2 \ \forall x \in \bar{\Omega}, \forall \xi \in \mathbb{R}^n, \delta > 0; \end{cases} \tag{1.3}$$

- L is a Hilbert space (with dual L' identified with L) and $\Lambda_1 \in \mathcal{L}(W, L)$ (W is defined just below).
- K and U are nonempty, closed, convex subsets of L and $L^2(\Gamma)$, respectively.

System (1.1) is well-posed: for every $(u, f) \in L^2(\Gamma) \times L^2(\Omega)$ there exists a unique solution $y = \mathcal{T}(u, f)$ in W, where

$$W = \{\ y \in L^2(\Omega) \mid Ay \in L^2(\Omega)\ ,\ y_{|\Gamma} \in L^2(\Gamma)\}.$$

Moreover $\mathcal{T}$ is continuous from $L^2(\Gamma) \times L^2(\Omega)$ to W, when W is endowed with the graph norm:

$$|y|_W^2 = |y|_\Omega^2 + |Ay|_\Omega^2 + |y_{|\Gamma}|_\Gamma^2.$$

For more details, one may refer to Lions and Magenes [7, Vol. 1, Chap. 2]. From now on, when H is a Hilbert space, we denote by $(\ ,\ )_H$ (resp., $(\ ,\ )_\Omega$ and $(\ ,\ )_\Gamma$) the H (resp., $L^2(\Omega)$ and $L^2(\Gamma)$) inner products and by $|\ |_H$, $|\ |_\Omega$, $|\ |_\Gamma$ the H, $L^2(\Omega)$, and $L^2(\Gamma)$ norms, respectively.

We assume that the feasible domain

$$\mathcal{D}\ =\ \{\ (y,u) \in W \times L^2(\Gamma) \mid Ay\ =\ f\ \text{ in } \Omega,\ y = u\ \text{ on } \Gamma,\ (\Lambda_1 y, u) \in K \times U\ \}$$

is nonempty. It is easy to see that problem $(\mathcal{P})$ has a unique solution $(\bar{y}, \bar{u})$ since the functional J is strictly convex and coercive and $\mathcal{D}$ is convex, closed, and nonempty. Our main purpose is to retrieve optimality conditions for such a problem, with a new "penalization" method and to use them as a basis for numerical algorithms. Indeed, this has been done via a penalization of the state equation only in Bergounioux [1], where the existence of Lagrange multipliers for the state equation has been proved under appropriate qualification conditions. Here we use a different point of view, since we also use a penalization of the nonsmooth constraints $\Lambda_1 y \in K,\ u \in U$ with an augmented Lagrangian method as in Ito and Kunisch [6]. Optimality systems have been derived by other authors before. We mention, for instance, the work of Bonnans and Casas [3, 4] and the references given in [1]. In contrast to our work, these contributions are not based on augmented Lagrangian formulations, and they do not analyze algorithmic aspects. Similarly, the algorithm we present in section 4 is based on the augmentation of both the state equation and *the state and control constraints*. The main contribution of this research is the elimination of these latter constraints from the set of explicit constraints by augmentation. Commonly augmented Lagrangian algorithms are based on the augmentation of the state equation only. This is the case for instance for all the methods described in [5].

2. Augmented Lagrangian formulation. In this section we use the framework of [6]. We denote

$$X = W \times L^2(\Gamma),\quad H = L \times L^2(\Gamma),\quad D = K \times U.$$

Let Λ be defined from X to H by $\Lambda(y,u) = (\Lambda_1 y, u)$ and φ be the characteristic function of the convex set D. Then, following [6], we define (for any $c > 0$) the function $\varphi_c : H \times H \to \mathbb{R}$ by

$$\varphi_c(x,\lambda) = \inf_{\xi \in H} \left\{\ \varphi(x-\xi) + (\lambda,\xi)_H + \frac{c}{2}|\xi|_H^2\ \right\}, \tag{2.1}$$

where $x = (y,u)$.

Here $(\ ,\ )_H$ is given by $(\lambda,\xi)_H = (\lambda_1,\xi_1)_\Omega + (\lambda_2,\xi_2)_\Gamma$, with $\lambda = (\lambda_1,\lambda_2)$ and $\xi = (\xi_1,\xi_2)$.

Let us give some properties of the function φ_c. (For the proof we refer to [6].)

PROPOSITION 2.1. *For all $x \in H,\ \lambda \in H$, the infimum in* (2.1) *is attained at a unique point $\xi_c(x,\lambda)$. φ_c is convex and Lipschitz-continuously Fréchet-differentiable in x, and*

$$\varphi_c'(x,\lambda) = \lambda + c\ \xi_c(x,\lambda)\ . \tag{2.2}$$

Moreover $\lim_{c\to+\infty} \varphi_c(x,\lambda) = \varphi(x)$. □

Now we compute φ_c for our case.

PROPOSITION 2.2. *For all $x = (y,u) \in H$ and $\lambda = (\lambda_1,\lambda_2) \in H$*

$$\begin{aligned}\varphi_c(x,\lambda) &= \frac{c}{2}\left|x - P_D\left(x+\frac{\lambda}{c}\right)\right|_H^2 + \left(\lambda, x - P_D\left(x+\frac{\lambda}{c}\right)\right)_H \\ &= \frac{c}{2}\left|y - P_K\left(y+\frac{\lambda_1}{c}\right)\right|_L^2 + \left(\lambda_1, y - P_K\left(y+\frac{\lambda_1}{c}\right)\right)_L \\ &\quad + \frac{c}{2}\left|u - P_U\left(u+\frac{\lambda_2}{c}\right)\right|_\Gamma^2 + \left(\lambda_2, u - P_U\left(u+\frac{\lambda_2}{c}\right)\right)_\Gamma,\end{aligned} \tag{2.3}$$

$$\varphi_c'(x,\lambda) = c\left(y + \frac{\lambda_1}{c} - P_K\left(y+\frac{\lambda_1}{c}\right), u + \frac{\lambda_2}{c} - P_U\left(u+\frac{\lambda_2}{c}\right)\right), \tag{2.4}$$

where P_K (resp., P_U, P_D) is the L (resp., $L^2(\Gamma)$, H) projection on K (resp., on U, D).

Proof. Setting $\tilde\xi = x - \xi$ in (2.1) we obtain the equivalent representation

$$\varphi_c(x,\lambda) = \inf_{\tilde\xi\in H}\left\{\ \varphi(\tilde\xi) + \left(\lambda, x-\tilde\xi\right)_H + \frac{c}{2}\ |x-\tilde\xi|_H^2\ \right\}.$$

As $(\lambda, x-\tilde\xi)_H + \frac{c}{2}\ |x-\tilde\xi|_H^2 = \frac{c}{2}\ |\tilde\xi - (x+\frac{\lambda}{c})|_H^2 - \frac{1}{2c}|\lambda|_H^2$ and $\varphi(\tilde\xi) = +\infty$, if $\tilde\xi \notin D$, $\varphi(\tilde\xi) = 0$ else, it follows that

$$\varphi_c(x,\lambda) = \frac{c}{2}\left[\inf_{\tilde\xi\in D}\left|\tilde\xi - \left(x+\frac{\lambda}{c}\right)\right|_H^2\right] - \frac{1}{2c}|\lambda|_H^2. \tag{2.5}$$

The infimum is attained at $\tilde\xi = P_D(x+\frac{\lambda}{c})$. We define ξ_c so that $\tilde\xi = x - \xi_c$; that is,

$$\xi_c = \left[y - P_K\left(y+\frac{\lambda_1}{c}\right), u - P_U\left(u+\frac{\lambda_2}{c}\right)\right]$$

and

$$\begin{aligned}\varphi_c(x,\lambda) &= \frac{c}{2}\ \left|P_D\left(x+\frac{\lambda}{c}\right) - \left(x+\frac{\lambda}{c}\right)\right|_H^2 - \frac{1}{2c}\ |\lambda|_H^2 \\ &= \frac{c}{2}\ \left|x - P_D\left(x+\frac{\lambda}{c}\right)\right|_H^2 + \left(\lambda, x - P_D\left(x+\frac{\lambda}{c}\right)\right)_H.\end{aligned}$$

Now we compute φ_c' with formula (2.2) of Proposition 2.1, $\varphi_c'(x,\lambda) = \lambda + c\ \xi_c(x,\lambda)$, and the desired result follows. □

Next we consider the "augmented" problem:

$$(\mathcal{P}_{c,\lambda}) \qquad \min\ \ \{\ F_{c,\lambda}(y,u)\ |\ Ay = f \text{ in } \Omega\ , y = u \text{ on } \Gamma\ \},$$

where $F_{c,\lambda}(y,u) = J(y,u) + \varphi_c(\Lambda(y,u),\lambda)$ is the augmented Lagrangian function of $(\mathcal{P})$ associated with the constraint $\Lambda(y,u) \in D$. We have first an asymptotic result.

THEOREM 2.1. *For all $\lambda \in H$ and $c > 0$, problem $(\mathcal{P}_{c,\lambda})$ has a unique solution $(y_{c,\lambda}, u_{c,\lambda})$.*

Moreover for every fixed $\lambda \in H$

$$\lim_{c\to+\infty} y_{c,\lambda} = \bar{y} \text{ strongly in } W \text{ and } \lim_{c\to+\infty} u_{c,\lambda} = \bar{u} \text{ strongly in } L^2(\Gamma).$$

Proof. Let $\lambda \in H$ be fixed. For convenience, we shall omit the subscript λ and write x_c for $x_{c,\lambda}$. Existence and uniqueness of a solution (y_c,u_c) to $(\mathcal{P}_{c,\lambda})$ follows easily since the feasible domain is nonempty, closed, and convex and $F_{c,\lambda}$ is strictly convex and coercive. We set $x_c = (\Lambda_1 y_c, u_c) \in H$. To prove convergence of (y_c,u_c) to the solution $(\bar{y},\bar{u})$ of $(\mathcal{P})$ we first argue that $\{(y_c,u_c)\}_{c\geq c_0}$ is bounded, where $c_0 > 0$ is arbitrary and fixed. Since $(\bar{y},\bar{u})$ is feasible for $(\mathcal{P}_{c,\lambda})$, we have

$$F_{c,\lambda}(y_c,u_c) \leq F_{c,\lambda}(\bar{y},\bar{u}) \text{ for all } c > 0.$$

Observe from the definition of φ_c in (2.1) that $\varphi_c(\Lambda(\bar{y},\bar{u}),\lambda) = 0$ for all c. Hence, using (2.5), we obtain

$$J(y_c,u_c) - \frac{1}{2c}|\lambda|_H^2 \leq J(y_c,u_c) + \varphi_c(\Lambda(y_c,u_c),\lambda) \leq J(\bar{y},\bar{u}) \quad \text{for all } c > 0. \tag{2.6}$$

It follows that $\{(y_c,u_c)\}_{c\geq c_0}$ is bounded in $L^2(\Omega)\times L^2(\Gamma)$. Since $Ay_c = f$ for all $c > 0$, the set $\{(y_c,u_c)\}_{c\geq c_0}$ is bounded in X as well. Hence there exists $(\tilde{y},\tilde{u}) \in X$ such that a subsequence of $\{(y_c,u_c)\}_{c>0}$, denoted by the same symbol, converges weakly in X to $(\tilde{y},\tilde{u})$. Wellposedness of (1.1) in W implies that $A\tilde{y} = f$ in Ω and $\tilde{y} = \tilde{u}$ on Γ. Due to Proposition 2.2 and (2.6)

$$\left|x_c - P_D\left(x_c + \frac{\lambda}{c}\right)\right|_H^2 + \frac{2}{c}\left(\lambda, x_c - P_D\left(x_c + \frac{\lambda}{c}\right)\right)_H \leq \frac{1}{c}J(\bar{y},\bar{u})$$

and consequently

$$\left|x_c + \frac{\lambda}{c} - P_D\left(x_c + \frac{\lambda}{c}\right)\right|_H^2 \leq \frac{2J(\bar{y},\bar{u})}{c} + \frac{|\lambda|^2}{c^2} \quad \text{for all } c > 0. \tag{2.7}$$

Thus $(x_c + \frac{\lambda}{c} - P_D(x_c + \frac{\lambda}{c}))$ converges strongly to 0 in H. As (y_c,u_c) converges weakly to $(\tilde{y},\tilde{u})$ in X and Λ is linear continuous, $(x_c + \frac{\lambda}{c})$ converges weakly to $\tilde{x} = (\Lambda_1\tilde{y},\tilde{u})$ in H. This yields that $P_D(x_c + \frac{\lambda}{c})$ converges weakly to $\tilde{x}$ as well. Since D is closed in H and convex, it is also weakly closed and $\tilde{x} \in D = K \times U$. Thus $(\tilde{y},\tilde{u})$ is a feasible pair for $(\mathcal{P})$.

Let us prove the strong convergence of (y_c,u_c) to $(\tilde{y},\tilde{u})$ in X. First we note that due to Proposition 2.1 $\lim_{c\to+\infty}\varphi_c(\tilde{x},\lambda) = \varphi(\tilde{x}) = 0$. As $(\tilde{y},\tilde{u})$ is a feasible pair for $(\mathcal{P})$, it is also a feasible pair for $(\mathcal{P}_{c,\lambda})$ for any $c > 0$ and we have

$$J(y_c,u_c) + \varphi_c(\Lambda(y_c,u_c),\lambda) \leq J(\tilde{y},\tilde{u}) + \varphi_c(\Lambda(\tilde{y},\tilde{u}),\lambda) \quad \text{for all } c > 0.$$

Relation (2.3) implies that $\varphi_c(\Lambda(y_c,u_c),\lambda) \geq (\lambda, x_c - P_D(x_c + \frac{\lambda}{c}))_H$, and consequently

$$J(y_c,u_c) + \left(\lambda, x_c - P_D\left(x_c + \frac{\lambda}{c}\right)\right)_H \leq J(\tilde{y},\tilde{u}) + \varphi_c(\Lambda(\tilde{y},\tilde{u}),\lambda) \text{ for all } c > 0. \tag{2.8}$$

We take the limits inferior in this relation. With the strong convergence of $(x_c - P_D(x_c + \frac{\lambda}{c}))$ to 0 in H, we obtain

$$0 \leq J(\tilde{y},\tilde{u}) \leq \liminf_{c\to+\infty} J(y_c,u_c) \leq J(\tilde{y},\tilde{u}) + \lim_{c\to+\infty} \varphi_c(\Lambda(\tilde{y},\tilde{u}),\lambda) = J(\tilde{y},\tilde{u}).$$

Finally

$$\lim_{c\to+\infty} J(y_c,u_c) = J(\tilde{y},\tilde{u}). \tag{2.9}$$

This implies that (y_c,u_c) converges strongly to $(\tilde{y},\tilde{u})$ in $L^2(\Omega)\times L^2(\Gamma)$. Moreover $Ay_c = f = A\tilde{y}$, and therefore (y_c,u_c) converges to $(\tilde{y},\tilde{u})$ strongly in X.

It remains to prove that $(\tilde{y},\tilde{u}) = (\bar{y},\bar{u})$. We use relation (2.8) with $(\bar{y},\bar{u})$ as a feasible pair for $(\mathcal{P})$ instead of $(\tilde{y},\tilde{u})$ and obtain

$$J(y_c,u_c) + \left(\lambda, x_c - P_D\left(x_c + \frac{\lambda}{c}\right)\right)_H \leq J(\bar{y},\bar{u}) + \varphi_c(\Lambda(\bar{y},\bar{u}),\lambda) \quad \text{for all } c>0.$$

Taking the limit as c tends to $+\infty$ we have $0 \leq J(\tilde{y},\tilde{u}) \leq J(\bar{y},\bar{u})(\leq J(\tilde{y},\tilde{u}))$. As $(\bar{y},\bar{u})$ is the unique solution of $(\mathcal{P})$ we get the result. □

The following section will be devoted to deriving optimality conditions. We first consider the augmented problem $\mathcal{P}_{c,\lambda}$, and we shall then pass to the limit with respect to c.

3. Optimality conditions.

3.1. Penalized optimality conditions. We first write the necessary optimality conditions for problem $(\mathcal{P}_{c,\lambda})$. This problem can be expressed as

$$\min \{ F_{c,\lambda}(y,u) \mid e(y,u) = 0\},$$

where e is defined by

$$\begin{array}{rccc} e: & W\times L^2(\Gamma) & \to & L^2(\Omega)\times L^2(\Gamma), \\ & (y,u) & \mapsto & (Ay-f, y_{|\Gamma}-u). \end{array}$$

As the Fréchet derivative $e'(y_c,u_c)$ of e at (y_c,u_c) given by

$$\begin{array}{rccc} e'(y_c,u_c): & W\times L^2(\Gamma) & \to & L^2(\Omega)\times L^2(\Gamma), \\ & (y,u) & \mapsto & (Ay, y_{|\Gamma}-u) \end{array}$$

is surjective, we may apply the general theory of Lagrange multipliers: There exist $q_c \in L^2(\Omega)$ and $r_c \in L^2(\Gamma)$ such that the (generalized) Lagrange functional

$$\mathcal{L}_{c,\lambda}(y,u,q,r) = J(y,u) + \varphi_c(\Lambda(y,u),\lambda) + (q,Ay-f)_\Omega + (r,y-u)_\Gamma \tag{3.1}$$

satisfies the optimality condition

$$\nabla_{(y,u)}\mathcal{L}_{c,\lambda}(y_c,u_c,q_c,r_c) = 0. \tag{3.2}$$

Let us detail the above relation: we may decouple and obtain

$$(y_c - z_d, y)_\Omega + (q_c, Ay)_\Omega + (r_c,y)_\Gamma + (\mu_{1,c},\Lambda_1 y)_L = 0 \quad \text{for all } y\in W,$$

$$\alpha\ (u_c-u_d,u)_\Gamma - (r_c,u)_\Gamma + (\mu_{2,c},u)_\Gamma = 0 \quad \text{for all } u\in L^2(\Gamma),$$

where $\mu_{1,c} = \nabla_y \varphi_c(\Lambda(y_c, u_c), \lambda) = c[\Lambda_1 y_c + \frac{\lambda_1}{c} - P_K(\Lambda_1 y_c + \frac{\lambda_1}{c})] \in L$ and $\mu_{2,c} = \nabla_u \varphi_c(\Lambda(y_c, u_c), \lambda) = c[u_c + \frac{\lambda_2}{c} - P_U(u_c + \frac{\lambda_2}{c})] \in L^2(\Gamma)$.

We summarize these calculations in the following theorem.

THEOREM 3.1. *Let λ be fixed in H and (y_c, u_c) be the optimal solution of $(\mathcal{P}_{c,\lambda})$. Then there exist $(\mu_{1,c}, \mu_{2,c}) \in H$ and $(q_c, r_c) \in L^2(\Omega) \times L^2(\Gamma)$ such that*

$$Ay_c = f \text{ in } \Omega, \quad y_c = u_c \text{ on } \Gamma,$$

$$(y_c - z_d, y)_\Omega + (q_c, Ay)_\Omega + (r_c, y)_\Gamma + (\mu_{1,c}, \Lambda_1 y)_L = 0 \quad \text{for all } y \in W, \tag{3.3}$$

$$\alpha\ (u_c - u_d) - r_c + \mu_{2,c} = 0, \tag{3.4}$$

where

$$\begin{aligned} \mu_{1,c} &= c\ \left[\Lambda_1 y_c + \frac{\lambda_1}{c} - P_K\left(\Lambda_1 y_c + \frac{\lambda_1}{c}\right)\right] \in L, \\ \mu_{2,c} &= c\ \left[u_c + \frac{\lambda_2}{c} - P_U\left(u_c + \frac{\lambda_2}{c}\right)\right] \in L^2(\Gamma). \end{aligned} \tag{3.5}$$

3.2. Passage to the limit. The approximate optimality systems of Theorem 3.1 were obtained without assumption beyond those that are required to ascertain existence of a solution to $(\mathcal{P})$. To obtain an optimality system for $(\mathcal{P})$ itself we pass to the limit as c tends to $+\infty$ in (3.3)–(3.5). This requires a priori estimates for q_c and r_c which depend upon qualification conditions.

More precisely, let $V = V_1 \times V_2$ be a dense separable Banach subspace of $L^2(\Omega) \times L^2(\Gamma)$. We introduce the following assumption:

$(\mathcal{H})$ *There exists a bounded (in $L^2(\Omega) \times L^2(\Gamma)$)* subset $\mathcal{M}$ of X *such that* $\Lambda(\mathcal{M}) \subset K \times U$ *and* $0 \in \mathrm{Int}_V(\mathcal{V}(\mathcal{M}))$, *where* Int_V *denotes the interior with respect to the V-topology and* $\mathcal{V}(y, u) = (Ay - f, y|_\Gamma - u)$.

We note that $(\mathcal{H})$ is equivalent to the following:

There exists an $L^2(\Omega) \times L^2(\Gamma)$-bounded subset $\mathcal{M} \subset X$ and $\rho > 0$ such that for all $\xi = (\xi_1, \xi_2) \in B_V(0, 1)$, there exists $(y_\xi, u_\xi) \in \mathcal{M}$ satisfying $(\Lambda_1 y_\xi, u_\xi) \in K \times U$ and $Ay_\xi = f - \rho\xi_1$ in Ω, $y_\xi = u_\xi - \rho\xi_2$ on Γ.

Here $B_V(0, 1)$ denotes the unit ball in V. For $f \equiv 0$ and $V = L^2(\Omega) \times L^2(\Gamma)$ condition $(\mathcal{H})$ is satisfied, for example, if $0 \in \mathrm{int}_{L \times L^2(\Gamma)}(K \times U)$.

Under this hypothesis we can pass to the limit in the previous optimality conditions to obtain the main result of this section.

THEOREM 3.2. *Let $(\bar{y}, \bar{u})$ be the optimal solution of $(\mathcal{P})$, and assume that $(\mathcal{H})$ holds. Then there exist $(\bar{q}, \bar{r}) \in V_1' \times V_2'$ and $(\bar{\mu}_1, \bar{\mu}_2) \in L_1' \times V_2'$ such that*

$$\begin{aligned} &A\bar{y} = f \text{ in } \Omega, \quad \bar{y} = \bar{u} \text{ on } \Gamma, \\ &(\bar{y} - z_d, y)_\Omega + \langle \bar{q}, Ay \rangle_{V_1', V_1} \\ &+ \langle \bar{r}, y \rangle_{V_2', V_2} + \langle \bar{\mu}_1, \Lambda_1 y \rangle_{L_1', L_1} = 0 \quad \text{for all } y \in W_{1,2}, \end{aligned} \tag{3.6}$$

$$\alpha\ (\bar u - u_d) - \bar r + \bar\mu_2 = 0 \ \textit{in}\ V_2', \tag{3.7}$$

$$\begin{aligned} &\langle \bar\mu_1, \Lambda_1(y-\bar y)\rangle_{L_1',L_1} \le 0 \quad \textit{for all}\ y \in \{\ \bar y + W_{1,2}\}\ \textit{such that}\ \Lambda_1 y \in K,\\ &\langle \bar\mu_2, u-\bar u\rangle_{V_2',V_2} \le 0 \quad \textit{for all}\ u \in U \cap \{\bar u + V_2\}, \end{aligned} \tag{3.8}$$

where $W_{1,2} = \{\ y \in L^2(\Omega) \mid Ay \in V_1,\ y|_\Gamma \in V_2\ \}$ *endowed with the norm*

$$|y|^2_{W_{1,2}} = |y|^2_\Omega + |Ay|^2_{V_1} + |y_{|\Gamma}|^2_{V_2},$$

$L_1 = \Lambda_1(W_{1,2})$ *endowed with the graph norm, and* $\langle\ \cdot\ ,\ \cdot\ \rangle_{V',V}$ *denotes the duality product between* V *and* V'.

Proof. Throughout the proof we assume that $(\lambda_1,\lambda_2) \in L_1 \times V_2$. We first remark that (3.5) implies

$$\begin{aligned} &(\mu_{1,c}, z - \Lambda_1 y_c)_L + \frac{|\mu_{1,c}|^2_L}{c} \le \frac{1}{c}\,(\mu_{1,c},\lambda_1)_L \quad \text{for all } z \in K,\\ &(\mu_{2,c}, u - u_c)_\Gamma + \frac{|\mu_{2,c}|^2}{c} \le \frac{1}{c}\,(\mu_{2,c},\lambda_2)_\Gamma \quad \text{for all } u \in U. \end{aligned} \tag{3.9}$$

We just prove the first inequality (the second one may be proved quite similarly).

The projection $P_K(\Lambda_1 y_c + \frac{\lambda_1}{c})$ is characterized by

$$\left(z - P_K\left(\Lambda_1 y_c + \frac{\lambda_1}{c}\right), \Lambda_1 y_c + \frac{\lambda_1}{c} - P_K\left(\Lambda_1 y_c + \frac{\lambda_1}{c}\right)\right)_L \le 0 \quad \text{for all } z \in K,$$

and with (3.5) this yields

$$(\mu_{1,c}, z - \Lambda_1 y_c)_L + \frac{|\mu_{1,c}|^2}{c} \le \frac{1}{c}\,(\mu_{1,c},\lambda_1)_L \quad \text{for all } z \in K.$$

Thus the first inequality in (3.9) is verified. We next note that (3.5) may be written as

$$\frac{\mu_c}{c} = x_c + \frac{\lambda}{c} - P_D\left(x_c + \frac{\lambda}{c}\right),$$

where $x_c = \Lambda(y_c,u_c)$. We have seen in the proof of Theorem 2.1 that $x_c - P_D(x_c + \frac{\lambda}{c})$ converges strongly to 0 in H. Therefore $\frac{\mu_c}{c}$ converges strongly to 0 in H as well, and there exists $c_o > 0$ and M such that

$$\left(\frac{\mu_{1,c}}{c},\lambda_1\right)_L + \left(\frac{\mu_{2,c}}{c},\lambda_2\right)_\Gamma \le M \quad \text{for all } c \ge c_0. \tag{3.10}$$

Now we may obtain estimates on q_c and r_c. Let ξ be in $B_V(0,1)$ and (y_ξ,u_ξ) be the associated pair given by $(\mathcal{H})$. We add relations (3.3) and (3.4) used with the pair $(y_\xi - y_c, u_\xi - u_c)$ to obtain

$$\begin{aligned} &(y_c - z_d, y_\xi - y_c)_\Omega + (q_c, A(y_\xi - y_c))_\Omega + (r_c, y_\xi - y_c)_\Gamma + (\mu_{1,c}, \Lambda_1(y_\xi - y_c))_L\\ &\quad +\alpha\ (u_c - u_d, u_\xi - u_c)_\Gamma + (\mu_{2,c}, u_\xi - u_c)_\Gamma - (r_c, u_\xi - u_c)_\Gamma = 0 \end{aligned}$$

and consequently

$$\begin{aligned} (q_c,\rho\xi_1)_\Omega + (r_c,\rho\xi_2)_\Gamma \ &= \ (y_c - z_d, y_\xi - y_c)_\Omega + \alpha\ (u_c - u_d, u_\xi - u_c)_\Gamma\\ &\quad + (\mu_{1,c}, \Lambda_1(y_\xi - y_c))_L + (\mu_{2,c}, u_\xi - u_c)_\Gamma\,. \end{aligned} \tag{3.11}$$

Furthermore, relations (3.9) and (3.10) imply that

$$(\mu_{1,c}, \Lambda_1(y_\xi - y_c))_L + (\mu_{2,c}, u_\xi - u_c)_\Gamma \le \left(\frac{\mu_{1,c}}{c}, \lambda_1\right)_L + \left(\frac{\mu_{2,c}}{c}, \lambda_2\right)_\Gamma \le M \text{ for } c \ge c_0.$$

The convergence properties of Theorem 2.1 and the boundedness assumption on $\mathcal{M}$ in $L^2(\Omega) \times L^2(\Gamma)$ imply that $(y_c - z_d, y_\xi - y_c)_\Omega + \alpha\ (u_c - u_d, u_\xi - u_c)_\Gamma$ is uniformly bounded with respect to $c \ge c_0$. So we obtain with (3.11) the existence of $k > 0$ such that

$$\langle q_c, \xi_1\rangle_{V_1', V_1} + \langle r_c, \xi_2\rangle_{V_2', V_2} \le \frac{k}{\rho} \quad \text{for all } \xi = (\xi_1, \xi_2) \in B_V(0,1) \quad \text{and } c \ge c_0.$$

Therefore $\{q_c\}_{c \ge c_0}$ is bounded in V_1', and a subsequence, again denoted by q_c, converges weakly * to some $\bar{q}$ in V_1'. Similarly r_c is bounded in V_2' and converges weakly * to some $\bar{r}$ in V_2'. As we have chosen $V_1 \subset L^2(\Omega)$ and $V_2 \subset L^2(\Gamma)$ we may apply to (3.3) "smooth" test functions in $W_{1,2}$. Let us consider the Gelfand triple

$$L_1 \subset \overline{\Lambda_1(W_{1,2})} \subset L_1', \tag{3.12}$$

where $\overline{\Lambda_1(W_{1,2})}$ is considered as a subset of L and $\overline{\Lambda_1(W_{1,2})}$ denotes the closure of $\Lambda_1(W_{1,2})$ in L. Further let $\mu_{1,c}^P$ denote the projection of $\mu_{1,c}$ in L onto $\overline{\Lambda_1(W_{1,2})}$. It follows that

$$\left\langle \mu_{1,c}^P, \Lambda_1 y\right\rangle_{L_1', L_1} = -(y_c - z_d, y)_\Omega - \langle q_c, Ay\rangle_{V_1', V_1} - \langle r_c, y\rangle_{V_2', V_2} \quad \text{for all } y \in W_{1,2}.$$

It follows that, $\mu_{1,c}^P$ is bounded in L_1'. Moreover the separability of V_1 and V_2 implies the separability of L_1 (see Lemma 3.1 below). So a subsequence of $\mu_{1,c}^P$ converges weakly * to $\bar{\mu}_1$ in L_1'. Taking the limit in the above equality gives

$$(\bar{y} - z_d, y)_\Omega + \langle \bar{\mu}_1, \Lambda_1 y\rangle_{L_1', L_1} + \langle \bar{q}, Ay\rangle_{V_1', V_1} + \langle \bar{r}, y\rangle_{V_2', V_2} = 0 \quad \text{for all } y \in W_{1,2}.$$

Similarly $\mu_{2,c} = r_c - \alpha(u_c - u_d)$ converges weakly to $\bar{\mu}_2 = \bar{r} - \alpha(\bar{u} - u_d)$ in V_2'. Thus (3.6) and (3.7) are verified. It remains to show (3.8). Let $y \in \bar{y} + W_{1,2}$ and $u \in \bar{u} + V_2$ be such that $\Lambda_1 y \in K$ and $u \in U$. Then we add (3.3) with $y - y_c = (y - \bar{y}) + (\bar{y} - y_c) \in W$, and the relation that results from taking the inner product of (3.4) with $u - u_c \in L^2(\Gamma)$:

$$\begin{aligned}(y_c - z_d, y - y_c)_\Omega + \alpha\,(u_c - u_d, u - u_c)_\Gamma + (q_c, A(y - y_c))_\Omega \\ +\ (r_c, (y - u) - (y_c - u_c))_\Gamma = -(\mu_{1,c}, \Lambda_1(y - y_c))_L - (\mu_{2,c}, u - u_c)_\Gamma.\end{aligned}$$

As $Ay_c = f = A\bar{y}$ in Ω and $y_c = u_c$ on Γ, we get

$$\begin{aligned}(y_c - z_d, y - \bar{y})_\Omega + \alpha\ (u_c - u_d, u - \bar{u})_\Gamma + (q_c, A(y - \bar{y}))_\Omega \\ +\ (r_c, y - u)_\Gamma = -(\mu_{1,c}, \Lambda_1(y - y_c))_L - (\mu_{2,c}, u - u_c)_\Gamma \\ -\ (y_c - z_d, \bar{y} - y_c)_\Omega - \alpha\ (u_c - u_d, \bar{u} - u_c)_\Gamma.\end{aligned} \tag{3.13}$$

Moreover relation (3.9) implies

$$\begin{aligned}-(\mu_{1,c}, \Lambda_1(y - y_c))_L \ge -\frac{1}{c}(\mu_{1,c}, \lambda_1)_\Omega \quad \text{for all } y \in W \text{ such that } \Lambda_1 y \in K, \\ -(\mu_{2,c}, u - u_c)_\Gamma \ge -\frac{1}{c}(\mu_{2,c}, \lambda_2)_\Gamma \quad \text{for all } u \in U.\end{aligned} \tag{3.14}$$

Thus (3.13) becomes

$$
\begin{aligned}
&(y_c - z_d, y - \bar{y})_\Omega + \alpha\ (u_c - u_d, u - \bar{u})_\Gamma \\
&\quad + \ (q_c, A(y - \bar{y}))_\Omega + (r_c, y - u)_\Gamma \\
&\geq \ -\frac{1}{c}\left[(\mu_{1,c}, \lambda_1)_\Omega + (\mu_{2,c}, \lambda_2)_\Gamma\right] \\
&- \ (y_c - z_d, \bar{y} - y_c)_\Omega - \alpha\ (u_c - u_d, \bar{u} - u_c)_\Gamma\,.
\end{aligned} \tag{3.15}
$$

Let us denote by σ_c the term on the right-hand side of (3.15). Since by assumption $(\lambda_1, \lambda_2) \in L_1 \times V_2$, it is easy to see that $\lim_{c\to+\infty} \sigma_c = 0$.

Next we set successively $u = \bar{u}$ and $y = \bar{y}$. First, we choose $u = \bar{u}$ so that inequality (3.15) becomes

$$(y_c - z_d, y - \bar{y})_\Omega + (q_c, A(y - \bar{y}))_\Omega + (r_c, y - \bar{u})_\Gamma \geq \sigma_c,$$

and consequently $(y_c - z_d, y - \bar{y})_\Omega + \langle q_c, A(y - \bar{y})\rangle_{V_1',V_1} + \langle r_c, y - \bar{y}\rangle_{V_2',V_2} \geq \sigma_c$. We may now pass to the limit in the previous expression to get

$$(\bar{y} - z_d, y - \bar{y})_\Omega + \langle \bar{q}, A(y - \bar{y})\rangle_{V_1',V_1} + \langle \bar{r}, y - \bar{y}\rangle_{V_2',V_2} \geq 0.$$

With (3.6) we finally have

$$\langle \bar{\mu}_1, y - \bar{y}\rangle_{W_{1,2}',W_{1,2}} \leq 0 \quad \text{for all } y \in \{\ \bar{y} + W_{1,2}\} \text{ such that } \Lambda_1 y \in K.$$

Now we choose $y = \bar{y}$ and inequality (3.15) gives

$$
\begin{aligned}
\alpha\ (u_c - u_d, u - \bar{u})_\Gamma + (r_c, \bar{y} - u)_\Gamma &\geq \sigma_c, \\
\alpha\ (u_c - u_d, u - \bar{u})_\Gamma - \langle r_c, u - \bar{u}\rangle_{V_2',V_2} &\geq \sigma_c.
\end{aligned}
$$

Once again, we may pass to the limit, and we obtain

$$\alpha\ (\bar{u} - u_d, u - \bar{u})_\Gamma - \langle \bar{r}, u - \bar{u}\rangle_{V_2',V_2} \geq 0.$$

Together with (3.7) this implies the second inequality in (3.8), and the proof is finished as soon as the following lemma is proved.

LEMMA 3.1. *L_1 is separable.*

Proof. As $L_1 = \Lambda_1(W_{1,2})$ with Λ_1 continuous, it is sufficient to prove that $W_{1,2}$ is separable. Let D_1 (resp., D_2) be dense countable subsets of V_1 (resp., V_2). Then the subset $D = \{y \in L^2(\Omega) \mid Ay \in D_1,\ y_{|\Gamma} \in D_2\}$ is a countable subset of $W_{1,2}$ (since $\mathcal{T}$ defined in section 1 is a bijection from $D_1 \times D_2$ onto D). Moreover, the linear operator $\mathcal{T}$ is continuous from $V_1 \times V_2$ to $W_{1,2}$. We may therefore assert that D is dense because of the properties of V_i and the continuity of $\mathcal{T}$. ∎

REMARK 3.1. *Let us still denote by Λ_1 the restriction of Λ_1 to $W_{1,2}$ (i.e., from $W_{1,2}$ to L_1). Then the adjoint operator Λ_1^* is defined from L_1' to $W_{1,2}'$ and satisfies*

$$\langle \mu, \Lambda_1 y\rangle_{L_1',L_1} = \langle \Lambda_1^* \mu, y\rangle_{W_{1,2}',W_{1,2}} \ \textit{for all } (\mu, y) \in L_1' \times W_{1,2}.$$

Then relation (3.6) *and the first part of relation* (3.8) *may be written as*

$$(\bar{y} - z_d, y)_\Omega + \langle \bar{q}, Ay\rangle_{V_1',V_1} + \langle \bar{r}, y\rangle_{V_2',V_2} + \langle \bar{\nu}_1, y\rangle_{W_{1,2}',W_{1,2}} = 0, \ \textit{for all } y \in W_{1,2}$$

$$\textit{and} \quad \langle \bar{\nu}_1, y - \bar{y}\rangle_{W_{1,2}',W_{1,2}} \leq 0 \quad \textit{for all } y \in \{\ \bar{y} + W_{1,2}\} \textit{ such that } \Lambda_1 y \in K,$$

where $\bar{\nu}_1 = \Lambda_1^* \bar{\mu}_1 \in W_{1,2}'$.

3.3. Example. To illustrate the previous abstract result, we give an example for a particular choice of spaces V and L. Here we set $V_1 = L^2(\Omega)$ and $V_2 = L^2(\Gamma)$ so that $V_1' = L^2(\Omega)$, $V_2' = L^2(\Gamma)$, $W_{1,2} = W$.

The previous theorem gives the following optimality system:

$$\begin{gathered}
\bar q \in L^2(\Omega),\ \bar r \in L^2(\Gamma), \quad \text{and } \bar\mu_1 \in L_1',\ \bar\mu_2 \in L^2(\Gamma),\\
A\bar y = f \quad \text{in } \Omega, \quad \bar y = \bar u \quad \text{on } \Gamma,\\
(\bar y - z_d, y)_\Omega + (\bar q, Ay)_\Omega + (\bar r, y)_\Gamma + \langle \bar\mu_1, \Lambda_1 y\rangle_{L_1', L_1} = 0 \quad \text{for all } y \in W,\\
\alpha\ (\bar u - u_d) = \bar r - \bar\mu_2 \in L^2(\Gamma),\\
\langle \bar\mu_1, \Lambda_1(y - \bar y)\rangle_{L_1', L_1} \le 0 \quad \text{for all } y \in W \text{ such that } \Lambda_1 y \in K,\\
(\bar\mu_2, u - \bar u)_\Gamma \le 0 \quad \text{for all } u \in U.
\end{gathered} \tag{3.16}$$

If in addition L is finite dimensional, we may identify the spaces L_1, $\overline{\Lambda_1(W)}$, and L_1' of the Gelfand triple in (3.12). In this very case the optimality system becomes

$$\bar q \in L^2(\Omega),\ \bar r \in L^2(\Gamma), \text{ and } \bar\mu_1 \in \Lambda_1(W),\ \bar\mu_2 \in L^2(\Gamma), \tag{3.17}$$

$$A\bar y = f \quad \text{in } \Omega,\ \bar y = \bar u \quad \text{on } \Gamma, \tag{3.18}$$

$$(\bar y - z_d, y)_\Omega + (\bar q, Ay)_\Omega + (\bar r, y)_\Gamma + (\bar\mu_1, \Lambda_1 y)_L = 0 \quad \text{for all } \ y \in W, \tag{3.19}$$

$$\alpha\ (\bar u - u_d) = \bar r - \bar\mu_2 \in L^2(\Gamma), \tag{3.20}$$

$$(\bar\mu_1, \Lambda_1(y - \bar y))_L \le 0 \quad \text{for all } y \text{ such that } \Lambda_1 y \in K, \tag{3.21}$$

$$(\bar\mu_2, u - \bar u)_\Gamma \le 0 \quad \text{for all } u \in U. \tag{3.22}$$

As a specific example, L can be chosen as the set of linear finite elements with respect to a triangulation of Ω and Λ_1: $W \to L$ can be the L^2-projection. (H^1-projection is not admitted since the elements of W are not in general H^1-smooth.)

REMARK 3.2. *Let us still consider the case with $V_1 = L^2(\Omega)$, $V_2 = L^2(\Gamma)$, and L finite dimensional and assume that $\Lambda_1^T(L) \subset L^2(\Omega)$, where $\Lambda_1^T : L \to W'$ denotes the transpose of Λ_1. In this case we may introduce $\bar p \in H^2(\Omega) \cap H_o^1(\Omega)$ as the solution of*

$$A^*\bar p = -(\bar y - z_d + \Lambda_1^T \bar\mu_1) \text{ in } \Omega,\ \bar p = 0 \ \text{ on } \ \Gamma, \tag{3.23}$$

where A^* is the adjoint operator of A. Then with Green's formula relation (3.19) *becomes*

$$(\bar q - \bar p, Ay)_\Omega + \left(\bar r - \frac{\partial \bar p}{\partial \nu_{A^*}}, y\right)_\Gamma = 0 \quad \text{for all } y \in W. \tag{3.24}$$

For all $z \in L^2(\Omega)$ there exists $y \in H^2(\Omega) \cap H_o^1(\Omega) \subset W$ such that $Ay = z$ in Ω. So (3.24) *implies $(\bar q - \bar p, z)_\Omega = 0$ for all $z \in L^2(\Omega)$, that is $\bar q = \bar p$. Then* (3.24) *gives*

$$\bar r = \frac{\partial \bar p}{\partial \nu_{A^*}}.$$

Thus we see that relations (3.19), (3.20) *are equivalent to*

$$\begin{gathered}
A^*\bar p + \bar y - z_d + \Lambda_1^T \bar\mu_1 = 0, \quad \bar p \in H^2(\Omega) \cap H_o^1(\Omega),\\
\alpha\ (\bar u - u_d) - \frac{\partial \bar p}{\partial \nu_{A^*}} + \bar\mu_2 = 0.
\end{gathered} \tag{3.25}$$

A specific case in which Λ_1 satisfies the assumption $\Lambda_1^T(L) \subset L^2(\Omega)$ is given if L is a finite-dimensional subspace of $L^2(\Omega)$ and Λ_1 is the L^2-orthogonal projection onto L.

4. Lagrangian algorithms. In this section we turn to the numerical realization of the constrained optimal control problem $(\mathcal{P})$. We shall combine the techniques from [1] and [6] augmenting the state equation *as well as the constraints* characterizing the feasible set D to obtain well-performing algorithms.

First we recall an augmented Lagrangian algorithm based on the penalization of the state equation (see [5], [1], and the references therein).

ALGORITHM $\mathcal{A}_o$.

- Step 1. Initialization: Set $n = 0$, and choose $\gamma > 0$, $q_o \in L^2(\Omega)$, $r_o \in L^2(\Gamma)$.
- Step 2. Compute

$$(y_n, u_n) = \text{ Arg min } \{ L_\gamma(y, v, q_n, r_n) \mid \Lambda(y, u) \in K \times U\},$$

where

$$L_\gamma(y, u, q, r) = J(y, u) + (q, Ay)_\Omega + (r, y - u)_\Gamma + \frac{\gamma}{2}|Ay - f|^2_\Omega + \frac{\gamma}{2}|y - u|^2_\Gamma$$

is the augmented Lagrangian with respect to the *state equation* constraint.

- Step 3. Set

$q_{n+1} = q_n + \rho_1\ (Ay_n - f), \quad$ where $\rho_1 \in (0, 2\gamma]$,
$r_{n+1} = r_n + \rho_2\ (y_{n|\Gamma} - u_n), \quad$ where $\rho_2 \in (0, 2\gamma]$.

The analysis of this algorithm is rather standard; see [1, 5] and the references there.

THEOREM 4.1. *Let $(\bar y, \bar u)$ be the solution to $(\mathcal{P})$, and suppose that $(\mathcal{H})$ holds with $V = L^2(\Omega) \times L^2(\Gamma)$. Then the iterates of Algorithm $\mathcal{A}_o$ satisfy*

$$|y_n - \bar y|^2_\Omega + \alpha|u_n - \bar u|^2_\Gamma + \frac{1}{2\rho_1}|q_{n+1} - \bar q|^2_\Omega + \frac{1}{2\rho_2}|r_{n+1} - \bar r|^2_\Gamma$$

$$+\ (\gamma - \frac{\rho_1}{2})|Ay_n - f|^2_\Omega + (\gamma - \frac{\rho_2}{2})|y_n - u_n|^2_\Gamma \le \frac{1}{2\rho_1}|q_n - \bar q|^2_\Omega + \frac{1}{2\rho_2}|r_n - \bar r|^2_\Gamma \tag{4.1}$$

for all $n = 0, 1, 2, \ldots$. With ρ_1 and ρ_2 given as in Step 3, this implies

$$\sum_{n=0}^{\infty} |y_n - \bar y|^2_\Omega + \alpha \sum_{n=0}^{\infty} |u_n - \bar u|^2_\Gamma + \Big(\gamma - \frac{\rho_1}{2}\Big) \sum_{n=0}^{\infty} |Ay_n - f|^2_\Omega$$

$$+\ \Big(\gamma - \frac{\rho_2}{2}\Big) \sum_{n=0}^{\infty} |y_n - u_n|^2_\Gamma \le \frac{1}{2\rho_1}|q_0 - \bar q|^2_\Omega + \frac{1}{2\rho_2}|r_0 - \bar r|^2_\Gamma \tag{4.2}$$

and in particular strong convergence of $(y_n, u_n) \to (\bar y, \bar u)$ in $L^2(\Omega) \times L^2(\Gamma)$ and boundedness of $\{(q_n, r_n)\}$. If, moreover, $\rho_1 < 2\gamma$ and $\rho_2 < 2\gamma$, then $(y_n, u_n) \to (\bar y, \bar u)$ in X, and every weak limit $(\tilde q, \tilde r)$ of (q_n, r_n) has the property that $(\bar y, \bar u, \tilde q, \tilde r)$ satisfies, for all $\Lambda(y, u) \in K \times U$,

$$\Big(J'(\bar y, \bar u), (y, u) - (\bar y, \bar u)\Big)_{\Omega\times\Gamma} + \Big(\bar q, A(y - \bar y)\Big)_\Omega + \Big(\bar r, y - \bar y - (u - \bar u)\Big)_\Gamma \ge 0$$

Proof. We refer to [2]. □

The main remaining problem is the resolution of the auxiliary problem of Step 2 in Algorithm $\mathcal{A}_o$, which can be written as

$$(y_n, u_n) = \text{Arg min } \{ L_\gamma(y, u) \mid \Lambda(y, u) \in D\}.$$

To simplify the notation we omit to indicate the dependence of L_γ on q and r. During Step 2 these functions are fixed. We are going to use the following algorithm and a splitting variant to solve the auxiliary problem.

ALGORITHM $\mathcal{A}_1$.

- Step 1. Initialization: Choose $\lambda^o \in H$ and $c > 0$.
- Step 2. Compute

$$(y^j, u^j) = \text{Arg min } \{ \ L_\gamma(y,u) + \varphi_c(\Lambda(y,u), \lambda^j) \mid \Lambda(y,u) \in X\},$$

  where φ_c has been defined in the previous section.
- Step 3. Set (see 2.4)

$$\begin{aligned}\lambda^{j+1} &= \varphi_c'(\Lambda(y^j,u^j),\lambda^j)\\ &= c\left(\Lambda_1 y^j + \frac{\lambda_1^j}{c} - P_K\left(\Lambda_1 y^j + \frac{\lambda_1^j}{c}\right), u^j + \frac{\lambda_2^j}{c} - P_U\left(u^j + \frac{\lambda_2^j}{c}\right)\right).\end{aligned}$$

The convergence of this algorithm under the assumption that L is finite dimensional follows from the result in [6]. The assumption on finite dimensionality of L entails that the duality pairing between L_1 and L_1' in (3.16) can be replaced by the inner product in L (see (3.19)), which is necessary for the convergence proof. We now write the version in which Algorithm $\mathcal{A}_1$ appears as an inner loop in algorithm $\mathcal{A}_o$.

ALGORITHM $\mathcal{A}$.

- Step 1. Initialization: Set $n = 0$, and choose $\gamma > 0,\ c > 0$.
  Choose $(q_o, r_o) \in L^2(\Omega) \times L^2(\Gamma)$ and $\lambda_o = (\lambda_{o1}, \lambda_{o2}) \in L \times L^2(\Gamma)$.
- Step 2. Choose $k_n \in \mathbb{N}$, set $\lambda_n^o = \lambda_n$, and for $j = 0, \dots, k_n$

$$(y_n^j, u_n^j) = \ \text{Arg min } \{L_\gamma(y,u,q_n,r_n) + \varphi_c(\Lambda(y,u),\lambda_n^j) \mid (y,u) \in W \times L^2(\Gamma)\},$$

$$\lambda_n^{j+1} = (\lambda_{n,1}^{j+1}, \lambda_{n,2}^{j+1}) \quad \text{with} \quad \begin{cases} \lambda_{n,1}^{j+1} = c\left[\Lambda_1 y_n^j + \dfrac{\lambda_{n,1}^j}{c} - P_K\left(\Lambda_1 y_n^j + \dfrac{\lambda_{n,1}^j}{c}\right)\right], \\ \lambda_{n,2}^{j+1} = c\left[u_n^j + \dfrac{\lambda_{n,2}^j}{c} - P_U\left(u_n^j + \dfrac{\lambda_{n,2}^j}{c}\right)\right]. \end{cases}$$

  End of the inner loop: $\lambda_{n+1} = \lambda_n^{k_n+1},\ y_n = y_n^{k_n},\ u_n = u_n^{k_n}$.
- Step 3. $q_{n+1} = q_n + \frac{\rho_1}{k_n+1}(\sum_{j=0}^{k_n} A y_n^j - f)$, where $\rho_1 \in (0, 2\gamma]$,
  $r_{n+1} = r_n + \frac{\rho_2}{k_n+1}(\sum_{j=0}^{k_n}(y_n^j|_\Gamma - u_n^j))$, $\rho_2 \in (0, 2\gamma]$.

THEOREM 4.2. *Let $(\bar y, \bar u)$ be the solution to $(\mathcal{P})$, and suppose that $(\mathcal{H})$ holds with $V = L^2(\Omega) \times L^2(\Gamma)$ and that L is finite dimensional. Let $(\bar q, \bar r, \bar\mu) \in L^2(\Omega) \times L^2(\Gamma) \times L \times L^2(\Gamma)$ be an associated Lagrange multiplier. Then the iterates of Algorithm $\mathcal{A}$ satisfy*

$$\begin{aligned}&|y_n - \bar y|_\Omega^2 + \alpha|u_n - \bar u|_\Gamma^2 + \frac{k_n+1}{2\rho_1}|q_{n+1} - \bar q|_\Omega^2 + \frac{k_n+1}{2\rho_2}|r_{n+1} - \bar r|_\Gamma^2 \\ &+ \left(\gamma - \frac{\rho_1}{2}\right)|Ay_n - f|_\Omega^2 + \left(\gamma - \frac{\rho_2}{2}\right)|u_n - y_n|_\Gamma^2 + \frac{1}{2c}|\lambda_{n+1} - \bar\mu|_{L\times L^2(\Gamma)}^2 \\ &\le \frac{k_n+1}{2\rho_1}|q_n - \bar q|_\Omega^2 + \frac{k_n+1}{2\rho_2}|r_n - \bar r|_\Gamma^2 + \frac{1}{2c}|\lambda_n - \bar\mu|_{L\times L^2(\Gamma)}^2\end{aligned} \tag{4.3}$$

for all $n = 0, 1, 2, \ldots$. *If* k_n *is nonincreasing, this implies*

$$\begin{aligned} &\sum_{n=0}^{\infty} |y_n - \bar{y}|_\Omega^2 + \alpha \sum_{n=0}^{\infty} |u_n - \bar{u}|_\Gamma^2 \\ &+ \left(\gamma - \frac{\rho_1}{2}\right) \sum_{n=0}^{\infty} |Ay_n - f|_\Omega^2 + \left(\gamma - \frac{\rho_2}{2}\right) \sum_{n=0}^{\infty} |u_n - y_n|_\Gamma^2 \\ &\leq \frac{k_0+1}{2\rho_1} |q_0 - \bar{q}|_\Omega^2 + \frac{k_0+1}{2\rho_2} |r_0 - \bar{r}|_\Gamma^2 + \frac{1}{2c} |\lambda_0 - \bar{\mu}|_{L\times L^2(\Gamma)}^2 \end{aligned} \tag{4.4}$$

and in particular strong convergence of $(y_n, u_n) \to (\bar{y}, \bar{u})$ *in* $L^2(\Omega) \times L^2(\Gamma)$ *and boundedness of* $\{(q_n, r_n, \lambda_n)\}$. *If, moreover,* $\rho_1 < 2\gamma$ *and* $\rho_2 < 2\gamma$, *then* $(y_n, u_n) \to (\bar{y}, \bar{u})$ *in* X *and every weak limit* $(\tilde{q}, \tilde{r}, \tilde{\lambda})$ *of* $\{(q_n, r_n, \lambda_n)\}$ *has the property that* $(\bar{y}, \bar{u}, \tilde{q}, \tilde{r}, \tilde{\lambda})$ *satisfies* (3.19), (3.20).

Proof. See [2]. □

REMARK 4.1. *The resolution of the unconstrained minimization problem occurring in algorithm* $\mathcal{A}$ *is equivalent to the resolution of*

$$\nabla_{(y,u)} L_\gamma(y_n, u_n, q_n, r_n) + \varphi_c'(\Lambda(y_n, u_n), \lambda_n^j) = 0;$$

that is,

$$\begin{aligned} &\nabla_y \; L_\gamma(y_n, u_n, q_n, r_n) + c \left[\Lambda_1 y_n + \frac{\lambda_{n,1}^j}{c} - P_K\left(\Lambda_1 y_n + \frac{\lambda_{n,1}^j}{c}\right)\right] = 0, \\ &\nabla_u \; L_\gamma(y_n, u_n, q_n, r_n) + c \left[u_n + \frac{\lambda_{n,2}^j}{c} - P_U\left(u_n + \frac{\lambda_{n,2}^j}{c}\right)\right] = 0. \end{aligned} \tag{4.5}$$

This can be done with a Newton or a descent method for instance.

Our final goal is the analysis of Gauss–Seidel splitting techniques to solve the auxiliary problems. The splitting avoids the minimization of the auxiliary problem with respect to y and u simultaneously. The resulting algorithm is as follows.

ALGORITHM $\mathcal{A}_o^{GS}$.

- Step 1. Initialization: Set $n = 0$; choose $\gamma > 0$, $q_o \in L^2(\Omega)$, $r_o \in L^2(\Gamma)$, $u_{-1} \in U$.
- Step 2.

$$\begin{aligned} y_n &= \text{ Arg min } \{ L_\gamma(y, u_{n-1}, q_n, r_n) \mid \Lambda_1 y \in K\}, \\ u_n &= \text{ Arg min } \{L_\gamma(y_n, u, q_n, r_n) \mid u \in U\}. \end{aligned}$$

- Step 3.

$$\begin{aligned} q_{n+1} &= q_n + \rho_1 \, (Ay_n - f), \quad \text{where } \rho_1 \in (0, 2\gamma], \\ r_{n+1} &= r_n + \rho_2 \, (y_{n|\Gamma} - u_n), \quad \text{where } \rho_2 \in (0, 2\gamma]. \end{aligned}$$

Once again, we may use Algorithm $\mathcal{A}_1$ to solve the first subproblem of Step 2. The second one is easily solved directly; see Remark 4.2 below. For convenience we shall henceforth delete the index 1 in the notation of the state component of the multiplier.

ALGORITHM $\mathcal{A}^{GS}$.

- Step 1. Initialization: Set $n = 0$ and choose $\gamma > 0$, $c > 0$.
  Choose $(q_o, r_o) \in L \times L^2(\Gamma)$, $\lambda_o \in L^2(\Omega)$ and $u_{-1} \in L^2(\Gamma)$.
- Step 2. Choose $k_n \in \mathbb{N}$; set $\lambda_n^o = \lambda_n, u_n^{-1} = u_{n-1}$, and for $j = 0, \ldots, k_n$

$$y_n^j = \text{ Arg min } \{L_\gamma(y, u_n^{j-1}, q_n, r_n) + \varphi_c(\Lambda(y, u_n^{j-1}), (\lambda_n^j, 0)) \mid y \in W\},$$

$$\lambda_n^{j+1} = c\left[\Lambda_1 y_n^j + \frac{\lambda_n^j}{c} - P_K\left(\Lambda_1 y_n^j + \frac{\lambda_n^j}{c}\right)\right],$$

$$u_n^j = \text{ Arg min } \{\ L_\gamma(y_n^j, u, q_n, r_n) \mid u \in U\}.$$

End of the inner loop: $\lambda_{n+1} = \lambda_n^{k_n+1},\ y_n = y_n^{k_n}\ , u_n = u_n^{k_n}$.

- Step 3.

$$q_{n+1} = q_n + \frac{\rho_1}{k_n+1}\sum_{j=0}^{k_n}(Ay_n^j - f), \qquad \text{where } \rho_1 \in (0, 2\gamma],$$

$$r_{n+1} = r_n + \frac{\rho_2}{k_n+1}\sum_{j=0}^{k_n}(y_{n|\Gamma}^j - u_n^j), \qquad \text{where } \rho_2 \in (0, \gamma].$$

REMARK 4.2. *We may solve the first unconstrained minimization problem occurring in the previous algorithm, as was mentioned in Remark* 4.1. *The second minimization problem is indeed equivalent to*

$$u_n^j = \text{ Arg min } \left\{ \left| u - \frac{\alpha u_d + r_n + \gamma y_n^j}{\alpha+\gamma}\right|_\Gamma \ : \ u \in U \right\};$$

that is, u_n^j *is the* $L^2(\Gamma)$*-projection of* $\frac{\alpha u_d + r_n + \gamma y_n^j}{\alpha+\gamma}$ *on* U.

We end this section with a convergence analysis for Algorithm $\mathcal{A}^{GS}$.

THEOREM 4.3. *Let* $(\bar y, \bar u)$ *be the solution to* $(\mathcal{P})$*, and suppose that* $(\mathcal{H})$ *holds with* $V = L^2(\Omega) \times L^2(\Gamma)$ *and that* L *is finite dimensional. Let* $(\bar q, \bar r, \bar\mu) \in L^2(\Omega) \times L^2(\Gamma) \times L \times L^2(\Gamma)$ *be a Lagrange multiplier associated with the state equation and the state constraint.*

Then the iterates (y_n, u_n, q_n, r_n) *of Algorithm* $\mathcal{A}^{GS}$ *satisfy*

$$\begin{aligned} &|y_n - \bar y|_\Omega^2 + \left(\alpha + \frac{\gamma}{2}\right)|u_n - \bar u|_\Gamma^2 + \frac{k_n+1}{2\rho_1}|q_{n+1} - \bar q|_\Omega^2 + \frac{k_n+1}{2\rho_2}|r_{n+1} - \bar r|_\Gamma^2 \\ &\quad + \left(\gamma - \frac{\rho_1}{2}\right)|Ay_n - f|_\Omega^2 + \frac{\gamma - \rho_2}{2}|u_n - y_n|_\Gamma^2 + \frac{1}{2c}|\lambda_{n+1} - \bar\mu|_L^2 \\ &\qquad \le \frac{k_n+1}{2\rho_1}|q_n - \bar q|_\Omega^2 + \frac{k_n+1}{2\rho_2}|r_n - \bar r|_\Gamma^2 \\ &\quad + \frac{1}{2c}|\lambda_n - \bar\mu|_L^2 + \frac{\gamma - \rho_2}{2}|u_{n-1} - y_{n-1}|_\Gamma^2 + \frac{\gamma}{2}|u_{n-1} - \bar u|_\Gamma^2 \end{aligned} \tag{4.6}$$

for all $n = 1, 2, \ldots$. *If* k_n *is nonincreasing, this implies*

$$\begin{aligned} &\sum_{n=1}^{\infty}\left(|y_n - \bar y|_\Omega^2 + \alpha|u_n - \bar u|_\Gamma^2 + \left(\gamma - \frac{\rho_1}{2}\right)|Ay_n - f|_\Omega^2 + \frac{\gamma}{2}|u_n - y_n|_\Gamma^2\right) \\ \le\ &\frac{k_1+1}{2\rho_1}|q_1 - \bar q|_\Omega^2 + \frac{k_1+1}{2\rho_2}|r_1 - \bar r|_\Gamma^2 + \frac{1}{2c}|\lambda_1 - \bar\mu|_L^2 + \frac{\gamma - \rho_2}{2}|y_o - u_o|_\Gamma^2 + \frac{\gamma}{2}|u_o - \bar u|_\Gamma^2. \end{aligned}$$

Proof. We use the optimality conditions issued from Step 2 of Algorithm $\mathcal{A}^{GS}$. The iterates (y_n^j, u_n^j) of Step 2 satisfy, for $j = 0, \ldots, k_n$ and for all $y \in W$,

$$
\begin{aligned}
&\big(J_y'(y_n^j,u_n^{j-1}),y)\big)_\Omega + \left(q_n+\frac{\rho_1}{k_n+1}(Ay_n^j-f),Ay\right)_\Omega\\
&+\left(\gamma-\frac{\rho_1}{k_n+1}\right)(Ay_n^j-f,Ay)_\Omega+\left(r_n+\frac{\rho_2}{k_n+1}(y_n^j-u_n^{j-1}),y\right)_\Gamma\\
&+\left(\gamma-\frac{\rho_2}{k_n+1}\right)(y_n^j-u_n^{j-1},y)_\Gamma+\big(\varphi_{c,1}'(\Lambda_1 y_n^j,\lambda_n^j),\Lambda_1 y)\big)_L=0,
\end{aligned}
\tag{4.7}
$$

and for all $u\in U_{ad}$

$$
\begin{aligned}
&\Big(J_u'(y_n^j,u_n^j),u-u_n^j\Big)_\Gamma-\left(r_n+\frac{\rho_2}{k_n+1}(y_n^j-u_n^j),u-u_n^j\right)_\Gamma\\
&-\left(\gamma-\frac{\rho_2}{k_n+1}\right)(y_n^j-u_n^j,u-u_n^j)_\Gamma\ge 0.
\end{aligned}
\tag{4.8}
$$

From (3.19) and (3.20) it follows that

$$
\begin{aligned}
&\Big(J'(\bar y,\bar u),(y,u-\bar u)\Big)_{\Omega\times\Gamma}\\
&+(\bar q,Ay)_\Omega+(\bar r,y-(u-\bar u))_\Gamma+\Big(\bar\mu,\Lambda_1 y\Big)_{L\times L^2(\Gamma)}\ge 0
\end{aligned}
\tag{4.9}
$$

for all $(y,u)\in W\times U_{ad}$. From [6] it is known that

$$
\begin{aligned}
&\Big(\varphi_c'(\Lambda(y_n^j,u_n^j),\lambda_n^j)-\varphi_c'(\Lambda(\bar y,\bar u),\bar\mu),\Lambda(y_n^j,u_n^j)-\Lambda(\bar y,\bar u)\Big)\\
&\qquad\ge\frac{1}{2c}|\lambda_n^{j+1}-\bar\mu|^2-\frac{1}{2c}|\lambda_n^j-\bar\mu|^2
\end{aligned}
\tag{4.10}
$$

for $j=0,1,\dots,k_n$. Combining (4.7)–(4.9) and (4.10) and setting

$$
q_n^j=q_n+\frac{\rho_1}{k_n+1}\sum_{i=0}^{j}(Ay_n^i-f)\ \text{and}\ r_n^j=r_n+\frac{\rho_2}{k_n+1}\sum_{i=0}^{j}(y_n^i-u_n^i)
$$

for $j=0,\dots,k_n$ and $q_n^{-1}:=q_n,\ r_n^{-1}:=r_n$ imply

$$
\begin{aligned}
&|y_n^j-\bar y|_\Omega^2+\alpha|u_n^j-\bar u|_\Gamma^2+\frac{k_n+1}{2\rho_1}|q_n^j-\bar q|_\Omega^2-\frac{k_n+1}{2\rho_1}|q_n^{j-1}-\bar q|_\Omega^2\\
&+\left(\gamma-\frac{\rho_1}{2(k_n+1)}\right)|Ay_n^j-f|_\Omega^2+\frac{k_n+1}{2\rho_2}|r_n^j-\bar r|_\Gamma^2-\frac{k_n+1}{2\rho_2}|r_n^{j-1}-\bar r|_\Gamma^2\\
&-\frac{\rho_2}{k_n+1}\sum_{i=0}^{j-1}(y_n^i-u_n^i,y_n^j-u_n^j)_\Gamma-\frac{\rho_1}{k_n+1}\sum_{i=0}^{j-1}(Ay_n^i-f,Ay_n^j-f)_\Omega\\
&-\left(\gamma-\frac{\rho_2}{2(k_n+1)}\right)|y_n^j-u_n^j|_\Gamma^2+\frac{1}{2c}(|\lambda_n^{j+1}-\bar\mu|_L^2-|\lambda_n^j-\bar\mu|_L^2)\\
&+\gamma\Big(u_n^j-u_n^{j-1},y_n^j-\bar y\Big)_\Gamma\le 0
\end{aligned}
$$

for $n,j=0,1,\dots,k_n$. Summing the above inequality over j and using the fact that

$$
\sum_{j=1}^{k_n}\sum_{i=0}^{j-1}(a_i,a_j)_H\le\frac{k_n}{2}\sum_{j=0}^{k_n}|a_j|^2
$$

we arrive at

$$\sum_{j=0}^{k_n}(|y_n^j-\bar y|_\Omega^2+\alpha|u_n^j-\bar u|_\Gamma^2)+\frac{k_n+1}{2\rho_1}|q_n^{k_n}-\bar q|_\Omega^2+\frac{k_n+1}{2\rho_2}|r_n^{k_n}-\bar r|_\Gamma^2$$
$$+\frac{1}{2c}|\lambda_{n+1}-\bar\mu|_L^2+\Big(\gamma-\frac{\rho_1}{2}\Big)\sum_{j=0}^{k_n}|Ay_n^j-f|_\Omega^2+\Big(\gamma-\frac{\rho_2}{2}\Big)\sum_{j=0}^{k_n}|y_n^j-u_n^j|_\Gamma^2$$
$$+\gamma\sum_{j=0}^{k_n}\Big(u_n^j-u_n^{j-1},y_n^j-\bar y\Big)_\Gamma\le\frac{k_n+1}{2\rho_1}|q_n-\bar q|_\Omega^2+\frac{k_n+1}{2\rho_2}|r_n-\bar r|_\Gamma^2+\frac{1}{2c}|\lambda_n^0-\bar\mu|_L^2.$$

The estimation of $(u_n^j-u_n^{j-1},y_n^j-\bar y)_\Gamma$ is standard (see [5]): we obtain, for $j=1,2,\dots$ and $n=0,1,\dots$

$$\gamma\Big(u_n^{j-1}-u_n^j,\bar y-y_n^j\Big)_\Gamma\ge\alpha|u_n^j-u_n^{j-1}|_\Gamma^2-\frac{\gamma}{2}(|y_n^{j-1}-u_n^{j-1}|_\Gamma^2+|u_n^{j-1}-\bar u|_\Gamma^2-|u_n^j-\bar u|_\Gamma^2).$$

A similar calculus provides the estimation of $(u_n^o-u_n^{-1},y_n^o-\bar y)_\Gamma$ for $n=1,2,\dots$:

$$\begin{aligned}\gamma\Big(u_n^{-1}-u_n^o,\bar y-y_n^o\Big)_\Gamma\ge\quad&\Big(\alpha+\frac{\rho_2}{2}\Big)|u_n^o-u_n^{-1}|_\Gamma^2+\frac{\rho_2-\gamma}{2}|y_{n-1}-u_n^{-1}|_\Gamma^2\\&+\frac{\gamma}{2}|u_n^o-\bar u|_\Gamma^2-\frac{\gamma}{2}|u_n^{-1}-\bar u|_\Gamma^2.\end{aligned}\tag{4.11}$$

We henceforth assume $n\ge1$. We obtain

$$\begin{aligned}\gamma\sum_{j=0}^{k_n}\Big(u_n^j-u_n^{j-1},y_n^j-\bar y\Big)_\Gamma\ge\Big(\alpha+\frac{\rho_2}{2}\Big)|u_n^o-u_{n-1}|_\Gamma^2+\frac{\rho_2-\gamma}{2}|y_{n-1}-u_{n-1}|_\Gamma^2\\+\frac{\gamma}{2}|u_n^o-\bar u|_\Gamma^2-\frac{\gamma}{2}|u_{n-1}-\bar u|_\Gamma^2+\alpha\sum_{j=1}^{k_n}|u_n^j-u_n^{j-1}|_\Gamma^2\\-\frac{\gamma}{2}\sum_{j=1}^{k_n}(|y_n^{j-1}-u_n^{j-1}|_\Gamma^2+|u_n^{j-1}-\bar u|_\Gamma^2-|u_n^j-\bar u|_\Gamma^2).\end{aligned}\tag{4.12}$$

We finally get for $k_n\ge1$

$$\sum_{j=0}^{k_n}(|y_n^j-\bar y|_\Omega^2+\alpha|u_n^j-\bar u|_\Gamma^2)+\frac{k_n+1}{2\rho_1}|q_{n+1}-\bar q|_\Omega^2+\frac{k_n+1}{2\rho_2}|r_{n+1}-\bar r|_\Gamma^2$$
$$+\frac{1}{2c}|\lambda_{n+1}-\bar\mu|_L^2+\Big(\gamma-\frac{\rho_1}{2}\Big)\sum_{j=0}^{k_n}|Ay_n^j-f|_\Omega^2+\frac{\gamma-\rho_2}{2}\sum_{j=0}^{k_n}|y_n^j-u_n^j|_\Gamma^2$$
$$+\frac{\gamma}{2}|u_n-\bar u|_\Gamma^2\le\frac{k_n+1}{2\rho_1}|q_n-\bar q|_\Omega^2+\frac{k_n+1}{2\rho_2}|r_n-\bar r|_\Gamma^2$$
$$+\frac{1}{2c}|\lambda_n-\bar\mu|_L^2+\frac{\gamma-\rho_2}{2}|y_{n-1}-u_{n-1}|_\Omega^2+\frac{\gamma}{2}|u_{n-1}-\bar u|_\Gamma^2.$$

Since $\rho_2\le\gamma$, we deduce that

$$|y_n-\bar y|^2_\Omega+\alpha|u_n-\bar u|^2_\Gamma+\frac{k_n+1}{2\rho_1}|q_{n+1}-\bar q|^2_\Omega+\frac{k_n+1}{2\rho_2}|r_{n+1}-\bar r|^2_\Gamma$$
$$+\left(\gamma-\frac{\rho_1}{2}\right)|Ay_n-f|^2_\Omega+\left(\gamma-\frac{\rho_2}{2}\right)|y_n-u_n|^2_\Gamma+\frac{1}{2c}|\lambda_{n+1}-\bar\mu|^2_\Omega+\frac{\gamma}{2}|u_n-\bar u|^2_\Gamma$$
$$\le\frac{k_n+1}{2\rho_1}|q_n-\bar q|^2_\Omega+\frac{k_n+1}{2\rho_2}|r_n-\bar r|^2_\Gamma+\frac{1}{2c}|\lambda_n-\bar\mu|^2_\Omega$$
$$+\frac{\gamma-\rho_2}{2}|y_{n-1}-u_{n-1}|^2_\Gamma+\frac{\gamma}{2}|u_{n-1}-\bar u|^2_\Gamma$$

if $k_n\ge 1$. Using (4.11) the same estimate follows for $k_n=0$. The final claim again follows with a telescoping argument. ∎

5. Numerical experiments.

5.1. Implementation. Numerical experiments were carried out for one- and two-dimensional problems. Since Algorithm $\mathcal{A}^{GS}$ is the simplest for implementation, we have used it for our tests. The discretization of the problem was done with finite-differences discretization schemes. The size of the grid was $\frac{1}{N}$ so that $L=\mathbb{R}^{N+1}$ for the one-dimensional case and $L=\mathbb{R}^{2(N+1)}$ for the two-dimensional case. Λ was chosen as the discretization operator with respect to the given equidistant grid.

The main difficulty that remains in applying Algorithm $\mathcal{A}^{GS}$ is given by the (unconstrained) minimization with respect to y. This was done via the adjoint state equation and results, for fixed u, q, and r, in the resolution of

$$\begin{aligned} A^*p &= y-z_d+c\left[y+\frac{\lambda}{c}-P_K\left(y+\frac{\lambda}{c}\right)\right] \quad \text{in } \Omega,\ p=0 \quad \text{on } \Gamma,\\ Ay &= f-\frac{q+p}{\gamma} \quad \text{in } \Omega,\ y=u-\frac{r}{\gamma}+\frac{1}{\gamma}\frac{\partial p}{\partial\nu_{A^*}} \quad \text{on } \Gamma, \end{aligned} \tag{5.1}$$

for p and y. Here

$$\frac{\partial p}{\partial\nu_{A^*}}$$

denotes the conormal derivative of p with respect of A^* (which is the adjoint operator of A). The coupled system (5.1) was solved via a descent algorithm combined with a relaxation method. The control function was computed using the L^∞-projection of $\frac{r+\alpha u_d+\gamma y}{\alpha+\gamma}$ on U_{ad}.

All numerical tests were carried out on a Hewlett-Packard workstation using the MATLAB package. For all examples that we report here, the required accuracy and stopping criteria were set to 10^{-6}.

5.2. Examples.

One-dimensional example. In this example we chose

- $\Omega=]0,1[$ and $N=30$; $A=-\Delta$ and $f(x)=-(x+2)\exp(x)$.
- $z_d\equiv -1,\ \alpha=0.1,\ u_d(0)=-2,\ u_d(1)=1$; $U_{ad}=[-3,3]$ and $K=\{\ Y\in L\ :\ -1.1\le Y\le 1\ \}$.

Note that z_d is quite close to the boundary of K.

In fact, as can be seen from Figure 1, the lower bound on the state is active. The active set is a singleton. In view of the fact that the influence of the boundary

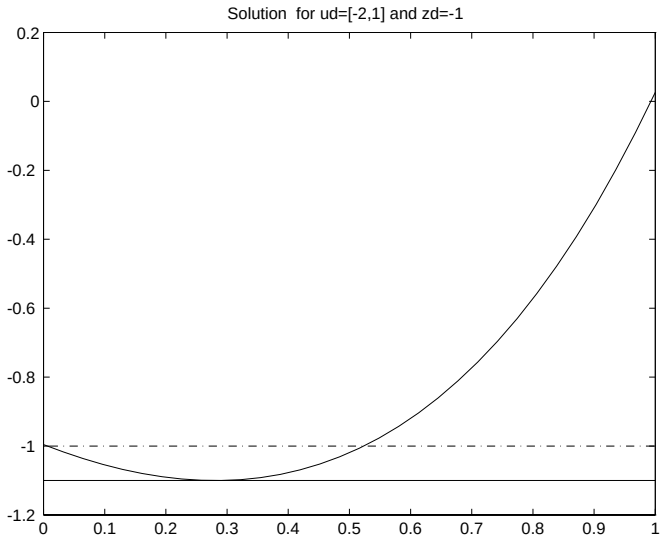

FIG. 1.

TABLE 1

c	γ	k_n (constant)	$\|\Delta y + f\|_\infty$	$\|y - v\|_\infty$	n	CPU units	min$[y-(-1.1)]$
10	1	10	4.8 e-07	4. e-07	58	1	4. e-10
10	1	1	9.3 e-07	6. e-07	154	2.17	2.5 e-06
10	1	100	2.2 e-07	5. e-07	13	1.35	-2 e-09
100	10	10	6.2 e-07	9. e-07	95	1.01	-1.3 e-11

control at $x = 0$ and $x = 1$ is restricted to the superposition of straight lines to the uncontrolled state, this is not surprising.

The numerical values for J and the control at the minimum are

$$J = 1.5862 \;\; 10^{-1} \text{ and } \bar{u}(0) = -9.9573 \;\; 10^{-1}, \quad \bar{u}(1) = 2.6314 \;\; 10^{-2}.$$

One of the main questions concerning the class of algorithms that we analyzed is the choice of the parameters ρ_i, c, and γ. From Table 1 we conclude that while the choice of the parameters certainly has an influence on the convergence properties of the algorithm, there is a wide range of parameters values for which convergence is achieved numerically, for this and other examples that we tested. In all calculations we chose $\rho_i = 1$. Some tests shows that the ratio $\frac{\gamma}{c} = \frac{1}{10}$ is a good one. For $(c, \gamma) = (1, 1)$, $(c, \gamma) = (100, 50)$, $(c, \gamma) = (1, 0.5)$ (all with $k_n = 10$ for all n), convergence is achieved, but it is slower than for those pairs that are presented in Table 1. From that table, as well as from other tests, it can also be seen that the auxiliary problem should be solved sufficiently accurately, before the Lagrange multipliers (q, r) for the state equation and the boundary condition are updated (see $k_n \equiv 1$). The values $(c, \gamma) = (10, 0.1)$ still with $\rho_i = 1$ led to divergence. This is not unexpected in view of the result of Theorem 4.3, which requires $\rho_2 \leq \gamma$.

Two-dimensional example. Now we consider

- $\Omega =]0, 1[\times]0, 1[$ and $N = 30$; $A = -\Delta$ and $f \equiv 20$.

- $z_d(x_1, x_2) = 5[x_1(x_1 - 1) * x_2(x_2 - 1)] + 3,\ u_d \equiv 0$, and $\alpha = 0.01$.
- $U_{ad} = [-10, 10]$ and $K = \{\ y \in L \mid 0 \le y \le 3.5\}$.

The results for selected values during the iteration procedure are shown in Table 2. The effect of the discretization is given in Table 3: the CPU time is approximately a linear function of N^2. The optimal state and control (on one side of the domain) are given in Figures 2 and 3, respectively.

In this case the upper bound $y \le 3.5$ is active, while the lower bound $y \ge 0$ is not, except in some corners of the domain. We must admit, however, that the numerical values of y may not be accurate in the corners since no special treatment of the discontinuities of the conormals at the corners was incorporated in the code. The results were obtained with $c = 10,\ \gamma = 1$, and $k_n = 10$ for all n.

6. Conclusion. The augmented Lagrangian algorithms with splitting into state and control variables can effectively be used to solve state and control constrained optimization problems. For the first-order methods that are presented in this paper, the auxiliary problems in the inner loop must be solved sufficiently accurately before

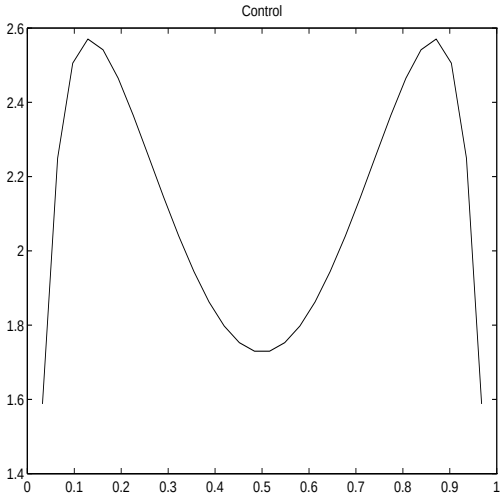

FIG. 3.

the Lagrange multipliers of the state equation and boundary condition are updated. Appropriate choices for the penalty parameters (here c and γ) and the step lengths ρ_i for the dual variables are easily determined since the algorithms are not particularly sensitive to them. It is our intention to also analyze second-order methods for the same class of problems.

DETERMINING THE ACOUSTIC IMPEDANCE IN THE 1-D WAVE EQUATION VIA AN OPTIMAL CONTROL PROBLEM*

V. BARBU† AND N. H. PAVEL‡

Abstract. This paper deals with a coefficient optimal control problem for the one-dimensional (1-D) wave equation with nonhomogeneous boundary periodic inputs. A main concept is the notion of "weak solution" for the 1-D wave equation with T-periodic conditions (Definition 2.1). For $T = (2k+1)/p$ the weak solution (hyperbolic) operator $A(u)$ (see 2.20) has important properties such as closed range $R(A(u))$, nontrival null space $N(A(u))$ (resonant case)—see Propositions 2.1 and 2.2. However, the u-dependence of $R(A(u))$ and $N(A(u))$ gives rise to major difficulties. The maximum principle (Theorem 4.1) can be viewed as information (necessary conditions) on the optimal acoustic impedance function u^* (the impedance for which the corresponding seismic waves have a minimal effect given as a cost functional).

Key words. acoustic impedance, one-dimensional wave equation, periodic solutions, optimal control, singular control systems, resonant case, trace theorems, eigenvalues and eigenfunctions, Fourier series

1. Introduction.

The propagation of seismic waves in a medium in the presence of a periodic seismic sourse g is described by the following wave equation:

$$u(x)y_{tt}(x,t) - (u(x)y_x(x,t))_x = 0, \quad x \in (0,1), t \in \mathbb{R}, \tag{1.1}$$

$$-u(0)y_x(0,t) = g, \quad y(1,t) = 0, \quad t \in \mathbb{R}, \tag{1.2}$$

with the T-periodic condition ($T > 0$)

$$y(x,t+T) = y(x,t), \quad y_t(x,t+T) = y_t(x,t) \quad \forall x \in [0,1], \forall t \in \mathbb{R}. \tag{1.3}$$

Here $u = (\rho\mu)^{1/2}$ is the acoustic impedance function (ρ is the density, μ is the elasticity modulus), $y(x,t)$ is the displacement at level x underground at time t, and g is a T-periodic seismic sourse at the surface $x = 0$. Throughout in this paper we assume that $u \in U$ with

$$U = \{u \in H^2(0,1); 0 < a \le u(x) < \infty; u(0) = u_0\} \tag{1.4}$$

as the set of all admissible impedances. The inverse problem in seismic consists in recovering the impedance distribution u from the observations of the displacements $y_0 = y_0(t)$ at the surface $x = 0$. The least square approach to this inverse problem leads to the following optimal control problem:

$$\begin{aligned} &\text{minimize } \int_0^T (y(0,t) - y_0(t))^2 dt + \gamma \int_0^1 ((u''(x))^2 + u^2(x))\, dx \\ &\text{subject to (1.1)–(1.3) and } u \in U, \text{ where } \gamma > 0. \end{aligned} \tag{1.5}$$

‡Department of Mathematics, Ohio University, Athens, OH 45701 (npavel1@ohio.edu).

Due to the resonance phenomenon in (1.1)–(1.3), the solution to this problem is not unique and does not exist for all g, so (1.5) may be viewed as a singular control problem. Moreover, the dependence of the range and null space of the hyperbolic operator (1.1) on the control variable u represents a major difficulty in the study of (1.5). For this reason section 2 is entirely devoted to existence and continuous dependence of the weak solution of (1.1)–(1.3) on u. The main result is that if

$$T \in \{(2k+1)/p; k = 0, 1, \dots ; p = 1, 2, \dots\} = Q_0, \tag{1.6}$$

which is dense in Q^+ (the set of all positive rational numbers), then for (f, g) in a closed space $S(u)$ (see (2.18)) of $L^2((0,1)\times(0,T))\times L^2(0,T)$, the problem (1.1)–(1.3) (with f in the right-hand side of (1.1)) has modulo $N(u)$ (the null space of (1.1)) a unique weak solution which is continuous as a function of u. In this context, the analysis of the weak solution is related to the literature devoted to periodic solutions for 1-D hyperbolic problems (see, e.g., [6], [7]). See also [1], [3]. In sections 3 and 4, one gives existence and a maximum principle for the optimal control u^*. For equations (1.1)–(1.2) with Cauchy initial values, a related problem was previously studied by G. Chavent and coworkers (see [2], [8], and [9]). For a parabolic equation, a similar problem was recently studied by the authors in [4].

However, there is no any overlap between this paper and the previous papers mentioned above. In addition, the methods used here are completely different.

The "cost functional" in (1.5) can be viewed as "the effect" of seismic waves $y(x,t)$ corresponding to the impedance function $u(x)$ (which is determined by the density and the elasticity modulus at level x underground). The maximal principles (conditions (4.2) and (4.3)) give information on the optimal acoustic impedance u^*—the impedance for which the corresponding seismic waves have a minimal effect. Numerical determinations of u^* would be therefore important, although difficult. We will try it elsewhere.

2. The controlled periodic system. For the study of the optimal control problem we need results on the existence, regularity, and continuous dependence of the periodic solution y (of the problem below) on f, g, and u.

Precisely, in this section we are concerned with the problem

$$uy_{tt} - (uy_x)_x = f(x,t) \quad \text{in } Q = (0,1)\times(0,T), \tag{2.1}$$

$$-u(0)y_x(0,t) = g(t), \quad y(1,t) = 0, \quad t \in [0,T], \tag{2.2}$$

$$y(x,0) = y(x,T), \quad y_t(x,0) = y_t(x,T), \quad x \in [0,1], \tag{2.3}$$

where $f \in L^2(Q)$, $g \in L^2(0,T)$, and $u \in U$ (given as in (1.4)).

DEFINITION 2.1. *A function $y \in L^2(Q)$ is said to be a weak solution of* (2.1)–(2.3) *if*

$$\int_Q y(u\varphi_{tt} - (u\varphi_x)_x)\,dxdt - \int_0^T g(t)\varphi(0,t)\,dt = \int_Q f(x,t)\varphi(x,t)\,dxdt \tag{2.4}$$

for all T-periodic $\varphi \in H^2(Q)$ with $\varphi_x(0,t) = 0$, $\varphi(1,t) = 0$ $\forall t \in [0,T]$.

The following operation will be useful:

$$\begin{aligned} &A_0(u)\varphi = u\varphi_{tt} - (u\varphi_x)_x, \\ &D(A_0(u)) = \{\varphi \in H^2(Q); \varphi_x(0,t) = 0, \varphi(1,t) = 0, \\ &\qquad\qquad \varphi(x,0) = \varphi(x,T), t \in [0,T], x \in [0,1]\} \end{aligned} \tag{2.5}$$

for $u \in U$.

In order to characterize the set of all (f,g) for which there is a weak solution y, we shall use the following complete orthonormal system of eigenfunctions $\{\psi_m\varphi_n\}_{\substack{m\in\mathbb{Z}\\ n\in\mathbb{N}}}$ in $L^2(Q)$ with

$$\psi_m(t)=\frac{1}{\sqrt{T}}e^{i\mu_m t},\ m\in\mathbb{Z}\ \text{(the set of all integers)},\ \mu_m=\frac{2m\pi}{T} \tag{2.6}$$

[12, p. 88] and λ_n,φ_n given by the Sturm–Liouville problem

$$-\frac{1}{u}(u\varphi_n')_x=\lambda_n^2\varphi_n,\quad \varphi_n'(0)=0,\quad \varphi_n(1)=0,\quad n\in\mathbb{N},u\in U, \tag{2.6$'$}$$

where $\varphi_n'(x)=\frac{d}{dx}\varphi_n(x)$ and λ_n is increasingly convergent to $+\infty$. Clearly $\lambda_n=\lambda_n(u)$ and $\varphi_n=\varphi_n(u)$ depend on $u\in U$. The inner product in $L^2(0,1)$ is defined by

$$\langle F,G\rangle=\int_0^1 u(x)F(x)\bar{G}(x)\,dx,\quad u\in U. \tag{2.7}$$

Accordingly, the $L^2(Q)$-norm of the solution $y=y^u$ is

$$|y|_{L^2(Q)}=\int_Q u(x)|y(x,t)|^2dxdt=\int_0^T|y(\cdot,t)|^2_{L^2(0,1)}dt, \tag{2.8}$$

so $|\varphi_n|^2=\int_0^1 u(x)\varphi_n^2(x)\,dx=1$. For $u=1$, the eigenvalues λ_n are $(2n+1)\frac{\pi}{2}$, and the corresponding eigenfunctions are

$$\varphi_n(x)=\sqrt{2}\cos(2n+1)\frac{\pi}{2}x,\quad n\in\mathbb{N}.$$

For a general $u\in U$, it follows that $\lambda_n=\lambda_n^u$ have the form

$$\lambda_n=(2n+1)\frac{\pi}{2}+\frac{1}{n}\theta_n>0\quad\text{with } |\theta_n|=|\theta_n^u|\le M(u) \tag{2.9}$$

with M bounded on bounded subsets of U.

In order to prove (2.9), set $z_n(x)=\left(\frac{u(x)}{u(0)}\right)^{1/2}\varphi_n(x)$. Then z_n satisfies the Sturm–Liouville problem

$$\begin{aligned} &z_n''(x)+(\lambda_n^2+\eta_u(x))z_n(x)=0,\\ &-u'(0)z_n(0)+2u(0)z_n'(0)=0,\quad z_n(1)=0, \end{aligned} \tag{2.10}$$

with $\eta_u(x)=\frac{1}{2}\frac{u''}{u}-\frac{1}{4}(\frac{u'}{u})^2$. This implies [10, p. 262] that λ_n has the form indicated in (2.9) and

$$z_n(x)=\cos(2n+1)\frac{\pi}{2}x+\frac{1}{n}H_n(x) \tag{2.11}$$

with $|H_n(x)|+|H_n'(x)|\le M(u)$, $x\in[0,1]$, $n\in\mathbb{N}$. Therefore,

$$|\varphi_n(x)|\le M(u),\quad n\in\mathbb{N},x\in[0,1].$$

We now can easily characterize the null space $N(A_0(u))$ of A_0u. Precisely,

$$N(A_0(u))=\text{Span}\{\psi_m\varphi_n,\forall m\in\mathbb{Z},n\in\mathbb{N}\text{ with }\lambda_n=|\mu_m|\}. \tag{2.12}$$

Indeed, let $A_0(u)\varphi=0$ and let φ_{mn} be the Fourier coefficients of φ in $L^2(Q)$, i.e.,

$$\varphi=\sum_{m,n}\varphi_{mn}\psi_m\varphi_n,\quad \varphi_{mn}=\int_Q u\varphi\bar{\psi}_m\varphi_n dxdt. \tag{2.13}$$

Clearly, $A_0(u)\varphi = 0$ if and only if $(\lambda_n^2 - \mu_m^2)\varphi_{mn} = 0$.

Remark 2.1. For $T = \frac{2k+1}{p}$, $N(A_0(u))$ is finite dimensional. Indeed, $\lambda_n = |\mu_m|$ means $(2n+1)(2k+1) + \frac{2(2K+1)}{\pi n}\theta_n = 4|m|p$, which has at most a finite number of solutions (m,n) (if any). For example, if $\theta_n = 0$ for all n, then $N(A_0(u)) = 0$. If $u(x) = (Cx+C_1)^2$ with $C_1^2 = u_0$ and $C = \frac{u_1}{2\sqrt{u_0}}$, then one can prove that $N(A_0(u)) = 0$ for $T = 1/2$. Moreover, by (2.9) we see that dim $N(u)$ is bounded on bounded subsets of U. Note also that the maps $u \to \lambda_n(u)$ (and $u \to \varphi_n(u)$) are continuous from $H^2(0,1) \cap U$ into R (and $H^1(0,1)$). This follows by the fact that $\lambda_n(u)$ and $\varphi_n(u)$ are bounded on bounded sets of U and the eigenvalues λ_n of Sturm–Liouville problem (2.6′) are simple. As $A_0(u)$ is self-adjoint in $L^2(Q)$, we have

$$L^2(Q) = N(A_0(u)) \oplus \overline{R(A_0(u))}. \tag{2.14}$$

We will see below that actually $R(A_0(u))$ is closed. We are now in a position to study the existence and regularity of the weak solutions y as in Definition 2.1 via Fourier series. Denote by y_{mn} the Fourier coefficients of the component of y which is in $N(A_0(u))^\perp$ (the orthogonal of $N(A_0(u))$), i.e.,

$$y = \sum_{\lambda_n \neq |\mu_m|} y_{mn}\psi_m\varphi_n, \quad y_{mn} = \int_Q uy\bar{\psi}_m\varphi_n dxdt. \tag{2.15}$$

Similarly, the Fourier coefficients of $u^{-1}f$ in $L^2(Q)$ and of $g \in L^2(0,T)$ are

$$\tilde{f}_{mn} = (u^{-1}f)_{mn} = \int_Q f\bar{\psi}_m\varphi_n dxdt, \quad g_m = \int_0^T g(t)\bar{\psi}_m(t)\,dt \tag{2.16}$$

with $\sum_{\substack{m\in\mathbb{Z}\\ n\in\mathbb{N}}} |\tilde{f}_{mn}|^2 = \int_Q u(fu^{-1})^2 dx \le a^{-2}\int_Q uf^2 dxdt = a^{-2}|f|^2_{L^2(Q)}$; $|g|^2_{L^2(0,T)} = \sum_{m\in\mathbb{Z}} |g_m|^2$. For $\varphi = \bar{\psi}_m(t)\varphi_n(x)$, (2.4) implies

$$(\lambda_n^2 - \mu_m^2)y_{mn} = \tilde{f}_{mn} + \varphi_n(0)g_m. \tag{2.17}$$

Set (for $u \in U$)

$$\begin{aligned} S(u) = \{&(f,g); f \in L^2(Q), g \in L^2(0,T);\\ &\tilde{f}_{mn} + \varphi_n(0)g_m = 0 \text{ for all } (m,n) \text{ with } |\mu_m| = \lambda_n\},\\ S_0(u) = \{&f \in L^2(Q); \tilde{f}_{mn} = 0 \text{ for all } (m,n) \text{ with } \lambda_n = |\mu_m|\}. \end{aligned} \tag{2.18}$$

These depend on u as λ_n depend on u. In view of (2.17), a necessary condition for the existence of a weak solution y is $(f,g) \in S(u)$. We will see that this is also sufficient (Proposition 2.1 below). The following spaces are also needed:

(2.19)

$$\begin{aligned} &H^j_\pi(0,T) = \{g \in H^j(0,T); g^{(k)}(0) = g^{(k)}(T), k = 0,1,\dots,j-1\}, \quad j = 1,2,\\ &H^1_\pi(Q) = \{f \in H^1(Q); f(x,0) = f(x,T) \text{ a.e. } x \in (0,1)\},\\ &H^2_\pi(Q) = \{f \in H^2(Q); f(x,0) = f(x,T); f_t(x,0) = f_t(x,T), x \in (0,1)\}. \end{aligned}$$

Finally, for each $u \in U$ we define the operator $A(u) : D(A(u)) \to L^2(Q) \times L^2(0,T)$ by

$$A(u)y = (f,g), \tag{2.20}$$

where y is a weak solution corresponding to f and g in the sense of Definition 2.1. The main result of this section is given by the following proposition.

PROPOSITION 2.1. *Assume that $T = (2k+1)/p$ as in (1.6). Then for each $u \in U$, $A(u)$ is a closed operator with a closed range $R(A(u)) = S(u)$ (as in (2.18)). Moreover, $A^{-1}(u)$ is continuous and one to one from $S(u)$ onto $S_0(u) = N(A(u))^{\perp}$. The following estimates hold for $y = A^{-1}(u)(f,g)$, with $(f,g) \in R(A(u))$:*

$$|A^{-1}(u)(f,g)|_{L^2(Q)} \le C(|f|_{L^2(Q)} + |g|_{L^2(0,T)}), \tag{2.21}$$

$$|A^{-1}(u)(f,g)|_{H^1(Q)} \le C(|f|_{L^2(Q)} + |g|_{H^1(0,T)}). \tag{2.22}$$

If $f \in H^1_\pi(Q)$ and $g \in H^2_\pi(0,T)$, then $y \in H^2(Q)$, $t \to y(0,t) \in H^1(0,T)$, and

$$|A^{-1}(u)(f,g)|_{H^2(Q)} \le C(|f|_{H^1(Q)} + |g|_{H^2(0,T)}). \tag{2.22$'$}$$

Remark 2.2. Here in (2.21)–(2.22$'$), as well as throughout this paper, $C = C(u)$ (with $u \in U$) denotes several positive constants which are bounded on bounded subsets of U.

Proof of Proposition 2.1. Let $(f,g) \in R(A(u))$. In view of (2.17), the Fourier coefficients of $y = A^{-1}(u)(f,g) = \sum y_{mn}\psi_m\varphi_n$ are given by

$$y_{mn} = \frac{\tilde{f}_{mn} + \varphi_n(0)g_m}{\lambda_n^2 - \mu_m^2} \quad \text{for } \lambda_n \ne |\mu_m|. \tag{2.23}$$

A key part of the proof is the estimate

$$\inf_{\lambda_n \ne |\mu_m|} |\lambda_n - |\mu_m|| \ge C > 0. \tag{2.24}$$

Indeed, according to (2.6) and (2.9)

$$|\lambda_n - |\mu_m|| = \frac{\pi}{2T}(|4|m| - (2n+1)T - \theta_n^1|)$$

with $\theta_n^1 \to 0$ as $n \to \infty$. As $T = \frac{2k+1}{p}$, for some $p \in \mathbb{N}$ and $k = 0, 1, \dots$, we have

$$|\lambda_n - |\mu_m|| = b|4|m|p - (2n+1)(2k+1) - \theta_n^2|, \tag{2.25}$$

with $\theta_n^2 \to 0$ as $n \to \infty$, $b = \frac{\pi}{2(2k+1)}$, which yields (2.24). We also have

$$\lambda_n + |\mu_m| \ge C(n + |m|) \quad \text{for some } C > 0, \tag{2.26}$$

which follows from

$$\lambda + |\mu_m| = b(8p|m| + (2n+1)(2k+1) + \theta_n^2) \tag{2.27}$$

with $2k+1+\theta_n^2 > 0$ for sufficiently large n and $(2n+1)(2k+1)+\theta_n^2 = (2k+1)\frac{\pi}{2}\lambda_n > 0$ for all $n \in \mathbb{N}$. According to Parseval's formula, $|y|^2_{L^2(Q)} = \sum_{m,n} y^2_{mn}$, so (2.23) yields

$$|y|^2_{L^2(Q)} \le C \sum_{\lambda_n \ne |\mu_m|} \frac{|\tilde{f}_{mn}|^2 + |g_m|^2}{m^2 + n^2} \le C(|f|^2_{L^2(Q)} + |g|^2_{L^2(0,T)}), \tag{2.28}$$

which is just (2.21). If $g \in H^1_\pi(0,T)$, then the Fourier coefficient $\tilde{g}_m$ of g' is

$$\tilde{g}_m = \int_0^T g'(t)\bar{\psi}_m(t)\,dt = i\mu_m g_m, \tag{2.29}$$

so $|g'|^2_{L^2(0,T)} = \sum_m \mu_m^2 g_m^2 = \sum_m \tilde{g}_m^2$. Therefore

$$
\begin{aligned}
|y_t|^2_{L^2(Q)} &= \sum_{\lambda_n \neq |\mu_m|} \mu_m^2 y_{mn}^2 \\
&\leq C\left(\sum_{m,n} \frac{\mu_m^2 |\tilde{f}_{mn}|^2}{m^2+n^2} + \sum_{m,n} \frac{|\tilde{g}_m|^2}{m^2+n^2}\right) \leq C(|f|^2_{L^2(Q)} + |g'|^2_{L^2(0,T)}).
\end{aligned} \tag{2.30}
$$

In order to estimate y_x we need to recall that $|\varphi_n|^2_{L^2(0,1)} = \int_0^1 u(x)\varphi_n^2(x)\,dx = 1$ and that the distributional derivative y_x is given by

$$
y_x = \sum_{\lambda_n \neq |\mu_m|} y_{mn} \psi_m \varphi_n'. \tag{2.31}
$$

The system $\{\varphi_n'\}$ is orthogonal in $L^2(0,1)$ and

$$
|\varphi_n'|_{L^2(0,1)} = \int_0^1 u(x)(\varphi_n')^2 dx = -\int_0^1 \varphi_n (u(x)\varphi_n')_x dx = \lambda_n^2. \tag{2.31$'$}
$$

Therefore, we have

$$
\begin{aligned}
|y_x|^2_{L^2(Q)} &= \sum_{\lambda_n \neq \mu_m} \lambda_n^2 |y_{mn}|^2 \\
&\leq C \sum_{\lambda_n \neq \mu_m} \frac{\lambda_n^2 |\tilde{f}_{mn}|^2}{\lambda_n^2 + \mu_m^2} + C \sum_{\lambda_n \neq \mu_m} \frac{\lambda_n^2 |g_m|^2}{(\lambda_n - |\mu_m|)^2(\lambda_n + |\mu_m|)^2} \\
&= C(I_1 + I_2).
\end{aligned} \tag{2.32}
$$

Clearly, $I_1 \leq |f|^2_{L^2(Q)}$. Let us estimate I_2. First, for $m \neq 0$, we have $|g_m|^2 = \frac{|\tilde{g}_m|^2}{\mu_m^2}$ (by (2.29)), so

$$
I_2 = C \sum_{\substack{\lambda_n \neq \mu_m \\ m \neq 0}} \frac{\lambda_n^2}{\mu_m^2} \frac{|\tilde{g}_m|^2}{(\lambda_n + |\mu_m|)^2(\lambda_n - |\mu_m|)^2} + C \sum_n \frac{|g_0|^2}{\lambda_n^2} = C(I_3 + I_4). \tag{2.33}
$$

Since $|g_0|^2 \leq |g|^2_{L^2(0,T)}$, we have $I_4 \leq C|g|^2_{L^2(0,T)}$. Finally, for I_3 we must proceed as follows:

$$
\begin{aligned}
I_3 = &\sum_{\substack{|\lambda_n - |\mu_m|| < \varepsilon\lambda_n \\ \lambda_n \neq |\mu_m|}} \frac{\lambda_n^2 |\tilde{g}_m|^2}{\mu_m^2(\lambda_n + |\mu_m|)^2(\lambda_n - |\mu_m|)^2} \\
&+ \sum_{|\lambda_n - |\mu_m|| \geq \varepsilon\lambda_n} \frac{\lambda_n^2 |\tilde{g}_m|^2}{\mu_m^2(\lambda_n + |\mu_m|)(\lambda_n - |\mu_m|)^2} = I_5 + I_6
\end{aligned}
$$

with $0 < \varepsilon < 1$. Clearly $|\lambda_n - |\mu_m|| < \varepsilon\lambda_n$ yields $|1 - \frac{|\mu_m|}{\lambda_n}| < \varepsilon$, so $\frac{|\mu_m|}{\lambda_n} > 1 - \varepsilon$, i.e., $\frac{\lambda_n}{|\mu_m|} < \frac{1}{1-\varepsilon}$. Therefore

$$
I_5 \leq (1-\varepsilon)^{-2} C \sum_{m,n} \frac{|\tilde{g}_m|^2}{m^2+n^2} \leq C|g'|^2_{L^2(0,T)}.
$$

For I_6 a similar estimate holds. Indeed, $|\lambda_n - |\mu_m|| \geq \varepsilon\lambda_n$ yields

$$I_6 \leq \varepsilon^{-2} \sum_{\substack{m\neq 0\\ n\in\mathbb{N}}} \frac{|\tilde{g}_m|^2}{\mu_m^2(m^2+n^2)} \leq C|g'|_{L^2(0,T)},$$

so we conclude that

$$|y_x|^2 \leq C(|f|^2_{L^2(Q)} + |g|^2_{H^1(Q)}), \tag{2.34}$$

and therefore $y \in H^1(Q)$. It is easy to see that $y(x,0) = y(x,T)$ a.e. $x \in (0,1)$, i.e., $y \in H^1_\pi(Q)$. If $f \in H^1_\pi(Q)$ and $g \in H^2_\pi(0,T)$, then

$$\begin{aligned} |y_{tt}|^2_{L^2(Q)} &= \sum_{\lambda\neq|\mu_m|} \mu_m^4 |y_{mn}|^2 \\ &\leq C \sum_{\lambda\neq|\mu_m|} \left(\frac{\mu_m^2(\mu_m^2|\tilde{f}_{mn}|^2)6}{\lambda_n^2+\mu_m^2} + \frac{\mu_m^4|g_m|^2}{\lambda_n^2+\mu_m^2} \right) \\ &\leq C(|f_t|_{L^2(Q)} + |g''|^2_{L^2(0,T)}), \end{aligned} \tag{2.35}$$

where $|g''|^2_{L^2(0,T)} = \sum_m \mu_m^4 |g_m|^2$. To estimate the distributional derivative y_{tx} one repeats the above procedure, namely,

$$\begin{aligned} |y_{tx}|^2_{L^2(Q)} &= \sum_{\lambda_n\neq\mu_m} \lambda_n^2\mu_m^2 |y_{mn}|^2 \\ &\leq C \sum_{\lambda_n\neq\mu_m} \frac{\lambda_n^2(\mu_m^2|\tilde{f}_{mn}|^2)}{\lambda_n^2+\mu_m^2} + C \sum_{\lambda_n\neq\mu_m} \frac{\lambda_n^2(\mu_m^4|g_m|^2)}{\mu_m^2(\lambda_n^2+\mu_m^2)(\lambda_n-|\mu_m|)^2} \\ &\leq C(|f_t|^2_{L^2(Q)} + |g''|^2_{L^2(0,T)}). \end{aligned} \tag{2.36}$$

Therefore y_{tt} and y_{tx} belong to $H^2(Q)$. Finally, as $(uy_x)_x = uy_{tt} + f$ in $D'(Q)$ and $y_x, y_{tt} \in L^2(Q)$, it follows that $y \in H^2(Q)$. Clearly, the estimate (2.21) implies that the range $R(A(u))$ of $A(u)$ is closed in $L^2(Q)\times L^2(0,T)$. Definition 2.1 implies directly that $A(u)$ is closed for every $u \in U$. Moreover, $D(A(u))$ is dense in $L^2(Q)$. This is because $D(A(u))$ contains $\{\varphi \in H^2(Q); \varphi_x(0,t) = \varphi(1,t) = 0\}$. Since $R(A)$ is closed we have $L^2(Q) \times L^2(0,T) = R(A(u)) \oplus N(A^*(u))$; $R(A(u)) = (N(A^*(u)))^\perp$ (i.e., $R(A(u))$ is orthogonal on $N(A^*(u))$, where $A^* : L^2(Q) \times L^2(0,T) \to L^2(Q)$ is the adjoint of A. We also have $L^2(Q) = R(A^*(u)) \oplus N(A(u))$, with $N(A(u)) = N(A_0(u))$ and $(N(A_0(u)))^\perp = S_0(u)$, $u \in U$. Since $R(A(u)) = S(u)$ we conclude that

$$A^{-1}(u) \in L(S(u), S_0(u)) \quad \forall u \in U.$$

This completes the proof.

In particular it follows from (2.22), (2.22′), and trace theorems that

$$|y(0,\cdot)|_{L^2(0,T)} \leq C(u)(|f|_{L^2(Q)} + |g|_{H^1(0,T)}), \tag{2.37}$$

$$|y(0,\cdot)|_{H^1(0,T)} \leq C(u)(|f|_{H^1(Q)} + |g|_{H^2(0,T)}) \tag{2.38}$$

for $y \in A^{-1}(f,g)$ with $(f,g) \in R(A(u))$. Note also that since $\dim N(A(u)) < \infty$ it follows from Proposition 2.1 that if $g \in H^1(0,T)$, each weak solution $y \in L^2(Q)$ to (2.4) is in $H^1(Q)$, i.e.,

$$A(u)y = (f,g), (f,g) \in R(A(u)) \text{ with } g \in H^1(Q) \implies y \in H^1(Q), \tag{2.39}$$

$$|y|_{H^3(Q)} \leq C(u)|g|_{H^3(0,1)}. \tag{2.39′}$$

Proposition 2.2 below gives additional information on the dependence of $A^{-1}(u)(f,g)$ on bounded subsets B_r of U, where

$$B_r = \{u \in H^2(0,1) \cap U; |u|_{H^2(0,1)} \le r\}. \tag{2.40}$$

Moreover, if $g \in H^3_\pi(0,T)$ and $f = 0$, a simple inspection of (2.35) and (2.36) shows that y_{ttt} and y_{ttx} are in $L^2(Q)$, which implies (by (2.1)) that y_{txx} and y_{xxx} are also in $L^2(Q)$ and therefore $y \in H^3(Q)$. We also get the following proposition.

PROPOSITION 2.2. *Let $u \in B_r$. Then there are two orthogonal subspaces $S_1(u)$ and $S_2(u)$ of $S_0(u)$ such that*

(1) *$S_0(u) = S_1(u) \oplus S_2(u)$; $\dim S_1(u) < +\infty$.*

(2) *For any $u \in B_r$ and $(f,g) \in R(A(u))$, $y(u) = A^{-1}(u)(f,g) = y_1^u + y_2^u$, $y_1 \in S_1(u)$; $y_2 \in S_2(u)$ and y_2 satisfies the estimates (2.21), (2.22), and (2.22′) with a constant C independent of $u \in B_r$.*

Proof. Denote $k_{mn} = 4|m|p-(2n+1)(2k+1)$. By (2.25) we have (with $\theta_n(u) = \theta_n^2$ and $\lambda_n \ne |\mu_m|$)

$$|\lambda_n - |\mu_m|| = b|k_{mn} - \theta_n(u)|, \quad b = \frac{\pi}{2(2k+1)}, \quad \theta_n \to 0 \text{ as } n \to \infty. \tag{2.41}$$

There is $d > 0$ such that

$$|\theta_n(u)| \le d \quad \forall u \in B_r.$$

Set

$$\begin{aligned} &Z_1 = \{(m,n); m \in \mathbb{Z}, n \in \mathbb{N}, |k_{mn}| \ge d+1\}, \\ &Z_2 = \{(m,n); |k_{mn}| < d+1\} \quad (\text{so } Z_1 \cap Z_2 = \emptyset). \end{aligned} \tag{2.42}$$

Let N_0 be a positive integer such that

$$|\theta_n(u)| \le \frac{1}{2} \quad \forall u \in B_r \text{ and } n \ge N_0. \tag{2.42′}$$

Set

$$Z_1' = \{(m,n) \in Z_2, n < N_0\}; \quad Z_2'' = \{(m,n) \in Z_2; n \ge N_0\}. \tag{2.43}$$

Obviously

$$\begin{aligned} &Z_2 = Z_2' \cup Z_2'', \quad Z_2' \cap Z_2'' = \emptyset, \\ &|\lambda_n - |\mu_m|| \ge b \quad \forall (m,n) \in Z_1, \\ &|\lambda_n - |\mu_m|| \ge \frac{b}{2} \quad \forall m \in \mathbb{Z}, \forall n \ge N_0 \text{ (as } |k_{mn}| \ge 1). \end{aligned} \tag{2.44}$$

Therefore, with $\lambda_n = \lambda_n(u)$ we have

$$|\lambda_n - |\mu_m|| \ge \frac{b}{2} \quad \forall (m,n) \in Z_1 \cup Z_2'', \forall u \in B_r, \tag{2.45}$$

and the set Z_2' is finite. We now have

$$\begin{aligned} &S_1(u) = \text{Span}\{\varphi_n e^{i\mu_m t}; (m,n) \in Z_2'\}, \quad \dim S_1(u) < +\infty, \\ &S_2(u) = \text{Span}\{\varphi_n e^{i\mu_m t}; (m,n) \in Z_1 \cup Z_2''\}. \end{aligned} \tag{2.46}$$

In view of (2.23), (2.45), and (2.46) it follows that

$$y(u) = \sum_{m,n\in Z_2'} y_{mn}\varphi_n\psi_m + \sum_{(m,n)\in Z_1\cup Z_2''} y_{mn}\varphi_n\psi_m \qquad (\psi_m = e^{i\mu_m t})$$
$$= y^1(u) + y^2(u), \quad y^1(u)\in S_1(u), \quad y^2(u)\in S_2(u),$$

and (as $|\varphi_n(0)\le C\ \forall u\in B_r$)

$$|y^2(u)|^2_{L^2(Q)} \le C_r \sum_{(m,n)\in Z_1\cup Z_2''} \frac{|\tilde f_{mn}|^2 + |g_m|^2}{m^2+n^2} \le C_r(|f|^2_{L^2(Q)} + |g|^2_{L^2(0,T)}) \tag{2.47}$$

with C_r independent of $u\in B_r$. The proof is complete.

Remark 2.3. If $y = A^{-1}(f,g)$ is in $H^1_\pi(Q)$, then it is readily seen that $y(1,t)=0$ a.e. $t\in(0,T)$ and (2.4) reduces to

$$\int_Q u(y_t\varphi_t - y_x\varphi_x)\,dx\,dt + \int_0^T g(t)\varphi(0,t)\,dt + \int_Q f\varphi\,dx\,dt = 0\ \forall\varphi\in V, \tag{2.48}$$

where $V = \{\varphi\in H^1_\pi(Q);\varphi(1,t)=0 \text{ a.e. } t\in(0,T)\}$.

3. The existence of optimal controllers. We are now in a position to define precisely the problem (1.5), namely,

$$\text{(P)}\quad \text{minimize}\left\{\int_0^T |y(0,t)-y_0(t)|^2dt + \gamma\int_0^1((u''(x))^2+u^2(x))dx;\right.$$
$$\left. A(u)y = (0,g), \quad u\in U\right\}, \tag{3.1}$$

where $\gamma>0, g\in H^1_\pi(0,T), y_0\in L^2(0,T), T=\frac{2k+1}{p}\in Q_0$ (as in (1.6)), and $A(u)$ as in Proposition 2.1. The control function $u\in U$ is said to be admissible if $(0,g)\in R(A(u)) = S(u)$, defined by (2.18) (Proposition 2.1), i.e., if $g_m=0$ for all (m,n) for which $|\mu_m|=\lambda_n$. Equivalently, u is admissible if the problem (1.1)–(1.3) has a weak solution (in the sense of Definition 2.1). An example of admissible control is $u(x)\equiv a$. Indeed, in this case the eigenvalues λ_n given by (2.6′) are $\lambda_n = (2n+1)\frac{\pi}{2}$, i.e., $\theta_n=0$ for all $n=1,2,\dots$, and according to Remark 2.1 and (2.18), the null space $N(A_0(u))=0$ so $R(A(u)) = L^2(Q)\times L^2(0,T)$ for $u=a$ and therefore $(0,g)\in R(A(a))$.

THEOREM 3.1. *The problem* (3.1) *has at least one solution* $(y^*,u^*)\in H^1_\pi(Q)\times U$. *If* $g\in H^2_\pi(0,T)$, *then* $y^*\in H^2_\pi(Q)$.

Proof. Let $(y_k,u_k)\in H^1_\pi(Q)\times U$ be a minimizing sequence, i.e.,

$$d \le \int_0^T |y_k(0,t)-y_0(t)|^2dt + \gamma|u_k''|^2_{L^2(0,1)} + \gamma|u|^2_{L^2(0,1)} \le d + \frac{1}{k}, \quad k\in\mathbb{N}, \tag{3.2}$$

where $d=$ infimum of problem (3.1) and $A(u_k)y_k = (0,g)$. Relabeling if necessary, we may assume that $u_k\to u^*$ and $u_k'\to u^{*\prime}$ in $C[0,1]$ as $k\to\infty$. We need to show that one can pass to limit for $k\to+\infty$ in (3.2) and

$$\int_Q u_k(y_{kt}\varphi_t - y_{kx}\varphi_x)dxdt = -\int_0^T g(t)\varphi(0,t)dt \quad \forall v\in V \tag{3.3}$$

with V defined as in (2.48), where $y_{kt} = (y_k)_t$, $y_{kx} = (y_k)_x$ ((3.3) is the meaning of $A(u_k)y_k = (0, g)$ as mentioned in (2.48)). On the basis of Propositions 2.1 and 2.2, y_k can be uniquely written as

$$y_k = y_k^1 + y_k^2 + y_k^3, \quad y_k^1 \in S_1(u_k), y_k^2 \in S_2(u_k), y_k^3 \in N(A(u_k)). \tag{3.4}$$

This is because, by (3.2) $u_k \in B_r$ for some suitable r. We know only that the trace $t \to y_k(0,t)$ is bounded in $L^2(0,T)$ (by (3.2)) and that $y_k = A^{-1}(u_k)(0,g)$, which yields

$$|y_k^2|_{H^1(Q)} \le C \quad \text{for all } k = 1, 2, \dots . \tag{3.5}$$

It follows that $t \to y_k^j(0,t), j = 1,2,3$, are bounded in $L^2(0,T)$, which will imply the boundedness of y_k^1 and y_k^3 in $H^2(Q)$ (as dim $S_1(u) \le N_1$ and dim $N(A(u_k)) \le N_2$ for all k, with N_1 and N_2 independent of k). Indeed,

$$N(A(u)) = \text{Span}\{\varphi_n \psi_m; (m,n) \text{ with } \lambda_n = |\mu_m|\} \tag{3.6}$$

(by (2.6) and (2.17)), and consequently

$$y_k^3(0,t) = \sum_{\substack{m,n \\ \lambda_n = |\mu_m|}} a_{mn}^k \varphi_n^k(0) e^{i\mu_m t}, \tag{3.7}$$

where $\lambda_n = \lambda_n^k$ and φ_n^k are the eigenvalues and eigenfunctions corresponding to $u = u_k$. A key remark is that for each n, $\varphi_n^k(0) \to \varphi_n^*(0)$ for $k \to +\infty$, where λ_n^* and φ_n^* are the eigenvalues and eigenfunctions corresponding to $u = u^*$. Therefore $\varphi_n^*(0) \ne 0$ (as $\varphi_n^*(0) = 0$ jointly $\varphi_n^{*\prime}(0) = 0$ would imply $\varphi_n^*(x) \equiv 0$ on $[0,1]$) since φ_n^* is an eigenfunction:

$$-(u^* \varphi_{nx}^*)_x = -\lambda_n^* u^* \varphi_n^*, \quad \varphi_n^{*\prime}(0) = \varphi_n^*(1) = 0.$$

By (3.7) with $y_k^3(0,t)$ in $L^2(0,T)$ and it follows that $|a_{mn}^k \varphi_n^k(0)| \le C$ for all k and (m,n) with $\lambda_n = |\mu_m|$. As there are only a finite number (independent of k) of such pairs (m,n), and $|\varphi_n^k(0)| \ge C_1 > 0$ for all k and a finite number of n, it follows that $|a_{mn}^k| \le C_2$ for all $k \in \mathbb{N}$ and (m,n) with $\lambda_n = |\mu_m|$. The conclusion is that y_k^3 is bounded in $H^2(Q)$. Similarly, by (2.23) and (2.46)

$$y_k^1(0,t) = \sum_{(m,n) \in Z_2'} \theta_{mn}^k |\varphi_n^k(0)|^2 g_m e^{i\mu_m t}, \quad \theta_{mn}^k = ((\lambda_n^k)^2 - \mu_m^2)^{-1} \tag{3.8}$$

with $|\varphi_n^k(0)| \ge C_1 > 0 \ \forall k \in \mathbb{N}$ and $(m,n) \in Z_2'$ (which is finite). We can also assume $g_m \ne 0$ in (3.8). Fix m with $(m,n) \in Z_2'$. By (3.8) it follows that

$$\left| \sum_{(m,n) \in Z_2'} \theta_{mn}^k (|\varphi_n^k(0)|^2 \right| \le C_3 \quad \text{for all } k \text{ as } t \to y_k^1(0,t) \tag{3.9}$$

is bounded in $L^2(0,T)$ independently of k. Finally, (3.9) implies $|\theta_{mn}^k| \le C_4$ for all k and $(m,n) \in Z_2'$. Indeed, the sequence $n \to \lambda_n^k$ is strictly increasing, so $|\theta_{mn}^k| \to +\infty$ as $k \to +\infty$ can occur only for at most one n which would be in conflict with (3.9). (Say that $n_1 < n_2$ are such that

$$\lambda_{n_1}^k < |\mu_m| < \lambda_{n_2}^k \quad (m, n_j) \in Z_2', \quad j = 1, 2.$$

Letting $k \to +\infty$ we can have (at most) either $\lambda^*_{n_1} < |\mu_m| \le \lambda^*_{n_2}$ or $\lambda^*_1 \le |\mu_m| < \lambda^*_{n_2}$ as $\lambda^*_{n_1} < \lambda^*_{n_2}$.)

Therefore, (3.9) proves the boundedness of the Fourier coefficients of $y^1_k(0,t)$; i.e., y^1_k is also bounded in $H^2(Q)$. We now can pass to limit in (3.2) and (3.3) for $k \to +\infty$. This is because (relabeling if necessary) we have $y_k \to y^*$ weakly in $H^1(Q)$ and strongly in $L^2(Q)$; $y_k(0,t) \to y^*(0,t)$ strongly in $L^2(0,T)$. $u_k \to u^*$ in $C^1([0,1])$. Therefore $(y^*, u^*) \in H^1(Q) \times U$ is an optimal pair.

4. The maximum principle. Throughout this (and the next) section one assumes that

$$T = \frac{2k+1}{p} \quad \text{as in (1.6)}; \quad y_0 \in H^2_\pi(0,T), g \in H^3_\pi(0,T). \tag{4.1}$$

The main result of this section is the following theorem.

THEOREM 4.1 (the maximum principle). *Let (y^*, u^*) be an optimal pair of problems* (3.1) *such that $N(A(u^*)) = \{0\}$. Then there is p in $H^1_\pi(Q)$ such that*

$$\begin{aligned} &u^* p_{tt} - (u^* p_x)_x = 0 \quad \text{in } Q, \\ &-u_0 p_x(0,t) = y^*(0,t) - y_0(t), \quad p(1,t) = 0, t \in (0,T), \end{aligned} \tag{4.2}$$

$$\int_0^1 \int_0^T (y^*_t p_t - y^*_x p_x)(u^* - u)\, dxdt \le \gamma \int_0^1 (u^*)''(u^* - u)'' dx + \gamma \int_0^1 u^*(u^* - u) dx \quad \forall u \in U. \tag{4.3}$$

Remark 4.1. Problem (4.2) should be viewed of course in the sense of Definition 2.1. However, since $p \in H^1_\pi(Q)$, this problem can be equivalently written as indicated by (2.48), i.e.,

$$\int_Q u^*(x)(p_t\varphi_t - p_x\varphi_x)\, dx\, dt = -\int_0^T (y^*(0,t) - y_0(t))\varphi(0,t)\, dt \quad \forall \varphi \in V. \tag{4.4}$$

Note that (in view of Proposition 2.1), $y^* \in H^1_\pi(Q)$. Equation (4.3) is a variational inequality which can be equivalently written as

$$\int_0^T (y^*_t(x,t)p_t(x,t) - y^*_x(x,t)p_x(x,t))\, dt \in N_U(u^*) + B(u^*), \tag{4.5}$$

where N_U is the normal cone to U in $(H^2(0,1))'$ and $B : H^2(0,1) \to (H^2(0,1))'$ is defined by

$$\langle Bu, v\rangle = \gamma \int_0^1 (u''v'' + uv) dx, \quad u, v \in H^2(0,1). \tag{4.6}$$

Formally, y^* is the solution to the following free boundary problem:

$$\begin{aligned} &\gamma u^* + \gamma u^{*(4)} = \int_0^T (y^*_t p_t - y^*_x p_x)\, dt \quad \text{in } \{x \in [0,1); u^*(x) > a\}, \\ &\gamma u^* + \gamma u^{*(4)} \ge \int_0^T (y^*_t p_t - y_x p_x)\, dt \quad \text{in } (0,1), \\ &u^*(0) = u_0, \quad u^{*\prime\prime}(0) = u''(1) = 0, \quad (u^*)'''(1) = 0. \end{aligned} \tag{4.7}$$

Anyway, the solution $u = u^*$ to (4.5) is given by $u^* = \lim_{\lambda \downarrow 0} u_\lambda$ strongly in $H^1(0,1)$ and weakly in $H^2(0,1)$, where u_λ is the solution of the problem

$$\begin{aligned} &u_\lambda^{\mathrm{IV}} + \beta_\lambda(u_\lambda - a) = h \quad \text{a.e. in } (0,1), \\ &u_\lambda(0) = u_0, \quad u_\lambda''(0) = u_\lambda''(1) = 0, \quad u_\lambda'''(1) = 0, \end{aligned} \tag{4.8}$$

where $\beta_r = -\lambda^{-1} r^-$ for $r \in R$ and $h(x) = \int_0^T (y_t^* p_t - y_x^* p_x) dt$ (see [5, p. 132]).

Proof of Theorem 4.1. The fact that $N(A(u^*)) = \{0\}$ implies by (2.18) that $S(u^*) = R(A(u^*)) = L^2(Q) \times L^2(0,T)$, so in view of Proposition 2.1, there is $p \in H_\pi^2(Q)$ such that $A(u^*)p = (0, y^*(0,\cdot) - y_0)$, which is just (4.2). In order to derive the variational inequality (4.3) we need the tangent cone $TK(u^*, y^*)$ to K at (u^*, y^*), where

$$K = \{(u,y) \in U \times H_\pi^2(Q); A(u)y = (0,g)\}. \tag{4.9}$$

First we prove that the hypothesis $N(A(u^*)) = 0$ implies (for each $w = u - u^*$, $u \in U$)

$$N(A(u^* + \varepsilon w)) = \{0\} \quad \text{for some } \varepsilon \downarrow 0. \tag{4.9$'$}$$

Indeed, by (2.12) and Proposition 2.1,

$$N(A(u^* + \varepsilon w)) = \mathrm{Span}\{\varphi_n(u^* + \varepsilon w) e^{i\mu_m t}; \lambda_n(u^* + \varepsilon w) = |\mu_m|\}. \tag{4.10}$$

If (4.9′) were not true, then there would exist (m,n) and a sequence $\varepsilon_p \to 0$ as $p \to +\infty$ such that $\lambda_n(u^* + \varepsilon_p w) = |\mu_m|$ (as $N(A(u))$ is finite dimensional for any $u \in U$). Passing to limit for $p \to \infty$ and taking into account the continuity of $u \to \lambda_n(u)$, we get $\lambda_n(u^*) = |\mu_m|$, which is in conflict with $N(A(u^*)) = 0$ (which means that there are no (m,n) such that $\lambda_n(u^*) = |\mu_m|$). As we mentioned above, (4.10) implies $R(u^* + \varepsilon w) = L^2(q) \times L^2(0,T)$, so the equation

$$A(u^* + \varepsilon w) z_\varepsilon = (-A_0(w) y^*, 0) \tag{4.11}$$

has a unique solution $z_\varepsilon \in H^2(Q)$. This is because $y^* \in H^3(Q)$ (by (2.39′)), so $A_0(w) y^* \in H^1(Q)$, and by (2.22′) it follows that $z_\varepsilon \in H^2(Q)$ and z_ε is bounded in $H^2(Q)$. We may assume that $z_\varepsilon \rightharpoonup z$ weakly in $H^1(Q)$, and letting $\varepsilon \downarrow 0$, (4.11) yields

$$A(u^*) z = (-A_0(w) y^*, 0). \tag{4.12}$$

Combining (4.11) and (4.12) one obtains

$$A(u^*)(z_\varepsilon - z) = -\varepsilon A(w) z_\varepsilon = (-\varepsilon A_0(w) z_\varepsilon, 0). \tag{4.13}$$

This implies $z_\varepsilon - z = \theta_\varepsilon \to 0$ as $\varepsilon \downarrow 0$ in $H^2(Q)$ and $(u^* + \varepsilon w, y^* + \varepsilon(z + \theta_\varepsilon)) \in TK(u^*, y^*)$, i.e., $A(u^* + \varepsilon w)(y^* + \varepsilon(z + \theta_\varepsilon)) = (0, g)$. Therefore,

$$\begin{aligned} &\int_0^T (y^*(0,t) - y_0(t))^2 dt + \gamma |u^*|_{H^2(0,1)}^2 \\ &\quad \le \int_0^T ((y^* + \varepsilon(z + \theta_\varepsilon))(0,t) - y_0(t))^2 + \gamma |u^* + \varepsilon w|_{H^2(0,1)}^2 \quad \forall \varepsilon > 0 \end{aligned}$$

with $|u^*|_{H^2(0,1)}^2 = |u^{*\prime\prime}|_{L^2(0,1)}^2 + |u^*|_{L^2(0,1)}^2$. This implies

$$\int_0^T (y^*(0,t) - y_0(t)) z(0,t) dt + \gamma \int_0^1 ((u^*)'' w'' + u^* w) dx \ge 0; \tag{4.14}$$

on the other hand p satisfies

$$\begin{aligned}\int_Q pA_0(u^*)z\,dx\,dt &= \int_0^T (y^*(0,t) - y_0(t))z(0,t)\,dt \\ &= -\int_Q pA_0(w)y^*\,dx\,dt = \int_Q (y_t^* p_t - y_x^* p_x)w\,dx\,dt.\end{aligned} \tag{4.15}$$

Clearly, (4.15) and (4.14) imply (4.3), which completes the proof.

Acknowledgments. We would like to thank the referee and the associate editor in charge of this paper (Professor John A. Burns) for some useful suggestions.

HOMOGENIZATION OF AN OPTIMAL CONTROL PROBLEM*

S. KESAVAN† AND J. SAINT JEAN PAULIN‡

Abstract. We consider an optimal control problem in which both the state equation and the cost functional have rapidly oscillating coefficients (characterized respectively by matrices A_ε and B_ε, where ε is a small parameter). We make no periodicity assumption. We study the limit of the problem when $\varepsilon \to 0$ and work in the framework of H-convergence. We prove that the limit satisfies a problem similar to the original one but with matrices A_0 (the H-limit of A_ε) and $B^\sharp$ (which is a perturbation of the H-limit B_0 of B_ε). We also study some particular cases. This paper extends former results obtained by Kesavan and Vanninathan in the periodic case.

Key words. homogenization, H-convergence, optimal control

1. Introduction.

The aim of this paper is to discuss the homogenization of an optimal control problem in which both the state equation (given by a second-order elliptic boundary value problem) and the cost function (involving a Dirichlet-type integral of the state function) have rapidly oscillating coefficients.

Let Ω be a bounded open set in $\mathbb{R}^n$. For any given constants $\alpha_M > \alpha_m > 0$, we denote by $\mathcal{M}(\alpha_m, \alpha_M, \Omega)$ the set of all $n \times n$ matrices $A = (a_{ij})$ whose entries are functions on Ω such that

$$\alpha_m \xi_i \xi_i \le a_{ij}(x)\xi_i\xi_j \le \alpha_M \xi_i \xi_i \quad \text{almost every (a.e.) } (x) \tag{1.1}$$

for all $\xi = (\xi_i) \in \mathbb{R}^n$. Here and throughout the sequel, we use the convention of summation over repeated indices.

Let $A \in \mathcal{M}(\alpha_m, \alpha_M, \Omega)$ and $B \in \mathcal{M}(\beta_m, \beta_M, \Omega)$, and assume that B is symmetric.

We define the optimal control problem as follows. Let $U_{ad} \subset L^2(\Omega)$ be a closed convex subset. Let $f \in L^2(\Omega)$ be a given function and $N > 0$ be a given constant. For $\theta \in U_{ad}$, the equation of state is given by

$$\begin{cases} -\mathrm{div}(A\nabla u) = f + \theta & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega. \end{cases} \tag{1.2}$$

The state $u = u(\theta)$ is thus defined as the weak solution in $H_0^1(\Omega)$ of problem (1.2).

Then the cost function is given by

$$J(\theta) = \frac{1}{2}\int_\Omega (B\nabla u, \nabla u)dx + \frac{N}{2}\int_\Omega \theta^2 dx. \tag{1.3}$$

The optimal control $\theta^\star$ is the function in U_{ad} which minimizes $J(\theta)$ for $\theta \in U_{ad}$.

‡Département de Mathématiques, Université de Metz, Ile du Saulcy, 57045 Metz cedex 01, France (sjpaulin@poncelet.univ-metz.fr).

The problem posed above is a standard one, and a discussion of this can be found in the book by Lions [3]. There exists a unique optimal control. The problem can be reduced to a system of equations by introducing the adjoint state p. Thus we get

$$\begin{cases} -\mathrm{div}(A\nabla u) = f + \theta & \text{in } \Omega, \\ \mathrm{div}({}^tA\nabla p - B\nabla u) = 0 & \text{in } \Omega, \end{cases} \tag{1.4}$$

where $u, p \in H_0^1(\Omega)$. The optimal control $\theta^\star$ is characterized by the variational inequality

$$\int_\Omega (p + N\theta^\star)(\theta - \theta^\star)dx \geq 0 \qquad \forall \theta \in U_{ad}\ . \tag{1.5}$$

The situation that we will be interested in is that in which, given a parameter $\varepsilon > 0$ which tends to zero, the matrices A and B above depend on ε. Thus we suppose that

$$A_\varepsilon \in \mathcal{M}(\alpha_m, \alpha_M, \Omega) \quad \text{and } B_\varepsilon \in \mathcal{M}(\beta_m, \beta_M, \Omega).$$

Then as usual, the optimal control $\theta_\varepsilon^\star$ exists and can be shown to be bounded in $L^2(\Omega)$. Thus (for a subsequence)

$$\theta_\varepsilon^\star \rightharpoonup \theta^\star \qquad \text{weakly in } L^2(\Omega),$$

and we would like to know whether $\theta^\star$ is an optimal control defined by a problem of the same type with matrices $A^\star$ and $B^\star$ and, if so, identify these matrices.

A special case of this situation was studied by Kesavan and Vanninathan [2]. They assumed that A_ε and B_ε are periodic, and they computed the matrices of the limiting problem. It turned out, as expected, that the matrix $A^\star$ was indeed the limit of the matrices A_ε in the topology of H-convergence (see Murat [4] or Tartar [6]) but the matrix $B^\star$ was a perturbation of the H-limit of the B_ε.

We will study the problem in the general case and identify the limiting problem. As in the case of Kesavan and Vanninathan [2], we will first study the homogenization of system (1.4) for a fixed θ in U_{ad}.

Given $A_\varepsilon \in \mathcal{M}(\alpha_m, \alpha_M, \Omega)$ and $B_\varepsilon \in \mathcal{M}(\beta_m, \beta_M, \Omega)$, it is easy to see that the corresponding solution $(u_\varepsilon, p_\varepsilon)$ of the system

$$\begin{cases} -\mathrm{div}(A_\varepsilon \nabla u_\varepsilon) = f + \theta & \text{in } \Omega, \\ \mathrm{div}({}^tA_\varepsilon \nabla p_\varepsilon - B_\varepsilon \nabla u_\varepsilon) = 0 & \text{in } \Omega, \\ u_\varepsilon = p_\varepsilon = 0 & \text{on } \partial\Omega \end{cases} \tag{1.6}$$

is bounded in $(H_0^1(\Omega))^2$, uniformly with respect to (w.r.t.) ε. Thus (for a subsequence, still denoted by the suffix ε)

$$\begin{aligned} u_\varepsilon &\rightharpoonup u_0 \qquad \text{weakly in } H_0^1(\Omega), \\ p_\varepsilon &\rightharpoonup p_0 \qquad \text{weakly in } H_0^1(\Omega). \end{aligned}$$

Since $\mathrm{div}(A_\varepsilon \nabla u_\varepsilon)$ is fixed, by the usual definition of the H-limit (see Murat [4]) we have

$$\begin{cases} \xi_\varepsilon \equiv A_\varepsilon \nabla u_\varepsilon \rightharpoonup A_0 \nabla u_0 & \text{weakly in } L^2(\Omega), \\ -\mathrm{div}(A_0 \nabla u_0) = f + \theta, \end{cases} \tag{1.7}$$

where $A_\varepsilon \xrightarrow{H} A_0$. By the H-limit of problem (1.6) we mean that in addition

$$\begin{cases} z_\varepsilon \equiv {}^t A_\varepsilon \nabla p_\varepsilon - B_\varepsilon \nabla u_\varepsilon \rightharpoonup z_0 & \text{weakly in } L^2(\Omega), \\ \text{div } (z_0) = 0. \end{cases} \tag{1.8}$$

We would like to express z_0 in a form similar to that of z_ε to identify the corresponding matrices and, if possible, to express them in terms of A_0 and B_0, the H-limits of A_ε and B_ε, respectively.

The plan of the paper is as follows. In section 2, we will briefly discuss the one-dimensional case which gives a nice formula for the limiting coefficients in terms of the H-limits. In section 3, we will prove that the limit satisfies a problem similar to the original problem. In particular, we will show that

$$z_0 = {}^t A_0 \nabla p_0 - B^\sharp \nabla u_0,$$

where A_0 is the H-limit of A_ε and $B^\sharp$ is a perturbation of B_0, the H-limit of B_ε. Section 4 is reserved for the study of some properties of $B^\sharp$.

2. The one-dimensional case. Let $0 < \alpha_m \le a_\varepsilon \le \alpha_M$ and $0 < \beta_m \le b_\varepsilon \le \beta_M$ on an interval $(c, d) \subset \mathbb{R}$. System (1.6) now reads as follows:

$$\begin{cases} -\dfrac{d}{dx}\left(a_\varepsilon(x)\dfrac{du_\varepsilon}{dx}\right) = f + \theta & \text{in } (c,d), \\ \dfrac{d}{dx}\left(a_\varepsilon(x)\dfrac{dp_\varepsilon}{dx} - b_\varepsilon(x)\dfrac{du_\varepsilon}{dx}\right) = 0 & \text{in } (c,d), \end{cases} \tag{2.1}$$

with u_ε and p_ε vanishing at c and d.

THEOREM 2.1. *Suppose that the functions a_0 and $b^\sharp$ are such that*

$$\begin{cases} \dfrac{1}{a_\varepsilon} \rightharpoonup \dfrac{1}{a_0} & \text{weakly } \star \text{ in } L^\infty(c,d), \\ b^\sharp = \dfrac{a_0^2}{g_0}, \end{cases} \tag{2.2}$$

where

$$\frac{1}{g_\varepsilon} \equiv \frac{b_\varepsilon}{a_\varepsilon^2} \rightharpoonup \frac{1}{g_0} \qquad \text{weakly } \star \text{ in } L^\infty(c,d). \tag{2.3}$$

Then the following convergences hold:

$$\begin{aligned} u_\varepsilon &\rightharpoonup u_0 \qquad \text{weakly in } H_0^1(c,d), \\ p_\varepsilon &\rightharpoonup p_0 \qquad \text{weakly in } H_0^1(c,d), \end{aligned}$$

where u_0 and p_0 satisfy the equations

$$\begin{cases} -\dfrac{d}{dx}\left(a_0\dfrac{du_0}{dx}\right) = f + \theta & \text{in } (c,d), \\ \dfrac{d}{dx}\left(a_0\dfrac{dp_0}{dx} - b^\sharp\dfrac{du_0}{dx}\right) = 0 & \text{in } (c,d). \end{cases} \tag{2.4}$$

Proof. Step 1. We define g_ε by (2.3) and set

$$\begin{cases} \xi_\varepsilon = a_\varepsilon \dfrac{du_\varepsilon}{dx}, \\ \xi_0 = a_0 \dfrac{du_0}{dx}. \end{cases}$$

It is easy to see that $\{u_e\}$ and $\{p_\varepsilon\}$ are bounded in $H_0^1(c,d)$ and hence possess weakly convergent subsequences. Working with such a subsequence (again denoted by ε) we define u_0 and p_0 to be the respective limits. By the usual arguments of H-convergence, it is obvious that $\xi_\varepsilon \rightharpoonup \xi_0$ weakly in $L^2(c,d)$ and that u_0 satisfies the first equation of (2.4).

Step 2. We now observe that the second equation in (2.1) implies that

$$a_\varepsilon \frac{dp_\varepsilon}{dx} - b_\varepsilon \frac{du_\varepsilon}{dx} = c_\varepsilon, \qquad \text{a constant},$$

and that the sequence $\{c_\varepsilon\}$ is bounded. We can thus assume that $c_\varepsilon \to c_0$ (after extracting a further subsequence if necessary). We write

$$\begin{cases} \dfrac{dp_\varepsilon}{dx} = \dfrac{c_\varepsilon}{a_\varepsilon} + \dfrac{b_\varepsilon}{a_\varepsilon}\ \dfrac{du_\varepsilon}{dx} \\ \qquad\quad = \dfrac{c_\varepsilon}{a_\varepsilon} + \dfrac{b_\varepsilon}{a_\varepsilon^2}\ \xi_\varepsilon. \end{cases} \tag{2.5}$$

Step 3. We wish to pass to the limit in this relation. Obviously

$$\frac{c_\varepsilon}{a_\varepsilon} \rightharpoonup \frac{c_0}{a_0} \text{ in } L^\infty \text{ weak } \star\,. \tag{2.6}$$

Moreover, since

$$-\frac{d\xi_\varepsilon}{dx} = f + \theta,$$

then $\xi_\varepsilon \in H^1(c,d)$ and

$$\|\xi_\varepsilon\|_{H^1(c,d)} \le C,$$

where C is a constant independent of ε. Note that this also holds when we have $\theta_\varepsilon^\star$ instead of θ since $\theta_\varepsilon^\star$ is bounded in $L^2(c,d)$ independently of ε. Thus there exists $\xi_0 \in H^1(c,d)$ such that, up to a subsequence,

$$\xi_\varepsilon \rightharpoonup \xi_0 \quad \text{weakly in } H^1(c,d) \quad \text{and} \quad \xi_\varepsilon \to \xi_0 \quad \text{strongly in } L^2(c,d).$$

Hence, using (2.3), we have

$$\frac{b_\varepsilon}{a_\varepsilon^2}\ \xi_\varepsilon \rightharpoonup \frac{\xi_0}{g_0}.$$

Thus

$$\frac{dp_0}{dx} = \frac{c_0}{a_0} + \frac{\xi_0}{g_0} = \frac{c_0}{a_0} + \frac{a_0}{g_0}\ \frac{du_0}{dx}.$$

Hence

$$a_0 \frac{dp_0}{dx} - \frac{a_0^2}{g_0}\ \frac{du_0}{dx} = c_0, \qquad \text{a constant},$$

which implies the second relation in (2.4). ∎

Remark 2.2. The limits u_0 and p_0 are not unique in general because the weak $\star$ limits $\frac{1}{a_0}$ and $\frac{1}{g_0}$ may not be unique.

Example 2.3. If $a_\varepsilon(x) = a(x/\varepsilon)$ and $b_\varepsilon(x) = b(x/\varepsilon)$, where a and b are periodic functions on, say, $[0,1]$, we have

$$\begin{cases} a_0 = \left[m\left(\dfrac{1}{a}\right)\right]^{-1}, \\ b^\sharp = \dfrac{a_0^2}{g_0}, \quad g_0 = \left[m\left(\dfrac{b}{a^2}\right)\right]^{-1}, \end{cases}$$

where $m(h) = \int_0^1 h(y)dy$ for a periodic function h on $[0,1]$. In this case, the limits u_0 and p_0 are unique.

Remark 2.4. One could try to imitate this proof in higher dimensions. If we set

$$L_\varepsilon = A_\varepsilon B_\varepsilon^{-1}\ {}^t A_\varepsilon,$$

then

$$\begin{cases} A_\varepsilon \xrightarrow{H} A_0, \\ L_\varepsilon \xrightarrow{H} L_0, \end{cases}$$

and one might expect $B^\sharp$ to be given by ${}^t A_0 (L_0)^{-1}\ A_0$. Unfortunately the arguments analogous to those of steps 2 and 3 are no longer valid. Indeed we will show in the next section, by means of an example, that $B^\sharp$ is not, in general, equal to ${}^t A_0 (L_0)^{-1} A_0$. □

3. Identification of the H-limit. We assume henceforth that $\Omega \subset \mathbb{R}^n$ is a bounded open set.

THEOREM 3.1. *Assume that $A_\varepsilon \in \mathcal{M}(\alpha_m, \alpha_M, \Omega)$ and $B_\varepsilon \in \mathcal{M}(\beta_m, \beta_M, \Omega)$. Assume also that A_0 and B_0 are H-limits of A_ε and B_ε. Let $(u_\varepsilon, p_\varepsilon)$ be the solution of system* (1.6). *Then $u_\varepsilon \rightharpoonup u_0$ and $p_\varepsilon \rightharpoonup p_0$ weakly in $H_0^1(\Omega)$. Furthermore*

$$z_\varepsilon \equiv {}^t A_\varepsilon \nabla p_\varepsilon - B_\varepsilon \nabla u_\varepsilon \rightharpoonup z_0 \text{ weakly in } L^2(\Omega),$$

where

$$z_0 = {}^t A_0 \nabla p_0 - B^\sharp \nabla u_0. \tag{3.1}$$

The matrix A_0 is the H-limit of $\{A_\varepsilon\}$ and the matrix $B^\sharp$ depends only on $\{B_\varepsilon\}$ and $\{A_\varepsilon\}$. It is given by formula (3.10) *below.*

Remark 3.2. In the case of the control problem, B_ε is a symmetric matrix. However, to study system (1.6), B_ε need not be taken to be symmetric. Also in order to prove that $B^\sharp$ is symmetric when the B_ε are symmetric, we will need to study the limit first without assuming the symmetry of the B_ε.

Proof of Theorem 3.1. *Step* 1. It is obvious from (1.6) that $\{u_\varepsilon\}$ and $\{p_\varepsilon\}$ are bounded sequences in $H_0^1(\Omega)$ and that $\{z_\varepsilon\}$ is bounded in $L^2(\Omega)$. Thus we assume (working, as usual, with convergent subsequences) that $u_\varepsilon \rightharpoonup u_0, p_\varepsilon \rightharpoonup p_0$ weakly in $H_0^1(\Omega)$, and $z_\varepsilon \rightharpoonup z_0$ weakly in $L^2(\Omega)$. We also have $\xi_\varepsilon \equiv A_\varepsilon \nabla u_\varepsilon$ bounded uniformly w.r.t. ε in $L^2(\Omega)$ and, by usual homogenization results,

$$\xi_\varepsilon \rightharpoonup \xi_0 \qquad \text{weakly in } L^2(\Omega)$$

with

$$\xi_0 = A_0 \nabla u_0, \tag{3.2}$$

where A_0 is the H-limit of $\{A_\varepsilon\}$. Thus we also have

$$-\operatorname{div}(A_0 \nabla u_0) = f + \theta. \tag{3.3}$$

Step 2. We define various test functions to be used in the identification of z_0. Let $e_k \in \mathbb{R}^n$ be the kth standard basis vector. Then we define X_k^ε, Y_k^ε, and ψ_k^ε in $H^1(\Omega)$ as follows:

$$\begin{cases} X_k^\varepsilon \rightharpoonup 0 & \text{weakly in } H^1(\Omega), \\ \operatorname{div}(A_\varepsilon \nabla(-X_k^\varepsilon + x_k)) \to \operatorname{div}(A_0 e_k) & \text{strongly in } H^{-1}(\Omega), \end{cases} \tag{3.4}$$

$$\begin{cases} Y_k^\varepsilon \rightharpoonup 0 & \text{weakly in } H^1(\Omega), \\ \operatorname{div}({}^t B_\varepsilon \nabla(-Y_k^\varepsilon + x_k)) \to \operatorname{div}(B_0 e_k) & \text{strongly in } H^{-1}(\Omega), \end{cases} \tag{3.5}$$

where B_0 is the usual H-limit of $\{B_\varepsilon\}$,

$$\begin{cases} \psi_k^\varepsilon \text{ bounded uniformly w.r.t. } \varepsilon \text{ in } H_0^1(\Omega), \\ \operatorname{div}\,({}^t A_\varepsilon \nabla \psi_k^\varepsilon + {}^t B_\varepsilon \nabla(-X_k^\varepsilon + x_k)) = 0. \end{cases} \tag{3.6}$$

Here x_k denotes the function mapping $x \in \mathbb{R}^n$ to its kth coordinate. The sequence $\{\psi_k^\varepsilon\}$ is bounded, and so it converges weakly in $H^1(\Omega)$ (up to a subsequence). We denote its limit by ψ_k^0.

Let us detail how these test functions can be built. Define X_k^ε by

$$\begin{cases} \operatorname{div}(A_\varepsilon \nabla(-X_k^\varepsilon + x_k)) = \operatorname{div}(A_0 e_k) & \text{in } \Omega, \\ X_k^\varepsilon = 0 & \text{on } \partial\Omega. \end{cases}$$

Multiplication of this relation by X_k^ε, integration by parts, and use of the fact that $A_\varepsilon \in \mathcal{M}(\alpha_m, \alpha_M, \Omega)$ imply that

$$\|X_k^\varepsilon\|_{H^1(\Omega)} \le C,$$

where the constant C is independent of ε. Hence, up to a subsequence,

$$X_k^\varepsilon \rightharpoonup X_k \quad \text{weakly in } H^1(\Omega)$$

and therefore

$$(-X_k^\varepsilon + x_k) \rightharpoonup (-X_k + x_k) \quad \text{weakly in } H^1(\Omega).$$

Then a well-known H-convergence result (see Murat [4, Theorem 1]) implies that

$$A_\varepsilon \nabla(-X_k^\varepsilon + x_k) \rightharpoonup A_0 \nabla(-X_k + x_k) \quad \text{weakly in } (L^2(\Omega))^n.$$

Hence X_k is the solution of

$$\begin{cases} \operatorname{div}(A_0 \nabla(-X_k + x_k)) = \operatorname{div}(A_0 e_k) & \text{in } \Omega, \\ X_k = 0 & \text{on } \partial\Omega; \end{cases}$$

that is,

$$X_k = 0 \quad \text{on } \Omega.$$

This holds for any subsequence X_k^ε, so this is true for the whole sequence X_k^ε.

Similar arguments obviously hold for (3.5).

To establish relation (3.6), let us define for instance ψ_k^ε by

$$\begin{cases} \operatorname{div}({}^tA_\varepsilon \nabla \psi_k^\varepsilon) = \operatorname{div}({}^tB_\varepsilon \nabla(-X_k^\varepsilon + x_k)) & \text{in } \Omega, \\ \psi_k^\varepsilon = 0 \quad \text{on } \partial\Omega. \end{cases}$$

Using the assumptions $A_\varepsilon \in \mathcal{M}(\alpha_m, \alpha_M, \Omega)$ and $B_\varepsilon \in \mathcal{M}(\beta_m, \beta_M, \Omega)$ and the fact that X_k^ε is bounded in $H^1(\Omega)$ independently of ε, we derive

$$\|\psi_k^\varepsilon\|_{H^1(\Omega)} \le C,$$

where the constant C is independent of ε. Thus relation (3.6) is established.

Let us point out that there are several others procedures to build functions X_k^ε, Y_k^ε, and ψ_k^ε satisfying relations (3.4)–(3.6). We detailed one of these for the reader's convenience.

Step 3. Let $\varphi \in \mathcal{D}(\Omega)$ be an arbitrary function. We multiply the second equation in (1.6) by $\varphi(-X_k^\varepsilon + x_k)$ and integrate by parts. Thus we get

$$\begin{aligned} 0 = &- \int_\Omega ({}^tA_\varepsilon \nabla p_\varepsilon - B_\varepsilon \nabla u_\varepsilon) \,.\, (\nabla\varphi)(-X_k^\varepsilon + x_k)dx \\ &- \int_\Omega ({}^tA_\varepsilon \nabla p_\varepsilon) \,.\, \nabla(-X_k^\varepsilon + x_k)\varphi \, dx + \int_\Omega (B_\varepsilon \nabla u_\varepsilon) \,.\, \nabla(-X_k^\varepsilon + x_k)\varphi \, dx \\ = &- \int_\Omega z_\varepsilon \,.\, (\nabla\varphi)(-X_k^\varepsilon + x_k)dx - \int_\Omega \nabla p_\varepsilon \,.\, A_\varepsilon \nabla(-X_k^\varepsilon + x_k)\varphi \, dx \\ &+ \int_\Omega \nabla u_\varepsilon \,.\, {}^tB_\varepsilon \nabla(-X_k^\varepsilon + x_k)\varphi \, dx, \end{aligned}$$

which yields

$$\begin{aligned} 0 = &- \int_\Omega z_\varepsilon \,.\, (\nabla\varphi)(-X_k^\varepsilon + x_k)dx + \int_\Omega p_\varepsilon \operatorname{div}\,(A_\varepsilon \nabla(-X_k^\varepsilon + x_k))\varphi \, dx \\ &+ \int_\Omega p_\varepsilon \, A_\varepsilon \nabla(-X_k^\varepsilon + x_k) \,.\, \nabla\varphi \, dx + \int_\Omega \nabla u_\varepsilon \,.\, {}^tB_\varepsilon \nabla(-X_k^\varepsilon + x_k)\varphi \, dx. \end{aligned} \tag{3.7}$$

Now, the first equation of (1.6) when multiplied by $\varphi\psi_k^\varepsilon$ and integrated by parts gives

$$\begin{aligned} \int_\Omega (f+\theta)\psi_k^\varepsilon\varphi \, dx &= \int_\Omega A_\varepsilon \nabla u_\varepsilon \,.\, (\nabla\varphi)\psi_k^\varepsilon dx + \int_\Omega A_\varepsilon \nabla u_\varepsilon \,.\, (\nabla\psi_k^\varepsilon)\varphi \, dx \\ &= \int_\Omega \xi_\varepsilon \,.\, (\nabla\varphi)\psi_k^\varepsilon dx + \int_\Omega \nabla u_\varepsilon \,.\, {}^tA_\varepsilon(\nabla\psi_k^\varepsilon)\varphi \, dx \\ &= \int_\Omega \xi_\varepsilon \,.\, (\nabla\varphi)\psi_k^\varepsilon dx - \int_\Omega u_\varepsilon \operatorname{div}({}^tA_\varepsilon \nabla\psi_k^\varepsilon)\varphi \, dx - \\ &\quad - \int_\Omega u_\varepsilon {}^tA_\varepsilon \nabla\psi_k^\varepsilon \,.\, \nabla\varphi \, dx \\ &= \int_\Omega \xi_\varepsilon \,.\, (\nabla\varphi)\psi_k^\varepsilon dx + \int_\Omega u_\varepsilon \operatorname{div}({}^tB_\varepsilon \nabla(-X_k^\varepsilon + x_k))\varphi \, dx \\ &\quad - \int_\Omega u_\varepsilon {}^tA_\varepsilon \nabla\psi_\varepsilon^k \,.\, \nabla\varphi \, dx, \end{aligned}$$

which yields

$$\begin{aligned}\int_\Omega (f+\theta)\psi_k^\varepsilon \varphi\ dx = &\int_\Omega \xi_\varepsilon\ .\ (\nabla\varphi)\psi_k^\varepsilon dx - \int_\Omega \nabla u_\varepsilon\ .\ {}^tB_\varepsilon \nabla(-X_k^\varepsilon + x_k)\varphi\ dx \\ &- \int_\Omega u_\varepsilon\, {}^tB_\varepsilon \nabla(-X_k^\varepsilon + x_k)\ .\ \nabla\varphi dx \\ &- \int_\Omega u_\varepsilon\, {}^tA_\varepsilon \nabla\psi_k^\varepsilon\ .\ \nabla\varphi\ dx.\end{aligned} \tag{3.8}$$

Adding (3.7) and (3.8), we get

$$\begin{cases}\displaystyle\int_\Omega (f+\theta)\psi_k^\varepsilon\varphi\ dx = -\int_\Omega z_\varepsilon\ .\ (\nabla\varphi)(-X_k^\varepsilon + x_k)dx \\ \qquad\qquad + \displaystyle\int_\Omega p_\varepsilon \mathrm{div}\ (A_\varepsilon\nabla(-X_k^\varepsilon + x_k))\varphi\ dx \\ \qquad\qquad + \displaystyle\int_\Omega p_\varepsilon A_\varepsilon \nabla(-X_k^\varepsilon + x_k)\ .\ \nabla\varphi\ dx + \int_\Omega \xi_\varepsilon\ .\ (\nabla\varphi)\psi_k^\varepsilon\ dx \\ \qquad\qquad - \displaystyle\int_\Omega u_\varepsilon[\ {}^tB_\varepsilon\nabla(-X_k^\varepsilon + x_k) + {}^tA_\varepsilon\nabla\psi_\varepsilon^k]\ .\ \nabla\varphi\ dx.\end{cases} \tag{3.9}$$

Step 4. We can pass to the limit as $\varepsilon \to 0$ in (3.9) since each of the terms in the right-hand side is a product of two sequences, one converging weakly and the other strongly in $L^2(\Omega)$ (since the injection of $H_0^1(\Omega)$ in $L^2(\Omega)$ is compact). In the second term we have a weak convergence in $H_0^1(\Omega)$ and a strong convergence in $H^{-1}(\Omega)$. Thus,

$$\begin{aligned}\int_\Omega (f+\theta)\psi_k^0\varphi\ dx = &-\int_\Omega z_0\ .\ (\nabla\varphi)\ x_k\ dx + \int_\Omega p_0\ \mathrm{div}(A_0e_k)\varphi\ dx \\ &+ \int_\Omega p_0(A_0e_k)\ .\ \nabla\varphi\ dx + \int_\Omega \xi_0\ .\ (\nabla\varphi)\psi_k^0\ dx \\ &- \int_\Omega u_0 \lim({}^tB_\varepsilon\nabla(-X_k^\varepsilon + x_k) + {}^tA_\varepsilon\nabla\psi_k^\varepsilon)\ .\ \nabla\varphi\ dx \\ = &\int_\Omega \mathrm{div}(z_0)\ (\varphi x_k)dx + \int_\Omega z_0\ .\ (\nabla x_k)\ \varphi\ dx + \int_\Omega p_0\ \mathrm{div}\ (A_0e_k)\varphi\ dx \\ &- \int_\Omega p_0\ \mathrm{div}(A_0e_k)\varphi\ dx - \int_\Omega \nabla p_0\ .\ A_0e_k\ \varphi\ dx \\ &- \int_\Omega \mathrm{div}(\xi_0)\ \psi_k^0\varphi\ dx - \int_\Omega \xi_0.(\nabla\psi_k^0)\ \varphi\ dx \\ &+ \int_\Omega \nabla u_0\ .\ \lim(\ {}^tB_\varepsilon\nabla(-X_k^\varepsilon + x_k) + {}^tA_\varepsilon\nabla\psi_k^\varepsilon)\varphi\ dx \\ &+ \int u_0\ \mathrm{div}\big(\lim(\ {}^tB_\varepsilon\nabla(-X_k^\varepsilon + x_k) + {}^tA_\varepsilon\nabla\psi_k^\varepsilon)\big)\varphi\ dx.\end{aligned}$$

Recall that

$$-\ \mathrm{div}\ \xi_0 = -\ \mathrm{div}(A_0\nabla u_0) = f + \theta.$$

Moreover

$$\mathrm{div}\ z_\varepsilon = 0 = \mathrm{div}(\ {}^tB_\varepsilon\ \nabla(-X_k^\varepsilon + x_k) + {}^tA_\varepsilon\nabla\psi_k^\varepsilon),$$

and so the same is true for the divergence of their weak limits in $L^2(\Omega)$. Thus we get, on eliminating φ,

$$z_0 \,.\, e_k = ({}^tA_0\nabla p_0) \,.\, e_k - \lim\big({}^tB_\varepsilon\nabla(-X_k^\varepsilon + x_k) + {}^tA_\varepsilon(\nabla\psi_k^\varepsilon)\big).\nabla u_0 + ({}^tA_0\nabla\psi_k^0) \,.\, \nabla u_0,$$

which we can write as

$$z_0 = {}^tA_0\nabla p_0 - B^\sharp\nabla u_0,$$

which completes the proof of the theorem. □

We would like to express $B^\sharp$ as a perturbation of the usual H-limit B_0. Hence we write

$${}^tB_\varepsilon\nabla(-X_k^\varepsilon + x_k) = {}^tB_\varepsilon\nabla(-X_k^\varepsilon + Y_k^\varepsilon) + {}^tB_\varepsilon\nabla(-Y_k^\varepsilon + x_k).$$

By (3.5) the second term on the right converges to B_0e_k. Thus, up to eventual subsequences

$$B^\sharp e_k = B_0e_k + \lim[\,{}^tA_\varepsilon\nabla\psi_k^\varepsilon - {}^tA_0\nabla\psi_k^0] + \lim[\,{}^tB_\varepsilon(Y_k^\varepsilon - X_k^\varepsilon)]. \tag{3.10}$$

To return to the control problem that we started with, we have the following result.

THEOREM 3.3. *Set $A_\varepsilon \in \mathcal{M}(\alpha_m, \alpha_M, \Omega)$ and $B_\varepsilon \in \mathcal{M}(\beta_m, \beta_M, \Omega)$ with B_ε symmetric. Let $\theta_\varepsilon^\star$ be the optimal control for the problem whose state equation is given by*

$$\begin{cases} -\operatorname{div}(A_\varepsilon\nabla u_\varepsilon) = f + \theta & \text{in } \Omega, \\ u_\varepsilon = 0 \quad \text{on } \partial\Omega \end{cases}$$

for $\theta \in U_{ad}$, and let the cost function be given by

$$J_\varepsilon(\theta) = \frac{1}{2}\int_\Omega (B_\varepsilon\nabla u_\varepsilon, \nabla u_\varepsilon)dx + \frac{N}{2}\int_\Omega \theta^2 dx.$$

Then

$$\theta_\varepsilon^\star \to \theta_0^\star \qquad \text{strongly in } L^2(\Omega),$$

and $\theta_0^\star$ is the optimal control for the corresponding problem defined by the matrices A_0 and $B^\sharp$. We also have

$$J_\varepsilon(\theta_\varepsilon^\star) \to J_0(\theta_0^\star) \equiv \frac{1}{2}\int_\Omega (B^\sharp\nabla u_0^\star, \nabla u_0^\star)\; dx + \frac{N}{2}\int_\Omega (\theta_0^\star)^2\; dx.$$

Proof. It is again obvious that $\theta_\varepsilon^\star$ is bounded in $L^2(\Omega)$ and so converges to some $\theta_0^\star$ weakly in $L^2(\Omega)$. If $u_\varepsilon^\star$ is the corresponding state function and $p_\varepsilon^\star$ the adjoint state function, we can repeat the proof of Theorem 3.1. (The fact that θ is replaced by $\theta_\varepsilon^\star$ in the first equation poses no problem.) Thus we get that $u_\varepsilon^\star \rightharpoonup u_0^\star$ and $p_\varepsilon^\star \rightharpoonup p_0^\star$ weakly in $H_0^1(\Omega)$ and that

$$\begin{cases} -\operatorname{div}(A_0\nabla u_0^\star) = f + \theta_0^\star & \text{in } \Omega, \\ \operatorname{div}({}^tA_0\nabla p_0^\star - B^\sharp\nabla u_0^\star) = 0 & \text{in } \Omega. \end{cases}$$

Further, we have, for every $\theta \in U_{ad}$,

$$\int_\Omega (p_\varepsilon^\star + N\theta_\varepsilon^\star)(\theta - \theta_\varepsilon^\star)dx \geq 0,$$

and we easily pass to the limit to get

$$\int_\Omega (p_0^\star + N\theta_0^\star)(\theta - \theta_0^\star)dx \geq 0.$$

Here we used the fact that $\underline{\lim} \int_\Omega \theta_\varepsilon^2 \, dx \geq \int_\Omega \theta_0^{\star 2} \, dx$. Further (as will be proven in the next section) $B^\sharp$ is both elliptic and symmetric. This proves that $\theta_0^\star$ is the optimal control for the problem involving A_0 and $B^\sharp$.

Moreover

$$\theta_\varepsilon^\star = \mathrm{proj}_{U_{ad}}(-p_\varepsilon/N) \quad \text{and} \quad \theta_0^\star = \mathrm{proj}_{U_{ad}}(-p_0/N),$$

where $\mathrm{proj}_{U_{ad}}$ denotes the projection on the set U_{ad}. Since

$$p_\varepsilon \to p_0^\star \quad \text{strongly in } L^2(\Omega)$$

and the projection is an L^2-contraction, we deduce that

$$\theta_\varepsilon^\star \to \theta_0^\star \quad \text{strongly in } L^2(\Omega).$$

Now

$$\begin{aligned}
\int_\Omega (B_\varepsilon \nabla u_\varepsilon^\star, \nabla u_\varepsilon^\star) \, dx &= -\int_\Omega \mathrm{div}\ (B_\varepsilon \nabla u_\varepsilon^\star)\ u_\varepsilon^\star \, dx \\
&= -\int_\Omega \mathrm{div}(\ {}^t A_\varepsilon \nabla p_\varepsilon^\star)\ u_\varepsilon^\star \, dx \\
&= \int_\Omega\ {}^t A_\varepsilon \nabla p_\varepsilon^\star \ .\ \nabla u_\varepsilon^\star \, dx \\
&= \int_\Omega \nabla p_\varepsilon^\star \ .\ A_\varepsilon \nabla u_\varepsilon^\star \, dx \\
&= \int_\Omega (f + \theta_\varepsilon^\star)\ p_\varepsilon^\star \, dx \\
&\to \int_\Omega (f + \theta_0^\star)\ p_0^\star \, dx = \int_\Omega (B^\sharp \nabla u_0^\star, \nabla u_0^\star) \, dx.
\end{aligned}$$

The last equality follows by retracing the above steps. This, together with the strong convergence of $\theta_\varepsilon^\star$, gives the convergence of $J_\varepsilon(\theta_\varepsilon^\star)$ to $J_0(\theta_0^\star)$. □

To conclude this section we will compute the matrix $B^\sharp$ in some special cases.

Example 3.4 (the periodic case). Let Y denote the unit cube $[0,1]^n$ in $\mathbb{R}^n$. Choose $A \in \mathcal{M}(\alpha_m, \alpha_M, Y)$ and $B \in \mathcal{M}(\beta_m, \beta_M, Y)$ such that their coefficients are all periodic. We also assume that B is symmetric. We define A_ε and B_ε on $\mathbb{R}^n$ by extending A and B by periodicity on a grid of size ε. More precisely, we define

$$a_{ij}^\varepsilon(x) = a_{ij}(x/\varepsilon)\ ,\ b_{ij}^\varepsilon(x) = b_{ij}(x/\varepsilon)$$

on $[0,\varepsilon]^n$ and then extend them to the whole of $\mathbb{R}^n$ by periodicity. Restricting the functions to Ω, we thus get $A_\varepsilon \in \mathcal{M}(\alpha_m, \alpha_M, \Omega)$ and $B_\varepsilon \in \mathcal{M}(\beta_m, \beta_M, \Omega)$.

Defining X_k^ε, Y_k^ε, and ψ_k^ε as in (3.4)–(3.6), we observe the following:

(i) Since A_0 is now a constant matrix, $\operatorname{div}(A_0 e_k) = 0$. In fact, we can define X_k^ε by

$$X_k^\varepsilon = X_k(x/\varepsilon),$$

where

$$\begin{cases} \operatorname{div}(A\nabla(-X_k + y_k)) = 0 & \text{in } Y, \\ X_k \text{ is } Y\text{-periodic}, \ \int_Y X_k dy = 0. \end{cases} \tag{3.11}$$

(ii) Similarly, $Y_k^\varepsilon(x) = Y_k(x/\varepsilon)$, where

$$\begin{cases} \operatorname{div}\ (B\nabla(-Y_k + y_k)) = 0 & \text{in } Y, \\ Y_k \text{ is } Y\text{-periodic}, \ \int_Y Y_k dy = 0. \end{cases} \tag{3.12}$$

(iii) Finally $\psi_k^\varepsilon(x) = \psi_k(x/\varepsilon)$, where $\psi_k(y)$ satisfies

$$\begin{cases} \operatorname{div}({}^t A\nabla\psi_k + B\nabla(-X_k + y_k)) = 0 & \text{in } Y, \\ \psi_k \text{ is } Y\text{-periodic}, \ \int_Y \psi_k dy = 0. \end{cases} \tag{3.13}$$

In the above definitions, y_k denotes the projection onto the kth coordinate of $y \in Y$.

Since the means of the test function are zero, the limits of X_k^ε, $Y_k^\varepsilon, \psi_k^\varepsilon$ are all zero. In particular, $\psi_k^0 = 0$. Thus

$$\begin{aligned} (B^\sharp)_{jk} &= \lim\Big[b_{ij}^\varepsilon \frac{\partial}{\partial x_i}(-X_k^\varepsilon + x_k) + a_{ij}^\varepsilon \frac{\partial \psi_k^\varepsilon}{\partial x_i}\Big] \\ &= \int_Y \Big[b_{ij}(y)\ \frac{\partial}{\partial y_i}\ (-X_k + y_k) + a_{ij}(y)\frac{\partial \psi_k}{\partial y_i}\Big] dy \end{aligned}$$

since $f(x/\varepsilon) \rightharpoonup \int_Y f(y)dy$ in $L^\infty(\Omega)$-weak $*$ for Y-periodic f. Hence

$$(B^\sharp)_{jk} = \int_Y b_{ij}(y)\frac{\partial}{\partial y_i}(-Y_k + y_k)dy + \int_Y \Big[a_{ij}\frac{\partial \psi_k}{\partial y_i} - b_{ij}\frac{\partial(X_k - Y_k)}{\partial y_i}\Big] dy.$$

Now

$$\int_Y b_{ij}(y)\frac{\partial}{\partial y_i}\ (-Y_k + y_k)dy = \int_Y b_{il}\frac{\partial(-Y_k + y_k)}{\partial y_i}\ \frac{\partial(-Y_j + y_j)}{\partial y_l} dy = (B_0)_{jk}$$

as per classical computations in homogenization (see, for example, Bensoussan, Lions,

and Papanicolaou [1]). The second term in $(B^\sharp)_{jk}$ is evaluated as follows:

$$\begin{aligned}
\int_Y a_{ij}\frac{\partial \psi_k}{\partial y_i}dy &= \int_Y a_{il}\frac{\partial \psi_k}{\partial y_i}\ \frac{\partial y_j}{\partial y_l}\ dy \\
&= \int_Y a_{il}\frac{\partial \psi_k}{\partial y_i}\ \frac{\partial X_j}{\partial y_l}\ dy \quad \text{(using (3.11))} \\
&= \int_Y b_{il}\frac{\partial (X_k - y_k)}{\partial y_i}\ \frac{\partial X_j}{\partial y_l}\ dy \quad \text{(using (3.13))} \\
&= \int_Y b_{il}\frac{\partial (X_k - Y_k)}{\partial y_i}\ \frac{\partial X_j}{\partial y_l}\ dy \quad \text{(using (3.12))} \\
&= \int_Y b_{il}\ \frac{\partial}{\partial y_i}(X_k - Y_k)\frac{\partial}{\partial y_l}(X_j - Y_j)dy + \int_Y b_{il}\frac{\partial}{\partial y_i}(X_k - Y_k)\frac{\partial Y_j}{\partial y_l}\ dy \\
&= \int_Y b_{il}\frac{\partial}{\partial y_i}\ (X_k - Y_k)\frac{\partial}{\partial y_l}\ (X_j - Y_j)dy \\
&\quad + \int_Y b_{ij}\frac{\partial}{\partial y_i}\ (X_k - Y_k)dy \quad \text{(using (3.12))}.
\end{aligned}$$

Thus,

$$\int_Y a_{ij}\frac{\partial \psi_k}{\partial y_i}\ dy - \int_Y b_{ij}\frac{\partial}{\partial y_i}\ (X_k - Y_k)dy = \int_Y b_{il}\frac{\partial}{\partial y_i}\ (X_k - Y_k)\ \frac{\partial}{\partial y_l}\ (X_j - Y_j)\ dy.$$

Finally we get

$$(B^\sharp)_{jk} = (B_0)_{jk} + \int_Y b_{il}\ \frac{\partial}{\partial y_i}\ (X^k - Y^k)\ \frac{\partial}{\partial y_l}\ (X^j - Y^j)dy, \tag{3.14}$$

which was announced by Kesavan and Vanninathan [2]. It is immediate from the above form that $B^\sharp$ is both symmetric and elliptic. □

Example 3.5. (the layered material). This time we assume that $n = 2$, that A and B are diagonal, and that a_{ii} and b_{ii}, $(i = 1, 2)$ depend periodically on x_1 and do not depend on x_2. Thus $a^\varepsilon_{ii}(x) = a_{ii}(x_1/\varepsilon)$ and $b^\varepsilon_{ii}(x) = b_{ii}(x_1/\varepsilon)$, where $a_{ii}(y)$ and $b_{ii}(y)$ are periodic on $[0, 1]$. In this case (see Murat [4])

$$A_0 = \begin{pmatrix} \dfrac{1}{m(1/a_{11})} & 0 \\ 0 & m(a_{22}) \end{pmatrix}, \tag{3.15}$$

where $m(\ .\ )$ denotes the mean, i.e., the integral over $[0, 1]$.

It is now easy to see that $X^\varepsilon_1,\ Y^\varepsilon_1$, and ψ^ε_1 are functions in x_1 alone defined by

$$X^\varepsilon_1(x) = X_1\left(\frac{x_1}{\varepsilon}\right), \quad Y^\varepsilon_1(x) = Y_1\left(\frac{x_1}{\varepsilon}\right), \quad \psi^\varepsilon_1(x) = \psi_1\left(\frac{x_1}{\varepsilon}\right),$$

where

$$\begin{cases}
-\dfrac{d}{dy_1}(a_{11}(y_1)\dfrac{d}{dy_1}(-X_1 + y_1)) = 0 \quad \text{in }]0, 1[, \\
-\dfrac{d}{dy_1}(b_{11}(y_1)\dfrac{d}{dy_1}(-Y_1 + y_1)) = 0 \quad \text{in }]0, 1[, \\
-\dfrac{d}{dy_1}(a_{11}(y_1)\dfrac{d\psi_1}{dy_1} + b_{11}(y_1)\dfrac{d}{dy_1}(-X_1 + y_1)) = 0 \quad \text{in }]0, 1[.
\end{cases} \tag{3.16}$$

Also, $X_2^\varepsilon = Y_2^\varepsilon = \psi_2^\varepsilon = 0$. Thus we get

$$B^\sharp = \begin{pmatrix} \dfrac{m\Big(b_{11}/a_{11}^2\Big)}{m\Big(1/a_{11}\Big)^2} & 0 \\ 0 & m(b_{22}) \end{pmatrix} \tag{3.17}$$

as per usual calculations. See the one-dimensional case in section 2 for this form of $(B^\sharp)_{11}$. One can also directly obtain this formula from the previous example. ∎

Example 3.5 also illustrates the fact that the generalization of the one-dimensional formula proposed in section 2 does not work. Indeed

$$L_\varepsilon = A_\varepsilon B_\varepsilon^{-1} A_\varepsilon = \begin{pmatrix} (a_{11}^\varepsilon)^2/b_{11}^\varepsilon & 0 \\ 0 & (a_{22}^\varepsilon)^2/b_{22}^\varepsilon \end{pmatrix}.$$

Thus

$$L_0 = \begin{pmatrix} \dfrac{1}{m(b_{11}/a_{11}^2)} & 0 \\ 0 & m\Big(a_{22}^2/b_{22}\Big) \end{pmatrix}$$

and so

$$A_0 L_0^{-1} A_0 = \begin{pmatrix} \dfrac{m(b_{11}/a_{11}^2)}{(m(1/a_{11}))^2} & 0 \\ 0 & \dfrac{m(a_{22})^2}{m\Big(a_{22}^2/b_{22}\Big)} \end{pmatrix},$$

which is not equal to $B^\sharp$.

4. Properties of the matrix $B^\sharp$. In this section we will study some of the properties of the matrix $B^\sharp$. In particular we will see that the ellipticity and symmetry of the B_ε are preserved.

THEOREM 4.1. *Let $A_\varepsilon \in \mathcal{M}(\alpha_m, \alpha_M, \Omega)$ and $B_\varepsilon \in \mathcal{M}(\beta_m, \beta_M, \Omega)$. Let $B^\sharp$ be the matrix obtained as indicated in Theorem* 3.1. *Consider the problem*

$$\begin{cases} -\operatorname{div}(A_\varepsilon \nabla u_\varepsilon) = f + \theta & \text{in } \Omega, \\ \operatorname{div}({}^t A_\varepsilon \nabla \widetilde{p}_\varepsilon - {}^t B_\varepsilon \nabla u_\varepsilon) = 0 & \text{in } \Omega, \\ u_\varepsilon = \widetilde{p}_\varepsilon = 0 & \text{on } \partial\Omega. \end{cases} \tag{4.1}$$

Then

$$\widetilde{z}_\varepsilon \equiv {}^t A_\varepsilon \nabla \widetilde{p}_\varepsilon - {}^t B_\varepsilon \nabla u_\varepsilon \ \rightharpoonup\ {}^t A_0 \nabla \widetilde{p}_0 - {}^t(B^\sharp)\nabla u_0 \qquad \text{weakly in } L^2(\Omega).$$

Proof. Step 1. Clearly, by Theorem 3.1, we obtain a matrix $B_1^\sharp$ such that

$$\widetilde{z}_\varepsilon = {}^t A_\varepsilon \nabla \widetilde{p}_\varepsilon - {}^t B_\varepsilon \nabla u_\varepsilon \ \rightharpoonup {}^t A_0 \nabla \widetilde{p}_0 - B_1^\sharp \nabla u_0 = \widetilde{z}_0.$$

We have to show that $B_1^\sharp = {}^t(B^\sharp)$.

Let $F \in H^{-1}(\Omega)$ be an arbitrary distribution. We define $(w_\varepsilon, q_\varepsilon) \in (H_0^1(\Omega))^2$ by

$$\begin{cases} -\operatorname{div}(A_\varepsilon \nabla w_\varepsilon) = F & \text{in } \Omega, \\ \operatorname{div}({}^t A_\varepsilon \nabla q_\varepsilon - B_\varepsilon \nabla w_\varepsilon) = 0 & \text{in } \Omega. \end{cases} \tag{4.2}$$

If we set

$$\widehat{z}_\varepsilon = {}^t A_\varepsilon \nabla q_\varepsilon - B_\varepsilon \nabla w_\varepsilon,$$

then $\widehat{z}_\varepsilon \rightharpoonup \widehat{z}_0$ weakly in $L^2(\Omega)$ and

$$\widehat{z}_0 = {}^t A_0 \nabla q_0 - B^\sharp \nabla w_0,$$

where $q_\varepsilon \rightharpoonup q_0$ and $w_\varepsilon \rightharpoonup w_0$ weakly in $H_0^1(\Omega)$. We also know that

$$\begin{cases} \widehat{\xi}_\varepsilon = A_\varepsilon \nabla w_\varepsilon \rightharpoonup A_0 \nabla w_0 = \widehat{\xi}_0, \\ \xi_\varepsilon = A_\varepsilon \nabla u_\varepsilon \rightharpoonup A_0 \nabla u_0 = \xi_0 \end{cases} \tag{4.3}$$

weakly in $L^2(\Omega)$.

Step 2. Since $\operatorname{div}\widetilde{z}_\varepsilon = \operatorname{div}\widehat{z}_\varepsilon = 0$, by the div-curl lemma of compensated compactness (see Murat [5]) we have

$$\begin{cases} \widetilde{z}_\varepsilon \,.\, \nabla w_\varepsilon \to \widetilde{z}_0 \,.\, \nabla w_0 & \text{in } \mathcal{D}'(\Omega), \\ \widehat{z}_\varepsilon \,.\, \nabla u_\varepsilon \to \widehat{z}_0 \,.\, \nabla u_0 & \text{in } \mathcal{D}'(\Omega). \end{cases}$$

Thus

$$\widetilde{z}_\varepsilon \,.\, \nabla w_\varepsilon - \widehat{z}_\varepsilon \,.\, \nabla u_\varepsilon \longrightarrow \widetilde{z}_0 \,.\, \nabla w_0 - \widehat{z}_0 \,.\, \nabla u_0 \quad \text{in } \mathcal{D}'(\Omega). \tag{4.4}$$

We now evaluate the left-hand side of (4.4) in a different manner.

$$\begin{aligned} \widetilde{z}_\varepsilon \,.\, \nabla w_\varepsilon - \widehat{z}_\varepsilon \,.\, \nabla u_\varepsilon &= {}^t A_\varepsilon \nabla \widetilde{p}_\varepsilon \,.\, \nabla w_\varepsilon - {}^t A_\varepsilon \nabla q_\varepsilon \,.\, \nabla u_\varepsilon \\ &\quad - {}^t B_\varepsilon \nabla u_\varepsilon \,.\, \nabla w_\varepsilon + B_\varepsilon \nabla w_\varepsilon \,.\, \nabla u_\varepsilon \\ &= \nabla \widetilde{p}_\varepsilon \,.\, A_\varepsilon \nabla w_\varepsilon - \nabla q_\varepsilon \,.\, A_\varepsilon \nabla u_\varepsilon \\ &= \nabla \widetilde{p}_\varepsilon \,.\, \widehat{\xi}_\varepsilon - \nabla q_\varepsilon \,.\, \xi_\varepsilon \\ &\to \nabla \widetilde{p}_0 \,.\, \widehat{\xi}_0 - \nabla q_0 \,.\, \xi_0 \end{aligned}$$

once again by compensated compactness. Thus by (4.4) we get

$$\begin{aligned} \widetilde{z}_0 \,.\, \nabla w_0 - \widehat{z}_0 \,.\, \nabla u_0 &= \nabla \widetilde{p}_0 \,.\, \widehat{\xi}_0 - \nabla q_0 \,.\, \xi_0 \\ &= \nabla \widetilde{p}_0 \,.\, A_0 \nabla w_0 - \nabla q_0 \,.\, A_0 \nabla u_0 \\ &= {}^t A_0 \nabla \widetilde{p}_0 \,.\, \nabla w_0 - {}^t A_0 \nabla q_0 \,.\, \nabla u_0 \\ &= \widetilde{z}_0 \,.\, \nabla w_0 - \widehat{z}_0 \,.\, \nabla u_0 \\ &\quad + \; B_1^\sharp \nabla u_0 \,.\, \nabla w_0 - B^\sharp \nabla w_0 \,.\, \nabla u_0. \end{aligned}$$

Hence we have

$$B_1^\sharp \nabla u_0 \,.\, \nabla w_0 = B^\sharp \nabla w_0 \,.\, \nabla u_0 = {}^t(B^\sharp) \nabla u_0 \,.\, \nabla w_0 \quad \text{in } \mathcal{D}'(\Omega).$$

As can be observed, the matrices $B^\sharp$ and $B_1^\sharp$ depend only on the A_ε and B_ε. Thus we can choose u_0 and w_0 arbitrarily. In particular, if $\omega \subset\subset \Omega$ is any relatively compact open set, we can find, for any $\lambda, \mu \in \mathbb{R}^n$, elements u_0 and w_0 in $H_0^1(\Omega)$ such that

$$\nabla u_0 = \lambda \quad \text{and} \quad \nabla w_0 = \mu \quad \text{in } \omega.$$

Thus

$$(B_1^\sharp - {}^t(B^\sharp))\lambda \,.\, \mu = 0 \quad \text{in} \quad \mathcal{D}'(\omega),$$

and so for any $\omega \subset\subset \Omega$, we have $B_1^\sharp = {}^t(B^\sharp)$ in ω. Hence

$$B_1^\sharp = {}^t(B^\sharp) \quad \text{in} \quad \Omega,$$

which completes the proof. ∎

The above theorem immediately gives the following result.

COROLLARY 4.2. *If B_ε is symmetric for each $\varepsilon > 0$, then $B^\sharp$ is symmetric.* ∎

We now turn to the ellipticity of $B^\sharp$.

In the periodic case we see immediately that $B^\sharp$ has the same ellipticity constant as B_0, which is β_m itself. We will now see that this is the case even without the periodicity assumption.

THEOREM 4.3. *Let $B_\varepsilon \in \mathcal{M}(\beta_m, \beta_M, \Omega)$. Then the ellipticity constant of $B^\sharp$ is also β_m, so for some $\widetilde{\beta}_M > 0$, we have*

$$B^\sharp \in \mathcal{M}(\beta_m, \widetilde{\beta}_M, \Omega).$$

Proof. Let $F \in H^{-1}(\Omega)$ be an arbitrary distribution. We define

$$(w_\varepsilon, q_\varepsilon) \in (H_0^1(\Omega))^2$$

as in (4.2). Now

$$\begin{aligned} B_\varepsilon \nabla w_\varepsilon \,.\, \nabla w_\varepsilon &= {}^t A_\varepsilon \nabla q_\varepsilon \,.\, \nabla w_\varepsilon - \widehat{z}_\varepsilon . \nabla w_\varepsilon \\ &= \nabla q_\varepsilon \,.\, A_\varepsilon \nabla w_\varepsilon - \widehat{z}_\varepsilon \,.\, \nabla w_\varepsilon \\ &= \nabla q_\varepsilon \,.\, \widehat{\xi}_\varepsilon - \widehat{z}_\varepsilon \,.\, \nabla w_\varepsilon, \end{aligned}$$

where $\widehat{z}_\varepsilon$ and $\widehat{\xi}_\varepsilon$ are as in Step 1 of the proof of Theorem 4.1. Then, once again by compensated compactness,

$$\begin{aligned} B_\varepsilon \nabla w_\varepsilon \,.\, \nabla w_\varepsilon \xrightarrow{\mathcal{D}'(\Omega)} & \nabla q_0 \,.\, \widehat{\xi}_0 - \widehat{z}_0 \,.\, \nabla w_0 \\ &= \nabla q_0 \,.\, A_0 \nabla w_0 - \widehat{z}_0 \,.\, \nabla w_0 \\ &= {}^t A_0 \nabla q_0 \,.\, \nabla w_0 - \widehat{z}_0 \,.\, \nabla w_0 \\ &= B^\sharp \nabla w_0 \,.\, \nabla w_0. \end{aligned}$$

Thus if $\varphi \geq 0$ is any function in $\mathcal{D}(\Omega)$,

$$\begin{aligned} \beta_m \int_\Omega \varphi |\nabla w_0|^2 \, dx &\leq \beta_m \, \underline{\lim} \int_\Omega \varphi |\nabla w_\varepsilon|^2 \, dx \\ &\leq \lim \int_\Omega (B_\varepsilon \nabla w_\varepsilon \,.\, \nabla w_\varepsilon) \varphi \, dx \\ &= \int_\Omega (B^\sharp \nabla w_0 \,.\, \nabla w_0) \varphi \, dx. \end{aligned}$$

We can now choose, for any $\lambda \in \mathbb{R}^n$, an element w_0 such that $\nabla w_0 = \lambda$ on the support of φ so that

$$(B^\sharp \lambda, \lambda) \geq \beta_m |\lambda|^2 \quad \text{in } \mathcal{D}'(\Omega),$$

which proves the theorem. □

Remark 4.4. We said nothing about the upper bound $\widetilde{\beta}_M$ for the norm of $B^\sharp$. In the case of H-convergence the upper bound for the norm of B_0 is dominated by β_M^2/β_m, and in the case of symmetric matrices, by β_M itself. However, in the case of $B^\sharp$, the upper bound cannot be expressed in terms of the ellipticity constant and upper bound of B_ε alone, as can be seen even in the one-dimensional case.

Indeed, in the one-dimensional case, let us take $b_\varepsilon = b$ constant and a_ε periodic. Thus

$$B^\sharp = b\ \frac{m(1/a^2)}{(m(1/a))^2}.$$

Let a be a step function, say,

$$a = a_F\ \chi_F + a_G\ \chi_G,$$

where the sets F and G are such that $F \cup G = [0,1]$ and $\overset{\circ}{F} \cap \overset{\circ}{G} = \emptyset$. For any set E, we denote by χ_E its characteristic function and $|E|$ its measure. Then

$$m(1/a^2) = |F|\ \frac{1}{a_F^2} + |G|\ \frac{1}{a_G^2},$$
$$(m(1/a))^2 = \left(|F|\frac{1}{a_F} + |G|\ \frac{1}{a_G}\right)^2.$$

Thus

$$\frac{m(1/a^2)}{(m(1/a))^2} = \frac{|F|\ a_G^2 + |G|\ a_F^2}{(|F|\ a_G + |G|\ a_F)^2}.$$

If $a_G \to +\infty$, the above quantity tends to $\frac{1}{|F|}$. Thus by choosing a_G large and $|F|$ small we can always arrive at

$$B^\sharp >> b = \frac{\beta_M^2}{\beta_m}$$

(since $\beta_M = \beta_m = b$). □

The above considerations show that the upper bounds should depend on the constant α_m and α_M as well as on β_m and β_M. But we have no conjecture to offer on the form of this dependence.

Acknowledgments. The authors gratefully acknowledge the referee, who made useful suggestions including a simplification of the proof of Theorem 2.1 and remarks which helped us improve the paper.

LOCALLY DISTRIBUTED CONTROL AND DAMPING FOR THE CONSERVATIVE SYSTEMS*

KANGSHENG LIU†

Abstract. In this paper we note the equivalence between exact controllability and exponential stabilizability for an abstract conservative system with bounded control. This enables us to establish a frequency domain characterization for the exact controllability/uniform exponential decay property of second-order elastic systems, such as the wave equation and the Petrovsky equation, with (locally) distributed control/damping. A piecewise multiplier method for frequency domain is introduced. For several classes of PDEs on regions which are not necessarily smooth, we obtain a sufficient condition for the subregion on which the application of control/damping will yield the exact controllability/uniform exponential decay property. This result provides useful information for designing the location of controllers/dampers for distributed systems with a law of conservation.

Key words. conservative partial differential equation, exact controllability, damping, uniform exponential decay property

1. Introduction.

Many examples of conservative partial differential equations (CPDEs) modelling wave propagations, quantum phenomena, and mechanical vibrations can be found in the engineering and physics literature. Boundary control/damping for CPDEs has been studied extensively (cf. Russell [Ru1] and Lions [Li1], [Li2]). The consideration of locally distributed control of CPDEs seems to have been initiated by Lagnese [La] in 1983. The general question is how to choose the location of the control/damping subregion so that the exact controllability and/or uniform exponential decay property (UEDP) for a CPDE can be achieved. Much work has been done on this problem for special regions, such as one-dimensional, rectangular, and spherical cases (see Lagnese [La], Chen et al. [CFNS], Haraux [Ha1], [Ha2], Ho [Ho], Jaffard [J], Kim [Ki1], [Ki2], and Komornik [Ko]). For a general n-dimensional region with appropriately smooth boundary, Zuazua [Li2, Chap. 7], [Zu] showed that applying distributed control on an ϵ-neighborhood of a part of the boundary with certain geometric properties is sufficient for the exact controllability of the wave equation and the Petrovsky equation.

As indicated by Bardos, Lebeau, and Rauch [BLR1], Ralston's result [Ra] suggests that for exact controllability/UEDP, control/damping should be applied to a subregion which satisfies the "geometric optics condition," that is, that each ray, reflected at the boundary in the usual way, meets the subregion. This principle was also noted by Lagnese [La] in contrapositive form. Indeed, Bardos, Lebeau, and Rauch [BLR2] showed by means of microlocal analysis that the "geometric optics condition" is necessary and sufficient for exact controllability/UEDP of a second-order hyperbolic PDE with locally distributed control/damping when the coefficients and the boundary are of class C^∞. The C^∞ condition recently has been relaxed by Burq [Bu1], by proving that the C^3 condition is sufficient.

In practice, the problem of optimal location of the controllers/dampers for the system modelled by the CPDE is more significant. When choosing as the cost function for this optimal design problem the integral of the energy over infinite time, we must select the admissible locations of the controllers/dampers so that exact controllability/UEDP can be achieved. This also leads to our problem.

In this paper, by introducing the frequency domain inequality and the piecewise multiplier method for frequency domain, we get a sufficient condition for the subregion on which the application of control/damping will yield exact controllability/UEDP of any of the wave equation, the Petrovsky equation, and the Schrödinger equation on a not necessarily smooth region. We illustrate the applicability of our result with a simple example. Consider the wave equation on a triangular region. It follows readily from our result that applying control/damping on an ϵ-neighborhood (in the region) of a straight line passing through any vertex and across the triangle is sufficient for exact controllability/UEDP (see Remark 4.3 for other examples). This provides a sufficient number of admissible locations for the optimal location problem. We point out that this example is not covered under the cases studied in Bardos, Lebeau, and Rauch [BLR2], Burq [Bu1], and Zuazua [Li2, Chap. 7]. Our sufficient condition is formulated in terms of general sets and vectors in $\mathbb{R}^N$, like the result in Zuazua [Li2, Chap. 7]. The "geometric optics condition" is formulated in terms of complicated vector bundles. Thus, for a nondisk region, it is not easy to check whether the "geometric optics condition" is satisfied, although it is easy to make a conjecture directly, based on its meaning in optics.

In section 2 we exhibit in a semigroup framework the equivalence between controllability and stabilizability for a conservative system, as well as necessary and sufficient conditions for both. The regularity of the control steering the system from a smoother state to zero state is also discussed. In section 3, the results in section 2 are applied to a second-order elastic system with control/damping. A frequency domain characterization for exact controllability is given. We consider the wave equation in section 4, and the Schrödinger and Petrovsky equations in section 5. A sufficient geometric control condition and piecewise multiplier techniques are developed. It is discovered that exact controllability of the wave equation with Dirichlet boundary condition implies exact controllability of the Petrovsky equation with the simply supported boundary condition, and also that the latter is equivalent to exact controllability of the Schrödinger equation with Dirichlet boundary condition.

Some consequences of our results (Remarks 4.3(b), 5.4, and 5.5) give answers to several conjectures posed by Chen et al. in [CFNS]. We also point out that the frequency domain inequality introduced in this paper has been applied to the Maxwell equation and the Kirchhoff plate-like equation to establish exact internal controllability [Zh], [LY].

2. Equivalence between controllability and stabilizability; necessary and sufficient conditions. Let $\mathcal{H}$ and $\mathcal{U}$ be Hilbert spaces. Consider the control system $(\mathcal{A}, \mathcal{B})$,

$$y(u,t) = e^{t\mathcal{A}}y_0 + \int_0^t e^{(t-s)\mathcal{A}}\mathcal{B}u(s)ds, \tag{2.1}$$

where $\mathcal{A}$ generates a C_0-semigroup $e^{t\mathcal{A}}$ on $\mathcal{H}$, $\mathcal{B} \in \mathcal{L}(\mathcal{U};\mathcal{H})$, $y_0 \in \mathcal{H}$.

DEFINITION 2.1. *The system $(\mathcal{A}, \mathcal{B})$ is said to be exactly controllable on $[0,T]$ if for every $y_0, y_1 \in \mathcal{H}$ there exists $u(\cdot) \in L^2(0,T;\mathcal{U})$ such that $y(u,0) = y_0$, $y(u,T) = y_1$; it is said to be exponentially stabilizable if there exists $\mathcal{K} \in \mathcal{L}(\mathcal{H};\mathcal{U})$ such that $\mathcal{A}+\mathcal{B}\mathcal{K}$ generates an exponentially stable C_0-semigroup on $\mathcal{H}$.*

Remark 2.2. When $\mathcal{A}$ is the infinitesimal generator of a C_0-group on $\mathcal{H}$, (uniform) exact controllability on some $[0,T]$, defined in Definition 2.1, is equivalent to exact null-controllability on $[0,T]$ ($y_1 \equiv 0$ in Definition 2.1) and to exact controllability on $[0,\infty)$. (For every $y_0, y_1 \in \mathcal{H}$ there exist $T > 0$ and $u(\cdot) \in L^2(0,T;\mathcal{U})$ such that $y(u,0) = y_0$, $y(u,T) = y_1$; see Zabczyk's Proposition 1 in [Za].) Thus, in this case we can generally say that the system $(\mathcal{A},\mathcal{B})$ is exactly controllable.

THEOREM 2.3. *Let $\mathcal{A}^* = -\mathcal{A}$, $\mathcal{B} \in \mathcal{L}(\mathcal{U};\mathcal{H})$. Then the following propositions are equivalent:*

(a) *The system $(\mathcal{A},\mathcal{B})$ is exponentially stabilizable with an arbitrary prefixed exponential decay rate.*
(b) *The system $(\mathcal{A},\mathcal{B})$ is exponentially stabilizable.*
(c) *For every positive-definite self-adjoint $\mathcal{S} \in \mathcal{L}(\mathcal{U})$ the operator $\mathcal{A} - \mathcal{B}\mathcal{S}\mathcal{B}^*$ generates an exponentially stable C_0-semigroup on $\mathcal{H}$.*
(d) *The system $(\mathcal{A},\mathcal{B})$ is exactly controllable.*
(e) *(observability inequality) There exist $T, \delta > 0$ such that*

$$\int_0^T \|\mathcal{B}^* e^{t\mathcal{A}} y\|^2 dt \geq \delta \|y\|^2 \quad \forall\ y \in \mathcal{H}. \tag{2.2}$$

(f) *The following frequency domain condition holds:*

$$i\mathbb{R} \subset \rho(\mathcal{A} - \mathcal{B}\mathcal{B}^*), \quad \textit{the resolvent set of } \mathcal{A} - \mathcal{B}\mathcal{B}^*, \tag{2.3}$$

$$\sup\{\|(\lambda - \mathcal{A} + \mathcal{B}\mathcal{B}^*)^{-1}\| \mid \lambda \in i\mathbb{R}\} < +\infty. \tag{2.4}$$

Proof. (a)⇒(b) This is obvious.

(b)⇒(c) For every positive-definite self-adjoint $\mathcal{S} \in \mathcal{L}(\mathcal{U})$ we consider the following algebraic inner product Riccati equation in $\mathcal{H}$:

$$\langle Py, -\mathcal{A}z\rangle + \langle -\mathcal{A}y, Pz\rangle + \langle \mathcal{C}y, \mathcal{C}z\rangle - \langle P\mathcal{B}\mathcal{R}^{-1}\mathcal{B}^* Py, z\rangle = 0, \quad P \geq 0, \tag{2.5}$$

for any $y, z \in D(\mathcal{A})$, where $\mathcal{C} = \mathcal{S}^{\frac{1}{2}}\mathcal{B}^*, \mathcal{R}^{-1} = \mathcal{S}$. It is obvious that $P = I$ is a solution. By (b) there is a $\mathcal{K} \in \mathcal{L}(\mathcal{H};\mathcal{U})$ such that $\mathcal{A} + \mathcal{B}\mathcal{K}$, and therefore its adjoint operator $-\mathcal{A} + \mathcal{K}^*\mathcal{S}^{-\frac{1}{2}}\mathcal{C}$, generates an exponentially stable C_0-semigroup on $\mathcal{H}$. This says that $(\mathcal{C}, -\mathcal{A})$ is detectable. It follows from Zabczyk's Theorem 1^o in [Za] that $-\mathcal{A} - \mathcal{B}\mathcal{R}^{-1}\mathcal{B}^* I$, and, hence, its adjoint operator $\mathcal{A} - \mathcal{B}\mathcal{S}\mathcal{B}^*$, generates an exponentially stable C_0-semigroup on $\mathcal{H}$.

(c)⇒(d) This follows from Russell's "controllability via stabilizability" [Ru1], [Ru2] and also from Theorem 2.4 in this section.

(d)⇒(e) This follows from $\|e^{t\mathcal{A}}\| = 1$ and the well-known necessary and sufficient condition for exact controllability.

(e)⇒(a) See Slemrod [S].

(c)⇒(f)⇒(b) Proposition (f) is equivalent to exponential stability of the semigroup $e^{t(\mathcal{A} - \mathcal{B}\mathcal{B}^*)}$, from the result in Gearhart [Ge] or Huang [Hu] or Prüss [Pr]. □

THEOREM 2.4. *Let $\mathcal{A}$ be the infinitesimal generator of a C_0-group on $\mathcal{H}$, and $\omega_0(-\mathcal{A}) = \lim_{t\to+\infty} t^{-1} \ln \|e^{-t\mathcal{A}}\|$, the type of $e^{-t\mathcal{A}}$. Let $\mathcal{B} \in \mathcal{L}(\mathcal{U};\mathcal{H})$. Then the system $(\mathcal{A},\mathcal{B})$ is exactly controllable if and only if there exist $\mathcal{K} \in \mathcal{L}(\mathcal{H};\mathcal{U}), \mu > \omega_0(-\mathcal{A})$, and $M_\mu > 0$ such that*

$$\left\| e^{t(\mathcal{A} + \mathcal{B}\mathcal{K})} \right\| \leq M_\mu e^{-\mu t} \quad \forall\ t \geq 0. \tag{2.6}$$

Proof. Also see Slemrod [S] for the case of necessity. Let

$$J = J(T) = e^{-T\mathcal{A}}e^{T(\mathcal{A}+\mathcal{B}\mathcal{K})}. \tag{2.7}$$

From (2.6) there exists $T > 0$ large enough such that $\|J\| = \|J(T)\| < 1$. Thus $(I-J)^{-1} \in \mathcal{L}(\mathcal{H})$. For every $y_0 \in \mathcal{H}, t \in [0,T]$, set

$$z_1(t) = e^{t(\mathcal{A}+\mathcal{B}\mathcal{K})}(I-J)^{-1}y_0, \quad z_2(t) = e^{t\mathcal{A}}[I-(I-J)^{-1}]y_0. \tag{2.8}$$

From the formula for perturbations of C_0-semigroups [Pa] we have

$$y(t) \equiv z_1(t) + z_2(t) = e^{t\mathcal{A}}y_0 + \int_0^t e^{(t-s)\mathcal{A}}\mathcal{B}\mathcal{K}z_1(t)ds. \tag{2.9}$$

Observing that $y(0) = y_0$ and

$$y(T) = e^{T\mathcal{A}}[J(I-J)^{-1} + I - (I-J)^{-1}]y_0 = 0, \tag{2.10}$$

we conclude that the control

$$u(\cdot) = \mathcal{K}z_1(\cdot) = \mathcal{K}e^{\cdot(\mathcal{A}+\mathcal{B}\mathcal{K})}(I-J)^{-1}y_0 \in C([0,T];\mathcal{U}) \tag{2.11}$$

steers the system $(\mathcal{A},\mathcal{B})$ from the initial state y_0 to rest at time T. □

It should be noted that μ in (2.6) can be negative when $\omega_0(-\mathcal{A}) < 0$.

Theorem 2.4 is an improvement of a known result on exact controllability of the system with time reversibility (see Theorem 3.14 in the survey article [PZ]). Our proof is suggested by Russell's "controllability via stabilizability" method. Taking advantage of the structure of the control in (2.11), we get the following regularity result.

THEOREM 2.5. *Let $\mathcal{A}$ and $\mathcal{B}$ be the same as in Theorem* 2.4. *If the system $(\mathcal{A},\mathcal{B})$ is exactly controllable then, for every $y_0 \in D(\mathcal{A})$, there exists $u(\cdot) \in C^1([0,T_1];\mathcal{U})$ with $T_1 > 0$ independent of y_0 such that $y(u,T_1) = 0$ and $y(u,\cdot) \in C^1([0,T_1];\mathcal{H}) \cap C([0,T_1];D(\mathcal{A}))$ strictly satisfies the differential equation in $\mathcal{H}$,*

$$\begin{cases} \dot{y}(t) = \mathcal{A}y(t) + \mathcal{B}u(t), & t \in [0,T_1], \\ y(0) = y_0. \end{cases} \tag{2.12}$$

Proof. From Theorem 2.4 there exist $\mathcal{K} \in \mathcal{L}(\mathcal{H};\mathcal{U}), \mu > \omega_0(-\mathcal{A})$, and $M_\mu > 0$ such that (2.6) holds. Let $J(T)$ and $u(\cdot)$ be defined by (2.7) and (2.11), respectively. Since

$$\begin{aligned} &(\mu+\mathcal{A})J(T)(\mu+\mathcal{A})^{-1} \\ &= e^{-T\mathcal{A}}(\mu+\mathcal{A})(\lambda-\mathcal{A}-\mathcal{B}\mathcal{K})^{-1}e^{T(\mathcal{A}+\mathcal{B}\mathcal{K})}(\lambda-\mathcal{A}-\mathcal{B}\mathcal{K})(\mu+\mathcal{A})^{-1} \end{aligned}$$

for some $\lambda > -\mu$ and all $T > 0$, and since

$$(\mu+\mathcal{A})(\lambda-\mathcal{A}-\mathcal{B}\mathcal{K})^{-1}, \ (\lambda-\mathcal{A}-\mathcal{B}\mathcal{K})(\mu+\mathcal{A})^{-1} \in \mathcal{L}(\mathcal{H}), \tag{2.13}$$

there exists a fixed $T_1 > 0$, sufficiently large, such that

$$\|J_1\| < 1, \quad \|(\mu+\mathcal{A})J_1(\mu+\mathcal{A})^{-1}\| < 1 \tag{2.14}$$

where $J_1 = J(T_1)$. Thus, for every $y_0 \in D(\mathcal{A})$,

$$(I-J_1)^{-1}y_0 = (\mu+\mathcal{A})^{-1}[I-(\mu+\mathcal{A})J_1(\mu+\mathcal{A})^{-1}]^{-1}(\mu+\mathcal{A})y_0 \in D(\mathcal{A}), \tag{2.15}$$

and, therefore, the control

$$u(\cdot) = \mathcal{K}e^{\cdot(\mathcal{A}+\mathcal{B}\mathcal{K})}(I-J_1)^{-1}y_0 \in C^1([0,T_1];\mathcal{H}) \tag{2.16}$$

satisfies all the requirements from the proof of Theorem 2.4 and from the well-known result on the regularity of the mild solution of (2.12). □

3. Frequency domain characterization for the exact controllability of second-order systems. Let H be a Hilbert space with the norm $\|\cdot\|$ and the inner product $\langle\cdot,\cdot\rangle$. We consider the second-order system with control

$$\ddot{w}(t) + Aw(t) = Bu(t), \quad t > 0, \tag{3.1}$$

$$w(0) = w_0, \quad \dot{w}(0) = w_1, \tag{3.2}$$

where A is a positive-definite, self-adjoint operator with defined domain $D(A) \subset H$, and $B \in \mathcal{L}(\mathcal{U}; H)$. It is clear that $V = D(A^{\frac{1}{2}})$ is also a Hilbert space with norm $\|\cdot\|_V = \|A^{\frac{1}{2}}\cdot\|$. Introduce the state space

$$\mathcal{H} = D(A^{\frac{1}{2}}) \times H \tag{3.3}$$

with the inner product induced by the energy norm

$$\langle (f_1, g_1), (f_2, g_2)\rangle_{\mathcal{H}} = \langle A^{\frac{1}{2}} f_1, A^{\frac{1}{2}} f_2\rangle + \langle g_1, g_2\rangle \tag{3.4}$$

for $(f_j, g_j) := (f_j, g_j)^T \in \mathcal{H},\ j = 1, 2$. (Throughout this paper we omit the symbol of transposition and use a row vector to denote the actual column vector.) It is obvious that $\mathcal{H}$ is a Hilbert space with inner product (3.4). In $\mathcal{H}$, define

$$\mathcal{A} = \begin{bmatrix} 0 & I \\ -A & 0 \end{bmatrix} \quad \text{with} \quad D(\mathcal{A}) = D(A) \times D(A^{\frac{1}{2}}), \tag{3.5}$$

and define $\mathcal{B} :\ \mathcal{U} \to \mathcal{H}$,

$$\mathcal{B}u = (0,\ Bu) \quad \forall\ u \in \mathcal{U}, \tag{3.6}$$

$$y_0 = (w_0, w_1). \tag{3.7}$$

Then we have that $\mathcal{A}^* = -\mathcal{A},\ \mathcal{B} \in \mathcal{L}(\mathcal{U}, \mathcal{H})$. We also have the following lemma showing that (2.1) is the variation-of-parameters formula for the first-order system reduced from (3.1).

LEMMA 3.1. *Let $\mathcal{A}, \mathcal{B}, y_0$ be defined as above and $y(u,t) = (w(t), w_1(t))$ be given by* (2.1). *If $y_0 \in \mathcal{H}$ and $u(\cdot) \in L^2_{loc}(0,\infty;\mathcal{U})$, then*

$$w(\cdot) \in C^1([0,\infty); H) \cap C([0,\infty); V),\ \ \dot{w}(\cdot) = w_1(\cdot) \tag{3.8}$$

satisfies the variational evolution equation

$$\frac{d}{dt}\langle \dot{w}(t), v\rangle + \langle A^{\frac{1}{2}} w(t), A^{\frac{1}{2}} v\rangle = \langle Bu(t), v\rangle\ \ \forall\, v \in V,\ \ a.e.\ \ t \in (0,\infty), \tag{3.9}$$

with initial state (3.2). *The associated energy is conservative when $u(\cdot) = 0$, i.e.,*

$$E(t) \equiv \frac{1}{2}\left(\|A^{\frac{1}{2}} w(t)\|^2 + \|\dot{w}(t)\|^2\right) = E(0) \quad \forall\ t \geq 0. \tag{3.10}$$

Moreover, if $y_0 \in D(\mathcal{A})$ and $u(\cdot) \in C^1([0,\infty);\mathcal{U})$, then a classical solution of the Cauchy problem (3.1)–(3.2) *satisfies*

$$w(\cdot) \in C^2([0,\infty); H) \cap C^1([0,\infty); V) \cap C([0,\infty); D(A)). \tag{3.11}$$

Proof. The lemma follows straightforwardly from C_0-semigroup theory and a standard limit argument. We omit the details. □

For every positive-definite, self-adjoint $\mathcal{K} \in \mathcal{L}(\mathcal{U})$, it can also be verified that the closed-loop system in $\mathcal{H}$,

$$\dot{y}(t) = (\mathcal{A} - \mathcal{B}\mathcal{K}\mathcal{B}^*)y(t) = \begin{bmatrix} 0 & I \\ -A & -B\mathcal{K}B^* \end{bmatrix} y(t), \tag{3.12}$$

is the first-order reduction of the damped second-order system in H,

$$\ddot{w}(t) + B\mathcal{K}B^*\dot{w}(t) + Aw(t) = 0, \tag{3.13}$$

which results from setting $y(t) = (w(t), \dot{w}(t))$.

The second-order system (3.1) is said to be *exactly controllable in* $\mathcal{H}$ if its first-order reduction, $(\mathcal{A}, \mathcal{B})$, is exactly controllable. The damped system (3.13) is said to possess the UEDP of energy if there exist $\mu > 0, M_\mu > 0$ such that

$$E(t) \equiv \frac{1}{2}\left(\|A^{\frac{1}{2}}w(t)\|^2 + \|\dot{w}(t)\|^2\right) \leq M_\mu e^{-\mu t}E(0) \quad \forall\ t \geq 0 \tag{3.14}$$

for every solution $w(\cdot)$ of (3.13) with initial state $(w(0), \dot{w}(0)) \in \mathcal{H}$. Obviously, the system (3.13) possesses UEDP of energy if and only if $\mathcal{A} - \mathcal{B}\mathcal{K}\mathcal{B}^*$ generates an exponentially stable C_0-semigroup on $\mathcal{H}$. As an immediate consequence of Theorem 2.3, we have Theorem 3.2.

THEOREM 3.2. *The following statements are equivalent:*

(a) *The second-order system* (3.1) *is exactly controllable in* $\mathcal{H}$.

(b) *The damped system* (3.13) *possesses UEDP of energy.*

(c) *(observability inequality) There exist* $T, \delta > 0$ *such that*

$$\int_0^T \|B^*\dot{w}(t)\|^2 dt \geq 2\delta E(0) \tag{3.15}$$

for every solution $w(\cdot)$ *of* (3.1) *with* $u(\cdot) = 0$ *and the initial state* $(w(0), \dot{w}(0)) \in \mathcal{H}$.

To characterize the frequency domain condition we need the following lemma.

LEMMA 3.3. *Let* $\mathcal{A}_B \equiv \mathcal{A} - \mathcal{B}\mathcal{B}^* = \left[\begin{smallmatrix} 0 & I \\ -A & -BB^* \end{smallmatrix}\right]$, *and define, in* H, $\Delta(\lambda) = \lambda^2 + \lambda BB^* + A$ *with* $D(\Delta(\lambda)) = D(A)$ *for* $\lambda \in \mathbb{C}$. *Then*

(a) $\lambda \in \rho(\mathcal{A}_B)$ *if and only if* $\Delta(\lambda)$ *has inverse* $\Delta^{-1}(\lambda) \in \mathcal{L}(H)$. *Moreover, for* $\lambda \in \rho(\mathcal{A}_B)$,

$$(\lambda - \mathcal{A}_B)^{-1} = \begin{bmatrix} \Delta^{-1}(\lambda)(\lambda + BB^*) & \Delta^{-1}(\lambda) \\ \lambda\Delta^{-1}(\lambda)(\lambda + BB^*) - I & \lambda\Delta^{-1}(\lambda) \end{bmatrix}; \tag{3.16}$$

(b) $0 \in \rho(\mathcal{A}_B)$, *and* $\mathcal{A}_B$ *has compact resolvent whenever* A *has;*

(c) *Let* $\Lambda = i(-\alpha, \alpha) \subset \rho(\mathcal{A}_B)$ *for some* $\alpha > 0$. *If there exists a constant* $M > 0$ *such that*

$$\sup\left\{\|A^{\frac{1}{2}}\Delta^{-1}(\lambda)\|_{\mathcal{L}(H)} \mid \lambda \in \Lambda\right\} \leq M, \tag{3.17}$$

then there exists a corresponding constant $C = C(A, B, M) > 0$ *such that*

$$\sup\left\{\|(\lambda-\mathcal{A}_B)^{-1}\|_{\mathcal{L}(\mathcal{H})} \mid \lambda\in\Lambda\right\}\le C. \tag{3.18}$$

Proof. (a) For $\lambda\in\mathbb{C}$, $(f,g)\in\mathcal{H}$, $(u,v)\in D(\mathcal{A}_B)$, we consider the resolvent equation

$$(\lambda-\mathcal{A}_B)(u,v)=(f,g). \tag{3.19}$$

This equation is equivalent to

$$\begin{cases} v=\lambda u-f,\\ \Delta(\lambda)u=g+(\lambda+BB^*)f. \end{cases} \tag{3.20}$$

If $\lambda\in\rho(\mathcal{A}_B)$, then for every $(f,g)\in\mathcal{H}$ there exists a unique $(u,v)\in D(\mathcal{A}_B)=D(A)\times D(A^{\frac12})$ such that (3.19) holds and, hence, that (3.20) holds. Taking $f=0$, we find that $\mathrm{Ker}\Delta(\lambda)=\{0\}$ and $R(\Delta(\lambda))=H$. From the closed graph theorem we have $\Delta^{-1}(\lambda)\in\mathcal{L}(H)$, and therefore (3.16) follows from (3.20). Conversely, if $\Delta^{-1}(\lambda)\in\mathcal{L}(H)$, then (3.20) yields (3.16). Thus $(\lambda-\mathcal{A}_B)^{-1}\in\mathcal{L}(H), \lambda\in\rho(\mathcal{A}_B)$.

(b) This follows from $\Delta^{-1}(0)=A^{-1}$ and (3.16).

(c) If (3.17) holds, then we have

$$\|A^{\frac12}\Delta^{-1}(\lambda)f\|\le M\|f\| \quad\forall\ \lambda\in\Lambda,\ \ f\in H. \tag{3.21}$$

Let $u=\Delta^{-1}(\lambda)f$. Since

$$\lambda^2\|u\|^2+\langle\lambda BB^*u,u\rangle+\|A^{\frac12}u\|^2=\langle f,u\rangle,$$

we have

$$\begin{aligned}\|\lambda u\|^2&\le\|A^{\frac12}u\|^2+\|\lambda u\|\,\|BB^*A^{-\frac12}\|\,\|A^{\frac12}u\|+\|A^{-\frac12}\|\,\|A^{\frac12}u\|\,\|f\|\\ &\le\frac12\|\lambda u\|^2+\left(2+\frac12\|BB^*A^{-\frac12}\|^2\right)\|A^{\frac12}u\|^2+\frac14\|A^{-\frac12}\|^2\|f\|^2,\end{aligned}$$

where $\|\cdot\|$ also denotes the norm in $\mathcal{L}(H)$. Thus there is a positive constant $M_2=M_2(A,B,M)$ such that

$$\|\lambda\Delta^{-1}(\lambda)f\|\le M_2\|f\| \quad\forall\ \lambda\in\Lambda,\ \ f\in H. \tag{3.22}$$

Observing that

$$[I-\lambda\Delta^{-1}(\lambda)(\lambda+BB^*)]^*=[\Delta^{-1}(\lambda)A]^*=A\Delta^{-1}(\bar\lambda)\in\mathcal{L}(H),$$

we obtain

$$\|[\lambda\Delta^{-1}(\lambda)(\lambda+BB^*)-I]A^{-\frac12}f\|\le M\|f\| \quad\forall\ \lambda\in\Lambda,\ \ f\in H. \tag{3.23}$$

Let $u_1=\lambda\Delta^{-1}(\lambda)A^{-\frac12}f$. We then have

$$\begin{aligned}\|\lambda u_1\|&\le M\|f\|+\|\lambda\Delta^{-1}(\lambda)\|\,\|BB^*A^{-\frac12}f\|+\|A^{-\frac12}f\|\\ &\le(M+M_2\|BB^*A^{-\frac12}\|+\|A^{-\frac12}\|)\|f\|\end{aligned}$$

and

$$\lambda^2\|u_1\|^2 + \langle \lambda BB^* u_1, u_1\rangle + \|A^{\frac{1}{2}}u_1\|^2 = \langle \lambda A^{-\frac{1}{2}} f, u_1\rangle.$$

Therefore, there is a constant $M_1 = M_1(A, B, M) > 0$ such that

$$\|\lambda A^{\frac{1}{2}}\Delta^{-1}(\lambda)A^{-\frac{1}{2}} f\| = \|A^{\frac{1}{2}}u_1\| \le M_1\|f\| \quad \forall\ \lambda \in \Lambda,\ \ f \in H. \tag{3.24}$$

Combining (3.16), (3.21)–(3.24), we know that there exists $C = C(A, B, M) > 0$ such that (3.18) holds. The proof is complete. □

THEOREM 3.4. *The system* (3.1) *is exactly controllable in* $V \times H$ *if and only if there exists a constant* $\delta > 0$ *such that the following frequency domain inequality holds:*

$$\|(\omega^2 - A)u\| + \|\omega BB^* u\| \ge \delta\|A^{\frac{1}{2}}u\| \quad \forall\ \omega \in \mathbb{R},\ \ u \in D(A), \tag{3.25}$$

or equivalently, there exists $\delta' > 0$ *such that*

$$\|(\omega^2 - A)u\| + \|\omega BB^* u\| \ge \delta'\|\omega u\| \quad \forall\ \omega \in \mathbb{R},\ \ u \in D(A). \tag{3.26}$$

Proof. It is easy to verify the equivalence of (3.25) and (3.26) by a contradiction argument. The inequality (3.25) is also equivalent to

$$\|\Delta(i\omega)u\| \ge \delta_0\|A^{\frac{1}{2}}u\| \quad \forall\ \omega \in \mathbb{R},\ \ u \in D(A) \tag{3.27}$$

for some $\delta_0 > 0$, where Δ is the same as in Lemma 3.3. In fact, (3.27) implies (3.25) immediately. On the other hand, if (3.27) is not valid, then there exist $\omega_n \in \mathbb{R}, u_n \in D(A)$ with $\|A^{\frac{1}{2}}u_n\| = 1$ such that $\Delta(i\omega_n)u_n = (-\omega_n^2 + i\omega_n BB^* + A)u_n \to 0$ in H. Observing that

$$-\|\omega_n u_n\|^2 + 1 = \mathrm{Re}\langle \Delta(i\omega_n)u_n, u_n\rangle \to 0, \tag{3.28}$$

we have

$$\langle BB^*\omega_n u_n, \omega_n u_n\rangle = \mathrm{Im}\langle \Delta(i\omega_n)u_n, \omega_n u_n\rangle \to 0. \tag{3.29}$$

This implies that $\omega_n BB^* u_n \to 0$ in H. Hence, $(-\omega_n^2 + A)u_n \to 0$ in H and (3.25) is not valid, either. Thus, from Theorem 2.3, we need only prove that the inequality (3.27) is necessary and sufficient for (2.3)–(2.4) with $\mathcal{A}$ and $\mathcal{B}$ defined by (3.5)–(3.6).

From Lemma 3.3(a), (2.3)–(2.4) obviously implies (3.27). On the other hand, from Lemma 3.3(c) it suffices to show that if (3.27) holds, then $i\mathbb{R} \subset \rho(\mathcal{A}_B)$, where $\mathcal{A}_B = \mathcal{A} - \mathcal{B}\mathcal{B}^*$. Since $0 \in \rho(\mathcal{A}_B)$, there exists $\alpha_0 > 0$ such that $i(-\alpha_0, \alpha_0) \subset \rho(\mathcal{A}_B)$. Let

$$\Lambda_n = i\left(-\alpha_0 - \frac{n}{2C}\ ,\ \alpha_0 + \frac{n}{2C}\right),\ \ n = 0, 1, 2, \ldots, \tag{3.30}$$

where $C = C(A, B, \frac{1}{\delta_0})$ is determined by Lemma 3.3(c) with $\Lambda := \Lambda_0$. Suppose $\Lambda_n \subset \rho(\mathcal{A}_B)$. Then by (3.27) we have (3.18) with $\Lambda := \Lambda_n$ and C independent of n. For any $\lambda \in \Lambda_{n+1}$, there is $\mu \in \Lambda_n$ such that $|\lambda - \mu| < \frac{2}{3C}$. This, combined with (3.18), yields

$$\left[I + (\lambda - \mu)(\mu - \mathcal{A}_B)^{-1}\right]^{-1} \in \mathcal{L}(\mathcal{H}), \tag{3.31}$$

and hence,

$$(\lambda - \mathcal{A}_B)^{-1} = (\mu - \mathcal{A}_B)^{-1}\left[I + (\lambda - \mu)(\mu - \mathcal{A}_B)^{-1}\right]^{-1} \in \mathcal{L}(\mathcal{H}). \tag{3.32}$$

We have proved that $\Lambda_n \subset \rho(\mathcal{A}_B)$ implies that $\Lambda_{n+1} \subset \rho(\mathcal{A}_B)$. By the induction principle we know that

$$\Lambda_n \subset \rho(\mathcal{A}_B) \quad \forall\, n = 0, 1, 2, \ldots. \tag{3.33}$$

Therefore, $i\mathbb{R} \subset \rho(\mathcal{A}_B)$. The proof is complete. □

In the next two sections we will use the following comparison theorem for exponential stability of C_0-semigroups of contractions on *Hilbert* spaces.

THEOREM 3.5. *Suppose that L generates an exponentially stable C_0-semigroup of contractions on a Hilbert space H. If $F \in \mathcal{L}(H)$ satisfies*

(F1) $\mathrm{Re}\langle Fy, y\rangle \le 0 \ \forall\ y \in H$,

(F2) $\mathrm{Re}\langle Fy_n, y_n\rangle \to 0 \Rightarrow \|Fy_n\| \to 0$ *for any sequence* $\{y_n\}_{n\in\mathbf{N}}$ *in* H,

then the semigroup $e^{t(L+F)}$ is also exponentially stable.

We omit the proof because the frequency domain condition [Hu] can be verified by following the contradiction argument in [CFNS]. If F is symmetric and nonpositive, the conditions (F1) and (F2) are naturally satisfied.

4. Control and damping for the wave equation. Consider the wave equation with locally distributed control/damping

$$\ddot{w}(t) - \Delta w(t) = \chi_G(x)u(x,t) \quad \text{in} \quad \Omega \times \mathbb{R}^+, \tag{4.1}_c$$

$$\ddot{w}(t) + d(x)\dot{w}(t) - \Delta w(t) = 0 \quad \text{in} \quad \Omega \times \mathbb{R}^+ \tag{4.1}_d$$

with the boundary and initial conditions

$$w = 0 \quad \text{on} \quad \partial\Omega \times \mathbb{R}^+, \tag{4.2}$$

$$w(x,0) = w_0(x), \quad \dot{w}(x,0) = w_1(x), \quad x \in \Omega, \tag{4.3}$$

where Ω is a bounded open subset in $\mathbb{R}^N$ with the Lipschitz boundary $\partial\Omega$, $G \subset \Omega$ is an L-measurable set, $\chi_G(\cdot)$ is the characteristic function of the set G, $0 \le d(\cdot) \in L^\infty(\Omega)$. A measurable subset D of supp$d(\cdot)$ is said to be an effective damping region of $(4.1)_d$ if there is a constant $d_0 > 0$ such that $d(x) \ge d_0$ on D. The system $(4.1)_c$–(4.2) can be rewritten in the form (3.1) by setting

$$H = \mathcal{U} = L^2(\Omega), \quad Bu = \chi_G(\cdot)u(\cdot), \ \ u \in \mathcal{U},$$
$$A = -\Delta \quad \text{with} \quad D(A) = \{w \in H_0^1(\Omega) \mid \Delta w \in H\}.$$

We refer the reader to [A] and [Gr] for a discussion of Sobolev spaces. It is easy to see that $A^* = A \ge 0$, $V \equiv D(A^{\frac{1}{2}}) = H_0^1(\Omega)$, and

$$\|A^{\frac{1}{2}}v\| = \| \, |\nabla v| \, \| \ge C(\Omega)\|v\| \quad \forall\ v \in V, \tag{4.4}$$

where $C(\Omega)$ is the Poincaré constant. Thus, from the Rellich–Kondrachov embedding theorem we know that $A^{-\frac{1}{2}}, A^{-1}$ are compact operators on H. Moreover, setting $B_d \in \mathcal{L}(H)$, $B_d v = d(\cdot)v(\cdot)$ for $v \in H$, we can rewrite $(4.1)_d$–(4.2) as

$$\ddot{w}(t) + B_d\dot{w}(t) + Aw(t) = 0, \quad t > 0. \tag{4.5}$$

G is said to be a control region giving exact controllability of $(4.1)_c$–(4.2) if the corresponding system (3.1) is exactly controllable in $\mathcal{H} = V \times H$. An effective damping region D is said to be the one giving the UEDP of $(4.1)_d$–(4.2) if the corresponding (4.5) has the UEDP of energy, defined analogously by (3.14). Applying Theorems 3.2 and 3.5 we immediately obtain the following theorem.

THEOREM 4.1. *Every $D \supset G$ is an effective damping region giving UEDP of $(4.1)_d$–(4.2) if G is a control region giving exact controllability of $(4.1)_c$–(4.2).*

We now assume that the following geometric conditions hold on Ω and G:

(g, Ω): Ω is either convex or of class $C^{1,1}$;

(g, G): There exist open sets $\Omega_j \subset \Omega$ with Lipschitz boundary $\partial\Omega_j$ and points $x_0^j \in \mathbb{R}^N$, $j = 1, 2, \ldots, J$, such that $\Omega_i \cap \Omega_j = \emptyset$ for any $1 \le i < j \le J$ and

$$G \supset \Omega \bigcap \mathcal{N}_\epsilon \left[\left(\bigcup_{j=1}^{J} \Gamma_j \right) \bigcup \left(\Omega \setminus \bigcup_{j=1}^{J} \Omega_j \right) \right] \tag{4.6}$$

for some $\epsilon > 0$ where

$$\mathcal{N}_\epsilon[S] := \bigcup_{x \in S} \{ y \in \mathbb{R}^N \mid |y - x| < \epsilon \} \quad \text{for } S \subset \mathbb{R}^N, \tag{4.7}$$

$$\Gamma_j = \{ x \in \partial\Omega_j \mid (x - x_0^j) \cdot \nu^j(x) > 0 \} \tag{4.8}$$

with $\nu^j(x)$, the unit normal vector of $\partial\Omega_j$ at x pointing towards the exterior of Ω_j, defined a.e. on $\partial\Omega_j$ and being in $L^\infty(\partial\Omega_j;\ \mathbb{R}^N)$ (cf. [A], [Gr]).

THEOREM 4.2. *If the geometric conditions (g, Ω) and (g, G) are satisfied, then G is a control region giving exact controllability of $(4.1)_c$–(4.2).*

Remark 4.3. We list several pairs of regions, (Ω, G), which satisfy the geometric conditions (g, Ω) and (g, G).

(a) Let $x = (y, z)$ with $y \in \mathbb{R}^{n-1}$ and $z \in \mathbb{R}$, Ω^{-1} be an open subset in $\mathbb{R}^{n-1}$, $f_1(y)$ and $f_2(y)$ be real-valued functions defined on $\overline{\Omega^{-1}}$, $f_1(y) < f_2(y)$ for all $y \in \Omega^{-1}$, and $f_1(y) = f_2(y) = 0$ for all $y \in \partial\Omega^{-1}$. Let $\Omega = \{(y, z) \mid y \in \Omega^{-1},\ f_1(y) < z < f_2(y)\}$ satisfy (g, Ω), which implies $f_1, f_2 \in C^{0,1}_{loc}(\Omega^{-1}) \cap C(\overline{\Omega^{-1}})$. Then $G = \Omega \cap \mathcal{N}_\epsilon[\{(y, z) | z = 0\}]$ for any $\epsilon > 0$ satisfies (g, G) with $J = 2$, $\Omega_1 = \{(y, z) \mid y \in \Omega^{-1},\ f_1(y) < z < -\epsilon/4\}$, $\Omega_2 = \{(y, z) \mid y \in \Omega^{-1}, \epsilon/4 < z < f_2(y)\}$, and $x_0^j = (y_0, z_j)$, where $y_0 \in \mathbb{R}^{n-1}$, $z_1 < 0$ small enough, and $z_2 > 0$ large enough.

Let $G = \Omega \cap \mathcal{N}_\epsilon[S]$ with $S = \{(y, z) | z = 0\}$ and any $\epsilon > 0$. We note the invariability of (g, Ω) and (g, G) under translation and rotation of coordinates, and we show some specific cases of (a) as follows:

(a1) Ω is a convex subset in $\mathbb{R}^2$ and S is one of the longest diameters of Ω;

(a2) Ω is an ellipsoid and S is one of the principal planes of Ω;

(a3) Ω is a convex quadrilateral in plane and S is either one of the straight lines passing through opposite vertices of Ω.

(b) Let Ω be a rectangle and S be two straight lines which are parallel to adjacent sides of the rectangle, respectively, and which intersect at a point in Ω. Then $G = \Omega \cap \mathcal{N}_\epsilon[S]$, for any $\epsilon > 0$, satisfies (g, G) with $J = 4$, Ω_j being subrectangles consisting of $\partial\Omega$ and S, x_0^j being vertices of the rectangle. Thus from Theorems 4.1 and 4.2 we know that the conjecture posed in [CFNS, pp. 288–289] is true.

(c) When $J = 1$ and $\Omega_1 = \Omega$ is of class C^2, Theorem 4.2 was given by Zuazua [Li2, Chap. 7].

Let

$$x = (x_1, x_2, \dots, x_n), \quad x_0^j = (x_{01}^j, x_{02}^j, \dots, x_{0n}^j),$$
$$m^j = (m_1^j, m_2^j, \dots, m_n^j), \quad m_k^j = x_k - x_{0k}^j, \ \ k = 1, 2, \dots, n,$$
$$D_k u = \frac{\partial u}{\partial x_k}, \quad \nu^j = (\nu_1^j, \nu_2^j, \dots, \nu_n^j), \ \ j = 1, 2, \dots, J.$$

We use the summation convention for repeated lower indices k and l. Then we recall that Green's formula is valid on any bounded open subset Ω' of $\mathbb{R}^N$ with Lipschitz boundary (see [Gr]), i.e.,

$$\int_{\Omega'} (vD_k u + uD_k v)dx = \int_{\partial\Omega'} uv\nu_k' d\sigma \quad \forall \ u, v \in H^1(\Omega'). \tag{4.9}$$

For every real-valued $\phi^j \in C_0^\infty(\mathbb{R}^N)$ and complex-valued $u \in H^2(\Omega_j)$, we apply (4.9) to get

$$\begin{aligned} \mathrm{Re}\int_{\Omega_j} \phi^j u m_k^j D_k \bar{u} dx &= \frac{1}{2}\int_{\partial\Omega_j} \phi^j(\nu^j \cdot m^j)|u|^2 d\sigma \\ &\quad -\frac{1}{2}\int_{\Omega_j} (n\phi^j + m_k^j D_k\phi^j)|u|^2 dx, \\ \mathrm{Re}\int_{\Omega_j} \phi^j m_k^j D_l u D_l D_k \bar{u} dx &= \frac{1}{2}\int_{\partial\Omega_j} \phi^j(\nu^j \cdot m^j)|\nabla u|^2 d\sigma \\ &\quad -\frac{1}{2}\int_{\Omega_j} (n\phi^j + m_k^j D_k\phi^j)|\nabla u|^2 dx. \end{aligned} \tag{4.10}$$

Hence,

$$\begin{aligned} \mathrm{Re}\int_{\Omega_j} \phi^j(\Delta u) m_k^j D_k \bar{u} dx &= \int_{\Omega_j} \phi^j \left(\frac{n}{2} - 1\right)|\nabla u|^2 dx + \mathrm{Re} X_j \\ &+ \ \mathrm{Re}\int_{\partial\Omega_j} \phi^j \left[(\nu^j \cdot \nabla u) m_k^j D_k \bar{u} - \frac{1}{2}(\nu^j \cdot m^j)|\nabla u|^2\right] d\sigma, \end{aligned} \tag{4.11}$$

where

$$X_j = \int_{\Omega_j} m_k^j \left(\frac{1}{2} D_k\phi^j |\nabla u|^2 - D_l\phi^j D_l u D_k \bar{u}\right) dx, \quad j = 1, \dots, J. \tag{4.12}$$

Proof of Theorem 4.2. We shall verify the frequency domain inequality (3.25) for A and B defined in this section. From the regularity results on elliptic problems [Gr] we know that the geometric condition (g, Ω) implies

$$D(A) = H^2(\Omega) \cap H_0^1(\Omega). \tag{4.13}$$

If (3.25) fails, there exist $\omega_p \in \mathbb{R}$, $u_p \in D(A)$, $p \in \mathbf{N}$, with

$$\|A^{\frac{1}{2}} u_p\|^2 = \int_\Omega |\nabla u_p|^2 dx = 1 \tag{4.14}$$

such that $\|(\omega_p^2 - A)u_p\| + \|\omega_p BB^* u_p\| \to 0$ as $p \to \infty$; i.e.,

$$\int_G |\omega_p u_p|^2 \, dx \to 0, \tag{4.15}$$

$$\omega_p^2 u_p + \Delta u_p \equiv f_p \to 0 \quad \text{in } L^2(\Omega). \tag{4.16}$$

Then, (4.4), (4.14), and (4.16) imply

$$\left| \frac{\omega_p}{C(\Omega)} \right|^2 \geq \int_\Omega |\omega_p u_p|^2 \, dx \to 1. \tag{4.17}$$

Let

$$S = \left(\bigcup_{j=1}^J \Gamma_j \right) \bigcup \left(\Omega \setminus \bigcup_{j=1}^J \Omega_j \right), \quad Q = \mathcal{N}_{\epsilon_o}[S] \tag{4.18}$$

for some $0 < \epsilon_0 < \epsilon$. Choose a fixed $\xi \in C_0^\infty(\mathbb{R}^N)$ satisfying $0 \leq \xi \leq 1$, $\xi = 1$ on $\overline{Q}$, and $\text{supp}\xi \subset \mathcal{N}_\epsilon[S]$. Then we have $\Omega \cap \text{supp}\xi \subset \Omega \cap \mathcal{N}_\epsilon[S] \subset G$ and $\xi = 1$ on $G_0 \equiv \Omega \cap Q$. It follows from (4.14)–(4.17) that

$$\begin{aligned} \int_{G_0} |\nabla u_p|^2 dx &\leq \int_\Omega \xi |\nabla u_p|^2 dx \\ &\leq |\langle f_p, \, \xi u_p \rangle| + \int_G (\xi |\omega_p u_p|^2 + |(\nabla \xi \cdot \nabla u_p)\bar{u}_p|) \, dx \to 0, \end{aligned} \tag{4.19}$$

$$\lim_{p \to \infty} \int_{\Omega \setminus G_0} |\nabla u_p|^2 dx = \lim_{p \to \infty} \int_{\Omega \setminus G_0} |\omega_p u_p|^2 dx = 1. \tag{4.20}$$

For Ω_j we can choose $0 \leq \phi^j \in C_0^\infty(\mathbb{R}^N)$ such that $\phi^j = 1$ on $\overline{\Omega}_j \cap Q^C$ and $\text{supp}\phi^j \subset \mathcal{N}_{\epsilon_1}[S]^C$, $j = 1, \ldots, J$, for some $0 < \epsilon_1 < \epsilon_0$. Here the notation Y^C means the relative complement $\mathbb{R}^N \setminus Y$ of any subset Y of $\mathbb{R}^N$. It is then easy to see that

$$\begin{cases} \displaystyle\int_{\Omega_j} m_k^j D_k \phi^j |\omega_p u_p|^2 dx = \int_{\Omega_j \cap Q} m_k^j D_k \phi^j |\omega_p u_p|^2 dx \to 0, \\ X_{j,p} \to 0, \end{cases} \tag{4.21}$$

where $X_{j,p} := X_j$ is defined by (4.12) with $u := u_p$. Multiplying (4.16) by $\phi^j m_k^j D_k \bar{u}_p$, then integrating on Ω_j, by (4.10)–(4.15), (4.19), (4.21) and the characteristics of ϕ^j, we obtain

$$\begin{aligned} \int_{\Omega_j \cap Q^C} |\nabla u_p|^2 dx &= \frac{n}{2} \int_{\Omega_j \cap Q^C} (|\nabla u_p|^2 - |\omega_p u_p|^2) dx + o(1)_j \\ &+ \int_{\partial \Omega_j} \phi^j (\nu^j \cdot \nabla u_p) m_k^j D_k \bar{u}_p \, d\sigma - \frac{1}{2} \int_{\partial \Omega_j} \phi^j (\nu^j \cdot m^j)(|\nabla u_p|^2 - |\omega_p u_p|^2) d\sigma, \end{aligned} \tag{4.22}$$

where $o(1)_j \to 0$ as $p \to \infty$, $j = 1, 2, \ldots, J$. Let $S_j = \Gamma_j \cup (\partial \Omega_j \cap \Omega)$. Then $u_p = 0$ on $\partial \Omega_j \setminus S_j \subset \partial \Omega \cap \Gamma_j^C$. This, when combined with (4.8), leads to

$$\nabla u_p = (\nu^j \cdot \nabla u_p) \nu^j \quad \text{and} \quad (m^j \cdot \nu^j) \leq 0 \quad \text{a.e. on } \partial \Omega_j \setminus S_j. \tag{4.23}$$

Applying (4.23) and $\phi^j = 0$ on $S_j \subset S$, we know that (4.22) implies

$$\int_{\Omega_j \cap Q^C} |\nabla u_p|^2 dx \le \frac{n}{2} \int_{\Omega_j \cap Q^C} (|\nabla u_p|^2 - |\omega_p u_p|^2) dx + o(1)_j. \tag{4.24}$$

It is easy to verify that $\Omega = \bigcup_{j=1}^J (\Omega_j \cup G_0)$, $\Omega \setminus G_0 = \bigcup_{j=1}^J (\Omega_j \cap Q^C)$. Hence, it follows from (4.24) that

$$\begin{aligned} \int_{\Omega \setminus G_0} |\nabla u_p|^2 dx &= \sum_{j=1}^J \int_{\Omega_j \cap Q^C} |\nabla u_p|^2 dx \\ &\le \frac{n}{2} \int_{\Omega \setminus G_0} (|\nabla u_p|^2 - |\omega_p u_p|^2) dx + o(1). \end{aligned} \tag{4.25}$$

This contradicts (4.20). The proof is complete. □

From the interior regularity of the solution of an elliptic equation [GT], the argument from (4.14) to (4.22) is also valid for $S = \partial\Omega$, $\Omega_j = \Omega$ even if both (g, Ω) and (g, G) are false. Therefore, we have the following theorem.

THEOREM 4.4. *$\Omega \cap \mathcal{N}_\epsilon(\partial\Omega)$ is always a control region giving exact controllability of $(4.1)_c$–(4.2).*

On the other hand, we next give a negative result which shows that the location of the control region is more essential than its size for exact controllability.

THEOREM 4.5. *Let Ω_1, Ω_2 be bounded open sets in $\mathbb{R}^m, \mathbb{R}^n$, respectively, and $\Omega = \Omega_1 \times \Omega_2 \subset \mathbb{R}^{m+n}$. Let G_1 be any nonempty open subset of Ω_1 and let Ω_2 have Lipschitz boundary. Then a control region G satisfying $G \cap (G_1 \times \Omega_2) = \emptyset$ is never the one giving exact controllability of $(4.1)_c$–(4.2).*

Proof. It is well known that the eigenproblem

$$-\Delta_y \psi = \omega^2 \psi, \quad \omega \in \mathbb{R}, \psi \in H_0^1(\Omega_2), \tag{4.26}$$

has a sequence of solutions (ω_p^2, ψ_p) such that

$$\omega_p^2 \to +\infty \quad \text{and} \quad \int_{\Omega_2} |\psi_p|^2 dy = 1. \tag{4.27}$$

Choose a fixed $\phi(x) \in C_0^\infty(\Omega_1)$ such that

$$\text{supp}\phi \subset G_1 \quad \text{and} \quad \int_{\Omega_1} |\phi|^2 dx = 1. \tag{4.28}$$

Set $u_p(x, y) = \phi(x)\psi_p(y)$. We then have

$$\begin{aligned} u_p \in D(A), \ \ \|u_p\|_\Omega = 1, \ \ BB^* u_p = \chi_G u_p = 0 \ \ \text{in } \Omega, \\ \|(\omega_p^2 - A)u_p\|_\Omega^2 = \|(\omega_p^2 + \Delta_x + \Delta_y)u_p\|_\Omega^2 = \int_{\Omega_1} |\Delta_x \phi|^2 dx. \end{aligned}$$

Hence, the frequency domain inequality (3.26) fails. □

Remark 4.6. When $\dim \Omega_2 = n = 1$, Theorem 4.5 can be deduced from Haraux's Proposition 1.4.1 in [Ha3] by means of Lions's HUM [Li1], [Li2]. We see that the size of the control region G can be arbitrarily close to that of the whole region Ω in Theorem 4.5.

Remark 4.7. From Theorem 4.2 in this section and the result in [BLR2] or [Bu1] we can conclude that the condition (g, G) implies the "geometric optics condition" when $\partial\Omega$ is sufficiently smooth. However, we have not been able to prove this by using geometric argument, except when Ω is the disk. To our knowledge, the following problem remains open: is a control region G whose closure is contained in the open convex set Ω with smooth boundary never the one giving exact controllability of $(4.1)_c$–(4.2)?

Remark 4.8. Thanks to the fact that in applications the frequency domain inequality (3.25) involves only elliptic problems, the regularity condition (g, Ω) posed on Ω can be replaced by the condition that Ω is either a curvilinear polygon of class $C^{1,\alpha}$ or an open set in $\mathbb{R}^N$ of class $C^{1,\alpha}$ for some $0 < \alpha < 1$ (Bian, Chen, and Liu [BCL]).

5. Control and damping for the Schrödinger and Petrovsky equations. Consider the controlled/damped Schrödinger equation with Dirichlet boundary condition

$$(Sch)_c \qquad \begin{cases} \dot{w} + i\Delta w = \chi_G \cdot u & \text{in } \Omega \times \mathbb{R}^+, \\ w = 0 & \text{on } \partial\Omega \times \mathbb{R}^+, \end{cases}$$

$$(Sch)_d \qquad \begin{cases} \dot{w} + i\Delta w - d(x)w = 0 & \text{in } \Omega \times \mathbb{R}^+, \\ w = 0 & \text{on } \partial\Omega \times \mathbb{R}^+ \end{cases}$$

and the controlled/damped Petrovsky equation with the simply supported boundary condition

$$(Pet)_c \qquad \begin{cases} \ddot{w} + \Delta^2 w = \chi_G \cdot u & \text{in } \Omega \times \mathbb{R}^+, \\ w = \Delta w = 0 & \text{on } \partial\Omega \times \mathbb{R}^+, \end{cases}$$

$$(Pet)_d \qquad \begin{cases} \ddot{w} + d(x)\dot{w} + \Delta^2 w = 0 & \text{in } \Omega \times \mathbb{R}^+, \\ w = \Delta w = 0 & \text{on } \partial\Omega \times \mathbb{R}^+. \end{cases}$$

Using the same notation as in section 4 we can rewrite the four above equations as the following abstract equations in H:

$$(Sch)'_c \qquad \dot{w}(t) = iAw(t) + Bu(t), \quad t > 0,$$

$$(Sch)'_d \qquad \dot{w}(t) = (iA - B_d)w(t), \quad t > 0,$$

$$(Pet)'_c \qquad \ddot{w}(t) + A^2 w(t) = Bu(t), \quad t > 0,$$

$$(Pet)'_d \qquad \ddot{w}(t) + B_d\dot{w}(t) + A^2 w(t) = 0, \quad t > 0.$$

By an argument analogous to those in section 4, we first have the following theorem.

THEOREM 5.1. *Every $D \supset G$ is an effective damping region giving UEDP of $(Sch)_d$, respectively, $(Pet)_d$, if G is a control region giving exact controllability of $(Sch)_c$, respectively, $(Pet)_c$.*

We show the relationship between exact controllability of the two systems $(Pet)_c$, $(Sch)_c$ and $(4.1)_c$–(4.2) by the following more general theorem.

THEOREM 5.2. *Consider the abstract systems $(Sch)'_c$, $(Pet)'_c$, and* (3.1) *with the same operators A and B. Then exact controllability of* (3.1) *in $D(A^{\frac{1}{2}}) \times H$ implies*

exact controllability of $(Pet)'_c$ *in* $D(A) \times H$*, and the latter is equivalent to exact controllability of* $(Sch)'_c$*.*

Proof. If the system (3.1) is exactly controllable in $D(A^{\frac{1}{2}}) \times H$, then from Theorem 3.4 there exists a constant $\delta > 0$ such that

$$\|\omega^{-1}(\omega^2 - A)u\| + \|BB^*u\| \geq \delta\|u\| \quad \forall\ u \in D(A),\ \ 0 \neq \omega \in \mathbb{R}. \tag{5.1}$$

Observing that $\omega^4 - A^2 = (\omega^2 + A)(\omega^2 - A)$ and

$$|\omega|^{-1}(\omega^2 + A) \geq 2\|A^{-\frac{1}{2}}\|^{-1}I \quad \forall\ 0 \neq \omega \in \mathbb{R},$$

we have that (5.1) implies

$$\|\omega^{-2}(\omega^4 - A^2)u\| + \|BB^*u\| \geq \delta_1\|u\|, \quad \forall\ u \in D(A^2),\ \ 0 \neq \omega \in \mathbb{R}, \tag{5.2}$$

where $\delta_1 = \delta \min\{1, 2\|A^{-\frac{1}{2}}\|^{-1}\}$. Again, from Theorem 3.4, we see that the system $(Pet)'_c$ is exactly controllable in $D(A) \times H$.

According to Theorem 2.3(e), the system $(Sch)'_c$ is exactly controllable if and only if there exist $T, \delta > 0$ such that

$$\int_0^T \|B^* e^{t(iA)} w_0\|^2 dt \geq \delta\|w_0\|^2 \quad \forall\ w_0 \in H. \tag{5.3}$$

Inequality (5.3) is equivalent to

$$\int_0^T \|B^* A e^{t(iA)} w_0\|^2 dt \geq \delta\|Aw_0\|^2 \quad \forall\ w_0 \in D(A^2) \tag{5.4}$$

because $D(A^2)$ is dense in $D(A)$ with the norm $\|A \cdot\|$. Set $w(t) = e^{t(iA)}w_0$ for $w_0 \in D(A^2)$. Then $\dot{w}(t) = iAe^{t(iA)}w_0$ and $\ddot{w}(t) = -A^2 w(t)$ for $t \geq 0$. Therefore, from Theorem 3.2(c) we find that (5.4) holds for some $T, \delta > 0$ if $(Pet)'_c$ is exactly controllable in $D(A) \times H$. The inverse proposition follows readily from the inequality

$$\|\omega^{-2}(\omega^4 - A^2)u\| \geq \|i(\omega^2 - A)u\| \quad \forall\ u \in D(A^2),\ \ 0 \neq \omega \in \mathbb{R},$$

and the frequency domain characterization for exact controllability. ∎

Remark 5.3. Liu and Yu [LY] have shown by means of the frequency domain inequality (3.25) that exact controllability of the Kirchhoff plate equation with the simply supported-like boundary condition is equivalent to exact controllability of the wave equation with Dirichlet boundary condition.

Remark 5.4. From Theorems 4.4, 5.1, and 5.2 we know that the conjecture about $(Sch)_d$ posed in [CFNS, p. 284] is valid and that the assumption they made concerning the convexity of Ω is not necessary.

Remark 5.5. It follows from Theorems 5.1 and 5.2 and Jaffard's result [J] that the damped system $(Sch)_d$ has UEDP when Ω is a rectangle and when the effective damping region D has nonempty interior. (Compare with Theorem 4.5; also see Burq [Bu2] for exact boundary controllability in the absence of the "geometric optics condition.") This gives a negative answer to the conjecture posed in [CFNS, p. 279].

Remark 5.6. For the case in which B is a nonnegative self-adjoint operator on H, Theorem 3.2 was proved by Haraux [Ha1]. This special case is sufficient for Theorems 4.1 and 5.1.

Acknowledgment. The author would like to thank Professor Xunjing Li for his helpful discussions.

RAPID BOUNDARY STABILIZATION OF LINEAR DISTRIBUTED SYSTEMS*

VILMOS KOMORNIK†

Abstract. We prove that under rather general assumptions an exactly controllable problem is uniformly stabilizable with arbitrarily prescribed decay rates. Our approach is direct and constructive and avoids many of the technical difficulties associated with the usual methods based on Riccati equations. We give several applications for the wave equation and for Petrovsky systems.

Key words. observability, controllability, stabilizability by feedback, partial differential equation, wave equation, Petrovsky system

1. Introduction.

Let Ω be a nonempty bounded open set in $\mathbb{R}^n$ having a boundary Γ of class C^2, and consider the following problem:

$$y'' - \Delta y = 0 \quad \text{in} \quad \Omega \times (0,\infty), \tag{1.1}$$

$$y(0) = y_0 \quad \text{and} \quad y'(0) = y_1 \quad \text{in} \quad \Omega, \tag{1.2}$$

$$y = u \quad \text{on} \quad \Gamma \times (0,\infty). \tag{1.3}$$

Considering u as a control function, a natural problem is to seek stabilizing feedback laws $u = F(y, y')$. In order to motivate our work, let us recall the following theorem of Lions [31, Theorem 10.1] (below, we shall denote by ν the outward unit normal vector to Γ).

THEOREM. *There exist two linear maps*

$$P : H^{-1}(\Omega) \to H_0^1(\Omega), \qquad Q : L^2(\Omega) \to H_0^1(\Omega) \tag{1.4}$$

and two positive constants M and ω such that, putting

$$u = \partial_\nu (Py' + Qy), \tag{1.5}$$

the problem (1.1), (1.2), (1.3), (1.5) *is well posed in $\mathcal{H} := L^2(\Omega) \times H^{-1}(\Omega)$, and its solutions satisfy the estimates*

$$\|(y(t), y'(t))\|_{\mathcal{H}} \le M \|(y_0, y_1)\|_{\mathcal{H}} e^{-\omega t} \tag{1.6}$$

for all $t \ge 0$ and for all $(y_0, y_1) \in \mathcal{H}$.

Several remarks are in order.

(a) This theorem was proved by applying a general and systematic approach based on the optimal control theory. Several other results of this type were also given in [31], and many more were provided by Lasiecka and Triggiani in [27]. See also [4], [5], and [42] for related results.

*Received by the editors April 8, 1996; accepted for publication June 25, 1996. Some results of this paper were announced earlier without proof in [*C. R. Acad. Sci. Paris Sér.* I *Math.*, 321 (1995), pp. 433–437, 581–586].

(b) This approach does not lead to any estimate of the constants ω and M: we have uniform exponential decay but with unknown speed.

(c) The existence of stabilizing operators P and Q was established without constructing them: they are obtained (in principle) by solving infinite-dimensional Riccati equations.

(d) Compared with the related problem of exact controllability, for which a simple and elegant approach (the Hilbert uniqueness method (HUM)) was introduced in [31], the above method of stabilization is technically much more involved. From a purely esthetic point of view, there is no reason for the stabilization problem to be much more difficult than the controllability problem.

In this paper we propose another approach for the stabilization, which is similar in spirit to the HUM. This method is as general as the former one; however, it provides stronger results with simpler proofs. For example, in section 4 this method will give the following improvement of Lions's theorem.

THEOREM. *Fix $\omega > 0$ arbitrarily (large). Then there exist two linear maps P and Q satisfying* (1.4) *and a positive constant M such that the problem* (1.1), (1.2), (1.3), (1.5) *is well posed in $\mathcal{H} := L^2(\Omega) \times H^{-1}(\Omega)$ and its solutions satisfy the estimates* (1.6) *for all $t \geq 0$ and for all $(y_0, y_1) \in \mathcal{H}$.*

The main novelty is that ω may be prescribed as large as we like. Furthermore, we shall construct the operators P and Q explicitly, and we shall also obtain an estimate of the constant M.

Let us remark at this point that many works were devoted to the construction of explicit boundary feedback laws and to the proof of exponential decay by the multiplier method or by microlocal analysis; see, e.g., [2], [3], [6], [14], [19], [24], [25], [31], [35], [39], [40]. Sometimes this approach led to good decay rate estimates with relatively elementary proofs; see, e.g., [16], [20], [21]. For example, for the wave equation above, the usual feedback law has the form

$$\begin{gathered} y = 0 \quad \text{on} \quad \Gamma_0 \times (0, \infty), \\ \partial_\nu y + ay + by' = 0 \quad \text{on} \quad \Gamma_1 \times (0, \infty), \end{gathered}$$

where Γ_0, Γ_1 is a partition of Γ and $a, b \in L^\infty(\Gamma_1)$ are given nonnegative functions. With this type of feedback (to our knowledge) no decay estimate was obtained with $\omega > 1/(2R)$, where R is the radius of the smallest open ball containing Ω (except the trivial one-dimensional case, however; see, e.g., the introduction of [19]). In any case, it follows from a recent result of Koch and Tataru [14] that in dimension $n \geq 2$ we cannot have arbitrarily large decay rate ω by using this type of feedback.

In order to explain the novelty of our approach, let us briefly recall Lions's proof of the above theorem. It consists of three steps.

First step: Observability of the dual problem. Consider the problem (1.1)–(1.3) with $u = 0$. Then the "observation" of the normal derivative of the solution during some time T allows one to determine the initial data y_0, y_1 provided T is sufficiently large. In technical terms, we have the equivalence of two norms:

$$\|(y_0, y_1)\|_{H_0^1(\Omega) \times L^2(\Omega)} \sim \|\partial_\nu y\|_{L^2(\Gamma \times (0,T))}.$$

Second step: Controllability of the primal problem. By duality, it follows from the preceding result that for any given initial data $(y_0, y_1) \in L^2(\Omega) \times H^{-1}(\Omega)$ there exists a function $u \in L^2(\Gamma \times (0, T))$ such that the solution of (1.1)–(1.3) satisfies

$$y(T) = y'(T) = 0 \quad \text{in} \quad \Omega.$$

Third step: Stabilization of the primal problem. Consider the "cost function"

$$J(y,u) := \int_0^\infty \int_\Omega y^2 \; dx \; dt + \int_0^\infty \int_\Gamma u^2 \; d\Gamma \; dt$$

defined on the set of pairs (y,u) satisfying (1.1)–(1.3). Thanks to the preceding step, this cost function has finite values, and hence its infimum is achieved at a unique pair (y,u). Applying the theory of optimal control, one can show that y and u are connected by (1.4) and (1.5). Finally, the estimate (1.6) follows by applying a theorem of Datko from the theory of semigroups.

Our main idea is to shortcut the implication chain

$$\text{observability} \Rightarrow \text{controllability} \Rightarrow \text{stabilization}$$

and to prove directly the implication

$$\text{observability} \Rightarrow \text{stabilization}.$$

As we shall see, our construction is analogous to the HUM, applied in [31] and [32] for the proof of the implication

$$\text{observability} \Rightarrow \text{controllability}.$$

The plan of the paper is as follows. For the reader's convenience and in order to compare our approach with the HUM, in the next section we recall briefly some basic notions and results (in the form needed later) on observability and controllability.

Section 3 is devoted to the proof of an abstract stabilization theorem.

In the rest of the paper (sections 4–7) we shall apply this theorem to the boundary stabilization of the wave equation and of a Petrovsky system.

2. Observability and controllability. A review. Consider a linear evolutionary problem

$$x' = Ax + Bu, \qquad x(0) = x_0, \tag{2.1}$$

where A is a densely defined, closed linear operator in some Hilbert space H, and B is a bounded linear operator of another Hilbert space G into $D(A^*)'$. Let us also consider the dual problem

$$\varphi' = -A^*\varphi, \qquad \varphi(0) = \varphi_0, \qquad \psi = B^*\varphi, \tag{2.2}$$

where A^*, B^* denote the adjoints of A and B. In control-theoretical terminology, B is a control operator, u is a control, and B^* is an observability operator.

Assume that the following three hypotheses are satisfied (we denote by G', H' the (anti)dual spaces of G and H).

(H1) The operator A^* generates a *group* e^{sA^*} in H';

(H2) There exist a *bounded* linear operator $E \in L(G,H)$ and a number $\lambda \in \mathbf{C}$ such that $B^* = E^*(A+\lambda I)^*$;

(H3) There exist two positive numbers T' and c' such that

$$\|\psi\|_{L^2(0,T';G')} \le c' \|\varphi_0\|_{H'}$$

for all $\varphi_0 \in D(A^*)$.

Let us explain these assumptions. In applications, hypothesis (H1) is usually satisfied for time-reversible problems.

Hypothesis (H2) can be considered as a weakening of the boundedness of B. Indeed, if B is bounded, then we may choose $E = (A + \lambda I)^{-1}B$, where $-\lambda$ is an arbitrary number in the resolvent set of A. In the bounded control case many results are available; see, e.g., [1], [11], [29], and [38]. On the other hand, in boundary control problems the operator B is usually unbounded, and this leads to serious difficulties. As was demonstrated in [27], the hypothesis (H2) is still satisfied for a large class of boundary control problems. (See also the applications in the second half of this paper.)

Finally, hypothesis (H3) is a regularity property: this corresponds to the so-called *direct inequality* in the terminology of HUM.

Let us begin by discussing the well-posedness of the problems (2.1) and (2.2).

It follows from (H1) that for every $\varphi_0 \in H'$ the equation in (2.2) has a unique solution $\varphi \in C(\mathbb{R}; H')$, and that $\varphi \in C^1(\mathbb{R}; H') \cap C(\mathbb{R}; D(A^*))$ if $\varphi_0 \in D(A^*)$. In particular, using (H2), we see that hypothesis (H3) is meaningful.

Furthermore, (H1)–(H3) imply the following strengthened version of (H3): for every $T > 0$, there exists a constant c_T such that the solutions of (2.2) satisfy the estimates

$$\|\psi\|_{L^2(-T,T;L^2(G'))} \le c_T \|\varphi_0\|_{H'} \tag{2.3}$$

for all $\varphi_0 \in D(A^*)$. Extending this inequality by continuity, we obtain that $\psi \in L^2_{loc}(\mathbb{R}; G')$ and ψ satisfies (2.3) for all $\varphi_0 \in H'$. This result also shows that the value of T' in (H3) has no importance: if it is satisfied for *some* $T' > 0$, then in fact it is satisfied for *every* $T' > 0$.

Next we *define* the solutions of (2.1) by transposition. Fix $x_0 \in H$ and $u \in L^2_{loc}(\mathbb{R}; G)$ arbitrarily. Multiply the equation in (2.1) by the solution φ of the equation in (2.2). Integrating by parts formally between 0 and $T \in \mathbb{R}$, we easily obtain the identity

$$\langle x(T), \varphi(T)\rangle_{H,H'} = \langle x_0, \varphi_0\rangle_{H,H'} + \int_0^T \langle u(s), \psi(s)\rangle_{G,G'}\, ds. \tag{2.4}$$

Hence we define a solution of (2.1) as a *continuous* function $x : \mathbf{R} \to H$ satisfying the identity (2.4) for all $\varphi_0 \in H'$ and for all $T \in \mathbb{R}$. This definition is justified by the following lemma.

LEMMA 2.1. *Given $x_0 \in H$ and $u \in L^2_{loc}(\mathbb{R}; G)$ arbitrarily, the problem* (2.1) *has a unique solution. Moreover, we have the estimates*

$$\|x\|_{L^\infty(-T,T;H)} \le c_T(\|x_0\|_H + \|u\|_{L^2(-T,T;G)}) \tag{2.5}$$

for all $T > 0$.

Proof. Thanks to the inequality (2.3), the right-hand side of (2.4) defines a bounded linear form of $\varphi_0 \in H'$. It follows from hypothesis (H1) that the map $\varphi_0 \mapsto \varphi(T)$ is an automorphism of H'; therefore the right-hand side of (2.4) is also a bounded linear form of $\varphi(T) \in H'$. Since $H'' = H$, we conclude the existence of a unique $x(T) \in H$ satisfying (2.4).

Since the bounded linear form of φ_0 defined by the right-hand side of (2.4) and the automorphism $\varphi_0 \mapsto \varphi(T)$ both depend continuously on $T \in \mathbb{R}$, the function $x : \mathbb{R} \to H$ is also continuous.

Finally, the estimates (2.5) follow easily from (2.4). □

Next we introduce some notions of controllability and observability.

DEFINITIONS. Let $T > 0$.

(1) The problem (2.1) is called *exactly null-controllable* in time T if for every given initial state $x_0 \in H$ there exists a function $u \in L^2_{loc}(\mathbb{R}; G)$ such that

$$\|u\|_{L^2(0,T;G)} \leq c\|x_0\|_H,$$

and that the solution of (2.1) satisfies the final condition $x(T) = 0$. (We say that the *control* u drives the system to rest in time T.)

(2) The problem (2.1) is called *exactly controllable* in time T if for every *pair* of data $x_0, x_1 \in H$ there exists a function $u \in L^2_{loc}(\mathbb{R}; G)$ such that

$$\|u\|_{L^2(0,T;G)} \leq c'(\|x_0\|_H + \|x_1\|_H),$$

and that the solution of (2.1) satisfies the final condition $x(T) = x_1$. (The control u drives the system from the initial state x_0 to the state x_1 in time T.)

(3) The problem (2.2) is called *exactly observable* in time T if

$$\|\varphi_0\|_{H'} \leq c''\|\psi\|_{L^2(0,T;G')} \tag{2.6}$$

for all $\varphi_0 \in D(A^*)$.

Observe that (2.6) is the inverse inequality to that in hypothesis (H3). Contrary to hypothesis (H3), in (2.6) the value of T is important. One can readily verify the existence of a number $0 \leq T_0 \leq \infty$ such that (2.6) is satisfied for all $T > T_0$ and is not satisfied for any $T < T_0$.

The following important result, essentially proved in [7], extends some classical results from the finite-dimensional case (see [29]) and from the case of bounded control operators (see [1]).

THEOREM 2.2. *Assume* (H1)–(H3). *Then, for any given $T > 0$, the following three properties are equivalent.*

(a) *The problem* (2.2) *is exactly observable in time T;*

(b) *The problem* (2.1) *is exactly null-controllable in time T;*

(c) *The problem* (2.1) *is exactly controllable in time T.*

Proof. (a) $\Rightarrow$ (b). Thanks to hypotheses (H1)–(H3) the formula

$$\langle \Lambda\varphi_0, \psi_0\rangle_{H,H'} := \int_0^T \langle JB^*e^{-sA^*}\varphi_0, B^*e^{-sA^*}\psi_0\rangle_{G,G'}\, ds,\ \varphi_0, \psi_0 \in D(A^*),$$

where $J : G' \to G$ denotes the canonical Riesz isomorphism, defines a positive definite self-adjoint operator Λ in $L(H', H)$. Applying the Riesz–Fréchet theorem it follows that Λ is an isomorphism of H' onto H. Now given $x_0 \in H$ arbitrarily, the control

$$u(s) := -JB^*e^{-sA^*}\Lambda^{-1}x_0$$

drives x_0 to rest in time T. Indeed, using the formula (2.4), we have

$$\langle x(T), \varphi(T)\rangle_{H,H'}$$

$$= \langle x_0, \varphi_0\rangle_{H,H'} + \int_0^T \langle u(s), \psi(s)\rangle_{G,G'}\, ds$$

$$= \langle x_0, \varphi_0\rangle_{H,H'} - \int_0^T \langle JB^*e^{-sA^*}\Lambda^{-1}x_0, B^*e^{-sA^*}\varphi_0\rangle_{G,G'}\, ds$$
$$= \langle x_0, \varphi_0\rangle_{H,H'} - \langle \Lambda\Lambda^{-1}x_0, \varphi_0\rangle_{H,H'}$$
$$= 0$$

for all $\varphi_0 \in H'$, and hence $x(T) = 0$. (Note that $\varphi(T)$ runs over H' if φ_0 does.)

(b) $\Rightarrow$ (c). Given $x_0, x_1 \in H$ arbitrarily, let u be a control driving $x_0 - e^{-TA}x_1$ to rest in time T. Since the zero control drives $e^{-TA}x_1$ to x_1 in time T, it follows that the control u drives x_0 to x_1 in time T.

(c) $\Rightarrow$ (a). Fix x_0 arbitrarily and let $u \in L^2(0,T;G)$ be a control satisfying

$$\|u\|_{L^2(0,T;G)} \le c\|x_0\|_H$$

and driving the system (2.1) to rest in time T. Given $\varphi_0 \in H'$ arbitrarily, by (2.4) the solution of (2.2) satisfies the equality

$$\langle x_0, \varphi_0\rangle_{H,H'} = -\int_0^T \langle u(s), \psi(s)\rangle_{G,G'}\, ds.$$

Hence

$$|\langle x_0, \varphi_0\rangle_{H,H'}| \le c\|x_0\|_H\|\psi\|_{L^2(0,T;G')}$$

for all $x_0 \in H$, and therefore

$$\|\varphi_0\|_{H'} \le c\|\psi\|_{L^2(0,T;G')},$$

proving the exact observability of (2.2). □

In [31] and [32] Lions developed a general and systematic approach for the study of exact controllability of linear distributed systems, the so-called HUM. It is based on the implication (a) $\Rightarrow$ (b) of the preceding theorem.

3. Observability and stabilizability. We continue to study the problems (2.1) and (2.2) under the assumptions (H1)–(H3). Moreover, we shall also assume that the problem (2.2) is exactly observable in some time $T > 0$; in other words, we assume that the following hypothesis (H4) is also satisfied.

(H4) There exist two positive numbers T and c such that

$$\|\varphi_0\|_{H'} \le c\|\psi\|_{L^2(0,T;G')}$$

for all $\varphi_0 \in D(A^*)$.

(This is the so-called *inverse inequality* in the terminology of HUM.)

Given an arbitrary real number $\omega > 0$, set $T_\omega = T + (2\omega)^{-1}$, $e_\omega(s) = e^{-2\omega s}$ if $0 \le s \le T$, and $e_\omega(s) = 2\omega e^{-2\omega T}(T_\omega - s)$ if $T \le s \le T_\omega$. It follows from assumptions (H1)–(H4) that the formula (see a note at the end of this paper)

$$\langle \Lambda_\omega\varphi_0, \psi_0\rangle_{H,H'} := \int_0^{T_\omega} e^\omega(s)\langle JB^*e^{-sA^*}\varphi_0, B^*e^{-sA^*}\psi_0\rangle_{G,G'}\, ds, \tag{3.1}$$

where $J : G' \to G$ denotes the canonical Riesz isomorphism, defines a positive definite self-adjoint operator $\Lambda_\omega \in L(H', H)$. Hence Λ_ω is an isomorphism of H' onto H, and the formula

$$\|x\|_\omega := \langle \Lambda_\omega^{-1}x, x\rangle_{H',H}^{1/2}$$

defines an *equivalent* norm in H.

THEOREM 3.1. *Assume* (H1)–(H4) *for some* $T > 0$. *Fix* $\omega > 0$ *arbitrarily and set*

$$F = -JB^*\Lambda_\omega^{-1}. \tag{3.2}$$

Then the operator $A + BF$ *generates a strongly continuous* group *in* H, *and the solutions of the closed-loop problem*

$$x' = Ax + BFx, \qquad x(0) = x_0 \tag{3.3}$$

satisfy the estimate

$$\|x(t)\|_\omega \le \|x_0\|_\omega e^{-\omega t}, \qquad \forall t > 0, \tag{3.4}$$

for all $x_0 \in H$ *and for all* $t \ge 0$.

Remark. The operator $A + BF$ is not an infinitesimal generator of a strongly continuous group in H: it is a densely defined restriction of such a generator, naturally related to the problem (3.3) in a sense explained in [8, pp. 99–100].

In order to explain the main ideas, let us first give a formal proof. (In fact, this proof is entirely correct in the finite-dimensional case.) We write $\Lambda_\omega \in L(H', H)$ in the following form:

$$\Lambda_\omega := \int_0^{T_\omega} e_\omega(s) e^{-sA} BJB^* e^{-sA^*}\, ds.$$

Fix $x_0 \in H$ arbitrarily and consider the solution of (3.2), (3.3). By a simple computation we obtain the following identity:

$$\frac{d}{dt}\langle \Lambda_\omega^{-1} x, x\rangle_{H',H} = \langle \Lambda_\omega^{-1} x, (A\Lambda_\omega + \Lambda_\omega A^* - 2BJB^*)\Lambda_\omega^{-1} x\rangle_{H',H}. \tag{3.5}$$

Since $2\omega e_\omega \le -e_\omega^1$, we have

$$\begin{aligned} A\Lambda_\omega + \Lambda_\omega A^* + 2\omega\Lambda_\omega &\le -\int_0^{T_\omega} \frac{d}{ds}\left(e_\omega(s) e^{-sA} BJB^* e^{-sA^*}\right) ds \\ &= BJB^*. \end{aligned} \tag{3.6}$$

Hence we obtain that

$$A\Lambda_\omega + \Lambda_\omega A^* - 2BJB^* \le -2\omega\Lambda_\omega.$$

(It means that the right-hand side minus the left-hand side is positive semidefinite.) Therefore, we deduce from the identity (3.5) the following inequality:

$$\frac{d}{dt}\langle \Lambda_\omega^{-1} x, x\rangle_{H',H} \le -2\omega \langle \Lambda_\omega^{-1} x, x\rangle_{H',H}.$$

Hence

$$\|x(t)\|_\omega^2 \le \|x_0\|_\omega^2 e^{-2\omega t}$$

for all $t \ge 0$, and the estimate (3.4) follows.

In the general case, the above proof is incorrect because even the strong solutions of (3.2), (3.3) are not sufficiently smooth so as to justify the computations. We shall overcome this difficulty by working with an equivalent integral equation.

We modify the equality (3.6) as follows. Fix $\varphi_0 \in D((A^*)^2)$ arbitrarily and consider the solution φ of (2.2). We have

$$-\|B^*\varphi_0\|_{G'}^2 = \int_0^{T_\omega} \frac{d}{ds}\left(e_\omega(s)\|B^*\varphi(s)\|_{G'}^2\right)\, ds$$

$$= \int_0^{T_\omega} e'_\omega(s)\|B^*\varphi(s)\|_{G'}^2\, ds - \langle \Lambda_\omega\varphi_0, A^*\varphi_0\rangle_{H,H'} - \langle A^*\varphi_0, \Lambda_\omega\varphi_0\rangle_{H',H},$$

and hence

$$\begin{aligned} &-\|B^*\varphi_0\|_{G'}^2 \\ &= \int_0^{T_\omega} e'_\omega(s)\|B^*\varphi(s)\|_{G'}^2\, ds - \langle \Lambda_\omega\varphi_0, A^*\varphi_0\rangle_{H,H'} - \langle A^*\varphi_0, \Lambda_\omega\varphi_0\rangle_{H',H} \end{aligned} \tag{3.7}$$

for all $\varphi_0 \in D(A^*)$ by an obvious density argument. Identifying H' with H, thanks to hypothesis (H3) there exists a nonnegative bounded self-adjoint operator $C \in L(H,H)$ (defined as a square root) such that

$$\|C\Lambda_\omega\varphi_0\|_H^2 = -\int_0^{T_\omega} e'_\omega(s)\|B^*\varphi(s)\|_{G'}^2\, ds \tag{3.8}$$

for all $\varphi_0 \in D(A^*)$. Then we conclude from (3.7) that Λ_ω satisfies the *algebraic Riccati equation*

$$A\Lambda_\omega + \Lambda_\omega A^* - BJB^* + \Lambda_\omega C^*C\Lambda_\omega = 0. \tag{3.9}$$

Thanks to hypothesis (H1)–(H3) we may apply a theorem of Flandoli [8, pp. 99–100] to conclude that Λ_ω^{-1} satisfies the *dual algebraic Riccati equation*

$$\Lambda_\omega^{-1}A + A^*\Lambda_\omega^{-1} - \Lambda_\omega^{-1}BJB^*\Lambda_\omega^{-1} + C^*C = 0 \tag{3.10}$$

in the following weak sense: the operator $A + BF = A - BJB^*\Lambda_\omega^{-1}$ generates (in a sense explained in [8]) a strongly continuous group $U(s)$ in H, and

$$\begin{aligned} \Lambda_\omega^{-1} &= U(t-s)^*\Lambda_\omega^{-1}U(t-s) \\ &+ \int_s^t U(\tau-s)^*(C^*C + \Lambda_\omega^{-1}BJB^*\Lambda_\omega^{-1})U(\tau-s)\, d\tau \end{aligned} \tag{3.11}$$

for all $t, s \in \mathbb{R}$. (In [8] the hypothesis (H2) is used with $\lambda = 0$, but his proof extends easily to the general case.)

Let us explain at least formally, for the convenience of the reader, the equivalence of (3.10) and (3.11). Fixing $s \in \mathbb{R}$ arbitrarily, and denoting by $f(t)$ the difference of the right-hand and left-hand sides of (3.11), we obviously have $f(s) = 0$. Hence (3.11) holds if and only if the derivative $f'(t)$ vanishes identically. Now, using the relation $U' = (A - BJB^*\Lambda_\omega^{-1})U$, a straightforward computation shows that

$$f'(t) = U(t-s)^*(\Lambda_\omega^{-1}A + A^*\Lambda_\omega^{-1} - \Lambda_\omega^{-1}BJB^*\Lambda_\omega^{-1} + C^*C)U(t-s).$$

Hence $f'(t)$ vanishes identically if and only if the equality (3.10) is satisfied.

Since we obviously have (see (3.8))

$$C^*C + \Lambda_\omega^{-1}BJB^*\Lambda_\omega^{-1} \geq C^*C \geq 2\omega\Lambda_\omega^{-1},$$

we deduce from (3.11) the inequality

$$\Lambda_\omega^{-1} \geq U(t-s)^* \Lambda_\omega^{-1} U(t-s) + 2\omega \int_s^t U(\tau - s)^* \Lambda_\omega^{-1} U(\tau - s)\ d\tau$$

for all $t \geq s$.

Now fix $x_0 \in H$ arbitrarily and consider the solution $x = x(t)$ of (3.2), (3.3). It follows from the preceding inequality that

$$\langle \Lambda_\omega^{-1} x(s), x(s) \rangle_{H',H} \geq \langle \Lambda_\omega^{-1} x(t), x(t) \rangle_{H',H} + 2\omega \int_s^t \langle \Lambda_\omega^{-1} x(\tau), x(\tau) \rangle_{H',H}\ d\tau$$

for all $t \geq s$. If we can infer from this estimate the inequality

$$\langle \Lambda_\omega^{-1} x(t), x(t) \rangle_{H',H} \leq \langle \Lambda_\omega^{-1} x_0, x_0 \rangle_{H',H} e^{-2\omega t} \tag{3.12}$$

for all $t \geq 0$, then the proof of Theorem 3.1 can be completed as above. Therefore, it only remains to verify the following simple lemma.

LEMMA 3.2. *Let $f : [0, +\infty) \to \mathbb{R}$ be a continuous function, satisfying for some constant $\omega > 0$ the inequalities*

$$f(s) \geq f(t) + 2\omega \int_s^t f(\tau)\ d\tau \tag{3.13}$$

for all $0 \leq s < t < +\infty$. Then

$$f(t) \leq f(0) e^{-2\omega t} \tag{3.14}$$

for all $t \geq 0$.

Proof of the lemma. Let us first assume that f is continuously differentiable. Dividing the inequality (3.13) by $t - s$ and letting $s \to t$ we obtain easily that

$$f'(t) + 2\omega f(t) \leq 0$$

for all $t \geq 0$. Hence the function $e^{2\omega t} f(t)$ is nonincreasing (its derivative is ≤ 0) and the estimate (3.14) follows.

In the general case we approximate the function f by the sequence of continuously differentiable functions f_k defined by

$$f_k(t) = k \int_t^{t+k^{-1}} f(s)\ ds, \qquad t \geq 0, \qquad k = 1, 2, \ldots.$$

Each function f_k satisfies the inequalities (3.13) with the same constant ω. Therefore $f_k(t) \leq f_k(0) e^{-2\omega t}$ for all $t \geq 0$ and for all k. Letting $k \to +\infty$, the lemma follows. □

COROLLARY 3.3. *Assume* (H1), (H2) *and assume that for some positive constants T, ω, c_1, and c_2 the following inequalities are satisfied:*

$$c_1 \|\varphi_0\|_{H'}^2 \leq \langle \Lambda_\omega \varphi_0, \varphi_0 \rangle_{H,H'} \leq c_2 \|\varphi_0\|_{H'}^2 \tag{3.15}$$

for all $\varphi_0 \in D(A^*)$. Then the operator $A - BJB^* \Lambda_\omega^{-1}$ generates (in the sense of [8]*) a strongly continuous* group *in H, and the solutions of the closed-loop problem*

$$x' = Ax - BJB^* \Lambda_\omega^{-1} x, \qquad x(0) = x_0$$

satisfy the estimate

$$\|x(t)\|_H \le (c_2/c_1)\|x_0\|_H e^{-\omega t} \qquad \forall t > 0, \tag{3.16}$$

for all $x_0 \in H$ *and for all* $t \ge 0$.

Proof. It follows from (3.15) that hypotheses (H3) and (H4) are also satisfied. Since Λ_ω is self-adjoint, (3.15) implies

$$c_1\|\varphi_0\|_{H'} \le \|\Lambda_\omega \varphi_0\|_{H'} \le c_2\|\varphi_0\|_{H'} \tag{3.17}$$

for all $\varphi_0 \in H'$. Therefore, we have

$$\|x_0\|_\omega^2 = \langle \Lambda_\omega^{-1} x_0, x_0\rangle_{H',H} \le \|\Lambda_\omega^{-1}\|\|x_0\|_H^2 \le c_1^{-1}\|x_0\|_H^2$$

and

$$\|x(t)\|_\omega^2 = \langle \Lambda_\omega^{-1} x(t), x(t)\rangle_{H',H} \ge c_1\|\Lambda_\omega^{-1}x(t)\|_{H'}^2 \ge c_1 c_2^{-2}\|x(t)\|_H^2.$$

Substituting these inequalities into (3.4), the inequality (3.16) follows.

Remarks. (1) Let us emphasize the following facts. First of all, given $\omega > 0$ *arbitrarily large*, the proof of Theorem 3.1 allows us to *construct* a feedback law leading to exponential decay with rate ω. Second, in the usual applications (as in the second half of this paper) the constants c_1, c_2 may be computed explicitly, and hence we can obtain explicit estimates of the type (3.16).

(2) A similar method was used earlier by Lukes [34] in the finite-dimensional case. His proof did not extend to the infinite-dimensional case.

(3) Subsequently, Slemrod [38] proved a variant of Theorem 3.1 by assuming instead of (H2) and (H3) that the operator B is bounded. (We recall that this assumption excludes the applications to boundary control.)

(4) There is another, earlier theorem of Lasiecka and Triggiani [27]: under the hypotheses (H1)–(H4) there exists a linear operator F from H into G such that $A+BF$ generates (in a weakened sense) a strongly continuous semigroup of bounded linear operators in H, and there are two positive constants M and ω such that the solutions of the closed-loop problem (3.3) satisfy the estimates

$$\|x(t)\|_H \le M\|x_0\|_H e^{-\omega t} \qquad \forall t > 0,$$

for all $x_0 \in H$ and for all $t \ge 0$. Unlike the results of this section, they did not obtain F explicitly, and they did not obtain estimates of ω and M. On the other hand, they proved the existence of feedback controls for a large class of cost functions. (See the next remark in this respect.)

(5) Let us note that the feedback F of Theorem 3.1 corresponds to the minimization of the cost function

$$\int_0^\infty \|Cx(t)\|_H^2 + \|u(t)\|_G^2 \, dt \tag{3.18}$$

on the set of pairs (x, u) satisfying (2.1). Indeed, applying the optimal control theory as in [27], [29], or [31], one can readily verify that this minimization problem leads to the feedback $F = -JB^*P$ where P is the (unique) solution of the algebraic Riccati equation

$$-A^*P - PA + PBJB^*P = C^*C.$$

It follows from (3.10) that $P = \Lambda_\omega^{-1}$ satisfies this equation, and our assertion follows.

This remark also explains the simplicity of our proof as compared to the usual Riccati approach. Indeed, the Riccati approach works for a large class of cost functions. Being only interested in the construction of feedbacks with good decay properties, we have chosen the very particular cost function (3.18) (which is different from those applied in [31]). Since for this cost function the solution of the corresponding Riccati equation may be found explicitly, we can in fact avoid all difficulties related to the resolution of this equation in the infinite-dimensional case.

4. Application to the wave equation I. Let us consider the problem

$$\begin{cases} y'' - \Delta y = 0 \quad \text{in} \quad \Omega \times \mathbb{R}, \\ y = 0 \quad \text{on} \quad \Gamma_0 \times \mathbb{R}, \\ y = u \quad \text{on} \quad \Gamma_1 \times \mathbb{R}, \\ y(0) = y_0 \quad \text{and} \quad y'(0) = y_1 \quad \text{in} \quad \Omega, \end{cases} \tag{4.1}$$

where Ω is a bounded open set in $\mathbb{R}^n$, Γ_1 is an open subset of its boundary Γ, and $\Gamma_0 = \Gamma \backslash \Gamma_1$. We shall denote by ν the outward unit normal vector to Γ.

Let us assume that Γ is analytic and that Γ_1 satisfies the *geometrical control condition* of Bardos, Lebeau, and Rauch [2], [3]: there exists a positive number T such that every ray of geometrical optics in $\overline{\Omega}$ hits Γ_1 at a nondiffractive point in some time $\leq T$. We refer to [2], [3] for the detailed explication and analysis of this important condition, practically necessary and sufficient for the uniform stabilizability of hyperbolic problems. This condition is obviously satisfied if $\Gamma_1 = \Gamma$; it suffices to choose the diameter of Ω for T.

We shall prove the following theorem.

THEOREM 4.1. *Fix an arbitrarily large positive number ω. Then there exist two bounded linear maps*

$$P : H^{-1}(\Omega) \to H_0^1(\Omega), \qquad Q : L^2(\Omega) \to H_0^1(\Omega) \tag{4.2}$$

and a constant M such that, putting

$$u = \frac{\partial}{\partial_\nu}(Py' + Qy), \tag{4.3}$$

the problem (4.1), (4.3) *is well posed in $\mathcal{H} := L^2(\Omega) \times H^{-1}(\Omega)$ and its solutions satisfy the estimates*

$$\|(y, y')(t)\|_{\mathcal{H}} \leq M \|(y_0, y_1)\|_{\mathcal{H}} e^{-\omega t} \tag{4.4}$$

for all $t \geq 0$ and for all $(y_0, y_1) \in \mathcal{H}$.

Remarks. (1) Assume instead of the geometrical control condition that Γ is only of class C^2 but that there exists a point $x^0 \in \mathbb{R}^n$ such that Γ_1 contains all points x of Γ satisfying $(x - x^0) \cdot \nu(x) > 0$. Then the above theorem remains valid: we shall indicate the necessary modification during the proof.

(2) Theorem 4.1 improves (in the sense mentioned in the introduction) some earlier results of Lions [31] and Lasiecka and Triggiani [27].

Turning to the proof of the theorem, let us first consider the following (dual) problem:

$$\begin{cases} \xi'' - \Delta \xi = 0 \quad \text{in} \quad \Omega \times \mathbb{R}, \\ \xi = 0 \quad \text{on} \quad \Gamma \times \mathbb{R}, \\ \xi(0) = \xi_0 \quad \text{and} \quad \xi'(0) = \xi_1 \quad \text{in} \quad \Omega, \\ \psi = \partial_\nu \xi|_{\Gamma_1} \quad \text{in} \quad \mathbb{R}. \end{cases} \tag{4.5}$$

Putting $\varphi = (\xi, \xi')$, $\varphi_0 = (\xi_0, \xi_1)$, and introducing the linear operators A^* and B^* by the formulae

$$D(A^*) = D(B^*) = (H^2(\Omega) \cap H_0^1(\Omega)) \times H_0^1(\Omega),$$
$$A^*(\eta_0, \eta_1) = -(\eta_1, \Delta\eta_0),$$
$$B^*(\eta_0, \eta_1) = \partial_\nu \eta_0|_{\Gamma_1},$$

we may rewrite (4.5) in the form (2.2):

$$\varphi' = -A^*\varphi, \qquad \varphi(0) = \varphi_0, \qquad \psi = B^*\varphi.$$

Let us show that choosing $H' = H_0^1(\Omega) \times L^2(\Omega)$ and $G' = L^2(\Gamma_1)$, the assumptions (H1)–(H4) of Theorem 3.1 are satisfied. In what follows, we shall identify $L^2(\Omega)$ and $L^2(\Gamma_1)$ with their respective duals, so that $G := G'' = L^2(\Gamma_1)$ and $H := H'' = H^{-1}(\Omega) \times L^2(\Omega)$.

It is well known that A^* generates a group in H'; see, e.g., [33].

To prove (H2) let us introduce the Dirichlet map $D : L^2(\Gamma_1) \to L^2(\Omega)$ defined by

$$\begin{cases} -\Delta Du = 0 & \text{in} \quad \Omega, \\ Du = 0 & \text{on} \quad \Gamma_0, \\ Du = u & \text{on} \quad \Gamma_1. \end{cases}$$

It is well known (see, e.g., [33]) that D is a bounded linear map of $L^2(\Gamma_1)$ into $H^{1/2}(\Omega)$. Let us define a bounded linear map $E \in L(G, H)$ by the formula $Eu = (0, -Du)$, $u \in G$. Now, given any $(\eta_0, \eta_1) \in D(A^*)$, we have for every $u \in H_0^{3/2}(\Gamma_1)$ the following equality:

$$\begin{aligned} \langle E^*A^*(\eta_0, \eta_1), u\rangle_{G',G} &= \langle A^*(\eta_0, \eta_1), Eu\rangle_{H',H} \\ &= \langle (-\eta_1, -\Delta\eta_0), (0, -Du)\rangle_{H',H} \\ &= \int_\Omega (\Delta\eta_0) Du \, dx \\ &= \int_\Omega \eta_0(\Delta Du) \, dx + \int_\Gamma (\partial_\nu\eta_0) Du - \eta_0(\partial_\nu Du) \, d\Gamma. \end{aligned}$$

(The last step is correct because $u \in H_0^{3/2}(\Gamma_1)$ implies $Du \in H^2(\Omega)$.) Since $\Delta Du \equiv 0$ in Ω, $\eta_0 \equiv 0$ on Γ, $Du \equiv 0$ on Γ_0, and $Du \equiv u$ on Γ_1, we conclude that

$$\langle E^*A^*(\eta_0, \eta_1), u\rangle_{G',G} = \langle \partial_\nu\eta_0, u\rangle_{G',G} = \langle B^*(\eta_0, \eta_1), u\rangle_{G',G}.$$

Using the density of $H_0^{3/2}(\Gamma_1)$ in $G = L^2(\Gamma_1)$, the equality $B^* = E^*A^*$ follows.

Rewriting the assumptions (H3) and (H4) for the original problem (4.5), we have to prove the existence of a positive number T and of two positive constants c_1, c_2 such that for every $(\xi_0, \xi_1) \in (H^2(\Omega) \cap H_0^1(\Omega)) \times H_0^1(\Omega)$ the solution of (4.5) satisfies the inequalities

$$c_1\|(\xi_0, \xi_1)\|^2_{H_0^1(\Omega)\times L^2(\Omega)} \le \int_0^T \int_{\Gamma_1} |\partial_\nu \xi|^2 \, d\Gamma \, dt \le c_2\|(\xi_0, \xi_1)\|^2_{H_0^1(\Omega)\times L^2(\Omega)}. \tag{4.6}$$

The second inequality of (4.6) was proven in [26] and [30]. The first one was established in [12] under the stronger geometrical condition mentioned in Remark (2)

after the formulation of Theorem 4.1. The estimates of T were subsequently improved in [31] and [15]. Finally, the general case was settled by Bardos, Lebeau, and Rauch [2], [3].

Since hypotheses (H1)–(H4) are all satisfied, we may apply Theorem 3.1 with A and B defined by $A := A^{**}$ and $B := B^{**}$.

Let us explicitly write the resulting closed-loop problem (3.2), (3.3). Consider the solutions of (4.1) and (4.5). We have, at least formally,

$$\begin{aligned} 0 &= \int_0^T \int_\Omega (y'' - \Delta y)\xi \; dx \; dt \\ &= \Big[\int_\Omega y'\xi - y\xi' \; dx\Big]_0^T + \int_0^T \int_\Omega y(\xi'' - \Delta\xi) \; dx \; dt \\ &\quad + \int_0^T \int_\Gamma -(\partial_\nu y)\xi + y(\partial_\nu \xi) \; d\Gamma \; dt. \end{aligned}$$

Using (4.1) and (4.5) this equality reduces to

$$0 = \Big[\int_\Omega y'\xi - y\xi' \; dx\Big]_0^T + \int_0^T \int_{\Gamma_1} u(\partial_\nu \xi) \; d\Gamma \; dt.$$

Putting $x = (-y', y)$, $x_0 = (-y_1, y_0)$, $\varphi = (\xi, \xi')$, and $\varphi_0 = (\xi_0, \xi_1)$ this equality may be rewritten as (2.4). Since (4.5) is equivalent to (2.2), we conclude that (by definition) (4.1) is equivalent to (2.1).

Furthermore, writing the operator

$$\Lambda_\omega^{-1} : H^{-1}(\Omega) \times L^2(\Omega) \to H_0^1(\Omega) \times L^2(\Omega)$$

in the matrix form

$$\Lambda_\omega^{-1} = \begin{pmatrix} P & -Q \\ -R & S \end{pmatrix},$$

we have

$$u = -JB^*\Lambda_\omega^{-1} x = \frac{\partial}{\partial_\nu}(Py' + Qy)$$

on Γ_1, and (4.3) follows. □

Let us end this section by writing more explicitly the feedback constructed in our proof. Given $(\xi_0, \xi_1) \in H_0^1(\Omega) \times L^2(\Omega)$ arbitrarily, first we solve the problem (4.5), and then the problem

$$\begin{cases} z'' - \Delta z = 0 \quad \text{in} \quad \Omega \times (0, T_\omega), \\ z(T_\omega) = z'(T_\omega) = 0 \quad \text{in} \quad \Omega, \\ z = e_\omega(s)\psi \quad \text{on} \quad \Gamma \times (0, T_\omega). \end{cases}$$

Thanks to the inequalities (4.6) the formula

$$\Lambda_\omega(\xi_1, \xi_0) = (-z(0), z'(0))$$

defines an isomorphism of $H_0^1(\Omega) \times L^2(\Omega)$ onto $H^{-1}(\Omega) \times L^2(\Omega)$.

Now our feedback law is the following: for each $t > 0$ we set $u(t) = \partial_\nu \xi_0$ where $(\xi_1, \xi_0) = \Lambda_\omega^{-1}(-y(t), y'(t))$.

5. Application to the wave equation II. We consider in this section the problem

$$\begin{cases} y'' - \Delta y = 0 \quad \text{in} \quad \Omega \times \mathbb{R}, \\ \partial_\nu y = u \quad \text{on} \quad \Gamma \times \mathbb{R}, \\ y(0) = y_0 \quad \text{and} \quad y'(0) = y_1 \quad \text{in} \quad \Omega \end{cases} \tag{5.1}$$

in an open ball Ω of radius R in $\mathbb{R}^n$. As in the preceding section, we denote by Γ the boundary of Ω and by ν the outward unit normal vector to Γ.

It follows from a theorem of Graham and Russell [9] (see also [18] for another proof) that for any fixed $T > 2R$ the formula

$$(\xi_0, \xi_1) \mapsto \|\xi\|_{L^2(0,T;L^2(\Gamma))},$$

where ξ denotes the solution of the homogeneous problem

$$\begin{cases} \xi'' - \Delta \xi = 0 \quad \text{in} \quad \Omega \times \mathbb{R}, \\ \partial_\nu \xi = 0 \quad \text{on} \quad \Gamma \times \mathbb{R}, \\ \xi(0) = \xi_0 \quad \text{and} \quad \xi'(0) = \xi_1 \quad \text{in} \quad \Omega, \end{cases} \tag{5.2}$$

defines a Euclidean *norm* in $H^1(\Omega) \times L^2(\Omega)$. Moreover, all the norms $\|\cdot\|_{L^2(0,T;L^2(\Gamma))}$ ($T > 2R$) are equivalent. Completing $H^1(\Omega) \times L^2(\Omega)$ with respect to any of these norms, we obtain a Hilbert space which we shall denote by H'.

As usual, let us identify $L^2(\Omega)$ with its dual. By a theorem proved in [32, Théorème III.1.6, p. 167] we also have the inclusions

$$H^1(\Omega) \times L^2(\Omega) \subset H' \subset L^2(\Omega) \times (H^1(\Omega))',$$

and therefore (putting $H := H''$),

$$L^2(\Omega) \times H^1(\Omega) \subset H \subset (H^1(\Omega))' \times L^2(\Omega).$$

(In [32] H' is denoted by F.) Setting for commodity

$$\mathcal{H} = \{(y_0, y_1) \mid (y_1, y_0) \in H\},$$

we shall prove the following theorem.

THEOREM 5.1. *Given $\omega > 0$ arbitrarily large, there exists a bounded linear operator*

$$\mathcal{F} : \mathcal{H} \to L^2(\Omega) \tag{5.3}$$

and a constant M such that putting

$$u = \mathcal{F}(y, y') \tag{5.4}$$

the problem (5.1), (5.4) *is well posed in $\mathcal{H}$, and its solutions satisfy the estimates*

$$\|(y, y')(t)\|_{\mathcal{H}} \le M \|(y_0, y_1)\|_{\mathcal{H}} e^{-\omega t} \tag{5.5}$$

for all $t \ge 0$ and for all $(y_0, y_1) \in \mathcal{H}$.

Remarks. (1) Using the (algebraical and topological) inclusion

$$H^1(\Omega) \times L^2(\Omega) \subset \mathcal{H},$$

it follows that the restriction of $\mathcal{F}$ to $H^1(\Omega)\times L^2(\Omega)$ has the form $\mathcal{F}(y,y')=Py'+Qy$ with two suitable bounded linear operators $P: L^2(\Omega)\to L^2(\Omega)$ and $Q: H^1(\Omega)\to L^2(\Omega)$.

(2) Unlike the other applications of this paper, here the estimate (5.5) involves a nontraditional space $\mathcal{H}$, which is not characterized completely by using the usual Sobolev spaces. (But we have at least two-sided estimates of this space.) This is a well-known feature of control problems with Neumann action, due to the absence of direct and inverse inequalities involving the same Sobolev spaces; cf., e.g., [32].

(3) There are many former results where estimates of this type were obtained for general domains with particular choices of the operators P and Q; see, e.g., [6], [16], [24], [35], [36], [39], [40]. However, in these results we never had $\omega > 1/(2R)$ where R denotes the radius of the smallest ball containing Ω. (Estimates with $\omega = 1/(2R)$ were obtained in [16].) The fact that arbitrarily large decay rates can be achieved by boundary feedbacks of this type seems to be new.

Let us turn to the proof of Theorem 5.1. Consider the problem

$$\begin{cases} \xi'' - \Delta\xi = 0 \quad \text{in} \quad \Omega\times\mathbb{R}, \\ \partial_\nu \xi = 0 \quad \text{on} \quad \Gamma\times\mathbb{R}, \\ \xi(0)=\xi_0 \quad \text{and} \quad \xi'(0)=\xi_1 \quad \text{in} \quad \Omega, \\ \psi = \xi|_\Gamma \quad \text{in} \quad \mathbb{R}. \end{cases} \tag{5.6}$$

Putting $\varphi=(\xi,\xi')$, $\varphi_0=(\xi_0,\xi_1)$ and introducing the linear operators A^* and B^* by the formulas

$$\begin{gathered} D(A^*)=D(B^*)=\{\eta_0\in H^2(\Omega)\mid \partial_\nu\eta_0=0 \ \text{ on } \ \Gamma\}\times H^1(\Omega), \\ A^*(\eta_0,\eta_1)=-(\eta_1,\Delta\eta_0), \\ B^*(\eta_0,\eta_1)=\eta_0|_\Gamma, \end{gathered}$$

we may rewrite (5.6) in the form (2.2):

$$\varphi' = -A^*\varphi, \qquad \varphi(0)=\varphi_0, \qquad \psi = B^*\varphi.$$

It is well known (see, e.g., [33]) that A^* generates a strongly continuous group in $H^1(\Omega)\times L^2(\Omega)$. It follows from the above-mentioned result of Graham and Russell that A^* also generates a strongly continuous group in H'. Hence hypothesis (H1) is satisfied.

Next we show that choosing $G=L^2(\Gamma)$, the hypothesis (H2) is also satisfied. (We shall identify G with its dual.) For this we introduce the Neumann map $N: L^2(\Gamma)\to H^1(\Omega)$ defined by

$$\begin{cases} -\Delta Nu + Nu = 0 \qquad \text{in} \qquad \Omega, \\ \partial_\nu Nu = u \qquad \text{on} \qquad \Gamma, \end{cases}$$

and then the operator $E\in L(G,H)$ defined by $Eu=(Nu,Nu)$. (We note that N is in fact a bounded linear operator of $L^2(\Gamma)$ into $H^{3/2}(\Omega)$.)

Given $(\eta_0,\eta_1)\in D(A^*)$ and $u\in G\cap H^{1/2}(\Gamma)$ arbitrarily, we have

$$\begin{aligned}
&\langle E^*(A+I)^*(\eta_0,\eta_1),u\rangle_{G',G}\\
&=\langle (A+I)^*(\eta_0,\eta_1),Eu\rangle_{H',H}\\
&=\langle (\eta_0-\eta_1,\eta_1-\Delta\eta_0),(Nu,Nu)\rangle_{H',H}\\
&=\int_\Omega (\eta_0-\Delta\eta_0)Nu\ dx\\
&=\int_\Omega \eta_0(-\Delta Nu+Nu)\ dx+\int_\Gamma -(\partial_\nu\eta_0)Nu+\eta_0(\partial_\nu Nu)\ d\Gamma\\
&=\int_\Gamma \eta_0 u\ d\Gamma\\
&=\langle B^*(\eta_0,\eta_1),u\rangle_{G',G}.
\end{aligned}$$

Since $G\cap H^{1/2}(\Gamma)$ is dense in G, we conclude that $E^*(A+I)^*=B^*$.

Finally, hypotheses (H3) and (H4) are satisfied by the *definition* of H'.

We may now apply Theorem 3.1 with $A:=A^{**}$ and $B:=B^{**}$. Let us determine the resulting closed-loop problem. If y solves (5.1) and ξ solves (5.6), then (at least formally)

$$\begin{aligned}
0&=\int_0^T\int_\Omega (y''-\Delta y)\xi\ dx\ dt\\
&=\Big[\int_\Omega y'\xi-y\xi'\ dx\Big]_0^T+\int_0^T\int_\Omega y(\xi''-\Delta\xi)\ dx\ dt\\
&\quad+\int_0^T\int_\Gamma -(\partial_\nu y)\xi+y(\partial_\nu\xi)\ d\Gamma\ dt.
\end{aligned}$$

Using (5.1) and (5.6), it follows that

$$0=\Big[\int_\Omega y'\xi-y\xi'\ dx\Big]_0^T+\int_0^T\int_\Gamma -u\xi\ d\Gamma\ dt.$$

Putting $x=(y',-y)$, $x_0=(y_1,-y_0)$, $\varphi=(\xi,\xi')$, and $\varphi_0=(\xi_0,\xi_1)$, this is equivalent to (2.4). Since (5.6) is equivalent to (2.2), we conclude that (by definition) (5.1) is equivalent to (2.1).

It follows easily from the boundedness of the operator $\Lambda_\omega^{-1}:H\to H'$ and from the definition of B^* that $u=-JB^*\Lambda_\omega^{-1}x$ may also be written as $u=\mathcal{F}(y,y')$ for a suitable bounded linear operator $\mathcal{F}:\mathcal{H}\to L^2(\Omega)$. □

6. Application to a Petrovsky system I. Let us consider the problem

$$\begin{cases} y''+\Delta^2 y=0 \quad \text{in} \quad \Omega\times\mathbb{R},\\ y=\partial_\nu y=0 \quad \text{on} \quad \Gamma_0\times\mathbb{R},\\ y=0 \quad \text{and} \quad \partial_\nu y=u \quad \text{on} \quad \Gamma_1\times\mathbb{R},\\ y(0)=y_0 \quad \text{and} \quad y'(0)=y_1 \quad \text{in} \quad \Omega, \end{cases} \tag{6.1}$$

where Ω is a bounded open set in $\mathbb{R}^n$, Γ_1 is an open subset of its boundary Γ, $\Gamma_0=\Gamma\backslash\Gamma_1$, and ν denotes the outward unit normal vector to Γ.

Let us assume that Γ is of class C^4 and that there exists a point $x^0\in\mathbb{R}^n$ such that Γ_1 contains all points x of Γ which satisfy the inequality $(x-x^0)\cdot\nu(x)>0$.

We shall prove the the following theorem.

THEOREM 6.1. *Fix an arbitrarily large positive number ω. Then there exist two bounded linear maps*

$$P : H^{-2}(\Omega) \to H_0^2(\Omega), \qquad Q : L^2(\Omega) \to H_0^2(\Omega) \tag{6.2}$$

and a constant M such that, putting

$$u = \Delta(Py' + Qy), \tag{6.3}$$

the problem (6.1), (6.3) *is well posed in $\mathcal{H} := L^2(\Omega) \times H^{-2}(\Omega)$, and its solutions satisfy the estimates*

$$\|(y, y')(t)\|_{\mathcal{H}} \le M\|(y_0, y_1)\|_{\mathcal{H}} e^{-\omega t} \tag{6.4}$$

for all $t \ge 0$ and for all $(y_0, y_1) \in \mathcal{H}$.

Remark. Theorem 6.1 improves some earlier results of Lasiecka and Triggiani [27], obtained by the Riccati equation approach.

Turning to the proof of the theorem, let us first consider the following problem:

$$\begin{cases} \xi'' + \Delta^2 \xi = 0 \quad \text{in} \quad \Omega \times \mathbb{R}, \\ \xi = \partial_\nu \xi = 0 \quad \text{on} \quad \Gamma \times \mathbb{R}, \\ \xi(0) = \xi_0 \quad \text{and} \quad \xi'(0) = \xi_1 \quad \text{in} \quad \Omega, \\ \psi = \Delta\xi|_{\Gamma_1} \quad \text{in} \quad \mathbb{R}. \end{cases} \tag{6.5}$$

Putting $\varphi = (\xi, \xi')$, $\varphi_0 = (\xi_0, \xi_1)$ and introducing the linear operators A^* and B^* by the formulas

$$\begin{gathered} D(A^*) = D(B^*) = (H^4(\Omega) \cap H_0^2(\Omega)) \times H_0^2(\Omega), \\ A^*(\eta_0, \eta_1) = (-\eta_1, \Delta^2 \eta_0), \\ B^*(\eta_0, \eta_1) = \Delta\eta_0|_{\Gamma_1}, \end{gathered}$$

we may rewrite (6.5) in the abstract form (2.2):

$$\varphi' = -A^*\varphi, \qquad \varphi(0) = \varphi_0, \qquad \psi = B^*\varphi.$$

We are going to show that, choosing $H' = H_0^2(\Omega) \times L^2(\Omega)$ and $G' = L^2(\Gamma_1)$, the assumptions (H1)–(H4) of Theorem 3.1 are satisfied. As before, we identify $L^2(\Omega)$ and $L^2(\Gamma_1)$ with their respective duals, so that $G := G'' = L^2(\Gamma_1)$ and $H := H'' = H^{-2}(\Omega) \times L^2(\Omega)$.

It is well known that A^* generates a group in H'; see, e.g., [33].

To prove (H2) let us introduce the Dirichlet map $D : L^2(\Gamma_1) \to L^2(\Omega)$ now by

$$\begin{cases} \Delta^2 Du = 0 \quad \text{in} \quad \Omega, \\ Du = \partial_\nu Du = 0 \quad \text{on} \quad \Gamma_0, \\ Du = 0 \quad \text{and} \quad \partial_\nu Du = u \quad \text{on} \quad \Gamma_1. \end{cases}$$

We recall from [33] that D is a bounded linear map. Let us define $E \in L(G, H)$ by the formula $Eu = (0, -Du)$, $u \in G$. Now, for every $(\eta_0, \eta_1) \in D(A^*)$ and $u \in H_0^{5/2}(\Gamma_1)$,

we have the following equality:

$$\begin{aligned}
&\langle E^*A^*(\eta_0,\eta_1),u\rangle_{G',G}\\
&=\langle A^*(\eta_0,\eta_1),Eu\rangle_{H',H}\\
&=\langle(-\eta_1,\Delta^2\eta_0),(0,-Du)\rangle_{H',H}\\
&=-\int_\Omega(\Delta^2\eta_0)Du\ dx\\
&=-\int_\Omega\eta_0(\Delta^2Du)\ dx\\
&+\int_\Gamma-(\partial_\nu\Delta\eta_0)Du+(\Delta\eta_0)(\partial_\nu Du)-(\partial_\nu\eta_0)(\Delta Du)+\eta_0(\partial_\nu\Delta Du)\ d\Gamma.
\end{aligned}$$

(The last step is correct because $u\in H_0^{5/2}(\Gamma_1)$ implies $Du\in H^4(\Omega)$.) Using the definition of Du and the property $\eta_0=\partial_\nu\eta_0\equiv 0$ on Γ, we conclude that

$$\langle E^*A^*(\eta_0,\eta_1),u\rangle_{G',G}=\langle\Delta\eta_0,u\rangle_{G',G}.$$

Using the density of $H_0^{5/2}(\Gamma_1)$ in $G=L^2(\Gamma_1)$, the equality $B^*=E^*A^*$ follows.

Rewriting the assumptions (H3) and (H4) for the original problem (6.5), we have to prove the existence of a positive number T and of two positive constants c_1, c_2 such that for every $(\xi_0,\xi_1)\in(H^4(\Omega)\cap H_0^2(\Omega))\times H_0^2(\Omega)$ the solution of (6.5) satisfies the inequalities

$$c_1\|(\xi_0,\xi_1)\|^2_{H_0^2(\Omega)\times L^2(\Omega)}\le\int_0^T\int_{\Gamma_1}|\Delta\xi|^2\ d\Gamma\ dt\le c_2\|(\xi_0,\xi_1)\|^2_{H_0^2(\Omega)\times L^2(\Omega)}. \tag{6.6}$$

These inequalities were established in [31]. (See also [15] for a better estimate of T by elementary means, and [41] and [19, Theorem 6.7] for two different proofs of these estimates for *any* positive T.)

We may now apply Theorem 3.1 with A and B defined by $A:=A^{**}$ and $B:=B^{**}$.

Let us explicitly write the resulting closed-loop problem (3.2), (3.3). Consider the solutions of (6.1) and of (6.5). We have

$$\begin{aligned}
0&=\int_0^T\int_\Omega(y''+\Delta^2y)\xi\ dx\ dt\\
&=\Big[\int_\Omega y'\xi-y\xi'\ dx\Big]_0^T+\int_0^T\int_\Omega y(\xi''+\Delta^2\xi)\ dx\ dt\\
&+\int_0^T\int_\Gamma(\partial_\nu\Delta y)\xi-(\Delta y)\partial_\nu\xi+(\partial_\nu y)\Delta\xi-y(\partial_\nu\Delta\xi)\ d\Gamma\ dt.
\end{aligned}$$

Using (6.1) and (6.5) this equality reduces to

$$0=\Big[\int_\Omega y'\xi-y\xi'\ dx\Big]_0^T+\int_0^T\int_{\Gamma_1}u\Delta\xi\ d\Gamma\ dt.$$

Putting $x=(-y',y)$, $x_0=(-y_1,y_0)$, $\varphi=(\xi,\xi')$, and $\varphi=(\xi_0,\xi_1)$, this equality may be rewritten as (2.4). Since (6.5) is equivalent to (2.2), we conclude that (6.1) is equivalent to (2.1).

Writing the operator

$$\Lambda_\omega^{-1} : H^{-2}(\Omega) \times L^2(\Omega) \to H_0^2(\Omega) \times L^2(\Omega)$$

in the matrix form

$$\Lambda_\omega^{-1} = \begin{pmatrix} P & -Q \\ -R & S \end{pmatrix},$$

we have

$$u = -JB^*\Lambda_\omega^{-1}x = \Delta(Py' + Qy)$$

on Γ_1, and (6.3) follows. □

7. Application to a Petrovsky system II. Consider the problem

$$\begin{cases} y'' + \Delta^2 y = 0 \quad \text{in} \quad \Omega \times \mathbb{R}, \\ y = \Delta y = 0 \quad \text{on} \quad \Gamma_0 \times \mathbb{R}, \\ y = 0 \quad \text{and} \quad \Delta y = u \quad \text{on} \quad \Gamma_1 \times \mathbb{R}, \\ y(0) = y_0 \quad \text{and} \quad y'(0) = y_1 \quad \text{in} \quad \Omega, \end{cases} \tag{7.1}$$

where Ω is a bounded open set in $\mathbb{R}^n$, Γ_1 is an open subset of its boundary Γ, and $\Gamma_0 = \Gamma \backslash \Gamma_1$. We shall denote by ν the outward unit normal vector to Γ.

As in section 4, assume that Γ is analytic and that Γ_1 satisfies the *geometrical control condition* of Bardos, Lebeau, and Rauch [2], [3]: there exists a positive number T such that every ray of geometrical optics in $\overline{\Omega}$ hits Γ_1 at a nondiffractive point in some time $\leq T$. Then we have the following theorem.

THEOREM 7.1. *Fix $\omega > 0$ arbitrarily. There exist two bounded linear maps*

$$P : H^{-1}(\Omega) \to H_0^1(\Omega), \qquad Q : H_0^1(\Omega) \to H_0^1(\Omega) \tag{7.2}$$

and a constant M such that, putting

$$u = \frac{\partial}{\partial \nu}(Py' + Qy), \tag{7.3}$$

the problem (7.1), (7.3) *is well posed in $\mathcal{H} := H_0^1(\Omega) \times H^{-1}(\Omega)$ and its solutions satisfy the estimates*

$$\|(y, y')(t)\|_{\mathcal{H}} \leq M \|(y_0, y_1)\|_{\mathcal{H}} e^{-\omega t} \tag{7.4}$$

for all $t \geq 0$ and for all $(y_0, y_1) \in \mathcal{H}$.

Remarks. (1) Theorem 6.1 improves some earlier results of Lasiecka and Triggiani [27].

(2) The same conclusion holds if Γ is only of class C^4 but there exists a point $x^0 \in \mathbb{R}^n$ such that Γ_1 contains all points x of Γ which satisfy the inequality $(x - x^0) \cdot \nu(x) > 0$.

