†Istituto per le Applicazioni del Calcolo, Consiglio Nationale delle Ricerche, viale del Policlinico, 137, 00161 Rome, Italy.

a generalization of the Ingham theorem [8], which we prove in section 3. Results on the reachability problem for plate equation with memory can be found in [9], [11], [12], [13].

1. Statement of the problem. We consider the axially symmetric vibrations of an elastic spherical membrane with middle ray R and opening angle θ_0. The meridional and radial components of the displacement vector $\mathbf{v} = (u(\theta,t),\ w(\theta,t))$ satisfy in $Q = (0,T)\times(0,\theta_0)$ the system

$$\begin{cases} du_{tt} - \mathcal{L}(u) - (1-\nu)u + (1+\nu)w' = 0, \\ dw_{tt} - \frac{(1+\nu)}{\sin\theta}(u\sin\theta)' + 2(1+\nu)w = 0 \end{cases} \tag{1.1}$$

with

$$u(0,t) = 0, \quad u(\theta_0,t) = g(t)$$

and

$$\mathbf{v}\,(\theta,0) = \mathbf{v}^{\,0}, \quad \mathbf{v}_t(\theta,0) = \mathbf{v}^{\,1},$$

where

$$\mathcal{L}(u) = \left(\frac{(u\sin\theta)'}{\sin\theta}\right)'. \tag{1.2}$$

The prime stands for the first derivative with respect to θ, $\nu \in (-1, 1/2)$, and $d = d_0\ R^2(1-\nu^2)/E$, where E is an elastic positive constant and d_0 is the density of the material. In what follows we change $t = \sqrt{d}\ t$. We introduce the following spaces:

$$L^2 = L^2(0,\theta_0;\sin\theta\,\mathrm{d}\theta) = \left\{ f : \int_0^{\theta_0} |f|^2 \sin\theta\,\mathrm{d}\theta < +\infty \right\},$$

$$\mathcal{U} = \left\{ u :\ \frac{\partial u}{\partial\theta}\,,\ u\cot\theta \in L^2(0,\theta_0;\sin\theta\,\mathrm{d}\theta)\ ,\quad u(0) = u(\theta_0) = 0 \right\}.$$

$\|f\|_0$ is the norm induced by the scalar product $(f,g)_0 = \int_0^{\theta_0} f\cdot g\sin\theta\,\mathrm{d}\theta$, and $\|u\|^2_{\mathcal{U}} = \|u'\|^2_0 + \|u\cot\theta\|^2_0$. The exact controllability problem requires that we find a control function $g(t)$ that drives the system to the rest in a finite time T. In [6] we proved that the membrane approximation is not exactly controllable for any $\{\mathbf{v}^{\,1}, \mathbf{v}^{\,0}\} \in (\mathcal{U}'\times L^2)\times\ (L^2\times L^2)$. We observed that for the hemispherical membrane there exists a subsequence of eigenfunctions $\mathbf{v}^{\,*}_n(\theta) = (u^*_n(\theta), w^*_n(\theta))$ such that

$$\lim_{n\to\infty} u^*_n(\pi/2) - (1+\nu)w^*_n(\pi/2) = 0.$$

Then the sequence $\{\mathbf{v}^{\,*}_n\ ,0\}$ with $\|\mathbf{v}^{\,*}_n\|_{\mathcal{U}\times L^2} = 1$ (initial data for the homogeneous problem associated with (1.1)) does not satisfy the necessary (and sufficient) condition of exact controllability.

Since the exact controllability for membrane approximation generally fails, we look for a partial result; i.e., we look for a PEC result.

The problem (1.1) is equivalently written in the form

$$u_{tt} - \mathcal{L}(u) - (1-\nu)u + (1+\nu)(w^0)' \cos t\sqrt{2(1+\nu)} + \frac{(1+\nu)}{\sqrt{2(1+\nu)}}(w^1)'$$
$$\cdot \sin t\sqrt{2(1+\nu)} + \frac{(1+\nu)^{3/2}}{\sqrt{2}} \int_0^t \sin((t-s)\sqrt{2(1+\nu)})\mathcal{L}(u(\theta,s))\,\mathrm{d}s = 0.$$

We consider the following partial controllability (PC) problem.

(PC) Given $T > 0$ and two functions $u^0(\theta)$, $u^1(\theta)$, find $g(t)$ such that the system

$$\begin{cases} u_{tt} - \mathcal{L}(u) - (1-\nu)u + (1+\nu)w' = 0, \\ w_{tt} - \frac{(1+\nu)}{\sin\theta}(u\sin\theta)' + 2(1+\nu)w = 0, \end{cases} \tag{1.3}$$

with boundary conditions

$$u(0,t) = 0, \quad u(\theta_0,t) = g(t) \tag{1.4}$$

and null initial data, i.e.,

$$\mathbf{v}\,(\theta,0) = 0, \quad \mathbf{v}_t(\theta,0) = 0, \tag{1.5}$$

verifies the final conditions

$$u(\theta,T) = u^0, \quad u_t(\theta,T) = u^1 \tag{1.6}$$

or, equivalently,

(PC)′ Given $T > 0$ and two functions $u^0(\theta)$, $u^1(\theta)$, find $g(t)$ such that the system

$$u_{tt} - \mathcal{L}(u) - (1-\nu)u + \frac{(1+\nu)^{3/2}}{\sqrt{2}} \int_0^t \sin((t-s)\sqrt{2(1+\nu)})\mathcal{L}(u(\theta,s))\,\mathrm{d}s = 0,$$

with

$$u(0,t) = 0, \quad u(\theta_0,t) = g(t)$$

and

$$\mathbf{v}\,(\theta,0) = 0, \quad \mathbf{v}_t(\theta,0) = 0,$$

verifies the conditions

$$u(\theta,T) = u^0, \quad u_t(\theta,T) = u^1.$$

To solve the problem (PC)′ we apply the RHUM method [11], [16].

We consider the adjoint system

$$z_{tt} - \mathcal{L}(z) - (1-\nu)z + \frac{(1+\nu)^{3/2}}{\sqrt{2}} \int_t^T \sin((s-t)\sqrt{2(1+\nu)})\mathcal{L}(z(\theta,s))\,\mathrm{d}s = 0 \tag{1.7}$$

with homogeneous boundary conditions

$$z(0,t) = 0, \quad z(\theta_0,t) = 0 \tag{1.8}$$

and final data

$$z(\theta,T)=z^0,\quad z_t(\theta,T)=z^1. \tag{1.9}$$

Then we consider the problem

$$\ddot{\phi}_{tt}-\mathcal{L}(\phi)-(1-\nu)\phi+\frac{(1+\nu)^{3/2}}{\sqrt{2}}\int_0^t \sin((t-s)\sqrt{2(1+\nu)})\mathcal{L}(\phi(\theta,s))\,\mathrm{d}s=0$$

with

$$\phi(0,t)=0,\quad \phi(\theta_0,t)=-\frac{(1+\nu)^{3/2}}{\sqrt{2}}\int_t^T \sin((s-t)\sqrt{2(1+\nu)})z'(\theta_0,s)\,\mathrm{d}s+z'(\theta_0,t)$$

and

$$\phi(\theta,0)=0,\quad \phi_t(\theta,0)=0.$$

We define $\mu\{z^0,z^1\}=\{\phi_t^0(T),-\phi_0(T)\}$ and put

$$G_z(\theta,t)=\int_0^t \sin((t-s)\sqrt{2(1+\nu)})z(\theta,s)\,\mathrm{d}s$$

and the adjoint operator of G by G^*, where

$$G_z^*(\theta,t)=\int_t^T \sin((s-t)\sqrt{2(1+\nu)})z(\theta,s)\,\mathrm{d}s. \tag{1.10}$$

With some simple computations we can prove

$$\langle\mu\{z^0,z^1\},\ \{z^0,z^1\}\rangle=\int_0^T \sin\theta_0\phi(\theta_0,t)z'(\theta_0,t)\,\mathrm{d}t$$
$$-\frac{(1+\nu)^{3/2}}{\sqrt{2}}\int_0^T G_{z'}^*(\theta_0,t)\phi(\theta_0,t)\sin\theta_0\,\mathrm{d}t.$$

Our aim is to prove that $\nu\{z^0,z^1\}$ is invertible in a suitable function space.

2. Analysis of the homogeneous problem. In order to prove existence and uniqueness results for (1.7), (1.8), and (1.9), we introduce the energy

$$E(t)=\frac{1}{2}\int_0^{\vartheta_0}(z_t^2+(z')^2+z^2\cot^2\vartheta+\nu z^2)\sin\vartheta\,\mathrm{d}\vartheta$$

and

$$E_T=\frac{1}{2}\int_0^{\vartheta_0}(z^{1^2}+(z^{0'})^2+(z^0)^2\cot^2\vartheta+\nu(z^0)^2)\sin\vartheta\,\mathrm{d}\vartheta.$$

We have the following proposition.

PROPOSITION 2.1. *There exist two constants $C_1(T,\nu)$ and $C_2(T,\nu)$ such that $E(t)\le C_1(T,\nu)E_T\cdot e^{C_2(T,\nu)(T-t)}$.*

Proof. To prove Proposition 2.1 we argue in similar way to [16, vol. 2, p. 242]. To this end we introduce

$$r_0(t) = \int_0^{\vartheta_0} \int_t^T \sin((s-t)\sqrt{2(1+\nu)})(z(\vartheta,s)\sin\vartheta)' \cdot \frac{1}{\sqrt{\sin\vartheta}}\,\mathrm{d}s[z(\vartheta,t)\sin\vartheta]'\frac{1}{\sqrt{\sin\vartheta}}\,\mathrm{d}\vartheta$$

and

$$r_1(t) = \int_0^{\vartheta_0} \int_t^T \cos((s-t)\sqrt{2(1+\nu)})(z(\vartheta,s)\sin\vartheta)' \cdot \frac{1}{\sqrt{\sin\vartheta}}\,\mathrm{d}s[z(\vartheta,t)\sin\vartheta]'\frac{1}{\sqrt{\sin\vartheta}}\,\mathrm{d}\vartheta.$$

Applying the Schwarz inequality after simple computations we obtain

$$|r_0(t)| \le 4\frac{E(t)}{\sqrt{27}} + \frac{\sqrt{27}}{16}\left\{\frac{T-t}{2} - \frac{1}{4}\frac{\sin 2(T-t)\sqrt{2(1+\nu)}}{\sqrt{2(1+\nu)}}\right\}\int_t^T E(s)\,\mathrm{d}s,$$

and similarly we obtain

$$|r_1(t)| \le E(t) + \frac{1}{4}\left(\frac{T-t}{2} + \frac{1}{4}\frac{\sin 2(T-t)\sqrt{2(1+\nu)}}{\sqrt{2(1+\nu)}}\right)\int_t^T E(s)\,\mathrm{d}s.$$

On the other hand, it is easy to show that

$$\frac{d}{dt}\left(E(t) + \frac{\sqrt{2}}{2}\sqrt{(1+\nu)^3}r_0(t)\right) = -(1+\nu)^2 r_1(t).$$

Hence,

$$E(t) \le E_T + \frac{\sqrt{2}}{2}\sqrt{(1+\nu)^3}|r_0(t)| + (1+\nu)^2\int_t^T |r_1(s)|\,\mathrm{d}s.$$

We compute

$$\int_t^T |r_1(s)|\,\mathrm{d}s \le \left(1 + \frac{1}{4}\int_t^T M_1^2(s)\,ds\right)\int_t^T E(s)\,\mathrm{d}s,$$

where

$$M_1^2 = \frac{T-t}{2} + \frac{1}{4}\frac{\sin 2(T-t)\sqrt{2(1+\nu)}}{\sqrt{2(1+\nu)}},$$

$$E(t) \le E_T + 2\sqrt{2(1+\nu)^3}\frac{E(t)}{\sqrt{27}} + \sqrt{27}\frac{1}{64}\left(T + \frac{1}{2\sqrt{2(1+\nu)}}\right)\sqrt{2(1+\nu)^3}\int_t^T E(s)\,\mathrm{d}s + (1+\nu)^2\left(1 + \frac{1}{4}\int_t^T M_1^2(s)\,\mathrm{d}s\right)\int_t^T E(s)\,\mathrm{d}s.$$

It is straightforward to find

$$\int_t^T M_1^2(t)\,\mathrm{d}t \le \frac{T^2}{4} + \frac{1}{8(1+\nu)}.$$

From the above estimates we conclude choosing

$$c_1(T,\nu) = \frac{E_T}{\left(1 - \frac{\sqrt{2}}{2}\sqrt{(1+\nu)^3}\frac{2}{\sqrt{27}}\right)},$$

$$c_2(T,\nu) = \left((1+\nu)^2\frac{T^2}{16} + \sqrt{27}\frac{1}{64}\sqrt{2(1+\nu)^3}T + \left(\sqrt{27}\frac{1}{128} + (1+\nu) + \frac{1}{8}\right)\right)(1+\nu). \qquad \square$$

From the above result we obtain the following.

PROPOSITION 2.2. *The problem* (1.2) *has a unique solution such that*

$$\{z, z'\} \in C([0,T];\ \mathcal{U} \times L^2).$$

Now we shall find the explicit solution of the equation (1.2) with boundary homogeneous conditions and the final state z^0, z^1.

So we consider the eigenvalues problem

$$-\mathcal{L}(z_k) = \lambda_k z_k, \tag{2.1}$$

where $\mathcal{L}$ is the operator given in (1.2) and $z_k(0) = z_k(\vartheta_0) = 0$.

We assume that the solution of our problem can be written as

$$z(\vartheta,t) = \sum_{k=1}^{+\infty} f_k(t) z_k(\vartheta), \tag{2.2}$$

where z_k is an orthonormal base in $(0,\theta_0)$.

Substituting z, given by (2.2), using the eigenvalue problem (2.1), and multiplying the equation by z_k we find the following integrodifferential equation in the unknown f (here the dot denotes the derivative with respect to t):

$$\ddot{f}_k(t) + (\lambda_k - 1 + \nu) f_k(t) - \lambda_k \frac{(1+\nu)^2}{\sqrt{2(1+\nu)}} \int_0^t \sin((t-s)\sqrt{2(1+\nu)}) f_k(s)\,\mathrm{d}s = 0.$$

Using [18, p. 149] and the method of Evans [18, p. 67], we find the solution

$$\begin{aligned} f_k(t) = {} & (f_k^T + \dot{f}_k^T t)\left(1 + \frac{b_k^1}{a_k^+} + \frac{b_k^2}{a_k^-}\right) - f_k^T\left(\frac{b_k^1}{a_k^+}\cos(a_k^+ t) + \frac{b_k^2}{a_k^-}\cos(a_k^- t)\right) \\ & - \dot{f}_k^T\left(\frac{b_k^1}{(a_k^+)^2}\sin(a_k^+ t) + \frac{b_k^2}{(a_k^-)^2}\sin(a_k^- t)\right) \end{aligned}$$

and b_k^1, b_k^2, a_k^+, a_k^- given, respectively, by

$$b_k^1 = -\frac{(\lambda_k - 1 + \nu)[(a_k^-)^2 - (\lambda_k - 1 + \nu)] - \lambda_k(1+\nu)^2}{a_k^+[(a_k^-)^2 - (a_k^+)^2]}, \tag{2.3}$$

$$b_k^2 = \frac{(\lambda_k - 1 + \nu)[(a_k^+)^2 - (\lambda_k - 1 + \nu)] - \lambda_k(1+\nu)^2}{a_k^-[(a_k^-)^2 - (a_k^+)^2]}, \tag{2.4}$$

$$a_k^{\pm} = \sqrt{\frac{(\lambda_k + 1 + 3\nu) \pm \sqrt{(\lambda_k + 1 + 3\nu)^2 - 4(1-\nu^2)(\lambda_k - 2)}}{2}}. \tag{2.5}$$

Doing the substitution $t = T - t$ in (2.2) we find the solution of (1.7)–(1.9): $z = \sum_{k=1}^{+\infty} f_k(t) z_k(\theta)$ with

$$\begin{aligned} f_k(t) = {} & (f_k^T - \dot{f}_k^T(T-t)) \left(1 + \frac{b_k^1}{a_k^+} + \frac{b_k^2}{a_k^-}\right) \\ & - f_k^T \left(\frac{b_k^1}{a_k^+}\cos(a_k^+(T-t)) + \frac{b_k^2}{a_k^-}\cos(a_k^-(T-t))\right) \\ & + \dot{f}_k^T \left(\frac{b_k^1}{(a_k^+)^2}\sin(a_k^+(T-t)) + \frac{b_k^2}{(a_k^-)^2}\sin(a_k^-(T-t))\right). \end{aligned}$$

Taking into account that

$$\frac{b_k^1}{a_k^+} + \frac{b_k^2}{a_k^-} = -1 \quad \forall\, \nu \quad \forall\, k,$$

we have

$$\begin{aligned} f_k(t) = {} & -f_k^T \left\{\frac{b_k^1}{a_k^+}\cos(a_k^+(T-t)) + \frac{b_k^2}{a_k^-}\cos(a_k^-(T-t))\right\} \\ & + \dot{f}_k^T \left\{\frac{b_k^1}{a_k^{+2}}\sin(a_k^+(T-t)) + \frac{b_k^2}{(a_k^-)^2}\sin(a_k^-(T-t))\right\}. \end{aligned}$$

PROPOSITION 2.3. *The following properties of the coefficients a_k^+ and a_k^- hold:*

$$(a_k^+)^2 = \lambda_k - 1 + \nu + c_k^+(1+\nu)^2,$$

$$(a_k^-)^2 = 2(1+\nu) + c_k^-(1+\nu)^2,$$

with

$$\lim_{k\to\infty} c_k^+ = +1, \qquad \lim_{k\to\infty} c_k^- = -1,$$

$$\lim_{k\to\infty} a_n^+ = +\infty, \qquad \lim_{k\to\infty} a_k^- = \sqrt{1-\nu^2}.$$

Remark 2.1. The solution of this problem can be easily given at least in the case $\vartheta_0 = \frac{\pi}{2}$. More precisely we have $z_k = a_k P_k'$ and $\lambda_k = k(k+1)$ with $k = 2, 4, 6, \ldots$, and P_k is the k–Legendre polynomial and a_k is the normalization factor; i.e., $(a_k P_k', a_j P_j') = \delta_j^k$.

3. Trigonometrical inequalities for almost periodic functions. The following theorem, on almost periodic functions [2], is a generalization of a result due to Ingham (see [8, Theorem 1]).

THEOREM 3.1. *Let*

$$f(t) = \sum_{n=-\infty}^{+\infty} A_n^+ e^{-ia_n^+ t} + A_n^- e^{-ia_n^- t} = \sum_n A_n^+ e^{-ia_n^+ t} + A_n^- e^{-ia_n^- t}, \tag{3.1}$$

where we assume $\sum_n A_n^+ e^{-ia_n^+ t} + A_n^- e^{-ia_n^- t}$ *is uniformly convergent in* $[-T, T]$ *and*

$$\exists \gamma_1 > 0 : |a_n^+ - a_{n-1}^+| \geq \gamma_1 \quad \forall\, n, \tag{3.2}$$

$$\exists \gamma_2 > 0 : |a_n^+ - a_j^-| \geq \gamma_2 \quad \forall\, n\ \forall\, j, \tag{3.3}$$

$$\exists \alpha \geq 1\,, C_2 > 0 :\ \forall\, k \qquad |A_k^-| \leq \frac{C_2}{k^\alpha}\,|A_k^+|. \tag{3.4}$$

Then $\exists\, T_0 : \forall\, T > T_0 : \exists C_3(T)$, $C_4(T) > 0$ *such that*

$$C_3(T) \sum_n |A_n^+|^2 \leq \int_{-T}^{T} |f|^2 \,\mathrm{d}t \leq C_4(T) \sum_n |A_n^+|^2.$$

Proof. We prove the first inequality. Let $h(t)$ be a nonnegative integrable function over $(-\infty, +\infty)$. We consider

$$\begin{aligned}
&\int_{-\infty}^{+\infty} h(t) |f(t) - \sum_k A_k^+ e^{-ia_k^+ t}|^2 \,\mathrm{d}t \\
&\quad = \int_{-\infty}^{+\infty} h(t) \left(f(t) - \sum_k A_k^+ e^{-ia_k^+ t} \right) \cdot \left(\overline{f}(t) - \sum_j \overline{A}_j^+ e^{ia_j^+ t} \right) \mathrm{d}t \\
&\quad = \int_{-\infty}^{+\infty} h(t) |f(t)|^2 \,\mathrm{d}t + \int_{-\infty}^{+\infty} \sum_k \sum_j A_k^+ \overline{A}_j^+ e^{i(a_j^+ - a_k^+)t} h(t) \,\mathrm{d}t \\
&\quad - \int_{-\infty}^{+\infty} h(t) \overline{f}(t) \cdot \sum_k A_k^+ e^{-ia_k^+ t} \,\mathrm{d}t - \int_{-\infty}^{+\infty} h(t) f(t) \sum_j \overline{A}_j^+ e^{+ia_j^+ t} \,\mathrm{d}t \\
&\quad = \int_{-\infty}^{+\infty} h(t) |f(t)|^2 \,\mathrm{d}t + \sum_k \sum_j A_k^+ \overline{A}_j^+ K(a_k^+ - a_j^+) \\
&\quad - \int_{-\infty}^{+\infty} h(t) \left(\sum_j \overline{A}_j^+ e^{ia_j^+ t} + \overline{A}_j^- e^{ia_j^- t} \right) \cdot \sum_k A_k^+ e^{-ia_k^+ t} \,\mathrm{d}t \\
&\quad - \int_{-\infty}^{+\infty} h(t) \left(\sum_k A_k^+ e^{-ia_k^+ t} + A_k^- e^{-ia_k^- t} \right) \cdot \sum_j \overline{A}_j^+ e^{ia_j^+ t} \,\mathrm{d}t,
\end{aligned}$$

where

$$K(u) = \int_{-\infty}^{+\infty} e^{-itu} \cdot h(t) \,\mathrm{d}t.$$

Hence, using $\sum_k \sum_j'$ to denote the sum for $k \neq j$,

$$\begin{aligned} 0 \leq & -\sum_k |A_k^+|^2 K(0) - \sum_k \sum_j{}' A_k^+ \overline{A}_j^+ K(a_k^+ - a_j^+) \\ & - \sum_j \sum_k \overline{A}_j^- A_k^+ K(a_k^+ - a_j^-) \\ & - \sum_k \sum_j A_k^- \overline{A}_j^+ K(a_k^- - a_j^+) + \int_{-\infty}^{+\infty} h(t)|f|^2 \, \mathrm{d}t, \end{aligned}$$

we take

$$h(t) = \begin{cases} \cos \frac{\pi t}{2T}, & |t| \leq T, \\ 0, & |t| > T, \end{cases}$$

with $T > \frac{\pi}{2\overline{\gamma}}$ and $\overline{\gamma} = \min\{\gamma_1, \gamma_2\}$

$$\int_{-\infty}^{+\infty} h(t) e^{i(a_k^+ - a_j^+)t} \, \mathrm{d}t = \begin{cases} \frac{4T\pi \cos(a_k^+ - a_j^+)T}{\pi^2 - 4T^2(a_k^+ - a_j^+)^2}, & k \neq j, \\ \frac{4T}{\pi}, & k = j. \end{cases}$$

By assumption (3.2)

$$\sum_k \left| \frac{4T\pi \cos(a_k^+ - a_j^+)}{\pi^2 - 4T^2(a_k^+ - a_j^+)^2} \right| \leq \frac{4\pi}{T\gamma_1^2} \leq \frac{4\pi}{T\overline{\gamma}^2}$$

and by assumption (3.3)

$$\sum_k \left| \frac{4T\pi \cos(a_k^+ - a_j^-)}{\pi^2 - 4T^2(a_k^+ - a_j^-)^2} \right| \leq \frac{4\pi}{T\gamma_2^2} \leq \frac{4\pi}{T\overline{\gamma}^2}$$

so that

$$\begin{aligned} \int_{-T}^{T} |f(t)|^2 \, \mathrm{d}t &\geq \frac{4T}{\pi} \sum_k |A_k^+|^2 + \sum_k \sum_j{}' A_k^+ \overline{A}_j^+ K(a_k^+ - a_j^+) \\ &\quad + \sum_k \sum_j A_k^- \overline{A}_j^+ K(a_k^- - a_j^+) + \sum_j \sum_k \overline{A}_j^- A_k^+ K(a_k^+ - a_j^-) \\ &\geq \frac{4T}{\pi} \sum_k |A_k^+|^2 - \frac{4\pi}{T\gamma_1^2} \sum_k |A_k^+|^2 \\ &\quad - C_2 \sum_k \sum_j |A_k^+||A_j^+| \frac{|K(a_k^- - a_j^+)|}{k^\alpha} - C_2 \sum_k \sum_j \frac{|A_j^+|}{j^\alpha} |A_k^+||K(a_k^+ - a_j^-)| \\ &\geq \sum_k |A_k^+|^2 \left(\frac{4T}{\pi} - \frac{4\pi}{T\gamma_1^2} \right) - \sum_k \sum_j |A_k^+|^2 |K(a_j^+ - a_k^-)| \\ &\quad - C_2^2 \sum_k \sum_j |A_j^+|^2 \frac{|K(a_j^+ - a_k^-)|}{k^{2\alpha}}. \end{aligned}$$

If we put $S = C_2^2 \sum_J \frac{1}{J^{2\alpha}}, \alpha \geq 1$, we have

$$\int_{-T}^{T} |f(t)|^2 \, \mathrm{d}t \geq \left(\frac{4T}{\pi} - \frac{4\pi}{T\gamma_1^2} - \frac{4\pi}{T\gamma_2^2} - \frac{S4\pi}{T\gamma_2^2} \right) \cdot \sum_k |A_k^+|^2.$$

This inequality is verified for any $T > T_0$ with

$$T_0 = \left\{ \inf T : \frac{4T}{\pi} - \frac{4\pi}{T\gamma_1^2} - \frac{4\pi}{T\gamma_2^2} - \frac{S4\pi}{T\gamma_2^2} > 0 \right\} = \pi \sqrt{\frac{1+S}{\gamma_2^2} + \frac{1}{\gamma_1^2}}. \tag{3.5}$$

Next, we prove the second inequality.