(3) Let us note that, contrary to the wave equation, the necessity of the geometrical control condition is far from clear here. (See [10], [13], and [17] for closely related exact *internal* controllability results in the "right spaces" in the absence of the geometrical control condition.)

For the proof, consider the following problem:

$$\begin{cases} \xi'' + \Delta^2 \xi = 0 \quad \text{in} \quad \Omega \times \mathbb{R}, \\ \xi = \Delta \xi = 0 \quad \text{on} \quad \Gamma \times \mathbb{R}, \\ \xi(0) = \xi_0 \quad \text{and} \quad \xi'(0) = \xi_1 \quad \text{in} \quad \Omega, \\ \psi = \partial_\nu \xi|_{\Gamma_1} \quad \text{in} \quad \mathbb{R}. \end{cases} \tag{7.5}$$

Putting $\varphi = (\xi, \xi')$, $\varphi_0 = (\xi_0, \xi_1)$, and introducing the linear operators A^* and B^* by the formulae

$$D(A^*) = D(B^*) = \{(\eta_0, \eta_1) \in H^3(\Omega) \times H^1(\Omega) \mid \eta_0 = \Delta\eta_0 = \eta_1 = 0 \text{ on } \Gamma\},$$
$$A^*(\eta_0, \eta_1) = (-\eta_1, \Delta^2\eta_0),$$
$$B^*(\eta_0, \eta_1) = \partial_\nu \eta_0|_{\Gamma_1},$$

we may rewrite (7.5) in the abstract form (2.2):

$$\varphi' = -A^*\varphi, \qquad \varphi(0) = \varphi_0, \qquad \psi = B^*\varphi.$$

Let us show that, choosing $H' = H_0^1(\Omega) \times H^{-1}(\Omega)$ and $G' = L^2(\Gamma_1)$, the assumptions (H1)–(H4) of Theorem 3.1 are satisfied. As usual, we identify $L^2(\Omega)$ and $L^2(\Gamma_1)$ with their respective duals, so that $G := G'' = L^2(\Gamma_1)$ and $H := H'' = H^{-1}(\Omega) \times H_0^1(\Omega)$.

It is well known that A^* generates a group in H'; see, e.g., [33].

To prove (H2) let us introduce the bounded linear map $D : L^2(\Gamma_1) \to H^2(\Omega) \cap H_0^1(\Omega)$ now by

$$\begin{cases} \Delta^2 Du = 0 & \text{in} \quad \Omega, \\ Du = \Delta Du = 0 & \text{on} \quad \Gamma_0, \\ Du = 0 \quad \text{and} \quad \Delta Du = u & \text{on} \quad \Gamma_1. \end{cases}$$

Let us define $E \in L(G, H)$ by the formula $Eu = (0, Du)$, $u \in G$. Now, given any $(\eta_0, \eta_1) \in D(A^*)$, we have for every $u \in H_0^{3/2}(\Gamma_1)$ the following equality:

$$\begin{aligned} &\langle E^*A^*(\eta_0, \eta_1), u\rangle_{G',G} \\ &= \langle A^*(\eta_0, \eta_1), Eu\rangle_{H',H} \\ &= \langle(-\eta_1, \Delta^2\eta_0), (0, Du)\rangle_{H',H} \\ &= \int_\Omega (\Delta^2\eta_0) Du \, dx \\ &= \int_\Omega \eta_0(\Delta^2 Du) \, dx \\ &+ \int_\Gamma (\partial_\nu \Delta\eta_0) Du - (\Delta\eta_0)(\partial_\nu Du) + (\partial_\nu\eta_0)(\Delta Du) - \eta_0(\partial_\nu \Delta Du) \, d\Gamma. \end{aligned}$$

(The last step is justified because $u \in H_0^{3/2}(\Gamma_1)$ implies $Du \in H^4(\Omega)$.) Using the definition of Du and the property $\eta_0 = \Delta\eta_0 \equiv 0$ on Γ, we conclude that

$$\langle E^*A^*(\eta_0, \eta_1), u\rangle_{G',G} = \langle \partial_\nu\eta_0, u\rangle_{G',G}.$$

Using the density of $H_0^{3/2}(\Gamma_1)$ in $G = L^2(\Gamma_1)$, the equality $B^* = E^*A^*$ follows.

Rewriting the assumptions (H3) and (H4) for the original problem (7.5), we have to prove the existence of a positive number T and of two positive constants c_1, c_2 such that for every $(\xi_0, \xi_1) \in D(A^*)$ the solution of (7.5) satisfies the inequalities

$$c_1\|(\xi_0, \xi_1)\|^2_{H_0^1(\Omega)\times H^{-1}(\Omega)} \le \int_0^T \int_{\Gamma_1} |\partial_\nu \xi|^2 \, d\Gamma \, dt \le c_2\|(\xi_0, \xi_1)\|^2_{H_0^1(\Omega)\times H^{-1}(\Omega)}. \tag{7.6}$$

The second inequality is essentially a special case of a theorem proved in [31]; see also [19, Theorem 2.10]. The first inequality was proved (improving some former

results of Lions [31]) in [19, Theorem 6.11] under the stronger geometrical assumption mentioned in Remark (2) above, and by Lebeau [28] in the general case. In the last two works these inequalities are established for every (arbitrarily small) positive T.

We may thus apply Theorem 3.1 with A and B defined by $A := A^{**}$ and $B := B^{**}$.

Let us show that the resulting closed-loop problem (3.2), (3.3) is equivalent to (7.1), (7.3). Consider the solutions of (7.1) and (7.5). We have

$$\begin{aligned} 0 &= \int_0^T \int_\Omega (y'' + \Delta^2 y)\xi \; dx \; dt \\ &= \Big[\int_\Omega y'\xi - y\xi' \; dx\Big]_0^T + \int_0^T \int_\Omega y(\xi'' + \Delta^2 \xi) \; dx \; dt \\ &+ \int_0^T \int_\Gamma (\partial_\nu \Delta y)\xi - (\Delta y)\partial_\nu \xi + (\partial_\nu y)\Delta\xi - y(\partial_\nu \Delta \xi) \; d\Gamma \; dt. \end{aligned}$$

Using (7.1) and (7.5), this equality reduces to

$$0 = \Big[\int_\Omega y'\xi - y\xi' \; dx\Big]_0^T - \int_0^T \int_{\Gamma_1} u\partial_\nu \xi \; d\Gamma \; dt.$$

Putting $x = (y', -y)$, $x_0 = (y_1, -y_0)$, $\varphi = (\xi, \xi')$, and $\varphi_0 = (\xi_0, \xi_1)$, this equality may be rewritten as (2.4). Since (7.5) is equivalent to (2.2), we conclude that (7.1) is equivalent to (2.1).

Writing the operator

$$\Lambda_\omega^{-1} : H^{-1}(\Omega) \times H_0^1(\Omega) \to H_0^1(\Omega) \times H^{-1}(\Omega)$$

in the matrix form

$$\Lambda_\omega^{-1} = -\begin{pmatrix} P & -Q \\ -R & S \end{pmatrix},$$

we have

$$u = -JB^*\Lambda_\omega^{-1} x = \partial_\nu(Py' + Qy)$$

on Γ_1, and (7.3) follows. □

Note added in proof. In an earlier version of this paper we used in Theorem 3.1 a different weight function (corresponding to the change of T_ω to T in the formula (3.1)). Frédéric Bourquin observed that in that case Flandoli's theorem cannot be applied unless the operator C is bounded. At the same time, he also suggested the use of the weight function appearing now in (3.1) in order to keep the formulation of the theorem and most of the proof unchanged. We are most grateful to him for allowing us to include his corrections in our paper.

The hypothesis (H2) of the paper is equivalent to hypothesis (H2′) below, which is easier to verify in the applications: instead of constructing a Dirichlet type map it suffices to invoke the elliptic regularity theory.

(H2′) We have $D(A^*) = D(B^*)$, and there exist two numbers $\lambda \in \mathbf{C}$ and $c \in \mathbf{R}$ such that

$$\|B^*\phi\| \le c\|(A + \lambda I)^*\phi\|$$

for all $\phi \in D(A^*)$.

Indeed, (H2) obviously implies (H2′) with $c = \|E^*\|$. Conversely, (H2′) implies that the formula

$$E^*(A + \lambda I^*)^*\phi := B^*\phi$$

defines a bounded linear map E^* from the range of $(A+\lambda I)^*$ in H' into G'. Extending it continuously to the closure of range $(A + \lambda I)^*$ and then defining E^* by zero on its orthogonal complement, we obtain an operator $E^* \in L(H', G')$ satisfying (H2). Finally we set $E := E^{**}$.

For example, in the example of section 4 we have

$$D(A^*) = D(B^*) = H^2(\Omega) \cap H_0^1(\Omega)$$

by definition and

$$\|B^*(\eta_0, \eta_1)\|_{G'} = \|\partial_\nu \eta_0\|_{L^2\Gamma_1)} \le c\|\eta_0\|_{H_2(\Omega)}$$
$$\le c\|\Delta\eta_0\|_{L^2(\Omega)} \le c\| - (\eta_1, \Delta\eta_0)\|_{H'} = \|A^*(\eta_0, \eta_1)\|_{H'},$$

proving (H2′).

Acknowledgments. Some results of this paper were announced earlier without proof in [22] and [23].

Let us remark that T. I. Seidman [37] constructed, using a different approach, stabilizing feedbacks leading to arbitrarily large decay rates in *augmented* state spaces.

The author is grateful to F. Bourquin, J. Lagnese, J.-L. Lions, O. J. Staffans, and G. Weiss for their useful advice concerning the presentation of our results.

BOUNDARY CONTROLLABILITY OF A LINEAR HYBRID SYSTEM ARISING IN THE CONTROL OF NOISE*

SORIN MICU† AND ENRIQUE ZUAZUA‡

Abstract. We consider a simple model arising in the control of noise. We assume that the two-dimensional cavity $\Omega = (0,1) \times (0,1)$ is occupied by an elastic, inviscid, compressible fluid. The potential ϕ of the velocity field satisfies the linear wave equation. The boundary of Ω is divided into two parts, Γ_0 and Γ_1. The first one, Γ_0, is flexible and occupied by a vibrating string that obeys the one-dimensional wave equation. On Γ_0 the continuity of the normal velocities of the fluid and the string is imposed. The subset Γ_1 of the boundary is assumed to be rigid, and therefore, the normal velocity of the fluid vanishes. This constitutes a conservative system of two coupled wave equations in dimensions two and one, respectively.

The control (an elastic force or an exterior source of noise) is assumed to act on the flexible part of the boundary. We are interested on the controllability problem: given a large enough control time, what are the initial conditions we can drive to the equilibrium by means of, say, L^2-controls? By using Fourier series the problem is decomposed into an infinite number of one-dimensional control problems that we solve by classical methods that combine the Hilbert uniqueness method, multiplier techniques, and Ingham-type inequalities. Putting these one-dimensional results together, we give a precise characterization of the space of controllable data in terms of Fourier series.

1. Introduction.

Let Ω be the two-dimensional square $\Omega = (0,1) \times (0,1) \subset \mathbb{R}^2$.

We assume that Ω is filled with an elastic, inviscid, compressible fluid whose velocity field $\vec{v}$ is given by the potential $\phi = \phi(x,y,t) : \vec{v} = \nabla\phi$. By linearization we assume that the potential ϕ satisfies the linear wave equation in $\Omega \times (0,\infty)$.

The boundary $\Gamma = \partial\Omega$ of Ω is divided into two parts: $\Gamma_0 = \{(x,0) : x \in (0,1)\}$ and $\Gamma_1 = \Gamma \backslash \Gamma_0$. The subset Γ_1 is assumed to be rigid, and we impose zero normal velocity of the fluid on it. The subset Γ_0 is supposed to be flexible and occupied by a flexible string that vibrates under the pressure of the fluid on the plane where Ω lies. The displacement of Γ_0, described by the scalar function $W = W(x,t)$, obeys the one-dimensional wave equation. On the other hand, on Γ_0 we impose the continuity of the normal velocities of the fluid and the string. The string is assumed to satisfy Neumann boundary conditions on its extremes. All deformations are supposed to be small enough that linear theory applies. Under natural initial conditions for ϕ and W the linear motion of this system is described by means of the following coupled wave equations:

$$
(1.1)\qquad \begin{cases} \phi_{tt} - \Delta\phi = 0 & \text{in} \quad \Omega \times (0,\infty), \\ \frac{\partial \phi}{\partial \nu} = 0 & \text{on} \quad \Gamma_1 \times (0,\infty), \\ \frac{\partial \phi}{\partial y} = -W_t & \text{on} \quad \Gamma_0 \times (0,\infty), \\ W_{tt} - W_{xx} + \phi_t = 0 & \text{on} \quad \Gamma_0 \times (0,\infty), \\ W_x(0,t) = W_x(1,t) = 0 & \text{for} \quad t > 0, \\ \phi(0) = \phi^0, \phi_t(0) = \phi^1 & \text{in} \quad \Omega, \\ W(0) = W^0, W_t(0) = W^1 & \text{on} \quad \Gamma_0. \end{cases}
$$

By ν we denote the unit outward normal to Ω.

In (1.1) we have chosen to take the various parameters of the system to be equal to one.

The system (1.1) is well posed in the energy space $\mathcal{X} = H^1(\Omega) \times L^2(\Omega) \times H^1(\Gamma_0) \times L^2(\Gamma_0)$ for the variables (ϕ, ϕ_t, W, W_t). The energy

$$
(1.2)\qquad E(t) = \frac{1}{2} \int_\Omega \left[|\, \nabla\phi \,|^2 + |\, \phi_t \,|^2 \right] dxdy + \frac{1}{2} \int_{\Gamma_0} \left[|\, W_x \,|^2 + |\, W_t \,|^2 \right] dx
$$

remains constant along trajectories.

We study the controllability of system (1.1) under the action of an exterior force or source of noise on the flexible part of the boundary Γ_0. The control is given by a scalar function $\beta = \beta(x,t)$, and the controlled system reads as follows:

$$
(1.3)\qquad \begin{cases} \phi_{tt} - \Delta\phi = 0 & \text{in} \quad \Omega \times (0,\infty), \\ \frac{\partial \phi}{\partial \nu} = 0 & \text{on} \quad \Gamma_1 \times (0,\infty), \\ \frac{\partial \phi}{\partial y} = -W_t & \text{on} \quad \Gamma_0 \times (0,\infty), \\ W_{tt} - W_{xx} + \phi_t = \beta & \text{on} \quad \Gamma_0 \times (0,\infty), \\ W_x(0,t) = W_x(1,t) = 0 & \text{for} \quad t > 0, \\ \phi(0) = \phi^0, \phi_t(0) = \phi^1 & \text{in} \quad \Omega, \\ W(0) = W^0, W_t(0) = W^1 & \text{on} \quad \Gamma_0. \end{cases}
$$

It is easy to see that the equilibria of these systems are of the form

$$
(1.4)\qquad (\phi, \phi_t, W, W_t) = (c_1, 0, c_2, 0),
$$

c_1 and c_2 being constant functions.

In view of the finite speed of propagation of the wave equation satisfied by ϕ, the geometry of Ω, and the support of the control β (the subset Γ_0 of the boundary of Ω), the minimal controllability time for system (1.3) is $T_0 = 2$.

We choose the control β to be in the space $H^{-2}(0,T;L^2(\Gamma_0))$. Of course, this is an arbitrary choice and many others make sense. However, this is the most natural one when solving the control problem by means of Lions's Hilbert uniqueness method (HUM) (see [10]), as we will do.

The problem of controllability can be formulated as follows: given $T > 2$, find the space of initial data $(\phi^0, \phi^1, W^0, W^1)$ that can be driven to an equilibrium of the form (1.4) in time T by means of a suitable control $\beta \in H^{-2}(0,T;L^2(\Gamma_0))$.

The control set Γ_0 does not satisfy the necessary geometric conditions for controllability given by Bardos, Lebeau, and Rauch in [6]. Indeed, any segment of the form $\{(x,\ell) : x \in (0,1)\}$ with $0 < \ell < 1$ constitutes a ray of geometric optics that never intersects the control region Γ_0. Therefore, we cannot expect the space of controllable initial data to be an energy space.

In this paper we give a complete characterization of the controllable space in terms of Fourier series. This space consists of initial data whose Fourier coefficients, roughly, decay exponentially as the frequency increases.

The Fourier analysis of the system is possible because of the boundary conditions we have chosen for W. Indeed, W is assumed to satisfy Neumann-type boundary conditions, which are compatible with those of ϕ, to develop solutions in Fourier series.

Indeed, let us decompose the control β, the solutions ϕ, W, and the initial data in the following way:

$$\begin{cases} \beta = \displaystyle\sum_{n=0}^{\infty} \beta_n(t)\cos(n\pi x), \\ \Phi = \displaystyle\sum_{n=0}^{\infty} \psi_n(y,t)\cos(n\pi x), \quad (\phi^0,\phi^1) = \displaystyle\sum_{n=0}^{\infty} (\psi_n^0(y),\psi_n^1(y))\cos(n\pi x), \\ W = \displaystyle\sum_{n=0}^{\infty} V_n(t)\cos(n\pi x), \quad (W^0,W^1) = \displaystyle\sum_{n=0}^{\infty} (V_n^0,V_n^1)\cos(n\pi x). \end{cases} \tag{1.5}$$

With this decomposition, system (1.3) can be split into the following sequence of one-dimensional controlled systems for $n = 0, 1, \ldots$:

$$\begin{cases} \psi_{n,tt} - \psi_{n,yy} + n^2\pi^2\psi_n = 0 & \text{for} \quad (y,t) \in (0,1)\times(0,\infty), \\ \psi_{n,y}(1,t) = 0 & \text{for} \quad t > 0, \\ \psi_{n,y}(0,t) = -V_t(t) & \text{for} \quad t > 0, \\ V_{n,tt}(t) + n^2\pi^2 V_n(t) + \psi_{n,t}(0,t) = \beta_n(t) & \text{for} \quad t > 0, \\ \psi_n(0) = \psi_n^0, \psi_{n,t}(0) = \psi_n^1 & \text{in} \quad (0,1), \\ V_n(0) = V_n^0, V_{n,t}(0) = V_n^1. \end{cases} \tag{1.6}$$

First we will study the controllability of system (1.6) by using classical methods that combine HUM, multiplier techniques, and Ingham-type inequalities (see [9] and [8]). Combining these one-dimensional results with the Fourier decomposition (1.5), the controllability result for system (1.3) will be proved. Although the techniques we use are well known, the obtainment of sharp estimates for the controls requires the use of them in a rather refined way.

The control β we obtain is of the form $\beta = \frac{\partial^2}{\partial t^2}\gamma$, with $\gamma \in L^2(\Gamma_0 \times (0,T))$ having compact support in time. Therefore $\int_0^T \beta = 0$. Taking this fact into account, it is easy to see that the constants c_1, c_2 of the equilibrium that we reach at time $t = T$ are determined a priori by the initial data. Indeed, integrating the first equation of (1.3) in Ω we obtain that $\int_\Omega \phi_t dxdy - \int_{\Gamma_0} W dx$ remains constant in time. Therefore, necessarily,

$$c_2 = \int_{\Gamma_0} W^0 dx - \int_\Omega \phi^1 dxdy. \tag{1.7}$$

On the other hand, integrating the equation satisfied by W on $\Gamma_0 \times (0,T)$ and taking into account that $\int_0^T \beta = 0$, we deduce that

$$\int_{\Gamma_0} W_t(T)dx + \int_{\Gamma_0} \phi(x,0,T)dx = \int_{\Gamma_0} W^1 dx + \int_{\Gamma_0} \phi^0(x,0)dx,$$

and therefore,

$$c_1 = \int_{\Gamma_0} \left(W^1 + \phi^0(x,0)\right) dx. \tag{1.8}$$

In terms of the Fourier coefficients (1.5) these constants can be written in the following way:

$$c_1 = V_0^1 + \psi_0^0(0), \quad c_2 = V_0^0 - \int_0^1 \psi_0^1(y)dy. \tag{1.9}$$

Therefore, the constants c_1 and c_2 of the equilibrium we may reach are uniquely determined by the Fourier coefficients of the initial data corresponding to the frequency $n = 0$ in the x-variable.

This fact is related to the different nature of systems (1.6) for $n = 0$ and $n \geq 1$. While for any $n \geq 1$, system (1.6) is exactly controllable to zero at any time $T > 2$, when $n = 0$ we can control the system to the equilibrium given by (1.9) only in terms of the initial data.

The system under consideration can be viewed as a hybrid system coupling a fluid with an elastic structure. From a mathematical point of view the system couples a two-dimensional wave equation with a one-dimensional one. This type of system is rather common when studying the vibrations of structures connecting several flexible bodies of different dimensions. Examples of this type can be found, for instance, in [11], [7], and [16]. However, in all these cases the coupling is of a different nature since the continuity of displacements is imposed, but not the continuity of normal velocities.

The model under consideration is inspired in and related to that of Banks et al. in [5]. However, there are some important differences between these two models. In [5] the flexible part of the boundary Γ_0 is occupied by a flexible damped beam instead of a flexible string. But the main difference is related to the nature of the controls. In [5] the control acts on the system through a finite number of piezoceramic patches located on Γ_0. This restricts very much the set of admissible controls, which are essentially second derivatives of Heaviside functions, and much weaker controllability results have to be expected. In [5] the controllability problem is not addressed. Instead, they consider a quadratic optimal control problem. More recently, in [3], a Riccati equation for the optimal control is derived. The problem of the controllability of one-dimensional beams with piezoelectric actuators has been successfully addressed by Tucsnak [17]. However, to our knowledge, there are no rigorous results on the controllability of fluid-structure systems under such controls. To our knowledge the present paper represents the first attempt to solve the controllability problem for the two-dimensional system although, as we said above, we do not address the problem in which the control is made through piezoelectric patches.

In [13], the authors have addressed the problem of the feedback stabilization of system (1.3) with a damping term concentrated on Γ_0. The results in [13] show that, in such a situation, every trajectory converges towards an equilibrium as time goes to infinity, but the decay rate is not uniform. A more detailed discussion on the lack of uniform decay can be found in [12] and [15]. More recently, in [2], the system introduced in [5] has been considered, with the condition $\frac{\partial \Phi}{\partial \nu} = -W_t$ on the continuity of the velocity fields replaced by a dissipative condition of the form $\frac{\partial \Phi}{\partial \nu} = -W_t + \Phi_t$. In [2] it is proven that when Ω is a general smooth bounded domain and the subset Γ_0 of the boundary is sufficiently large (in the spirit of the geometric conditions arising in the boundary stabilization of the wave equation), then the energy decays uniformly to zero. In [13] the existence of periodic solutions of this dissipative system on the presence of a periodic source of noise acting on the system through the flexible part of the boundary is considered too. Due to the very weak effect that the damping located

on Γ_0 has on the fluid inside Ω, in order to guarantee the existence of such periodic solutions of finite energy, the exterior source of noise has to be assumed to belong to a rather small class of functions with rapidly decreasing Fourier coefficients. In this sense, this result is very close to the controllability one we present in this paper. For a detailed discussion, see [12].

The rest of the paper is organized as follows. In section 2 we rigorously present the main results of this paper and make a discussion on their optimality. In section 3 we address the one-dimensional control problem (1.6). First, distinguishing the cases $n = 0$ and $n \geq 1$, we derive the necessary observability inequalities. Then, applying HUM, the one-dimensional controllability result is deduced. In section 4, combining the results of the previous one, we derive the controllability result for system (1.3).

In an appendix at the end of the paper we give a detailed proof of an Ingham-type inequality that provides explicit estimates of the constants appearing in it.

2. The main results: Statements and discussion. As we said in the introduction, the controllability problem of system (1.3) is reduced to study the one-parameter family of one-dimensional systems (1.6). When $n \geq 1$ we have the following controllability result for (1.6).

THEOREM 2.1. *Let $\mathcal{Y}$ be the space $H^1(0,1) \times L^2(0,1) \times \mathbb{R} \times \mathbb{R}$. Assume that $T > 2$ and $n \geq 1$. Then, for any $(\psi^0, \psi^1, V^0, V^1) \in \mathcal{Y}$, there exists a control $\beta \in H^{-2}(0,T)$ with compact support such that the solution (ψ, V) of (1.6) satisfies*

$$\psi(T) = \psi_t(T) \equiv 0 \text{ in } (0,1), \quad V(T) = V_t(T) = 0. \tag{2.1}$$

Remark 1. In the statement of Theorem 2.1 and below, we drop the index n from the unknowns (ψ, V) to simplify the notation.

The solution (ψ, V) is defined by transposition. Therefore, (2.1) has to be understood in a suitable weak sense. We will return to this question in the proof of the theorem.

The proof of Theorem 2.1 provides the continuous dependence of the control β on the initial data. More precisely,

$$\|\beta\|^2_{H^{-2}(0,T)} \leq C_n \left\{ \|(\psi^1, \psi^0, V^1, V^0)\|^2_{\mathcal{Y}'} + \mid \psi^0(0) \mid^2 \right\} \tag{2.2}$$

for any initial data $(\psi^0, \psi^1, V^0, V^1)$, as in the statement of Theorem 2.1. By $\mathcal{Y}'$ we denote the dual of the space $\mathcal{Y}$, $(\mathcal{Y}' = (H^1(0,1)) \times L^2(0,1) \times \mathbb{R}^2)$. The constant C_n in (2.2) will be evaluated in the next section (see also Remark 4).

As we said in the introduction, when $n = 0$ one can not expect the same controllability result due to the conservation of the quantities (1.9) along the trajectories. In this case the controllability result reads as follows.

THEOREM 2.2. *Assume that $T > 2$ and $n = 0$. Then, for any $\left(\psi^0, \psi^1, V^0, V^1\right) \in \mathcal{Y}$, there exists a control $\beta \in H^{-2}(0,T)$ with compact support such that the solution (ψ, V) of (1.6) satisfies*

$$\psi(T) = V^1 + \psi^0(0), \psi_t(T) = 0 \text{ in } (0,1),\ V(T) = V^0 - \int_0^1 \psi^1 dy, V_t(T) = 0. \tag{2.3}$$

Remark 2. This result asserts that, when $n = 0$, any solution of (1.6) can be driven to an equilibrium configuration which is determined a priori by the initial data.

Let us now state the controllability results for the two-dimensional system (1.3).

We use the Fourier decomposition method described in the introduction. Thus we develop the initial data $\left(\phi^0, \phi^1, W^0, W^1\right)$ to be controlled in Fourier series:

$$\left\{\begin{array}{ll} \phi^0 = \displaystyle\sum_{n=0}^{\infty} \psi_n^0(y)\cos(n\pi x), & \phi^1 = \displaystyle\sum_{n=0}^{\infty} \psi_n^1(y)\cos(n\pi x), \\ W^0 = \displaystyle\sum_{n=0}^{\infty} V_n^0 \cos(n\pi x), & W^1 = \displaystyle\sum_{n=0}^{\infty} V_n^1 \cos(n\pi x). \end{array}\right. \tag{2.4}$$

We assume that for every $n = 0, 1, \ldots$ the initial data satisfy the assumptions of Theorems 2.1 and 2.2. We set

$$\rho_n^0 = \psi_n^0, \quad \rho_n^1 = -\psi_n^1 + V_n^0\delta_0, \quad \mu^0 = -V_n^0, \mu_n^1 = V_n^1 + \psi_n^0(0). \tag{2.5}$$

We introduce the following space of initial data:

$$\begin{aligned} H = \Bigg\{ & \left(\phi^0, \phi^1, W^0, W^1\right) \in \mathcal{X} : \\ & \sum_{n=0}^{\infty} C_n \left\| \left(\rho_n^1, \rho_n^0, \mu_n^1, \mu_n^0\right)\right\|_{\mathcal{Y}'}^2 = \left\|\left(\phi^0, \phi^1, W^0, W^1\right)\right\|_H^2 < \infty \Bigg\}, \end{aligned} \tag{2.6}$$

where the constants C_n are those appearing in (2.2).

THEOREM 2.3. *Assume that $T > 2$. Then, for every initial data $\left(\phi^0, \phi^1, W^0, W^1\right)$ in H, there exists a control $\beta \in H^{-2}(0, T; L^2(0,1))$ such that the solution (ϕ, W) of (1.3) satisfies*

$$\left\{\begin{array}{l} \phi(T) \equiv \mu^1 = \displaystyle\int_0^1 W^1(x)dx + \int_0^1 \psi^0(x,0)dx,\ \phi_t(T) \equiv 0, \\ W(T) \equiv \langle \rho^1, 1\rangle = \displaystyle\int_0^1 W^0(x)dx - \int_0^1\int_0^1 \psi^1(x,y)dxdy,\ W_t(T) \equiv 0. \end{array}\right. \tag{2.7}$$

Moreover, there exists a constant $C > 0$ such that

$$\|\beta\|_{H^{-2}(0,T;L^2(0,1))} \leq C \| \left(\phi^0, \phi^1, W^0, W^1\right) \|_H. \tag{2.8}$$

Remark 3. The control time $T > 2$ is optimal. Indeed, when $T < 2$ it is easy to see that the set of controllable data is not dense in the space of finite energy data. Actually, when $T < 2$, none of the one-dimensional problems (1.6) is approximately controllable; i.e., the space of controllable data is not even dense in $\mathcal{Y}'$.

Remark 4. The developments of this article allow us to show that $C_n = \mathcal{O}\left(e^{n^\alpha}\right)$ as $n \to \infty$ for any $\alpha > 1$. Thus, roughly speaking, the Fourier coefficients in the x-variable have to decay exponentially to guarantee the controllability. Let us explain in more detail why this result is natural.

From the definition (2.6) of H and from the fact that C_n grows exponentially, it is clear that there is no Sobolev space that might be contained in H (observe that Sobolev spaces correspond roughly to polynomial weights C_n). But this is known a priori. Indeed, as we said in the introduction, our control problem does not verify the geometric control property given in [6], and as a consequence of this, no Sobolev space of initial data may be exactly controllable with β in $H^{-2}(0, T; L^2(0,1))$.

After the first version of this paper was written, Allibert in [1] obtained some complementary results. In [1], he proved that for any ε there exists $T(\varepsilon) > 0$ such

that system (1.3) is controllable in time $T(\varepsilon)$ for all initial data in the space $H(\varepsilon)$ which is defined as in (2.6) but with $C_n = \exp(\varepsilon n)$ as $n \to \infty$. Thus, the result in [1] shows, roughly, that as $t \to \infty$, the system is controllable in a larger and larger class of analytic functions. The results in [1] are an extension of previous results by the same author on the controllability of the classical wave equation in the square Ω and with control in Γ_0. Observe that all these problems have in common the fact that the geometric control condition of [6] is not satisfied. The structure of the set of controllable data in those situations is mainly unknown.

Since the constants C_n in our estimates are of order e^{n^α}, we can control all the initial data which belong to the Gevrey classes of exponent $\alpha > 1$ in the x-variable.

Remark 5. Finally, let us mention that if a second control $\alpha \in L^2(0,T)$ is allowed to act in the system through the condition of continuity of the velocity fields

$$\frac{\partial \Phi}{\partial y} = -W_t + \alpha \text{ in } \Gamma_0 \times (0,T), \tag{2.9}$$

the same result holds with $C_n = \mathcal{O}(n^4 e^{2n\pi})$. This is a consequence of Proposition 3.2 below. From the proof of Proposition 3.2 it follows that this constant is sharp. However, introducing controls of the form (2.9) does not seem to be realistic. This is the reason for using only the control β, which requires important additional developments.

3. Controllability of the one-dimensional systems. This section is devoted to proving the controllability results for the one-dimensional systems (1.6) that are necessary to derive the controllability of system (1.3). In section 3.1, by using classical multiplier techniques, we derive some hidden regularity results. In section 3.2, with the same techniques, we get the first observability inequalities. In section 3.3, by using Ingham's inequalities, we obtain a refined version of these observability inequalities. Finally, in sections 3.4 and 3.5, we apply HUM and prove the controllability result for (1.6).

3.1. Hidden regularity. Let us consider the system

$$\begin{cases} \eta_{tt} - \eta_{yy} + n^2\pi^2\eta = f & \text{in} \quad (0,1)\times(0,T), \\ \eta_y(1) = 0 & \text{for} \quad t \in (0,T), \\ \eta_y(0) = u_t & \text{for} \quad t \in (0,T), \\ u_{tt} + n^2\pi^2 u - \eta_t(0) = g & \text{for} \quad t \in (0,T), \\ \eta(0) = \eta^0, \eta_t(0) = \eta^1 & \text{in} \quad (0,1), \\ u(0) = u^0, u_t(0) = u^1. \end{cases} \tag{3.1}$$

System (3.1) is the adjoint of (1.6). The unknowns are $\eta = \eta(y,t)$ and $u = u(t)$. Of course, since the coefficients of the system depend on $n = 0, 1 \ldots$, solutions (η, u) depend on n too. However, in order to simplify the notations, we will not use the index n to distinguish the solutions of (3.1) for the different values of n.

The energy space for system (3.1) is the Hilbert space $\mathcal{Y} = H^1(0,1) \times L^2(0,1) \times \mathbb{R} \times \mathbb{R}$.

It is easy to see that for any $(\eta^0, \eta^1, u^0, u^1) \in \mathcal{Y}$ and $(f,g) \in L^1(0,T; L^2(0,1)\times\mathbb{R})$ system (3.1) has a unique solution in the class

$$\eta \in C\left([0,T]; H^1(0,1)\right) \cap C^1\left([0,T]; L^2(0,1)\right); \qquad u \in C^1([0,T];\mathbb{R}). \tag{3.2}$$

In other words, $(\eta, \eta_t, u, u_t) \in C\left([0,T]; \mathcal{Y}\right)$.

The energy of the system

$$F(t) = \frac{1}{2}\int_0^1 \left[\mid \eta_t \mid^2 + \mid \eta_y \mid^2 + n^2\pi^2\eta^2 \right] dy + \frac{1}{2}\left[\mid u_t \mid^2 + n^2\pi^2 \mid u \mid^2 \right] \tag{3.3}$$

satisfies

$$\frac{dF(t)}{dt} = \int_0^1 f(y,t)\eta_t(y,t)dy + g(t)u_t(t). \tag{3.4}$$

Therefore, when $f \equiv 0$ and $g \equiv 0$, the energy F remains constant along trajectories.

We observe that when $n \geq 1$, the square root of F defines a norm in $\mathcal{Y}$ equivalent to the canonical norm $\| \cdot \|_{\mathcal{Y}}$ of $\mathcal{Y}$:

$$\|(u,v,w,z,)\|_{\mathcal{Y}} = \left[\int_0^1 \left(\mid u_y \mid^2 + \mid u \mid^2 + \mid v \mid^2 \right) dy + w^2 + z^2 \right]^{1/2}. \tag{3.5}$$

However, when $n = 0$, this is not the case. Actually, for $n = 0, (\eta, u) = (c_1, c_2)$ with c_1, c_2 real constants are stationary solutions of (3.1) with $f \equiv 0, g \equiv 0$ for which the energy F vanishes.

We have the following "hidden regularity" result.

PROPOSITION 3.1. *For any $T > 0$ there exists a constant $C(T) > 0$ independent of $n = 0, 1, \ldots$ such that*

$$\begin{aligned} &\left(\int_0^T \mid u_{tt} \mid dt \right)^2 + \int_0^T \left[\mid u_t \mid^2 + (1 + n^4\pi^4)u^2 + (1 + n^2\pi^2)\eta^2(0,t) \right] dt \\ &\leq C\left(n^4 + 1\right) \left[\| \left(\eta^0, \eta^1, u^0, u^1\right) \|^2_{\mathcal{Y}} + \|f\|^2_{L^1(0,T;L^2(0,1))} + \|g\|^2_{L^1(0,T)} \right] \end{aligned} \tag{3.6}$$

for any $(\eta^0, \eta^1, u^0, u^1) \in \mathcal{Y}$, $f \in L^1(0,T;L^2(0,1))$, and $g \in L^1(0,T)$.

If $g \in L^2(0,T)$, then $u \in H^2(0,T)$, and we also have

$$\begin{aligned} &\int_0^T \mid u_{tt} \mid^2 dt \\ &\leq C(n^4 + 1) \left[\|(\eta^0, \eta^1, u^0, u^1)\|^2_{\mathcal{Y}} + \|f\|^2_{L^1(0,T;L^2(0,1))} + \|g\|^2_{L^2(0,T)} \right]. \end{aligned} \tag{3.7}$$

Remark 6. This proposition shows that u is more smooth than what (3.2) guarantees. This is due to the structure of the second-order (in time) equations that u satisfies. The fact that the constant in (3.6) and (3.7) does not depend on the index n is worth mentioning.

Proof of Proposition 3.1. It is enough to consider smooth solutions since a classical density argument allows us to extend inequalities (3.6) and (3.7) to any solution with finite right-hand side. We use a classical multiplier technique (see, for instance, [10]). We multiply the first equation in (3.1) by $(1-y)\eta_y$ and integrate over $(0,1) \times (0,T)$. Integrating by parts we obtain

$$\begin{aligned} &\frac{1}{2}\int_0^T \left[\mid \eta_t \mid^2 + \mid \eta_y \mid^2 - n^2\pi^2\eta^2 \right](0,t)dt = -\int_0^1 \eta_t(1-y)\eta_y dy \Big|_0^T \\ &+\frac{1}{2}\int_0^T \int_0^1 \left[\eta_t^2 + \eta_y^2 - n^2\pi^2\eta^2 \right] dydt + \int_0^T \int_0^1 f(1-y)\eta_y dydt = X. \end{aligned}$$

In this identity we use the notation $L\mid_0^T = L(T) - L(0)$. The right-hand side of this identity can be easily bounded as follows:

$$\mid X \mid \leq \frac{1}{2}\int_0^1 \left[\eta_t^2 + \eta_y^2\right](y,0)dy + \frac{1}{2}\int_0^1 \left[\eta_t^1 + \eta_y^2\right](y,T)dy + \int_0^T F(t)dt$$

$$+\frac{1}{2}\left[\|f\|^2_{L^1(0,T;L^2(0,1))} + \|\eta_y\|^2_{L^\infty(0,T;L^2(0,1))}\right] \leq F(0) + F(T) + \int_0^T F(t)dt$$

$$+\|F(t)\|_{L^\infty(0,T)} + \frac{1}{2}\|f\|^2_{L^1(0,T;L^2(0,1))} \leq C\left[\|F\|_{L^\infty(0,T)} + \|f\|^2_{L^1(0,T;L^2(0,1))}\right],$$

with $C > 0$ independent of n.

Below, if some constant in the inequalities depends on n, we will make it explicit by means of an index n on that constant.

On the other hand, from identity (3.4) and using Gronwall's inequality, it is easy to deduce that

$$\|F\|^2_{L^\infty(0,T)} \leq C\left[\|f\|^2_{L^1(0,T;L^2(0,1))} + \|g\|^2_{L^1(0,T)} + F(0)\right].$$

Since $H^1(0,1)$ is continuously embedded in $C([0,1];\mathbb{R})$ we also have

$$\int_0^T \eta^2(0,t)dt \leq C\int_0^T F(t)dt \leq C\left[\|f\|^2_{L^1(0,T;L^2(0,1))} + \|g\|^2_{L^1(0,T)} + F(0)\right].$$

Combining these inequalities we deduce that

$$\int_0^T \left[\mid \eta_t \mid^2 + \mid \eta_y \mid^2 + n^2\pi^2\eta^2\right](0,t)dt$$

$$\leq C(n^2+1)\left[\|(\eta^0,\eta^1,u^0,u^1)\|^2_{\mathcal{Y}} + \|f\|^2_{L^1(0,T;L^2(0,1))} + \|g\|^2_{L^1(0,T)}\right]. \tag{3.8}$$

On the other hand,

$$n^4\pi^4\int_0^T u^2(t)dt \leq 2n^2\pi^2\int_0^T F(t)dt$$

$$\leq Cn^4\left[\|(\eta^0,\eta^1,u^0,u^1)\|^2_{\mathcal{Y}} + \|f\|^2_{L^1(0,T;L^2(0,1))} + \|g\|^2_{L^1(0,T)}\right]. \tag{3.9}$$

Inequalities (3.6) and (3.7) are a direct consequence of (3.8) and (3.9) and the coupling conditions between η and u given in system (3.1), i.e.,

$$\eta_y(0,t) = u_t(t); u_{tt}(t) = g(t) + \eta_t(0,t) - n^2\pi^2 u(t) \text{ for } t \in (0,T). \tag{3.10}$$ □

3.2. Observability inequalities. In this paragraph we consider the adjoint system (3.1) in the particular case where $f \equiv 0$ and $g \equiv 0$. More precisely, assume that η and u solve

$$\begin{cases} \eta_{tt} - \eta_{yy} + n^2\pi^2\eta = 0 & \text{in} \quad (0,1)\times(0,T), \\ \eta_y(1,t) = 0 & \text{for} \quad t \in (0,T), \\ \eta_y(0,t) = u_t(t) & \text{for} \quad t \in (0,T), \\ u_{tt}(t) + n^2\pi^2 u(t) - \eta_t(0,t) = 0 & \text{for} \quad t \in (0,T), \\ \eta(0) = \eta^0, \eta_t(0) = \eta^1 & \text{in} \quad (0,1), \\ u(0) = u^0, u_t(0) = u^1. \end{cases} \tag{3.11}$$

We have the following observability result.

PROPOSITION 3.2. *For any $T > 2$ there exists a constant $C > 0$ which is independent of $n = 0, 1, \ldots$ such that*

$$2F(0) + \|\eta^0\|^2_{L^2(0,1)} + |u^0|^2 \leq Ce^{2n\pi} \int_0^T \left[|u_{tt}|^2 + |u_t|^2 + (1+n^4\pi^4)|u|^2 + (1+n^2\pi^2)|\eta(0,t)|^2 \right] dt \tag{3.12}$$

for any solution of (3.11).

Remark 7. Let $\rho : (0,T) \to [0,1]$ be a nonnegative smooth function with compact support and $\rho \equiv 1$ in $(\varepsilon, T-\varepsilon)$ with $\varepsilon > 0$ small enough such that $T - 2\varepsilon > 2$. In view of the time invariance of system (3.11), we deduce that

$$2F(\varepsilon) + \|\eta(\varepsilon)\|^2_{L^2(0,1)} + |u(\varepsilon)|^2 \leq Ce^{2n\pi} \int_0^T \rho(t) \left[|u_{tt}|^2 + (1+n^4\pi^4)|u|^2 + (1+n^2\pi^2)|\eta(0,t)|^2 \right] dt.$$

Using the conservation of energy, we deduce that

$$\begin{aligned} \|(\eta^0, \eta^1, u^0, u^1)\|^2_{\mathcal{Y}} &\leq 2F(0) + \|\eta^0\|^2_{L^2(0,1)} + |u^0|^2 \\ &\leq Ce^{2n\pi} \int_0^T \rho(t) \left[|u_{tt}|^2 + |u_t|^2 + (1+n^4\pi^4)|u|^2 \right. \\ &\qquad \left. + (1+n^2\pi^2)|\eta(0,t)|^2 \right] dt. \end{aligned} \tag{3.13}$$

This estimate will allow us to construct controls with compact support in time.

Proof of Proposition 3.2. The proof of this result is obtained by means of a genuinely one-dimensional method which consists roughly on viewing the wave equation in (3.11) as being an evolution equation with respect to y, while t plays the role of the space variable. This argument was used in [18] when studying the controllability of the one-dimensional semilinear wave equation.

For any $0 \leq y \leq 1$, we define

$$G(y) = \frac{1}{2} \int_y^{T-y} \left[|\eta_t|^2 + |\eta_y|^2 + n^2\pi^2 |\eta|^2 \right](y,t) dt.$$

We have

$$G(0) = \frac{1}{2} \int_0^T \left[|\eta_t|^2 + |\eta_y|^2 + n^2\pi^2 |\eta|^2 \right](0,t) dt. \tag{3.14}$$

On the other hand,

$$\begin{aligned} G'(y) = &\int_y^{T-y} \left[|\eta_{yy}\eta_y + \eta_{ty}\eta_t + n^2\pi^2\eta_y\eta| \right](y,t) dt \\ &- \frac{1}{2} \sum_{t=y,T-y} \left[|\eta_y(y,t)|^2 + |\eta_t(y,t)|^2 + n^2\pi^2 |\eta(y,t)|^2 \right] \end{aligned}$$

and

$$\int_y^{T-y} \eta_{ty}(y,t)\eta_t(y,t) dt = - \int_y^{T-y} \eta_y(y,t)\eta_{tt}(y,t) dt + \eta_y(y,t)\eta_t(y,t) \Big|_{t=y}^{t=T-y}.$$

Therefore

$$G'(y) = \int_y^{T-y} \left[\eta_{yy} - \eta_{tt} + n^2\pi^2\eta\right] \eta_y(y,t)dt + \eta_y(y,t)\eta_t(y,t)\Big|_{t=y}^{t=T-y}$$

$$- \frac{1}{2} \sum_{t=y,T-y} \left[\mid \eta_y(y,t) \mid^2 + \mid \eta_t(y,t) \mid^2 + n^2\pi^2 \mid \eta(y,t) \mid^2\right]. \tag{3.15}$$

Using the first equation in (3.11) we have that

$$\int_y^{T-y} \left[\eta_{yy} - \eta_{tt} + n^2\pi^2\eta\right] \eta_y(y,t)dt = 2n^2\pi^2 \int_y^{T-y} \eta\eta_y(y,t)dt,$$

and on the other hand,

$$\eta_y(y,t)\eta_t(y,t)|_{t=y}^{t=T-y} - \frac{1}{2} \sum_{t=y,T-y} \left[\mid \eta_y(y,t) \mid^2 + \mid \eta_t(y,t) \mid^2 + n^2\pi^2 \mid \eta(y,t) \mid^2\right] \leq 0.$$

Combining these identities with (3.15), we deduce that

$$G'(y) \leq 2n^2\pi^2 \int_y^{T-y} \eta\eta_y(y,t)dt$$

$$\leq n\pi \int_y^{T-y} \left[\mid \eta_y \mid^2 + n^2\pi^2 \mid \eta \mid^2\right](y,t)dt \leq 2n\pi G(y).$$

Thus $G(y) \leq e^{2n\pi}G(0)$, for all $y \in (0,1)$, and therefore $\int_0^1 G(y) \leq e^{2n\pi}G(0)$.

In particular,

$$(T-2)F(T) = \int_1^{T-1} F(t)dt$$

$$= \frac{1}{2}\int_1^{T-1} \left\{\left[\int_0^1 \mid \eta_y \mid^2 + \mid \eta_t \mid^2 + n^2\pi^2\eta^2\right] dy + \mid u_t \mid^2 + n^2\pi^2u^2\right\} dt$$

$$\leq \int_0^1 G(y)dy + \frac{1}{2}\int_1^{T-1} \left[\mid u_t \mid^2 + n^2\pi^2u^2\right] dt$$

$$\leq \frac{e^{2n\pi}}{2} \int_0^T \left[\mid \eta_y \mid^2 + \mid \eta_t \mid^2 + n^2\pi^2\eta^2\right](0,t)dt + \frac{1}{2}\int_0^T \left[\mid u_t \mid^2 + n^2\pi^2u^2\right] dt. \tag{3.16}$$

Using the relations (3.11) at $y = 0$, we deduce that (3.12) holds when $n \geq 1$.

When $n = 0$, it is sufficient to add in (3.16) the extra quantity $\int_0^T [\mid \eta \mid^2 (0,t) + \mid u \mid^2 (t)]dt$ to deduce that (3.12) holds in that case too. □

Remark 8. When $n = 0$, inequality (3.12) shows that

$$\|\eta_y^0\|^2_{L^2(0,1)} + \|\eta^1\|^2_{L^2(0,1)} + \mid u^1 \mid^2 \leq C \int_0^T \left[\mid u_{tt} \mid^2 + \mid u_t \mid^2\right] dt. \tag{3.17}$$

This inequality does not provide any estimate on u^0. This is related to the fact that, when $n = 0$, system (1.6) cannot be driven exactly to zero but rather to the equilibrium given by the constants c_1, c_2 in (1.9).

3.3. Improved observability inequalities. The goal of this section is to obtain observability inequalities of the form (3.12) but in which the only term appearing on the right-hand side is $\int_0^T \mid u_{tt} \mid^2 dt$. As we will see, this is related to the controllability of system (1.6) using the sole control β. We have the following theorem.

THEOREM 3.3. *Assume that $T > 2$. Then*

(i) *for any $n \geq 1$ there exists a constant $C = C(T, n) > 0$ such that*

$$\|(\eta^0, \eta^1, u^0, u^1)\|^2_{\mathcal{Y}} \leq C(T, n) \int_0^T \mid u_{tt} \mid^2 dt \tag{3.18}$$

for any solution of (3.11). *Moreover, $C(T, n) = \mathcal{O}\left(e^{n^\alpha}\right)$, for any $\alpha > 1$.*

(ii) *if $n = 0$ there exists a constant $C = C(T) > 0$ such that*

$$\|\eta^0_y\|^2_{L^2(0,1)} + \mid u^1 \mid^2 \leq C(T) \int_0^T \mid u_{tt} \mid^2 dt \tag{3.19}$$

for any solution of (3.11).

Remark 9. As observed in Remark 7, in estimates (3.18) and (3.19) one can replace the right-hand side by the quantity $\int_0^T \rho(t) \mid u_{tt}(t) \mid^2 dt$, where ρ is a smooth nonnegative function with compact support in $(0, T)$ and such that $\rho \equiv 1$ in $(\varepsilon, T - \varepsilon)$ with $\varepsilon > 0$ small enough such that $T - 2\varepsilon > 2$.

To prove Theorem 3.3 we need the following refined version of a result by Haraux [8] on nonharmonic Fourier series.

THEOREM 3.4. *Let $f = f(t)$ be of the form $f(t) = \sum_{n \in \mathbb{Z}} a_n e^{i\lambda_n t}$, where λ_n is a sequence of real numbers. We assume that there exist $N \in \mathbb{N}, \gamma > 0$, and $\gamma_\infty > 0$ such that*

$$\lambda_{n+1} - \lambda_n \geq \gamma_\infty > 0 \text{ if } \mid n \mid > N, \tag{3.20}$$

$$\lambda_{n+1} - \lambda_n \geq \gamma > 0 \text{ for any } n \in \mathbb{Z}. \tag{3.21}$$

Let $J = [0, T] \subset \mathbb{R}$ be a finite interval with $T > \frac{2\pi}{\gamma_\infty}$. Then, there exist two positive constants $C_1, C_2 > 0$ such that

$$C_1 \sum_{n \in \mathbb{Z}} \mid a_n \mid^2 \leq \int_J \mid f(t) \mid^2 dt \leq C_2 \sum_{n \in \mathbb{Z}} \mid a_n \mid^2 \tag{3.22}$$

for all $(a_n)_n \in l^2$.

More precisely $C_1 = C_1(2N + 1)$ and $C_2 = C_2(2N + 1)$, where $C_i(j), i = 1, 2$, are given by the following recurrent formulas:

$$\begin{cases} C_1(j+1) = \left[\left(\dfrac{2C_2(j)}{\mid J \mid} + 1\right) \dfrac{4}{C_1(j)(\mid J \mid \gamma_\infty - 2\pi)^2 \gamma^2} + \dfrac{2}{\mid J \mid}\right]^{-1}, \\ C_2(j+1) = 2\left(\mid J \mid (j+1) + C_2(0)\right), \; j = 0, 1, \ldots, \end{cases} \tag{3.23}$$

and $C_1(0), C_2(0)$ are such that (3.22) *holds in the particular case in which $\gamma_\infty = \gamma > 0$.*

Remark 10. (a) When $\gamma_\infty = \gamma$, a sequence on the conditions of Theorem 3.4 satisfies $\lambda_{n+1} - \lambda_n \geq \gamma > 0\,, \forall n \in \mathbb{Z}$. In this particular case the classical result by Ingham [9] shows the existence of $c_1, c_2 > 0$ such that (3.22) holds when $\mid J \mid > \frac{2\pi}{\gamma}$.

Theorem 3.4 allows us to deduce that (3.22) holds when the length of the interval J is smaller. Indeed, it suffices that $\mid J \mid > 2\pi/\gamma_\infty, \gamma_\infty$ being the "asymptotic gap" of the sequence $\{\lambda_n\}$, which is in general larger than γ. This relaxed gap condition was shown to be sufficient for (3.22) in [4]. Later, Haraux in [8] gave a constructive proof which allows us to give explicit estimates on the constants C_1 and C_2. Following the construction in [8], one can easily see that (3.23) suffices. In the appendix at the end of this paper, we give all the details of this construction.

(b) Clearly, the constants C_1 and C_2 degenerate as $N \to \infty$. More precisely, $C_2(N) = \mathcal{O}(N)$ while $\gamma^{2N}(C_1(N))^{-1} = \mathcal{O}\left(e^{N^\alpha}\right)$ for any $\alpha > 1$. Indeed, we have

$$(C_1(N))^{-1} \leq \frac{2C_2(N)}{|J|}\frac{4}{(\mid J \mid \gamma_\infty - 2\pi)^2\gamma^2}(C_1(N-1))^{-1} = \frac{16N(C_1(N-1))^{-1}}{(\mid J \mid \gamma_\infty - 2\pi)^2\gamma^2}.$$

Hence

$$\gamma^{2N}(C_1(N))^{-1} \leq \left(\frac{16}{(\mid J \mid \gamma_\infty - 2\pi)^2\gamma^2}\right)^N N!\,(C_1(0))^{-1} \leq e^{N^\alpha}\,(C_1(0))^{-1}.$$

In order to apply Theorem 3.4 and deduce that Theorem 3.3 holds, we need precise estimates on the spectrum of (3.11). We look for solutions of (3.11) in separated variables of the form $(\eta, u) = e^{\nu t}(\varphi(y), \omega)$ with $\varphi = \varphi(y)$ and $\omega \in \mathbb{R}$. Due to the conservative character of the system, we know that all eigenvalues ν are purely imaginary. On the other hand, the spectrum is symmetric with respect to the real axis. Thus, for any $n = 0, 1, \ldots$ there exists a sequence of eigenvalues $\nu_{n,m}$ with $\overline{\nu}_{n,m} = -\nu_{n,m} = \nu_{-n,m}$.

We have the following estimates.

THEOREM 3.5 (see [12] and [14]). *For any $n = 0, 1, \ldots$ and $m \in \mathbb{Z}$ such that $\mid m \mid > n$ we have*

$$\begin{cases} \left|\nu_{n,m} - \sqrt{m^2+n^2}\pi i\right| & \leq \dfrac{24}{\sqrt{m^2+n^2}\pi} \quad \text{if } m > n, \\ \left|\nu_{n,m} + \sqrt{m^2+n^2}\pi i\right| & \leq \dfrac{24}{\sqrt{m^2+n^2}\pi} \quad \text{if } m < -n. \end{cases} \tag{3.24}$$

Remark 11. This theorem shows that, for sufficiently high frequencies, the eigenvalues of (3.11) are uniformly close to the eigenvalues $\lambda = \pm\sqrt{m^2+n^2}\pi i$ of the wave equation with Neumann boundary conditions

$$\begin{cases} \eta_{tt} - \eta_{yy} + n^2\pi^2\eta = 0 & \text{in} \quad (0,1)\times(0,\infty), \\ \eta_y(0,t) = \eta_y(1,t) = 0 & \text{for} \quad t > 0. \end{cases} \tag{3.25}$$

Clearly, system (3.25) corresponds to the decomposition of the wave equation with Neumann boundary conditions in the square Ω following the development (1.5) in Fourier series. In other words, Theorem 3.5 asserts that the spectrum of the adjoint system of (1.1), i.e.,

$$\begin{cases} \phi_{tt} - \Delta\phi = 0 & \text{in} \quad \Omega\times(0,\infty), \\ \frac{\partial\phi}{\partial\nu} = 0 & \text{on} \quad \Gamma_1\times(0,\infty), \\ \frac{\partial\phi}{\partial y} = W_t & \text{on} \quad \Gamma_0\times(0,\infty), \\ W_{tt} - W_{xx} - \phi_t = 0 & \text{on} \quad \Gamma_0\times(0,\infty), \\ W_x(0,t) = W_x(1,t) = 0 & \text{for} \quad t > 0, \end{cases}$$

at high frequencies is uniformly close to the eigenvalues of the wave equation with Neumann boundary conditions on the whole boundary of the cavity Ω:

$$\begin{cases} \phi_{tt} - \Delta\phi = 0 & \text{in} \quad \Omega \times (0,\infty), \\ \frac{\partial\phi}{\partial\nu} = 0 & \text{on} \quad \partial\Omega \times (0,\infty). \end{cases}$$

This means roughly that the effect of the flexible boundary in the interior of the cavity is negligible for high frequencies. However, it is worth mentioning that the high frequency asymptotics are of a different nature in the region $\mid m \mid \leq n$.

From Theorem 3.5 it is easy to get explicit bounds on the gaps γ and γ_∞ associated with the sequence $\{\nu_{n,m}\}_{m\in\mathbb{Z}}$ for each $n = 0, 1, \ldots$.

PROPOSITION 3.6. *Given any $n = 0, 1, \ldots$ and $0 < \delta < \pi$ we have*

$$\mid \nu_{n,m+1} - \nu_{n,m} \mid \geq \pi - \delta \tag{3.26}$$

for any m with $\mid m \mid \geq N(n,\delta)$, where

$$N(n,\delta) = \max\left[\sqrt{\frac{96}{\pi\delta} - n^2}, \frac{2n\pi}{\delta} - n - \frac{1}{2}\right]. \tag{3.27}$$

On the other hand,

$$\begin{cases} \mid \nu_{n,m+1} - \nu_{n,m} \mid \geq \frac{\pi}{4} \quad \forall m \in \mathbb{Z} & \text{if} \quad n = 0, 1, \\ \mid \nu_{n,m+1} - \nu_{n,m} \mid \geq \frac{\pi}{1+2n} \quad \forall m \in \mathbb{Z} & \text{if} \quad n \geq 2. \end{cases} \tag{3.28}$$

Furthermore, (3.22) *holds for functions f of the form*

$$f(t) = \sum_{m\in\mathbb{Z}^\star} a_{n,m} e^{-\nu_{n,m}t} + a_n^\star e^{-\nu_n^\star t} + a_n^{\star\star} e^{-\nu_n^{\star\star} t} \tag{3.29}$$

with $C_2 = C_2(2N(n,\delta)+1) = \mathcal{O}(n)$ and $(C_1)^{-1} = (C_1(2N(n,\delta)+1))^{-1}$. Moreover, $C_2 = \mathcal{O}(n)$ and $(C_1)^{-1} = \mathcal{O}\left(e^{n^\alpha}\right)$ for any $\alpha > 1$.

Proof. In view of (3.24) we have

$$\begin{aligned} &\mid \nu_{n,m+1} - \nu_{n,m} \mid \\ &\geq \pi \left|\sqrt{(m+1)^2+n^2} - \sqrt{m^2+n^2}\right| - \tfrac{24}{\pi}\left[\tfrac{1}{\sqrt{(m+1)^2+n^2}} + \tfrac{1}{\sqrt{m^2+n^2}}\right] \\ &\geq \tfrac{(2|m|+1)\pi}{(2|m|+1)+2n} - \tfrac{48}{\pi\sqrt{m^2+n^2}} \geq \pi - \left[\tfrac{48}{\pi\sqrt{m^2+n^2}} + \tfrac{2n\pi}{2|m|+1+2n}\right]. \end{aligned}$$

It is easy to see that when $\mid m \mid \geq N(n,\delta)$, where $N(n,\delta)$ is given by (3.27), then

$$\frac{48}{\pi\sqrt{m^2+n^2}} + \frac{2n\pi}{2 \mid m \mid +1+n} \leq \delta.$$

This concludes the proof of (3.26).

To prove (3.28) we observe that, for any $n = 0, 1, \ldots$, the eigenvalues $\nu_{n,m}$ with $m > 0$ are of the form

$$\nu_{n,m} = \sqrt{z_{n,m}^2 + n^2\pi^2}, \tag{3.30}$$

where $z_{n,m}$ are the zeros (ordered so that $z_{n,m}$ increases as m does) of the equation

$$tgz = \frac{z^2 + n^2\pi^2}{z^3}. \tag{3.31}$$

There are also two eigenvalues, which we denote by $\nu_n^\star$ and $\nu_n^{\star\star}$, that do not satisfy (3.30). Indeed, they are given by

$$\nu_n^\star = \sqrt{n^2\pi^2 - (z_n^\star)^2}, \tag{3.32}$$

where $z_n^\star$ is the unique real positive solution of

$$e^{2z} = \frac{z^3 - z^2 + n^2\pi^2}{z^3 + z^2 - n^2\pi^2}, \tag{3.33}$$

when $n \geq 1$ and $\nu_0^\star = 0$, and $\nu_n^{\star\star} = \overline{\nu_n^\star}$.

By analyzing the graphs of the functions in (3.31) and (3.33) it is easy to see that (3.28) holds. We refer to [14] for a detailed proof.

To finish the proof we have to apply Theorem 3.4 for $\gamma = \min\left\{\frac{\pi}{4}, \frac{\pi}{1+2n}\right\}$ and $\gamma_\infty = \pi - \delta$. We obtain that (3.22) holds for functions f of the form (3.29).

In order to evaluate the constants, we use the recurrent formulas (3.23). We have

$$C_2 = C_2(2N(n,\delta)+1) = 2(T(N(n,\delta)+1) + C_2(0)) = \mathcal{O}(n).$$

On the other hand,

$$(C_1)^{-1} = (C_1(2N(n,\delta)+1))^{-1} \leq \frac{8C_2(N(n,\delta)+1)(C_1(2N(n,\delta)))^{-1}}{T(T\gamma_\infty - 2\pi)^2\gamma^2}$$

$$\leq Mn^3(C_1(2N(n,\delta)))^{-1} \leq M^{2N(n,\delta)+1}((N(n,\delta)+1)!)^3(C_1(0))^{-1} \leq C(\alpha)e^{n^\alpha},$$

where M is a positive constant and $\alpha > 1$. □

Now we have all the ingredients we need to prove Theorem 3.3.

Proof of Theorem 3.3. Let us consider first the case $n \geq 1$. In view of Proposition 3.2 it is sufficient to show the existence of a constant C (depending on n and T) such that

$$\int_0^T \left[\mid u_t \mid^2 + n^4\pi^4 \mid u \mid^2 + n^2\pi^2 \mid \eta(0,t) \mid^2 \right] dt \leq C \int_0^T \mid u_{tt} \mid^2 dt \tag{3.34}$$

holds for any solution of (3.11).

Let $U(t) = (\eta(t), \eta_t(t), u(t), u_t(t))$ be the vector-valued unknown associated with (3.11) viewed as a first-order (in time) system. Let us denote by $\xi_\nu = (\xi_\nu^1, \xi_\nu^2, \xi_\nu^3, \xi_\nu^4)$ the vector-valued eigenfunction of system (3.11) associated with the eigenvalue ν.

The solutions η and u of (3.11) can be written as follows:

$$\eta(t) = \sum_{m\in\mathbb{Z}^\star} a_{n,m}e^{-\nu_{n,m}t}\xi_{n,m}^1 + a_n^\star e^{-\nu_n^\star t}\xi_{\nu_n^\star}^1 + a_n^{\star\star}e^{-\nu_n^{\star\star}t}\xi_{\nu_n^{\star\star}}^1,$$

$$u(t) = \sum_{m\in\mathbb{Z}^\star} a_{n,m}e^{-\nu_{n,m}t}\xi_{n,m}^3 + a_n^\star e^{-\nu_n^\star t}\xi_{\nu_n^\star}^3 + a_n^{\star\star}e^{-\nu_n^{\star\star}t}\xi_{\nu_n^\star}^3,$$

where the coefficients $\{a_{n,m}, a_n^\star, a_n^{\star\star}\}$ are those associated with the development of the initial data on the orthogonal basis generated by the eigenfunctions.

To get the bounds in (3.34) we first observe that

$$\eta(0,t)=\sum_{m\in\mathbb{Z}^\star} a_{n,m}e^{-\nu_{n,m}t}\xi^1_{n,m}(0)+a^\star_n e^{-\nu^\star_n t}\xi^1_{\nu^\star_n}(0)+a^{\star\star}_n e^{-\nu^{\star\star}_n t}\xi^1_{\nu^\star_n}(0)$$

and

$$\eta_t(0,t)=-\sum_{m\in\mathbb{Z}^\star} a_{n,m}\nu_{n,m}e^{-\nu_{n,m}t}\xi^1_{n,m}(0)-a^\star_n\nu^\star_n e^{-\nu^\star_n t}\xi^1_{\nu^\star_n}(0)-a^{\star\star}_n\nu^{\star\star}_n e^{-\nu^{\star\star}_n t}\xi^1_{\nu^\star_n}(0).$$

In view of Proposition 3.6 we can apply Theorem 3.4 to these series in any time interval $J=(0,T)$ with $T>2$. Therefore, taking into account that $\mid \nu^\star_n \mid = \min\{\mid \nu_{n,m}\mid, \mid \nu^\star_n\mid, \mid \nu^{\star\star}_n\mid\}$, we have

$$\int_0^T \mid \eta(0,t)\mid^2 dt \le C_2\left(\sum_{m\in\mathbb{Z}^\star}\mid a_{n,m}\xi^1_{n,m}(0)\mid^2+\mid a^\star_n\xi^1_{\nu^\star_n}(0)\mid^2+\mid a^{\star\star}_n\xi^1_{\nu^\star_n}(0)\mid^2\right)$$

$$\le \frac{C_2}{\mid\nu^\star_n\mid^2}\left(\sum_{m\in\mathbb{Z}^\star}\mid a_{n,m}\xi^1_{n,m}(0)\,\nu_{n,m}\mid^2+\mid a^\star_n\xi^1_{\nu^\star_n}(0)\,\nu^\star_n\mid^2+\mid a^{\star\star}_n\xi^1_{\nu^\star_n}(0)\,\nu^{\star\star}_n\mid^2\right)$$

$$\le \frac{C_2}{C_1\mid\nu^\star_n\mid^2}\int_0^T\mid\eta_t(0,t)\mid^2 dt.$$

On the other hand, from the equation that u satisfies in (3.11), we have

$$\int_0^T(\eta_t(0,t))^2\,dt\le 2\int_0^T\left[\mid u_{tt}\mid^2+n^4\pi^4\mid u\mid^2\right]dt.$$

Thus, in order to conclude (3.34), it is sufficient to show that

$$\int_0^T\left[\mid u_t\mid^2+n^4\pi^4u^2\right]dt\le C\int_0^T\mid u_{tt}\mid^2\,dt$$

holds. The argument we have used to bound $\int_0^T\mid\psi(0,t)\mid^2 dt$ allows us to show that

$$\int_0^T\mid u\mid^2 dt\le\frac{C_2}{C_1\mid\nu^\star_n\mid^4}\int_0^T\mid u_{tt}\mid^2 dt \text{ and } \int_0^T\mid u_t\mid^2 dt\le\frac{C_2}{C_1\mid\nu^\star_n\mid^2}\int_0^T\mid u_{tt}\mid^2 dt.$$

Combining these results we deduce that (3.34) holds with a constant C of the order of

$$C=\frac{C_2}{C_1}\left\{\frac{1}{\mid\nu^\star_n\mid^2}+\frac{n^4\pi^4}{\mid\nu^\star_n\mid^4}\left(1+\frac{2C_1}{C_1\mid\nu^\star_n\mid^2}\right)+\frac{2C_2}{C_1\mid\nu^\star_n\mid^2}\right\}, \tag{3.35}$$

where $C_1=C_1(2N+1), C_2=C_2(2N+1)$ are given by (3.23) with $N=N(n,\delta)$ as in (3.27), and $\delta>0$ such that $T=\frac{2\pi}{\pi-\delta}$.

We now proceed to estimate the constant C of (3.35). In [14] we prove that $\nu^\star_n\sim n\pi$. On the other hand, from Proposition 3.3, we have that $C_2(C_1)^{-1}=\mathcal{O}\left(e^{n^\alpha}\right)$. Finally, we obtain that $C=\mathcal{O}\left(e^{n^\alpha}\right)$ for all $\alpha>1$.

Let us now consider the case $n=0$. In view of (3.17) we have

$$\|\eta^0_y\|^2_{L^2(0,1)}+\|\eta^1\|^2_{L^2(0,1)}+\mid u^1\mid^2\le\frac{1}{T-2}\int_0^T\left[\mid u_{tt}\mid^2+2\mid u_t\mid^2\right]dt. \tag{3.36}$$

Therefore, it is sufficient to show that

$$\int_0^T \mid u_t \mid^2 dt \leq C \int_0^T \mid u_{tt} \mid^2 . \tag{3.37}$$

Proceeding as above, we see that (3.37) holds with $C = C_2/C_1 \mid \nu_{n,1} \mid^2$, where $C_1 = C_1(2N+1), C_2 = C_2(2N+1)$, and $N = N(0,\delta)$ with $\delta > 0$ such that $T = \frac{2\pi}{\pi - \delta}$. □

3.4. Controllability in one space dimension for $n \geq 1$: Proof of Theorem 2.1. In this section, applying HUM, we prove Theorem 2.1 as a consequence of the observability inequality (3.18).

Given any $(\eta^0, \eta^1, u^0, u^1) \in \mathcal{Y}$ we solve the adjoint system (3.11).

We fix some nonnegative smooth function $\rho : (0,T) \to \mathbb{R}$ with compact support such that $\rho \equiv 1$ in $(\varepsilon, T-\varepsilon)$ with $T - 2\varepsilon > 2$.

We then solve the backward system

$$\begin{cases} \psi_{tt} - \psi_{yy} + n^2\pi^2\psi = 0 & \text{in} \quad (0,1)\times(0,T), \\ \psi_y(1,t) = 0 & \text{for} \quad t \in (0,T), \\ \psi_y(0,t) = -V_t(t) & \text{for} \quad t \in (0,T), \\ V_{tt} + n^2\pi^2 V + \psi_t(0,t) = -\frac{d^2}{dt^2}(\rho(t)u_{tt}(t)) & \text{for} \quad t \in (0,T), \\ \psi(T) = \psi_t(T) = 0 & \text{in} \quad (0,1), \\ V(T) = V_t(T) = 0. \end{cases} \tag{3.38}$$

The solution of (3.38) is defined by transposition (see [10]). If we multiply in (3.38) by any solution $(\widetilde{\eta}, \widetilde{u})$ of (3.1) and integrate (formally) by parts, we obtain the following identity:

$$\int_0^T \rho(t)u_{tt}(t)\widetilde{u}_{tt}(t)dt + \int_0^T \int_0^1 \widetilde{f}\psi dydt - \int_0^T \widetilde{g}V dt = \int_0^1 [-\psi_t(0)\widetilde{\eta}(0)$$

$$+\psi(0)\widetilde{\eta}_t(0)]\, dy + V(0)\widetilde{\eta}(0,0) + \psi(0,0)\widetilde{u}(0) - V(0)\widetilde{u}_t(0) + V_t(0)\widetilde{u}(0). \tag{3.39}$$

Notice that in the obtainment of (3.39) we have used the fact that ρ and its first derivative vanish for $t = 0$ and T.

We adopt (3.39) as the definition of weak solution in the sense of transposition of (3.38). More precisely, we say that (ψ, V) solve (3.38) if (3.39) holds for any $(\widetilde{\eta}^0, \widetilde{\eta}^1, \widetilde{u}^0, \widetilde{u}^1) \in \mathcal{Y}$ and $(\widetilde{f}, \widetilde{g}) \in L^1(0,T; L^2(0,1)\times\mathbb{R})$.

We observe that (3.39) can be rewritten in the following way:

$$\begin{aligned} \int_0^T \rho(t)u_{tt}(t)\widetilde{u}_{tt}dt - \int_0^T \int_0^1 \widetilde{f}\psi dydt + \int_0^T \widetilde{g}V dt = &- \langle \psi_t(0) + V(0)\delta_0, \widetilde{\eta}(0)\rangle \\ &+ \langle \psi(0), \widetilde{\eta}_t(0)\rangle + (V_t(0) + \psi(0,0))\,\widetilde{u}(0) - V(0)\widetilde{u}_t(0), \end{aligned} \tag{3.40}$$

where $\langle\cdot,\cdot\rangle$ denotes both the duality pairing between $(H^1(0,1))'$ and $H^1(0,1)$ and the scalar product in $L^2(0,1)$, and $\delta_0 \in (H^1(0,1))'$ denotes the Dirac delta at $y = 0$.

We have the following existence and uniqueness result of solutions in the sense of transposition.

PROPOSITION 3.7. *System* (3.38) *has a unique solution in the sense of transposition. More precisely, for any solution* (η, u) *of* (3.11) *with initial data in* $\mathcal{Y}$*, there*

exists a unique $(\psi, V) \in C([0,T]; L^2(0,1)) \times L^2(0,T)$, $\rho^0 \in L^2(0,1)$, $\rho^1 \in (H^1(0,1))'$, $\mu^0 \in \mathbb{R}, \mu^1 \in \mathbb{R}$ *satisfying*

$$\begin{aligned}\int_0^T \rho(t) u_{tt}(t) \widetilde{u}_{tt} dt &= \int_0^T \int_0^1 \widetilde{f} \psi dy dt - \int_0^T \widetilde{g} V dt \\ &+ \left\langle \rho^1, \widetilde{\eta}(0) \right\rangle + \left\langle \rho^0, \widetilde{\eta}_t(0) \right\rangle + \mu^1 \widetilde{u}(0) + \mu^0 \widetilde{u}_t(0)\end{aligned} \tag{3.41}$$

for any solution $(\widetilde{\eta}, \widetilde{u})$ *of* (3.1) *with*

$$(\widetilde{\eta}^0, \widetilde{\eta}^1, \widetilde{u}^0, \widetilde{u}^1) \in \mathcal{Y}, \quad \widetilde{f} \in L^1\left(0,T; L^2(0,1)\right), \quad \widetilde{g} \in L^2(0,1). \tag{3.42}$$

Remark 12. In the identity (3.41), ρ^0, ρ^1, μ^0, and μ^1 play, respectively, the roles of $\psi(0), -\psi_t(0) + V(0)\delta_0, -V(0)$, and $V_t(0) + \psi(0,0)$. It is easy to see that, in the frame of smooth functions, there is a one to one correspondence between $\left(\rho^0, \rho^1, \mu^0, \mu^1\right)$ and $(\psi(0), \psi_t(0), V(0), V_t(0))$.

Proof of Proposition 3.7. In view of Proposition 3.1 we know that the map

$$\left(\widetilde{\eta}^0, \widetilde{\eta}^1, \widetilde{u}^0, \widetilde{u}^1, \widetilde{f}, \widetilde{g}\right) \longrightarrow \int_0^T \rho(t) u_{tt}(t) \widetilde{u}_{tt}(t) dt$$

is linear and continuous from $\mathcal{Y} \times L^1\left(0,T; L^2(0,1)\right) \times L^2(0,T)$ into $\mathbb{R}$. This implies the existence and uniqueness of $\left(\rho^1, \rho^0, \mu^1, \mu^0\right) \times (\psi, V) \in \mathcal{Y}' \times L^\infty\left(0,T; L^2(0,1)\right) \times L^2(0,T)$ such that (3.41) holds. Moreover, there exists a constant $C > 0$ such that

$$\begin{aligned}\|(\psi, V)\|_{L^\infty(0,T;L^2(0,1)) \times L^2(0,T)} + \| \left(\rho^1, \rho^0, \mu^1, \mu^0\right) \|_{\mathcal{Y}'} &\leq C \|u_{tt}\|_{L^2(0,T)} \\ &\leq C \| \left(\eta^1, \eta^0, u^1, u^0\right) \|_{\mathcal{Y}'}.\end{aligned} \tag{3.43}$$

The fact that $\psi \in C\left([0,T]; L^2(0,1)\right)$ can be deduced from (3.43) by a classical density argument. □

Remark 13. When the data of (3.11) are smooth, the solution (η, u) is smooth too. It is easy to see that (3.38) has a finite energy solution. In this case one can check that the element $\left(\rho^1, \rho^0, \mu^1, \mu^0\right) \in \mathcal{Y}'$ obtained in Proposition 3.7 is such that

$$\rho^0 = \psi(0), \quad \rho^1 = -\psi_t(0) + V(0)\delta_0, \quad \mu^0 = -V(0), \quad \mu^1 = V_t(0) + \psi(0,0).$$

By a density argument, one can then deduce that the solution (ψ, V) obtained in Proposition 3.7 is such that the traces

$$\psi\,|_{t=0}, -\psi_t + V\delta_0|_{t=0}, \quad -V\,|_{t=0}, V_t + \psi(0,t)|_{t=0}$$

are well defined and coincide with $\left(\rho^0, \rho^1, \mu^0, \mu^1\right)$.

The same argument allows us to show that the traces are also well defined at $t = T$. This suffices to assert that the weak solution of (3.38) we have constructed by transposition is at rest at $t = T$.

We can now complete the proof of Theorem 2.1. □

End of the proof of Theorem 2.1. In view of Proposition 3.7 and Remark 13, we can define a linear and continuous map Λ from $\mathcal{Y}$ into $\mathcal{Y}'$ such that

$$\Lambda\left(\eta^0, \eta^1, u^0, u^1\right) = \left(-\psi_t + V\delta_0\,|_{t=0}, \psi(0), V_t + \psi(0,t)\,|_{t=0}, -V\,|_{t=0}\right).$$

Taking, in (3.41), $\widetilde{f} \equiv 0, \widetilde{g} \equiv 0$ and $(\widetilde{\eta}, \widetilde{u}) = (\eta, u)$, we deduce that

$$\left\langle \Lambda\left(\eta^0, \eta^1, u^0, u^1\right), \left(\eta^0, \eta^1, u^0, u^1\right) \right\rangle = \int_0^T \rho(t) \left|u_{tt}(t)\right|^2 dt,$$

and in view of Theorem 3.3 and Remark 9, we deduce that there exists $C > 0$ such that

$$\left\langle \Lambda\left(\eta^0, \eta^1, u^0, u^1\right), \left(\eta^0, \eta^1, u^0, u^1\right)\right\rangle \geq C \left\| \left(\eta^0, \eta^1, u^0 u^1\right)\right\|_{\mathcal{Y}}^2.$$

Actually, $C = [C(T,n)]^{-1}$, where $C(T,n)$ is as in (3.18).

This implies that Λ is an isomorphism.

This shows that given any $\left(\rho^1, \rho^0, \mu^1, \mu^0\right) \in \mathcal{Y}'$ there exists $\left(\eta^0, \eta^1, u^0, u^1\right) = \Lambda^{-1}\left(\rho^1, \rho^0, \mu^1, \mu^0\right)$ such that the corresponding solution of (3.38) in the sense of transposition satisfies

$$\psi(0) = \rho^0, \quad -\psi_t + V\delta_0 \left|_{t=0} = \rho^1, \quad -V \right|_{t=0} = \mu^0, \quad V_t + \psi(0,t) \left|_{t=0} = \mu^1. \tag{3.44}$$

If we want this to be equivalent to the initial data of (1.6), we have to take

$$\rho^0 = \psi^0, \quad \rho^1 = -\psi^1 + V^0\delta_0, \quad \mu^0 = -V^0, \quad \mu^1 = V^1 + \psi^0(0). \tag{3.45}$$

This makes sense when the data $\left(\psi^0, \psi^1, V^0, V^1\right)$ are in $\mathcal{Y}$.

The control we have obtained is of the form $\beta = -\frac{d^2}{dt^2}(\rho u_{tt})$, where u corresponds to the solution (η, u) of (3.11) with data $\left(\eta^0, \eta^1, u^0, u^1\right) = \Lambda^{-1}\left(\rho^1, \rho^0, \mu^1, \mu^0\right)$, where $\left(\rho^0, \rho^1, \mu^0, \mu^1\right)$ is given by (3.44). From the identities above, we see that

$$\begin{aligned} \|\beta\|^2_{H^{-2}(0,T)} \leq \|\rho u_{tt}\|^2_{L^2(0,T)} &\leq C\| \left(\rho^1, \rho^0, \mu^1, \mu^0\right) \|^2_{\mathcal{Y}'} \\ &\leq C\left\{\| \left(\psi^1, \psi^0, V^1, V^0\right) \|^2_{\mathcal{Y}'} + \mid \psi^0(0) \mid^2\right\}, \end{aligned}$$

where $C = C(T,n)$ is the constant obtained in (3.18). □

Remark 14. In fact, in some sense, we obtain a stronger result, since we prove that we can control the problem (3.41) for any initial data $\left(\rho^1, \rho^0, \mu^1, \mu^0\right) \in \mathcal{Y}'$. In order to give an interpretation of the control problem in terms of the initial data $\left(\psi^0, \psi^1, V^0, V^1\right)$, we have to ensure that $\psi^0(0)$ makes sense. For this reason we consider that $\left(\psi^0, \psi^1, V^0, V^1\right) \in \mathcal{Y}$.

3.5. Controllability in one space dimension for $n = 0$: Proof of Theorem 2.2. First, we observe that proving Theorem 2.2 is equivalent to showing that for any initial data as in the statement of Theorem 2.2 and satisfying the further assumptions

$$V^1 + \psi^0(0) = 0, \quad V^0 - \int_0^1 \psi^1(y)dy = 0, \tag{3.46}$$

there exists a control β such that

$$\psi(T) = \psi_t(T) \equiv 0 \text{ in } (0,1), \quad V(T) = V_t(T) = 0. \tag{3.47}$$

Indeed, this is an immediate consequence of the remark made in the introduction, which shows that when β is of zero average the following identities hold:

$$V_t(T) + \psi(0,T) = V^1 + \psi^0(0), \quad V(T) - \int_0^1 \psi_t(y,T)dy = V^0 - \int_0^1 \psi^1(y)dy. \tag{3.48}$$

Thus, below we focus on initial data $\left(\psi^0, \psi^1, V^0, V^1\right)$ satisfying (3.46). For the adjoint system

$$\left\{\begin{array}{lll} \eta_{tt} - \eta_{yy} = 0 & \text{in} & (0,1)\times(0,T), \\ \eta_y(1) = 0 & \text{for} & t \in (0,T), \\ \eta_y(0) = u_t & \text{for} & t \in (0,T), \\ u_{tt} - \eta_t(0) = 0 & \text{for} & t \in (0,T), \\ \eta(0) = \eta^0, \eta_t(0) = \eta^1 & \text{in} & (0,1), \\ u(0) = u^0, u_t(0) = u^1 & & \end{array}\right. \tag{3.49}$$

we consider initial data in the following subspace $\mathcal{Y}_0$ of $\mathcal{Y}$:

$$\mathcal{Y}_0 = \left\{ \left(\eta^0, \eta^1, u^0, u^1\right) \in \mathcal{Y} : u^1 - \eta^0(0) = 0, \int_0^1 \eta^1 dy + u^0 = 0 \right\}. \tag{3.50}$$

It is easy to see that the subspace $\mathcal{Y}_0$ is invariant under the flow generated by (3.49).

Given $\left(\eta^0, \eta^1, u^0, u^1\right) \in \mathcal{Y}_0$, we solve first (3.49) and then the backward system

$$\left\{\begin{array}{lll} \psi_{tt} - \psi_{yy} = 0 & \text{in} & (0,1)\times(0,T), \\ \psi_y(1,t) = 0 & \text{for} & t \in (0,T), \\ \psi_y(0,t) = -V_t(t) & \text{for} & t \in (0,T), \\ V_{tt}(t) + \psi_t(0,t) = -\frac{d^2}{dt^2}\left(\rho(t) u_{tt}(t)\right) & \text{for} & t \in (0,T), \\ \psi(T) = \psi_t(T) = 0 & \text{in} & (0,1), \\ V(T) = V_t(T) = 0, & & \end{array}\right. \tag{3.51}$$

where ρ is as in the proof of Theorem 2.1.

Proceeding as in the proof of Proposition 3.7 one can show that (3.51) has a unique solution defined by transposition such that the traces (3.47) are well defined. On the other hand, integrating the equations in (3.51), we deduce that

$$\int_0^1 \rho^1(y) dy = 0, \quad \mu^1 = 0. \tag{3.52}$$

Let us denote by Z the subspace of $\mathcal{Y}'$ satisfying (3.52). More precisely,

$$Z = \left\{ \left(\rho^1, \rho^0, \mu^1, \mu^0\right) \in \mathcal{Y}' : \text{ (3.52) holds } \right\}. \tag{3.53}$$

It is easy to check that Z is actually the dual of $\mathcal{Y}_0$. Indeed, the dual of $\mathcal{Y}_0$ is a quotient space of $\mathcal{Y}'$, and there is a one-to-one correspondence between Z and this quotient space in the sense that, in Z, we have chosen the unique element of each class of the quotient space satisfying (3.52).

As in the proof of Theorem 2.1, we can define a linear and continuous operator $\Lambda : \mathcal{Y}_0 \longrightarrow Z$ that associates the trace $\left(\rho^1, \rho^0, \mu^1, \mu^0\right) \in Z$ in (3.41) with each $\left(\eta^0, \eta^1, u^0, u^1\right) \in \mathcal{Y}_0$.

We also have

$$\left\langle \Lambda\left(\eta^0, \eta^1, u^0, u^1\right), \left(\eta^0, \eta^1, u^0, u^1\right) \right\rangle = \int_0^T \rho(t) \left|u_{tt}(t)\right|^2 dt.$$

In view of Theorem 3.3 and Remark 9 we deduce the existence of a constant $C > 0$ such that

$$\left\langle \Lambda\left(\eta^0, \eta^1, u^0, u^1\right), \left(\eta^0, \eta^1, u^0, u^1\right) \right\rangle \geq C \left\| \left(\eta^0, \eta^1, u^0, u^1\right) \right\|_{\mathcal{Y}'}^2, \ \forall \left(\eta^0, \eta^1, u^0, u^1\right) \in \mathcal{Y}_0,$$

since the quantity $\left[\|\eta_y^0\|^2_{L^2(0,1)} + \|\eta^1\|^2_{L^2(0,1)} + |\ u^1\ |^2\right]^{1/2}$ defines a norm in $\mathcal{Y}_0$ which is equivalent to the norm induced by $\mathcal{Y}$.

We deduce that $\Lambda : \mathcal{Y}_0 \longrightarrow Z$ is an isomorphism.

Then, given initial data as in the statement of Theorem 2.2 and such that (3.46) holds, we define $\left(\rho^1, \rho^0, \mu^1, \mu^0\right) \in Z$ by (3.45). The control we are looking for is $\beta = -\frac{d^2}{dt^2}\left(\rho(t) u_{tt}(t)\right)$, where u is the second component of the solution (η, u) of (3.49) with initial data $\left(\eta^0, \eta^1, u^0, u^1\right) = \Lambda^{-1}\left(\rho^1, \rho^0, \mu^1, \mu^0\right)$.

This concludes the proof of Theorem 3.5. □

4. Controllability of the two-dimensional system: Proof of Theorem 2.3. In view of Theorems 2.1 and 2.2 for any $n = 0, 1, \ldots$, there exists a control $\beta_n \in H^{-2}(0,T)$ such that the solution (ψ_n, V_n) of (1.6) satisfies

$$\psi_n(T) \equiv \psi_{n,t}(T) = 0 \text{ in } (0,1), \quad V_n(T) = V_{n,t}(T) = 0 \tag{4.1}$$

for $n \geq 1$ and

$$\psi_0(T) = \mu^1, \quad \psi_{0,t}(T) = 0 \text{ in } (0,1), \quad V_0(T) = \left\langle \rho^1, 1 \right\rangle, \quad V_{0,t}(T) = 0 \tag{4.2}$$

when $n = 0$.

On the other hand,

$$\|\beta_n\|^2_{H^{-2}(0,T)} \leq C_n \left\| \left(\rho_n^1, \rho_n^0, \mu_n^1, \mu_n^0\right) \right\|^2_{\mathcal{Y}'}. \tag{4.3}$$

We construct the following control for the two-dimensional system:

$$\beta(x,t) = \sum_{n=0}^{\infty} \beta_n \cos(n\pi x). \tag{4.4}$$

We have, in view of (4.3),

$$\|\beta\|^2_{H^{-2}(0,T;L^2(0,1))} = \sum_{n=0}^{\infty} \|\beta_n(t)\|^2_{H^{-2}(0,T)}$$

$$\leq \sum_{n=0}^{\infty} C_n \left\| \left(\rho_n^1, \rho_n^0, \mu_n^1, \mu_n^0\right) \right\|^2_{\mathcal{Y}'} = \left\| \left(\psi^0, \psi^1, W^0, W^1\right) \right\|^2_H < \infty.$$

Therefore, $\beta \in H^{-2}\left(0,T; L^2(0,1)\right)$. On the other hand,

$$\psi(x,y,t) = \sum_{n=0}^{\infty} \psi_n(y,t) \cos(n\pi x), \quad W(x,t) = \sum_{n=0}^{\infty} V_n(t) \cos(n\pi x)$$

solves (1.3) with the control β given in (4.4), and satisfies (2.7) at time $t = T$.

This concludes the proof of this theorem. □

5. Appendix: Proof of Theorem 3.4. First, we recall a classical result due to Ingham.

THEOREM A (see Ingham [9, Thms. 1 and 2]). *Let $f = f(t)$ be of the form $f(t) = \sum_{n\in\mathbb{Z}} a_n e^{i\lambda_n t}$, where λ_n is a sequence of real numbers.*

We assume that there exists $\gamma > 0$ *such that*

$$\lambda_{n+1} - \lambda_n \geq \gamma, \ \forall n \in \mathbb{Z}. \tag{5.1}$$

Let $J = [0, T]$ *with* $T > \frac{2\pi}{\gamma}$. *Then there exist two positive constants* $C_1^0, C_2^0 > 0$ *such that*

$$C_1^0 \sum_{n\in\mathbb{Z}} |\, a_n \,|^2 \leq \int_J |\, f(t) \,|^2 \, dt \leq C_2^0 \sum_{n\in\mathbb{Z}} |\, a_n \,|^2 \tag{5.2}$$

for all $a_n \in \ell^2$

Remark 15. The constants C_1^0 and C_2^0 depend only on $T - \frac{2\pi}{\gamma}$.

To prove (3.22) we follow the ideas of Haraux [8], paying special attention to the evaluation of the constants appearing there.

The second inequality of (3.22) results, with $C_2 = 2C_2^0 + 2|J|(2N+1)$, immediately using Theorem A. Indeed we have

$$\int_J |f(t)|^2 \, dt = \int_J \left| \sum_{|n|>N} a_n e^{i\lambda_n t} + \sum_{|n|\leq N} a_n e^{i\lambda_n t} \right|^2$$

$$\leq 2 \int_J \left(\left| \sum_{|n|>N} a_n e^{i\lambda_n t} \right|^2 + \left| \sum_{|n|\leq N} a_n e^{i\lambda_n t} \right|^2 \right).$$

Now, applying Theorem A to the function $g(t) = \sum_{|n|\geq N} a_n e^{i\lambda_n t}$, we obtain

$$\int_J |f(t)|^2 \, dt \leq 2C_2^0 \sum_{|n|>N} |a_n|^2 + 2|J| \left(\sum_{|n|\leq N} |a_n| \right)^2$$

$$\leq 2C_2^0 \sum_{|n|>N} |a_n|^2 + 2|J|(2N+1) \sum_{|n|\leq N} |a_n|^2 \leq \left(2C_2^0 + 2|J|(2N+1)\right) \sum_{n\in\mathbb{Z}} |a_n|^2.$$

We now proceed to prove the first inequality of (3.22). We do this by induction in p, the number of indexes $n \in \mathbb{Z}$ for which $\lambda_{n+1} - \lambda_n < \gamma_\infty$.

If $p = 0$, the result follows from Theorem A with $C_1 = C_1(0) = C_1^0$. Suppose now that $p > 0$.

We write the function f in the form $f(t) = \sum_{n\neq 0} a_n e^{i\lambda_n t} + a_0 e^{i\lambda_0 t}$, where λ_0 is one of those values for which $\lambda_{n+1} - \lambda_n < \gamma_\infty$. Moreover, without loss of generality, we may suppose that $\lambda_0 = 0$ (since we can consider the function $f(t)e^{-i\lambda_0 t}$ instead of $f(t)$). We now apply the induction hypothesis for the function $g(t) = \sum_{n\neq 0} a_n e^{i\lambda_n t}$, and we obtain that

$$C_1(p-1) \sum_{n\neq 0} |a_n|^2 \leq \int_J |g(t)|^2 \leq C_2(p-1) \sum_{n\neq 0} |a_n|^2. \tag{5.3}$$

We know that $C_2(p-1) = 2C_2^0 + 2|J|(p-1)$. Let $\varepsilon > 0$ be such that $T' = T - \varepsilon > \frac{2\pi}{\gamma_\infty}$.

We have

$$\int_0^\varepsilon (f(t+\eta) - f(t)) \, d\eta = \sum_{n\neq 0} a_n \left(\frac{e^{i\lambda_n \varepsilon} - 1}{i\lambda_n} - \varepsilon \right) e^{i\lambda_n t} \quad \forall t \in [0, T'].$$

Applying the induction hypothesis to the function $h(t)=\int_0^\varepsilon (f(t+\eta)-f(t))\,d\eta$, we obtain that

$$C_1(p-1)\sum_{n\neq 0}\left|\frac{e^{i\lambda_n\varepsilon}-1}{i\lambda_n}-\varepsilon\right||a_n|^2\leq\int_0^{T'}\left|\int_0^\varepsilon (f(t+\eta)-f(t))\,d\eta\right|^2. \tag{5.4}$$

We now evaluate the coefficients $\dfrac{e^{i\lambda_n\varepsilon}-1}{i\lambda_n}-\varepsilon$. We have

$$\left|e^{i\lambda_n\varepsilon}-1-\varepsilon i\lambda_n\right|^2=|\cos(\lambda_n\varepsilon)-1|^2+|\sin(\lambda_n\varepsilon)-\lambda_n\varepsilon|^2$$

$$=4\sin^4\left(\frac{\lambda_n\varepsilon}{2}\right)+(\sin(\lambda_n\varepsilon)-\lambda_n\varepsilon)^2\geq\begin{cases}4\left(\frac{\lambda_n\varepsilon}{2}\operatorname{arctg}\left(\frac{\pi}{2}\right)\right)^4 & \text{if } |\lambda_n|\varepsilon\leq\frac{\pi}{2},\\ \left(|\lambda_n|\varepsilon-1\right)^2 & \text{if } |\lambda_n|\varepsilon>\frac{\pi}{2}.\end{cases}$$

Finally, taking into account that $|\lambda_n|\geq\gamma$, we obtain that, for ε small enough,

$$\left|\frac{e^{i\lambda_n\varepsilon}-1}{i\lambda_n}-\varepsilon\right|^2\geq\gamma^2\varepsilon^4.$$

We now return to (5.4), and we get that

$$\gamma^2\varepsilon^4C_1(p-1)\sum_{n\neq 0}|a_n|^2\leq\int_0^{T'}\left|\int_0^\varepsilon (f(t+\eta)-f(t))\,d\eta\right|^2. \tag{5.5}$$

On the other hand,

$$\int_0^{T'}\left|\int_0^\varepsilon (f(t+\eta)-f(t))\,d\eta\right|^2\leq\int_0^{T'}\varepsilon\int_0^\varepsilon|f(t+\eta)-f(t)|^2\,d\eta$$

$$\leq 2\varepsilon\int_0^{T'}\int_0^\varepsilon\left(|f(t+\eta)|^2+|f(t)|^2\right)d\eta\leq 2\varepsilon^2\int_0^T|f(t)|^2$$

$$+2\varepsilon\int_0^\varepsilon\int_0^{T'}|f(t+\eta)|^2\,dt\,d\eta\leq 4\varepsilon^2\int_0^T|f(t)|^2.$$

From (5.5) it follows that

$$\sum_{n\neq 0}|a_n|^2\leq\frac{4}{\varepsilon^2\gamma^2C_1(p-1)}\int_0^T|f(t)|^2. \tag{5.6}$$

Observe that

$$|a_0|^2=\left|f(t)-\sum_{n\neq 0}a_ne^{i\lambda_nt}\right|^2=\frac{1}{T}\int_0^T\left|f(t)-\sum_{n\neq 0}a_ne^{i\lambda_nt}\right|^2dt$$

$$\leq\frac{2}{T}\left(\int_0^T|f(t)|^2+\int_0^T\left|\sum_{n\neq 0}a_ne^{i\lambda_nt}\right|^2\right)\leq\frac{2}{T}\left(\int_0^T|f(t)|^2+C_2(p-1)\sum_{n\neq 0}|a_n|^2\right)$$

$$\leq\left(\frac{2}{T}+\frac{8C_2(p-1)}{T\varepsilon^2\gamma^2C_1(p-1)}\right)\int_0^T|f(t)|^2.$$

From (5.6) we get that

$$\sum_{n\in\mathbb{Z}} |a_n|^2 \le \left[\frac{4}{\varepsilon^2\gamma^2 C_1(p-1)}\left(\frac{2C_2(p-1)}{T}+1\right)+\frac{2}{T}\right]\int_0^T |f(t)|^2 .$$

We obtain the desired result and a recurrent formula to compute the constant $C_1(p)$:

$$C_1(p) = \left[\frac{4}{\varepsilon^2\gamma^2 C_1(p-1)}\left(\frac{2C_2(p-1)}{T}+1\right)+\frac{2}{T}\right]^{-1}. \qquad \square$$

PIERRE CARDALIAGUET†

Abstract. In control theory, a semipermeable surface is an (in general nonsmooth) oriented surface that, on one hand, contains solutions (the so-called barrier solutions) of the controlled system and, on the other hand, may be crossed by the solutions of this system in only one direction. Without making any assumption on the regularity of the boundary of the semipermeable surface, we show that the barrier solutions contained in this semipermeable surface satisfy the Pontryagin principle, that this surface is a Lipschitz manifold, and that it is, locally, the graph of a semiconcave function. Applying these results to the optimal exit-time function from a given open set yields, without any controllability assumption at the boundary of the open set, that this function is semiconcave on an open dense subset of its domain.

Key words. semipermeable surfaces, differential inclusion, viability theory, minimal time function

Introduction. Let

$$\begin{cases} x'(t) = f(x(t), u(t)),\ u(t) \in U, \\ x(0) = x_0 \end{cases} \tag{1}$$

be a controlled system with a hamiltonian defined by

$$H(x,p) := \inf_{u \in U(x)} \langle f(x,u), p \rangle.$$

A *smooth*, *semipermeable surface* is an oriented hypersurface S such that the outward normal p at each point $x \in S$ satisfies $H(x,p) = 0$. Such a surface S is called semipermeable because

- (α) S can be crossed in only one direction by the trajectories of the controlled system.
- (β) From any initial position $x_0 \in S$ at least one solution $x(\cdot)$ of (1) starts, and remains locally on S (namely, $\exists \tau > 0$ such that, $\forall t \in [0,\tau]$, $x(t) \in S$).

A solution satisfying condition (β) is called *a barrier solution*.

In many problems, one encounters closed sets (which are not necessarily smooth) with a boundary enjoying properties (α) and (β). We still say that their boundary is "a semipermeable surface." The aim of this work is to show that a closed set with semipermeable boundary enjoys some regularity properties. Namely, under suitable assumptions on f, the boundary of such a set is a Lipschitz (and even semiconcave) manifold, and the barrier solutions satisfy the Pontryagin principle.

To our knowledge, this problem has never been treated, although it is of great interest for qualitative and quantitative control problems (see the examples below). However, our work is related to several studies on the regularity of the value function

of optimal control problems (see, for instance, [1], [8], [9], [11], [14], [19], [20] [21]). It is not easy to compare our results (which are of geometric nature) with those given in the previous references (which are concerned with the regularity of functions). For this reason, we illustrate our results through the study of the regularity of the optimal exit-time function.

(1) *The optimal exit-time function* θ_Ω from the open subset $\Omega \subset \mathbb{R}^N$ is defined by, $\forall x_0 \in \Omega$,

$$\theta_\Omega(x_0) := \inf \{t \geq 0 \mid \exists x(\cdot) \text{ solution to (1) such that } x(t) \notin \Omega\}.$$

Roughly speaking, $\theta_\Omega(x_0)$ is the minimal time any solution of the controlled system (1) starting from x_0 needs to leave Ω. The regularity of the optimal exit-time function is the aim of several works [23], [24], [6], [7], [9], [10]. In [9] Cannarsa and Sinestrari prove that θ_Ω is semiconcave on its (open) domain under the following assumptions: (a) f is smooth; (b) $\partial\Omega$ enjoys some regularity (roughly speaking, its curvature is bounded); (c) a "controllability condition" on the boundary of Ω is required, which ensures that θ_Ω is Lipschitz continuous. Thanks to conditions (b) and (c), θ_Ω is "smooth" in a neighborhood of $\partial\Omega$. Then condition (a) ensures, by using the Pontryagin principle, that this "smoothness" propagates along the (smooth) optimal trajectories.[1] So, in this method, the crucial points are, on one hand, the smoothness of θ_Ω at the boundary of Ω and, on the other hand, the propagation of this regularity.

Our method is, on the contrary, based on the local study of the epigraph of θ_Ω. Combining the results of [10] and of [25] yields that this epigraph has a semipermeable boundary for some dynamics Φ_f constructed from f. Thanks to the regularity results of semipermeable surfaces given in this paper, we prove, without conditions (b) and (c), that θ_Ω is (locally) Lipschitz and semiconcave on an open dense subset of its domain.

(2) *Boundary of the viability kernel:* The first definition of (nonsmooth) semipermeability is due to Quincampoix and appeared in the framework of viability theory (Aubin [3]). If $K \subset \mathbb{R}^N$ is a closed set, the *viability kernel* $\mathrm{Viab}_f(K)$ of K for f is

$$\mathrm{Viab}_f(K) := \left\{ x_0 \in K \mid \begin{array}{l} \exists x(\cdot) \text{ solution to (1)} \\ \text{such that } x(t) \in K \ \forall t \geq 0 \end{array} \right\}.$$

Under suitable assumptions, the viability kernel of K for f is a closed subset of K (see also [5], [15]). In [25], Quincampoix proves that the boundary of $\mathrm{Viab}_f(K)$ enjoys the semipermeability property in the interior of K.

(3) *Boundary of the reachable set:* The reachable set for f starting from a point $x_0 \in \mathbb{R}^N$ is the set of points y for which there exists a solution $x(\cdot)$ of (1) and a time $t \geq 0$ such that $x(t) = y$.

If, for instance, 0 belongs to the interior of $\bigcup_u f(x_0, u)$ and f is Lipschitz continuous, then the reachable set is open. Moreover, its boundary is semipermeable for $-f$ (see Quincampoix [26]).

This research is presented as follows. In the present paper, Part I, we give two equivalent definitions of the semipermeability, and we also prove that semipermeable boundaries are Lipschitz manifolds. Then we show that semipermeable surfaces are "smooth" along barrier solutions. We also explain how to recover the Pontryagin principle.

[1] A similar method based on the propagation of the regularity of the final data along optimal trajectories is also applied to Mayer's problem in [14] and to the Bolza problem in [11].

Part II, also in this issue, is devoted to the regularity results for the closed sets with semipermeable boundaries. We first show that the contingent cone to such closed sets is a union of half-spaces and enjoys some upper semicontinuity property. We then show, under a stronger assumption on the dynamics, that the boundaries of such closed sets are locally graphs of semiconcave functions. We complete this paper by applying these results to the case of the optimal exit-time functions.

1. Semipermeable boundaries.

1.1. Definition of semipermeability. Let us from now on replace the controlled system (1) by the differential inclusion

$$\begin{cases} x'(t) \in F(x(t)), \\ x(0) = x_0, \end{cases} \tag{2}$$

where $F(x) := \bigcup_{u\in U} f(x,u)$. The advantage of using differential inclusions instead of controlled systems lies in the fact that the regularity properties explained below depend on the geometrical properties of the sets $F(x)$ and not on its representation as a controlled system. Moreover, the formulation as differential inclusions simplifies the statements and the proofs of the results.

It is well known that, under conditions that we impose here, controlled system (1) has the same solutions as differential inclusion (2). We denote by $\mathcal{S}_F(x_0)$ the set of (Carathéodory) solutions of differential inclusion (2). With a set-valued map $F : \mathbb{R}^N \rightsquigarrow \mathbb{R}^N$, we associate the hamiltonian H_F defined by

$$\forall (x,p) \in \mathbb{R}^N \times \mathbb{R}^N, \qquad H_F(x,p) := \inf_{v\in F(x)} \langle v, p\rangle. \tag{3}$$

Note that the hamiltonian H_F is concave with respect to p.

Let us now recall two basic definitions of nonsmooth analysis.

If K is a closed subset of $\mathbb{R}^N$ and x belongs to K, the *contingent cone to K at x* is the set of vectors $v \in \mathbb{R}^N$ such that

$$\liminf_{h\to 0^+} d_K(x+hv)/h = 0$$

($d_K(y)$ denotes the distance from the point y to the set K). The contingent cone is a closed cone. It is denoted by $T_K(x)$.

We also denote by $T_K(x)^-$ the polar cone of $T_K(x)$, i.e.,

$$T_K(x)^- := \{p \in \mathbb{R}^N \mid \forall v \in T_K(x),\ \langle p, v\rangle \le 0\}.$$

The polar cone is a closed convex cone. The contingent cone plays the role of tangent half-space, while the polar cone plays the role of exterior normal for nonsmooth sets.

If K is a subset of $\mathbb{R}^N$ and x belongs to K, the Dubovitsky–Miljutin cone to K at x is the set of vectors $v \in \mathbb{R}^N$ for which there exists some $\alpha > 0$ such that

$$x +]0,\alpha](v + \alpha B) \subset K.$$

The Dubovitsky–Miljutin cone to K at x is denoted by $D_K(x)$. It is an open cone. If K is a closed subset of $\mathbb{R}^N$, then $D_{\mathbb{R}^N\setminus K}(x) = \mathbb{R}^N \setminus T_K(x)$ for $x \in K$ [25]. Moreover, $D_K(x) \subset \mathrm{Int}\,(T_K(x))$, but there is no equality in general even if the set K is a Lipschitz manifold.

Notation. Below, B_N denotes the closed unit ball of $\mathbb{R}^N$ (endowed with the euclidean topology). If there is no ambiguity, we write only B. In the same way, $\overset{o}{B}_N$ denotes the open unit ball of $\mathbb{R}^N$.

DEFINITION 1.1 (semipermeability). *A closed set M has a semipermeable boundary for the set-valued map $F : \mathbb{R}^N \rightsquigarrow \mathbb{R}^N$ (or enjoys the semipermeability property) in a neighborhood of $x_0 \in \partial M$ if there is some positive radius r such that*

$$\forall x \in M \cap (x_0 + rB),\ \forall p \in T_M(x)^-,\ H_F(x,p) = 0.$$

An equivalent definition of semipermeability in terms of trajectories is the following.

PROPOSITION 1.1 (semipermeability). *Assume that the set-valued map F satisfies the following conditions:*

$$\text{(4)} \qquad \begin{cases} \text{(a)} & F : \mathbb{R}^N \rightsquigarrow \mathbb{R}^N \text{ has convex compact values;} \\ \text{(b)} & F \text{ is } \ell\text{-Lipschitz, i.e.,} \\ & \quad \forall x, y \in \mathbb{R}^N \times \mathbb{R}^N,\ F(y) \subset F(x) + \ell B. \end{cases}$$

Then a closed set $M \subset \mathbb{R}^N$ has a semipermeable boundary in a neighborhood of $x_0 \in \partial M$ if and only if there are open subsets O and O' of $\mathbb{R}^N$ with $x_0 \in O \subset O'$ and a time $T > 0$ such that

(i) *$\forall x \in M \cap O$, there is at least one solution $x(\cdot) \in \mathcal{S}_F(x)$ which remains in $M \cap O'$ on $[0,T]$;*

(ii) *$\forall x \in M \cap O'$, any solution of the differential inclusion for $-F$ remains in M on $[0,T]$;*

(iii) *$\forall x \in \partial M \cap O'$, any solution of the differential inclusion for F remains in $\widehat{M} := \overline{\mathbb{R}^N \backslash M}$ on $[0,T]$.*

The notations of this definition are kept throughout this paper.

Before proving that result, let us point out an important consequence.

COROLLARY 1.1 (barrier solutions). *Assume that F and M are as in Proposition* 1.1.

If M enjoys the semipermeability property, then any solution $x(\cdot)$ of the differential inclusion for F starting from $\partial M \cap O$ which remains in M on $[0,T]$ remains in ∂M on $[0,T]$.

Such a solution is "a barrier solution."

Remarks.

(1) Thanks to Proposition 1.1(i), at least one barrier solution starts from any initial position of $\partial M \cap O$.

(2) Combining Proposition 1.1 and Corollary 1.1, we recover the definition of semipermeability given at the beginning of this paper. Property (α) holds true thanks to (iii), and Corollary 1.1 is exactly the same as property (β).

Proof. The solution $x(\cdot)$ remains in $\widehat{M}$ from Proposition 1.1(iii), and in M from assumption. Since $M \cap \widehat{M} = \partial M$, the corollary holds true. □

Proof of Proposition 1.1. Assume that the set M satisfies the described property in a neighborhood of a point x_0. Then M is (locally) viable[2] for F in O, so that the

[2]If $K \subset \mathbb{R}^N$ is locally compact, the *viability theorem* [3], [4], [17] gives the equivalence among the following statements.
(i) K is a viability domain for F; i.e.,$\forall x \in K,\ F(x) \cap T_K(x) \neq \emptyset$.
(ii) K is viable for F; i.e., $\forall x \in K,\ \exists x(\cdot) \in \mathcal{S}_F(x)$ and $t > 0$ such that $x(s) \in K\ \forall s \in [0,t]$.
(iii) K satisfies the following: $\forall x \in K,\ \forall p \in T_K(x)^-,\ H_F(x,p) \leq 0$.

viability theorem, applied to the locally compact set $M \cap O$, states that $H_F(x,p) \leq 0$ for $x \in O \cap M$ and $p \in T_M(x)^-$. Moreover, M is locally invariant[3] for $-F$, so that the invariance theorem, applied to the locally compact set $M \cap O$ again, states that $H_{-F}(x,-p) \geq 0$ for $x \in O \cap M$ and $p \in T_M(x)^-$. Since

$$H_{-F}(x,-p) = \inf_{v \in F(x)} \langle -v, -p \rangle = H_F(x,p),$$

we have finally proved that $H_F(x,p) = 0$ for any $x \in O \cap M$ and $p \in T_M(x)^-$.

Conversely, if the boundary of M is semipermeable, there is some radius $r > 0$ such that

$$\forall x \in (x_0 + rB) \cap M,\ \forall p \in T_M(x)^-,\ H_F(x,p) = 0.$$

Set $\rho := \max_{x \in (x_0+rB)} \max_{v \in F(x)} \|v\|$ and $T := \frac{r}{4\rho}$. Define, for any $i = 1, \ldots, 4$,

$$O_i := x_0 + \frac{ir}{4} \overset{o}{B}.$$

Note that any solution of the differential inclusion for F (or for $-F$) starting from O_i $(i = 1, \ldots, 3)$ remains in O_{i+1} on $[0,T]$.

Since the tangential condition

$$\forall x \in (x_0 + rB) \cap M,\ \forall p \in T_M(x)^-,\ H_F(x,p) \leq 0$$

is satisfied, the viability theorem states that for any initial position $x \in O_1 \cap M$, there is an $x(\cdot) \in S_F(x)$ such that $x(t) \in M$ as long as $x(t) \in x_0 + rB$, i.e., at least on $[0,T]$. In particular, such a solution remains in $M \cap O_2$ on $[0,T]$. Thus (i) holds true with $O := O_1$ and $O' := O_2$.

Since $H_F(x,p) = 0$ implies that $H_{-F}(x,-p) \geq 0$, the tangential condition

$$\forall x \in (x_0 + rB) \cap M,\ \forall p \in T_M(x)^-,\ H_{-F}(x,-p) \geq 0$$

is fulfilled. Thus M is locally invariant for $-F$, and any solution of the differential inclusion for $-F$ starting from $M \cap O_2$ (and also from $M \cap O_3$) remains in M as long as it remains in $x_0 + rB$, and in particular, on $[0,T]$. Thus (ii) holds true.

Assume, contrary to our claim, that (iii) is false. There is a solution $x(\cdot)$ of the differential inclusion for F starting from $\partial M \cap O_2$ which does not remain in $\widehat{M}$ on $[0,T]$. We already know that $x(\cdot)$ remains in O_3 on $[0,T]$. There is some time $t \in]0,T]$ such that $x(t)$ belongs to the interior of M and to O_3. From Filippov's theorem [12], the set-valued map $x \rightsquigarrow \mathcal{S}_F(x)$, endowed with the uniform topology, is continuous. Thus there is a neighborhood W of $x(0)$ such that, from any initial position $y \in W$, at least one solution $y(\cdot) \in \mathcal{S}_F(y)$ sufficiently close to $x(\cdot)$ on $[0,T]$ starts so that $y(t)$ belongs to the interior of M and to O_3. Since x belongs to ∂M, there is some $\bar{y} \in W$ which does not belong to M. Let us denote by $\bar{y}(\cdot)$ the associated solution. We now consider the function $z(\cdot)$ defined by $z(s) := \bar{y}(t-s)$ for $s \in [0,T]$. Then $z(\cdot)$ is a solution of the differential inclusion for $-F$ starting from $M \cap O_3$, which leaves M before T. This is in contradiction to the proof of (ii). So (iii) holds true. □

[3]The *invariance theorem* [3] states that, for F satisfying (4) and for $K \subset \mathbb{R}^N$ locally compact, there is an equivalence among the following statements.
(i) K is an invariance domain for F, i.e.,$\forall x \in K,\ F(x) \subset T_K(x)$.
(ii) K is invariant for F, i.e., $\forall x \in K,\ \exists t > 0$ such that $\forall x(\cdot) \in \mathcal{S}_F(x),\ \forall s \in [0,t],\ x(s) \in K$.
(iii) K satisfies the following: $\forall x \in K,\ \forall p \in T_K(x)^-,\ H_F(x,-p) \geq 0$.

1.2. Semipermeable boundaries are Lipschitz manifolds.

PROPOSITION 1.2. *Assume that the boundary of M is semipermeable in a neighborhood of x_0 for a set-valued map $F : \mathbb{R}^N \rightsquigarrow \mathbb{R}^N$ satisfying* (4). *If the values of F have a nonempty interior, then ∂M is a Lipschitz manifold in a neighborhood of x_0.*

To prove Proposition 1.2, let us recall a sufficient condition for a closed set to be a Lipschitz manifold (see [16, Thm. 1.2.2.2, p. 12]).

LEMMA 1.1. *Let K be a closed subset of $\mathbb{R}^N$ and let x belong to ∂K. Assume that there exist some open set C, some $\rho > 0$, and some neighborhood U of x such that*

$$\forall y \in \partial M \cap U, \ \begin{cases} y + [0,\rho]C \subset K, \\ y - [0,\rho]C \subset \widehat{K}, \end{cases}$$

where $\widehat{K} := \overline{\mathbb{R}^N \backslash K}$.

Then ∂K is a Lipschitz manifold in a neighborhood of x.

Proof of Proposition 1.2. It is enough to combine Lemma 1.1 with the following lemma.

LEMMA 1.2. *Let M be as in Proposition* 1.1 *and let F satisfy* (4). *Also let x belong to $\partial M \cap O$ and $v \in \mathrm{Int}(F(x))$. Then*

$$\begin{aligned} x + [0,t](v + \tfrac{a}{2}B) &\subset \widehat{M}, \\ x + [0,t](-v + \tfrac{a}{2}B) &\subset M, \end{aligned}$$

where $a := d_{\partial F(x)}(v)$ and $t := \min\{T, \frac{a}{\ell(2\|v\|+a)}\}$.

Proof of Lemma 1.2. Note that $v + aB \subset F(x)$.

LEMMA 1.3. *If C_1, C_2, and C_3 are compact convex subsets of $\mathbb{R}^N$,*

$$[C_1 + C_3 \subset C_2 + C_3] \ \Rightarrow \ [C_1 \subset C_2].$$

Since the set-valued map F is ℓ-Lipschitz, use Lemma 1.3 to obtain

$$\forall y \in x + \frac{a}{2\ell}B, \qquad v + \frac{a}{2}B \subset F(y).$$

The map $s \to x + s(v + \frac{a}{2}u)$ is a solution of the differential inclusion for F on $[0,t]$ (for any $u \in B$) because $\|s(v + \frac{a}{2\ell}u)\| \le \frac{a}{2\ell}$ for $s \in [0,t]$. Since $x \in \partial M \cap O$ and M is semipermeable, any solution of the differential inclusion for F remains in $\widehat{M}$ (see Proposition 1.1(iii)). Thus

$$x + [0,t]\left(v + \frac{a}{2}B\right) \subset \widehat{M}.$$

We can prove in a similar way (using the fact that M is locally invariant by $-F$ from Proposition 1.1(ii)) that

$$x + [0,t]\left(-v + \frac{a}{2}B\right) \subset M. \qquad \square$$

To complete the proof of Proposition 1.2, let v belong to the interior of $F(x)$ and set $a := d_{\partial F(x)}(v)$. Then

$$\forall y \in x + \frac{a}{2\ell}, \qquad v + \frac{a}{2}B \subset F(y).$$

In particular, v belongs to the interior of $F(y)$ and $d_{\partial F(y)}(v) \geq \frac{a}{2}$. Thus, from Lemma 1.2,

$$\forall y \in x + \frac{a}{2\ell}, \begin{cases} y + [0,t](-v + \frac{a}{4}\overset{o}{B}) \subset M, \\ y + [0,t](v + \frac{a}{4}\overset{o}{B}) \subset \widehat{M}, \end{cases}$$

where $t := \min\{T, \frac{a}{\ell(4\|v\|+a)}\}$. □

Recall that equality $\mathbb{R}^N \backslash T_M(x) = D_{\widehat{M}}(x)$ is always fulfilled. Moreover, we have the following corollary.

COROLLARY 1.2. *Under the assumptions and notations of Proposition* 1.2*, we have, for any* $x \in \partial M \cap O$*,*

$$D_{\widehat{M}}(x) = D_{\mathbb{R}^N \backslash M}(x) \quad \textit{and} \quad \mathbb{R}^N \backslash T_{\widehat{M}}(x) = D_M(x) = D_{\mathbb{R}^N \backslash \widehat{M}}(x).$$

Note, moreover, that

$$\mathrm{Int}(F(x)) \cap T_M(x) = \emptyset \quad \textit{and} \quad -\mathrm{Int}(F(x)) \cap T_{\widehat{M}}(x) = \emptyset.$$

Proof. We prove only the first equality, the proof of the second one being essentially the same. Since $\mathbb{R}^N \backslash T_M(x) = D_{\mathbb{R}^N \backslash M}(x) \subset D_{\widehat{M}}(x)$, it remains to prove that

$$D_{\widehat{M}}(x) \subset D_{\mathbb{R}^N \backslash M}(x).$$

Let v belong to $D_{\widehat{M}}(x)$. Since ∂M is a Lipschitz manifold, there is a Lipschitz function $\phi : W \to \mathbb{R}$ ($W \subset \mathbb{R}^{N-1}$ open) and an open neighborhood $W' \subset \mathbb{R}^N$ of x such that

$$\partial M \cap W' = \{(y, \phi(y)) \mid y \in W\}.$$

We can assume, without loss of generality, that M is the epigraph of ϕ, while $\widehat{M}$ is the hypograph of ϕ and

$$\left(\mathbb{R}^N \backslash M\right) \cap W' = \{(y,t) \mid t < \phi(y) \ \&\ y \in W\}.$$

Set $x := (x_y, x_t)$ and $v := (v_y, v_t)$ (where x_y and v_y belong to $\mathbb{R}^{N-1}$ and x_t and v_t belong to $\mathbb{R}$). There is some $\alpha > 0$ such that

$$(x_y, x_t) +]0, \alpha] \left((v_y, v_t) + \alpha B_N\right) \subset \widehat{M}.$$

Thus, for any $u := (u_y, u_t) \in B_N$ and for any $\theta \in]0, \alpha]$,

$$\phi(x_y + \theta\,(v_y + \alpha u_y)) \geq x_t + \theta(v_t + \alpha u_t).$$

In particular, for any $u := (u_y, u_t) \in B_N$ and for any $\theta \in]0, \alpha/2]$,

$$\phi\left(x_y + \theta\left(v_y + \frac{\alpha}{2}u_y\right)\right) \geq x_t + \theta\left(v_t + \frac{\alpha}{\sqrt{2}}\right) > x_t + \theta\left(v_t + \frac{\alpha}{2}u_t\right),$$

because $(\frac{1}{2}u_y, \frac{\sqrt{2}}{2}) \in B_N$. This actually means that

$$(x_y, x_t) + \left]0, \frac{\alpha}{2}\right] \left((v_y, v_t) + \frac{\alpha}{2}B_N\right) \subset \mathbb{R}^N \backslash M,$$

so that v belongs to $D_{\mathbb{R}^N \backslash M}(x)$. □

2. Regularity of barrier solutions. We show here that, with any barrier solution, we can associate a Lipschitzian function $p(\cdot) : [0,T] \to \mathbb{R}^N$ such that $\|p(t)\| = 1$ and

$$0 = \langle x'(t), p(t)\rangle = H(x(t), p(t)) \text{ for almost every } t \in [0,T].$$

Moreover, $p(t)$ is an exterior normal to M at $x(t)$:

$$\forall t \in]0,T[, \qquad T_M(x(t)) = (p(t))^- .$$

The function $p(\cdot)$ is called the adjoint of $x(\cdot)$. In the case when the hamiltonian H is derivable, this adjoint coincides with the usual adjoint up to a multiplicative coefficient, and $(x(\cdot), p(\cdot))$ satisfies the Pontryagin principle.

2.1. Two preliminary lemmas. We first estimate the variations of the contingent cone to closed sets with semipermeable boundaries along the barrier solutions.

LEMMA 2.1. *Let M be as in Proposition* 1.1 *and let F satisfy* (4). *Assume that x belongs to $\partial M \cap O$ and that $x(\cdot) \in \mathcal{S}_F(x)$ is a barrier solution* (*i.e., it remains in $\partial M \cap O'$ on $[0,T]$*).

There is a constant C, which only depends on T and on the Lipschitz constant ℓ of F, such that

$$\forall 0 \le t \le T,\ \forall v \in T_M(x(t)),\ d_{T_M(x)}(v) \le Ct\|v\|. \tag{5}$$

Moreover,

$$\forall 0 \le s \le t \le T,\ \forall v \in T_{\widehat{M}}(x(s)),\ d_{T_{\widehat{M}}(x(t))}(v) \le C(t-s)\|v\|. \tag{6}$$

Proof of Lemma 2.1. We prove only (5), since the proof of (6) is essentially the same. If v belongs to $T_M(x(t))$, there exist $h_n \to 0^+$, $v_n \to v$ such that $x(t) + h_n v_n$ belongs to M for any n. The Filippov theorem [12] provides the existence of solutions $y_n(\cdot) \in \mathcal{S}_{-F}(x(t) + h_n v_n)$ such that

$$\|x'(t-s) + y_n'(s)\| \le \ell e^{\ell s} h_n \|v_n\| \text{ for almost every } s \in [0,t]. \tag{7}$$

The solutions $y_n(\cdot)$ remain in M on $[0,T]$ because M is (locally) invariant for $-F$ from Proposition 1.1.

Set $w_n := \frac{y_n(t)-x}{h_n}$. We now prove that the sequence $\{w_n\}$ converges, up to a subsequence, to some $w \in T_M(x)$ such that $\|v - w\| \le (e^{\ell t} - 1)\|v\|$. Indeed,

$$\begin{aligned} y_n(t) - x &= (y_n(t) - (x(t) + h_n v_n)) + (x(t) - x) + h_n v_n \\ &= \textstyle\int_0^t (y_n'(s) + x'(t-s))ds + h_n v_n. \end{aligned}$$

Combining this latter equality with (7) yields

$$\|w_n - v_n\| \le \frac{1}{h_n} \int_0^t \|y_n'(s) + x'(t-s)\| ds \le \|v_n\|(e^{\ell t} - 1).$$

Thus $\{w_n\}$ is bounded and converges, up to a subsequence, to some w which belongs to $T_M(x)$ and satisfies

$$\|w - v\| \le \|v\|(e^{\ell t} - 1).$$

So Lemma 2.1 is proved by setting $C := \sup_{t \in [0,T]} \frac{e^{\ell t} - 1}{t}$. ∎

We now compute $D_M(x)$ for some particular points x.

LEMMA 2.2. *Let $x(\cdot)$ be a barrier solution on $[0,T]$ and assume that condition* (4) *and the following condition are satisfied:*

$$\forall x \in O',\ \forall v \in \partial F(x),\ T_{F(x)}(v) \text{ is a half-space.} \tag{8}$$

For each $t \in]0,T[$ where the derivative $x'(t)$ exists,

$$-\mathrm{Int}[T_{F(x(t))}(x'(t))] \ = \ D_M(x(t)) \tag{9}$$

and

$$\mathrm{Int}[T_{F(x(t))}(x'(t))] \ = \ D_{\widehat{M}}(x(t)). \tag{10}$$

In particular, $D_M(x(t))$ and $D_{\widehat{M}}(x(t))$ are both equal to open half-spaces.

Assumption (8) plays a major role below. It is equivalent to

$$\begin{cases} \text{(i)} & \partial F(x) \text{ is a } \mathcal{C}^1 \text{ manifold for any } x \in O'. \\ \text{(ii)} & F(x) \text{ is convex with a nonempty interior for any } x \in O'. \end{cases}$$

Proof of Lemma 2.2. Let $t \in]0,T[$ be such that the derivative $v := x'(t)$ exists at time t. Recall that v belongs to $F(x(t)) \cap T_M(x(t))$. Let us first prove that

$$-\mathrm{Int}[T_{F(x(t))}(v)] \ \subset \ D_M(x(t)). \tag{11}$$

Let w belong to the interior of $-T_{F(x(t))}(v)$. Since $F(x)$ is convex, there are some $\lambda > 0$ and $a > 0$ such that $w + aB$ is contained in $\lambda(v - F(x(t)))$, i.e.,

$$v - \tau w + \tau a B \subset F(x(t)),$$

with $\tau := 1/\lambda$. Since F is ℓ-Lipschitz, Lemma 1.3 implies that

$$\forall y \in x(t) + \frac{a}{2\tau\ell}B, \qquad v - \tau w + \frac{a\tau}{2}B \subset F(y).$$

For $h > 0$ sufficiently small (say, $h \in [0,\epsilon]$ with $\epsilon > 0$) the solutions of the differential inclusion for $-F$ starting from $x(t+h)$ remain in $x(t) + \frac{a}{2\tau\ell}B$ on $[0,h]$. In particular, $s \to x(t+h) - s(v - \tau w + u)$ is a solution of the differential inclusion for $-F$ on $[0,h]$ if $\|u\| \le \frac{a\tau}{2}$. Since $x(t+h)$ belongs to M, the solutions of the differential inclusion for $-F$ starting from $x(t+h)$ remain in M on $[0,T]$. Thus

$$\forall s \in [0,h], \quad x(t+h) - s\left(v - \tau w + \frac{a\tau}{2}B\right) \subset M. \tag{12}$$

Since $v = x'(t)$, there is some $\epsilon' > 0$ such that, for $h \in [0,\epsilon']$,

$$\|x(t+h) - x(t) - hv\| \le \frac{ha\tau}{4}. \tag{13}$$

Combining (12) with $s = h$ with (13) yields, for any $h \in [0, \inf\{\epsilon, \epsilon'\}]$,

$$x(t) + h\tau w + \frac{ha\tau}{4}B \ \subset \ M.$$

Thus w belongs to $D_M(x(t))$.

We can prove in the same way that

$$\mathrm{Int}[T_{F(x(t))}(v)] \subset D_{\widehat{M}}(x(t))$$

because $\widehat{M}$ is (locally) invariant by F. Since $D_M(x(t)) \cap D_{\widehat{M}}(x(t)) = \emptyset$, and since both sets contain an open half-space and are open, $D_M(x(t))$ and $D_{\widehat{M}}(x(t))$ are, respectively, equal to the interiors of the half-spaces $-T_{F(x(t))}(x'(t))$ and $T_{F(x(t))}(x'(t))$. □

2.2. The adjoint of a barrier solution.

THEOREM 2.1 (definition of the adjoint). *Let M be a closed set with a semipermeable boundary and let x belong to $\partial M \cap O$ (cf. Proposition 1.1). Let $x(\cdot) \in \mathcal{S}_F(x)$ be a barrier solution on $[0,T]$ and C be the constant defined by Lemma 2.1. There is a $2C$-Lipschitzian function $p(\cdot) : [0,T] \to \mathbb{R}^N$ such that $\|p(t)\| = 1$ for any $t \in [0,T]$ and*

$$\forall t \in]0,T[, \quad T_M(x(t)) = (p(t))^-,$$

where $(p(t))^- = \{v \in \mathbb{R}^N \mid \langle p(t), v\rangle \le 0\}$. The function $p(\cdot)$ is called the adjoint of $x(\cdot)$ on $[0,T]$. Moreover, if $p(\cdot)$ is the adjoint of some barrier solution $x(\cdot)$, then

$$(p(0))^- \subset T_M(x(0)). \tag{14}$$

The adjoint $p(\cdot)$ is uniquely defined. Theorem 2.1 states that the contingent cone $T_M(x(t))$ is a half-space for $t > 0$ and $p(t)$ is the unique outward normal at $x(t)$. This means that, at $x(t)$, the closed set M is "smooth."

Proof of Theorem 2.1. *Existence.* If $x'(t)$ exists, Corollary 1.2 states that

$$D_M(x(t)) \subset T_M(x(t)) = \mathbb{R}^N \backslash D_{\mathbb{R}^N \backslash M}(x(t)) = \mathbb{R}^N \backslash D_{\widehat{M}}(x(t)).$$

From Lemma 2.2, the left- and right-hand sides of the inclusions are half-spaces. Thus $T_M(x(t))$ is a half-space and there is some $p(t)$ satisfying $\|p(t)\| = 1$ and $T_M(x(t)) = (p(t))^-$.

Now fix any $t \in]0,T[$. Since the solution $x(\cdot)$ is absolutely continuous, there are $t_n \to t^+$ and $s_n \to t^-$ such that the derivatives $x'(t_n)$ and $x'(s_n)$ exist. The sequences $(p(t_n))_{n\in\mathbb{N}}$ and $(p(s_n))_{n\in\mathbb{N}}$ converge, respectively, to p_1 and p_2 (up to a subsequence). Lemma 2.1 yields

$$(p_1)^- \subset \operatorname{Limsup} (p(t_n))^- \subset T_M(x(t))$$

(where Limsup denotes the Kuratowski upper limit [2]) and, for any $v \in T_M(x(t))$,

$$0 = \liminf_n d(v, T_M(x(s_n))) = \liminf_n \langle v, p(s_n)\rangle_+ = \langle v, p_2\rangle_+$$

(where $s_+ := \max\{s, 0\}$), so that $\langle v, p_2\rangle \le 0$.

Thus $(p_1)^- \subset T_M(x(t)) \subset (p_2)^-$ and $T_M(x(t))$ is equal to a half-space. Let us denote by $p(t)$ the common value $p_1 = p_2$. Then $T_M(x(t)) = (p(t))^-$. The function $p(\cdot)$ is defined on $]0,T[$.

Note that, for $t = 0$, the same proof shows that any upper limit p_1 of the functions $p(t_n)$ satisfies $(p_1)^- \subset T_M(x(0))$. Let us now prove that $p(\cdot)$ is Lipschitz continuous and so can be defined (uniquely) on $[0,T]$.

The adjoint is Lipschitzian. Let C be the constant of Lemma 2.1 and let $0 < s < t < T$. There are two cases.

(1) Either $\langle p(t), p(s)\rangle \ge 0$. Then we denote by v the projection of $p(s)$ onto $T_M(x(t))$, and by w the projection of v onto $T_M(x(s))$. From Lemma 2.1, the distance between v and w is smaller than or equal to $C(t-s)\|v\|$. Since

$$v = p(s) - \langle p(t), p(s)\rangle p(t) \quad \text{and} \quad w = v - \langle p(s), v\rangle p(s),$$

we have $\|v - w\| = 1 - \langle p(t), p(s)\rangle^2$.

Moreover, $\|v\|^2 = 1 - \langle p(t), p(s)\rangle^2 = \|v - w\|$. Combining this equation with $\|v - w\| \leq C(t-s)\|v\|$ yields

$$\|v - w\| \leq C^2(t-s)^2.$$

Note that

$$\|p(t) - p(s)\|^2 = 2 - 2\langle p(t), p(s)\rangle.$$

We conclude that

$$\|p(t) - p(s)\|^2 \leq 2 - 2\langle p(t), p(s)\rangle^2 \leq 2C^2(t-s)^2.$$

Thus

$$\|p(t) - p(s)\| \leq 2C|t-s|. \tag{15}$$

(2) Or $\langle p(t), p(s)\rangle \leq 0$. Then $p(s)$ belongs to $(p(t))^- = T_M(x(t))$. Thus Lemma 2.1 states that

$$d(p(s), (p(s))^-) \leq C(t-s).$$

Since the left-hand side is equal to 1, $\langle p(t), p(s)\rangle \leq 0$ cannot occur unless $t - s \geq 1/C$. In that case, equation (15) is fulfilled. Thus we have proved that $p(\cdot)$ is a $2C$-Lipschitz function. □

LEMMA 2.3 (characterization of the adjoint). *The adjoint $p(\cdot)$ of a barrier solution $x(\cdot)$ on $[0,T]$ is the unique continuous function satisfying*

$$\begin{cases} \text{(a)} & \forall t \in [0,T],\ \|p(t)\| = 1, \\ \text{(b)} & H_F(x(t), p(t)) = \langle x'(t), p(t)\rangle = 0 \text{ for almost every } t \in [0,T]. \end{cases} \tag{16}$$

COROLLARY 2.1. *Under the notations and the assumptions of Lemma* 2.3,

$$T_M(x(t)) = -T_{F(x(t))}(x'(t)) = (p(t))^-$$

for almost every $t \in]0,T[$.

COROLLARY 2.2. *Assume, moreover, that $F(x)$ is strictly convex for any $x \in O'$. Then any barrier solution is $\mathcal{C}^1$.*

Proof. Indeed, the set-valued map $t \rightsquigarrow \operatorname{Arg\,min}_{v \in F(x(t))} \langle v, p(t)\rangle$ is upper semicontinuous and, in fact, single-valued because $F(x)$ is strictly convex. So it is continuous. From Lemma 2.3, $x'(t)$ is almost everywhere equal to the continuous function $t \to \operatorname{Arg\,min}_{v \in F(x(t))} \langle v, p(t)\rangle$ and so is continuous. □

Proof of Lemma 2.3 Assume that $p(\cdot)$ is the adjoint of $x(\cdot)$ on $[0,T]$. We have to prove (16). Let $t \in]0,T[$. The set $F(x(t))$ is convex and has a nonempty interior from assumption (8). Let w belong to the interior of $F(x(t))$. From Corollary 1.2, $w \notin T_M(x(t))$. Thus $\langle w, p(t)\rangle > 0$ from Theorem 2.1. Since $F(x(t)) = \overline{\operatorname{Int}(F(x(t)))}$, we have proved $H_F(x(t), p(t)) \geq 0$. If $x'(t)$ exists, then $x'(t)$ belongs to $F(x(t))$ and so $\langle x'(t), p(t)\rangle \geq 0$. Moreover, $x'(t)$ belongs to $T_M(x(t)) = (p(t))^-$, and thus $\langle x'(t), p(t)\rangle \leq 0$. So (16(b)) holds true because $x(\cdot)$ is almost everywhere derivable.

Conversely, let us now assume that some continuous function $p(\cdot) : [0,T] \to \mathbb{R}^N$ satisfies (16). We have to prove that $p(\cdot)$ is the adjoint of $x(\cdot)$ on $[0,T]$. Fix any $t \in (0,T]$ where the derivative $x'(t)$ exists and where (16(b)) is fulfilled. Combining

Lemma 2.2 and Theorem 2.1 yields that $T_M(x(t))$ is the closure of the half-space $D_M(x(t))$. Thus

$$T_M(x(t)) = -T_{F(x(t))}(x'(t)) = \overline{\bigcup_{\lambda>0} \lambda(x'(t) - F(x(t)))}. \tag{17}$$

Thanks to (16), for any $\lambda \geq 0$ and any $w \in F(x(t))$, one has

$$\langle \lambda(x'(t) - w), p(t)\rangle \leq 0. \tag{18}$$

Combining (17) and (18) yields

$$\forall v \in T_M(x(t)),\ \langle v, p(t)\rangle \leq 0.$$

So $(p(t))^- = T_M(x(t))$ for almost every $t \in (0,T]$. In particular, $p(t)$ coincide almost everywhere with the adjoint of $x(\cdot)$, which is continuous. So $p(\cdot)$ is equal to the adjoint of $x(\cdot)$. □

We study here the regularity properties of the function which associates its adjoint to a solution.

PROPOSITION 2.1. *Assume that $x_n(\cdot)$ are barrier solutions starting from $x_n \in \partial M \cap O$ and converging to some $x(\cdot)$ barrier solution starting from $x \in \partial M \cap O$. If $p_n(\cdot)$ are the adjoint of $x_n(\cdot)$ on $[0,T]$, then the $p_n(\cdot)$ converge uniformly to the adjoint of $x(\cdot)$ on $[0,T]$.*

Proof of Proposition 2.1. Since the $(p_n(\cdot))$ are uniformly continuous, Ascoli's theorem states that $p_n(\cdot)$ converge uniformly to some continuous function $p(\cdot)$ (up to a subsequence). To prove that $p(\cdot)$ is the adjoint of $x(\cdot)$, it is sufficient to show that $p(\cdot)$ satisfies (16). For any $t \in [0,T]$, $\|p(t)\| = 1$. From Lemma 2.3, for almost every $t \in (0,T]$, $\langle x_n'(t), p_n(t)\rangle = 0$. Thus

$$\forall t \in [0,T],\ \int_0^t \langle x_n'(s), p_n(s)\rangle ds = 0.$$

The sequence of functions $p_n(\cdot)$ converges uniformly to $p(\cdot)$, and the sequence $x_n'(\cdot)$ converges weakly to $x(\cdot)$. Thus

$$\forall t \in [0,T],\ \int_0^t \langle x'(s), p(s)\rangle ds = 0,$$

which implies that $\langle x'(t), p(t)\rangle = 0$ for almost every $t \in]0,T[$.

Let $t \in (0,T]$ and v belong to $F(x(t))$. We are going to prove that $\langle v, p(t)\rangle \geq 0$. From Michael's theorem [22], a continuous function $\tilde{v}(\cdot) : \mathbb{R}^N \to V$ exists, such that

$$\forall x \in \mathbb{R}^N, \quad \tilde{v}(x) \in F(x) \quad \text{and} \quad \tilde{v}(x(t)) = v.$$

Note that $\tilde{v}(x_n(t))$ converge to $\tilde{v}(x(t))$, and that $\langle \tilde{v}(x_n(t)), p_n(t)\rangle \geq 0$. Letting $n \to +\infty$ yields $\langle v, p(t)\rangle \geq 0$ for any $v \in F(x(t))$ and any $t \in (0,T]$.

Thus $p(\cdot)$ satisfies (16) and is indeed the adjoint of $x(\cdot)$. Since any converging subsequence of the uniformly continuous sequence $(p_n(\cdot))$ converges to the adjoint of $x(\cdot)$, we have proved that the $p_n(\cdot)$ converge to the adjoint of $x(\cdot)$. □

2.3. Barrier solutions and the Pontryagin principle. We now prove that, under some assumptions of differentiability of the hamiltonian H, barrier solutions satisfy the Pontryagin principle.

In Isaacs' pioneering work on differential games [18], semipermeable hypersurfaces are constructed by using the method of characteristics, which is very close to the Pontryagin principle. We show here that this method of construction is a priori justified since the barrier solutions indeed satisfy the Pontryagin principle.

THEOREM 2.2. *Assume that the set-valued map F satisfies* (4), (8) *and, moreover, that its associated hamiltonian H is $\mathcal{C}^2$ on $\mathbb{R}^N \times [\mathbb{R}^N \backslash \{0\}]$.*

Let M be a closed set with a semipermeable boundary. If $x(\cdot)$ is a barrier solution and $p(\cdot)$ is its adjoint, and if $q(\cdot) : [0,T] \to \mathbb{R}^N$ is defined by

$$\forall t \in [0,T],\ q(t) := p(t) \exp\left(- \int_0^t \left\langle \frac{\partial H}{\partial x}(x(s),p(s)),p(s) \right\rangle ds \right),$$

then $(x(\cdot),q(\cdot))$ is a solution to the hamiltonian system

$$\left\{ \begin{array}{l} x'(t) = \frac{\partial H}{\partial p}(x(t),q(t)), \\ q'(t) = -\frac{\partial H}{\partial x}(x(t),q(t)), \\ q(0) := p(0). \end{array} \right. \tag{19}$$

COROLLARY 2.3. *Suppose that the assumptions of the previous theorem are satisfied. If $x(\cdot)$ is a barrier solution, then $x(\cdot)$ is $\mathcal{C}^1$ on $[0,T]$. Moreover, for any $q \neq 0$ such that*

$$\langle q, x'(0) \rangle = H(x(0),q) = 0,$$

the solution $(x(\cdot),q(\cdot))$ of (19) *with initial condition $(x(0),q)$ satisfies*

$$\forall t \in]0,T[, \quad T_M(x(t)) = (q(t))^-.$$

Proof of Theorem 2.2. Since, for any $t \in [0,T]$, $H(x(t),p(t)) = 0$, since $\langle x'(t),p(t) \rangle = 0$ for almost every $t \in [0,T]$, and since H is differentiable, one has

$$x'(t) = \mathrm{Arg} \min_{v \in F(x(t))} \langle v, p(t) \rangle = \frac{\partial H}{\partial p}(x(t),p(t))$$

for almost every $t \in [0,T]$. In fact, these equalities hold true everywhere because the right-hand side is continuous. Thus $x'(\cdot)$ is defined everywhere on $[0,T]$ and is continuous.

Let $t \in]0,T[$ be such that $p'(t)$ exists. Let us prove that

$$\forall v \perp p(t),\ \left\langle v, \left(\frac{\partial^2 H}{\partial x \partial p}(x(t),p(t)) \right)^* p(t) + p'(t) \right\rangle \geq 0. \tag{20}$$

Since $v \perp p(t)$, v belongs to the boundary of $T_M(x(t))$ from Theorem 2.1, and so to $T_{\partial M}(x(t))$. Thus there are $h_n \to 0^+$ and $v_n \to v$ with $x(t) + h_n v_n \in \partial M$. For any n, let us consider the solutions $x_n(\cdot)$ (with final conditions) to

$$\left\{ \begin{array}{l} x_n'(s) = \frac{\partial H}{\partial p}(x_n(s),p(s)) \text{ for } s \in [0,t], \\ x_n(t) := x(t) + h_n v_n. \end{array} \right.$$

Note that the $x_n(\cdot)$ converge to $x(\cdot)$ and that, moreover,

$$\forall s \in [t,T],\ \frac{x_n(s)-x(s)}{h_n} \to z(s), \tag{21}$$

where $z(\cdot)$ is the solution to

$$\begin{cases} z'(s) = \frac{\partial^2 H}{\partial x \partial p}(x(s),p(s))z(s), \\ z(t) = v. \end{cases}$$

Since $x_n(t) \in \partial M$, the functions $s \to x_n(t-s)$ are solutions of the differential inclusion for $-F$ starting from M, and thus remain in M from the semipermeability of M. From Theorem 2.1, $T_M(x(s)) = (p(s))^-$ for every s. From (21), $z(s)$ belongs to $T_M(x(s))$ so that $\langle z(s), p(s)\rangle \le 0$. In particular,

$$\forall s \in [0,t],\ \langle z(s),p(s)\rangle - \langle z(t),p(t)\rangle \le 0,$$

because $\langle z(t),p(t)\rangle = \langle v,p(t)\rangle = 0$. Dividing by $s-t$ and letting $s \to t^-$ gives

$$\langle z'(t),p(t)\rangle + \langle z(t),p'(t)\rangle \ge 0,$$

and thus inequality (20) holds true.

Since H is positively homogeneous, Euler's rule states that

$$\left(\frac{\partial^2 H}{\partial x \partial p}(x(t),p(t))\right)^* p(t) = \frac{\partial H}{\partial x}(x(t),p(t)).$$

From (20), for every t where $p'(t)$ exists, there is some $\lambda(t) \in \mathbb{R}$ such that

$$p'(t) = -\frac{\partial H}{\partial x} + \lambda(t)p(t).$$

(Note that one can compute $\lambda(t)$ explicitly because $\|p(t)\| = 1$ implies that $\langle p(t),p'(t)\rangle = 0$, and thus $\lambda(t) = \langle \frac{\partial H}{\partial x}, p(t)\rangle$.)

Now let $\mu(t) := \exp(-\int_0^t \lambda(s)ds)$ and $q(t) := \mu(t)p(t)$. Using the fact that H is positively homogeneous, it is easy shown that $(x(\cdot),q(\cdot))$ is a solution to the hamiltonian system. □

Acknowledgment. We would like to warmly thank Pr. T. Rzeżuchowski for his helpful suggestions and friendly advice.

ON THE REGULARITY OF SEMIPERMEABLE SURFACES IN CONTROL THEORY WITH APPLICATION TO THE OPTIMAL EXIT-TIME PROBLEM (PART II)*

PIERRE CARDALIAGUET†

Abstract. In control theory, a semipermeable surface is an (in general nonsmooth) oriented surface that, on one hand, contains solutions (the so-called barrier solutions) of the controlled system and, on the other hand, may be crossed by the solutions of this system in only one direction. Without making any assumption on the regularity of the boundary of the semipermeable surface, we show that the barrier solutions contained in this semipermeable surface satisfy the Pontryagin principle, that this surface is a Lipschitz manifold, and that it is, locally, the graph of a semiconcave function. Applying these results to the optimal exit-time function from a given open set yields, without any controllability assumption at the boundary of the open set, that this function is semiconcave on an open dense subset of its domain.

Key words. semipermeable surfaces, differential inclusion, viability theory, minimal time function

Introduction. In this paper, we continue our investigation of the regularity of semipermeable surfaces for the differential inclusion

$$\begin{cases} x'(t) \in F(x(t)), \\ x(0) = x_0, \end{cases}$$

where F is given by $F(x) := \bigcup_{u \in U} f(x,u)$. (See Part I of this paper, published in the same issue.)

In this paper, we prove that, under suitable assumptions, semipermeable surfaces for f are locally the graph of some semiconcave function. We apply this result to the optimal exit-time function, which is proved to be locally semiconcave in an open dense subset of its domain.

1. Regularity of semipermeable boundaries. In this section, we show that the contingent cone and the Dubovitsky–Miljutin cone at a point x to a closed set M with semipermeable boundary are determined by the "regulation map" [3], which is the set-valued map $\mathcal{R} : M \rightsquigarrow \mathbb{R}^N$ defined by

$$\forall x \in M,\ \mathcal{R}(x) := F(x) \cap T_M(x).$$

We also show that, if the boundary of M is semipermeable in a neighborhood of $x \in \partial M$, then $T_M(x)$ is a union of closed half-spaces and

$$D_M(x) = \mathrm{Int}\left(T_M(x)\right).$$

Moreover, we give a formula relating $T_M(x)$ and $\mathcal{R}(x)$.

We finally prove that the restriction of $T_M(\cdot)$ to $\partial M \cap O$ has a closed graph.

1.1. Characterization formula for the computation of the contingent cone.

PROPOSITION 1.1. *Assume that F satisfies*

$$\text{(1)}\qquad \begin{cases} \text{(i)} & F : \mathbb{R}^N \rightsquigarrow \mathbb{R}^N \text{ has convex compact values,} \\ \text{(ii)} & F \text{ is } \ell\text{-Lipschitz, i.e.,} \\ & \quad \forall x, y \in \mathbb{R}^N \times \mathbb{R}^N,\ F(y) \subset F(x) + \ell B, \end{cases}$$

and that the boundary of M is semipermeable in a neighborhood of $x \in \partial M$. Then we have the following estimate of $T_M(x)$:

$$\text{(2)}\qquad \bigcup_{v \in \mathcal{R}(x)} -T_{F(x)}(v) \ \subset\ T_M(x).$$

Proof. Let v belong to $F(x) \cap T_M(x)$. There exist sequences $v_n \to v$ and $h_n \to 0^+$ such that, for any n, $x + h_n v_n$ belongs to M. Any solution of the differential inclusion for $-F$ remains in M on $[0, T]$. So for $t \in [0, T]$,

$$\mathcal{A}_{-F}(x + h_n v_n)(t) \subset M,$$

where $\mathcal{A}_G(y)(s)$ denotes the reachable set from y at time s for the set-valued map G. Then[1]

$$x + h_n v_n - tF(x + h_n v_n) \subset \mathcal{A}_{-F}(x + h_n v_n)(t) + o(t)B,$$

where $o(t)/t \to 0^+$ if $t \to 0^+$. (Note that $o(t)$ does not depend on n.) Thus we have

$$x + h_n v_n - tF(x + h_n v_n) \subset M + o(t)B.$$

If we set $t = h_n$, we deduce

$$x + h_n(v - F(x)) \subset M + o(h_n)B,$$

which proves that $v - F(x)$ is contained in $T_M(x)$. Since $T_M(x)$ is a closed cone, this completes the proof of (2) because

$$-T_{F(x)}(v) = \overline{\bigcup_{\lambda > 0} \lambda(v - F(x))}. \qquad \square$$

Unfortunately, inclusion (2) may be strict. Moreover, it may happen that the contingent cone to a closed set with a semipermeable boundary is not completely determined by the regulation map.

Example. Let $F(x, y, z) := [0, 1] \times [0, 1] \times [2, 3]$ be the dynamics. Set $K_1 := \{(x, y, z) \mid x \le 0\}$ and $K_2 := \{(x, y, z) \mid x \le 0 \text{ or } x + y \le 0\}$. Then ∂K_1 and ∂K_2 are semipermeable barriers for F. Moreover,

$$F(0, 0, z) \cap T_{K_1}(0, 0, z) = F(0, 0, z) \cap T_{K_2}(0, 0, z) = \{0\} \times [0, 1] \times [2, 3]$$

[1] If $G : \mathbb{R}^N \rightsquigarrow \mathbb{R}^N$ is an ℓ-Lipschitzian set-valued map, with compact values; then

$$y + tG(y) \subset \mathcal{A}_G(y)(t) + o(t)B,$$

where $o(t)/t \to 0^+$ if $t \to 0^+$, and $o(t)$ depend only on ℓ (see Frankowska [7]).

for any $z \in \mathbb{R}$. But

$$T_{K_1}(0,0,z) \neq T_{K_2}(0,0,z). \qquad \square$$

However, under some additional assumptions on F, there is an equality in equation (2).

THEOREM 1.1 (characterization formula for the contingent cone). *Let F satisfy* (1) *and*

$$\forall x \in O',\ \forall v \in \partial F(x),\ T_{F(x)}(v) \text{ is a half-space.} \tag{3}$$

Let M be a closed set with a semipermeable boundary in a neighborhood of $x \in \partial M$. Then

$$\bigcup_{v \in \mathcal{R}(x)} -T_{F(x)}(v) \ = \ T_M(x). \tag{4}$$

Thus, in general, $T_M(x)$ is a union of half-spaces.

To prove Theorem 1.1, we need two remarks.

LEMMA 1.1. *Let F satisfy* (1). *If $x_n \to x$, $h_n \to 0^+$, and, for any n, $x_n(\cdot) \in \mathcal{S}_F(x_n)$, then $(\frac{x_n(h_n)-x_n}{h_n})$ converges, up to a subsequence, to some element of $F(x)$.*

LEMMA 1.2. *Let C be a convex compact subset of $\mathbb{R}^N$, $v_n \in C$ converge to v, and $l_n \to +\infty$. Then*

$$-T_C(v) \subset \ \operatorname*{Limsup}_{n\to\infty}\ l_n(v_n - C).$$

The proof of Lemma 1.1 is straightforward, so we give only the proof of Lemma 1.2. If w belongs to C, then

$$[m < l] \ \Rightarrow \ [m(w - C) \subset l(w - C)], \tag{5}$$

because $(w - C)$ is a convex set and contains 0. If we can find a subsequence of the (v_n) such that $v_{n_k} = v$ for any k, then the result is an obvious consequence of equation (5) with $w = v$. If it is not the case, set

$$m_n = \inf\{\sqrt{l_n}, \|v - v_n\|^{-1/2}\}.$$

Then $l_n(v_n - C)$ contains $m_n(v_n - C)$, because v_n belongs to C and $m_n \leq l_n$. Moreover,

$$m_n(v_n - C) = m_n(v - C) + m_n(v_n - v).$$

Since the sequence $m_n(v_n - v)$ converges to 0 and the upper limit of $m_n(v - C)$ is equal to $-T_C(v)$ because $m_n \to +\infty$, we have proved Lemma 1.2. $\square$

Proof of Theorem 1.1. Let w belong to $T_M(x)$. There exist $h_n \to 0^+$ and $w_n \to w$ such that, for any n, $x + h_n w_n$ belongs to M. For any $n \in \mathbb{N}$, there exists $x_n(\cdot) \in S_F(x + h_n w_n)$, which remains in M on $[0, T]$.

From Lemma 1.1, for any fixed $l > 0$, the sequence $v_l^n := \frac{x_n(lh_n)-(x+h_n w_n)}{lh_n}$ converges (up to a subsequence) to a limit v_l, which belongs to $F(x)$.

With the same ideas used in the proof of Proposition 1.1, we have

$$x_n(lh_n) - tF(x_n(lh_n)) \ \subset \ M + o(t)B$$

so that, by setting $t = mh_n$, with $m > 0$, we can deduce

$$x + h_n w_n + l h_n v_l^n - m h_n F(x) \ \subset \ M + o(mh_n)B.$$

Thus

$$w + l v_l - m F(x) \ \subset \ T_M(x). \tag{6}$$

Dividing by l and letting $l \to +\infty$ yield

$$\operatorname*{Limsup}_{l \to +\infty} \ v_l \subset T_M(x).$$

This upper limit (in the Kuratowski sense) is nonempty because the v_l belong to $F(x)$, which is compact. Let v belong to this upper limit. Note that v belongs to $\mathcal{R}(x)$ because $F(x)$ and $T_M(x)$ are closed. There exists l_n converging to $+\infty$ such that the limit of v_{l_n} is equal to v. For simplicity, we set $v_n := v_{l_n}$.

Inclusion (6) holds true for any $m \geq 0$. So, with $m := l_n$,

$$w + l_n[v_n - F(x)] \subset T_M(x).$$

Since $T_M(x)$ is closed, Lemma 1.2 yields

$$w - T_{F(x)}(v) \subset T_M(x).$$

Assume for a while that w does not belong to $-T_{F(x)}(v)$. From assumption (3), $-T_{F(x)}(v)$ is a half-space. So the cone spanned by $w - T_{F(x)}(v)$ is equal to $\mathbb{R}^N$ and is contained in $T_M(x)$. This is impossible, since $T_M(x)$ cannot be the full space, as we showed in Corollary 1.2 in Part I of this paper.

1.2. The Dubovitsky–Miljutin cone. We now compute the Dubovitsky–Miljutin cone in terms of the regulation map. For that purpose, we shall need a result concerning the existence of particular barrier solutions.

Throughout this section, we assume that the set-valued map F satisfies (1) and (3).

PROPOSITION 1.2. *Let M be a closed set with a semipermeable boundary in a neighborhood of $x \in \partial M$. Assume that w belongs to $\mathcal{R}(x)$. Then there is some barrier solution $x(\cdot)$ starting from x such that the adjoint $p(\cdot)$ of $x(\cdot)$ satisfies*

$$\langle w, p(0) \rangle = 0.$$

Let us point out a particular case of that proposition.

COROLLARY 1.1. *Assume, moreover, that $F(x)$ is strictly convex. Then there is a barrier solution $x(\cdot)$ starting from x such that $x'(0) = w$.*

The proof of this corollary is a straightforward consequence of Proposition 1.2 and of the following lemma.

LEMMA 1.3. *Let $x(\cdot)$ be a barrier solution and $p(\cdot)$ be its adjoint. Set*

$$F_p := \{v \in F(x) \mid \langle v, p(0) \rangle = 0\}.$$

Then

$$\operatorname*{Limsup}_{t \to 0^+} \ \frac{x(t) - x(0)}{t} \subset F_p,$$

where Limsup *denotes the Kuratowski upper limit* [2].

Proof. The upper limit of $\frac{x(t)-x}{t}$ is contained in $F(x)$. It remains to prove that, if z belongs to this upper limit, then $\langle z, p(0)\rangle = 0$. But

$$\begin{aligned} |\langle \tfrac{x(t)-x}{t}, p(0)\rangle| &\leq \tfrac{1}{t}\int_0^t |\langle x'(s), p(0)\rangle| ds \\ &\leq \tfrac{1}{t}\int_0^t |\langle x'(s), p(s)\rangle| ds + \tfrac{1}{t}\int_0^t \|x'(s)\| 2Cs ds \\ &\leq \rho C t, \end{aligned}$$

where $\rho := \max_{t\in[0,T]} \|x'(t)\|$ and the constant C comes from Theorem 2.1 of Part I. Letting $t \to 0^+$ proves our claim. □

Proof of Proposition 1.2. We use the same kind of ideas as in the proof of Theorem 1.1. Since w belongs to $T_{\partial M}(x)$, there exists $h_n \to 0^+$, $w_n \to w$ such that $x + h_n w_n$ belongs to ∂M. There also exist barrier solutions $x_n(\cdot)$ starting from $x + h_n w_n$. We denote by $p_n(\cdot)$ their adjoint. From Theorem 5.3.1 of [2], the $x_n(\cdot)$ converge, up to a subsequence, to some solution $x(\cdot)$ starting from x while the $p_n(\cdot)$ converge to some function $p(\cdot)$ which is the adjoint of $x(\cdot)$ (see Proposition 2.1 of Part I).

As in Theorem 1.1, for any $\lambda > 0$, there exists $v_\lambda \in F(x)$ such that

$$\frac{x_n(\lambda h_n) - (x + h_n w_n)}{\lambda h_n} \to v_\lambda$$

up to a subsequence. Moreover, a subsequence of the (v_λ) converge to some $v \in F(x) \cap T_M(x)$. As in the proof of Theorem 1.1, we can prove that

$$w \in -T_{F(x)}(v). \tag{7}$$

We want to prove that $\langle w, p(0)\rangle = 0$. For that purpose, let us first show that $\langle p(0), v\rangle = 0$. We denote by ρ the following bound:

$$\rho := \sup\{\|F(x_n(t))\| \mid n \in \mathbb{N} \text{ and } t \in [0,T]\}.$$

For any $n \in \mathbb{N}$,

$$\begin{aligned} |\langle p_n(0)\ , &\ x_n(\lambda h_n) - (x + h_n w_n)\rangle| \\ &\leq \textstyle\int_0^{\lambda h_n} |\langle p_n(0), x_n'(s)\rangle| ds \\ &\leq \textstyle\int_0^{\lambda h_n} |\langle p_n(s), x_n'(s)\rangle| ds + \int_0^{\lambda h_n} 2Cs\|x_n'(s)\| ds \\ &\leq \rho C \lambda^2 h_n^2 \end{aligned}$$

because $p_n(\cdot)$ are $2C$-Lipschitz. Dividing these inequalities by λh_n and letting $n \to +\infty$ yields $\langle p(0), v_\lambda\rangle = 0$. Finally, letting $\lambda \to +\infty$ gives the desired formula: $\langle p(0), v\rangle = 0$.

Since $p(\cdot)$ is an adjoint,

$$0 = \inf_{z\in F(x)} \langle z, p(0)\rangle = \langle v, p(0)\rangle.$$

To complete the proof, we need the following remark.

LEMMA 1.4. *Assume that F satisfies* (3). *If $p \in \mathbb{R}^N\backslash\{0\}$ and $v \in F(x)$ are such that $H(x,p) = \langle v, p\rangle$, then*

$$T_{F(x)}(v) = (p)^+,$$

where $(p)^+ := \{w \in \mathbb{R}^N \mid \langle w, p\rangle \geq 0\ \}$.

Thus Lemma 1.4 states that

$$(p(0))^- = -T_{F(x)}(v).$$

Since, from (7), w belongs to the right-hand side of the equality, $\langle w, p(0)\rangle \le 0$. But w belongs to $F(x)$. So $\langle w, p(0)\rangle \ge 0$ from Theorem 2.1 of Part I. So $\langle w, p(0)\rangle = 0$, and Proposition 1.2 is proved. □

THEOREM 1.2 (the Dubovitsky–Miljutin cone). *Let M be a closed set with a semipermeable boundary in a neighborhood of $x \in \partial M$. The Dubovitsky–Miljutin cone is determined by the regulation map*

$$D_M(x) \;=\; \bigcup_{v\in\mathcal{R}(x)} \operatorname{Int}\left(-T_{F(x)}(v)\right) \;=\; \operatorname{Int} T_M(x).$$

COROLLARY 1.2. *Under the notations and assumptions of the previous theorem,*

$$T_{\widehat{M}}(x) = \bigcap_{v\in\mathcal{R}(x)} T_{F(x)}(v) \quad \textit{and} \quad D_{\widehat{M}}(x) = \bigcap_{v\in\mathcal{R}(x)} \operatorname{Int}\left(T_{F(x)}(v)\right).$$

Proof. Combining Corollary 1.2 of Part I with Theorem 1.2 gives the first formula. The second formula comes from Theorem 1.1.

Proof of Theorem 1.2.

(1) Let us first prove that

$$\bigcup_{v\in\mathcal{R}(x)} \operatorname{Int}\left(-T_{F(x)}(v)\right) \;=\; \operatorname{Int} T_M(x). \tag{8}$$

The left-hand side of the equality is contained in the right-hand side of Theorem 1.1. Let us prove the converse inclusion. For that purpose, we denote by A the left-hand side of the equality.

Let w belong to the interior of $T_M(x)$. Let us set

$$\mathcal{P} := \{p \in \mathbb{R}^N,\ \|p\| \le 1 \text{ and } \exists v \in \mathcal{R}(x) \text{ with } (p)^+ = -T_{F(x)}(v)\}.$$

Note that $\mathcal{P}$ is compact since $\mathcal{R}(x)$ is compact. Since w belongs to $\operatorname{Int}(T_M(x))$, Theorem 1.1 states that there is some positive α such that, for any $b \in B$, there is some $v \in \mathcal{R}(x)$ such that $w + \alpha b \in -T_{F(x)}(v)$. Then

$$\inf_{b\in B} \sup_{p\in\mathcal{P}} \langle w + \alpha b, p\rangle \ge 0$$

so that

$$\sup_{p\in\overline{Co}(\mathcal{P})} \inf_{b\in B} \langle w + \alpha b, p\rangle \ge 0.$$

In particular,

$$\sup_{p\in\overline{Co}(\mathcal{P})} \langle w, p\rangle \;\ge\; \alpha \inf_{p\in\overline{Co}(\mathcal{P})} \|p\|.$$

Note that the right-hand side of the inequality is positive since, otherwise, there would exist $p_i \in \mathcal{P}$, $\lambda_i \in [0,1]$, $\Sigma\lambda_i = 1$, such that $\sum_i \lambda_i p_i = 0$. Then $\mathbb{R}^N = \bigcup_i (p_i)^+ \subset$

$T_M(x)$, which is in contradiction with Corollary 1.2 of Part I. So we have proved that there is some $p \in \mathcal{P}$ such that $\langle w, p\rangle > 0$, and so w belongs to the interior of $-T_{F(x)}(v)$ for some $v \in \mathcal{R}(x)$. Thus equality (8) is proved.

(2) Since $D_M(x)$ is open and contained in $T_M(x)$, $D_M(x)$ is contained in the interior of $T_M(x)$. So, from equality (8), it remains to prove that

$$\bigcup_{v\in\mathcal{R}(x)} \operatorname{Int}\left(-T_{F(x)}(v)\right) \subset D_M(x).$$

For that purpose, let v belong to $\mathcal{R}(x)$.

From Proposition 1.2, there is some solution $x(\cdot)$ which remains on ∂M and some adjoint $p(\cdot)$ to $x(\cdot)$ on $[0,T]$ such that $\langle p(0), v\rangle = 0$. Let us denote

$$F_p := \{z \in F(x) \mid \langle z, p(0)\rangle = 0\}.$$

Lemma 1.3 states that

$$\operatorname*{Limsup}_{t\to 0^+} \frac{x(t)-x}{t} \subset F_p. \tag{9}$$

Now let w belong to the interior of $-T_{F(x)}(v)$. We have to prove that w belongs to $D_M(x)$. For any $z \in F_p$,

$$\langle z, p(0)\rangle = \inf_{v'\in F(x)} \langle v', p(0)\rangle = 0,$$

and so, Lemma 1.4 states that

$$-T_{F(x)}(z) = (p(0))^- = -T_{F(x)}(v).$$

Since, for any $z \in F_p$,

$$\operatorname{Int}\left(-T_{F(x)}(z)\right) = \bigcup_{\lambda>0} \lambda(z - \operatorname{Int}(F(x))),$$

there is some $\lambda_z > 0$ such that w is contained in the interior of $\lambda_z(z - F(x))$. Since F_p is compact, the λ_z are bounded on F_p by some $\lambda > 0$ and there is some $\alpha > 0$ such that $w + \alpha B$ is contained in $\lambda(z - F(x))$ for any $z \in F_p$. Since we want to prove that $w \in D_M(x)$ and that $D_M(x)$ is a cone, we can assume, without loss of generality, that $\lambda = 1$. So, $z - w + \alpha B$ is contained in $F(x)$ for any $z \in F_p$.

Since F is Lipschitz,

$$\forall y \in x + \frac{\alpha}{2\ell}B,\ \forall z \in F_p, \quad z - w + \frac{\alpha}{2}B \subset F(y).$$

For t sufficiently small (say, $t \le \epsilon$ with $\epsilon > 0$), the reachable set for $-F$ from $x(t)$ at time t is contained in $x + \frac{\alpha}{2\ell}B$. Thus

$$\forall z \in F_p,\ \ x(t) - t\left(z - w + \frac{\alpha}{2}B\right) \subset \mathcal{A}_{-F}(x(t))(t). \tag{10}$$

From (9), there is some $\epsilon' > 0$ such that $\frac{x(t)-x}{t}$ is contained in $F_p + \frac{\alpha}{4}B$ for $t \in]0, \epsilon']$. Thus, for any $t \le \inf\{\epsilon, \epsilon'\}$,

$$\begin{aligned} x + t(w + \tfrac{\alpha}{4}B) &\subset x - t[z_t - \tfrac{x(t)-x}{t} - w + \tfrac{\alpha}{2}B] \\ &= x(t) - t[z_t - w + \tfrac{\alpha}{2}B], \end{aligned} \tag{11}$$

where $z_t \in F_p$ is the projection onto F_p of $\frac{x(t)-x}{t}$. Since $\mathcal{A}_{-F}(x(t))(t)$ is contained in M, combining (10) and (11) yields that $x + t(w + \frac{\alpha}{4}B)$ is contained in M for any $t \in \inf\{\epsilon, \epsilon'\}$. Thus w belongs to $D_M(x)$, which completes the proof of Theorem 1.2. □

1.3. Upper semicontinuity of the contingent cone. We are now ready to state the main theorem of this section.

THEOREM 1.3 (regularity of the contingent cone). *Assume that F satisfies* (1) *and* (3) *and that the boundary of M is semipermeable in a neighborhood of $x \in \partial M$. Then*

$$\operatorname*{Limsup}_{x' \to x,\ x' \in \partial M} T_M(x') \subset T_M(x).$$

In other words, the set-valued map $x \rightsquigarrow T_M(x) \cap B$ from $\partial M \cap O$ to $\mathbb{R}^N$ is upper semicontinuous.

Remarks.

(1) In some problems, we already know that M is convex. Then the set-valued map $x \rightsquigarrow T_M(x)$ is lower semicontinuous with convex values [2]. Thus Theorem 1.3 yields that the set-valued map $x \rightsquigarrow T_M(x)$ is continuous on ∂M, and $T_M(x)$ is always equal to a half-space. This means that ∂M is a $\mathcal{C}^1$ manifold. This is, in particular, the case when

• K is convex and F has a convex graph[2]; then the viability kernel $\mathrm{Viab}_F(K)$ is convex [4]. Thus the boundary of $\mathrm{Viab}_F(K)$, which is semipermeable in the interior of K, is a smooth manifold in the interior of K.

• F has a convex graph and 0 belongs to $\mathrm{Int}(F(x_0))$; then the reachable set from x_0 is convex. Thus its boundary, which is semipermeable, is a smooth manifold.

(2) From Corollary 1.2, $T_{\widehat{M}}(x) = \overline{\mathbb{R}^N \backslash T_M(x)}$ for $x \in \partial M$. Thus the set-valued map $x \rightsquigarrow T_{\widehat{M}}(x)$ is lower semicontinuous; i.e., $\widehat{M}$ is sleek [2].

Proof of Theorem 1.3. Let w_n belong to $T_M(x_n)$, with $x_n \to x$, $w_n \to w$, x_n and x belonging to $\partial M \cap O$. We have to prove that w belongs to $T_M(x)$.

Theorem 1.1 yields the existence of some $v_n \in \mathcal{R}(x_n)$ such that w_n belong to $-T_{F(x_n)}(v_n)$. From Proposition 1.2, for any $n \in \mathbb{N}$, there exists some barrier solution $x_n(\cdot)$ starting from x_n, with associated adjoint denoted by $p_n(\cdot)$ and satisfying $\langle v_n, p_n(0)\rangle = 0$.

From Theorem 5.3.1 in [2], a subsequence of the $x_n(\cdot)$ converges to some barrier solution $x(\cdot)$ starting from x. Moreover, the adjoint maps $p_n(\cdot)$ converge to the adjoint function $p(\cdot)$ of $x(\cdot)$ from Proposition 2.1 of Part I.

Since, $H_F(x_n, p_n(0)) = \langle v_n, p_n(0)\rangle = 0$, Lemma 1.4 states that

$$-T_{F(x_n)}(v_n) = (p_n(0))^-.$$

Thus, for any $n \in \mathbb{N}$, $\langle w_n, p_n(0)\rangle \le 0$, and so $\langle w, p(0)\rangle \le 0$. Moreover, $p(\cdot)$ is the adjoint of the solution $x(\cdot)$, so that Theorem 2.1 of Part I states that

$$(p(0))^- \subset T_M(x(0)).$$

In particular, w belongs to $T_M(x)$. □

[2]This assumption is satisfied in particular if the controlled system is affine in x.

2. Semiconcavity property. The aim of this section is to show that, under suitable assumptions, semipermeable surfaces are locally the graphs of semiconcave functions.

2.1. A new assumption on the controlled system. We now introduce a new assumption:

$$\begin{aligned} &\text{(a)}\quad \text{The values of } F \text{ are convex and have nonempty interior.}\\ &\text{(b)}\quad \exists \gamma > 0 \text{ such that}\\ &\qquad \forall x \in O',\ \forall v \in \partial F(x) \text{ and } \forall w \in T_{F(x)}(v),\\ &\qquad\qquad d_{F(x)}(v+w) \le \gamma \|w\|^2. \end{aligned} \tag{12}$$

It can be proved that condition (12) is stronger than (3). Condition (12) is related to the boundedness of the curvature of the convex sets $F(x)$ for $x \in O'$. It is also related to some property of "uniform strict concavity" of the hamiltonian H. Namely, we have the following proposition.

PROPOSITION 2.1. *Let F satisfy* (1) *and $H : \mathbb{R}^N \times \mathbb{R}^N \to \mathbb{R}$ be the hamiltonian associated with F. The following assertions are equivalent.*

(i) *F satisfies* (12).

(ii)

$$\begin{aligned} &\textit{There is some } \epsilon > 0 \textit{ such that}\\ &\forall x \in O',\ p \to H(x,p) + \epsilon\|p\| \textit{ is concave.} \end{aligned} \tag{13}$$

(iii) *There is some convex set-valued map $F_0 : O' \rightsquigarrow \mathbb{R}^N$ and some $\epsilon > 0$ such that $F(x) = F_0(x) + \epsilon B$.*

(iv) *F has $\mathcal{C}^1$ convex values with a nonempty interior, and the normal map*[3] *$n_x : \partial F(x) \to \partial B_N$ is λ-Lipschitz, with λ independent of $x \in O'$.*

Proposition 2.1 can be proved by using classical arguments of convex analysis, and thus we do not give its proof.

Remark. If F is Lipschitz, then the set-valued map F_0 defined in (iii) is also Lipschitz.

Let us now give an example of a set-valued map satisfying (12).

PROPOSITION 2.2. *Assume that $f : \mathbb{R}^N \to \mathbb{R}^N$ is Lipschitz and that $A : \mathbb{R}^N \to \mathcal{L}(\mathbb{R}^N, \mathbb{R}^N)$ and $A^{-1} : \mathbb{R}^N \to \mathcal{L}(\mathbb{R}^N, \mathbb{R}^N)$ are Lipschitz. Then the set-valued map*

$$F(x) := f(x) + \bigcup_{u \in B} A(x)u$$

satisfies (1) *and* (12) *on bounded sets.*

Proof. The hamiltonian associated with F is

$$H(x,p) = \langle f(x), p\rangle - \|A^*(x)p\|,$$

and it satisfies (13) thanks to the following lemma.

LEMMA 2.1. *Assume that Q is a positive definite quadratic form with largest eigenvalue a and smallest eigenvalue b. Then, for any $\alpha \in [0, b/a^{\frac{1}{2}}]$, the map*

$$p \to (\langle p, Qp\rangle)^{\frac{1}{2}} - \alpha\|p\|$$

is convex. □

[3] That is, the map such that $\|n_x(v)\| = 1$ for any $v \in \partial F(x)$ and $n_x(v)$ is an outward normal to $F(x)$ at v.

2.2. Further regularity.

THEOREM 2.1. *Assume that the boundary of M is semipermeable and that $F : \mathbb{R}^N \rightsquigarrow \mathbb{R}^N$ satisfies* (1) *and* (12). *There is some constant k such that, for any $x \in \partial M \cap O$, for any $w \in T_M(x)$ with $\|w\| \leq T^2$,*

$$d_M(x+w) \leq k\|w\|^{\frac{3}{2}}. \tag{14}$$

The notations O and T are defined in Proposition 1.1 of Part I.

The exponent $\frac{3}{2}$ is rather surprising: one would expect an exponent 2, as for F. We have an example proving that this exponent is optimal at least when F is Lipschitz. For smooth hamiltonians, the problem is still open.

Proof. If the vector w belongs to $T_M(x)$ with $x \in \partial M$, Proposition 1.2 states that there is some barrier solution $x(\cdot) \in \mathcal{S}_F(x)$ which remains in ∂M on $[0,T]$ and some adjoint $p(\cdot)$ of $x(\cdot)$ on $[0,T]$ such that $\langle p(0), w\rangle \leq 0$.

Set $\tau := \|w\|^{\frac{1}{2}}$ and let $w(t)$ be the projection of w onto $T_M(x(t))$. Let us set, for any $t \leq \tau$,

$$\alpha(t) := d_{F(x(t))}\left(x'(t) - \frac{w(t)}{\tau}\right).$$

Let $y(\cdot)$ be defined on $[0,\tau]$ by

$$\begin{cases} y'(t) := -x'(\tau - t) + \frac{1}{\tau} w(\tau - t), \\ y(0) := x(\tau). \end{cases}$$

(Recall that $\|w\| \leq T^2$, so that $\tau \leq T$.) The Filippov theorem yields the existence of a solution $z(\cdot) \in \mathcal{S}_{-F}(x(\tau))$ such that

$$\forall t \in [0,\tau],\ \|z(t) - y(t)\| \leq e^{\ell t} \int_0^t \alpha(s)ds. \tag{15}$$

Let us prove that

$$\int_0^\tau \alpha(s)ds \leq \gamma\|w\|^{\frac{3}{2}} \tag{16}$$

and that

$$\|y(\tau) - (x+w)\| \leq C\|w\|^{\frac{3}{2}}. \tag{17}$$

Proof of (16). From Corollary 2.1 of Part I, for almost every $t \in]0,T[$, $T_M(x(t)) = -T_{F(x(t))}(x'(t))$. From its very definition, $w(t)$ belongs to $T_M(x(t))$, so $-w(t)$ belongs to $T_{F(x(t))}(x'(t))$. Thus assumption (12) yields that

$$\alpha(t) := d_{F(x(t))}\left(x'(t) - \frac{w(t)}{\tau}\right) \leq \gamma\frac{\|w(t)\|^2}{\tau^2} \leq \gamma\|w\|$$

(note that $\|w(t)\| \leq \|w\|$ because $w(t)$ is the projection of w onto a half-space). After integration, we obtain (16).

Proof of (17). From Corollary 2.1 of Part I, for almost every $t \in]0,T[$, $T_M(x(t)) = (p(t))^-$. Thus

$$w(t) = w - \langle p(t), w\rangle_+ p(t),$$

where x_+ denotes $\sup\{0, x\}$. Recall that $p(\cdot)$ is $2C$-Lipschitz. (See Theorem 2.1 of Part I.) Thus

$$\langle w, p(t)\rangle_+ \leq [\langle w, p(0)\rangle + 2Ct\|w\|]_+ \leq 2Ct\|w\|,$$

which implies

$$\|w(t) - w\| \leq 2Ct\|w\|.$$

After integration, we obtain

$$\left\| \int_0^\tau w(\tau - s)ds - \tau w \right\| \leq C\|w\|\tau^2.$$

Since $y(\tau) := x + \frac{1}{\tau}\int_0^\tau w(\tau - s)ds$, we have obtained (17).

Combining (15), (16), and (17), we conclude that

$$\|z(\tau) - (x + w)\| \leq (C + e^{\ell T^2}\gamma)\|w\|^{\frac{3}{2}}.$$

Let us now recall that $z(\cdot)$ is a solution of the differential inclusion for $-F$ starting from $x(\tau)$ which belongs to $M \cap O'$. Thus $z(t)$ belongs to M for any $t \leq \tau$ and

$$d_M(x + w) \leq \|z(\tau) - (x + w)\| \leq k\|w\|^{\frac{3}{2}},$$

which is the desired conclusion. □

2.3. A criteria of semiconcavity. We show here that the result described in Theorem 2.1 is related to semiconcavity of a function. Let us first recall what a semiconcave function is [8].

DEFINITION 2.1. *Let Ω be a open convex subset of $\mathbb{R}^N$ and $\phi : \Omega \to \mathbb{R}$. The function ϕ is semiconcave on Ω if, $\forall x, y \in \Omega$, $\forall \lambda \in [0, 1]$,*

$$\lambda\phi(x) + (1 - \lambda)\phi(y) \leq \phi\left(\lambda x + (1 - \lambda)y\right) + \lambda(1 - \lambda)\omega(\|y - x\|),$$

where $\omega : \mathbb{R}^+ \to \mathbb{R}^+$ is the modulus of semiconcavity, $\omega(t) \to 0^+$ if $t \to 0^+$.

We now provide a criterion for semiconcavity.

PROPOSITION 2.3. *Let Ω be a convex open subset of $\mathbb{R}^N$ and $\phi : \Omega \to \mathbb{R}$. Assume that ϕ satisfies the following conditions:*

(i) *ϕ is ρ-Lipschitz;*
(ii) *$\forall x \in \Omega$, $-T_{Epi(\phi)}(x, \phi(x)) \bigcup T_{Epi(\phi)}(x, \phi(x)) = \mathbb{R}^{N+1}$;*
(iii) *There exists a constant k such that, $\forall x \in \Omega$, $\forall (v_x, v_t) \in T_{Epi(\phi)}(x, \phi(x))$ such that $x + v_x \in \Omega, d_{Epi(\phi)}\left((x, \phi(x)) + (v_x, v_t)\right) \leq k\|(v_x, v_t)\|^{\frac{3}{2}}$.*

Then ϕ is semiconcave with a modulus $\omega(t) := k(\rho^2 + 1)^2 t^{\frac{3}{2}}$.

Let us point out that condition (ii) is fulfilled in particular if $T_{Epi(\phi)}(x, \phi(x))$ is a union of half-spaces, as in Theorem 1.1. Condition (iii) is exactly the same as (14).

Proof of Proposition 2.3. *First step.* We claim that condition (ii) implies that, if (v_x, v_t) belongs to $\partial T_{Epi(\phi)}(x, \phi(x))$, then $-(v_x, v_t)$ belongs to $T_{Epi(\phi)}(x, \phi(x))$. Indeed, since (v_x, v_t) belongs to $\partial T_{Epi(\phi)}(x, \phi(x))$, there exists a sequence $(v_x^n, v_t^n) \notin T_{Epi(\phi)}(x, \phi(x))$ converging to (v_x, v_t). From assumption (ii), $-(v_x^n, v_t^n)$ belongs to $T_{Epi(\phi)}(x, \phi(x))$ for any n. Letting $n \to +\infty$ yields $-(v_x, v_t) \in T_{Epi(\phi)}(x, \phi(x))$, which is the desired conclusion.

Second step. We now prove that, if (v_x, v_t) belongs to $T_{Epi(\phi)}(z, \phi(z))$, then, for any $h \in [0,1]$ such that $z + hv_x \in \Omega$, one has

$$\phi(z + hv_x) - (\phi(z) + hv_t) \leq k(\rho^2+1)^{\frac{1}{2}} \left(h\|(v_x, v_t)\|\right)^{\frac{3}{2}}.$$

Let (y_h, ρ_h) belong to the projection of $(z + hv_x, \phi(z) + hv_t)$ onto $\mathrm{Epi}(\phi)$. Then

$$\begin{aligned}
&\phi(z + hv_x) - (\phi(z) + hv_t)\\
&\quad = (\phi(z + hv_x) - \phi(y_h)) + (\phi(y_h) - \rho_h) + (\rho_h - (\phi(z) + hv_t))\\
&\quad \leq \rho\|y_h - (z + hv_x)\| + 0 + |\rho_h - (\phi(z) + hv_t)|\\
&\quad \leq (\rho^2+1)^{\frac{1}{2}} \|(y_h, \rho_h) - (z + hv_x, \phi(z) + hv_t)\|\\
&\quad \leq k(\rho^2+1)^{\frac{1}{2}} (h\|(v_x, v_t)\|)^{\frac{3}{2}}
\end{aligned}$$

from assumption (iii).

Third step. Let x and y belong to Ω and $\lambda \in (0,1)$. Set $z := \lambda x + (1-\lambda)y$. Let us define τ by

$$\tau := \min\{t \mid (y - x, t) \in T_{Epi(\phi)}(z, \phi(z))\}.$$

Note that $\tau > -\infty$ because ϕ is ρ-Lipschitz. In fact, it is easily seen that $|\tau| \leq \rho\|y - x\|$. Note also that $(y - x, \tau)$ belongs to the boundary of $T_{Epi(\phi)}(z, \phi(z))$. Thus, from the first step, $-(y - x, \tau)$ belongs to $T_{Epi(\phi)}(z, \phi(z))$. Applying the second step with $v_x := -(y - x)$, $v_t := -\tau$, and $h := 1 - \lambda$ yields

$$\phi(x) - (\phi(z) - (1-\lambda)\tau) \leq k(\rho^2+1)^{\frac{1}{2}} ((1-\lambda)\|(y - x, \tau)\|)^{\frac{3}{2}}, \tag{18}$$

while applying the second step with $h := \lambda$ and $(v_x, v_t) := (y - x, \tau)$ yields

$$\phi(y) - (\phi(z) + \lambda\tau) \leq k(\rho^2+1)^{\frac{1}{2}} (\lambda\|(y - x, \tau)\|)^{\frac{3}{2}}. \tag{19}$$

Summing (18) multiplied by λ and (19) multiplied by $(1 - \lambda)$ gives

$$\begin{aligned}
&\lambda\phi(x) + (1-\lambda)\phi(y) - \phi(\lambda x + (1-\lambda)y)\\
&\leq k(\rho^2+1)^{\frac{1}{2}} [\lambda((1-\lambda)\|(y - x, \tau)\|)^{\frac{3}{2}} + (1-\lambda)(\lambda\|(y - x, \tau)\|)^{\frac{3}{2}}]\\
&\leq k(\rho^2+1)^{\frac{1}{2}} \lambda(1-\lambda)\|(y - x, \tau)\|^{\frac{3}{2}}.
\end{aligned}$$

Since $|\tau| \leq \rho\|y - x\|$, $\|(y - x, \tau)\| \leq (\rho^2+1)^{\frac{1}{2}}\|y - x\|$. Thus we have finally proved that

$$\begin{aligned}
&\lambda\phi(x) + (1-\lambda)\phi(y) - \phi(\lambda x + (1-\lambda)y)\\
&\qquad \leq k(\rho^2+1)^2 \lambda(1-\lambda)\|y - x\|^{\frac{3}{2}},
\end{aligned}$$

which is the desired conclusion. □

COROLLARY 2.1. *Suppose that the assumptions of Theorem* 2.1 *are fulfilled. Assume that the boundary of M is semipermeable. Then M is locally the epigraph of a semiconcave function with a modulus of semiconcavity of the form $\omega(t) := kt^{\frac{3}{2}}$.*

Semiconcave functions enjoy nice regularity properties. For instance, singularities of semiconcave functions (i.e., the points at which this function is not differentiable) propagate [1].

Corollary 2.1 is an application of Proposition 1.2 of Part I, Theorem 2.1, and Proposition 2.3.

3. Regularity of the optimal exit-time map. An important application of the previous results is the study of the optimal exit-time problem. For an open set Ω, we study the map

$$\theta_\Omega(x) := \inf\{t \geq 0 \mid \exists x(\cdot) \in \mathcal{S}_F(x) \text{ with } x(t) \notin \Omega\}. \tag{20}$$

We set $\theta_\Omega(x) := +\infty$ if no solution reaches the complement of Ω. We refer to the introduction of the first part for bibliographical comments on the regularity of θ_Ω. In Cardaliaguet, Quincampoix, and Saint-Pierre [5], it is proved that the epigraph of θ_Ω, denoted by $\mathrm{Epi}(\theta_\Omega)$, is the viability kernel of $\mathcal{H} := \overline{\Omega} \times \mathbb{R}^+$ for the set-valued map $\Phi : \mathbb{R}^{N+1} \rightsquigarrow \mathbb{R}^{N+1}$ defined by

$$\forall (x,t) \in \mathbb{R}^{N+1},\ \Phi(x,t) := \begin{cases} F(x) \times \{-1\} & \text{if } x \in \Omega, \\ \overline{Co}\,(\{0\} \times \{0\} \bigcup F(x) \times \{-1\}) & \text{otherwise.} \end{cases}$$

The set-valued map Φ obviously satisfies condition (1) on $\Omega \times \mathbb{R}$.

Since, for any $x \in \Omega$, $\theta_\Omega(x) > 0$, $(x, \theta_\Omega(x))$ belongs to the boundary of $\mathrm{Viab}_\Phi(\mathcal{H})$ and to the interior of $\mathcal{H}$. Thus the Quincampoix theorem [9] states that the boundary of $\mathrm{Epi}(\theta_\Omega)$ is semipermeable for Φ in a neighborhood of any point $(x, \phi(x))$ for $x \in \Omega$.

Unfortunately, the set-valued map Φ never satisfies condition (3) (because $\Phi(x)$ always has an empty interior), and we cannot straightforwardly apply the regularity results previously obtained. For this reason, we first prove the existence of a set-valued map Ψ satisfying (12) (provided that F satisfies (12)) such that the boundary of $\mathrm{Viab}_\Phi(\mathcal{H})$ is still semipermeable for Ψ. Then we apply Theorems 1.3 and 2.1 to the particular case of the map θ_Ω. We complete this paper by showing that θ_Ω is smooth along some optimal trajectories.

Notation. Below, the variable in $\mathbb{R}^{N+1}$ is divided into (x,t), with x belonging to the state space $\mathbb{R}^N$ and t to the time space $\mathbb{R}$.

3.1. Reduction of the problem. The hamiltonian associated with map Φ is

$$H_\Phi(x,t,p_x,p_t) := -p_t + H(x,p_x),$$

where H is the hamiltonian associated with F.

PROPOSITION 3.1. *Assume that the set-valued map $F : \mathbb{R}^N \rightsquigarrow \mathbb{R}^N$ satisfies* (1) *and* (12). *Then there is a set-valued map $\Psi : \mathbb{R}^{N+1} \rightsquigarrow \mathbb{R}^{N+1}$ satisfying* (1) *and* (12) *such that*

$$\begin{aligned} &\forall (x,t) \in \mathbb{R}^{N+1},\ \forall (p_x,p_t) \in \mathbb{R}^{N+1}, \\ &\quad H_\Psi(x,t,p_x,p_t) = 0 \iff H_\Phi(x,t,p_x,p_t) = 0, \end{aligned} \tag{21}$$

and moreover, $\Phi(x,t) \subset \Psi(x,t)$ for any $(x,t) \in \mathbb{R}^{N+1}$.

In that case, Proposition 1.1 of Part I states that it is equivalent for a closed set M to enjoy the semipermeability property for Φ and to enjoy the semipermeability property for Ψ.

Proof of Proposition 3.1. *Construction of* Ψ. From Proposition 2.1, there is some set-valued map $F_0 : \mathbb{R}^N \rightsquigarrow \mathbb{R}^N$ such that $F(x) = F_0(x) + \epsilon B$ and has associated hamiltonian $h(x,p) := H(x,p) + \epsilon\|p\|$. Since F is Lipschitz, F_0 is Lipschitz.

Let us define Ψ by

$$\Psi(x,t) := \overline{Co}\left(\bigcup_{\|u_x\|^2 + |u_t|^2 \leq 2} (2 + u_t)[F_0(x) \times \{-1\}] + \epsilon\{u_x\} \times \{0\} \right).$$

The set-valued map Ψ satisfies the regularity condition (1). Setting $u_t = -1$, it is easily seen that $\Phi(x,t) \subset \Psi(x,t)$. So it remains to show that the hamiltonian H_Ψ of Ψ satisfies (13) and (21).

H_Ψ satisfies (13) *and* (21). A little computation gives

$$H_\Psi(x,t,p_x,p_t) = \min_{v\in F_0(x)} \left[-2p_t + 2\langle v,p_x\rangle - \sqrt{2}\left((-p_t+\langle v,p_x\rangle)^2 + \epsilon^2\|p_x\|^2\right)^{\frac12}\right].$$

Note that equivalence (21) is fulfilled. The eigenvalues of the quadratic form Q_v defined by $(p_x,p_t) \to (-p_t+\langle v,p_x\rangle)^2 + \epsilon^2\|p_x\|^2$ are

$$\begin{cases} \lambda_1 = \epsilon^2 & \text{(eigenvector } (w,0) \text{ where } w \perp v\text{)},\\ \lambda_2 = \frac{\epsilon^2+\|v\|^2+1+\left((\epsilon^2+\|v\|^2+1)^2-4\epsilon^2\right)^{\frac12}}{2} & \text{(eigenvector } (v,\epsilon^2+\|v\|^2-\lambda_2)\text{)},\\ \lambda_3 = \frac{\epsilon^2+\|v\|^2+1-\left((\epsilon^2+\|v\|^2+1)^2-4\epsilon^2\right)^{\frac12}}{2} & \text{(eigenvector } (v,\epsilon^2+\|v\|^2-\lambda_3)\text{)}. \end{cases}$$

Thus Q_v is positive definite and Lemma 2.1 states that, for

$$\alpha := \min_{x\in O'} \min_{v\in F_0(x)} \frac{\epsilon^2}{(\epsilon^2+\|v\|^2+1)^{\frac32}},$$

the map $(p_x,p_t) \to \left[(-p_t+\langle v,p_x\rangle)^2 + \epsilon^2\|p_x\|^2\right]^{\frac12} - \alpha\|(p_x,p_t)\|$ is convex. So $(p_x,p_t) \to H_\Psi(p_x,p_t) + \alpha\sqrt{2}\|(p_x,p_t)\|$ is concave, and Proposition 3.1 is proved since $\alpha > 0$. □

3.2. The regularity results. We now apply Theorems 1.3 and 2.1 in the case when M is the epigraph of θ_Ω.

THEOREM 3.1 (regularity of θ_Ω). *Let $F : \mathbb{R}^N \rightsquigarrow \mathbb{R}^N$ be a set-valued map satisfying* (1) *and* (12). *Then*

(i) *θ_Ω is Lipschitz continuous in a open subset $\mathcal{L}$ of $\mathbb{R}^N$ which is dense in* $\mathrm{dom}(\theta_\Omega)$. *Moreover, θ_Ω is also semiconcave in $\mathcal{L}$ with a modulus of semiconcavity of the form $\omega(t) = kt^{\frac32}$.*

(ii) *A point x belongs to* $\mathrm{dom}(\theta_\Omega)\backslash\mathcal{L}$ *if and only if*

$$\liminf_{x'\to x} \frac{\theta_\Omega(x') - \theta_\Omega(x)}{\|x'-x\|} = -\infty.$$

Remarks.

(1) We do not assume in Theorem 3.1 that the set Ω is smooth or that the hamiltonian is differentiable. In this situation, assumption (12) is crucial. For instance, for the dynamic $F(x,y) := [-1,1]\times[-1,1]$ (which clearly does not satisfy (12)), there are open sets Ω such that the optimal exit-time θ_Ω for F is not continuous in any open subset of Ω.

(2) Theorem 3.1 still holds partially true for constrained optimal exit-time problems (for the formulation of this problem, see [5]). Then $\mathcal{L}$ is an open dense subset of $\mathrm{dom}(\theta_\Omega) \cap \mathrm{Int}(K)$, where K is the constraint and θ_Ω is (locally) Lipschitz and semiconcave in $\mathcal{L}$.

(3) In the proof of Theorem 3.1, we never need the fact that the function we are studying is the optimal exit-time function. So our results are still valid in any case when the boundary of the epigraph of the lower semicontinuous function is semipermeable for a set-valued map Ψ satisfying (1) and (12).

Before beginning the proof of Theorem 3.1, let us recall some basic facts concerning the epigraph of a lower semicontinuous function.

LEMMA 3.1. *Let $\phi : \mathbb{R}^N \to \mathbb{R} \cup \{+\infty\}$ be a lower semicontinuous function. We set* $\mathrm{dom}(\phi) := \{x \mid \phi(x) < +\infty\}$ *and* $M := \mathrm{Epi}(\phi)$. *Let $x \in \mathrm{dom}(\phi)$.*

(α) If (v_x, v_t) belongs to $D_M(x, \phi(x))$, then v_x belongs to $D_{dom(\phi)}(x)$.

(β) If ϕ is not continuous at x, then there is some $t > 0$ such that $(x, \phi(x) + t)$ belongs to $\partial\mathrm{Epi}(\phi)$.

(γ) If x belongs to $\mathrm{dom}(\phi)$, *then, for any $t > 0$, the vector $(0, -1)$ belongs to $T_{Epi(\phi)}(x, \phi(x) + t)$.*

Proof of Theorem 3.1. Thanks to the construction of Proposition 3.1, $M := \mathrm{Epi}(\theta_\Omega)$ satisfies the conclusion of Theorems 1.3 and 2.1.

Set

$$A := \{x \in \mathrm{dom}(\theta_\Omega) \mid (0, -1) \in T_M(x, \theta_\Omega(x))\}$$

and $\mathcal{L} := \mathrm{dom}(\theta_\Omega) \backslash A$.

Let us show that A is closed in $\mathrm{dom}(\theta_\Omega)$ and has an empty interior, and that $\mathcal{L}$ is open. Then we prove that θ_Ω is locally Lipschitz on $\mathcal{L}$. Note that, from the very definition of the contingent cone, (b) is satisfied.

• *A is closed.* Let (x_n) be a sequence of A converging to $x \in \mathrm{dom}(\theta_\Omega)$. We have to prove that x belongs to A. There are two cases.

(1) Either

$$\liminf_n \theta_\Omega(x_n) = \theta_\Omega(x).$$

Then a subsequence $(x_{n'}, \theta_\Omega(x_{n'}))$ converges to $(x, \theta_\Omega(x))$ and so

$$\mathrm{Limsup}\, T_M(x_{n'}, \theta_\Omega(x_{n'})) \subset T_M(x, \theta_\Omega(x))$$

from Theorem 1.3. In particular, $(0, -1)$ belongs to $T_M(x, \theta_\Omega(x_n))$ and thus belongs to $T_M(x, \theta_\Omega(x))$. So x belongs to A.

(2) Or θ_Ω is not continuous at x. Then Lemma 3.1 (β) states that there is some $\tau > 0$ such that $(x, \tau + \theta_\Omega(x))$ belongs to ∂M. So, for any $t \in (0, \tau]$, the point $(x, \theta_\Omega(x) + t)$ belongs to the boundary of M and $(0, -1)$ belongs to $T_M(x, \theta_\Omega(x) + t)$ (Lemma 3.1 (γ)). Letting $t \to \theta_\Omega(x)$ means that $(0, -1)$ belongs to $T_M(x, \theta_\Omega(x))$.

So we have proved that, in both cases, x belongs to A. Thus A is closed in $\mathrm{dom}(\theta_\Omega)$.

• *A has an empty interior.* Assume to the contrary that $x + rB$ is contained in A. Then, if (y, ρ) belongs to $[(x + rB) \times \mathbb{R}] \cap M$, $(0, -1)$ belongs to $T_M(y, \rho)$ because either $\rho = \theta_\Omega(y)$ (and so it is true from the very definition of A) or $\rho > \theta_\Omega(y)$ (and then it is true from Lemma 3.1). So $[(x + r\overset{o}{B}) \times \mathbb{R}] \cap M$ is a locally compact viability domain for the map $(y, \rho) \to (0, -1)$. The viability theorem states that there is some $\tau > 0$ such that $(x, \theta_\Omega(x) - t)$ remains in M on $[0, \tau]$. This is impossible, because M is the epigraph of θ_Ω.

• *$\mathcal{L} := dom(\theta_\Omega) \backslash A$ is open.* Let x belong to $\mathrm{dom}(\theta_\Omega)$, but not to A. From Theorem 1.1, $T_M(x, \theta_\Omega(x))$ is a union of half-spaces, so that there is some $(p_x, p_t) \in \mathbb{R}^{N+1}$ such that $(p_x, p_t)^- \subset T_M(x, \theta_\Omega(x))$. Since $(0, -1)$ does not belong to $T_M(x, \theta_\Omega(x))$, $p_t < 0$. Moreover, Theorem 1.2 states that

$$\mathrm{Int}[(p_x, p_t)]^- \subset D_M(x, \theta_\Omega(x)).$$

Since, for any $v \in \mathbb{R}^N$, one can find some ρ such that $\langle p_x, v\rangle + p_t\rho < 0$ because $p_t \neq 0$, v belongs to $D_{dom(\theta_\Omega)}(x)$ from Lemma 3.1 (α). Thus $\mathbb{R}^N\backslash\{0\}$ is contained in $D_{dom(\theta_\Omega)}(x)$, which means that x belongs to the interior of $\mathrm{dom}(\theta_\Omega)$.

• *θ_Ω is locally Lipschitz on $\mathcal{L}$.* Let $x + rB$ be contained in $\mathcal{L}$. In a first step, we prove that θ_Ω is continuous on $x + rB$. Then we prove that there is some $\gamma > 0$ such that

$$\forall y \in x + rB,\ \forall v \in \mathbb{R}^N,\ \left(\{v\} \times \left[-\frac{\|v\|}{\gamma}, \frac{\|v\|}{\gamma}\right]\right) \cap T_{\partial M}(x, \phi(x)) \neq \emptyset. \tag{22}$$

We finally show that θ_Ω is $1/\gamma$-Lipschitz on $x + rB$.

First step. From Lemma 3.1, if θ_Ω is not continuous at a point $y \in \mathrm{dom}(\theta_\Omega)$, there is some $\tau > 0$ such that $(y, \theta_\Omega(y)+\tau)$ belongs to ∂M. From Lemma 3.1 again, $(0, -1)$ belongs then to $T_M(y, \theta_\Omega(y) + \tau)$. With the same arguments as we used previously, we can show that $(0, -1)$ belongs to $T_M(x, \theta_\Omega(x))$, which contradicts $y \in \mathcal{L}$. So θ_Ω is continuous on $x + rB$.

Second step. The graph of the restriction of θ_Ω to $x+rB$ is compact because θ_Ω is continuous on $x + rB$. From Theorem 1.3, the set-valued map $T_M(\cdot)$ on the compact $\mathrm{Graph}(\theta_\Omega)$ restricted to $x + rB$ has a closed graph. Let $\epsilon > 0$ be the distance from $(0, -1)$ to this closed graph. Set $\gamma := \epsilon/2$.

Let $y \in x + rB$ and $v \in \mathbb{R}^N$. Since

$$\left(v, -\frac{\|v\|}{\gamma}\right) \in \bigcup_{\lambda\geq 0} \lambda\left((0, -1) + \epsilon\, \overset{o}{B}_{N+1}\right),$$

$(v, -\frac{\|v\|}{\gamma})$ does not belong to $T_M(y, \theta_\Omega(y))$. From Theorem 1.1, $T_M(y, \theta_\Omega(y))$ is a union of half-spaces. Thus $(-v, \frac{\|v\|}{\gamma})$ belongs to $T_M(y, \phi(y))$. So we have obtained, $\forall w \in \mathbb{R}^N$,

$$\left(w, \frac{\|w\|}{\gamma}\right) \in T_M(y, \theta_\Omega(y)) \quad \text{and} \quad \left(w, -\frac{\|w\|}{\gamma}\right) \notin T_M(y, \theta_\Omega(y)).$$

Then the Quincampoix lemma [9] gives (22).

Third step. Thanks to (22), the set $\partial M \cap ((x+r\ \overset{o}{B}) \times \mathbb{R})$ is a locally viable domain for the constant set-valued map G_v defined by $y \rightsquigarrow \{v\} \times [-\|v\|\gamma^{-1}, \|v\|\gamma^{-1}]$ and for any $v \in \mathbb{R}^N$.

Let y and z belong to $x + rB$. For $v := z - y$, the viability theorem states that there is a solution $(y(\cdot), \rho(\cdot))$ of the differential inclusion for G_v starting from $(y, \theta_\Omega(y))$ which remains in ∂M until it leaves $(x + rB) \times \mathbb{R}$. For $t = 1$ the solution still satisfies $(y(1), \rho(1)) \in \partial M$. Thus $\rho(1)$ is equal to $\theta_\Omega(z)$. From the very definition of the set-valued map G_v, $|\rho(1) - \rho(0)| \leq \frac{\|z-y\|}{\gamma}$, i.e.,

$$|\theta_\Omega(z) - \theta_\Omega(y)| \leq \frac{\|z - y\|}{\gamma}.$$

So θ_Ω is Lipschitz. Thanks to Proposition 2.3, θ_Ω is semiconcave with a modulus of semiconcavity of the form $\omega(t) = kt^{\frac{3}{2}}$. This completes the proof of Theorem 3.1. □

3.3. Regularity along optimal trajectories. With any initial position $x \in \Omega$, one can associate at least one optimal solution $x(\cdot) \in \mathcal{S}_F(x)$ with the optimal exit-time problem, i.e., a solution such that

$$\theta_\Omega(x) = \inf\{t \geq 0 \mid x(t) \notin \Omega\}.$$

The aim of this section is to show that, for any optimal trajectory $x(\cdot)$, either the optimal exit-time θ_Ω is differentiable at $x(t)$ for any $t \in]0, \theta_\Omega(x(0))[$ or it is not differentiable at any point $x(t)$ for any $t \in]0, \theta_\Omega(x(0))[$. A similar phenomenon is observed in [6] for the Bolza problem, where any optimal solution enters immediately into the differentiability domain of the (Lipschitz continuous) value function.

Throughout this section, we assume that the set-valued map F satisfies (1) and (12).

LEMMA 3.2. *If a solution $x(\cdot) \in \mathcal{S}_F(x)$ is optimal for the optimal exit-time problem, then the map $(x(\cdot), \theta_\Omega(x(\cdot)))$ is a barrier solution for the set-valued map Ψ and the closed set* $\mathrm{Epi}(\theta_\Omega)$.

Proof. Note first that $\theta_\Omega(x(t)) = \theta_\Omega(x) - t$. Thus $(x(\cdot)), \theta_\Omega(x(\cdot)))$ is a solution for Φ and so for Ψ (because $\Phi(x,t) \subset \Psi(x,t)$ from Proposition 3.1). This solution remains on the boundary of $\mathrm{Epi}(\theta_\Omega)$ from the very definition of the epigraph of a function. Thus this solution is a barrier solution. ∎

PROPOSITION 3.2. *Let $x \in \Omega$ and $x(\cdot) \in \mathcal{S}_F(x)$ be an optimal solution of the optimal exit-time problem.*

If x belongs to $\mathcal{L}$, then $x(t)$ belongs to $\mathcal{L}$ for any $t \in]0, \theta_\Omega(x)[$.

If x does not belong to $\mathcal{L}$ and if the adjoint $(p_x(\cdot), p_t(\cdot))$ of the barrier solution $(x(\cdot), \theta_\Omega(x(\cdot)))$ satisfies $p_t(0) = 0$, then $x(t)$ does not belong to $\mathcal{L}$ for $t \in [0, \theta_\Omega(x)[$.

COROLLARY 3.1. *Let $x \in \Omega$ and $x(\cdot) \in \mathcal{S}_F(x)$ be an optimal solution of the optimal exit-time problem.*

- *If x belongs to $\mathcal{L}$, then θ_Ω is differentiable at $x(t)$ for $t \in]0, \theta_\Omega(x)[$.*
- *If θ_Ω is not differentiable at some point $x(t)$ with $t \in]0, \theta_\Omega(x)[$, then θ_Ω is not differentiable at any point $x(s)$ for $s \in [0, \theta_\Omega(x)[$. Moreover, $x(s)$ does not belong to $\mathcal{L}$ for $s \in]0, \theta_\Omega(x)[$.*

Proof of Corollary 3.1. We set $M := \mathrm{Epi}(\theta_\Omega)$. From Proposition 3.2, $x(t)$ belongs to $\mathcal{L}$ for $t \in [0, \theta_\Omega(x)[$. From Lemma 3.2, $(x(\cdot), \theta_\Omega(x(\cdot)))$ is a barrier solution. Thus Theorem 2.1 of Part I states that there is a function $(p_x(\cdot), p_t(\cdot))$ adjoint of $(x(\cdot), \theta_\Omega(x(\cdot)))$ on $]0, \theta_\Omega(x)[$. Moreover,

$$T_{Epi(\theta_\Omega)}(x(t), \theta_\Omega(x(t))) = (p_x(t), p_t(t))^-.$$

Since $x(t)$ belongs to $\mathcal{L}$ for $t \in [0, \theta_\Omega(x)[$, $p_t(t) \neq 0$ on $[0, \theta_\Omega(x)[$. In particular,

$$\nabla \theta_\Omega(x(t)) = -\frac{p_x(t)}{p_t(t)},$$

and θ_Ω is derivable on $[0, \theta_\Omega(x)[$.

For proving the second point, note first that $x(t) \notin \mathcal{L}$. Indeed, since $t > 0$, $T_M(x(t), \theta_\Omega(x(t)))$ is a half-space (Theorem 2.1 of Part I). Thus θ_Ω is derivable at $x(t)$ unless the half-space $T_M(x(t), \theta_\Omega(x(t)))$ is vertical, i.e., $x(t) \notin \mathcal{L}$.

If $0 \leq s < t$, then $x(s)$ does not belong to $\mathcal{L}$ from Proposition 3.2, and thus θ_Ω is not derivable at $x(s)$. If we denote by $(p_x(\cdot), p_t(\cdot))$ the adjoint of $(x(\cdot), \theta_\Omega(x(\cdot)))$, Theorem 2.1 of Part I states that

$$\forall s \in]0, \theta_\Omega(x)[,\ T_M(x(s), \theta_\Omega(x(s))) = (p_x(\cdot), p_t(\cdot))^-.$$

Since $x(t) \notin \mathcal{L}$, $p_t(t) = 0$. Thus Proposition 3.2 states that $x(s) \notin \mathcal{L}$ for $s \in [t, \theta_\Omega(x)[$. This completes the proof of the corollary. ∎

Proof of Proposition 3.2.

- Let us assume that $x(t)$ does not belong to $\mathcal{L}$ for some $t \in]0, \theta_\Omega(x)[$. Thus $(0, -1)$ belongs to $T_M(x(t), \theta_\Omega(x(t)))$ and there are sequences $h_n \to 0^+$, $v_n \to 0$, and

$\tau_n \to -1$ such that, for any n, $(x(t)+h_nv_n, \theta_\Omega(x(t))+h_n\tau_n)$ belongs to M, i.e.,

$$\theta_\Omega(x(t)+h_nv_n) \le \theta_\Omega(x(t))+h_n\tau_n.$$

From Filippov's theorem applied to $-F$, there is a sequence of solutions $y_n(\cdot) \in \mathcal{S}_{-F}(x+h_nv_n)$, such that

$$\forall s \in [0,t],\ \|y_n(s)-x(t-s)\|_{[0,t]} \le e^{\ell t}h_n\|v_n\|.$$

Since $y_n(\cdot)$ are solutions to the differential inclusion for $-F$, $(y_n(\cdot), \theta_\Omega(x(t))+h_n\tau_n+\cdot)$ is a solution for $-\Phi$ and so for $-\Psi$ starting from M and remaining in M from semipermeability of M. Let us recall that $\theta_\Omega(x(t)) = \theta_\Omega(x)-t$. Thus

$$(y_n(t), \theta_\Omega(x)+h_n\tau_n) \in M.$$

Since $\|y_n(t)-x\| \le h_n\|v_n\|$ from the very definition of $y_n(\cdot)$, we have finally proved that $(0,-1)$ belongs to $T_M(x,\theta_\Omega(x))$.

• Let us now assume that x does not belong to $\mathcal{L}$, that $x(\cdot)$ is an optimal solution starting from x, and that the adjoint $(p_x(\cdot),p_t(\cdot))$ of $(x(\cdot),\theta_\Omega(x(\cdot)))$ satisfies $p_t(0)=0$.

In a first step, we show that, if $0<s<t<\theta_\Omega(x)$ and if (v,τ) belongs to $T_{\widehat{M}}(x(s),\theta_\Omega(x(s)))$, then there is some w with $(w,\tau) \in T_{\widehat{M}}(x(t),\theta_\Omega(x(t)))$ and $\|w-v\| \le e^{\ell t}\|v\|$.

Since (v,τ) belongs to $T_{\widehat{M}}(x(s),\theta_\Omega(x(s)))$, there are sequences $h_n \to 0^+$, $v_n \to v$, and $\tau_n \to \tau$ such that $(x(s)+h_nv_n, \theta_\Omega(x(s))+h_n\tau_n)$ belongs to $\widehat{M}$. From Filippov's theorem, there are solutions $x_n(\cdot)$ of the differential inclusion for F starting from $x(s)+h_nv_n$ at time s such that

$$\|x_n(\cdot)-x(\cdot)\|_{[s,t]} \le e^{\ell t}h_n\|v_n\|.$$

Then $\frac{x_n(t)-x(t)}{h_n}$ converges, up to a subsequence, to some w with $\|w-v\| \le e^{\ell t}\|v\|$. Moreover, the solutions $(x_n(\cdot), \theta_\Omega(x(s))+h_n\tau_n-\cdot)$ start from $\widehat{M}$, so that, for semipermeability, $(x_n(t), \theta_\Omega(x(t))+h_n\tau_n)$ belongs to $\widehat{M}$. So (w,τ) belongs to $T_{\widehat{M}}(x(t), \theta_\Omega(x(t)))$ with $\|w-v\| \le e^{\ell t}\|v\|$, and our claim is proved.

Let us now prove that, for any $t \in]0,\theta_\Omega(x)[$, $p_t(t)=0$. Recall that, from Theorem 2.1 of Part I, the adjoint $(p_x(\cdot),p_t(\cdot))$ is Lipschitz. In particular, $p_t(s) \to 0$ when $s \to 0^+$. Fix $t \in]0,\theta_\Omega(x)[$ and let $0<s<t$. Let (v_s,τ_s) be the projection of $(0,1)$ onto $T_{\widehat{M}}(x(s),\theta_\Omega(x(s))) = (p_x(s),p_t(s))^+$. Note that (v_s,τ_s) converges to $(0,1)$ when $s \to 0^+$ since $(p_x(s),p_t(s)) \to (p_x(0),0)$. We previously proved that there is some w_s such that (w_s,τ_s) belongs to $T_{\widehat{M}}(x(t),\theta_\Omega(x(t)))$ and $\|w_s-v_s\| \le e^{\ell t}\|v_s\|$. Since $v_s \to 0$, $w_s \to 0$ when $s \to 0^+$. The contingent cone $T_{\widehat{M}}(x(t),\theta_\Omega(x(t)))$ is closed, so that $(0,1)$, which is the limit of (w_s,τ_s), belongs to $T_{\widehat{M}}(x(t),\theta_\Omega(x(t)))$. Thus we have proved that, for any $t \in]0,\theta_\Omega(x)[$, $(0,1)$ belongs to $T_{\widehat{M}}(x(t),\theta_\Omega(x(t)))$, which is equal to $(p_x(t),p_t(t))^+$; thus $p_t(t) \ge 0$. Since M is an epigraph, $p_t(t)$ is nonpositive, and so $p_t=0$ for any $t \in]0,\theta_\Omega(x)[$.

To complete the proof, let us recall that $T_M(x(t),\theta_\Omega(x(t)))$ is equal to $(p_x(t),p_t(t))^-$ for any $t \in]0,\theta_\Omega(x)[$. Since $p_t(t)=0$, the vector $(0,-1)$ belongs to $T_M(x(t),\theta_\Omega(x(t)))$, which means that $x(t)$ does not belong to $\mathcal{L}$ for any $t \in]0,\theta_\Omega(x)]$. □

MIXED OBJECTIVE CONTROL SYNTHESIS: OPTIMAL $\ell_1/\mathcal{H}_2$ CONTROL*

MURTI V. SALAPAKA†, MOHAMMED DAHLEH†, AND PETROS VOULGARIS‡

Abstract. In this paper we consider the problem of minimizing the ℓ_1 norm of the transfer function from the exogenous input to the regulated output over all internally stabilizing controllers while keeping its $\mathcal{H}_2$ norm under a specified level. The problem is analyzed for the discrete-time, single-input single-output (SISO), linear-time invariant case. It is shown that an optimal solution always exists. Duality theory is employed to show that any optimal solution is a finite impulse response sequence, and an a priori bound is given on its length. Thus, the problem can be reduced to a finite-dimensional convex optimization problem with an a priori determined dimension. Finally, it is shown that, in the region of interest of the $\mathcal{H}_2$ constraint level, the optimal is unique and continuous with respect to changes in the constraint level.

1. Notation.

The following notation is employed in this paper:

$\text{int}(X)$	The interior of a set X.
$\|x\|_1$	The 1-norm of the vector $x \in R^n$.
$\|x\|_2$	The 2-norm of the vector $x \in R^n$.
$\hat{x}(\lambda)$	The λ transform of a right-sided real sequence $x = (x(k))_{k=0}^{\infty}$ defined as $\hat{x}(\lambda) := \sum_{k=0}^{\infty} x(k)\lambda^k$.
ℓ_1	The Banach space of right-sided absolutely summable real sequences with the norm given by $\| x \|_1 := \sum_{k=0}^{\infty} \|x(k)\|$.
ℓ_∞	The Banach space of right-sided, bounded sequences with the norm given by $\| x \|_\infty := \sup_k \|x(k)\|$.
c_0	The subspace of ℓ_∞ with elements x that satisfy $\lim_{k\to\infty} x(k) = 0$.
ℓ_2	The Banach space of right-sided square summable sequences with the norm given by $\| x \|_2 := \left[\sum_{k=0}^{\infty} x(k)^2\right]^{\frac{1}{2}}$.
$\mathcal{H}_2$	The isometric isomorphic space of l_2 under the λ transform $\hat{x}(\lambda)$ with the norm given by $\| \hat{x}(\lambda) \|_2 = \| x \|_2$.
X^*	The dual space of the Banach space X. $\langle x, x^* \rangle$ denotes the value of the bounded linear functional x^* at $x \in X$.
$W(X^*, X)$	The weak star topology on X^* induced by X. In this topology, $x_n^* \to x^*$ if and only if $\langle x, x_n^* \rangle \to \langle x, x^* \rangle$ for all $x \in X$.
T^*	The adjoint operator of $T : X \to Y$ which maps Y^* to X^*.

The following identities also hold (see, e.g., [7]): $(\ell_1)^* = \ell_\infty,\ (c_0)^* = \ell_1,\ (\ell_2)^* = \ell_2$.

2. Introduction.

Consider the finite-dimensional linear time invariant system depicted in Figure 2.1, where P denotes the plant and K denotes the controller. The

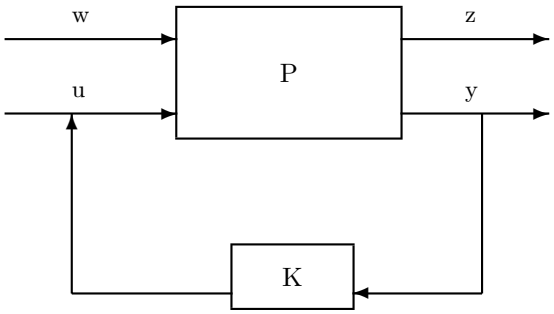

FIG. 2.1. *Plant controller configuration.*

signal w is the exogenous input and z is the regulated output. The signals u and y denote the control input and the measured output, respectively. Let T_{zw} be the closed-loop transfer function which maps w to z.

Many important control problems can be reduced to the above setup, where the objective is to minimize a suitably defined measure of T_{zw}. In the standard ℓ_1 problem the design of an internally stabilizing controller such that the ℓ_∞ norm of the regulated output z due to the worst-case magnitude bounded disturbance w is addressed. It is shown in [3] that this problem reduces to solving finite-dimensional linear programs. The analogous problem, with the signal measures being the ℓ_2 norm, is the standard $\mathcal{H}_\infty$ problem. The standard $\mathcal{H}_2$ problem is concerned with the minimization of the energy contained in the pulse response of the closed loop, T_{zw}. This can be viewed as minimizing the variance of the regulated output z due to a white noise input w. Both problems are discussed in [4].

It is well known (see, e.g., [2]) that optimization with respect to a particular norm may not necessarily yield good performance with respect to another. Thus, if enhanced performance is required with respect to multiple measures, then it is necessary to include all these measures directly into the design process. As a logical step, the design of controllers to satisfy mixed performance criteria has recently been the focus of researchers. Several state-space results on the interplay between the $\mathcal{H}_2$ and $\mathcal{H}_\infty$ are available (see, e.g., [5]). In [1] it is shown that a wide variety of mixed control problems reduce to convex optimization problems, and it is argued that the present technology makes it possible to deem the problem solved if it can be reduced to a convex optimization problem. In this light it is appropriate to exploit as much structure in the problem as possible, so that the standard software available becomes computationally efficient. In [6] the problem of minimizing the ℓ_1 norm of the closed loop under linear inequality constraints is addressed. Every such problem is equivalent to a linear programming problem which has a canonical dual problem associated with it. Contrary to the finite-dimensional case, it is not true that every infinite-dimensional linear program has the same optimal value as its dual. However, it was shown by the authors that under some conditions this "duality gap" does not exist between the primal and the dual, which is advantageous from a computational point of view. The problem of minimizing the ℓ_1 norm of the closed loop while keeping the $\mathcal{H}_\infty$ norm under a prescribed level falls under the above category. In [8] the problem of minimizing the ℓ_1 norm of a single-input single-output (SISO) transfer function while keeping the $\mathcal{H}_\infty$ norm of the closed-loop system under a specified value is reduced to solving a sequence of finite-dimensional convex optimization problems and an unconstrained $\mathcal{H}_\infty$ problem. In [9] it is shown that the $\mathcal{H}_2/\ell_1$ problem, the

problem of minimizing the $\mathcal{H}_2$ norm of the closed loop while maintaining the ℓ_1 norm below a prescribed value, reduces to a finite-dimensional convex optimization problem. However, no a priori bound on its dimension is furnished, which substantially degrades the efficiency of the solution procedure since it may require a large number of iterations.

In this paper, the $\ell_1/\mathcal{H}_2$ problem, which is the problem of minimizing the ℓ_1 norm of T_{zw} while keeping the $\mathcal{H}_2$ norm below a prescribed level, is considered. This problem not only complements the one studied in [9], but it also turns out that much stronger results can be obtained which make this problem considerably more attractive to solve. In particular, it is shown that the problem reduces to a convex finite-dimensional one, and an a priori bound on its dimension is established. The latter feature is important in reducing the computational burden. Furthermore, the developments in this paper are substantially different than those in [9] and are more far reaching.

The paper is organized as follows. In section 3 relevant duality theory results are given. In section 4 the problem statement is made precise. In section 5 it is shown that an optimal solution always exists, and that it is a finite impulse response sequence. An a priori bound is given on its length. In section 6 the region of interest of the constraint level on the $\mathcal{H}_2$ norm is determined. It is shown that in this region the optimal is unique and is continuous with respect to changes in the constraint level. In section 7 an example is given to demonstrate the theory developed.

3. Mathematical preliminaries. In this section we present a Lagrange duality theorem that applies to the minimization of a convex functional subject to both equality and inequality constraints. A sensitivity result which follows directly from the Lagrange duality theorem is presented. We employ the terminology used in [7], which is standard. First, we need the following definitions.

DEFINITION 3.1. *Let P be a convex positive cone in a vector space X. We write $x \geq y$ if $x-y \in P$. We write $x > 0$ if $x \in \text{int}(P)$. Similarly, $x \leq y$ if $x-y \in -P := N$ and $x < 0$ if $x \in \text{int}(N)$. Given a vector space X with positive cone P the positive cone in X^*, $P^{\oplus}$ is defined as*

$$P^{\oplus} := \{x^* \in X^* : \langle x, x^* \rangle \geq 0 \text{ for all } x \in P\}.$$

DEFINITION 3.2. *Let X be a vector space and Z be a vector space with positive cone P. A mapping $G : X \to Z$ is convex if $G(tx+(1-t)y) \leq tG(x)+(1-t)G(y)$ for all x, y in X and t with $0 \leq t \leq 1$ and is strictly convex if $G(tx+(1-t)y) < tG(x)+(1-t)G(y)$ for all $x \neq y$ in X and t with $0 < t < 1$.*

The following is a Lagrange duality theorem.

THEOREM 3.3. *Let X be a Banach space, Ω be a convex subset of X, Y be a finite-dimensional normed space, and Z be a normed space with positive cone P. Let Z^* denote the dual space of Z with a positive cone $P^{\oplus}$. Let $f : \Omega \to R$ be a real valued convex functional, $g : X \to Z$ be a convex mapping, $H : X \to Y$ be an affine linear map, and $0 \in \text{int}[\text{range(H)}]$. Define*

$$\mu_0 := \inf\{f(x) : \ g(x) \leq 0, \ H(x) = 0, \ x \in \Omega\}. \tag{3.1}$$

Suppose that there exists $x_1 \in \Omega$ such that $g(x_1) < 0$ and $H(x_1) = 0$, and suppose that μ_0 is finite. Then

$$\mu_0 = \max\{\varphi(z^*, y) : z^* \geq 0, \ z^* \in Z^*, \ y \in Y\}, \tag{3.2}$$

where $\varphi(z^*,\ y) := \inf\{f(x) + \langle g(x), z^*\rangle + \langle H(x), y\rangle : x \in \Omega\ \}$, *and the maximum is achieved for some* $z_0^* \geq 0,\ z_0^* \in Z^*,\ y_0 \in Y$.

Furthermore, if the infimum in (3.1) *is achieved by some* $x_0 \in \Omega$, *then*

$$\langle g(x_0), z_0^*\rangle + \langle H(x_0), y_0\rangle = 0, \tag{3.3}$$

and

$$x_0 \text{ minimizes } f(x) + \langle g(x), z_0^*\rangle + \langle H(x), y_0\rangle \text{ over all } x \in \Omega. \tag{3.4}$$

Proof. Given any $z^* \geq 0,\ y \in Y$, we have $\inf\{f(x)+\langle g(x), z^*\rangle+\langle H(x), y\rangle : x \in \Omega\}$ $\leq \inf\{f(x) + \langle g(x), z^*\rangle + \langle H(x), y\rangle : x \in \Omega,\ g(x) \leq 0,\ H(x) = 0\} \leq \inf\{f(x) : x \in \Omega,\ g(x) \leq 0,\ H(x) = 0\} = \mu_0$. Therefore, it follows that $\max\{\varphi(z^*, y) : z^* \geq 0,\ y \in Y\} \leq \mu_0$. From Problem 7 of [7, Chap. 8] (see Lemma 9.1 in the Appendix for problem statement and proof), we know that there exists $z_0^* \in Z^*, z_0^* \geq 0,\ y_0 \in Y$ such that $\mu_0 = \varphi(z_0^*,\ y_0)$. This proves (3.2).

Suppose there exists $x_0 \in \Omega, H(x_0) = 0,\ g(x_0) \leq 0$, and $\mu_0 = f(x_0)$; then $\mu_0 = \varphi(z_0^*,\ y_0) \leq f(x_0) + \langle g(x_0), z_0^*\rangle + \langle H(x_0), y_0\rangle \leq f(x_0) = \mu_0$. Therefore, we have $\langle g(x_0), z_0^*\rangle + \langle H(x_0), y_0\rangle = 0$ and $\mu_0 = f(x_0) + \langle g(x_0), z_0^*\rangle + \langle H(x_0), y_0\rangle$. This proves the theorem. ∎

We refer to (3.1) as the *primal* problem and (3.2) as the *dual* problem.

COROLLARY 3.4. *Let* X, Y, Z, f, H, g, Ω *be as in Theorem* 3.3. *Let* x_0 *be the solution to the problem*

$$\begin{gathered} \text{minimize } f(x) \\ \text{subject to } x \in \Omega,\ H(x) = 0,\ g(x) \leq z_0, \end{gathered}$$

with (z_0^*, y_0) *as the dual solution. Let* x_1 *be the solution to the problem*

$$\begin{gathered} \text{minimize } f(x) \\ \text{subject to } x \in \Omega,\ H(x) = 0,\ g(x) \leq z_1, \end{gathered}$$

with (z_1^*, y_1) *as the dual solution. Then*

$$\langle z_1 - z_0, z_1^*\rangle\ \leq f(x_0) - f(x_1)\ \leq \langle z_1 - z_0, z_0^*\rangle. \tag{3.5}$$

Proof. From Theorem 3.3 we know that for any $x \in \Omega$,

$$\begin{aligned} &f(x_0) + \langle g(x_0) - z_0, z_0^*\rangle + \langle H(x_0), y_0\rangle \\ &\leq\ f(x) + \langle g(x) - z_0, z_0^*\rangle + \langle H(x), y_0\rangle. \end{aligned}$$

In particular, we have

$$\begin{aligned} &f(x_0) + \langle g(x_0) - z_0, z_0^*\rangle + \langle H(x_0), y_0\rangle \\ &\leq\ f(x_1) + \langle g(x_1) - z_0, z_0^*\rangle + \langle H(x_1), y_0\rangle. \end{aligned}$$

From Theorem 3.3 we know that $\langle g(x_0) - z_0, z_0^*\rangle + \langle H(x_0), y_0\rangle = 0$ and $H(x_1) = 0$. This implies

$$f(x_0) - f(x_1)\ \leq \langle g(x_1) - z_0, z_0^*\rangle\ \leq \langle z_1 - z_0, z_0^*\rangle.$$

A similar argument gives the other inequality. This proves the corollary. ∎

4. Problem formulation. Consider the standard feedback problem represented in Figure 2.1, where P and K are the plant and the controller, respectively. Let w represent the exogenous input, z represent the output of interest, y be the measured output, and u be the control input where z and w are assumed scalar. Let ϕ be the closed-loop map which maps $w \to z$. From the Youla parametrization (see, e.g., [2]) it is known that all achievable closed-loop maps under stabilizing controllers are given by $\phi = h - u * q$ ($*$ denotes convolution), where $h, u, q \in \ell_1$, h, u depend only on the plant P, and q is a free parameter in ℓ_1. Throughout the paper we make the following assumption.

ASSUMPTION 1. All the zeros of $\hat{u}$ (the λ transform of u) inside the unit disc are real and distinct. Also, $\hat{u}$ has no zeros on the unit circle.

The assumption that all zeros of $\hat{u}$ which are inside the open unit disc are real and distinct is not restrictive and is made to streamline the presentation of the paper. Let the zeros of u which are inside the unit disc be given by $z_1, z_2, \ldots, z_n$. Let

$$\Theta := \{\phi : \text{ there exists } q \in \ell_1 \text{ with } \phi = h - u * q\}.$$

Θ is the set of all achievable closed-loop maps under stabilizing controllers. Let $A : \ell_1 \to R^n$ be given by

$$A = \begin{pmatrix} 1 & z_1 & z_1^2 & z_1^3 & \ldots \\ 1 & z_2 & z_2^2 & z_2^3 & \ldots \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ 1 & z_n & z_n^2 & z_n^3 & \ldots \end{pmatrix},$$

and $b \in R^n$ be given by

$$b = \begin{pmatrix} \hat{h}(z_1) \\ \hat{h}(z_2) \\ \vdots \\ \hat{h}(z_n) \end{pmatrix}.$$

THEOREM 4.1. *The following is true:*

$$\begin{aligned} \Theta &= \{\phi \in \ell_1 : \hat{\phi}(z_i) = \hat{h}(z_i) \text{ for all } i = 1, \ldots, n\} \\ &= \{\phi \in \ell_1 : A\phi = b\}. \end{aligned}$$

Proof. The proof is given in [2, pp. 104–105]. ∎

The problem

$$\begin{aligned} \nu_\infty &:= \inf\{\| h - u * q \|_1 : q \in \ell_1\} \\ &= \inf\{\| \phi \|_1 : \phi \in \ell_1 \text{ and } A\phi = b\} \end{aligned} \tag{4.1}$$

is the standard ℓ_1 problem. In [3] it is shown that this problem has a solution which is possibly nonunique. Optimal solutions are shown to be finite impulse response sequences. Let

$$\begin{aligned} \mu_\infty &:= \inf\{\| h - u * q \|_2{}^2 : q \in \ell_1\}, \\ &= \inf\{\| \phi \|_2{}^2 : \phi \in \ell_1 \text{ and } A\phi = b\}, \end{aligned} \tag{4.2}$$

which is the standard $\mathcal{H}_2$ problem. The solution to this problem is unique, and the solution is an infinite impulse response sequence. Define

$$m_1 := \inf_{A\phi=b, \|\phi\|^2 \le \mu_\infty} \| \phi \|_1, \tag{4.3}$$

which is the ℓ_1 norm of the unique optimal solution of the standard $\mathcal{H}_2$ problem. Let

$$m_2 := \inf_{A\phi=b, \|\phi\| \le \nu_\infty} \| \phi \|_2{}^2, \tag{4.4}$$

which is the infimum over the ℓ_2 norms of the optimal solutions of the standard ℓ_1 problem.

The problem of interest is as follows: *given a positive constant $\gamma > \mu_\infty$ obtain a solution to the following mixed objective problem:*

$$\begin{aligned} \nu_\gamma &:= \inf\{\| h - u * q \|_1 : q \in \ell_1 \text{ and} \langle h - u * q, h - u * q \rangle \le \gamma\} \\ &= \inf\{\| \phi \|_1 : \phi \in \ell_1 \ , A\phi = b \text{ and } \langle \phi, \phi \rangle \le \gamma\}. \end{aligned} \tag{4.5}$$

Note that $\langle ., . \rangle$ is the inner product associated with ℓ_2. In the following sections we will study this problem from the point of view of existence, structure, continuity, and computation of the optimal solutions.

5. Analysis of optimal solutions and their properties. In the first part of this section we show that (4.5) always has a solution. In the second part we show that any solution to (4.5) is of finite length, and in the third, we give an a priori bound on the length.

5.1. Existence of a solution. Here we show that a solution to (4.5) always exists. We use the following lemma (see, e.g., [7]) to prove the main result of this subsection.

LEMMA 5.1 (Banach–Alaoglu). *Let X be a Banach space with X^* as its dual. Then the set $\{x^* : x^* \in X^*, \| x^* \| \le M\}$ is $W(X^*, X)$ compact for any $M \in R$.*

THEOREM 5.2. *There exists $\phi_0 \in \Phi$ such that*

$$\| \phi_0 \|_1 = \inf_{\phi \in \Phi} \{\| \phi \|_1\},$$

where Φ:=$\{\phi \in \ell_1 : A\phi = b$ and$\langle \phi, \phi \rangle \le \gamma\}$ with $\gamma > \mu_\infty$. Therefore, the infimum in (4.5) *is a minimum.*

Proof. We denote the feasible set of our problem by Φ:=$\{\phi \in \ell_1 : A\phi = b$ and$\langle \phi, \phi \rangle \le \gamma\}$. $\nu_\gamma < \infty$ because $\gamma > \mu_\infty$, and therefore the feasible set is not empty. Let $B := \{\phi \in \ell_1 : \| \phi \|_1 \le \nu_\gamma + 1\}$. It is clear that

$$\nu_\gamma = \inf_{\phi \in \Phi \cap B} \{\| \phi \|_1\}.$$

Therefore, given $i > 0$, there exists $\phi_i \in \Phi \cap B$ such that $\| \phi_i \|_1 \le \nu_\gamma + \frac{1}{i}$. B is a bounded set in $\ell_1 = c_0^*$. It follows from the Banach–Alaoglu lemma that B is $W(c_0^*, c_0)$ compact. Using the fact that c_0 is separable, we know that there exists a subsequence $\{\phi_{i_k}\}$ of $\{\phi_i\}$ and $\phi_0 \in \Phi \cap B$ such that $\phi_{i_k} \to \phi_0$ in the $W(c_0^*, c_0)$ sense; that is, for all v in c_0,

$$\langle v, \phi_{i_k} \rangle \to \langle v, \phi_0 \rangle \text{ as } k \to \infty. \tag{5.1}$$

Let the jth row of A be denoted by a_j and the jth element of b be given by b_j. Then, as $a_j \in c_0$ we have

$$\langle a_j, \phi_{i_k} \rangle \to \langle a_j, \phi_0 \rangle \text{ as } k \to \infty \text{ for all } j = 1, 2, \ldots, n. \tag{5.2}$$

As $A(\phi_{i_k}) = b$ we have $\langle a_j, \phi_{i_k} \rangle = b_j$ for all k and for all j which implies $\langle a_j, \phi_0 \rangle = b_j$ for all j. Therefore, we have $A(\phi_0) = b$. As $l_2 \subset c_0$ we have from (5.1) that for all v in l_2,

$$\langle v, \phi_{i_k} \rangle \to \langle v, \phi_0 \rangle \text{ as } k \to \infty, \tag{5.3}$$

which shows that $\phi_{i_k} \to \phi_0$ in $W(l_2^*, l_2)$. Also, from the construction of ϕ_{i_k}, we know that $\| \phi_{i_k} \|_2 \leq \sqrt{\gamma}$. From Lemma 5.1 we conclude that $\langle \phi_0, \phi_0 \rangle \leq \gamma$, and therefore we have shown that $\phi_0 \in \Phi$. Recall that ϕ_{i_k} were chosen so that $\| \phi_{i_k} \|_1 \leq \nu_\gamma + \frac{1}{i_k}$. From Lemma 5.1 we have that $\| \phi_0 \|_1 \leq \nu_\gamma + \frac{1}{i_k}$ for all k. Therefore $\| \phi_0 \|_1 \leq \nu_\gamma$. As $\phi_0 \in \Phi$ (which is the feasible set) we have $\| \phi_0 \|_1 = \nu_\gamma$. This proves the theorem. ∎

5.2. Structure of optimal solutions. In this subsection we use Lagrange duality results to show that every optimal solution is of finite length. The following two lemmas establish the dual problem.

LEMMA 5.3.

$$\nu_\gamma = \max\{\varphi(y_1, y_2) : y_1 \geq 0 \text{ and } y_2 \in R^n\}, \tag{5.4}$$

where

$$\varphi(y_1, y_2) := \inf_{\phi \in \ell_1} \{\| \phi \|_1 + y_1(\langle \phi, \phi \rangle - \gamma) + \langle b - A\phi, y_2 \rangle\}.$$

Proof. We will apply Theorem 3.3 to get the result. Let X, Ω, Y, Z in Theorem 3.3 correspond to ℓ_1, ℓ_1, R^n, and R, respectively. Let $g(\phi) := \langle \phi, \phi \rangle - \gamma$, $H(\phi) := b - A\phi$. With this notation, we have $Z^* = R$.

A has full range, which implies $0 \in \text{int}[\text{range}(H)]$. $\gamma > \mu_\infty$, and therefore there exists ϕ_1 such that $\langle \phi_1, \phi_1 \rangle - \gamma < 0$ and $H(\phi_1) = 0$. Therefore, all the conditions of Theorem 3.3 are satisfied. From Theorem 3.3 we have

$$\nu_\gamma = \max_{y_1 \geq 0, y_2 \in R^n} \inf_{\phi \in \ell_1} \{\| \phi \|_1 + y_1(\langle \phi, \phi \rangle - \gamma) + \langle b - A\phi, y_2 \rangle\}.$$

This proves the lemma. ∎

The right-hand side of (5.4) is the *dual problem.*

LEMMA 5.4. *The dual problem is given by*

$$\max\{\varphi(y_1, y_2) : y_1 \geq 0 \text{ and } y_2 \in R^n\}, \tag{5.5}$$

where

$$\varphi(y_1, y_2) := \inf_{\phi \in \ell_1, \phi(i)v(i) \geq 0} \{\| \phi \|_1 + y_1(\langle \phi, \phi \rangle - \gamma) + \langle b, y_2 \rangle - \langle \phi, v \rangle\}.$$

$v(i)$ *is defined by* $v(i) := A^* y_2(i)$.

Proof. Let $y_1 \geq 0,\ y_2 \in R^n$. It is clear that

$$\begin{aligned} &\inf_{\phi \in \ell_1} \{\| \phi \|_1 + y_1(\langle \phi, \phi \rangle - \gamma) + \langle b - A\phi, y_2 \rangle\} \\ &= \inf_{\phi \in \ell_1} \{\| \phi \|_1 + y_1(\langle \phi, \phi \rangle - \gamma) + \langle b, y_2 \rangle - \langle \phi, v \rangle\}. \end{aligned}$$

Suppose $\phi \in \ell_1$ and there exists i such that $\phi(i)v(i) < 0$; then define $\phi^1 \in \ell_1$ such that $\phi^1(j) = \phi(j)$ for all $j \neq i$ and $\phi^1(i) = 0$. Therefore, we have $\| \phi \|_1 + y_1(\langle \phi, \phi \rangle - \gamma) + \langle b, y_2 \rangle - \langle \phi, v \rangle \geq \| \phi^1 \|_1 + y_1(\langle \phi^1, \phi^1 \rangle - \gamma) + \langle b, y_2 \rangle - \langle \phi^1, v \rangle$. This shows that we can restrict ϕ in the infimization to satisfy $\phi(i)v(i) \geq 0$. This proves the lemma. ∎

The following theorem is the main result of this subsection. It shows that any solution of (4.5) is a finite impulse response sequence.

THEOREM 5.5. *Define* $\mathcal{T}$:=$\{\phi \in \ell_1 : \text{there exists } L^* \text{ with } \phi(i) = 0 \text{ if } i \geq L^*\}$. *The dual of the problem is given by*

$$\max\{\varphi(y_1, y_2) : y_1 \geq 0, y_2 \in R^n\}, \tag{5.6}$$

where

$$\varphi(y_1, y_2) := \inf_{\phi \in \mathcal{T}, \phi(i)v(i) \geq 0} \{\| \phi \|_1 + y_1(\langle \phi, \phi \rangle - \gamma) + \langle b, y_2 \rangle - \langle \phi, v \rangle\}.$$

$v(i)$ *defined by* $v(i) = A^* y_2(i)$. *Also, any optimal solution* ϕ_0 *of* (4.5) *belongs to* $\mathcal{T}$.

Proof. Let $y_1^\gamma \geq 0,\ y_2^\gamma \in R^n$ be the solution to

$$\max_{y_1 \geq 0, y_2 \in R^n} \inf_{\phi \in \ell_1, \phi(i)v(i) \geq 0} \{\| \phi \|_1 + y_1(\langle \phi, \phi \rangle - \gamma) + \langle b - A\phi, y_2 \rangle\}.$$

It is easy to show that there exists L^* such that $v^\gamma(i) := (A^* y_2^\gamma)(i)$ satisfies $|v^\gamma(i)| < 1$ if $i \geq L^*$. If $\phi(i)v^\gamma(i) \geq 0$ for all i, then,

$$\begin{aligned}
&\| \phi \|_1 + y_1^\gamma(\langle \phi, \phi \rangle - \gamma) + \langle b, y_2^\gamma \rangle - \langle \phi, v^\gamma \rangle \\
&= \sum_{i=0}^{\infty} \{|\phi(i)| + y_1^\gamma(\phi(i))^2 - \phi(i)v^\gamma(i)\} - y_1^\gamma \gamma + \langle y_2^\gamma, b \rangle \\
&= \sum_{i=0}^{\infty} \{\phi(i)(\operatorname{sgn}(v^\gamma(i)) - v^\gamma(i)) + y_1^\gamma(\phi(i))^2\} - y_1^\gamma \gamma + \langle y_2^\gamma, b \rangle \\
&= \sum_{i=0}^{L^*} \{\phi(i)(\operatorname{sgn}(v^\gamma(i)) - v^\gamma(i)) + y_1^\gamma(\phi(i))^2\} \\
&\quad + \sum_{i=L^*+1}^{\infty} \{\phi(i)(\operatorname{sgn}(v^\gamma(i)) - v^\gamma(i)) + y_1^\gamma(\phi(i))^2\} - y_1^\gamma \gamma + \langle y_2^\gamma, b \rangle.
\end{aligned}$$

Suppose $|v^\gamma(i)| < 1$. Then we have

$$\phi(i)(\operatorname{sgn}(v^\gamma(i)) - v^\gamma(i)) + y_1^\gamma(\phi(i))^2 \geq 0$$

and equal to zero only if $\phi(i) = 0$. Therefore, in the infimization, we can restrict $\phi(i) = 0$ whenever $|v^\gamma(i)| < 1$. As $|v^\gamma(i)| < 1$ for all $i \geq L^*$ it follows that we can restrict ϕ to $\mathcal{T}$ in the infimization. In Theorem 5.2 we showed that there exists a solution ϕ_0 to the primal. From Theorem 3.3 we have that ϕ_0 minimizes

$$\| \phi \|_1 + y_1^\gamma(\langle \phi, \phi \rangle - \gamma) + \langle b, y_2^\gamma \rangle - \langle \phi, v^\gamma \rangle,$$

over all ϕ in ℓ_1. From the previous discussion it follows that $\phi_0 \in \mathcal{T}$. This proves the theorem. ∎

5.3. An a priori bound on the length of any optimal solution. In this subsection we give an a priori bound on the length of any solution to (4.5). First we establish the following three lemmas.

LEMMA 5.6. *Let* $\gamma > \mu_\infty$, $m_1 := \inf_{A\phi=b, \langle\phi,\phi\rangle\leq\mu_\infty} \| \phi \|_1$, *and* $\nu_\gamma := \inf_{A\phi=b, \langle\phi,\phi\rangle\leq\gamma} \| \phi \|_1$. *Let* y_1^γ, y_2^γ *represent a dual solution as obtained in* (5.5). *Then* $y_1^\gamma \leq M_\gamma$ *where* $M_\gamma := \frac{m_1}{\gamma-\mu_\infty}$.

Proof. Let $\gamma > \gamma_1 > \mu_\infty$ and $\nu_{\gamma_1} := \inf_{A\phi=b, <\phi,\phi>\leq\gamma_1} \| \phi \|_1$. Let y_1^γ, y_2^γ represent a dual solution as obtained in (5.5). From Corollary 3.4 we have

$$\langle \gamma - \gamma_1, y_1^\gamma \rangle \leq \nu_{\gamma_1} - \nu_\gamma \leq \nu_{\gamma_1} \leq m_1,$$

which implies that $y_1^\gamma \leq \frac{m_1}{\gamma-\gamma_1}$. This holds for all $\gamma > \gamma_1 > \mu_\infty$. Therefore, $M_\gamma := \frac{m_1}{\gamma-\mu_\infty}$ is an a priori bound on y_1^γ. This proves the lemma. ∎

LEMMA 5.7. *Let* ϕ_0 *be a solution of the primal* (4.5). *Let* y_1^γ, y_2^γ *represent the corresponding dual solution as obtained in* (5.5). *Let* $v^\gamma := A^* y_2^\gamma$, *then*

$$\begin{aligned} y_1^\gamma \phi_0(i) &= \frac{v^\gamma(i) - 1}{2} \; if \; v^\gamma(i) > 1 \\ &= \frac{v^\gamma(i) + 1}{2} \; if \; v^\gamma(i) < -1 \\ &= \quad 0 \qquad if \; |v^\gamma(i)| \leq 1. \end{aligned}$$

Also, $\| v^\gamma \|_\infty \leq \alpha_\gamma$ *where* $\alpha_\gamma = \frac{2m_1\sqrt{\gamma}}{\gamma-\mu_\infty} + 1$.

Proof. Let

$$L(\phi) := \sum_{i=0}^{\infty} \{\phi(i)(\mathrm{sgn}(v^\gamma(i)) - v^\gamma(i)) + y_1^\gamma(\phi(i))^2\} - \gamma y_1^\gamma + \langle b, y_2^\gamma \rangle.$$

Suppose $|v^\gamma(i)| = 1$. Now, if $y_1^\gamma = 0$, then it is clear that $y_1^\gamma \phi_0(i) = 0$. If $y_1^\gamma > 0$, then as ϕ_0 minimizes $L(\phi)$ we have $\phi_0(i) = 0$. We have already shown that if $|v^\gamma(i)| < 1$, then $\phi_0(i) = 0$. Therefore, $y_1^\gamma \phi_0(i) = 0$ if $|v^\gamma(i)| \leq 1$.

Suppose $v^\gamma(i) > 1$. Then it is easy to show that there exists $\phi(i)$ such that $\phi(i) \geq 0$ and $\phi(i)(\mathrm{sgn}(v^\gamma(i)) - v^\gamma(i)) + y_1^\gamma(\phi(i))^2 < 0$. As any optimal minimizes $L(\phi)$, we know that $\phi_0(i)(\mathrm{sgn}(v^\gamma(i)) - v^\gamma(i)) + y_1^\gamma(\phi_0(i))^2 < 0$, which implies $\phi_0(i) > 0$ and therefore $1 - v^\gamma(i) + 2y_1^\gamma\phi_0(i) = 0$. This implies that $y_1^\gamma\phi_0(i) = \frac{v^\gamma(i)-1}{2}$. Similarly, the result follows when $v^\gamma(i) < -1$. Therefore, $\| v^\gamma \|_\infty \leq 2M_\gamma \| \phi_0 \|_\infty + 1 \leq \frac{2m_1}{\gamma-\mu_\infty} \| \phi_0 \|_\infty + 1 \leq \frac{2m_1\sqrt{\gamma}}{\gamma-\mu_\infty} + 1$. The last inequality follows from the fact that $\langle \phi_0, \phi_0 \rangle \leq \gamma$. This implies that $\alpha_\gamma := \frac{2m_1\sqrt{\gamma}}{\gamma-\mu_\infty} + 1$ is an a priori upper bound on $\| v^\gamma \|_\infty$. This proves the lemma. ∎

LEMMA 5.8 (see [2]). *If* $y_2 \in R^n$ *is such that* $\| A^* y_2 \|_\infty \leq \alpha_\gamma$, *then there exists a positive integer* L^* *independent of* y_2 *such that* $|(A^* y_2)(i)| < 1$ *for all* $i \geq L^*$.

Proof. Define

$$A_L^* = \begin{pmatrix} 1 & 1 & 1 & \dots & 1 \\ z_1 & z_2 & z_3 & \dots & z_n \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ z_1^L & z_2^L & z_3^L & \dots & z_n^L \end{pmatrix},$$

$A_L^* : R^n \to R^{L+1}$. With this definition we have $A_\infty^* = A^*$. Let $y_2 \in R^n$ be such that $\| A^* y_2 \|_\infty \leq \alpha_\gamma$. Choose any L such that $L \geq (n-1)$. As $z_i, i = 1, \ldots, n$, are distinct, A_L^* has full column rank. A_L^* can be regarded as a linear map taking $(R^n, \| \, . \, \|_1) \to (R^{L+1}, \| \, . \, \|_\infty)$. As A_L^* has full column rank, we can define the left inverse of A_L^*, $(A_L^*)^{-l}$, which takes $(R^{L+1}, \| \, . \, \|_\infty) \to (R^n, \| \, . \, \|_1)$. Let the induced norm of $(A_L^*)^{-l}$ be given by $\| \, (A_L^*)^{-l} \, \|_{\infty,1}$. $y_2 \in R^n$ is such that $\| A^* y_2 \|_\infty \leq \alpha_\gamma$, and therefore $\| A_L^* y_2 \|_\infty \leq \alpha_\gamma$. It follows that

$$\| y_2 \|_1 \leq \| \, (A_L^*)^{-l} \, \|_{\infty,1} \, \| A_L^* y_2 \|_\infty \leq \| \, (A_L^*)^{-l} \, \|_{\infty,1} \, \alpha_\gamma. \tag{5.7}$$

Choose L^* such that

$$\max_{k=1,\ldots,n} |z_k|^{L^*} \ \| \, (A_L^*)^{-l} \, \|_{\infty,1} \, \alpha_\gamma < 1. \tag{5.8}$$

There always exists such an L^* because $|z_k| < 1$ for all $k = 1, \ldots, n$. Note that L^* does not depend on y_2. For any $i \geq L^*$ we have

$$\begin{aligned} |(A^* y_2)(i)| = \left| \sum_{k=1}^{k=n} z_k^i y_2(k) \right| &\leq \max_{k=1,\ldots,n} |z_k|^i \| \, y_2 \, \|_1 \\ &\leq \max_{k=1,\ldots,n} |z_k|^i \ \| \, (A_L^*)^{-l} \, \|_{\infty,1} \, \alpha_\gamma \\ &\leq \max_{k=1,\ldots,n} |z_k|^{L^*} \ \| \, (A_L^*)^{-l} \, \|_{\infty,1} \, \alpha_\gamma. \end{aligned}$$

The second inequality follows from (5.7). From (5.8) we have $|(A^* y_2)(i)| < 1$ if $i \geq L^*$. This proves the lemma. □

The following theorem is the main result of the section.

THEOREM 5.9. *Every solution ϕ_0 of the primal* (4.5) *is such that $\phi(i) = 0$ if $i \geq L^*$, where L^* given in Lemma* 5.8 *can be determined a priori. Furthermore, the upper bound on lengths of the optimal solutions is nonincreasing as a function of γ.*

Proof. Using Lemma 5.7 we can bound on $\| \, v^\gamma \, \|_\infty$ by α_γ. Applying Lemma 5.8, we conclude that there exists L_γ^* (which can be determined a priori) such that $|v^\gamma(i)| < 1$ if $i \geq L_\gamma^*$. Using the fact that $\phi_0(i) = 0$ if $|v^\gamma(i)| < 1$, we conclude that $\phi_0 = 0$ if $i \geq L_\gamma^*$. L_γ^*; was chosen to satisfy

$$\max_{k=1,\ldots,n} |z_k|^{L^*} \ \| \, (A_L^*)^{-l} \, \|_{\infty,1} \, \alpha_\gamma < 1.$$

α_γ is nonincreasing as a function of γ. Therefore L_γ^* is nonincreasing as a function of γ. This proves the theorem. □

Note that as $\alpha_\gamma = \frac{2m_1\sqrt{\gamma}}{\gamma - \mu_\infty} + 1$, we have that the upper bound on lengths of the solutions increases to infinity as γ decreases to μ_∞. This is commensurate with the fact that the optimal solution for the standard $\mathcal{H}_2$ problem (4.2) is an infinite impulse response sequence.

The above theorem shows that the problem at hand is a finite-dimensional convex problem of a priori determined dimension. In particular, in view of Theorem 5.9 the problem that needs to be solved is as follows:

$$\nu_\gamma = \min_{A_{L^*}\phi = b, \langle \phi, \phi \rangle \leq \gamma} \sum_{k=0}^{L^*} |\phi(k)|, \tag{5.9}$$

where

$$A_{L^*} = \begin{pmatrix} 1 & z_1 & z_1^2 & \dots & z_1^{L^*} \\ 1 & z_2 & z_2^2 & \dots & z_2^{L^*} \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ 1 & z_n & z_n^2 & \dots & z_n^{L^*} \end{pmatrix},$$

and L^* is given in Lemma 5.8. An alternative representation can be given, as the following lemma suggests.

LEMMA 5.10. *The primal is given by*

$$\begin{aligned} & \textit{minimize} \sum_{k=0}^{L^*} \phi^+(k) + \phi^-(k) \\ \textit{subject to} \quad & A_{L^*}(\phi^+ - \phi^-) = b \\ & \langle \phi^+ - \phi^-, \phi^+ - \phi^- \rangle \le \gamma \\ & \phi^+, \phi^- \textit{ in } R^{L^*} \textit{ with } \phi^+, \phi^- \ge 0. \end{aligned} \tag{5.10}$$

Proof. Note that in the above theorem the ordering is componentwise for the inequalities. We will show that (5.9) is equivalent to (5.10). Let p_0 denote the value attained by the objective functional in (5.10). Suppose ϕ^+, ϕ^- satisfy the constraints of (5.10). Let $\phi := \phi^+ - \phi^-$. Then it is clear that ϕ satisfies the constraints of (5.9). Also, for each k, $|\phi(k)| = |\phi^+ - \phi^-| \le |\phi^+| + |\phi^-| = \phi^+(k) + \phi^-(k)$. This implies that $\nu_\gamma \le p_0$.

Suppose that ϕ satisfies the constraints of (5.9). Define ϕ^+ such that $\phi^+(k) = \phi(k)$ if $\phi(k) \ge 0$, and 0 otherwise. Similarly, define ϕ^- such that $\phi^-(k) = -\phi(k)$ if $\phi(k) \le 0$, and 0 otherwise. It is clear that $\phi = \phi^+ - \phi^-$ and that ϕ^+, ϕ^- satisfy the constraints of (5.10). Also, $|\phi(k)| = \phi^+(k) + \phi^-(k)$. This proves that $\nu_\gamma \ge p_0$. Therefore, $\nu_\gamma = p_0$. It is easy to show that if ϕ_0^+, ϕ_0^- is optimal for (5.10) then $\phi_0 := \phi_0^+ - \phi_0^-$ is optimal for (5.9). This proves the lemma. ∎

This type of convex problem can be solved efficiently using standard methods [1].

6. Uniqueness and continuity of the optimal solution. In this section we address the issue of uniqueness and continuity of solutions to the primal problem with respect to changes in the constraint level on the $\mathcal{H}_2$ norm of the closed-loop map. In the first part we address the issue of uniqueness, and in the second part, we show that the optimal solution is continuous in the region where it is unique.

6.1. Uniqueness of the optimal solution. The following three lemmas are established before the main result of this subsection.

LEMMA 6.1. *Let $y_1^\gamma \ge 0$, $y_2^\gamma \in R^n$ be a solution to* (5.5). *If $y_1^\gamma = 0$, then $\nu_\gamma = \nu_\infty$. This implies that* (4.5) *reduces to solving a standard ℓ_1 problem.*

Proof. Let $v := A^* y_2$ and ϕ^1 be such that $A\phi^1 = b$. If $y_1^\gamma = 0$, then the dual (5.5) is given by

$$\begin{aligned} & \max_{y_2 \in R^n} \inf_{\phi(i)v(i) \ge 0} \{ \| \phi \|_1 + \langle b - A\phi, y_2 \rangle \} \\ = & \max_{y_2 \in R^n} \inf_{\phi(i)v(i) \ge 0} \sum_{i=0}^{\infty} \{ \phi(i)(\operatorname{sgn}(v(i)) - v(i)) \} + \langle \phi^1, v \rangle \\ = & \max_{v \in Range(A^*)} \inf_{\phi(i)v(i) \ge 0} \sum_{i=0}^{\infty} \{ \phi(i)(\operatorname{sgn}(v(i)) - v(i)) \} + \langle \phi^1, v \rangle. \end{aligned}$$

Suppose $\| v \|_\infty > 1$; then there exists j such that $|v(j)| > 1$. Thus we can choose $\phi(j)$ with $\phi(j)v(j) \geq 0$ such that $\phi(j)(\text{sgn}(v(j)) - v(j)) < M$ for any M. This implies that

$$\inf_{\phi(i)v(i)\geq 0} \sum_{i=0}^{\infty} \{\phi(i)(\text{sgn}(v(i)) - v(i))\} + \langle \phi^1, v\rangle = -\infty.$$

Therefore, we can restrict v in the maximization to satisfy $\| v \|_\infty \leq 1$. From arguments similar to that of the proof of Theorem 5.9, $\phi(i) = 0$ whenever $|v(i)| < 1$. Therefore, the infimum term is zero whenever $\| v \|_\infty \leq 1$. This implies that the dual problem reduces to

$$\max_{v\in Range(A^*), \|v\|_\infty \leq 1} \langle \phi^1, v\rangle,$$

which is the same as the dual of the standard ℓ_1 problem as given in (4.1) [2]. This proves the lemma. □

LEMMA 6.2. *Let Ω be a convex subset of a Banach space X and $f : \Omega \to R$ be strictly convex. If f achieves its minimum on Ω then the minimizer is unique.*

Proof. Let $m := \min_{x\in\Omega} f(x)$. Let $x_1, x_2 \in \Omega$ be such that $f(x_1) = f(x_2) = m$. Let $0 < \lambda < 1$. From convexity of Ω we have $\lambda x_1 + (1-\lambda)x_2 \in \Omega$. From strict convexity of f we have that if $x_1 \neq x_2$ then $f(\lambda x_1 + (1-\lambda)x_2) < \lambda f(x_1) + (1-\lambda)f(x_2) = m$, which is a contradiction. Therefore $x_1 = x_2$. This proves the lemma. □

LEMMA 6.3. *Let $y_1^\gamma \geq 0$, $y_2^\gamma \in R^n$ be a solution in* (5.5). *If $y_1^\gamma > 0$ then the solution ϕ_0 of* (4.5) *is unique.*

Proof. Let $L(\phi) := \| \phi \|_1 + y_1^\gamma(\langle \phi, \phi\rangle - \gamma) + \langle b - A\phi, y_2^\gamma\rangle$. From Theorem 3.3 we know that ϕ_0 minimizes $L(\phi)$, $\phi \in \ell_1$. If $y_1^\gamma > 0$ then it is easy to show that $L(\phi)$ is strictly convex in ℓ_1. From the previous lemma it follows that ϕ_0 is unique. This proves the lemma. □

The main result of this subsection is now presented.

THEOREM 6.4. *Define $S := \{\phi : A\phi = b$ and $\| \phi \|_1 = \nu_\infty\}$, $m_2 := \inf_{\phi\in S}\langle \phi, \phi\rangle$. The following is true.*

(1) *If $\gamma \geq m_2$, then problem* (4.5) *is equivalent to the standard ℓ_1 problem whose solution is possibly nonunique.*

(2) *If $\mu_\infty < \gamma < m_2$, then the solution to* (4.5) *is unique.*

Proof. Suppose $m_2 < \gamma$. Then there exists $\phi_1 \in \ell_1$ such that $A\phi_1 = b$, $\| \phi_1 \|_1 = \nu_\infty$, and $\langle \phi_1, \phi_1\rangle \leq \gamma$. This implies that $\nu_\gamma = \inf_{A\phi=b, \langle\phi,\phi\rangle\leq\gamma} \| \phi \|_1 \leq \nu_\infty$. The other inequality is obvious. This proves (1).

Let $\mu_\infty < \gamma < m_2$ and suppose $y_1^\gamma = 0$; then we have shown in Lemma 6.1 that $\nu_\gamma = \nu_\infty$. Therefore, there exists $\phi_1 \in \ell_1$ such that $\| \phi_1 \|_1 = \nu_\infty$, $A\phi_1 = b$, and $\langle \phi_1, \phi_1\rangle \leq \gamma < m_2$. This implies that $\phi_1 \in S$ and $\langle \phi_1, \phi_1\rangle < m_2$, which is a contradiction. Therefore $y_1^\gamma > 0$. From Lemma 6.3 we know that ϕ_0 is unique. This proves (2). □

The above theorem shows that in the region where the constraint level on the $\mathcal{H}_2$ is essentially of interest (i.e., active) the optimal solution is unique.

6.2. Continuity of the optimal solution. Following is a theorem which shows that the ℓ_1 norm of the optimal solution is continuous with respect to changes in the constraint level γ.

THEOREM 6.5. *Let $\nu_\gamma := \inf_{A\phi=b, \langle\phi,\phi\rangle\leq\gamma} \| \phi \|_1$. Then ν_γ is a continuous function of γ on (μ_∞, ∞).*

Proof. If $\gamma \in (\mu_\infty, \infty)$, then it is obvious that $\gamma \in \text{int}\{\text{dom}(\nu_\gamma)\}$, where $\text{dom}(\nu_\gamma) := \{\gamma : -\infty < \nu_\gamma < \infty\}$ is the domain of ν_γ. From Proposition 1 of [7, §8.3] we know that ν_γ is a convex function of γ. The theorem follows from the fact that every convex function is continuous in the interior of its domain. ∎

Now we prove that the optimal solution is continuous with respect to changes in the constraint level in the region where the optimal is unique.

THEOREM 6.6. *Let $\mu_\infty < \gamma < m_2$. Let ϕ_γ represent the solution of $\nu_\gamma = \min_{A\phi=b, \langle\phi,\phi\rangle \le \gamma} \| \phi \|_1$. Then $\phi_{\gamma_k} \to \phi_\gamma$ in the norm topology if $\gamma_k \to \gamma$.*

Proof. Let $m_1 := \min_{A\phi=b, \langle\phi,\phi\rangle \le \mu_\infty} \| \phi \|_1$. Then it is obvious that $\| \phi_\gamma \|_1 = \nu_\gamma \le m_1$. Without loss of generality, assume that $\gamma_k \ge \gamma/2$. Let L^* represent the upper bound on the length of $\phi_{\frac{\gamma}{2}}$. Then, as the upper bound is nonincreasing (see Theorem 5.9) we can assume that $\phi_{\gamma_k} \in R^{L^*}$. Let $B := \{x : x \in R^{L^*} : \| x \|_1 \le m_1\}$; then we have $\phi_{\gamma_k} \in B$. Therefore, there exists a subsequence ϕ_{k_i} of ϕ_{γ_k} and ϕ_1 such that

$$\phi_{k_i} \to \phi_1 \text{ as } i \to \infty \text{ in } (R^{L^*}, \| \, . \, \|_1). \tag{6.1}$$

It is clear, as in the proof of Theorem 5.2, that $A\phi_1 = b$ as $A\phi_{k_i} = b$ for all i. Also,

$$\| \phi_1 \|_2{}^2 \le \| \phi_1 - \phi_{k_i} \|_2{}^2 + \| \phi_{k_i} \|_2{}^2 \le \| \phi_1 - \phi_{k_i} \|_2{}^2 + \gamma_{k_i}.$$

Taking limits on both sides as $i \to \infty$ we get $\langle \phi_1, \phi_1 \rangle \le \gamma$. This implies that ϕ_1 is a feasible element in the problem of ν_γ. From Theorem 6.5 we have $\| \phi_{k_i} \|_1 \to \nu_\gamma$. From (6.1) we have $\| \phi_1 \|_1 = \nu_\gamma$. From uniqueness of the optimal solution we have $\phi_1 = \phi_\gamma$. From uniqueness of the optimal solution, it also follows that $\phi_{\gamma_k} \to \phi_\gamma$. This proves the theorem. ∎

7. An example. In this section we illustrate the theory developed in the previous sections with an example. Consider the SISO plant,

$$\hat{P}(\lambda) = \lambda - \frac{1}{2}, \tag{7.1}$$

where we are interested in the sensitivity map $\phi := (I - PK)^{-1}$. Using Youla parametrization, we get that all achievable transfer functions are given by $\hat{\phi} = (I - \hat{P}\hat{K})^{-1} = 1 - (\lambda - \frac{1}{2})\hat{q}$ where $\hat{q}$ is a stable map. The matrices A and b are given by

$$A = \left(1, \frac{1}{2}, \frac{1}{2^2}, \dots\right), \quad b = 1.$$

It is easy to check that for this problem

$$\mu_\infty := \inf\{\| \phi \|_2{}^2 : \phi \in \ell_1 \text{ and } A\phi = b\} = 0.75$$

and

$$m_1 := \inf_{A\phi=b, \|\phi\|_2{}^2 \le \mu_\infty} \| \phi \|_1 = 1.5,$$

with the optimal solution ϕ_2 given by

$$\hat{\phi}_2(\lambda) = \sum_{t=0}^{\infty} \frac{0.75}{2^t} \lambda^t.$$

Performing a standard ℓ_1 optimization [2] we obtain

$$\nu_\infty := \inf\{\| \phi \|_1 : \phi \in \ell_1 \text{ and } A\phi = b\} = 1$$

and

$$m_2 := \inf_{A\phi=b, \|\phi\|_1 \le \nu_\infty} \| \phi \|_2{}^2 = 1,$$

with the optimal solution $\phi_1 = 1$. We choose the constraint level to be 0.95. Therefore, $\alpha_\gamma = \frac{2m_1\sqrt{\gamma}}{\gamma - \mu_\infty} + 1 = 15.62$. For this example $n = 1$ and $z_1 = \frac{1}{2}$. L^*, the a priori bound on the length of the optimal, is chosen to satisfy

$$\max_{k=1,\ldots,n} |z_k|^{L^*} \ \| (A_L^*)^{-l} \|_{\infty,1} \ \alpha_\gamma < 1, \tag{7.2}$$

where L is any positive integer such that $L \ge (n-1)$. We choose $L = 0$, and therefore $A_L = 1$ and $\| (A_L^*)^{-l} \|_{\infty,1} = 1$. We choose $L^* = 4$, which satisfies (7.2). Therefore, the optimal solution ϕ_0 satisfies $\phi_0(i) = 0$ if $i \ge 4$. The problem reduces to the following finite-dimensional convex optimization problem:

$$\nu_\gamma = \min_{A_{L^*}\phi=1, \|\phi\|_2{}^2 \le 0.95} \left\{ \sum_{k=0}^{3} |\phi(k)| : \phi \in R^4 \right\},$$

where $A_{L^*} = (1, \frac{1}{2}, \frac{1}{2^2}, \frac{1}{2^3})$. We obtain (using Matlab Optimization Toolbox) the optimal solution ϕ_0 to be

$$\hat{\phi}_0(\lambda) = 0.9732 + 0.0535\lambda.$$

Therefore, we have $\| \phi_0 \|_1 = 1.02670$ and $\| \phi_0 \|_2{}^2 \cong 0.95$. The same computation was carried out for various values of the constraint level, $\gamma \in [0.75,\ 1]$. The tradeoff curve between the ℓ_1 and the $\mathcal{H}_2$ norms of the optimal solution is given in Figure 7.1. For all values of γ in the chosen range, the square of the $\mathcal{H}_2$ norm of the optimal closed loop was equal to the constraint level γ. Although, when the constraint level γ equals 0.75, the optimal closed-loop map is an infinite impulse response sequence, the optimal closed-loop map has very few nonzero terms in its impulse response even for values of γ very close to 0.75. For example, with $\gamma = 0.755$ the optimal closed-loop map is given by

$$\hat{\phi}_{0.755} = 0.7708 + 0.3632\lambda + 0.1596\lambda^2 + 0.0578\lambda^3 + 0.0065\lambda^4.$$

As a final remark, we can use the structure of this example to illustrate that the optimal unconstrained $\mathcal{H}_2$ solution can have $\mathcal{H}_2$ norm much smaller than the $\mathcal{H}_2$ norm of the optimal ℓ_1 (unconstrained) solution. Hence, minimizing only the ℓ_1 norm, which is an upper bound on the $\mathcal{H}_2$ norm, may require substantial sacrifices in terms of $\mathcal{H}_2$ performance. Indeed, instead of the P used in the example before, consider the plant $\hat{P}_a(\lambda) = \lambda - a$, where now a is a zero in the unit disk (i.e., $|a| < 1$) and very close to the unit circle (i.e., $|a| \cong 1$). Then the optimal unconstrained $\mathcal{H}_2$ norm given by

$$(b_a(A_aA_a^*)^{-1}b_a)^{1/2} = (1 - |a|^2)^{1/2},$$

where $A_a = (1, a, a^2, \ldots)$, $b_a = 1$ [2], is close to 0. On the other hand, for the optimal ℓ_1 unconstrained solution $\phi_{a,1}$, we have $\phi_{a,1} = 1$, which has $\mathcal{H}_2$ norm equal to 1. Therefore, minimizing only with respect to ℓ_1 may lead to undesirable $\mathcal{H}_2$ performance.

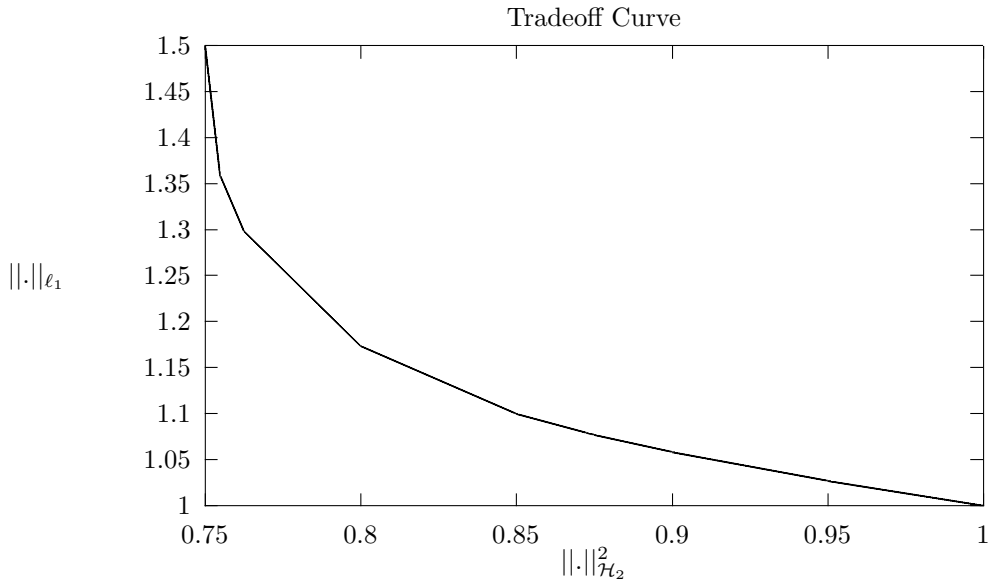

FIG. 7.1. *Here the ℓ_1 and the $\mathcal{H}_2$ norms of the optimal closed loop for various values of γ are plotted. The x axis can be read as the square of $\mathcal{H}_2$ norm or the value of γ.*

8. Conclusions. In this paper the mixed problem of $\ell_1/\mathcal{H}_2$ for the SISO discrete-time case is solved. The problem was reduced to a finite-dimensional convex optimization problem with an a priori determined dimension. The region of the constraint level in which the optimal is unique was determined, and it was shown that in this region the optimal solution is continuous with respect to changes in the constraint level of the $\mathcal{H}_2$ norm. A Lagrange duality theorem and a sensitivity result were used. The techniques used in obtaining the results of this paper are general enough to be adapted to analyze other mixed objective problems. Also, several of the results seem to have natural extensions for the multiple-input, multiple-output case, but a full investigation of this case is beyond the scope of this paper.

9. Appendix. Here we give the lemma needed in the proof of Theorem 3.3.

LEMMA 9.1. *Let X be a Banach space, Ω be a convex subset of X, Y be a finite-dimensional normed space, and Z be a normed space with positive cone P. Let Z^* denote the dual space of Z with a positive cone $P^{\oplus}$. Let $f : \Omega \to R$ be a real valued convex functional, $g : X \to Z$ be a convex mapping, $H : X \to Y$ be an affine linear map, and $0 \in \text{int}[\{y \in Y : \ H(x) = y \text{ for some } x \in \Omega\}]$. Define*

$$\mu_0 := \inf\{f(x) : \ g(x) \leq 0, \ H(x) = 0, \ x \in \Omega\}. \tag{9.1}$$

Suppose there exists $x_1 \in \Omega$ such that $g(x_1) < 0$ and $H(x_1) = 0$ and suppose μ_0 is finite. Then, there exist $z_0^* \geq 0$ and y_0^* such that

$$\mu_0 = \inf\{f(x) + \langle g(x), z_0^* \rangle + \langle H(x), y_0^* \rangle : x \in \Omega\}. \tag{9.2}$$

Proof. Let

$$\Omega_1 := \{x : \ x \in \Omega, \ H(x) = 0\}.$$

Applying Theorem 8.3.1 of [7, p. 217] to Ω_1 we know that there exists $z_0^* \in P^{\oplus}$ such that

$$\mu_0 = \inf\{f(x) + \langle g(x), z_0^* \rangle : x \in \Omega_1\}. \tag{9.3}$$

Consider the convex subset

$$H(\Omega) := \{y \in Y : \ y = H(x) \text{ for some } x \in \Omega\}$$

of Y. For $y \in H(\Omega)$, define

$$k(y) := \inf\{f(x) + \langle g(x), z_0^* \rangle : \ x \in \Omega, \ H(x) = y\}.$$

We now show that k is convex. Suppose $y, y' \in H(\Omega)$ and x, x' are such that $H(x) = y$ and $H(x') = y'$. Suppose $0 < \lambda < 1$. We have

$$\begin{aligned} \lambda(f(x) + \langle g(x), z_0^* \rangle) + (1-\lambda)(f(x') + \langle g(x'), z_0^* \rangle) \quad &\geq \quad f(\lambda x + (1-\lambda)x') \\ &\quad +\langle g(\lambda x + (1-\lambda)x'), z_0^* \rangle \\ &\geq \quad k(\lambda y + (1-\lambda)y'). \end{aligned}$$

(The first inequality follows from the convexity of f and g. The second inequality is true because $H(\lambda x + (1-\lambda)x') = (\lambda y + (1-\lambda)y')$. Taking the infimum on the left-hand side, we obtain $\lambda k(y) + (1-\lambda)k(y') \geq k(\lambda y + (1-\lambda)y')$. This proves that k is a convex function.

We now show that $k : H(\Omega) \to R$ (i.e., we show that $k(y) > -\infty$ for all $y \in H(\Omega)$). As $0 \in \text{int}[H(\Omega)]$, we know that there exists an $\epsilon > 0$ such that if $||y|| \leq \epsilon$, then $y \in H(\Omega)$. Take any $y \in H(\Omega)$ such that $y \neq 0$. Choose λ, y' such that

$$\lambda = \frac{\epsilon}{2||y||} \text{ and } y' = -\lambda y.$$

This implies that $y' \in H(\Omega)$. Let $\beta = \dfrac{\lambda}{\lambda + 1}$. We have

$$(1-\beta)y' + \beta y = 0.$$

Therefore, from convexity of the function k, we have

$$\beta k(y) + (1-\beta)k(y') \geq k(0) = \mu_0.$$

But $\mu_0 > -\infty$ by assumption. Therefore, $k(y) > -\infty$. Note that for all $y \in H(\Omega)$, $k(y) < \infty$. This proves that k is a well-defined function.

Let $[k, H(\Omega)]$ be defined as given below:

$$[k, H(\Omega)] := \{(r, y) \in R \times Y : y \in H(\Omega), \ k(y) \leq r\}.$$

We first show that $[k, H(\Omega)]$ has a nonempty interior. As k is a well-defined convex function on the finite-dimensional convex set $H[\Omega]$ and $0 \in \text{int}[H(\Omega)]$, we have from Corollary 7.9.1 of [7, p. 194] that k is continuous at 0. Let $r_0 = k(0) + 2$ and choose ϵ' such that $0 < \epsilon' < 1$. As k is continuous at 0 we know that there exists $\delta > 0$ such that $y \in H(\Omega)$, and $||y|| \leq \delta$ implies that

$$|k(y) - k(0)| < \epsilon'.$$

This means that if $y \in H(\Omega)$ and $||y|| \leq \delta$, then

$$k(y) < k(0) + \epsilon' < k(0) + 1 < r_0 - \frac{1}{2}.$$

Therefore, for all $y \in H(\Omega)$ with $||y|| \leq \delta$, we have $k(y) < r_0 - \frac{1}{2}$. This implies that for all $(r, y) \in R \times Y$ such that $|r - r_0| < \frac{1}{4}, y \in H(\Omega)$, and $||y|| \leq \delta$, we have $k(y) < r$. This proves that $(r_0, 0) \in \text{int}([k, H(\Omega)])$.

It is clear that $(k(0), 0) \in R \times Y$ is not in the interior of $[k, H(\Omega)]$. Using Theorem 5.12.2 of [7, p. 133] we know that there exists $(s, y^*) \neq (0, 0) \in R \times Y^*$ such that for all $(r, y) \in [k, H(\Omega)]$ the following is true:

$$\langle y, y^* \rangle + rs \geq \langle 0, y^* \rangle + k(0)s = s\mu_0. \tag{9.4}$$

In particular, $rs \geq s\mu_0$ for all $r \geq \mu_0$ (note that $(r, 0) \in [k, H(\Omega)]$ for all $r \geq \mu_0$). This means that $s \geq 0$.

Suppose $s = 0$. We have from (9.4) that $\langle y, y^* \rangle \geq 0$ for all $y \in H(\Omega)$. As $0 \in \text{int}[H(\Omega)]$, it follows that there exists an $\epsilon \in R$ such that $||y|| \leq \epsilon$ implies that $\langle y, y^* \rangle \geq 0$ and $\langle -y, y^* \rangle \geq 0$. This implies that if $||y|| \leq \epsilon$, then $\langle y, y^* \rangle = 0$. But then, for any $y \in Y$, one can choose a positive constant α such that $||\alpha y|| \leq \epsilon$, and therefore $\langle \alpha y, y^* \rangle = 0$. This implies that $(s, y^*) = (0, 0)$, which is not possible. Therefore, we conclude that $s > 0$.

Let $y_0^* = y^*/s$. From (9.4) we have

$$\langle y, y_0^* \rangle + r \geq \mu_0 \quad \text{for all } (r, y) \in [k, H(\Omega)]. \tag{9.5}$$

This implies that for all $y \in H(\Omega)$,

$$\langle y, y_0^* \rangle + k(y) \geq \mu_0. \tag{9.6}$$

(This is because $(k(y), y) \in [k, H(\Omega)]$.) Therefore, for all $x \in \Omega$,

$$\langle H(x), y_0^* \rangle + f(x) + \langle g(x), z_0^* \rangle \geq \mu_0, \tag{9.7}$$

which implies that

$$\inf\{f(x) + \langle g(x), z_0^* \rangle + \langle H(x), y_0^* \rangle : \ x \in \Omega\} \geq \mu_0. \tag{9.8}$$

But if $x \in \Omega$ is such that $H(x) = 0$, then

$$f(x) + \langle g(x), z_0^* \rangle = f(x) + \langle g(x), z_0^* \rangle + \langle H(x), y_0^* \rangle \tag{9.9}$$

$$\geq \inf\{f(x) + \langle g(x), z_0^* \rangle + \langle H(x), y_0^* \rangle : \ x \in \Omega\} \geq \mu_0. \tag{9.10}$$

Taking the infimum on the left-hand side of the above inequality over all $x \in \Omega$ which satisfy $H(x) = 0$ (that is infimum over all $x \in \Omega_1$), we have

$$\mu_0 = \inf\{f(x) + \langle g(x), z_0^* \rangle + \langle H(x), y_0^* \rangle : \ x \in \Omega\}. \tag{9.11}$$

This proves the lemma. □

NUMERICALLY RELIABLE COMPUTATION OF OPTIMAL PERFORMANCE IN SINGULAR H_∞ CONTROL*

PASCAL GAHINET† AND ALAN J. LAUB‡

Abstract. A numerically stable algorithm is described for the computation of the optimal H_∞ performance $\gamma_{\rm opt}$ when the feedthrough matrices D_{12} or D_{21} are rank-deficient. Using only orthogonal transformations, the singular H_∞ problem is reduced to a regular subproblem and a standard Riccati-based γ-iteration is applied to this subproblem to compute $\gamma_{\rm opt}$. Various interpretations of this scheme are given in terms of the infinite zero structure of the plant and the deflation of Hamiltonian pencils. The implementation of this algorithm is straightforward and its performance and reliability are confirmed by extensive numerical testing.

Key words. H_∞ optimal control, singular problem, numerical computation, algebraic Riccati equation, linear matrix inequality

1. Introduction.

It is well known that the solvability of regular H_∞ problems can be characterized in terms of the stabilizing solutions X_∞ and Y_∞ of two indefinite Riccati equations [9]. In addition, a particular solution, called the central controller, is given by explicit formulas in terms of X_∞ and Y_∞ [18, 9, 20]. Extensions of this Riccati-based characterization to singular problems where D_{12} or D_{21} are rank-deficient have been proposed in [32, 34, 5, 27]. The suboptimality conditions of [32, 34] involve reduced-order algebraic Riccati equations (AREs) that are extracted via coordinate transformations on the plant matrices. Suboptimal controllers are then obtained by solving an almost disturbance decoupling problem on the transformed plant. Unfortunately, this approach involves nonorthogonal similarity transformations and is therefore prone to numerical instability.

A numerically more appealing approach is proposed in [5, 6]. There the authors consider ϵ-regularizations of singular H_∞ problems and characterize suboptimality in terms of the limits as ϵ goes to zero of the regularized Riccati solutions $X_\infty(\epsilon)$ and $Y_\infty(\epsilon)$. It is further argued that these limits can be directly computed via standard pencil-based algorithms. However, the possible singularity of the pencils considered in [5, 6] may also be a source of numerical difficulties as shown in subsection 5.1 of this paper. Moreover, the controller formulas in [5] are obtained as the limit of the entropy-maximizing central controller of [9]. As discussed previously in [33], this limit may be improper and even ill defined in terms of transfer functions (see also [5]). The zero-compensation scheme of [6] is also likely to produce improper controllers.

The main contribution of the present paper is a new algorithm for computing the optimal H_∞ performance in the singular case. While relying on the suboptimality conditions of [5, 6], this algorithm proceeds by reducing these conditions to standard, reduced-order Riccati equations. In contrast to [32, 34], this reduction involves only numerically stable singular value decompositions (SVDs) and is straightforward to

implement. And even though our algorithm amounts to a unitary deflation of the pencil W_{12_∞} considered in [5], it does not attempt to explicitly compute the stable eigenspace of this potentially singular pencil. This makes it an efficient and reliable alternative to previously available schemes.

The paper is organized as follows. Section 2 gives some background on matrix pencils, in particular on singular pencils. Section 3 recalls the problem statement and the linear matrix inequality (LMI)–based suboptimality conditions for general H_∞ problems. Section 4 explores the connection between the LMI- and Riccati-based characterizations of suboptimality for singular H_∞ problems. While leading to Riccati-based conditions similar to those of [5, 6], this analysis lays the ground for the subsequent derivation of our algorithm. Section 5 contains the main results on the computation of the Riccati "solutions" X_∞ and Y_∞ in the singular case. An iterative scheme to extract a regular subproblem is presented, and it is shown that the resulting subproblem fully determines X_∞ and Y_∞. The overall algorithm for the computation of γ_{opt} is presented in section 6, and section 7 discusses numerical stability issues. Finally, section 8 reports the results of numerical testing.

2. Background on singular matrix pencils. This section recalls basic notions on matrix pencils that are useful in the subsequent analysis. A more complete discussion is found in [17, 37]. A matrix pencil is any pair (A, B) of matrices of the same dimensions and is usually denoted by $A-\lambda B$. Note that A, B need not be square. The pencil $A-\lambda B$ is called *regular* if A is square and $\det(A-\lambda B) \neq 0$ for some $\lambda \in \mathbb{C}$, and is called *singular* otherwise. Two pencils $A_1-\lambda B_1$ and $A_2-\lambda B_2$ are said to be *equivalent* if there exist two invertible matrices P, Q such that $A_2-\lambda B_2 = P(A_1-\lambda B_1)Q$.

Kronecker's theory of matrix pencils [17] shows that any pencil $A-\lambda B$ can be brought by equivalence transformation to the canonical form

$$P(A-\lambda B)Q = \text{Diag}\left(R_{p_1}, \ldots, R_{p_r}, C_{q_1}, \ldots, C_{q_s}, I-\lambda N, M-\lambda I\right), \tag{2.1}$$

where

- R_{p_i} is a $p_i \times (p_i+1)$ bidiagonal matrix of the form $\begin{pmatrix} -\lambda & 1 & & \\ & \ddots & \ddots & \\ & & -\lambda & 1 \end{pmatrix}$;
- C_{q_j} is a $(q_j+1) \times q_j$ bidiagonal matrix of the form $\begin{pmatrix} 1 & & \\ -\lambda & \ddots & \\ & \ddots & 1 \\ & & -\lambda \end{pmatrix}$;
- $N \in \mathbb{R}^{m\times m}$ is a nilpotent Jordan matrix and $M \in \mathbb{R}^{n\times n}$.

The rectangular R and C blocks determine the Kronecker row and column structure, respectively, and constitute the singular part of the pencil. The two regular pencils $M-\lambda I$ and $I-\lambda N$ constitute the regular part of the pencil and determine its finite and infinite eigenstructure, respectively. Indeed, all generalized eigenvalues of $I-\lambda N$ are at infinity since N is nilpotent, while all eigenvalues of $M-\lambda I$ are finite.

While computing the decomposition (2.1) is an ill-conditioned problem, the singular/regular decomposition and the pencil eigenstructure can be computed in a backward stable manner using Van Dooren's deflation algorithm [37]. Using orthogonal transformations P and Q, this algorithm deflates any pencil $A-\lambda B$ to the staircase

form

$$P(A-\lambda B)Q = \begin{pmatrix} A_r-\lambda B_r & \star & \star & \star \\ 0 & A_f-\lambda B_f & \star & \star \\ 0 & 0 & A_i-\lambda B_i & \star \\ 0 & 0 & 0 & A_c-\lambda B_c \end{pmatrix}, \tag{2.2}$$

where

- $A_f-\lambda B_f$ and $A_i-\lambda B_i$ are square regular pencils associated with the finite and infinite generalized eigenvalues, respectively;
- $A_r-\lambda B_r$ and $A_c-\lambda B_c$ are singular rectangular pencils, A_r having full row rank and A_c having full column rank.

Note that backward stability does not suppress the intrinsic sensitivity of this decomposition to rounding errors. In particular, the dimensions of each characteristic subpencil can be drastically altered by small perturbations of the data.

Note finally that the finite generalized eigenvalues of $A-\lambda B$ have the following simple rank characterization.

LEMMA 2.1. *If*

$$\nu := \max_{\lambda} \ \mathrm{Rank}(A-\lambda B)$$

denotes the normal rank of the pencil $A-\lambda B$, the finite generalized eigenvalues of $A-\lambda B$ are the complex values λ_k such that

$$\mathrm{Rank}\,(A-\lambda_k B) < \nu\ . \tag{2.3}$$

Proof. The proof is essentially in [17] and is included for completeness. The rank of $A-\lambda B$ is readily assessed from the canonical decomposition (2.1). Observing that each R_{p_i} is of rank p_i and each C_{q_j} is of rank q_j regardless of λ, it follows that

$$\mathrm{Rank}(A-\lambda B) = \sum_{i=1}^{r} p_i + \sum_{j=1}^{s} q_j + \mathrm{Rank}(I-\lambda N) + \mathrm{Rank}(M-\lambda I).$$

Now, $I-\lambda N$ remains invertible for all λ since N is a nilpotent Jordan matrix. Thus, the overall rank can change only when $\mathrm{Rank}(M-\lambda I)$ drops, that is, when λ is an eigenvalue of M and hence a finite generalized eigenvalue of $A-\lambda B$. ∎

3. Singular H_∞ control.

3.1. Problem statement. Consider a linear time-invariant plant $P(s)$ with state-space equations

$$\left\{ \begin{array}{rcl} \dot{x} &=& Ax + B_1 w + B_2 u, \\ z &=& C_1 x + D_{11} w + D_{12} u, \\ y &=& C_2 x + D_{21} w + D_{22} u, \end{array} \right. \tag{3.1}$$

where the vectors w, u, z, and y denote the exogenous inputs, control inputs, controlled outputs, and measured outputs, respectively. The plant dimensions are summarized by

$$A \in \mathbb{R}^{n\times n}, \qquad D_{11} \in \mathbb{R}^{p_1\times m_1}, \qquad D_{22} \in \mathbb{R}^{p_2\times m_2}\ .$$

Let $T_{wz}(s)$ denote the closed-loop transfer function from w to z under dynamic output-feedback $u = K(s)y$.

Given some performance level $\gamma > 0$, the suboptimal H_∞ control problem consists of finding an internally stabilizing controller $K(s)$ such that

$$\|T_{wz}(s)\|_\infty < \gamma.$$

Solutions of this problem (if any) will be called γ-*suboptimal* controllers. The optimal H_∞ gain $\gamma_{\rm opt}$ is defined as the smallest achievable performance γ. The following assumptions on the plant matrices are made throughout the paper:

(A1) (A, B_2, C_2) is stabilizable and detectable;
(A2) $D_{22} = 0$;
(A3) the matrix pencils $\left(\begin{smallmatrix} A-\lambda I & B_2 \\ C_1 & D_{12} \end{smallmatrix}\right)$ and $\left(\begin{smallmatrix} A-\lambda I & B_1 \\ C_2 & D_{21} \end{smallmatrix}\right)$ have no finite generalized eigenvalue on the imaginary axis.

Note that (A2) incurs no loss of generality and merely amounts to redefining the measured outputs as $y - D_{22}u$. For simplicity, most results and proofs are stated for the case $D_{11} = 0$. See section 6 for the general case $D_{11} \neq 0$.

Of particular interest in this paper are plants where D_{12} and/or D_{21} are rank-deficient. The corresponding H_∞ problem is traditionally referred to as *singular*, following the LQG terminology. Singular problems are more difficult since they cannot be handled by the standard Riccati-based approach to H_∞ control [9]. Note, however, that such problems are all but ill-posed from both theoretical and control viewpoints. On the contrary, most singular H_∞ problems have meaningful solutions, especially suboptimal ones. Singularity means only that *Riccati-based* central controllers [9] are not well defined [5]. Note finally that singular problems are by no means exotic and do frequently arise in applications such as loop-shaping, μ-synthesis, etc.

3.2. LMI-based conditions for solvability. The derivation of the algorithm presented in this paper makes extensive use of the LMI-based characterization of H_∞ suboptimality [12, 24]. This result is recapped in the next theorem and applies to any plant, whether it be regular or singular.

THEOREM 3.1 (solvability of the suboptimal H_∞ problem). *Consider a proper continuous-time plant $P(s)$ of order n and minimal realization* (3.1)*, and assume* (A1)–(A2) *and $D_{11} = 0$. Given bases $\mathcal{N}_{12}$ and $\mathcal{N}_{21}$ of the null spaces of $(B_2^T,\ D_{12}^T)$ and (C_2, D_{21}), respectively, the suboptimal H_∞ problem with performance γ is solvable if and only if there exist pairs of symmetric matrices (R, S) in $\mathbb{R}^{n\times n}$ such that*

$$\mathcal{N}_{12}^T \begin{pmatrix} AR + RA^T + \gamma^{-2} B_1 B_1^T & RC_1^T \\ C_1 R & -I \end{pmatrix} \mathcal{N}_{12} < 0, \tag{3.2}$$

$$\mathcal{N}_{21}^T \begin{pmatrix} A^T S + SA + \gamma^{-2} C_1^T C_1 & SB_1 \\ B_1^T S & -I \end{pmatrix} \mathcal{N}_{21} < 0, \tag{3.3}$$

$$R > 0, \qquad S > 0, \qquad \lambda_{\min}(RS) \geq \gamma^{-2}. \tag{3.4}$$ ∎

Theorem 3.1 shows that the performance γ is achievable if and only if the following feasibility problem is solvable:

$$\text{find } R \in \mathcal{R} \text{ and } S \in \mathcal{S} \text{ such that } \ \lambda_{\min}(RS) \geq \gamma^{-2}, \tag{3.5}$$

where

$$\mathcal{R} := \{R > 0 : \ \ (3.2) \text{ holds}\}, \qquad \mathcal{S} := \{S > 0 : \ \ (3.3) \text{ holds}\}. \tag{3.6}$$

Since (3.2)–(3.4) are LMI constraints on the matrices R and S [12], this feasibility problem could be tackled directly by convex optimization techniques. In particular, it

falls within the scope of efficient LMI solvers such as those described in [3, 26, 36, 25]. However, solving LMIs is of higher complexity than solving Riccati equations. For this reason, solvability conditions involving only standard linear algebra techniques remain computationally appealing.

4. Riccati-based conditions for singular problems. Henceforth, the discussion is implicitly specialized to the singular case (D_{12} or D_{21}^T column-rank deficient), most results becoming trivial in the regular case. Although the Riccati-based characterization of [9] is not applicable to singular problems, it can be generalized along the lines of [5]. This section sheds new light on the results of [5], in particular on the connection between the LMI- and Riccati-based characterizations of suboptimality. This analysis is the foundation of the new algorithm proposed in section 5.

4.1. From LMIs to Riccati equations. We first outline the procedure for turning the LMI conditions of Theorem 3.1 into Riccati equations. This procedure is adapted from [31, 12] and relies on the following two technical lemmas.

LEMMA 4.1 (Finsler's lemma [35, 28]). *Given a symmetric matrix M, an unstructured matrix P, and any matrix W_P whose columns form a basis for the null space of P, there exists $\alpha > 0$ such that $M - \alpha\, P^T P < 0$ if and only if $W_P^T\, M\, W_P < 0$.*

LEMMA 4.2. *Given any matrices $A \in \mathbb{R}^{n\times n}$, $F = F^T \in \mathbb{R}^{n\times n}$, $C \in \mathbb{R}^{m\times n}$ such that (C, A) has no unobservable mode on the imaginary axis, the set*

$$\mathcal{R} := \{R > 0 : AR + RA^T + RC^T CR + F < 0\} \tag{4.1}$$

is nonempty if and only if the Riccati equation $A^T X + XA + XFX + C^T C = 0$ has a stabilizing solution $X_{\rm st} \geq 0$. (Here "stabilizing" means that the closed-loop matrix $A + FX$ has all its eigenvalues in the open left-half plane.)

Moreover, $X_{\rm st}$ is a lower limit point for the set $\mathcal{R}_{\rm inv} := \{R^{-1} : R \in \mathcal{R}\}$ in such cases. That is,

- *$X_{\rm st} < R^{-1}$ for all $R \in \mathcal{R}$;*
- *there exists a sequence $\{R_n\}$ of elements of $\mathcal{R}$ such that $\lim_{n\to\infty} R_n^{-1} = X_{\rm st}$. In other words, $X_{\rm st}$ lies on the boundary of $\mathcal{R}_{\rm inv}$.*

Proof. See Appendix A. ∎

A straightforward application of these two lemmas leads to the following ARE-based condition for the existence of *positive definite* solutions to the LMI (3.2).

LEMMA 4.3. *Assume* (A3) *and let*

$$\pi_{12} := I - D_{12}^+ D_{12}, \quad \hat{B}_2 := B_2 D_{12}^+, \quad \hat{A} := A - \hat{B}_2 C_1, \quad \hat{C}_1 := (I - D_{12} D_{12}^+) C_1. \tag{4.2}$$

The set $\mathcal{R}$ defined in (3.6) *is nonempty if and only if the Riccati equation*

$$\hat{A}^T X + X\hat{A} + X(\gamma^{-2} B_1 B_1^T - \hat{B}_2 \hat{B}_2^T) X + \hat{C}_1^T \hat{C}_1 \;-\; \alpha\, X B_2 \pi_{12} B_2^T X = 0 \tag{4.3}$$

has a stabilizing solution $X(\alpha) \geq 0$ for $\alpha > 0$ large enough.

Proof. Following [12], (3.2) is equivalent to

$$W_{12}^T \left\{ \hat{A}R + R\hat{A}^T + R\hat{C}_1^T \hat{C}_1 R + \gamma^{-2} B_1 B_1^T - \hat{B}_2 \hat{B}_2^T \right\} W_{12} < 0, \tag{4.4}$$

where W_{12} denotes any full-rank matrix whose columns span the null space of $\pi_{12} B_2^T$. Invoking Lemma 4.1, this inequality is feasible if and only if

$$\hat{A}R + R\hat{A}^T + R\hat{C}_1^T \hat{C}_1 R + \gamma^{-2} B_1 B_1^T - \hat{B}_2 \hat{B}_2^T \;-\; \alpha\, B_2 \pi_{12} B_2^T < 0. \tag{4.5}$$

is feasible for some $\alpha > 0$. Now, $(\hat{C}_1, \hat{A})$ has no unobservable mode on the imaginary axis by virtue of (A3). By Lemma 4.2, it follows that (4.5) has positive definite solutions if and only if the ARE (4.3) has a stabilizing solution $X(\alpha) \geq 0$ for $\alpha > 0$ large enough. □

Remark 4.4. The Riccati equation (4.3) can be viewed as the standard H_∞ ARE for some ϵ-regularization of the plant $P(s)$. Specifically, define $\epsilon := \sqrt{1/\alpha}$; introduce an orthogonal transformation $V = (V_1, V_2)$ such that $D_{12}(V_1, V_2) = (\Delta, 0)$, where Δ has full column rank; and consider the plant obtained by replacing C_1, D_{11}, and D_{12} with

$$\begin{pmatrix} C_1 \\ 0 \end{pmatrix}, \qquad \begin{pmatrix} D_{11} \\ 0 \end{pmatrix}, \qquad \begin{pmatrix} \Delta & 0 \\ 0 & \epsilon I \end{pmatrix} V^T,$$

respectively. The resulting D_{12} matrix has full column rank, and it is readily verified from the definition (4.2) of $\hat{A}$, $\hat{B}_2$, and $\hat{C}_1$ that the corresponding controller ARE for X_∞ coincides with (4.3).

4.2. Riccati-based characterization of suboptimality. In the regular case (full-rank D_{12}), (4.3) reduces to the usual ARE for X_∞ since $\pi_{12} = 0$. In the singular case, however, (4.3) defines a family of AREs parametrized by α, and testing the existence of a stabilizing solution for large enough α becomes nontrivial. To remove the dependence on α, note that $X(\alpha)$ has the following properties:

(i) there exists $\alpha_0 > 0$ such that (4.3) has a stabilizing solution $X(\alpha)$ for all $\alpha > \alpha_0$;

(ii) $X(\alpha)$ is a monotonically decreasing function of α on the half-line $(\alpha_0, +\infty)$ [39].

When $\mathcal{R}$ is nonempty, (i) is an immediate consequence of Lemma 4.3. More generally, observe that the dependence on α and the dependence on γ are of the same nature. As a result, (i) follows from the analysis in [30, 11] (see, e.g., Corollary 5.2 in [11]).

Since $X(\alpha)$ is a decreasing function of $\alpha > \alpha_0$, it has a (not necessarily finite) limit as α goes to $+\infty$. This suggests introducing the following extension of the usual Riccati solution X_∞.

DEFINITION 4.5 (asymptotic stabilizing solution). *The family of Riccati equations* (4.3) *is said to have an asymptotic stabilizing solution X_∞ if and only if*

(1) *these equations have a stabilizing solution $X(\alpha)$ on some interval $(\alpha_0, +\infty)$;*

(2) *$X(\alpha)$ has a finite limit X_∞ as α goes to $+\infty$:*

$$X_\infty := \lim_{\alpha \to +\infty} X(\alpha). \tag{4.6}$$

Note that X_∞ coincides with the limit of the Riccati solutions $X(\epsilon)$ considered in [5] (see Remark 4.1 above). Lemma 4.3 has a simple reformulation in terms of asymptotic stabilizing solution.

LEMMA 4.6. *The set $\mathcal{R}$ defined in* (3.6) *is nonempty if and only if the family of α-parametrized Riccati equations* (4.3) *has an asymptotic stabilizing solution $X_\infty \geq 0$. Moreover, X_∞ is a lower limit point for the set $\mathcal{R}_{\text{inv}} := \{R^{-1} : R \in \mathcal{R}\}$.*

Proof. Sufficiency is immediate from Lemma 4.3, Definition 4.5, and the fact that $X_\infty \leq X(\alpha)$ since $X(\alpha)$ is monotonically decreasing in α. To prove necessity, recall from Lemma 4.3 that $\mathcal{R} \neq \emptyset$ implies that $X(\alpha) \geq 0$ for α large enough. Hence, $X(\alpha)$ is bounded from below as $\alpha \to +\infty$, and its limit X_∞ is finite and satisfies $X_\infty \geq 0$.

Finally, recall from Lemma 4.2 that, for α large enough, $X(\alpha)$ is a lower limit point for the set $\{R^{-1} : R > 0$ and R solves (4.5)$\}$. Now, as α goes to $+\infty$, this set

tends to $\{R^{-1} : R > 0 \text{ and } R \text{ solves (4.4)}\}$. Since (4.4) and (3.2) are equivalent [12], we conclude that X_∞ is a lower limit point for $\mathcal{R}_{\text{inv}}$. □

By duality, similar properties hold for the stabilizing solutions $Y(\alpha)$ of

$$\tilde{A}Y + Y\tilde{A}^T + Y(\gamma^{-2}C_1^TC_1 - \tilde{C}_2^T\tilde{C}_2)Y + \tilde{B}_1\tilde{B}_1^T - \alpha Y C_2^T(I - D_{21}D_{21}^+)C_2Y = 0, \tag{4.7}$$

where $\tilde{C}_2 = D_{21}^+C_2$, $\tilde{A} = A - B_1\tilde{C}_2$, and $\tilde{B}_1 = B_1(I - D_{21}^+D_{21})$. Defining Y_∞ as

$$Y_\infty := \lim_{\alpha \to +\infty} Y(\alpha), \tag{4.8}$$

the solvability of the suboptimal singular H_∞ problem can be characterized as follows (see also Theorem 4 in [5]).

THEOREM 4.7. *The singular H_∞ problem with performance γ is solvable if and only if both*

(a) *the α-dependent Riccati equations* (4.3) *and* (4.7) *have asymptotic stabilizing solutions X_∞ and Y_∞;*

(b) *X_∞ and Y_∞ further satisfy*

$$X_\infty \geq 0, \qquad Y_\infty \geq 0, \qquad \rho(X_\infty Y_\infty) \leq \gamma^2. \tag{4.9}$$

Proof. Necessity is immediate from the previous discussion. Note that the condition $\rho(X_\infty Y_\infty) \leq \gamma^2$ follows from the existence of $(R, S) \in \mathcal{R} \times \mathcal{S}$ such that $\lambda_{\min}(RS) \geq \gamma^{-2}$, and from the fact that $0 \leq X_\infty < R^{-1}$ and $0 \leq Y_\infty < S^{-1}$ for all $(R, S) \in \mathcal{R} \times \mathcal{S}$. As for sufficiency, (a) together with Lemma 4.3 and Definition 4.5 ensure that $\mathcal{R}$ and $\mathcal{S}$ are nonempty. Moreover, there exist sequences $R_n \in \mathcal{R}$ and $S_n \in \mathcal{S}$ such that $R_n^{-1} \to X_\infty$ and $S_n^{-1} \to Y_\infty$. Since $\rho(X_\infty Y_\infty) < \gamma^2$, we deduce that $\rho(R_n^{-1}S_n^{-1}) < \gamma^2$ for n large enough, or equivalently that $\lambda_{\min}(R_nS_n) > \gamma^{-2}$. Hence, there exist $R \in \mathcal{R}$ and $S \in \mathcal{S}$ such that $\lambda_{\min}(RS) \geq \gamma^{-2}$, which ensures that the H_∞ performance γ is achievable by virtue of Theorem 3.1. □

Remark 4.8. From Lemma 4.6, the asymptotic stabilizing solution X_∞ coincides with the strict lower limit point $P(\mu)$ in Theorem 13 of [32]. The matrix X_∞ is also a particular solution of the quadratic matrix inequality (QMI)

$$\begin{pmatrix} A^TX + XA + \gamma^{-2}XB_1B_1^TX + C_1^TC_1 & XB_2 + C_1^TD_{12} \\ B_2^TX + D_{12}^TC_1 & D_{12}^TD_{12} \end{pmatrix} \geq 0 \tag{4.10}$$

considered in [34]. To see this, let $V = (V_1, V_2)$ be any orthogonal matrix such that $D_{12}(V_1, V_2) = (\Delta, 0)$ with Δ full-column-rank. Postmultiplying and premultiplying by $\text{diag}(I, V)$, the QMI (4.10) reads

$$\begin{pmatrix} A^TX + XA + \gamma^{-2}XB_1B_1^TX + C_1^TC_1 & XB_2V_1 + C_1^T\Delta & XB_2V_2 \\ V_1^TB_2^TX + \Delta^TC_1 & \Delta^T\Delta & 0 \\ V_2^TB_2^TX & 0 & 0 \end{pmatrix} \geq 0,$$

which is equivalent to

$$XB_2V_2 = 0, \qquad \hat{A}^TX + X\hat{A} + X(\gamma^{-2}B_1B_1^T - \hat{B}_2\hat{B}_2^T)X + \hat{C}_1^T\hat{C}_1 \geq 0. \tag{4.11}$$

To show that X_∞ satisfies these constraints, recall that

$$\hat{A}^TX(\alpha) + X(\alpha)\hat{A} + X(\alpha)(\gamma^{-2}B_1B_1^T - \hat{B}_2\hat{B}_2^T)X(\alpha) + \hat{C}_1^T\hat{C}_1 = \alpha X(\alpha)B_2\pi_{12}B_2^TX(\alpha) \geq 0.$$

Taking the limit as $\alpha \to +\infty$ shows that X_∞ satisfies the inequality in (4.11) and that $0 = X_\infty B_2\pi_{12}B_2^TX_\infty = X_\infty B_2V_2V_2^TB_2^TX_\infty$, whence $X_\infty B_2V_2 = 0$.

5. Computation of X_∞ and Y_∞ in the singular case. From Theorem 4.7, the main task when testing the feasibility of some H_∞ performance γ is the computation of the asymptotic stabilizing solutions X_∞ and Y_∞ defined by (4.6) and (4.8). This section contains the main results of the paper. It begins with a discussion of the pencil-based algorithm proposed in [5] and brings out some numerical shortcomings of that approach. A new and numerically stable algorithm to compute X_∞ and Y_∞ is then presented. Using only SVDs, this algorithm proceeds by iterative row/column compressions of the plant matrices A, B_1, B_2, C_1, D_{12} until a reduced-order, regular subproblem has been extracted. That is, until obtaining a standard reduced-order Riccati equation that is equivalent to the LMI feasibility condition (3.2). A formal description and a justification of this algorithm are given in subsections 5.2 and 5.3. Finally, subsection 5.4 brings out insightful connections with the deflation of the Hamiltonian pencil considered in [5].

5.1. Pencil-based computation of X_∞. In principle, to determine whether a given performance γ is achievable, we could approximate X_∞ and Y_∞ by $X(\alpha)$ and $Y(\alpha)$ for α large enough and iteratively increase α until (4.3) and (4.7) have stabilizing solutions that satisfy

$$X(\alpha) \geq 0, \qquad Y(\alpha) \geq 0, \qquad \rho(X(\alpha)Y(\alpha)) \leq \gamma^2.$$

In practice, however, this scheme will run into two difficulties. First, the convergence toward X_∞ or Y_∞ may be very slow, thus requiring a large number of iterations. Worse, the computation of the Riccati solutions $X(\alpha)$ and $Y(\alpha)$ becomes ill conditioned for large values of α. For these reasons, a direct computation of X_∞ and Y_∞ is numerically desirable.

To this end, Copeland and Safonov [5] recall that the stabilizing solution $X(\alpha)$ is related to the stable eigenspace $\mathbf{S}(\alpha)$ of the matrix pencil

$$M(\alpha)-\lambda N = \begin{pmatrix} \hat{A} & \gamma^{-2}B_1B_1^T - \hat{B}_2\hat{B}_2^T & B_2\pi_{12} \\ -\hat{C}_1^T\hat{C}_1 & -\hat{A}^T & 0 \\ 0 & \pi_{12}B_2^T & \alpha^{-1}I \end{pmatrix} - \lambda \begin{pmatrix} I & 0 & 0 \\ 0 & I & 0 \\ 0 & 0 & 0 \end{pmatrix} \tag{5.1}$$

("stable eigenspace" refers to the invariant subspace associated with the *finite and stable* generalized eigenvalues) [22, 38]. Specifically, given any basis

$$\begin{pmatrix} P_\alpha \\ Q_\alpha \\ Z_\alpha \end{pmatrix}$$

of $\mathbf{S}(\alpha)$, (4.3) has a stabilizing solution if and only if P_α is square invertible, in which case $X(\alpha)$ is given by $X(\alpha) = Q_\alpha P_\alpha^{-1}$. As a result, computing X_∞ amounts to computing the limit of $\mathbf{S}(\alpha)$ as α goes to infinity. Introducing $M_\infty := \lim_{\alpha\to+\infty} M(\alpha)$, this limit is explicitly characterized in [5] as

$$\lim_{\alpha\to+\infty} \mathbf{S}(\alpha) = \text{Span} \begin{pmatrix} P_1 \\ Q_1 \\ Z_1 \end{pmatrix} \oplus \text{Span} \begin{pmatrix} P_2 \\ 0 \\ Z_2 \end{pmatrix}, \tag{5.2}$$

where the first subspace is the stable eigenspace $\mathbf{S}_\infty$ of the limit pencil $M_\infty - \lambda N$, and the columns of $\left(\begin{smallmatrix} P_2 \\ Z_2 \end{smallmatrix}\right)$ span the lower infinite eigenspace of $\left(\begin{smallmatrix} A-\lambda I & B_2 \\ C_1 & D_{12} \end{smallmatrix}\right)$ (see [5] for details). Consequently, the asymptotic stabilizing solution X_∞ of (4.3) exists if and

only if (P_1, P_2) is square and invertible, in which case it is given by

$$X_\infty = (Q_1,\ 0)\ (P_1,\ P_2)^{-1}.$$

In fact, [19] further shows that X_∞ depends only on P_1 and Q_1.

The computation of $\mathbf{S}_\infty$ requires deflation of the pencil $M_\infty - \lambda N$. To enhance numerical stability, [5] advises using the deflation algorithm 3.6 of [37] rather than the QZ algorithm because of possible generalized eigenvalues at infinity. In fact, the most pressing reason for ruling out the QZ algorithm is the possible singularity of the pencil $M_\infty - \lambda N$ (or equivalently, of the pencil $W_{12_\infty}(0, s)$ considered in [5]). Such singularities have been overlooked in [5] and complicate the computation of the required eigenspace. First, a combination of Algorithms 4.1 and 4.5 in [37] should be used rather than Algorithm 3.6. Second, the computation of the finite spectrum of a singular pencil is a badly conditioned problem [37]. Finally, the algorithms of [37] will not produce, in general, the regular decomposition assumed in [5, equation (293), p. 387]. Instead, they will deflate $M_\infty - \lambda N$ to the staircase form (2.2).

To compute the stable eigenspace $\mathbf{S}_\infty$ in the presence of the singular component $M_r - \lambda N_r$, we must either swap the diagonal blocks $M_r - \lambda N_r$ and $M_f - \lambda N_f$ or block-diagonalize the subpencil $\left(\begin{smallmatrix} M_r - \lambda N_r & \star \\ 0 & M_f - \lambda N_f \end{smallmatrix}\right)$. Both operations involve nonorthogonal equivalence transformations [8]. Besides their possible ill-conditioning, these transformations are often nonunique, in which case the remaining degrees of freedom add dimensions to the stable eigenspace $\mathbf{S}_\infty$. These various difficulties are illustrated by the simple example below.

Example 5.1. Consider a plant with state-space matrices

$$A = \begin{pmatrix} 3 & -2 \\ -2 & 0 \end{pmatrix},\ B_1 = \begin{pmatrix} 1 \\ 1 \end{pmatrix},\ B_2 = \begin{pmatrix} 1 & 5 \\ -1 & 0 \end{pmatrix},\ C_1 = \begin{pmatrix} 2 & -1 \\ 0 & 1 \end{pmatrix},\ D_{11} = 0,\ D_{12} = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix};$$

take $\gamma = 1$; and form the pencil $M_\infty - \lambda N$. Running Algorithms 4.1 and 4.5 of [37] on this pencil yields the following deflated form (2.2):

$$M_\infty - \lambda N \equiv \left(\begin{array}{cc|cc|c} 5 & 1-\lambda & 1 & 2 & 0 \\ \hline 0 & 0 & -1-\lambda & 0 & -2 \\ 0 & 0 & 1 & 1-\lambda & 1 \\ \hline 0 & 0 & 0 & 0 & 1+\lambda \\ 0 & 0 & 0 & 0 & 5 \end{array}\right). \tag{5.3}$$

This pencil is clearly singular with regular part $M_f - \lambda N_f = \left(\begin{smallmatrix} -1-\lambda & 0 \\ 1 & 1-\lambda \end{smallmatrix}\right)$. The only stable eigenvalue being $\lambda = -1$, the stable eigenspace is spanned by the nontrivial solutions of the linear system of equations

$$\left(\begin{array}{cc|cc} 5 & 2 & 1 & 2 \\ \hline 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 2 \end{array}\right) \begin{pmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \end{pmatrix} = 0. \tag{5.4}$$

The stable eigenspace is therefore of dimension 2, whereas the stable eigenspace of $M_f - \lambda N_f$ is of dimension 1. This extra dimension comes from the nonuniqueness of the diagonalizing equivalence transformations.

In the general case when $M_f - \lambda N_f$ has several stable eigenvalues, we need either to assemble and solve the system (5.4) for each eigenvalue or to diagonalize the pencil [8] while keeping a record of the remaining degrees of freedom. Both approaches involve nonorthogonal equivalence transformations, are difficult to implement, and

will produce nonorthonormal bases for the stable eigenspace in general. A more extensive discussion of these difficulties is found in [8].

Finally, the finite spectrum of singular pencils is highly sensitive to rounding errors. For instance, a perturbation $\epsilon = 1.0 \times 10^{-10}$ in the (2,2) entry of the pencil (5.3) is enough to make its finite spectrum vanish entirely! Computing the stable eigenspace of singular pencils may thus be numerically hazardous. □

Circumventing such numerical hazards was our main motivation for seeking an alternative algorithm to compute X_∞. The results of this research are presented next.

5.2. A new algorithm to compute X_∞. We begin with an overall description of the algorithm in terms of computational procedure and major operations performed.

ALGORITHM 5.2

Purpose: Test the existence of a nonnegative asymptotic stabilizing solution X_∞ to the α-parametrized Riccati equation (4.3), and compute it when it exists.

Initialization: Set $k := 0$, $Z := I$, and

$$\mathcal{A}_0 := A, \qquad \mathcal{G}_0 := B_1, \qquad \mathcal{B}_0 := B_2, \qquad \mathcal{C}_0 := C_1, \qquad \mathcal{D}_0 := D_{12}.$$

Regularization loop: Iteratively update the matrices $\mathcal{A}_k$, $\mathcal{G}_k$, $\mathcal{B}_k$, $\mathcal{C}_k$, and $\mathcal{D}_k$ at iteration k as follows:

1. Perform a column compression on $\mathcal{D}_k$. That is, compute (via SVD, say) an orthogonal matrix $V = (V_1, V_2)$ such that

$$\mathcal{D}_k\,(V_1, V_2) = \,(\Delta\,,\,0) \tag{5.5}$$

with Δ full column rank. Terminate if $\mathcal{D}_k$ has full column rank.

2. Perform a row compression on $\mathcal{B}_k V_2$. That is, compute (via SVD, say) an orthogonal matrix $W = (W_1, W_2)$ such that

$$\begin{pmatrix} W_1^T \\ W_2^T \end{pmatrix} \mathcal{B}_k V_2 = \begin{pmatrix} 0 \\ L \end{pmatrix} \tag{5.6}$$

with L full row rank. Terminate if $\mathcal{B}_k V_2$ is either full row rank or identically zero.

3. Define

$$\begin{aligned} &\mathcal{A}_{k+1} := W_1^T\,\mathcal{A}_k\,W_1\,, \qquad \mathcal{G}_{k+1} := W_1^T\,\mathcal{G}_k\,, \qquad \mathcal{C}_{k+1} := \mathcal{C}_k\,W_1 \\ &\mathcal{B}_{k+1} := W_1^T\,(\mathcal{A}_k W_2\,,\,\mathcal{B}_k V_1)\,, \qquad \mathcal{D}_{k+1} := (\mathcal{C}_k W_2\,,\,\mathcal{D}_k V_1). \end{aligned} \tag{5.7}$$

4. Overwrite Z by ZW_1, set $k := k + 1$, and return to Step 1.

Reduced-order Riccati equation: Let K denote the number of iterations performed in the regularization loop, and let $\hat{\mathcal{A}}_K$, $\hat{\mathcal{B}}_K$, and $\hat{\mathcal{C}}_K$ be the counterparts of $\hat{A}$, $\hat{B}_2$, and $\hat{C}_1$ in (4.2) when replacing A, B_2, C_1, and D_{12} with $\mathcal{A}_K$, $\mathcal{B}_K V_1$, $\mathcal{C}_K$, and $\mathcal{D}_K V_1$.

If $\mathcal{B}_K V_2$ has full row rank, $X_\infty = 0$. Otherwise, (4.3) has a nonnegative asymptotic stabilizing solution X_∞ if and only if the Riccati equation

$$\hat{\mathcal{A}}_K^T X_r + X_r \hat{\mathcal{A}}_K + X_r\,(\gamma^{-2}\mathcal{G}_K\mathcal{G}_K^T - \hat{\mathcal{B}}_K\hat{\mathcal{B}}_K^T)\,X_r + \hat{\mathcal{C}}_K^T\hat{\mathcal{C}}_K = 0 \tag{5.8}$$

has a stabilizing solution $X_r \geq 0$, and X_∞ is then given by

$$X_\infty \;=\; Z\,X_r\,Z^T. \tag{5.9}$$

□

In simple terms, this algorithm extracts a regular subproblem from the original singular H_∞ problem. Specifically, it iteratively reduces the original plant (A, B_1, B_2,

C_1, D_{12}) to the subproblem of state-space data ($\mathcal{A}_K$, $\mathcal{G}_K$, $\mathcal{B}_K V_1$, $\mathcal{C}_K$, $\mathcal{D}_K V_1$). This subproblem is then handled in the usual way by solving the reduced-order Riccati equation (5.8). Since the size of $\mathcal{A}_k$ is strictly decreasing, the regularization loop will terminate in a finite number of steps. Note that the row and column compressions involve only numerically stable operations (SVDs). In addition, the matrix Z relating X_r to X_∞ has orthonormal columns since each W_1 satisfies $W_1^T W_1 = I$. Thus, the overall regularization amounts to an orthonormal change of coordinates that isolates the nontrivial part of X_∞ (simply observe from (5.9) that the orthogonal complement of Span(Z) lies entirely in the null space of X_∞). Incidentally, this regularization is equivalent to an implicit unitary deflation of the pencil $W_{12_\infty}(0, s)$ considered in [5], as will be seen in subsection 5.4. Finally, note that (5.9) is closely related to the identity in Theorem 13 of [32], the main difference here being the orthogonality of the coordinate transformation Z.

5.3. Justification. To justify the regularization scheme of Algorithm 5.2, we show that each iteration of the regularization loop produces an equivalent problem of smaller dimension. This property is best seen by working with the LMI-based characterization of Theorem 3.1. For notational simplicity, start with the original problem data A, B_1, B_2, C_1, D_{12} and apply one iteration of Algorithm 5.2. Denote the resulting matrices by

$$\begin{aligned} \mathcal{A} &:= W_1^T A W_1, \quad \mathcal{G} := W_1^T B_1, \quad \mathcal{B} := W_1^T (A W_2, B_2 V_1), \\ \mathcal{C} &:= C_1 W_1, \quad \mathcal{D} := (C_1 W_2, \Delta), \end{aligned} \tag{5.10}$$

where $V = (V_1, V_2)$ and $W = (W_1, W_2)$ are orthogonal matrices such that

$$D_{12}\,(V_1, V_2) = (\Delta\,,\,0), \qquad (B_2 V_2)^T\,(W_1, W_2) = (0,\,L^T). \tag{5.11}$$

(Δ and L have full column and row rank, respectively.) The next theorem shows that X_∞ is fully determined by the reduced problem of data $(\mathcal{A}, \mathcal{G}, \mathcal{B}, \mathcal{C}, \mathcal{D})$.

THEOREM 5.3. *With the notation* (5.10), (5.11) *and the assumptions* (A1)–(A3), *there is equivalence between the following two statements:*

(a) *the α-parametrized Riccati equation* (4.3) *has an asymptotic stabilizing solution $X_\infty \geq 0$;*

(b) *the counterpart of* (4.3) *resulting from the substitutions*

$$(A, B_1, B_2, C_1, D_{12}) \to (\mathcal{A}, \mathcal{G}, \mathcal{B}, \mathcal{C}, \mathcal{D})$$

has an asymptotic stabilizing solution $X_1 \geq 0$.
Moreover, X_∞ and X_1 are related by

$$X_\infty = W_1 X_1 W_1^T. \tag{5.12}$$

Proof. See Appendix B. ∎

By applying Theorem 5.3 to each iteration of the regularization loop, we can characterize X_∞ in terms of the stabilizing solution of the final reduced-order Riccati equation (5.8). This corollary completes the justification of Algorithm 5.2.

COROLLARY 5.4. *For plants satisfying* (A1)–(A3), *there is equivalence between*

(a) (4.3) *has an asymptotic stabilizing solution $X_\infty \geq 0$;*

(b) *the reduced-order Riccati equation* (5.8) *has a stabilizing solution $X_r \geq 0$ (with the convention $X_r = 0$ when $\mathcal{B}_K V_2$ has full row rank upon termination).*

If either property holds, the asymptotic stabilizing solution X_∞ of (4.3) *is given by*

$$X_\infty = Z X_r Z^T, \tag{5.13}$$

where Z is the matrix accumulated during the iterative regularization of the plant. ∎

Summing up, the regularization loop clears the way to turning the LMI (3.2) into a well-defined Riccati equation that can be solved with standard Riccati solvers [21, 2] (see section 6 for more details).

5.4. Interpretation in terms of pencil deflation. This subsection gives two interpretations of Algorithm 5.2 in terms of the deflation of

(1) the system matrix

$$P_{12}(\lambda) = \begin{pmatrix} A - \lambda I & B_2 \\ C_1 & D_{12} \end{pmatrix}, \tag{5.14}$$

(2) the extended Hamiltonian pencil associated with the H_∞ controller ARE

$$\hat{A}^T X + X\hat{A} + X(\gamma^{-2} B_1 B_1^T - \hat{B}_2 \hat{B}_2^T)X + \hat{C}_1^T \hat{C}_1 = 0. \tag{5.15}$$

Algorithm 5.2 is shown to perform an orthogonal deflation of these pencils to extract their finite eigenstructures. However, this algorithm differs from the pencil algorithm discussed in [5] in two important ways:

- the deflation is performed implicitly in a highly efficient and numerically stable manner;
- no attempt is made to compute the stable eigenspace of the Hamiltonian pencil associated with (5.15) or to deal with related difficulties when this pencil is singular (see discussion in subsection 5.1). Instead, Algorithm 5.2 extracts a reduced Hamiltonian pencil which is regular, contains all information needed to compute X_∞, and can be deflated in a numerically stable way.

First consider the effect of one iteration of Algorithm 5.2 on the system matrix $P_{12}(\lambda)$. With the notation (5.10), (5.11), we have

$$\begin{pmatrix} W^T & 0 \\ 0 & I \end{pmatrix} P_{12}(\lambda) \begin{pmatrix} W & 0 \\ 0 & V \end{pmatrix} = \left(\begin{array}{cc|cc} \mathcal{A} - \lambda I & W_1^T A W_2 & W_1^T B_2 V_1 & 0 \\ \star & \star & \star & W_2^T B_2 V_2 \\ \hline \mathcal{C} & C_1 W_2 & \Delta & 0 \end{array}\right)$$

$$\equiv \left(\begin{array}{cc|cc} W_2^T B_2 V_2 & & \star & \star \\ \hline 0 & & \mathcal{A} - \lambda I & \mathcal{B} \\ 0 & & \mathcal{C} & \mathcal{D} \end{array}\right), \tag{5.16}$$

where $\equiv$ stands for "equivalent by row and column permutations." Recalling that $W_2^T B_2 V_2$ has full row rank by construction, it is immediate from Lemma 2.1 that $P_{12}(\lambda)$ and $\left(\begin{smallmatrix} \mathcal{A}-\lambda I & \mathcal{B} \\ \mathcal{C} & \mathcal{D} \end{smallmatrix}\right)$ have the same finite zeros. Repeating the argument for each iteration, we conclude that $P_{12}(\lambda)$ and

$$P_K(\lambda) = \begin{pmatrix} \mathcal{A}_K - \lambda I & \mathcal{B}_K V_1 \\ \mathcal{C}_K & \mathcal{D}_K V_1 \end{pmatrix} \tag{5.17}$$

share the same finite eigenvalues (finite zeros). Moreover, the deflated system matrix $P_K(\lambda)$ is associated with a regular problem since $\mathcal{D}_K V_1$ has full column rank, and subsection 5.3 shows that this problem contains all the information needed to compute X_∞. A more complete interpretation in terms of infinite zero structure can be found

in [32]. From [10, 11], note that the finite zeros of $P_K(\lambda)$ are exactly the unobservable modes of

$$(\hat{\mathcal{C}}_K, \hat{\mathcal{A}}_K) = \left((I - (\mathcal{D}_K V_1)(\mathcal{D}_K V_1)^+)\mathcal{C}_K\,,\ \mathcal{A}_K - \mathcal{B}_K V_1 (\mathcal{D}_K V_1)^+ \mathcal{C}_K\right).$$

The previous analysis has an immediate counterpart in terms of extended Hamiltonian pencils. Recall that the Hamiltonian matrix associated with (5.15) is

$$H_X := \begin{pmatrix} \hat{A} & \gamma^{-2} B_1 B_1^T - \hat{B}_2 \hat{B}_2^T \\ -\hat{C}_1^T \hat{C}_1 & -\hat{A}^T \end{pmatrix}. \tag{5.18}$$

Following [38, 22, 2], we can eliminate all pseudoinversions by replacing H_X with the extended Hamiltonian pencil

$$\begin{aligned} \mathcal{H} - \lambda\mathcal{E} &= \begin{pmatrix} H_{11} & H_{12} \\ H_{21} & H_{22} \end{pmatrix} - \lambda \begin{pmatrix} I & 0 \\ 0 & 0 \end{pmatrix} \\ &:= \left(\begin{array}{cc|cc} A & \gamma^{-2} B_1 B_1^T & 0 & B_2 \\ 0 & -A^T & -C_1^T & 0 \\ \hline C_1 & 0 & -I & D_{12} \\ 0 & -B_2^T & -D_{12}^T & 0 \end{array}\right) - \lambda \left(\begin{array}{cc|cc} I & 0 & 0 & 0 \\ 0 & I & 0 & 0 \\ \hline 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{array}\right). \end{aligned} \tag{5.19}$$

In the regular case, H_{22} is invertible since D_{12} has full column rank. Hence, $\mathcal{H} - \lambda\mathcal{E}$ is a regular pencil and given any basis

$$\begin{pmatrix} P \\ Q \\ \star \\ \star \end{pmatrix}$$

of its stable eigenspace, it is easily verified from the identity $H_X = H_{11} - H_{12} H_{22}^{-1} H_{21}$ that the columns of $\binom{P}{Q}$ span the stable eigenspace of the Hamiltonian matrix H_X. Consequently, $X = QP^{-1}$ is the stabilizing solution of (5.15) whenever P is invertible [2]. Note that the pencil $\mathcal{H} - \lambda\mathcal{E}$ is an extended version of the pencil $W_{12_\infty}(0, s)$ considered in [5].

When D_{12} is rank-deficient, by contrast, the pencil $\mathcal{H} - \lambda\mathcal{E}$ may be singular and the connection with the (asymptotic) stabilizing ARE solution becomes fuzzier. To understand the deflating action of Algorithm 5.2, observe that $\mathcal{H} - \lambda\mathcal{E}$ is equivalent by row and column permutations to

$$\mathcal{H} - \lambda\mathcal{E} \equiv \left(\begin{array}{c|c} P_{12}(\lambda) & \mathrm{Diag}(\gamma^{-2} B_1 B_1^T, -I) \\ \hline 0 & -P_{12}^T(-\lambda) \end{array}\right). \tag{5.20}$$

From the previous discussion and (5.16), we readily infer that one iteration of Algorithm 5.2 deflates the pencil $\mathcal{H} - \lambda\mathcal{E}$, via orthogonal transformations, to the equivalent pencil

$$\left(\begin{array}{c|c|c} W_2^T B_2 V_2 & \star & \star \\ \hline 0 & \mathcal{H}_1 & \star \\ \hline 0 & 0 & -V_2^T B_2^T W_2 \end{array}\right) - \lambda \left(\begin{array}{c|c|c} 0 & \star & 0 \\ \hline 0 & \mathcal{E}_1 & \star \\ \hline 0 & 0 & 0 \end{array}\right), \tag{5.21}$$

where

$$\mathcal{H}_1 - \lambda\mathcal{E}_1 := \left(\begin{array}{cc|cc} \mathcal{A} & \gamma^{-2}\mathcal{G} & 0 & \mathcal{B} \\ 0 & -\mathcal{A}^T & -\mathcal{C}^T & 0 \\ \hline \mathcal{C} & 0 & -I & \mathcal{D} \\ 0 & -\mathcal{B}^T & -\mathcal{D}^T & 0 \end{array}\right) - \lambda \left(\begin{array}{cc|cc} I & 0 & 0 & 0 \\ 0 & I & 0 & 0 \\ \hline 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{array}\right). \tag{5.22}$$

By inspection of (5.21), (5.22), it follows that

- one iteration of Algorithm 5.2 extracts a subpencil $\mathcal{H}_1 - \lambda\mathcal{E}_1$ with the same Hamiltonian structure;
- $\mathcal{H} - \lambda\mathcal{E}$ and $\mathcal{H}_1 - \lambda\mathcal{E}_1$ have the same finite generalized eigenvalues. This follows from (5.21) together with Lemma 2.1 and the fact that $W_2^T B_2 V_2$ has full row rank;
- upon termination, either $\mathcal{H}_K$ is empty (case $X_\infty = 0$) or $\mathcal{H}_K - \lambda\mathcal{E}_K$ is the regular extended Hamiltonian pencil associated with the reduced-order ARE (5.8).

Summing up, Algorithm 5.2 amounts to a particular orthogonal deflation of the Hamiltonian pencil $\mathcal{H} - \lambda\mathcal{E}$. Unlike in [5], the stable eigenspace of $\mathcal{H} - \lambda\mathcal{E}$ is not explicitly computed. Instead, X_∞ is computed from the stable eigenspace of the reduced pencil $\mathcal{H}_K - \lambda\mathcal{E}_K$.

6. Computation of $\gamma_{\mathbf{opt}}$. This section summarizes the overall procedure for computing the optimal H_∞ performance γ_{opt} in the singular case. The algorithm is given for the general case $D_{11} \neq 0$, which is a straightforward extension of the previous results. The regularization loop of Algorithm 5.2 remains unchanged in this general setup, and its SVD-based implementation is straightforward. Once the reduced-order ARE (5.8) has been extracted, it can be solved by standard Schur techniques. To enhance numerical stability, we recommend using the generalized eigenproblem implementation described in [2] as follows.

(1) Form the (regular) extended pencil

$$\mathcal{H}_K - \lambda\mathcal{E}_K = \left(\begin{array}{cc|ccc} \mathcal{A}_K & 0 & 0 & \gamma^{-1}\mathcal{G}_K & \mathcal{B}_K V_1 \\ 0 & -\mathcal{A}_K^T & -\mathcal{C}_K^T & 0 & 0 \\ \hline \mathcal{C}_K & 0 & -I & \gamma^{-1}D_{11} & \mathcal{D}_K V_1 \\ 0 & \gamma^{-1}\mathcal{G}_K^T & \gamma^{-1}D_{11}^T & -I & 0 \\ 0 & (\mathcal{B}_K V_1)^T & (\mathcal{D}_K V_1)^T & 0 & 0 \end{array}\right) - \lambda \left(\begin{array}{cc|ccc} I & 0 & 0 & 0 & 0 \\ 0 & I & 0 & 0 & 0 \\ \hline 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{array}\right),$$

where $\mathcal{A}_K$, $\mathcal{G}_K$, $\mathcal{B}_K$, $\mathcal{C}_K$, $\mathcal{D}_K$, and V_1 are the matrices returned by Algorithm 5.2 upon termination.

(2) Eliminate its infinite eigenstructure by using Algorithm 3.6 of [37].

(3) Compute an orthonormal basis for its stable eigenspace by using the QZ algorithm with reordering of the stable eigenvalues [38].

Algorithm 5.2 is readily dualized to test the existence of Y_∞ and compute it: simply replace $(A, B_1, B_2, C_1, D_{11}, D_{12})$ with $(A^T, C_1^T, C_2^T, B_1^T, D_{11}^T, D_{21}^T)$ in the initialization step.

Combining this regularization algorithm with the characterization of Theorem 4.7, the optimal H_∞ performance γ_{opt} is estimated to the desired accuracy via the usual γ-iteration scheme. Note that the trick proposed in [29] to avoid numerical difficulties when testing $X_\infty \geq 0$ or $Y_\infty \geq 0$ is also applicable to our context.

7. Numerical stability and related issues. This section discusses the numerical reliability of the algorithm outlined in section 6. Recall that the main difficulty is the computation of X_∞ and Y_∞. Since Algorithm 5.2 relies on SVDs and since the SVD is a backward stable operation, the computed γ_{opt} is the exact value for a nearby problem (i.e., for slightly perturbed values of the plant matrices). Yet this is not enough to guarantee that this computed value is meaningful from a control viewpoint. Indeed, it was shown in [13] that the optimal H_∞ gain γ_{opt} may be discontinuous near singular problems. In other words, arbitrarily small perturbations of

the plant data may result in large variations of $\gamma_{\rm opt}$. To understand how this might affect Algorithm 5.2, we first recall a few important facts about such discontinuities.

7.1. Discontinuities of $\gamma_{\rm opt}$. As shown in [13], $\gamma_{\rm opt}$ is an upper semicontinuous function of the plant data that may be discontinuous near singular plants. Consider a singular plant $P(s)$ with optimal performance $\gamma^* := \gamma_{\rm opt}(P)$, and suppose that $\gamma_{\rm opt}$ is discontinuous at P with a gap $\delta > 0$ between its upper and lower limits. Then there exist arbitrarily small perturbations P_ϵ of P such that

$$\gamma_{\rm opt}(P_\epsilon) < \gamma^* - \delta/2 \; .$$

While the value $\gamma_{\rm opt}(P_\epsilon)$ is mathematically correct, it is clearly not meaningful from a control standpoint. Indeed, the H_∞ performance should be robust to small perturbations in the state-space data, while here $\gamma_{\rm opt}(P_\epsilon)$ jumps up by at least $\delta/2$ (a possibly large amount) when P_ϵ is perturbed to P.

For these reasons, we claim that only the upper limit γ^* is meaningful in the vicinity of the singular plant P. This value is typically insensitive to small perturbations of the data and can be achieved with reasonable control effort. In contrast, the lower limit(s) are only achievable via high gain or marginal closed-loop stability.

7.2. Implementation tips. Based on the previous discussion, we recommend the following "singularity-preferring" policy: if the plant is nearly singular, make it singular and compute the optimal H_∞ performance for the resulting singular plant. This amounts to computing the upper limit of $\gamma_{\rm opt}$ in the vicinity of the plant. Now, singularity has to do with the rank of the matrices $\mathcal{D}_k$ and $\mathcal{B}_k V_2$ in Algorithm 5.2. (The regularization is complete when these matrices have full rank.) Thus, "nearly singular" is equivalent to "nearly rank-deficient," which in turn has to do with small singular values. Due to the finite precision of computer arithmetic, singular values should be considered zero when they fall below some adequate relative tolerance TOL:

SVD truncation rule: Given the SVD of a matrix M, zero all singular values smaller than $\text{TOL} \times \sigma_{\max}(M)$ where $\sigma_{\max}(M)$ denotes the largest singular value of M.

To implement our singularity-preferring policy, it suffices to set TOL to some conservative value, e.g., the square root of the relative machine precision. This will automatically turn nearly singular problems into truly singular ones. Note that steering clear of nearly rank-deficient matrices also improves the numerical conditioning of the reduced Riccati equation (5.8).

8. Numerical experiments. The following simple example illustrates the performance of Algorithm 5.2.

Example 8.1. Consider the plant data

$$A = \begin{pmatrix} 0 & -1 & 2 \\ 1 & -2 & 3 \\ 0 & 1 & 0 \end{pmatrix}, \quad B_1 = \begin{pmatrix} 1 \\ -1 \\ 0 \end{pmatrix}, \quad B_2 = \begin{pmatrix} 1 & 0 \\ 0 & 0 \\ 0 & -1 \end{pmatrix},$$

$$C_1 = \begin{pmatrix} 1 & 0 & 1 \\ 1 & 0 & 1 \end{pmatrix}, \quad D_{12} = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}.$$

Clearly D_{12} is rank-deficient and the standard Riccati equation for X_∞ is ill-defined for this problem.

With this data and $\gamma = 1$, Algorithm 5.2 performs one regularization iteration and returns the asymptotic stabilizing solution

$$X_\infty = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0.06857 & 0.18733 \\ 0 & 0.18733 & 0.51180 \end{pmatrix}.$$

The eigenvalues of X_∞ are $0.58037, 0, 0$.

By comparison, the eigenvalues of the computed solution $X(\alpha)$ of (4.3) for $\alpha = 10^{10}$ are $0.5804, 1.12 \times 10^{-5}$, and 7.73×10^{-12}. This illustrates the relatively slow convergence of $X(\alpha)$ to X_∞. Note that $\alpha = 10^{10}$ corresponds to the following ϵ-regularization of the true plant data:

$$C_1 \to \begin{pmatrix} 1 & 0 & 1 \\ 1 & 0 & 1 \\ 0 & 0 & 0 \end{pmatrix}, \qquad D_{12} \to \begin{pmatrix} 0 & 1 \\ 0 & 0 \\ 10^{-5} & 0 \end{pmatrix}. \qquad \square$$

Algorithm 5.2 has been implemented in MATLAB's *LMI Control Toolbox* [16] developed by the authors and Nemirovski. To solve the reduced-order Riccati equations we used the Riccati solvers developed by Laub [23]. The algorithm was tested on a large number of randomly generated singular problems, and the computed γ_{opt} was compared with (1) the optimal value obtained from LMI-based optimization using Nestorov and Nemirovski's projective method [14, 25, 16] and (2) the optimal value obtained with a standard γ-iteration algorithm after ϵ-regularization of the plant. Algorithm 5.2 proved extremely reliable and always returned an optimal value within 1% of the LMI-based optimum. In contrast, the ϵ-regularization scheme proved very sensitive to the choice of ϵ. Algorithm 5.2 therefore appears as a fast and reliable alternative to ϵ-regularization for singular problems.

9. Concluding remarks. We have presented a new and numerically stable algorithm to compute the optimal H_∞ gain γ_{opt} when D_{12} or D_{21} are rank-deficient. Its efficiency and reliability have been confirmed by extensive numerical testing.

Given γ_{opt}, there remains the issue of computing (sub)optimal controllers that achieve some performance $\gamma \geq \gamma_{\text{opt}}$. As pointed out in [5], the usual central controller formulas applied to the asymptotic stabilizing solutions X_∞ and Y_∞ do not always yield a proper or well-posed controller. In fact, there does not seem to be any obvious way of deriving adequate controllers from knowledge of X_∞ and Y_∞ (see [15] for insight drawn from the LMI approach). Consequently, the ϵ-regularization of the plant data remains useful for the computation of the H_∞ controller. Even so, exact knowledge of the optimal performance prior to any regularization proves valuable for two reasons. First, it eliminates the dependence of the computed optimal performance on the chosen regularization level ϵ. Here the true value is obtained at once and without the possible numerical instability introduced by ϵ. Second, increasing ϵ tends to improve numerical conditioning and to yield better-behaved controllers. Once some performance $\gamma > 0$ has been unambiguously diagnosed as feasible with Algorithm 5.2, it is easy to maximize ϵ subject to γ remaining feasible.

Appendix A.

Proof of Lemma 4.2. The proof is adapted from [31]. Temporarily assuming that $(C, -A)$ is detectable, Theorem 2.23 of [31] shows that the set

$$\mathcal{G} := \{R = R^T : AR + RA^T + RC^TCR + F < 0\}$$

is nonempty if and only if the Riccati equation

$$-AR - RA^T - RC^TCR - F = 0 \tag{A.1}$$

has a stabilizing solution $R_{\rm st}$. Moreover, it is shown that $R_{\rm st}$ is then an upper limit point of $\mathcal{G}$.

If $\mathcal{R} \neq \emptyset$, the set $\mathcal{G}$ contains a positive definite element R_0 and consequently $R_{\rm st} > R_0$ is positive definite and invertible. Defining $X_{\rm st} := R_{\rm st}^{-1}$, it is readily verified that $X_{\rm st}$ is a positive definite and stabilizing solution of $A^TX+XA+XFX+C^TC = 0$. In addition, from $0 < R < R_{\rm st}$ for all $R \in \mathcal{R}$, we deduce that $0 < X_{\rm st} < R^{-1}$ for all $R \in \mathcal{R}$. This, together with the upper limiting property of $R_{\rm st}$, guarantees that $X_{\rm st}$ is a lower limit point of $\mathcal{R}_{\rm inv}$.

Conversely, if $A^TX + XA + XFX + C^TC = 0$ has a stabilizing solution $X_{\rm st} > 0$, it retains a positive definite stabilizing solution $X_{\rm st}(\epsilon)$ when C^TC is perturbed to $C^TC + \epsilon I$ with $\epsilon > 0$ small enough [7]. Hence, $\mathcal{R}$ is nonempty since $X_{\rm st}^{-1}(\epsilon) \in \mathcal{R}$.

Finally, the case where (C, A) has stable unobservable modes can be handled by a limiting argument (see, e.g., Lemma 8.1 in [12]). Note that the stable unobservable subspace of (C, A) determines the null space of $X_{\rm st}$. ∎

Appendix B. We begin with a useful technical lemma.

LEMMA B.1 (Projection lemma) [12, 4]. *Consider a symmetric matrix M and matrices P, Q of compatible dimensions, and let W_P and W_Q be any matrices whose columns form bases for the null spaces of P and Q, respectively.*

With this notation, the matrix inequality $M + Q^TXP + P^TX^TQ < 0$ is solvable for X if and only if the inequalities $W_P^T\,M\,W_P < 0$ and $W_Q^T\,M\,W_Q < 0$ hold.

The regularizing effect of Algorithm 5.2 is best analyzed in the LMI framework, that is, using the LMI characterization of Theorem 3.1. The implications in terms of asymptotic stabilizing Riccati solutions are then easily deduced from the results of section 4. The next theorem shows that one regularization iteration reduces the characteristic LMI (3.2) to a smaller LMI with the same structure and where A, B_1, B_2, C_1, and D_{12} are replaced by $\mathcal{A}$, $\mathcal{G}$, $\mathcal{B}$, $\mathcal{C}$, and $\mathcal{D}$, respectively.

THEOREM B.2. *Assume that D_{12} is column-rank deficient. With the notation* (5.10), (5.11) *there exists a symmetric matrix R satisfying the LMI*

$$\mathcal{N}_{12}^T \begin{pmatrix} AR + RA^T + \gamma^{-2}B_1B_1^T & RC_1^T \\ C_1R & -I \end{pmatrix} \mathcal{N}_{12} < 0 \tag{B.1}$$

if and only if there exists a symmetric matrix R_1 satisfying the reduced-order LMI

$$\tilde{\mathcal{N}}^T \begin{pmatrix} \mathcal{A}R_1 + R_1\mathcal{A}^T + \gamma^{-2}\mathcal{G}\mathcal{G}^T & R_1\mathcal{C}^T \\ \mathcal{C}R_1 & -I \end{pmatrix} \tilde{\mathcal{N}} < 0, \tag{B.2}$$

where $\tilde{\mathcal{N}}$ is any orthonormal basis for the null space of $(\mathcal{B}^T, \mathcal{D}^T)$. Moreover, all solutions of (B.1) *are of the form*

$$R = W \begin{pmatrix} R_1 & \star \\ (\star)^T & \Psi \end{pmatrix} W^T, \tag{B.3}$$

where R_1 solves (B.2) *and Ψ is an arbitrary symmetric matrix.*

Proof. Applying Lemma 4.1 with $P = (B_2^T, D_{12}^T)$, the LMI (B.1) is feasible if and only if there exists $R = R^T$ such that

$$\begin{pmatrix} AR + RA^T + \gamma^{-2}B_1B_1^T & RC_1^T \\ C_1R & -I \end{pmatrix} - \alpha \begin{pmatrix} B_2 \\ D_{12} \end{pmatrix} \begin{pmatrix} B_2 \\ D_{12} \end{pmatrix}^T < 0\,, \qquad \alpha > 0\,. \tag{B.4}$$

Using the decomposition $\left(\begin{smallmatrix} B_2 \\ D_{12} \end{smallmatrix}\right)V = \left(\begin{smallmatrix} B_2V_1 & B_2V_2 \\ \Delta & 0 \end{smallmatrix}\right)$, (B.4) can also be written as

$$\begin{pmatrix} AR + RA^T + \gamma^{-2}B_1B_1^T & RC_1^T \\ C_1R & -I \end{pmatrix} - \alpha \begin{pmatrix} B_2V_1 \\ \Delta \end{pmatrix}\begin{pmatrix} B_2V_1 \\ \Delta \end{pmatrix}^T$$
$$-\alpha \begin{pmatrix} B_2V_2 \\ 0 \end{pmatrix}\begin{pmatrix} B_2V_2 \\ 0 \end{pmatrix}^T < 0.$$

Recalling that W_1 is a basis for the null space of $V_2^TB_2^T$ by construction, we can eliminate the last term by invoking Lemma 4.1 once again, this time with $P = (V_2^TB_2^T, 0)$ and $W_P = \left(\begin{smallmatrix} W_1 & 0 \\ 0 & I \end{smallmatrix}\right)$. It follows that (B.4) is feasible if and only if

$$\begin{pmatrix} W_1^T(AR + RA^T + \gamma^{-2}B_1B_1^T)W_1 & W_1^TRC_1^T \\ C_1RW_1 & -I \end{pmatrix} - \alpha \begin{pmatrix} W_1^TB_2V_1 \\ \Delta \end{pmatrix}\begin{pmatrix} W_1^TB_2V_1 \\ \Delta \end{pmatrix}^T < 0 \tag{B.5}$$

holds for some $\alpha > 0$. With the notation (5.10), (5.11) and

$$(R_1, R_2) := W_1^TR\,(W_1, W_2), \qquad \Omega_1 := \begin{pmatrix} W_1^TAW_2 \\ C_1W_2 \end{pmatrix}, \qquad \Omega_2 := \begin{pmatrix} W_1^TB_2V_1 \\ \Delta \end{pmatrix},$$

condition (B.5) is equivalent to the existence of $\alpha > 0$ and of matrices $R_1 = R_1^T$ and R_2 such that

$$\left\{\begin{pmatrix} \mathcal{A}R_1 + R_1\mathcal{A}^T + \gamma^{-2}\mathcal{G}\mathcal{G}^T & R_1\mathcal{C}^T \\ \mathcal{C}R_1 & -I \end{pmatrix} - \alpha\,\Omega_2\Omega_2^T\right\} + \begin{pmatrix} I \\ 0 \end{pmatrix} R_2\,\Omega_1^T + \Omega_1R_2^T\,(I\,,\,0) < 0. \tag{B.6}$$

To obtain the reduced LMI (B.2), it now suffices to eliminate the variable R_2 by invoking Lemma B.1 with $P = \Omega_1^T$ and $Q = (I\,,\,0)$. Observing that the projected inequality $W_Q^T\,M\,W_Q < 0$ is trivial here, we conclude that (B.4) is feasible if and only if the other projected inequality $W_P^T\,M\,W_P < 0$ holds or, equivalently from Lemma 4.1, if and only if the LMI

$$\left\{\begin{pmatrix} \mathcal{A}R_1 + R_1\mathcal{A}^T + \gamma^{-2}\mathcal{G}\mathcal{G}^T & R_1\mathcal{C}^T \\ \mathcal{C}R_1 & -I \end{pmatrix} - \alpha\,\Omega_2\Omega_2^T\right\} - \beta\,\Omega_1\Omega_1^T < 0$$

holds for some symmetric R_1 and positive scalars α, β. Without loss of generality, we may take $\alpha = \beta$ and group the last two terms into the single term

$$-\alpha(\Omega_1, \Omega_2)\begin{pmatrix} \Omega_1^T \\ \Omega_2^T \end{pmatrix}.$$

Then the LMI condition (B.2) readily follows by applying Lemma 4.1 with $P = (\Omega_1, \Omega_2)^T = (\mathcal{B}^T, \mathcal{D}^T)$ and $W_P = \tilde{\mathcal{N}}$.

By construction, the solutions R of (B.1) are related to the solutions R_1 of (B.2) by

$$R = W\begin{pmatrix} R_1 & R_2 \\ R_2^T & \Psi \end{pmatrix}W^T,$$

where R_2 satisfies (B.6) and $\Psi = \Psi^T$ is arbitrary: the proof is complete. □

To prove Theorem 5.3, it now suffices to reinterpret this result in terms of asymptotic stabilizing solutions of the corresponding AREs.

Proof of Theorem 5.3. First observe that Theorem B.2 can be strengthened to positive definite solutions of the LMIs (B.1), (B.2). Specifically, if $R > 0$ solves (B.1), then $R_1 = W_1^T R W_1$ is a positive definite solution of (B.2) from the proof of Theorem B.2. Conversely, given a solution $R_1 > 0$ of (3.3) and any R_2 solving (B.6), the matrix

$$R := W \begin{pmatrix} R_1 & R_2 \\ R_2^T & \Psi \end{pmatrix} W^T \tag{B.7}$$

solves (B.1) for any symmetric Ψ, and Ψ can always be chosen to make R positive definite.

Now, from Lemma 4.3 together with (A3), the LMI (B.1) has positive definite solutions if and only if (a) holds. Similarly, (B.2) has positive definite solutions if and only if (b) holds since the pencil

$$P(\lambda) = \begin{pmatrix} \mathcal{A} - \lambda I & \mathcal{B} \\ \mathcal{C} & \mathcal{D} \end{pmatrix}$$

has no finite eigenvalue on the imaginary axis. Indeed, $P_{12}(\lambda)$ and $P(\lambda)$ share the same finite spectra as established in subsection 5.4. Consequently, (a) and (b) are equivalent.

This leaves us with proving the identity $X_\infty = W_1 X_1 W_1^T$. Schematically, this identity stems from the correspondence (B.7) between solutions of the LMIs (B.1) and (B.2) as well the fact that X_∞ and X_1 are lower limit points for these LMIs (see Lemma 4.2). Specifically, $X_\infty \le R^{-1}$ for all solutions $R > 0$ of (B.1) while $X_1 \le R_1^{-1}$ for all solutions $R_1 > 0$ of (B.2).

Let $R > 0$ solve (B.1), and partition R as in (B.7). By the standard inversion formula for 2×2 block matrices, we have

$$\begin{aligned} W^T R^{-1} W &= \begin{pmatrix} R_1^{-1} & 0 \\ 0 & 0 \end{pmatrix} + \begin{pmatrix} R_1^{-1} R_2 \\ -I \end{pmatrix} (\Psi - R_2^T R_1^{-1} R_2)^{-1} \begin{pmatrix} R_1^{-1} R_2 \\ -I \end{pmatrix}^T \\ &\ge \begin{pmatrix} R_1^{-1} & 0 \\ 0 & 0 \end{pmatrix}. \end{aligned}$$

Since R_1 solves (B.2), it follows that $R^{-1} \ge W_1 R_1^{-1} W_1^T \ge W_1 X_1 W_1^T$. Now this holds for any solution $R > 0$ of (B.1), whence $X_\infty \ge W_1 X_1 W_1^T$.

Conversely, for any $R_1 > 0$ solving (B.2), construct a solution $R > 0$ of (B.1) as indicated above and choose $\Psi = \alpha I$ with $\alpha > 0$ large enough. Then

$$W \begin{pmatrix} R_1 & R_2 \\ R_2^T & \alpha I \end{pmatrix}^{-1} W^T = R^{-1} \ge X_\infty,$$

which, by letting α go to $+\infty$, ensures that $W_1 R_1^{-1} W_1^T \ge X_\infty$. Since this must hold for any $R_1 > 0$ solving (B.2), we infer that $W_1 X_1 W_1^T \ge X_\infty$, and the proof is complete. ∎

By applying these results to each iteration, it becomes clear that Algorithm 5.2 generates a sequence of LMIs that are equivalent to (B.1) and of decreasing order (i.e., the size of the matrix variable R is strictly decreasing). From the algorithm description, the regularization loop terminates with either of the following two situations.

Termination type (A): $\mathcal{B}_K V_2$ has full row rank. Then W_1 is "empty," (B.5) is trivially satisfied, and any $R > 0$ solves (B.1). From Lemma 4.6, this case yields $X_\infty = 0$.

Termination Type (B): $\mathcal{D}_K$ has full column rank or $\mathcal{B}_K V_2 = 0$. In both cases, the resulting data $\mathcal{A}_K, \mathcal{G}_K, \mathcal{B}_K, \mathcal{C}_K, \mathcal{D}_K$ define a *regular* problem, and the final "reduced" LMI is equivalent to the Riccati inequality (with the notation of Algorithm 5.2):

$$\hat{\mathcal{A}}_K R_r + R_r \hat{\mathcal{A}}_K^T + R_r\, \hat{\mathcal{C}}_K^T \hat{\mathcal{C}}_K\, R_r + \gamma^{-2} \mathcal{G}_K \mathcal{G}_K^T - \hat{\mathcal{B}}_K \hat{\mathcal{B}}_K^T < 0. \tag{B.8}$$

When $\mathcal{D}_K$ has full column rank, this last equivalence readily follows from subsection 3.3. When $\mathcal{B}_K V_2 = 0$ instead, the identity

$$\begin{pmatrix} \mathcal{B}_K \\ \mathcal{D}_K \end{pmatrix} V_2 = 0$$

shows that the input directions along V_2 are disconnected from both the plant dynamics and the output z; hence, they can be discarded to obtain a regular problem.

THE RELATIONSHIP BETWEEN THE MAXIMUM PRINCIPLE AND DYNAMIC PROGRAMMING FOR THE CONTROL OF PARABOLIC VARIATIONAL INEQUALITIES*

CĂTĂLIN POPA†

Abstract. We show that the well-known relationship between the dual extremal arc in the maximum principle and the optimal value function (of dynamic programming), calculated on the optimal trajectory, is valid for the control of parabolic variational inequalities. It follows that every optimal control is given by a feedback law. In the case when the functions defining the performance index are convex also with respect to the state variable, a more specific result is obtained.

Key words. optimal control, dual extremal arc, optimal value function, parabolic variational inequality, optimality conditions, dynamic programming principle, feedback law

1. Introduction. The aim of this paper is to establish the expected relationship between the maximum principle and dynamic programming for optimal control problems governed by a certain class of variational inequalities of parabolic type, including the parabolic obstacle problem and semilinear parabolic equations.

Let Ω be an open and bounded subset of $\mathbf{R}^N$ having a sufficiently smooth boundary. The control system we deal with is described by an abstract version of the following nonlinear parabolic equation (with boundary and initial conditions):

$$\begin{cases} \dfrac{\partial y}{\partial t} + A_0 y + \beta(y) \ni Bu + f \text{ a.e. in } Q = (0,T)\times\Omega, \\ \alpha_1 y + \alpha_2 \dfrac{\partial y}{\partial \nu} = 0 \text{ on } (0,T)\times\partial\Omega, \\ y(0,x) = y_0(x) \text{ in } \Omega, \end{cases} \tag{1.1}$$

where $-A_0$ is a strictly elliptic differential operator in Ω having its principal part in divergence form, β is a maximal monotone graph in $\mathbf{R}^2$, and B is a linear continuous operator from a given Hilbert space $\mathcal{U}$ (the control space) to $L^2(\Omega)$ (the state space). Of course, the cases of semilinear parabolic equations and parabolic obstacle problem are covered by (1.1).

In the present paper we shall be concerned with a certain class of free final state optimal control problems of Bolza type governed by (1.1), in which the involved integrand is convex, lower semicontinuous and possibly $+\infty$ with respect to the control variable u, and Lipschitz continuous (on bounded subsets of $L^2(\Omega)$) with respect to the state variable y. For such problems, V. Barbu has obtained in [2] (see also [1] for the convex case) first-order necessary conditions of optimality (the maximum principle) by an approach involving their regularization and penalization. For systems governed by the parabolic obstacle problem or by semilinear parabolic equations, these conditions (in fact the adjoint equations) take a more explicit form.

Now let $(t,y) \mapsto V(t,y)$ be the optimal value function of dynamic programming associated with one of the optimal control problems of the considered class. Our main

*Received by the editors November 22, 1994; accepted for publication (in revised form) July 15, 1996.

†Facultatea de Matematică, Universitatea "Al. I. Cuza," Bdul. Copou 11, 6600 Iaşi, Romania.

result states that, for every optimal pair (u^*, y^*) of the fixed problem, we can select a dual extremal arc p which besides the optimality conditions (in Barbu's form) also satisfies the following inclusion:

$$-p(t) \in \partial_y V(t, y^*(t)) \text{ a.e. } t \in (0, T). \tag{1.2}$$

This is the above-mentioned connection between the maximum principle and dynamic programming. Moreover, we shall prove that it is possible to choose p such that the following additional inclusion is simultaneously verified:

$$-p(0) \in \partial_y V(0, y_0). \tag{1.3}$$

However, when the domain of the elliptic operator $y \mapsto A_0 y + \beta(y)$ is not dense in $L^2(\Omega)$ but its closure is a convex cone (this is the case of parabolic obstacle problem), a less precise result is established: the inclusions (1.2) and (1.3) must be adjusted by adding the normal cones to the closure of the domain at its vertex and at y_0, respectively.

In the finite-dimensional case, the inclusions (1.2), (1.3) have been proved for a very large class of nonsmooth free endpoint problems by F. H. Clarke and R. B. Vinter in [7]. Let us describe in a few words the ingenious idea behind their approach. According to the dynamic programming principle, they introduce an auxiliary control variable v (in our notation) into the state equation, corresponding to the new term

$$-\int_0^T \inf\{(p, v(t)) : p \in \partial_y V(t, y), |y - y^*(t)| \le \delta\}\, dt$$

in the performance index. So the optimal control problem obtained in this way is solved by the same optimal pair as the original one. The part of the maximum principle which refers to the additional control variable is just the relation (1.2), as $\delta \to 0$.

This paper shows that the above idea works also in our infinite-dimensional framework. But here we shall combine it with Barbu's approach to the optimality conditions for the control of parabolic variational inequalities. However, some specific difficulties arise when we try to adapt the approach in [7] to our case. First, the way used there to prove that the given optimal pair solves also the auxiliary optimal control problem involves a certain approximation procedure for the new state equation. Expressing this approximation in the form of an integral equation, one easily shows that it converges uniformly on $[0, T]$. But this does not work here mainly due to the fact that the operator $y \mapsto A_0 y + \beta(y)$ in (1.1) is not Lipschitz continuous in $L^2(\Omega)$ norm. (Generally, differential operators are not continuous.) How could we surpass this difficulty? The key idea is based on the following simple observation: the approximation proposed in [7] for the new state equation (applied to our situation) can be regarded as a Trotter product formula approximation in $L^2(\Omega)$; its convergence will follow by applying an extension due to Y. Kobayashi of a well-known result of Brézis and Pazy. The reduction of the convergence to this result is rather technical and requires a previous approximation of both original and auxiliary controls by step functions followed by a refined partition of the time interval. (It is the author's opinion that, for infinite-dimensional control systems, Trotter-type product formulas represent just the adequate tool to prove the convergence of such an approximation scheme as that proposed in [7] for the new state equation.) On the other hand, the adjoint equation of (1.1) arising in the optimality conditions is a much more complicated object than

in the finite-dimensional case. So the procedure of passing to the limit as $\delta \to 0$ used in [7] must be modified according to Barbu's approach to optimality conditions. In a few words, we can express the new situation in the following way: since a new parameter η arises in the regularization process, we have to take limits when both δ and η tend to zero.

For optimal control problems involving parabolic infinite-dimensional systems, the inclusion (1.2) was proved by Barbu for two special situations by using two types of arguments. The first refers to convex optimal control problems governed by linear parabolic equations (see [3, p. 319]). In this case every dual extremal arc satisfies (1.2). This happens because the necessary optimality conditions here are also sufficient, and so any optimal pair of the considered problem solves also all the problems defining $V(t, y^*(t))$ for $t \in [0, T]$. The second situation concerns optimal control of semilinear parabolic equations, but under two very restrictive additional hypotheses: the integrand in the performance index is Gâteaux differentiable with respect to the control variable u (therefore the subdifferential of the integrand with respect to u is single valued) and B^* is injective (see [2, Cor. 5.1, p. 209]).

But here we work under natural hypotheses, i.e., those under which the necessary conditions of optimality are obtained in [2]. However, as in the finite-dimensional case, additional assumptions lead to more specific results. So we shall show that if the two functions defining the performance index are convex also with respect to the state variable, then (1.2) holds not only *almost everywhere* but even *everywhere* (see [7, Prop. 5.5] for a related finite-dimensional result). As an intermediate stage we shall prove the convexity of the optimal value function with respect to the space variable. This involves a Trotter-type product formula for the corresponding dynamic programming equation.

Finally, let us mention that, as a consequence of the main results (Theorems 2.1 and 2.2), we find that every optimal control of our considered problems is given by a feedback law (Theorems 2.3 and 2.4).

2. The framework and the main results. Let $\mathcal{U}$ be a real Hilbert space, and set $\mathcal{H} = L^2(\Omega)$, where Ω is a fixed open and bounded subset of $\mathbf{R}^N$ having a sufficiently smooth boundary. The scalar products and norms of $\mathcal{U}$ and $\mathcal{H}$ are denoted by the same symbols: $(\cdot, \cdot)$ and $|\cdot|$, respectively. Also, let $\mathcal{V}$ be a real Hilbert space continuously and densely imbedded in $\mathcal{H}$ with $\mathcal{V}'$ its dual space. Identifying $\mathcal{H}$ with its own dual, we assume

$$\mathcal{V} \subset \mathcal{H} \subset \mathcal{V}'.$$

Denote by $(\cdot, \cdot)$ the pairing between $\mathcal{V}$ and $\mathcal{V}'$, and by $|\cdot|_{\mathcal{V}}$ the norm of $\mathcal{V}$.

Consider the following optimal control problem:

(P) Minimize

$$\int_0^T (h(u(t)) + g(y(t)))\, dt + \ell(y(T)) \tag{2.1}$$

over all $u \in L^2(0, T; \mathcal{U})$, where $y \in W^{1,2}([0, T]; \mathcal{H})$ satisfies the state equation

$$y'(t) + Ay(t) + \beta(y(t) - \psi) \ni Bu(t) + f(t) \text{ a.e. } t \in (0, T) \tag{2.2}$$

and the initial condition

$$y(0) = y_0. \tag{2.3}$$

We impose on the data of (P) the following hypotheses:
(H1) The inclusion $\mathcal{V} \subset \mathcal{H}$ is compact.
(H2) $A : \mathcal{V} \to \mathcal{V}'$ is a linear continuous and symmetric operator which, for some $\omega > 0$ and $\alpha \in \mathbf{R}$, satisfies

$$(Ay, y) \geq \omega |y|_{\mathcal{V}}^2 - \alpha |y|^2 \text{ for all } y \in \mathcal{V}. \tag{2.4}$$

Moreover, there exists $c \geq 0$ such that, for every nondecreasing function $\xi \in C^1(\mathbf{R})$ with $\xi(0) = 0$ and $\xi' \leq 1$,

$$(Ay, \xi(y)) \geq -c(1 + |\xi(y)|)(1 + |y|) \text{ for all } y \in D(A) = \{z \in \mathcal{V} : Az \in \mathcal{H}\}. \tag{2.5}$$

(H3) β is a maximal monotone graph in $\mathbf{R} \times \mathbf{R}$ with $0 \in D(\beta)$ and ψ is a given function in $\mathcal{H}$ such that for some $c \geq 0$,

$$(Ay, \beta_\eta(y - \psi)) \geq -c(1 + |\beta_\eta(y - \psi)|)(1 + |y|) \text{ for all } y \in D(A) \text{ and } \eta > 0, \tag{2.6}$$

where $\beta_\eta(r) = \eta^{-1}(r - (I + \eta\beta)^{-1}r)$ for all $r \in \mathbf{R}, \eta > 0$.
(H4) $B : \mathcal{U} \to \mathcal{H}$ is a linear continuous operator.
(H5) $f \in L^2(0, T; \mathcal{H})$.
(H6) y_0 is a given function in $\mathcal{V}$ such that

$$\int_\Omega j(y_0(x) - \psi(x))\, dx < +\infty,$$

where $j : \mathbf{R} \to (-\infty, +\infty]$ is a convex function whose subdifferential is β.
(H7) $h : \mathcal{U} \to (-\infty, +\infty]$ is convex, lower semicontinuous, and not identically $+\infty$ and, for some $c_1 > 0$ and $c_2 \in \mathbf{R}$, satisfies

$$h(u) \geq c_1 |u|^2 - c_2 \text{ for all } u \in \mathcal{U}. \tag{2.7}$$

(H8) $g, \ell : \mathcal{H} \to \mathbf{R}$ are Lipschitz continuous on bounded subsets and bounded from below by affine functions.
By means of j (specified in (H6)), we define the following convex function $\phi : \mathcal{H} \to (-\infty, +\infty]$:

$$\phi(y) = \int_\Omega j(y(x) - \psi(x))\, dx. \tag{2.8}$$

We have (see [2, Prop. 1.9, p. 24])

$$\partial\phi(y) = \{w \in \mathcal{H} : w(x) \in \beta(y(x) - \psi(x)) \text{ a.e. } x \in \Omega\}$$

so that we may write (2.2) like this:

$$y' + Ay + \partial\phi(y) \ni Bu + f \text{ a.e. } t \in (0, T). \tag{2.9}$$

Notice that (H6) can be rewritten as
(H6)′ $y_0 \in \mathcal{V} \cap D(\phi)$.

A standard existence result (see [2, Thm. 4.3, p. 131]) states that, under the hypotheses (H2)–(H6) (except (2.5)), for every $u \in L^2(0, T; \mathcal{U})$, the problem (2.9), (2.3) has a unique solution $y \in W^{1,2}([0, T]; \mathcal{H}) \cap L^2(0, T; D(A)) \cap C([0, T]; \mathcal{V})$. If, instead of (H6), $y_0 \in \overline{\mathcal{V} \cap D(\phi)} = \overline{D(\phi)}$, then (2.9), (2.3) has a unique solution

$y \in C([0,T];\mathcal{H})$ such that $\sqrt{t}y' \in L^2(0,T;\mathcal{H})$ and $\sqrt{t}y \in L^2(0,T;D(A))$. Let us mention that (2.6) ensures the maximal monotonicity of $A+\partial\phi$ in $\mathcal{H}\times\mathcal{H}$.

One also knows that, under the hypotheses (H2)–(H5) (without (2.5)), (H7), and (H8), the control problem (P) admits at least one optimal pair for every $y_0 \in \overline{D(\phi)}$ (see [2, Prop. 5.1, p. 173]). (Note only that (2.7) and the boundedness from below by affine functions of g and ℓ ensure here that the functional (2.1) tends to $+\infty$ as $\int_0^T |u|^2\,dt \to \infty$.)

We associate with the optimal control problem (P) the corresponding optimal value function $V : [0,T]\times\overline{D(\phi)} \to \mathbf{R}$, i.e.,

(2.10)
$$V(t,y) = \inf\left\{ \int_t^T (h(u(s)) + g(z(s)))\,ds + \ell(z(T)) : \right.$$
$$\left. z' + Az + \beta(z-\psi) \ni Bu + f \text{ a.e. } s \in (t,T), z(t) = y, u \in L^2(t,T;\mathcal{U}) \right\}.$$

The following result is well known, but we shall give its proof for the reader's convenience.

PROPOSITION 2.1. *Under the hypotheses* (H2)–(H5) (*except* (2.5)), (H7), *and* (H8), *the function* $\overline{D(\phi)} \ni y \mapsto V(t,y)$ *is Lipschitz continuous on bounded subsets, uniformly with respect to* $t \in [0,T]$.

(Note that only here and in the proof of the existence of an optimal pair the condition (2.7) and the boundedness from below by affine functions of g and ℓ are needed.)

Proof. Let $y_1, y_2 \in \overline{D(\phi)}$, arbitrary, such that $|y_1|, |y_2| \le r$. By (2.10), we have

$$V(t,y_2) - V(t,y_1) \le \int_t^T (g(z_2(s)) - g(z_1(s)))\,ds + \ell(z_2(T)) - \ell(z_1(T)),$$

where z_2 and z_1 are the solutions of (2.2) corresponding to the initial states y_2 and y_1 at the time t, and the infimum defining $V(t,y_1)$ is attained. Taking (2.7) into account, we obtain

$$\int_t^T |u(s)|^2\,ds \le \text{ const.},$$

where the above constant depends only on r. (It is independent of t.) So $|z_1(s)|$ and $|z_2(s)|$ are bounded by a constant which depends only on r. Thus we may use the Lipschitz continuity on bounded subsets of g and ℓ to deduce the same thing for $V(t,\cdot)$ uniformly with respect to $t \in [0,T]$. The proof is finished.

Now to give a sense to the gradient of V with respect to y also at those points of $\overline{D(\phi)}$ which are not interior points for $\overline{D(\phi)}$, we consider the extension of V to the whole space $\mathcal{H}$ denoted by $\tilde{V}$ and defined as follows:

$$\tilde{V}(t,y) = V(t,P_K y) \text{ for } (t,y) \in [0,T]\times\mathcal{H},$$

where P_K is the projection operator of $\mathcal{H}$ onto $K = \overline{D(\phi)}$. Obviously, by virtue of Proposition 2.1, the function $\mathcal{H} \ni y \mapsto \tilde{V}(t,y)$ is also Lipschitz continuous on bounded subsets uniformly with respect to $t \in [0,T]$. So we may define

$$\partial_y V(t,y) = \partial_y \tilde{V}(t,y) \text{ for } (t,y) \in [0,T]\times\overline{D(\phi)},$$

where $\partial_y \tilde{V}(t,y)$ is the generalized gradient (in Clarke's sense) of $y \mapsto \tilde{V}(t,y)$.

Finally, let $\mathcal{Y} = H^s(\Omega) \cap \mathcal{V}$, where $s > N/2$, and set $Q = (0,T) \times \Omega$. We are now prepared to state our main results.

THEOREM 2.1. *Let (u^*, y^*) be an arbitrary optimal pair of the control problem* (P) *where $\beta : \mathbf{R} \to \mathbf{R}$ is Lipschitz continuous on bounded subsets. Suppose that* (H1)–(H8) *are satisfied. Then there exist $p \in BV([0,T];\mathcal{Y}') \cap L^\infty(0,T;\mathcal{H}) \cap L^2(0,T;\mathcal{V})$ and $\mu \in (L^\infty(Q))'$ such that*

$$p' - Ap - \mu \in \partial g(y^*) \text{ a.e. in } Q, \quad p' - Ap - \mu \in L^\infty(0,T;\mathcal{H}), \tag{2.11}$$

$$\mu_a(t,x) \in p(t,x)\partial\beta(y^*(t,x) - \psi(x)) \text{ a.e. in } Q, \tag{2.12}$$

$$-p(T) \in \partial\ell(y^*(T)), \tag{2.13}$$

$$B^*p(t) \in \partial h(u^*(t)) \text{ a.e. } t \in (0,T), \tag{2.14}$$

and

$$-p(t) \in \partial_y V(t, y^*(t)) \text{ a.e. } t \in (0,T). \tag{2.15}$$

If the following additional hypothesis on β holds:

(H9) *ϕ (given by* (2.8)*) is bounded on bounded subsets of $\mathcal{V} \cap D(\phi)$ in the $\mathcal{V}$ norm, then p (together with μ) can be chosen such that besides* (2.11)–(2.15) *it also satisfies*

$$-p(0) \in \partial_y V(0, y_0). \tag{2.16}$$

Moreover, if, for some $c \geq 0$, β satisfies

$$\beta'(r) \leq c(|\beta(r)| + |r| + 1) \text{ a.e. } r \in \mathbf{R}, \tag{2.17}$$

then $p \in AC([0,T];\mathcal{Y}') \cap C_w([0,T];\mathcal{H})$ and $\mu = \mu_a \in L^1(Q)$.

Here p' is the derivative of p in the sense of $\mathcal{V}'$-valued distribution and $\mu_a \in L^1(Q)$ is the absolutely continuous part of μ; also, $\partial\beta$, ∂g, and $\partial\ell$ are the generalized gradients of β, g, and ℓ, and ∂h is the subdifferential of h. Finally, $C_w([0,T];\mathcal{H})$ is the space of weakly continuous functions from $[0,T]$ to $\mathcal{H}$.

Now set $K = \{y \in L^2(\Omega) : y \geq \psi \text{ a.e. in } \Omega\}$.

THEOREM 2.2. *Let (u^*, y^*) be an arbitrary optimal pair for the control problem* (P) *where β is defined by*

$$\beta(r) = \begin{cases} 0 & if\ r > 0, \\ (-\infty, 0] & if\ r = 0, \\ \emptyset & if\ r < 0. \end{cases} \tag{2.18}$$

Suppose that (H1)–(H8) *hold. Then there exists a function $p \in BV([0,T];\mathcal{Y}') \cap L^\infty(0,T;\mathcal{H}) \cap L^2(0,T;\mathcal{V})$, which with the necessary conditions of optimality*

$$(p' - Ap)_a \in \partial g(y^*) \text{ a.e. in } \{(t,x) \in Q : y^*(t,x) > \psi(x)\}\ (p' - Ap \in (L^\infty(Q))'), \tag{2.19}$$

$$p(f + Bu^* - Ay^* - y^{*\prime}) = 0 \text{ a.e. in } Q, \tag{2.20}$$

$$-p(T) \in \partial\ell(y^*(T)), \tag{2.21}$$

$$B^*p(t) \in \partial h(u^*(t)) \text{ a.e. } t \in (0,T) \tag{2.22}$$

also satisfies

$$-p(t) \in \partial_y V(t, y^*(t)) + N_K(\psi) \text{ a.e. } t \in (0,T), \tag{2.23}$$

$$-p(0) \in \partial_y V(0, y_0) - N_K(y_0). \tag{2.24}$$

Here $N_K(\psi)$ and $N_K(y_0)$ denote the normal cones to K at ψ and y_0, respectively; for example, $N_K(\psi) = \{w \in \mathcal{H} : (w, y - \psi) \leq 0 \text{ for all } y \in K\}$. Note also that $K = \overline{D(\phi)} = D(\phi)$, where ϕ (defined by (2.8)) corresponds to β given by (2.18).

Remark 2.1. While for semilinear parabolic equations (in Theorem 2.1), $\overline{D(\phi)} = \mathcal{H}$ and therefore all points of $\overline{D(\phi)}$ are interior (consequently, in (2.15), (2.16), $\partial_y V(t,\cdot)$ is just Clarke's generalized gradient), in the case of the parabolic obstacle problem (of Theorem 2.2), $\overline{D(\phi)} = \{y \in L^2(\Omega) : y \geq \psi \text{ a.e. in } \Omega\}$, and no point of $\overline{D(\phi)}$ is interior.

Remark 2.2. It would be interesting to see if similar results (to those above) can be obtained if we use other (possibly more intrinsic) notions of gradient of V (with respect to y) at the noninterior points of $\overline{D(\phi)}$. An alternative way to define $\partial_y V(t,y)$ is to consider as extension $\tilde{V}$ the function

$$\tilde{V}(t,y) = \begin{cases} V(t,y) & \text{if } y \in K, \\ +\infty & \text{if } y \notin K, \end{cases}$$

and as $\partial_y \tilde{V}(t,y)$, the subdifferential of $\tilde{V}$ with respect to y at (t,y) defined in [11] with the aid of the upper subderivative $h \mapsto \tilde{V}^{\uparrow}(t,y;h)$. It would also be useful to compare the results corresponding to various notions of gradient.

Let us give now some examples of parabolic variational inequalities covered by the abstract formulation (2.2) and satisfying (H1)–(H3). Let A_0 be the second-order elliptic differential operator defined by

$$A_0 y = -\sum_{i,j=1}^{N} \frac{\partial}{\partial x_i}\left(a_{ij}(x)\frac{\partial y}{\partial x_i}\right) + a_0(x)y,$$

where $a_{ij} \in C^1(\Omega), a_0 \in L^\infty(\Omega), a_{ij} = a_{ji}$ for all $i,j, a_0(x) \geq 0$ a.e. $x \in \Omega$ and, for some $\omega > 0$,

$$\sum_{i,j=1}^{N} a_{ij}(x)\xi_i\xi_j \geq \omega \sum_{i=1}^{N} |\xi_i|^2 \text{ for all } (\xi_1, \ldots, \xi_N) \in \mathbf{R}^N \text{ a.e. } x \in \Omega.$$

Consider the following mixed boundary value problem:

$$\begin{cases} \dfrac{\partial y}{\partial t}(t,x) + A_0 y(t,x) + \beta(y(t,x) - \psi(x)) \ni Bu(t) + f(t,x) \text{ a.e. } (t,x) \in Q, \\ \alpha_1 y + \alpha_2 \dfrac{\partial y}{\partial \nu} = 0 \text{ on } (0,T) \times \partial\Omega, \\ y(0,x) = y_0(x), \ x \in \Omega, \end{cases} \tag{2.25}$$

where β, B, f, and y_0 satisfy (H3)–(H6), $\psi \in H^2(\Omega)$, and $\alpha_1, \alpha_2 \geq 0$ with $\alpha_1 + \alpha_2 > 0$. By shifting the range of β, we may assume, without any loss of generality, that

$0 \in \beta(0)$. To interpret (2.25) as an evolution equation of the form (2.2), we have to specify the space $\mathcal{V}$ and the operator A: If $\alpha_2 \neq 0$, we take $\mathcal{V} = H^1(\Omega)$ and we define $A : \mathcal{V} \to \mathcal{V}'$ by

$$(Ay, z) = \sum_{i,j=1}^{N} \int_\Omega a_{ij} \frac{\partial y}{\partial x_i} \frac{\partial z}{\partial x_j}\, dx + \int_\Omega a_0 yz\, dx + \frac{\alpha_1}{\alpha_2} \int_{\partial\Omega} yz d\sigma \text{ for all } y, z \in \mathcal{V}. \tag{2.26}$$

If $\alpha_2 = 0$, take $\mathcal{V} = H_0^1(\Omega)$ and define $A : H_0^1(\Omega) \to H^{-1}(\Omega)$ by

$$(Ay, z) = \sum_{i,j=1}^{N} \int_\Omega a_{ij} \frac{\partial y}{\partial x_i} \frac{\partial z}{\partial x_j}\, dx + \int_\Omega a_0 yz\, dx \text{ for all } y, z \in H_0^1(\Omega). \tag{2.27}$$

We have $(Ay)(x) = (A_0 y)(x)$ a.e. $x \in \Omega$ for all $y \in D(A)$, where $D(A) = \{y \in H^2(\Omega) : \alpha_1 y + \alpha_2 \partial y/\partial\nu = 0 \text{ a.e. on } \partial\Omega\}$. In particular, $D(A) = H_0^1(\Omega) \cap H^2(\Omega)$ if $\alpha_2 = 0$. Obviously, for $\mathcal{V}$ and A defined as above, (H1) and (H2) hold. It remains to examine (2.6). It is easy to show (see [2, p. 137]) that, in the case when $\alpha_2 \neq 0$, the condition (2.6) is satisfied if one assumes in addition that

$$\left(\alpha_1 \psi + \alpha_2 \frac{\partial \psi}{\partial \nu}\right) \beta_\eta(y - \psi) \geq 0 \text{ a.e. on } \partial\Omega \text{ for all } y \in D(A) \text{ and } \eta > 0. \tag{2.28}$$

If $\alpha_2 = 0$, the condition (2.6) is satisfied if one has

$$\beta_\eta(-\psi) = 0 \text{ a.e. on } \partial\Omega \text{ for all } \eta > 0. \tag{2.29}$$

In the case of the parabolic obstacle problem (in which β is given by (2.18)), $\beta_\eta(r) = \eta^{-1} \min(r, 0)$, and, consequently, the conditions (2.28), (2.29) are satisfied if

$$\alpha_1 \psi + \alpha_2 \frac{\partial \psi}{\partial \nu} \leq 0 \text{ a.e. on } \partial\Omega,$$

respectively,

$$\psi \leq 0 \text{ a.e. on } \partial\Omega.$$

Remark 2.3. The additional hypothesis (H9), which assures the validity of (2.16) in Theorem 2.1, is automatically verified for β given by (2.18). Indeed, in this case $\phi = I_K$, where I_K is the indicator function of $K = \{y \in L^2(\Omega) : y \geq \psi \text{ a.e. in } \Omega\}$; therefore $\phi = 0$ on $D(\phi) = K$. As regards Theorem 2.1, if, for some $c_1 \geq 0$, $c_2 \in \mathbf{R}$, β satisfies also the growth condition

$$|\beta(r)| \leq c_1 |r| + c_2 \text{ for all } r \in \mathbf{R}$$

(in particular, if β is Lipschitz continuous on $\mathbf{R}$), then (H9) clearly holds. But this happens even for a sharper growth of β at ∞. Here is an example. Take (2.2) given by (2.25) as state equation with $N \leq 4$, $\beta(r) = r^3$, and $\alpha_2 = 0$. We have $\mathcal{V} = H_0^1(\Omega), D(\phi) = L^4(\Omega)$, and

$$\phi(y) = \frac{1}{4} \int_\Omega y^4(x)\, dx.$$

By Sobolev imbedding theorem, $H^1(\Omega) \subset L^4(\Omega)$ for $N \leq 4$, whence (H9) immediately follows.

Finally, combining (2.14) and (2.22) (after a previous use of [3, Prop. 2.1, p. 103]) with (2.15) and (2.23), respectively, we obtain the following direct consequences of Theorems 2.1 and 2.2, which state that every optimal control for the problem (P) is also a feedback optimal control.

THEOREM 2.3. *Let (u^*, y^*) be an arbitrary optimal pair of the control problem* (P) *where, as in Theorem* 2.1, *$\beta : \mathbf{R} \to \mathbf{R}$ is Lipschitz continuous on bounded subsets. Suppose that* (H1)–(H8) *hold. Then*

$$u^*(t) \in \partial h^*(-B^* \partial_y V(t, y^*(t))) \text{ a.e. } t \in (0,T).$$

THEOREM 2.4. *Under the assumptions of Theorem* 2.2, *if (u^*, y^*) is an arbitrary optimal pair of the problem* (P), *then*

$$u^*(t) \in \partial h^*(-B^*(\partial_y V(t, y^*(t)) + N_K(\psi))) \text{ a.e. } t \in (0,T).$$

Under the additional assumption (2.17), Theorem 2.3 was proved by V. Barbu [2, Thm. 5.6, p. 208].

3. Proofs of Theorems 2.1 and 2.2. Likewise as in [7] we shall construct an auxiliary optimal control problem by introducing a new control variable v into the control system (2.2). So we consider the following perturbed system:

$$\begin{cases} y' + Ay + \beta(y - \psi) \ni Bu + f + v, \\ y(0) = y^0. \end{cases} \tag{3.1}$$

For every $\delta > 0$, define the function $k_\delta : [0,T] \times \mathcal{H} \to \mathbf{R}$ by

$$k_\delta(t, v) = \sup\{(p, v) : p \in \partial_y V(t, y), |y - y^*(t)| \le \delta\}. \tag{3.2}$$

It is easy to see that $v \mapsto k_\delta(t, v)$ is convex on $\mathcal{H}$ and Lipschitz continuous on $\mathcal{H}$ uniformly with respect to $t \in [0,T]$ (by virtue of Proposition 2.1). So $\partial_v k_\delta(t, v)$ is well defined. Also, for every $v \in L^2(0,T;\mathcal{H})$, the function $t \mapsto k_\delta(t, v(t))$ is measurable (see [7, Lem. 8.1] and [6]); moreover, it belongs to $L^2(0,T)$.

Now let $0 < \delta' < \delta$. The following lemma is an expression of the dynamic programming principle, and it is the key of the proof (see [7, Lem. 8.4] for the finite-dimensional version).

LEMMA 3.1. *Suppose that* (H2)–(H5) (*except* (2.5)), (H7), *and* (H8) *hold and, in addition, $K = \overline{D(\phi)}$ is a* (*closed*) *convex cone in $\mathcal{H}$ with the vertex ψ. Let $u \in L^2(0,T;\mathcal{U})$, $v \in L^2(0,T;\mathcal{H})$, and $y^0 \in K$ such that $h(u) \in L^1(0,T)$, $v(t) \in K - \psi$ a.e. $t \in (0,T)$ and $|y(t) - y^*(t)| \le \delta'$ for all $t \in [0,T]$, where y is the solution of* (3.1) *corresponding to the given u, v and y^0. Then*

$$\int_0^T (h(u(t)) + g(y(t)))\, dt + \ell(y(T)) + \int_0^T k_\delta(t, -v(t))\, dt - V(0, y^0) \ge 0. \tag{3.3}$$

Proof. We shall prove Lemma 3.1 in several steps.

1. *Reduction to the case in which u and v are step functions.* We assert that it suffices to prove Lemma 3.1 for every triple of step functions $u : [0,T] \to \mathcal{U}$, $v : [0,T] \to \mathcal{H}$, $f : [0,T] \to \mathcal{H}$, which are constant on the same subintervals of the form $(k\theta, (k+1)\theta]$, $k = 0, 1, \dots, p-1$, such that $h(u) \in L^1(0,T)$, $v(t) \in K - \psi$, and $|y(t) - y^*(t)| \le \delta''$ for all $t \in [0,T]$, where y is the solution of (3.1) and $\delta' < \delta'' < \delta$.

Indeed, let us assume that we have proved Lemma 3.1 in this case. Then the general case will immediately follow if, for every u, v, y^0 as in the statement of Lemma 3.1, we construct two sequences of step functions $u_m : [0,T] \to \mathcal{U}, v_m : [0,T] \to \mathcal{H}$ taking constant values on $(k\theta_m, (k+1)\theta_m], k = 0, 1, \dots, p_m - 1$, such that $h(u_m) \in L^1(0,T), v_m(t) \in K - \psi$ for all $t \in [0,T]$, and

$$u_m \to u \text{ strongly in } L^2(0,T;\mathcal{U}), \tag{3.4}$$

$$\int_0^T h(u_m(t))\,dt \to \int_0^T h(u(t))\,dt, \tag{3.5}$$

$$v_m \to v \text{ strongly in } L^2(0,T;\mathcal{H}). \tag{3.6}$$

To see this, let y_m satisfy

$$\begin{cases} y_m' + Ay_m + \beta(y_m - \psi) \ni Bu_m + f_m + v_m \text{ a.e. in } (0,T), \\ y_m(0) = y^0, \end{cases}$$

where $f_m \to f$ strongly in $L^2(0,T;\mathcal{H})$. We have

$$y_m \to y \text{ strongly in } C([0,T];\mathcal{H}),$$

and, by uniform Lipschitz continuity of $v \mapsto k_\delta(t,v)$,

$$\int_0^T k_\delta(t, -v_m(t))\,dt \to \int_0^T k_\delta(t, -v(t))\,dt.$$

But for sufficiently large m, $|y_m(t) - y^*(t)| \le \delta''$ for all $t \in [0,T]$, whence, by virtue of our assumption,

$$\int_0^T (h(u_m(t)) + g(y_m(t)))\,dt + \ell(y_m(T)) + \int_0^T k_\delta(t, -v_m(t))\,dt - V(0,y^0) \ge 0.$$

Letting $m \to \infty$, we obtain the statement of Lemma 3.1 in the general case.

It remains only to indicate the construction of $\{u_m\}$, $\{v_m\}$. Clearly, there exist two sequences of step functions $\tilde{u}_m : [0,T] \to \mathcal{U}$, $\tilde{v}_m : [0,T] \to \mathcal{H}$, which are constant on $(k\theta_m, (k+1)\theta_m], k = 0, 1, \dots, p_m - 1$, such that $\tilde{u}_m \to u$ strongly in $L^2(0,T;\mathcal{U})$, $\tilde{v}_m \to v$ strongly in $L^2(0,T;\mathcal{H})$. Define the function u_m, v_m by

$$u_m(t) = (I + \lambda_m \partial h)^{-1} \tilde{u}_m(t) \text{ with } \lambda_m = \left(\int_0^T |\tilde{u}_m(s) - u(s)|^2\,ds \right)^{1/2},$$

$$v_m(t) = \left(I + \frac{1}{m} \partial I_{K-\psi} \right)^{-1} \tilde{v}_m(t)$$

for all $t \in [0,T]$, where, of course, $I_{K-\psi}$ is the indicator function of $K - \psi$. Obviously, u_m, v_m are step functions, $v_m(t) \in K - \psi$ for all $t \in [0,T]$, and by assumptions on $\tilde{u}_m, \tilde{v}_m$ we obtain (3.4) and (3.6). For the proof of (3.5) we refer to [9, Lem. 1].

2. *Approximation of the perturbed system.* Let u, v, and f be a triple of step functions as above, which are constant on $(k\theta, (k+1)\theta], k = 0, 1, \dots, p-1$ (do not forget that $v(t) \in K - \psi$ for all $t \in [0,T]$), and let y be the solution of (3.1) corresponding to these u, v, and y^0. By virtue of Proposition 7.1 from [7] (note that $t \mapsto k_\delta(t, -v(t))$ is

an essentially bounded function), we can choose $\tau \in (0,T)$ and a subsequence $\{N_j\}$ of the positive integers such that T/τ is an irrational number and

$$\sum_{i=m_j}^{n_j} \frac{T}{N_j} k_\delta \left(\tau + i\frac{T}{N_j}, -v\left(\tau + i\frac{T}{N_j}\right)\right) \to \int_0^T k_\delta(t, -v(t))\,dt \text{ as } j \to \infty, \tag{3.7}$$

where

$$m_j = \min\left\{i : \tau + i\frac{T}{N_j} > 0\right\}, \qquad n_j = \max\left\{i : \tau + i\frac{T}{N_j} < T\right\}.$$

Clearly, since T/τ is irrational, $\tau + iT/N_j$ cannot be either 0 or T.

Define $y_j : [0,T] \to \mathcal{H}$ as being the solution of

$$\begin{cases} y_j' + Ay_j + \beta(y_j - \psi) \ni Bu + f, \\ y_j(0) = y^0 \end{cases} \tag{3.8}$$

on the subinterval $[0, m_jT/N_j + \tau)$; the solution of

$$\begin{cases} y_j' + Ay_j + \beta(y_j - \psi) \ni Bu + f, \\ y_j(iT/N_j + \tau) = y_j(iT/N_j + \tau - 0) + \dfrac{T}{N_j} v(iT/N_j + \tau) \end{cases} \tag{3.9}$$

on the subinterval $[iT/N_j + \tau, (i+1)T/N_j + \tau), i = m_j, \ldots, n_j - 1$; and the solution of (3.9) but with $i = n_j$ on the subinterval $[n_jT/N_j + \tau, T]$. We shall show that for every $t \in [0,T]$

$$y_j(t) \to y(t) \text{ strongly in } \mathcal{H}. \tag{3.10}$$

Moreover, an uniform estimate holds at the points $t = iT/N_j + \tau$: For any $\eta > 0$, we can find a positive integer j_η such that if $j \geq j_\eta$, then

$$|y_j(iT/N_j + \tau) - y(iT/N_j + \tau)| < \eta \text{ for } i = m_j, \ldots, n_j. \tag{3.11}$$

To prove these, for every $j = 1, 2, \ldots$, consider the moments $t_j^{(0)}, t_j^{(1)}, \ldots, t_j^{(p)}$ and the positive integers $\nu_j^{(1)}, \nu_j^{(2)}, \ldots, \nu_j^{(p)}$ defined by

$$\begin{aligned} &t_j^{(k)} = t_j^{(k-1)} + \frac{T}{N_j} + \nu_j^{(k)} \frac{T}{N_j}, \qquad k = 1, 2, \ldots, p, \\ &t_j^{(0)} = (m_j - 1)\frac{T}{N_j} + \tau, \\ &t_j^{(k)} < k\theta < t_j^{(k)} + \frac{T}{N_j}, \qquad k = 1, 2, \ldots, p. \end{aligned}$$

Since T/τ is irrational, $t_j^{(k)}$ are well defined (because $k\theta$ cannot take the values $iT/N_j + \tau$). Obviously, $t_j^{(p)} = n_jT/N_j + \tau$. Next, for $k = 1, 2, \ldots, p$, define the operators $\mathcal{A}_k, \mathcal{B}_k$ by

$$\begin{aligned} &\mathcal{A}_k y = Ay + \beta(y - \psi) - Bu(k\theta) - f(k\theta), \qquad y \in D(A) \cap D(\partial\phi), \\ &\mathcal{B}_k y = -v(k\theta) \in -(K - \psi), y \in \mathcal{H}. \end{aligned}$$

Clearly, since K is a cone, if $y \in K$, $e^{-\mathcal{B}_k t}y = y + tv(k\theta)$ also belongs to K for $t \geq 0$, and so the expression $e^{-\mathcal{A}_k t}e^{-\mathcal{B}_k t}y$ makes sense. Therefore we may define the operators $T_k(t)$ with $t \geq 0$ like this:

$$T_k(t)y = e^{-\mathcal{A}_k t}e^{-\mathcal{B}_k t}y \text{ for } y \in K, k = 1, 2, \ldots, p.$$

Finally, denote by $S_k(t)$ the nonlinear semigroup generated by the operator $y \mapsto Ay + \beta(y - \psi) - Bu(k\theta) - f(k\theta) - v(k\theta)$.

Let $t \in (0, T]$ arbitrary but fixed. Let us denote by k_0 that integer for which $t \in (k_0\theta, (k_0 + 1)\theta]$. Define t_j and the positive integer ν_j by

$$t_j = t_j^{(k_0)} + \frac{T}{N_j} + \nu_j \frac{T}{N_j}, \quad t_j \leq t < t_j + \frac{T}{N_j}.$$

We set now the following notations:

$$\varepsilon_j = \frac{T}{N_j}, \quad \varepsilon_j^{(k)} = t_j^{(k-1)} + \frac{T}{N_j} - (k-1)\theta, \quad \overline{\varepsilon}_j^{(k)} = k\theta - t_j^{(k)}, \quad \theta_j^{(k)} = t_j^{(k)} - t_j^{(k-1)} - \frac{T}{N_j}.$$

We can write y_j (given by (3.8), (3.9)) as

$$y_j(t) = \begin{cases} e^{-\mathcal{A}_{k_0+1}(t-t_j)}e^{-\mathcal{B}_{k_0+1}\varepsilon_j}T_{k_0+1}\left(\dfrac{t_j - t_j^{(k_0)} - \varepsilon_j}{\nu_j}\right)^{\nu_j} e^{-\mathcal{A}_{k_0+1}\varepsilon_j^{(k_0+1)}} \\ \qquad \times \left(\displaystyle\prod_{k=1}^{k_0} e^{-\mathcal{A}_k\overline{\varepsilon}_j^{(k)}}e^{-\mathcal{B}_k\varepsilon_j}T_k\left(\frac{\theta_j^{(k)}}{\nu_j^{(k)}}\right)^{\nu_j^{(k)}} e^{-\mathcal{A}_k\varepsilon_j^{(k)}}\right) y^0 \text{ for } t \in (\theta, T], \\ e^{-\mathcal{A}_1(t-t_j)}e^{-\mathcal{B}_1\varepsilon_j}T_1\left(\dfrac{t_j - t_j^{(0)} - \varepsilon_j}{\nu_j}\right)^{\nu_j} e^{-\mathcal{A}_1\varepsilon_j^{(1)}} \text{ for } t \in (0, \theta]. \end{cases}$$

For simplicity we set

$$Y_j^{(k)} = e^{-\mathcal{A}_k\overline{\varepsilon}_j^{(k)}}e^{-\mathcal{B}_k\varepsilon_j}T_k\left(\frac{\theta_j^{(k)}}{\nu_j^{(k)}}\right)^{\nu_j^{(k)}} e^{-\mathcal{A}_k\varepsilon_j^{(k)}}, \qquad k = 1, 2, \ldots, p,$$

$$Y_j^{(k_0+1)}(t - k_0\theta) = e^{-\mathcal{A}_{k_0+1}(t-t_j)}e^{-\mathcal{B}_{k_0+1}\varepsilon_j}T_{k_0+1}\left(\frac{t_j - t_j^{(k_0)} - \varepsilon_j}{\nu_j}\right)^{\nu_j} e^{-\mathcal{A}_{k_0+1}\varepsilon_j^{(k_0+1)}},$$

$$Y_j^{(k+1)}(t - k\theta) = Y_j^{(k_0+1)}(t - k_0\theta)Y_j^{(k_0)} \cdots Y_j^{(k+1)}, \qquad k = 1, 2, \ldots, k_0 - 1.$$

Obviously, all the above operators are contractions. In order to estimate $|y_j(t) - y(t)|$, we shall write

(3.12)

$$
\begin{aligned}
&y_j(t)-y(t)\\
&=\sum_{k=1}^{k_0}\Bigg(Y_j^{(k+1)}(t-k\theta)Y_j^{(k)}y((k-1)\theta)\\
&\quad-\ Y_j^{(k+1)}(t-k\theta)e^{-\mathcal{A}_k\bar{\varepsilon}_j^{(k)}}e^{-\mathcal{B}_k\varepsilon_j}T_k\left(\frac{\theta_j^{(k)}}{\nu_j^{(k)}}\right)^{\nu_j^{(k)}}y((k-1)\theta)\\
&\quad+\ Y_j^{(k+1)}(t-k\theta)e^{-\mathcal{A}_k\bar{\varepsilon}_j^{(k)}}e^{-\mathcal{B}_k\varepsilon_j}T_k\left(\frac{\theta_j^{(k)}}{\nu_j^{(k)}}\right)^{\nu_j^{(k)}}y((k-1)\theta)\\
&\qquad\qquad-Y_j^{(k+1)}(t-k\theta)e^{-\mathcal{A}_k\bar{\varepsilon}_j^{(k)}}e^{-\mathcal{B}_k\varepsilon_j}S_k(\theta_j^{(k)})y((k-1)\theta)\\
&\quad+\ Y_j^{(k+1)}(t-k\theta)e^{-\mathcal{A}_k\bar{\varepsilon}_j^{(k)}}e^{-\mathcal{B}_k\varepsilon_j}y((k-1)\theta+\theta_j^{(k)})-Y_j^{(k+1)}(t-k\theta)e^{-\mathcal{A}_k\bar{\varepsilon}_j^{(k)}}e^{-\mathcal{B}_k\varepsilon_j}y(k\theta)\\
&\quad+\ Y_j^{(k+1)}(t-k\theta)e^{-\mathcal{A}_k\bar{\varepsilon}_j^{(k)}}e^{-\mathcal{B}_k\varepsilon_j}y(k\theta)-Y_j^{(k+1)}(t-k\theta)y(k\theta)\Bigg)\\
&\quad+\ Y_j^{(k_0+1)}(t-k_0\theta)y(k_0\theta)-e^{-\mathcal{A}_{k_0+1}(t-t_j)}e^{-\mathcal{B}_{k_0+1}\varepsilon_j}T_{k_0+1}\left(\frac{t_j-t_j^{(k_0)}-\varepsilon_j}{\nu_j}\right)^{\nu_j}y(k_0\theta)\\
&\quad+\ e^{-\mathcal{A}_{k_0+1}(t-t_j)}e^{-\mathcal{B}_{k_0+1}\varepsilon_j}T_{k_0+1}\left(\frac{t_j-t_j^{(k_0)}-\varepsilon_j}{\nu_j}\right)^{\nu_j}y(k_0\theta)\\
&\qquad\qquad-e^{-\mathcal{A}_{k_0+1}(t-t_j)}e^{-\mathcal{B}_{k_0+1}\varepsilon_j}S_{k_0+1}(t_j-t_j^{(k_0)}-\varepsilon_j)y(k_0\theta)\\
&\quad+\ e^{-\mathcal{A}_{k_0+1}(t-t_j)}e^{-\mathcal{B}_{k_0+1}\varepsilon_j}y(k_0\theta+t_j-t_j^{(k_0)}-\varepsilon_j)-e^{-\mathcal{A}_{k_0+1}(t-t_j)}e^{-\mathcal{B}_{k_0+1}\varepsilon_j}y(t)\\
&\quad+\ e^{-\mathcal{A}_{k_0+1}(t-t_j)}e^{-\mathcal{B}_{k_0+1}\varepsilon_j}y(t)-y(t)\ \text{for } t\in(\theta,T].
\end{aligned}
$$

If $t\in(0,\theta]$ (therefore $k_0=0$), then the corresponding expression for $y_j(t)-y(t)$ consists only of the last five lines of (3.12). Take $j\to\infty$ in (3.12). Since $\varepsilon_j,\varepsilon_j^{(k)},\bar{\varepsilon}_j^{(k)}$ tend to 0, $t_j^{(k)}\to k\theta, t_j\to t, \nu_j^{(k)}$ and ν_j tend to $+\infty$, and $\theta_j^{(k)}\to\theta$, we obtain (3.10). Here we have used the continuity at 0 of the functions $s\mapsto e^{-\mathcal{A}_k s}y((k-1)\theta)$ for $k=1,2,\dots,k_0+1, s\mapsto e^{-\mathcal{A}_k s}y(k\theta)$, and $s\mapsto e^{-\mathcal{B}_k s}y(k\theta)$ for $k=1,2,\dots,k_0$, $s\mapsto e^{-\mathcal{A}_{k_0+1}s}y(t)$, and $s\mapsto e^{-\mathcal{B}_{k_0+1}s}y(t)$; the uniform continuity of y; and a Trotter-type product formula due to Brézis and Pazy (see [4, Prop. 4.4]), and proved for multivalued operators (our case) by Y. Kobayashi in [8]; that is,

$$
\begin{aligned}
&T_k\left(\frac{s}{\nu_j^{(k)}}\right)^{\nu_j^{(k)}}y((k-1)\theta)\to S_k(s)y((k-1)\theta)\ \text{as}\ \nu_j^{(k)}\to\infty,\quad k=1,2,\dots,k_0,\\
&T_{k_0+1}\left(\frac{s}{\nu_j}\right)^{\nu_j}y(k_0\theta)\to S_{k_0+1}(s)y(k_0\theta)\ \text{as}\ \nu_j\to\infty,
\end{aligned}
$$

both uniformly in $s\in[0,T]$.

Now let $t=iT/N_j+\tau$. In this case $t_j=t$. According to (3.12), we shall obtain (3.11) as soon as we show that for any $\eta'>0$ there exits $j_{\eta'}>0$ such that, if $j\le j_{\eta'}$,

we have

$$\left| T_{k_0+1}\left(\frac{t_j - t_j^{(k_0)} - \varepsilon_j}{\nu_j}\right)^{\nu_j} y(k_0\theta) - S_{k_0+1}(t_j - t_j^{(k_0)} - \varepsilon_j)y(k_0\theta)\right| < \eta'$$
$$\text{for } \nu_j = 1, 2, \ldots, \theta_j^{(k_0+1)}/\varepsilon_j, \quad k_0 = 0, 1, \ldots, p-1.$$

(Note that $e^{-\mathcal{B}_{k_0+1}\varepsilon_j} y(t) - y(t) = \varepsilon_j v((k_0+1)\theta) \to 0$ uniformly in t as $j \to \infty$.) To this end, first, by the above-mentioned Trotter product formula, we choose a positive integer $\nu_{\eta'}$ such that if $\nu > \nu_{\eta'}$, then

$$|T_{k_0+1}(\varepsilon_j)^\nu y(k_0\theta) - S_{k_0+1}(\nu\varepsilon_j)y(k_0\theta)| < \eta', \qquad k_0 = 0, 1, \ldots, p-1. \tag{3.13}$$

Next choose $j_{\eta'}$ such that for $j > j_{\eta'}$

$$|T_{k_0+1}(\varepsilon_j)y(k_0\theta) - y(k_0\theta)| < \frac{\eta'}{2\nu_{\eta'}},$$

$$|S_{k_0+1}(\varepsilon_j)y(k_0\theta) - y(k_0\theta)| < \frac{\eta'}{2\nu_{\eta'}},$$

$k_0 = 0, 1, \ldots, p-1$. (Obviously, $j_{\eta'}$ depends on η' also via $\nu_{\eta'}$.) Hence, if $j > j_{\eta'}$, (3.13) holds also for $\nu \le \nu_{\eta'}$, therefore for all ν.

3. *The case when u and v are step functions.* The rest of the proof is similar to the proof of Lemma 8.4 from [7]. Using a variant of the dynamic programming principle (see [7, Lem. 8.3]) applied to the problem (P), we have

$$\int_0^{m_jT/N_j+\tau} (h(u(t)) + g(y_j(t)))\,dt + V(m_jT/N_j + \tau, y_j(m_jT/N_j + \tau - 0)) - V(0, y^0) \geq 0,$$

$$\int_{iT/N_j+\tau}^{(i+1)T/N_j+\tau} (h(u(t)) + g(y_j(t)))\,dt + V((i+1)T/N_j + \tau, y_j((i+1)T/N_j + \tau - 0)) - V(iT/N_j + \tau, y_j(iT/N_j + \tau)) \geq 0, \qquad i = m_j, \quad m_j + 1, \ldots, n_j - 1,$$

$$\int_{n_jT/N_j+\tau}^{T} (h(u(t)) + g(y_j(t)))\,dt + V(T, y_j(T)) - V(n_jT/N_j + \tau, y_j(n_jT/N_j + \tau)) \geq 0.$$

We can write the sum of all these inequalities as follows:

$$\int_0^T (h(u(t)) + g(y_j(t)))\,dt + V(T, y_j(T)) - V(0, y^0) - \sum_{i=m_j}^{n_j} (V(iT/N_j + \tau, y_j(iT/N_j + \tau)) - V(iT/N_j + \tau, y_j(iT/N_j + \tau - 0))) \geq 0. \tag{3.14}$$

But by the mean value theorem for generalized gradients (see [2, Cor. 1.2]), we have when $v(iT/N_j + \tau) \neq 0$

$$-\left(V\left(iT/N_j+\tau, y_j(iT/N_j+\tau-0)+\frac{T}{N_j}v(iT/N_j+\tau)\right)\right.$$
$$\left.-\ V(iT/N_j+\tau, y_j(iT/N_j+\tau-0))\right)$$
$$=\frac{T}{N_j}(p_j(iT/N_j+\tau), -v(iT/N_j+\tau)),$$

where

$$p_j(iT/N_j+\tau)\in\partial_y V(iT/N_j+\tau, z_j(iT/N_j+\tau)),$$
$$z_j(iT/N_j+\tau)=\lambda y_j(iT/N_j+\tau-0)+(1-\lambda)y_j(iT/N_j+\tau) \text{ for some } \lambda\in(0,1).$$

Since $|y(t)-y^*(t)|\le\delta''<\delta$ for all $t\in[0,T]$, by using (3.11), we obtain for j large enough

$$|y_j(iT/N_j+\tau-0)-y^*(iT/N_j+\tau)|\le\delta \text{ and } |y_j(iT/N_j+\tau)-y^*(iT/N_j+\tau)|\le\delta,$$

whence

$$|z_j(iT/N_j+\tau)-y^*(iT/N_j+\tau)|\le\delta, \qquad i=m_j,\dots,n_j.$$

Returning to (3.14), we have for sufficiently large j

$$\int_0^T (h(u(t))+g(y_j(t)))\,dt+\ell(y_j(T))-V(0,y^0)+\sum_{i=m_j}^{n_j}\frac{T}{N_j}k_\delta(iT/N_j+\tau,-v(iT/N_j+\tau))\ge 0.$$

Letting now $j\to\infty$, by Lebesgue dominated convergence theorem, (3.10) and (3.7) one obtains (3.3), which completes the proof of Lemma 3.1.

Remark 3.1. Obviously, in both our situations, $\overline{D(\phi)}$ is a (closed) convex cone in $\mathcal{H}$.

In other words, Lemma 3.1 states that $u^*, v^*\equiv 0$ and y_0 solve the following optimal control problem (remind that $0<\delta'<\delta$):

($\mathrm{P}_{\delta,\delta'}$) Minimize

$$\int_0^T (h(u(t))+g(y(t)))\,dt+\ell(y(T))+\int_0^T k_\delta(t,-v(t))\,dt-V(0,y^0)$$

over all $u\in L^2(0,T;\mathcal{U}), v\in L^2(0,T;\mathcal{H})$ with $v(t)\in K-\psi$ a.e. $t\in(0,T), y^0\in\mathcal{V}\cap D(\phi)$, where $y\in W^{1,2}([0,T];\mathcal{H})$ satisfies

$$\begin{cases} y'+Ay+\beta(y-\psi)\ni Bu+f+v \text{ a.e. in } (0,T),\\ y(0)=y^0, \end{cases}$$

and

$$|y(t)-y^*(t)|\le\delta' \text{ for all } t\in[0,T]. \tag{3.15}$$

But we can introduce the constraint on v and the state constraint (3.15) into the performance index. Indeed, for $\delta>0$, consider the function $I_\delta:[0,T]\times\mathcal{H}\to(-\infty,+\infty]$ defined by

$$I_\delta(t,y)=\begin{cases} 0 & \text{if } |y-y^*(t)|\le\dfrac{\delta}{2},\\ +\infty & \text{otherwise.}\end{cases}$$

Then, for $\delta' = \delta/2$, the problem $(P_{\delta,\delta'})$ is clearly equivalent with the following one:

(P_δ) Minimize

$$\begin{aligned}\int_0^T (h(u(t)) + g(y(t)))\,dt + \ell(y(T)) + \int_0^T k_\delta(t, -v(t))\,dt - V(0, y^0)\\ + \int_0^T I_{K-\psi}(v(t))\,dt + \int_0^T I_\delta(t, y(t))\,dt\end{aligned} \tag{3.16}$$

over all $u \in L^2(0,T;\mathcal{U}), v \in L^2(0,T;\mathcal{H}), y^0 \in \mathcal{V} \cap D(\phi)$, where $y \in W^{1,2}([0,T];\mathcal{H})$ satisfies

$$\begin{cases} y' + Ay + \beta(y - \psi) \ni Bu + f + v \text{ a.e. in } (0,T),\\ y(0) = y^0. \end{cases} \tag{3.17}$$

Suppose for the rest of the proof that the additional hypothesis (H9) holds (see Remark 2.3). If this is not the case, we impose on the initial state y^0 of the problem (P_δ) to be fixed, i.e., $y^0 = y_0$, the modifications which must be made being obvious.

As we have already mentioned in the introduction, the inclusions (2.15), (2.16) and (2.23), (2.24) will follow from a set of optimality conditions for (P_δ) as $\delta \to 0$. To this end, we associate with (P_δ) the following family of smooth (and penalized) problems:

$(P_{\delta,\eta})$ Minimize

$$\begin{aligned}\int_0^T (h(u(t)) + g_\eta(y(t)))\,dt + \ell_\eta(y(T)) + \int_0^T k_\delta(t, -v(t))\,dt - V_\eta(0, y^0)\\ + \int_0^T I_{K-\psi}(v(t))\,dt + \int_0^T I_{\delta,\eta}(t, y(t))\,dt\\ + \frac{1}{2}\int_0^T |u(t) - u^*(t)|^2\,dt + \frac{1}{2}\int_0^T |v(t)|^2\,dt\\ + \frac{1}{2}|V_\eta(0, y^0) - V_\eta(0, y_0)|^2 + \frac{1}{2}|y^0 - y_0|^2_{\mathcal{V}}\end{aligned} \tag{3.18}$$

over all $u \in L^2(0,T;\mathcal{U}), v \in L^2(0,T;\mathcal{H}), y^0 \in \mathcal{V} \cap D(\phi)$, where $y \in W^{1,2}([0,T];\mathcal{H})$ satisfies

$$\begin{cases} y' + Ay + \beta^\eta(y - \psi) = Bu + f + v \text{ a.e. in } (0,T),\\ y(0) = y^0. \end{cases} \tag{3.19}$$

Here $g_\eta, \ell_\eta, V_\eta$ are regularizations of g, ℓ, V, respectively (see [2, p. 28]), $I_{\delta,\eta}(t,\cdot)$ is the convex regularization of $I_\delta(t,\cdot)$, i.e., $I_{\delta,\eta}(t,y) = \inf\{|z-y|^2/2\eta : |z - y^*(t)| \le \delta/2\}$, and β^η is a certain regularization of β_η (see [2, p. 75]).

LEMMA 3.2. *Each of the problems* $(P_{\delta,\eta})$ *has at least one solution* $(u_{\delta,\eta}, v_{\delta,\eta}, y^0_{\delta,\eta}) \in L^2(0,T;\mathcal{U}) \times L^2(0,T;\mathcal{H}) \times (\mathcal{V} \cap D(\phi))$.

Proof. Let $\{(u_{\delta,\eta,m}, v_{\delta,\eta,m}, y^0_{\delta,\eta,m})\} \subset L^2(0,T;\mathcal{U}) \times L^2(0,T;\mathcal{H}) \times (\mathcal{V} \cap D(\phi))$ be a minimizing sequence for $(P_{\delta,\eta})$. For simplicity, we set $u_m = u_{\delta,\eta,m}, v_m = v_{\delta,\eta,m}$ and $y^0_m = y^0_{\delta,\eta,m}$. It is easy to see that

$$k_\delta(t,v) \ge -L|v|, (t,v) \in [0,T] \times \mathcal{H}, \tag{3.20}$$

where L is a nonnegative constant which depends only on the bounds of $t \mapsto |y^*(t)|$. Using (2.7), the boundedness from below by affine functions of g and ℓ, (3.20), and

the fact that $I_{K-\psi}$ and $I_{\delta,\eta}$ are nonnegative, we easily deduce that $\{u_m\}, \{v_m\}$, and $\{y_m^0\}$ are bounded in $L^2(0,T;\mathcal{U}), L^2(0,T;\mathcal{H})$, and $\mathcal{V}$, respectively. Hence, we find $(u_{\delta,\eta}, v_{\delta,\eta}, y_{\delta,\eta}^0) \in L^2(0,T;\mathcal{U}) \times L^2(0,T;\mathcal{H}) \times \mathcal{V}$ such that, on a subsequence of $\{m\}$, again denoted $\{m\}$, $u_m \to u_{\delta,\eta}$ weakly in $L^2(0,T;\mathcal{U})$, $v_m \to v_{\delta,\eta}$ weakly in $L^2(0,T;\mathcal{H})$, and $y_m^0 \to y_{\delta,\eta}^0$ weakly in $\mathcal{V}$ and strongly in $\mathcal{H}$ (because the inclusion $\mathcal{V} \subset \mathcal{H}$ is compact). Moreover, by hypothesis (H9) (which is verified also for β given by (2.18)) and the lower semicontinuity of ϕ, we see that $\phi(y_{\delta,\eta}^0) < +\infty$, that is, $y_{\delta,\eta}^0 \in D(\phi)$.

Now let y_m be the solution of (3.19) corresponding to $u = u_m, v = v_m$, and $y^0 = y_m^0$. We can rewrite (3.19) as

$$\begin{cases} y_m' + Ay_m + \beta_\eta(y_m - \psi) = Bu_m + f + v_m + \beta_\eta(y_m - \psi) - \beta^\eta(y_m - \psi), \\ y_m(0) = y_m^0. \end{cases} \tag{3.21}$$

Note that, by definition of β^η, $|\beta^\eta(r) - \beta_\eta(r)| \le 2\eta$ for all $r \in \mathbf{R}$ (see [2, p. 75]). Define

$$\phi_\eta(y) = \int_\Omega \int_0^{y(x)-\psi(x)} \beta_\eta(r)\, dr\, dx \text{ for all } y \in \mathcal{H}.$$

It is easy to see that ϕ_η is just the convex regularization of ϕ, i.e., $\phi_\eta(y) = \inf\{|z - y|^2/2\eta + \phi(z) : z \in \mathcal{H}\}$. Moreover, for every $y \in \mathcal{H}$, we have

$$\nabla \phi_\eta(y) = \beta_\eta(y - \psi) \text{ a.e. in } \Omega.$$

Fix $y^1 \in \mathcal{V} \cap D(\partial\phi)$. We multiply (scalarly in $\mathcal{H}$) (3.21) first by $y_m - y^1$ and then by y_m', and next we integrate on $[0,t]$. After some calculation (do not forget (2.4)), we obtain for every $t \in [0,T]$:

$$\begin{aligned} |y_m(t)| \le \Bigg(|y_m^0| + \int_0^t (|Bu_m(s)| + |v_m(s)| + |f(s)|)\, ds \\ + \ t(|Ay^1| + |(\partial\phi)^0(y^1)| + 2\eta(\mathrm{meas}\Omega)^{1/2}) \Bigg) e^{\alpha t} + (1 + e^{\alpha t})|y^1| \end{aligned}$$

and

$$\begin{aligned} &\frac{1}{2}\int_0^t |y_m'(s)|^2\, ds + \frac{1}{2}\omega|y_m(t)|_{\mathcal{V}}^2 + \phi_\eta(y_m(t)) \le \frac{1}{2}(Ay_m^0, y_m^0) + \phi_\eta(y_m^0) \\ &+\frac{1}{2}\alpha|y_m(t)|^2 + 2\int_0^t (|Bu_m(s)|^2 + |v_m(s)|^2 + |f(s)|^2)\, ds + 8t\eta^2 \mathrm{meas}\Omega. \end{aligned}$$

Here $|(\partial\phi)^0(y^1)| = \inf\{|z| : z \in \partial\phi(y^1)\}$. Using the boundedness in $\mathcal{V}$ of y_m^0 and the hypothesis (H9), we see that (Ay_m^0, y_m^0) and $\phi_\eta(y_m^0)$ ($\phi_\eta(y_m^0) \le \phi(y_m^0)$) are bounded. Thus, in view of the above two estimates, we may apply the Arzelà–Ascoli theorem (do not forget that the inclusion $\mathcal{V} \subset \mathcal{H}$ is compact) to conclude that, on a subsequence,

$$y_{\delta,\eta,m} \to \overline{y}_{\delta,\eta} \text{ strongly in } C([0,T];\mathcal{H}) \text{ as } m \to \infty. \tag{3.22}$$

Denote by $y_{\delta,\eta}$ the solution of the equation (with initial condition)

$$\begin{cases} y_{\delta,\eta}' + Ay_{\delta,\eta} + \beta^\eta(y_{\delta,\eta} - \psi) = Bu_{\delta,\eta} + f + v_{\delta,\eta}, \\ y_{\delta,\eta}(0) = y_{\delta,\eta}^0. \end{cases} \tag{3.23}$$

Subtracting (3.23) from (3.21) and multiplying the difference by $y_{\delta,\eta,m}-y_{\delta,\eta}$, we have (after an integration on $[0,t]$)

$$\frac{1}{2}|y_{\delta,\eta,m}(t)-y_{\delta,\eta}(t)|^2 \le \frac{1}{2}|y^0_{\delta,\eta,m}-y^0_{\delta,\eta}|^2+\alpha\int_0^t |y_{\delta,\eta,m}(s)-y_{\delta,\eta}(s)|^2\,ds$$
$$+\int_0^t (B(u_{\delta,\eta,m}(s)-u_{\delta,\eta}(s))+v_{\delta,\eta,m}(s)-v_{\delta,\eta}(s), y_{\delta,\eta,m}(s)-y_{\delta,\eta}(s))\,ds.$$

Letting $m\to\infty$ and taking (3.22) into account, we obtain

$$y_{\delta,\eta,m}\to y_{\delta,\eta} \text{ strongly in } C([0,T];\mathcal{H}).$$

Finally, by standard arguments, it follows that $(u_{\delta,\eta}, v_{\delta,\eta}, y^0_{\delta,\eta})$ solves the problem $(\mathrm{P}_{\delta,\eta})$, thereby completing the proof.

Fix now $\delta>0$. The following result is an effect of the penalization terms.

LEMMA 3.3. *Let $(u_{\delta,\eta}, v_{\delta,\eta}, y^0_{\delta,\eta})\in L^2(0,T;\mathcal{U})\times L^2(0,T;\mathcal{H})\times(\mathcal{V}\cap D(\phi))$ be a solution for the problem $(\mathrm{P}_{\delta,\eta})$. Then we have as $\eta\to 0$*

$$u_{\delta,\eta}\to u^* \textit{ strongly in } L^2(0,T;\mathcal{U}),$$
$$v_{\delta,\eta}\to v^*\equiv 0 \textit{ strongly in } L^2(0,T;\mathcal{H}),$$
$$y^0_{\delta,\eta}\to y_0 \textit{ strongly in } \mathcal{V}.$$

Proof. Let us denote by $J_{\delta,\eta}(u,v,y^0)$ the functional (3.18) and by $J_\delta(u,v,y^0)$ the functional (3.16). Also, we denote by $\tilde{J}_{\delta,\eta}(u,v,y^0)$ the functional obtained from (3.18) by eliminating the penalization terms $\frac{1}{2}\int_0^T|u(t)-u^*(t)|^2\,dt$, $\frac{1}{2}\int_0^T|v(t)|^2\,dt$, $\frac{1}{2}|V_\eta(0,y^0)-V_\eta(0,y_0)|^2$, and $\frac{1}{2}|y^0-y_0|^2_{\mathcal{V}}$.

Let $y^*_{\delta,\eta}$ be the solution of (3.19) corresponding to $u=u^*$, $v=v^*\equiv 0$, and $y^0=y_0$. Arguing as below, one shows that $y^*_{\delta,\eta}\to y^*$ strongly in $C([0,T];\mathcal{H})$ as $\eta\to 0$. At the same time one observes that $I_{\delta,\eta}(t,y^*_{\delta,\eta}(t))=0$ when $|y^*_{\delta,\eta}(t)-y^*(t)|\le\delta/2$. Taking these into account, for each $\delta>0$, we find $\eta_\delta>0$ such that if $\eta\le\eta_\delta$,

$$J_{\delta,\eta}(u_{\delta,\eta},v_{\delta,\eta},y^0_{\delta,\eta})\le J_{\delta,\eta}(u^*,0,y^0)\le 1. \tag{3.24}$$

Now, as in the proof of the preceding lemma, there exists $M>0$ (which can be chosen independent of δ) such that if $\eta\le\eta_\delta$,

$$\left(\int_0^T|u_{\delta,\eta}(t)|^2\,dt\right)^{1/2}\le M,\qquad \left(\int_0^T|v_{\delta,\eta}(t)|^2\,dt\right)^{1/2}\le M,\qquad |y^0_{\delta,\eta}|_{\mathcal{V}}\le M.$$

Consequently, there exists $(u_\delta,v_\delta,y^0_\delta)\in L^2(0,T;\mathcal{U})\times L^2(0,T;\mathcal{H})\times(\mathcal{V}\cap D(\phi))$ such that, on a subsequence of $\{\eta\}$,

$$u_{\delta,\eta}\to u_\delta \text{ weakly in } L^2(0,T;\mathcal{U}),$$
$$v_{\delta,\eta}\to v_\delta \text{ weakly in } L^2(0,T;\mathcal{H}),$$
$$y^0_{\delta,\eta}\to y^0_\delta \text{ weakly in } \mathcal{V}.$$

Next, let $y_{\delta,\eta}$ be the solution of (3.23) (where, of course, $u_{\delta,\eta}$, $v_{\delta,\eta}$, and $y^0_{\delta,\eta}$ are those from the statement of this lemma). We shall show that if the above convergences hold, then $y_{\delta,\eta}$ converges (possibly on a subsequence) to the solution of (3.17)

corresponding to $u = u_\delta$, $v = v_\delta$, $y^0 = y^0_\delta$. As in the proof of Lemma 3.2, one obtains

$$|y_{\delta,\eta}(t)| \ \leq \ \text{const. and} \ \int_0^T |y'_{\delta,\eta}(s)|^2 \, ds + |y_{\delta,\eta}(t)|^2_{\mathcal{V}} \ \leq \ \text{const. for } t \in [0,T],$$

where the constants are independent of η (and even of δ). Multiplying (3.23) by $\nabla\phi_\eta(y_{\delta,\eta}(t))$, we also obtain (after an integration on $[0,T]$)

$$\int_0^T |\nabla\phi_\eta(y_{\delta,\eta}(s))|^2 \, ds \leq \ \text{const.},$$

with the constant as above. Thus we have as $\eta \to 0$

$$y_{\delta,\eta} \to y_\delta \text{ strongly in } C([0,T];\mathcal{H}) \text{ and weakly in } W^{1,2}([0,T];\mathcal{H})$$

$$(\text{therefore } y'_{\delta,\eta} \to y'_\delta \text{ weakly in } L^2(0,T;\mathcal{H})),$$

$$\nabla\phi_\eta(y_{\delta,\eta}) \to \xi_\delta \text{ weakly in } L^2(0,T;\mathcal{H}).$$

Hence,

$$Ay_{\delta,\eta} \to Bu_\delta + f + v_\delta - y'_\delta - \xi_\delta \text{ weakly in } L^2(0,T;\mathcal{H}).$$

But since $Ay_{\delta,\eta} \to Ay_\delta$ weakly in $L^2(0,T;\mathcal{V}')$ (because $y_{\delta,\eta} \to y_\delta$ weakly in $L^2(0,T;\mathcal{V})$), we have

$$y'_\delta + Ay_\delta + \xi_\delta = Bu_\delta + f + v_\delta \text{ a.e. in } (0,T).$$

Now we define the lower semicontinuous convex function $\Phi : L^2(0,T;\mathcal{H}) \to (-\infty, +\infty]$ by

$$\Phi(y) = \int_0^T \phi(y(t)) \, dt.$$

We have

$$\partial\Phi(y) = \{w \in L^2(0,T;\mathcal{H}) : w(t) \in \partial\phi(y(t)) \text{ a.e. } t \in (0,T)\}$$

and, if we denote by Φ_η the convex regularization of Φ,

$$\nabla\Phi_\eta(y_{\delta,\eta}) = \nabla\phi_\eta(y_{\delta,\eta}) \text{ a.e. in } (0,T).$$

Since $y_{\delta,\eta} \to y_\delta$ strongly in $L^2(0,T;\mathcal{H})$ and $\nabla\Phi_\eta(y_{\delta,\eta}) \to \xi_\delta$ weakly in $L^2(0,T;\mathcal{H})$, by a well-known result (see [2, Thm. 1.2]) $\xi_\delta \in \partial\Phi(y_\delta)$, whence, as we have stated above,

$$\begin{cases} y'_\delta + Ay_\delta + \partial\phi(y_\delta) \ni Bu_\delta + f + v_\delta \text{ a.e. in } (0,T), \\ y_\delta(0) = y^0_\delta. \end{cases}$$

We still need the following semicontinuity property:

$$\liminf_{\eta \to 0} \int_0^T I_{\delta,\eta}(t, y_{\delta,\eta}(t)) \, dt \geq \int_0^T I_\delta(t, y_\delta(t)) \, dt. \tag{3.25}$$

To see this, let us observe that, by virtue of (3.24), $\int_0^T I_{\delta,\eta}(t, y_{\delta,\eta}(t))\,dt$ is bounded with respect to η. Hence, by a well-known expression of the convex regularization (see [3, p. 121]), it readily follows that

$$(I + \eta\partial I_\delta(t,\cdot))^{-1} y_{\delta,\eta}(t) - y_{\delta,\eta}(t) \to 0 \text{ strongly in } L^2(0,T;\mathcal{H}) \text{ as } \eta \to 0,$$

whence, by the lower semicontinuity of $y \mapsto I_\delta(t,y)$, we derive (3.25).

Now, using the convergence of $\{u_{\delta,\eta}\}, \{v_{\delta,\eta}\}$, and $\{y_{\delta,\eta}\}$ in conjunction with (3.25) and the weak lower semicontinuity of $u \mapsto \int_0^T (h(u(t)) + \frac{1}{2}|u(t) - u^*(t)|^2)\,dt$, $v \mapsto \int_0^T (k_\delta(t,-v(t)) + I_{K-\psi}(v(t)) + \frac{1}{2}|v(t)|^2)\,dt$, and $y^0 \mapsto \frac{1}{2}|y^0 - y_0|^2_{\mathcal{V}}$, we obtain the following chain of inequalities:

$$\begin{aligned}
&\liminf_{\eta\to 0} J_{\delta,\eta}(u_{\delta,\eta}, v_{\delta,\eta}, y^0_{\delta,\eta}) \geq \liminf_{\eta\to 0} \tilde{J}_{\delta,\eta}(u_{\delta,\eta}, v_{\delta,\eta}, y^0_{\delta,\eta}) \\
&\geq J_\delta(u_\delta, v_\delta, y^0_\delta) \geq J_\delta(u^*, 0, y_0) = \lim_{\eta\to 0} J_{\delta,\eta}(u^*, 0, y_0) \\
&\geq \limsup_{\eta\to 0} J_{\delta,\eta}(u_{\delta,\eta}, v_{\delta,\eta}, y^0_{\delta,\eta}) \geq \limsup_{\eta\to 0} \tilde{J}_{\delta,\eta}(u_{\delta,\eta}, v_{\delta,\eta}, y^0_{\delta,\eta}).
\end{aligned}$$

Consequently,

$$\lim_{\eta\to 0} J_{\delta,\eta}(u_{\delta,\eta}, v_{\delta,\eta}, y^0_{\delta,\eta}) = \lim_{\eta\to 0} \tilde{J}_{\delta,\eta}(u_{\delta,\eta}, v_{\delta,\eta}, y^0_{\delta,\eta}) = J_\delta(u^*, 0, y_0),$$

and hence the conclusion of the lemma follows.

Remark 3.2. As a by-product of the preceding proof we have obtained the following statement: If

$$(u_{\delta,\eta}, v_{\delta,\eta}, y^0_{\delta,\eta}) \to (u_\delta, v_\delta, y^0_\delta) \text{ weakly in } L^2(0,T;\mathcal{U}) \times L^2(0,T;\mathcal{H}) \times \mathcal{V} \text{ as } \eta \to 0,$$

then, on a subsequence of $\{\eta\}$,

$$y_{\delta,\eta} \to y_\delta \text{ strongly in } C([0,T];\mathcal{H})$$

and

$$\beta_\eta(y_{\delta,\eta} - \psi) \to \xi \text{ weakly in } L^2(0,T;\mathcal{H}),$$

where y_δ and ξ satisfy

$$\begin{cases} y'_\delta + Ay_\delta + \xi = Bu_\delta + f + v_\delta \text{ a.e. in } (0,T), \\ y_\delta(0) = y^0_\delta, \end{cases}$$

and

$$\xi \in \beta(y_\delta - \psi) \text{ a.e. in } (0,T).$$

Remark 3.3. One can obtain in addition

$$y_{\delta,\eta} \to y_\delta \text{ strongly in } L^2(0,T;\mathcal{V}) \text{ as } \eta \to 0$$

(see [2, Thm. 4.5]).

In order to obtain the needed optimality conditions for $(\mathrm{P}_{\delta,\eta})$, we shall compare the optimal value with the values of $J_{\delta,\eta}$ corresponding to $u = u_{\delta,\eta} + \lambda\overline{u}, v = v_{\delta,\eta} + \lambda\overline{v}$,

and $y^0 = y^0_{\delta,\eta} + \lambda\overline{y}^0$, where $0 < \lambda < 1$ and $\overline{u} \in L^2(0,T;\mathcal{U}), \overline{v} \in L^2(0,T;\mathcal{H}), \overline{y}^0 \in (\mathcal{V} \cap D(\phi)) - y^0_{\delta,\eta}$ are arbitrary. We have

(3.26)
$$J_{\delta,\eta}(u_{\delta,\eta} + \lambda\overline{u}, v_{\delta,\eta} + \lambda\overline{v}, y^0_{\delta,\eta} + \lambda\overline{y}^0) - J_{\delta,\eta}(u_{\delta,\eta}, v_{\delta,\eta}, y^0_{\delta,\eta}) \geq 0$$
$$\text{for all } \lambda \in (0,1) \text{ and } (\overline{u},\overline{v},\overline{y}^0) \in L^2(0,T;\mathcal{U}) \times L^2(0,T;\mathcal{H}) \times ((\mathcal{V} \cap D(\phi)) - y^0_{\delta,\eta}).$$

(Note that $y^0_{\delta,\eta} + \lambda\overline{y}^0 \in \mathcal{V} \cap D(\phi)$ since $\mathcal{V} \cap D(\phi)$ is convex.)

Let $y_{\delta,\eta,\lambda}$ be the solution of (3.19) corresponding to $u = u_{\delta,\eta} + \lambda\overline{u}, v = v_{\delta,\eta} + \lambda\overline{v}$, and $y^0 = y^0_{\delta,\eta} + \lambda\overline{y}^0$. It is easy to show that

$$\frac{1}{\lambda}(y_{\delta,\eta,\lambda} - y_{\delta,\eta}) \to z_{\delta,\eta} \text{ strongly in } C([0,T];\mathcal{H}) \text{ as } \eta \to 0,$$

where $z_{\delta,\eta}$ is the solution of the following equation (with initial condition):

$$\begin{cases} z' + Az + (\beta^\eta)'(y_{\delta,\eta} - \psi)z = B\overline{u} + \overline{v} \text{ a.e. in } (0,T), \\ z(0) = \overline{y}^0. \end{cases} \tag{3.27}$$

Divide (3.26) by λ and then let $\lambda \to 0$. Since $I_{\delta,\eta}(t, y_{\delta,\eta,\lambda}(t)) = I_{\delta,\eta}(t, y_{\delta,\eta}(t)) = 0$ for all $t \in [0,T]$ if $\eta > 0$ and $\lambda > 0$ are sufficiently small, we obtain for η small enough

$$\begin{aligned} &\int_0^T h'(u_{\delta,\eta}(t); \overline{u}(t))\,dt + \int_0^T (\nabla g_\eta(y_{\delta,\eta}(t)), z_{\delta,\eta}(t))\,dt \\ &+ (\nabla \ell_\eta(y_{\delta,\eta}(T)), z_{\delta,\eta}(T)) + \int_0^T k'_\delta(t, -v_{\delta,\eta}(t); -\overline{v}(t))\,dt \\ &- (\nabla_y V_\eta(0, y^0_{\delta,\eta}), \overline{y}^0) + \int_0^T I'_{K-\psi}(v_{\delta,\eta}(t); \overline{v}(t))\,dt \\ &+ \int_0^T (u_{\delta,\eta}(t) - u^*(t), \overline{u}(t))\,dt + \int_0^T (v_{\delta,\eta}(t), \overline{v}(t))\,dt \\ &+ ((V_\eta(0, y^0_{\delta,\eta}) - V_\eta(0, y_0)) \cdot \nabla_y V_\eta(0, y^0_{\delta,\eta}), \overline{y}^0) + (y^0_{\delta,\eta} - y_0, \overline{y}^0)_{\mathcal{V}} \geq 0 \\ &\text{for all } (\overline{u},\overline{v},\overline{y}^0) \in L^2(0,T;\mathcal{U}) \times L^2(0,T;\mathcal{H}) \times ((\mathcal{V} \cap D(\phi)) - y^0_{\delta,\eta}), \end{aligned} \tag{3.28}$$

where $h'(u_{\delta,\eta}(t); \overline{u}(t))$ and $k'_\delta(t, -v_{\delta,\eta}(t); -\overline{v}(t)), I'_{K-\psi}(v_{\delta,\eta}(t); \overline{v}(t))$ denote the directional derivatives of h and $v \mapsto k_\delta(t,v), I_{K-\psi}$ at $u_{\delta,\eta}(t)$ and $-v_{\delta,\eta}(t)$ in the directions $\overline{u}(t)$ and $-\overline{v}(t)$, respectively.

Next, define $p_{\delta,\eta}$ as the unique solution in $C([0,T];\mathcal{H}) \cap L^2(0,T;\mathcal{V})$ (with $p'_{\delta,\eta} \in L^2(0,T;\mathcal{V}')$) of the following equation (with initial condition):

$$\begin{cases} p' - Ap - (\beta^\eta)'(y_{\delta,\eta} - \psi)p = \nabla g_\eta(y_{\delta,\eta}) \text{ a.e. in } (0,T), \\ p(T) = -\nabla \ell_\eta(y_{\delta,\eta}(T)). \end{cases} \tag{3.29}$$

Some calculation in (3.28) involving (3.27) and (3.29) together with an integration by

parts gives for sufficiently small $\eta > 0$

$$\begin{aligned}
&\int_0^T (h'(u_{\delta,\eta};\overline{u}) + (-B^*p_{\delta,\eta} + u_{\delta,\eta} - u^*, \overline{u}))\,dt \\
&+ \int_0^T (k'_\delta(t, -v_{\delta,\eta}; -\overline{v}) + I'_{K-\psi}(v_{\delta,\eta};\overline{v}) + (-p_{\delta,\eta} + v_{\delta,\eta}, \overline{v}))\,dt \\
&+ (-p_{\delta,\eta}(0) - \nabla_y V_\eta(0, y^0_{\delta,\eta}) + (V_\eta(0, y^0_{\delta,\eta}) - V_\eta(0, y_0)) \cdot \nabla_y V_\eta(0, y^0_{\delta,\eta}), \overline{y}^0) \\
&+ (y^0_{\delta,\eta} - y_0, \overline{y}^0)_{\mathcal{V}} \geq 0 \\
&\qquad \text{for all } (\overline{u}, \overline{v}, \overline{y}^0) \in L^2(0,T;\mathcal{U}) \times L^2(0,T;\mathcal{H}) \times ((\mathcal{V} \cap D(\phi)) - y^0_{\delta,\eta}).
\end{aligned}$$

So, using [3, Prop. 2.3, p. 106], we infer for $\eta > 0$ small enough

$$B^*p_{\delta,\eta}(t) + u^*(t) - u_{\delta,\eta}(t) \in \partial h(u_{\delta,\eta}(t)) \text{ a.e. } t \in (0,T), \tag{3.30}$$

$$-p_{\delta,\eta}(t) + v_{\delta,\eta}(t) \in \partial_v k_\delta(t, -v_{\delta,\eta}(t)) + \partial I_{K-\psi}(v_{\delta,\eta}(t)) \text{ a.e. } t \in (0,T), \tag{3.31}$$

$$\begin{aligned}
&(-p_{\delta,\eta}(0) - \nabla_y V_\eta(0, y^0_{\delta,\eta}) + (V_\eta(0, y^0_{\delta,\eta}) - V_\eta(0, y_0)) \cdot \nabla_y V_\eta(0, y^0_{\delta,\eta}), \overline{z}^0 - y^0_{\delta,\eta}) \\
&\qquad + (y^0_{\delta,\eta} - y_0, \overline{z}^0 - y^0_{\delta,\eta})_{\mathcal{V}} \geq 0 \text{ for all } \overline{z}^0 \in \mathcal{V} \cap D(\phi).
\end{aligned} \tag{3.32}$$

Now, we shall take limits in (3.30)–(3.32) as $\delta \to 0$, $\eta \to 0$. To this end, we use Lemma 3.3. Thus, for each $\delta > 0$, we choose $\eta_\delta > 0$ such that

$$\int_0^T |u_{\delta,\eta_\delta}(t) - u^*(t)|^2\,dt < \delta, \ \int_0^T |v_{\delta,\eta_\delta}(t)|^2\,dt < \delta, \ |y^0_{\delta,\eta_\delta} - y_0|_{\mathcal{V}} < \delta. \tag{3.33}$$

Obviously, we can choose η_δ such that, in addition, $\lim_{\delta\to 0} \eta_\delta = 0$. For simplicity, set $u_{\delta,\eta_\delta} = u_\delta$, $v_{\delta,\eta_\delta} = v_\delta$, and $y^0_{\delta,\eta_\delta} = y^0_\delta$. Let $y_\delta = y_{\delta,\eta_\delta}$ be the solution of (3.19) corresponding to $\eta = \eta_\delta$, $u = u_\delta$, $v = v_\delta$, and $y^0 = y^0_\delta$. Since, by (3.33), we have as $\delta \to 0$

$$u_\delta \to u^* \text{ strongly in } L^2(0,T;\mathcal{U}), \tag{3.34}$$

$$v_\delta \to 0 \text{ strongly in } L^2(0,T;\mathcal{H}), \tag{3.35}$$

$$y^0_\delta \to y_0 \text{ strongly in } \mathcal{V}, \tag{3.36}$$

likewise as in the proof of Lemma 3.3 (see also Remark 3.2), one obtains on a subsequence of $\{\delta\}$:

$$y_\delta \to y^* \text{ strongly in } C([0,T];\mathcal{H}), \tag{3.37}$$

$$\begin{aligned}
&\beta_{\eta_\delta}(y_\delta - \psi) \to \xi \text{ weakly in } L^2(0,T;\mathcal{H}), \\
&\text{where } \xi = Bu^* + f - y^{*'} - Ay^* \in \beta(y^* - \psi) \text{ a.e. in } (0,T).
\end{aligned} \tag{3.38}$$

Also we have

$$V_{\eta_\delta}(0, y^0_\delta) - V_{\eta_\delta}(0, y_0) \to 0 \text{ as } \delta \to 0. \tag{3.39}$$

Let p_δ be the solution of (3.29) corresponding to $\eta = \eta_\delta$. The proof of the following lemma is given in [2, Lem. 5.3]. (Note that only here one needs the assumption (2.5).)

LEMMA 3.4. *For all $\delta > 0$, we have*

$$|p_\delta(t)| \le \text{const. } for \text{ all } t \in [0,T],$$
$$\int_0^T |p_\delta(t)|_{\mathcal{V}}^2 \, dt \le \text{const.},$$
$$\int_Q |(\beta^{\eta_\delta})'(y_\delta - \psi)p_\delta| \, dx \, dt \le \text{const.},$$

where the constants are independent of δ.

By Lemma 3.4, arguing as in [2, p. 181], we find $p \in BV([0,T];\mathcal{Y}') \cap L^\infty(0,T;\mathcal{H}) \cap L^2(0,T;\mathcal{V})$ and $\mu \in (L^\infty(Q))'$ such that, on a subsequence of $\{\delta\}$, $p_\delta(t) \to p(t)$ strongly in $\mathcal{Y}'$ for every $t \in [0,T]$ and

$$p_\delta \to p \text{ weak star in } L^\infty(0,T;\mathcal{H}) \text{ and weakly in } L^2(0,T;\mathcal{V}), \tag{3.40}$$

$$p_\delta \to p \text{ strongly in } L^2(0,T;\mathcal{H}), \tag{3.41}$$

$$(\beta^{\eta_\delta})'(y_\delta - \psi)p_\delta \to \mu \text{ weak star in } (L^\infty(Q))'. \tag{3.42}$$

Using (3.37) in conjunction with (H8), we obtain on a subsequence of $\{\delta\}$:

$$\nabla g_{\eta_\delta}(y_\delta) \to \gamma \text{ weak star in } L^\infty(0,T;\mathcal{H}). \tag{3.43}$$

Next, an application of [2, Lem. 5.4] (do not forget (3.37)) gives

$$\gamma(t) \in \partial g(y^*(t)) \text{ a.e. } t \in (0,T). \tag{3.44}$$

Similarly,

$$\nabla \ell_{\eta_\delta}(y_\delta(T)) = -p_\delta(T) \to -p(T) \text{ weakly in } \mathcal{H} \text{ (and strongly in } \mathcal{Y}').$$

Applying this time [2, Prop. 1.12], we obtain (2.13) (or (2.21)).

Likewise as above (take (3.36) into account),

$$\nabla_y V_{\eta_\delta}(0, y_\delta^0) \to q \text{ weakly in } \mathcal{H}, \text{ where } q \in \partial_y V(0, y_0).$$

By Lemma 3.4, we have on a subsequence of $\{\delta\}$

$$p_\delta(0) \to p(0) \text{ weakly in } \mathcal{H} \text{ (and strongly in } \mathcal{Y}').$$

Hence, as $\delta \to 0$, (3.32) (with $\eta = \eta_\delta$) becomes (do not forget (3.36), (3.39))

$$(p(0) + q, \overline{z}^0 - y_0) \le 0 \text{ for all } \overline{z}^0 \in \mathcal{V} \cap D(\phi).$$

Since $\mathcal{V} \cap D(\phi)$ is dense in $K = \overline{D(\phi)}$, the above inequality holds for all $\overline{z}^0 \in K$. But this means (2.16) or (2.24). (In the case of Theorem 2.1, $K = \mathcal{H}$; therefore $I_K \equiv 0$ and $\partial I_K(y_0) = \{0\}$.)

Now letting $\delta \to 0$ in (3.29) with $\eta = \eta_\delta$, by (3.40)–(3.44), it follows that

$$p' - Ap - \mu \in \partial g(y^*) \text{ a.e. in } (0,T),$$

where $p' - Ap - \mu = \gamma \in L^\infty(0,T;\mathcal{H})$; but this is just (2.11). (Recall that p' is considered in the sense of $\mathcal{V}'$-valued distributions.)

Passing to the limit also in (3.30) with $\eta = \eta_\delta$ as $\delta \to 0$, since $\partial h : \mathcal{U} \to \mathcal{U}$ is demiclosed, by (3.34), (3.41) we obtain (2.14) (or (2.22)).

It remains to take limits only in (3.31) with $\eta = \eta_\delta$. To this end, let us write (3.31) as

$$p_\delta(t) - v_\delta(t) = p_\delta^{(1)}(t) + p_\delta^{(2)}(t) \text{ a.e. } t \in (0,T), \tag{3.45}$$

where

$$-p_\delta^{(1)}(t) \in \partial_v k_\delta(t, -v_\delta(t)) \text{ a.e. } t \in (0,T) \tag{3.46}$$

and

$$-p_\delta^{(2)}(t) \in \partial I_{K-\psi}(v_\delta(t)) \text{ a.e. } t \in (0,T). \tag{3.47}$$

Since $v \mapsto k_\delta(t,v)$ is Lipschitz continuous on $\mathcal{H}$ uniformly with respect to $t \in [0,T]$, $p_\delta^{(1)}$ is bounded in $L^\infty(0,T;\mathcal{H})$; consequently, it is bounded in $L^2(0,T;\mathcal{H})$. But, by (3.40) and (3.35), the same is true also for $p_\delta^{(2)}$. Therefore, on a subsequence of $\{\delta\}$, we have

$$p_\delta^{(1)} \to p^{(1)} \text{ weakly in } L^2(0,T;\mathcal{H}) \text{ (even weak star in } L^\infty(0,T;\mathcal{H})), \tag{3.48}$$

$$p_\delta^{(2)} \to p^{(2)} \text{ weakly in } L^2(0,T;\mathcal{H}). \tag{3.49}$$

Taking (3.40), (3.35), (3.48), and (3.49) into account, let $\delta \to 0$ in (3.45). We obtain

$$p(t) = p^{(1)}(t) + p^{(2)}(t) \text{ a.e. } t \in (0,T). \tag{3.50}$$

Next, (3.35), (3.49), and (3.47) give

$$-p^{(2)}(t) \in \partial I_{K-\psi}(0) = \partial I_K(\psi) \text{ a.e. } t \in (0,T). \tag{3.51}$$

Finally, we shall briefly repeat (with small differences) considerations from [7], but in our infinite-dimensional context. Let us clarify at first the meaning of (3.46). We assert that (3.46) implies

$$-p_\delta^{(1)}(t) \in \overline{\text{co}} \bigcup_{|y-y^*(t)|\le\delta} \partial_y V(t,y) \text{ a.e. } t \in (0,T). \tag{3.52}$$

Indeed, otherwise, there exists a closed hyperplane strictly separating $-p_\delta^{(1)}(t)$ and the closed convex set from the right-hand side of (3.52) (see [3, Cor. 1.9, p. 22]), i.e., there is $v \in \mathcal{H}$ such that

$$\begin{aligned}
&(-p_\delta^{(1)}(t), -v + v_\delta(t)) \\
>\ &\sup\left\{(p, -v + v_\delta(t)) : p \in \overline{\text{co}} \bigcup_{|y-y^*(t)|\le\delta} \partial_y V(t,y)\right\} \\
=\ &\sup\left\{(p, -v + v_\delta(t)) : p \in \bigcup_{|y-y^*(t)|\le\delta} \partial_y V(t,y)\right\} \\
\ge\ &\sup\{(p,-v) - k_\delta(t, -v_\delta(t)) : p \in \partial_y V(t,y), |y - y^*(t)| \le \delta\} \\
=\ &k_\delta(t,-v) - k_\delta(t, -v_\delta(t)),
\end{aligned}$$

which contradicts (3.46). (Here we have used also the definition (3.2).) Now, we take limits in (3.52). Let t be fixed but arbitrary in the subset of full measure of $[0,T]$ in which (3.52) holds on a subsequence of $\{\delta\}$. As before, $p_\delta^{(1)}(t)$ is bounded in $\mathcal{H}$; therefore, on a subsequence of $\{\delta\}$,

$$p_\delta^{(1)}(t) \to p^{(1)}(t) \text{ weakly in } \mathcal{H}.$$

Letting $\delta \to 0$ in (3.52), we obtain

$$-p^{(1)}(t) \in \bigcap_{\delta>0} \overline{\text{co}} \bigcup_{|y-y^*(t)|\le\delta} \partial_y V(t,y)$$

for all t in a subset of full measure of $[0,T]$. But this implies

$$-p^{(1)}(t) \in \partial_y V(t,y^*(t)) \text{ a.e. } t \in (0,T) \tag{3.53}$$

by the same argument as at the end of the proof of Theorem 3.1 from [7]. (Among others things, one uses Propositions 2.1.2 and 2.1.1 from [5].) We can write (3.50), (3.51), and (3.53) as (2.15) or (2.23).

As regards the proofs of (2.12) and (2.19), (2.20) as well as the proof of the last assertion of Theorem 2.1, we refer to [2, Thms. 5.1, 5.2]. (These will require also (3.38).) Thus, the proofs of Theorems 2.1 and 2.2 are complete.

Remark 3.4. A discrete variant of (1.2) also holds when the equation (2.2) is replaced by a certain Trotter product formula approximation (see [10, Thm. 6.1]).

Remark 3.5. While the arising of the normal cone $N_K(y_0)$ in (2.24) is (to all appearances) intrinsic for the case when $K \neq \mathcal{H}$, that of $N_K(\psi)$ in (2.23) seems to be caused by our approach. Indeed, in the proof of Lemma 3.1, we need that $e^{-\mathcal{B}_k t}$ maps K into K (to make sense $e^{-\mathcal{A}_k t}e^{-\mathcal{B}_k t}y$ for all $y \in K$), so we must impose on the auxiliary control v the constraint $v(t) \in K - \psi$ a.e. $t \in (0,T)$. But there are signs (see also the formula (6.24) from [10], to which Remark 3.4 refers) that the presence of $N_K(\psi)$ in (2.23) can be removed. Can a modification of our approximation procedure for the perturbed state equation (3.1) lead to such an effect (without making major changes in our approach)?

4. The convex case. Inspired by [7], we also raise the question: Can the inclusion (1.2) be satisfied *everywhere* on $[0,T]$ (instead of *almost everywhere*) in our infinite-dimensional context? We shall show that the answer is positive at least in the case when the control system is governed by semilinear parabolic equations with β nondecreasing and concave, and the functions g and ℓ are convex. More specifically, we impose on g and ℓ the following hypothesis:

(H8)′ $g, \ell : \mathcal{H} \to \mathbf{R}$ are convex and bounded on bounded subsets.

It is clear (by virtue of some well-known results) that (H8) follows from (H8)′. In particular, (H8)′ implies that g and ℓ are Lipschitz continuous on bounded subsets of $\mathcal{H}$ and, at every point, the generalized gradients of g and ℓ coincide with their convex subdifferentials. An additional monotonicity condition is assumed to be verified by the functions g and ℓ:

(H10) If $y, z \in \mathcal{H}$ satisfy $y \le z$ a.e. on Ω, then $g(y) \le g(z)$ and $\ell(y) \le \ell(z)$.

We are now prepared to state the following result.

THEOREM 4.1. *Besides the hypotheses of Theorem* 2.1 *but with* (H8)′ *replacing* (H8)*, assume that* A *is given by* (2.27) (*consequently* (H1) *and* (H2) *are automatically verified*)*,* β *is concave,* $\psi \equiv 0$*, and* $f \equiv 0$*. Finally, suppose* (H10) *holds. Then, the dual extremal arc* p *given by Theorem* 2.1 *satisfies*

$$-p(t) \in \partial_y V(t,y^*(t)) \text{ for } t \in [0,T] \text{ except possibly a countable subset.} \tag{4.1}$$

If in addition β satisfies (2.17)*, then the above inclusion holds for all $t \in [0,T]$.*

Remark 4.1. The above result may be viewed as a generalization of Proposition 5.5 from [7] to the case of infinite-dimensional and nonlinear systems.

The proof of Theorem 4.1 is, in essence, a succession of three lemmas.

LEMMA 4.1. *Under the assumptions of Theorem* 4.1*, $y \mapsto V(t,y)$ is convex on $\mathcal{H}$ for all $t \in [0,T]$.*

Proof. It is easy to verify that $V(t,y) = W(T-t,y)$, where

$$W(t,y) = \inf\left\{ \int_0^t (h(u(s)) + g(z(s)))\, ds + \ell(z(T)) : \right.$$
$$\left. z' + Az + \beta(z-\psi) \ni Bu + f \text{ a.e. } s \in (0,t), z(0) = y, u \in L^2(0,t;\mathcal{U}) \right\}.$$

So we have to prove that $y \mapsto W(t,y)$ is convex on $\mathcal{H}$ for every $t \in [0,T]$. To this end, we shall use a Trotter-type product formula from [10] for the dynamic programming equation associated with (P).

Let $\varepsilon = T/n$ (n being a positive integer). Define

$$W^\varepsilon(t,y) = \begin{cases} \inf\{\varepsilon h(u) + \varepsilon g((I+\varepsilon A)^{-1}(I+\varepsilon\partial\phi)^{-1}(y+\varepsilon Bu)) \\ \quad + W^\varepsilon(t-\varepsilon, (I+\varepsilon A)^{-1}(I+\varepsilon\partial\phi)^{-1}(y+\varepsilon Bu)) : u \in \mathcal{U}\} \\ \qquad \text{for } (t,y) \in (\varepsilon, T] \times \mathcal{H}, \\ \inf\{th(u) + \varepsilon g((I+\varepsilon A)^{-1}(I+\varepsilon\partial\phi)^{-1}(y+tBu)) \\ \quad + \ell((I+\varepsilon A)^{-1}(I+\varepsilon\partial\phi)^{-1}(y+tBu)) : u \in \mathcal{U}\} \\ \qquad \text{for } (t,y) \in (0, \varepsilon] \times \mathcal{H}, \end{cases}$$

$$W^\varepsilon(0,y) = \ell(y) \text{ for } y \in \mathcal{H}.$$

Obviously,

$$((I+\varepsilon\partial\phi)^{-1}y)(x) = (I+\varepsilon\beta)^{-1}(y(x)) \text{ a.e. } x \in \Omega.$$

By convexity of g, ℓ, and $r \mapsto (I+\varepsilon\beta)^{-1}(r)$ (do not forget that β is concave), using also (H10), we deduce that the functions $y \mapsto g((I+\varepsilon A)^{-1}(I+\varepsilon\partial\phi)^{-1}y)$ and $y \mapsto \ell((I+\varepsilon A)^{-1}(I+\varepsilon\partial\phi)^{-1}y)$ are convex on $\mathcal{H}$. Also, these functions are nondecreasing in the sense of (H10). (Indeed, it suffices to apply the monotonicity of $r \mapsto (I+\varepsilon\beta)^{-1}(r)$ and the maximum principle to the elliptic operator $I + \varepsilon A_0$.) Assume that t/ε is not an integer (the other case is completely similar). Let $y_1, y_2 \in \mathcal{H}$ and $0 \le \lambda \le 1$. We have

$$\lambda W^\varepsilon\left(t - \left[\frac{t}{\varepsilon}\right]\varepsilon, y_1\right) + (1-\lambda) W^\varepsilon\left(t - \left[\frac{t}{\varepsilon}\right]\varepsilon, y_2\right) \ge \left(t - \left[\frac{t}{\varepsilon}\right]\varepsilon\right) h(\lambda u_1 + (1-\lambda)u_2)$$
$$+\varepsilon g\left((I+\varepsilon A)^{-1}(I+\varepsilon\partial\phi)^{-1}\left(\lambda y_1 + (1-\lambda)y_2 + \left(t - \left[\frac{t}{\varepsilon}\right]\varepsilon\right) B(\lambda u_1 + (1-\lambda)u_2)\right)\right)$$
$$+\ell\left((I+\varepsilon A)^{-1}(I+\varepsilon\partial\phi)^{-1}\left(\lambda y_1 + (1-\lambda)y_2 + \left(t - \left[\frac{t}{\varepsilon}\right]\varepsilon\right) B(\lambda u_1 + (1-\lambda)u_2)\right)\right)$$
$$\ge W^\varepsilon\left(t - \left[\frac{t}{\varepsilon}\right]\varepsilon, \lambda y_1 + (1-\lambda)y_2\right).$$

Here $u_1, u_2 \in \mathcal{U}$ are minimizing elements in the expressions defining $W^\varepsilon(t-[t/\varepsilon]\varepsilon, y_1)$ and $W^\varepsilon(t-[t/\varepsilon]\varepsilon, y_2)$, respectively. Also, one readily shows that $y \mapsto W^\varepsilon(t-[t/\varepsilon]\varepsilon, y)$ is nondecreasing. Now we successively argue $[t/\varepsilon]$ times as above to obtain that $y \mapsto W^\varepsilon(t, y)$ is convex on $\mathcal{H}$ (and nondecreasing).

But the following Trotter-type product formula holds (see [10, Thm. 3.2]):

$$\lim_{\varepsilon \to 0} W^\varepsilon(t, y) = W(t, y) \text{ for every } (t, y) \in [0, T] \times \mathcal{H}.$$

So letting ε tend to zero in the inequality proving the convexity of $W^\varepsilon(t, y)$, we obtain the conclusion of Lemma 4.1.

Remark 4.2. As a by-product of the above proof, we have also obtained that $y \mapsto V(t, y)$ is nondecreasing in the sense of (H10).

Remark 4.3. Compare the proof of Lemma 4.1 with that of Proposition 5.5 from [7].

Remark 4.4. Lemma 4.1 remains valid (with the same proof) but with $\overline{D(\phi)}$ instead of $\mathcal{H}$ if we replace β from Theorem 2.1 with β from Theorem 2.2 (given by (2.18)). Also, in the above proof, we can change the places of the resolvents $(I+\varepsilon A)^{-1}, (I+\varepsilon\partial\phi)^{-1}$ between them, but in this case we must apply [10, Thm. 3.1].

Remark 4.5. The hypothesis (H10) is needed only in the proof of Lemma 4.1.

Remark 4.6. We point out that the Trotter-type product formulas for the dynamic programming equation are proved to be adequate tools to establish some qualitative properties for the optimal value function such as convexity or monotonicity.

LEMMA 4.2. *Under the hypotheses of Theorem* 2.1*, the optimal value function* $(t, y) \mapsto V(t, y)$ *is continuous on* $[0, T] \times \mathcal{H}$.

Proof. Similar arguments to those from the proof of Proposition 2.1 lead to the continuity of $t \mapsto V(t, y)$ for all $y \in \mathcal{H}$. But this in conjunction with Proposition 2.1 gives the statement of the lemma.

The following result is an infinite-dimensional version of Corollary 5.2 from [7].

LEMMA 4.3. *Under the assumptions of Theorem* 4.1*, the multifunction* $(t, y) \mapsto \partial_y V(t, y)$ *is strongly-weakly closed.*

Proof. The proof is the same with that of Corollary 5.2 from [7]; however, we give it for the reader's convenience. First let us remark that, by Lemmas 4.1 and 4.2, the gradient $\partial_y V(t, y)$ coincides with the convex subdifferential of $y \mapsto V(t, y)$. Now let $t_m \to t$, $y_m \to y$ strongly in $\mathcal{H}$, and $p_m \to p$ weakly in $\mathcal{H}$, where $p_m \in \partial_y V(t_m, y_m)$, that is,

$$V(t_m, z) - V(t_m, y_m) \geq (z - y_m, p_m) \text{ for all } z \in \mathcal{H}.$$

Letting $m \to \infty$ in the above inequality, by Lemma 4.2, we obtain

$$V(t, z) - V(t, y) \geq (z - y, p) \text{ for all } z \in \mathcal{H},$$

that is, $p \in \partial_y V(t, y)$, and the proof of Lemma 4.3 is complete.

Proof of Theorem 4.1. The conclusion of the theorem will follow by combining Lemma 4.3 with the continuity properties of the function p. Indeed, since $p \in BV([0, T]; \mathcal{Y}')$, $p : [0, T] \to \mathcal{Y}'$ is continuous on $[0, T]$ except a countable subset. Let $t \in [0, T]$ be an arbitrary point of continuity for $p : [0, T] \to \mathcal{Y}'$. By virtue of (2.15) and the fact that p belongs also to $L^\infty(0, T; \mathcal{H})$, there exists a sequence $\{t_m\} \subset [0, T]$ converging to t such that, for every m,

$$-p(t_m) \in \partial_y V(t_m, y^*(t_m)),$$

$$|p(t_m)| \leq ||p||_{L^\infty(0,T;\mathcal{H})}.$$

Hence, extracting a subsequence of $\{m\}$, $p(t_m) \to p \in \mathcal{H}$ weakly in $\mathcal{H}$. Since $p(t_m) \to p(t)$ strongly in $\mathcal{Y}'$, on a subsequence of $\{m\}$, we have

$$p(t_m) \to p(t) \text{ weakly in } \mathcal{H}.$$

But we also have

$$y^*(t_m) \to y^*(t) \text{ strongly in } \mathcal{H},$$

so that, by applying Lemma 4.3, we get

$$-p(t) \in \partial_y V(t, y^*(t)).$$

If also the condition (2.17) holds, then, by Theorem 2.1, $p \in C_w([0,T];\mathcal{H})$, whence, arguing as above, one obtains (4.1) for all $t \in [0,T]$. This completes the proof.

Remark 4.7. When β is given by (2.18), one cannot expect to obtain a similar result to Theorem 4.1 by using the same proof as above and the same definition for $\partial_y V(t,y)$. Indeed, although $y \mapsto V(t,y)$ is convex on $\overline{D(\phi)}$ also in this case (see Remark 4.4), $y \mapsto \tilde{V}(t,y)$ is not in general convex on $\mathcal{H}$, so it is possible that, at some points $y \in \overline{D(\phi)}$, $\partial_y V(t,y)$ does not coincide with the subdifferential of any convex extension of $y \mapsto V(t,y)$; consequently, the argument in the proof of Lemma 4.3 does not work.

Acknowledgment. The author is greatly indebted to Professor V. Barbu for suggesting the problem and for the useful discussions.

CONSTRAINED LQR PROBLEMS IN ELLIPTIC DISTRIBUTED CONTROL SYSTEMS WITH POINT OBSERVATIONS—ON CONVERGENCE RATES*

PUHONG YOU† AND JIANXIN ZHOU†

Abstract. In this paper, we continue to study the (bound constrained) linear-quadratic regulator problem in distributed boundary control systems governed by the elliptic equation with point observations. Due to the appearance of singularities in the problem, the traditional Galerkin variational method that leads to an adjoint system is not desirable, and the classical Lagrangian multiplier method is not reliable for providing numerical results. A characterization formula of the optimal control and its singularity decomposition formula are derived in [Z. Ding, L. Ji, and J. Zhou, *SIAM J. Control Optim.*, 34 (1996), pp. 264–294; Z. Ding and J. Zhou, *Appl. Math. Optim.*, to appear] by using the boundary integral equation and potential theory coupled with a variational inequality in a Banach space setting. Based on the characterization formula, a conditioned gradient projection method (CGPM) has been proposed in [Z. Ding and J. Zhou, *Appl. Math. Optim.*, to appear]. Numerical experiment has shown that CGPM is efficient and also insensitive to the partition number of the boundary. In this paper, we estimate the rate of convergence for CGPM. First it is proved that for $\mathcal{N}=2$, CGPM converges exponentially in the L^2 norm, and for $\mathcal{N}=3$, CGPM converges subexponentially in the L^p norm. Then, under a reasonable condition, it is proved that for $\mathcal{N}=2$, CGPM converges uniformly exponentially, and for $\mathcal{N}=3$, CGPM converges uniformly subexponentially.

1. Introduction.

Let Ω be an (interior or exterior) open domain in $\Re^{\mathcal{N}}$ ($\mathcal{N}=2,3$) with a bounded, C^∞ boundary Γ. In this paper, we study numerical methods to solve the following constrained linear-quadratic regulator (LQR) problem in a distributed boundary control system governed by the elliptic equation with point observations:

$$\text{(LQR)}\begin{cases}\min\limits_u J(u)=\sum\limits_{k=1}^{M}\mu_k|w(P_k)-Z_k|^2+\gamma\displaystyle\int_\Gamma u^2(x)d\sigma_x\\ \text{subject to (1.1)}\begin{cases}\Delta w(x) = 0 & \text{in } \Omega\\ \dfrac{\partial w(x)}{\partial n} = u(x) & \text{on } \Gamma\end{cases}\\ u\in\mathcal{U},\end{cases}\tag{1.2}$$

where $\mathcal{U}$ is the admissible control set defined by

$$\mathcal{U}=\{v\in L_0^p(\Gamma)\mid Bl(x)\le v(x)\le Bu(x) \text{ on } \Gamma\},\tag{1.3}$$

$$L_0^p(\Gamma)=\left\{f\in L^p(\Gamma)\Big|\int_\Gamma f(\xi)d\sigma_\xi=0\right\},\quad 1\le p<\infty,$$

and the lower and upper bounds $Bl \le Bu \in L^p(\Gamma)$ are given s.t.

$$\int_\Gamma Bl(\xi)d\sigma_\xi < 0, \quad \int_\Gamma Bu(\xi)d\sigma_\xi > 0.$$

Throughout this paper, we assume that $p = 2$ for $\mathcal{N} = 2$ and $p > 2$ for $\mathcal{N} = 3$, and $q \le 2$ is given s.t. $\frac{1}{p} + \frac{1}{q} = 1$. In the above setting,

$\frac{\partial}{\partial n}$ is the outward normal derivative,
$u \in \mathcal{U}$ is a Neumann-type boundary control on Γ,
$\gamma, \mu_k > 0, 1 \le k \le M$, are given weighting factors,
$P_k \in \partial\Omega, 1 \le k \le M$, are prescribed "sensor locations,"
$Z_k \in \Re, 1 \le k \le M$, are prescribed "target values" at P_k.

The objective of the above problem is to find the distribution of $u(x)$ on Γ s.t. at sensor locations $P_k, 1 \le k \le M$, the observation values $w(P_k)$ are as close as possible to the target values Z_k with least possible control cost $\int_\Gamma u^2(x)d\sigma_x$. The well-posedness of the problem has been justified in [2, 3, 4].

The study of the above system is motivated by problems in cathodic protection systems in corrosion engineering [20, 21] and contemporary "smart sensors." Since in most applications, point sensors are much cheaper and easier to design than distributed sensors [19, 15, 18], point sensors (observations) are used in our problem setting. Once point sensors are placed on the boundary, singularities will appear in the problem. Mathematically and computationally, it becomes very tough to handle. The usual Galerkin variational method [13] leading to an adjoint system cannot effectively handle this problem.

Recently, Ji and Chen [11] studied a similar problem by using the potential theory and boundary element method (BEM). Their approach has certain important advantages over others. It can provide rather explicit information about the control and state, and it is amenable to direct numerical computation through BEM. In [2, 3], Ding, Ji, and Zhou and Ding and Zhou applied this approach to study the above-constrained LQR problems. They derived a feedback characterization of the optimal control and established a singularity decomposition formula for the characterization of the optimal control to overcome the singularity problem. They also pointed out that the classical Lagrangian multiplier method (LMM) is not reliable for providing a numerical solution for unconstrained LQR; the finite-dimensional gradient projection method is sensitive to the partition number of the boundary. In [4], Ding and Zhou proposed a conditioned gradient projection method (CGPM) to solve the above-constrained LQR problem. Strong convergence and uniform convergence have been verified numerically and mathematically in [4].

In this paper, we estimate the rate of convergence for CGPM. Due to the different space settings, for $\mathcal{N} = 2$, our problem is in a Hilbert space L^2 setting, and for $\mathcal{N} = 3$, it is in a Banach space L^p setting. Thus we have to treat these two cases differently. We prove that for $\mathcal{N} = 2$, CGPM converges exponentially in the L^2 norm and that for $\mathcal{N} = 3$, CGPM converges subexponentially in the L^p norm; i.e., it converges faster than any power of $\frac{1}{n}$, where n is the number of iterations. Finally, under a quite reasonable assumption, we prove that for $\mathcal{N} = 2$, CGPM converges uniformly exponentially, and for $\mathcal{N} = 3$, CGPM converges uniformly subexponentially. The motivation to investigate uniform convergence and uniform convergence rate is due to the concern about the discretization of the above-constrained LQR problem, as partially explained in [2, 4]. First, for a discretization of a constrained optimal control problem, if a numerical algorithm is sensitive to the partition of the boundary

(dimension) (such as the finite-dimensional gradient projection method used in [4]), a refinement of the partition on the boundary will add more constraints to the problem. It then slows down the computation and convergence and ultimately fails to provide reliable numerical solutions if the partition number is very large. While our governing differential equation is a PDE, the partition number on the boundary can be quite large. On the other hand, if the optimal control u^* is in $L^p(\Gamma)$, the strong convergence cannot guarantee the convergence of $u^*(x)$ on a set of zero measure. While in real computation, we can only approximate the optimal control u^* at a finite number of boundary points. Therefore, it is important to study uniform convergence and uniform convergence rate.

Let

$$E(x,\xi) = \begin{cases} -\dfrac{1}{2\pi}\ln|x-\xi|, & x,\xi \in \Re^2, \\ \dfrac{1}{4\pi}\dfrac{1}{|x-\xi|}, & x,\xi \in \Re^3 \end{cases} \tag{1.4}$$

be the fundamental solution of the Laplacian operator. For $f \in L^2(\Gamma)$, define operators

$$\mathcal{S}(f)(x) = \int_\Gamma E(x,\xi) f(\xi) d\sigma_\xi, \quad x \in \Re^{\mathcal{N}}, \tag{1.5}$$

$$\mathcal{K}(f)(x) = \lim_{\varepsilon \to 0+} \int_{\Gamma \bigcap \{|x-\xi|>\varepsilon\}} \frac{\partial}{\partial n_\xi} E(x,\xi) f(\xi) d\sigma_\xi, \quad x \in \Gamma, \tag{1.6}$$

$$\mathcal{K}^*(f)(x) = \lim_{\varepsilon \to 0+} \int_{\Gamma \bigcap \{|x-\xi|>\varepsilon\}} \frac{\partial}{\partial n_x} E(x,\xi) f(\xi) d\sigma_\xi, \quad x \in \Gamma. \tag{1.7}$$

Their basic properties can be found in [2, 3]. According to [1, Chap. 6], a solution w of (1.2) can be written as

$$w(x) = \mathcal{S}(\eta)(x), \quad x \in \overline{\Omega}, \tag{1.8}$$

where η is the layer density to be determined from the boundary condition

$$\frac{\partial w(x)}{\partial n} = \left(\frac{1}{2} I + \mathcal{K}^*\right)(\eta)(x) = u(x), \quad x \in \Gamma. \tag{1.9}$$

Once the layer density η is found, the solution $w(x)$ of (1.1) can be computed from (1.8).

By Theorem 2.4 in [3], for each given $u \in \mathcal{U}$, (1.2) has a unique solution $w \in C(\overline{\Omega})$ s.t.

$$\sum_{k=1}^{M} \mu_k (w(P_k) - Z_k) = 0. \tag{1.10}$$

Once a control u is given, the corresponding optimal state can be obtained by solving (1.2) and (1.10). From now on, we use $w(x,u)$ to stand for this solution.

Remark 1. The difference between the cases $\mathcal{N} = 2$ and $\mathcal{N} = 3$ is that for each fixed x, $E(x,\cdot) \in L^2(\Gamma)$ for $\mathcal{N} = 2$ and $E(x,\cdot) \in L^{2-\varepsilon}(\Gamma)$ $(0 < \varepsilon < 2)$ for $\mathcal{N} = 3$.

LEMMA 1.1. *For any $u \in L_0^p(\Gamma)$, (1.2) and (1.10) have a unique solution $w(x,u)$, and for any $\alpha, \beta \in \Re$, $v_1, v_2 \in L_0^p(\Gamma)$, we have*

$$w(x, \alpha v_1 + \beta v_2) = \alpha w(x, v_1) + \beta w(x, v_2) + (1 - \alpha - \beta)\mu, \tag{1.11}$$

where $\mu = \sum_{k=1}^{M} \mu_k Z_k / \sum_{k=1}^{M} \mu_k$. *In addition, for any* $u \in L_0^p(\Gamma)$, *we have*

$$|w(x,u) - \mu| \le C(x,\Omega)\|u\|_2 \quad \text{for } \mathcal{N} = 2, \tag{1.12}$$

$$|w(x,u) - \mu| \le C(x,\Omega,p)\|u\|_p \quad \text{for } \mathcal{N} = 3, \tag{1.13}$$

where the constant $C(x,\Omega)$ *depends only on* x *and* Ω, *and the constant* $C(x,\Omega,p)$ *depends only on* x, Ω, *and* p.

Proof. (1.11) can be verified directly. (1.12) and (1.13) follow from Theorem 2.4 in [3] and (1.10). ∎

Notice that $\mathcal{U}$ is a bounded, convex, and closed subset in $L^p(\Gamma)$. Let

$$D = \max\{2\|Bl\|_p, 2\|Bu\|_p, 1\};$$

then

$$\|u\|_p \le D, \qquad \|u - v\|_p \le D \qquad \forall\, u, v \in \mathcal{U}.$$

Define the truncation $[u]_{Bl}^{Bu}$ of any function $u(x)$ on Γ by

$$[u]_{Bl}^{Bu}(x) = [u(x)]_{Bl(x)}^{Bu(x)} = \begin{cases} Bl(x) & \text{if} \quad u(x) < Bl(x), \\ u(x) & \text{if} \quad Bl(x) \le u(x) \le Bu(x), \\ Bu(x) & \text{if} \quad u(x) > Bu(x). \end{cases} \tag{1.14}$$

Introduce the projection operator $P_{\mathcal{U}} : L^p(\Gamma) \to \mathcal{U}$:

$$P_{\mathcal{U}}(u) = [u + c_u]_{Bl}^{Bu} \qquad \forall\, u \in L^p(\Gamma), \tag{1.15}$$

where c_u is a constant defined in Lemma 6 in [4] s.t. $P_{\mathcal{U}}(u) \in L_0^p(\Gamma)$. Applying the characterization of truncation from Lemma 8 in [4], we obtain the following lemma.

LEMMA 1.2 (see (2.8) and Theorem 1 in [4]). u^* *is an optimal control to the constrained LQR problem if and only if*

$$\begin{aligned} u^* &= \left[u^* - \frac{1}{2\gamma} \nabla J(u^*) + c_* \right]_{Bl}^{Bu} \\ &= \left[-\frac{1}{\gamma} \left(\frac{1}{2} I + \mathcal{K} \right)^{-1} \sum_{k=1}^{M} \mu_k (w^*(P_k, u^*) - Z_k) E(P_k, \cdot)(\xi) + C^* \right]_{Bl}^{Bu}, \end{aligned} \tag{1.16}$$

where c_* *is defined by Lemma* 6 *in* [4] *s.t.*

$$\int_\Gamma \left[u^*(x) - \frac{1}{2\gamma} \nabla J(u^*)(x) + c_* \right]_{Bl}^{Bu} d\sigma_x = 0. \tag{1.17}$$

Let $\langle \cdot, \cdot \rangle$ be the pairing on $L^q(\Gamma)$ and $L^p(\Gamma)$. The following facts on the objective function J are needed.

LEMMA 1.3. *The functional* $J(u)$ *is convex (quadratic) and differentiable, so for any* $t \in \Re$ *and* $u, v \in L_0^p(\Gamma)$, *we have*

$$J(u + tv) = J(u) + t\langle \nabla J(u), v \rangle + t^2 \left\{ \sum_{k=1}^{M} \mu_k |w(P_k, v) - \mu|^2 + \gamma \int_\Gamma v^2(x) d\sigma_x \right\}, \tag{1.18}$$

$$J(u) - J(v) \le \langle \nabla J(u), u - v \rangle, \tag{1.19}$$

$$J\left(\frac{u+v}{2} \right) \le \max\{J(u), J(v)\} - \frac{1}{4}\gamma \|u - v\|_2^2. \tag{1.20}$$

Proof. (1.18) and (1.19) can be verified directly. By virtue of (1.11) and (1.18), we get

$$J(u)+J(v)-2J\left(\frac{u+v}{2}\right)=\frac{1}{2}\sum_{k=1}^{M}|w(P_k,u)-w(P_k,v)|^2+\frac{1}{2}\gamma\|u-v\|_2^2.$$

(1.20) then follows from the fact that $(J(u)+J(v))\le 2\max\{J(u),J(v)\}$. ∎

2. Numerical algorithm. Based on the characterization of the optimal control, Lemma 1.2, a CGPM has been proposed in [4] to solve the constrained LQR problem. Its strong convergence and uniform convergence are proved in [4]. To estimate its convergence rate, we modify CGPM as follows.

Given $\frac{1}{2}<\alpha<1$. Choose any initial trial $u^1\in\mathcal{U}$.

$$u^{n+1}=u^n+\lambda_n^* d_n,\quad n=1,2,3,\dots, \tag{2.1}$$

where

$$d_n=\bar{u}^n-u^n, \tag{2.2}$$

$$\bar{u}^n=P_{\mathcal{U}}\left(u^n-\frac{1}{2\gamma}\nabla J(u^n)\right)=\left[u^n(x)-\frac{1}{2\gamma}\nabla J(u^n)+C_n\right]_{Bl(x)}^{Bu(x)}, \tag{2.3}$$

$$\lambda_n^*=\min\{\alpha,\lambda_n\}, \tag{2.4}$$

$$\lambda_n=\arg\min_{\lambda}J(u^n+\lambda d_n), \tag{2.5}$$

and C_n has the smallest magnitude s.t.

$$\int_\Gamma\left[u^n(x)-\frac{1}{2\gamma}\nabla J(u^n)+C_n\right]_{Bl}^{Bu}d\sigma_x=0. \tag{2.6}$$

Remark 2.

(i) In order to estimate the convergence rate, the CGPM in [4] has been modified s.t. the constant C_n in (2.6) has the smallest magnitude. Due to Lemma 6 in [4], the function

$$\phi_n(\lambda)=\int_\Gamma\left[u_n(x)-\frac{1}{2\gamma}\nabla J(u_n)+\lambda\right]_{Bl}^{Bu}d\sigma_x$$

is monotonically increasing in λ. So the constant C_n with the smallest magnitude s.t. $\phi_n(C_n)\in L_0^p(\Gamma)$ can be easily found. Once the convergence rates are obtained, we may use Lemma 7 in [4]; i.e., if $\phi_n(\lambda_1),\phi_n(\lambda_2)\in L_0^p(\Gamma)$, then $\phi_n(\lambda_1)=\phi_n(\lambda_2)$, a.e. in Γ, to relax this condition.

(ii) Due to the appearance of singularities in the control variable, an adaptive local refinement scheme has been used in numerical computation to enhance the convergence stability; see [2, 4].

3. Results on the convergence rate. In this section, we estimate the convergence rate of the above CGPM. Due to different natures of the space settings, we have to treat $\mathcal{N}=2$ and $\mathcal{N}=3$ separately.

LEMMA 3.1. *For the above CGPM, we obtain the following:*

(i) $J(u^n)$ *is decreasing, so* $\lim_{n\to\infty}J(u^n)\ge J(u^*)$;

(ii) $J(u^n)-J(u^*)\ge\frac{1}{4}\gamma\|u^n-u^*\|_2^2$;

(iii) $\langle\nabla J(u^n),\bar{u}^n-z\rangle\le 2\gamma\langle u^n-\bar{u}^n,\bar{u}^n-z\rangle\quad\forall\, z\in\mathcal{U}$.

In particular, if $z = u^n$, we have

$$\langle \nabla J(u^n), d_n \rangle \le -2\gamma \|d_n\|_2^2.$$

Proof. (i) follows from a direct computation that leads to

$$J(u^{n+1}) - J(u^n) \begin{cases} = \dfrac{-\frac{1}{4}|\langle \nabla J(u^n), d^n \rangle|^2}{\left\{ \sum_{k=1}^{M} \mu_k |w(P_k, d_n) - \mu|^2 + \gamma \|d_n\|_2^2 \right\}} < 0 & \text{if } \lambda_n^* = \lambda_n, \\ \le \dfrac{\alpha}{2} \langle \nabla J(u^n), d^n \rangle < 0 & \text{if } \lambda_n^* = \alpha, \end{cases} \tag{3.1}$$

where we have used the fact that $\lambda_n^* = \alpha < \lambda_n$ means

$$2\alpha \left\{ \sum_{k=1}^{M} \mu_k |w(P_k, d_n) - \mu|^2 + \gamma \|d_n\|_2^2 \right\} < -\langle \nabla J(u^n), d^n \rangle.$$

Point (ii) can be derived from (1.20), and (iii) follows from Lemma 8 in [4], by taking $u = \bar{u}^n$. ∎

The following lemma is a special case of Lemma 1.4 in [5], which will be used in estimating the convergence rate.

LEMMA 3.2. *Suppose that $\{r_n\}_{n=1}^{\infty} \subset [0, \infty)$ and $q > 0$ satisfy*

$$r_n - q r_n^k \ge r_{n+1}$$

for $n \ge 0$, with k a fixed exponent in the range $(1, \infty)$; then

$$r_n \le r_0 [1 + (k-1) r_0^{k-1} q n]^{-\frac{1}{k-1}}$$

for all n, i.e.,

$$\lim_{n \to \infty} \sup r_n n^{\frac{1}{k-1}} \le [(k-1)q]^{-\frac{1}{k-1}}.$$

Case 1. $\mathcal{N} = 2$.

THEOREM 3.3. *For $\mathcal{N} = 2$, let $\{u_n\}_{n=1}^{\infty}$ and $\{\bar{u}^n\}_{n=1}^{\infty}$ be the sequences generated by the algorithm CGPM, (2.1)–(2.5); then $r_n = J(u^n) - J(u^*)$, u^n, and $\bar{u}^n$ all converge exponentially; i.e.,*

$$r_n \le r_1 \delta^n, \tag{3.2}$$

where $\delta = 1 - \frac{15 - 6\sqrt{6}}{8} \frac{\gamma}{L} \in (0, 1)$, with $L = \sum_{k=1}^{M} \mu_k C^2(P_k, \Omega) + \gamma$. Hence

$$\|u^n - u^*\|_2 \le \sqrt{\frac{4r_1}{\gamma}} \delta^{\frac{n}{2}} \tag{3.3}$$

and

$$\|\bar{u}^n - u^*\|_2 \le \frac{2\sqrt{L} + 2\sqrt{3\gamma}}{\sqrt{3}\gamma} r_1^{\frac{1}{2}} \delta^{\frac{n}{2}}. \tag{3.4}$$

LEMMA 3.4. *For λ_n^* defined in the algorithm* (2.1)–(2.5)*, we have $\lambda_n^* \geq \lambda_0^* \,\forall\, n$, where $\lambda_0^* = \min\{\alpha, \frac{\gamma}{L}\} \in (0,1)$.*

Proof. From (1.12), (1.18), and Lemma 3.1 (iii), we get

$$\begin{aligned}\lambda_n &= \frac{-\langle \nabla J(u_n), d_n\rangle}{2\left\{\sum_{k=1}^M \mu_k |w(P_k,d_n)-\mu|^2 + \gamma \int_\Gamma d_n^2(x)d\sigma_x\right\}} \\ &\geq \frac{\gamma}{\sum_{k=1}^M \mu_k C^2(P_k,\Omega)+\gamma}.\end{aligned}$$

This completes our proof. ∎

Proof of Theorem 3.3. Let $n > 0$; by (1.19) and Lemma 3.1 (iii), we have

$$\begin{aligned} r_n :&= J(u^n) - J(u^*) \\ &\leq \langle \nabla J(u^n), u^n - u^*\rangle \\ &\leq \langle \nabla J(u^n), u^n - \bar{u}^n\rangle + \langle \nabla J(u^n), \bar{u}^n - u^*\rangle \\ &\leq \langle \nabla J(u^n), u^n - \bar{u}^n\rangle + 2\gamma\langle u^n - \bar{u}^n, \bar{u}^n - u^*\rangle \qquad (3.5)\\ &= \langle \nabla J(u^n), u^n - \bar{u}^n\rangle + 2\gamma\langle u^n - \bar{u}^n, u^n - u^*\rangle - 2\gamma\|u^n - \bar{u}^n\|_2^2 \\ &\leq -\langle \nabla J(u^n), d_n\rangle + 2\gamma\|u^n - \bar{u}^n\|_2\|u^n - u^*\|_2. \end{aligned}$$

On the other hand, for any $\beta \in [0, \lambda_0^*]$, from (1.18), Lemma 3.4, and Lemma 3.1 (iii), we obtain

$$\begin{aligned} r_{n+1} - r_n &= J(u^{n+1}) - J(u^n) \\ &\leq \beta\langle \nabla J(u^n), d_n\rangle + L\beta^2\|u^n - \bar{u}^n\|_2^2 \qquad (3.6)\\ &\leq (-2\gamma\beta + L\beta^2)\|u^n - \bar{u}^n\|_2^2. \end{aligned}$$

Let $\beta = \frac{\gamma}{2L} < \lambda_0^* = \min\{\alpha, \frac{\gamma}{L}\}$; then

$$\|u^n - \bar{u}^n\|_2 \leq \frac{2\sqrt{L}}{\sqrt{3}\gamma}(r_n - r_{n+1})^{\frac{1}{2}}. \qquad (3.7)$$

From (3.6), we get

$$-\langle \nabla J(u^n), d_n\rangle \leq \frac{2L}{\gamma}(r_n - r_{n+1}) + \frac{1}{\gamma}\|u^n - \bar{u}^n\|_2^2. \qquad (3.8)$$

Also from Lemma 3.1 (ii), we have

$$\|u^n - u^*\|_2 \leq \frac{2}{\sqrt{\gamma}} r_n^{\frac{1}{2}}. \qquad (3.9)$$

Substituting (3.7), (3.8), and (3.9) into (3.5), we have

$$\begin{aligned} r_n &\leq \frac{2L}{\gamma}(r_n - r_{n+1}) + \frac{\gamma}{2}\|u^n - \bar{u}^n\|_2^2 + 2\gamma\|u^n - \bar{u}^n\|_2\|u^n - u^*\|_2 \\ &\leq \frac{8L}{3\gamma}(r_n - r_{n+1}) + 8\sqrt{\frac{L}{3r}}(r_n - r_{n+1})^{\frac{1}{2}} r_n^{\frac{1}{2}} \qquad (3.10)\\ &= \frac{8L}{3\gamma}\left((r_n - r_{n+1})^{\frac{1}{2}} + \frac{1}{2}\sqrt{\frac{3\gamma}{L}} r_n^{\frac{1}{2}}\right)^2 - 2r_n. \end{aligned}$$

Thus

$$\frac{9\gamma}{8L}r_n \le \left((r_n - r_{n+1})^{\frac{1}{2}} + \frac{1}{2}\sqrt{\frac{3\gamma}{L}}r_n^{\frac{1}{2}}\right)^2.$$

Taking the square root on both sides and rearranging the terms, we obtain

$$\frac{3-\sqrt{6}}{2\sqrt{2}}\sqrt{\frac{\gamma}{L}}r_n^{\frac{1}{2}} \le (r_n - r_{n+1})^{\frac{1}{2}}.$$

From here we get

$$r_{n+1} \le \left(1 - \frac{15-6\sqrt{6}}{8}\frac{\gamma}{L}\right) r_n. \tag{3.11}$$

So, letting $\delta = (1 - \frac{15-6\sqrt{6}}{8}\frac{\gamma}{L})$, we get (3.2). (3.3) follows directly from Lemma 3.1 (ii). For (3.4), notice (3.7) and (3.9). We then have

$$\begin{aligned}\|\bar{u}^n - u^*\|_2 &\le \|\bar{u}^n - u^n\|_2 + \|u^n - u^*\|_2 \\ &\le \frac{2\sqrt{L}}{\sqrt{3}\gamma}(r_n - r_{n+1})^{\frac{1}{2}} + \frac{2}{\sqrt{\gamma}}r_n^{\frac{1}{2}} \\ &\le \left(\frac{2\sqrt{L}}{\sqrt{3}\gamma} + \frac{2}{\sqrt{\gamma}}\right) r_n^{\frac{1}{2}}.\end{aligned}$$

Thus (3.4) follows. ∎

Case 2. $\mathcal{N} = 3$.

For any $2 < p' \le p$, notice that Γ is a compact set. We thus have $L^p(\Gamma) \subset L^{p'}(\Gamma) \subset L^2(\Gamma)$, and the interpolation inequality gives

$$\|u\|_{p'} \le \|u\|_2^{\frac{2(p-p')}{p'(p-2)}} \|u\|_p^{\frac{p(p'-2)}{p'(p-2)}}.$$

Thus

$$\|u\|_{p'} \le D\|u\|_2^{1-\nu} \quad \forall\, u \in \mathcal{U}, \tag{3.12}$$

where $\nu = \frac{p(p'-2)}{p'(p-2)}$.

THEOREM 3.5. *For $\mathcal{N} = 3$, let $\{u^n\}_{n=1}^{\infty}$ and $\{\bar{u}^n\}_{n=1}^{\infty}$ be the sequences generated by the algorithm CGPM,* (2.1)–(2.5)*; then $r_n = J(u^n) - J(u^*)$, u^n, and $\bar{u}^n$ all converge subexponentially, i.e.,*

$$r_n \le E_1 n^{-s}, \tag{3.13}$$

where

$$s = \frac{1-\nu}{2\nu} = \frac{p-p'}{p(p'-2)} \quad \textit{for any} \quad 2 < p' \le p. \tag{3.14}$$

Moreover,

$$\|u^n - u^*\|_2 \le E_2 n^{-\frac{s}{2}} \tag{3.15}$$

and

$$\|\bar{u}^n - u^*\|_2 \le E_3 n^{-\frac{s}{2(1+\nu)}}, \tag{3.16}$$

where E_1, E_2, and E_3 are constants depending only on Ω, γ, p', and P_k, Z_k, μ_k, $k = 1, \dots, M$.

Proof. Letting $n > 0$, by the last inequality in (3.5), we get

$$\begin{aligned} r_n :&= J(u^n) - J(u^*) \\ &\le -\langle \nabla J(u^n), d_n\rangle + 2\gamma \|u^n - \bar{u}^n\|_2 \|u^n - u^*\|_2. \end{aligned} \tag{3.17}$$

On the other hand, we have

$$J(u^{n+1}) - J(u^n) = \lambda_n^* \langle \nabla J(u^n), d_n\rangle + {\lambda_n^*}^2 \left\{ \sum_{k=1}^M \mu_k |w(P_k, d_n) - \mu|^2 + \gamma \|d_n\|_2^2 \right\}, \tag{3.18}$$

where

$$\lambda_n^* = \min\left\{ \alpha, \frac{-\langle \nabla J(u^n), d_n\rangle}{2\{\sum_{k=1}^M \mu_k |w(P_k, d_n) - \mu|^2 + \gamma \|d_n\|_2^2\}} \right\}. \tag{3.19}$$

If $\lambda_n^* = \alpha$, i.e.,

$$-\langle \nabla J(u^n), d_n\rangle \ge 2\alpha \left\{ \sum_{k=1}^M \mu_k |w(P_k, d_n) - \mu|^2 + \gamma \|d_n\|_2^2 \right\},$$

then

$$\begin{aligned} r_{n+1} - r_n &= J(u^{n+1}) - J(u^n) \\ &= \alpha \langle \nabla J(u^n), d_n\rangle + \alpha^2 \left\{ \sum_{k=1}^M \mu_k |w(P_k, d_n) - \mu|^2 + \gamma \|d_n\|_2^2 \right\} \\ &\le \frac{\alpha}{2} \langle \nabla J(u^n), d_n\rangle. \end{aligned}$$

Taking $\alpha \ge \frac{1}{2}$ into account, we have

$$-\langle \nabla J(u^n), d_n\rangle \le \frac{2}{\alpha}(r_n - r_{n+1}) \le 4(r_n - r_{n+1}) \tag{3.20}$$

and

$$\|d_n\|_2 \le \sqrt{\frac{2}{\gamma}} (r_n - r_{n+1})^{\frac{1}{2}}. \tag{3.21}$$

If $\lambda_n^* < \alpha$, i.e., if

$$\begin{aligned} -\langle \nabla J(u^n), d_n\rangle &< 2\alpha \left\{ \sum_{k=1}^M \mu_k |w(P_k, d_n) - \mu|^2 + \gamma \|d_n\|_2^2 \right\} \\ &< 2 \left\{ \sum_{k=1}^M \mu_k |w(P_k, d_n) - \mu|^2 + \gamma \|d_n\|_2^2 \right\}, \end{aligned}$$

then by (1.13), (3.12), and Lemma 3.1 (iii), we get

$$
\begin{aligned}
r_n - r_{n+1} &= J(u^n) - J(u^{n+1}) \\
&= \frac{1}{4}\frac{|\langle \nabla J(u^n), d_n\rangle|^2}{\sum_{k=1}^M \mu_k |w(P_k, d_n) - \mu|^2 + \gamma \|d_n\|_2^2} \\
&\geq \frac{1}{4}\frac{(2\gamma\|d_n\|_2^2)^2}{\sum_{k=1}^M \mu_k C^2(P_k, \Omega, p')\|d_n\|_{p'}^2 + \gamma\|d_n\|_2^2} \\
&\geq \frac{\gamma^2}{\sum_{k=1}^M \mu_k C^2(P_k, \Omega, p')D^2 + \gamma D^{2\nu}} \|d_n\|_2^{2(1+\nu)}.
\end{aligned} \tag{3.22}
$$

Therefore

$$
\|d_n\|_2 \leq \left(\frac{L_1}{\gamma^2}\right)^{\frac{1}{2(1+\nu)}} (r_n - r_{n+1})^{\frac{1}{2(1+\nu)}}, \tag{3.23}
$$

where $L_1 = (\sum_{k=1}^M \mu_k C^2(P_k, \Omega, p') + \gamma)D^2$. And

$$
\begin{aligned}
-\langle \nabla J(u^n), d_n\rangle &< 2\left\{\sum_{k=1}^M \mu_k |w(P_k, d_n) - \mu|^2 + \gamma\|d_n\|_2^2\right\} \\
&< 2\left\{\sum_{k=1}^M \mu_k C^2(P_k, \Omega, p')D^2 + \gamma D^{2\nu}\right\} \|d_n\|_2^{2(1-\nu)} \\
&\leq 2\frac{L_1^{\frac{2}{1+\nu}}}{\gamma^{2\frac{1-\nu}{1+\nu}}} (r_n - r_{n+1})^{\frac{1-\nu}{1+\nu}}.
\end{aligned}
$$

Combining (3.20), (3.21), (3.22), and (3.23), and using the fact that $\nu < 1$ and $\{|r_n - r_{n+1}|\}_{n=1}^\infty$ is bounded by $B = 2r_1$, we obtain that in all cases

$$
\|d_n\|_2 \leq C_1 (r_n - r_{n+1})^{\frac{1}{2(1+\nu)}} \tag{3.24}
$$

and

$$
-\langle \nabla J(u^n), d_n\rangle \leq C_2 (r_n - r_{n+1})^{\frac{1-\nu}{1+\nu}}, \tag{3.25}
$$

where

$$
C_1 = \sqrt{2}\max\left\{\frac{B^{\frac{\nu}{2(1+\nu)}}}{\sqrt{\gamma}}, \left(\frac{L_1}{\gamma^2}\right)^{\frac{1}{2(1+\nu)}}\right\},
$$

$$
C_2 = 2\max\left\{2B^{\frac{2\nu}{1+\nu}}, \frac{L_1^{\frac{2}{1+\nu}}}{\gamma^{2\frac{1-\nu}{1+\nu}}}\right\}.
$$

Substituting (3.24), (3.25), and (3.9) into (3.17), we obtain

$$
\begin{aligned}
r_n &\leq C_2 (r_n - r_{n+1})^{\frac{1-\nu}{1+\nu}} + 4\sqrt{\gamma} C_1 (r_n - r_{n+1})^{\frac{1}{2(1+\nu)}} r_n^{\frac{1}{2}} \\
&\leq C_2 (r_n - r_{n+1})^{\frac{1-\nu}{1+\nu}} + 4\sqrt{\gamma} C_1 (r_n - r_{n+1})^{\frac{1-\nu}{2(1+\nu)}} r_n^{\frac{1}{2}} \\
&\leq \left(\sqrt{C_2}(r_n - r_{n+1})^{\frac{1-\nu}{2(1+\nu)}} + \frac{2\sqrt{\gamma} C_1}{\sqrt{C_2}} r_n^{\frac{1}{2}}\right)^2 - \frac{4\gamma C_1^2}{C_2} r_n.
\end{aligned}
$$

Thus

$$\sqrt{C_2}(r_n - r_{n+1})^{\frac{1-\nu}{2(1+\nu)}} + \frac{2\sqrt{\gamma}C_1}{\sqrt{C_2}} r_n^{\frac{1}{2}} \geq \left(1 + \frac{4\gamma C_1^2}{C_2}\right)^{\frac{1}{2}} r_n^{\frac{1}{2}}.$$

Rearranging the terms and simplifying, we get

$$r_n - r_{n+1} \geq C_3 r_n^{\frac{1+\nu}{1-\nu}}, \tag{3.26}$$

where

$$C_3 = ((C_2 + 4\gamma C_1^2)^{\frac{1}{2}} + 2\sqrt{\gamma}C_1)^{-2\frac{1+\nu}{1-\nu}}.$$

By Lemma 3.2, we have

$$r_n \leq r_0 \left[1 + \left(\frac{2\nu}{1-\nu}\right) C_3 r_0^{\frac{2\nu}{1-\nu}} n\right]^{-\frac{1-\nu}{2\nu}}. \tag{3.27}$$

Now (3.9) gives

$$\|u^n - u^*\|_2 \leq \frac{2}{\sqrt{\gamma}} r_0^{\frac{1}{2}} \left[1 + \left(\frac{2\nu}{1-\nu}\right) C_3 r_0^{\frac{2\nu}{1-\nu}} n\right]^{-\frac{1-\nu}{4\nu}}. \tag{3.28}$$

Combining (3.9) with (3.24) leads to

$$\begin{aligned}
\|\bar{u}^n - u^*\|_2 &\leq \|d_n\|_2 + \|u^n - u^*\|_2 \\
&\leq C_1(r_n - r_{n+1})^{\frac{1}{2(1+\nu)}} + \frac{2}{\sqrt{\gamma}} r_n^{\frac{1}{2}} \\
&\leq \left(C_1 + \frac{2}{\sqrt{\gamma}}\right) r_n^{\frac{1}{2(1+\nu)}} \\
&\leq \left(C_1 + \frac{2}{\sqrt{\gamma}}\right) r_0^{\frac{1}{2(1+\nu)}} \left[1 + \left(\frac{2\nu}{1-\nu}\right) C_3 r_0^{\frac{2\nu}{1-\nu}} n\right]^{-\frac{1-\nu}{4\nu(1+\nu)}}.
\end{aligned}$$

So the proof is complete. ∎

Next we provide the rate estimate of the uniform convergence.

THEOREM 3.6. *Let $\{\bar{u}^n\}_{n=1}^{\infty}$ be the sequence generated by the algorithm CGPM, (2.1)–(2.5). If we assume that $w(P_k, u^*) \neq Z_k$ and that Bu and Bl are locally bounded at P_k for all $k = 1, 2, \ldots, M$, then for $\mathcal{N} = 2$, $\bar{u}^n$ converges uniformly exponentially, and for $\mathcal{N} = 3$, $\bar{u}^n$ converges uniformly subexponentially; i.e., for all $x \in \Gamma$,*

$$|\bar{u}^n(x) - \bar{u}^*(x)| \leq \begin{cases} B_2 \delta^{\frac{n}{2}} & \text{for } \mathcal{N} = 2, \\ B_3 n^{-\frac{s}{2}} & \text{for } \mathcal{N} = 3, \end{cases} \tag{3.29}$$

where the constants B_2 and B_3 are independent of n and x, $\delta = 1 - \frac{15-6\sqrt{6}}{8}\frac{\gamma}{L} \in (0,1)$ with $L = \sum_{k=1}^{M} \mu_k C^2(P_k, \Omega) + \gamma$, and $s = \frac{p-p'}{p(p'-2)}$ for all $2 < p' < p$.

Proof. By taking account of (1.8), (1.9), (1.17), and Lemmas 1 and 2 in [4], we may denote

$$\begin{aligned}
\bar{w}(P_k, u) &= \int_\Gamma E(P_k, \xi) \left[\left(\frac{1}{2}I + \mathcal{K}^*\right)^{-1} u\right](\xi)\, d\sigma_\xi \\
&= \int_\Gamma \left(\frac{1}{2}I + \mathcal{K}\right)^{-1} [E(P_k, \cdot) - C_E](\xi) \cdot u(\xi)\, d\sigma_\xi,
\end{aligned}$$

where the constant C_E is defined s.t. $E(P_k,\cdot)-C_E\in L^q_{\perp f_0}(\Gamma)$; see [4]. Due to the fact that $\mathcal{S}(f_0)=$ constant, C_E is independent of k. We have

$$w(P_k,u^n)=\bar{w}(P_k,u^n)+\rho^n,$$

where by (1.10),

$$\rho^n=-\frac{\sum_{k=1}^M\mu_k(\bar{w}(P_k,u^n)-Z_k)}{\sum_{k=1}^M\mu_k}.$$

By Lemma 2 in [4], we obtain

$$\begin{aligned}&|w(P_k,u^n)-w(P_k,u^*)|\\&=\left|\int_\Gamma\left(\frac{1}{2}I+\mathcal{K}\right)^{-1}(E(P_k,\cdot)-C_E)(\xi)\cdot(u^n(\xi)-u^*(\xi))\,d\sigma_\xi+(\rho^n-\rho^*)\right|\\&\le B_0\|u^n-u^*\|_p,\end{aligned}\tag{3.30}$$

where

$$B_0=2\max_{1\le k\le M}\left\{\left\|\left(\frac{1}{2}I+\mathcal{K}\right)^{-1}(E(P_k,\cdot)-C_E)\right\|_q\right\}.$$

Applying (1.16) and the singularity decomposition formula, Lemma 3 in [2], we write

$$\begin{aligned}\bar{u}^n(x)&=\left[u^n(x)-\frac{1}{2\gamma}\nabla J(u^n)(x)+c_n\right]_{Bl}^{Bu}\\&=\left[-\frac{2}{\gamma}\sum_{k=1}^M\mu_k(w(P_k,u^n)-Z_k)E(P_k,x)+\sum_{k=1}^M\mu_k(w(P_k,u^n)-Z_k)f_0(P_k,x)\right.\\&\quad\left.+\sum_{k=1}^M\mu_k(w(P_k,u^n)-Z_k)f_1(P_k,x)+c_n\right]_{Bl}^{Bu},\end{aligned}$$

where for $\mathcal{N}=2$, $f_0\equiv 0$, and for $\mathcal{N}=3$, $f_0(P_k,x)$ has the only singularity at $x=P_k$, which is dominated by $E(P_k,x)$ and while $f_1(P_k,x)$ is continuous and bounded. Since we assume that $w(P_k,u^*)\neq Z_k$ and both Bu and Bl are locally bounded at P_k for all $k=1,2,\dots,M$ and also notice the fact that $\lim_{x\to P_k}E(P_k,x)=+\infty$ and all c_n and c_* are bounded, there exist $N>0$, $\delta_0>0$, $e_n>0$ and $e_*>0$ s.t. for all $n>N$, $-e_n\le e^n\le e_n$, $-e_*\le e^*\le e_*$ and for all $x\in\Gamma$ with $|x-P_k|<\delta_0$ for some $k=1,2,\dots,M$,

$$\left[u^n(x)-\frac{1}{2\gamma}\nabla J(u^n)(x)+c_n+e^n\right]_{Bl}^{Bu}=\text{ either } Bu(x)\text{ or }Bl(x)$$

and

$$\left[u^*(x)-\frac{1}{2\gamma}\nabla J(u^*)(x)+c_*+e^*\right]_{Bl}^{Bu}=\text{ either } Bu(x)\text{ or }Bl(x),$$

but only one of them is reached for each k. Let

$$\begin{aligned}\Gamma_1&=\{x\in\Gamma:|x-P_k|<\delta_0\ \text{ for some } k=1,2,\dots,M\},\\\Gamma_2&=\{x\in\Gamma:|x-P_k|\ge\delta_0\ \text{ for all } k=1,2,\dots,M\}.\end{aligned}$$

By the uniform convergence theorem, Theorem 3 in [4], we have for all $n > N$ and $x \in \Gamma_1$,

$$\left[u^n(x) - \frac{1}{2\gamma}\nabla J(u^n)(x) + c_n + e^n\right]_{Bl}^{Bu} = \left[u^*(x) - \frac{1}{2\gamma}\nabla J(u^*)(x) + c_* + e^*\right]_{Bl}^{Bu}. \tag{3.31}$$

As for $x \in \Gamma_2$, all functions $E(P_k, x)$, $f_0(P_k, x)$, and $f_1(P_k, x)$ are continuous and bounded, and there exists a constant $B_1 = B_1(\delta_0) > 0$, independent of n, s.t.

$$\begin{aligned}
&\left|\left\{u^n(x) - \frac{1}{2\gamma}\nabla J(u^n)(x)\right\} - \left\{u^*(x) - \frac{1}{2\gamma}\nabla J(u^*)(x)\right\}\right| \\
&= \left|\sum_{k=1}^{M} \mu_k(w(P_k, u^n) - w(P_k, u^*))\left\{\frac{2}{\gamma}E(P_k, x) + f_0(P_k, x) + f_1(P_k, x)\right\}\right| \\
&\le B_1 B_0 \|u^n - u^*\|_p. \qquad (3.32)
\end{aligned}$$

Next we prove that $|c_n - c_*| \le B_1 B_0 \|u^n - u^*\|_p$. Write

$$\delta_n = B_1 B_0 \|u^n - u^*\|_p$$

and

$$\begin{aligned}
F_l(x) &= u^l(x) - \frac{1}{2\gamma}\nabla J(u^l)(x) \\
&= \sum_{k=1}^{M} \mu_k(w(P_k, u^l) - Z_k)\left\{\frac{2}{\gamma}E(P_k, x) + f_0(P_k, x) + f_1(P_k, x)\right\}
\end{aligned}$$

for $l = n$ or $l = *$. Then (3.31) becomes

$$[F_n(x) + c_n]_{Bl}^{Bu} = [F_n(x) + c_n + e^n]_{Bl}^{Bu} = [F_*(x) + c_* + e^*]_{Bl}^{Bu} = [F_*(x) + c_*]_{Bl}^{Bu} \tag{3.33}$$

for all $n > N$, $x \in \Gamma_1$, $-e_n \le e^n \le e_n$, and $-e_* \le e^* \le e_*$. (3.32) now means

$$|F_n(x) - F_*(x)| \le \delta_n \quad \forall\, n > N,\ \forall\, x \in \Gamma_2. \tag{3.34}$$

Notice that c_n and c_* are of the smallest magnitudes s.t.

$$\int_\Gamma [F_n(x) + c_n]_{Bl}^{Bu}\, d\sigma_x = 0 \quad \text{and} \quad \int_\Gamma [F_*(x) + c_*]_{Bl}^{Bu}\, d\sigma_x = 0. \tag{3.35}$$

So, for all $-e_n \le e^n \le e_n$ and $-e_* \le e^* \le e_*$, we have

$$\begin{aligned}
\int_{\Gamma_2} [F_*(x) + c_*]_{Bl}^{Bu}\, d\sigma_x &= -\int_{\Gamma_1} [F_*(x) + c_* + e^*]_{Bl}^{Bu}\, d\sigma_x \\
&= -\int_{\Gamma_1} [F_n(x) + c_n + e^n]_{Bl}^{Bu}\, d\sigma_x \qquad (3.36) \\
&= \int_{\Gamma_2} [F_n(x) + c_n]_{Bl}^{Bu}\, d\sigma_x.
\end{aligned}$$

If $|c_n - c_*| = \delta_n + e_n'$ with $e_n' > 0$ (e.g., $c_* = c_n + \delta_n + e_n'$), then by (3.36) we have

$$\begin{aligned}
\int_{\Gamma_2} [F_n(x) + c_n]_{Bl}^{Bu}\, d\sigma_x &= \int_{\Gamma_2} [F_*(x) + c_*]_{Bl}^{Bu}\, d\sigma_x \\
&= \int_{\Gamma_2} [F_*(x) + c_n + \delta_n + e_n']_{Bl}^{Bu}\, d\sigma_x \\
&\ge \int_{\Gamma_2} [F_n(x) + c_n + e_n']_{Bl}^{Bu}\, d\sigma_x.
\end{aligned}$$

By Lemma 6 in [4], we have

$$\int_{\Gamma_2} [F_n(x) + c_n]_{Bl}^{Bu} \, d\sigma_x = \int_{\Gamma_2} [F_n(x) + c_n + e'_n]_{Bl}^{Bu} \, d\sigma_x$$

and then

$$\int_{\Gamma_2} [F_n(x) + c_n]_{Bl}^{Bu} \, d\sigma_x = \int_{\Gamma_2} [F_n(x) + c_n + e^n]_{Bl}^{Bu} \, d\sigma_x \quad \forall\, 0 \le e^n \le e'_n.$$

It follows that

$$\int_{\Gamma} [F_n(x) + c_n + e^n]_{Bl}^{Bu} \, d\sigma_x = 0, \quad \forall\, 0 \le e^n \le \min\{e_n, e'_n\}. \tag{3.37}$$

Since c_n has the smallest magnitude s.t.

$$\int_{\Gamma} [F_n(x) + c_n]_{Bl}^{Bu} \, d\sigma_x = 0,$$

(3.37) implies $c_n \ge 0$. On the other hand, we have

$$\begin{aligned} \int_{\Gamma_2} [F_*(x) + c_*]_{Bl}^{Bu} \, d\sigma_x &= \int_{\Gamma_2} [F_n(x) + c_n]_{Bl}^{Bu} \, d\sigma_x \\ &= \int_{\Gamma_2} [F_n(x) + c_* - \delta_n - e'_n]_{Bl}^{Bu} \, d\sigma_x \\ &\le \int_{\Gamma_2} [F_*(x) + c_* - e'_n]_{Bl}^{Bu} \, d\sigma_x. \end{aligned}$$

Again by Lemma 6 in [4], we obtain

$$\int_{\Gamma_2} [F_*(x) + c_*]_{Bl}^{Bu} \, d\sigma_x = \int_{\Gamma_2} [F_*(x) + c_* - e'_n]_{Bl}^{Bu} \, d\sigma_x,$$

and then

$$\int_{\Gamma_2} [F_*(x) + c_*]_{Bl}^{Bu} \, d\sigma_x = \int_{\Gamma_2} [F_*(x) + c_* - e^n]_{Bl}^{Bu} \, d\sigma_x \quad \forall\, 0 \le e^n \le e'_n.$$

It follows that

$$\int_{\Gamma} [F_*(x) + c_* - e^n]_{Bl}^{Bu} \, d\sigma_x = 0, \quad \forall\, 0 \le e^n \le \min\{e_*, e'_n\}. \tag{3.38}$$

Since c_* has the smallest magnitude s.t.

$$\int_{\Gamma} [F_*(x) + c_*]_{Bl}^{Bu} \, d\sigma_x = 0,$$

(3.38) implies $c_* \le 0$. It leads to

$$0 \ge c_* = c_n + \delta_n + e_n > 0,$$

which is a contradiction. Similarly, we can show that $c_n = c_* + \delta_n + e'_n$ with $e'_n > 0$ will also lead to a contradiction. Therefore

$$|c_n - c_*| \le \delta_n = B_1 B_0 \|u^n - u^*\|_p. \tag{3.39}$$

Now for all $n > N$ and for all $x \in \Gamma_1$, by applying (3.33), we get

$$|\bar{u}^n(x) - \bar{u}^*(x)| = \left| [F_n(x) + c_n]_{Bl}^{Bu} - [F_*(x) + c_*]_{Bl}^{Bu} \right| = 0,$$

and for all $x \in \Gamma_2$, taking account of (3.34) and (3.39), we have

$$\begin{aligned} |\bar{u}^n(x) - \bar{u}^*(x)| &= \left| [F_n(x) + c_n]_{Bl}^{Bu} - [F_*(x) + c_*]_{Bl}^{Bu} \right| \\ &\le |F_n(x) + c_n - F_*(x) - c_*| \\ &\le 2B_1 B_0 \|u^n - u^*\|_p. \end{aligned}$$

For $n = 1, 2, \ldots, N$, let

$$B_3 = \max \left\{ \max_{1 \le n \le N} \max_{|x - P_k| \ge \delta_0} |F_n(x) + c_n - F_*(x) - c_*|, \right.$$
$$\left. \max_{1 \le k \le M} \sup_{|x - P_k| < \delta_0} [Bu(x) - Bl(x)] \right\}.$$

Then

$$|\bar{u}^n(x) - \bar{u}^*(x)| \le B_3 \le B_4 \|u^n - u^*\|_p$$

with

$$B_4 = \max \left\{ \frac{B_3}{\|u^n - u^*\|_p} : 1 \le n \le N,\ \|u^n - u^*\|_p \ne 0 \right\}.$$

In the above, since $\|u^n - u^*\|_p = 0$ implies $\bar{u}^n(x) = \bar{u}^*(x)$ for all $x \in \Gamma$, the iterate will stop, and the case in which $\|u^n - u^*\|_p = 0$ may be excluded. If we denote

$$B = \max\{B_4, 2B_1 B_0\},$$

then for all $x \in \Gamma$ we have

$$|\bar{u}^n(x) - \bar{u}^*(x)| \le B\|u^n - u^*\|_p \le \begin{cases} 2B\sqrt{\dfrac{r_1}{\gamma}}\delta^{\frac{n}{2}} & \text{for} \quad \mathcal{N} = 2, \\ BE_2 n^{-\frac{s}{2}} & \text{for} \quad \mathcal{N} = 3, \end{cases}$$

where r_1 and δ are defined in (3.3), and E_2 and s are defined in (3.14) and (3.15). Therefore the proof is complete. □

Remark 3. Notice that in (3.13), (3.14), (3.15), (3.16), and (3.29), $s = \frac{p - p'}{p(p'-2)}$ and $2 < p' < p$. So s can be made to be greater than any number by a proper choice of p'. Therefore, the convergence is faster than any power of $\frac{1}{n}$. That is why we call it subexponential convergence. Of course, the constants E_1, E_2, and E_3 in (3.13), (3.15), and (3.16), respectively, and the constant B_3 in (3.29) all depend on s but are independent of n.

Also, the assumption that $w(P_k, u^*) \ne Z_k$ for all $k = 1, 2, \ldots, M$ is important in computing the value of the optimal control $\bar{u}^*$ at $x = P_k$. When $w(P_k, u^*) = Z_k$ for some k, since the term $E(P_k, x)$ has a singularity at $x = P_k$, any error in computing $w(P_k, u^*)$ will result in a huge error in computing $(w(P_k, u^*) - Z_k)E(P_k, x)$, as x is sufficiently close to P_k and then destroys the reliability of the numerical value of the optimal control at $x = P_k$. So the strong convergence of u^n cannot guarantee the convergence of $u^n(P_k)$. Therefore, the condition that $w(P_k, u^*) \ne Z_k$ for all $k = 1, 2, \ldots, M$ is indeed a necessary and sufficient condition for u^n to converge at $P_k,\ k = 1, 2, \ldots, M$.

NONLINEAR UNCERTAIN SYSTEMS AND NECESSARY CONDITIONS OF OPTIMALITY*

N. U. AHMED† AND X. XIANG‡

Abstract. In this paper we consider an optimal control problem for a class of systems governed by nonlinear evolution equations containing a nonlinear monotone operator and a nonmonotone operator with uncertain parameters. We prove existence of solutions and present necessary conditions of optimality. Our result is illustrated by an example from quasi-linear partial differential equations with uncertain coefficients. This result is further illustrated by a more practical example.

Key words. uncertain system, monotone operator, existence, Galerkin method, optimal control, necessary conditions

1. Introduction.

Many physical systems arising from thermodynamics, electrodynamics, and population biology are modeled by differential equations, integrodifferential equations, and evolution inequalities with uncertain (or undetermined) parameters. Generally, such models can be described by differential inclusions on Banach spaces as follows:

$$\begin{cases} \dot{x} \in -A(t,x) + F(t,x), \\ x(0) = x^0, \end{cases} \tag{1}$$

where A is a linear or a nonlinear unbounded operator in a suitable Banach space and F is a multivalued map. An associated control system may be described as

$$\begin{cases} \dot{x} \in -A(t,x) + \tilde{F}(t,x,u), \\ x(0) = x^0, \end{cases} \tag{2}$$

where $\tilde{F}$ is a multivalued map and u is a suitable function representing the control actions. In recent years optimal control of systems governed by differential inclusions and, more generally, functional differential inclusions has been studied by Ahmed and Papageorgiou (see [2, 8, 9, 10] and the references therein). These studies were mainly concerned with the question of existence of optimal controls or parameters. Here we are concerned with the necessary conditions of optimality for a min-max problem (see [3, 5]).

For each admissible control u, $\mathcal{X}(u)$ denotes the set of solutions of (2) corresponding to u (usually generalized solutions). A natural problem (P) is to find $u_0 \in \mathcal{U}_{ad}$ (admissible controls) so that

$$J_0(u_0) = \inf_{u \in \mathcal{U}_{ad}} J_0(u), \tag{3}$$

where

$$J_0(u) = \sup_{x \in \mathcal{X}(u)} \left\{ \int_I l(t,x,u)dt \right\}.$$

The system designer wishes to find a control policy to minimize the maximum risk or maximize the minimum revenue. Since competing interests are involved, this is precisely a problem of game theory—here, conflicting with nature. Similar and closely related problems have been studied by Papageorgiou in [11, 12] and Ahmed and Xiang in [2, 4, 6, 7]. In [11, 4] existence questions were addressed. Here we are concerned with the necessary conditions of optimality.

In the case when $\tilde{F}$ admits a parameterization in the following form:

$$\tilde{F}(t,x,u) \equiv \left\{ \int_{\Sigma} \tilde{g}(t,x,u,\sigma)\ \mu(d\sigma), \quad \mu \in \mathcal{M}(\Sigma) \right\}, \tag{4}$$

where $\mathcal{M}(\Sigma)$ is the space of probability measures, we obtained a series of results. We studied the question of existence of optimal controls for nonlinear uncertain systems (see [4]) and presented necessary conditions of optimality for semilinear uncertain systems whose principal operator is the infinitesimal generator of a strongly continuous semigroup or a linear monotone operator (see [6], [7]).

In this paper we will present necessary conditions of optimality for problem (P) subject to the more general class of systems given by (2). Here A is assumed to be a nonlinear monotone operator and $\tilde{g}(t,x,u,\sigma)$ is a nonlinear but not monotone operator. For this purpose we prove, in section 2, the existence and uniqueness of solutions of nonlinear first-order evolution equations. In section 3, we study some necessary regularity properties of solutions of the associated nonlinear control system. In section 4 we give the necessary conditions of optimality, and in section 5 we present an example of a system, governed by a quasi-linear partial differential equation with uncertain parameters to which our results apply. This is further illustrated by a reaction-diffusion-transport system. The differences between the work of Papageorgiou [11, 12] on this topic and that considered in this paper are as follows. In [11], the system model considered consists of a nonlinear monotone operator perturbed by a nonmonotone but regular operator (mapping within the same Hilbert space, thereby excluding differential expressions) with controls appearing linearly. In [12] the principal operator is also a monotone operator arising from the subdifferential of a proper, convex, lower semicontinuous functional. The lower-order terms are Lipschitz and contain the uncertain parameters. In contrast, in this paper the perturbing operator admits differential expressions (though more regular than the principal operator) with controls appearing nonlinearly. This is a significant difference. Our assumptions, like those of Papageorgiou on the nonlinear monotone operator and the cost integrand, are standard and match those of Papageorgiou. Further, Papageorgiou considers existence questions, and we consider necessary conditions of optimality. These approaches are complementary.

2. Existence and uniqueness of solutions. Let H be a Hilbert space and V be a subspace of H having the structure of a reflexive Banach space, with the embedding $V \hookrightarrow H$ being dense and continuous. Identifying H with its dual, we have $V \hookrightarrow H \hookrightarrow V^*$, where V^* is the topological dual of V. The system model considered here is based on this evolution triple.

Let $\langle x, y\rangle$ denote the pairing of an element $x \in V$ and an element $y \in V^*$. If $x, y \in H$, then $\langle x, y\rangle = (x, y)$, where $(\ ,\ )$ is the scalar product on H. The norm in any Banach space X will be denoted by $\|.\|_X$.

Let $\{e_1, e_2, \ldots\}$ be a basis of V and set

$$H_n = \text{lin.span}\{e_1, \ldots, e_n\}.$$

We introduce in the n-dimensional space H_n the scalar product of Hilbert space H. Note $H_n \subseteq V \subseteq H$.

Let $0 < t \le T < \infty,\ I_t \equiv [0,t],\ I \equiv [0,T]$, and let $p, q \ge 1$ such that

$$1/p + 1/q = 1 \quad \text{and} \quad 2 \le p < \infty.$$

For economy of notation, we write $L_p^t(V) \equiv L_p(I_t, V),\ L_p(V) \equiv L_p(I, V),\ L_q^t(V^*) \equiv L_q(I_t, V^*),\ L_q(V^*) \equiv L_q(I, V^*)$. For p, q satisfying the preceding conditions, it follows from the reflexivity of V that both $L_p^t(V)$ and $L_q^t(V^*)$ are reflexive Banach spaces (see Theorem 1.1.17 of [1]). The pairing of $L_p^t(V)$ and $L_q^t(V^*)$ is denoted by $\langle\langle , \rangle\rangle_t$. In particular, for $t = T$, we use $\langle\langle , \rangle\rangle \equiv \langle\langle , \rangle\rangle_T$. Clearly, for $u, v \in L_2(H), \langle\langle u, v\rangle\rangle = ((u, v))$ is the scalar product in Hilbert space $L_2(H)$.

Define

$$W_{p,q} = \{x : x \in L_p(V), \dot{x} \in L_q(V^*)\},$$

$$\|x\|^2_{W_{p,q}} = \|x\|^2_{L_p(V)} + \|\dot{x}\|^2_{L_q(V^*)}.$$

$\{W_{p,q}, \| \ \|_{W_{p,q}}\}$ is a Banach space, and the embedding $W_{p,q} \hookrightarrow C(I, H)$ is continuous. If the embedding $V \hookrightarrow H$ is compact, then $W_{p,q} \hookrightarrow L_p(H)$ is also compact (see Proposition 23.23 and problem 23.13 of [3]).

Let $\mathcal{L}(X, Z)$ denote the space of bounded linear operators from X to Z and A^* the dual of the operator A.

We introduce the following assumptions.

(A1) $A : I \times V \to V^*$.

(1) $t \to A(t, x)$ is measurable.

(2) $x \to A(t, x)$ is uniformly monotone and hemicontinuous; i.e., there exists a constant $c > 0$ such that

$$\langle A(t, x_1) - A(t, x_2), x_1 - x_2\rangle \ge c\ \|x_1 - x_2\|^p_V \quad \forall\ x_1, x_2 \in V, \quad t \in I;$$

$$A(t, x + sy) \xrightarrow{w} A(t, x) \quad \text{in } V^* \quad \forall\ x, y \in V, \quad \text{as } s \to 0.$$

(3) There exist positive constants c_1, c_2, c_3 and a nonnegative function $c_4(t) \in L_q(I, R)$ such that

$$\langle A(t, x), x\rangle \ge c_1\|x\|^p_V - c_2 \quad \forall\ x \in V,\ t \in I;$$

$$\|A(t, x)\|_{V^*} \le c_4(t) + c_3\|x\|^{p-1}_V \quad \forall\ x \in V,\ t \in I.$$

(G1) $g : I \times H \to\ V^*$.

(1) g is measurable in the first variable and continuous in the second argument.

(2) There exist a constant $\alpha \ge 0$ and $h \in L_q(I, R_+)$ such that

$$\|g(t, x)\|_{V^*} \le h(t) + \alpha\|x\|^{\frac{2}{q}}_H \quad \forall\ x \in V,\ t \in I.$$

(3) g is locally Lipschitz continuous with respect to x, that is, for any $b > 0$, there exists a constant $L(b)$ such that for $x_1, x_2 \in H,\ \|x_1\|_H, \|x_2\|_H \le b$,

$$\|g(t, x_1) - g(t, x_2)\|_{V^*} \le L(b)\|x_1 - x_2\|_H \quad \forall\ t \in I.$$

Remark 2.1. Note that assumption (A1) implies coerciveness (see [3]).

Under the above assumptions we consider the following basic initial value problem:

$$\begin{cases} \dot{x} + A(t,x) = g(t,x), \\ x(0) = x^0. \end{cases} \tag{5}$$

For given $x^0 \in H$, we seek a function $x \in W_{p,q}$ such that (5) is satisfied in a weak sense, as explained later.

For $x \in L_p(V)$, we set

$$A(x)(t) = A(t, x(t)), \quad G(x)(t) = g(t, x(t)), \quad t \in I.$$

It follows from Theorem 30.A of [3] that the operator $A : L_p(V) \to L_q(V^*)$ is bounded, uniformly monotone, hemicontinuous, and coercive. The operator $G : L_p(V) \to L_q(V^*)$ is also bounded (see assumption (G1)) and has the following important properties.

LEMMA 2.2. *Suppose that the embedding $V \hookrightarrow H$ is compact. Then, whenever $x_n \overset{w}{\to} x$ in $W_{p,q}$, $G(x_n) \to G(x)$ in $L_q(V^*)$.*

Proof. Since the embedding $V \hookrightarrow H$ is compact, the embedding $W_{p,q} \hookrightarrow L_p(H)$ is compact. This means that if

$$x_n \overset{w}{\to} x \quad \text{in } W_{p,q},$$

then

$$x_n \to x \quad \text{in } L_p(H).$$

Since $x_n \overset{w}{\to} x$ in $W_{p,q}$, there exists a constant $b > 0$ such that $\|x\|_{C(I,H)} \le b$, $\|x_n\|_{C(I,H)} \le b$. By virtue of assumption (G1) and the embeddings $L_p(H) \hookrightarrow L_q(H) \hookrightarrow L_q(V^*)$, one can easily verify that

$$\begin{aligned} &\|G(x_n) - G(x)\|_{L_q(V^*)} \\ &= \left(\int_I \|g(t, x_n(t)) - g(t, x(t))\|_{V^*}^q dt \right)^{1/q} \\ &\le L(b) \left(\int_I \|x_n(t) - x(t)\|_H^q dt \right)^{1/q} \\ &\le L^* \left(\int_I \|x_n(t) - x(t)\|_H^p dt \right)^{1/p}, \end{aligned}$$

where L^* is a constant depending on p, q, b and the Lebesgue measure of I. Hence the conclusion follows.

Remark 2.3. In fact, following a similar argument as in the proof of Lemma 2.5.1 of [1], we can prove Lemma 2.2 without the local Lipschitz continuity.

It is often convenient to write system (5) as an operator equation in

$$W_{p,q}^0 \equiv \{x \in W_{p,q} : x(0) = x^0\} :$$

$$\begin{cases} \dot{x} + A(x) = G(x), \\ x \in W_{p,q}^0. \end{cases} \tag{6}$$

The purpose of this section is to present an existence result for equation (5) based on Galerkin approximation. At first, we give an a priori bound and prove the uniqueness of the solution.

LEMMA 2.4. *There exists a finite positive number b such that*

$$\|x\|_{C(I,H)} \le b, \quad \|x\|_{L_p(V)} \le b,$$
$$\|\dot{x}\|_{L_q(V^*)} \le b,$$

for any solution x (if one exists) of equation (5).

Proof. If x is any solution of (5), then for each $t \in I$,

$$\langle\langle \dot{x}, x\rangle\rangle_t + \langle\langle A(x), x\rangle\rangle_t = \langle\langle G(x), x\rangle\rangle_t,$$

giving

$$\frac{1}{2}(\|x(t)\|_H^2 - \|x(0)\|_H^2) + \langle\langle A(x), x\rangle\rangle_t = \langle\langle G(x), x\rangle\rangle_t.$$

Using the assumptions and the Cauchy inequality, for any $\varepsilon > 0$, we have

$$\begin{aligned}
&\frac{1}{2}(\|x(t)\|_H^2 - \|x(0)\|_H^2) + c_1 \ \|x\|^p_{L_p^t(V)} \\
&\le c_2 + \int_0^t \|g(t, x(t))\|_{V^*}\|x(t)\|_V dt \\
&\le c_2 + \int_0^t (h(t) + \|x(t)\|_H^{\frac{2}{q}})\|x(t)\|_V dt \\
&\le c_2 + \frac{1}{q\varepsilon^q}\int_0^t (h(t) + \|x(t)\|_H^{\frac{2}{q}})^q dt + \frac{\varepsilon^p}{p}\int_0^t \|x(t)\|_V^p dt.
\end{aligned}$$

Choosing $\varepsilon > 0$ sufficiently small, one can easily verify that there exist positive constants c_5, c_6, c_7 such that

$$\|x(t)\|_H^2 + c_5\|x\|^p_{L_p^t(V)} \le c_6 + c_7\int_0^t \|x(t)\|_H^2 dt. \tag{7}$$

From the Gronwall lemma it follows from the above inequality that

$$\|x(t)\|_H \le c_8 \quad \forall\ t \in I,$$

for some constant c_8 depending on c_6 and c_7. Again, by virtue of assumptions (3) of (A1) and (2) of (G1) and inequality (7), it is easy to verify that there exist positive constants c_9, c_{10} such that

$$\|x\|_{L_p(V)} \le c_9, \quad \|\dot{x}\|_{L_q(V^*)} \le c_{10}.$$

Choosing $b = \max\{c_8, c_9, c_{10}\}$, the assertion follows.

LEMMA 2.5. *The solution of* (5)*, if one exists, is unique.*

Proof. Let $x_1, x_2 \in W^0_{p,q}$ be two solutions of (5). Using integration by parts and the monotonicity of the operator A, we obtain that

$$\begin{aligned}
&\frac{1}{2}\|x_1(t) - x_2(t)\|_H^2 + c\|x_1 - x_2\|^p_{L_p^t(V)} \\
&\le \int_0^t \langle g(t, x_1(t)) - g(t, x_2(t)), x_1(t) - x_2(t)\rangle dt.
\end{aligned}$$

By virtue of assumption (G1), Lemma 2.4, and the Cauchy inequality, for any $\varepsilon > 0$, we have

$$\begin{aligned}
&\frac{1}{2}\|x_1(t) - x_2(t)\|_H^2 + c\|x_1 - x_2\|_{L_p^t(V)}^p \\
&\le \int_0^t \|g(t, x_1(t)) - g(t, x_2(t))\|_{V^*}\|x_1(t) - x_2(t)\|_V dt \\
&\le L(b)\int_0^t \|x_1(t) - x_2(t)\|_H\|x_1(t) - x_2(t)\|_V dt \\
&\le \frac{L(b)\varepsilon}{2}\int_0^t \|x_1(t) - x_2(t)\|_V^2 dt + \frac{L(b)}{2\varepsilon}\int_0^t \|x_1(t) - x_2(t)\|_H^2 dt.
\end{aligned}$$

Using Lemma 2.3 and the continuous embedding $L_p^t(V) \hookrightarrow L_2^t(V)$, we obtain

$$\begin{aligned}
&\|x_1(t) - x_2(t)\|_H^2 + 2c\|x_1 - x_2\|_{L_p^t(V)}^p \\
&\le L_1\varepsilon\int_0^t \|x_1(t) - x_2(t)\|_V^p dt + \frac{L(b)}{\varepsilon}\int_0^t \|x_1(t) - x_2(t)\|_H^2 dt,
\end{aligned}$$

where L_1 is a constant depending on b and the embedding constant. Consequently, for sufficiently small $\varepsilon > 0$, there exists a constant $c' > 0$ such that

$$\begin{aligned}
&\|x_1(t) - x_2(t)\|_H^2 + c'\|x_1 - x_2\|_{L_p^t(V)}^p \\
&\le \frac{L(b)}{\varepsilon}\int_0^t \|x_1(t) - x_2(t)\|_H^2 dt.
\end{aligned}$$

Using the Gronwall lemma, uniqueness follows from the above inequality.

THEOREM 2.A. *Under assumptions* (A1) *and* (G1)*, the evolution equation* (5) *has a unique solution.*

Proof. Let the sequence $\{x_n^0\}$ be an approximation of the given initial state $x^0 \in H$, i.e., $x_n^0 \in H_n$, $x_n^0 \to x^0$ in H, as $n \to \infty$.

Consider the sequence

$$x_n(t) = \sum_{k=1}^n C_{k,n}(t)e_k,$$

and seek a function x_n such that

$$\text{(8)} \qquad \begin{cases} \langle \dot{x}_n(t), e_j\rangle + \langle A(t, x_n(t)), e_j\rangle = \langle g(t, x_n(t)), e_j\rangle, & j = 1, 2, \ldots, n; \\ x_n(0) = x_n^0; \\ x_n \in L_p(I, H_n),\ \dot{x}_n \in L_q(I, H_n). \end{cases}$$

It follows from the existence theorem of Carathéodory for ordinary differential equations in R^n (see problem 30.3 of [3]) and Lemma 2.4 that, for each $n \in N$, the finite-dimensional system (8) has a unique solution x_n. It can be seen from Lemma 2.4 that $\{x_n\}$ is contained in a bounded subset of $W_{p,q}$. Hence, by assumption (A1), $\{A(x_n)\}$ is bounded in $L_q(V^*)$. Since $L_p(V)$ and $L_q(V^*)$ are reflexive Banach spaces, there exists a subsequence, again denoted by $\{x_n\}$; an element $x \in L_p(V)$ with its distributional derivative $\dot{x} \in L_q(V^*)$; and $W \in L_q(V^*)$ such that

$$\begin{aligned}
x_n &\xrightarrow{w} x \qquad \text{in } L_p(V), \\
\dot{x}_n &\xrightarrow{w} \dot{x} \qquad \text{in } L_q(V^*), \\
A(x_n) &\xrightarrow{w} W \quad \text{in } L_q(V^*)
\end{aligned}$$

as $n \to \infty$. Combining the assumptions with Lemma 2.2, we have

$$\begin{aligned} G(x_n) &\to G(x) \quad \text{in } L_q(V^*), \\ x_n(0) &\to x^0 \quad \text{in } H, \\ x_n(T) &\xrightarrow{w} z \quad \text{in } H \end{aligned}$$

as $n \to \infty$.

Let $\psi \in C^\infty(I, R)$ and $v \in H_n$. Using equation (8) and integration by parts, one can obtain

$$\begin{aligned} &(x_n(T), \psi(T)v) - (x_n(0), \psi(0)v) \\ &= \int_I \langle g(t, x_n(t)) - A(t, x_n(t)), \psi(t)v\rangle + \langle \dot{\psi}(t)v, x_n(t)\rangle dt. \end{aligned}$$

Letting $n \to \infty$, we have

$$(z, \psi(T)v) - (x^0, \psi(0)v) = \langle\langle G(x) - W, \psi v\rangle\rangle + \langle\langle \dot{\psi} v, x\rangle\rangle. \tag{9}$$

Using this, one can easily verify that the limit elements x, W, z satisfy

$$\begin{cases} \dot{x} + W = G(x), \quad x \in W_{p,q}, \\ x(0) = x^0, \ x(T) = z. \end{cases}$$

Again using equation (8) and integration by parts, we have

$$\frac{1}{2}(\|x_n(T)\|_H^2 - \|x_n(0)\|_H^2) = \langle\langle G(x_n) - A(x_n), x_n\rangle\rangle.$$

By virtue of the fact that

$$\underline{\lim}_{n\to\infty} \|x_n(T)\|_H \geq \|x(T)\|_H,$$

we obtain

$$\begin{aligned} &\overline{\lim_{n\to\infty}} \langle\langle A(x_n), x_n\rangle\rangle \\ &\leq \langle\langle G(x), x\rangle\rangle + \frac{1}{2}(\|x(0)\|_H^2 - \|x(T)\|_H^2) \\ &= \langle\langle W, x\rangle\rangle. \end{aligned}$$

Since A is monotone and hemicontinuous, A satisfies property (M) (see section 27.1 of [3]), and hence

$$W = A(x).$$

Thus the limit element x satisfies equation (6) and hence is a solution of (5). The uniqueness follows from Lemma 2.5. This finishes the proof of the theorem.

Remark 2.6. It follows from Proposition 21.23 of [3] and Lemma 2.5 that the Galerkin sequence $\{x_n\}$ weakly converges to x in $L_p(V)$. Furthermore, following an argument similar to that in Lemma 30.7 of [3], one can show that $x_n \to x$ in $C(I, H)$.

3. Controlled uncertain system. Let Σ be a compact Polish space and $\mathcal{M}(\Sigma)$ be the space of probability measures on Σ. A sequence $\mu^n \in \mathcal{M}(\Sigma)$ is said to converge weakly to $\mu \in \mathcal{M}(\Sigma)$ if

$$\int_\Sigma g(\sigma)\mu^n(d\sigma) \ \to \int_\Sigma g(\sigma)\mu(d\sigma)$$

for every $g \in C(\Sigma)$.

In addition to assumption (A1) we shall introduce the following assumptions.

(U) (1) Y is a reflexive Banach space.

(2) $U : I \to CC(Y) = \{$class of nonempty, closed, convex subsets of $Y\}$ is a measurable multifunction satisfying $U(t) \subseteq \mathcal{U}$ for almost all $t \in I$, where $\mathcal{U}$ is a fixed weakly compact convex subset of Y. For the admissible controls, we choose the set $\mathcal{U}_{ad} \equiv \{u \in L_r(Y) : u(t) \in U(t)$ a.e.$\}$ $(r \geq 2)$.

(G) $\tilde{g} : I \times H \times Y \times \Sigma \to V^*$, for $\mu \in \mathcal{M}(\Sigma)$, $g(t,x,u,\mu) \equiv \int_\Sigma \tilde{g}(t,x,u,\sigma)\mu(d\sigma)$.

(1) g is measurable in the first variable and continuous in the last three arguments.

(2) $g(.,.,u,\mu)$ satisfies assumption (G1) uniformly with respect to $u \in \mathcal{U}$, $\mu \in \mathcal{M}(\Sigma)$.

(3) g is Fréchet-differentiable with respect to $x \in H$ and $u \in Y$, and the mappings

$$G_1(x,u,\mu) : L_p(H) \times L_r(Y) \times \mathcal{M}(\Sigma) \to \mathcal{L}(L_p(H), L_q(V^*)),$$
$$G_2(x,u,\mu) : L_p(H) \times L_r(Y) \times \mathcal{M}(\Sigma) \to \mathcal{L}(L_r(Y), L_q(V^*))$$

are bounded and continuous, where

$$G_1(x,u,\mu)(t) \equiv g_x(t,x(t),u(t),\mu),$$
$$G_2(x,u,\mu)(t) \equiv g_u(t,x(t),u(t),\mu).$$

(L) $l : I \times H \times Y \to R \bigcup \{\infty\}$ is continuous and Fréchet-differentiable in both x and u on H and Y, respectively, so that $l_x \in L_q(I,H)$ and $l_u \in L_{r'}(I,Y^*)$ $(r' = r/r-1)$ in the neighborhood of the optimal control state pair (u_0, x_0), whenever such a pair exists.

Under the above assumptions, we consider the following controlled uncertain system:

$$\text{(10)} \qquad \begin{cases} \dot{x}(t) + A(t,x(t)) = g(t,x(t),u(t),\mu) \quad \text{for almost all } t \in I, \\ x(0) = x^0 \in H. \end{cases}$$

DEFINITION 3.1. *A function x is said to be a solution of the problem* (10) *corresponding to $u \in \mathcal{U}_{ad}$ if*

(1) $x \in W_{p,q}$,

(2) *for a given $\mu \in \mathcal{M}(\Sigma)$, x satisfies* (10).

Define the solution set

$$\mathcal{X}(u) \equiv \{x \mid x \text{ is a solution of (10) corresponding to } u\}.$$

Our problem, called (P), is to find $u_0 \in \mathcal{U}_{ad}$ such that

$$J_0(u_0) = \inf_{u \in \mathcal{U}_{ad}} J_0(u)$$

where

$$J_0(u) = \sup_{x \in \mathcal{X}(u)} \left\{ \int_I l(t,x,u)dt \right\}.$$

Occasionally, we use the notation $x(u,\mu)$ to denote the solution of (10) corresponding to $u \in \mathcal{U}_{ad}$ and $\mu \in \mathcal{M}(\Sigma)$. Then we can write

$$\mathcal{X}(u) = \bigcup_{\mu \in \mathcal{M}(\Sigma)} x(u,\mu).$$

Set

$$\mathcal{X} = \bigcup_{u \in \mathcal{U}_{ad}} \mathcal{X}(u).$$

Using the results of section 2, one can easily obtain the following theorem.

THEOREM 3.A. *Suppose that assumptions* (A1), (G), *and* (U) *hold. Then for every* $u \in \mathcal{U}_{ad}$ *and* $\mu \in \mathcal{M}(\Sigma)$, *equation* (10) *has a unique solution. Further, the set* $\mathcal{X}$ *is a bounded subset of* $W_{p,q}$.

For necessary conditions, we need some results on continuous dependence of solutions on controls u and parameters μ.

PROPOSITION 3.2. *Suppose that assumptions* (A1), (G), *and* (U) *hold. For any fixed* $\mu_0 \in \mathcal{M}(\Sigma)$, *let* $u, u_0 \in \mathcal{U}_{ad}$ *and* $u_\varepsilon = u_0 + \varepsilon(u - u_0)$ $(0 \le \varepsilon \le 1)$. *Then we have*

$$x_\varepsilon \equiv x(u_\varepsilon, \mu_0) \to x_0 \equiv x(u_0, \mu_0) \quad \text{in } C(I,H) \bigcap L_p(V),$$

as $\varepsilon \to 0$.

Proof. Define

$$G_1^\varepsilon = \int_0^1 G_1(x_0 + s(x_\varepsilon - x_0), u_\varepsilon, \mu_0) ds,$$
$$G_2^\varepsilon = \int_0^1 G_2(x_0, u_0 + s(u_\varepsilon - u_0), \mu_0) ds.$$

By assumptions (G) and (U), there exists a constant K such that

$$\|G_1^\varepsilon\|_{\mathcal{L}(L_p(H), L_q(V^*))} \le K, \quad \|G_2^\varepsilon\|_{\mathcal{L}(L_r(Y), L_q(V^*))} \le K.$$

Following similar steps as in the proof of Lemma 2.5, we have

$$\begin{aligned}
&\frac{1}{2}\|x_\varepsilon(t) - x_0(t)\|_H^2 + \langle\langle A(x_\varepsilon) - A(x_0), x_\varepsilon - x_0\rangle\rangle_t \\
&= \int_0^t \langle g(t, x_\varepsilon, u_\varepsilon, \mu_0) - g(t, x_0, u_0, \mu_0), x_\varepsilon - x_0\rangle dt \\
&= \int_0^t \langle g(t, x_\varepsilon, u_\varepsilon, \mu_0) - g(t, x_0, u_\varepsilon, \mu_0), x_\varepsilon - x_0\rangle dt \\
&\quad + \int_0^t \langle g(t, x_0, u_\varepsilon, \mu_0) - g(t, x_0, u_0, \mu_0), x_\varepsilon - x_0\rangle dt \\
&= \langle\langle G_1^\varepsilon(x_\varepsilon - x_0), x_\varepsilon - x_0\rangle\rangle_t + \varepsilon\langle\langle G_2^\varepsilon(u_\varepsilon - u_0), x_\varepsilon - x_0\rangle\rangle_t.
\end{aligned}$$

Using assumptions (3) of (A1) and (3) of (G1), Lemma 2.4, and the Cauchy inequality, one can verify that there exist positive constants c'', K_1, and K_2 such that

$$\begin{aligned}
&\|x_\varepsilon(t) - x_0(t)\|_H^2 + c''\|x_\varepsilon - x_0\|_{L_p^t(V)}^p \\
&\le K_1\varepsilon + K_2 \int_0^t \|x_\varepsilon - x_0\|_H^2 dt.
\end{aligned}$$

The conclusion now follows from the Gronwall lemma.

Remark 3.3. Note that Proposition 3.2 remains valid if g is merely locally Lipschitz continuous with respect to x and u.

PROPOSITION 3.4. *Suppose that the assumptions* (A1), (G), *and* (U) *hold. For any fixed* $u_0 \in \mathcal{U}_{ad}$, *let* $\mu, \mu_0 \in \mathcal{M}(\Sigma)$ *and* $\mu^\varepsilon = \mu_0 + \varepsilon(\mu - \mu_0)$ $(0 \le \varepsilon \le 1)$. *Then*

$$x^\varepsilon \equiv x(u_0, \mu^\varepsilon) \to x_0 \equiv x(u_0, \mu_0) \quad \text{in } C(I, H) \bigcap L_p(V),$$

as $\varepsilon \to 0$.

Proof. The proof is similar to that of Proposition 3.2.

4. Necessary conditions of optimality. In this section, we present our main results, the necessary conditions of optimality for the problem (P) as stated in section 3. In what follows, we shall assume that an optimal control exists (see [4, 11, 12]).

DEFINITION 4.1. *The pair* $(u_0, \mu_0) \in \mathcal{U}_{ad} \times \mathcal{M}(\Sigma)$ *is said to be the optimal strategy pair for the problem* (P) *if*

$$\inf_{u \in \mathcal{U}_{ad}} \sup_{\mu \in \mathcal{M}(\Sigma)} J(u, \mu) = \sup_{\mu \in \mathcal{M}(\Sigma)} \inf_{u \in \mathcal{U}_{ad}} J(u, \mu) = J(u_0, \mu_0),$$

where $J(u, \mu) = \int_I l(t, x(u, \mu), u)dt$, *with* $x(u, \mu)$ *being the solution of equation* (10). *In other words, the optimal strategy pair is the saddle point of the loss (cost) functional* J.

Clearly, if (u_0, μ_0) is the saddle point, the following system of inequalities must hold:

$$J(u_0, \mu) \le J(u_0, \mu_0) \le J(u, \mu_0) \quad \forall\ u \in \mathcal{U}_{ad},\ \mu \in \mathcal{M}(\Sigma). \tag{11}$$

In the game-theoretic language, $J(u_0, \mu_0)$ is called the value of the game.

Letting x_0 denote the solution corresponding to the saddle point $\{u_0, \mu_0\}$, we have the optimal triple $\{u_0, x_0, \mu_0\}$. In this section we assume that $p = q = 2$.

In order to derive the necessary optimality conditions, we need some additional assumptions for the operator A.

(A) $A : I \times V \to V^*$.

(1) A satisfies conditions (A1).

(2) A is Fréchet-differentiable with respect to $x \in V$ and for each $\xi \in W_{2,2}$ the Nemytski operator A_x defined by $A_x(\xi)(t) \equiv A_x(t, \xi(t))$ belongs to $\mathcal{L}(L_2(V), L_2(V^*))$. Further, the map $\xi \longrightarrow A_x(\xi)$ is continuous and bounded on bounded subsets of $W_{2,2}$.

Remark 4.2. Under assumption (A), for any $x \in V$, $A_x(t, x)$ is strictly positive, i.e.,

$$\langle A_x(t, x)y, y\rangle \ge c\|y\|_V^2 \quad \forall\ t \in I, \quad \forall\ y \in V.$$

In fact, by the monotonicity of A, we have, for $s > 0$,

$$\langle A(t, x + sy) - A(t, x), sy\rangle \ge c\|sy\|_V^2;$$

hence

$$\left\langle \frac{A(t, x + sy) - A(t, x)}{s}, y \right\rangle \ge c\|y\|_V^2.$$

The assertion follows upon letting $s \to 0$.

For the optimal triple $\{u_0, x_0, \mu_0\}$, define

$$A^0 \equiv A_x(x_0), \quad G_1^0 \equiv G_x(x_0, u_0, \mu_0),$$
$$G_2^0 \equiv G_u(x_0, u_0, \mu_0).$$

LEMMA 4.3. *For each $f \in L_2(V^*)$, the linear evolution equation*

$$\begin{cases} \dot{y} + A^0 y = G_1^0 y + f, \\ y(0) = 0 \end{cases} \tag{12}$$

has a unique solution $y \in W_{2.2}$.

Proof. By virtue of assumptions (A) and (G), it is easy to verify that A^0 and G_1^0 satisfy (A1) and (G1), respectively. Then, by Theorem 2.A, equation (12) has a unique solution $y \in W_{2.2}$.

As usual, in the study of optimal control problems, we need an associated adjoint problem. Here we present an existence result for the following adjoint Cauchy problem.

THEOREM 4.A. *Define $l_x^0(t) \equiv l_x(t, x_0(t), u_0(t))$. The adjoint problem*

$$\begin{cases} -\dot{\psi} + (A^0)^* \psi = (G_1^0)^* \psi + l_x^0, \\ \psi(T) = 0 \end{cases} \tag{13}$$

has a unique solution $\psi \in W_{2.2}$.

Proof. By assumption (L), $l_x^0 \in L_2(H)$. Since $L_2(H) \hookrightarrow L_2(V^*)$, $l_x^0 \in L_2(V^*)$. Reversing the flow of time $t \to T - t$, the conclusion follows from Lemma 4.3.

THEOREM 4.B (necessary conditions). *Suppose that assumptions* (A), (G), (U), *and* (L) *hold. In order that $\{u_0, x_0, \mu_0\}$ be the optimal triple for problem* (P), *it is necessary that there exist a $\psi \in W_{2,2}$ such that the following equations and inequalities hold:*

(1) $\dot{x_0} + A(t, x_0) = g(t, x_0, u_0, \mu_0), \quad x_0(0) = x^0;$
(2) $-\dot{\psi} + (A^0)^* \psi = (G_1^0)^* \psi + l_x^0(t), \quad \psi(T) = 0;$
(3) $\int_I \langle (G_2^0)^* \psi + l_u^0, u - u_0 \rangle_{Y^*, Y} dt \geq 0 \quad \forall\ u \in \mathcal{U}_{ad},$
where $l_u^0(t) = l_u(t, x_0(t), u_0(t))$;
(4) $\int_I \langle \psi, G(x_0, u_0, \mu) \rangle dt \leq \int_I \langle \psi, G(x_0, u_0, \mu_0) \rangle dt \ \forall\ \mu \in \mathcal{M}(\Sigma)$.

Proof. Let (u_0, μ_0) be a saddle point for the problem (P) and $x_0 = x(u_0, \mu_0)$ be the corresponding optimal trajectory. For any $u \in \mathcal{U}_{ad}$, by the convexity of $\mathcal{U}_{ad}$, $u_\varepsilon \equiv u_0 + \varepsilon(u - u_0) \in \mathcal{U}_{ad}$ for $0 \leq \varepsilon \leq 1$. By Theorem 3.A, the state equation (10) has a unique strong solution $x_\varepsilon = x(u_\varepsilon, \mu_0)$ corresponding to the control u_ε and parameter μ_0.

Using the second part of the inequality (11), we have

$$\int_I l(t, x_\varepsilon(t), u_\varepsilon(t)) dt - \int_I l(t, x_0(t), u_0(t)) dt \geq 0 \quad \forall\ u \in \mathcal{U}_{ad}. \tag{14}$$

Define $y_\varepsilon = (x_\varepsilon - x_0)/\varepsilon$, $A_x^\varepsilon = \int_0^1 A_x(x_0 + s(x_\varepsilon - x_0)) ds$, $G_1^\varepsilon = \int_0^1 G_1(x_0 + s(x_\varepsilon - x_0), u_\varepsilon, \mu_0) ds$, $G_2^\varepsilon = \int_0^1 G_2(x_0, u_0 + s(u_\varepsilon - u_0), \mu_0) ds$. Note that y_ε satisfies the following equation:

$$\begin{aligned} \dot{y}_\varepsilon + \frac{A(x_\varepsilon) - A(x_0)}{\varepsilon} &= [G(x_\varepsilon, u_\varepsilon, \mu_0) - G(x_0, u_0, \mu_0)]/\varepsilon \\ &= [G(x_\varepsilon, u_\varepsilon, \mu_0) - G(x_0, u_\varepsilon, \mu_0)]/\varepsilon \\ &\quad + [G(x_0, u_\varepsilon, \mu_0) - G(x_0, u_0, \mu_0)]/\varepsilon, \end{aligned}$$

which can be written as

$$\begin{cases} \dot{y}_\varepsilon + A_x^\varepsilon y_\varepsilon = G_1^\varepsilon y_\varepsilon + G_2^\varepsilon (u - u_0), \\ y_\varepsilon(0) = 0. \end{cases} \tag{15}$$

Following similar steps as in the proof of Lemma 2.4, using assumptions (A), (G), and (U), we can obtain the following a priori estimate: there exists a constant d such that for all $0 \le \varepsilon \le 1$,

$$\|y_\varepsilon\|_{C(I,H)} \le d, \quad \|y_\varepsilon\|_{L_2(V)} \le d.$$

Consider the following equation:

$$\begin{cases} \dot{y} + A^0 y = G_1^0 y + G_2^0 (u - u_0), \\ y(0) = 0. \end{cases} \tag{16}$$

Since $G_2^0(u - u_0) \in L_2(V^*)$, by Lemma 4.3, equation (16) has a unique solution $y_0 \in W_{2.2}$.

To show that $y_\varepsilon \longrightarrow y_0$, use integration by parts to obtain

$$\begin{aligned} &\frac{1}{2}\|y_\varepsilon(t) - y_0(t)\|_H^2 + \langle\langle A_x^\varepsilon y_\varepsilon - A^0 y_0, y_\varepsilon - y_0\rangle\rangle_t \\ &= \frac{1}{2}\|y_\varepsilon(t) - y_0(t)\|_H^2 + \langle\langle A_x^\varepsilon (y_\varepsilon - y_0), y_\varepsilon - y_0\rangle\rangle_t \\ &\quad + \langle\langle (A_x^\varepsilon - A^0) y_0, y_\varepsilon - y_0\rangle\rangle_t \\ &\le \langle\langle G_1^\varepsilon (y_\varepsilon - y_0), y_\varepsilon - y_0\rangle\rangle_t + \langle\langle (G_1^\varepsilon - G_1^0) y_0, y_\varepsilon - y_0\rangle\rangle_t \\ &\quad + \langle\langle (G_2^\varepsilon - G_2^0)(u - u_0), y_\varepsilon - y_0\rangle\rangle_t. \end{aligned}$$

From assumptions (A) and (G), Remark 4.2, and the Cauchy inequality, it follows that there exist constants $c^*, \eta_0, \eta_1, \eta_2$, and η_3 such that

$$\begin{aligned} &\|y_\varepsilon(t) - y_0(t)\|_H^2 + c^* \|y_\varepsilon - y_0\|_{L_2^t(V)}^2 \\ &\le \eta_0 \int_0^t \|y_\varepsilon(t) - y_0(t)\|_H^2 dt + \eta_1 \|(A_x^\varepsilon - A^0) y_0\|_{L_2^t(v^*)}^2 \\ &\quad + \eta_2 \|(G_1^\varepsilon - G_1^0) y_0\|_{L_2^t(v^*)}^2 + \eta_3 \|(G_2^\varepsilon - G_2^0)(u - u_0)\|_{L_2^t(v^*).}^2 \end{aligned} \tag{17}$$

Since $u_\varepsilon \to u_0$ in $L_r(Y)$ and $x_\varepsilon \to x_0$ in $C(I,H) \bigcap L_2(V)$ (see Proposition 3.2), we have

$$\begin{aligned} &\|(A_x^\varepsilon - A^0) y_0\|_{L_2^t(v^*)}^2 \to 0, \\ &\|(G_1^\varepsilon - G_1^0) y_0\|_{L_2^t(v^*)}^2 \to 0, \\ &\|(G_2^\varepsilon - G_2^0)(u - u_0)\|_{L_2^t(v^*)}^2 \to 0. \end{aligned}$$

By virtue of the Gronwall lemma, it follows from (17) that

$$y_\varepsilon \to y_0 \quad \text{in } C(I,H) \bigcap L_2(V),$$

as $\varepsilon \to 0$, where y_0 is the Gâteaux differential of x with respect to u in the direction $u - u_0$.

By the use of hypothesis (L), after some elementary computations, one obtains from inequality (14) that

$$\int_I [(l_x^0, y_0) + \langle l_u^0, u - u_0\rangle_{Y^*,Y}]dt \geq 0. \tag{18}$$

By Theorem 4.A, the adjoint equation (13) has a unique solution $\psi \in W_{2.2}$, and $y_0 \in W_{2,2}$ is the solution of (16). Hence

$$\begin{aligned}\langle\langle l_x^0, y_0\rangle\rangle &= \langle\langle -\dot{\psi} + (A^0)^*\psi - (G_1^0)^*\psi, y_0\rangle\rangle \\ &= \langle\langle \psi, \dot{y_0} + A^0 y_0 - G_1^0 y_0\rangle\rangle \\ &= \langle\langle \psi, G_2^0(u - u_0)\rangle\rangle \\ &= \langle\langle (G_2^0)^*\psi, u - u_0\rangle\rangle.\end{aligned}$$

It follows from (14) and the preceding arguments that

$$\int_I \langle (G_2^0)^*\psi + l_u^0, u - u_0\rangle dt \geq 0 \quad \forall\ u \in \mathcal{U}_{ad}.$$

This proves the inequality (3) as stated in Theorem 4.B.

Since (u_0, μ_0) is an optimal solution of problem (P), it follows from the first part of inequality (11) that

$$\int_I l(t, x(u_0, \mu), u_0)\ dt - \int_I l(t, x_0, u_0)\ dt \leq 0 \quad \forall\ \mu \in \mathcal{M}(\Sigma). \tag{19}$$

For any $\mu \in \mathcal{M}$, $\mu^\varepsilon = \mu_0 + \varepsilon(\mu - \mu_0) \in \mathcal{M}(\Sigma)$ $(0 \leq \varepsilon \leq 1)$, $x^\varepsilon \equiv x(u_0, \mu^\varepsilon)$ is the unique solution of the system (10) corresponding to the control u_0 and parameter μ^ε. Clearly, we have

$$\int_I l(t, x^\varepsilon, u_0)\ dt - \int_I l(t, x_0, u_0)\ dt \leq 0. \tag{20}$$

Define $\omega^\varepsilon = (x^\varepsilon - x_0)/\varepsilon$, $\tilde{A}_x^\varepsilon = \int_0^1 A_x(x_0 + s(x^\varepsilon - x_0))ds$, $\tilde{G}_1^\varepsilon = \int_0^1 G_1(x_0 + s(x^\varepsilon - x_0), u_0, \mu^\varepsilon)ds$. Clearly, ω^ε satisfies the following equation:

$$\begin{aligned}\dot{\omega}^\varepsilon + \tilde{A}_x^\varepsilon\omega^\varepsilon &= [G(x^\varepsilon, u_0, \mu^\varepsilon) - G(x_0, u_0, \mu_0)]/\varepsilon \\ &= \tilde{G}_1^\varepsilon\omega^\varepsilon + [G(x_0, u_0, \mu) - G(x_0, u_0, \mu_0)].\end{aligned}$$

Following similar steps, as in the case of controls, one can verify that the Gâteaux differential of x with respect to μ in the direction $\mu - \mu_0$ is the solution of the following equation:

$$\begin{cases} \dot{\omega} + A^0\omega = G_1^0\omega + [G(x_0, u_0, \mu) - G(x_0, u_0, \mu_0)], \\ \omega(0) = 0. \end{cases} \tag{21}$$

Again, following similar arguments as in the case of control, proving inequality (3), one can verify that

$$\int_I \langle \psi, G(x_0, u_0, \mu)\rangle dt \leq \int_I \langle \psi, G(x_0, u_0, \mu_0)\rangle dt \quad \forall\ \mu \in \mathcal{M}(\Sigma),$$

where ψ satisfies the adjoint equation (13). This completes the proof of Theorem 4.B.

5. An example. Let Ω be an open connected bounded region in R^n with smooth boundary $\partial\Omega$, $Q_T = I \times \Omega$, $(I = (0,T),\ 0 < T < \infty)$. Let $\alpha = (\alpha_1, \ldots, \alpha_n)$ be a multi-index with $\{\alpha_i\}$ nonnegative integers and $\mid \alpha \mid = \sum_1^n \alpha_i$. Suppose $p \geq 2$ and $q = p/(p-1)$, $W^{m,p}(\Omega)$, $mp > n$, denotes the standard Sobolev space with the usual norm:

$$\|\varphi\|_{W^{m,p}} = \left(\sum_{|\alpha| \leq m} \|D^\alpha \varphi\|^p_{L^p(\Omega)} \right)^{1/p}, \qquad m = 0, 1, \ldots.$$

Let $W_o^{m,p} \equiv \{\varphi \in W^{m,p} \mid D^\beta \varphi \mid_{\partial\Omega} = 0, \mid \beta \mid \leq m-1\}$. It is well known that $C_0^\infty \subset W_0^{m,p} \subset L^2 \subset W^{-m,p}$ and the embedding $W_0^{m,p} \hookrightarrow L^2$ is compact.

We consider a minimax problem of a typical uncertain system governed by the following controlled quasi-linear parabolic partial differential equation of order $2m$ with uncertain coefficients as described below:

$$\text{(22)} \qquad \begin{cases} \partial/\partial t \varphi(\xi,t) + \sum_{|\alpha| \leq m} (-1)^{|\alpha|} D^\alpha A_\alpha(\xi, t, \eta(\varphi)(\xi,t)) \\ \qquad = \sum_{|\alpha| \leq m} D^\alpha [\sigma_\alpha(\xi) f_\alpha(\xi, t, \varphi, u)], \\ D^\beta \varphi(\xi,t) = 0 \quad \text{on} \quad \partial\Omega \times [0,T] \qquad \forall \beta : \mid \beta \mid \leq m-1, \\ \varphi(\xi, 0) = \varphi^0(\xi) \in L^2(\Omega), \end{cases}$$

where $\eta(\varphi) \equiv \{(D^\alpha \varphi),\ \mid \alpha \mid \leq m\}$. Let $M \equiv card\{\mid \alpha \mid \leq m\}$.

The coefficients $\{\sigma_\alpha, \mid \alpha \mid \leq m\}$ are the uncertain parameters. Suppose $\{\lambda_{i,\alpha}\}(i = 1, 2; \mid \alpha \mid \leq m)$ are given constants and $\sigma_\alpha : \Omega \to R$ are bounded measurable functions satisfying

$$\lambda_{1,\alpha} \leq \sigma_\alpha(\xi) \leq \lambda_{2,\alpha} \qquad \forall\ \xi \in \Omega, \mid \alpha \mid \leq m.$$

We denote this class of functions by Σ. It is assumed that these functions are not known to the control system designer, except their range Σ. In other words, the system has unknown (uncertain) coefficients. For example, in the mathematical models for pollutant transport equations described by reaction-diffusion-transport equations (see the comments following this example), the three-dimensional velocity distribution of the water (or air) is impossible to determine at every point of the medium. However, it is possible to set lower and upper limits to these quantities.

Let $\beta_1(\xi,t), \beta_2(\xi,t) : Q_T \to R$ be bounded continuous functions so that

$$\beta_1(\xi,t) \leq \beta_2(\xi,t) \quad \forall\ (\xi,t) \in Q_T.$$

Set

$$U(t) \equiv \{w \in L_\infty(\Omega, R^{M_1}) \equiv Z : \beta_1(\xi,t) \leq w_i(\xi) \leq \beta_2(\xi,t), \quad \xi \in \Omega, 1 \leq i \leq M_1\}.$$

The set of admissible controls $\mathcal{U}_{ad}$ is chosen as

$$\mathcal{U}_{ad} \equiv \{u \in L_\infty(I, Z) : u(t) \in U(t) \text{ a.e.}\}.$$

The cost function for the control problem is given by

$$J_0(u) \equiv \sup_{\sigma \in \Sigma} \int_I \int_\Omega l_0(\xi, t, \eta(\varphi(\sigma)(\xi,t)), u(\xi,t)) d\xi dt.$$

Our problem (P*) is to find u_0 such that

$$J_0(u_0) = \inf\{J_0(u), u \in \mathcal{U}_{ad}\}.$$

For $\varphi, \psi \in W_0^{m,p},\ t \in I$, we set

$$a(t,\varphi,\psi) \equiv \int_\Omega \sum_{|\alpha|\le m} A_\alpha(\xi,t,\eta(\varphi(\xi)))D^\alpha\psi d\xi$$

and assume that the function $A_\alpha(|\ \alpha\ | \le m) : Q_T \times R^M \to R$ satisfies the following properties.

(A1) $(\xi,t) \to A_\alpha(\xi,t,\eta)$ is measurable on Q_T for $\eta \in R^M, \eta \to A_\alpha(\xi,t,\eta)$ is continuously differentiable on R^M for almost all $(\xi,t) \in Q_T$.

(A2) There exist positive constants c, c_1, c_2, c_3, c_4 for $\eta = (\eta^\alpha) \in R^M$ such that

$$\sum_{|\alpha|\le m} (A_\alpha(\xi,t,\eta) - A_\alpha(\xi,t,\tilde\eta))(\eta_\alpha - \tilde\eta_\alpha) \ge c \sum_{|\alpha|\le m} |\ \eta_\alpha - \tilde\eta_\alpha\ |^p;$$

$$\sum_{|\alpha|\le m} A_\alpha(\xi,t,\eta)\eta_\alpha \ge c_1 \sum_{|\alpha|\le m} |\ \eta_\alpha\ |^p - c_2;$$

$$|\ A_\alpha(\xi,t,\eta)\ | \le c_4 + c_3 \sum_{|\alpha|\le m} |\ \eta_\alpha\ |^{p-1}\ .$$

Under the above assumptions one can verify that for each $\varphi \in W_0^{m,p}$ and $t \in I$, $\psi \to a(t,\varphi,\psi)$ is a continuous linear form on $W_0^{m,p}$ and hence there exists exactly one operator $A : I \times W_0^{m,p} \to W^{-m,q}$ such that

$$\langle A(t,\varphi),\psi\rangle_{W^{-m,q},W_0^{m,p}} = a(t,\varphi,\psi).$$

Identifying $V \equiv W_0^{m,p}, H \equiv L_2(\Omega), V^* \equiv W^{-m,q}$, it follows from the above assumptions that the operator A as defined above satisfies the assumption (A) of section 4.

Clearly, the set Σ is a closed bounded convex subset of $L_\infty(\Omega, R^M)$, and hence w^* is compact. Thus, with respect to the w^* topology, it is a compact Hausdorff space. Since $L_1(\Omega, R^M)$ is separable, the set Σ is metrizable with respect to which it is a complete separable metric space and hence a compact Polish space. Therefore $\mathcal{M}(\Sigma)$ is a compact Polish space. For our control problem we choose this as our parameter set.

Assume the function $f_\alpha : Q_T \times R \times R^{M_1} \to R \quad (|\ \alpha\ | \le m)$ satisfies the following properties:

(F1) $(\xi,t) \to f_\alpha(\xi,t,\gamma,v)$ is measurable on Q_T for all $(\gamma,v) \in R \times R^{M_1}$; $(\gamma,v) \to f_\alpha(\xi,t,\gamma,v)$ is continuously differentiable on $R \times R^{M_1}$ for almost all $(\xi,t) \in Q_T$.

(F2) There exist $b_1 \in L_q(Q_T)$ and $b_2 \ge 0$ such that

$$|\ f_\alpha(\xi,t,\gamma,v)\ | \le b_1(\xi,t) + b_2\ |\ \gamma\ |^{2/q}$$

for all $(\xi,t) \in Q_T,\ v \in U(t)$.

For $\varphi \in L^2(\Omega),\ v \in U(t),\ t \in I$, set

$$b^{v,\sigma}(t,\varphi,\psi) \equiv \int_\Omega \sum_{|\alpha|\le m} \sigma_\alpha(\xi) f_\alpha(\xi,t,\varphi,v) D^\alpha\psi d\xi.$$

Under the above assumptions it is not difficult to verify that $\psi \to b^{v,\sigma}(t,\varphi,\psi)$ is a continuous linear form on $W_0^{m,p}$, and hence, for each $\sigma \in \Sigma$, there exists an operator $F_\sigma : I \times L^2(\Omega) \times U(t) \to W^{-m,q}$ such that

$$b^{v,\sigma}(t,\varphi,\psi) = \langle F_\sigma(t,\varphi,v),\psi\rangle_{V^*,V},$$

and F_σ satisfies assumption (G) of section 3.

Using the operators A and F_σ as defined above, equation (22) can be written as the abstract evolution equation

$$\begin{cases} \dot{\varphi} + A(t,\varphi) = F_\sigma(t,\varphi,u), \\ \varphi(0) = \varphi^0. \end{cases} \tag{23}$$

For each $u \in \mathcal{U}_{ad}$, define the set

$$\mathcal{X}(u) \equiv \{\varphi \in C(I,H) \mid \varphi \text{ is a generalized solution of (23)}\}$$

(see section 30.4 of [3]). Theorem 3.A shows that $\mathcal{X}(u) \neq \emptyset$.

For $\phi \in W_0^{m,p},\ v \in U(t)$, define

$$l(t,\phi,v) = \int_\Omega l_0(\xi,t,\eta(\phi(\xi)),v)d\xi.$$

Suppose that the function $l_0 : Q_T \times R^M, \times R^{M_1} \to R \cup \{\infty\}$ is continuous and continuously differentiable with respect to the last $M + M^1$ variables and, further, the inequality

$$\mid l_0(\xi,t,\eta,v) \mid \leq k(1+ \mid \eta \mid^2_{R^M}), \quad v \in U(t), \quad (\xi,t) \in Q_T,$$

holds. Under the above hypothesis, it is easy to see that the function $l(t,\varphi,v) : I \times W_0^{m,p} \times U(t) \to R$ satisfies assumption (L) of section 4. Thus the problem (P*) can be restated as follows.

Minimize $J_0(u), u \in \mathcal{U}_{ad}$, subject to the differential equation (23), where

$$J_0(u) = \sup\left\{\int_I l(t,\varphi,u)dt, \varphi \in \mathcal{X}(u)\right\}.$$

Hence our result of Theorem 4.B can be used to solve this problem.

Further remarks. For further illustration we present here a more practical example dealing with a reaction-diffusion-transport system, as remarked earlier. The system is governed by

$$\begin{cases} (\partial/\partial t)C(\xi,t) - D\triangle C + \nabla C\sigma = f(\sigma,C,u) \quad \text{on} \quad \Omega \times (0,T], \\ C(\xi,t) = 0 \quad \text{on} \quad \partial\Omega \times [0,T], \\ C(\xi,0) = C^0(\xi), \quad \xi \in \Omega. \end{cases} \tag{24}$$

Here, Ω is an open bounded subset of R^3 with smooth boundary representing, for example, the aquatic body (lakes, rivers); C represents the concentration of n different biochemical pollutants in the aquatic system. $D \equiv \text{diag}\{d_1, d_2, \ldots, d_n\}$ is the diffusion matrix, $\sigma = \sigma(\xi)$ represents the three-dimensional velocity field of the water body, and $u = u(t,\xi)$ represents the control vector. The second term in the equation accounts for pollutant movement by diffusion, the third represents transport (of pollutants) by the flow field, and the last term on the right-hand side of the equation represents interaction between the pollutants and the control agents. Note that ∇C is an $n \times 3$ matrix. The controls may consist of (a) biological agents such as micro-organisms capable of producing biodegradation of pollutants, (b) chemicals, or (c) simple physical means of extraction. For the mathematical setting, we take $p = q = 2$, $H = L_2(\Omega, R^n)$, $V = H_0^1(\Omega, R^n)$, with V^* being the dual of V. Assuming that D is positive definite, we take, for the operator A, the $L_2(\Omega, R^n)$ realization of

the Laplacian $-D\triangle$ with Dirichlet boundary condition. It is obvious in this case that the operator $A \in \mathcal{L}(V, V^*)$, and it is coercive and hence monotone. For the nonlinear operator F_σ, we take

$$F_\sigma(C, u) \equiv -\nabla C\sigma + f(\sigma, C, u).$$

Here we assume that the velocity field σ is unknown and that

$$\sigma \in \Sigma \equiv \{\sigma \in L_\infty(\Omega, R^3) : \ \mathrm{div}\sigma = 0, \lambda_1 \le \sigma_i(\xi) \le \lambda_2, \xi \in \Omega, i = 1, 2, 3\},$$

where the upper and lower bounds are known. For the admissible controls, define

$$U \equiv \{v \in L_\infty(\Omega, R^m) \equiv Z : \beta_i(\xi) \le v_i(\xi) \le \gamma_i(\xi), i = 1, 2, \ldots, m\},$$

where $\beta_i, \gamma_i \in L_\infty(\Omega)$ are a given set of functions satisfying $\beta_i(\xi) \le \gamma_i(\xi), \xi \in \Omega$. The admissible controls are given by

$$\mathcal{U}_{ad} \equiv \{u \in L_\infty([0, T], Z) : u(t) \in U \text{ a.e.}\}.$$

We assume that f is locally Lipschitz in $y \in R^n$ and continuous in all the variables satisfying

$$|f(\sigma, y, v)|_{R^n} \le b_1(\xi) + b_2|y|_{R^n}, \quad \text{for all } \sigma \in \Sigma, v \in U,$$

where $b_1 \in L_2^+(\Omega), b_2 > 0$. For Lotka–Volterra-type logistical interactions, the local Lipschitz property holds. Under the above assumptions it is easy to verify that for each $\sigma \in \Sigma$,

$$F_\sigma : H \times U \mapsto V^* \ \text{ and also } F_\sigma : V \times U \mapsto H.$$

Hence equation (24) can be written in abstract form as

$$\left\{ \begin{array}{l} \dot{C} + AC = F_\sigma(C, u), \\ C(0) = C^0. \end{array} \right. \tag{25}$$

For the cost integrand l, one may choose the quadratic function

$$l(C, u) \equiv \int_\Omega \{(Q(\xi, t)(C - C^d), C - C^d)_{R^n} + (R(\xi, t)u, u)_{R^m}\} d\xi,$$

where Q and R are positive semidefinite matrix-valued functions on $\Omega \times [0, T]$, possibly with essentially bounded measurable entries and C^d denotes the acceptable pollution level. Note that variables Q and R signify regional and temporal variation in the cost of pollutant extraction. Since all the assumptions of our abstract result and those of the example are satisfied in this particular case, our result applies.

Remark. The optimal strategy pair can be computed by use of the computational algorithm for the min-max problem given in [6]. This algorithm is based on similar optimality conditions as given in our Theorem 4.B. For details, the reader may see [6].

EXACT CONTROLLABILITY OF THE DAMPED WAVE EQUATION*

MARIANNA A. SHUBOV†, CLYDE F. MARTIN†, JERALD P. DAUER‡, AND BORIS P. BELINSKIY‡

Abstract. We study the controllability problem for a distributed parameter system governed by the damped wave equation

$$u_{tt} - \frac{1}{\rho(x)}\frac{d}{dx}\left(p(x)\frac{du}{dx}\right) + 2d(x)u_t + q(x)u = g(x)f(t),$$

where $x \in (0, a)$, with the boundary conditions

$$u(0) = 0, \quad (u_x + hu_t)(a) = 0, \quad h \in \mathbb{C} \cup \{\infty\}.$$

This equation describes the forced motion of a nonhomogeneous string subject to a viscous damping with the damping coefficient $d(x)$ and with damping (if Re $h > 0$) or energy production (if Re $h < 0$) at one end. (All results extend to the case when a similar condition is imposed at the other end as well.) The function $f(t)$ is considered as a control. Generalizing well-known results by D. Russell concerning the string with $d(x) = 0$, we give necessary and sufficient conditions for exact unique controllability and approximate controllability of the system. Our proofs are based on recent results by M. Shubov concerning the spectral analysis of a class of nonselfadjoint operators and operator pencils generated by the above equation.

Key words. nonselfadjoint operators, exact and approximate controllability, eigenvectors and root vectors, Riesz basis, nonharmonic exponential basis, hyperbolic equations, damping, distributed parameter control, stability

1. Introduction.

We consider the one-dimensional wave equation which governs the vibrations of a string with spatially nonhomogeneous positive damping, modulus of elasticity, and density coefficients. The equation is defined on a finite interval with linear first-order nonselfadjoint boundary conditions containing damping terms. We use the spectral decomposition method to construct a control law that brings the system to rest in a specified finite time. This control law is implemented through the forcing term of the form $g(x)f(t)$, where g is the force distribution function and f is the control. We give necessary and sufficient conditions on the initial data and the force distribution function under which the construction of the desired control is possible, and then we give an explicit construction of the control. If these conditions are not satisfied but are replaced by weaker conditions, the system is, nevertheless, approximately controllable.

Our results can be considered as generalization of classic results by D. Russell [1]–[4], who solved the above controllability problem for the one-dimensional wave equation without damping term. The main difference between the damped wave equation and the undamped one [1]–[6] is the fact that our equation generates a nonselfadjoint

operator, for which the spectral theory has only recently been developed. Our solution is based on recent results obtained by M. Shubov [7]–[9], who showed that the system of eigenvectors and associated vectors of the aforementioned nonselfadjoint operator forms a Riesz basis in the energy space. The case of a string with constant density, nonconstant damping, and the Dirichlet boundary conditions was recently studied in [23], [24]. For the case of a nonconstant density, zero damping coefficient and damping in the boundary conditions see [25]–[28], [6]. However, the combination of nonconstant damping and density with the damping in the boundary conditions makes the problem significantly more complicated even if the coefficients are smooth.

This paper is organized as follows. In section 2 we provide all necessary definitions, collect the necessary information from [7]–[9], and formulate our main results. In section 3 we reformulate the original problem in operator format and reduce it to a nonclassical moment problem. The solution of the moment problem is based on the fact that the system of nonharmonic exponentials $\{e^{i\lambda_n t}\}$, where λ_n are the complex eigenfrequencies of the string, forms a Riesz basis in the space $L^2(0,T)$, where T is the control time. This fact follows from the asymptotic formulas for λ_n obtained in [7] in the general case (even if the density has zeros or singularities) and in [6], [23]–[27] in the aforementioned particular cases.

In section 3 we, also, define the strong solution of the original initial-boundary problem following the spirit of works by J.-L. Lions [10], [11] and mention that our solution obtained by the method of spectral decomposition satisfies all the requirements of this definition if the initial data are sufficiently regular. In section 4 we use the variational approach to define the weak solution. However, our definition is nonstandard. It is adapted to our operator formulation of the control problem, and we suggest that it might be of interest in itself. We prove the uniqueness of our weak solution using the spectral properties of the dynamics generator and show that the solution of the control problem satisfies this definition for a wider class of initial data.

Using the spectral decomposition method, we give an explicit construction of the control function in terms of the eigenvalues and the eigenvectors of the nonselfadjoint operator, which is the dynamic generator of the damped string. We also give the formula for the minimal time which is required to damp the motion. This time turns out to be equal to twice the time it takes for a wave to travel from one end of the string to the other. This means that the control time for the damped string is the same as in the case of undamped string [2].

We mention in conclusion that the controllability problem for hyperbolic equations is treated in an extensive literature (see, e.g., the classic book [29] and references therein). The general controllability results for linear hyperbolic equations are given in [30]. However, as far as we know, the controllability problem for the damped wave equation has never been treated by the spectral decomposition method. This method allows one to consider the control of the form $g(x)f(t)$ and to provide an explicit construction of the control function.

2. Auxiliary propositions and statement of main results. Our main object of interest is the following wave equation:

$$u_{tt} - \frac{1}{\rho(x)}\frac{d}{dx}\left(p(x)\frac{du}{dx}\right) + 2d(x)u_t + q(x)u = g(x)f(t), \quad x \in [0,a,], \quad t \geq 0. \tag{2.1}$$

Equation (2.1) describes forced motion of a string with density $\rho(x)$ and modulus of elasticity $p(x)$, subject to an external harmonic force with the rigidity coefficient $q(x)$ and in the presence of viscous damping $2d(x)$. Precise conditions for these functions

will be formulated later. The force distribution function is denoted by $g \in L^2(0,a)$, and $f(t)$ is called an admissible control function on the interval $[0,T]$ if it is an element of $L^2(0,T)$.

We will assume that $u(x,t)$ satisfies the boundary conditions

$$u(0,t) = 0, \quad (u_x + hu_t)(a) = 0, \quad h \in \mathbb{C} \cup \{\infty\}, \tag{2.2}$$

and the initial conditions

$$u(x,0) = u_0^0(x), \quad u_t(x,0) = u_1^0(x). \tag{2.3}$$

Let us mention some particular cases of problem (2.1)–(2.3). If $h = 0$ (the Neumann boundary condition at $x = a$), the problem describes the vibrations of a finite string with the left end fixed and the right end free. If $h = \infty$ (the Dirichlet boundary condition $u(a) = 0$), we deal with the vibrations of a finite string with both ends fixed. If $h = 1$ (the so-called Sommerfeld radiation boundary condition), the problem describes the resonance phenomena in the scattering of acoustical waves on the semi-infinite string. (For more details on the resonance phenomenon see [6], [8]). We consider the Dirichlet condition at $x = 0$ only for the simplification of the exposition. All our proofs can be extended to the case $(u_x + ku_t)(0) = 0$, $k \in \mathbb{C} \cup \{\infty\}$. We consider the following problem.

Let initial conditions (2.3) *and* $T > 0$ *be given. Does there exist an admissible control* f *on* $[0,T]$ *such that the solution of problem* (2.1)–(2.3) *also satisfies an additional condition at* $t = T$*:*

$$u(x,T) = 0, \quad u_t(x,T) = 0, \ x \in [0,a]? \tag{2.4}$$

Due to the uniqueness theorem, (2.4) *means that* $u(x,t) = 0$ *for* $t \geqslant T$.

For a satisfactory solution of the control problem it is necessary that the set of aforementioned initial conditions be sufficiently large. Conditions (2.13), (2.14) of our main Theorem 2.4 below define a dense linear subspace of the energy space $\mathcal{H}$ which consists of initial data that can be steered to zero in time $T = 2\mathcal{M}$ (see (2.10) below).

To describe the energy space we first formulate the precise conditions on the coefficients of (2.1):

$$\rho(x), p(x), d(x) > 0, \quad q(x) \geq 0, \quad \rho, p \in H^2(0,a), \quad d \in H^1(0,a), \quad q \in L^\infty(0,a). \tag{2.5}$$

Remark 2.1. (a) As was already mentioned in the introduction, in this paper we consider the case of a nonconstant positive viscous damping. It is certainly possible that $d(x) = \text{const} > 0$, but it is important that $d(x)$ does not vanish identically. Assumptions (2.5) about the coefficients of our problem are sufficient for Theorems 2.1–2.3 below to be correct. These theorems are also correct in the case $d(x) = 0$ for all $x \in [0,a]$ (see the aforementioned works [25]–[28], [6]) or if $d(x)$ vanishes on a set of a positive Lebesgue measure. However, in these cases certain additional assumptions about the parameters of the problem should be satisfied. See Remark 2.2 below for a more detailed commentary.

(b) In fact, the assumption $d(x) > 0$ is also unnecessary. It is introduced in order to treat $d(x)u_t$ as a dissipative term. $d(x)$ may take negative values on $[0,a]$. In this case we should require that $d(x) = 0$ only on a set of Lebesgue measure zero and a certain integral involving d, p, and ρ does not vanish (see [7], [8]). (If $d(x) = 0$ on a set of a positive measure, then the aforementioned conditions from Remark 2.2 must be satisfied.)

(c) Note that due to (2.5) and the embedding $H^1(0,a) \subset C[0,a]$, the function $d(x)$ is continuous. So, the condition $d(x) > 0$ for $x \in [0,a]$ means that $d(x) \geq d_0 > 0$.

As the space $\mathcal{H}$ we take the closure of all smooth, two-component functions $U(x) = \binom{u_0(x)}{u_1(x)}$, such that $u_0(x) = 0$ in a vicinity of $x = 0$ with respect to the standard energy metric:

$$\|U\|^2_{\mathcal{H}} = \frac{1}{2}\int_0^a \left[p(x)|u_0'|^2 + q(x)\rho(x)|u_0|^2 + \rho(x)|u_1|^2\right] dx. \tag{2.6}$$

Under our assumption ($q \geqslant 0$) the above quantity is always positive and can be treated as the energy of the system. The case $q \leq 0$ is also treatable as a problem with indefinite metric [12].

Now we reproduce some important corollaries of the results from [7]–[9]. Let us look for a solution of (2.1), (2.2) in the form $e^{i\lambda t}u(x)$, and for $u(x)$ we obtain the following one-dimensional boundary value problem:

$$\frac{d}{dx}\left(p(x)\frac{du}{dx}\right) + \lambda^2\rho(x)u - 2i\lambda d(x)\rho(x)u - q(x)\rho(x)u = 0, \quad x \in [0,a], \tag{2.7}$$

$$u(0) = 0, \quad (u_x + i\lambda h u)(a) = 0, \quad h \in \mathbb{C} \cup \{\infty\}. \tag{2.8}$$

Problem (2.7), (2.8) is nonselfadjoint for two reasons: the damping term in the equation ($d(x) \neq 0$) and the complex parameter h in the boundary condition.

DEFINITION 2.1. *We say that $\lambda \in \mathbb{C}$ is an eigenvalue of the nonselfadjoint quadratic operator pencil generated by* (2.1), (2.2) *if problem* (2.7), (2.8) *has a nontrivial solution, which is called an* eigenfunction.

The necessary results from [7]–[9] are given by Theorems 2.1–2.3 below.

THEOREM 2.1. (1) *The problem defined by* (2.7), (2.8) *has an infinite discrete spectrum $\{\lambda_n\}_{n\in\mathbb{Z}}$. All eigenvalues, except for at most a finite number of finite multiplicity, are simple. There are no real eigenvalues.*

(2) *All eigenvalues are located in a strip parallel to the real axis, and* $\mathrm{Re}\lambda_n \to \pm\infty$ *as $n \to \pm\infty$. The simple eigenvalues are strongly separated:*

$$\inf_{n,m,n\neq m} |\lambda_n - \lambda_m| > 0. \tag{2.9}$$

The following asymptotics are valid for $\{\lambda_n\}_{n\in\mathbb{Z}}$:

$$\lim_{n\to\pm\infty} \lambda_n/n = \mathcal{M}, \quad \mathcal{M} = \int_0^a \sqrt{\rho(x)/p(x)}dx < \infty. \tag{2.10}$$

The next statement (Theorem 2.2 below) describes the geometry of the set of eigenfunctions. We notice that each eigenvalue of the quadratic operator pencil (2.7), (2.8) may have only a finite number of associated functions. (For the definition of associated functions of an operator pencil see [13, p. 56].) In the future, we will denote by $\{\varphi_n\}_{n\in\mathbb{Z}}$ the set of all linearly independent eigenfunctions and associated functions, making no difference between them. (For more information about the structure of this set see [8]).

THEOREM 2.2. (1) *The eigenfunctions $\{\varphi_n\}_{n\in\mathbb{Z}}$, specified by the condition $\varphi_n'(0) = d_0\lambda_n$, where d_0 is an absolute constant that can be given in terms of $\rho, p, d,$ and q, and corresponding associated functions are almost normalized (i.e., their norms are bounded from above and below by positive constants) in the space $L^2_\eta(0,a)$, where $\eta = \rho/p$.*

(2) *The set of two-component vectors*

$$\Phi_n(x) = \begin{pmatrix} \dfrac{1}{i\lambda_n} & \varphi_n(x) \\ & \varphi_n(x) \end{pmatrix}, \quad -\infty < n < \infty, \tag{2.11}$$

forms a Riesz basis in the energy space (*see* (2.6)).

THEOREM 2.3. *The set of nonharmonic exponentials* $\{e^{i\overline{\lambda}_n t}\}_{n\in\mathbb{Z}}$ *forms a Riesz basis in the space* $L^2(0, 2\mathcal{M})$, *where* $\mathcal{M}$ *is given in* (2.10).

This theorem follows immediately from the results established in [8]. It is shown in [8] that the points $\{\lambda_n\}_{n\in\mathbb{Z}}$ coincide with the roots of the so-called generalized Jost function. The latter function (see [8, Theorem 2.1]) is an entire function of the first order and of the exponential type $\mathcal{M}$, which is also a sine-type function with the width of the indicator diagram equal to $2\mathcal{M}$. All these properties imply the statement of Theorem 2.3 due to the Levin–Golovin theorem (see, e.g., [28]).

An alternative proof of Theorem 2.3 can be obtained based on the combination of Theorem 2.1 with the general approach to bases of exponentials developed in [28] (see also references in [28]). The latter approach gives additional information about the above set of exponentials. Namely, this set forms a Riesz basis in its closed linear span in $L^2(0, \ell)$ for any $\ell : 2\mathcal{M} \le \ell > \infty$. For $\ell < 2\mathcal{M}$, the set of exponentials is overloaded in $L^2(0, \ell)$. The only value of ℓ for which the above exponentials form a Riesz basis in the whole space $L^2(0, \ell)$ is $\ell = 2\mathcal{M}$. We briefly outline the argument which leads to all of the above conclusions. It follows immediately from statement (2) of Theorem 2.1 that the set of points $\{\lambda_n\}_{n\in\mathbb{Z}}$ satisfies the well-known Carleson condition [14], [15]:

$$\inf_i \prod_{\substack{j=-\infty \\ j\ne i}}^{\infty} \left| \frac{\lambda_j - \lambda_i}{\lambda_j - \overline{\lambda}_i} \right| = \delta > 0. \tag{C}$$

Condition (C) is necessary and sufficient for a system of exponentials to form a Riesz basis in its closed linear span E in the space $L^2(0, \infty)$. Consider the natural projection $P_\ell : L^2(0, \infty) \to L^2(0, \ell)$, $0 < \ell < \infty$. If the restriction $P_\ell|_E$ of this projection to the subspace E is a linear isomorphism, then the set $\{e^{i\lambda_n t}\}_{n\in\mathbb{Z}}$ is a Riesz basis in its closed span in the space $L^2(0, \ell)$ as well. The information about the spectrum, contained in Theorem 2.1, combined with the results in [28] allows us to conclude that the latter statement is true precisely for $2\mathcal{M} \le \ell < \infty$. If $\ell = 2\mathcal{M}$, then the range of $P_\ell|_E$ coincides with $L^2(0, 2\mathcal{M})$, and therefore, the exponentials form a Riesz basis in $L^2(0, 2\mathcal{M})$. We refer to [28] for more details.

Remark 2.2. Theorems 2.1–2.3 are also correct without any additional assumptions in the case when $d(x) \equiv 0$, $x \in [0, a]$, and $\operatorname{Im} h \ne 0$. However, if $d(x) \equiv 0$ or vanishes on a set of positive Lebesgue measure and h is real, one must assume, in addition to (2.5), that at least one of the following three conditions is satisfied:

(a) $\sqrt{p(a)/\rho(a)} \ne |h|$;

(b) $\lim\limits_{x\to a^-} \dfrac{d}{dx}\sqrt{\dfrac{p(x)}{\rho(x)}} \ne 0$;

(c) $\lim\limits_{x\to a^-} \dfrac{d^2}{dx^2}\sqrt{\dfrac{p(x)}{\rho(x)}} \ne 0$.

If all of the above relations (a)–(c) are not satisfied, i.e., we have equalities, and $p, \rho \in C^2(0,a) \cap C[0,a]$, then Theorems 2.1–2.3 do not take place. In this case the spectrum (it is not empty if $p(x)/\rho(x)$ is not identically equal to $|h|$) does not belong to a strip parallel to the real axis: Im $\lambda_n \to \infty$. This behavior of the spectrum destroys the basis property of both the eigenfunctions and the nonharmonic exponentials. In particular, the above conditions are not satisfied if $p(x) = \rho(x) = \text{const}$, $h = 1$. In this case, since it is easy to check by an elementary computation, the spectrum of the problem is empty. However, we stress once again that if $d(x) > 0$ for $x \in [0,a]$, then the behavior of the spectrum described in Theorem 2.1 is immediately restored and all three theorems take place. We refer to [6]–[8] for more detailed information.

The above-described situation has a natural physical interpretation. Assume for simplification that $p(x) = 1$, $d(x) = 0$, $h = 1$, but $\rho(x)$ may be nonconstant. Let us extend $\rho(x)$ to the whole semiaxis $[0,\infty)$ by the rule $\rho(x) = 1$ for $x \in (a,\infty)$. As was mentioned above, in this case our problem describes the scattering of elastic waves on an obstacle concentrated on the interval $[0,a]$. Problem (2.7), (2.8) describes the so-called resonances and resonance states, i.e., quasi-stationary oscillations of the string with finite lifetime. The lifetime of a particular resonance is $\tau_n = |\mathrm{Im}\lambda_n|^{-1}$. If the eigenvalues λ_n behave as described in Theorem 2.1, then $\tau_n \geq \tau^\circ > 0$. So we have an infinite series of "long-lived" resonance states (eigenfunctions of pencil (2.7), (2.78)) ($\tau_n \nrightarrow 0$). The above conditions (a)–(c) adapted to this case say that for an existence for such a series of resonances it is necessary that at least one of the functions $\rho(x)$, $\rho'(x)$, or $\rho''(x)$ have a jump at $x = a$; i.e., the obstacle is not "too smooth." If the conditions (a)–(c) are not satisfied and the density (extended to $[0,\infty)$ by the above rule) is smooth ($\rho \in C^2[0,\infty)$) but nonconstant ($\rho(x) \neq$ const for $x \in [0,a]$), then the resonance spectrum $\{\lambda_n\}$ still exists. However, in this case $\mathrm{Im}\,\lambda_n \to \infty$ and the lifetime of resonance states $\tau_n \to 0$. In other words, for a smooth obstacle we have an infinite series of "short-lived" resonance states. Such a behavior of the spectrum destroys the Riesz basis property of the resonance states and of the corresponding nonharmonic exponentials. Finally, if $\rho(x) = 1$ for all $x \in [0,\infty)$, then there is no obstacle at all and, therefore, there are no resonances, i.e., the spectrum is empty.

We remark in conclusion that the case when Im $h \neq 0$ also has a natural physical interpretation. In this case we have a jump of the "refraction coefficient" at $x = a$. In other words, there is a refraction of elastic waves at the boundary of the obstacle. This explains why the nonsmoothness conditions (a)–(c) are not necessary for the existence of long-lived resonance states if Im $h \neq 0$.

Now we make the following important remark. From this moment on, we assume that for each eigenvalue we have only one normalized eigenvector and no associated vectors. The above assumption makes the exposition below more transparent. If we took into account a possible finite number of nonsimple eigenvalues, then the formulation of our main result would become somewhat more complicated. However, its proof would not become significantly more difficult.

Now we formulate our main results.

THEOREM 2.4 (unique controllability). *Let*

$$U_0(x) = \begin{pmatrix} u_0^0(x) \\ u_1^0(x) \end{pmatrix}$$

be initial data (2.3) *and* $G(x) = \begin{pmatrix} 0 \\ g(x) \end{pmatrix}$, *where* $g(x)$ *is the force distribution function from* (2.1). *Assume that* U_0, $G \in \mathcal{H}$ *have the following expansions with respect to*

basis (2.11):

$$U_0(x) = \sum_{n\in\mathbb{Z}} u_n^0 \Phi_n(x), \quad G(x) = \sum_{n\in\mathbb{Z}} g_n \Phi_n(x). \tag{2.12}$$

(1) *Assume that*

$$g_n \neq 0 \text{ for all } n \in \mathbb{Z}. \tag{2.13}$$

The following statements hold.

(a) *System* (2.1)–(2.3) *is controllable in the time interval* $[0, 2\mathcal{M}]$ *if and only if*

$$\{\gamma_n = u_n^0/g_n\}_{n\in\mathbb{Z}} \in \ell^2(\mathbb{Z}), \text{ i.e., } \sum_{n\in\mathbb{Z}} |\gamma_n|^2 < \infty. \tag{2.14}$$

(b) *Let* $\{\omega_n(t)\}_{n\in\mathbb{Z}}$ *be the Riesz basis in* $L^2(0, 2\mathcal{M})$, *biorthogonal* [13], [15] *to the basis* $\{e^{i\overline{\lambda}_n t}\}_{n\in\mathbb{Z}}$, *i.e.,* $\int_0^{2\mathcal{M}} e^{-i\lambda_m t}\omega_n(t)dt = \delta_{m,n}$. *The desired control function which brings the system to zero state on the time interval* $[0, 2\mathcal{M}]$ *is uniquely defined by the formula*

$$f(t) = -\sum_{n\in\mathbb{Z}} \gamma_n \omega_n(t). \tag{2.15}$$

(c) *If* $T < 2\mathcal{M}$, *then the system is not controllable in time* T.

(d) *If* $T > 2\mathcal{M}$, *then the system is controllable in time* T *and our control problem has infinitely many solutions* $f \in L^2(0, T)$.

(2) *Assume now that* (2.13) *is not satisfied, and let* $R = \{n \in \mathbb{Z} : g_n = 0\}$. *Let* γ_n *be defined by* (2.14) *only for* $n \in \mathbb{Z}\backslash R$. *Let* $S = \{n \in \mathbb{Z} : u_n^\circ = 0\}$.

The following statements hold.

(a) *The system is controllable in time* $T = 2\mathcal{M}$ *if and only if*

$$R \subseteq S \text{ and } \sum_{n\in\mathbb{Z}\backslash S} |\gamma_n|^2 < \infty. \tag{2.16}$$

(b) *The desired control function is not unique and can be given by*

$$f(t) = -\sum_{n\in\mathbb{Z}\backslash S} \gamma_n \omega_n(t) + \sum_{m\in R} \alpha_m \omega_m(t), \tag{2.17}$$

where $\alpha_m \in \mathbb{C}$ *are arbitrary coefficients such that* $\sum_{m\in R} |\alpha_m|^2 < \infty$.

(c) *If the set* $R\backslash(R \cap S)$ *is not empty, then the problem is not controllable in any time.*

Remark 2.1. (a) An explicit formula for $\omega_n(t)$ (in terms of the truncated Blaschke product) is known but is rather complicated [17], [18]. (b) Statement (2) of Theorem 2.4 is a generalization of statement (1). We formulate statement (1) separately because of its importance.

THEOREM 2.5 (approximate controllability). *Assume that condition* (2.14) *is not satisfied but*

$$\{\gamma_n\}_{n\in\mathbb{Z}} \in \ell^p(\mathbb{Z}) \text{ for some } p \in (2, \infty], \tag{2.18}$$

$$\text{i.e., } \sum_{n\in\mathbb{Z}} |\gamma_n|^p < \infty \quad (\text{if } 2 < p < \infty) \text{ or } \sup_{n\in\mathbb{Z}} |\gamma_n| < \infty \quad (\text{if } p = \infty).$$

Then for any $\epsilon > 0$, there exists N such that for the control function

$$f_N(t) = -\sum_{|n|\leqslant N} \gamma_n \omega_n(t) \tag{2.19}$$

we have

$$\|U(\cdot,T)\|_{\mathcal{H}} \leqslant \epsilon \quad \text{for } T = 2\mathcal{M}. \tag{2.20}$$

However, $\|f_N\|_{L^2(0,2\mathcal{M})} \to \infty$ as $N \to \infty$.

3. Reduction to the moment problem and strong solution of the control problem. In this section we first give an operator reformulation of the problem and then using the generalized Fourier method obtain a formal solution. This allows us to prove our main results from section 2. If the initial data are sufficiently regular (Theorem 3.2 below), then our formal solution is, in fact, the strong solution of the control problem.

Let us represent our initial-boundary problem in the form of the following nonselfadjoint operator equation for the function $U = \left(\begin{smallmatrix} u \\ u_t \end{smallmatrix}\right) \equiv \left(\begin{smallmatrix} u_0 \\ u_1 \end{smallmatrix}\right)$:

$$U_t = i\mathcal{L}U + \widehat{G}, \quad U|_{t=0} = U_0 \in \mathcal{H}, \tag{3.1}$$

where

$$U_0(x) = \begin{pmatrix} u_0^0(x) \\ u_1^0(x) \end{pmatrix}, \quad \widehat{G}(x,t) = f(t)G(x), \quad G(x) = \begin{pmatrix} 0 \\ g(x) \end{pmatrix},$$

and $\mathcal{L}$ is the following matrix differential operator in $\mathcal{H}$:

$$\mathcal{L} = -i \begin{pmatrix} 0 & 1 \\ \dfrac{1}{\rho(x)} \dfrac{d}{dx}\left(p(x)\dfrac{d}{dx}\right) - q(x) & -2d(x) \end{pmatrix}. \tag{3.2}$$

$\mathcal{L}$ is a closed maximal (dissipative if $\operatorname{Re} h \geq 0$) nonselfadjoint operator in $\mathcal{H}$ with the domain

$$D(\mathcal{L}) = \{U \in \mathcal{H} : u_0 \in H^2(0,a), u_1 \in H^1(0,a), u_1(0) = 0, (u_0' + hu_1)(a) = 0.\} \tag{3.3}$$

LEMMA 3.1. *The set of all root vectors (eigenvectors and associated vectors together) of $\mathcal{L}$ forms a Riesz basis (linear isomorphic image of an orthonormal basis) in $\mathcal{H}$. It coincides with the set of two-component functions* (2.11).

Proof. If $\Phi \in \mathcal{H}$ is an eigenvector of $\mathcal{L}$, then we see that the second component of $\Phi = \left(\begin{smallmatrix} \varphi_1 \\ \varphi_2 \end{smallmatrix}\right)$ satisfies (2.1) and conditions (2.2), while the first component $\varphi_1 = (i\lambda)^{-1}\varphi_2$. If we normalize the function φ_1 by the condition $\varphi_1'(0) = 1$, then Theorems 2.1 and 2.2 provide the Riesz-basis property of the set of root-vectors of $\mathcal{L}$. ∎

Utilizing the Fourier method and the Riesz basis property of vectors (2.11), we look for a solution of (3.1) in the form

$$U(x,t) = \sum_{n\in\mathbb{Z}} a_n(t)\Phi_n(x). \tag{3.4}$$

We also decompose both functions $\widehat{G}$ and U_0 with respect to $\{\Phi_n\}_{n\in\mathbb{Z}}$:

$$\widehat{G}(x,t) = f(t)\begin{pmatrix} 0 \\ g(x) \end{pmatrix} = f(t)\sum_{n\in\mathbb{Z}} g_n\Phi_n(x), \quad \sum |g_n|^2 < \infty, \tag{3.5}$$

$$U_0(x) = \begin{pmatrix} u_0^0(x) \\ u_1^0(x) \end{pmatrix} = \sum_{n\in\mathbb{Z}} u_n^0\Phi_n, \quad \sum_{n\in\mathbb{Z}} |u_n^0|^2 < \infty. \tag{3.6}$$

Substituting (3.4)–(3.6) into (3.1) gives the following formal series for $U(x,t)$:

$$U(x,t) = \sum_{n\in\mathbb{Z}} \left[u_n^0 e^{i\lambda_n t} + g_n \int_0^t e^{i\lambda_n(t-\tau)} f(\tau)d\tau \right] \Phi_n(x). \tag{3.7}$$

Assume for now that series (3.7) does represent the solution of (3.1). (All necessary justifications are given below.) *Can we find the moment T such that $u(x,T) = u_t(x,T) = 0$?* From (3.7) and the Riesz basis property of $\{\Phi_n\}$ it follows that $U(x,T) = 0$ if and only if the following infinite system has a solution $f \in L^2(0,T)$:

$$u_n^0 + g_n \int_0^T e^{-i\lambda_n\tau} f(\tau)d\tau = 0, \quad n \in \mathbb{Z}. \tag{3.8}$$

Theorem 3.1 below provides the proof of Theorem 2.4 (up to necessary justifications given at the end of this section and in section 4).

THEOREM 3.1.

(1) *Assume that* (2.13) *is satisfied and $\gamma_n = u_n^0/g_n$ are defined by* (2.12). *Then moment problem* (3.8) *has a unique solution if and only if condition* (2.14) *is satisfied. This solution is given by* (2.15).

(2) *Assume that* (2.13) *is not satisfied. Then the moment problem* (3.8) *has a solution if and only if conditions* (2.16) *are satisfied. This solution is not unique and is given by* (2.19), (2.20).

Proof. If (2.13) is satisfied, (3.8) can be written as

$$(f, \chi_n)_{L^2(0,T)} = -\gamma_n, \quad n \in \mathbb{Z}. \tag{3.9}$$

Thus $\{-\gamma_n\}_{n\in\mathbb{Z}}$ is just the sequence of generalized Fourier coefficients of f with respect to the Riesz basis $\{\chi_n = e^{i\overline{\lambda}_n t}\}_{n\in\mathbb{Z}}$. It follows from the Riesz-basis property of the system $\{\chi_n\}_{n\in\mathbb{Z}}$ that (3.9) has a unique solution $f \in L^2(0,T)$ if and only if (2.13) is satisfied. This solution (see [16, 21]) has the form

$$f(t) = \sum_{n\in\mathbb{Z}} (f, \chi_n)_{L^2(0,T)}\omega_n(t), \tag{3.10}$$

where $\{\omega_n\}_{n\in\mathbb{Z}}$ is the basis in $L^2(0,T)$, which is biorthogonal to $\{\chi_n\}_{n\in\mathbb{Z}}$. Substituting (3.9) into (3.10) we obtain precisely (2.15).

Assume now that (2.13) is not satisfied, i.e., $g_n = 0$ for $n \in R \subset \mathbb{Z}$, but (2.16) takes place. Then (3.18) is equivalent to the system

$$(f, \chi_n)_{L^2(0,T)} = -\gamma_n, \quad n \in \mathbb{Z}\backslash R \quad \text{and} \quad (f, \chi_n)_{L^2(0,T)} = \alpha_n, \quad n \in R, \tag{3.11}$$

where α_n, $n \in R$, are arbitrary complex numbers. Since $\{\chi_n\}_{n\in\mathbb{Z}}$ is a Riesz basis, the solution to (3.11) exists if and only if (2.16) and is satisfied. This solution again has

the form (3.10). Substituting (3.11) into (3.10) and taking into account that $\gamma_n \neq 0$ only if $n \in \mathbb{Z}\backslash S$, we obtain (2.17). □

In the conclusion we prove the proposition, which implies Theorem 2.5.

PROPOSITION 3.1. *Assume that the sequence* $\{\gamma_n\}_{n\in\mathbb{Z}}$ *from* (2.9) *is bounded:*

$$|\gamma_n| \leq \Gamma < \infty. \tag{3.12}$$

Assume also that the control function $f(t) = f_N(t)$ *where* $f_N(t)$ *is defined in* (2.19). *Then the following statement takes place for the function* $U(x,t)$ *defined by* (3.7)*: for every* $\varepsilon > 0$ *there exists* N_0 *such that*

$$\|U(\cdot,T)\|_{\mathcal{H}} \leqslant \varepsilon \quad \textit{for} \quad N \geq N_0. \tag{3.13}$$

Proof. Substituting control function (2.19) into (3.7) and taking $t = T$, we obtain

$$U(x,T) = \sum_{|n|=N+1}^{\infty} e^{i\lambda_n t} u_n^0 \Phi_n(x). \tag{3.14}$$

Now we estimate the $\mathcal{H}$-norm of (3.14) using (3.12) and the fact that the system $\{\Phi_n\}$ is almost normalized (we write $\varphi \asymp \psi$ if $C_1\varphi \leq \psi \leq C_2\varphi$, C_1, $C_2 > 0$):

$$\begin{aligned} \|U(\cdot,T)\|_{\mathcal{H}}^2 \asymp \sum_{|n|=N+1}^{\infty} |u_n^0|^2 &= \sum_{|n|=N+1}^{\infty} |g_n|^2 |\gamma_n|^2 \\ &\leqslant \Gamma^2 \sum_{|n|=N+1}^{\infty} |g_N|^2 \to 0 \text{ as } N \to \infty. \end{aligned} \tag{3.15}$$

□

Remark 3.1. (a) If $\{\gamma_n\}_{n\in\mathbb{Z}} \in \ell^q(\mathbb{Z})$ with $q > 2$, then we can make the estimate (3.15) more precise. Indeed, due to the R-basis property of $\{\gamma_n\}_{n\in\mathbb{Z}}$ we can change the numeration of the sequence $\{\lambda_n\}$ such that each sequence $\{|\gamma_n|\}_{n=1}^{\infty}$ and $\{|\gamma_n|\}_{n=-\infty}^{-1}$ becomes nonincreasing: $|\gamma_{|n|}| \geqslant |\gamma_{|n+1|}|$. Then estimate (3.15) can be continued:

$$\|U(\cdot,T)\|_{\mathcal{H}}^2 \leqslant \max\{|\gamma_{N+1}|^2, |\gamma_{-N-1}|^2\} \sum_{|n|=N+1}^{\infty} |g_n^0|^2. \tag{3.16}$$

As $|\gamma|_{|N+1|} \to 0$, we see that $\|U\|_{\mathcal{H}}$ from (3.16) decreases much faster than in (3.15).

(b) As follows from (2.19), for the control function f_N we have $\|f_N\|_{L^2(0,T)}^2 \asymp \sum_{|n|=1}^{N} |\gamma_n|^2$. If $|\gamma_n| \leqslant \Gamma < \infty$, then $\|f_N\| \asymp N \to \infty$ as $N \to \infty$. This means that we can "kill" as many low-frequency harmonics as we need but at the expense of the increasing of the norm of f_N.

(c) If $\{\gamma_n\}_{n\in\mathbb{Z}} \in \ell^q(\mathbb{Z})$, then we can give an approximation for the number of harmonics, which should "be killed" to keep estimate (3.16). Namely, if $\alpha = \|G\|_{\mathcal{H}}$, then we can take $N = [(\varepsilon\alpha)^{-q}] + 1$, where ε is the same as in (3.13) and $[x]$ denotes the greatest integer that does not exceed x.

Now we come back to formula (3.7) and show that under appropriate conditions on U_0 and $\widehat{G}$ it defines the strong solution of problem (3.1). The existence and uniqueness theorems for a linear evolutionary problem (3.1) are well known both for abstract Hilbert space setting [21] and for hyperbolic equations [22]. Using the semigroup approach we can construct a mild or a strong solution of (3.1). However, in our case a complete spectral information about the nonselfadjoint operator $\mathcal{L}$ allows

us to point out some additional properties of the solution which cannot be obtained by purely semigroup methods.

The operator $\mathcal{L}$ generates a continuous scale of Hilbert spaces $\mathcal{H}_\alpha (\alpha \geq 0)$ in the following way. Based on Theorem 2.2 and the Bari's theorem [15], any vector $\Psi \in \mathcal{H}$ can be expanded as

$$\Psi(x) = \sum_{n\in\mathbb{Z}} \psi_n \Phi_n(x), \quad \sum_{n\in\mathbb{Z}} |\psi_n|^2 < \infty. \tag{3.17}$$

We define $\mathcal{H}_\alpha (\alpha \geq 0)$ as the set of all vectors $\Psi \in \mathcal{H}$ such that

$$\|\Psi\|^2_{\mathcal{H}_\alpha} \equiv \sum_{n\in\mathbb{Z}} |\lambda_n|^\alpha |\psi_n|^2 < \infty. \tag{3.18}$$

Since $\lambda = 0$ does not belong to the spectrum of $\mathcal{L}$, $\mathcal{H}_\alpha$ is a Hilbert space with the norm given by (3.18). It is clear that $\mathcal{H}_0 = \mathcal{H}$ and the norm $\|\cdot\|_{\mathcal{H}_0}$ is equivalent to the energy norm (2.6). It is possible to show that $\mathcal{H}_2 = D(\mathcal{L})$ (see (3.3)). Moreover, $\mathcal{H}_\alpha = D(\mathcal{L}^{\alpha/2})$, where powers of $\mathcal{L}$ can be defined based on its spectral decomposition.

DEFINITION 3.1. *Let $\widehat{G} \in L^2(0,T;\mathcal{H}_2)$ ($\widehat{G}$ is not necessarily of form* (3.5)*). A function $U : [0,T] \to \mathcal{H}_2$ is a strong solution of problem* (3.1) *on the interval $[0,T]$ if it satisfies the following conditions:* (i) *$U \in C(0,T;\mathcal{H}_2)$;* (ii) *$U$ is differentiable with respect to t in the sense of distributions with values in $\mathcal{H}$ and the derivative $U_t \in L^2(0,T;\mathcal{H})$;* (iii) *$U$ is strongly differentiable with respect to t in the sense of $\mathcal{H}$-norm a.e. on $[0,T]$ and the strong derivative coincides a.e. with the distributional derivative U_t;* (iv) *U satisfies* (3.1) *for almost all $t \in [0,T]$;* (v) *$U = U_0 \in \mathcal{H}_2$ for $t = 0$.*

There are two classic approaches to the notion of a strong solution of an evolution equation $U_t + AU = \widehat{G}(t)$ in a Banach space X [11, p. 405]. If $\widehat{G} \in C(0,T;X)$, it is required that U is strongly differentiable for all $t \in [0,T]$ and $U(t) \in D(A)$ for all t. If, however, $\widehat{G} \in L^p(0,T;X)$ $(p \geq 1)$, then the first definition is not applicable. It is required that U_t exists in the sense of distributions with values in X, $U(t) \in D(A)$ a.e., and the equation is satisfied a.e. on $[0,T]$. In our problem the control $f \in L^2(0,T)$. So we have to use the second approach. However, our Definition 3.1 differs from the classical one in two aspects. First, $U \in C(0,T;D(A))$, and second, we point out (property (iii)) that the strong $\mathcal{H}$-derivative of U exists a.e. and coincides with the distributional derivative. This property cannot be obtained based on purely semigroup argument, and it takes place due to our spectral representation for A.

THEOREM 3.2. *Assume that $\widehat{G} \in L^2(0,T;\mathcal{H}_2)$ and $U_0 \in \mathcal{H}_2$. Then the series in* (3.7) *is convergent in the norm of $\mathcal{H}_2$ for any $t \in [0,T]$ and defines the unique strong solution of problem* (3.1)*. (If $\widehat{G}$ is not of form* (3.5)*, then formula* (3.7) *can be easily modified and the statement of the theorem remains valid.)*

We omit the proof of this theorem since it is based on standard estimates. The only step which might require some commentary is the proof of the property (iii). It is obvious that the distributional derivative of U has the form

$$U_t(x,t) = \sum_{n\in\mathbb{Z}} \dot{a}_n(t)\Phi_n(x) \ \text{ for almost all } \ t \in [0,T],$$

since distributional derivatives commute with limits. So to prove (iii) one estimates the $\mathcal{H}$ norm of the difference between this expression and $\delta^{-1}[U(x,t+\delta) - U(x,t)]$.

We also recall that, according to Theorem 2.1 (statement (2)), the spectrum belongs to a strip parallel to the real axis and, therefore, the imaginary parts of

the eigenvalues are bounded. The latter fact is necessary for the series (3.7) to be convergent.

4. Weak solution of the control problem. In this section we show that for a wider class of U_0 and $\widehat{G}$ than in Theorem 3.2 formula (3.7) gives a weak solution of problem (3.1). The definition of the weak solution, as well as its existence and uniqueness, for problem (2.1), (2.2) are well known [10, 11, 22]. However, the standard definition is inconvenient for us. We need a modified definition of the weak solution which is adjusted to the operator formulation (3.1) of the problem. To simplify the exposition we give proofs only for the case of the Dirichlet boundary conditions at $x = a (h = \infty)$.

Since $\{\Phi_n\}_{n\in\mathbb{Z}}$ forms a Riesz basis in $\mathcal{H}$, its biorthogonal system $\{\mathcal{X}_n\}_{n\in\mathbb{Z}}$ (defined by $(\Phi_n, \mathcal{X}_m)_{\mathcal{H}} = \delta_{nm}$) also forms a Riesz basis [19]. From the Riesz-basis property it follows that the operator $\mathcal{L}$ admits the spectral representation which allows us to define powers of $\mathcal{L}$:

$$\mathcal{L}^\alpha \Psi = \sum_{n\in\mathbb{Z}} \lambda_n^\alpha (\Psi, \chi_n)_{\mathcal{H}} \Phi_n, \quad \Psi \in D(\mathcal{L}^\alpha), \quad \alpha \geq 0. \tag{4.1}$$

To define λ_n^α uniquely one should use the principal branch of the logarithm. $\mathcal{L}$ generates the scale of Hilbert spaces

$$\mathcal{H}_\alpha = D(\mathcal{L}^{\alpha/2}) = \left\{ \Psi \in \mathcal{H} : \|\Psi\|^2_{\mathcal{H}_\alpha} = \sum_{n\in\mathbb{Z}} |\lambda_n|^\alpha |(\Psi, \mathcal{X}_n)_{\mathcal{H}}|^2 < \infty \right\}. \tag{4.2}$$

The operator $\mathcal{L}^*$ adjoint to $\mathcal{L}$ in $\mathcal{H}$ can be described as the differential operator

$$\mathcal{L}^* = -i \begin{pmatrix} 0 & 1 \\ \dfrac{1}{\rho(x)} \dfrac{d}{dx} \left(p(x) \dfrac{d}{dx} \right) - q(x) & 2d(x) \end{pmatrix} \tag{4.3}$$

on the domain

$$D(\mathcal{L}^*) = D(\mathcal{L}) = \{U \in \mathcal{H} : u_0 \in H^2(0,a), \quad u_1 \in H^1(0,a), \quad u_1(0) = u_0(a) = 0\}.$$

The operator $\mathcal{L}$ has the discrete spectrum $\{\bar{\lambda}_n\}_{n\in\mathbb{Z}}$ of the same multiplicity as the spectrum of $\mathcal{L}$. The system of the root vectors of $\mathcal{L}^*$ coincides with the biorthogonal basis $\{\mathcal{X}_n\}_{n\in\mathbb{Z}}$. The adjoint operator $\mathcal{L}^*$ and its powers have the spectral representation

$$(\mathcal{L}^*)^\alpha \Psi = \sum_{n\in\mathbb{Z}} \bar{\lambda}_n^\alpha (\Psi, \Phi_n)_{\mathcal{H}} \mathcal{X}_n, \quad \Psi \in D((\mathcal{L}^*)^\alpha), \quad \alpha \geq 0, \tag{4.4}$$

and $\mathcal{L}^*$ also defines a scale of Hilbert spaces:

$$\widehat{\mathcal{H}}_\alpha = D((\mathcal{L}^*)^{\alpha/2}) = \left\{ \Psi \in \mathcal{H} : \|\Psi\|^2_{\widehat{\mathcal{H}}_\alpha} = \sum_{n\in\mathbb{Z}} |\lambda_n|^\alpha |(\Psi, \Phi_n)_{\mathcal{H}}|^2 < \infty \right\}. \tag{4.5}$$

It follows from the general properties of the biorthogonal Riesz bases that $\mathcal{H}_\alpha$ and $\widehat{\mathcal{H}}_\alpha$ coincide as vector spaces. We use different notation for these spaces to emphasize that norms (4.2) and (4.5) are different. These norms are, however, equivalent.

In the following we will use the space $W(0,T;\widehat{\mathcal{H}}_\alpha)$. It consists of all functions $V \in L^2(0,T;\widehat{\mathcal{H}}_\alpha)$ which have derivative, V_t, in the sense of distributions with values in $\mathcal{H}_\alpha$ (see, e.g., [11, Chap. 3]) and $V_t \in L^2(0,T;\mathcal{H}_\alpha)$. The norm in $W(0,T;\widehat{\mathcal{H}}_\alpha)$ is

$$\|V\|_W^2 = \int_0^T (\|V(\cdot,t)\|_{\widehat{\mathcal{H}}_\alpha}^2 + \|V_t(\cdot,t)\|_{\widehat{\mathcal{H}}_\alpha}^2)dt. \tag{4.6}$$

It is equivalent to the norm

$$|V|_W^2 = \sum_{n\in\mathbb{Z}} |\lambda_n|^\alpha \|\widehat{v}_n\|_{H^1(0,T)}^2, \quad \widehat{v}_n(t) = (V(\cdot,t),\Phi_n)_{\mathcal{H}}. \tag{4.7}$$

The following bounded embedding takes place: $W(0,T;\widehat{\mathcal{H}}_\alpha) \subset C(0,T;\widehat{\mathcal{H}}_\alpha)$ ([26] or [11, Chap. 3]). We use the notation $(\cdot,\cdot)_{\mathbb{L}}$ for the inner product in $L^2(0,T;\mathcal{H})$.