We compute

$$\begin{aligned}
&\int_{-T}^{T} |f(t)|^2 h(t) \, \mathrm{d}t \\
&\quad = \int_{-T}^{T} \left(\sum_k A_k^+ e^{-ia_k^+ t} + A_k^- e^{-ia_k^- t} \right) \cdot \left(\sum_j \overline{A}_j^+ e^{+ia_j^+ t} + \overline{A}_j^- e^{ia_j^- t} \right) h(t) \, \mathrm{d}t \\
&= \int_{-T}^{T} \sum_k \sum_j A_k^+ \overline{A}_j^+ e^{i(a_j^+ - a_k^+)t} h(t) \, \mathrm{d}t + \int_{-T}^{T} \sum_k \sum_j A_k^- \overline{A}_j^- e^{i(a_j^- - a_k^-)t} \cdot h(t) \, \mathrm{d}t \\
&+ \int_{-T}^{T} \sum_k \sum_j A_k^+ \overline{A}_j^- e^{i(a_j^- - a_k^+)t} \cdot h(t) \, \mathrm{d}t + \int_{-T}^{T} \sum_k \sum_j A_k^- \overline{A}_j^+ e^{i(a_j^+ - a_k^-)t} \cdot h(t) \, \mathrm{d}t,
\end{aligned}$$

$$\begin{aligned}
\int_{-T}^{T} |f|^2 h(t) \, \mathrm{d}t &= \sum_k \sum_j A_k^+ \overline{A}_j^+ K(a_k^+ - a_j^+) \\
&\quad + \sum_k \sum_j A_k^- \overline{A}_j^- K(a_k^- - a_j^-) + \sum_k \sum_j A_k^+ \overline{A}_j^- K(a_k^+ - a_j^-) \\
&\quad + \sum_k \sum_j A_k^- \overline{A}_j^+ K(a_k^- - a_j^+) \leq \sum_k \sum_j |A_k^+| |A_j^+| |K(a_k^+ - a_j^+)| \\
&\quad + \sum_k \sum_j \frac{|A_k^+|}{k^\alpha} \frac{|A_j^+|}{j^\alpha} |K(a_k^- - a_j^-)| + 2 \sum_k \sum_j |A_k^+| \frac{|A_j^+|}{j^\alpha} |K(a_k^+ - a_j^-)|
\end{aligned}$$

$$\begin{aligned}
&\leq \left(\frac{4T}{\pi} + \frac{4\pi}{T\overline{\gamma}^2} \right) \sum_k |A_k^+|^2 + \frac{4T}{\pi} C_2^2 \left\{ \sum_k |A_k^+|^2 \sum_j \frac{1}{j^{2\alpha}} + \sum_j |A_j^+|^2 \sum_k \frac{1}{k^{2\alpha}} \right\} \\
&\quad + C_2^2 \sum_k |A_k^+|^2 \sum_j \frac{|K(a_j^- - a_k^+)|}{j^{2\alpha}} + \sum_j |A_j^+|^2 \sum_k |K(a_j^- - a_k^+)| \\
&\leq \left(\frac{4T}{\pi} + \frac{4\pi}{T\overline{\gamma}^2} + \frac{8T\ S}{\pi} \right) \sum_k |A_k^+|^2 + \left(\frac{4\pi}{T\overline{\gamma}^2} S + \frac{4\pi}{T\overline{\gamma}^2} \right) \sum_k |A_k^+|^2 = \overline{C}_4(T) \sum_k |A_k^+|^2.
\end{aligned}$$

We conclude the proof choosing $C_4(T) = \frac{2}{\sqrt{2}} \overline{C}_4(2T)$. □

Remark 3.1. In an analogous way to [1] (see also [7]), the assumptions (3.2) and (3.3) can be relaxed with

$$\exists \gamma_1 > 0 : \quad |a_{k+1}^+ - a_k^+| \geq \gamma_1 \quad \forall |k| > K, \tag{3.2'}$$

$$\exists \gamma_2 > 0 : \quad |a_k^+ - a_j^-| \geq \gamma_2 \qquad \forall |k| > K \quad \text{and} \quad \forall j. \tag{3.3'}$$

If $\gamma_2 \to +\infty$ as $K \to +\infty$ (as in the case of spherical membranes, see Proposition 2.3), we find from (3.5) that the proof of Theorem 3.1 holds with

$$T_0 = \frac{\pi}{\overline{\gamma}}. \tag{3.6}$$

4. Controllability. In what follows we put $\alpha = \frac{(1+\nu)^{3/2}}{\sqrt{2}}$.

LEMMA 4.1. *For every fixed $T > 0$, there exist two positive constants $c_0 = c_0(T, \alpha)$ and $c_1 = c_1(T, \alpha)$ such that*

$$c_0 \int_0^T (z' - \alpha G_{z'}^*(\theta_0, t))^2 \, \mathrm{d}t \leq \int_0^T (z'(\theta_0, t))^2 \, \mathrm{d}t \leq c_1 \int_0^T (z' - \alpha G_{z'}^*(\theta_0, t))^2 \, \mathrm{d}t.$$

Proof. The left inequality follows by simple computations. To prove the right inequality we assume that there exists a sequence $\tilde{z}_n'$ such that $\|\tilde{z}_n'\|_{L^2} = 1$ and

$$\tilde{z}_n'(t) - \alpha G^* \tilde{z}_n'(t) = \tilde{f}_n(t), \tag{4.1}$$

with

$$\lim_{n \to \infty} \|\tilde{f}_n\|_{L^2} = 0.$$

By simple computation [18, p. 45] we have by (4.1),

$$\tilde{z}_n'(t) = \tilde{f}_n(t) - \int_t^T Q(s,t) \tilde{f}_n(s) \, \mathrm{d}s, \tag{4.2}$$

where Q is a reciprocal kernel of (4.1), (1.10) given by

$$Q(s,t) = \sum_{h=1}^{\infty} P^{(h)}(s,t),$$

where

$$|P^{(h)}(s,t)| \leq \frac{|\alpha|^h |s-t|^{h-1}}{(h-1)!}.$$

It is easy to prove that

$$|Q(s,t)| \leq |\alpha| e^{|\alpha| \, |s-t|}.$$

On the other hand,

$$\int_t^T Q^2(s,t) \, \mathrm{d}s \leq \alpha^2 \int_t^T e^{2|\alpha| \, |s-t|} \, \mathrm{d}s = \frac{\alpha^2}{2|\alpha|} (e^{(T-t) \cdot 2|\alpha|} - 1)$$

and

$$\int_0^T \int_t^T Q^2(s,t)\,\mathrm{d}s \le \frac{|\alpha|}{2}\int_0^T (e^{(T-t)2|\alpha|}-1)\,\mathrm{d}t = \frac{1}{4}e^{2T|\alpha|} - \frac{1}{4} - \frac{|\alpha|}{2}T,$$

so that

$$\int_0^T (\tilde{z}_n'(\theta_0,t)^2\,\mathrm{d}t \le 2\int_0^T (\tilde{f}_n(s))^2\,\mathrm{d}s\left\{\frac{3}{4}+\frac{1}{4}e^{2T|\alpha|}-\frac{|\alpha|}{2}T\right\}.$$

Hence we find a contradiction. □

THEOREM 4.1. *If the generalized assumptions of Theorem* 3.1 *are verified, then we can solve the partial controllability problem in a suitable space.*

Proof. We take

$$A_k^+ = \frac{b_k^1}{(a_k^+)^2}\, z_k'(\theta_0)\left[a_k^+ f_k^T + \frac{1}{i}\,\dot{f}_k^T\right],$$

$$A_k^- = \frac{b_k^2}{(a_k^-)^2}\, z_k'(\theta_0)\left[a_k^- f_k^T + \frac{1}{i}\,\dot{f}_k^T\right],$$

where a_k^+, a_k^-, b_k^1, and b_k^2 are given by (2.3), (2.4), and (2.5). By Lemma 4.1 and Theorem 3.1 we have that there exist two positive constants $C_1(T)$ and $C_2(T)$ such that

$$C_1(T)\sum_k |A_k^+|^2 \le \langle \mu(z_0,z_1),(z_0,z_1)\rangle \le C_2(T)\sum_k |A_k^+|^2.$$

This ends the proof. □

Example 4.1 (PEC for the hemispherical shell).

For $\theta_0 = \pi/2$, we have

$$\lambda_k = 2k(2k+1), \qquad k = 1,2,\ldots,$$

$$a_k^+ \sim 2k+\frac{1}{2} \qquad \text{as} \quad k\to\infty,$$

$$|a_{k+1}^+ - a_k^+| = 2\ , \qquad \lim_{k\to\infty} a_k^- = \sqrt{1-\nu^2} < a_1^+.$$

Moreover,

$$\frac{b_k^1}{(a_k^+)^2} \sim \frac{\text{const}}{k} \quad \text{as} \qquad k\to\infty$$

and

$$\frac{b_k^2}{(a_k^-)^2} \sim \frac{\text{const}}{k^2} \quad \text{as} \quad k\to\infty.$$

Moreover, we assume the data $\{f^T, \dot{f}^T\}$ are given in a suitable space in order for $\sum_k |A_k^+| < +\infty$. Hence the hypotheses of Theorem 3.1 are verified, and we can apply Theorem 4.1.

DYNAMICS FOR CONTROLLED NAVIER–STOKES SYSTEMS WITH DISTRIBUTED CONTROLS*

L. S. HOU† AND Y. YAN‡

Abstract. The long-time behavior of solutions for an optimal distributed control problem associated with the Navier–Stokes equations is studied. First, a linear feedback solution for the Navier–Stokes equations is constructed; this feedback solution possesses decay (in time) properties. Then, some preliminary estimates for the long-time behavior of all solutions of the Navier–Stokes equations are derived. Next, the existence of a solution for the optimal control problem is proved. Finally, the long-time decay properties for the optimal solutions are established.

Key words. dynamics, optimal control, feedback control, Navier–Stokes equations

1. Introduction.

In this article we study the long-time behavior of the solutions for optimal control problems associated with the Navier–Stokes equations on the infinite time interval. In this paper, we concentrate on the following prototype problem: minimize the functional

$$\mathcal{J}(\mathbf{u},\mathbf{f}) = \frac{\alpha}{2}\int_0^\infty\int_\Omega |\mathbf{u}-\mathbf{U}|^2\,d\mathbf{x}\,dt + \frac{\beta}{2}\int_0^\infty\int_\Omega |\mathbf{f}-\mathbf{F}|^2\,d\mathbf{x}\,dt \tag{1.1}$$

subject to the Navier–Stokes equations

$$\partial_t\mathbf{u} - \nu\Delta\mathbf{u} + (\mathbf{u}\cdot\nabla)\mathbf{u} + \nabla p = \mathbf{f} \qquad \text{in } \Omega\times(0,\infty)\,, \tag{1.2}$$

$$\operatorname{div}\mathbf{u} = 0 \qquad \text{in } \Omega\times(0,\infty)\,, \tag{1.3}$$

$$\mathbf{u} = \mathbf{0} \qquad \text{on } \partial\Omega\times(0,\infty), \tag{1.4}$$

and

$$\mathbf{u}(\cdot,0) = \mathbf{u}_0 \qquad \text{in } \Omega\,. \tag{1.5}$$

Here, $\alpha,\beta>0$ are given constants, Ω is a bounded domain in $\mathbb{R}^2$ which is of class C^2 or convex, $\partial\Omega$ denotes the boundary of Ω, $\mathbf{U}$ is a given desired flow field, and $\mathbf{F}$ is a given body force. Also, $\mathbf{f}$ is the distributed control (body force), and $(\mathbf{u},p)$ denote the velocity field and the pressure field. The first term in the functional (1.1) measures the $L^2(0,\infty;\mathbf{L}^2(\Omega))$-distance between the candidate flow and the desired flow. Thus, the physical objective of this minimization problem is to match a desired flow field (in the L^2 sense) by adjusting (controlling) the body force $\mathbf{f}$. The second term in the functional measures the size of the control with respect to some fixed force

$\mathbf{F}$. The inclusion of this term in the functional will keep the body force $\mathbf{f}$ (i.e., the control) within a reasonable distance from $\mathbf{F}$ so that the optimal $\mathbf{f}$ we find can still be physically realized. This functional reflects a trade-off between achieving a physical objective and minimizing the work. It is worth mentioning that $(\mathbf{U}, \mathbf{F})$ in general is not an optimal solution, for $\mathbf{U}(\cdot, 0) \not\equiv \mathbf{u}_0$ in general.

Through the change of variables $\mathbf{v} = \mathbf{u} - \mathbf{U}$ and $\mathbf{g} = \mathbf{f} - \mathbf{F}$, we may interpret the optimal control problem from another physical point of view; i.e., one seeks a candidate flow $\mathbf{v}$ and a candidate body force $\mathbf{g}$ such that the $L^2(\Omega \times (0, \infty))$-energy and the total work done by the body force in the flow's entire life span is minimized. Many other physical cost functionals such as the drag functional can be formulated in a similar optimal control setting wherein one minimizes the total cost such as the total drag and the total work done by the body force in the flow's entire life span.

If our goal is only to match the desired flow $\mathbf{U}$ by the designed flow $\mathbf{u}$ (without considering minimizing the energy and work), then a linear body force feedback control can be used instead of the optimal control. In this paper we will study both optimal control and feedback control. The feedback control solution we will construct has exponential decay properties, but, unlike the optimal solution, the feedback solution can be too costly to realize physically.

The study of optimal flow control problems in the infinite time interval is of great importance in many physical applications, such as in drag and turbulence minimization in the entire life span of a flow. (Of course, the functional will be chosen differently in these cases from the functional introduced above.) Much effort has been made by mathematicians and scientists in the study of the asymptotic behaviors and dynamics of solutions for the Navier–Stokes equations. Naturally, we are motivated to study the asymptotic behaviors and dynamics of solutions for the controlled Navier–Stokes equations. There is also an interest in controlling the dynamics of flows which will be studied elsewhere. Although the methods and techniques used in this paper are applicable to the study of optimal control problems for many other cost functionals, we will only deal with the functional (1.1) throughout this paper. As was explained above, the physical objective behind (1.1) is to match the candidate flow field with a desired one. Ideally, one wishes to match the desired flow at each time instance; the functional that describes this ideal objective involves L^∞-norm in t. Such an ideal objective is in general too costly to achieve physically, and numerical solutions of such an ideal control problem can be computationally expensive (numerical methods will be discussed elsewhere). It is natural to introduce the time-averaged functional (1.1) for the matching objective. But how good is the optimizer for (1.1) as an optimizer for pointwise matching in t? This will be the main question to be answered in this paper. Our main conclusion is that for large t, the time-averaged optimizer will indeed give us pointwise matching in t.

We comment on some works extant in the literature that are related to this paper. In [2], [8], [9], [10], and [14] optimal distributed control problems for the time-dependent Navier–Stokes equations on finite time intervals were studied. In [8], [9], and [10], the existence of optimal distributed controls was shown, an optimality system of equations was derived, and the question of the uniqueness of optimal solutions was resolved. The optimality system of equations established in these references on finite time intervals will be very useful in our derivation of an analogous system for the infinite time interval.

Controllability is somewhat related to our interest in controlling the pointwise-in-t behavior for the solutions of the Navier–Stokes equations. In [7], [11], and [12]

the distributed approximate controllability problem was studied. It was shown in [7] that in the special case of control acting everywhere in the domain, the Navier–Stokes system is approximately controllable; i.e., one may match a given flow field with arbitrary accuracy at time instance $t = T$. In [11] it was proved that one can exactly match the zero vector field at $t = T$ by distributed control. However, the techniques used in [7] and [12] cannot be applied to more general controllability or approximate controllability problems for the Navier–Stokes system. The results of [12] on the noncontrollability of the Burgers equation seem to indicate that in general one cannot obtain approximate controllability for the Navier–Stokes system. In any case, the controllability approach does not give us information on the matching of flow fields over a time period, nor could it give us any information beyond $t = T$.

We also point out that some results on the asymptotic behaviors/dynamics for the (uncontrolled) Navier–Stokes equations can be found in the literature, such as [3], [15], [16], [18], and [19]. Also, in [4] and [5], the dynamics for the controlled Burgers equation was studied. Although the properties for the controlled Burgers equations can be substantially different from that for the controlled Navier–Stokes equations, results on Burgers equations often give us some insight into the results for the Navier–Stokes equations.

We summarize the major components of this paper as follows.

• A feedback control solution is constructed which can be treated as a quasi optimizer for the optimal control problem.

• The results of [8], [9], and [10] for finite time intervals are generalized to the infinite time interval $[0, \infty)$; i.e., we prove the existence of a solution for the distributed optimal control problem of minimizing (1.1) subject to (1.2)–(1.5) and derive an optimality system of equations from which optimal solutions may be deduced.

• The long-time behavior (dynamics) of the optimal solution is derived and the main result is that $\|\widehat{\mathbf{u}}(t) - \mathbf{U}(t)\|$ and $\|\nabla\widehat{\mathbf{u}}(t) - \nabla\mathbf{U}(t)\|$; i.e., the $\mathbf{L}^2(\Omega)$-distance and the $\mathbf{H}^1(\Omega)$-distance between the optimal solution $\widehat{\mathbf{u}}(t)$ and the desired flow field $\mathbf{U}(t)$ both decay to zero as time $t \to \infty$. Note that the distances are measured pointwise in t despite the fact that the (time-averaged) functional (1.1) seems to provide only L^2-information in t. Moreover, although the functional (1.1) provides only $\mathbf{L}^2$-information in $\mathbf{x}$, the decay property can be upgraded to the $\mathbf{H}^1(\Omega)$-distance in $\mathbf{x}$.

• We also obtain as by-products some estimates for the solutions of the optimality system on both finite and infinite intervals.

Our plan of the paper is as follows. In section 2, we construct a feedback control solution and obtain some preliminary estimates for all solution of the Navier–Stokes equations and, in particular, for optimal solutions. In section 3, we first recall the results of [8], [9], and [10] on finite time intervals and establish some estimates for the Lagrange multiplier (the adjoint state variable). We then prove the existence of an optimal solution on the infinite time interval. Finally, in section 4, we prove the decay of the controlled dynamics to the desired dynamics.

2. Statement of the problem, feedback control, and preliminary estimates.

2.1. Functional spaces and notations, statement of the problem. Throughout this paper, C denotes a generic constant depending only on the physical domain Ω. We will use the standard notations for the function space $L^r(\Omega)$ and the Sobolev spaces $H^m(\Omega)$ with its norm denoted by $\|\cdot\|_m$. $H^0(\Omega) = L^2(\Omega)$. Also, $H_0^r(\Omega)$ is the closure of $C_0^\infty(\Omega)$ under the $\|\cdot\|_r$-norm. The dual space of $H_0^r(\Omega)$ is denoted by $H^{-r}(\Omega)$, $r > 0$. The vector-valued ($\mathbb{R}^2$-valued) counterparts of these spaces are

denoted by $\mathbf{L}^r(\Omega)$, $\mathbf{H}^m(\Omega)$, $\mathbf{H}_0^r(\Omega)$, and $\mathbf{H}^{-r}(\Omega)$. For details, see [1] and [13]. We introduce the solenoidal spaces

$$\mathbf{V}^r(\Omega) = \{\mathbf{u} \in \mathbf{H}_0^r(\Omega) \ : \ \nabla \cdot \mathbf{u} = 0\}$$

equipped with the norm $\|\cdot\|_r$ for $r \geq 0$,

$$\mathbf{V} = \mathbf{V}^1(\Omega) = \{\mathbf{u} \in \mathbf{H}_0^1(\Omega) \ : \ \nabla \cdot \mathbf{u} = 0\}$$

equipped with the norm $\|\cdot\|_1$, and

$$\mathbf{W} = \{\mathbf{u} \in \mathbf{L}^2(\Omega) \ : \ \nabla \cdot \mathbf{u} = 0, \ (\mathbf{u} \cdot \mathbf{n})|_\Gamma = 0\}$$

(i.e., the closure of div-free $\mathbf{C}_0^\infty(\Omega)$-functions under the $\|\cdot\|_0$-norm) equipped with the norm $\|\cdot\|_0$. The dual space of $\mathbf{V}^r(\Omega)$, $r > 0$, is denoted by $\mathbf{V}^{-r}(\Omega)$. The dual space of $\mathbf{V}$ is denoted by $\mathbf{V}^*$. We identify the dual space of $\mathbf{W}$ with $\mathbf{W}$ itself under the $\mathbf{L}^2(\Omega)$-inner product. We next introduce the temporal–spatial function spaces defined on $Q_T = \Omega \times (0,T)$ for $T \in (0,\infty]$ (note that Q_∞ is also simply denoted by Q):

$$L^m(0,T;\mathbf{H}^r(\Omega))$$

equipped with the norm

$$\|\mathbf{u}\|_{L^m(0,T;\mathbf{H}^r(\Omega))} = \left(\int_0^T \|\mathbf{u}(t)\|_r^m \, dt\right)^{1/m},$$

and the solenoidal temporal–spatial function space

$$\mathcal{V}^{(s)}(Q_T) = \{\mathbf{v} \in L^2(0,T;\mathbf{V}^s(\Omega)) : \partial_t \mathbf{v} \in L^2(0,T;\mathbf{V}^{s-2}(\Omega))\}$$

with the norm

$$\|\mathbf{v}\|_{\mathcal{V}^{(s)}(Q_T)}^2 = \|\mathbf{v}\|_{L^2(0,T;\mathbf{V}^s(\Omega))}^2 + \|\partial_t \mathbf{v}\|_{L^2(0,T;\mathbf{V}^{s-2}(\Omega))}^2 .$$

For a function $\mathbf{u}$ in the temporal–spatial space, we often use the abbreviated notation

$$\mathbf{u}(t) \stackrel{\text{def}}{=\!=} \mathbf{u}(\cdot,t),$$

which is defined over the spatial domain Ω.

We introduce the simplified norm notation

$$\|\cdot\| \stackrel{\text{def}}{=\!=} \|\cdot\|_{L^2(\Omega)} . \tag{2.1}$$

Let $\lambda_1 > 0$ be the greatest real number satisfying the Poincaré inequality

$$\|\nabla \mathbf{w}\|^2 \geq \lambda_1 \|\mathbf{w}\|^2 \qquad \forall\, \mathbf{w} \in \mathbf{H}_0^1(\Omega) . \tag{2.2}$$

We now define the solution for the Navier–Stokes equations in a weak sense (see [6] or [18]). To this end, we introduce two continuous linear forms:

$$a(\mathbf{u},\mathbf{v}) = \nu \int_\Omega \nabla \mathbf{u} : \nabla \mathbf{v} \, d\mathbf{x} \qquad \forall\, \mathbf{u},\mathbf{v} \in \mathbf{H}^1(\Omega)$$

and

$$c(\mathbf{u},\mathbf{v},\mathbf{w}) = \int_\Omega (\mathbf{u}\cdot\nabla)\mathbf{v}\cdot\mathbf{w}\,d\mathbf{x} \qquad \forall\,\mathbf{u},\mathbf{v},\mathbf{w}\in\mathbf{H}^1(\Omega)\,,$$

where the colon notation : denotes the inner product on $\mathbb{R}^{2\times 2}$. Also, $(\cdot,\cdot)$ denotes the $\mathbf{L}^2(\Omega)$-inner product and $\langle\cdot,\cdot\rangle$ the duality pairing between a Banach space and its dual.

DEFINITION 2.1. *Given $T\in(0,\infty)$, $\mathbf{u}_0\in\mathbf{W}$, and $\mathbf{f}\in L^2(0,T;\mathbf{V}^*)$, $\mathbf{u}$ is said to be a solution of the Navier–Stokes equations iff $\mathbf{u}\in\mathcal{V}^{(1)}(Q_T)$ and $\mathbf{u}$ satisfies*

$$\begin{aligned}&\langle\partial_t\mathbf{u}(t),\mathbf{w}\rangle + a(\mathbf{u}(t),\mathbf{w}) + c(\mathbf{u}(t),\mathbf{u}(t),\mathbf{w})\\ &\qquad = \langle\mathbf{f}(t),\mathbf{w}\rangle \qquad \forall\,\mathbf{w}\in\mathbf{V}\ \text{(almost everywhere)}\ t\in(0,T)\end{aligned}\tag{2.3}$$

and

$$\lim_{t\to 0^+}\mathbf{u}(t) = \mathbf{u}_0 \qquad \text{in } \mathbf{W}.\tag{2.4}$$

We point out that $\mathbf{u}\in\mathcal{V}^{(1)}(Q_T)$ implies $\mathbf{u}\in C([0,T];\mathbf{W})$, so that (2.4) makes sense. It is well known that if $T\in(0,\infty)$ and $\mathbf{f}\in L^2(0,T;\mathbf{L}^2(\Omega))$, then there is indeed a solution $\mathbf{u}$ for the Navier–Stokes equations. Furthermore, $\mathbf{u}$ satisfies the regularity result $\mathbf{u}\in L^2_{\rm loc}(0,T;\mathbf{H}^2(\Omega))$.

For $T=\infty$, we define a solution for the Navier–Stokes equations as follows.

DEFINITION 2.2. *Given $\mathbf{u}_0\in\mathbf{W}$ and $\mathbf{f}\in L^2_{\rm loc}(0,\infty;\mathbf{V}^*)$, $\mathbf{u}$ is said to be a solution of the Navier–Stokes equations on $(0,\infty)$ iff $\mathbf{u}\in L^2_{\rm loc}(0,\infty;\mathbf{V})\cap L^\infty(0,\infty;\mathbf{W})$, $\partial_t\mathbf{u}\in L^2_{\rm loc}(0,\infty;\mathbf{V}^*)$, and $\mathbf{u}$ satisfies* (2.3), (2.4) *with $T=\infty$.*

Intuitively, if a flow field $\mathbf{u}$ is close to the desired field $\mathbf{U}$, then the body forces corresponding to the two fields $\mathbf{u}$ and $\mathbf{U}$ should also be close. Hence, in order that the optimal control solution of the Navier–Stokes flow is close to the desired flow $\mathbf{U}$, we must place some restrictions on the desired body force $\mathbf{F}$ involved in the cost functional (1.1). In fact, throughout this paper we will simply choose

$$\mathbf{F} = \mathbf{N}(\mathbf{U}) \stackrel{\rm def}{=\!=} \partial_t\mathbf{U} - \nu\Delta\mathbf{U} + (\mathbf{U}\cdot\nabla)\mathbf{U},\tag{2.5}$$

which is the body force corresponding to the desired flow $\mathbf{U}$. Here note that, for convenience, the pressure term is not included in the definition of $\mathbf{F}=\mathbf{N}(\mathbf{U})$, since it is not involved in the cost functional. The omission of the pressure term will not affect any of the results in this paper. In fact, the pressure term does not even appear in our definition of the solutions (in the weak sense) for the Navier–Stokes equations. The restriction (2.5) implies that when the functional (1.1) is minimized, $\mathbf{u}$ is close to the desired flow $\mathbf{U}$ and $\mathbf{f}$ is close to the body force corresponding to the desired flow. Note that the pair $(\mathbf{U},\mathbf{F})$ in general is not an optimal solution, for $\mathbf{U}$ in general does not satisfy the initial condition (2.4).

Throughout this paper, in addition to (2.5), we make the following hypothesis for the desired flow $\mathbf{U}$ and the fixed body force $\mathbf{F}=\mathbf{N}(\mathbf{U})$:

$$\begin{cases}\mathbf{U}=\mathbf{U}(\mathbf{x},t)\in L^\infty(0,\infty;\mathbf{H}^2(\Omega)\cap\mathbf{V})\,,\\ \mathbf{F}=\mathbf{N}(\mathbf{U})\in L^\infty(0,\infty;\mathbf{L}^2(\Omega))\,.\end{cases}\tag{2.6}$$

Hypothesis (2.6) implies

$$\partial_t\mathbf{U}\in L^\infty(0,\infty;\mathbf{L}^2(\Omega))\cap L^2_{\rm loc}(0,\infty;\mathbf{L}^2(\Omega))\,.$$

Note that these hypotheses permit the special case of steady state $\mathbf{U}$. Thus one application of the optimal control problem is to match a steady state flow field through the control of external forces.

We also introduce the following simplified norm notations:

$$|||\cdot||| \stackrel{\text{def}}{=\!=} \|\cdot\|_{L^\infty(0,\infty;\mathbf{L}^2(\Omega))} \tag{2.7}$$

and

$$|||\cdot|||\!| \stackrel{\text{def}}{=\!=} \|\cdot\|_{\mathbf{L}^\infty(\Omega\times(0,\infty))}\,. \tag{2.8}$$

These norms will be applied solely to $\mathbf{U}$, $\nabla\mathbf{U}$, ..., etc.

We now turn to the precise statement of the optimal control problem.

For each $T \in (0,\infty]$ we define the functional $\mathcal{J}_T$ by

$$\mathcal{J}_T(\mathbf{u},\mathbf{f}) = \frac{\alpha}{2}\int_0^T\int_\Omega |\mathbf{u}-\mathbf{U}|^2\,d\mathbf{x}\,dt + \frac{\beta}{2}\int_0^T\int_\Omega |\mathbf{f}-\mathbf{F}|^2\,d\mathbf{x}\,dt \tag{2.9}$$

for all $\mathbf{u} \in \mathbf{U} + \mathbf{L}^2(\Omega\times(0,T))$ and $\mathbf{f} \in \mathbf{N}(\mathbf{U}) + \mathbf{L}^2(\Omega\times(0,T))$. Note that $\mathcal{J}_\infty$ is also simply denoted by $\mathcal{J}$.

We point out that in the case of $T=\infty$, which we will eventually consider, if we choose the control $\mathbf{f}$ in the space $\mathbf{L}^2(\Omega\times(0,\infty))$, it may happen (e.g., in the case of a steady state $\mathbf{U}$) that the value of the cost functional $\mathcal{J}_\infty(\mathbf{u},\mathbf{f})$ is always infinite for every pair $(\mathbf{u},\mathbf{f})$ under consideration. Therefore, the choice of the control set should also involve $\mathbf{U}$ and $\mathbf{F}$. We define the admissible elements as follows with $\mathbf{X}_T$ and $\mathbf{Y}_T$ denoting, respectively, the functional spaces

$$\mathbf{X}_T = \begin{cases} \mathcal{V}^{(1)}(Q_T) & \text{if } T \in (0,\infty)\,, \\ \{\mathbf{u} \in L^2_{\text{loc}}(0,\infty;\mathbf{V}) \cap L^\infty(0,\infty;\mathbf{W}) : \partial_t\mathbf{u} \in L^2_{\text{loc}}(0,\infty;\mathbf{V}^*)\} & \text{if } T=\infty \end{cases}$$

and

$$\mathbf{Y}_T = \begin{cases} L^2(0,T;\mathbf{V}^*) & \text{if } T \in (0,\infty)\,, \\ L^2_{\text{loc}}(0,\infty;\mathbf{V}^*) & \text{if } T=\infty\,. \end{cases}$$

DEFINITION 2.3. *For a given $T \in (0,\infty]$, a pair $(\mathbf{u},\mathbf{f}) \in \mathbf{X}_T \times \mathbf{Y}_T$ is called an* admissible element *if $\mathcal{J}_T(\mathbf{u},\mathbf{f}) < \infty$ and $(\mathbf{u},\mathbf{f})$ satisfies (2.3)–(2.4). The set of all admissible elements is denoted by $\mathcal{U}_{ad}(T)$.*

Now for each $T \in (0,\infty]$, we state the optimal control problem on $(0,T)$ as follows:

$$\begin{aligned} &\text{find a } (\mathbf{u},\mathbf{f}) \in \mathcal{U}_{ad}(T) \text{ such that} \\ &\mathcal{J}_T(\mathbf{u},\mathbf{f}) \le \mathcal{J}_T(\mathbf{w},\mathbf{h}) \qquad \forall\,(\mathbf{w},\mathbf{h}) \in \mathcal{U}_{ad}(T)\,. \end{aligned} \tag{2.10}$$

We point out that in general, the initial state $\mathbf{u}_0$ is a certain distance away from the desired flow, or, $\mathbf{u}_0 \neq \mathbf{U}(\cdot,t)$ for all t, the cost functional generally has a positive minimum. Therefore our optimal control problem has nontrivial solutions.

With the change of variables

$$\mathbf{v} = \mathbf{u} - \mathbf{U} \qquad \text{and} \qquad \mathbf{g} = \mathbf{f} - \mathbf{N}(\mathbf{U})\,, \tag{2.11}$$

(2.3), (2.4) are equivalent to $(\mathbf{v},\mathbf{g}) \in \mathbf{X}_T \times \mathbf{Y}_T$ satisfying

$$\begin{aligned} &\langle \partial_t\mathbf{v}(t),\mathbf{w}\rangle + a(\mathbf{v}(t),\mathbf{w}) + c(\mathbf{v}(t),\mathbf{v}(t),\mathbf{w}) + c(\mathbf{U}(t),\mathbf{v}(t),\mathbf{w}) \\ &\qquad + c(\mathbf{v}(t),\mathbf{U}(t),\mathbf{w}) = (\mathbf{g}(t),\mathbf{w}) \qquad \forall\,\mathbf{w} \in \mathbf{V} \text{ a.e. } t \in (0,T) \end{aligned} \tag{2.12}$$

and

$$\lim_{t\to 0^+} \mathbf{v}(t) = \mathbf{u}_0 - \mathbf{U}_0 \qquad \text{in } \mathbf{W}\,. \tag{2.13}$$

The cost functional can be rewritten as

$$\mathcal{K}_T(\mathbf{v},\mathbf{g}) \stackrel{\text{def}}{=\!=} \mathcal{J}_T(\mathbf{v}+\mathbf{U},\mathbf{g}+\mathbf{N}(\mathbf{U})) = \frac{\alpha}{2}\int_0^T\int_\Omega |\mathbf{v}|^2\,d\mathbf{x}dt + \frac{\beta}{2}\int_0^T\int_\Omega |\mathbf{g}|^2 d\mathbf{x}dt\,. \tag{2.14}$$

By defining

$$\mathcal{V}_{\text{ad}}(T) \stackrel{\text{def}}{=\!=} \{(\mathbf{v},\mathbf{g}) \in \mathbf{X}_T \times \mathbf{Y}_T : \mathcal{K}_T(\mathbf{v},\mathbf{g}) < \infty,\ (\mathbf{v},\mathbf{g}) \text{ satisfies (2.12), (2.13)}\}$$

for each $T \in (0,\infty]$, we can restate the optimization problem (2.10) in terms of the auxiliary variables $(\mathbf{v},\mathbf{g})$:

$$\begin{aligned} &\text{find a } (\mathbf{v},\mathbf{g}) \in \mathcal{V}_{\text{ad}}(T) \text{ such that}\\ &\mathcal{K}_T(\mathbf{v},\mathbf{g}) \le \mathcal{K}_T(\mathbf{w},\mathbf{h}) \qquad \forall\,(\mathbf{w},\mathbf{h}) \in \mathcal{V}_{\text{ad}}(T)\,. \end{aligned} \tag{2.15}$$

2.2. A linear feedback distributed control—a quasi optimizer. To estimate the dynamics of the optimal control solution, we need to find a sharp bound for the value of $\inf_{(\mathbf{u},\mathbf{f})\in\mathcal{U}_{ad}(T)} \mathcal{J}_T(\mathbf{u},\mathbf{f})$. It is important that this bound is uniform in T. We now construct a quasi optimizer $(\widetilde{\mathbf{u}},\widetilde{\mathbf{f}}) \in \mathcal{U}_{ad}(\infty)$ for $\mathcal{J}_\infty(\cdot,\cdot)$ by means of a linear feedback. We can in turn derive some preliminary estimates for the optimal solutions. By a quasi optimizer we mean an element $(\widetilde{\mathbf{u}},\widetilde{\mathbf{f}}) \in \mathcal{U}_{ad}(\infty)$ satisfying $\|\widetilde{\mathbf{u}}(t) - \mathbf{U}(t)\| \to 0$ as $t \to \infty$. The following theorem asserts the existence of such an element.

THEOREM 2.4. *There exists a pair* $(\widetilde{\mathbf{u}},\widetilde{\mathbf{f}}) \in \mathcal{U}_{ad}(\infty)$ *satisfying*

$$\|\widetilde{\mathbf{u}}(t) - \mathbf{U}(t)\|^2 \le \|\mathbf{u}_0 - \mathbf{U}_0\|^2 \exp\{-(\tilde{k} + \nu\lambda_1 - C_1\,|||\nabla\mathbf{U}|||^2/\nu)t\} \tag{2.16}$$

for some $\tilde{k} > M$, *where* $C_1 > 0$ *is a constant depending only on* Ω, $\lambda_1 > 0$ *is the Poincaré constant in* (2.2),

$$M = M(|||\nabla\mathbf{U}|||) \stackrel{\text{def}}{=\!=} \frac{C_1\,|||\nabla\mathbf{U}|||^2}{\nu} - \nu\lambda_1, \tag{2.17}$$

and

$$\mathcal{J}_T(\widetilde{\mathbf{u}},\widetilde{\mathbf{f}}) \le K\,\|\mathbf{u}_0 - \mathbf{U}_0\|^2 \left(1 - \exp\{-T\sqrt{\beta^2M^2 + 4\alpha\beta}/\beta\}\right) \quad \forall\, T \in (0,\infty], \tag{2.18}$$

where

$$K = K(\nabla\mathbf{U},\alpha,\beta) \stackrel{\text{def}}{=\!=} \frac{4\alpha\beta + \left(\sqrt{\beta^2M^2 + 4\alpha\beta} + \beta M\right)^2}{8\sqrt{\beta^2M^2 + 4\alpha\beta}}. \tag{2.19}$$

If, in addition, $\nabla\mathbf{U} \in L^\infty(\Omega\times(0,\infty))$, *then the constant* M *in* (2.18), (2.19) *can be replaced by*

$$M' = M'(|||\nabla\mathbf{U}|||) \stackrel{\text{def}}{=\!=} 4\,|||\nabla\mathbf{U}||| - 2\nu\lambda_1. \tag{2.20}$$

Proof. Let $k > 0$ be an arbitrary (fixed) constant, and we seek a solution $\mathbf{u} \in \mathbf{X}_\infty$ for the following Navier–Stokes equations with a linear feedback in the body force:

$$\begin{aligned} &\langle \partial_t \mathbf{u}(t), \mathbf{w}\rangle + a(\mathbf{u}(t), \mathbf{w}) + c(\mathbf{u}(t), \mathbf{u}(t), \mathbf{w}) \\ &\quad = -\frac{k}{2}(\mathbf{u}(t), \mathbf{w}) + (k\mathbf{U}(t)/2 + \mathbf{N}(\mathbf{U}(t)), \mathbf{w}) \qquad \forall\, \mathbf{w} \in \mathbf{V} \text{ a.e. } t \in (0, \infty) \end{aligned} \tag{2.21}$$

and

$$\lim_{t \to 0^+} \mathbf{u}(t) = \mathbf{u}_0 \qquad \text{in } \mathbf{W}\,. \tag{2.22}$$

As the term $-k(\mathbf{u}/2, \mathbf{w})$ has the right sign when moved to the left-hand side and by (2.6), $\mathbf{U} \in L^\infty(0, T; \mathbf{L}^2(\Omega))$, we can use the techniques for the Navier–Stokes equations (see [6] and [18]) to show that there exists a $\mathbf{u} \in \mathbf{X}_\infty$ that satisfies (2.21), (2.22) provided k is bounded from below by a certain finite number (the range of k will be determined later in the proof). By setting $\mathbf{v} = \mathbf{u} - \mathbf{U}$ we see that $\mathbf{v}$ satisfies

$$\begin{aligned} &\langle \partial_t \mathbf{v}(t), \mathbf{w}\rangle + a(\mathbf{v}(t), \mathbf{w}) + c(\mathbf{v}(t), \mathbf{v}(t), \mathbf{w}) + c(\mathbf{U}(t), \mathbf{v}(t), \mathbf{w}) \\ &\qquad + c(\mathbf{v}(t), \mathbf{U}(t), \mathbf{w}) = -\frac{k}{2}(\mathbf{v}(t), \mathbf{w}) \qquad \forall\, \mathbf{w} \in \mathbf{V} \text{ a.e. } t \in (0, \infty) \end{aligned} \tag{2.23}$$

and

$$\lim_{t \to 0^+} \mathbf{v}(t) = \mathbf{u}_0 - \mathbf{U}_0 \qquad \text{in } \mathbf{W}\,. \tag{2.24}$$

Setting $\mathbf{w} = \mathbf{v}(t)$ in (2.23), we obtain

$$\frac{1}{2}\frac{d}{dt}\|\mathbf{v}(t)\|^2 + \nu\|\nabla \mathbf{v}(t)\|^2 + \frac{k}{2}\|\mathbf{v}(t)\|^2 = -c(\mathbf{v}(t), \mathbf{U}(t), \mathbf{v}(t))\,. \tag{2.25}$$

We deduce from the Ladyzhenskaya inequality $\|\mathbf{v}\|^2_{\mathbf{L}^4(\Omega)} \le C\,\|\mathbf{v}\|\,\|\nabla \mathbf{v}\|$ for all $\mathbf{v} \in \mathbf{H}^1(\Omega)$ that

$$\begin{aligned} |c(\mathbf{v}(t), \mathbf{U}(t), \mathbf{v}(t))| &\le \|\mathbf{v}(t)\|^2_{\mathbf{L}^4(\Omega)}\, \|\nabla \mathbf{U}(t)\| \le C\,\|\mathbf{v}(t)\|\,\|\nabla \mathbf{v}(t)\|\,\, |||\nabla \mathbf{U}||| \\ &\le \frac{\nu}{2}\|\nabla \mathbf{v}(t)\|^2 + \frac{C}{\nu}\|\mathbf{v}(t)\|^2\,\, |||\nabla \mathbf{U}|||^2\,, \end{aligned} \tag{2.26}$$

so that from (2.25) and Poincaré inequality (2.2) we obtain

$$\frac{d}{dt}\|\mathbf{v}(t)\|^2 + \left(k + \nu\lambda_1 - \frac{C_1\,|||\nabla \mathbf{U}|||^2}{\nu}\right)\|\mathbf{v}(t)\|^2 \le 0\,, \tag{2.27}$$

where λ_1 is the Poincaré constant in (2.2) and $C_1 > 0$ is a constant depending only on Ω. Thus, if k satisfies

$$k > M = M\left(|||\nabla \mathbf{U}|||\right) \stackrel{\text{def}}{=\!=} \frac{C_1\,|||\nabla \mathbf{U}|||^2}{\nu} - \nu\lambda_1\,, \tag{2.28}$$

then we may apply the Gronwall inequality to (2.27) to obtain

$$\|\mathbf{v}(\cdot, t)\|^2 \le \|\mathbf{u}_0 - \mathbf{U}_0\|^2\, \exp\{-(k - M)t\}. \tag{2.29}$$

Setting $\mathbf{f} = -k\mathbf{v}/2 + \mathbf{N}(\mathbf{U})$ and $\mathbf{g} = -k\mathbf{v}/2$, we see that for each $T \in (0, \infty]$,

$$\begin{aligned} \mathcal{J}_T(\mathbf{u}, \mathbf{f}) = \mathcal{K}_T(\mathbf{v}, \mathbf{g}) &= \frac{\alpha}{2} \int_0^T \int_\Omega |\mathbf{v}|^2 \, d\mathbf{x} \, dt + \frac{\beta}{2} \int_0^T \int_\Omega |\mathbf{g}|^2 \, d\mathbf{x} \, dt \\ &\le \frac{\left(4\alpha + \beta k^2\right) \|\mathbf{u}_0 - \mathbf{U}_0\|^2}{8} \int_0^T \exp\{-(k-M)t\} \, dt \\ &= \frac{\left(4\alpha + \beta k^2\right) \|\mathbf{u}_0 - \mathbf{U}_0\|^2 \cdot (1 - \exp\{-(k-M)T\})}{8(k-M)} \, . \end{aligned} \tag{2.30}$$

We now choose a particular k and define $\widetilde{\mathbf{u}}$. We notice that the function

$$\theta(k) \stackrel{\text{def}}{=\!=} \frac{4\alpha + \beta k^2}{k - M}$$

defined for $k \in (M, \infty)$ attains its minimum at

$$\tilde{k} \stackrel{\text{def}}{=\!=} \frac{1}{\beta} \left(\sqrt{\beta^2 M^2 + 4\alpha\beta} + \beta M \right) > M \, . \tag{2.31}$$

We let $\widetilde{\mathbf{u}}$ denote the solution of (2.21), (2.22) with $k = \tilde{k}$. Upon setting $\widetilde{\mathbf{v}} = \widetilde{\mathbf{u}} - \mathbf{U}$, $\widetilde{\mathbf{f}} = -k\widetilde{\mathbf{v}}/2 + \mathbf{N}(\mathbf{U})$, and $\widetilde{\mathbf{g}} = -k\widetilde{\mathbf{v}}/2$, and using (2.30), we are led to

$$\begin{aligned} \mathcal{J}_T(\widetilde{\mathbf{u}}, \widetilde{\mathbf{f}}) &\le \frac{1}{8} \theta(\tilde{k}) \, \|\mathbf{u}_0 - \mathbf{U}_0\|^2 \, (1 - \exp\{-(\tilde{k} - M)T\}) \\ &= \frac{(4\alpha + \beta\tilde{k}^2) \|\mathbf{u}_0 - \mathbf{U}_0\|^2}{8(\tilde{k} - M)} \, (1 - \exp\{-(\tilde{k} - M)T\}) \end{aligned} \tag{2.32}$$

for all $T \in (0, \infty]$, so that (2.18) is proved with

$$K \stackrel{\text{def}}{=\!=} \frac{4\alpha + \beta\tilde{k}^2}{8(\tilde{k} - M)} = \frac{4\alpha\beta + \left(\sqrt{\beta^2 M^2 + 4\alpha\beta} + \beta M\right)^2}{8\sqrt{\beta^2 M^2 + 4\alpha\beta}} \, .$$

Also, (2.16) follows from (2.29) with $k = \tilde{k}$.

If, in addition, $\nabla \mathbf{U} \in \mathbf{L}^\infty(\Omega \times (0, \infty))$, then from (2.25) we have, instead of (2.26),

$$|c(\mathbf{v}(t), \mathbf{U}(t), \mathbf{v}(t))| \le 2 \, |||\nabla \mathbf{U}||| \, \|\mathbf{v}(t)\|^2$$

so that, instead of (2.27),

$$\frac{d}{dt} \|\widetilde{\mathbf{v}}(t)\|^2 + (k + 2\nu\lambda_1 - 4 \, |||\nabla \mathbf{U}|||) \, \|\widetilde{\mathbf{v}}(t)\|^2 \le 0 \, .$$

Evidently, upon replacing M by M' (defined by (2.20)) in the foregoing arguments after (2.27), we see that (2.16) and (2.18) now hold with $M = M'$. □

In what follows, the element $(\widetilde{\mathbf{u}}, \widetilde{\mathbf{f}})$ will always denote the one constructed in Theorem 2.4. As a consequence of (2.18) and the intermediate-value theorem we obtain the following bound for $\mathcal{J}_T(\widetilde{\mathbf{u}}, \widetilde{\mathbf{f}})$:

COROLLARY 2.5. *If the assumptions of Theorem* 2.4 *hold, then*

$$\mathcal{J}_T(\widetilde{\mathbf{u}}, \widetilde{\mathbf{f}}) \le \min \left\{ K, \frac{T}{8}(4\alpha + \beta\tilde{k}^2) \right\} \, \|\mathbf{u}_0 - \mathbf{U}_0\|^2 \tag{2.33}$$

for all $T \in (0, \infty]$, where $\tilde{k}$ is given by (2.31) *and K is given by* (2.19). □

It follows trivially from Corollary 2.5 that

$$\min_{(\mathbf{u},\mathbf{f})\in\mathcal{U}_{ad}(T)} \mathcal{J}_T(\mathbf{u},\mathbf{f}) = O(T) \quad \text{as } T \to 0^+. \tag{2.34}$$

Remark 2.6. In Theorem 2.4, we see that a quasi optimizer $(\widetilde{\mathbf{u}},\widetilde{\mathbf{f}})$ has been created in the sense that $\|\widetilde{\mathbf{u}}(t)-\mathbf{U}(t)\| \to 0$ and $\mathcal{J}_\infty(\widetilde{\mathbf{u}},\widetilde{\mathbf{f}})$ is finite. In fact, $\|\widetilde{\mathbf{u}}(t)-\mathbf{U}(t)\| \to 0$ exponentially as $t\to\infty$. Also, the computation of $(\widetilde{\mathbf{u}},\widetilde{\mathbf{f}}) \stackrel{\text{def}}{=\!=} (\mathbf{U}+\widetilde{\mathbf{v}}, \mathbf{N}(\mathbf{U})-\tilde{k}\widetilde{\mathbf{v}}/2)$ is straightforward—one only needs to integrate the initial value problem (2.21), (2.22) with $k=\tilde{k}$. However, we point out that $-\tilde{k}\widetilde{\mathbf{v}}/2+\mathbf{N}(\mathbf{U})$ acts as an external force to the flow, and both $\widetilde{\mathbf{v}}$ and $\tilde{k}$ can be large; therefore the work (external force) required to achieve the quasi optimizer may be prohibitively expensive. The true optimizer $\widehat{\mathbf{u}}$ is expected to have the property $\|\widehat{\mathbf{u}}(t)-\mathbf{U}(t)\| \to 0$ as $t\to\infty$ and, at the same time, minimize the work involved to realize and maintain the optimized flow.

2.3. Preliminary estimates for the dynamics of admissible elements. With the aid of the quasi optimizer constructed in Theorem 2.4, we are prepared to derive some estimates for the dynamics of all solutions of (2.3), (2.4). These estimates in turn will allow us to derive preliminary estimates for the dynamics of the optimal solutions. First, we consider the $L^\infty(0,T;\mathbf{L}^2(\Omega))$ estimates in terms of the initial data and the functional values.

THEOREM 2.7. *Let $T\in(0,\infty]$. Assume that $(\mathbf{u},\mathbf{f})\in\mathcal{U}_{ad}(T)$. Then*

$$\|\mathbf{u}(t)-\mathbf{U}(t)\|^2 \le \|\mathbf{u}_0-\mathbf{U}_0\|^2 + \frac{C}{\nu}\max\left\{\frac{|||\nabla\mathbf{U}|||^2}{\alpha},\frac{1}{\beta}\right\}\mathcal{J}_T(\mathbf{u},\mathbf{f}) \tag{2.35}$$

for all $t\in[0,T]$. If, in addition,

$$\mathcal{J}_T(\mathbf{u},\mathbf{f}) \le \mathcal{J}_T(\widetilde{\mathbf{u}},\widetilde{\mathbf{f}}), \tag{2.36}$$

then

$$\|\mathbf{u}(t)-\mathbf{U}(t)\|^2 \le K_0\cdot\|\mathbf{u}_0-\mathbf{U}_0\|^2, \tag{2.37}$$

where

$$K_0 = K_0(\nabla\mathbf{U},\alpha,\beta) \stackrel{\text{def}}{=\!=} 1+\frac{C}{\nu}\max\left\{\frac{|||\nabla\mathbf{U}|||^2}{\alpha},\frac{1}{\beta}\right\}\cdot K \tag{2.38}$$

with $K=K(\nabla\mathbf{U},\alpha,\beta)$ defined by (2.19).

Proof. Since $(\mathbf{v},\mathbf{g}) \stackrel{\text{def}}{=\!=} (\mathbf{u}-\mathbf{U},\mathbf{f}-\mathbf{N}(\mathbf{U}))$ satisfies (2.12), by setting $\mathbf{w}=\mathbf{v}(t)$ in (2.12) and using the inequality $\|\mathbf{v}\|^2_{\mathbf{L}^4(\Omega)} \le C\,\|\mathbf{v}\|\,\|\nabla\mathbf{v}\|$ for all $\mathbf{v}\in\mathbf{H}^1(\Omega)$, we obtain that for a.e. $t\in(0,T)$,

$$\begin{aligned}
\frac{1}{2}\frac{d}{dt}\|\mathbf{v}(t)\|^2+\nu\,\|\nabla\mathbf{v}(t)\|^2 &= c(\mathbf{v}(t),\mathbf{U}(t),\mathbf{v}(t))+(\mathbf{g}(t),\mathbf{v}(t))\\
&\le C\,|||\nabla\mathbf{U}|||\,\|\mathbf{v}(t)\|\,\|\nabla\mathbf{v}(t)\|+\|\mathbf{g}(t)\|\,\|\mathbf{v}(t)\|\\
&\le \frac{C}{\nu}\left(|||\nabla\mathbf{U}|||^2\,\|\mathbf{v}(t)\|^2+\|\mathbf{g}(t)\|^2\right)+\frac{\nu}{2}\|\nabla\mathbf{v}(t)\|^2
\end{aligned}$$

so that

$$\frac{d}{dt}\|\mathbf{v}(t)\|^2+\nu\|\nabla\mathbf{v}(t)\|^2 \le \frac{C}{\nu}\max\left\{\frac{|||\nabla\mathbf{U}|||^2}{\alpha},\frac{1}{\beta}\right\}\left(\alpha\|\mathbf{v}(t)\|^2+\beta\|\mathbf{g}(t)\|^2\right). \tag{2.39}$$

Multiplying the last inequality by $e^{\nu\lambda_1 t}$ and integrating over $(0,t)$, we arrive at

$$\|\mathbf{v}(t)\|^2 \le \|\mathbf{u}_0 - \mathbf{U}_0\|^2 e^{-\nu\lambda_1 t} + \frac{C}{\nu}\max\left\{\frac{|||\nabla\mathbf{U}|||^2}{\alpha}, \frac{1}{\beta}\right\}\int_0^t \left(\alpha\|\mathbf{v}(s)\|^2 + \beta\|\mathbf{g}(s)\|^2\right) e^{-\nu\lambda_1(t-s)}\, ds,$$

which easily yields (2.35). We see that (2.37) follows from (2.35) and (2.18). □

Now, we derive the $L^\infty(0,T;\mathbf{H}^1(\Omega))$ estimates. To this end, we recall two well-known results. The first result is the uniform Gronwall inequality (see [19, Lemma III.1.1]).