We give a formal "derivation" of the definition of the weak solution. Let us take the $L^2(0,T;\mathcal{H})$-inner product of (3.1) with arbitrary two-component function $V(x,t) = \left(\begin{smallmatrix} v_0(x,t) \\ v_1(x,t) \end{smallmatrix}\right)$, $v_0,\ v_1 \in C^\infty(\Omega\times[0,T])$. Using the initial condition (3.1) we obtain for $(U_t,V)_{\mathbb{L}}$

$$(U_t,V)_{\mathbb{L}} = (U(\cdot,T),V(\cdot,T))_{\mathcal{H}} - (U_0,V(\cdot,0))_{\mathcal{H}} - (U,V_t)_{\mathbb{L}} = i(\mathcal{L}U,V)_{\mathbb{L}} + (\widehat{G},V)_{\mathbb{L}}. \tag{4.8}$$

From (4.8) we get the first necessary condition $V(x,T)=0$ for all $x\in\overline{\Omega}$. We rewrite $i(\mathcal{L}U,V)_{\mathbb{L}}$ from (4.8) as follows:

$$i(\mathcal{L}U,V)_{\mathbb{L}} = \frac{1}{2}\int_0^T dt \int_0^a [p(x)(u_1'\overline{v}_0' - u_0'\overline{v}_1') + q(x)\rho(x)(u_1\overline{v}_0 - u_0\overline{v}_1)$$

$$-2d(x)\rho(x)u_1\overline{v}_1]dx + \frac{1}{2}\int_0^T [p(x)u_0'(x,t)v_1(x,t)]_{x=a}^{x=0}dt. \tag{4.9}$$

To get rid of the boundary term we impose the second restriction on V: $v_1(0,t) = v_1(a,t) = 0$. Our next step is to rewrite (4.9) in the operator form. Setting $\tau(x) = i\sqrt{p(x)/\rho(x)}$, we introduce the following matrix operators on $\mathcal{H}$:

$$\mathcal{A} = \begin{pmatrix} 0 & 1 \\ -\tau(x)\frac{d}{dx} & 0 \end{pmatrix}, \quad \mathcal{B} = \begin{pmatrix} 1 & 0 \\ 0 & \tau(x)\frac{d}{dx} \end{pmatrix}, \quad \mathcal{C} = \begin{pmatrix} 0 & 0 \\ -q(x) & -2d(x) \end{pmatrix}. \tag{4.10}$$

It can be verified by a straightforward calculation that by taking into account the boundary conditions on V and the fact $V(x,T)=0$, we can rewrite (4.9) as follows:

$$(U_0,V(\cdot,0))_{\mathcal{H}} + (U,V_t)_{\mathbb{L}} = (\mathcal{A}U,\mathcal{B}V)_{\mathbb{L}} + (\mathcal{C}U,V)_{\mathbb{L}} + (\widehat{G},V)_{\mathbb{L}}. \tag{4.11}$$

DEFINITION 4.1. *A function $U\in L^2(0,T;\mathcal{H}_1)$ is a weak solution of problem* (3.1) *if for any $V\in W(0,T;\widehat{\mathcal{H}}_1)$, $V(\cdot,T)=0$, $v_1(0,t)=v_1(a,t)=0$ integral identity* (4.11) *holds.*

To show that the definition makes sense, we describe the domains of $\mathcal{A}$ and $\mathcal{B}$ and give an alternative description of $\mathcal{H}_1 = \mathcal{D}(\mathcal{L}^{1/2})$ in terms of Sobolev spaces.

LEMMA 4.1. (a) *$\mathcal{A}$ and $\mathcal{B}$ are closed operators in $\mathcal{H}$ with the domains*

$$D(\mathcal{A}) = H_0^1(0,a)\times H_0^1(0,a); \quad D(\mathcal{B}) = H_0^1(0,a)\times H^1(0,a). \tag{4.12}$$

(*With our assumptions about* p, ρ, *and* d *we have* $\mathcal{H} = H_0^1(0,a) \times L^2(0,a)$).

(b) *The space* $\mathcal{H}_1$ *can be described in terms of Sobolev spaces as follows:*

$$\mathcal{H}_1 = D(\mathcal{L}^{1/2}) = D((\mathcal{L}^*)^{1/2}) = H^{3/2}(0,a) \times H_0^1(0,a). \tag{4.13}$$

Here and below $H_0^\alpha(0,a) = \{u \in H^\alpha(0,a), u(0) = u(a) = 0\}, \alpha > 1/2$. For $\alpha > 1/2$ the restriction $u(0) = u(a) = 0$ makes sense due to the embedding theorems.

Remark 4.1. First, from (4.12) and (4.13) we have $\mathcal{H}_1 \subset \mathcal{D}(\mathcal{A}) \subset \mathcal{D}(\mathcal{B})$ and, therefore, definition (4.11) makes sense. Second, it is clear from (4.13) that all functions $U \in L^2(0,T;\mathcal{H}_1)$ satisfy the necessary boundary condition a.e. on $[0,T]$.

Proof of Lemma 4.1. Formula (4.12) follows immediately from the definitions of the operators $\mathcal{A}$ and $\mathcal{B}$. To prove (4.13) we note that it can be verified by a straightforward calculation that the operator $\mathcal{L}^{1/2}$ can be represented in the form $\mathcal{L}^{1/2} = (I + K)\mathcal{L}_0^{1/2}$, with K given by the formula

$$K = I - (I + \mathcal{P}\mathcal{L}_0^{-1})^{1/2}, \qquad \mathcal{P} = -i \begin{pmatrix} 0 & 0 \\ -q(x) & -2d(x) \end{pmatrix}, \tag{4.14}$$

where $\mathcal{L}_0$ is the positive selfadjoint operator

$$\mathcal{L}_0 = -i \begin{pmatrix} 0 & I \\ \dfrac{1}{\rho(x)} \dfrac{d}{dx} \left(p(x) \dfrac{d}{dx} \right) & 0 \end{pmatrix} \tag{4.15}$$

with the domain $D(\mathcal{L}_0) = D(\mathcal{L}) = \mathcal{H}_2 = H_0^2(\Omega) \times H_0^1(\Omega)$. We see from (4.14) that K is a compact Hilbert–Schmidt operator [20]. Therefore, $D(\mathcal{L}^{1/2}) = D(\mathcal{L}_0^{1/2})$. It is not difficult to check by a straightforward computation that

$$\mathcal{L}_0^{1/2} = \frac{i}{2} L^{1/4} \begin{pmatrix} I & -L^{1/2} \\ L^{1/2} & I \end{pmatrix}, \tag{4.16}$$

where L is the selfadjoint operator on $L^2(0,a)$ given by the expression

$$L = \frac{1}{\rho(x)} \frac{d}{dx} \left(p(x) \frac{d}{dx} \right), \qquad D(L) = H_0^2(0,a). \tag{4.17}$$

Using (4.16), (4.17), for any $U \in \mathcal{H}$ we have

$$\mathcal{L}_0^{1/2} U = \frac{i}{2} \begin{pmatrix} L^{1/4} u_0 - L^{-1/4} u_1 \\ L^{3/4} u_0 + L^{1/4} u_1 \end{pmatrix} \in \mathcal{H} = H_0^1(0,a) \times L^2(0,a).$$

From the latter relation, (4.13) follows immediately. □

THEOREM 4.1. *The weak solution of the problem* (3.1) *in the sense of Definition* 4.1 *is unique.*

Proof. Using a contradiction argument, assume that we have two different weak solutions. Their difference U satisfies the homogeneous integral identity

$$(U, V_t)_{\mathbb{L}} + (\mathcal{A}U, \mathcal{B}V)_{\mathbb{L}} + (\mathcal{C}U, V)_{\mathbb{L}} = 0. \tag{4.18}$$

Due to the completeness of $\{\mathcal{X}_n\}_{n\in\mathbb{Z}}$ in $\mathcal{H}$, we claim that there exists a number n_0 such that $u(t) = (U, \mathcal{X}_{n_0})_{\mathcal{H}} \neq 0$, i.e., $\|u\|_{L^2(0,T)}0$. Let us choose a particular test function $V(x,t)$:

$$V(x,t) = \widehat{g}(t)\mathcal{X}_{n_0}, \quad \widehat{g}(t) = \int_t^T e^{-i\overline{\lambda}_{n_0}(t-\tau)}\overline{u}(t)dt. \tag{4.19}$$

Since $\mathcal{X}_{n_0} \in D(\mathcal{L}^*)$, we have $V(0,t) = V(a,t) = V(x,T) = 0$. So V can be used as a test function. For this test function relation (4.18) has the form

$$(U, (\widehat{g}_t + i\overline{\lambda}_{n_0}\widehat{g})\mathcal{X}_{n_0})_{\mathbb{L}} = \int_0^T (\widehat{g}_t + i\overline{\lambda}_{n_0}\widehat{g})\overline{(U, \mathcal{X}_{n_0})}_{\mathcal{H}}dt = 0. \tag{4.20}$$

A straightforward computation shows that for $\widehat{g}(t)$ from (4.20) we have

$$\widehat{g}_t + i\overline{\lambda}_{n_0}\widehat{g} = -u(t). \tag{4.21}$$

Substituting (4.21) into (4.20) we obtain $\|u\|_{L^2(0,T)} = 0$, which contradicts our assumption. □

THEOREM 4.2. *Let $\widehat{G} \in L^2(0,T;\mathcal{H}_1)$ and $U_0 \in \mathcal{H}_1$. Then the series in* (3.7) *is convergent in the norm of $\mathcal{H}_1$ for any $t \in [0,T]$ and defines the unique weak solution U of problem* (3.1). *Moreover, $U \in C(0,T;\mathcal{H}_1)$.*

Proof. First, the fact that series (3.17) defines a function from $C(0,T;\mathcal{H}_1)$ can be shown by means of standard estimates. The only nontrivial step is to show that the function given by (3.17) satisfies integral identity (4.11).

Consider the following sequences of functions:

$$U_m = \sum_{|n|\leqslant m} a_n(t)\Phi_n(x), \quad U_{0m} = \sum_{|n|\leqslant m} u_n^0\Phi_n(x), \quad \widehat{G}_m = f(t)\sum_{|n|\leqslant m} g_n\Phi_n(x), \tag{4.22}$$

where u_n^0 and g_n are defined by (3.5), (3.6) and $a_n(t)$ are the coefficients from (3.7). The following integral identity holds for every $m \geqslant 1$ and any $V \in W(0,T;\widehat{\mathcal{H}}_1)$, $V(\cdot,T) = 0$:

$$(U_{0m}, V(\cdot,0))_{\mathcal{H}} + (U_m, V_t)_{\mathbb{L}} = (\mathcal{A}U_m, \mathcal{B}V)_{\mathbb{L}} + (\mathcal{C}U_m, V)_{\mathbb{L}} + (\widehat{G}_m, V)_{\mathbb{L}}. \tag{4.23}$$

Now we show that every sequence in (4.23) is a Cauchy sequence. In order to conserve space, we will prove the convergence for the two of the five sequences which are the most complicated: $\{\mathbf{S}_1(m)\}_{m-1}^{\infty} = \{(U_m, V_t)\}_{m=1}^{\infty}$ and $\{\mathbf{S}_2(m)\}_{m=1}^{\infty} = \{(\mathcal{A}U_m, \mathcal{B}V)_{\mathbb{L}}\}_{m=1}^{\infty}$. For any positive integers p and m we have

$$|\mathbf{S}_1(p) - \mathbf{S}_1(m)| \leqslant |(U_p - U_m)_t, V)_{\mathbb{L}}| + |(U_{0p} - U_{0m}, V(\cdot,0))_{\mathcal{H}}|$$

$$\leqslant \left|\left(f, \sum_{|n|=m}^{p} \overline{g}_n v_n(t)\right)_{L^2(0,T)}\right| + \left|\sum_{|n|=m}^{p} i\lambda_n(a_n(t), v_n(t))_{L^2(0,T)}\right| + \left|\sum_{|n|=m}^{p} u_n^0\overline{v}_n(0)\right|.$$

The following estimates are valid:

(a)

$$\left|\left(f(t), \sum_{|n|=m}^{p} \overline{g}_n v_n(t)\right)_{L^2(0,T)}\right| \leqslant \|f\|_{L^2(0,T)}\sqrt{\sum_{|n|=m}^{p} |g_n|^2}\sqrt{\sum_{n\in\mathbb{Z}} \|v_n\|^2_{H^1(0,T)}}.$$

(b)

$$\left|\sum_{|n|=m}^{p} i\lambda_n(a_n(t),v_n(t))_{L^2(0,T)}\right| \leqslant \sqrt{\sum_{|n|=m}^{p}|\lambda_n|\|a_n\|^2_{L^2(0,T)}}\sqrt{\sum_{n\in\mathbb{Z}}|\lambda_n|\|v_n\|^2_{H^1(0,T)}}.$$

Since $V\in W(0,T;\widehat{\mathcal{H}}_1)$, the latter series in (b) converges.

(c)

$$\left|\sum_{|n|=m}^{p} u_n^0\overline{v}_n(0)\right| \leqslant \sqrt{\sum_{|n|=m}^{p}|u_n^0|^2}\sqrt{\sum_{n\in\mathbb{Z}}|v_n(0)|^2}.$$

Collecting together (a)–(c) we obtain with some absolute constant d:

$$|((U_p-U_m),V_t)_{\mathbb{L}}| \leqslant d\left[\|V(\cdot,0)\|_{\mathbb{L}}\sqrt{\sum_{|n|=m}^{p}|u_n^0|^2}\right.$$

$$\left.+\|V\|_{W(0,T;\widehat{\mathcal{H}}_1)}\left(\sqrt{\sum_{|n|=m}^{p}|g_n|^2}+\sqrt{\sum_{|n|=m}^{p}|\lambda_n|\ \|a_n\|^2_{L^2(0,T)}}\right)\right]. \tag{4.24}$$

Due to (4.22) we can pass to the limit: $\lim_{m\to\infty}\mathbf{S}_1(m)=(\lim U_m,V_t)_{\mathbb{L}}=(U,V_t)_{\mathbb{L}}$. At last we justify the passage to the limit for $\mathbf{S}_2$. We have

$$|(\mathbf{S}_2(p)-\mathbf{S}_2(m))+(\mathcal{C}(U_p-U_m),V)_{\mathbb{L}}| \leqslant \sum_{|n|=m}^{p}|\lambda_n|\left|(a_n(t),v_n(t))_{L^2(0,T)}\right|$$

$$\leqslant\ d_1\|U\|_{L^2(0,T;\mathcal{H}_1)}\|V\|_{W(0,T;\widehat{\mathcal{H}}_1)}\sqrt{\sum_{|n|=m}^{p}|\lambda_n|\ \|a_n\|^2_{L^2(0,T)}}. \tag{4.25}$$

Based on (4.22) and $\lim_{m\to\infty}(\mathcal{C}U_m,V)_{\mathbb{L}}=(\mathcal{C}U,V)_{\mathbb{L}}$ we have $\lim_{m\to\infty}\mathbf{S}_2(m)=(\mathcal{A}U,\mathcal{B}V)_{\mathbb{L}}$, and thus, the integral identity is shown. □

RISK-SENSITIVE CONTROL OF FINITE STATE MACHINES ON AN INFINITE HORIZON I*

W. H. FLEMING† AND D. HERNÁNDEZ-HERNÁNDEZ‡

Abstract. In this paper we consider robust and risk-sensitive control of discrete time finite state systems on an infinite horizon. The solution of the state feedback robust control problem is characterized in terms of the value of an average cost dynamic game. The risk-sensitive stochastic optimal control problem is solved using the policy iteration algorithm, and the optimal rate is expressed in terms of the value of a stochastic dynamic game with average cost per unit time criterion. By taking a small noise limit, a deterministic dynamic game which is closely related to the robust control problem is obtained.

Key words. risk-sensitive control, robust control, finite state machines, large deviations

1. Introduction.

There are various approaches to treating disturbances in control systems. In stochastic control, disturbances are modelled as stochastic processes (random noise). On the other hand, in H_∞/robust control theory, disturbances are modelled deterministically. The theory of risk-sensitive optimal control provides a link between stochastic and deterministic approaches. The link is made by considering small noise limits for stochastic control problems with exponential cost criteria. For continuous variable, finite time horizon problems this idea was introduced by Whittle [18], [19]. For the state feedback (complete state observation) case, Whittle's idea was put on a mathematically rigorous basis in [14], [9] using viscosity solution methods. Discrete time, output feedback (partial state information) problems on a finite time horizon were treated in [15]. See also [7], where a solution approach for risk-sensitive control problems for hidden Markov models is given.

In [1] robust and risk-sensitive control of discrete time finite state systems on a finite horizon is considered. The purpose of the present paper is to study such systems on an infinite time horizon. We consider here only the state feedback case. In a sequel, output feedback control on an infinite horizon will be considered. Our approach is similar in spirit to [10], [11], where continuous variable systems modelled by differential equations are considered. However, the technical details are quite different for the discrete (finite state machine) case.

To illustrate the ideas in a simple setting, we begin in section 2 with uncontrolled finite state machines described by the difference equation (2.1). In the robust/H_∞ formulation, deterministic perturbations are described by (2.2). The H_∞-norm is characterized in terms of a deterministic optimal control problem, in which the

This research was performed while the author visited the Division of Applied Mathematics, Brown University.

perturbations (or disturbances) are chosen to maximize some long run average cost per unit time criterion. The maximum average cost λ_0 is nonnegative, and is zero if and only if H_∞-control is achieved. The corresponding cost potential function $W_0(x)$ has the role of a "storage function" in H_∞-control terminology. It is unique, provided that the H_∞-norm parameter γ exceeds the critical value γ^*.

Following [1], stochastic perturbations of the finite state machine model are introduced in section 2.2. The strength of the perturbations are described through a parameter ε. Stochastic analogues $\lambda_\varepsilon, W_\varepsilon$ of λ_0, W_0 are introduced, with λ_ε the maximal expected average cost per unit time for a corresponding ergodic stochastic control problem. In section 3, convergence of $\lambda_\varepsilon, W_\varepsilon$ to λ_0, W_0 as $\varepsilon \to 0$ is proved.

In section 4, we consider controlled finite state machines. With the deterministic robust $/H_\infty$ formulation, the optimal H_∞-norm is characterized in terms of a dynamic game with average cost per unit time. In the stochastic risk-sensitive formulation, a corresponding stochastic difference game is introduced, with payoff involving a relative entropy function. Results like those in section 3 are obtained as the noise intensity parameter $\varepsilon \to 0$.

2. Risk-sensitive analysis. In this section we consider both deterministic and stochastic perturbations of a discrete time finite state system. In order to measure the size of the deterministic perturbations, an analogous definition of the H_∞-norm for nonlinear continuous variable systems is given. This norm is characterized in terms of the value of a long run average cost deterministic control problem. The risk-sensitive index is used to measure the effect of the stochastic perturbations, and it is expressed as the value of an average cost stochastic optimal control problem.

2.1. The H_∞-norm. Consider the deterministic finite state machine

$$x_{t+1} = f(x_t), \quad t = 0, 1, \ldots; \quad x_0 = x, \tag{2.1}$$

where x_t takes values in the finite set X and f is a function from X into itself that defines the dynamics of the system. The set X has N elements, $X = \{x_1, \ldots, x_N\}$.

Let us now define a perturbed system Σ,

$$x_{t+1} = b(x_t, w_t), \quad t = 0, 1, \cdots; \quad x_0 = x. \tag{2.2}$$

Here the exogenous inputs (disturbances) w_t take values in a finite set W, the state variable x_t evolves in X, and $b : X \times W \to X$ is a given function.

Remark 2.1 (notation). Throughout this paper we denote by $[0, T]$ the time interval $\{0, 1, \ldots, T\}$. If Z is a generic set, then $Z[0, T]$ denotes the set of functions $\underline{z} : [0, T] \to Z$. Moreover, given any function $v : Z \to \mathbb{R}$, $\|v\|$ stands for the supremum norm of v, i.e., $\|v\| = \sup_{z \in Z} |v(z)|$.

We assume the following.

(A1) There exists a null state x_ϕ and a null disturbance $w_\phi \in W$ such that

$$\text{(i)} \quad f(x_\phi) = x_\phi \quad \text{and} \qquad \text{(ii)} \quad b(x, w_\phi) = f(x) \text{ for all } x \in X.$$

(A2) Given $x, x'' \in X$, there exist T_1, $0 < T_1 \leq N$, and $\underline{w} \in W[0, T_1]$ such that, for the initial condition $x_0 = x$ and input $\underline{w}$, the system Σ reaches x'' after T_1 steps.

(A3) There exists a positive integer N_0 such that for any initial condition $x_0 = x$, the unperturbed system (2.1) reaches the null state x_ϕ after N_0 steps.

Let us introduce a pair of functions $\theta : W \to \mathbb{R}$ and $\ell : X \to \mathbb{R}$ such that

$$\begin{cases} \theta(w_\phi) = 0, \\ \theta(w) > 0 \quad \text{if} \quad w \neq w_\phi \in W \end{cases} \tag{2.3}$$

and

$$\begin{cases} \ell(x_\phi) = 0, \\ \ell(x) > 0 \qquad \text{if} \quad x \neq x_\phi \in X. \end{cases}$$

The values $\theta(w)$ and $\ell(x)$ represent the magnitude of disturbance w and the cost per stage generated by the system (2.2), respectively.

Now, let us give the definition of the H_∞-norm of the discrete system Σ; this definition is analogous to the one given for nonlinear continuous variable systems; see, e.g., [17, 2].

DEFINITION 2.2. *We say that the H_∞-norm $\|\Sigma\|_{H_\infty}$ is less than or equal to a positive number γ if and only if for every $x_0 = x$, there exists a nonnegative constant $K(x)$, with $K(x_\phi) = 0$, such that*

$$K(x) + \sum_{t=0}^{T} \left[\gamma^2 \theta(w_t) - \ell(x_t)\right] \geq 0 \text{ for all } \underline{w} \in W[0,T], T \geq 0. \tag{2.4}$$

Then $\|\Sigma\|_{H_\infty}$ is the smallest γ such that $\|\Sigma\|_{H_\infty} \leq \gamma$.

Straightforward calculations show that $\|\Sigma\|_{H_\infty} \leq \gamma$ if and only if there exists a nonnegative function W_0 defined on X, called a *storage function*, such that

$$\begin{cases} W_0(x) \geq \sup\limits_{T>0} \sup\limits_{\underline{w} \in W[0,T]} \left\{ W_0(x_{T+1}) - \sum\limits_{t=0}^{T} \left[\gamma^2 \theta(w_t) - \ell(x_t)\right] \right\}, \\ W_0(x_\phi) = 0. \end{cases} \tag{2.5}$$

If there exists a storage function, then the system Σ is called *dissipative* with respect to the supply rate $(x, w) \to \gamma^2 \theta(w) - \ell(x)$. Actually, the inequality (2.5) can be rewritten as

$$\begin{cases} W_0(x) \geq \max\limits_{w \in W} \{W_0(b(x,w)) + \ell(x) - \gamma^2 \theta(w)\}, \\ W_0(x_\phi) = 0. \end{cases} \tag{2.5$'$}$$

The H_∞-norm shall be characterized in terms of the value of an average cost optimal control problem, but first we introduce some preliminary results.

PROPOSITION 2.3. *Assume* (A2). *Then there exist a nonnegative number λ_0 and a function $W_0 : X \to \mathbb{R}$ such that*

$$\lambda_0 + W_0(x) = \max_{w \in W} [W_0(b(x,w)) + \ell(x) - \gamma^2 \theta(w)]. \tag{2.6}$$

Proof. The proof is based on the standard vanishing discount approach.

Define the value function

$$V_\beta(x) := \sup_{\underline{w} \in W[0,\infty)} \sum_{t=0}^{\infty} \beta^t [\ell(x_t) - \gamma^2 \theta(w_t)], \tag{2.7}$$

where $\beta \in (0,1)$ and x_t obeys the dynamic described by (2.2). This function satisfies the dynamic programming equation

$$V_\beta(x) = \sup_{w \in W} [\beta V_\beta(b(x,w)) + \ell(x) - \gamma^2 \theta(w)] \text{ for all } x \in X. \tag{2.8}$$

On the other hand, from (2.7), we have

$$0 \le (1-\beta)V_\beta(x) \le \|\ell\|. \tag{2.9}$$

Then, for each $x \in X$, (2.8)–(2.9) yield

$$\begin{aligned} V_\beta(x) &\ge \beta V_\beta(b(x,w)) - \gamma^2\|\theta\| \\ &= V_\beta(b(x,w)) - [(1-\beta)V_\beta(b(x,w)) + \gamma^2\|\theta\|] \\ &\ge V_\beta(b(x,w)) - C_1 \text{ for all } w \in W, \end{aligned} \tag{2.10}$$

with $C_1 = \|\ell\| + \gamma^2\|\theta\|$. Thus, given $x, x'' \in X$, from (A2) and iterating (2.10) T_1 times, we have

$$V_\beta(x) \ge V_\beta(x'') - T_1 C_1.$$

Thus, interchanging the roles of x and x'', for some constant T' depending on x and x'',

$$|V_\beta(x) - V_\beta(x'')| \le T' C_1. \tag{2.11}$$

Let $\beta_n \to 1$ be a sequence in $(0,1)$. Then, (2.9)–(2.11) imply that, by a suitable diagonalization, we may pick a subsequence $\{\beta_n\}$ (denoting it again by $\{\beta_n\}$) along which $V_{\beta_n}(x) - V_{\beta_n}(x_\phi), x \in X$, and $(1-\beta_n)V_{\beta_n}(x_\phi)$ converge to some limits $W_0(x)$ and λ_0, respectively.

Set $\bar{V}_\beta(x) := V_\beta(x) - V_\beta(x_\phi), x \in X$. Then, $\bar{V}_\beta(x_\phi) = 0$ and

$$(1-\beta)V_\beta(x_\phi) + \bar{V}_\beta(x) = \max_{w\in W}\left[\beta\bar{V}_\beta(b(x,w)) + \ell(x) - \gamma^2\theta(w)\right].$$

Passing to the limit $\beta_n \to 1$, we get

$$\lambda_0 + W_0(x) = \max_{w\in W}[W_0(b(x,w)) + \ell(x) - \gamma^2\theta(w)]. \qquad \square$$

Remark 2.4. The number λ_0 in the above theorem is unique, as follows from the next theorem. Regarding the uniqueness of the function W_0 (up to an additive constant), at the end of this subsection we prove that if $\gamma > \gamma^*$, for γ^* being the H_∞-norm, then this holds. For $\gamma \le \gamma^*$ we still do not have any uniqueness result.

The equation (2.6) corresponds to the dynamic programming equation of the following average cost deterministic optimal control problem. The dynamic is given by

$$x_{t+1} = b(x_t, w_t), \quad t = 0, 1, \ldots; \quad x_0 = x, \tag{2.12}$$

where the disturbances $\underline{w} = \{w_t\} \in W[0,\infty)$ play the role of a maximizing control. The cost per stage is $(x,w) \to \ell(x) - \gamma^2\theta(w)$, and the cost functional we try to maximize is given by

$$J^{\underline{w}}(x) = \limsup_{T\to\infty} \frac{1}{T}\sum_{t=0}^{T-1}[\ell(x_t) - \gamma^2\theta(w_t)].$$

The next theorem is a straightforward application of standard dynamic programming arguments.

THEOREM 2.5. *For any* $x \in X$,

$$\lambda_0 = \sup_{\underline{w} \in W[0,\infty)} J^{\underline{w}}(x),$$

and an optimal control is $w_t^* = w^*(x_t)$, *where* $w^*(x)$ *achieves the maximum in* (2.6).

The link between the above optimal control problem and the H_∞-norm of the system Σ is given in the next theorem.

THEOREM 2.6. *Assume that* (A.1)–(A.3) *hold. Then* $\lambda_0 = 0$ *if and only if* $\|\Sigma\|_{H_\infty} \leq \gamma$.

Proof. Assume $\lambda_0 = 0$. Let W_0 be the function defined in Proposition 2.3. Since this function satisfies (2.6), it solves in particular the first part of (2.5′), and the second part follows from the construction of W_0. To prove that W_0 is nonnegative, let $T > 0$ and $\underline{w} \in W[0,T]$ with $w_t = w_\phi$ for all $t = 0, 1, \ldots, T$. Then, in view of (2.6), it follows that

$$W_0(x) \geq \sum_{t=0}^{T} \ell(x_t) + W_0(x_{T+1}),$$

where x_t evolves according to the dynamic (2.12) (or equivalently (2.1)) with initial condition $x_0 = x$. However, from (A3), $x_T = x_\phi$ for $T \geq N_0$. Hence

$$W_0(x) \geq W_0(x_\phi) = 0.$$

Conversely, assume (2.5′). Then, for any $T > 0$ and $\underline{w} \in W[0,T]$,

$$\sum_{t=0}^{T} [\ell(x_t) - \gamma^2 \theta(w_t)] \leq W_0(x_\phi) - W_0(x_{T+1}) \leq 0,$$

where the state dynamics (2.12) start at the initial condition $x_0 = x_\phi$. This implies that

$$\limsup_{T\to\infty} \frac{1}{T} \sum_{t=0}^{T-1} [\ell(x_t) - \gamma^2 \theta(w_t)] \leq 0.$$

Then, from Theorem 2.5, $\lambda_0 \leq 0$. However, in view of Proposition 2.3, $\lambda_0 \geq 0$. Hence, $\lambda_0 = 0$. □

For the rest of this subsection let us make explicit the dependence on γ of λ_0 and W_0 in Proposition 2.3, denoting them by λ_0^γ and W_0^γ, respectively.

Define the set

$$\Gamma = \{\gamma : \lambda_0^\gamma = 0\}.$$

Note that this set is not empty, since for γ great enough, the optimal control w^* in Theorem 2.5 is such that $w^*(x_\phi) = w_\phi$, and in view of (A1), $\lambda_0^\gamma = 0$. Note also that, from Theorem 2.5, λ_0^γ is a nonincreasing function of γ. Let $\gamma^* = \inf \Gamma$. Then, in view of the above facts, $\Gamma = [\gamma^*, \infty)$, and by Theorem 2.6,

$$\gamma^* = \|\Sigma\|_{H_\infty}. \tag{2.13}$$

PROPOSITION 2.7. *For any* $\gamma > \gamma^*$ *the function* W_0^γ, *with* $W_0^\gamma(x_\phi) = 0$, *is the unique solution of* (2.6).

Proof. Let $\gamma > \gamma^*$ be arbitrary but fixed, and define the value function

$$\tilde{W}_0(x) = \sup_{\underline{w} \in \tilde{W}[0,\infty)} \left\{ \sum_{t=0}^{\infty} \left[\ell(x_t) - \gamma^2 \theta(w_t) \right] \right\}, \ x \in X.$$

Here x_t obeys the dynamic (2.12), and $\tilde{W}[0,\infty) = \{\underline{w} \in W[0,\infty) : \ w_t = w_\phi$ except for finitely many $t\}$. Then, by well-known dynamic programming methods (see, e.g., [3]), it follows that $\tilde{W}_0$ is a solution of (2.6) with $\lambda_0 = 0$.

We claim that $\tilde{W}_0 = W_0^\gamma$. Actually, by (2.6) with $\lambda_0 = 0$ and the definition of $\tilde{W}_0$, it follows immediately that $W_0^\gamma \geq \tilde{W}_0$. Thus, we shall just prove the reverse inequality, i.e., that $W_0^\gamma(x) \leq \tilde{W}_0(x) \ \forall \ x \in X$. Let $x \in X$ and $\gamma_1 \in (\gamma^*, \gamma)$. Then, (2.6) yields

$$W_0^{\gamma_1}(x) \geq \sum_{t=0}^{T-1} \left[\ell(x_t) - \gamma_1^2 \theta(w_t) \right] + W_0^{\gamma_1}(x_T) \text{ for all } \underline{w} \in W[0,\infty), T > 0.$$

On the other hand, if $\underline{w}^*$ is the optimal control defined in Theorem 2.5, then

$$\begin{aligned} W_0^\gamma(x) &= \sum_{t=0}^{T-1} \left[\ell(x_t^*) - \gamma^2 \theta(w_t^*) \right] + W_0^\gamma(x_T^*) \\ &= \sum_{t=0}^{T-1} \left[\ell(x_t^*) - \gamma_1^2 \theta(w_t^*) \right] - (\gamma^2 - \gamma_1^2) \sum_{t=0}^{T-1} \theta(w_t^*) + W_0^\gamma(x_T^*) \end{aligned} \tag{2.14}$$

for all $T > 0$. Therefore,

$$\begin{aligned} \sum_{t=0}^{T-1} \theta(w_t^*) &\leq \frac{W_0^{\gamma_1}(x) - W_0^\gamma(x) + W_0^\gamma(x_T^*)}{\gamma^2 - \gamma_1^2} \\ &\leq \frac{C}{\gamma^2 - \gamma_1^2} \end{aligned} \tag{2.15}$$

for some suitable constant C.

Thus, in view of (2.3), (2.15) implies that $\underline{w}^* \in \tilde{W}[0,\infty)$, and by (A3), if T is large enough, $x_t^* = x_\phi$ for $t \geq T$. Finally, the above facts and (2.14) imply that $W_0^\gamma(x) \leq \tilde{W}_0(x)$. This completes the proof. ∎

2.2. Stochastic perturbation. In this subsection we define a finite state Markov chain, which represents a stochastic perturbation of the system (2.1). This model has been described in [1].

Throughout this subsection we assume (A2). However, we will need (A1) and (A3) for the small noise limit analysis in section 3.

Let $V : X \times X \to \mathbb{R} \cup \{+\infty\}$ be the function defined by

$$V(x, x'') = \min\{\theta(w) : x'' = b(x,w)\},$$

with the standard convention that the minimum over an empty set equals $+\infty$. The value $V(x, x'')$ represents the minimum "magnitude" associated with the disturbances (see (2.3)) to go from x to x'' in one time step.

Let us define the following stochastic matrix Π_ε: given $x, x'' \in X$,

$$\Pi_\varepsilon(x, x'') = \frac{1}{Z_\varepsilon(x)} e^{-\frac{V(x,x'')}{\varepsilon}},$$

where $\varepsilon > 0$ is a small noise parameter and $Z_\varepsilon(x)$ is a normalizing constant satisfying $\sum_{x'' \in X} \Pi_\varepsilon(x, x'') = 1$.

This stochastic matrix satisfies the consistency condition

$$\lim_{\varepsilon \to 0} \Pi_\varepsilon(x, x'') = \begin{cases} 1 \text{ if } x'' = f(x), \\ 0 \text{ otherwise.} \end{cases}$$

Remark 2.8. Note that (A2) implies that Π_ε is irreducible. Remember that an $N \times N$ nonnegative matrix M is irreducible if, for every $x, x'' \in X$, there exist $T > 0$ such that $M^T(x, x'') > 0$, where M^T denotes the T-power of M.

DEFINITION 2.9. *The risk-sensitive index for* Π_ε *is defined by*

$$\lambda_\varepsilon = \lim_{T \to \infty} \frac{\varepsilon}{\mu} \cdot \frac{1}{T} \log E_x \exp\left\{ \frac{\mu}{\varepsilon} \sum_{t=0}^{T-1} \ell(x_t) \right\}, \tag{2.16}$$

where $\mu > 0$ *has the role of a risk-averse factor.*

The existence of the limit in (2.16) is implied by Sanov's theorem (see, e.g., [4]), and it coincides with the optimal value of an average cost infinite horizon optimal control problem, which we will define later in this section. Keeping this in mind, we shall prove that $e^{\frac{\mu}{\varepsilon}\lambda_\varepsilon}$ is the dominant eigenvalue of the nonnegative matrix defined by

$$L(x, x'') = e^{\frac{\mu}{\varepsilon}\ell(x)} \Pi_\varepsilon(x, x'') \quad \text{for} \quad x, x'' \in X.$$

Note that, since Π_ε is irreducible, so is L.

Remark 2.10 (notation). If M is any matrix on X and $h : X \to \mathbb{R}$ is any function, we denote by Mh their product, that is,

$$Mh(x) = \sum_{x'' \in X} M(x, x'') h(x'') \quad \text{for each} \quad x \in X.$$

On the other hand, given $x \in X$, the x-row vector of M is denoted by $M(x)$, i.e., $M(x) = (M(x, x_1), \ldots, M(x, x_N))$.

THEOREM 2.11. *There exist* $\alpha_\varepsilon > 0$ *and a unique strictly positive function* $\Psi_\varepsilon : X \to \mathbb{R}$, *with* $\Psi_\varepsilon(x_\phi) = 1$, *such that*

$$\alpha_\varepsilon \Psi_\varepsilon = L \Psi_\varepsilon. \tag{2.17}$$

Further,

$$\lambda_\varepsilon = \frac{\varepsilon}{\mu} \log \alpha_\varepsilon. \tag{2.18}$$

Proof. The first part follows from the Perron–Frobenios theorem; see, e.g., [16]. To prove the rest, let x_t be the Markov chain governed by Π_ε with initial condition $x_0 = x$.

Thus, (2.17) yields

$$\begin{aligned} E_x \exp\{\frac{\mu}{\varepsilon} \sum_{t=0}^{T-1} \ell(x_t)\} &= E_x \prod_{t=0}^{T-1} \alpha_\varepsilon \frac{\Psi_\varepsilon(x_t)}{\Pi_\varepsilon \Psi_\varepsilon(x_t)} \\ &= \alpha_\varepsilon^T E_x \prod_{t=0}^{T-1} \left[\frac{\Psi_\varepsilon(x_t)}{\Pi_\varepsilon \Psi_\varepsilon(x_t)} \right]. \end{aligned} \tag{2.19}$$

Using the Markovian property of x_t, we have

$$E_x\left[\prod_{t=0}^{T-1}\frac{\Psi_\varepsilon(x_t)}{\Pi_\varepsilon\Psi_\varepsilon(x_t)}\cdot\Pi_\varepsilon\Psi_\varepsilon(x_{T-1})\right]=\Psi_\varepsilon(x). \tag{2.20}$$

Since Ψ_ε is strictly positive, so is $\Pi_\varepsilon\Psi_\varepsilon$, and in view of (2.20), there follows the existence of suitable positive constants K_1 and K_2 such that

$$K_1\le\frac{\Psi_\varepsilon(x)}{\max_{x\in X}\Pi_\varepsilon\Psi_\varepsilon(x)}\le E_x\left[\prod_{t=0}^{T-1}\frac{\Psi_\varepsilon(x_t)}{\Pi_\varepsilon\Psi_\varepsilon(x_t)}\right]\le\frac{\Psi_\varepsilon(x)}{\min_{x\in X}\Pi_\varepsilon\Psi_\varepsilon(x)}\le K_2. \tag{2.21}$$

Therefore, from (2.19)–(2.21) we have

$$\frac{\varepsilon}{\mu}\log\alpha_\varepsilon=\lim_{T\to\infty}\frac{\varepsilon}{\mu}\cdot\frac{1}{T}\log E_x\exp\left\{\frac{\mu}{\varepsilon}\sum_{t=0}^{T-1}\ell(x_t)\right\}.$$

This completes the proof. □

Let us define $W_\varepsilon(x)=\frac{\varepsilon}{\mu}\log\Psi_\varepsilon(x), x\in X$, and rewrite (2.17) as

$$\lambda_\varepsilon+W_\varepsilon(x)=\frac{\varepsilon}{\mu}\log\Pi_\varepsilon e^{\frac{\mu}{\varepsilon}W_\varepsilon(x)}+\ell(x)\text{ for all }x\in X. \tag{2.22}$$

In order to transform (2.22) into the dynamic programming equation of some ergodic cost optimal control problem, we now introduce the relative entropy function. Let $P(X)$ be the set of probability vectors on X, i.e.,

$$P(X)=\left\{\pi=(\pi_1,\dots,\pi_N):\pi_i\ge0,\sum_{i=1}^{N}\pi_i=1\right\}.$$

Let us fix $\nu\in P(X)$. We define the relative entropy function $I(\cdot\|\nu):P(X)\to\mathbb{R}\cup\{+\infty\}$ by

$$I(\pi\|\nu)=\begin{cases}\displaystyle\sum_{x''\in X}\log[r(x'')]\pi(x'') & \text{if }\pi<<\nu,\\ +\infty & \text{otherwise,}\end{cases}$$

where

$$r(x'')=\begin{cases}\frac{\pi(x'')}{\nu(x'')} & \text{if }\nu(x'')>0,\\ 1 & \text{otherwise.}\end{cases}$$

The next lemma is proved in an appendix at the end of the paper. Actually, it is a particular case of Proposition II.4.2 in [5].

LEMMA 2.12. *The pair $\lambda_\varepsilon, W_\varepsilon$ satisfies the equation*

$$\lambda_\varepsilon+W_\varepsilon(x)=\sup_{\pi\in P(X)}\left\{\sum_{x''\in X}W_\varepsilon(x'')\pi(x'')+\ell(x)-\frac{\varepsilon}{\mu}I(\pi\|\Pi_\varepsilon(x))\right\}. \tag{2.23}$$

Moreover, the supremum in the right-hand side (r.h.s.) is attained at the unique probability vector $\eta^*(x)$ defined by

$$\eta^*(x,x'')=\frac{e^{\frac{\mu}{\varepsilon}W_\varepsilon(x'')}}{\Pi_\varepsilon e^{\frac{\mu}{\varepsilon}W_\varepsilon(x)}}\Pi_\varepsilon(x,x''),\ x''\in X. \tag{2.24}$$

Now we describe the stochastic optimal control problem associated with the dynamic programming equation (2.23). The set $P(X)$ plays the role of a control set, and we denote by Q the set of stationary controls, i.e., the set of functions $\eta : X \to P(X)$. Actually, the set Q can be identified with the set of stochastic matrices on X, which we denote again by Q.

Given a stationary control $\eta \in Q$ and an initial condition $x_0 = x$, the controlled process is the Markov chain x_t with stochastic matrix η and initial condition $x_0 = x$. On the other hand, $(x, \eta(x)) \to \ell(x) - \frac{\varepsilon}{\mu} I(\eta(x) \| \Pi_\varepsilon(x))$ is the reward per stage. Note that we are allowing rewards equal to $-\infty$. Finally, the associated reward functional is

$$J^\eta(x) = \limsup_{T\to\infty} \frac{1}{T} \sum_{t=0}^{T-1} E_x^\eta \left[\ell(x_t) - \frac{\varepsilon}{\mu} I(\eta(x_t) \| \Pi_\varepsilon(x_t)) \right].$$

Then, by standard dynamic programming methods, it follows that, for any $x \in X$,

$$\lambda_\varepsilon = \sup_{\eta \in Q} J^\eta(x),$$

and the optimal control is given by (2.24).

3. Small noise limit. In order to relate the H_∞-norm of the system Σ and the risk-sensitive index λ_ε, we will take the limit when the noise intensity ε goes to zero in (2.23). Therefore, we are first concerned about the existence of a limit point of the family $\{\lambda_\varepsilon, W_\varepsilon\}$; that is, we want to prove the existence of a sequence $\{\varepsilon_n\}$, with $\varepsilon_n \to 0$, and a pair λ_0, W_0 such that

$$\begin{cases} \lim\limits_{\varepsilon_n \to 0} \lambda_{\varepsilon_n} = \lambda_0, \\ \lim\limits_{\varepsilon_n \to 0} W_{\varepsilon_n}(x) = W_0(x) \text{ for all } x \in X. \end{cases} \tag{3.1}$$

Since X is finite, in order to get (3.1) we just need to prove that the family $\{\lambda_\varepsilon, W_\varepsilon\}$ is uniformly bounded.

By (2.16), we have

$$0 \le \lambda_\varepsilon \le \|\ell\|. \tag{3.2}$$

So it just remains to prove that $\{W_\varepsilon\}$ is uniformly bounded.

Throughout this section we assume the following condition.

(A4) There exists a positive integer T_2 such that $\Pi_\varepsilon^{T_2}(x, x'') > 0$ for all $x, x'' \in X$.

Remark 3.1. Note that (A1)–(A2) imply that the stochastic matrix Π_ε is aperiodic irreducible. In particular, (A1)–(A2) imply (A4).

THEOREM 3.2. *Let W_ε be the solution of* (2.23) *satisfying the normalizing condition $W_\varepsilon(x_\phi) = 0$. Then, for any $\varepsilon_0 > 0$, there exists a constant K_1 such that for $\varepsilon < \varepsilon_0$*

$$\|W_\varepsilon\| \le K_1.$$

Proof. Let x_t be the Markov chain with stochastic matrix Π_ε with initial condition $x_0 = x$, and let $T > 0$ be arbitrary.

Let us define

$$e^{\frac{\mu}{\varepsilon} V_\varepsilon(x,T)} := E_x e^{\frac{\mu}{\varepsilon} \sum_{t=0}^{T-1} \ell(x_t) + \frac{\mu}{\varepsilon} W_\varepsilon(x_T)}.$$

Then, one can prove by induction that

$$e^{\frac{\mu}{\varepsilon}V_\varepsilon(x,T)} = L^T e^{\frac{\mu}{\varepsilon}W_\varepsilon(x)}, \tag{3.3}$$

where L^T is the T-power of the matrix L; see Theorem 2.11. Indeed, by (2.17)

$$L^T e^{\frac{\mu}{\varepsilon}W_\varepsilon(x)} = e^{\frac{\mu}{\varepsilon}[T\lambda_\varepsilon + W_\varepsilon(x)]}.$$

Substituting this in (3.3), and making the logarithmic transformation on both sides, we get

$$V_\varepsilon(x,T) - T\lambda_\varepsilon = W_\varepsilon(x).$$

Since x was chosen arbitrarily, in particular we have

$$V_\varepsilon(x,T) - V_\varepsilon(x_\phi,T) = W_\varepsilon(x). \tag{3.4}$$

Now we shall get a uniform bound for $x \to V_\varepsilon(x,T) - V_\varepsilon(x_\phi,T)$. Let $x, x'' \in X$, and let ν_0 ($\tilde{\nu}_0$) be the distribution of x_{T_2} with initial condition $x_0 = x$ ($x_0 = x''$, respectively), with T_2 as in (A4). Then, in view of the definition of the stochastic matrix Π_ε,

$$\frac{1}{N^{T_2}} e^{\frac{-T_2\|\theta\|}{\varepsilon}} \le \tilde{\nu}_0(y) \le 1 \text{ for all } y \in X,$$

and therefore,

$$\frac{\nu_0(y)}{\tilde{\nu}_0(y)} \le e^{\frac{T_2\|\theta\|}{\varepsilon}} N^{T_2} \text{ for all } y \in X.$$

Thus,

$$\begin{aligned} e^{\frac{\mu}{\varepsilon}V_\varepsilon(x,T)} &\le e^{\frac{\mu}{\varepsilon}T_2\|\ell\|} E_{\tilde{\nu}_0}\left[e^{\frac{\mu}{\varepsilon}\sum_{t=T_2}^{T-1}\ell(x_t) + \frac{\mu}{\varepsilon}W_\varepsilon(x_T)} \cdot \frac{\nu_0(x_{T_2})}{\tilde{\nu}_0(x_{T_2})}\right] \\ &\le N^{T_2} e^{\frac{1}{\varepsilon}T_2(\mu\|\ell\| + \|\theta\|)} \cdot e^{\frac{\mu}{\varepsilon}V_\varepsilon(x'',T)} \text{ for all } T > T_2. \end{aligned}$$

Then,

$$V_\varepsilon(x,T) \le V_\varepsilon(x'',T) + T_2\left(\|\ell\| + \frac{1}{\mu}\|\theta\|\right) + \frac{\varepsilon}{\mu}T_2 \log N,$$

and therefore, given any $\varepsilon_0 > 0$ arbitrary but fixed,

$$V_\varepsilon(x,T) - V_\varepsilon(x'',T) \le T_2\left(\|\ell\| + \frac{1}{\mu}\|\theta\| + \frac{\varepsilon_0}{\mu}\log N\right)$$

for $\varepsilon < \varepsilon_0$. Hence, interchanging the roles of x and x'', we get

$$|V_\varepsilon(x,T) - V_\varepsilon(x'',T)| \le T_2\left(\|\ell\| + \frac{1}{\mu}\|\theta\| + \frac{\varepsilon_0}{\mu}\log N\right). \tag{3.5}$$

Therefore, in view of (3.4)–(3.5), taking $K_1 = T_2(\|\ell\| + \frac{1}{\mu}\|\theta\| + \frac{\varepsilon_0}{\mu}\log N)$ and $x'' = x_\phi$, the theorem follows. □

THEOREM 3.3. *There exist a number $\lambda_0 \geq 0$ and a function $W_0 : X \to \mathbb{R}$ limit point of the family $\{(\lambda_\varepsilon, W_\varepsilon)\}$, such that*

$$\lambda_0 + W_0(x) = \max_{w \in W} \left\{ W_0(b(x,w)) + \ell(x) - \frac{1}{\mu}\theta(w) \right\}. \tag{3.6}$$

Proof. Estimate (3.2) and Theorem 3.2 imply the existence of a limit point (λ_0, W_0) of the family $(\lambda_\varepsilon, W_\varepsilon)$ through a sequence $\varepsilon_n \to 0$. Now we rewrite (2.22) as follows:

$$\lambda_\varepsilon + W_\varepsilon(x) = \frac{\varepsilon}{\mu} \log \sum_{x'' \in X} e^{\frac{\mu}{\varepsilon} W_\varepsilon(x'')} \cdot \frac{e^{-\frac{1}{\varepsilon}V(x,x'')}}{Z_\varepsilon(x)} + \ell(x). \tag{3.7}$$

Using a version of the Laplace–Varadhan lemma (see the appendix), it follows that the r.h.s. of (3.7) converges to

$$\sup_{w \in W} \left\{ W_0(b(x,w)) + \ell(x) - \frac{1}{\mu}\theta(w) \right\} \text{ as } \varepsilon_n \to 0.$$

Thus, letting $\varepsilon = \varepsilon_n$ and $\varepsilon_n \to 0$ in (3.7), we get that the pair (λ_0, W_0) solves (3.6). □

Remark 3.4. Note that (3.6) is the equation (2.6) we had introduced in Proposition 2.3 with $\gamma^2 = \frac{1}{\mu}$. Actually, assuming (A1)–(A3), W_0 is the same as in section 2.1 for μ small enough (by uniqueness); see Proposition 2.7. Note also that uniqueness of $\lambda_0 (= 0)$ and W_0 implies convergence of λ_ε to 0 and $W_\varepsilon(x)$ to $W_0(x)$ as $\varepsilon \to 0$—not just convergence for sequences $\varepsilon_n \to 0$.

4. Risk-sensitive control problem. In this section we set up the state feedback robust control problem. Paralleling the approach of the previous sections, we introduce an infinite horizon risk-sensitive control problem that is solved using the policy iteration algorithm. The optimal rate is interpreted as the upper value of a stochastic dynamic game with average cost per unit time criterion.

4.1. State feedback control problem. Consider the finite state controlled machine defined by

$$x_{t+1} = f(x_t, u_t), \quad t = 0, 1, \ldots; \quad x_0 = x, \tag{4.1}$$

where the state x_t takes values in the finite set X, the control u_t evolves in the finite set U, and $f : X \times U \to X$ is a given function. We recall that N is the number of states in X.

We now define a deterministic perturbation of the system (4.1). Let $b : X \times U \times W \to X$ be the function that defines the dynamics of the system Σ^u given by

$$x_{t+1} = b(x_t, u_t, w_t), \tag{4.2}$$

where x_t and u_t take values in X and U, respectively, and the disturbance w_t takes values in a finite set W.

We assume the following.

(H1) There exist a null control $u_\phi \in U$, an equilibrium state $x_\phi \in X$, and a null disturbance $w_\phi \in W$ such that

(i) $f(x_\phi, u_\phi) = x_\phi$ and (ii) $b(x, u, w_\phi) = f(x, u)$ for all $x \in X, u \in U$.

(H2) Let $\mathcal{U}$ be the *finite* set of all stationary control policies $\tilde{u} : X \to U$. Given $\tilde{u} \in \mathcal{U}$ and $x, x'' \in X$, there exist $T_1,\ 0 < T_1 \leq N$, and $\underline{w} \in W[0, T_1]$ such that for the initial condition $x_0 = x$, the system $\sum^{\tilde{u}}$ reaches x'' after T_1 steps.

Let $\theta : W \to \mathbb{R}$ and $\ell : X \times U \to \mathbb{R}$ be functions such that

$$\begin{cases} \theta(w_\phi) = 0, \\ \theta(w) > 0 \ \text{ for } \ w \neq w_\phi \in W \end{cases}$$

and

$$\begin{cases} \ell(x_\phi, u_\phi) = 0, \\ \ell(x, u) > 0 \ \text{ for } \ (x, u) \neq (x_\phi, u_\phi) \in X \times U. \end{cases} \tag{4.3}$$

The functions θ and ℓ play the same role as in previous sections.

Let $\mathcal{U}_1 \subset \mathcal{U}$ be the subset of stationary policies $\tilde{u}$ such that the following condition is satisfied. For each initial condition $x_0 = x$, there exists a positive integer N_0 such that the system (4.1) reaches the equilibrium state x_ϕ after N_0 steps, and $\tilde{u}(x_\phi) = u_\phi$. Note that, given $\tilde{u} \in \mathcal{U}$ ($\tilde{u} \in \mathcal{U}_1$), letting $f^{\tilde{u}}(x) = f(x, \tilde{u}(x))$, with $b^{\tilde{u}}(x, w)$ and $\ell^{\tilde{u}}(x)$ defined similarly, then (A2) ((A1) and (A3), respectively) of section 2 holds, with f, b replaced by $f^{\tilde{u}}, b^{\tilde{u}}$. Indeed, for $\tilde{u} \in \mathcal{U}_1$, the H_∞-norm $\| \sum^{\tilde{u}} \|_{H_\infty}$ is defined (see (2.13)).

The state feedback robust control problem is the following; see, e.g., [2]. Given $\gamma > 0$, find a control $\tilde{u} \in \mathcal{U}_1$ such that for each initial condition $x_0 = x$, there exists a nonnegative constant $K(x)$, with $K(x_\phi) = 0$, satisfying

$$K(x) + \sum_{t=0}^{T} \left[\gamma^2 \theta(w_t) - \ell(x_t)\right] \geq 0 \ \text{ for all } \ \underline{w} \in W[0, T], T > 0.$$

In other words, given $\gamma > 0$ we want to find $\tilde{u} \in \mathcal{U}_1$ such that $\|\Sigma^{\tilde{u}}\|_{H_\infty} \leq \gamma$.

Following the same arguments as in section 2, we deduce that the existence of a nonnegative function $W_0 : X \to \mathbb{R}$ such that

$$\begin{cases} W_0(x) \geq \min\limits_{u \in U} \ \max\limits_{w \in W} \{W_0(b(x, u, w)) + \ell(x, u) - \gamma^2 \theta(w)\}, \\ W_0(x_\phi) = 0 \end{cases}$$

is a necessary and sufficient condition for the existence of solution to the state feedback robust control problem. Actually, the solution can be characterized in terms of the value of an average cost dynamic game, as we shall see later in this section.

The proof of the next proposition is structurally similar to the one given for Proposition 2.3, and we sketch it in the appendix at the end of the paper.

PROPOSITION 4.1. *If* (H2) *holds, then there exist a nonnegative number* λ_0 *and a function* $W_0 : X \to \mathbb{R}$ *such that*

$$\lambda_0 + W_0(x) = \min_{u \in U} \max_{w \in W} \left[W_0(b(x, u, w)) + \ell(x, u) - \gamma^2 \theta(w)\right]. \tag{4.4}$$

COROLLARY 4.2. *Let* $\tilde{u}^* \in \mathcal{U}$ *be a control achieving the minimum in the r.h.s. of* (4.4). *If* (H1)–(H2) *hold, then the following conditions are equivalent:*

(i) $\lambda_0 = 0$,

(ii) $\|\Sigma^{\tilde{u}^*}\| \leq \gamma$.

Proof. The proof of this corollary is the same as that of Theorem 2.6, noting that $\lambda_0 = 0$ implies that $\tilde{u}^* \in \mathcal{U}_1$. To see this, note that, for any $x \in X$ and $T > 0$,

$$\sum_{t=0}^{T} \ell(x_t, \tilde{u}^*(x_t)) \leq W_0(x) - W_0(x_{T+1}),$$

where x_t obeys the dynamic (4.1). Thus, for T great enough, $\ell(x_T, \tilde{u}^*(x_T)) = 0$, and in view of (4.3), $x_T = x_\phi$ and $\tilde{u}^*(x_T) = u_\phi$. □

The equation (4.4) is the Isaacs equation of the following average cost zero-sum dynamic game.

Dynamic game. Consider the difference equation

$$x_{t+1} = b(x_t, u_t, w_t), \quad t = 0, 1, \ldots; \quad x_0 = x.$$

Here $\underline{u} = \{u_t\} \in U[0, \infty)$ and $\underline{w} = \{w_t\} \in W[0, \infty)$, and they play the role of controls for Player 1 (minimizer) and Player 2 (maximizer), respectively. The associated cost functional is

$$J(x; \underline{u}, \underline{w}) = \limsup_{T \to \infty} \frac{1}{T} \sum_{t=0}^{T-1} \left[\ell(x_t, u_t) - \gamma^2 \theta(w_t) \right]. \tag{4.5}$$

We use the following definition of value of a dynamic game [8], which is given in terms of strategies. A strategy $\vec{u}$ for Player 1 consists of a sequence of functions $\bar{u}_0, \bar{u}_1, \ldots$, with values in U such that $\bar{u}_t$ is a function of $x_s, x_t, w_s, 0 \leq s < t$. A strategy $\vec{w}$ for Player 2 is a sequence of functions $\bar{w}_0, \bar{w}_1, \ldots$, with values in W such that $\bar{w}_t$ is a function of x_s, u_s, $0 \leq s \leq t$. We say that a strategy $\vec{u}$ is *stationary feedback* if $\bar{u}_t$ depends only on the current state x_t, i.e., $\bar{u}_t : X \to U$, and $\bar{u}_t = \tilde{u}$ is independent of t. Analogously, $\vec{w}$ is *stationary feedback* if $\bar{w}_t$ depends only on the current state x_t and the current control u_t of Player 1, and $\bar{w}_t = \tilde{w} : X \times U \to W$ is independent of t.

Given a pair of strategies $(\vec{u}, \vec{w})$ and the initial condition $x_0 = x$, the controls for Player 1 and Player 2 are generated recursively as

$$u_0 = \bar{u}_0(x), \ w_0 = \bar{w}_0(x, u_0), \ u_1 = \bar{u}_1(x, x_1, w_0), \ w_1 = \bar{w}_1(x, x_1, u_0, u_1), \ldots.$$

DEFINITION 4.3. *When there exists a pair of strategies* $(\vec{u}^*, \vec{w}^*)$ *such that*

$$J(x; \vec{u}^*, \vec{w}) \leq J(x, \vec{u}^*, \vec{w}^*) \leq J(x, \vec{u}, \vec{w}^*) \text{ for all } \vec{u}, \vec{w},$$

the value $V(x) = J(x, \vec{u}^*, \vec{w}^*)$ *is called the* value of the game*, and* $(\vec{u}^*, \vec{w}^*)$ *are referred to as* optimal strategies*.*

Remark 4.4. $V(x)$ is often called the upper value of this infinite horizon dynamic game, since the maximizing Player 2 has the advantage of knowing Player 1's choice u_t before choosing w_t. This is also reflected in the order min max (rather than max min) in the Isaacs equation (4.4). For continuous variable differential games, an alternative definition due to Elliott and Kalton is often used. See, e.g., [6]. The discrete time version of the Elliott–Kalton definition is as follows. The minimizing Player 1 chooses any control sequence $\underline{u} \in U[0, \infty)$, while the maximizing Player 2 chooses a map $\xi : U[0, \infty) \to W[0, \infty)$ such that $\xi[\underline{u}]_t$ depends only on $u_0, u_1, \ldots, u_t$. The Elliott–Kalton upper value of our discrete time dynamic game can be easily shown to be the same as the one defined above.

PROPOSITION 4.5. *For every $x \in X$,*

$$\lambda_0 = V(x).$$

Furthermore, the stationary strategies

$$\tilde{u}^*(x) \in \arg\min_{u\in U}\left\{\max_{w\in W}\left[W_0(b(x,u,w)) + \ell(x,u) - \gamma^2\theta(w)\right]\right\}$$

and

$$\tilde{w}^*(x,u) \in \arg\max_{w\in W}\left\{W_0(b(x,u,w)) + \ell(x,u) - \gamma^2\theta(w)\right\}$$

are optimal.

The proof of this proposition is an immediate application of (4.4), and we omit it.

4.2. Risk-sensitive optimal control problem. We regard system (4.1) as a deterministic controlled Markov chain and define a random perturbation as follows. Given $x, x'' \in X$ and $u \in U$ we define

$$V(x,u;x'') = \min\left\{\theta(w) : x'' = b(x,u,w)\right\}.$$

Here the minimum over an empty set is defined as $+\infty$.

For each $u \in U$, we define the stochastic matrix

$$\Pi_\varepsilon^u(x,x'') = \frac{1}{Z_\varepsilon(x,u)}\exp\left\{-\frac{1}{\varepsilon}V(x,u;x'')\right\}, \tag{4.6}$$

where $\varepsilon > 0$ is a noise parameter and $Z_\varepsilon(x,u)$ is a normalizing constant satisfying the condition $\Sigma_{x''\in X}\Pi_\varepsilon^u(x,x'') = 1$.

Throughout this subsection we assume (H2).

For each $\tilde{u} \in \mathcal{U}$ the cost functional (to be minimized) is the infinite horizon exponential growth criterion

$$\lambda_\varepsilon(\tilde{u}) = \lim_{T\to\infty}\frac{\varepsilon}{\mu}\cdot\frac{1}{T}\log E_x\exp\left\{\frac{\mu}{\varepsilon}\sum_{t=0}^{T-1}\ell(x_t,\tilde{u}(x_t))\right\}, \tag{4.7}$$

where $\mu > 0$ is given.

The risk-sensitive optimal control problem is to find a control $\tilde{u}^* \in \mathcal{U}$ that minimizes $\lambda_\varepsilon(\tilde{u})$. Let

$$\Lambda_\varepsilon := \inf_{\tilde{u}\in\mathcal{U}}\lambda_\varepsilon(\tilde{u}).$$

Next we have a verification theorem.

THEOREM 4.6. *Suppose that there exist a number $\alpha > 0$ and a strictly positive function $\Psi : X \to \mathbb{R}$ such that*

$$\alpha\Psi(x) = \min_{u\in U}\left\{e^{\frac{\mu}{\varepsilon}\ell(x,u)}\Pi_\varepsilon^u\Psi(x)\right\} \text{ for all } x \in X.$$

Then $\Lambda_\varepsilon = \frac{\varepsilon}{\mu}\log\alpha$, and the control $\tilde{u}^* \in \mathcal{U}$, with $\tilde{u}^*(x)$ achieving the minimum on the r.h.s., is optimal.

Proof. Let $\tilde{u} \in \mathcal{U}$. Following the same arguments as in the proof of Theorem 2.11, we have

$$\frac{\varepsilon}{\mu} \log \alpha \leq \lambda_\varepsilon(\tilde{u}),$$

with equality for the control $\tilde{u}^*$. □

Now, in order to get an optimal policy, we use the policy iteration algorithm, which is described as follows. Given an arbitrary policy $\tilde{u}_0 \in \mathcal{U}$, we have proved already the existence of a number $\alpha_0 > 0$ and a function $\Psi_0 : X \to \mathbb{R}$ strictly positive (see Theorem 2.11), such that for all $x \in X$

$$\begin{aligned} \alpha_0 \Psi_0(x) &= e^{\frac{\mu}{\varepsilon}\ell(x,\tilde{u}_0(x))} \Pi_\varepsilon^{\tilde{u}_0} \Psi_0(x) \\ &\equiv T_0 \Psi_0(x). \end{aligned}$$

Let $\tilde{u}_1 \in \mathcal{U}$ be defined by

$$\tilde{u}_1(x) \in \arg\min_{u \in U} \left\{ e^{\frac{\mu}{\varepsilon}\ell(x,u)} \Pi_\varepsilon^u \Psi_0(x) \right\}.$$

Calculate α_1 and Ψ_1, and repeat the process. If we reach a point where

$$T_k \Psi_k(x) = \min_{u \in U} [e^{\frac{\mu}{\varepsilon}\ell(x,u)} \Pi_\varepsilon^u \Psi_k(x)] \text{ for all } x \in X,$$

then, according to Theorem 4.6, $\tilde{u}_k$ is optimal, and we stop.

THEOREM 4.7. *The policy iteration generates a finite sequence of controls* $\{\tilde{u}_0, \tilde{u}_1, \ldots, \tilde{u}_m = \tilde{u}^*\}$ *with strictly monotonically decreasing* $\lambda_\varepsilon(\tilde{u}_k)$ *until the iteration reaches a stopping point.*

Proof. Let $\tilde{u}_k$ and $\tilde{u}_{k+1}$ be control policies generated by the policy iteration algorithm, and α_k, Ψ_k (α_{k+1}, Ψ_{k+1}) be the dominant eigenvalue and eigenfunction of T_k (T_{k+1}, respectively). Thus,

$$T_{k+1} \Psi_k \leq \alpha_k \Psi_k (= T_k \Psi_k). \tag{4.8}$$

If $T_{k+1}\Psi_k = \alpha_k \Psi_k$, then

$$T_k \Psi_k(x) = \min_{u \in U} \left\{ e^{\frac{\mu}{\varepsilon}\ell(x,u)} \Pi_\varepsilon^u \Psi_k(x) \right\} \text{ for all } x \in X,$$

and the iteration terminates. In this case, $\tilde{u}_k$ is optimal by Theorem 4.6.

So, assume that there exists some component $x_0 \in X$ such that the inequality (4.8) is strict, i.e.,

$$T_{k+1} \Psi_k(x_0) < \alpha_k \Psi_k(x_0).$$

Then, Theorem 1.6 in [16] implies that $\alpha_{k+1} < \alpha_k$, and therefore,

$$\lambda_k(\tilde{u}_{k+1}) < \lambda_\varepsilon(\tilde{u}_k).$$

Thus, since there exist just a finite number of policies, the iteration will stop after a finite number of steps. □

COROLLARY 4.8. *There exist* $\Lambda_\varepsilon > 0$ *and a function* $W_\varepsilon : X \to \mathbb{R}$ *such that*

$$\exp\left\{ \frac{\mu}{\varepsilon} (\Lambda_\varepsilon + W_\varepsilon(x)) \right\} = \min_{u \in U} \left[e^{\frac{\mu}{\varepsilon}\ell(x,u)} \Pi_\varepsilon^u e^{\frac{\mu}{\varepsilon} W_\varepsilon(x)} \right]. \tag{4.9}$$

Proof. The proof follows immediately taking $e^{\frac{\mu}{\varepsilon}\Lambda_\varepsilon} = \alpha_m$ and $e^{\frac{\mu}{\varepsilon}W_\varepsilon} = \Psi_m$, where m is the step where the iteration finishes. □

Using the variational equality (A.1) in the appendix, we rewrite (4.9) as

$$(4.9') \quad \Lambda_\varepsilon + W_\varepsilon(x) = \min_{u\in U}\max_{\pi\in P(X)}\left\{\sum_{x''\in X} W_\varepsilon(x'')\pi(x'') + \ell(x,u) - \frac{\varepsilon}{\mu}I(\pi\|\Pi_\varepsilon^u(x))\right\}.$$

This equation is the Isaacs equation associated with the following stochastic game with average cost per unit time criterion.

Stochastic dynamic game. Let X be the state space, U be the control set for Player 1 (minimizer), and $P(X)$ (the set of probability vectors on X) be the control set for Player 2 (maximizer). On the other hand, $(x,u,\pi) \to \ell(x,u) - I(\pi\|\Pi_\varepsilon^u(x))$, with $(x,u,\pi) \in X\times U\times P(X)$, is the reward function. Note that the reward function is allowed to take the value $-\infty$.

The system evolves as follows: at each time $t \in \{0,1,\ldots\}$ the state of the system is observed, say $x_t = x \in X$. Then, a control $u_t \in U$ is chosen for Player 1, and $\pi_t \in P(X)$ is chosen for Player 2. (Actually, π_t will turn out to be a conditional probability based on the past up to time t.) Then, a reward $\ell(x_t,u_t) - I(\pi_t\|\Pi_\varepsilon^{u_t}(x_t))$ is earned, and the state of the system moves to the state x_{t+1} according to the probability distribution π_t.

Strategies. For each $t \geq 0$, let H_t and K_t be the set of feasible histories up to time t for Player 1 and Player 2, respectively. That is, $H_0 = X$ and $H_t = (X\times P(X))^t \times X$, while $K_0 = X\times U$ and $K_t = (X\times U)^t \times (X\times U)$. A strategy for Player 1 is a sequence $\vec{u} = \{\bar{u}_t\}$ of functions $\bar{u}_t$ from H_t to U. We say that $\vec{u}$ is *stationary feedback* (or stationary Markov policy) if, for all $t \geq 0$, $\bar{u}_t$ depends only on the current state x_t, and $\bar{u}_t = \tilde{u}$ is independent of t; i.e., $\bar{u}_t \equiv \tilde{u} : X \to U$ for all $t \geq 0$. A strategy for Player 2 is a sequence $\vec{\pi} = \{\bar{\pi}_t\}$ of functions $\bar{\pi}_t$ from K_t to $P(X)$. Analogously, $\vec{\pi}$ is *stationary feedback* (or stationary Markov policy) if for all $t \geq 0$, $\bar{\pi}_t \equiv \tilde{\pi} : X\times U \to P(X)$.

Let $\Omega := X[0,\infty)$ and $\mathcal{B}(\Omega) = \sigma$-field generated by the subsets of the form $A_1\times A_2\times\cdots\times A_T\times X\cdots$, with $A_t \subset X, t = 1,\ldots,T$. A generic element of Ω is an infinite sequence $\omega = (\xi_0,\xi_1,\ldots)$, and the state process is defined as the projection from Ω to X, i.e., $x_t(\omega) = \xi_t$. Given the initial condition $x_0 = x$ and the strategies $\vec{u},\vec{\pi}$ being used, there exists a unique probability measure $P^{\vec{u},\vec{\pi}}$ on $(\Omega,\mathcal{B}(\Omega))$ such that

$$\text{(i)} \quad P^{\vec{u},\vec{\pi}}(x_0 = x) = 1,$$

$$\text{(ii)} \quad P^{\vec{u},\vec{\pi}}(x_{t+1} = \xi_{t+1}|x_t = \xi_t,\ldots,x_0 = \xi_0) = \bar{\pi}_t[\xi_0,u_0,\xi_1,u_1,\ldots,\xi_t,u_t](\xi_{t+1}).$$

We denote by $E_x^{\vec{u},\vec{\pi}}$ the corresponding expectation operator. Finally, we observe that, under the action of stationary strategies, the state process $\{x_t\}_{t=0}^\infty$ is a Markov chain with stationary transition matrix. Now let us define the associated cost functional

$$J(x,\vec{u},\vec{\pi}) = \limsup_{T\to\infty}\frac{1}{T}\sum_{t=0}^{T-1} E^{\vec{u},\vec{\pi}}\left[\ell(x_t,u_t) - \frac{\varepsilon}{\mu}I(\pi_t\|\Pi_\varepsilon^{u_t}(x_t))\right].$$

The same definition of value given for deterministic dynamic games is applied for stochastic dynamic games; see Definition 4.3. We denote by $V_\varepsilon(x)$ the value of the game.

THEOREM 4.9. *Let Λ_ε and W_ε be as in (4.9′). Then, for every $x \in X$,*

$$\Lambda_\varepsilon = V_\varepsilon(x).$$

Furthermore, the stationary strategies $\tilde{u}^*$ and $\tilde{\pi}^*$, with

$$\tilde{u}^*(x) \in \arg\min_{u\in U}\left[e^{\frac{\mu}{\varepsilon}\ell(x,u)}\Pi^u_\varepsilon e^{\frac{\mu}{\varepsilon}W_\varepsilon(x)}\right]$$

and

$$\tilde{\pi}^*[x,u](x'') = \frac{e^{\frac{\mu}{\varepsilon}W_\varepsilon(x'')}}{\Pi^u_\varepsilon e^{\frac{\mu}{\varepsilon}W_\varepsilon(x)}}\Pi^u_\varepsilon(x,x'')$$

are optimal.

The proof of this theorem is based on standard dynamic programming arguments and the variational equation (A.1) in the Appendix.

Remark 4.10. A stochastic analogue of the Elliott–Kalton definition of strategy for differential games has been given in [12]. In order to make an analogous definition here, it would be necessary to model the disturbances w_t as exogenous random inputs (in analogy with the Brownian motions, which drive the stochastic differential game dynamics). This could be done. However, following [1], we have instead modelled the stochastic effects via conditional state probabilities.

4.3. Small noise limit and deterministic dynamic game. Paralleling section 3, in this section we relate the state feedback robust control problem and the risk-sensitive optimal control problem taking small noise limit. First, we introduce the following condition, which is analogous to (A4) in section 3.

(H4) For each $\tilde{u} \in \mathcal{U}$, there exists a positive integer T_2 such that all the entries of the T_2-power of $\Pi^{\tilde{u}}_\varepsilon$ are strictly positive.

THEOREM 4.11. *If* (H4) *holds, then there exist a number $\lambda_0 \geq 0$ and a function $W_0 : X \to \mathbb{R}$ limit point of the family $\{\lambda_\varepsilon, W_\varepsilon\}$, such that*

$$\lambda_0 + W_0(x) = \min_{u\in U}\max_{w\in W}\left\{W_0(b(x,u,w)) + \ell(x,u) - \frac{1}{u}\theta(w)\right\}.$$

Sketch of proof. The proof of this theorem will be reduced to the one given for Theorem 3.3. Let $\{\varepsilon_n\}$ be a sequence converging to zero as $n \to \infty$, and denote by $\tilde{u}^*_{\varepsilon_n}$ the optimal policy defined in Theorem 4.9. Since there exist just a finite number of policies, there exist a subsequence of $\{\varepsilon_n\}$, which we denote again as $\{\varepsilon_n\}$, and a policy $\tilde{u}^* = \tilde{u}^*_{\varepsilon_n}$ independent of n. Then, in view of (H4), the same arguments used in the proof of Theorem 3.3 can be applied again. □

THEOREM 4.12. *Assume* (H2) *and that $\mathcal{U}_1$ is not empty. Then there exists $\tilde{\mu}^*$ with the following property. For $\mu < \tilde{\mu}^*$ there exist a sequence $\{\varepsilon_n\}$, with $\varepsilon_n \to 0$ as $n \to \infty$, and a policy $\tilde{u}^* \in \mathcal{U}_1$ not depending on n, such that*

$$\Lambda_{\varepsilon_n} = \lambda_{\varepsilon_n}(\tilde{u}^*) \text{ for } n = 1, 2, \ldots.$$

Furthermore,

$$\lim_{n\to\infty}\Lambda_{\varepsilon_n} = 0.$$

Proof. Let $\tilde{u} \in \mathcal{U}_1$. Then (2.13) implies the existence of $\tilde{\mu}^*$ such that $\lim_{\varepsilon\to 0}\lambda_\varepsilon(\tilde{u}) = 0$ for $\mu < \tilde{\mu}^*$. Therefore, since $\lambda_\varepsilon(\tilde{u}) \geq \Lambda_\varepsilon \geq 0$, letting $\varepsilon \to 0$, we get

$$\lim_{\varepsilon\to 0}\Lambda_\varepsilon = 0. \tag{4.10}$$

Let $\{\varepsilon_n\}$ be a sequence converging to zero as $n \to \infty$, and $\tilde{u}^*_{\varepsilon_n}$ be the optimal policy defined in Theorem 4.9. Since there are just a finite number of policies, there exist a subsequence of $\{\varepsilon_n\}$, which we denote again as $\{\varepsilon_n\}$, and a policy $\tilde{u}^* = \tilde{u}^*_{\varepsilon_n}$ independent of n. Now, to prove that $\tilde{u}^*$ belongs to $\mathcal{U}_1$, we need to verify that (i) given any initial condition $x_0 = x \in X$, there exists a positive integer N_0 such that the system (4.1), with $u_t = \tilde{u}^*(x_t)$, reaches the null state x_ϕ after N_0 steps, and (ii) $\tilde{u}^*(x_\phi) = u_\phi$. We will just prove the first part, since the argument to prove the second one is the same.

So, suppose that $\tilde{u}^*$ does not satisfy (i). Since $\tilde{u}^*$ is optimal for each ε_n,

$$\Lambda_{\varepsilon_n} = \lim_{T\to\infty} \frac{\varepsilon_n}{\mu} \cdot \frac{1}{T} \log E_x \left\{ \frac{\mu}{\varepsilon_n} \sum_{t=0}^{T-1} \ell(x_t, \tilde{u}^*(x_t)) \right\} \text{ for all } n = 1, 2, \ldots.$$

Then, in view of our assumption, and noting that the functions Z_ε and V defined in (4.6) satisfy

$$1 \le Z_\varepsilon \le N \quad \text{and} \quad V(x, u, x'') = 0 \text{ if } x'' = f(x, u),$$

we have

$$E_x \exp \left\{ \frac{\mu}{\varepsilon_n} \sum_{t=0}^{T-1} \ell(x_t, \tilde{u}^*(x_t)) \right\} \ge \left[\frac{e^{\frac{\mu}{\varepsilon_n}\ell^*}}{N} \right]^T,$$

where $\ell^* := \min_{\substack{x \neq x_\phi \in X \\ u \in U}} \ell(x, u)$ and N is the number of states.

Therefore,

$$\frac{1}{T} \frac{\varepsilon_n}{\mu} \log E_x \exp \left\{ \frac{\mu}{\varepsilon_n} \sum_{t=0}^{T-1} \ell(x_t, \bar{u}^*(x_t)) \right\} \ge \ell^* - \frac{\varepsilon_n}{\mu} \log N.$$

Letting $T \to \infty$ and $n \to \infty$, we have

$$\lim_{n\to\infty} \Lambda_{\varepsilon_n} \ge \ell^* > 0,$$

which contradicts (4.10). Thus, $\tilde{u}^*$ satisfies (i). □

COROLLARY 4.13. *If $\mathcal{U}_1$ is not empty and μ is small enough, then there exists a unique nonnegative function $W_0 : X \to \mathbb{R}$, with $W_0(x_\phi) = 0$, such that*

$$W_0 = \min_{u\in U} \max_{w\in W} \left\{ W_0(b(x, u, w)) + \ell(x, u) - \frac{1}{\mu}\theta(w) \right\}.$$

In particular, the control $\tilde{u}^*$, where $\tilde{u}^*$ achieves the minimum in the r.h.s., solves the state feedback robust control problem.

This corollary is a straightforward consequence of Theorems 4.12 and 3.3 and Proposition 2.7.

Appendix.

Proof of Lemma 2.12. From (2.22), it is sufficient to prove that

$$\frac{\varepsilon}{\mu} \log \Pi^\varepsilon e^{\frac{\mu}{\varepsilon} W_\varepsilon(x)} = \sup_{\pi \in P(X)} \left\{ \sum_{x'' \in X} W_\varepsilon(x'')\pi(x'') - \frac{\varepsilon}{\mu} I(\pi \| \Pi_\varepsilon(x)) \right\}, \tag{A.1}$$

and that the supremum on the r.h.s. is achieved at the unique probability vector $\eta^*(x)$ defined by

$$\eta^*(x,x'') = \frac{e^{\frac{\mu}{\varepsilon}W_\varepsilon(x'')}}{\Pi_\varepsilon e^{\frac{\mu}{\varepsilon}W_\varepsilon(x)}}\Pi_\varepsilon(x,x'').$$

Let $\pi \in P(X)$, and fix $x \in X$. Let us assume that π is absolutely continuous with respect to $\Pi_\varepsilon(x)$. Then, since $\Pi_\varepsilon(x)$ is absolutely continuous with respect to $\eta^*(x)$, we have

$$\begin{aligned}
-I(\pi\|\Pi_\varepsilon(x)) \quad + \quad & \frac{\mu}{\varepsilon}\sum_{x''\in X} W_\varepsilon(x'')\pi(x'') = -\sum_{x''\in X}\log\left[\frac{\pi(x'')}{\Pi_\varepsilon(x,x'')}\right]\pi(x'') \\
& +\frac{\mu}{\varepsilon}\sum_{x''\in X} W_\varepsilon(x'')\pi(x'') \\
= \quad & -\sum_{x''\in X}\log\left[\frac{\pi(x'')}{\eta^*(x,x'')}\right]\pi(x'') - \sum_{x''\in X}\log\left[\frac{\eta^*(x,x'')}{\Pi_\varepsilon(x,x'')}\right]\pi(x'') \\
& +\frac{\mu}{\varepsilon}\sum_{x''\in X} W_\varepsilon(x'')\pi(x'') \\
= \quad & -I(\pi\|\eta^*(x)) + \log\Pi_\varepsilon e^{\frac{\mu}{\varepsilon}W_\varepsilon(x)}.
\end{aligned}$$

Noting that $I(\pi\|\eta^*(x)) \geq 0$, and that $I(\pi\|\eta^*(x)) = 0$ if and only if $\pi = \eta^*(x)$, (A.1) follows. □

The next lemma is a version of the Varadhan–Laplace lemma. See [13].

LEMMA A.1. *Let A be a finite set, and F_a^ε, F_a be real valued functions defined on a finite set X such that*

$$\lim_{\varepsilon\to 0}\max_{a\in A}\max_{x\in X}|F_a^\varepsilon(x) - F_a(x)| = 0.$$

Then

$$\lim_{\varepsilon\to 0}\max_{a\in A}\left|\varepsilon\log\sum_{x\in X} e^{\frac{F_a^\varepsilon(x)}{\varepsilon}} - \max_{x\in X}F_a(x)\right| = 0 \tag{A.2}$$

Proof. Define

$$\bar{F}_a^\varepsilon := \max_{x\in X}F_a^\varepsilon(x),\ \ \bar{F}_a := \max_{x\in X}F_a(x).$$

Then

$$\lim_{\varepsilon\to 0}\max_{a\in A}\bar{F}_a^\varepsilon = \bar{F}_a.$$

Therefore,

$$e^{\frac{\bar{F}_a}{\varepsilon}} \leq \sum_{x\in X} e^{\frac{F_a^\varepsilon(x)}{\varepsilon}} \leq Ne^{\frac{\bar{F}_a}{\varepsilon}},$$

where N is the number of elements of X, and (A.2) follows. □

Sketch of proof of Proposition 4.1. Consider the dynamic game described at the end of section 4.2, but with the cost functional given by

$$J(x, \underline{u}, \underline{w}) = \sum_{t=0}^{\infty} \beta^t [\ell(x_t, u_t) - \gamma^2 \theta(w_t)],$$

where β is the discount factor, $0 < \beta < 1$.

Let $V_\beta(x)$ be the value of the game; see Definition 4.3. Then V_β is the unique solution of the Isaacs equation

$$V_\beta(x) = \min_{u \in U} \max_{w \in W} [\beta V_\alpha(b(x, u, w)) + \ell(x, u) - \gamma^2 \theta(w)]. \tag{A.3}$$

Following the same arguments as in the proof of Proposition 2.3, we get

$$\text{(i)} \quad |V_\beta(x) - V_\beta(x_\phi)| < C^1,$$
$$\text{(ii)} \quad 0 \le (1 - \beta) V_\beta(x) \le \|\ell\|$$

for some suitable constant C^1. Then, the above estimates imply the existence of a sequence $\{\beta_n\}$, with $\beta_n \to 1$ as $n \to \infty$, such that $(1 - \beta_n) V_{\beta_n}(x_\phi)$ and $V_{\beta_n}(x) - V_{\beta_n}(x_\phi)$ converge to some limit λ_0 and $W_0(x)$ as $n \to \infty$. Then, rewriting (A.3) as

$$(1 - \beta) V_\beta(x_\phi) + \bar{V}_\beta(x) = \min_{u \in U} \max_{w \in W} [\beta \bar{V}_\beta(b(x, u, w)) + \ell(x, u) - \gamma^2 \theta(u)],$$

with $\bar{V}_\beta(x) := V_\beta(x) - V_\beta(x_\phi)$, and passing the limit $\beta_n \to 1$,

$$\lambda_0 + W_0(x) = \min_{u \in U} \max_{w \in W} [\alpha W_0(b(x, u, w)) + \ell(x, u) - \gamma^2 \theta(w)]. \qquad \square$$

WEIGHTED MEANS IN STOCHASTIC APPROXIMATION OF MINIMA*

J. DIPPON† AND J. RENZ‡

Abstract. Weighted averages of Kiefer–Wolfowitz-type procedures, which are driven by larger step lengths than usual, can achieve the optimal rate of convergence. A priori knowledge of a lower bound on the smallest eigenvalue of the Hessian matrix is avoided. The asymptotic mean squared error of the weighted averaging algorithm is the same as would emerge using a Newton-type adaptive algorithm. Several different gradient estimates are considered; one of them leads to a vanishing asymptotic bias. This gradient estimate applied with the weighted averaging algorithm usually yields a better asymptotic mean squared error than applied with the standard algorithm.

Key words. stochastic approximation, acceleration by weighted averaging, weak invariance principle, consistency, Kiefer–Wolfowitz procedure, gradient estimation, optimization

1. Introduction.

In stochastic approximation the minimizer ϑ of an unknown regression function $f : \mathbb{R}^d \to \mathbb{R}$ can be estimated by running the recursion

$$X_{n+1} = X_n - a_n Y_n, \tag{1.1}$$

where Y_n is a gradient estimate of f at the point X_n and a_n are positive step lengths decreasing to zero. For instance, for $d = 1$ and decreasing span c_n, Kiefer and Wolfowitz [11] used divided differences $Y_n = (Y_{n,1} - Y_{n,2})/(2c_n)$ as approximation of $f'(X_n)$, where $Y_{n,1}$ and $Y_{n,2}$ are error-contaminated observations of $f(X_n + c_n)$ and $f(X_n - c_n)$, respectively. If f is p-times differentiable at ϑ, and if the gradient estimates Y_n are constructed appropriately, one can obtain

$$n^{\frac{\alpha}{2}\left(1-\frac{1}{p}\right)}(X_n - \vartheta) \xrightarrow{\mathcal{D}} N(\mu, K) \quad (n \to \infty)$$

with step lengths $a_n = an^{-\alpha}$ for some $a > 0$ and $\alpha \in (0, 1]$ (see Fabian [8] for $p \geq 3$ odd). Hence, for step lengths $a_n = a/n$, the convergence rate $n^{(1-1/p)/2}$ is obtained. This is the exact minimax order in the problem of estimating the minimizer of f for f belonging to a certain class of p-times differentiable functions (Polyak and Tsybakov [18]).

In this paper we investigate *weighted means*

$$\widetilde{X}_{n,\delta} = \tfrac{1+\delta}{n^{1+\delta}} \sum_{i=1}^{n} i^{\delta} X_i \tag{1.2}$$

of Kiefer–Wolfowitz-type processes (X_n) generated by recursion (1.1) with some gradient estimates Y_n for p-times differentiable regression functions and step lengths converging slower to zero than $1/n$. We obtain

$$n^{\frac{1}{2}\left(1-\frac{1}{p}\right)}\left(\widetilde{X}_{n,\delta} - \vartheta\right) \xrightarrow{\mathcal{D}} N(\widetilde{\mu}, \widetilde{K}) \quad (n \to \infty)$$

for some weight parameters δ and various types of gradient estimates (Theorems 3.2 and 4.2). The main advantages are the following. First, a priori knowledge of a lower bound on the smallest eigenvalue λ_0 of the Hessian $Hf(\vartheta)$ of f at ϑ is avoided. If, in the standard algorithm with $a_n = a/n$, the constant a is chosen too small, i.e., $a \leq (1 - 1/p)/(2\lambda_0)$, convergence can be very slow. To be safe one might choose a pretty large. But the asymptotic mean squared error (AMSE) produced by the standard algorithm grows approximately linearly in a. These problems do not arise when the averaging algorithm is applied. On the other side, if an asymptotic bias is present, the AMSE of the averaging algorithm cannot be greater than four times the AMSE of the standard algorithm with the optimal, but usually unknown, constant a. In this sense the averaging algorithm can be considered to be more stable than the standard one. Furthermore, the averaging algorithm shows the same limit distribution as the Newton-type adaptive procedure suggested by Fabian [9] (section 5).

The method proposed in this paper is inspired by an idea of Ruppert [21] and Polyak [16], who suggested considering the arithmetic mean of the trajectories of a Robbins–Monro process, which is driven by step lengths slower than $1/n$, too. In this case one obtains the best possible convergence rate and the optimal covariance of the asymptotic distribution in a certain sense [17]. Since then Yin [27], Pechtl [15], Kushner and Yang [13], Györfi and Walk [10], Nazin and Shcherbakov [14], and others have studied this idea.

A further contribution of this paper is a new design to estimate the gradient which leads to a vanishing asymptotic bias $\widetilde{\mu}$ (for $d = 1$ see Renz [19]) regardless of which method (with or without averaging, or with adaptation) is used. Applying the weighted averaging algorithm together with this gradient estimate leads to a second moment of the asymptotic distribution which is minimal within a large class of procedures (relation (5.4)).

Spall [22] introduced another gradient estimate Y_n, the so-called simultaneous gradient perturbation method. It uses only two observations at each step instead of $2d$ observations, as in the standard Kiefer–Wolfowitz method in $\mathbb{R}^d$. This makes it suitable for certain optimization problems in high-dimensional spaces $\mathbb{R}^d$. Taking weighted averages of the process generated with Spall's gradient estimate stabilizes the performance as discussed below (Theorem 4.2 and section 5).

All these central limit theorems require consistency of the stochastic approximation method (Propositions 3.1 and 4.1). To prove the central limit theorems we apply a weak invariance principle stated in Lemma 7.1. Taking weighted averages of the trajectories leads to an accumulation of terms due to the nonlinearity of the regression function. To cope with this effect the assumptions of this lemma are partly stronger than those of a functional central limit theorem for the nonweighted case (see Walk [24]). But fortunately, the additional conditions can be shown to be fulfilled for many stochastic approximation procedures. The assertions of both central limit theorems in this paper can be formulated as invariance principles in the spirit of Lemma 7.1.

As already indicated in Dippon and Renz [4], taking weighted averages of the trajectories works well with the original gradient estimate of Kiefer and Wolfowitz ($p = 3$).

2. Notations. For a d-dimensional Euclidean space the linear space of $d \times d$ matrices is denoted by $\mathcal{L}(\mathbb{R}^d)$. x^* is the transposed vector of $x \in \mathbb{R}^d$, A^* is the adjoint matrix, and $\operatorname{tr} A$ is the trace of $A \in \mathcal{L}(\mathbb{R}^d)$. The tensor product $x \otimes y : \mathbb{R}^d \to \mathbb{R}^d$ is defined by $\langle y, \cdot \rangle x$, where $x, y \in \mathbb{R}^d$ and $\langle \cdot, \cdot \rangle$ is the usual inner product. The space $C([0,1], \mathbb{R}^d)$ of $\mathbb{R}^d$-valued continuous functions on $[0,1]$ is equipped with the maximum

norm. $Hf(\vartheta)$ is the Hessian of a function $f : \mathbb{R}^d \to \mathbb{R}$ at $\vartheta \in \mathbb{R}^d$. For $x \in \mathbb{R}$ we use $\lfloor x \rfloor$ and $\lceil x \rceil$, denoting the integer part of x and the least integer greater than or equal to x, respectively.

Let $(\Omega, \mathcal{A}, P)$ be a probability space. Then a sequence (X_n) of $\mathbb{R}^d$-valued random variables (r.v.'s) is called bounded in probability whenever $\lim_{R\to\infty} \overline{\lim}_n P(\|X_n\| \geq R) = 0$; (X_n) converges to zero almost in L^r or is bounded almost in L^r ($r \in (0,\infty)$) if for each $\varepsilon > 0$ there exists an $\Omega_\varepsilon \in \mathcal{A}$ with $P(\Omega_\varepsilon) \geq 1-\varepsilon$ such that $(\int_{\Omega_\varepsilon} \|X_n\|^r \, dP)^{1/r} = o(1)$ or $= O(1)$, respectively. Convergence almost in L^r implies convergence in probability, but it is weaker than a.s. convergence or convergence in the rth mean.

3. A Kiefer–Wolfowitz procedure with an improved gradient estimate. The Kiefer–Wolfowitz procedure, which finds the minimizer ϑ of a regression function $f : \mathbb{R}^d \to \mathbb{R}$, has been modified by Fabian [6] in such a way that the rate of convergence nearly reaches the rate of a Robbins–Monro procedure if f is assumed to be sufficiently smooth in a neighborhood of ϑ. The method uses multiple observations per step.

We consider here, including the Fabian procedure, a modified Kiefer–Wolfowitz procedure which is given by recursion (1.1). There Y_n is an estimate of the gradient $\nabla f(X_n)$ based on error-contaminated observations of f. It is defined by

$$(3.1)\quad Y_n = c_n^{-1} \sum_{j=1}^{m} v_j \Big(\{ f(X_n + c_n u_j e_i) - V_{n,2j-1}^{(i)} \} - \{ f(X_n - c_n u_j e_i) - V_{n,2j}^{(i)} \} \Big)_{i=1,\dots,d},$$

where the following definitions and relations are used throughout section 3: $m \in \mathbb{N}$, $0 < u_1 < \cdots < u_m \leq 1$, $v_1, \dots, v_m$ are real numbers with $\sum_{j=1}^m v_j u_j^{2i-1} = (1/2)\delta_{1i}$ for all $i = 1, \dots, m$ (as to the existence, compare Fabian [6]), and $c_n = cn^{-\gamma}$ with $c > 0$ and $0 < \gamma < 1/2$. The unit vectors in $\mathbb{R}^d$ are denoted by $e_1, \dots, e_d$.

For future reference, we state the following additional conditions:

(A) ∇f exists on $\mathbb{R}^d$ with $\nabla f(\vartheta) = 0$.

Concerning the local differentiability of f at ϑ we consider two cases. In the first case ($p = 2$) we assume that there exists $\varepsilon > 0$, $\tau \in (0,1]$, K_1 and K_2 such that

(B1a) $Hf(\vartheta)$ exists with $\|\nabla f(x) - Hf(\vartheta)(x-\vartheta)\| \leq K_1 \|x-\vartheta\|^{1+\tau}$ for all $x \in U_\varepsilon(\vartheta)$,
(B1b) $\|\nabla f(x) - \nabla f(y)\| \leq K_2 \|x-y\|$ for all $x, y \in U_\varepsilon(\vartheta)$.

(B1b) holds, for instance, if all second partial derivatives of f exist and are bounded on $U_\varepsilon(\vartheta)$. For the second case ($p \geq 3$), we assume that there exist $\varepsilon > 0$ and L such that

(B2a) derivatives of f up to order $p-1$ exist on $U_\varepsilon(\vartheta)$,
(B2b) the pth derivative of f at ϑ exists,
(B2c) $\|Hf(x) - Hf(y)\| \leq L\|x-y\|$ for all $x, y \in U_\varepsilon(\vartheta)$.

A sufficient condition for (B2c) to hold is that all third partial derivatives of f exist and are bounded on $U_\varepsilon(\vartheta)$.

For brevity, (B1) stands for (B1a) and (B1b), and (B2) for (B2a), (B2b), and (B2c). We use (B) to indicate that either (B1) or (B2) holds.

So far, m has not been specified. The number m must be adapted to the particular value of p given by (B1) or (B2). Fabian [6] considers in this connection the case

(C1) $m := \lfloor p/2 \rfloor = (p-1)/2$ for an odd $p \geq 3$, $\gamma := 1/(2p)$.

We will consider in addition the following case (for $d = 1$ see Renz [19]):

(C2) $m := \lceil p/2 \rceil$ for $p \geq 2$ (p not necessarily odd), $\gamma := 1/(2p)$,

which will result in an unbiased limit distribution, whereas (C1) generally leads to a nonzero bias (Theorem 3.2).

Similarly as above, (C) means that either (C1) or (C2) holds. We note here that the assumptions (B1) and (C1) do not occur together.

The sequence (W_n) of random variables $W_n := \sum_{j=1}^m v_j \left(V_{n,2j-1}^{(i)} - V_{n,2j}^{(i)}\right)_{i=1,\dots,d}$ satisfies

$$\text{(D)} \qquad \underset{n\geq m}{\forall} \quad \|EW_m \otimes W_n\| \leq \varrho_{n-m}(E\|W_m\|^2 E\|W_n\|^2)^{\frac{1}{2}}$$
$$\text{with } \sum_{l=0}^{\infty} \varrho_l < \infty \text{ and } E\|W_n\|^2 = O(1).$$

Regarding assumption (B2b) it is worthwhile to note that this condition is invariant under rotation of coordinates (compare Fabian [8]). As a further comparison with related work (Fabian [8], Spall [23]), we remark that our results, Theorems 3.2 and 4.2, do not assume continuity of the highest-order partial derivatives.

Results about asymptotic normality in stochastic approximation usually rely on local smoothness of the regression function f around ϑ and on the consistency of the procedure. The next proposition shows consistency of the modified procedure. The assumptions imposed on f allow us to decouple the influence of the r.v.'s W_n and to use the weak dependence condition (D).

PROPOSITION 3.1. *Let $a_n = a/n^\alpha$ with $\alpha \in (\max\{1/2 + 1/(2p), 1 - 1/p\}, 1)$ or $a_n = (a \ln n)/n$, $a > 0$. For recursion (1.1) with gradient estimate (3.1), assume that conditions (A) and (D) hold, f is bounded from below and has a Lipschitz continuous derivative with $\nabla f(x) \neq 0$ for all $x \neq \vartheta$, and $\sup\{\|x\| : f(x) \leq \lambda\} < \infty$ for all $\lambda > \inf\{f(x) : x \in \mathbb{R}^d\}$. Then $X_n \to \vartheta$ $(n \to \infty)$ a.s.*

Under condition (C1) a nonweighted analogue of the next theorem can be found in Fabian [8].

THEOREM 3.2. *Let $a_n = (a \ln n)/n$ for $p = 2$ and $a_n = a/n^\alpha$ with $\alpha \in (1/2+1/(2p), 1)$ for $p \geq 3$. For recursion (1.1) with gradient estimate (3.1), assume that conditions (A)–(D) hold, $A := Hf(\vartheta)$ is positive definite, and $X_n \to \vartheta$ a.s. Let $B_n(t) := n^{-1/2}\left\{\sum_{i=1}^{\lfloor nt\rfloor} W_i + (nt - \lfloor nt\rfloor)W_{\lfloor nt\rfloor+1}\right\}$. Suppose the existence of a Brownian motion B with covariance matrix S of $B(1)$ and*

$$B_n \xrightarrow{\mathcal{D}} B \quad \text{in } C([0,1], \mathbb{R}^d) \quad (n \to \infty).$$

Then, for all $\delta > -(p+1)/(2p)$,

$$n^{\frac{1}{2}\left(1-\frac{1}{p}\right)}\left(\widetilde{X}_{n,\delta} - \vartheta\right) \xrightarrow{\mathcal{D}} N\left(\tfrac{2p(1+\delta)}{p+1+2p\delta}\, c^{p-1}A^{-1}b, \tfrac{p(1+\delta)^2}{p+1+2p\delta}\, c^{-2}A^{-1}SA^{-1}\right) \quad (n \to \infty),$$

where $b = -\frac{1}{p!}\left(\sum_{j=1}^m v_j u_j^p (1 + (-1)^{p+1}) \frac{\partial^p}{(\partial x_i)^p} f(\vartheta)\right)_{i=1,\dots,d}$ and $\widetilde{X}_{n,\delta}$ is defined in (1.2). In particular, under condition (C2), $b = 0$.

REMARK 3.3. *The choices $\delta = 0$ and $\delta = -2\gamma = -1/p$ are of special interest. Provided $b \neq 0$, the pair $(\delta, c) = (0, c_0)$ with c_0 as given in (5.1) minimizes the second moment of the limit distribution. However, for fixed $c > 0$, the limit's covariance is minimized by $\delta = -2\gamma = -1/p$. In particular, Theorem 3.2 yields for $n \to \infty$*

$$n^{\frac{1}{2}\left(1-\frac{1}{p}\right)}\left(n^{-1}\sum_{k=1}^n X_k - \vartheta\right) \xrightarrow{\mathcal{D}} N\left(\tfrac{2p}{p+1}\, c^{p-1}A^{-1}b, \tfrac{p}{p+1}\, c^{-2}A^{-1}SA^{-1}\right),$$

$$n^{\frac{1}{2}\left(1-\frac{1}{p}\right)}\left(\tfrac{p-1}{p}\, n^{-\frac{p-1}{p}}\sum_{k=1}^n k^{-\frac{1}{p}} X_k - \vartheta\right) \xrightarrow{\mathcal{D}} N\left(2\, c^{p-1}A^{-1}b,\ \tfrac{p-1}{p}\, c^{-2}A^{-1}SA^{-1}\right).$$

4. A Kiefer–Wolfowitz procedure with simultaneous perturbation gradient approximation. The classical Kiefer–Wolfowitz (finite difference) stochastic approximation method (FDSA) needs $2d$ observations to obtain a finite difference approximation of the gradient belonging to the function $f : \mathbb{R}^d \to \mathbb{R}$ of which the minimizer ϑ is sought. To reduce the number of observations in each step, randomized gradient approximation methods have been considered in the literature. Two examples are random direction stochastic approximation (RDSA), suggested by Kushner and Clark [12], and simultaneous perturbation stochastic approximation (SPSA), suggested by Spall [22]. Both methods are based on only two observations in each iteration. Depending on the dimension d and the third derivatives of the regression function f the AMSE of the SPSA method can be better or worse than that of the FDSA and RDSA methods. At least for second-order polynomials f, the FDSA method needs d times more observations than the SPSA method to achieve the same level of mean squared error asymptotically, when the same span $c_n = cn^{-\gamma}$ is used (Spall [23]).

Before the idea of weighted averages is applied to the SPSA method, we will describe this algorithm in more detail. Again recursion (1.1) is used, but with step lengths $a_n = an^{-\alpha}$ and with the following so-called *simultaneous perturbation gradient estimate* of $\nabla f(X_n)$:

$$Y_n = \frac{1}{2c_n} \begin{pmatrix} (\Delta_n^{(1)})^{-1} \\ \vdots \\ (\Delta_n^{(d)})^{-1} \end{pmatrix} ([f(X_n + c_n\Delta_n) - W_{n,1}] - [f(X_n - c_n\Delta_n) - W_{n,2}]) \tag{4.1}$$

consisting of (artificially generated) random vectors $\Delta_n \in \mathcal{M}(\Omega, \mathbb{R}^d)$, observation errors $W_{n,1}$, $W_{n,2} \in \mathcal{M}(\Omega, \mathbb{R})$, and span c_n.

We consider the following set of conditions.

(E) The components $\Delta_n^{(i)}$ of Δ_n, $i = 1, \dots, d$, for $n \in \mathbb{N}$ fixed, form a set of independent, identically and symmetrically distributed r.v.'s with $|\Delta_n^{(l)}|$ having values between fixed positive numbers $\alpha_0 < \alpha_1$. The r.v. Δ_n is assumed to be independent of $\{X_1, \dots, X_n, \Delta_1, \dots, \Delta_{n-1}\}$. Furthermore, we use $\xi^2 = E|\Delta_n^{(l)}|^2$ and $\rho^2 = E|\Delta_n^{(l)}|^{-2}$. For simplicity, the column vector appearing in (4.1) is denoted by Δ_n^{-1}.

(F) The difference $W_n = W_{n,1} - W_{n,2}$ of the observation errors satisfies $E(W_n \mid \mathcal{F}_n) = 0$ and $\sup_n E\left(W_n^2 \mid \mathcal{G}_n\right) < \infty$ a.s., where $\mathcal{F}_n$ and $\mathcal{G}_n$ denote the σ-fields generated by $\{X_1, \dots, X_n, \Delta_1, \dots, \Delta_n\}$ and $\{X_1, \dots, X_n, \Delta_1, \dots, \Delta_{n-1}\}$, respectively.

(G) $\infty > E(W_n^2 \mid \mathcal{F}_n) \to \sigma^2$ a.s. and $E(W_n^2 1_{[W_n^2 \geq rn]} \mid \mathcal{F}_n) \to 0$ a.s. for every $r > 0$.

(H) (B2) holds for $p = 3$, and $A = Hf(\vartheta)$ is a positive definite matrix.

The proposition below presents conditions for the recursion's consistency. It is related to Blum's result [2] on multivariate Kiefer–Wolfowitz procedures. Under different and less intuitive assumptions and with a different method of proof, Spall [23] asserts consistency as well.

PROPOSITION 4.1. *Let $a_n = a/n^\alpha$ with $\alpha \in (\max\{\gamma + 1/2, 1 - 2\gamma\}, 1]$ and $\gamma > 0$. For recursion* (1.1) *with gradient estimate* (4.1)*, assume that conditions* (A), (E), *and* (F) *hold, and that f is bounded from below and has a Lipschitz continuous gradient.*

(a) *If $\sup\{\|x\| : f(x) \leq \lambda\} < \infty$ for all $\lambda > \inf\{f(x) : x \in \mathbb{R}^d\}$, then $\sup_n \|X_n\| < \infty$ a.s.*

(b) *Assume* $\nabla f(x) \neq 0$ *and* $f(x) > f(\vartheta)$ *for all* $x \neq \vartheta$. *If* $\sup_n \|X_n\| < \infty$ *a.s., then* $X_n \to \vartheta$ $(n \to \infty)$ *a.s.*

A nonweighted analogue of the following theorem is stated in Spall [23].

THEOREM 4.2. *Let* $\alpha \in (2/3, 1)$ *and* $\gamma = 1/6$. *For recursion* (1.1) *with gradient estimate* (4.1), *assume conditions* (A), (E)–(H), *and* $X_n \to \vartheta$ *a.s. Then, for all* $\delta > -2/3$,

$$n^{\frac{1}{3}} \left(\widetilde{X}_{n,\delta} - \vartheta \right) \xrightarrow{\mathcal{D}} N \left(\tfrac{1+\delta}{2/3+\delta} c^2 A^{-1} b, \tfrac{(1+\delta)^2}{4/3+2\delta} c^{-2} A^{-1} S A^{-1} \right) \quad (n \to \infty),$$

where

$$S = \frac{\sigma^2 \rho^2}{4} I, \qquad b = -\frac{1}{6} \xi^2 \left(\frac{\partial^3}{(\partial x_i)^3} f(\vartheta) + 3 \sum_{j=1,\, j \neq i}^{d} \frac{\partial^3}{\partial x_i (\partial x_j)^2} f(\vartheta) \right)_{i=1,\ldots,d},$$

and $\widetilde{X}_{n,\delta}$ *is as defined in* (1.2).

5. Comparison of stochastic approximation procedures with respect to their asymptotic mean squared error and further comments. Based on recursion (1.1) with any of the gradient estimates Y_n discussed in this paper, we consider the following three variants of algorithms:

(i) the basic recursion with $a_n = a/n$,
(ii) an adaptive variant obtained from the basic recursion with $a_n = (a/n) M_n$ and random matrices M_n converging to $M = Hf(\vartheta)^{-1}$ a.s.,
(iii) the basic recursion with a_n converging to zero slower than $1/n$ combined with averaging of the trajectories

and compare the corresponding estimators with regard to their asymptotic behavior. Some of these estimators have been treated in the literature (Fabian [6], [9], Spall [22], [23]). The adaptive procedure has been introduced by Fabian [9] to improve the limit distribution. There the auxiliary sequence M_n is built up from information available up to stage n. For both algorithms (i) and (ii), with any gradient estimate considered in this paper, the limit distribution can be obtained by Theorem 1 in Walk [24] and by the representations derived in the proofs of Theorems 3.2 and 4.2.

Assuming that $A = Hf(\vartheta)$ is a positive definite matrix, the related second moments of the asymptotic distributions turn out to be

$$E(a,c) := \left(2c^{p-1} a \|(2aA - \beta)^{-1} b\| \right)^2 + \frac{a^2}{c^2} \operatorname{tr} \left((2aA - \beta)^{-1} S \right), \quad a > \beta/(2\lambda_0),$$

$$\widehat{E}(a,c) := \left(\frac{2c^{p-1} a}{2a - \beta} \|A^{-1} b\| \right)^2 + \frac{a^2}{c^2 (2a - \beta)} \operatorname{tr} \left(A^{-1} S A^{-1} \right), \quad a > \beta/2,$$

$$\widetilde{E}(\delta,c) := \left(\frac{2c^{p-1}(1+\delta)}{2 - \beta + 2\delta} \|A^{-1} b\| \right)^2 + \frac{(1+\delta)^2}{c^2 (2 - \beta + 2\delta)} \operatorname{tr} \left(A^{-1} S A^{-1} \right), \quad \delta > \beta/2 - 1,$$

respectively, where $\beta = 1 - 1/p$, $\lambda_0 = \min\{\lambda : \lambda \in \operatorname{spec} A\}$, and $c > 0$ (concerning E and $\widehat{E}$, use Theorem 5.8 and Remark 5.9 of [25]). Under appropriate assumptions these quantities are equal to the AMSEs $\lim_n E\|n^{\frac{1}{2}(1-\frac{1}{p})}(X_n - \vartheta)\|^2$ shown by algorithm (i) or (ii), and $\lim_n E\|n^{\frac{1}{2}(1-\frac{1}{p})}(\widetilde{X}_{n,\delta} - \vartheta)\|^2$ shown by algorithm (iii). Apparently it holds that $\widehat{E}(a,c) = \widetilde{E}(a-1,c)$.

If $b \neq 0$, the asymptotic distribution is biased. In this case $\widehat{E}$ and $\widetilde{E}$ are minimized by $(a, c) = (1, c_0)$ and $(\delta, c) = (0, c_0)$, respectively, with

$$c_0 = \left(\frac{(2-\beta)}{4(p-1)} \frac{\operatorname{tr}(A^{-1}SA^{-1})}{\|A^{-1}b\|^2} \right)^{\frac{1}{2p}}, \tag{5.1}$$

which is usually unknown. At the end of section 6 we show that

$$\forall c > 0 \qquad \frac{1}{4} < \left(\frac{p+1}{2p} \right)^2 < \min_{a > \beta/(2\lambda_0)} \frac{E(a,c)}{\widetilde{E}(0,c)} < \sup_{a > \beta/(2\lambda_0)} \frac{E(a,c)}{\widetilde{E}(0,c)} = \infty \tag{5.2}$$

and

$$\frac{1}{4} < \left(\frac{p+1}{2p} \right)^2 < \min_{a > \beta/(2\lambda_0)} \min_{c > 0} \frac{E(a,c)}{\widetilde{E}(0,c_0)} < \sup_{a > \beta/(2\lambda_0)} \min_{c > 0} \frac{E(a,c)}{\widetilde{E}(0,c_0)} = \infty. \tag{5.3}$$

Noticing the last equation of the preceding paragraph, these relations can be rewritten in terms of $\widehat{E}$ instead of $\widetilde{E}$. Thus the AMSE of the adaptive algorithm (ii) and the averaging algorithm (iii) is less than four times the AMSE of the standard algorithm (i) for any admissible a, no matter whether a common c is used or the optimal values of c are chosen. On the opposite side, a bad choice of a (a close to $\beta/(2\lambda_0)$ or a too large) results in an arbitrarily large AMSE of the standard algorithm (i), whereas this difficulty does not arise when the adaptive or averaging method is used. In this sense one may say that the averaging and adaptive algorithms are more stable than the standard algorithm.

In the one-dimensional case the AMSE of the standard algorithm (i) is minimized by $a_0' = 1/A$ and $c_0' = (\frac{2-\beta}{4(p-1)} \frac{S}{b^2})^{1/(2p)}$. Hence, for $d = 1$, the second relation in (5.3) can be sharpened to $E(a_0', c_0')/\widetilde{E}(0, c_0) = 1$.

In section 3 the design $(u_1, \ldots, u_m)$ was fixed. If condition (C1) holds, the gradient estimate (3.1) usually produces an asymptotic bias. In this case Fabian [7] and Erickson, Fabian, and Mařik [5] investigated how the AMSE can be further reduced by the choice of an optimal design.

If the gradient estimate (3.1) is constructed under condition (C2), the bias is vanishing (since $b = 0$). Then, for a fixed positive c, the AMSEs $\widehat{E}$ and $\widetilde{E}$ attain their minimum $c^{-2}(1 - 1/p) \operatorname{tr}(A^{-1}SA^{-1})$ for $a = 1 - 1/p$ and $\delta = -1/p$, respectively. We get

$$\forall c > 0 \qquad 1 \leq \min_{a > \beta/(2\lambda_0)} \frac{E(a,c)}{\widetilde{E}(-1/p, c)} < \sup_{a > \beta/(2\lambda_0)} \frac{E(a,c)}{\widetilde{E}(-1/p, c)} = \infty. \tag{5.4}$$

Assume that a_0 ($> \beta/(2\lambda_0)$) minimizes $E(a, c)$ for a fixed c. Then, only in special cases can $E(a_0, c) = \widetilde{E}(-1/p, c)$ be achieved. In any of the three variants the related AMSE can be made arbitrarily small by choosing c sufficiently large. Hence, with respect to the AMSE criterion, the procedures using the gradient estimate leading to $b = 0$ are superior to those leading to $b \neq 0$, although they need $2d$ more observations per step.

It must be emphasized that in the case $b \neq 0$ the adaptive recursion employing consistent estimators (M_n) of $M = A^{-1}$ instead of some other matrix M is, due to (5.2) and (5.3), a fairly good choice but not the best one with respect to the optimal AMSE. For fixed $c > 0$, a better choice would require consistent estimators M_n of

a matrix M which minimizes $c^{2p-2}\|(MA-\frac{\beta}{2}I)^{-1}Mb\|^2 + c^{-2}\operatorname{tr} Z$ where $\min\{\operatorname{re}\lambda : \lambda \in \operatorname{spec}(MA-\frac{\beta}{2}I)\} > 0$ and Z is the unique solution of $(MA-\frac{\beta}{2}I)Z + Z(MA-\frac{\beta}{2}I)^* = MSM^*$. Hence, averaging applied in the Kiefer–Wolfowitz situation with nonvanishing asymptotic bias does not optimize the AMSE. This is in contrast to the Robbins–Monro situation. Minimizing the expression above in both M and c would lead to an even better AMSE, but we do not pursue this possibility here.

Let $\vartheta_n(f)$ be an estimator of the minimum $\vartheta(f)$ of a p-times differentiable regression function f on $\mathbb{R}$ using n observations. Consider, for fixed $c > 0$,

$$\sup_f P[n^{\frac{p-1}{2p}}|\vartheta_n(f) - \vartheta(f)| > c],$$

where the supremum is taken over all regression functions f satisfying conditions (A) and (B) and some further boundedness conditions. Then, according to results by Chen [3] and by Polyak and Tsybakov [18], this supremum as a function of n has a universal positive lower bound independent of the choice of $\vartheta_n(f)$. This raises the interesting problem of determining which type of algorithm, together with which type of gradient estimate, leads to the smallest supremum above.

The condition $\sup\{\|x\| : f(x) \le \lambda\} < \infty$ for all $\lambda > \inf\{f(x) : x \in \mathbb{R}^d\}$ appearing in Propositions 3.1 and 4.1 is equivalent to $\inf\{f(x) : \|x\| \ge K\} \to \infty$ as $K \to \infty$. In applications this condition can be satisfied by adding the function values of an appropriate increasing and differentiable function to the basic observations taken at x. A possible choice is $x \mapsto \|x - d\frac{x}{\|x\|}\|^2 1_{[\|x\|\ge d]}$ for a fixed d large enough.

Finally, it is worth mentioning that the weighted means $\widetilde{X}_{n,\delta}$ can easily be recursified by

$$\begin{pmatrix} X_{n+1} \\ \widetilde{X}_{n+1,\delta} \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ \frac{1+\delta}{n+1} & \left(\frac{n}{n+1}\right)^{1+\delta} \end{pmatrix} \begin{pmatrix} X_n \\ \widetilde{X}_{n,\delta} \end{pmatrix} - a_n \begin{pmatrix} Y_n \\ \frac{1+\delta}{n+1} Y_n \end{pmatrix}, \quad \widetilde{X}_{1,\delta} = (1+\delta)X_1.$$

6. Proofs.

Proof of Proposition 3.1. For $x \in \mathbb{R}^d$ and $h > 0$ define

$$g(x,h) := \left(g^{(i)}(x,h)\right)_{i=1,\dots,d} := \sum_{j=1}^m v_j (f(x+hu_je_i) - f(x-hu_je_i))_{i=1,\dots,d}.$$

Then, with $V_n := c^{-1}W_n$ and $H_n := \nabla f(X_n) - c_n^{-1}g(X_n, c_n)$, we obtain

$$X_{n+1} = X_n - a_n(\nabla f(X_n) - n^\gamma V_n - H_n). \tag{6.1}$$

By Lipschitz continuity of ∇f we have $f \in C^1(\mathbb{R}^d)$. This leads, with a Lipschitz constant K, to

$$\begin{aligned} \left|h^{-1}g^{(i)}(x,h) - \tfrac{\partial}{\partial x_i} f(x)\right| &= \left|\sum_{j=1}^m v_j u_j \int_{-1}^1 (\tfrac{\partial}{\partial x_i} f(x + shu_je_i) - \tfrac{\partial}{\partial x_i} f(x))\, ds\right| \\ &\le \sum_{j=1}^m |v_j| u_j \int_{-1}^1 \|\nabla f(x + shu_je_i) - \nabla f(x)\|\, ds \le K \sum_{j=1}^m |v_j| u_j^2 h. \end{aligned}$$

Therefore $\|H_n\| \le \sqrt{d}K \sum_{j=1}^m |v_j| u_j^2 c_n$. Our assumptions yield $\sum a_n^2 n^{1/p} (\log n)^2 < \infty$ and $\sum a_n n^{-1/p} < \infty$. Proposition 4.1 in Dippon and Renz [4] implies the assertion. ∎

Proof of Theorem 3.2. *First step*: *Expansions for* $h^{-1}g(x,h)$. In what follows, we assume $x \in U_{\varepsilon/2}(\vartheta)$ and $h \in (0, \varepsilon/2)$. As a consequence we have $x + she_i$, $\vartheta + t(x - \vartheta) \pm hu_j e_i \in U_\varepsilon(\vartheta)$ for all $t \in [0,1]$ and $s \in [-1,1]$.

First we consider the case of an at least three-times differentiable function f ($p \geq 3$). Using (B2c), we obtain $f \in C^2(U_\varepsilon(\vartheta))$, and therefore, according to Taylor's formula,

$$
\begin{aligned}
(6.2)\quad g^{(i)}(x,h) &= \sum_{j=1}^{m} v_j (f(x + hu_j e_i) - f(x - hu_j e_i)) \\
&= \sum_{j=1}^{m} v_j (f(\vartheta + hu_j e_i) - f(\vartheta - hu_j e_i)) \\
&\quad + \sum_{j=1}^{m} v_j (\nabla f(\vartheta + hu_j e_i) - \nabla f(\vartheta - hu_j e_i))^* (x - \vartheta) \\
&\quad + (x - \vartheta)^* \int_0^1 (1-t) \sum_{j=1}^{m} v_j (Hf(\vartheta + t(x - \vartheta) + hu_j e_i) \\
&\qquad\qquad - Hf(\vartheta + t(x - \vartheta) - hu_j e_i))\, dt\, (x - \vartheta)\,.
\end{aligned}
$$

Let us denote the first term of this sum by $t^{(i)}(h)$ $(i = 1, \ldots, d)$. (B2a) implies

$$
\tfrac{d^l}{(dh)^l} t^{(i)}(h) = \sum_{j=1}^{m} v_j u_j^l \left(\tfrac{\partial^l}{(\partial x_i)^l} f(\vartheta + hu_j e_i) + (-1)^{l+1} \tfrac{\partial^l}{(\partial x_i)^l} f(\vartheta - hu_j e_i) \right)
$$

for $l = 0, \ldots, p-1$. Then $\frac{d^l}{(dh)^l} t^{(i)}(0) = 0$ for all $l = 0, \ldots, p-1$. This is obvious for l even. For l odd with $1 \leq l \leq 2m-1$, this follows from (A) and the choice of the v_k. In the case $m := \lceil p/2 \rceil$, we have $p - 1 \leq 2m - 1$, and in the case $m := \lfloor p/2 \rfloor = (p-1)/2$, p odd, we have $2m - 1 = p - 2$ and $p - 1$ is even. (B2b) implies

$$
\tfrac{d^p}{(dh)^p} t^{(i)}(0) = \sum_{j=1}^{m} v_j u_j^p \left(1 + (-1)^{p+1}\right) \tfrac{\partial^p}{(\partial x_i)^p} f(\vartheta).
$$

In the case $m := \lceil p/2 \rceil$ we obtain $\frac{d^p}{(dh)^p} t^{(i)}(0) = 0$. For p even, this is again obvious, and for p odd, it follows from $2m - 1 = p$ and from the choice of the v_k. Taylor's formula yields

$$
(6.3)\qquad t^{(i)}(h) = \tfrac{h^p}{p!} \left(\tfrac{d^p}{(dh)^p} t^{(i)}(0) + o(1) \right) \quad (h \to 0).
$$

For the discussion of the second term of the sum on the right-hand side (r.h.s.) in (6.2) we define

$$
s^{(i,k)}(h) := \sum_{j=1}^{m} v_j \left(\tfrac{\partial}{\partial x_k} f(\vartheta + hu_j e_i) - \tfrac{\partial}{\partial x_k} f(\vartheta - hu_j e_i) \right) \quad (i,k = 1, \ldots, d).
$$

Using (B2a) we obtain by a consideration analogous to that above

$$
\tfrac{d^l}{(dh)^l}\, s^{(i,k)}(h) = \sum_{j=1}^{m} v_j u_j^l \left(\tfrac{\partial^l}{(\partial x_i)^l} \tfrac{\partial}{\partial x_k} f(\vartheta + hu_j e_i) + (-1)^{l+1} \tfrac{\partial^l}{(\partial x_i)^l} \tfrac{\partial}{\partial x_k} f(\vartheta - hu_j e_i) \right)
$$

for $l = 0, \dots, p-2$, where $s^{(i,k)}(0) = 0$, $\frac{d}{dh} s^{(i,k)}(0) = \frac{\partial}{\partial x_i} \frac{\partial}{\partial x_k} f(\vartheta)$ and $\frac{d^l}{(dh)^l} s^{(i,k)}(0) = 0$ for all $l = 2, \dots, p-2$. (B2b) implies, by reasoning similar to that in the case of $\frac{d^p}{(dh)^p} t^{(i)}(0)$,

$$\tfrac{d^{p-1}}{(dh)^{p-1}} s^{(i,k)}(0) \;=\; \sum_{j=1}^{m} v_j u_j^{p-1} \left(1 + (-1)^p\right) \tfrac{\partial^{p-1}}{(\partial x_i)^{p-1}} \tfrac{\partial}{\partial x_k} f(\vartheta) \;=\; 0.$$

Again, by using Taylor's formula, we obtain

$$s^{(i,k)}(h) = h \tfrac{\partial}{\partial x_i} \tfrac{\partial}{\partial x_k} f(\vartheta) + h^{p-1} o(1) \quad (h \to 0). \tag{6.4}$$

Finally, for every $i = 1, \dots, d$, the expression

$$q^{(i)}(x,h) \;:=\; (x-\vartheta)^* \int_0^1 (1-t) \sum_{j=1}^{m} v_j \left(Hf(\vartheta + t(x-\vartheta) + h u_j e_i) - Hf(\vartheta + t(x-\vartheta) - h u_j e_i)\right) dt$$

can be bounded in the following way by using (B2c):

$$\|q^{(i)}(x,h)\| \;\le\; h \sum_{j=1}^{m} |v_j|\, u_j\, L \|x - \vartheta\|. \tag{6.5}$$

Because of (6.2), (6.3), (6.4), and (6.5) we obtain the following representation:

$$h^{-1} g(x,h) = \left(Hf(\vartheta) + h^{p-2} P(h) + Q(x,h)\right)(x-\vartheta) - \tfrac{h^{p-1}}{c^{p-1}} T(h) \tag{6.6}$$

with matrices $P(h)$, $Q(x,h)$ and a vector $T(h)$ satisfying the relations $\|P(h)\| = o(1)$ $(h \to 0)$, $\|Q(x,h)\| \le \sqrt{d} L \sum_{j=1}^{m} |v_j|\, u_j \, \|x - \vartheta\|$, and $T(h) \to T = c^{p-1} b$ $(h \to 0)$. Notice that Q is a measurable function $(x \in U_{\varepsilon/2}(\vartheta),\, h \in (0, \varepsilon/2))$.

Now we are going to consider the case of a twice differentiable function f $(p = 2)$. (B1a) implies the existence of a measurable matrix-valued function R with

$$\nabla f(x) = \left(Hf(\vartheta) + R(x)\right)(x - \vartheta), \;\; \text{where } \|R(x)\| \le K_1 \|x - \vartheta\|^\tau \text{ for } x \in U_\varepsilon(\vartheta).$$

Because of $p = 2$ we have $m = 1$. Without loss of generality, we may assume that $u_1 = 1$. Then we have $v_1 = 1/2$. By (B1b) we obtain $f \in C^1(U_\varepsilon(\vartheta))$, and therefore

$$\begin{aligned} g^{(i)}(x,h) &= \tfrac{1}{2}(f(x + h e_i) - f(x - h e_i)) = \tfrac{1}{2} h \int_{-1}^{1} \tfrac{\partial}{\partial x_i} f(x + s h e_i)\, ds \\ &= \tfrac{1}{2} h \int_{-1}^{1} (\tfrac{\partial}{\partial x_i} f(x + s h e_i) - \tfrac{\partial}{\partial x_i} f(x))\, ds + h \tfrac{\partial}{\partial x_i} f(x). \end{aligned}$$

Putting the last two relations together gives the following representation:

$$h^{-1} g(x,h) = \left(Hf(\vartheta) + R(x)\right)(x - \vartheta) + s(x,h) \tag{6.7}$$

with vector $s(x,h)$ satisfying $\|s(x,h)\| \le 0.5 \sqrt{d} K_2\, h$. Notice that s is also a measurable function $(x \in U_{\varepsilon/2}(\vartheta),\, h \in (0, \varepsilon/2))$.

While the last representation and Lemma 7.1(b) yield a rate of convergence, we will need a second representation to apply Lemma 7.1(a). We obtain

$$g^{(i)}(x,h) = \tfrac{1}{2}\,h\int_{-1}^{1}\Big(\tfrac{\partial}{\partial x_i}f(x+she_i) - (\nabla\tfrac{\partial}{\partial x_i}f(\vartheta))^*(x-\vartheta+she_i)\Big)\,ds \\ +h\,(\nabla\tfrac{\partial}{\partial x_i}f(\vartheta))^*(x-\vartheta).$$

For $r^{(i)}(x,h) := \frac{1}{2}\int_{-1}^{1}(\frac{\partial}{\partial x_i}f(x+she_i)-(\nabla\frac{\partial}{\partial x_i}f(\vartheta))^*(x-\vartheta+she_i))\,ds$, our assumptions imply

$$|r^{(i)}(x,h)| \\ \le \tfrac{1}{2}\int_{-1}^{1}\|\nabla f(x+she_i) - Hf(\vartheta)(x-\vartheta+she_i)\|\,ds \;\le\; \tfrac{1}{2}\int_{-1}^{1}K_1\,\|x-\vartheta+she_i\|^{1+\tau}\,ds \\ \le 2^{\tau-1}K_1\int_{-1}^{1}\big(\|x-\vartheta\|^{1+\tau}+|s|^{1+\tau}h^{1+\tau}\big)\,ds \;\le\; 2^{\tau}K_1\left(\|x-\vartheta\|^{1+\tau}+\tfrac{h^{1+\tau}}{2+\tau}\right).$$

As a consequence of the last two relations we obtain the following representation:

$$h^{-1}g(x,h) = Hf(\vartheta)(x-\vartheta) + r(x,h), \tag{6.8}$$

where the vector $r(x,h) = (r^{(i)}(x,h))$ is bounded by $\|r(x,h)\| \le 2^{\tau}\sqrt{d}K_1(\|x-\vartheta\|^{1+\tau} + h^{1+\tau}/(2+\tau))$. Again, r is a measurable function ($x \in U_{\varepsilon/2}(\vartheta)$, $h \in (0,\varepsilon/2)$).

Second step: *Rate of convergence for $X_n \to \vartheta$ and proof of asymptotic normality.* Let us define $U_n := X_n - \vartheta$, $V_n := c^{-1}W_n$, and $\Omega(n) := [\|U_n\| < \varepsilon/2 \text{ and } c_n < \varepsilon/2]$.

First we consider the case $p \ge 3$. We define $A_n := (Hf(\vartheta) + c_n^{p-2}P(c_n) + Q(X_n,c_n))1_{\Omega(n)}$ and $T_n := T(c_n)1_{\Omega(n)} - n^{1/2}c^{-1}g(X_n,c_n)1_{\Omega(n)^c}$. In the case $p=2$ we define $A_n := (Hf(\vartheta)+R(X_n))1_{\Omega(n)}$ and $T_n := -n^{1/4}s(X_n,c_n)1_{\Omega(n)} - n^{1/2}c^{-1}g(X_n,c_n)\cdot 1_{\Omega(n)^c}$. Regarding properties (6.1), (6.6), and (6.7), the so-defined quantities fulfill recursion (7.2) and satisfy $A_n \to A = Hf(\vartheta)$ a.s. and $T_n = O(1)$ almost in L^2. Condition (7.12) holds by assumption (D). Therefore, Lemma 7.1(b) yields $U_n = O(a_n^{1/2}n^{1/(2p)})$ almost in L^2.

For $p \ge 3$ the above quantities satisfy $T_n \to T$ a.s. and $\|A_n - A\| \le C_1\,n^{-(p-2)/(2p)} + C_2\,\|U_n\| + C_3 1_{\Omega(n)^c}$. In the case $p=2$ we have to alter the definition of A_n and T_n. Let $A_n := Hf(\vartheta)1_{\Omega(n)}$ and $T_n := -n^{1/4}r(X_n,c_n)1_{\Omega(n)} - n^{1/2}c^{-1}g(X_n,c_n)1_{\Omega(n)^c}$. Due to (6.8) recursion (7.2) holds. Note that $\|n^{1/4}r(X_n,c_n)1_{\Omega(n)}\| \le C_4\,n^{1/4}\|U_n\|^{1+\tau} + C_5\,n^{-\tau/4}$.

In both cases we get $T_n - T = o(1)$ almost in L^1 and $A_n - A = o(1/\sqrt{na_n})$ almost in L^2 , where we have used $2/p \le 1/2 + 1/(2p) < \alpha$ for $p \ge 3$. Thus the assertion follows from Lemma 7.1 (a). □

Proof of Proposition 4.1. We may assume $\vartheta = 0$ and $f(\vartheta) = 0$. Lipschitz continuity of ∇f implies

$$|f(x+h) - f(x-h) - \langle 2h, \nabla f(x)\rangle| = \left|\int_{-1}^{1}\langle h, \nabla f(x+sh) - \nabla f(x)\rangle\,ds\right| \\ \le \|h\|\int_{-1}^{1}K|s|\,\|h\|\,ds \;=\; K\|h\|^2, \tag{6.9}$$

where K is, here and in the following inequalities, a constant that may vary from formula to formula. The last inequality, together with

$$E\left(\tfrac{\Delta_n^{(k)}}{\Delta_n^{(l)}}\tfrac{\partial}{\partial x_k}f(X_n) \mid \mathcal{G}_n\right) = \delta_{kl}\tfrac{\partial}{\partial x_k}f(X_n) \text{ a.s.},$$

proves

$$\|E\,(Y_n \mid \mathcal{G}_n) - \nabla f(X_n)\| \le K c_n \quad \text{a.s.} \tag{6.10}$$

Due to (6.9), (6.10), and assumption (F), we obtain

$$E(\|Y_n\|^2 \mid \mathcal{G}_n) \le K c_n^2 + K\,\|\nabla f(X_n)\|^2 + K\,c_n^{-2}\,E(W_n^2 \mid \mathcal{G}_n) \quad \text{a.s.} \tag{6.11}$$

and

$$\langle \nabla f(X_n), E\,(Y_n \mid \mathcal{G}_n)\rangle \ge \|\nabla f(X_n)\|^2 - K c_n\,\|\nabla f(X_n)\| \quad \text{a.s.} \tag{6.12}$$

Lipschitz continuity of ∇f implies, as above,

$$f(X_{n+1}) \le f(X_n) - a_n\langle \nabla f(X_n), Y_n\rangle + K a_n^2\,\|Y_n\|^2.$$

Taking conditional expectations and using inequalities (6.11) and (6.12), we obtain

$$\begin{aligned}
&E\,(f(X_{n+1}) \mid \mathcal{G}_n)\\
&\le f(X_n) - a_n\left(\|\nabla f(X_n)\|^2 - K c_n\,\|\nabla f(X_n)\|\right)\\
&\qquad\qquad + K a_n^2\,\|\nabla f(X_n)\|^2 + K a_n^2/c_n^2\left(E(W_n^2 \mid \mathcal{G}_n) + 1\right)\\
&\le f(X_n) - a_n/2\,\left(\|\nabla f(X_n)\| - K c_n\right)^2 + K^2/2\,a_n c_n^2 + K a_n^2/c_n^2\left(E(W_n^2 \mid \mathcal{G}_n) + 1\right) \quad \text{a.s.}
\end{aligned}$$

for all n with $K a_n < 1/2$. Let $A_n := a_n/2\,(\|\nabla f(X_n)\| - K c_n)^2$ and $B_n := K^2/2\,a_n c_n^2 + K a_n^2/c_n^2\left(E(W_n^2 \mid \mathcal{G}_n) + 1\right)$. For n large enough

$$E\,(f(X_{n+1}) \mid \mathcal{G}_n) \le f(X_n) - A_n + B_n \quad \text{a.s.},$$

where $A_n \ge 0$, $B_n \ge 0$, and $\sum_{n=1}^{\infty} B_n < \infty$ a.s. On a set Ω_0 of measure 1 we have convergence of $f(X_n)$ and $\sum_{n=1}^{\infty} A_n$ according to a theorem of Robbins and Siegmund [20] for nonnegative almost-supermartingales.

Fix $\omega \in \Omega_0$ and denote $x_n := X_n(\omega)$. Then for almost all n the relation $f(x_n) \le \lambda := \lim f(x_n) + 1$ holds. Since $\{x : f(x) \le \lambda\}$ is bounded, (x_n) is bounded as well.

To prove (b) fix $\omega \in \Omega_0$ with $\sup_n \|x_n\| < \infty$. Select a subsequence $(x_{n'})$ with $\nabla f(x_{n'}) \to 0$. Then there exists a convergent subsequence $(x_{n''})$ of $(x_{n'})$. Since $\nabla f(x_{n''}) \to 0$ and ∇f is continuous, $(x_{n''})$ converges to zero. Hence $f(x_{n''}) \to 0$ and $f(x_n) \to 0$. Choose $\varepsilon > 0$ such that $\|x_n\| < 1/\varepsilon$ for all n. For n sufficiently large we have $f(x_n) < \inf\{f(x) : \varepsilon < \|x\| < 1/\varepsilon\}$. This proves $x_n \to 0$. □

Proof of Theorem 4.2. We will verify the assumptions of Lemma 7.1. For this purpose let us define $U_n := X_n - \vartheta$, $D_n := (2c_n)^{-1}\Delta_n^{-1}(f(X_n + c_n\Delta_n) - f(X_n - c_n\Delta_n))$, $V_{n,1} := (2c)^{-1}\Delta_n^{-1}W_n$, $\Omega(n) := [\|U_n\| < \varepsilon/2$ and $c_n < \varepsilon/(2d^{1/2}\alpha_1)]$, $V_{n,2} := -n^{-1/6}(D_n 1_{\Omega(n)} - E(D_n 1_{\Omega(n)} \mid \mathcal{G}_n))$, $V_n := V_{n,1} + V_{n,2}$, and $T := c^2 b$.

For $x, z \in \mathbb{R}^d$ and $h > 0$ with $x, x \pm hz, \vartheta \pm hz \in U_\varepsilon(\vartheta)$, we obtain by condition (H)

$$\begin{aligned}
&f(x + hz) - f(x - hz)\\
&\quad = f(\vartheta + hz) - f(\vartheta - hz) + \langle \nabla f(\vartheta + hz) - \nabla f(\vartheta - hz), x - \vartheta\rangle\\
&\qquad + (x - \vartheta)^* \int_0^1 (1-t)(Hf(\vartheta + t(x - \vartheta) + hz) - Hf(\vartheta + t(x - \vartheta) - hz))dt\,(x - \vartheta)
\end{aligned}$$

where

$$f(\vartheta + hz) - f(\vartheta - hz) = \frac{2h^3}{6}\sum_{i,j,k} \tfrac{\partial^3}{\partial x_i \partial x_j \partial x_k} f(\vartheta)\, z_i z_j z_k \;+\; o(h^3\|z\|^3),$$

$$\nabla f(\vartheta + hz) - \nabla f(\vartheta - hz) = 2h\,Hf(\vartheta)z \;+\; o(h^2\|z\|^2),$$

and

$$\left\| \int_0^1 (1-t)(Hf(\vartheta + t(x-\vartheta) + hz) - Hf(\vartheta + t(x-\vartheta) - hz))dt \right\| \leq Lh \, \|z\|.$$

This expansion, together with condition (E), leads to the following representation:

$$E\left(D_n 1_{\Omega(n)} \mid \mathcal{G}_n\right) = \left(Hf(\vartheta) + o(c_n) + O(\|U_n\|)\right) U_n 1_{\Omega(n)} - n^{-\frac{1}{3}} \left(T + o(1)\right) 1_{\Omega(n)}.$$

With $A_n := (Hf(\vartheta)+o(c_n)+O(\|U_n\|))1_{\Omega(n)}$, $T_n := (T+o(1))1_{\Omega(n)} - n^{1/3} D_n 1_{\Omega(n)^c}$, and the quantities defined at the beginning of the proof, recursion (1.1) can be rewritten in the form of recursion (7.2).

Let $B_{n,j}(t) := 1/\sqrt{n}\,(\sum_{i=1}^{\lfloor nt \rfloor} V_{i,j} + (nt - \lfloor nt \rfloor) V_{\lfloor nt \rfloor + 1, j})$, $t \in [0,1]$, $j \in \{1,2\}$. To show that $B_{n,1}$ converges in distribution to a Brownian motion B, and that $B_{n,2}$ converges to zero in probability, we apply an invariance principle for martingale difference sequences of Berger [1].

We first consider the case $j = 1$. Since

$$E(V_{n,1} \mid \mathcal{F}_n) = \tfrac{1}{2c} \Delta_n^{-1} E(W_n \mid \mathcal{F}_n) = 0 \text{ a.s.}$$

and $V_{n,1}$ is $\mathcal{F}_{n+1}$-measurable, $(V_{n,1})$ is a martingale difference sequence with respect to $(\mathcal{F}_{n+1})$. Similarly, we get from the assumptions,

$$\begin{aligned}
&\tfrac{1}{n} \sum_{i=1}^n E(V_{i,1} \otimes V_{i,1} \mid \mathcal{F}_i) \\
&\quad = \tfrac{1}{4c^2} \tfrac{1}{n} \sum_{i=1}^n \Delta_i^{-1} \otimes \Delta_i^{-1} E(W_i^2 \mid \mathcal{F}_i) \\
&\quad = \tfrac{\sigma^2}{4c^2} \tfrac{1}{n} \sum_{i=1}^n \Delta_i^{-1} \otimes \Delta_i^{-1} + \tfrac{1}{4c^2} \tfrac{1}{n} \sum_{i=1}^n \Delta_i^{-1} \otimes \Delta_i^{-1} \left(E(W_i^2 \mid \mathcal{F}_i) - \sigma^2\right) \\
&\quad \to \frac{\sigma^2 \rho^2}{4c^2} I \quad (n \to \infty) \text{ a.s.}
\end{aligned}$$

according to Kolmogorov's strong law of large numbers. Further, we obtain

$$\begin{aligned}
\tfrac{1}{n} \sum_{i=1}^n E(\|V_{i,1}\|^2 1_{[\|V_{i,1}\|^2 \geq ri]} \mid \mathcal{F}_i) &\leq \tfrac{1}{n} \sum_{i=1}^n E(\tfrac{d}{4c^2\alpha_0^2} W_i^2 1_{\left[W_i^2 \geq \frac{4c^2\alpha_0^2 r}{d} i\right]} \mid \mathcal{F}_i) \\
&\xrightarrow{P} 0 \quad (n \to \infty)
\end{aligned}$$

since $E(W_i^2 1_{[W_i^2 \geq \tilde{r} i]} \mid \mathcal{F}_i)$ is converging to zero a.s.

To get (7.4) for the sequence $(V_{n,1})$, we check that

$$\sup_n E\left(\|V_{n,1}\|^2 \mid \mathcal{F}_n\right) \leq \tfrac{1}{4c^2} \sup_n \|\Delta_n^{-1}\|^2 \sup_n E\left(W_n^2 \mid \mathcal{F}_n\right) < \infty \quad \text{a.s.},$$

which holds in view of the assumptions.

Likewise, we treat the case $j = 2$. Note that $V_{n,2}$ is $\mathcal{G}_{n+1}$-measurable, and $E(V_{n,2} \mid \mathcal{G}_n) = 0$ a.s. Condition (H) implies

$$\begin{aligned}
\|E\left(V_{n,2} \otimes V_{n,2} \mid \mathcal{G}_n\right)\| &\leq \tfrac{d}{4c^2\alpha_0^2} E\left(|f(X_n + c_n\Delta_n) - f(X_n - c_n\Delta_n)|^2 \; 1_{\Omega(n)} \mid \mathcal{G}_n\right) \\
&\leq (dL\alpha_1/\alpha_0)^2 n^{-2\gamma} \to 0 \quad (n \to \infty) \quad \text{a.s.}
\end{aligned}$$

This implies $\sup_n E(\|V_{n,2}\|^2 \mid \mathcal{G}_n) < \infty$ a.s., and thus validity of (7.4) for the sequence $(V_{n,2})$. Additionally

$$E\left(\|V_{n,2}\|^2 1_{[\|V_{n,2}\|^2 \geq rn]} \mid \mathcal{G}_n\right) \to 0 \quad (n \to \infty) \quad \text{a.s.}$$

Once more, the invariance principle in Berger [1] can be applied to prove the desired result.

Since $X_n \to \vartheta$ a.s., we obtain $A_n \to A$ and $T_n \to T = c^2 b$ a.s. The latter is sufficient for (7.5) and (7.9). Furthermore, the sequence (V_n) fulfills (7.10) and (7.11) with respect to $(\mathcal{G}_{n+1})$. Now Lemma 7.1(b) asserts $U_n = O(n^{(1/6)-(\alpha/2)})$ almost in L^2. To obtain $A_n - A = o(n^{(\alpha-1)/2})$ almost in L^2, one has to choose $\alpha > 2/3$. This completes the proof. □

Proof of relations (5.2)–(5.4). Since $\operatorname{spec}(2aA - \beta) \subset (0, \infty)$ we obtain

$$\begin{aligned} a\|(2aA-\beta)^{-1}b\| &= \tfrac{1}{2} \left\| \left(\tfrac{2a}{\beta}A - I\right)^{-1} \left(\tfrac{2a}{\beta}A - I\right) A^{-1}b + \left(\tfrac{2a}{\beta}A - I\right)^{-1} A^{-1}b \right\| \\ &= \tfrac{1}{2} \left\| \left(I + \left(\tfrac{2a}{\beta}A - I\right)^{-1}\right) A^{-1}b \right\| \\ &\geq \tfrac{1}{2} \min\left\{ \lambda \in \operatorname{spec}\left(I + \left(\tfrac{2a}{\beta}A - I\right)^{-1}\right)\right\} \|A^{-1}b\| \\ &\geq \tfrac{1}{2} \|A^{-1}b\| \end{aligned}$$

and, by Theorem 1 in Wei [26],

$$\operatorname{tr}\left(a^2(2aA-\beta)^{-1}S\right) \geq \operatorname{tr}\left(\beta A^{-1}SA^{-1}\right). \tag{6.13}$$

Noticing that $4\beta/(2-\beta) > 1$ and $(2-\beta)/2 > 1/2$, this yields

$$E(a,c) \geq c^{2p-2}\|A^{-1}b\|^2 + \tfrac{\beta}{c^2}\operatorname{tr}(A^{-1}SA^{-1}) \;>\; \left(\tfrac{2-\beta}{2}\right)^2 \widetilde{E}(0,c) \;>\; \tfrac{1}{4}\widetilde{E}(0,c).$$

The last relation of (5.2) is obvious.

The first two relations of (5.3) follow from (5.2). To prove the last one, we find for a given admissible a that

$$c_0(a) = \left(\frac{\operatorname{tr}((2aA-\beta)^{-1}S)}{4(p-1)\|(2aA-\beta)^{-1}b\|^2}\right)^{\frac{1}{2p}}$$

minimizes $E(a,c)$. Now observe that $E(a, c_0(a)) \to \infty$ as $a \to \infty$ or $a \searrow \beta/(2\lambda_0)$.

The first relation of (5.4) follows from (6.13), and the third one is as shown above. □

7. Appendix: A weak invariance principle for weighted means in stochastic approximation. For the following lemma, which is a consequence of Theorems 3.1 and 4.1 in Dippon and Renz [4], let (a_n) be a sequence decreasing to 0 with

$$na_n \nearrow \infty \quad (n \to \infty) \tag{7.1}$$

and satisfying the relation $a_n - a_{n+1} = o_n a_n^2$ with

$$\sum_{n=1}^{\infty} |o_n - o_{n+1}| < \infty.$$

Note that under (7.1) $o_n \le 1/(na_n) \to 0$ as $n \to \infty$. Examples for sequences having all these properties are (a/n^α) and $(a \log n/n)$ with $\alpha \in (0,1)$, $a > 0$.

LEMMA 7.1. *Let $\gamma \in [0, 1/2)$ and $\delta > -1/2 - \gamma$. For $\mathbb{R}^d$-valued random variables U_n, V_n, T_n and $\mathcal{L}(\mathbb{R}^d)$-valued random variables A_n, assume the following recursion:*

$$U_{n+1} = (I - a_n A_n)\, U_n + a_n n^\gamma \left(V_n + n^{-\frac{1}{2}} T_n \right). \tag{7.2}$$

Suppose that $A \in \mathcal{L}(\mathbb{R}^d)$ satisfies

$$\min\{\operatorname{re} \lambda : \lambda \in \operatorname{spec} A\} > 0.$$

(a) *Let $B_n(t) := n^{-1/2} \left\{ \sum_{i=1}^{\lfloor nt \rfloor} V_i + (nt - \lfloor nt \rfloor) V_{\lfloor nt \rfloor + 1} \right\}$, $t \in [0,1]$, $n \in \mathbb{N}$. Assume the existence of a centered Brownian motion B with covariance matrix S of $B(1)$ and with*

$$B_n \xrightarrow{\mathcal{D}} B \quad \text{in } C([0,1], \mathbb{R}^d) \qquad (n \to \infty), \tag{7.3}$$

$$B_n(1) = O(1) \quad \text{almost in } L^1. \tag{7.4}$$

If there exists $T \in \mathbb{R}^d$ such that

$$T_n - T = o(1) \quad \text{almost in } L^1, \tag{7.5}$$

$$U_n = O\left(n^\gamma \sqrt{a_n}\right) \quad \text{almost in } L^2, \tag{7.6}$$

$$A_n - A = o\left(1/\sqrt{na_n}\right) \quad \text{almost in } L^2, \tag{7.7}$$

then

$$n^{1/2-\gamma}\, t^{-\min\{1,\gamma+\delta\}} \tfrac{1+\delta}{n^{1+\delta}} \left(\sum_{k=1}^{\lfloor nt \rfloor} k^\delta U_k + (nt - \lfloor nt \rfloor)(\lfloor nt \rfloor + 1)^\delta U_{\lfloor nt \rfloor + 1} \right)$$

$$\xrightarrow{\mathcal{D}} G(t) := (1+\delta)\, t^{\max\{0,\gamma+\delta-1\}} A^{-1} \left(\int_{(0,1]} u^{\gamma+\delta}\, dB(tu) + \tfrac{t^{1/2}}{1/2+\gamma+\delta} T \right)$$

in $C([0,1], \mathbb{R}^d)$ for $n \to \infty$, where $G(1)$ is a Gaussian distributed random variable in $\mathbb{R}^d$ with expectation $2(1+\delta)/(1+2\gamma+2\delta) A^{-1} T$ and covariance matrix $(1+\delta)^2/(1+2\gamma+2\delta)$ $A^{-1} S A^{-1*}$.

(b) *Assume*

$$A_n \to A \ \text{ a.s. } (n \to \infty), \tag{7.8}$$

$$T_n = O(1) \ \text{ almost in } L^2, \tag{7.9}$$

and

$$E(V_n \mid \mathcal{F}_{n-1}) = 0 \ \text{ a.s.}, \tag{7.10}$$

$$\sup_n E(\|V_n\|^2 \mid \mathcal{F}_{n-1}) < \infty \ \text{ a.s. or } \ E\|V_n\|^2 = O(1), \tag{7.11}$$

where $(\mathcal{F}_n)$ is a filtration and (V_n) is adapted to $(\mathcal{F}_n)$, or, instead of (7.10) *and* (7.11), *alternatively:*

$$\underset{n \ge m}{\forall} \ \|EV_m \otimes V_n\| \le \varrho_{n-m} (E\|V_m\|^2 E\|V_n\|^2)^{\frac{1}{2}} \tag{7.12}$$

$$\text{with } \sum_{l=0}^{\infty} \varrho_l < \infty \ \text{ and } \ E\|V_n\|^2 = O(1).$$

Then condition (7.6) *holds.*

REMARK 7.2. (a) *For conditions implying* (7.3) *in case of a martingale difference sequence* (V_n)*, see Theorem* 5.1 *in Berger* [1].

(b) *Condition* (7.4) *is implied by* (7.10) *and* (7.11)*, or by* (7.12).

(c) *In applications,* (7.6) *can often be used to show* (7.7). *Usually,* (7.8) *follows from the consistency of the stochastic approximation procedure.*

NECESSARY CONDITIONS FOR OPTIMAL IMPULSIVE CONTROL PROBLEMS*

G. N. SILVA† AND R. B. VINTER‡

Abstract. Necessary conditions of optimality, in the form of a maximum principle, are derived for a class of optimal control problems, certain of whose controls are represented by measures and whose state trajectories are functions of bounded variation. State trajectories are interpreted as robust solutions of the dynamic equations, a concept of solutions which takes account of the interaction between the measure control and the state variables during the jumps. The maximum principle which is derived improves on earlier optimality conditions for problems of this nature, by allowing nonsmooth data, measurable time dependence, and a possibly time-varying constraint set for the conventional controls.

Key words. impulsive control, necessary conditions, nonsmooth analysis, maximum principle

1. Introduction.

In this paper, optimal control problems in which certain control variables are represented by measures ("impulsive" control variables) and the state trajectories are functions of bounded variation are studied. Necessary conditions of optimality in the form of a maximum principle are derived for these problems. Specifically, we consider the following problem:

$$\text{(P)} \qquad \begin{cases} \text{Minimize} \quad h\,(x(0), x(1)) \\ \text{subject to} \quad dx(t) = f\,(t, x(t), u(t))\,dt + g(t, x(t))\mu(dt), \quad t \in [\,0, 1], \\ (x(0),\ x(1)) \in C, \\ u(t) \in U_t, \quad \mathcal{L} - \text{a.e. } t \in [\,0, 1], \quad \text{and} \quad \mu \geq 0. \end{cases}$$

Here $h : \Re^n \times \Re^n \longrightarrow \Re$, $f : [0,1] \times \Re^n \times \Re^m \longrightarrow \Re^n$, and $g : [\,0, 1] \times \Re^n \longrightarrow \Re^n$ are given functions. U is a Borel subset of $[\,0, 1] \times \Re^m$ (U_t denotes the "section" $\{x : (t, x) \in U\}$), and C is a closed subset of $\Re^n \times \Re^n$.

A control policy is taken to be a pair of elements $(u : [\,0, 1] \longrightarrow \Re, \mu)$, in which the "conventional control" component u is a Lebesgue measurable function satisfying $u(t) \in U_t$ a.e. with respect to Lebesgue measure and the "impulsive" control μ is a regular, Borel, nonnegative valued measure. A *process* is a triple (x, u, μ), comprising a control policy (u, μ) and a corresponding *state trajectory* x; that is, x is a function of bounded variation which is a solution (appropriately defined) of the dynamical equation of problem (P). The control problem is to minimize the cost function $h(x(0), x(1))$ over processes (x, u, μ) for which $(x(0), x(1)) \in C$.

We particularly stress that, in our formulation, the coefficient $g(t, x)$ associated with the impulsive control is allowed to be x-dependent. This raises at the outset

questions of how we should interpret state trajectories to take account of the interaction between the evolving state trajectory and the impulsive control at times when jumps occur.

It is natural to regard the state equation as shorthand for the integral equation

$$x(t) = x(0) + \int_0^t f(\tau, x(\tau), u(\tau))d\tau + \int_{[0,t]} g(\tau, x(\tau))\mu(d\tau) \quad \forall\ t \in (0,1]. \tag{1.1}$$

The second term on the right is affected by the value of the integral at an atom τ of the impulsive control μ. But here an ambiguity arises, because x can be expected to jump at τ and it is not obvious how we should interpret $g(t, x(t))$: a left limit, $g(t, x(t^-))$ as in [23], some averaged value, or what?

Our approach to defining state trajectories is in the spirit of recent work by Bressan, Dal Maso, and Rampazzo [1], [2], [6] and Miller [13], which in turn has its origins in the reparameterization techniques of Rishel [16] and refinements due to Warga [22]. The control problem studied here arises in the calculation of optimal flight trajectories, "midcourse guidance problems" [8], [10], in which context an impulsive control μ is the idealization of a "conventional" control which, at the "atoms" of μ, takes large values over a small interval of time. To be consistent with this view of an impulsive control, we need to be sure that the state trajectory corresponding to the idealized μ approximates the conventional control with which it is associated. We might require, say,

$$x_i(t) \to x(t) \qquad \forall\ t \in C_\mu \cup \{0,1\},$$

where C_μ denotes the points in $[\,0,1]$ which are not atoms of μ (the "continuity points" of μ). In this relationship, $\{x_i(t)\}$ is a sequence of state trajectories, with initial value $x(0)$, corresponding to a sequence of conventional controls $\{m_i(t)\} \subset L^1$ (think of m_i as defining a Borel measure $m_i(t)dt$), with $m_i(t) \geq 0$ a.e. for each i, for which

$$m_i(t)dt \xrightarrow{*} \mu(dt) \quad \text{weak}^*.$$

As shown by Dal Maso and Rampazzo [6] there is a concept of solutions with this continuous dependence property; we call them *robust solutions* to the state equation. A robust solution x is a solution of the integral equation

$$x(t) = x(0) + \int_0^t f(\tau, x(\tau), u(\tau))d\tau + \int_{[0,t]} \tilde{g}(\tau, x(\tau^-); \mu(\{t\}))\mu(d\tau) \quad \text{for} \quad t \in (\,0,1], \tag{1.2}$$

(in which $x(\tau^-)$ denotes limit from the left). Here one takes account of interaction between the state trajectory and the measure by choosing the integrand $\tilde{g}(\tau, x(\tau^-); \mu(\{t\}))$ of the impulsive term on the right to depend, at time τ, on $\mu(\{\tau\})$. $\tilde{g}(\tau, x(\tau^-); \mu(\{t\}))$ is determined by motion along integral curves of the impulsive dynamics, from the initial state $x(\tau^-)$. The magnitude of $\mu(\{\tau\})$ governs how far we move along an integral curve. If τ is not an atom of μ, then $\mu(\{\tau\}) = 0$ and there is no motion. In this case $\tilde{g}(\tau, x(\tau^-); \mu(\{t\})) = g(\tau, x(\tau))$.

The central result in this paper is a necessary condition, in the form of a maximum principle, governing minimizers for (P) over control policies and corresponding state trajectories, when the latter are interpreted as robust solutions of the dynamic equations. Our derivation of the condition covers problems involving a general, time-dependent control constraint set U_t associated with the conventional control and

having dynamics which are nonsmooth in the state variable and measurably time dependent.

There is a substantial literature on necessary conditions of optimality for problem (P), relating to robust solutions of the dynamical equations. (See [11] and the survey article, with extensive bibliography, provided by Miller [12].) Earlier necessary conditions have been proven under the assumptions that the control constraint set is time independent and that the dynamics are at least Lipschitz continuous in the time variable. Indeed these conditions do not even make sense when the data are merely measurably dependent on the time variable, because they involve time derivatives of the data. Earlier approaches have been to reparameterize the independent variable in such a manner that the measure-driven dynamic equation reduces to a conventional equation, and (P) is transformed into a standard optimal control problem. Necessary conditions for (P) follow directly from the maximum principle (as conventionally understood) applied to the transformed problem. The transformation renders the original time variable a state variable: the extra restrictions arise then, because the conventional maximum principle does not allow for a state dependent control constraint set or data measurable in the state variable.

The proof given here follows a different route, in which we approximate (P) by a conventional problem with the help of Ekeland's theorem and pass to the limit. No reparameterization of the independent variable is involved in this approximation itself (this would appear to be crucial for problems with data measurably dependent on the time variable and with a time-dependent control set), although a delicate consideration of the dynamical equations in both their original and their reparameterized forms is involved in the convergence analysis. A similar, simpler approximation procedure was followed in [21], which does not allow state dependence of g.

The optimality conditions assert the existence of a costate function p which satisfies, among other things, a measure-driven Hamiltonian system involving state derivatives of the data. Because the data are nonsmooth, and the derivatives are set valued, the Hamiltonian system is a measure-driven inclusion. The formulation and derivation of the optimality conditions make use of the concept of "robust solutions" to measure driven differential inclusions, and associated closure properties, provided in a recent paper [18].

The impulse controls considered here are scalar valued. For problems involving vector-valued controls the picture is complicated by the possibility that different sequences of approximating measures (absolutely continuous with respect to Lebesgue measure) of the same measure μ can give different "state trajectories" (for a fixed initial state and conventional control); see, e.g., [2], [3], [4], [19]. The optimal control problem posed over processes (x, u, μ) still makes sense even though a unique "state trajectory" x no longer is associated with a fixed control policy and initial state. In the case that the data are smooth with respect to the time variable and the conventional control constraint set is constant, necessary conditions can once again be derived by applying the conventional maximum principle to a standard optimal control problem obtained by transforming the time variable (see Motta and Rampazzo [15] and Miller [12]). It would appear that necessary conditions for problems involving vector-valued impulse controls, when the data are assumed merely measurable in time, can be derived by reformulating the problem as one with scalar impulsive controls but one whose dynamics involve a measure differential inclusion, and adapting the techniques of this paper to allow for these more general dynamics.

We list notation and conventions adhered to below.

B denotes the open unit ball in Euclidean space. $C([0,1];\Re^n)$ denotes the vector space of continuous $\Re^n$-valued functions on $[\,0,1]$ with supremum norm, and $C^*([0,1];\Re^n)$ its topological dual.

$C^+([0,1];\Re^n) \subset C^*([0,1];\Re^n)$ is the cone of functionals taking nonnegative values on nonnegative functions.

$AC\,([\,0,1]\,;\Re^n)$ is the space of absolutely continuous $\Re^n$-valued functions on $[\,0,1]$.

$BV^+([0,1];\Re^n)$ denotes the vector space of $\Re^n$-valued functions on $[\,0,1]$, of bounded variation, which are continuous from the right on $(0,1)$. The Borel measure associated with some $x \in BV^+\,([0,1];\Re^n)$ is denoted dx.

For brevity we often do not distinguish between elements in $C^*([0,1];\Re^n)$ and the Borel measures which represent them.

The weak* topology on $BV^+\,([0,1];\Re^n)$ refers to the weak* topology on $(\Re^n \times C([0,1];\Re^n))^*$ under the isomorphism

$$x \to (x(0), dx).$$

Thus "$x_i \to x$ (weakly*)" indicates that $x_i(0) \to x(0)$ and $dx_i \to dx$ (weakly* in $C^*([0,1];\Re^n)$). For simplicity we write $C(0,1)$ in place of $C([0,1];\Re^1)$, $C^*(0,1)$ in place of $C^*([0,1];\Re^1)$, and so on.

$\mathcal{L}$ denotes the Lebesgue subsets of $[\,0,1]$, $\mathcal{B}$ the Borel sets in $\Re^k$, and $\mathcal{L} \times \mathcal{B}$ the product σ-field.

The following concepts from nonsmooth analysis are required. Consider a closed set $A \in \Re^k$ and points $x \in A,\ p \in \Re^k$. We say that p is a *limiting normal* to A at x if and only if there exist $p_i \to p$ and $x_i \overset{A}{\to} x$ such that for each i we have

$$p_i \cdot (z - x_i) \le o(|z - x_i|) \quad \forall\ z \in A$$

(i.e., limiting normals are limits of vectors which support A at points near x, to first order). The *limiting normal cone* to A at x, written $N_A(x)$, comprises the limiting normals to A at x.

Given a lower semicontinuous function $f : \Re^k \to \Re \cup \{+\infty\}$ and a point $x \in \Re^k$ such that $f(x) < \infty$, we define the *limiting subdifferential* of f at x, written $\partial f(x)$, to be

$$\partial f(x) := \{\xi : (-1, \xi) \in N_{\mathrm{epi}\{f\}}(f(x), x)\},$$

in which epi$\{f\}$ denotes the epigraph set $\{(\eta, x) : \eta \ge f(x)\}$. In the event f is Lipschitz continuous on a neighborhood of x, co$\partial\{f(x)\}$ coincides with the *(Clarke) generalized gradient* of f at x, which may be defined directly [5].

The properties of limiting normal cones, limiting subdifferentials, and generalized gradients are developed in [9], [14] and [5].

2. Change of variables. We outline a change of variables technique, previously used in Rishel [16], Warga [22], Dal Maso and Rampazzo [6], and elsewhere, whose role will be to reduce measure-driven differential equations and inclusions to ordinary differential equations and inclusions.

Fix a measure $\mu \in C^+(0,1)$. Let F be its distribution function

$$F(t) := \begin{cases} \int_{[0,t]} \mu(ds), & t \in (0,1], \\ 0 & \text{if} \quad t = 0. \end{cases}$$

Define the *reparameterization function* η corresponding to μ to be

$$\eta(t) := \begin{cases} (t + \int_{[0,t]} \mu(d\tau))/(1 + \mu([\,0,1])), & t \in (0,1], \\ 0 & \text{if} \quad t = 0. \end{cases}$$

Evidently, η is a $BV^+(0,1)$ function which is strictly increasing. Define also the continuous, nondecreasing function $\theta : [0,1] \to [0,1]$ to be

$$\theta(s) := \sup\{t \in [0,1] : \eta(t) \le s\} \quad \forall\ s \in [0,1].$$

Let $\{t_i\}$ be an enumeration of the atoms of μ, and let $S_i (= [\sigma_i', \sigma_i''])$ be the subintervals $S_i := \theta^{-1}(\{t_i\})$ for $i = 1, 2, \ldots$. Now define the function $\gamma : [0,1] \to \Re^+$ to be

$$\gamma(s) := \begin{cases} F(\theta(s)) & \text{if} \quad s \in [0,1] \setminus \bigcup_{i=1}^{\infty} S_i, \\ F(t_i^-) + \frac{(s-\sigma_i')}{(\sigma_i''-\sigma_i')}(F(t_i) - F(t_i^-)) & \text{for} \quad s \in S_i, \quad i = 1, 2, \ldots. \end{cases}$$

(In this formula $F(t_i^-)$ and $F(t_i)$ are interpreted as $F(0)$ and $F(0^+)$ if $t_i = 0$.)

The function $(\theta, \gamma) : [0,1] \to (\Re^+)^2$ is called the *graph completion* of the measure μ. It is so called because it corresponds to filling in with straight line segments the graph of F and reparameterizing the resulting curve in $\Re^2$.

Basic properties of the graph completion are as follows.

PROPOSITION 2.1. *Let (θ, γ) be the graph completion of $\mu \in C^+(0,1)$. Then*

(i) *θ and γ are Lipschitz continuous, nonnegative, nondecreasing functions and*

$$\dot\theta(s) + \dot\gamma(s) = 1 + \mu([0,1]) \quad \mathcal{L} - a.e.$$

(ii) *For any Borel measurable function h which is μ integrable and any Borel set $T \subset [0,1]$ we have*

$$\int_{\theta^{-1}(T)} h(\theta(s))\dot\gamma(s)ds = \int_T h(\tau)\mu(d\tau).$$

(iii) *For any $\mathcal{L}$-integrable function g and Borel set $S \subset [0,1]$, $\theta(S)$ is also a Borel set and*

$$\int_S g(\theta(s))\dot\theta(s)ds = \int_{\theta(S)} g(\tau)d\tau.$$

(iv) *Let $\{\mu_i\}$ be a sequence of elements in $C^+(0,1)$, and let $\{(\theta_i, \gamma_i)\}$ be the corresponding graph completions. Suppose that $\mu_i \to \mu$ (weakly*). Then $(\theta_i, \gamma_i) \to (\theta, \gamma)$ uniformly and $(\dot\theta_i, \dot\gamma_i) \to (\dot\theta, \dot\gamma)$ weakly in L^1.*

Parts (i) and (iv) are proven by Dal Maso and Rampazzo [6]. We comment briefly on the other assertions. (ii) will be recognized as an example of the "change of variables" lemma [7, Theorem 6.9], since μ can be interpreted as the measure induced by the measure $\dot\gamma(s)ds$ under the mapping θ, i.e.,

$$\mu(A) = \int_{\theta^{-1}(A)} \dot\gamma(s)ds \qquad \forall\ A \in \mathcal{B}.$$

As for (iii), $\theta(S)$ is a Borel set since θ is monotone. The identity is another consequence of the change-of-variables lemma in view of the fact that

$$\int_{\theta^{-1}\circ\theta(S)} h\dot\theta ds = \int_S h\dot\theta ds.$$

This last relationship comes about because $\dot\theta(s) = 0$ almost everywhere on the set where θ is not one-to-one.

3. Measure-driven differential inclusions. In this section we give precise meaning to robust solutions of measure-driven differential inclusions (MDIs) of the form

$$\left\{ \begin{array}{lcl} dx(t) & \in & F_1(t,x(t))dt + F_2(t,x(t))\mu(dt), \quad t \in [\,0,1\,], \\ x(0) & = & x_0 \end{array} \right. \tag{3.1}$$

for which the data are multifunctions $F_1 : [\,0,1\,] \times \Re^n \longmapsto \Re^n$ and $F_2 : [\,0,1\,] \times \Re^n \longmapsto \Re^n$. In the equation, $\mu \in C^+(0,1)$ is a given measure, and $x_0 \in \Re^n$ a given initial state.

The definition of robust solution involves the multifunction $\tilde{F}_2 : [\,0,1\,] \times \Re^n \times [0,\infty) \longmapsto \Re^n$:

$$\tilde{F}_2(t,v;\alpha) := \big\{\alpha^{-1}[\xi(1)-\xi(0)] : \xi \in AC([0,1];\Re^n),\ \dot{\xi}(\sigma) \in \alpha F_2(t,\xi(\sigma)) \text{ a.e.}, \text{ and } \xi(0) = v\big\}$$

if $\alpha > 0$ and $\tilde{F}_2(t,v;0) := F_2(t,v)$.

DEFINITION 3.1. *We say that a function $x \in BV^+([0,1];\Re^n)$ is a* robust solution *to* (3.1) *if there exist an $\mathcal{L}$-integrable function ϕ_1 and μ-integrable function ϕ_2 such that*

$$\begin{aligned} &\phi_1(t) \in F_1(t,x(t)), \qquad \mathcal{L}\text{-a.e.}, \\ &\phi_2(t) \in \tilde{F}_2(t,x(t^-);\mu(\{t\})), \qquad \mu\text{-a.e.}, \end{aligned}$$

and

$$x(t) = x(0) + \int_0^t \phi_1(\tau)d\tau + \int_{[0,t]} \phi_2(\tau)\mu(d\tau) \qquad \forall \quad t \in (0,1].$$

Reparameterization by means of the graph completion of μ results in a (conventional) differential inclusion as described in the following proposition. Here η is the reparameterization function of μ, and $(\theta(\cdot),\gamma(\cdot))$ is the graph completion of this measure (see section 2).

PROPOSITION 3.1. *Suppose that the data for MDI* (3.1) *satisfies the following:*

- *F_1 has values-closed sets and is $\mathcal{L} \times \mathcal{B}$ measurable*

and

- *F_2 has values-closed sets and is Borel measurable.*

Fix a measure $\mu \in C^+(0,1)$ and an initial state x_0. We have the following:

(i) *Suppose that $x(\cdot) \in BV^+([0,1];\Re^n)$ is a robust solution to MDI* (3.1). *Then there exists a solution $y(\cdot) \in AC([\,0,1\,];\Re^n)$ to*

$$\left\{ \begin{array}{lcl} \dot{y}(s) & = & F_1(\theta(s),y(s))\dot{\theta}(s) + F_2(\theta(s),y(s))\dot{\gamma}(s), \quad s \in [0,1], \\ y(0) & = & x_0 \end{array} \right. \tag{3.2}$$

for which

$$x(t) = y(\eta(t)) \qquad \forall \quad t \in [\,0,1\,]. \tag{3.3}$$

Conversely,

(ii) *suppose that $y(\cdot) \in AC([\,0,1\,];\Re^n)$ is a solution to* (3.2). *Then there exists a robust solution $x(\cdot) \in BV^+([0,1];\Re^n)$ to MDI* (3.1) *for which* (3.3) *is satisfied.*

Proof. See [18, Theorem 4.1]. □

Solutions to the MDI (3.1) (as defined above) are "robust" in the sense that the set of solutions has desirable "closure" properties with respect to perturbations of the driving measure μ and the initial state. A result of this kind, suitable for future applications, is conveniently described in terms of a sequence of MDIs approximating (3.1), namely,

$$\left\{ \begin{array}{lcl} dx_i(t) & \in & F_1^{(i)}(t, x_i(t))dt + F_2(t, x_i(t))\mu_i(dt) \quad \text{on} \quad [\,0,1\,], \\ x_i(0) & = & x_0^i, \end{array} \right. \tag{3.4}$$

$i = 1, 2, \ldots$.

Here $F_1^{(i)} : [0,1] \times \Re^n \rightrightarrows \Re^n, \quad i = 1, 2, \ldots;\ F_1 : [0,1] \times \Re^n \rightrightarrows \Re^n$; and $F_2 : [0,1] \times \Re^n \longmapsto \Re^n$ are given multifunctions. $\mu_i,\ i = 1, 2, \ldots$, and μ are elements in $C^+(0,1)$, and $x_0^i, i = 1, 2, \ldots$, and x_0 are n-vectors.

The associated reparameterized equations are

$$\left\{ \begin{array}{lcl} \dot{y}_i(s) & \in & F_1^{(i)}(\theta_i(s), y_i(s))\dot{\theta}_i(s) + F_2(\theta_i(s), y_i(s))\dot{\gamma}_i(s), \quad s \in [0,1], \\ y_i(0) & = & x_0^i, \end{array} \right. \tag{3.5}$$

in which (θ_i, γ_i) is the graph completion of $\mu_i,\ i = 1, 2, \ldots$, and (θ, γ) is the graph completion of μ. Denote by $\eta : [\,0,1\,] \to [\,0,1\,]$ the reparameterization function for μ. We refer also to the reparameterization function $\eta_i : [0,1] \to [0,1]$ of $\mu_i,\ i = 1, 2, \ldots$. Reparameterization of the nominal MDI (3.1) results in the differential inclusion

$$\left\{ \begin{array}{lcl} \dot{y}(s) & \in & F_1(\theta(s), y(s))\dot{\theta}(s) + F_2(\theta(s), y(s))\dot{\gamma}(s), \quad s \in [0,1], \\ y(0) & = & x_0. \end{array} \right. \tag{3.6}$$

We have the following proposition.

PROPOSITION 3.2. *Consider multifunctions $F_1,\ F_1^{(i)},\ i = 1, 2, \ldots$, and F_2 with domain $[\,0,1\,] \times \Re^n$ and taking values-compact subsets of $\Re^n$. Assume that*

- *$F_1^{(i)}(t, \cdot),\ i = 1, 2, \ldots$, and $F_1(t, \cdot)$ have closed graph and $F_1^{(i)}(\cdot, \cdot),\ i = 1, 2, \ldots$, and $F_1(\cdot, \cdot)$ are $\mathcal{L} \times \mathcal{B}$ measurable.*
- *$F_1(t, x)$ is convex for all (t, x).*
- *$F_2(\cdot, \cdot)$ has closed graph and takes values convex sets.*

Assume further that

- *$\mathcal{L}$-measure$\{t : F_1^{(i)}(t, x) = F_1(t, x) \ \ \forall\ x \in \Re^n\} \to 1$ as $t \to \infty$.*

Take a sequence $\{x_0^i\}$ in $\Re^n$, a sequence $\{\mu_i\}$ in $C^+(0,1)$, and elements $x_0 \in \Re^n$ and $\mu \in C^+(0,1)$. Take also a sequence $\{x_i\} \in BV^+([0,1]; \Re^n)$ such that x_i is a robust solution to (3.4) *for each i and*

$$x_0^{(i)} \to x_0 \quad \textit{and} \quad \mu_i \to \mu \ \ (\textit{weakly}^*) \quad \textit{as} \ \ i \to \infty.$$

Assume that there exists $\beta(t) \in L^1$ and $c > 0$ such that $F_1^{(i)}(t, x_i(t)) \subset \beta(t)B$ a.e. and $F_2(t, x_i(t)) \subset cB$ for all t.

Then there exists a sequence $\{y_i\} \subset AC\,([\,0,1\,]\,; \Re^n)$ such that y_i is a solution to (3.5) *for each i, a solution y to* (3.6)*, and a robust solution x to* (3.1) *such that*

$$x_i(t) = y_i(\eta_i(t)) \quad \forall \quad t \in [0,1]$$

and

$$x(t) = y(\eta(t)) \quad \forall \quad t \in [0,1].$$

Along a subsequence we have

$$x_i \longrightarrow x \quad (\textit{weakly}^*),$$
$$x_i(t) \longrightarrow x(t) \quad \forall \quad t \in \Big([0,1] \setminus \mathcal{M}_\mu\Big) \cup \{0,1\}$$

(where $\mathcal{M}_\mu$ denotes the set of atoms of μ), and

$$y_i \longrightarrow y \qquad \textit{strongly in} \;\; C([0,1];\Re^n).$$

Proof. See [18, Theorem 5.1]. □

Consider now the dynamic equation of the problem (P) (the optimal control problem introduced in section 1)

$$\left\{ \begin{array}{lcl} dx(t) & = & f(t,x(t),u(t))dt + g(t,x(t))\mu(dt), \\ x(0) & = & x_0. \end{array} \right. \tag{3.7}$$

For a fixed control policy (u,μ) this is just an example of MDI (3.1) (set $F_1(t,x) = \{f(t,x,u(t))\}$ and $f_2 = \{g\}$). We may therefore speak of robust solutions of the dynamic equation (3.4) (corresponding to a control policy (u,μ)). Henceforth, a process is taken to be a triple of elements (x,u,μ), in which (u,μ) is a control policy (see section 1) and x is a robust solution of the dynamical equation (3.7). Notice that, under the hypotheses imposed below there will be a unique robust solution to (3.7) for given (u,μ). This follows from the characterization of robust solutions provided by Proposition (3.1) since, for the MDI associated with (3.7), the differential inclusion (3.2) reduces to a differential equation which is known to have a unique solution.

4. A maximum principle. Our aim is to obtain optimality conditions for problem (P) in the form of a maximum principle. These will follow from conditions on processes (as defined is section 3) which generate boundary points of some "reachable set" of the control system with dynamic equations:

$$\begin{array}{c} dx(t) = f(t,x(t),u(t))dt + g(t,x(t))\mu(dt), \quad t \in [0,1], \\ u(t) \in U_t \quad \text{a.e. } t \in [\,0,1\,]\,. \end{array}$$

Take a locally Lipschitz continuous function $\psi : \Re^n \to \Re^k$ and a closed set $D \subset \Re^n$. We define the (ψ, D)-reachable set $\mathcal{R}_{\psi,D}$ to be

$$\mathcal{R}_{\psi,D} := \{\psi(x(1)) : (x,u,\mu) \text{ is a process and } x(0) \in D\}.$$

The following hypotheses will be invoked:

(H1) There exists a constant $K_f(\cdot) \in L^1$ such that

$$|f(t,x,u) - f(t,y,u)| \;\leq K_f(t)\;|x-y| \;\text{ for }\; (x,u) \in \Re^n \times \Re^m \text{ and } t \in [\,0,1\,].$$

(H2) $f(\cdot,x,\cdot)$ is $\mathcal{L} \times \mathcal{B}$ -measurable.

(H3) $g(\cdot,\cdot)$ is continuous and there exists a constant K_g such that

$$|g(t,x) - g(t,y)| \;\leq K_g\;|x-y| \quad \forall\; x,\; y \in \Re^n,\; t \in [\,0,1\,]\,.$$

(H4) $U \in \Re^{1+m}$ is a Borel set.

THEOREM 4.1. *Let $\{\bar{x}(\cdot),\bar{u}(\cdot),\bar{\mu}(\cdot)\}$ be a process for which $x(0) \in D$ and $\psi(\bar{x}(1))$ is a boundary point of $\mathcal{R}_{\psi,D}$. Assume that hypotheses* (H1)–(H4) *are satisfied. Then*

there exist a function $p \in BV^+([0,1];\Re^n)$ *and a unit vector* $d \in \Re^k$ *such that* $(\bar{x}(\cdot), p(\cdot))$ *is a robust solution of the MDI*

$$d\begin{bmatrix}\bar{x}(t)\\ p(t)\end{bmatrix} \in \begin{bmatrix} f(t,\bar{x}(t),\bar{u}(t))\\ -p(t)\cdot co\partial_x f(t,\bar{x}(t),\bar{u}(t))\end{bmatrix}dt + \begin{bmatrix} g(t,\bar{x}(t))\\ -p(t)\cdot \overline{\partial_x} g(t,\bar{x}(t))\end{bmatrix}\bar{\mu}(dt). \tag{4.1}$$

Furthermore,

$$-p(1) \in d\cdot\partial\psi(\bar{x}(1)), \tag{4.2}$$

$$p(0) \in N_D(\bar{x}(0)), \tag{4.3}$$

$$p(t)\cdot f(t,\bar{x}(t),\bar{u}(t)) = \max_{u\in U_t}\{p(t)\cdot f(t,\bar{x}(t),u)\} \quad a.e.\ t\in[0,1], \tag{4.4}$$

$$p(t)\cdot g(t,\bar{x}(t)) \le 0 \quad \forall\ t\in(0,1), \tag{4.5}$$

$$p(t)\cdot g(t,\bar{x}(t)) \ge 0, \quad \bar{\mu}-a.e.\ t\in[0,1],$$

and corresponding to every atom t *of* $\bar{\mu}$*, there exists a solution* (ξ_t,α_t) *to*

$$\begin{bmatrix}\dot{\xi}_t(s)\\ \dot{\alpha}_t(s)\end{bmatrix} \in \bar{\mu}(\{t\})\begin{bmatrix} g(t,\xi_t(s))\\ -\alpha_t(s)\cdot\overline{\partial_x} g(t,\xi_t(s))\end{bmatrix}, \quad t\in[0,1],$$

$$(\xi_t(0),\alpha_t(0)) = (\bar{x}(t^-),p(t^-)), \quad (\xi_t(1),\alpha_t(1)) = (\bar{x}(t),p(t)) \tag{4.6}$$

that satisfies

$$\alpha_t(s)\cdot g(t,\xi_t(s)) \ge 0 \quad \forall\ s\in[0,1]. \tag{4.7}$$

Here (4.6) is interpreted as

$$(\xi_t(0),\alpha_t(0)) := (\bar{x}(0),p(0)), \quad (\xi_t(1),\alpha_t(1)) := (\bar{x}(0^+),p(0^+))$$

if $t=0$. Also $\overline{\partial_x} g(t,x)$ denotes the set

$$\overline{\partial_x} g(t,x) := \left\{\lim_i a_i : a_i \in co\partial_x g(t_i,x_i) \text{ for some } t_i\to t,\ x_i\to x\right\}.$$

A proof is given in section 5.

The transition from Theorem 4.1 to a maximum principle for problem (P) follows the standard lines. Indeed, suppose that $h:\Re^n\times\Re^n\to\Re$ is a locally Lipschitz continuous function and C is a closed subset of $\Re^n\times\Re^n$, and let $(\bar{x},\bar{u},\bar{\mu})$ be a minimizing process for problem (P).

Consider the control system in which state trajectories are triples (x,y,z):

$$d\left(x(t),y(t),z(t)\right) = \left(f(t,x(t),u(t)),0,0\right)dt + \left(g\left(t,x(t)\right),0,0\right)\mu(dt),$$
$$(x(0),y(0),z(0)) \in D.$$

Here

$$D := \{(x,y,z) : (x,y)\in C \text{ and } z\ge h(x,y)\}.$$

It is easy to deduce from the optimality of $(\bar{x},\bar{u},\bar{\mu})$ that $(0,h(\bar{x}(0),\bar{x}(1))$ is a boundary point of $\mathcal{R}_{\psi,D}$, $\psi(x,y,z) := (y-x,z)$.

Applying the earlier theorem to this boundary process we arrive at the following maximum principle for (P).

THEOREM 4.2. *Let $(\bar{x}(\cdot), \bar{u}(\cdot), \bar{\mu}(\cdot))$ be a minimizing process for* (P). *Assume that h is locally Lipschitz continuous, that C is a closed subset, and that hypotheses* (H1)–(H4) *are satisfied.*

Then there exist $\lambda \geq 0$ and $p \in BV^+([0,1]; \Re^n)$ such that $\|p(\cdot)\|_{L^\infty} + \lambda > 0$ and $(\bar{x}(\cdot), p(\cdot))$ is a robust solution of the MDI

$$d\begin{bmatrix} \bar{x}(t) \\ p(t) \end{bmatrix} \in \begin{bmatrix} f(t, \bar{x}(t), \bar{u}(t)) \\ -p(t) \cdot co\partial_x f(t, \bar{x}(t), \bar{u}(t)) \end{bmatrix} dt + \begin{bmatrix} g(t, \bar{x}(t)) \\ -p(t) \cdot \overline{\partial_x} g(t, \bar{x}(t)) \end{bmatrix} \bar{\mu}(dt).$$

Furthermore,

$$\begin{aligned} &(p(0), -p(1)) \in N_C(\bar{x}(0),\ \bar{x}(1)) + \lambda \partial h(\bar{x}(0),\ \bar{x}(1)), \\ &p(t) \cdot f(t, \bar{x}(t), \bar{u}(t)) = \max_{u \in U_t} \{p(t) \cdot f(t, \bar{x}(t), u)\} \quad a.e.\ t \in [0,1], \\ &p(t) \cdot g(t, \bar{x}(t)) \leq 0 \quad \forall\ t \in [0,1], \\ &p(t) \cdot g(t, \bar{x}(t)) = 0, \quad \bar{\mu} - a.e.\ on\ [0,1]. \end{aligned}$$

Corresponding to every atom t of $\bar{\mu}$, there exists a solution $\left[\begin{smallmatrix} \xi_t(\cdot) \\ \alpha_t(\cdot) \end{smallmatrix}\right]$ to

$$\begin{bmatrix} \dot{\xi}_t(s) \\ \dot{\alpha}_t(s) \end{bmatrix} \in \bar{\mu}(\{t\}) \begin{bmatrix} g(t, \xi_t(s)) \\ -\alpha_t(s) \cdot \bar{\partial}_x g(t, \xi_t(s)) \end{bmatrix} \quad on\ [0,1]$$

which satisfies

$$\begin{gathered} (\xi_t(0), \alpha_t(0)) = (\bar{x}(t^-), p(t^-)), \quad (\xi_t(1), \alpha_t(1)) = (\bar{x}(t), p(t)), \\ \alpha_t(s) \cdot g(t, \xi_t(s)) \geq 0 \quad \forall\ s \in [0,1]. \end{gathered}$$

5. Proof of Theorem 4.1. Take a process $(\bar{x}, \bar{u}, \bar{\mu})$ with the stated "boundary" property. The assertions of the theorem are proven first in the special case when an interim hypothesis,

($\bar{\text{H}}$) There exists $\alpha \in L^1$ such that $\sup_{u \in U(t)} |f(t, \bar{x}(t), u)| \leq \alpha(t)$ a.e.

is added to (H1)–(H4). We show how to remove ($\bar{\text{H}}$) in the final stage of the proof. ($\bar{\text{H}}$) has the role of ensuring suitable "linear growth properties" of the data, namely, the following lemma.

LEMMA 5.1. *There exist $\alpha_1,\ \alpha_2 \in L^1$ and $\beta_1 \geq 0,\ \beta_2 \geq 0$ such that*

$$|f(t,x,u)| \ \leq \alpha_1(t)|x| + \alpha_2(t) \quad \forall \quad x \in \Re^n \ and \ \ u \in U_t,\ \mathcal{L}-a.e.$$

and

$$|g(t,x)| \ \leq \beta_1|x| + \beta_2 \quad \forall \quad x \in \Re^n \ and \ \ t \in [0,1].$$

Proof. An appeal to (H1), (H3), and ($\overline{\text{H}}$) and repeated applications of the triangle inequality validate the inequalities with

$$\begin{aligned} \alpha_1(t) &:= K_f(t), \qquad \alpha_2(t) := \alpha(t) + K_f(t)\ \|\bar{x}(\cdot)\|_{L^\infty}, \\ \beta_1 &:= K_g, \quad \beta_2 := \sup_{s \in [0,1]} |g(s, \bar{x}(s))| + K_g\ \|\bar{x}(\cdot)\|_{L^\infty}. \end{aligned}$$

□

Next, we have a lemma describing the continuity properties of state trajectories with respect to control policies and initial states.

LEMMA 5.2. *Given any control policy (u, μ) and initial state x_0 there is a unique robust solution x of the dynamical equation*

$$\left[\begin{array}{l} dx(t) = f\,(t, x(t), u(t))\,dt + g\,(t, x(t))\,\mu(dt), \quad t \in [\,0, 1\,], \\ x(0) = x_0 \end{array}\right. \tag{5.1}$$

and a unique solution y of the reparameterized equation

$$\left[\begin{array}{l} \dot{y}(s) = f\,(\theta(s), y(s), u(\theta(s)))\,\dot{\theta}(s) + g\,(\theta(s), y(s))\,\dot{\gamma}(s), \quad s \in [0, 1], \\ y(0) = x_0. \end{array}\right. \tag{5.2}$$

(Here $(\theta(s), \gamma(s))$ is the graph completion of the measure μ.) If $\{(u_i(\cdot), \mu_i)\}$ and $\{x_0^i\}$ are sequences of control policies and initial states, respectively, such that

$$\mathcal{L}\text{-}meas\{t : u_i(t) \neq u(t)\} \to 0,$$
$$\mu_i \to \mu \quad weakly^*,$$

and

$$x_0^i \to x_0,$$

then $x_i(t) \to x(t)\ \forall\ t \in \mathcal{C}_\mu \cup \{0, 1\}$, $dx_i \to dx$ (weakly), and $y_i(t) \to y(t)$ uniformly, where $\{x_i(\cdot)\}$ and $\{y_i(\cdot)\}$ are the corresponding sequences of state trajectories and reparameterized state trajectories and $\mathcal{C}_\mu$ is the set of continuity points of μ.*

Proof. Notice that the right-hand side

$$\phi(s, y) := f(\theta(s), y, u(\theta(s)))\ \dot{\theta}\ (s) + g(\theta(s), y)\ \dot{\gamma}\ (s)$$

of the reparameterized equation (5.2) satisfies the growth condition,

$$|\phi(s, y)| \leq \alpha_1^{'}(s)|y| + \alpha_2^{'}(s) \quad \text{a.e.} \quad s \in [0, 1] \tag{5.3}$$

$\forall\ y \in \Re^n$, where $\alpha_1^{'}$ and $\alpha_2^{'}$ are the integrable functions

$$\begin{array}{l} \alpha_1^{'}(s) := \alpha_1(\theta(s))\ \dot{\theta}\ (s) + \beta_1(1 + \mu([0, 1])), \\ \alpha_2^{'}(s) := \alpha_2(\theta(s))\ \dot{\theta}\ (s) + \beta_2(1 + \mu([0, 1])), \end{array} \tag{5.4}$$

and also the Lipschitz condition,

$$|\phi(s, y) - \phi(s, z)| \leq k^{'}(s)|y - z|$$

for all $y, z \in \Re^n$, where $k^{'}(s)$ is the integrable function

$$k^{'}(s) := K_f(\theta(s))\ \dot{\theta}\ (s) + K_g(1 + \mu([0, 1])).$$

These are known conditions under which the reparameterized equation (5.2) has a unique solution $y \in AC([0, 1]; \Re^n)$. But then by Proposition 3.1 there is a unique robust solution to (5.1).

An important observation is that, if $c > 0$ is a constant such that $\mu([0, 1]) < c$, then the coefficients in the linear growth inequality (5.3) have L^1 norm bounded above by a number which depends only on c. (This is clear from (5.4) and the fact that $\int \alpha_1^{'}(\theta(s))\ \dot{\theta}(s)ds = \int \alpha_1^{'}(t)dt$.) Since $\{\mu_i\}$ is a weak* convergent sequence, the μ_i's and μ are uniformly bounded in total variation, and the x_0^i's too are uniformly

bounded, it follows from an application of Gronwall's lemma that the solutions y_i to the reparameterized equations, resulting from replacing (u, μ) by (u_i, μ_i) and x_0 by $x_o^{(i)}$, $i = 1, 2, \ldots$, are uniformly bounded in the supremum norm. Since $\|x_i\|_{L^\infty} \leq \|y_i\|_{L^\infty}$, $i = 1, 2, \ldots$, the x_i's are likewise bounded. The y_i's are, in addition, equicontinuous. To show this, we choose constants $r > 0$ such that $\|y_i\|_{L^\infty} \leq r$, $i = 1, 2, \ldots$, and $\rho > 0$ such that $|g(t, y)| \leq \rho$ for all $(t, y) \in [0, 1] \times r\bar{B}$. Fix $\epsilon > 0$. Choose $\delta > 0$ and let $[\sigma_1, \sigma_2] \subset [0, 1]$ be an arbitrarily interval such that $|\sigma_2 - \sigma_1| < \delta$ and i an arbitrary index value. We have

$$\begin{aligned}
|y_i(\sigma_2) - y_i(\sigma_1)| &\leq \left| \int_{\sigma_1}^{\sigma_2} f(\theta_i(s), y_i(s), u_i(\theta_i(s)))\dot{\theta}(s)ds \right| \\
&\quad + \left| \int_{\sigma_1}^{\sigma_2} g(\theta_i(s), y_i(s))\dot{\gamma}(s)ds \right| \\
&\leq \left| \int_{t_1}^{t_2} f(t, x_i(t), u_i(t))dt \right| + \rho(1 + \mu([0, 1]))|\sigma_2 - \sigma_1| \\
&\leq r \int_{t_1}^{t_2} \alpha_1(t)dt + \int_{t_1}^{t_2} \alpha_2(t)dt + \rho(1 + \mu([0, 1]))|\sigma_2 - \sigma_1|.
\end{aligned}$$

Here $t_1 = \theta_i(\sigma_1)$ and $t_2 = \theta_i(\sigma_2)$. Since $|t_2 - t_1| \leq (1 + \mu_i([0, 1]))|\sigma_2 - \sigma_1|$ and the $|\mu_i([0, 1])|$'s are uniformly bounded, this last inequality implies that, by choosing $\delta > 0$ sufficiently small, we can arrange that $|y_i(\sigma_2) - y_i(\sigma_1)| < \epsilon$ independently of our choice of interval $[\sigma_1, \sigma_2]$ and index value i. This confirms the equicontinuity of the y_i's.

The hypotheses are satisfied under which Proposition 3.2 may be applied when $F_1^i(t, x) := \{f(t, x, u_i(t))\}$, $i = 1, 2, \ldots$, and $F_2(t, x) := \{g(t, x)\}$. For arbitrary subsequences, further subsequences may be chosen such that $\{y_i\}$ and $\{x_i\}$ converge as described. Since, however, the limits are unique, the original sequences must converge. □

Since $\psi(\bar{x}(1)) \in \partial\mathcal{R}_{\psi,D}$ there exists a sequence of vectors $\{\xi_j\}$ such that $\xi_j \notin \mathcal{R}_{\psi,D}$ for $j = 1, 2, \ldots$ and

$$\xi_j \to \psi(\bar{x}(1)) \quad \text{as } j \to \infty.$$

We may construct, using standard procedures (see, e.g., [20]), a sequence of nonnegative-valued L^∞ functions $\{\bar{m}_j(\cdot)\}$ such that

$$\bar{m}_j(t)dt \to \bar{\mu}(dt) \qquad \text{weakly*}.$$

Let $\bar{x}_j(\cdot)$ be the state trajectory corresponding to the conventional and measure controls, $\bar{u}(\cdot)$ and $m_j(t)dt$, and initial state $\bar{x}_0$. According to Lemma 5.2,

$$\bar{x}_j \to \bar{x}(t) \qquad \forall\ t \in C_{\bar{\mu}} \cup \{0, 1\}$$

and

$$d\bar{x}_j(t) \to d\bar{x}(t) \qquad \text{weakly*}.$$

Now define $\epsilon_j := |\xi_j - \psi(\bar{x}(t))|^{1/2}$. Note that, by the properties of $\{\xi_j\}$, $\epsilon_j \to 0$ as $i \to \infty$.

For each j, set $r_j := j + \|\bar{m}_j(\cdot)\|_{L^\infty}$ and consider the optimal control problem

$$(\overline{\mathrm{P}}_j) \qquad \begin{cases} \text{Minimize} \quad |\xi_j - \psi(\bar{x}(t))| \\ \text{subject to} \quad \dot{x}(t) = f\,(t, x(t), u(t)) + g(t, x(t))m(t), \quad t \in\ [\,0, 1], \\ (u(t),\ m(t)) \in U_t \times [0, r_j] \ \ \mathcal{L}\text{-a.e.}, \\ x_0 \in D. \end{cases}$$

Since the dynamic constraint defines a unique state trajectory $x_{a,u,m}(\cdot)$ corresponding to a given control function $(u(\cdot), m(\cdot))$ and initial state a, we may regard this as a minimization problem over triples $(a, u(\cdot), m(\cdot))$ such that $a \in D$; $u(\cdot)$ and $m(\cdot)$ are measurable functions; and $(u(t), m(t)) \in U_t \times [0, r_j]$ a.e. Denote this collection of triples by W_j. We provide W_j with the metric

$$\begin{aligned} \rho((a, u, m); (a', u', m')) := |a - a'| \quad &+ \ \mathcal{L}\text{-meas}\{t \in [0, 1] : u(t) \neq u'(t)\} \\ &+ \int_0^1 |m(t) - m'(t)|dt. \end{aligned}$$

The newly reformulated problem can be expressed as

$$\text{minimize}\{\Psi_j(a, u, m) :\ (a, u, m) \in W_j\},$$

in which

$$\Psi_j(a, u, m) := |\xi_j - \psi(x_{a,u,m}(1))|.$$

By Lemma 5.2, W_j is a complete space and Ψ_j is continuous with respect to the above metric. According to Ekeland's theorem [5] then there exists a triple $(a_j, u_j, m_j) \in W_j$ such that

$$\Psi_j(a_j, u_j, m_j) \leq \Psi_j(a, u, m) + \epsilon_j \rho((a, u, m), (a_j, u_j, m_j)) \tag{5.5}$$

for all $(a, u, m) \in W_j$ and

$$\rho(\bar{x}(0), \bar{u}, \bar{m}_j), (a_j, u_j, m_j)) \leq \epsilon_j \tag{5.6}$$

for each j. Let x_j be the trajectory corresponding to (a_j, u_j, m_j). Since $\epsilon_j \to 0$ we deduce from (5.6) that

$$\begin{gathered} x_j(0) \to \overline{x}(0), \\ \mathcal{L} - \text{meas}\{t \in [0, 1] : u_j(t) \neq \overline{u}(t)\} \to 0, \end{gathered}$$

and

$$m_j(t)dt \to \overline{\mu}(dt) \quad \text{ weakly*}.$$

For each j, (5.5) implies that $(x_j(\cdot), u_j(\cdot), m_j(\cdot))$ is a minimizer for the problem

$$\begin{aligned} \text{Minimize} \quad & |\xi_j - \psi(x(1))| + \epsilon_j \left\{ |x(0) - x_j(0)| \right. \\ & \qquad \left. + \int_0^1 |m_j(t) - m(t)|dt + \int_0^1 \chi_j(t, u(t))dt \right\} \\ \text{subject to} \quad & \dot{x}(t) = f(t, x(t), u(t)) + g(t, x(t))m(t) \quad \mathcal{L}\text{-a.e.}, \\ & (u(t), m(t)) \in U_t \times [0, r_j] \quad \mathcal{L}\text{-a.e.}, \end{aligned}$$

in which

$$\chi_j(t,u) := \begin{cases} 0 & \text{if } u = u_j(t), \\ 1 & \text{if } u \neq u_j(t). \end{cases}$$

Now apply the maximum principle to this last problem (see, e.g., [17]). Since $\xi_j \notin \Psi(x_j(1))$, this tells us that there exists an absolutely continuous function p_j and a vector $d_j \in \Re^k$ of unit length such that

$$-\dot{p}_j(t) \in p_j \cdot \mathrm{co}\partial_x f(t, x_j(t), u_j(t)) + p_j \cdot \mathrm{co}\partial_x g(t, x_j(t))m_j, \quad t \in [0,1],$$

$$p_j(0) \in N_D(x_j(0)) + \epsilon_j \partial_x |x - x_0|_{x=x_j(0)}, \tag{5.7}$$

$$-p_j(1) \in d_j \cdot \partial\psi(x_j(1)), \tag{5.8}$$

and

$$H_j(t, u_j(t), m_j(t)) = \max\{H_j(t,u,m) : \ u \in U_t, \ m \in [0, r_j]\} \text{ a.e.} \tag{5.9}$$

Here

$$H_j(t,u,m) := p_j(t) \cdot f(t, x_j(t), u) + p_j(t) \cdot g(t, x_j(t))m - \epsilon_j(|m - m_j(t)| + \chi_j(t,u)).$$

Notice that the maximization of the Hamiltonian condition (5.9) implies that $m_j(t) = r_j$ a.e. on the set $\{t : p_j(t) \cdot g(t, x_j(t) > \epsilon_j\}$. Since $m_j(t)dt \to \bar{\mu}(dt)$ weakly*, the sequence $\{m_j\}$ is bounded in L^1 norm. Observing that $r_j \to \infty$, we deduce

$$\mathcal{L}\text{-meas}\{t : p_j(t) \cdot g(t, x_j(t) \leq \epsilon_j\} \to 1 \quad \text{as } j \to \infty. \tag{5.10}$$

It follows also from (5.9) that $p_j(t) \cdot g(t, x_j(t)) \geq -\epsilon_j$ a.e. (with respect to Lebesgue measure) on $\{t : m_j(t) > 0\}$. This property can be expressed as

$$\int_0^1 \max\{-p_j(t) \cdot g(t, x_j(t)) - \epsilon_j, \ 0\} m_j(t) dt = 0, \quad j = 1, 2, \ldots. \tag{5.11}$$

We can regard x_j and p_j as solutions to the following MDI, corresponding to controls $(u, \mu) = (u_j, \ m_j(t)dt)$ and initial values $(x_j(0), p_j(0))$:

$$d(x(t), p(t)) \in F_1(t, x(t), p(t), u(t))dt + F_2(t, x(t), p(t))\mu(dt), \tag{5.12}$$

in which

$$F_1(t,x,p,u) := \{f(t,x,u)\} \times \{-p \cdot \mathrm{co}\partial_x f(t,x,u)\}$$

and

$$F_2(t,x,p) := \{g(t,x)\} \times \{-p \cdot \overline{\partial_x} g(t,x)\}.$$

Incorporation of the hybrid gradient $\overline{\partial_x g}$ in these relationships ensures that F_2 has the requisite upper semicontinuity properties for application of the convergence results of section 5.

Bearing in mind the sequences $\{x_j\}$ and $\{p_j\}$ are uniformly bounded (in the case of p_j this follows from the uniform bound on the right endpoints, and an application of Gronwall's lemma), we deduce from Proposition 4.2 that (following an extraction

of subsequences) there exist $\overline{x} \in BV^+([0,1],\Re^n)$, $p \in BV^+([0,1],\Re^n)$, and absolutely continuous functions $y(\cdot)$ and $q(\cdot)$ with the following properties:

$$\begin{aligned} &x_j(t) \to \overline{x}(t) \quad \text{and} \quad p_j(t) \to p(t) \quad \forall \quad t \in \mathcal{C}_\mu \cup \{0,1\}, \\ &x_j(\theta_j(s)) \to y(s) \quad \text{and} \quad p_j(\theta_j(s)) \to q(t) \text{ uniformly,} \end{aligned} \tag{5.13}$$

and

$$\bar{x}(t) = y(\eta(t)) \quad \text{and} \quad p\,(t) = q(\eta(t)) \quad \forall \quad t \in [0,1]. \tag{5.14}$$

Here η is the reparameterization function of μ, (θ,γ) is the graph completion of μ, and (θ_j,γ_j) is the graph completion of μ_j for $j = 1,2,\ldots$. Furthermore $(\overline{x}(\cdot),p(\cdot))$ is a robust solution of the MDI (5.12), and y and q satisfy the differential inclusion

$$\begin{aligned} (\dot{y}(s),\dot{q}(s)) \in &\{f(\theta(s),y(s),\overline{u}(\theta(s)))\} \times \{-q(s)\cdot \mathrm{co}\partial_x f(\theta(s),y(s),\overline{u}(\theta(s)))\}\dot{\theta}(s) \\ &+ \{g(\theta(s),y(s))\} \times \{-q(s)\cdot \overline{\partial_x} g(\theta(s),y(s))\}\dot{\gamma}(s), \quad s \in [0,1]. \end{aligned} \tag{5.15}$$

Notice that we are justified in taking the cluster point of the sequence $\{x_j(\cdot)\}$ to be the "boundary" state trajectory $\overline{x}(\cdot)$ because the *original* sequence is known to have converged to $\overline{x}(\cdot)$ on $\mathcal{C}_\mu \cup \{0,1\}$, and two functions in $BV^+([0,1];\Re^n)$ coincide if they have the same values on a dense set including $\{0,1\}$.

We now arrange, by further subsequence extraction, that the sequence of vectors $\{d_j\}$ in (5.8) has a limit:

$$d_j \to d \quad \text{as } j \to \infty$$

for some vector d of unit length.

We have seen that $(\overline{x},p)$ can be interpreted as a robust solution of the combined state and costate equations (5.12). Our goal now is to show that the $p(\cdot)$ and d we have constructed satisfy the remaining conditions in the theorem statement.

For each j let S_j be the set of points $t \in [0,1]$ such that

$$p_k(t)\cdot g(t,x_k(t)) \le \epsilon_k \qquad \forall\ k \ge j,$$

$$u_k(t) = \overline{u}(t) \qquad \forall\ k \ge j,$$

$$H_k(t,u_k(t),m_k(t)) = \max\{H_k(t,u,m) : u \in U_t, m \in [0,r_k]\} \quad \forall\ k \ge j,$$

and

$$x_k \to \overline{x}(t), \quad p_k(t) \to p(t).$$

In view of (5.6), (5.9), (5.10), and (5.13), we can arrange by a further subsequence extraction that $\mathcal{L}$-meas $\{S_j\} \to 1$.

Take any $t \in \cup_j S_j$ and any $u \in U_t$. The above relationships imply that, in the limit,

$$p(t)\cdot f(t,\overline{x}(t),\overline{u}(t)) = \max\{p(t)\cdot f(t,\overline{x}(t),u) :\ u \in U_t\}$$

and

$$p(t)\cdot g(t,\overline{x}(t)) \le 0.$$

We have shown (4.5) on $\cup_j S_j$. But then (4.5) holds on $(0,1)$ because $\cup_j S_j$ is dense and $t \to p(t) \cdot g(t, \overline{x}(t))$ is right continuous on $(0,1)$. The boundary conditions on the costate function $p(\cdot)$ are verified by passage to the limit in (5.7) and (5.8).

Next we examine the consequences of (5.11). Since $\{m_j(\cdot)\}$ is bounded in L^1 norm, we know that

$$\lim_{j\to\infty} \int_0^1 \max\{-p_j(t) \cdot g(t, x_j(t)),\ 0\} m_j(t) dt = 0.$$

Applying the change-of-variables lemma and using the facts that

$$p_j(\theta_j(s)) \cdot g(\theta_j(s), x_j(\theta_j(s))) \to q(s) \cdot g(\theta(s), y(s))$$

uniformly and

$$\dot{\gamma}_j(\cdot) \to \dot{\gamma}(\cdot) \quad \text{weakly in } L^1$$

(see Proposition 2.1), we conclude that

$$\begin{aligned} &\int_0^1 \max\{-q(s) \cdot g(\theta(s), y(s)),\ 0\} \dot{\gamma}(s) ds \\ &= \lim_j \int_0^1 \max\{-p_j(\theta_j(s)) \cdot g(\theta_j(s), x_j(\theta_j(s))),\ 0\} \dot{\gamma}_j(s) ds = 0. \end{aligned}$$

Since the integrand of the expression on the left is nonnegative, it follows that

$$\int_{[0,1]\setminus(\cup_i I_i)} \max\{-p(\theta(s)) \cdot g(\theta(s), \overline{x}(\theta(s))),\ 0\} \dot{\gamma}(s) ds = 0 \tag{5.16}$$

(we have noted that $\overline{x}(\theta(s)) = y(s),\ p(\theta(s)) = q(s)$ on $[0,1] \setminus (\cup_i I_i)$) and, for each i,

$$\int_{[s_i^{'}, s_i^{''}]} \max\{-q(s) \cdot g(t_i, y(s)),\ 0)\} ds = 0 \tag{5.17}$$

(in view of the fact that $\dot{\gamma} \equiv 1 + \mu([0,1])$ on $[s_i^{'}, s_i^{''}]$). Here $\{t_i\}$ is an enumeration of the atoms of μ and

$$[s_i^{'}, s_i^{''}] = I_i = \theta^{-1}(\{t_i\}),\ i = 1, 2, \ldots.$$

The change-of-variables lemma applied to (5.16) gives

$$\int_{[0,1]\setminus\cup\{t_i\}} \max\{-p(t) \cdot g(t, \overline{x}(t)),\ 0\} \overline{\mu}(dt) = 0. \tag{5.18}$$

Since the integrand in (5.17) is continuous, we conclude from this equation that

$$q(s) \cdot g(t_i, y(s)) \geq 0 \quad \forall\ s \in [s_i^{'}, s_i^{''}],\ i = 1, 2, \ldots. \tag{5.19}$$

We note, however, that, by (5.14), the continuity of y and q, and the continuity of $\bar{x}$ from the right,

$$\bar{x}(t_i) = y(s_i^{''}) \quad \text{and} \quad p(t_i) = q(s_i^{''}), \tag{5.20}$$

and

$$x(t_i^-) = y(s_i^{'}) \quad \text{and} \quad p(t_i^-) = q(s_i^{'}). \tag{5.21}$$

Equations (5.19) and (5.20) now give

$$p(t_i) \cdot g(t, \overline{x}(t_i)) = q(s_i^{''}) \cdot g(t_i, y(s_i^{''})) \geq 0$$

for all i. Combining this relationship with (5.18) we conclude that

$$p(t) \cdot g(t, \overline{x}(t) \geq 0 \quad \mu\text{-a.e.}$$

Next, for each i, define $\xi_i : [0,1] \to \Re^n,\ \pi_i : [0,1] \to \Re^n$ to be

$$\xi_i(\sigma) = y(s_i^{'} + \sigma(s_i^{''} - s_i^{'})),\ \pi_i(\sigma) = q(s_i^{'} + \sigma(s_i^{''} - s_i^{'})).$$

By (5.20) and (5.21)

$$(\xi_i(0), \pi_i(0)) = (x(t_i^-), p(t_i^-)), \quad (\xi_i(1), \pi_i(1)) = (x(t_i), p(t_i))$$

for each i. Furthermore, since $\dot{\theta}(s) \equiv 0$ and $\dot{\gamma}(s) \cdot |s_i^{''} - s_i^{'}| \equiv \mu(\{t_i\})$ on $[s_i^{'}, s_i^{''}]$, we deduce from (5.2) that

$$(\dot{\xi}_i(s), \dot{\pi}_i(s)) \in g(t_i, \xi_i(s)) \times (-\xi_i(s) \cdot \overline{\partial_x} g(t_i, \xi_i(s)) \mu(\{t_i\}) \quad \text{a.e.}$$

This concludes the proof of the theorem in the case that ($\bar{\text{H}}$) is added to the hypotheses. It remains to deal with the case when ($\bar{\text{H}}$) is not valid. For each index value k replace $U(t)$ with $\widetilde{U}_k(t)$:

$$\widetilde{U}_k(t) = U(t) \bigcap \{u \in \Re^m : |f(t, \overline{x}(t), u)| \leq |f(t, \overline{x}(t), \overline{u}(t))| + k\}.$$

We see that $(\overline{x}, \overline{u}, \overline{\mu})$ remains a minimizer. Furthermore, ($\bar{\text{H}}$) is now satisfied. By our earlier analysis there exist $(p_k(\cdot), d_k)$ with the properties described in the above theorem (except that now $\widetilde{U}_k(t)$ replaces $U(t)$). Passage to the limit as $k \to \infty$ (the convergence analysis is along the lines of the first half of the proof) yields the assertions of Theorem 4.1 in this case also. □

DYNAMICS AND APPROXIMATIONS OF A VELOCITY TRACKING PROBLEM FOR THE NAVIER–STOKES FLOWS WITH PIECEWISE DISTRIBUTED CONTROLS*

L. S. HOU† AND Y. YAN‡

Abstract. We study the dynamics of a piecewise (in time) distributed optimal control problem for the Navier–Stokes equations which models velocity tracking over time. We also study the dynamics of semidiscrete and fully discrete approximations of this velocity tracking problem. We prove that the rates of velocity tracking are exponential. Some computational results are presented, which reinforces the theoretical results derived.

Key words. optimal control, Navier–Stokes equations, semidiscrete approximations, fully discrete approximations

1. Introduction.

1.1. Motivation. This work is motivated by the desire to steer over time a candidate viscous, incompressible velocity field $\mathbf{u}$ to a target velocity field $\mathbf{U}$ by appropriately controlling (adjusting) the body force. The control of body force can be affected by appropriately adjusting the external magnetic field in the case of electromagneto fluids such as liquid metal. Thus the study of body force control problems is important in its own right. Boundary velocity control is far more common in practical applications than body force control, but there has been a lack of adequate mathematical theories for both the (uncontrolled) boundary value problems and the boundary control problems for viscous, incompressible flows (see [FGH] for some recent progress in this direction). For this reason, the study of body force control problems is also important in that it provides some insight into boundary velocity control problems.

In [HY], a velocity tracking problem on the infinite time interval was formulated as an optimal control problem: find a triplet $(\mathbf{u}, p, \mathbf{f})$ such that the functional

$$\mathcal{J}_{(0,\infty)}(\mathbf{u}, \mathbf{f}) = \frac{\alpha}{2} \int_0^\infty \int_\Omega |\mathbf{u} - \mathbf{U}|^2 \, d\mathbf{x} \, dt + \frac{\beta}{2} \int_0^\infty \int_\Omega |\mathbf{f} - \mathbf{F}|^2 \, d\mathbf{x} \, dt$$

is minimized subject to the two-dimensional Navier–Stokes equations with an initial condition $\mathbf{u}_0$ and the zero boundary condition. Here, Ω is a two-dimensional bounded domain which is convex or of class C^2, and $\partial\Omega$ denotes its boundary; $\mathbf{u}$ and p denote the velocity field and the pressure field, respectively; $\mathbf{f}$ is the body force—the control field; $\mathbf{u}_0$ is the initial velocity field; and $\mathbf{F}$ is a prescribed body force. α and β are two positive parameters that adjust the relative weight of the two terms in the functional. Also, the viscosity $\nu > 0$ appears in the Navier–Stokes equations. This optimal control

problem on the infinite time interval is of both physical and mathematical interest. The dynamics of the solutions for this problem were studied and an optimality system of equations was derived in [HY]. In particular, it was shown that $\|\mathbf{u}(t)-\mathbf{U}(t)\|_{\mathbf{L}^2(\Omega)} \to 0$ and $\|\nabla\mathbf{u}(t) - \nabla\mathbf{U}(t)\|_{\mathbf{L}^2(\Omega)} \to 0$ as $t \to \infty$. However, the computation of the controlled flows based on solving the derived optimality system is difficult due to the fact that the system needs to be resolved on the infinite time interval $(0,\infty)$ and more importantly that it involves a coupled system of the state variables $(\mathbf{u}, p)$ and the adjoint state variables $(\boldsymbol{\mu}, \pi)$ with forward and backward "initial" conditions—in other words, this system has to be solved on the entire time-space cylinder and it cannot be solved by marching in time. Also, although the $\mathbf{L}^2(\Omega)$ norm and $\mathbf{H}^1(\Omega)$ norm of the difference between the controlled flow $\mathbf{u}$ and the desired flow $\mathbf{U}$ both decay to zero in time, the decay rates can be slow. Therefore, there are practical interests and needs to develop other approaches for velocity tracking on the infinite interval that are devoid of these aforementioned difficulties.

The purpose of this paper is to design an appropriate optimal control mechanism—piecewise (in time) distributed controls—which possesses the following features: the physical objective of tracking the velocity field over time is achieved; $\mathbf{u}(t) - \mathbf{U}(t)$ and $\nabla\mathbf{u}(t) - \nabla\mathbf{U}(t)$ decay to zero exponentially as $t \to \infty$; and the optimal control problem can be solved numerically by marching in time. Precisely, we will study the following piecewise (in time) optimal control problem:

- First, choose a sufficiently small $\delta > 0$, choose a sequence $\{t_n\}_{n=0}^{\infty}$ defined by $t_n = n\delta$, and define $\widehat{\mathbf{u}}^{(0)}(0) = \mathbf{u}_0$.
- Then, inductively, for each $n \geq 0$, find a solution $(\widehat{\mathbf{u}}^{(n+1)}, \widehat{p}^{(n+1)}, \widehat{\mathbf{f}}^{(n+1)})$ on the interval (t_n, t_{n+1}) which minimizes the (localized) functional

$$\begin{aligned} &\mathcal{J}_{(t_n,t_{n+1})}(\mathbf{u},\mathbf{f}) \\ &\stackrel{\text{def}}{=\!=} \frac{\alpha}{2}\int_{t_n}^{t_{n+1}}\int_{\Omega}|\mathbf{u}-\mathbf{U}|^2\,d\mathbf{x}\,dt + \frac{\beta}{2}\int_{t_n}^{t_{n+1}}\int_{\Omega}|\mathbf{f}-\mathbf{F}|^2\,d\mathbf{x}\,dt \end{aligned} \tag{1.1}$$

subject to the (localized) two-dimensional Navier–Stokes equations:

$$\partial_t\mathbf{u} - \nu\Delta\mathbf{u} + (\mathbf{u}\cdot\nabla)\mathbf{u} + \nabla p = \mathbf{f} \qquad \text{in } \Omega\times(t_n,t_{n+1})\,, \tag{1.2}$$

$$\operatorname{div}\mathbf{u} = 0 \qquad \text{in } \Omega\times(t_n,t_{n+1})\,, \tag{1.3}$$

$$\mathbf{u} = \mathbf{0} \qquad \text{on } \partial\Omega\times(t_n,t_{n+1}), \tag{1.4}$$

and

$$\mathbf{u}(\cdot,t_n) = \widehat{\mathbf{u}}^{(n)}(t_n) \qquad \text{in } \Omega\,. \tag{1.5}$$

We define a global (in time) solution $(\widehat{\mathbf{u}}, \widehat{p}, \widehat{\mathbf{f}})$ by patching together all the local optimal control solutions $(\widehat{\mathbf{u}}^{(n)}, \widehat{p}^{(n)}, \widehat{\mathbf{f}}^{(n)})$, i.e., $\widehat{\mathbf{u}}|_{(t_n,t_{n+1})} \stackrel{\text{def}}{=\!=} \widehat{\mathbf{u}}^{(n+1)}$, $\widehat{p}|_{(t_n,t_{n+1})} \stackrel{\text{def}}{=\!=} \widehat{p}^{(n+1)}$ and $\widehat{\mathbf{f}}|_{(t_n,t_{n+1})} \stackrel{\text{def}}{=\!=} \widehat{\mathbf{f}}^{(n+1)}$ for all n. Note that this global solution is determined by marching in time with a sequence of local optimal control problems; therefore, a velocity tracking problem on a finite time interval $(0,T)$ with $T < \infty$ can be studied in the same manner by patching together only a finite number of the local optimal control solutions. In the finite time interval case, we terminate the marching in time after a finite number of time steps.

In this paper, we will analyze the long-time behavior of global solutions for the piecewise optimal control problem; define and analyze the dynamics of semidiscrete approximations; and define and analyze the dynamics of fully discrete approximations. The main results of this paper are that the $\mathbf{L}^2(\Omega)$ and $\mathbf{H}^1(\Omega)$ norms of the difference between $\mathbf{U}(t)$ and $\widehat{\mathbf{u}}(t)$ decay to zero exponentially in time, with the rates independent of the interval length δ; the same is true of the $\mathbf{L}^2(\Omega)$ and $\mathbf{H}^1(\Omega)$ norms of the difference between $\mathbf{U}(t_n)$ and $\widehat{\mathbf{u}}^n$ ($\widehat{\mathbf{u}}^n$ denotes the solution of the semidiscrete piecewise optimal control problem), modular the error due to the approximation of the time derivative; the same is also true of the $\mathbf{L}^2(\Omega)$ norm of the difference between $\mathbf{U}(t_n)$ and $\widehat{\mathbf{u}}_h^n$ ($\widehat{\mathbf{u}}_h^n$ denotes the solution of the fully discrete piecewise optimal control problem), modular the error due to the approximation of the time derivative and the error due to spatial discretizations. In short, the piecewise optimal control approach achieves the physical objective of steering $\mathbf{u}$ to $\mathbf{U}$ over time. This analytical result is also supported by the error analysis and by the computational results presented at the end of the paper.

We mention that in [HRY], further computational results of the fully discrete schemes were presented and some implementation issues were discussed. It should also be noted that the fully discrete approximation schemes bear similarities to those used in some other situations, e.g., [CTMK] for the Burgers equation and [Ra] for an electrically conducting fluid, wherein fully discrete schemes were introduced from a viewpoint different from that taken in this paper and wherein no error analysis were given.

1.2. Preliminaries. Throughout this paper, C denotes a generic constant depending only on the physical domain Ω and the viscosity constant ν. We will use the standard notations for the function spaces $L^r(\Omega)$ with the norm denoted by $\|\cdot\|_{L^r(\Omega)}$ and the Sobolev spaces $H^m(\Omega)$ with the norm denoted by $\|\cdot\|_m$. $H^0(\Omega) = L^2(\Omega)$. Also, $H_0^m(\Omega)$ is the closure of $C_0^\infty(\Omega)$ under the $\|\cdot\|_m$ norm. The dual space of $H_0^r(\Omega)$ is denoted by $H^{-r}(\Omega)$, $r > 0$. The vector-valued ($\mathbb{R}^2$-valued) counterparts of these spaces are denoted by $\mathbf{L}^r(\Omega)$, $\mathbf{H}^m(\Omega)$, $\mathbf{H}_0^m(\Omega)$, and $\mathbf{H}^{-m}(\Omega)$. For details, see [Ad] and [GR]. We introduce the solenoidal spaces

$$\mathbf{W} = \{\mathbf{u} \in \mathbf{L}^2(\Omega) \ : \ \nabla \cdot \mathbf{u} = 0, \ (\mathbf{u} \cdot \mathbf{n})|_\Gamma = 0\} \qquad \text{equipped with the } \|\cdot\|_0 \text{ norm}$$

and

$$\mathbf{V} = \{\mathbf{u} \in \mathbf{H}_0^1(\Omega) \ : \ \nabla \cdot \mathbf{u} = 0\} \qquad \text{equipped with the } \|\cdot\|_1 \text{ norm},$$

i.e., the closure of div-free, $\mathbf{C}_0^\infty(\Omega)$-functions under the $\|\cdot\|_0$ and $\|\cdot\|_1$ norms, respectively; see [GR] or [Te] for a discussion of this functional spaces. We identify the dual space of $\mathbf{W}$ with $\mathbf{W}$ itself under the $\mathbf{L}^2(\Omega)$ inner product. We will also need the following subspace of $L^2(\Omega)$:

$$L_0^2(\Omega) \stackrel{\text{def}}{=\!=} \left\{ r \in L^2(\Omega) : \int_\Omega r \, d\mathbf{x} = 0 \right\}.$$

We next introduce the temporal-spatial function spaces, defined on $\Omega \times (T_1, T_2)$ with $(T_1, T_2) \subset (0, \infty)$, $r \in [1, \infty]$, and $s \in (-\infty, \infty)$:

$$L^r\left(T_1, T_2; \mathbf{H}^s(\Omega)\right) \qquad r \in [1, \infty], \ s \in (-\infty, \infty),$$

equipped with the norm

$$\|\mathbf{u}\|_{L^r(T_1,T_2;\mathbf{H}^s(\Omega))} = \left(\int_{T_1}^{T_2} \|\mathbf{u}(t)\|_s^r \, dt \right)^{1/r}$$

and with $s \geq 1$:

$$\mathcal{H}^{(s)}\left(\Omega \times (T_1, T_2)\right) = \left\{ \mathbf{v} \in L^2\left(T_1, T_2; \mathbf{H}^s(\Omega) \cap \mathbf{H}_0^1(\Omega)\right) : \partial_t \mathbf{v} \in L^2\left(T_1, T_2; \mathbf{H}^{s-2}(\Omega)\right) \right\}$$

equipped with the norm

$$\|\mathbf{v}\|^2_{\mathcal{H}^{(s)}(\Omega\times(T_1,T_2))} = \|\mathbf{v}\|^2_{L^2(T_1,T_2;\mathbf{H}^s(\Omega))} + \|\partial_t \mathbf{v}\|^2_{L^2(T_1,T_2;\mathbf{H}^{s-2}(\Omega))}.$$

For a function $\mathbf{u}$ in a temporal-spatial space, we often use the notation

$$\mathbf{u}(t) \stackrel{\text{def}}{=\!=} \mathbf{u}(\cdot, t)$$

to stand for the restriction of $\mathbf{u}$ at time t as a function defined over the spatial domain Ω.

We introduce the simplified norm notations

$$\|\cdot\| \stackrel{\text{def}}{=\!=} \|\cdot\|_{L^2(\Omega)} \qquad \text{or} \qquad \|\cdot\| \stackrel{\text{def}}{=\!=} \|\cdot\|_{\mathbf{L}^2(\Omega)}, \tag{1.6}$$

$$|||\cdot||| \stackrel{\text{def}}{=\!=} \|\cdot\|_{L^\infty(0,\infty;\mathbf{L}^2(\Omega))}, \tag{1.7}$$

and

$$|||\cdot|||_\infty \stackrel{\text{def}}{=\!=} \|\cdot\|_{\mathbf{L}^\infty(\Omega\times(0,\infty))}. \tag{1.8}$$

Also, $(\cdot,\cdot)$ denotes the inner product on $L^2(\Omega)$ or $\mathbf{L}^2(\Omega)$ and $\langle\cdot,\cdot\rangle$ denotes the duality pairing between $\mathbf{H}_0^1(\Omega)$ and $\mathbf{H}^{-1}(\Omega)$.

To define the solution for the Navier–Stokes equations (in a weak sense), we introduce some standard continuous bilinear or trilinear forms:

$$a(\mathbf{u}, \mathbf{v}) = \nu \int_\Omega \nabla \mathbf{u} : \nabla \mathbf{v}\, d\mathbf{x} \qquad \forall\, \mathbf{u}, \mathbf{v} \in \mathbf{H}^1(\Omega),$$

$$b(\mathbf{u}, p) = -\int_\Omega p \operatorname{div} \mathbf{u}\, d\mathbf{x} \qquad \forall\, \mathbf{u} \in \mathbf{H}^1(\Omega); \forall\, p \in L^2(\Omega),$$

and

$$c(\mathbf{u}, \mathbf{v}, \mathbf{w}) = \int_\Omega (\mathbf{u}\cdot\nabla)\mathbf{v}\cdot\mathbf{w}\, d\mathbf{x} \qquad \forall\, \mathbf{u}, \mathbf{v}, \mathbf{w} \in \mathbf{H}^1(\Omega),$$

where the colon notation: denotes the inner product on $\mathbb{R}^{2\times 2}$. We have the following useful properties for the trilinear form $c(\cdot,\cdot,\cdot)$:

$$c(\mathbf{u}, \mathbf{v}, \mathbf{w}) = -c(\mathbf{u}, \mathbf{w}, \mathbf{v}) \qquad \forall\, \mathbf{u} \in \mathbf{V},\ \forall\, \mathbf{v}, \mathbf{w} \in \mathbf{H}^1(\Omega) \tag{1.9}$$

and

$$c(\mathbf{u}, \mathbf{v}, \mathbf{v}) = 0 \qquad \forall\, \mathbf{u} \in \mathbf{V},\ \forall\, \mathbf{v} \in \mathbf{H}^1(\Omega). \tag{1.10}$$

We denote by C_0 the continuity constant for the trilinear form $c(\cdot,\cdot,\cdot)$, i.e.,

$$|c(\mathbf{u}, \mathbf{v}, \mathbf{w})| \leq C_0 \|\nabla \mathbf{u}\|\, \|\nabla \mathbf{v}\|\, \|\mathbf{w}\|_{\mathbf{L}^4(\Omega)} \qquad \forall\, \mathbf{u} \in \mathbf{V},\ \forall\, \mathbf{v}, \mathbf{w} \in \mathbf{H}^1(\Omega). \tag{1.11}$$

We now give the following definitions of a solution for the Navier–Stokes equations on a finite time interval and on the infinite time interval, respectively.

DEFINITION 1.1. *Given* $(T_1, T_2) \subset (0, \infty)$ *with* $T_2 < \infty$, $\mathbf{f} \in L^2(T_1, T_2; \mathbf{H}^{-1}(\Omega))$ *and* $\boldsymbol{\xi} \in \mathbf{W}$, $(\mathbf{u}, p)$ *is said to be a solution of the Navier–Stokes equations on* (T_1, T_2) *iff* $\mathbf{u} \in \mathcal{H}^{(1)}(\Omega \times (T_1, T_2))$, $p \in L^2(T_1, T_2; L^2_0(\Omega))$, *and* $(\mathbf{u}, p)$ *satisfies*

$$\begin{aligned} \langle \partial_t \mathbf{u}(t), \mathbf{w} \rangle + a(\mathbf{u}(t), \mathbf{w}) + c(\mathbf{u}(t), \mathbf{u}(t), \mathbf{w}) + b(\mathbf{w}, p(t)) \\ = \langle \mathbf{f}(t), \mathbf{w} \rangle \qquad \forall\, \mathbf{w} \in \mathbf{H}^1_0(\Omega),\ \textit{a.e. } t \in (T_1, T_2), \end{aligned} \tag{1.12}$$

$$b(\mathbf{u}(t), r) = 0 \qquad \forall\, r \in L^2_0(\Omega),\ \textit{a.e. } t \in (T_1, T_2) \tag{1.13}$$

and

$$\lim_{t \to T_1^+} \mathbf{u}(t) = \boldsymbol{\xi} \qquad \textit{in } \mathbf{W}. \qquad \square \tag{1.14}$$

We point out that $\mathbf{u} \in \mathcal{H}^{(1)}(\Omega \times (T_1, T_2))$ implies $\mathbf{u} \in C([T_1, T_2]; \mathbf{W})$ so that (1.14) makes sense. It is well known that if (T_1, T_2) is a finite subinterval of $(0, \infty)$ and if $\mathbf{f} \in L^2\left(T_1, T_2; \mathbf{L}^2(\Omega)\right)$, then there is indeed a strong solution $\mathbf{u}$ for the Navier–Stokes equations satisfying the regularity result $\mathbf{u} \in \mathbf{L}^2(T_1, T_2; \mathbf{H}^1_0(\Omega)) \cap L^2(T_1 + \varepsilon, T_2; \mathbf{H}^2(\Omega))$ and $\mathbf{u}_t \in L^2(T_1 + \varepsilon, T_2; \mathbf{W})$ for all $\varepsilon > 0$. Furthermore, if $\boldsymbol{\xi} \in \mathbf{V}$, then $\mathbf{u} \in C([T_1, T_2]; \mathbf{V}) \cap L^2(T_1, T_2; \mathbf{H}^2(\Omega))$ (see [CF] and [Te]).

For $T = \infty$, we define a solution for the Navier–Stokes equations as follows.

DEFINITION 1.2. *Given* $\boldsymbol{\xi} \in \mathbf{W}$ *and* $\mathbf{f} \in L^2(0, T'; \mathbf{H}^{-1}(\Omega))$ *for all* $T' > 0$, $(\mathbf{u}, p)$ *is said to be a solution of the Navier–Stokes equations on* $(0, \infty)$ *iff* $\mathbf{u} \in L^\infty(0, \infty; \mathbf{W})$ *and* $(\mathbf{u}, p)$ *is a solution of the Navier–Stokes equations on* $(0, T')$ *for all* $T' > 0$. $\square$

We now turn to the definition of the piecewise optimal control problem. We introduce the (local) functional

$$\mathcal{J}_{(T_1, T_2)}(\mathbf{u}, \mathbf{f}) = \frac{\alpha}{2} \int_{T_1}^{T_2} \int_\Omega |\mathbf{u} - \mathbf{U}|^2 \, d\mathbf{x}\, dt + \frac{\beta}{2} \int_{T_1}^{T_2} \int_\Omega |\mathbf{f} - \mathbf{F}|^2 \, d\mathbf{x}\, dt. \tag{1.15}$$

We choose the fixed body force $\mathbf{F}$ as

$$\mathbf{F} = \mathbf{N}(\mathbf{U}) \stackrel{\text{def}}{=\!=} \partial_t \mathbf{U} - \nu \Delta \mathbf{U} + (\mathbf{U} \cdot \nabla)\mathbf{U}. \tag{1.16}$$

We make the following regularity assumptions on the prescribed data $\mathbf{U}$ and $\mathbf{F}$:

$$\text{(A1)} \qquad \begin{cases} \mathbf{U} = \mathbf{U}(\mathbf{x}, t) \in C\left([0, \infty); \mathbf{H}^2(\Omega) \cap \mathbf{H}^1_0(\Omega)\right) \cap L^\infty\left(0, \infty; \mathbf{H}^2(\Omega)\right), \\ \operatorname{div} \mathbf{U} = 0, \\ \mathbf{F} = \mathbf{N}(\mathbf{U}) \in L^\infty\left(0, \infty; \mathbf{L}^2(\Omega)\right). \end{cases}$$

We define the (local) admissible elements as follows.

DEFINITION 1.3. *Let* $(T_1, T_2) \subset (0, \infty)$ *with* $T_2 < \infty$ *and* $\boldsymbol{\xi} \in \mathbf{W}$ *be given. A triplet* $(\mathbf{u}, p, \mathbf{f})$ *is said to be an admissible element on* (T_1, T_2) *if* $\mathbf{u} \in \mathcal{H}^{(1)}(\Omega \times (T_1, T_2))$, $p \in L^2\left(T_1, T_2; L^2_0(\Omega)\right)$, $\mathbf{f} \in L^2\left(T_1, T_2; \mathbf{L}^2(\Omega)\right)$, *and* $(\mathbf{u}, p, \mathbf{f})$ *satisfies* (1.12)–(1.14). *The set of all admissible elements on* (T_1, T_2) *is denoted by* $\mathcal{V}_{\text{ad}}(T_1, T_2, \boldsymbol{\xi})$. $\square$

We are now prepared to state precisely the piecewise optimal control problem to be studied in this paper.

- Choose $\delta > 0$ sufficiently small, and set $t_n = n\delta$ for $n = 0, 1, 2, \ldots$.
- Set $\widehat{\mathbf{u}}^{(0)}(0) \stackrel{\text{def}}{=\!=} \mathbf{u}_0$.
- For $n = 0, 1, 2, \ldots$, find $(\widehat{\mathbf{u}}^{(n+1)}, \widehat{p}^{(n+1)}, \widehat{\mathbf{f}}^{(n+1)}) \in \mathcal{V}_{\text{ad}}(t_n, t_{n+1}, \widehat{\mathbf{u}}^{(n)}(\cdot, t_n))$ such that

$$\mathcal{J}_{(t_n, t_{n+1})}(\widehat{\mathbf{u}}^{(n+1)}, \widehat{\mathbf{f}}^{(n+1)}) \le \mathcal{J}_{(t_n, t_{n+1})}(\mathbf{u}, \mathbf{f})$$

  for all admissible elements $(\mathbf{u}, p, \mathbf{f}) \in \mathcal{V}_{\text{ad}}(t_n, t_{n+1}, \widehat{\mathbf{u}}^{(n)}(\cdot, t_n))$.

The global optimal solution $(\widehat{\mathbf{u}}, \widehat{p}, \widehat{\mathbf{f}})$ is defined as in section 1.1 by patching together local optimal solutions $(\widehat{\mathbf{u}}^{(n+1)}, \widehat{p}^{(n+1)}, \widehat{\mathbf{f}}^{(n+1)})$.

We terminate this section with some useful inequalities. The first inequality is the Poincaré inequality

$$\|\nabla \mathbf{w}\|^2 \geq \lambda_1 \|\mathbf{w}\|^2 \qquad \forall\, \mathbf{w} \in \mathbf{H}_0^1(\Omega), \tag{1.17}$$

where $\lambda_1 > 0$ is the greatest real number such that (1.17) holds. The second inequality is connected with the Leray operator

$$\Pi : \mathbf{L}^2(\Omega) \to \mathbf{W} \tag{1.18}$$

(i.e., the orthogonal projection with respect to the $\mathbf{L}^2(\Omega)$ norm). It is well known (see [CF]) that there is a constant $C_\Pi > 0$ depending only on Ω such that

$$C_\Pi \|\mathbf{w}\|_2 \leq \|\Pi \Delta \mathbf{w}\| \leq \|\mathbf{w}\|_2 \qquad \forall\, \mathbf{w} \in \mathbf{H}^2(\Omega) \cap \mathbf{V}\,. \tag{1.19}$$

In other words, $\|\Pi\Delta \cdot \|$ is equivalent to the $\mathbf{H}^2(\Omega)$ norm on $\mathbf{H}^2(\Omega) \cap \mathbf{V}$.

2. Dynamics of the piecewise optimal control problem. We now study the dynamics of the piecewise optimal control problem stated in the last section. We point out that for each n, the existence of an optimal solution was established in [Fu1], [Fu2], [Fu3], and [Li] (see also [AT]) for finite time interval and in [HY] for infinite time interval. Recall from our physical objective that we wish the optimal solution $\widehat{\mathbf{u}}$ to match $\mathbf{U}$ over time; i.e., we wish $\|\widehat{\mathbf{u}}(t) - \mathbf{U}(t)\| \to 0$ and $\|\nabla \widehat{\mathbf{u}}(t) - \nabla \mathbf{U}(t)\| \to 0$ as $t \to \infty$. Such decay properties are established in [HY] for the solutions of the infinite-time optimal control problem. We will prove in this paper that these decay properties are true for the solutions of the piecewise optimal control problem, and, more importantly, the decay rates are exponential.

For technical reasons, we will need the following assumption:

$$\|\mathbf{U}\|_{L^\infty(0,\infty;\mathbf{L}^4(\Omega))} \leq \frac{\nu}{2C_0}, \tag{A2}$$

where C_0 is the constant in (1.11).

PROPOSITION 2.1. *Assume that* (A1) *and* (A2) *hold. Then for any* T_1 *and* T_2 *with* $0 \leq T_1 < T_2$ *and any* $\boldsymbol{\xi} \in \mathbf{W}$,

$$\begin{aligned} \inf_{(\mathbf{u},p,\mathbf{f}) \in \mathcal{V}_{\rm ad}(T_1,T_2,\boldsymbol{\xi})} \mathcal{J}_{(T_1,T_2)}(\mathbf{u},\mathbf{f}) &\leq \frac{\alpha \|\boldsymbol{\xi} - \mathbf{U}(T_1)\|^2}{\nu\lambda_1} \left(1 - e^{-\nu\lambda_1 (T_2 - T_1)/2}\right) \\ &\leq \frac{\alpha(T_2 - T_1)}{2} \|\boldsymbol{\xi} - \mathbf{U}(T_1)\|^2, \end{aligned} \tag{2.1}$$

where $\lambda_1 > 0$ *is the Poincaré constant defined by* (1.17).

Proof. Let $(\widetilde{\mathbf{u}}, \widetilde{p}) \in \mathcal{H}^{(1)}((T_1,T_2)\times\Omega) \times L^2(T_1,T_2;L_0^2(\Omega))$ be the solution of

$$\begin{aligned} &\langle \partial_t \widetilde{\mathbf{u}}(t), \mathbf{w}\rangle + a(\widetilde{\mathbf{u}}(t),\mathbf{w}) + c(\widetilde{\mathbf{u}}(t),\widetilde{\mathbf{u}}(t),\mathbf{w}) + b(\mathbf{w},\widetilde{p}(t)) \\ &\qquad\qquad = (\mathbf{F}(t),\mathbf{w}) \qquad \forall\, \mathbf{w} \in \mathbf{H}_0^1(\Omega),\ \text{a.e. } t \in (T_1,T_2)\,, \\ &b(\widetilde{\mathbf{u}}(t), r) = 0 \qquad \forall\, r \in L_0^2(\Omega),\ \text{a.e. } t \in (T_1,T_2), \end{aligned}$$

and

$$\lim_{t \to T_1^+} \widetilde{\mathbf{u}}(t) = \boldsymbol{\xi} \qquad \text{in } \mathbf{W}\,.$$

Let $\widetilde{\mathbf{f}} \stackrel{\text{def}}{=\!=} \mathbf{F}$. Then $(\widetilde{\mathbf{u}}, \widetilde{p}, \widetilde{\mathbf{f}}) \in \mathcal{V}_{ad}(T_1, T_2, \boldsymbol{\xi})$. Setting $\widetilde{\mathbf{v}} = \widetilde{\mathbf{u}} - \mathbf{U}$, we obtain

$$\begin{aligned} &\langle \partial_t \widetilde{\mathbf{v}}(t), \mathbf{w} \rangle + a\left(\widetilde{\mathbf{v}}(t), \mathbf{w}\right) + c\left(\widetilde{\mathbf{v}}(t), \widetilde{\mathbf{v}}(t), \mathbf{w}\right) + c\left(\mathbf{U}(t), \widetilde{\mathbf{v}}(t), \mathbf{w}\right) \\ &\qquad + c\left(\widetilde{\mathbf{v}}(t), \mathbf{U}(t), \mathbf{w}\right) + b\left(\mathbf{w}, \widetilde{q}(t)\right) = 0 \qquad \forall\, \mathbf{w} \in \mathbf{H}_0^1(\Omega), \text{ a.e. } t \in (T_1, T_2)\,, \end{aligned} \tag{2.2}$$

$$b\left(\widetilde{\mathbf{v}}(t), r\right) = 0 \qquad \forall\, r \in L_0^2(\Omega), \text{ a.e. } t \in (T_1, T_2), \tag{2.3}$$

and

$$\lim_{t \to T_1^+} \widetilde{\mathbf{v}}(t) = \boldsymbol{\xi} - \mathbf{U}(\cdot, T_1) \qquad \text{in } \mathbf{W}\,. \tag{2.4}$$

By setting $\mathbf{w} = \widetilde{\mathbf{v}}$ in (2.2), we have that

$$\frac{1}{2}\frac{d}{dt}\left\|\widetilde{\mathbf{v}}(t)\right\|^2 + \nu\left\|\nabla\widetilde{\mathbf{v}}(t)\right\|^2 + c\left(\widetilde{\mathbf{v}}(t), \mathbf{U}(t), \widetilde{\mathbf{v}}(t)\right) = 0. \tag{2.5}$$

By (1.9) and (1.11),

$$\left|c\left(\widetilde{\mathbf{v}}(t), \mathbf{U}(t), \widetilde{\mathbf{v}}(t)\right)\right| \le C_0 \|\mathbf{U}(t)\|_{\mathbf{L}^4(\Omega)} \cdot \left\|\nabla\widetilde{\mathbf{v}}(t)\right\|^2\,. \tag{2.6}$$

Then, from (2.5) and (2.6), we have that

$$\frac{1}{2}\frac{d}{dt}\left\|\widetilde{\mathbf{v}}(t)\right\|^2 + \left(\nu - C_0\|\mathbf{U}(t)\|_{L^\infty(0,\infty;\mathbf{L}^4(\Omega))}\right)\left\|\nabla\widetilde{\mathbf{v}}(t)\right\|^2 \le 0.$$

Since (A2) implies $\nu - C_0\|\mathbf{U}(t)\|_{L^\infty(0,\infty;\mathbf{L}^4(\Omega))} \ge \frac{\nu}{2}$, we see that

$$\frac{d}{dt}\left\|\widetilde{\mathbf{v}}(t)\right\|^2 + \frac{\nu}{2}\left\|\nabla\widetilde{\mathbf{v}}(t)\right\|^2 \le 0.$$

Applying the Poincaré inequality and then Gronwall's inequality, we obtain

$$\left\|\widetilde{\mathbf{v}}(t)\right\|^2 \le \left\|\widetilde{\mathbf{v}}(T_1)\right\|^2 \cdot e^{-\nu\lambda_1(t-T_1)/2} = \left\|\boldsymbol{\xi} - \mathbf{U}(T_1)\right\|^2 \cdot e^{-\nu\lambda_1(t-T_1)/2}. \tag{2.7}$$

Hence,

$$\begin{aligned} \mathcal{J}_{(T_1,T_2)}(\widetilde{\mathbf{u}}, \widetilde{\mathbf{f}}) &= \frac{\alpha}{2}\int_{T_1}^{T_2}\left\|\widetilde{\mathbf{v}}(t)\right\|^2 dt \le \frac{\alpha}{2}\left\|\boldsymbol{\xi} - \mathbf{U}(T_1)\right\|^2 \int_{T_1}^{T_2} e^{-\nu\lambda_1(t-T_1)/2}\, dt \\ &= \frac{\alpha\|\boldsymbol{\xi} - \mathbf{U}(T_1)\|^2}{\nu\lambda_1}\left(1 - e^{-\nu\lambda_1(T_2-T_1)/2}\right) \le \frac{\alpha}{2}(T_2 - T_1)\|\boldsymbol{\xi} - \mathbf{U}(T_1)\|^2, \end{aligned}$$

where we have used the fact that $1 - e^{-y} \le y$ for all $y \in [0, \infty)$. This completes the proof. ∎

LEMMA 2.2. *Let η, σ, and γ be positive numbers satisfying $\gamma < 1$ and $\sigma \le \eta$. Then there is a constant $\delta_0 > 0$ such that*

$$0 < \varphi(s) \stackrel{\text{def}}{=\!=} e^{-\eta s} + \gamma\left(1 - e^{-\sigma s}\right) < 1 \qquad \textit{for } s \in (0, \delta_0).$$

Proof. Note that $\varphi(0) = 1$ and $\varphi'(0) = -\eta + \gamma\sigma < 0$. Thus the lemma follows by elementary calculus. ∎

We are now prepared to show that $\|\mathbf{u}(t_n) - \mathbf{U}(t_n)\|$ is monotonically decreasing.

THEOREM 2.3. *Assume that* (A1) *and* (A2) *hold. Assume further that*

$$\frac{\alpha}{\beta} < \left(\frac{\nu\lambda_1}{2}\right)^2. \tag{A3}$$

Then there are constants

$$\delta_0 = \delta_0(\nu, \Omega) > 0,$$

$$\mu = \mu(\nu, \Omega) \in (0, 1),$$

and

$$M_1 = M_1(\nu, \Omega) > 0$$

such that if $T_2 - T_1 \le \delta_0$ *and* $(\mathbf{u}, p, \mathbf{f}) \in \mathcal{V}_{ad}(T_1, T_2, \boldsymbol{\xi})$ *satisfies*

$$\mathcal{J}_{(T_1,T_2)}(\mathbf{u}, \mathbf{f}) \le \mathcal{J}_{(T_1,T_2)}(\mathbf{w}, \mathbf{k}) \qquad \forall\, (\mathbf{w}, r, \mathbf{k}) \in \mathcal{V}_{\mathrm{ad}}(T_1, T_2; \boldsymbol{\xi})$$

(*i.e.,* $(\mathbf{u}, p, \mathbf{f})$ *is an optimal solution on* (T_1, T_2))*, then the terminal state* $\mathbf{u}(T_2)$ *satisfies*

$$\|\mathbf{u}(T_2) - \mathbf{U}(T_2)\|^2 \le \mu \|\mathbf{u}(T_1) - \mathbf{U}(T_1)\|^2$$

and the intermediate state $\mathbf{u}(t)$ *satisfies*

$$\|\mathbf{u}(t) - \mathbf{U}(t)\|^2 \le M_1 \|\mathbf{u}(T_1) - \mathbf{U}(T_1)\|^2 \qquad \forall\, t \in [T_1, T_2].$$

Proof. As usual we set $\mathbf{v} = \mathbf{u} - \mathbf{U}$ and $\mathbf{g} = \mathbf{f} - \mathbf{F}$; then $(\mathbf{v}, p, \mathbf{g})$ satisfies

$$\begin{aligned} &\langle \partial_t \mathbf{v}, \mathbf{w}\rangle + c(\mathbf{v}, \mathbf{v}, \mathbf{w}) + c(\mathbf{U}, \mathbf{v}, \mathbf{w}) + c(\mathbf{v}, \mathbf{U}, \mathbf{w}) \\ &\qquad + a(\mathbf{v}, \mathbf{w}) + b(\mathbf{w}, p) = (\mathbf{g}, \mathbf{w}) \qquad \forall \mathbf{w} \in \mathbf{H}_0^1(\Omega), \quad \text{a.e. } t \in (T_1, T_2) \end{aligned} \tag{2.2a}$$

and (2.3), (2.4). Setting $\mathbf{w} = \mathbf{v}$ in (2.2a) and using (A2), (1.11), and Young's inequality, we have

$$\begin{aligned} \frac{1}{2}\frac{d}{dt}\|\mathbf{v}(t)\|^2 + \nu \|\nabla \mathbf{v}(t)\|^2 &\le C_0 \|\mathbf{U}(t)\|_{\mathbf{L}^4(\Omega)} \cdot \|\nabla \mathbf{v}(t)\|^2 + \|\mathbf{v}(t)\| \cdot \|\mathbf{g}(t)\| \\ &\le \frac{\nu}{2}\|\nabla \mathbf{v}(t)\|^2 + \frac{1}{2\sqrt{\alpha\beta}}\left(\alpha \|\mathbf{v}(t)\|^2 + \beta \|\mathbf{g}(t)\|^2\right), \end{aligned}$$

so that by applying the Poincaré inequality,

$$\begin{aligned} \frac{d}{dt}\|\mathbf{v}(t)\|^2 + \nu\lambda_1 \|\mathbf{v}(t)\|^2 &\le \frac{d}{dt}\|\mathbf{v}(t)\|^2 + \nu \|\nabla \mathbf{v}(t)\|^2 \\ &\le \frac{1}{\sqrt{\alpha\beta}}\left(\alpha \|\mathbf{v}(t)\|^2 + \beta \|\mathbf{g}(t)\|^2\right). \end{aligned} \tag{2.8}$$

Multiplying both sides of the last equation by $e^{\nu\lambda_1(t-T_1)}$ and integrating over (T_1, t),

$$\|\mathbf{v}(t)\|^2 e^{\nu\lambda_1 t} - \|\mathbf{v}(T_1)\|^2 e^{\nu\lambda_1 T_1} \le \frac{1}{\sqrt{\alpha\beta}} \int_{T_1}^{t} \left(\alpha \|\mathbf{v}(s)\|^2 + \beta \|\mathbf{g}(s)\|^2\right) e^{\nu\lambda_1 s} ds$$

or

$$\begin{aligned} &\|\mathbf{v}(t)\|^2 - \|\mathbf{v}(T_1)\|^2 e^{-\nu\lambda_1(t-T_1)} \\ &\qquad \le \frac{1}{\sqrt{\alpha\beta}} \int_{T_1}^{t} \left(\alpha \|\mathbf{v}(s)\|^2 + \beta \|\mathbf{g}(s)\|^2\right) e^{-\nu\lambda_1(t-s)} ds \\ &\qquad \le \frac{1}{\sqrt{\alpha\beta}} \int_{T_1}^{t} \left(\alpha \|\mathbf{v}(s)\|^2 + \beta \|\mathbf{g}(s)\|^2\right) ds \le \frac{2}{\sqrt{\alpha\beta}} \mathcal{J}_{(T_1,T_2)}(\mathbf{u}, \mathbf{f}). \end{aligned} \tag{2.9}$$

We obtain, upon applying Proposition 2.1,

$$\begin{aligned}\|\mathbf{v}(t)\|^2 &\le \|\mathbf{v}(T_1)\|^2 e^{-\nu\lambda_1(t-T_1)} + \frac{2}{\sqrt{\alpha\beta}}\cdot \mathcal{J}_{(T_1,T_2)}(\mathbf{u},\mathbf{f}) \\ &\le \|\mathbf{v}(T_1)\|^2 \left(e^{-\nu\lambda_1(t-T_1)} + \frac{2}{\nu\lambda_1}\sqrt{\frac{\alpha}{\beta}}\cdot\left(1-e^{-\nu\lambda_1(T_2-T_1)/2}\right)\right).\end{aligned} \tag{2.10}$$

Set

$$\eta \stackrel{\text{def}}{=\!=} \nu\lambda_1, \quad \sigma \stackrel{\text{def}}{=\!=} \nu\lambda_1/2, \quad \gamma \stackrel{\text{def}}{=\!=} \frac{2}{\nu\lambda_1}\sqrt{\frac{\alpha}{\beta}},$$
$$\delta \stackrel{\text{def}}{=\!=} T_2 - T_1 \quad \text{and} \quad \varphi(r) \stackrel{\text{def}}{=\!=} e^{-\eta r} + \gamma(1-e^{-\sigma\delta}) \ \ \forall r \in [0,\delta].$$

Then (2.10) can be rewritten as

$$\|\mathbf{v}(t)\|^2 \le \|\mathbf{v}(T_1)\|^2 \varphi(t-T_1) \qquad \forall\, t \in [T_1,T_2]\,.$$

Clearly, $\varphi(r) \le 1+\gamma$ for all $r \in [0,\delta]$ so that by setting $M_1 = 1+\gamma$, $\|\mathbf{v}(t)\|^2 \le M_1\|\mathbf{v}(T_1)\|^2$ for all $t \in [T_1,T_2]$. Moreover, by (A2) and (A3), the conditions of Lemma 2.2 are satisfied. Thus it follows from Lemma 2.2 that there exists a $\delta_0 > 0$ such that $0 < \varphi(\delta) < 1$ if $\delta \in (0,\delta_0]$ and, in particular,

$$\mu \stackrel{\text{def}}{=\!=} \varphi(T_2 - T_1) < 1.$$

Hence $\|\mathbf{v}(T_2)\|^2 \le \mu\|\mathbf{v}(T_1)\|^2$. □

Set $\widehat{\mathbf{u}}^{(0)}(0) = \mathbf{u}_0$ and fix $\delta \in (0,\delta_0]$, where δ_0 is as in Theorem 2.3. For $n = 0,1,2,\dots$, let $t_n = n\delta$ and $(\widehat{\mathbf{u}}^{(n+1)}, \widehat{p}^{(n+1)}, \widehat{\mathbf{f}}^{(n+1)}) \in \mathcal{V}_{\text{ad}}(t_n, t_{n+1}, \widehat{\mathbf{u}}^{(n)}(t_n))$ be the optimizer minimizing $\mathcal{J}_{(t_n,t_{n+1})}(\mathbf{u},\mathbf{f})$ over $\mathcal{V}_{\text{ad}}(t_n,t_{n+1},\widehat{\mathbf{u}}^{(n)}(t_n))$. Define $(\widehat{\mathbf{u}},\widehat{p},\widehat{\mathbf{f}})$ by

$$\begin{aligned}&\widehat{\mathbf{u}}(\mathbf{x},t) = \widehat{\mathbf{u}}^{(n+1)}(\mathbf{x},t), \qquad \widehat{p}(\mathbf{x},t) = \widehat{p}^{(n+1)}(\mathbf{x},t), \\ &\text{and} \quad \widehat{\mathbf{f}}(\mathbf{x},t) = \widehat{\mathbf{f}}^{(n+1)}(\mathbf{x},t) \qquad \text{for } t \in [t_n,t_{n+1})\ \forall\, n\,.\end{aligned} \tag{2.11}$$

We can easily verify that $(\widehat{\mathbf{u}},\widehat{p})$ gives a solution of the Navier–Stokes equations (with a forcing term $\widehat{\mathbf{f}}$) on the infinite time interval $(0,\infty)$ in the sense of Definition 1.2.

PROPOSITION 2.4. *Assume that the hypotheses of Theorem* 2.3 *hold. Let* η, σ, γ, δ_0, *and* $\mu = e^{-\eta\delta} + \gamma(1-e^{-\sigma\delta})$ *be as in Theorem* 2.3 *with* $\delta \le \delta_0$. *Then* $(\widehat{\mathbf{u}},\widehat{p},\widehat{\mathbf{f}})$ *constructed in* (2.11) *satisfies*

$$\widehat{\mathbf{u}} \in C([0,\infty);\mathbf{W}) \tag{2.12}$$

and

$$\mathcal{J}_{(t_n,\infty)}(\widehat{\mathbf{u}},\widehat{\mathbf{f}}) \le \frac{\alpha\delta}{2(1-\mu)}\cdot\|\mathbf{u}_0-\mathbf{U}_0\|^2\cdot\mu^n, \qquad n = 0,1,2,\dots. \tag{2.13}$$

In particular,

$$\mathcal{J}_{(0,\infty)}(\widehat{\mathbf{u}},\widehat{\mathbf{f}}) \le \frac{\alpha\delta}{2(1-\mu)}\cdot\|\mathbf{u}_0-\mathbf{U}_0\|^2$$

and

$$\widehat{\mathbf{u}} - \mathbf{U} \in L^2(0,\infty;\mathbf{W}) \qquad \textit{and} \qquad \widehat{\mathbf{f}} - \mathbf{F} \in L^2(0,\infty;\mathbf{W}).$$

Proof. By the classical results for the Navier–Stokes equations (see [Te]) we have that $\widehat{\mathbf{u}}|_{(t_n,t_{n+1})} = \widehat{\mathbf{u}}^{(n+1)} \in C([t_n, t_{n+1}]; \mathbf{W})$ for each $n \geq 0$. The initial conditions $\widehat{\mathbf{u}}^{(n+1)}(t_n) = \widehat{\mathbf{u}}^{(n)}(t_n)$ guarantee the continuity of $\widehat{\mathbf{u}}$ at each t_n in $\mathbf{W}$. Hence, (2.12) is proven.

Applying Proposition 2.1 and Theorem 2.3, we obtain

$$\begin{aligned}\mathcal{J}_{(t_n,t_{n+1})}(\widehat{\mathbf{u}},\widehat{\mathbf{f}}) &\leq \mathcal{J}_{(t_n,t_{n+1})}(\widetilde{\mathbf{u}}^{(n+1)},\widetilde{\mathbf{f}}^{(n+1)}) \\ &\leq \frac{\alpha}{\nu\lambda_1}\left(1-e^{-\nu\lambda_1\delta/2}\right)\cdot\left\|\widehat{\mathbf{u}}^{(n)}(t_n)-\mathbf{U}(t_n)\right\|^2 \\ &\leq \frac{\alpha}{\nu\lambda_1}\left(1-e^{-\nu\lambda_1\delta/2}\right)\cdot\mu^n\left\|\mathbf{u}_0-\mathbf{U}_0\right\|^2.\end{aligned}$$

Hence

$$\mathcal{J}_{(t_n,\infty)}(\widehat{\mathbf{u}},\widehat{\mathbf{f}}) = \sum_{m=n}^{\infty}\mathcal{J}_{(t_m,t_{m+1})}(\widehat{\mathbf{u}},\widehat{\mathbf{f}}) \leq \frac{\alpha\left(1-e^{-\nu\lambda_1\delta/2}\right)}{\nu\lambda_1(1-\mu)}\cdot\left\|\mathbf{u}_0-\mathbf{U}_0\right\|^2\cdot\mu^n.$$

When $n=0$, this reduces to

$$\mathcal{J}_{(0,\infty)}(\widehat{\mathbf{u}},\widehat{\mathbf{f}}) \leq \frac{\alpha\delta}{2(1-\mu)}\cdot\|\mathbf{u}_0-\mathbf{U}_0\|^2,$$

which in turn implies (from the definition of $\mathcal{J}_{(0,\infty)}$) that

$$\widehat{\mathbf{u}}-\mathbf{U}\in L^2(0,\infty;\mathbf{W}) \qquad \text{and} \qquad \widehat{\mathbf{f}}-\mathbf{F}\in L^2(0,\infty;\mathbf{W}). \qquad \square$$

Remark 2.5. As a consequence of Lemma 2.2 and Theorem 2.3 we note that when $0<\delta\ll 1$, $\mu=\varphi(\delta)=e^{-\eta\delta}+\gamma\left(1-e^{-\sigma\delta}\right)=1-(\eta-\gamma\sigma)\delta+O\left(\delta^2\right)$ so that

$$\mathcal{J}_{(0,\infty)}(\widehat{\mathbf{u}},\widehat{\mathbf{f}}) \leq \frac{\alpha\|\mathbf{u}_0-\mathbf{U}_0\|^2}{2(\eta-\gamma\sigma)}+O(\delta).$$

Hence $\mathcal{J}_{(0,\infty)}(\widehat{\mathbf{u}},\widehat{\mathbf{f}})$ remains bounded as $\delta\to 0^+$. $\square$

LEMMA 2.6. *Suppose that a function $\psi(t)$ defined on $[0,\infty)$ is nonnegative and that there exist constants $\mu\in(0,1)$, $M_1>0$ and $\delta\in(0,\infty)$ such that*

$$\psi(n\delta)\leq\mu\psi\left((n-1)\delta\right), \qquad n=1,2,\ldots$$

and

$$\psi(s)\leq M_1\psi(n\delta) \qquad \forall\, s\in[n\delta,(n+1)\delta),\ n=0,1,2,\ldots.$$

Then

$$\psi(t)\leq M_2\, e^{-\kappa t} \qquad \forall\, t\in[0,\infty),$$

where

$$M_2 \stackrel{\text{def}}{=\!=} \frac{M_1}{\mu}\psi(0)\geq 0 \qquad \textit{and} \qquad \kappa \stackrel{\text{def}}{=\!=} \frac{-\ln\mu}{\delta}>0.$$

Proof. We can verify by induction that $\psi(n\delta)\leq\mu^n\psi(0)$. Then for each $t\in[0,\infty)$, there is a unique integer n such that $n\delta\leq t\leq(n+1)\delta$, which yields

$$\begin{aligned}\psi(t) &\leq M_1\psi(n\delta)\leq M_1\mu^n\psi(0)=M_1\psi(0)e^{n\ln\mu} \\ &= M_1\psi(0)e^{(n\delta-t)(\ln\mu)/\delta}\cdot e^{t(\ln\mu)/\delta}\leq\left[M_1\psi(0)e^{-\ln\mu}\right]\cdot e^{t(\ln\mu)/\delta}=M_2e^{-\kappa t}. \qquad \square\end{aligned}$$

THEOREM 2.7. *Assume that the conditions of Theorem* 2.3 *hold and let* δ_0 *and* μ *be as defined in Theorem* 2.3 *and* $\delta \le \delta_0$. *Then* $\|\widehat{\mathbf{u}}(t) - \mathbf{U}(t)\|$ *decays exponentially:*

$$\|\widehat{\mathbf{u}}(t) - \mathbf{U}(t)\|^2 \le M_3 \|\mathbf{u}_0 - \mathbf{U}_0\|^2 e^{-\kappa t}, \tag{2.14}$$

where

$$M_3 = M_3(\nu, \Omega) \stackrel{\text{def}}{=\!=} \frac{M_1}{\mu} \quad \textit{and} \quad \kappa = M_3(\nu, \Omega) \stackrel{\text{def}}{=\!=} -\frac{\ln \mu}{\delta}.$$

Proof. (2.14) is a direct consequence of Theorem 2.3 and Lemma 2.6. ∎

Remark 2.8. By Theorems 2.3 and 2.7 together with (A2), we see that when $0 < \delta \ll 1$,

$$M_3 = \frac{1+\gamma}{1+O(\delta)} = 1 + \frac{2}{\nu\lambda_1}\sqrt{\frac{\alpha}{\beta}} + O(\delta) \le 2 + O(\delta)$$

and

$$\kappa = \frac{-\ln \mu}{\delta} = \frac{-\ln\left[1 - (\eta - \gamma\sigma)\delta + O\left(\delta^2\right)\right]}{\delta} = (1 - \gamma/2)\nu\lambda_1 + O(\delta);$$

both remain bounded as $\delta \to 0^+$. ∎

To prove the exponential decay property of $\|\nabla\mathbf{u}(t) - \nabla\mathbf{U}(t)\|$, we study the local behavior of the optimizer $(\widehat{\mathbf{u}}^{(n+1)}, \widehat{p}^{(n+1)}, \widehat{\mathbf{f}}^{(n+1)})$ defined by (2.11). We need to assume the following global regularity on the desired flow $\mathbf{U}$:

$$\sup_{t\in(0,\infty)} \|\nabla\mathbf{U}(t)\|_{\mathbf{L}^\infty(\Omega)} < \infty. \tag{A4}$$

Also, it follows from (A1) and the continuous embedding $\mathbf{H}^2(\Omega) \hookrightarrow \mathbf{L}^\infty(\Omega)$ that

$$\sup_{t\in(0,\infty)} \|\mathbf{U}(t)\|_{\mathbf{L}^\infty(\Omega)} < \infty\,.$$

LEMMA 2.9. *Suppose that the conditions of Theorem* 2.7 *and* (A4) *hold. Denote by* $\widehat{\mathbf{v}} = \widehat{\mathbf{u}} - \mathbf{U}$ *and* $\widehat{\mathbf{g}} = \widehat{\mathbf{f}} - \mathbf{F}$. *Then*

$$\nu \int_{t_n}^{\infty} \|\nabla\widehat{\mathbf{v}}(t)\|^2 dt \le \|\widehat{\mathbf{v}}^{(n)}(t_n)\|^2 + \frac{1}{\sqrt{\alpha\beta}}\mathcal{J}_{(t_n,\infty)}(\widehat{\mathbf{u}}, \widehat{\mathbf{f}})\,. \tag{2.15}$$

Also, there exist constants $C_1, C_2 > 0$ *such that for* δ *as in Theorem* 2.7,

$$\begin{aligned} &\|\nabla\widehat{\mathbf{v}}(T_2)\|^2 \exp\left\{-C_2\|\widehat{\mathbf{v}}(t_{n_0})\|^2 \int_{t_{n_0}}^{T_2} \|\nabla\widehat{\mathbf{v}}(s)\|^2 ds\right\} \\ &\qquad - \|\nabla\widehat{\mathbf{v}}(T_1)\|^2 \exp\left\{-C_2\|\widehat{\mathbf{v}}(t_{n_0})\|^2 \int_{t_{n_0}}^{T_1} \|\nabla\widehat{\mathbf{v}}(s)\|^2 ds\right\} \\ &\le C_1 \int_{T_1}^{T_2} \left(\|\nabla\widehat{\mathbf{v}}(s)\|^2 + \|\widehat{\mathbf{g}}(s)\|^2\right) \exp\left\{-C_2\|\widehat{\mathbf{v}}(t_{n_0})\|^2 \int_{t_{n_0}}^{s} \|\nabla\widehat{\mathbf{v}}(\sigma)\|^2 d\sigma\right\} ds \end{aligned} \tag{2.16}$$

for all $[T_1, T_2] \subset [t_n, t_{n+1}]$ *if* $n \ge 1$ *or* $[T_1, T_2] \subset (t_0, t_1]$. *Here, in* (2.16), $t_{n_0} \le T_1$ *is arbitrarily fixed.*

Proof. Note that for $t \in (t_n, t_{n+1})$, $(\widehat{\mathbf{u}}(t), \widehat{\mathbf{f}}(t)) = (\widehat{\mathbf{u}}^{(n+1)}(t), \widehat{\mathbf{f}}^{(n+1)}(t))$ and $(\widehat{\mathbf{v}}^{(n+1)}(t), \widehat{\mathbf{f}}^{(n+1)}(t)) = (\widehat{\mathbf{u}}^{(n+1)}(t) - \mathbf{U}(t), \widehat{\mathbf{f}}^{(n+1)}(t) - \mathbf{F}(t))$. For each $j \geq n$, integrating the second inequality of (2.8), we obtain

$$\|\mathbf{v}(t_{j+1})\|^2 - \|\mathbf{v}(t_j)\|^2 \leq \frac{1}{\sqrt{\alpha\beta}} \int_{t_j}^{t_{j+1}} \left(\alpha \|\mathbf{v}(s)\|^2 + \beta \|\mathbf{g}(s)\|^2\right) ds \qquad \forall j \geq n.$$

Summing over $j \geq n$, we obtain (2.15).

By classical arguments (see [Te] and [CF]), the weak form (2.2a) implies that $(\mathbf{v}, p, \mathbf{g})$ satisfies the strong form

$$\partial_t \mathbf{v} - \Delta \mathbf{v} + (\mathbf{v} \cdot \nabla)\mathbf{v} + (\mathbf{U} \cdot \nabla)\mathbf{v} + (\mathbf{v} \cdot \nabla)\mathbf{U} + \nabla p = \mathbf{g} \qquad \text{a.e. } t \in (T_1, T_2). \tag{2.17}$$

Taking the inner product of (2.17) with $-\Pi\Delta\widehat{\mathbf{v}}$, where Π is the Leray projector defined in (1.18), and applying the Schwarz inequality, we obtain, for $t \in (t_n, t_{n+1})$,

$$\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\|\nabla\widehat{\mathbf{v}}(t)\|^2 + \nu\|\Pi\Delta\widehat{\mathbf{v}}(t)\|^2 \\
&\leq ((\widehat{\mathbf{v}}(t) \cdot \nabla)\widehat{\mathbf{v}}(t), \Pi\Delta\widehat{\mathbf{v}}(t)) + ((\mathbf{U}(t) \cdot \nabla)\widehat{\mathbf{v}}(t), \Pi\Delta\widehat{\mathbf{v}}(t)) \\
&\quad + ((\widehat{\mathbf{v}}(t) \cdot \nabla)\mathbf{U}(t), \Pi\Delta\widehat{\mathbf{v}}(t)) - (\mathbf{g}(t), \Pi\Delta\widehat{\mathbf{v}}(t)) \\
&\leq C\|\widehat{\mathbf{v}}(t)\|_{\mathbf{L}^4(\Omega)} \|\nabla\widehat{\mathbf{v}}(t)\|_{\mathbf{L}^4(\Omega)} \|\Pi\Delta\widehat{\mathbf{v}}(t)\| \\
&\quad + \left(\|\mathbf{U}(t)\|_{\mathbf{L}^\infty(\Omega)} \|\nabla\widehat{\mathbf{v}}(t)\| + \|\nabla\mathbf{U}(t)\|_{\mathbf{L}^\infty(\Omega)} \|\widehat{\mathbf{v}}(t)\| + \|\mathbf{g}(t)\|\right) \cdot \|\Pi\Delta\widehat{\mathbf{v}}(t)\|.
\end{aligned} \tag{2.18}$$

But $\|\mathbf{w}\|_{L^4} \leq C\|\mathbf{w}\|^{1/2}\|\nabla\mathbf{w}\|^{1/2}$ for all $\mathbf{w} \in \mathbf{H}_0^1(\Omega)$, so together with (1.19), we have that $\|\widehat{\mathbf{v}}\|_{L^4}\|\nabla\widehat{\mathbf{v}}\|_{L^4}\|\Pi\Delta\widehat{\mathbf{v}}\| \leq C\|\widehat{\mathbf{v}}\|^{1/2}\|\nabla\widehat{\mathbf{v}}\| \cdot \|\Pi\Delta\widehat{\mathbf{v}}\|^{3/2}$. By applying Young's inequality, (2.18) yields

$$\begin{aligned}
\frac{d}{dt}\|\nabla\widehat{\mathbf{v}}(t)\|^2 + \nu\|\Pi\Delta\widehat{\mathbf{v}}(t)\|^2 &\leq C\|\widehat{\mathbf{v}}(t)\|^2 \|\nabla\widehat{\mathbf{v}}(t)\|^4 \\
&\quad + C(\|\mathbf{U}(t)\|^2_{\mathbf{L}^\infty(\Omega)} + \|\nabla\mathbf{U}(t)\|^2_{\mathbf{L}^\infty(\Omega)} + 1) \cdot (\|\nabla\widehat{\mathbf{v}}(t)\|^2 + \|\widehat{\mathbf{g}}(t)\|^2),
\end{aligned} \tag{2.19}$$

where, and from now on, C is a generic constant depending only on Ω and ν. By (A4),

$$C_1 = C_1(\nu, \Omega, \mathbf{U}) \stackrel{\text{def}}{=\!=} C \sup_{s \in (0,\infty)} \left\{ \|\mathbf{U}(s)\|^2_{\mathbf{L}^\infty(\Omega)} + \|\nabla\mathbf{U}(s)\|^2_{\mathbf{L}^\infty(\Omega)} + 1 \right\} < \infty\,. \tag{2.20}$$

Theorem 2.3 and the fact that $t \geq T_1 \geq t_n \geq t_{n_0}$ imply that

$$C\|\widehat{\mathbf{v}}(t)\|^2 \leq CM_1\mu^{n-n_0}\|\widehat{\mathbf{v}}(t_{n_0})\|^2 \leq CM_1\|\widehat{\mathbf{v}}(t_{n_0})\|^2 \qquad \forall\, t \in [T_1, T_2].$$

Setting $C_2 = C_2(\nu, \Omega) = CM_1$, we obtain from (2.19) that

$$\frac{d}{dt}\|\nabla\widehat{\mathbf{v}}(t)\|^2 - C_2\|\widehat{\mathbf{v}}(t_{n_0})\|^2\|\nabla\widehat{\mathbf{v}}(t)\|^4 \leq C_1(\|\nabla\widehat{\mathbf{v}}(t)\|^2 + \|\widehat{\mathbf{g}}(t)\|^2).$$

Multiplying this inequality by $\exp\{-C_2\|\widehat{\mathbf{v}}(t_{n_0})\|^2 \int_{t_{n_0}}^t \|\nabla\widehat{\mathbf{v}}(s)\|^2 ds\}$ and integrating over $t \in (T_1, T_2)$, we obtain (2.16). ∎

Now we can prove the exponential decay of $\|\nabla\widehat{\mathbf{v}}(t)\| = \|\nabla\widehat{\mathbf{u}}(t) - \nabla\mathbf{U}(t)\|$. We will keep the above notations.

THEOREM 2.10. *Assume that the conditions of Theorem* 2.7 *and* (A4) *hold. Then, for each fixed* $\tau \in (0,1)$,

$$\|\nabla\widehat{\mathbf{v}}(t)\|^2 \le C_3\|\mathbf{u}_0-\mathbf{U}_0\|^2 e^{-\kappa t}\exp\left\{C_4\|\mathbf{u}_0-\mathbf{U}_0\|^4 e^{-2\kappa t}\right\} \qquad \forall\, t\ge\tau,$$

where

$$\begin{aligned} C_3 &= C_3(\nu,\Omega,\mathbf{U}) \\ &\overset{\text{def}}{=\!=} \left(\left(\frac{1}{\tau}+C_1\right)\left(M_3+\frac{\delta}{2(1-\mu)}\sqrt{\frac{\alpha}{\beta}}\right)\frac{e^{\kappa\delta}}{\nu}+\frac{\alpha C_1\delta}{\beta(1-\mu)}\right)e^{\kappa(\tau+\delta)} \end{aligned}$$

and

$$C_4 = C_4(\nu,\Omega,\mathbf{U}) \overset{\text{def}}{=\!=} C_2M_3\left(M_3+\frac{\delta}{2(1-\mu)}\sqrt{\frac{\alpha}{\beta}}\right)e^{\kappa(2\tau+3\delta)}$$

with κ, μ, *and* δ *defined in Theorem* 2.7 *and* C_1 *and* C_2 *defined in Lemma* 2.9.

Proof. Let $\tau\in(0,1)$ and $t>\tau$ be given. Denote by $[s]$ the maximum integer not greater than s. Then $n_1 \overset{\text{def}}{=\!=} [(t-\tau)/\delta]\ge 0$ and $t_{n_1}\le t-\tau$. For any $s_1\in[t-\tau,t]$, by repeatedly applying (2.16) for $(T_1,T_2)=(s_1,t_{[s_1/\delta]+1}),(t_{[s_1/\delta]+1},t_{[s_1/\delta]+2}),\dots,(t_{[t/\delta]},t)$ and taking the summation, we obtain

$$\begin{aligned} &\|\nabla\widehat{\mathbf{v}}(t)\|^2\exp\left\{-C_2\|\widehat{\mathbf{v}}(t_{n_1})\|^2\int_{t_{n_1}}^t\|\nabla\widehat{\mathbf{v}}(s)\|^2ds\right\} \\ &\qquad\qquad -\|\nabla\widehat{\mathbf{v}}(s_1)\|^2\exp\left\{-C_2\|\widehat{\mathbf{v}}(t_{n_1})\|^2\int_{t_{n_1}}^{s_1}\|\nabla\widehat{\mathbf{v}}(s)\|^2ds\right\} \\ &\le C_1\int_{s_1}^t\left(\|\nabla\widehat{\mathbf{v}}(s)\|^2+\|\widehat{\mathbf{g}}(s)\|^2\right)\exp\left\{-C_2\|\widehat{\mathbf{v}}(t_{n_1})\|^2\int_{t_{n_1}}^s\|\nabla\widehat{\mathbf{v}}(\sigma)\|^2d\sigma\right\}ds \end{aligned}$$

or

$$\begin{aligned} \|\nabla\widehat{\mathbf{v}}(t)\|^2 &\le \|\nabla\widehat{\mathbf{v}}(s_1)\|^2\exp\left\{C_2\|\widehat{\mathbf{v}}(t_{n_1})\|^2\int_{s_1}^t\|\nabla\widehat{\mathbf{v}}(s)\|^2ds\right\} \\ &\quad + C_1\int_{s_1}^t\left(\|\nabla\widehat{\mathbf{v}}(s)\|^2+\|\widehat{\mathbf{g}}(s)\|^2\right)\exp\left\{C_2\|\widehat{\mathbf{v}}(t_{n_1})\|^2\int_s^t\|\nabla\widehat{\mathbf{v}}(\sigma)\|^2d\sigma\right\}ds \\ &\le \left(\|\nabla\widehat{\mathbf{v}}(s_1)\|^2+C_1\int_{t-\tau}^t\left(\|\nabla\widehat{\mathbf{v}}(s)\|^2+\|\widehat{\mathbf{g}}(s)\|^2\right)ds\right) \\ &\qquad\qquad\cdot\exp\left\{C_2\|\widehat{\mathbf{v}}(t_{n_1})\|^2\int_{t-\tau}^t\|\nabla\widehat{\mathbf{v}}(s)\|^2ds\right\}. \end{aligned}$$

Integrating this inequality over $s_1\in(t-\tau,t)$, we obtain

$$\begin{aligned} \|\nabla\widehat{\mathbf{v}}(t)\|^2 &\le \left(\left(\frac{1}{\tau}+C_1\right)\int_{t-\tau}^t\|\nabla\widehat{\mathbf{v}}(s)\|^2\,ds + C_1\int_{t-\tau}^t\|\widehat{\mathbf{g}}(s)\|^2\,ds\right) \\ &\qquad\qquad\cdot\exp\left\{C_2\|\widehat{\mathbf{v}}(t_{n_1})\|^2\int_{t-\tau}^t\|\nabla\widehat{\mathbf{v}}(s)\|^2\,ds\right\}. \end{aligned} \tag{2.21}$$

Now we apply Lemma 2.9 and Theorem 2.3 to obtain

$$\nu\int_{t-\tau}^t\|\nabla\widehat{\mathbf{v}}(s)\|^2ds \le \nu\int_{t_{n_1}}^\infty\|\nabla\widehat{\mathbf{v}}(s)\|^2ds \le \|\widehat{\mathbf{v}}(t_{n_1})\|^2+\frac{1}{\sqrt{\alpha\beta}}\mathcal{J}_{(t_{n_1},\infty)}(\widehat{\mathbf{u}},\widehat{\mathbf{f}}).$$

By Theorem 2.7 and Proposition 2.4,

$$\int_{t-\tau}^{t} \|\nabla \widehat{\mathbf{v}}(s)\|^2 ds \le \left(M_3 + \frac{\delta}{2(1-\mu)} \sqrt{\frac{\alpha}{\beta}} \right) \frac{e^{\kappa\delta}}{\nu} \|\mathbf{u}_0 - \mathbf{U}_0\|^2 \mu^{[t-\tau]} e^{-\kappa(t-\tau)},$$

$$\int_{t-\tau}^{t} \|\widehat{\mathbf{g}}(s)\|^2 ds \le \frac{2}{\beta} \mathcal{J}_{(t_{n_1}, t_{n_2})}(\widehat{\mathbf{u}}^{(n)}, \widehat{\mathbf{f}}^{(n)}) \le \frac{\alpha\delta e^{\kappa\delta}}{\beta(1-\mu)} \|\mathbf{u}_0 - \mathbf{U}_0\|^2 e^{-\kappa(t-\tau)},$$

and

$$\|\widehat{\mathbf{v}}(t_{n_1})\|^2 \le M_3 \|\mathbf{u}_0 - \mathbf{U}_0\|^2 e^{-\kappa(t-\tau)}.$$

The theorem is therefore proven when one combines the last three estimates and (2.21). ∎

Remark 2.11. By virtue of Remarks 2.5 and 2.8, C_3 and C_4 in Theorem 2.10 remain bounded as $\delta \to 0^+$. ∎

COROLLARY 2.12. *Assume that the conditions of Theorem* 2.10 *hold. Then there exists a function* $\theta(\delta) = \theta(\delta; \mathbf{u}_0, \mathbf{U}_0, \nu, \Omega)$ *which is continuous in* $\delta \in (0, \delta_0]$ *such that* $\lim_{\delta \to 0^+} \theta(\delta) < \infty$ *and*

$$\|\nabla \widehat{\mathbf{v}}(t)\| \le \theta(\delta) t^{-1/2} \qquad \forall t \le 1.$$

Namely,

$$\|\nabla \widehat{\mathbf{v}}(t)\| = O(t^{-1/2}) \qquad \text{as } t \to 0^+$$

holds uniformly for $\delta > 0$ *small enough.*

Proof. Set $t = 2\tau$ in Theorem 2.10; then the corollary is evident. ∎

3. Semidiscrete approximations of the piecewise optimal control problem. In order to compute the optimal solutions of the piecewise optimal control problem analyzed in section 2, we need to discretize this problem in both time and space. In this section we will discuss only semidiscretizations (i.e., time discretizations).

3.1. Definition of the semidiscrete piecewise optimal control problem. We semidiscretize the functional $\mathcal{J}_{(t_n, t_{n+1})}(\mathbf{u}, \mathbf{f})$ by the right-endpoint rectangle rule $\int_{t_n}^{t_{n+1}} \varphi(t)\, dt \approx \delta\varphi(t_{n+1})$ so that the semidiscretized functional becomes

$$\mathcal{J}^{n+1}(\mathbf{u}, \mathbf{f}) = \frac{\delta\alpha}{2} \|\mathbf{u} - \mathbf{U}^{n+1}\|^2 + \frac{\delta\beta}{2} \|\mathbf{f} - \mathbf{F}^{n+1}\|^2 \qquad \forall\, \mathbf{u} \in \mathbf{H}_0^1(\Omega), \forall\, \mathbf{f} \in \mathbf{L}^2(\Omega)\,,$$

where $\mathbf{U}^{n+1} = \mathbf{U}^{n+1}(\mathbf{x}) = \mathbf{U}(\mathbf{x}, t_{n+1})$ and $\mathbf{F}^{n+1} = \mathbf{F}^{n+1}(\mathbf{x}) = \mathbf{F}(\mathbf{x}, t_{n+1})$ with $t_n = n\delta$ for $n = 0, 1, 2, \ldots$. Since δ is fixed, the minimization of $\mathcal{J}^{n+1}(\mathbf{u}, \mathbf{f})$ is equivalent to the minimization of $\mathcal{L}^{n+1}(\mathbf{u}, \mathbf{f}) \stackrel{\text{def}}{=\!=} \delta^{-1} \mathcal{J}^{n+1}(\mathbf{u}, \mathbf{f})$. Thus, instead of the functional $\mathcal{J}^{n+1}(\mathbf{u}, \mathbf{f})$, we will use the functional

$$\mathcal{L}^{n+1}(\mathbf{u}, \mathbf{f}) = \frac{\alpha}{2} \|\mathbf{u} - \mathbf{U}^{n+1}\|^2 + \frac{\beta}{2} \|\mathbf{f} - \mathbf{F}^{n+1}\|^2 \qquad \forall\, \mathbf{u} \in \mathbf{H}_0^1(\Omega), \forall\, \mathbf{f} \in \mathbf{L}^2(\Omega)\,.$$

To semidiscretize the Navier–Stokes equations on (t_n, t_{n+1}), we in principle may choose a time step Δt independent of δ (of course $\Delta t \le \delta$). From the analysis in the last section, the exponential decay rates remain bounded as $\delta \to 0^+$. In other words, the piecewise controlled dynamics eventually remain unchanged for arbitrarily small δ. Therefore it is reasonable to choose $\Delta t = \delta$, i.e., the functional and the Navier–Stokes equations are semidiscretized by the same time stepping. We state the semidiscrete approximation of the piecewise optimal control problem as follows.

- Set $\Delta t = \delta$.
- Define $\widehat{\mathbf{u}}^0 = \mathbf{U}_0$.
- *The $(n+1)$th semidiscrete optimal control problem*: for $n = 0, 1, 2, \ldots$, find $(\widehat{\mathbf{u}}^{n+1}, \widehat{p}^{n+1}, \widehat{\mathbf{f}}^{n+1}) \in \mathbf{H}_0^1(\Omega) \times L_0^2(\Omega) \times \mathbf{L}^2(\Omega)$ such that the functional $\mathcal{L}^{n+1}(\mathbf{u}^{n+1}, \mathbf{f}^{n+1})$ is minimized subject to the semidiscrete Navier–Stokes equations

$$\begin{aligned} &\frac{1}{\Delta t}(\mathbf{u}^{n+1}, \mathbf{w}) + a(\mathbf{u}^{n+1}, \mathbf{w}) + c(\mathbf{u}^{n+1}, \mathbf{u}^{n+1}, \mathbf{w}) + b(\mathbf{w}, p^{n+1}) \\ &\qquad = \frac{1}{\Delta t}(\widehat{\mathbf{u}}^n, \mathbf{w}) + (\mathbf{f}^{n+1}, \mathbf{w}) \qquad \forall\, \mathbf{w} \in \mathbf{H}_0^1(\Omega) \end{aligned} \tag{3.1}$$

and

$$b(\mathbf{u}^{n+1}, r) = 0 \qquad \forall\, r \in L_0^2(\Omega)\,. \tag{3.2}$$

Note that for each $n = 0, 1, 2, \ldots$, the $(n+1)$th optimal control problem is a *steady-state* problem for the state variable pair $(\mathbf{u}^{n+1}, p^{n+1})$ and the control variable $\mathbf{f}^{n+1}$. Using the techniques of [GHS] concerning optimal control problems for the steady-state Navier–Stokes equations, we can show the existence of a solution $(\widehat{\mathbf{u}}^{n+1}, \widehat{p}^{n+1}, \widehat{\mathbf{f}}^{n+1})$ for the $(n+1)$th optimal control problem. The remainder of this section will be devoted to the study of $\widehat{\mathbf{u}}^n$ as $n \to \infty$.

3.2. Dynamics of the semidiscrete solutions of the piecewise optimal control problem. We now study the behavior of the semidiscrete solution $\widehat{\mathbf{u}}^n$ as $n \to \infty$.

By the finite difference approximation formula

$$\partial_t \mathbf{U}(\mathbf{x}, t) = \frac{\mathbf{U}(\mathbf{x}, t + \Delta t) - \mathbf{U}(\mathbf{x}, t)}{\Delta t} + \partial_{tt}^2 \mathbf{U}(\mathbf{x}, t + \theta \Delta t)\Delta t,$$

where $\theta = \theta(\mathbf{x}, t)$ and $|\theta| < 1$, we have that

$$\begin{aligned} &\frac{1}{\Delta t}(\mathbf{U}^{n+1}, \mathbf{w}) + a(\mathbf{U}^{n+1}, \mathbf{w}) + c(\mathbf{U}^{n+1}, \mathbf{U}^{n+1}, \mathbf{w}) \\ &\qquad = \frac{1}{\Delta t}(\mathbf{U}^n, \mathbf{w}) + (\mathbf{F}^{n+1} - \boldsymbol{\tau}^{n+1}, \mathbf{w}) \qquad \forall\, \mathbf{w} \in \mathbf{H}_0^1(\Omega) \end{aligned} \tag{3.3}$$

and

$$b(\mathbf{U}^{n+1}, r) = 0 \qquad \forall\, r \in L_0^2(\Omega)\,, \tag{3.4}$$

where

$$\boldsymbol{\tau}^{n+1} = \Delta t\, \partial_{tt} \mathbf{U}\left(\mathbf{x}, t_n + \theta(\mathbf{x}, t_n)\Delta t\right). \tag{3.5}$$

LEMMA 3.1. *Assume that* (A1)–(A2) *and*

$$\text{(A5)} \quad \partial_t \mathbf{U} \in C\left([0, \infty); \mathbf{H}^1(\Omega)\right), \qquad \partial_{tt} \mathbf{U} \in \mathbf{L}^\infty\left(\Omega \times (0, \infty)\right) \cap C\left([0, \infty); \mathbf{L}^2(\Omega)\right)$$

hold. Assume further that $(\widehat{\mathbf{u}}^{n+1}, \widehat{p}^{n+1}, \widehat{\mathbf{f}}^{n+1})$ is a solution of the $(n+1)$th semidiscrete optimal control problem for $n = 1, 2, \ldots$. Then

$$\mathcal{L}^{n+1}(\widehat{\mathbf{u}}^{n+1}, \widehat{\mathbf{f}}^{n+1}) \le \frac{\alpha}{2}\left(\frac{\|\widehat{\mathbf{u}}^n - \mathbf{U}^n\|^2}{1 + C_5 \Delta t} + \frac{C_6 (\Delta t)^3}{1 + C_5 \Delta t}\right),$$

where

$$C_5 = C_5(\nu,\Omega) \stackrel{\text{def}}{=\!=} \frac{\nu\lambda_1}{2} \qquad \textit{and} \qquad C_6 = C_6(\nu,\Omega,\mathbf{U}) \stackrel{\text{def}}{=\!=} \frac{2\,|||\partial_{tt}\mathbf{U}|||^2}{\nu\lambda_1} \tag{3.6}$$

with the norm $|||\cdot|||$ *defined by* (1.7).

Proof. Let $(\widetilde{\mathbf{u}}^{n+1},\widetilde{p}^{n+1})$ be a solution of the equations

$$\begin{aligned}\frac{1}{\Delta t}(\widetilde{\mathbf{u}}^{n+1},\mathbf{w}) + a(\widetilde{\mathbf{u}}^{n+1},\mathbf{w}) + c(\widetilde{\mathbf{u}}^{n+1},\widetilde{\mathbf{u}}^{n+1},\mathbf{w}) + b(\mathbf{w},\widetilde{p}^{n+1})\\ = \frac{1}{\Delta t}(\widehat{\mathbf{u}}^{n},\mathbf{w}) + (\mathbf{F}^{n+1},\mathbf{w}) \qquad \forall\,\mathbf{w}\in\mathbf{H}_0^1(\Omega)\end{aligned} \tag{3.7}$$

and

$$b(\widetilde{\mathbf{u}}^{n+1},r) = 0 \qquad \forall\, r\in L_0^2(\Omega)\,. \tag{3.8}$$

(The existence of such a $(\widetilde{\mathbf{u}}^{n+1},\widetilde{p}^{n+1})$ can be proved by using the techniques for proving the existence of a solution for the steady-state Navier–Stokes equations.) Set $\widetilde{\mathbf{f}}^{n+1} = \mathbf{F}^{n+1}$; then we see that $(\widetilde{\mathbf{u}}^{n+1},\widetilde{p}^{n+1},\widetilde{\mathbf{f}}^{n+1})$ satisfies the semidiscrete Navier–Stokes equations (3.7), (3.8). Let $\widetilde{\mathbf{v}}^{n+1} = \widetilde{\mathbf{u}}^{n+1} - \mathbf{U}^{n+1}$ and $\widetilde{q}^{n+1} = \widetilde{p}^{n+1}$. Then by subtracting (3.3), (3.4) from (3.7), (3.8), we obtain

$$\begin{aligned}&\frac{1}{\Delta t}(\widetilde{\mathbf{v}}^{n+1},\mathbf{w}) + a(\widetilde{\mathbf{v}}^{n+1},\mathbf{w}) + c(\widetilde{\mathbf{v}}^{n+1},\widetilde{\mathbf{v}}^{n+1},\mathbf{w}) + c(\mathbf{U}^{n+1},\widetilde{\mathbf{v}}^{n+1},\mathbf{w})\\ &+ c(\widetilde{\mathbf{v}}^{n+1},\mathbf{U}^{n+1},\mathbf{w}) + b(\mathbf{w},\widetilde{q}^{n+1}) = \frac{1}{\Delta t}(\widehat{\mathbf{v}}^{n},\mathbf{w}) + (\boldsymbol{\tau}^{n+1},\mathbf{w}) \quad \forall\,\mathbf{w}\in\mathbf{H}_0^1(\Omega)\end{aligned} \tag{3.9}$$

and

$$b(\widetilde{\mathbf{v}}^{n+1},r) = 0 \qquad \forall\, r\in L_0^2(\Omega)\,. \tag{3.10}$$

Setting $\mathbf{w} = \widetilde{\mathbf{v}}^{n+1}$ in (3.9), integrating by parts, and using (1.11), we obtain

$$\begin{aligned}&\frac{1}{2\Delta t}\left(\|\widetilde{\mathbf{v}}^{n+1}\|^2 - \|\widehat{\mathbf{v}}^{n}\|^2 + \|\widetilde{\mathbf{v}}^{n+1}-\widehat{\mathbf{v}}^{n}\|^2\right) + \nu\|\nabla\widetilde{\mathbf{v}}^{n+1}\|^2\\ &= -c(\widetilde{\mathbf{v}}^{n+1},\mathbf{U}^{n+1},\widetilde{\mathbf{v}}^{n+1}) + (\boldsymbol{\tau}^{n+1},\widetilde{\mathbf{v}}^{n+1})\\ &= c(\widetilde{\mathbf{v}}^{n+1},\widetilde{\mathbf{v}}^{n+1},\mathbf{U}^{n+1}) + (\boldsymbol{\tau}^{n+1},\widetilde{\mathbf{v}}^{n+1})\\ &\le C_0\|\mathbf{U}^{n+1}\|_{\mathbf{L}^4(\Omega)}\|\nabla\widetilde{\mathbf{v}}^{n+1}\|^2 + \|\boldsymbol{\tau}^{n+1}\|\,\|\widetilde{\mathbf{v}}^{n+1}\|,\end{aligned}$$

so that by (A2) and Young's inequality

$$\begin{aligned}&\frac{1}{2\Delta t}\left(\|\widetilde{\mathbf{v}}^{n+1}\|^2 - \|\widehat{\mathbf{v}}^{n}\|^2 + \|\widetilde{\mathbf{v}}^{n+1}-\widehat{\mathbf{v}}^{n}\|^2\right) + \nu\|\nabla\widetilde{\mathbf{v}}^{n+1}\|^2\\ &\le \frac{\nu}{2}\|\nabla\widetilde{\mathbf{v}}^{n+1}\|^2 + \frac{1}{\nu\lambda_1}\|\boldsymbol{\tau}^{n+1}\|^2 + \frac{\nu\lambda_1}{4}\|\widetilde{\mathbf{v}}^{n+1}\|^2.\end{aligned} \tag{3.11}$$

Dropping the term $\|\widetilde{\mathbf{v}}^{n+1}-\widehat{\mathbf{v}}^{n}\|^2$ and rearranging, we have

$$\frac{1}{2\Delta t}\left(\|\widetilde{\mathbf{v}}^{n+1}\|^2 - \|\widehat{\mathbf{v}}^{n}\|^2\right) + \frac{\nu}{4}\|\nabla\widetilde{\mathbf{v}}^{n+1}\|^2 \le \frac{1}{\nu\lambda_1}\|\boldsymbol{\tau}^{n+1}\|^2 \tag{3.12}$$

so that using the estimate $\|\boldsymbol{\tau}^{n+1}\| \le \Delta t\,|||\partial_{tt}\mathbf{U}|||$ and the Poincaré inequality, we are led to

$$(1 + C_5\Delta t)\,\|\widetilde{\mathbf{v}}^{n+1}\|^2 \le \|\widehat{\mathbf{v}}^{n}\|^2 + C_6(\Delta t)^3,$$

where C_5 and C_6 are defined by (3.6). Hence, we arrive at

$$\mathcal{L}^{n+1}(\widetilde{\mathbf{u}}^{n+1},\widetilde{\mathbf{f}}^{n+1}) = \frac{\alpha}{2}\|\widetilde{\mathbf{v}}^{n+1}\|^2 \le \frac{\alpha}{2}\left[\frac{\|\widehat{\mathbf{v}}^n\|^2}{1+C_5\Delta t} + \frac{C_6(\Delta t)^3}{1+C_5\Delta t}\right].$$

$(\widehat{\mathbf{u}}^{n+1},\widehat{p}^{n+1},\widehat{\mathbf{f}}^{n+1})$ being a solution for the $(n+1)$th optimal control problem, the desired estimate follows trivially from this last inequality. ∎

THEOREM 3.2. *Assume that* (A1)–(A3) *and* (A5) *hold and* $0 < \Delta t \le 1$. *Then there are positive constants* C_7, C_8, κ_1, *and* ρ_1 *such that*

$$\|\widehat{\mathbf{u}}^{n+1} - \mathbf{U}^{n+1}\|^2 \le (1 - C_7\Delta t)\|\widehat{\mathbf{u}}^n - \mathbf{U}^n\|^2 + C_8(\Delta t)^3$$

with $1 - C_7\Delta t > 0$ *and*

$$\|\widehat{\mathbf{u}}^n - \mathbf{U}^n\|^2 \le \|\mathbf{u}_0 - \mathbf{U}_0\|^2\, e^{-\kappa_1 t_n} + \rho_1\Delta t^2. \tag{3.13}$$

Proof. The optimizer $(\widehat{\mathbf{u}}^{n+1},\widehat{p}^{n+1},\widehat{\mathbf{f}}^{n+1})$ satisfies (3.1), (3.2). By setting $\widehat{\mathbf{v}}^{n+1} = \widehat{\mathbf{u}}^{n+1} - \mathbf{U}^{n+1}$, $\widehat{q}^{n+1} = \widehat{p}^{n+1}$, $\widehat{\mathbf{g}}^{n+1} = \widehat{\mathbf{f}}^{n+1} - \mathbf{F}^{n+1}$, and subtracting (3.3), (3.4) from (3.1), (3.2), we see that

$$\begin{aligned}
&\frac{1}{\Delta t}(\widehat{\mathbf{v}}^{n+1},\mathbf{w}) + a(\widehat{\mathbf{v}}^{n+1},\mathbf{w}) + c(\widehat{\mathbf{v}}^{n+1},\widehat{\mathbf{v}}^{n+1},\mathbf{w}) \\
&\quad + c(\mathbf{U}^{n+1},\widehat{\mathbf{v}}^{n+1},\mathbf{w}) + c(\widehat{\mathbf{v}}^{n+1},\mathbf{U}^{n+1},\mathbf{w}) + b(\mathbf{w},\widehat{q}^{n+1}) \\
&\quad = \frac{1}{\Delta t}(\widehat{\mathbf{v}}^n,\mathbf{w}) + (\widehat{\mathbf{g}}^{n+1} + \boldsymbol{\tau}^{n+1},\mathbf{w}) \qquad \forall\, \mathbf{w} \in \mathbf{H}_0^1(\Omega)
\end{aligned} \tag{3.14}$$

and

$$b(\widehat{\mathbf{v}}^{n+1}, r) = 0 \qquad \forall\, r \in L_0^2(\Omega)\,.$$

Setting $\mathbf{w} = \widehat{\mathbf{v}}^{n+1}$ in (3.14) and using the same techniques as in the proof of (3.11) and (3.12), we obtain

$$\begin{aligned}
&\frac{1}{2\Delta t}\left(\|\widehat{\mathbf{v}}^{n+1}\|^2 - \|\widehat{\mathbf{v}}^n\|^2\right) + \frac{\nu}{4}\|\nabla\widehat{\mathbf{v}}^{n+1}\|^2 \\
&\le \left(\widehat{\mathbf{g}}^{n+1},\widehat{\mathbf{v}}^{n+1}\right) + \frac{1}{\nu\lambda_1}\,\|\boldsymbol{\tau}^{n+1}\|^2 \\
&\le \frac{1}{\sqrt{\alpha\beta}}\left(\frac{\alpha}{2}\|\widehat{\mathbf{v}}^{n+1}\|^2 + \frac{\beta}{2}\|\widehat{\mathbf{g}}^{n+1}\|^2\right) + \frac{C_6(\Delta t)^2}{2}\,.
\end{aligned} \tag{3.15}$$

It thus follows from Lemma 3.1 and the Poincaré inequality that

$$\begin{aligned}
&\left(1 + \frac{\nu\lambda_1}{2}\Delta t\right)\|\widehat{\mathbf{v}}^{n+1}\|^2 \\
&\le \left(1 + \frac{\Delta t}{1+C_5\Delta t}\sqrt{\frac{\alpha}{\beta}}\right)\|\widehat{\mathbf{v}}^n\|^2 + C_6(\Delta t)^3\left(1 + \frac{\Delta t}{1+C_5\Delta t}\sqrt{\frac{\alpha}{\beta}}\right).
\end{aligned}$$

By (A3) and the fact that $\Delta t \le 1$, we can find constants

$$C_7 = C_7(\nu,\Omega) \overset{\text{def}}{=\!=} \left(\sqrt{\frac{\alpha}{\beta}} - \frac{\nu\lambda_1}{2}\right) \Big/ \left(1 + \sqrt{\frac{\alpha}{\beta}}\right) > 0$$

and $C_8 = C_8(\nu, \Omega, \mathbf{U}) \stackrel{\text{def}}{=\!=} C_6(\nu, \Omega, \mathbf{U}) > 0$ such that

$$\|\widehat{\mathbf{v}}^{n+1}\|^2 \le (1 - C_7\Delta t)\|\widehat{\mathbf{v}}^n\|^2 + C_8(\Delta t)^3 \qquad \forall\, n \ge 0.$$

It is straightforward to verify by induction that

$$\begin{aligned}\|\widehat{\mathbf{v}}^n\|^2 &\le (1 - C_7\Delta t)^n\|\widehat{\mathbf{v}}^0\|^2 + C_8(\Delta t)^3\sum_{j=0}^{n-1}(1 - C_7\Delta t)^j \\ &= (1 - C_7\Delta t)^n\|\widehat{\mathbf{v}}^0\|^2 + [1 - (1 - C_7\Delta t)^n]\,\frac{C_8}{C_7}(\Delta t)^2 \\ &\le \left[(1 - C_7\Delta t)^{\frac{1}{C_7\Delta t}}\right]^{C_7\, n\Delta t}\|\widehat{\mathbf{v}}^0\|^2 + \frac{C_8}{C_7}(\Delta t)^2\,.\end{aligned}$$

Applying the inequality $1 - y \le e^{-y}$ for all $y \ge 0$, we are led to

$$\|\widehat{\mathbf{v}}^n\|^2 \le \|\widehat{\mathbf{v}}^0\|^2 e^{-C_7\, t_n} + \frac{C_8}{C_7}(\Delta t)^2.$$

Setting $\kappa_1 = \kappa_1(\nu, \Omega) = C_7$ and $\rho_1 = \rho_1(\nu, \Omega, \mathbf{U}) = C_8/C_7$ completes the proof. ∎

As an easy consequence of Theorem 3.2, we obtain the following estimate for the difference between the continuous and semidiscrete solutions of the piecewise optimal control problem.

COROLLARY 3.3. *Assume the hypotheses of Theorem* 3.2 *hold. Let* $\widehat{\mathbf{u}}(t)$ *denote the global solution of the piecewise optimal control problem as defined in section* 2. *Let* $\widehat{\mathbf{u}}^n$ *denote the semidiscrete solution of the piecewise optimal control problem as defined section* 3.1. *Then there exist positive constants* $K_1 = K_1(\nu, \Omega)$, $K_2 = K_2(\nu, \Omega)$, *and* $K_3 = K_3(\nu, \Omega, \mathbf{U})$ *such that*

$$\|\widehat{\mathbf{u}}(t_n) - \widehat{\mathbf{u}}^n\| \le K_1\|\widehat{\mathbf{u}}_0 - \mathbf{U}_0\|\, e^{-K_2 t_n} + K_3\Delta t, \qquad n = 0, 1, 2, \ldots. \qquad ∎$$

Remark 3.4. In the semidiscretization of the Navier–Stokes equations we used the first-order backward Euler scheme. Therefore, the appearance of the term $O(\Delta t)$ in the last estimate is expected. If we use higher-order approximation schemes (see, e.g., [HR]), we expect to obtain improved estimates. However, the analysis in the context of semidiscrete piecewise optimal control with more sophisticated schemes becomes complicated. ∎

The proof of Theorem 3.2 gives a rough estimate of $\|\nabla\widehat{\mathbf{u}}^n - \nabla\mathbf{U}^n\| = \|\nabla\widehat{\mathbf{v}}^n\|$.

PROPOSITION 3.5. *Assume that the conditions of Theorem* 3.2 *hold. Then*

$$\begin{aligned}\Delta t\,\|\nabla\widehat{\mathbf{u}}^n - \nabla\mathbf{U}^n\|^2 \le{}& \frac{2}{\nu}\left(1 + \sqrt{\frac{\alpha}{\beta}}\right) e^{\kappa_1\delta}\|\mathbf{u}_0 - \mathbf{U}_0\|^2 e^{-\kappa_1 t_n} \\ &+ \frac{2}{\nu}\left(1 + \sqrt{\frac{\alpha}{\beta}}\right)(\rho_1 + C_6)\,(\Delta t)^2.\end{aligned} \tag{3.16}$$

Proof. By (3.15), we have that

$$\Delta t\,\|\nabla\widehat{\mathbf{v}}^n\|^2 \le \frac{2}{\nu}\|\widehat{\mathbf{v}}^{n-1}\|^2 + \frac{4\Delta t}{\nu\sqrt{\alpha\beta}}\,\mathcal{L}^n(\widehat{\mathbf{u}}^n, \widehat{\mathbf{f}}^n) + \frac{4C_6}{\nu}(\Delta t)^3. \tag{3.17}$$

But from Lemma 3.1 and Theorem 3.2, we obtain

$$\mathcal{L}^n(\widehat{\mathbf{u}}^n, \widehat{\mathbf{f}}^n) \le \frac{\alpha}{2}\left(\|\widehat{\mathbf{v}}^{n-1}\|^2 + C_6(\Delta t)^3\right)$$

and

$$\|\widehat{\mathbf{v}}^{n-1}\|^2 \le \|\mathbf{u}_0 - \mathbf{U}_0\|^2 e^{-\kappa t_{n-1}} + \rho_1(\Delta t)^2.$$

By substituting these inequalities into (3.17) and noting that $e^{-\kappa_1 t_{n-1}} = e^{\kappa_1 \delta}\, e^{-\kappa_1 t_n}$, the proposition is proven. ∎

Remark 3.6. Because the left-hand side of (3.16) involves Δt, a bound of the eventual error in $\|\cdot\|_1$ is

$$\limsup_{t\to\infty} \|\nabla\widehat{\mathbf{u}}^n - \nabla\mathbf{U}^n\| = O\left((\Delta t)^{1/2}\right) \qquad \text{as } \Delta t \to 0^+,$$

which is of only half the order of the truncation error for the implicit Euler's scheme. On the other hand, however, the bound of the finite time error is singular:

$$\sup_{t\in[0,T]} \|\nabla\widehat{\mathbf{u}}^n - \nabla\mathbf{U}^n\| = O((\Delta t)^{-1/2}) \qquad \text{as } \Delta t \to 0^+. \qquad ∎$$

We next derive an improved bound for the eventual error in $\mathbf{H}^1(\Omega)$ norm. Such an improvement is not always possible for the full discretization. We first observe the following direct consequence of (3.16).

COROLLARY 3.7. *Assume that the conditions of Theorem* 3.2 *hold. Then for any constant* $\sigma > 0$*, there exist constants* $\varepsilon_0 = \varepsilon_0(\Omega, \nu; \sigma) > 0$ *and* $\widetilde{t} = \widetilde{t}(\Omega, \nu, \|\mathbf{u}_0 - \mathbf{U}_0\|; \sigma) > 0$ *such that*

$$\Delta t \|\nabla\widehat{\mathbf{v}}^n\|^2 \le \sigma \qquad \forall\, t_n \ge \widetilde{t},\ \forall\, \Delta t \in (0, \varepsilon_0). \qquad ∎ \tag{3.18}$$

We also need a stronger version of Proposition 3.5.

PROPOSITION 3.8. *Assume the conditions of Theorem* 3.2 *hold. Then for each* $n \ge 1$*,*

(3.19)

$$\mathcal{L}^{n+1}(\widehat{\mathbf{u}}^{n+1}, \widehat{\mathbf{f}}^{n+1}) \le \frac{\alpha}{2}\left(\|\mathbf{u}_0 - \mathbf{U}_0\|^2 e^{-\kappa_1 t_n} + \rho_1(\Delta t)^3 + C_6(\Delta t)^3\right)/(1 + C_5\Delta t).$$

Moreover, for all $n_2 \ge n_1 \ge 1$*,*

$$\Delta t \sum_{n=n_1+1}^{n_2} \|\nabla\widehat{\mathbf{v}}^n\|^2 \le \|\widehat{\mathbf{v}}^{n_1}\|^2 + C_9(t_{n_2} - t_{n_1})\left(\|\mathbf{u}_0 - \mathbf{U}_0\|^2 e^{-\kappa_1 t_{n_1}} + (\Delta t)^2\right), \tag{3.20}$$

where

$$C_9 = C_9(\nu, \Omega, \mathbf{U}) = (1 + \rho_1 + C_6)\sqrt{\frac{\alpha}{\beta}}.$$

Proof. (3.19) follows from Lemma 3.1 and (3.13). By using (3.15) together with (3.19) and (3.13), we obtain that

$$\begin{aligned} &\|\widehat{\mathbf{v}}^{n+1}\|^2 - \|\widehat{\mathbf{v}}^n\|^2 + \frac{\nu\Delta t}{2}\|\nabla\widehat{\mathbf{v}}^{n+1}\|^2 \\ &\le \sqrt{\frac{\alpha}{\beta}}\|\mathbf{u}_0 - \mathbf{U}_0\|^2\, e^{-\kappa_1 t_{n+1}}\Delta t + (\rho_1 + C_6)\sqrt{\frac{\alpha}{\beta}}\,(\Delta t)^3. \end{aligned} \tag{3.21}$$

Summing up (3.21), (3.20) is proven. ∎

We are ready to derive the improved estimates of the $\mathbf{H}^1(\Omega)$ error $\|\nabla\widehat{\mathbf{u}}^n - \nabla\mathbf{U}^n\|$ in (3.16).

THEOREM 3.9. *Suppose that* (A1)–(A5) *hold. Then there exist constants* $\varepsilon \in (0,1)$ *depending only on* Ω *and* ν *and* $\widetilde{t}$ *depending only on* Ω, ν, *and* $\mathbf{U}$ *such that*

$$\begin{aligned}\|\nabla\widehat{\mathbf{u}}^n - \nabla\mathbf{U}^n\|^2 \le C_{10}\left(\frac{1}{\tau}+1+\tau\right)\left(\|\mathbf{u}_0-\mathbf{U}_0\|^2 e^{-\kappa_1(t_n-\tau)}+(\Delta t)^2\right)\\ \cdot\exp\left\{C_{11}(1+\tau)\left(\|\mathbf{u}_0-\mathbf{U}_0\|^4 e^{-2\kappa_1(t_n-\tau)}+(\Delta t)^4\right)\right\}\end{aligned} \tag{3.22}$$

$\forall\,\Delta t \in (0,\varepsilon)$ *and* $\forall\, t_n \ge \widetilde{t}$, *where* κ_1 *is as in Theorem* 3.2 *and* C_{10} *and* C_{11} *are constants depending only on* Ω, ν, *and* $\mathbf{U}$.

Proof. By the standard theory for the Navier–Stokes equations, $\widehat{\mathbf{v}}^{n+1}$ satisfying the strong form of (3.14),

$$\begin{aligned}&\frac{1}{\Delta t}(\widehat{\mathbf{v}}^{n+1}-\widehat{\mathbf{v}}^n)-\nu\Delta\widehat{\mathbf{v}}^{n+1}+(\widehat{\mathbf{v}}^{n+1}\cdot\nabla)\widehat{\mathbf{v}}^{n+1}\\ &+(\mathbf{U}^{n+1}\cdot\nabla)\widehat{\mathbf{v}}^{n+1}+(\widehat{\mathbf{v}}^{n+1}\cdot\nabla)\mathbf{U}^{n+1}-\nabla\widehat{q}^{n+1}=\widehat{\mathbf{g}}^{n+1}+\boldsymbol{\tau}^{n+1}\end{aligned} \tag{3.23}$$

with $\operatorname{div}\widehat{\mathbf{v}}^{n+1}=0$. Taking the $\mathbf{L}^2(\Omega)$ inner product of (3.23) with $-\Pi\Delta\widehat{\mathbf{v}}^{n+1}$, noting that

$$\begin{aligned}\frac{1}{\Delta t}\left(\widehat{\mathbf{v}}^{n+1}-\widehat{\mathbf{v}}^n\,,\,-\Pi\Delta\widehat{\mathbf{v}}^{n+1}\right)&=\frac{1}{\Delta t}\left(\nabla\widehat{\mathbf{v}}^{n+1}-\nabla\widehat{\mathbf{v}}^n\,,\,\nabla\widehat{\mathbf{v}}^{n+1}\right)\\ &=\frac{1}{2\Delta t}\left(\|\nabla\widehat{\mathbf{v}}^{n+1}\|^2-\|\nabla\widehat{\mathbf{v}}^n\|^2+\|\nabla\widehat{\mathbf{v}}^{n+1}-\nabla\widehat{\mathbf{v}}^n\|^2\right)\end{aligned}$$

and

$$\left(-\nu\Delta\widehat{\mathbf{v}}^{n+1}\,,\,-\Pi\Delta\widehat{\mathbf{v}}^{n+1}\right)=\nu\,\|\Pi\Delta\widehat{\mathbf{v}}^{n+1}\|^2\ge\nu C_\Pi\,\|\nabla\widehat{\mathbf{v}}^{n+1}\|^2$$

with $C_\Pi>0$ defined by (1.19) depending only on Ω, and using the similar treatment in (2.18) and (2.19), we arrive at

$$\begin{aligned}&\frac{1}{\Delta t}\left(\|\nabla\widehat{\mathbf{v}}^{n+1}\|^2-\|\nabla\widehat{\mathbf{v}}^n\|^2+\|\nabla\widehat{\mathbf{v}}^{n+1}-\nabla\widehat{\mathbf{v}}^n\|^2\right)+\nu\|\Pi\Delta\widehat{\mathbf{v}}^{n+1}\|^2\\ &\le C\|\widehat{\mathbf{v}}^{n+1}\|^2\|\nabla\widehat{\mathbf{v}}^{n+1}\|^4+C\left(\|\mathbf{U}^{n+1}\|_{L^\infty}^2+\|\nabla\mathbf{U}^{n+1}\|_{L^\infty}^2+1\right)\\ &\qquad\cdot\left(\|\nabla\widehat{\mathbf{v}}^{n+1}\|^2+\|\widehat{\mathbf{g}}^{n+1}\|^2+\|\boldsymbol{\tau}^{n+1}\|^2\right),\end{aligned} \tag{3.24}$$

where C is a constant depending only on Ω and ν.