UNIFORM GRONWALL LEMMA. *Let g, h, and y be three nonnegative locally integrable functions on $t \in (t_0,\infty)$ such that y' is locally integrable on (t_0,∞) and that*

$$\frac{dy}{dt} \le gy + h \qquad \forall\, t \ge t_0\,,$$

$$\int_t^{t+r} g(s)ds \le a_1\,, \quad \int_t^{t+r} h(s)ds \le a_2\,, \quad \text{and} \quad \int_t^{t+r} y(s)ds \le a_3 \qquad \forall\, t \ge t_0,$$

where $r > 0$ and a_1, a_2, a_3 are constants. Then

$$y(t+r) \le \left(\frac{a_3}{r} + a_2\right) e^{a_1} \qquad \forall\, t \ge t_0. \tag{2.40}$$ □

The second result is that for the Leray operator

$$P : \mathbf{L}^2(\Omega) \to \mathbf{W} \tag{2.41}$$

(i.e., the orthogonal projection with respect to the $\mathbf{L}^2(\Omega)$-norm), it is well known (see [6]) that there is a constant $\gamma > 0$ depending only on Ω such that

$$\gamma\|\mathbf{w}\|_2 \le \|P\Delta\mathbf{w}\| \le \|\mathbf{w}\|_2 \qquad \forall\, \mathbf{w} \in \mathbf{H}^2(\Omega)\cap\mathbf{V}\,, \tag{2.42}$$

so that $\|P\Delta\cdot\|$ is equivalent to the $\mathbf{H}^2(\Omega)$-norm on $\mathbf{H}^2(\Omega)\cap\mathbf{V}$.

THEOREM 2.8. *Let $T \in (0,\infty]$. Assume that $(\mathbf{u},\mathbf{f}) \in \mathcal{U}_{ad}(T)$ and that (2.36) holds. Then for each $\varepsilon > 0$,*

$$\mathbf{u} - \mathbf{U} \in L^2(0,T;\mathbf{H}^1(\Omega)) \cap L^\infty(\varepsilon,T;\mathbf{H}^1(\Omega)) \cap C([\varepsilon,T];\mathbf{H}^1(\Omega)), \tag{2.43}$$

$$\int_0^T \|\nabla\mathbf{u}(s) - \nabla\mathbf{U}(s)\|^2 ds \le \overline{K}_1 \cdot \|\mathbf{u}_0 - \mathbf{U}_0\|^2, \tag{2.44}$$

and

$$\|\nabla\mathbf{u}(t) - \nabla\mathbf{U}(t)\|^2 \le K_1(\varepsilon)\cdot\|\mathbf{u}_0 - \mathbf{U}_0\|^2 \qquad \forall\, t \in [\varepsilon,T]\,, \tag{2.45}$$

where

$$\overline{K}_1 = \overline{K}_1(\nabla\mathbf{U},\alpha,\beta) \stackrel{\text{def}}{=\!=} \frac{1}{\nu} + \frac{C}{\nu^2}\max\left\{\frac{|||\nabla\mathbf{U}|||^2}{\alpha}, \frac{1}{\beta}\right\} K = K_0/\nu\,, \tag{2.46}$$

with K_0 and K given in Theorems 2.7 and 2.4, and

$$K_1(\varepsilon) = K_1(\varepsilon,\mathbf{U},\alpha,\beta) \stackrel{\text{def}}{=\!=} \exp\left\{\|\mathbf{u}_0 - \mathbf{U}_0\|^4 K_0\overline{K}_1/\nu^3\right\} \cdot \left\{\frac{1}{\varepsilon}\overline{K}_1 + \frac{C}{\nu^3}\left[(|||\mathbf{U}|||^2\ |||\nabla\mathbf{U}|||^2 + \nu^2\,|||\nabla\mathbf{U}|||\ |||\Delta\mathbf{U}|||)\overline{K}_1 + \frac{\nu^2 K}{\beta}\right]\right\}. \tag{2.47}$$

Proof. Let $T \in (0,\infty]$ be given and set $\mathbf{v} = \mathbf{u} - \mathbf{U}$. We first note that (2.45) follows from integrating (2.39). Thus $\mathbf{u} - \mathbf{U} \in L^2(0,T;\mathbf{H}^1(\Omega))$.

To show $\mathbf{u} - \mathbf{U} \in L^\infty(\varepsilon,T;\mathbf{H}^1(\Omega))$ for any $\varepsilon > 0$, it suffices to derive the estimate (2.45). We set $\mathbf{w} = -P\Delta\mathbf{v}(t)$ in (2.12) to obtain

$$\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\|\nabla\mathbf{v}(t)\|^2 + \nu\|P\Delta\mathbf{v}(t)\|^2 \\
&\qquad = ([\mathbf{v}(t)\cdot\nabla]\mathbf{v}(t), -P\Delta\mathbf{v}(t)) - ([\mathbf{U}(t)\cdot\nabla]\mathbf{v}(t), -P\Delta\mathbf{v}(t)) \\
&\qquad\qquad - ([\mathbf{v}(t)\cdot\nabla]\mathbf{U}(t), -P\Delta\mathbf{v}(t)) + (\mathbf{g}(t), -P\Delta\mathbf{v}(t))\,.
\end{aligned}$$

Applying Sobolev imbedding and interpolation results, together with Young's inequality and (2.42), we have

$$\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\|\nabla\mathbf{v}(t)\|^2 + \nu\,\|P\Delta\mathbf{v}(t)\|^2 \\
&\quad \le C(\|\mathbf{v}(t)\|_{\mathbf{L}^4(\Omega)}\,\|\nabla\mathbf{v}(t)\|_{\mathbf{L}^4(\Omega)} + \|\mathbf{U}(t)\|_{\mathbf{L}^4(\Omega)}\,\|\nabla\mathbf{v}(t)\|_{\mathbf{L}^4(\Omega)} \\
&\qquad\qquad + \|\mathbf{v}(t)\|_{\mathbf{L}^4(\Omega)}\,\|\nabla\mathbf{U}(t)\|_{\mathbf{L}^4(\Omega)} + \|\mathbf{g}(t)\|)\,\|P\Delta\mathbf{v}(t)\| \\
&\quad \le C(\|\mathbf{v}(t)\|^{1/2}\|\nabla\mathbf{v}(t)\|\,\|P\Delta\mathbf{v}(t)\|^{1/2} \\
&\qquad + \|\mathbf{U}(t)\|^{1/2}\,\|\nabla\mathbf{U}(t)\|^{1/2}\,\|\nabla\mathbf{v}(t)\|^{1/2}\,\|P\Delta\mathbf{v}(t)\|^{1/2} \\
&\qquad\quad + \|\nabla\mathbf{U}(t)\|^{1/2}\,\|P\Delta\mathbf{U}(t)\|^{1/2}\,\|\mathbf{v}(t)\|^{1/2}\,\|\nabla\mathbf{v}(t)\|^{1/2} + \|\mathbf{g}(t)\|)\,\|P\Delta\mathbf{v}(t)\| \\
&\quad \le \frac{\nu}{2}\|P\Delta\mathbf{v}(t)\|^2 + \frac{C}{\nu^3}(\|\mathbf{v}(t)\|^2\,\|\nabla\mathbf{v}(t)\|^4 + \|\mathbf{U}(t)\|^2\,\|\nabla\mathbf{U}(t)\|^2\,\|\nabla\mathbf{v}(t)\|^2 \\
&\qquad\qquad + \nu^2\|\nabla\mathbf{U}(t)\|\,\|\Delta\mathbf{U}(t)\|\,\|\nabla\mathbf{v}(t)\|^2 + \nu^2\|\mathbf{g}(t)\|^2).
\end{aligned}$$

Rearranging terms and applying Theorem 2.7 and (2.42), we obtain

$$\begin{aligned}
&\frac{d}{dt}\|\nabla\mathbf{v}(t)\|^2 + \nu\|P\Delta\mathbf{v}(t)\|^2 \le \frac{CK_0\|\mathbf{u}_0 - \mathbf{U}_0\|^2\,\|\nabla\mathbf{v}(t)\|^2}{\nu^3}\,\|\nabla\mathbf{v}(t)\|^2 \\
&+ \frac{C}{\nu^3}[(\|\mathbf{U}(t)\|^2\,\|\nabla\mathbf{U}(t)\|^2 + \nu^2\|\nabla\mathbf{U}(t)\|\,\|\Delta\mathbf{U}(t)\|)\|\nabla\mathbf{v}(t)\|^2 + \nu^2\|\mathbf{g}(t)\|^2]\,.
\end{aligned} \tag{2.48}$$

We introduce

$$\begin{aligned}
y(t) &\overset{\text{def}}{=\!=} \|\nabla\mathbf{v}(t)\|^2\,, \\
g(t) &\overset{\text{def}}{=\!=} \frac{CK_0\|\mathbf{u}_0 - \mathbf{U}_0\|^2\,\|\nabla\mathbf{v}(t)\|^2}{\nu^3},
\end{aligned}$$

and

$$h(t) \overset{\text{def}}{=\!=} \frac{C}{\nu^3}[(\|\mathbf{U}(t)\|^2\,\|\nabla\mathbf{U}(t)\|^2 + \nu^2\|\nabla\mathbf{U}(t)\|\,\|\Delta\mathbf{U}(t)\|)\|\nabla\mathbf{v}(t)\|^2 + \nu^2\|\mathbf{g}(t)\|^2]\,.$$

For each $\varepsilon > 0$, by Theorem 2.7 and (2.44) we have

$$\int_t^{t+\varepsilon} y(s)ds \le \|\mathbf{u}_0 - \mathbf{U}_0\|^2 \cdot \overline{K}_1\,,$$

$$\int_t^{t+\varepsilon} g(s)ds \le \|\mathbf{u}_0 - \mathbf{U}_0\|^4\,\frac{CK_0\overline{K}_1}{\nu^3},$$

and

$$\begin{aligned}
&\int_t^{t+\varepsilon} h(s)ds \\
&\le \|\mathbf{u}_0 - \mathbf{U}_0\|^2 \frac{C}{\nu^3} \left(|||\mathbf{U}|||^2 \, |||\nabla \mathbf{U}|||^2 + \nu^2 \, |||\nabla \mathbf{U}||| \, |||\Delta \mathbf{U}||| \right) \overline{K}_1 + \frac{C}{\nu} \int_t^{t+\varepsilon} \|\mathbf{g}(s)\|^2 ds \\
&\le \|\mathbf{u}_0 - \mathbf{U}_0\|^2 \frac{C}{\nu^3} \left(|||\mathbf{U}|||^2 \, |||\nabla \mathbf{U}|||^2 + \nu^2 \, |||\nabla \mathbf{U}||| \, |||\Delta \mathbf{U}||| \right) \overline{K}_1 + \frac{C}{\nu\beta} \mathcal{J}_T(\mathbf{u}, \mathbf{f})
\end{aligned}$$

so that by (2.36) and (2.18),

$$\begin{aligned}
&\int_t^{t+\varepsilon} h(s)ds \\
&\le \|\mathbf{u}_0 - \mathbf{U}_0\|^2 \frac{C}{\nu^3 \beta} \left\{ \beta \left[|||\mathbf{U}|||^2 \, |||\nabla \mathbf{U}|||^2 + \nu^2 \, |||\nabla \mathbf{U}||| \, |||\Delta \mathbf{U}||| \right] \overline{K}_1 + \nu^2 K \right\} .
\end{aligned}$$

Hence, (2.45) follows from the uniform Gronwall inequality (2.40) (applied to (2.48)) and the last three estimates for y, g, and h.

Finally, we prove $\mathbf{u} - \mathbf{U} \in C([\varepsilon, T]; \mathbf{H}^1(\Omega))$. Integrating (2.48) for $t \in [\varepsilon, T]$ and utilizing the bounds for $g(t)$, $h(t)$, and $y(t)$, we obtain

$$\begin{aligned}
\nu\lambda_1 \int_\varepsilon^T \|P\Delta v(t)\|^2 \, dt &\le y(\varepsilon) + \int_\varepsilon^T \left(g(t)y(t) + h(t) \right) \, dt \\
&\le \int_\varepsilon^T h(t) \, dt + \left(\sup_{t \in (\varepsilon, T)} y(t) \right) \cdot \left(1 + \int_\varepsilon^T g(t) \, dt \right) < \infty.
\end{aligned}$$

Hence $\mathbf{v} \in L^2(\varepsilon, T; \mathbf{H}^2(\Omega))$. From (2.39) we easily see that $\mathbf{v}_t = \nu P\Delta \mathbf{v} - P(\mathbf{v} \cdot \nabla)\mathbf{v} - P(\mathbf{U} \cdot \nabla)\mathbf{v} - P(\mathbf{v} \cdot \nabla)\mathbf{U} + P\mathbf{f} \in L^2(\varepsilon, T; \mathbf{L}^2(\Omega))$, where P is the Leray operator defined in (2.41). Therefore, $\nabla \mathbf{v} \in L^2(\varepsilon, T; (\mathbf{H}^1(\Omega))^2)$ and $(\nabla \mathbf{v})_t \in L^2(\varepsilon, T; (\mathbf{H}^{-1}(\Omega))^2)$. From [17, Lemma 5.5.1], we conclude that $\nabla \mathbf{v} \in C([\varepsilon, T]; \mathbf{L}^2(\Omega))$, which implies $\mathbf{v} \in C([\varepsilon, T]; \mathbf{H}^1(\Omega))$. ∎

An immediate consequence of Theorems 2.7 and 2.8 is the following preliminary estimates for the optimal solutions.

THEOREM 2.9. *Let $T \in (0, \infty]$. Assume $(\widehat{\mathbf{u}}, \widehat{\mathbf{f}}) \in \mathcal{U}_{ad}(T)$ is an optimal solution for* (2.10). *Then*

$$\|\widehat{\mathbf{u}}(t) - \mathbf{U}(t)\|^2 \le K_0 \cdot \|\mathbf{u}_0 - \mathbf{U}_0\|^2 \qquad \forall\, t \in [\varepsilon, T] \,, \tag{2.49}$$

$$\int_0^T \|\nabla \widehat{\mathbf{u}}(s) - \nabla \mathbf{U}(s)\|^2 ds \le \overline{K}_1 \cdot \|\mathbf{u}_0 - \mathbf{U}_0\|^2 \,, \tag{2.50}$$

and

$$\|\nabla \widehat{\mathbf{u}}(t) - \nabla \mathbf{U}(t)\|^2 \le K_1(\varepsilon) \cdot \|\mathbf{u}_0 - \mathbf{U}_0\|^2 \quad \forall\, t \in [\varepsilon, T] \,, \tag{2.51}$$

where all the constants are as defined in Theorems 2.7 *and* 2.8. ∎

Remark 2.10. The quantity $K_1(\varepsilon)$ is unbounded as $\varepsilon \to 0$:

$$K_1(\varepsilon) = O(1/\varepsilon) \qquad \text{as } \varepsilon \to 0^+. \tag{2.52}$$

Remark 2.11. If $T = \infty$, then the interval $[\varepsilon, T]$ in (2.43), (2.45), (2.49), and (2.51) (and elsewhere in this paper) should be understood as $[\varepsilon, \infty)$.

3. Existence of an optimal control.

3.1. The case of finite time intervals. In this subsection, we first quote the results of [8], [9], and [10] concerning the existence of an optimal solution for (2.10) with $T < \infty$ and concerning an optimality system. We then derive some estimates for the adjoint equations.

With the notion of admissible elements, admissible sets and optimal solutions were introduced in section 2.1 together with the functional spaces. We may state the results of [8], [9], and [10] as follows.

THEOREM 3.1. *Let $T \in (0,\infty)$. Then there exists a optimal solution $(\widehat{\mathbf{u}},\widehat{\mathbf{f}}) \in \mathcal{U}_{ad}(T)$ for the problem* (2.10)*. Furthermore, there exists $\widehat{\boldsymbol{\xi}} \in \mathcal{V}^{(1)}(Q_T)$ such that*

$$-\langle \partial_t \widehat{\boldsymbol{\xi}}(t), \mathbf{w}\rangle + a(\widehat{\boldsymbol{\xi}}(t),\mathbf{w}) + c(\widehat{\mathbf{u}}(t),\mathbf{w},\widehat{\boldsymbol{\xi}}(t)) + c(\mathbf{w},\widehat{\mathbf{u}}(t),\widehat{\boldsymbol{\xi}}(t)) = \alpha\,(\widehat{\mathbf{v}}(t),\mathbf{w}) \qquad \forall\,\mathbf{w}\in\mathbf{V} \text{ a.e. } t\in(0,T)\,, \tag{3.1}$$

$$\lim_{t\to T^-} \widehat{\boldsymbol{\xi}}(t) = \mathbf{0} \qquad \text{in } \mathbf{W}, \tag{3.2}$$

and

$$\widehat{\boldsymbol{\xi}} + \beta\,\widehat{\mathbf{g}} = \mathbf{0} \qquad \text{in } \Omega\times(0,T), \tag{3.3}$$

where $\widehat{\mathbf{v}} \overset{\text{def}}{=\!=} \widehat{\mathbf{u}} - \mathbf{U}$ and $\widehat{\mathbf{g}} \overset{\text{def}}{=\!=} \widehat{\mathbf{f}} - \mathbf{N}(\mathbf{U})$. □

From this theorem we see that the optimal solution $(\widehat{\mathbf{u}},\widehat{\mathbf{f}})$ together with the Lagrange multiplier $\widehat{\boldsymbol{\xi}}$ satisfies equations (2.12), (2.13) and (3.1), (3.3). Note that (3.3) allows us to eliminate the variable $\mathbf{f}$ in (2.12). We collect these equations here to form an optimality system of equations:

$$\langle \partial_t \widehat{\mathbf{u}}(t),\mathbf{w}\rangle + a(\widehat{\mathbf{u}}(t),\mathbf{w}) + c(\widehat{\mathbf{u}}(t),\widehat{\mathbf{u}}(t),\mathbf{w}) = (\widehat{\mathbf{f}}(t),\mathbf{w}) \qquad \forall\,\mathbf{w}\in\mathbf{V} \text{ a.e. } t\in(0,T), \tag{3.4}$$

$$\lim_{t\to 0^+} \widehat{\mathbf{u}}(t) = \mathbf{u}_0 \qquad \text{in } \mathbf{W}\,, \tag{3.5}$$

$$-\langle \partial_t \widehat{\boldsymbol{\xi}}(t),\mathbf{w}\rangle + a(\widehat{\boldsymbol{\xi}}(t),\mathbf{w}) + c(\widehat{\mathbf{u}}(t),\mathbf{w},\widehat{\boldsymbol{\xi}}(t)) + c(\mathbf{w},\widehat{\mathbf{u}}(t),\widehat{\boldsymbol{\xi}}(t)) = \alpha\,(\widehat{\mathbf{v}}(t),\mathbf{w}) \qquad \forall\,\mathbf{w}\in\mathbf{V} \text{ a.e. } t\in(0,T), \tag{3.6}$$

and

$$\lim_{t\to T^-} \widehat{\boldsymbol{\xi}}(t) = \mathbf{0} \qquad \text{in } \mathbf{W}\,. \tag{3.7}$$

Based on the optimality system and the preliminary estimates for the optimal solutions, we may obtain estimates for $\widehat{\boldsymbol{\xi}}$ on finite time intervals.

THEOREM 3.2. *Let $T \in (0,\infty)$. Assume that $(\widehat{\mathbf{u}},\widehat{\mathbf{f}}) \in \mathcal{U}_{ad}(T)$ is a solution for* (2.10) *and that $\widehat{\boldsymbol{\xi}} \in \mathcal{V}^{(1)}(Q_T)$ is a solution for* (3.1)–(3.3)*. Then, for each $\varepsilon > 0$,*

$$\|\widehat{\boldsymbol{\xi}}(t)\|^2 + \nu\int_t^T \|\nabla\widehat{\boldsymbol{\xi}}(s)\|^2 ds \le \frac{C}{\nu}\max\{\alpha,\beta\rho_1^2(\varepsilon)\}\mathcal{J}_T(\widehat{\mathbf{u}},\widehat{\mathbf{f}}) \qquad \forall\, t\in[\varepsilon,T]\,, \tag{3.8}$$

where

$$\rho_1(\varepsilon) \overset{\text{def}}{=\!=} K_1(\varepsilon)\,\|\mathbf{u}_0 - \mathbf{U}_0\| + |||\nabla\mathbf{U}||| < \infty\,. \tag{3.9}$$

Proof. For each $\varepsilon > 0$, we clearly have $\rho_1(\varepsilon) < \infty$. Equation (3.3) yields

$$\widehat{\boldsymbol{\xi}} = -\beta\, \widehat{\mathbf{g}}\,.$$

Setting $\mathbf{w} = \widehat{\boldsymbol{\xi}}(t)$ in (3.1), we have

$$\begin{aligned} -\frac{1}{2}\frac{d}{dt}\|\widehat{\boldsymbol{\xi}}(t)\|^2 + \nu\,\|\nabla\widehat{\boldsymbol{\xi}}(t)\|^2 &= \alpha\,(\widehat{\mathbf{v}}(t),\widehat{\boldsymbol{\xi}}(t)) - c(\widehat{\boldsymbol{\xi}}(t),\widehat{\mathbf{u}}(t),\widehat{\boldsymbol{\xi}}(t)) \\ &\le \alpha\,\|\widehat{\mathbf{v}}(t)\|\,\|\widehat{\boldsymbol{\xi}}(t)\| + C\,\|\nabla\widehat{\mathbf{u}}(t)\|\,\|\widehat{\boldsymbol{\xi}}(t)\|\,\|\nabla\widehat{\boldsymbol{\xi}}(t)\|\,. \end{aligned} \tag{3.10}$$

From the triangle inequality and estimate (2.51) we obtain

$$\|\nabla\widehat{\mathbf{u}}(t)\| \le \|\nabla\widehat{\mathbf{u}}(t) - \nabla\mathbf{U}(t)\| + \|\nabla\mathbf{U}(t)\| \le \rho_1(\varepsilon) \qquad \forall\, t \in [\varepsilon, T]\,.$$

Using Young's inequality in (3.10) and using the last relation, we are led to

$$\begin{aligned} -\frac{d}{dt}\|\widehat{\boldsymbol{\xi}}(t)\|^2 + \nu\,\|\nabla\widehat{\boldsymbol{\xi}}(t)\|^2 &\le \frac{C}{\nu}(\alpha^2\|\widehat{\mathbf{v}}(t)\|^2 + \|\nabla\widehat{\mathbf{u}}(t)\|^2\,\|\widehat{\boldsymbol{\xi}}(t)\|^2) \\ &\le \frac{C}{\nu}\max\left\{\alpha, \beta\rho_1^2(\varepsilon)\right\}\,\left(\alpha\|\widehat{\mathbf{v}}(t)\|^2 + \beta\|\widehat{\mathbf{g}}(t)\|^2\right)\,. \end{aligned}$$

Integrating both sides over the interval $(t, T') \subset (0, T)$ and using the fact that $\lim_{T'\to T^-}\widehat{\boldsymbol{\xi}}(T') = \mathbf{0}$, we obtain the desired estimate for $\boldsymbol{\xi}$. ∎

3.2. The case of the infinite time interval. We now prove the existence of an optimal solution for (2.10) on the infinite time interval $(0, \infty)$. We will make use of the existence results on finite time intervals.

THEOREM 3.3. *There exists a solution* $(\widehat{\mathbf{u}}, \widehat{\mathbf{f}}) \in \mathcal{U}_{ad}(\infty)$ *for* (2.10) *with* $T = \infty$. *Furthermore, there exists a* $\widehat{\boldsymbol{\xi}} \in \mathcal{V}^{(1)}_{\rm loc}(Q)$ *which satisfies* (3.1) *and* (3.3) *with* $T = \infty$.

Proof. For each $T \in (0, \infty)$, we may use Theorem 3.1 to choose a $(\mathbf{u}_T, \mathbf{f}_T) \in \mathcal{U}_{ad}(T)$ which solves (2.10). Thus, $(\mathbf{u}_T, \mathbf{f}_T)$ satisfies

$$\mathcal{J}_T(\mathbf{u}_T, \mathbf{f}_T) = \inf_{(\mathbf{w},\mathbf{h})\in\mathcal{U}_{ad}(T)} \mathcal{J}_T(\mathbf{w}, \mathbf{h})\,, \tag{3.11}$$

$$\begin{aligned} \langle \partial_t \mathbf{u}_T(t), \mathbf{w}\rangle + a(\mathbf{u}_T(t), \mathbf{w}) + c(\mathbf{u}_T(t), \mathbf{u}_T(t), \mathbf{w}) \\ = (\mathbf{f}_T(t), \mathbf{w}) \qquad \forall\, \mathbf{w} \in \mathbf{V} \text{ a.e. } t \in (0, T), \end{aligned} \tag{3.12}$$

and

$$\lim_{t\to 0^+} \mathbf{u}_T(t) = \mathbf{u}_0 \qquad \text{in } \mathbf{W}\,. \tag{3.13}$$

Furthermore, there exists a $\boldsymbol{\xi}_T \in \mathcal{V}^{(1)}(Q_T)$ which satisfies (3.1)–(3.3).