Denote $K_4=C(\|\mathbf{U}\|^2_{L^\infty(0,\infty;\mathbf{L}^2(\Omega))}+\|\nabla\mathbf{U}\|^2_{L^\infty(0,\infty;\mathbf{L}^2(\Omega))}+1)$ and $\sigma_n=C\|\widehat{\mathbf{v}}^n\|^2$. Then, by Theorem 3.2, for $n=0,1,2,\ldots$

$$\sigma_n\le C\left(\|\mathbf{u}_0-\mathbf{U}_0\|^2e^{-\kappa_1 t_n}+\rho_1(\Delta t)^2\right). \tag{3.25}$$

Hence σ_n is uniformly bounded in n. Now we apply Corollary 3.7 to choose $\varepsilon>0$ and $\widetilde{t}>0$ such that

$$\sigma_n\cdot\Delta t\|\nabla\widehat{\mathbf{v}}^n\|^2\le y_0\qquad\forall\,\Delta t\in(0,\varepsilon),\,\forall\,t_n\ge\widetilde{t},$$

where the constant $y_0>0$ is chosen such that $1-y\ge e^{-2y}$ for each $y\in[0,y_0]$. Hence (3.24) gives rise to, for all $t_n\ge\widetilde{t}$,

$$\begin{aligned}&\exp\left\{-2\sigma_{n+1}\Delta t\,\|\nabla\widehat{\mathbf{v}}^{n+1}\|^2\right\}\|\nabla\widehat{\mathbf{v}}^{n+1}\|^2\\ &\le\left(1-\sigma_{n+1}\Delta t\,\|\nabla\widehat{\mathbf{v}}^{n+1}\|^2\right)\|\nabla\widehat{\mathbf{v}}^{n+1}\|^2\\ &\le\|\nabla\widehat{\mathbf{v}}^n\|^2+(\Delta t)K_4\left(\|\nabla\widehat{\mathbf{v}}^{n+1}\|^2+\|\widehat{\mathbf{g}}^{n+1}\|^2+\|\boldsymbol{\tau}^{n+1}\|^2\right).\end{aligned} \tag{3.26}$$

Let us fix $\tau > 2\Delta t$ and $n_0 > 0$ such that $t_{n_0} \geq \widetilde{t}$. Let n_2 be the largest integer such that $t_{n_2} \leq t_{n_0} + \tau$. Then for each n_1 satisfying $n_0 \leq n_1 \leq n_2$, we have that, by (3.26) and induction,

$$\begin{aligned}
&\exp\left\{-2\Delta t \sum_{j=n_1+1}^{n_2} \sigma_j \|\nabla \widehat{\mathbf{v}}^j\|^2\right\} \|\nabla \widehat{\mathbf{v}}^{n_2}\|^2 \\
&\leq \exp\left\{-2\Delta t \sum_{j=n_1+1}^{n_2-1} \sigma_j \|\nabla \widehat{\mathbf{v}}^j\|^2\right\} \\
&\qquad \cdot \left(\|\nabla \widehat{\mathbf{v}}^{n_2-1}\|^2 + (\Delta t) K_4 \left(\|\nabla \widehat{\mathbf{v}}^{n_2}\|^2 + \|\widehat{\mathbf{g}}^{n_2}\|^2 + \|\boldsymbol{\tau}^{n_2}\|^2\right)\right) \\
&\leq \exp\left\{-2\Delta t \sum_{j=n_1+1}^{n_2-1} \sigma_j \|\nabla \widehat{\mathbf{v}}^j\|^2\right\} \|\nabla \widehat{\mathbf{v}}^{n_2-1}\|^2 + (\Delta t) K_4 \left(\|\nabla \widehat{\mathbf{v}}^{n_2}\|^2 + \|\widehat{\mathbf{g}}^{n_2}\|^2 + \|\boldsymbol{\tau}^{n_2}\|^2\right) \\
&\leq \cdots \\
&\leq \|\nabla \widehat{\mathbf{v}}^{n_1}\|^2 + (\Delta t) K_4 \sum_{j=n_1+1}^{n_2} \left(\|\nabla \widehat{\mathbf{v}}^j\|^2 + \|\widehat{\mathbf{g}}^j\|^2 + \|\boldsymbol{\tau}^j\|^2\right).
\end{aligned}$$

Multiplying the above inequality by Δt and summing up n_1 over $n_0 \leq n_1 \leq n_2 - 1$, we obtain

$$\begin{aligned}
&(t_{n_2} - t_{n_0}) \exp\left\{-2\Delta t \sum_{j=n_0}^{n_2} \sigma_j \|\nabla \widehat{\mathbf{v}}^j\|^2\right\} \|\nabla \widehat{\mathbf{v}}^{n_2}\|^2 \\
&\leq \Delta t \sum_{j=n_0}^{n_2} \|\nabla \widehat{\mathbf{v}}^j\|^2 + K_4 (t_{n_2} - t_{n_0}) \Delta t \sum_{j=n_0}^{n_2} \left(\|\nabla \widehat{\mathbf{v}}^j\|^2 + \|\widehat{\mathbf{g}}^j\|^2 + \|\boldsymbol{\tau}^j\|^2\right).
\end{aligned}$$

Hence

$$\begin{aligned}
\|\nabla \widehat{\mathbf{v}}^{n_2}\|^2 \leq \exp\left\{2\Delta t \sum_{j=n_0}^{n_2} \sigma_j \|\nabla \widehat{\mathbf{v}}^j\|^2\right\} \cdot \Bigg(&\frac{\Delta t}{t_{n_2} - t_{n_0}} \sum_{j=n_0}^{n_2} \|\nabla \widehat{\mathbf{v}}^j\|^2 \\
&+ K_4 (\Delta t) \sum_{j=n_0}^{n_2} \left(\|\nabla \widehat{\mathbf{v}}^j\|^2 + \|\widehat{\mathbf{g}}^j\|^2 + \|\boldsymbol{\tau}^j\|^2\right)\Bigg).
\end{aligned} \tag{3.27}$$

But $\tau > 2\Delta t$ implies

$$\frac{1}{t_{n_2} - t_{n_0}} \leq \frac{1}{\tau - \Delta t} \leq \frac{2}{\tau}.$$

Moreover, by (3.5),

$$\Delta t \sum_{j=n_0}^{n_2} \|\boldsymbol{\tau}^j\|^2 \leq (\Delta t)^3 \|\|\partial_{tt} \mathbf{U}\|\|_\infty^2 \sum_{j=n_0}^{n_2} 1 \leq \tau \|\|\partial_{tt} \mathbf{U}\|\|_\infty^2 \cdot (\Delta t)^2,$$

and by Proposition 3.8 and Theorem 3.2, there exists a constant $\widetilde{C}$ depending only on Ω and ν such that

$$\Delta t \sum_{j=n_0}^{n_2} \|\widehat{\mathbf{g}}^j\|^2 \leq \frac{2\Delta t}{\beta} \sum_{j=n_0}^{n_2} \mathcal{L}^j(\widehat{\mathbf{u}}^j, \widehat{\mathbf{f}}^j) \leq \widetilde{C}(1+\tau)\left(\|\mathbf{u}_0 - \mathbf{U}_0\|^2 e^{-\kappa_1 t_{n_0}} + (\Delta t)^3\right)$$

and

$$\Delta t \sum_{j=n_0}^{n_2} \|\nabla \widehat{\mathbf{v}}^j\|^2 \le \widetilde{C}(1+\tau)\left(\|\mathbf{u}_0 - \mathbf{U}_0\|^2 e^{\kappa_1 t_{n_0}} + (\Delta t)^2\right).$$

Therefore, by (3.27) and (3.25), we conclude that there exist constants C_{10} and C_{11} depending only on Ω, ν, and $\mathbf{U}$ such that

$$\|\widehat{\mathbf{v}}^{n_2}\|^2 \le C_{10}\left(\frac{1}{\tau} + 1 + \tau\right)\left(\|\mathbf{u}_0 - \mathbf{U}_0\|^2 e^{-\kappa_1 t_{n_0}} + (\Delta t)^2\right) \cdot \exp\left\{C_{11}(1+\tau)\left(\|\mathbf{u}_0 - \mathbf{U}_0\|^4 e^{-2\kappa_1 t_{n_0}} + (\Delta t)^4\right)\right\}. \qquad \square$$

Remark 3.10. According to Theorem 3.9 together with its proof, the exponential decay rate for $\|\nabla\widehat{\mathbf{u}}^n - \nabla\mathbf{U}^n\|$ starts to be effective when $t_n \ge \widetilde{t}$, where $\widetilde{t}$ is independent of Δt. In other words, for each fixed, sufficiently small Δt,

$$\limsup_{n\to\infty} \|\nabla\widehat{\mathbf{u}}^n - \nabla\mathbf{U}^n\| = O(\Delta t),$$

with the bound uniform in $\Delta t \in (0, \varepsilon)$. The error in the $\mathbf{H}^1(\Omega)$ norm is reduced in $t_n = n\Delta t$ exponentially with the exponential rate independent of Δt. We emphasize that $\|\nabla\widehat{\mathbf{u}}^n - \nabla\mathbf{U}^n\|$ remains finite for $t_n \in (0, \widetilde{t})$. But unless $\mathbf{u}_0 - \mathbf{U}_0 \in \mathbf{H}_0^1(\Omega)$, we expect the singular behavior of $\|\nabla\widehat{\mathbf{u}}^n - \nabla\mathbf{U}^n\|$ for small t_n as in Remark 3.6. This type of singular behavior is true even when computing the solutions of the uncontrolled continuous Navier–Stokes equations.

Remark 3.11. We defined the solution for the $(n+1)$th semidiscrete piecewise optimal control problem and analyzed the dynamics of the solutions as $n \to \infty$. However, we said nothing about how to solve the $(n+1)$th optimal control problem. We point out that by introducing a Lagrange multiplier $(\widehat{\boldsymbol{\mu}}^{n+1}, \widehat{\pi}^{n+1}) \in \mathbf{H}_0^1(\Omega) \times L_0^2(\Omega)$, we can convert the problem of solving the $(n+1)$th optimal control problem into the problem of solving the optimality system of equations for $(\widehat{\mathbf{u}}^{n+1}, \widehat{p}^{n+1}, \widehat{\mathbf{f}}^{n+1}, \widehat{\boldsymbol{\mu}}^{n+1}, \widehat{\pi}^{n+1})$ which consists of (3.1), (3.2),

$$\frac{1}{\Delta t}(\boldsymbol{\mu}^{n+1}, \boldsymbol{\omega}) + a(\boldsymbol{\mu}^{n+1}, \boldsymbol{\omega}) + c(\boldsymbol{\omega}, \mathbf{u}^{n+1}, \boldsymbol{\mu}^{n+1}) + c(\mathbf{u}^{n+1}, \boldsymbol{\omega}, \boldsymbol{\mu}^{n+1}) + b(\boldsymbol{\omega}, \pi^{n+1}) = \alpha(\mathbf{u}^{n+1} - \mathbf{U}^{n+1}, \boldsymbol{\omega}) \qquad \forall\, \boldsymbol{\omega} \in \mathbf{H}_0^1(\Omega),$$

$$b(\boldsymbol{\mu}^{n+1}, \tau) = 0 \qquad \forall\, \tau \in L_0^2(\Omega),$$

and

$$(\beta\mathbf{f}^{n+1} - \beta\mathbf{F}^{n+1} + \boldsymbol{\mu}^{n+1}, \mathbf{z}) = 0 \qquad \forall\, \mathbf{z} \in \mathbf{L}^2(\Omega).$$

Using the techniques of [GHS] for the study of optimal control problems for the steady-state Navier–Stokes equations, we can show that the above optimality system of equations indeed has a solution. $\square$

4. Fully discrete approximations of the piecewise optimal control problem. Based on the semidiscrete approximations of the piecewise control problem, we now turn to the study of fully discrete approximations. We will discretize the spatial variables by finite element methods.

4.1. Definition of the fully discrete piecewise optimal control problem. We choose families of finite dimensional subspaces $\mathbf{X}_h \subset \mathbf{H}_0^1(\Omega)$ and $S_h \subset L_0^2(\Omega)$. These families are parameterized by the parameter h that tends to zero; commonly, this parameter is chosen to be some measure of the grid size in a subdivision of Ω into finite elements. One may choose any pair of subspaces $\mathbf{X}_h$ and S_h that can be used for finding finite element solutions of the steady-state Navier–Stokes equations. Thus, concerning these subspaces, we make the following standard assumptions. First, we have the approximation properties: there exist an integer $k \geq 1$ and a constant $C' > 0$, independent of h, $\mathbf{v}$, and q such that

$$\inf_{\mathbf{v}_h \in \mathbf{X}_h} \|\mathbf{v} - \mathbf{v}_h\|_1 \leq C' h^m \|\mathbf{v}\|_{m+1} \quad \forall\, \mathbf{v} \in \mathbf{H}^{m+1}(\Omega) \cap \mathbf{H}_0^1(\Omega)\,,\ 1 \leq m \leq k, \tag{4.1}$$

and

$$\inf_{q_h \in S_h} \|q - q_h\|_0 \leq C' h^m \|q\|_m \quad \forall\, q \in H^m(\Omega) \cap L_0^2(\Omega)\,,\ 1 \leq m \leq k\,. \tag{4.2}$$

Next, we assume the *inf-sup condition*, or *Ladyzhenskaya–Babuska–Brezzi condition*: there exists a constant C'', independent of h, such that

$$\inf_{0 \neq q_h \in S_h} \sup_{\mathbf{0} \neq \mathbf{v}_h \in \mathbf{V}_h} \frac{\int_\Omega q_h \operatorname{div} \mathbf{v}_h \, d\mathbf{x}}{\|\mathbf{v}_h\|_1 \, \|q_h\|_0} \geq C''\,. \tag{4.3}$$

This condition assures the stability of finite element discretizations of the Navier–Stokes equations. For thorough discussions of the approximation properties (4.1), (4.2), see, e.g., [Ci] or [GR], and for like discussions of the stability condition (4.3), see, e.g., [GR]. The reference [GR] may also be consulted for a catalogue of finite element subspaces that meet the requirements of (4.1), (4.2).

For each $n \geq 0$, we define the affine space $\mathbf{Y}_h^{n+1} \stackrel{\text{def}}{=\!=} \{\mathbf{f}_h = \mathbf{y}_h + \mathbf{F}_h^{n+1} : \mathbf{y}_h \in \mathbf{X}_h\}$ for the approximate distributed controls, where $\mathbf{F}_h^{n+1}$ is the L^2 projection of $\mathbf{F}^{n+1}$ onto $\mathbf{X}_h$. Note that $\mathbf{Y}_h^{n+1} \subset \mathbf{X}_h$. To preserve the antisymmetry of the trilinear form $c(\cdot,\cdot,\cdot)$ on the finite element spaces which are in general not divergent-free, we introduce the modified trilinear form (see [Te])

$$\overline{c}(\mathbf{u},\mathbf{v},\mathbf{w}) \stackrel{\text{def}}{=\!=} \frac{1}{2}\{c(\mathbf{u},\mathbf{v},\mathbf{w}) - c(\mathbf{u},\mathbf{w},\mathbf{v})\} \qquad \forall\, \mathbf{u},\mathbf{v},\mathbf{w} \in \mathbf{H}_0^1(\Omega)\,.$$

It can be easily verified that

$$\overline{c}(\mathbf{u},\mathbf{v},\mathbf{w}) = c(\mathbf{u},\mathbf{v},\mathbf{w}) \qquad \forall\, \mathbf{u} \in \mathbf{V},\ \forall\, \mathbf{v},\mathbf{w} \in \mathbf{H}_0^1(\Omega)\,, \tag{4.4}$$

$$\overline{c}(\mathbf{u},\mathbf{v},\mathbf{w}) = -\overline{c}(\mathbf{u},\mathbf{w},\mathbf{v}) \qquad \forall\, \mathbf{u},\mathbf{v},\mathbf{w} \in \mathbf{H}_0^1(\Omega)\,, \tag{4.5}$$

$$\overline{c}(\mathbf{u},\mathbf{v},\mathbf{v}) = 0 \qquad \forall\, \mathbf{u},\mathbf{v} \in \mathbf{H}_0^1(\Omega)\,, \tag{4.6}$$

$$|\overline{c}(\mathbf{u},\mathbf{v},\mathbf{w})| \leq \overline{C}_0 \|\nabla \mathbf{u}\| \, \|\mathbf{v}\|_{\mathbf{L}^4(\Omega)} \, \|\nabla \mathbf{w}\| \qquad \forall\, \mathbf{u},\mathbf{v},\mathbf{w} \in \mathbf{H}_0^1(\Omega)\,, \tag{4.7}$$

$$|\overline{c}(\mathbf{u},\mathbf{v},\mathbf{w})| \leq \overline{C}_1 \|\nabla \mathbf{u}\| \, \|\nabla \mathbf{v}\| \, \|\nabla \mathbf{w}\| \qquad \forall\, \mathbf{u},\mathbf{v},\mathbf{w} \in \mathbf{H}_0^1(\Omega) \tag{4.8}$$

and

$$\left.\begin{array}{l} |\overline{c}(\mathbf{u},\mathbf{v},\mathbf{w})| \leq \overline{C}_2 \|\mathbf{u}\|_2 \, \|\mathbf{v}\| \, \|\nabla \mathbf{w}\| \\ |\overline{c}(\mathbf{v},\mathbf{u},\mathbf{w})| \leq \overline{C}_2 \|\mathbf{u}\|_2 \, \|\mathbf{v}\| \, \|\nabla \mathbf{w}\| \end{array}\right\} \qquad \forall\, \mathbf{u} \in \mathbf{H}^2(\Omega) \cap \mathbf{H}_0^1(\Omega), \forall\, \mathbf{v},\mathbf{w} \in \mathbf{H}_0^1(\Omega)\,. \tag{4.9}$$

Once the finite element spaces $\mathbf{X}_h$ and S_h have been chosen, we define the fully discrete approximations of the piecewise optimal control problem as follows (the time discretization is the same as that for the semidiscrete approximations).

- Set $\Delta t = \delta$.
- Define $\widehat{\mathbf{u}}_h^0 = \mathbf{u}_{0,h}$ where $\mathbf{u}_{0,h}$ is the $\mathbf{L}^2(\Omega)$-projection (or interpolation) of $\mathbf{u}_0$ onto $\mathbf{X}_h$.
- *The $(n+1)$th fully discrete optimal control problem*:
  For $n = 0, 1, 2, \ldots$, find a $(\widehat{\mathbf{u}}_h^{n+1}, \widehat{p}_h^{n+1}, \widehat{\mathbf{f}}_h^{n+1}) \in \mathbf{X}_h \times S_h \times \mathbf{Y}_h^{n+1}$ such that the functional

$$\mathcal{L}_h^{n+1}(\mathbf{u}_h^{n+1}, \mathbf{f}_h^{n+1}) \stackrel{\text{def}}{=\!=} \frac{\alpha}{2}\|\mathbf{u}_h^{n+1} - \mathbf{U}^{n+1}\|^2 + \frac{\beta}{2}\|\mathbf{f}_h^{n+1} - \mathbf{F}^{n+1}\|^2 \qquad \forall\, \mathbf{u}_h^{n+1} \in \mathbf{X}_h,\ \forall\, \mathbf{f}_h^{n+1} \in \mathbf{Y}_h^{n+1}$$

  is minimized subject to the fully discrete Navier–Stokes equations

$$\begin{aligned} &\frac{1}{\Delta t}(\mathbf{u}_h^{n+1}, \mathbf{w}_h) + a(\mathbf{u}_h^{n+1}, \mathbf{w}_h) + \overline{c}(\mathbf{u}_h^{n+1}, \mathbf{u}_h^{n+1}, \mathbf{w}_h) + b(\mathbf{w}_h, p_h^{n+1}) \\ &\qquad = (\mathbf{f}_h^{n+1}, \mathbf{w}_h) + \frac{1}{\Delta t}(\widehat{\mathbf{u}}_h^n, \mathbf{w}_h) \qquad \forall\, \mathbf{w}_h \in \mathbf{X}_h \end{aligned} \tag{4.10}$$

  and

$$b(\mathbf{u}_h^{n+1}, r_h) = 0 \qquad \forall\, r_h \in S_h\,. \tag{4.11}$$

Using the techniques of [GHS] concerning the finite element approximations of optimal control problems for the steady-state Navier–Stokes equations, we can show that for each integer $n \geq 0$, there is a solution $(\widehat{\mathbf{u}}_h^{n+1}, \widehat{\mathbf{f}}_h^{n+1})$ for the $(n+1)$th fully discrete optimal control problem.

4.2. Dynamics of the fully discrete solutions of the piecewise optimal control problem. We now study the behavior of the fully discrete solutions $\widehat{\mathbf{u}}_h^n$ as $n \to \infty$.

For every t, we introduce an auxiliary element $(\mathbf{U}_h(t), P_h(t)) \in \mathbf{X}_h \times S_h$ determined by

$$a\,(\mathbf{U}_h(t), \mathbf{w}_h) + b\,(\mathbf{w}_h, P_h(t)) = a\,(\mathbf{U}(t), \mathbf{w}_h) \qquad \forall\, \mathbf{w}_h \in \mathbf{X}_h \tag{4.12}$$

and

$$b\,(\mathbf{U}_h(t), r_h) = 0 \qquad \forall\, r_h \in S_h\,. \tag{4.13}$$

The existence of such a $(\mathbf{U}_h(t), P_h(t))$ follows from the well-known results for the finite element approximations of the steady-state Stokes equations. Furthermore, under the assumption that there is a $k \geq 1$ such that

$$\mathbf{U} \in L^\infty\left(0, \infty; \mathbf{H}^{k+1}(\Omega)\right) \cap C\left([0, \infty); \mathbf{H}^{k+1}(\Omega)\right)\,, \tag{A6}$$

the following error estimates hold:

$$\begin{aligned} &\|\mathbf{U}_h(t) - \mathbf{U}(t)\|_1 + \|P_h(t)\| \\ &\qquad \leq \overline{C}_3 h^k \|\mathbf{U}(t)\|_{k+1} \leq \overline{C}_3 h^k \|\mathbf{U}\|_{L^\infty(0,\infty;\mathbf{H}^{k+1}(\Omega))} \end{aligned} \tag{4.14}$$

and

$$\|\mathbf{U}_h(t) - \mathbf{U}(t)\| \leq \overline{C}_4 h^{k+1} \|\mathbf{U}(t)\|_{k+1} \leq \overline{C}_4 h^{k+1} \|\mathbf{U}\|_{L^\infty(0,\infty;\mathbf{H}^{k+1}(\Omega))}, \tag{4.15}$$

where $\overline{C}_3$ and $\overline{C}_4$ are constants depending on Ω only; see, e.g., [GR] and [GH]. By differentiating (4.12), (4.13) with respect t, we see that $(\partial_t \mathbf{U}_h(t), \partial_t P_h(t))$ satisfies a system of equations similar to (4.12), (4.13) so that under the assumption

$$\partial_t \mathbf{U} \in L^\infty\left(0,\infty;\mathbf{H}^{k+1}(\Omega)\right) \cap C\left([0,\infty);\mathbf{H}^{k+1}(\Omega)\right) \tag{A7}$$

we have the error estimates

$$\begin{aligned} &\|\partial_t \mathbf{U}_h(t) - \partial_t \mathbf{U}(t)\|_1 + \|\partial_t P_h(t)\| \\ &\quad \le \overline{C}_3 h^k \|\partial_t \mathbf{U}(t)\|_{k+1} \le \overline{C}_3 h^k \|\partial_t \mathbf{U}\|_{L^\infty(0,\infty;\mathbf{H}^{k+1}(\Omega))} \end{aligned} \tag{4.16}$$

and

$$\begin{aligned} &\|\partial_t \mathbf{U}_h(t) - \partial_t \mathbf{U}(t)\| \\ &\quad \le \overline{C}_4 h^{k+1} \|\partial_t \mathbf{U}(t)\|_{k+1} \le \overline{C}_4 h^{k+1} \|\partial_t \mathbf{U}\|_{L^\infty(0,\infty;\mathbf{H}^{k+1}(\Omega))} \qquad \forall\, s \in [0,2]\,. \end{aligned} \tag{4.17}$$

By differentiating (4.12), (4.13) twice with respect t, we see that $(\partial_{tt} \mathbf{U}_h(t), \partial_{tt} P_h(t))$ also satisfies a system of equations similar to (4.12), (4.13) so that under the assumption

$$\partial_{tt} \mathbf{U} \in L^\infty\left(0,\infty;\mathbf{H}^1(\Omega)\right) \cap C\left([0,\infty);\mathbf{H}^1(\Omega)\right)\,, \tag{A8}$$

we have the error estimates for $(\partial_{tt} \mathbf{U}_h(t), \partial_{tt} P_h(t))$:

$$\|\partial_{tt} \mathbf{U}_h(t) - \partial_{tt} \mathbf{U}(t)\|_1 + \|\partial_{tt} P_h(t)\| \le \overline{C}_3 \|\partial_{tt} \mathbf{U}(t)\|_1 \le \overline{C}_3 \|\partial_{tt} \mathbf{U}\|_{L^\infty(0,\infty;\mathbf{H}^1(\Omega))}$$

and

$$\|\partial_{tt} \mathbf{U}_h(t) - \partial_{tt} \mathbf{U}(t)\| \le \overline{C}_4 h^s \|\partial_{tt} \mathbf{U}(t)\|_s \le \overline{C}_4 h^s \|\partial_{tt} \mathbf{U}\|_{L^\infty(0,\infty;\mathbf{H}^s(\Omega))} \qquad \forall\, s \in [0,1]\,;$$

in particular,

$$\|\partial_{tt} \mathbf{U}_h(t) - \partial_{tt} \mathbf{U}(t)\| \le \overline{C}_4 \|\partial_{tt} \mathbf{U}(t)\| \le \overline{C}_4 \|\partial_{tt} \mathbf{U}\|_{L^\infty(0,\infty;\mathbf{H}^1(\Omega))}\,. \tag{4.18}$$

Note that the regularity assumption (A8) for $\partial_{tt}\mathbf{U}$ is weaker than the assumptions (A6) for $\mathbf{U}$ or (A7) for $\partial_t \mathbf{U}$. As a result, the error estimate (4.18) is weaker than (4.15) or (4.17).

LEMMA 4.1. *Assume that hypotheses* (A1), (A2), (A5), (A6), (A7), *and* (A8) *hold. Assume further*

$$\|\mathbf{U}\|_{L^\infty(0,\infty;\mathbf{L}^4(\Omega))} < \frac{\nu}{\overline{C}_0}. \tag{A9}$$

For each integer $n \ge 0$, let $(\widehat{\mathbf{u}}_h^{n+1}, \widehat{p}_h^{n+1}, \widehat{\mathbf{f}}_h^{n+1})$ be a solution of the $(n+1)$th fully discrete optimal control problem. Then there exists an $h_0 > 0$ and constants $\overline{K}_1$, $\overline{K}_2$, and $\overline{K}_3$ such that for all $h \le h_0$ and all n,

$$\begin{aligned} &\mathcal{L}_h^{n+1}(\widehat{\mathbf{u}}_h^{n+1}, \widehat{\mathbf{f}}_h^{n+1}) \\ &\le \alpha\left(\frac{\|\widehat{\mathbf{u}}_h^n - \mathbf{U}_h^n\|^2}{1+\lambda_1 \overline{K}_1 \Delta t} + \frac{\overline{K}_2 h^{2k+2} \Delta t}{1+\lambda_1 \overline{K}_1 \Delta t} + \frac{\overline{K}_3 (\Delta t)^3}{1+\lambda_1 \overline{K}_1 \Delta t}\right) + \alpha \overline{C}_4^2 h^{2k+2} \|\mathbf{U}\|^2_{L^\infty(0,\infty;\mathbf{H}^{k+1}(\Omega))}\,, \end{aligned}$$

where

$$h_0 = h_0(\nu, \Omega, \mathbf{U}) \stackrel{\text{def}}{=\!=} \min\left\{ \left\{ \frac{\nu - \overline{C}_0 \|\mathbf{U}\|_{L^\infty(0,\infty;\mathbf{L}^4(\Omega))}}{2\overline{C}_1 \overline{C}_3 \|\mathbf{U}\|_{L^\infty(0,\infty;\mathbf{H}^{k+1}(\Omega))}} \right\}^{1/k}, 1 \right\}, \tag{4.19}$$

$$\begin{aligned}\overline{K}_1 &= \overline{K}_1(\nu,\Omega,\mathbf{U})\\ &\stackrel{\text{def}}{=\!=} \frac{1}{2}\left(\nu - \overline{C}_0\|\mathbf{U}\|_{L^\infty(0,\infty;\mathbf{L}^4(\Omega))} - \overline{C}_1\overline{C}_3 h_0^k \|\mathbf{U}\|_{L^\infty(0,\infty;\mathbf{H}^{k+1}(\Omega)))}\right),\end{aligned} \tag{4.20}$$

$$\begin{aligned}\overline{K}_2 = \overline{K}_2(\nu,\Omega,\mathbf{U}) \stackrel{\text{def}}{=\!=} \frac{4}{\overline{K}_1}\Bigg(&\left[\overline{C}_1^2\overline{C}_3^4 + 4\overline{C}_2^2\overline{C}_4^2\right]\|\mathbf{U}\|^4_{L^\infty(0,\infty;\mathbf{H}^{k+1}(\Omega))}\\ &+\frac{1}{\lambda_1}\overline{C}_4^2\,\|\partial_t\mathbf{U}\|^2_{L^\infty(0,\infty;\mathbf{H}^{k+1}(\Omega))}\Bigg),\end{aligned} \tag{4.21}$$

and

$$\overline{K}_3 = \overline{K}_3(\nu,\Omega,\mathbf{U}) \stackrel{\text{def}}{=\!=} \frac{8(\overline{C}_4^2+1)}{\lambda_1\overline{K}_1}\,\|\partial_{tt}\mathbf{U}\|^2_{L^\infty(0,\infty;\mathbf{H}^1(\Omega))} \tag{4.22}$$

with the constants $\overline{C}_0$, $\overline{C}_1$, $\overline{C}_2$, $\overline{C}_3$, *and* $\overline{C}_4$ *defined by* (4.7), (4.8), (4.9), (4.14), *and* (4.15), *respectively.*

Proof. Let $(\widetilde{\mathbf{u}}_h^{n+1}, \widetilde{p}_h^{n+1}) \in \mathbf{X}_h \times S_h$ be a solution of the equations

$$\begin{aligned}\frac{1}{\Delta t}(\widetilde{\mathbf{u}}_h^{n+1},\mathbf{w}_h) + a(\widetilde{\mathbf{u}}_h^{n+1},\mathbf{w}_h) + \overline{c}(\widetilde{\mathbf{u}}_h^{n+1},\widetilde{\mathbf{u}}_h^{n+1},\mathbf{w}_h) + b(\mathbf{w},\widetilde{q}_h^{n+1})\\ = (\mathbf{F}_h^{n+1},\mathbf{w}_h) + \frac{1}{\Delta t}(\widehat{\mathbf{u}}_h^n,\mathbf{w}_h) \qquad \forall\,\mathbf{w}_h \in \mathbf{X}_h\end{aligned} \tag{4.23}$$

and

$$b(\widetilde{\mathbf{u}}_h^{n+1}, r_h) = 0 \qquad \forall\, r_h \in S_h\,. \tag{4.24}$$

(The existence of such a $(\widetilde{\mathbf{u}}^{n+1}, \widetilde{p}^{n+1})$ can be proved by using the techniques for proving the existence of finite element solutions for the steady-state Navier–Stokes equations; see, e.g., [GR].) Set $\widetilde{\mathbf{f}}_h^{n+1} = \mathbf{F}_h^{n+1} \in \mathbf{Y}_h$.

From (1.16), (A1), and (4.4), we obtain

$$\begin{aligned}(\partial_t\mathbf{U}(t_{n+1}),\mathbf{w}_h) + a\left(\mathbf{U}(t_{n+1}),\mathbf{w}_h\right) + \overline{c}\left(\mathbf{U}(t_{n+1}),\mathbf{U}(t_{n+1}),\mathbf{w}_h\right)\\ = (\mathbf{F}(t_{n+1}),\mathbf{w}_h) \qquad \forall\,\mathbf{w}_h \in \mathbf{X}_h\end{aligned}$$

and

$$b\left(\mathbf{U}(t_{n+1}), r_h\right) = 0 \qquad \forall\, r_h \in S_h\,.$$

Let $(\mathbf{U}_h(t), P_h(t))$ be defined by (4.12), (4.13). Setting $\mathbf{V}_h(t) = \mathbf{U}_h(t) - \mathbf{U}(t)$ and using (4.12), (4.13) and the fact that $(\mathbf{F}_h^{n+1},\mathbf{w}_h) = (\mathbf{F}^{n+1},\mathbf{w}_h)$ for all $\mathbf{w}_h \in \mathbf{X}_h$, we are led to

$$\begin{aligned}(\partial_t\mathbf{U}_h(t_{n+1}),\mathbf{w}_h) - (\partial_t\mathbf{V}_h(t_{n+1}),\mathbf{w}_h) + a\left(\mathbf{U}_h(t_{n+1}),\mathbf{w}_h\right) + b\left(\mathbf{w}_h, P_h(t_{n+1})\right)\\ + \overline{c}\left(\mathbf{U}(t_{n+1}),\mathbf{U}(t_{n+1}),\mathbf{w}_h\right) = (\mathbf{F}(t_{n+1}),\mathbf{w}_h) \qquad \forall\,\mathbf{w}_h \in \mathbf{X}_h\end{aligned} \tag{4.25}$$

and

$$b\left(\mathbf{U}_h(t_{n+1}), r_h\right) = 0 \qquad \forall\, r_h \in S_h\,. \tag{4.26}$$

We introduce the notations $\mathbf{U}_h^{n+1} = \mathbf{U}_h(t_{n+1})$, $P_h^{n+1} = P_h(t_{n+1})$, $\mathbf{V}_h^{n+1} = \mathbf{V}_h(t_{n+1})$, and $(\partial_t\mathbf{V}_h)^{n+1} = \partial_t\mathbf{V}_h(t_{n+1})$ (also recall $\mathbf{F}^{n+1} = \mathbf{F}(t_{n+1})$). By plugging into (4.25) the finite difference approximation formula

$$\partial_t\mathbf{U}_h(\mathbf{x},t_{n+1}) = \frac{\mathbf{U}_h^{n+1}(\mathbf{x}) - \mathbf{U}_h^n(\mathbf{x})}{\Delta t} + \boldsymbol{\tau}_h^{n+1}(\mathbf{x})\,,$$

we obtain

(4.27)
$$\frac{1}{\Delta t}\left(\mathbf{U}_h^{n+1}-\mathbf{U}_h^n,\mathbf{w}_h\right)+a\left(\mathbf{U}_h^{n+1},\mathbf{w}_h\right)+\overline{c}\left(\mathbf{U}^{n+1},\mathbf{U}^{n+1},\mathbf{w}_h\right)+b\left(\mathbf{w}_h,P_h^{n+1}\right)$$
$$=\left(\mathbf{F}^{n+1},\mathbf{w}_h\right)-\left(\boldsymbol{\tau}_h^{n+1},\mathbf{w}_h\right)+\left((\partial_t\mathbf{V}_h)^{n+1},\mathbf{w}_h\right)\qquad\forall\,\mathbf{w}_h\in\mathbf{X}_h$$

and

$$b\left(\mathbf{U}_h^{n+1},r_h\right)=0\qquad\forall\,r_h\in S_h\,. \tag{4.28}$$

We now examine the error term $\boldsymbol{\tau}_h^{n+1}(\mathbf{x})$ in the previous finite difference formula. Since

$$\begin{aligned}\boldsymbol{\tau}_h^{n+1}(\mathbf{x})&=\partial_t\mathbf{U}(\mathbf{x},t_{n+1})-\frac{\mathbf{U}_h(\mathbf{x},t_{n+1})-\mathbf{U}_h(\mathbf{x},t_n)}{\Delta t}\\&=\frac{1}{\Delta t}\int_{t_n}^{t_{n+1}}\int_s^{t_{n+1}}\partial_{tt}\mathbf{U}_h(\mathbf{x},\sigma)\,d\sigma\,ds,\end{aligned}$$

we see that

$$\begin{aligned}\|\boldsymbol{\tau}_h^{n+1}\|^2=(\boldsymbol{\tau}_h^{n+1},\boldsymbol{\tau}_h^{n+1})&=\frac{1}{\Delta t}\int_{t_n}^{t_{n+1}}\int_s^{t_{n+1}}\int_\Omega\partial_{tt}\mathbf{U}_h(\mathbf{x},\sigma)\cdot\boldsymbol{\tau}_h^{n+1}(\mathbf{x})\,d\mathbf{x}\,d\sigma\,ds\\&\le\frac{1}{\Delta t}\int_{t_n}^{t_{n+1}}\int_s^{t_{n+1}}\|\partial_{tt}\mathbf{U}_h(\sigma)\|\,\|\boldsymbol{\tau}_h^{n+1}\|\,d\sigma\,ds\,.\end{aligned}$$

Hence

$$\begin{aligned}\|\boldsymbol{\tau}_h^{n+1}\|&\le\|\partial_{tt}\mathbf{U}_h\|_{L^\infty(0,\infty;\mathbf{L}^2(\Omega))}\cdot\frac{1}{\Delta t}\int_{t_n}^{t_{n+1}}\int_s^{t_{n+1}}d\sigma\,ds\\&\le\Delta t\,\|\partial_{tt}\mathbf{U}_h\|_{L^\infty(0,\infty;\mathbf{L}^2(\Omega))}.\end{aligned}$$

We note that by (4.18),

$$\begin{aligned}\|\boldsymbol{\tau}_h^{n+1}\|^2&\le2(\Delta t)^2\left(\|\partial_{tt}\mathbf{V}_h\|^2_{L^\infty(0,\infty;\mathbf{L}^2(\Omega))}+\|\partial_{tt}\mathbf{U}\|^2_{L^\infty(0,\infty;\mathbf{L}^2(\Omega))}\right)\\&\le2(\Delta t)^2\left(\overline{C}_4^2+1\right)\|\partial_{tt}\mathbf{U}\|^2_{L^\infty(0,\infty;\mathbf{H}^1(\Omega))}\,.\end{aligned} \tag{4.29}$$

Now, let $\widetilde{\mathbf{v}}_h^{n+1}=\widetilde{\mathbf{u}}_h^{n+1}-\mathbf{U}_h^{n+1}$, $\widetilde{q}_h^{n+1}=\widetilde{p}_h^{n+1}-P_h^{n+1}$, and $\widehat{\mathbf{v}}_h^n=\widehat{\mathbf{u}}_h^n-\mathbf{U}_h^n$. Then by subtracting (4.27), (4.28) from (4.23), (4.24) and again by using $(\mathbf{F}_h^{n+1},\mathbf{w}_h)=(\mathbf{F}^{n+1},\mathbf{w}_h)$ for all $\mathbf{w}_h\in\mathbf{X}_h$, we obtain

$$\begin{aligned}&\frac{1}{\Delta t}(\widetilde{\mathbf{v}}_h^{n+1},\mathbf{w}_h)-\frac{1}{\Delta t}(\widehat{\mathbf{v}}_h^n,\mathbf{w}_h)+a(\widetilde{\mathbf{v}}_h^{n+1},\mathbf{w}_h)+\overline{c}(\widetilde{\mathbf{v}}_h^{n+1},\widetilde{\mathbf{v}}_h^{n+1},\mathbf{w}_h)+\overline{c}(\widetilde{\mathbf{v}}_h^{n+1},\mathbf{V}_h^{n+1},\mathbf{w}_h)\\&\quad+\overline{c}(\mathbf{V}_h^{n+1},\widetilde{\mathbf{v}}_h^{n+1},\mathbf{w}_h)+\overline{c}(\widetilde{\mathbf{v}}_h^{n+1},\mathbf{U}^{n+1},\mathbf{w}_h)+\overline{c}(\mathbf{U}^{n+1},\widetilde{\mathbf{v}}_h^{n+1},\mathbf{w}_h)\\&\quad+\overline{c}(\mathbf{V}_h^{n+1},\mathbf{V}_h^{n+1},\mathbf{w}_h)+\overline{c}(\mathbf{V}_h^{n+1},\mathbf{U}^{n+1},\mathbf{w}_h)+\overline{c}(\mathbf{U}^{n+1},\mathbf{V}_h^{n+1},\mathbf{w}_h)\\&\quad+b(\mathbf{w}_h,\widetilde{q}_h^{n+1})=(\boldsymbol{\tau}_h^{n+1},\mathbf{w}_h)-\left((\partial_t\mathbf{V}_h)^{n+1},\mathbf{w}_h\right)\qquad\forall\,\mathbf{w}_h\in\mathbf{X}_h\end{aligned}$$

and

$$b(\widetilde{\mathbf{v}}_h^{n+1},r_h)=0\qquad\forall\,r_h\in S_h\,.$$

Setting $\mathbf{w}_h = \widetilde{\mathbf{v}}_h^{n+1}$ in the first of the last two equations and using (4.5)–(4.9), we have

$$\begin{aligned}
&\frac{1}{2\Delta t}\left(\|\widetilde{\mathbf{v}}_h^{n+1}\|^2 - \|\widehat{\mathbf{v}}_h^{n}\|^2 + \|\widetilde{\mathbf{v}}_h^{n+1} - \widehat{\mathbf{v}}_h^{n}\|^2\right) + \nu\|\nabla\widetilde{\mathbf{v}}_h^{n+1}\|^2 \\
&= -\overline{c}(\widetilde{\mathbf{v}}_h^{n+1}, \mathbf{V}_h^{n+1}, \widetilde{\mathbf{v}}_h^{n+1}) - \overline{c}(\widetilde{\mathbf{v}}_h^{n+1}, \mathbf{U}^{n+1}, \widetilde{\mathbf{v}}_h^{n+1}) - \overline{c}(\mathbf{V}_h^{n+1}, \mathbf{V}_h^{n+1}, \widetilde{\mathbf{v}}_h^{n+1}) \\
&\quad - \overline{c}(\mathbf{V}_h^{n+1}, \mathbf{U}^{n+1}, \widetilde{\mathbf{v}}_h^{n+1}) - \overline{c}(\mathbf{U}^{n+1}, \mathbf{V}_h^{n+1}, \widetilde{\mathbf{v}}_h^{n+1}) \\
&\quad + (\boldsymbol{\tau}_h^{n+1}, \widetilde{\mathbf{v}}_h^{n+1}) - \left((\partial_t \mathbf{V}_h)^{n+1}, \widetilde{\mathbf{v}}_h^{n+1}\right) \\
&\le \overline{C}_1\|\nabla\widetilde{\mathbf{v}}_h^{n+1}\|^2\,\|\nabla\mathbf{V}_h^{n+1}\| + \overline{C}_0\|\nabla\widetilde{\mathbf{v}}_h^{n+1}\|^2\,\|\mathbf{U}^{n+1}\|_{\mathbf{L}^4(\Omega)} + \overline{C}_1\|\nabla\mathbf{V}_h^{n+1}\|^2\,\|\nabla\widetilde{\mathbf{v}}_h^{n+1}\| \\
&\quad + 2\overline{C}_2\,\|\mathbf{V}_h^{n+1}\|\,\|\mathbf{U}^{n+1}\|_2\,\|\nabla\widetilde{\mathbf{v}}_h^{n+1}\| + \|\boldsymbol{\tau}_h^{n+1}\|\,\|\widetilde{\mathbf{v}}_h^{n+1}\| + \|(\partial_t\mathbf{V}_h)^{n+1}\|\,\|\widetilde{\mathbf{v}}_h^{n+1}\|\,.
\end{aligned}$$

By choosing h_0 as in (4.19) and using (4.14) we see that for all $h \le h_0$,

$$\|\nabla\mathbf{V}_h^{n+1}\| \le \overline{C}_3 h^k \|\mathbf{U}\|_{L^\infty(0,\infty;\mathbf{H}^{k+1}(\Omega))} \le \overline{C}_3 h_0^k \|\mathbf{U}\|_{L^\infty(0,\infty;\mathbf{H}^{k+1}(\Omega))}\,.$$

We define the constant $\overline{K}_1 = \overline{K}_1(\nu, \Omega, \mathbf{U})$ by (4.20) and continue the last inequality involving $\widetilde{\mathbf{v}}_h^{n+1}$ to obtain (by using (4.14) and the inequality $ab \le \epsilon a^2 + \epsilon^{-1}b^2/4$)

$$\begin{aligned}
&\frac{1}{2\Delta t}\left(\|\widetilde{\mathbf{v}}_h^{n+1}\|^2 - \|\widehat{\mathbf{v}}_h^{n}\|^2\right) + \nu\|\nabla\widetilde{\mathbf{v}}_h^{n+1}\|^2 \\
&\le \overline{C}_1\overline{C}_3 h_0^k \|\mathbf{U}\|_{L^\infty(0,\infty;\mathbf{H}^{k+1}(\Omega))}\,\|\nabla\widetilde{\mathbf{v}}_h^{n+1}\|^2 + \overline{C}_0\|\nabla\widetilde{\mathbf{v}}_h^{n+1}\|^2\,\|\mathbf{U}\|_{L^\infty(0,\infty;\mathbf{L}^4(\Omega))} \\
&\quad + \frac{2\overline{C}_1^2}{\overline{K}_1}\|\nabla\mathbf{V}_h^{n+1}\|^4 + \frac{\overline{K}_1}{8}\|\nabla\widetilde{\mathbf{v}}_h^{n+1}\|^2 + \frac{8\overline{C}_2^2}{\overline{K}_1}\|\mathbf{V}_h^{n+1}\|^2\,\|\mathbf{U}^{n+1}\|_2^2 + \frac{\overline{K}_1}{8}\|\nabla\widetilde{\mathbf{v}}_h^{n+1}\|^2 \\
&\quad + \frac{2}{\lambda_1\overline{K}_1}\|\boldsymbol{\tau}_h^{n+1}\|^2 + \frac{\lambda_1\overline{K}_1}{8}\|\widetilde{\mathbf{v}}_h^{n+1}\|^2 + \frac{2}{\overline{K}_1\lambda_1}\|(\partial_t\mathbf{V}_h)^{n+1}\|^2 + \frac{\overline{K}_1\lambda_1}{8}\|\widetilde{\mathbf{v}}_h^{n+1}\|^2\,.
\end{aligned}$$

Using Poincaré inequality for the terms involving $\lambda_1\|\widetilde{\mathbf{v}}_h^{n+1}\|^2$ and simplifying, we obtain

$$\begin{aligned}
&\frac{1}{2\Delta t}\left(\|\widetilde{\mathbf{v}}_h^{n+1}\|^2 - \|\widehat{\mathbf{v}}_h^{n}\|^2\right) + \frac{\overline{K}_1}{2}\|\nabla\widetilde{\mathbf{v}}_h^{n+1}\|^2 \\
&\le \frac{2}{\overline{K}_1}\left(\overline{C}_1^2\,\|\nabla\mathbf{V}_h^{n+1}\|^4 + 4\overline{C}_2^2\,\|\mathbf{V}_h^{n+1}\|^2\,\|\mathbf{U}^{n+1}\|_2^2 + \frac{1}{\lambda_1}\,\|(\partial_t\mathbf{V}_h)^{n+1}\|^2 + \frac{1}{\lambda_1}\,\|\boldsymbol{\tau}_h^{n+1}\|^2\right),
\end{aligned}$$

so that using (4.14)–(4.18) and (4.29), we are led to

$$\begin{aligned}
&\|\widetilde{\mathbf{v}}_h^{n+1}\|^2 + \overline{K}_1\Delta t\,\|\nabla\widetilde{\mathbf{v}}_h^{n+1}\|^2 \\
&\le \|\widehat{\mathbf{v}}_h^{n}\|^2 + \frac{4\Delta t}{\overline{K}_1}\left(\overline{C}_1^2\overline{C}_3^4\,h^{4k}\,\|\mathbf{U}\|^4_{L^\infty(0,\infty;\mathbf{H}^{k+1}(\Omega))} + 4\overline{C}_2^2\overline{C}_4^2\,h^{2k+2}\,\|\mathbf{U}\|^4_{L^\infty(0,\infty;\mathbf{H}^{k+1}(\Omega))}\right. \\
&\qquad\qquad + \frac{1}{\lambda_1}\overline{C}_4^2\,h^{2k+2}\,\|\partial_t\mathbf{U}\|^2_{L^\infty(0,\infty;\mathbf{H}^{k+1}(\Omega))} \\
&\qquad\qquad \left. + \frac{2(\Delta t)^2(\overline{C}_4^2+1)}{\lambda_1}\,\|\partial_{tt}\mathbf{U}\|^2_{L^\infty(0,\infty;\mathbf{H}^{1}(\Omega))}\right).
\end{aligned}$$

Hence, using Poincaré inequality again for the second term on the left-hand side of the last inequality, we obtain

$$\|\widetilde{\mathbf{v}}_h^{n+1}\|^2 \le \frac{\|\widehat{\mathbf{v}}_h^n\|^2}{1+\lambda_1\overline{K}_1\Delta t} + \frac{\overline{K}_2 h^{2k+2}(\Delta t)}{1+\lambda_1\overline{K}_1\Delta t} + \frac{\overline{K}_3(\Delta t)^3}{1+\lambda_1\overline{K}_1\Delta t}\,,$$

where $\overline{K}_2$ and $\overline{K}_3$ are defined by (4.21), (4.22). Using the definition of the functional $\mathcal{L}_h^{n+1}$ and (4.15), we obtain

$$\mathcal{L}_h^{n+1}(\widetilde{\mathbf{u}}_h^{n+1},\widetilde{\mathbf{f}}_h^{n+1}) = \frac{\alpha}{2}\|\widetilde{\mathbf{v}}_h^{n+1}+\mathbf{U}_h^{n+1}-\mathbf{U}^{n+1}\|^2 \le \alpha\,\|\widetilde{\mathbf{v}}_h^{n+1}\|^2 + \alpha\,\|\mathbf{U}_h^{n+1}-\mathbf{U}^{n+1}\|^2$$
$$\le \alpha\left[\frac{\|\widehat{\mathbf{v}}_h^n\|^2}{1+\lambda_1\overline{K}_1\Delta t} + \frac{\overline{K}_2 h^{2k+2}\Delta t}{1+\lambda_1\overline{K}_1\Delta t} + \frac{\overline{K}_3(\Delta t)^3}{1+\lambda_1\overline{K}_1\Delta t}\right] + \alpha\overline{C}_4^2 h^{2k+2}\,\|\mathbf{U}\|^2_{L^\infty(0,\infty;\mathbf{H}^{k+1}(\Omega))}.$$

$(\widehat{\mathbf{u}}_h^{n+1},\widehat{p}_h^{n+1},\widehat{\mathbf{f}}_h^{n+1})$ being a solution for the $(n+1)$th fully discrete optimal control problem, the desired estimate follows trivially from the last inequality. ∎

THEOREM 4.2. *Assume that the hypotheses of Lemma* 4.1 *hold. Assume further that* $\mathbf{u}_0 \in \mathbf{H}^{k+1}(\Omega)$ *and*

$$\frac{\alpha}{\beta} < \frac{(\lambda_1\overline{K}_1)^2}{16}, \tag{A10}$$

where $\overline{K}_1$ *is defined by* (4.20). *Let* h_0 *be defined by* (4.19). *Then there are positive constants* $\delta_0 = \delta_0(\nu,\Omega,\mathbf{U})$, $\overline{K}_4 = \overline{K}_4(\nu,\Omega,\mathbf{U})$, $\overline{K}_5 = \overline{K}_5(\nu,\Omega,\mathbf{U})$, $\overline{K}_6 = \overline{K}_6(\nu,\Omega,\mathbf{U})$, $\overline{\gamma} = \overline{\gamma}(\nu,\Omega,\mathbf{U})$, *and* $\overline{\kappa} = \overline{\kappa}(\nu,\Omega,\mathbf{U})$ *such that for all* $h \le h_0$ *and all* $\Delta t \le \delta_0$,

$$\|\widehat{\mathbf{u}}_h^{n+1}-\mathbf{U}_h^{n+1}\|^2 \le (1-\overline{K}_4\Delta t)\|\widehat{\mathbf{u}}_h^n-\mathbf{U}_h^n\|^2 + \overline{K}_5\Delta t^3 + \overline{K}_6 h^{2k+2}(\Delta t)$$

and

$$\|\widehat{\mathbf{u}}_h^n-\mathbf{U}^n\|^2 \le 3e^{-\overline{\gamma}t_n}\|\widehat{\mathbf{u}}_0-\mathbf{U}^0\|^2 + \overline{\kappa}\left[(\Delta t)^2 + h^{2k+2}\right].$$

Proof. The optimizer $(\widehat{\mathbf{u}}_h^{n+1},\widehat{p}_h^{n+1},\widehat{\mathbf{f}}_h^{n+1})$ satisfies (4.10), (4.11). Let $\mathbf{U}_h^{n+1}$, P_h^{n+1}, $\mathbf{V}_h^{n+1}$, and $(\partial_t\mathbf{V}_h)^{n+1}$ be defined as in the proof of Lemma 4.1 and satisfy (4.25), (4.26). By setting $\widehat{\mathbf{v}}_h^{n+1} = \widehat{\mathbf{u}}_h^{n+1} - \mathbf{U}_h^{n+1}$, $\widehat{q}_h^{n+1} = \widehat{p}_h^{n+1} - \widehat{P}^{n+1}$, $\widehat{\mathbf{g}}_h^{n+1} = \widehat{\mathbf{f}}_h^{n+1} - \mathbf{F}_h^{n+1}$ and subtracting (4.25), (4.26) from (4.10), (4.11) with $(\mathbf{u}_h^{n+1},p_h^{n+1},\mathbf{f}_h^{n+1}) = (\widehat{\mathbf{u}}_h^{n+1},\widehat{p}_h^{n+1},\widehat{\mathbf{f}}_h^{n+1})$, we see that

(4.30)
$$\frac{1}{\Delta t}(\widehat{\mathbf{v}}_h^{n+1},\mathbf{w}_h) + a(\widehat{\mathbf{v}}_h^{n+1},\mathbf{w}_h) + \overline{c}(\widehat{\mathbf{v}}_h^{n+1},\widehat{\mathbf{v}}_h^{n+1},\mathbf{w}_h) + \overline{c}(\widehat{\mathbf{v}}_h^{n+1},\mathbf{V}_h^{n+1},\mathbf{w}_h)$$
$$+ \overline{c}(\mathbf{V}_h^{n+1},\widehat{\mathbf{v}}_h^{n+1},\mathbf{w}_h) + \overline{c}(\widehat{\mathbf{v}}_h^{n+1},\mathbf{U}^{n+1},\mathbf{w}_h) + \overline{c}(\mathbf{U}^{n+1},\widehat{\mathbf{v}}_h^{n+1},\mathbf{w}_h)$$
$$+ \overline{c}(\mathbf{V}_h^{n+1},\mathbf{V}_h^{n+1},\mathbf{w}_h) + \overline{c}(\mathbf{V}_h^{n+1},\mathbf{U}^{n+1},\mathbf{w}_h) + \overline{c}(\mathbf{U}^{n+1},\mathbf{V}_h^{n+1},\mathbf{w}_h) + b(\mathbf{w}_h,\widehat{q}_h^{n+1})$$
$$= (\widehat{\mathbf{g}}_h^{n+1}+\boldsymbol{\tau}_h^{n+1},\mathbf{w}_h) + \frac{1}{\Delta t}(\widehat{\mathbf{v}}_h^n,\mathbf{w}_h) - \left((\partial_t\mathbf{V}_h)^{n+1},\mathbf{w}_h\right) \qquad \forall\,\mathbf{w}_h \in \mathbf{X}_h$$

and

$$b(\widehat{\mathbf{v}}_h^{n+1},r_h) = 0 \qquad \forall\, r_h \in S_h\,. \tag{4.31}$$

Setting $\mathbf{w}_h = \widehat{\mathbf{v}}_h^{n+1}$ in the first of the last two equations and using the same tricks as in the proof of Lemma 4.1 (with $\widehat{\mathbf{u}}_h^{n+1}$ replacing $\widetilde{\mathbf{u}}_h^{n+1}$ and $\widehat{\mathbf{g}}_h^{n+1}+\boldsymbol{\tau}_h^{n+1}$ replacing

$\boldsymbol{\tau}_h^{n+1}$), we obtain

$$\begin{aligned}
&\frac{1}{2\Delta t}\left(\|\widehat{\mathbf{v}}_h^{n+1}\|^2-\|\widehat{\mathbf{v}}_h^{n}\|^2\right)+\frac{\overline{K}_1}{2}\|\nabla\widehat{\mathbf{v}}_h^{n+1}\|^2\\
&\le\frac{2}{\overline{K}_1}\Big(\overline{C}_1^2\,\|\nabla\mathbf{V}_h^{n+1}\|^4+4\overline{C}_2^2\,\|\mathbf{V}_h^{n+1}\|^2\,\|\mathbf{U}^{n+1}\|_2^2\\
&\qquad+\frac{1}{\lambda_1}\,\|(\partial_t\mathbf{V}_h)^{n+1}\|^2+\frac{1}{\lambda_1}\,\|\widehat{\mathbf{g}}_h^{n+1}+\boldsymbol{\tau}_h^{n+1}\|^2\Big)\\
&\le\frac{4\|\widehat{\mathbf{g}}_h^{n+1}\|^2}{\lambda_1\overline{K}_1}+\frac{2}{\overline{K}_1}\Big(\overline{C}_1^2\overline{C}_3^4\,h^{4k}\,\|\mathbf{U}\|^4_{L^\infty(0,\infty;\mathbf{H}^{k+1}(\Omega))}\\
&\qquad\qquad+4\overline{C}_2^2\overline{C}_4^2\,h^{2k+2}\,\|\mathbf{U}\|^4_{L^\infty(0,\infty;\mathbf{H}^{k+1}(\Omega))}\\
&\qquad\qquad+\frac{1}{\lambda_1}\overline{C}_4^2\,h^{2k+2}\,\|\partial_t\mathbf{U}\|^2_{L^\infty(0,\infty;\mathbf{H}^{k+1}(\Omega))}\\
&\qquad\qquad+\frac{4(\Delta t)^2(\overline{C}_4^2+1)}{\lambda_1}\,\|\partial_{tt}\mathbf{U}\|^2_{L^\infty(0,\infty;\mathbf{H}^{1}(\Omega))}\Big)
\end{aligned}$$

so that

$$\|\widehat{\mathbf{v}}_h^{n+1}\|^2+\overline{K}_1\Delta t\,\|\nabla\widehat{\mathbf{v}}_h^{n+1}\|^2\le\|\widehat{\mathbf{v}}_h^{n}\|^2+\overline{K}_2h^{2k+2}(\Delta t)+2\overline{K}_3(\Delta t)^3+\frac{8\Delta t}{\lambda_1\overline{K}_1}\|\widehat{\mathbf{g}}^{n+1}\|^2,$$

where $\overline{K}_1$, $\overline{K}_2$, and $\overline{K}_3$ are defined by (4.20), (4.21), and (4.22), respectively. Using Lemma 4.1 we see that

$$\begin{aligned}
(\beta/2)\|\widehat{\mathbf{g}}_h^{n+1}\|^2&\le\mathcal{L}_h^{n+1}(\widehat{\mathbf{u}}_h^{n+1},\widehat{\mathbf{f}}_h^{n+1})\\
&\le\alpha\,\left(\|\widehat{\mathbf{v}}_h^{n}\|^2+\overline{K}_2h^{2k+2}\Delta t+\overline{K}_3(\Delta t)^3\right)+\alpha\overline{C}_4^2h^{2k+2}\,\|\mathbf{U}\|^2_{L^\infty(0,\infty;\mathbf{H}^{k+1}(\Omega))}.
\end{aligned}$$

By combining the last two inequalities we are led to

$$\begin{aligned}
&\|\widehat{\mathbf{v}}_h^{n+1}\|^2+\overline{K}_1\Delta t\,\|\nabla\widehat{\mathbf{v}}_h^{n+1}\|^2\\
&\le\|\widehat{\mathbf{v}}_h^{n}\|^2+\overline{K}_2h^{2k+2}(\Delta t)+2\overline{K}_3(\Delta t)^3\\
&\qquad+\frac{16\alpha\Delta t}{\beta\lambda_1\overline{K}_1}\left(\|\widehat{\mathbf{v}}_h^{n}\|^2+\overline{K}_2h^{2k+2}(\Delta t)+\overline{K}_3(\Delta t)^3\right)\\
&\qquad+\frac{16\alpha\overline{C}_4^2(\Delta t)h^{2k+2}}{\beta\lambda_1\overline{K}_1}\,\|\mathbf{U}\|^2_{L^\infty(0,\infty;\mathbf{H}^{k+1}(\Omega))}\qquad(4.32)\\
&\le\left[1+16\alpha(\beta\lambda_1\overline{K}_1)^{-1}\Delta t\right]\,\|\widehat{\mathbf{v}}_h^{n}\|^2+\left(2\overline{K}_3+\frac{16\alpha\overline{K}_3\Delta t}{\beta\lambda_1\overline{K}_1}\right)(\Delta t)^3\\
&\qquad+\left(\overline{K}_2+\frac{16\alpha\overline{K}_2\Delta t}{\beta\lambda_1\overline{K}_1}+\frac{16\alpha\overline{C}_4^2}{\beta\lambda_1\overline{K}_1}\,\|\mathbf{U}\|^2_{L^\infty(0,\infty;\mathbf{H}^{k+1}(\Omega))}\right)h^{2k+2}(\Delta t).
\end{aligned}$$

Using (A10), we can find a sufficiently small positive constant $\delta_0=\delta_0(\nu,\Omega,\mathbf{U})$ and a positive constant $\overline{K}_4=\overline{K}_4(\nu,\Omega,\mathbf{U})$ such that

$$0<\frac{\left[1+16\alpha(\beta\lambda_1\overline{K}_1)^{-1}\Delta t\right]}{1+\lambda_1\overline{K}_1\Delta t}\le(1-\overline{K}_4\Delta t)$$

for all $\Delta t \le \delta_0$. Defining

$$\begin{aligned}\overline{K}_5 &\stackrel{\text{def}}{=\!=} \overline{K}_5(\nu,\Omega,\mathbf{U})\\ &= \overline{K}_2 + \frac{16\alpha\overline{K}_2\delta_0}{\beta\lambda_1\overline{K}_1} + \frac{16\alpha\overline{C}_4^2}{\beta\lambda_1\overline{K}_1}\,\|\mathbf{U}\|^2_{L^\infty(0,\infty;\mathbf{H}^{k+1}(\Omega))}\end{aligned}$$

and

$$\overline{K}_6 \stackrel{\text{def}}{=\!=} \overline{K}_6(\nu,\Omega,\mathbf{U}) = 2\overline{K}_3 + \frac{16\alpha\overline{K}_3\delta_0}{\beta\lambda_1\overline{K}_1},$$

we obtain from (4.32) that

$$\|\widehat{\mathbf{v}}_h^{n+1}\|^2 + \overline{K}_1\Delta t\,\|\nabla\widehat{\mathbf{v}}_h^{n+1}\|^2 \le \|\widehat{\mathbf{v}}_h^n\|^2 + \overline{K}_5 h^{2k+2}(\Delta t) + \overline{K}_6(\Delta t)^3\,, \tag{4.33}$$

so by noting

$$\|\widehat{\mathbf{v}}_h^{n+1}\|^2 + \overline{K}_1\Delta t\,\|\nabla\widehat{\mathbf{v}}_h^{n+1}\|^2 \ge (1+\lambda_1\overline{K}_1\Delta t)\,\|\widehat{\mathbf{v}}_h^{n+1}\|^2\,,$$

we are led to

$$\|\widehat{\mathbf{v}}_h^{n+1}\|^2 \le (1-\overline{K}_4\Delta t)\|\widehat{\mathbf{v}}_h^n\|^2 + \overline{K}_5 h^{2k+2}(\Delta t) + \overline{K}_6(\Delta t)^3\,.$$

By induction, we may prove

$$\begin{aligned}\|\widehat{\mathbf{v}}_h^n\|^2 &\le (1-\overline{K}_4\Delta t)^n\|\widehat{\mathbf{v}}_h^0\|^2 + \left(\overline{K}_5 h^{2k+2}(\Delta t) + \overline{K}_6(\Delta t)^3\right)\sum_{j=0}^{n-1}(1-\overline{K}_4\Delta t)^j\\ &= (1-\overline{K}_4\Delta t)^n\|\widehat{\mathbf{u}}_{0,h} - \mathbf{U}_h^0\|^2 + \left(\frac{\overline{K}_5}{\overline{K}_4}h^{2k+2} + \frac{\overline{K}_6}{\overline{K}_4}(\Delta t)^2\right)\left[1-(1-\overline{K}_4\Delta t)^n\right]\\ &\le \left[(1-\overline{K}_4\Delta t)^{\frac{1}{\overline{K}_4\Delta t}}\right]^{\overline{K}_4 n\Delta t}\|\mathbf{u}_{0,h} - \mathbf{U}_h^0\|^2 \ + \frac{\overline{K}_5}{\overline{K}_4}h^{2k+2} + \frac{\overline{K}_6}{\overline{K}_4}(\Delta t)^2\,.\end{aligned}$$

Applying the inequality $1-y \le e^{-y}$ for all $y \ge 0$, we are led to

$$\|\widehat{\mathbf{v}}_h^n\|^2 \le e^{-\overline{K}_4 t_n}\|\mathbf{u}_{0,h} - \mathbf{U}_h^0\|^2 + \frac{\overline{K}_5}{\overline{K}_4}h^{2k+2} + \frac{\overline{K}_6}{\overline{K}_4}(\Delta t)^2\,.$$

Using the triangle inequality we obtain

$$\begin{aligned}\|\widehat{\mathbf{u}}_h^n - \mathbf{U}^n\|^2 &\le 2\|\widehat{\mathbf{u}}_h^n - \mathbf{U}_h^n\|^2 + 2\|\mathbf{U}_h^n - \mathbf{U}^n\|^2\\ &\le e^{-\overline{K}_4 t_n}\|\widehat{\mathbf{u}}_{0,h} - \mathbf{U}_h^0\|^2 + \frac{\overline{K}_5}{\overline{K}_4}h^{2k+2} + \frac{\overline{K}_6}{\overline{K}_4}(\Delta t)^2 + 2\overline{C}_4^2\,h^{2k+2}\,\|\mathbf{U}\|^2_{L^\infty(0,\infty;\mathbf{H}^2(\Omega))}\,.\end{aligned}$$

Using the triangle inequality again we also have

$$\begin{aligned}\|\mathbf{u}_{0,h} - \mathbf{U}_h^0\|^2 &\le 3\|\mathbf{u}_{0,h} - \mathbf{u}_0\|^2 + 3\|\mathbf{u}^0 - \mathbf{U}^0\|^2 + 3\|\mathbf{U}^0 - \mathbf{U}_h^0\|^2\\ &\le 3Ch^{2k+2}\|\mathbf{u}_0\|^2_{\mathbf{H}^{k+1}(\Omega))} + 3\|\widehat{\mathbf{u}}^0 - \mathbf{U}^0\|^2 + 3\overline{C}_4^2 h^{2k+2}\|\mathbf{U}\|^2_{L^\infty(0,\infty;\mathbf{H}^{k+1}(\Omega))}\,.\end{aligned}$$

By combining the last two inequalities we arrive at

$$\|\widehat{\mathbf{u}}_h^n - \mathbf{U}^n\|^2 \le 3e^{-\overline{\gamma}t_n}\|\widehat{\mathbf{u}}_0 - \mathbf{U}^0\|^2 + \overline{\kappa}\left[(\Delta t)^2 + h^{2k+2}\right],$$

where $\overline{\gamma} = \overline{K}_4$ and

$$\overline{\kappa} = \max\left\{\overline{K}_6/\overline{K}_4\,,\, 5\overline{C}_4^2\|\mathbf{U}\|^2_{L^\infty(0,\infty;\mathbf{H}^{k+1}(\Omega))} + 3C\|\mathbf{u}_0\|^2_{\mathbf{H}^{k+1}(\Omega))} + \overline{K}_5/\overline{K}_4\right\}. \qquad \square$$

As an easy consequence of Theorem 4.2, Theorem 2.7, and the inequality

$$\|\widehat{\mathbf{u}}(t_n) - \widehat{\mathbf{u}}_h^n\|^2 \le 2\|\widehat{\mathbf{u}}(t_n) - \mathbf{U}^n\|^2 + 2\|\mathbf{U}^n - \widehat{\mathbf{u}}_h^n\|^2,$$

we obtain the following estimate for the difference between the continuous and fully discrete solutions of the piecewise optimal control problem.

COROLLARY 4.3. *Assume that the hypotheses of Theorems* 4.2 *and* 2.7 *hold. Let* $\widehat{\mathbf{u}}$ *denote the global solution of the piecewise optimal control problem and* $\widehat{\mathbf{u}}_h^n$ *denote the fully discrete solutions of the piecewise optimal control problem. Then there are positive constants* $\overline{M} = \overline{M}(\nu, \Omega, \mathbf{U})$, $\overline{K}_7 = \overline{K}_7(\nu, \Omega, \mathbf{U})$, *and* $\overline{K}_8 = \overline{K}_8(\nu, \Omega, \mathbf{U})$ *such that*

$$\|\widehat{\mathbf{u}}(t_n) - \widehat{\mathbf{u}}_h^n\|^2 \le \overline{M}\, e^{-\overline{K}_7\, t_n}\|\widehat{\mathbf{u}}_0 - \mathbf{U}^0\|^2 + \overline{K}_8\left[(\Delta t)^2 + h^{2k+2}\right]. \qquad \square$$

We now estimate the dynamics in $\mathbf{H}^1(\Omega)$ norm between the fully discrete solution $\mathbf{u}_h^n$ and the desired flow $\mathbf{U}^n$ as $n \to \infty$.

THEOREM 4.4. *Assume that the hypotheses of Lemma* 4.1 *and Theorem* 4.2 *hold. Then there are positive constants* $\overline{K}_9 = \overline{K}_9(\nu, \Omega, \mathbf{U})$ *and* $\overline{\kappa}' = \overline{\kappa}'(\nu, \Omega, \mathbf{U})$ *such that for all* $h \le h_0$ *and* $\Delta t \le \delta_0$,

$$\|\nabla\widehat{\mathbf{u}}_h^n - \nabla\mathbf{U}^n\|^2 \le \frac{\overline{K}_9}{\Delta t}e^{-\overline{\gamma}t_n}\|\mathbf{u}_0 - \mathbf{U}^0\|^2 + \overline{\kappa}'\left((\Delta t) + \frac{h^{2k+2}}{\Delta t}\right), \tag{4.34}$$

where the constants h_0, δ_0, *and* $\overline{\gamma}$ *are as defined in the proof of Theorem* 4.2.

Proof. We use the same notations $(\widehat{\mathbf{u}}_h^{n+1}, \widehat{p}_h^{n+1}, \widehat{\mathbf{f}}_h^{n+1})$, $\widehat{\mathbf{U}}_h^{n+1}$, $\widehat{P}_h^{n+1}$, $(\partial_t\widehat{\mathbf{V}}_h)^{n+1}$, $\widehat{\mathbf{V}}_h^{n+1}$, $\widehat{\mathbf{v}}_h^{n+1}$, $\widehat{q}_h^{n+1}$, and $\widehat{\mathbf{g}}_h^{n+1}$ as in the proof of Theorem 4.2. From the proof of Theorem 4.2, in particular from (4.33), we have

$$\|\widehat{\mathbf{v}}_h^{n+1}\|^2 + \overline{K}_1\Delta t\,\|\nabla\widehat{\mathbf{v}}_h^{n+1}\|^2 \le \|\widehat{\mathbf{v}}_h^n\|^2 + \overline{K}_5 h^{2k+2}(\Delta t) + \overline{K}_6(\Delta t)^3,$$

where the various constants are as defined in the proof of Lemma 4.1 and Theorem 4.2. By dropping the term $\|\widehat{\mathbf{v}}_h^{n+1}\|^2$ and using Theorem 4.2 we obtain

$$\begin{aligned}
&\|\nabla\widehat{\mathbf{v}}_h^{n+1}\|^2 \\
&\le \frac{1}{\overline{K}_1\Delta t}\,\|\widehat{\mathbf{v}}_h^n\|^2 + \overline{K}_5 h^{2k+2} + \overline{K}_6(\Delta t)^2 \\
&\le \frac{1}{\overline{K}_1\Delta t}\left(3e^{-\overline{\gamma}t_n}\|\widehat{\mathbf{u}}_0 - \mathbf{U}^0\|^2 + \overline{\kappa}\left[(\Delta t)^2 + h^{2k+2}\right]\right) + \overline{K}_5 h^{2k+2} + \overline{K}_6(\Delta t)^2 \\
&\le \frac{\overline{K}_9}{\Delta t}e^{-\overline{\gamma}t_n}\|\widehat{\mathbf{u}}_0 - \mathbf{U}^0\|^2 + \overline{\kappa}'\left((\Delta t) + \frac{h^{2k+2}}{\Delta t}\right),
\end{aligned}$$

where $\overline{K}_9 \stackrel{\text{def}}{=\!=} 3/\overline{K}_1$ and $\overline{\kappa}' \stackrel{\text{def}}{=\!=} \max\{\overline{\kappa}, \overline{K}_5, \overline{K}_6\}$. $\square$

Remark 4.5. We note that whenever Δt is fixed, the first term on the right-hand side of (4.34) decays to zero exponentially as $n \to \infty$. If $h = \Delta t^s$ with $s > 0$, then the second term on the right-hand side of (4.34) is of order $O((\Delta t) + (\Delta t)^{2ks+2s-1})$, i.e.,

$$\limsup_{t\to\infty}\|\nabla\widehat{\mathbf{u}}_h^n - \nabla\mathbf{U}^n\| = O((\Delta t)^{1/2} + (\Delta t)^{ks+s-1/2}),$$

which is optimal when $h = (\Delta t)^{1/(k+1)}$. $\square$

Remark 4.6. Naturally one wishes to improve the estimate (4.34) to

$$\|\nabla\widehat{\mathbf{u}}_h^n - \nabla\mathbf{U}^n\|^2 \le \overline{K}_{10}e^{-\overline{\gamma}t_n}\|\mathbf{u}_0 - \mathbf{U}^0\|^2 + \overline{K}_{11}\left((\Delta t) + h^{2k+2}\right). \tag{4.35}$$

It does not appear that one can do so without major modifications in the statement of the problem. We mention one such modification that allows us to obtain the improved estimate (4.35); namely, if we consider the penalized functional

$$\mathcal{P}_h^{n+1}(\mathbf{u}_h^{n+1}, \mathbf{f}_h^{n+1}) \stackrel{\text{def}}{=\!=} \frac{\alpha}{2}\|\mathbf{u}_h^{n+1} - \mathbf{U}^{n+1}\|^2 + \frac{\beta}{2}\|\mathbf{f}_h^{n+1} - \mathbf{F}^{n+1}\|^2 + \frac{\gamma}{2}\left\|\frac{\mathbf{f}_h^{n+1} - \mathbf{f}_h^n}{\Delta t} - \frac{\mathbf{F}^{n+1} - \mathbf{F}^n}{\Delta t}\right\|^2$$

in place of $\mathcal{L}_h^{n+1}(\mathbf{u}_h^{n+1}, \mathbf{f}_h^{n+1})$ and the hypothesis $\partial_{tt}\mathbf{U} \in L^\infty(0,\infty;\mathbf{H}^{k+1}(\Omega)) \cap C([0,\infty);\mathbf{H}^{k+1}(\Omega))$ holds (in addition to the hypotheses of Theorem 4.4, of course), then the estimate (4.35) holds. An outline of a proof for this result is as follows. By virtue of the penalty term in the new functional $\mathcal{P}_h^{n+1}(\mathbf{u}_h^{n+1}, \mathbf{f}_h^{n+1})$, one can estimate the decay property of the discrete time derivative $(\widehat{\mathbf{v}}_h^{n+1} - \widehat{\mathbf{v}}_h^n)/\Delta t$ by taking the difference of the equations for $\widehat{\mathbf{v}}_h^{n+1}$ and $\widehat{\mathbf{v}}_h^n$ and setting $\mathbf{w}_h = (\widehat{\mathbf{v}}_h^{n+1} - \widehat{\mathbf{v}}_h^n)/\Delta t$. Then, (4.35) is proven by estimating $\nu\|\nabla\widehat{\mathbf{v}}_h^{n+1}\|^2$ in (4.30) with $\mathbf{w}_h = \widehat{\mathbf{v}}_h^{n+1}$. We omit the details of the proof because it is very lengthy and, more importantly, by introducing the penalized functional $\mathcal{P}_h^{n+1}(\mathbf{u}_h^{n+1}, \mathbf{f}_h^{n+1})$, we are too far removed from the original control objectives. □

Remark 4.7. In order to solve the $(n+1)$th fully discrete optimal control problem for each n, we need to introduce a Lagrange multiplier $(\widehat{\boldsymbol{\mu}}_h^{n+1}, \widehat{\pi}_h^{n+1})$ to convert the $(n+1)$th fully discrete optimal control problem into a discrete optimality system of equations (similar to the semidiscrete case). A solution for the $(n+1)$th fully discrete optimal control problem can be found by solving the discrete optimality system of equations which consists of (4.10), (4.11),

$$\begin{aligned}\frac{1}{\Delta t}(\boldsymbol{\mu}_h^{n+1}, \boldsymbol{\omega}_h) + a(\boldsymbol{\mu}_h^{n+1}, \boldsymbol{\omega}_h) + \overline{c}(\boldsymbol{\omega}_h, \mathbf{u}_h^{n+1}, \boldsymbol{\mu}_h^{n+1}) + \overline{c}(\mathbf{u}_h^{n+1}, \boldsymbol{\omega}_h, \boldsymbol{\mu}_h^{n+1}) \\ + b(\boldsymbol{\omega}_h, \pi_h^{n+1}) = \alpha(\mathbf{u}_h^{n+1} - \mathbf{U}^{n+1}, \boldsymbol{\omega}_h) \qquad \forall\, \boldsymbol{\omega}_h \in \mathbf{X}_h,\end{aligned} \tag{4.36}$$

$$b(\boldsymbol{\mu}_h^{n+1}, \tau_h) = 0 \qquad \forall\, \tau_h \in S_h, \tag{4.37}$$

and

$$(\boldsymbol{\mu}_h^{n+1} + \beta\mathbf{f}_h^{n+1} - \beta\mathbf{F}^{n+1}, \mathbf{z}_h) = 0 \qquad \forall\, \mathbf{z}_h \in \mathbf{X}_h\,. \tag{4.38}$$

Using the techniques of [GHS], we can show that the above discrete optimality system of equations indeed has a solution $(\widehat{\mathbf{u}}_h^{n+1}, \widehat{p}_h^{n+1}, \widehat{\mathbf{f}}_h^{n+1}, \widehat{\boldsymbol{\mu}}_h^{n+1}, \widehat{\pi}_h^{n+1})$. By eliminating $\mathbf{f}_h^{n+1}$, we arrive at the slightly simplified optimality system of equations for the $(n+1)$th fully discrete optimal control problem, which consists of

$$\begin{aligned}\frac{1}{\Delta t}(\mathbf{u}_h^{n+1}, \mathbf{w}_h) + a(\mathbf{u}_h^{n+1}, \mathbf{w}_h) + \overline{c}(\mathbf{u}_h^{n+1}, \mathbf{u}_h^{n+1}, \mathbf{w}_h) + b(\mathbf{w}_h, p_h^{n+1}) \\ = (\mathbf{F}_h^{n+1} - \beta^{-1}\boldsymbol{\mu}_h^{n+1}, \mathbf{w}_h) + \frac{1}{\Delta t}(\mathbf{u}_h^n, \mathbf{w}_h) \qquad \forall\, \mathbf{w}_h \in \mathbf{X}_h\,,\end{aligned} \tag{4.39}$$

(4.11), (4.36), and (4.37). □

5. An algorithm and a computational example. From the definition of the fully discrete piecewise optimal control problem and Remark 4.6, we summarize an algorithm for solving the fully discrete piecewise optimal control problem.

ALGORITHM 5.1.

- Choose a (sufficiently small) $\delta > 0$ and set $\Delta t = \delta$. Choose a (sufficiently small) h.
- Define $\mathbf{u}_h^0 = \mathbf{U}_h^0$, where $\mathbf{U}_h^0$ is the $\mathbf{L}^2(\Omega)$-projection (or interpolation) of $\mathbf{U}^0$ onto $\mathbf{X}_h$.
- (*Solving the* $(n+1)$*th fully discrete optimal control problem*)
  For $n = 0, 1, 2, \ldots$, find a $(\mathbf{u}_h^{n+1}, p_h^{n+1}, \boldsymbol{\mu}_h^{n+1}, \pi_h^{n+1}) \in \mathbf{X}_h \times S_h \times \mathbf{X}_h \times S_h$ such that

$$\frac{1}{\Delta t}(\mathbf{u}_h^{n+1}, \mathbf{w}_h) + a(\mathbf{u}_h^{n+1}, \mathbf{w}_h) + \overline{c}(\mathbf{u}_h^{n+1}, \mathbf{u}_h^{n+1}, \mathbf{w}_h) + b(\mathbf{w}_h, p_h^{n+1})$$
$$= (\mathbf{F}_h^{n+1} - \beta^{-1}\boldsymbol{\mu}_h^{n+1}, \mathbf{w}_h) + \frac{1}{\Delta t}(\mathbf{u}_h^n, \mathbf{w}_h) \qquad \forall\, \mathbf{w}_h \in \mathbf{X}_h\,,$$

$$b(\mathbf{u}_h^{n+1}, r_h) = 0 \qquad \forall\, r_h \in S_h\,,$$

$$\frac{1}{\Delta t}(\boldsymbol{\mu}_h^{n+1}, \boldsymbol{\omega}_h) + a(\boldsymbol{\mu}_h^{n+1}, \boldsymbol{\omega}_h) + \overline{c}(\boldsymbol{\omega}_h, \mathbf{u}_h^{n+1}, \boldsymbol{\mu}_h^{n+1}) + \overline{c}(\mathbf{u}_h^{n+1}, \boldsymbol{\omega}_h, \boldsymbol{\mu}_h^{n+1})$$
$$+ b(\boldsymbol{\omega}_h, \pi_h^{n+1}) = \alpha(\mathbf{u}_h^{n+1} - \mathbf{U}^{n+1}, \boldsymbol{\omega}_h) \qquad \forall\, \boldsymbol{\omega}_h \in \mathbf{X}_h,$$

  and
$$b(\boldsymbol{\mu}_h^{n+1}, \tau_h) = 0 \qquad \forall\, \tau_h \in S_h\,.$$

- Set $\mathbf{f}_h^{n+1} = \mathbf{F}_h^{n+1} - \beta^{-1}\boldsymbol{\mu}_h^{n+1}$.

We now report some computational results for solving the piecewise optimal control problem by implementing Algorithm 5.1. This example demonstrates that the piecewise optimal control mechanism does a very good job of tracking the velocity field. Also, in the solution process an optimal body force distribution can be obtained. The computational example also reinforces the theoretical results.

Here are some detailed data of the example. We choose the domain $\Omega = (0,1) \times (0,1)$ (i.e., the unit square). The desired velocity field

$$\mathbf{U}(\mathbf{x}, t) = \begin{pmatrix} \varphi_y(x_1, x_2, t) \\ -\varphi_x(x_1, x_2, t) \end{pmatrix}$$

is constructed from the stream function

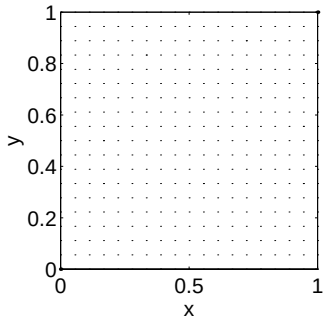
$$\varphi(x_1, x_2, t) = \theta(x_1, t)\theta(x_2, t)$$

with

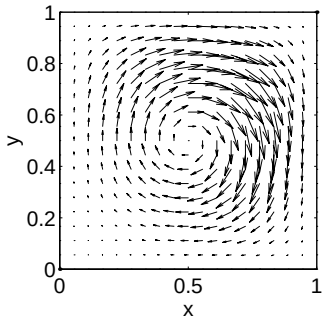
$$\theta(y, t) = (1-y)^2\,(1 - \cos(2k\pi y t))\,, \qquad y \in [0, 1].$$

The integer parameter k ($k = 2$ for the current computation) involved in $\mathbf{U}$ adjusts the number of eddies of circulation presented in the desired flow, thus determines the complexity of the desired flow. Note that $\mathbf{U}$ defined in such a way satisfies the divergence-free condition and the zero boundary conditions. The desired body force is computed by (1.16), namely,

$$\mathbf{F} = \mathbf{u}_t - \nu\Delta\mathbf{U} + (\mathbf{U} \cdot \nabla)\mathbf{U}.$$

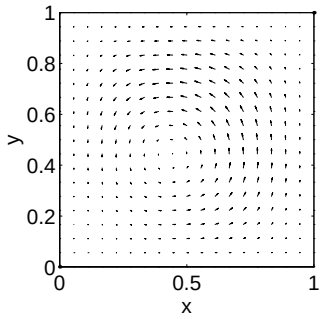


Desired flow: $t = 0$.

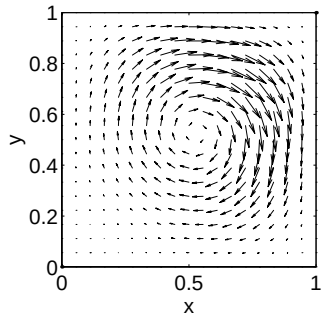


Controlled flow: $t = 0$.

FIG. 1.



Desired flow: $t = 0.3$.



Controlled flow: $t = 0.3$.

FIG. 2.

The uncontrolled initial state is

$$\mathbf{u}_0(\mathbf{x}) = e \begin{pmatrix} (\cos(2\pi x_1) - 1)\sin(2\pi x_2) \\ \sin(2\pi x_1)(1 - \cos(2\pi x_2)) \end{pmatrix}.$$

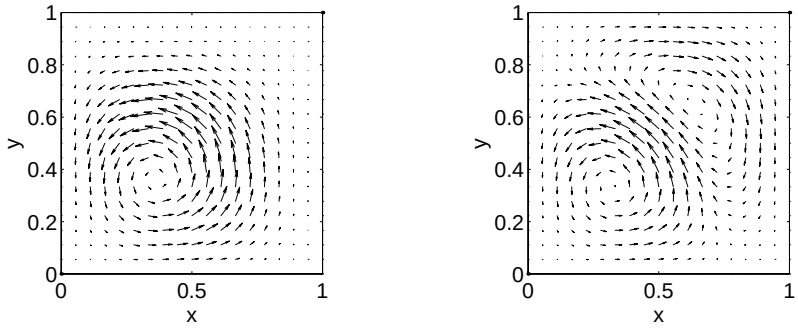
We choose the viscosity constant $\nu = 0.1$ and the time step $\Delta t = \delta = 0.1$ for the computation. The finite elements are chosen to be the Taylor–Hood elements; i.e., the finite element space $\mathbf{X}_h$ is chosen to be piecewise quadratic elements (for $\mathbf{u}_h$ and $\boldsymbol{\mu}_h$) and S_h is chosen to be piecewise linear elements (p_h and π_h). Thus we have $k = 2$ in (4.1), (4.2). The finite-dimensional nonlinear optimality system of equations in Algorithm 5.1 needs to be solved by a nonlinear solver. Newton's method is used to solve the finite-dimensional nonlinear system of equations. Note that our finite element spaces are nonconforming in the sense that the discrete divergence-free condition $b(\mathbf{u}_h^n, r_h) = 0$ does not imply the continuous divergence-free condition, i.e., $\nabla \cdot \mathbf{u}_h^n \neq 0$.

The computational results obtained by implementing Algorithm 5.1 with the above data are presented in graphical form with Figures 1–10.

For better graphics purposes, we plot

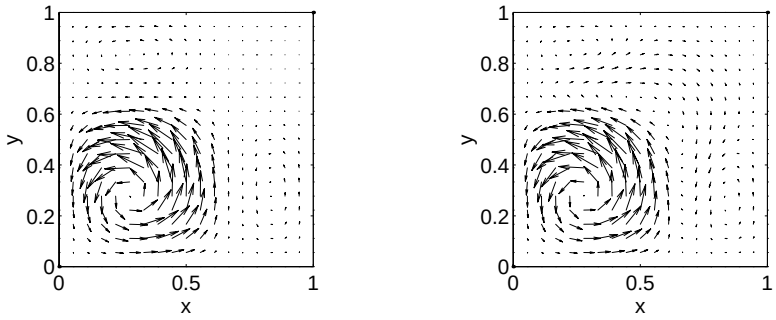
$$\sigma(1 + 100(x_1^2 + x_2^2))\mathbf{u}(\mathbf{x}, t),$$

instead of $\mathbf{u}$, where $\sigma > 0$ is a scaling factor. The purpose of the scaling is to magnify the small structure of the desired flow $\mathbf{U}(\mathbf{x}, t)$ close to the upper right corner of the physical domain Ω.



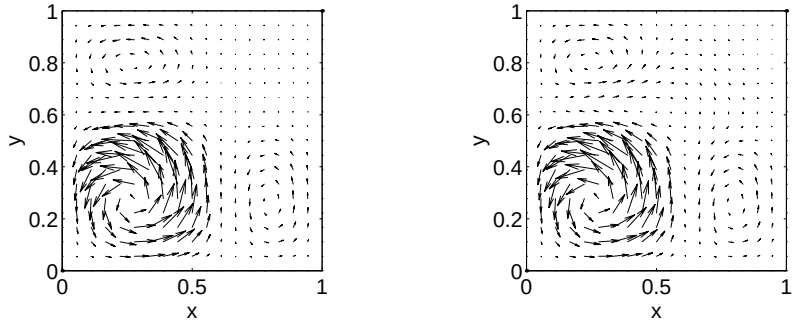
Desired flow: $t = 0.5$. *Controlled flow:* $t = 0.5$.

FIG. 3.



Desired flow: $t = 0.8$. *Controlled flow:* $t = 0.8$.

FIG. 4.



Desired flow: $t = 0.9$. *Controlled flow:* $t = 0.9$.

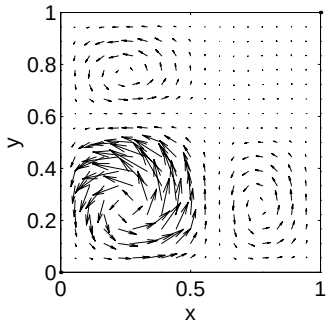
FIG. 5.

Figure 1 shows the initial states $\mathbf{U}_0$ and $\mathbf{u}_0$ of the desired and controlled flows with $\sigma = 0.0005$. Note that $\mathbf{u}_0$ is far away from the zero vector field $\mathbf{U}_0$.

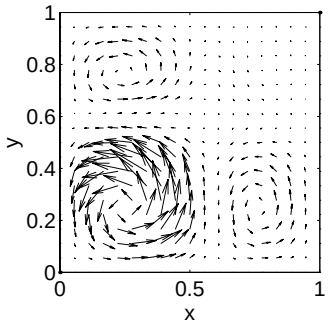
When $t > 0$ becomes larger, the magnitude of the desired flow $\mathbf{U}(t)$ increases but that of the controlled flow $\mathbf{u}(t)$ decreases significantly at the first few steps.

Figures 2–9 are plotted with $\sigma = 0.002$.

During $0 \le t \le 0.7$, the control is in the transient stage. At $t = 0.3$ (Figure 2), neither the position of the eddy nor the magnitude of the velocity field $\mathbf{u}$ matches well with $\mathbf{U}$. At $t = 0.5$, the large eddy of the controlled flow $\mathbf{u}$ splits into two

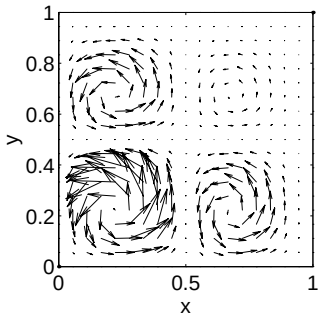


Desired flow: $t = 1.0$.

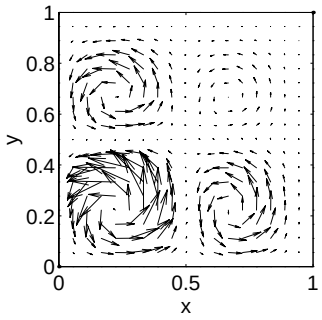


Controlled flow: $t = 1.0$.

FIG. 6.

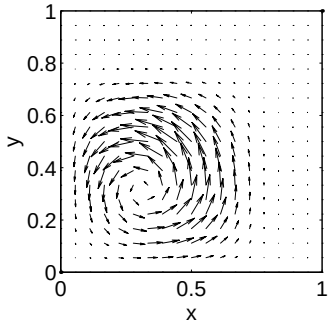


Desired flow: $t = 1.5$.

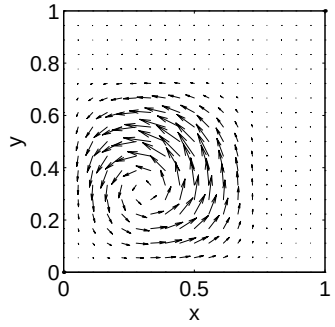


Controlled flow: $t = 1.5$.

FIG. 7.



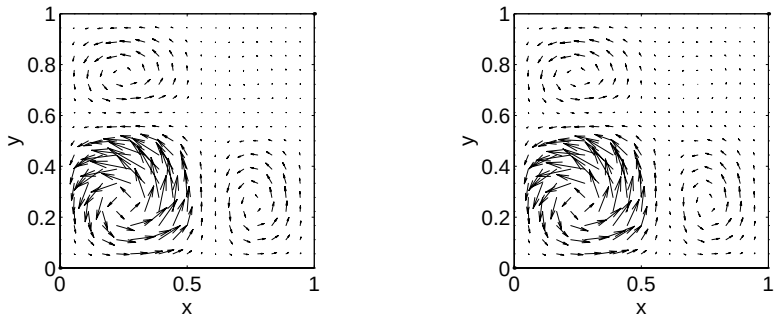
Desired flow: $t = 3.8$.



Controlled flow: $t = 3.8$.

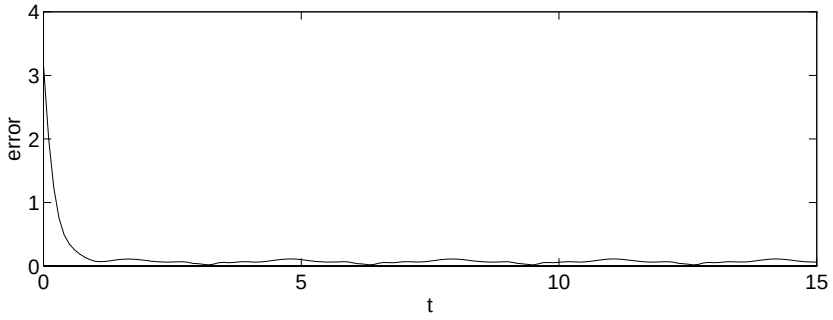
FIG. 8.

eddies, with one at the right position and the other fading as t increases. Starting from $t = 0.8$, the controlled flow matches the desired flow so well that we can hardly distinguish one from the other with naked eyes (Figures 4–6 for $t = 0.8, 0.9, 1.0$). Of course, $\mathbf{u}$ is not identical to $\mathbf{U}$ at this stage, but the difference is at a very small scale. The controlled flow fine-tunes itself to match the desired flow quantitatively. As the distributed control continues to be applied, "perfect matching" (to our naked eyes) is preserved. Some pictures for long time control are included in Figures 7–9 for $t = 1.5, 3.8, 14.7$.



Desired flow: $t = 14.7$. *Controlled flow:* $t = 14.7$.

FIG. 9.



Error reduction in t.

FIG. 10.

In summary, in very short time (starting from $t \sim 0.8$), the controlled velocity field is in nice agreement with the target field. These results reinforce the theoretical exponential decay estimate of $\|\mathbf{u}_h^n - \mathbf{U}^n\|$ (see Corollary 4.3).

On the other hand, in Figure 10, we see that the error $\|\mathbf{u}_h^n - \mathbf{U}^n\|$ is quickly reduced initially and then oscillates between 0 and 0.11 rather than being further reduced. This is due to the discretization error $O(h^3 + \Delta t)$ in Corollary 4.3. By choosing smaller h and Δt, we can reduce the eventual error in the velocity tracking. For more computational details, see [HRY].

ANNEALING OF ITERATIVE STOCHASTIC SCHEMES*

HAITAO FANG†, GUANGLU GONG‡, AND MINPING QIAN†

Abstract. Annealing of general iterative stochastic schemes is studied by using Wentzell's large deviation theory. The convergence of this algorithm is shown under some conditions. The closed form of the critical constant is specified in terms of its potential function of the mean model.

Key words. global minimum, iterative stochastic schemes, large deviation, potential function, simulated annealing

1. Introduction.

Adaptive algorithms with stochastics appear frequently in various applications, such as learning algorithms [17], optimization (simulated annealing [16], genetic algorithms [9], evolution computation [15]), neural networks [12], system identification, adaptive controls, signal modeling, filtering, and transmission [12], [21]. The function of these algorithms is to adjust a state vector (or monitored parameter vector) X_n for specifying the system considered, where n refers to the time of observation of the system. In most cases of applications mentioned above, the rule used to update $X.$ will typically be of the form

$$X_{n+1} = X_n + r_n b\left(X_n, \xi_n\right), \tag{1.1}$$

where $\{r_n\}$ is a sequence of small gains and ξ_n is the input of the system at time n, either deterministic or stochastic. These algorithms have been studied (see [1] and references therein). It is shown that they do not always converge to the desired result. For instance, when a cost (or, say, potential) function $U(x)$ is given, the algorithm will be constructed by the method in [1]; however, it isn't always successful in finding an element in the set $\underline{S} = \{z \in R^d,\, U(z) = \min_{x \in R^d} U(x)\}$. To avoid getting trapped in local minima, stochastic perturbation is added as follows:

$$X_{n+1} = X_n + r_n b\left(X_n, \xi_n\right) + h_n \zeta_n, \tag{1.2}$$

where ζ_n is a sequence of independently and identically distributed (i.i.d.) random variables. Borrowing the idea of annealing process in statistical mechanics, it is called the simulated annealing algorithm [16].

In various special cases, the asymptotic behavior of (1.2) as $n \to \infty$ has been studied in [18], [6], [7], [19], [20]. In [18], the global optimization result is achieved for the case of $b\left(X_n, \xi_n\right) = -\nabla U\left(X_n\right)$, $h_n = r_n$ and $\zeta_n = W_n$ being i.i.d. Gaussian random variables. In [19], using the result of Dubrushin for inhomogeneous Markov chains, the convergence result is achieved, in which the appropriate choice of $\{r_n\}$ depends on the distribution of ξ_n. One of the cases which can be represented explicitly is that ξ_n is also Gaussian; in this case, $\{r_n\}$ is the solution of the equation $cr_n / \ln r_n =$

$1/\ln n$ and $h_n = -1/\ln r_n$ with a large constant c. The model with $\zeta_n = W_n$, $b(X_n, \xi_n) = -\nabla U(x) + \xi_n$ and $r_n = A/n$, $h_n = \sqrt{B/(n \ln\ln n)}$ is studied in [6], [7], and based on the result of [3], the following result is obtained: If $U(x)$, $\{\xi_n\}$ are suitably behaved and $B/A > \Lambda$ (a constant depending only on $U(x)$), then $X_n \to \underline{S}$ in probability as $n \to +\infty$.

Similar to (1.2), the stochastic differential equation in continuous time

$$dX_t = -\nabla U(X_t)\, dt + c_t dW_t \tag{1.3}$$

is studied, which is a rather familiar model in probability theory called a Langevin-type Markov diffusion. Especially, [14] gives a comprehensive observation of the large time behavior of (1.3), where Hwang and Sheu's main result can be roughly stated as follows: Under some mild conditions on $U(x)$ and $c_t = \sqrt{c/\ln t}$ for large t, there exist Λ, $d^* > 0$ such that, when $c > \Lambda$, for $f \in C_b(R^d)$,

$$E_{0,y}(f(X_t)) \to \int f(x)\, \mu(dx) \qquad \text{as } t \to +\infty$$

uniformly for y in a compact set, where $\mu(dx)$ is the weak limit of the measures $\frac{1}{Z_\epsilon} \exp\{-\frac{U(x)}{\epsilon}\}dx$ as $\epsilon \to 0 (Z_\epsilon = \int \exp\{-\frac{U(x)}{\epsilon}\}dx)$; and when $c > d^*$,

$$P_{0,y}\{X_t \in B(\underline{S},\ l)\} \to 1 \qquad \text{as } t \to +\infty \tag{1.4}$$

uniformly for y in any compact set, where $B(\underline{S},\ l)$ is the l-neighborhood of $\underline{S}$, while for $c < d^*$, (1.4) fails. The proof of these results is based on the large deviation estimates of small Gaussian perturbations of the dynamical system [5].

The model of (1.2) in such a general form studied in the present article provides more flexibility for application. In fact, in many cases, the mechanism of systems is not as simple as those in [18], [19], where the increments of X at time n are only sums of ξ_n and a function of X_n. It often appears as a complicated multivariable function of ξ_n and X_n, e.g., in Kohonen's algorithm and many other algorithms. Hence a consideration for model (1.2) is not only of theoretical generality but also of practical significance. The work of [6], [7] is based on this general form, while $\{r_n\}$ and $\{h_n\}$ therein are too restricted and there is a lack of information on the convergence rate of the algorithm. To obtain the corresponding results of asymptotic behavior in [14] for the model (1.2), the methods used in [6], [7], [19], [14], etc., seem not to be enough. Based on the idea of using large deviations theory to study simulated annealing for a finite number of states in [24], we borrow the generalized large deviation theory of Wentzell [25] and then give a uniform treatment and convergence theorem which includes results in [6], [7], [19].

In [14], the critical constants Λ, $d^*(c^*,\ d^*$ in [14]) are specified by a sequence of definitions connected with cycles, which become rather complicated to reveal their meaning through $U(x)$. In [13], Λ is identified by

$$\Lambda = 2 \sup_{x,y \in R^d} \inf_{\varphi} \sup_{0 \le t \le 1} \left(U(\varphi(t)) - U(x) - U(y) + U_0\right),$$

where φ belongs to the set of continuous routes which link x to y.

In the present article, under the conditions

(1) $b(x, y)$ is a bounded measurable function such that $\bar{b}(x) = Eb(x, \xi_n)$ is uniformly continuous,

(2) ζ_n is an i.i.d. random sequence and $E\zeta_n = 0$,

(3) $\{r_n\}$ and $\{h_n\}$ satisfy assumptions (A1)–(A3) in section 2 and (A4) (or (A4′), (A4″)) in section 3 (we will show that these assumptions do include a fairly wide class of $\{r_n\}$ and $\{h_n\}$),

the large deviation principle for the family of $\{X_n\}$ as $n \to +\infty$ is observed in section 3, which is used mainly as a tool to reach our goal.

The main result of this article is exploited in section 5: If $\bar{b}(x)$ has a potential function $U(x)$, then under some restrictions on the behavior of $\bar{b}(x)$ and $b(x, \xi_n)$ at infinity ((B1)–(B3)), for $\{r_n\}$ in a wide class, one can always choose $\{h_n\}$ such that

$$P_{0,y}\{X_n \in B(\underline{S}, l)\} \to 1 \qquad \text{as } n \to +\infty \tag{1.5}$$

uniformly for y in an arbitrary compact set F. Moreover, for the convergence of X_n in the sense of (1.5), h_n has to be chosen decreasing slowly enough. How slow this is depends on the order of r_n. For instance, when $r_n = 1/n^\gamma + o(1/n^\gamma)(\gamma < 1)$, the critical rate of h_n is $c/\left((1-\gamma) n^{\gamma/2} \ln n\right)$ for c large enough. Furthermore, we identify the closed form of the lower bound d^* of c for convergence:

$$d^* = 2 \sup_{x \in S \setminus \underline{S}} \inf_{y \in \underline{S}} \inf_{\varphi} \sup_{0 \le t \le 1} (U(\varphi(t)) - U(x)) \vee 0,$$

which is analogous to that obtained for finite state processes in [11], where $S = \left\{x \in R^d, \nabla U(x) = 0\right\}$ and $\varphi \in C\left([0, 1], R^d\right)$, $\varphi(0) = x$, $\varphi(1) = y$. We also show that the convergence rate of the algorithm is not the same for different $\{r_n\}$ and $\{h_n\}$. Moreover, changing $\{r_n\}$, $\{h_n\}$ given in [6], [7] will accelerate the convergence speed of the algorithm.

The materials in the appendix are devoted to exploiting the complicated definition of cycles.

2. Preliminaries. We consider the following stochastic approximation model:

$$X_{n+1} = X_n + r_n b(X_n, \xi_n) + \sqrt{r_n h_n}\zeta_n, \tag{2.1}$$

where $\{r_n\}$ is a sequence of small gains monotonically decreasing to zero, satisfying $\sum_n r_n = +\infty$, and $\{h_n\}$ also tends to zero monotonically. We also assume that $\{\xi_n\}$ and $\{\zeta_n\}$ are i.i.d. random vectors respectively, and $\{\xi_n\}$ and $\{\zeta_n\}$ are mutually independent.

Let us make some assumptions on $\{r_n\}$ and $\{h_n\}$. Define t_n and $m(t)$ by

$$t_n = \sum_{i=1}^{n} r_i,$$

$$m(t) = \inf\{n > 0, t_n > t\}.$$

Assume that there are continuous functions $k(s)$ and $t(s)$ such that

$$\frac{r_{m(t_N+s)}}{r_N} \to k(s) \qquad \text{as } N \to +\infty, \tag{A1}$$

$$\frac{h_{m(t_N+s)}}{h_N} \to 1 \qquad \text{as } N \to +\infty, \tag{A2}$$

$$k\left(t_{[s/r_N+N]} - t_N\right) \to q(s) \qquad \text{as } N \to +\infty, \tag{A3}$$

where $[\cdot]$ is the function of taking the integer part.

(A1)–(A3) are too abstract for application. The following propositions and corollary show that in most cases we encounter, these assumptions are satisfied.

PROPOSITION 2.1. *If* $\{r_n\}$ *satisfies following conditions*

(1) *there exists* $\epsilon > 0$, *such that* $\chi \cdot r_{[\chi n]} \geq r_n$ *for large enough* n *and any* $\chi \in (1, 1+\epsilon)$,

(2) $\liminf_{n\to+\infty} r_n \frac{n}{(\ln n)^\alpha} > 0$ *for some* $\alpha > 0$,

then the assumption (A1) *holds and* $k(s) = 1$, *which implies assumption* (A3) *automatically.*

Proof. For the case of $r_n = (\ln n)^\alpha / n$, we have $t_n \sim (\ln n)^{1+\alpha}$. Consider

$$(\ln(n + n/\ln\ln n))^{1+\alpha} - (\ln n)^{1+\alpha},$$

which is equal to

$$\left(\ln n + \ln\left(1 + \frac{1}{\ln\ln n}\right)\right)^{1+\alpha} - (\ln n)^{1+\alpha}$$

$$= (\ln n)^{1+\alpha}\left(1 + \frac{1+\alpha}{\ln n \ln\ln n} + o\left(\frac{1}{\ln n \ln\ln n}\right)\right) - (\ln n)^{1+\alpha} \to \infty, \qquad n \to \infty. \tag{2.2}$$

For any $s > 0$, there exists N such that $r_{m(t_n+s)} \geq r_{n+n/\ln\ln n}$ for $n > N$. Hence

$$1 \geq \limsup_{n\to+\infty} \frac{r_{m(t_n+s)}}{r_n} \geq \liminf_{n\to+\infty} \frac{r_{m(t_n+s)}}{r_n} \geq \liminf_{n\to+\infty} \frac{\left(\ln\left(n + \frac{n}{\ln\ln n}\right)\right)^\alpha}{n + \frac{n}{\ln\ln n}} \frac{n}{(\ln n)^\alpha} = 1, \tag{2.3}$$

i.e.,

$$k(s) = \lim_{n\to+\infty} \frac{r_{m(t_n+s)}}{r_n} = 1.$$

For general $\{r_n\}$ satisfying (1) and (2), there exist N and $c' > 0$ such that for $n > N$,

$$t_{[n+n/\ln\ln n]} - t_n \geq c'\left(\left(\ln\left(n + \frac{n}{\ln\ln n}\right)\right)^{1+\alpha} - (\ln n)^{1+\alpha}\right) \to +\infty, \qquad n \to +\infty,$$

holds. Similarly to (2.3), we obtain

$$1 \geq \limsup_{n\to+\infty} \frac{r_{m(t_n+s)}}{r_n} \geq \liminf_{n\to+\infty} \frac{r_{m(t_n+s)}}{r_n} \geq \liminf_{n\to+\infty} \frac{r_{\left[n+\frac{n}{\ln\ln n}\right]}}{r_n},$$

which implies $k(s) = 1$, since by (1) we have

$$\frac{r_{\left[n+\frac{n}{\ln\ln n}\right]}}{r_n} \geq \frac{r_n}{\left(1 + \frac{1}{\ln\ln n}\right) r_n} \to 1, \qquad n \to +\infty.$$

The proof is complete. □

Remark. $r_n = c/(\ln\ln n)^\alpha (\alpha > 0)$, $r_n = c/(\ln n)^\alpha (\alpha > 0)$, $r_n = c(\ln n)^\beta / n^\alpha (0 < \alpha < 1, \beta \in (-\infty, +\infty))$, and $r_n = c(\ln n)^\alpha / n (\alpha > 0)$ are typical examples satisfying the conditions of Proposition 2.1.

COROLLARY 2.2. *If* $r_n = \hat{r}_n + o(\hat{r}_n)$, *where* $\{\hat{r}_n\}$ *satisfies the conditions of Proposition* 2.1, *then the results of Proposition* 2.1 *hold.*

Proof. The proof is immediate. □

PROPOSITION 2.3. *If* $r_n = c/n + o(1/n)$, *then assumptions* (A1) *and* (A3) *are satisfied with* $k(s) = e^{-s/c}$ *and* $q(s) = c/(s + c)$.

Proof. For any $\epsilon > 0$, there exists N such that for $n > N$,

$$(c-\epsilon)\ln\frac{n+1}{N+1} \le t_n - t_N \le (c+\epsilon)\ln\frac{n}{N}. \tag{2.4}$$

Thus

$$\left[e^{s/(c+\epsilon)}N\right] \le m(t_N+s) \le \left[e^{s/(c-\epsilon)}N+1\right].$$

It follows that

$$\liminf_{n\to+\infty}\frac{r_{m(t_N+s)}}{r_N} \ge e^{-s/(c-\epsilon)} \quad \text{and} \quad \limsup_{n\to+\infty}\frac{r_{m(t_N+s)}}{r_N} \le e^{-s/(c+\epsilon)}$$

for any ϵ and

$$\frac{r_{m(t_N+s)}}{r_N} \to e^{-s/c}, \qquad N \to +\infty.$$

Then we have

$$\begin{aligned}\left(\frac{N}{[sN/(c+o(1))+N]}\right)^{c/(c+\epsilon)} &\le k\left(t_{[sN/(c+o(1))+N]} - t_N\right)\\ &\le \left(\frac{N+1}{[sN/(c+o(1))+N]+1}\right)^{c/(c-\epsilon)}\end{aligned}$$

by (2.4), which shows

$$k\left(t_{[s/r_N+N]} - t_N\right) \to \frac{c}{s+c} \qquad \text{as } N\to+\infty \text{ and } \epsilon\to 0, \tag{2.5}$$

i.e., $q(s) = c/(s+c)$. The proposition is proven. □

Remark. If r_n is given as Corollary 2.2, then assumption (A2) on $\{h_n\}$ can be also specialized as conditions of Corollary 2.2, and if $r_n = c/n + o(1/n)$, then for (A2) h_n can be taken as $c/(\ln\ln n)^\alpha (\alpha > 0)$, or $c/(\ln n)^\alpha (\alpha > 0)$.

3. Large deviation principle. In order to obtain the convergence properties of the model (2.1) under different choices of $\{r_n\}$ and $\{h_n\}$, we investigate the Freidlin–Wentzell-type large deviation law of the following model:

$$X_{n+1}^N = \begin{cases} X_n^N + r_{N+n}b(X_n^N,\xi_{N+n}) + \sqrt{r_{N+n}h_{N+n}}\zeta_{N+n} & \text{if } n < G(N),\\ X_n^N + r_N q(n\cdot r_N)b(X_n^N,\xi_{N+n}) + \sqrt{r_N h_N q(n\cdot r_N)}\zeta_{N+n} & \text{otherwise,}\end{cases} \tag{3.1}$$

where we take $G(N)$ such that $G(N)\cdot r_N \to +\infty$ and let it make

$$\frac{\tilde r_{[s/r_N]}^N}{r_N} \to q(s) \qquad \text{uniformly in } s \text{ as } N\to+\infty \tag{3.2}$$

and

$$\frac{\tilde h_n^N}{h_N} \to 1 \qquad \text{uniformly in } n \text{ as } N\to+\infty, \tag{3.3}$$

where

$$\tilde r_n^N := \begin{cases} r_{n+N} & \text{if } n < G(N),\\ r_N q(n\cdot r_N) & \text{otherwise}\end{cases} \tag{3.4}$$

and

$$\tilde{h}_n^N := \begin{cases} h_{n+N} & \text{if } n < G(N), \\ h_N & \text{otherwise.} \end{cases} \tag{3.5}$$

In the cases of $\{r_n\}$ and $\{h_n\}$ satisfying the conditions of Corollary 2.2, we can take $G(N) = N/\ln\ln N$. When $r_n = c/n + o(1/n)$ and $h_n \approx d/\ln\ln n$, $G(N)$ may be N^k for any $k > 1$.

Remark. The important role of $G(N)$ is clear if one realizes that for $n < G(N)$, we have $X_{n+N} = X_n^N$, which is crucial for our argument in order to make use of Wentzell's powerful estimation of the large deviation principle [25].

Let $\mu(du)$ be the probability measure of ζ_1 and $\nu(dv)$ be the probability measure of ξ_1. We denote

$$A_{ij} = \int_{R^n} u^i u^j \mu(du), \tag{3.6}$$

$$H_0(s,x,y) = \frac{1}{2}\sum_{i,j=1}^{n} (q(s))^{-1} A^{ij} \left(y^i - q(s)\bar{b}^i(x)\right) \cdot \left(y^j - q(s)\bar{b}^j(x)\right), \tag{3.7}$$

$$S_{0,T}(\phi) = \int_0^T H_0\left(s, \phi(s); \dot{\phi}(s)\right) ds, \tag{3.8}$$

where $\left(A^{ij}\right)$ is the inverse of the matrix (A_{ij}) and $\bar{b}(x) = \int_{R^n} b(x,v)\nu(dv)$.

For later use, we cite the following result.

LEMMA 3.1 (see [25, Theorem 3.3.2′]). *Let the following conditions be satisfied:*

(1)

$$\lim_{N\to+\infty} h_N \ln\left(r_N^{-1} \sup_{t\in\{kr_N\},\, x\in R^d} P_{t,x}^N\left\{\left(x, X_{k+1}^N\right) \notin V\right\}\right) = -\infty,$$

where $V = \left\{(x,y) \in R^d \times R^d,\ |x-y| < 1\right\}$.

(2) *For all* $t \in [0,T]$, $x \in R^d$, *and* $|z| \le z_0$,

$$r_N^{-1} h_N G_V^N\left(t,x; h_N^{-1} z\right) - G_0(t,x;z) \to 0 \qquad \textit{uniformly as } N \to +\infty,$$

where

$$G_V^N(z,x;z) = \ln\left[1 + \iint_{\tilde{V}} \left(\exp\left\{Q_{t,x}^N(z,u,v)\right\} - 1\right)\mu(du)\nu(dv)\right], \tag{3.9}$$

$$Q_{t,x}^N(z,u,v) = \tilde{r}_{[t/r_N]}^N z \cdot b(x,v) + \sqrt{\tilde{r}_{[t/r_N]}^N \tilde{h}_{[t/r_N]}^N}\, z \cdot u, \tag{3.10}$$

$$\tilde{V} = \left\{(u,v) \in R^d \times R^d, \left|\tilde{r}_{[t/r_N]}^N b(x,v) + \sqrt{\tilde{r}_{[t/r_N]}^N \tilde{h}_{[t/r_N]}^N}\, u\right| < 1\right\} \tag{3.11}$$

$$G_0(t,x;z) = q(t)\bar{b}(x)\cdot z + \frac{q(t)}{2}\sum_{i,j=1}^{d} A_{ij} z^i z^j. \tag{3.12}$$

(3) *For all* $t \in [0,T]$, $x \in R^d$, *and* $|z| < z_0$,

$$\nabla_z\left(r_N^{-1} h_N G_V^N\left(t,x; h_N^{-1} z\right) - G_0(t,x;z)\right) \to 0 \qquad \textit{uniformly as } N \to +\infty.$$

(4) *For* $|z| \le z_0 < +\infty$, *sufficiently large* N, *and all* t, x,

$$\left| \frac{\partial^2}{\partial z_i \partial z_j} \left(r_N^{-1} h_N G_V^N \left(t, x; h_N^{-1} z \right) \right) \right| \le c < +\infty.$$

Then $\left\{ X_n^N \right\}$ *possesses the large deviation principle as* $N \to +\infty$ *and* $S_{0,T}\{\phi\}$ *is the action functional uniformly with respect to the initial point.*

In the following theorem, the time scale kr_N is used, which means that for any $\phi(t)$, the large deviation of $\left\{ X_k^N - \phi(kr_N) \right\}_k$ is under consideration.

THEOREM 3.2. *Let* $\int_{R^d} u\mu(du) = 0$, $\mu\{u : |u| \ge y\} \le \exp\left\{-ly^\beta\right\}$ *for large enough* y *with* $0 < \beta < 1$, $l > 0$. *For bounded* $b(x, v)$, *uniformly continuous* $\bar{b}(x)$, *and continuous* $q(s)$, *if* $\{r_n\}$ *and* $\{h_n\}$ *satisfy assumptions* (A1)–(A3) *and*

$$r_N^\beta h_N^{\beta-2} \to 0 \qquad \text{as } N \to +\infty, \tag{A4}$$

then $\left\{ X_n^N \right\}$ *possesses the large deviation principle as* $N \to +\infty$ *and* $S_{0,T}\{\phi\}$ *is the action functional uniformly with respect to the initial point.*

Proof. We need only to prove that conditions (1)–(4) of Lemma 3.1 are satisfied.

For any $k > 0$,

$$P_{kr_N,x}^N \left\{ \left(x, X_{k+1}^N \right) \notin V \right\} = \iint_{R^n \times R^n} 1_{\left\{ \left| \tilde{r}_k^N b(x,v) + \sqrt{\tilde{r}_k^N \tilde{h}_k^N} u \right| > 1 \right\}} \nu(dv)\, \mu(du).$$

When N is large enough, it is less than

$$\int_{R^d} 1_{\left\{ \left| 4\sqrt{\tilde{r}_k^N \tilde{h}_k^N} u \right| > \frac{1}{2} \right\}} \mu(du) \le \exp\left\{ -l \left(4\tilde{r}_k^N \tilde{h}_k^N \right)^{-\beta/2} \right\} \le \exp\left\{ -l \left(4 r_N h_N \right)^{-\beta/2} \right\},$$

since $\mu\{u : |u| \ge y\} \le \exp\left\{-ly^\beta\right\}$, $b(x, v)$ is bounded, and $\tilde{r}_k^N \le r_N$ and $\tilde{h}_k^N \le h_N$ for any $k > 0$. Then condition (1) follows.

To prove condition (2), we need to consider the limit of the term

$$r_N^{-1} h_N \iint_{\tilde{V}} \left(\exp\left\{ Q_{t,x}^N \left(h_N^{-1} z, u; v \right) \right\} - 1 \right) \mu(du)\, \nu(dv),$$

which is equal to

$$\begin{aligned} & r_N^{-1} h_N \iint_{\tilde{V}} \left(\exp\left\{ Q_{t,x}^N \left(h_N^{-1} z, u; v \right) \right\} - 1 - Q_{t,x}^N \left(h_N^{-1} z, u; v \right) \right) \mu(du)\, \nu(dv) \\ & + r_N^{-1} h_N \iint_{\tilde{V}} Q_{t,x}^N \left(h_N^{-1} z, u; v \right) \mu(du)\, \nu(dv). \end{aligned} \tag{3.13}$$

The second term can be separated into the following two parts:

$$r_N^{-1} \iint_{\tilde{V}} \tilde{r}_{[t/r_N]}^N z b(x, v)\, \mu(du)\, \nu(dv) + r_N^{-1} \iint_{\tilde{V}} \sqrt{\tilde{r}_{[t/r_N]}^N \tilde{h}_{[t/r_N]}^N} z \cdot u\mu(du)\, \nu(dv). \tag{3.14}$$

By the Hölder inequality and $\int_{R^n} u\mu(du) = 0$, the second term of (3.14) tends to zero uniformly in t, x and $|z| < z_0$ as $N \to +\infty$, and the first part of (3.14) is

$$\frac{\tilde{r}_{[t/r_N]}^N}{r_N} \iint_{R^n \times R^n} z \cdot b(x, v)\, \mu(du)\, \nu(dv) - \frac{\tilde{r}_{[t/r_N]}^N}{r_N} \iint_{\tilde{V}^c} z \cdot b(x, v)\, \mu(du)\, \nu(dv),$$

of which the first part approaches $q(t)\bar{b}(x)\cdot z$ uniformly in t, x and $|z|<z_0$ as $N\to+\infty$, and the second one is bounded by

$$\frac{\tilde{r}^N_{[t/r_N]}}{r_N}z_0 M\mu\left\{u:\left|\sqrt{\tilde{r}^N_{[t/r_N]}\tilde{h}^N_{[t/r_N]}}u\right|>\frac{1}{2}\right\};$$

the latter also goes to zero uniformly in t,x and $|z|<z_0$ as $N\to+\infty$. Now we consider the first term of (3.13). Since

$$\begin{aligned}&\frac{1}{2}r_N^{-1}h_N\iint_{\tilde{V}}\left\{Q^N_{t,x}\left(h_N^{-1}z,u;v\right)\right\}^2\mu(du)\nu(dv)\\&=\frac{1}{2}\iint_{\tilde{V}}\left[\frac{\tilde{r}^N_{[t/r_N]}}{r_N}(z\cdot b(x,v))^2+\frac{\left(\tilde{r}^N_{[t/r_N]}\right)^{1\frac{1}{2}}\left(\tilde{h}^N_{[t/r_N]}\right)^{\frac{1}{2}}}{r_N h_N}(z\cdot b(x,v))(z\cdot u)\right.\\&\qquad\left.+\frac{\tilde{r}^N_{[t/r_N]}\tilde{h}^N_{[t/r_N]}}{r_N h_N}|z\cdot u|^2\right]d\mu d\nu,\end{aligned}$$

it is not difficult to see that the first two terms tend to zero uniformly in t, x, and $|z|<z_0$ as $N\to\infty$, and by (3.1) and (3.2), the limit of the third term is

$$\frac{1}{2}q(t)\sum_{i,j=1}^{d}\left(\int_{R^n}u^iu^j\mu(du)\right)z^iz^j$$

uniformly in t, x, $|z|<z_0$ by a method similar to that above.

Now, we verify

$$r_N^{-1}h_N\iint_{\tilde{V}}\left\{\exp\left\{Q^N_{t,x}\right\}-1-Q^N_{t,x}-\frac{1}{2}\left\{Q^N_{t,x}\right\}^2\right\}\mu(du)\nu(dv)\to 0 \tag{3.15}$$

uniformly in t, x, $|z|<z_0$. Separating $\tilde{V}$ into two parts,

$$\begin{aligned}\tilde{V}_1&=\left\{(u,v)\in R^n\times R^d,\left|\tilde{r}^N_{[t/r_N]}b(x,v)+\sqrt{\tilde{r}^N_{[t/r_N]}\tilde{h}^N_{[t/r_N]}}u\right|<\frac{h_N}{z_0}\right\},\\\tilde{V}_2&=\tilde{V}\backslash\tilde{V}_1,\end{aligned}$$

(3.15) is written as

$$\begin{aligned}&r_N^{-1}h_N\iint_{\tilde{V}_1}\left\{\exp\left\{Q^N_{t,x}\right\}-1-Q^N_{t,x}-\frac{1}{2}\left\{Q^N_{t,x}\right\}^2\right\}\mu(du)\nu(dv)\\&+r_N^{-1}h_N\iint_{\tilde{V}_2}\left\{\exp\left\{Q^N_{t,x}\right\}-1-Q^N_{t,x}-\frac{1}{2}\left\{Q^N_{t,x}\right\}^2\right\}\mu(du)\nu(dv).\end{aligned}\tag{3.16}$$

The first term of (3.16) is less than

$$r_N^{-1}h_N\iint_{\tilde{V}_1}\left\{\left\{Q^N_{t,x}\left(h_N^{-1}z,u;v\right)\right\}^2\right\}\mu(du)\nu(dv),$$

which converges to zero uniformly in t, x, $|z| < z_0$. Let us consider the second term of (3.16). It is less than

$$\left| r_N^{-1} h_N \int_{\frac{h_N}{2z_0}}^{2} \exp\left\{2h_N^{-1} z_0 y\right\} d\mu \left\{ u : |u| \geq \frac{y}{\sqrt{\tilde{r}^N_{[t/r_N]} \tilde{h}^N_{[t/r_N]}}} \right\} \right|$$

$$\leq r_N^{-1} h_N \exp\left\{4h_N^{-1} z_0\right\} \exp\left\{ -l \left(\frac{2}{r_N h_N} \right)^{\beta/2} \right\} + 3 r_N^{-1} h_N \exp\left\{ -l \left(\frac{h_N}{4 z_0^2 r_N} \right)^{\beta/2} \right\}$$

$$+ 2 r_N^{-1} z_0 \int_{\frac{h_N}{2z_0}}^{2} \exp\left\{2h_N^{-1} z_0 y\right\} \exp\left\{ -l \left(\frac{y^2}{r_N h_N} \right)^{\beta/2} \right\} dy,$$

since $\left|Q^N_{t,x}\left(h_N^{-1} z, u; v\right)\right| \leq h_N^{-1} z_0 \left| \sqrt{\tilde{r}^N_{[t/r_N]} \tilde{h}^N_{[t/r_N]}}\, u \right|$ for large enough N, and $e^x - 1 - x - \frac{1}{2}x^2 \leq e^{|x|}$. In terms of $r_N^{-\beta/2} h_N^{1-\beta/2} \to \infty$, it converges to zero. Therefore, condition (2) is checked.

We can verify conditions (3) and (4) similarly. The theorem is then complete. □

Remark. If $Ee^{\lambda \zeta_n} < +\infty$ for some $\lambda > 0$, (A4) may be weakened to

$$r_N h_N^{-1} \to 0 \qquad \text{as } N \to +\infty. \tag{A4$'$}$$

If $\mu\{u : |u| \geq y\} \leq c y^{-\beta}$, $\beta > 4$, $c > 0$, (A4) should be more restricted by assuming

$$h_N^{-1} = o\left(-\ln\left(r_N\right)\right). \tag{A4$''$}$$

But according to the time scale kr_N, the action functional isn't invariant under time shift. To achieve a better form of the action functional, we consider another time scale. Let $s(t) = \int_0^t q(u)\, du$; then we have

$$\int_0^T \frac{1}{2} \sum_{i,j=1}^{d} \left(q(u)\right)^{-1} A^{ij} \left(\dot{\phi}^i(u) - q(u) \bar{b}^i\left(\phi(u)\right) \right) \cdot \left(\dot{\phi}^j(u) - q(u) \bar{b}^j\left(\phi(u)\right) \right) du$$

$$= \int_0^{s(T)} \frac{1}{2} \sum_{i,j=1}^{d} A^{ij} \left(\frac{d\phi_s^i}{du}(u) - \bar{b}^i\left(\phi_s(u)\right) \right) \cdot \left(\frac{d\phi_s^j}{du}(u) - \bar{b}^j\left(\phi_s(u)\right) \right) du,$$

where $\phi_s = \phi \circ s^{-1}$. Denote

$$\tilde{S}_{0,T}(\phi) = \frac{1}{2} \int_0^T \sum_{i,j=1}^{d} A^{ij} \left(\phi^i(v) - \bar{b}^i\left(\phi(v)\right) \right) \cdot \left(\phi^j(v) - \bar{b}^j\left(\phi(v)\right) \right) dv. \tag{3.17}$$

Mapping $\phi(v) \longmapsto \left(\phi \circ s^{-1}\right)(v)$ is bijective in $B(R, R^d)$, the set of Borel mappings from R to R^d; then we have the following.

COROLLARY 3.3. *Denote by $\Phi_{x,T}(\gamma)$ the set of all functions $\phi(t)$, $0 \leq t \leq T$, such that $\phi(0) = x$ and $\tilde{S}_{0,T}(\phi) \leq \gamma$. Then*

(1) *the functional $\tilde{S}_{0,T}(\phi)$ is lower semicontinuous, and $\Phi_{x,T}(\gamma)$ is compact;*

(2) *for any $\delta > 0$, $l > 0$, $\phi \in \Phi_{x,T}(\gamma)$, and sufficiently large N,*

$$P^N_{0,x} \left\{ \sup_{0 \leq s(nr_N) - T_1 \leq T} \left| X^N_n - \phi\left(s(nr_N) - T_1\right) \right| < \delta \right\} \geq \exp\left\{ -h_N^{-1} \left(\tilde{S}_{0,T}(\phi) + l \right) \right\};$$

(3) *for any* $\delta > 0$, $l > 0$, *and sufficiently large* N,

$$P_{0,x}^{N}\left\{\inf_{\phi\in\Phi_{x,T}(\gamma)}\sup_{0\le s(nr_N)-T_1\le T}\left|X_n^N-\phi(s(nr_N)-T_1)\right|\ge\delta\right\}\le\exp\{-h_N^{-1}(\gamma-l)\}.$$

Define

$$V(x,y):=\inf\left\{\tilde{S}_{0,T}(\phi):\phi_0=x,\phi_T=y,\phi\in C([0,T]),T\ge 0\right\}$$

for later use.

4. Lemmas. As in [5], we will give some lemmas to show the relations between the stochastic process $\{X_n^N\}$ and the trajectory $X^0(\cdot)$ of the dynamical system

$$\frac{dX^0(t)}{dt}=\bar{b}\left(X^0(t)\right). \tag{4.1}$$

We have the following lemma.

LEMMA 4.1. *Let* K *be a compact set not entirely containing any* ω*-limit sets of the dynamical system* (4.1) *and* $\tau=\inf\{n>0,X_n^N\notin K\}$. *Assume that the assumptions* (A1)–(A3) *and* (A4) (*or* (A4′), (A4″)) *hold. Then there exist* c, T_0, *and* N_0 *such that*

$$P_x\{s(\tau\cdot r_N)>T\}\le\exp\left\{-c(T-T_0)h_N^{-1}\right\} \tag{4.2}$$

for $N\le N_0$, $T>T_0$.

Proof. The lemma can be proven by using a method similar to that of [5]. □

LEMMA 4.2. *Let* F *be a compact set and the assumptions* (A1)–(A3) *and* (A4) (*or* (A4′), (A4″)) *hold. Then for any* $c>0$, $\delta>0$ *there is* $R>0$ *such that*

$$P_x\left\{s(\theta\cdot r_N)\le\exp\left(ch_N^{-1}\right)\right\}\le\exp\left\{-\delta h_N^{-1}\right\} \tag{4.3}$$

for all $x\in F$, *where* $\theta=\inf\{n>0,|X_n^N|\ge R\}$.

Proof. Choose $R_1>0$, $R_2>0$, and $R_1>R_2$ such that $\{x,|x|\le R_1\}$ contains F and all ω-limit sets of (4.1). Assume $\inf\{V(x,y),|x|\le R_1,|y|\ge R_2\}=d_1>0$, and for any $R>R_2$,

$$d_2(R)=\inf\{V(x,y),|x|\le R_2,|y|>R\}>0.$$

Suppose that $\{\theta_n\}$, $\{\rho_n\}$ are two sequences of stopping times which satisfy

$$\begin{aligned}
\theta_1&=\inf\left\{n\ge 0,\left|X_n^N\right|\ge R_2\right\},\\
\rho_1&=\inf\left\{n\ge\theta_1,\left|X_n^N\right|\le R_1\right\},\\
&\vdots\\
\theta_n&=\inf\left\{n\ge\rho_{n-1},\left|X_n^N\right|\ge R_2\right\},\\
\rho_n&=\inf\left\{n\ge\theta_n,\left|X_n^N\right|\le R_1\right\},\\
&\vdots
\end{aligned}$$

Then for any M,

$$\begin{aligned}&P_x\left\{s\left(\theta\cdot r_N\right)<\exp\left\{ch_N^{-1}\right\}\right\}\\&\le P_x\left\{s\left(\theta_M\cdot r_N\right)\ge s\left(\theta\cdot r_N\right)\right\}+P_x\left\{s\left(\theta_M\cdot r_N\right)<\exp\left\{ch_N^{-1}\right\}\right\}.\end{aligned}$$

To estimate the first term, for sufficiently small ϵ, and $x\in\{R_2\le|x|\le R_2+\epsilon\}$, we have

$$\begin{aligned}&P_x\left\{s\left(\theta_M\cdot r_N\right)<s\left(\theta\cdot r_N\right)\right\}\\&\ge P_x\left\{s\left(\theta_M\cdot r_N\right)<s\left(\theta\cdot r_N\right),R_2\le\left|X_{\theta_M}^N\right|\le R_2+\epsilon\right\}\\&\ge E_x1_{\left\{\tau>\theta_{M-1},R_2\le\left|X_{\theta_{M-1}}^N\right|\le R_2+\epsilon,P_{X_{\theta_{M-1}}^N}\left\{\theta_1<\theta,R_2\le\left|X_{\theta_1}^N\right|\le R_2+\epsilon\right\}\right\}}\\&\ge\left(\inf_{R_2\le|y|\le R_2+\epsilon}P_y\left\{\theta_1<\theta,R_2\le\left|X_{\theta_1}^N\right|\le R_2+\epsilon\right\}\right)^M.\end{aligned}\tag{4.4}$$

Notice that

$$P_x\left\{\theta\le\theta_1\right\}\le\exp\left\{-\frac{d_2\left(R\right)}{2}h_N^{-1}\right\},\tag{4.5}$$

and for N large enough, by Theorem 3.2, there is $\beta>d_2\left(R\right)$ such that

$$P_x\left\{\theta\ge\theta_1,\left|X_{\theta_1}^N\right|>R_2+\epsilon\right\}\le\sup_{t\in(kr_N),x\in R^d}P_{t,x}^N\left\{\left(x,X_{k+1}^N\right)\notin V^\epsilon\right\}\le\exp\left\{-\frac{\beta}{2}h_N^{-1}\right\},\tag{4.6}$$

where $V^\epsilon=\left\{(x,y)\in R^d\times R^d,|x-y|<\epsilon\right\}$. Choosing $M=\exp\{\frac{d_2(R)}{3}h_N^{-1}\}$, by (4.5), (4.6), and

$$P_x\left\{\theta\le\theta_1\text{ or }\left|X_{\theta_1}^N\right|>R_2+\epsilon\right\}\le P_x\left\{\theta\le\theta_1\right\}+P_x\left\{\theta\ge\theta_1,\left|X_{\theta_1}^N\right|>R_2+\epsilon\right\},\tag{4.7}$$

we conclude that (4.4) is bigger than

$$\begin{aligned}&\left(1-\exp\left\{-\frac{d_2\left(R\right)}{2}h_N^{-1}\right\}-\exp\left\{-\frac{\beta}{2}h_N^{-1}\right\}\right)^M\\&=1-\exp\left\{-\frac{d_2\left(R\right)}{6}h_N^{-1}\right\}+o\left(\exp\left\{-\frac{d_2\left(R\right)}{6}h_N^{-1}\right\}\right).\end{aligned}$$

The remainder of the proof is similar to [5, p. 128]. □

Now we consider the following conditions:

$$\limsup_{|y|\to+\infty}\frac{\left|\bar{b}\left(y\right)\right|}{|y|}\le M_1<+\infty,\tag{B1}$$

$$\limsup_{|y|\to+\infty}\frac{\left\langle\bar{b}\left(y\right),y\right\rangle}{|y|^2}\le-c<0,\tag{B2}$$

$$\limsup_{|y|\to+\infty}\frac{E\left(b\left(y,\xi_n\right)-\bar{b}\left(y\right)\right)^2}{|y|^2}\le M_2<+\infty.\tag{B3}$$

LEMMA 4.3. *Suppose that the stochastic approximation model* (2.1) *satisfies conditions* (B1), (B2), *and* (B3). *Then for any compact set* $F \subset R^d$ *and fixed* N, *the family of probability measures*

$$\{P_{N,y}\{X_n \in \cdot\}; N < n, y \in F\}$$

is tight, where $P_{N,y}$ *is the probability starting at* y *at time* N.

Proof. To prove this lemma, we need only to check $E_{N,y}|X_n|^2 \le M$ for any $n > N$ and $y \in F$.

Denote

$$V_N := |y|^2 \text{ and } V_n := \exp\left\{l\sum_{i=N}^{n-1} r_i\right\}\int_{R^d}|x|^2 P_{n,z}^N(dx),$$

where $P_{n,z}^N(dx)$ is the transition probability of $\{X_n\}$ from N to n. Picking $l \le c/4$, we have

$$\begin{aligned}
&V_{n+1} - V_n\\
&= \exp\left\{l\sum_{i=N}^{n} r_i\right\}\int_{R^{2d+n}}\left|y + r_n b(y,v) + \sqrt{r_n h_n}u\right|^2 \nu(dv)\mu(du)P_{n,z}^N(dy)\\
&\quad - \exp\left\{l\sum_{i=N}^{n-1} r_i\right\}\int_{R^d}|y|^2 P_{n,z}^N(dy)\\
&= \exp\left\{l\sum_{i=N}^{n-1} r_i\right\}\left[\int_{R^d}\left[(e^{lr_n}-1)|y|^2 + e^{lr_n}\left(r_n^2|\bar b(y)|^2 + 2r_n\langle y, \bar b(y)\rangle\right)\right]P_{n,z}^N(dy)\right.\\
&\quad \left. + e^{lr_n}\left(\int_{R^{n+d}} r_n^2\left|b(y,v) - \bar b(y)\right|^2\nu(dv)P_{n,z}^N(dy) + \int_{R^{2d}} r_n h_n|u|^2\mu(du)P_{n,z}^N(dy)\right)\right].
\end{aligned}$$

By (B1)–(B3), there exists R such that $\left|\bar b(y)\right| \le (M_1+1)|y|$, $\left\langle \bar b(y), y\right\rangle \le -\frac{2c}{3}|y|^2$, and $E\left(b(y,\xi_n) - \bar b(y)\right)^2 \le (M_2+1)|y|^2$ for all $|y| \ge R$. Then

$$\begin{aligned}
&\int_{\{|y|>R\}}\left[(e^{lr_n}-1)|y|^2 + e^{lr_n}r_n\left[2\langle y, \bar b(y)\rangle + r_n E\left|b(y,\xi_n) - \bar b(y)\right|^2 + h_n E\zeta_n^2\right]\right]P_{n,z}^N(dy)\\
&\le \int_{\{|y|>R\}}\left[-\frac{5c}{6}r_n|y|^2 + 2(M_2+2)r_n^2|y|^2 + 2r_n h_n E\zeta_n^2\right]P_{n,z}^N(dy) \le 0
\end{aligned}$$

for large enough n, and the integral taking over $|y| \le R$ is less than

$$\begin{aligned}
&r_n\int_{\{|y|\le R\}}\left[\frac{c}{2}|y|^2 + 4\left|\left\langle y, \bar b(y)\right\rangle\right| + 2r_n E|b(y,\xi_n)|^2 + h_n E|\zeta_n|^2\right]P_{n,z}^N(dy)\\
&\le Ar_n
\end{aligned}$$

with a constant A. Thus, we obtain

$$V_{n+1} - V_n \le Ar_n\exp\left\{l\sum_{i=N}^{n-1} r_i\right\}$$

and then

$$V_n \le \sum_{i=N+1}^{n-1} Ar_n \exp\left\{l\sum_{i=N}^{i-1} r_i\right\} + V_N \le A\int_0^{\sum_{j=N}^{n-1} r_j} e^{lx}dx + |y|^2,$$

which implies

$$E_{N,y}|X_n|^2 \le \frac{A}{l}\left(1-\exp\left\{-l\sum_{i=N}^{n-1} r_i\right\}\right) + |y|^2 \exp\left\{-l\sum_{i=N}^{n-1} r_i\right\}.$$

This shows that $E_{N,y}|X_n|^2$ are bounded for all $n > N$ and $y \in F$. The lemma is proven. □

Suppose that there exists a continuous function $U(x)$ such that $\bar{b}(x) = -\nabla U(x)$, $A_{ij} = \delta_{ij}$, and $S := \{x \in R^d, \nabla U(x) = 0\}$. If $\liminf_{|x|\to+\infty} |\nabla U(x)| = +\infty$, then S is compact. We assume that S consists of a finite number of connected compact sets $\{K_1, K_2, \ldots, K_L\}$.

LEMMA 4.4. *Let F be a compact set, and suppose that the assumptions* (A1)–(A3), (A4) (*or* (A4′), (A4″)) *hold. Then for given $l > 0$ and $M_0 > 0$, there exists $T^* > 0$ such that for sufficiently large N and $x \in F$,*

$$P_x\{s(\rho \cdot r_N) > T^*\} \le \exp\{-M_0 h_N^{-1}\}, \tag{4.8}$$

with $\rho = \inf\{n \ge 0, X_n^N \in B(S, l)\}$, where $B(\cdot, l)$ stands for the l-neighborhood of a set.

Proof. If $x \in F \cap B(S, l)$, the lemma is obvious. Then we assume $F \cap B(S, l) = \emptyset$. By Lemma 4.1, there is T^* such that

$$P_x\{s(\tau \cdot r_N) < T^*\} \le \frac{1}{2}\exp\{-M_0 h_N^{-1}\}.$$

Choose sufficiently large R such that

$$P_x\{s(\theta \cdot r_N) \le T^*\} \le \exp\{-M_0 h_N^{-1}\},$$

where θ and τ are stopping times defined in Lemmas 4.1 and 4.2, and

$$K := \{x \in R^d, |x| \le R\} \setminus B(S, l).$$

Now we have

$$\begin{aligned} P_x\{s(\tau \cdot r_N) > T^*\} &\ge P_x\{s(\rho \cdot r_N) > T^*, s(\theta \cdot r_N) > T^*\} \\ &\ge P_x\{s(\rho \cdot r_N) > T^*\} - P_x\{s(\theta \cdot r_N) < T^*\}, \end{aligned}$$

since $\tau = \rho \wedge \theta$. Thus the lemma holds. □

For $x, y \in R^d$, suppose that $\mathcal{B}_{x,y}$ is the set of paths linking x and y, i.e., the set of continuous maps $\varphi : [0,1] \to R^d$ such that $\varphi(0) = x$ and $\varphi(1) = y$. For any path $\varphi \in \mathcal{B}_{x,y}$, define

$$e(\varphi) = 2\left(\max_{0\le t\le 1} U(\varphi(t)) - U(x)\right) \text{ and } I(x,y) = \inf_{\varphi\in\mathcal{B}_{x,y}} e(\varphi).$$

By the definition of S, $I(x,y)$ is a constant for fixed y and any $x \in K_1 (\subset S)$. Similarly, $I(x,y)$ is a constant for fixed x and any $y \in K_2 (\subset S)$, $I(x,y)$ is the same for any $x \in$

$K_1\,(\subset S)$ and $y \in K_2\,(\subset S)$. We denote them by $I(K_1, y)$, $I(x, K_2)$, and $I(K_1, K_2)$ correspondingly.

For any $c \geq 0$ and $K \in S$, we define

$$\pi_K^c := \{x \in S, I\,(y, x) \leq c, y \in K\}\,, \quad I\,(\pi_K^c) := \max_{y \in \pi_K^c} \min_{x \in S \backslash \pi_K^c} I\,(y, x)\,,$$

and

$$\underline{S} = \left\{x \in R^d, U\,(x) = \min_{y \in R^d} U\,(y)\right\},$$
$$\underline{S}_c = \left\{x \in S, \inf_{y \in \underline{S}} I\,(y, x) \leq c\right\}.$$

LEMMA 4.5. *For any π_K^c, $\alpha_0 > 0$ and $\delta < \alpha_0$, under the assumptions* (A1)–(A3) *and* (A4) (*or* (A4′), (A4″)) *there exist N_0, l_0 such that*

$$P_x\left\{s\left(\tau_{\pi_k^c} \cdot r_N\right) < \exp\left\{\left(I\left(\pi_K^c\right) - \alpha\right) h_N^{-1}\right\}\right\} \leq \exp\left\{-\delta h_N^{-1}\right\},$$
$$P_x\left\{s\left(\tau_{\pi_k^c} \cdot r_N\right) > \exp\left\{\left(I\left(\pi_K^c\right) + \alpha\right) h_N^{-1}\right\}\right\} \leq \exp\left\{-\delta h_N^{-1}\right\}$$

for $l \leq l_0$, $N > N_0$, and $\alpha > \alpha_0$, where $\tau_{\pi_K^c} = \inf\left\{n > 0, X_n^N \in B\left(S \backslash \pi_K^c, l\right)\right\}$, $x \in B\left(\pi_K^c, l\right)$.

Proof. By Lemma A.4 and Lemma 4.2 of [14], it is obvious. □

LEMMA 4.6. *For any $\alpha_0 > 0$, $c < c'$, under assumptions* (A1)–(A3) *and* (A4) (*or* (A4′), (A4″)), *there is l_0 such that for $l \leq l_0$, $K_i \subset \underline{S}_{c'} \backslash \underline{S}_c$, and $x \in B\left(K_i, l\right)$, we have*

$$E_x\left\{s\left(\tau_{\underline{S}_c} \cdot r_N\right) \middle| \tau_{\underline{S}_{c'}} \leq \rho_{\underline{S}_{c'}}\right\} \leq \exp\left\{-(\bar{d}_{c'}^c + \alpha_0) h_N^{-1}\right\},$$

where

$$\tau_{\underline{S}_c} = \inf\left\{n > 0, X_n^N \in B\left(\underline{S}_c, l\right)\right\},$$
$$\rho_{\underline{S}_{c'}} = \inf\left\{n > 0, X_n^N \notin B\left(\underline{S}_{c'}, l\right)\right\},$$
$$\bar{d}_{c'}^c = \max_{y \in \underline{S}_{c'} \backslash \underline{S}_c} \min_{x \in \underline{S}_c} I\,(y, x)\,.$$

Proof. It is equivalent to the statement that the Markov chain is contained in $\underline{S}_l$. By Lemma 1.6 of [14] and Lemma A.5, the result is obvious. □

LEMMA 4.7. *Under the same assumptions as in Lemma* 4.6, *we have*

$$P_x\left\{s\left(\tau_{\underline{S}_c} \cdot r_N\right) \geq \exp\left\{\left(\bar{d}_{c'}^c + \bar{\alpha}\right) h_N^{-1}\right\} \middle| \tau_{\underline{S}_c} \leq \rho_{\underline{S}_{c'}}\right\} \leq \exp\left\{-\delta h_N^{-1}\right\}$$

for any $\bar{\alpha} > \alpha_0 + \delta$.

Proof. It can be obtained directly by using Lemma 4.6 and the Chebyshev inequality. □

5. Main results. Recall $\underline{S} = \{x \in R^d, U\,(x) = \min_{y \in R^d} U\,(y)\}$, and define $d^* := \max_{x \in S \backslash \underline{S}} \min_{y \in \underline{S}} I\,(x, y)$. Then we have the following lemma.

LEMMA 5.1. *For any compact set $F_0 \in R^d$ and $\alpha > 0$, under assumptions* (B1)–(B3), *if $\{r_n\}$ and $\{h_n\}$ satisfy assumptions* (A1)–(A3), (A4) ((A4′) *or* (A4″)), *and*

$$r_N^{-1} s^{-1}\left(\exp\left\{(d^* + \alpha^*) h_N^{-1}\right\}\right) < G\,(N) \ \ (\textit{defined in } (3.1))$$

for large enough N, then there are $\delta > 0$ and $N_0 > 0$ such that

$$P_{N,y}\left\{X_{N+r_N^{-1}s^{-1}\left(\exp\left\{(d^*+\alpha)h_N^{-1}\right\}\right)} \in B\left(\underline{S},l\right)\right\} \geq 1-\exp\left\{-\delta h_N^{-1}\right\} \tag{5.1}$$

for all $N > N_0$, $\alpha^*/2 \leq \alpha \leq \alpha^*$ and $y \in F_0$.

Proof. For all $n \leq r_N^{-1}s^{-1}\left(\exp\left\{\left(d^*+\alpha\right)h_N^{-1}\right\}\right) < G\left(N\right)$, $X_{N+n} = X_n^N$; therefore we can use all results valid for X_n^N.

For simplicity, we denote

$$T\left(N,c\right) = r_N^{-1}s^{-1}\left(\exp\left\{ch_N^{-1}\right\}\right).$$

Let $\sigma = \inf\left\{n > N, X_n \in B\left(S,l\right)\right\}$. By Lemma 4.4, there is $T^* > 0$ such that for $y \in F_0$ and sufficiently large N,

$$P_{N,y}\left\{\sigma > N + r_N^{-1}s^{-1}\left(T^*\right)\right\} \leq \exp\left\{-M_0h_N^{-1}\right\}$$

for some $M_0 > 0$.

Now for fixed $y \in F_0$,

$$\begin{aligned}
&P_{N,y}\left\{X_{N+T(N,d^*+\alpha)} \in B\left(\underline{S},l\right)\right\}\\
&\geq E_{N,y}\left\{\sigma < N + r_N^{-1}s^{-1}\left(T^*\right), P_{\sigma,X_\sigma}\left\{X_{N+T(N,d^*+\alpha)} \in B\left(\underline{S},l\right)\right\}\right\}\\
&\geq \inf_{\substack{N \leq N_1 \leq N + r_N^{-1}s^{-1}(T^*)\\ y_1 \in B(S,l)}} P_{N_1,y_1}\left\{X_{N+T(N,d^*+\alpha)} \in B(\underline{S},l)\right\} \times \left(1-\exp\{-M_0h_N^{-1}\}\right).
\end{aligned} \tag{5.2}$$

Recall $\underline{S}_{d^*} = \{x \in S, \inf_{y\in\underline{S}} I\left(y,x\right) \leq d^*\}$. Clearly, we have $S\backslash\underline{S}_{d^*} \neq \emptyset$. Fix N_1 with $N \leq N_1 \leq N + r_N^{-1}s^{-1}\left(T^*\right)$ and $y_1 \in B\left(S,l\right)$, and define the stopping time θ by

$$\theta = \inf\left\{n \geq N, X_n \in B\left(\underline{S}_{d^*},l\right)\right\}.$$

Then

$$\begin{aligned}
&P_{N_1,y_1}\left\{X_{N+T(N,d^*+\alpha)} \in B\left(\underline{S},l\right)\right\}\\
&\geq E_{N_1,y_1}\left\{\theta < N + T\left(N,d^*+\frac{\alpha}{2}\right), P_{\theta,X_\theta}\left\{X_{N+T(N,d^*+\alpha)} \in B\left(\underline{S},l\right)\right\}\right\}\\
&\geq P_{N_1,y_1}\left\{\theta < N + T\left(N,d^*+\frac{\alpha}{2}\right)\right\}\\
&\times \inf_{\substack{N \leq N_2 \leq N + T\left(N,\,d^*+\frac{\alpha}{2}\right)\\ y_2 \in B\left(\underline{S}_{d^*},\,l\right)}} P_{N_2,y_2}\left\{X_{N+T(N,d^*+\alpha)} \in B\left(\underline{S},l\right)\right\}.
\end{aligned} \tag{5.3}$$

Now let us estimate

$$P_{N_1,y_1}\left\{\theta < N + T\left(N,d^*+\frac{\alpha}{2}\right)\right\} \text{ and } P_{N_2,y_2}\left\{X_{N+T(N,d^*+\alpha)} \in B\left(\underline{S},l\right)\right\}.$$

For the first estimate, for $y_1 \in B\left(S\backslash\underline{S}_{d^*},l\right)$, there is $\min_{x\in\underline{S}_{d^*}} I\left(y_1,x\right) \leq d^*$, since $\underline{S} \subset \underline{S}_{d^*}$. And by Lemma 4.7, we have

$$P_{N_1,y_1}\left\{\theta \geq N + T\left(N,d^*+\frac{\alpha}{2}\right)\right\} \leq \exp\left\{-\delta h_N^{-1}\right\}; \tag{5.4}$$

otherwise, $y_1 \in B\left(\underline{S}_{d^*},l\right)$. In this case,

$$P_{N_1,y_1}\left\{\theta < N + T\left(N,d^*+\frac{\alpha}{2}\right)\right\} = 1. \tag{5.5}$$

For $P_{N_2,y_2}\left\{X_{N+T(N,d^*+\alpha)}\in B\left(\underline{S},l\right)\right\}$, we assume $y_2\in B\left(\pi_K^{d^*},l\right)$, where $N\le N_2\le N+T\left(N,d^*+\frac{\alpha}{2}\right)$ and $K\subset\underline{S}$, and define

$$d\left(\pi_K^{d^*}\right):=\max_{x\in\pi_K^{d^*}\setminus\underline{S}}\min_{y\in\pi_K^{d^*}\cap\underline{S}}I\left(x,y\right).$$

Fix $y_2\in B\left(\pi_K^{d^*},l\right)$, and define

$$\begin{aligned}\bar{N}_0&=N+T\left(N,d^*+\alpha\right)-T\left(N,d\left(\pi_K^{d^*}\right)+\alpha\right),\\ \bar{N}_1&=N+T\left(N,d^*+\alpha\right)-T\left(N,d\left(\pi_K^{d^*}\right)+\frac{\alpha}{2}\right),\\ \rho&=\inf\left\{n\ge\bar{N}_0,X_n\in B\left(\pi_K^{d^*},l\right)\right\}.\end{aligned}$$

Then

$$\begin{aligned}&P_{N_2,y_2}\left\{X_{N+T(N,d^*+\alpha)}\in B\left(\underline{S},l\right)\right\}\\ &\ge P_{N_2,y_2}\left\{P_{\rho,X_\rho}\left\{X_{N+T(N,d^*+\alpha)}\in B\left(\underline{S},l\right)\right\},\rho\le\bar{N}_1\right\}\\ &\ge\inf_{\substack{\bar{N}\in[\bar{N}_0,\bar{N}_1]\\ y\in B\left(\pi_K^{d^*},l\right)}}P_{\bar{N},y}\left\{X_{N+T(N,d^*+\alpha)}\in B\left(\underline{S},l\right)\right\}\cdot P_{N_2,y_2}\left\{\rho\le\bar{N}_1\right\}.\end{aligned}\tag{5.6}$$

Notice

$$\begin{aligned}P_{N_2,y_2}\left\{\rho>\bar{N}_1\right\}&=P_{N_2,y_2}\left\{X_n\notin B\left(\pi_K^{d^*},l\right)\text{ for all }n\in\left[\bar{N}_0,\bar{N}_1\right]\right\}\\ &\le P_{N_2,y_2}\left\{X_n\notin B\left(S,l\right)\text{ for all }n\in\left[\bar{N}_0,\bar{N}_1\right]\right\}+P_{N_2,y_2}\left\{\tau_1\le\bar{N}_1\right\},\end{aligned}$$

where $\tau_1=\inf\left\{n>N_2,X_n\in B\left(S\backslash\pi_K^{d^*},l\right)\right\}$. Clearly, $I\left(\pi_K^{d^*}\right)>d^*$. Therefore, Lemma 4.5 implies that there is $\delta_1>0$ such that for large N and α small enough,

$$P_{N_2,y_2}\left\{\tau_1\le\bar{N}_1\right\}\le\exp\left\{-\delta_1h_N^{-1}\right\}.$$

On the other hand, for large N, by Lemma 4.1 and 4.2, we obtain

$$P_{N_2,y_2}\left\{X_n\notin S\text{ for all }n\in\left[\bar{N}_0,\bar{N}_1\right]\right\}\le\exp\left\{-M_1h_N^{-1}\right\}.$$

Thus there is $\delta_2>0$ such that

$$P_{N_2,y_2}\left\{\rho\le\bar{N}_1\right\}\ge1-2\exp\left\{-\delta_2h_N^{-1}\right\}.\tag{5.7}$$

Combining (5.3), (5.4), (5.5), (5.6), (5.7), for $N\le N_1\le N+r_N^{-1}s^{-1}\left(T^*\right)$, $y_1\in B\left(S,l\right)$, any $M>0$, and large N, we have

$$\begin{aligned}&P_{N_1,y_1}\left\{X_{N+T(N,d^*+\alpha)}\in B\left(\underline{S},l\right)\right\}\\ &\ge\left(1-\exp\left\{-M_1h_N^{-1}\right\}\right)\left(1-2\exp\left\{-\delta_1h_N^{-1}\right\}\right)\\ &\quad\times\inf_{\substack{N_2\ge N\\ y_2\in B\left(\pi_K^{d^*},l\right)\\ \pi_K^{d^*}\subset\underline{S}_{d^*}}}P_{N_2,y_2}\left\{X_{N_2+T\left(N_2,d\left(\pi_K^{d^*}\right)+\alpha\right)}\in B\left(\underline{S},l\right)\right\}.\end{aligned}$$

Analogously, we also have

$$\inf_{\substack{N \le N_1 \le N + r_N s^{-1}(T^*) \\ y_1 \in B(S,l)}} P_{N_1,y_1}\left\{X_{N+T(N,d^*+\alpha)} \in B(\underline{S},l)\right\} \ge \left(1 - \exp\left\{-\delta h_N^{-1}\right\}\right)^{L+1}.$$

Together with (5.2), we have proved the lemma. □

THEOREM 5.2. *Suppose that $\bar{b}$, the gradient of the potential function $-U(x)$, and $b(x,\xi)$ satisfy* (B1)–(B3). *If $\{r_n\}$ and $\{h_n\}$ meet assumptions* (A1)–(A3) *and* (A4) ((A4′) *or* (A4″)) *and*

$$r_n^{-1} s^{-1}\left(\exp\left\{(d^*+\alpha) h_n^{-1}\right\}\right) < G(n) \,(\textit{defined in } (3.1))$$

for n large enough and some $\alpha > 0$, then

$$P_{0,y}\{X_n \in B(\underline{S},l)\} \to 1 \qquad \textit{as } n \to +\infty$$

uniformly for y in an arbitrary compact set F.

Proof. For any $\epsilon > 0$, by Lemma 4.3, there is a compact set F_0 such that

$$P_{0,y}\{X_n \in F_0\} \ge 1 - \frac{\epsilon}{2} \tag{5.8}$$

for all $y \in F$ and $n > 0$. Note that $T(N,c) := N + r_N^{-1} s^{-1}\left(\exp\left\{c h_N^{-1}\right\}\right)$ is monotonically increasing to infinity as $N \to +\infty$. For any n, there is a unique N_n such that

$$T\left(N_n, d^* + \frac{\alpha^*}{2}\right) \le n < T\left(N_n + 1, d^* + \frac{\alpha^*}{2}\right),$$

where $N_n \to +\infty$, as $n \to +\infty$. By $h_{N+1}/h_N \to 1$ and $r_{N+1}/r_N \to 1$, as $N \to +\infty$, we have $\alpha^*/2 \le \alpha \le \alpha^*$ such that $n = T(N_n, d^* + \alpha)$ for n large enough. In terms of Lemma 5.1, it implies

$$P_{N_n,z}\{X_n \in B(\underline{S},l)\} \ge 1 - \exp\left\{-\delta h_{N_n}^{-1}\right\} > 1 - \frac{\epsilon}{2} \tag{5.9}$$

for all $z \in F_0$ and n large enough. Then the result follows immediately. □

Remarks. (1) If $\{r_n\}$ satisfies the condition of Corollary 2.2, we can choose $G(n) = n/\ln\ln n$. By $s(t) = 1$, we see that $r_n^{-1} s^{-1}\left(\exp\left\{(d^*+\alpha) h_n^{-1}\right\}\right) < n/\ln\ln n$ is equal to

$$h_n^{-1} < \frac{1}{d^* + \alpha}\left(\ln n + \ln r_n - \ln\ln n\right).$$

When $r_n \le 1/\ln^{\alpha} n$, $\alpha > 1$, assumptions (A1)–(A3) and (A4′) are satisfied. To require (A4) or (A4″), we need more restricted conditions on $\{r_n\}$, $\{h_n\}$ such as $r_n \ge 1/n^{\gamma}$, $\gamma < 1$ to meet (A4), etc.

(2) If $r_n = c/n + o(1/n)$,

$$G(n) = n^l \text{ for any } l > 1,$$
$$s(t) = \ln t,$$

then the theorem is valid when $h_n \ge (d+\alpha)/\ln\ln n$.

(3) For given $\epsilon > 0$, in the case of $r_n = 1/n^\gamma$, $\gamma < 1$, and $h_n = (d^* + \alpha)/(1-\gamma)\ln n$, we have $P_{0,x}\{X_N \in \underline{S}\} \geq 1 - \epsilon$, if $N > \exp\left\{-\frac{d^*+\alpha}{\delta(1-\gamma)}\ln(2\epsilon)\right\}$. When $r_n = c/n$, $h_n = (d^*+\alpha)/\ln\ln n$, to obtain the same result above, we need $N > \exp\left\{\exp\left\{-\frac{d^*+\alpha}{\delta}\ln(2\epsilon)\right\}\right\}$, where δ is a constant given in Lemma 5.1.

Here we point out that the $\{h_n\}$ given above is the best possibility for annealing in many cases. In this direction, we consider only when $r_n = c/n^\gamma + o(1/n^\gamma)$, $\gamma < 1$, and $r_n = c/n + o(1/n)$. As in [11], we have the following propositions.

PROPOSITION 5.3. *If $r_n = c/n^\gamma + o(1/n^\gamma)$ and $h_n \leq (d^* - \beta)/((1-\gamma)\ln n)$ for some $\beta > 0$, then there exists a compact set $K \in S\backslash\underline{S}$ satisfying $\pi_K^{d^*-\beta} \cap \underline{S} = \emptyset$, and for any $l > 0$, there is $c_1 > 0$ such that for large N and $y \in B(K, l)$,*

$$P_{N,y}\{\tau < +\infty\} \leq c_1 N^{-\beta(1-\gamma)/(2(d^*-\beta))},$$

where $\tau = \inf\{n > N, X_n \in B(S\backslash\pi_K^{d^*-\beta}, l)\}$.

Proof. Since $d^* = \max_{x\in S\backslash\underline{S}} \min_{y\in\underline{S}} I(x,y)$, we can find a $K \in S\backslash\underline{S}$, which satisfies $\min_{y\in\underline{S}} I(K,y)$. At this time, $\pi_K^{d^*-\beta} \cap \underline{S} = \emptyset$. Now we will prove the remaining part of the proposition. For simplicity, we assume that there is a $\hat{d} > 0$ such that

$$h_n > \frac{\hat{d}}{(1-\gamma)\ln n}.$$

Define

$$N_0 = N^{1/(1-\alpha)}, \quad N_n = (n+N)^{1/(1-\alpha)},\ \alpha < 1, \text{ and } \quad N_n^* = \left(n + N - \frac{1}{2}\right)^{1/(1-\alpha)}.$$

Then

$$N_{n+1} - N_n = cN_n^\alpha + o(N_n^\alpha).$$

Fixing R_0 large enough and considering

$$\tau_0 = \inf\{n > N, |X_n| > R_0\} \wedge \tau,$$

we have

$$P_{N_0,y}\{\tau_0 < N_n\} = \sum_{i=1}^{n} P_{N_0,y}\{N_{i-1} \leq \tau_0 \leq N_i\}.$$

Let ρ be the stopping time defined by

$$\rho = \inf\left\{n > N_{i-1}^*, X_n \in B(S,l)\right\}.$$

Then

$$\begin{aligned} P_{N_0,y}\{N_{i-1} \leq \tau_0 \leq N_i\} &= P_{N_0,y}\left\{N_{i-1} \leq \tau_0 \leq N_i, \rho \leq N_{i-1}^* + r_{N_{i-1}^*}^{-1} T^*\right\} \\ &\quad + P_{N_0,y}\left\{N_{i-1} \leq \tau_0 < N_i, \rho > N_{i-1}^* + r_{N_{i-1}^*}^{-1} T^*\right\}. \end{aligned}$$

Thus for fixed large T^* and by Lemma 4.5, we achieve the upper bound for the second term on the right,

$$\begin{aligned} &P_{N_0,y}\left\{\left|X_{N_{i-1}^*}\right| \leq R_0, \rho > N_{i-1}^* + r_{N_{i-1}^*}^{-1} T^*\right\} \leq \exp\left\{-Mh_{N_{i-1}^*}^{-1}\right\} \\ &\leq \left(N_{i-1}^*\right)^{-\frac{1-\gamma}{d^*-\beta}M}, \end{aligned}$$

where M can be chosen as large as we want if T^* is large enough. The first term is less than

$$P_{N_0,y}\left\{0 \le \tau_0 - N_{i-1} < N_{i-1}^{\alpha} \exp\left\{\left(\frac{\alpha-\gamma}{1-\gamma}\left(d^*-\beta\right) h_{N_{i-1}}^{-1}\right)\right\}, \rho \le N_{i-1}^* + r_{N_{i-1}^*}^{-1} T^*\right\}$$
$$\le \exp\left\{-\delta h_{N_{i-1}}^{-1}\right\} \le \left(N_{i-1}\right)^{-\frac{\delta(1-\alpha)}{d^*-\beta}},$$

where we choose $\gamma < \alpha < \frac{\hat{d}}{d^*-\beta}(1-\gamma)+\gamma$. By Lemma 4.5, there exists δ such that $0 < \delta < \frac{1-\alpha}{1-\gamma}\left(d^*-\beta\right)+\beta$ and satisfying the above inequality. Hence we may take $\delta = \frac{1-\alpha}{1-\gamma}\left(d^*-\beta\right)+\beta/2$ and come to

$$\begin{aligned} P_{N_0,y}\left\{\tau_0 < N_n\right\} &\le \sum_{i=1}^{n} \left(i-1+N\right)^{-\frac{1}{1-\alpha}\left(1-\alpha+\frac{\beta(1-\gamma)}{2(d^*-\beta)}\right)} \\ &= \sum_{i=1}^{n} \left(i-1+N\right)^{-1-\frac{\beta(1-\gamma)}{2(1-\alpha)(d^*-\beta)}} \\ &\le c_1 \left(N-1\right)^{-\frac{\beta(1-\gamma)}{2(1-\alpha)(d^*-\beta)}}. \end{aligned}$$

Let $n \to +\infty$, we complete the proof of the proposition. □

PROPOSITION 5.4. *When $r_n = c/n + o\left(1/n\right)$, if there is $\beta > 0$ such that $h_n \le \left(d^*-\beta\right)/\ln\ln n$, then there exists a set $K \in S\backslash\underline{S}(\pi_K^{d^*-\beta} \cap \underline{S} = \emptyset)$, for any $l > 0$, there is $c_1 > 0$ such that for large N and $y \in B\left(K,l\right)$,*

$$P_{N,y}\left\{\tau < +\infty\right\} \le c_1 \left(\ln N\right)^{-\beta/2(d^*-\beta)},$$

where $\tau = \inf\{n > N, X_n \in B(S\backslash\pi_K^{d^*-\beta}, l)\}$.

Proof. The proof is similar to that of Proposition 5.3. □

Appendix A. In this section, some properties of $I(x,y)$ are studied. Lemma A.1 shows the connection of $I(x,y)$ and $U(\cdot)$; other lemmas are devoted to show the connection between $I(x,y)$ and the cycle given in [14] and reveal the information including the complex definition of cycle.

For any $x \in K \subset S$, $U\left(x\right)$ is a constant, which we also denote by $U(K)$.

LEMMA A.1. *If x and y belong to the same domain of attraction, then $I\left(x,y\right) = 2\left(U\left(y\right)-U\left(x\right)\right) \vee 0$. Otherwise, if $I\left(x,y\right) \ne 2\left(U\left(y\right)-U\left(x\right)\right) \vee 0$, then there exists $K \in S$ such that for any $\epsilon > 0$, we have $\varphi \in \mathcal{B}_{x,y}$ satisfying $e\left(\varphi\right) < I\left(x,y\right)+\epsilon$, which passes through one point of K, and $I(x,K) = I(x,y) = 2(U(K)-U(x))$.*

Proof. The first part is obvious. To prove the second part of the lemma, we define

$$A_n := \left\{z \in R^d,\, U\left(z\right) \le U\left(x\right) + \frac{I\left(x,y\right)}{2} + \frac{1}{n}\right\}.$$

By the continuity of $U(x)$ and the assumption of S consisting of a finite number of components, so has A_n. We also use A_n to denote the component containing x. By the definition of $I(x,y)$, y belongs to A_n, too. Thus,

$$A := \cap_{n=1}^{\infty} A_n \subseteq \left\{z \in R^d,\, U\left(z\right) \le U\left(x\right) + I\left(x,y\right)/2\right\}$$

is closed and connected. Denote

$$\tilde{A} := A \cap \left\{z \in R^d,\, U\left(z\right) = U\left(x\right) + \frac{I\left(x,y\right)}{2}\right\}.$$

We claim that there exists $z \in \tilde{A}$, $\nabla U(x) = 0$. In fact, if on the contrary, for all $z \in \tilde{A}$, $\nabla U(x) \neq 0$, then by the continuity of $\nabla U(x)$ and $\tilde{A}$ being a level set, for any $z_0 \in \tilde{A}$, there exists $l > 0$ such that for any $z \in B(z_0, l) \cap \tilde{A}$ and δ less than some δ_0, it holds that $U(z + \delta \cdot \nabla U(z)) > U(x) + I(x, y)$ and $U(z - \delta \cdot \nabla U(z)) < U(x) + I(x, y)$. These imply that there exists an $\tilde{\delta} > 0$ such that $B(z_0, \tilde{\delta}) \cap A$ is homeomorphic to $R^{d-1} \times [0, +\infty)$, which is path connected. Moreover, A is locally path connected, since $A \backslash \tilde{A}$ is open. Consequently, A is path connected. Therefore, there is a $\varphi(\subset A) \in \mathcal{B}_{x,y}$. Denote

$$B := \left\{ z \in R^d, U(z) < U(x) + \frac{I(x, y)}{2} \right\}.$$

Then B consists of finite number of connected open domains and x and y are in different ones. Let B_x be the component containing x and B_y be that containing y. Assume that if $\varphi(t)$, $0 \leq t \leq 1$, is the path satisfying $I(x, y) = 2(\max_{0 \leq t \leq 1} U(\varphi(t)) - U(x))$. Let $t_1 = \inf \left\{ t > 0, \varphi(t) \notin \bar{B}_x \right\}$. Obviously, $\varphi(t_1) = z_0 \in \partial \bar{B}_x$. We assert $\nabla U(z_0) = 0$ (which leads to contradiction). If $\nabla U(z_0) \neq 0$, as we show above, there is a $\delta > 0$ such that $U(z) > U(x) + I(x, y)$ for $z \in B(z_0, \delta) \backslash \bar{B}_x$. By $\varphi(t) \leq U(x) + I(y, x)$ there exists t_0 for any $t < t_1 + t_0$, $\varphi(t) \in \bar{B}_x$. This contradicts to the assumption of t_1. Hence $\nabla U(z_0) = 0$.

For any $\epsilon > 0$, let A_ϵ be one of the components of

$$\left\{ z \in R^d, U(z) < U(x) + I(x, y)/2 + \epsilon \right\}$$

containing x and y. Then A_ϵ is path connected. By the assertion above, there are $z_0 \in K \subset S$, $z_0 \in \tilde{A}$, and a path $\varphi \in A_\epsilon$ with $\varphi(0) = x$, $\varphi\left(\frac{1}{2}\right) = z_0$, $\varphi(1) = y$. Hence $I(x, K) \leq I(x, y)$. Because of $K \subset \tilde{A}$, we have $I(x, K) \geq I(x, y)$, i.e., $I(x, K) = I(x, y)$. The proof is complete. □

Here we will recall the definition of the hierarchy of cycles and some related notations which are given in [14], and show their connection with $I(x, y)$.

To go back to $V(x, y)$, we define

$$V(K_i, K_j) := \inf \left\{ \tilde{S}_{0,T}(\phi); \phi(0) \in K_i, \phi(T) \in K_j, \phi(t) \notin K_l, l \neq i, j, 0 < t < T \right\}.$$

In the same way, we define $V(x, K_j)$, $V(K_i, y)$. Let $V(K_i) := \min_{j \neq i} V(K_i, K_j)$ and denote $V(K_i, K_j) = V(K_i)$ by $K_i \Longrightarrow K_j$. All of these K_i's with relation "$\Longrightarrow$" define a graph which is still denoted by S. We say K_i is connected to K_j if there are $i_1, \ldots, i_n$ such that $i = i_1$, $j = i_n$, and $K_{i_1} \Longrightarrow K_{i_2} \Longrightarrow \cdots \Longrightarrow K_{i_n}$.

DEFINITION A.2. *A cycle π in S is a subgraph of S satisfying*

(1) *$K \in \pi$ and $K \Longrightarrow K'$ imply $K' \in \pi$;*

(2) *for any $K \neq K'$ in π, K is connected to K' in π.*

DEFINITION A.3. *Let*

$$S^1 = \{\pi : \pi \text{ is a cycle in } S\} \cup \{K : K \in S \text{ and } K \text{ is not in any cycle}\}.$$

An element of S^1 is called a 1-cycle(in S). We use π^1 to denote a 1-cycle.

For each $\pi \in S^1$, let $\hat{V}(\pi) = \max\{V(K); K \in \pi\}$. For $\pi_1, \pi_2 \in S^1$, and $\pi_1 \neq \pi_2$, define

$$V(\pi_1, \pi_2) = \hat{V}(\pi_1) + \min\{V(K_1, K_2) - V(K_1); K_1 \in \pi_1, K_2 \in \pi_2\},$$
$$V(\pi_1) = \min\{V(\pi_1, \pi_2); \pi_1 \neq \pi_2\},$$

and $\pi_1 \Longrightarrow \pi_2$ if $V(\pi_1, \pi_2) = V(\pi_1)$.

To use S^1 instead of S, we can define S^2 and 2-cycles and use the notation π^2 for a specified one. Inductively, if we have defined up to m-cycles π^m in S_m, we will give the following for $m+1$:

$$\hat{V}(\pi^m) = \max\left\{V\left(\pi^{m-1}\right); \pi^{m-1} \in \pi^m\right\},$$
$$V(\pi_1^m, \pi_2^m) = \hat{V}(\pi_1^m) + \min\left\{V(\pi_1^{m-1}, \pi_2^{m-1}) - V(\pi_1^{m-1}); \pi_1^{m-1} \in \pi_1^m, \pi_2^{m-1} \in \pi_2^m\right\},$$
$$V(\pi^m) = \min\left\{V(\pi^m, \hat{\pi}^m); \pi^m \neq \hat{\pi}^m, \hat{\pi}^m \in S^m\right\},$$

and $\pi^m \Longrightarrow \hat{\pi}^m$ if $V(\pi^m) = V(\pi^m, \hat{\pi}^m)$. Then the $(m+1)$-cycle is constructed in the same way as in the 1-cycle case.

For convenience, π^k stands for

$$\cup_{\pi^{k-1}\in\pi^k}\pi^{k-1} \text{ or } \cup_{\pi^{k-1}\in\pi^k}\left(\cup\pi_{k-2} \in \pi_{k-1}\left(\cdots\left(\cup_{\pi^1\in\pi^2}\pi^1\right)\cdots\right)\right).$$

Set $I\left(\pi_1^k, \pi_1^k\right) = \sup_{x\in\pi_1^k}\inf_{y\in\pi_2^k} I(x,y)$ and $I\left(\pi_1^k\right) = \sup_{x\in\pi_1^k}\inf_{y\in S\setminus\pi_1^k} I(x,y)$. Recalling the definition of π_K^c and $I(\pi_K^c)$ in section 4, we have the following lemma, which can be verified by using Lemma A.1 and the cycle decomposition of [23].

LEMMA A.4. *For any $K \in S$, $c > 0$. there exist k and j such that $\pi_K^c = \pi_k^j$ and $V(\pi_k^j) = I(\pi_K^c)$.*

Let $G_{\underline{S}_l}(\underline{S}_c)$, $c < l$, denote the set of all $\underline{S}_c$-graphs in $\underline{S}_l$ (cf. [5], [14]) and

$$V(g) = \sum_{(m\to n)\in g} V(K_m, K_n), \qquad g \in G_{\underline{S}_l}(\underline{S}_c),$$

where $m \to n$ denotes a directed edge of g. (If $\underline{S}_l \backslash \underline{S}_c = \emptyset, V(g) := 0$.)

The following lemma is used to prove Lemma 4.6. To prove it, we need Lemmas A.6 and A.7. However, the detail is omitted; readers are also referred to [23].

LEMMA A.5. *For any $K_i \in \underline{S}_l \backslash \underline{S}_c$,*

$$\begin{aligned}&\min\left\{V(g); g \in G_{\underline{S}_l}(\underline{S}_c)\right\} - \min\left\{V(g); g \in G_{\underline{S}_l}(\underline{S}_c \cup \{K_i\})\right.\\ &\left.\text{or } g \in G_{\underline{S}_l\{K_iK_j\}}(\underline{S}_c \cup \{K_j\}), K_i \neq K_j, K_j \in \underline{S}_l \backslash \underline{S}_c\right\}\\ &\leq \max_{x\in\underline{S}_l\backslash\underline{S}_c}\min_{y\in\underline{S}_c} I(x,y),\end{aligned}$$

where $G_{\underline{S}_l\{K_iK_j\}}(\underline{S}_c \cup \{K_j\})$ denotes the set of $\underline{S}_c \cup \{K_j\}$-graphs in $\underline{S}_l$, in which the sequence of arrows leading from K_i into $\underline{S}_c \cup \{K_j\}$ ends at K_j.

LEMMA A.6. *For any $g_0 \in G_{\underline{S}_l}(\underline{S}_c)$, there is $g \in G_{\underline{S}_l}(\underline{S}_c)$ such that $V(g) \leq V(g_0)$, and for any $\pi^1 \in \underline{S}_l \backslash \underline{S}_c$, we can find $K_0 \in \pi^1$ such that there is a graph h satisfying $h \in G_{\pi^1}(K_0), h \subset g$.*

For $A \in S^k \cap \underline{S}_l$, denote by $G_{\underline{S}_l}^A(\underline{S}_l)$ a new $\underline{S}_c$-graph in $\underline{S}_l$, in which A is considered globally as a node in $\underline{S}_l$; then we have the following lemma.

LEMMA A.7. *For any $K_i \in \underline{S}_l \backslash \underline{S}_c$, if $K_i \in A$, then*

$$\begin{aligned}&\min\left\{V(g); g \in G_{\underline{S}_l}(\underline{S}_c)\right\} - \min\left\{V(g); g \in G_{\underline{S}_l}(\underline{S}_c \cup \{K_i\})\right.\\ &\qquad\left.\text{or } g \in G_{\underline{S}_l\{K_iK_j\}}(\underline{S}_c \cup \{K_j\}), K_i \neq K_j, K_j \in \underline{S}_l \backslash \underline{S}_c\right\}\\ &= \min\left\{V(g); g \in G_{\underline{S}_l}^A(\underline{S}_c)\right\} - \min\left\{V(g); g \in G_{\underline{S}_l}^A(\underline{S}_c \cup \{A\})\right.\\ &\qquad\left.\text{or } g \in G_{\underline{S}_l\{AK_j\}}^A(\underline{S}_c \cup \{K_j\}), K_j \notin A, K_j \in \underline{S}_l \backslash \underline{S}_c\right\};\end{aligned} \tag{A.1}$$

otherwise,

$$\textit{left-hand side} = \min\left\{V(g); g \in G^A_{\underline{S}_l}(\underline{S}_c)\right\} - \min\left\{V(g); g \in G^A_{\underline{S}_l}(\underline{S}_c \cup \{K_i\}) \textit{ or}\right.$$

$$\left. g \in G^A_{\underline{S}_l\{K_iK_j\}}(\underline{S}_c \cup \{K_j\}), K_j \notin \underline{S}_c \cup A \cup \{K_i\} \textit{ or } g \in G^A_{\underline{S}_l\{K_iA\}}(\underline{S}_c \cup A)\right\}. \quad \text{(A.2)}$$

EXACT FINITE-DIMENSIONAL FILTERS FOR MAXIMUM LIKELIHOOD PARAMETER ESTIMATION OF CONTINUOUS-TIME LINEAR GAUSSIAN SYSTEMS*

ROBERT J. ELLIOTT† AND VIKRAM KRISHNAMURTHY‡

Abstract. In this paper, we derive a new class of finite-dimensional filters for integrals and stochastic integrals of moments of the state for continuous-time linear Gaussian systems. Apart from being of significant mathematical interest, these new filters can be used with the expectation maximization (EM) algorithm to yield maximum likelihood estimates of the model parameters.

Key words. stochastic systems, finite-dimensional filters, Kalman filter, expectation maximization algorithm, parameter estimation

1. Introduction.

The Kalman filter is widely used in engineering, economics, and other fields. It considers linear Gaussian dynamics for the state x and observation y processes of the form

$$dx_t = A_t\, x_t\, dt + B_t\, dw_t, \quad x_0 \in \mathbb{R}^m, \tag{1.1}$$

$$dy_t = C_t\, x_t\, dt + D_t\, dv_t, \quad y_0 = 0 \in \mathbb{R}^n. \tag{1.2}$$

The Kalman filter determines the conditional density of the unobserved signal x_t given the observations to time t, $\mathcal{Y}_t = \sigma\{y_s : s \le t\}$, as a Gaussian random variable with mean m_t and variance Σ_t. Here m_t is the conditional mean of x_t given $\mathcal{Y}_t$, and Σ_t is the conditional variance of x_t, although Σ_t turns out to be deterministic and given by the Riccati equation.

To apply the Kalman filter, however, the parameters of the model, that is, the entries in the matrices A, B, C, and D, need to be known. Maximum likelihood estimation of these parameters via the expectation maximization (EM) algorithm has been studied in discrete time in [1], [2], [3] and in continuous time in [9]. In continuous time, the EM algorithm requires computation of the filtered estimates of quantities such as $\int_0^t x_s\, dx'_s$, $\int_0^t x_s\, dy'_s$, $\int_0^t x_s\, x'_s\, ds$.

In all the existing literature on parameter estimation of linear Gaussian models via the EM algorithm, filtered estimates of the above quantities are computed via Kalman smoothing, which requires large memory in any numerical implementation. The main result of this paper, Theorem 3.10, provides *finite-dimensional filters for (the components of) such integral processes.* In fact, as pointed out in section 4, finite-dimensional filters exist for integrals and stochastic integrals of moments of all orders

of the state process. In [18] and [19], finite-dimensional filters are described using Lie algebra methods, for time integrals of powers of the state variable. However, our techniques are quite different; we also obtain results for stochastic integrals of powers of the process, and we apply our results to maximum likelihood parameter estimation. Few finite-dimensional filters are known, so our results were certainly a surprise.

The analogous results in discrete time are derived in a companion paper [17]. The continuous-time methods and results in this paper are different from, and not just adaptations of, the discrete-time results in [17]. As described in [17], estimation of the state-space parameters arises in several areas of signal processing and control, including multisensor signal enhancement and speech coding, and also in econometrics.

Parameter estimation for diffusion processes is nicely discussed in [9]; this work also includes a discussion of the EM algorithm. Section 5 describes this application of the results of section 4. The techniques of this paper extend those for Markov chains presented in [5] and the recent book, [6].

The paper is organized as follows: in section 2 we present a standard measure change that simplifies the derivation of our filters. In section 3 the new finite-dimensional filters are derived. Section 4 derives a finite-dimensional filter for higher order moments of the state. In section 5, the filters in section 3 are used to implement a filter-based EM algorithm for maximum likelihood parameter estimation.

2. Dynamics. Consider the classical linear Gaussian model for the signal model and observation processes. That is, the signal $\{x_t\}$, $t \geq 0$, is described by the equation

$$dx_t = A_t\, x_t\, dt + B_t\, dw_t, \qquad x_0 \in \mathbb{R}^m, \tag{2.1}$$

and the observation process $\{y_t\}$, $t \geq 0$, is described as

$$dy_t = C_t\, x_t\, dt + D_t\, dv_t, \qquad y_0 = 0 \in \mathbb{R}^n. \tag{2.2}$$

Here w and v are independent r-dimensional and n-dimensional Brownian motions, respectively, defined on a probability space $(\Omega, \mathcal{F}, P)$. Further, w and v are independent of x_0. We assume that x_0 is a random variable with normal density $\pi_0(x)$, which is $N(\hat{x}_0, P_0)$.

The matrix functions $A_t \in \mathbb{R}^{m\times m}$, $B_t \in \mathbb{R}^{m\times r}$, $C_t \in \mathbb{R}^{n\times m}$, and $D_t \in \mathbb{R}^{n\times n}$ are measurable functions of t. We assume D_t is a positive definite matrix.

We model the above dynamics by supposing that initially we have a probability space $(\Omega, \mathcal{F}, \bar{P})$ such that under $\bar{P}$

1. w is r-dimensional Brownian motion and $\{x_t\}$ is defined by (2.1).
2. $\{y_t\}$ is n-dimensional Brownian motion, independent of w and x_0, and having quadratic variation $\langle y\rangle_t = D_t > 0$; i.e., D_t is a positive definite matrix.

Notation. Consider the complete right continuous filtrations

$$\mathcal{G}_t = \sigma\{x_s, y_s : s \leq t\},$$
$$\mathcal{Y}_t = \sigma\{y_s : s \leq t\}.$$

Vectors x, y will be considered as column vectors. Write

$$\nabla = \left(\frac{\partial}{\partial x_1}, \frac{\partial}{\partial x_2}, \ldots, \frac{\partial}{\partial x_n}\right)'. \tag{2.3}$$

For any function $g : \mathbb{R}^m \to \mathbb{R}$, write

$$\nabla^2 g = \begin{bmatrix} \frac{\partial^2 g}{\partial x_1^2} & \cdots & \frac{\partial^2 g}{\partial x_1 \partial x_m} \\ \vdots & \vdots & \vdots \\ \frac{\partial^2 g}{\partial x_m \partial x_1} & \cdots & \frac{\partial^2 g}{\partial x_m^2} \end{bmatrix}.$$

For a vector field $g(x) = [g_1(x)\ g_2(x)\ \cdots\ g_m(x)]'$ defined on $\mathbb{R}^m$, define

$$\operatorname{div}(g) = \frac{\partial g_1}{\partial x_1} + \frac{\partial g_2}{\partial x_2} + \cdots + \frac{\partial g_m}{\partial x_m}.$$

Consider the exponential

$$\Lambda_t = \exp\left(\int_0^t (C_s\, x_s)' \left(D_s^{-1}\right)' D_s^{-1}\, dy_s - \frac{1}{2} \int_0^t x_s'\, C_s' \left(D_s^{-1}\right)' D_s^{-1}\, C_s\, x_s\, ds \right). \tag{2.4}$$

Then

$$d\Lambda_t = \Lambda_t\, x_t'\, C_t' \left(D_s^{-1}\right)' D_s^{-1}\, dy_t \tag{2.5}$$

and $\bar{\mathbf{E}}\{\Lambda_t\} = 1$, where $\bar{\mathbf{E}}$ denotes expectation under $\bar{P}$.

If we define a measure P in terms of $\bar{P}$ by setting

$$\left.\frac{dP}{d\bar{P}}\right|_{\mathcal{G}_t} = \Lambda_t,$$

then Girsanov's theorem implies that under P, v_t is a standard n-dimensional Brownian motion if we define

$$dv_t = D_t^{-1}\,(dy_t - C_t\, x_t\, dt), \quad v_0 = 0.$$

That is, under P,

$$dy_t = C_t\, x_t\, dt + D_t\, dv_t.$$

Note that under P, the process $\{x_t\}$ still satisfies (2.1). Consequently, under P the processes $\{x_t\}$ and $\{y_t\}$ satisfy the real world dynamics (2.1) and (2.2). However, $\bar{P}$ is a more convenient measure with which to work.

Below, we assume that $g : \mathbb{R}^m \to \mathbb{R}$ is an arbitrary "test" function, which is in $\mathbb{C}^2$ and has compact support.

Filtering is concerned with estimates of the form $\mathbf{E}\{g(x_t)|\mathcal{Y}_t\}$. Using a version of Bayes's theorem [6], we have

$$\mathbf{E}\{g(x_t)|\mathcal{Y}_t\} = \frac{\bar{\mathbf{E}}\{\Lambda_t\, g(x_t)|\mathcal{Y}_t\}}{\bar{\mathbf{E}}\{\Lambda_t|\mathcal{Y}_t\}}. \tag{2.6}$$

Write $\sigma(g)_t = \bar{\mathbf{E}}\{\Lambda_t\, g(x_t)|\mathcal{Y}_t\}$ so that

$$\mathbf{E}\{g(x_t)|\mathcal{Y}_t\} = \frac{\sigma(g)_t}{\sigma(1)_t}.$$

Consequently, $\sigma(g)_t$ is a measure-valued process; it is an unnormalized conditional expectation of $g(x_t)$ given $\mathcal{Y}_t$.

Suppose that $\sigma(\cdot)_t$ has a density $\alpha_t(x)$; then

$$\sigma(g)_t = \bar{\mathbf{E}}\{\Lambda_t\, g(x_t)|\mathcal{Y}_t\} = \int_{\mathbb{R}^m} g(x)\,\alpha_t(x)\,dx.$$

We now give a proof of the well-known Zakai equation for α.

THEOREM 2.1.

$$\begin{aligned}\alpha_t(x) = \alpha_0(x) &- \int_0^t \operatorname{div}\left(A_s\, x\, \alpha_s(x)\right)\, ds + \frac{1}{2}\int_0^t \operatorname{Tr}\left(\nabla^2\alpha_s(x)\, B_s\, B_s'\right)\, ds \\ &+ \int_0^t \alpha_s(x)\, x'\, C_s'\left(D_s^{-1}\right)'\, D_s^{-1}\, dy_s,\end{aligned} \tag{2.7}$$

where $\alpha_0(x) = \pi_o(x)$, the density of x_0.

Proof. From Ito's rule

$$\begin{aligned}g(x_t) = g(x_0) &+ \int_0^t \left(\nabla g(x_s)\right)'\, A_s\, x_s\, ds + \int_0^t \left(\nabla g(x_s)\right)'\, B_s\, dw_s \\ &+ \frac{1}{2}\int_0^t \operatorname{Tr}\left(\nabla^2 g(x_s)\, B_s\, B_s'\right)\, ds.\end{aligned} \tag{2.8}$$

From (2.5) and (2.8)

$$\begin{aligned}\Lambda_t\, g(x_t) = g(x_0) &+ \int_0^t \Lambda_s\, \left(\nabla g(x_s)\right)'\, A_s\, x_s\, ds + \int_0^t \Lambda_s\, \left(\nabla g(x_s)\right)'\, B_s\, dw_s \\ &+ \frac{1}{2}\int_0^t \Lambda_s \operatorname{Tr}\left(\nabla^2 g(x_s) B_s\, B_s'\right) ds + \int_0^t \Lambda_s\, g(x_s)\, x_s'\, C_s'\left(D_s^{-1}\right)'\, D_s^{-1}\, dy_s.\end{aligned} \tag{2.9}$$

Conditioning each side of (2.9) on $\mathcal{Y}_t$ (see Lemma 3.2, p. 261, of [13]) we have

$$\begin{aligned}\sigma(g)_t = \sigma(g)_0 &+ \int_0^t \sigma\left(\left(\nabla g\right)'\, A\, x\right)_s\, ds + \frac{1}{2}\int_0^t \sigma\left(\operatorname{Tr}(\nabla^2 g) B_s\, B_s'\right)\, ds \\ &+ \int_0^t \sigma(g\, x')_s\, C_s'\left(D_s^{-1}\right)'\, D_s^{-1}\, dy_s.\end{aligned} \tag{2.10}$$

Integrating each term by parts as on p. 277 of [7] gives (2.7). □

Remarks. The Zakai equation (2.7) is a stochastic partial differential equation for the unnormalized conditional density of x_t given $\mathcal{Y}_t$. In general, the solution of this equation is a conditional density function, evolving stochastically in time. For the linear, Gaussian dynamics (2.1) and (2.2), however, $\alpha_t(x)$ has a simple form. In fact (see [10] or [11]),

$$\alpha_t(x) = \frac{\nu_t}{(2\,\pi)^{m/2}\,|\Sigma_t|^{1/2}}\, \exp\left(-\frac{1}{2}(x - m_t)'\,\Sigma_t^{-1}\,(x - m_t)\right). \tag{2.11}$$

Here $m_t = \mathbf{E}\{x_t|\mathcal{Y}_t\}$, $m_0 = \hat{x}_0$, $\Sigma_t = \mathbf{E}\{(x_t - m_t)(x_t - m_t)'|\mathcal{Y}_t\}$, $\Sigma_0 = P_0$, and ν_t is a normalizing factor.

It is well known that m_t and Σ_t are given by the Kalman filter equations

$$dm_t = A_t\, m_t\, dt + \Sigma_t\, C_t'\left(D_t^{-1}\right)'\, D_t^{-1}\left(dy_t - C_t\, m_t\, dt\right), \tag{2.12}$$

$$\dot{\Sigma}_t = \Sigma_t\, A_t' + A_t\, \Sigma_t + B_t\, B_t' - \Sigma_t\, C_t'\left(D_t^{-1}\right)'\, D_t^{-1}\, C_t\, \Sigma_t. \tag{2.13}$$

Note that Σ_t is deterministic and can be computed off-line. Also,

(2.14)
$$\nu_t = (2\,\pi)^{m/2} \exp\left(\int_0^t m_s'\, C_s' \big(D_s^{-1}\big)'\, D_s^{-1}\, dy_s - \frac{1}{2} \int_0^t m_s'\, C_s'\, \big(D_s^{-1}\big)'\, D_s^{-1}\, C_s\, m_s\, ds \right).$$

3. Finite-dimensional filters. Let e_i, $e_j \in \mathbb{R}^m$ denote unit vectors with 1 in the ith and jth positions, respectively. Write

$$H_t^{ij} = \int_0^t \langle x_s, e_i \rangle \, \langle e_j, x_s \rangle \, ds = \int_0^t x_s' \, (e_i \, e_j') \, x_s \, ds, \tag{3.1}$$

$$L_t^{ij} = \int_0^t \langle x_s, e_i \rangle \, \langle e_j, dx_s \rangle = \int_0^t x_s' \, (e_i \, e_j') \, dx_s; \tag{3.2}$$

here $\langle \cdot, \cdot \rangle$ denotes the scalar product.

Also let $f_j \in \mathbb{R}^n$ denote the unit vector with 1 in the jth position. Write

$$J_t^{ij} = \int_0^t \langle x_s, e_i \rangle \, \langle f_j, dy_s \rangle = \int_0^t x_s' \, (e_i \, f_j') \, dy_s. \tag{3.3}$$

The parameters of our model are the entries in the matrices A_t, B_t, C_t, and D_t. To estimate these parameters using the EM algorithm (see section 5), it is necessary to obtain filtered estimates of these processes. That is, we wish to obtain expressions for

$$\mathbf{E}\{H_t^{ij} | \mathcal{Y}_t\}, \quad \mathbf{E}\{L_t^{ij} | \mathcal{Y}_t\}, \quad \mathbf{E}\{J_t^{ij} | \mathcal{Y}_t\}.$$

Previously, these estimates have been obtained by smoothing procedures. For example,

$$\mathbf{E}\{H_t^{ij} | \mathcal{Y}_t\} = \int_0^t \mathbf{E}\{x_s' \, (e_i \, e_j) \, x_s | \mathcal{Y}_t\} \, ds.$$

However, this involves a considerable memory requirement. In this section we prove the remarkable result that the filtered estimates for H_t^{ij}, L_t^{ij}, and J_t^{ij} can be described in terms of a finite number of statistics.

Motivated by the techniques in [6], we define a measure associated with H_t^{ij} as follows.

DEFINITION 3.1. *For any test function $g : \mathbb{R}^m \to \mathbb{R}$, define a measure-valued process $\bar{\mathbf{E}}\{\Lambda_t \, H_t^{ij} \, g(x_t) | \mathcal{Y}_t\}$. This has a density $\beta_t^{ij}(x)$ so that*

$$\bar{\mathbf{E}}\{\Lambda_t \, H_t^{ij} \, g(x_t) | \mathcal{Y}_t\} = \int_{\mathbb{R}^m} \beta_t^{ij}(x) \, g(x) \, dx.$$

The existence of the density $\beta_t^{ij}(x)$ follows from the existence and uniqueness of solutions of stochastic partial differential equations such as (3.9). This is established in section 4.2 of [10] and on page 140 of [12].

The following theorem shows the surprising result that we can describe the measure $\beta_t^{ij}(x)$ exactly as a quadratic in x multiplying the $\alpha_t(x)$ of (2.7).

THEOREM 3.2. *At time t, the density $\beta_t^{ij}(x)$ is completely described by the five statistics a_t^{ij}, b_t^{ij}, c_t^{ij}, Σ_t, and m_t as follows:*

$$\beta_t^{ij}(x) = \left(a_t^{ij} + x' \, b_t^{ij} + x' \, c_t^{ij} \, x \right) \alpha_t(x). \tag{3.4}$$

Here $a_t^{ij} \in \mathbb{R}$, $b_t^{ij} \in \mathbb{R}^m$, and $c_t^{ij} \in L_s(\mathbb{R}^m, \mathbb{R})$, the space of symmetric $m \times m$ matrices. Further,

$$\frac{da_t^{ij}}{dt} = \operatorname{Tr}\left(c_t^{ij}\, B_t\, B_t'\right) + b_t^{ij\prime}\, B_t\, B_t'\, \Sigma_t^{-1}\, m_t, \quad a_0^{ij} = 0 \in \mathbb{R}, \tag{3.5}$$

$$\frac{db_t^{ij}}{dt} = -\left(A_t' + \Sigma_t^{-1}\, B_t\, B_t'\right) b_t^{ij} + 2\, c_t^{ij}\, B_t\, B_t'\, \Sigma_t^{-1}\, m_t, \quad b_0^{ij} = 0 \in \mathbb{R}^m, \tag{3.6}$$

$$\frac{dc_t^{ij}}{dt} = -\left(A_t' + \Sigma_t^{-1}\, B_t\, B_t'\right) c_t^{ij} - c_t^{ij}\left(A_t + B_t\, B_t'\, \Sigma_t^{-1}\right) + \frac{1}{2}(e_j\, e_i' + e_i\, e_j'),$$

$$c_0^{ij} = 0 \in L_s(\mathbb{R}^m, \mathbb{R}). \tag{3.7}$$

Proof. First note that for any test function g, applying Ito's rule to (2.1) and (2.5),

$$\begin{aligned}\Lambda_t\, H_t^{ij}\, g(x_t) = {} & \int_0^t \Lambda_s\, H_s^{ij}\ (\nabla g(x_s))'\, A_s\, x_s\, ds + \int_0^t \Lambda_s\, H_s^{ij}\ (\nabla g(x_s))'\, B_s\, dw_s \\ & + \frac{1}{2}\int_0^t \Lambda_s\, H_s^{ij} \operatorname{Tr}\left(\nabla^2 g(x_s)\, B_s\, B_s'\right) ds \\ & + \int_0^t \Lambda_s\, H_s^{ij}\, g(x_s)\, x_s'\, C_s'\left(D_s^{-1}\right)' D_s^{-1}\, dy_s \\ & + \int_0^t \Lambda_s\, g(x_s)\, x_s'\, (e_i\, e_j')\, x_s\, ds. \end{aligned} \tag{3.8}$$

Conditioning on $\mathcal{Y}_t$ under $\bar{P}$ (see Lemma 3.2, p. 261, of [13]) we have

$$\begin{aligned}\bar{\mathbf{E}}\{\Lambda_t\, H_t^{ij}\, g(x_t)|\mathcal{Y}_t\} = {} & \int_0^t \bar{\mathbf{E}}\{\Lambda_s\, H_s^{ij}\ (\nabla g(x_s)'\, A_s\, x_s)\,|\mathcal{Y}_s\}\, ds \\ & + \frac{1}{2}\int_0^t \bar{\mathbf{E}}\{\Lambda_s\, H_s^{ij} \operatorname{Tr}\left(\nabla^2 g(x_s) B_s\, B_s'\right)|\mathcal{Y}_s\}\, ds \\ & + \int_0^t \bar{\mathbf{E}}\{\Lambda_s\, H_s^{ij}\, g(x_s)\, x_s'\, C_s'\left(D_s^{-1}\right)' D_s^{-1}|\mathcal{Y}_s\}\, dy_s \\ & + \int_0^t \bar{\mathbf{E}}\{\Lambda_s\, g(x_s)\, x_s'\, (e_i\, e_j')\, x_s|\mathcal{Y}_s\}\, ds. \end{aligned}$$

That is, in terms of the densities $\beta_t^{ij}(x)$ and $\alpha_t(x)$,

$$\begin{aligned}\int_{\mathbb{R}^m} \beta_t^{ij}(x)\, g(x)\, dx = {} & \int_0^t \int_{\mathbb{R}^m} \beta_s^{ij}(x)\ (\nabla g(x))'\ A_s\, x\, dx\, ds \\ & + \frac{1}{2}\int_0^t \int_{\mathbb{R}^m} \beta_s^{ij}(x) \operatorname{Tr}\left(\nabla^2 g(x)\, B_s\, B_s'\right) dx\, ds \\ & + \int_0^t \int_{\mathbb{R}^m} \beta_s^{ij}(x)\, g(x)\, x'\, C_s'\left(D_s^{-1}\right)' D_s^{-1}\, dx\, dy_s \\ & + \int_0^t \int_{\mathbb{R}^m} \alpha_s(x)\, g(x)\, x'\, (e_i\, e_j')\, x\, dx\, ds. \end{aligned}$$

Integrating by parts in x, because this equation holds for all test functions g, we see

that $\beta_t^{ij}(x)$ must satisfy the stochastic partial differential equation:

$$\begin{aligned}\beta_t^{ij}(x) = &-\int_0^t \operatorname{div}\left(\beta_s^{ij}(x)\, A_s\, x\right)\, ds + \frac{1}{2}\int_0^t \operatorname{Tr}\left(\nabla^2\beta_s^{ij}(x)\, B_s\, B_s'\right)\, ds \\ &+\int_0^t \beta_s^{ij}(x)\, x'\, C_s'\left(D_s^{-1}\right)' D_s^{-1}\, dy_s + \int_0^t \alpha_s(x)\, x'\,(e_i\, e_j')\, x\, ds. \end{aligned} \tag{3.9}$$

We look for a solution of (3.9) of the form

$$\bar\beta_s(x) = \left(a_s^{ij} + x' b_s^{ij} + x'\, c_s^{ij}\, x\right)\alpha_s(x). \tag{3.10}$$

As noted just after Definition 3.1, if such a solution exists, it is unique.

To simplify notation we drop the superscripts i, j on a, b, and c. Then

$$\begin{aligned}\operatorname{div}\left(\bar\beta_s(x)\, A_s\, x\right) &= \operatorname{div}\left((a_s + b_s'\, x + x'\, c_s\, x)\,\alpha_s(x)\, A_s\, x\right) \\ &= (b_s + 2\, c_s\, x)'\, A_s\, x\, \alpha_s(x) + (a_s + b_s'\, x + x'\, c_s\, x)\operatorname{div}\left(\alpha_s(x)\, A_s\, x\right), \\ \nabla\bar\beta_s(x) &= \nabla\left((a_s + b_s'\, x + x'\, c_s\, x)\,\alpha_s(x)\right) \\ &= (b_s + 2\, c_s\, x)\,\alpha_s(x) + (a_s + b_s'\, x + x'\, c_s\, x)\,\nabla\alpha_s(x), \\ \nabla^2\bar\beta_s(x) &= 2\, c_s\,\alpha_s(x) + 2\,(b_s + 2\, c_s\, x)(\nabla\alpha_s(x))' \\ &\quad + (a_s + b_s'\, x + x'\, c_s\, x)\,\nabla^2\alpha_s(x), \\ \operatorname{Tr}\left(\nabla^2\bar\beta_s(x)\, B_s\, B_s'\right) &= 2\,\alpha_s(x)\operatorname{Tr}\left(c_s\, B_s\, B_s'\right) + 2\,(b_s + 2\, c_s\, x)'\, B_s\, B_s'\,\nabla\alpha_s(x) \\ &\quad + (a_s + b_s'\, x + x'\, c_s\, x)\,\operatorname{Tr}\left(\nabla^2\alpha_s(x)\, B_s\, B_s'\right). \end{aligned}$$

Now from (2.11)

$$\nabla\alpha_s(x) = -\Sigma_s^{-1}(x - m_s)\,\alpha_s(x).$$

Consequently, if we substitute $\bar\beta_t(x)$, given by (3.10) in the differential form of the right-hand side of (3.9), we obtain

$$\begin{aligned}&-(b_s + 2\, c_s\, x)'\, A_s\, x\,\alpha_s(x)\, ds - (a_s + b_s'\, x + x'\, c_s\, x)\operatorname{div}\left(\alpha_s(x)\, A_s\, x\right)\, ds \\ &\quad +\alpha_s(x)\operatorname{Tr}\left(c_s\, B_s\, B_s'\right)\, ds - (b_s + 2\, c_s\, x)' B_s\, B_s'\,\Sigma_s^{-1}\,(x - m_s)\,\alpha_s(x)\, ds \\ &\quad +\frac{1}{2}(a_s + b_s'\, x + x'\, c_s\, x)\operatorname{Tr}\left(\nabla^2\alpha_s(x)\, B_s'\, B_s\right)\, ds \\ &\quad +(a_s + b_s'\, x + x'\, c_s\, x)\,\alpha_s(x)\, x'\, C_s'\left(D_s^{-1}\right)' D_s^{-1}\, dy_s \\ &\quad +\alpha_s(x)\, x'\,(e_i\, e_j')\, x\, ds. \end{aligned} \tag{3.11}$$

Also,

$$d\bar\beta_s(x) = (da_s + db_s'\, x + x'\, dc_s\, x)\,\alpha_s(x) + (a_s + b_s'\, x + x'\, c_s\, x)\, d\alpha_s(x). \tag{3.12}$$

Consequently, $\bar\beta_s(x)$, given by (3.10), is a solution of (3.9) if (3.11) equals (3.12). However, $\alpha_s(x)$ solves the Zakai equation (2.7), so

$$d\alpha_s(x) = -\operatorname{div}\left(\alpha_s(x)\, A_s\, x\right)\, ds + \frac{1}{2}\operatorname{Tr}\left(\nabla^2\alpha_s(x)\, B_s\, B_s'\right)\, ds + \alpha_s(x)\, x'\, C_s'\left(D_s^{-1}\right)' D_s^{-1}\, dy_s.$$

Therefore, substituting the above expression for $d\alpha_s(x)$ into (3.12) yields

$$\begin{aligned}d\bar\beta_s(x) = &(da_s + db_s'\, x + x'\, dc_s\, x)\,\alpha_s(x) \\ &-(a_s + b_s'\, x + x'\, c_s\, x)\operatorname{div}\left(\alpha_s(x)\, A_s\, x\right)\, ds \\ &+\frac{1}{2}(a_s + b_s' + x'\, c_s\, x)\operatorname{Tr}\left(\nabla^2\alpha_s(x)\, B_s\, B_s'\right)\, ds \\ &+(a_s + b_s'\, x + x'\, c_s\, x)\, x'\, C_s'\left(D_s^{-1}\right)' D_s^{-1}\,\alpha_s(x)\, dy_s. \end{aligned} \tag{3.13}$$

Finally equating the coefficients of x, x', x and the constants in (3.11) and (3.13), we see that the result holds if (3.5), (3.6), and (3.7) hold. □

We now explicitly solve the ordinary differential equations (3.6) and (3.7).

Write G_t for the matrix solution of

$$\frac{dG_t}{dt} = -(A_t' + \Sigma_t^{-1} B_t B_t')G_t, \quad G_0 = I_{m\times m}. \tag{3.14}$$

Note that G_t is deterministic and can be calculated off-line. Also, as an exponential matrix, G_t has an inverse G_t^{-1}.

LEMMA 3.3. *The explicit solutions of* (3.6) *and* (3.7) *are*

$$b_t^{ij} = 2\,G_t \left(\int_0^t G_s^{-1}\, c_s^{ij}\, B_s\, B_s'\, \Sigma_s^{-1}\, m_s\, ds\right), \tag{3.15}$$

$$c_t^{ij} = \frac{1}{2}\, G_t \left(\int_0^t G_s^{-1}\, (e_j\, e_i' + e_i\, e_j')\, (G_s')^{-1}\, ds\right) G_t'. \tag{3.16}$$

Proof. The above equations follow using variation of constants. □

Remark. We proceed similarly with the process J_t^{ij} and L_t^{ij}, omitting details.

DEFINITION 3.4. *For any test function $g \in \mathbb{C}_0^2(\mathbb{R}^m)$ define the measure-valued process $\bar{\mathbf{E}}\{\Lambda_t\, J_t^{ij}\, g(x_t)|\mathcal{Y}_t\}$. From the results of* [10] *and* [12]*, this has a density $\gamma_t^{ij}(x)$ so that*

$$\bar{\mathbf{E}}\{\Lambda_t\, J_t^{ij}\, g(x_t)|\mathcal{Y}_t\} = \int_{\mathbb{R}^m} \gamma_t^{ij}(x)\, g(x)\, dx.$$

THEOREM 3.5. *At time t, the density $\gamma_t^{ij}(x)$ is completely described by the five statistics $\bar{a}_t^{ij}$, $\bar{b}_t^{ij}$ $\bar{c}_t^{ij}$, Σ_t, and m_t as follows:*

$$\gamma_t^{ij}(x) = \left(\bar{a}_t^{ij} + x'\,\bar{b}_t^{ij} + x'\,\bar{c}_t^{ij}\,x\right)\,\alpha_t(x). \tag{3.17}$$

Here, $\bar{a}_t^{ij} \in \mathbb{R}$, $\bar{b}_t^{ij} \in \mathbb{R}^m$, and $\bar{c}_t^{ij} \in L_s(\mathbb{R}^m, \mathbb{R}^m)$. Further,

$$\frac{d\bar{a}_t^{ij}}{dt} = \mathrm{Tr}\left(\bar{c}_t^{ij}\, B_t\, B_t'\right) + \bar{b}_t^{ij\prime}\, B_t\, B_t'\, \Sigma_t^{-1}\, m_t, \quad \bar{a}_0^{ij} = 0 \in \mathbb{R}, \tag{3.18}$$

$$d\bar{b}_t^{ij} = \left[-(A_t' + \Sigma_t^{-1}\, B_t\, B_t')\bar{b}_t^{ij} + 2\bar{c}_t^{ij}\, B_t\, B_t'\, \Sigma_t^{-1}\, m_t\right]\, dt + dy_t'\, f_j\, e_i, \quad b_0^{ij} = 0 \in \mathbb{R}^m, \tag{3.19}$$

$$\frac{d\bar{c}_t^{ij}}{dt} = -\left(A_t' + \Sigma_t^{-1}\, B_t\, B_t'\right)\, \bar{c}_t^{ij} - \bar{c}_t^{ij}\, \left(A_t + B_t\, B_t'\, \Sigma_t^{-1}\right) + \frac{1}{2}\left(e_i\, f_j'\, C_t + C_t'\, f_j\, e_i'\right), \tag{3.20}$$

$$\bar{c}_0^{ij} = 0 \in L_s(\mathbb{R}^m, \mathbb{R}^m).$$

Proof. The product $\Lambda_t\, J_t^{ij}\, g(x_t)$ is calculated and each side conditioned on $\mathcal{Y}_t$. After integration by parts, the following stochastic partial differential equation is obtained for $\gamma_t^{ij}(x)$:

$$\begin{aligned} d\gamma_t^{ij}(x) = &-\mathrm{div}\left(\gamma_t^{ij}(x)\, A_t\, x\right)\, dt + \frac{1}{2}\mathrm{Tr}\left(\nabla^2\gamma_t^{ij}(x)\, B_t\, B_t'\right)\, dt + \gamma_t^{ij}\, x'\, C_t'\, (D_t')^{-1}\, D_t^{-1}\, dy_t \\ &+ \alpha_t(x)\, x'\, e_i\, f_j'\, dy_t + \alpha_t(x)\, (x'\, C_t'\, f_j\, e_i'\, x)\, dt \end{aligned} \tag{3.21}$$

Recalling that $\alpha_t(x)$ satisfies the Zakai equation (2.7), we see that

$$\left(\bar{a}_t^{ij} + x'\,\bar{b}_t^{ij}\,x + x'\,\bar{c}_t^{ij}\,x\right)\,\alpha_t(x)$$

is a solution of (3.21) if $\bar{a}_t^{ij}$, $\bar{b}_t^{ij}$, and $\bar{c}_t^{ij}$ satisfy (3.18), (3.19), and (3.20), respectively. □

We now obtain explicit solutions to the above equations. Note that $f_j'\,dy_t = dy_t'\,f_j = dy_t^j$, where y_t^j denotes the jth component of y_t.

LEMMA 3.6. *The explicit solutions of* (3.19) *and* (3.20) *are*

$$\bar{b}_t^{ij} = 2\,G_t\,\left(\int_0^t G_s^{-1}\bar{c}_s^{ij}\,B_s\,B_s'\,\Sigma_s^{-1}\,m_s\,ds + \int_0^t G_s^{-1}\,e_i\,dy_s^j\right) \tag{3.22}$$

and

$$\bar{c}_t^{ij} = \frac{1}{2}\,G_t\,\left(\int_0^t G_s^{-1}(e_i\,f_j'\,C_s + C_s'\,f_j\,e_i')\,\left(G_s^{-1}\right)'\,ds\right)\,G_t'. \tag{3.23}$$

DEFINITION 3.7. *For any test function $g \in \mathbb{C}_0^2(\mathbb{R}^m)$ define the measure-valued process $\bar{\mathbf{E}}\{\Lambda_t\,L_t^{ij}\,g(x_t)|\mathcal{Y}_t\}$. From the results of* [10] *and* [12]*, this has a density $\lambda_t^{ij}(x)$ so that*

$$\bar{\mathbf{E}}\{\Lambda_t\,L_t^{ij}\,g(x_t)|\mathcal{Y}_t\} = \int_{\mathbb{R}^m}\lambda_t^{ij}(x)\,g(x)\,dx.$$

THEOREM 3.8. *At time t, the density $\lambda_t^{ij}(x)$ is completely characterized by the five statistics r_t^{ij}, s_t^{ij}, and u_t^{ij} as follows:*

$$\lambda_t^{ij}(x) = \left(r_t^{ij} + x'\,s_t^{ij}\,x + x'\,u_t^{ij}\,x\right)\,\alpha_t(x). \tag{3.24}$$

Here, $r_t^{ij} \in \mathbb{R}$, $s_t^{ij} \in \mathbb{R}^m$, and $u_t^{ij} \in L_s(\mathbb{R}^n, \mathbb{R}^m)$. Further,

$$\frac{dr_t^{ij}}{dt} = \mathrm{Tr}\left(u_t^{ij}\,B_t\,B_t'\right) + s_t^{ij\prime}\,B_t\,B_t'\,\Sigma_t^{-1}\,m_t - \mathrm{Tr}\left(B_t\,B_t'\,e_i\,e_j'\right), \qquad r_0^{ij} = 0 \in \mathbb{R}, \tag{3.25}$$

$$\begin{aligned}\frac{ds_t^{ij}}{dt} &= -\left(A_t' + \Sigma_t^{-1}\,B_t\,B_t'\right)\,s_t^{ij} + 2\,u_t^{ij}\,B_t\,B_t'\,\Sigma_t^{-1}\,m_t \\ &\quad - (e_j\,e_i')\;B_t\,B_t'\,\Sigma_t^{-1}\,m_t, \qquad s_0^{ij} = 0 \in \mathbb{R}^m,\end{aligned} \tag{3.26}$$

$$\begin{aligned}\frac{du^{ij}}{dt} &= -\left(A_t' + \Sigma_t^{-1}\,B_t\,B_t'\right)\,u_t^{ij} - u_t^{ij}\,\left(A_t + B_t\,B_t'\,\Sigma_t^{-1}\right) \\ &\quad + \frac{1}{2}\left(e_i\,e_j'\,\left(A_t + B_t\,B_t'\,\Sigma_t^{-1}\right) + \left(A_t' + \Sigma_t^{-1}\,B_t\,B_t'\right)\,e_j\,e_i'\right), \\ &\quad u_0^{ij} = 0 \in L_s(\mathbb{R}^m, \mathbb{R}^m).\end{aligned} \tag{3.27}$$

Proof. The product $\Lambda_t\,L_t^{ij}\,g(x_t)$ is calculated and each side conditioned on $\mathcal{Y}_t$. After integration by parts, the following stochastic partial differential equation is obtained for $\lambda_t^{ij}(x)$:

$$\begin{aligned}d\lambda_t^{ij}(x) &= -\mathrm{div}\left(\lambda_t^{ij}(x)\,A_t\,x\right)\,dt \\ &\quad + \frac{1}{2}\,\mathrm{Tr}\left(\nabla^2\lambda_t^{ij}(x)\,B_t\,B_t'\right)\,dt + \lambda_t^{ij}(x)\,x'\,C_t'\,\left(D_t^{-1}\right)'\,D_t^{-1}\,dy_t \\ &\quad + \alpha_t(x)\,x'\,e_i\,e_j'\,A_t\,x\,dt - \mathrm{div}\left(x'\,e_i\,e_j'\,B_t\,B_t'\,\alpha_t(x)\right)\,dt.\end{aligned} \tag{3.28}$$

We see that

$$\left(r_t^{ij} + x'\, s_t^{ij}\, x + x'\, u_t^{ij}\, x\right)\, \alpha_t(x)$$

solves (3.28) if r_t^{ij}, s_t^{ij}, and u_t^{ij} satisfy (3.25), (3.26), and (3.27) . □

Again, (3.26) and (3.27) can be solved by variation of constants. We summarize this in the following lemma.

LEMMA 3.9. *The explicit solutions of* (3.26) *and* (3.27) *are*

$$s_t^{ij} = G_t \left(\int_0^t G_s^{-1} (2\, u_s^{ij} - e_j\, e_i')\, \Sigma_s^{-1}\, B_s\, B_s'\, m_s\, ds \right), \tag{3.29}$$

$$u_t^{ij} = \frac{1}{2}\, G_t \left(\int_0^t \left[G_s^{-1} (e_i\, e_j' \left(A_s + B_s\, B_s'\, \Sigma_s^{-1}\right) + (A_s' + \Sigma_s^{-1}\, B_s\, B_s') e_j\, e_i' \right) \left(G_s^{-1}\right)' \right] ds \right) G_t. \tag{3.30}$$

Remark. We observe from the definition of G_t, (3.14), that the integrand in (3.30) includes only half of the four terms in the derivative of $G_t^{-1}(e_i\, e_j' + e_j\, e_i') \left(G_t^{-1}\right)'$, and so the integral cannot be evaluated in closed form.

THEOREM 3.10. *Finite-dimensional filters for* H_t^{ij}, J_t^{ij}, *and* L_t^{ij} *defined in* (3.1), (3.3), *and* (3.2) *are given by*

$$\mathbf{E}\{H_t^{ij} | \mathcal{Y}_t\} = a_t^{ij} + m_t'\, b_t^{ij} + \sum_{p=1}^m \sum_{q=1}^m c_t^{ij}(p,q)\, \Sigma_t(p,q) + m_t'\, c_t^{ij}\, m_t, \tag{3.31}$$

$$\mathbf{E}\{J_t^{ij} | \mathcal{Y}_t\} = \bar{a}_t^{ij} + m_t'\, b_t^{ij} + \sum_{p=1}^m \sum_{q=1}^m \bar{c}_t^{ij}(p,q)\, \Sigma_t(p,q) + m_t'\, \bar{c}_t^{ij}\, m_t, \tag{3.32}$$

$$\mathbf{E}\{L_t^{ij} | \mathcal{Y}_t\} = r_t^{ij} + m_t' s_t^{ij} + \sum_{p=1}^m \sum_{q=1}^m u_t^{ij}(p,q)\, \Sigma_t(p,q) + m_t'\, u_t^{ij}\, m_t. \tag{3.33}$$

Proof. Recall from (2.11) that α_t is an unnormalized Gaussian density with mean m_t and variance Σ_t. Therefore,

$$\int_{\mathbb{R}^m} \alpha_t(x)\, dx = \nu_t.$$

Note that for any $k \in \mathbb{R}^m$

$$\int_{\mathbb{R}^m} k'\, x\, \alpha_t(x)\, dx = (k'\, m_t)\nu_t.$$

Also for any matrix $M \in L(\mathbb{R}^m, \mathbb{R}^m)$ with entries $M(p,q)$, $1 \le p, q \le m$,

$$\begin{aligned} \int_{\mathbb{R}^m} x'\, M\, x\, \alpha_t(x)\, dx &= \int_{\mathbb{R}^m} (x - m_t)'\, M\, (x - m_t)\, \alpha_t(x)\, dx + m_t'\, M\, m_t \int_{\mathbb{R}^m} \alpha_t(x)\, dx \\ &= \left(\sum_{p=1}^M \sum_{q=1}^M M(p,q)\, \Sigma_t(p,q) + m_t'\, M\, m_t \right) \nu_t. \end{aligned}$$

Now from Bayes's theorem (2.6), we have

$$\begin{aligned}\mathbf{E}\{H_t^{ij}|\mathcal{Y}_t\} &= \frac{\bar{\mathbf{E}}\{\Lambda_t\, H_t^{ij}|\mathcal{Y}_t\}}{\bar{\mathbf{E}}\{\Lambda_t|\mathcal{Y}_t\}} \\ &= \frac{\int_{\mathbb{R}^m} \beta_t^{ij}(x)\,dx}{\int_{\mathbb{R}^m} \alpha_t(x)\,dx} \\ &= a_t^{ij} + m_t'\, b_t^{ij} + \sum_{p=1}^{m}\sum_{q=1}^{m} c_t^{ij}(p,q)\,\Sigma_t(p,q) + m_t'\, c_t^{ij}\, m_t\end{aligned}$$

by (3.4) and because the factors ν_t cancel. The proofs of equations (3.32) and (3.33) are similar. □

4. Finite-dimensional filter for higher order moments. The techniques of the previous section can be generalized to show that integrals and stochastic integrals of higher moments of the state variables have filtered estimates which can be expressed in terms of a finite number of statistics. The results also hold for other functions of the state and will be investigated in a subsequent paper.

Assumption 4.1. For notational simplicity, in this section we assume that the state and observation processes are scalar valued, i.e., that $m = n = 1$ in (2.1) and (2.2).

Let Γ_t be the process defined as

$$\Gamma_t = \int_0^t x_s^p\, ds, \quad p \in \mathbb{Z}^+.$$

Suppose $g : \mathbb{R} \to \mathbb{R}$ is any test function and suppose for a density-valued process $\mu_t(x)$,

$$\bar{\mathbf{E}}\{\Lambda_t\, \Gamma_t\, g(x_t)|\mathcal{Y}_t\} = \int_{\mathbb{R}} \mu_t(x)\, g(x)\, dx.$$

We now show that $\mathbf{E}\{\Gamma_t|\mathcal{Y}_t\}$ can be computed via a finite-dimensional filter.

THEOREM 4.2. *At time t, the density μ_t is completely characterized by the $p+3$ statistics, $a_t(0), a_t(1), \ldots, a_t(p)$, Σ_t, and m_t as follows:*

$$\mu_t(x) = \left[\sum_{i=0}^{p} a_t(i)\, x^p\right]\, \alpha_t(x), \tag{4.1}$$

where $a_0(i) = 0$, $i = 1, \ldots, p$, and

$$\begin{aligned}\frac{da_t(p)}{dt} &= -p\left(A_t + \Sigma_t^{-1}\, B_t^2\right)\, a_t(p) + 1, \\ \frac{da_t(p-1)}{dt} &= -(p-1)\left(A_t + \Sigma_t^{-1}\, B_t^2\right)\, a_t(p-1) + p\, a_t(p)\, \Sigma_t^{-1}\, B_t^2\, m_t, \\ \frac{da_t(i)}{dt} &= -i\left(A_t + \Sigma_t^{-1}\, B_t^2\right)\, a_t(i) + \frac{1}{2}\,(i+1)\,(i+2)\, a_t(i+2) \\ &\quad + (i+1)\, a_t(i+1)\, \Sigma_t^{-1}\, B_t^2, \\ &\qquad\qquad\qquad\qquad\qquad\qquad i = 1, \ldots, p-2, \\ \frac{da_t(0)}{dt} &= B_t^2\, a_t(2) + \Sigma_t^{-1}\, B_t^2\, a_t(1)\, m_t. \end{aligned} \tag{4.2}$$

Proof.

$$\Lambda_t\,\Gamma_t\,g(x_t) = \int_0^t \Lambda_s\,\Gamma_s\,\nabla g(x_s)\,A_s\,x_s\,ds + \int_0^t \Lambda_s\,\Gamma_s\,\nabla g(x_s)\,B_s\,dw_s + \frac{1}{2}\int_0^t \Lambda_s\,\Gamma_s\,\nabla^2 g(x_s)\,B_s^2\,ds + \int_0^t \Lambda_s\,\Gamma_s\,g(x_s)\,x_s\,C_s\,D_s^{-2}\,dy_s + \int_0^t \Lambda_s\,g(x_s)\,x_s^p\,ds.$$

Conditioning on $\mathcal{Y}_t$, as in [13],

$$\int_{\mathbb{R}} \mu_t(x)\,g(x)\,dx = \int_0^t \int_{\mathbb{R}} \mu_s(x)\,\nabla g(x)\,A_s\,x\,dx\,ds + \frac{1}{2}\int_0^t \int_{\mathbb{R}} \mu_s(x)\nabla^2 g(x)\,B_s^2\,dx\,ds + \int_0^t \int_{\mathbb{R}} \mu_s(x)\,g(x)\,x\,C_s\,D_s^{-2}\,dx\,dy_s + \int_0^t \int_{\mathbb{R}} x^p\,g(x)\,\alpha_s(x)\,dx\,ds.$$

Integrating by parts in x, we see that $\mu_t(\cdot)$ satisfies the stochastic partial differential equation

$$\mu_t(x) = -\int_0^t \frac{d}{dx}\left(\mu_s(x)\,A_s\,x\right)\,ds + \frac{1}{2}\int_0^t \frac{d^2}{dx^2}\mu_s(x)\,B_s^2\,ds + \int_0^t \mu_s(x)\,x\,C_s\,D_s^{-2}\,dy_s + \int_0^t x^p\,\alpha_s(x)\,ds.$$

It can then be verified that (4.1) is a solution to the above equation if the time-varying coefficients $a_t(0),\ldots,a_t(p)$ satisfy the ordinary differential equations (4.2). □

Remark. The ordinary differential equations (4.2) can be solved explicitly by variation of constants.

Finally, we note that a similar derivation to that given in this section yields finite-dimensional filters for $\int_0^t x_s^p\,dx_s$ and $\int_0^t x_s^p\,dy_s$, $p = 1, 2, 3, \ldots$.

5. Filtered EM algorithm for Gaussian state-space models. The aim of this section is to derive a filter-based EM algorithm for computing maximum-likelihood (ML) parameter estimates of a linear Gaussian state-space system. The finite-dimensional filters of section 3 are used in implementing the E-step of the EM algorithm, resulting in a filter-based EM algorithm.

Consider the time-invariant version of the state-space model (2.1), (2.2):

$$dx_t = A\,x_t\,dt + B\,dw_t, \tag{5.1}$$

$$dy_t = C\,x_t\,dt + D\,dv_t. \tag{5.2}$$

Our aim is to compute ML estimates of the parameters $\theta = (A, C)$ given the observations $\mathcal{Y}_t = \sigma\{y_s : s \le t\}$ and assuming B, D are known. We do this via the EM algorithm.

Remark. Unlike the discrete-time case, in continuous time, it is not possible to obtain ML estimates of the variance terms B and D because measures corresponding to Wiener processes with different variances are not absolutely continuous (see Chapter 6.1 in [13]). At the end of this section, we give estimates for B and D in terms of the quadratic variations of the state and observation processes.

EM ALGORITHM. Suppose that we have observation history $\mathcal{Y}_t$ available. Let $\{P_\theta\,,\,\theta\in\Theta\}$ be a family of probability measures on $(\Omega,\mathcal{F})$, all absolutely continuous with respect to a fixed probability measure P_0. The log likelihood function for computing an estimate of the parameter θ based on the information available in $\mathcal{Y}_t$ is

$$\mathcal{L}(\theta)=\mathbf{E}_0\left\{\log\frac{dP_\theta}{dP_0}\mid\mathcal{Y}_t\right\},$$

and the maximum likelihood estimate (MLE) is defined by

$$\widehat{\theta}\in\operatorname*{argmax}_{\theta\in\Theta}\mathcal{L}(\theta).$$

The EM algorithm is an iterative numerical method for computing the MLE. Let $\hat{\theta}_0$ be the initial parameter estimate. The EM algorithm generates a sequence of parameter estimates as follows.

Each iteration of the EM algorithm consists of two steps:

Step 1 (E-step). Set $\tilde{\theta}=\widehat{\theta}_j$ and compute $Q(\cdot,\tilde{\theta})$, where

$$Q(\theta,\tilde{\theta})=\mathbf{E}_{\tilde{\theta}}\left\{\log\frac{dP_\theta}{dP_{\tilde{\theta}}}\mid\mathcal{Y}_t\right\}.$$

Step 2 (M-step). Find $\widehat{\theta}_{j+1}\in\operatorname*{argmax}_{\theta\in\Theta}Q(\theta,\theta_j)$.

The sequence-generated $\{\widehat{\theta}_j\,,\,j\geq 0\}$ gives nondecreasing values of $\mathcal{L}(\hat{\theta}_j)$ with equality if and only if $\widehat{\theta}_{j+1}=\widehat{\theta}_j$.

It is shown in the appendix that

(5.3)

$$\begin{aligned}Q(\theta,\tilde{\theta})=\mathbf{E}&\left\{\int_0^t x_s'\,A'\,[BB']^{\#}\,dx_s-\frac{1}{2}\int_0^t x_s'\,A'\,[B\,B']^{\#}\,A\,x_s\,ds|\mathcal{Y}_t\right\}\\&+\mathbf{E}\left\{\int_0^t x_s'\,C'\,(D\,D')^{-1}\,dy_s-\frac{1}{2}\int_0^t x_s'\,C'(DD')^{-1}\,C\,x_s\,ds|\mathcal{Y}_t\right\}+\mathbf{E}\{R(\tilde{\theta}|\mathcal{Y}_t\},\end{aligned}$$

where # denotes the pseudoinverse and $R(\tilde{\theta})$ does not involve θ.

To implement the M-step we set the derivatives $\partial Q/\partial\theta=0$. This yields

$$A=\mathbf{E}\left\{\int_0^t dx_s\,x_s'|\mathcal{Y}_t\right\}\left(\mathbf{E}\left\{\int_0^t x_s\,x_s'\,ds|\mathcal{Y}_t\right\}\right)^{-1}=\hat{L}_t'\,\hat{H}_t^{-1},\tag{5.4}$$

$$C=\mathbf{E}\left\{\int_0^t dy_s\,x_s'|\mathcal{Y}_t\right\}\left(\mathbf{E}\left\{\int_0^t x_s\,x_s'\,ds|\mathcal{Y}_t\right\}\right)^{-1}=\hat{J}_t'\,\hat{H}_t^{-1},\tag{5.5}$$

where $\hat{H}_t$ and $\hat{L}_t\in\mathbb{R}^{m\times m}$ denote matrices with elements $\hat{H}_t^{ij}\triangleq\mathbf{E}\{H_t^{ij}|\mathcal{Y}_t\}$ and $\hat{L}_t^{ij}\triangleq\mathbf{E}\{L_t^{ij}|\mathcal{Y}_t\}$, $i,j\in\{1,\dots,m\}$. Also, $\hat{J}_t\in\mathbb{R}^{m\times n}$ denotes the matrix with elements $\hat{J}_t^{ij}\triangleq\mathbf{E}\{J_t^{ij}|\mathcal{Y}_t\}$, $i=1,\dots,m$, $j=1,\dots,n$. The terms $\hat{H}_t^{ij}$, $\hat{L}^{ij}$, and $\hat{J}_t^{ij}$ are computed using Theorems 3.2, 3.8, and 3.5 together with the filters in Theorem 3.10. Thus we have a filter-based EM algorithm.

Remark. We have presented the EM algorithm for updating the parameters of a general state-space model. However, we have not addressed identifiability issues of our state-space model.

Indeed, identifiability and consistency of the ML estimator have been studied in special cases of our model (where our filter-based algorithm also applies). For example, in [9], A is of a known structure but parametrized by an unknown vector θ. Consistency of the ML estimators is proved in [16].

Estimation of B and D. First consider the tensor product of x_t with itself:

$$x_t\, x_t' = x_0\, x_0' + \int_0^t x_s\, dx_s' + \int_0^t dx_s\, x_s' + \int_0^t B\, B'\, ds. \tag{5.6}$$

Conditioning both sides of (5.6) on $\mathcal{Y}_t$, we have

$$\Sigma_t = \mathbf{E}\{x_0\, x_0' | \mathcal{Y}_t\} + \mathbf{E}\left\{ \int_0^t x_s\, dx_s' + \int_0^t dx_s\, x_s' \,\middle|\, \mathcal{Y}_t \right\} + B\, B'\, t. \tag{5.7}$$

$\mathbf{E}\{x_0\, x_0' | \mathcal{Y}_t\}$ in (5.7) is the smoothed second moment and is given in terms of finite-dimensional statistics; see Theorem 12.11, section 12.4 in [8]. The components of the conditioned stochastic integrals in (5.7) are given by the filtered estimates of L_t^{ij}. Consequently, we have a procedure for estimating the matrix $B\, B'$.

Similarly, consider the tensor product of y_t with itself:

$$y_t\, y_t' = \int_0^t y_s\, dy_s' + \int_0^t dy_s\, y_s' + D\, D'\, t. \tag{5.8}$$

This expression simply amounts to evaluating DD' in terms of the quadratic variation of y.

6. Conclusion and extensions. For linear Gaussian dynamics, new finite-dimensional filters have been derived which estimate integrals and stochastic integrals of the moments of the state variable. Used in the EM algorithm, these quantities provide maximum likelihood estimates of the parameters in the dynamics of the Kalman filter.

We mention two extensions of the results. First, similar filters can be derived for nonlinear systems with Benes-type nonlinearity. Details are presented in [21]. Second, techniques similar to those developed in this paper can be applied in the reconstruction of doubly stochastic autoregressive (AR) processes, as we now outline.

Assuming the scalar version ($m = n = 1$) of the state-space model (2.1), (2.2), consider the continuous-time doubly stochastic AR process $z_t \in \mathbb{R}$ defined as

$$dz_t = f(x_t)\, z_t\, dt + du_t, \quad z_0 = 1. \tag{6.1}$$

Here u is a scalar Brownian process independent of v and w, and $f : \mathbb{R} \to \mathbb{R}$ is a polynomial function. Suppose our aim is to derive a filter for computing $\mathbf{E}\{z_t | \mathcal{Y}_t\}$.

In (6.1), z_t can be viewed as a continuous-time AR process with random coefficient $f(x_t)$, where x_t itself evolves according to another AR process. In [4] we derived finite-dimensional filters for such problems in discrete time. The above model can be viewed as a continuous-time version of [4]. The problem of reconstructing z_t when x_t is a finite state Markov chain (instead of a continuous-valued Gaussian process) has recently been studied in the context of maneuvering target tracking [20]. Therefore, (6.1) can be viewed as the continuous-valued analogue of the model in [20].

Let us compute $\mathbf{E}\{z_t | \mathcal{Y}_t\}$. Note that we can solve (6.1) explicitly for z_t; this yields

$$z_t = \exp\left(\int_0^t f(x_s)\, ds \right) \left[1 + \int_0^t \exp\left(- \int_0^s f(x_r) dr \right) du_s \right].$$

Since u is independent of x and y, our aim can be re-expressed as follows: compute the filtered estimate

$$\mathbf{E}\{z_t|\mathcal{Y}_t\} = \mathbf{E}\left\{\exp\left(\int_0^t f(x_s)\,ds\right)|\mathcal{Y}_t\right\}.$$

Using techniques similar to those presented in this paper, it is possible to derive a finite-dimensional filter for $\mathbf{E}\{z_t|\mathcal{Y}_t\}$. Details are presented in [22].

Appendix A. Derivation of $Q(\theta, \tilde{\theta})$. To update the estimate from $\tilde{A}$ to A, we employ Girsanov's theorem and introduce the density

$$\left.\frac{dP(A)}{dP(\tilde{A})}\right|_{\mathcal{G}_t} = \exp\left(\int_0^t x_s'(A'-\tilde{A}')(BB')^{\#}\,dx_s \right.$$
$$\left. -\frac{1}{2}\int_0^t x_s'(A'-\tilde{A}')(BB')^{\#}(A+\tilde{A})x_s\,ds\right),$$

where # denotes the pseudoinverse. Then

(A.1)
$$\mathbf{E}\left\{\log\left.\frac{dP(A)}{dP(\tilde{A})}\right|_{\mathcal{G}_t}|\mathcal{Y}_t\right\} = \mathbf{E}\left\{\int_0^t x_s'\,A'\,(BB')^{\#}\,dx_s - \frac{1}{2}\int_0^t x_s'\,A'\,(BB')^{\#}\,A\,x_s\,ds|\mathcal{Y}_t\right\}$$
$$+R(\tilde{A}),$$

where $R(\tilde{A})$ does not involve A.

Similarly, to update the estimate from $\tilde{C}$ to C, we again apply Girsanov's theorem and introduce the density

$$\left.\frac{dP(C)}{dP(\tilde{C})}\right|_{\mathcal{G}_t} = \exp\left(\int_0^t x_s'(C'-\tilde{C}')(DD')^{-1}\,dy_s \right.$$
$$\left. -\frac{1}{2}\int_0^t x_s'(C'-\tilde{C}')(DD')^{-1}(C+\tilde{C})x_s\,ds\right).$$

Consequently,

(A.2)
$$\mathbf{E}\left\{\log\left.\frac{dP(C)}{dP(\tilde{C})}\right|_{\mathcal{G}_t}|\mathcal{Y}_t\right\} = \mathbf{E}\left\{\int_0^t x_s'C'\,(DD')^{-1}\,dy_s \right.$$
$$\left. -\frac{1}{2}\int_0^t x_s'\,C'\,(DD')^{-1}\,Cx_s\,ds|\mathcal{Y}_t\right\} + S(\tilde{C}),$$

where $S(\tilde{C})$ does not involve C.

Adding (A.1) and (A.2) yields (5.3).

SYSTEM IDENTIFICATION BY DYNAMIC FACTOR MODELS*

C. HEIJ†, W. SCHERRER‡, AND M. DEISTLER‡

Abstract. This paper concerns the modeling of stochastic processes by means of dynamic factor models. In such models the observed process is decomposed into a structured part called the latent process and a remainder that is called noise. The observed variables are treated in a symmetric way so that no distinction between inputs and outputs is required. This motivates the additional condition that the prior assumptions on the noise are symmetric in nature. One of the central questions in this paper is how uncertainty about the noise structure translates into nonuniqueness of the possible underlying latent processes. We investigate several possible noise specifications and analyze properties of the resulting class of observationally equivalent factor models. This concerns in particular the characterization of optimal models and properties of continuity and consistency.

Key words. linear systems, stationary processes, identification, factor analysis, errors in variables, least squares, consistency

1. Introduction.

In this paper we are concerned with the identification of linear systems. The most commonly used models in system identification are ARMA and ARMAX models; we refer to [17], [4], and [13]. An ARMA model is symmetric and nonopen in the sense that all observed variables are treated in a symmetric way and they are completely described by the model. On the other hand, ARMAX models are nonsymmetric and open, as a distinction is made between inputs and outputs and the noise is added to the outputs, and the inputs are not modeled.

We will consider linear factor models where the noise model is symmetric and where we have a deterministic, symmetric, and open system model. In a sense, these models combine the symmetry which is inherent in, for example, ARMA models, with the flexibility of models that leave certain process aspects unexplained, as, for example, in input-output models.

Of course, the classical ARMA and ARMAX models are appropriate in a great number of cases. For instance, if we are interested in predicting the outputs from the inputs, then the ARMAX setting is appropriate. On the other hand, there are also situations where this approach can not be justified and may lead to prejudiced results.

- A prediction-based error model is not appropriate, for example, if we are interested in the "true" underlying system and there is noise on the inputs and the outputs.
- There may be uncertainty about the number of system equations or about the classification of the system variables into inputs and outputs. In this case

we have to perform a more symmetric way of system modeling, which in turn demands a symmetric noise model.

- In multivariate time series analysis one is confronted with the so-called curse of dimensionality. One method of reducing the dimension of the parameter space for the system model is dynamic factor analysis, which is an essential aspect of the approach described here.

Factor models have been used in statistics, psychometrics, and econometrics for a long time; see [9], [1], [10]. The theory is most well developed for the case of static models. Most applications are also reported within this framework, although there are also contributions on the identification of dynamic factor models; see [11], [8], [5]. Within the area of systems and control there has recently been increasing interest in symmetric modeling. We mention the introduction of the behavioral approach in systems theory in [24], [26], the attention paid to the Frisch problem (see [18], [23], [2]), and low-noise modeling, as proposed in [15]. Most contributions on factor models in this area deal either with the mathematical structure of dynamic models or with data modeling by means of static models. In a certain sense, nonparametric-framework, results on the identification of dynamic factor models within a stochastic setting have been presented in [6], [7]. Procedures for symmetric time series modeling within a deterministic behavioral framework have been proposed in [25], [14], and [21].

In this paper we try to integrate the above two frameworks, i.e., stochastic factor models and deterministic behavioral modeling. The model class consists of stochastic dynamic factor models where the latent process satisfies deterministic behavioral laws. This means that stochastic structure is added to the deterministic behavioral framework, which provides additional tools of analysis. On the other hand, our approach allows for an analysis of dynamic factor models in terms of finite-dimensional systems, as opposed to the nonparametric results that were previously obtained.

We consider a situation that is idealized insofar as we commence from the population second moments of the data. In other words, we analyze the relation between the spectral density of the observed process and the corresponding factor models. Nevertheless, this is done from the point of view of requirements connected with the identification from observed data, and we will indicate how the results of this paper can be used for this purpose. A detailed analysis of procedures for the identification of dynamic factor models from observed time series falls beyond the scope of this paper and will be investigated elsewhere.

One of the issues studied in this paper is the nonuniqueness of the behaviour for given second-order moments. This means that uncertainty about the precise noise structure leads to a corresponding nonuniqueness of the possible factor models that are compatible with the observed process. As is well known, in the mainstream approach of modeling with exogenous inputs, the population second moments of the observations determine, under very general conditions, the transfer function of the underlying system uniquely. This is due to the assumption that the noise is uncorrelated with the inputs. Uniqueness in general does not hold true in cases when all the variables may be corrupted by noise. This means that the set of observationally equivalent models, that is, the set of all models compatible with the population second moments, will in general not be a singleton. Of course, by imposing sufficiently strong conditions, uniqueness can be achieved, but in many cases it may be hard to justify such assumptions. The question then becomes how the lack of knowledge about the error structure translates into nonuniqueness of the resulting model. This is a kind of uncertainty about the underlying system that can not be removed, even in an infinite sample.

We now give an outline of the topics treated in this paper. A dynamic factor model is of the form

$$w = \hat{w} + \tilde{w}, \tag{1}$$

where w is the observed process, $\hat{w}$ is a (in general unobserved) latent process satisfying exact linear dynamic equations, and $\tilde{w}$ is the noise process. The restrictions on $\hat{w}$ can be expressed in terms of deterministic system behaviors as introduced in [24], [26]. The processes $(w, \hat{w}, \tilde{w})$ are assumed to be jointly stationary, and in this case the latent process has a singular spectrum. The noise process represents the error resulting from the approximation of the observations w by the latent process $\hat{w}$.

The central question considered in this paper is how to obtain the restrictions satisfied by the latent process from the observations. Without imposing further conditions, no solutions can be excluded from the knowledge of the observed process alone. This means that we have to impose additional assumptions on the noise structure in order to make meaningful statements about the underlying system. The main topics of this paper can be summarized as follows.

(i) The formulation of noise assumptions and an analysis of their effect on the class of observationally equivalent models. We consider in particular the assumptions of orthogonality (the latent process and the noise process are mutually uncorrelated), observability (the latent process can be expressed as a linear function of the observed process), and bounded noise (the noise process satisfies an a priori specified bound).

(ii) An analysis of the structural properties of identification procedures corresponding to different noise assumptions. This involves an analysis of the mapping relating an observed process to the class of observationally equivalent system models. Continuity of this mapping is related to consistency in case of modeling from observed time series.

(iii) An analysis of the complexity and goodness of fit of factor models, with special attention for optimal models of restricted complexity.

This paper has the following structure. In section 2 we define the dynamic factor model. For this purpose we review the behavioral approach in linear system theory. Factor models are characterized on the behavioral level and also in terms of spectral properties, and we define the complexity and goodness of fit of factor models. The general framework is illustrated by the special case of a white noise process and nondynamic system equations, and it is shown that in this case our set-up coincides with the classical formulation of static factor models. Section 3 is concerned with optimal models, in the sense of minimizing the noise under restrictions on the complexity of the latent process. Section 4 investigates structural properties of the corresponding identification problem, with special attention paid to continuity and consistency. Section 5 contains concluding remarks. Some technical proofs are collected in section 6, the appendix.

2. Dynamic factor models.

2.1. Linear systems. For the formulation of dynamic factor models it is convenient to use the behavioral approach as developed by Willems in [24], [26]. Since this approach may not be well known to the reader, we discuss in this section those aspects that are relevant for our purposes. Readers with an interest in further details and proofs are referred to [24], [26].

In this subsection $\hat{w} : \mathbf{Z} \to \mathbf{R}^q$ denotes a trajectory rather than a process; that is, it is a q-variate time series observed in discrete time. The behaviour of a deterministic

system is defined as the set of all trajectories $\hat{w}$ that may arise within the restrictions imposed by the system. So a behavior is a subset $\mathcal{B}$ of $(\mathbf{R}^q)^{\mathbf{Z}}$. Of special interest are behaviors that are linear, time invariant, and complete. This means that $\mathcal{B} \subset (\mathbf{R}^q)^{\mathbf{Z}}$ is a linear subspace that is invariant under the shift operator σ, defined by $(\sigma\,\hat{w})(t) := \hat{w}(t+1)$, and that the behaviour is in addition closed in the topology of pointwise convergence. The last condition means that for a sequence $\hat{w}_n \in \mathcal{B}$ which converges pointwise (in $\mathbf{R}^q$) to $\hat{w}_0 \in (\mathbf{R}^q)^{\mathbf{Z}}$, it holds that also $\hat{w}_0 \in \mathcal{B}$. These conditions imply that the behavior corresponds to a linear, time invariant, finite-dimensional system. Below, we will simply use the term linear system to refer to a linear, time invariant, complete behaviour $\mathcal{B} \subset (\mathbf{R}^q)^{\mathbf{Z}}$.

Linear systems can be represented in several ways. Here we discuss representations in terms of polynomial equations, state space models with driving variables, and corresponding transfer functions.

Every linear system can be represented in polynomial form as the solution set of the polynomial equations

$$R(\sigma, \sigma^{-1})\,\hat{w} = 0 \tag{2}$$

Here R is a polynomial matrix in the forward and backward shifts. The representation of a given system by a polynomial matrix is highly nonunique. Without loss of generality we could have restricted ourselves to polynomials in either σ or σ^{-1} alone, but (2) is in accordance with [24], [26]. The set of behavioral laws of a linear system $\mathcal{B}$ is defined as the set of all polynomial equations satisfied by the system; that is, it is the module of $1 \times q$ polynomials $\mathcal{L} = \{r; r(\sigma, \sigma^{-1})\,\hat{w} = 0 \text{ for all } \hat{w} \in \mathcal{B}\}$. Every polynomial representation of a given system has the same (polynomial) rank p, which is equal to the dimension of the module $\mathcal{L}$. Full row rank representations are unique up to left multiplication by a unimodular matrix, i.e., a polynomial matrix which has a polynomial inverse. These representations can also be interpreted as input-output systems in polynomial form, where p is the number of outputs and $m := q - p$ is the number of inputs. We denote by n the minimal number of initial conditions required to express future outputs in terms of future inputs, which is equal to the sum of the Kronecker observability indices of the system.

An alternative representation is in terms of state models with driving variables. Every linear system can be represented as

$$\sigma x = Ax + Bv, \quad \hat{w} = Cx + Dv. \tag{3}$$

Here v is an auxiliary vector of unrestricted driving variables and x is a vector of state variables. In contrast with the usual input-state-output model, here all the external variables are described as outputs of a system driven by forces which need not have any external meaning. For a given system this kind of representation is highly nonunique. Minimal representations have n states and m driving variables, and the class of all minimal representations is described by the feedback group $(S(A+BF)S^{-1}, SBR, (C+DF)S^{-1}, DR)$.

Until now no assumptions were made concerning the controllability of systems. For example, if A is a $q \times q$ invertible matrix then the set $\{\hat{w} : \mathbf{Z} \to \mathbf{R}^q; \hat{w}(t+1) = A\,\hat{w}(t), t \in \mathbf{Z}\}$ defines a linear system with autonomous evolution which is clearly not controllable. A system $\mathcal{B}$ is called controllable if every future in $\mathcal{B}$ is attainable from every past in $\mathcal{B}$, that is, if for every $\hat{w}_1, \hat{w}_2 \in \mathcal{B}$ there exist $\hat{w} \in \mathcal{B}$ and $h \geq 0$ such that $\hat{w}(t) = \hat{w}_1(t)$ for $t < 0$ and $\hat{w}(t) = \hat{w}_2(t)$ for $t \geq h$. In terms of the kernel representations (2) this means that $R(z, z^{-1})$ has constant rank over $z \in \mathbf{C} \setminus \{0\}$. In

this case the system can also be represented as the image of a polynomial operator, that is, $\hat{w} \in \mathcal{B}$ is represented as

$$\hat{w} = M(\sigma, \sigma^{-1})f, \tag{4}$$

where f has the interpretation of the underlying generating factors. There is a close connection between the notion of controllability as defined before and the usual notion in terms of state space models, because minimal state models (3) of controllable systems $\mathcal{B}$ are characterized by the property that (A, B) is a controllable pair and (A, C) an observable pair. In this case we can obtain isometric state models (see [21]), that is, representations with the property that

$$\begin{pmatrix} A & B \\ C & D \end{pmatrix}' \begin{pmatrix} A & B \\ C & D \end{pmatrix} = \begin{pmatrix} I_n & O \\ O & I_m \end{pmatrix}, \tag{5}$$

where I_d denotes the d-dimensional identity matrix and Q' denotes the transposed of a matrix Q. If (A, B, C, D) is a minimal isometric state representation of a controllable system, then all such representations are given by (UAU', UBV, CU', DV) with U and V orthogonal matrices.

The model (4) gives a finite impulse response representation of controllable systems. This gives a clear description how to generate all time series belonging to a given system. Alternative descriptions are in terms of transfer functions. For controllable systems we can always choose A to be asymptotically stable, and in this case the square summable time series in the system can be generated as $\hat{w} = G(\sigma^{-1})v$, where v is square summable and G is the causal transfer function defined by $G(z) = D + \sum_{k=1}^{\infty} CA^{k-1}Bz^k$. The rank of the transfer function G is m, and its McMillan degree is n. For an isometric state model this transfer function becomes an isometry, sometimes also called an all-pass transfer function. The driving variables needed to generate a given square summable time series are then obtained by $v = G^*(\sigma^{-1})\,\hat{w}$, where G^* is the adjoint defined by $G^*(\sigma^{-1}) := G'(\sigma)$.

In our analysis we will often make use of isometric representations of linear systems. A state space method for obtaining these models is described in [21]. They can also be obtained from polynomial representations, as follows. Let $\mathcal{B}$ be a controllable linear system with kernel representation $\mathcal{B} = \ker(R) = \{\hat{w}; R(\sigma, \sigma^{-1})\,\hat{w} = 0\}$ and image representation $\mathcal{B} = \mathrm{im}(M) = \{\hat{w}; \hat{w} = M(\sigma, \sigma^{-1})f\}$. If m is the number of inputs of the system, then R can be chosen with $q - m$ rows and M with m columns. Controllability implies that $R(z, z^{-1})$ has constant rank over $\mathbf{C}\backslash\{0\}$, and M can also be chosen of constant rank. In this case the projections $P = M(M^*M)^{-1}M^*$ and $Q = R^*(RR^*)^{-1}R$ are well-defined rational functions with constant rank over the domain $\mathbf{C}\backslash\{0\}$. So there exist causal, miniphase spectral factorizations $P = \hat{G}\,\hat{G}^*$ and $Q = \tilde{G}\,\tilde{G}^*$; see [22, Theorem I.10.1]. These spectral factors are isometric; that is, $\hat{G}^*\,\hat{G} = I_m$ and $\tilde{G}^*\,\tilde{G} = I_{q-m}$. Then the spectral factor $\hat{G}$ is an isometric transfer function for $\mathcal{B}$, and all square summable time series in $\mathcal{B}$ are obtained as the image of $\hat{G}$. Therefore we call this an isometric image representation. Further, all square summable time series in $\mathcal{B}$ are annihilated by $\tilde{G}^*$, and therefore we call $\tilde{G}$ an isometric kernel representation. As R and M describe the same system, it follows that $RM = 0$ so that $\tilde{G}^*\,\hat{G} = 0$. This shows that the $q \times q$ rational matrix $[\hat{G}, \tilde{G}]$ is inner, that is, it is stable and unitary. Conversely, every rational inner matrix $[\hat{G}, \tilde{G}]$ describes a linear system with isometric image representation $\hat{G}$ and isometric kernel representation $\tilde{G}$.

2.2. Factor models and spectra. Let $(\Omega, \mathcal{A}, \mathrm{P})$ denote an underlying probability space and let $\mathbf{L}_2$ be the corresponding Hilbert space of square integrable real-valued

random variables. We assume that the observed process w is a q-dimensional, weakly stationary process, so that $w \in (\mathbf{L}_2^q)^{\mathbf{Z}}$. A dynamic factor model is a process decomposition of the form $w = \hat{w} + \tilde{w}$, where $\tilde{w} \in (\mathbf{L}_2^q)^{\mathbf{Z}}$ is the noise process and $\hat{w} \in (\mathbf{L}_2^q)^{\mathbf{Z}}$ is the latent process that is essentially restricted to a linear system. The behaviour $\mathcal{B}$ of $\hat{w}$ is defined as the smallest linear, time invariant, complete system which contains almost all process realizations, that is, $P\{\hat{w}(\omega) \in \mathcal{B}\} = 1$. The following result states that this definition makes sense.

PROPOSITION 2.1. *For every stochastic process the behavior is well defined.*

Proof. We call a behavior $\mathcal{B}$ compatible with a process $\hat{w}$ if $\mathcal{B}$ contains almost all process realizations. Of course, $(\mathbf{R}^q)^{\mathbf{Z}}$ is always compatible, and countable intersections of compatible behaviors are compatible.

Now let $\mathcal{B}$ be a compatible behavior. If it contains a strictly smaller compatible behavior $\mathcal{B}' \subset \mathcal{B}$, $\mathcal{B}' \neq \mathcal{B}$, then we proceed with $\mathcal{B}'$. This system has either fewer inputs than $\mathcal{B}$ or equal number of inputs and fewer states. Continuing in this way, we end up after a finite number of steps with a compatible behavior $\mathcal{B}^*$ that contains no strictly smaller compatible behavior. This implies that for every compatible $\mathcal{B}$ there holds $\mathcal{B} \cap \mathcal{B}^* = \mathcal{B}^*$, and thus $\mathcal{B}^* \subseteq \mathcal{B}$. This proves that $\mathcal{B}^*$ is the smallest compatible behavior. ∎

We call a behavior nontrivial if $\mathcal{B} \neq (\mathbf{R}^q)^{\mathbf{Z}}$. Dynamic factor models are defined as follows.

DEFINITION 2.2. *A dynamic factor model of a process w is a decomposition $w = \hat{w} + \tilde{w}$, where the latent process $\hat{w}$ has nontrivial behavior $\mathcal{B}$, which is called the behavior of the factor model.*

In this paper we will be mainly concerned with the behavior of factor models, as in many cases this is the main point of interest in system identification. In order to simplify our analysis of dynamic factor models we make some additional assumptions on the processes. Some of these assumptions could be relaxed, but they are imposed to prevent technical complications that could obscure the underlying modeling ideas. To formulate the assumptions we use the following terminology. Let S_t denote the subspace of $\mathbf{L}_2$ spanned by the zero mean random variables $\{w_i(t); i = 1, \ldots, q\}$. Let the Hilbert spaces $\mathbf{H}(w)$ and $\mathbf{H}_t(w)$ be generated by, respectively, $\{S_t; t \in \mathbf{Z}\}$ and $\{S_s; s \leq t\}$, so that $\mathbf{H}(w)$ is generated by the process and $\mathbf{H}_t(w)$ by the past of this process. The process is said to have full rank if the space $\mathbf{H}_t(w) \cap \{\mathbf{H}_{t-1}(w)\}^{\perp}$ has dimension q, that is, if no nontrivial linear combination of the variables $w(t)$ can be predicted without error from the past. It is called purely nondeterministic if $\bigcap_{-\infty}^{\infty} \mathbf{H}_t(w) = \{0\}$, that is, if the prediction of $w(t+h)$ from $\mathbf{H}_t(w)$ converges to zero for $h \to \infty$. As is well known, every purely nondeterministic process can be written as

$$w = T(\sigma^{-1})\varepsilon, \tag{6}$$

that is, $w(t) = \sum_{k=0}^{\infty} T_k \varepsilon(t-k)$, where ε is a white noise process with $\mathrm{E}\{\varepsilon(t)\varepsilon'(t)\} = I_q$ and $\varepsilon(t) \in \mathbf{H}_t(w)$, and where $\sum_{k=0}^{\infty} \|T_k\|_2^2 < \infty$ with $\|\cdot\|_2$ the Frobenius norm of a matrix. This is called a Wold representation of the process; see, e.g., [19]. If $\sum_{k=0}^{\infty} \|T_k\|_2 < \infty$, then this representation is called absolutely summable. In this paper we will always make the following assumptions.

Assumptions.

- A1. The processes w, $\hat{w}$, and $\tilde{w}$ are jointly weakly stationary, with zero mean.
- A2. The observed process w is purely nondeterministic and has full rank.
- A3. The latent process $\hat{w}$ and the noise process $\tilde{w}$ are purely nondeterministic.
- A4. The Wold representations of w, $\hat{w}$, and $\tilde{w}$ are absolutely summable.

The assumption A1 is imposed for convenience, as this means that the usual tools of time series analysis and linear systems theory can be applied. The full rank assumption in A2 implies that the behavior of the observed process is unrestricted, so that it can not be modeled by a factor model without noise. Concerning assumption A3, note that a latent process with nontrivial behavior can not be of full rank. We assume that it is purely nondeterministic, and that the same holds true for the noise. This seems a reasonable requirement in view of assumption A2. Finally, assumption A4 is imposed for technical reasons. It implies that the spectral densities of the processes are continuous functions on the unit circle.

Stated in terms of behaviors, assumption A3 for the latent process means the following.

PROPOSITION 2.3. *The behavior of a purely nondeterministic process is controllable.*

Proof. Let $\hat{w}$ be a purely nondeterministic process. Further let $\mathcal{B}$ be a noncontrollable system with full row rank polynomial representation R, with the property that $R(\sigma, \sigma^{-1})\,\hat{w} = 0$ almost surely. Let $R = UDV$ be the Smith form, with U and V unimodular matrices and with $D = (\Delta, 0)$ where Δ is a diagonal matrix with one-dimensional polynomials unequal to zero on the diagonal.

Define $w^* = V\,\hat{w}$ and let $w^* = (w_1^*, w_2^*)$ be a partitioning corresponding to that of $D = (\Delta, 0)$. Then there holds $\Delta w_1^* = 0$ almost surely. So this process evolves according to an autonomous difference equation and can be predicted without error; that is, w_1^* belongs to $\mathbf{H}_t(\hat{w})$ for all t, the space spanned by the past of $\hat{w}$. As $\hat{w}$ is purely nondeterministic, this means that $w_1^* = 0$. This shows that also $R^*(\sigma, \sigma^{-1})\,\hat{w} = 0$ almost surely, where $R^* = (I, 0)V$. As $R^*(z, z^{-1})$ has constant rank it follows that this defines a controllable system, and of course it defines a system that is strictly smaller than $\mathcal{B}$. So the behavior of $\hat{w}$ is also controllable. ∎

We mention that the converse of this result does not hold true; that is, a latent process with controllable behavior need not be purely nondeterministic. In terms of the representations of controllable systems discussed in section 2.1, the above result means that a factor model can be described as follows:

$$w = M(\sigma, \sigma^{-1})f + \tilde{w}, \tag{7}$$

$$w = Cx + Dv + \tilde{w}, \quad \sigma x = Ax + Bv. \tag{8}$$

Here M is a polynomial matrix and (A, B, C, D) are real-valued matrices. The first representation is a generalization of the static model of classical factor analysis and explains the observed variables in terms of a number of unobserved underlying factors. The second representation gives a more explicit description of the dynamical evolution of the latent process $\hat{w} = Cx + Dv$ in terms of unrestricted factors v and additional factors x that exhibit the memory structure.

Factor models can also be described by means of spectra. In terms of the Wold representation (6), where ε is white noise with unit covariance and where T is an (in general nonrational) causal transfer function with causal inverse, the spectrum of w is given by $\Sigma = TT^*$. The spectra of $\hat{w}$ and $\tilde{w}$ are denoted, respectively, by $\hat{\Sigma}$ and $\tilde{\Sigma}$, and the cross spectrum between $\hat{w}$ and $\tilde{w}$ is denoted by Σ_c. Under assumptions A1–A4, all these spectra are bounded functions on the unit circle. A factor model corresponds to a decomposition

$$\Sigma = \hat{\Sigma} + \tilde{\Sigma} + \Sigma_c + \Sigma_c{}'. \tag{9}$$

By assumption, the behavior of the latent process is nontrivial so that $\hat{\Sigma}$ is singular. The rank of this spectrum corresponds to the number of unrestricted factor components. This is made precise in the following result. Here we denote by $\ker(\hat{\Sigma})$ the set of $1 \times q$ polynomials $r(s, s^{-1})$ for which $r(z, z^{-1})\,\hat{\Sigma}(z) = 0$ on the unit circle. The polynomial rank of $\hat{\Sigma}$ is defined as $q - p$, where p is the dimension of the module $\ker(\hat{\Sigma})$. Further, by $\mathrm{im}(\hat{\Sigma})$ we denote the smallest linear system that contains all time series of the form $\hat{\Sigma}(\sigma)v$, where v is a $q \times 1$ time series with finite support.

THEOREM 2.4.

(i) *A latent process $\hat{w}$ with spectrum $\hat{\Sigma}$ has behavior $\mathcal{B} = \mathrm{im}(\hat{\Sigma})$, and the behavioral laws are given by $\mathcal{L} = \ker(\hat{\Sigma})$.*

(ii) *The number of inputs of the behavior is equal to the polynomial rank of $\hat{\Sigma}$.*

(iii) *A latent process has behavior $\mathcal{B}$ if and only if it can be generated as $\hat{w} = \hat{G}\,v$, where $\hat{G}$ is an isometric image representation of $\mathcal{B}$ and v is a weakly stationary process with zero mean and finite second-order moments that has trivial behavior.*

Proof. (i) Let $\mathcal{B}$ be the behavior of $\hat{w}$ and $\mathcal{L}$ the corresponding set of laws. Then a $1 \times q$ polynomial belongs to $\mathcal{L}$ if and only if $r\,\hat{w} = 0$ holds almost surely, and this is equivalent to the condition $r\,\hat{\Sigma} = 0$, that is, $\mathcal{L} = \ker(\hat{\Sigma})$.

Now let $\mathcal{B}^* = \mathrm{im}(\hat{\Sigma})$ be the smallest linear system that contains all time series of the form $\hat{\Sigma}(\sigma)v$, where v is a $q \times 1$ time series with finite support. Let $\mathcal{L}^*$ denote the set of laws of the system $\mathcal{B}^*$. The system $\mathcal{B}^*$ consists of pointwise limits of time series $\hat{\Sigma}(\sigma)v_n$, $n = 1, 2, \ldots$, where v_n are time series with finite support. If $r \in \mathcal{L}$, then $r\,\hat{\Sigma} = 0$ implies $r(\sigma)\,\hat{\Sigma}(\sigma)v_n = 0$, and the same holds true for the pointwise limit of $\hat{\Sigma}(\sigma)v_n$. This shows that $\mathcal{L} \subseteq \mathcal{L}^*$. Now let r be a $1 \times q$ polynomial with $r\,\hat{\Sigma} \neq 0$, and let $w \in \mathcal{B}^*$ be defined by $w = \hat{\Sigma}(\sigma)v$ where v has Z-transform r'. As $r\,\hat{\Sigma}\,r' \neq 0$, it follows that $r(\sigma)\,\hat{\Sigma}(\sigma)v \neq 0$, so that r does not belong to $\mathcal{L}^*$. This implies that $\mathcal{L}^* \subseteq \mathcal{L}$, so that $\mathcal{L}^* = \mathcal{L}$. As $\mathcal{B}$ and $\mathcal{B}^*$ satisfy the same relations, it follows that $\mathcal{B} = \mathcal{B}^*$.

(ii) The number of inputs of $\mathcal{B}$ is given by $m = q - p$, where p is the dimension of the module $\mathcal{L} = \ker(\hat{\Sigma})$. This was also defined as the polynomial rank of $\hat{\Sigma}$.

(iii) First assume that $\hat{w}$ has behavior $\mathcal{B}$ with m inputs. Let R be a $(q - m) \times q$ polynomial matrix with full rank so that $\mathcal{B} = \ker(R)$, and let $\hat{G}$ be an isometric image representation of $\mathcal{B}$ as defined in section 3.1, so that $R\,\hat{G} = 0$. As $\hat{G}$ is rational it can be written as $p^{-1}Q$, with p a scalar polynomial and Q a $q \times m$ matrix polynomial with full column rank. As $\hat{G}$ is stable, so that it has no poles on the unit circle, it follows that $\hat{v} = \hat{G}^*\,\hat{w}$ is a well-defined stationary process with zero mean and finite second-order moments. As $\hat{G}\,\hat{G}^*$ is the projection onto $\mathcal{B}$ and realizations of the factor process belong almost surely to $\mathcal{B}$, it follows that $\hat{G}\,\hat{v} = \hat{G}\,\hat{G}^*\,\hat{w} = \hat{w}$. It remains to show that $\hat{v}$ has trivial behavior $(\mathbf{R}^m)^{\mathbf{Z}}$. Suppose that this was not the case; then there is a $1 \times m$ polynomial $r \neq 0$ such that $r\,\hat{v} = 0$. As Q has rank m there exists a $1 \times q$ polynomial π so that $\pi Q = r$ and $\pi\,\hat{w} = p^{-1}\pi Q\,\hat{v} = 0$, so that π is a law of the process $\hat{w}$. It then follows that $(R', \pi')'\,\hat{G} = (0, r')'$, where $r \neq 0$. This implies that $(R', \pi')'$ is a polynomial matrix of rank $q - m + 1$ with the property that $(R', \pi')'\,\hat{w} = 0$. This means that the behavior of $\hat{w}$ has fewer than m inputs, but this contradicts (ii).

Second, suppose that $\hat{w} = \hat{G}\,\hat{v}$. As $\hat{v}$ has trivial behavior it follows that r is a behavioral law of $\hat{w}$ if and only if $r\,\hat{G} = 0$, or equivalently $r\,\hat{G}\,\hat{G}^* = rP = 0$ with P the projection operator onto $\mathcal{B}$. This shows that the behavior of $\hat{w}$ is given by $\mathcal{B}$. □

Concerning (ii), note that the polynomial rank of $\hat{\Sigma}$ is $q - p$, where p is the number of independent polynomial relations satisfied by the latent process $\hat{w}$. In

general, the polynomial rank may be larger than the dimension of the innovation space $\mathbf{H}_t(\hat{w}) \cap \{\mathbf{H}_{t-1}(\hat{w})\}^{\perp}$. This dimension is the usual definition of the rank of the process $\hat{w}$, and this is equal to the maximum of $\operatorname{rank}(\hat{\Sigma}(z))$ on the unit circle. This implies that for all $|z| = 1$ the rank of $\hat{\Sigma}(z)$ is smaller than or equal to the polynomial rank of $\hat{\Sigma}$, and if $\hat{w}$ satisfies additional linear relations that are not polynomial, then the rank of $\hat{\Sigma}(z)$ is strictly smaller than the polynomial rank of $\hat{\Sigma}$. As nonpolynomial relations correspond to infinite-dimensional systems, they fall outside the behavioral setting discussed in section 2.1.

2.3. Factor schemes. The basic question considered in this paper concerns the relationship between the spectrum of the observed process and the class of observationally equivalent factor models. Under assumption A2 there exists for every linear system $\mathcal{B}$ a factor model with behavior $\mathcal{B}$, because we can simply define the noise as $\tilde{w} = w - \hat{w}$ for every latent process $\hat{w}$. In the words of Kalman [15], within this setting we can obtain no models without prejudice. So we have to impose additional restrictions on the noise process in order to make meaningful statements about the underlying system. These restrictions should be motivated in each practical situation. Here we consider the following possible specifications, which we call factor schemes.

- The factor model is called orthogonal if the latent process and the noise process are mutually uncorrelated, that is, if $\mathrm{E}\{\hat{w}(t)\,\tilde{w}(s)'\} = 0$ for all t, s. Stated otherwise, there holds $\mathbf{H}(\hat{w}) \perp \mathbf{H}(\tilde{w})$ and $\Sigma_c = 0$.
- The factor model is called observable if $\hat{w}$ is a linear function of w, that is, if $\mathbf{H}(\hat{w}) \subseteq \mathbf{H}(w)$. Stated otherwise, there holds $\hat{\Sigma} = F\,\Sigma\,F^*$, $\tilde{\Sigma} = (I - F)\,\Sigma(I - F)^*$, and $\Sigma_c = F\,\Sigma(I - F)^*$ for some, possibly noncausal, transfer function F.
- The factor model is said to have bounded noise if it satisfies an a priori specified bound in terms of the noise spectrum $\tilde{\Sigma}$.

The quality of factor models is expressed in terms of the complexity and the goodness of fit of the model.

DEFINITION 2.5. *The* complexity *of a dynamic factor model is defined as the pair* (m, n)*, where* m *is the number of driving variables and* n *the number of states of the behavior of the factor model.*

The complexity measures the dimension of the latent process, in the sense that the set of possible realizations $\{\hat{w}(\omega); \omega \in \Omega\}$ on a time interval of length $L \geq n$ is (almost surely) contained in an $(mL+n)$-dimensional subspace of $\mathbf{R}^{qL}$. In parametric terms, the complexity can also be expressed as follows.

PROPOSITION 2.6.

(i) *In terms of a kernel representation* $R(\sigma, \sigma^{-1})\,\hat{w} = 0$*, the complexity is given by* $m = q - \operatorname{rank}(R)$ *and* $n = \sum_{k=1}^{q-m} \nu_k$*, where* $\{\nu_1, \ldots, \nu_{q-m}\}$ *are the Kronecker observability indices.*

(ii) *In terms of an isometric image representation* $\hat{G}$ *of the factor behavior, the complexity is given by the rank* m *and McMillan degree* n *of* $\hat{G}$*.*

Proof. (i) This follows from Theorem 6 in [24].

(ii) This follows from Theorem 4.9 and Lemma 4.10 in Chapter 4 of [14]. ∎

Below, we will sometimes consider another measure of complexity in case the factor model is observable and the spectrum Σ is rational, that is, $w = T(\sigma^{-1})\varepsilon$ in (6), where T is now a rational transfer function. Then a special class of latent processes is obtained by prefiltering the noise, that is, $\hat{w} = T(\sigma^{-1})F(\sigma^{-1})\varepsilon$, where F is a rational, rank deficient transfer function. We define the effective noise space by $\mathcal{N} = \operatorname{im}(F)$, that is, the behavior of the filtered noise process $F(\sigma^{-1})\varepsilon$. In this case the behavior of the latent process is given by $\mathcal{B} = \operatorname{im}(TF)$. As TF is rational

and rank deficient, it follows that $\mathcal{B}$ is a nontrivial linear system. An alternative characterization of complexity is the pair (m', n'), the number of inputs and states of the effective noise behavior $\mathcal{N}$. This measures the complexity of the noise process underlying the latent process.

DEFINITION 2.7. *Let a process with rational Wold representation $w = T(\sigma^{-1})\varepsilon$ and a latent process $\hat{w} = (TF)(\sigma^{-1})\varepsilon$ be given. Then the* noise complexity *of the corresponding factor model is defined as (m', n'), the number of inputs and states of the effective noise space $\mathcal{N} = \mathrm{im}(F)$.*

The two foregoing notions of complexity are not equivalent. If $\mathcal{N}$ is the effective noise space of a factor model with behavior $\mathcal{B}$ and if (m, n) and (m', n') are the complexities of $\mathcal{B}$ and $\mathcal{N}$, respectively, then $m = m'$, but in general $n \neq n'$.

The goodness of fit of factor models is measured in terms of the second moments of the noise process $\tilde{w}$. As is well known, the choice of norms may have an essential effect on the obtained models. Here we will restrict the attention to the mean squares norm and the uniform norm. In the following we use the notation $\tilde{\Sigma}^{1/2}$ for a spectral factor of the noise spectrum $\tilde{\Sigma}$ so that $\tilde{\Sigma} = \tilde{\Sigma}^{1/2}(\tilde{\Sigma}^{1/2})^*$. We define the norm of a $1 \times q$ polynomial $r(\sigma, \sigma^{-1}) = \sum r_k \sigma^k$ by $\|r\|_2^2 := \sum \|r_k'\|^2$, where $\|\cdot\|$ denotes the Euclidean norm on $\mathbf{R}^q$. Further, we define the following norms for spectral factors, where $\lambda_{\max}(Q)$ denotes the spectral radius, that is, the maximum of the absolute values of the eigenvalues of a matrix Q.

$$\| \tilde{\Sigma}^{1/2} \|_2^2 = \frac{1}{2\pi} \int_{-\pi}^{\pi} \mathrm{trace}\{\tilde{\Sigma}(e^{-i\lambda})\} d\lambda, \tag{10}$$

$$\| \tilde{\Sigma}^{1/2} \|_\infty^2 = \sup_{\lambda \in [-\pi, \pi]} \lambda_{\max}\{\tilde{\Sigma}(e^{-i\lambda})\}. \tag{11}$$

DEFINITION 2.8. *For a factor model with noise process $\tilde{w}$ with spectrum $\tilde{\Sigma}$, the mean squares and uniform fit are, respectively, defined by*

$$\| \tilde{w} \|_2 := [\mathrm{E}\{\tilde{w}(t)' \tilde{w}(t)\}]^{1/2} = \| \tilde{\Sigma}^{1/2} \|_2, \tag{12}$$

$$\| \tilde{w} \|_\infty := \sup\{[\mathrm{E}\{(r(\sigma, \sigma^{-1}) \tilde{w})(t)\}^2]^{1/2}; \|r\|_2 = 1\} = \| \tilde{\Sigma}^{1/2} \|_\infty. \tag{13}$$

Because of assumption A3, the noise process is purely nondeterministic, so that the coefficients of $\tilde{\Sigma}^{1/2}$ are square summable and $\|\cdot\|_2$ is well defined, and because of assumption A4, the spectrum is bounded on the unit circle so that $\|\cdot\|_\infty$ is also well defined. The mean squares and uniform norms are monotonic, since they become larger if the spectrum becomes larger in the sense of positive semidefinite matrix functions on the unit circle. Sometimes, when results hold true for both norms, we make no distinction in notation and write $\| \tilde{w} \|$ and $\| \tilde{\Sigma}^{1/2} \|$.

2.4. Illustrations.

2.4.1. Static factor models. As a simple illustration we show that the framework as introduced before is an extension to the dynamic case of the well-known class of static factor models that have been analyzed in [18] and [23], among others. In later sections we will use the static case for further illustration.

Suppose that the observations are uncorrelated over time, so that w is a white noise process. In this subsection we restrict our attention to factor models $w = \hat{w} + \tilde{w}$, where $\hat{w}$ and $\tilde{w}$ are also white noise processes. We further impose the condition that the behavior of the factor model is static in the sense that the state dimension is $n = 0$.

The corresponding linear systems are described by linear nondynamic equations of the form $R\,\hat{w} = 0$, where R is a full row rank $p \times q$ real matrix. Let M be a $q \times (q-p)$ matrix with $\mathrm{im}(M) = \ker(R)$; then the factor model can be written as

$$w(t) = Mf(t) + \tilde{w}(t).$$

This corresponds to the classical static factor model with factors f. If the covariance matrix of f has full rank, then the complexity of this factor model is $(m, 0)$, where $m = q - p$ is the number of factors.

In the literature several possible factor schemes have been proposed. For example, in the principal component analysis of multivariate statistics the aim is to keep the noise process $\tilde{w}$ as small as possible, under a restriction on the number of independent factors m. In the so-called Frisch scheme the aim is to minimize the complexity of the model under the restrictions that the processes $\hat{w}$ and $\tilde{w}$ are orthogonal and that, in addition, the q components of the noise process $\tilde{w}$ are mutually orthogonal.

Our approach resembles principal component analysis. In the next section we will consider minimization of the noise under a restriction of the complexity of the behavior of the latent process.

2.4.2. Dynamic system example. Here we give a simple example of a dynamic factor model. Suppose that the data generating process consists of a single input, single output system where both the input u and the output y are observed under additive noise. That is, we assume that the data $w = (u, y)$ are generated as $w = \hat{w} + \tilde{w}$, with $\tilde{w}$ the noise and $(\hat{u}, \hat{y})$ the latent process with $\hat{y} = g\,\hat{u}$, where g denotes the underlying rational transfer function. For simplicity we assume that the latent input $\hat{u}$ is white noise and that the noise process $\tilde{w}$ is also white noise, all uncorrelated and with unit variance. In this case the spectrum of the data generating process is given by

$$\Sigma = \begin{pmatrix} 2 & g^* \\ g & gg^* + 1 \end{pmatrix}.$$

An obvious factor model for this process is the above decomposition in the latent process $\hat{w}$ and the white noise process $\tilde{w}$. If $g(\sigma, \sigma^{-1}) = r_1(\sigma, \sigma^{-1})/r_2(\sigma, \sigma^{-1})$, then this factor model has a behavior described by the equation $R(\sigma, \sigma^{-1})\,\hat{w} = 0$ where $R = (-r_1, r_2)$. The complexity is $(m, n) = (1, d)$, where d is the maximum of the degrees of the polynomials r_1 and r_2. The mean squares fit is $\| \tilde{w} \|_2 = \sqrt{2}$, and the uniform fit is $\| \tilde{w} \|_\infty = 1$. Because of our assumptions, this factor model is orthogonal but not observable.

Of course, the real question is whether we can identify the underlying transfer function g from the spectrum Σ. This will be investigated in section 3.3.2.

3. Pareto optimal models. The quality of a factor model for an observed process w is measured by its complexity and goodness of fit. In general, the fit can become better if the model is allowed to be more complex. We use a lexicographic ordering of complexities, so that (m_1, n_1) is less complex than (m_2, n_2) if $m_1 < m_2$ or $m_1 = m_2, n_1 < n_2$. A factor model is called Pareto optimal if it satisfies the following two conditions: every less complex model has a strictly worse fit, and no equally complex model has strictly better fit. This means that the fit can not be improved without increasing the complexity and that the complexity can not be reduced without deteriorating the fit.

We characterize Pareto optimal models by optimizing the fit for a given bound on the complexity. This problem is analyzed in three steps. In section 4.1 we investigate

two cases: modeling with a specified behavior and modeling with a restricted number of inputs where the number of states is left free. In section 4.2 we derive Pareto optimal models of restricted complexity, where both the number of inputs and the number of states is limited. The optimality of models depends of course on the specification of the factor scheme, that is, on the choice of norms for the noise and on possible conditions of orthogonality and observability.

3.1. Optimal models of restricted rank. First assume that the behavior of the factor model has been specified a priori, so that the factor equations are given. The aim is to find a model with minimal error that satisfies these equations. Let $\mathcal{B}$ denote the given controllable linear system with polynomial representation $R(\sigma, \sigma^{-1})\,\hat{w} = 0$. The isometric image and kernel representations of the system are denoted, respectively, by $\hat{G}$ and $\tilde{G}$, so that $P_{\mathcal{B}} := \hat{G}\,\hat{G}^* = I - R^*(RR^*)^{-1}R$ is the projection operator onto the system and $\tilde{G}\,\tilde{G}^* = I - P_{\mathcal{B}}$ is the projection onto the set of behavioral equations. The following results hold true both for the mean squares and for the uniform norm.

THEOREM 3.1. *Let w be a process with spectrum Σ and let $\mathcal{B}$ be the required behavior of a factor model.*

(i) *A latent process with optimal fit is given by $\hat{w}_0 := P_{\mathcal{B}} w$, with noise spectrum $\tilde{\Sigma}_0 = (I - P_{\mathcal{B}})\,\Sigma(I - P_{\mathcal{B}}) = \tilde{G}\,\tilde{G}^*\,\Sigma\,\tilde{G}\,\tilde{G}^*$. The corresponding factor model is observable but, in general, not orthogonal.*

(ii) *Among orthogonal models, a latent process with optimal fit is given by $\hat{w}_0 := [I - \Sigma R^*(R\Sigma R^*)^{-1}R]w$, with corresponding noise spectrum $\tilde{\Sigma}_0 = \Sigma R^*(R\Sigma R^*)^{-1}R\Sigma = \Sigma\,\tilde{G}(\tilde{G}^*\,\Sigma\,\tilde{G})^{-1}\,\tilde{G}^*\,\Sigma$.*

Proof.

(i) The relation $\tilde{G}^*\,\hat{w} = 0$ implies for the mean squares norm

$$\begin{aligned} \|\,\tilde{\Sigma}^{1/2}\,\|_2^2 &= \oint_{|z|=1} \operatorname{trace}(\hat{G}^*\,\tilde{\Sigma}\,\hat{G})(z)dz + \oint_{|z|=1} \operatorname{trace}(\tilde{G}^*\,\tilde{\Sigma}\,\tilde{G})(z)dz \\ &\geq \oint_{|z|=1} \operatorname{trace}(\tilde{G}^*\,\Sigma\,\tilde{G})(z)dz. \end{aligned}$$

Therefore the misfit is minimal if and only if $\hat{G}^*\,\tilde{w} = 0$ holds, so that $\hat{w} = (\hat{G}\,\hat{G}^* + \tilde{G}\,\tilde{G}^*)\,\hat{w} = \hat{G}\,\hat{G}^*(w - \tilde{w}) = P_{\mathcal{B}} w$. This model is also optimal for the uniform norm, since

$$\lambda_{\max}(\tilde{\Sigma}(z)) \geq \lambda_{\max}((\tilde{G}\,\tilde{G}^*\,\tilde{\Sigma}\,\tilde{G}\,\tilde{G}^*)(z)) \quad = \quad \lambda_{\max}((\tilde{G}\,\tilde{G}^*\,\Sigma\,\tilde{G}\,\tilde{G}^*)(z))$$

holds for all points z of the unit circle. This optimal model is, in general, not orthogonal since $P_{\mathcal{B}}\,\Sigma(I - P_{\mathcal{B}})$ is not zero in general.

(ii) We show that $\tilde{\Sigma}(z) \geq \tilde{\Sigma}_0(z)$ holds for all points z of the unit circle. For simplicity of notation we omit the argument z in the following. Let $G = [\hat{G}, \tilde{G}]$; then, because of $\tilde{G}^*\,\hat{\Sigma} = 0$, it follows that $\tilde{G}^*\,\Sigma = \tilde{G}^*\,\tilde{\Sigma}$ and hence

$$\begin{aligned} G^*\,\tilde{\Sigma}\,G &= \begin{pmatrix} \hat{G}^*\,\tilde{\Sigma}\,\hat{G} & \hat{G}^*\,\Sigma\,\tilde{G} \\ \tilde{G}^*\,\Sigma\,\hat{G} & \tilde{G}^*\,\Sigma\,\tilde{G} \end{pmatrix} \\ &\geq \begin{pmatrix} (\hat{G}^*\,\Sigma\,\tilde{G})(\tilde{G}^*\,\Sigma\,\tilde{G})^{-1}(\tilde{G}^*\,\Sigma\,\hat{G}) & \hat{G}^*\,\Sigma\,\tilde{G} \\ \tilde{G}^*\,\Sigma\,\hat{G} & \tilde{G}^*\,\Sigma\,\tilde{G} \end{pmatrix} \\ &= G^*\,\Sigma\,\tilde{G}(\tilde{G}^*\,\Sigma\,\tilde{G})^{-1}\,\tilde{G}^*\,\Sigma\,G. \end{aligned}$$

The above inequality is a consequence of the fact that $G^*\,\tilde{\Sigma}\,G \geq 0$. So all orthogonal factor models with behavior $\mathcal{B}$ must satisfy $\tilde{\Sigma} \geq \Sigma\,\tilde{G}(\tilde{G}^*\,\Sigma\,\tilde{G})^{-1}\,\tilde{G}^*\,\Sigma = \tilde{\Sigma}_0$. This

shows the second expression for $\tilde{\Sigma}_0$. The first expression follows from the fact that $\tilde{G} = R^*Q$ where Q is a spectral factor of $(RR^*)^{-1}$, that is, $QQ^* = (RR^*)^{-1}$. □

The optimal factor model is unique in the case of the mean squares norm, but not generally in case of the uniform norm. If we are interested in factor behaviors only, then the above results show that we may restrict our attention to observable models. This leaves four factor schemes of interest: those for the mean squares and the uniform norm, and according to whether orthogonality is imposed or not. We define the distance between a behavior and a spectral density as the fit of the optimal factor model with this behavior. That is, the misfit function is given by

$$\mathrm{d}(\Sigma, \mathcal{B}) = \| \tilde{\Sigma}_0^{1/2} \|, \tag{14}$$

where $\tilde{\Sigma}_0$ is the noise spectrum of the optimal factor models for $\mathcal{B}$ given in Theorem 3.1 and where $\tilde{\Sigma}_0^{1/2}$ denotes a spectral factor of $\tilde{\Sigma}_0$. We use the same notation for the four different factor schemes.

Next we describe optimal models of restricted rank, so that only the number of inputs of the latent process is restricted, but not the number of state variables. Under the assumptions A1–A4 of section 2.2, the observed spectrum Σ is a well-defined matrix function on the unit circle that can be pointwise decomposed in terms of its eigenvalues and eigenvectors as $\Sigma = U\Lambda U^*$. Here U is a $q \times q$ unitary matrix function (i.e., $UU^* = U^*U = I_q$), and Λ is a diagonal matrix of ordered eigenfunctions. For simplicity we assume that the eigenvalues are distinct everywhere on the unit circle, so that $\Lambda = \mathrm{diag}(\lambda_1, \ldots, \lambda_q)$ with $\lambda_1(z) > \lambda_2(z) > \cdots > \lambda_q(z) > 0$ on the unit circle. Let $U = [U_1, U_2]$, where U_1 consists of the first m columns of U and U_2 of the remaining columns, and let $\Lambda = \mathrm{diag}(\Lambda_1, \Lambda_2)$ be a corresponding partitioning. The principal component model of rank m is defined by the factor $\hat{w} = U_1U_1^*w$ and noise $\tilde{w} = U_2U_2^*w$. In terms of the spectra, this gives

$$\hat{\Sigma}_m = U_1\Lambda_1U_1^*, \quad \tilde{\Sigma}_m = U_2\Lambda_2U_2^*, \quad \Sigma_c = 0. \tag{15}$$

Under the above assumptions, this model is well defined and unique (See [3, Theorems 9.3.1, 9.3.2, and 9.3.3]), and it is clearly observable and orthogonal. The latent process spectrum has rank m, but the factor behavior will in general be trivial; that is, it will be $(\mathbf{R}^q)^{\mathbf{Z}}$. This is because, in general, there exist no nontrivial polynomial equations such that $R(z, z^{-1})\,\hat{\Sigma}_m(z) = 0$.

The following result states that the principal component model has optimal fit, and that it can be approximated arbitrarily closely by factor models with complexity (m, n) if the number of state variables n is chosen sufficiently large. The results hold true for all factor schemes, that is, for mean squares and uniform fit and irrespective of whether orthogonality and observability are imposed or not.

THEOREM 3.2.

(i) *No factor model of complexity (m, n) has better fit than the fit $\| \tilde{\Sigma}_m^{1/2} \|$ of the principal component model of rank m.*

(ii) *For every $\varepsilon > 0$ there is a factor model of complexity (m, n), for some finite n, with better fit than $\| \tilde{\Sigma}_m^{1/2} \| + \varepsilon$.*

Proof. Under the assumption $\lambda_1(z) > \lambda_2(z) > \cdots > \lambda_q(z) > 0$ for all $|z| = 1$, the eigenvector matrix $U(z)$ has an absolutely summable Laurent series expansion; see [3, Theorems 9.3.1, 9.3.2, and 9.3.3]. This implies that $\tilde{w}_m = U_2U_2^*w$ and $\hat{w}_m = w - \tilde{w}_m = U_1U_1^*w$ are well-defined processes.

(i) As $\Sigma(z)$ is continuous on the unit circle it follows also that the eigenvalues $\lambda_i(z)$ are continuous functions (See Lemma 6.1 in the appendix), and thus $\| \tilde{\Sigma}_m^{1/2} \|_2^2 =$

$\oint_{|z|=1}\{\lambda_{m+1}(z)+\cdots+\lambda_q(z)\}dz$ and $\|\,\tilde{\Sigma}_m^{1/2}\,\|_\infty^2 = \sup_{|z|=1}\lambda_{m+1}(z)$ are well defined. If $\tilde{G}$ is the isometric kernel representation of a behavior $\mathcal{B}$, then the optimal noise covariance corresponding to $\mathcal{B}$ is, according to Theorem 3.1 given by $\tilde{\Sigma} = \tilde{G}\,\tilde{G}^*\,\Sigma\,\tilde{G}\,\tilde{G}^*$. As $\tilde{G}^*(z)\,\tilde{G}(z) = I$, Lemma 6.1 implies the optimality of the principal component model.

(ii) Since $U_2(\sigma)$ is an absolutely summable filter, we can find a positive integer N and a finite filter $\tilde{G}_N(\sigma) = \sum_{|k|\le N}\tilde{G}_k\,\sigma^k$ such that $\|U_2 - \tilde{G}_N\,\|_\infty$ is arbitrarily small. Thus we can choose N such that $\|I - \tilde{G}_N^*\,\tilde{G}_N\,\|_\infty$ and also $\|U_2U_2^* - \tilde{G}_N(\tilde{G}_N^*\,\tilde{G}_N)^{-1}\,\tilde{G}_N^*\,\|_\infty$ become arbitrarily small. The transfer function $P_N = \tilde{G}_N(\tilde{G}_N^*\,\tilde{G}_N)^{-1}\,\tilde{G}_N^*$ is a rational projection matrix of rank m, so that $(I - P_N)$ is the isometric image representation of a behavior $\mathcal{B}_N$ with m inputs and a finite number of states. Then, analogous to the proof of Proposition 6.3 in the appendix, it follows that $\|\,\tilde{\Sigma}_N - \tilde{\Sigma}_m\,\|_\infty \to 0$, and thus $\|\,\tilde{\Sigma}_N^{1/2}\,\| \to \|\,\tilde{\Sigma}_m^{1/2}\,\|$ by Lemma 6.2. Here U_2 corresponds to $\tilde{G}_0$ in the proof of Proposition 6.3, and this proof can easily be extended to the case where $\tilde{G}_0 = U_2$ is not rational but only absolutely summable. □

So the principal component model gives an optimal reduced rank approximation of the spectrum. Further, this gives a first idea of achievable combinations of complexity and fit. A sufficient condition for the existence of a factor model with fit δ and complexity (m, n), for some finite n, is that $\|\,\tilde{\Sigma}_m^{1/2}\,\| < \delta$, and a necessary condition is that $\|\,\tilde{\Sigma}_m^{1/2}\,\| \le \delta$.

We conclude this section by considering the effect of using weighted norms or, stated otherwise, the effect of prefiltering the observed process. Let Q be a $q \times q$ positive definite matrix function which is bounded on the unit circle. Then the Q-weighted norm is defined as $\|\,\tilde{w}\,\|_Q = \|T^*\,\tilde{w}\,\|$ for a spectral factorization $Q = TT^*$. This norm is well defined, as it does not depend on the choice of the spectral factor.

PROPOSITION 3.3. *Let $\mathcal{B}$ be a controllable linear system of complexity (m, n). Then there is a choice of Q-weights such that $\mathcal{B}$ is the behavior of a factor model that minimizes the Q-weighted norm over the set of all factor models with m inputs.*

Proof. Let $R(\sigma, \sigma^{-1})$ be a full row rank polynomial matrix with rows that form a basis for the set of laws of the behavior $\mathcal{B}$. As $\|\,\tilde{w}\,\|_Q = \|T^*\,\tilde{w}\,\|$ we can use the result of Theorem 3.2 on the transformed data $\bar{w} := T^*w$, with spectrum $T^*\,\Sigma\,T$. The transformed latent process $\hat{\bar{w}} = T^*\,\hat{w}$ satisfies the relation $R(T^*)^{-1}\hat{\bar{w}} = 0$. Thus, by Theorem 3.2, $\mathcal{B}$ is optimal with respect to the weighted norm $\|\,\tilde{w}\,\|_Q$ if $R(T^*)^{-1}$ is a basis of the left eigenspace of $T^*\,\Sigma\,T$ corresponding to the $q-m$ smallest eigenvalues, pointwise on the unit circle. In this case $\bar{w} = \hat{\bar{w}} + \tilde{\bar{w}}$ is the principal component model for the transformed data.

Now let $\bar{S}(\sigma, \sigma^{-1})$ be a full column rank polynomial matrix with columns that form a basis of the right kernel of R (i.e., $R\bar{S} = 0$), and let $S = \Sigma^{-1}\,\bar{S}$ and $Q = \Sigma^{-1} + SS^*$. If $\bar{Q} = \Sigma^{*/2}\,Q\,\Sigma^{1/2}$, then it follows that $R\,\Sigma^{1/2}\,\bar{Q} = R\,\Sigma^{1/2}$ and $S^*\,\Sigma^{1/2}\,\bar{Q} = (I + S^*\,\Sigma\,S)S^*\,\Sigma^{1/2}$. Thus the $q-m$ smallest eigenvalues of $\bar{Q}(z)$ are equal to 1, and $R(z, z^{-1})\,\Sigma^{1/2}(z)$ is a basis of the corresponding left eigenspace. Let $Q = TT^*$ and $\bar{\Sigma} = T^*\,\Sigma\,T$; then there holds $x\,\Sigma^{1/2}\,\bar{Q} = \lambda x\,\Sigma^{1/2}$ if and only if $x(T^*)^{-1}\bar{\Sigma} = \lambda x(T^*)^{-1}$. So the $q-m$ smallest eigenvalues of $\bar{\Sigma} = T^*\,\Sigma\,T$ are equal to one and $U_2 = R(T^*)^{-1}$ is a basis of the corresponding eigenspace. This shows that T is the appropriate transformation and Q the appropriate norm. □

This shows that the choice of norms is decisive for the obtained behaviors. So, in practical applications, it is imperative to take care of appropriate weighting of the data. In our opinion the norms should not be chosen on mathematical grounds alone,

but must be related to the information and objectives of each specific application. Here we will further restrict attention to the unweighted norms, which may be relevant in applications if the observed variables have been transformed appropriately.

3.2. Optimal models of restricted complexity. A straightforward method for determining Pareto optimal models is to fix the complexity and to optimize the fit under this constraint. A model of optimal fit is then Pareto optimal if there are no less complex models of at least equal fit. For complexity (m, n), this can be checked by comparing, first, with the optimal fit of models of complexity $(m, n-1)$ and, second, with the fit achievable by models having less than m inputs. The second comparison is simplified by the result of Theorem 3.2 for the principal component model of rank $m-1$. Because of these considerations, we restrict our attention to the determination of optimally fitting models of given complexity.

The main complication of the corresponding optimization problem is that the set of systems of given complexity (m, n) is not convex and also not compact. We restrict the attention to the mean squares norm and consider both the factor schemes with and without orthogonality. We will not investigate several other questions that are of interest in this context, such as the existence and unicity of optimal models and the case of the uniform norm.

The solution for the mean squares norm is given in terms of the so-called global total least squares algorithm presented in [21]. Let $W = (W_1, \dots, W_r)$ be a square summable $q \times r$ matrix sequence, that is, with $\|W\|_2^2 := \sum_{t=-\infty}^{\infty} \|W(t)\|_2^2 < \infty$, where $\|W(t)\|_2$ denotes the Frobenius norm of the matrix $W(t)$. Further, let the l_2-distance between this sequence and a linear system $\mathcal{B}$ be defined as $\mathrm{d}(W, \mathcal{B}) := \min\{\|W - V\|_2; V = (V_1, \dots, V_r)$ with $V_i \in \mathcal{B}, i = 1, \dots, r\}$. The objective in global total least squares is to determine an optimal model of restricted complexity, that is, one which minimizes the l_2-distance over the set of controllable systems with m inputs and n states. In general the optimal model exists and is unique, but existence and uniqueness may fail to hold true in exceptional cases. For algorithmic details we refer to [21] and [20], where a Gauss–Newton algorithm for the involved projections is described. If $\mathcal{B}$ is the optimal system, then $P_{\mathcal{B}}W$ is called the optimal l_2-approximation of W.

THEOREM 3.4. *Let $w = T\varepsilon$ be a given process with spectrum $\Sigma = TT^*$. For given complexity (m, n), a factor model with optimal mean squares fit is given by $w = \hat{w} + \tilde{w}$, where $\hat{w} = \hat{T}\,\varepsilon$ and $\tilde{w} = (T - \hat{T})\varepsilon$. Here $\hat{T}$ is the optimal l_2-approximation of complexity (m, n) for the spectral factor T. This model is observable but in general not orthogonal.*

Proof. According to Theorem 3.1, it is no restriction of generality if we consider only observable models. So let $\hat{w}(t) = [G_t(\sigma, \sigma^{-1})\varepsilon](t)$; then assumption A1 of joint stationarity of w and $\hat{w}$ implies that G_t is time invariant, say $G_t = G$. This means that we can write $\hat{w} = F(\sigma)w = G(\sigma)\varepsilon$ for some transfer function $G(\sigma) = F(\sigma)T(\sigma)$. As ε has full rank, it follows that the latent process has complexity (m, n), that is, $R\,\hat{w} = 0$ for a polynomial matrix R representing a system $\mathcal{B}$ with complexity (m, n) if and only if $RG = 0$; that is, all columns of G should belong to the system $\mathcal{B}$. The noise $\tilde{w} = (T - G)\varepsilon$ has spectrum $(T - G)(T - G)^*$ and mean squares norm $\|\,\tilde{w}\,\|_2^2 = \frac{1}{2\pi}\int_{-\pi}^{\pi} \mathrm{trace}\{(T - G)(T - G)^*(e^{-i\lambda})\}d\lambda$. But this is precisely equal to $\|T - G\|_2^2$, the l_2-distance between T and G. So this minimization problem is the l_2- approximation problem for T where each of the q columns of G should belong to the same system of complexity (m, n). The optimal choice over this class is by definition given by $\hat{T}$.

It can be shown that the factor filter $\hat{T}$ and the noise filter $\tilde{T} := T - \hat{T}$ satisfy $\hat{T}^*\,\tilde{T} = 0$, but in general $\Sigma_c = \hat{T}\,\tilde{T}^* \neq 0$ so that the processes $\hat{w}$ and $\tilde{w}$ are not orthogonal. ∎

Next we characterize optimal models under the condition of orthogonality. In order to simplify the analysis, we restrict our attention to observed processes with rational spectrum Σ and use the alternative definition of complexity in terms of the effective noise space; see Definition 2.7.

THEOREM 3.5. *Let $w = T\varepsilon$ be a given process with spectrum $\Sigma = TT^*$. For given noise complexity (m, n), an orthogonal factor model with optimal mean squares fit is given by $w = \hat{w} + \tilde{w}$, where $\hat{w} = S\varepsilon$ and $\tilde{w} = (T - S)\varepsilon$. Here S^* is the optimal l_2-approximation of complexity (m, n) for the adjoint T^* of the spectral factor T.*

Proof. Within this setting a latent process is given by $\hat{w} = TF\varepsilon$ where the factor noise space $\mathcal{N} = \mathrm{im}(F)$ has complexity (m, n). The noise is then given by $\tilde{w} = T(I - F)\varepsilon$, and the orthogonality condition is equivalent to requiring $TF(I - F)^*T^* = 0$. As T has full rank everywhere, it follows that $F = F^* = F^2$ is a projection, namely the orthogonal projection onto the system $\mathcal{N}$. The noise has norm $\| \tilde{w} \|_2^2 = \frac{1}{2\pi} \int_{-\pi}^{\pi} \mathrm{trace}\{T(I - F)T^*(e^{-i\lambda})\} d\lambda$. This is equal to $\|(I - F)T^*\|_2^2 = \|T^* - S^*\|_2^2$, where each column of S^* is the optimal l_2-approximation within the system $\mathcal{N}$ of the corresponding column of T^*, as F is the projection onto this system. The optimal choice of the model, that is, of F or equivalently of $\mathcal{N}$ of complexity (m, n), is precisely the optimal l_2-approximation problem of T^*. ∎

3.3. Illustrations.

3.3.1. The static case. The foregoing results can easily be applied to the case of static factor models. Let w be a white noise process, so that the spectrum Σ is a constant function, the covariance matrix of the process. The principal component model is then obtained by the eigenvalue decomposition of the matrix Σ. The optimal latent process with m factors is given by the projection of the observations onto the space spanned by the eigenvectors corresponding to the m leading eigenvalues of Σ. Therefore, in the optimal factor model, both the latent process and the noise are white noise processes. It follows from Theorem 3.2(i) that the principal component model is Pareto optimal among all models of complexity (m, n) for all $n \geq 0$. That is, no gain of fit is possible by allowing for dynamic equations.

For the static case, the result in Proposition 3.3 has also been pointed out in [15] and [16]. In the ordinary least squares scheme the indeterminateness of optimal models is resolved by the assumption that certain variables are noise free, i.e., that a principal submatrix of the noise covariance $\tilde{\Sigma}$ is zero. In terms of the weighting matrix Q this means that certain noise directions are assigned an infinite weight. In our approach, however, we treat all variables in a symmetric way.

3.3.2. Dynamic system example. Next we consider the dynamic errors-in-variables system described in section 2.4.2, and we use the notation introduced there. So let the spectrum Σ be given, and assume that the complexity (m, n) has been specified with $m = 1$ and $n \geq d$. The principal component decomposition for fixed frequency is easily obtained, with eigenvalues $\lambda_1 = 2 + gg^*$ and $\lambda_2 = 1$ and the eigenvector corresponding to λ_2 given by $(-g, 1)^*$. We denote the corresponding latent process by $\hat{w}_* = (\hat{u}_*, \hat{y}_*)$ and the noise process by $\tilde{w}_*$. This shows that the principal component model has a behavior that is finite dimensional, and this model is Pareto optimal among all models of complexity $(1, n)$ with $n \geq d$. The underlying transfer function g has been identified, because $\hat{y}_* = g\,\hat{u}_*$.

Although the underlying behavior has been identified, this is not the case for the true latent process and noise process. This can be seen from the spectral properties of the noise processes. The noise that affects the data has spectrum I_2 of rank 2, whereas the noise $\tilde{w}_*$ has a spectrum of only rank 1. Further, the factor model $w = \hat{w} + \tilde{w}$ has

a mean squares error $\| \tilde{w} \|_2 = \sqrt{2}$, whereas the principal component model has error $\| \tilde{w}_* \|_2 = 1$. We remark that both models are in fact optimal for the uniform norm.

This shows that in this case the Pareto optimal model indeed identifies the latent transfer function g from the observed spectrum Σ, at least when the complexity is not chosen too small. We should remark that this result depends in a crucial way on our assumptions about the way the data are generated. For example, if the observation noise $\tilde{w}$ would not be white, then Pareto optimal models will in general not have transfer function g. In terms of Proposition 3.3 this would require an appropriate prefiltering of the data. In our example, the required filter Q is the identity, that is, our data generating process is such that the unweighted norm is appropriate to identify the underlying transfer function. For practical applications this means that, in order to find good approximations of the underlying system, one should incorporate available information on the noise properties.

4. Consistency.

4.1. System topology. We introduce the topologies on linear systems and spectra that we will use in our analysis of continuity properties of factor models. For linear systems the gap metric is defined in terms of the projections described at the end of section 2.1.

DEFINITION 4.1. *Let $\mathcal{B}_1, \mathcal{B}_2$ be linear systems with isometric image representations $\hat{G}_1$ and $\hat{G}_2$, respectively; then the gap between these systems is defined by*

$$\mathrm{d}(\mathcal{B}_1, \mathcal{B}_2) = \| \hat{G}_1 \hat{G}_1^* - \hat{G}_2 \hat{G}_2^* \|_\infty. \tag{16}$$

This is analogous to the usual definition of the gap between two closed linear subspaces of a Hilbert space as $\|P_1 - P_2\|$, where P_1 and P_2 are the orthogonal projection operators onto the two spaces. Here $\hat{G}_i \hat{G}_i^*$ is the orthogonal projection onto the set of square summable time series in the behavior $\mathcal{B}_i$, $i = 1, 2$.

PROPOSITION 4.2.

(i) *The gap* d *is a metric on the class of controllable linear systems.*

(ii) *In terms of system restrictions, if $\tilde{G}_i$ denotes an isometric kernel representation of $\mathcal{B}_i$, $i = 1, 2$, then* $\mathrm{d}(\mathcal{B}_1, \mathcal{B}_2) = \| \tilde{G}_1 \tilde{G}_1^* - \tilde{G}_2 \tilde{G}_2^* \|_\infty$.

(iii) *If two systems have a different number of inputs, then their gap equals one.*

Proof. (i) This holds true for so-called l_2 systems, and this implies the same result for controllable systems since these are in one-to-one correspondence with l_2 systems. See Corollaries 3-4 and 5-3 of Chapter 4 in [14].

(ii) This follows from the fact that $[\hat{G}, \tilde{G}]$ is inner, so that $\hat{G}\hat{G}^* + \tilde{G}\tilde{G}^* = I$.

(iii) See Proposition 5-5 of Chapter 4 in [14]. ∎

In the following, we denote by $\mathbf{B}(m, n)$ the set of all controllable linear systems with m inputs and n states, by $\overline{\mathbf{B}}(m, n) := \bigcup_{k=1}^{n} \mathbf{B}(m, k)$ the set of all controllable linear systems with m inputs and at most n states, and by $\mathbf{B} := \bigcup_{m=0}^{q} \bigcup_{n=0}^{\infty} \mathbf{B}(m, n)$ the set of all controllable linear systems.

PROPOSITION 4.3.

(i) *For $n > 0$ the set $\mathbf{B}(m, n)$ is neither open nor closed in $\mathbf{B}$.*

(ii) *The set $\overline{\mathbf{B}}(m, n)$ is the closure of $\mathbf{B}(m, n)$ in $\mathbf{B}$.*

(iii) *The sets $\mathbf{B}$ and $\overline{\mathbf{B}}(m, n)$, for $n > 0$, are not compact.*

Proof. (i) For $n = 0$ the only controllable systems are described by the isometric state parameters $(A, B, C, D) = (-, -, -, D)$ with corresponding static projection operator DD'. It follows that $\mathbf{B}(m, 0)$ is a compact set, and this will be described in more detail in section 4.4. We will now consider the case $n > 0$.

In order to show that $\mathbf{B}(m,n)$ is not open it suffices to construct a sequence of systems $\mathcal{B}_k \in \mathbf{B}(m,n+1)$ with $\mathrm{d}(\mathcal{B}_k,\mathcal{B}_0) \to 0$ where $\mathcal{B}_0 \in \mathbf{B}(m,n)$. Let (A_0,B_0,C_0,D_0) be a minimal isometric state representation of $\mathcal{B}_0$ and let $a \in \mathbf{R}, b \in \mathbf{R}^{1\times m}$, and $c \in \mathbf{R}^{q\times 1}$ be such that $A = \left(\begin{smallmatrix} A_0 & 0 \\ 0 & a \end{smallmatrix}\right)$, $B = \left(\begin{smallmatrix} B_0 \\ b \end{smallmatrix}\right)$, $C_k = (C_0, \varepsilon_k c)$ is an observable and controllable quadruple for all $\varepsilon_k > 0$. The system $\mathcal{B}_0$ has transfer function $\hat{G}_0 = D_0 + C_0(zI - A_0)^{-1}B_0$, and let the system $\mathcal{B}_k$ be defined by the transfer function $\hat{G}_k = D_0 + C_k(zI-A)^{-1}B = \hat{G}_0 + \varepsilon_k(z-a)^{-1}cb$ with $\varepsilon_k \to 0$ for $k \to \infty$. Then $\mathcal{B}_k \in \mathbf{B}(m,n+1)$ and clearly $\|G_k - G_0\|_\infty \to 0$ and $\mathrm{d}(\mathcal{B}_k,\mathcal{B}_0) = \| \hat{G}_k(\hat{G}_k^* \hat{G}_k)^{-1} \hat{G}_k^* - \hat{G}_0 \hat{G}_0^* \|_\infty \to 0$ for $k \to \infty$.