For each finite T, we obviously have $[\mathcal{U}_{ad}(\infty)]|_{(0,T)} \subset \mathcal{U}_{ad}(T)$. Thus, for each $(\mathbf{w}, \mathbf{h}) \in \mathcal{U}_{ad}(\infty)$,

$$\mathcal{J}_T(\mathbf{u}_T, \mathbf{f}_T) \le \mathcal{J}_T(\mathbf{w}, \mathbf{h}) \le \mathcal{J}_\infty(\mathbf{w}, \mathbf{h})\,. \tag{3.14}$$

Since $\mathcal{J}_\infty(\widetilde{\mathbf{u}}, \widetilde{\mathbf{f}}) < \infty$ so that $(\widetilde{\mathbf{u}}, \widetilde{\mathbf{f}}) \in \mathcal{U}_{ad}(\infty)$, where $(\widetilde{\mathbf{u}}, \widetilde{\mathbf{f}})$ is constructed in section 2.2, it follows that $\inf_{(\mathbf{w},\mathbf{h})\in\mathcal{U}_{ad}(\infty)} \mathcal{J}_\infty(\mathbf{w}, \mathbf{h}) < \infty$. For each $T \in (0, \infty)$, we obtain from (3.14) that

$$\mathcal{J}_T(\mathbf{u}_T, \mathbf{f}_T) \le \inf_{(\mathbf{w},\mathbf{h})\in\mathcal{U}_{ad}(\infty)} \mathcal{J}_\infty(\mathbf{w}, \mathbf{h}) < \infty\,. \tag{3.15}$$

For each integer $k > 0$, we denote by $(\mathbf{u}_k, \mathbf{f}_k)$ a solution of (3.11)–(3.13) for $T = k$ and denote by $\boldsymbol{\xi}_k$ the corresponding multiplier which satisfies (3.1)–(3.3). We set $(\mathbf{v}_k, \mathbf{g}_k) \stackrel{\text{def}}{=\!=} (\mathbf{u}_k - \mathbf{U}, \mathbf{f}_k - \mathbf{N}(\mathbf{U}))$. Then, $(\mathbf{v}_k, \mathbf{g}_k)$ is a solution of (2.12), (2.13) with $T = k$. Using (3.15) and standard estimates for the Navier–Stokes equations on finite time intervals, we obtain that $\|\mathbf{g}_k\|_{L^2(0,k;\mathbf{L}^2(\Omega))}$, $\|\mathbf{u}_k\|_{\mathcal{V}^{(1)}(Q_k)}$, and $\|\mathbf{u}_k\|_{L^\infty(0,k;\mathbf{W})}$ are uniformly bounded for all k. Using the estimate (3.8), we obtain that $\|\boldsymbol{\xi}_k\|_{\mathcal{V}^{(1)}(\Omega\times(\epsilon,k))}$ and $\|\boldsymbol{\xi}_k\|_{L^\infty(\epsilon,k;\mathbf{W})}$ are uniformly bounded for all $\varepsilon > 0$ and k. Hence, by induction we may choose successive subsequences of positive integers $\{k_n^{(m)}\}_{n=1}^\infty$ for $m = 1, 2, \dots$ such that $\{k_n^{(1)}\}_{n=1}^\infty \supset \{k_n^{(2)}\}_{n=1}^\infty \supset \{k_n^{(3)}\}_{n=1}^\infty \supset \cdots$ and

$$
\begin{aligned}
&\mathbf{v}_{k_n^{(m)}} \rightharpoonup \mathbf{v}^{(m)} \quad \text{in } \mathcal{V}^{(1)}(Q_m) \text{ as } n \to \infty\,,\\
&\mathbf{v}_{k_n^{(m)}} \stackrel{*}{\rightharpoonup} \mathbf{v}^{(m)} \quad \text{in } L^\infty(0, m; \mathbf{W}) \text{ as } n \to \infty\,,\\
&\mathbf{g}_{k_n^{(m)}} \rightharpoonup \mathbf{g}^{(m)} \quad \text{in } L^2(0, m; \mathbf{W}) \text{ as } n \to \infty\,,\\
&\boldsymbol{\xi}_{k_n^{(m)}} \rightharpoonup \boldsymbol{\xi}^{(m)} \quad \text{in } \mathcal{V}^{(1)}(\Omega \times (1/m, m)) \text{ as } n \to \infty,
\end{aligned}
$$

and

$$
\boldsymbol{\xi}_{k_n^{(m)}} \stackrel{*}{\rightharpoonup} \boldsymbol{\xi}^{(m)} \quad \text{in } L^\infty(1/m, m; \mathbf{W}) \text{ as } n \to \infty
$$

for some $\mathbf{v}^{(m)} \in \mathcal{V}^{(1)}(Q_m)$, $\mathbf{g}^{(m)} \in L^2(0, m; \mathbf{W})$, and $\boldsymbol{\xi}^{(m)} \in \mathcal{V}^{(1)}(\Omega \times (1/m, m))$. (We remark that $\mathcal{V}^{(1)}(Q_m) \rightharpoonup L^\infty(0, m; \mathbf{W})$ and $\mathcal{V}^{(1)}(\Omega \times (1/m, m)) \rightharpoonup L^\infty(\varepsilon, m; \mathbf{W})$.) Hence, by extracting the diagonal subsequence, we have that for each m',

$$
\mathbf{v}_{k_m^{(m)}} \rightharpoonup \mathbf{v}^{(m')} \quad \text{in } \mathcal{V}^{(1)}(Q_{m'}) \text{ as } m \to \infty\,, \tag{3.16}
$$

$$
\mathbf{v}_{k_m^{(m)}} \stackrel{*}{\rightharpoonup} \mathbf{v}^{(m')} \quad \text{in } L^\infty(0, m'; \mathbf{W}) \text{ as } m \to \infty\,, \tag{3.17}
$$

$$
\mathbf{g}_{k_m^{(m)}} \rightharpoonup \mathbf{g}^{(m')} \quad \text{in } L^2(0, m'; \mathbf{W}) \text{ as } m \to \infty\,, \tag{3.18}
$$

$$
\boldsymbol{\xi}_{k_m^{(m)}} \rightharpoonup \boldsymbol{\xi}^{(m')} \quad \text{in } \mathcal{V}^{(1)}(\Omega \times (1/m', m')) \text{ as } m \to \infty \tag{3.19}
$$

and

$$
\boldsymbol{\xi}_{k_m^{(m)}} \stackrel{*}{\rightharpoonup} \boldsymbol{\xi}^{(m')} \quad \text{in } L^\infty(1/m', m'; \mathbf{W}) \text{ as } m \to \infty\,. \tag{3.20}
$$

For each integer $m' > 0$, (3.16)–(3.18) and standard techniques for the Navier–Stokes equations (see, e.g., [18]) allow us to pass to the limit as $m \to \infty$ in the equation

$$
\begin{aligned}
&\int_0^{m'} \langle \partial_t \mathbf{v}_{k_m^{(m)}}(t), \mathbf{w}\rangle \psi(t)\, dt + \int_0^{m'} a(\mathbf{v}_{k_m^{(m)}}(t), \mathbf{w})\psi(t)\, dt\\
&\quad + \int_0^{m'} c(\mathbf{v}_{k_m^{(m)}}(t), \mathbf{v}_{k_m^{(m)}}(t), \mathbf{w})\psi(t)\, dt\\
&\quad + \int_0^{m'} c(\mathbf{U}(t), \mathbf{v}_{k_m^{(m)}}(t), \mathbf{w})\psi(t)\, dt + \int_0^{m'} c(\mathbf{v}_{k_m^{(m)}}(t), \mathbf{U}(t), \mathbf{w})\psi(t)\, dt\\
&\quad = \int_0^{m'} (\mathbf{g}_{k_m^{(m)}}(t), \mathbf{w})\psi(t)\, dt \qquad \forall\, \mathbf{w} \in \mathbf{V},\ \psi \in C[0, m'] \text{ with } \psi(m') = 0
\end{aligned} \tag{3.21}
$$

to obtain

$$
\begin{aligned}
(3.22)\quad &\int_0^{m'} \langle \partial_t \mathbf{v}^{(m')}(t), \mathbf{w}\rangle \psi(t)\,dt + \int_0^{m'} a(\mathbf{v}^{(m')}(t), \mathbf{w})\psi(t)\,dt \\
&\quad + \int_0^{m'} c(\mathbf{v}^{(m')}(t), \mathbf{v}^{(m')}(t), \mathbf{w})\psi(t)\,dt \\
&\quad + \int_0^{m'} c(\mathbf{U}(t), \mathbf{v}^{(m')}(t), \mathbf{w})\psi(t)\,dt + \int_0^{m'} c(\mathbf{v}^{(m')}(t), \mathbf{U}(t), \mathbf{w})\psi(t)\,dt \\
&\quad = \int_0^{m'} (\mathbf{g}^{(m')}(t), \mathbf{w})\psi(t)\,dt \qquad \forall\, \mathbf{w} \in \mathbf{V},\ \psi \in C[0, m'] \text{ with } \psi(m') = 0,
\end{aligned}
$$

which is equivalent to

$$
\begin{aligned}
(3.23)\quad &\langle \partial_t \mathbf{u}^{(m')}(t), \mathbf{w}\rangle + a(\mathbf{u}^{(m')}(t), \mathbf{w}) + c(\mathbf{u}^{(m')}(t), \mathbf{u}^{(m')}(t), \mathbf{w}) \\
&\qquad = (\mathbf{f}^{(m')}(t), \mathbf{w}) \qquad \forall\, \mathbf{w} \in \mathbf{V} \text{ a.e. } t \in (0, m'),
\end{aligned}
$$

where $\mathbf{u}^{(m')} = \mathbf{v}^{(m')} + \mathbf{U}$. Similarly, for each positive integer m', we may pass to the limit as $m \to \infty$ in the equations

$$
\begin{aligned}
(3.24)\quad &-\langle \partial_t \boldsymbol{\xi}_{k_m^{(m)}}(t), \mathbf{w}\rangle + a(\boldsymbol{\xi}_{k_m^{(m)}}(t), \mathbf{w}) + c(\mathbf{u}_{k_m^{(m)}}(t), \mathbf{w}, \boldsymbol{\xi}_{k_m^{(m)}}(t)) \\
&\quad + c(\mathbf{w}, \mathbf{u}_{k_m^{(m)}}(t), \boldsymbol{\xi}_{k_m^{(m)}}(t)) = \alpha\,(\mathbf{v}_{k_m^{(m)}}(t), \mathbf{w}) \qquad \forall\, \mathbf{w} \in \mathbf{V} \text{ a.e. } t \in (0, m')
\end{aligned}
$$

and

$$
(3.25)\qquad \boldsymbol{\xi}_{k_m^{(m)}} + \beta\, \mathbf{g}_{k_m^{(m)}} = \mathbf{0} \qquad \text{in } \Omega \times (1/m', m')
$$

to obtain

$$
\begin{aligned}
&-\langle \partial_t \boldsymbol{\xi}^{(m')}(t), \mathbf{w}\rangle + a(\boldsymbol{\xi}^{(m')}(t), \mathbf{w}) + c(\mathbf{u}^{(m')}(t), \mathbf{w}, \boldsymbol{\xi}^{(m')}(t)) \\
&\quad + c(\mathbf{w}, \mathbf{u}^{(m')}(t), \boldsymbol{\xi}^{(m')}(t)) = \alpha\,(\mathbf{v}^{(m')}(t), \mathbf{w}) \qquad \forall\, \mathbf{w} \in \mathbf{V} \text{ a.e. } t \in (0, m')
\end{aligned}
$$

and

$$
\boldsymbol{\xi}^{(m')} + \beta\, \mathbf{g}^{(m')} = \mathbf{0} \qquad \text{in } \Omega \times (1/m', m').
$$

By the uniqueness of weak limits, we have that $\mathbf{v}^{(m_1)}|_{(0,m_2)} = \mathbf{v}^{(m_2)}$, $\mathbf{g}^{(m_1)}|_{(0,m_2)} = \mathbf{g}^{(m_2)}$ and $\boldsymbol{\xi}^{(m_1)}|_{(0,m_2)} = \boldsymbol{\xi}^{(m_2)}$ for all m_1, m_2 with $m_1 < m_2$. Thus, the functions

$$
\widehat{\mathbf{v}}(t) \stackrel{\text{def}}{=\!=} \mathbf{v}^{(m)}(t) \qquad (\text{if } t \le m)\,,
$$

$$
\widehat{\mathbf{g}}(t) \stackrel{\text{def}}{=\!=} \mathbf{g}^{(m)}(t) \qquad (\text{if } t \le m),
$$

and

$$
\widehat{\boldsymbol{\xi}}(t) \stackrel{\text{def}}{=\!=} \boldsymbol{\xi}^{(m)}(t) \qquad (\text{if } (1/m) \le t \le m)
$$

are well defined on $(0, \infty)$; furthermore, $\widehat{\mathbf{v}} \in \mathcal{V}^{(1)}_{\text{loc}}(Q)$, $\widehat{\mathbf{g}} \in L^2(0, \infty; \mathbf{L}^2(\Omega))$, and $\widehat{\boldsymbol{\xi}} \in \mathcal{V}^{(1)}_{\text{loc}}(Q)$. Upon setting $\widehat{\mathbf{u}} = \widehat{\mathbf{v}} + \mathbf{U}$ and $\widehat{\mathbf{f}} = \mathbf{g} + \mathbf{F}$ and noting that m' is arbitrary in (3.23)–(3.25), we are easily led to

$$
\begin{aligned}
(3.26)\quad &\langle \partial_t \widehat{\mathbf{u}}(t), \mathbf{w}\rangle + a(\widehat{\mathbf{u}}(t), \mathbf{w}) + c(\widehat{\mathbf{u}}(t), \widehat{\mathbf{u}}(t), \mathbf{w}) \\
&\qquad = (\widehat{\mathbf{f}}(t), \mathbf{w}) \qquad \forall\, \mathbf{w} \in V \text{ a.e. } t \in (0, \infty)\,,
\end{aligned}
$$

$$-\langle \partial_t \widehat{\boldsymbol{\xi}}(t), \mathbf{w}\rangle + a(\widehat{\boldsymbol{\xi}}(t), \mathbf{w}) + c(\mathbf{u}(t), \mathbf{w}, \widehat{\boldsymbol{\xi}}(t)) + c(\mathbf{w}, \mathbf{u}(t), \widehat{\boldsymbol{\xi}}(t)) = \alpha\,(\widehat{\mathbf{v}}(t), \mathbf{w}) \qquad \forall\, \mathbf{w} \in \mathbf{V} \text{ a.e. } t \in (0,\infty)\,,$$

and

$$\widehat{\boldsymbol{\xi}} + \beta\,\widehat{\mathbf{g}} = \mathbf{0} \qquad \text{in } \Omega \times (0,\infty)\,.$$

We now examine the initial condition for $\widehat{\mathbf{u}}$. Let ψ be a continuously differentiable function in $[0,\infty)$ with a bounded support. Equation (3.21) can be rewritten as

$$\langle \partial_t \mathbf{u}_{k_m^{(m)}}(t), \mathbf{w}\rangle + a(\mathbf{u}_{k_m^{(m)}}(t), \mathbf{w}) + c(\mathbf{u}_{k_m^{(m)}}(t), \mathbf{u}_{k_m^{(m)}}(t), \mathbf{w}) = (\mathbf{f}_{k_m^{(m)}}(t), \mathbf{w}) \qquad \forall\, \mathbf{w} \in \mathbf{V} \text{ a.e. } t \in (0, m') \quad (m > m')\,.$$

Multiplying the last equation by $\psi(t)$, integrating by parts, and using the fact that $\mathbf{u}_{k_m^{(m)}}(0) = \mathbf{u}_0$, we are led to

$$-\int_0^\infty (\mathbf{u}_{k_m^{(m)}}(t), \mathbf{z})\,\psi'(t)\,dt + \nu\int_0^\infty\int_\Omega \psi(t)\nabla \mathbf{u}_{k_m^{(m)}}(t) : \nabla \mathbf{z}\,d\mathbf{x}\,dt + \int_0^\infty\int_\Omega \psi(t)\,(\mathbf{u}_{k_m^{(m)}}(t)\cdot\nabla)\mathbf{u}_{k_m^{(m)}}(t)\cdot\mathbf{z}\,d\mathbf{x}\,dt = \psi(0)\,(\mathbf{u}_0, \mathbf{z}) \qquad \forall\, \mathbf{z} \in \mathbf{V}\,.$$

Thus, by passing to the limit in the last equation we obtain

$$-\int_0^\infty (\widehat{\mathbf{u}}(t), \mathbf{z})\,\psi'(t)\,dt + \nu\int_0^\infty\int_\Omega \psi(t)\nabla \widehat{\mathbf{u}}(t) : \nabla \mathbf{z}\,d\mathbf{x}\,dt + \int_0^\infty\int_\Omega \psi(t)\,(\widehat{\mathbf{u}}(t)\cdot\nabla)\widehat{\mathbf{u}}(t)\cdot\mathbf{z}\,d\mathbf{x}\,dt = \psi(0)\,(\mathbf{u}_0, \mathbf{z}) \qquad \forall\, \mathbf{z} \in \mathbf{V}\,. \tag{3.27}$$

On the other hand, by multiplying (3.26) by $\psi(t)$ and integrating by parts we obtain

$$-\int_0^\infty (\widehat{\mathbf{u}}(t), \mathbf{z})\,\psi'(t)\,dt + \nu\int_0^\infty\int_\Omega \psi(t)\nabla \widehat{\mathbf{u}}(t) : \nabla \mathbf{z}\,d\mathbf{x}\,dt + \int_0^\infty\int_\Omega \psi(t)\,(\widehat{\mathbf{u}}(t)\cdot\nabla)\widehat{\mathbf{u}}(t)\cdot\mathbf{z}\,d\mathbf{x}\,dt = \psi(0)\,(\widehat{\mathbf{u}}(0), \mathbf{z}) \qquad \forall\, \mathbf{z} \in \mathbf{V}\,. \tag{3.28}$$

Here we have used the continuous imbedding result $\mathcal{V}^{(1)}(Q) \hookrightarrow \mathbf{C}([0,T];\mathbf{W})$ so that $\widehat{\mathbf{u}}(0)$ is well defined in $\mathbf{W}$. A comparison of (3.27) and (3.28) yields $\widehat{\mathbf{u}}(0) = \mathbf{u}_0$ in $\mathbf{W}$.

Finally, using the lower semicontinuity of the functional $\mathcal{J}_T(\cdot,\cdot)$ and the fact that $\widehat{\mathbf{v}} = \widehat{\mathbf{u}} - \mathbf{U} \in L^2(0,\infty;\mathbf{V})$ and $\widehat{\mathbf{g}} = \widehat{\mathbf{f}} - \mathbf{F} \in L^2(0,\infty;\mathbf{W})$, we obtain

$$\mathcal{J}_{k_m^{(m)}}(\widehat{\mathbf{u}}, \widehat{\mathbf{f}}) \le \liminf_{m\to\infty} \mathcal{J}_{k_m^{(m)}}(\mathbf{u}_{k_m^{(m)}}, \mathbf{f}_{k_m^{(m)}}) \le \mathcal{J}_\infty(\mathbf{w}, \mathbf{h}) \quad \forall\,(\mathbf{w}, \mathbf{h}) \in \mathcal{U}_{ad}(\infty)$$

so that by letting $m \to \infty$,

$$\mathcal{J}_\infty(\widehat{\mathbf{u}}, \widehat{\mathbf{f}}) \le \mathcal{J}_\infty(\mathbf{w}, \mathbf{h}) \quad \forall\,(\mathbf{w}, \mathbf{h}) \in \mathcal{U}_{ad}(\infty)\,.$$

Hence we have shown that $(\widehat{\mathbf{u}}, \widehat{\mathbf{f}})$ is the desired optimizer for (2.10) with $T = \infty$. □

4. Dynamics of optimal control solutions on the infinite time interval. As mentioned in the introduction, one of the motivations of considering infinite time optimal control is that one wishes the dynamics, or at least the eventual dynamics, of optimal control solutions to match well with the desired dynamics. Minimizing the cost functional (1.1) forces the controlled flow $\widehat{\mathbf{u}}$ to be close to the desired flow $\mathbf{U}$ only in the L^2 sense in t. For some t $\|\mathbf{u}(t) - \mathbf{U}(t)\|$ can still be very large. To reduce the error of the dynamics in t, e.g., to reduce the value of $\|\mathbf{u}(t) - \mathbf{U}(t)\|$ as $t \to \infty$, one needs to control the system for a long time. For many feedback control models, the controlled flow exponentially decays to the desired flow. For the optimal control system with a functional of the type (1.1), this is not expected to be true. But we may still obtain some results on their pointwise dynamics. Theorems 2.7 and 2.8 gave some preliminary results in this regard, i.e., $\|\mathbf{u}(t) - \mathbf{U}(t)\|$ and $\|\nabla\mathbf{u}(t) - \nabla\mathbf{U}(t)\|$ stay bounded. We will prove much stronger results in this section: $\|\mathbf{u}(t) - \mathbf{U}(t)\|$ and $\|\nabla\mathbf{u}(t) - \nabla\mathbf{U}(t)\|$ approach zero as t goes to ∞. We point out that these last results are not unique to the solutions of the optimal control system; these results can be proved under weaker conditions.

We first establish the "reverse" inequalities as opposed to the inequalities in Theorem 2.7.

LEMMA 4.1. *Let $T \in (0, \infty]$. Assume $(\mathbf{u}, \mathbf{f}) \in \mathcal{U}_{ad}(T)$. If $\|\mathbf{u}(t) - \mathbf{U}(t)\| > 0$ for all $t \in (t_1, t_2) \subset [0, T]$, then*

$$\begin{aligned} \|\mathbf{u}(t_1) - \mathbf{U}(t_1)\| &\geq \|\mathbf{u}(t_2) - \mathbf{U}(t_2)\| \\ &\quad - C\sqrt{t_2 - t_1}\left(\frac{|||\nabla\mathbf{U}|||^4}{\alpha\nu^2} + \frac{1}{\beta}\right)^{1/2} \left(\mathcal{J}_T(\mathbf{u}, \mathbf{f})\right)^{1/2}. \end{aligned} \tag{4.1}$$

Assume further that (2.36) *holds, i.e., $\mathcal{J}_T(\mathbf{u}, \mathbf{f}) \leq \mathcal{J}_T(\widetilde{\mathbf{u}}, \widetilde{\mathbf{f}})$, where $(\widetilde{\mathbf{u}}, \widetilde{\mathbf{f}})$ is as defined in* Theorem 2.4, *then*

$$\begin{aligned} \|\mathbf{u}(t_1) - \mathbf{U}(t_1)\| &\geq \|\mathbf{u}(t_2) - \mathbf{U}(t_2)\| \\ &\quad - C\sqrt{t_2 - t_1}\,\|\mathbf{u}_0 - \mathbf{U}_0\|\left(\frac{|||\nabla\mathbf{U}|||^4}{\alpha\nu^2} + \frac{1}{\beta}\right)^{1/2} \left(K(\nabla\mathbf{U}, \alpha, \beta)\right)^{1/2}. \end{aligned} \tag{4.2}$$

Proof. By setting $\mathbf{w} = \mathbf{v}(t)$ in (2.12) we obtain

$$\begin{aligned} \|\mathbf{v}\|\frac{d}{dt}\|\mathbf{v}(t)\| + \nu\|\nabla\mathbf{v}(t)\|^2 &\leq C\,|||\nabla\mathbf{U}|||\,\|\mathbf{v}(t)\|\,\|\nabla\mathbf{v}(t)\| + \|\mathbf{g}(t)\|\,\|\mathbf{v}(t)\| \\ &\leq \frac{\nu}{2}\|\nabla\mathbf{v}(t)\|^2 + \frac{C\,|||\nabla\mathbf{U}|||^2}{\nu}\|\mathbf{v}(t)\|^2 + \|\mathbf{g}(t)\|\,\|\mathbf{v}(t)\| \end{aligned}$$

for all $t \in (0, T)$. If $\|\mathbf{u}(t) - \mathbf{U}(t)\| > 0$ for all $t \in (t_1, t_2)$, then we may divide the last inequality by $\|\mathbf{v}(t)\|$ to obtain

$$\begin{aligned} \frac{d}{dt}\|\mathbf{v}(t)\| + \frac{\nu\lambda_1}{2}\|\mathbf{v}(t)\| &\leq C\left(\frac{|||\nabla\mathbf{U}|||^2}{\nu}\|\mathbf{v}(t)\| + \|\mathbf{g}(t)\|\right) \\ &\leq C\left(\frac{|||\nabla\mathbf{U}|||^4}{\alpha\nu^2} + \frac{1}{\beta}\right)^{1/2} \left(\alpha\|\mathbf{v}(t)\|^2 + \beta\|\mathbf{g}(t)\|^2\right)^{1/2} \end{aligned}$$

for all $t \in (t_1, t_2)$. Multiplying the last inequality by $e^{\nu\lambda_1 t/2}$ and integrating over (t_1, t_2), we are led to

$$\begin{aligned}
\|\mathbf{v}(t_2)\| &\le \|\mathbf{v}(t_1)\|\, e^{-\nu\lambda_1(t_2-t_1)/2} \\
&\quad + Ce^{-\nu\lambda_1 t_2/2}\left(\frac{|||\nabla\mathbf{U}|||^4}{\alpha\nu^2}+\frac{1}{\beta}\right)^{1/2}\int_{t_1}^{t_2}\left(\alpha\|\mathbf{v}(s)\|^2+\beta\|\mathbf{g}(s)\|^2\right)^{1/2} e^{\nu\lambda_1 s/2}\,ds \\
&\le \|\mathbf{v}(t_1)\| + C\left(\frac{|||\nabla\mathbf{U}|||^4}{\alpha\nu^2}+\frac{1}{\beta}\right)^{1/2} \\
&\quad \cdot\left(\int_{t_1}^{t_2}\left[\alpha\|\mathbf{v}(s)\|^2+\beta\|\mathbf{g}(s)\|^2\right]ds\right)^{1/2}\left(e^{-\nu\lambda_1 t_2}\int_{t_1}^{t_2} e^{\nu\lambda_1 s}\,ds\right)^{1/2} \\
&\le \|\mathbf{v}(t_1)\| + C\left(\frac{|||\nabla\mathbf{U}|||^4}{\alpha\nu^2}+\frac{1}{\beta}\right)^{1/2}\left(\mathcal{J}_T(\mathbf{u},\mathbf{f})\right)^{1/2}\left(\frac{1-\exp\{-\nu\lambda_1(t_2-t_1)\}}{\nu\lambda_1}\right)^{1/2}
\end{aligned}$$

so that by applying the mean value theorem to the last factor we have shown (4.1). (4.2) simply follows from the bound (2.18). □

We are now prepared to establish the asymptotic decay property of $\|\mathbf{u}(t)-\mathbf{U}(t)\|$ as $t\to\infty$ for any $(\mathbf{u},\mathbf{f})\in\mathcal{U}_{ad}(\infty)$.

THEOREM 4.2. *Assume that* $(\mathbf{u},\mathbf{f})\in\mathcal{U}_{ad}(\infty)$. *Then*

$$\lim_{t\to\infty}\|\mathbf{u}(t)-\mathbf{U}(t)\| = 0. \tag{4.3}$$

Proof. The theorem is trivial if $J_\infty(\mathbf{u},\mathbf{f})=0$. Thus we assume $J_\infty(\mathbf{u},\mathbf{f})>0$ and proceed to prove (4.3) by contradiction. Assume that (4.3) is false. Then we may choose an $\varepsilon_0>0$ and a sequence $\{t_n\}$ such that $t_n\to\infty$ and

$$\|\mathbf{u}(t_n)-\mathbf{U}(t_n)\|\ge\varepsilon_0>0.$$

Upon setting

$$\delta \stackrel{\text{def}}{=\!=} \frac{\varepsilon_0^2}{4C^2}\Big/\left[\left(\frac{|||\nabla\mathbf{U}|||^4}{\alpha\nu^2}+\frac{1}{\beta}\right)J_\infty(\mathbf{u},\mathbf{f})\right]>0,$$

we may assume, without loss of generality (by choosing a subsequence if necessary), that

$$|t_{n+1}-t_n|\ge\delta\,.$$

We claim that for each n

$$\|\mathbf{u}(t)-\mathbf{U}(t)\|>0 \qquad \forall\, t\in(t_n-\delta,t_n)\,.$$

If the claim were not true, then there would exist an $\bar n$ such that $\bar t_{\bar n}\stackrel{\text{def}}{=\!=}\sup\{t\in(-\infty,t_{\bar n}):\|\mathbf{u}(t)-\mathbf{U}(t)\|=0\}\in(t_{\bar n-1},t_{\bar n})$ satisfies $|\bar t_{\bar n}-t_{\bar n}|<\delta$ and $\|\mathbf{u}(t)-\mathbf{U}(t)\|>0$ on $(\bar t_{\bar n},t_{\bar n})$ so that by (4.1),

$$\begin{aligned}
\|\mathbf{u}(\bar t_{\bar n})-\mathbf{U}(\bar t_{\bar n})\| &\ge \|\mathbf{u}(t_{\bar n})-\mathbf{U}(t_{\bar n})\| - C\,\delta^{1/2}\left(\frac{|||\nabla\mathbf{U}|||^4}{\alpha\nu^2}+\frac{1}{\beta}\right)^{1/2}\left(J_\infty(\mathbf{u},\mathbf{f})\right)^{1/2} \\
&\ge \varepsilon_0-\varepsilon_0/2=\varepsilon_0/2>0\,,
\end{aligned}$$

which would contradict $\|\mathbf{u}(\bar{t}_{\bar{n}}) - \mathbf{U}(\bar{t}\bar{n})\| = 0$. This proves the claim. Now using (4.1) again, we have

$$\begin{aligned}\|\mathbf{u}(t) - \mathbf{U}(t)\| &\geq \|\mathbf{u}(t_n) - \mathbf{U}(t_n)\| - C\,\delta^{1/2}\left(\frac{|||\nabla \mathbf{U}|||^4}{\alpha\nu^2} + \frac{1}{\beta}\right)^{1/2} (J_\infty(\mathbf{u},\mathbf{f}))^{1/2} \\ &\geq \varepsilon_0 - \varepsilon_0/2 = \varepsilon_0/2 \qquad \forall\, t \in (t_n - \delta, t_n)\,.\end{aligned}$$

Thus

$$J_\infty(\mathbf{u},\mathbf{f}) \geq \frac{\alpha}{2}\sum_{n=2}^{\infty}\int_{t_n-\delta}^{t_n} \|\mathbf{u}(t) - \mathbf{U}(t)\|^2\, dt \geq \frac{\alpha\varepsilon_0^2}{8}\sum_{n=2}^{\infty}\int_{t_n-\delta}^{t_n} dt = \infty\,,$$

contradicting the assumption $J_\infty(\mathbf{u},\mathbf{f}) < \infty$. Hence, (4.3) is true. ∎

We now turn to the study of the asymptotic behavior of $\|\nabla\mathbf{u}(t) - \nabla\mathbf{U}(t)\|$. Note that Theorem 4.2 is true for arbitrary $(\mathbf{u},\mathbf{f}) \in \mathcal{U}_{ad}(\infty)$. Under some additional assumptions on $\mathbf{u}$, we can establish a similar asymptotic result for $\|\nabla\mathbf{u}(t) - \nabla\mathbf{U}(t)\|$. In particular, we can establish the asymptotic behavior for $\mathbf{u} = \widehat{\mathbf{u}}$, where $(\widehat{\mathbf{u}},\widehat{\mathbf{f}})$ is the optimizer for (2.10) with $T = \infty$. With $\widehat{\boldsymbol{\xi}} \in L^2(\varepsilon,\infty;\mathbf{V})$ for each $\varepsilon > 0$, we can prove an analog of (4.1) in the $H^1(\Omega)$ norm.

LEMMA 4.3. *Let $T \in (0,\infty]$. Assume that $(\widehat{\mathbf{u}},\widehat{\mathbf{f}}) \in \mathcal{U}_{ad}(T)$ is a solution of* (2.10). *Assume further that $\|\nabla(\widehat{\mathbf{u}} - \mathbf{U})(t)\| > 0$ for all $t \in (t_1,t_2) \subset [\varepsilon,T]$. Then*

$$\begin{aligned}&\|\nabla(\widehat{\mathbf{u}} - \mathbf{U})(t_1)\| \geq \|\nabla(\widehat{\mathbf{u}} - \mathbf{U})(t_2)\| - \frac{C}{\nu}(\sigma_0^2\sigma_1^3(\varepsilon) + \sigma_1(\varepsilon)\,|||\mathbf{U}|||^2\,|||\nabla\mathbf{U}|||^2 \\ &+ \nu^2\sigma_1(\varepsilon)\,|||\nabla\mathbf{U}|||\,|||\Delta\mathbf{U}|||)(t_2 - t_1) - \frac{C\,\max\{\sqrt{\alpha},\sqrt{\beta}\rho_1(\varepsilon)\}}{\beta\nu}[\mathcal{J}_T(\widehat{\mathbf{u}},\widehat{\mathbf{f}})]^{1/2}\sqrt{t_2 - t_1}\,,\end{aligned}$$

where $\rho_1(\varepsilon)$ is defined by (3.9) *and*

$$\begin{aligned}\sigma_0 &\stackrel{\text{def}}{=\!=} \sqrt{K_0}\|\mathbf{u}_0 - \mathbf{U}_0\|, \\ \sigma_1(\varepsilon) &\stackrel{\text{def}}{=\!=} \sqrt{K_1(\varepsilon)}\,\|\mathbf{u}_0 - \mathbf{U}_0\|\end{aligned}$$

with K_0 defined by (2.37) *and $K_1(\varepsilon)$ defined by* (2.45).

Proof. We first note that from (2.37) and (2.45),

$$\begin{aligned}\sup_{t\in[\varepsilon,T]}\|\widehat{\mathbf{u}}\| &\leq \rho_1(\varepsilon)\,, \\ \sup_{t\in[0,T]}\|\widehat{\mathbf{v}}(t)\| &\leq \sigma_0\,,\end{aligned}$$

and

$$\sup_{t\in[\varepsilon,T]}\|\nabla\widehat{\mathbf{v}}(t)\| \leq \sigma_1(\varepsilon)\,.$$

Setting $\mathbf{w} = -P\Delta\widehat{\mathbf{v}}(t)$ in (2.12) and by similar treatments as in the proof of Theorem 2.8, we obtain

$$\begin{aligned}&\frac{1}{2}\frac{d}{dt}\|\nabla\widehat{\mathbf{v}}(t)\|^2 + \frac{3\nu}{4}\|P\Delta\widehat{\mathbf{v}}(t)\|^2 \\ &\leq \frac{C}{\nu^3}\Big(\|\widehat{\mathbf{v}}(t)\|^2\|\nabla\widehat{\mathbf{v}}(t)\|^4 + \|\mathbf{U}(t)\|^2\|\nabla\mathbf{U}(t)\|^2\|\nabla\widehat{\mathbf{v}}(t)\|^2 \\ &\qquad +\nu^2\|\nabla\mathbf{U}(t)\|\cdot\|\Delta\mathbf{U}(t)\|\cdot\|\nabla\widehat{\mathbf{v}}(t)\|^2 + \frac{\nu^3}{\beta}|(\widehat{\boldsymbol{\xi}}(t), -P\Delta\widehat{\mathbf{v}}(t))|\Big)\,.\end{aligned} \tag{4.4}$$

Since $\operatorname{div}\widehat{\boldsymbol{\xi}}(t)=\mathbf{0}$, we have $\widehat{\boldsymbol{\xi}}(t)=P\widehat{\boldsymbol{\xi}}(t)$. Thus

$$\left|(\widehat{\boldsymbol{\xi}}(t),-P\Delta\widehat{\mathbf{v}}(t))\right|=(\nabla\widehat{\boldsymbol{\xi}}(t),\nabla\widehat{\mathbf{v}}(t))\le\|\nabla\widehat{\boldsymbol{\xi}}(t)\|\cdot\|\nabla\widehat{\mathbf{v}}(t)\|\ .$$

Using (2.42) and dividing both sides by $\|\nabla\widehat{\mathbf{v}}\|$, we have

$$\frac{1}{2}\frac{d}{dt}\|\nabla\widehat{\mathbf{v}}(t)\|+\frac{\gamma\nu}{2}\|\nabla\widehat{\mathbf{v}}(t)\|\le\frac{C}{\nu^3}\Big(\sigma_0^2\sigma_1^3(\varepsilon)+\sigma_1(\varepsilon)\,|||\mathbf{U}|||^2\,|||\nabla\mathbf{U}|||^2 +\nu^2\sigma_1(\varepsilon)\,|||\nabla\mathbf{U}|||\cdot|||\Delta\mathbf{U}|||+\frac{\nu^3}{\beta}\|\nabla\widehat{\boldsymbol{\xi}}(t)\|\Big)$$

for all $t\in(t_1,t_2)$. Multiplying both sides by $e^{\gamma\nu\lambda_1 t}$ and integrating over (t_1,t_2), we are led to

$$\begin{aligned}\|\nabla\widehat{\mathbf{v}}(t_2)\|\le{}&\|\nabla\widehat{\mathbf{v}}(t_1)\|\,\exp\{-\gamma\nu(t_2-t_1)\}\\&+\frac{C}{\nu^3}(\sigma_0^2\sigma_1^3(\varepsilon)+\sigma_1(\varepsilon)\,|||\mathbf{U}|||^2\,|||\nabla\mathbf{U}|||^2\\&\qquad+\sigma_1(\varepsilon)\nu^2\,\big|\big|\big|\nabla\mathbf{U}\big|\big|\big|\cdot|||\Delta\mathbf{U}|||)\,\frac{1-\exp\{-\gamma\nu(t_2-t_1)\}}{\gamma\nu}\\&+\frac{C\exp\{-\gamma\nu t_2\}}{\beta}\int_{t_1}^{t_2}\|\nabla\widehat{\boldsymbol{\xi}}(s)\|\,\exp\{\gamma\nu s\}\,ds.\end{aligned}$$

By the Schwarz inequality and (3.8),

$$\begin{aligned}&\int_{t_1}^{t_2}\|\nabla\widehat{\boldsymbol{\xi}}(s)\|\,\exp\{\gamma\nu s\}\,ds\\&\le\left(\int_{t_1}^{t_2}\|\nabla\widehat{\boldsymbol{\xi}}(s)\|^2\,ds\right)^{1/2}\left(\int_{t_1}^{t_2}\exp\{2\gamma\nu s\}\,ds\right)^{1/2}\\&\le\frac{C}{\nu}\,\max\{\sqrt{\alpha},\sqrt{\beta}\rho_1(\varepsilon)\}\,\left(\mathcal{J}_\tau(\widehat{\mathbf{u}},\widehat{\mathbf{f}})\right)^{1/2}\left(\frac{\exp\{2\gamma\nu t_2\}-\exp\{2\gamma\nu t_1\}}{2\gamma\nu}\right)^{1/2}.\end{aligned}$$

Hence, by the mean value theorem,

$$\begin{aligned}\|\nabla\widehat{\mathbf{v}}(t_2)\|\le{}&\|\nabla\widehat{\mathbf{v}}(t_1)\|+\frac{C}{\nu}\,(\sigma_0^2\sigma_1^3(\varepsilon)+\sigma_1(\varepsilon)\,|||\mathbf{U}|||^2\,|||\nabla\mathbf{U}|||^2\\&\qquad+\sigma_1(\varepsilon)\nu^2\,|||\nabla\mathbf{U}|||\cdot|||\Delta\mathbf{U}|||)\,(t_2-t_1)\\&+\frac{C}{\beta\nu}\,\max\{\sqrt{\alpha},\sqrt{\beta}\rho_1(\varepsilon)\}\,[\mathcal{J}_\tau(\widehat{\mathbf{u}},\widehat{\mathbf{f}})]^{1/2}\,\sqrt{t_2-t_1}.\end{aligned}$$

□

Based on Lemma 4.3, we may establish the long-time behavior for $\|\nabla\widehat{\mathbf{u}}(t)-\nabla\mathbf{U}(t)\|$.

THEOREM 4.4. *Let* $(\widehat{\mathbf{u}},\widehat{\mathbf{f}})$ *be an solution for* (2.10) *with* $T=\infty$. *Then*

$$\lim_{t\to\infty}\|\nabla\widehat{\mathbf{u}}(t)-\nabla\mathbf{U}(t)\|=0. \tag{4.5}$$

The proof is similar to that of Theorem 4.2 (now we use the bound (2.44) of Theorem 2.8 in place of $\mathcal{J}_\tau(\mathbf{u},\mathbf{f})<\infty$) and is omitted here.

Remark 4.5. From Theorem 4.4 and the proof of Lemma 4.3, we see that the condition $(\widehat{\mathbf{u}},\widehat{\mathbf{f}})$ being an optimizer for (2.10) is not essential. If a pair $(\mathbf{u},\mathbf{f})\in\mathcal{U}_{ad}(\infty)$ satisfies

$$\int_0^\infty\int_\Omega|\mathbf{u}-\mathbf{U}|^2d\mathbf{x}dt+\int_0^\infty\int_\Omega|\nabla(\mathbf{f}-\mathbf{F})|^2d\mathbf{x}dt<\infty, \tag{4.6}$$

$$(\mathbf{f}-\mathbf{F})\cdot\mathbf{n}=0 \qquad \text{in } \Omega, \tag{4.7}$$

and

$$\operatorname{div}(\mathbf{f}-\mathbf{F})=0 \qquad \text{on } \partial\Omega\,, \tag{4.8}$$

then (4.5) holds for such $\mathbf{u}$. The condition (4.6) requires higher regularity of $\mathbf{f}-\mathbf{F}$, (4.7) requires that the boundary conditions of $\mathbf{f}$ and $\mathbf{F}$ agree with each other, and (4.8) requires $\operatorname{div}\mathbf{f}=\operatorname{div}\mathbf{F}$, where we recall that $\mathbf{F}=\partial_t\mathbf{U}-\nu\Delta\mathbf{U}+(\mathbf{U}\cdot\nabla)\mathbf{U}$. ∎

For each finite T, $\widehat{\boldsymbol{\xi}}_T$ satisfies $\widehat{\boldsymbol{\xi}}_T(\cdot,T)=\mathbf{0}$. This is also true for $T=\infty$, namely $\lim_{t\to\infty}\widehat{\boldsymbol{\xi}}_\infty(\cdot,t)=\mathbf{0}$. To prove this, we first establish the following inequality.

LEMMA 4.6. *Let $T\in(0,\infty]$ and $\varepsilon>0$. Assume that $(\widehat{\mathbf{u}},\widehat{\mathbf{f}})$ is a solution for* (2.10) *and $\widehat{\boldsymbol{\xi}}$ is a solution of* (3.1)–(3.3). *Assume further that $\|\widehat{\boldsymbol{\xi}}(t)\|>0$ for all $t\in(t_1,t_2)\subset[\varepsilon,T]$. Then*

$$\|\widehat{\boldsymbol{\xi}}(t_2)\|\ge\|\widehat{\boldsymbol{\xi}}(t_1)\|-\sqrt{t_2-t_1}\left(\alpha+\frac{C\beta\sigma_1^4(\varepsilon)}{\nu^2}\right)\left(\mathcal{J}_T(\widehat{\mathbf{u}},\widehat{\mathbf{f}})\right)^{1/2},$$

where $\rho_1(\varepsilon)$ is defined as in (3.9).

Proof. (3.10) and Young's inequality yield

$$-\frac{1}{2}\frac{d}{dt}\|\widehat{\boldsymbol{\xi}}(t)\|^2+\nu\,\|\nabla\widehat{\boldsymbol{\xi}}(t)\|^2\le\alpha\|\widehat{\mathbf{v}}(t)\|\,\|\widehat{\boldsymbol{\xi}}(t)\|+\frac{C\|\nabla\widehat{\mathbf{u}}(t)\|^2}{\nu}\,\|\widehat{\boldsymbol{\xi}}(t)\|^2.$$

Then, by applying Poincaré inequality, dividing both sides by $\|\widehat{\boldsymbol{\xi}}(t)\|$, and then applying the Schwarz inequality, we obtain

$$-\frac{d}{dt}\,\|\widehat{\boldsymbol{\xi}}(t)\|+\nu\,\lambda_1\,\|\widehat{\boldsymbol{\xi}}(t)\|\le\left(\alpha+\frac{C\beta\,\|\nabla\widehat{\mathbf{u}}\|^4}{\nu^2}\right)^{1/2}\left(\alpha\|\widehat{\mathbf{v}}(t)\|^2+\frac{1}{\beta}\|\widehat{\boldsymbol{\xi}}(t)\|^2\right)^{1/2}.$$

By integrating both sides over $(t_1,t_2)\subset[\varepsilon,T]$ and applying the Schwarz inequality, the lemma is proved. ∎

Similar to the proof of Theorem 4.2 (we now use the bound (3.8) of Theorem 3.2), we have the following result on the long-time behavior of $\|\boldsymbol{\xi}(t)\|$ as $t\to\infty$.

THEOREM 4.7. *Assume that the hypotheses of Lemma* 4.6 *hold. Then*

$$\lim_{t\to\infty}\|\widehat{\boldsymbol{\xi}}(t)\|=\lim_{t\to\infty}\beta\,\|\mathbf{f}-\mathbf{F}\|=0\,. \qquad \blacksquare$$

Remark 4.8. We make some comparison between the optimizer $(\widehat{\mathbf{u}},\widehat{\mathbf{f}})$ and the quasi optimizer $(\widetilde{\mathbf{u}},\widetilde{\mathbf{f}})$. The optimizer $\widehat{\mathbf{u}}(t)$ matches well with $\mathbf{U}(t)$ for large t and $\nabla\widehat{\mathbf{u}}(t)$ matches well with $\nabla\mathbf{U}(t)$ for large t. We see from the functional (1.1) that in obtaining a good matching of $\widehat{\mathbf{u}}(t)$ with $\mathbf{U}(t)$ for large t, the work done by the external force $\mathbf{f}$ is also minimized. However, we are unable to prove the exponential decay of $\|\widehat{\mathbf{u}}(t)-\mathbf{U}(t)\|$. The optimizer is costly to compute numerically (one needs to solve the optimality system). The quasi optimizer $\widetilde{\mathbf{u}}$ gives us an acceptable matching of $\widetilde{\mathbf{u}}(t)$ with $\mathbf{U}(t)$ with an exponential decay rate for $\|\widetilde{\mathbf{u}}(t)-\mathbf{U}(t)\|$. $\widetilde{\mathbf{u}}$ is defined by a Navier–Stokes–like equation and is therefore easy to compute (compared with the optimizer). However, we have no control over the work involved (i.e., the corresponding external force) in maintaining the quasi optimizer. The work to maintain the quasi optimizer can be formidable.

Remark 4.9. In Theorems 2.4, 2.7, 2.8, 2.9, and 3.2 and Lemmas 4.1, 4.3, and 4.6, the quantities on the right-hand side of all the estimates were independent of T (such

as K_0, K_1, $|||\nabla \mathbf{U}|||$, etc). This facilitated the derivation of estimates on $(0,\infty)$ and the passage to the limit as $T \to \infty$. However, if one is only interested in corresponding estimates on the finite time interval, then one can replace the quantities on the right-hand side of all the estimates by their finite time counterparts (such as K_0 replaced by $K_0(T)$, K_1 by $K_1(T)$, $|||\nabla \mathbf{U}|||$ by $|||\nabla \mathbf{U}|||_T \stackrel{\text{def}}{=\!=} \|\mathbf{U}\|_{L^\infty(0,T;\mathbf{L}^2(\Omega))}$, etc., where the definitions of the quantities $K_0(T)$, $K_1(T)$, etc., are the obvious modifications of the definitions for the quantities K_0, K_1, etc.).

ON-LINE PARAMETER ESTIMATION FOR INFINITE-DIMENSIONAL DYNAMICAL SYSTEMS*

J. BAUMEISTER†, W. SCONDO‡, M. A. DEMETRIOU§, AND I. G. ROSEN¶

Abstract. The on-line or adaptive identification of parameters in abstract linear and nonlinear infinite-dimensional dynamical systems is considered. An estimator in the form of an infinite-dimensional linear evolution system having the state and parameter estimates as its states is defined. Convergence of the state estimator is established via a Lyapunov estimate. The finite-dimensional notion of a plant being sufficiently rich or persistently excited is extended to infinite dimensions. Convergence of the parameter estimates is established under the additional assumption that the plant is persistently excited. A finite-dimensional approximation theory is developed, and convergence results are established. Numerical results for examples involving the estimation of both constant and functional parameters in one-dimensional linear and nonlinear heat or diffusion equations and the estimation of stiffness and damping parameters in a one-dimensional wave equation with Kelvin–Voigt viscoelastic damping are presented.

Key words. on-line estimation, adaptive identification, parameter convergence, persistence of excitation, distributed parameter systems, infinite-dimensional systems, finite-dimensional approximation

1. Introduction.

In this paper we develop an abstract framework for the on-line, or adaptive, identification of unknown parameters for a class of infinite-dimensional and, in general, nonlinear dynamical systems. The estimator we construct takes the form of an infinite-dimensional linear evolution system with time-varying *coefficients* whose states consist of an estimator for the state of the plant and an estimator for the unknown parameters. Our scheme can estimate both constant and functional (e.g., spatially varying) parameters including the nonlinearity itself. That is, both the state space of the plant and the parameter space may be infinite dimensional.

The results reported here were in fact obtained independently by two separate groups of researchers. The efforts of the first two authors (Baumeister and Scondo) culminated in the Ph.D. thesis of Dr. Scondo [30], while the investigation by the second two authors (Demetriou and Rosen) led to the Ph.D. thesis of Dr. Demetriou [6]. In this paper we have attempted to capture the essence of the problem and its solution as treated independently by both groups of researchers in a clear and coherent manner. However, it should be noted that, as would be expected, there are some variations between the two treatments. Thus, the interested reader may also wish to consult the two theses, [6] and [30], in addition to the study that we present here.

The approach we take here represents an infinite-dimensional analogue, or extension, of some portion of the finite-dimensional treatment in [22] (see also [23] and [24]). Convergence of the state estimator is established using a Lyapunov estimate–based argument and an argument in the spirit of the one used to verify Barbălat's lemma (see [27]). In order to establish the convergence of the parameter estimates, we require an additional assumption. This assumption, which is a *richness* condition on the plant data, is an infinite-dimensional analogue of the notion of *persistence of excitation* defined in [22] and [23]. In mathematical terms, we establish that the solution to the error equations derived from the plant dynamics and the estimator with arbitrary initial data, tends to the trivial solution as time tends to infinity. Our primary motivation for studying these on-line identification schemes is that we ultimately intend to use them as a part of an indirect adaptive control algorithm for distributed parameter systems.

Because the estimator is infinite dimensional, its implementation requires some form of finite-dimensional approximation. Consequently, we have also developed a rather complete approximation theory and established corresponding convergence results. In addition, while our treatment is in the context of abstract first-order systems, we have also shown how our theory can be applied to certain classes of abstract second-order systems. A number of examples along with numerical studies have been included to demonstrate the feasibility of our schemes.

There has been a great deal of research activity in the area of identification of distributed parameter systems over the past two decades. An extensive treatment of off-line schemes (e.g., output least squares, equation error, etc.) together with a rather comprehensive survey of the literature can be found in the monograph by Banks and Kunisch [2]. In the case of on-line, or adaptive, schemes, the available literature is less extensive and more recent. In [1] Alt, Hoffmann, and Sprekels developed an asymptotic embedding method for the identification of functional parameters in linear elliptic (stationary) partial differential equations. In their approach, the elliptic equation is embedded in a nonautonomous pseudoparabolic evolution equation in such a way that the elliptic equation's solution is an asymptotic steady state of the evolution equation. In [14] Hoffmann and Sprekels introduce a form of regularization into their embedding equations, and in [15] an abstract functional analytic framework for the earlier results summarized above is developed. They also extend their earlier results to certain classes of stationary elliptic and evolutionary parabolic nonlinear variational inequalities.

In [4] Baumeister and Scondo consider parameter estimation techniques for finite-dimensional evolution equations, while in [5] they treat linear elliptic partial differential equations. The elliptic equation is embedded in a pseudoparabolic evolution equation having the solution to the elliptic equation and the true parameters as an equilibrium point. Using a *richness*-like assumption and linear semigroup theory, they are able to establish uniform exponential convergence to this equilibrium as $t \to \infty$. The extension of the treatment in [5] to abstract evolution equations via infinite-dimensional analogues of the arguments in [22] is, to a large extent, the contribution of the effort that we are reporting on here.

Recently Hong and Bentsman (see [16] and [17]) have studied model reference adaptive control (MRAC) of linear n-dimensional parabolic partial differential equations. Although, strictly speaking, MRAC is not the same problem that we treat here, there are some connections (and a number of significant differences) between their efforts and ours. For example, the resulting error equations are formally the same, and both treatments are concerned with state and parameter convergence. On

the other hand, however, they deal with a specific system, while our approach is more abstract. Their analysis is more classical, while ours is more functional analytic in nature.

In a recent series of papers [9], [10], [11], [12], [13], [25] Duncan and Pasik-Duncan and their coworkers have developed and analyzed adaptive control algorithms for classes of linear stochastic distributed parameter systems. In particular, they have considered indirect adaptive control schemes in the form of consistent least squares and maximum likelihood estimators for the unknown parameters combined with linear quadratic (LQ) control design techniques. They consider a variety of classes of infinite-dimensional systems, including hereditary systems [10] and systems involving unbounded input, such as boundary and point control [9], [13]. The schemes that they propose and techniques that they use to argue convergence are, in general, very different from and largely unrelated to the theory that we develop here.

An outline of the remainder of the paper is as follows. In section 2 we define the plant and the estimator equations. In section 3 we establish convergence of the state estimator. We define the notion of persistence of excitation and establish parameter convergence. The notion of partial persistence of excitation also is defined, and a corresponding partial parameter convergence result is given. Our approximation results are presented in section 4, and the extension of our results to a class of abstract second order systems is discussed in section 5. Examples together with the results of our numerical studies are presented in section 6.

In general all notation is standard. For X and Y Banach spaces, $\mathcal{L}(X,Y)$ denotes the space of *bounded* linear operators from X into Y. All inner products, $\langle\cdot,\cdot\rangle$, are assumed to be linear in the first argument and conjugate linear in the second. Finally, for X a linear space and Y a space of linear or conjugate linear functionals on X, $\langle x,\varphi\rangle = \langle x,\varphi\rangle_{X,Y}$ denotes the action of the linear functional $\varphi \in Y$ on the element $x \in X$, and $\langle \varphi, x\rangle = \langle \varphi, x\rangle_{Y,X}$ denotes the action of the conjugate linear functional $\varphi \in Y$ on the element $x \in X$.

2. The plant and the estimator. Let H be a Hilbert space with inner product $\langle\cdot,\cdot\rangle$ and corresponding induced norm $|\cdot|$. Let V be a reflexive Banach space with norm denoted by $\|\cdot\|$, and assume that V is embedded densely and continuously in H. Let V^* denote the *conjugate* dual of V (i.e., the space of continuous conjugate linear functionals on V) and $\|\cdot\|_*$ denote the usual uniform operator norm on V^*. It follows that

$$V \hookrightarrow H \hookrightarrow V^*, \tag{2.1}$$

with both embeddings dense and continuous. In particular we assume that

$$|\varphi| \le K\|\varphi\|, \qquad \varphi \in V, \tag{2.2}$$

for some positive constant K. The notation $\langle\cdot,\cdot\rangle$ will also be used to denote the duality pairing between V^* and V induced by the continuous and dense embeddings given in (2.1). We note that while we have chosen to develop our theory in the generality of complex Hilbert and Banach spaces H and V, all that follows is easily modified (simplified) to allow for H and V to be chosen to be real.