That $\mathbf{B}(m,n)$ is not closed follows in a similar way, by constructing a sequence in $\mathbf{B}(m,n)$ that converges to a system in $\mathbf{B}(m,n-1)$.

(ii) Let cl $\mathbf{B}(m,n)$ denote the closure of $\mathbf{B}(m,n)$. Systems with $m' \neq m$ do not belong to this closure, since such systems have gap one with respect to all systems in $\mathbf{B}(m,n)$; see Proposition 4.2(iii). Systems with m inputs and less than n states can be obtained as the limit of sequences of systems in $\mathbf{B}(m,n)$, by similar constructions as in the proof of (i). It remains to prove that systems in $\mathbf{B}(m,n')$ with $n' > n$ do not belong to cl $\mathbf{B}(m,n)$. Let $\mathcal{B} \in \mathbf{B}(m,n')$ with $n' > n$ have isometric image representation $\hat{G}$; then the projection operator $P = \hat{G}\hat{G}^*$ is a rational function with rank m and McMillan degree $2n'$. As projection operators corresponding to systems in $\mathbf{B}(m,n)$ have rank m and McMillan degree $2n$, it follows that such operators can not converge to P, so that $\mathcal{B}$ does not belong to cl $\mathbf{B}(m,n)$.

(iii) As $\mathbf{B}$ is a metric space, it suffices to prove that there exists a sequence of systems $\mathcal{B}_k \in \overline{\mathbf{B}}(m,n)$ which has no convergent subsequence in the set $\mathbf{B}$ of all controllable linear systems. Consider the case $q = 2, m = 1, n = 1$ and the systems described by the isometric state parameters $\left(\begin{smallmatrix} a & \beta\delta C'D \\ \gamma C & \delta D \end{smallmatrix}\right)$, where $0 < a < 1$ is a real number, C and D are 2×1 vectors of unit length, and β, γ, δ are real numbers to obtain an isometric matrix; that is, $\gamma = \sqrt{1-a^2}$, $\beta = -\gamma/a$, and $\delta = \{1 + \beta^2(C'D)^2\}^{-1/2}$. To guarantee minimality it is further assumed that $C'D \neq 0$. The corresponding isometric image representations are given by $\hat{G}(z) = \delta D + \beta\gamma\delta(C'D)C(z-a)^{-1}$, and the projection operators by $P = \hat{G}\hat{G}^*$. If $a \uparrow 1$ then $\gamma \to 0, \beta \to 0$, and $\delta \to 1$, so that the pointwise limit of $\hat{G}(z)$ is D for $z \neq 1$ and $\hat{G}(1)$ converges to $D - 2(C'D)C$. If the corresponding sequence of systems would have a limiting point, say with projection operator P_0, then it should hold that $\|P_0 - P\|_\infty \to 0$ for $a \uparrow 1$. As $P_0(z)$ is continuous on the unit circle the only candidate for P_0 is given by DD', but as $P(z)$ is also continuous and $P(1) \not\to DD'$ for $a \uparrow 1$, it follows that no subsequence can converge to a system in $\mathbf{B}$. □

In our analysis, not only the distance between two systems but also the distance between two sets of systems is of relevance. If $\mathbf{B}_1$ and $\mathbf{B}_2$ are two compact subsets of $\mathbf{B}$, then the Hausdorff distance between these sets is defined as

$$\mathrm{d_H}(\mathbf{B}_1,\mathbf{B}_2) := \max\{\rho(\mathbf{B}_1,\mathbf{B}_2), \rho(\mathbf{B}_2,\mathbf{B}_1)\}, \tag{17}$$

where $\rho(\mathbf{B}_1,\mathbf{B}_2) := \sup_{\mathcal{B}_1\in\mathbf{B}_1} \inf_{\mathcal{B}_2\in\mathbf{B}_2} \mathrm{d}(\mathcal{B}_1,\mathcal{B}_2)$.

In order to investigate continuity properties we also need a topology on the set of spectral densities. We use the metric defined by

$$\mathrm{d}(\Sigma_1,\Sigma_2) = \| \Sigma_1 - \Sigma_2 \|_\infty := \sup_{\lambda\in[-\pi,\pi]} \lambda_{\max}\{\Sigma_1(e^{-i\lambda}) - \Sigma_2(e^{-i\lambda})\}. \tag{18}$$

Under assumption A4 the spectra are bounded on the unit circle, so that this is a well-defined metric.

4.2. Continuity. We consider the relation between observed spectra and identified factor behaviors. For given spectrum Σ, complexity (m, n), and noise bound δ, we denote by $\mathbf{B}(\Sigma; \delta, m, n) \subseteq \mathbf{B}(m, n)$ the set of all behaviors of factor models $w = \hat{w} + \tilde{w}$ satisfying the conditions that the factor behavior has m inputs and n states and that the noise process has norm $\| \tilde{w} \| \leq \delta$. So this corresponds to the factor scheme with bounded noise. The set $\mathbf{B}(\Sigma; \delta, m, n)$ depends of course on the measure of fit and on the possible condition of orthogonality. As the results in this section hold true for all the four corresponding factor schemes, we will make no explicit distinction between them. Systems in $\mathbf{B}(\Sigma; \delta, m, n)$ are called feasible for the data Σ and the specified complexity and fit. The feasibility of a given behavior can be checked by means of the results in Theorem 3.1.

PROPOSITION 4.4.

(i) *The set of feasible systems* $\mathbf{B}(\Sigma; \delta, m, n)$ *depends on whether orthogonality is imposed or not, but it does not depend on whether observability is imposed or not.*

(ii) *The set* $\mathbf{B}(\Sigma; \delta, m, n)$ *is closed in* $\mathbf{B}(m, n)$ *but in general not in* $\mathbf{B}$.

(iii) *If* $\mathcal{B} \in \mathbf{B}(\Sigma; \delta, m, n)$ *has fit strictly better than* δ, *then it is an inner point of* $\mathbf{B}(\Sigma; \delta, m, n)$.

Proof. (i) This follows from Theorem 3.1.

(ii) The set $\mathbf{B}(\Sigma; \delta, m, n)$ is closed in $\mathbf{B}(m, n)$ by Proposition 6.3 in the appendix, but not in $\mathbf{B}$, as follows from Proposition 4.3(i).

(iii) This is immediate from Proposition 6.3. ∎

In order to use the Hausdorff metric (17) we next formulate a sufficient condition for compactness. We call a state dimension n *minimal* for given (Σ, δ, m) if there exists a feasible model of complexity (m, n) but not one of complexity (m, n') with $n' < n$, that is, if $\mathbf{B}(\Sigma; \delta, m, n) \neq \emptyset$ and $\mathbf{B}(\Sigma; \delta, m, n') = \emptyset$ for all $n' < n$. If we are only interested in Pareto optimal models, then this minimality condition can be imposed without loss of generality.

PROPOSITION 4.5. *If* n *is minimal for* (Σ, δ, m), *then the set of feasible systems* $\mathbf{B}(\Sigma; \delta, m, n)$ *is compact.*

Proof. We prove this in terms of isometric state space representations. For this purpose we first describe this parametrization in some more detail. By definition, systems in $\mathbf{B}(m, n)$ are controllable and so can be represented by an isometric state model that satisfies (5). Let $\Pi(m, n) \subset \mathbf{R}^{(n+q)\times(n+m)}$ be the set of all such minimal isometric system matrices and let $\Pi = \bigcup_{m=0}^{q} \bigcup_{n=1}^{\infty} \Pi(m, n)$. On this set we define the metric $\mathrm{d}(\pi_1, \pi_2) = \|\pi_1 - \pi_2\|_\infty$ if $(m_1, n_1) = (m_2, n_2)$ and $\mathrm{d}(\pi_1, \pi_2) = 3$ otherwise. It is easily verified that this is a metric on Π and that $\Pi(m, n)$ is open in Π. That the parametrization of $\mathbf{B}$ by Π is continuous can be seen as follows. Let $\pi_k \to \pi_0$; then for k sufficiently large there holds $(m_k, n_k) = (m_0, n_0)$. As π_0 is a minimal isometric representation, it follows that $A_0 A_0' + C_0 C_0' = I$ with (A_0, C_0) observable, so that A_0 has all its eigenvalues strictly within the unit circle. Then the mapping from (A, B, C, D) to the isometric image representation $\hat{G} = D + C(zI - A)^{-1}B$ is continuous in π_0, and so $\mathrm{d}(\mathcal{B}_k, \mathcal{B}_0) = \| \hat{G}_k \hat{G}_k^* - \hat{G}_0 \hat{G}_0^* \| \to 0$ for $k \to \infty$.

Because the parametrization is continuous, in order to prove that $\mathbf{B}(\Sigma; \delta, m, n)$ is a compact subset of $\mathbf{B}$ it suffices to prove that the corresponding set of parameters denoted by $\Pi_0 \subset \Pi$ is compact. As $\Pi(m, n) \subset \Pi$ is open, it suffices to prove that Π_0 is a compact subset of $\Pi(m, n)$, or also that it is a closed and bounded subset of the Euclidean space $\mathbf{R}^{(n+q)\times(n+m)}$. Because of the isometry condition, boundedness is evident, so it remains to prove the closedness of Π_0. We prove this by contradiction.

Suppose that there is a sequence of systems $\mathcal{B}_k \in \mathbf{B}(\Sigma;\delta,m,n)$ with minimal isometric representations $(A_k,B_k,C_k,D_k) \to (A_0,B_0,C_0,D_0)$ so that the system $\mathcal{B}_0$ corresponding to these limit parameters does not belong to $\mathbf{B}(\Sigma;\delta,m,n)$. Then A_0 has eigenvalues on the unit circle. Indeed, if this were not the case, then the parametrization would be continuous in (A_0,B_0,C_0,D_0) and hence, by Proposition 6.3, it would follow that $\mathrm{d}(\Sigma,\mathcal{B}_0) = \lim \mathrm{d}(\Sigma,\mathcal{B}_k) \le \delta$. As $\mathcal{B}_0$ has m inputs and n is assumed to be minimal for (Σ,δ,m), it would follow that $\mathcal{B}_0 \in \mathbf{B}(\Sigma;\delta,m,n)$, contradicting our assumption. Now, state directions corresponding to eigenvectors of unit eigenvalues of A_0 are not observable because of the isometry condition $A_0'A_0 + C_0'C_0 = I$. So the state space for $\mathcal{B}_0$ can be reduced by deleting such unobservable directions. Let (A,B,C,D_0) be the restriction of (A_0,B_0,C_0,D_0) to the observable subspace, so that A has all its eigenvalues strictly within the unit circle. Because the two representations describe the same system $\mathcal{B}_0$ with the same driving variables, it follows that $G_0(z) := D_0 + C(zI-A)^{-1}B = D_0 + C_0(zI-A_0)^{-1}B_0$ pointwise on the unit circle, with the exception of the eigenvalues $\{e^{-i\lambda_j}; j=1,\dots,r\}$ of A_0. Moreover, as G_0 is the pointwise limit of $G_k = D_k + C_k(zI-A_k)^{-1}B_k$ it follows that G_0 is an isometric image representation of $\mathcal{B}_0$, with m inputs and at most $n-r$ states.

We consider first the factor scheme without orthogonality and with the uniform norm. Using the notation (14), we obtain from Theorem 3.1(i) that the fit of the system in this case is given by $\mathrm{d}(\Sigma,\mathcal{B}_0) = \| \tilde{\Sigma}_0^{1/2} \|_\infty$, where $\tilde{\Sigma}_0 = (I - G_0G_0^*)\,\Sigma(I - G_0G_0^*)$. As n is minimal for (Σ,δ,m) and $\mathcal{B}_0$ has less than n states, it follows that $\sup_{\lambda\in[-\pi,\pi]} \lambda_{\max}\{\tilde{\Sigma}_0(e^{-i\lambda})\} > \delta^2$. Because of the continuity of $G_0(z)$ and $\Sigma(z)$ on the unit circle, there exists an $\varepsilon > 0$ so that also $\sup_{\lambda\in\Lambda} \lambda_{\max}\{\tilde{\Sigma}_0(e^{-i\lambda})\} > \delta^2$ where $\Lambda = \{\lambda \in [-\pi,\pi]; |\lambda - \lambda_j| \ge \varepsilon \text{ for all } j = 1,\dots,r\}$. As G_k converges pointwise to G_0 on the compact set Λ this implies that for k sufficiently large $\{\mathrm{d}(\Sigma,\mathcal{B}_k)\}^2 \ge \sup_{\lambda\in\Lambda} \lambda_{\max}\{(I-G_kG_k^*)\,\Sigma(I-G_kG_k^*)(e^{-i\lambda})\} > \delta^2$, but this contradicts the statement that $\mathcal{B}_k \in \mathbf{B}(\Sigma;\delta,m,n)$. This proves compactness for the factor scheme without orthogonality and with the uniform norm.

The result for the orthogonal factor scheme with uniform norm follows in a similar way by using Theorem 3.1(ii). For the mean squares norm the reasoning is similar. Under the previous assumptions, there would exist an $\varepsilon > 0$ such that $\frac{1}{2\pi}\int_\Lambda \mathrm{trace}\{\tilde{\Sigma}_0(e^{-i\lambda})\}d\lambda > \delta^2$, and as G_k converges uniformly to G_0 on the compact set Λ, this gives a contradiction as before. □

The set of feasible systems does not in general depend in a fully continuous way on the observed spectrum. Therefore, we use the weaker concept of upper semicontinuity. We call the set of feasible systems $\mathbf{B}(\Sigma;\delta,m,n)$ upper semicontinuous in (Σ,δ) if for all $(\Sigma_k,\delta_k) \to (\Sigma,\delta)$ and for $\mathcal{B}_k \in \mathbf{B}(\Sigma_k;\delta_k,m,n)$ with $\mathcal{B}_k \to \mathcal{B}_0$ it holds that $\mathcal{B}_0 \in \mathbf{B}(\Sigma;\delta,m,n)$. As the sets of feasible systems are in general not compact, upper semicontinuity is not equivalent to the condition that $\rho(\mathbf{B}_k,\mathbf{B}_0) = \sup_{\mathcal{B}_k\in\mathbf{B}_k} \inf_{\mathcal{B}_0\in\mathbf{B}_0} \mathrm{d}(\mathcal{B}_k,\mathcal{B}_0) \to 0$, where $\mathbf{B}_k := \mathbf{B}(\Sigma_k;\delta_k,m,n)$ and $\mathbf{B}_0 := \mathbf{B}(\Sigma;\delta,m,n)$. The following continuity results for feasible systems are valid for all factor schemes, that is, for the mean squares and uniform fit and for the cases with and without orthogonality constraint. We use the notation $\overline{\mathbf{B}}(\Sigma;\delta,m,n)$ for the set of all feasible systems for (Σ,δ) with m inputs and at most n states.

PROPOSITION 4.6.

(i) *The set* $\overline{\mathbf{B}}(\Sigma;\delta,m,n)$ *is upper semicontinuous in* (Σ,δ).

(ii) *If* n *is minimal for* (Σ,δ,m), *then* $\mathbf{B}(\Sigma;\delta,m,n)$ *is upper semicontinuous in* (Σ,δ).

(iii) *Let n be minimal for $(\Sigma; \delta+\eta, m, n)$ for some $\eta > 0$ and let $\mathbf{B}(\Sigma; \delta, m, n)$ be nonempty; then $\rho(\mathbf{B}(\Sigma_k; \delta_k, m, n), \mathbf{B}(\Sigma; \delta, m, n)) \to 0$ if $(\Sigma_k, \delta_k) \to (\Sigma, \delta)$.*

(iv) *Under the conditions in* (iii), *$\mathbf{B}(\Sigma; \delta, m, n)$ is continuous from the right in δ.*

Proof. (i) Let $(\Sigma_k, \delta_k) \to (\Sigma, \delta)$ and $\mathcal{B}_k \in \overline{\mathbf{B}}(\Sigma_k; \delta_k, m, n)$ with $\mathcal{B}_k \to \mathcal{B}$; then we have to prove that $\mathcal{B} \in \overline{\mathbf{B}}(\Sigma; \delta, m, n)$. That $\mathcal{B}$ has m inputs and at most n states follows from the fact that $\overline{\mathbf{B}}(m, n)$ is closed; see Proposition 4.3(ii). Further, Proposition 6.3 in the appendix implies that $\mathrm{d}(\Sigma_k, \mathcal{B}_k) \to \mathrm{d}(\Sigma, \mathcal{B})$, and this implies that $\mathrm{d}(\Sigma, \mathcal{B}) \le \delta$ so that $\mathcal{B} \in \overline{\mathbf{B}}(\Sigma; \delta, m, n)$.

(ii) This corresponds to the situation in (i), where now $\mathcal{B}_k$ all have complexity (m, n). If $\mathcal{B}_k \to \mathcal{B}$ then $\mathcal{B} \in \overline{\mathbf{B}}(m, n)$ and $\mathrm{d}(\Sigma, \mathcal{B}) \le \delta$. As n is minimal for (Σ, δ, m), it follows that $\mathcal{B} \in \mathbf{B}(m, n)$, so that $\mathcal{B} \in \mathbf{B}(\Sigma; \delta, m, n)$.

(iii) In a first step we prove that n is minimal for $(\Sigma_k, \delta+\eta, m)$ for all k large enough. If this is not true, then there exist $n' < n$ and infinitely many indices k, so that $\mathbf{B}(\Sigma_k; \delta+\eta, m, n')$ is not empty. For such indices let $\mathcal{B}_k \in \mathbf{B}(\Sigma_k; \delta+\eta, m, n')$ have minimal isometric representation (A_k, B_k, C_k, D_k); then the isometry condition implies that this sequence has a limit point, denoted by (A_0, B_0, C_0, D_0). Let $\mathcal{B}_0$ be the behavior corresponding to these parameters; then $\mathcal{B}_0 \in \mathbf{B}(m, n'')$ with $n'' \le n'$. As in the proof of Proposition 4.5, the isometric kernel representations $\tilde{G}_k$ converge pointwise on the unit circle to the kernel representation $\tilde{G}_0$ of $\mathcal{B}_0$, except for a finite number of points. This implies that $\mathrm{d}(\Sigma_0, \mathcal{B}_0) \le \delta+\eta$, which contradicts the minimality of n for $(\Sigma, \delta+\eta, m)$. So n is minimal for $(\Sigma_k, \delta+\eta, m)$ and therefore $\mathbf{B}(\Sigma_k; \delta_k, m, n)$ is compact for k sufficiently large.

Now suppose that there exists an $\varepsilon > 0$ and a sequence of systems $\mathcal{B}_k \in \mathbf{B}(\Sigma_k; \delta_k, m, n)$ so that $\mathrm{d}(\mathcal{B}_k, \mathcal{B}) \ge \varepsilon$ for all $\mathcal{B} \in \mathbf{B}(\Sigma; \delta, m, n)$. As $\mathrm{d}(\Sigma_k, \mathcal{B}_k) \le \delta_k$ and $(\Sigma_k, \delta_k) \to (\Sigma, \delta)$, it follows from Proposition 6.3 in the appendix that for k sufficiently large, $\mathcal{B}_k \in \mathbf{B}(\Sigma; \delta+\eta, m, n)$. As n is minimal for $(\Sigma, \delta+\eta, m)$, this is according to Proposition 4.5 a compact set, so the sequence $\mathcal{B}_k$ contains a limit point, that we denote by $\mathcal{B}_0 \in \mathbf{B}(\Sigma; \delta+\eta, m, n)$. It follows from Proposition 6.3 that $\mathrm{d}(\Sigma, \mathcal{B}_0) \le \delta$ and thus $\mathcal{B}_0 \in \mathbf{B}(\Sigma; \delta, m, n)$. From the assumption that $\mathrm{d}(\mathcal{B}_k, \mathcal{B}) \ge \varepsilon$ for all $\mathcal{B} \in \mathbf{B}(\Sigma; \delta, m, n)$ this implies that $\mathrm{d}(\mathcal{B}_k, \mathcal{B}_0) \ge \varepsilon$, but this contradicts the fact that $\mathcal{B}_0$ is a limit point of the sequence $\mathcal{B}_k$.

(iv) Let $\delta_k \downarrow \delta$; then, according to Proposition 4.5, the sets $\mathbf{B}(\Sigma; \delta_k, m, n)$ are compact for k sufficiently large. It follows from the result in (iii) that there holds $\rho(\mathbf{B}(\Sigma; \delta_k, m, n), \mathbf{B}(\Sigma; \delta, m, n)) \to 0$, and as $\mathbf{B}(\Sigma; \delta, m, n) \subseteq \mathbf{B}(\Sigma; \delta_k, m, n)$ it is trivial that $\rho(\mathbf{B}(\Sigma; \delta, m, n), \mathbf{B}(\Sigma; \delta_k, m, n)) = 0$. This proves convergence in the Hausdorff metric. ∎

It is also of interest to consider the continuity of Pareto optimal models. Continuity in this respect is connected with robustness in the sense that small perturbations in the data should lead to a small perturbation of optimal models. We analyze this for models that optimize the fit under a complexity constraint. For given spectrum Σ we denote by $\mathbf{B}^*(\Sigma; m, n)$ the set of behaviors of optimally fitting factor models with m inputs and n states, and by $\overline{\mathbf{B}}^*(\Sigma; m, n)$ the set of optimally fitting behaviors with m inputs and at most n states.

PROPOSITION 4.7.

(i) *The set $\overline{\mathbf{B}}^*(\Sigma; m, n)$ is upper semicontinuous in the spectrum Σ.*

(ii) *Let δ^* be the optimal fit in $\mathbf{B}(m, n)$ and let n be minimal for $(\Sigma, \delta^*+\eta, m)$ for some $\eta > 0$; then $\rho(\mathbf{B}^*(\Sigma_k; m, n), \mathbf{B}^*(\Sigma; m, n)) \to 0$ for $\Sigma_k \to \Sigma$.*

Proof. (i) Let $\Sigma_k \to \Sigma$ and let $\mathcal{B}_k$ be an optimal behavior in $\overline{\mathbf{B}}(m, n)$ for Σ_k with $\mathcal{B}_k \to \mathcal{B}$ for $k \to \infty$; then we have to prove that $\mathcal{B}$ is optimal for Σ. As $\overline{\mathbf{B}}(m, n)$

is closed, it follows that $\mathcal{B} \in \overline{\mathbf{B}}(m,n)$, and if this limit system is not optimal, then there exists a system $\mathcal{B}_0 \in \overline{\mathbf{B}}(m,n)$ so that $\mathrm{d}(\Sigma,\mathcal{B}_0) < \mathrm{d}(\Sigma,\mathcal{B})$. It then follows from Proposition 6.3 in the appendix that for k sufficiently large, $\mathrm{d}(\Sigma_k,\mathcal{B}_0) < \mathrm{d}(\Sigma_k,\mathcal{B}_k)$, but this contradicts the optimality of $\mathcal{B}_k$.

(ii) If this is not true, then there exists an $\varepsilon > 0$ and a sequence of systems $\mathcal{B}_k \in \mathbf{B}^*(\Sigma_k;m,n)$ so that for all $\mathcal{B} \in \mathbf{B}^*(\Sigma;m,n)$ there holds $\mathrm{d}(\mathcal{B}_k,\mathcal{B}) \geq \varepsilon$. Now let $\mathcal{B} \in \mathbf{B}^*(\Sigma;m,n)$, so that $\mathrm{d}(\Sigma,\mathcal{B}) = \delta^*$ and $\mathrm{d}(\Sigma_k,\mathcal{B}) \leq \delta^* + \eta_k$ with $\eta_k \downarrow 0$ for $k \to \infty$. It then follows that $\mathrm{d}(\Sigma_k,\mathcal{B}_k) \leq \delta^* + \eta_k$ and hence $\mathrm{d}(\Sigma,\mathcal{B}_k) \leq \delta^* + \eta$ for k sufficiently large. Because n is minimal for $(\Sigma,\delta^*+\eta,m)$ it follows that $\mathbf{B}(\Sigma;\delta^*+\eta,m,n)$ is compact, so that the sequence $\mathcal{B}_k$ has a limit point, say $\mathcal{B}_0 \in \mathbf{B}(m,n)$. As $\mathrm{d}(\mathcal{B}_k,\mathcal{B}) \geq \varepsilon$ for all $\mathcal{B} \in \mathbf{B}^*(\Sigma;m,n)$, the same holds true for $\mathcal{B}_0$, but this contradicts the fact that $\mathrm{d}(\Sigma,\mathcal{B}_0) = \lim \mathrm{d}(\Sigma_k,\mathcal{B}_k) = \delta^*$, so that $\mathcal{B}_0 \in \mathbf{B}^*(\Sigma;m,n)$. ∎

4.3. Consistency. Next we investigate the consistency of dynamic factor models when the spectrum is estimated from observed data. In applications the spectrum of the observed process will in general be unknown. Suppose that, apart from assumptions A1–A4, the available information on the process consists of an observed time series of length T. Let Σ_T denote an estimator of the process spectrum Σ that is based on this time series. In order to simplify the analysis we assume that the estimator is strongly consistent, so that $\mathrm{d}(\Sigma,\Sigma_T) \to 0$ almost surely for $T \to \infty$. A strongly consistent estimator can be obtained, for example, as follows. Let the observed process have spectrum $\Sigma(z) = \sum_{k=-\infty}^{\infty} R(k) z^{-k}$, where $R(k) := \mathrm{E}\{w(t)w'(t-k)\}$ are the process covariances, and let $\hat{R}_T(k) = \frac{1}{T}\sum_{t=k+1}^{T} w(t)w'(t-k)$ be the sample covariances.

PROPOSITION 4.8. *Under weak conditions on the data generating process, a strongly consistent estimator of Σ is given by $\Sigma_T(z) = \sum_{|k|\leq k_T} \hat{R}_T(k) z^{-k}$, where $k_T = \log(T)$.*

Proof. The estimation error is bounded by

$$\|\Sigma(z) - \Sigma_T(z)\|_\infty \leq (2k_T+1) \sup_{|k|\leq k_T} \|R(k) - \hat{R}_T(k)\| + \sum_{|k|>k_T} \|R(k)\|.$$

The second term converges to zero by assumption A4, and the first term converges to zero almost surely under weak conditions. A sufficient condition is that the spectrum Σ is rational, but the result also holds true for a broad class of nonrational spectra. For these results we refer to [13, Theorems 5.3.2 and 7.4.3]. ∎

In the following, let $\mathbf{B}_0 := \mathbf{B}(\Sigma;\delta,m,n)$ be the class of feasible models and $\mathbf{B}_0^* \subset \mathbf{B}(m,n)$ be the set of optimal models of complexity (m,n), that is, with optimal fit in this class. By $\overline{\mathbf{B}}_0$ and $\overline{\mathbf{B}}_0^*$ we denote the sets of feasible and optimal models, respectively, with m inputs and at most n states. Further, let $\mathbf{B}_T := \mathbf{B}(\Sigma_T;\delta,m,n)$ be the set of feasible models and $\mathbf{B}_T^*$ the set of optimal models of complexity (m,n) for the estimated spectrum Σ_T, and let $\overline{\mathbf{B}}_T$ and $\overline{\mathbf{B}}_T^*$ be the sets of feasible and optimal models, respectively, with m inputs and at most n states. These are random sets, since they depend on the observed time series. The next two theorems state consistency properties for feasible and optimal models, where it is assumed that the estimator Σ_T is strongly consistent.

THEOREM 4.9.

(i) *Behaviors with better fit than the noise bound are estimated consistently; that is, if a factor model has behavior $\mathcal{B}$ of complexity (m,n) and fit δ, then for $\delta' > \delta$, it holds almost surely that $\mathcal{B} \in \mathbf{B}(\Sigma_T;\delta',m,n)$ for $T \to \infty$.*

(ii) *The sample estimator of the set of feasible behaviors in $\overline{\mathbf{B}}(m,n)$ is upper semi-consistent, in the sense that $\{\mathcal{B}_T \in \overline{\mathbf{B}}_T, \mathcal{B}_T \to \mathcal{B}_0\} \Rightarrow \{\mathcal{B}_0 \in \overline{\mathbf{B}}_0\}$ holds almost*

surely; that is, the set of data with this convergence property has probability one.

(iii) *If n is minimal for $(\Sigma, \delta+\eta, m)$ for some $\eta > 0$, then the set of feasible sample behaviors in $\mathbf{B}(m,n)$ converges to a subset of the feasible behaviors for the process, in the sense that $\rho(\mathbf{B}_T, \mathbf{B}_0) \to 0$ almost surely for $T \to \infty$.*

Proof. (i) This is evident as $\Sigma_T \to \Sigma$ almost surely and $\mathrm{d}(\Sigma, \mathcal{B})$ is continuous; see Proposition 6.3 in the appendix.

(ii) This follows from Proposition 4.6(i).

(iii) This follows from Proposition 4.6(iii). ∎

THEOREM 4.10.

(i) *The sample estimator of the set of optimal behaviors in $\overline{\mathbf{B}}(m,n)$ is upper semiconsistent in the sense that $\{\mathcal{B}_T \in \overline{\mathbf{B}}^*_T, \mathcal{B}_T \to \mathcal{B}_0\} \Rightarrow \{\mathcal{B}_0 \in \overline{\mathbf{B}}^*_0\}$ almost surely.*

(ii) *If the process spectrum has a unique optimal factor behavior $\mathcal{B}^*_0$ of complexity (m,n) and if the infimum of the fits of models in $\overline{\mathbf{B}}(m,n-1)$ is strictly larger than the fit of $\mathcal{B}^*_0$, then this behavior is estimated consistently in the sense that $\mathrm{d_H}(\mathbf{B}^*_T, \{\mathcal{B}^*_0\}) \to 0$ almost surely for $T \to \infty$.*

Proof. (i) This follows from Proposition 4.7(i).

(ii) As it is given that $\mathbf{B}^*_0 = \{\mathcal{B}^*_0\}$ is a singleton, it follows that $\rho(\{\mathcal{B}^*_0\}, \mathbf{B}^*_T) = \inf_{\mathcal{B}\in\mathbf{B}^*_T} \mathrm{d}(\mathcal{B}^*_0, \mathcal{B}) \le \sup_{\mathcal{B}\in\mathbf{B}^*_T} \mathrm{d}(\mathcal{B}^*_0, \mathcal{B}) = \rho(\mathbf{B}^*_T, \{\mathcal{B}^*_0\})$, so it suffices to prove that the last expression converges to zero. Let the optimal fit for Σ_T among models of complexity (m,n) be given by δ^*_T and let $\delta^*_0 = \mathrm{d}(\Sigma, \mathcal{B}^*_0)$; then it follows from $\mathrm{d}(\Sigma_T, \mathcal{B}^*_0) \to \delta^*_0$ that $\delta^*_T \to \delta^*_0$ almost surely. Further, because of the assumption that $\inf\{\mathrm{d}(\Sigma, \mathcal{B}); \mathcal{B} \in \overline{\mathbf{B}}(m, n-1)\} > \delta^*_0$, it follows that n is minimal for all $(\Sigma, \delta^*_0+\eta, m)$ with $\eta \ge 0$ sufficiently small, and the same then holds true almost surely for $(\Sigma_T, \delta^*_T+\eta, m)$ if $T \to \infty$. Then, for T sufficiently large, $\mathbf{B}^*_T$ is a closed subset of the compact set $\mathbf{B}(\Sigma_T; \delta^*_T+\eta, m, n)$, so that $\mathbf{B}^*_T$ is compact. This means that the Hausdorff distance is well defined. Further, as $(\Sigma_T, \delta^*_T) \to (\Sigma, \delta^*_0)$ almost surely, it follows from Proposition 4.6(iii) that

$$\rho(\mathbf{B}^*_T, \{\mathcal{B}^*_0\}) = \rho(\mathbf{B}(\Sigma_T; \delta^*_T, m, n), \mathbf{B}(\Sigma; \delta^*_0, m, n)) \to 0 \text{ almost surely.} \qquad ∎$$

This means that, under the above conditions, the feasible and optimal finite sample systems are in the limit also feasible and optimal for the data generating process. However, it is possible that not all feasible and optimal systems are identified in this way.

4.4. Low noise consistency. We conclude our analysis by considering another kind of consistency, inspired by the concept of low noise as defined in [15]. This is based on the idea that an identification method which aspires to deal with noisy data must, as a minimal requirement, function well when dealing with data having low noise content. Let the observed process be given by $w = \hat{w}_0 + \tilde{w}_0$, where the latent process $\hat{w}_0$ is fixed and has behavior $\mathcal{B}_0$ of complexity (m_0, n_0) and where the noise process $\tilde{w}_0$ has norm δ_0. Low noise consistency corresponds to the condition that the factor behavior $\mathcal{B}_0$ is identified uniquely if the noise vanishes in the limit. The following result shows that this holds true, provided that the factor scheme is specified correctly.

PROPOSITION 4.11.

(i) *If the factor scheme, noise bound, and complexity have been specified correctly, then the factor behavior is identified; that is, if $\delta \ge \delta_0$, $m = m_0$, and $n = n_0$, then $\mathcal{B}_0 \in \mathbf{B}(\Sigma; \delta, m, n)$. If orthogonality is imposed but the data generating process does not satisfy this property, then the system need not be identified.*

(ii) *Correctly specified factor schemes are low noise consistent; that is, if* $\delta_0 \leq \delta \downarrow 0$, *then the set of feasible behaviors* $\mathbf{B}(\Sigma; \delta, m, n) \to \{\mathcal{B}_0\}$ *(in the sense of the Hausdorff metric) for* $(m, n) = (m_0, n_0)$, *and* $\mathbf{B}(\Sigma; \delta, m, n) \to \emptyset$ *if* $m < m_0$ *or* $m = m_0, n < n_0$. *Consistency is generally lost if orthogonality is imposed but the data generating process does not satisfy this property.*

Proof. (i) This is evident from the definition of $\mathbf{B}(\Sigma; \delta, m, n)$.

(ii) The process decomposition $w = \hat{w}_0 + \tilde{w}_0$ induces a corresponding spectral decomposition $\Sigma = \hat{\Sigma}_0 + \tilde{\Sigma}_0 + \Sigma_c + \Sigma_c{}'$, where $\hat{\Sigma}_0$ is the spectrum of the latent process $\hat{w}_0$, $\tilde{\Sigma}_0$ is the spectrum of the noise $\tilde{w}_0$, and Σ_c is the cross spectrum between $\hat{w}_0$ and $\tilde{w}_0$. As the latent process $\hat{w}_0$ is fixed and the noise converges to zero, it follows that $\| \Sigma - \hat{\Sigma}_0 \|_\infty = \| \tilde{\Sigma}_0 + \Sigma_c + \Sigma_c{}' \|_\infty \to 0$.

First we consider the factor scheme without orthogonality constraint. Then the misfit function $\mathrm{d}(\hat{\Sigma}_0, \mathcal{B})$ is also well defined for the singular spectral density $\hat{\Sigma}_0$; i.e., if P is the projection onto $\mathcal{B}$ and $\tilde{\Sigma} = (I - P)\, \hat{\Sigma}_0 (I - P)$, then $\mathrm{d}(\hat{\Sigma}_0, \mathcal{B}) = \| \tilde{\Sigma}^{1/2} \|$ and $\mathbf{B}(\hat{\Sigma}_0; \delta, m, n) = \{\mathcal{B} \in \mathbf{B}(m, n);\ \mathrm{d}(\hat{\Sigma}_0, \mathcal{B}) \leq \delta\}$. It can easily be shown, along the lines of the proof of Proposition 6.3 in the appendix, that $\mathrm{d}(\Sigma, \mathcal{B}) \to \mathrm{d}(\hat{\Sigma}_0, \mathcal{B}_*)$ if $\Sigma \to \hat{\Sigma}_0$ and $\mathcal{B} \to \mathcal{B}_*$. In addition, it holds that

$$\left| \mathrm{d}^2(\Sigma, \mathcal{B}) - \mathrm{d}^2(\hat{\Sigma}_0, \mathcal{B}) \right| \leq c \| \Sigma - \hat{\Sigma}_0 \|_\infty,$$

where $c = 2$ for the uniform norm and $c = 2\pi q$ for the mean squares norm. The above result follows from the proof of Lemma 6.2 in the appendix and the inequality $\|(I - P)(\Sigma - \hat{\Sigma}_0)(I - P)\|_\infty \leq \| \Sigma - \hat{\Sigma}_0 \|_\infty$.

We now first show that for $m < m_0$ or $m = m_0$, $n < n_0$, the infimum of the misfits $\mathrm{d}(\hat{\Sigma}_0, \mathcal{B})$ over the set of behaviors $\mathbf{B}(m, n)$ is strictly larger than zero. If this were not true, then there would exist a sequence of behaviors $\mathcal{B}_k \in \mathbf{B}(m, n)$ with corresponding projections P_k, such that $\mathrm{d}(\hat{\Sigma}_0, \mathcal{B}_k) \to 0$. As in the proof of Proposition 4.5, it follows that there exists a subsequence $k(l)$ and a behavior $\mathcal{B}_* \in \mathbf{B}(m, n'), n' \leq n$, with a corresponding projection P_*, such that $P_{k(l)}(z) \to P_*(z)$ for $l \to \infty$, pointwise on the unit circle except for a finite number of points. Then $\mathrm{d}(\hat{\Sigma}_0, \mathcal{B}_k) \to 0$ implies that $\mathrm{d}(\hat{\Sigma}_0, \mathcal{B}_*) = 0$, and this means that $\mathcal{B}_0 \subseteq \mathcal{B}_*$. This contradicts the assumption that the complexity (m, n) is smaller than the complexity (m_0, n_0) of $\mathcal{B}_0$. We conclude that the infimum of misfits of models of complexity $m < m_0$ or $m = m_0$, $n < n_0$ is given by a strictly positive number δ_*. Since $\| \Sigma - \hat{\Sigma}_0 \|_\infty$ converges to zero for $\delta \downarrow 0$, there exists a $\delta_+ > 0$ such that $c \| \Sigma - \hat{\Sigma}_0 \|_\infty < \delta_*^2$ for $\delta \leq \delta_+$. By the above considerations and inequalities, it holds for $\delta \leq \delta_+$ that

$$\mathrm{d}^2(\Sigma, \mathcal{B}) \geq \mathrm{d}^2(\hat{\Sigma}_0, \mathcal{B}) - c \| \Sigma - \hat{\Sigma}_0 \|_\infty > \delta_*^2 - \delta_*^2 = 0.$$

This shows that $\mathbf{B}(\Sigma; \delta, m, n)$ is empty for $m < m_0$ and for $m = m_0$, $n < n_0$ if $\delta \leq \delta_+$.

Now suppose that the complexity has been specified correctly. In this case $\mathcal{B}_0 \in \mathbf{B}(\Sigma; \delta, m_0, n_0)$ so that $\rho(\{\mathcal{B}_0\}, \mathbf{B}(\Sigma; \delta, m_0, n_0)) = 0$. Further, from the foregoing, it follows that n_0 is minimal for $(\hat{\Sigma}_0; \delta_+, m_0)$, as $\mathbf{B}(\hat{\Sigma}_0; \delta_+, m_0, n) = \emptyset$ for $n < n_0$ and $\mathbf{B}(\hat{\Sigma}_0; \delta_+, m_0, n_0)$ is not empty, and also $\mathbf{B}(\hat{\Sigma}_0; 0, m_0, n_0) = \{\mathcal{B}_0\}$. It follows from Proposition 4.6(iii) that $\rho(\mathbf{B}(\Sigma; \delta, m_0, n_0), \{\mathcal{B}_0\}) \to 0$.

Next we consider the factor scheme with orthogonality. By imposing the orthogonality constraint the sets $\mathbf{B}(\Sigma; \delta, m, n)$ generally become smaller. Since $\mathcal{B}_0 \in \mathbf{B}(\Sigma; \delta, m_0, n_0)$ for $\delta_0 \leq \delta$, the above results imply that $\mathbf{B}(\Sigma; \delta, m, n) \to \emptyset$ if the complexity (m, n) is smaller than (m_0, n_0) and that $\mathbf{B}(\Sigma; \delta, m_0, n_0) \to \{\mathcal{B}_0\}$.

That consistency is lost if orthogonality is imposed but the data generating process is not orthogonal is evident from Theorem 3.1(i), because this shows that in this

case the misfit δ_0 can in general not be obtained in the class of orthogonal models in $\mathbf{B}(m,n)$. □

4.5. Illustration. We will illustrate the foregoing results for static factor models, as in this case more explicit characterizations can be obtained. We will not further discuss the dynamic system example of sections 2.4 and 3.3, as the consistency analysis for dynamic factor models will be the topic of another paper.

So assume that the observed process w is white noise, and let Σ denote the covariance matrix of w. As we have seen in section 3.3.1, we can without loss of fit restrict ourselves to static relations. The set of all static systems $\mathbf{B}(m,0)$ is isomorphic to the set of all m-dimensional linear subspaces of $\mathbf{R}^q$. Isometric kernel representations of static systems are isometric matrices $\tilde{G} \in \mathbf{R}^{q\times m}$.

It can easily be seen that $\mathcal{B} \in \mathbf{B}(\Sigma;\delta,m,0)$ if and only if the isometry $\tilde{G}$ satisfies the following inequalities: for the nonorthogonal factor scheme, $\operatorname{trace}(\tilde{G}'\,\Sigma\,\tilde{G}) \le \delta^2$ for the mean squares norm and $\tilde{G}'(\Sigma - \delta^2 I)\,\tilde{G} \le 0$ for the uniform norm, and for the orthogonal factor scheme, $\operatorname{trace}(\Sigma\,\tilde{G}(\tilde{G}'\,\Sigma\,\tilde{G})^{-1}\,\tilde{G}'\,\Sigma) \le \delta^2$ and $\tilde{G}'(\Sigma^2 - \delta^2\,\Sigma)\,\tilde{G} \le 0$, respectively. From this characterization it follows that the sets $\mathbf{B}(\Sigma;\delta,m,0)$ of static systems are always compact.

Let $\lambda_1 > \lambda_2 > \cdots > \lambda_q > 0$ denote the eigenvalues of Σ, and let $\Sigma = \hat{\Sigma}_m + \tilde{\Sigma}_m$ be the principal component decomposition of Σ with m factors as in (15). The set $\mathbf{B}(\Sigma;\delta,m,0)$ is nonempty if and only if $\|\,\tilde{\Sigma}_m\,\| \le \delta$, that is, $\lambda_{m+1}^{1/2} \le \delta$ for the uniform norm and $(\lambda_{m+1} + \cdots + \lambda_q)^{1/2} \le \delta$ for the mean squares norm. Furthermore, one can show that the sets $\mathbf{B}(\Sigma;\delta,m,0)$ depend continuously on (Σ,δ) with the exception of points where $\|\,\tilde{\Sigma}_m\,\| = \delta$.

Let Σ_T denote a strongly consistent estimator of Σ. If $\|\,\tilde{\Sigma}_m\,\| < \delta$ then $\mathbf{B}(\Sigma_T;\delta,m,0)$ is a strongly consistent estimator of $\mathbf{B}(\Sigma;\delta,m,0)$. The principal component model of Σ_T is a strongly consistent estimator of the principal component model of Σ, so that the Pareto optimal models are estimated consistently.

5. Conclusion. Dynamic factor models decompose an observed process in terms of an underlying latent component and additional noise. The variables are treated in a completely symmetric way, and no assumptions on inputs and outputs are required. The latent process has a singular spectrum as it satisfies deterministic dynamic relationships. This means that the factor behavior consists of a linear dynamical system. In particular, the latent process has fewer free variables than the observed process. Depending on the chosen factor scheme, several interpretations of the noise process are possible. If the noise can be assumed to be uncorrelated with the latent process, this is called the orthogonal factor scheme. This is the usual assumption in the classical models of factor analysis. In other situations it is more natural to consider the latent process as an approximation of the observed process and to assume that the factor components are constructed from the observations. This is called the observable factor scheme.

Within this framework we investigated the representation of dynamic factor models and defined notions of complexity and goodness of fit. Concerning the identification of factor models we presented characterizations of Pareto optimal models and we derived results on consistency, both in the case of observed data and in the case of low noise.

An advantage of our approach is that it deals explicitly with the symmetric modeling of observed data by means of dynamic stochastic models. Other contributions in symmetric system modeling have been developed in the behavioral identification

of systems and in the structural analysis of factor models. In a sense, our approach can be seen as an extension of these two frameworks. It enriches the deterministic behavioral framework with a stochastic analysis, and it extends the traditionally structure-oriented analysis of factor models to a more empirical modeling setting.

Several questions deserve further investigation. Of special interest is the analysis of identification procedures within this framework. Another issue is the incorporation of prior knowledge, for example, concerning the input-output structure of the model. A further analysis of the probabilistic structure of factor models is needed in order to develop statistical test procedures, for example, to estimate the complexity of factor models from observed data.

6. Appendix.

LEMMA 6.1. *Let $A, B \in \mathbf{C}^{q\times q}$ be two positive semidefinite matrices, and let $\lambda_1(A) \geq \cdots \geq \lambda_q(A) \geq 0$ and $\lambda_1(B) \geq \cdots \geq \lambda_q(B) \geq 0$ be the eigenvalues of A and B, respectively. Then*

(i) $|\lambda_i(A) - \lambda_i(B)| \leq \|A - B\|_\infty$.

(ii) *For every unitary matrix $U \in \mathbf{C}^{q\times m}$, $U^*U = I$, there holds*

$$\begin{aligned} \operatorname{trace}(UU^*AUU^*) &= \operatorname{trace}(UAU^*) \geq \lambda_{m+1}(A) + \cdots + \lambda_q(A), \\ \lambda_{\max}(UU^*AUU^*) &= \lambda_{\max}(UAU^*) \geq \lambda_{m+1}(A). \end{aligned}$$

The lower bound is reached if the columns of U form a basis for the eigenspace of A corresponding to the $q - m$ smallest eigenvalues.

Proof. See [12, Corollary 8.1.3 and Theorem 8.1.2]. □

LEMMA 6.2. *Let Σ_k be a sequence of spectral densities that converges to Σ_0 in the sense that $\| \Sigma_k - \Sigma_0 \|_\infty \to 0$. Then*

(i) $\| \Sigma_k^{1/2} \| \to \| \Sigma_0^{1/2} \|$.

(ii) *if Σ_0 is positive definite, then Σ_k is positive definite for all k sufficiently large and $\| \Sigma_k^{-1} - \Sigma_0^{-1} \|_\infty \to 0$.*

Proof. (i) By Lemma 6.1 $|\lambda_i(\Sigma_k(z)) - \lambda_i(\Sigma_0(z))| \leq \| \Sigma_k - \Sigma_0 \|_\infty$ pointwise on the unit circle, so that

$$\begin{aligned} |\| \Sigma_k^{1/2} \|_2^2 - \| \Sigma_0^{1/2} \|_2^2| &= |\oint_{|z|=1} \operatorname{trace}(\Sigma_k(z) - \Sigma_0(z))dz| \\ &\leq 2\pi q \| \Sigma_k - \Sigma_0 \|_\infty, \\ |\| \Sigma_k^{1/2} \|_\infty^2 - \| \Sigma_0^{1/2} \|_\infty^2| &= |\sup_{|z|=1} \lambda_{\max}(\Sigma_k(z)) - \sup_{|z|=1} \lambda_{\max}(\Sigma_0(z))| \\ &\leq 2\| \Sigma_k - \Sigma_0 \|_\infty. \end{aligned}$$

(ii) By the assumption $\Sigma_0 > 0$ and the result in Lemma 6.1 for the eigenvalues of Σ_k, it follows that $\| \Sigma_0^{-1} \|_\infty = 1/\{\inf_{|z|=1} \lambda_{\min}(\Sigma_0(z))\}$ and $\| \Sigma_k^{-1} \|_\infty$ are bounded. The result then follows from

$$\| \Sigma_k^{-1} - \Sigma_0^{-1} \|_\infty = \| \Sigma_k^{-1}(\Sigma_0 - \Sigma_k) \Sigma_0^{-1} \|_\infty \leq \| \Sigma_k^{-1} \|_\infty \|(\Sigma_0 - \Sigma_k)\|_\infty \| \Sigma_0^{-1} \|_\infty. \qquad \square$$

PROPOSITION 6.3. *The misfit function $\mathrm{d}(\Sigma, \mathcal{B})$ is continuous in $(\Sigma, \mathcal{B})$ for all positive definite spectral densities Σ.*

Proof. Let $\Sigma_k \to \Sigma_0 > 0$ and $\mathcal{B}_k \to \mathcal{B}_0$ be convergent sequences of spectral densities and behaviors, respectively. The corresponding isometric kernel representations of $\mathcal{B}_k$, $\mathcal{B}_0$ are denoted by $\tilde{G}_k$ and $\tilde{G}_0$, respectively. The optimal noise spectra, given in Theorem 3.1, corresponding to the spectral densities Σ_k, Σ_0 and the behaviors $\mathcal{B}_k$, $\mathcal{B}_0$ are denoted by $\tilde{\Sigma}_k$ and $\tilde{\Sigma}_0$, respectively. By Lemma 6.2 it suffices to show that $\| \tilde{\Sigma}_k - \tilde{\Sigma}_0 \|_\infty \to 0$.

For the case without orthogonality the noise spectra are given by

$$\tilde{\Sigma}_k = \tilde{G}_k \, \tilde{G}_k^* \, \Sigma_k \, \tilde{G}_k \, \tilde{G}_k^* \quad \text{and} \quad \tilde{\Sigma}_0 = \tilde{G}_0 \, \tilde{G}_0^* \, \Sigma_0 \, \tilde{G}_0 \, \tilde{G}_0,$$

in which case $\| \tilde{\Sigma}_k - \tilde{\Sigma}_0 \|_\infty \to 0$ is evident.

For the case with orthogonality, let $\bar{G}_k = \tilde{G}_k \, \tilde{G}_k^* \, \tilde{G}_0$; then $\|\bar{G}_k - \tilde{G}_0 \|_\infty \leq \| \tilde{G}_k \, \tilde{G}_k^* - \tilde{G}_0 \, \tilde{G}_0^* \|_\infty \| \tilde{G}_0 \|_\infty \to 0$. The noise spectra for this factor scheme are given by

$$\tilde{\Sigma}_0 = \Sigma_0 \, \tilde{G}_0 (\tilde{G}_0^* \, \Sigma_0 \, \tilde{G}_0)^{-1} \, \tilde{G}_0^* \, \Sigma_0,$$

$$\tilde{\Sigma}_k = \Sigma_k \, \tilde{G}_k (\tilde{G}_k^* \, \Sigma_k \, \tilde{G}_k)^{-1} \, \tilde{G}_k^* \, \Sigma_k = \Sigma_k \, \bar{G}_k (\bar{G}_k^* \, \Sigma_k \, \bar{G}_k)^{-1} \bar{G}_k^* \, \Sigma_k,$$

where the last equality follows from the fact that $\tilde{G}_k^* \, \tilde{G}_0 \to I$, so that this is invertible for k sufficiently large. The result now follows from Lemma 6.2. ∎

ERGODIC CONTROL OF SWITCHING DIFFUSIONS*

MRINAL K. GHOSH†, ARISTOTLE ARAPOSTATHIS‡, AND STEVEN I. MARCUS§

Abstract. We study the ergodic control problem of switching diffusions representing a typical hybrid system that arises in numerous applications such as fault-tolerant control systems, flexible manufacturing systems, etc. Under fairly general conditions, we establish the existence of a stable, nonrandomized Markov policy which almost surely minimizes the pathwise long-run average cost. We then study the corresponding Hamilton–Jacobi–Bellman (HJB) equation and establish the existence of a unique solution in a certain class. Using this, we characterize the optimal policy as a minimizing selector of the Hamiltonian associated with the HJB equations. As an example we apply the results to a failure-prone manufacturing system and obtain closed form solutions for the optimal policy.

Key words. switching diffusions, Markov policy, ergodicity, pathwise average cost, Hamilton–Jacobi–Bellman equations

1. Introduction.

We address the problem of controlling switching diffusions by continually monitoring the continuous and discrete component of the state. The objective is to minimize, almost surely (a.s.), the pathwise long-run average (ergodic) cost over all admissible policies. A controlled switching diffusion is a typical example of a hybrid system which arises in numerous applications of systems with multiple modes or failure modes, such as fault-tolerant control systems, multiple target tracking, flexible manufacturing systems, etc. [13], [14], [23]. The state of the system at time t is given by a pair $\big(X(t), S(t)\big) \in \mathbb{R}^d \times \mathcal{S}$, $\mathcal{S} = \{1, 2, \dots, N\}$. The continuous component $X(t)$ is governed by a "controlled diffusion process" with a drift vector which depends on the discrete component $S(t)$. Thus, $X(t)$ switches from one diffusion path to another as the discrete component $S(t)$ jumps from one state to another. On the other hand, the discrete component $S(t)$ is a "controlled Markov chain" with a transition matrix depending on the continuous component. The evolution of the process $\big(X(t), S(t)\big)$ is governed by the following equations:

$$dX(t) = b\big(X(t), S(t), u(t)\big)dt + \sigma\big(X(t), S(t)\big)dW(t), \tag{1.1}$$

$$P\big(S(t+\delta t) = j \mid S(t) = i, X(s), S(s), s \le t\big) = \lambda_{ij}\big(X(t), u(t)\big)\delta t + o(\delta t), \quad i \ne j, \tag{1.2}$$

for $t \ge 0$, $X(0) = X_0$, $S(0) = S_0$, where b, σ, λ are suitable functions, $\lambda_{ij} \ge 0$ for $i \ne j$, $\sum_{j=1}^{N} \lambda_{ij} = 0$, $W(\cdot)$ is a standard Brownian motion, and $u(\cdot)$ is a nonanticipative

control process (admissible policy). The latter is called a Markov policy if $u(t) = v\big(X(t), S(t)\big)$ for a suitable function v. Our goal is to minimize a.s. over all admissible policies the functional

$$\limsup_{T\to\infty} \frac{1}{T}\int_0^T c\big(X(t), S(t), u(t)\big)dt\,, \tag{1.3}$$

where c is the running-cost function. Note that in (1.3) there is no expectation; we are minimizing the limiting pathwise average cost. Such a criterion is very important in practical applications since we often deal with a single realization. Under certain conditions, we show that there exists a Markov policy v^* and constant ρ^* such that

$$\lim_{T\to\infty} \frac{1}{T}\int_0^T c\big(X(t), S(t), v^*(X(t), S(t))\big)dt = \rho^* \quad \text{a.s.},$$

and for any other admissible policy $v(\cdot)$

$$\liminf_{T\to\infty} \frac{1}{T}\int_0^T c\big(X(t), S(t), v(t)\big)dt \geq \rho^* \quad \text{a.s.}$$

This establishes that v^* is optimal in a much stronger sense; viz., the most "pessimistic" average cost under v^* is no worse than the most "optimistic" average cost under any other admissible policy. Also, under the conditions assumed in this paper, the optimal pathwise average cost coincides with the optimal expected average cost. So we do not distinguish between these two criteria.

Our paper is organized as follows. In section 2 we present and analyze a motivating example, while in section 3 we introduce a concise mathematical model of the switching diffusion. Section 4 is devoted to the study of recurrence and ergodicity of switching diffusions. The existence of an optimal policy is established in section 5. The HJB equations are studied in section 6. Conclusions are in section 7.

2. A motivating example. The failure-prone manufacturing system presented in [1], [5], [14] is a very good example of the class of systems studied in this paper. This section is devoted to the analysis of this manufacturing model. Results from subsequent sections will be used in this example and thus the reader will have the opportunity to glimpse some of the key developments of the paper.

Suppose that there is one machine producing a single commodity. We assume that the demand rate is a constant $d > 0$. Let the machine state $S(t)$ take values in $\{0, 1\}$, $S(t) = 0$ or 1, according as the machine is down or functional. We model $S(t)$ as a continuous time Markov chain with generator

$$\begin{bmatrix} -\lambda_0 & \lambda_0 \\ \lambda_1 & -\lambda_1 \end{bmatrix},$$

where λ_0 and λ_1 are positive constants corresponding to the infinitesimal rates of repair and failure, respectively. The inventory $X(t)$ is governed by the Ito equation

$$dX(t) = \big(u(t) - d\big)dt + \sigma dW(t)\,, \tag{2.1}$$

where $\sigma > 0$, $u(t)$ is the production rate, and $W(t)$ is a one-dimensional Wiener process independent of $S(t)$. The last term in (2.1) can be interpreted as "sales

return," "inventory spoilage," "sudden demand fluctuations," etc. A negative value of $X(t)$ represents backlogged demand. The production rate is constrained by

$$u(t) \in \begin{cases} \{0\} & \text{if } S(t) = 0, \\ [0, r] & \text{if } S(t) = 1. \end{cases}$$

Let $c : \mathbb{R} \to \mathbb{R}_+$ be the cost function which is assumed to be convex and Lipschitz. Also, $c(x) \geq g(|x|)$ for some increasing function $g : \mathbb{R}_+ \to \mathbb{R}_+$. Thus, c satisfies (5.3), a required condition for the validity of our results. We show later in this section that a certain hedging-point policy is stable. Therefore, by the results of section 5, there exists an a.s. optimal nonrandomized Markov policy with respect to the cost criterion

$$\limsup_{T\to\infty} \frac{1}{T} \int_0^T c(X(t))dt\,.$$

The HJB equations in this case are

$$\begin{aligned} (2.2) \quad & \begin{pmatrix} \frac{\sigma^2}{2}V''(x,0) - dV'(x,0) \\ \frac{\sigma^2}{2}V''(x,1) + \min\limits_{u\in[0,r]}\{(u-d)V'(x,1)\} \end{pmatrix} + \begin{bmatrix} -\lambda_0 & \lambda_0 \\ \lambda_1 & -\lambda_1 \end{bmatrix} \begin{pmatrix} V(x,0) \\ V(x,1) \end{pmatrix} \\ & \qquad + \begin{pmatrix} 1 \\ 1 \end{pmatrix} c(x) = \begin{pmatrix} 1 \\ 1 \end{pmatrix} \rho\,. \end{aligned}$$

The results of section 6 ensure existence of a C^2 solution (V, ρ^*) of (2.2), where ρ^* is the optimal cost. Using the convexity of $c(\cdot)$, it can be shown that $V(\cdot, i)$ is convex for each i. Hence, there exists an x^* such that

$$\begin{aligned} & V'(x,1) \leq 0 \qquad \text{for } x \leq x^*, \\ (2.3) \quad & V'(x,1) \geq 0 \qquad \text{for } x \geq x^*. \end{aligned}$$

It follows from (2.3) that the value of u which minimizes $(u-d)V'(x,1)$ is

$$u = \begin{cases} r & \text{if } x < x^*, \\ 0 & \text{if } x > x^*. \end{cases}$$

Since $V'(x^*,1) = 0$, any $u \in [0,r]$ minimizes $(u-d)V'(x^*,1)$. Therefore, in view of Theorem 6.2, the action $u \in [0,r]$ can be chosen arbitrarily at $x = x^*$. To be specific, we let $u(x^*) = d$, i.e., we produce at the level that meets the demand exactly. Thus, the following stable, nonrandomized Markov policy is optimal:

$$(2.4) \qquad v^*(x,0) = 0, \qquad v^*(x,1) = \begin{cases} r & \text{if } x < x^*, \\ d & \text{if } x = x^*, \\ 0 & \text{if } x > x^*. \end{cases}$$

Note that the stability of the policy (2.4) follows from Theorem 6.3 provided that the set of stable, nonrandomized Markov policies is nonempty. We show next that the

zero-inventory policy v given by

$$v(x,0)=0, \qquad v(x,1)=\begin{cases} r & \text{if } x\le 0,\\ 0 & \text{if } x>0 \end{cases} \tag{2.5}$$

is stable if and only if

$$\frac{(r-d)}{\lambda_1} > \frac{d}{\lambda_0}\,. \tag{2.6}$$

The condition (2.6) is in accord with intuition. Note that λ_0^{-1} and λ_1^{-1} are the mean sojourn times of the chain in states 0 and 1, respectively. In state 0 the mean inventory depletes at a rate d while in state 1 it builds up at a rate $(r-d)$. Thus, if (2.6) is satisfied, one would expect the zero-inventory policy to stabilize the system. Our analysis confirms this intuition. We first show that under v the process $\big(X(\cdot),S(\cdot)\big)$ has an invariant probability measure η_v with a strictly positive density. In view of Lemma 4.1, it then follows from the ergodic theory of Markov processes [25, Chap. 1] that $\big(X(\cdot),S(\cdot)\big)$ is positive recurrent, or equivalently that v is stable.

By Lemma 5.2, the density φ of the invariant probability measure η_v can be obtained by solving the adjoint system

$$(L^v)^*\varphi(x,i)=0\,, \tag{2.7}$$

subject to

$$\varphi(x,i)>0, \qquad \sum_{i\in\{0,1\}}\int_{\mathbb{R}}\varphi(x,i)\,dx=1\,, \tag{2.8}$$

where L^v is the differential generator defined in (3.6)–(3.8). Define

$$\tilde\lambda_0:=\frac{2\lambda_0}{\sigma^2}, \quad \tilde\lambda_1:=\frac{2\lambda_1}{\sigma^2}, \quad \tilde d:=\frac{2d}{\sigma^2}, \quad \text{and} \quad \tilde r:=\frac{2r}{\sigma^2}\,.$$

Then (2.7) is equivalent to

$$\begin{aligned} &\varphi''(x,0)+\tilde d\varphi'(x,0)-\tilde\lambda_0\varphi(x,0)+\tilde\lambda_1\varphi(x,1)=0\\ &\varphi''(x,1)+\tilde d\varphi'(x,1)-\tilde\lambda_1\varphi(x,1)+\tilde\lambda_0\varphi(x,0)=0 \end{aligned} \qquad \text{for } \ x>0, \tag{2.9a}$$

$$\begin{aligned} &\varphi''(x,0)+\tilde d\varphi'(x,0)-\tilde\lambda_0\varphi(x,0)+\tilde\lambda_1\varphi(x,1)=0\\ &\varphi''(x,1)-(\tilde r-\tilde d)\varphi'(x,1)-\tilde\lambda_1\varphi(x,1)+\tilde\lambda_0\varphi(x,0)=0 \end{aligned} \qquad \text{for } \ x<0. \tag{2.9b}$$

A solution of (2.9), subject to the constraint (2.8), exists if and only if (2.6) holds and takes the form

$$\varphi(x)=\begin{pmatrix}\varphi(x,0)\\ \varphi(x,1)\end{pmatrix}=\begin{cases} a_1\begin{pmatrix}\tilde\lambda_1\\ \tilde\lambda_0\end{pmatrix}e^{-s_1x}+a_2\begin{pmatrix}-\tilde\lambda_1\\ \tilde\lambda_1\end{pmatrix}e^{-s_2x} & \text{for } x\ge 0,\\ a_3\begin{pmatrix}\tilde\lambda_1\\ -\psi(s_3)\end{pmatrix}e^{s_3x}+a_4\begin{pmatrix}-\tilde\lambda_1\\ \psi(s_4)\end{pmatrix}e^{s_4x} & \text{for } x<0, \end{cases} \tag{2.10}$$

where $\psi(s) = s^2 + \tilde{d}s - \tilde{\lambda}_0$, $s_1 = \tilde{d}$, $s_2 = \frac{\tilde{d}}{2} + \frac{1}{2}\big[\tilde{d}^2 + 4(\tilde{\lambda}_0 + \tilde{\lambda}_1)\big]^{1/2}$, and s_3, s_4 are the positive roots of the polynomial

$$s^3 - (\tilde{r} - 2\tilde{d})s^2 - \big[(\tilde{r} - \tilde{d})\tilde{d} + \tilde{\lambda}_0 + \tilde{\lambda}_1\big]s + \big[(\tilde{r} - \tilde{d})\tilde{\lambda}_0 - \tilde{d}\tilde{\lambda}_1)\big]\,,$$

ordered by $0 < s_3 < s_4$. Also, the coefficients $\{a_1, a_2, a_3, a_4\}$ are given by

$$\begin{aligned}
a_1 &= \frac{1}{\Delta}\Big\{\frac{(s_4 - s_3)s_2}{\tilde{\lambda}_0 + \tilde{\lambda}_1} + \frac{s_4 + s_2}{s_3 + \tilde{d}} - \frac{s_3 + s_2}{s_4 + \tilde{d}}\Big\},\\
a_2 &= \frac{1}{\Delta}\frac{(s_4 - s_3)s_2}{\tilde{\lambda}_0 + \tilde{\lambda}_1},\\
a_3 &= \frac{1}{\Delta}\frac{s_4 + s_2}{s_3 + \tilde{d}},\\
a_4 &= \frac{1}{\Delta}\frac{s_3 + s_2}{s_4 + \tilde{d}},\\
\Delta &= \frac{(s_4 - s_3)(s_2 - \tilde{d})}{\tilde{d}} + \frac{\tilde{\lambda}_0 + \tilde{\lambda}_1}{\tilde{d}}\Big\{\frac{s_4 + s_2}{s_3} - \frac{s_3 + s_2}{s_4}\Big\}.
\end{aligned} \tag{2.11}$$

Note that if $\varphi_{x^*}(\cdot)$ denotes the density of the invariant measure corresponding to a hedging-point policy as in (2.4), then

$$\varphi_{x^*}(x) = \varphi(x - x^*)\,.$$

Given a convex cost function, the average cost $\rho(x^*)$ corresponding to such a policy can be readily computed and is a convex function of the threshold value x^*.

In [5], Bielecki and Kumar have studied the mean square stability of the piecewise deterministic system, i.e., (2.1) with $\sigma = 0$. They have shown that under (2.6) the policy (2.5) is mean square stable, and have computed the optimal threshold value x^* in (2.4). These results can be easily reproduced here by computing the limiting value of the invariant distribution as $\sigma \to 0$, which we do next. The roots s_2, s_3, and s_4 have the following asymptotic dependence on σ:

$$s_2 = \frac{2d}{\sigma^2} + \mathcal{O}(1), \quad s_3 = \frac{(r-d)\lambda_0 - d\lambda_1}{d(r-d)} + \mathcal{O}(\sigma^2), \quad s_4 = \frac{2(r-d)}{\sigma^2} + \mathcal{O}(1)\,. \tag{2.12}$$

Thus, using (2.11), we obtain

$$\begin{aligned}
a_1, a_2 &= \frac{d\big[(r-d)\lambda_0 - d\lambda_1\big]}{r(\lambda_0 + \lambda_1)^2} + \mathcal{O}(\sigma^2),\\
a_3 &= \frac{\sigma^2}{2}\frac{\big[(r-d)\lambda_0 - d\lambda_1\big]}{d(r-d)(\lambda_0 + \lambda_1)} + \mathcal{O}(\sigma^4),\\
a_4 &= \frac{\sigma^2}{2}\frac{d\big[(r-d)\lambda_0 - d\lambda_1\big]}{r^2(r-d)(\lambda_0 + \lambda_1)} + \mathcal{O}(\sigma^4)\,.
\end{aligned} \tag{2.13}$$

Let

$$\alpha_0 := \frac{(r-d)\lambda_0 - d\lambda_1}{d(r-d)}$$

and $\delta_z(x)$ denote the Dirac measure centered at z. Using (2.12) and (2.13), we can show that as $\sigma \to 0$, $\varphi_{x^*}(\cdot)$ converges weakly to a distribution with "density" $\overline{\varphi}_{x^*}(\cdot)$, given by

$$\overline{\varphi}_{x^*}(x,i) = \begin{cases} \frac{\lambda_1\alpha_0}{\lambda_0+\lambda_1} e^{\alpha_0(x-x^*)} & \text{for } x \le x^*,\ i=0, \\ \frac{d\alpha_0}{\lambda_0+\lambda_1}\delta_{x^*}(x) + \frac{d\lambda_1\alpha_0}{(r-d)(\lambda_0+\lambda_1)} e^{\alpha_0(x-x^*)} & \text{for } x \le x^*,\ i=1, \\ 0 & \text{for } x > x^*. \end{cases}$$

Using, as in [5], a cost of the form

$$c(x) = \frac{c^+ + c^-}{2}|x| + \frac{c^+ - c^-}{2}x\,, \tag{2.14}$$

with c^+ and c^- positive constants, the average cost corresponding to the policy in (2.4) takes the form

$$\begin{aligned} \rho(x^*) &= \sum_{i=0,1} \int_{-\infty}^{x^*} c(x)\overline{\varphi}_{x^*}(x,i)\,dx \\ &= c^+x^* - \frac{c^+r\lambda_1}{(r-d)(\lambda_0+\lambda_1)\alpha_0} + \frac{r\lambda_1(c^+ + c^-)}{(r-d)(\lambda_0+\lambda_1)\alpha_0} e^{-\alpha_0 x^*}. \end{aligned}$$

In this manner, the results in [5] are reproduced exactly. One advantage of our approach is that the class of admissible policies does not have to be restricted as is done in [5], in order to guarantee the existence of solutions. With our method, optimality is obtained with respect to the class of all nonanticipative policies. Furthermore, our analysis shows that the stability of the zero-inventory policy is retained under additive noise in (2.1). Let us also note that conditions for the optimality of the zero-inventory policy under additive noise can be readily obtained for the cost in (2.14) using the density in (2.10).

3. The mathematical model. We first show that the switching diffusion (1.1), (1.2) can be constructed on a given probability space. Our presentation follows [13], [14]; we repeat it here for the sake of clarity and completeness. Let U be a compact metric space, $\mathcal{S} := \{1, 2, \dots, N\}$, and

$$\begin{aligned} &\overline{b} = \big[\overline{b}_1, \dots, \overline{b}_d\big]' : \mathbb{R}^d \times \mathcal{S} \times U \to \mathbb{R}^d, \\ &\sigma = \big[\sigma_{ij}(\cdot,\cdot)\big] : \mathbb{R}^d \times \mathcal{S} \to \mathbb{R}^{d\times d}, \\ &\overline{\lambda}_{ij} : \mathbb{R}^d \times U \to \mathbb{R}, \qquad i,j \in \mathcal{S}\,, \\ &\overline{\lambda}_{ij} \ge 0 \text{ for } i \ne j, \qquad \sum_{j\in\mathcal{S}} \overline{\lambda}_{ij} = 0 \text{ for any } i \in \mathcal{S}. \end{aligned}$$

We also define the matrix $\widetilde{\Lambda} : \mathbb{R}^d \times U \to \mathbb{R}^{N\times N}$ by

$$\big[\widetilde{\Lambda}(x,u)\big]_{ij} = \begin{cases} \overline{\lambda}_{ij}(x,u)\,, & i \ne j, \\ 0\,, & i = j\,. \end{cases}$$

We make the following assumptions which will be in effect throughout the paper.

Assumption 3.1.

(i) The functions $\overline{b}(x,k,u)$, $\sigma_{ij}(x,k)$, and $\overline{\lambda}_{ij}(x,u)$ are continuous and Lipschitz in x, uniformly with respect to u, with a Lipschitz constant γ_0. Let m_0 denote the least upper bound of $\|\overline{b}(0,k,\cdot)\|_\infty$, $|\sigma_{ij}(0,k)|$, and $\|\overline{\lambda}_{ij}(0,\cdot)\|_\infty$.

(ii) $\sigma_{ij}(\cdot,\cdot)$ is uniformly elliptic; i.e., there exists a constant $m>0$ such that $\sigma(\cdot,k)\sigma'(\cdot,k)\ge mI$.

(iii) The matrix $\widetilde{\Lambda}(x,u)$ is irreducible for all $(x,u)\in\mathbb{R}^d\times U$.

For a Polish space Y, $\mathfrak{B}(Y)$ denotes its Borel σ-field and $\boldsymbol{\mathcal{P}}(Y)$ the space of probability measures endowed with the Prohorov topology, i.e., the topology of weak convergence. Let $\mathfrak{M}(Y)$ be the set of all nonnegative, integer-valued, σ-finite measures on $\mathfrak{B}(Y)$. Let $\mathfrak{M}_\sigma(Y)$ be the smallest σ-field on $\mathfrak{M}(Y)$ with respect to which all the maps from $\mathfrak{M}(Y)$ to $\mathbb{N}\bigcup\{\infty\}$ of the form $\mu\mapsto\mu(B)$ with $B\in\mathfrak{B}(Y)$ are measurable. $\mathfrak{M}(Y)$ is assumed to be endowed with this measurability structure. Let $\mathcal{V}=\boldsymbol{\mathcal{P}}(U)$ and $b=\big[b_1,\dots,b_d\big]'\colon\mathbb{R}^d\times\mathcal{S}\times\mathcal{V}\to\mathbb{R}^d$ be defined by

$$b_i(\cdot,\cdot,v)=\int_U \overline{b}_i(\cdot,\cdot,u)v(du)\,. \tag{3.1}$$

Similarly, for $i,j\in\mathcal{S}$ and $v\in\mathcal{V}$, λ_{ij} is defined as

$$\lambda_{ij}(\cdot,v)=\int_U \overline{\lambda}_{ij}(\cdot,u)v(du)\,. \tag{3.2}$$

For $i,j\in\mathcal{S}$, $x\in\mathbb{R}^d$, and $v\in\mathcal{V}$, let $\Delta_{ij}(x,v)$ be consecutive (with respect to the lexicographic ordering on $\mathcal{S}\times\mathcal{S}$), left closed, right open intervals of the real line, each having length $\lambda_{ij}(x,v)$. Define a function $h:\mathbb{R}^d\times\mathcal{S}\times\mathcal{V}\times\mathbb{R}\longrightarrow\mathbb{R}$ by

$$h(x,i,v,z)=\begin{cases} j-i & \text{if } z\in\Delta_{ij}(x,v),\\ 0 & \text{otherwise.}\end{cases} \tag{3.3}$$

Let $\big(X(t),S(t)\big)$ be the $(\mathbb{R}^d\times\mathcal{S})$-valued, controlled, switching diffusion process given by the following stochastic differential equations:

$$\begin{aligned} dX(t)&=b\big(X(t),S(t),v(t)\big)\,dt+\sigma\big(X(t),S(t)\big)dW(t),\\ dS(t)&=\int_{\mathbb{R}} h\big(X(t),S(t-),v(t),z\big)\,\mathfrak{p}(dt,dz)\end{aligned} \tag{3.4}$$

for $t\ge0$ with $X(0)=X_0$, $S(0)=S_0$, where

(i) X_0 is a prescribed $\mathbb{R}^d$-valued random variable.

(ii) S_0 is a prescribed $\mathcal{S}$-valued random variable.

(iii) $W(\cdot)=\big[W_1(\cdot),\dots,W_d(\cdot)\big]'$ is a d-dimensional standard Wiener process.

(iv) $\mathfrak{p}(dt,dz)$ is an $\mathfrak{M}(\mathbb{R}_+\times\mathbb{R})$-valued Poisson random measure with intensity $dt\times m(dz)$, where m is the Lebesgue measure on $\mathbb{R}$.

(v) $\mathfrak{p}(\cdot,\cdot)$, $W(\cdot)$, X_0, and S_0 are independent.

(vi) $v(\cdot)$ is a $\mathcal{V}$-valued process with measurable sample paths satisfying the nonanticipativity property that the σ-fields $\mathfrak{F}_t^v$ and $\mathfrak{F}_{[t,\infty)}^{W,\mathfrak{p}}$ given by

$$\begin{aligned}\mathfrak{F}_t^v&=\sigma\{v(s),s\le t\},\\ \mathfrak{F}_{[t,\infty)}^{W,\mathfrak{p}}&=\sigma\big\{W(s)-W(t),\mathfrak{p}(A,B)\ :\ A\in\mathfrak{B}\big([s,\infty)\big),B\in\mathfrak{B}(\mathbb{R}),s\ge t\big\}\end{aligned}$$

are independent for each $t\in\mathbb{R}$.

A process $v(\cdot)$ satisfying (vi) is called an *admissible (control) policy*. If $v(\cdot)$ is a Dirac measure, i.e., $v(\cdot) = \delta_{u(\cdot)}$, where $u(\cdot)$ is U-valued, then it is called an admissible *nonrandomized* policy. An admissible policy is called *feedback* if $v(\cdot)$ is progressively measurable with respect to the natural filtration $\mathfrak{F}_t = \{X(s), S(s),\ s \le t\}$.

A particular subclass of feedback policies is of special interest. A feedback policy $v(\cdot)$ is called a (homogeneous) Markov policy if $v(t) = \tilde{v}\big(X(t), S(t)\big)$ for a measurable map $\tilde{v} : \mathbb{R}^d \times \mathcal{S} \to \mathcal{V}$. With an abuse in notation the map $\tilde{v}$ itself is called a Markov policy. Let Π, Π_M, and Π_{MD} denote the sets of all admissible, Markov, and nonrandomized Markov policies, respectively.

If $\big(W(\cdot), \mathfrak{p}(\cdot,\cdot), X_0, S_0, v(\cdot)\big)$ satisfying (i)–(vi) above are given on a prescribed probability space $(\Omega, \mathfrak{G}, P)$, then under Assumption 3.1, equation (3.4) admits an almost sure unique strong solution [17, Chap. 3], and $X(\cdot) \in C(\mathbb{R}_+; \mathbb{R}^d)$, $S(\cdot) \in D(\mathbb{R}_+; \mathcal{S})$, where $D(\mathbb{R}_+; \mathcal{S})$ is the space of right continuous functions on $\mathbb{R}_+$ with left limits taking values in $\mathcal{S}$. However, if $v(\cdot)$ is a feedback policy, then there exists a measurable map

$$f : \mathbb{R}_+ \times C(\mathbb{R}_+; \mathbb{R}^d) \times D(\mathbb{R}_+; \mathcal{S}) \longrightarrow \mathcal{V}$$

such that for each $t \ge 0$, $v(t) = f\big(t, X(\cdot), S(\cdot)\big)$ and is progressively measurable with respect to $\{\mathfrak{F}_t\}$. Thus, $v(\cdot)$ cannot be specified a priori in (3.4). Instead, one has to replace $v(t)$ by $f\big(t, X(\cdot), S(\cdot)\big)$, and (3.4) takes the form

$$\begin{aligned} dX(t) &= b\big(X(t), S(t), f(t, X(\cdot), S(\cdot))\big)dt + \sigma\big(X(t), S(t)\big)dW(t), \\ dS(t) &= \int_{\mathbb{R}} h\big(X(t), S(t-), f(t, X(\cdot), S(\cdot)), z\big)\mathfrak{p}(dt, dz)\,, \end{aligned} \tag{3.5}$$

for $t \ge 0$ with $X(0) = X_0$, $S(0) = S_0$. In general, (3.5) does not even admit a weak solution. However, if the feedback policy is Markov, then the existence of a unique strong solution can be established.

If $\boldsymbol{\mathcal{K}}(\mathbb{R}^d)$ is a vector space of real functions over $\mathbb{R}^d$, we adopt the notation $\boldsymbol{\mathcal{K}}(\mathbb{R}^d \times \mathcal{S})$ to indicate the space $\big(\boldsymbol{\mathcal{K}}(\mathbb{R}^d)\big)^N$, endowed with the product topology. For example,

$$L^p(\mathbb{R}^d \times \mathcal{S}) := \Big\{ f : \mathbb{R}^d \times \mathcal{S} \to \mathbb{R} \,:\, f(\cdot, i) \in L^p(\mathbb{R}^d) \text{ for all } i \in \mathcal{S} \Big\},$$

and similarly, we define $C^k(\mathbb{R}^d \times \mathcal{S})$, $W^{k,p}(\mathbb{R}^d \times \mathcal{S})$, etc. For $f \in W^{2,p}_{\ell oc}(\mathbb{R}^d \times \mathcal{S})$ and $u \in U$, we write

$$L^u f(x,k) = L^u_k f(x,k) + \sum_{j \in \mathcal{S}} \overline{\lambda}_{kj}(x,u) f(x,j)\,, \tag{3.6}$$

where

$$L^u_k = \frac{1}{2} \sum_{i,j,\ell=1}^{d} \sigma_{i\ell}(x,k)\sigma_{j\ell}(x,k) \frac{\partial^2}{\partial x_i \partial x_j} + \sum_{j=1}^{d} \overline{b}_j(x,k,u) \frac{\partial}{\partial x_j} \tag{3.7}$$

and, more generally, for $v \in \mathcal{V}$,

$$L^v f(x,k) = \int_U L^u f(x,k) v(du)\,. \tag{3.8}$$

The following result is proved in [14].

THEOREM 3.1. *Under a Markov policy v,* (3.4) *admits an almost sure unique strong solution such that $\big(X(\cdot), S(\cdot)\big)$ is a strong Feller process with differential generator L^v.*

A Markov policy v is called *stable* if the corresponding process $\big(X(\cdot), S(\cdot)\big)$ is positive recurrent. In this case, the process has a unique invariant probability measure, denoted by $\eta_v \in \boldsymbol{\mathcal{P}}(\mathbb{R}^d \times \mathcal{S})$. The uniqueness of η_v is guaranteed by Assumption 3.1. We assume that the set of stable Markov policies is nonempty.

The optimization problem. Let $\overline{c} : \mathbb{R}^d \times \mathcal{S} \times U \to \mathbb{R}_+$ be the cost function. The following assumption on the cost, $\overline{c}$, will be in effect throughout the paper.

Assumption 3.2. For each $i \in \mathcal{S}$, $\overline{c}(\cdot, i, \cdot)$ is continuous.

We define $c : \mathbb{R}^d \times \mathcal{S} \times \mathcal{V} \to \mathbb{R}_+$ by

$$c(x, i, v) = \int_U \overline{c}(x, i, u) v(du)\,. \tag{3.9}$$

Let $v(\cdot)$ be an admissible policy and $\big(X(\cdot), S(\cdot)\big)$ the corresponding process. The pathwise (long-run) average cost incurred under $v(\cdot)$ is

$$\limsup_{T\to\infty} \frac{1}{T} \int_0^T c\big(X(t), S(t), v(t)\big) dt\,. \tag{3.10}$$

We wish to a.s. minimize (3.10) over all admissible policies. Our goal is to establish the existence of a stable Markov policy which is a.s. optimal. In general, this is not the case, as the following simple counterexample shows [6]. Let $\overline{c}(x, i) = \exp(-\|x\|^2)$. Then for every stable Markov policy the average cost is positive a.s., while we can find an unstable Markov policy for which the average cost is a.s. zero, making it an optimal policy. We want to rule out this possibility, as stability is a very desirable property. We carry out our study under two alternate sets of hypotheses: (a) a condition on the cost which penalizes unstable behavior, (b) a blanket stability condition which implies that all Markov policies are stable. We describe these conditions in section 6.

4. Recurrence, ergodicity, and harmonic functions of switching diffusions. Due to the interaction between the continuous and discrete components, the study of recurrence and ergodicity of switching diffusions is quite involved. Let v be a Markov policy which will be fixed throughout this section unless explicitly stated otherwise. Let $P^v : \mathbb{R}_+ \times \mathbb{R}^d \times \mathcal{S} \to \boldsymbol{\mathcal{P}}(\mathbb{R}^d \times \mathcal{S})$ denote the transition function of the corresponding process $\big(X(\cdot), S(\cdot)\big)$. Also $P^v_{x,i}$ and $E^v_{x,i}$ denote the probability measure and the expectation operator, respectively, on the canonical space of the process $\big(X(\cdot), S(\cdot)\big)$ starting at $(x, i) \in \mathbb{R}^d \times \mathcal{S}$. The following result plays a crucial role in recurrence.

LEMMA 4.1. *For any $(t, x, i) \in \mathbb{R}_+ \times \mathbb{R}^d \times \mathcal{S}$, the support of $P^v(t, x, i; \cdot)$ is $\mathbb{R}^d \times \mathcal{S}$.*

Proof. For each $i \in \mathcal{S}$, let τ_i denote the sojourn time of $S(t)$ in state i. Then

$$P^v_{x,i}\big(\tau_i > t\big) = E^v_{x,i}\bigg[\exp\Big(\int_0^t \lambda_{ii}\big(X(s), v(X(s), S(s))\big) ds\Big)\bigg].$$

Let $\lambda^v_{ij}(s) := \lambda_{ij}\big(X(s), v(X(s), S(s))\big)$, $I_{A,j}(s) := I\{X(s) \in A, S(s) = j\}$, and P^v_i be the transition function of the diffusion corresponding to L^v_i, i.e., the diffusion with no

switching and $S(t) \equiv i$. For $A \in \mathfrak{B}(\mathbb{R}^d)$, $i, j \in \mathcal{S}$, and $t > 0$,

(4.1)
$$\begin{aligned} P^v\big(t,x,i,A\times\{j\}\big) &= E^v_{x,i}\big[I_{A,j}(t) \bigm| \tau_i > t\big] P^v_{x,i}\big(\tau_i > t\big) + E^v_{x,i}\big[I_{A,j}(t) I\{\tau_i < t\}\big] \\ &= E^v_{x,i}\biggl[\exp\Big(\int_0^t \lambda^v_{ii}(s)\,ds\Big)\biggr] P^v_i(t,x,A)\delta_{ij} \\ &\quad + E^v_{x,i}\biggl[\int_0^t -\lambda^v_{ii}(s)\exp\Big(\int_0^s \lambda^v_{ii}(s')ds'\Big)ds \\ &\qquad\qquad \int_{\mathbb{R}^d} P^v_i(s,x,dy)\sum_{k\neq i}\lambda^v_{ik}(s)P^v\big(t-s,y,k,A\times\{j\}\big)\biggr] \\ &= E^v_{x,i}\biggl[\exp\Big(\int_0^t \lambda^v_{ii}(s)\,ds\Big)\biggr] P^v_i(t,x,A)\delta_{ij} \\ &\quad + \sum_{k\neq i}\int_0^t E^v_{x,i}\biggl[-\lambda^v_{ii}(s)\lambda^v_{ik}(s)\exp\Big(\int_0^s \lambda^v_{ii}(s')ds'\Big)\biggr] \\ &\qquad\qquad \int_{\mathbb{R}^d} P^v_i(s,x,dy)P^v\big(t-s,y,k,A\times\{j\}\big)ds\,. \end{aligned}$$

Define the transition matrix $\widetilde{\Pi}^v$ by

$$[\widetilde{\Pi}^v(t,x,A)]_{ij} = P^v\big(t,x,i,A\times\{j\}\big)\,.$$

Then we can suitably define the matrix measures

$$\Gamma^v_1, \Gamma^v_2 : \mathbb{R}\times\mathbb{R}^d \to \big(\boldsymbol{\mathcal{P}}(\mathbb{R}^d)\big)^{N\times N}$$

with $\Gamma^v_1(t,x,A)$ positive, diagonal and $\Gamma^v_2(t,x,A)$ nonnegative, irreducible (by Assumption 3.1 (iii)), for all $(t,x,A) \in \mathbb{R}_+ \times \mathbb{R}^d \times \mathfrak{B}(\mathbb{R}^d)$, provided A has positive Lebesgue measure, so as to write (4.1) in the form

$$\widetilde{\Pi}^v(t,x,A) = \Gamma^v_1(t,x,A) + \int_0^t\int_{\mathbb{R}^d} \Gamma^v_2(s,x,dy)\widetilde{\Pi}^v(t-s,y,A)ds\,. \tag{4.2}$$

The desired result follows from (4.2), using the irreducibility of $\Gamma^v_2(t,x,A)$. □

Let τ_{ii}, τ_j be the stopping times defined as follows:

$$\tau_{ii} = \inf\big\{t > 0 \,:\, S(t) = i \text{ and } S(t') \neq i, \text{ for some } 0 < t' < t\big\}, \tag{4.3}$$

$$\tau_j = \inf\big\{t > 0 \,:\, S(t) = j\big\}. \tag{4.4}$$

Let $D \subset \mathbb{R}^d$ be a bounded open set and J a subset of $\mathcal{S}$. Define

$$\tau_{D,J} = \inf\big\{t \geq 0 \,:\, \big(X(t),S(t)\big) \notin D\times J\big\}, \tag{4.5}$$

$$\tau_D = \inf\big\{t \geq 0 \,:\, X(t) \notin D\big\}. \tag{4.6}$$

Using (4.2) and well-known arguments in Markov processes [12, Vol. I, p. 111] the following results can be proved.

LEMMA 4.2. *If τ is a stopping time of the form τ_{ii}, τ_j, $\tau_{D,J}$, or τ_D, as defined in* (4.3)–(4.6)*, then, for each compact set $K \subset \mathbb{R}^d$,*

$$\sup_{v\in\Pi_M,\, x\in K} E^v_{x,i}[\tau] < \infty\,.$$

It is well known that harmonic functions play an important role in the study of recurrence and ergodicity of Markov processes [3]. Therefore, we now turn to the analysis of some properties of the harmonic functions of the process $\big(X(\cdot), S(\cdot)\big)$ under the Markov policy v. The function f is called *L^v-harmonic* in D if it is bounded on compact subsets of D, and for all $x \in D$, $i \in \mathcal{S}$,

$$f(x,i) = E^v_{x,i} f\big(X(\tau_{V,J}), S(\tau_{V,J})\big) \tag{4.7}$$

for every neighborhood V of x having compact closure $\overline{V}$ in D and every subset $J \subset \mathcal{S}$ containing i. It is clear that if f is L^v-harmonic then

$$f(x,i) = E^v_{x,i} f\big(X(\tau_V), S(\tau_V)\big). \tag{4.8}$$

On the other hand, if (4.8) holds, then by conditioning on $\mathfrak{F}_{\tau_{V,J}}$ we obtain

$$\begin{aligned} f(x,i) &= E^v_{x,i}\Big[E^v\big[f\big(X(\tau_V), S(\tau_V)\big) \mid \mathfrak{F}_{\tau_{V,J}}\big]\Big] \\ &= E^v_{x,i}\Big[E^v_{X_{\tau_{V,J}}, S_{\tau_{V,J}}}\big[f\big(X(\tau_V - \tau_{V,J}), S(\tau_V - \tau_{V,J})\big)\big]\Big] \\ &= E^v_{x,i}\big[f\big(X(\tau_{V,J}), S(\tau_{V,J})\big)\big]\,, \end{aligned}$$

concluding that (4.7) and (4.8) are actually equivalent.

LEMMA 4.3. *Let $D \subset \mathbb{R}^d$ be open. Then we have the following:*

(i) *Every L^v-harmonic function in D is continuous in D.*

(ii) *If $L^v f = 0$ in D and $f \in W^{2,p}(D \times \mathcal{S})$, then f is L^v-harmonic. Conversely, if f is L^v-harmonic and $f \in W^{2,p}_{\ell oc}(D \times \mathcal{S})$, then $L^v f = 0$ in D.*

(iii) *(Maximum principle) Let D be connected and $f \ge 0$ and L^v-harmonic in D. Then f is either strictly positive in $D \times \mathcal{S}$ or identically zero.*

Proof. The proof of (i) is standard [3], [12, Vol. II, Chap. 13], and (ii) can easily be proved using the generalized Ito formula [18]. Let $x_0 \in D$, $i_0 \in \mathcal{S}$, and $r > 0$ be such that $f(x_0, i_0) = 0$ and $\overline{B}(x_0, r) \subset D$, where $\overline{B}(x_0, r) = \big\{x \in \mathbb{R}^d : \|x - x_0\| \le r\big\}$. Then

$$0 = f(x_0, i_0) = \sum_{j \in \mathcal{S}} \int_{\partial B(x_0, r)} f(y, j) P^v_{x_0, i_0}\big(X(\tau_{B(x_0,r)}) \in dy, S(\tau_{B(x_0,r)}) = j\big).$$

Then, by Lemma 4.1, we can show using standard arguments [16, Chap. 6] that the support of the measure $P^v_{x_0,i_0}\big(X(\tau_{B(x_0,r)}) \in dy, S(\tau_{B(x_0,r)}) = j\big)$ is $\partial B(x_0, r) \times \mathcal{S}$. Hence,

$$f(y, j) = 0, \qquad \text{for all } y \in \partial B(x_0, r),\ j \in \mathcal{S}\,.$$

It follows that the set $\big\{y : f(y, j) = 0,\ j \in \mathcal{S}\big\}$ is open in D, and since D is connected, the result follows. □

We next state Harnack's inequality for L^v-harmonic functions, which extends a very important result in partial differential equations. This inequality plays a crucial role in proving the existence of a solution to the HJB equation via the vanishing discount method, as is done in section 6. As far as we know, this result is not known in the literature on partial differential equations. The detailed proof of Harnack's inequality is quite elaborate and can be found in the appendix. The proof follows the method introduced for diffusions by Krylov and Safonov [19] for deriving estimates for the oscillation of a harmonic function. For the system of coupled elliptic operators

characterizing switching diffusions, considerable complications arise in trying to follow the same methodology due to the vector-valued nature of the L^v-harmonic functions. A crucial step in the proof is "coupling" together the oscillations of the distinct components of the harmonic function. The irreducibility of the matrix $\widetilde{\Lambda}$ is essential in accomplishing this task.

THEOREM 4.1 (Harnack's inequality). *Let $\Omega \subset \mathbb{R}^d$ be a bounded domain and $K \subset \Omega$ a closed set. There exists a constant $C > 0$, depending only on Ω, K, the dimension d, N, the bounds m, m_0, and the Lipschitz constant γ_0 introduced in Assumption* 3.1*, such that for any nonnegative function $f \in W^{2,p}_{\ell oc}(\Omega \times \mathcal{S})$, $p \in [1, \infty)$, satisfying $L^v f = 0$ in $\Omega \times \mathcal{S}$, for some Markov policy v,*

$$f(x,i) \le C f(y,j) \qquad \forall\, x, y \in K \quad \forall\, i, j \in \mathcal{S}\,.$$

We now discuss the recurrence properties of switching diffusions. Our treatment closely follows [3], so we skip the details in several places. A point $(x,i) \in \mathbb{R}^d \times \mathcal{S}$ is said to be *recurrent* if, given any $\varepsilon > 0$,

$$P^v_{x,i}\big(X(t_n) \in B(x,\varepsilon),\ S(t_n) = i,\ \text{for a sequence } t_n \uparrow \infty\big) = 1. \tag{4.9}$$

A point (x,i) is *transient* if

$$P^v_{x,i}\big(\|X(t)\| \to \infty,\ \text{as } t \to \infty\big) = 1. \tag{4.10}$$

If all points of the switching diffusion are recurrent, then it is called recurrent. A transient switching diffusion is similarly defined. Note that the discrete component of the process has been ignored in the definition (4.10). The reason for doing so is that, in view of Assumption 3.1 (iii), we can show that, provided the continuous component visits a bounded set infinitely often with probability 1, then the discrete component is recurrent. More generally, a switching diffusion exhibits a dichotomy in that it is either recurrent or transient, as we will later show.

LEMMA 4.4. *The following statements are equivalent.*

(i) *The switching diffusion is recurrent;*

(ii) $P^v_{x,i}\big(X(t) \in D,\ S(t) = j,\ \text{for some } t \ge 0\big) = 1$*, for any open set $D \subset \mathbb{R}^d$ and any $j \in \mathcal{S}$.*

Proof. We prove (i) $\to$ (ii) (the converse is easier). We distinguish two cases.

Case 1. Let $x \in D$, $i \ne j$. Let $B = B(x,\varepsilon)$ and B_1 be bounded open sets such that $\overline{B} \subset B_1$ and $\overline{B}_1 \subset D$. Let

$$\eta_1 = \inf\big\{t \ge 0\ :\ X(t) \in \partial B_1\big\},$$

and inductively, for $n = 1, 2, \dots,$

$$\eta_{2n} = \inf\big\{t > \eta_{2n-1}\ :\ X(t) \in \partial B\big\},$$
$$\eta_{2n+1} = \inf\big\{t > \eta_{2n}\ :\ X(t) \in \partial B_1\big\}.$$

Then, by recurrence, $\eta_n < \infty$, $P^v_{x,i}$ a.s. Note that

$$y, \ell \mapsto P^v_{y,\ell}\big(\tau_{(\overline{B}\times\{j\})^c} < \tau_{B_1}\big)$$

is L^v-harmonic in $B_1 \times \mathcal{S}$ and not identically zero. Therefore, by Lemma 4.3,

$$\inf_{(y,\ell)\in\overline{B}\times\mathcal{S}} P^v_{y,\ell}\big(\tau_{(\overline{B}\times\{j\})^c} < \tau_{B_1}\big) > \delta_1 > 0 \tag{4.11}$$

for some $\delta_1 > 0$. Next we define

$$A_0 = \{S(t) = j \text{ for some } t \in [0, \eta_1)\},$$
$$A_n = \{S(t) = j \text{ for some } t \in [\eta_{2n}, \eta_{2n+1})\}.$$

By (4.11) and the strong Markov property,

$$P^v_{x,i}(A_0^c) \le (1 - \delta_1), \qquad P^v_{x,i}\Big(\bigcap_{k=0}^{n} A_k^c\Big) \le (1 - \delta_1)^{n+1}.$$

Now,

$$\begin{aligned} P^v_{x,i}\big(X(t) \in D,\ S(t) = j \text{ for no } t \ge 0\big) &\le P^v_{x,i}\big(X(t) \in \overline{B}_1,\ S(t) = j \text{ for no } t \ge 0\big) \\ &\le \lim_{n\to\infty} P^v_{x,i}\Big(\bigcap_{k=0}^{n} A_k^c\Big) = 0. \end{aligned}$$

Case 2. Suppose $x \notin D$ and let $B = B(x, \varepsilon)$, B_1, and D_1 be bounded open sets such that $B \bigcap D = \emptyset$, $\overline{B}_1 \subset D$, and $\overline{B} \bigcup \overline{B}_1 \subset D_1$. Let

$$\eta'_1 = \tau_{D_1},$$
$$\eta'_{2n} = \{t > \eta'_{2n-1} \,:\, X(t) \in \partial B\},$$
$$\eta'_{2n+1} = \{t > \eta'_{2n} \,:\, X(t) \in \partial D_1\}.$$

Let $\delta_2 > 0$ be such that

$$\inf_{(y,\ell)\in \partial D_1 \times \mathcal{S}} P^v_{y,\ell}\big(\tau_{(\overline{B}_1 \times \{j\})^c} < \tau_{(\overline{B}\times\{i\})^c}\big) > \delta_2 > 0.$$

Define

$$A'_n = \{X(t) \in \overline{B}_1, S(t) = j \text{ for some } t \in [\eta_{2n-1}, \eta_{2n})\}.$$

Then, as in the previous case,

$$P^v_{x,i}\big(X(t) \in D,\ S(t) = j \text{ for no } t \ge 0\big) = 0. \qquad \square$$

In view of Lemma 4.4, the following results can be proved the same way as in [3], [4].

LEMMA 4.5. *The following statements are equivalent.*

(i) *The switching diffusion is recurrent.*

(ii) $P^v_{x,i}\big(X(t) \in D \text{ for some } t \ge 0\big) = 1$ *for all* $x \in \mathbb{R}^d$, $i \in \mathcal{S}$, *and any nonempty open set* D.

(iii) *There exists a compact set* $K \subset \mathbb{R}^d$ *such that* $P^v_{x,i}\big(X(t) \in K \text{ for some } t \ge 0\big) = 1$ *for all* $(x, i) \in \mathbb{R}^d \times \mathcal{S}$.

(iv) $P^v_{x,i}\big(X(t_n) \in D, \text{ for a sequence } t_n \uparrow \infty\big) = 1$ *for all* $x \in \mathbb{R}^d$, $i \in \mathcal{S}$, *and any nonempty open set* D.

(v) *There exists a point* $z \in \mathbb{R}^d$, *a pair of numbers* r_0, r_1, $0 < r_0 < r_1$, *and a point* $y \in \partial B(z, r_1)$ *such that* $P^v_{y,i}\big(\tau_{\overline{B}(z,r_0)^c} < \infty\big) = 1$ *for any* $i \in \mathcal{S}$.

THEOREM 4.2. *For any Markov policy, the switching diffusion is either recurrent or transient.*

A recurrent switching diffusion admits a unique (up to a constant multiple) σ-finite invariant measure. The switching diffusion is called *positive recurrent* if it is recurrent and admits a finite invariant measure.

A Markov policy v is called *stable* if the corresponding process is positive recurrent; the corresponding invariant probability measure is denoted by η_v.

As is well known from the general theory of dynamical systems, even if L_i^v generates a positive recurrent diffusion, for each $i \in \mathcal{S}$, and the parametric Markov chain is ergodic, there is no reason to expect that the policy v is stable; i.e., the switching diffusion is positive recurrent. Indeed, as the following example shows, the hybrid process can be anything from transient to positive recurrent.

Example 4.1. We first consider a piecewise deterministic system with state dependent Markovian switching. Let $E_+, E_- \subset \mathbb{R}^2$ be defined as follows:

$$E_+ = \{(x_1, x_2) \,:\, x_1 > 0\} \bigcup \{x_2 \le 0, x_1 = 0\},$$
$$E_- = \{(x_1, x_2) \,:\, x_1 < 0\} \bigcup \{x_2 \ge 0, x_1 = 0\}.$$

Let

$$A_0 = \begin{bmatrix} 2 & 1 \\ -1 & 2 \end{bmatrix}, \qquad A_1 = \begin{bmatrix} -3 & 1 \\ -1 & -3 \end{bmatrix}.$$

Consider two stable dynamical systems $\mathcal{D}_0$ and $\mathcal{D}_1$ defined by

$$\mathcal{D}_0 : \quad \dot{x} = \begin{cases} A_0 x, & x \in E_+, \\ A_1 x, & x \in E_-, \end{cases}$$

and

$$\mathcal{D}_1 : \quad \dot{x} = \begin{cases} A_1 x, & x \in E_+, \\ A_0 x, & x \in E_-. \end{cases}$$

For $\delta > 0$, let Z be a (parameterized) Markov chain taking values in $\{0, 1\}$ with rate matrix

$$\begin{bmatrix} -\delta & \delta \\ \frac{1}{\delta} & -\frac{1}{\delta} \end{bmatrix} \text{ on } E_+ \quad \text{and} \quad \begin{bmatrix} -\frac{1}{\delta} & \frac{1}{\delta} \\ \delta & -\delta \end{bmatrix} \text{ on } E_-$$

and consider the dynamical system

$$\mathcal{D} := \mathcal{D}_Z.$$

If we define η by

$$\eta = \begin{cases} Z, & x \in E_+, \\ 1 - Z, & x \in E_-, \end{cases}$$

then η is Markovian with rate matrix

$$\begin{bmatrix} -\delta & \delta \\ \frac{1}{\delta} & -\frac{1}{\delta} \end{bmatrix},$$

and $\mathcal{D}$ can represented as

$$\dot{x} = A_\eta x.$$

Define

$$T_0(t) = \{\tau \le t \,:\, \eta(\tau) = 0\},$$
$$T_1(t) = \{\tau \le t \,:\, \eta(\tau) = 1\},$$

and $\lambda_0(t) = m(T_0(t))$, $\lambda_1(t) = m(T_1(t))$, where m is the Lebesgue measure on $\mathbb{R}_+$. Then, the solution to $\mathcal{D}$ can be expressed as

$$x(t) = \exp\bigl(2\lambda_0(t) - 3\lambda_1(t)\bigr) \begin{bmatrix} \cos t & -\sin t \\ \sin t & \cos t \end{bmatrix} x(0).$$

By the ergodic theory of Markov processes [25, Chap. 1], as $t \to \infty$,

$$\lambda_1(t) \sim \frac{\delta^2 t}{1+\delta^2}\,, \qquad \lambda_0(t) \sim \frac{t}{1+\delta^2}\,.$$

Thus,

$$2\lambda_0(t) - 3\lambda_1(t) \sim \frac{2-3\delta^2}{1+\delta^2}\,t\,.$$

Therefore, $\mathcal{D}$ is stable for $\delta < \sqrt{\frac{2}{3}}$ and unstable for $\delta \ge \sqrt{\frac{2}{3}}$. The matrices A_0, A_1 can be suitably altered to exhibit various other possibilities.

Now let $X(t)$ be defined as $dX(t) = A_{\eta(t)}X(t)dt + \sigma dW(t)$, where $W(\cdot)$ is a standard two-dimensional Wiener process and $\sigma\sigma'$ is a 2×2 positive definite matrix with constant entries. Then it is easily shown that the stability (instability) of $\mathcal{D}$ implies the positive recurrence (transience) of $X(t)$. Note that in this example the drift is unbounded. However, in the study of recurrence, boundedness of the drift can be replaced by local boundedness.

Remark 4.1. In view of the above example, it is clear that two positive recurrent processes with suitable switching may result in a transient process. Similarly, the random combination of two transient processes may give rise to a positive recurrent process. This phenomenon can be exploited in many practical situations such as fault-tolerant control systems, flexible manufacturing systems, etc. In a control system with multiple modes, we can trade off the stability of some (or all) nodes to gain a desired degree of flexibility. Addition of a few redundant nodes and/or the incorporation of a suitable switching mechanism among the nodes could result in global stability of the system, thereby gaining flexibility without sacrificing reliability.

A general criterion for positive recurrence of a switching diffusion is provided by the following theorem.

THEOREM 4.3. *Let z, r_0, r_1 be as in Lemma* 4.5(v). *Then the switching diffusion is positive recurrent if*

$$\sup_{y \in \partial B(z,r_1), i \in \mathcal{S}} E^v_{y,i}\bigl[\tau_{\overline{B}(z,r_0)^c}\bigr] < \infty\,. \tag{4.12}$$

The proof is standard [3]. Note that it may be very difficult to verify (4.12) for general b, σ, λ. One usually verifies (4.12) by constructing a Lyapunov function [3]. For switching diffusions such a construction seems difficult, since it involves solving a system of ordinary differential equations in closed form. However, we present some criteria for positive recurrence and discuss some implications.

(C1) There exists a $w \in C^2(\mathbb{R}^d \times \mathcal{S})$, $w \geq 0$, such that

(i) $w(x,i) \to \infty$, as $\|x\| \to \infty$.

(ii) For each $v \in \Pi_M$, $E^v_{x,i}\big[w\big(X(t),S(t)\big)\big]$ and $E^v_{x,i}\big|L^v w\big(X(t),S(t)\big)\big|$ are locally bounded.

(iii) There exists $p > 0$, $q > 0$ such that $L^u w(x,i) \leq p - qw(x,i)$, for each $u \in U$.

(C2) There exists a C^2 function $w : \mathbb{R}^d \times \mathcal{S} \to \mathbb{R}_+$ such that

(i) $\lim_{\|x\|\to\infty} w(x,i) = +\infty$.

(ii) There exists $a > 0$ and $\varepsilon > 0$ such that for $\|x\| > a$, $L^u w(x,i) < -\varepsilon$, for all $u \in U$, $i \in \mathcal{S}$, and $\|\nabla w(x,i)\|^2 \geq m^{-1}$, where m is the constant in Assumption 3.1 (ii).

(iii) $w(x,i)$ and $\|\nabla w(x,i)\|$ have polynomial growth.

THEOREM 4.4. *Under either* (C1) *or* (C2)*, the process* $\big(X(\cdot),S(\cdot)\big)$ *under any Markov policy* v *is positive recurrent. Thus, all Markov policies are stable.*

Proof. Under (C1), the result follows from [25, Theorem 25, p. 70]. Under (C2), the technique of the proof of [6, Lemma 6.2.2, p. 150] can be closely paralleled to draw the desired conclusion. □

Remark 4.2. If $\sigma \equiv I$ and $\bar{b}$ is such that $\langle \bar{b}(x,i,u), x\rangle < -(d+1)/2$ for all $i \in \mathcal{S}$ and $\|x\|$ sufficiently large, then $w(x) = \|x\|^2$ is a Lyapunov function for the system. We can construct several examples using this idea. Note that in this case all the diffusion generators L^u_i give rise to positive recurrent diffusions and have a common Lyapunov function (i.e., one which is independent of i). If all L^u_i have a common Lyapunov function, then switching does not destabilize the hybrid system. Of course, this is a very strong condition and is rarely met.

5. Existence of an optimal policy. In this section we establish the existence of a stable, nonrandomized Markov optimal policy under certain conditions. We follow the methodology developed in [6], [8], [9], [10] for controlled diffusions. For switching diffusions, similar techniques carry through with some extra effort. Therefore, we present the main ideas, skipping some of the technical details.

Let Π_{SM} and Π_{SMD} denote the set of stable Markov and stable nonrandomized Markov policies, respectively. Since we are searching for an optimal policy in Π_{SMD}, it is natural to assume that Π_{SM} is nonempty. Let $v \in \Pi_{SM}$. Then

$$\begin{aligned}\rho_v &:= \sum_{i\in\mathcal{S}} \int_{\mathbb{R}^d} c\big(x,i,v(x,i)\big)\eta_v(dx,i) \\ &= \lim_{T\to\infty} \frac{1}{T} \int_0^T c\big(X(s),S(s),v(X(s),S(s))\big)ds \quad \text{a.s.}\end{aligned} \tag{5.1}$$

Let

$$\rho^* := \inf_{v\in\Pi_{SM}} \big\{\rho_v\big\}. \tag{5.2}$$

We assume that $\rho^* < \infty$. We now state a condition on the cost function which penalizes unstable behavior.

(C3) Assume that for each $i \in \mathcal{S}$,

$$\liminf_{\|x\|\to\infty} \big\{ \inf_{u\in U} \bar{c}(x,i,u)\big\} > \rho^*. \tag{5.3}$$

Intuitively, (5.3) penalizes trajectories lying outside the set $\inf_{u\in U}\big\{\bar{c}(x,i,u)\big\} \leq \rho^*$, forcing an optimal process to spend a nonvanishing fraction of time in a bounded

neighborhood of this compact set. This behavior results in the stability of every optimal policy. If $\overline{c}(x,i,u) = K(\|x\|)$ for some increasing function $K : \mathbb{R}_+ \to \mathbb{R}_+$ then it can be easily seen that (5.3) holds. Such cost functions arise quite often in practice. Condition (C3) is referred to as the *near-monotonicity* condition [6, Chap. 6].

For $v \in \Pi_{SM}$ (or Π_{SMD}), we define the ergodic occupation measure $\mu[v] \in \boldsymbol{\mathcal{P}}(\mathbb{R}^d \times \mathcal{S} \times U)$ as

$$\mu[v](dx,i,du) = \eta_v(dx,i)v(x,i)(du). \tag{5.4}$$

Let

$$I_1 = \big\{\mu[v] \,:\, v \in \Pi_{SM}\big\},$$
$$I_2 = \big\{\mu[v] \,:\, v \in \Pi_{SMD}\big\}.$$

The following results can be proved as in [10], [14].

LEMMA 5.1. *The sets I_1, I_2 are closed, I_1 is convex, and the set of extreme points of I_1 lies in I_2.*

Let $v(\cdot)$ be an arbitrary admissible policy. Define the $\boldsymbol{\mathcal{P}}(\mathbb{R}^d \times \mathcal{S} \times U)$-valued empirical process $\mu_t(v)$ for $t > 0$ by

$$\mu_t(v)\big(A \times \{i\} \times B\big) = \frac{1}{t}\int_0^t I\big\{X(s) \in A, S(s) = i\big\}\, v(s)(B)\, ds\,, \tag{5.5}$$

with $A \in \mathfrak{B}(\mathbb{R}^d)$, $B \in \mathfrak{B}(U)$, and $i \in \mathcal{S}$. Let $\overline{\mathbb{R}}^d = \mathbb{R}^d \bigcup \{\infty\}$ be the one-point compactification of $\mathbb{R}^d$. We identify $\mu_t(v)$ with an element of $\boldsymbol{\mathcal{P}}(\overline{\mathbb{R}}^d \times \mathcal{S} \times U)$ by assigning zero mass at $\{\infty\} \times \mathcal{S} \times U$. Since $\boldsymbol{\mathcal{P}}(\overline{\mathbb{R}}^d \times \mathcal{S} \times U)$ is compact, $\{\mu_t(v)\}$, viewed as a $\boldsymbol{\mathcal{P}}(\overline{\mathbb{R}}^d \times \mathcal{S} \times U)$-valued process, converges to a sample path-dependent compact limit set in $\boldsymbol{\mathcal{P}}(\overline{\mathbb{R}}^d \times \mathcal{S} \times U)$. Note that any element $\mu \in \boldsymbol{\mathcal{P}}(\overline{\mathbb{R}}^d \times \mathcal{S} \times U)$ can be decomposed as

$$\mu(C) = \delta_\mu\, \mu'\big(C \bigcap (\mathbb{R}^d \times \mathcal{S} \times U)\big) + (1 - \delta_\mu)\mu''\big(C \bigcap (\{\infty\} \times \mathcal{S} \times U)\big)\,, \tag{5.6}$$

for $C \in \mathfrak{B}\big(\overline{\mathbb{R}}^d \times \mathcal{S} \times U\big)$. In this decomposition $\delta_\mu \in [0,1]$ is always uniquely defined, and $\mu' \in \boldsymbol{\mathcal{P}}(\mathbb{R}^d \times \mathcal{S} \times U)$ (respectively, $\mu'' \in \boldsymbol{\mathcal{P}}(\{\infty\} \times \mathcal{S} \times U)$) is also unique if $\delta_\mu > 0$ (respectively, $\delta_\mu < 1$). We may render μ', μ'' unique at all times by imposing an arbitrary fixed choice thereof when $\delta_\mu = 0$, respectively, 1.

Combining the results in [20] with the technique in [6, Lemma 6.1.1, p. 144], we establish the following lemma.

LEMMA 5.2. *If $\mu \in \boldsymbol{\mathcal{P}}(\mathbb{R}^d \times \mathcal{S})$ satisfies*

$$\sum_{i \in \mathcal{S}} \int_{\mathbb{R}^d} L^v f(x,i)\mu(dx,i) = 0 \qquad \forall\ f \in H \tag{5.7}$$

for some Markov policy v, where H is a dense subset of $C_0^2(\mathbb{R}^d \times \mathcal{S})$, then $\mu = \eta_v$.

Proof. Using the usual approximation procedure we can show that (5.7) is true for all $f \in C_b^2(\mathbb{R}^d \times \mathcal{S})$. Let $\big(X(\cdot), S(\cdot)\big)$ be the process corresponding to the policy v with initial law μ. The law μ_t of this process, for $t > 0$, satisfies the Kolmogorov forward equation

$$\sum_{i \in \mathcal{S}} \int_{\mathbb{R}^d} f(x,i)\mu_t(dx,i) = \sum_{i \in \mathcal{S}} \int_{\mathbb{R}^d} f(x,i)\mu(dx,i) + \sum_{i \in \mathcal{S}} \int_0^t \int_{\mathbb{R}^d} L^v f(x,i)\mu_s(dx,i)\, ds$$

for all $f \in C_b^2(\mathbb{R}^d \times \mathcal{S})$. The uniqueness of the solution to the above equation is established in [26]. Since $\mu_t \equiv \mu$ is a solution to (5.7), it follows that $\mu = \eta_v$. ∎

We disintegrate $\mu' \in \boldsymbol{\mathcal{P}}(\mathbb{R}^d \times \mathcal{S} \times U)$ as

$$\mu'(dx, i, du) = \mu^*(dx, i) v_\mu(x, i)(du)\,, \tag{5.8}$$

where μ^* is the marginal of μ' on $\mathbb{R}^d \times \mathcal{S}$ and v_μ is a version of the regular conditional law defined as μ^* a.s. We select an arbitrary version and keep it fixed henceforth. Using the martingale stability theorem, the following characterization of the limit points of $\{\mu_t(\cdot)\}$ can be established as in [6, Lemma 6.1.2].

LEMMA 5.3. *Outside a set of zero probability, each limit point μ of $\{\mu_t(\cdot)\}$ for which $\delta_\mu > 0$ satisfies $\mu^* = \eta_{v_\mu}$.*

We now establish the existence of an optimal policy under (C3). Since the proof closely follows the steps in [6, Theorem 6.1.1], we only present a brief sketch.

THEOREM 5.1. *Under* (C3)*, there exists a stable Markov policy which is a.s. optimal.*

Proof. Let $v_n \in \Pi_{SM}$ be such that

$$\int \overline{c}\, d\mu[v_n] \downarrow \rho^*.$$

We extend $\mu[v_n]$ to $\boldsymbol{\mathcal{P}}(\overline{\mathbb{R}}^d \times \mathcal{S} \times U)$ in the usual manner and denote it also by $\mu[v_n]$. Let μ_∞ be a limit point of $\{\mu[v_n]\}$ and denote $v_\infty = v_{\mu_\infty}$, where v_{μ_∞} is obtained from μ_∞ by the decomposition in (5.6) and (5.8). Then, for $f \in C_0^2(\mathbb{R}^d \times \mathcal{S})$,

$$\sum_{i \in \mathcal{S}} \int_{\mathbb{R}^d} L^{v_n} f(x, i) \eta_{v_n}(dx, i) = \sum_{i \in \mathcal{S}} \int_{\overline{\mathbb{R}}^d \times U} L^u f(x, i) \mu[v_n](dx, i, du) = 0\,.$$

Hence,

$$\sum_{i \in \mathcal{S}} \int_{\overline{\mathbb{R}}^d \times U} L^u f(x, i) \mu_\infty(dx, i, du) = 0\,.$$

Thus, by Lemmas 5.2 and 5.3, $\mu_\infty^* = \eta_{v_\infty}$, if $\delta_{\mu_\infty} > 0$. Using (C3), we can demonstrate as in [6, Lemma 6.1.3] that this is indeed the case. Therefore,

$$\min_{v \in \Pi_{SM}} \int \overline{c}\, d\mu[v] = \int \overline{c}\, d\mu[v_\infty] = \rho^*.$$

Finally, following the technique in [6, Lemma 6.1.3], we can now show that for an arbitrary policy u,

$$\liminf_{T \to \infty} \frac{1}{T} \int_0^T c\big(X(s), S(s), u(s)\big) ds \geq \rho^* \quad \text{a.s.},$$

which establishes the optimality of v_∞ in a much stronger sense. ∎

THEOREM 5.2. *Under* (C3) *there exists a $v^* \in \Pi_{SMD}$ which is a.s. optimal.*

Proof. We have already established the existence of $v_\infty \in \Pi_{SM}$ which is a.s. optimal. We argue as in [7, p. 58]. Embed I_1 in $\boldsymbol{\mathcal{P}}(\overline{\mathbb{R}}^d \times \mathcal{S} \times U)$ by assigning zero mass at $\{\infty\} \times \mathcal{S} \times U$. Let $\overline{I}_1$ denote the closure of I_1 in $\boldsymbol{\mathcal{P}}(\overline{\mathbb{R}}^d \times \mathcal{S} \times U)$. Then $\overline{I}_1$ is a compact convex set. By Choquet's theorem [24], each element μ of $\overline{I}_1$ is the

barycenter of a probability measure m supported on the set of extreme points of $\overline{I}_1$. Now, each extreme point of I_1 must be an extreme point of $\overline{I}_1$, since otherwise it would be assigning a strictly positive mass to $\{\infty\} \times \mathcal{S} \times U$. If m assigns a strictly positive mass to extreme points of $\overline{I}_1$, which are not extreme points of I_1, then μ must assign a strictly positive probability to $\{\infty\} \times \mathcal{S} \times U$, which is not true. Thus, m must be supported on the set I_1^e consisting of the extreme points of I_1. In particular,

$$\int \overline{c}\, d\mu[v_\infty] = \int_{I_1^e} \left(\int \overline{c}\, d\nu \right) m(d\nu)\,.$$

It follows that there exists a $v^* \in \Pi_{SMD}$ such that

$$\int \overline{c}\, d\mu[v_\infty] = \int \overline{c}\, d\mu[v^*],$$

and since $v_\infty \in \Pi_{SM}$ is optimal, the optimality of $v^* \in \Pi_{SMD}$ follows. □

We now investigate the existence of an optimal Markov policy under the blanket stability conditions in (C1)–(C2).

LEMMA 5.4. *Under either* (C1) *or* (C2)*, for any admissible policy $v \in \Pi$, the empirical process $\{\mu_t(v)\}$ defined in* (5.5) *is tight.*

The proof of Lemma 5.4 closely follows the arguments in the proof of [6, Theorem 6.2.2]. Topologize the space Π_M as in [6], [14]. We now state another result, the proof of which closely follows [14, Theorem 3.3, Lemma 4.4].

LEMMA 5.5. *Under either* (C1) *or* (C2)*, the sets I_1, I_2 are compact in total variation and the map $v \mapsto \mu[v]$ (as defined in* (5.4)*) is continuous.*

THEOREM 5.3. *Under either* (C1) *or* (C2)*, there exists a $v^* \in \Pi_{SMD}$ which is a.s. optimal.*

Proof. First note that under (C1) or (C2), $\Pi_{SM} = \Pi_M$ and $\Pi_{SMD} = \Pi_{SD}$. By Lemma 5.5, there exists a $\overline{v} \in \Pi_{SM}$ such that

$$\min_{v \in \Pi_{SM}} \int \overline{c}\, d\mu[v] = \int \overline{c}\, d\mu[\overline{v}].$$

In view of Lemma 5.4 and the decomposition and disintegration of the measure as defined in (5.6), (5.8), it suffices to confine our attention to Π_{SM} for optimality. Thus, the existence of an a.s. optimal $v^* \in \Pi_{SMD}$ then follows via Choquet's theorem as in Theorem 5.2. □

6. HJB Equations. In this section, we study the HJB equations and characterize the optimal policy in terms of their solution. We introduce the following condition:

(C4) The cost function $\overline{c}$ is bounded, continuous, and Lipschitz in its first argument uniformly with respect to the third.

We follow the vanishing discount approach; i.e., we derive the HJB equations for the ergodic criterion by taking the limit of the HJB equations for the discounted criterion as the discount factor approaches zero. The results and the broad outline of these proofs follow those of [9]. However, they differ in important technical details.

Let $V_\alpha(x,i)$ denote the discounted value function with discount factor $\alpha > 0$; i.e.,

$$V_\alpha(x,i) = \inf_{v \in \Pi} E^v_{x,i}\left[\int_0^\infty e^{-\alpha t} c\big(X(t), S(t), u(t)\big) dt \right], \qquad x \in \mathbb{R}^d, \quad i \in \mathcal{S}\,. \tag{6.1}$$

The following result is proved in [14].

THEOREM 6.1. *Under* (C4), V_α *is the unique solution in* $C^2\big(\mathbb{R}^d\times\mathcal{S}\big)\bigcap C_b\big(\mathbb{R}^d\times\mathcal{S}\big)$ *of*

$$\inf_{u\in U}\big\{L^uV_\alpha(x,i)+\overline{c}(x,i,u)\big\}=\alpha V_\alpha(x,i). \tag{6.2}$$

For $i\in\mathcal{S}$, define

$$G_i:=\big\{x\in\mathbb{R}^d\ :\ \inf_{u\in U}\overline{c}(x,i,u)\le\rho^*\big\},$$
$$G:=\bigcup_{i\in\mathcal{S}}G_i\,. \tag{6.3}$$

Observe that by (C3), G is compact.

The following result plays a very crucial role.

LEMMA 6.1. *Under* (C3) *and* (C4), *there exists* $\alpha_0\in(0,1)$ *such that if* $\alpha\in(0,\alpha_0]$, $\inf_{(x,i)\in\mathbb{R}^d\times\mathcal{S}}V_\alpha(x,i)$ *is attained on the set* G *as defined in* (6.3).

Proof. Let $v_\alpha\in\Pi_{MD}$ be an optimal policy for the discount factor α. By the results of [14], for $i\in\mathcal{S}$,

(6.4)
$$\sum_{k=1}^d\overline{b}_k(x,i,v_\alpha(x,i))\frac{\partial V_\alpha(x,i)}{\partial x_k}+\sum_{j\in\mathcal{S}}\overline{\lambda}_{ij}(x,v_\alpha(x,i))V_\alpha(x,j)+\overline{c}(x,i,v_\alpha(x,i))$$
$$=\inf_{u\in U}\left\{\sum_{k=1}^d\overline{b}_k(x,i,u)\frac{\partial V_\alpha(x,i)}{\partial x_k}+\sum_{j\in\mathcal{S}}\overline{\lambda}_{ij}(x,u)V_\alpha(x,j)+\overline{c}(x,i,u)\right\}\quad\text{a.e.}$$

We let $\|x_n\|\to\infty$ in $\mathbb{R}^d$ and fix $i\in\mathcal{S}$. For given α, let $\big(X^n(\cdot),S^n(\cdot)\big)$ be the process under the policy v_α with $X^n(0)=x_n$ and $S^n(0)=i$. We can show as in [21] that $\{X^n(\cdot)-x_n\}$ are tight as $C\big([0,\infty);\mathbb{R}^d\big)$-valued random variables. Dropping to a subsequence and using Skorohod's theorem [16, p. 9] we may assume that they are defined on a common probability space and converge a.s. in $C\big([0,\infty);\mathbb{R}^d\big)$ to some process $Y(\cdot)$. Hence, $\|X^n(t)\|\to\infty$ uniformly in $t\in[0,T]$ for each $T<\infty$, a.s. By (C3), there exist $\varepsilon>0$ and $M>0$, such that

$$\inf_{u\in U}\big\{\overline{c}(x,i,u)\big\}>\rho^*+2\varepsilon\qquad\text{if}\quad\|x\|>M\,,\quad\forall\ i\in\mathcal{S}\,.$$

We select a constant T_α such that

$$(\rho^*+2\varepsilon)\big(1-e^{-\alpha T_\alpha}\big)>\rho^*+\varepsilon;$$

i.e., $e^{-\alpha T_\alpha}<\frac{\varepsilon}{(\rho^*+2\varepsilon)}$. Since

$$V_\alpha(x_n,i)\ge E^{v_\alpha}_{x_n,i}\left[\int_0^{T_\alpha}e^{-\alpha t}c\big(X^n(t),S^n(t),v_\alpha(X^n(t),S^n(t))\big)dt\right],$$

it follows that

$$V_\alpha(x_n,i)>\frac{\rho^*+\varepsilon}{\alpha} \tag{6.5}$$

for n sufficiently large. On the other hand, by a standard Tauberian theorem,

$$\limsup_{\alpha\to0}\big\{\alpha V_\alpha(x,i)\big\}\le\rho^*\qquad\forall\ (x,i)\in\mathbb{R}^d\times\mathcal{S}\,. \tag{6.6}$$

Fix $x_0 \in \mathbb{R}^d$. By (6.6), there exists $\alpha_0 = \alpha_0(x_0)$ such that $V_\alpha(x_0,\cdot) \le (\rho^* + \frac{\varepsilon}{2})/\alpha$, for all $\alpha \le \alpha_0$. Hence, it follows from (6.5) that if $\alpha \le \alpha_0$, then $\inf_{x\in\mathbb{R}^d} V_\alpha(x,i)$ is attained in a set $\{x \in \mathbb{R}^d : \|x\| \le R(\alpha)\}$ for all $i \in \mathcal{S}$. Let

$$x_{\alpha,i} := \underset{x\in\mathbb{R}^d}{\to} \arg\min\{V_\alpha(x,i)\}, \qquad (x_\alpha, i_\alpha) := \underset{i\in\mathcal{S}}{\to} \arg\min\{V_\alpha(x_{\alpha,i},i)\}.$$

Using (6.2) and the fact that, at a minimum, the gradient of $V_\alpha(\cdot,i)$ vanishes and its Hessian is positive semidefinite, we have, for $\alpha \le \alpha_0$,

$$\inf_{u\in U}\left\{\overline{c}\big(x_{\alpha,i},i,u\big) + \sum_{j\in\mathcal{S}} \overline{\lambda}_{ij}\big(x_{\alpha,i},u\big)V_\alpha\big(x_{\alpha,i},j\big)\right\} \le \alpha V_\alpha(x_{\alpha,i},i). \tag{6.7}$$

In turn, from (6.7),

$$\inf_{u\in U}\big\{\overline{c}(x_\alpha,i_\alpha,u)\big\} \le \alpha V_\alpha(x_\alpha,i_\alpha) \qquad \forall\ \alpha \le \alpha_0\,. \tag{6.8}$$

We claim that $\alpha V_\alpha(x_\alpha,i_\alpha) \le \rho^*$ for all $\alpha > 0$. Indeed, for any $v \in \Pi_{SM}$,

$$V_\alpha(x,i) \le E^v_{x,i}\left[\int_0^\infty e^{-\alpha t} c\big(X(t),S(t),v(X(t),S(t))\big)dt\right] \qquad \forall\ (x,i) \in \mathbb{R}^d \times \mathcal{S}\,. \tag{6.9}$$

Integrating both sides of (6.9) with respect to $\eta_v(dx,i)$ and using Fubini's theorem, we obtain

$$\sum_{i\in\mathcal{S}} \int_{\mathbb{R}^d} V_\alpha(x,i)\eta_v(dx,i) \le \frac{\rho_v}{\alpha}\,.$$

Hence,

$$V_\alpha(x_\alpha,i_\alpha) \le \frac{\rho^*}{\alpha}\,. \tag{6.10}$$

From (6.8),

$$\inf_{u\in U}\big\{c(x_\alpha,i_\alpha,u)\big\} \le \rho^*,$$

concluding that $(x_\alpha,i_\alpha) \in G \times \mathcal{S}$. □

LEMMA 6.2. *Under* (C3) *and* (C4)*, the map* $(x,y,i,j) \mapsto |V_\alpha(x,i) - V_\alpha(y,j)|$ *is bounded on compact subsets, uniformly in* $\alpha \in (0,\alpha_0]$.

Proof. Let $\overline{V}_\alpha(\cdot,\cdot) := V_\alpha(\cdot,\cdot) - V_\alpha(x_\alpha,i_\alpha)$. In view of Lemma 6.1, it suffices to prove that $\overline{V}_\alpha$ is uniformly bounded on compacta. By (6.2) and (6.4),

$$L^{v_\alpha}V_\alpha(x,i) = \alpha V_\alpha(x,i) - \overline{c}\big(x,i,v_\alpha(x,i)\big) \quad \text{a.e.}$$

Let $R > 0$ be large enough so that $G \subset B(0,R)$. Let $\big(X(\cdot),S(\cdot)\big)$ be the process under the policy v_α and define $\tau = \inf\{t \ge 0 : X(t) \notin B(0,2R)\}$. Then for $x \in B(0,R)$, using the strong Markov property,

$$\begin{aligned} V_\alpha(x,i) &= E^{v_\alpha}_{x,i}\left[\int_0^\infty e^{-\alpha t}\overline{c}\big(X(t),S(t),v_\alpha(X(t),S(t))\big)dt\right] \\ &= E^{v_\alpha}_{x,i}\left[\int_0^\tau e^{-\alpha t}\Big\{\overline{c}\big(X(t),S(t),v_\alpha(X(t),S(t))\big) - \alpha V_\alpha\big(X(\tau),S(\tau)\big)\Big\}dt\right] \\ &\qquad + E^{v_\alpha}_{x,i}\Big[V_\alpha\big(X(\tau),S(\tau)\big)\Big]. \end{aligned}$$

Thus,

$$\begin{aligned}&\big|V_\alpha(x,i)-E^{v_\alpha}_{x,i}V_\alpha\big(X(\tau),S(\tau)\big)\big|\\&\qquad=\left|E^{v_\alpha}_{x,i}\int_0^\tau e^{-\alpha t}\Big\{\overline{c}\big(X(t),S(t),v_\alpha(X(t),S(t))\big)-\alpha V_\alpha\big(X(\tau),S(\tau)\big)\Big\}dt\right|.\end{aligned}$$

Using (C4) and Lemma 4.2, we deduce that there exists a constant C_1 (independent of α) such that

$$\big|V_\alpha(x,i)-E^{v_\alpha}_{x,i}V_\alpha\big(X(\tau),S(\tau)\big)\big|\le C_1\qquad\forall\ (x,i)\in B(0,R)\times\mathcal{S}\,. \tag{6.11}$$

We write

$$\begin{aligned}V_\alpha(x,i)-V_\alpha(x_\alpha,i_\alpha)&=\Big(V_\alpha(x,i)-E^{v_\alpha}_{x,i}V_\alpha\big(X(\tau),S(\tau)\big)\Big)\\&+\Big(E^{v_\alpha}_{x,i}V_\alpha\big(X(\tau),S(\tau)\big)-V_\alpha(x_\alpha,i_\alpha)\Big).\end{aligned} \tag{6.12}$$

Let

$$f(x,i)=E^{v_\alpha}_{x,i}V_\alpha\big(X(\tau),S(\tau)\big)-V_\alpha(x_\alpha,i_\alpha).$$

We observe that $f\ge 0$ and $L^{v_\alpha}f=0$ in $W^{2,p}\big(B(0,2R)\times\mathcal{S}\big)$, $2\le p<\infty$. Then, by Theorem 4.1, there exists a constant C_2 (independent of α) such that, in view of (6.11),

$$f(x,i)\le C_2 f(x_\alpha,i_\alpha)\le C_1C_2\qquad\forall\ (x,i)\in B(0,R)\times\mathcal{S}\,.$$

Hence,

$$V_\alpha(x,i)-V_\alpha(x_\alpha,i_\alpha)\le C_1(1+C_2)\qquad\forall\ (x,i)\in B(0,R)\times\mathcal{S}\,.\qquad\square$$

COROLLARY 6.1. *For any $\varepsilon>0$ and any compact $K\subset\mathbb{R}^d$, there exists $\alpha_\varepsilon\in(0,\alpha_0]$ such that for all $x\in K$, $i\in\mathcal{S}$, and $\alpha\in(0,\alpha_\varepsilon)$,*

$$\alpha V_\alpha(x,i)<\rho^*+\varepsilon. \tag{6.13}$$

Proof. The proof follows directly from Lemma 6.2 and (6.10). $\square$

THEOREM 6.2. *Under* (C3) *and* (C4)*, there exists a function $V\in C^2(\mathbb{R}^d\times\mathcal{S})$ and a scalar $\rho\in\mathbb{R}$ such that for some fixed $i_0\in\mathcal{S}$,*

$$\rho\le\rho^*,\qquad V(0,i_0)=0,\qquad\inf_{(x,i)\in\mathbb{R}^d\times\mathcal{S}}V(x,i)>-\infty \tag{6.14}$$

and the pair (V,ρ) satisfies the HJB equations given by

$$\inf_{u\in U}\big\{L^uV(x,i)+\overline{c}(x,i,u)\big\}=\rho. \tag{6.15}$$

Moreover, among all pairs $(\varphi,\rho)\in W^{2,p}_{\ell oc}(\mathbb{R}^d\times\mathcal{S})\times\mathbb{R}$, $2\le p<\infty$, satisfying (6.15)*, (V,ρ^*) is the unique one satisfying* (6.14).

Proof. Set $\overline{V}_\alpha(x,i)=V_\alpha(x,i)-V_\alpha(0,i_0)$. Then $\overline{V}(0,i_0)=0$, and by (6.2), (6.4),

$$L^{v_\alpha}\overline{V}_\alpha(x,i)=\alpha V_\alpha(x,i)-\overline{c}(x,i,v_\alpha(x,i)).$$

By Corollary 6.1, Lemma 6.2, and the interior estimates for solutions of uniformly elliptic systems [22, pp. 398–402], we can show using a standard bootstrap argument that for any $R > 0$, $2 \le p < \infty$,

$$\sup_{\alpha\in(0,\alpha_\varepsilon)} \left\| \overline{V}_\alpha(\cdot,\cdot) \right\|_{W^{2,p}(B(0,R)\times\mathcal{S})} \le C$$

for some constant C. Since $W^{2,p}_{\ell oc} \hookrightarrow W^{1,p}_{\ell oc}$ is compact for $p \ge 1$, $\{\overline{V}_\alpha(\cdot), \alpha \in (0,\alpha_\varepsilon)\}$ is sequentially compact in $W^{1,p}_{\ell oc}$. Let $\alpha_n \to 0$ in $(0,\alpha_\varepsilon)$. By dropping to a subsequence, if necessary, let $\overline{V}_{\alpha_n} \to V$ in $W^{1,p}_{\ell oc}$ for some V. By the Sobolev imbedding theorem, this convergence is also uniform on compact subsets of $\mathbb{R}^d$. Let ρ be a limit point of $\alpha_n V_{\alpha_n}(0,i_0)$ and hence of $\alpha_n V_{\alpha_n}(x,i)$ for any $(x,i) \in \mathbb{R}^d \times \mathcal{S}$, in view of Lemma 6.2. By (6.13), $\rho \le \rho^*$. It can be shown as in [2], [22, p. 420] that

$$\inf_{u\in U} \left\{ \sum_{k=1}^d \overline{b}_k(x,i,u) \frac{\partial \overline{V}_{\alpha_n}(x,i)}{\partial x_k} + \sum_{j\in\mathcal{S}} \overline{\lambda}_{ij}(x,u) \overline{V}_{\alpha_n}(x,j) + \overline{c}(x,i,u) \right\}$$
$$\underset{n\to\infty}{\longrightarrow} \inf_{u\in U} \left\{ \sum_{k=1}^d \overline{b}_k(x,i,u) \frac{\partial V(x,i)}{\partial x_k} + \sum_{j\in\mathcal{S}} \overline{\lambda}_{ij}(x,u) V(x,j) + \overline{c}(x,i,u) \right\}$$

in $L^p_{\ell oc}$ strongly. From the above discussion, it follows that $V \in W^{1,p}_{\ell oc}$, for any $2 \le p < \infty$, and V satisfies (6.15) in D' (i.e., in the sense of distributions). By elliptic regularity, $V \in W^{2,p}_{\ell oc}$, $2 \le p < \infty$. In turn, by the Sobolev imbedding theorem, $V \in C^{1,\gamma}(\mathbb{R}^d \times \mathcal{S})$ for $0 < \gamma < 1$, γ arbitrarily close to 1. Hence by (C4), it is easy to see that

$$\inf_{u\in U} \left\{ \sum_{k=1}^d \overline{b}_k(x,i,u) \frac{\partial V(x,i)}{\partial x_k} + \sum_{j\in\mathcal{S}} \overline{\lambda}_{ij}(x,u) V(x,j) + \overline{c}(x,i,u) \right\}$$

is in $C^{0,\gamma}(\mathbb{R}^d \times \mathcal{S})$. By elliptic regularity [15, p. 287] applied to (6.15), we conclude that $V \in C^{2,\gamma}(\mathbb{R}^d \times \mathcal{S})$. Clearly, $V(0,i_0) = 0$. It suffices to show that V is bounded below. For any $x \in \mathbb{R}^d$, $i \in \mathcal{S}$,

(6.16)
$$V(x,i) = \lim_{n\to\infty} \left[V_{\alpha_n}(x,i) - V_{\alpha_n}(0,i_0) \right]$$
$$\ge \lim_{n\to\infty} \left[V_{\alpha_n}(x_{\alpha_n},i) - V_{\alpha_n}(0,i_0) \right] + \lim_{n\to\infty} \left[V_{\alpha_n}(x_{\alpha_n},i_{\alpha_n}) - V_{\alpha_n}(x_{\alpha_n},i) \right].$$

Using Lemmas 6.1 and 6.2, it follows from (6.16) that for each $i \in \mathcal{S}$,

$$\inf_{(x,i)\in\mathbb{R}^d\times\mathcal{S}} V(x,i) > -\infty,$$

and the proof of the first part of the theorem is complete. The second assertion can be shown by following the methodology in [9]. □

Further, based on Lemmas 6.1 and 6.2 and Theorem 4.1, the following theorem can be proved using the techniques presented in [9]. We therefore skip the proof.

THEOREM 6.3. *Assume* (C3) *and* (C4). *Let* $v^* \in \Pi_{MD}$ *be such that for each* i

(6.17)
$$\inf_{u\in U}\left\{\sum_{k=1}^{d}\overline{b}_k(x,i,u)\frac{\partial V(x,i)}{\partial x_k}+\sum_{j\in\mathcal{S}}\overline{\lambda}_{ij}(x,u)V(x,j)+\overline{c}(x,i,u)\right\}$$
$$=\sum_{k=1}^{d}\overline{b}_k\big(x,i,v^*(x,i)\big)\frac{\partial V(x,i)}{\partial x_k}+\sum_{j\in\mathcal{S}}\overline{\lambda}_{ij}\big(x,v^*(x,i)\big)V(x,j)+\overline{c}\big(x,i,v^*(x,i)\big)\quad a.e.$$

Then $v^* \in \Pi_{SMD}$. *The scalar* ρ *in* (6.15) *equals* ρ^*, *and* v^* *is a.s. optimal. Moreover,* $v \in \Pi_{SMD}$ *is a.s. optimal if and only if it satisfies* (6.17).

Remark 6.1. The boundedness condition on the cost function $\overline{c}$ may be relaxed. For unbounded $\overline{c}$ we can use a suitable truncation procedure to approximate $\overline{c}$ by a sequence of bounded functions. Then the arguments in [9, p. 202] can be paralleled to establish the results in Theorems 6.2–6.3.

We now study the HJB equation under (C1) and (C4). Recall that under (C1), $\Pi_M = \Pi_{SM}$.

LEMMA 6.3. *Let* w *satisfy* (C1). *Then for any* $v \in \Pi_{SM}$,

(i) $\sum_{i\in\mathcal{S}}\int_{\mathbb{R}^d} w(x,i)\eta_v(dx,i) < \infty$,

(ii) $\lim_{t\to\infty}\frac{1}{t}E^v_{x,i}\big[w\big(X(t),S(t)\big)\big]=0$.

Proof. Let $R>0$ and τ_R be the exit time of $X(t)$ from $B(0,R)$. Then by Ito's formula

$$E^v_{x,i}\Big[w\big(X(t\wedge\tau_R),S(t\wedge\tau_R)\big)\Big]-w(x,i)=E^v_{x,i}\left[\int_0^{t\wedge\tau_R}L^v w\big(X(s),S(s)\big)ds\right].$$

Letting $R\to\infty$, we have

$$E^v_{x,i}\big[w\big(X(t),S(t)\big)\big]-w(x,i)=E^v_{x,i}\left[\int_0^{t}L^v w\big(X(s),S(s)\big)ds\right].$$

Therefore, by using (C1), we have

$$\frac{d}{dt}E^v_{x,i}\big[w\big(X(t),S(t)\big)\big]\le p-qE^v_{x,i}\big[w\big(X(t),S(t)\big)\big].$$

Then by Gronwall's inequality,

$$E^v_{x,i}\big[w\big(X(t),S(t)\big)\big]\le\frac{p}{q}+w(x,i)e^{-qt}. \tag{6.18}$$

Both (i) and (ii) follow directly from (6.18). □

LEMMA 6.4. *Assume* (C1) *holds. Let* $a>0$ *be such that*

$$L^u w(x,i)\le -1\qquad \textit{for all}\quad \|x\|>a\,,\ u\in U\,,\ i\in\mathcal{S}\,.$$

If

$$\tau_a:=\inf\big\{t\ge 0\,:\,\|X(t)\|\le a\big\}\,, \tag{6.19}$$

then, for all $v\in\Pi_M$, $\|x\|>a$, *and* $i\in\mathcal{S}$,

$$E^v_{x,i}\big[\tau_a\big]\le w(x,i)\,. \tag{6.20}$$

Proof. Let $v \in \Pi_M$. Choose $R > 0$ such that $a < \|x\| < R$. Let

$$\tau'_R = \inf\{t \geq 0 \,:\, X(t) \notin B(0,R) \setminus B(0,a)\}.$$

Then by Ito's formula

$$E^v_{x,i}\Big[w\big(X(t\wedge\tau'_R), S(t\wedge\tau'_R)\big)\Big] = w(x,i) + E^v_{x,i}\bigg[\int_0^{t\wedge\tau'_R} L^v w\big(X(s),S(s)\big)ds\bigg].$$

Therefore,

$$E^v_{x,i}\Big[w\big(X(t\wedge\tau'_R), S(t\wedge\tau'_R)\big)\Big] \leq w(x,i) - E^v_{x,i}\big[t\wedge\tau'_R\big].$$

Thus,

$$E^v_{x,i}\big[t\wedge\tau'_R\big] \leq w(x,i). \tag{6.21}$$

Letting first $t\to\infty$ and then $R\to\infty$, invoking Fatou's lemma at each step, we obtain (6.20). ∎

THEOREM 6.4. *Under* (C1) *and* (C4)*, the HJB equation* (6.15) *admits a unique solution* (V,ρ) *in the class* $C^2(\mathbb{R}^d\times\mathcal{S})\bigcap\mathcal{O}(w)$*, satisfying* $V(0,i_0)=0$ *for some fixed* $i_0\in\mathcal{S}$.

Proof. Let $v^*\in\Pi_{SMD}$ be a.s. optimal. The existence of such a v^* is guaranteed by Theorem 5.3. Let

$$K_1 = \sup_{x,i,u}\{\overline{c}(x,i,u)\},$$
$$K_2 = \sup_{v\in\Pi_{SMD}}\int \overline{c}\,d\mu[v].$$

We select an arbitrary sequence of smooth functions $\psi_n:\mathbb{R}^d\to[0,K_1+4K_2]$, $n\geq 1$, that are zero on $B(0,n)$ and equal to K_1+4K_2 on the complement of $B(0,n+1)$, and define

$$c_{1n}(x,i,u) = \frac{1}{2}\big[\overline{c}(x,i,u)+\psi_n(x)\big],$$
$$c_{2n}(x,i,u) = \frac{1}{2}\big[\psi_n(x)-\overline{c}(x,i,u)\big].$$

Then, for a sufficiently large n, c_{1n} and c_{2n} both satisfy the penalizing condition (C3). We select one such term of the sequence from now on and drop the subscript n for notational convenience. Let $\big(X(\cdot),S(\cdot)\big)$ be the process under the policy v^*. For $\alpha>0$, we define

$$V_{\alpha,1}(x,i) = E^{v^*}_{x,i}\bigg[\int_0^\infty e^{-\alpha t}c_1\big(X(t),S(t),v^*(X(t),S(t))\big)dt\bigg],$$
$$V_{\alpha,2}(x,i) = E^{v^*}_{x,i}\bigg[\int_0^\infty e^{-\alpha t}c_2\big(X(t),S(t),v^*(X(t),S(t))\big)dt\bigg],$$
$$V_{\alpha}(x,i) = E^{v^*}_{x,i}\bigg[\int_0^\infty e^{-\alpha t}\overline{c}\big(X(t),S(t),v^*(X(t),S(t))\big)dt\bigg].$$

Then we can modify the arguments in the proof of Lemma 6.2 to conclude that for a fixed $i_0 \in \mathcal{S}$, $\big(V_{\alpha,1}(x,i) - V_{\alpha,1}(0,i_0)\big)$ and $\big(V_{\alpha,2}(x,i) - V_{\alpha,2}(0,i_0)\big)$ are bounded on compacta uniformly in $\alpha \in (0,\alpha_0]$, for some $\alpha_0 > 0$. Hence,

$$\begin{aligned}\overline{V}_\alpha(x,i) &:= V_\alpha(x,i) - V_\alpha(0,i_0)\\ &= \big[V_{\alpha,1}(x,i) - V_{\alpha,1}(0,i_0)\big] - \big[V_{\alpha,2}(x,i) - V_{\alpha,2}(0,i_0)\big]\end{aligned}$$

is bounded on compact sets, uniformly in $\alpha \in (0,\alpha_0]$. Arguing as in the proof of Theorem 6.2 we conclude that $\overline{V}_\alpha(x,i) \to V(x,i)$, as $\alpha \to 0$, uniformly on compacta and in $W^{2,p}_{\ell oc}(\mathbb{R}^d \times \mathcal{S})$ for any $p \in [2,\infty)$, and that the limit V satisfies

$$L^{v^*} V(x,i) + \overline{c}(x,i,v^*(x,i)) = \rho^*,$$

with $V(0,i_0) = 0$. Using the strong Markov property, relative to the stopping time τ_a in (6.19), we obtain

$$\begin{aligned}\overline{V}_\alpha(x,i) = E^{v^*}_{x,i}\bigg[\int_0^{\tau_a} e^{-\alpha t}\Big\{\overline{c}\big(X(t),S(t),v^*(X(t),S(t))\big) - \alpha V_\alpha(0,i_0)\Big\}dt\bigg]\\ + E^{v^*}_{x,i}\Big[e^{-\alpha\tau_a}\overline{V}_\alpha\big(X(\tau_a),S(\tau_a)\big)\Big].\end{aligned}$$

Hence, by Lemma 6.4, for $\alpha \in (0,\alpha_0]$ and $\|x\| > a$,

$$\begin{aligned}\big|\overline{V}_\alpha(x,i)\big| &\le C_1 + C_2 E^{v^*}_{x,i}[\tau_a]\\ &\le C_1 + C_2 w(x,i),\end{aligned}$$

where C_1, C_2 are positive constants independent of α. Passing to the limit as $\alpha \to 0$, it follows that V is in the class $\mathcal{O}(w)$. Next we let $v \in \Pi_{SMD}$ be such that for each $i \in \mathcal{S}$,

$$\begin{aligned}&\sum_{k=1}^d \overline{b}_k(x,i,v(x,i))\frac{\partial V(x,i)}{\partial x_k} + \sum_{j\in\mathcal{S}} \overline{\lambda}_{ij}(x,v(x,i))V(x,j) + \overline{c}(x,i,v(x,i))\\ &\qquad = \inf_{u\in U}\left\{\sum_{k=1}^d \overline{b}_k(x,i,u)\frac{\partial V(x,i)}{\partial x_k} + \sum_{j\in\mathcal{S}} \overline{\lambda}_{ij}(x,u)V(x,j) + \overline{c}(x,i,u)\right\} \quad \text{a.e.}\end{aligned}$$

Suppose that for some $i' \in \mathcal{S}$, there exist $\delta > 0$ such that the set

$$D = \Big\{x \in \mathbb{R}^d \,:\, L^v V(x,i') \le \rho^* - \overline{c}\big(x,i',v(x,i')\big) - \delta\Big\}$$

has positive Lebesgue measure. By Ito's formula

$$E^v_{x,i}\big[V\big(X(t),S(t)\big)\big] - V(x,i) = E^v_{x,i}\bigg[\int_0^t L^v V\big(X(s),S(s)\big)ds\bigg].$$

This is justified because V is $\mathcal{O}(w)$. Therefore,

$$\begin{aligned}E^v_{x,i}\big[V\big(X(t),S(t)\big)\big] - V(x,i) \le E^v_{x,i}\bigg[\int_0^t \Big[\rho^* - \overline{c}\big(X(s),S(s),v(X(s),S(s))\big)\Big]ds\bigg]\\ - \delta E^v_{x,i}\bigg[\int_0^t I\big\{X(s)\in D, S(s) = i'\big\}ds\bigg].\end{aligned}$$

Dividing by t, letting $t \to \infty$, and using Lemma 6.3, we have

$$\rho_v \le \rho^* - \delta\eta_v\big(D \times \{i'\}\big).$$

Lemma 4.1 implies that η_v is mutually absolutely continuous with respect to the Lebesgue measure. Therefore, $\eta_v\big(D \times \{i'\}\big) > 0$. Hence, $\rho_v < \rho^*$, which contradicts the optimality of v^*. Thus, for each $i \in \mathcal{S}$,

$$\inf_{u \in U} \big\{ L^u V(x,i) + \overline{c}(x,i,u) \big\} = \rho^* \quad \text{a.e.} \tag{6.22}$$

Similar arguments as in the proof of Theorem 6.2 establish that $V \in C^{2,\gamma}(\mathbb{R}^d \times \mathcal{S})$, where $0 < \gamma < 1$, γ arbitrarily close to 1. We now proceed to show uniqueness. Let (V', ρ') be another solution of (6.15) in the desired class satisfying $V'(0, i_0) = 0$. Using Ito's formula and Lemma 6.3, it again follows that $\rho' = \rho^*$. Therefore,

$$L^{v^*}\big(V'(x,i) - V(x,i)\big) \ge 0.$$

Let $\big(X(t), S(t)\big)$ be the process governed by v^* and with initial law η_{v^*}. Then,

$$M(t) := V'\big(X(t), S(t)\big) - V\big(X(t), S(t)\big)$$

is a submartingale satisfying

$$\sup_{t \ge 0} E^{v^*} |M(t)| \le C_1' + C_2' \sum_{i \in \mathcal{S}} \int_{\mathbb{R}^d} w(x,i) \eta_{v^*}(dx, i) < \infty,$$

by Lemma 6.3, where C_1', C_2' are suitable constants. Here we are using the fact that both V and V' are of $\mathcal{O}(w)$. By the submartingale convergence theorem, $M(t)$ converges a.s. Since $\big(X(t), S(t)\big)$ is ergodic and irreducible under v^*, it follows that $V'(x,i) - V(x,i)$ must be constant a.s. This constant must be zero, since $V'(0, i_0) - V(0, i_0) = 0$. □

Remark 6.2. For the stable case we have carried out our analysis under the Lyapunov condition (C1). Analogous results can be derived under the condition (C2).

7. Conclusions. We have analyzed the optimal control of switching diffusions with a pathwise average cost criterion. Under certain conditions we have established the existence of a stable, nonrandomized Markov policy which is a.s. optimal in the class of all admissible policies. Also, we demonstrate the existence of a unique solution to the associated HJB equations in C^2, under varying conditions, and the optimal policy is characterized as a minimizing selector of the Hamiltonian. We have applied our results to a manufacturing model of Bielecki and Kumar and have shown that our methodology affords both greater generality and ease of solution. By studying the recurrence and ergodic properties of switching diffusions we have also obtained two new results in partial differential equations, viz. a strong maximum principle and Harnack's inequality for a weakly coupled elliptic system.

Appendix. This appendix is devoted to the proof of Theorem 4.1.

Given a domain $\Omega \subset \mathbb{R}^d$, a real function $\boldsymbol{u}$ defined on $\Omega \times \mathcal{S}$ is viewed as a vector-valued function $\boldsymbol{u} = (u_1, \dots, u_N)$, with each component u_i being a real function on Ω.

Consider a second order operator L defined by (note that L_k is different from the operator in (3.7))

$$(L\boldsymbol{u})_k(x) := L_k u_k(x) + \sum_{\substack{j\in\mathcal{S}\\ j\neq k}} c_{kj}(x)u_j(x)\,, \qquad k\in\mathcal{S},$$

$$L_k := \sum_{i,j=1}^{d} a_{ij}^k(x)\frac{\partial^2}{\partial x_i\partial x_j} + \sum_{i=1}^{d} b_i^k(x)\frac{\partial}{\partial x_i} + c_{kk}(x)\,. \tag{A.1}$$

Let $m, \overline{m}, \overline{\gamma}$, and ε_Ω be given positive constants, the last depending on the choice of a bounded domain Ω. We denote by $\mathfrak{L} = \mathfrak{L}(m, \overline{m}, \overline{\gamma}, \varepsilon_\Omega)$ the class of all such operators L, with coefficients $a_{ij}^k(\cdot) \in C^{0,1}(\mathbb{R}^d)$ and $b_i^k(\cdot), c_{kj}(\cdot) \in L^\infty(\mathbb{R}^d)$, satisfying

(A.2) $m\|\zeta\|^2 \le \sum_{i,j=1}^{d} a_{ij}^k(x)\zeta_i\zeta_j \le \overline{m}\|\zeta\|^2$ for all $x, \zeta \in \mathbb{R}^d$, $k \in \mathcal{S}$.

(A.3) $\|b_i^k\|_\infty \le \overline{m}$, $\|c_{k\ell}\|_\infty \le \overline{m}$ and $\|a_{ij}^k(x) - a_{ij}^k(y)\|_\infty \le \overline{\gamma}\|x-y\|$ for all $x, y \in \mathbb{R}^d$, $i, j \in \{1, \dots, d\}$, $k, \ell \in \mathcal{S}$.

(A.4) $\sum_{i\in\mathcal{S}} c_{ki}(\cdot) = 0$ and $c_{kj} \ge 0$, for $j \neq k$.

(A.5) The matrix $\boldsymbol{C}(x;\varepsilon_\Omega) := \big[c_{ij}(x) \,:\, c_{ij}(x) \ge \varepsilon_\Omega, i \neq j\big]$ is irreducible at each $x \in \Omega$.

We denote by $\mathfrak{U}_\Omega$ the class of all nonnegative functions $\boldsymbol{u} \in W^{2,d}_{\ell oc}(\Omega\times\mathcal{S}) \bigcap C^0(\overline{\Omega}\times\mathcal{S})$, satisfying $L\boldsymbol{u} = 0$ in Ω, for some $L \in \mathfrak{L}$. If $\xi \in \mathbb{R}$, then $\boldsymbol{u} \ge \xi$ is to be interpreted as $u_i \ge \xi$ for all $i \in \mathcal{S}$, and if $\boldsymbol{\xi} = (\xi_1, \dots, \xi_N) \in \mathbb{R}^N$, then $\boldsymbol{u} \ge \boldsymbol{\xi} \iff u_i \ge \xi_i$ for all $i \in \mathcal{S}$. For better clarity, we denote all $\mathbb{R}^N$-valued quantities by a bold letter. Also, operations such as "inf" on $\mathbb{R}^N$-valued functions are meant to be componentwise. If Γ is a closed subset of Ω, we define, for $x \in \Omega$ and $\boldsymbol{\xi} \in \mathbb{R}^N_+$,

$$\boldsymbol{\Psi}_x\big(\mathfrak{U}_\Omega, \Gamma; \boldsymbol{\xi}\big) := \inf_{\boldsymbol{u}\in\mathfrak{U}_\Omega} \big\{\boldsymbol{u}(x) \,:\, \boldsymbol{u} \ge \boldsymbol{\xi} \text{ on } \Gamma\big\}\,.$$

Deviating from the usual vector space notation, if D is a cube in $\mathbb{R}^d$ and $\delta > 0$, δD denotes the cube which is *concentric* to D and whose edges are δ times as long. For a measurable set $A \subset \mathbb{R}^d$, $|A|$ denotes the Lebesgue measure of A, while $\mathcal{B}(A)$ and $L^d(A)$ denote the sets of real-valued, measurable functions on A such that

$$\|f\|_{\mathcal{B}(A)} := \operatorname*{ess\,sup}_{x\in A} |f(x)| < \infty \qquad \forall\ f \in \mathcal{B}(A)$$

and

$$\|f\|_{d;A} := \left(\int_A |f(x)|^d dx\right)^{1/d} < \infty \qquad \forall\ f \in L^d(A)\,.$$

We use quite frequently the following comparison principle, which can be viewed as a weaker version of the maximum principle in that it holds even without condition (A.5): If $\boldsymbol{\varphi}, \boldsymbol{\psi} \in W^{2,d}_{\ell oc}(\Omega\times\mathcal{S}) \bigcap C^0(\overline{\Omega}\times\mathcal{S})$ satisfy $L\boldsymbol{\varphi} \le L\boldsymbol{\psi}$ in Ω and $\boldsymbol{\varphi} \ge \boldsymbol{\psi}$ on $\partial\Omega$, then $\boldsymbol{\varphi} \ge \boldsymbol{\psi}$ in $\overline{\Omega}$. The same comparison principle holds for $\varphi, \psi \in W^{2,d}_{\ell oc}(\Omega) \bigcap C^0(\overline{\Omega})$ relative to the set of operators $\{L_k\}_{k\in\mathcal{S}}$ as defined in (A.1).

We start with a measure-theoretic result, announced in [19].

LEMMA A.1. *Let $K \subset \mathbb{R}^d$ be a cube, $\Gamma \subset K$ be a closed subset, and $0 < \alpha < 1$. Define*

$$\boldsymbol{\mathcal{Q}} := \big\{Q \,:\, Q \text{ is a subcube of } K \text{ and } |Q \bigcap \Gamma| \geq \alpha |Q|\big\},$$
$$\widetilde{\Gamma} := \bigcup_{Q \in \boldsymbol{\mathcal{Q}}} (3Q \bigcap K)\,.$$

Then either $\widetilde{\Gamma} = K$ or $|\widetilde{\Gamma}| \geq \frac{1}{\alpha}|\Gamma|$.

Proof. If $|\Gamma| \geq \alpha |K|$, then $K \in \boldsymbol{\mathcal{Q}}$ and $\widetilde{\Gamma} = K$. So we assume $|\Gamma| < \alpha |K|$ or, equivalently, $K \notin \boldsymbol{\mathcal{Q}}$. We subdivide K into 2^d congruent subcubes with disjoint interiors. We select the ones in $\boldsymbol{\mathcal{Q}}$, while the remaining ones are similarly subdivided and the process is repeated indefinitely. Let $\boldsymbol{\mathcal{Q}}_0$ be the collection thus obtained, and with $\widehat{Q}$ denoting the ancestor of Q, we define

$$\widehat{\Gamma} := \bigcup_{Q \in \boldsymbol{\mathcal{Q}}_0} \widehat{Q}.$$

Clearly, $\widehat{Q} \subset 3Q \bigcap K$; hence, $\widetilde{\Gamma} \supset \widehat{\Gamma}$. Note that, discarding repetitions, $\widehat{\Gamma}$ can be represented as a disjoint union of cubes $\widehat{Q}$ which are not in $\boldsymbol{\mathcal{Q}}$. Therefore, each member $\widehat{Q}$ of this union satisfies $|\widehat{Q} \bigcap \Gamma| < \alpha |\widehat{Q}|$, and by σ-additivity, we obtain

$$|\widehat{\Gamma} \bigcap \Gamma| < \alpha |\widehat{\Gamma}| \leq \alpha |\widetilde{\Gamma}|\,.$$

By the regularity properties of the Lebesgue measure, $|\widehat{\Gamma} \bigcap \Gamma| = |\Gamma|$ and the proof is complete. ∎

Next we state without proof a ramification of the weak maximum principle of A. D. Aleksandroff.

LEMMA A.2. *There exist constants $C_1 > 0$ and $\kappa_0 \in (0, 1]$ such that if $D \subset \mathbb{R}^d$ is any cube of volume $|D| \leq \kappa_0$ and $\varphi \in W^{2,d}_{\ell oc}(D) \bigcap C^0(\overline{D})$, $f \in L^d(D)$ satisfy $L_k \varphi \geq f$ in D, and $\varphi = 0$ on ∂D for some $L \in \mathfrak{L}$, then*

$$\sup_{x \in D} \big\{\varphi(x)\big\} \leq C_1 |D|^{1/d} \|f\|_{d;D}\,.$$

For the remainder of this appendix, D will denote an open cube in $\mathbb{R}^d$ of volume not exceeding the constant κ_0 in Lemma A.2.

LEMMA A.3. *There exist constants $\beta_0 > 0$ and $\alpha_0 < 1$ such that, if Γ is a closed subset of some cube $D \subset \mathbb{R}^d$, satisfying $|\Gamma| \geq \alpha_0 |D|$, then*

$$\inf_{x \in \frac{1}{3} D} \boldsymbol{\Psi}_x\big(\mathfrak{U}_D, \Gamma; \boldsymbol{\xi}\big) \geq \beta_0 \boldsymbol{\xi} \qquad \forall\, \boldsymbol{\xi} \in \mathbb{R}^N_+\,.$$

Proof. Observe that if $\boldsymbol{u} \in \mathfrak{U}_D$, then each component u_k satisfies $L_k u_k \leq 0$ in D. Define $\varphi', \varphi'' \in W^{2,d}_{\ell oc}(D) \bigcap C^0(\overline{D})$ by

$$L_k \varphi'(x) = -I_\Gamma(x), \quad L_k \varphi''(x) = -I_{\Gamma^c}(x) \qquad \text{in } \ D$$
$$\text{and} \quad \varphi'(x) = \varphi''(x) = 0 \qquad \text{on } \ \partial D\,.$$

Then $\varphi := \varphi' + \varphi''$ satisfies $L_k \varphi = -1$ in D and $\varphi = 0$ on ∂D. Without loss of generality, suppose that D is centered at the origin and consider the function

$$\psi(x) := \prod_{i=1}^{d} \big(|D|^{2/d} - 4x_i^2\big).$$

Note that $\psi = 0$ on ∂D and $\psi > 0$ in D. In addition, there exists a positive constant C_2 such that

$$\inf_{x\in\frac{1}{3}D}\{\psi(x)\} \ge C_2|D|^{2/d}\|L_k\psi\|_{\mathcal{B}(D)} \qquad \forall\, L\in\mathfrak{L}\,.$$

Therefore, by the comparison principle,

$$\varphi(x) \ge \frac{\psi(x)}{\|L_k\psi\|_{\mathcal{B}(D)}} \ge C_2|D|^{2/d} \qquad \forall\, x\in\tfrac{1}{3}D\,. \tag{A.6}$$

Using Lemma A.2, we obtain

$$\begin{aligned} \varphi' &\le C_1|D|^{1/d}|\Gamma|^{1/d} = C_1|D|^{2/d}\Big(\tfrac{|\Gamma|}{|D|}\Big)^{1/d},\\ \varphi'' &\le C_1|D|^{1/d}|\Gamma^c|^{1/d} = C_1|D|^{2/d}\Big(1-\tfrac{|\Gamma|}{|D|}\Big)^{1/d}. \end{aligned} \tag{A.7}$$

By (A.6) and (A.7),

$$\varphi'(x) \ge C_2|D|^{2/d} - C_1|D|^{2/d}\Big(1-\tfrac{|\Gamma|}{|D|}\Big)^{1/d} \qquad \forall\, x\in\tfrac{1}{3}D\,.$$

On the other hand, since $L_k\varphi' = 0$ in $D\setminus\Gamma$ and $\varphi' = 0$ on ∂D, the comparison principle yields

$$\inf_{x\in\frac{1}{3}D}\{u_k(x)\} \ge \xi_k\frac{C_2 - C_1\Big(1-\frac{|\Gamma|}{|D|}\Big)^{1/d}}{C_1\Big(\frac{|\Gamma|}{|D|}\Big)^{1/d}}\,. \tag{A.8}$$

Selecting α_0 to satisfy

$$\alpha_0 \ge 1 - \Big(\frac{C_2}{2C_1}\Big)^d,$$

(A.8) yields

$$\inf_{x\in\frac{1}{3}D}\{u_k(x)\} \ge \frac{C_2\xi_k}{2C_1}.$$

Hence, the claim follows with $\beta_0 = \frac{C_2}{2C_1}$. □

LEMMA A.4. *For each $\delta > 0$, there exists a constant $k'_\delta > 0$ such that if $Q \subset (1-\delta)D$ is a subcube of an open cube $D\subset\mathbb{R}^d$, then*

$$\boldsymbol{\Psi}_x\big(\mathfrak{U}_D, \tfrac{1}{3}Q;\boldsymbol{\xi}\big) \ge k'_\delta\boldsymbol{\xi} \qquad \forall\, x\in 3Q\bigcap(1-\delta)D \quad \forall\,\boldsymbol{\xi}\in\mathbb{R}^N_+\,.$$

Proof. Let $B(r)\subset\mathbb{R}^d$ denote the ball of radius r centered at the origin. We claim that there exists a constant $m_0 > 0$ such that if $r\le 1$, then

$$\inf_{x\in B(\frac{3r}{4})}\boldsymbol{\Psi}_x\big(\mathfrak{U}_{B(r)}, B\big(\tfrac{r}{4}\big);\boldsymbol{\xi}\big) \ge m_0\,\boldsymbol{\xi} \qquad \forall\,\boldsymbol{\xi}\in\mathbb{R}^N_+\,. \tag{A.9}$$

In order to establish (A.9) we use the function

$$\varphi(x) := \exp\Big\{a\Big(1-\tfrac{\|x\|^2}{r^2}\Big)\Big\} - 1\,, \qquad a := \tfrac{\overline{m}}{m}(16d+2)\,, \qquad x\in B(r)\,,$$

which satisfies $L_k\varphi(x) \ge 0$ for all $L \in \mathfrak{L}$, provided $\|x\| \ge \frac{r}{4}$ and $r \le 1$. By the comparison principle, (A.9) holds with

$$m_0 = \frac{e^{\frac{7a}{16}} - 1}{e^{\frac{15a}{16}} - 1}\,.$$

It follows that if $B(r,y)$ is a ball of radius r centered at y, and x is an arbitrary point in D such that the distance between ∂D and the line segment joining x and y is at least r, then

$$\boldsymbol{\Psi}_x\big(\mathfrak{U}_D, B\big(\tfrac{r}{4}, y\big); \boldsymbol{\xi}\big) \ge (m_0)^{\ell}\, \boldsymbol{\xi}\,, \qquad \text{with} \quad \ell = \left\lceil \tfrac{4\|x-y\|-r}{2r} \right\rceil \qquad \forall\, \boldsymbol{\xi} \in \mathbb{R}^N_+\,. \tag{A.10}$$

Choosing $r = \min\big\{\frac{2}{3}, \frac{\delta}{2}\big\}|Q|^{1/d}$ and applying (A.10), an easy calculation shows that the result holds with

$$k'_\delta := m_0^{\ell(\delta)}\,, \qquad \ell(\delta) := \left\lceil \frac{6\sqrt{d}}{\min\{1,\delta\}} \right\rceil. \qquad \square$$

LEMMA A.5. *Suppose that there exist constants ε and θ such that if $\Gamma \subset (1-\delta)D$ is a closed subset of some cube D and $\boldsymbol{\xi} \in \mathbb{R}^N_+$, then*

$$\inf_{x \in \frac{1}{3}D} \boldsymbol{\Psi}_x\big(\mathfrak{U}_D, \Gamma; \boldsymbol{\xi}\big) \ge \varepsilon \boldsymbol{\xi} \quad \textit{whenever} \quad |\Gamma| \ge \theta |D|\,.$$

Then there exists a constant $k_\delta > 0$ such that

$$\inf_{x \in \frac{1}{3}D} \boldsymbol{\Psi}_x\big(\mathfrak{U}_D, \Gamma; \boldsymbol{\xi}\big) \ge \varepsilon k_\delta \boldsymbol{\xi} \quad \textit{whenever} \quad |\Gamma| \ge \alpha_0 \theta |D|\,,$$

where α_0 is the constant in Lemma A.3.

Proof. Suppose $|\Gamma| \ge \alpha_0\theta|D|$ and let $y \in \widetilde{\Gamma}$, with $\widetilde{\Gamma}$ as defined in Lemma A.1 corresponding to $\alpha = \alpha_0$ and $K = (1-\delta)D$. Then there exists a subcube $Q \subset K$ such that $|\Gamma \bigcap Q| \ge \alpha_0|Q|$ and $y \in 3Q \bigcap K$. We use the identities

$$\boldsymbol{\Psi}_x\big(\mathfrak{U}_D, \Gamma; \boldsymbol{\xi}\big) \ge \boldsymbol{\Psi}_x\Big(\mathfrak{U}_D, \widetilde{\Gamma};\ \inf_{y \in \widetilde{\Gamma}} \boldsymbol{\Psi}_y\big(\mathfrak{U}_D, \Gamma; \boldsymbol{\xi}\big)\Big) \tag{A.11}$$

and

$$\begin{aligned} \boldsymbol{\Psi}_y\big(\mathfrak{U}_D, \Gamma; \boldsymbol{\xi}\big) &\ge \boldsymbol{\Psi}_y\Big(\mathfrak{U}_D, \tfrac{1}{3}Q;\ \inf_{z \in \frac{1}{3}Q} \boldsymbol{\Psi}_z\big(\mathfrak{U}_D, \Gamma; \boldsymbol{\xi}\big)\Big) \\ &\ge \boldsymbol{\Psi}_y\Big(\mathfrak{U}_D, \tfrac{1}{3}Q;\ \inf_{z \in \frac{1}{3}Q} \boldsymbol{\Psi}_z\big(\mathfrak{U}_Q, \Gamma \bigcap Q; \boldsymbol{\xi}\big)\Big)\,. \end{aligned} \tag{A.12}$$

From Lemma A.3, we have

$$\inf_{z \in \frac{1}{3}Q} \boldsymbol{\Psi}_z\big(\mathfrak{U}_Q, \Gamma \bigcap Q; \boldsymbol{\xi}\big) \ge \beta_0 \boldsymbol{\xi}\,. \tag{A.13}$$

From Lemma A.4, we obtain $\boldsymbol{\Psi}_y\big(\mathfrak{U}_D, \frac{1}{3}Q; \beta_0\boldsymbol{\xi}\big) \ge \beta_0 k'_\delta \boldsymbol{\xi}$, for all $y \in 3Q \bigcap K$. Hence, combining (A.12) and (A.13) yields

$$\inf_{y \in \widetilde{\Gamma}} \boldsymbol{\Psi}_y\big(\mathfrak{U}_D, \Gamma; \boldsymbol{\xi}\big) \ge k_\delta \boldsymbol{\xi}\,, \qquad \text{with} \quad k_\delta := \beta_0 k'_\delta\,. \tag{A.14}$$

From Lemma A.1, $|\widetilde{\Gamma}| \ge \frac{1}{\alpha_0}|\Gamma| \ge \theta|D|$. Therefore, by hypothesis,

$$\inf_{x\in\frac{1}{3}D} \boldsymbol{\Psi}_x\big(\mathfrak{U}_D, \widetilde{\Gamma}; k_\delta\boldsymbol{\xi}\big) \ge \varepsilon k_\delta\boldsymbol{\xi}\,,$$

which along with (A.11) and (A.14) yield the desired result. ∎

THEOREM A.1. *The following estimates hold.*

(i) *Let D be a cube and $\Gamma \subset (1-\delta)D$ a closed subset. Then for all $\boldsymbol{\xi} \in \mathbb{R}^N_+$,*

$$\inf_{x\in\frac{1}{3}D} \boldsymbol{\Psi}_x\big(\mathfrak{U}_D, \Gamma; \boldsymbol{\xi}\big) \ge \beta_0 \left(\tfrac{|\Gamma|}{|D|}\right)^{\rho(\delta)} \boldsymbol{\xi}\,, \qquad \rho(\delta) := \frac{\log k_\delta}{\log \alpha_0}, \tag{A.15}$$

where the constants α_0, β_0, and k_δ are as in Lemmas A.3 *and* A.5.

(ii) *There exists a real function F defined in $[0,1]$, with $F(\theta) > 0$ if $\theta > 0$, such that if $\Gamma \subset D$ is a closed subset of a cube D, then*

$$\inf_{x\in\frac{1}{3}D} \boldsymbol{\Psi}_x\big(\mathfrak{U}_D, \Gamma; \boldsymbol{\xi}\big) \ge F\left(\tfrac{|\Gamma|}{|D|}\right) \boldsymbol{\xi} \qquad \forall\ \boldsymbol{\xi} \in \mathbb{R}^N_+\,. \tag{A.16}$$

Proof. Part (i) is a direct consequence of Lemmas A.3 and A.5. For part (ii), choose $\delta = \frac{|\Gamma|}{4d|D|}$. Then,

$$\frac{|\Gamma \bigcap (1-\delta)D|}{|D|} \ge \frac{|\Gamma|}{|D|} - \big(1-(1-\delta)^d\big) \ge \frac{|\Gamma|}{|D|} - d\delta \ge \frac{3|\Gamma|}{4|D|}\,. \tag{A.17}$$

Since

$$\boldsymbol{\Psi}_x\big(\mathfrak{U}_D, \Gamma; \boldsymbol{\xi}\big) \ge \boldsymbol{\Psi}_x\big(\mathfrak{U}_D, \Gamma \bigcap (1-\delta)D; \boldsymbol{\xi}\big)\,,$$

the bound in (A.16) follows from (A.15) and (A.17), with

$$F(\theta) := \beta_0 \left(\tfrac{3\theta}{4}\right)^{\rho(\frac{\theta}{4d})}\,. \qquad \blacksquare$$

Definition A.1. If $A \subset \Omega$ we define the oscillation of a function $\boldsymbol{u} \in C^0(\overline{\Omega} \times \mathcal{S})$ over A by

$$\operatorname{osc}(\boldsymbol{u}; A) = \max_{k\in\mathcal{S}} \sup_{x\in A}\big\{u_k(x)\big\} - \min_{k\in\mathcal{S}} \inf_{x\in A}\big\{u_k(x)\big\}\,.$$

The oscillation of a function in $C^0(\overline{\Omega})$ is defined in the usual manner.

THEOREM A.2. *If D is a cube, $\boldsymbol{u} \in \mathfrak{U}_D$ and $q = F\big(\frac{1}{2}\big)$, with $F(\cdot)$ as defined in Theorem* A.1 (ii)*, then*

$$\operatorname{osc}(u_k; \tfrac{1}{3}D) \le \big(1 - \tfrac{q}{2}\big) \operatorname{osc}(\boldsymbol{u}; D) \qquad \forall\ k \in \mathcal{S}\,.$$

Proof. Let

$$M^a_k := \sup_{x\in\frac{1}{3}D}\big\{u_k(x)\big\}\,, \qquad M^a := \max_{k\in\mathcal{S}} M^a_k,$$
$$m^a_k := \inf_{x\in\frac{1}{3}D}\big\{u_k(x)\big\}\,, \qquad m^a := \min_{k\in\mathcal{S}} m^a_k,$$

and M^b, m^b be the corresponding quantities relative to D. Consider the sets

$$\Gamma_1^{(k)} := \Big\{ x \in D \,:\, u_k(x) \le \tfrac{M^b+m^b}{2} \Big\},$$
$$\Gamma_2^{(k)} := \Big\{ x \in D \,:\, u_k(x) \ge \tfrac{M^b+m^b}{2} \Big\}.$$

Suppose $|\Gamma_2^{(k)}| \ge \frac{1}{2}|D|$. Since $\boldsymbol{u} - m^b$ is nonnegative and $u_k - m^b \ge \frac{M^b-m^b}{2}$ in $\Gamma_2^{(k)}$, applying Theorem A.1 (ii) yields

$$u_k(x) - m^b \ge q\tfrac{M^b-m^b}{2} \qquad \forall\, x \in \tfrac{1}{3}D\,.$$

Consequently, $m_k^a \ge m^b + q\frac{M^b-m^b}{2}$, and since $M^a \le M^b$, we obtain

$$M^a - m_k^a \le M^b - m^b - q\tfrac{M^b-m^b}{2} \le \big(1-\tfrac{q}{2}\big)(M^b-m^b)\,. \tag{A.18}$$

On the other hand, if $|\Gamma_1^{(k)}| \ge \frac{1}{2}|D|$, then using the nonnegative function $M^b - \boldsymbol{u}$, we similarly obtain

$$M_k^a - m^a \le \big(1-\tfrac{q}{2}\big)(M^b-m^b)\,, \tag{A.19}$$

and the result follows by (A.18)–(A.19). □

THEOREM A.3. *There exists a constant $M_1 > 0$ such that, for any $\boldsymbol{u} \in \mathfrak{U}_D$,*

$$\sup_{x\in\frac{1}{9}D} \big\{u_i(x)\big\} \le M_1 \max_{k\in\mathcal{S}} \inf_{x\in\frac{1}{9}D} \big\{u_k(x)\big\} \qquad \forall\, i \in \mathcal{S}\,.$$

Proof. Let β_0 be as given in Lemma A.3, and with $\rho(\cdot)$ and q as in (A.15) and Theorem A.2, respectively, define

$$\rho := \frac{1}{d\rho(\frac{2}{3})} \qquad \text{and} \qquad q_0 := \frac{(1-\frac{q}{4})}{(1-\frac{q}{2})}\,. \tag{A.20}$$

We claim that the value of the constant M_1 may be chosen as

$$M_1 := \frac{4q_0}{q\beta_0}\left[\frac{27N^{1/d}}{2\big(q_0^\rho-1\big)}\right]^{1/\rho}. \tag{A.21}$$

We argue by contradiction. Suppose $\boldsymbol{u} \in \mathfrak{U}_D$ violates this bound. Let $\big\{x^{(1)},\dots,x^{(N)}\big\}$ denote the points in $\frac{1}{9}\overline{D}$ where the minima of $\boldsymbol{u}$ are attained; i.e.,

$$\inf_{x\in\frac{1}{9}D} \big\{u_k(x)\big\} = u_k(x^{(k)})\,, \qquad k \in \mathcal{S}\,.$$

Without loss of generality, suppose that $\max_{k\in\mathcal{S}}\big\{u_k(x^{(k)})\big\} = 1$ ($\boldsymbol{u}$ can always be scaled to satisfy this) and that for some $y_0 \in \frac{1}{9}D$ and $k_0 \in \mathcal{S}$, $u_{k_0}(y_0) = M > aM_1$ with $a > 1$. Using the estimate for the growth of the oscillation of $\boldsymbol{u}$ in Theorem A.2, we will show that $\boldsymbol{u}$ has to be unbounded in $\frac{1}{3}D$. By hypothesis, $\frac{M}{a}$ exceeds M_1 in (A.21), and in order to facilitate the construction that follows, we choose to express this as

$$\tfrac{1}{9} + 3N^{1/d}\big(\tfrac{4a}{q\beta_0 M}\big)^\rho \sum_{n=0}^{\infty} \big(\tfrac{1}{q_0}\big)^{n\rho} < \tfrac{1}{3}\,. \tag{A.22}$$

For $\xi > 0$, define

$$\mathcal{D}_k^{(\xi)} := \big\{ z \in \tfrac{1}{3}\overline{D} \,:\, u_k(z) \ge \xi \big\}\,, \qquad \mathcal{D}^{(\xi)} := \bigcup_{k\in\mathcal{S}} \mathcal{D}_k^{(\xi)}\,.$$

If $\mathbf{1}_k \in \mathbb{R}^N_+$ stands for the vector whose kth component is equal to 1 and the others 0, then

$$\boldsymbol{u}(x^{(k)}) \ge \boldsymbol{\Psi}_{x^{(k)}}\big(\mathfrak{U}_D, \mathcal{D}_k^{(\xi)}; \xi\mathbf{1}_k\big) \qquad \forall\, k \in \mathcal{S}\,, \tag{A.23}$$

while, on the other hand, Theorem A.1 yields,

$$\boldsymbol{\Psi}_{x^{(k)}}\big(\mathfrak{U}_D, \mathcal{D}_k^{(\xi)}; \xi\mathbf{1}_k\big) \ge \beta_0 \left(\frac{|\mathcal{D}_k^{(\xi)}|}{|D|}\right)^{\rho(\frac{2}{3})} \xi\mathbf{1}_k \qquad \forall\, k \in \mathcal{S}\,. \tag{A.24}$$

By (A.23)–(A.24) and using (A.20), we obtain the estimate

$$|\mathcal{D}^{(\xi)}| \le \sum_{k\in\mathcal{S}} |\mathcal{D}_k^{(\xi)}| \le \sum_{k\in\mathcal{S}} \left(\frac{u_k(x^{(k)})}{\xi\beta_0}\right)^{\rho d} |D| \le N\left(\frac{1}{\xi\beta_0}\right)^{\rho d} |D| \qquad \forall\, \xi > 0\,. \tag{A.25}$$

Choosing $\xi = \frac{qM}{4}$, we have by (A.25)

$$\left| \Big\{ x \in \tfrac{1}{3}D \,:\, \max_{k\in\mathcal{S}} \big\{u_k(x)\big\} \ge \tfrac{qM}{4} \Big\} \right| \le N(\tfrac{4}{q\beta_0 M})^{\rho d} |D|\,.$$

Hence, if Q_0 is a cube of volume $|Q_0| = N\big(\frac{4a}{q\beta_0 M}\big)^{\rho d}|D|$ centered at y_0, then

$$\operatorname{osc}(u_{k_0}; Q_0) \ge \big(1 - \tfrac{q}{4}\big) M\,. \tag{A.26}$$

By Theorem A.2, we obtain from (A.26)

$$\operatorname{osc}(\boldsymbol{u}; 3Q_0) \ge \frac{(1-\frac{q}{4})}{(1-\frac{q}{2})} M = q_0 M\,. \tag{A.27}$$

Since $\boldsymbol{u}$ is nonnegative, (A.27) implies that there exists $y^{(1)} \in 3Q_0$ and $k_1 \in \mathcal{S}$ such that

$$u_{k_1}(y^{(1)}) \ge q_0 M\,.$$

Note that (A.22) implies that $3Q_0 \subset \frac{1}{3}D$. Therefore, we can repeat the argument, now choosing $\xi = q_0 \frac{qM}{4}$ in (A.25) and a cube Q_1 of volume $N\big(\frac{4a}{q_0 q\beta_0 M}\big)^{\rho d}|D|$ centered at $y^{(1)}$, to conclude that there exists $y^{(2)} \in 3Q_1$ and $k_2 \in \mathcal{S}$ such that $u_{k_2}(y^{(2)}) \ge q_0^2 M$. Inductively, we can construct a sequence $\big\{y^{(n)}, k_n, Q_n\big\}_{n=0}^{\infty}$ satisfying, for all $n = 0, 1, \ldots,$

$$\begin{aligned} y^{(0)} = y_0 \in \tfrac{1}{9}\overline{D} \bigcap Q_0\,, \qquad y^{(n)} \in Q_n \bigcap 3Q_{n-1}\,, \\ |Q_n|^{1/d} = N^{1/d}\big(\tfrac{1}{q_0}\big)^{n\rho}\big(\tfrac{4a}{q\beta_0 M}\big)^{\rho}|D|^{1/d}\,, \\ u_{k_n}(y^{(n)}) \ge q_0^n M\,. \end{aligned} \tag{A.28}$$

The inequality in (A.22) guarantees that $y^{(n)} \in \frac{1}{3}D$ for all n. But (A.28) implies that $\boldsymbol{u}$ is unbounded in $\frac{1}{3}D$, which is a contradiction. ∎

Remark A.1. By the comparison principle, Lemmas A.3–A.5 and Theorem A.1 clearly hold unmodified for the class of L_k-superharmonic, nonnegative functions, i.e., functions $u \in W^{2,d}_{\ell oc}(D) \bigcap C^0(\overline{D})$, satisfying $L_k u \le 0$ in D, for some $k \in \mathcal{S}$ and $L \in \mathfrak{L}$. This fact will be used in the next result.

LEMMA A.6. *Let $L \in \mathfrak{L}$, $k \in \mathcal{S}$ and suppose φ is a solution to the Dirichlet problem $L_k\varphi = -f$ in a cube $D \subset \mathbb{R}^d$, with $\varphi = 0$ on ∂D, with f satisfying*

$$0 \le f(x) \le M \quad \forall\, x \in D \qquad \text{and} \qquad \|f\|_{d;D} \ge \varepsilon > 0$$

for some constants M and ε. Then there exists a constant $C' = C'(M, \varepsilon, m, \overline{m}, \overline{\gamma})$ such that

$$\inf_{x \in \frac{1}{3}D} \{\varphi(x)\} \ge C'.$$

Proof. First note that the Dirichlet problem as defined has a unique strong solution $\varphi \in W^{2,p}_{\ell oc}(D) \bigcap C^0(\overline{D})$ for all $p \in [d, \infty)$. We argue by contradiction. Suppose there exists a sequence of operators $\{L^{(n)}\}_{n=1}^{\infty} \subset \mathfrak{L}$ and a sequence of functions $\{f^{(n)}\}_{n=1}^{\infty}$, in accord with the hypotheses of the lemma, such that the corresponding solutions $\{\varphi^{(n)}\}_{n=1}^{\infty}$ of $L_k^{(n)}\varphi^{(n)} = -f^{(n)}$ satisfy

$$\inf_{x \in \frac{1}{3}D} \{\varphi^{(n)}(x)\} < \frac{1}{n^2}\,, \qquad n = 1, 2, \dots\,.$$

Thus, by Theorem A.1,

$$\left|\{x \in D \,:\, \varphi^{(n)}(x) \ge \tfrac{1}{n}\}\right| \le \left(\frac{1}{\beta_0 n}\right)^{\rho d} |D|\,,$$

with ρ as defined in (A.20). Since the sequence $\varphi^{(n)}$ is bounded in $L^\infty(D)$ (by Lemma A.2), it follows that $\varphi^{(n)} \to 0$ in $L^p(D)$, as $n \to \infty$, for all $p \in [1, \infty)$. Let $D' = \delta D$, with $\delta < 1$, be a subcube of D, and let $\|\cdot\|_{2,p;D'}$ denote the standard norm of $W^{2,p}(D')$. We use the well-known estimate

$$\|\varphi^{(n)}\|_{2,p;D'} \le C''\big(\|\varphi^{(n)}\|_{p;D} + \|f^{(n)}\|_{p;D}\big)\,,$$

for some constant $C'' = C''(|D|, p, \delta, d, m, \overline{m}, \overline{\gamma})$, to conclude that the first and second derivatives of $\varphi^{(n)}$ converge weakly to 0 in $L^p(D')$, for all $p \in [1, \infty)$. In turn, since $W^{2,p}_0(D') \hookrightarrow W^{1,p}_0(D')$ is compact for $p > d$, using the standard approximation argument we deduce that $\frac{\partial \varphi^{(n)}}{\partial x_i}$ converges in $L^p(D')$ strongly for all $i = 1, \dots, d$. Also, since the second order coefficients of $L_k^{(n)}$ are uniformly Lipschitz, we can extract a subsequence, along which they converge uniformly. Combining all the previous arguments, we deduce that the sequence $\{L_k^{(n)}\varphi^{(n)}\}$ converges weakly to 0 in $L^p(D')$, $p \in [1, \infty)$. On the other hand, if we choose $\delta \ge (1 - \frac{\varepsilon}{2M|D|})^{1/d}$, an easy calculation yields

$$\int_{D'} f^{(n)}(x)\, dx \ge \frac{\varepsilon}{2}\,, \qquad n = 1, 2, \dots\,,$$

resulting in a contradiction. ∎

We pause to note that (A.5) has not been utilized in any of the results obtained thus far. It will be used in the next result to provide the necessary "coupling" between distinct components of the harmonic function.

LEMMA A.7. *For each cube $D \subset \mathbb{R}^d$ there exists a constant $M_2 > 0$ such that, for any $\boldsymbol{u} \in \mathfrak{U}_D$,*

$$\inf_{x \in \frac{1}{9}D} \{u_i(x)\} \le M_2 \inf_{x \in \frac{1}{9}D} \{u_j(x)\} \qquad \forall\, i, j \in \mathcal{S}\,.$$

Proof. Let ε_D be the constant in hypothesis (A.5). Define a collection of functions $\{\varphi_{ij}(x),\ \ i, j \in \mathcal{S}\} \subset W^{2,d}_{\ell oc}(\frac{1}{3}D) \bigcap C^0(\frac{1}{3}\overline{D})$, relative to some $L \in \mathfrak{L}$, by

$$\begin{aligned} &L_i\varphi_{ij}(x) = -c_{ij}(x) \quad \text{in } \tfrac{1}{3}D \qquad \text{and} \quad \varphi_{ij}(x) = 0 \quad \text{on } \partial\big(\tfrac{1}{3}D\big) \qquad \text{if} \quad i \neq j, \\ &\varphi_{ij}(x) = 0 \qquad \text{if} \quad i = j\,, \end{aligned} \tag{A.29}$$

and let $\boldsymbol{\Phi}(x)$, $\boldsymbol{C}(x)$ denote the matrices with elements $\{\varphi_{ij}(x)\}$ and $\{c_{ij}(x)\}_{i \neq j}$, respectively. By (A.4), there exists a constant irreducible matrix $\boldsymbol{C}_D \subset \mathbb{R}^{N \times N}$, with elements equal to 0 or 1 such that

$$\Big|\big\{x \in \tfrac{1}{3}D \,:\, \boldsymbol{C}(x) \ge \varepsilon_D \boldsymbol{C}_D\big\}\Big| \ge \tfrac{1}{N^2 3^d}|D|\,. \tag{A.30}$$

It follows by (A.29), (A.30), and Lemma A.6 that there exists a constant $\varepsilon'_D > 0$ such that

$$\boldsymbol{\Phi}(x) \ge \varepsilon'_D \boldsymbol{C}_D \qquad \forall\, x \in \tfrac{1}{9}D\,, \tag{A.31}$$

and (A.31) holds relative to any $L \in \mathfrak{L}$ used to generate φ_{ij}. Therefore, if $\boldsymbol{u} \in \mathfrak{U}_D$ and we define $\underline{\boldsymbol{u}} := \inf_{x \in \frac{1}{9}D} \boldsymbol{u}(x)$ and $\underline{\boldsymbol{u}}' := \inf_{x \in \frac{1}{3}D} \boldsymbol{u}(x)$, it is a direct consequence of the comparison principle that

$$\boldsymbol{u}(x) \ge \boldsymbol{\Phi}(x)\underline{\boldsymbol{u}}' \qquad \forall\, x \in \tfrac{1}{3}D\,. \tag{A.32}$$

On the other hand, by Theorem A.1,

$$\underline{\boldsymbol{u}}' \ge F\big(\tfrac{1}{9^d}\big)\underline{\boldsymbol{u}}\,. \tag{A.33}$$

By (A.31)–(A.33),

$$\boldsymbol{u}(x) \ge \varepsilon'_D F\big(\tfrac{1}{9^d}\big)\boldsymbol{C}_D\underline{\boldsymbol{u}} \qquad \forall\, x \in \tfrac{1}{9}D\,,$$

which yields $\underline{\boldsymbol{u}} \ge \varepsilon'_D F\big(\frac{1}{9^d}\big)\boldsymbol{C}_D\underline{\boldsymbol{u}}$. In turn, the irreducibility of $\boldsymbol{C}_D$ implies that

$$\underline{\boldsymbol{u}}_i \ge \Big(\varepsilon'_D F\big(\tfrac{1}{9^d}\big)\Big)^{N-1} \underline{\boldsymbol{u}}_j \qquad \forall\, i, j \in \mathcal{S}\,. \qquad \square$$

Combining Theorem A.3 and Lemma A.7 and letting $M := M_1 M_2$, we have the following theorem.

THEOREM A.4. *For each cube $D \subset \mathbb{R}^d$, $|D| \le \kappa_0$, there exists a constant $M > 0$ such that, for any $\boldsymbol{u} \in \mathfrak{U}_D$,*

$$u_i(y) \le M u_j(x) \qquad \forall\, x, y \in \tfrac{1}{9}D \quad \forall\, i, j \in \mathcal{S}\,.$$

Theorem 4.1 easily follows from Theorem A.4 by covering the domain Ω with a collection of congruent cubes D of suitable size. For an elegant exposition of this technique, see [11, p. 153]. The existence of a constant $\varepsilon_\Omega > 0$ satisfying (A.5) is guaranteed by the continuity and irreducibility conditions in Assumption 3.1 (i) and (iii), along with the compactness of U. Concerning (A.3), (A.4), and the upper bound in (A.2), observe that for each bounded domain Ω, Assumption 3.1 (i) implies the existence of constants $\overline{m}$ and $\overline{\gamma}$ satisfying all these conditions in Ω. This suffices for our purposes.

Acknowledgment. The authors wish to thank Prof. S. R. S. Varadhan for explaining to us the work of Krylov and Safonov. The appendix in this paper is both inspired by and based in part on his notes on the proof of Harnack's inequality for a uniformly elliptic operator.

AVERAGING THEOREMS FOR HIGHLY OSCILLATORY DIFFERENTIAL EQUATIONS AND ITERATED LIE BRACKETS*

WENSHENG LIU†

Abstract. Using averaging techniques and developing proper algebraic formalisms, we study the limiting process of ordinary differential equations with highly oscillatory right-hand sides. We give sufficient conditions, generalizing earlier work by Kurzweil and Jarnik, for a sequence $\{u^j = (u_1^j, \dots, u_m^j)\} \subseteq L^1([0,T], \mathbb{R}^m)$ to be such that, for every choice of smooth vector fields $f_k, k = 1, \dots, m$, on a smooth manifold, the trajectories of $\dot{x} = \sum_{k=1}^m u_k^j(t) f_k(x)$ converge to the trajectories of an "extended system" $\dot{x} = \sum_{k=1}^r v_k(t) f_k(x)$, where the new directions $f_{m+1}, \dots, f_r$ are Lie brackets of $f_1, \dots, f_m$.

Key words. control affine systems, extended inputs, averaging, Lie brackets, continuous dependence

1. Introduction.

Consider control-affine systems of the form

$$\dot{x} = \sum_{k=1}^{m} u_k(t) f_k(x), \tag{1}$$

where $f_1, \dots, f_m$ are smooth vector fields on a smooth manifold M and the inputs $u = (u_1, \dots, u_m)$ are functions belonging to $L^1([0,T], \mathbb{R}^m)$. It is well known in the control theory literature that trajectories of (1) generated by a sequence of highly oscillatory inputs may converge to a function that is no longer a trajectory of (1). In many cases it happens that the limiting function is a solution of a differential equation whose right-hand side involves not only the vector fields $f_1, \dots, f_m$ but also various Lie brackets of them; cf. the example below. The purpose of this paper is to give a systematic study of the Lie brackets that can occur in the limit and to clarify the underlying algebraic structures. By developing proper algebraic formalisms, we can study the limiting processes of (1) corresponding to sequences $\{u^j\} \subseteq L^1([0,T], \mathbb{R}^m)$ in pure algebraic levels, and it turns out that the limiting processes are closely related to the limiting behavior of the *Chen–Fliess series* determined by the u^j. (The Chen–Fliess series techniques have been widely used in control theory, e.g., by Fliess, Sussmann, etc.; cf. [4], [9], [11].) We then show that under very general conditions the trajectories of (1) generated by a sequence $\{u^j\} \subseteq L^1([0,T], \mathbb{R}^m)$ converge to trajectories of a system of the form

$$\dot{x} = \sum_{k=1}^{r} v_k(t) f_k(x), \tag{2}$$

where the first m vector fields $f_1, \dots, f_m$ are the same as in (1), and $f_{m+1}, \dots, f_r$ are Lie brackets of the f_k, $k \in \{1, \dots, m\}$, so the limiting equation involves resonance terms of Lie brackets of $f_1, \dots, f_m$.

For a simple illustration of the phenomenon that Lie brackets can occur in limiting equations, consider the system

$$\dot{x}_1 = u_1,$$
$$\dot{x}_2 = u_2,$$
$$\dot{x}_3 = u_2 x_1,$$

with initial condition $(0,0,0)$. If $u^j(t) = j^{\frac{1}{2}}(\cos jt, \sin jt)$, then the u^j "converge to 0" in the sense that their indefinite integrals $U^j(t) = \int_0^t u^j(s)\,ds$ converge to 0 uniformly. So, if we let $u^\infty = (0,0)$, we might think that the solutions x^j converge uniformly to $(0,0,0)$. However, a simple calculation shows that this is not so, and in fact the x^j converge uniformly to $x^\infty = (0,0,\frac{t}{2})$. On the other hand, the vector fields f_1, f_2 have components $(1,0,0)$ and $(0,1,x_1)$, respectively. So the Lie bracket $f_3 = [f_1, f_2]$ has components $(0,0,1)$, and the limiting function x^∞ turns out to satisfy $\dot{x} = \frac{1}{2} f_3(x)$.

Using integration by parts, it is easy to show that the sequence $\{u^j\}$ in the above example has the stronger convergence property that for *every* initial condition $x(0) = p \in \mathbb{R}^n$, *every* choice of C^2 vector fields f_1, f_2 on $\mathbb{R}^n$, the solutions of $\dot{x} = u_1^j(t) f_1(x) + u_2^j(t) f_2(x), x(0) = p$ are defined on $[0,T]$ for j large enough and converge uniformly to the solution x^∞ of $\dot{x} = \frac{1}{2}[f_1, f_2](x)$, $x(0) = p$, provided only that the latter exists on $[0,T]$. In this paper we will explore these "universal convergence" properties for sequences $\{u^j\} \subseteq L^1([0,T], \mathbb{R}^m)$. We will give general convergence results which in particular include the above example as a special case.

The main technical difficulty of studying the limiting process of (1) corresponding to sequences $\{u^j\}$ is not to prove the convergence of trajectories but to show that the limiting equations are of the form (2) and to have simple formulas to compute the v_k. In fact, it is fairly easy to establish the convergence of trajectories and to show that the right-hand sides of the limiting equations are equal to finite linear combinations of functions that involve Jacobian matrices of $f_1, \ldots, f_m$, but it is not obvious a priori that these linear combinations give rise to (time-varying) vector fields. In [5], [6], [7], Kurzweil and Jarnik have studied the problem of finding the proper forms of limiting equations for some special input sequences. For those special cases, using lengthy combinatorial proofs, they have shown that the limiting equations are of the form (2). Here we provide a different approach. Using proper algebraic formalisms, that the limiting equations are of the form (2) follows naturally, and we can give simple algebraic formulas to compute the v_k.

The key point for our algebraic formalism is to reformulate the problem of convergence of trajectories in terms of *convergence of inputs*. For instance, we can reformulate the universal convergence property of the sequence $\{u^j\}$ in the above example in the language of "input convergence" as follows. First we introduce formal noncommuting *indeterminates* $X_1, X_2, \ldots, X_m$ and define an *extended input value* (EIV) to be a linear combination of $X_1, \ldots, X_m$ and various Lie brackets such as $[X_1, X_2]$, $[X_1, [X_1, X_2]]$, etc. Define an *extended input* to be a Lebesgue integrable function on an interval $[0,T]$ whose values are EIVs. So, for example (if $m = 2$), an expression such as

$$(3)\quad v(t) = v_1(t)X_1 + v_2(t)X_2 + v_3(t)[X_1, X_2] + v_4(t)[X_1, [X_1, X_2]] + v_5(t)[X_2, [X_1, X_2]],$$

with integrable coefficient functions v_k on $[0,T]$, is an extended input. It is clear that an ordinary input can then be regarded in a natural way as a special kind of extended input, namely, one that contains only terms with $X_1, \ldots, X_m$ but no higher-order Lie brackets. For any m-tuple of vector fields $(f_1, \ldots, f_m)$ on M, extended

inputs can be plugged into a control system such as (1) exactly as ordinary inputs can, by substituting the vector fields f_k for the indeterminates X_k. The results are (nonautonomous) ordinary differential equations. For example, the extended input above gives rise to the following differential equation:

$$\dot{x} = v_1(t)f_1(x)+v_2(t)f_2(x)+v_3(t)[f_1,f_2](x)+v_4(t)[f_1,[f_1,f_2]](x)+v_5(t)[f_2,[f_1,f_2]](x).$$

Therefore we can talk about trajectories corresponding to an extended input once the vector fields $f_1,\dots,f_m$ are known. (This requires only that the f_k be smooth enough for the appropriate Lie brackets to exist.) We can then say that a sequence $\{u^j\}$ of ordinary inputs *converges* to an extended input u^∞ if for *every* initial condition $x(0)=p$, *every* choice of sufficiently smooth vector fields f_k, the solutions x^j generated by the u^j converge uniformly to the solution x^∞ generated by u^∞.[1] With this terminology, our example above simply says that the ordinary inputs $u^j(t) = j^{\frac{1}{2}}\cos(jt)X_1 + j^{\frac{1}{2}}\sin(jt)X_2$ converge to the extended input $u^\infty(t) = \frac{1}{2}[X_1,X_2]$. In this paper, we will give various sufficient conditions for a sequence of ordinary inputs to converge to an extended input.

The convergence theorems in this paper are *high-order* generalizations of the convergence results for control affine systems discussed in [13]. In there it is given a convergence result that roughly says the following. A sequence $\{u^j = u_1^jX_1+\cdots+u_m^jX_m\}$ of ordinary inputs converges to an ordinary input $u^\infty = u_1^\infty X_1+\cdots+u_m^\infty X_m$ if and only if

(c1) the indefinite integrals $U^j(t) = \int_0^t u^j(s)\,ds$ converge uniformly on $[0,T]$ to $U^\infty(t) = \int_0^t u^\infty(s)\,ds$; i.e., u^∞ is the averaged limit of the u^j.

(c2) the functions u^j are uniformly bounded in L^1; i.e., there exists a finite constant C such that $\int_0^T \|u^j(t)\|dt \le C$ for all j.

This is a first-order convergence result since the limiting extended input u^∞ does not contain any high-order Lie brackets. The fact that u^∞ is still an ordinary input is due to the boundedness assumption (c2). The above example shows that if this condition fails, it is indeed possible for the u^j to converge to an extended input that is not an ordinary input.

Our generalization of this first-order convergence result to high-order extended inputs is as follows. Instead of (c1) we will assume that all the iterated integrals

$$U_I^j(t) \stackrel{\text{def}}{=} \int_0^t\int_0^{t_k}\int_0^{t_{k-1}}\cdots\int_0^{t_2} u_{i_k}^j(t_k)u_{i_{k-1}}^j(t_{k-1})\dots u_{i_1}^j(t_1)dt_1\dots dt_k \tag{4}$$

converge uniformly, as $j\to\infty$, to the indefinite integrals H_I of certain L^1 functions h_I, for all multiindices $I=(i_1,\dots,i_k)\in\{1,\dots,m\}^k$, $k=1,2,\dots$, such that $|I| \stackrel{\text{def}}{=} k \le r$. (In that case, we will say that the u^j *converge to* $H=\{H_I\}_{|I|\le r}$ *in the* r*th-order iterated integral sense* or, for short, that they *ii*(r)*-converge* to H.) As will be explained in section 2, the *ii*(r)-convergence is equivalent to the convergence of the trajectories for one special system, the "rth-order truncated formal system."

Instead of (c2), we will assume an r*th-order boundedness condition* (c2(r)), which states that certain sequences $\{\widetilde{uv}_I^j\}$ of functions associated with the multiindices I such that $|I|=r$ are bounded in L^1 norm. The conclusion is that the ordinary inputs

[1] This is not made precise yet, since the solutions may have explosions. The precise definition is given in section 3.

u^j converge as $j \to \infty$ to an extended input u^∞ given by

$$u^\infty(t) = \sum_{|I| \le r} u_I^\infty(t)[X_I],$$

where, for any index $I = (i_1, \dots, i_k)$, we define $[X_I]$ by

$$[X_I] \stackrel{\text{def}}{=} [X_{i_1}, [X_{i_2}, [\dots, [X_{i_{k-1}}, X_{i_k}] \cdots],$$

and the u_I^∞ are certain integrable real-valued functions on $[0, T]$. Unfortunately, the statement of the convergence result is somewhat less transparent than might be desired, because the limiting extended input involves the u_I^∞ rather than the h_I, and the boundedness condition (c2(r)) involves another family $\{\widetilde{uv}_I^j\}$ of sequences of functions. (For more applicability, the $\widetilde{uv}_I^j$ are allowed to depend on another collection $\{v_I^j\}$ of sequences of functions; cf. section 2.) It turns out, however, that the u_I^∞ and the $\widetilde{uv}_I^j$ can be computed from the h_I, u^j, and v_I^j by very simple algebraic formulas, provided that everything is reformulated in an appropriate algebraic context; cf. (9) and (18). See also (46) and (47).

One particular situation where the definition of the u_I^∞ is extremely simple is the case when the only terms that occur in the limit are the rth-order ones, i.e., when the h_I for $|I| < r$ vanish. In that case the u_I^∞ vanish for $|I| < r$ and are equal to $\frac{h_I}{r}$ for $|I| = r$. (This special case was studied, under stronger assumptions, in [5], [6], [7].)

In the formulation of the convergence theorems, it is convenient to let $U_k(t) = \int_0^t u_k(s)\, ds$ and to rewrite equation (1) in the following form:

$$dx = \sum_{k=1}^{m} f_k(x)\, dU_k. \tag{5}$$

However, this is not simply a rewriting of (1) since for this system we can use more general inputs, e.g., continuous inputs with bounded variations, or Hölder continuous inputs with Hölder exponents $> \frac{1}{2}$. Moreover, one can consider stochastic differential equations, where $U = (U_1, \dots, U_m)$ is a standard m-dimensional Brownian motion. When the U_k are absolutely continuous, system (5) has no difference from (1).

In this paper we will restrict ourselves to study the limiting process of (5) corresponding to a sequence $\{U^j\}$ of functions in $BVC([0, T], \mathbb{R}^m)$. (Here $BVC([0, T], \mathbb{R}^m)$ denotes the set of $\mathbb{R}^m$-valued functions on $[0, T]$ that are continuous and of bounded variations.) It turns out that the limiting theorems presented in this paper are also true if we use Hölder continuous inputs, and can be generalized to stochastic differential equations too. These will be given in forthcoming papers.

The organization of the paper is as follows. In section 2 we develop the needed algebraic formalisms. We begin by reviewing some basic terminologies on free associative algebras and free Lie algebras. We then introduce the concepts of *extended inputs, formal trajectories, generalized differences*, etc., and study systematically the relations between them in pure algebraic level. Using the algebraic formalisms, in section 3, we present the main convergence theorems. In section 4 we discuss briefly the necessity of the conditions of our main convergence theorems. We conclude the paper with an appendix that contains the proof of a lemma and an approximation result.

2. Algebraic preliminaries and formalisms. In this section we develop the necessary algebraic formalisms for our convergence theorems. We follow the notation and definitions of [11].

2.1. Review of basic terminology on free associative algebras and free Lie algebras. As in [11], let $\mathbf{X} = \{X_1, \ldots, X_m\}$ be a finite sequence of objects, which will be called *indeterminates*. We let $A(\mathbf{X})$ denote the free associative algebra generated over $\mathbb{R}$ by $\mathbf{X}$. For any multiindex $I = (i_1, \ldots, i_k)$ with $i_1, \ldots, i_k \in \{1, \ldots, m\}$, we let $X_I = X_{i_1} \cdots X_{i_k}$. (There is a special multiindex $I = \emptyset$. It is understood that $X_\emptyset = 1$.) Then $A(\mathbf{X})$ is the set of all sums $\sum_I a_I X_I$, where the coefficients a_I are real numbers, the summation runs over all possible multiindices I, and all but finitely many a_I vanish. Therefore the *monomials* X_I form a basis of $A(\mathbf{X})$ and every element of $A(\mathbf{X})$ is a finite linear combination of the X_I.

We also consider the algebra $\hat{A}(\mathbf{X})$ of all formal power series in $\mathbf{X}$. The elements of $\hat{A}(\mathbf{X})$ are the formal sums $\sum_I a_I X_I$, where I ranges over all multiindices. This is the sum as above except that the a_I are no longer required to vanish for all but finitely many I. In both $A(\mathbf{X})$ and $\hat{A}(\mathbf{X})$, addition is done componentwise, and multiplication is carried out using the formula $X_I X_J = X_{IJ}$, where IJ is the concatenation of I and J, namely, the multiindex obtained by writing, in order, first the components of I and then those of J.

For any integer $r \geq 0$, let us use $A^r(\mathbf{X})$ to denote the *free nilpotent associative algebra of step* $r+1$ in the indeterminates $\mathbf{X}$. Therefore $A^r(\mathbf{X})$ is defined like $\hat{A}(\mathbf{X})$, except that now all the monomials X_I with $|I| > r$ are set equal to zero. (Here $|I|$ is the length of I; i.e., $|I| = k$ if $I = (i_1, \ldots, i_k)$.) Then $A^r(\mathbf{X})$ can be thought of as the quotient of $A(\mathbf{X})$ or $\hat{A}(\mathbf{X})$ modulo the two-side ideal of all sums of monomials of degree strictly larger than r. (The degree of a monomial X_I is $|I|$.) The canonical projection $\mathbf{Tr}(r)$ from $\hat{A}(\mathbf{X})$ to $A^r(\mathbf{X})$ is the operator that assigns to each series $S \in \hat{A}(\mathbf{X})$ the finite series $\mathbf{Tr}(r)(S)$ obtained from S by deleting all the terms of degree $> r$. (The symbol $\mathbf{Tr}$ comes from the word "truncation." It is used to indicate that the map $\mathbf{Tr}(r) : \hat{A}(\mathbf{X}) \to A^r(\mathbf{X})$ is in essence a truncation map; i.e., for any $S \in \hat{A}(\mathbf{X})$, $\mathbf{Tr}(r)(S)$ is the truncation of S "up to order r.") The kernel of $\mathbf{Tr}(r)$ is denoted by $\hat{A}_r(\mathbf{X})$. In particular, $\hat{A}_0(\mathbf{X})$ is the set of all formal power series $\sum_I a_I X_I$ for which $a_\emptyset = 0$. The exponential map is a well-defined bijection

$$\exp : \ \hat{A}_0(\mathbf{X}) \to 1 + \hat{A}_0(\mathbf{X}),$$

whose inverse is a map from $1 + \hat{A}_0(\mathbf{X})$ to $\hat{A}_0(\mathbf{X})$ denoted by "log." (Here $1 + \hat{A}_0(\mathbf{X})$ is the subset of $\hat{A}(\mathbf{X})$ that contains all the elements S such that $S - 1 \in \hat{A}_0(\mathbf{X})$.) If $S \in \hat{A}_0(\mathbf{X})$, then $\exp(S)$ and $\log(1+S)$ are given by the usual series

$$\exp(S) = \sum_{n=0}^{\infty} \frac{S^n}{n!},$$

$$\log(1+S) = \sum_{n=1}^{\infty} \frac{(-1)^{(n-1)} S^n}{n}.$$

One can also define $A^r_\tau(\mathbf{X})$ to be the set of all elements of $A^r(\mathbf{X})$ that are linear combinations of monomials of degree $> \tau$. Then $A^r_\tau(\mathbf{X}) = \mathbf{Tr}(r)(\hat{A}_\tau(\mathbf{X}))$. The exponential map

$$\exp_r : \ A^r_0(\mathbf{X}) \to 1 + A^r_0(\mathbf{X})$$

and its inverse $\log_r$ are given in the case by power series that are actually finite sums due to the nilpotency of $A^r(\mathbf{X})$.

The algebras $A(\mathbf{X}), \hat{A}(\mathbf{X}), A^r(\mathbf{X})$ are Lie algebras in the usual way. (If A with a product $(a, b) \to ab$ is an associative algebra, then with the bracket product $[a, b] \stackrel{\text{def}}{=}$

$ab-ba$, A is a Lie algebra.) We let $L(\mathbf{X})$ denote the Lie subalgebra of $A(\mathbf{X})$ generated by the indeterminates $X_1, \ldots, X_m$. An element S of $A(\mathbf{X})$ will be said to be a *Lie element* if $S \in L(\mathbf{X})$. It is clear that an $S \in A(\mathbf{X})$ is a Lie element iff all the *homogeneous* components of S are Lie elements. (An $S \in \hat{A}(\mathbf{X})$ is homogeneous if it is a linear combination of monomials with equal degree.)

We can also define $\hat{L}(\mathbf{X})$ to be the set of all those elements of $\hat{A}(\mathbf{X})$ whose components are Lie brackets in $X_1, \ldots, X_m$. Therefore $\hat{L}(\mathbf{X})$ contains those $S \in \hat{A}(\mathbf{X})$ whose homogeneous components are Lie elements. The elements of $\hat{L}(\mathbf{X})$ are called *Lie series* in $X_1, \ldots, X_m$. For each multiple index $I = (i_1, \ldots, i_k)$, let $[X_I] \stackrel{\text{def}}{=} [X_{i_1}, [X_{i_2}, [\ldots, [X_{i_{k-1}}, X_{i_k}] \cdots]$. Then $L(\mathbf{X})$ and $\hat{L}(\mathbf{X})$ are spanned by the $[X_I]$. Naturally the $[X_I]$ are not linearly independent. There are several systematic procedures of figuring out a basis of $L(\mathbf{X})$. But we will not need this here.

Let $\hat{G}(\mathbf{X}) = \{\exp(Z), Z \in \hat{L}(\mathbf{X})\}$, the set of exponentials of the elements of $\hat{L}(\mathbf{X})$. The Campbell–Hausdorff formula implies (cf., e.g., [3]) that $\hat{G}(\mathbf{X})$ is in fact a group under the operation of multiplication in $\hat{A}(\mathbf{X})$. The elements of $\hat{G}(\mathbf{X})$ are called *exponential Lie series*. We let $L^r(\mathbf{X})$ be the Lie subalgebra of $A^r(\mathbf{X})$ generated by $\mathbf{X}$ and define $G^r(\mathbf{X})$ to be the subset of $A^r(\mathbf{X})$ consisting of all the exponentials of elements of $L^r(\mathbf{X})$. Now $L^r(\mathbf{X})$ is a finite-dimensional Lie algebra and $G^r(\mathbf{X})$ is its corresponding simply connected Lie group.

2.2. Polynomial inputs and formal trajectories. Let $BVC[0,T]$ be the set of real-valued functions U on $[0,T]$ which are continuous and of bounded variations. We will say that a function is *B-continuous* if it is in $BVC[0,T]$. If $f \in BVC[0,T]$, we will use $TV[f;0,T]$ to denote the total variation of f on $[0,T]$.

Let V be a function on $[0,T]$ with values in $\hat{A}(\mathbf{X})$. We say that V is *B-continuous* if we write $V(t) = \sum_I V_I(t) X_I$; then all the functions V_I are in $BVC[0,T]$.

We define two bilinear products on $BVC([0,T], A)$,

$$(F, G) \to F \stackrel{\rightarrow}{*} G,$$
$$(F, G) \to F \stackrel{\leftarrow}{*} G,$$

where

$$(F \stackrel{\rightarrow}{*} G)(t) \stackrel{\text{def}}{=} \int_0^t F(s)\, dG(s),$$
$$(F \stackrel{\leftarrow}{*} G)(t) \stackrel{\text{def}}{=} \int_0^t dF(s)\, G(s),$$

and A could be $A(\mathbf{X})$, $\hat{A}(\mathbf{X})$, or $A^r(\mathbf{X})$ for some integer $r \geq 0$. (Here $BVC([0,T], A)$ denotes the set of B-continuous A-valued functions.) If $F = \sum_I a_I X_I$ and $G = \sum_I b_I X_I$, then by definition

$$(F \stackrel{\rightarrow}{*} G)(t) = \sum_I \left(\sum_{J_1 J_2 = I} (a_{J_1} \stackrel{\rightarrow}{*} b_{J_2})(t) \right) X_I = \sum_I \left(\sum_{J_1 J_2 = I} \int_0^t a_{J_1}(s) db_{J_2}(s) \right) X_I,$$

$$(F \stackrel{\leftarrow}{*} G)(t) = \sum_I \left(\sum_{J_1 J_2 = I} (a_{J_1} \stackrel{\leftarrow}{*} b_{J_2})(t) \right) X_I = \sum_I \left(\sum_{J_1 J_2 = I} \int_0^t b_{J_2}(s) da_{J_1}(s) \right) X_I,$$

where the inner summation above runs over all ways of expressing the multiindex I as a concatenation $J_1 J_2$ of 2 indices, and the integral is the usual Riemann–Stieltjes

integral. If $F_1, \dots, F_k \in BVC([0,T], A)$, we use the conventions

$$(F_1 \overrightarrow{*} F_2 \overrightarrow{*} \cdots \overrightarrow{*} F_k)(t) = (\cdots (F_1 \overrightarrow{*} F_2) \overrightarrow{*} F_3) \overrightarrow{*} \cdots) \overrightarrow{*} F_k)(t),$$
$$(F_1 \overleftarrow{*} F_2 \overleftarrow{*} \cdots \overleftarrow{*} F_k)(t) = (F_1 \overleftarrow{*} (F_2 \overleftarrow{*} (\cdots \overleftarrow{*} (F_{k-1} \overleftarrow{*} F_k) \cdots)(t).$$

Note that when $r = 0$, $A^r(\mathbf{X}) = A^0(\mathbf{X})$ can be identified with $\mathbb{R}$, so by definition $BVC([0,T], A^0(\mathbf{X})) = BVC[0,T]$. In this case $\overrightarrow{*}, \overleftarrow{*}$ reduce to maps from $BVC[0,T] \times BVC[0,T] \to BVC[0,T]$. Let f and g be two functions in $BVC[0,T]$; then by definition

$$(f \overrightarrow{*} g)(t) = \int_0^t f(s)\, dg(s),$$
$$(f \overleftarrow{*} g)(t) = \int_0^t g(s)\, df(s).$$

The functions $f \overrightarrow{*} g, f \overleftarrow{*} g$ are clearly in $BVC[0,T]$.

Let us say that two B-continuous $\hat{A}_0(\mathbf{X})$-valued functions V_1, V_2 on $[0,T]$ are *equivalent* if $V_1 - V_2$ is an element of $\hat{A}_0(\mathbf{X})$; i.e., $V_1 - V_2$ does not depend on t. Then the set of all B-continuous $\hat{A}_0(\mathbf{X})$-valued functions is divided into equivalence classes. Let us use $\mathcal{P}$ to denote the set of all equivalence classes. For each B-continuous $\hat{A}_0(\mathbf{X})$-valued function V we use $\mathbf{V}$ to denote the equivalence class determined by V, and V will be called a *representative* of $\mathbf{V}$.

DEFINITION 1. *Any element $\mathbf{V}$ of $\mathcal{P}$ will be called a polynomial input.*

Therefore a polynomial input is an equivalence class $\mathbf{V}$, whose representatives V are B-continuous functions on $[0,T]$ with values in $\hat{A}_0(\mathbf{X})$. In general we will use $\mathbf{V}$ to denote a polynomial input and V to denote a representative of $\mathbf{V}$. But, if there is no confusion, we sometimes write $\mathbf{V} = V$ to denote the equivalence class determined by V.

DEFINITION 2. *A polynomial input $\mathbf{V}$ is an extended input if $\mathbf{V}$ has a representative that is $\hat{L}(\mathbf{X})$-valued.*

An ordinary input $U = (U_1, \dots, U_m) \in BVC([0,T], \mathbb{R}^m)$ can be regarded as a polynomial input by identifying it with the equivalence class $\mathbf{U}$ determined by $U = U_1X_1 + \cdots + U_mX_m$. It is an extended input in fact by the above definition. In most cases we will make no difference between $U = (U_1, \dots, U_m)$ and $U = U_1X_1 + \cdots + U_mX_m$. We will call the equivalence class $\mathbf{U} = U$ an ordinary input too. Therefore an ordinary input $\mathbf{U}$ is an equivalence class that has a representative U whose values are linear combinations of the $X_k, k = 1, \dots, m$.

Let $V = \sum_I V_I X_I$ be an $\hat{A}(\mathbf{X})$-valued function on $[0,T]$. We say that V is B-continuous, absolutely continuous, differentiable, etc., on $[0,T]$ if all the V_I are B-continuous, absolutely continuous, differentiable, etc. We say that a sequence $\{V^j = \sum_I V_I^j X_I\}$, $j \in \{1, 2, \dots, \} \cup \{\infty\}$, of $\hat{A}(\mathbf{X})$-valued functions on $[0,T]$ *converges* to V^∞ uniformly if, for each I, the V_I^j converge to V_I^∞ uniformly on $[0,T]$ as $j \to \infty$. We say that a polynomial input $\mathbf{V}$ is *absolutely continuous* or *differentiable* if there is a representative of $\mathbf{V}$ which is absolutely continuous or differentiable. Therefore if $\mathbf{V}$ is absolutely continuous (differentiable) all the representatives of $\mathbf{V}$ are absolutely continuous (differentiable). And if $\mathbf{V}$ is an absolutely continuous polynomial input, then $\mathbf{v} = \dot{\mathbf{V}}$ is well defined. The result is an $\hat{A}_0(\mathbf{X})$-valued integrable function on $[0,T]$.

DEFINITION 3. *Let $\mathbf{V}$ be a polynomial input. The Chen–Fliess series determined by $\mathbf{V}$ is the $\hat{A}(\mathbf{X})$-valued function $S_{\mathbf{V}}$ on $[0,T]$ that satisfies the initial value problem*

$$dS = SdV, S(t) \in \hat{A}(\mathbf{X}), \tag{6}$$

$$S(0) = 1, \tag{7}$$

where V is any representative of $\mathbf{V}$.

A solution of (6) and (7) is an $\hat{A}(\mathbf{X})$-valued function S on $[0,T]$, which is B-continuous, satisfying

$$S = 1 + S \overrightarrow{*} V.$$

Such a solution clearly exists, is unique, and depends only on $\mathbf{V}$. Moreover, if $S_{\mathbf{V}}$ is the solution of (6) and (7), it is clear that

$$S_{\mathbf{V}} = 1 + \sum_{k=1}^{\infty} 1 \overrightarrow{*} \overbrace{V \overrightarrow{*} V \overrightarrow{*} \cdots \overrightarrow{*} V}^{k}.$$

Equation (6) will be called the *formal equation* determined by $\mathbf{V}$. The Chen–Fliess series $S_{\mathbf{V}}$ will be called the *formal trajectory* of $\mathbf{V}$.

By definition, the function $t \to S_{\mathbf{V}}(t)$ is B-continuous as an $\hat{A}(\mathbf{X})$-valued function. It is in fact $1 + \hat{A}_0(\mathbf{X})$-valued. Conversely, define a *formal trajectory* to be a B-continuous $1 + \hat{A}_0(\mathbf{X})$-valued function S on $[0,T]$. Then every formal trajectory S is the formal trajectory of a polynomial input $\mathbf{V}$ given by $\mathbf{V} = (S^{-1} \overrightarrow{*} S)$. Therefore the map $\mathbf{V} \to S_{\mathbf{V}}$ is a one-to-one correspondence between the set of polynomial inputs and that of formal trajectories, whose inverse is given by $\mathbf{V} = (S_{\mathbf{V}}^{-1} \overrightarrow{*} S_{\mathbf{V}})$. (Note that if $S = \sum_I a_I X_I$ is an element of $\hat{A}(\mathbf{X})$ with $a_\emptyset \neq 0$, then S^{-1} exists and is given by (for simplicity assume $a_\emptyset = 1$)

$$\begin{aligned} S^{-1} &= \left(1 + \sum_{|I|>0} a_I X_I\right)^{-1} = \sum_{k=0}^{\infty} (-1)^k \left(\sum_{|I|>0} a_I X_I\right)^k \\ &= 1 + \sum_{|I|>0} \left(\sum_{k=1}^{\infty} (-1)^k \sum_{J_1 \ldots J_k = I} a_{J_1} \ldots a_{J_k}\right) X_I, \end{aligned} \tag{8}$$

where the inner summation in the last equality above is over all ways of expressing the multiindex I as a concatenation $J_1 \cdots J_k$ of k indices.)

Remark 1. It follows from the results of [10] that $S_{\mathbf{V}}$ is $\hat{G}(\mathbf{X})$-valued if $\mathbf{V}$ is an extended input. The converse of this is also true; i.e., if S is a $\hat{G}(\mathbf{X})$-valued formal trajectory, then $\mathbf{V} = (S^{-1} \overrightarrow{*} S)$ is an extended input. To see this, it is enough to prove that in this case the function $(S^{-1} \overrightarrow{*} S)$ is $\hat{L}(\mathbf{X})$-valued. This is true when S is C^∞, since in that case $(S^{-1} \overrightarrow{*} S)(t) = \int_0^t S^{-1}(\tau)\dot{S}(\tau)\,d\tau$, and $S^{-1}(t)\dot{S}(t) = \lim_{h\to 0} \frac{1}{h} S^{-1}(t)(S(t+h) - S(t)) = \lim_{h\to 0} \frac{1}{h}(S^{-1}(t)S(t+h) - 1)$. Using the Campbell–Hausdorff formula we conclude that $S^{-1}(t)S(t+h) = \exp(\Lambda(t,h))$, where $\Lambda(t,h)$ is a Lie series that goes to zero as $h \to 0$. So $S^{-1}(t)\dot{S}(t) = \lim_{h\to 0} \frac{1}{h}(\Lambda(t,h) + \frac{1}{2}\Lambda(t,h)^2 + \cdots) = \lim_{h\to 0} \frac{\Lambda(t,h)}{h}$. So $S^{-1}\dot{S}$ is Lie series valued, which implies that $\mathbf{V} = (S^{-1} \overrightarrow{*} S)$ is an extended input. In the general case, let $S(t) = \exp(Z(t))$, where $Z(t) = \sum_{|I|>0} Z_I(t)[X_I]$, $Z_I \in BVC[0,T]$, $Z(0) = 0$. From Proposition 4 in the appendix, for each I, we can take a sequence $\{Z_I^j\} \subseteq C^\infty[0,T]$, $Z_I^j(0) = 0$, such that the Z_I^j converge to Z_I uniformly as $j \to \infty$ and the $\|\dot{Z}_I^j\|_{L^1}$ are uniformly bounded in j. Let $Z^j = \sum_{|I|>0} Z_I^j[X_I]$. Then we know that the Z^j converge to Z uniformly in $\hat{A}_0(\mathbf{X})$. Let $S^j(t) = \exp(Z^j(t))$. We have $S^j \to \exp(Z) = S$ uniformly. Since $(S^j)^{-1} = \exp(-Z^j)$, the $(S^j)^{-1}$ converge to $\exp(-Z) = S^{-1}$ uniformly as

$j \to \infty$. Since the $\dot{Z}_I^j$ are uniformly bounded in $L^1[0,T]$ for each I, if we write $S^j = 1 + \sum_{|I|>0} H_I^j X_I$, then the L^1 norms of the $\dot{H}_I^j$ are also uniformly bounded in j for each I. The following lemma implies that the $((S^j)^{-1} \overrightarrow{*} S^j)$ converge to $(S^{-1} \overrightarrow{*} S)$ uniformly. Since the $((S^j)^{-1} \overrightarrow{*} S^j)$ are Lie series valued functions, $(S^{-1} \overrightarrow{*} S)$ is a Lie series. Therefore $\mathbf{V} = (S^{-1} \overrightarrow{*} S)$ is an extended input.

LEMMA 1. *Let $\{f^j\}$ be a sequence of continuous functions on $[0,T]$ that converges to f uniformly on $[0,T]$ as $j \to \infty$. Let $\{g^j\}$ be a sequence of functions belonging to $BVC[0,T]$. Assume that the functions g^j converge to g uniformly on $[0,T]$ as $j \to \infty$ and the total variations $TV[g^j;0,T]$ of the g^j on $[0,T]$ are uniformly bounded in j. Then the integrals $\int_0^t f^j(s)\,dg^j(s)$ converge to $\int_0^t f(s)\,dg(s)$ uniformly as $j \to \infty$.*

The proof of this lemma is given in the appendix.

The polynomial input $\mathbf{V}$ can be computed from $S_{\mathbf{V}}$ using standard algebraic tools. If $S_{\mathbf{V}} = 1 + \sum_{|I|>0} H_I X_I$, from (8) we know that

$$S_{\mathbf{V}}^{-1} = 1 + \sum_{|I|>0} \left(\sum_{k=1}^{\infty} (-1)^k \sum_{J_1 \dots J_k = I} H_{J_1} \dots H_{J_k} \right) X_I.$$

We have

$$(S_{\mathbf{V}}^{-1} \overrightarrow{*} S_{\mathbf{V}})(t) = \left(\left(1 + \sum_{|I|>0} \left(\sum_{k=1}^{\infty} (-1)^k \sum_{J_1 \dots J_k = I} H_{J_1} \dots H_{J_k} \right) X_I \right) \overrightarrow{*} \left(1 + \sum_{|I|>0} H_I X_I \right) \right)(t)$$

$$= \sum_{|I|>0} \left(H_I + \sum_{k=1}^{\infty} (-1)^k \sum_{J_1 \dots J_k J_{k+1} = I} (H_{J_1} \dots H_{J_k}) \overrightarrow{*} H_{J_{k+1}} \right) X_I,$$

where the inner summation above runs over all ways of expressing the multiindex I as a concatenation $J_1 \cdots J_k J_{k+1}$ of $k+1$ indices. So, if we let $V(t) = (S_{\mathbf{V}}^{-1} \overrightarrow{*} S_{\mathbf{V}})(t) = \sum_{|I|>0} V_I(t) X_I$, then the V_I are given by

$$V_I = H_I + \sum_{k=1}^{\infty} (-1)^k \sum_{J_1 \dots J_k J_{k+1} = I} (H_{J_1} \dots H_{J_k}) \overrightarrow{*} H_{J_{k+1}}. \tag{9}$$

Let π be the linear map of $A(\mathbf{X})$ onto $L(\mathbf{X})$ defined by $\pi(X_I) = \frac{1}{|I|}[X_I]$. It is well known (cf., e.g., [3]) that the restriction of π to $L(\mathbf{X})$ is the identity map; i.e., π is a projector of $A(\mathbf{X})$ onto $L(\mathbf{X})$. Let $\hat{\pi}$ be the linear projection map from $\hat{A}(\mathbf{X})$ to $\hat{L}(\mathbf{X})$ that extends π. From Remark 1 we know that if $S = 1 + \sum_{|I|>0} H_I X_I$ is a $\hat{G}(\mathbf{X})$-valued formal trajectory, $V = (S^{-1} \overrightarrow{*} S)$ is a Lie series valued function. In that case we have $\hat{\pi}(V) = V$, so

$$V(t) = \sum_{|I|>0} \frac{1}{|I|} V_I(t)[X_I], \tag{10}$$

where the V_I are given by (9).

In the particular case when $\mathbf{V}$ is an ordinary input $\mathbf{U} = U_1X_1 + \cdots + U_mX_m$, the Chen–Fliess series $S_{\mathbf{U}}$ is given by the formula

$$S_{\mathbf{U}}(t) = 1 + \sum_{|I|>0} \hat{U}_I(t)X_I,$$

where, if $I = (i_1, \ldots, i_k)$, then $\hat{U}_I$ is the iterated integral defined by

$$\hat{U}_I \stackrel{\text{def}}{=} 1 \overrightarrow{*} U_{i_1} \overrightarrow{*} U_{i_2} \overrightarrow{*} \cdots \overrightarrow{*} U_{i_k}. \tag{11}$$

DEFINITION 4. *A sequence $\{\mathbf{V}^j\}$ of polynomial inputs FT-converges (converges in the formal trajectory sense) to a polynomial input $\mathbf{V}^\infty$ if the corresponding formal trajectories $S_{\mathbf{V}^j}$ converge uniformly to $S_{\mathbf{V}^\infty}$ as $j \to \infty$.*

Hence, if $\{\mathbf{U}^j\}$ is a sequence of ordinary inputs and $\mathbf{V}$ is a polynomial input such that

$$S_{\mathbf{V}}(t) = 1 + \sum_{|I|>0} H_I(t)X_I, \tag{12}$$

then $\{\mathbf{U}^j\}$ FT-converges to $\mathbf{V}$ if and only if the sequence $\{\hat{U}_I^j\}$ of functions converges uniformly to H_I for each I. Using formula (9), we can explicitly compute the limiting polynomial input $\mathbf{V}$ in terms of the limits H_I of the iterated integrals $\hat{U}_I^j$.

DEFINITION 5. *Given two polynomial inputs $\mathbf{V}_1 = V_1$ and $\mathbf{V}_2 = V_2$, we define a generalized difference (GD for short) of $\mathbf{V}_1$ and $\mathbf{V}_2$ to be a B-continuous $\hat{A}_0(\mathbf{X})$-valued function W that satisfies*

$$dW = -dV_1W + dV_2 - dV_1, \quad W(t) \in \hat{A}_0(\mathbf{X}). \tag{13}$$

Clearly a solution W of (13) is uniquely determined by its initial condition $W(0)$. We will use $GD\{\mathbf{V}_1, \mathbf{V}_2\}$ to denote the set of all generalized differences of $\mathbf{V}_1$ and $\mathbf{V}_2$.

Remark 2. If $W(0) = 0$, then it is clear that W has some of the properties of a "difference of $\mathbf{V}_1$ and $\mathbf{V}_2$." (For instance, $W \equiv 0$ iff $\mathbf{V}_1 = \mathbf{V}_2$.) In general, if $W(0)$ is "small" in some sense, then it is reasonable to expect that $W(t)$ is "small" for all t if and only if $\mathbf{V}_1$ and $\mathbf{V}_2$ are "close." The convergence theorems will make this precise. Let W be a solution of (13) with initial condition $W(0) = W_0 \in \hat{A}_0(\mathbf{X})$. Then W satisfies the integral equation

$$W = W_0 - V_2(0) + V_1(0) - V_1 \overleftarrow{*} W + V_2 - V_1$$

and can be calculated by the formula

$$W = \sum_{k=0}^{\infty} (-1)^k \overbrace{V_1 \overleftarrow{*} V_1 \overleftarrow{*} \cdots \overleftarrow{*} V_1}^{k} \overleftarrow{*} (V_2 - V_1 + \tilde{W}), \tag{14}$$

where $\tilde{W} = W_0 - V_2(0) + V_1(0)$. Let $\mathbf{U}$ be an ordinary input and $\mathbf{V}$ be a polynomial input. Let $U = U_1X_1 + \cdots + U_mX_m$ and $V = \sum_{|I|>0} V_IX_I$ be a representative of $\mathbf{U}$ and $\mathbf{V}$, respectively. Let

$$(\mathbf{U} \stackrel{\text{g.d.}}{-} \mathbf{V})(t) = \sum_{|I|>0} \widetilde{UV}_I(t)X_I$$

be a generalized difference of $\mathbf{U}$ and $\mathbf{V}$ with initial value $(\mathbf{U} \overset{\text{g.d.}}{-} \mathbf{V})(0) = \sum_{|I|>0} \hat{W}_I X_I$. Let $\tilde{W} = \sum_{|I|>0} \tilde{W}_I X_I = \sum_{|I|>0} \hat{W}_I X_I - V(0) + U(0)$. From (14) we have

$$\widetilde{UV}_{i_1,\dots,i_k} = \sum_{\ell=0}^{k} (-1)^\ell U_{i_1} \overset{\leftarrow}{*} U_{i_2} \overset{\leftarrow}{*} \cdots \overset{\leftarrow}{*} U_{i_\ell} \overset{\leftarrow}{*} (V_{i_{\ell+1},\dots,i_k} + \tilde{W}_{i_{\ell+1},\dots,i_k}). \tag{15}$$

Formula (15) implies the recursive formula (this also follows directly from (13))

$$\widetilde{UV}_i = V_i + \tilde{W}_i - U_i,$$

$$\widetilde{UV}_{i_1,\dots,i_k} = V_{i_1,\dots,i_k} + \tilde{W}_{i_1,\dots,i_k} - U_{i_1} \overset{\leftarrow}{*} \widetilde{UV}_{i_2,\dots,i_k} = V_{i_1,\dots,i_k} + \tilde{W}_{i_1,\dots,i_k} - \widetilde{UV}_{i_2,\dots,i_k} \overset{\rightarrow}{*} U_{i_1}.$$

Remark 3. If $\tilde{W} = \sum_{|I|>0} \tilde{W}_I X_I = \sum_{|I|>0} \hat{W}_I X_I - V(0) + U(0) = 0$, then the above recursive formula becomes

$$\widetilde{UV}_{i_1,\dots,i_k} = V_{i_1,\dots,i_k} - U_{i_1} \overset{\leftarrow}{*} \widetilde{UV}_{i_2,\dots,i_k}. \tag{16}$$

For example, if we take a representative V of $\mathbf{V}$ with $V(0) = \hat{W} + U(0)$, then $\tilde{W} = 0$.

Remark 4. If $\mathbf{V}_1$ and $\mathbf{V}_2$ are two polynomial inputs, we use $(\mathbf{V}_1 \overset{\text{g.d.}}{-} \mathbf{V}_2)(t)$ to denote a generalized difference of $\mathbf{V}_1$ and $\mathbf{V}_2$. If $\mathbf{U}$ is an ordinary input and $\mathbf{V}$ is a polynomial input, we will use $\widetilde{UV}_I$ to denote the coefficients of X_I in $(\mathbf{U} \overset{\text{g.d.}}{-} \mathbf{V})(t)$ with the understanding that the $\widetilde{UV}_I$ are given by (15). The notations $(\mathbf{V}_1 \overset{\text{g.d.}}{-} \mathbf{V}_2)(t)$, $(\mathbf{U} \overset{\text{g.d.}}{-} \mathbf{V})(t)$, and $\widetilde{UV}_I(t)$ are slightly ambiguous because they depend also on the initial values $(\mathbf{V}_1 \overset{\text{g.d.}}{-} \mathbf{V}_2)(0)$, $(\mathbf{U} \overset{\text{g.d.}}{-} \mathbf{V})(0)$, and $\widetilde{UV}_I(0)$, but we will use them anyhow.

DEFINITION 6. *Let $\{\mathbf{V}_1^j\}$ and $\{\mathbf{V}_2^j\}$ be two sequences of polynomial inputs. We say that $\{\mathbf{V}_1^j, \mathbf{V}_2^j\}$ GD-converges to zero if there exist generalized differences $(\mathbf{V}_1^j \overset{\text{g.d.}}{-} \mathbf{V}_2^j)(t)$ of $\mathbf{V}_1^j$ and $\mathbf{V}_2^j$ that converge to zero uniformly as $j \to \infty$. We say that a sequence $\{\mathbf{V}^j\}$ of polynomial inputs GD-converges to a polynomial input $\mathbf{V}$ if $\{\mathbf{V}^j, \mathbf{V}\}$ GD-converges to* 0.

Remark 5. As the following simple examples shows, the positions of $\mathbf{V}_1^j$ and $\mathbf{V}_2^j$ are not symmetric in the definition of GD-convergence. Namely, the fact that $\{\mathbf{V}_1^j, \mathbf{V}_2^j\}$ GD-converges to 0 does not imply that $\{\mathbf{V}_2^j, \mathbf{V}_1^j\}$ GD-converges to 0. Similarly the condition that a sequence $\{\mathbf{V}^j\}$ GD-converges to $\mathbf{V}$ is not equivalent to the condition that $\{\mathbf{V}^j - \mathbf{V}\}$ GD-converges to 0.

Example. Let $m = 2$, $\mathbf{U}_1^j = j^{-\frac{1}{3}} \sin jt X_1 + j^{-\frac{1}{3}}(1 - \cos jt) X_2$, and $\mathbf{U}_2^j \equiv 0$ be two sequences of ordinary inputs. Then it is easy to see that $\{\mathbf{U}_2^j, \mathbf{U}_1^j\}$ GD-converges to 0. Indeed the differential equation (13) corresponding to $\mathbf{U}_2^j, \mathbf{U}_1^j$ is given by $dW = d\mathbf{U}_1^j$. On the other hand, the differential equation (13) corresponding to $\mathbf{U}_1^j, \mathbf{U}_2^j$ is given by

$$dW = -d\mathbf{U}_1^j W - d\mathbf{U}_1^j. \tag{17}$$

The solution $W^j(t) = \sum_{|I|>0} W_I^j(t) X_I$ of (17) with initial condition $W^j(0) = \hat{W}^j = \sum_{|I|>0} \hat{W}_I^j X_I$ can be computed explicitly and

$$W_{2,1}^j(t) = \hat{W}_{2,1}^j + j^{-\frac{1}{3}} \hat{W}_1^j (\cos jt - 1) + \frac{t}{2} j^{\frac{1}{3}} + \frac{1}{4} j^{-\frac{1}{3}} \sin 2jt,$$

which does not converge to 0 no matter what $\hat{W}$ is.

Remark 6. If $\{\mathbf{U}^j\}$ is a sequence of ordinary inputs and $\{\mathbf{V}^j\}$ a sequence of polynomial inputs, we will use the abused notation $\widetilde{UV}_I^j$ to denote the coefficients of a generalized difference of $\mathbf{U}^j$ and $\mathbf{V}^j$. (For simplicity we will use $\widetilde{UV}_I^j$ rather than $\widetilde{U^jV^j}_I$.) Therefore if $U^j = U_1^jX_1 + \cdots + U_m^jX_m$ and $V^j = \sum_{|I|>0} V_I^jX_I$ are representatives of $\mathbf{U}^j$ and $\mathbf{V}^j$, respectively, and $(\mathbf{U}^j \overset{\text{g.d.}}{-} \mathbf{V}^j)(t)$ is a generalized difference of $\mathbf{U}^j$ and $\mathbf{V}^j$ with $(\mathbf{U}^j \overset{\text{g.d.}}{-} \mathbf{V}^j)(0) = \sum_{|I|>0} \hat{W}_I^jX_I$, then the $\widetilde{UV}_I^j$ are given by

$$\widetilde{UV}_{i_1,\dots,i_k}^j = \sum_{\ell=0}^{k}(-1)^\ell U_{i_1}^j \overset{\leftarrow}{*} U_{i_2}^j \overset{\leftarrow}{*} \cdots \overset{\leftarrow}{*} U_{i_\ell}^j \overset{\leftarrow}{*} (V_{i_{\ell+1},\dots,i_k}^j + \tilde{W}_{i_{\ell+1},\dots,i_k}^j). \tag{18}$$

So it is clear that $\{\mathbf{U}^j, \mathbf{V}^j\}$ GD-converges to 0 if and only if there exist sequences of constants $\hat{W}_I^j$ such that the functions $\widetilde{UV}_I^j$ determined by the $\hat{W}_I^j$ converge to 0 uniformly for all multiindices $|I| > 0$.

DEFINITION 7. *Let $V = \sum_I V_IX_I \in BVC([0,T], \hat{A}(\mathbf{X}))$ be a B-continuous $\hat{A}(\mathbf{X})$-valued function and $\{V^j = \sum_I V_I^jX_I\}$ be a sequence in $BVC([0,T], \hat{A}(\mathbf{X}))$. We say that $\{V^j\}$ converges to V strongly if the functions V_I^j converge to V_I uniformly for all I and the total variations $TV[V_I^j; 0, T]$ of the V_I^j are uniformly bounded in j for each I.*

DEFINITION 8. *Let $\mathbf{V}$ be a polynomial input and $\{\mathbf{V}^j\}$ be a sequence of polynomial inputs. Then we say that $\{\mathbf{V}^j\}$ converges to $\mathbf{V}$ strongly if there are representatives V^j and V of $\mathbf{V}^j$ and $\mathbf{V}$, respectively, such that the V^j converge to V strongly.*

We will use $STCON(\mathbf{V})$ to denote the set of all sequences of polynomial inputs that converge to $\mathbf{V}$ strongly, so

$$STCON(\mathbf{V}) = \Big\{ \{\mathbf{V}^j\} \;\Big|\; \{\mathbf{V}^j\} \to \mathbf{V} \text{ strongly as } j \to \infty \Big\}.$$

Let $\{\mathbf{V}^j\}$ be an element of $STCON(\mathbf{V})$. Let us take a representative $V = \sum_{|I|>0} V_IX_I$ and $V^j = \sum_{|I|>0} V_I^jX_I$ of $\mathbf{V}$ and $\mathbf{V}^j$, respectively, such that the V^j converge to V strongly. Let $S_{\mathbf{V}^j} = 1 + \sum_{|I|>0} H_I^jX_I$ and $S_{\mathbf{V}} = 1 + \sum_{|I|>0} H_IX_I$ be the formal trajectories determined by $\mathbf{V}^j$ and $\mathbf{V}$, respectively. Then it is easy to see that the total variations $TV[H_I^j; 0, T]$ of the functions H_I^j are uniformly bounded in j for each I. From

$$\begin{aligned} S_{\mathbf{V}^j}(t) - S_{\mathbf{V}}(t) &= (S_{\mathbf{V}^j} \overset{\rightarrow}{*} V^j)(t) - (S_{\mathbf{V}} \overset{\rightarrow}{*} V)(t) \\ &= ((S_{\mathbf{V}^j} - S_{\mathbf{V}}) \overset{\rightarrow}{*} V^j)(t) + (S_{\mathbf{V}} \overset{\rightarrow}{*} (V^j - V))(t) \end{aligned}$$

we see that

$$\begin{aligned} H_\ell^j(t) - H_\ell(t) &= V_\ell^j(t) - V_\ell^j(0) - V_\ell(t) + V_\ell(0), \\ H_I^j(t) - H_I(t) &= \sum_{J_1J_2=I} \Big((H_{J_1}^j - H_{J_1}) \overset{\rightarrow}{*} V_{J_2}^j\Big)(t) + \sum_{J_1J_2=I} \Big(H_{J_1} \overset{\rightarrow}{*} (V_{J_2}^j - V_{J_2})\Big)(t) \\ &\quad + V_I^j(t) - V_I(t) - V_I^j(0) + V_I(0). \end{aligned}$$

Using this and induction we can show easily that the H_I^j converge to H_I for each I; cf. Lemma 1. Therefore $\{\mathbf{V}^j\} \in STCON(\mathbf{V})$ implies that $\{\mathbf{V}^j\}$ FT-converges to $\mathbf{V}$.

Let $\mathbf{U} = U_1X_1 + \cdots + U_mX_m$ be an ordinary input and $\mathbf{V} = \sum_{|I|>0} V_I X_I$ be a polynomial input. Assume that $U(0) = V(0) = 0$. Let $(\mathbf{U} \overset{\text{g.d.}}{-} \mathbf{V}) = \sum_{|I|>0} \widetilde{UV}_I X_I$ be a generalized difference of $\mathbf{U}$ and $\mathbf{V}$. Let $S_{\mathbf{U}}$ be the formal trajectory of $\mathbf{U}$. Now we establish a formula that relates $S_{\mathbf{U}}$, $\mathbf{V}$ and $(\mathbf{U} \overset{\text{g.d.}}{-} \mathbf{V})$. We know that the functions U_ℓ, V_I and $\widetilde{UV}_I$ are related by (15). Therefore we have

$$\begin{aligned} S_{\mathbf{U}}(t) &= 1 + \sum_{i_1=1}^{m} \int_0^t S_{\mathbf{U}}(\tau)\, dU_{i_1}(\tau)\, X_{i_1} \\ &= 1 + \sum_{i_1=1}^{m} \int_0^t S_{\mathbf{U}}(\tau)\, dV_{i_1}(\tau)\, X_{i_1} - \sum_{i_1=1}^{m} \int_0^t S_{\mathbf{U}}(\tau) d\widetilde{UV}_{i_1}(\tau)\, X_{i_1}. \end{aligned}$$

Applying integration by parts and noticing that $\widetilde{UV}_{i_1,i_2}(t) = \widetilde{UV}_{i_1,i_2}(0) + V_{i_1,i_2}(t) - (U_{i_1} \overset{\leftarrow}{*} \widetilde{UV}_{i_2})(t)$, we get

$$\begin{aligned} S_{\mathbf{U}}(t) &= 1 + \sum_{i_1=1}^{m} \int_0^t S_{\mathbf{U}}(\tau)\, dV_{i_1}(\tau)\, X_{i_1} + \sum_{i_1,i_2=1}^{m} \int_0^t S_{\mathbf{U}}(\tau)\, dV_{i_1,i_2}(\tau)\, X_{i_1}X_{i_2} \\ &- \sum_{i_1=1}^{m} S_{\mathbf{U}}(t)\widetilde{UV}_{i_1}(t)\, X_{i_1} + \sum_{i_1=1}^{m} \widetilde{UV}_{i_1}(0)\, X_{i_1} - \sum_{i_1,i_2=1}^{m} \int_0^t S_{\mathbf{U}}(\tau) d\widetilde{UV}_{i_1,i_2}(\tau)\, X_{i_1}X_{i_2}. \end{aligned}$$

Continuing the integration by parts in this way up to order k, we get

$$\begin{aligned} S_{\mathbf{U}}(t) &= 1 + \left(S_{\mathbf{U}} \overset{\rightarrow}{*} \left(\sum_{0<|I|\le k} V_I\, X_I \right) \right)(t) - \left(S_{\mathbf{U}} \overset{\rightarrow}{*} \left(\sum_{|I|=k} \widetilde{UV}_I X_I \right) \right)(t) \\ &- S_{\mathbf{U}}(t) \left(\sum_{0<|I|<k} \widetilde{UV}_I(t)\, X_I \right) + \sum_{0<|I|<k} \widetilde{UV}_I(0)\, X_I. \end{aligned} \tag{19}$$

PROPOSITION 1. *Let $\{\mathbf{U}^j\}$ be a sequence of ordinary inputs and $\mathbf{V}$ be a polynomial input. Then*

(a) *the following conditions are equivalent:*
   (i) *the $\mathbf{U}^j$ FT-converge to $\mathbf{V}$;*
   (ii) *the $\mathbf{U}^j$ GD-converge to $\mathbf{V}$;*
   (iii) *there is one element $\{\mathbf{V}^j\}$ of $STCON(\mathbf{V})$ such that $\{\mathbf{U}^j, \mathbf{V}^j\}$ GD-converges to 0;*
   (iv) *for any element $\{\mathbf{V}^j\}$ of $STCON(\mathbf{V})$ and any $(\mathbf{U}^j \overset{\text{g.d.}}{-} \mathbf{V}^j) \in GD\{\mathbf{U}^j, \mathbf{V}^j\}$, if the initial values $(\mathbf{U}^j \overset{\text{g.d.}}{-} \mathbf{V}^j)(0) \to 0$, then the sequence $\{(\mathbf{U}^j \overset{\text{g.d.}}{-} \mathbf{V}^j)\}$ converges to 0 uniformly as $j \to \infty$.*

(b) *if the $\mathbf{U}^j$ FT-converge to $\mathbf{V}$, then $\mathbf{V}$ is an extended input.*

Proof. First notice that conclusion (b) follows from Remark 1. (We know that the $S_{\mathbf{U}^j}$ are $\hat{G}(\mathbf{X})$ valued, so $S_{\mathbf{U}^j} = \exp(Z^j)$ for some $Z^j \in BVC([0,T], \hat{L}(\mathbf{X}))$. Now the fact that $\{S_{\mathbf{U}^j}\}$ converges to $S_{\mathbf{V}}$ uniformly implies that $\{Z^j\}$ converges to $\log(S_{\mathbf{V}})$ uniformly. Therefore $\log(S_{\mathbf{V}})$ is $\hat{L}(\mathbf{X})$-valued, which implies that $S_{\mathbf{V}}$ is a $\hat{G}(\mathbf{X})$-valued formal trajectory.)

Now we prove (a). It is clear that (iv) $\Rightarrow$ (ii) $\Rightarrow$ (iii). Therefore we need only to show that (i) implies (iv) and (iii) implies (i).

First we show that (i) implies (iv). Assume that $\{\mathbf{U}^j\}$ FT-converges to $\mathbf{V}$. Take any element $\{\mathbf{V}^j\}$ of $STCON(\mathbf{V})$ and generalized differences $(\mathbf{U}^j \overset{\text{g.d.}}{-} \mathbf{V}^j) = \sum_{|I|>0} \widetilde{UV}_I^j X_I$ of $\mathbf{U}^j$ and $\mathbf{V}^j$ with $(\mathbf{U}^j \overset{\text{g.d.}}{-} \mathbf{V}^j)(0) \to 0$. Let $U^j = U_1^j X_1 + \cdots + U_m^j X_m$ and $V = \sum_{|I|>0} V_I X_I$ be representatives of $\mathbf{U}^j$ and $\mathbf{V}$. Let $V^j = \sum_{|I|>0} V_I^j X_I$ be representatives of $\mathbf{V}^j$ that converge to V strongly. Without loss of generality we may assume that $U^j(0) = V^j(0) = V(0) = 0$. We use induction to show that the $\widetilde{UV}_I^j$ converge to 0 uniformly. Since the $\mathbf{U}^j$ FT-converge to $\mathbf{V}$, we know that $U_\ell^j \to V_\ell$ uniformly. (Notice that U_ℓ^j and V_ℓ are the coefficients of X_ℓ in $S_{\mathbf{U}^j}$ and $S_{\mathbf{V}}$, respectively.) It then follows that the $\widetilde{UV}_\ell^j = V_\ell^j - U_\ell^j + \widetilde{UV}_\ell^j(0)$ converge to 0 uniformly for $\ell = 1, \ldots, m$. Assume that $\widetilde{UV}_I^j \to 0$ uniformly for all I with $0 < |I| < k$. Now from (19) we get

$$S_{\mathbf{U}^j}(t) = 1 + \left(S_{\mathbf{U}^j} \overset{\rightarrow}{*} \left(\sum_{0<|I|\le k} V_I^j X_I\right)\right)(t) - \left(S_{\mathbf{U}^j} \overset{\rightarrow}{*} \left(\sum_{|I|=k} \widetilde{UV}_I^j X_I\right)\right)(t)$$

$$- S_{\mathbf{U}^j}(t) \left(\sum_{0<|I|<k} \widetilde{UV}_I^j(t)\, X_I\right) + \sum_{0<|I|<k} \widetilde{UV}_I^j(0)\, X_I. \tag{20}$$

Since $V^j(0) = 0$, we know that $V^j(t) = (S_{\mathbf{V}^j}^{-1} \overset{\rightarrow}{*} S_{\mathbf{V}^j})(t)$. Therefore

$$\sum_{0<|I|\le k} V_I^j(t)\, X_I = (S_{\mathbf{V}^j}^{-1} \overset{\rightarrow}{*} S_{\mathbf{V}^j})(t) - \sum_{|I|>k} V_I^j(t)\, X_I.$$

Notice that $\{S_{\mathbf{V}^j}\} \to S_{\mathbf{V}}$ uniformly implies that $\{S_{\mathbf{V}^j}^{-1}\}$ converges $S_{\mathbf{V}}^{-1}$ uniformly. Then we have

$$S_{\mathbf{U}^j} S_{\mathbf{V}^j}^{-1} \to S_{\mathbf{V}} S_{\mathbf{V}}^{-1} = 1 \tag{21}$$

uniformly as $j \to \infty$. Let $S_{\mathbf{V}^j} = 1 + \sum_{|I|>0} H_I^j X_I$ be the formal trajectories determined by $\mathbf{V}^j$. Then from the uniform boundedness of the $TV[V_I^j; 0, T]$ for each I we know that the $TV[H_I^j; 0, T]$ are also uniformly bounded in j for each I. Combining this with (21) we get that the $\hat{A}(\mathbf{X})$-valued functions

$$S_{\mathbf{U}^j}(t) - 1 - (S_{\mathbf{U}^j} \overset{\rightarrow}{*} (S_{\mathbf{V}^j}^{-1} \overset{\rightarrow}{*} S_{\mathbf{V}^j}))(t) = S_{\mathbf{U}^j}(t) - 1 - (S_{\mathbf{U}^j} S_{\mathbf{V}^j}^{-1} \overset{\rightarrow}{*} S_{\mathbf{V}^j})(t)$$

converge to zero uniformly. By induction, the $S_{\mathbf{U}^j}(\sum_{0<|I|<k} \widetilde{UV}_I^j X_I)$ converge to 0 uniformly. Therefore we have

$$S_{\mathbf{U}^j} \overset{\rightarrow}{*} \left(\sum_{|I|=k} \widetilde{UV}_I^j X_I\right) + S_{\mathbf{U}^j} \overset{\rightarrow}{*} \left(\sum_{|I|>k} V_I^j X_I\right) \to 0$$

uniformly. If we just take the degree k parts we get that the $\widetilde{UV}_I^j - \widetilde{UV}_I^j(0)$ converge to 0 uniformly for $|I| = k$, which implies that the $\widetilde{UV}_I^j$ converge to zero uniformly.

(iii) $\Longrightarrow$ (i). Let $\{\mathbf{V}^j\}$ be an element of $STCON(\mathbf{V})$ such that $\{\mathbf{U}^j, \mathbf{V}^j\}$ GD-converges to 0. Let $(\mathbf{U}^j \overset{\text{g.d.}}{-} \mathbf{V}^j) = \sum_{|I|>0} \widetilde{UV}_I^j X_I$ be generalized differences of $\mathbf{U}^j$

and $\mathbf{V}^j$ that converge to 0 uniformly. Let U^j, V, V^j be representatives of $\mathbf{U}^j, \mathbf{V}$, and $\mathbf{V}^j$ as above with $U^j(0) = V^j(0) = V(0) = 0$. Let $S_{\mathbf{U}^j} = 1 + \sum_{|I|>0} \hat{U}_I^j X_I$, $S_{\mathbf{V}} = 1 + \sum_{|I|>0} H_I X_I$, and $S_{\mathbf{V}^j} = 1 + \sum_{|I|>0} H_I^j X_I$ be the formal trajectories determined by $\mathbf{U}^j$, $\mathbf{V}$, and $\mathbf{V}^j$, respectively. We use induction to show that the $\hat{U}_I^j$ converge to H_I uniformly as $j \to \infty$ for each I. We know that $\{H_I^j\} \to H_I$ uniformly as $j \to \infty$. From (18) we have $\hat{U}_\ell^j = V_\ell^j - \widetilde{UV}_\ell^j + \widetilde{UV}_\ell^j(0) \to H_\ell$ uniformly for $\ell = 1, \dots, m$. Assume that the $\hat{U}_I^j$ converge to H_I for all $|I| < k$ with $k \geq 2$. Let I be such that $|I| = k$. Then from (20) we have

$$\hat{U}_I^j(t) = \sum_{J_1 J_2 = I} (\hat{U}_{J_1}^j \overrightarrow{*} V_{J_2}^j)(t) + V_I^j(t) - \widetilde{UV}_I^j(t) + \widetilde{UV}_I^j(0) - \sum_{J_1 J_2 = I} \hat{U}_{J_1}^j(t) \widetilde{UV}_{J_2}^j(t).$$

From this we see easily that the $\hat{U}_I^j$ converge to $V_I + \sum_{J_1 J_2 = I} H_{J_1} \overrightarrow{*} V_{J_2}$ uniformly. But since $S_{\mathbf{V}} = 1 + S_{\mathbf{V}} \overrightarrow{*} V$, we know that $H_I = V_I + \sum_{J_1 J_2 = I} H_{J_1} \overrightarrow{*} V_{J_2}$. Therefore we get that the $\hat{U}_I^j$ converge to H_I uniformly. □

2.3. Polynomial inputs of finite order and truncated formal trajectories. The concepts of polynomial inputs, extended inputs, formal trajectories, generalized differences, etc., have truncated analogues. Let us say that a polynomial input $\mathbf{V}$ has *order* $\leq r$ if there exists a representative of $\mathbf{V}$ whose values are linear combinations of monomials of degree $\leq r$. The smallest such an r is called the *order* of $\mathbf{V}$. We say that $\mathbf{V}$ is of *finite order* if it has order r for some integer $r > 0$.

If $\mathbf{V}$ is a polynomial input of order $\leq r$, we can regard $\mathbf{V}$ as an equivalence class of $A_0^r(\mathbf{X})$-valued rather than $\hat{A}_0(\mathbf{X})$-valued functions. The *rth-order truncated formal trajectory* determined by $\mathbf{V}$ is the solution of the initial value problem

$$dS = SdV, \quad S(t) \in A^r(\mathbf{X}), \tag{22}$$

$$S(0) = 1, \tag{23}$$

where V is any representative of $\mathbf{V}$. We will use $S_{\mathbf{V}}^r$ to denote the rth-order truncated formal trajectory determined by $\mathbf{V}$ in $A^r(\mathbf{X})$. Equation (22) is the *rth-order truncated formal equation* determined by $\mathbf{V}$.

We will say that a sequence $\{\mathbf{U}^j = U_1^j X_1 + \cdots + U_m^j X_m\}$ of ordinary inputs *FT(r)-converges* to a polynomial input $\mathbf{V}$ of order $\leq r$, with Chen–Fliess series $S_{\mathbf{V}} = 1 + \sum_{|I|>0} H_I X_I$, if the iterated integrals $\hat{U}_I^j$ converge uniformly to the functions H_I for all multiindices I such that $0 < |I| \leq r$. Equivalently, $\{\mathbf{U}^j\}$ FT(r)-converges to $\mathbf{V}$ if the rth-order truncated formal trajectories $S_{\mathbf{U}^j}^r$ converge uniformly to $S_{\mathbf{V}}^r$. In that case, the components V_I of a representative V of $\mathbf{V}$ are still given by (9). (In (9), we can use either the H_I of the series $S_{\mathbf{V}}$ or those of the truncated version, in which case we would set H_I to be 0 for $|I| > r$. Both yield the same result, because $\mathbf{V}$ is of order $\leq r$.)

If $\mathbf{V}_1$ and $\mathbf{V}_2$ are polynomial inputs of order $\leq r$, we can also define an *rth-order truncated generalized difference* of $\mathbf{V}_1$ and $\mathbf{V}_2$, which is a B-continuous $A_0^r(\mathbf{X})$-valued function that satisfies

$$dW = -dV_1 W + dV_2 - dV_1, \quad W(t) \in A_0^r(\mathbf{X}), \tag{24}$$

where V_1 and V_2 are representatives of $\mathbf{V}_1$ and $\mathbf{V}_2$, respectively. We will use the abused notation $(\mathbf{V}_1 \overset{\text{g.d.(r)}}{-} \mathbf{V}_2)$ to denote an rth-order truncated generalized difference of $\mathbf{V}_1$

and $\mathbf{V}_2$. It is uniquely determined by $(\mathbf{V}_1 \overset{\text{g.d.(r)}}{-} \mathbf{V}_2)(0)$. Let $U = U_1X_1 + \cdots + U_mX_m$ be an ordinary input and $\mathbf{V} = \sum_{0<|I|\le r} V_I X_I$ be a polynomial input of order $\le r$. Let $(\mathbf{U} \overset{\text{g.d.(r)}}{-} \mathbf{V})(t) = \sum_{0<|I|\le r} \widetilde{UV}_I(t) X_I$ be an rth-order truncated generalized difference of $\mathbf{U}$ and $\mathbf{V}$. Then the $\widetilde{UV}_I, 0 < |I| \le r$, can still be calculated by (15) once the initial values $\widetilde{UV}_I(0)$ are known. Similarly if $\{\mathbf{V}_1^j\}$ and $\{\mathbf{V}_2^j\}$ are two sequences of polynomial inputs of order $\le r$, then $\{\mathbf{V}_1^j, \mathbf{V}_2^j\}$ *GD(r)-converges* to 0 if there exist $(\mathbf{V}_1^j \overset{\text{g.d.(r)}}{-} \mathbf{V}_2^j)$ of $\mathbf{V}_1^j$ and $\mathbf{V}_2^j$ that converge to 0 uniformly as $j \to \infty$. Let $\{\mathbf{V}^j\}$ be a sequence of polynomial inputs of order $\le r$ and $\mathbf{V}$ be a polynomial input of order $\le r$. We say that $\mathbf{V}^j$ *GD(r)-converges* to $\mathbf{V}$ if $\{\mathbf{V}^j, \mathbf{V}\}$ GD(r)-converges to 0. If $\mathbf{V}$ is a polynomial input of order $\le r$, the set $STCON_r(\mathbf{V})$ contains those sequences $\{\mathbf{V}^j\}$ of polynomial inputs of order $\le r$ that there exist representatives $V^j = \sum_{0<|I|\le r} V_I^j X_I$ and $V = \sum_{0<|I|\le r} V_I X_I$ of $\mathbf{V}^j$ and $\mathbf{V}$, respectively, such that the V^j converge to V strongly. It is still true that a sequence $\{\mathbf{U}^j\}$ of ordinary inputs FT(r)-converges to a polynomial input $\mathbf{V}$ of order $\le r$ iff $\{\mathbf{U}^j, \mathbf{V}^j\}$ GD(r)-converge to zero for all elements $\{\mathbf{V}^j\}$ of $STCON_r(\mathbf{V})$. In particular $\{\mathbf{U}^j\}$ FT(r)-converges to $\mathbf{V}$ iff $\{\mathbf{U}^j\}$ GD(r)-converges to $\mathbf{V}$.

We conclude this section with a remark.

Remark 7. If we restrict ourselves to absolutely continuous polynomial inputs instead of considering B-continuous inputs, using the derivatives $\mathbf{v}$ of $\mathbf{V}$, everything can be reformulated in terms of $\mathbf{v}$. For example, we can define a polynomial input to be an $\hat{A}_0(\mathbf{X})$-valued integrable function $\mathbf{v} = \sum_{|I|>0} v_I X_I$ on $[0,T]$. An ordinary input $u = (u_1, \ldots, u_m) \in L^1([0,T], \mathbb{R}^m)$ can be identified with a polynomial input $\mathbf{u} = u_1X_1 + \cdots + u_mX_m$. In this case all the differential equations such as (6) and (13) become ordinary equations. We need not consider equivalence classes any more. Almost every concept can be defined in terms of $\mathbf{u}$ and $\mathbf{v}$. For example, the formal trajectory $S_{\mathbf{v}}$ determined by a polynomial input $\mathbf{v}$ is the solution of the following initial value problem:

$$\dot{S} = S\mathbf{v}, \quad S(t) \in \hat{A}(\mathbf{X}), \tag{25}$$

$$S(0) = 1. \tag{26}$$

Let $\mathbf{v} = \sum_{|I|>0} v_I X_I$ be a polynomial input and $\{\mathbf{v}^j = \sum_{|I|>0} v_I^j X_I\}$ be a sequence of polynomial inputs. Then $\{\mathbf{v}^j\}$ converges to $\mathbf{v}$ strongly if the indefinite integrals $\int_0^t v_I^j(s)ds$ converge to $\int_0^t v_I(s)ds$ uniformly and the L^1 norms of the v_I^j are uniformly bounded in j for each I. The $STCON(\mathbf{v})$ is the set that contains all the sequences $\{\mathbf{v}^j\}$ of polynomial inputs that converge to $\mathbf{v}$ strongly. If $\mathbf{v}_1$ and $\mathbf{v}_2$ are two polynomial inputs. A generalized difference of $\mathbf{v}_1$ and $\mathbf{v}_2$ is an absolutely continuous $\hat{A}_0(\mathbf{X})$-valued function W that satisfies

$$\dot{W} = -\mathbf{v}_1 W + \mathbf{v}_2 - \mathbf{v}_1.$$

Again if $\mathbf{u} = u_1X_1 + \cdots + u_mX_m$ is an ordinary input and $\mathbf{v} = \sum_{|I|>0} v_I X_I$ is a polynomial input, if we let $(\mathbf{u} \overset{\text{g.d.}}{-} \mathbf{v}) = \sum_{|I|>0} \widetilde{UV}_I X_I$ be a generalized difference of $\mathbf{u}$ and $\mathbf{v}$, then the functions $U_k(t) = \int_0^t u_k(s)ds, V_I(t) = \int_0^t v_I(s)ds$, and $\widetilde{UV}_I(t)$ are related by (15). The coefficients $\widetilde{UV}_I$ in this case are absolutely continuous functions. Similarly we can consider polynomial inputs of finite order. If r is a positive integer,

we can define rth-order truncated formal trajectories, rth-order truncated generalized differences, the set of $STCON_r(\mathbf{v})$, etc.

3. The convergence theorems. In this section we study the limiting behavior of trajectories of systems

$$dx = \sum_{k=1}^{m} f_k(x) dU_k \tag{27}$$

generated by a sequence $\{U^j = (U_1^j, \ldots, U_m^j)\} \subseteq BVC([0,T], \mathbb{R}^m)$ of inputs. Let U be a function in $BVC([0,T], \mathbb{R}^m)$ and $\bar{x}$ be a point in $\mathbb{R}^n$. First we review some existence and uniqueness results of solutions of the following initial value problem:

$$dx = \sum_{k=1}^{m} f_k(x)\, dU_k, \tag{28}$$

$$x(0) = \bar{x}, \tag{29}$$

where $f_k, k = 1, \ldots, m$, are continuous vector fields on $\mathbb{R}^n$. If the functions U_k in (28) are absolutely continuous, letting $u \in L^1([0,T], \mathbb{R}^m)$ be the derivative of U, then (28) and (29) becomes an ordinary initial value problem

$$\dot{x} = \sum_{k=1}^{m} u_k(t) f_k(x), \tag{30}$$

$$x(0) = \bar{x}. \tag{31}$$

For this initial value problem, the well-known Carathéodory theorem on existence and uniqueness of solutions says that

(1) if the vector fields f_k are continuous on $\mathbb{R}^n$, u_k are in $L^1[0,T]$, then the initial value problem (30), (31) has solutions;[2]
(2) if, moreover, the f_k are locally Lipschitz continuous, then uniqueness of solutions is guaranteed.

Let f_k, $k = 1, \ldots, m$, be continuous vector fields on $\mathbb{R}^n$. Let U be a function in $BVC([0,T], \mathbb{R}^m)$. By a *solution* of (28) and (29) we mean a continuous function x, defined on some subinterval $J \subseteq [0,T]$ that contains 0 and has positive length, that satisfies

$$x(t) = \bar{x} + \sum_{k=1}^{m} \int_0^t f_k(x(s))\, dU_k(s).$$

(Here the integral is the usual Riemann–Stieltjes integral.) The interval J is called the *domain* of the solution x. Clearly if x is a solution with domain J, then x is B-continuous on J. (We recall that a function x defined on an interval J (not necessarily closed) is of bounded variation if for any $a < b \in J$, x is of bounded variation on $[a,b]$ and $\sup_{a<b\in J}\{TV[x;a,b]\} < \infty$. A function x is *B-continuous* on an interval J if it is both continuous and of bounded variation on J.) Every solution x of (28) and (29) can be extended to a *maximal solution.*[3] We say that the initial value problem (28)

[2]Recall that a solution of (30) and (31) is an absolutely continuous function x on a subinterval $J \subseteq [0,T]$ that contains 0 and has positive length such that $x(0) = \bar{x}$ and (30) holds almost everywhere on J.

[3]A solution x of (28) and (29) with domain J is called a maximal solution if whenever $\hat{x}$ is another solution with domain $\hat{J}$, then $J \subseteq \hat{J}$, $x = \hat{x}$ on J imply that $J = \hat{J}$.

and (29) has a *unique* solution if it has one and only one maximal solution. For the initial value problem (28), (29), the Carathéodory kind of conditions on existence and uniqueness of solutions as 1 and 2 above for (30) and (31) is still true. More precisely we have the following proposition.

PROPOSITION 2. *Let U be a function in $BVC([0,T],\mathbb{R}^m)$ and $\bar{x}$ be a point in $\mathbb{R}^n$. Then the initial value problem* (28), (29) *has solutions if the vector fields f_k are continuous on $\mathbb{R}^n$. It has a unique solution if the f_k are locally Lipschitz continuous.*

The proof of this proposition is similar to the usual case when all the U_k are absolutely continuous.

As we said in the introduction, an extended input $\mathbf{V}$ of finite order can be thought of as an object that contains "slots" (the indeterminates X_k) where vector fields can be plugged in, giving rise to a differential equation. (The only requirement for this is that the vector fields should be smooth enough such that the various brackets in $\mathbf{V}$ exist.) For example, the extended input $\mathbf{V} = V_1(t)X_1 + V_2(t)X_2 + V_3(t)[X_1, X_2]$ gives rise, for each choice of C^1 vector fields $f_1, \ldots, f_m$ on $\mathbb{R}^n$, to the differential equation

$$dx = f_1(x)dV_1(t) + f_2(x)dV_2(t) + [f_1, f_2](x)dV_3(t).$$

More precisely, let $\mathbf{f} = (f_1, \ldots, f_m)$ be an m-tuple of vector fields on $\mathbb{R}^n$. We say that $\mathbf{f}$ is of *class* C^κ if all the f_ℓ are of class C^κ. Let $\mathbf{V} = \sum_{0<|I|\le r} V_I[X_I]$ be an extended input of order r on $[0,T]$. Let $\mathbf{f} = (f_1, \ldots, f_m)$ be a system of vector fields of class C^{r-1} on $\mathbb{R}^n$ and $\bar{x}$ be a point in $\mathbb{R}^n$. Then we can consider the following initial value problem:

$$dx = \sum_{0<|I|\le r} [f_I](x)dV_I(t), \tag{32}$$

$$x(0) = \bar{x}. \tag{33}$$

(Here we write

$$[f_I] \stackrel{\text{def}}{=} [f_{i_1}, [f_{i_2}, [\cdots, [f_{i_{k-1}}, f_{i_k}]\cdots]$$

for $I = (i_1, \ldots, i_k)$.) We will call (32), (33) the initial value problem determined by the triple $(\mathbf{f}, \mathbf{V}, \bar{x})$ and use $IVP(\mathbf{f}, \mathbf{V}, \bar{x})$ to denote it. We say that an $IVP(\mathbf{f}, \mathbf{V}, \bar{x})$ has the *uniqueness property* (UP for short), if it has a unique solution.

DEFINITION 9. *Let ξ be an $\mathbb{R}^n$-valued function whose domain is a subinterval I of $\mathbb{R}$. Let $\{\xi^j\}$ be a sequence of $\mathbb{R}^n$-valued functions. Let I^j be the domain of ξ^j, and assume that each I^j is a subinterval of $\mathbb{R}$. We say that $\{\xi^j\}$ converges to ξ on compact sets if for every compact subset $\tilde{I} \subseteq I$ there exists a J such that $\tilde{I} \subseteq I^j$ for $j \ge J$ and $\{\xi^j\}$ converges to ξ uniformly on $\tilde{I}$.*

DEFINITION 10. *Let $\mathbf{V}$ be an extended input of order $\le r$. A sequence $\{\mathbf{U}^j\}$ of ordinary inputs EI(r)-converges to $\mathbf{V}$ if for every integer $n > 0$, every point $\bar{x} \in \mathbb{R}^n$, every sequence $\{\bar{x}^j\} \subseteq \mathbb{R}^n$ that converges to $\bar{x}$, and every $\mathbf{f} = (f_1, \ldots, f_m)$ of class C^{r-1} on $\mathbb{R}^n$, the following holds. For each j let x^j be a maximal solution of the $IVP(\mathbf{f}, \mathbf{U}^j, \bar{x}^j)$. For every subsequence $\{x^{j(k)}\}$ of $\{x^j\}$, there exist a maximal solution x of the $IVP(\mathbf{f}, \mathbf{V}, \bar{x})$ and a further subsequence $\{x^{j(k(\ell))}\}$ of $\{x^{j(k)}\}$ such that the $x^{j(k(\ell))}$ converge to x on compact sets.*

The following proposition gives a stronger convergence result for the case when an $IVP(\mathbf{f}, \mathbf{V}, \bar{x})$ has UP.

PROPOSITION 3. *Assume that a sequence $\{\mathbf{U}^j\}$ of ordinary inputs EI(r)-converges to an extended input $\mathbf{V}$ of order $\le r$. Let $\bar{x} \in \mathbb{R}^n$ be a point and $\mathbf{f}$ be a system of*

class C^{r-1} on $\mathbb{R}^n$ such that the IVP$(\mathbf{f}, \mathbf{V}, \bar{x})$ has the UP. Let x be the unique maximal solution of the IVP$(\mathbf{f}, \mathbf{V}, \bar{x})$. Let $\{\bar{x}^j\}$ be a sequence of points in $\mathbb{R}^n$ that converges to $\bar{x}$. Let x^j be a maximal solution of the IVP$(\mathbf{f}, \mathbf{U}^j, \bar{x}^j)$. Then the x^j converge to x on compact sets.

The proof of the proposition follows directly from the definition of EI(r)-convergence.

With these preliminaries, we are ready to state the main convergence theorem of this section.

THEOREM 1. *Let $\{\mathbf{U}^j = U_1^j X_1 + \cdots + U_m^j X_m\}$ be a sequence of ordinary inputs. Let r be a positive integer, and $\mathbf{V} = \sum_{0<|I|\le r} V_I X_I$ be a polynomial input of order $\le r$. Let $\{\mathbf{V}^j\}$ be a sequence of polynomial inputs of order $\le r$ that converges to $\mathbf{V}$ strongly. Assume that there exist rth-order truncated generalized differences $(\mathbf{U}^j \overset{\text{g.d.(r)}}{-} \mathbf{V}^j) = \sum_{0<|I|\le r} \widetilde{UV}_I^j X_I$ of $\mathbf{U}^j$ and $\mathbf{V}^j$ such that*

(c1(r)) *the $(\mathbf{U}^j \overset{\text{g.d.(r)}}{-} \mathbf{V}^j)$ converge to 0 uniformly as $j \to \infty$;*

(c2(r)) *the total variations $TV[\widetilde{UV}_I^j; 0, T]$ of the $\widetilde{UV}_I^j$ are uniformly bounded for $|I| = r$.*

Then

(C1) $\mathbf{V}$ *is an extended input of order $\le r$, i.e.,*

$$\mathbf{V} = \sum_{0<|I|\le r} \frac{V_I}{|I|}[X_I];$$

(C2) *the $\mathbf{U}^j$ EI(r)-converge to $\mathbf{V}$.*

Remark 8. Condition (c1(r)) says that $\{\mathbf{U}^j, \mathbf{V}^j\}$ GD(r)-converges to 0, which is equivalent to the FT(r)-convergence of $\{\mathbf{U}^j\}$ to $\mathbf{V}$, i.e., the convergence of the trajectories of $\mathbf{U}^j$ to that of $\mathbf{V}$ for one particular initial value problem $\mathbf{U}(r)$, namely, the rth-order truncated formal equation (22) with initial condition (23). Therefore this initial value problem plays the "universal" role for the rth-order convergence. Theorem 1 simply says that, if the trajectories of $\mathbf{U}^j$ converge to that of $\mathbf{V}$ for the initial value problem $\mathbf{U}(r)$, then they converge for every problem with sufficiently smooth vector fields f_k, provided that a boundedness condition (c2(r)) holds to prevent the occurrence of brackets of higher order.

Proof of Theorem 1. From Proposition 1 we know that, under condition (c1(r)), $\mathbf{V}$ is an extended input of order $\le r$. We show (C2). Let $n > 0$ be an integer. Let $\bar{x}$ be a point in $\mathbb{R}^n$ and $\{\bar{x}^j\} \subseteq \mathbb{R}^n$ be a sequence of points that converges to $\bar{x}$ as $j \to \infty$. Let $\mathbf{f} = (f_1, \ldots, f_m)$ be a system of vector fields of class C^{r-1} on $\mathbb{R}^n$. For each j, let x^j be a maximal solution of the IVP$(\mathbf{f}, \mathbf{U}^j, \bar{x}^j)$ with domain I^j.

Let $\{K^\ell\}_{\ell=1}^\infty$ be a sequence of compact subsets of $\mathbb{R}^n$ such that (1) $\bar{x} \in \mathrm{Int}(K^1)$, (2) $K^j \subseteq \mathrm{Int}(K^{j+1})$, and (3) $\cup_j K^j = \mathbb{R}^n$. (Here $\mathrm{Int}(K)$ denotes the interior of K.) Since the $\bar{x}^j \to \bar{x}$, we may assume that all the $\bar{x}^j$ are contained in the interior of K^1. Now for each integer $\ell > 0$, let $a_\ell^j = \sup\{a : x^j(t) \in K^\ell \text{ for } t \in [0, a]\}$. Then for each j, ℓ, either $a_\ell^j = T$ or $x^j(a_\ell^j) \in \partial K^\ell$, the boundary of K^ℓ. Let x_ℓ^j denote the restriction $x^j|_{[0,a_\ell^j]}$ of x^j to $[0, a_\ell^j]$. Our next step is to show that for each $\ell > 0$, the sequence $\{x_\ell^j\}_{j=1}^\infty$ of functions is equicontinuous. Let's fix an $\ell > 0$. Let θ be a smooth real-valued function on $\mathbb{R}^n$ with compact support such that $\theta(x) = 1$ on K^ℓ. Let $\tilde{\mathbf{f}} = (\theta f_1, \ldots, \theta f_m)$. Then x_ℓ^j is a solution of the IVP$(\tilde{\mathbf{f}}, \mathbf{U}^j, \bar{x}^j)$. Let $\tilde{x}^j$ be a maximal solution of the IVP$(\tilde{\mathbf{f}}, \mathbf{U}^j, \bar{x}^j)$ that extends x_ℓ^j. Then $\tilde{x}^j$ is defined on

$[0,T]$. If we can show that $\{\tilde{x}^j\}_{j=1}^{\infty}$ is equicontinuous, then the $\{x_\ell^j\}_{j=1}^{\infty}$ would be also equicontinuous. So in order to show that the $\{x_\ell^j\}_{j=1}^{\infty}$ is equicontinuous, we may without loss of generality assume that the f_i are compactly supported and the x^j are defined on $[0,T]$, and show that $\{x^j\}$ is equicontinuous.

By definition, each x^j satisfies

$$dx = \sum_{k=1}^{m} f_k(x)\, dU_k^j, \tag{34}$$

$$x(0) = \bar{x}^j. \tag{35}$$

Let $V^j = \sum_{0<|I|\le r} V_I^j X_I$ be representatives of $\mathbf{V}^j$ that converge to $V = \sum_{0<|I|\le r} V_I X_I$ uniformly and the $TV[V_I^j;0,T]$ are uniformly bounded. Then the functions U_ℓ^j, V_I^j and $\widetilde{UV}_I^j$ are related by (18). Let φ be a smooth function from $\mathbb{R}^n$ to $\mathbb{R}$. From (34) and (35), by repeated integration by parts (cf. the proof of Proposition 1), we have

$$\varphi(x^j(t)) = \varphi(\bar{x}^j) + \sum_{0<|I|\le r} \int_0^t (f_I\varphi)(x^j(s))\, dV_I^j(s) - \sum_{|I|=r} \int_0^t (f_I\varphi)(x^j(s))\, d\widetilde{UV}_I^j(s)$$

$$- \sum_{0<|I|<r} \Big\{ \widetilde{UV}_I^j(t)\,(f_I\varphi)(x^j(t)) - \widetilde{UV}_I^j(0)(f_I\varphi)(\bar{x}^j) \Big\}, \tag{36}$$

where $(f_I\varphi)$ denotes the function $(f_{i_1}\cdots f_{i_k}\varphi)$ for $I=(i_1,\dots,i_k)$. (Each f_ℓ can be viewed as a differential operator on smooth real-valued functions on $\mathbb{R}^n$, so here $(f_\ell\varphi)$ is the derivative of φ in the direction of f_ℓ.) By our assumption we know that the $\widetilde{UV}_I^j$ converge to 0 uniformly for all $0<|I|\le r$ as j goes to ∞. Therefore we have

$$\varphi(x^j(t)) = \varphi(\bar{x}^j) + \sum_{0<|I|\le r} \int_0^t (f_I\varphi)(x^j(s))\, dV_I^j(s)$$

$$- \sum_{|I|=r} \int_0^t (f_I\varphi)(x^j(s))\, d\widetilde{UV}_I^j(s) \; + o(1), \tag{37}$$

where $o(1)$ denotes the term $-\sum_{0<|I|<r}\{\widetilde{UV}_I^j(t)(f_I\varphi)(x^j(t)) - \widetilde{UV}_I^j(0)(f_I\varphi)(\bar{x}^j)\}$, which converges to 0 uniformly. Equality (37) clearly holds for vector functions too. So we can apply it to the identity map from $\mathbb{R}^n$ to $\mathbb{R}^n$. Now let us still use φ to denote the identity map from $\mathbb{R}^n$ to $\mathbb{R}^n$. We get

$$x^j(t) = \bar{x}^j + \sum_{0<|I|\le r} \int_0^t (f_I\varphi)(x^j(s))\, dV_I^j(s) - \sum_{|I|=r} \int_0^t (f_I\varphi)(x^j(s))\, d\widetilde{UV}_I^j(s) + o(1). \tag{38}$$

To show that $\{x^j\}$ is equicontinuous, we need a lemma.

LEMMA 2. *Let $g_\alpha : \mathbb{R}^n \to \mathbb{R}^n$ be continuous and bounded functions, where $\alpha \in A$ and A is some finite index set. Let $\{V_\alpha^j\}$ be sequences of functions in $BVC[0,T]$ with the $TV[V_\alpha^j;0,T]$ being uniformly bounded in j for all $\alpha \in A$. Assume that $\{V_\alpha^j\}$ converges to $H_\alpha \in BVC[0,T]$ uniformly for each $\alpha \in A$. Let $\{\xi^j\} : [0,T] \to \mathbb{R}^n$ be*

a sequence of vector-valued functions which is equicontinuous and uniformly bounded. Let x^j be continuous functions on $[0,T]$ that satisfy

$$x^j(t) = \sum_{\alpha\in A} \int_0^t g_\alpha(x^j(s))\, dV_\alpha^j(s) + \xi^j(t).$$

Then $\{x^j\}$ is uniformly bounded and equicontinuous.

Proof. The sequence $\{x^j\}$ is clearly uniformly bounded. Without loss of generality we may assume that the g_α are compactly supported in $\mathbb{R}^n$. (Otherwise, let K be a compact set in $\mathbb{R}^n$ that contains all the x^j and ξ^j in its interior. Then multiply each g_α by a smooth compactly supported function on $\mathbb{R}^n$ which is equal to 1 on K.) In order to show that $\{x^j\}$ is equicontinuous, we need only show that every subsequence of $\{x^j\}$ is equicontinuous. Therefore we may further assume that $\{\xi^j\}$ converges to some continuous function ξ uniformly.

Let $K = \sup_j\{\sum_{\alpha\in A} TV[V_\alpha^j;0,T]\}$. For any given $\varepsilon > 0$, since the g_α are uniformly continuous on $\mathbb{R}^n$, there exists a $\delta > 0$ such that, for all $\alpha \in A$, $\|g_\alpha(x_2) - g_\alpha(x_1)\| < \frac{\varepsilon}{4K}$ if $\|x_2 - x_1\| < \delta$. We may assume $\delta < \varepsilon$. Choose a smooth vector-valued function η on $[0,T]$ such that $\|\eta(t) - \xi(t)\| < \delta/8$ for all $t \in [0,T]$. Let

$$y^j(t) = \sum_{\alpha\in A} \int_0^t g_\alpha(x^j(s))\, dV_\alpha^j(s) + \eta(t).$$

Then

$$\|y^j(t) - x^j(t)\| \le \|\xi^j(t) - \xi(t)\| + \frac{\delta}{8}.$$

Since the ξ^j converge to ξ uniformly, take J large enough such that $\|\xi^j - \xi\| < \frac{\delta}{8}$ if $j \ge J$. So, when $j \ge J$, $\|x^j(t) - y^j(t)\| < \frac{\delta}{4} < \frac{\varepsilon}{4}$. In order to show that $\{x^j\}$ is equicontinuous, we need only show that the sequence $\{y^j\}$ is equicontinuous. Let

$$\zeta^j(t) = \sum_{\alpha\in A} \int_0^t g_\alpha(y^j(s))\, dV_\alpha^j(s) + \eta(t).$$

Then

$$\|\zeta^j(t) - y^j(t)\| \le \sum_{\alpha\in A} \Big\| \int_0^t (g_\alpha(y^j(s)) - g_\alpha(x^j(s)))dV_\alpha^j(s)\Big\| < \frac{\varepsilon}{4}$$

for $j \ge J$. Therefore we need only to show that $\{\zeta^j\}$ is equicontinuous.

For each $\alpha \in A$, let $G_\alpha : \mathbb{R}^n \to \mathbb{R}^n$, which is of class C^1 and has compact support, be such that

$$\|G_\alpha - g_\alpha\| \stackrel{\text{def}}{=} \sup_{x\in\mathbb{R}^n} \|G_\alpha(x) - g_\alpha(x)\| < \frac{\varepsilon}{8K}.$$

Then

$$\zeta^j(t) = \sum_{\alpha\in A} \int_0^t G_\alpha(y^j(s))dV_\alpha^j(s) + \sum_{\alpha\in A} \int_0^t (g_\alpha(y^j(s)) - G_\alpha(y^j(s)))dV_\alpha^j(s) + \eta(t).$$

The second summation in the right-hand side above is clearly less than $\frac{\varepsilon}{8}$, so

$$\sum_{\alpha\in A} \Big\| \int_{t_1}^{t_2} (g_\alpha(y^j(s)) - G_\alpha(y^j(s)))dV_\alpha^j(s)\Big\| < \frac{\varepsilon}{4}$$

for any $t_1, t_2 \in [0,T]$. Now η is a fixed continuous function. So, in order to show that $\{\zeta^j\}$ is equicontinuous, all we need is to show that the sequence $\{\int_0^t G_\alpha(y^j(s))dV_\alpha^j(s)\}$ is equicontinuous for each $\alpha \in A$. We can write

$$\int_0^t G_\alpha(y^j(s))dV_\alpha^j(s) = \int_0^t G_\alpha(y^j(s))d(V_\alpha^j(s) - V_\alpha(s)) + \int_0^t G_\alpha(y^j(s))dV_\alpha(s).$$

Since $\{G_\alpha(y^j(t))\}$ is uniformly bounded and V_α is a fixed function in $BVC[0,T]$, the sequence $\{\int_0^t G_\alpha(y^j(s))dV_\alpha(s)\}$ is equicontinuous. By integration by parts we can rewrite the first integral $\int_0^t G_\alpha(y^j(s))d(V_\alpha^j(s) - V_\alpha(s))$ as

$$\begin{aligned}\int_0^t G_\alpha(y^j(s))\, d\,(V_\alpha^j(s) - V_\alpha(s)) &= G_\alpha(y^j(t))(V_\alpha^j(t) - V_\alpha(t)) - G_\alpha(y^j(0))(V_\alpha^j(0) - V_\alpha(0)) \\ &\quad - \sum_{\beta\in A}\int_0^t (V_\alpha^j(s) - V_\alpha(s))DG_\alpha(y^j(s))g_\beta(x^j(s))dV_\beta^j(s) \\ &\quad - \int_0^t (V_\alpha^j(s) - V_\alpha(s))DG_\alpha(y^j(s))\dot\eta(s)ds.\end{aligned}$$

(Here DG_α denotes the Jacobian matrix of G_α.) Since the $V_\alpha^j - V_\alpha$ converge to 0 uniformly, the $\|g_\beta\|_{\sup}$, $\|G_\alpha\|_{\sup}$, $\|DG_\alpha\|_{\sup}$, and $\|\dot\eta\|_{\sup}$ are fixed constants and the total variations $TV[V_\beta^j; 0, T]$ are uniformly bounded, we see that all the four terms above go to zero uniformly as $j \to \infty$. Therefore $\{\int_0^t G_\alpha(y^j(s))d(V_\alpha^j(s) - V_\alpha(s))\} \to 0$ uniformly, which implies that $\{\int_0^t G_\alpha(y^j(s))dV_\alpha^j(s)\}$ is equicontinuous. We then conclude that the sequence $\{\zeta^j\}$ is equicontinuous. This completes the proof of the lemma. □

Now we go back to the proof of Theorem 1. Lemma 2 implies that for each ℓ, the $\{x_\ell^j\}_{j=1}^\infty$ is equicontinuous.

Now let $\ell = 1$. Since the sequence $\{x_1^j\}_{j=1}^\infty$ is equicontinuous, there exists a subsequence $\{x_1^{j_1(k)}\}$ of $\{x_1^j\}_{j=1}^\infty$ that converges to a function x_1^∞ on some interval $[0, a_1^\infty]$ uniformly. (We say that a sequence $\{\xi^j\}_{j=1}^\infty$ of $\mathbb{R}^n$-valued functions with domains $[a^j, b^j]$ converges to a function ξ with domain $[a,b]$ uniformly if $\{a^j\}_{j=1}^\infty$ converges to a, $\{b^j\}_{j=1}^\infty$ converges to b, and, for any $t^j \in [a^j, b^j]$ such that the t^j converge to t, $\xi^j(t^j) \to \xi(t)$.) So $\{x^{j_1(k)}\}$ is a subsequence of $\{x^j\}$. Now let $\ell = 2$. Since the $\{x_2^{j_1(k)}\}$ is also equicontinuous, there exists a further subsequence $\{x^{j_2(k)}\}$ of $\{x^{j_1(k)}\}$ such that the $x_2^{j_2(k)}$ converge to a function x_2^∞ with domain $[0, a_2^\infty]$ uniformly. Continuing this way we can construct a sequence $\{x_\ell^\infty\}_{\ell=1}^\infty$ of functions and a collection $\{x^{j_\ell(k)}\}, \ell = 1, 2, \ldots$, of subsequences of $\{x^j\}$ such that

(1) the domain of x_ℓ^∞ is $[0, a_\ell^\infty]$, $a_\ell^\infty \le a_{\ell+1}^\infty$, and $x_{\ell+1}^\infty|_{[0,a_\ell^\infty]} = x_\ell^\infty$;
(2) each $\{x^{j_\ell(k)}\}$ is a subsequence of $\{x^{j_{\ell-1}(k)}\}$, and $\{x^{j_1(k)}\}$ is a subsequence of $\{x^j\}$;
(3) for each fixed ℓ, the $x_\ell^{j_\ell(k)}$ converge to x_ℓ^∞ uniformly.

Let $I = \cup_\ell [0, a_\ell^\infty]$. Then there is a well-defined function x^∞ on I given by $x^\infty(t) = x_\ell^\infty(t)$ if $t \in [0, a_\ell^\infty]$. Moreover, for each fixed ℓ, the sequence $\{x_\ell^{j_\ell(k)}\}$ converges to $x^\infty|_{[0,a_\ell^\infty]}$ uniformly. A standard diagonal argument implies that there exists a subsequence $\{x^{j(k)}\}$ of $\{x^j\}$ such that $\{x^{j(k)}\}$ is a subsequence of $\{x^{j_\ell(k)}\}$ for every ℓ. This implies that the $x^{j(k)}$ converge to x^∞ on compact sets. Now we show that x^∞ on I is a solution of the $IVP(\mathbf{f}, \mathbf{V}, \bar{x})$.

For any $t \in I$, then there exists a J large enough such that t is in the domain of $x^{j(k)}$ if $j(k) \geq J$. From (38) we have

$$\begin{aligned} x^{j(k)}(t) = \bar{x}^{j(k)} &+ \sum_{0<|I|\leq r} \int_0^t (f_I\varphi)(x^{j(k)}(s))\, dV_I^{j(k)}(s) \\ &- \sum_{|I|=r} \int_0^t (f_I\varphi)(x^{j(k)})(s))\, d\widetilde{UV}_I^{j(k)}(s) + o(1). \end{aligned} \tag{39}$$

From Lemma 1, by letting $j(k) \to \infty$ in (39), we get

$$x^\infty(t) = \bar{x} + \sum_{0<|I|\leq r} \int_0^t (f_I\varphi)(x^\infty(s))\, dV_I(s);$$

i.e., x^∞ satisfies

$$\begin{aligned} dx &= \sum_{0<|I|\leq r} (f_I\varphi)(x)\, dV_I, \\ x(0) &= \bar{x}. \end{aligned}$$

Now we need to establish that for any continuous function $\xi : [0,T] \to \mathbb{R}^n$,

$$\sum_{0<|I|\leq r} \int_0^t (f_I\varphi)(\xi(s))\, dV_I(s) = \sum_{0<|I|\leq r} \int_0^t \frac{1}{|I|}[f_I](\xi(s))\, dV_I(s). \tag{40}$$

From (C1) we know that $\mathbf{V} = \sum_{0<|I|\leq r} V_I\, X_I$ is an extended input. Therefore

$$\sum_{0<|I|\leq r} V_I\, X_I = \sum_{0<|I|\leq r} \frac{1}{|I|} V_I\, [X_I]. \tag{41}$$

Let $C^\kappa(\mathbb{R}^n)$, $\kappa \in \{0,1,2,\dots,\} \cup \{\infty\}$, be the set of real-valued C^κ functions on $\mathbb{R}^n$. Now each member f_k of $\mathbf{f} = (f_1, \dots, f_m)$ can be viewed as a differential operator from $C^\infty(\mathbb{R}^n)$ to $C^{r-1}(\mathbb{R}^n)$. For each $I = (i_1, \dots, i_k)$, $k \leq r$, the

$$f_I \stackrel{\text{def}}{=} f_{i_1} f_{i_2} \cdots f_{i_k}$$

can be viewed as a high-order differential operator that maps each $\theta \in C^\infty(\mathbb{R}^n)$ to the function $(f_I\theta) \in C^{r-k}(\mathbb{R}^n)$. Let $A_0^r(\mathbf{f})$ be the vector space of differential operators that map $C^\infty(\mathbb{R}^n)$ to $C^0(\mathbb{R}^n)$ spanned by $\{f_I, 0 < |I| \leq r\}$ over $\mathbb{R}$, i.e., $A_0^r(\mathbf{f}) = \{\sum_{0<|I|\leq r} a_I f_I : a_I \in \mathbb{R}\}$. Let $L^r(\mathbf{f})$ be the vector space of vector fields on $\mathbb{R}^n$ spanned by $\{[f_I], 0 < |I| \leq r\}$ over $\mathbb{R}$, so $L^r(\mathbf{f}) = \{\sum_{0<|I|\leq r} a_I\, [f_I] : a_I \in \mathbb{R}\}$. Then each element of $L^r(\mathbf{f})$ also gives rise to a differential operator from $C^\infty(\mathbb{R}^n)$ to $C^0(\mathbb{R}^n)$ and $L^r(\mathbf{f})$ can be viewed as a subset of $A_0^r(\mathbf{f})$. There is a well-defined *evaluation* map

$$\mathrm{Ev}(\mathbf{f}) : A_0^r(\mathbf{X}) \to A_0^r(\mathbf{f})$$

obtained by "plugging in the f_k for the X_k" so that

$$\mathrm{Ev}(\mathbf{f})(\textstyle\sum_I a_I X_I) = \sum_I a_I f_I.$$

The evaluation map $\mathrm{Ev}(\mathbf{f})$ can be restricted to $L^r(\mathbf{X})$. Let us still denote by $\mathrm{Ev}(\mathbf{f})$ the restriction of $\mathrm{Ev}(\mathbf{f})$ to $L^r(\mathbf{X})$. It is obvious that $\mathrm{Ev}(\mathbf{f})$ maps $L^r(\mathbf{X})$ onto $L^r(\mathbf{f})$. Letting $\mathrm{Ev}(\mathbf{f})$ act on (41) we get

$$\sum_{0<|I|\le r} f_I\, V_I(t) = \sum_{0<|I|\le r} \frac{1}{|I|}[f_I]\, V_I(t),$$

i.e., for any function $\theta \in C^\infty(\mathbb{R}^n)$, $x \in \mathbb{R}^n$,

$$\sum_{0<|I|\le r} (f_I\theta)(x)\, V_I(t) = \sum_{0<|I|\le r} \frac{1}{|I|}([f_I]\theta)(x)\, V_I(t). \tag{42}$$

Equality (42) also holds for vector functions too. So we can apply it to the identity map φ from $\mathbb{R}^n$ to $\mathbb{R}^n$. It is clear that $[f_I](x) = ([f_I]\varphi)(x)$. We then get

$$\sum_{0<|I|\le r} (f_I\varphi)(x)\, V_I(t) = \sum_{0<|I|\le r} \frac{1}{|I|}[f_I](x)\, V_I(t) \tag{43}$$

for any $x \in \mathbb{R}^n$ and $t \in [0,T]$. Take a sequence of partitions $\Gamma_\rho = \{0 = t_0 < t_1 < \cdots < t_\rho = t\}$ of $[0,t]$ with $|\Gamma_\rho| = \max_i\{t_{i+1} - t_i\} \to 0$ as $\rho \to \infty$. It follows by the definition of Riemann–Stieltjes integrals that

$$\begin{aligned}
\sum_{0<|I|\le r} \int_0^t (f_I\varphi)(\xi(s))dV_I(s) &= \sum_{0<|I|\le r} \lim_{\rho\to\infty} \sum_{i=0}^{\rho-1} (f_I\varphi)(\xi(t_i))(V_I(t_{i+1}) - V_I(t_i)) \\
&= \sum_{0<|I|\le r} \lim_{\rho\to\infty} \sum_{i=0}^{\rho-1} \frac{[f_I](\xi(t_i))}{|I|}(V_I(t_{i+1}) - V_I(t_i)) \\
&= \sum_{0<|I|\le r} \int_0^t \frac{[f_I](\xi(s))}{|I|} dV_I(s),
\end{aligned}$$

which establishes (40). Therefore x^∞ satisfies

$$dx = \sum_{0<|I|\le r} \frac{1}{|I|}[f_I](x)\, dV_I, \tag{44}$$

$$x(0) = \bar{x}; \tag{45}$$

i.e., x^∞ is a solution of the $IVP(\mathbf{f}, \mathbf{V}, \bar{x})$.

It remains to show that x^∞ is a maximal solution. Assume that there was an extension $\tilde{x}^\infty : \tilde{I} \to \mathbb{R}^n$ of x^∞ to a strictly large interval $\tilde{I} \subseteq [0,T]$. Let τ be a point in $\tilde{I}$ that is not contained in I. Then $\tau > a_\ell^\infty$ for all ℓ. The set $\{\tilde{x}(t) : t \in [0,\tau]\}$ is a compact subset of $\mathbb{R}^n$, so it is contained in some K^i. This implies that $x^\infty(a_\ell^\infty) \in K^i$ for all ℓ. Now for every ℓ, we know that $\{x^{j(k)}\}$ is a subsequence of $\{x^{j_\ell(k)}\}$. So the $a_\ell^{j(k)}$ converges to a_ℓ^∞ as $j(k) \to \infty$ for every ℓ. In particular $a_{i+1}^{j(k)} < \tau \le T$ for $j(k)$ large enough. By the definition of the a_ℓ^j, this implies that $x^{j(k)}(a_{i+1}^{j(k)}) \in \partial K^{i+1}$ for $j(k)$ large enough. On the other hand, the $x^{j(k)}(a_{i+1}^{j(k)})$ converge to $x^\infty(a_{i+1}^\infty) \in K^i$, so we have reached a contradiction since K^i is contained in the interior of K^{i+1}. The contradiction shows that x^∞ is a maximal solution of the $IVP(\mathbf{f}, \mathbf{V}, \bar{x})$ and the proof of Theorem 1 is therefore complete. □

Remark 9. In applications, the typical situation is that we just have the sequence $\{\mathbf{U}^j\}$. We do not know a priori if it is convergent or what its limit $\mathbf{V}$ is even if it converges. We have to find an r, sequences $\{\mathbf{V}^j\}$ and $(\mathbf{U}^j \overset{\text{g.d.(r)}}{-} \mathbf{V}^j)$ so that the conditions of Theorem 1 are satisfied. If we can find an integer r and B-continuous functions V_I^j for $0 < |I| \le r$ such that

(c1′(r)) the V_I^j converge to B-continuous functions V_I uniformly for all $0 < |I| \le r$,

(c2′(r)) the $\widetilde{UV}_I^j$ determined recursively by

$$\widetilde{UV}_i^j(t) = V_i^j(t) - U_i^j(t), \tag{46}$$

$$\widetilde{UV}_{i_1,\dots,i_k}^j(t) = V_{i_1,\dots,i_k}^j(t) - (U_{i_1}^j \overset{\leftarrow}{*} \widetilde{UV}_{i_2,\dots,i_k}^j)(t) \tag{47}$$

converge to 0 uniformly for $0 < |I| \le r$, and

(c3′(r)) the $TV[\widetilde{UV}_I^j; 0, T]$ for $|I| = r$ and the $TV[V_I^j; 0, T]$ for $0 < |I| \le r$ are uniformly bounded, then the conclusions (C1) and (C2) of Theorem 1 hold, and the EI(r)-limit of the $\mathbf{U}^j$ is equal to $\mathbf{V} = \sum_{0<|I|\le r} V_I(t)X_I$. To show how Theorem 1 can be applied, we consider the following example. We consider the case when there are two inputs, the $\mathbf{U}^j = U_1^j X_1 + U_2^j X_2$ are absolutely continuous, and $\mathbf{u}^j = \dot{\mathbf{U}}^j = u_1^j X_1 + u_2^j X_2$ are given (which is typical in applications).

Example. Consider the ordinary input sequence $\mathbf{u}^j = u_1^j X_1 + u_2^j X_2$ with

$$u_1^j(t) = \eta_1(t) + j^{\frac{2}{3}} \cos jt,$$
$$u_2^j(t) = \eta_2(t) + j^{\frac{2}{3}} \eta_3(t) \cos 2jt,$$

where the η_i are functions of class C^1 on $[0, T]$. Using Theorem 1 we can show that $\{u^j\}$ converges to some $\mathbf{V}$, and we can find $\mathbf{V}$ explicitly.

As the first step, we let

$$U_1^j(t) = \int_0^t u_1^j(s)ds = \int_0^t \eta_1(s)\, ds + j^{-\frac{1}{3}} \sin jt,$$
$$U_2^j(t) = \int_0^t u_2^j(s)ds = \int_0^t \eta_2(s)\, ds + \frac{j^{-\frac{1}{3}}}{2}\eta_3(t) \sin 2jt - \frac{j^{-\frac{1}{3}}}{2} \int_0^t \eta_3'(s) \sin 2js\, ds.$$

Letting

$$V_1^j(t) = \int_0^t \eta_1(s)\, ds,$$
$$V_2^j(t) = \int_0^t \eta_2(s)\, ds - \frac{j^{-\frac{1}{3}}}{2} \int_0^t \eta_3'(s) \sin 2js\, ds$$

and using (46) and (47) we have

$$\widetilde{UV}_1^j(t) = -j^{-\frac{1}{3}} \sin jt, \quad \widetilde{UV}_2^j(t) = -\frac{j^{-\frac{1}{3}}}{2}\eta_3(t) \sin 2jt.$$

Now it is easily computed that

$$\int_0^t u_1^j(s)\widetilde{UV}_1^j(s)\, ds = \int_0^t \eta_1(s)\widetilde{UV}_1^j(s)ds + \frac{j^{-\frac{2}{3}}}{4}[\cos 2jt - 1],$$

$$\int_0^t u_1^j(s)\widetilde{UV}_2^j(s)\,ds = \int_0^t \eta_1(s)\widetilde{UV}_2^j(s)ds + \frac{j^{-\frac{2}{3}}\eta_3(t)}{4}\left[\frac{1}{3}\cos 3jt + \cos jt\right]$$
$$-\frac{1}{3}j^{-\frac{2}{3}}\eta_3(0) - \frac{j^{-\frac{2}{3}}}{4}\int_0^t \eta_3'(s)\Big[\frac{1}{3}\cos 3js + \cos js\Big]ds,$$
$$\int_0^t u_2^j(s)\widetilde{UV}_1^j(s)\,ds = \int_0^t \eta_2(s)\widetilde{UV}_1^j(s)ds + \frac{j^{-\frac{2}{3}}\eta_3(t)}{2}\Big[\frac{1}{3}\cos 3jt - \cos jt\Big]$$
$$+\frac{1}{3}j^{-\frac{2}{3}}\eta_3(0) - \frac{j^{-\frac{2}{3}}}{2}\int_0^t \eta_3'(s)\Big[\frac{1}{3}\cos 3js - \cos js\Big]ds,$$

$$\int_0^t u_2^j(s)\widetilde{UV}_2^j(s)\,ds = \int_0^t \eta_2(s)\widetilde{UV}_2^j(s)ds + \frac{j^{-\frac{2}{3}}}{16}\Big[\eta_3^2(t)\cos 4jt - \eta_3^2(0)\Big]$$
$$-\frac{j^{-\frac{2}{3}}}{8}\int_0^t \eta_3(s)\eta_3'(s)\cos 4js\,ds.$$

So if we let

$$V_{1,1}^j(t) = \int_0^t \eta_1(s)\widetilde{UV}_1^j(s)ds - \frac{j^{-\frac{2}{3}}}{4},$$
$$V_{1,2}^j(t) = \int_0^t \eta_1(s)\widetilde{UV}_2^j(s)ds - \frac{1}{3}j^{-\frac{2}{3}}\eta_3(0) - \frac{j^{-\frac{2}{3}}}{4}\int_0^t \eta_3'(s)\Big[\frac{1}{3}\cos 3js + \cos js\Big]ds,$$
$$V_{2,1}^j(t) = \int_0^t \eta_2(s)\widetilde{UV}_1^j(s)ds + \frac{1}{3}j^{-\frac{2}{3}}\eta_3(0) - \frac{j^{-\frac{2}{3}}}{2}\int_0^t \eta_3'(s)\Big[\frac{1}{3}\cos 3js - \cos js\Big]ds,$$
$$V_{2,2}^j(t) = \int_0^t \eta_2(s)\widetilde{UV}_2^j(s)ds - \frac{j^{-\frac{2}{3}}\eta_3^2(0)}{16} - \frac{j^{-\frac{2}{3}}}{8}\int_0^t \eta_3(s)\eta_3'(s)\cos 4js\,ds,$$

then we get

$$\widetilde{UV}_{1,1}^j(t) = -\frac{j^{-\frac{2}{3}}}{4}\cos 2jt,$$
$$\widetilde{UV}_{1,2}^j(t) = -\frac{j^{-\frac{2}{3}}\eta_3(t)}{4}\Big[\frac{1}{3}\cos 3jt + \cos jt\Big],$$
$$\widetilde{UV}_{2,1}^j(t) = -\frac{j^{-\frac{2}{3}}\eta_3(t)}{2}\Big[\frac{1}{3}\cos 3jt - \cos jt\Big],$$
$$\widetilde{UV}_{2,2}^j(t) = -\frac{j^{-\frac{2}{3}}\eta_3^2(t)}{16}\cos 4jt.$$

There are eight indices of degree 3, namely, $(1,1,1), (1,1,2), (1,2,1), (1,2,2), (2,1,1), (2,1,2), (2,2,1)$, and $(2,2,2)$. We simply let $V_{i_1,i_2,i_3}^j(t) = \int_0^t u_{i_1}^j(s)\widetilde{UV}_{i_2,i_3}^j(s)ds$ so that $\widetilde{UV}_{i_1,i_2,i_3}^j(t) \equiv 0$. The V_{i_1,i_2,i_3}^j can be computed explicitly. We just compute $V_{1,1,2}^j$. By definition we have

$$V_{1,1,2}^j(t) = \int_0^t u_1^j(s)\widetilde{UV}_{1,2}^j(s)$$
$$= \int_0^t \eta_1(s)\widetilde{UV}_{1,2}^j(s)\,ds - \frac{1}{4}\int_0^t \eta_3(s)\Big[\frac{1}{3}\cos js\cos 3js + \cos^2 js\Big]ds$$
$$= -\frac{1}{8}\int_0^t \eta_3(s)\,ds + o(1),$$

where $o(1)$ denotes the terms that converge to 0 uniformly as $j \to \infty$. Similarly one can compute all the other $V^j_{i_1,i_2,i_3}$.