Let Q be a Hilbert space with inner product $\langle\cdot,\cdot\rangle_Q$ and corresponding induced norm $|\cdot|_Q$. Let $Q^* = Q$ denote the conjugate dual of Q. The Hilbert space Q is known as the parameter space. The Hilbert space Q could be taken to be real as well.

For each $q \in Q$, let $A_0(q) : V \to V^*$ be a, in general, nonlinear operator satisfying the following assumptions:

(A1) (Q-linearity) The map $q \to A_0(q)\varphi$ is affine from Q into V^* for each $\varphi \in V$. That is, for $q \in Q$ and $\varphi \in V$ we have $A_0(q)\varphi = A_1(q)\varphi + A_2\varphi$, where $A_1(q) : V \to V^*$ and $A_2 : V \to V^*$ are, in general, nonlinear operators from V into V^* with the map $q \to A_1(q)\varphi$ from Q into V^* linear for each $\varphi \in V$.

(A2) ($V \mapsto V^*$-boundedness) There exist $\alpha_1, \alpha_2 > 0$ such that $|\langle A_1(q)\varphi, \psi\rangle| \leq \alpha_1 |q|_Q \|\varphi\| \|\psi\|$ for $\varphi, \psi \in V$ and $q \in Q$, and $|\langle A_2\varphi, \psi\rangle| \leq \alpha_2 \|\varphi\| \|\psi\|$ for $\varphi, \psi \in V$.

In order to simplify our treatment we have assumed that for $q \in Q$ the operator $A_0(q)$ is time invariant. However, it would be relatively straightforward to extend all of the results in this section and those in the subsequent sections to the case of a time-dependent operator, $A_0(t; q)$, $t \geq 0$. Of course for some of these results to remain valid, additional, but rather standard, assumptions on the regularity of the map $t \to A_0(t; q)$, $t \geq 0$ would be required (see, for example, [3], [19], [26], [32]).

For $\varphi \in V$, let $B(\varphi) : V \to Q$ be the linear operator defined by

$$\langle B(\varphi)\psi, q\rangle_Q = \overline{\langle A_1(q)\varphi, \psi\rangle}, \qquad \psi \in V, \quad q \in Q. \tag{2.3}$$

Note that assumption (A2) implies that for $\varphi \in V$, $B(\varphi) \in \mathcal{L}(V, Q)$ with

$$\|B(\varphi)\|_{\mathcal{L}(V,Q)} \leq \alpha_1 \|\varphi\|. \tag{2.4}$$

Let $u_0 \in H$, let $f \in L_2(0, T, V^*)$ for all $T > 0$, and for each $q \in Q$ consider the initial value problem

$$D_t u(t) + A_0(q)u(t) = f(t), \qquad \text{almost every (a.e.) } t > 0, \tag{2.5}$$

$$u(0) = u_0. \tag{2.6}$$

By a solution to the initial value problem (2.5), (2.6) we mean a weak or variational solution. That is, a function $u \in L_2(0, T; V)$ with $D_t u \in L_2(0, T; V^*)$ for all $T > 0$ which satisfies (2.5) and (2.6). Note that if u is a solution to (2.5), (2.6), then for all $T > 0$, u agrees almost everywhere with a function in $C([0, T]; H)$ (see [20]). Note also that $A_0(q)$ monotone (i.e., $\langle A_0(q)\varphi - A_0(q)\psi, \varphi - \psi\rangle \geq 0$), hemicontinuous (i.e., $\lim_{\lambda \to 0}\langle A_0(q)\{\varphi + \lambda\psi\}, \chi\rangle = \langle A_0(q)\varphi, \chi\rangle$, $\varphi, \psi, \chi \in V$), and coercive (i.e., $\mathrm{Re}\langle A_0(q)\varphi, \varphi\rangle \geq \beta_0(q)\|\varphi\|^2 + \lambda_0(q)$, $\varphi \in V$, for some $\beta_0(q), \lambda_0(q) \in \mathbf{R}$ with $\beta_0(q) > 0$), for example, is sufficient to guarantee the existence of a unique solution to (2.5), (2.6) (see, for example, [3], [19], [26], [32]).

DEFINITION 2.1. *A plant is a pair* $(\overline{q}, \overline{u})$ *for which* $\overline{q} \in Q$, $\overline{u}$ *is a solution to* (2.5), (2.6) *with* $q = \overline{q}$, *and there exists a constant* $\gamma = \gamma(\overline{u})$ *such that* $|\langle B(\overline{u}(t))\varphi, q\rangle_Q| \leq \gamma(\overline{u})|q|_Q\|\varphi\|$, $t > 0$, $q \in Q$, $\varphi \in V$.

Note that if $(\overline{q}, \overline{u})$ is a plant, then $B(\overline{u}(\cdot)) \in L_2(0, T; \mathcal{L}(V, Q))$ for all $T > 0$. Note also that (2.4) implies that if $(\overline{q}, \overline{u})$ is such that $\|\overline{u}(t)\| \leq \gamma$, a.e. $t > 0$, for some $\gamma > 0$, then $(\overline{q}, \overline{u})$ is a plant.

To demonstrate that it is in fact possible to provide sufficient conditions for a pair $(\overline{q}, \overline{u})$ to be a plant, let $\overline{q} \in Q$, let $\overline{u}$ be the solution to the initial value problem (2.5), (2.6) with $q = \overline{q}$, and assume that $A_0(\overline{q}) \in \mathcal{L}(V, V^*)$ is coercive,

$$\mathrm{Re}\,\langle A_0(\overline{q})\varphi, \varphi\rangle \geq \beta_0(\overline{q})\|\varphi\|^2, \qquad \varphi \in V, \tag{2.7}$$

for some $\beta_0(\overline{q}) > 0$. It follows (see [32, Theorem 3.6.1]) that $-A_0(\overline{q}) : V \subset V^* \to V^*$ is the infinitesimal generator of an analytic semigroup, $\{T_0(t; \overline{q}) : t \geq 0\}$, of bounded

linear operators on V^* and that

$$\overline{u}(t) = T_0(t;\overline{q})u_0 + \int_0^t T_0(t-s;\overline{q})f(s)ds, \qquad t \geq 0. \tag{2.8}$$

Suppose further that $u_0 \in V$ and that $f \in C([0,\infty];V^*)$ is uniformly V^*-Hölder continuous. That is, there exists $C > 0$ and $\rho \in (0,1)$ such that $\|f(t)-f(s)\|_* \leq C|t-s|^\rho$, $0 \leq t,s < \infty$. Assume also that there exists $f_\infty \in V^*$ such that $\lim_{t\to\infty}\|f(t) - f_\infty\|_* = 0$.

It can be shown (see [32, Theorem 5.6.1]) that $\overline{u}(t) \in V$, $t \geq 0$, there exists an element $\overline{u}_\infty \in V$ such that $A_0(\overline{q})\overline{u}_\infty = f_\infty$, and

$$\lim_{t\to\infty} \|A_0(\overline{q})\overline{u}(t) - A_0(\overline{q})\overline{u}_\infty\|_* = 0. \tag{2.9}$$

Now

$$\|\overline{u}(t)\| \leq \|\overline{u}(t) - \overline{u}_\infty\| + \|\overline{u}_\infty\|, \tag{2.10}$$

and for $t \geq 0$, coercivity (i.e., (2.7)) implies that

$$\begin{aligned}
\|\overline{u}(t) - \overline{u}_\infty\|^2 &\leq \frac{1}{\beta_0(\overline{q})}\mathrm{Re}\,\langle A_0(\overline{q})\{\overline{u}(t) - \overline{u}_\infty\}, \overline{u}(t) - \overline{u}_\infty\rangle \\
&\leq \frac{1}{\beta_0(\overline{q})}\,|\langle A_0(\overline{q})\{\overline{u}(t) - \overline{u}_\infty\}, \overline{u}(t) - \overline{u}_\infty\rangle| \\
&\leq \frac{1}{\beta_0(\overline{q})}\|A_0(\overline{q})\overline{u}(t) - A_0(\overline{q})\overline{u}_\infty\|_*\|\overline{u}(t) - \overline{u}_\infty\|.
\end{aligned}$$

Consequently, (2.9) yields

$$\lim_{t\to\infty} \|\overline{u}(t) - \overline{u}_\infty\| = 0. \tag{2.11}$$

Similarly, recalling that $u_0 \in V$, (2.7) and (2.8) imply that for all $t \geq 0$

$$\begin{aligned}
\|\overline{u}(t) - u_0\| &\leq \frac{1}{\beta_0(\overline{q})}\|A_0(\overline{q})\{\overline{u}(t) - u_0\}\|_* \\
&\leq \frac{1}{\beta_0(\overline{q})}\|A_0(\overline{q})\{T_0(t;\overline{q})u_0 - u_0\}\|_* + \frac{1}{\beta_0(\overline{q})}\|A_0(\overline{q})\overline{v}(t)\|_* \\
&= \frac{1}{\beta_0(\overline{q})}\|T_0(t;\overline{q})A_0(\overline{q})u_0 - A_0(\overline{q})u_0\|_* + \frac{1}{\beta_0(\overline{q})}\|A_0(\overline{q})\overline{v}(t)\|_*,
\end{aligned}$$

where $\overline{v}(t) = \int_0^t T_0(t-s;\overline{q})f(s)ds$, $t \geq 0$. Since $\{T_0(t;\overline{q}) : t \geq 0\}$ is an analytic semigroup on V^* and f was assumed to be uniformly Hölder continuous, Lemma IX.1.28 in [18] (see also the proof of Theorem 3.34 in [32]) implies that $\lim_{t\to 0}\|A_0(\overline{q})\overline{v}(t)\|_* = 0$. It follows from the elementary properties of strongly continuous semigroups that

$$\lim_{t\to 0} \|\overline{u}(t) - u_0\| = 0. \tag{2.12}$$

Since for $t \geq 0$, $\|\overline{u}(t)\| \leq \|\overline{u}(t) - u_0\| + \|u_0\|$, (2.10), (2.11), and (2.12) yield that $\|\overline{u}(t)\|$ is bounded on $[0,\infty)$. This, together with assumption (A2), implies that $(\overline{q},\overline{u})$ is a plant.

There is also another, alternative set of assumptions on $A_0(\overline{q})$, f, and u_0 that lead to the conclusion that $\|\overline{u}(t)\|$ is uniformly bounded for $t \geq 0$ and therefore that

$(\overline{q}, \overline{u})$ is a plant. Indeed, suppose once again that $A_0(\overline{q}) \in \mathcal{L}(V, V^*)$ is coercive; that is, (2.7) holds. Suppose further that $A_0(\overline{q})$ is symmetric in the sense that $\langle A_0(\overline{q})\varphi, \psi\rangle = \langle A_0(\overline{q})\psi, \varphi\rangle$, $\varphi, \psi \in V$, and that $f \in L_2(0, \infty; H)$ and $u_0 \in V$. Then, if we consider the operator $A_0(\overline{q})$ restricted to the subspace of H, $\mathrm{Dom}(A_0(\overline{q})) = \{\varphi \in V : A_0(\overline{q})\varphi \in H\}$, then $A_0(\overline{q}) : \mathrm{Dom}(A_0(\overline{q})) \subset H \to H$ is positive definite and self-adjoint. It follows that the square root of $A_0(\overline{q})$, $A_0(\overline{q})^{\frac{1}{2}}$, can be defined with $\mathrm{Dom}(A_0(\overline{q})^{\frac{1}{2}}) = V$ (see, for example, Theorem 2.2.3 on page 29 of [32]). Moreover, for $\varphi \in V$, $\|\varphi\|_0 = |A_0(\overline{q})^{\frac{1}{2}}\varphi|$ defines a norm on V and, by assumption (A2) and (2.7), we have that

$$\beta_0(\overline{q})\|\varphi\|^2 \le \langle A_0(\overline{q})\varphi, \varphi\rangle = \langle A_0(\overline{q})^{\frac{1}{2}}\varphi, A_0(\overline{q})^{\frac{1}{2}}\varphi\rangle = \|\varphi\|_0^2 = \langle A_0(\overline{q})\varphi, \varphi\rangle \le \alpha_0(\overline{q})\|\varphi\|^2$$

for all $\varphi \in V$, where $\alpha_0(\overline{q}) = \alpha_1|\overline{q}|_Q + \alpha_2$. Thus the two norms $\|\cdot\|$ and $\|\cdot\|_0$ on V are equivalent.

We require also that $\overline{u}(t) \in \mathrm{Dom}(A_0(\overline{q}))$ for almost all $t > 0$. Note that since $\{T_0(t; \overline{q}) : t \ge 0\}$, the semigroup of bounded linear operators on H generated by the operator $-A_0(\overline{q})$, is analytic, this can be guaranteed if, for example, we require that f be H-Hölder continuous for $t \ge 0$. That is, if for $t \ge 0$, $|f(t) - f(s)| \le C|t - s|^\rho$, $0 \le t, s < \infty$, where $C > 0$ and $\rho \in (0, 1]$ (see, for example, [18] and [26]). Then, from (2.5) we obtain that

$$\langle D_t\overline{u}(t), A_0(\overline{q})\overline{u}(t)\rangle + |A_0(\overline{q})\overline{u}(t)|^2 = \langle f(t), A_0(\overline{q})\overline{u}(t)\rangle, \qquad \text{a.e. } t > 0,$$

and therefore that

$$\frac{1}{2}D_t\|\overline{u}(t)\|_0^2 + |A_0(\overline{q})\overline{u}(t)|^2 \le |f(t)||A_0(\overline{q})\overline{u}(t)| \le \frac{1}{2}|f(t)|^2 + \frac{1}{2}|A_0(\overline{q})\overline{u}(t)|^2, \quad \text{a.e. } t > 0.$$

Integrating the above estimate from 0 to t and recalling (2.6), we find that

$$\|\overline{u}(t)\|_0^2 + \int_0^t |A_0(\overline{q})\overline{u}(s)|^2 ds \le \|u_0\|_0^2 + \int_0^t |f(s)|^2 ds \le \|u_0\|_0^2 + \|f\|^2_{L_2(0,\infty;H)}, \qquad t \ge 0.$$

It follows that $\|\overline{u}(t)\|$ is bounded uniformly in t for $t \ge 0$ and consequently, via (2.3) and assumption (A2), that $(\overline{q}, \overline{u})$ is a plant.

Let $(\overline{q}, \overline{u})$ be a plant, and assume that $\overline{u}$ is available and $\overline{q}$ is unknown. The on-line identification problem is to define a dynamical system which uses $\overline{u}$ to asymptotically estimate $\overline{q}$. Toward this end, we define an infinite-dimensional analogue of the finite-dimensional estimator treated in [22] and [24].

Let $A \in \mathcal{L}(V, V^*)$ satisfy the following two assumptions:

(A3) ($V \mapsto V^*$-boundedness) There exist $\alpha > 0$ for which $|\langle A\varphi, \psi\rangle| \le \alpha\|\varphi\|\|\psi\|$, $\varphi, \psi \in V$.

(A4) (V-coercivity) There exist $\beta > 0$ for which $\mathrm{Re}\,\langle A\varphi, \varphi\rangle \ge \beta\|\varphi\|^2$, $\varphi \in V$.

We define our estimator in the form of the initial value problem

$$D_t u(t) + Au(t) + B(\overline{u}(t))^* q(t) = f(t) + A\overline{u}(t) - A_2\overline{u}(t), \qquad \text{a.e. } t > 0, \tag{2.13}$$

$$D_t q(t) - B(\overline{u}(t))u(t) = -B(\overline{u}(t))\overline{u}(t), \qquad \text{a.e. } t > 0, \tag{2.14}$$

$$u(0) \in H, \qquad q(0) \in Q, \tag{2.15}$$

where for $\varphi \in V$, $B(\varphi)^* \in \mathcal{L}(Q, V^*)$ is the Banach space adjoint of $B(\varphi)$. That is, recalling (2.3), for $\varphi \in V$

$$\langle B(\varphi)^* p, \psi\rangle = \langle p, B(\varphi)\psi\rangle_Q = \langle A_1(p)\varphi, \psi\rangle, \qquad \psi \in V, \quad p \in Q. \tag{2.16}$$

To establish the well-posedness of the initial value problem (2.13)–(2.15), we let $X = H \times Q$ and $Y = V \times Q$. Endowing X and Y with the usual product topologies, X becomes a Hilbert space and Y a reflexive Banach space, and we have the dense and continuous embeddings $Y \hookrightarrow X \hookrightarrow Y^*$. For $t > 0$ define $\mathcal{A}(t) : Y \to Y^*$ by

$$\mathcal{A}(t) = \begin{bmatrix} A & B(\overline{u}(t))^* \\ -B(\overline{u}(t)) & 0 \end{bmatrix}, \tag{2.17}$$

and define $F(t) \in Y^*$ by

$$F(t) = \begin{bmatrix} f(t) + A\overline{u}(t) - A_2\overline{u}(t) \\ -B(\overline{u}(t))\overline{u}(t) \end{bmatrix}$$

for a.e. $t > 0$. The fact that $(\overline{q}, \overline{u})$ is a plant implies that $F \in L_2(0, T; Y^*)$ for all $T > 0$. Assumptions (A3) and (A4) together with $(\overline{q}, \overline{u})$ being a plant imply that $\mathcal{A}(t) \in \mathcal{L}(Y, Y^*)$, $t > 0$, and that for $t > 0$, Re $\langle \mathcal{A}(t)\varphi, \varphi \rangle_{Y^*,Y} + \rho|\varphi|_X^2 \geq \sigma\|\varphi\|_Y^2$, $\varphi \in Y$, where $|\cdot|_X$ and $\|\cdot\|_Y$ denote, respectively, the norms on X and Y, and ρ, $\sigma > 0$. It follows (see, for example, [19], [31], [32]) that the initial value problem

$$\begin{aligned} &D_t x(t) + \mathcal{A}(t)x(t) = F(t), \quad \text{a.e. } t > 0, \\ &x(0) \in X, \end{aligned}$$

admits a unique solution $x \in L_2(0, T; Y)$ with $D_t x \in L_2(0, T; Y^*)$, all $T > 0$. Consequently, the estimator (2.13)–(2.15) admits a unique solution $(q, u) \in L_2(0, T; Q) \times L_2(0, T; V)$ with $(D_t q, D_t u) \in L_2(0, T; Q) \times L_2(0, T; V^*)$, all $T > 0$. Moreover, for each $T > 0$, q and u agree almost everywhere with functions in $C([0, T]; Q)$ and $C([0, T]; H)$, respectively.

Let $e(t) = u(t) - \overline{u}(t)$ and $r(t) = q(t) - \overline{q}$, where $(\overline{q}, \overline{u})$ is a plant and (q, u) is a solution to the initial value problem (2.13)–(2.15). The functions e and r are solutions to the *error equations* given by

$$D_t e(t) + Ae(t) + B(\overline{u}(t))^* r(t) = 0, \quad \text{a.e. } t > 0, \tag{2.18}$$

$$D_t r(t) - B(\overline{u}(t))e(t) = 0, \quad \text{a.e. } t > 0, \tag{2.19}$$

or equivalently

$$D_t \begin{bmatrix} e(t) \\ r(t) \end{bmatrix} + \mathcal{A}(t) \begin{bmatrix} e(t) \\ r(t) \end{bmatrix} = 0, \quad \text{a.e. } t > 0, \tag{2.20}$$

where the operator $\mathcal{A}(t)$ is given by (2.17). In the next section we show that under appropriate hypotheses (i.e., that the plant $(\overline{q}, \overline{u})$ is *persistently excited*), the solution of (2.18), (2.19), or (2.20) with arbitrary initial data tends strongly to the trivial solution as $t \to \infty$. That is, in particular, for any $u(0) \in H$ and $q(0) \in Q$ we have $\lim_{t\to\infty} |u(t) - \overline{u}(t)| = \lim_{t\to\infty} |e(t)| = 0$ and $\lim_{t\to\infty} |q(t) - \overline{q}|_Q = \lim_{t\to\infty} |r(t)|_Q = 0$. (We in fact show that the convergence of the state estimator holds without any additional assumptions. The assumption of persistence of excitation is required only to establish parameter convergence).

3. Convergence. Throughout this section we assume that $(\overline{q}, \overline{u})$ is a plant. We begin by establishing the convergence of the state estimator. Define the function $E : [0, \infty) \to R^1$ by

$$E(t) = \frac{1}{2} \left| \begin{bmatrix} e(t) \\ r(t) \end{bmatrix} \right|_X^2 = \frac{1}{2} \left\{ |e(t)|^2 + |r(t)|_Q^2 \right\}, \qquad t \geq 0. \tag{3.1}$$

We require the following lemma.

LEMMA 3.1. *For all* $t \geq 0$

$$E(t) + \beta \int_0^t \|e(s)\|^2 ds \leq \xi, \tag{3.2}$$

where $\xi = E(0) = \frac{1}{2}\left\{|e(0)|^2 + |r(0)|_Q^2\right\}$ *and* β *is as defined in assumption* (A4).

Proof. From (2.18), (2.19), and assumption (A4) we find that for $s > 0$

$$\begin{aligned} D_s E(s) &= \operatorname{Re}\langle D_s e(s), e(s)\rangle + \operatorname{Re}\langle D_s r(s), r(s)\rangle_Q \\ &= -\operatorname{Re}\langle Ae(s), e(s)\rangle \\ &\leq -\beta\|e(s)\|^2. \end{aligned} \tag{3.3}$$

Integrating from 0 to t, we obtain the desired result. □

Using Lemma 3.1, we show that the state error, $e(t)$, converges to zero asymptotically as $t \to \infty$. The proof is in the spirit of the arguments used in [27] to verify a result known as Barbălat's lemma. A somewhat different proof of this result can be found in [30] (see also [2]).

THEOREM 3.2. *The function* E *given in* (3.1) *is nonincreasing and*

$$\lim_{t\to\infty} |e(t)| = 0.$$

Proof. That E is nonincreasing follows immediately from the estimate (3.3). For $t_2 > t_1$, (2.18), assumption (A4), Definition 2.1, and Lemma 3.1 (more precisely, (3.1) and (3.2)) yield

$$\begin{aligned} |e(t_2)|^2 - |e(t_1)|^2 &= \int_{t_1}^{t_2} D_t|e(t)|^2 dt \\ &= 2\int_{t_1}^{t_2} \operatorname{Re}\langle D_t e(t), e(t)\rangle dt \\ &= 2\int_{t_1}^{t_2} \{-\operatorname{Re}\langle Ae(t), e(t)\rangle - \operatorname{Re}\langle B(\overline{u}(t))^* r(t), e(t)\rangle\} dt \\ &\leq -2\beta\int_{t_1}^{t_2} \|e(t)\|^2 dt + 2\int_{t_1}^{t_2} |\langle B(\overline{u}(t))^* r(t), e(t)\rangle| dt \\ &\leq 2\gamma(\overline{u})\int_{t_1}^{t_2} \|e(t)\||r(t)|_Q dt \\ &\leq 2\gamma(\overline{u})\left\{\int_{t_1}^{t_2} |r(t)|_Q^2 dt\right\}^{\frac{1}{2}}\left\{\int_{t_1}^{t_2} \|e(t)\|^2 dt\right\}^{\frac{1}{2}} \\ &\leq \frac{2\sqrt{2}\gamma(\overline{u})\xi}{\sqrt{\beta}}(t_2 - t_1)^{\frac{1}{2}}. \end{aligned}$$

Note that the estimate (3.2) implies that for all $L > 0$

$$\lim_{t\to\infty} \int_{t-L}^{t} \|e(s)\|^2 ds = 0, \tag{3.4}$$

and suppose that $\lim_{t\to\infty} |e(t)|^2 \neq 0$. Then there exist $\epsilon > 0$ and a sequence $\{t_n\}_{n=1}^{\infty}$ with $t_n > 0$ and $\lim_{n\to\infty} t_n = \infty$ for which

$$|e(t_n)|^2 > \epsilon, \qquad n = 1, 2, \ldots. \tag{3.5}$$

It follows from (3.4) and (3.5) that for $\delta > 0$ and $n = 1, 2, \ldots$

$$\begin{aligned}\int_{t_n-\delta}^{t_n} |e(t)|^2 dt &= \int_{t_n-\delta}^{t_n} |e(t_n)|^2 dt - \int_{t_n-\delta}^{t_n} \{|e(t_n)|^2 - |e(t)|^2\} dt \\ &> \epsilon\delta - \frac{2\sqrt{2}\gamma(\overline{u})\xi}{\sqrt{\beta}} \int_{t_n-\delta}^{t_n} (t_n - t)^{\frac{1}{2}} dt \\ &= \epsilon\delta - \mu\delta^{\frac{3}{2}},\end{aligned}$$

where $\mu = \frac{4\sqrt{2}\gamma(\overline{u})\xi}{3\sqrt{\beta}}$. Choosing $\delta = \frac{\epsilon^2}{4\mu^2}$, we obtain that

$$\int_{t_n-\delta}^{t_n} |e(t)|^2 dt > \frac{\epsilon^3}{8\mu^2} = \frac{\epsilon\delta}{2}, \qquad n = 1, 2, \ldots. \tag{3.6}$$

The estimate (3.6) together with (2.2) implies that for $n = 1, 2, \ldots,$

$$\int_{t_n-\delta}^{t_n} \|e(t)\|^2 dt \geq K^{-2} \int_{t_n-\delta}^{t_n} |e(t)|^2 dt > \frac{\epsilon\delta}{2K^2}, \qquad n = 1, 2 \ldots.$$

However, this contradicts (3.4). Consequently, $\lim_{t\to\infty} |e(t)|^2 = 0$, and the proof is complete. ∎

To establish parameter convergence, an additional hypothesis is required. We extend the finite-dimensional notion of persistence of excitation to infinite dimensions and argue parameter convergence using ideas similar to those used in [22] (see also [23]) to study the uniform asymptotic stability of certain classes of linear nonautonomous finite dimensional systems.

DEFINITION 3.3. *A plant $(\overline{q}, \overline{u})$ is said to be persistently excited, or an input f is said to be persistently exciting for the plant $(\overline{q}, \overline{u})$, if there exist T_0, δ_0, $\epsilon_0 > 0$ such that for each $q \in Q$ with $|q|_Q = 1$ and each $t > 0$ sufficiently large, there exists a $\tilde{t} \in [t, t + T_0]$ such that*

$$\left\| \int_{\tilde{t}}^{\tilde{t}+\delta_0} B(\overline{u}(\tau))^* q d\tau \right\|_* \geq \epsilon_0,$$

where for $t \geq 0$, $B(\overline{u}(t))^* \in \mathcal{L}(Q, V^*)$ is the Banach space adjoint of the operator $B(\overline{u}(t))$ defined in (2.16).