From the definition of the V^j_I we can get that

$$\lim_{j\to\infty} V^j_1(t) = \int_0^t \eta_1(s)\,ds,\ \lim_{j\to\infty} V^j_2(t) = \int_0^t \eta_2(s)\,ds,\ \lim_{j\to\infty} V^j_{1,1,2}(t) = -\frac{1}{8}\int_0^t \eta_3(s)ds,$$

$$\lim_{j\to\infty} V^j_{1,2,1}(t) = \frac{1}{4}\int_0^t \eta_3(s)ds,\ \lim_{j\to\infty} V^j_{2,1,1}(t) = -\frac{1}{8}\int_0^t \eta_3(s)ds,$$

and all the other V^j_I for $0 < |I| \le 3$ converge to 0 uniformly. It is also clear that the $\widetilde{UV}^j_I$ and V^j_I satisfy conditions (c2′(r)) and (c3′(r)). Therefore if we let

$$\begin{aligned}\mathbf{V} &= \int_0^t \eta_1(s)ds\,X_1 + \int_0^t \eta_2(s)ds\,X_2 - \frac{1}{8}\int_0^t \eta_3(s)ds\ [X_1X_1X_2 - 2X_1X_2X_1 + X_2X_1X_1]\\ &= \int_0^t \eta_1(s)ds\,X_1 + \int_0^t \eta_2(s)ds\,X_2 - \frac{1}{8}\int_0^t \eta_3(s)\,ds\,[X_1,[X_1,X_2]],\end{aligned}$$

from Theorem 1 we can conclude that the $\mathbf{u}^j$ EI(3)-converge to $\mathbf{V}$.

In control theory, one often considers systems with a *drift* term, i.e., systems of the form

$$\dot{x} = f_0(x) + \sum_{k=1}^m u_k(t) f_k(x).$$

Since such systems arise frequently in applications, we state explicitly the result generalizing Theorem 1 to systems with a drift. First we give a definition similar to EI(r)-convergence.

DEFINITION 11. *We say that a sequence $\{\mathbf{U}^j = \sum_{i=1}^m U^j_i X_i\}$ of ordinary inputs EI′(r)-converges to an extended input $\mathbf{V} = \sum_{0<|I|\le r} V_I[X_I]$ of order $\le r$ if the following holds. For every integer $n > 0$, any vector field f_0 of class C^0, and vector fields f_k, $k = 1,\dots,m$, of class C^{r-1} on $\mathbb{R}^n$, if*

(1) *$\{\mathbf{U}^{j(k)}\}$ is a subsequence of $\{\mathbf{U}^j\}$,*

(2) *$\{\bar{x}^{j(k)}\}$ is a sequence of points in $\mathbb{R}^n$ that converges to a limit $\bar{x} \in \mathbb{R}^n$,*

(3) *$x^{j(k)}$ is a maximal solution of*

$$\begin{aligned} dx &= f_0(x)dt + \sum_{i=1}^m f_i(x)dU_i^{j(k)}(t),\\ x(0) &= \bar{x}^{j(k)},\end{aligned}$$

then there exist a maximal solution x^∞ of

$$dx = f_0(x)dt + \sum_{0<|I|\le r} [f_I](x)dV_I(t), \tag{48}$$

$$x(0) = \bar{x}, \tag{49}$$

and a subsequence $\{x^{j(k(\ell))}\}$ of $\{x^{j(k)}\}$ that converges to x^∞ on compact sets.

Then similar to Theorem 1, we have the following theorem.

THEOREM 2. *Let $\{\mathbf{U}^j\}$, r, and $\mathbf{V}$ be as in Theorem 1. Then under the same conditions of Theorem 1 the $\{\mathbf{U}^j\}$ EI′(r)-converge to $\mathbf{V}$.*

One can also consider time-varying systems

$$dx = f_0(x,t)dt + \sum_{k=1}^{m} f_k(x,t)\, dU_k \tag{50}$$

with a drift, where $f_k : \mathbb{R}^n \times [0,T] \to \mathbb{R}^n$, $k = 0, 1, \dots m$, are time-varying vector fields. Let $\mathbf{f} = (f_1, \dots, f_m)$ be an m-tuple of time-varying vector fields on $\mathbb{R}^n$. We say that $\mathbf{f} \in C_t^{r-1}(\mathbb{R}^n)$ if for any smooth function ψ from $\mathbb{R}^n$ to $\mathbb{R}$, and for any $I = (i_1, \dots, i_k)$ with $|I| < r$, $(f_{i_1} \cdots f_{i_k}\psi)(x,t)$ is of class C^1 on $\mathbb{R}^n \times [0,T]$. Then one can similarly prove the following.

THEOREM 3. *Let $\{\mathbf{U}^j\}$, r, and $\mathbf{V}$ be as in Theorem* 1. *Let $f_k : \mathbb{R}^n \times [0,T] \to \mathbb{R}^n, k = 0, 1, \dots, m$, be time-varying vector fields on $\mathbb{R}^n$ and let $\mathbf{f} = (f_1, \dots, f_m)$. Assume that $\mathbf{f} \in C_t^{r-1}(\mathbb{R}^n)$ and f_0 is continuous. Let $\bar{x} \in \mathbb{R}^n$ be a point and $\{\bar{x}^j\}$ be a sequence of points in $\mathbb{R}^n$ converging to $\bar{x}$. Then under the same conditions of Theorem* 1 *the following holds. Let x^j be a maximal solution of* (50) *corresponding to inputs $\mathbf{U}^j$ with initial values $x(0) = \bar{x}^j$. Then for any subsequence $\{x^{j(k)}\}$ of $\{x^j\}$, there exist a maximal solution x^∞ of*

$$dx = f_0(x,t)\, dt + \sum_{0<|I|\le r} \frac{1}{|I|}[f_I](x,t)\, dV_I, \qquad x(0) = \bar{x}, \tag{51}$$

and a further subsequence $\{x^{j(k(\ell))}\}$ of $\{x^{j(k)}\}$ such that the $x^{j(k(\ell))}$ converge to x^∞ on compact sets.

It is easy to see that the main theorems of [5], [7] are consequences of Theorem 3.

Remark 10. We point out that one can weaken the regularity assumptions on the vector fields $f_1, \dots, f_m$ in the definition of EI(r)-convergence in many ways. To see how this can be done, cf. [16].

4. The necessity of the conditions of Theorem 2. When $r = 1$, Theorem 2 reduces to the following theorem discussed in [13].

THEOREM 4. *Let $\{\mathbf{U}^j\}$, $j \in \{1, 2, \dots\} \cup \{\infty\}$, be a sequence of ordinary inputs. Assume that there exist representatives $U^j = U_1^j X_1 + \dots + U_m^j X_m$ of the $\mathbf{U}^j$ such that*

(c1) *the U^j converge to U^∞ uniformly on $[0,T]$,*

(c2) *the total variations $TV[U_i^j; 0, T]$ are uniformly bounded; i.e., there exists a finite constant C such that $TV[U_i^j; 0, T] \le C$ for $i = 1, \dots, m$ and all j.*

Then $\{\mathbf{U}^j\}$ EI$'$(1)-converges to $\mathbf{U}^\infty$.

As point out in [13], conditions (c1), (c2) are also necessary for $\{\mathbf{U}^j\}$ to EI$'$(1)-converge to $\mathbf{U}^\infty$; namely, the following theorem holds.

THEOREM 5. *Let $\{\mathbf{U}^j\}$, $j \in \{1, 2, \dots\} \cup \{\infty\}$, be a sequence of ordinary inputs. Then the $\mathbf{U}^j$ EI$'$(1)-converge to $\mathbf{U}^\infty$ iff there are representatives $U^j = U_1^j X_1 + \cdots + U_m^j X_m$ of the $\mathbf{U}^j$ that satisfy conditions* (c1) *and* (c2) *in Theorem* 4.

This theorem is proven in [13] for the case when all the U_i^j, U_i^∞ are absolutely continuous. For completeness we include the proof here since it is very simple anyhow.

Proof of Theorem 5. Assume that the $\mathbf{U}^j$ EI$'$(1)-converge to $\mathbf{U}^\infty$. For each j let $U^j = U_1^j X_1 + \cdots + U_m^j X_m$ be a representative of $\mathbf{U}^j$ with $U_i^j(0) = 0$ for $i = 1, \dots, m$. Condition (c1) follows from applying the EI$'$(1)-convergence of the $\mathbf{U}^j$ to $\mathbf{U}^\infty$ with $n = m$, $\bar{x}^j = \bar{x} = (0, \dots, 0)$, $f_0(x) = (0, \dots, 0)$, $f_1 = (1, 0, \dots, 0), \dots, f_m = (0, \dots, 0, 1)$.

To show (c2), let φ be a function in $C[0,T]$, the set of all real-valued continuous functions on $[0,T]$. Let $n = 2$, and fix $1 \le \ell \le m$. For any $x = (x_1, x_2) \in \mathbb{R}^2$, let

$f_0(x) = (1, 0), f_i(x) = (0, 0)$ except for $i = \ell$, and $f_\ell(x) = (0, \varphi(x_1))$. For $1 \le j \le \infty$, let x^j be the unique maximal solution of

$$dx = f_0(x)dt + \sum_{i=1}^{m} f_i(x)dU_i^j(t), \quad x(0) = (0, 0).$$

Then we have $x_1^j(t) = t$, and $x_2^j(t) = \int_0^t \varphi(s)dU_\ell^j(s)$. Since the $\mathbf{U}^j$ $\mathrm{EI}'(1)$-converge to $\mathbf{U}^\infty$, we know that the functions $x_2^j(t) = \int_0^t \varphi(s)dU_\ell^j(s)$ converge to $x_2^\infty(t) = \int_0^t \varphi(s)dU_\ell^\infty(s)$ uniformly. In particular the integrals $\int_0^T \varphi(s)dU_\ell^j(s)$ converge to $\int_0^T \varphi(s)dU_\ell^j(s)$. Now each U_ℓ^j can be viewed as a linear functional on the Banach space $C[0, T]$ given by $\langle U_\ell^j, \varphi\rangle = \int_0^T \varphi(s)dU_\ell^j(s)$. It is well known that if U is any function in $BVC([0, T], \mathbb{R})$, the norm of the linear functional $\varphi \longrightarrow \int_0^T \varphi(s)dU(s)$ is equal to the total variation of U on $[0, T]$, i.e., $TV[U; 0, T]$. Now the above implies that for each φ, the set $\{\langle U_\ell^j, \varphi\rangle : j = 1, 2, \ldots\}$ is bounded. By the Banach–Steinhaus theorem we know that the set $\{TV[U_\ell^j; 0, T] : j = 1, 2, \ldots\}$ is also bounded. Since ℓ is arbitrary between 1 and m, we know that (c2) holds. ∎

It is easy to see that condition (c1(r)) is still necessary for a sequence $\{\mathbf{U}^j\}$ to $\mathrm{EI}'(r)$-converge to an extended input $\mathbf{V}$ of order r; namely, if a sequence $\{\mathbf{U}^j\}$ of ordinary inputs $\mathrm{EI}'(r)$-converges to an extended $\mathbf{V}$ of order r, then $\{\mathbf{U}^j\}$ $\mathrm{FT}(r)$-converges to $\mathbf{V}$ (cf. Remark 8). To see this, let $F_k^r, k = 0, \ldots, m$, be the linear vector fields on $A^r(\mathbf{X})$ given by $F_0^r(S) = 0, F_k^r(S) = SX_k$ for $k = 1, \ldots, m$. Since the $\mathbf{U}^j$ $\mathrm{EI}'(r)$-converge to $\mathbf{V}$, in particular the solutions of the initial value problems

$$dS = F_0^r(S)dt + \sum_{k=1}^{m} F_k^r(S)dU_k^j,$$
$$S(0) = 1$$

converge to the function S that satisfies $dS = Sd\mathbf{V}, S(0) = 1$ on $[0, T]$ in $A^r(\mathbf{X})$, which is equivalent to the $\mathrm{FT}(r)$-convergence of the $\mathbf{U}^j$ to $\mathbf{V}$. However, condition (c2(r)) may not be necessary anymore. An interesting problem is of course to get simple characterizations for sequences of ordinary inputs to $\mathrm{EI}'(r)$-converge to extended inputs of order r for $r \ge 2$.

Appendix: Proof of Lemma 1 and an auxiliary result. We now complete the proof of Lemma 1 and give an approximation result of B-continuous functions by smooth functions (in the weak convergence sense), which was used in section 2. This result is well known, but we provide a proof for completeness.

Proof of Lemma 1. Let $\tilde{g}^j = g^j - g$ and $K = \sup_j\{TV[g^j; 0, T]\}$. Our assumptions imply that f is continuous and g is B-continuous with $TV[g; 0, T] \le K$. We have

$$\Big|\int_0^t f^j(s)\,dg^j(s)\Big| \le \Big|\int_0^t (f^j(s) - f(s))\,dg^j(s)\Big| + \Big|\int_0^t f(s)\,dg^j(s)\Big|$$
$$\le K|f^j - f|_\infty + \Big|\int_0^t f(s)\,dg^j(s)\Big|.$$

(Here $|f^j - f|_\infty$ denotes the sup-norm of the function $f^j - f$ on $[0, T]$.) Since the f^j converge to f uniformly, the $K|f^j - f|_\infty$ converge to 0. The integrals $\int_0^t f(s)\,dg^j(s)$ can be rewritten as $\int_0^t f(s)d\tilde{g}^j(s) + \int_0^t f(s)dg(s)$. So all we need is to show that the $\int_0^t f(s)d\tilde{g}^j(s)$ converge to 0 uniformly as $j \to \infty$. For any given $\varepsilon > 0$, let $\tilde{f}$ be a

smooth function on $[0,T]$ such that $|f-\tilde{f}|_\infty < \frac{\varepsilon}{4K}$. Then

$$\Big|\int_0^t f(s)d\tilde{g}^j(s)\Big| \le \Big|\int_0^t (f(s)-\tilde{f}(s))d\tilde{g}^j(s)\Big| + \Big|\int_0^t \tilde{f}(s)d\tilde{g}^j(s)\Big|.$$

The first term in the right-hand side is less than $\frac{\varepsilon}{2}$. The second integral can be rewritten via integration by parts as

$$\int_0^t \tilde{f}(s)d\tilde{g}^j(s) = \tilde{f}(t)\tilde{g}^j(t) - \tilde{f}(0)\tilde{g}^j(0) - \int_0^t \dot{\tilde{f}}(s)\tilde{g}^j(s)ds.$$

Since the $\tilde{g}^j$ converge to 0 uniformly, we see that the $\int_0^t \tilde{f}(s)d\tilde{g}^j(s)$ converge to 0 uniformly as $j\to\infty$. This completes the proof of the lemma. ∎

PROPOSITION 4. *Let V be a function in $BVC[0,T]$. Then there exists a sequence $\{v_n\}$ of smooth functions on $[0,T]$ with the $\|v_n\|_{L^1}$ being uniformly bounded such that, for any $g\in C[0,T]$,*

$$\lim_{n\to\infty}\int_0^t g(s)v_n(s)\,ds = \int_0^t g(s)\,dV(s)$$

uniformly in t.

Proof. Without lost of generality we may assume that $V\in BVC[0,T]$ is increasing and $V(0)=0$. Divide $[0,T]$ into 2^n equal parts. Let $\Gamma_n = \{0=t_0^n < t_1^n < \cdots < t_{2^n}^n = T\}$ be the partition. Let $\tilde{v}_n$ be functions on $[0,T]$ defined $\tilde{v}_n(t) = \frac{V(t_l^n)-V(t_{l-1}^n)}{t_l^n - t_{l-1}^n}$ on $[t_{l-1}^n, t_l^n)$ and $\tilde{v}_n(T) = V(T)$. Clearly $\int_0^T |\tilde{v}_n(s)|\,ds = V(T)$. Let $g\in C[0,T]$ and $M = \max_{0\le t\le T}|g(t)|$. We first show that

$$\lim_{n\to\infty}\int_0^t g(s)\tilde{v}_n(s)\,ds = \int_0^t g(s)\,dV(s)$$

uniformly. Given any $\varepsilon>0$, since V is continuous, there exists a $\delta>0$ such that $|V(t_2)-V(t_1)| < \frac{\varepsilon}{3M}$ if $|t_2-t_1|<\delta$. Let m_l^n, M_l^n be the minimum and the maximum values of g on $[t_{l-1}^n, t_l^n]$, respectively. Let

$$s_{\Gamma_n} = \sum_{l=1}^{2^n} m_l^n(V(t_l^n)-V(t_{l-1}^n)),$$
$$S_{\Gamma_n} = \sum_{l=1}^{2^n} M_l^n(V(t_l^n)-V(t_{l-1}^n)).$$

Then we know that

$$0 \le S_{\Gamma_n} - s_{\Gamma_n} \to 0 \quad \text{as } n\to\infty.$$

For the given $\varepsilon>0$, take N_1 large enough such that $0\le S_{\Gamma_n}-s_{\Gamma_n} < \frac{\varepsilon}{3}$ when $n>N_1$. Let N be such that $\frac{T}{2^N} < \delta$ and $N>N_1$. For any $t\in[0,T]$, let $t(n)$ be the integer such that $t\in[t_{t(n)}^n, t_{t(n)+1}^n)$. Then, via the mean value theorem, we have

$$\int_0^t g(s)\tilde{v}^n(s)\,ds = \sum_{l=1}^{t(n)}\int_{t_{l-1}^n}^{t_l^n} g(s)\tilde{v}_n(s)\,ds + \int_{t_{t(n)}^n}^t g(s)\tilde{v}_n(s)\,ds$$
$$= \sum_{l=1}^{t(n)} g(\xi_l^n)(V(t_l^n)-V(t_{l-1}^n)) + \frac{V(t_{t(n)+1}^n)-V(t_{t(n)}^n)}{t_{t(n)+1}^n - t_{t(n)}^n} g(\xi_{t(n)+1}^n)(t-t_{t(n)}^n),$$

where $\xi_l^n \in [t_{l-1}^n, t_l^n]$. We know that when $n > N$

$$\left| \frac{V(t_{t(n)+1}^n) - V(t_{t(n)}^n)}{t_{t(n)+1}^n - t_{t(n)}^n} g(\xi_{t(n)+1}^n)(t - t_{t(n)}^n) \right| < \frac{\varepsilon}{3}.$$

So we have

$$-\frac{\varepsilon}{3} + \sum_{l=1}^{t(n)} m_l^n (V(t_l^n) - V(t_{l-1}^n)) \le \int_0^t g(s)\tilde{v}_n(s)\,ds \le \frac{\varepsilon}{3} + \sum_{l=1}^{t(n)} M_l^n (V(t_l^n) - V(t_{l-1}^n)).$$

We also have

$$\sum_{l=1}^{t(n)} m_l^n (V(t_l^n) - V(t_{l-1}^n)) + m_{t(n)+1}^n (V(t) - V(t_{t(n)}^n)) \le \int_0^t g(s)\,dV(s)$$

$$\le \sum_{l=1}^{t(n)} M_l^n (V(t_l^n) - V(t_{l-1}^n)) + M_{t(n)+1}^n (V(t) - V(t_{t(n)}^n)).$$

So when $n > N$, we have

$$\int_0^t g(s)\,dV(s) - \int_0^t g(s)\tilde{v}_n(s)\,ds \le \sum_{l=1}^{t(n)} (M_l^n - m_l^n)(V(t_l^n) - V(t_{l-1}^n)) + M_{t(n)+1}^n (V(t) - V(t_{t(n)}^n)) + \frac{\varepsilon}{3}$$

$$\le S_{\Gamma_n} - s_{\Gamma_n} + \frac{\varepsilon}{3} + M_{t(n)+1}^n (V(t) - V(t_{t(n)}^n)) \le \varepsilon$$

and

$$\int_0^t g(s)\,dV(s) - \int_0^t g(s)\tilde{v}_n(s)\,ds \ge \sum_{l=1}^{t(n)} (m_l^n - M_l^n)(V(t_l^n) - V(t_{l-1}^n)) + m_{t(n)+1}^n (V(t) - V(t_{t(n)}^n)) - \frac{\varepsilon}{3}$$

$$\ge s_{\Gamma_n} - S_{\Gamma_n} - \frac{\varepsilon}{3} + m_{t(n)+1}^n (V(t) - V(t_{t(n)}^n)) \ge -\varepsilon,$$

i.e.,

$$\left| \int_0^t g(s)\,dV(s) - \int_0^t g(s)\tilde{v}_n(s)\,ds \right| \le \varepsilon.$$

Now taking $\{v_n\} \in C^\infty[0,T]$ such that $\|\tilde{v}_n - v_n\|_{L^1} \to 0$ as $n \to \infty$, we get

$$\lim_{n\to\infty} \left| \int_0^t g(s)\,dV(s) - \int_0^t g(s)v_n(s)\,ds \right| \le \lim_{n\to\infty} \left\{ \left| \int_0^t g(s)\,dV(s) - \int_0^t g(s)\tilde{v}_n(s)\,ds \right| + \int_0^t |g(s)|\,|\tilde{v}_n(s) - v_n(s)|\,ds \right\} = 0$$

uniformly on t. Clearly the $\|v_n\|_{L^1}$ are uniformly bounded. □

Acknowledgment. The author is very grateful to Professor H. J. Sussmann for proposing to him the topic, for his help, and for many fruitful discussions.

RISK-SENSITIVE AND ROBUST ESCAPE CRITERIA*

PAUL DUPUIS† AND WILLIAM M. MCENEANEY‡

Abstract. The problem of controlling a noisy process so as to prevent it from leaving a prescribed set has a number of interesting applications. In this paper, new approaches to this problem are considered. First, a risk-sensitive criterion for a stochastic diffusion process model is examined, and it is shown that the value is a classical solution of a related PDE. The qualitative properties of this criterion are favorably contrasted with those of existing criteria in the risk-averse limit. It is proved that in the risk-averse limit the value of the risk-sensitive criterion converges to a viscosity solution of a first-order PDE. It is then demonstrated that the value function of a deterministic differential game is also a viscosity solution to the PDE. This game gives a robust control formulation of the escape time problem and is analogous to H^∞ control. In particular, the opposing player attempts to push the process out of the prescribed set and suffers an L^2 cost for his efforts. Lower bounds on the escape time as a function of this cost are obtained.

Key words. exit time control, risk-sensitive control, large deviations, robust control

1. Introduction.

In problems that cover a range of interesting applications, there is a stochastic process model for a system, and the goal is to keep the process in a given fixed open set G. In this paper we will consider such problems in the context of optimization and control. Here, as with many other problems to which control theory is applied, the selection of a cost is subjective. Typically, one chooses a cost with the purpose of inducing desirable qualitative behavior. For example, in many control problems the goal is to keep the controlled process near a certain operating point. In this case one would choose a criterion so that the corresponding optimal controls will "stabilize" the process about this operating point. For our problem the situation is different, in that the goal is not so much to keep the process near a particular point as it is to keep it away from the "bad" set G^c, where the c denotes complement. For a problem to fit well into such a framework, it must be the case that entry into the set G^c is in a certain sense catastrophic, and avoiding such an event must be a high priority. Examples are the failure of a machine, loss of data in a communication network, loss of "lock" in an adaptive tracking device, and entry of bistable adaptive control algorithms, such as those using ALOHA-type protocols, into the "bad" region.

There are two criteria that are often associated with the problem described above. The first criterion is the probability of escape over some interval $[0, T]$:

$$P_x \{X_t \notin G \text{ for some } t \in [0, T]\},$$

where P_x denotes probability conditioned on $X_0 = x$. If the process is controlled, then obviously one would like to choose the control to minimize this probability. The

second criterion is the mean escape time, $E_x\tau$, where τ is the first time the process X_t escapes from G. Here we maximize when a control is available. As we discuss in detail in section 3, both these cost criteria have some theoretical and computational shortcomings. One of the contributions of the present paper is the introduction of new cost criteria for this problem. To have a concrete model for the purposes of discussion, consider the case of a Markov process described by the stochastic differential equation

$$dX_t^\varepsilon = f(X_t^\varepsilon)dt + \varepsilon^{1/2}\sigma(X_t^\varepsilon)dB_t, \qquad X_0^\varepsilon = x,$$

where the dimensions of the Wiener process B_t, f, and σ are compatible. The quantity $\varepsilon > 0$ is a parameter whose role will be explained shortly.

One of the criteria we consider takes the form

$$E_x \exp\left[-\theta\tau^\varepsilon/\varepsilon\right], \tag{1.1}$$

where θ is a positive design parameter and τ^ε is the first time the process X_t^ε exits G. If the process is controlled, we choose the control to minimize this quantity. We will consider the qualitative properties of this cost from two different perspectives. The first perspective is that of control of "small noise" systems. In this setting, the term small noise essentially means that escape from G is a relatively rare event. For the particular model under consideration, and under appropriate conditions on f and σ, this corresponds to $\varepsilon > 0$ being small. Many problems of interest, such as the control of communication devices, fall into this "small noise" category, since design tolerances are quite strict and a system in which escape was common would not even be worth considering. As we discuss in section 3, the quantity (1.1) has desirable properties when compared to standard criteria for problems of this type.

One can also view (1.1) as a "risk-sensitive" analogue of a more standard criterion. We consider the same limit as in the small noise perspective. Based on the now well-known connection between limits of risk-sensitive control problems and nonlinear robust control, one might expect the limit $\varepsilon \to 0$ to lead to a robust control problem for escape time problems that is analogous to H^∞ control. The second cost criterion we study is the one associated with this robust control problem. In this setting, we do not assume that the true system is "small noise."

Hence in both cases we are interested in the limit problem obtained when $\varepsilon \to 0$ in the cost (1.1). In order to obtain a well-defined limit, it is necessary to work with the scaled quantity

$$-\varepsilon \log E_x \exp\left[-\theta\tau^\varepsilon/\varepsilon\right]. \tag{1.2}$$

Because of the additional minus sign, the objective is to maximize this quantity. Depending on the means by which the designer may influence the system, we distinguish three classes of progressively more difficult optimization problems. The first case is that of "performance analysis." Here the designer cannot really influence the system at all. Instead, the designer would be interested in approximating (1.2) or its limit as $\varepsilon \to 0$ so that it could be used to compare two or more system designs. The second case is one we call "parametric optimization." Here the designer has control over a collection of parameters that determine the dynamics of the system. In this case the designer could use the limit of (1.2) as a convenient criterion when optimizing with respect to these parameters. In both of these cases, the limit of (1.2) as $\varepsilon \to 0$ can be characterized as the solution to a minimal cost deterministic optimal control problem. The last case is that in which the designer can choose an active, state-dependent control. In this case the limit as $\varepsilon \to 0$ of the supremum of (1.2) over admissible controls

can be characterized as the solution to a deterministic differential game. The control that seeks to maximize the limit of (1.2) will be opposed by a minimizing control. In order to distinguish the prelimit control problem for this case from the limit control problem obtained in the previous two, we refer to it as the case of "maximizing control." To simplify the exposition, in several places the case without maximizing control is treated separately and before the more general case.

A summary of the paper is as follows. In order to illustrate some of the main issues and suggest some of the applications, we describe several motivational examples in section 2. In section 3 we turn our attention to possible design criteria. We describe shortcomings of the standard criteria from the small noise perspective, and show how these shortcomings are avoided by considering the limit of (1.2) as the design criterion. The "risk-sensitive" interpretation of (1.2) is given in this section, and we also discuss generalizations of (1.1). Since the qualitative comparisons do not rely heavily on the use of a specific model, the discussion in sections 2 and 3 is in a general setting. However, for the asymptotic analysis and interpretation of the limit problem it is convenient to fix a model, and accordingly a diffusion model and the associated model for the robust control problem are assumed throughout sections 4–6. In section 4 we characterize the limit of (1.2) for the various cases when $\varepsilon \to 0$, and state the convergence theorem. As noted previously, the established connections between risk-sensitive control, risk-averse limits, and robust control suggest that the limit problem for the case of maximizing control would define a control that has an interpretation as a robust control. This is the case, and the precise interpretation is stated in section 5. To ease the presentation, a number of proofs are postponed to section 6.

2. Examples. In this section we describe examples that fit into the framework of the last section. The examples are intended only to be illustrative. They provide the basis for the qualitative comparisons of the next section and motivate the criteria that will be considered later. Some of the examples fall outside the class of diffusion processes, and hence indicate interesting extensions that are not covered by the theory developed in this paper. However, since the qualitative properties discussed in section 3 require only a certain type of large deviation behavior, the remarks of this section apply to all the examples.

Problems for which escape time criteria are appropriate fit into one of two categories. In the first category, exit from the region of desired operation essentially causes the system to shut down, and the system is more or less "off-line" until the state of the system can be steered back into the good operating region. For example, when an ALOHA-type system exits its stable operating region the entire system is shut down and then restarted. In Example 1 below, exit from the operating region means that the pair of communicating satellites must suspend data transmission and initiate the procedure to regain "lock." In the second category exit from the domain is not fatal, but still an event to be avoided because of a drastic decline in performance when outside the good region. An example in this category is the queueing example given below, in which escape from G corresponds to a nonnegligible fraction of incoming customers being turned away. For additional examples the reader can consult the references in [28].

Example 1 (satellite laser communication problem). In space-based laser communication an essential role is played by the tracking and pointing subsystems of the satellites that are involved. In particular, data may be transmitted between two satellites by a laser communication crosslink. In order that the communication links not be broken, the pointing system of each satellite must keep the laser focused on the

detector of the other. Since the communication beams are very narrow, the pointing requirements are rather stringent [26]. In this example the set G is defined in terms of an angular cone of allowable orientations of the gimbal-mounted optics used to control the beam direction. At any given time one of the satellites is allowed to transmit data at a high rate while the other transmits a "beacon" signal at a low rate, the purpose of which is to help maintain the "lock." Owing to "noises" (such as internal vibrations) the operating state of the system can be driven from G, at which time there will be a communication interruption, and lock between the transmitter and receiver will have to be re-established via a separate acquisition algorithm. It is desirable to have the time between losses of lock be quite large (e.g., several months).

For such a system linear methods automatically make little sense, since the effective state space in which the system can operate is not itself a linear space. This is true even if the system dynamics are linear. The criterion described in the introduction and the robust criterion we will define in section 5 are more natural for this problem, since they focus on the event that is actually of interest. In this problem one may be interested in parametric optimization or feedback control.

Example 2 (tracking problem). Many synchronization systems in advanced communication systems are digital. One might model such a system as

$$X_{i+1}^n = X_i^n + \frac{1}{n} b(X_i^n, \xi_i).$$

In this equation ξ_i is a random sequence composed of noise and the inputs to the system. The discrete time parameter i is used because time is "slotted," and data are communicated only at discrete times. The factor $1/n$ reflects the fact that the state X_i^n of the system changes slowly as a function of each new piece of data ξ^i, although the data rates are very high. In order that the system operate properly, it is crucial that the transmitter and receiver both be on the same "clock," so that it is clear when a discrete time interval begins and ends. In a synchronization system, one of the components of X_i^n (say $(X_i^n)_1$) will be the difference between an estimate of a phase timing indicator and the true value. For accurate communication or tracking, one needs a very good estimate. Here the set G will be of the form $\{x : -a_1 \le x_1 \le a_2\}$. As part of the design procedure "stabilizing" dynamics are always built into the system in order to keep X_i^n in the acceptable region G. However, owing to the presence of noise, the difference between the estimate of the phase timing indicator and the true value is eventually driven from G. A risk-sensitive escape criterion is natural in this context. For these problems, one is typically interested only in performance analysis (for purposes of comparing competing designs), or at most in parametric optimization.

This example is illustrative of a large class of similar problems from statistics and adaptive stochastic algorithms [4]. The large deviation analysis, numerical computations, and simulations for a related analog device known as a phase-locked loop appear in [7, 9].

Example 3 (queueing problems). Numerous problems involving the design and optimization of queues can be cast in terms of the risk-sensitive criterion. Escape criteria will be suitable whenever the main purpose of the design is to reduce the possibility of very large buffers. A number of examples and references to additional examples are given in the book [30]. Although there is at the present time no theory of robust control for queueing systems, one would expect by analogy with the case for diffusions that controls designed on the basis of a risk-sensitive criterion would enjoy the features one would desire of such a robust control.

Escape criteria are suitable whenever buffer overflow constitutes a critical event. This is often true for problems associated with the analysis and design of high-speed data networks. These networks carry many types of data in digitized form, e.g., voice, computer, and video data. Each of these classes has its own requirements and characteristics. In addition, for some classes of data there may be contractually agreed upon requirements regarding network performance. These requirements will be stringent (e.g., probabilities of data loss in the 10^{-9} range). Data loss occurs when buffer capacities are exceeded, and thus corresponds to an "escape." There are numerous difficult and interesting design and control problems that are associated with such networks.

Example 4 (power system stability). In this example a diffusion model is believed to be appropriate for describing the time evolution of the system (cf. [6] and the references therein). The state of the system is a vector whose components consist of various generator frequencies, voltage phase angles, and voltage magnitudes. The set G is defined to be a region in which the "security" of the system is acceptable. Exit from the region may require substantial intervention to return the state of the system to the stable region, and hence is an event to be avoided. Coefficient matrices in the system of equations that describe operation provide the system parameters over which optimization can be performed. In addition, feedback control in various forms can also be possible.

3. Comparison and interpretation of the cost criterion. In this section we study the optimization criterion

$$E_x \exp\left[-\theta\tau^\varepsilon/\varepsilon\right] \tag{3.1}$$

from a qualitative point of view. In section 3.1 a comparison is made between this cost and more standard cost criteria in the small noise setting. In section 3.2, (3.1) is interpreted from the risk-sensitive point of view. Generalizations of the cost are briefly discussed in section 3.3.

3.1. The small noise setting. In many of the problems for which a criterion based on escape times is appropriate, it is useful to assume that the stochastic process model is in some sense a "small noise" model. Indeed, if this were not the case, then (essentially regardless of system design) escapes from the acceptable operating region would be common, and for many problems the models might not be worth considering.

As remarked in the introduction, there are two criteria that are often associated with such problems, namely, the probability of escape over some interval $[0, T]$,

$$P_x\left\{X_t^\varepsilon \notin G \text{ for some } t \in [0,T]\right\}$$

and the mean escape time

$$E_x\tau^\varepsilon, \text{ where } \tau^\varepsilon = \inf\{t : X_t^\varepsilon \notin G\}.$$

The parameter $\varepsilon > 0$ indicates the "strength" of the noise, with zero noise in the limit $\varepsilon \to 0$.

Unfortunately, both of these criteria have shortcomings. We first consider the escape probability. While this criterion might be acceptable for problems for which the duration T is fixed and known, it is probably not appropriate otherwise. In many problems one has a rough idea of the interval of interest, but not much more than that. The escape probability criterion can be inconvenient to work with even when

the interval of interest is known. For example, in the control setting it typically results in controls that are not stationary. A second difficulty is of a computational nature. In cases where the control space is large, there can be numerical difficulties due to the fact that the controls become somewhat singular near the final time T. A final problem is greater sensitivity (relative to more well-behaved functionals) with regard to the parameter that measures the strength of the noise. Hence escape probabilities can be more difficult to approximate than smoother functionals of a process (such as an expectation of a smooth function of the process). Because of this, the behavior of systems designed on such a criterion is less reliably predicted by the asymptotic theory.

While the mean escape time criterion has the advantage of yielding time-independent feedback controls, it too can be problematic, especially in the desired situation where the probability of escape over $O(1)$ time intervals is rare. In this setting, computation and approximation of the mean escape time, even for the case of a fixed control, can be difficult. In order to make this statement precise, we return to the small noise diffusion model

$$dX_t^\varepsilon = f(X_t^\varepsilon)dt + \varepsilon^{1/2}\sigma(X_t^\varepsilon)dB_t, \qquad X_0^\varepsilon = x. \tag{3.2}$$

It is well known (under some assumptions) that $W^\varepsilon(x) \doteq E_x\tau^\varepsilon$ satisfies a second-order PDE

$$\mathcal{L}^\varepsilon W^\varepsilon(x) = -1, \quad x \in G^0, \;\; W^\varepsilon(x) = 0, \quad x \in \partial G, \tag{3.3}$$

where

$$\mathcal{L}^\varepsilon g(x) \doteq \frac{\varepsilon}{2}\mathrm{tr}\left[g_{xx}(x)a(x)\right] + \langle f(x), g_x(x)\rangle, \qquad a(x) = \sigma(x)\sigma^T(x),$$

and $\mathrm{tr}B$ denotes the trace of the square matrix B. The case with control involves obvious modifications of this equation. The smallness of the noise translates into the small ε coefficient in front of the second derivative term. This produces a solution that is essentially flat over much of G^0 but with steep gradients close to ∂G. Because of these properties, it is very difficult to accurately approximate the solution numerically. This is rather unsatisfactory, since the very conditions that are required for escapes to be a rare event lead to difficult computational problems.

A problem that may be even more important than the one just discussed is that in the small noise setting the mean escape time (and by extension any controls that are designed using it as the performance criterion) may focus on events that are not of any practical interest, since the dominant contribution to this criterion comes from paths that take a very long time to escape. Under certain technical conditions on f, σ, and their relation to ∂G, one can show [20] there exists a constant $C^* > 0$ such that the limit

$$\lim_{\varepsilon\to 0} \varepsilon \log E_x\tau^\varepsilon = C^*$$

holds uniformly for x in compact subsets of G. For any $\delta \in (0, C^*)$, the scaling in ε of this quantity implies that when $\varepsilon > 0$ is sufficiently small the dominant contribution to $E_x\tau^\varepsilon$ is due to sample paths that take at least $\exp\left([C^* - \delta]/\varepsilon\right)$ units of time to escape. While this may be a moot point if one is absolutely certain that the mean escape time is the criterion of interest, it is an important point when this is not the case. Consider, for example, a telecommunication problem involving routing of data through a network. For obvious reasons, the true process representing loading

of the network is nonstationary, with cyclical variations (e.g., periods of one day). For this problem the mean escape criterion, even if it were computable, would be an inappropriate basis on which to design controls if the dominant contribution is due to sample paths that take longer than one day to escape. Such a criterion is clearly not desirable, since controls designed on it may allow a large number of escapes over a short time interval, as long as this is balanced by relatively few sample paths which take the very long time $\exp([C^* - \delta]/\varepsilon)$ to escape. Moreover, these paths would not even contribute to the overall performance of the true system, owing to its nonstationarity.

As we will see, the escape time criterion (3.1) and controls based on its asymptotic behavior avoid these difficulties. The controls will automatically be independent of time, and by appropriately choosing the design parameter θ, one can to some degree "tune" the system to focus on escapes over different $O(1)$ time intervals. By working with the logarithmic transform of (3.1), we obtain a Hamilton–Jacobi equation that is much more well behaved than (3.3), especially with regard to computational approximations. We also note that in comparison with the escape probability, the relative smoothness of the functional mapping $X^\varepsilon \to \tau^\varepsilon$ under the distribution of X^ε suggests that (3.1) (or rather the logarithmic transform of (3.1)) should be more reliably predicted by the asymptotic theory when $\varepsilon \to 0$.

3.2. The risk-sensitive interpretation. The theory of risk-sensitive control investigates the manner in which modifications of cost structures affect the associated optimal policies. For example, one might be interested in the effect of so-called "risk-sensitizing transformations." At an intuitive level, the goal of such a transformation is to amplify the effect that certain outcomes have in determining the overall cost, and thereby force the optimal control (or any nearly optimal control) to "pay more attention" to these more heavily weighted outcomes. In particular, in the risk-averse case, "bad" events are weighed more heavily, and the control becomes more conservative with regard to allowing these events to occur.

From this perspective, for each fixed $\varepsilon > 0$, one may view the criterion (3.1) as a risk-sensitive version of the mean escape time criterion $E_x\tau^\varepsilon$. The effect of the nonlinear mapping $\tau \to \exp -\theta\tau/\varepsilon$ is to shift the attention toward paths that escape in a relatively short time, at the expense of optimizing the mean escape time. As noted in the previous section, this makes sense for many problems, especially those that may involve some type of nonstationarity. The design parameter $\theta > 0$ controls the degree to which these short time escapes are emphasized, with larger values of θ focusing attention more heavily on such escapes. On the other hand, if we fix $\varepsilon > 0$ and take the limit $\theta \to 0$, one can show (under suitable uniform integrability conditions) that the design criterion (3.1) becomes equivalent in this limit to the mean escape time.

For various reasons, including computational simplicity, model simplification, and because of the connection with robust control design, one may also be interested in taking limits with respect to a family of risk-sensitizing transformations. This is in fact the second motivation for the asymptotic analysis to be carried out in the next few sections. The interpretation of the limit in terms of robust control will be discussed further in section 5. As the reader can easily check, unless the dynamics of the process model are modified in an ε-dependent way such as that of (3.2), then it will be difficult to normalize the quantity (3.1) so as to obtain a well-defined limit as $\varepsilon \to 0$. The limit problem will be interpreted as a robust control problem in section 5. The link between the two allows one to connect these two rather different modeling perspectives. It is important to observe that the robust interpretation of the limit control problem is independent of the asymptotic analysis.

The relationship between risk-sensitive control and robust control in the linear setting was discussed at length in [33]. Connections between the two have also been examined in several nonlinear contexts. It was shown in [14, 15, 23] that the values of certain risk-sensitive infinite time horizon control problems converge to the values of H^∞ disturbance attenuation problems. In [16, 27] the connection between finite time horizon risk-sensitive control and robust finite time horizon control was made. Finally, in [29] and [12] the connection was examined in the Markov chain and hidden Markov cases, respectively.

3.3. Generalizations of the cost. Depending on the problem, one might consider various generalizations of the cost criterion

$$E_x \exp\left[-\theta\tau^\varepsilon/\varepsilon\right].$$

For example, one can measure "time until escape" in a state-dependent way by considering a cost of the form

$$E_x \exp\left[-\int_0^{\tau^\varepsilon} \theta(X_s^\varepsilon)ds/\varepsilon\right],$$

where $\theta(\cdot)$ is a continuous function on $\bar{G}$. As long as $\inf_{x\in\bar{G}}\theta(x) > 0$, the analysis for this case is essentially the same as for the case $\theta(\cdot) \doteq \theta$ that is considered in sections 4–6.

For maximizing control problems where the control space is potentially unbounded, one might consider a cost of the form

$$E_x \exp\left[-\int_0^{\tau^\varepsilon} \left[\theta - \langle u_s, Au_s\rangle\right] ds/\varepsilon\right],$$

where A is a positive definite matrix of appropriate dimensions. Because of the lack of compactness in the control variable, the analysis in this case is more complicated than that given in sections 4–6.

4. Asymptotic analysis. For the remainder of this paper attention is restricted to controlled and uncontrolled diffusion processes, and it is further assumed that the control only affects the drift. Hence the dynamics of the controlled process are given by

$$dX_t^\varepsilon = f(X_t^\varepsilon, u_t)\,dt + \varepsilon^{1/2}\,\sigma(X_t^\varepsilon)\,dB_t, \tag{4.1}$$

with the obvious modification for the uncontrolled case. B is a Brownian motion with sample space Ω, filtration F_t, and measure P. The control process u is F_t-progressively measurable (see [18]) and takes values in a compact set U.

In this section, the results for the small noise/risk-sensitive escape problem are developed. Since the proofs for the case with a maximizing control are not significantly more complex than those for the case without control, all the results in this section will be stated only for the case with control. For the case without control, the modifications are obvious.

The following conditions will be assumed for the remainder of the paper; no additional assumptions will appear. Recall that $G \subseteq \Re^n$ denotes the set one wishes to keep the process in, with G open and $\overline{G}$ compact. Let ∂G denote the boundary

of G and for $y \in \Re^n$ let $B_a(y) \doteq \{x : |x-y| \le a\}$, where $|\cdot|$ denotes the Euclidean norm.

CONDITION 4.1. *$\overline{G}$ satisfies a uniform exterior sphere condition. Thus there exists $r > 0$ such that for any $x \in \partial G$ there is $y \in (\overline{G})^c$ with $|x-y| = r$ and*

$$B_r(y) \cap \overline{G} = \{x\}.$$

CONDITION 4.2. *$f \in C(\overline{G}, U)$, and furthermore f is uniformly Lipschitz in x in the sense that there exists $K_f < \infty$ such that*

$$|f(x,u) - f(y,u)| \le K_f |x-y| \qquad \text{for all } (x,y,u) \in \overline{G} \times \overline{G} \times U.$$

CONDITION 4.3. *$\sigma \in C^1(\overline{G})$, and there exists $\mu > 0$ such that*

$$\xi^T \sigma(x) \sigma^T(x) \xi \ge \mu |\xi|^2 \qquad \text{for all } (x,\xi) \in \overline{G} \times \Re^n.$$

Note that the last assumption implies that σ is Lipschitz on $\overline{G}$ with some constant $K_\sigma < \infty$.

Let $\mathcal{U}_\nu$ be the set of F_t-progressively measurable control processes with values in U with respect to the reference probability system $\nu = (\Omega, \{F_t\}, P, B)$ (see [18]). Although X^ε and τ^ε depend on $u \in \mathcal{U}_\nu$, we omit this dependence from the notation. Define

$$\Phi^\varepsilon(x) \doteq \inf_{u \in \mathcal{U}_\nu} E_x \exp\left[-\theta \tau^\varepsilon / \varepsilon\right],$$

where θ is a positive constant, $\tau^\varepsilon \doteq \inf\{t : X_t^\varepsilon \notin G\}$, and E_x indicates expectation conditioned on an initial state x. As is well known (and easy to prove using a large deviation calculation), for each fixed control the quantity

$$E_x \exp\left[-\theta \tau^\varepsilon / \varepsilon\right]$$

scales exponentially in ε as $\varepsilon \to 0$, in the sense that for each $x \in G$ there exists $c(x) \in \mathbb{R}$ such that

$$-\varepsilon \log E_x \exp\left[-\theta \tau^\varepsilon / \varepsilon\right] \to c(x)$$

as $\varepsilon \to 0$.

Thus it is natural to apply a logarithmic transform (see, e.g., [13, 18]) and consider a criterion of the form

$$V^\varepsilon(x) \doteq -\varepsilon \log \Phi^\varepsilon(x) = \sup_{u \in \mathcal{U}_\nu} -\varepsilon \log E_x \exp\left[-\theta \tau^\varepsilon / \varepsilon\right]. \tag{4.2}$$

(As noted in section 3, the cost in (4.2) is similar to $E_x\{\theta\tau\}$ but with the insertion of a risk-sensitizing transformation.) Starting with the quasi-linear PDE satisfied by Φ^ε and taking the log transform, one formally obtains the PDE

$$\begin{aligned} &\theta + \frac{\varepsilon}{2} \operatorname{tr}\left[a(x) V_{xx}(x)\right] + H(x, V_x(x)) = 0, \quad x \in G, \\ &V(x) = 0, \qquad\qquad\qquad\qquad\qquad\qquad\quad x \in \partial G, \end{aligned} \tag{4.3}$$

with

$$H(x,p) \doteq \max_{v \in U} \langle f(x,v), p \rangle - \frac{1}{2} \langle p, a(x) p \rangle, \tag{4.4}$$

and $a(x) \doteq \sigma(x) \sigma^T(x)$.

Criterion (4.2) is analogous to the risk-sensitive criteria applied in many stochastic control problems (see [14, 15, 16, 23, 27, 29], among others). The following results support this interpretation. The first lemma is standard (see, e.g., [18, Theorem 15.18]).

LEMMA 4.1. *There exists a solution* $\widetilde{V}^\varepsilon \in C^2(G) \cap C^0(\overline{G})$ *to* (4.3).

Define the cost for a fixed control $u \in \mathcal{U}_\nu$ by

$$J^\varepsilon(x,u) \doteq -\varepsilon \log E_x \exp\left[-\theta\tau^\varepsilon/\varepsilon\right].$$

THEOREM 4.2. *Given any* $x \in \overline{G}$ *and* $u \in \mathcal{U}_\nu$ $\widetilde{V}^\varepsilon(x) \geq J^\varepsilon(x,u)$. *Let* $\bar{u}$ *be a Borel measurable function such that*

$$\bar{u}(x) \in \operatorname{argmax}_{v\in U}\langle f(x,v), \widetilde{V}^\varepsilon_x(x)\rangle,$$

and let $\bar{X}^\varepsilon$ *be a solution of* (4.1) *with* $u_t \doteq \bar{u}(\bar{X}^\varepsilon_t)$ [32]. *Then* u *is in* $\mathcal{U}_\nu$, *and* $\widetilde{V}^\varepsilon(x) = J^\varepsilon(x,u)$. *Consequently,* $V^\varepsilon(x) = \widetilde{V}^\varepsilon(x)$ *for all* $x \in \overline{G}$.

Although the proof of this assertion is delayed until section 6, we note here that Theorem 4.2 follows from Girsanov's Theorem and an application of Ito's rule.

For reasons discussed in section 3, we would like to determine the limit as $\varepsilon \downarrow 0$ for this problem. Two common techniques for proving convergence are based on large deviations ideas (see [8], among others) and viscosity solutions (see [19], among others). The first is a probabilistic method, while the second is a PDE approach. The viscosity solution approach is used here. Since it is assumed that the prelimit ($\varepsilon > 0$) problem is uniformly nondegenerate, the viscosity solution approach is relatively easy to apply. Before applying it we must obtain bounds on the behavior of V^ε which are uniform in $\varepsilon > 0$. These are supplied by the following two lemmas. Their proofs, which are given in section 6, are standard.

LEMMA 4.3. *There exists* $M_1 < \infty$ *such that* $0 \leq V^\varepsilon(x) \leq M_1$ *for all* $x \in \overline{G}$ *and all* $\varepsilon > 0$.

LEMMA 4.4. *Given any* $\varepsilon_0 < \infty$, *there exists* $M_2 < \infty$ *such that* $|V^\varepsilon(x) - V^\varepsilon(y)| \leq M_2|x-y|$ *for all* $x \in \partial G$, *all* $y \in \overline{G}$, *and all* $\varepsilon \in (0, \varepsilon_0)$.

As $\varepsilon \downarrow 0$, one formally obtains from (4.3) the limit PDE problem

$$\begin{aligned} -\theta - H(x, V_x(x)) &= 0, \quad x \in G, \\ V(x) &= 0, \qquad\qquad x \in \partial G, \end{aligned} \tag{4.5}$$

where H is given by (4.4). (The minus sign in (4.5) is a consequence of the definition of viscosity solutions used in section 5.) In section 5 we will prove the existence of a unique continuous viscosity solution to (4.5) which satisfies the boundary condition pointwise. Let this solution be denoted by W. In that section we will also apply the method of Barles and Perthame [2, 18] to show that

$$\lim_{\varepsilon\downarrow 0} V^\varepsilon(x) = W(x) \qquad \forall\, x \in \overline{G}. \tag{4.6}$$

The cited method does not require gradient bounds which are uniform in $\varepsilon > 0$ and $x \in \overline{G}$, and in fact such bounds are only needed on the boundary (Lemma 4.4). Define

$$\begin{aligned} V^*(x) &\doteq \limsup\{V^\varepsilon(y) : \ y \to x, \ \varepsilon \downarrow 0, \ y \in \overline{G}\}, \\ V_*(x) &\doteq \liminf\{V^\varepsilon(y) : \ y \to x, \ \varepsilon \downarrow 0, \ y \in \overline{G}\}. \end{aligned} \tag{4.7}$$

It follows from Lemma 4.4 that

$$V^*(x) = 0 = V_*(x) \qquad \forall\, x \in \partial G.$$

Because $W(x) = 0$ for all $x \in \partial G$, one also has

$$V^*(x) = V_*(x) = W(x) \qquad \forall\, x \in \partial G. \tag{4.8}$$

Since a consequence of the definitions given in (4.7) is

$$V^*(x) \geq V_*(x) \qquad \forall\, x \in G,$$

to prove (4.6) it suffices to show

$$V^*(x) \leq W(x) \leq V_*(x) \qquad \forall\, x \in \overline{G}.$$

The proof of this last statement is delayed until section 6. However, it immediately implies the following.

THEOREM 4.5. *$V^\varepsilon(x) \to W(x)$ uniformly on $\overline{G}$.*

Thus one has the characterization of the limit of the value function as a continuous viscosity solution to (4.5). Furthermore, the comparison result at the heart of the proof of Theorem 4.5 also implies uniqueness of the solution of (4.5) among the class of continuous viscosity solutions. In section 5 it will be shown that W is the value of the deterministic game that corresponds to the associated robust control problem. (In the case where there is no control in the risk-sensitive problem, W is simply the value of a deterministic minimizing control problem rather than a game.) This game serves two roles. In the small noise problem it provides a convenient starting point for the analysis and construction of controls for the prelimit problem. It will also serve as the starting point for the interpretation of the maximizing control in the game as a robust control. In this paper we will only use W in the latter role. For an example of how it can be used in the first role, we refer to [8].

5. The robust limit problem. In this section we consider the robust problem corresponding to the limit $\varepsilon \to 0$. The term robust is used here to denote a system where the effect on the system output due to a given disturbance is bounded by a function of the power of that disturbance. This notion takes different forms in different contexts. The most well-known example is H^∞ control. In the state-space formulation, a system is said to satisfy an H^∞ bound if there exists a bound on the L^2 norm of an output in the form of a product of disturbance attenuation constant and the L^2 norm of the disturbance. This H^∞ disturbance attenuation control problem may be formulated as a deterministic differential game. The robust (maximizing) control escape time problem will also be formulated as a game. In particular, the maximizing player in the game will correspond to the original maximizing control, and an opposing player will be introduced who will try to minimize the same payoff. In the robust problem, the "noise" is a process chosen by this new minimizing player, rather than a stochastic process. The player will select the noise so as to drive the process from the set G, but must pay a quadratic cost. Since there is only one player for the case without maximizing control (i.e., the performance evaluation or parameter optimization problems discussed in section 1), the robust formulation in this case is a control problem rather than a game.

In the analysis of the limit problem the case with no control is significantly easier than the case with a maximizing controller. To simplify the presentation, we consider these two cases separately.

5.1. The case without control. Consider the deterministic dynamics

$$\frac{dY_t}{dt} = f(Y_t) + \sigma(Y_t)w_t, \qquad Y_0 = x \tag{5.1}$$

for $t \in [0, \tau]$, where $\tau \doteq \inf\{t : Y_t \notin G\}$. The functions f and σ are those introduced in section 4. Note that the disturbance w is now a deterministic process. The function w is assumed to be in

$$\mathcal{W}^0 \doteq \left\{ w : [0,\infty) \to \Re^m : w \text{ is measurable and } \int_0^T |w_t|^2 dt < \infty \text{ for all } T < \infty \right\}.$$

The cost criterion takes the form

$$J(x,w) \doteq \int_0^\tau \left[\theta + \frac{1}{2}|w_t|^2\right] dt, \tag{5.2}$$

where again $\theta > 0$ is a constant. The control problem which will yield the robust value, $\widetilde{W}$, is

$$\widetilde{W}(x) \doteq \inf_{w \in \mathcal{W}^0} J(x,w). \tag{5.3}$$

The Hamilton–Jacobi–Bellman (HJB) equation corresponding to control problem (5.1)–(5.3) is

$$-\theta - H_{\rm nc}(x, W_x(x)) = 0, \quad x \in G, \qquad W(x) = 0, \quad x \in \partial G\ , \tag{5.4}$$

where

$$H_{\rm nc}(x,p) \doteq \langle f(x), p\rangle + \min_{w \in \Re^m} \left[\langle \sigma(x)w, p\rangle + \frac{1}{2}|w|^2\right].$$

Evaluation of the minimum yields

$$H_{\rm nc}(x,p) = \langle f(x), p\rangle - \frac{1}{2}\langle p, a(x)p\rangle.$$

Hence (5.4) is the same as (4.5) for the case with no (maximizing) control. For easy reference, we recall the definition of viscosity solution that is appropriate for our problem. $W \in C(\overline{G})$ is a continuous viscosity subsolution of (5.4) if

$$-\theta - H_{\rm nc}(x_0, g_x(x_0)) \le 0$$

whenever $g \in C^1(G)$ and $W - g$ attains a maximum at $x_0 \in G$. $W \in C(\overline{G})$ is a continuous viscosity supersolution of (5.4) if

$$-\theta - H_{\rm nc}(x_0, g_x(x_0)) \ge 0$$

whenever $g \in C^1(G)$ and $W - g$ attains a minimum at $x_0 \in G$. If W is both a subsolution and a supersolution, then it is a solution. Due to the nondegeneracy (Condition 4.3), it is not necessary to formulate the boundary conditions in the viscosity framework; only solutions satisfying the boundary conditions pointwise will be considered. In particular, all assertions of uniqueness are within the class of continuous viscosity solutions satisfying the boundary conditions pointwise. (For modifications relevant

to extending the proof of Theorem 4.5 to viscosity solutions satisfying the weaker viscosity form of the boundary conditions, see [18, section 7.8].)

THEOREM 5.1. *$\widetilde{W}$ is the unique continuous viscosity solution of* (5.4).

Proof. Theorem 5.1 is just a variant of what are by now standard results. With this in mind, only an outline of the proof is provided.

First note that there exists $M_3 < \infty$ such that

$$0 \leq \inf_{w \in \mathcal{W}^0} J(x,w) \leq M_3$$

for all $x \in \overline{G}$. This follows from the fact that one can choose a constant control w which guarantees exit prior to some fixed time T, where T is independent of x. The nonnegativity of θ then implies the existence of $C < \infty$ such that $\int_0^\tau |w_s|^2 ds \leq C$ for all $x \in \overline{G}$ and all w such that $J(x,w) \leq \widetilde{W}(x) + 1$. Thus,

$$\widetilde{W}(x) = \inf_{w \in \mathcal{W}_b^0} J(x,w)$$

where

$$\mathcal{W}_b^0 \doteq \left\{ w \in \mathcal{W}^0 : \ \|w\|_{L^2(0,\infty)} \leq C \right\}.$$

The bounds on f and σ imply that given $\delta > 0$ there is an $\eta > 0$ such that

$$|Y_t - x| \leq \delta \qquad \forall\, t \in [0,\eta], \ \ \forall\, w \in \mathcal{W}_b^0 \tag{5.5}$$

and also such that for all $w \in \mathcal{W}_b^0$, $\tau = \tau(x,w)$ is bounded from below by a function $h(x)$ that is strictly positive on G.

Dynamic programming principles for $\widetilde{W}$ are easily obtained, and in fact are contained as special cases of the corresponding results in the next subsection. In particular, one has

$$\widetilde{W}(x) = \inf_{w \in \mathcal{W}_b^0} \left[\int_0^{T \wedge \tau} \left(\theta + \frac{1}{2}|w_t|^2 \right) dt + \widetilde{W}(Y_{T \wedge \tau}) \right]$$

for all $x \in G$ and $T \in [0,\infty)$, and

$$\widetilde{W}(x) \leq \inf_{w \in \widehat{\mathcal{W}}_m^0} \left[\int_0^{T \wedge \tau} \left(\theta + \frac{1}{2}|w_t|^2 \right) dt + \widetilde{W}(Y_{T \wedge \tau}) \right]$$

for all $x \in G$, $T \in [0,\infty)$, and $m \in (0,\infty)$, where

$$\widehat{\mathcal{W}}_m^0 \doteq \left\{ w \in \mathcal{W}^0 : |w_t| \leq m \ \forall\, t \right\}.$$

The last two paragraphs provide all that is needed for the proof of Theorem 5.1. The continuity of $\widetilde{W}$ follows from the nondegeneracy of σ and the boundedness of f. In particular, these properties imply that given $\delta > 0$ there exists $\varepsilon > 0$ such that for any point y within ε of x, one can construct a control that moves Y_t from x to y with cost less than δ and in time less than δ. This in turn implies the continuity. Uniqueness (among the class of continuous viscosity solutions satisfying the boundary conditions pointwise) follows from the comparison principle used in the proof of Theorem 4.5 (cf.

section 6.1.4). The proof of the present theorem is completed by showing that $\widetilde{W}$ is both a viscosity subsolution and supersolution of (5.4).

We first prove that $\widetilde{W}$ is a viscosity supersolution to (5.4). Suppose that $g \in C^1(\overline{G})$ and that $\widetilde{W} - g$ has a local minimum at $x_0 \in G$. To prove that $\widetilde{W}$ is a viscosity supersolution, it must be shown that

$$-\theta - H_{\mathrm{nc}}(x_0, g_x(x_0)) \geq 0.$$

If this inequality is not valid, then there exists $\alpha > 0$ such that

$$\theta + H_{\mathrm{nc}}(x_0, g_x(x_0)) > \alpha.$$

By using (5.5), the definition of H_{nc}, and the uniform lower bound $\tau = \tau(x, w) \geq h(x) > 0$, it follows that there is $\eta_0 \in (0, \tau)$ such that for all $\eta \in (0, \eta_0)$ and $w \in \mathcal{W}_b^0$

$$\int_0^\eta \left\{ \theta + \frac{1}{2}|w_t|^2 + \langle f(Y_t) + \sigma(Y_t) w_t, g_x(Y_t) \rangle \right\} dt \geq \frac{\eta \alpha}{2} > 0, \tag{5.6}$$

where Y_t is given by (5.1) with initial condition x_0. However, because $\widetilde{W} - g$ has a local minimum at x_0, for sufficiently small $\eta \in (0, \eta_0)$,

$$\widetilde{W}(x_0) - g(x_0) \leq \widetilde{W}(Y_t) - g(Y_t) \qquad \forall\, t \in [0, \eta].$$

By the first dynamic programming principle above, this implies

$$\inf_{w \in \mathcal{W}_b^0} \left\{ \int_0^\eta \left[\theta + \frac{1}{2}|w_t|^2 \right] dt + g(Y_\eta) - g(x_0) \right\} \leq 0. \tag{5.7}$$

But (5.6) and (5.7) form a contradiction, and consequently $\widetilde{W}$ is a viscosity supersolution. The proof that $\widetilde{W}$ is a viscosity subsolution is analogous and employs the second dynamic programming principle above. Therefore $\widetilde{W}$ is a continuous viscosity solution.

5.2. Case with control. In this subsection we consider the following deterministic differential game. For $t \in [0, \tau]$ the dynamics are given by

$$\frac{dY_t}{dt} = f(Y_t, u_t) + \sigma(Y_t) w_t, \qquad Y_0 = x, \tag{5.8}$$

where τ is the time of first escape from G. The function u is the (deterministic) measurable control for the maximizing player, which takes values in U. Let this set of controls be denoted by $\mathcal{U}^0$. The function w is the deterministic control for the minimizing player, and we assume

$$w \in \mathcal{W}^0 \doteq \left\{ w : [0, \infty) \to \Re^m : w \text{ is measurable and } \int_0^T |w_t|^2 dt < \infty \text{ for all } T < \infty \right\}.$$

The Elliott–Kalton [10] definition of the game will be used, and consequently the set of strategies for each player must be defined. A strategy for the maximizing player is a mapping $\phi : \mathcal{W}^0 \to \mathcal{U}^0$ which is nonanticipating in the following sense. Let any $t \in [0, \infty)$ be given. If $w, \tilde{w} \in \mathcal{W}^0$ satisfy $w_r = \tilde{w}_r$ for a.e. $r \in [0, t]$, then we require $\phi[w]_r = \phi[\tilde{w}]_r$ for a.e. $r \in [0, t]$. We use Φ to denote the set of strategies for the

maximizing player. A strategy for the minimizing player is a mapping $\lambda : \mathcal{U}^0 \to \mathcal{W}^0$ which is nonanticipating in the analogous sense. Let Λ denote the set of strategies for the minimizing player. The payoff for the game is

$$J(x,u,w) \doteq \int_0^\tau \left[\theta + \frac{1}{2}|w_t|^2\right] dt.$$

The upper and lower values in the Elliott–Kalton sense are given by

$$\widetilde{W}(x) \doteq \sup_{\phi\in\Phi} \inf_{w\in\mathcal{W}^0} J(x,\phi[w],w) \text{ and } \widehat{W}(x) \doteq \inf_{\lambda\in\Lambda} \sup_{u\in\mathcal{U}^0} J(x,u,\lambda[u]).$$

If $\widetilde{W} = \widehat{W}$, then the game is said to have value.

The Isaacs equation corresponding to this game is given by

$$-\theta - H(x, W_x(x)) = 0, \quad x \in G, \qquad W(x) = 0, \quad x \in \partial G, \tag{5.9}$$

where

$$H(x,p) \doteq \max_{v\in U}\langle f(x,v),p\rangle + \min_{w\in\Re^m}\left[\langle\sigma(x)w,p\rangle + \frac{1}{2}|w|^2\right].$$

Evaluation of the minimum gives

$$H(x,p) = \max_{v\in U}\langle f(x,v),p\rangle - \frac{1}{2}\langle p, a(x)p\rangle.$$

We next show that the upper value, $\widetilde{W}$, is a continuous viscosity solution of (5.9). The same result holds for the lower value. For a fixed finite time horizon problem under stronger assumptions, Evans–Souganidis [11] showed that a class of deterministic differential games had value and that this common value function was a viscosity solution of the corresponding Isaacs equation. The method of proof was to first obtain the dynamic programming principle and then combine this relation with some arguments regarding the continuity of the state trajectories to prove that the value was the viscosity solution. In adapting this approach, some technical difficulties arise due to the unbounded controls for the minimizing player, the weaker assumptions on the dynamics and payoff, and the fact that this is not a fixed finite time horizon problem. Thus, some preliminary lemmas are necessary, as are some variations on the method of proof. In the statement and proofs of these lemmas, Y_t will denote the solution to (5.6) for the given controls and τ will be $\inf\{t : Y_t \notin G\}$.

LEMMA 5.2. *There exists $M_3 < \infty$ such that*

$$0 \le \inf_{w\in\mathcal{W}^0} J(x,\phi[w],w) \le M_3 \qquad \forall\,\phi\in\Phi,\ \forall\, x\in\overline{G}.$$

The proof of Lemma 5.2 will be delayed until section 6. The method is standard and involves the construction of a piecewise constant control $w.$ which guarantees exit prior to some fixed time T that is independent of x and ϕ. Since the control so constructed will also be bounded, the result will follow. We note that a similar approach is used in [5]. The following result is an immediate consequence of Lemma 5.2 and the form of the cost.

LEMMA 5.3. *Let $\varepsilon_0 > 0$ be fixed, and let M_3 satisfy the conclusion of Lemma* 5.2. *Then for all $x \in \overline{G}$, $\phi \in \Phi$, and any $\tilde{w}$ that satisfies*

$$J(x,\phi[\tilde{w}],\tilde{w}) \le \inf_{w\in\mathcal{W}^0} J(x,\phi[w],w) + \epsilon_0,$$

we have the bound

$$\int_0^\tau |\tilde{w}_t|^2\,dt \le 2(M_3+\epsilon_0).$$

Now let

$$\mathcal{W}_b^0 \dodoteq \left\{w \in \mathcal{W}^0 :\ \|w\|_{L^2(0,\infty)} \le 2(M_3+\epsilon_0)\right\},$$

and note that

$$\widetilde{W}(x) = \sup_{\phi\in\Phi}\inf_{w\in\mathcal{W}_b^0} J(x,\phi[w],w).$$

LEMMA 5.4. *Let $w \in \mathcal{W}_b^0$ and $u \in \mathcal{U}^0$ be given. Then there exist $B_1, B_2 < \infty$ such that*

$$|Y_t - x| \le B_1 t + B_2\sqrt{t} \qquad \forall\, t \in [0,\tau].$$

Proof. By (5.8)

$$|Y_t - x| \le \int_0^t |f(Y_r,u_r)|\,dr + \int_0^t |\sigma(Y_r)||w_r|\,dr.$$

Under Conditions 4.1 and 4.2, there exist $C_f, C_\sigma < \infty$ such that the right-hand side of this inequality is less than or equal to

$$C_f t + C_\sigma \int_0^t |w_r|\,dr.$$

According to Lemma 5.3 this can be bounded above by

$$C_f t + C_\sigma[2(M_3+\varepsilon_0)]^{1/2}\sqrt{t}. \qquad \square$$

From Lemma 5.4, one immediately obtains the following result.

LEMMA 5.5. *Let $x \in G$, $w \in \mathcal{W}_b^0$, and $u \in \mathcal{U}^0$ be given. Then*

$$B_1\tau + B_2\sqrt{\tau} \ge d(x, G^c).$$

Lemmas 5.2–5.5 serve to bound the controls for the minimizing player and demonstrate continuity of the state with respect to time. Next, dynamic programming principles will be obtained.

THEOREM 5.6.

$$\widetilde{W}(x) = \sup_{\phi\in\Phi}\inf_{w\in\mathcal{W}_b^0}\left[\int_0^{T\wedge\tau}\left(\theta + \frac{1}{2}|w_t|^2\right)\,dt + \widetilde{W}(Y_{T\wedge\tau})\right]$$

for all $x \in G$ and $T \in [0,\infty)$.

The proof of this theorem is standard and by now a little tedious; it will be delayed until section 6. The proof of the following variation on this theorem involves only simple modifications of the proof of Theorem 5.6.

THEOREM 5.7.

$$\widetilde{W}(x) \le \sup_{\phi\in\Phi}\inf_{w\in\widehat{\mathcal{W}}_m^0}\left[\int_0^{T\wedge\tau}\left(\theta + \frac{1}{2}|w_t|^2\right)\,dt + \widetilde{W}(Y_{T\wedge\tau})\right]$$

for all $x \in G$, $T \in [0,\infty)$ *and* $m > 0$, *where*

$$\widehat{\mathcal{W}}_m^0 \doteq \left\{ w \in \mathcal{W}^0 : |w_t| \le m \ \forall\, t \right\}.$$

Given the validity of these dynamic programming principles, one can prove that the upper value $\widetilde{W}$ is a continuous viscosity solution of the Isaacs equation (5.9). The next two lemmas imply certain semicontinuity properties of $\widetilde{W}(Y.)$ that are needed.

LEMMA 5.8. *Let* $g \in C^1(\overline{G})$ *satisfy*

$$0 > -\alpha \ge -\theta - H(x_0, g_x(x_0))$$

for some $x_0 \in G$ *and* $\alpha > 0$. *Then there exists* $\phi \in \Phi$ *and* $\eta_0 > 0$ *such that for all* $w \in \mathcal{W}_b^0$ *and all* $\eta \in (0, \eta_0)$,

$$\int_0^{\eta \wedge \tau} \left\{ \theta + \frac{1}{2}|w_t|^2 + \langle f(Y_t, \phi[w]_t) + \sigma(Y_t) w_t, g_x(Y_t) \rangle \right\} dt \ge \frac{\eta \alpha}{2},$$

where Y_t *is given by* (5.8) *with initial condition* x_0.

Proof. Define

$$F(x,u,w) \doteq \theta + \frac{1}{2}|w|^2 + \langle f(x,u) + \sigma(x)w, g_x(x) \rangle, \tag{5.10}$$

and let $u_0 \in \operatorname{argmax} F(x_0, u, w)$. Note that

$$\theta + H(x, g_x(x)) = \max_{u \in U} \min_{w \in \mathbb{R}^m} F(x,u,w)$$

and that u_0 is independent of w since the Isaacs condition is satisfied. The assumption on g and x_0 implies

$$F(x_0, u_0, w) \ge \theta + H(x_0, g_x(x_0)) \ge \alpha \qquad \forall\, w \in \Re^m.$$

Let $w \in \mathcal{W}_b^0$ and $\phi[w]_t \doteq u_0$. Then by Lemma 5.4 there exists $\eta > 0$ such that

$$F(Y_t, \phi[w]_t, w_t) \ge \frac{\alpha}{2}$$

for all $t \in [0, \eta]$ and $w \in \mathcal{W}_b^0$. Integrating and using Lemma 5.5 to assert that $\eta \wedge \tau = \eta$ for η sufficiently small yields the result. □

LEMMA 5.9. *Let* $g \in C^1(\overline{G})$ *satisfy*

$$0 < \alpha \le -\theta - H(x_0, g_x(x_0))$$

for some $x_0 \in G$ *and* $\alpha > 0$. *Then there exists* $\eta > 0$ *and a bounded* $w \in \mathcal{W}^0$ *such that for all* $\phi \in \Phi$

$$\int_0^{\eta \wedge \tau} \left\{ \theta + \frac{1}{2}|w_t|^2 + \langle f(Y_t, \phi[w]_t) + \sigma(Y_t) w_t, g_x(Y_t) \rangle \right\} dt \le -\frac{\eta \alpha}{2},$$

where Y_t *is given by* (5.8) *with initial condition* x_0.

The proof of Lemma 5.9 is very similar to that of Lemma 5.8. In particular, here one lets $w_t \doteq w^*$, where $w^* \in \operatorname{argmin} F(x_0, u, w)$, with F as given by (5.10) (note that w^* is independent of u).

The way is now clear for the main theorem of this subsection. The proof is delayed until section 6.

THEOREM 5.10. $\widetilde{W}$ *is the unique continuous viscosity solution of* (5.9).

5.3. Robust interpretation. After reviewing the nonlinear H^∞ disturbance attenuation problem, the analogous robust interpretation for the limit problem considered here will be presented. For the nonlinear H^∞ disturbance attenuation problem, one typically considers games with payoffs of the form

$$\int_0^T \left[L(X_t, u_t) - \gamma^2 |w_t|^2\right] \, dt,$$

where X is the state, u is the (true) control for the minimizing player, and w is the disturbance which becomes the control for the maximizing player. L is the running cost, and it is often taken to be a quadratic function. Further, one assumes an initial value for the state, $X_0 = x_0$, such that $L(x_0, 0) = 0$. If there exists a strategy for the minimizing player (ideally a feedback control leading to well-defined dynamics) such that the value of the game is zero for all T, then

$$\left[\int_0^T L(X_t, u_t)\, dt\right]^{1/2} \leq \gamma \|w\|_{L^2(0,T)} \qquad \forall\, T < \infty.$$

Thus there is a bound for the cost in the form of a product of the disturbance attenuation constant γ and the L^2 norm of the disturbance. This bound is valid for all time horizons and disturbances. See, for instance, [1, 3, 22, 24, 31].

For the escape time problem, large time averages do not make any sense, since it is the transient behavior that is of primary importance. Because we cannot eliminate escape entirely, the best one should hope for in the robust problem is a bound on the escape time in terms of the energy of the player representing the disturbance. Clearly, this bound will depend on the initial position of the controlled process. For the case without maximizing control, let

$$\overline{W}(x) \doteq \widetilde{W}(x) = \inf_{w \in \mathcal{W}^0} J(x, w) \qquad \forall\, x \in G.$$

(This new notation is being introduced so that both the controlled and uncontrolled cases can be treated together.) For the case with maximizing control, choose some (optimal or suboptimal) strategy ϕ_0 given in a feedback form such that the dynamics are well defined. Let $\overline{W}$ be the value of the game with this control, i.e.,

$$\overline{W}(x) \doteq \inf_{w \in \mathcal{W}^0} J(x, \phi_0[w], w) \qquad \forall\, x \in G.$$

Then by (5.1) and (5.2) in the case without control (or by their analogues in the case with maximizing control),

$$\overline{W}(x) \leq \left[\theta + \frac{1}{2\tau} \int_0^\tau |w_t|^2 \, dt\right] \tau \qquad \forall\, w \in L^2, \ \forall\, x \in G,$$

or

$$\tau \geq \frac{\overline{W}(x)}{\theta + \frac{1}{2\tau} \int_0^\tau |w_t|^2 \, dt} \qquad \forall\, w \in L^2, \ \forall\, x \in G. \tag{5.11}$$

Let

$$\mathcal{W}^P \doteq \left\{ w : [0, \infty) \to \mathbb{R}^m : w \text{ is measurable and } \frac{1}{T} \int_0^T |w_t|^2 \, dt \leq P \quad \forall\, T \in [0, \infty) \right\}.$$

Then (5.11) has the interpretation

$$\tau \geq \frac{\overline{W}(x)}{\theta + \frac{1}{2}P} \qquad \forall\, w \in \mathcal{W}^P,\ \forall\, x \in G.$$

This is a lower bound on the escape time as a function of the power of the input noise. It is analogous to the attenuation bound of H^∞ control.

6. Proofs. This section contains proofs for results that appeared in sections 4 and 5.

6.1. Proofs for section 4.

6.1.1. Proof of Theorem 4.2. Let $u \in \mathcal{U}_\nu$ and $x \in G$. By (4.1), for any bounded, F_t-progressively measurable process w, one has

$$\begin{aligned} X_t^\varepsilon &= x + \int_0^t f(X_r^\varepsilon, u_r)\, dr + \sqrt{\varepsilon} \int_0^t \sigma(X_r^\varepsilon)\, dB_r \\ &= x + \int_0^t [f(X_r^\varepsilon, u_r) + \sigma(X_r^\varepsilon) w_r]\, dr + \sqrt{\varepsilon} \int_0^t \sigma(X_r^\varepsilon)\, dB_r - \int_0^t \sigma(X_r^\varepsilon) w_r\, dr \\ &= x + \int_0^t [f(X_r^\varepsilon, u_r) + \sigma(X_r^\varepsilon) w_r]\, dr + \sqrt{\varepsilon} \int_0^t \sigma(X_r^\varepsilon)\, dB_r^0, \end{aligned} \tag{6.1}$$

where the last equality defines B^0.

Fix any $T < \infty$. We would like a probability measure P^0 under which B^0 is a Brownian motion. By Girsanov's theorem [25, p. 191], such a measure exists on (Ω, F_T). For any set A in F_T, this measure satisfies

$$P^0(A) = \int_A \exp\left[\sqrt{\frac{1}{\varepsilon}} \int_0^T \langle w_r,\, dB_r^0 \rangle + \frac{1}{2\varepsilon} \int_0^T |w_r|^2\, dr \right] P(d\omega).$$

In terms of this measure, we can write

$$E_x \exp\left[-\frac{\theta(\tau^\varepsilon \wedge T)}{\varepsilon} \right] = E_x^0 \exp \frac{1}{\varepsilon} \left[-\int_0^{\tau^\varepsilon \wedge T} \left(\theta + \frac{1}{2}|w_r|^2 \right) dr - \varepsilon^{1/2} \int_0^{\tau^\varepsilon \wedge T} \langle w_r,\, dB_r^0 \rangle \right]. \tag{6.2}$$

Since $\widetilde{V}^\varepsilon$ is a solution of the PDE (4.3), an application of Ito's rule with the new dynamics (6.1) gives

$$\begin{aligned} \widetilde{V}^\varepsilon(X_t^\varepsilon) - \widetilde{V}^\varepsilon(x) &= \int_0^t \left[\frac{\varepsilon}{2} \mathrm{tr} \left[a(X_r^\varepsilon) \widetilde{V}_{xx}^\varepsilon(X_r^\varepsilon) \right] + \langle f(X_r^\varepsilon, u_r), \widetilde{V}_x^\varepsilon(X_r^\varepsilon) \rangle \right. \\ &\quad \left. + \langle \sigma(X_r^\varepsilon) w_r, \widetilde{V}_x^\varepsilon(X_r^\varepsilon) \rangle \right] dr \\ &\quad + \varepsilon^{1/2} \int_0^t \langle \widetilde{V}_x^\varepsilon(X_r^\varepsilon), \sigma(X_r^\varepsilon) dB_r^0 \rangle \\ &\leq \int_0^t [-\theta + \frac{1}{2} \langle \widetilde{V}_x^\varepsilon(X_r^\varepsilon), a(X_r^\varepsilon) \widetilde{V}_x^\varepsilon(X_r^\varepsilon) \rangle + \langle \sigma(X_r^\varepsilon) w_r, \widetilde{V}_x^\varepsilon(X_r^\varepsilon) \rangle] \, dr \\ &\quad + \varepsilon^{1/2} \int_0^t \langle \widetilde{V}_x^\varepsilon(X_r^\varepsilon), \sigma(X_r^\varepsilon) dB_r^0 \rangle. \end{aligned} \tag{6.3}$$

If the disturbance process is taken to be $w_r = -\sigma^T(X_r^\varepsilon)\widetilde{V}_x^\varepsilon(X_r^\varepsilon)$, then (6.3) implies

$$\begin{aligned}\widetilde{V}^\varepsilon(X_t^\varepsilon) - \widetilde{V}^\varepsilon(x) &\le -\int_0^t \left(\theta + \frac{1}{2}|w_r|^2\right) dr + \varepsilon^{1/2}\int_0^t \langle \widetilde{V}_x^\varepsilon(X_r^\varepsilon), \sigma(X_r^\varepsilon) dB_r^0\rangle \\ &= -\int_0^t \left(\theta + \frac{1}{2}|w_r|^2\right) dr - \varepsilon^{1/2}\int_0^t \langle w_r,\, dB_r^0\rangle.\end{aligned} \tag{6.4}$$

Combining (6.2) and (6.4), one obtains

$$\begin{aligned}E_x \exp\left[-\frac{\theta(\tau^\varepsilon \wedge T)}{\varepsilon}\right] &\ge E_x^0 \exp\frac{1}{\varepsilon}[\widetilde{V}^\varepsilon(X^\varepsilon_{\tau^\varepsilon\wedge T}) - \widetilde{V}^\varepsilon(x)] \\ &= \exp\left[-\frac{1}{\varepsilon}\widetilde{V}^\varepsilon(x)\right] E_x^0 \exp\frac{1}{\varepsilon}\widetilde{V}^\varepsilon(X^\varepsilon_{\tau^\varepsilon\wedge T}).\end{aligned}$$

Note that $\widetilde{V}^\varepsilon(\cdot)$ is bounded on $\overline{G}$ and that $\widetilde{V}^\varepsilon(X^\varepsilon_{\tau^\varepsilon\wedge T}) \to 0$ in distribution under E_x^0 as $T \to \infty$. Sending $T \to \infty$ and applying the dominated convergence theorem to the left side of the last display gives

$$E_x \exp\left[-\frac{\theta\tau^\varepsilon}{\varepsilon}\right] \ge \exp\left[-\frac{1}{\varepsilon}\widetilde{V}^\varepsilon(x)\right],$$

which implies the first assertion of the theorem.

To obtain the second assertion, simply note that such a $\bar{u}$ exists (see, for example, [17]) and use $u_t = \bar{u}(\bar{X}_t^\varepsilon)$ to obtain equality in the argument above. □

6.1.2. Proof of Lemma 4.3. The bounds are obtained from standard applications of the comparison principle. In particular, for the lower bound, one compares with $Z(x) \doteq 0$. For the upper bound, one compares V^ε with $Z(x) \doteq A + q \cdot x$, where A and q are constants independent of ε. Using the uniform ellipticity, it is easy to show that for $|q|$ sufficiently large there exists $\delta > 0$ such that

$$0 > -\delta \ge \theta + \frac{\varepsilon}{2}\mathrm{tr}\,[a(x)Z_{xx}(x)] + H(x, Z_x(x)) \qquad \forall\, x \in G,\ \ \forall\, \varepsilon > 0.$$

Further, for A sufficiently large, $Z(x) \ge 0 = V^\varepsilon(x)$ for all $x \in \partial G$. The upper bound then follows from the comparison principle and the compactness of $\overline{G}$. □

6.1.3. Proof of Lemma 4.4. The barrier method (see, for instance, [21]) will be used. Fix $x_0 \in \partial G$ and note that by Lemma 4.3

$$V^\varepsilon(x) \ge 0 = V^\varepsilon(x_0) \qquad \forall\, x \in \overline{G}. \tag{6.5}$$

Recall Condition 4.1, which states that the uniform exterior sphere condition holds. This implies there exists r independent of x_0 and $y \in \overline{G}^c$ such that $|x_0 - y| = r$ and

$$B_r(y) \cap \overline{G} = \{x_0\}.$$

Fix this value of y, and define

$$Z(x) \doteq \alpha(|x - y| - r) \qquad \forall\, x \in \overline{G}, \tag{6.6}$$

where α is a positive constant that will be chosen independent of $\varepsilon \in (0, \varepsilon_0)$ and $x_0 \in \partial G$. By (6.5) and (6.6), it suffices to prove that

$$V^\varepsilon(x) \le Z(x) \qquad \forall\, x \in G,\ \ \forall\, \varepsilon \in (0, \varepsilon_0). \tag{6.7}$$

On the boundary, of course,

$$V^\varepsilon(x) = 0 \le Z(x). \tag{6.8}$$

In terms of $v_x \doteq \frac{x-y}{|x-y|} = \frac{1}{\alpha} Z_x(x)$,

$$\begin{aligned}
&\theta + \frac{\varepsilon}{2}\mathrm{tr}\,[a(x)Z_{xx}(x)] + H(x, Z_x(x)) \\
&\quad = \theta + \frac{\varepsilon}{2}\frac{\alpha}{|x-y|}\left[\mathrm{tr}(a(x)) - \langle v_x, a(x)v_x\rangle\right] + \alpha \max_{v\in U}\langle f(x,v), v_x\rangle - \frac{\alpha^2}{2}\langle v_x, a(x)v_x\rangle \\
&\quad \le \theta + \alpha\left\{\frac{\varepsilon}{2|x-y|}\left[C_a - \langle v_x, a(x)v_x\rangle\right] + C_f - \frac{\alpha}{2}\langle v_x, a(x)v_x\rangle\right\},
\end{aligned}$$

where

$$C_a \doteq \max_{x\in\overline{G}} |\mathrm{tr}(a(x))| \text{ and } C_f \doteq \max_{(x,v)\in\overline{G}\times U} |f(x,v)|.$$

Using the uniform ellipticity of a, for α sufficiently large we have

$$\theta + \frac{\varepsilon}{2}\mathrm{tr}\,[a(x)Z_{xx}(x)] + H(x, Z_x(x)) \le \theta + \alpha\left\{\frac{C_a\varepsilon}{2r} + C_f - \frac{\alpha}{2}\mu\right\} < 0 \tag{6.9}$$

for all $\varepsilon \in (0, \varepsilon_0)$ and $x_0 \in \partial G$. From (6.8), (6.9), and the comparison principle, one obtains (6.7). □

6.1.4. Proof of Theorem 4.5. We recall the definitions of V^* and V_* given in equation (4.7). As noted in section 4, it is sufficient to prove that

$$V^*(x) \le W(x) \le V_*(x) \qquad \forall\, x \in \overline{G}.$$

By a simple modification of the proof of [18, Prop. 7.6.1], one can show that V^* is a subsolution of (4.5) and V_* is a supersolution. In addition, Lemma 4.4 implies that the boundary conditions are achieved pointwise. We now show that $W \le V_*$ on G; the proof that $V^* \le W$ is similar and is thus omitted.

Let $\delta > 0$ and suppose

$$\tilde{a} \doteq \min_{x\in\overline{G}}\left[(1+\delta)V_*(x) - W(x)\right] < 0. \tag{6.10}$$

By (4.8) and the respective semicontinuity and continuity properties of V_* and $\widetilde{W}$, the minimum in (6.10) occurs at some point $\tilde{x} \in G$. Let

$$\phi^\eta(x,y) \doteq (1+\delta)V_*(x) - W(y) + \frac{1}{2\eta}|x-y|^2 \tag{6.11}$$

and

$$(x^\eta, y^\eta) \in \mathrm{argmin}\,\phi^\eta(x,y).$$

It is easy to see that

$$|x^\eta - y^\eta| \to 0 \ \text{ as } \ \eta \downarrow 0. \tag{6.12}$$

Further, since (x^η, y^η) minimizes ϕ^η,

$$\phi^\eta(x^\eta, y^\eta) \le \phi^\eta(x^\eta, x^\eta).$$

When combined with (6.11) this implies

$$\frac{|x^\eta - y^\eta|^2}{\eta} \le 2m_W(|x^\eta - y^\eta|),$$

where $m_W(\cdot)$ is the modulus of continuity of W over $\overline{G}$. Thus by (6.12)

$$\frac{|x^\eta - y^\eta|^2}{\eta} \to 0 \quad \text{as} \quad \eta \downarrow 0. \tag{6.13}$$

Since $\overline{G}$ is compact, there exists a sequence $\eta_k \downarrow 0$ and an $x^0 \in \overline{G}$ such that

$$x^{\eta_k} \to x^0 \text{ and } y^{\eta_k} \to x^0$$

as $k \to \infty$. To simplify the notation, we retain η as the index of this convergent sequence. By the choice of (x^η, y^η), (6.10), and (6.11),

$$\phi^\eta(x^\eta, y^\eta) \le \tilde{a} < 0 \qquad \forall\, \eta > 0.$$

Then by (6.13), the lower semicontinuity of V_*, and the continuity of W,

$$(1+\delta)V_*(x^0) - W(x^0) < 0. \tag{6.14}$$

If x^0 were in ∂G, then (6.14) would contradict (4.7) and (4.8). Therefore $x^0 \in G$, which implies that for η sufficiently small (in our reindexed subsequence)

$$x^\eta, y^\eta \in G.$$

Now let

$$\psi(x) \doteq \frac{1}{1+\delta}\left[W(y^\eta) - \frac{1}{2\eta}|x - y^\eta|^2\right]$$

and note that $V_* - \psi$ has a minimum at x^η. Since V_* is a supersolution, one has

$$-\theta - H(x^\eta, \psi_x(x^\eta)) \ge 0,$$

which implies

$$-(1+\delta)\theta \ge \frac{1}{\eta}\max_{v\in U}\langle -f(x^\eta, v), (x^\eta - y^\eta)\rangle - \frac{1}{2\eta^2(1+\delta)}\langle (x^\eta - y^\eta), a(x^\eta)(x^\eta - y^\eta)\rangle.$$

(6.15)

Also, let

$$\widetilde{\psi}(y) \doteq (1+\delta)V_*(x^\eta) + \frac{1}{2\eta}|x^\eta - y|^2,$$

which implies that $W - \widetilde{\psi}$ has a maximum at y^η. Since W is a subsolution (as well as a supersolution), one has

$$-\theta - H(y^\eta, \widetilde{\psi}_x(y^\eta)) \le 0,$$

which implies

$$\theta \geq -\frac{1}{\eta}\max_{v\in U}\langle -f(y^\eta, v), (x^\eta - y^\eta)\rangle + \frac{1}{2\eta^2}\langle (x^\eta - y^\eta), a(y^\eta)(x^\eta - y^\eta)\rangle. \tag{6.16}$$

Adding (6.15) and (6.16) yields

$$\begin{aligned} -\delta\theta \geq{}& \frac{1}{\eta}\max_{v\in U}\langle -f(x^\eta, v), (x^\eta - y^\eta)\rangle - \frac{1}{\eta}\max_{v\in U}\langle -f(y^\eta, v), (x^\eta - y^\eta)\rangle \\ &+ \frac{1}{2\eta^2}\left\langle (x^\eta - y^\eta), \left[a(y^\eta) - \frac{1}{1+\delta}a(x^\eta)\right](x^\eta - y^\eta)\right\rangle. \end{aligned} \tag{6.17}$$

Recall that by Conditions 4.2 and 4.3, f and a are Lipschitz continuous with constants K_f and K_a on $\overline{G}$, respectively. Consequently, (6.17) implies

$$\begin{aligned} -\delta\theta \geq{}& \frac{|x^\eta - y^\eta|^2}{2\eta^2}\left[-2\eta K_f - K_a|x^\eta - y^\eta|\right] \\ &+ \frac{1}{2\eta^2}\left\langle (x^\eta - y^\eta), \left(1 - \frac{1}{1+\delta}\right)a(x^\eta)(x^\eta - y^\eta)\right\rangle, \end{aligned}$$

and since a is uniformly elliptic with constant μ,

$$-\delta\theta \geq \frac{|x^\eta - y^\eta|^2}{2\eta^2}\left[-2\eta K_f - K_a|x^\eta - y^\eta| + \left(1 - \frac{1}{1+\delta}\right)\mu\right]. \tag{6.18}$$

But by (6.12), for η sufficiently small,

$$-2\eta K_f - K_a|x^\eta - y^\eta| + \left(1 - \frac{1}{1+\delta}\right)\mu > 0.$$

This implies that for η sufficiently small the right-hand side of (6.18) is nonnegative, which is a contradiction. Therefore, (6.10) is false, and consequently

$$\min_{x\in\overline{G}}(1+\delta)V_*(x) - W(x) \geq 0.$$

Since this is true for all $\delta > 0$, $W \leq V_*$ for all $x \in \overline{G}$. □

6.2. Proofs for section 5.

6.2.1. Proof of Lemma 5.2. Since the lower bound is obvious, only the upper bound will be considered. It is sufficient to prove that for each $\phi \in \Phi$ there exists $w \in \mathcal{W}^0$ such that $J(x, \phi[w], w) \leq M_3$. The control w will be constructed in a feedback fashion; the existence of an open loop w with the same values will be clear.

Let $b \in \Re^n$ be any vector with $|b| = 1$. Let $t_n = n\Delta$ for all nonnegative integers n where the value of Δ is yet to be specified. The control w will be constant over each interval $[t_n, t_{n+1})$. Let C_f be a bound for f over $\overline{G}$ and fix $\phi \in \Phi$. Define

$$w_t \doteq w^0 \qquad \forall\, t \in [t_0, t_1),$$

where $w^0 = 2C_f\sigma^{-1}(x)b$ and x is the initial state. Let the dynamics over $[t_0, t_1)$ be given by (5.8) with controls w and $\phi[w]$. Then for $t \in [t_0, t_1]$,

$$\begin{aligned} \langle Y_t - x, b\rangle &\geq -C_f t + 2C_f t + 2C_f\int_0^t \langle b, \left[\sigma(Y_r)\sigma^{-1}(x) - I\right]b\rangle\, dr \\ &\geq C_f t + 2C_f\int_0^t \langle b, \left[\sigma(Y_r) - \sigma(x)\right]\sigma^{-1}(x)b\rangle\, dr. \end{aligned} \tag{6.19}$$

But by Condition 4.3, there exists $\overline{m}_\sigma < \infty$ such that $\|\sigma^{-1}(x)\| \le \overline{m}_\sigma$ for all $x \in \overline{G}$. Further, since $\sigma \in C^1(\overline{G})$, it is Lipschitz on $\overline{G}$ with constant K_σ. Employing these bounds in (6.19) yields

$$\langle Y_t - x, b\rangle \ge C_f t - 2C_f \overline{m}_\sigma K_\sigma \int_0^t |Y_r - x|\, dr.$$

Since there exists $\overline{C}$ (depending on the bounds on f, σ, and σ^{-1}) such that $|Y_t - x| \le \overline{C}t$, one has

$$\langle Y_t - x, b\rangle \ge C_f t - C_f \overline{m}_\sigma K_\sigma \overline{C} t^2,$$

which implies that there is a $\Delta > 0$ (independent of x) such that

$$\langle Y_t - x, b\rangle \ge \frac{C_f}{2} t \qquad \forall\, t \in [0, \Delta]. \tag{6.20}$$

This is the desired choice for Δ.

Turning now to the second segment, let

$$w_t = w^1 \doteq 2C_f \sigma^{-1}(Y_{t_1}) b \qquad \forall\, t \in [t_1, t_2).$$

Proceeding as for the first segment, one finds

$$\langle Y_t - Y_{t_1}, b\rangle \ge \frac{C_f}{2}(t - t_1) \qquad \forall\, t \in [t_1, t_2]. \tag{6.21}$$

Combining (6.20) and (6.21) yields

$$\langle Y_{t_2} - x, b\rangle \ge 2\frac{C_f}{2}\Delta.$$

Continuing this process, one has

$$w_t = 2C_f \sigma^{-1}(Y_{t_n}) b \qquad \forall\, t \in [t_n, t_{n+1}]$$

and

$$\langle Y_{t_{n+1}} - x, b\rangle \ge (n+1)\frac{C_f}{2}\Delta \qquad \forall\, n.$$

Therefore,

$$\tau \le \frac{2\mathrm{diam}(\overline{G})}{C_f},$$

and consequently

$$M_3 \doteq \frac{2\mathrm{diam}(\overline{G})}{C_f}\left[\theta + \frac{1}{2}[2C_f\overline{m}_\sigma]^2\right] \ge J(x, \phi[w], w). \qquad \square$$

6.2.2. Proof of Theorem 5.6. The proof follows the standard form. The equality in the dynamic programming principle is obtained by proving inequalities in both directions. Let τ_x indicate the time to escape given the initial state x.

Define

$$R(x) \doteq \sup_{\phi\in\Phi}\inf_{w\in\mathcal{W}_b^0}\left[\int_0^{T\wedge\tau_x}\left(\theta+\frac{1}{2}|w_t|^2\right)\,dt+\widetilde{W}(Y_{T\wedge\tau_x})\right], \tag{6.22}$$

and let $\varepsilon\in(0,1]$. Then there exists $\widetilde{\phi}\in\Phi$ such that

$$R(x)\le\inf_{w\in\mathcal{W}_b^0}\left[\int_0^{T\wedge\tau_x}\left(\theta+\frac{1}{2}|w_t|^2\right)\,dt+\widetilde{W}(Y_{T\wedge\tau_x})\right]+\varepsilon \tag{6.23}$$

when $\widetilde{\phi}[w]$ is used to define Y in (5.8). For any $y\in G$,

$$\widetilde{W}(y)=\sup_{\phi\in\Phi}\inf_{w\in\mathcal{W}_b^0}\left[\int_0^{\tau_y}\left(\theta+\frac{1}{2}|w_t|^2\right)\,dt\right],$$

which implies there exists $\widetilde{\phi}'_y\in\Phi$ such that

$$\widetilde{W}(y)\le\inf_{w\in\mathcal{W}_b^0}\left[\int_0^{\tau_y}\left(\theta+\frac{1}{2}|w_t|^2\right)\,dt\right]+\varepsilon \tag{6.24}$$

when $\widetilde{\phi}'_y[w]$ is used in the dynamics (5.8).

Define a strategy $\widehat{\phi}$ as follows. For each $w\in\mathcal{W}_b^0$, let

$$\widehat{\phi}[w]_t\doteq\begin{cases}\widetilde{\phi}[w]_t & \text{if } t\le T,\\ \widetilde{\phi}'_{Y_T}[w_{\cdot-T}]_{t-T} & \text{if } t>T.\end{cases}$$

Note that $\widehat{\phi}\in\Phi$. (6.23) and (6.24) imply

$$R(x)\le\inf_{w^1\in\mathcal{W}_b^0}\inf_{w^2\in\mathcal{W}_b^0}\left[\int_0^{T\wedge\tau_x}\left(\theta+\frac{1}{2}|w_t^1|^2\right)\,dt\;+I(T<\tau_x)\int_T^{\hat{\tau}_{Y_T}}\left(\theta+\frac{1}{2}|w_t^2|^2\right)\,dt\right]+2\varepsilon,$$

where

$$Y_t=x+\int_0^t\left[f(Y_r,\widehat{\phi}[\widehat{w}]_r)+\sigma(Y_r)\widehat{w}_r\right]\,dr,$$

$$\widehat{w}_t\doteq\begin{cases}w_t^1 & \text{if } t\le T,\\ w_t^2 & \text{if } t>T,\end{cases}$$

and where $\hat{\tau}_y$ is the first escape time of Y_t after T given $Y_T=y$. This implies

$$R(x)\le\inf_{w\in\mathcal{W}_b^0}\left[\int_0^{\tau_x}\left(\theta+\frac{1}{2}|w_t|^2\right)\,dt\right]+2\varepsilon\le\sup_{\phi\in\Phi}\inf_{w\in\mathcal{W}_b^0}J(x,\phi[w],w)+2\varepsilon,$$

which, since $\varepsilon\in(0,1]$ was arbitrary, implies

$$R(x)\le\widetilde{W}(x).$$

Now the reverse inequality is proved. Given $\varepsilon > 0$, there exists $\widetilde{\phi} \in \Phi$ such that

$$\widetilde{W}(x) \le \inf_{w \in \mathcal{W}_b^0} \left[\int_0^{\tau_x} \left(\theta + \frac{1}{2}|w_t|^2 \right) dt \right] + \varepsilon \tag{6.25}$$

when $\widetilde{\phi}[w]$ is used in the dynamics. On the other hand, by (6.22),

$$R(x) \ge \inf_{w \in \mathcal{W}_b^0} \left[\int_0^{T \wedge \tau_x} \left(\theta + \frac{1}{2}|w_t|^2 \right) dt + \widetilde{W}(Y_{T \wedge \tau_x}) \right],$$

where again $\widetilde{\phi}[w]$ is being used in the dynamics. This implies there exists $\widetilde{w} \in \mathcal{W}_b^0$ such that

$$R(x) \ge \int_0^{T \wedge \tau_x} \left(\theta + \frac{1}{2}|\widetilde{w}_t|^2 \right) dt + \widetilde{W}(Y_{T \wedge \tau_x}) - \varepsilon. \tag{6.26}$$

If $T < \tau_x$ then we can continue to use the strategy $\tilde{\phi}$ for $t \ge T$. In this case, the definition of $\widetilde{W}$ implies the existence of $\hat{w}'_t$ defined on $[T, \infty)$ such that $\hat{w}'_{\cdot - T} \in \mathcal{W}_b^0$ and

$$\widetilde{W}(Y_{T \wedge \tau_x}) \ge \int_T^{\hat{\tau}_{Y_T}} \left(\theta + \frac{1}{2}|\hat{w}'_t|^2 \right) dt - \varepsilon. \tag{6.27}$$

Now let

$$\hat{w}_t = \begin{cases} \widetilde{w}_t & \text{if } t \le T, \\ \hat{w}'_t & \text{if } t > T. \end{cases}$$

Then (6.26) and (6.27) imply

$$R(x) \ge \int_0^{\tau_x} \left(\theta + \frac{1}{2}|\hat{w}_t|^2 \right) dt - 2\varepsilon$$

when the strategy $\tilde{\phi}$ is used. Equation (6.25) then implies $R(x) \ge \widetilde{W}(x) - 3\varepsilon$. Since $\varepsilon > 0$ was arbitrary, the proof is complete. □

6.2.3. Proof of Theorem 5.10. First note that continuity of $\widetilde{W}$ follows from Lemma 5.4 and constructions similar to those used in the proof of Lemma 5.2. Once it has been proved that $\widetilde{W}$ is a viscosity solution, the uniqueness will then follow from the comparison principle used in the proof of Theorem 4.5. Thus, it is sufficient to prove that $\widetilde{W}$ is a viscosity solution. This is done by proving that it is both a supersolution and a subsolution.

Suppose we are given $g \in C^1(\overline{G})$ such that $\widetilde{W} - g$ has a local minimum at $x_0 \in G$. To prove that $\widetilde{W}$ is a viscosity supersolution, it must be shown that

$$-\theta - H(x_0, g_x(x_0)) \ge 0.$$

If the last inequality is not valid, then there exists $\alpha > 0$ such that

$$-\alpha \ge -\theta - H(x_0, g_x(x_0)).$$

Then, by Lemmas 5.5 and 5.8, there exist $\phi \in \Phi$ and $\eta > 0$ such that for all $w \in \mathcal{W}_b^0$

$$\int_0^{\eta} \left\{ \theta + \frac{1}{2}|w_t|^2 + \langle [f(Y_t, \phi[w]_t) + \sigma(Y_t) w_t], g_x(Y_t) \rangle \right\} dt \ge \frac{\eta \alpha}{2},$$

where Y_t is given by (5.8) with initial condition x_0 and controls w and $\phi[w]$. This implies

$$\sup_{\phi\in\Phi}\inf_{w\in\mathcal{W}_b^0}\left[\int_0^\eta\left\{\theta+\frac{1}{2}|w_t|^2+\langle[f(Y_t,\phi[w]_t)+\sigma(Y_t)w_t],g_x(Y_t)\rangle\right\}dt\right]\geq\frac{\eta\alpha}{2}. \tag{6.28}$$

On the other hand, since $\widetilde{W}-g$ has a local minimum at x_0, Lemma 5.4 implies

$$\widetilde{W}(x_0)-g(x_0)\leq\widetilde{W}(Y_t)-g(Y_t)\qquad\forall\, t\leq\eta,\ \forall\,\phi\in\Phi,\ \forall\, w\in\mathcal{W}_b^0, \tag{6.29}$$

where $\eta>0$ may have to be reduced in size. Also, since η has been chosen so that $\tau\geq\eta$, Theorem 5.6 implies

$$\widetilde{W}(x_0)=\sup_{\phi\in\Phi}\inf_{w\in\mathcal{W}_b^0}\left[\int_0^\eta\left(\theta+\frac{1}{2}|w_t|^2\right)dt+\widetilde{W}(Y_\eta)\right]. \tag{6.30}$$

Substituting (6.29) into (6.30) yields

$$\begin{aligned}0&\geq\sup_{\phi\in\Phi}\inf_{w\in\mathcal{W}_b^0}\left[\int_0^\eta\left(\theta+\frac{1}{2}|w_t|^2\right)dt+g(Y_\eta)-g(x_0)\right]\\&=\sup_{\phi\in\Phi}\inf_{w\in\mathcal{W}_b^0}\left[\int_0^\eta\left\{\left(\theta+\frac{1}{2}|w_t|^2\right)+\langle[f(Y_t,\phi[w]_t)+\sigma(Y_t)w_t],g_x(Y_t)\rangle\right\}dt\right].\end{aligned} \tag{6.31}$$

But (6.28) and (6.31) form a contradiction. Therefore $\widetilde{W}$ is a supersolution.

The analogous proof that $\widetilde{W}$ is a subsolution is as follows. Consider $g\in C^1(\overline{G})$ such that $\widetilde{W}-g$ has a local maximum at $x_0\in G$. To prove that $\widetilde{W}$ is a subsolution, it must be shown that

$$-\theta-H(x_0,g_x(x_0))\leq 0.$$

If this inequality is not true, then there exists $\alpha>0$ such that

$$\alpha\leq-\theta-H(x_0,g_x(x_0)).$$

Then, by Lemmas 5.5 and 5.9, there exist a bounded $w\in\mathcal{W}^0$ and $\eta>0$ such that for all $\phi\in\Phi$

$$\int_0^\eta\left\{\theta+\frac{1}{2}|w_t|^2+\langle[f(Y_t,\phi[w]_t)+\sigma(Y_t)w_t],g_x(Y_t)\rangle\right\}dt\leq-\frac{\eta\alpha}{2},$$

where Y_t is given by (5.8) with initial condition x_0 and controls w and $\phi[w]$. This implies

$$\sup_{\phi\in\Phi}\inf_{w\in\mathcal{W}_*^0}\left[\int_0^\eta\left\{\theta+\frac{1}{2}|w_t|^2+\langle[f(Y_t,\phi[w]_t)+\sigma(Y_t)w_t],g_x(Y_t)\rangle\right\}dt\right]\leq-\frac{\eta\alpha}{2}, \tag{6.32}$$

where $\mathcal{W}_*^0=\{w\in\mathcal{W}^0:\,|w_t|\leq M_*\ \forall\, t\}$ and M_* is the bound on the function w whose existence is asserted in Lemma 5.9.

On the other hand, since $\widetilde{W}-g$ has a local maximum at x_0, Lemma 5.4 implies

$$\widetilde{W}(x_0)-g(x_0)\geq\widetilde{W}(Y_t)-g(Y_t)\qquad\forall\, t\leq\eta,\ \forall\,\phi\in\Phi,\ \forall\, w\in\mathcal{W}_*^0, \tag{6.33}$$

where $\eta > 0$ may have to be reduced in size. Also, from Theorem 5.7,

$$\widetilde{W}(x_0) \le \sup_{\phi\in\Phi}\inf_{w\in\mathcal{W}^0_*}\left[\int_0^\eta \left(\theta + \frac{1}{2}|w_t|^2\right)\,dt + \widetilde{W}(Y_\eta)\right]. \tag{6.34}$$

Combining (6.33) and (6.34) yields

$$\begin{aligned} 0 &\le \sup_{\phi\in\Phi}\inf_{w\in\mathcal{W}^0_*}\left[\int_0^\eta \left(\theta + \frac{1}{2}|w_t|^2\right)\,dt + g(Y_\eta) - g(x_0)\right] \\ &= \sup_{\phi\in\Phi}\inf_{w\in\mathcal{W}^0_*}\left[\int_0^\eta \left\{\left(\theta + \frac{1}{2}|w_t|^2\right) + \langle [f(Y_t,\phi[w]_t) + \sigma(Y_t)w_t], g_x(Y_t)\rangle\right\}\,dt\right]. \end{aligned} \tag{6.35}$$

But (6.32) and (6.35) form a contradiction. Therefore $\widetilde{W}$ is a subsolution. ∎

BOLZA PROBLEMS WITH GENERAL TIME CONSTRAINTS*

P. D. LOEWEN† AND R. T. ROCKAFELLAR‡

Abstract. This work provides necessary conditions for optimality in problems of optimal control expressed as instances of the generalized problem of Bolza, with the added feature that the fundamental planning interval is allowed to vary. A central product of the analysis is a generalization of the conservation-of-Hamiltonian condition for problems on either fixed or variable intervals. The results, which allow for unprecedented generality in the problem data, are derived from known properties of fixed-interval problems under the hypothesis that the time-dependence of the objective integrand has the same modest level of regularity as the state-dependence.

Key words. optimal control, calculus of variations, Bolza problem, free time, minimum-time problem, Erdmann condition, Euler–Lagrange condition, Hamiltonian condition, transversality condition, nonsmooth analysis

1. Introduction.

This paper provides necessary conditions for local optimality in a general optimal control problem where the endpoints of the underlying time interval are choice variables. The problem is to choose a nondegenerate interval $[a, b]$ and an absolutely continuous function (or *arc*) $x\colon [a, b] \to \mathbb{R}^n$ in such a way as to

$$\text{(P)} \qquad \text{minimize} \quad l(a, x(a), b, x(b)) + \int_a^b L(t, x(t), \dot{x}(t))\, dt.$$

The usefulness of this simple-looking model is directly correlated to the mildness of the hypotheses under which conclusive results can be obtained. In the current work, both the endpoint cost l and the integrand L are allowed to be nondifferentiable and even to take the value $+\infty$. These features allow for enormous flexibility in modeling applied problems—in particular, a wide range of differential and endpoint constraints can be introduced implicitly by encoding them in l and L.

The introduction of extended-real-valued functionals as practical modeling tools in dynamic optimization can be traced to the early work of Rockafellar [17] in the convex case. Many authors have since addressed the technical challenges raised in this context: we mention in particular Rockafellar [18, 19] and Clarke [3, 4]. The hypotheses in this paper are in some respects weaker than those of Clarke [4] and moreover allow for a variable time interval. We handle this additional complication by using the classical Erdmann transform to reduce (P) to a fixed-time problem in which the time plays the role of an additional state variable. This forces us to assume a degree of regularity in the problem's time-dependence that matches what we require on the state-dependence. Clarke, Loewen, and Vinter [7], using other methods, have

discussed optimality conditions for related problems in which the time-dependence is merely measurable.

Our most general assertions about minimizers in problem (P) appear in Theorem 1.1 below. The remainder of section 1 is devoted to clarifying the scope and content of this result. In section 2 we review the implications of these developments for a special case of (P) arising frequently in practice, while in section 3 we explain how the hypotheses of Theorem 1.1 can be weakened in the presence of additional structure on the problem data. The technical details of most proofs are assembled in section 4. Finally, in section 5 we sketch the modifications required when unilateral state constraints are imposed on the basic problem.

1.1. Subgradients and normals. We will treat instances of (P) whose data lie well beyond the scope of classical first-order approximations. Thus the terminology and methods of nonsmooth analysis will be needed throughout. In this work, the symbols $\partial f(x)$ and $\partial^\infty f(x)$ stand for the sets of *limiting proximal subgradients* and *singular limiting proximal subgradients* associated with an extended-valued function $f\colon \mathbb{R}^m \to \mathbb{R}\cup\{\infty\}$ at a point x such that $f(x)$ is finite and the epigraph of f is locally closed near $(x, f(x))$. Given a closed set S, we will write Ψ_S for the corresponding *indicator function,* which equals 0 at points in S and $+\infty$ elsewhere. The set of *limiting proximal normals* associated with S at a point $s \in S$ will be denoted by $N_S(s)$; note $N_S(s) = \partial\Psi_S(s) = \partial^\infty\Psi_S(s)$. For simplicity, we refer to these limiting objects simply as "subgradients," "singular subgradients," and "normals"; further discussion of their constructions and relationships to other fundamental objects is now widely available (e.g., [5], [10], [15]). However, we will often refer to the basic relationships

$$\begin{aligned} \partial f(x) &= \{\xi \,:\, (\xi,-1) \in N_{\operatorname{epi} f}(x, f(x))\}, \\ \partial^\infty f(x) &= \{\xi \,:\, (\xi,0) \in N_{\operatorname{epi} f}(x, f(x))\}. \end{aligned} \tag{1.1}$$

We will write $\mathbb{B}$ for the *closed* unit ball centered at the origin in various Euclidean spaces distinguished by the context.

1.2. Hypotheses. An arc $\overline{x}$ is given, together with its associated interval of definition $[\overline{a}, \overline{b}]$; one has $\overline{b} - \overline{a} > 0$. For some $\rho > 0$, the open set

$$\Omega = \big\{(t,x) \,:\, |(t,x) - (r, \overline{x}(r))| < \rho \text{ for some } r \in [\overline{a}, \overline{b}]\big\}, \tag{1.2}$$

with sections $\Omega_t = \{x \,:\, (t,x) \in \Omega\}$, is one in which the data of problem (P) satisfy hypotheses (H1)–(H4) below. These conditions refer to the *Hamiltonian* $H\colon \Omega \times \mathbb{R}^n \to \mathbb{R}\cup\{\infty\}$, defined by

$$H(t,x,p) := \sup\{\langle p\,,\, v\rangle - L(t,x,v) \,:\, v \in \mathbb{R}^n\}. \tag{1.3}$$

In (H4) and throughout the paper, we use the shorthand $\overline{L}(t) := L\big(t, \overline{x}(t), \dot{\overline{x}}(t)\big)$.

(H1) The endpoint cost $l\colon \mathbb{R}\times\mathbb{R}^n\times\mathbb{R}\times\mathbb{R}^n \to \mathbb{R}\cup\{\infty\}$ is lower semicontinuous on the set $\big\{(a,x,b,y) \,:\, |(a,x) - (\overline{a}, \overline{x}(\overline{a}))| < \rho,\ \big|(b,y) - (\overline{b}, \overline{x}(\overline{b}))\big| < \rho\big\}$.

(H2) For each fixed (t,x) in Ω, the function $v \mapsto L(t,x,v)$ is convex on $\mathbb{R}^n$.

(H3) The function L is lower semicontinuous on $\Omega\times\mathbb{R}^n$ and epicontinuous in (t,x): that is, for any point (t,x,v) in $\Omega\times\mathbb{R}^n$ where $L(t,x,v)$ is finite, and any sequence $(t_k, x_k) \to (t,x)$, there exists a sequence $v_k \to v$ along which $L(t_k, x_k, v_k) \to L(t,x,v)$.

(H4) There are positive constants δ and κ such that the following statement is true for almost every t in $[\overline{a}, \overline{b}]$: for every point (r,x,v) in $\Omega\times\mathbb{R}^n$ satisfying the three conditions

(i) $|(r,x)-(t,\overline{x}(t))\,|<\rho$,
(ii) $\big|v-\dot{\overline{x}}(t)\big|<\delta\big[1+\big|\dot{\overline{x}}(t)\big|\big]$,
(iii) $\big|L(r,x,v)-L(t,\overline{x}(t),\dot{\overline{x}}(t))\big|<\delta\big[1+\big|L(t,\overline{x}(t),\dot{\overline{x}}(t))\big|\big]$,
one has the subgradient inequality

$$|(u,w)|\le\kappa[1+|p|+|H(r,x,p)|]\qquad\forall(u,w,p)\in\partial L(r,x,v).$$

To understand (H2)–(H4), consider this multifunction $E\colon\Omega\rightrightarrows\mathbb{R}^n\times\mathbb{R}$:

$$E(t,x):=\operatorname{epi}L(t,x,\,\cdot\,)=\{(v,\gamma)\,:\,\gamma\ge L(t,x,v)\}\,.$$

Note that a scalar arc y obeys $y(t)\ge y(a)+\int_a^t L(r,x(r),\dot{x}(r))\,dr$ if and only if $(\dot{x}(t),\dot{y}(t))\in E(t,x(t))$ a.e. This observation furnishes a link between the objective values in (P) and the endpoint values of trajectories for the differential inclusion based on E: this reformulation, detailed in [13], provides for a geometric perspective on the hypotheses.

Hypothesis (H2), together with the lower semicontinuity part of (H3), ensures that the set $E(t,x)$ is closed and convex for every (t,x)—an important condition in the existence theory for problem (P).

Hypothesis (H3) is equivalent to the requirement that the multifunction E be continuous on Ω, in the sense that for every (t,x) in Ω

$$\liminf_{(t',x')\to(t,x)}E(t',x')\supseteq E(t,x)\supseteq\limsup_{(t',x')\to(t,x)}E(t',x')\,. \tag{1.4}$$

As a consequence of Wijsman's theorem, which asserts that the correspondence between Lagrangian and Hamiltonian under the Legendre–Fenchel transform preserves epicontinuity, we can express (H3) in three equivalent ways (cf. [22, Prop. 2.1]):

(i) The (closed) set $\operatorname{epi}L(t,x,\,\cdot\,)$ depends continuously on (t,x) in Ω.
(ii) The (closed) set $\operatorname{epi}H(t,x,\,\cdot\,)$ depends continuously on (t,x) in Ω.
(iii) The function H is lower semicontinuous on $\Omega\times\mathbb{R}^n$, and epicontinuous in (t,x): that is, for any point (t,x,p) in $\Omega\times\mathbb{R}^n$ at which H is finite and for any sequence $(t_k,x_k)\to(t,x)$, there is a sequence $p_k\to p$ along which $H(t_k,x_k,p_k)\to H(t,x,p)$.

This equivalence reveals an appealing symmetry between the requirements on L and H.

Hypothesis (H4) is a subgradient sufficient condition for the multifunction E to display a type of Lipschitz continuity around the points $\big(t,\overline{x}(t),\dot{\overline{x}}(t),\overline{L}(t)\big)$. The continuity property we require was introduced for general multifunctions by Aubin [2]; in our context, we require that the graph of $\overline{x}$ have a neighborhood in which, for some constants R and K, one has

$$E(s,x)\cap\big(\big(\dot{\overline{x}}(t),\overline{L}(t)\big)+R\mathbb{B}\big)\subseteq E(t,y)+K|(s,x)-(t,y)|\mathbb{B}. \tag{1.5}$$

Mordukhovich [14] has shown that a necessary and sufficient condition for the validity of this "Aubin continuity property" near a given point $\big(t,\overline{x}(t),\dot{\overline{x}}(t),\overline{L}(t)\big)$ is that $|(u,w)|\le K|(p,-\lambda)|$ for all vectors $(u,w,p,-\lambda)$ normal to the set $\operatorname{gph}E=\operatorname{epi}L$ at points near $\big(t,\overline{x}(t),\dot{\overline{x}}(t),\overline{L}(t)\big)$. The subgradient inequality in (H4) arises from just such considerations (compare (1.1)), weakened somewhat thanks to the technical advantages of the Erdmann transform.

Another helpful perspective on (H4) is available if we consider the stronger hypothesis obtained by omitting the Hamiltonian term from the right side of the central

inequality. For any integrand L that satisfies the resulting condition with respect to $\overline{x}$, the same hypothesis holds (with a larger coefficient κ) for any integrand $L + G_1$ involving a function G_1 that is Lipschitz with respect to (t, x). This insensitivity to Lipschitzian perturbations reveals that the real job of (H4) is to regulate the integrand's non-Lipschitz dependence on (t, x), if any, near the nominal trajectory.

It is important to note that both (H3) and (H4) can be checked easily for several classes of integrand L. We describe some of these reductions in the discussion of special cases below, and we treat this matter more generally in section 3.

Local minimizers. Given an arc $\overline{x}$ and an open set Ω relative to which (H1)–(H4) hold, we will always consider problem (P) under the implicit constraint $x(t) \in \Omega$ for all t in $[a, b]$. Thus all of our results pertain to *strong local minimizers* in the basic problem. Here is the main theorem.

THEOREM 1.1. *Let the arc $\overline{x}$ with interval $[\overline{a}, \overline{b}]$ provide the minimum in problem* (P). *Assume* (H1)–(H4). *Then some arc (h, p) taking values in $\mathbb{R} \times \mathbb{R}^n$ satisfies either the normal conditions or the singular conditions below.*
Normal conditions:

(a) $\Big(\dot{h}(t), \dot{p}(t)\Big) \in \operatorname{co}\big\{(u, w) \,:\, (-u, w, p(t)) \in \partial L\big(t, \overline{x}(t), \dot{\overline{x}}(t)\big)\big\}$
$= \operatorname{co}\big\{(u, w) \,:\, \big(u, -w, \dot{\overline{x}}(t)\big) \in \partial H\big(t, \overline{x}(t), p(t)\big)\big\}$ *a.e.* $t \in [\overline{a}, \overline{b}]$.

(b) $h(t) = H(t, \overline{x}(t), p(t))$ *a.e.* $t \in [\overline{a}, \overline{b}]$ (*but see Proposition* 1.2);
$h(t) = \big\langle p(t)\,,\, \dot{\overline{x}}(t)\big\rangle - L\big(t, \overline{x}(t), \dot{\overline{x}}(t)\big)$ *a.e.* $t \in [\overline{a}, \overline{b}]$.

(c) $\big(-h(\overline{a}), p(\overline{a}), h(\overline{b}), -p(\overline{b})\big) \in \partial l\big(\overline{a}, \overline{x}(\overline{a}), \overline{b}, \overline{x}(\overline{b})\big)$.

Singular conditions: *One has $|(h(t), p(t))| > 0$ for all t in $[\overline{a}, \overline{b}]$, and*

(a^∞) $(\dot{h}(t), \dot{p}(t)) \in \operatorname{co}\big\{(u, w) \,:\, (-u, w, p(t)) \in \partial^\infty L(t, \overline{x}(t), \dot{\overline{x}}(t))\big\}$ *a.e.* $t \in [\overline{a}, \overline{b}]$.

(b^∞) $h(t) = \big\langle p(t)\,,\, \dot{\overline{x}}(t)\big\rangle$ *a.e.* $t \in [\overline{a}, \overline{b}]$.

(c^∞) $\big(-h(\overline{a}), p(\overline{a}), h(\overline{b}), -p(\overline{b})\big) \in \partial^\infty l\big(\overline{a}, \overline{x}(\overline{a}), \overline{b}, \overline{x}(\overline{b})\big)$.

In particular, if the only arc (h, p) satisfying conditions (a^∞)–(c^∞) *is identically zero, then the normal conditions must hold.*

The proof of Theorem 1.1 is given in section 4 below. Before discussing this technical development, we pause to emphasize some of the result's useful implications.

1.3. General time constraints. The formulation of (P) covers the full range of situations from the case of a fixed planning interval $[a, b] = [0, 1]$, through the situation where there is a required relationship between the final time and state (like the target condition $(b, x(b)) \in C$ for a given set C), to the case where the interval $[a, b]$ is completely unrestricted. For example, to treat a problem where the final time is fixed at T, it suffices to include the additive term $\Psi_{\{T\}}(b)$ in the endpoint cost l. Such extended-valued and discontinuous behavior is allowed by the hypotheses, but it will of course be reflected in conclusions (c) and (c^∞) of Theorem 1.1. In this instance, the third components of conclusions 1.1(c)/(c^∞) would give only the redundant statement "$h(T) \in \mathbb{R}$" because of the elementary identity $\partial\Psi_{\{T\}}(T) = \partial^\infty\Psi_{\{T\}}(T) = \mathbb{R}$; in variable-endtime problems the corresponding conclusions would be richer, providing nontrivial algebraic conditions linking the final value of h with other ingredients of the extremal system.

1.4. Conservation of the Hamiltonian. Conclusion (b) in the normal case of Theorem 1.1 generalizes the classical equation

$$\dot{h}(t) = H_t(t, \overline{x}(t), p(t))\,, \text{ where } h(t) = H(t, \overline{x}(t), p(t))\,. \tag{1.6}$$

In particular, if the integrand L is free of explicit t-dependence, then the Hamiltonian must be constant along normal extremal trajectories—a conclusion that recalls the law of conservation of energy in classical mechanics, or the second Weierstrass–Erdmann condition in the calculus of variations. This condition is useful in fixed-time problems, where the constant value of h is unknown, and indispensable in free-time problems, where the constant value of h is determined through the transversality inclusion (c) or (c^∞) of Theorem 1.1, as noted above.

1.5. Maximization conditions. Eliminating h between the two equations in Theorem 1.1(b) leads to the first of two equivalent maximization conditions:

$$\langle p(t)\,,\,\dot{\overline{x}}(t)\rangle - L\big(t,\overline{x}(t),\dot{\overline{x}}(t)\big) = \max_{v\in\mathbb{R}^n}\{\langle p(t)\,,\,v\rangle - L(t,\overline{x}(t),v)\}\ \text{ a.e. } t\in\big[\overline{a},\overline{b}\big]\,, \tag{1.7}$$

$$\big\langle p(t)\,,\,\dot{\overline{x}}(t)\big\rangle - H(t,\overline{x}(t),p(t)) = \max_{q\in\mathbb{R}^n}\big\{\big\langle q\,,\,\dot{\overline{x}}(t)\big\rangle - H(t,\overline{x}(t),q)\big\}\ \text{ a.e. } t\in\big[\overline{a},\overline{b}\big]\,. \tag{1.8}$$

(Here (1.7) simply restates $p(t)\in\partial_v L\big(t,\overline{x}(t),\dot{\overline{x}}(t)\big)$, while (1.8) is a transcription of $\dot{\overline{x}}(t)\in\partial_p H(t,\overline{x}(t),p(t))$; these inclusions are equivalent by convex analysis.) Condition (1.7) is the analogue in this theory of the maximization condition in Pontryagin's maximum principle and can be derived directly from the adjoint inclusion (a) of Theorem 1.1. To see this, notice that (a) implicitly asserts that for almost every t, there are points (u,w) such that

$$(-u,w,p(t))\in\partial L\big(t,\overline{x}(t),\dot{\overline{x}}(t)\big)\,. \tag{1.9}$$

Under our hypotheses on L, this inclusion implies the partial-subgradient relation $p(t)\in\partial_v L\big(t,\overline{x}(t),\dot{\overline{x}}(t)\big)$. (See [22, Prop. 2.2]; the Lipschitz case is in [3, Prop. 2.5.3].) The definition of the convex subgradient allows this inclusion to be expressed as shown in (1.7). Thus inclusion (1.9) implies

$$\big\langle p(t)\,,\,\dot{\overline{x}}(t)\big\rangle - L\big(t,\overline{x}(t),\dot{\overline{x}}(t)\big) = H(t,\overline{x}(t),p(t))\,. \tag{1.10}$$

This derivation of (1.10) from (1.9) proceeds equally well for any evaluation point in $\Omega\times\mathbb{R}^n$, and its more general form will be used repeatedly in what follows. To illustrate, we note that the subgradient inequality in (H4) is equivalent to

$$|(u,w)|\le\kappa[1+|p|+|\langle p\,,\,v\rangle - L(r,x,v)|]\quad\forall(u,w,p)\in\partial L(r,x,v). \tag{1.11}$$

1.6. Lipschitzian minimizers. Problem (P) involves minimization over the space of all absolutely continuous functions x. However, it often happens that the solution lies in the subspace of Lipschitzian arcs. (Sufficient conditions guaranteeing this desirable outcome may be found in [8, 9, 6, 1], for example.) In this situation, our results can be simplified: the hypotheses can be weakened by dropping the term $\big|\dot{\overline{x}}(t)\big|$ from the right-hand side of (H4(ii)), while the conclusions can be strengthened by demonstrating the identity in the first line of Theorem 1.1(b) for all t in $\big[\overline{a},\overline{b}\big]$ *without exception.* The latter assertion follows from our next result, in which m denotes Lebesgue measure, and we write $I^+=\bigcup_{R>0}I_R^+$ and $I^-=\bigcup_{R>0}I_R^-$, where

$$I_R^+ = \big\{t\in\big[\overline{a},\overline{b}\big)\ :\ \forall\varepsilon>0,\ m\{s\in[t,t+\varepsilon]\ :\ \big|\dot{\overline{x}}(s)\big|\le R\}>0\big\}\,,$$
$$I_R^- = \big\{t\in\big(\overline{a},\overline{b}\big]\ :\ \forall\varepsilon>0,\ m\{s\in[t-\varepsilon,t]\ :\ \big|\dot{\overline{x}}(s)\big|\le R\}>0\big\}\,.$$

(Note that for Lipschitzian $\overline{x}$, $I^+=\big[\overline{a},\overline{b}\big)$ and $I^-=\big(\overline{a},\overline{b}\big]$.)

PROPOSITION 1.2. *Let (h,p) be a function of bounded variation on $\big[\overline{a},\overline{b}\big]$ for which the two statements in Theorem* 1.1(b) *hold. Then*

(a) $h(t^+) = H\big(t, \overline{x}(t), p(t^+)\big)\ \ \forall t \in I^+$,
(b) $h(t^-) = H\big(t, \overline{x}(t), p(t^-)\big)\ \ \forall t \in I^-$.

In particular, if $\overline{x}$ is Lipschitzian and (h,p) is an arc, then $h(t) = H(t, \overline{x}(t), p(t))$ for all t in $\big[\overline{a}, \overline{b}\big]$ without exception.

Proof. (a) Fix any t in I^+. Since h and p have bounded variation on $\big[\overline{a}, \overline{b}\big]$, their right limits $h(t^+)$ and $p(t^+)$ exist finitely and can be realized along any sequence $s_k \to t^+$. Also, $t \in I^+_R$ for some $R > 0$, so each interval $[t, t + 1/k]$ contains a nonnull set on which $\big|\dot{\overline{x}}(s)\big| \le R$. Thus we may choose a sequence $s_k \to t^+$ along which $\dot{\overline{x}}(s_k)$ exists, the two equations in Theorem 1.1(b) hold, and $\sup_k \big|\dot{\overline{x}}(s_k)\big| \le R$.

Now H is lower semicontinuous on $\Omega \times \mathbb{R}^n$ by (H3), so

$$(*) \qquad h(t^+) = \liminf_{k\to\infty} H(s_k, \overline{x}(s_k), p(s_k)) \ge H\big(t, \overline{x}(t), p(t^+)\big)\,.$$

On the other hand, H is epicontinuous on Ω. Line $(*)$ shows that $(t, \overline{x}(t), p(t^+))$ is a point where H is finite, and we have a sequence $(s_k, \overline{x}(s_k))$ converging to $(t, \overline{x}(t))$. Thus there must be a sequence $q_k \to p(t^+)$ along which $H(s_k, \overline{x}(s_k), q_k) \to H(t, \overline{x}(t), p(t^+))$. The maximum condition (1.8) (a consequence of Theorem 1.1(b)) then supplies the inequality

$$\begin{aligned} h(t^+) &= \lim_{k\to\infty} H(s_k, \overline{x}(s_k), p(s_k)) \\ &\le \liminf_{k\to\infty} \big[H(s_k, \overline{x}(s_k), q_k) - \big\langle q_k - p(s_k)\,,\, \dot{\overline{x}}(s_k)\big\rangle\big] \qquad (**) \\ &= H\big(t, \overline{x}(t), p(t^+)\big) - 0. \end{aligned}$$

Combining $(*)$ and $(**)$ gives $h(t^+) \le H\big(t, \overline{x}(t), p(t^+)\big) \le h(t^+)$, as required.

(b) This proof is similar.

Now if (h,p) is continuous on $\big[\overline{a}, \overline{b}\big]$, then we have $h(t) = H(t, \overline{x}(t), p(t))$ for all t in $I^- \cup I^+$. Furthermore, $I^- \cup I^+ = \big[\overline{a}, \overline{b}\big]$ when $\overline{x}$ is Lipschitzian, so the upgraded form of Theorem 1.1(b) follows. □

2. Problems with explicit velocity constraints. The fully intrinsic formulation of (P) enjoys both a simple statement and a rich heritage of classical antecedents. On the other hand, its practical importance comes from its applicability to problems with velocity and endpoint constraints beyond the scope of its predecessors. Take, for example, the problem of choosing an interval $[a,b]$ and an arc x on $[a,b]$ in order to

$$\begin{aligned} &\text{minimize } \Gamma[a,b;x] := g_1(a, x(a), b, x(b)) + \int_a^b G_1(t, x(t), \dot{x}(t))\ dt \\ &\text{subject to } \dot{x}(t) \in F(t, x(t)) \text{ a.e. } t \in [a,b], \\ &\qquad (a, x(a), b, x(b)) \in S. \end{aligned} \tag{2.1}$$

This problem is an instance of (P) with endpoint cost $l = g_1 + \Psi_S$ and integrand $L = G_1 + \Psi_{\operatorname{gph} F}$. Suitable hypotheses of Lipschitz continuity on g_1 and G_1, together with mild conditions on the multifunction F, will not only establish (H1)–(H4) but also allow us to derive from the conclusions of Theorem 1.1 the usual dichotomy between the normal and abnormal forms of standard necessary conditions. To express this concisely, let us write for any $\lambda \ge 0$

$$\begin{aligned} l_\lambda(a,x,b,y) &:= \lambda g_1(a,x,b,y) + \Psi_S(a,x,b,y), \\ L_\lambda(t,x,v) &:= \lambda G_1(t,x,v) + \Psi_{\operatorname{gph} F}(t,x,v), \\ H_\lambda(t,x,p) &:= \sup_{v\in\mathbb{R}^n} \{\langle p\,,\, v\rangle - L_\lambda(t,x,v)\} \\ &\qquad = \sup\{\langle p\,,\, v\rangle - \lambda G_1(t,x,v)\ :\ v \in F(t,x)\}\,. \end{aligned} \tag{2.2}$$

The hypotheses in question are as follows. Again we state them in terms of a given arc $\overline{x}$ with associated interval $[\overline{a}, \overline{b}]$ assumed to solve problem (2.1), and a fixed open set Ω containing the graph of $\overline{x}$. We also assume that $\overline{x}$ is Lipschitzian.

(h_1) The target set S is closed, and the endpoint cost g_1 is Lipschitzian on the set

$$\left\{(a,x,b,y) \,:\, |(a,x)-(\overline{a},\overline{x}(\overline{a}))|<\rho,\ \left|(b,y)-(\overline{b},\overline{x}(\overline{b}))\right|<\rho\right\}.$$

(h_2) For each fixed (t,x) in Ω, both the function $v \mapsto G_1(t,x,v)$ and the set $F(t,x)$ are convex.

(h_3) The function G_1 is finite valued and continuous on $\Omega \times \mathbb{R}^n$. The multifunction F is continuous on Ω, in the sense that (1.4) holds for $E = F$, at every point (t,x) in Ω.

(h_4) There are positive constants δ and R for which almost all t in $(\overline{a}-\rho, \overline{b}+\rho)$ have this property: for every point (r,x,v) in $\Omega \times \mathbb{R}^n$ satisfying the three conditions

$$|(r,x)-(t,\overline{x}(t))|<\rho, \qquad \left|v-\dot{\overline{x}}(t)\right|<\delta, \qquad v \in F(r,x),$$

both subgradient estimates below are valid:

$$\begin{aligned} |(u_1,w_1,p_1)| &\le R && \forall (u_1,w_1,p_1) \in \partial G_1(r,x,v), \\ |(u_\nu,w_\nu)| &\le R[1+|p_\nu|] && \forall (u_\nu,w_\nu,p_\nu) \in N_{\operatorname{gph} F}(r,x,v). \end{aligned}$$

Notice that the conditions on F imposed by (h_3)–(h_4) amount to nothing more than continuity in general together with a sort of uniform Aubin property near the minimizing arc of interest. Since the arc $\overline{x}$ is Lipschitzian, the first subgradient inequality in (h_4) will be satisfied (for some R) by any locally Lipschitzian integrand G_1, while a sufficient condition for the second is the qualification condition

$$(u,w,0) \in \partial L_0\big(t,\overline{x}(t),\dot{\overline{x}}(t)\big) \implies (u,w)=(0,0) \qquad \text{a.e. } t \in [\overline{a},\overline{b}].$$

(This follows from Theorem 3.2 below and the special structure of L.) In particular, there is no requirement that F be bounded or compact valued—the next result applies even when $F \equiv \mathbb{R}^n$, so (2.1) reduces to a standard variational problem with Lipschitzian data and a general target set.

THEOREM 2.1. *Let the arc $\overline{x}$ with interval $[\overline{a},\overline{b}]$ provide the minimum in problem (2.1). Suppose that $\overline{x}$ is Lipschitzian and (h_1)–(h_4) hold. Then there exist a scalar $\lambda \in \{0,1\}$ and an absolutely continuous pair $(h,p)\colon [\overline{a},\overline{b}] \to \mathbb{R} \times \mathbb{R}^n$, with $\lambda + |(h(t),p(t))| > 0$ for all t in $[\overline{a},\overline{b}]$, such that*

(a) $$\Big(\dot{h}(t),\dot{p}(t)\Big) \in \operatorname{co}\left\{(u,w) \,:\, (-u,w,p(t)) \in \partial L_\lambda\big(t,\overline{x}(t),\dot{\overline{x}}(t)\big)\right\}$$
$$= \operatorname{co}\left\{(u,w) \,:\, (u,-w,\dot{\overline{x}}(t)) \in \partial H_\lambda(t,\overline{x}(t),p(t))\right\} \ \text{a.e. } t \in [\overline{a},\overline{b}].$$

(b) $h(t) = H_\lambda(t,\overline{x}(t),p(t))\ \forall t \in [\overline{a},\overline{b}]$;
$$h(t) = \big\langle p(t)\,,\,\dot{\overline{x}}(t)\big\rangle - \lambda G_1\big(t,\overline{x}(t),\dot{\overline{x}}(t)\big) \ \text{a.e. } t \in [\overline{a},\overline{b}].$$

(c) $\big(-h(\overline{a}),p(\overline{a}),h(\overline{b}),-p(\overline{b})\big) \in \partial l_\lambda\big(\overline{a},\overline{x}(\overline{a}),\overline{b},\overline{x}(\overline{b})\big)$.

Again, we note that condition (b) in the statement of Theorem 2.1 implies two (equivalent) maximization conditions valid for almost all t:

$$\begin{aligned} \dot{\overline{x}}(t) &\in \partial_p H_\lambda(t,\overline{x}(t),p(t)) = \arg\max_{v\in\mathbb{R}^n}\left\{\langle p(t)\,,\,v\rangle - L_\lambda(t,\overline{x}(t),v)\right\}, \\ p(t) &\in \partial_v L_\lambda(t,\overline{x}(t),\dot{\overline{x}}(t)) = \arg\max_{q\in\mathbb{R}^n}\left\{\big\langle q\,,\,\dot{\overline{x}}(t)\big\rangle - H_\lambda(t,\overline{x}(t),q)\right\}. \end{aligned} \tag{2.3}$$

Proof. We reduce to an application of Theorem 1.1, by choosing $l = l_1$ and $L = L_1$. For $i = 1,2,3$, (Hi) follows directly from (h_i); for $i = 4$, this statement can be justified

as follows. Using the constant R provided by (h_4), define $\kappa = R^2 + 2R$. Then consider any point (r, x, v) of the sort described in (H4(i)–(iii)) and any subgradient $(u, w, p) \in \partial L(r, x, v)$. Conditions (H4(i)–(ii)) imply that (h_4(i)–(ii)) hold for the evaluation point (r, x, v); condition (H4(iii)) certainly requires the finiteness of $L(r, x, v)$ so that (h_4(iii)) must follow. With the three prerequisites of (h_4) in place, we observe that the given subgradient has a decomposition as

$$(u, w, p) = (u_1, w_1, p_1) + (u_\nu, w_\nu, p_\nu)$$

for some $(u_1, w_1, p_1) \in \partial G_1(r, x, v)$ and some $(u_\nu, w_\nu, p_\nu) \in N_{\operatorname{gph} F}(r, x, v)$. The two estimates in ($h_4$) then give the second inequality in the estimate

$$\begin{aligned} |(u, w)| &\le |(u_1, w_1)| + |(u_\nu, w_\nu)| \\ &\le R + R[1 + |p_\nu|] \\ &\le R + R[1 + |p_1 + p_\nu| + |-p_1|] \\ &\le R + R[1 + |p|] + R^2 \\ &\le \kappa[1 + |p|]\,. \end{aligned}$$

In the last step we have used the choice $\kappa = R^2 + 2R$ mentioned above. The resulting inequality confirms (H4).

We may now apply Theorem 1.1 to $\overline{x}$ on $[\overline{a}, \overline{b}]$. If the conclusions of Theorem 1.1 hold in normal form, then conditions (a)–(c) follow immediately, with $\lambda = 1$. The nontriviality condition is evident. Suppose, therefore, that we have only the singular conditions of Theorem 1.1, satisfied by some nonvanishing pair (h, p). Again the nontriviality condition is immediate, but now the special form of l and L allows conclusions (a^∞)–(c^∞) to be simplified. Specifically, since the endpoint cost g_1 and integrand G_1 are locally Lipschitz, we have

$$\begin{aligned} \partial^\infty l\big(\overline{a}, \overline{x}(\overline{a}), \overline{b}, \overline{x}(\overline{b})\big) &= N_S\left(\overline{a}, \overline{x}(\overline{a}), \overline{b}, \overline{x}(\overline{b})\right) = \partial l_0\big(\overline{a}, \overline{x}(\overline{a}), \overline{b}, \overline{x}(\overline{b})\big)\,, \\ \partial^\infty L\big(t, \overline{x}(t), \dot{\overline{x}}(t)\big) &= N_{\operatorname{gph} F}\left(t, \overline{x}(t), \dot{\overline{x}}(t)\right) = \partial L_0\big(t, \overline{x}(t), \dot{\overline{x}}(t)\big)\,. \end{aligned}$$

Thus the transversality inclusion (c) with $\lambda = 0$ follows directly from condition (c^∞) of Theorem 1.1, while condition (a^∞) of that result gives

$$(*) \qquad \Big(\dot{h}(t), \dot{p}(t)\Big) \in \operatorname{co}\left\{(u, w) \,:\, (-u, w, p(t)) \in \partial L_0\big(t, \overline{x}(t), \dot{\overline{x}}(t)\big)\right\} \text{ a.e. } t \in [\overline{a}, \overline{b}]\,.$$

Apply to this inclusion the results of Rockafellar [22, Thm. 1.1] as they pertain to the function $L_0 = \Psi_{\operatorname{gph} F}$. Hypothesis ($h_3$) implies that L_0 is lower semicontinuous and has the required epicontinuity property. Furthermore, any point $(u, w, 0) \in \partial^\infty L_0\big(t, \overline{x}(t), \dot{\overline{x}}(t)\big) = N_{\operatorname{gph} F}\left(t, \overline{x}(t), \dot{\overline{x}}(t)\right)$ must satisfy

$$\alpha(u, w, 0) \in N_{\operatorname{gph} F}\left(t, \overline{x}(t), \dot{\overline{x}}(t)\right) \quad \forall \alpha > 0,$$

whereupon (h_4) requires $\alpha|(u, w)| \le R$ for all $\alpha > 0$, i.e., $|(u, w)| = 0$. Thus the calculus qualification of [22] is in force, and we may conclude that

$$\begin{aligned} &\operatorname{co}\left\{(u, w) \,:\, (-u, w, p(t)) \in \partial L_0\big(t, \overline{x}(t), \dot{\overline{x}}(t)\big)\right\} \\ &\qquad = \operatorname{co}\left\{(u, w) \,:\, \big(u, -w, \dot{\overline{x}}(t)\big) \in \partial H_0(t, \overline{x}(t), p(t))\right\} \text{ a.e. } t \in [\overline{a}, \overline{b}]\,. \end{aligned}$$

In conjunction with $(*)$ above, this equation establishes conclusion (a) with $\lambda = 0$.

Turning finally to the maximum condition, we note that inclusion $(*)$ implies $p(t) \in \partial_v L_0\big(t, \overline{x}(t), \dot{\overline{x}}(t)\big) = N_{F(t, \overline{x}(t))}\big(\dot{\overline{x}}(t)\big)$. In particular, $\langle p(t)\,, \dot{\overline{x}}(t)\rangle \ge \langle p(t)\,, v\rangle$ for all v in $F(t, \overline{x}(t))$, which can be restated as $\langle p(t)\,, \dot{\overline{x}}(t)\rangle = H_0(t, \overline{x}(t), p(t))$. We already have $h(t) = \langle p(t)\,, \dot{\overline{x}}(t)\rangle$ from conclusion (b^∞), so conclusion (b) holds for almost all t. The first line can be upgraded to an equation valid for all t by applying Proposition 1.2. ∎

2.1. Minimum-time problems. A further specialization of (2.1) is the problem of steering the state trajectory from the origin at time 0 to a moving target set C in least time, subject to given differential constraints. Here the termination condition is $x(b) \in C(b)$, and the following choices put this problem into the form (2.1):

$$G_1 \equiv 0, \qquad g_1(a,x,b,y) = b, \qquad S = \{(0,0)\} \times \operatorname{gph} C.$$

Here (h_1) holds for any target multifunction C whose graph is closed, (h_2) reduces to a convexity requirement on the velocity sets $F(t,x)$, (h_3) changes only slightly, and the first of the subgradient estimates in (h_4) becomes self-evident. In addition, one has $L_\lambda = \Psi_{\operatorname{gph} F} = L_0$, and hence $H_\lambda = H_0$, for all $\lambda \geq 0$. Thus a Lipschitzian minimizer $\overline{x}$ with interval $\big[0,\overline{b}\big]$ must have an associated scalar $\lambda \in \{0,1\}$ and arc $(h,p)\colon \big[0,\overline{b}\big] \to \mathbb{R} \times \mathbb{R}^n$, not both zero, such that

(a) $\Big(\dot{h}(t), \dot{p}(t)\Big) \in \operatorname{co}\big\{(u,w) \,:\, (u,-w,\dot{\overline{x}}(t)) \in \partial H_0(t,\overline{x}(t),p(t))\big\}$ a.e. $t \in \big[0,\overline{b}\big]$.

(b) $h(t) = H_0(t,\overline{x}(t),p(t))\ \forall t \in \big[\overline{a},\overline{b}\big]$, and $h(t) = \big\langle p(t)\,,\,\dot{\overline{x}}(t)\big\rangle$ a.e. $t \in \big[\overline{a},\overline{b}\big]$.

(c) $\big(-h(0), p(0), h(\overline{b}), -p(\overline{b})\big) \in \lambda(0,0,1,0) + \mathbb{R} \times \mathbb{R}^n \times N_{\operatorname{gph} C}\big(\overline{b}, \overline{x}(\overline{b})\big)$.

The cost multiplier λ appears only in (c), which reduces to

$$(\mathrm{c}')\ \big(h(\overline{b}) - \lambda, -p(\overline{b})\big) \in N_{\operatorname{gph} C}\big(\overline{b}, \overline{x}(\overline{b})\big).$$

In the case where the target set multifunction $t \rightrightarrows C(t)$ is single valued and moves smoothly with time, this conclusion coincides with the classical one, namely,

$$\big(h(\overline{b}) - \lambda, -p(\overline{b})\big) \in \big(1, C'(\overline{b})\big)^\perp, \quad \text{i.e.,} \quad h(\overline{b}) - \big\langle p(\overline{b})\,,\,C'(\overline{b})\big\rangle = \lambda.$$

Another possibility is that the target is stationary: $C(t) = C$ for all $t > 0$. Here $\operatorname{gph} C(\cdot) = \mathbb{R} \times C$, so (c') decouples to yield the well-known relations

$$h(\overline{b}) = \lambda, \qquad -p(\overline{b}) \in N_C\big(\overline{x}(\overline{b})\big).$$

In the further special case where the velocity sets $F(t,x)$ have no explicit t-dependence, conditions (a) and (b) imply that the Hamiltonian is constant along extremal trajectories, with the fixed value $\lambda = 1$ for normal problems and $\lambda = 0$ for singular ones.

3. On the continuity conditions. Both the epicontinuity condition (H3) and the Aubin continuity hypothesis (H4) follow from more elementary assumptions when the integrand L has suitable structure. We discuss some of these reductions in this section, paying particular attention to simplifications available when the function $L(t,x,v)$ is convex in (x,v) for each fixed t.

Our first result is a sufficient condition for the Aubin continuity property (H4). A simplified version appears as Theorem 3.2 below.

PROPOSITION 3.1. *Suppose that $\dot{\overline{x}}$ and $\overline{L}$ are essentially bounded. Then, upon reducing $\rho > 0$ if necessary, hypothesis* (H4) *holds whenever there exists a multifunction $\Gamma\colon \mathbb{R} \times \mathbb{R}^n \times \mathbb{R}^n \rightrightarrows \mathbb{R}$ with these three properties*:

(a) *The graph of Γ is a compact subset of* $\operatorname{epi} L$; *the images of Γ are compact convex sets.*

(b) *If $\Gamma(t,x,v) \neq \emptyset$, then $L(t,x,v) \in \Gamma(t,x,v)$; moreover, $\Gamma\big(t,\overline{x}(t),\dot{\overline{x}}(t)\big) \neq \emptyset$ for almost all t in $\big[\overline{a},\overline{b}\big]$.*

(c) *One has*

$$(3.1) \qquad \forall \gamma \in \Gamma(t,x,v), \qquad (u,w,0,0) \in N_{\operatorname{epi} L}\,(t,x,v,\gamma) \implies (u,w) = (0,0).$$

Conditions (a) and (b) require, among other things, that the graph of Γ be a compact superset of the "curve" $\big\{\big(t,\overline{x}(t),\dot{\overline{x}}(t),L\big(t,\overline{x}(t),\dot{\overline{x}}(t)\big)\big) \,:\, t \in [\overline{a},\overline{b}]\big\}$. This curve

will admit a compact superset if and only if both $\dot{\overline{x}}$ and $\overline{L}$ are essentially bounded, which we have emphasized by making it an explicit hypothesis in the statement above. In the case where both $\dot{\overline{x}}$ and $\overline{L}$ are continuous, the curve in question is itself compact, and conditions (a) and (b) are satisfied by the multifunction

$$\Gamma(t,x,v) = \begin{cases} \{L(t,x,v)\} & \text{if } (t,x,v) = \big(t,\overline{x}(t),\dot{\overline{x}}(t)\big),\ t \in \big[\overline{a},\overline{b}\big], \\ \emptyset & \text{otherwise.} \end{cases} \tag{3.2}$$

At any point where $\Gamma(t,x,v) = \{L(t,x,v)\}$, the key condition (3.1) can be rewritten in terms of singular subgradients using (1.1):

$$(u,w,0) \in \partial^\infty L(t,x,v) \implies (u,w) = (0,0). \tag{3.3}$$

The discrepancy between (3.1) and (3.3) shows up only when (3.1) refers to normals to $\operatorname{epi} L$ at points (r,x,v,γ) where $\gamma > L(r,x,v)$.

Proof of Proposition 3.1. The essential boundedness of $\dot{\overline{x}}$ and $\overline{L}$ allows the right sides in (H4(ii)–(iii)) to be replaced by δ. This is the form of (H4) that we will confirm.

First, fix any point $(t,\overline{x},\overline{v},\overline{\gamma})$ in $\operatorname{gph}\Gamma$. We claim that there exists $M > 0$ so large that the following geometrical relation holds near the given point:

$$(*) \qquad \left.\begin{array}{l} |(r,x,v) - (t,\overline{x},\overline{v})| < 1/M \\ \gamma < \overline{\gamma} + 1/M \end{array}\right\} \\ \implies |(u,w)| \le M[|p| + |q|] \quad \forall (u,w,p,q) \in N_{\operatorname{epi} L}\,(r,x,v,\gamma)\,.$$

Indeed, if this claim were false, then it would have to fail for every positive integer m. Each m would give rise to a point (r_m,x_m,v_m,γ_m) satisfying the antecedent inequalities in $(*)$ but associated with a normal vector (u_m,w_m,p_m,q_m) in $N_{\operatorname{epi} L}\,(r_m,x_m,v_m,\gamma_m)$ for which

$$(\dagger) \qquad \frac{1}{m}|(u_m,w_m)| > [|p_m| + |q_m|]\,, \qquad |(u_m,w_m,p_m,q_m)| = 1.$$

Now since $(r_m,x_m,v_m) \to (t,\overline{x},\overline{v})$ and $\gamma_m \ge L(r_m,x_m,v_m)$ as $m \to \infty$, $(\dagger)$ gives

$$\begin{aligned} \overline{\gamma} \ge \limsup_{m\to\infty} \gamma_m &\ge \limsup_{m\to\infty} L(r_m,x_m,v_m) \\ &\ge \liminf_{m\to\infty} L(r_m,x_m,v_m) \\ &\ge L(t,\overline{x},\overline{v}) \quad \text{(by lower semicontinuity).} \end{aligned}$$

Conditions (a) and (b) imply that all the limit points of the sequence γ_m lie in the compact interval $\Gamma(t,\overline{x},\overline{v})$; by passing to a subsequence if necessary, we may assume that $\gamma_m \to \widehat{\gamma}$, where $L(t,\overline{x},\overline{v}) \le \widehat{\gamma} \le \overline{\gamma}$ and $\widehat{\gamma} \in \Gamma(t,\overline{x},\overline{v})$. Along a further subsequence, the given normals converge to a unit vector (u,w,p,q) with the property that

$$0 \ge |p| + |q|, \qquad (u,w,p,q) \in N_{\operatorname{epi} L}\,(t,\overline{x},\overline{v},\widehat{\gamma})\,.$$

This contradicts (3.1), so the claim involving $(*)$ must hold.

Second, we use the compact-graph condition (a). Fix any point $(t,\overline{x},\overline{v},\overline{\gamma})$ in $\operatorname{gph}\Gamma$. Let $M = M(t,\overline{x},\overline{v},\overline{\gamma})$ be a constant with the properties specified in $(*)$; use it to define an open set in $\mathbb{R}^{1+n+n+1}$:

$$\Omega(t,\overline{x},\overline{v},\overline{\gamma}) = \{(r,x,v,\gamma)\ :\ |(r,x) - (t,\overline{x})| < 1/M,\ |v - \overline{v}| < 1/M,\ \gamma < \overline{\gamma} + 1/M\}\,.$$

Now as $(t,\overline{x},\overline{v},\overline{\gamma})$ runs through $\operatorname{gph}\Gamma$, the open sets $\Omega(t,\overline{x},\overline{v},\overline{\gamma})$ cover $\operatorname{gph}\Gamma$. Thus we can extract a finite list of points $(t_i,\overline{x}_i,\overline{v}_i,\overline{\gamma}_i)$ in $\operatorname{gph}\Gamma$, $i=1,\dots,N$, such that

$$(**)\qquad \operatorname{gph}\Gamma \subseteq \bigcup_{i=1}^{N} \Omega(t_i,\overline{x}_i,\overline{v}_i,\overline{\gamma}_i).$$

Since the left side is compact and the right side is open, there is a positive constant δ such that any point (r,x,v,γ) satisfying the three conditions below for some point $(t,\overline{x},\overline{v},\overline{\gamma})$ in $\operatorname{gph}\Gamma$ will lie in the right side of $(**)$:

$$|(r,x)-(t,\overline{x})|<\delta, \qquad |v-\overline{v}|<\delta, \qquad \gamma<\overline{\gamma}+\delta.$$

In particular, fix any time t in $[\overline{a},\overline{b}]$ at which the inclusion in (b) holds. Then the point $(t,\overline{x},\overline{v},\overline{\gamma})=\big(t,\overline{x}(t),\dot{\overline{x}}(t),L\big(t,\overline{x}(t),\dot{\overline{x}}(t)\big)\big)$ lies in $\operatorname{gph}\Gamma$, so the three hypotheses below are enough to situate the point $(r,x,v,L(r,x,v))$ in the right side of $(**)$:

(i) $|(r,x)-(t,\overline{x}(t))|<\delta$,
(ii) $\big|v-\dot{\overline{x}}(t)\big|<\delta$,
(iii) $L(r,x,v)<L(t,\overline{x}(t),\dot{\overline{x}}(t))+\delta$.

This means that there is some index i for which $(r,x,v,L(r,x,v))$ lies in $\Omega(t_i,\overline{x}_i,\overline{v}_i,\overline{\gamma}_i)$, and hence that any vector (u,w,p,q) in $N_{\operatorname{epi}L}(r,x,v,L(r,x,v))$ obeys

$$|(u,w)|\le M_i[|p|+|q|]\le \widehat{M}[|p|+|q|],$$

where $\widehat{M}=\max\{M_1,\dots,M_N\}$. In particular, if $(u,w,p)\in\partial L(r,x,v)$, then $|(u,w)|\le \widehat{M}[1+|p|]$. This establishes (H4), with constants δ and $\widehat{M}$. ∎

THEOREM 3.2. *Suppose that both $\dot{\overline{x}}$ and $\overline{L}$ are essentially bounded. Then, upon reducing $\rho>0$ if necessary, the following condition implies* (H4): *there exists $\delta>0$ so small that for almost all $t\in[\overline{a},\overline{b}]$, the three inequalities*

$$(3.4)\qquad |(r,x)-(t,\overline{x}(t))|<\delta, \qquad \big|v-\dot{\overline{x}}(t)\big|<\delta, \qquad \big|\gamma-\overline{L}(t)\big|<\delta$$

imply the geometrical condition

$$(3.5)\qquad (u,w,0,0)\in N_{\operatorname{epi}L}(t,x,v,\gamma) \implies (u,w)=(0,0).$$

Proof. It suffices to construct a multifunction Γ satisfying conditions (a) and (b) of Proposition 3.1 such that any quadruple (r,x,v,γ) satisfying the three inequalities above automatically lies in $\operatorname{gph}\Gamma$. We do this using the "essential value" multifunctions [7]

$$V(t):=\big\{v\in\mathbb{R}^n \,:\, \forall\varepsilon>0,\ 0<m\big\{s\in[t-\varepsilon,t+\varepsilon]\cap[\overline{a},\overline{b}] \,:\, \big|v-\dot{\overline{x}}(s)\big|<\varepsilon\big\}\big\},$$
$$I(t):=\big\{\gamma\in\mathbb{R} \,:\, \forall\varepsilon>0,\ 0<m\big\{s\in[t-\varepsilon,t+\varepsilon]\cap[\overline{a},\overline{b}] \,:\, \big|\gamma-\overline{L}(s)\big|<\varepsilon\big\}\big\}.$$

Evidently both $\operatorname{gph}V$ and $\operatorname{gph}I$ are compact, while $\dot{\overline{x}}(t)\in V(t)$ and $\overline{L}(t)\in I(t)$ for almost all t. Fix any $\delta_0\in(0,\delta)$, and let

$$G:=\{(r,x,v,\gamma) \,:\, \text{for some } t \text{ in } [\overline{a},\overline{b}], \text{ one has } v\in V(t)+\delta_0\mathbb{B},$$
$$\gamma\in\operatorname{co}I(t)+\delta_0\mathbb{B}, \text{ and } |(r,x)-(t,\overline{x}(t))|\le\delta_0\}.$$

This set is compact, contains almost all the points $(t,\overline{x}(t),\dot{\overline{x}}(t),\overline{L}(t))$ for t in $[\overline{a},\overline{b}]$, and has convex sections in the last variable. Thus the relation $\operatorname{gph}\Gamma=G$ defines a multifunction Γ satisfying Theorem 3.1(a) and (b). For almost all t, any quadruple (r,x,v,γ) obeying the three inequalities in (3.4) will satisfy $\gamma\in\Gamma(r,x,v)$. Thus condition (3.5) implies (3.1), and the result follows. ∎

3.1. The convex case. Necessary (and sufficient) conditions for the fixed-time case of problem (P) where the Lagrangian is jointly convex in (x, v) for each fixed t have been known for some time: see [17, 18, 19], for example. These early results have a role not only in the direct solution of applied problems but also as test cases for the correctness of further generalizations. Thus we seek to confirm that our results in this paper represent faithful generalizations of the convex theory. The key issue, of course, is the extent to which convex problems can be expected to satisfy our standing hypotheses (H3) and (H4). Here is a precise formulation of our joint convexity assumption.

(H2)$_c$ For each fixed t in $\big(\overline{a} - \rho, \overline{b} + \rho\big)$, the function $(x, v) \mapsto L(t, x, v)$ is convex on $\Omega_t \times \mathbb{R}^n$. Furthermore, one has $\operatorname{dom} L(t, x, \cdot) \neq \emptyset$ for each (t, x) in Ω.

We will show that for autonomous problems, both (H3) and (H4) follow from (H2)$_c$ and more generally, that assuming (H2)$_c$ allows (H3) and (H4) to be derived from their weakened analogues below, in which only the t-dependence is involved:

(H3)$_c$ The function L is lower semicontinuous on $\Omega \times \mathbb{R}^n$ and epicontinuous in t: that is, for any point (t, x, v) in $\Omega \times \mathbb{R}^n$ where $L(t, x, v)$ is finite and for any sequence $t_k \to t$, there exists a sequence $(x_k, v_k) \to (x, v)$ along which $L(t_k, x_k, v_k) \to L(t, x, v)$.

(H4)$_c$ Both $\dot{\overline{x}}$ and $\overline{L}$ are essentially bounded, and there are positive constants δ and κ such that for almost all t in $\big[\overline{a}, \overline{b}\big]$, every point (r, x, v, γ) in $\Omega \times \mathbb{R}^n \times \mathbb{R}$ obeying the three inequalities

$$|(r, x) - (t, \overline{x}(t))| < \rho, \qquad \big|v - \dot{\overline{x}}(t)\big| < \delta, \qquad \big|\gamma - \overline{L}(t)\big| < \delta,$$

satisfies the geometrical condition

$$(u, 0, 0, 0) \in N_{\operatorname{epi} L}\,(r, x, v, \gamma) \implies u = 0.$$

Both (H3)$_c$ and (H4)$_c$ hold trivially if L has no explicit dependence on t, provided that both $\dot{\overline{x}}$ and $\overline{L}$ are essentially bounded. (In the autonomous case, Lipschitz continuity of minimizers is a consequence of other modest hypotheses—see [1].) Notice that (H4)$_c$ is a geometrical sufficient condition for the uniform Aubin continuity of the multifunction $t \rightrightarrows \operatorname{epi} L(t, \cdot, \cdot)$ near the optimal trajectory.

We deal first with the epicontinuity conditions (H3) and (H3)$_c$, starting from a technical lemma.

LEMMA 3.3. *Let $\overline{x}_0, \ldots, \overline{x}_n$ be points of $\mathbb{R}^n$ such that*

$$0 \in \operatorname{int} \operatorname{co} \{\overline{x}_0, \ldots, \overline{x}_n\}. \tag{3.6}$$

For each $j = 0, \ldots, n$, let $\{\overline{x}_j^k\}_k$ be a sequence converging to $\overline{x}_j$. Given any sequence $w_k \to 0$ in $\mathbb{R}^n$, there exists for each index k sufficiently large a collection $\lambda_0^k, \lambda_1^k, \ldots, \lambda_n^k \geq 0$ such that

$$\text{(i) } w_k = \sum_{j=0}^n \lambda_j^k \overline{x}_j^k, \qquad\qquad \text{(ii) } \sum_{j=0}^n \lambda_j^k \to 0 \text{ as } k \to \infty.$$

Proof. Use (3.6) to fix $\sigma > 0$ so small that $\operatorname{co}\{\overline{x}_0, \ldots, \overline{x}_n\}$ contains $2\sigma\mathbb{B}$. Then for all k sufficiently large, the set $S^k := \operatorname{co}\{\overline{x}_0^k, \ldots, \overline{x}_n^k\}$ contains the smaller ball $\sigma\mathbb{B}$. In particular, $\sigma w_k/|w_k|$ lies in S^k for all such k and therefore has a representation in terms of scalars $\mu_j^k \geq 0$, $\sum_{j=0}^n \mu_j^k = 1$:

$$\sigma \frac{w_k}{|w_k|} = \sum_{j=0}^n \mu_j^k \overline{x}_j^k, \text{ i.e., } w_k = \sum_{j=0}^n \left(\frac{\mu_j^k |w_k|}{\sigma}\right) \overline{x}_j^k.$$

Choosing $\lambda_j^k = \sigma^{-1} \mu_j^k |w_k|$ gives (i), while (ii) holds because $\sum_{j=0}^n \lambda_j^k = |w_k|/\sigma$. ∎

Here is an abstract result concerning epicontinuity, phrased in notation that will facilitate its application to our problem.

THEOREM 3.4. *Let $L\colon \mathbb{R}\times\mathbb{R}^n\times\mathbb{R}^n \to \mathbb{R}\cup\{\infty\}$ be lower semicontinuous at every point in $\big\{(\overline{t},\overline{x})\big\}\times\mathbb{R}^n$, and suppose that for some $\eta>0$, the function $(x,v)\mapsto L(t,x,v)$ is convex for each fixed t obeying $\big|t-\overline{t}\big|\le\eta$. Assume further that*

(i) $\operatorname{dom} L(\overline{t},x,\cdot)\neq\emptyset$ *for all x where $|x-\overline{x}|\le\eta$;*

(ii) *L is epicontinuous in t at the point $t=\overline{t}$.*

Then L is epicontinuous in (t,x) at the point $(\overline{t},\overline{x})$.

Proof. Without loss of generality, take $\overline{t}=0$ and $\overline{x}=0$. Fix unit vectors $\widehat{u}_0,\dots,\widehat{u}_n$ such that $0\in\operatorname{int}\operatorname{co}\{\widehat{u}_0,\dots,\widehat{u}_n\}$. Then for each j, let $\overline{x}_j=\eta\widehat{u}_j$ $(j=0,\dots,n)$, note that $\operatorname{dom} L(0,\overline{x}_j,\cdot)\neq\emptyset$ by (i), and pick some $\overline{v}_j$ where $L(0,\overline{x}_j,\overline{v}_j)<\infty$.

Now fix any v in $\operatorname{dom} L(0,0,\cdot)$, and let any sequence $(t_k,x_k)\to(0,0)$ be given. We must construct a sequence $v_k\to v$ along which $L(t_k,x_k,v_k)\to L(0,0,v)$. To do this, we apply the epicontinuity property (ii) $n+2$ times: once to generate a sequence

$$(*)\qquad (x_k^*,v_k^*)\to(0,v) \text{ along which } L(t_k,x_k^*,v_k^*)\to L(0,0,v)$$

and $n+1$ more times to find for each $j=0,\dots,n$ a sequence

$$(**)\qquad (\overline{x}_j^k,\overline{v}_j^k)\to(\overline{x}_j,\overline{v}_j) \text{ along which } L(t_k,\overline{x}_j^k,\overline{v}_j^k)\to L(0,\overline{x}_j,\overline{v}_j).$$

Now $w_k=x_k-x_k^*$ is a sequence with limit 0. By Lemma 3.3, with moving simplex $\big\{\overline{x}_j^k-x_k^*\,:\,j=0,\dots,n\big\}$, there are sequences of scalars $\lambda_j^k\ge0$ $(j=0,\dots,n)$ such that both

$$x_k-x_k^*=\sum_{j=0}^n\lambda_j^k\big(\overline{x}_j^k-x_k^*\big)\,,\ \text{i.e., } x_k=\sum_{j=0}^n\lambda_j^k\overline{x}_j^k+\left(1-\sum_{j=0}^n\lambda_j^k\right)x_k^*$$

and $\sum_{j=0}^n\lambda_j^k\to0$ as $k\to\infty$. We use these scalars to define

$$v_k=\sum_{j=0}^n\lambda_j^k\overline{v}_j^k+\left(1-\sum_{j=0}^n\lambda_j^k\right)v_k^*.$$

For each k, the convexity of the function $L(t_k,\cdot,\cdot)$ now yields

$$\begin{aligned}L(t_k,x_k,v_k)&=L\left(t_k,\sum_{j=0}^n\lambda_j^k(\overline{x}_j^k,\overline{v}_j^k)+\left(1-\sum_{j=0}^n\lambda_j^k\right)(x_k^*,v_k^*)\right)\\&\le\sum_{j=0}^n\lambda_j^kL(t_k,\overline{x}_j^k,\overline{v}_j^k)+\left(1-\sum_{j=0}^n\lambda_j^k\right)L(t_k,x_k^*,v_k^*).\end{aligned}$$

On the right side of this estimate, each of the sequences $L(t_k,\overline{x}_j^k,\overline{v}_j^k)$ in the first term is bounded, by $(**)$. The sequence $L(t_k,x_k^*,v_k^*)$ in the second term converges to $L(0,0,v)$, by $(*)$. The construction of the coefficient sequences λ_j^k therefore implies that the right side above converges to $L(0,0,v)$. This gives the first inequality in the estimate

$$\begin{aligned}L(0,0,v)&\ge\limsup_{k\to\infty}L(t_k,x_k,v_k)\\&\ge\liminf_{k\to\infty}L(t_k,x_k,v_k)\ge L(0,0,v).\end{aligned}$$

The second inequality is obvious, and the third follows from the lower semicontinuity of L. Taken together, they show that $L(t_k, x_k, v_k) \to L(0, 0, v)$, as required. ∎

COROLLARY 3.5. *Together* (H2)$_c$ *and* (H3)$_c$ *imply* (H3).

The autonomous case of Theorem 3.4 is of independent interest.

COROLLARY 3.6. *Let* $g\colon \mathbb{R}^m \times \mathbb{R}^n \to \mathbb{R} \cup \{\infty\}$ *be lower semicontinuous and jointly convex. Let* $(\overline{x}, \overline{v})$ *be a point where* g *is finite. Then the following statements are equivalent:*

(a) *There exists* $\eta > 0$ *such that* $\operatorname{dom} g(x, \cdot) \neq \emptyset$ *for all* x *with* $|x - \overline{x}| < \eta$.

(b) g *is epicontinuous in* x *at the point* $x = \overline{x}$.

Now we turn from epicontinuity to the Aubin property.

THEOREM 3.7. *Together* (H2)$_c$–(H4)$_c$ *imply* (H4).

Proof. Write $\psi(t, x, v, \gamma) := \Psi_{\operatorname{epi} L}(t, x, v, \gamma)$. It follows from (H3)$_c$ that the function ψ is both lower semicontinuous and epicontinuous in t. Meanwhile, (H2)$_c$ implies that for each fixed t, the function $(x, v, \gamma) \mapsto \psi(t, x, v, \gamma)$ is convex. Thus we have [22, Prop. 2.2]

$$\begin{aligned} N_{\operatorname{epi} L}\,(t, x, v, \gamma) &= \partial\psi(t, x, v, \gamma) \\ &\subseteq \mathbb{R} \times \partial_{x,v,\gamma}\psi(t, x, v, \gamma) = \mathbb{R} \times N_{\operatorname{epi} L(t,\cdot,\cdot)}\,(x, v, \gamma)\,. \end{aligned}$$

It follows that any point $(u, w, 0, 0)$ normal to $\operatorname{epi} L$ at (t, x, v, γ) will have a projection $(w, 0, 0)$ normal to $\operatorname{epi} L(t, \cdot, \cdot)$ at (x, v, γ). But the latter relation concerns a closed convex set, for which normality has a simple characterization by inequalities:

$$0 \geq \langle (w, 0, 0)\,,\, (x', v', \gamma') - (x, v, \gamma) \rangle = \langle w\,,\, x' - x \rangle \qquad \forall (x', v', \gamma') \in \operatorname{epi} L(t, \cdot, \cdot).$$

Evidently any x' for which $\operatorname{dom} L(t, x', \cdot) \neq \emptyset$ must satisfy the inequality above; in view of (H2)$_c$, this includes all x' in the neighborhood Ω_t of x. Thus $w = 0$. It follows that the key condition (3.5) of Theorem 3.2 can be rewritten as

$$\forall \gamma \in \Gamma(t, x, v), \qquad (u, 0, 0, 0) \in N_{\operatorname{epi} L}\,(t, x, v, \gamma) \implies u = 0.$$

This is precisely the condition supplied by (H4)$_c$. ∎

3.2. Lipschitzian perturbations of convex problems. The various formulations of (H3) and (H4) described above are all designed to regulate non-Lipschitz behavior in the (t, x)-dependence of the integrand L. Perhaps the easiest way to see this is to note that if (H3) and (H4) hold for a given integrand L, then they also hold for the integrand $L + G_1$, under the sole hypothesis that G_1 is Lipschitzian of constant rank on some neighborhood of $\operatorname{gph}\big(\overline{x}, \dot{\overline{x}}\big)$. It follows that the simplified conditions outlined in Corollary 3.5 and Theorem 3.7 apply not just to convex integrands but equally well to Lipschitzian perturbations of convex integrands. An interesting family of such functions has the form $L(t, x, v) = G_1(t, x, v) + k(t, v - A(t)x)$, where G_1 is locally Lipschitzian on $\mathbb{R} \times \mathbb{R}^n \times \mathbb{R}^n$, and $k(t, \cdot)$ is a lower semicontinuous, proper convex function for each fixed t. If we deal with a Lipschitzian arc $\overline{x}$ along which $\overline{L}$ is essentially bounded, conditions (H3) and (H4) for L are consequences of (H3)$_c$ and (H4)$_c$ for the integrand $K(t, x, v) = k(t, v - A(t)x)$. Here Corollary 3.5 and Theorem 3.7 apply directly, under the additional assumption that the matrix-valued function A is Lipschitzian, to show that (H3) and (H4) hold whenever k is epicontinuous in t and one has the Aubin continuity condition below on a suitable neighborhood of the points $(t, \overline{x}(t), \dot{\overline{x}}(t), \overline{L}(t))$:

$$(u, 0, 0) \in N_{\operatorname{epi} k}\,(t, v - A(t)x, \gamma) \implies u = 0.$$

4. Proof of Theorem 1.1. The proof of Theorem 1.1 takes up this whole section; in particular, hypotheses (H1)–(H4) are in force throughout. The unifying idea is a classical one. We formulate an autonomous fixed-time problem for which a relative of $\overline{x}$ provides the solution, and then deduce the main result from the fixed-time theory of Loewen and Rockafellar [13].

4.1. The Erdmann transform. There is a standard method for transforming problem (P) and its solution $\overline{x}$ on $[\overline{a}, \overline{b}]$ into a fixed-time problem solved by an arc related to $\overline{x}$. (See, for example, Clarke [3, sect. 3.6].) We use Greek characters to describe states and costates in the latter problem, for which the underlying time interval is $[0,1]$ and the state is a vector (θ, ξ) in $\mathbb{R} \times \mathbb{R}^n$. Here ξ is a transformed version of the original state x, while θ is a new state which keeps track of the variable time in problem (P).

Choose any constant m such that $0 < m < \overline{b} - \overline{a}$. The transformed problem is to

$$(\Pi) \qquad \begin{aligned} &\text{minimize} \quad l(\theta(0), \xi(0), \theta(1), \xi(1)) + \int_0^1 \widetilde{L}(\theta(\tau), \xi(\tau), \theta'(\tau), \xi'(\tau))\, d\tau \\ &\text{subject to} \quad (\theta(\tau), \xi(\tau)) \in \widetilde{\Omega}_\tau \ \forall \tau \in [0,1]. \end{aligned}$$

Here the integrand $\widetilde{L}$ and domain $\widetilde{\Omega}$ are given by

$$(4.1) \qquad \begin{aligned} &\widetilde{L}(\theta, \xi, \theta', \xi') = \begin{cases} \theta' L(\theta, \xi, \xi'/\theta') & \text{if } \theta' \geq m, \\ +\infty, & \text{otherwise,} \end{cases} \\ &\widetilde{\Omega} := [0,1] \times \Omega. \end{aligned}$$

Comparing the objective functional in problem (Π) with that in problem (P) provides the key to understanding this reduction, as the following lemma reveals.

LEMMA 4.1. *The arc* $\overline{\theta}(\tau) = \overline{a} + \tau(\overline{b} - \overline{a})$, $\overline{\xi}(\tau) = \overline{x}\left(\overline{\theta}(\tau)\right)$ *solves* (Π).

Proof. Consider any pair $(x, [a,b])$ admissible for (P), with $b - a \geq m$. Define $\theta(\tau) := a + \tau(b-a)$ and $\xi(\tau) = x(\theta(\tau))$. Notice that $(\theta(\tau), \xi(\tau)) \in \widetilde{\Omega}_\tau = \Omega$, so this pair satisfies the localization constraint in (Π). On some subset of $[0,1]$ with full Lebesgue measure, $\xi'(\tau) = \dot{x}(\theta(\tau))\theta'(\tau)$, so the substitution $t = \theta(\tau)$ yields

$$(4.2) \qquad (a, x(a), b, x(b)) = (\theta(0), \xi(0), \theta(1), \xi(1)),$$

$$(4.3) \qquad \int_{t=a}^{b} L(t, x(t), \dot{x}(t))\, dt = \int_{\tau=0}^{1} L(\theta(\tau), \xi(\tau), \xi'(\tau)/\theta'(\tau))\, \theta'(\tau)\, d\tau.$$

It follows that the cost of $(x, [a,b])$ in problem (P) equals the cost of (θ, ξ) in problem (Π). Applying this transformation to the pair $(\overline{x}, [\overline{a}, \overline{b}])$ solving (P), we find

$$(4.4) \qquad \begin{aligned} \inf(\Pi) &\leq l(\overline{\theta}(0), \overline{\xi}(0), \overline{\theta}(1), \overline{\xi}(1)) + \int_0^1 \widetilde{L}(\overline{\theta}(\tau), \overline{\xi}(\tau), \overline{\theta}'(\tau), \overline{\xi}'(\tau))\, d\tau \\ &= l(\overline{a}, \overline{x}(\overline{a}), \overline{b}, \overline{x}(\overline{b})) + \int_{\overline{a}}^{\overline{b}} L(t, \overline{x}(t), \dot{\overline{x}}(t))\, dt = \inf \text{(P)}. \end{aligned}$$

Conversely, consider any arc (θ, ξ) admissible for (Π). One has $\theta'(\tau) \geq m$ for all $\tau \in [0,1]$, so the function θ is strictly increasing, hence invertible. Define $a = \theta(0)$, $b = \theta(1)$, and let $x(t) = \xi(\theta^{-1}(t))$ for $t \in [a,b]$. Evidently $x(t) \in \Omega_t$ for all t in $[a,b]$, while the same substitution as before gives both (4.2) and

$$\int_{\tau=0}^{1} \widetilde{L}(\theta(\tau), \xi(\tau), \theta'(\tau), \xi'(\tau))\, d\tau = \int_{t=a}^{b} L(t, x(t), \dot{x}(t))\, dt.$$

Thus the pair $(x,[a,b])$ is admissible for (P), where it is assigned the same objective value as the pair (θ,ξ) receives in (Π). Consequently $\inf(\mathrm{P}) \le \inf(\Pi)$. Thus equality holds throughout in (4.4) above, and the lemma follows. □

4.2. Verification of hypotheses. The fixed-time problem (Π), with its solution $(\overline{\theta},\overline{\xi})$, has the form to which the necessary conditions of Loewen and Rockafellar [13] may be applied. The first step is to confirm the hypotheses. It is evident that the endpoint cost in problem (Π) is lower semicontinuous and that the (autonomous) integrand $\widetilde{L}$ is lower semicontinuous, hence Borel measurable. Also, for each fixed (θ,ξ), the mapping $(\theta',\xi') \mapsto \widetilde{L}(\theta,\xi,\theta',\xi')$ is convex on the set $(0,\infty)\times\mathbb{R}^n$—the proof is a standard exercise in convex analysis. Only two of the requirements of [13] remain to check.

First, we must verify the epicontinuity of $\widetilde{L}$. To do this, fix τ in $[0,1]$, and choose any point $(\widehat{\theta},\widehat{\xi},\widehat{\theta}',\widehat{\xi}')$ in $\Omega\times\mathbb{R}^{1+n}$ where $\widetilde{L}$ is finite and $|(\widehat{\theta},\widehat{\xi}) - (\overline{\theta}(\tau),\overline{\xi}(\tau))| < \rho$. Consider any sequence $(\theta_k,\xi_k)\to(\widehat{\theta},\widehat{\xi})$. Then the finiteness of $\widetilde{L}$ implies that $\widehat{\theta}' \ge m$, so $L(\widehat{\theta},\widehat{\xi},\widehat{\xi}'/\widehat{\theta}')$ is finite; also $|(\widehat{\theta},\widehat{\xi}) - (t,\overline{x}(t))| < \rho$ for $t=\overline{\theta}(\tau)$. Taking $\widehat{v}=\widehat{\xi}'/\widehat{\theta}'$, we recognize this as a situation to which (H3) applies: that hypothesis provides a sequence $v_k\to\widehat{v}$ along which $L(\theta_k,\xi_k,v_k)\to L(\widehat{\theta},\widehat{\xi},\widehat{v})$. Upon defining $\widehat{\theta}'_k=\widehat{\theta}'$ and $\xi'_k=\widehat{\theta}'v_k$, we deduce that $\widetilde{L}(\theta_k,\xi_k,\theta'_k,\xi'_k)\to\widetilde{L}(\widehat{\theta},\widehat{\xi},\widehat{\theta}',\widehat{\xi}')$, as required.

Second, we must verify the differential inequality in [13, (H5)]. This requires us to produce nonnegative functions $\widetilde{\delta}$ and $\widetilde{\kappa}$ in $L^1[0,1]$, with $\widetilde{\kappa}/\widetilde{\delta}$ in $L^\infty[0,1]$, such that for almost all τ in $[0,1]$, the three conditions

(i) $\big|(\theta,\xi) - (\overline{\theta}(\tau),\overline{\xi}(\tau))\big| < \rho,$

(ii) $\Big|(\theta',\xi') - (\overline{\theta}'(\tau),\overline{\xi}'(\tau))\Big| < \widetilde{\delta}(\tau),$

(iii) $\Big|\widetilde{L}(\theta,\xi,\theta',\xi') - \widetilde{L}(\overline{\theta}(\tau),\overline{\xi}(\tau),\overline{\theta}'(\tau),\overline{\xi}'(\tau))\Big| < \widetilde{\delta}(\tau)$

imply the subgradient inequality

$$|(u,w)| \le \widetilde{\kappa}(\tau)[1+|p|+|q|] \qquad \forall (u,w,q,p)\in\partial\widetilde{L}(\theta,\xi,\theta',\xi'). \tag{4.5}$$

Upon expressing $\widetilde{L}(\theta,\xi,\theta',\xi') = \theta' L(\theta,\xi,\xi'/\theta') + \Psi_{[m,+\infty)}(\theta')$, we can estimate the subgradient set appearing in (4.5) using the calculus rules of Rockafellar [21, Cor. 7.1.2]: for evaluation points where $\theta' > m$, we obtain

$$\partial\widetilde{L}(\theta,\xi,\theta',\xi') \subseteq \Big\{(u\theta', w\theta', -H(\theta,\xi,p), p) \,:\, (u,w,p)\in\partial L(\theta,\xi,\xi'/\theta')\Big\}. \tag{4.6}$$

(A direct application of the cited chain rule produces a third component of the form $L(\theta,\xi,\xi'/\theta') - \langle p\,,\,\xi'/\theta'\rangle$ on the right side. However, this expression equals $-H(\theta,\xi,p)$, as explained in subsection 1.5.) Thus a sufficient condition for (4.5) (at least when $\theta' > m$) is

$$|(u,w)| \le \frac{\widetilde{\kappa}(\tau)}{\theta'}[1+|p|+|H(\theta,\xi,p)|] \quad \forall (u,w,p)\in\partial L(\theta,\xi,\xi'/\theta'). \tag{4.7}$$

Let us prove that under our assumption (H4), conditions (i)–(iii) imply both $\theta' > m$ and (4.7), using the constant functions

$$\widetilde{\kappa} = \Big(\overline{\theta}'(\tau) + m\Big)\,\kappa, \qquad \widetilde{\delta} = \min\Big\{m\delta,\, \overline{\theta}'(\tau) - m,\, m\Big\}. \tag{4.8}$$

Indeed, fix τ in $[0,1]$ and a point $(\theta,\xi,\theta',\xi')$ obeying (i)–(iii). By (ii) and our choice of $\widetilde{\delta}$,

$$m \le \overline{\theta}'(\tau) - \widetilde{\delta} < \theta' < \overline{\theta}'(\tau) + \widetilde{\delta} < \overline{\theta}'(\tau) + m, \tag{4.9}$$

so we have $\theta' > m$ as required. Next, using the triangle inequality with condition (ii), we have

$$\begin{aligned}\left|\frac{\xi'}{\theta'} - \frac{\overline{\xi}'(\tau)}{\overline{\theta}'(\tau)}\right| &\le \frac{1}{\theta'}\left|\xi' - \overline{\xi}'(\tau)\right| + \left|\frac{\overline{\xi}'(\tau)}{\overline{\theta}'(\tau)}\right|\frac{\left|\overline{\theta}'(\tau) - \theta'\right|}{\theta'} \\ &\le \frac{1}{m}\left[1 + \left|\frac{\overline{\xi}'(\tau)}{\overline{\theta}'(\tau)}\right|\right]\widetilde{\delta}.\end{aligned} \tag{4.10}$$

Likewise, consider condition (iii). Expanding the definition of $\widetilde{L}$, and using the shorthand $L = L(\theta, \xi, \xi'/\theta')$ and $\overline{L} = L(\overline{\theta}(\tau), \overline{\xi}(\tau), \overline{\xi}'(\tau)/\overline{\theta}'(\tau))$, we derive

$$\widetilde{\delta} > \left|\theta' L - \overline{\theta}'\overline{L}\right| \ge \theta'\left|L - \overline{L}\right| - \left|\left(\overline{\theta}'(\tau) - \theta'\right)\overline{L}\right| \ge m\left|L - \overline{L}\right| - \widetilde{\delta}\left|\overline{L}\right|.$$

This implies

$$\left|L - \overline{L}\right| \le \frac{\widetilde{\delta}}{m}\left[1 + \left|\overline{L}\right|\right]. \tag{4.11}$$

Now for $\widetilde{\kappa}$ and $\widetilde{\delta}$ as shown in (4.8) above, we have $\widetilde{\delta}/m \le \delta$. Thus, with the change of variable $t = \overline{\theta}(\tau)$, under which

$$\tau = \overline{\theta}^{-1}(t), \quad \overline{\xi}(\tau) = \overline{x}(t), \quad \overline{\xi}'(\tau)/\overline{\theta}'(\tau) = \dot{\overline{x}}(t), \tag{4.12}$$

and the parallel change of notation $r = \theta$, $\xi = x$, $\xi'/\theta' = v$, condition (i) states

(i′) $|(r, x) - (t, \overline{x}(t))| < \rho$.

Meanwhile, condition (ii) implies, through (4.10), that

(ii′) $\left|v - \dot{\overline{x}}(t)\right| \le \delta\left[1 + \left|\dot{\overline{x}}(t)\right|\right]$.

Finally, estimate (4.11)—a consequence of (iii)—becomes

(iii′) $\left|L(r, x, v) - L(t, \overline{x}(t), \dot{\overline{x}}(t))\right| \le \delta\left[1 + \left|L(t, \overline{x}(t), \dot{\overline{x}}(t))\right|\right]$.

These are precisely the conditions under which (H4) implies

$$|(u, w)| \le \kappa[1 + |p| + |H(r, x, p)|] \qquad \forall (u, w, p) \in \partial L(r, x, v).$$

Our choice of $\widetilde{\kappa}$ and inequality (4.9) imply that $\kappa = \widetilde{\kappa}/(\overline{\theta}'(\tau) + m) < \widetilde{\kappa}/\theta'$ for all points of interest, so inequality (4.7) follows. This establishes [13, (H5)].

4.3. Retrieval of conclusions. Having confirmed the hypotheses of [13], we may now use its conclusions. In the state-constraint-free case at hand, these are expressed most clearly in [13, Thm. 2.1]. They assert the existence of an absolutely continuous function $(\eta, \pi)\colon [0, 1] \to \mathbb{R} \times \mathbb{R}^n$ satisfying adjoint equations of either normal or singular type. We will rewrite these conclusions in terms of the absolutely continuous functions $h(t) = -\eta(\overline{\theta}^{-1}(t))$ and $p(t) = \pi(\overline{\theta}^{-1}(t))$.

In the normal conditions, [13] provides the transversality relation

$$(\eta(0), \pi(0), -\eta(1), -\pi(1)) \in \partial l\big(\overline{\theta}(0), \overline{\xi}(0), \overline{\theta}(1), \overline{\xi}(1)\big) \tag{4.13}$$

and the Euler–Lagrange inclusion

$$(\eta'(\tau), \pi'(\tau)) \in \operatorname{co}\left\{(\alpha, \beta) : (\alpha, \beta, \eta(\tau), \pi(\tau)) \in \partial\widetilde{L}(\overline{\theta}(\tau), \overline{\xi}(\tau), \overline{\theta}'(\tau), \overline{\xi}'(\tau))\right\} \tag{4.14}$$

for almost all τ in $[0, 1]$. The subgradient estimate (4.6) reveals that the inclusion involving $\partial\widetilde{L}$ in the latter condition implies that for some (u, w, p) in $\partial L(\overline{\theta}(\tau), \overline{\xi}(\tau),$

$\overline{\xi}'(\tau)/\overline{\theta}'(\tau)$), one has $\alpha = u\overline{\theta}'(\tau)$, $\beta = w\overline{\theta}'(\tau)$, $\eta(\tau) = -H\big(\overline{\theta}(\tau), \overline{\xi}(\tau), p\big)$, and $\pi(\tau) = p$. Consequently the Euler–Lagrange inclusion implies

$$(\eta'(\tau), \pi'(\tau)) \in \mathrm{co}\Big\{\Big(u\overline{\theta}'(\tau), w\overline{\theta}'(\tau)\Big) : (u, w, \pi(\tau)) \in \partial L\Big(\overline{\theta}(\tau), \overline{\xi}(\tau), \overline{\xi}'(\tau)/\overline{\theta}'(\tau)\Big), \\ \eta(\tau) = -H\big(\overline{\theta}(\tau), \overline{\xi}(\tau), \pi(\tau)\big)\Big\}.$$

In particular, the arcs h and p defined above obey, for almost all t in $[\overline{a}, \overline{b}]$,

$$\Big(-\dot{h}(t), \dot{p}(t)\Big) \in \mathrm{co}\{(u, w) : (u, w, p(t)) \in \partial L(t, \overline{x}(t), \dot{\overline{x}}(t)), h(t) = H(t, \overline{x}(t), p(t))\}.$$

The second condition defining the set on the right side places no restrictions on the points (u, w) in this set, but it does serve to make the set empty at every time t where the condition fails. Thus the indicated inclusion can be split apart to give the Euler–Lagrange inclusion stated in Theorem 1.1(a) and the identity

$$h(t) = H(t, \overline{x}(t), p(t)) \text{ a.e. } t \in \big[\overline{a}, \overline{b}\big]\,. \tag{4.15}$$

The Hamiltonian form of the set on the right in Theorem 1.1(a) is provided by Rockafellar [22]. Theorem 1.1(b) then follows from (4.15), as explained in subsection 1.5.

In the singular case, the transversality relation in [13] states

$$(\eta(0), \pi(0), -\eta(1), -\pi(1)) \in \partial^\infty l\big(\overline{\theta}(0), \overline{\xi}(0), \overline{\theta}(1), \overline{\xi}(1)\big) \tag{4.16}$$

and the Euler–Lagrange inclusion is replaced by

$$(\eta'(\tau), \pi'(\tau)) \in \mathrm{co}\Big\{(\alpha, \beta) : (\alpha, \beta, \eta(\tau), \pi(\tau)) \in \partial^\infty \widetilde{L}(\overline{\theta}(\tau), \overline{\xi}(\tau), \overline{\theta}'(\tau), \overline{\xi}'(\tau))\Big\}$$

for almost all τ in $[0, 1]$. The analysis of this statement parallels the developments in the normal case line by line, starting with an estimate of the singular subgradients of $\widetilde{L}$ again furnished by [21, Cor. 7.1.2]:

$$\partial^\infty \widetilde{L}(\theta, \xi, \theta', \xi') \subseteq \Big\{(u\theta', w\theta', -\langle p\,,\, \xi'/\theta'\rangle\,, p) : (u, w, p) \in \partial^\infty L(\theta, \xi, \xi'/\theta')\Big\}. \tag{4.17}$$

As before, the subgradient estimate leads to the conclusion that the arcs h and p defined above obey, for almost all t in $[\overline{a}, \overline{b}]$,

$$\Big(-\dot{h}(t), \dot{p}(t)\Big) \in \mathrm{co}\{(u, w) : (u, w, p(t)) \in \partial^\infty L(t, \overline{x}(t), \dot{\overline{x}}(t)), h(t) = \big\langle p(t)\,,\, \dot{\overline{x}}(t)\big\rangle\}.$$

The latter inclusion implies both the Euler–Lagrange inclusion stated as conclusion (a^∞) of Theorem 1.1 and the identity $h(t) = \big\langle p(t)\,,\, \dot{\overline{x}}(t)\big\rangle$ of conclusion (b^∞).

4.4. Nontriviality. A direct application of [13, Thm. 2.1] yields an apparently weaker nontriviality assertion than the one made in Theorem 1.1 in that the singular conditions of [13] refer to an adjoint arc that is *not the zero function,* whereas those in the present paper assert that it is a function that *never takes the value zero.* Under our hypotheses, these two properties are actually equivalent—although the second, being more explicit, is clearly preferable. We justify this claim in the context of our earlier paper [13] so as to sharpen the results in that work at the same time that we note their consequences for our current investigation. No generality is lost in working on the fixed time interval $[0, 1]$.

Assume [13, (H5)], which provides two positive-valued functions $\kappa, \delta \in L^1[0, 1]$ such that $\kappa/\delta \in L^\infty[0, 1]$ and the three inequalities

$$|x - \overline{x}(t)| < \rho, \quad \big|v - \dot{\overline{x}}(t)\big| < \delta(t), \quad \big|L(t, x, v) - L\big(t, \overline{x}(t), \dot{\overline{x}}(t)\big)\,\big| < \delta(t) \tag{4.18}$$

imply the subgradient inequality

$$|w| \le \kappa(t)[1+|p|] \quad \forall (w,p) \in \partial L(t,x,v). \tag{4.19}$$

(Here the subgradient is taken only with respect to the pair (x,v).) It is easy to deduce that the same three inequalities also imply the *singular* subgradient estimate

$$|w| \le \kappa(t)|p| \quad \forall (w,p) \in \partial^\infty L(t,x,v). \tag{4.20}$$

Now if an arc p satisfies the singular Euler–Lagrange inclusion of [13, Thm. 2.1], i.e.,

$$\dot p(t) \in \operatorname{co}\{w : (w,p(t)) \in \partial^\infty L\big(t,\overline{x}(t),\dot{\overline{x}}(t)\big)\} \text{ a.e. } t \in [0,1],$$

then for almost all t, the representation $\dot p(t) = \sum \lambda_j w_j$ for suitable scalars $\lambda_j \ge 0$, $\sum \lambda_j = 1$, and pairs $(w_j, p(t)) \in \partial^\infty L\big(t,\overline{x}(t),\dot{\overline{x}}(t)\big)$, leads via (4.20) to the inequality

$$|\dot p(t)| \le \sum \lambda_j |w_j| \le \sum \lambda_j [\kappa(t)|p(t)|] = \kappa(t)|p(t)|. \tag{4.21}$$

Under (4.21), the statements, "$p(t) \ne 0$ for *all* $t \in [0,1]$" and "$p(t) \ne 0$ for *some* $t \in [0,1]$" are known to be equivalent, in consequence of Gronwall's lemma.

5. Unilateral state constraints. The methods described above apply equally well when the basic problem (P) is augmented by a unilateral constraint of the form

$$x(t) \in X(t) \quad \forall t \in [a,b]. \tag{5.1}$$

Under the standing hypotheses (H1)–(H4), we can treat any such constraint for which

(H5) the multifunction $X\colon [\overline{a}-\rho, \overline{b}+\rho] \rightrightarrows \mathbb{R}^n$ has closed graph.

To state the corresponding extension of Theorem 1.1, we use the block-structured $(1+n)\times(1+n)$ matrix $A = \left[\begin{smallmatrix} -I & 0 \\ 0 & I \end{smallmatrix}\right]$ and the Clarke normal cone [3] to $\operatorname{gph} X$,

$$\overline{N}_{\operatorname{gph} X}(t,x) = \operatorname{cl}\operatorname{co} N_{\operatorname{gph} X}(t,x) \qquad \forall (t,x) \in \operatorname{gph} X.$$

We also rely on the terminology and conventions explained in [12] (see also [13]).

THEOREM 5.1. *Let the arc $\overline{x}$ with interval $[\overline{a},\overline{b}]$ provide the minimum in problem* (P) *under the additional constraint* (5.1). *If* (H1)–(H5) *hold and*

(CQ) *the normal cone $N_{\operatorname{gph} X}(t,\overline{x}(t))$ is pointed for all t in $[\overline{a},\overline{b}]$,*

then there is a function $(h,p)\colon [\overline{a},\overline{b}] \to \mathbb{R}\times\mathbb{R}^n$ of bounded variation satisfying either the normal conditions or the singular conditions below. In either case, the singular part of the measure $(-dh, dp)$ is $\overline{N}_{\operatorname{gph} X}(t,\overline{x}(t))$-valued, so its support is a subset of

$$\{t : \overline{N}_{\operatorname{gph} X}(t,\overline{x}(t)) \ne \{0\}\} = \{t \in [\overline{a},\overline{b}] : (t,\overline{x}(t)) \in \operatorname{bdy}\operatorname{gph} X(t)\}.$$

Normal conditions: *For almost every t in $[\overline{a},\overline{b}]$,*

(a) $(\dot h(t), \dot p(t)) \in \operatorname{co}\{(u,w) : (-u,w,p(t)) \in \partial L\big(t,\overline{x}(t),\dot{\overline{x}}(t)\big)\} + A\overline{N}_{\operatorname{gph} X}(t,\overline{x}(t))$
$= \operatorname{co}\{(u,w) : \big(u,-w,\dot{\overline{x}}(t)\big) \in \partial H\big(t,\overline{x}(t),p(t)\big)\} + A\overline{N}_{\operatorname{gph} X}(t,\overline{x}(t))$.

(b) $h(t) = H(t,\overline{x}(t),p(t))$,
$h(t) = \langle p(t), \dot{\overline{x}}(t)\rangle - L\big(t,\overline{x}(t),\dot{\overline{x}}(t)\big)$.

(c) $\big(-h(\overline{a}), p(\overline{a}), h(\overline{b}), -p(\overline{b})\big) \in \partial l\big(\overline{a},\overline{x}(\overline{a}),\overline{b},\overline{x}(\overline{b})\big)$.

Singular conditions: *The pair (h,p) is not identically zero, and for a.e. t in $[\overline{a},\overline{b}]$,*

(a^∞) $(\dot h(t), \dot p(t)) \in \operatorname{co}\{(u,w) : (-u,w,p(t)) \in \partial^\infty L(t,\overline{x}(t),\dot{\overline{x}}(t))\} + A\overline{N}_{\operatorname{gph} X}(t,\overline{x}(t))$.

(b^∞) $h(t) = \langle p(t)\,,\, \dot{\overline{x}}(t)\rangle$.

(c^∞) $(-h(a), p(a), h(b), -p(b)) \in \partial^\infty l(\overline{a}, \overline{x}(a), \overline{b}, \overline{x}(b))$.

In particular, if the only function pair (h,p) satisfying conditions (a^∞)–(c^∞) is identically zero, then the normal conditions are satisfied.

Remarks. (1) If the state constraint is inactive along the optimal arc, i.e., $(t, \overline{x}(t))$ is an interior point of $\operatorname{gph} X$ for all t, then the singular part of (dh, dp) must be $\{(0,0)\}$-valued. That is, (h,p) is actually an arc, and we recover the conclusions of Theorem 1.1.

(2) The times when the first equation in conclusion (b) holds can be estimated using Proposition 1.2, as explained in subsection 1.6.

ASYMPTOTIC OPTIMIZATION OF A NONLINEAR HYBRID SYSTEM GOVERNED BY A MARKOV DECISION PROCESS*

EITAN ALTMAN† AND VLADIMIR GAITSGORY‡

Abstract. We consider in this paper a continuous time stochastic hybrid control system with finite time horizon. The objective is to minimize a nonlinear function of the state trajectory. The state evolves according to a nonlinear dynamics. The parameters of the dynamics of the system may change at discrete times $l\epsilon$, $l = 0, 1, ...$, according to a controlled Markov chain which has finite state and action spaces. Under the assumption that ϵ is a small parameter, we justify an averaging procedure allowing us to establish that our problem can be approximated by the solution of some deterministic optimal control problem.

Key words. hybrid stochastic systems, asymptotic optimality, nonlinear dynamics, Markov decision processes, averaging

1. Introduction and statement of the problem.

Consider the following hybrid stochastic control system. The state $Z_t \in \mathbb{R}^n$ evolves according to the following dynamics:

$$\frac{d}{dt} Z_t = f(Z_t, Y_t), \qquad t \in [0,1], \qquad Z_0 = z, \tag{1}$$

where $Y_t \in \mathbb{R}^k$ is the "control" to be specified later and z is the initial state. f is assumed to be linear in the second argument (for each value of the first argument), i.e.,

$$f(z,y) = f^1(z) + f^2(z)y, \tag{2}$$

where f^1 is an n-dimensional vector and f^2 is an $n \times k$ matrix; $f^2(z)y$ is the multiplication between the matrix $f_2(z)$ and the vector y. The functions $f^1(z)$ and $f^2(z)$ are supposed to be bounded and to satisfy the Lipschitz condition

$$\left\| f^i(z) - f^i(z') \right\|_1 \le C_1 \left\| z - z' \right\|_1 \qquad \forall z, z', \tag{3}$$

$$\left\| f^i(z) \right\|_1 \le C_2, \tag{4}$$

where z, z' are from a sufficiently large domain which contains all possible trajectories of (1), C_1 and C_2 are constants, and $\|\cdot\|_1$ stands for the L_1 norm in the finite-dimensional space. That is, $\|q\|_1 = \max_{i=1,...,k} |q_i|$ for the vector $q = \{q_i\}, i = 1, ..., k$, and $\|A\|_1 = \max_{\|q\|_1 = 1} \|Aq\|_1$ for the matrix $A(n \times k)$.

It is assumed in what follows that there exists a bounded domain containing all the trajectories of (1), and, thus, (4), in fact, is implied by (3).

Y_t is not chosen directly by the controller but is obtained as a result of controlling the following underlying stochastic discrete event system. Let ϵ be the basic time unit. Time is discretized; i.e., transitions occur at times $t = n\epsilon,\ n = 0, 1, 2, ..., \lfloor \epsilon^{-1} \rfloor$, where $\lfloor x \rfloor$ stands for the greatest integer which is smaller than or equal to x. There is a finite state space $\mathbf{X} = \{1, ..., N\}$ and a finite action space $\mathbf{A}$. If a state is v and an action a is chosen, then the next state is w with the probability P_{vaw}. A policy $u = \{u_0, u_1, ...\}$ in the set of policies U is a sequence of probability measures on $\mathbf{A}$; at each time $t = n\epsilon$ the controller chooses u_n based on the history of all previous states and actions, as well as the present state. Thus, u_n is a function that maps histories of the form $h_n = (x_0, a_0, x_1, a_1, ..., x_{n-1}, a_{n-1}, x_n)$ to probability measures on $\mathbf{A}$.

We shall be especially interested in the following classes of policies:

- the Markov policies, denoted by $\mathcal{M}$, i.e., policies for which u_t depends only on the current state and does not depend on previous states and actions.
- the stationary policies, denoted by $\mathcal{S}$, i.e., policies for which u_t depends only on the current state and does not depend on previous states and actions nor on the time.

The stochastic process $\{X_n, A_n\}$ is known as a controlled Markov chain, or Markov decision process (MDP); see Derman [11, pp. 2–4]. We assume throughout the paper that under any stationary policy, the state space forms an aperiodic Markov chain such that all states communicate (regular Markov chain). The results of the paper hold, in fact, under weaker ergodicity assumptions; however, the restricted assumption makes the presentation clearer.

Denote by $\mathbf{H}$ the set of all possible states and actions histories which can be observed until time $\lfloor \epsilon^{-1} \rfloor$:

$$\mathbf{H} = \bigcup \{h\}, \qquad h = \left\{ (x_n, a_n), n = 0, 1, ..., \lfloor \epsilon^{-1} \rfloor \right\}.$$

Let $\mathcal{F}$ be the σ-algebra of all subsets of $\mathbf{H}$. Each policy u and initial state x determines a probability measure on $\mathcal{F}$, on which the stochastic state and action process $H = \left\{ X_n, A_n, n = 0, 1, ..., \lfloor \epsilon^{-1} \rfloor \right\}$ is defined. Denote by P_x^u and E_x^u the probability measure and mathematical expectation that correspond to an initial state $X_0 = x$ and a policy u. Sometimes we shall assume an initial distribution ξ on X_0, instead of a fixed initial state. In that case P_ξ^u, E_ξ^u denote the corresponding probability measure and mathematical expectation.

Let $y : \mathbf{X} \times \mathbf{A} \to \mathbb{R}^k$, $j = 1, ..., k$, be some given vector-valued function. Then Y_t in (1) is given by

$$Y_t = y(X_{\lfloor t/\epsilon \rfloor}, A_{\lfloor t/\epsilon \rfloor}). \tag{5}$$

The system (1) with thus-defined Y_t is called hybrid, first, because Y_t changes its values via some random jumps whereas Z_t is a smooth (differentiable) function of time and, second, because, as follows from the consideration below, Y_t being controlled "statistically" through controlling the transition probabilities plays by itself the role of a "direct" control with respect to Z_t.

Let $g : \mathbb{R}^n \to \mathbb{R}$ be some operating cost related to the process Z_t. We assume that it is Lipschitz continuous; i.e.,

$$\|g(z) - g(z')\|_1 \le C_1 \|z - z'\|_1 .$$

We consider the following control problem with ϵ and x fixed.

$\mathbf{Q}_\epsilon$: find a policy u that achieves $F^\epsilon(z,x) = \inf_{u\in U} E_x^u g(Z_1)$, where Z_1 is obtained through (1).

Our model is characterized by the fact that ϵ is supposed to be a small parameter and our objective is to construct a policy (depending, in general, on ϵ) which is asymptotically optimal for $\mathbf{Q}_\epsilon$. That is, the difference between the cost under this policy and $F^\epsilon(z,x)$ converges to zero as $\epsilon \to 0$.

The type of model which we introduce is natural in the control of inventories or of production, where we deal with material whose quantity may "slowly" change in a continuous (linear) way. Breakdowns, repairs, and other control decisions yield the underlying MDP. Our model may also be used in the control of highly loaded queueing networks for which the fluid approximation holds (see Kleinrock [20, p. 56]). The slow variables Z_t may then represent the number of customers in the different queues, whereas the underlying MDP may correspond to routing, or flow control of, say, some long on/off traffic.

The fact that ϵ is chosen to be small means that the variables Y_t along with the MDP X_t can be considered to be fast with respect to the time scale t in which Z_t evolves. Indeed, Y_t and X_t may have large jumps between $t = m\epsilon$ and $t = (m+1)\epsilon$, whereas the corresponding change in Z_t in that period is of order ϵ. The problem is, thus, close in nature to stochastic singular perturbed control problems intensively studied in the literature (see, for example, [1], [5], [6], [7], [9], [10], [21], [23], [24], [25] and references therein). A common approach to this kind of problem is an application of singular perturbations or averaging techniques to the Hamilton–Jacobi–Bellman (HJB) equation for problems in continuous time (as in [5], [6], [21]) or to the dynamic programming equation for singularly perturbed MDPs [1], [7], [9], [10], [24], [25]. In contrast to this approach, we, as in [23], apply an averaging method directly to the "slow" stochastic equation. Our model differs, however, from the ones in [23] in many respects—mainly in the type of fast motions involved, which implies the differences in both the technique used and the results obtained.

In our previous paper [2], we considered the problem similar to $\mathbf{Q}_\epsilon$ for the case of linear dynamics f and cost g and showed that an asymptotically optimal policy can be constructed via maximization of the Hamiltonian of some linear deterministic system. The technique we used was, however, strongly related to the linearity of the model, and it is not applicable to the case when the dynamics and/or the cost are nonlinear. As opposed to the linear case, the consideration for the nonlinear case is much more involved and based on an ergodicity-type result for MDPs obtained in this paper (see Theorem 4.1 below). Using this result we establish that the trajectories of stochastic hybrid system (1) are approximated by the trajectories of some nonlinear deterministic control system, and the problem $\mathbf{Q}_\epsilon$ is approximated by the corresponding deterministic optimal control problem allowing us, in particular, to construct an asymptotically optimal policy for $\mathbf{Q}_\epsilon$. Notice that this result can be viewed as an extension of the averaging technique for deterministic singularly perturbed control systems (see, e.g., [15]) to the stochastic case under consideration. On the other hand, it can be viewed as an extention of results on uncontrolled motions establishing that the solution of the original stochastic system is approximated by the solution of some deterministic system obtained via averaging over the fast random dynamics [16], [19], [22] to the case when this random dynamics is defined by the controlled Markov chain.

The paper consists of four sections. Section 1 is this introduction; section 2 describes the main results about the approximation of the problem of optimal control

of the hybrid system by a deterministic optimal control problem. In section 3 we discuss ways that the solution of the deterministic optimal control problem can be characterized and how it can be used to obtain an asymptotically optimal policy. Section 4 contains the above-mentioned Theorem 4.1, as well as the proofs of some basic lemmas used in section 2.

2. Description of main results. Let

$$\mathbf{Y}(m,x) \stackrel{\text{def}}{=} \bigcup_{u\in U} \left\{ (m+1)^{-1} \sum_{t=0}^{m} E_x^u Y_t \right\},$$

where the union is taken over all policies. As follows from Theorem 3 in [2], the set $\mathbf{Y}(m,x)$ converges in the Haussdorff metric to a set $\mathbf{Y}$ defined below:

$$\lim_{m\to\infty} \mathbf{Y}(m,x) = \mathbf{Y} \stackrel{\text{def}}{=} \bigcup_{u\in\mathcal{S}} \left\{ \sum_{v,a} \eta(u;v,a) y(v,a) \right\}, \tag{6}$$

where the union is taken over all stationary policies, and $\eta(u) = \{\eta(u;v,a)\}$ is the vector of steady state probabilities of state-action pairs obtained when using a stationary policy u. That is,

$$\eta(u;v,a) = \lim_{n\to\infty} P_x^u(X_n = v, A_n = a). \tag{7}$$

Notice that due to the ergodicity assumption on our model, $\eta(u;v,a)$ does not depend on the initial distribution. Notice also that, since the set

$$W \stackrel{\text{def}}{=} \bigcup_{u\in\mathcal{S}} \{\eta(u)\} \tag{8}$$

is a polyhedron (see, for example, [11, pp. 93–95]), the set $\mathbf{Y}$ is a polyhedron as well.

Define now the averaged deterministic control system as

$$\frac{d}{dt} z_t = f(z_t, y_t), \qquad z_0 = z, \tag{9}$$

where y_t is a measurable function of t taking values in $\mathbf{Y}$. The set of such functions

$$y : [0,1] \to \mathbf{Y}$$

will be called the set of admissible controls.

Our claim is that the set of all random trajectories of (1) is approximated by the set of solutions of (9) obtained with all admissible controls. More specifically, we establish that there exists a function $\gamma(\epsilon)$ satisfying

$$\lim_{\epsilon\to 0} \gamma(\epsilon) = 0$$

such that the following holds.

LEMMA 2.1. *Corresponding to any admissible control $y = \{y_t, t \in [0,1]\}$, there exists a Markov policy $u_\epsilon(y)$ such that the random trajectory Z_t of (1), obtained with this policy $u_\epsilon(y)$, and the deterministic solution z_t^y of (9), obtained with y, satisfy the inequality*

$$\max_{t\in[0,1]} E_x^{u_\epsilon(y)} \left\| Z_t - z_t^y \right\|_1 \le \gamma(\epsilon). \tag{10}$$

LEMMA 2.2. *There exists a function* $\tilde{y}^\epsilon_t(h)$,

$$\tilde{y}^\epsilon : [0,1] \times \mathbf{H} \to \mathbf{Y},$$

such that (a) *for each* $h \in \mathbf{H}$, $\tilde{y}^\epsilon_t(h)$ *is a piecewise constant function of* t *and* (b) *for any policy* u,

$$\max_{t\in[0,1]} E^u_x \left\| Z_t - \tilde{z}^\epsilon_t(H) \right\|_1 \le \gamma(\epsilon), \tag{11}$$

where Z_t *is the solution of* (1), $\tilde{z}^\epsilon_t(H)$ *is the solution of* (9) *obtained with* $y_t = \tilde{y}^\epsilon_t(H)$, *and* H *is the random realization of the state-action trajectories.*

Notice that the quantity under the expectation sign in (11) is a random variable for any policy u since $\mathbf{H}$ is a finite set and $\mathcal{F}$ is the σ-algebra of all subsets of $\mathbf{H}$.

Notice also that a construction of a policy $u_\epsilon(y)$ which allows an estimate (10) in Lemma 2.1 is described below in section 3. This is just a stationary policy when the deterministic control y is a constant function of time, and it consists of a finite number of stationary policies (and thus is not stationary itself) when y is piecewise constant.

Define the "deterministic" optimal control problem $\mathbf{Q_0}$ as follows.

$\mathbf{Q_0}$: Find an admissible control y which minimizes the cost function

$$F^0(z) \stackrel{\text{def}}{=} \inf_y g(z_1)$$

over the trajectories z of system (9). The following theorem about approximation of $\mathbf{Q}_\epsilon$ by $\mathbf{Q_0}$ is then easily established on the basis of Lemmas 2.1 and 2.2.

THEOREM 2.1. *The values* $F^\epsilon(z,x)$ *of the original problem* $\mathbf{Q}_\epsilon$ *converge to the value* $F^0(z)$ *of the problem* $\mathbf{Q_0}$, *as* $\epsilon \to 0$. *More precisely,*

$$\left| F^\epsilon(z,x) - F^0_x(z) \right| \le C_1 \gamma(\epsilon).$$

If y^* *is an optimal control for* $\mathbf{Q_0}$, *then the Markov policy* $u_\epsilon(y^*)$ *allowing estimate* (10) *with* $y = y^*$ *satisfies the inequality*

$$\left| E^{u_\epsilon(y^*)}_x g(Z_1) - F^\epsilon(z,x) \right| \le C_1 \gamma(\epsilon).$$

That is, $u_\epsilon(y^*)$ *is asymptotically optimal for* $\mathbf{Q}_\epsilon$.

Remark 2.1. In the linear case studied in [2], γ can be chosen such that

$$\lim_{\epsilon\to 0} \epsilon^{-(1/2)} \gamma(\epsilon) = 0.$$

Hence, for the linear case, simple bounds on the rate of convergence are available for Lemmas 2.1 and 2.2 as well as for Theorem 2.1.

Proof of Theorem 2.1. Let u be an arbitrary policy and $\tilde{y}^\epsilon(h) \in \mathbf{Y}$ be the function defined in Lemma 2.2. Then

$$|E^u_x g(Z_1) - E^u_x g(\tilde{z}^\epsilon_1(H))| \le C_1 E^u_x \left\| Z_1 - \tilde{z}^\epsilon_1(H) \right\|_1 \le C_1 \gamma(\epsilon), \tag{12}$$

where C_1 is defined in (3). Being piecewise constant, the function $\tilde{y}^\epsilon$ is measurable in t. Hence,

$$g(\tilde{z}^\epsilon_1(h)) \ge F^0(z) \qquad \forall h \in \mathbf{H},$$

which implies

$$E_x^u g(\tilde{z}_1^\epsilon(H)) \geq F^0(z)$$

for any policy u. From the last inequality and (12), it follows that

$$E_x^u g(Z_1) \geq F^0(z) - C_1\gamma(\epsilon),$$

so that

$$F^\epsilon(z,x) = \inf_u E_x^u g(Z_1) \geq F^0(z) - C_1\gamma(\epsilon). \tag{13}$$

Now let y^* be an optimal control in $\mathbf{Q_0}$. By (10),

$$\left|E_x^{u_\epsilon(y^*)} g(Z_1) - F^0(z)\right| = \left|E_x^{u_\epsilon(y^*)} g(Z_1) - g(z_1^{y^*})\right| \leq C_1 E_x^{u_\epsilon(y)} \left\|Z_1 - z_1^{y^*}\right\|_1 \leq C_1\gamma(\epsilon).$$

Hence

$$E_x^{u_\epsilon(y^*)} g(Z_1) \leq F^0(z) + C_1\gamma(\epsilon). \tag{14}$$

Since $E_x^{u_\epsilon(y^*)} g(Z_1) \geq F^\epsilon(z,x)$, the inequalities (13) and (14) conclude the proof of the theorem. □

3. Construction of an asymptotically optimal policy. Let y be an arbitrary admissible control for $\mathbf{Q_0}$. We show below how to construct the policy $u_\epsilon(y)$ (appearing in Lemmas 2.1 and 2.2 and in Theorem 2.1). Choose a function $\Delta = \Delta(\epsilon)$ in such a way that

$$\lim_{\epsilon\to 0} \Delta(\epsilon) = 0, \qquad \lim_{\epsilon\to 0} \frac{\Delta(\epsilon)}{\epsilon} = \infty, \tag{15}$$

and set $\tau_l = \tau(l,\epsilon) := l\Delta(\epsilon),\ l = 0,1,2,...,\ell(\epsilon)$, where $\ell(\epsilon) := \lfloor \Delta(\epsilon)^{-1} \rfloor$. Let

$$r_l^\epsilon(y) \stackrel{\text{def}}{=} (\Delta(\epsilon))^{-1} \int_{\tau_l}^{\tau_{l+1}} y_t dt, \qquad l = 0,1,...,\ell(\epsilon) - 1. \tag{16}$$

Since $\mathbf{Y}$ is a convex set, $r_l^\epsilon(y) \in \mathbf{Y}$. Hence there exists a stationary policy $s_l^\epsilon(y)$ such that

$$r_l(\epsilon) = \sum_{v,a} \eta(s_l^\epsilon(y); v, a) y(v,a). \tag{17}$$

Now construct $u_\epsilon(y)$ as the Markov policy obtained by applying $s_l^\epsilon(y)$ during $n = \lfloor \tau_l/\epsilon \rfloor, \lfloor \tau_l/\epsilon \rfloor + 1, ..., \lfloor \tau_{l+1}/\epsilon \rfloor - 1$, where $l = 0,1,...,\ell(\epsilon) - 1$, and by applying an arbitrary stationary policy during $\lfloor \tau_{\ell(\epsilon)}/\epsilon \rfloor, \lfloor \tau_{\ell(\epsilon)}/\epsilon \rfloor + 1, ..., \lfloor \epsilon^{-1} \rfloor$. In the proof of Lemma 2.1 it is established that the policy $u_\epsilon(y)$ thus constructed satisfies inequality (10).

As follows from Theorem 2.1, the described procedure for obtaining the policy $u_\epsilon(y^*)$, on the basis of a control y_t^* which is optimal for the deterministic problem $\mathbf{Q_0}$, yields an asymptotically optimal policy for problems $\mathbf{Q}_\epsilon$. The optimal control y_t^* can by itself be characterized by necessary and sufficient optimality conditions. To formulate these, let us consider a parametrized set $\mathcal{L} = \{L(z,\lambda)\}$ of MDPs, $(z,\lambda) \in \mathbb{R}^n \times \mathbb{R}^n$, all of which have $\mathbf{X}$ and $\mathbf{A}$ as state and action spaces, and $\mathcal{P} = \{P_{vaw}, v, w \in$

$\mathbf{X}, a \in \mathbf{A}\}$ as transition probabilities. They differ by the immediate cost, which is given by

$$r(z,\lambda;v,a) = \lambda^T f(z, y(v,a)) = \lambda^T f^1(z) + \lambda^T f^2(z) y(v,a).$$

Consider the problem of minimization of the infinite horizon expected average cost related to an initial distribution ξ over $\mathbf{X}$:

(18)

$$J_\xi(z,\lambda) \stackrel{\text{def}}{=} \inf_u J_\xi(z,\lambda;u), \qquad J_\xi(z,\lambda;u) \stackrel{\text{def}}{=} \varliminf_{m\to\infty} \frac{1}{m+1} E_\xi^u \sum_{j=0}^{m} r(z,\lambda;X_j,A_j).$$

It is well known (see Derman [11, section 6]) that

a) The optimal value of the above problem does not depend on the initial distribution ξ, and it is equal to the optimal value of the following linear programming problem:

$$\begin{aligned} J_\xi(z,\lambda) = J(z,\lambda) &\stackrel{\text{def}}{=} \min_\eta \left\{ \sum_{v,a} r(z,\lambda;v,a)\eta(v,a) | \eta = \{\eta(v,a)\} \in W \right\} \\ &= \lambda^T f^1(z) + \min_\eta \left\{ \lambda^T f^2(z) \sum_{v,a} y(v,a)\eta(v,a) | \eta = \{\eta(v,a)\} \in W \right\}. \end{aligned} \tag{19}$$

b) There is a one-to-one correspondence between optimal stationary policies of $L(z,\lambda)$ and the optimal solutions of (19).

The following statement describes necessary optimality conditions for $\mathbf{Q_0}$.

THEOREM 3.1. *Let y_t^* be an optimal control in $\mathbf{Q_0}$ and let z_t^* be the solution of* (9) *obtained with y^*. That is,*

$$\frac{d}{dt} z_t^* = f(z_t^*, y_t^*), \qquad z_0 = z. \tag{20}$$

Then, for almost all $t \in [0,1]$,

$$y_t^* = \sum_{v,a} \eta(z_t^*, \lambda_t; v, a) y(v,a),$$

where $\eta(z,\lambda) = \{\eta(z,\lambda;v,a\}_{v,a}$ stands for a solution of (19) *and λ_t is the solution of the conjugate system*

$$\frac{d}{dt}\lambda_t = -f_z(z_t^*, y_t^*)\lambda_t, \qquad \lambda_1 = g_z(1); \tag{21}$$

f_z and g_z are $n\times n$ and $n\times 1$ matrices of the partial derivatives of f and g, respectively, over the components of z.

Proof. The proof follows from a direct application of the Pontryagin maximum principle [8, 13] to problem $\mathbf{Q_0}$. □

Notice that if the solution of (19) with $z = z_t^*$ and $\lambda = \lambda_t$ is unique for all $t \in [0,1]$ except for a finite number of switching points and, thus, for all these $t \in [0,1]$, the corresponding stationary policy $u(z_t^*, \lambda_t)$ achieving inf in (18) with $z = z_t^*$ and $\lambda = \lambda_t$ is unique, then an asymptotically optimal policy for $\mathbf{Q}_\epsilon$ can be defined by simply applying $u(z_{\tau_l}^*, \lambda_{\tau_l})$ during $\lfloor \tau_l/\epsilon \rfloor, \lfloor \tau_l/\epsilon \rfloor + 1, \lfloor \tau_{l+1}/\epsilon \rfloor - 1$, where $l = 0, 1, ..., \ell(\epsilon) - 1$.

Another way to characterize the optimal control in the problem $\mathbf{Q_0}$ is related to the HJB equation written for this problem in the form

$$B_t^0(z,t) + \min_{y\in\mathbf{Y}}\{(B_z^0(z,t))^T f(z,y)\} = 0, \qquad B^0(z,1) = g(z), \tag{22}$$

where $B_t^0(z,t)$, $B_z^0(z,t)$ stand for the partial derivatives of $B^0(z,t)$ over t and components of z, respectively. By (2), (6), (8), for any z and λ,

$$\min_{y\in\mathbf{Y}} \lambda^T f(z,y) = \lambda^T f^1(z) + \min_y\{\lambda^T f^2(z)y | y\in\mathbf{Y}\} = \lambda^T f^1(z)$$

$$+ \min_\eta \left\{ \sum_{v,a} \lambda^T f^2(z) y(v,a)\eta(v,a) | \eta = \{\eta(v,a)\} \in W \right\} = J(z,\lambda),$$

where $J(z,\lambda)$ is the optimal value of (19). Hence, HJB equation (22) can be rewritten in the form

$$B_t^0(z,t) + J(z, B_z^0(z,t)) = 0, \qquad B^0(z,1) = g(z). \tag{23}$$

This equation allows us to construct both necessary and sufficient conditions of optimality for $\mathbf{Q_0}$ and, in particular, to verify whether a given admissible control y_t and the corresponding solution z_t of (9) are optimal in $\mathbf{Q_0}$ (see details in [8]). On the other hand, the viscosity solution of (23) (see, e.g., [14]) defines the optimal value of the problem $\mathbf{Q_0}$ on the interval $[s,1]$ subject to the initial condition $z_s = z$, which provides an approximation for the optimal value $B^\epsilon(z,x,s)$ of the problem $\mathbf{Q}_\epsilon$ on the same interval $[s,1]$ subject to the same initial condition $z_s = z$ and with the initial state of the MDP being x. More precisely, since, by definition, $B^\epsilon(z,x,0) = F^\epsilon(z,x)$ and $B^0(z,0) = F^0(z)$, from Theorem 2.1 it follows that

$$\lim_{\epsilon\to 0} B^\epsilon(z,x,0) = B^0(z,0).$$

As in this theorem, one can also establish that

$$\lim_{\epsilon\to 0} B^\epsilon(z,x,s) = B^0(z,s),$$

with the convergence being uniform with respect to $s\in[0,1]$, $x\in\mathbf{X}$, and $z\in\mathcal{Z}$, where $\mathcal{Z}$ is a compact subset of $\mathbb{R}^n$.

Notice that the described approach has a decomposition structure. It consists of two phases. First is the optimization of the fast motions which is achieved via the solution of (18) with fixed "slow variables" z and λ. Second is the "slow optimization" achieved via the solution of HJB (23). Notice also that in a general case the solution of equation (23) can be quite complicated. If, however,

$$f(z,y) = Az + By, \qquad g(z) = c^T z, \tag{24}$$

where $A(n\times n)$, $B(n\times k)$, and $c(n\times 1)$ are matrices (that is, if as in [2], $\mathbf{Q_0}$ is a linear optimal control problem), then the solution of (23) is obvious:

$$B^0(z,s) = \lambda_s^T z + \int_s^1 J(\lambda(t))dt,$$

where $J(\lambda) \stackrel{\text{def}}{=} J(z,\lambda) - \lambda^T Az$ and λ_t is the solution of (21) under assumption (24).

4. Proof of Lemmas 2.1 and 2.2.

LEMMA 4.1. *Let $y_t^i(h)$, $i=1,2$, be functions of time t and state-action histories h. Let $z_t^i(h)$ be the solution of (9) obtained with $y_t^i(h)$ (h is fixed), $i=1,2$. Then there exists a constant L such that for any policy u and any initial state x,*

$$\max_{t\in[0,1]} E_x^u \left\|z_t^1(H)-z_t^2(H)\right\|_1 \le L\left(\Delta(\epsilon)+(\Delta(\epsilon))^{-1}\max_{l=0,\dots,\ell(\epsilon)-1} E_x^u\left\|\int_{\tau_l}^{\tau_{l+1}}[y_t^1(H)-y_t^2(H)]dt\right\|_1\right), \tag{25}$$

where H is the random realization of the state-action trajectories.

Proof. For the sake of brevity, we omit H from the notation below and write Δ and ℓ instead of $\Delta(\epsilon)$ and $\ell(\epsilon)$. By definition,

$$z_{\tau_{l+1}}^i = z_{\tau_l}^i + \int_{\tau_l}^{\tau_{l+1}} f(z_t^i, y_t^i)dt.$$

Hence, denoting

$$\delta_l := E_x^u \left\|z_{\tau_l}^1 - z_{\tau_l}^2\right\|_1$$

and taking into account (2), one can write

$$\begin{aligned}
\delta_{l+1} &\le \delta_l + \int_{\tau_l}^{\tau_{l+1}} E_x^u \left\|f(z_t^1,y_t^1)-f(z_{\tau_l}^1,y_t^1)\right\|_1 dt \\
&\quad + E_x^u\left\|\int_{\tau_l}^{\tau_{l+1}}\left[f(z_{\tau_l}^1,y_t^1)-f(z_{\tau_l}^1,y_t^2)\right]dt\right\|_1 \\
&\quad + \int_{\tau_l}^{\tau_{l+1}} E_x^u \left\|f(z_{\tau_l}^1,y_t^2)-f(z_{\tau_l}^2,y_t^2)\right\|_1 dt + \int_{\tau_l}^{\tau_{l+1}} E_x^u \left\|f(z_{\tau_l}^2,y_t^2)-f(z_t^2,y_t^2)\right\|_1 dt \\
&\le \delta_l + L_1\Delta E_x^u\left\|\frac{1}{\Delta}\int_{\tau_l}^{\tau_{l+1}}(y_t^1-y_t^2)dt\right\|_1 + L_3\Delta\delta_l + L_1\Delta^2,
\end{aligned}$$

where L_i are constants defined by C_1 and C_2 in (3) and (4) (and thus do not depend on H). Applying now Proposition 5.1 of Gaitsgory [15], one obtains that for any $K=0,1,...,\ell$,

$$\delta_K \le \tilde{L}\left(\Delta + \max_{l=0,\dots,\ell-1} E_x^u\left\|\frac{1}{\Delta}\int_{\tau_l}^{\tau_{l+1}}(y_t^1-y_t^2)dt\right\|_1\right), \tag{26}$$

where $\tilde{L}$ is a constant. Since

$$\left\|z_t^i - z_{\tau_l}^i\right\|_1 \le L_4\Delta \qquad \forall t\in[\tau_l,\tau_{l+1}]$$

for some constant L_4, (26) implies (25) with $L=\tilde{L}+2L_4$. □

We need another general result on MDPs that establishes the uniform convergence of the state-action frequencies to their limits. More precisely, consider arbitrary integers m and K, and define the random variables

$$\psi_m^K(v,a) = \psi_m^K(H;v,a) := \frac{1}{K}\sum_{n=m+1}^{m+K} 1\{X_n=v, A_n=a\}.$$

Let $\psi_m^K := \{\psi_m^K(v,a)\}_{v,a}$ denote the vector of state-action frequencies. Denote

$$d_K^1 = \operatorname{dist}\{\psi_0^K, W\} = \inf_{\eta \in W} \left\|\psi_0^K - \eta\right\|_1.$$

It follows from Derman [11, Chapter 8, p. 98] (see also [3, section 3]) that for any policy u and initial distribution ξ,

$$\lim_{K\to\infty} d_K^1 = 0, \qquad P_\xi^u \text{ a.s.} \tag{27}$$

This implies, by the bounded convergence theorem, that

$$\lim_{K\to\infty} E_\xi^u d_K^1 = 0. \tag{28}$$

For any stationary policy $u \in \mathcal{S}$ the limit

$$\psi_0 := \lim_{K\to\infty} \psi_0^K$$

exists (P_ξ^u a.s.), and it does not depend on the initial distribution ξ (in fact, $\psi_0(v,a) = \eta(u;v,a)$). Define

$$d_K^2 = \left\|\psi_0^K - \psi_0\right\|_1.$$

THEOREM 4.1. *The following holds:*

$$\lim_{K\to\infty} \sup_\xi \sup_{u\in U} E_\xi^u d_K^1 = 0, \tag{29}$$

$$\lim_{K\to\infty} \sup_\xi \sup_{u\in \mathcal{S}} E_\xi^u d_K^2 = 0. \tag{30}$$

Proof. In order to prove the theorem, we define some operations on policies. A k-shift $v = \Theta^k u$ of a policy u is defined to be a sequence $v = \{v_k, v_{k+1}, ...\}$, where

$$v_{n+k}(x_0, a_0, x_1, a_1, ..., x_{n+k-1}, a_{n+k-1}, x_{n+k})$$

$$= u_n(x_k, a_k, x_{k+1}, a_{k+1}, ..., x_{n+k-1}, a_{n+k-1}, x_{n+k}).$$

A policy w is defined to be a concatenation of u and v from time k if

$$w_n = \begin{cases} u_n, & n < k, \\ (\Theta^k v)_n, & n \geq k. \end{cases}$$

We then denote this policy by $w = [u\{k\}v]$. We similarly define a concatenation of a sequence of policies u^i with times t^i, and denote it by $[u^1\{t^1\}u^2\{t^2\}...]$ (where policy u^i is used for a duration of t^i time units).

Assume (29) does not hold. Then there exist sequences of initial distribution over the states $\xi(i) = \{\xi_1(i), ..., \xi_N(i)\}$, of strictly increasing times $t(i)$ and of policies $u(i)$, and a constant $\alpha_1 > 0$ such that for all i,

$$E_{\xi(i)}^{u(i)} d_{t(i)}^1 \geq \alpha_1. \tag{31}$$

It follows that there exist sequences of strictly increasing times $t'(i)$ and of policies $u'(i)$, and a constant $\alpha_2 > 0$ such that for all i,

$$E_{\xi'}^{u'(i)} d_{t'(i)}^1 \geq \alpha_2 \tag{32}$$

for any initial distribution ξ'. Indeed, fix $t'(i) = t(i) + N, i = 1, 2, ...$ (N is the number of states). Fix some stationary policy s and let $u'(i)$ be the policy $[s\{N\}\Theta^N u(i)]$, i.e., the policy obtained by using s during the first N steps, and then using a shifted policy $\Theta^N u(i)$. Due to the unichain and aperiodicity assumption, the Markov chain induced by the stationary policy s is regular, and it follows (see [18]) that there exists some $\alpha_3 > 0$ such that $P^s_{\xi'}(X_N = z) > \alpha_3$ for any z and ξ'. (31) then implies that (32) holds for all i sufficiently large and ξ' with $\alpha_2 = \alpha_1\alpha_3/2$. Indeed, let i be such that

$$t(i) \geq \frac{4N}{\alpha_1\alpha_3}.$$

It then follows that

$$|d^1_{t(i)} - d^1_{t'(i)}| \leq 2N/t(i) \leq \frac{\alpha_1\alpha_3}{2}.$$

This implies that

$$\begin{aligned}
E^{u'(i)}_{\xi'} d^1_{t'(i)} &= \sum_z P^{u'(i)}_{\xi'}(X_N = z)\left[E^{u'(i)}_{\xi'} d^1_{t'(i)} \middle| X_N = z\right] \\
&= \sum_z P^{s}_{\xi'}(X_N = z)\left[E^{u'(i)}_{\xi'} d^1_{t'(i)} \middle| X_N = z\right] \\
&\geq \sum_z P^{s}_{\xi'}(X_N = z) E^{u(i)}_z d^1_{t(i)} - \frac{\alpha_1\alpha_3}{2} \geq \alpha_3 \sum_z E^{u(i)}_z d^1_{t(i)} - \frac{\alpha_1\alpha_3}{2} \\
&\geq \alpha_3 \sum_z \xi_z(i) E^{u(i)}_z d^1_{t(i)} - \frac{\alpha_1\alpha_3}{2} = \alpha_3 E^{u(i)}_{\xi(i)} d^1_{t(i)} - \frac{\alpha_1\alpha_3}{2} \geq \frac{\alpha_1\alpha_3}{2}. \qquad (33)
\end{aligned}$$

Equation (33) is due to the following. Policy $u'(i)$ behaves like the stationary policy s during the first N steps. So, at time N, we reach state z with probability $P^s_{\xi'}(X_N = z)$. Then the behavior during the interval $[N, t'(i)]$, according to policy $u'(i)$, is that of the policy u during the interval $[0, t'(i) - N] = [0, t(i)]$.

Consider now some subsequence $t'(i)$ for which (32) holds and for which

$$\frac{\sum_{l=1}^i t'(l)}{t'(i+1)} \leq \frac{\alpha_2}{4}.$$

Consider the concatenated policy $\tilde{u}$ defined as $\tilde{u} = [u'(1)\{t'(1)\}u'(2)\{t'(2)\}...]$. (32) implies that

$$\overline{\lim_{K\to\infty}} E^{\tilde{u}}_{\xi'} d^1_K \geq \frac{\alpha_2}{2} > 0 \qquad (34)$$

for any initial distribution ξ'. Indeed, choose any integer n and define $K = \sum_{i=1}^n t'(i)$, $K' = \sum_{i=1}^{n+1} t'(i)$. Then

$$|E^{\bar{u}}_{\xi'}[d^1_{K'}|X(K) = z] - E^{u'(i+1)}_z d^1_{t'(i+1)}| \leq \frac{2\sum_{l=1}^i t'(l)}{t'(i+1)} \leq \frac{\alpha_2}{2},$$

which implies that

$$\begin{aligned}
E^{\tilde{u}}_{\xi'} d^1_{K'} &= \sum_z P^{\tilde{u}}_{\xi'}(X(K) = z) E^{\tilde{u}}_{\xi'}[d^1_{K'}|X(K) = z] \\
&\geq \sum_z P^{\tilde{u}}_{\xi'}(X(K) = z) E^{u'(i+1)}_z d^1_{t'(i+1)} - \frac{\alpha_2}{2} \geq \frac{\alpha_2}{2}. \qquad (35)
\end{aligned}$$

This, however, contradicts (28) for $u = \tilde{u}$. We thus conclude that the convergence in (28) is uniformly in ξ and $u \in U$.

Next, assume that (30) does not hold. Below, if u is stationary, we understand $u(a|x)$ to be the probability of choosing action a when in state x. The class of stationary policies is compact; i.e., for any sequence $u(i) \in \mathcal{S}$, there exists a subsequence $u(i_j)$ such that the policy $u^* = \lim_{j\to\infty} u(i_j)$ (i.e., the policy for which $u^*(a|x) = \lim_{j\to\infty} u(i_j)(a|x)$ for all a and x) is stationary.

It follows by arguments as in the first part of the proof that there exist sequences of times $t(i)$ and of stationary policies $s(i)$, and a constant $\alpha_4 > 0$ such that for all i,

$$E_\xi^{s(i)} d_{t(i)}^2 \geq \alpha_4 \tag{36}$$

for any initial distribution ξ. Moreover, due to the compactness of $\mathcal{S}$, $s(i)$ can be chosen to be a convergent sequence, with s^* its limit. It then follows that

$$\lim_{i\to\infty} \eta(s(i)) = \eta(s^*) \tag{37}$$

(see [17, p. 82]).

Consider now the Markov policy $\tilde{s}$ that follows policy $s(1)$ until time $t(1)$, then switches to $s(2)$ and uses that policy until $t(2)$, then switches to $s(3)$ and uses it until $t(3)$, and so on. Since for any initial distribution ξ and for any stationary policy $s(i)$, we have

$$\psi_0 = \eta(s(i)), \qquad P_\xi^{s(i)} \text{ a.s.}, \tag{38}$$

it follows by choosing the sequence of times $t(i)$ so that the intervals $t(i+1) - t(i)$ are sufficiently large, that (36) implies that

$$\overline{\lim_{i\to\infty}} E_\xi^{\tilde{s}} \left\| \psi_0^{t(i)} - \eta(s(i)) \right\|_1 > 0 \tag{39}$$

for any initial distribution ξ. It then follows from (37) and (39) that

$$\overline{\lim_{t\to\infty}} E_\xi^{\tilde{s}} \left\| \psi_0^{t} - \eta(s^*) \right\|_1 > 0 \tag{40}$$

for any initial distribution ξ.

Since $s(i)$ converges to s^*, it follows that $\tilde{s}$ is an asymptotically stationary policy (see (1.2) in [3]), and therefore,

$$\lim_{K\to\infty} \psi_0^K = \eta(s^*), \qquad P_\xi^{\tilde{s}} \text{ a.s.}$$

(see Lemma 6.3 in [3]; also see [4]). Hence

$$\lim_{K\to\infty} E_\xi^{\tilde{s}} \left\| \psi_0^K - \eta(s^*) \right\|_1 = 0 \tag{41}$$

for any initial distribution ξ. This contradicts (40), and thus (30) is established. □

Proof of Lemma 2.1. Let y_t be an admissible control for $\mathbf{Q_0}$ and let $u_\epsilon(y)$ be constructed as indicated in the beginning of section 3. Consider the policy $u_\epsilon(y)$ and a random realization of states and actions history $H \in \mathbf{H}$. The solution Z_t of (1) is the solution of (9) obtained with the random control

$$y_t(H) \stackrel{\text{def}}{=} y(X_{\lfloor t/\epsilon \rfloor}, A_{\lfloor t/\epsilon \rfloor}).$$

By Lemma 4.1, the mathematical expectation of the norm of the difference between Z_t and the solution z_t^y of (9) with the control y_t is bounded by

$$E_x^{u_\epsilon(y)} \|Z_t - z_t^y\|_1 \le L \left(\Delta + \max_{l=0,\dots,\ell-1} E_x^{u_\epsilon(y)} \left\| \frac{1}{\Delta} \int_{\tau_l}^{\tau_{l+1}} y_s(H) ds - \frac{1}{\Delta} \int_{\tau_l}^{\tau_{l+1}} y_s ds \right\|_1 \right)$$

for any $t \in [0,1]$. Hence, taking into account (16) and (17),

$$\begin{aligned} (42) \quad & \max_{t\in[0,1]} E_x^{u_\epsilon(y)} \|Z_t - z_t^y\|_1 \\ & \le L \left(\Delta + \max_{l=0,\dots,\ell-1} E_x^{u_\epsilon(y)} \left\| \frac{1}{\Delta} \int_{\tau_l}^{\tau_{l+1}} y_s(H) ds - \sum_{v,a} \eta(s_l^\epsilon(y); v, a) y(v,a) \right\|_1 \right). \end{aligned}$$

To bound the right-hand side in (42), consider the state-action frequencies ψ_m^K corresponding to the realization H. It follows from Theorem 4.1 that there exists some $\mu : \mathbb{N} \to \mathbb{R}$ with

$$\lim_{K\to\infty} \mu(K) = 0 \tag{43}$$

such that for any stationary policy s applied during $n = m+1, ..., m+K$, and any probability distribution ζ over X_m,

$$E_\zeta^s \left(\max_{v,a} |\psi_m^K(v,a) - \eta(s; v, a)| \right) \le \mu(K). \tag{44}$$

Denote

$$K(\epsilon) \stackrel{\text{def}}{=} \min_{l=0,1,\dots,\ell-1} \left(\lfloor \tau_{l+1}/\epsilon \rfloor - \lfloor \tau_l/\epsilon \rfloor \right),$$

and notice that

$$\begin{aligned} & 2 \ge \lfloor \tau_{l+1}/\epsilon \rfloor - \lfloor \tau_l/\epsilon \rfloor - K(\epsilon) \ge 0, \qquad \left| K(\epsilon) - \frac{\Delta(\epsilon)}{\epsilon} \right| \le 1 \\ (45) \quad & \Rightarrow \qquad \left| \frac{1}{K(\epsilon)} - \frac{\epsilon}{\Delta(\epsilon)} \right| \le \frac{\epsilon^2}{\Delta(\epsilon)^2} \left(\frac{1}{1 - \epsilon/\Delta(\epsilon)} \right). \end{aligned}$$

From (45) it follows that there exist constants L_1 and L_2 such that

$$\left\| \frac{1}{\Delta(\epsilon)} \int_{\tau_l}^{\tau_{l+1}} y_t(H) dt - \frac{\epsilon}{\Delta(\epsilon)} \sum_{n=\lfloor \tau_l/\epsilon \rfloor + 1}^{\lfloor \tau_l/\epsilon \rfloor + K(\epsilon)} y(X_n, A_n) \right\|_1 \le L_1 \frac{\epsilon}{\Delta(\epsilon)}, \tag{46}$$

$$\left\| \frac{\epsilon}{\Delta(\epsilon)} \sum_{n=\lfloor \tau_l/\epsilon \rfloor + 1}^{\lfloor \tau_l/\epsilon \rfloor + K(\epsilon)} y(X_n, A_n) - \frac{1}{K(\epsilon)} \sum_{n=\lfloor \tau_l/\epsilon \rfloor + 1}^{\lfloor \tau_l/\epsilon \rfloor + K(\epsilon)} y(X_n, A_n) \right\|_1 \le L_2 \frac{\epsilon}{\Delta(\epsilon)}. \tag{47}$$

Since

$$\frac{1}{K(\epsilon)} \sum_{n=\lfloor \tau_l/\epsilon \rfloor + 1}^{\lfloor \tau_l/\epsilon \rfloor + K(\epsilon)} y(X_n, A_n) = \sum_{v,a} \psi_{\lfloor \tau_l/\epsilon \rfloor}^{K(\epsilon)}(H; v, a) y(v,a), \tag{48}$$

one can obtain, using (44), (46), and (47),

$$
\begin{aligned}
&E_x^{u_\epsilon(y)}\left\|\frac{1}{\Delta(\epsilon)}\int_{\tau_l}^{\tau_{l+1}} y_t(H)dt-\sum_{v,a}\eta(s_l^\epsilon(y);v,a)y(v,a)\right\|_1\\
&\le (L_1+L_2)\frac{\epsilon}{\Delta(\epsilon)}+E_x^{u_\epsilon(y)}\left\{E^{s_l^\epsilon(y)}_{X_{\lfloor\tau_l/\epsilon\rfloor}}\sum_{v,a}\left(\left|\psi^{K(\epsilon)}_{\lfloor\tau_l/\epsilon\rfloor}(H;v,a)-\eta(s_l^\epsilon(y);v,a)\right|\|y(v,a)\|_1\right)\right\}\\
&\le (L_1+L_2)\frac{\epsilon}{\Delta(\epsilon)}+L_3\mu(K(\epsilon)),
\end{aligned}
$$

where

$$L_3=\sum_{v,a}\|y(v,a)\|_1.$$

Substituting the last inequality in (42), one obtains

$$\max_{t\in[0,1]}E_x^{u_\epsilon(y)}\|Z_t-z_t^y\|_1\le L\left[\Delta(\epsilon)+(L_1+L_2)\frac{\epsilon}{\Delta(\epsilon)}+L_3\mu(K(\epsilon))\right],$$

which, by (43), completes the proof of the lemma. □

Proof of Lemma 2.2. Let $h=\left\{x_0,a_0,...,x_{\lfloor\epsilon^{-1}\rfloor},a_{\lfloor\epsilon^{-1}\rfloor}\right\}\in\mathbf{H}$ be some state-action trajectory, and define

$$y_t(h)\overset{\text{def}}{=}y(x_{\lfloor t/\epsilon\rfloor},a_{\lfloor t/\epsilon\rfloor}).$$

As in (46)–(48), one obtains

$$\left\|\frac{1}{\Delta(\epsilon)}\int_{\tau_l}^{\tau_{l+1}} y_t(h)dt-\sum_{v,a}\psi^{K(\epsilon)}_{\lfloor\tau_l/\epsilon\rfloor}(h;v,a)y(v,a)\right\|_1\le(L_1+L_2)\frac{\epsilon}{\Delta(\epsilon)}. \tag{49}$$

Denote by $\sigma_l(H)$ the projection of $\psi^{K(\epsilon)}_{\lfloor\tau_l/\epsilon\rfloor}(H)$ on W; i.e., $\sigma_l(H):=\{\sigma_l(H;v,a)\}_{v,a}$ is the solution of

$$\min_\eta\left\{\left\|\psi^{K(\epsilon)}_{\lfloor\tau_l/\epsilon\rfloor}(H)-\eta\right\|_1\Big|\,\eta\in W\right\}. \tag{50}$$

It follows from Theorem 4.1 that there exists a function $\nu(K)$,

$$\lim_{K\to\infty}\nu(K)=0,$$

such that for any policy u,

$$E_x^u\text{dist}\left\{\psi_m^K(H),W\right\}\le\nu(K)$$

where

$$\text{dist}\left\{\psi_m^K(H),W\right\}\overset{\text{def}}{=}\min_\eta\left\{\left\|\psi_m^K(H)-\eta\right\|_1\Big|\,\eta\in W\right\}.$$

Hence,

$$E_x^u\left\{\max_{v,a}\left|\psi^{K(\epsilon)}_{\lfloor\tau_l/\epsilon\rfloor}(H;v,a)-\sigma_l(H;v,a)\right|\right\}\le\nu(K(\epsilon)). \tag{51}$$

Define the vectors $y_l : \mathbf{H} \to \mathbb{R}$ as

$$y_l(h) = \sum_{v,a} \sigma_l(h; v, a) y(v, a). \tag{52}$$

Since, by definition, $\sigma_l(h) \in W$, then

$$y_l(h) \in \mathbf{Y} \qquad \forall l = 0, 1, ..., \ell - 1.$$

Define now the piecewise constant function $\tilde{y}^\epsilon_t(h)$ as follows: for $t \in [0, \ell\Delta)$, set $\tilde{y}^\epsilon_t(h) := y_l(h)$ for $t \in [\tau_l, \tau_{l+1})$, $l = 0, 1, ..., \ell - 1$. For $t \in [\ell\Delta, 1]$, set $\tilde{y}^\epsilon(h) = \overline{y}$ where $\overline{y}$ is an arbitrary element of $\mathbf{Y}$. Let u be an arbitrary policy. Taking into account (49), (51), and (52), one obtains

$$\begin{aligned}
&E^u_x \left\| \frac{1}{\Delta(\epsilon)} \int_{\tau_l}^{\tau_{l+1}} y_t(H) dt - \frac{1}{\Delta(\epsilon)} \int_{\tau_l}^{\tau_{l+1}} \tilde{y}^\epsilon_t(H) dt \right\|_1 \\
&\leq (L_1 + L_2) \frac{\epsilon}{\Delta(\epsilon)} + E^u_x \max_{v,a} \left| \psi^{K(\epsilon)}_{\lfloor \tau_l / \epsilon \rfloor}(H; v, a) - \sigma_l(H; v, a) \right| \sum_{v,a} \|y(v, a)\|_1 \\
&\leq (L_1 + L_2) \frac{\epsilon}{\Delta(\epsilon)} + L_3 \nu(K(\epsilon)).
\end{aligned}$$

Applying (25) one obtains

$$\max_{t \in [0,1]} E^u_x \left\| Z_t - \tilde{z}^\epsilon_t(H) \right\|_1 \leq L \left[\Delta(\epsilon) + (L_1 + L_2) \frac{\epsilon}{\Delta(\epsilon)} + L_3 \nu(K(\epsilon)) \right],$$

which completes the proof. □

PERTURBATION FORMULA FOR REGULAR FREE BOUNDARIES IN ELLIPTIC AND PARABOLIC OBSTACLE PROBLEMS*

SRDJAN STOJANOVIC†

Abstract. The perturbation formula for regular free boundaries with respect to various parameters of the obstacle problem, which has been known in the case of elliptic problems, is proved by a new method. The method introduced here extends easily to parabolic problems as well. This enables a study of optimal control of regular free boundaries in elliptic and parabolic obstacle problems.

Key words. obstacle problem, free boundary, perturbation formula

1. Introduction.

In the past 20 years or so, there have been many works on so-called optimal control theory of variational inequalities (see [18, 10, 1, 11, 12, 9]). One could say that the problem of distributed control, i.e., the problem where the objective is to control a solution of the variational inequality (more precisely, a solution of the obstacle problem), is well understood. Also, various attempts were made to handle the issue of controlling the free boundary via different types of regularizations or relaxations (see, e.g., [1, 2] and references given there).

More appropriately, optimal control of the free boundary in the elliptic obstacle problem was considered in [17] via a perturbation formula for free boundaries. In such an approach no regularization or relaxation of the optimal control problem is needed. The proof of the perturbation formula in [17] applies to the elliptic problem. Moreover, in [17], authors assume differentiability (of the obstacle map).

In this paper we introduce a new proof of the perturbation formula, which, contrary to [17], naturally extends to the parabolic case, providing a unified theory for various optimal control problems for regular free boundaries in elliptic and parabolic obstacle problems. Furthermore, as opposed to [17], we discuss the relationship between the issue of regularity of the free boundary and the issue of differentiability of the obstacle map and of the cost functional.

We shall state the perturbation formula for the free boundary in the case when the perturbation of data is in the right-hand side of the obstacle problem. Many other kinds of data perturbations can be considered by the same method.

In this paper, by optimal control, we mean only characterizing the gradient of the cost functional. This can be used either for numerical minimization or for further analysis, to characterize possible minimizers.[1] Neither is in the scope of the present paper.

In several crucial places[2] in this paper, we shall exploit the viewpoint that the obstacle problem is a semilinear *equation*. Namely, as was discussed in detail in [14] by the present author, the obstacle problem (2.10) is equivalent to the semilinear

[1] That appears possible, but not in full generality. One has to consider particular examples, as in the study of regularity of the free boundary; see, e.g., [8].

[2] See the proofs of Lemma 1, Theorem 4, and Theorem 5.

equation

$$Az + uI_{\{z^u>0\}} = 0, \qquad z \in W^{2,2}(\Omega), \tag{1.1}$$

with appropriate boundary condition (for the notation, see (2.1), (2.8), and (2.49)). In [14] the variational principle for equation (1.1) is given, as well.

Some of the results of this paper were announced in [15]. Some further developments can be found in [16].

2. Perturbation formula for regular free boundaries in elliptic obstacle problems. Let Ω be a bounded domain in R^n such that $\partial\Omega$ is locally in $C^{2,\alpha}$ for some $\alpha > 0$. Let A be an elliptic operator defined by

$$Az = -\sum_{i,j=1}^{n} a_{ij}\frac{\partial^2 z}{\partial x_i \partial x_j} + \sum_{i=1}^{n} b_i \frac{\partial z}{\partial x_i} + cz. \tag{2.1}$$

We assume that

$$a_{ij} = a_{ji}, \quad a_{ij} \in C^{2,\alpha}(\Omega) \cap C^{1,\alpha}(\bar{\Omega}), \tag{2.2}$$

$$b_i, c \in C^{\alpha}(\bar{\Omega}), \tag{2.3}$$

$$\sum_{i,j=1}^{n} a_{ij}(x)\xi_i\xi_j \geq \lambda_0|\xi|^2 \quad \forall x \in \Omega,\ \xi \in R^n \ \ (\lambda_0 > 0), \tag{2.4}$$

$$c \geq 0. \tag{2.5}$$

Functions a_{ij}, b_i, and c are going to be referred to as *data*. Consider also the associated bilinear form

$$a(z,\zeta) = \int_\Omega \left\{ \sum_{i,j=1}^{n} a_{ij}\frac{\partial z}{\partial x_i}\frac{\partial \zeta}{\partial x_j} + \sum_{i=1}^{n}\left(b_i + \sum_{j=1}^{n}\frac{\partial a_{ij}}{\partial x_j}\right)\frac{\partial z}{\partial x_i}\zeta + cz\zeta \right\} dx, \tag{2.6}$$

and assume that a is coercive, that is, that

$$a(z,z) \geq \beta\|z\|^2_{H_0^1(\Omega)} \ \ \forall z \in H_0^1(\Omega) \ \ (\beta > 0). \tag{2.7}$$

Let $u \in C^{0,1}(\bar{\Omega})$ and $g \in C^{2,\alpha}(\bar{\Omega})$ be given. We also assume here that

$$u \geq \lambda_1 > 0 \ \text{ in } \bar{\Omega}, \tag{2.8}$$

$$g > 0 \ \text{ in } \bar{\Omega}. \tag{2.9}$$

Consider the following obstacle problem: find $z \in K$, such that

$$a(z, \zeta - z) \geq -\int_\Omega u(\zeta - z)dx \ \ \forall \zeta \in K, \tag{2.10}$$

where K is the following closed convex set in $H^1(\Omega)$:

$$K = \left\{\zeta \in H^1(\Omega); \zeta - g \in H_0^1(\Omega), \zeta \geq 0 \text{ a.e.}\right\}. \tag{2.11}$$

Remark 1. We have taken the obstacle to be equal to 0. It is trivial to extend everything that follows to the case when the obstacle is any $C^{2,\alpha}(\bar{\Omega})$ function ψ, such that $\psi < g$ on $\partial\Omega$ (see Remark 3).

It is very well known (see, e.g., [8]; see also [14] for a new proof of $W^{2,p}$-regularity) that under the above assumptions, the obstacle problem has a unique solution z, and

$$z \in W^{2,p}(\Omega) \cap W^{2,\infty}_{loc}(\Omega)\ \forall p < \infty. \tag{2.12}$$

Moreover, by the fundamental theorem of Caffarelli [3, 4, 5], (see also [13]). In some cases, it is possible to claim smoothness of the free boundary $\partial\{z > 0\} \cap \Omega$ (see also Chapter 2 of [8]). For the convenience of the reader, we state those results here. To this end we need some notation.

DEFINITION 1. *For any bounded set $D \subset R^n$ the* minimum diameter *of D, $m.d.(D)$, is the infimum of the distances between pairs Π_1, Π_2 of parallel planes such that D is contained in the strip determined by Π_1, Π_2. Let $B_r(x) = \{y \in R^n; |x-y| < r\}$.*

NOTATION 1.

$$\Gamma^u = \partial\{z^u > 0\} \cap \Omega, \tag{2.13}$$

$$D_{-\epsilon} = \{x \in D \subset R^n; \operatorname{dist}(x, R^n \setminus D) > \epsilon\}, \tag{2.14}$$

$$\eta_r(D; x) = \frac{m.d.(D \cap B_r(x))}{r}, \tag{2.15}$$

$$\eta_r(D) = \eta_r(D; 0). \tag{2.16}$$

THEOREM 1 (Caffarelli). *There exists a positive nondecreasing function $\sigma(r)(0 < r < r_0)$ with $\sigma(0^+) = 0$ such that, if for some $0 < r < r_0$,*

$$\eta_r(\{z^u = 0\}) > \sigma(r), \tag{2.17}$$

then for some $\tilde{r} > 0$, $\Gamma^u \cap B_{\tilde{r}}(0)$ is a C^1 surface given by

$$x_i = k(x_1, ..., x_{i-1}, x_{i+1}, ..., x_n) \qquad (k \in C^1) \tag{2.18}$$

for $\sqrt{x_1^2 + \cdots + x_{i-1}^2 + x_{i+1}^2 + \cdots + x_n^2} < \tilde{r}$, and for some $i \in \{1, ..., n\}$, and moreover

$$z^u \in C^2\left(\left(\{z^u > 0\} \cup \Gamma^u\right) \cap B_{\tilde{r}}(0)\right). \tag{2.19}$$

The nonexplicit nature of function σ prevents us from applying Theorem 1 directly. Nevertheless, from the properties of σ and η_r, one can see that the following holds.

COROLLARY 1. *If*

$$\limsup_{r \to 0} \frac{\mathcal{L}^n(\{z^u > 0\} \cap B_r(0))}{r^n} > 0, \tag{2.20}$$

then the assertions of Theorem 1 are valid.

COROLLARY 2. *If $\Gamma^u \subset \Omega$ is a Lipschitz continuous surface, then it is a C^1 surface, and z^u is C^2 in the closure of the noncoincidence set $\{z^u > 0\}$.*

DEFINITION 2. *If the assumptions of Theorem 1 are (not) fulfilled at each free boundary point $x \in \Gamma^u$, we shall say either that the free boundary Γ^u is* (not) regular

(or that it is irregular*) or that the coincidence set* $\{z^u = 0\}$ *is* not too thin *(is too thin).*

Example 1. Let $\Omega = (-1, 1)$, $g = 1$, $Az = -\frac{1}{2}z''$, $u = v = 1$. Then it is elementary to compute

$$z^{u+\lambda v}(x) = \left[(1+\lambda)x^2 - 2(1+\lambda-\sqrt{1+\lambda})|x| + 2 + \lambda - 2\sqrt{1+\lambda}\right] \cdot \left(1 - I_{\left(-1+\frac{1}{\sqrt{1+\lambda}}, 1-\frac{1}{\sqrt{1+\lambda}}\right)}(x)\right) \tag{2.21}$$

if $\lambda \geq 0$, and

$$z^{u+\lambda v}(x) = (1+\lambda)x^2 - \lambda \tag{2.22}$$

if $\lambda \leq 0$. So there is no free boundary if $\lambda < 0$, and otherwise, if $\lambda \geq 0$, then

$$\eta_r(\{z^{u+\lambda v} = 0\}) = \frac{m.d.(\{z^{u+\lambda v} = 0\} \cap B_r)}{r} = \begin{cases} 1, & \lambda > 0, \\ 0, & \lambda = 0, \end{cases} \tag{2.23}$$

if r is small enough. According to Definition 2, the free boundary is regular if $\lambda > 0$, but it is *not* regular if $\lambda = 0$, i.e., the coincidence set *is* too thin.[3]

THEOREM 2 (Caffarelli). *If*

$$\|z^u - z^v\|_{L^\infty(\Omega)} < \epsilon^2, \tag{2.24}$$

then

$$\{z^u = 0\}_{-C\epsilon} \subset \{z^v = 0\}, \tag{2.25}$$

where C *depends on the data, on the* $C^{1,1}$ *norm of* z^u *and* z^v*, and on* λ_1*.*

THEOREM 3 (Caffarelli). *Let* K', K *be domains with* C^1 *boundary such that* $K' \subset K, \bar{K} \subset \Omega, c_0 = \operatorname{dist}(K', \partial K) > 0$*. If* $\Gamma^u \cap K$ *is a* C^1 *surface, then* $\Gamma^v \cap K'$ *is a* C^1 *surface provided that*

$$\|z^u - z^v\|_{L^\infty(\Omega)} < \epsilon_0, \tag{2.26}$$

where ϵ_0 *is sufficiently small, depending on the data and on the* $C^{0,1}$ *norms of* u *and* v*, the* $C^{1,1}$ *norms of* z^u *and* z^v*,* λ_1*,* c_0*, and a* C^1 *bound on* $\Gamma^u \cap K$*.*

PROPOSITION 1. *The obstacle map* $u \mapsto z^u$ *is Lipschitz continuous in the following sense:*

$$\|z^u - z^v\|_{H^1(\Omega)} \leq c\|u - v\|_{H^{-1}(\Omega)} \tag{2.27}$$

and, for $p > \frac{n}{2}$*,*

$$\|z^u - z^v\|_{L^\infty(\Omega)} \leq c\|u - v\|_{L^p(\Omega)}. \tag{2.28}$$

[3]Indeed, it is a single point: $\{z^u = 0\} = \{0\}$. So, we notice that, conceptually, the statement about regularity of the free boundary is more about the thickness of the coincidence set than about the smoothness of the free boundary. Indeed, in dimension one, like in the above example, both regular and irregular free boundaries are isolated points, so that the issue of smoothness of the free boundary does not make sense, while the issue of thickness of the coincidence set does.

Proof. Estimate (2.27) is well known. We shall prove (2.28). To this end we prove the following lemma.

LEMMA 1. *If* $u - v \le \epsilon \in L^p(\Omega), p > \frac{n}{2}, \epsilon \ge 0$, *then*

$$z^v - z^u \le \delta \in L^\infty(\Omega), \tag{2.29}$$

where $0 \le \delta \in W^{2,p}(\Omega) \cap H_0^1(\Omega)$ *solves*

$$A\delta = \epsilon. \tag{2.30}$$

Proof. Recall $u, v \ge 0$.[4] Let

$$\bar{u} = uI_{\{z^u > 0\}}, \qquad \bar{v} = \min\{\bar{u}, v\}. \tag{2.31}$$

Then

$$z^{\bar{u}} = z^u, \qquad z^{\bar{v}} \ge z^v. \tag{2.32}$$

Notice also

$$(\bar{u} - \bar{v})I_{\{z^u > 0\}} \le \epsilon \tag{2.33}$$

and

$$\bar{v}I_{\{z^u = 0\}} = 0. \tag{2.34}$$

So it suffices to show that

$$(z^{\bar{v}} - (z^{\bar{u}} + \delta))^+ = 0. \tag{2.35}$$

We have

$$Az^{\bar{v}} + \bar{v}I_{\{z^{\bar{v}} > 0\}} = 0 \tag{2.36}$$

and

$$A(z^{\bar{u}} + \delta) + \bar{u}I_{\{z^{\bar{u}} > 0\}} - \epsilon = 0. \tag{2.37}$$

Subtracting, we get

$$A(z^{\bar{v}} - (z^{\bar{u}} + \delta)) + \bar{v}(I_{\{z^{\bar{v}} > 0\}} - I_{\{z^{\bar{u}} > 0\}}) = (\bar{u} - \bar{v})I_{\{z^{\bar{u}} > 0\}} - \epsilon \le 0. \tag{2.38}$$

Multiplying (2.38) by $(z^{\bar{v}} - (z^{\bar{u}} + \delta))^+$ and using the fact that

$$\bar{v}(I_{\{z^{\bar{v}} > 0\}} - I_{\{z^{\bar{u}} > 0\}})(z^{\bar{v}} - z^{\bar{u}}) \ge 0, \tag{2.39}$$

we get

$$\lambda_0 \int_\Omega |\nabla(z^{\bar{v}} - (z^{\bar{u}} + \delta))^+|^2 - \int_{\{z^{\bar{v}} - (z^{\bar{u}} + \delta) > 0\}} \bar{v}(I_{\{z^{\bar{v}} > 0\}} - I_{\{z^{\bar{u}} > 0\}})\delta \le 0. \tag{2.40}$$

[4] This assumption can be removed.

But, using (2.34),

$$\int_{\{z^{\bar v}-(z^{\bar u}+\delta)>0\}} \bar v(I_{\{z^{\bar v}>0\}}-I_{\{z^{\bar u}>0\}})\delta$$

$$= \int_{\{z^{\bar v}-(z^{\bar u}+\delta)>0\}} \bar v I_{\{z^{\bar v}>0\}} I_{\{z^{\bar u}=0\}}\delta = 0. \qquad \square \tag{2.41}$$

To prove the theorem, one needs only to apply the L^p-estimate and the imbedding theorem for problem (2.30). $\square$

From Theorems 2 and 3 and from Proposition 1, it is not difficult to conclude (cf. [9]) the following proposition.

PROPOSITION 2. *If u is such that the corresponding free boundary Γ^u is regular, then the obstacle map is differentiable at u in the following sense:*

$$\frac{z^{u+\lambda v}-z^u}{\lambda} \rightharpoonup w^{u;v} \quad \textit{weakly in } H_0^1(\Omega) \textit{ and weakly* in } L^\infty(\Omega) \tag{2.42}$$

as $\lambda \to 0$, where

$$w^{u;v} = \begin{cases} \delta^{u;v} & \textit{in } \{z^u>0\}, \\ 0 & \textit{in } \{z^u=0\} \end{cases} \tag{2.43}$$

and where $\delta = \delta^{u;v}$ is the unique solution of the elliptic equation

$$\begin{aligned} A\delta &= -v \quad \textit{in } \{z^u>0\}, \\ \delta &= 0 \quad \textit{on } \partial\{z^u>0\}. \end{aligned} \tag{2.44}$$

Example 2. We continue Example 1. It is elementary to compute that

$$\frac{z^{u+\lambda v}-z^u}{\lambda} \longrightarrow \begin{cases} x(x+1), & x\in(-1,0), \\ x(x-1), & x\in(0,1), \end{cases} \tag{2.45}$$

as $\lambda \downarrow 0$, and

$$\frac{z^{u+\lambda v}-z^u}{\lambda} = (x-1)(x+1) \tag{2.46}$$

as $\lambda \uparrow 0$. Comparing (2.45) and (2.46) we see that (2.42) does not hold.

So, if the coincidence set corresponding to the control u is too thin, then differentiability of the obstacle map may fail at u.

NOTATION 2. *Let $d\Gamma^u$ denote the measure (cf.* [6])

$$d\Gamma^u = \mathcal{H}^{n-1}\lfloor \Gamma^u, \tag{2.47}$$

the restriction of the $(n-1)$-dimensional Hausdorff measure $\mathcal{H}^{n-1}$ on the set $\Gamma^u \subset R^n$.

Remark 2. If $\Gamma^u \subset \Omega$ is a Lipschitz continuous surface, then by the trace theorem,

$$d\Gamma^u \in H^{-1}(\Omega). \tag{2.48}$$

Let ν^u be the unit normal to Γ^u exterior to $\{z^u>0\}$. Also, let ν_A^u be a conormal, i.e., $(\nu_A^u)_i = \sum_{j=1}^n a_{ij}(\nu^u)_j$.

NOTATION 3.

$$I_D(x) = \begin{cases} 1, & x \in D, \\ 0, & x \notin D. \end{cases} \tag{2.49}$$

We have the following theorem.

THEOREM 4 (perturbation formula for regular free boundaries in elliptic obstacle problems). *Suppose that z^u has a regular free boundary. Then the following perturbation formula holds:*

$$\frac{I_{\{z^{u+\lambda v}>0\}} - I_{\{z^u>0\}}}{\lambda} \rightharpoonup -\frac{1}{u}\frac{\partial \delta^{u;v}}{\partial \nu_A^u} d\Gamma^u \tag{2.50}$$

weakly in $H^{-1}(\Omega)$, as $\lambda \to 0$. Also,

$$-\frac{1}{u}\frac{\partial \delta^{u;v}}{\partial \nu_A^u} d\Gamma^u = -\frac{\dfrac{\partial \delta^{u;v}}{\partial \nu^u}}{\dfrac{\partial^2 z^u}{(\partial \nu^u)^2}} d\Gamma^u. \tag{2.51}$$

Proof. z^u solves the semilinear equation.

$$\begin{aligned} Az^u + uI_{\{z^u>0\}} &= 0 \ \text{ a.e. in } \Omega, \\ z^u &= g \ \text{ on } \partial\Omega. \end{aligned} \tag{2.52}$$

So, writing (2.52) in the weak form for $z^{u+\lambda v}$ and z^u, subtracting and dividing by λ, we get, for every $\varphi \in H_0^1(\Omega)$,

$$\begin{aligned} &-a\left(\frac{z^{u+\lambda v} - z^u}{\lambda}, \varphi\right) \\ &\quad = \int_\Omega v I_{\{z^{u+\lambda v}>0\}} \varphi dx + \int_\Omega u \frac{1}{\lambda}\left(I_{\{z^{u+\lambda v}>0\}} - I_{\{z^u>0\}}\right)\varphi dx. \end{aligned} \tag{2.53}$$

We can pass the limit $\lambda \to 0$ in (2.53) to conclude

$$\begin{aligned} &-a(w, \varphi) \\ &\quad = \int_\Omega v I_{\{z^u>0\}} \varphi dx + \lim_{\lambda\to 0} \int_\Omega u \frac{1}{\lambda}\left(I_{\{z^{u+\lambda v}>0\}} - I_{\{z^u>0\}}\right)\varphi dx. \end{aligned} \tag{2.54}$$

Now, from (2.43) and (2.54), we conclude that

$$\lim_{\lambda\to 0} \int_\Omega u \frac{1}{\lambda}\left(I_{\{z^{u+\lambda v}>0\}} - I_{\{z^u>0\}}\right)\varphi dx = -\int_{\Gamma^u} \frac{\partial \delta^{u;v}}{\partial \nu_A^u} \varphi d\sigma, \tag{2.55}$$

and hence, since $\varphi \in H_0^1(\Omega)$ if and only if $\frac{\varphi}{u} \in H_0^1(\Omega)$,

$$\lim_{\lambda\to 0} \int_\Omega \frac{1}{\lambda}\left(I_{\{z^{u+\lambda v}>0\}} - I_{\{z^u>0\}}\right)\varphi dx = -\int_{\Gamma^u} \frac{1}{u}\frac{\partial \delta^{u;v}}{\partial \nu_A^u} \varphi d\sigma, \tag{2.56}$$

and hence (2.50) is proved.

Notice that, since on Γ^u,

$$z^u = |\nabla z^u| = 0, \tag{2.57}$$

we have

$$u(x) = -Az^u(x) = \sum_{i,j=1}^{n} a^{ij} z_{x_i x_j}(x) \ \ \forall x \in \Gamma^u. \tag{2.58}$$

Notice that (2.58) makes sense, since Γ^u is regular, and hence (2.19) holds. Furthermore, fix $x^0 \in \Gamma^u$ and notice that, without loss of generality, we can suppose that $\nu^u(x^0) = e_n$. Then it is easy to see, using (2.57), that

$$\sum_{i,j=1}^{n} a_{ij} z_{x_i x_j}(x^0) = a_{nn} z_{x_n x_n}(x^0) \tag{2.59}$$

and, since $\delta^{u;v} = 0$ on Γ^u, we deduce also

$$\sum_{i,j=1}^{n} a_{ij} (\delta^{u;v})_{x_i} (\nu^u)_j = a_{nn} (\delta^{u;v})_{x_n}. \tag{2.60}$$

We conclude that, in general,

$$\frac{\displaystyle\sum_{i,j=1}^{n} a_{ij} (\delta^{u;v})_{x_i} (\nu^u)_j}{\displaystyle\sum_{i,j=1}^{n} a_{ij} z_{x_i x_j}} = \frac{(\delta^{u;v})_{\nu^u}}{(z^u)_{\nu^u \nu^u}} \ \text{ on } \ \Gamma^u, \tag{2.61}$$

and hence (2.51) follows. □

Remark 3. It is easy to see that in the case of the general obstacle $\psi \in C^{2,\alpha}(\bar{\Omega})$, formula (2.50) becomes

$$\frac{I_{\{z^{u+\lambda v}>0\}} - I_{\{z^u>0\}}}{\lambda} \rightharpoonup -\frac{1}{u + A\psi} \frac{\partial \delta^{u;v}}{\partial \nu_A^u} d\Gamma^u \tag{2.62}$$

weakly in $H^{-1}(\Omega)$, as $\lambda \to 0$.

DEFINITION 3. *If there exists a function $s^{u;v}$ on Γ^u, such that*

$$\frac{I_{\{z^{u+\lambda v}>0\}} - I_{\{z^u>0\}}}{\lambda} \rightharpoonup s^{u;v} d\Gamma^u \tag{2.63}$$

weakly in $H^{-1}(\Omega)$, as $\lambda \to 0$, then $s^{u;v}$ is called the perturbation function.

We can rephrase Theorem 4 now as follows.

PERTURBATION FORMULA 1.

$$s^{u;v} = -\frac{1}{u} \frac{\partial \delta^{u;v}}{\partial \nu_A^u}, \tag{2.64}$$

where $\delta^{u;v}$ is defined by (2.44).

3. Optimal control of free boundaries. Again, we emphasize that, in this paper, by optimal control we mean only characterizing the gradient of the cost functional.

3.1. Linear growth functional. Let $\mathcal{O}$ be a closed set such that $\mathcal{O} \subset \Omega$. The set of controls is

$$\mathcal{C}_1 = \{u \in C^{0,1}(\bar{\Omega}); u \geq \lambda_1 > 0\}. \tag{3.1}$$

Consider a problem of finding $u \in \mathcal{C}_1$ such that the corresponding coincidence set $\{z^u = 0\}$ is, in some sense, as close as possible to $\mathcal{O}$. For example, one can try to minimize the following functional:

$$\begin{aligned} \Phi_1(u) &= \int_\Omega (I_{\{z^u>0\}} - I_{\mathcal{O}^c})^2 dx \\ &= \mathcal{L}^n\left((\{z^u > 0\} \setminus \mathcal{O}^c) \cup (\mathcal{O}^c \setminus \{z^u > 0\})\right). \end{aligned} \tag{3.2}$$

Various regularizations of this functional have been considered (see, e.g., [1]). On the contrary, using formula (2.50), we can consider (3.2) without any regularization.

Compute the directional derivative $\Phi_1'(u; v)$:

$$\begin{aligned} \Phi_1'(u;v) &= \lim_{\lambda\to 0} \frac{\Phi_1(u+\lambda v) - \Phi_1(u)}{\lambda} \\ &= \lim_{\lambda\to 0} \int_\Omega \frac{1}{\lambda}\left[(I_{\{z^{u+\lambda v}>0\}} - I_{\mathcal{O}^c})^2 - (I_{\{z^u>0\}} - I_{\mathcal{O}^c})^2\right] dx \\ &= \lim_{\lambda\to 0} \int_\Omega \frac{1}{\lambda}(I_{\{z^{u+\lambda v}>0\}} - I_{\{z^u>0\}})(I_{\{z^{u+\lambda v}>0\}} + I_{\{z^u>0\}} - 2I_{\mathcal{O}^c})dx \\ &= \lim_{\lambda\to 0} \int_\Omega \frac{1}{\lambda}(I_{\{z^{u+\lambda v}>0\}} - I_{\{z^u>0\}})(I_{\mathcal{O}} - I_{\mathcal{O}^c})dx \\ &= -\int_{\Gamma^u} \frac{1}{u}\frac{\partial \delta^{u;v}}{\partial \nu_A^u}(I_{\mathcal{O}} - I_{\mathcal{O}^c})d\sigma \end{aligned} \tag{3.3}$$

provided, say,[5]

$$\partial\{z^u > 0\} \cap \partial\mathcal{O} \text{ consists of finitely many points.} \tag{3.4}$$

Define the adjoint operator A^* by

$$A^* z = -\sum_{i,j=1}^n \frac{\partial^2}{\partial x_i \partial x_j}(a_{ij} z) - \sum_{i=1}^n \frac{\partial}{\partial x_i}(b_i z) + cz. \tag{3.5}$$

Define the (adjoint) function $p = p^u$ as a solution of

$$\begin{aligned} A^* p &= 0 \text{ in } \{z^u > 0\}, \\ p &= \frac{1}{u} \text{ on } \Gamma^u \cap \mathcal{O}, \\ p &= -\frac{1}{u} \text{ on } \Gamma^u \cap \mathcal{O}^c, \\ p &= 0 \text{ on } \partial\Omega, \\ p &= 0 \text{ in } \{z^u = 0\}. \end{aligned} \tag{3.6}$$

Then

$$\begin{aligned} -\int_{\Gamma^u} \frac{1}{u}\frac{\partial \delta^{u;v}}{\partial \nu_A^u}(I_{\mathcal{O}^c} - I_{\mathcal{O}})d\sigma &= \int_{\Gamma^u} p^u \frac{\partial \delta^{u;v}}{\partial \nu_A^u} d\sigma \\ &= \int_{\{z^u>0\}} (\delta^{u;v} A^* p^u - p^u A \delta^{u;v})\, dx = \int_\Omega p^u v dx, \end{aligned} \tag{3.7}$$

and we have proved the following proposition.

[5] See Remark 5.

PROPOSITION 3. *Let $u \in \mathcal{C}_1$ be such that the corresponding free boundary Γ^u is regular. Also, let* (3.4) *hold. Then Φ_1 is differentiable at u, and*

$$\Phi_1'(u;v) = \int_\Omega p^u v dx, \tag{3.8}$$

where p^u is defined in (3.6).

Remark 4. Under the above assumption, if $\nabla\Phi_1(u)$ is identified as an element of $L^2(\Omega)$, then

$$\nabla\Phi_1(u) = p^u. \tag{3.9}$$

This can be used for numerical calculations (e.g., steepest descent method) or for further analysis.

Remark 5. It does not seem possible to state reasonable a priori conditions to ensure the fulfillment of the assumption (3.4). The value of (3.3) and (3.4) is then in numerical computations: for given u, one computes z^u and checks (3.4); if (3.4) holds, one proceeds as explained. If, on the other hand, $\mathcal{H}^{n-1}(\partial\{z^u > 0\} \cap \partial\mathcal{O}) \neq 0$, then Φ_1 is not differentiable at u. In that case, formally, the best selection (for numerical calculations) of an element of "$\partial\Phi_1(u)$" would be achieved by imposing $p = 0$ on $\partial\{z^u > 0\} \cap \partial\mathcal{O}$ in (3.6).

Remark 6 (minimizing the noncoincidence set). Let

$$\Phi_2(u) = \int_\Omega \left[I_{\{z^u > 0\}} + \frac{\epsilon}{2} u^2 \right] dx \tag{3.10}$$

for $\epsilon > 0$.[6] The first term in Φ_2 corresponds to the case when $\mathcal{O} = \emptyset$, i.e., $\mathcal{O}^c = \Omega$. Then, if Γ^u is regular, Φ_2 is differentiable at u, and

$$\Phi_2'(u;v) = \int_\Omega (p^u + \epsilon u) v dx, \tag{3.11}$$

where $p = p^u$ is a solution of

$$\begin{aligned} A^* p &= 0 \ \text{ in } \{z^u > 0\}, \\ p &= -\frac{1}{u} \ \text{ on } \Gamma^u, \\ p &= 0 \ \text{ on } \partial\Omega, \\ p &= 0 \ \text{ in } \{z^u = 0\}. \end{aligned} \tag{3.12}$$

Remark 7 (minimizing a solution). We want to compare Φ_2 from Remark 6 with a "distributed" functional, say,

$$\Psi(u) = \int_\Omega \left[z^u + \frac{\epsilon}{2} u^2 \right] dx. \tag{3.13}$$

Then, if Γ^u is regular, Ψ is differentiable at u, and it is not difficult to see that

$$\Psi'(u;v) = \int_\Omega (q^u + \epsilon u) v dx, \tag{3.14}$$

[6] Of course, this L^2-penalization is insufficient to claim existence of a minimizer, since the control set imposes $C^{0,1}$-regularity on control functions. Its purpose is only to avoid monotonicity of Φ_2, which may be viewed as trivial. Indeed, if $\epsilon = 0$, then by the monotonicity of the obstacle problem, $u \geq v \Rightarrow z^u \leq z^v \Rightarrow \Phi_2(u) \leq \Phi_2(v)$ and, formally, $\Phi_2(+\infty) = 0$.

where $q = q^u$ is the solution of

$$\begin{aligned} A^*q &= -1 \ \text{ in } \{z^u > 0\}, \\ q &= 0 \ \text{ on } \partial\{z^u > 0\}, \\ q &= 0 \ \text{ in } \{z^u = 0\}. \end{aligned} \tag{3.15}$$

Notice that p^u in (3.12) is discontinuous on Γ_u, so the global regularity of p^u is, say, $L^2(\Omega)$, while q^u in (3.15) is continuous on Γ^u, and then the global regularity of q^u is one derivative more, say, $H^1(\Omega)$.

3.2. Quadratic functional. Without dwelling on details, now change the boundary conditions and introduce other conditions that ensure that z^u is monotone, say, $z^u_{x_n} \le 0$ for some class of admissible controls u. So the corresponding free boundaries Γ^u are graphs: $x_n = \gamma^u(x_1, ..., x_{n-1}) = \gamma^u(x')$. Let Ω_1 be an appropriate domain in R^{n-1}, and consider the functional

$$\Phi_3(u) = \frac{1}{2}\int_{\Omega_1} (\gamma^u - \gamma^*)^2 dx'. \tag{3.16}$$

Then, if Γ^u is regular, Φ_3 is differentiable (in suitable directions) and

$$\begin{aligned} &\Phi_3'(u; v) \\ &\quad = -\int_{\Omega_1} \frac{(\gamma^u(x') - \gamma^*(x'))\dfrac{\partial \delta^{u;v}}{\partial \nu^u_A}(x', \gamma^u(x'))}{u(x', \gamma^u(x'))\sqrt{1 + |\nabla_{x'}\gamma^u(x')|^2}} dx' \\ &\quad = \int_{\Omega_u} p^u v dx, \end{aligned} \tag{3.17}$$

where $p = p^u$ is defined as a solution of

$$\begin{aligned} &A^*p = 0 \ \text{ in } \{z^u > 0\}, \\ &\quad p(x', \gamma^u(x')) = -\frac{(\gamma^u(x') - \gamma^*(x'))}{u(x', \gamma^u(x'))(1 + |\nabla_{x'}\gamma^u(x')|^2)} \ \text{ for } x' \in \Omega_1, \\ &\quad p = 0 \ \text{ on the rest of } \Gamma^u, \\ &\quad p = 0 \ \text{ in } \{z^u = 0\}, \end{aligned} \tag{3.18}$$

with appropriate conditions on $\partial\Omega \cap \partial\{z^u > 0\}$.

4. Extension to parabolic problems.

4.1. Perturbation formula for regular free boundaries in parabolic obstacle problems. For simplicity, we shall consider the heat operator. Results can be extended to the case of general parabolic operator (cf. [7]).

As before, let Ω be a bounded domain in R^n such that $\partial\Omega$ is locally in $C^{2,\alpha}$ for some $\alpha > 0$. Let $Q_T = \Omega \times \{0 < t < T\}$. We assume

$$\begin{aligned} g, D_x g, D_x^2 g, D_t g &\in C^{\alpha}(\bar{Q_T}), \\ u &\in C^{0,1}(\bar{Q_T}). \end{aligned} \tag{4.1}$$

We also assume

$$u \ge \lambda_1 > 0, \qquad g > 0 \ \text{ in } \ \bar{Q_T}. \tag{4.2}$$

Consider the following obstacle problem: find $z \in K$ such that

$$\begin{aligned} &\int_\Omega [z_t(\zeta - z) + \nabla z \cdot \nabla(\zeta - z)]\, dx \\ &\geq -\int_\Omega u(\zeta - z)dx \quad \text{for a.e. } t \ \ \forall \zeta \in K, \end{aligned} \tag{4.3}$$

where K is the following closed convex set in $H^1(Q_T)$:

$$K = \{\zeta \in H^1(Q_T); \zeta = g \ \text{ on } \ \partial_p Q_T, \ \zeta \geq 0 \text{ a.e.}\}. \tag{4.4}$$

∂_p represents the parabolic boundary, in the above case $\partial_p Q_T = \Omega \times \{0\} \cup \partial\Omega \times \{0 < t < T\}$, and the boundary value is taken in the trace sense.

It is well known (see, e.g., [8]) that the obstacle problem (4.3) has a unique solution z, and

$$\begin{aligned} z, D_x z, D_x^2 z, D_t z \in L^p(\Omega) \quad &\text{for a.e. } t \quad \forall p < \infty, \\ z, D_x z, D_x^2 z, D_t z \in L^\infty_{loc}(Q_T). \end{aligned} \tag{4.5}$$

Moreover, by Caffarelli's theorem [3], in some cases, it is possible to claim smoothness of the free boundary $\partial\{z > 0\} \cap Q_T$.

The stability of the free boundaries in the parabolic case is discussed in [8]. The result is similar as in the case of an elliptic obstacle problem.

As before, we denote z^u as the solution of the obstacle problem (4.3) corresponding to the right-hand side u. It is known (see, e.g., [1]) that the map $u \mapsto z^u$ is

$$\text{Lipschitz from } L^2(Q_T) \text{ to } C([0,T]; L^2(\Omega)) \cap L^2(0,T; H^1(\Omega)). \tag{4.6}$$

As in (2.28) in Proposition 1, we can prove the following.

PROPOSITION 4. *The (parabolic) obstacle map $u \mapsto z^u$ is Lipschitz in the following sense:*

$$\|z^u - z^v\|_{L^\infty(Q_T)} \leq c\|u - v\|_{L^p(Q_T)} \tag{4.7}$$

for $p > n$.

Hence, it is not difficult to prove the following proposition.

PROPOSITION 5. *Let u be such that the corresponding free boundary $\partial\{z > 0\} \cap Q_T$ is regular, and that the problem* (4.10) *admits a unique solution. Then*

$$\frac{z^{u+\lambda v} - z^u}{\lambda} \rightharpoonup w^{u;v} \tag{4.8}$$

weakly in $L^2(0,T; H_0^1(\Omega))$ and weakly in $L^\infty(Q_T)$, as $\lambda \to 0$, where*

$$w^{u;v} = \begin{cases} \delta^{u;v} & \text{in } \{z^u > 0\}, \\ 0 & \text{in } \{z^u = 0\}, \end{cases} \tag{4.9}$$

and where $\delta = \delta^{u;v}$ is the unique solution of the parabolic equation

$$\begin{aligned} \delta_t - \Delta\delta &= -v \ \text{ in } \{z^u > 0\}, \\ \delta &= 0 \ \text{ on } \partial_p\{z^u > 0\}. \end{aligned} \tag{4.10}$$

Let $\Gamma^u = \partial\{z^u > 0\} \cap Q_T$, and let, for every $t \in (0,T)$, $\Gamma^u(t) = \partial\{z^u(\cdot,t) > 0\} \cap \Omega$. Also let $\{z^u > 0\}(t) = \{z^u(\cdot,t) > 0\} \cap \Omega$.

NOTATION 4. *Let*

$$X = \{\varphi \in H^1(0,T; H_0^1(\Omega)); \varphi|_{t=T} = 0\} \tag{4.11}$$

and let X^* be the dual of X.

We have the following theorem.

THEOREM 5 (perturbation formula for regular free boundaries; parabolic obstacle problem case). *Under the previous assumptions the following perturbation formula holds:*

$$\frac{I_{\{z^{u+\lambda v}>0\}}-I_{\{z^u>0\}}}{\lambda}\rightharpoonup -\frac{1}{u}\frac{\partial\delta^{u;v}}{\partial\nu_x^u}d\Gamma^u(t)dt \tag{4.12}$$

weakly in X^*, *as* $\lambda\to 0$.

Proof. It is easy to see that z^u solves the semilinear equation

$$\begin{aligned} z_t^u-\Delta z^u+uI_{\{z^u>0\}}&=0 \ \text{ a.e. in } Q_T,\\ z^u&=g \ \text{ on } \partial_pQ_T. \end{aligned} \tag{4.13}$$

So, writing (4.13) in the weak form for $z^{u+\lambda v}$ and z^u, subtracting and dividing by λ, we get, for any $\varphi\in X$,

$$\begin{aligned} \int_{Q_T}\frac{z^{u+\lambda v}-z^u}{\lambda}\varphi_t dxdt-\int_{Q_T}\nabla\left(\frac{z^{u+\lambda v}-z^u}{\lambda}\right)\cdot\nabla\varphi dxdt&\\ =\int_{Q_T}vI_{\{z^{u+\lambda v}>0\}}\varphi dxdt&\\ +\int_{Q_T}u\frac{1}{\lambda}\left(I_{\{z^{u+\lambda v}>0\}}-I_{\{z^u>0\}}\right)\varphi dxdt.& \end{aligned} \tag{4.14}$$

Using (4.8) and the stability theorem of [8], we can pass the limit $\lambda\to 0$ in (2.53) to conclude

$$\begin{aligned} \int_{Q_T}w^{u;v}\varphi_t dxdt-\int_{Q_T}\nabla w^{u;v}\cdot\nabla\varphi dxdt&\\ =\int_{Q_T}vI_{\{z^u>0\}}\varphi dxdt&\\ +\lim_{\lambda\to 0}\int_{Q_T}u\frac{1}{\lambda}\left(I_{\{z^{u+\lambda v}>0\}}-I_{\{z^u>0\}}\right)\varphi dxdt.& \end{aligned} \tag{4.15}$$

Now, from (4.9) and (4.15), we conclude that

$$\begin{aligned} \lim_{\lambda\to 0}\int_0^T\int_\Omega u\frac{1}{\lambda}\left(I_{\{z^{u+\lambda v}>0\}}-I_{\{z^u>0\}}\right)\varphi dxdt&\\ =-\int_0^T\int_{\Gamma^u(t)}\frac{\partial\delta^{u;v}}{\partial\nu_x^u}\varphi d\sigma_x dt& \end{aligned} \tag{4.16}$$

and hence

$$\begin{aligned} \lim_{\lambda\to 0}\int_0^T\int_\Omega\frac{1}{\lambda}\left(I_{\{z^{u+\lambda v}>0\}}-I_{\{z^u>0\}}\right)\varphi dxdt&\\ =-\int_0^T\int_{\Gamma^u(t)}\frac{1}{u}\frac{\partial\delta^{u;v}}{\partial\nu_x^u}\varphi d\sigma_x dt,& \end{aligned} \tag{4.17}$$

which proves the theorem. □

DEFINITION 4. *If there exists a function* $s^{u;v}$ *on* Γ^u, *such that*

$$\frac{I_{\{z^{u+\lambda v}>0\}}-I_{\{z^u>0\}}}{\lambda}\rightharpoonup s^{u;v}d\Gamma^u(t)dt \tag{4.18}$$

weakly in X^*, *as* $\lambda\to 0$, *then* $s^{u;v}$ *is called the* perturbation function.

We can rephrase Theorem 5 now as the following formula.

PERTURBATION FORMULA 2.

$$s^{u;v} = -\frac{1}{u}\frac{\partial \delta^{u;v}}{\partial \nu_x^u}, \tag{4.19}$$

where $\delta^{u;v}$ *is defined by* (4.10).

Remark 8. If, instead of the heat operator $\frac{\partial}{\partial t} - \Delta$, we are dealing with the general parabolic operator $\frac{\partial}{\partial t} + A$, then the differentiation formula (4.12) becomes

$$\frac{I_{\{z^u+\lambda v>0\}} - I_{\{z^u>0\}}}{\lambda} \rightharpoonup -\frac{1}{u}\frac{\partial \delta^{u;v}}{\partial \nu_A^u} d\Gamma^u(t)dt \tag{4.20}$$

weakly in X^*, as $\lambda \to 0$.

4.2. An optimal control problem. We shall consider here only the problem of minimizing the noncoincidence set. So let

$$\Phi_4(u) = \int_{Q_T} \left[I_{\{z^u>0\}} + \frac{\epsilon}{2} u^2 \right] dxdt \tag{4.21}$$

for $\epsilon > 0$. The set of controls is

$$\mathcal{C}_2 = \{u \in C^{0,1}(\bar{Q_T}); u \geq \lambda_1 > 0\}. \tag{4.22}$$

We compute the directional derivative

$$\begin{aligned} \Phi_4'(u;v) &= \lim_{\lambda\to 0} \int_{Q_T} \frac{1}{\lambda} \left[I_{\{z^{u+\lambda v}>0\}} - I_{\{z^u>0\}} \right] dxdt + \int_{Q_T} \epsilon uv dxdt \\ &= -\int_0^T \int_{\Gamma^u(t)} \frac{1}{u}\frac{\partial \delta^{u;v}}{\partial \nu_x^u} d\sigma_x dt + \int_{Q_T} \epsilon uv dxdt. \end{aligned} \tag{4.23}$$

Let $p = p^u$ be defined by

$$\begin{aligned} p_t + \Delta p = 0 \ \text{ in } \{z^u > 0\}, \\ p = -\frac{1}{u} \ \text{ on } \Gamma^u, \\ p = 0 \ \text{ on } \partial_{bp}\{z^u > 0\} \setminus \Gamma^u, \\ p = 0 \ \text{ in } \{z^u = 0\}. \end{aligned} \tag{4.24}$$

Here ∂_{bp} represents the backward parabolic boundary. Then

$$\begin{aligned} \Phi_4'(u;v) &= \int_0^T \int_{\Gamma^u(t)} p^u \frac{\partial \delta^{u;v}}{\partial \nu_x^u} d\sigma_x dt + \int_{Q_T} \epsilon uv dxdt \\ &= \int_0^T \int_{\{z^u>0\}(t)} [(\Delta \delta^{u;v}) p^u - \delta^{u;v} \Delta p^u] \, dxdt + \int_{Q_T} \epsilon uv dxdt \\ &= \int_0^T \int_{\{z^u>0\}(t)} [(\delta_t^{u;v} + v) p^u + \delta^{u;v} p_t^u] \, dxdt + \int_{Q_T} \epsilon uv dxdt \\ &= \int_{Q_T} (p^u + \epsilon u) v dxdt, \end{aligned} \tag{4.25}$$

and we have proved the following proposition.

PROPOSITION 6. *Let $u \in \mathcal{C}_2$ be such that the corresponding free boundary Γ^u is regular and that problems* (4.10) *and* (4.24) *admit unique solutions. Then Φ_4 is differentiable at u, and*

$$\Phi_4'(u;v) = \int_\Omega (p^u + \epsilon u)v dx, \tag{4.26}$$

where p^u is defined in (4.24).

Acknowledgment. The author wishes to thank very much an anonymous referee for very useful remarks regarding the previous version of this paper.

APPROXIMATIONS IN DYNAMIC ZERO-SUM GAMES II*

MABEL M. TIDBALL†, ODILE POURTALLIER‡, AND EITAN ALTMAN‡

Abstract. We pursue in this paper our study of approximations of values and ϵ-saddle-point policies in dynamic zero-sum games. After extending the general theorem for approximation, we study zero-sum stochastic games with countable state space and unbounded immediate reward. We focus on the expected average payoff criterion. We use some tools developed in [M. M. Tidball and E. Altman, *SIAM J. Control Optim.*, 34 (1996), pp. 311–328] to obtain the convergence of the values as well as the convergence of the ϵ saddle-point policies in various approximation problems. We consider several schemes of truncation of the state space (e.g., finite state approximation) and approximations of games with discount factor close to one for the game with expected average cost. We use the extension of the general theorem for approximation to study approximations in stochastic games with complete information. Finally, we consider the problem of approximating the sets of policies. We obtain some general results that we apply to a pursuit evasion differential game.

Key words. zero-sum games, approximations, stochastic games, pursuit evasion games

1. Introduction.

We pursue in this paper our study of approximations of values and saddle-point policies in dynamic zero-sum games. In a previous paper [34], we developed some tools for approximating zero-sum games and applied them to stochastic games with discounted payoff criterion. In this paper we extend the general theory for approximation to handle cases where a value does not exist for the limit game, and we apply the general theorems for approximation to some dynamic zero-sum games.

We first consider approximation problems arising in stochastic games with expected average cost: finite state approximation of stochastic games with a countable state space, and convergence of stochastic games with discounted cost to the stochastic game with average cost. We then consider approximations in stochastic games with complete information, and problems in dynamic games related to discretization of the strategy sets.

There is a rich literature on finite state approximation in the context of a single controller. The discounted reward was extensively studied; see [2, 13, 21, 22, 35, 36] and [29, 37, 38] for related discretization results. For the expected average cost, there exist only few works on state approximations in the context of control, and none in the context of stochastic games. Even if existing schemes could be extended to the setting of a stochastic game, they are still quite restricted since their convergence (in the setting of control) was established under conditions that seem very strong, and are quite often nonapplicable. Thomas and Stengos [33] obtained several schemes for finite state approximations. They impose some scrambling conditions which should hold uniformly in the states. They do not seem to hold for queueing applications, such as the models in [3, 4, 7]. Altman introduced several finite state approximation schemes [1, 2] for constrained control. They do not require the scrambling conditions, but

have other restrictive conditions: the scheme in [1] requires some monotone structure on the immediate cost, and holds for immediate costs that are only functions of the state, not of the actions. The scheme in [2] has the "finite neighbor" restriction; i.e., from each state, only finitely many states are accessible within one step.

The two approximation schemes that we introduce in the current paper relax the above restrictions and are thus also useful and new in the case of a single controller. In addition to the convergence of the value, which is the question studied in most of the papers on state approximations, we obtain (i) the convergence of the policies and (ii) the robustness of policies; i.e., an equilibrium point for the limiting (infinite state) stochastic game $G = G_\infty$ is shown to be an ϵ-equilibrium for the approximating games G_n for n large enough. On the other hand, for any ϵ, the equilibrium policies for G_n are almost optimal for the limiting game for all n large enough.

In the previous paper [34] we focused on approximations of stochastic games with discounted cost and bounded reward, and mentioned that standard techniques can be used to transform problems with unbounded reward to problems with bounded ones. This is, however, not the case for the expected average payoff criterion. The question of existence of value and of equilibrium stationary policies (under some recurrence conditions) for the case of unbounded reward was solved recently in [7, 8, 12, 30]. The growing interest in stochastic games with unbounded cost in recent years was partly driven by applications of stochastic games in telecommunications systems in general, and in queueing systems in particular. Although queues are always finite in practice (which results in a finite state space description), models of infinite queues are frequently more useful, since they are usually easier to solve. Indeed, several dynamic games arising in such applications were explicitly solved [7, 9] or at least reduced to the search for equilibrium policies among small classes of policies [4, 5, 7]. The scheduling problem described in [7, 9], the problem of routing into two queues [4, 7], and the flow and service control problem in [5] have not been solved for the case of finite state space, since there is an effect of the boundaries due to the finiteness of the queues that destroys the nice structure of the problem with infinite state space. In all the above problems, it is unnatural to consider bounded costs. Since costs represent queue lengths or waiting times, these typically grow to infinity as the number of "customers" in the queues grows to infinity. The theory developed in this paper allows the use of the equilibrium policies obtained for the infinite queues to construct ϵ-equilibrium policies for the corresponding problems with finite queues, provided that they are sufficiently large.

A second issue in this paper is the convergence of stochastic games in the discount factor. The convergence of the value and equilibrium policies for discounted cost stochastic games to those of the average cost game are well known; see, e.g., [18]. These were extended recently to unbounded cost (see [8, 30]). We obtain not only an alternative proof for the above convergence of the values and policies but also new robustness results.

When the players are restricted to using pure strategies in a stochastic game, the game in general does not have a value anymore. Using an extension of the general approximation theorems, we study approximations under that restriction. This yields approximation theorems for stochastic games with complete information (where player 2 knows at time t the action taken by player 1 at time t).

Finally, we consider the problem of approximating the set of policies by other sets. We obtain a general approximating theorem for the case when the strategy sets are endowed with the Hausdorff metric. We apply the theorem to a zero-sum pursuit evasion differential game introduced in [11, 31].

The structure of the paper is as follows. We begin in section 2 by citing and extending the general theory for approximations developed in [34]. We then introduce in section 3 the model, notation, and assumptions for the stochastic game. We present two schemes for state approximation in section 4. The convergence in the discount factor is established in section 5. In section 6 we discuss approximations for stochastic games with complete information. The approximation of the strategy sets is finally presented in section 7 together with the application to the pursuit evasion game.

2. Key theorems for approximations. We consider the following sequence $G_n = (S_n, U_n, V_n),\ n = 1, 2, ..., \infty$, of generic zero-sum games where U_n is the set of strategies (or policies) of player 1 and V_n is the set of strategies of player 2 for the nth game. We assume that both U_n and V_n are endowed with some topology. $S_n : U_n \times V_n \to \mathbb{R}$ is a measurable function for all n. We define the upper (lower) value of the game:

$$\overline{R_n} = \inf_{v\in V_n} \sup_{u\in U_n} S_n(u,v) \quad \left(\underline{R_n} = \sup_{u\in U_n} \inf_{v\in V_n} S_n(u,v)\right). \tag{2.1}$$

$G = (S, U, V) \stackrel{\text{def}}{=} (S_\infty, U_\infty, V_\infty)$ will be called the limit game. It will first be assumed (Theorem 2.1) that it has a value $R \stackrel{\text{def}}{=} R_\infty = \mathbf{Val}\{S(u,v)\}_{u,v}$. This assumption will be relaxed in Theorem 2.5.

A strategy $u^* \in U_n$ is said to be ϵ-optimal for player 1 in game n if

$$\inf_{v\in V_n} S_n(u^*, v) \geq \inf_{v\in V_n} S_n(u,v) - \epsilon \qquad \forall u \in U_n, \tag{2.2}$$

which is equivalent to $\inf_{v\in V_n} S_n(u^*, v) \geq \underline{R}_n - \epsilon$. It is said to be strong ϵ-optimal for player 1 in game n if it satisfies

$$\inf_{v\in V_n} S_n(u^*, v) \geq \overline{R}_n - \epsilon.$$

A strategy $v^* \in V_n$ is said to be ϵ-optimal for player 2 in game n if

$$\sup_{u\in U_n} S_n(u, v^*) \leq \sup_{u\in U_n} S_n(u,v) + \epsilon \qquad \forall v \in V_n, \tag{2.3}$$

which is equivalent to $\sup_{u\in U_n} S_n(u, v^*) \leq \overline{R}_n + \epsilon$. It is said to be strong ϵ-optimal if

$$\sup_{u\in U_n} S_n(u, v^*) \leq \underline{R}_n + \epsilon.$$

Note that strong ϵ-optimality implies ϵ-optimality. If a game has a value $\underline{R}_n = \overline{R}_n$, then strong ϵ-optimality is equivalent to ϵ-optimality.

Assume that (S_n, U_n, V_n) converge (in some sense) to (S, U, V). We are interested in the following questions:

(Q1) Convergence of the values: does $\underline{R}_n$ (or $\overline{R}_n$) converge to R?

(Q2) Convergence of policies: fix some $\epsilon \geq 0$. Let ϵ_n be a sequence of positive real numbers such that $\overline{\lim}_{n\to\infty} \epsilon_n \leq \epsilon$. Assume that u_n^* and v_n^* are ϵ_n-optimal policies for the nth game. Are u_n^* and v_n^* "almost" optimal for the limit game, for all n large enough?

(Q3) Let $\overline{u} \in U$ (resp., $\overline{v} \in V$) be some limit point of u_n^* (resp., v_n^*), defined above. Is $\overline{u}$ (resp., $\overline{v}$) ϵ-optimal for the limit game?

(Q4) Robustness of the optimal policy: if u^* (resp., v^*) is an ϵ-optimal policy for the limit game, can we derive from it an "almost" (strong) optimal policy for the nth approximating game for all n large enough?

A straightforward generalization of Theorem 2.1 in [34] yields our Theorem 2.1.

THEOREM 2.1. *Assume that for any $\epsilon_1 > 0$ there exists a sequence of functions, $\pi_n^1 : U_n \to U$, $\pi_n^2 : V_n \to V$, $\sigma_n^1 : U \to U_n$, $\sigma_n^2 : V \to V_n$, $n = 1, 2, ...$, such that*

($\mathcal{A}1$) $\overline{\lim}_{n\to\infty}[S_n(u, \sigma_n^2(v)) - S(\pi_n^1(u), v)] \le \epsilon_1$ *uniformly in $u \in U_n$ for each $v \in V$.*

($\mathcal{A}2$) $\underline{\lim}_{n\to\infty}[S_n(\sigma_n^1(u), v) - S(u, \pi_n^2(v))] \ge -\epsilon_1$ *uniformly in $v \in V_n$ for each $u \in U$.*

Then

(1) $\lim_{n\to\infty} \underline{R}_n = \lim_{n\to\infty} \overline{R}_n = R$.

(2) *For any $\epsilon' > \epsilon + 3\epsilon_1$, there exists N such that $\pi_n^1(u_n^*)$ (resp., $\pi_n^2(v_n^*)$, see definitions in* (Q2)) *is ϵ'-optimal for the limit game for all $n \ge N$.*

(3) *Let u^* (resp., v^*) be ϵ-optimal for the limit game. Then for all $\epsilon' > \epsilon + 3\epsilon_1$, there exists $N(\epsilon')$ such that $\sigma_n^1(u^*)$ (resp., $\sigma_n^2(v^*)$) is strong ϵ'-optimal for the nth approximating game for all $n \ge N(\epsilon')$.*

(4) *Suppose that*

($\mathcal{A}3$) *$S(u, v)$ is a lower semicontinuous function in u for each v.*

($\mathcal{A}4$) *$S(u, v)$ is an upper semicontinuous function in v for each u.*

Suppose that $\bar{u} \in U$ (resp., $\bar{v} \in V$) is a limit point of $\pi_n^1(u_n^*)$ (resp., $\pi_n^2(v_n^*)$). Then $\bar{u}$ (resp., $\bar{v}$) is $(\epsilon + 5\epsilon_1)$-optimal for the limit game.

Remark 2.2. (i) Whenever $U_n = U$ and $V_n = V$ do not depend on n, π_n and σ_n will be chosen as the identity maps.

(ii) It follows from the proof of part (1) in the above theorem that if for every G_n, $n = 1, 2, ..., \infty$, there exist optimal policies for both players, and if $U_n = U$ and $V_n = V$ do not depend on n, then

$$|\overline{R}_n - R| \le \sup_{u,v} |S_n(u, v) - S(u, v)|, \qquad |\underline{R}_n - R| \le \sup_{u,v} |S_n(u, v) - S(u, v)|.$$

Remark 2.3. Some results related to those in Theorem 2.1 can be found in [10, 17, 20, 26] and in [27], whose authors also consider additional constraints on the policies studied there.

We now relax the assumption that the limit game has a value $\underline{R}_\infty \ne \overline{R}_\infty$. We show that Theorem 2.1 still holds, by appropriately enlarging the policy spaces and redefining the cost, so that the upper (or lower) value becomes a real value of a new game.

We consider the convergence of the upper values (and corresponding optimal or almost optimal policies) of the approximating games to those of the limit game. The corresponding convergence for the lower values are obtained in a similar way. Define $\mathcal{U}_n = \{$the class of functions $V_n \to U_n\}$. Define the cost $\hat{\mathcal{S}}_n : \mathcal{U}_n \times V_n \to \mathbb{R}$ by $\hat{\mathcal{S}}_n(\psi, v) = S_n(\psi(v), v)$.

LEMMA 2.4. (i) *For all n, the new game $\mathcal{G}_n = (\hat{\mathcal{S}}_n, \mathcal{U}_n, V_n)$ has a value $\mathcal{R}_n$, and $\mathcal{R}_n = \overline{R}_n$.*

(ii) *v^* is ϵ-optimal for player 2 in game $\mathcal{G}_n$ if and only if it is ϵ-optimal in game G_n.*

Proof.

$$\inf_{v\in V_n} \sup_{\psi\in\mathcal{U}_n} \hat{\mathcal{S}}_n(\psi, v) = \inf_{v\in V_n} \sup_{\psi\in\mathcal{U}_n} S_n(\psi(v), v) = \inf_{v\in V_n} \sup_{u\in U_n} S_n(u, v) = \overline{R}_n. \tag{2.4}$$

On the other hand,

$$\inf_{v\in V_n}\sup_{\psi\in\mathcal{U}_n} S_n(\psi(v),v)=\sup_{\psi\in\mathcal{U}_n}\inf_{v\in V_n} S_n(\psi(v),v)=\sup_{\psi\in\mathcal{U}_n}\inf_{v\in V_n}\hat{\mathcal{S}}_n(\psi,v). \tag{2.5}$$

The first equality in (2.5) is due to the following. Clearly,

$$\inf_{v\in V_n}\sup_{\psi\in\mathcal{U}_n} S_n(\psi(v),v)\geq\sup_{\psi\in\mathcal{U}_n}\inf_{v\in V_n} S_n(\psi(v),v),$$

and we have to show that the reverse inequality also holds. Fix some $\epsilon'>0$ and let ψ^* be such that for all v and all $\psi\in\mathcal{U}_n$,

$$S_n(\psi^*(v),v)\geq S_n(\psi(v),v)-\epsilon'.$$

Hence,

$$\inf_{v\in V_n} S_n(\psi^*(v),v)\geq\inf_{v\in V_n}\sup_{\psi\in\mathcal{U}_n} S_n(\psi(v),v)-\epsilon'.$$

We conclude that

$$\sup_{\psi\in\mathcal{U}_n}\inf_{v\in V_n} S_n(\psi(v),v)\geq\inf_{v\in V_n}\sup_{\psi\in\mathcal{U}_n} S_n(\psi(v),v)-\epsilon',$$

which establishes the first equality in (2.5). (i) is obtained by combining (2.4) and (2.5). (ii) follows, since for any $v\in V_n$,

$$\sup_{u\in U_n} S_n(u,v)=\sup_{\psi\in\mathcal{U}_n}\hat{\mathcal{S}}_n(\psi,v). \qquad \square$$

By using the new games for which the values exist, and applying Theorem 2.1, we may conclude the following convergence properties of the original games.

THEOREM 2.5. *Assume that the functions π_n and σ_n exist as in Theorem* 2.1*, and that conditions* ($\mathcal{A}$1) *and* ($\mathcal{A}$2) *hold. Then*

(1) $\lim_{n\to\infty}\overline{R}_n=\overline{R}$, $\lim_{n\to\infty}\underline{R}_n=\underline{R}$.

(2) *For any $\epsilon'>\epsilon+3\epsilon_1$, there exists N such that $\pi_n^1(u_n^*)$ (resp., $\pi_n^2(v_n^*)$; see definitions in* (Q2)*) is ϵ'-optimal for the limit game for all $n\geq N$.*

(3) *Let u^* (resp., v^*) be ϵ-optimal for the limit game. Then for all $\epsilon'>\epsilon+3\epsilon_1$, there exists $N(\epsilon')$ such that $\sigma_n^1(u^*)$ (resp., $\sigma_n^2(v^*)$) is ϵ'-optimal for the n approximating game for all $n\geq N(\epsilon')$.*

Proof. Consider the new games $\mathcal{G}_n$ defined above. We show that the assumptions of Theorem 2.1 hold also for $\mathcal{G}_n$. The mapping $\tilde{\pi}_n^2,\tilde{\sigma}_n^2$ for the new games are unchanged:

$$\tilde{\pi}_n^2=\pi_n^2,\qquad \tilde{\sigma}_n^2=\sigma_n^2.$$

The mappings $\tilde{\pi}_n^1:\mathcal{U}_n\to\mathcal{U}$ and $\tilde{\sigma}_n^1:\mathcal{U}\to\mathcal{U}_n$ for the new games are defined as

$$[\tilde{\pi}_n^1(\psi)](v)=\pi_n^1(\psi(v))\qquad\forall v\in V,\qquad [\tilde{\sigma}_n^1(\psi)](v)=\sigma_n^1(\psi(v))\qquad\forall v\in V_n.$$

With these definitions, as well as the definition of the costs $\hat{\mathcal{S}}_n$, it follows that ($\mathcal{A}$1) and ($\mathcal{A}$2) hold for $\mathcal{G}_n$. The proof now follows by Lemma 2.4. $\square$

We may further obtain convergence results for the optimal (or ϵ-optimal) *responses* (in case the value of the limit game does not exist). To simplify the formulation, this is done below in terms of the new games $\mathcal{G}_n$.

THEOREM 2.6. *Consider the new games $\mathcal{G}_n$, and let ψ_n^*, v_n^* be defined as u_n^* in* (Q2) *(above Theorem* 2.1*). Under the conditions of Theorem* 2.5*,*

(1) $\lim_{n\to\infty} \mathcal{R}_n = \mathcal{R} = \overline{R}$.

(2) *For any $\epsilon' > \epsilon + 3\epsilon_1$, there exists N such that $\tilde{\pi}_n^1(\psi_n^*)$ (resp., $\tilde{\pi}_n^2(v_n^*)$) is ϵ'-optimal for $\mathcal{G}_\infty$ for all $n \geq N$.*

(3) *Let ψ^* be ϵ-optimal for player* 1 *in the limit game $\mathcal{G}_\infty$. Then, for all $\epsilon' > \epsilon + 3\epsilon_1$, there exists $N(\epsilon')$ such that $\tilde{\sigma}_n^1(\psi^*)$ (resp., $\tilde{\sigma}_n^2(v^*)$) is ϵ'-optimal for the n approximating game $\mathcal{G}_n$ for all $n \geq N(\epsilon')$.*

Next, we consider the result corresponding to statement (4) in Theorem 2.1.

THEOREM 2.7. *Assume that the conditions of Theorem* 2.6 *hold, that the set of response strategies for player* 2 *in games $\mathcal{G}_n$ is endowed with some topology, and that* ($\mathcal{A}$3) *and* ($\mathcal{A}$4) *hold for game $\mathcal{G}_\infty$. Then statement* (4) *of Theorem* 2.1 *holds for games $\mathcal{G}_n$.*

3. Stochastic games with expected average payoff. We consider the two-person, zero-sum stochastic game defined by the objects $\{\mathbf{I}, \mathbf{A}, \mathbf{B}, P, r\}$, where

- $\mathbf{I}$ is a countable state space;
- $\mathbf{A}$ and $\mathbf{B}$ are sets of actions for player 1 and player 2, respectively; at each state $j \in \mathbf{I}$, the available actions for the players are $\mathbf{A}_j$ and $\mathbf{B}_j$, respectively. These sets are assumed to be compact metric sets.
- $P(a,b) = [p(i,a,b,j)]_{i,j}$, $a \in \mathbf{A}$, $b \in \mathbf{B}$, $i,j \in \mathbf{I}$, are the transition probabilities, so that $p(i,a,b,j)$ is the probability of moving from i to j if the players use actions a and b.
- $r : \mathbf{I} \times \mathbf{A} \times \mathbf{B} \to \mathbb{R}$ is an immediate reward function.

The game is played in stages $t = 0, 1, 2, \ldots$. If at some stage t, the state is i, then the players independently choose actions $a \in \mathbf{A}_i$, $b \in \mathbf{B}_i$. Player 2 then pays player 1 the amount $r(i,a,b)$, and at stage $t+1$, the new state is chosen according to the transition probabilities $p(i,a,b,\bullet)$. The game continues at this new state.

Let U and V be the set of behavioral strategies for both players. A strategy $u \in U$ is a sequence $u = (u_0, u_1, \ldots)$, where u_t is a probability measure over the available actions, given the whole history of previous states and of previous actions of both players as well as the current state.

A Markov policy $q = \{q_0, q_1, \ldots\}$ is a policy (for either player 1 or 2) where q_t is allowed to depend only on t and on the state at time t.

A *stationary (mixed) policy* g for player 1 is characterized by a conditional distribution $p^g(\bullet \mid j)$ over $\mathbf{A}_j$, so that $p^g(\mathbf{A}_j \mid j) = 1$, which is interpreted as the distribution over the actions available at state j which player 1 uses when it is in state j. With some abuse of notation, we shall set $g(\bullet \mid j) = p^g(\bullet \mid j)$ for stationary g. Let U_S be the set of stationary policies for player 1, and define similarly the stationary policies V_S for player 2. If both players use stationary policies, say u and v, then $\{X_t\}$ becomes a Markov chain with stationary transition probabilities, given by

$$p(j,u,v,k) := \int_{\mathbf{A}_j} \int_{\mathbf{B}_j} p(j,a,b,k) u(da|j) v(db|j). \tag{3.1}$$

The expected immediate reward at state j becomes

$$r(j,u,v) := \int_{\mathbf{A}_j} \int_{\mathbf{B}_j} r(j,a,b) u(da|j) v(db|j).$$

Denote by $P(u,v)$ the (infinite-dimensional) matrix whose (j,k)th component equals $p(j,u,v,k)$. Similarly, denote by $r(u,v)$ the column vector whose jth component equals $r(j,u,v)$.

Next, we introduce a topology on the sets of stationary policies. For any compact metric set Γ, let $M_1(\Gamma)$ denote the set of probability measures on the Borel subsets of Γ endowed with the weak topology $\xi(\Gamma)$ (see [28]). The class of stationary policies for player 1 (and similarly for player 2) can be identified with the set $\prod_{i\in\mathbf{I}} M_1(\mathbf{A}_i) \times M_1(\mathbf{B}_i)$; moreover, it is compact with respect to the product topology $\prod_{i\in\mathbf{I}}\xi(\mathbf{A}_i) \times \xi(\mathbf{B}_i)$, and it is metrizable (by virtue of Theorem 4.14 in Kelley [23]).

Let (u, v) be a pair of strategies and let $i \in \mathbf{I}$ be a fixed initial state. Let $I_t, A_t, B_t, t = 0, ...,$ be the resulting stochastic process of the states and actions of the players. Let $E_i^{u,v}$ denote the expectation with respect to the measure defined by u, v, i.

Let $\mu : \mathbf{I} \to \mathbb{R}$ be some positive function. Following Dekker and Hordijk [16] and Spieksma [32], define the μ-norm of any vector $x \in \mathbb{R}^{\mathbf{I}}$ as

$$\| x \|_\mu = \sup_{i\in\mathbf{I}} \frac{|x_i|}{\mu_i}.$$

In a similar way, we will use the μ-J-norm, for any finite subset J of the state space I, defined by

$$\| x \|_\mu^J = \sup_{i\in J} \frac{|x_i|}{\mu_i}.$$

Define the μ-norm of matrices $Q \in \mathbb{R}^{\mathbf{I}\times\mathbf{I}}$ as

$$\|Q\|_\mu = \sup_{i\in\mathbf{I}} \mu_i^{-1} \sum_{j\in\mathbf{I}} |Q_{ij}|\mu_j.$$

We denote by $\bigvee_\mu = \{x : \| x \|_\mu < \infty\}$ the space of all vectors that are μ-bounded.

We introduce the following assumptions:

- ($\mathcal{B}1$)
  - i) The instantaneous reward $r(i, a, b)$ is continuous and μ-bounded, i.e.,

$$\sup_{i\in\mathbf{I}} \sup_{a,b} \frac{|r(i, a, b)|}{\mu_i} \le M < +\infty.$$

    This condition can be rewritten as $\|r(\cdot, u, v)\|_\mu \le M < +\infty$ for all pure stationary policies u and v.
  - ii) The transition probabilities are μ-continuous; i.e., if $a(n) \to a$, $b(n) \to b$ when $n \to +\infty$, then

$$\lim_{n\to\infty} \sum_{j\in\mathbf{I}} |p(i, a(n), b(n), j) - p(i, a, b, j)|\, \mu_j = 0 \qquad \forall i \in I.$$

- ($\mathcal{B}2$)
  - i) Under any pure stationary policies for the players, the state space does not contain more than one ergodic class.
  - ii) There exists a finite set $\mathcal{M} \subset E$ and a constant $\beta < 1$ such that

$$\sum_{j\in I} {}_{\mathcal{M}}p(i, a, b, j)\, \mu_j \le \beta\, \mu_i \qquad \forall a, b,\ \forall i \in \mathbf{I}, \tag{3.2}$$

    where ${}_{\mathcal{M}}p(i, a, b, j) = p(i, a, b, j)$ if j does not belong to the set $\mathcal{M}$, and is null otherwise. (3.2) can be rewritten as $\sum_{j\notin\mathcal{M}} p(i, a, b, j)\, \mu_j \le \beta\, \mu_i \ \ \forall a, b, \forall i \in \mathbf{I}$, or as $\|{}_{\mathcal{M}}P(u, v)\|_\mu \le \beta$ for all pure stationary policies u and v.

Remark 3.1. If assumptions ($\mathcal{B}1$) and ($\mathcal{B}2$) hold for some $\mathcal{M}$ and μ, then one can choose a state $0 \in \mathcal{M}$ and another μ' such that these assumptions hold with the set $\mathcal{M}' = \{0\}$ replacing $\mathcal{M}$, and μ' replacing μ (see [32]). Therefore, we assume in the sequel, without loss of generality, that $\mathcal{M} = \{0\}$ for some state 0.

Define

$$S(i,u,v) = \overline{\lim_{t\to\infty}} \frac{1}{t} E_i^{u,v} \sum_{s=0}^{t-1} r(I_s, A_s, B_s). \tag{3.3}$$

THEOREM 3.2 (see [8]). *Suppose that assumptions* ($\mathcal{B}1$) *and* ($\mathcal{B}2$) *hold. Then*

(i) *The stochastic game with expected average payoff criterion has a value.*

(ii) *There exists a unique solution pair* (g, v), $g \in \mathbb{R}$, $v \in R^{\mathbf{I}}$, *to the functional equation*

$$v(i) = \mathbf{Val}\left\{ r(i,a,b) - g + \sum_{j\in\mathbf{I}} p(i,a,b,j) v(j) \right\}_{a,b}, \qquad i \in \mathbf{I}, \tag{3.4}$$

such that $\|v\|_\mu$ *is finite and* $v(0) = 0$.

(iii) $g = R(i) = \mathbf{Val}\{S(i,u,v)\}_{u,v}$ *is the unique value of the stochastic game.*

(iv) *Let* (u, v) *be stationary policies such that* $u(i), v(i)$ *are optimal for the dummy game in the curly brackets in* (3.4). *Then they are optimal for the stochastic game.*

4. State truncation and approximation. In the following approximating schemes, we modify the "limit" stochastic game in the following way. We consider an increasing sequence of sets of states $\mathbf{I}_1, \mathbf{I}_2, \ldots$ converging to $\mathbf{I}$, such that $0 \in \mathbf{I}_1$. The nth stochastic game is restricted to the set $\mathbf{I}_n$. In the game G_n, we modify the transition probabilities so as to eliminate all transitions outside the set $\mathbf{I}_n$. The two schemes will differ by the way that such transitions will be replaced. Introduce the following assumption:

- ($\mathcal{B}3$) $\quad \delta(r,n) = \sup_{\substack{i\in\mathbf{I}_r \\ a\in\mathbf{A}, b\in\mathbf{B}}} \sum_{j\notin\mathbf{I}_n} p(i,a,b,j)\mu(j) \to 0 \text{ as } n \to +\infty \quad \forall r.$

Under the assumptions of our model (i.e., ($\mathcal{B}1$)–($\mathcal{B}2$)), ($\mathcal{B}3$) holds if $\mathbf{I}_n$ are finite sets $\forall n$ (the proof is similar to the one in [34]).

4.1. Scheme I. In the game G_n, we modify the transition probabilities so as to eliminate all transitions outside the set $\mathbf{I}_n$; we replace transitions outside of $\mathbf{I}_n$ by transitions to state 0. Hence, $p^n(i,a,b,j)$ is defined by

$$p^n(i,a,b,j) = \begin{cases} p(i,a,b,0) + \sum_{l\notin\mathbf{I}_n} p(i,a,b,l), & j = 0, i \in \mathbf{I}_n, \\ p(i,a,b,j), & j \neq 0, i,j \in \mathbf{I}_n, \\ 0, & j \notin \mathbf{I}_n, \\ 1\{j=0\}, & i \notin \mathbf{I}_n. \end{cases} \tag{4.1}$$

For $i \in \mathbf{I}_n$, $S_n(i,u,v)$ is defined as (3.3), where the expectation is taken with respect to the signed measure generated by the new transition probabilities (4.1). $S_n(i,u,v)$ is defined to be 0 for $i \notin \mathbf{I}_n$, for all u and v.

For $n \in \mathbb{N}$, let the pair $(g_n, v_n \in \bigvee_\mu)$ be the solutions of the dynamic programming equation

$$\begin{array}{ll} v_n(i) = \mathbf{Val}\left\{r(i,a,b) - g_n + \sum_{j\in\mathbf{I}} p^n(i,a,b,j)v_n(j)\right\}_{a,b}, & i \in \mathbf{I}_n, \quad i \neq 0, \\ v_n(i) = 0, & i \notin \mathbf{I}_n \text{ or } i = 0. \end{array} \tag{4.2}$$

One can show using Theorem 3.2 that for all n, g_n and v_n indeed exist and are unique. Moreover, we have that

$$R_n(i) = \mathbf{Val}\left\{S_n(i,u,v)\right\}_{u,v} = g_n \qquad \forall i \in \mathbf{I}.$$

In order to prove the convergence of the state approximation scheme we introduce the following quantities:

- $\tau := \inf\{t \geq 1, I_t = 0\}$ is the time to reach state zero (with the convention that $\inf\{t : t \in \emptyset\} = \infty$).
- $w(i,u,v)$:= the total cost to reach zero from state i when policies u and v are used:

$$w(i,u,v) = E_i^{u,v} \sum_{s=0}^{\tau} r(I_s, A_s, B_s),$$

  which can be rewritten in vector form as

$$w(u,v) = \sum_{s=0}^{\infty} [{}_0P(u,v)]^s r(u,v).$$

- $w^n(i,u,v)$:= the total cost to reach zero from state i when policies u and v are used, when the transition probabilities are replaced by (4.1).
- $\overline{\tau}(i,u,v), \overline{\tau}^n(i,u,v)$:= the expectations of τ when using the original transition probabilities, and when using those in (4.1), respectively. For $i \notin \mathbf{I}_n$ we have $\overline{\tau}^n(i,u,v) = 1$ for all policies u and v.

We note that $w(\cdot,u,v)$, $w^n(\cdot,u,v)$, $\overline{\tau}(\cdot,u,v)$, and $\overline{\tau}^n(\cdot,u,v)$ are uniformly μ bounded. Indeed,

$$\left\|w(u,v)\right\|_\mu \leq \sum_{s=0}^{\infty} \left[\left\|{}_0P(u,v)\right\|_\mu\right]^s \left\|r(u,v)\right\|_\mu \leq \frac{M}{1-\beta} \tag{4.3}$$

with the same bound for $w^n(u,v)$. Similarly, $\left\|\overline{\tau}(u,v)\right\|_\mu$ and $\left\|\overline{\tau}^n(u,v)\right\|_\mu$ are bounded by $(1-\beta)^{-1}$. It is easily seen that $w(\cdot,u,v)$, $w^n(\cdot,u,v)$, $\overline{\tau}(\cdot,u,v)$, and $\overline{\tau}^n(\cdot,u,v)$ are the unique solutions in $\bigvee_\mu$ of the fixed point equations

$$w(i,u,v) = r(i,u,v) + \sum_{j\neq 0} p(i,u,v,j)w(j,u,v), \tag{4.4}$$

$$w^n(i,u,v) = \begin{cases} r(i,u,v) + \sum_{j\neq 0} p^n(i,u,v,j)w^n(j,u,v) \text{ for } i \in I_n, \\ 0 \text{ for } i \notin I_n, \end{cases} \tag{4.5}$$

$$\overline{\tau}(i,u,v) = 1 + \sum_{j\neq 0} p(i,u,v,j)\overline{\tau}(j,u,v), \tag{4.6}$$

$$\overline{\tau}^n(i,u,v) = \begin{cases} 1 + \sum_{j\neq 0} p^n(i,u,v,j)\overline{\tau}^n(j,u,v) \text{ for } i \in I_n, \\ 1 \text{ for } i \notin I_n. \end{cases} \tag{4.7}$$

The uniqueness follows from the fact that the above equations are contracting due to ($\mathcal{B}2$). Note that functions $w(.,u,v)$ and $w^n(.,u,v)$ are μ-bounded for all pairs (u,v) on every subset J of $\mathbf{I}$. Since both $\overline{\tau}^n(0,u,v)$ and $\overline{\tau}(0,u,v)$ are both nonzero and finite, it follows (see Chung [14, pp. 91–92]) that the expected average cost is given by the following ratio between the total cost and the expected hitting time of state zero:

$$S(i,u,v)=\frac{w(0,u,v)}{E\tau(0,u,v)} \quad \text{and} \quad S_n(i,u,v)=\frac{w^n(0,u,v)}{E\tau^n(0,u,v)}. \tag{4.8}$$

THEOREM 4.1. *Assume* ($\mathcal{B}1$)–($\mathcal{B}3$). *All statements of Theorem* 2.1 *hold, where* S_n *and* S *are the expected average payoffs defined in* (3.3)*, with the transition probabilities* p *and* p^n (*defined in* (4.1))*, respectively.*

Proof. Fix some initial state i. We use Theorem 2.1. We begin by establishing conditions ($\mathcal{A}1$) and ($\mathcal{A}2$). Since $U=U_n$ and $V_n=V$ for each n, it suffices to show that $S_n(u,v):=S_n(i,u,v)$ converges to $S(u,v):=S(i,u,v)$ uniformly on $\mathbf{I}$. Hence, we set π_n^1, π_n^2, σ_n^1, and σ_n^2 to be identical.

Let J be a given subset of $\mathbf{I}$, and (u,v) a pair of strategies. To avoid cumbersome notations we will write $w(.)$ (resp., $w^n(.)$) instead of $w(.,u,v)$ (resp., $w^n(.,u,v)$). We first want to prove that

$$\lim_{n\to+\infty} \parallel w^n-w \parallel_\mu^J = 0.$$

Once we show that, one obtains in the same way that $\lim_{n\to+\infty} \parallel E\tau-E\tau^n \parallel_\mu^J = 0$, and the uniform convergence of $S_n(u,v)$ to $S(u,v)$ now follows from (4.8).

We use an idea introduced by Cavazos-Cadena [13] and used in [34] for a similar problem. Fix ϵ arbitrarily small and define the sequence g_k in the following way. $g_0=\min\{m : J\subset \mathbf{I}_m\}$ and, recursively,

$$g_k=g(\epsilon,g_{k-1}), \qquad g(\epsilon,r)=\min\{m:\delta(r,m)\le\epsilon\},$$

where δ is defined in ($\mathcal{B}3$). Due to assumption ($\mathcal{B}3$), this sequence is well defined, and for all k, g_k is finite. Let ν be a given integer; define also

$$m^\nu(\epsilon)=\max\{g_m, m=0,1,...,\nu\}.$$

Let $n\ge m^\nu(\epsilon)$, $i\in J$. Let us now compute $\parallel w^n-w\parallel_\mu^J$. We obviously have that $\parallel w^n-w\parallel_\mu^J \le \parallel w^n-w\parallel_\mu^{I_{g_0}}$, since $J\subset I_{g_0}$, and for $i\in\mathbf{I}_{g_0}$,

$$\begin{aligned}
\frac{1}{\mu_i}|w^n(i)-w(i)| &= \frac{1}{\mu_i}\left|\sum_{j\neq 0} p^n(i,u,v,j)w^n(j)-p(i,u,v,j)w(j)\right| \\
&\le \frac{1}{\mu_i}\sum_{j\in\mathbf{I}_{g_1}\setminus\{0\}} |p^n(i,u,v,j)w^n(j)-p(i,u,v,j)w(j)| \\
&\quad +\frac{1}{\mu_i}\sum_{j\in\mathbf{I}_n\setminus\mathbf{I}_{g_1}} |p^n(i,u,v,j)w^n(j)-p(i,u,v,j)w(j)| \\
&\le \sum_{j\in\mathbf{I}_{g_1}\setminus\{0\}} \frac{p(i,u,v,j)\mu_j}{\mu_i}\frac{|w^n(j)-w(j)|}{\mu_j} \\
&\quad +\frac{1}{\mu_i}\sum_{j\in\mathbf{I}_n\setminus\mathbf{I}_{g_1}} p(i,u,v,j)|w^n(j)-w(j)|.
\end{aligned}$$

In the last inequality the first term can be bounded by $\beta \parallel w - w^n \parallel_\mu^{\mathbf{I}_{g_1}}$ because of assumption ($\mathcal{B}2$(ii)), and the second by $2\frac{M}{1-\beta}\epsilon$, since

$$\sum_{j\in\mathbf{I}_n\setminus\mathbf{I}_{g_1}} p(i,u,v,j)|w^n(j)-w(j)| \le \sum_{j\in\mathbf{I}_n\setminus\mathbf{I}_{g_1}} \mu_j p(i,u,v,j)\left[\frac{|w^n(j)|}{\mu_j}+\frac{|w(j)|}{\mu_j}\right].$$

This is due to the definition of the sequence I_{g_k}, since i belongs to I_{g_0} due to ($\mathcal{B}3$), and since w^n and w are bounded by $\frac{M}{1-\beta}$; see (4.3). We obtain

$$\parallel w^n - w \parallel_\mu^{\mathbf{I}_{g_0}} \;\le\; \beta \parallel w^n - w \parallel_\mu^{\mathbf{I}_{g_1}} + 2\frac{M}{1-\beta}\epsilon.$$

In exactly the same way we get for $k \le m^\nu(\epsilon)$,

$$\parallel w^n - w \parallel_\mu^{\mathbf{I}_{g_k}} \;\le\; \beta \parallel w^n - w \parallel_\mu^{\mathbf{I}_{g_{k+1}}} + 2\frac{M}{1-\beta}\epsilon,$$

and finally,

$$\parallel w^n - w \parallel_\mu^{J} \;\le\; \beta^\nu \frac{2M}{1-\beta} + \frac{2M\epsilon}{1-\beta}\left(\frac{1-\beta^\nu}{1-\beta}\right). \tag{4.9}$$

Since ν can be chosen arbitrarily large when n tends to infinity, and β is strictly lower than 1, this bound can be as small as needed for n large enough. This establishes ($\mathcal{A}1$)–($\mathcal{A}2$) in Theorem 2.1. It follows from [8] that S is a continuous function of u and v, which implies ($\mathcal{A}3$)–($\mathcal{A}4$) of Theorem 2.1. This completes the proof. □

4.2. Scheme II. In the previous scheme, we replaced transitions outside of $\mathbf{I}_n$ by transitions to state 0. In some applications this may be undesirable; this is the case when the games with truncated space describe real problems that we wish to approximate by some game with an infinite state space. To illustrate this, consider a queue with a finite length L, and assume that the state is the number of customers in the queue. Then, typically, if a transition from state L to state $L+1$ were possible in the case of an infinite queue, then in the problem with truncated state space, which corresponds to a finite queue, it is replaced by a transition from L to L. In the previous scheme, it would be replaced by a transition to state 0. This would be especially undesirable, since in queueing problems, we usually have the property of transitions to closest neighbors: from each state, only finitely many neighboring states can be reached in one step. So, having a transition from state L to 0 does not describe a realistic model of a finite queue.

Let $\{q^n(i,a,b,j), i,j \in \mathbf{I}, a \in \mathbf{A}, b \in \mathbf{B}\}$ be sequences of measures such that for all n, $i \in \mathbf{I}$, $a \in \mathbf{A}, b \in \mathbf{B}$,

$$q^n(i,a,b,j) \le 0 \text{ for } j \in \mathbf{I}_n, \qquad q^n(i,a,b,j) = 0 \text{ for } j \notin \mathbf{I}_n,$$

$$\sum_{j\in\mathbf{I}_n} (p(i,a,b,j) + q^n(i,a,b,j)) = 1.$$

The transitions for the approximating problems are then given by

$$p^n(i,a,b,j) = \begin{cases} p(i,a,b,j) + q^n(i,a,b,j), & i,j \in \mathbf{I}_n, \\ 0 & \text{otherwise.} \end{cases} \tag{4.10}$$

It follows that

$$\sum_{j\in\mathbf{I}_n} q^n(i,a,b,j) = \sum_{j\notin\mathbf{I}_n} p(i,a,b,j). \tag{4.11}$$

We make the following assumption on μ and on $\mathbf{I}_n$:

$$\text{for any } n>m \text{ and } i\in\mathbf{I}_n\setminus\mathbf{I}_m,\ \mu(i)\geq \sup_{j\in\mathbf{I}_m}\mu(j).$$

For $i\in\mathbf{I}_n$, $S_n(i,u,v)$ is defined as (3.3), where the expectation is taken with respect to the measure generated by the new transition probabilities (4.10). We set $S_n(i,u,v)=0$ for all $i\notin\mathbf{I}_n$.

THEOREM 4.2. *Assume* ($\mathcal{B}1$)–($\mathcal{B}3$)*, and consider the above finite approximation scheme. Then all statements of Theorem* 2.1 *hold.*

Proof. We consider, as in the previous section, the total expected cost and total expected time between consecutive epochs until state 0 is reached. By similar arguments to those in the previous scheme, one then establishes that $S_n(u,v)$ converge to $S(u,v)$ uniformly in all stationary policies (the exact proof can be found in [6, Chapter 8]). This implies assumptions ($\mathcal{A}1$) and ($\mathcal{A}2$). Assumptions ($\mathcal{A}3$) and ($\mathcal{A}4$) relate only to the limit game, and therefore the proof is the same as in the previous section. The theorem now follows from Theorem 2.1. □

5. Convergence of the discounted cost to the average cost. Conditions for the convergence of the value and equilibrium policies for discounted cost stochastic games to those of the average cost game are well known; see, e.g., [18]. These were extended recently to unbounded cost (see [8, 30]). Theorem 2.1 enables us not only to obtain an alternative proof for the above convergence of the values and policies but also to obtain new robustness results, as in Theorem 5.2 below.

Define the *β-discounted game payoff*

$$S_\beta(i,u,v) = (1-\beta)E_i^{u,v}\sum_{t=0}^{\infty}\beta^t r(I_t,A_t,B_t). \tag{5.1}$$

The following was proved in [8, Theorem 3.4], (see also [15]).

THEOREM 5.1. *Assume* ($\mathcal{B}1$) *and* ($\mathcal{B}2$)*. Then*

(1) *A value $R_\beta(i)$ exists for the discounted cost.*

(2) *Optimal stationary policies exist for both players for any discount factor $0<\beta<1$ (they are said to be β-optimal).*

(3) *Any limit-point (as β tends to 1) of β-optimal stationary policies is expected to be average optimal; moreover, the value of the discounted games converges to the value of the expected average game.*

THEOREM 5.2. (1) *Let (u^*,v^*) be any stationary policy pair which is expected to be average optimal. Then for any $\epsilon>0$, (u^*,v^*) is ϵ-optimal for the β-discounted cost for all β sufficiently close to* 1*, and for all $u\in U$, $v\in V$,*

$$\overline{\lim_{\beta\to1}}[S_\beta(i,u,v^*)-S_\beta(i,u^*,v^*)]\leq 0, \qquad \underline{\lim_{\beta\to1}}[S_\beta(i,u^*,v)-S_\beta(i,u^*,v^*)]\geq 0.$$

(2) *For any $\epsilon>0$ there exists some $\beta_0<1$ such that for any $\beta_0\leq\beta<1$ and any stationary pair u^β,v^β which is β-optimal, (u^β,v^β) is ϵ-optimal for the expected average game.*

Proof. It is sufficient to prove that ($\mathcal{A}1$) and ($\mathcal{A}2$) in Theorem 2.1 hold. This follows indeed from the fact that

$$\lim_{\beta \to 1} \|S_\beta(\cdot, u, v) - S(\cdot, u, v)\|_\mu = 0$$

uniformly over all stationary policies u and v; see [2, p. 166]. □

6. Stochastic games with complete information. In sections 4 and 5 and in [34] we described several approximation problems in stochastic games, where we had a value in the limit game. In all those cases, we considered (without loss of optimality) the (randomized) stationary or the (randomized) Markov policies. Consider now the game $G^0 = (S, U_D, V_D)$, where S is given in (3.3) for some fixed initial state i, and where U_D and V_D are the classes of the pure stationary policies. Then the game will generally not have any value: it will have typically a lower and an upper value.

Since we established conditions ($\mathcal{A}1$) and ($\mathcal{A}2$) for all the problems considered in sections 4 and 5 (and also for the discounted cost, in [34]), they hold in particular if we restrict to purely stationary strategies. Therefore, the convergence of $\underline{R}_n^D$ and $\overline{R}_n^D$ to the upper and lower values of the limit game ($\underline{R}^D$ and $\overline{R}^D$) as well as the convergence of the policies in Theorems 2.5 and 2.6 hold for all these problems. (G_n^0 is the nth approximating game, and $\overline{R}_n^D$ and $\underline{R}_n^D$, its upper and lower values.)

Applying Theorem 2.7 is more delicate, since only in special cases can we define a topology over the space of responses of player 2 such that assumptions ($\mathcal{A}3$) and ($\mathcal{A}4$) hold (as opposed to standard stochastic games, where ($\mathcal{A}3$) and ($\mathcal{A}4$) need to hold for policies, and not for responses). When the action space available to player 1 is finite, one may identify the class of pure stationary response strategies of player 2 (corresponding to purely stationary policies of player 1) with the set of functions $\mathbf{I} \times \mathbf{A} \to \mathbf{B}$, endowed with topology of weak convergence of measures. The continuity assumptions ($\mathcal{A}3$) and ($\mathcal{A}4$) can now be established using arguments as in Remark 3.1 in [34] and [8].

We shall now show the usefulness of the above results for stochastic games with complete information in the sense used, e.g., by Küenle [24, 25]. There, one of the players—say, player 2—has at each time t the additional information of the action chosen by player 1 at time t (i.e., in addition to the information of all past states and actions of both players, plus the current state). The information structure for the other player is unchanged. We thus define the class of policies V^* to be the set of policies of the form $v = (v_0, v_1, ...)$, where v_t is a probability measure over $\mathbf{B}$ conditioned on the history $(x_0, a_0, b_0, x_1, a_1, b_1, ..., x_{t-1}, a_{t-1}, b_{t-1}, x_t, a_t)$.

Consider the following game: $G^1 = (S, U, V^*)$, where S is given by (3.3) for some fixed initial state i. (The results below will also hold for the expected discounted cost with infinite horizon, considered in [34].) We shall be interested in approximating

$$\underline{R}^1 = \sup_{u \in U} \inf_{v \in V^*} S(u, v).$$

Under quite general conditions [18, 24, 25], there exists optimal policies in U_D for player 1 in the sense that there exists some $u^1 \in U_D$ such that

$$\underline{R}^1 = \sup_{u \in U} \inf_{v \in V^*} S(u, v) = \sup_{u \in U_D} \inf_{v \in V^*} S(u, v) = \inf_{v \in V^*} S(u^1, v).$$

(This property does not hold for non-zero-sum games, for which there are counter-examples; see [18].)

On the other hand, under the conditions in section 3, we have for any $u \in U_D$,

$$\inf_{v \in V^*} S(u,v) = \inf_{v \in V} S(u,v) = \inf_{v \in V_D} S(u,v).$$

The first equality follows from the fact that $u \in U_D$, so that for any policy $v^* \in V^*$, we have $S(u,v) = S(u,v^*)$, where $v = (v_0, v_1, ...)$ is given by

$$v_t(x_0, a_0, b_0, ..., x_{t-1}, a_{t-1}, b_{t-1}, x_t) = v_t^*(x_0, a_0, b_0, ..., x_{t-1}, a_{t-1}, b_{t-1}, x_t, u(x_t)).$$

The second equality follows, since for any $u \in U_D$, player 2 is now faced with a standard Markov decision process (see, e.g., [32]). We thus conclude that $\underline{R}^1 = \underline{R}^D$. Thus, the convergence of $\underline{R}_n^D$ to $\underline{R}^D$ implies convergence of lower values for the game with complete information. Similarly, the convergence of the policies in Theorems 2.5 and 2.6 for games G_n^0 implies the convergence of policies for player 1 in the games with complete information that approximate G^1.

Remark 6.1. An alternative approach to obtaining convergence of values and policies for games with complete information is to transform these into standard stochastic games [25]. Note, however, that if the action space is uncountably infinite (e.g., an interval), then the transformation results in an uncountable state space.

7. A finite approximation of strategy sets. Another type of approximation that arises in dynamic games is the countable or finite approximation of strategy sets. This step is necessary when we want to perform numerical computations, and when the strategy sets are infinite or continuous, or both.

Let $\mathcal{U}$ and $\mathcal{V}$ be metric sets of policies for players 1 and 2, and let $S(u,v)$ correspond to the cost associated to the pair of strategies $u \in \mathcal{U}, v \in \mathcal{V}$. Introduce the following sets of strategies: $U \subset \mathcal{U}$ and $V \subset \mathcal{V}$, and the sequences $\{U_n\}_{n \in \mathbb{N}} \subset \mathcal{U}$ and $\{V_n\}_{n \in \mathbb{N}} \subset \mathcal{V}$. U_n and V_n are assumed to be countable or finite sets of policies.

THEOREM 7.1. *Suppose that*

($\mathcal{A}'1$) $\lim_{n \to +\infty} U_n = U$ *and* $\lim_{n \to +\infty} V_n = V$, *in the Hausdorff topology sense,*

($\mathcal{A}'3$) $S(u,v)$ *is a lower semicontinuous function in* $u \in U$ *uniformly in* $v \in V$,

($\mathcal{A}'4$) $S(u,v)$ *is an upper semicontinuous function in* $v \in V$ *uniformly in* $u \in U$.

Then the conclusions of Theorem 2.1 *hold (where* $\overline{R}_n$ *and* $\underline{R}_n$ *are defined in* (2.1) *and* R *is defined with respect to the policy sets* U *and* V *for* $\epsilon_1 = 0$*).*

Proof. We need to prove that under the set of assumptions ($\mathcal{A}'1$), ($\mathcal{A}'3$), and ($\mathcal{A}'4$) the hypotheses of Theorem 2.1 are satisfied. ($\mathcal{A}'3$) and ($\mathcal{A}'4$) directly imply ($\mathcal{A}3$) and ($\mathcal{A}4$). We shall prove only that ($\mathcal{A}1$) holds, since the proof of ($\mathcal{A}2$) is identical. Choose any ϵ_0 and introduce some sequence of functions:

$$\pi_n^1 : U_n \longrightarrow U \text{ such that } d(u_n, \pi_n^1(u_n)) < \inf_{u \in U} d(u_n, u) + \epsilon_0$$

and

$$\sigma_n^2 : V \longrightarrow V_n \text{ such that } d(\sigma_n^2(v), v) < \inf_{v_n \in V_n} d(v_n, v) + \epsilon_0.$$

By ($\mathcal{A}'1$), for all ϵ_2, there exists $N_1 = N_1(\epsilon_2)$ such that for all $n > N_1$,

$$\max\left(\sup_{u_n \in U_n} \inf_{u \in U} d(u_n, u) \; ; \; \sup_{u \in U} \inf_{u_n \in U_n} d(u_n, u) \right) \leq \epsilon_2;$$

that is, for all $u_n \in U_n$,

$$\inf_{u \in U} d(u_n, u) \leq \epsilon_2,$$

so for all $u_n \in U_n$,

$$d(u_n, \pi_n^1(u_n)) \leq \epsilon_0 + \epsilon_2. \tag{7.1}$$

Similarly, for all ϵ_3, there exists $N_3 = N_3(\epsilon_3)$ such that for all $n > N_3$ and for all $v \in V$,

$$d(v, \sigma_n^2(v)) \leq \epsilon_0 + \epsilon_3. \tag{7.2}$$

To prove $(\mathcal{A}1)$ we shall show that for all ϵ, there exists $N = N(\epsilon)$ such that for all $n > N$, and for all $u_n \in U_n$, $v \in V$, we have

(7.3)

$$S(u_n, \sigma_n^2(v)) - S(\pi_n^1(u_n), v) = S(u_n, \sigma_n^2(v)) - S(u_n, v) + S(u_n, v) - S(\pi_n^1(u_n), v) < \epsilon.$$

Since S is upper semicontinuous in v uniformly in u, there exists η_1 such that if $d(\sigma_n^2(v), v) \leq \eta_1$, $S(u_n, \sigma_n^2(v)) - S(u_n, v) \leq \epsilon/2$. Choose ϵ_0 and ϵ_3 such that $\epsilon_0 + \epsilon_3 = \eta_1$ in (7.2); there exists N_1 such that for all $n > N_1$,

$$S(u_n, \sigma_n^2(v)) - S(u_n, v) \leq \frac{\epsilon}{2}. \tag{7.4}$$

Similarly, it follows from (7.1) and the fact that S is lower semicontinuous in u uniformly in v that there exists N_2 such that for all $n > N_2$,

$$S(u_n, v) - S(\pi_n^1(u_n), v) \leq \frac{\epsilon}{2}. \tag{7.5}$$

Equations (7.4) and (7.5) imply (7.3) by choosing $N = \sup(N_1, N_2)$, which concludes the proof. □

Remark 7.2. In many applications (e.g., [11, 31]), the strategy sets are compact. Hence it suffices to require in $(\mathcal{A}'3)$ and $(\mathcal{A}'4)$ the semicontinuity properties; the uniform semicontinuity is then a consequence of the compactness of the strategy sets.

As an application of Theorem 7.1, we present the following continuous-time differential pursuit evasion game by Bernhard and Shinar [11, 31]. We shall use the same notation as in [11, 31]. The game is governed by a differential equation

$$\frac{dx}{dt} = f(x, a, b), \quad x \in \mathbf{I}, \quad a \in \mathbf{A}, \quad b \in \mathbf{B},$$

where $\mathbf{A}$ and $\mathbf{B}$ are compact subsets of $\mathbb{R}^{m_1}$ and $\mathbb{R}^{m_2}$, respectively, and $\mathbf{I}$ is a domain of $\mathbb{R}^n$. Some regularity and growth conditions on f ensure the existence of the solution of the differential equation over $(0, \infty)$ for every pair of measurable functions $a(\cdot)$ (and $b(\cdot)$) from $(0, \infty)$ to $\mathbf{A}$ (resp., $\mathbf{B}$). The players have access to noisy partial information

$$y_a = h_a(x, w), \qquad y_b = h_b(x, w),$$

where w is a noise and h_a, h_b are globally Lipschitz over $\mathbf{I}$. They are restricted to using feedback strategies $(a(t) = \delta_1(y_a(t)), b(t) = \delta_2(y_b(t)))$ Lipschitz continuous; then the set of strategies is compact in the topology of the uniform convergence. It is assumed that the noise model and the solution concept of the differential equations are such that the payoff P (the expected value of a continuous function of closest approach) is a continuous function of the strategies for the topology of uniform convergence.

If Ω_1 and Ω_2 are compact metric strategy spaces, and Δ_1 and Δ_2 are closed subsets of Ω_1 and Ω_2, respectively, and $U = M_1(\Delta_1)$ and $V = M_1(\Delta_2)$ are the sets of probability measures over Δ_1 and Δ_2, we know that there exist optimal mixed strategies that achieve the value

$$V(\Delta_1, \Delta_2) = \min_{u \in U} \max_{v \in V} J(u, v) = \int_{\Delta_1} \int_{\Delta_2} P(\delta_1, \delta_2) du(\delta_1) dv(\delta_2).$$

Bernhard and Shinar establish the convergence of the values of some approximating problems to the value of the original one.

We show that, in fact, all the statements concerning the convergence of policies in Theorem 2.1 also hold (with $\epsilon_1 = 0$). In [11], the continuity of $V(.,.)$ is proved; i.e., $(\mathcal{A}'3)$ and $(\mathcal{A}'4)$ are established. They present a finite approximation of this problem by considering finite subsets of Δ_i $i = 1, 2$, that converge to Δ_i in the Hausdorff topology (and thus, $(\mathcal{A}'1)$ holds).

NP-HARDNESS OF SOME LINEAR CONTROL DESIGN PROBLEMS*

VINCENT BLONDEL† AND JOHN N. TSITSIKLIS‡

Abstract. We show that some basic linear control design problems are NP-hard, implying that, unless P=NP, they cannot be solved by polynomial time algorithms. The problems that we consider include simultaneous stabilization by output feedback, stabilization by state or output feedback in the presence of bounds on the elements of the gain matrix, and decentralized control. These results are obtained by first showing that checking the existence of a stable matrix in an interval family of matrices is NP-hard.

Key words. control design, complexity, linear control

1. Introduction.

Consider the following three problems; the first was mentioned as a "major open problem in systems and control theory" in a recent survey [5] of experts in the systems and control field, and the other two were mentioned indirectly.

Stabilization by static output feedback. This is perhaps the most basic problem in control theory. We are given a linear system

$$\dot{x}(t) = Ax(t) + Bu(t),$$
$$y(t) = Cx(t),$$

and we consider a static feedback control law of the form

$$u(t) = Ky(t).$$

The resulting closed loop system is

$$\dot{x}(t) = (A + BKC)x(t).$$

The problem is to find necessary and sufficient conditions on the triplet of real matrices (A, B, C) under which there exists a feedback gain matrix K such that $A + BKC$ is stable. In the case of state feedback ($C = I$), a necessary and sufficient stabilizability condition is given by the stabilizability of the pair (A, B) [17]. However, if C is not invertible, no general necessary and sufficient conditions are known.

Simultaneous stabilization by static output or state feedback. (This problem should not be confused with what is usually referred to as the "simultaneous stabilization problem" [16, 4], in which dynamic—instead of static—compensation is sought.) Our second problem is a generalization of the static output feedback problem. Suppose

that for each $i = 1, \ldots, k$ we are given a linear system

$$\dot{x}(t) = A_i x(t) + B_i u(t),$$
$$y(t) = C_i x(t).$$

Under the feedback control law,

$$u(t) = Ky(t),$$

the ith closed loop system is

$$\dot{x}(t) = (A_i + B_i K C_i) x(t).$$

The problem is to find conditions on the triplets of real matrices (A_i, B_i, C_i), $i = 1, \ldots, k$, under which there exists a matrix K such that $A_i + B_i K C_i$ is stable for each i. This problem is unsolved, even if $C_i = I$ for all i (simultaneous stabilization by state feedback).

Stabilization by decentralized static output feedback. We now impose some structure on the feedback gains. Consider a linear system of the form

$$\dot{x}(t) = Ax(t) + \sum_{i=1}^{k} B_i u_i(t),$$
$$y_i(t) = C_i x(t), \qquad i = 1, \ldots, k,$$

and suppose that we are interested in a static decentralized controller of the form

$$u_i(t) = K_i y_i(t), \qquad i = 1, \ldots, k.$$

The closed loop system is

$$\dot{x}(t) = \left(A + \sum_{i=1}^{k} B_i K_i C_i \right) x(t),$$

which is of the same form as in stabilization by static output feedback, except that several of the entries of K are forced to zero. This leads us to the problem of finding conditions on the triplet of real matrices (A, B, C) under which there exists a matrix K with a given structure such that $A + BKC$ is stable. The problem can be further constrained by requiring the matrix structure to be block diagonal, the blocks to have a bounded norm, or the blocks to be identical (we discuss all of these cases later).

The reader is referred to [3, p. 420], where the above three problems are presented and motivated and where references can be found. A common feature of these three problems is that, although they are easy to state, neither closed form nor efficient algorithmic solutions are known. It is rather improbable that closed form solutions to these problems are possible. On the other hand, algorithmic solutions do exist, as we now argue.

All of the problems that we have described are finitely parametrized. They all involve the search for a controller—the (possibly partitioned) matrix K—which can be specified in terms of finitely many real parameters. In theory, it is thus possible to apply the following methodology: (a) parametrize the gain matrix K in terms of finitely many real coefficients; (b) express the matrix stability condition(s) in terms

of the coefficients of the system(s) and of the controller; (c) use the Routh–Hurwitz test on the resulting characteristic polynomial(s). One is then left with a (large) set of multivariable polynomial inequalities that have to be simultaneously satisfied for some choice of the controller coefficients. As explained in [1], checking the existence of controller coefficients that satisfy this system of multivariable inequalities can be performed using the Tarski–Seidenberg elimination theory. The Tarski–Seidenberg elimination method leads, after a finite number of rational operations, to a yes-no answer regarding the existence of a solution. The method is systematic and amenable to computer implementation. Thus, *all three problems described above are algorithmically solvable*.

The advantage of the Tarski–Seidenberg method is its generality; its drawback is the fact that its computational complexity increases at least exponentially. The examples that can be worked on paper are very small (the example given in [1] involves only two parameters), and computer algorithms cannot digest more than five or six parameters in reasonable time.

In this paper we show that some of the above problems and their variations are very unlikely to allow for *efficient* algorithmic solutions. We adhere to the general consensus in computer science that identifies algorithmic efficiency with polynomial time computability. We then show that some of the above problems are NP-hard [8, 13], meaning that every problem in NP can be reduced to them. Thus, unless P=NP, these problems are not polynomial time solvable.

Our results are as follows (see later for precise definitions):

1. The static output feedback stabilization problem is NP-hard if one constrains the coefficients of the controller K to lie in prespecified intervals. The same is true in the case of static *state* feedback ($C = I$). We have not been able to establish the complexity of the problem in the absence of constraints on K, but we conjecture that it is also NP-hard.
2. Simultaneous stabilization by output feedback is NP-hard.
3. Stabilization by decentralized static output feedback is NP-hard if one imposes a bound on the norm of the controller or if the blocks are constrained to be identical.

These results will be proved as corollaries of the following main theorem: testing for the presence of a stable matrix in a family of matrices whose members have entries that are either fixed to some given real number or vary in the closed unit interval $[-1, 1]$ is an NP-hard problem. This latter result complements a recent theorem of Nemirovskii [11], who showed that testing for the stability of *all* elements of such a family of matrices is an NP-hard problem. Our proof is in fact inspired from his. This general research direction was initiated by Poljak and Rohn, who showed that checking nonsingularity of an interval family of matrices is NP-hard [14]. In other related research, NP-hardness of the computation of the structured singular value μ was shown by Braatz et al. [6] for the case where some perturbations are complex. (NP-completeness for the case of real perturbations was a corollary of the results of Poljak and Rohn.) Also, Coxson and DeMarco show that approximating the minimal perturbation scaling to achieve instability in an interval matrix is MAX-SNP-hard [7]. See also [15] for a review of other complexity results for problems in control theory.

In the next section, we prove the main result and derive some general corollaries. In the last section we link these results with the linear control design problems mentioned in this introduction.

2. Checking the existence of a stable matrix in an interval family of matrices is NP-hard. In this section we show that checking the existence of a stable matrix in a unit interval family of matrices is an NP-hard problem (a unit interval family of matrices is a family of matrices whose members have entries that are either fixed to some given real number or vary in the closed unit interval $[-1, 1]$). We prove this result by means of a polynomial time reduction from the following problem, which is already known to be NP-complete [10, 8].

PARTITION

Instance: A positive integer l, a set of l integers $a_i \in \mathcal{Z}$.

Question: Do there exist $t_1, \ldots, t_l \in \{-1, +1\}$ such that $\sum_{i=1}^{l} a_i t_i = 0$?

We now formally define the problem of interest.

STABLE MATRIX IN UNIT INTERVAL FAMILY

Instance: A positive integer n, a partition of $I = \{(i, j) : 1 \leq i, j \leq n\}$ into disjoint sets I_1 and I_2, rational numbers a_{ij}^* for $(i, j) \in I_1$.

Question: Does the set $\mathcal{A}$ of $n \times n$ matrices defined by

$$\mathcal{A} = \{A = (a_{ij}) : a_{ij} = a_{ij}^* \text{ for } (i, j) \in I_1,\ a_{ij} \in [-1, 1] \text{ for } (i, j) \in I_2\}$$

contain a stable matrix?

Remark. Throughout this paper, when writing "stable" we actually mean "asymptotically stable," i.e., "all eigenvalues have a negative real part." A slightly different problem is obtained if we are interested in marginal stability ("all eigenvalues have a nonpositive real part"). We call this second problem MARGINALLY STABLE MATRIX IN UNIT INTERVAL FAMILY.

The main result of this paper is as follows.

THEOREM 1. STABLE MATRIX IN UNIT INTERVAL FAMILY *and* MARGINALLY STABLE MATRIX IN UNIT INTERVAL FAMILY *are NP-hard.*

Proof. We prove NP-hardness of STABLE MATRIX IN UNIT INTERVAL FAMILY. NP-hardness of MARGINALLY STABLE MATRIX IN UNIT INTERVAL FAMILY can be shown in a similar way; we make a comment on this at the end of the proof.

Since PARTITION is NP-complete, it suffices to show that any instance of PARTITION can be transformed in polynomial time into an equivalent instance of STABLE MATRIX IN UNIT INTERVAL FAMILY.

Let $a_i \in \mathcal{Z}$ $(i = 1, \ldots, l)$ be an instance of PARTITION. We construct a unit interval matrix as follows. Let m be a positive integer such that $l < m = k^2$ for some positive integer k, and define the m-dimensional vector a by $a^T = (a_1, a_2, \ldots, a_l, 0, \ldots, 0) \in \mathcal{Z}^m$ (the superscript ^{T} denotes matrix transposition). Let $\gamma = a^T a$, $\beta = 1 - 1/(2m(1+\gamma))$, and

$$A(x, y) = \begin{pmatrix} -k(I_m + aa^T) & y \\ x^T & k\beta \end{pmatrix}, \tag{1}$$

with I_m the identity matrix of size m and $x, y \in \Re^m$ (note that $\gamma > 0$ and $0 < \beta < 1$).

The set of matrices

$$\mathcal{A} = \{A(x, y) : x, y \in [-1, 1]^m\} \tag{2}$$

forms an instance of STABLE MATRIX IN UNIT INTERVAL FAMILY and is constructed in polynomial time from the initial instance of PARTITION. It remains thus to show that $\mathcal{A}$ contains a stable matrix if and only if there exist $t_i \in \{-1, +1\}$ such that $\sum_{i=1}^{l} a_i t_i = 0$. We prove this in two steps.

Assume first that $t_i \in \{-1, +1\}$ satisfy $\sum_{i=1}^{l} a_i t_i = 0$. Define $x_0^T = (t_1, t_2, \ldots, t_l, 1, \ldots, 1) \in \mathcal{Z}^m$, $y_0 = -x_0$, and note that $a^T x_0 = x_0^T a = 0$. We claim that the matrix $A_0 = A(x_0, y_0) \in \mathcal{A}$ is stable. Indeed, A_0 can be decomposed as

$$A_0 = A_1 + A_2 + A_3 \tag{3}$$

$$= -kI_{m+1} + \begin{pmatrix} -kaa^T & 0 \\ 0 & 0 \end{pmatrix} + \begin{pmatrix} 0 & -x_0 \\ x_0^T & k(1+\beta) \end{pmatrix}. \tag{4}$$

The spectrum of A_0 is the spectrum of $A_2 + A_3$ shifted to the left by k. The matrix A_0 will thus be stable, provided that the real part of every eigenvalue of $A_2 + A_3$ is strictly less than k.

The matrix A_2 has rank one; it has one eigenvalue at $-k\gamma$ and m eigenvalues at the origin. The characteristic polynomial of the matrix A_3 is

$$s^{m-1}(s^2 - k(1+\beta)s + k^2), \tag{5}$$

whose roots are either at the origin or have a real part equal to $k(1+\beta)/2$ which is always strictly less than k, since we have already observed that $0 < \beta < 1$.

Due to the fact that $a^T x_0 = x_0^T a = 0$, we have $A_2 A_3 = A_3 A_2 = 0$. Let λ and w be an eigenvalue and an eigenvector, respectively, of $A_2 + A_3$. Thus, $(A_2 + A_3)w = \lambda w$. Multiplying by A_2, we obtain $A_2^2 w = \lambda A_2 w$. If $A_2 w \neq 0$, then λ is an eigenvalue of A_2. If $A_2 w = 0$, then λ is an eigenvalue of A_3. Consequently, every eigenvalue of $A_2 + A_3$ is either an eigenvalue of A_2 or of A_3. These eigenvalues have a real part which is smaller than k, and by our earlier comment, the matrix $A_0 \in \mathcal{A}$ is stable.

For the reverse implication, assume that $\mathcal{A}$ contains a stable matrix and let $x_0, y_0 \in [-1, 1]^m$ be such that $A_0 = A(x_0, y_0) \in \mathcal{A}$ is stable. Consider then the parametrized family of matrices

$$B(\theta) = A(\theta x_0, \theta y_0)/k. \tag{6}$$

We now study the dependence of the stability of $B(\theta)$ on the variable $\theta \in [0, 1]$. When $\theta = 0$, we have

$$B(0) = \begin{pmatrix} -(I_m + aa^T) & 0 \\ 0 & \beta \end{pmatrix}. \tag{7}$$

The matrix $-(I_m + aa^T)$ is negative definite, hence stable, and thus $B(0)$ has a single unstable eigenvalue (at $\beta > 0$). When $\theta = 1$, we have $B(1) = A_0/k$, and so $B(1)$ is stable since A_0 is.

The eigenvalues of $B(\theta)$ are symmetric with respect to the real axis (complex conjugate), and they vary continuously with θ. When moving from $\theta = 0$ to $\theta = 1$, we move from a configuration where there is exactly one unstable eigenvalue to a configuration with no unstable eigenvalues. When a conjugate pair of eigenvalues crosses the $j\omega$ axis, the number of unstable eigenvalues changes by an even number. Thus, for the number of unstable eigenvalues to change from one to zero, some eigenvalue must cross the $j\omega$ axis at the origin. Therefore, there exists some $\theta_0 \in (0, 1)$ for which $B(\theta_0)$ has an eigenvalue at the origin and $B(\theta_0)$ is singular. Elementary matrix manipulations show that the singularity condition for $B(\theta_0)$ is equivalent to

$$\theta_0^2 x_0^T (I_m + aa^T)^{-1} y_0 = -k^2 \beta. \tag{8}$$

A standard inversion formula [9, p. 19] gives

$$\theta_0^2 x_0^T (I_m - aa^T/(1+\gamma)) z_0 = k^2 \beta, \tag{9}$$

where we have defined $z_0 = -y_0$ and used the definition $\gamma = a^T a$. Remembering that $m = k^2$ and $\theta_0 \in (0,1)$, we finally obtain

$$x_0^T (I_m - aa^T/(1+\gamma)) z_0 > m\beta. \tag{10}$$

The matrix $(I_m - aa^T/(1+\gamma))$ is symmetric and positive definite. Using also the fact that the maximum of a convex function over a bounded polyhedron is attained at an extreme point, we obtain

$$\max_{x,y \in [-1,1]^m} x^T (I_m - aa^T/(1+\gamma)) y = \max_{x \in [-1,1]^m} x^T (I_m - aa^T/(1+\gamma)) x \tag{11}$$

$$= \max_{x \in \{-1,1\}^m} x^T (I_m - aa^T/(1+\gamma)) x \tag{12}$$

$$= m - \min_{x \in \{-1,1\}^m} (x^T a)^2/(1+\gamma). \tag{13}$$

In particular, this shows that

$$m - \min_{x \in \{-1,1\}^m} (x^T a)^2/(1+\gamma) \geq x_0^T (I - aa^T/(1+\gamma)) z_0. \tag{14}$$

Combining inequalities (10) and (14), we obtain

$$m - \min_{x \in \{-1,1\}^m} (x^T a)^2/(1+\gamma) > m\beta. \tag{15}$$

Using the definition of β, we finally arrive at

$$\min_{x \in \{-1,1\}^m} (x^T a)^2 < 1/2. \tag{16}$$

The left-hand side in this inequality is a nonnegative integer; we are thus forced to the conclusion

$$\min_{x \in \{-1,1\}^m} (x^T a)^2 = 0. \tag{17}$$

Assume that the minimum in (17) is obtained for $x^T = (x_1, x_2, \ldots, x_l, \ldots, x_m)$; we conclude the proof by setting $t_i = x_i$ for $i = 1, \ldots, l$.

Let us now briefly comment on the case where we are interested in marginal stability. NP-hardness for this case can be obtained by a small adaptation of the preceding proof. Let, as before, $a_i \in \mathcal{Z}$ $(i = 1, \ldots, l)$ be an instance of PARTITION. We construct an interval matrix as follows. Let m be a positive integer such that $l < m = k^2$ for some positive integer k and define the m-dimensional vector a by $a^T = (a_1, a_2, \ldots, a_l, 0, \ldots, 0) \in \mathcal{Z}^m$ and

$$A(x,y) = \begin{pmatrix} -k(I_m + aa^T) & y \\ x^T & k \end{pmatrix}. \tag{18}$$

The set of matrices $\mathcal{A} = \{A(x,y) : x, y \in [-1,1]^m\}$ forms an instance of MARGINALLY STABLE MATRIX IN UNIT INTERVAL FAMILY and is constructed in polynomial time from the initial instance of PARTITION. Moreover, by the same argument as above, it is clear that $\mathcal{A}$ contains a marginally stable matrix if and only if there exist $t_i \in \{-1, +1\}$ such that $\sum_{i=1}^{l} a_i t_i = 0$. This shows the equivalence between the instances and hence proves the second part of the theorem. ∎

Suppose now that we change the problem by including the additional requirement that the matrix A must be symmetric. Consider the problem of minimizing λ subject to $\lambda I - A$ being a positive semidefinite symmetric matrix and subject to the interval constraints on A. This is a semidefinite programming problem and can be solved, within any desired accuracy ϵ, in time which is polynomial in the size of the problem and the "size" $\log(1/\epsilon)$ of ϵ. Furthermore, the optimal cost in this minimization problem is less than or equal to zero (respectively, negative) if and only if there exists a marginally stable (respectively, stable) matrix A in the family. This argument, brought to our attention by M. Overton [12], comes close but does not quite establish polynomiality of the problem STABLE MATRIX IN UNIT INTERVAL FAMILY for the symmetric case; that would require an exact (as opposed to approximate) polynomial time solution of the semidefinite programming problem. If the symmetric problem is indeed polynomial time solvable, this would be in contrast to the results of Nemirovskii [11], who showed that deciding the stability of all elements of the interval family is NP-hard even if one restricts to symmetric matrices.

As a direct application of our main theorem, we introduce a few matrix and polynomial stability problems and show that they are NP-hard.

STABLE MATRIX IN INTERVAL FAMILY
Instance: A positive integer n, rational numbers $\underline{a}_{ij}, \overline{a}_{ij}$ for $1 \le i, j \le n$.
Question: Does there exist a stable matrix $A = (a_{ij})$ with $\underline{a}_{ij} \le a_{ij} \le \overline{a}_{ij}$?

STABLE MATRIX IN RANK ONE PERTURBED MATRIX
Instance: Positive integers n, k, and $k+1$ real $n \times n$ matrices $A_0, A_1, \ldots, A_k$ with rational entries, all of which have rank one, with the exception of A_0.
Question: Do there exist real values $q_i^* \in [-1, 1]$ such that $A = A_0 + q_1^* A_1 + \cdots + q_k^* A_k$ is stable?

STABLE POLYNOMIAL IN FAMILY OF BILINEAR POLYNOMIALS
Instance: A positive integer r, a multivariable polynomial $p(x, q_1, \ldots, q_r)$ with rational coefficients whose dependence on the real variables q_i is bilinear.
Question: Do there exist real values $q_i^* \in [-1, 1]$ for which the polynomial $p(x, q_1^*, \ldots, q_r^*)$ is stable?

COROLLARY 1. *The above three problems are all NP-hard.*

Proof. STABLE MATRIX IN INTERVAL FAMILY is NP-hard because it is a generalization of STABLE MATRIX IN UNIT INTERVAL FAMILY.

A matrix A in the unit interval family defined by I_1 and a_{ij}^*, $(i, j) \in I_1$, can be written in the form

$$A = A_0 + \sum_{(i,j) \notin I_1} q_{ij} A_{ij},$$

where A_0 has entries

$$\begin{aligned} a_{ij}^0 &= a_{ij}^* \quad \text{if } (i, j) \in I_1, \\ &= 0 \quad \text{if } (i, j) \notin I_1. \end{aligned}$$

A_{ij} is a matrix with all entries equal to zero except for the (i, j)th entry, which is equal to 1, and $q_{ij} \in [-1, 1]$; note that A_{ij} has rank one. This reduces STABLE MATRIX IN UNIT INTERVAL FAMILY to STABLE MATRIX IN RANK ONE PERTURBED MATRIX and shows that the latter problem is NP-hard.

In order to prove that STABLE POLYNOMIAL IN FAMILY OF BILINEAR POLYNOMIALS is NP-hard, we argue as in the proof of Theorem 1. Let $a_i \in \mathcal{Z}$ $(i = 1, \ldots, l)$ be an instance of PARTITION. Let m be a positive integer such that $l < m = k^2$ for some

positive integer k and define $\beta = 1 - 1/(2m(1 + \sum_{i=1}^{l} a_i^2))$ and

$$A(q_1, \ldots, q_k, q_{k+1}, \ldots, q_{2k}) = \begin{pmatrix} -k(I_m + aa^T) & (q_{k+1}, \ldots, q_{2k})^T \\ (q_1, \ldots, q_k) & k\beta \end{pmatrix}.$$

From the proof of Theorem 1, we know that the set of matrices $\mathcal{A} = \{A(q_1, \ldots, q_k, q_{k+1}, \ldots, q_{2k}) : q_i \in [-1, 1]\}$ contains a stable matrix if and only if there exist $t_i \in \{-1, +1\}$ such that $\sum_{i=1}^{l} a_i t_i = 0$. The set of matrices $\mathcal{A}$ contains a stable matrix if and only if the multivariable polynomial $p(x, q_1, \ldots, q_{2k}) = \det(xI_{2k} - A(q_1, \ldots, q_k, q_{k+1}, \ldots, q_{2k}))$ is stable for some choice of $q_i \in [-1, 1]$. The latter polynomial is bilinear in the variables q_i. We therefore have an instance of STABLE POLYNOMIAL IN FAMILY OF BILINEAR POLYNOMIALS which is equivalent to the original instance of PARTITION. □

Remarks.

1. All three problems addressed by Corollary 1 remain NP-hard if "stability" is replaced by "marginal stability"; the proof is similar.

2. By a similar proof, both Theorem 1 and Corollary 1 remain valid if the interval constraints $a_{ij} \in [-1, 1]$ are replaced by the open interval constraints $a_{ij} \in (-1, 1)$.

3. The decision problem for the existential theory of the reals is solvable in $s^{k+1} d^{O(k)}$ arithmetic operations where k denotes the number of variables, s is the number of polynomial (in)equalities, and d is the highest polynomial degree [2]. This shows that for fixed k, a polynomial time algorithm is possible. In particular, STABLE MATRIX IN INTERVAL FAMILY becomes polynomial time solvable if an a priori bound is given on the size of the matrix. The problems discussed in Corollary 1 also become polynomial time solvable when suitably constrained.

3. Application to linear control design problems. As explained in the introduction, our initial motivation for this work was to address the computational complexity of linear control design problems. We now introduce some such problems and show that they are NP-hard.

STATE FEEDBACK STABILIZATION BY BOUNDED CONTROLLER

Instance: A positive integer n, $n \times n$ matrices A and B with rational coefficients, rational numbers $\underline{k}_{ij}, \overline{k}_{ij}$ for $1 \le i, j \le n$.

Question: Does there exist a real matrix $K = (k_{ij})$ satisfying $\underline{k}_{ij} \le k_{ij} \le \overline{k}_{ij}$ and such that $A + BK$ is stable?

SIMULTANEOUS STABILIZATION BY OUTPUT FEEDBACK

Instance: Positive integers n, m, p, k, a collection of k triplets of matrices (A_i, B_i, C_i) with rational coefficients of respective sizes $n \times n, n \times m, p \times n$.

Question: Does there exist a real $m \times p$ matrix K such that $A_i + B_i K C_i$ is stable for all $i = 1, \ldots, k$?

DECENTRALIZED OUTPUT FEEDBACK STABILIZATION BY NORM BOUNDED CONTROLLER

Instance: Positive integers n and k with $n \ge k$, $n \times n$ matrices A, B and C with rational coefficients. A partition of n into k positive integers $n = n_1 + n_2 + \cdots + n_k$.

Question: Does there exist a $n \times n$ block-diagonal matrix K with blocks K_i of successive sizes $n_i \times n_i$ and $||K_i|| < 1$ such that $A + BKC$ is stable?

DECENTRALIZED STABILIZATION WITH IDENTICAL CONTROLLERS

Instance: Positive integers n_1, n_2, three $(n_1 n_2) \times (n_1 n_2)$ matrices A, B and C with rational coefficients.

Question: Does there exist a $n_1 \times n_1$ matrix M such that the $(n_1 n_2 \times n_1 n_2)$ block diagonal matrix K constructed with n_2 identical blocks M is such that $A + BKC$ is stable?

COROLLARY 2. *The above four problems are all NP-hard.*

Proof. (a) STATE FEEDBACK STABILIZATION BY BOUNDED CONTROLLER: Let n and $\underline{a}_{ij}$, $\overline{a}_{ij}$, for $1 \leq i, j \leq n$ be an instance of STABLE MATRIX IN INTERVAL FAMILY. An equivalent instance of STATE FEEDBACK STABILIZATION BY BOUNDED CONTROLLER is given by n, $A = 0$, $B = I_n$, $\underline{k}_{ij} = \underline{a}_{ij}$, and $\overline{k}_{ij} = \overline{a}_{ij}$ for $1 \leq i, j \leq n$.

(b) SIMULTANEOUS STABILIZATION BY OUTPUT FEEDBACK:

We prove NP-hardness for the case of marginal stability. Let n and $\underline{a}_{kl}, \overline{a}_{kl}$ $(1 \leq i, j \leq n)$ be an instance of STABLE MATRIX IN INTERVAL FAMILY. Define the $n \times n$ matrices A_{ij}^+, A_{ij}^-, B_i, and C_j by

$A_{ij}^+ = (a_{kl})$ with

$$a_{kl} = -\overline{a}_{ij} \text{ if } (k,l) = (1,1),$$
$$= 0 \text{ otherwise;}$$

$A_{ij}^- = (a_{kl})$ with

$$a_{kl} = \underline{a}_{ij} \text{ if } (k,l) = (1,1),$$
$$= 0 \text{ otherwise;}$$

$B_i = (b_{kl})$ with

$$b_{kl} = 1 \text{ if } (k,l) = (1,i),$$
$$= 0 \text{ otherwise;}$$

and $C_j = (c_{kl})$ with

$$c_{kl} = 1 \text{ if } (k,l) = (j,1),$$
$$= 0 \text{ otherwise.}$$

It is immediate to see that $(A_{ij}^+ + B_i K C_j)$ is marginally stable if and only if $k_{ij} \leq \overline{a}_{ij}$, and similarly, $(A_{ij}^- + B_i K C_j)$ is marginally stable if and only if $k_{ij} \geq \underline{a}_{ij}$. Thus, if we require the simultaneous stabilization of the $2n^2 + 1$ triplets $(0, I, I), (A_{ij}^+, B_i, C_j)$, and (A_{ij}^-, B_i, C_j) for $1 \leq i, j \leq n$, we have constructed an equivalent instance of SIMULTANEOUS STABILIZATION BY OUTPUT FEEDBACK.

(c) DECENTRALIZED OUTPUT FEEDBACK STABILIZATION BY NORM BOUNDED CONTROLLER: We prove that the problem is NP-hard even for the special case where all blocks are of size 1×1, in which case $A + BKC$ can be written as $A + \sum_{i=1}^n k_i b_i c_i^T$, where b_i is the ith column of B, c_i^T is the ith row of C, and k_i is the ith diagonal entry of K. Given that an arbitrary rank one matrix can be expressed in the form bc^T for some vectors b and c, it follows that every instance of STABLE MATRIX IN RANK ONE PERTURBED MATRIX can be expressed as an instance of DECENTRALIZED OUTPUT FEEDBACK STABILIZATION BY NORM BOUNDED CONTROLLER

(d) DECENTRALIZED STABILIZATION WITH IDENTICAL CONTROLLERS: We prove NP-hardness for the case of marginal stability. Consider k triplets of $n \times n$ matrices (A_i, B_i, C_i) that form an instance of SIMULTANEOUS STABILIZATION BY OUTPUT FEEDBACK. We define an equivalent instance of DECENTRALIZED STABILIZATION WITH IDENTICAL CONTROLLERS by letting $n_1 = n, n_2 = k, A = A_1 \oplus A_2 \oplus \cdots \oplus A_k, B = B_1 \oplus B_2 \oplus \cdots \oplus B_k$ and $C = C_1 \oplus C_2 \oplus \cdots \oplus C_k$, where $\oplus$ denotes direct sum of matrices. ∎

Remarks.

1. For some of the problems, we provided the proof for the case of stability; for others, we dealt with marginal stability. With little work and using the remarks at the end of the preceding section, it is easily shown that all problems are NP-hard for the case of either stability or marginal stability.

2. STATE FEEDBACK STABILIZATION BY BOUNDED CONTROLLER is easily shown to remain NP-hard even if the bounds $\underline{k}_{ij}, \overline{k}_{ij}$ are constrained to be either 0 or 1. We have assumed that we are dealing with square systems; the more general case of rectangular systems is at least as hard and is therefore also NP-hard. Finally, the problem of *output* feedback stabilization by a bounded controller is at least as hard as that of *state* feedback and is thus also NP-hard.

3. Our proof shows that SIMULTANEOUS STABILIZATION BY OUTPUT FEEDBACK remains NP-hard even if all the matrices involved are of the same size ($n = m = p$). The degenerate case $m = p = 1$ corresponds to simultaneous stabilization of single-input, single-output systems by proportional feedback and can be solved in polynomial time. (An argument for this follows from footnote 1 on p. 54 of [1].) For a priori fixed n, m, and p, the problem can also be solved in polynomial time (see Remark 3 in section 2). We do not know whether the state feedback formulation of this problem is NP-hard.

ON APPROXIMATE SOLUTIONS IN CONVEX VECTOR OPTIMIZATION*

SIEN DENG†

Abstract. Necessary and sufficient conditions are obtained for the existence of ϵ-weak minima for constrained convex vector optimization problems. The characterization of ϵ-weak minima is given in terms of ϵ-optimal solutions of the associated scalar optimization problems and ϵ-directional derivatives of objective functions. The Lipschitzian continuity of ϵ-weak minima is proved under mild conditions.

Key words. convex vector optimization, ϵ-weak minima, ϵ-directional derivatives, error bounds, Lipschitzian stability

1. Introduction.

Consider the following convex vector optimization problem:

$$(\mathcal{P}) \qquad \begin{aligned} &\text{minimize} \quad F(x) \\ &\text{subject to} \quad x \in C, \end{aligned}$$

where $F(x) = (f_1(x), \ldots, f_m(x))^T : \mathbb{R}^n \to \mathbb{R}^m$, each component f_i of F is a finite convex function on $\mathbb{R}^n$, and $C \subset \mathbb{R}^n$ is a nonempty closed convex set.

Much has been said about the existence and stability of solutions of problem $(\mathcal{P})$ [1, 2, 3, 18].

The main theme of this paper is to study approximate solutions of problem $(\mathcal{P})$. Various concepts of approximate solutions were introduced in [4]. In this paper we focus on the existence, the characterization, and the Lipschitzian stability of ϵ-weak minima of problem $(\mathcal{P})$. In section 2, we provide necessary and sufficient conditions for the existence of ϵ-weak minima of problem $(\mathcal{P})$, and characterize ϵ-weak minima of problem $(\mathcal{P})$ in terms of ϵ-optimal solutions of the associated scalar optimization problems. In section 3, we consider a family of parametrized convex vector optimization problems and investigate the behavior of ϵ-weak minima with respect to perturbations on the problem data. Using the results in section 2 and an error bound result of Robinson for convex inequality systems, we obtain the main result of this paper: the Lipschitzian continuity of ϵ-weak minima, which generalizes a similar result in scalar optimization.

We will use the following notation throughout this paper. All vectors are column vectors. The superscript T denotes the transpose of vectors. The vector inequalities $\leq$ or $<$ are assumed to hold pointwise. We denote by $[1, k]$ the set $\{1, 2, \ldots, k\}$. We denote by $\mathbb{B}(x, \rho)$ the closed Euclidean ball in $\mathbb{R}^n$ of radius ρ around a point x. We denote by $\|\cdot\|$ and $\|\cdot\|_\infty$ the Euclidean norms on $\mathbb{R}^n$, $\mathbb{R}^m$, and $\mathbb{R}^l$ and the ∞-norms on $\mathbb{R}^n$, $\mathbb{R}^m$, and $\mathbb{R}^l$, respectively. For a vector x and a nonempty closed set U in some Euclidean space, we denote by $d(x, U) = \min\{\|x - y\| \mid y \in U\}$ the Euclidean distance from any x to U. Given nonempty closed sets U_1 and U_2 in some Euclidean space,

†Department of Mathematical Sciences, Northern Illinois University, DeKalb, IL 60115 (deng@math.niu.edu).

we define the Hausdorff distance between them as

$$\operatorname{haus}(U_1, U_2) = \max\left\{\sup_{x\in U_1} d(x, U_2), \sup_{x\in U_2} d(x, U_1)\right\}.$$

We denote by S^m the unit-simplex of $\mathbb{R}^m$; that is,

$$S^m = \left\{\mu \in \mathbb{R}^m \mid \mu_i \geq 0, i \in [1, m], \sum_{i=1}^{m} \mu_i = 1\right\}.$$

For a proper lower semicontinuous (l.s.c.) function ϕ on $\mathbb{R}^n$, its *effective* domain is the set

$$\operatorname{dom} \phi = \{x \in \mathbb{R}^n \mid \phi(x) < +\infty\}.$$

For a proper l.s.c. convex function ϕ, we denote by ϕ^* the convex conjugate function of ϕ. Given $\epsilon \geq 0$, for a proper l.s.c. convex function ϕ, and $x \in \operatorname{dom} \phi$, we define the ϵ-subdifferential of ϕ at x as

$$\partial_\epsilon \phi(x) = \left\{y \in \mathbb{R}^n \mid \phi(z) \geq \phi(x) + y^T(z - x) - \epsilon \quad \text{for all } z \in \mathbb{R}^n\right\}. \tag{1}$$

When $\epsilon = 0$, $\partial_0 \phi(x) = \partial\phi(x)$, the usual subdifferential of ϕ at x. Given $\epsilon \geq 0$, for a finite convex function ϕ on $\mathbb{R}^n$, we define its ϵ-directional derivative at x in the direction d as

$$\phi'_\epsilon(x; d) = \inf_t \{(\phi(x + td) - \phi(x) + \epsilon)/t \mid t > 0\}. \tag{2}$$

When $\epsilon = 0$, $\phi'_0 = \phi'$, the usual directional derivative of ϕ. For more about ϵ-subdifferentials, ϵ-directional derivatives, and their applications in scalar optimization, see [5, 6].

2. ϵ-weak minima. We first introduce the definition of ϵ-weak minima of problem $(\mathcal{P})$ and then study basic properties of ϵ-weak minima.

Let $W = \mathbb{R}^m \backslash (-\operatorname{int} \mathbb{R}^m_+)$, where int denotes interior. A vector $y \in C$ is a weak minimum of problem $(\mathcal{P})$ if and only if

$$F(x) - F(y) \in W \quad \text{for all } x \in C.$$

We denote by E the set of all weak minima of problem $(\mathcal{P})$. For various characterizations of the nonemptiness and compactness of E, see [13].

Let $\epsilon \geq 0$, and let $\mathbf{1} \in \mathbb{R}^m$ be the vector all of whose coordinates are 1. A vector $y \in C$ is an ϵ-weak minimum of problem $(\mathcal{P})$ if and only if

$$F(x) + \epsilon\mathbf{1} - F(y) \in W \quad \text{for all } x \in C.$$

We denote by E_ϵ the set of all ϵ-weak minima of problem $(\mathcal{P})$. Note that $E_0 = E$.

PROPOSITION 1. *Consider problem $(\mathcal{P})$. The following statements hold.*

(a) *E_ϵ is a closed set for $\epsilon \geq 0$.*

(b) *Let $\epsilon_k \downarrow 0$. Suppose that $\{x(\epsilon_k)\}$ is a sequence such that $x(\epsilon_k) \in E_{\epsilon_k}$. Then any cluster point of $\{x(\epsilon_k)\}$ is a weak minimum of problem $(\mathcal{P})$.*

Proof. (a) The result is trivially true when E_ϵ is empty. Suppose that $\{x^k\} \subset E_\epsilon$ and $x^k \to y$. Then $y \in C$ by the closedness of C, and

$$F(x) + \epsilon\mathbf{1} - F(x^k) \in W \quad \text{for all } x \in C.$$

The vector $y \in E_\epsilon$ follows from the continuity of F and the closedness of W.

(b) Since $x(\epsilon_k) \in E_{\epsilon_k}$, $F(x) + \epsilon_k \mathbf{1} - F(x(\epsilon_k)) \in W$ for all $x \in C$. Without loss of generality, suppose that $x(\epsilon_k) \to z$. Then, it follows from the closedness of C that z is in C. Since $\epsilon_k \downarrow 0$, by the continuity of F and the closedness of W, we have

$$F(x) - F(z) \in W \quad \text{for all } x \in C.$$

This is what we wanted to prove. □

For $\mu \in S^m$, and $\epsilon \geq 0$, we define the ϵ-optimal solution set of minimizing $\mu^T F(x)$ over all $x \in C$ as

$$\epsilon\text{-argmin}_x \left\{\mu^T F(x) \mid x \in C\right\} = \left\{y \in C \mid \mu^T F(y) \leq \inf_x \left\{\mu^T F(x) \mid x \in C\right\} + \epsilon\right\}.$$

Given below is the first main result of this section, which characterizes the set E_ϵ in terms of ϵ-optimal solutions of scalar optimization problems.

THEOREM 2.1. *Consider problem* $(\mathcal{P})$. *Let* $\epsilon \geq 0$. *A vector* $y \in E_\epsilon$ *if and only if there is some* $\mu \in S^m$ *such that* $y \in \epsilon\text{-argmin}_x \left\{\mu^T F(x) \mid x \in C\right\}$.

Proof. (Necessity) Let $y \in E_\epsilon$. Then $F(x) + \epsilon\mathbf{1} - F(y) \in W$ for all $x \in C$. It follows that

$$\left(F(C) + \mathbb{R}^m_+ + \epsilon\mathbf{1} - F(y)\right) \cap \left(-\text{int } \mathbb{R}^m_+\right) = \emptyset.$$

Since $\left(F(C) + \mathbb{R}^m_+ + \epsilon\mathbf{1} - F(y)\right)$ and $\left(-\text{int } \mathbb{R}^m_+\right)$ are two nonempty disjoint convex sets, by the separation theorem (see Theorem 11.3 of [5]), there is some nonzero $\mu \in \mathbb{R}^m$ such that

$$\mu^T(-d') \leq 0 \quad \text{for all } d' \in \text{int } \mathbb{R}^m_+, \text{ and} \tag{3}$$

$$\mu^T(F(x) + d + \epsilon\mathbf{1} - F(y)) \geq 0 \quad \text{for all } x \in C \text{ and for all } d \in \mathbb{R}^m_+. \tag{4}$$

It follows from (3) that $\mu \in \mathbb{R}^m_+$. Normalizing μ if necessary, we can assume that $\mu \in S^m$. Thus by (4), $\mu^T F(x) \geq \mu^T F(y) - \epsilon$ for all $x \in C$. Therefore, $\inf_x \left\{\mu^T F(x) \mid x \in C\right\}$ is finite and $y \in \epsilon\text{-argmin}_x \left\{\mu^T F(x) \mid x \in C\right\}$.

(Sufficiency) Suppose that $y \in \epsilon\text{-argmin}_x \left\{\mu^T F(x) \mid x \in C\right\}$ for some $\mu \in S^m$, but $y \notin E_\epsilon$. Then there is a vector $z \in C$ such that $F(z) + \epsilon\mathbf{1} - F(y) \in -\text{int } \mathbb{R}^m_+$. Consequently, $\mu^T(F(z) + \epsilon\mathbf{1} - F(y)) < 0$, which implies that $y \notin \epsilon\text{-argmin}_x \left\{\mu^T F(x) \mid x \in C\right\}$. The contradiction completes the proof. □

To obtain necessary and sufficient conditions for the existence of ϵ-weak minima of problem $(\mathcal{P})$, we quote Theorem 1.1.2 and Proposition 1.2.1 in Chapter XI of [6] as the following proposition.

PROPOSITION 2. *Let* ϕ *be a proper l.s.c. convex function. Then the following statements hold.*

(a) *For all* $x \in \text{dom } \phi$, $\partial_\epsilon \phi(x) \neq \emptyset$ *whenever* $\epsilon > 0$.

(b) *For all* $x \in \text{dom } \phi$, *and* $\epsilon \geq 0$, *a vector* $y \in \partial_\epsilon \phi(x)$ *if and only if* $x \in \partial_\epsilon \phi^*(y)$.

THEOREM 2.2. *Consider problem* $(\mathcal{P})$. *For* $\epsilon > 0$, E_ϵ *is nonempty if and only if there is some* $\bar{\mu} \in S^m$ *such that* $\inf_x \left\{\bar{\mu}^T F(x) \mid x \in C\right\}$ *is finite.*

Proof. (Necessity) Since E_ϵ is nonempty, there is a y in E_ϵ. By Theorem 2.1, there is some $\bar{\mu} \in S^m$ such that $y \in \epsilon\text{-argmin}_x \left\{\bar{\mu}^T F(x) \mid x \in C\right\}$. It follows that $\inf_x \left\{\bar{\mu}^T F(x) \mid x \in C\right\}$ is finite.

(Sufficiency) Suppose that there is some $\bar{\mu} \in S^m$ such that $\inf_x \left\{\bar{\mu}^T F(x) \mid x \in C\right\}$ is finite. Let $\psi(x) = \bar{\mu}^T F(x) + \delta_C(x)$, where $\delta_C(\cdot)$ is the indicator function of C. Then ψ is a proper l.s.c. convex function and $\{x \mid 0 \in \partial_\epsilon \psi(x)\} = \epsilon\text{-argmin}_x \left\{\bar{\mu}^T F(x) \mid x \in C\right\}$

(see (1)). Furthermore, for $\epsilon > 0$, by Theorem 2.1, ϵ-$\operatorname{argmin}_x \{\bar{\mu}^T F(x) \mid x \in C\} \subset E_\epsilon$. By Proposition 2, $\{x \mid 0 \in \partial_\epsilon \psi(x)\} = \partial_\epsilon \psi^*(0)$, and $\partial_\epsilon \psi^*(0)$ is nonempty whenever $0 \in \operatorname{dom} \psi^*$. Thus we only have to show that $0 \in \operatorname{dom} \psi^*$. This is true because

$$\begin{aligned}\psi^*(0) &= \sup_x \{0^T x - \psi(x) \mid x \in \mathbb{R}^n\} = \sup_x \{-\bar{\mu}^T F(x) \mid x \in C\} \\ &= -\inf_x \{\bar{\mu}^T F(x) \mid x \in C\} < +\infty.\end{aligned}$$

This completes the proof of the desired result. □

We denote by $(f_i)'_\epsilon(x; d)$ the ϵ-directional derivative of f_i at x in the direction d, where f_i is the ith component of F. The next theorem uses ϵ-directional derivatives of f_i to describe the set E_ϵ.

THEOREM 2.3. *Consider problem* $(\mathcal{P})$. *Let* $\epsilon \geq 0$. *If*

$$((f_1)'_\epsilon(y; x-y), \ldots, (f_m)'_\epsilon(y; x-y))^T \in W \quad \text{for all } x \in C, \tag{5}$$

then $y \in E_\epsilon$. *When* $\epsilon = 0$, *the converse is also true; that is, if* $y \in E$, *then* (5) *holds with* $\epsilon = 0$.

Proof. For $\epsilon \geq 0$, by the definition of ϵ-directional derivative of a convex function (see (2)), we have

$$(F(x) + \epsilon \mathbf{1} - F(y)) - ((f_1)'_\epsilon(y; x-y), \ldots, (f_m)'_\epsilon(y; x-y))^T \in \mathbb{R}^m_+ \quad \text{for all } x \in C.$$

Since $((f_1)'_\epsilon(y; x-y), \ldots, (f_m)'_\epsilon(y; x-y))^T \in W$ for all $x \in C$, it follows that

$$F(x) + \epsilon \mathbf{1} - F(y) \in \mathbb{R}^m_+ + W \subset W \quad \text{for all } x \in C.$$

This proves the first part of the theorem.

When $\epsilon = 0$, by Theorem 23.1 of [5], $(f_i)'_0(y; d) = \lim_{t \downarrow 0} \{(f_i(y + td) - f_i(y))/t\}$ for all $i \in [1, m]$. Suppose that $y \in E$. For any $x \in C$, let $0 < \alpha < 1$. Then $y + \alpha(x - y) \in C$ by the convexity of C. Consequently, we have

$$(F(y + \alpha(x-y)) - F(y))/\alpha \in W \quad \text{for all } \alpha \in (0, 1).$$

The result thus follows from the fact that W is closed and each component f_i of F has one-sided directional derivatives. □

Remark 2.1. When $\epsilon = 0$, Theorem 2.3 is an extension of Theorem 2.1 of [1], where each f_i is differentiable.

3. Lipschitzian stability of ϵ-weak minima. We consider a family of parametrized convex vector optimization problems,

$$(\mathcal{P}(u)) \qquad \begin{aligned} &\text{minimize} \quad F(x) \\ &\text{subject to} \quad G(x) \leq u, \end{aligned}$$

where F is the same as in problem $(\mathcal{P})$, $u \in \mathbb{R}^l$, and $G(x) = (g_1(x), \ldots, g_l(x))^T$ with each component g_i of G being a finite convex function on $\mathbb{R}^n$. For $\epsilon \geq 0$, we denote by $E_\epsilon(u)$ all ϵ-weak minima of problem $(\mathcal{P}(u))$. In this section, our focus is on Lipschitzian stability of the multifunction $E_\epsilon : \mathbb{R}^l \rightrightarrows \mathbb{R}^n$. Recall [7] that a multifunction $\Gamma : \mathbb{R}^l \rightrightarrows \mathbb{R}^n$ is Lipschitzian relative to V, a subset of $\mathbb{R}^l$, if $\Gamma(v)$ is nonempty and compact for every $v \in V$, and there is a positive scalar λ such that

$$\operatorname{haus}(\Gamma(v'), \Gamma(v'')) \leq \lambda \|v' - v''\| \quad \text{for all } v', v'' \in V.$$

We denote by $C(u)$ the solution set of the convex system $G(x) \leq u$, which is a closed convex set. We make the following assumption regarding the convex inequality system $G(x) \leq 0$ throughout this section.

Assumption 3.1. For the convex inequality system $G(x) \leq 0$, suppose that there are some $x^*, \hat{x} \in \mathbb{R}^n$, and some positive scalars δ, Δ such that $\max_{1\leq i\leq l}\{g_i(x^*)\} \leq -2\delta$ (the Slater condition) and $C(0) \subset \mathbb{B}(\hat{x}, \Delta/2)$ (the boundedness condition).

Assumption 3.1 amounts to ensuring that the multifunction $C(\cdot)$ is Lipschitzian near 0. To derive the Lipschitzian continuity of E_ϵ near 0, we need the following form of Robinson's result on error bounds for convex inequality systems (see [8]). For related error bound results, see [12, 15, 16, 17].

PROPOSITION 3. *Consider an inequality system $H(x) \leq 0$, where $H(x) = (h_1(x), \ldots, h_k(x))^T$ and each component h_i of H is a finite convex function on $\mathbb{R}^n$. Let $S = \{x \mid H(x) \leq 0\}$. Suppose that there are some $z^*, \hat{z}$ of $\mathbb{R}^n$, and some positive scalars θ, Θ such that $\max_{1\leq i\leq k}\{h_i(z^*)\} \leq -\theta$ and $S \subset \mathbb{B}(\hat{z}, \Theta/2)$. Then*

$$d(z, S) \leq \theta^{-1}\Theta\|[H(z)]_+\| \quad \text{for all } z \in \mathbb{R}^n,$$

where $[\cdot]_+$ is the positive part of a vector.

Consider problem $(\mathcal{P}(u))$. For $\mu \in \mathbb{R}^m$, $u \in \mathbb{R}^l$, and $\epsilon \geq 0$, define

$$\begin{aligned} p(\mu, u) &= \inf_x \left\{\mu^T F(x) \mid x \in C(u)\right\}, \\ P(\mu, u) &= \operatorname{argmin}_x \left\{\mu^T F(x) \mid x \in C(u)\right\}, \\ P_\epsilon(\mu, u) &= \left\{x \in C(u) \mid \mu^T F(x) \leq p(\mu, u) + \epsilon\right\}. \end{aligned}$$

For $\epsilon > 0$ and $u \in \mathbb{R}^l$, $E_\epsilon(u) = \cup_{\mu\in S^m} P_\epsilon(\mu, u)$ by Theorem 2.1. We will prove that E_ϵ is Lipschitzian near 0 by showing that $P_\epsilon(\mu, \cdot)$ is Lipschitzian near 0 with a uniform Lipschitzian modulus for all $\mu \in S^m$. For this purpose, we need three lemmas.

LEMMA 3.1. *Suppose that Assumption* 3.1 *holds. Let $\mathcal{N}_1 = \{u \in \mathbb{R}^l \mid \|u\| \leq \delta\}$. Then for every $u \in \mathcal{N}_1$, the Slater condition holds for system $G(x) \leq u$, and $C(u) \subset \mathbb{B}(\hat{x}, \Delta)$. In particular, for $u \in \mathcal{N}_1$ and $\epsilon \geq 0$, $E_\epsilon(u)$ is nonempty, and $E_\epsilon(u) \subset \mathbb{B}(\hat{x}, \Delta)$.*

Proof. We first show that for every $u \in \mathcal{N}_1$, the Slater condition holds for the convex inequality system $G(x) \leq u$. Indeed, since $\|u\| \leq \delta$, $\max_{1\leq i\leq l}\{|u_i|\} \leq \delta$. Thus $g_i(x^*) - u_i \leq -\delta$ for $i \in [1, l]$. By applying Proposition 3 to the convex inequality system $G(x) \leq 0$, which has $C(0)$ as the solution set, we have, for any $z \in C(u)$,

$$\begin{aligned} d(z, C(0)) &\leq 1/2\delta^{-1}\Delta\|[G(z)]_+\| \\ &\leq 1/2\delta^{-1}\Delta\|u\| \leq 1/2\Delta. \end{aligned}$$

A straightforward calculation shows that $C(u) \subset \mathbb{B}(\hat{x}, \Delta)$ whenever $u \in \mathcal{N}_1$. This completes the first part of the proof. For $u \in \mathcal{N}_1$ and $\mu \in S^m$, since $C(u)$ is nonempty and compact, $P_\epsilon(\mu, u)$ is nonempty and $P_\epsilon(\mu, u) \subset C(u)$. It follows that $E_\epsilon(u)$ is nonempty, and $E_\epsilon(u) \subset C(u) \subset \mathbb{B}(\hat{x}, \Delta)$. □

For $u \in \mathcal{N}_1$, by the nonemptiness and the compactness of $C(u)$, $p(\mu, u)$ is finite for every $\mu \in S^m$. In view of Lemma 3.1, and by invoking Theorem 3.1 of [7], we obtain the following lemma about the Lipschitzian continuity of the optimal value function p. The proof is given in the appendix.

LEMMA 3.2. *Suppose that Assumption* 3.1 *holds and that $\mathcal{N}_1$ is the same as in Lemma* 3.1. *Then for any $(\mu, u) \in S^m \times \mathcal{N}_1$, the function p is finite and locally Lipschitzian relative to some neighborhood $V(\subset \mathbb{R}^m \times \mathbb{R}^l)$ of (μ, u).*

Thanks to the convexity and compactness of $S^m \times \mathcal{N}_1$, it follows from Lemma 3.2 that p is Lipschitzian on $S^m \times \mathcal{N}_1$; that is, there is a constant $L > 0$, which is independent of (μ, u) in $S^m \times \mathcal{N}_1$, such that

$$|p(\mu,u) - p(\mu',u')| \le L(\|\mu - \mu'\| + \|u - u'\|) \quad \text{for all } (\mu,u),(\mu',u') \in S^m \times \mathcal{N}_1. \tag{6}$$

Also, by the compactness of $S^m \times \mathcal{N}_1$, there is some positive scalar M_1 such that

$$\sup_{(\mu,u)\in S^m\times\mathcal{N}_1} |\mu^T F(x^*) - p(\mu,u)| \le M_1, \tag{7}$$

where x^* is given by Assumption 3.1.

The following lemma, which plays the crucial role for deriving the Lipschitzian continuity of E_ϵ, establishes a "uniform" Slater condition on $P_\epsilon(\mu,u)$.

LEMMA 3.3. *Suppose that Assumption* 3.1 *holds and that* ϵ *is given with* $0 < \epsilon < 2M_1$, *where* M_1 *is given by* (7). *Let* $\mathcal{N}(\epsilon) = \mathcal{N}_1 \cap \mathcal{N}_2$, *where* $\mathcal{N}_2 = \left\{u \in \mathbb{R}^l \mid \|u\|_\infty \le (\epsilon\delta)/(2M_1)\right\}$ *and* $\mathcal{N}_1$ *is the same as in Lemma* 3.1. *Then for any* $(\mu,u) \in S^m \times \mathcal{N}(\epsilon)$, *there is a* $y(\mu,u) \in P_\epsilon(\mu,u)$ *such that*

$$\mu^T F(y(\mu,u)) - p(\mu,u) - \epsilon \le -\tilde{\delta}(\epsilon),\ g_1(y(\mu,u)) - u_1 \le -\tilde{\delta}(\epsilon), \ldots, g_l(y(\mu,u)) - u_l \le -\tilde{\delta}(\epsilon),$$

where $\tilde{\delta}(\epsilon) = \min\{(\epsilon\delta)/(2M_1), \epsilon/2\}$.

Proof. Suppose that ϵ is given with $0 < \epsilon < 2M_1$. For $\mu \in S^m$ and $u \in \mathcal{N}(\epsilon)$, $P(\mu,u)$ is nonempty since $C(u)$ is nonempty and compact. Choose a vector $x(\mu,u) \in P(\mu,u)$, and let x^* be given by Assumption 3.1. Let $0 < \alpha < 1$. Then $\alpha x(\mu,u) + (1-\alpha)x^* \in C(u)$. By the convexity of g_i and $\mu^T F$, we have, for $i \in [1,l]$,

$$\begin{aligned} g_i(\alpha x(\mu,u) + (1-\alpha)x^*) - u_i &\le \alpha g_i(x(\mu,u)) + (1-\alpha)g_i(x^*) - u_i \\ &\le \alpha\left(g_i(x(\mu,u)) - u_i\right) + (1-\alpha)\left(g_i(x^*) - u_i\right) \\ &\le (1-\alpha)(-2\delta + \delta) = (1-\alpha)(-\delta) \end{aligned} \tag{8}$$

and

$$\begin{aligned} \mu^T F(\alpha x(\mu,u) + (1-\alpha)x^*) - p(\mu,u) - \epsilon &\le \alpha\mu^T F(x(\mu,u)) + (1-\alpha)\mu^T F(x^*) \\ &\quad - p(\mu,u) - \epsilon \\ &= (1-\alpha)\left(\mu^T F(x^*) - p(\mu,u)\right) - \epsilon \\ &\le (1-\alpha)M_1 - \epsilon \qquad \text{(by (7))}. \end{aligned} \tag{9}$$

Letting $\alpha = 1 - \epsilon/(2M_1)$ and $y(\mu,u) = (1-\epsilon/(2M_1))\,x(\mu,u) + (\epsilon/(2M_1))\,x^*$, we have, in view of (8) and (9),

$$\begin{gathered} g_i(y(\mu,u)) - u_i \le (1-\alpha)(-\delta) = -(\epsilon\delta)/(2M_1) \le -\tilde{\delta}(\epsilon) \quad \text{for } i \in [1,l], \text{ and} \\ \mu^T F(y(\mu,u)) - p(\mu,u) - \epsilon \le (1-\alpha)M_1 - \epsilon \le -\epsilon/2 \le -\tilde{\delta}(\epsilon). \end{gathered}$$

This completes the proof. ∎

We observe that the positive scalar $\tilde{\delta}(\epsilon)$ in Lemma 3.3 is independent of μ. This enables us to obtain the main result of this paper.

THEOREM 3.4. *Suppose that Assumption* 3.1 *holds and that* ϵ *is given with* $0 < \epsilon < 2M_1$, *where* M_1 *is given by* (7). *Let* $\mathcal{N}(\epsilon)$ *be the same as in Lemma* 3.3 *according to the given* ϵ. *Then the multifunction* $E_\epsilon(\cdot)$ *is Lipschitzian relative to* $\mathcal{N}(\epsilon)$, *a closed*

neighborhood of 0, *with the Lipschitzian modulus* $M = 2(\tilde{\delta}(\epsilon))^{-1}\Delta\sqrt{L^2+1}$, *where* $\tilde{\delta}(\epsilon)$ *is the same as in Lemma* 3.3 *and* L *is given by* (6). *That is,*

$$\text{haus}(E_\epsilon(u), E_\epsilon(v)) \le M\|u-v\| \quad \textit{for all } u, v \in \mathcal{N}(\epsilon).$$

Proof. Throughout the proof, suppose that ϵ is given with $0 < \epsilon < 2M_1$. For $u \in \mathcal{N}(\epsilon)$, $\mu \in S^m$, $\mathcal{P}_\epsilon(\mu, u)$ is nonempty since $C(u)$ is nonempty and compact. By Theorem 2.1, $E_\epsilon(u) = \cup_{\mu\in S^m} P_\epsilon(\mu, u)$ for every $u \in \mathcal{N}(\epsilon)$. The result follows if we can show that, for every $\mu \in S^m$,

$$\text{haus}(P_\epsilon(\mu, v), P_\epsilon(\mu, u)) \le M\|u-v\| \quad \text{for all } u, v \in \mathcal{N}(\epsilon).$$

Indeed, for given $u, v \in \mathcal{N}(\epsilon)$, let $z \in P_\epsilon(\mu, v)$. Applying Proposition 3 along with Lemmas 3.1 and 3.3 to the convex inequality system $\mu^T F(x) \le p(\mu, u) + \epsilon,\ g_1(x) \le u_1, \ldots, g_l(x) \le u_l$, which has $P_\epsilon(\mu, u)$ as the solution set, we obtain an upper bound for $d(z, P_\epsilon(\mu, u))$.

$$\begin{aligned}
d(z, P_\epsilon(\mu, u)) &\le 2(\tilde{\delta}(\epsilon))^{-1}\Delta \left\| \left[\left(\mu^T F(z) - p(\mu, u) - \epsilon, g_1(z) - u_1, \ldots, g_l(z) - u_l\right)^T \right]_+ \right\| \\
&\le 2(\tilde{\delta}(\epsilon))^{-1}\Delta \left\| \left[\left(p(\mu, v) - p(\mu, u), v_1 - u_1, \ldots, v_l - u_l\right)^T \right]_+ \right\| \\
&\le 2(\tilde{\delta}(\epsilon))^{-1}\Delta \left\| \left[\left(L\|u-v\|, v_1 - u_1, \ldots, v_l - u_l\right)^T \right]_+ \right\| \qquad \text{(by (6))} \\
&\le 2(\tilde{\delta}(\epsilon))^{-1}\Delta\sqrt{L^2+1}\|u-v\|.
\end{aligned}$$

Thus $\sup_{z\in P_\epsilon(\mu,v)} d(z, P_\epsilon(\mu, u)) \le M\|u-v\|$. Since u, v are any two vectors in $\mathcal{N}(\epsilon)$, we establish the theorem. □

Remark 3.1. A similar result in scalar optimization can be found in [9] and [14]. The difficulties in convex vector optimization are to show that the constant M is independent of μ, which is trivial in the scalar optimization case.

4. Appendix. For a multifunction $\Gamma : \mathbb{R}^d \rightrightarrows \mathbb{R}^n$, we shall use the notation

$$\Gamma(V) = \cup_{v\in V}\Gamma(v) \quad \text{for any } V \subset \mathbb{R}^d.$$

We shall say that Γ is locally bounded at $\bar{v}$ if there is a neighborhood V of $\bar{v}$ such that the set $\Gamma(V)$ is bounded (see [7]). To prove Lemma 3.2, Theorem 3.1 of [7] is quoted.

THEOREM 4.1. *Let* $h : \mathbb{R}^d \times \mathbb{R}^n \to \mathbb{R}$ *and* $H : \mathbb{R}^d \times \mathbb{R}^n \to \mathbb{R}^l$ *be locally Lipschitzian functions. Let*

$$\begin{aligned}
\psi(v) &= \inf_x \left\{ h(v, x) \mid H(v, x) \in \tilde{C},\ (v, x) \in \tilde{D} \right\}, \\
\Psi(v) &= \text{argmin}_x \left\{ h(v, x) \mid H(v, x) \in \tilde{C},\ (v, x) \in \tilde{D} \right\},
\end{aligned}$$

where $\tilde{C}$ *and* $\tilde{D}$ *are closed. Let* $\bar{v}$ *be a point at which* $\psi(\bar{v})$ *is finite and suppose that for some* $\beta > \psi(\bar{v})$ *the multifunction*

$$\Psi_\beta(v) = \left\{ x \in \mathbb{R}^n \mid h(v, x) \le \beta,\ H(v, x) \in \tilde{C},\ (v, x) \in \tilde{D} \right\} \quad \textit{is locally bounded at } \bar{v}. \tag{10}$$

Suppose further that the following constraint qualification holds for every $\bar{x} \in \Psi(\bar{v})$: *the only vectors* $y \in \mathbb{R}^l$ *and* $z \in \mathbb{R}^d$ *such that*

$$y \in N_{\tilde{C}}(H(\bar{v},\bar{x})) \quad \textit{and} \quad (z,0) \in y^T \partial H(\bar{v},\bar{x}) + N_{\tilde{D}}(\bar{v},\bar{x}) \quad \textit{are } y = 0, z = 0, \tag{11}$$

where the set $\partial H(\bar{v},\bar{x})$ *denotes the Clarke generalized Jacobian of* H *at* $(\bar{v},\bar{x})$ (*see p.* 69 *of* [10]).

Then, relative to some neighborhood V *of* $\bar{v}$, ψ *is finite and locally Lipschitzian.*

Proof of Lemma 3.2. Let $v = (\mu, u)$, $h(v,x) = \mu^T F(x)$, $H(v,x) = G(x) - u$, $d = m + l$, $\tilde{C} = \mathbb{R}^l_-$, and $\tilde{D} = \mathbb{R}^m \times \mathbb{R}^l \times \mathbb{R}^n$. Then

$$p(\mu,u) = \inf_x \left\{ \mu^T F(x) \mid G(x) - u \in \mathbb{R}^l_- \right\} = \psi(v), \quad \text{and}$$
$$P(\mu,u) = \operatorname{argmin}_x \left\{ \mu^T F(x) \mid G(x) - u \in \mathbb{R}^l_- \right\} = \Psi(v).$$

For $(\bar{\mu},\bar{u}) \in S^m \times \mathcal{N}_1$, we will show that p is locally Lipschitzian at $(\bar{\mu},\bar{u})$. In view of Lemma 3.1, for $(\bar{\mu},\bar{u}) \in S^m \times \mathcal{N}_1$, it is easy to see that $p(\bar{\mu},\bar{u})$ is finite and (10) holds (since $C(\cdot)$ is locally bounded at $\bar{u}$). Thus we only have to verify that (11) holds. Indeed, for every $\bar{x} \in P(\bar{\mu},\bar{u})$, the fact that $y \in N_{\mathbb{R}^l_-}(G(\bar{x}) - \bar{u})$ implies for $i \in [1,l]$

$$y_i = \begin{cases} 0 & \text{if } g_i(\bar{x}) - \bar{u}_i < 0, \\ \geq 0 & \text{if } g_i(\bar{x}) - \bar{u}_i = 0. \end{cases} \tag{12}$$

By Proposition 2.6 of [11], $y^T \partial H(\bar{v},\bar{x}) = \partial_{(v,x)} \left(y^T H(\bar{v},\bar{x}) \right) = \left(0, -y, \partial_x \left(y^T G(\bar{x}) \right) \right)$. Since $N_{\mathbb{R}^m \times \mathbb{R}^l \times \mathbb{R}^n}(\bar{v},\bar{x}) = \{0\}$, we only have to show that the only vector $y \in \mathbb{R}^l$ such that

$$y \in N_{\mathbb{R}^l_-}(G(\bar{x}) - \bar{u}) \text{ and } 0 \in \partial_x \left(y^T G(\bar{x}) \right) \tag{13}$$

is $y = 0$. Suppose to the contrary that there is a nonzero y satisfying (13). By (12), $y^T G(\cdot)$ is convex, and $y_i \geq 0$ if $g_i(\bar{x}) - \bar{u}_i = 0$ for $i \in [1,l]$. Let $I_0 = \{ i \in [1,l] \mid g_i(\bar{x}) = \bar{u}_i \}$ and x^* be given by Assumption 3.1. By Lemma 3.1, $g_i(x^*) - \bar{u}_i < 0$ for all $i \in [1,l]$. It follows that

$$y^T (G(x^*) - G(\bar{x})) = \sum_{i \in I_0} y_i (g_i(x^*) - \bar{u}_i) < 0,$$

which contradicts $0 \in \partial_x \left(y^T G(\bar{x}) \right)$. Therefore, by Theorem 4.1, p is locally Lipschitzian at $(\bar{\mu},\bar{u})$. This completes the proof.

Acknowledgment. The author thanks an anonymous referee for making a careful reading of this paper and offering many insightful comments on the presentation.

OPTIMAL CONTROL OF LINEAR PERIODIC RESONANT SYSTEMS IN HILBERT SPACES*

VIOREL BARBU†

Abstract. This work concerns existence, the maximum principle, and synthesis for optimal control problems with linear periodic dynamics in Hilbert spaces in the resonant case. Applications to distributed and boundary periodic control problems are given.

Key words. distributed optimal control problems, maximum principle, closed range, p-stabilizable

AMS subject classifications. 93B50, 93C35, 93C05

PII. S036301299529478X

1. Introduction.

In this work we shall study the optimal control problem

$$\text{minimize} \quad \int_0^T (g(Cy(t)) + h(u(t)))dt \tag{1.1}$$

subject to $u \in L^2(0,T;U)$ and $y \in C([0,T];H)$ satisfying the state system

$$\begin{aligned} &\frac{dy}{dt} + Ay = Bu + f, \qquad t \in (0,T), \\ &y(0) = y(T). \end{aligned} \tag{1.2}$$

Here H, U, and Z are real Hilbert spaces, $-A$ is the infinitesimal generator of a C_0 semigroup e^{-At} on H, $B \in L(U,H)$, $C \in L(H,Z)$, $g : Z \to \bar{R} = (-\infty, +\infty]$, and $h : U \to \bar{R}$ are lower semicontinuous convex functions. The solution y to state system (1.1) is considered in the "mild sense," i.e.,

$$y(t) = e^{-At}y(T) + \int_0^t e^{-A(t-s)}(Bu(s) + f(s))ds \quad \forall t \in [0,T]. \tag{1.2}'$$

This is the general framework for representing distributed optimal control problems. In the resonant case, i.e., when the null space of the operator $\frac{d}{dt}+A$ with periodic condition is not trivial, this is a singular optimal control problem which so far was studied under the key assumptions that the pair (A,B) is stabilizable and (A,C) is detectable (see, e.g., [5], [7], [8]). However, though these assumptions are natural for infinite horizon problems, they are too restrictive for periodic control problems. It is our aim here to relax them to a closed range hypothesis which will be discussed in some details in section 2 below. It will be in this framework that we shall treat in sections 3 and 5 the existence, the Pontryagin maximum principle, and the synthesis of optimal controllers. In section 4 we shall briefly discuss the corresponding boundary control problem, while section 5 is devoted to construction of optimal feedback controllers for the linear quadratic problem. In section 6 we shall study the optimal control problem (1.1) with the dynamics

$$y'' + Ay = Bu + f, \quad t \in (0,T); \quad y(0) = y(T), \quad y'(0) = y'(T), \tag{1.3}$$

where A is a self-adjoint, positive definite operator on H and $B \in L(U,H)$.

We shall use the standard notations for the spaces of vector-valued functions on the interval [0,T]. In particular, $W^{1,2}([0,T];H)$ is the space of absolutely continuous functions $y:[0,T]\to H$ such that $y'=\frac{dy}{dt}\in L^2(0,T;H)$. The norms and the scalar products of H, U, Z are denoted by $|\cdot|$, $|\cdot|_U$, $|\cdot|_Z$ and $(\cdot,\cdot)$, $(\cdot,\cdot)_U$, $(\cdot,\cdot)_Z$, respectively. Given the lower semicontinuous, convex function φ on the Hilbert space X, we shall denote by $\partial\varphi$ the subdifferential of φ and by φ^* the conjugate of φ, i.e.,

$$\partial\varphi(y)=\{z\in H;\varphi(y)\le\varphi(p)+(z,y-p)\quad\forall p\in H\},$$

$$\varphi^*(p)=\sup\{(y,p)-\varphi(y);y\in H\}.$$

By φ_ε we denote the Moreau–Brezis regularization of φ, i.e.,

$$\varphi_\varepsilon(x)=\inf\{(2\varepsilon)^{-1}|x-y|^2+\varphi(y);\ y\in X\}. \tag{1.4}$$

(We refer to [1] and [4] for basic results on convex analysis relevant to this paper.) Given a linear, densely defined operator W on a Banach space we shall denote by $D(W)$ the domain of W and by $R(W)$ its range. The dual operator will be denoted by W^*. In a slightly different form part of the results of this paper were presented in [3].

2. Weak solutions and the closed range property. Let $\mathcal{A}$ be the linear operator defined in $L^2(0,T;H)$ as

$$\mathcal{A}y=f \tag{2.1}$$

if and only if

$$\int_0^T((y(t),\varphi'(t)-A^*\varphi(t))+(f(t),\varphi(t)))dt=0$$

for all $\varphi\in W^{1,2}([0,T];H)$ such that $A^*\varphi\in L^2(0,T;H);\varphi(0)=\varphi(T)$. A function $y\in L^2(0,T;H)$ satisfying (2.1) is called a *weak solution* to the periodic problem

$$\frac{dy}{dt}+Ay=f;\qquad y(0)=y(T). \tag{2.2}$$

It is readily seen that the operator $\mathcal{A}$ is closed and densely defined in $L^2(0,T;H)$. Moreover, the dual operator $\mathcal{A}^*$ is defined as

$$\mathcal{A}^*z=g \tag{2.3}$$

if and only if

$$\int_0^T((z(t),\varphi'(t)+A\varphi(t))-(\varphi(t),g(t)))dt=0 \tag{2.4}$$

for all $\varphi\in W^{1,2}([0,T];H)$ such that $A\varphi\in L^2(0,T;H),\varphi(0)=\varphi(T)$.

Let $N(\mathcal{A})$ and $N(\mathcal{A}^*)$ be the null spaces of $\mathcal{A}$ and $\mathcal{A}^*$, respectively. If $R(\mathcal{A})$ (the range of $\mathcal{A}$) is closed in $L^2(0,T;H)$, then by virtue of the closed range theorem (see, e.g., [19, p. 205]), so is $R(\mathcal{A}^*)$ and

$$L^2(0,T;H)=R(\mathcal{A})\oplus N(\mathcal{A}^*)=R(\mathcal{A}^*)\oplus N(\mathcal{A}). \tag{2.5}$$

This means that for each $f \in R(\mathcal{A})$ the solutions y to equation $\mathcal{A}y = f$ are expressed as $y = y_1 + N(\mathcal{A})$ where $y_1 \in R(\mathcal{A}^*)$ is uniquely defined. We define $\mathcal{A}^{-1}f = y_1$ and note that by the closed graph theorem, $\mathcal{A}^{-1} \in L(R(\mathcal{A}), L^2(0,T;H))$. The operator $(\mathcal{A}^*)^{-1} \in L(R(\mathcal{A}^*), L^2(0,T;H))$ is similarly defined.

Proposition 1 below is related to some earlier result of Prüss [15] (see also Haraux [9]).

PROPOSITION 1. *Assume that for each $m \in Z$, the range Y_m of $\mu_m iI + A$ is closed in H and*

$$\sup\{\|(\mu_m iI + A)^{-1}\|_{L(Y_m,H)}; m \in Z\} < \infty, \tag{2.6}$$

where $\mu_m = 2m\pi/T$. Then $R(\mathcal{A})$ is closed in $L^2(0,T;H)$.

Here we have again denoted A the realization of operator A into the complexified space H.

Proof. If $f \in R(\mathcal{A})$, then there is a $y \in L^2(0,T;H)$ such that

$$y(t) = \sum_m y_m \exp(\mu_m it), \qquad t \in (0,T), \tag{2.7}$$

where

$$y_m = (\mu_m i + A)^{-1} f_m, \qquad f_m = T^{-\frac{1}{2}} \int_0^T \exp(-\mu_m it) f(t)dt,$$

and so by (2.6) and Parseval's identity we get

$$\|y\|_{L^2(0,T;H)} \le C\|f\|_{L^2(0,T;H)}$$

where $\mathcal{A}y = f$. This implies that $R(\mathcal{A})$ is closed in $L^2(0,T;H)$, as claimed.

Let $\mathcal{A}_0 : D(\mathcal{A}_0) \subset L^2(0,T;H) \to L^2(0,T;H)$ be the linear operator defined as

$$\mathcal{A}_0 y = f \tag{2.8}$$

if and only if

$$y(t) = e^{-At}y(T) + \int_0^t e^{-A(t-s)} f(s)ds, \qquad t \in (0,T).$$

In other words, $\mathcal{A}_0 y = f$ if and only if y is continuous and it is a "mild" periodic solution to (2.2). It is easily seen that $\mathcal{A}_0$ is itself closed and densely defined in $L^2(0,T;H)$. Moreover, a simple integration by parts shows that $\mathcal{A}_0 \subset \mathcal{A}$. As a matter of fact we have the following proposition.

PROPOSITION 2. $\mathcal{A}_0 = \mathcal{A}$.

Proof. Since, as noticed earlier, the inclusion $\mathcal{A}_0 \subset \mathcal{A}$ is immediate, we confine ourselves to checking that $\mathcal{A} \subset \mathcal{A}_0$. Let $(y,f) \in \mathcal{A}$. We have

$$y(t) = \sum_{m \in Z} y_m \exp(\mu_m it) \text{ in } L^2(0,T;H); \qquad (\mu_m i + A)y_m = f_m. \tag{2.9}$$

Then the sequence

$$y_N(t) = \sum_{|m| \le N} y_m \exp(i\mu_m t)$$

is convergent to y in $L^2(0,T;H)$, and for each N, y_N is a mild solution to (2.2) where $f = f_N = \sum_{|m|\le N} f_m \exp(i\mu_m t)$. Hence

$$y_N(t) = e^{-A(t-s)}y_N(s) + \int_s^t e^{-A(t-r)}f_N(r)dr, \qquad 0 < s < t < T, \tag{2.10}$$

$$y_N(0) = y_N(T).$$

Since $y_N \to y$ and $f_N \to f$ in $L^2(0,T;H)$ and a.e. on $(0,T)$ (on some subsequence), we infer by (2.10) that $\{y_N(T)\}$ is strongly convergent in H to some y_1 and therefore $y_N(t)$ is uniformly convergent to $y(t) \in C([0,T];H)$ and $\mathcal{A}y = f$ as claimed.

By Proposition 2 we have

$$R(\mathcal{A}) = \left\{ f \in L^2(0,T;H); \int_0^T e^{-A(T-t)}f(t)dt \in R(I - e^{-AT}) \right\}, \tag{2.11}$$

$$N(\mathcal{A}) = \{y \in L^2(0,T;H); y(t) = e^{-At}y_0, (I - e^{-AT})y_0 = 0\}. \tag{2.12}$$

Moreover, the dual operator $\mathcal{A}^*$ is given by $\mathcal{A}^*z = g$ if and only if

$$z(t) = e^{-A^*(T-t)}z(0) + \int_t^T e^{-A^*(s-t)}g(s)ds \quad \forall t \in [0,T]. \tag{2.13}$$

PROPOSITION 3. *$R(\mathcal{A})$ is closed in $L^2(0,T;H)$ if and only if $R(I - e^{-AT})$ is closed in H.*

Proof. If $R(I - e^{-AT})$ is closed in H, then by (2.11) we see that $R(\mathcal{A})$ is closed in $L^2(0,T;H)$. Assume now that $R(\mathcal{A})$ is closed and consider the linear subspace of H,

$$X = \{x \in H; (e^{-At}x) \in R(\mathcal{A})\}.$$

(Here we have denoted by $(e^{-At}x)$ the function $t \longrightarrow e^{-At}x$.) We have

$$X = R(I - e^{-AT}). \tag{2.14}$$

Here is the argument. If $x \in R(I - e^{-AT})$, then $Te^{-AT}x \in R(I - e^{-AT})$, and so the equation

$$(I - e^{-AT})y_0 = Te^{-AT}x$$

has at least one solution $y_0 \in H$. Then the function

$$y(t) = e^{-At}y_0 + \int_0^t e^{-A(t-s)}e^{-As}xds = e^{-At}y_0 + te^{-At}x$$

is a solution to $\mathcal{A}y = e^{-At}x$, i.e., $x \in X$. Now let x be in X and let $y(t) = e^{-At}y(0) + te^{-At}x$ be a solution to $\mathcal{A}y = e^{-At}x$. Since $y(0) = y(T)$ the latter implies that $e^{-AT}x \in R(I - e^{-AT})$, and therefore $x \in R(I - e^{-AT})$. Since X is closed it follows from (2.14) that so is $R(I - e^{-AT})$.

COROLLARY 1. *If $R(\mathcal{A})$ is closed in $L^2(0,T;H)$, then $\mathcal{A}^{-1}f \in C([0,T];H)$ for each $f \in R(\mathcal{A})$ and*

$$\|\mathcal{A}^{-1}f\|_{C([0,T];H)} \le C\|f\|_{L^1(0,T;H)} \quad \forall\ f \in R(\mathcal{A}). \tag{2.15}$$

Proof. Since $R(\mathcal{A})$ is closed, so is $R(I - e^{-AT})$, and we have therefore

$$\mathcal{A}^{-1}f(t) = e^{-At}(I - e^{-AT})^{-1}\int_0^T e^{-A(T-t)}f(t)dt + \int_0^t e^{-A(t-s)}f(s)ds$$

$\forall t \in [0,T]$. Recalling that $(I - e^{-AT})^{-1}$ is continuous on $R(I - e^{-AT})$ the latter implies (2.15), as desired.

By the Riesz–Fredholm theory we also have the following corollary.

COROLLARY 2. *If e^{-AT} is compact, then $R(\mathcal{A})$ is closed and $N(\mathcal{A})$, $N(\mathcal{A}^*)$ are finite-dimensional.*

Given $F \in L(H,U)$ we shall denote by $\mathcal{A}_F$ the operator $\mathcal{A} + BF$ defined from $L^2(0,T;H)$ to itself and by $\mathcal{A}_F^* = \mathcal{A}^* + F^*B^*$ its dual.

DEFINITION 1. *The pair (A,B) is said to be p-stabilizable if there is an $F \in L(H,U)$ such that $R(\mathcal{A}_F)$ is closed in $L^2(0,T;H)$ and $N(\mathcal{A}_F^*)$ is finite-dimensional.*

By virtue of Proposition 3 and of (2.12), the pair (A,B) is p-stabilizable if and only if there is an $F \in L(H,U)$ such that $R(I - e^{-(A+BF)T})$ is closed in H and dim $N(I - e^{-(A^*+F^*B^*)T}) < \infty$. In particular, this happens if either e^{-AT} is compact in H or if the pair (A,B) is stabilizable, i.e., there is an $F \in L(H,U)$ such that $A+BF$ generates an exponentially stable semigroup.

DEFINITION 2. *The pair (A,C) is said to be p-detectable if there is a $K \in L(Z,H)$ such that $R(\mathcal{A}_K)$ is closed in $L^2(0,T;H)$ and* dim $N(\mathcal{A}_K) < \infty$.

Here $\mathcal{A}_K = \mathcal{A} + KC$.

Throughout this paper, by solution y to the state equation (1.2), we mean a weak solution, i.e., $\mathcal{A}y = Bu + f$.

3. Existence and the maximum principle. We shall study first the existence in problem (1.1) under the following assumptions.

(i) The pair (A,C) is p-detectable.

(ii) $g : Z \to \bar{R}, h : U \to \bar{R}$ are convex and lower semicontinuous and

$$g(z) \geq \alpha|z|_Z + \beta \quad \forall z \in Z, \tag{3.1}$$

$$h(u) \geq \omega|u|_U^2 + \gamma \quad \forall u \in U, \tag{3.2}$$

where $\alpha, \omega > 0$ and $\beta, \gamma \in R$.

THEOREM 1. *Assume that there is at least one admissible pair (y,u) in problem* (1.1). *Then, under hypotheses* (i), (ii), *problem* (1.1) *has at least one solution, $(y^*,u^*) \in C([0,T];H) \times L^2(0,T;U)$.*

Proof. Let $(y_n,u_n) \in C([0,T];H) \times L^2(0,T;U)$ be such that $\mathcal{A}y_n = Bu_n + f$ and

$$\inf(1.1) = d \leq \int_0^T (g(Cy_n(t)) + h(u_n(t)))dt \leq d + n^{-1}. \tag{3.3}$$

By (3.1), (3.2) we have

$$\|Cy_n\|_{L^1(0,T;H)} + \|u_n\|_{L^2(0,T;U)} \leq C_1. \tag{3.4}$$

By (i) there is a $K \in L(Z,H)$ such that $R(\mathcal{A}_K)$ is closed ($\mathcal{A}_K = \mathcal{A} + KC$) and dim $N(\mathcal{A}_K) < \infty$. We have

$$\mathcal{A}_K y_n = Bu_n + KCy_n + f \tag{3.5}$$

and set $y_n = y_n^1 + y_n^2$, where $y_n^1 = \mathcal{A}_K^{-1}(Bu_n + KCy_n + f) \in R(\mathcal{A}_K^*)$ and $y_n^2 \in N(\mathcal{A}_K)$. Then by (2.15) and (3.4) we have

$$\|y_n^1\|_{C([0,T];H)} \leq C_2 \quad \forall n \in N. \tag{3.6}$$

On the other hand, by the closed range theorem we know that

$$N(\mathcal{A}_K) = N(\mathcal{C}_K) \oplus R(\mathcal{C}_K^*).$$

We have denoted by $\mathcal{C}_K \in L(N(\mathcal{A}_K), L^2(0,T;Z))$ the operator $y \longrightarrow Cy$ restricted to $N(\mathcal{A}_K)$. Since $N(\mathcal{A}_K)$ is finite-dimensional, $\mathcal{C}_K$ has closed range in $L^2(0,T;Z)$, and because $\{Cy_n^2\}$ if bounded in $L^1(0,T;Z)$, it is bounded in $L^2(0,T;Z)$ as well. We have, therefore,

$$y_n^2 = z_n^1 + z_n^2,$$

where $\{z_n^1\}$ is bounded in $L^2(0,T;H)$ and $Cz_n^2 = 0$ a.e. in $(0,T)$. We may assume, therefore, that the sequence $\{y_n^1 + z_n^1\}$ is weakly compact in $L^2(0,T;H)$ and on a subsequence again denoted $\{n\}$ we have

$$\begin{array}{lcll} u_n & \longrightarrow & u^* & \text{weakly in } L^2(0,T;U), \\ y_n^1 + z_n^1 & \longrightarrow & y^* & \text{weakly in } L^2(0,T;H). \end{array}$$

Recalling that $\mathcal{A}(y_n^1 + z_n^1) = Bu_n + f$ we infer that $\mathcal{A}y^* = Bu^* + f$, and since the convex integrand is weakly lower semicontinuous we get

$$d = \int_0^T (g(Cy^*(t)) + h(u^*(t)))dt; \tag{3.7}$$

i.e., (y^*, u^*) is optimal in problem (1.1). This completes the proof.

In order to get the maximum principle for problem (1.1) we shall use the following assumptions.

(j) The pair (A, B) is p-stabilizable.

(jj) The function $g : Z \to R$ is convex and continuous, $h : U \to \bar{R}$ is convex and lower semicontinuous, int $D(h) \neq \emptyset$.

(jjj) The function f is in $C([0,T];H)$ and one of the following two conditions hold:

$(\text{jjj})_1$ $D(h) = U$ and h is bounded on every bounded subset of U.

$(\text{jjj})_2$ $f(t) = Bf_0(t)$ where $f_0 \in C([0,T];U)$ and $-f_0(t) \in \text{int}D(h)\, \forall t \in [0,T]$.

Here $D(h) = \{u \in U; h(u) < +\infty\}$ is the effective domain of h and int stands for interior.

THEOREM 2. *Assume that hypotheses* (j), (jj), (jjj) *hold. Then the pair* $(y^*, u^*) \in C([0,T];H) \times L^2(0,T;U)$ *is optimal in problem* (1.1) *if and only if there are* $p \in C([0,T];H)$ *and* $\eta \in L^\infty(0,T;Z)$ *such that*

$$\frac{dy^*}{dt} + Ay^* = Bu^* + f \text{ in } (0,T); \qquad y^*(0) = y^*(T), \tag{3.8}$$

$$\frac{dp}{dt} - A^*p = C^*\eta \text{ in } (0,T); \qquad p(0) = p(T), \tag{3.9}$$

$$\eta(t) \in \partial g(Cy^*(t)) \quad \text{a.e. } t \in (0,T), \tag{3.10}$$

$$u^*(t) \in \partial h^*(B^*p(t)) \quad \text{a.e. } t \in (0,T). \tag{3.11}$$

The system (3.8), (3.9) is considered, of course, in the weak sense:

$$\mathcal{A}y = Bu^* + f; \qquad \mathcal{A}^*p = -C^*\eta. \tag{3.8}'$$

Proof. It is readily seen that equations (3.8)–(3.11) are sufficient for optimality. To prove necessity we fix an optimal pair (y^*, u^*) and consider the approximating control problem

$$\text{Min}\left\{\int_0^T (g_\varepsilon(Cy) + h(u) + 2^{-1}(|y - y^*|^2 + |u - u^*|_U^2 + \varepsilon^{-1}|v|^2))\right\} dt \tag{3.12}$$

subject to

$$\mathcal{A}y = Bu + v + f, \quad u \in L^2(0,T;U), \quad v \in L^2(0,T;H), \quad y \in C([0,T];H).$$

Here $g_\varepsilon \in C^1(Z)$ is defined as in (1.4).

Arguing as above, it is easily seen that problem (3.12) has a unique solution $(y_\varepsilon, u_\varepsilon, v_\varepsilon) \in C([0,T];H) \times L^2(0,T;U) \times L^2(0,T;H)$, and by a standard device (see, e.g., [1], [4]) we have

$$u_\varepsilon \longrightarrow u^* \text{ strongly in } L^2(0,T;U), \tag{3.13}$$

$$y_\varepsilon \longrightarrow y^* \text{ strongly in } L^2(0,T;H).$$

We also have that

$$v_\varepsilon \longrightarrow 0 \text{ strongly in } L^2(0,T;H).$$

Next we have

$$\int_0^T ((C^*\nabla g_\varepsilon(Cy_\varepsilon), z) + (y_\varepsilon - y^*, z) + (u_\varepsilon - u^*, w)_U + h'(u_\varepsilon, w) + \varepsilon^{-1}(v_\varepsilon, v))dt \geq 0 \tag{3.14}$$

$\forall (z, w, v) \in C([0,T];H) \times L^2(0,T;U) \times L^2(0,T;H)$ such that $\mathcal{A}z = Bw + v$. We set $p_\varepsilon = \varepsilon^{-1}v_\varepsilon$. Then (3.14) yields

$$\int_0^T (C^*\nabla g_\varepsilon(Cy_\varepsilon) + y_\varepsilon - y^*, z) + (u_\varepsilon - u^*, w)_U + h'(u_\varepsilon, w) + (p_\varepsilon, \mathcal{A}z - Bw))dt \geq 0 \tag{3.14}'$$

$\forall z \in D(\mathcal{A})$, $\forall w \in L^2(0,T;U)$. (Here h' is the directional derivative of h.) For $w = 0$ the latter yields

$$\mathcal{A}^*p_\varepsilon = -C^*\nabla g_\varepsilon(Cy_\varepsilon) + y^* - y_\varepsilon. \tag{3.15}$$

Substituting the latter into (3.14)′, we get

$$\int_0^T (B^*p_\varepsilon + u^* - u_\varepsilon, w)_U dt \leq \int_0^T h'(u_\varepsilon, w)dt \quad \forall w \in U.$$

This yields

$$B^*p_\varepsilon \in \partial h(u_\varepsilon) + u_\varepsilon - u^* \quad \text{a.e.} \in (0,T). \tag{3.16}$$

We note also that

$$\mathcal{A}y_\varepsilon = Bu_\varepsilon + \varepsilon p_\varepsilon + f. \tag{3.17}$$

We are going to let ε tend to 0 in equations (3.15), (3.16) in order to get (3.9)–(3.11). To this aim, some a priori estimates on p_ε are necessary. Assume first that condition $(jjj)_2$ holds. Then by (3.16) and by the definition of ∂h, we have

$$\begin{aligned}(B^*p_\varepsilon(t) + u^*(t) - u_\varepsilon(t), u_\varepsilon(t) + f_0(t) - \rho w)_U \\ \geq h(u_\varepsilon(t)) - h(\rho w - f_0(t)) \quad \text{a.e. } t \in (0,T)\end{aligned} \tag{3.18}$$

$\forall w \in U, |w|_U = 1$, and ρ positive and sufficiently small. This yields

$$\rho \int_0^T |B^*p_\varepsilon(t)|_U dt \leq \int_0^T (p_\varepsilon(t), \mathcal{A}y_\varepsilon(t) - \varepsilon p_\varepsilon(t))dt + C_3.$$

Finally,

$$\begin{aligned}\rho \int_0^T (|B^*p_\varepsilon(t)|_U + \varepsilon |p_\varepsilon(t)|^2)dt \\ \leq -\int_0^T ((\nabla g_\varepsilon(Cy_\varepsilon(t)), Cy_\varepsilon(t))_Z + (y_\varepsilon(t) - y^*(t), y_\varepsilon(t)))dt \leq C_4\end{aligned}$$

because ∇g_ε is monotone. On the other hand, it follows that $\{y_\varepsilon\}$ is strongly convergent to y^* in $C([0,T];H)$. Indeed, by (3.17), we see that

$$\begin{aligned}y_\varepsilon(t) = e^{-\mathcal{A}_F(t-s)}y_\varepsilon(s) + \int_s^t e^{-\mathcal{A}_F(t-r)}(Bu_\varepsilon(r) + \varepsilon p_\varepsilon(r) \\ + BFy_\varepsilon(r))dr, \qquad 0 \leq s \leq t \leq T,\end{aligned}$$

and the conclusion follows by (3.13). (Here and everywhere in the following, $F \in L(H,U)$ is chosen as in Definition 1.) Since ∂g is locally bounded in H and

$$\nabla g_\varepsilon(z) \in \partial g((I + \varepsilon \partial g)^{-1}z) \quad \forall z \in Z; \qquad \int_0^T g_\varepsilon(Cy_\varepsilon)dt \leq C_5,$$

we have

$$|\nabla g_\varepsilon(Cy_\varepsilon(t))|_Z \leq C_6 \quad \forall \varepsilon > 0, \quad t \in [0,T]. \tag{3.19}$$

We may rewrite equation (3.15) as

$$\mathcal{A}_F^* p_\varepsilon = -C^* \nabla g_\varepsilon(Cy_\varepsilon) - (y_\varepsilon - y^*) + F^*B^*p_\varepsilon. \tag{3.20}$$

Then by (3.19) and Corollary 1 it follows that

$$|p_\varepsilon^1(t)| \leq C_7 \quad \forall t \in [0,T], \tag{3.21}$$

where $p_\varepsilon = p_\varepsilon^1 + p_\varepsilon^2$ and

$$p_\varepsilon^1 \in R(\mathcal{A}_F) = N(\mathcal{A}_F^*)^\perp, \qquad p_\varepsilon^2 \in N(\mathcal{A}_F^*).$$

Denote by $\mathcal{B}_F^*$ the operator $y \longrightarrow B^*y$ defined from $N(\mathcal{A}_F^*)$ to $L^2(0,T;U)$. Recalling that the space $N(\mathcal{A}_F^*)$ is finite-dimensional, we infer that $\mathcal{B}_F^*$ has closed range in $L^2(0,T;U)$, and so by the closed range theorem, it has a bounded inverse on its range. Since $N(\mathcal{A}_F^*) \subset C([0,T];H)$ and $\{\mathcal{B}_F^* p_\varepsilon^2\}$ is bounded in $L^1(0,T;U)$, it is bounded in $L^2(0,T;U)$ too, and we have $p_\varepsilon^2 = q_\varepsilon^1 + q_\varepsilon^2$ where $\{q_\varepsilon^1\}$ is bounded in $L^2(0,T;H)$ and $B^*q_\varepsilon^2 = 0$ a.e. in $(0,T)$. We conclude, therefore, that the sequence $\{p_\varepsilon^1 + q_\varepsilon^1\}$ is weakly compact in $L^2(0,T;H)$. Moreover, we may write (3.20) as

$$\mathcal{A}_F^*(p_\varepsilon^1 + q_\varepsilon^1) = -C^*\nabla g_\varepsilon(Cy_\varepsilon) - (y_\varepsilon - y^*) + F^*B^*(p_\varepsilon^1 + q_\varepsilon^1). \tag{3.20$'$}$$

Selecting further subsequences, if necessary, we may assume that

$$\begin{array}{lcll} p_\varepsilon^1 + q_\varepsilon^1 & \longrightarrow & p & \text{weakly in } L^2(0,T;H), \\ \nabla g_\varepsilon(Cy_\varepsilon) & \longrightarrow & \eta & \text{weak star in } L^\infty(0,T;Z). \end{array}$$

Since ∂g and ∂h are maximal monotone (and therefore weakly/strongly closed), we may pass to the limit in (3.15) and (3.20)$'$ to get the optimality system (3.8)–(3.11).

Assume now that condition $(\mathrm{jjj})_1$ is satisfied. We set $p_\varepsilon = p_\varepsilon^1 + q_\varepsilon^1$. Then by (3.16) we have

$$h(u_\varepsilon) - h(\rho w) \le (B^*p_\varepsilon + u^* - u_\varepsilon, u_\varepsilon - \rho w)$$

for all $w \in H, \rho > 0$. This yields

$$\begin{aligned} \rho \int_0^T |B^*p_\varepsilon(t)|_U dt &\le C_8 + Th(\rho w) + \int_0^T (p_\varepsilon(t), \mathcal{A}y_\varepsilon(t) - f(t))dt \\ &\le Th(\rho w) + C_9\left(1 + \int_0^T |p_\varepsilon(t)|dt\right). \end{aligned}$$

Finally,

$$\int_0^T |B^*p_\varepsilon(t)|_U dt \le C_\rho + C_{10}\rho^{-1}\int_0^T |p_\varepsilon(t)|dt \tag{3.22}$$

for all $\rho > 0$. Choosing ρ sufficiently large it follows by (3.20)$'$ and (3.2) that $\{p_\varepsilon^1 + q_\varepsilon^1\}$ is bounded in $L^2(0,T;H)$, and so we may conclude the proof as in the previous case.

Remark 1. The proof reveals that Theorem 2 remains true if assumption (j) is relaxed to: there is an $F \in L(H,U)$ such that $\mathcal{A}_F$ has closed range in $L^2(0,T;H)$ and $\mathcal{B}_F^*$ has closed range in $L^1(0,T;U)$.

The optimal control problem

$$\begin{aligned} \mathrm{Min}\Bigg\{ &\int_0^T (g_*(v(t)) + h^*(B^*p(t)) + (f(t), p(t)))dt; \\ &p \in C([0,T];H), v \in L^2(0,T;H)\Bigg\} \end{aligned} \tag{3.23}$$

subject to

$$\mathcal{A}^*p = -v \tag{3.24}$$

is the dual of (1.1) in the sense of Rockafellar (see, e.g., [17]). Here h^* is the conjugate of h, and g_* is the conjugate of the function $y \to g(Cy)$.

THEOREM 3. *Under the assumptions of Theorem* 2 *the pair* (y^*, u^*) *is optimal in problem* (1.1) *if and only if the dual problem* (3.23) *has a solution* (p^*, v^*) *and*

$$\int_0^T (g(Cy^*(t) + h(u^*(t))dt + \int_0^T (g_*(v^*(t)) + h^*(B^*p^*(t))) + (f(t), p^*(t)))dt = 0. \tag{3.25}$$

Proof. The argument is standard (see, e.g., [4], [16]), so only the proof will be sketched. If (y^*, u^*) is optimal in (1.1), then by Theorem 2 the optimality system (3.8)–(3.11) has a solution $(p^*, v^* = C^*\eta)$, and in virtue of the conjugacy relation, we have

$$h(u^*) + h^*(B^*p^*) = (B^*p^*, u^*)_U, \tag{3.26}$$

$$g(Cy^*) + g_*(v^*) = (y^*, v^*).$$

Integrating from 0 to T we get (3.25). On the other hand, for all $(p, v) \in C([0,T]; H) \times L^2(0,T;H), \mathcal{A}^*p = -v$, we have

$$h(u^*) + h^*(B^*p) \geq (B^*p, u^*)_U \quad \text{a.e. on } (0,T), \tag{3.27}$$

$$g(Cy^*) + g_*(v) \geq (y^*, v) \quad \text{a.e. on } (0,T),$$

which imply that the pair (p^*, v^*) is optimal in problem (3.23). Conversely, if (3.25) holds, then by (3.26) and (3.27), we see that y^*, p^*, u^* satisfy the optimality system (3.8)–(3.11), and therefore (y^*, u^*) is optimal in problem (1.1).

We end this section with a few examples of linear control systems of the form (1.2) for which the previous theorems are applicable.

1. *Parabolic control problems.* Consider the system

$$\begin{aligned} &\tfrac{\partial y}{\partial t} - \Delta y + b(x) \cdot \nabla y + c(x)y = Bu + f(x,t), \qquad (x,t) \in \Omega \times R, \\ &y(x,t) = 0 \quad \forall (x,t) \in \partial\Omega \times R, \\ &y(x,t+T) = y(x,t) \quad \forall (x,t) \in \Omega \times R, \end{aligned} \tag{3.28}$$

where $b \in W^{1,\infty}(\Omega; R^n)$, $c \in L^\infty(\Omega)$, $f \in L^2_{\text{loc}}(R; L^2(\Omega))$ is T-periodic in t, while $B \in L(L^2(\Omega), L^2(\Omega))$. Here Ω is a bounded and open subset of R^n with a sufficiently smooth boundary $\partial\Omega$. We may write (3.28) under the form (1.2) where $H = U = L^2(\Omega)$ and

$$Ay = -\Delta y + b \cdot \nabla y + cy, \qquad D(A) = H_0^1(\Omega) \cap H^2(\Omega). \tag{3.29}$$

Since the semigroup e^{-At} generated by $-A$ on $L^2(\Omega)$ is compact, it follows that $R(\mathcal{A})$ is closed in $L^2(0,T;H)$ and $N(\mathcal{A}^*)$ is finite-dimensional (Corollary 2). Hence the p-stabilizability hypothesis (j) is satisfied in the present situation with $F = 0$. A similar conclusion can be reached for the p-detectability hypothesis (i).

2. *Linear delay control systems.* Consider the control system governed by the delay system

$$\begin{aligned} &y'(t) + A_0y(t) + A_1y(t-h) = B_0u(t) + f(t), \\ &y(t) = y(t+T) \quad \forall t \in R, \end{aligned} \tag{3.30}$$

where A_0, A_1 are $n\times n$ matrices, B_0 is an $n\times l$ matrix, $f \in L^2_{\rm loc}(R; R^n)$, $f(t+T) = f(t)$, $u \in L^2_{\rm loc}(R; R^l)$, and $u(t) = u(t+T)$. It is well known that this system can be written in the form (1.2), where $H = M_2 = R^n \times L^2(-h, 0; R^n)$, $U = R^l$, $B = (B_0, 0)$, and

$$A(y_0, y^0) = \left\{ A_0 y_0 + A_1 y^0(-h), -\frac{dy^0}{ds} \right\},$$

$$D(A) = \{(y_0, y^0) \in R^n \times W^{1,2}([-h, 0]; R^n), y_0 = y^0(0)\}.$$

For each $m \in Z$, we may rewrite the equation $(\mu_m iI + A)y = (f_0, f_1)$ as

$$(i\mu_m I + A_0 + e^{-i\mu_m h} A_1) y_0 = f_0 + \int_0^{-h} e^{-i\mu_m (h+s)} A_1 f_1(s) ds, \tag{3.31}$$

$$y^0(s) = e^{-i\mu_m s} y_0 - \int_0^s e^{i\mu_m (s-t)} f_1(t) dt,$$

where $\mu_m = 2m\pi T^{-1}$. Moreover, after some calculation, we see that

$$N(\mathcal{A}^*) = \left\{ \sum_m (y_m e^{i\mu_m t}, -A_1^* y_m e^{i\mu_m (t-s-h)}); \right. \tag{3.32}$$

$$\left. (i\mu_m I + A_0^* + e^{-i\mu_m h} A_1^*) y_m = 0 \right\}.$$

By (3.31) we see that $R(i\mu_m I + A)$ is closed and condition (2.5) in Proposition 1 is satisfied. We conclude, therefore, that the corresponding operator $\mathcal{A}$ has closed range in $L^2(0, T; H)$. Moreover, by (3.31) and (3.32), it follows that $N(\mathcal{A})$ and $N(\mathcal{A}^*)$ are finite-dimensional.

3. *First-order hyperbolic systems.* Consider the control system governed by the linear system

$$y_t(x,t) - z_x(x,t) = u(x,t) + f(x,t), \quad x \in (0,1), \quad t \in (0,T), \tag{3.33}$$

$$z_t(x,t) - y_x(x,t) = B_0 v(x,t) + g(x,t), \quad x \in (0,1), \quad t \in (0,T),$$

$$y(0,t) = y(1,t) = 0; \quad y(x,T) = y(x,0), \quad z(x,T) = z(x,0) \quad \forall x \in (0,1).$$

Here $B_0 \in L(L^2(0,1), L^2(0,1))$ and $f, g \in C([0,T]; L^2(0,1))$ are given functions. System (3.33) can be written in the form (1.2) where $H = U = L^2(0,1) \times L^2(0,1)$ $B(u,v) = (u, B_0 v)$, and $A(y,z) = (-z_x, -y_x)$, $D(A) = \{y, z \in H^1(0,1), y(0) = y(1) = 0\}$. Consider the feedback control $F(y,z) = (-y, 0)$. Then it is easily seen that the corresponding operator $\mathcal{A}_F$ has closed range in $L^2(0,T;H)$, $N(\mathcal{A}_F) = N(\mathcal{A}_F^*) = \{(0,C); C \in R\}$, and therefore the pair (A,B) is p-stabilizable. This simple example extends to linear control hyperbolic systems in $R^n \times R^n$, and it is instructive to notice that in this case if T is irrational, then $R(\mathcal{A})$ is not closed and so assumption (j) does not hold with $F = 0$.

4. Periodic boundary control problems. Here we shall extend the previous results to boundary control problem

$$\text{Min} \left\{ \int_0^T (g(Cy(t)) + h(u(t)))dt, u \in L^2(0,T;U) \right\} \tag{4.1}$$

subject to

$$z' + Az = Du + (\lambda I + A)^{-1} f \quad \text{in } (0,T), \tag{4.2}$$

$$z(0) = z(T), \quad y = (\lambda I + A)z.$$

Here $-A$ is the infinitesimal generator of a C_0 semigroup in H, $\lambda \in \rho(-A)$, and $D \in L(U,H)$. We set $B = (\lambda I + A)D$. Clearly $B \in L(U, (D(A^*)'))$ and the dual operator B^* is in $L(D(A^*), U)$. Dealing with system (4.2), we shall use one of the following two conditions:

$$\|B^* e^{-A^* t}\|_{L(H,H)} \le C_1 t^{\gamma - 1} \quad \forall t \in (0,T) \tag{H_1}$$

where $\gamma \in (0,1)$.

$$\int_0^T |B^* e^{-A^* t} x|_U^2 dt \le C_2 |x|^2 \quad \forall x \in H. \tag{H_2}$$

It is well known that condition (H_1) is satisfied by parabolic equations with Dirichlet boundary control, while condition (H_2), due to Lasiecka and Triggiani, is specific to hyperbolic boundary control systems (see [10]). The state equation (4.2) is considered in the weak sense, i.e.,

$$\mathcal{A} z = Du + (\lambda I + A)^{-1} f. \tag{4.3}$$

We shall study problem (4.1) under the assumption

$$R(\mathcal{A}) \text{ is closed in } L^2(0,T;H) \text{ and } \dim N(\mathcal{A}^*) < +\infty. \tag{4.4}$$

Since, as seen earlier (Proposition 3), this implies that $(I - e^{-AT})^{-1} \in L(R(I - e^{-AT}); H)$, it follows that under assumption (H_2) the weak solution $y = (\lambda I + A)z$ is in $C([0,T];H)$, while under assumption (H_1), $y \in L^2(0,T;H)$.

THEOREM 4. *Assume that $R(\mathcal{A})$ is closed in $L^2(0,T;H)$ and $N(\mathcal{A})$ is finite-dimensional. Then problem* (4.1) *has at least one solution $(y^*, u^*) \in L^2(0,T;H) \times L^2(0,T;U)$.*

Proof. Let y_n, u_n be as in the proof of Theorem 1 where $y_n = (\lambda I + A)z_n$, $\mathcal{A} z_n = Du_n + (\lambda I + A)^{-1} f$. We have

$$\|Cy_n\|^2_{L^1(0,T;Z)} + \|u_n\|^2_{L^2(0,T;U)} \le C_3.$$

We set $y_n = y_n^1 + y_n^2$, where $y_n^1 \in R(\mathcal{A}^*)$ and $y_n^2 \in N(\mathcal{A})$. Since $N(\mathcal{A})$ is finite-dimensional we may write $y_n^2 = z_n^1 + z_n^2$ where $\{z_n^1\}$ is compact in $L^2(0,T;H)$ and $z_n^2 \in N(\mathcal{C}_K) \cap N(\mathcal{A})$. Hence $\{y_n^1 + z_n^1\}$ is weakly compact in $L^2(0,T;H)$, and so we may pass to the limit in (3.4) to conclude the proof.

As regards the maximum principle, we have the following theorem.

THEOREM 5. *Assume that hypotheses* (4.4) *and* (jj), (jjj) *hold. Then the pair (y^*, u^*) is optimal in problem* (4.1) *if and only if the system* (3.8)–(3.11) *is satisfied.*

Proof. The proof is essentially the same as that of Theorem 2, and so we shall omit it. We notice only that though B and B^* are not bounded (or closed), equations (3.15), (3.16) make sense in this case because

$$B^* p(t) = B^* e^{-A^*(T-t)} (I - e^{-A^* T})^{-1} \int_0^T e^{-A^* s} g(s) ds$$

$$+ \int_t^T B^* e^{-A^*(s-t)} g(s) ds \quad \forall t \in [0,T]$$

for all solutions p to equation $\mathcal{A}^*p = g$. The latter is also used to pass to the limit in equations (3.15), (3.16).

As an example, consider the optimal control problem with state dynamics

$$\begin{array}{ll} y_t - \Delta y + b(x)\cdot\nabla y + c(x)y = f(x,t), & (x,t)\in\Omega\times R, \\ y(x,t) = a(x)u(x,t) & \forall (x,t)\in\partial\Omega\times R, \\ y(x,t+T) = y(x,t) & \forall (x,t)\in\Omega\times R, \end{array} \tag{4.5}$$

where $b\in W^{1,\infty}(\Omega;R^n)$, $c\in L^\infty(\Omega)$, and $a\in C(\partial\Omega)$ is not identically 0.

Define $Du = y^0$, where y^0 is the solution to boundary value problem

$$\lambda y^0 - \Delta y^0 + b\cdot\nabla y^0 + cy^0 = 0 \text{ in } \Omega,$$

$$y^0 = au \text{ in } \partial\Omega,$$

and

$$Ay = -\Delta y + b\cdot\nabla y + cy, \qquad D(A) = H_0^1(\Omega)\cap H^2(\Omega).$$

We are in the case described by (H_1), where $H = L^2(\Omega)$, $U = L^2(\partial\Omega)$, and $B^*p = a\frac{\partial p}{\partial\nu}$ $\forall p\in D(A)$.

5. Synthesis of periodic optimal controller. Here we shall study the existence of optimal feedback controllers for problem (1.1) in the linear quadratic case,

$$g(y) = 2^{-1}|Cy|_Z^2, \qquad h(u) = 2^{-1}|u|_U^2,$$

i.e.,

$$\text{Min}\left\{2^{-1}\int_0^T (|Cy|_Z^2 + |u|_U^2)dt; \mathcal{A}y = Bu + f\right\}, \tag{5.1}$$

where $B\in L(U,H), C\in L(H,Z)$, and the pair (A,C) is detectable, i.e., there is a $K\in L(Z,H)$ such that $A+KC$ generates an exponentially stable semigroup. It is readily seen that under these assumptions problem (5.1) has a unique optimal pair (y^*,u^*). The existing results on feedback representation of optimal controller of problem (5.1) require the stabilizability of pair (A,B) (see, e.g., [7], [8]). Here we shall obtain such a representation under the following weaker hypothesis.

(j)′ The pair (A,B) is p-stabilizable and

$$N(\mathcal{A}^*)\cap\{p\in L^2(0,T;H); B^*p(t) = 0, \text{ a.e. } t\in(0,T)\} = \{0\}.$$

THEOREM 6. *Assume that the pair (A,C) is detectable and that hypothesis* (j)′ *holds. Then the optimal controller u^* of problem* (5.1) *is given by the feedback formula*

$$u^*(t) = B^*P^{-1}(y^*(t) - r(t) + z(t)) \quad \forall t\in[0,T], \tag{5.2}$$

where $P\in L(H,H)$ is a self-adjoint and positive solution to the algebraic Riccati equation

$$AP + PA^* + PC^*CP = BB^*, \tag{5.3}$$

$r\in C([0,T];H)$ is a weak solution to the periodic problem

$$r' + (A + PC^*C)r = f \quad \text{in } (0,T); \qquad r(0) = r(T), \tag{5.4}$$

and $z \in C([0,T];H)$ *is such that* $z(t) \in N(C^*C), \forall t \in [0,T]$. *In* (5.2) P^{-1} *is the generalized inverse of* P.

Proof. By Theorem 3 it follows that the solution (y^*, u^*) to problem (5.1) is given by

$$u^* = B^*p^*, \qquad C^*Cy^* = -v^*, \tag{5.5}$$

where $(p^*, v^*) \in C([0,T];H) \times L^2(0,T;H)$ is a solution to the optimal control problem

$$\text{Min}\left\{\int_0^T (2^{-1}|B^*p|_U^2 + H(v))dt + \int_0^T (f,p)dt;\ \mathcal{A}^*p = v\right\}, \tag{5.6}$$

where $H(v) = \sup\{(y,v) - 2^{-1}|Cy|_Z^2; y \in H\}$. Since the function H is strictly convex, the optimal control v^* is unique and can be expressed as

$$v^*(t) = -C^*CPp^*(t) - C^*Cr(t), \tag{5.7}$$

where $P \in L(H,H)$ is a self-adjoint, positive solution to the algebraic Riccati equation (5.3) and $r \in C([0,T];H)$ is a weak solution to (5.4). The solution P to (5.3) is considered in the following weak sense:

$$2(Px, A^*x) + |CPx|^2 = |B^*x|^2 \quad \forall x \in D(A).$$

In fact, it is easily seen, via the optimality system, that the feedback controller v^* given by (5.7) is optimal in problem (5.6). The existence of a positive, self-adjoint solution P to Riccati equation (5.3) follows from the general theory of linear quadratic infinite horizon control problems (see, e.g., [7, p. 265]) because the pair (A^*, C^*) is stabilizable. We shall prove now that with a such a P equation, (5.4) has at least one weak solution, $r \in C([0,T];H)$.

Let $\mathcal{A}_1$ be the operator defined in $L^2(0,T;H)$ by

$$\mathcal{A}_1 = \mathcal{A} + PC^*C.$$

Then equation (5.4) can be written as

$$\mathcal{A}_1 r = f. \tag{5.8}$$

We shall prove that $R(\mathcal{A}_1)$ is closed in $L^2(0,T;H)$ and $N(\mathcal{A}_1^*) = \{0\}$. Indeed, if $\mathcal{A}_1^*p = 0$, then

$$p' - (A^* + C^*CP)p = 0; \qquad p(0) = p(T).$$

After some calculation involving this latter equation and (5.3), we get

$$\int_0^T (|B^*p(t)|_U^2 + |CPp(t)|_Z^2)dt = 0.$$

Hence $B^*p = 0, CPp = 0$. In particular, this implies that $p \in N(\mathcal{A}^*)$, and so by assumption (j)$'$, we infer that $p(t) = 0\ \forall t \in (0,T)$. It remains to check that $R(\mathcal{A}_1)$ is closed. To this end it suffices to show that $R(\mathcal{A}_1^*)$ is closed in $L^2(0,T;H)$. Let $\{f_n\} \subset L^2(0,T;H)$ and $\{y_n\} \subset C([0,T];H)$ be such that $\mathcal{A}_1^*y_n = f_n$ and

$$f_n \longrightarrow f \quad \text{strongly in} \quad L^2(0,T;H).$$

Then, by equation (5.3), we get

$$\int_0^T (|B^*y_n|_U^2 + |CPy_n|_Z^2 - 2(f_n, Py_n))dt = 0,$$

and this yields

$$\|B^*y_n\|^2_{L^2(0,T;U)} + \|Py_n\|^2_{L^2(0,T;H)} \leq C_1. \tag{5.9}$$

On the other hand, we have

$$\mathcal{A}_F^* y_n = f_n - C^*CPy_n + F^*B^*y_n$$

where F is as in Definition 1. Then by (2.15) and (5.9) we get the estimate

$$\|y_n^1\|_{C([0,T];H)} + \|B^*y_n^2\|_{L^2(0,T;U)} \leq C_2, \tag{5.10}$$

where

$$y_n = y_n^1 + y_n^2, \quad y_n^1 \in R(\mathcal{A}_F), \quad y_n^2 \in N(\mathcal{A}_F^*).$$

Since $N(\mathcal{A}_F^*)$ is finite-dimensional, it follows by (5.10) and assumption (j)′ that$\{y_n^2\}$ is bounded in $C([0,T];H)$. Hence $\{y_n\}$ is bounded in $L^2(0,T;H)$, and therefore $\mathcal{A}_1^* y = f$ where y is a weak limit point of $\{y_n\}$ in $L^2(0,T;H)$. Hence equation (5.4) has at least one weak solution, and so the feedback controller (5.7) is well defined. Now, by (5.5) and (5.7), we get (5.3), thereby completing the proof.

Let us check hypothesis (j)′ in the case of control system (3.30), where $Bu = au$, $a \in C(\overline{\Omega})$. We shall assume also that a is not identically 0. If $p \in N(\mathcal{A}^*)$ and $B^*p = ap = 0$ a.e. in $Q = \Omega \times (0,T)$, then p is the solution to the parabolic boundary value problem

$$\begin{aligned} \frac{\partial p}{\partial t} + \Delta p + \operatorname{div}(bp) - cp = 0 \quad &\text{in } Q, \\ p = 0 \quad &\text{in } \partial\Omega \times (0,T). \end{aligned} \tag{5.11}$$

Then, by the unique continuation property of solutions to parabolic equations (see, e.g., [18]), we infer that $p \equiv 0$, and therefore hypothesis (j)′ is satisfied.

Coming back to the second example, delay control problems, we note that by (3.32) it follows that if

$$N(i\mu_m I + A_0^* + e^{-\mu_m ih}A_1^*) \cap N(B_0^*) = \{0\} \quad \forall m \in Z, \tag{5.12}$$

then hypothesis (j)′ holds. It should be mentioned, however, that the latter condition does not imply the stabilizability of the pair (A,B), as the following example shows:

$$x_1'(t) = x_1(t) + x_3(t-h), \quad x_2'(t) = x_2(t) + x_3(t), \quad x_3'(t) = u(t).$$

It is readily seen that condition (5.12) is satisfied, though the system is not stabilizable [13].

6. The optimal control of the wave equation. We shall study here the optimal control problem

$$\text{minimize} \quad \int_0^T (2^{-1}|Cy(t)|_Z^2 + h(u(t)))dt \tag{6.1}$$

subject to $u \in L^2(0,T;H), y \in L^2(0,T;U)$,

$$\begin{aligned} &y'' + Ay = Bu + f, \qquad t \in (0,T), \\ &y(0) = y(T), \qquad y'(0) = y'(T), \end{aligned} \tag{6.2}$$

where A is a self-adjoint, linear, and positively defined operator in H, $B \in L(U,H)$, $C \in L(H,Z)$, and h is a lower semicontinuous convex function on U. By *weak solution* to equation (6.2), we mean a function $y \in L^2(0,T;H)$ such that

$$\int_0^T (y(t), \varphi''(t) + A\varphi(t))dt = \int_0^T (f(t) + Bu(t), \varphi(t))dt, \tag{6.3}$$

for all $\varphi \in Y = \{\varphi \in C^2([0,T];H) \cap C([0,T];D(A));\ \varphi(0) = \varphi(T),\ \varphi'(0) = \varphi'(T)\}$. Equivalently,

$$\mathcal{W}y = Bu + f, \tag{6.2}'$$

where $\mathcal{W} : D(\mathcal{W}) \subset L^2(0,T;H) \to L^2(0,T;H)$ is the linear operator defined by

$$\mathcal{W}y = f \ \text{ iff } \ \int_0^T (y(t), \varphi''(t) + A\varphi(t))dt = \int_0^T (f(t), \varphi(t))dt \quad \forall \varphi \in Y. \tag{6.4}$$

It is readily seen that $\mathcal{W}$ is densely defined and closed in $L^2(0,T;H)$.

Writing equation (6.2) as a first-order differential equation on the product space $D(A^{\frac{1}{2}}) \times H$, we may apply the general results obtained in the previous section to problem (6.1). However, a direct treatment of such a problem requires less restrictive conditions in specific examples. On the other hand, for the sake of simplicity, we shall not put the results of this section in the general framework of the p-stabilizability condition; we shall confine ourselves to assuming that $R(\mathcal{W})$ is closed in $L^2(0,T;H)$. By virtue of the closed range theorem, this assumption implies that

$$L^2(0,T;H) = R(\mathcal{W}) \oplus N(\mathcal{W}); \quad \mathcal{W}^{-1} \in L(R(\mathcal{W}), L^2(0,T;H)).$$

Arguing as in the proof of Theorem 1, it follows that if $R(\mathcal{W})$ is closed in $L^2(0,T;H)$ and $N(\mathcal{W})$ is finite-dimensional, then problem (6.1) has at least one solution $(y,u) \in L^2(0,T;H) \times L^2(0,T;U)$. As regards the maximum principle, we have the following theorem.

THEOREM 7. *Assume that $R(\mathcal{W})$ is closed,* dim $N(\mathcal{W}) < \infty$, *and h, f satisfy hypotheses* (jj), (jjj). *Then the pair $(y^*, u^*) \in L^2(0,T;H) \times L^2(0,T;U)$ is optimal in problem* (6.1) *if and only if there is a $p \in L^2(0,T;H)$ such that*

$$\mathcal{W}p = -C^*Cy, \tag{6.5}$$

$$u^*(t) \in \partial h^*(B^*p(t)), \ \textit{a.e. } t \in (0,T). \tag{6.6}$$

We omit the proof because it is identical with that of Theorem 2. Since in most applications the null space $N(\mathcal{W})$ is infinite-dimensional (the state equation is highly resonant), we shall relax this condition as follows.

(k) $R(\mathcal{W})$ is closed and the operator $y \longrightarrow B^*y$ defined from $N(\mathcal{W})$ to $L^2(0,T;H)$ has closed range.

THEOREM 8. *Assume that hypotheses* (jj), (k) *hold, $f \in C([0,T];H)$, and h has quadratic growth, i.e.,*

$$h(u) \le \alpha_1 |u|_U^2 + \beta_1 \quad \forall u \in U. \tag{6.7}$$

Then the pair $(y^*, u^*) \in L^2(0,T;H) \times L^2(0,T;U)$ is optimal in problem (6.1) *if and only if it satisfies system* (6.5), (6.6).

Proof. Let $(y_\varepsilon, u_\varepsilon, v_\varepsilon)$ be the solution to the approximating problem (see (3.12))

$$\text{Min}\left\{\int_0^T (2^{-1}|Cy|_Z^2 + h(u) + 2^{-1}(|y-y^*|^2 + |u-u^*|_U^2 + \varepsilon^{-1}|v|^2))dt; \right.$$
$$\left. \mathcal{W}y = Bu + v + f \right\}.$$

As in the proof of Theorem 2, we get (3.13) and (see (3.15), (3.16))

$$\mathcal{W}p_\varepsilon = -C^*Cy_\varepsilon + y^* - y_\varepsilon, \tag{6.8}$$

$$B^*p_\varepsilon \in \partial h(u_\varepsilon) + u_\varepsilon - u^* \quad \text{a.e. in } (0,T). \tag{6.9}$$

By (6.7) and (6.8) we have

$$\|B^*p_\varepsilon\|^2_{L^2(0,T;U)} \le C_1 \quad \forall \varepsilon > 0,$$

and so, by virtue of assumption (k), we conclude via the closed range theorem that

$$\{p_\varepsilon^1 + p_\varepsilon^3\} \text{ is bounded in } L^2(0,T;H),$$

where

$$p_\varepsilon = p_\varepsilon^1 + p_\varepsilon^3 + p_\varepsilon^4$$

and $p_\varepsilon^1 \in R(\mathcal{W}), p_\varepsilon^3, p_\varepsilon^4 \in N(\mathcal{W})$, and $B^*p_\varepsilon^4 = 0$ a.e. $t \in (0,T)$. Hence we may pass to the limit in equations (6.8), (6.9) to get (6.5), (6.6), as desired.

The dual problem of (6.1) is (see (3.23), (3.24))

$$\text{Min}\left\{\int_0^T (g_*(v) + h^*(B^*p) + (f,p))dt; \mathcal{W}^*p = -v; v \in L^2(0,T;H)\right\}. \tag{6.10}$$

By using exactly the same argument, it follows that under the assumptions of Theorem 7 or 8, the conclusions of duality Theorem 3 remain valid in the present case.

Now we shall present two examples.

4. *The one-dimensional wave equation.* Consider the control system

$$\begin{aligned} &y_{tt}(x,t) - v^{-1}(x)(v(x)y_x(x,t))_x = Bu(x,t) + f(x,t), \\ &\qquad\qquad (x,t) \in (0,\pi)\times R, \\ &y(0,t) = y(\pi,t) = 0, \qquad\qquad t \in R, \\ &y(x,t+T) = y(x,t), \quad y_t(x,t+T) = y_t(x,t), \quad (x,t) \in (0,\pi)\times R, \end{aligned} \tag{6.11}$$

where $v \in H^2(0,T)$, $v(x) > 0 \ \ \forall x \in [0,\pi]$, $B \in L(L^2(0,\pi), L^2(0,\pi))$, and

$$\text{ess sup}\{(v'(x))^2 - 2v''(x)v(x);\ x \in (0,\pi)\} < 0.$$

In this case $U = L^2(0,\pi)$, $H = L^2(0,\pi)$ is endowed with the scalar product $(y,z) = \int_0^\pi v(x)y(x)z(x)dx$ and

$$Ay = -v^{-1}(vy_x)_x, \qquad D(A) = H_0^1(0,\pi) \cap H^2(0,\pi).$$

Equation (6.11) models the forced vibrations of a nonhomogeneous string as well as the propagation of waves in nonisotropic media. If T is a rational multiple of π then $R(\mathcal{W})$ is closed, $N(\mathcal{W})$ is finite-dimensional [6], and so Theorem 8 is applicable.

5. *The n-dimensional wave equation.* Consider the control system

$$\begin{aligned} &y_{tt} - \Delta y = a(x)u + f, \quad x \in \Omega, \quad t \in R, \\ &y = 0 \text{ in } \partial\Omega \times R; \\ &y(x, t+T) = y(x,t), \qquad y_t(x, t+T) = y_t(x,t), \end{aligned} \tag{6.12}$$

where $\Omega = (0,\pi)^n$, $a \in C(\overline{\Omega})$, $a \not\equiv 0$, $f \in C([0,T]; L^2(\Omega))$, and $f(x, t+T) \equiv f(x,t)$. We may write (6.12) in the form (6.2) where $H = L^2(\Omega)$, $A = -\Delta$, $D(A) = H_0^1(\Omega) \cap H^2(\Omega)$, and $Bu = au \ \forall u \in U = L^2(\Omega)$. If T is a rational multiple of π, then the corresponding operator $\mathcal{W} : L^2(Q) \longrightarrow L^2(Q)$, $Q = \Omega \times (0,T)$, has closed range. Here is the argument (see [14]). If

$$\mathcal{W}y = f; \qquad (y,f) \in L^2(Q) \times L^2(Q),$$

then

$$y = \sum_{m \in Z, k \in N^n} f_{mk}(\mu_m^2 - \lambda_k^2)^{-1} e^{i\mu_m t}\varphi_k, \tag{6.13}$$

where $\mu_m = 2m\pi T^{-1}$, $\lambda_k^2 = k_1^2 + k_2^2 + \cdots + k_n^2$, $k_i \in N$, are the eigenvalues of A and φ_k are the corresponding eigenfunctions; f_{mk} are the Fourier coefficients of f. If T is a rational multiple of π we have

$$\inf\{|\lambda_k^2 - \mu_m^2|; \lambda_k^2 = \mu_m^2\} > 0.$$

Then by (6.13) we see that there is a $y_1 \in L^2(Q)$ such that $\mathcal{W}y_1 = f$ and

$$\|y_1\|_{L^2(Q)} \leq C_1 \|f\|_{L^2(Q)} \quad \forall f \in L^2(Q).$$

This implies that $R(\mathcal{W})$ is closed in $L^2(Q)$.

One might suspect that assumption (k) is true in this case and so that Theorem 8 could be applied to the optimal control problem with dynamics (6.12) and payoff

$$2^{-1} \int_Q |Cy(x,t)|_Z^2 dxdt + \int_0^T h(u(t))dt$$

where $C \in L(L^2(\Omega), Z)$. In the special case $a = 1$ the maximum principle follows for general domains Ω, because if we write equation (6.12) under the form (1.2) on the product space $H_0^1(\Omega) \times L^2(\Omega)$, the corresponding pair (A,B) is stabilizable. For a general $a \in C(\overline{\Omega})$ this happens if the support of a has the optical geometric property [16], [12]. Note also that in the case $n = 1$ and $m \equiv 1$, the interiority condition in $(\text{jjj})_2$ can be weakened to a similar condition in $L^\infty(\Omega)$ [2], but the argument uses the special structure of $N(\mathcal{A})$.

We shall conclude this section with the boundary control version of problem (6.1), i.e.,

$$\text{Min}\left\{\int_0^T (2^{-1}|Cy(t)|_Z^2 + h(u(t)))dt; (y,u) \in L^2(0,T;H) \times L^2(0,T;U)\right\} \tag{6.14}$$

subject to

$$z'' + Az = Du + A^{-1}f; \quad z(0) = z(T), \quad z'(0) = z'(T); \quad y = Az. \tag{6.15}$$

Here A is a self-adjoint, positive definite operator on H, $f \in L^2(0,T;H)$, g, h, C are as above, and $D \in L(U,H)$ satisfies the following condition:

$$\int_0^T |B^*S(t)y|_U^2 dt \le C_3|y|^2 \quad \forall y \in H, \tag{6.16}$$

where $B^* = D^*A \in L(D(A),U)$ and $S(t)$ is the sine operator associated with A. In particular, condition (6.16) is verified by the wave equation with Dirichlet boundary input on a bounded open set Ω of R^n with smooth boundary (or if Ω is a parallelepiped) (see [11]). In this case $A = -\Delta$, $D(A) = H_0^1(\Omega) \cap H^2(\Omega)$, $U = H = L^2(\Omega)$, and $D \in L(U, L^2(\Omega))$ is defined as

$$\Delta Du = 0 \quad \text{in } \Omega; \qquad Du = B_0 u \quad \text{in } \partial\Omega, \tag{6.17}$$

where $B_0 \in L(U,U)$. Note also that if $R(\mathcal{W})$ is closed in $L^2(0,T;H)$, then by (6.16) it follows that

$$\|A\mathcal{W}^{-1}(Du + A^{-1}f)\|_{L^2(0,T;H)} \le C_4(\|u\|_{L^2(0,T;U)} + \|f\|_{L^2(0,T;H)}). \tag{6.18}$$

THEOREM 9. *Assume that condition* (6.16) *is satisfied. Then, under the assumptions of Theorems* 7 *and* 8 *with* B^* *defined as above, the pair* (y^*, u^*) *is optimal in problem* (6.14) *if and only if it satisfies system* (6.5), (6.6).

The proof is essentially the same as that of Theorems 2 and 8. We mention only that in this case one uses condition (6.16) and inequality (6.18) in order to pass to the limit in the corresponding approximating equations

$$\mathcal{W}p_\varepsilon = -C^*Cy_\varepsilon - y_\varepsilon + y^*,$$

$$B^*p_\varepsilon \in \partial h(u_\varepsilon) + u_\varepsilon - u^*.$$

BLACKWELL OPTIMALITY IN BORELIAN CONTINUOUS-IN-ACTION MARKOV DECISION PROCESSES*

ALEXANDER A. YUSHKEVICH†

Abstract. We prove the existence of stationary Blackwell optimal policies in Markov decision processes with a Borel state space, compact action sets, and continuous-in-action and bounded transition densities and rewards, satisfying a simultaneous Doeblin-type condition. The proof is based on a compactification of the randomized stationary policy space in a weak-strong topology, on the continuity of Laurent coefficients of the discounted rewards in this topology, and on a lexicographical policy improvement. Until now similar results were obtained for the models with a denumerable state space or with a Borel state space and finite action sets.

Key words. Markov decision process, Borel space, compact action sets, Blackwell optimality

1. Introduction.

In a Markov decision process (MDP) with finite state and action spaces, a Blackwell optimal policy is optimal for all discount factors $\beta < 1$ close to 1. This concept of optimality was introduced in a pioneering work by Blackwell [3]. In another basic work Veinott [29] has shown that Blackwell optimality is the limiting, most selective concept in an infinite series of sensitive criteria starting from the average optimality, and has developed the Laurent expansions technique for the analysis of sensitive criteria. Initially studied in MDPs with finite state and action spaces, sensitive criteria have since been explored in more general MDPs and in some renewal and continuous-time models. Other early contributions to this field are due to Chitashvili [6], [7] (see also his survey in [34]), Denardo [10], Denardo and Miller [11], Lippman [19], Miller and Veinott [20], Puterman [21], Rothblum [22], Sladký [25], [26], and Veinott [28].

Sensitive optimality in MDPs with a countable state space is treated in more recent works by Cavazos-Cadena and Lasserre [4], [5], Dekker and Hordijk [8], [9], Hordijk and Sladký [17], and Lasserre [18]. In the countable models, the definition of Blackwell optimality required a modification suggested in [8]: to get some kind of existence results, it appeared necessary to allow the interval $\beta_0 < \beta < 1$, where the optimal policy exceeds any other policy, to depend on that policy and on the initial state. In discrete-time models with a Borel state space, sensitive optimality began to be studied in our papers [31], [32]. For a more detailed survey and a discussion of the concept of Blackwell optimality we refer the reader to [8] and [31]. These two references are the closest to our work.

Dekker and Hordijk [8] studied the existence of Blackwell optimal policies in MDPs with a countable state space, compact action sets, and continuous-in-action transition probabilities and rewards; the rewards were allowed to be unbounded (or more precisely, unbounded, but bounded in the so-called μ-norms). To get the existence of Blackwell optimal policies in the class of deterministic stationary policies by lexicographically maximizing coefficients of the related Laurent series, they assumed

†Department of Mathematics, University of North Carolina at Charlotte, Charlotte, NC 28223 (fma00aay@unccvm.uncc.edu).

either a uniform geometric ergodicity of Markov chains generated by such policies or some substitutes for it directly in terms of those coefficients (in [9] a different uniform recurrence condition was used). They also introduced lexicographical analogues of the policy improvement and of the Bellman optimality equation, which they called the Blackwell optimality equation, and found an elegant way to prove that a policy Blackwell optimal within the class of stationary policies is Blackwell optimal in comparison with all other policies too. All of these ideas are utilized in the present work, with substantial changes due to a more general state space and a different structure of the transition law. However, our approach is limited to the case of bounded rewards, and we do not use the concept of μ-norms.

Progress toward Blackwell optimality in the case of a Borel state space became possible in models with transition densities (instead of more general transition functions). In contrast to noncontrolled Markov chains, the transition densities are rarely used in the theory of MDPs. A paper by Georgin [14] on the discounted and average optimality is an exception, and our assumptions are essentially the same as some of Georgin's hypotheses.

In [31] we proved the existence of Blackwell optimal policies in the case of a Borel state space, a countable action space, and finite action sets. In the present work we extend this result to the case of compact action sets (in a topological Borel space). As in [31], we suppose that the transition density and the reward function are bounded and assume that the transition density satisfies a simultaneous Doeblin-type condition, which guarantees uniform geometric convergence of the multistep transition densities of the involved Markov chains, and therefore a uniform convergence of the Laurent series for the discounted rewards. This condition is simple but restrictive; it means the existence of a minorant in the case of transition densities. For the place of this condition in the variety of recurrence conditions considered in different works on the Borel state MDPs, see Hernández-Lerma, Montes-de-Oca, and Cavazos-Cadena [15]. Similar to works on MDPs with a countable state space, we require the continuity-in-action of transition densities and rewards. But in contrast to [8], where the maximization of Laurent coefficients is performed directly for every initial state in the class of deterministic stationary policies, we have to work with the wider class of randomized stationary policies and with an absolutely continuous initial distribution. We proceed in this way because the space of deterministic stationary policies does not allow a suitable compactification, and in the compactified space of randomized policies each policy is determined only up to a set of measure 0 in the state space.

An essential novelty with respect to [31] is the utilization of a weak-strong topology for the above compactification. This topology, in a more general context of nonstationary dynamic programming, was studied by Schäl [23], [24] and Balder [1]; a different approach for our specific case is given in [33]. The transition from a randomized stationary policy maximizing the Laurent coefficients for an absolutely continuous initial distribution to a deterministic stationary policy maximizing them for each initial state is made by lexicographical policy improvement. The related measurability matters are resolved by means of the Novikov–Kunigui theorem. The proof that a Blackwell optimal policy within the class of stationary policies is at the same time Blackwell optimal in the class of all policies is a combination of a similar proof in [8] with a compactness result in the weak-strong topology.

The paper is organized in the following way. In section 2 we introduce the terminology and notations and formulate the definitions, assumptions, and necessary measurability results. In section 3 we obtain the Laurent expansions of the expected

discounted rewards for stationary policies, define a space $\mathcal{H}$ of sequences H which contains all sequences of the corresponding Laurent coefficients, and introduce operators L^σ on the space $\mathcal{H}$ associated with stationary policies σ and used afterwards for the policy improvement. In section 4 we define the lexicographical ordering in $\mathcal{H}$ and prove a key comparison lemma for the operators L^σ. As a consequence we get the lexicographical policy improvement, the Blackwell optimality equation $H = TH$ where $T = \operatorname{Lexmax}_\sigma L^\sigma$ is the lexicographical Bellman operator, and the necessary and sufficient conserving condition of optimality. In section 5 we aggregate the space Σ of all stationary policies into a space S of measures which is compact in the weak-strong topology, and prove another key result stating that for absolutely continuous initial distributions the Laurent coefficients are continuous functions on S. In section 6 we prove the existence of a deterministic stationary maximizer φ for the equation $H = TH$, so that φ is Blackwell optimal within the class of stationary policies. It follows that the equation $H = TH$ has a unique solution in $\mathcal{H}$. In section 7 we prove that φ is optimal in the class of all policies. Section 8 contains examples. In section 9 we discuss our assumptions and some open problems, in particular, problems related to the concept of strong Blackwell optimality.

Instead of numerous references to [31] with indications of alterations in the proofs, we give here a self-contained and more readable exposition. However, when closely following some proof in [31], we first focus on its idea and omit secondary technicalities, which can be easily reproduced by the reader.

2. Definitions and assumptions. We start by detailing the notations and terminology. In a space M, let $\mathcal{O}_M$ and $\mathcal{B}_M$ denote, respectively, the systems of all open and all measurable sets (if there are any). It is supposed that in a Polish (i.e., complete separable metric) space M the system $\mathcal{O}_M$ is generated by the metric and the system $\mathcal{B}_M$ is generated by $\mathcal{O}_M$. Any Borel set B in a Polish space M (i.e., a set $B \in \mathcal{B}_M$) is considered as a topological space $(B, \mathcal{O}_B)$ with $\mathcal{O}_B = B \cap \mathcal{O}_M$ and as a measurable space with $\mathcal{B}_B = B \cap \mathcal{B}_M$. By a *Borel space* (i.e., standard Borel space) we understand, as usual, an isomorphic image of $(B, \mathcal{B}_B)$, where B is a Borel set in a Polish space. By a *topological Borel space* we understand a homeomorphic image of $(B, \mathcal{O}_B)$, where B is a Borel set in a Polish space. Every topological Borel space E is also considered a Borel space with $\mathcal{B}_E$ generated by $\mathcal{O}_E$. The term "compactness" means everywhere the sequential compactness (in a topological Borel space, these two concepts are equivalent). In a Borel space E, $B(E)$ is the set of all bounded measurable (with respect to $\mathcal{B}_E$) real-valued functions, and $\|\cdot\|$ denotes the corresponding supremum norm. Given two Borel spaces X and A, $\mathcal{B}_{X\times A} = \mathcal{B}_X \times \mathcal{B}_A$. In this case $\mathcal{B}_K = K \cap \mathcal{B}_{X\times A}$ for every $K \in \mathcal{B}_{X\times A}$, and if in addition A is a topological Borel space, then $\operatorname{Car}(K)$ denotes the set of all *Carathéodory functions* on K, i.e., functions $f \in B(K)$ which are continuous in the second coordinate a at every point $(x, a) \in K$, $x \in X$, $a \in A$.

An *MDP* is defined by a state space X, an action space A, action sets A_x, a transition function $P(x, a, B)$, and a reward function $r(x, a)$ ($x \in X$, $a \in A_x \subset A$, $B \in \mathcal{B}_X$). The components of MDP have the following meaning. At each of the time epochs $t = 0, 1, 2, \ldots$ a controller observes the state $x_t \in X$ of the process and selects an action $a_{t+1} \in A_{x_t}$ on the basis of this and the previous information . The selection of a_{t+1} determines the immediate reward $r(x_t, a_{t+1})$ of the controller and the distribution $P(x_t, a_{t+1}, \cdot)$ of the next state x_{t+1}. The aim of the controller is to maximize the expectation of the total discounted reward $r(x_0, a_1) + \beta r(x_1, a_2) + \beta^2 r(x_2, a_3) + \cdots$ for the values of the discount factor $\beta < 1$ arbitrary close to 1.

The following assumptions are supposed throughout the paper.

Assumption 2.1 (measurability and compactness). X is a Borel space, A is a topological Borel space, all A_x are nonempty compact subsets of A, and

$$K = \{(x,a) : a \in A_x, x \in X\} \in \mathcal{B}_{X\times A}.$$

Assumption 2.2 (existence of a bounded continuous transition density). For every $x \in X$, $a \in A_x$, and $B \in \mathcal{B}_X$

$$P(x,a,B) = \int_B p(x,a,y)m(dy),$$

where m is a given probability measure on X (a reference measure), and the function $p \in B(K \times X)$ is nonnegative, continuous in $a \in A_x$ for every pair $(x,y) \in X \times X$, and such that $P(x,a,X) = 1$ for all $(x,a) \in K$.

Assumption 2.3 (simultaneous Doeblin-type condition). There exist a number δ and a set $D \in \mathcal{B}_X$ with $0 < \delta m(D) < 1$ such that

$$p(x,a,y) \geq \delta \text{ for all } (x,a) \in K,\ y \in D. \tag{2.1}$$

Assumption 2.4 (continuity and boundedness of the reward function). $r \in \mathrm{Car}(K)$.

The policies are defined as usual in dynamic programming; our notations are closer to those in [13]. A *deterministic stationary policy*, or *selector*, is a measurable map φ from X to A with its graph in the set K; under such a policy the actions are selected by a rule $a_{t+1} = \varphi(x_t)$, $t = 0,1,\dots$. A *stationary* (i.e., randomized stationary) *policy* is a stochastic kernel σ from X to A (i.e., a function $\sigma(x,C)$, $x \in X$, $C \in \mathcal{B}_A$ measurable in x and such that $\sigma(x,\cdot)$ is a probability measure on A), satisfying the constraints $\sigma(x,A_x) = 1$, $x \in X$. Under such a policy each a_{t+1} is selected by random with a (conditional) distribution $\sigma(x_t,\cdot)$. A *Markov policy* is a sequence $\mu = \{\sigma_1,\sigma_2,\dots\}$ of stationary policies σ_t; under this policy the action a_{t+1} has a (conditional) distribution $\sigma_t(x_t,\cdot)$. Finally, under an *arbitrary policy* π the distribution of a_{t+1} depends on the whole history $x_0a_1x_1a_2\dots x_t$ (we omit a formal definition of π since it is not used in the paper). The sets of all selectors, stationary policies, Markov policies, and arbitrary policies are denoted, respectively, by $\Phi \subset \Sigma \subset \mathrm{M} \subset \Pi$. These sets are nonempty in accordance with the following general measurability and selection result, also utilized in the following.

PROPOSITION 2.5. *Under Assumption* 2.1

(i) *there exists a measurable map φ from X to A such that $\varphi(x) \in A_x, x \in X$;*

(ii) *for every $f \in \mathrm{Car}(K)$ and every $x \in X$ there exists $\hat{f}(x) = \max_{a\in A_x} f(x,a)$, and $\hat{f} \in B(X)$.*

See, for example, [16, pp. 391–392, Theorems 2 and 3] (where only the upper semicontinuity of $f(x,\cdot)$ is assumed).

To every initial state $x \in X$ and policy $\pi \in \Pi$ there corresponds a probability distribution $\mathbf{P}_x^\pi$ in the space of all infinite-horizon trajectories $x_0a_1x_1a_2\dots$, defined by the formulas

$$\begin{aligned}
&\mathbf{P}_x^\pi\{x_0 = x\} = 1,\\
&\mathbf{P}_x^\pi\{a_{t+1} \in C \mid x_0a_1\dots x_t\} = \pi(C \mid x_0a_1\dots x_t),\\
&\mathbf{P}_x^\pi\{x_{t+1} \in B \mid x_0a_1\dots x_ta_{t+1}\} = P(x_t,a_{t+1},B).
\end{aligned}$$

The corresponding expectation is denoted by $\mathbf{E}_x^\pi$. Since r is bounded (Assumption 2.4), the *expected total discounted reward*

$$v_\beta(x,\pi) = \mathbf{E}_x^\pi \sum_{t=0}^{\infty} \beta^t r(x_t, a_{t+1}) \tag{2.2}$$

is well defined for every initial state $x \in X$, policy $\pi \in \Pi$, and discount factor $0 < \beta < 1$. The corresponding *value function* is defined by

$$v_\beta(x) = \sup_{\pi\in\Pi} v_\beta(x,\pi),\ x \in X.$$

According to the original definition due to Blackwell, a policy π^* is optimal if there exists a number β_0 such that

$$v_\beta(x,\pi^*) = v_\beta(x) \ \text{ for all } \ x \in X,\ \beta_0 < \beta < 1. \tag{2.3}$$

This definition worked well in the case of finite spaces X and A. We do not know any existence results for Blackwell optimal policies in the sense (2.3) in MDPs with infinite X and A. Following Dekker and Hordijk [8, p. 399], we will use a weaker definition, in which π^* is compared separately with each other policy π, and β_0 may depend on x and π.

DEFINITION 2.6. *For a set $\Pi' \subset \Pi$, a policy $\pi^* \in \Pi'$ is said to be Blackwell optimal within the class Π', if for every $x \in X$ and every $\pi \in \Pi'$ there exists a number $\beta_0(x,\pi) < 1$ such that*

$$v_\beta(x,\pi^*) \geq v_\beta(x,\pi) \text{ for all } \ \beta_0(x,\pi) < \beta < 1. \tag{2.4}$$

If $\Pi' = \Pi$ then π^* is said to be Blackwell optimal.

In the case when (2.3) holds, i.e., when in (2.4) one may take $\beta_0 < 1$ independent of x and π, the policy π^* is called *strong Blackwell optimal*. It is an easy exercise to show that if X is finite and if there exists a strong Blackwell optimal policy, then every Blackwell optimal policy is strong Blackwell optimal. The existence of deterministic stationary strong Blackwell optimal policies in MDPs with finite state and action spaces was proved by Blackwell [3]. Therefore, in this case, the two concepts of Blackwell optimality coincide.

3. Laurent series and operators related to stationary policies. As in previous works on sensitive optimality, starting from the original paper by Veinott [29], our analysis is based on the Laurent series for discounted rewards in terms of a small parameter as β approaches 1. Following Chitashvili (see Yushkevich and Chitashvili [34]), we take for such a parameter the variable

$$\alpha = 1 - \beta, \qquad 0 < \alpha < 1.$$

In Veinott [29] and most of the subsequent works, the interest rate $\rho = \frac{1-\beta}{\beta}$ is used for this purpose. The expansion formulas in terms of α and ρ are essentially the same, so that the content of this section is mostly standard. However, in contrast to Dekker and Hordijk [8], we need the Laurent expansions for all stationary policies, not only the deterministic ones.

In the case of a stationary policy σ, the sequence $x_0x_1x_2\ldots$ of the observed states is a Markov chain with a transition function

$$Q^\sigma(x,B) = \int_A P(x,a,B)\sigma(x,da) = \int_B q^\sigma(x,y)m(dy), \quad x \in X, \quad B \in \mathcal{B}_X$$

where

$$q^\sigma(x,y)=\int_{A_x} p(x,a,y)\sigma(x,da),\qquad x,y\in X; \tag{3.1}$$

this follows from the structure of $\mathbf{P}_x^\pi$ in the case of $\pi=\sigma\in\Sigma$ and from Assumption 2.2. Moreover, $0\le q^\sigma\le\|p\|$, and as follows from Assumption 2.3 and (3.1),

$$q^\sigma(x,y)\ge\delta \ \text{ for all } \ x\in X,\ y\in D. \tag{3.2}$$

The one-step and multistep transition densities of a Markov chain in general are not unique. We will use their versions uniquely determined by the recurrence relation

$$q_t^\sigma(x,y)=\int_X q_{t-1}^\sigma(x,z)q^\sigma(z,y)m(dz), \tag{3.3}$$

$x,y\in X$, $t=2,3,\dots$, with $q_1^\sigma=q^\sigma$. In these notations

$$\mathbf{P}_x^\sigma\{x_t\in B\}=\int_B q_t^\sigma(x,y)m(dy),\quad x\in X,\quad B\in\mathcal{B}_X. \tag{3.4}$$

For a stationary policy σ also define $r^\sigma\in B(X)$ by

$$r^\sigma(x)=\int_{A_x} r(x,a)\sigma(x,da),\quad x\in X;\qquad \|\,r^\sigma\|\le\|\,r\|. \tag{3.5}$$

Then by the structure of $\mathbf{P}_x^\sigma$ we have $\mathbf{E}_x^\sigma[r(x_t,a_{t+1})\mid x_0a_1\dots x_t]=r^\sigma(x_t)$, so that in view of (3.4) the definition (2.2) of the discounted reward reduces to

$$v_\beta(x,\sigma)=\mathbf{E}_x^\sigma\sum_{t=0}^\infty\beta^t r^\sigma(x_t)=r^\sigma(x)+\sum_{t=1}^\infty\beta^t\int_X q_t^\sigma(x,y)r^\sigma(y)m(dy). \tag{3.6}$$

The condition (3.2) is a special case of the general Doeblin condition for Markov chains considered in Doob [12] (p. 197, Case (b), and pp. 216–217, Examples 2, 3 (continued)). It is proved there that this condition implies a uniform geometric convergence of the density $q_t^\sigma(x,y)$ to a limit $\bar q^\sigma(y)$ as $t\to\infty$, where $\bar q^\sigma(y)$ is a version of the density of the unique stationary distribution of the corresponding Markov chain. Namely,

$$|\,q_t^\sigma(x,y)-q^\sigma(y)\,|\le 2\,\|\,p\|\rho^{t-2},\quad x,y\in X,\quad t=1,2,\dots,\ \sigma\in\Sigma \tag{3.7}$$

where

$$0<\rho=1-\delta m(D)<1.$$

(Formally, to apply Doob's result to our case, one should multiply m and divide q^σ and δ by $\|p\|$.) It follows that there exists a bounded *deviation density*

$$z^\sigma(x,y)=\sum_{t=1}^\infty[q_t^\sigma(x,y)-\bar q^\sigma(y)],\ x,y\in X;\qquad \|z^\sigma\|\le\frac{2\|p\|}{\rho(1-\rho)}. \tag{3.8}$$

Next consider the limit of the expected one-step reward corresponding to σ (the average expected reward known in MDPs):

$$g^\sigma=\lim_{t\to\infty}\int_X q_t^\sigma(x,y)r^\sigma(y)m(dy)=\int_X\bar q^\sigma(y)r^\sigma(y)m(dy);\qquad |\,g^\sigma\,|\le\|r\|, \tag{3.9}$$

and subtract termwise the identity

$$\frac{g^\sigma}{\alpha} = (1+\beta+\beta^2+\cdots)g^\sigma = g^\sigma + \sum_{t=1}^{\infty}\beta^t \int_X \bar{q}^\sigma(y) r^\sigma(y) m(dy)$$

from (3.6). This leads to a relation

$$v_\beta(x,\sigma) - \frac{g^\sigma}{\alpha} = r^\sigma(x) - g^\sigma + \sum_{t=1}^{\infty}\beta^t \int_X [q_t^\sigma(x,y) - \bar{q}^\sigma(y)] r^\sigma(y) m(dy). \tag{3.10}$$

In view of the bounds in (3.5) and (3.7), the integral factor at β^t in (3.10) is majorized by $c\rho^t$ with $c = 2\|r\| \cdot \|p\|\rho^{-2}$. Therefore the power series in (3.10), as a function of a complex variable β, is analytic in the circle C_1 of radius $R_1 = \frac{1}{\rho}$ centered at 0. Consider another circle C_2: $|\beta - 1| < 1-\rho$ centered at 1 and of radius $R_2 = 1-\rho$. Since $\rho < 1$, we have $R_2 = 1-\rho < \frac{1-\rho}{\rho} = \frac{1}{\rho} - 1 < R_1 - 1$, so that $C_2 \subset C_1$. Therefore the right side of (3.10) is analytic in C_2 too, and can be expanded into a converging series in powers of $\beta - 1 = \alpha$ with a radius of convergence $\geq 1-\rho$. Thus from (3.10) we get a Laurent expansion

$$v_\beta(x,\sigma) = \frac{g^\sigma}{\alpha} + \sum_{n=0}^{\infty} h_n^\sigma(x)\alpha^n = \sum_{n=-1}^{\infty} h_n^\sigma(x)\alpha^n, \quad x \in X, \quad 0 < \alpha < 1-\rho. \tag{3.11}$$

By substituting $\beta = 1-\alpha$ into (3.10) and applying the binomial formula, one may express the coefficients h_n^σ in a form of uniformly convergent series containing integrals of q_t^σ, $\bar{q}^\sigma$, and r^σ, and see that $h_n^\sigma \in B(X)$, $n \geq -1$.

More useful formulas for h_n^σ are obtained by a substitution of the series (3.11) into the equation

$$v_\beta(x,\sigma) = r^\sigma(x) + (1-\alpha)\int_X q^\sigma(x,y) v_\beta(y,\sigma) m(dy), \qquad x \in X, \tag{3.12}$$

which is an immediate consequence of (3.3) and (3.6). The calculations are standard, and we briefly outline the main steps, leaving the details to the reader (they may be found also in [31, pp. 264–266]).

At this point it is convenient to introduce the operator notations. The relations

$$\begin{aligned} Q^\sigma f(x) &= \int_X q^\sigma(x,y) f(y) m(dy), \qquad \bar{Q}^\sigma f(x) = \int_X \bar{q}^\sigma(y) f(y) m(dy), \\ Z^\sigma f(x) &= \int_X z^\sigma(x,y) f(y) m(dy), \qquad x \in X \end{aligned} \tag{3.13}$$

define the (evidently bounded) operators Q^σ, $\bar{Q}^\sigma$, and Z^σ on the space $B(X)$. In view of (3.7), $(Q^\sigma)^t \to \bar{Q}^\sigma$ as $t \to \infty$. Also let I be the identity operator, and let $v_\beta^\sigma = v_\beta(\cdot,\sigma)$. In these notations the equation (3.12) becomes

$$v_\beta^\sigma = r^\sigma + (1-\alpha)Q^\sigma v_\beta^\sigma, \tag{3.14}$$

and (3.6) simplifies to

$$v_\beta^\sigma = \left[I + \sum_{t=1}^{\infty}(\beta Q^\sigma)^t\right] r^\sigma = \sum_{t=0}^{\infty}(\beta Q^\sigma)^t r^\sigma. \tag{3.15}$$

A substitution of (3.11) into (3.14) yields an identity

$$\frac{g^\sigma}{\alpha} + h_0^\sigma + h_1^\sigma\alpha + \cdots = r^\sigma + (1-\alpha)\left(\frac{Q^\sigma g^\sigma}{\alpha} + Q^\sigma h_0^\sigma + Q^\sigma h_1^\sigma\alpha + \cdots\right)$$

valid for $0 < \alpha < 1-\rho$. In view of the uniqueness of the Laurent coefficients, it follows that

$$g^\sigma = Q^\sigma g^\sigma;\ h_0^\sigma = r^\sigma + Q^\sigma(h_0^\sigma - g^\sigma);\ h_n^\sigma = Q^\sigma(h_n^\sigma - h_{n-1}^\sigma), n = 1, 2, \ldots . \tag{3.16}$$

These equations are solved with the help of relations

$$\bar{Q}^\sigma Q^\sigma = \bar{Q}^\sigma, \tag{3.17}$$

$$(I + Z^\sigma)(I - Q^\sigma) = I - \bar{Q}^\sigma, \tag{3.18}$$

$$(I + Z^\sigma)Q^\sigma = Z^\sigma + \bar{Q}^\sigma, \tag{3.19}$$

known in the theory of Markov chains and implied by the geometric convergence $(Q^\sigma)^t \to \bar{Q}^\sigma$ obtained in (3.7) (see, for example, [31, p. 264]). By iterating the first equation in (3.16), we get $g^\sigma = (Q^\sigma)^t g^\sigma$, and in the limit, $g^\sigma = \bar{Q}^\sigma g^\sigma$. Next, multiplying the second equation by $\bar{Q}^\sigma$ and utilizing (3.17), we obtain $\bar{Q}^\sigma h_0^\sigma = \bar{Q}^\sigma r^\sigma + \bar{Q}^\sigma h_0^\sigma - \bar{Q}^\sigma g^\sigma$, so that $g^\sigma = \bar{Q}^\sigma r^\sigma$ (as in (3.9)).

This same multiplication applied to the third equation in (3.16) shows that $\bar{Q}^\sigma h_{n-1}^\sigma = 0$ for $n \geq 1$. In particular, $\bar{Q}^\sigma h_0^\sigma = 0$. Multiplying the second equation by $I + Z^\sigma$ we get $(I + Z^\sigma)(I - Q^\sigma)h_0^\sigma = (I + Z^\sigma)(r^\sigma - Q^\sigma g^\sigma)$ or, in view of (3.18) and since $\bar{Q}^\sigma h_0^\sigma = 0$, $h_0^\sigma = (I + Z^\sigma)(r^\sigma - Q^\sigma g^\sigma)$. Here $Q^\sigma g^\sigma = g^\sigma$ is a constant, and therefore $Z^\sigma Q^\sigma g^\sigma = 0$. Hence $h_0^\sigma = (I + Z^\sigma)r^\sigma - g^\sigma$.

In a similar way, the third equation $h_n^\sigma = Q^\sigma(h_n^\sigma - h_{n-1}^\sigma)$, being multiplied by $I + Z^\sigma$, with the help of (3.19) and the relation $\bar{Q}^\sigma h_{n-1}^\sigma = 0$, is finally transformed into $h_n^\sigma = -Z^\sigma h_{n-1}^\sigma$, $n \geq 1$. Summarizing and taking into account the bounds in (3.5), (3.8), and (3.9), we have the following results.

LEMMA 3.1. *For every policy $\sigma \in \Sigma$, the expected discounted reward v_β^σ expands into the Laurent series* (3.11) *with the coefficients*

$$g^\sigma = h_{-1} = \bar{Q}^\sigma r^\sigma, \qquad \|g^\sigma\| \leq \|r\|;$$

$$h_n^\sigma = (-Z^\sigma)^n(r^\sigma + Z^\sigma r^\sigma - g^\sigma),\ \|h_n^\sigma\| \leq (2+\kappa)\kappa^n,\ \kappa = \frac{2\|p\|}{\rho(1-\rho)},\ n \geq 0. \tag{3.20}$$

These coefficients belong to $B(X)$ and are uniquely determined by the equations (3.16).

Notice that $\|p\| \geq 1$ since $\int_X p(x,a,y)m(dx) = 1$ and $m(X) = 1$. Therefore, for the constant κ in (3.20), we have

$$\frac{1}{\kappa} \leq \frac{\rho(1-\rho)}{2} < 1 - \rho.$$

The above results suggest two definitions. In the first of them we specify a vector space $\mathcal{H}$ such that all possible sequences of the Laurent coefficients of $v_\beta(x,\sigma)$ belong to $\mathcal{H}$, and we introduce some notations.

DEFINITION 3.2.

(i) *The space $\mathcal{H}$ consists of all sequences $H = \{h_n\}$ of functions $h_n \in B(X)$, $n = -1, 0, 1, \ldots$, satisfying the following two conditions:* 1) *h_{-1} is a constant (often denoted by g),* 2) *for every $H \in \mathcal{H}$ there exists a constant $C(H)$ such that $\|h_n\| \leq C(H)\kappa^n$, where κ is defined in* (3.20).

(ii) *With every $H \in \mathcal{H}$ we associate a function $V_\beta(x; H)$ defined by the relation*

$$V_\beta(x; H) = \sum_{n=-1}^{\infty} h_n(x)\alpha^n, \quad x \in X, \quad 0 < \alpha = 1 - \beta < \frac{1}{\kappa}. \tag{3.21}$$

(iii) *If for a policy $\pi \in \Pi$ there exists an (evidently unique) element $H \in \mathcal{H}$ such that $V_\beta(x; H) = v_\beta(x, \pi)$, $0 < 1 - \beta < \frac{1}{\kappa}$, then this element is denoted $H^\pi = \{h_n^\pi\}$.*

The second definition relates with every stationary policy σ an operator L^σ on the space $\mathcal{H}$ such that, similar to (3.14),

$$V_\beta(x; L^\sigma H) = r^\sigma(x) + \beta Q^\sigma V_\beta(x; H), \qquad H \in \mathcal{H}. \tag{3.22}$$

In the same way as we obtained (3.16) from (3.14), we come to the following definition.

DEFINITION 3.3. *The operator $L^\sigma, \sigma \in \Sigma$, transforms every $H = \{h_n\} \in \mathcal{H}$ into $H' = \{h'_n\} \in \mathcal{H}$ according to the formulas*

$$g' = g; \quad h'_0 = r^\sigma + Q^\sigma(h_0 - g); \quad h'_n = Q^\sigma(h_n - h_{n-1}), \quad n \geq 1 \tag{3.23}$$

(since $\|Q^\sigma\| = 1$, $H' \in \mathcal{H}$ together with H).

In these notations we have the following evident consequence of Lemma 3.1.

COROLLARY 3.4. *For every $\sigma \in \Sigma$, H^σ is the unique solution in $\mathcal{H}$ of the equation*

$$L^\sigma H = H.$$

4. Lexicographical policy improvement and Blackwell optimality equation. In this section we obtain lexicographical analogues of the policy improvement and of the Bellman optimality equation, known in dynamic programming. These two concepts are closely related: the optimality equation means that it is impossible to improve.

Similar to Definitions 3.2 and 3.3, we will denote throughout the paper by $\{b_n\}$, $\{f_n\}$, etc., sequences of real numbers or of functions on the same space E indexed by $n = -1, 0, 1, 2, \dots$; the sequence as a whole will be denoted by the same capital letter. In particular, instead of $\{0, 0, \dots\}$ we may write 0. For two numerical sequences B and B', the notation $B \prec B'$ (or $B' \succ B$) means that either $b_{-1} < b'_{-1}$ or, for some index $N \geq 0$, $b_n = b'_n$ for all $n < N$, while $b_N < b'_N$. The notations $B \preceq B'$ and $B' \succeq B$ are self-evident. For a family $\{B^\gamma\}$ of numerical sequences depending on a parameter $\gamma \in \Gamma$, the notation $B = \operatorname{Lexmax}_{\gamma\in\Gamma} B^\gamma$ means that $B \succeq B^\gamma$ for all $\gamma \in \Gamma$, and $B = B^\gamma$ for at least one $\gamma \in \Gamma$.

In the case of functions on a space E, the notation $F \preceq F'$ (or $F' \succeq F$) means that $F(x) \preceq F'(x)$ for all $x \in E$. An integral of $F = \{f_n\}$ is understood termwise. Elementary properties of this partial ordering will be used without stating them explicitly. We formulate only the following less evident one.

PROPOSITION 4.1. *Let E be a Borel space with a finite measure ν. If $F = \{f_n\} \preceq F' = \{f'_n\}$, where $f_n, f'_n \in B(E)$, then*

$$\int_E F(x)\nu(dx) \preceq \int_E F'(x)\nu(dx);$$

if in addition $\nu\{x \in E : F(x) \prec F'(x)\} > 0$, then the same holds with the sign "$\prec$".

Proof. Consider $N = \{\min n : \nu\{x : f_n(x) \neq f'_n(x)\} > 0\}$. □

The following comparison lemma is a key one.

LEMMA 4.2. *If $L^\sigma H \succeq H$ for some $\sigma \in \Sigma$ and $H \in \mathcal{H}$, then $H^\sigma \succeq H$. If in addition $L^\sigma H(x_0) \succ H(x_0)$ at some $x_0 \in X$, then $H^\sigma(x_0) \succ H(x_0)$. Similar results are valid with the opposite inequality signs. If $L^\sigma H = H$ then $H^\sigma = H$.*

Proof. To prove the first statement, it is sufficient to show that for an arbitrary fixed $x \in X$ we have $v_\beta(x,\sigma) \geq V_\beta(x;H)$ for β sufficiently close to 1 (see (3.11) and (3.21)). Since $V_\beta(H)$ is linear in H, from (3.22) we have

$$r^\sigma - V_\beta(H) + \beta Q^\sigma V_\beta(H) = V_\beta(L^\sigma H - H).$$

To each term of this relation we apply the (geometrically convergent) operator $I + \beta Q^\sigma + (\beta Q^\sigma)^2 + \cdots$. Then the term r^σ transforms into v_β^σ in accordance with (3.15). The next two terms transform into $-(I + \beta Q^\sigma + (\beta Q^\sigma)^2 + \cdots)(I - \beta Q^\sigma)V_\beta(H) = -V_\beta(H)$, so that we get

$$v_\beta^\sigma - V_\beta(H) = \sum_{t=0}^{\infty} (\beta Q^\sigma)^t V_\beta(L^\sigma H - H).$$

Since $1 + \beta + \beta^2 + \cdots = \frac{1}{\alpha}$ and $Z^\sigma = \sum_1^\infty [(Q^\sigma)^t - \bar{Q}^\sigma]$ (see (3.8)), the operator on the right side can be transformed into

$$\begin{aligned}\sum_0^\infty (\beta Q^\sigma)^t &= \frac{\bar{Q}^\sigma}{\alpha} + \sum_0^\infty \beta^t [(Q^\sigma)^t - \bar{Q}^\sigma] \\ &= \frac{\bar{Q}^\sigma}{\alpha} + (I - \bar{Q}^\sigma) + Z^\sigma + \sum_1^\infty (\beta^t - 1)[(Q^\sigma)^t - \bar{Q}^\sigma].\end{aligned}$$

In terms of densities, we obtain in that way

$$v_\beta(x,\sigma) - V_\beta(x;H) = V_\beta(x; L^\sigma H - H) + \int_X u(\alpha,x,y) V_\beta(y; L^\sigma H - H) m(dy), \tag{4.1}$$

where

$$u(\alpha,x,y) = \frac{\bar{q}^\sigma(y)}{\alpha} - \bar{q}^\sigma(y) + z^\sigma(x,y) + \sum_{t=1}^\infty (\beta^t - 1)[q_t^\sigma(x,y) - \bar{q}^\sigma(y)]. \tag{4.2}$$

Since $L^\sigma H - H \succeq 0$, the first term at the right side of (4.1) is nonnegative for positive α close enough to 0, so that it remains to prove that the integral in (4.1) becomes nonnegative as $\alpha \downarrow 0$.

For this purpose consider the Laurent series for $V_\beta^\sigma(y; L^\sigma H - H)$:

$$V_\beta(y; L^\sigma H - H) = \sum_{n=-1}^\infty l_n(y)\alpha^n, \quad y \in X, \quad 0 < \alpha < \frac{1}{\kappa}.$$

In accordance with Definitions 3.2 and 3.3, here $\{l_n\} \in \mathcal{H}$, so that $\|l_n\| \leq C\kappa^n$ for some constant C, and $l_{-1} = 0$. Since $L^\sigma H - H \succeq 0$, we may define disjoint sets $Y_n, n = 0, 1, 2, \ldots$ in either of the following two ways:

$$\begin{aligned}Y_n &= \{y \in X : \ l_0(y) = l_1(y) = \cdots = l_{n-1}(y) = 0, l_n(y) \neq 0\} \\ &= \{y \in X : \ l_0(y) = l_1(y) = \cdots = l_{n-1}(y) = 0, l_n(y) > 0\}.\end{aligned}$$

Consider also the sets

$$X_1 = \{y \in X :\ \bar{q}^\sigma(y) > 0\},$$
$$X_2 = X_2(x) = \{y \in X :\ \bar{q}^\sigma(y) = 0,\ z^\sigma(x,y) > 0\}.$$

By (3.1) and (3.3), the transition densities $q_t^\sigma(x,y)$ are nonnegative. Therefore, if $\bar{q}^\sigma(y) = 0$ for some $y \in X$, then $z^\sigma(x,y) = \sum_1^\infty q^\sigma(x,y) \geq 0$ for the same y; and if also $z^\sigma(x,y) = 0$, then $u(\alpha,x,y) = 0$ (see (4.2)). Hence the integral in (4.1) splits into a sum of integrals over X_1 and X_2, where

$$u(\alpha,x,y) = \begin{cases} \frac{\bar{q}^\sigma(y)}{\alpha} + O(1),\ \bar{q}^\sigma(y) > 0 & \text{if } y \in X_1, \\ z^\sigma(x,y) + o(1),\ z^\sigma(x,y) > 0 & \text{if } y \in X_2; \end{cases} \tag{4.3}$$

here $O(1)$ and $o(1)$ are uniform in y as $\alpha \to 0$ according to the bounds obtained in (3.7) and (3.8).

To prove that the integral over X_1 becomes nonnegative as $\alpha \downarrow 0$, consider $N = \min\{n :\ m(X_1 Y_n) > 0\}$. If $N = \infty$, then $l_n = 0$ (a.e. m) on X_1 for all $n = 0,1,2,\ldots,$ and the integral is equal to 0. If $N < \infty$, then $l_n = 0$ (a.e. m) on X_1 for $n = 0,1,\ldots,N-1$, so that

$$\begin{aligned} \int_{X_1} u(\alpha,x,y) V_\beta(y; L^\sigma H - H) m(dy) &= \int_{X_1} \left[\frac{\bar{q}^\sigma}{\alpha} + O(1)\right] \sum_{n=N}^\infty l_n(y)\alpha^n m(dy) \\ &= \alpha^{N-1} \int_{X_1} \bar{q}^\sigma(y) l_N(y) m(dy) + o(\alpha^{N-1}) \end{aligned}$$

as $\alpha \downarrow 0$ (here the bounds $\|l_n\| \leq C\kappa^n$ are used). By the selection of N, we have (1) $l_N \geq 0$ (a.e. m) on X_1 since $L^\sigma H - H \succeq 0$ and since all the preceding l_n vanish a.e. on X_1; (2) $l_N > 0$ on the set $X_1 Y_N$ of a positive measure m. By (4.3) the factor $\bar{q}^\sigma$ is also strictly positive on X_1, so that the same is true for the integral factor at α^{N-1}. Hence, in the case $N < \infty$, the integral over X_1 in (4.1) becomes positive as $\alpha \downarrow 0$. Thus, in any case, it is nonnegative for α close enough to 0.

The integral over X_2 is treated in a similar way, with $N = \min\{n :\ m(X_2 Y_n) > 0\}$. In the case $N = \infty$ this integral is 0, while in the case $N < \infty$, in accordance with (4.3),

$$\int_{X_2} u(\alpha,x,y) V_\beta(y; L^\sigma H - H) m(dy) = \alpha^N \int_{X_2} z^\sigma(x,y) l_N(y) m(dy) + o(\alpha^N) > 0$$

as $\alpha \downarrow 0$. For the case "$\succeq$" the lemma is proved.

The case $H^\sigma(x_0) \succ H(x_0)$ follows from the already proven nonnegativity of the integral in (4.1) and from the strict inequality $V_\beta(x_0; L^\sigma H - H) > 0$ implied by the relation $L^\sigma H(x_0) \succ H(x_0)$. The case of the opposite inequalities is similar, only with negative l_N and $V_\beta(x; L^\sigma H - H)$. The equality case is a consequence of the preceding cases, since in that case both nonstrict inequalities are satisfied. □

COROLLARY 4.3 (lexicographical policy improvement). *If $L^\tau H^\sigma \succeq H^\sigma$ for two stationary policies σ and τ, then $H^\tau \succeq H^\sigma$. If, in addition, $L^\tau H^\sigma(x_0) \succ H^\sigma(x_0)$ at some $x_0 \in X$, then $H^\tau(x_0) \succ H^\sigma(x_0)$.*

The next lemma is an immediate consequence of the Laurent expansion (3.11) and the definition of the sign "$\succeq$".

LEMMA 4.4. *For two policies $\sigma,\tau \in \Sigma$, the relation $H^\tau \succeq H^\sigma$ is equivalent to the existence for every $x \in X$ of a number $\beta_0 = \beta(x,\sigma,\tau)$ such that*

$$v_\beta(x,\tau) \geq v_\beta(x,\sigma) \quad \text{for all} \quad \beta_0 < \beta < 1. \tag{4.4}$$

Consider now the following operator T on the space $\mathcal{H}$:

$$TH(x) = \operatorname*{Lexmax}_{\sigma\in\Sigma} L^\sigma H(x), \quad x \in X, \tag{4.5}$$

defined for those $H \in \mathcal{H}$ for which the Lexmax in (4.5) exists (we avoid a lexicographical supremum, since it is something awkward: $\operatorname{Lexsup}_n\{-\frac{1}{n}, 0, 0, \dots\} = \{0, -\infty, -\infty, \dots\}$).

THEOREM 4.5. *For a policy $\tau \in \Sigma$ the following statements are equivalent:*

(i) *τ is Blackwell optimal within the class Σ;*

(ii) *$H^\tau \succeq H^\sigma$ for every $\sigma \in \Sigma$;*

(iii) *H^τ is a solution of the equation*

$$H = TH, \quad H \in \mathcal{H}; \tag{4.6}$$

(iv) *$L^\tau H = H$ for some solution of* (4.6).

Proof. The equivalence of (i) and (ii) follows from Lemma 4.4 and Definition 2.6. It remains to prove the implications (iv)→(iii)→(ii) and (ii)→(iii)→(iv). If (iv) holds, then $H^\tau = H$ by Lemma 4.2; therefore $H^\tau = TH^\tau$, and we have (iii). If $TH^\tau = H^\tau$, then $L^\sigma H^\tau \preceq H^\tau$ for every $\sigma \in \Sigma$ by the definition of T, hence $H^\sigma \preceq H^\tau$ by Corollary 4.3, and (ii) holds. The implication (ii)→(iii) is proved by a contradiction. If (iii) does not hold, then, in view of Corollary 3.4, for some $\sigma \in \Sigma$ and some $x_0 \in X$ we have $L^\sigma H^\tau(x_0) \succeq H^\tau(x_0)$. In this case consider a policy

$$\rho(x,\cdot) = \begin{cases} \sigma(x,\cdot) & \text{if } x = x_0, \\ \tau(x,\cdot) & \text{if } x \neq x_0, \end{cases}$$

for which L^ρ coincides with L^σ at the point x_0 and coincides with L^τ at all other points $x \in X$ (see (3.1), (3.5), and (3.23)). For this policy $L^\rho H^\tau(x_0) \succ H^\tau(x_0)$, and by Corollary 3.4 $L^\rho H^\tau(x) = H^\tau(x)$ at all other $x \in X$. Hence $H^\rho(x_0) \succ H^\tau(x_0)$ by Corollary 4.3, in contradiction with (ii). Finally, (iii) implies (iv) because $L^\tau H^\tau = H^\tau$ (Corollary 3.4). □

Following Dekker and Hordijk [8, p. 402] we use the name *Blackwell optimality equation* for the equation (4.6) and the name *conserving condition* for the relation (iv) of Theorem 4.5. For the operator T we suggest the name *lexicographical Bellman operator*. Another form of this operator is given in section 6, where the existence of a unique solution of the Blackwell optimality equation is also proved.

5. Continuity of Laurent coefficients. Our next goal is to compactify the space Σ in such a way that the Laurent coefficients of $v_\beta(x,\sigma)$ become continuous functions of σ. We will not achieve this goal literally. First, the needed compactification of Σ requires an aggregation of Σ into a space S of measures on K; the topology in S is introduced by means of Carathéodory functions. Furthermore, to turn H^σ into a function on S, it is necessary to replace in $v_\beta(x,\sigma)$ the initial state x by an absolutely continuous initial distribution. Moreover, to prove the continuity of h_n^σ by an induction in n, we need to consider initial "distributions" with arbitrary bounded, maybe negative densities.

DEFINITION 5.1.

(i) *The space S consists of all probability measures s on K satisfying the condition*

$$\Pr_X s = m, \tag{5.1}$$

where m is the reference measure (see Assumption 2.2) and where the projection of a measure is defined by $\Pr_X s(B) = s(K \cap (B \times X))$, $B \in \mathcal{B}_X$.

(ii) *The weak-strong topology in S is defined by the condition $s_n \overset{ws}{\to} s$ if*

$$\lim_{n\to\infty} \int_K f ds_n = \int_K f ds \qquad \text{for every } f \in \mathrm{Car}(K). \tag{5.2}$$

PROPOSITION 5.2. *The space S is (sequentially) compact in the weak-strong topology.*

This is a known result. With a somewhat different class of functions f, in the context of relaxed controls in the deterministic control theory, it is a part of Theorem IV.3.11 in Warga [30, p. 287]. In the form we need here, it follows from the existence of resolution topologies in the dynamic programming proved in Schäl [23], [24] and Balder [1]. Our Proposition 5.2 is a consequence of Theorem 2.1 and Proposition 3.2 in [1, pp. 144, 148], obtained by a reduction of the dynamic programming model to its first step. A simpler direct proof is given in [33].

LEMMA 5.3. *There is a unique mapping $j : \Sigma \to S$ such that*

$$\int_X \int_{A_x} f(x,a)\sigma(x,da)m(dx) = \int_K f ds \qquad \text{for every } f \in B(K) \tag{5.3}$$

if $s = j(\sigma)$, and j maps Σ onto S.

Proof. Evidently, (5.3) is satisfied if and only if the measure s on K is defined by $s(dxda) = \sigma(x,da)m(dx)$. To verify (5.1) for the so-defined $s = j(\sigma)$, it is sufficient to apply (5.3) to the indicator of the set $(B \times A) \cap K$, $B \in \mathcal{B}_X$. It remains to prove that j is a map onto S. For this purpose, given $s \in S$, we first extend s to the product space $X \times A$ by setting $s((X \times A) \setminus K) = 0$ and then factorize s into $s(dxda) = \sigma(x,da)m(dx)$ where $\sigma(x,\cdot)$ is a regular conditional distribution on A given x. (The marginal distribution on X coincides with m in view of (5.1), and the existence of regular conditional distributions in the case of standard Borel spaces is a well-known fact.) The so-obtained σ satisfies the definition of a stationary policy, except that instead of $\sigma(x, A_x) = 1$ we have $\sigma(x, A) = 1$, so that maybe $\sigma(x, A_x) < 1$ for some $x \in X$. From (5.3) with $f = 1$ we get

$$\int_X \sigma(x, A_x)m(dx) = s(K) = 1 = \int_X 1m(dx),$$

and since $\sigma(x, A_x) \le 1$, it follows that $\sigma(x, A_x) = 1$ (a.e. m). It remains to fix some $\sigma_0 \in \Sigma$ and to change $\sigma(x,\cdot)$ to $\sigma_0(x,\cdot)$ on the set $\{x \in X : \sigma(x, A_x) < 1\}$ of measure 0. □

LEMMA 5.4. *Suppose that $f \in \mathrm{Car}(K)$ and that $g(x,s), x \in X, s \in S$ is a bounded function, measurable in x and continuous in s. Then the function*

$$F(s) = \int_K f(x,a)g(x,s)s(dxda), \qquad s \in S,$$

is continuous on S.

Proof. For $s, s' \in S$ we have $F(s') - F(s) = I_1 + I_2$, where

$$I_1 = \int_K f(x,a)[g(x,s') - g(x,s)]ds', \quad I_2 = \int_K f(x,a)g(x,s)(ds' - ds).$$

Here I_2 vanishes as $s' \overset{ws}{\to} s$ by the definition of the topology in S, since the integrand (with s fixed) is a Carathéodory function on K. For I_1, in accordance with (5.1), we have a bound

$$| I_1 | \le \|f\| \int_K | g(x,s') - g(x,s) | s'(dxda) = \|f\| \int_X | g(x,s') - g(x,s) | m(dx).$$

The last integrand is uniformly bounded by $\|g\|$ and converges to 0 at every x as $s' \overset{ws}{\to} s$. Since $m(X) = 1 < \infty$, the integral also converges to 0 by the majorized convergence theorem. □

Next we have to replace the initial states $x \in X$ by initial densities $l \in B(X)$. Avoiding formalities, we will use the same notations for l as for x, so that

$$q_t^\sigma(l,y) = \int_X l(x) q_t^\sigma(x,y) m(dx), \quad t \geq 1, \quad \bar{q}^\sigma(l,y) = \int_X l(x) \bar{q}^\sigma(y) m(dx), \tag{5.4}$$

and $z^\sigma(l,y)$, $H^\sigma(l) = \{h_n^\sigma(l)\}$, $v_\beta(l,\sigma)$ are similar integrals of $z^\sigma(x,y)$, $H^\sigma(x) = \{h_n^\sigma(x)\}$, $v_\beta(x,\sigma)$; to avoid confusion, x, y, z will always denote the states, while $l, l^s, 1$ will denote the elements of $B(X)$. It is clear that the new functions satisfy relations similar to (3.3), (3.8), and (3.11) and are bounded by the same constants as the previous functions, only multiplied by $\|l\|$ (see (3.8), (3.9), and (3.20)).

Our goal is the continuity of $h_n^\sigma(1), n \geq -1$, as functions of $s = j(\sigma)$, but in order to proceed with an induction in n, we need to replace the density 1 by an arbitrary $l \in B(X)$.

LEMMA 5.5. *For every $l \in B(X)$ and $y \in X$, the functions $q_t^\sigma(l,y)$ $(t \geq 1)$, $\bar{q}^\sigma(l,y)$, $z^\sigma(l,y)$, $h_n^\sigma(l,y)$ $(n \geq -1)$ of σ depend only on $s = j(\sigma)$ and are continuous in $s \in S$.*

As soon as this result is proved for some function, we feel free to use s in place of σ in the notation of that function.

Proof. For $q_t^\sigma(l,y)$, $t \geq 1$, we proceed by an induction in t. For $t = 1$ from (3.1), (5.4), and (5.3) we have

$$\begin{aligned} q^\sigma(l,y) &= \int_X \int_{A_x} l(x) p(x,a,y) \sigma(x,da) m(dx) \\ &= \int_K l(x) p(x,a,y) s(dxda) = q^s(l,y), \quad s = j(\sigma), \end{aligned}$$

and the continuity of $q^s(l,y)$ follows from Lemma 5.4 ($l(\cdot)p(\cdot,\cdot,y) \in \mathrm{Car}(K)$ in accordance with Assumption 2.2). From (3.1), (3.3), and (5.3) we have

$$\begin{aligned} q_{t+1}^\sigma(l,y) &= \int_X q_t^\sigma(l,z) q^\sigma(z,y) m(dz) = \int_X q_t^s(l,z) \int_{A_x} p(z,a,y) \sigma(z,da) m(dz) \\ &= \int_K q_t^s(l,z) p(z,a,y) s(dzda) = q_{t+1}^s(l,y), \quad s = j(\sigma), \end{aligned}$$

and by Lemma 5.4, $q_{t+1}^s(l,y)$ is continuous in s together with $q_t^s(l,y)$.

Since a uniform limit of a sequence of continuous functions is again a continuous function, the continuity of $\bar{q}^\sigma$ and z^σ in $s = j(\sigma)$ follows from the relations

$$| q_t^s(l,y) - q^\sigma(l,y) | \leq 2\|l\| \cdot \|p\| \cdot \rho^{t-2}, \quad z^\sigma(l,y) = \sum_{t=1}^{\infty} [q_t^s(l,y) - \bar{q}^s(l,y)]$$

implied by (3.7) and (3.8).

Now consider $h_n^\sigma(l)$. For $n=-1$, in accordance with (3.20), (3.9), (3.5), and (5.4), we have

$$\begin{aligned} h_{-1}^\sigma(l) &= \int_X l(x) \int_X \bar{q}^\sigma(y) r^\sigma(y) m(dy) m(dx) \\ &= \int_X \bar{q}^\sigma(l,y) \int_{A_y} r(a,y)\sigma(y,da) m(dy) \\ &= \int_K \bar{q}^s(l,y) r(y,a) s(dyda) = h_{-1}^s(l), \qquad s = j(\sigma). \end{aligned}$$

Since $\bar{q}^s(l,y)$ is continuous in s, and $r \in \mathrm{Car}(K)$, the continuity of $h_{-1}^s(l)$ follows from Lemma 5.4. For $n=0$ by (3.20), (3.5), and (3.13) we have

$$\begin{aligned} & h_0^\sigma(l) \\ &= \int_X l(x) \left[\int_{A_x} r(x,a)\sigma(x,da) + \int_X z^\sigma(x,y) \int_{A_y} r(y,a), \sigma(y,da) m(dy) \right] m(dx) - h_{-1}^\sigma(l) \\ &= \int_K l(x) r(x,a) s(dxda) + \int_X z^s(l,y) \int_{A_y} r(y,a)\sigma(y,da) m(dy) - h_{-1}^s(l) \\ &= \int_K [l(x) + z^s(l,x)] r(x,a) s(dxda) - h_{-1}^s(l) = h_0^s(l), \quad s = j(\sigma). \end{aligned}$$

Since $z^s(l,x)$ is continuous in s, by Lemma 5.4 the same is true for $h_0^s(l)$.

Further, we proceed by induction. Suppose that for some $n \geq 0$ the continuity of $h_n^s(l)$ $(= h_n^\sigma(l)$ in $s = j(\sigma))$ for every $l \in B(X)$ is already known. In accordance with (3.13) and (3.20), and since $z^\sigma(l,y) = z^s(l,y)$, we have

$$\begin{aligned} h_{n+1}^\sigma(l) &= -\int_X l(x) \int_X z^\sigma(x,y) h_n^\sigma(y) m(dy) m(dx) \\ &= -\int_X z^s(l,y) h_n^\sigma(y) m(dy) = h_n^\sigma(l^s), \quad s = j(\sigma), \end{aligned} \tag{5.5}$$

where $l^s(\cdot) = -z^s(l,\cdot) \in B(X)$ (cf. (5.4)). If also $s = j(\tau)$ for some $\tau \in \Sigma$, then in a similar way $h_{n+1}^\tau(l) = h_n^\tau(l^s)$. By the supposition of induction applied to l^s in place of l, we have $h_n^\sigma(l^s) = h_n^\tau(l^s)$. It follows from (5.5) that $h_{n+1}^\sigma(l) = h_{n+1}^\tau(l)$, so that $h_{n+1}^\sigma(l)$ is indeed a function of $s = j(\sigma)$ and that

$$h_{n+1}^s(l) = h_n^s(l^s), \quad s \in S.$$

It remains to show that the difference

$$h_{n+1}^t(l) - h_{n+1}^s(l) = [h_n^t(l^t) - h_n^t(l^s)] + [h_n^t(l^s) - h_n^s(l^s)]$$

converges to 0 as $t \overset{ws}{\to} s$ $(s,t \in S)$. The second difference at the right side tends to 0 by the supposition of induction applied to l^s in place of l. The first difference is equal to the integral

$$\int_X [z^s(l,y) - z^t(l,y)] h_n^\tau(y) m(dy), \qquad \text{where } j(\tau) = t.$$

Here the integrand is uniformly bounded by the constant $(2+\kappa)\kappa^n \parallel r\| \cdot 2\|l\|\kappa$ (see (3.8) and (3.20)) and converges to 0 at every $y \in X$ as $t \overset{ws}{\to} s$ since $z^s(l,y)$ is continuous

in $s \in S$. Since $m(X) < \infty$, the integral converges to 0 by the majorized convergence theorem. □

COROLLARY 5.6. *The average reward $g^\sigma, \sigma \in \Sigma$, is a continuous function of $s = j(\sigma)$.*

Proof. The proof follows from the continuity of $h^s_{-1}(l)$ in s for every $l \in B(X)$ and the relation $h^\sigma_{-1}(1) = g^\sigma \int_X 1m(dx) = g^\sigma$. □

6. Blackwell optimality within the class of stationary policies. In this section we prove the existence of a selector φ which is Blackwell optimal within Σ. This is done in two steps. First we obtain a policy $\tau \in \Sigma$ which is the best for a given initial density l. After that, we obtain φ from τ by policy improvement. To be definite, we take $l = 1$. The existence of an optimal selector allows us to complete the results of Theorem 4.5 by proving the existence of a unique solution to the Blackwell optimality equation.

Notice that in accordance with Lemma 3.1 and with notations introduced in Lemma 5.5,

$$v_\beta(1, s) = \frac{g^s}{\alpha} + \sum_{n=0}^{\infty} h^s_n(1)\alpha^n, \quad 0 < \alpha < \frac{1}{\kappa}, \quad s \in S, \tag{6.1}$$

where $\{g^s, h^s_0(1), \dots\} = \{h^s_n(1)\} = H^s(1)$ and $H^\sigma(1) = H^s(1)$ if $s = j(\sigma), \sigma \in \Sigma$.

LEMMA 6.1. *There exists a policy $\tau \in \Sigma$ such that*

$$H^\tau(1) = \operatorname*{Lexmax}_{\sigma\in\Sigma} H^\sigma(1). \tag{6.2}$$

Proof. By Lemma 5.5, all the coefficients of the Laurent series (6.1) are continuous in s. By Proposition 5.2, S is a compact space. Therefore $g^s = h^s_{-1}(1)$ attains its maximum over S on a nonempty compact set $S_0 \subseteq S$. In a similar way, by induction, $h^s_n(1)$ attains its maximum over S_n on a nonempty compact set $S_{n+1} \subseteq S_n$, $n = 0, 1, \dots$. The intersection S_∞ of the sets $S \supseteq S_0 \supseteq S_1 \supseteq \cdots$ is also a nonempty compact set, and evidently $H^t(1) = \operatorname{Lexmax}_{s\in S} H^s(1)$ for any $t \in S_\infty$. By Lemma 5.3 the set $j^{-1}(t)$ is nonempty, and by Lemma 5.5 the relation (6.2) holds for any $\tau \in j^{-1}(t)$. □

To perform the next step, we need the analogues $L^a, a \in A$, of the operators L^σ such that

$$L^\sigma H(x) = \int_{A_x} L^a H(x)\sigma(x, da), \quad x \in X, \quad \sigma \in \Sigma \quad H \in \mathcal{H} \tag{6.3}$$

(see Definition 3.3). In accordance with (3.1) and (3.13), the following definition implies (6.3).

DEFINITION 6.2. *For every $H = \{g, h_0, h_1, \dots\} \in \mathcal{H}$, $x \in X$, and $a \in A_x$,*

$$L^a H(x) = \{g,\ r(x, a) + P^a h_0(x) - g,\ P^a(h_1 - h_0)(x),\ P^a(h_2 - h_1)(x), \dots\} \tag{6.4}$$

where

$$P^a f(x) = \int_X p(x, a, y) f(y) m(dy), \quad f \in B(X). \tag{6.5}$$

(It is easy to see that $L^a H^\sigma(x)$ is indeed the sequence of Laurent coefficients of $v_\beta(x, \pi)$, where π assigns the action a at the state x at the first step of the control and coincides with σ afterwards.)

THEOREM 6.3.

(i) *The lexicographical Bellman operator T introduced in* (4.5) *is defined on the whole space $\mathcal{H}$, and*

$$TH(x) = \operatorname*{Lexmax}_{a\in A_x} L^a H(x), \quad x \in X,\ H \in \mathcal{H}; \tag{6.6}$$

(ii) *for every $H \in \mathcal{H}$ there exists a selector φ such that $L^\varphi H = H$;*

(iii) *$TH \in \mathcal{H}$ for every $H \in \mathcal{H}$.*

Proof. We first prove that the maximum in (6.6) is attained and determine the corresponding subsets of the sets A_x. Given $H = \{h_n\} \in \mathcal{H}$, denote by $h_n(x,a)$, $n \geq -1$, the components of $L^a H(x)$ defined in (6.4), and fix x. Since $h_n \in B(X)$, it follows from (6.4)–(6.5) and Assumptions 2.2 and 2.4 by the majorized convergence theorem that all $h_n(x,a)$ are continuous in a on the compact A_x (so that $h_n(\cdot,\cdot) \in \mathrm{Car}(K)$). The constant term $h_{-1}(x,a) = g$ of $L^a H(x)$ attains its maximum $\hat{h}_{-1}(x)$ $(= \hat{g})$ over A_x on the set $A_{-1}(x) = A_x$. The next term $h_0(x,a)$ attains its maximum $\hat{h}_0(x)$ over $A_{-1}(x)$ on a nonempty compact set $A_0(x) \subset A_{-1}(x)$, etc. By an evident induction, we get nonempty compact sets $A_x = A_{-1}(x) \supset A_0(x) \supset A_1(x) \supset \cdots$ such that $h_n(x,a)$ attains its maximum $\hat{h}_n(x)$ over $A_{n-1}(x)$ on $A_n(x), n \geq 0$. The intersection $A_\infty(x)$ of the sets $A_n(x), n \geq 0$, is a nonempty compact subset of A_x. It is clear that $\hat{H}(x) = \{\hat{h}_n(x)\}$ is the lexicographical maximum on the right side of (6.6) and that this maximum is attained if and only if $a \in A_\infty(x)$.

Since x is arbitrary, we have $L^a H\,(x) \preceq \hat{H}(x)$ for every $x \in X, a \in A_x$. Hence by (6.3) and Proposition 4.1, $L^\sigma H \preceq \hat{H}$ for every $\sigma \in \Sigma$.

In accordance with the preceding paragraph, the set

$$K_\infty = \{(x,a) : a \in A_\infty(x), x \in X\}$$

has nonempty compact x-sections $A_\infty(x)$. To choose a selector φ with its graph in K_∞, we need to prove that this set is measurable (belongs to $\mathcal{B}_{X\times A}$). Since $K_\infty = \bigcap_n K_n$, it is sufficient to show that the sets

$$K_n = \{(x,a) : a \in A_n(x), x \in X\}, \qquad n \geq -1,$$

are measurable. This is done by induction in n. The set $K_{-1} = K$ is measurable by Assumption 2.1. Suppose that K_{n-1} is measurable. Since K_{n-1} has nonempty compact x-sections, by Proposition 2.5(ii) applied to the Carathéodory function $h_n(x,a)$ and the set K_{n-1}, the function $\hat{h}_n(x)$ is measurable on X and therefore is also measurable on K_{n-1} as a function of both x and a. It follows that the set

$$K_n = \{(x,a) \in K_{n-1} : h_n(x,a) = \hat{h}_n(x)\}$$

is measurable too, and this completes the induction.

Since K_∞ is measurable and has nonempty compact x-sections, by Proposition 2.5(i) there exists a selector $\varphi \in \Phi$ such that $\varphi(x) \in A_\infty(x)$, $x \in X$. For this selector we have $L^{\varphi(x)} H(x) = \hat{H}(x)$ for all x, so that $L^\varphi H = \hat{H}$. Therefore, because $\varphi \in \Phi \subset \Sigma$, and since we already know that $L^\sigma H \preceq \hat{H}$ for every $\sigma \in \Sigma$, we have $L^\varphi H = \mathrm{Lexmax}_{\sigma\in\Sigma} L^\sigma H$. Thus both (i) and (ii) are proved. Since $L^\varphi H \in \mathcal{H}$ together with H, we also have (iii). □

THEOREM 6.4.

(i) *There exists a selector $\varphi \in \Phi$ Blackwell optimal within Σ;*

(ii) *the Blackwell optimality equation $H = TH$ has a unique solution H^* in $\mathcal{H}$.*

Proof. By Lemma 6.1 there exists a policy $\tau \in \Sigma$ lexicographically maximizing $H^\sigma(1)$ over Σ, and by Theorem 6.3 there exists a selector φ such that

$$L^\varphi H^\tau = TH^\tau. \tag{6.7}$$

Therefore, utilizing the definition (4.5) of T and Corollary 3.4, we have $L^\varphi H^\tau \succeq L^\tau H^\tau = H^\tau$. Hence, by Corollary 4.3, $H^\varphi \succeq H^\tau$. Thus, by Proposition 4.1, $H^\varphi(1) \succeq H^\tau(1)$, and therefore, since (6.2) holds in particular for $\sigma = \varphi$, $H^\varphi(1) = H^\tau(1)$. The last relation together with $H^\varphi \succeq H^\tau$ means that

$$\int_X H^\varphi(x)m(dx) = \int_X H^\tau(x)m(dx)$$

while $H^\varphi(x) \succeq H^\tau(x)$ everywhere on X. Therefore $H^\varphi(x) = H^\tau(x)$ (a.e. m) on X. Since the nonconstant components of H enter into $L^a H(x)$ only integrated with respect to $m(dx)$ (Definition 6.2), it follows that $L^a H^\varphi(x) = L^a H^\tau(x)$ for all $(x, a) \in K$ (Proposition 4.1). Therefore $TH^\varphi = TH^\tau$ and $L^\varphi H^\tau = L^\varphi H^\varphi$, (see (6.3) and (6.6)). In accordance with (6.7) and Corollary 3.4, it follows that

$$TH^\varphi = TH^\tau = L^\varphi H^\tau = L^\varphi H^\varphi = H^\varphi.$$

Thus $H^\varphi \in \mathcal{H}$ is a solution of the Bellman optimality equation $TH = H$, and also, by Theorem 4.5, φ is Blackwell optimal within Σ.

To prove the uniqueness of the solution, suppose that $H^* \in \mathcal{H}$ is another solution of the equation $TH = H$. Then $L^\varphi H^* \preceq TH^* = H^*$, so that by Lemma 4.2 we have $H^\varphi \preceq H^*$. On the other hand, by Theorem 6.3 there exists a selector ψ such that $L^\psi H^* = TH^* = H^*$. By Lemma 4.2, $H^\psi = H^*$, and by Theorem 4.5(ii) $H^\varphi \succeq H^\psi = H^*$. Since both $H^\varphi \preceq H^*$ and $H^\varphi \succeq H^*$, we have $H^\varphi = H^*$. □

7. Blackwell optimality in the space of all policies. In this section we extend to our model the elegant proof of Theorem 5.4 in Dekker and Hordijk [8, pp. 414–416], leading to the conclusion that a policy Blackwell optimal within the class Σ is Blackwell optimal within the class Π too (in fact, Theorem 5.4 in [8] is stated in slightly different terms). For the case of a Borel space X and finite sets A_x, such an extension is done in [31, pp. 283–287]. We give here a more condensed presentation, with novelties in the definitions of measures corresponding to the components of a Markov policy and of the limiting measure. The following version of Proposition 5.2 is used in the proof.

PROPOSITION 7.1. *For every constant $C > 0$, the set S_C of all measures s on K satisfying the condition*

$$\Pr_X s \le Cm \tag{7.1}$$

is (sequentially) compact in the weak-strong topology.

Proof. For the case $C = 1$ this is proved in [33], and our Proposition 5.2 is obtained as a corollary. It is easy to proceed in the opposite direction too. Namely, one must add a fictitious action a^* to A and each of the sets A_x, and assign the measure $m - \Pr_X s$ to $X \times a^*$; then (7.1) will turn into an equality. To reduce the case of an arbitrary $C > 0$ to the case $C = 1$, one must multiply f and divide s by C in the relation (5.2) defining the topology. □

THEOREM 7.2. *If a stationary policy τ is Blackwell optimal within the class Σ of stationary policies, then τ is also Blackwell optimal within the class Π of all policies.*

Proof. According to a well-known result by Strauch [27], for every $x \in X$ and $\pi \in \Pi$ there exists a Markov policy μ such that for each pair $x_t a_{t+1}$ its $\mathbf{P}_x^\pi$-distribution coincides with its $\mathbf{P}_x^\mu$-distribution, and therefore $v_\beta(x,\pi) = v_\beta(x,\mu)$ for all $0 < \beta < 1$. Hence it is sufficient to prove that τ is Blackwell optimal within the class M, i.e., that for every $x \in X$ and $\mu \in \mathrm{M}$ there exists a number $\beta_0 = \beta_0(x,\tau,\mu) < 1$ such that

$$v_\beta(x,\tau) - v_\beta(x,\mu) \geq 0 \qquad \text{for all} \qquad \beta_0 < \beta < 1. \tag{7.2}$$

Here $\mu = \{\sigma_1, \sigma_2, \dots\}$, where $\sigma_t \in \Sigma$. To simplify the subsequent formulas, we denote the components of $H^\tau = H^*$ by $h_{-1} = g, h_0, h_1, \dots$ and write $q^{(t)}, r^{(t)}, Q^{(t)}, L^{(t)}$ instead of q^{σ_t}, r^{σ_t}, Q^{σ_t}, L^{σ_t} $(t \geq 1)$. Consider also the t-step transition densities q_t corresponding to the policy μ, defined, similar to (3.3), as convolutions $q_{t+1} = q_t * q^{(t+1)}$ with $q_1 = q^{(1)}$, and the corresponding t-step operators $Q_0 = I$, $Q_t = Q^{(1)}Q^{(2)}\dots Q^{(t)}$, $t \geq 1$. It is easy to see that the bounds $0 \leq q^\sigma \leq \|p\|$, $\sigma \in \Sigma$, imply the same bounds for q_t and that Q_t are stochastic operators, so that

$$\|q_t\| \leq \|p\|, \ \|Q_t\| \leq 1, \quad t \geq 1. \tag{7.3}$$

Under the policy μ, the consecutive states $x_0\ x_1\ x_2\ \dots$ form a nonstationary Markov chain with the transition operators $Q^{(t)}$ and one-step rewards $r^{(t)}$, so that (2.2) simplifies to

$$v_\beta(x,\mu) = \sum_{t=0}^{\infty} \beta^t Q_t r^{(t+1)}(x), \quad x \in X, \quad 0 < \beta < 1. \tag{7.4}$$

On the other hand, by a remarkable identity exploited in Sladký [25], Hordijk and Sladký [17], and Dekker and Hordijk [8], we can transform the Laurent expansion (3.11) of $v_\beta(x,\tau)$ into

$$v_\beta(x,\tau) = \sum_{n=-1}^{\infty} h_n(x)\alpha^n = \sum_{n=0}^{\infty} \alpha^n \sum_{t=0}^{\infty} \beta^t Q_t[h_n - Q^{(t+1)}(h_n - h_{n-1})](x), \tag{7.5}$$
$$x \in X, \qquad 0 < \alpha = 1 - \beta < \frac{1}{\kappa}.$$

The identity used in (7.5) is an algebraic one, it is a direct consequence of the relations $Q_t Q^{(t+1)} = Q_{t+1}$, $\alpha \sum \beta^t = 1$, $h_{-1} = \text{const.}$; the absolute convergence of the double series in the indicated interval follows from the bounds (3.20) and (7.3) for h_n and Q_t.

Next we fix $x = x_0 \in X$, subtract (7.4) from (7.5), collect the like terms with β^t in (7.4) and with $\alpha^n\beta^t$ in (7.5), and compare the coefficients of the resulting double series with the components of $L^\sigma H$ (see (3.23)). This gives, for the difference in (7.2), a representation of the form

$$v_\beta(x_0,\tau) - v_\beta(x_0,\mu) = \sum_{n=0}^{\infty}\sum_{t=0}^{\infty} a_{tn}\alpha^n\beta^t, \quad 0 < \alpha < \frac{1}{\kappa}, \tag{7.6}$$

where

$$a_{tn} = Q_t b_{tn}(x_0), \quad \{0, b_{t0}, b_{t1}, \dots\} = H - L^{(t+1)}H. \tag{7.7}$$

We need to express the coefficients a_{tn} through the components $f_n(x,a)$ of the difference

$$H(x) - L^a H(x) = \{0, f_0(x,a), f_1(x,a), \dots\}, \quad (x,a) \in K \tag{7.8}$$

(see Definition 6.2). In accordance with (6.3),

$$b_{tn}(x) = \int_{A_x} f_n(x,a)\sigma_{t+1}(x,da), \quad x \in X. \tag{7.9}$$

A substitution of (7.9) into (7.7) gives a representation

$$a_{tn} = \int_X q_t(x_0,x) \int_{A_x} f_n(x,a)\sigma_{t+1}(x,da)m(dx) = \int_K q_t(x_0,x) f_n(x,a) ds_t, \tag{7.10}$$
$$s_t = j(\sigma_{t+1}) \in S, \quad n \geq 0, \quad t \geq 1,$$

while for the coefficients with $t = 0$ we have

$$a_{0n} = b_{0n}(x_0), \quad n \geq 0, \tag{7.11}$$

since $Q_0 = I$. Finally, we change in (7.10) from ds_t to ds'_t where the measure s'_t on K is defined by

$$s'_t(dxda) = q_t(x_0,x)s_t(dxda), \quad t \geq 1. \tag{7.12}$$

Then (7.10) becomes

$$a_{tn} = \int_K f_n(x,a) ds'_t, \quad n \geq 0, \quad t \geq 1. \tag{7.13}$$

Next, since H $(= H^\tau = H^*)$ is the solution of the Blackwell optimality equation, both $H - L^{(t+1)}H$ and $H(x) - L^a H(x)$ are lexicographically nonnegative (see Theorems 4.5 and 6.3). It follows from (7.8), (7.13), and Proposition 4.1 (or directly from (7.7) and (7.11) in the case $t = 0$) that

$$\{a_{t0}, a_{t1}, a_{t2}, \dots\} \succeq 0, \quad t \geq 0. \tag{7.14}$$

From (7.7), (7.11)–(7.13), and the bounds (3.20) and (7.3) for h_n and q_t, we conclude that

$$| a_{tn} | \leq C\kappa^n, \quad n \geq 0, \quad t \geq 0, \tag{7.15}$$

and that

$$s'_t \in S_C, \quad t \geq 1, \tag{7.16}$$

for a sufficiently large $C > 0$ (see Proposition 7.1). In the proof of Theorem 6.3 we have seen that the components $h_n(x,a)$ of $L^a H(x)$ are continuous in a. By (7.8) $f_n(x,a) = h_n(x) - h_n(x,a)$, and therefore

$$f_n \in \mathrm{Car}(K), \quad n \geq 0. \tag{7.17}$$

To prove the theorem, it remains to show that the relations (7.6), (7.14), (7.15) together with (7.13), (7.16), (7.17) imply (7.2) for $x = x_0$.

Following Dekker and Hordijk [8, pp. 414–416], we consider various possibilities for (7.14) to be satisfied.

Case I. All $a_{tn} = 0$. Then (7.2) obviously holds at $x = x_0$ with the equality sign.

Case II. There is an integer $N \geq 0$ such that all a_{tn} with $n < N$ (if any) are zeros, but not all a_{tN} are equal to 0. Then evidently

$$a_{tN} \geq 0 \text{ for all } t \geq 0, \quad \text{while } a_{0N} + a_{1N} + a_{2N} + \cdots = b > 0, \tag{7.18}$$

and this case splits into two subcases: $b = \infty$ and $b < \infty$.

The subcase $b = \infty$ is also rather trivial. From (7.6) and (7.18) we have, for α converging to 0,

$$v_\beta(x_0, \tau) - v_\beta(x_0, \mu) = \alpha^N \sum_{t=0}^{\infty} a_{tN}\beta^t + R(\alpha), \tag{7.19}$$

where in accordance with (7.15), and since $\alpha \sum \beta^t = 1$,

$$| R(\alpha) | \leq C \sum_{n>N} \sum_{t=0}^{\infty} (\alpha\kappa)^n \beta^t = C\kappa^{N+1}\alpha^N(1 - \alpha\kappa)^{-1} = O(\alpha^N).$$

In view of (7.18), and since $\beta = 1-\alpha$, $b = \infty$, the sum of the series in (7.19) approaches ∞ as $\alpha \downarrow 0$, and this implies (7.2) for $x = x_0$.

The subcase $0 < b < \infty$ is the most interesting one. In this subcase $\sum_{t=0}^{\infty} a_{tN}\beta^t = b + o(1)$, so that similar to the preceding subcase, only taking into account the two lowest powers of α, we have

$$\begin{aligned} v_\beta(x_0, \tau) - v_\beta(x_0, \mu) &= \alpha^N \sum_{t=0}^{\infty} a_{tN}\beta^t + \alpha^{N+1} \sum_{t=0}^{\infty} a_{t,N+1}\beta^t + O(\alpha^{N+1}) \\ &= \alpha^N(b + R(\alpha)) + o(\alpha^N), \end{aligned}$$

where

$$R(\alpha) = \alpha \sum_{t=0}^{\infty} a_{t,N+1}\beta^t. \tag{7.20}$$

Since $b > 0$, it is sufficient to prove that $\liminf_{\alpha\downarrow 0} R(\alpha) \geq 0$ or, as follows from (7.20), that $\liminf_{t\to\infty} a_{t,N+1} \geq 0$.

This is proved by contradiction. If $\liminf_{t\to\infty} a_{t,N+1} < 0$, then for some $\varepsilon > 0$ and some sequence of the values of t we must have $\lim a_{t,N+1} = -\varepsilon$. By Proposition 7.1 and in view of (7.16), there exists a subsequence $\{t_j\}$ of the above sequence and a measure $s' \in S_C$ such that $s'_{t_j} \overset{ws}{\to} s'$. By the definition of the weak-strong topology and in view of (7.13) and (7.17), this implies the existence of the limits

$$a_n = \lim_{j\to\infty} a_{t_j n} = \int_K f_n(x, a) ds', \quad n \geq 0. \tag{7.21}$$

Since all a_{tn} with $n < N$ are zeros in Case II, we have $a_n = 0$ for $n < N$. Because $b < \infty$ in the subcase we consider, the series in (7.18) converges; therefore $\lim_{t\to\infty} a_{tN} = 0$, and we also have $a_N = 0$. By the selection of $\{t_j\}$, $a_{N+1} = -\varepsilon$. It follows that

$$\{0, a_0, a_1, \dots, a_N, a_{N+1}, a_{N+2}, \dots\} = \{0, 0, 0, \dots, 0, -\varepsilon, a_{N+2}, \dots\} \prec 0. \tag{7.22}$$

On the other hand, as we have seen,

$$\{0, f_0(x,a), f_1(x,a), \dots\} = H(x) - L^a H(x) \succeq 0, \quad (x,a) \in K. \tag{7.23}$$

By Proposition 4.1 we may integrate the nonstrict lexicographical inequalities. Therefore, (7.22) contradicts (7.21) and (7.23). □

8. Examples.

Example 8.1 (the water regulation problem). We consider the water regulation problem as described in [13, section 2.8]. The water is stored in a reservoir of a finite capacity M. The amount x_t of water in the reservoir after the tth period of time is

$$x_t = (x_{t-1} - a_t + \xi_t) \wedge M, \quad t = 1, 2, \dots, \tag{8.1}$$

where a_t is the extent of water taken for the consumption and ξ_t is the random influx of water during the tth period of time. Here $0 \le a_t \le x_{t-1}$, and ξ_t are nonnegative i.i.d. (independent identically distributed) random variables. The utility of the consumption is measured by a function $R(a_t)$.

To fit into the definitions of section 2, we suppose that the random variables ξ_t have an absolutely continuous distribution function

$$F(x) = \int_0^x f(z)dz, \qquad 0 \le z < \infty. \tag{8.2}$$

Then the components of the model can be defined in the following way. The state space $X = [0, M]$, the action space $A = [0, M]$, the action sets $A_x = [0, x]$, $x \in X$. The reference measure

$$m(B) = \begin{cases} \frac{\lambda(B)}{2M} & \text{if } B \subset [0, M),\ B \in \mathcal{B}_X, \\ \frac{1}{2} & \text{if } B = \{M\}, \end{cases} \tag{8.3}$$

where λ is the Lebesgue measure. The transition density

$$p(x,a,y) = \begin{cases} 0 & \text{if } 0 \le y < x - a, \\ 2Mf(y - x + a) & \text{if } x - a \le y < M, \\ 2\int_{M-x+a}^{\infty} f(z)dz & \text{if } y = M. \end{cases} \quad a \in A_x, \quad x \in X, \tag{8.4}$$

The reward function $r(x,a) = R(a)$, $a \in A_x, x \in X$. (It is easy to see that with these m and p,

$$\int_B p(x,a,y)m(dy) = \mathbf{P}\{x_t \in B \mid x_{t-1} = x, a_t = a\} = \mathbf{P}\{(x - a + \xi_t) \wedge M \in B\}$$

for every interval B, and hence for every Borel set $B \subset [0, M]$, as should be in accordance with (8.1).)

Assumptions 2.1–2.4 are satisfied if

(i) the density $f(x)$ is continuous (and therefore nonnegative and bounded) on the interval $[0, M]$;

(ii) $f(0) = 0$;

(iii) $1 - F(M)$ $(= \mathbf{P}\{\xi_t \ge M\}) > 0$;

(iv) $R(a)$ is a continuous function on $[0, M]$.

Indeed, Assumption 2.1 trivially holds, Assumption 2.2 follows from (i) and (ii), and Assumption 2.4 is implied by (iv). The simultaneous Doeblin-type condition (Assumption 2.3) follows from (iii) with $D = \{M\}$ and $\delta = 2(1 - F(M))$. Thus, conditions (i)–(iv) imply the existence of a deterministic stationary Blackwell optimal policy.

Example 8.2 (the inventory problem). The inventory model goes back to Bellman [2]. In the case of a single commodity, the evolution of the system can be described by the equation

$$x_t = (x_{t-1} + a_t - \xi_t) \vee 0, \qquad t = 1, 2, \dots,$$

where x_{t-1} is the stock level at the beginning of the tth period of time, a_t is the amount of the additional stock that is reordered, the nonnegative i.i.d. random variables ξ_t represent the demands, and the stock level is bounded above by a constant M (the capacity of the storehouse). The (expected) one-step cost is $c(x_{t-1}, a_t)$ (it consists of the costs of ordering, stockholding, and shortage).

This model is "symmetric" to the water regulation problem. As in that model, we suppose that ξ_t have the distribution function (8.2). As above, we have $X = A = [0, M]$, but now $A_x = [0, M - x]$. The reference measure is similar to (8.3), with the only difference being that the atom $\frac{1}{2}$ is at $x = 0$ instead of $x = M$. The transition density, similar to (8.4), is

$$p(x, a, y) = \begin{cases} 2\int_{x+a}^{\infty} f(z)dz & \text{if } y = 0, \\ 2Mf(x + a - y) & \text{if } 0 < y \le x + a, \quad a \in A_x, x \in X, \\ 0 & \text{if } x + a < y \le M, \end{cases}$$

and the reward function is $r(x, a) = -c(x, a)$.

Assumptions 2.1–2.4 are satisfied under the same conditions (i)–(iii) as above and the condition

(iv′) $c(x, a), \qquad 0 \le a \le M - x \le M$ is continuous in a, bounded and measurable.

Notice that in both examples we have a recurrent state x^* such that $P(x, a, x^*) > \delta > 0$ for all $(x, a) \in K$.

Example 8.3 (the stabilization problem on a circle). This is a circular version of the well-known linear regulator problem with Gaussian disturbances (cf. [13, sections 3.11, 6.12, 7.12]). The state of the system is described by an angle x which should be kept close to 0 but is subject to random fluctuations. The actions a are corrections of x. Larger deviations of x from 0 and larger values of $\mid a \mid$ induce larger costs. To be definite, let $X = A = [-1, 1)$ with the topology of a circle, so that $\lim_{x \uparrow 1} x = -1$. Then both X and A are compact spaces. The evolution of the system is described by the equation

$$x_t = x_{t-1} - a_t + \xi_t \bmod(2), \quad t = 1, 2, \dots,$$

where ξ_t are independent normal random variables with $\mathbf{E}\xi_t = 0$, $\mathbf{E}\xi_t^2 = \sigma^2 > 0$. The costs are of a form $R_1(a_t^2) + R_2(x_t^2)$, where R_i are nondecreasing continuous functions on $[0, 1]$ with $R_i(0) = 0$.

Let $A_x = A$ for every $x \in X$, and define the reference measure by $m(dx) = \frac{1}{2}dx$. Then the transition density is

$$p(x, a, y) = \sum_{n=-\infty}^{\infty} \frac{2}{\sqrt{2\pi}\sigma} e^{-\frac{(y-x+a-2n)^2}{2\sigma^2}}, \quad -1 \le x, a, y < 1.$$

This series converges uniformly in (x, a, y), and it follows that p is bounded, strictly positive, and continuous on the compact $X \times A \times X$. Hence $p(\cdot)$ is bounded from below by a positive constant δ, so that Assumption 2.3 holds with $D = X$. Assumptions 2.1 and 2.3 are trivially satisfied. The reward function

$$r(x, a) = -R_1(a^2) - \int_{-1}^{1} R_2(y^2) p(x, a, y) dy$$

is bounded and continuous (in both variables) together with p, R_1, and R_2. It follows that there exists a deterministic stationary Blackwell optimal policy.

9. Comments and open problems. The measurability and compactness (Assumption 2.1) and the continuity in a of the transition law and of the reward function (parts of Assumptions 2.2 and 2.4) are standard in dynamic programming, when proving the existence of exactly optimal policies.

The absolute continuity of the transition probabilities and the boundedness of the transition densities (Assumption 2.2) are restrictions crucial for our analysis. Only a few works in the theory of MDPs are made in the framework of densities, although models of this kind are encountered in applications. As a separate object of study, controlled Markov chains with transition densities are treated by Georgin [14]. In this paper the discounted and the average rewards are studied. In general, our assumptions are more restrictive than in [14]. Hypothesis 1a in [14] is similar to our Assumption 2.2, except that the density is not uniformly bounded there, but (in our notations) $p(x, a, y) \le q(x, y)$ where $\int_X q(x, y) m(dy) < \infty$ for every $x \in X$.

Another crucial point for our analysis is the boundedness of the reward function r (Assumption 2.4). This is a severe restriction not satisfied in many applications. However, if the state space X is a compact set, this assumption is reasonable, and such models are encountered in practice.

The simultaneous Doeblin-type condition (Assumption 2.3) is an easily checked assumption needed only for the uniform geometric convergence of the t-step transition densities $q_t^\sigma(x, y)$ to their limit $\bar{q}^\sigma(y)$ (see (3.7)). This condition is equivalent to the existence of a nonnegative function $f \in B(X)$ such that $p(x, a, y) \ge f(y)$ for all x, a, y, and $\int_X f(y) m(dy) > 0$ (given (2), one may define $f(x) = \delta \mathbf{1}_D(x)$; given f, one may set $D = \{x : f(x) \ge \delta\}$ where $\delta > 0$ is so small that $m(D) > 0$). In terms of the transition function, the above condition means that $P(x, a, B) \ge \nu(B)$ where ν is a nontrivial measure on X (in our case $\nu(dx) = f(x) m(dx)$). In [13, section 7.1] such a measure ν is called a minorant. Models with a minorant are well known in MDPs, especially in the particular case when ν is concentrated at a single point $x^* \in X$, so that a simpler uniform recurrence condition holds: $P(x, a, \{x^*\}) \ge \delta \ (= \nu(x^*)) > 0$ (cf. Examples 8.1 and 8.2). For a comprehensive survey of recurrence conditions in MDPs with a Borel state space and their relation to the convergence of t-step transition probabilities, see Hernández-Lerma, Montes-de-Oca, and Cavazos-Cadena [15]. Our Assumption 2.3 and its version in terms of a minorant are labeled there as R1(a) and R1(b).

We need the geometric convergence of the transition densities for all randomized stationary policies. A simple way to weaken Assumption 2.3 is to extend the more sophisticated convergence conditions known for Markov chains to all chains generated by $\sigma \in \Sigma$. For example, the geometric convergence (3.7) still holds, and our results remain valid, if Assumption 2.3 is replaced by the following condition considered in Doob [12, section 5.5, case (b)] for a single Markov chain.

Assumption 9.1. There exist an integer $k \geq 1$ and numbers $\delta > 0$ and $\varepsilon > 0$ such that for every policy $\sigma \in \Sigma$ there is a set $D^\sigma \in \mathcal{B}_X$ with $m(D^\sigma) \geq \varepsilon$ and with

$$q_k^\sigma(x, y) \geq \delta \text{ for all } x \in X,\ y \in D^\sigma.$$

However, this assumption is difficult to verify. An open problem is whether Assumption 9.1 follows from a similar condition for the deterministic policies $\varphi \in \Phi$.

The existence of a *strong Blackwell optimal policy* is an interesting open question. A related problem is the asymptotics of the value function v_β as β approaches 1. Indeed, we have the following result.

LEMMA 9.2. *The following three statements are equivalent:*

(i) *there exists a strong Blackwell optimal selector* $\varphi \in \Phi$*;*

(ii) *every Blackwell optimal stationary policy* $\sigma \in \Sigma$ *is strong Blackwell optimal;*

(iii) *there exists a number* $0 < \beta_0 < 1$ *such that*

$$v_\beta(x) = \sum_{n=-1}^{\infty} h_n^*(x)\alpha^n, \quad x \in X, \quad \beta_0 < \beta = 1 - \alpha < 1 \tag{9.1}$$

where H^* *is the unique solution of the Blackwell optimality equation* $H = TH$ *in* $\mathcal{H}$.

Proof. (iii)→(ii). By Theorems 4.5 and 6.4, for a Blackwell optimal $\sigma \in \Sigma$ we have $H^\sigma = H^*$, and therefore, if (9.1) holds, $v_\beta(x, \sigma)$ has the same Laurent expansion as $v_\beta(x)$, only in the interval $\rho < \beta < 1$. Hence $v_\beta(x) = v_\beta(x, \sigma)$ if $\rho \vee \beta_0 < \beta < 1$, so that σ is strong Blackwell optimal.

(ii)→(i). The proof follows from Theorems 6.4(i) and 7.2.

(i)→(iii). Given (i), we have $v_\beta(x) = v_\beta(x, \varphi)$, $x \in X$, $\beta_0 < \beta < 1$ for some $\beta_0 < 1$, and (9.1) follows from the Laurent expansion for $v_\beta(x, \varphi)$ (with $\beta_0 \vee \rho$ in place of β_0). □

The main term of the supposed expansion (9.1) is well known. Utilizing an approach due to Cavazos-Cadena and Lasserre [4], in [32] we have justified the next term in (9.1) and proved that

$$v_\beta(x) = \frac{g^*}{\alpha} + h_0^*(x) + o(1)$$

uniformly in x as $\alpha \downarrow 0$ in the case of Assumptions 2.1–2.4, but we have no idea how to obtain the next terms.

Acknowledgments. The author is thankful to the referees and the associate editor for helpful suggestions, remarks, and additional references.

A CONTROL METHOD FOR ASSIMILATION OF SURFACE DATA IN A LINEARIZED NAVIER–STOKES-TYPE PROBLEM RELATED TO OCEANOGRAPHY*

AZIZ BELMILOUDI† AND FRANÇOISE BROSSIER†

Abstract. A method of control is developed in order to compute the variability of the velocity and pressure (u, p) in an oceanic doman Ω during a time T. The observation is the variability of p of $\Gamma_0 \times]0, T[$, where Γ_0 is the upper surface of Ω and corresponds to the undisturbed sea surface. The observation is deduced from satellite data. The control is the variability of the wind-stress f, which acts as the forcing of the perturbation. The mean circulation in Ω is supposed to be known. The equations verified by (u, p) are linearized around this mean circulation. The continuity of the application: $f \to (u(f), p(f))$ in convenient functional spaces is proved. We deduce from this result the existence and uniqueness of an optimal control, which is characterized by a set of equations including the direct problem of linearized Navier–Stokes type verified by (u, p) and the adjoint problem. The cost function and consequently the optimal control depend on a real parameter α. We prove the convergence of the sequence (f_α), when α tends to 0, toward a wind-stress f which minimizes the distance between the observed and computed pressures. This result is obtained by means of minimizing sequences.

Key words. optimal control, Navier–Stokes, assimilation of surface data, minimizing sequences, oceanography

1. Introduction.

The method developed in this paper allows us to obtain the deep oceanic circulation from satellite measurements which are obviously surface observations. Altimetric measurements give the distance between the satellite and the sea surface. It is now possible to extract from these data the sea level variability with a precision in the order of centimeters. The pressure variability at a given depth can be deduced from the sea level and will act as the observation in our model (cf. Appendix).

The oceanic phenomenon that we want to modelize occurs in the tropical Atlantic and Pacific oceans: the circulation there is characterized by steady zonal currents driven by the trade winds and by long waves propagating westward along the equator, driven by the variability of the wind-stress and superimposed to the mean currents. The mean velocity u_0 is known for each tropical season. The total velocity $\tilde{u}$ can therefore be considered as the sum of two terms: u_0, which is given, and a variability u corresponding to the waves. The same expansion is valid for the pressure: $\tilde{p} = p_0 + p$. The equations of motion in an oceanic domain Ω are of Navier–Stokes type. We assume that, at initial time $t = 0$, the flow Ω is the mean circulation (u_0, p_0), which verifies steady equations. In this paper we are dealing only with the linearized case. The equations verified by the perturbation (u, p) are the following:

$$\frac{\partial u}{\partial t} + (u_0.\nabla)u + (u.\nabla)u_0 + F\Lambda u - \nu_h(\Delta_2 u) - \frac{\partial}{\partial z}\left(\nu_v \frac{\partial u}{\partial z}\right) + \frac{1}{\rho}\nabla p = 0, \tag{1.1a}$$

$$\text{div } u = 0, \tag{1.1b}$$

$$u(0) = 0, \tag{1.1c}$$

$\Delta_2 \frac{\partial^2}{\partial x^2} + \frac{\partial}{\partial y^2}$. (x, y, z) are the Cartesian coordinates: x and y are measured in the horizontal plane of the undisturbed sea surface (x toward the east, y toward the north), and z is vertically ascendant. The density ρ is a constant mean value. Afterward we will take $\rho = 1$ g.cm^{-3}. $F = (0, 0, 2\omega \sin\varphi)$ is the Coriolis force, ω is the rotation rate of earth, and φ is the latitude. The dissipative term corresponds to Reynolds stresses with a coefficient of eddy viscosity ν. Observation of turbulent flows leads to distinguish between horizontal eddy viscosity ν_h and vertical eddy viscosity ν_v. From now on ν_h will be constant and ν_v variable.

We consider a time interval $(0, T)$ and an oceanic domain Ω extending on both sides of the equator ($10°S$–$10°N$) and of constant depth H (for example, $H = 3000$ m). The curvature of the earth is neglected. The vertical extension of Ω ($-H \leq z \leq 0$) corresponds to a part of the physical domain. We assume that for depths greater than H the variability is negligible. The perturbation (u, p) is not computed in the thin surface layer $0 \leq z \leq \xi(x, y)$, where $\xi(x, y)$ is the free sea surface observed by the satellite. The perturbation of the mean flow is made of zonal propagating waves. We can thus choose the zonal extension of Ω as the greatest wavelength and impose periodic boundary conditions on the eastern and western boundaries.

The oceanic domain can be defined as $\Omega =]0, Lx[\times]-Ly, Ly[\times]-H, 0[$. Γ denotes its boundary; $\Gamma = \cup_{i=0,5}\Gamma_i$, where Γ_0 denotes the surface ($z = 0$), Γ_5 denotes the bottom ($z = -H$), Γ_1 and Γ_2 denote the western and eastern boundaries, and Γ_3 and Γ_4 denote the southern and northern boundaries. n is the unit outward vector normal to Γ. On account of the phenomena that we want to describe, we set mixed boundary conditions.

- The flow is periodic in the x-direction:

$$u_{/\Gamma_1} = u_{/\Gamma_2}. \tag{1.2a}$$

- We have the following:

$$u_2 = 0, \quad \frac{\partial u_1}{\partial y} = 0, \quad \text{and} \quad \frac{\partial u_3}{\partial y} = 0 \quad \text{on } \Gamma_3 \text{ and } \Gamma_4. \tag{1.2b}$$

- The perturbation vanishes at $z = -H$:

$$u = 0 \ \text{ on } \ \Gamma_5. \tag{1.2c}$$

- The perturbation is driven by the perturbation of the wind-stress f:

$$u_3 = 0, \quad \frac{\partial u_1}{\partial z} = -\frac{f_1}{\nu_v}, \quad \text{and} \quad \frac{\partial u_2}{\partial z} = -\frac{f_2}{\nu_v} \quad \text{on } \Gamma_0 \tag{1.2d}$$

with : $u = (u_1, u_2, u_3)$ and $f = (f_1, f_2)$.

The variability of the pressure on Γ_0, deduced from altimetric data, constitutes the observation. The variability of the wind-stress f acts as the forcing of the perturbation and is unknown. We take f as the control. $(u(f), p(f))$ are the velocity and pressure corresponding to any control f and satisfying problem (1.1), (1.2). The optimal control is defined as the wind-stress minimizing a given cost function which measures the distance between the observed pressure and the pressure $p(f)$ solution of (1.1),

(1.2). The pressure observed on Γ_0 is the trace of a circulation (u_e, p_e) driven by a wind f_e. The solution $(u(f), p(f))$ of problem (1.1), (1.2) induced by the optimal control f has to approach the real circulation (u_e, p_e). The control method then makes it possible to compute the velocity and pressure in all the domain Ω by means of data on a part of the boundary.

In order to solve the problem of optimal control, we have to consider the adjoint equations associated to (1.1). We then apply the control theory introduced by J. L. Lions [4]. More recently, G. I. Marchuk developed the method of adjoint equations in mathematical physics and performed variational data assimilation in environmental problems [6, 7]. The classical control problem arising in meteorology or oceanography is the adjustment of the initial condition in order to obtain velocity and temperature fields which agree with observations in situ. Our purpose is quite different since we control by the variability of the wind-stress in order to restitute the observed surface pressure deduced from altimetric data.

The paper is organized as follows.

Section 2 is devoted to problem (1.1), (1.2) satisfied by the perturbation of the mean flow. Here are some regularity results proven in [2]: if the forcing f is sufficiently regular, then the weak solution of (1.1), (1.2) is such that $u \in L^2(0, T, H^2(\Omega))$, $p \in L^2(0, T, H^1(\Omega))$. We can then define the trace $\gamma_0 p$ of the pressure on Γ_0. We prove the continuity of the applications $f \to u(f)$, $f \to p(f)$, $f \to \gamma_0 p(f)$ in convenient functional spaces.

Section 3 is devoted to the problem of control. We prove the existence and uniqueness of the solution. The optimal control is given as a function of u^*, the solution of the adjoint problem associated with the direct problem (1.1), (1.2). We thus obtain a set of equations characterizing the optimal control.

The cost function and consequently the optimal control depend on a parameter α. In section 4 we prove a convergence result for the sequence (f_α) of optimal controls by means of minimizing sequences.

2. Regularity and continuity results. We introduce the functional spaces

$$H = \{v \in (L^2(\Omega))^3 / \mathrm{div} v = 0, v.n = 0 \text{ on } \Gamma_0 \cup \Gamma_3 \cup \Gamma_4 \cup \Gamma_5, (v.n)/_{\Gamma_1} = -(v.n)/_{\Gamma_2}\},$$
$$W = \{v \in (H^1(\Omega))^3 / v = 0 \text{ on } \Gamma_5, v.n = 0 \text{ on } \Gamma_0 \cup \Gamma_3 \cup \Gamma_4, v/_{\Gamma_1} = v/_{\Gamma_2}\},$$
$$V = \{v \in W / \mathrm{div}\ v = 0\}.$$

The norm $\|\,.\,\|_{1,\Omega}$ and the seminorm $[\,.\,]_{1,\Omega}$ defined on $H^1(\Omega)$ are equivalent in V and W. We then set $\|v\| = \|v\|_V = \|v\|_W = [v]_{1,\Omega}$. $|\,.\,|$ denotes the norm in $L^2(\Omega)$.

We define

$$a(u, v) = \nu_h(\nabla_2 u, \nabla_2 v) + \left(\nu_v \frac{\partial u}{\partial z}, \frac{\partial v}{\partial z}\right), \quad \text{with } \nabla_2 u = \begin{pmatrix} \frac{\partial u}{\partial x} \\ \frac{\partial u}{\partial y} \end{pmatrix},$$

$d(u, v) = (F\Lambda\ u, v)$,

$b(u, v, w) = ((u.\nabla)v, w)$,

$\ell(u, v) = b(u, u_0, v) + b(u_0, u, v) + d(u, v)$, where u_0 is the mean velocity given in V,

$c(v, q) = -(\mathrm{div}\ v, q)$.

a and d are bilinear continuous forms on W, b is a trilinear continuous form on W, a is coercive on W, and we denote by ν the constant of coercivity ($\nu = \mathrm{Min}\ (\nu_h, \mathrm{Min}\ \nu_v)$).

c is a bilinear continuous form on $W \times L^2(\Omega)$ and verifies the Inf Sup condition

$$\exists\ \beta > 0 \quad \text{such that} \quad \inf_{q \in L^2(\Omega)} \sup_{v \in W} \frac{c(v,q)}{|q|\ \|v\|} \geq \beta.$$

The initial problem (1.1), (1.2) verified by the perturbation (u,p) of the mean flow admits two equivalent weak formulations.

Find $u \in L^2(0,T,V)$ such that

$$\left(\frac{\partial u}{\partial t}, v\right) + a(u,v) + \ell(u,v) = -(f, \gamma_0 v) \quad \forall v \in V, \tag{2.1a}$$

$$u(0) = 0 \tag{2.1b}$$

and

find $(u,p) \in L^2(0,T,W) \times L^2(0,T,L^2(\Omega))$ such that

$$\left(\frac{\partial u}{\partial t}, v\right) + a(u,v) + \ell(u,v) + c(v,p) = -(f, \gamma_0 v) \quad \forall v \in W, \tag{2.2a}$$

$$c(u,q) = 0 \quad \forall q \in L^2(\Omega), \tag{2.2b}$$

$$u(0) = 0. \tag{2.2c}$$

$\gamma_0 v$ denotes the trace of v on Γ_0, and $(f, \gamma_0 v)$ denotes the scalar product in $L^2(\Gamma_0)$.

These results and the following concerning the existence and regularity of the weak solution (u,p) are proven in [2].

PROPOSITION 2.1. *For given u_0 and f, $u_0 \in V$, and $f \in L^2(0,T,L^2(\Gamma_0))$, there exists a unique solution u of problem* (2.1) *satisfying*

$$u \in L^2(0,T,V) \cap C^0([0,T],H), \qquad \frac{\partial u}{\partial t} \in L^2(0,T,V').$$

There is a pressure $p \in L^2(0,T,L^2(\Omega))$, defined regardless of any time-dependent function, such that (u,p) verifies the problem (1.1), (1.2) *in a distribution sense.*

We want to choose the pressure p on Γ_0 as the observation of the method of control. The regularity $p \in L^2(\Omega)$ doesn't make it possible to define $\gamma_0 p$, the trace of p on Γ_0. We have to make stronger assumptions in order to have $p \in H^1(\Omega)$.

From now on we assume the following regularity of the wind-stress:

$$f \in L^2(0,T,H^1(\Gamma_0)), \qquad \frac{\partial f}{\partial t} \in L^2(0,T,L^2(\Gamma_0)), \tag{2.3}$$

Equation (2.3) implies that $f \in C^0([0,T],L^2(\Gamma_0))$ a.e. on $[0,T]$ [5].

f must be consistent with the initial and boundary conditions imposed on the velocity u. We then have to impose the following compatibility conditions:

$$f(0) = 0 \quad \text{on } \Gamma_0, \tag{2.4a}$$

$$f_2 = 0 \quad \text{and} \quad \frac{\partial f_1}{\partial y} = 0 \quad \text{on } \gamma_3 \cup \gamma_4, \tag{2.4b}$$

$$f/_{\gamma_1} = f/_{\gamma_2}. \tag{2.4c}$$

Notation: f is defined on the open set $\Gamma_0 =]0, Lx[\times]-Ly, Ly[$. γ denotes the boundary of Γ_0. $\gamma = \cup_{i=1,4}\gamma_i$, where γ_1 and γ_2 are the western and eastern boundaries and γ_3

and γ_4 the southern and northern boundaries. n is the unit outward vector normal to γ.

PROPOSITION 2.2. *If the wind-stress f verifies the regularity* (2.3) *and the initial and boundary conditions* (2.4)*, then the solution (u,p) of problem* (2.1) *is such that*

$$u \in L^2(0,T,H^2(\Omega)), \quad p \in L^2(0,T,H^1(\Omega)).$$

This result is proven in [2] by an extension method, using even–odd reflection on the boundaries. The presence of corners in the open set Ω makes it impossible to directly apply a standard result of regularity given in [1].

Remarks.

(i) Since $p \in H^1(\Omega)$, we can now define the trace of p on the boundary Γ. p is defined regardless of any time-dependent function. We now determine this function by setting the condition

$$\int_{\Gamma_0} p \, d\Gamma = \int_{\Gamma_0} p_d \, d\Gamma,$$

where p_d is the observation.

(ii) The velocity u is such that

$$u \in C^0([0,T],V), \qquad \frac{\partial u}{\partial t} \in L^2(0,T,V) \cap C^0([0,T],H).$$

PROPOSITION 2.3. *If the wind-stress f verifies the regularity* (2.3) *and the conditions* (2.4)*, then the solution (u,p) of problem* (2.1) *satisfies the following estimates:*

(i) $\|u\|_{L^2(0,T,H^2(\Omega))} \le C\|f\|_{\mathcal{U}}$,

(ii) $\|p\|_{L^2(0,T,H^1(\Omega))} \le C\|f\|_{\mathcal{U}}$,

where

$$\mathcal{U} = \left\{ f / f \in L^2(0,T,H^1(\Gamma_0)), \frac{\partial f}{\partial t} \in L^2(0,T,L^2(\Gamma_0)) \right\},$$

$$\|f\|_{\mathcal{U}} = \left(\|f\|^2_{L^2(0,T,H^1(\Gamma_0))} + \left\| \frac{\partial f}{\partial t} \right\|^2_{L^2(0,T,L^2(\Gamma_0))} \right)^{1/2}.$$

We denote by C any positive constant.

Proof. The solution (u,p) of problem (2.1) verifies (1.1a) in a distribution sense. Equation (1.1a) can also be written

$$-\nu_h \Delta_2 u - \frac{\partial}{\partial z}\left(\nu_v \frac{\partial u}{\partial z}\right) + \nabla p = -\left(\frac{\partial u}{\partial t} + F\Lambda u + (u_0.\nabla)u + (u.\nabla)u_0\right).$$

Set $G = -(\frac{\partial u}{\partial t} + F\Lambda u + (u_0.\nabla)u + (u.\nabla)u_0)$. If $u_0 \in V$, then $G \in C^0([0,T],L^2(\Omega))$ [2].

At each time $t \in [0,T]$, the initial problem (1.1), (1.2) can be written as follows: Given $G \in L^2(\Omega)$, find $(u,p) : \Omega \to \mathbb{R}^3 \times \mathbb{R}$ such that

$$-\nu_h \Delta_2 u - \frac{\partial}{\partial z}\left(\nu_v \frac{\partial u}{\partial z}\right) + \nabla p = G \quad \text{in } \Omega, \tag{2.5a}$$

$$\text{div } u = 0 \quad \text{in } \Omega, \tag{2.5b}$$

and satisfying the boundary conditions (1.2).

After extension of problem (2.5) in an open set $\tilde{\Omega} =]0, Lx[\times]-2Ly, 2Ly[\times]-H, 0[$ in order to cancel the corners of Ω, we obtain the following estimate [2]:

$$\|u\|_{H^2(\Omega)} + |\nabla p|_{L^2(\Omega)} \leq C(|G|_{L^2(\Omega)} + \|f\|_{H^1(\Gamma_0)}) \quad \text{a.e. on } [0,T]. \tag{2.6}$$

C is positive, time-independent constant.

Equation (2.6) implies

$$\|u\|^2_{L^2(0,T,H^2(\Omega))} \leq C\left(\|G\|^2_{L^2(0,T,L^2(\Omega))} + \|f\|^2_{L^2(0,T,H^1(\Gamma_0))}\right), \tag{2.7}$$

$$\|\nabla p\|^2_{L^2(0,T,L^2(\Omega))} \leq C\left(\|G\|^2_{L^2(0,T,L^2(\Omega))} + \|f\|^2_{L^2(0,T,H^1(\Gamma_0))}\right). \tag{2.8}$$

If $u_0 \in V$, we have the inequality

$$\|G\|^2_{L^2(0,T,L^2(\Omega))} \leq C\left(\left\|\frac{\partial u}{\partial t}\right\|^2_{L^2(0,T,L^2(\Omega))} + \|u\|^2_{L^2(0,T,L^2(\Omega))} + \|u\|^2_{L^2(0,T,V)}\right).$$

Setting $v = u$, (2.1a) gives

$$\frac{d}{dt}|u|^2 + 2a(u,u) + 2\ell(u,u) = -2(f, \gamma_0 u).$$

The bilinear form a is coercive on V: $a(u,u) \geq \nu\|u\|^2_V$.

$$\ell(u,u) = b(u, u_0, u);$$

therefore, if $u_0 \in V$: $2|\ell(u,u)| \leq C_1|u|^2$.

γ_0 is the application trace on Γ_0, which is continuous from V into $L^2(\Gamma_0)$. Set C_0, the constant of continuity.

$$2|(f, \gamma_0 u)| \leq 2C_0|f|_{L^2(\Gamma_0)}\|u\| \leq C_2\|f\|^2_{H^1(\Gamma_0)} + \nu\|u\|^2.$$

We then obtain from (2.1a)

$$\frac{d}{dt}|u|^2 + \nu\|u\|^2 \leq C_2\|f\|^2_{H^1(\Gamma_0)} + C_1|u|^2. \tag{2.9}$$

Applying the Gronwall lemma now gives

$$|u(t)| \leq C\|f\|_{L^2(0,T,H^1(\Gamma_0))} \quad \forall t \in [0,T],$$

and therefore

$$\|u\|_{L^2(0,T,L^2(\Omega))} \leq C\|f\|_{L^2(0,T,H^1(\Gamma_0))}. \tag{2.10}$$

We deduce from (2.9), (2.10) that

$$\|u\|_{L^2(0,T,V)} \leq C\|f\|_{L^2(0,T,H^1(\Gamma_0))}. \tag{2.11}$$

Setting $v = \frac{\partial u}{\partial t} = u'$ in (2.1a) gives

$$|u'|^2 + a(u,u') + \ell(u,u') = -(f, \gamma_0 u')$$

and after integration with respect to time

$$-2\int_0^t |u'(s)|^2 ds + a(u(t),u(t)) = -2\int_0^t \ell(u,u')ds + 2\int_0^t (f',\gamma_0 u)\,ds$$
$$-2(f(t),\gamma_0 u(t)) \quad \forall\ t\in[0,T].$$

$\ell(u,u') = b(u,u_0,u') + b(u_0,u,u')$, which yields $|\ell(u,u')| \le C\|u\|\ |u'|$, since u_0 is given in V.

Applying the coercivity yields

$$2\int_0^t |u'|^2 + \nu\|u\|^2 \le C\int_0^t \|u\|\ |u'| + 2C_0\int_0^t |f'|\ \|u\| + 2C_0|f|\ \|u\|.$$

Since $f(t) = \int_0^t f'(s)\,ds$, we have $|f(t)|^2 \le C\|f'\|^2_{L^2(0,T,L^2(\Gamma_0))} \forall\ t\in[0,T]$, and we obtain the inequality

$$\|u'\|^2_{L^2(0,T,L^2(\Omega))} \le C\left(\|u\|^2_{L^2(0,T,V)} + \|f'\|^2_{L^2(0,T,L^2(\Gamma_0))}\right),$$

which implies, according to (2.11),

$$\|u'\|^2_{L^2(0,T,L^2(\Omega))} \le C\left(\|f\|^2_{L^2(0,T,H^1(\Gamma_0))} + \|f'\|^2_{L^2(0,T,L^2(\Gamma_0))}\right),$$

i.e.,

$$\|u'\|_{L^2(0,T,L^2(\Omega))} \le C\|f\|_{\mathcal{U}}. \tag{2.12}$$

We deduce from (2.10)–(2.12) that $\|G\|_{L^2(0,T,L^2(\Omega))} \le C\|f\|_{\mathcal{U}}$, and (2.7) now implies estimate (i).

According to (2.8) we also obtain the majoration

$$\|\nabla p\|_{L^2(0,T,L^2(\Omega))} \le C\|f\|_{\mathcal{U}}. \tag{2.13}$$

To prove estimate (ii) we now use the mixed formulation (2.2). According to the Inf Sup condition verified by c, we have

$$|p| \le \frac{1}{\beta}\operatorname*{Sup}_{v\in W}\frac{c(v,p)}{\|v\|}. \tag{2.14}$$

Equation (2.2a) can also be written

$$c(v,p) = -((u',v) + a(u,v) + \ell(u,v) + (f,\gamma_0 v)). \tag{2.15}$$

Equations (2.14) and (2.15) imply

$$|p| \le C(|u'| + \|u\| + |f|),$$

which gives, according to estimates (2.11), (2.12),

$$\|p\|_{L^2(0,T,L^2(\Omega))} \le C\|f\|_{\mathcal{U}}. \tag{2.16}$$

Equations (2.13) and (2.16) prove estimate (ii).

COROLLARY.

(i) *The application $f \longrightarrow (u(f),p(f))$ is linear and continuous from $\mathcal{U}$ into $L^2(0,T,H^2(\Omega)) \times L^2(0,T,H^1(\Omega))$.*

(ii) *The application $f \longrightarrow \gamma_0 p$ is linear and continuous from $\mathcal{U}$ into $L^2(0,T,L^2(\Gamma_0))$.*

Proof. The application trace is continuous from $H^1(\Omega)$ in $L^2(\Gamma_0)$. We thus have

$$\|\gamma_0 p\|_{L^2(0,T,L^2(\Gamma_0))} \le C\|p\|_{L^2(0,T,H^1(\Omega))} \le C\|f\|_{\mathcal{U}}. \tag{2.17}$$

3. Characterization of the optimal control. The problem is controlled by the variability of the wind-stress f. The observation is the pressure on Γ_0, deduced from altimetric measurements. Controls and observations are thus defined on Γ_0, which is a part of the boundary Γ. The control f has to verify the regularity condition (2.3) in order to obtain $p \in H^1(\Omega)$.

Thereby $\mathcal{U} = \{f/f \in L^2(0,T,H^1(\Gamma_0)), \frac{\partial f}{\partial t} \in L^2(0,T,L^2(\Gamma_0))\}$ will be the control space; $\mathcal{H} = L^2(0,T,L^2(\Gamma_0))$ will be the observation space. For each control f, $(u(f),p(f))$ is the solution of the weak problem (2.1) or (2.2), and the cost function J is defined by

$$J(f) = \frac{1}{2}(\|\mathcal{C}p(f) - p_d\|^2_{\mathcal{H}} + \alpha\|f\|^2_{\mathcal{U}}). \tag{3.1}$$

$p_d \in \mathcal{H}$ is the observation. p_d is the trace of the real pressure p_e, which is supposed to be in $L^2(0,T,H^1(\Omega))$. $\mathcal{C}$ is the application trace on Γ_0. $\mathcal{C} : p \in L^2(0,T,H^1(\Omega)) \longrightarrow \mathcal{C}\ p = \gamma_0 p \in \mathcal{H}$. α is a given positive constant ($\alpha \neq 0$). The optimal control problem then is as follows: find $f \in \mathcal{U}$ such that

$$J(f) = \operatorname*{Inf}_{h\in\mathcal{U}} J(h). \tag{3.2}$$

PROPOSITION 3.1. *Problem* (3.2) *admits one unique solution* $f \in \mathcal{U}$.

Proof.

(i) J is continuous on $\mathcal{U}$. Set

$$r(f,h) = (\mathcal{C}p(f), \mathcal{C}p(h))_{\mathcal{H}} + \alpha(f,h)_{\mathcal{U}}$$

and

$$s(f) = (\mathcal{C}p(f), p_d)_{\mathcal{H}} \quad \forall f \text{ and } h \in \mathcal{U}.$$

We have

$$J(f) = \frac{1}{2}r(f,f) - s(f) + \frac{1}{2}\|p_d\|^2_{\mathcal{H}}.$$

According to (2.17), we can write

$$|r(f,h)| \leq C\|f\|_{\mathcal{U}}\|h\|_{\mathcal{U}} \quad \text{and} \quad |s(f)| \leq C\|f\|_{\mathcal{U}},$$

where C denotes any positive constant. The applications r and s are continuous, and therefore J is continuous on $\mathcal{U}$.

(ii) J is coercive on $\mathcal{U}$ since $J(f) \geq \frac{\alpha}{2}\|f\|^2_{\mathcal{U}} \quad \forall\ f \in \mathcal{U}$.

(iii) J is strictly convex.

J is differentiable, and

$$(J'(f), h) = r(f,h) - s(h) \quad \forall\ f \text{ and } h \in \mathcal{U},$$

which gives

$$(J'(f) - J'(h), f - h) = r(f-h, f-h) > \alpha\|f-h\|^2_{\mathcal{U}}.$$

(i), (ii), and (iii) imply that problem (3.2) admits one unique solution in $\mathcal{U}$ ([4]).

$f \in \mathcal{U}$ is solution of problem (3.2) if and only if $J'(f) = 0$. In order to characterize the optimal control f we introduce the adjoint problem associated with problem (2.2).

The bilinear form a is selfadjoint. Let ℓ^* be the adjoint of ℓ. For a wind-stress $f \in \mathcal{U}, (u(f), p(f))$ is the solution of problem (2.2). We note $(u^*(f), p^*(f))$, the adjoint state which is the solution of the adjoint problem (3.3):

$$-\left(\frac{\partial u^*}{\partial t}(f), v\right) + a(u^*(f), v) + \ell^*(u^*(f), v) + c(v, p^*(f)) = 0 \quad \forall\, v \in W, \tag{3.3a}$$

$$-c(u^*(f), q) = (\mathcal{C}p(f) - p_d, \mathcal{C}q) \quad \forall q \in H^1(\Omega), \tag{3.3b}$$

$$u^*(f)(T) = 0. \tag{3.3c}$$

PROPOSITION 3.2. *The adjoint problem* (3.3) *admits one unique solution such that* $u^*(f) \in L^2(0, T, W), p^*(f) \in L^2(0, T, L^2(\Omega))$.

Proof. The compatibility condition $\int_{\Gamma_0} (\mathcal{C}p(f) - p_d)\, d\Gamma = 0$ is satisfied. So, almost everywhere on $]0, T[$, there exists $u_i \in W$ such that

$$-c(u_1, q) = (\text{div } u_1, q) = (\mathcal{C}p(f) - p_d, \mathcal{C}q) \quad \forall\, q \in H^1(\Omega).$$

Set $\tilde{u} = u^*(f) - u_1$. Equations (3.3) can be written

$$-\left(\frac{\partial \tilde{u}}{\partial t}, v\right) + a(\tilde{u}, v) + \ell^*(\tilde{u}, v) + c(v, p^*(f)) = (G, v) \quad \forall\, v \in W, \tag{3.4a}$$

$$-c(\tilde{u}, q) = 0 \quad \forall\, q \in H^1(\Omega), \tag{3.4b}$$

$$\tilde{u}(T) = 0. \tag{3.4c}$$

G depends on u_1 and $G \in L^2(\Omega)$.

Problem (3.4), being similar to problem (2.2), admits one unique solution: $\tilde{u} \in L^2(0, T, W)$. $u^* = \tilde{u} + u_1 \in L^2(0, T, W)$ and verifies equation (3.3). The existence of a solution being proven, demonstrating the uniqueness is fairly simple. There exists a pressure $p^* \in L^2(0, T, L^2(\Omega))$ such that equations (3.4a) and (3.3a) are verified [8].

PROPOSITION 3.3. $J'(f) = 0$ *if and only if* $\alpha f + \Lambda^{-1}\gamma_0 u^*(f) = 0$ *in* $\mathcal{U}$.

Λ is the canonical isomorphism $\mathcal{U} \longrightarrow \mathcal{U}'$ such that

$$\langle h, v\rangle_{\mathcal{U},\mathcal{U}'} = (\Lambda h, v)_{\mathcal{U}'} = (h, \Lambda^{-1} v)_{\mathcal{U}} \quad \forall\, h \in \mathcal{U}, \quad \forall\, v \in \mathcal{U}'.$$

Proof.

$$(J'(f), h) = r(f, h) - s(h) = (\mathcal{C}p(f) - p_d, \mathcal{C}p(h))_{\mathcal{H}} + \alpha(f, h)_{\mathcal{U}} \quad \forall\, f \text{ and } h \in \mathcal{U}.$$

Equation (3.3b) implies

$$(\mathcal{C}p(f) - p_d, \mathcal{C}p(h))_{L^2(\Gamma_0)} = -c(u^*(f), p(h))$$

and therefore

$$(J'(f), h) = \alpha(f, h)_{\mathcal{U}} - \int_0^T c(u^*(f), p(h))\, dt \quad \forall\, f \text{ and } h \in \mathcal{U}.$$

$(u(h), p(h))$ is the solution of problem (2.2),

$$\left(\frac{\partial u(h)}{\partial t}, v\right) + a(u(h), v) + \ell(u(h), v) + c(v, p(h)) = -(h, \gamma_0 v) \quad \forall\, \mathrm{v} \in W,$$

and so, by setting $v = u^*(f)$,

$$-c(u^*(f), p(h)) = \left(\frac{\partial}{\partial t}u(h), u^*(f)\right) + a(u(h), u^*(f)) + \ell(u(h), u^*(f)) + (h, \gamma_0 u^*(f)),$$

we obtain

$$(J'(f), h) = \alpha(f, h)_{\mathcal{U}} + \int_0^T \left(-\left(\frac{\partial}{\partial t}u^*(f), u(h)\right) + a(u^*(f), u(h)) + \ell^*(u^*(f), u(h)\right) dt + \int_0^T (h, \gamma_0 u^*(f)) dt.$$

$u^*(f)$ is the solution of the adjoint problem (3.3). We thus have

$$(J'(f), h) = \alpha(f, h)_{\mathcal{U}} - \int_0^T c(u(h), p^*(f)) dt + \int_0^T (h, \gamma_0 u^*(f))\, dt.$$

According to equation (2.2b),

$$c(u(h), p^*(f)) = 0$$

and thus

$$\begin{aligned}(J'(f), h) &= \alpha(f, h)_{\mathcal{U}} + \int_0^T (h, \gamma_0 u^*(f)) \\ &= \alpha(f, h)_{\mathcal{U}} + (h, \gamma_0 u^*(f))_{L^2(0,T,L^2(\Gamma_0))} \\ &= \alpha(f, h)_{\mathcal{U}} + \langle h, \gamma_0 u^*(f)\rangle_{\mathcal{U},\mathcal{U}'} \\ &= \alpha(f, h)_{\mathcal{U}} + (\Lambda^{-1}\gamma_0 u^*(f), h)_{\mathcal{U}} \\ &= (\alpha f + \Lambda^{-1}\gamma_0 u^*(f), h)_{\mathcal{U}}.\end{aligned}$$

We can now conclude that $J'(f) = 0$ if and only if $\alpha f + \Lambda^{-1}\gamma_0 u^*(f) = 0$ in $\mathcal{U}$.

Characterization of the optimal control. We have proved that the optimal control f, the solution of problem (3.2), is characterized by the following set of equations:

$$\begin{aligned}\left(\frac{\partial}{\partial t}u(f), v\right) + a(u(f), v) + \ell(u(f), v) + c(v, p(f)) &= -(f, \gamma_0 v) \quad \forall\, v \in W, \\ -c(u(f), q) &= 0 \quad \forall\, q \in H^1(\Omega), \\ -\left(\frac{\partial}{\partial t}u^*(f), v\right) + a(u^*(f), v) + \ell^*(u^*(f), v) + c(v, p^*(f)) &= 0 \quad \forall\, v \in W, \\ -c(u^*(f), q) &= (\mathcal{C}p(f) - p_d, \mathcal{C}q) \\ &\quad \forall\, q \in H^1(\Omega), \\ u(f)(0) &= 0, \\ u^*(f)(T) &= 0, \\ \alpha f + \Lambda^{-1}\gamma_0 u^*(f) &= 0 \text{ in } \mathcal{U}.\end{aligned}$$

4. A convergence result. J_α will now denote the cost function

$$J_\alpha(h) = \frac{1}{2}(\|\mathcal{C}p(h) - p_d\|^2_{\mathcal{H}} + \alpha\|h\|^2_{\mathcal{U}}).$$

Problem (3.2) becomes the following: find $f_\alpha \in \mathcal{U}$ such that

$$J_\alpha(f_\alpha) = \operatorname*{Inf}_{h\in\mathcal{U}} J_\alpha(h). \tag{4.1}$$

We set

$$J_0(h) = \frac{1}{2}\|\mathcal{C}p(h) - p_d\|^2_{\mathcal{H}}, \qquad \Pi(h) = \mathcal{C}p(h).$$

We have already proved that Π is a linear continuous application from $\mathcal{U}$ into $\mathcal{H}$. We consider the functional spaces

$$\mathcal{U} = \left\{h/h \in L^2(0,T,H^1(\Gamma_0)), \frac{\partial h}{\partial t} \in L^2(0,T,L^2(\Gamma_0))\right\}, \qquad \mathcal{U}^* = \mathcal{U}_{\operatorname{Ker}\Pi}.$$

LEMMA.
(i) Ker Π *is a closed subset of* $\mathcal{U}$.
(ii) $\mathcal{U}^*$ *is a Hilbert space.*
Proof.
(i) Let (f_m) be a sequence in Ker Π such that (f_m) converges towards f in $\mathcal{U}$. Since Π is continuous, $\Pi(f_m)$ converges toward $\Pi(f)$. $\Pi(f_m) = 0 \quad \forall\ m$; therefore, $\Pi(f) = 0$ and $f \in$ Ker Π.
(ii) Ker Π is a closed subset of the Hilbert space $\mathcal{U}$. Hence Ker Π and $(\text{Ker }\Pi)^\perp$ are Hilbert spaces.

Let $f^* \in \mathcal{U}^*$: f^* is a coset of $\mathcal{U}$ modulo Ker Π; let f be any element of f^*. $f = f_1 + f_2, f_1 \in$ Ker $\Pi, f_2 \in (\text{Ker }\Pi)^\perp$.

We set $\|f^*\|_{\mathcal{U}^*} = \|f_2\|_{\mathcal{U}} = \text{Inf}_{f\in f^*}\|f\|_{\mathcal{U}}$. We define the linear application ψ:

$$\begin{aligned}\Psi : \mathcal{U}^* &\longrightarrow (\text{Ker }\Pi)^\perp,\\ f^* &\longrightarrow f_2.\end{aligned}$$

Ψ is a bijection:
- if $f_2 \in (\text{Ker }\Pi)^\perp, f = f_2 + f_1 \in \mathcal{U}^*\ \forall\ f_1 \in$ Ker Π.
- $\Psi(f^*) = 0$ implies $f \in$ Ker Π, i.e., $f^* = 0$.

According to the definition of the norm in $\mathcal{U}^*$, ψ and ψ^{-1} are continuous. ψ is therefore an homeomorphism; since $(\text{Ker }\Pi)^\perp$ is a Hilbert space, $\mathcal{U}^*$ is also an Hilbert space.

We now introduce the following problem: find $f^* \in \mathcal{U}^*$ such that

$$J_0(f^*) = \operatorname*{Inf}_{h^*\in\mathcal{U}^*} J_0(h^*). \tag{4.2}$$

If there exists $f \in \mathcal{U}$ such that

$$J_0(f) = \inf_{h\in\mathcal{U}} J_0(h), \tag{4.3}$$

then problem (4.2) admits one unique solution $f^* \in \mathcal{U}^*$. The solution f of (4.3) is an element of the coset f^*. This will be verified if we assume that $f \in \mathcal{U}_{ad}$,

$\mathcal{U}_{ad} = \{h \in \mathcal{U} / \|h\|_{\mathcal{U}} \leq c\}$ [4]. f is the variability of the wind-stress and the assumption that f bounded is sensible.

PROPOSITION 4.1. *Let f_α be the solution of problem* (4.1) *and f^* be the solution of problem* (4.2). *When α tends to* 0, *then*

(i) (f_α) *converges toward f^* strongly in $\mathcal{U}^*$.*

(ii) $J_\alpha(f_\alpha)$ *converges toward $J_0(f^*)$.*

Proof.

(ii) Since f^* verifies (4.2), any element $f \in f^*$ verifies (4.3):

$$J_0(f) \leq J_0(h) \quad \forall\ h \in \mathcal{U}.$$

Definitions of J_0 and J_α imply

$$J_0(h) \leq J_\alpha(h) \quad \forall h \in \mathcal{U}.$$

We thus obtain

$$J_0(f) \leq J_\alpha(f_\alpha) \quad \forall\ \alpha \in \mathbb{R}_+^*. \tag{4.4}$$

Since $J_0(f) = \mathrm{Inf}_{h\in\mathcal{U}}\, J_0(h)\ \forall\ \varepsilon > 0, \exists\ h_\varepsilon \in \mathcal{U}$ such that $J_0(h_\varepsilon) \leq \frac{\varepsilon}{2} + J_0(f)$, and therefore $J_\alpha(h_\varepsilon) \leq \frac{\varepsilon}{2} + J_0(f) + \frac{\alpha}{2}\|h_\varepsilon\|^2_{\mathcal{U}}$. Set $\alpha^* = \frac{\varepsilon}{\|h_\varepsilon\|^2_{\mathcal{U}}}$. We thus have $J_{\alpha^*}(h_\varepsilon) \leq \varepsilon + J_0(f)$.

According to (4.4), this gives the following: $\forall\ \varepsilon > 0, \exists\ \alpha^*$ such that $\forall\ \alpha, 0 < \alpha < \alpha^*$, we have

$$J_0(f) \leq J_\alpha(f_\alpha) \leq \varepsilon + J_0(f). \tag{4.5}$$

We deduce from (4.5) that $\lim_{\alpha\to 0} J_\alpha(f_\alpha) = J_0(f) = J_0(f^*)$.

(i) f_α and f verify (4.1) and (4.3), respectively. We thus have

$$(J_\alpha^{'}(f_\alpha), h - f_\alpha) \geq 0 \quad \forall\ h \in \mathcal{U}$$

and

$$(J_0^{'}(f), h - f) \geq 0 \quad \forall\ h \in \mathcal{U};$$

i.e.,

$$(\Pi(f_\alpha) - p_d, \Pi(h - f_\alpha))_{\mathcal{H}} + \alpha(f_\alpha, h - f_\alpha)_{\mathcal{U}} \geq 0 \quad \forall\ h \in \mathcal{U}, \tag{4.6}$$

$$(\Pi(f) - p_d, \Pi(h - f))_{\mathcal{H}} \geq 0 \quad \forall\ h \in \mathcal{U}. \tag{4.7}$$

Setting $h = f$ in (4.6) and $h = f_\alpha$ in (4.7) gives

$$\alpha(f_\alpha, f - f_\alpha)_{\mathcal{U}} \geq \|\Pi(f - f_\alpha)\|^2_{\mathcal{H}} \geq 0,$$

which yields

$$\|f_\alpha\|^2_{\mathcal{U}} \leq (f, f_\alpha)_{\mathcal{U}} \leq \|f\|_{\mathcal{U}}\|f_\alpha\|_{\mathcal{U}},$$

i.e.,

$$\|f_\alpha\|_{\mathcal{U}} \leq \|f\|_{\mathcal{U}}. \tag{4.8}$$

The sequence (f_α) is bounded in $\mathcal{U}$. We can extract from (f_α) a subsequence also denoted (f_α) which converges toward $\tilde{f}$, weakly in $\mathcal{U}$. Since J_α is lower semicontinuous, we have [3], [4]

$$\liminf J_\alpha(f_\alpha) \geq J_\alpha(\tilde{f}) \geq J_0(\tilde{f}).$$

The inequality (4.5) implies

$$\limsup J_\alpha(f_\alpha) \leq J_0(f)$$

and so

$$J_0(\tilde{f}) \leq \liminf J_\alpha(f_\alpha) \leq \limsup J_\alpha(f_\alpha) \leq J_0(f).$$

f verifies (4.3). Therefore, $J_0(\tilde{f}) = J_0(f) = J_0(f^*)$.

The sequence (f_α) converges towards an element $\tilde{f}$ of f^*, weakly in $\mathcal{U}$. According to (4.8) we have $\|f_\alpha\|_{\mathcal{U}} \leq \|\tilde{f}\|_{\mathcal{U}}$, which implies $\limsup \|f_\alpha\|_{\mathcal{U}} \leq \|\tilde{f}\|_{\mathcal{U}}$.

Therefore, (f_α) converges towards $\tilde{f}$ strongly in $\mathcal{U}$ [3]; i.e., (f_α) converges toward f^* strongly in $\mathcal{U}^*$.

5. Conclusion. The sea level variability is obtained from altimetric measurements. We can deduce from these data the variability of the pressure on Γ_0. Γ_0 corresponds to the horizontal undisturbed sea surface and is the upper boundary of the oceanic domain considered in this paper. We have developed a control method in order to calculate the perturbation (u, p) of the mean velocity and pressure corresponding to the observed variability of p on Γ_0. The control is the variability of the wind-stress f which acts as the forcing of the perturbation. The cost function depends on a real parameter α. For any $\alpha > 0$ we have proved the existence and uniqueness of an optimal control f_α. To characterize f_α we must consider the direct problem verified by (u, p) and its adjoint. When α tends to 0, the sequence (f_α) converges toward a wind-stress f. f is an approximation of the unknown real wind-stress f_e, which induced the observed situation. The perturbation (u_α, p_α) driven by f_α is the unique solution of a linearized Navier–Stokes-type problem. Velocity and pressure are continuous functions of the wind-stress; therefore, when α tends to 0, (u_α, p_α) converges toward the solution (u, p) of the linearized Navier–Stokes problem forced by f. Since f approaches f_e, the perturbation (u, p) is an approximation of the real circulation (u_e, p_e) observed by the satellite. We can thus compute the variability of the velocity and pressure in an oceanic domain Ω, during a time T, from satellite observations of the sea surface. The assumptions of the model correspond to the physical features of equatorial waves. It is then easy to deduce from the variability (u, p) the characteristics of the excited waves.

Appendix. Choice of the observation for the control method. The assumption of hydrostatic pressure is standard in oceanography and justified by the difference between horizontal and vertical scalings in an oceanic domain. The equation of hydrostatic pressure is

$$\frac{\partial \tilde{p}}{\partial z} + \rho g = 0, \tag{A.1}$$

where $\tilde{p}$ is the total pressure, ρ is the density, and g is the constant of gravity.

The sea level is a free surface of equation $z = \tilde{\xi}(x, y, t)$. We suppose that the density ρ is constant in the upper layer $0 \leq z \leq \tilde{\xi}$. Integrating (A.1) with respect to

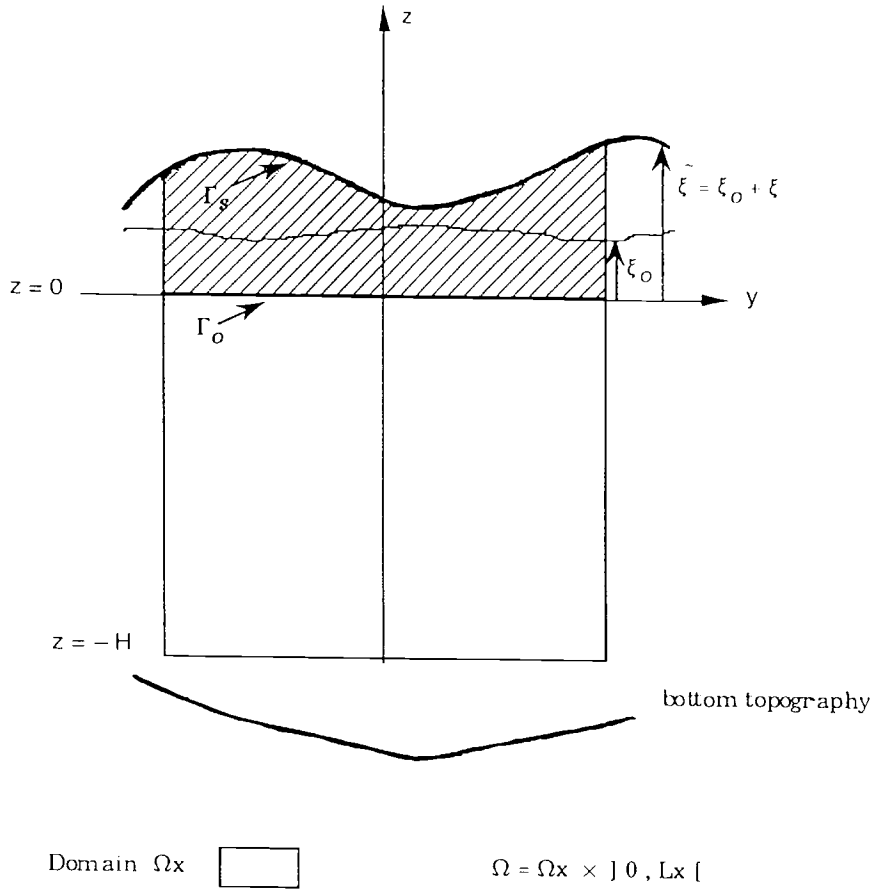

FIG. 1.

z between $z = 0$ and $z = \tilde{\xi}$ gives

$$(\tilde{p})_{z=\tilde{\xi}} = (\tilde{p})_{z=0} - \rho g \tilde{\xi}. \tag{A.2}$$

The surface pressure is equal to the atmospheric pressure: $(\tilde{p})_{z=\tilde{\xi}} = \tilde{p}_{\text{atm}}$.

We assume that the velocity $\tilde{u}$ can be considered as the sum of two terms: a mean given velocity u_0 and a perturbation u. The same expansion is valid for the pressure and the sea level:

$$\tilde{p} = p_0 + p,$$
$$\tilde{\xi} = \xi_0 + \xi.$$

p_0 and ξ_0 are the pressure and the free surface corresponding to the mean flow. p and ξ are the variability of pressure and sea level corresponding to the variability u of the current.

Equation (A.2) is verified by the mean flow and by the complete evolutive situation. This implies

$$p_{\text{atm}} = (p)_{z=0} - \rho g \xi. \tag{A.3}$$

Neglecting the variability of the atmospheric pressure gives

$$(p)_{z=0} = \rho g \xi. \tag{A.4}$$

The variability of the sea level ξ is known from altimetric measurements. Relation (A.4) makes it possible to take the variability of the pressure at a fixed level ($z = 0$) as the observation. Relation (A.4) also induces the choice of the domain Ω. The vertical extension of Ω is $-H \leq z \leq 0$, H being a constant. We denote by Γ_0 the part of the boundary of equation $z = 0$. The observation is therefore given on Γ_0.

It has to be noted that the studied domain Ω differs from the physical domain, which extends from the bottom Γ_B to the free sea surface Γ_S (Fig. 1).