THEOREM 3.4. *If the plant $(\overline{q}, \overline{u})$ is persistently excited, then* $\lim_{t\to\infty} |r(t)|_Q = 0$.

The proof of Theorem 3.4 is argued using two lemmas, which we now state and prove.

LEMMA 3.5. *Let $\delta > 0$ be given. If the plant $(\overline{q}, \overline{u})$ is persistently excited, then there exist positive numbers $\epsilon = \epsilon(\delta)$, $T_1 = T_1(\delta)$, and T such that for all $t_1 \geq T_1$, if $|r(t)|_Q \geq \delta$ for $t \in [t_1, t_1 + T]$, then there exists a $\hat{t} \in [t_1, t_1 + T]$ such that $|e(\hat{t})| \geq \epsilon$.*

Proof. Let T_0, δ_0, ϵ_0, and $\tilde{t}$ be as in Definition 3.3 with $t = t_1$ (t_1 assumed to be sufficiently large to apply the condition of persistence of excitation), and $q = p(t_1) = r(t_1)/|r(t_1)|_Q$. Set $T = T_0 + \delta_0$ and assume that $|r(t)|_Q \geq \delta$ for all $t \in [t_1, t_1 + T]$. Integrating (2.18) over the interval $[\tilde{t}, \tilde{t} + \delta_0]$, taking norms in V^*, and applying the triangle inequality we obtain

$$\|e(\tilde{t} + \delta_0)\|_* \geq \left\| \int_{\tilde{t}}^{\tilde{t}+\delta_0} B(\overline{u}(\tau))^* r(\tau) d\tau \right\|_* - \left\| e(\tilde{t}) - \int_{\tilde{t}}^{\tilde{t}+\delta_0} Ae(\tau) d\tau \right\|_*. \tag{3.7}$$

The second term on the right-hand side of (3.7) can be estimated using assumption (A3), (2.2), and the Cauchy–Schwarz inequality. Indeed

$$\left\| e(\tilde{t}) - \int_{\tilde{t}}^{\tilde{t}+\delta_0} Ae(\tau)d\tau \right\|_* \leq \|e(\tilde{t})\|_* + \alpha \int_{\tilde{t}}^{\tilde{t}+\delta_0} \|e(\tau)\|d\tau \leq K|e(\tilde{t})| + \alpha\sqrt{\delta_0}\sqrt{\int_{\tilde{t}}^{\tilde{t}+\delta_0} \|e(\tau)\|^2 d\tau}. \tag{3.8}$$

Applying the backward triangle inequality to the first term on the right-hand side of (3.7), we obtain

$$\left\| \int_{\tilde{t}}^{\tilde{t}+\delta_0} B(\overline{u}(\tau))^* r(\tau)d\tau \right\|_* \geq \left\| \int_{\tilde{t}}^{\tilde{t}+\delta_0} B(\overline{u}(\tau))^* p(t_1)|r(t_1)|_Q d\tau \right\|_* - \left\| \int_{\tilde{t}}^{\tilde{t}+\delta_0} B(\overline{u}(\tau))^* \left\{ p(t_1)|r(t_1)|_Q - r(\tau) \right\} d\tau \right\|_*. \tag{3.9}$$

Using the fact that $(\overline{q}, \overline{u})$ is a plant, integrating (2.19) over the interval $[t_1, \tau]$, for $\tau > t_1$, taking norms in Q, and applying the Cauchy–Schwarz inequality we obtain

$$\begin{aligned} |r(t_1) - r(\tau)|_Q &= \left| \int_{t_1}^{\tau} B(\overline{u}(t))e(t)dt \right|_Q \\ &\leq \int_{t_1}^{\tau} |B(\overline{u}(t))e(t)|_Q \, dt \\ &\leq \gamma(\overline{u}) \int_{t_1}^{\tau} \|e(t)\|dt \\ &\leq \gamma(\overline{u})(\tau - t_1)^{\frac{1}{2}} \sqrt{\int_{t_1}^{\tau} \|e(t)\|^2 dt}. \end{aligned} \tag{3.10}$$

Definition 2.1, $\tilde{t} \in [t_1, t_1 + T_0]$, and (3.10) then imply that

$$\begin{aligned} &\left\| \int_{\tilde{t}}^{\tilde{t}+\delta_0} B(\overline{u}(\tau))^* \left\{ p(t_1)|r(t_1)|_Q - r(\tau) \right\} d\tau \right\|_* \\ &\qquad \leq \int_{\tilde{t}}^{\tilde{t}+\delta_0} \|B(\overline{u}(\tau))^*\|_{\mathcal{L}(Q,V^*)} |r(t_1) - r(\tau)|_Q d\tau \\ &\qquad \leq \gamma(\overline{u})^2 \delta_0 \sqrt{\tilde{t} + \delta_0 - t_1} \sqrt{\int_{t_1}^{\tilde{t}+\delta_0} \|e(t)\|^2 dt} \\ &\qquad \leq \gamma(\overline{u})^2 \delta_0 \sqrt{T} \sqrt{\int_{t_1}^{t_1+T} \|e(t)\|^2 dt}. \end{aligned} \tag{3.11}$$

Since by assumption $|r(t)|_Q \geq \delta$, $t \in [t_1, t_1 + T]$, and $(\overline{q}, \overline{u})$ is persistently excited, (3.9) and (3.11) imply that

$$\left\| \int_{\tilde{t}}^{\tilde{t}+\delta_0} B(\overline{u}(\tau))^* r(\tau)d\tau \right\|_* \geq \delta\epsilon_0 - \gamma(\overline{u})^2 \delta_0 \sqrt{T} \sqrt{\int_{t_1}^{t_1+T} \|e(t)\|^2 dt}. \tag{3.12}$$

Then, from (3.7), (3.8), and (3.12), we obtain that

$$\|e(\tilde{t}+\delta_0)\|_* \geq \delta\epsilon_0 - K|e(\tilde{t})| - \left\{\alpha\sqrt{\delta_0} + \gamma(\overline{u})^2\sqrt{T}\delta_0\right\}\sqrt{\int_{t_1}^{t_1+T}\|e(t)\|^2 dt}. \tag{3.13}$$

Applying Lemma 3.1 and Theorem 3.2, let $T_1 = T_1(\delta)$ be so large that

$$|e(t)| \leq \frac{\delta\epsilon_0}{2K} \qquad \text{and} \qquad \sqrt{\int_t^{t+T}\|e(t)\|^2 dt} \leq \frac{\delta\epsilon_0}{4(\alpha\sqrt{\delta_0} + \gamma(\overline{u})^2\sqrt{T}\delta_0)} \tag{3.14}$$

for all $t \geq T_1$. It then follows from (3.13), (3.14), and (2.2) that $|e(\hat{t})| \geq \epsilon$, where $\hat{t} = \tilde{t} + \delta_0 \in [t_1 + \delta_0, t_1 + T_0 + \delta_0] \subset [t_1, t_1 + T]$ and $\epsilon = \frac{\delta\epsilon_0}{4K}$, and thus the lemma is proven. ∎

LEMMA 3.6. *Let $\delta > 0$ be given and $T_1 = T_1(\delta)$ and T be as they were defined in Lemma 3.5. If the plant $(\overline{q}, \overline{u})$ is persistently excited, then there exists $T_2 = T_2(\delta) > 0$ with $T_2 \geq T_1$ such that if $t_1 \geq T_2$, then there exists $t_2 \in [t_1, t_1 + T]$ such that $|r(t_2)|_Q < \delta$.*

Proof. Let $\epsilon = \epsilon(\delta) = \frac{\epsilon_0\delta}{4K}$ be as it was defined in the proof of Lemma 3.5. Theorem 3.2 implies that there exists $S = S(\epsilon)$ such that

$$|e(s)| < \epsilon = \frac{\epsilon_0\delta}{4K}, \qquad s \geq S. \tag{3.15}$$

Set $T_2 = T_2(\delta) = \max\{T_1(\delta), S(\epsilon)\}$. Now if the lemma were not true, there would exist a $t_1 \geq T_2$ such that $|r(t)|_Q \geq \delta$ for all $t \in [t_1, t_1 + T]$. But then Lemma 3.5 would imply that there exist $\hat{t} \in [t_1, t_1 + T]$ such that $|e(\hat{t})| \geq \epsilon$. Since $\hat{t} \geq t_1 \geq T_2 \geq S$, this contradicts (3.15), and the lemma is proven. ∎

We are now prepared to prove Theorem 3.4.

Proof of Theorem 3.4. We show that for any $\epsilon > 0$, there exists a $\hat{t}$ such that

$$E(\hat{t}) \leq \epsilon, \tag{3.16}$$

where the function E is given by (3.1). Since, by Theorem 3.2, E is nonincreasing, (3.16) implies that $\lim_{t\to\infty} E(t) = 0$ and, therefore, that $\lim_{t\to\infty} |r(t)|_Q = 0$.

To establish (3.16), first note that if $E(t_1) \leq \epsilon$, then we are finished. On the other hand, if $E(t_1) > \epsilon$, we show that there exist $M > 0$ and $\gamma \in (0, 1)$, both depending only on the estimator (2.13)–(2.15) and the plant $(\overline{q}, \overline{u})$ (i.e., A, T_0, δ_0, ϵ_0, f, etc.), such that there exists a $\hat{t}_1 \in [t_1, t_1 + M]$ for which

$$E(\hat{t}_1) \leq \gamma E(t_1) + \rho(t_1), \tag{3.17}$$

where ρ is such that $\rho(t) \geq 0$, $t \geq 0$, and $\lim_{t\to\infty} \rho(t) = 0$. It follows that there exists a positive integer $\overline{K}$ which depends only on ϵ such that $E(t_1 + \overline{K}M) \leq \epsilon$. Indeed, by repeating the argument that leads to (3.17), we obtain the difference inequality $E_{k+1} \leq \gamma E_k + \rho_k$, $k = 0, 1, 2, \ldots$, where $E_k = E(t_1 + kM)$, $k = 0, 1, 2, \ldots$, $\rho_0 = \rho(t_1)$, $\rho_k \geq 0$, $k = 0, 1, 2, \ldots$, and $\lim_{k\to\infty} \rho_k = 0$. It follows that

$$E_k \leq \gamma^k E_0 + \sum_{j=0}^{k-1} \gamma^{k-j-1}\rho_j, \qquad k = 0, 1, 2, \ldots.$$

Letting J be so large that $\rho_j \le \frac{\epsilon(1-\gamma)}{3}$, $j \ge J$, and choosing $\overline{K} > J$ so large that $\gamma^k E_0 = \gamma^k E(t_1) \le \frac{\epsilon}{3}$ and $\gamma^k \sum_{j=0}^{J} \gamma^{-(j+1)} \rho_j \le \frac{\epsilon}{3}$, $k \ge \overline{K}$, we obtain

$$\begin{aligned} E(t + \overline{K}M) = E_{\overline{K}} &\le \gamma^{\overline{K}} E_0 + \gamma^{\overline{K}} \sum_{j=0}^{J-1} \gamma^{-(j+1)} \rho_j + \sum_{j=J}^{\overline{K}-1} \gamma^{\overline{K}-j-1} \rho_j \\ &\le \frac{\epsilon}{3} + \frac{\epsilon}{3} + \frac{\epsilon}{3}(1 - \gamma^{\overline{K}-J}) \le \epsilon. \end{aligned} \tag{3.18}$$

Consequently, (3.18) yields (3.16) with $\hat{t} = t_1 + \overline{K}M$.

Let $\epsilon > 0$ be given and $c_1, c_2 > 0$ be chosen so that

$$0 < \beta K^{-2} c_2 \{(2 - c_1) - 2\gamma(\overline{u}) c_2\} < 1. \tag{3.19}$$

For example, set $c_1 = 1$ and $c_2 < \min\{\frac{1}{2\gamma(\overline{u})}, \frac{K^2}{\beta}\}$. Note that the values of c_1 and c_2 depend only on the plant and the estimator dynamics, A. Apply Lemma 3.6 with $\delta = \sqrt{\epsilon c_1}$ to obtain T_2. Let $t_1 \ge T_2$ and let $t_2 \in [t_1, t_1 + T]$ be such that $|r(t_2)|_Q < \delta$.

If $E(t_2) \le \epsilon$, we are finished. So assume that

$$E(t_2) > \epsilon. \tag{3.20}$$

Now

$$E(t_2) = \frac{1}{2}\left\{|e(t_2)|^2 + |r(t_2)|_Q^2\right\} \le \frac{1}{2}\left\{|e(t_2)|^2 + \delta^2\right\} = \frac{1}{2}\left\{|e(t_2)|^2 + \epsilon c_1\right\}.$$

But then (3.20) implies that

$$|e(t_2)|^2 \ge 2E(t_2) - \epsilon c_1 > (2 - c_1) E(t_2). \tag{3.21}$$

For $t \ge t_2$, (2.18), assumption (A3), Definition 2.1, and the Cauchy–Schwarz inequality imply that

$$\begin{aligned} |e(t_2)|^2 - |e(t)|^2 &\le \left| \int_{t_2}^{t} D_s |e(s)|^2 ds \right| = \left| 2 \int_{t_2}^{t} \operatorname{Re} \langle D_s e(s), e(s) \rangle ds \right| \\ &= \left| -2 \int_{t_2}^{t} \operatorname{Re} \langle Ae(s), e(s) \rangle ds - 2 \int_{t_2}^{t} \operatorname{Re} \langle B(\overline{u}(s))^* r(s), e(s) \rangle ds \right| \\ &\le 2\alpha \int_{t_2}^{t} \|e(s)\|^2 ds + 2\gamma(\overline{u}) \int_{t_2}^{t} |r(s)|_Q \|e(s)\| ds \\ &\le \{2\alpha + \gamma(\overline{u})\} \int_{t_2}^{t} \|e(s)\|^2 ds + \gamma(\overline{u}) \int_{t_2}^{t} |r(s)|_Q^2 ds. \end{aligned} \tag{3.22}$$

Recalling (3.1) and Theorem 3.2, (3.22) implies that for $t \in [t_2, t_2 + c_2]$ we have

$$|e(t_2)|^2 - |e(t)|^2 \le \{2\alpha + \gamma(\overline{u})\} \int_{t_2}^{t_2 + c_2} \|e(s)\|^2 ds + 2\gamma(\overline{u}) c_2 E(t_2). \tag{3.23}$$

Combining (3.21) and (3.23), we find that for $t \in [t_2, t_2 + c_2]$

$$|e(t)|^2 \ge \{(2 - c_1) - 2\gamma(\overline{u}) c_2\} E(t_2) - \{2\alpha + \gamma(\overline{u})\} \int_{t_2}^{t_2 + c_2} \|e(s)\|^2 ds. \tag{3.24}$$

Recalling (3.3), we have that

$$E(t) - E(t_2) \leq -\beta \int_{t_2}^{t} \|e(s)\|^2 ds. \tag{3.25}$$

Setting $t = t_2 + c_2$ in (3.25) and recalling (2.2), (3.24) implies that

$$\begin{aligned} &E(t_2) - E(t_2 + c_2) \geq \beta \int_{t_2}^{t_2+c_2} \|e(s)\|^2 ds \\ &\geq \beta K^{-2} \int_{t_2}^{t_2+c_2} |e(s)|^2 ds \\ &\geq \beta K^{-2} c_2 \left\{(2 - c_1) - 2\gamma(\overline{u})c_2\right\} E(t_2) - \beta K^{-2} c_2 \left\{2\alpha + \gamma(\overline{u})\right\} \int_{t_2}^{t_2+c_2} \|e(s)\|^2 ds, \end{aligned}$$

or

$$\begin{aligned} E(t_2 + c_2) &\leq \left\{1 - \beta K^{-2} c_2 \left\{(2 - c_1) - 2\gamma(\overline{u})c_2\right\}\right\} E(t_2) \\ &\quad + \beta K^{-2} c_2 \left\{2\alpha + \gamma(\overline{u})\right\} \int_{t_2}^{t_2+c_2} \|e(s)\|^2 ds \\ &\leq (1 - \gamma_0) E(t_1) + \rho(t_1), \end{aligned} \tag{3.26}$$

where $\gamma_0 = \beta K^{-2} c_2 \left\{(2 - c_1) - 2\gamma(\overline{u})c_2\right\}$ and $\rho(t) = \frac{\beta c_2 \{2\alpha + \gamma(\overline{u})\}}{K^2} \int_t^{t+T+c_2} \|e(s)\|^2 ds$. In the estimate (3.26) we have used the fact that $t_2 \in [t_1, t_1 + T]$ and, since E is nonincreasing and (3.19) implies that $\gamma_0 \in (0, 1)$, that $(1 - \gamma_0)E(t_2) \leq (1 - \gamma_0)E(t_1)$. Recalling Lemma 3.1, we have $\lim_{t\to\infty} \rho(t) = 0$. Thus (3.26) yields (3.17) with $\gamma = 1 - \gamma_0 \in (0, 1)$ and $\hat{t_1} = t_2 + c_2 \in [t_1, t_1 + M]$, where $M = T + c_2$. This proves the theorem. ∎

Considerable insight can be gained from the proofs of Lemma 3.5, Lemma 3.6, and Theorem 3.4. In particular, the arguments and estimates used in these proofs suggest how the persistence of excitation parameters T_0, δ_0, and ϵ_0 and the choice of the estimator dynamics A retard or accelerate convergence. The following observations can be made.

(i) As ϵ_0 increases, the value of ϵ in Lemma 3.5 increases, and therefore the value of T_2 in Lemma 3.6 decreases. Consequently, convergence will be more rapid.

(ii) As either T_0 or δ_0 decrease, the values of T and T_1 in Lemma 3.5, the value of T_2 in Lemma 3.6, and the value of M in Theorem 3.4 decrease as well. It follows that more rapid convergence results.

(iii) As the value of β in assumption (A4) increases, the convergence of $|e(t)|$ to zero as $t \to \infty$ is more rapid (see Theorem 3.2). Thus the value of T_1 in Lemma 3.5 and the value of T_2 in Lemma 3.6 decrease, and convergence will be more rapid. Also, in the proof of Theorem 3.4, if β increases, either the value of γ_0 will increase or the value of c_2 will decrease, and therefore either the value of $\gamma = 1 - \gamma_0$ will decrease or the value of M will decrease. In either case the rate of convergence will be enhanced.

One way to either increase ϵ_0 or decrease δ_0 or T_0 in Definition 3.3 is to increase the *gain* on the input f. Assuming that the plant is linear and initially at rest, the linearity of (2.5) implies that an increase in the gain on $\overline{u}$ will result, and therefore, it is likely that the value of $\gamma(\overline{u})$ will also increase. However, in the proof of Theorem 3.4, if $\gamma(\overline{u})$ increases for a fixed value of c_2 (and therefore M), γ_0 will decrease and consequently γ will increase, thus slowing convergence.

For $\tau > 0$, integrating (2.19) from t to $t+\tau$, taking norms, and using the fact that $(\overline{q}, \overline{u})$ is a plant, we find that

$$\begin{aligned} |r(t+\tau) - r(t)|_Q &= \left| \int_t^{t+\tau} B(\overline{u}(s))e(s)ds \right|_Q \\ &\leq \gamma(\overline{u}) \int_t^{t+\tau} \|e(s)\| ds \\ &\leq \gamma(\overline{u})\sqrt{\tau}\sqrt{\int_t^{t+\tau} \|e(s)\|^2 ds}, \qquad t \geq 0. \end{aligned}$$

It follows that

$$\left| \frac{\Delta_\tau r(t)}{\tau} \right|_Q \leq \gamma(\overline{u})\sqrt{\frac{1}{\tau}\int_t^{t+\tau} \|e(s)\|^2 ds}, \quad t \geq 0,$$

where $\Delta_\tau r(t) = r(t+\tau) - r(t)$, $t \geq 0$. Recalling Lemma 3.1, we have that for each $\tau > 0$

$$\lim_{t\to\infty} \left| \frac{\Delta_\tau r(t)}{\tau} \right|_Q = 0. \tag{3.27}$$

Moreover, from Lemma 3.1, and in particular (3.2), it follows that the rate of convergence in (3.27) increases with increasing β. Consequently, if the estimator dynamics, A, are chosen so that β is too large, the average rate of change in r, the parameter error, will tend to zero too rapidly. In effect, the estimator will be *overdamped* and sluggish parameter convergence will result.

The remarks above indicate that making an appropriate choice of an input, f, and the estimator dynamics, A, is delicate. One must balance those factors which tend to enhance convergence with those that tend to retard it. In [8] a careful study of this phenomenon was undertaken. By looking at a plant consisting of a one-dimensional heat equation with a monochromatic modal input, and an estimator whose dynamics are also described by a one-dimensional heat equation, it was observed that the error equations (2.18), (2.19), or (2.20), to first order, took the form of a damped linear harmonic oscillator. The damping was determined by the magnitude of β, and the stiffness was related to the value of $\gamma(\overline{u})^2$. If β was too large (relative to $\gamma(\overline{u})$), the system was overdamped and parameter convergence was slow. If, on the other hand, $\gamma(\overline{u})$ was too large (relative to β), the system was stiff and underdamped. Oscillations, which are particularly undesirable in a parameter estimator being used as a part of an indirect adaptive control algorithm, resulted. Choosing the estimator dynamics, A, and input f to optimize the performance of the estimator required finding an appropriate compromise between these two extremes.

It is possible to establish a parameter convergence result in the absence of persistence of excitation in the spirit of the treatment in [2] for the identification of second-order elliptic partial differential equations via an asymptotic embedding technique. The result which we will establish below also provides insight into a phenomenon which we refer to as *partial persistence of excitation*. That is, the plant is persistently excited with respect to some subset of the unknown parameters and is not, or is to a lesser degree, persistently excited with respect to the rest.

For ξ as defined in the statement of Lemma 3.1, let $B_\xi = \{q \in Q : |q|_Q \leq \sqrt{\xi}\}$ and

$$\hat{Q} = \left\{ q \in Q : \lim_{t\to\infty} \left| \int_t^{t+L} \langle B(\overline{u}(\tau))^* q, \varphi \rangle d\tau \right| = 0, \varphi \in V, L > 0 \right\}.$$

We assume that for $q \in Q$, $A_0(q) \in \mathcal{L}(V, V^*)$, and that in assumption (A1) $A_0(q) = A_1(q)$ (i.e., that $A_2\varphi = 0$, $\varphi \in V$). We assume further that $u_0 \in V$, $f \in C([0,\infty); V)$ is uniformly Hölder continuous, and there exists $f_\infty \in V^*$ such that $\lim_{t\to\infty} \|f(t) - f_\infty\|_* = 0$. Then, as was discussed in section 2, it follows that there exists $\overline{u}_\infty \in V$ such that

$$\lim_{t\to\infty} \|\overline{u}(t) - \overline{u}_\infty\| = 0. \tag{3.28}$$

Under these assumptions, we obtain the following theorem.

THEOREM 3.7. *For r satisfying* (2.19) *we have*

$$\lim_{t\to\infty} w - \operatorname{dist}(r(t), \hat{Q} \cap B_\xi) = 0, \tag{3.29}$$

where $w - \operatorname{dist}(\cdot,\cdot)$ denotes the distance function with respect to the weak topology on Q.

Proof. Suppose that (3.29) does not hold. Then there would exist a sequence, $\{t_n\}_{n=1}^\infty$, and $\eta > 0$ such that $\lim_{n\to\infty} t_n = \infty$ and $w - \operatorname{dist}(r(t_n), \hat{Q} \cap B_\xi) \geq \eta$. Since $Q \cap B_\xi$ is a bounded subset of the Hilbert space Q, it is weakly compact. Consequently there exists a subsequence which we will again denote by $\{t_n\}_{n=1}^\infty$, and $r_\infty \in B_\xi$ such that $w - \lim_{n\to\infty} r(t_n) = r_\infty$ and $w - \operatorname{dist}(r_\infty, \hat{Q} \cap B_\xi) \geq \eta$. It follows that $r_\infty \notin \hat{Q}$ and therefore that there exists $\tilde{\varphi} \in V$ and $\epsilon > 0$ such that

$$\overline{\lim_{n\to\infty}} \left| \int_{t_n}^{t_n+\epsilon} \langle B(\overline{u}(\tau))^* r_\infty, \tilde{\varphi} \rangle d\tau \right| = \delta > 0. \tag{3.30}$$

But (3.30) implies that there exists a subsequence, $\{t_{n_k}\}_{k=1}^\infty$, of $\{t_n\}_{n=1}^\infty$ such that

$$\left| \int_{t_{n_k}}^{t_{n_k}+\epsilon} \langle B(\overline{u}(\tau))^* r(t_{n_k}), \tilde{\varphi} \rangle d\tau \right| > \frac{\delta}{2} \tag{3.31}$$

for all $k = 1, 2, \ldots$. Indeed, if this were not the case, then there would exist N such that $|\int_{t_n}^{t_n+\epsilon} \langle B(\overline{u}(\tau))^* r(t_n), \tilde{\varphi} \rangle d\tau| \leq \frac{\delta}{2}$ for all $n > N$. It would then follow that for $n > N$

$$\begin{aligned}
&\left| \int_{t_n}^{t_n+\epsilon} \langle B(\overline{u}(\tau))^* r_\infty, \tilde{\varphi} \rangle d\tau \right| \\
&\quad \leq \left| \int_{t_n}^{t_n+\epsilon} \langle B(\overline{u}(\tau))^* \{r_\infty - r(t_n)\}, \tilde{\varphi} \rangle d\tau \right| + \left| \int_{t_n}^{t_n+\epsilon} \langle B(\overline{u}(\tau))^* r(t_n), \tilde{\varphi} \rangle d\tau \right| \\
&\quad \leq \left| \int_0^\epsilon \langle r(t_n) - r_\infty, B(\overline{u}(t_n+\tau))\tilde{\varphi} \rangle_Q d\tau \right| + \frac{\delta}{2} \\
&\quad \leq \left| \int_0^\epsilon \langle A_1(r(t_n) - r_\infty)\overline{u}(t_n+\tau) - A_1(r(t_n) - r_\infty)\overline{u}_\infty, \tilde{\varphi} \rangle d\tau \right| \\
&\qquad + \left| \int_0^\epsilon \langle A_1(r(t_n) - r_\infty)\overline{u}_\infty, \tilde{\varphi} \rangle d\tau \right| + \frac{\delta}{2} \\
&\quad \leq 2\alpha_1 \sqrt{\xi} \|\tilde{\varphi}\| \int_0^\epsilon \|\overline{u}(t_n+\tau) - \overline{u}_\infty\| d\tau + \epsilon \left| \langle r(t_n) - r_\infty, B(\overline{u}_\infty)\tilde{\varphi} \rangle_Q \right| + \frac{\delta}{2},
\end{aligned} \tag{3.32}$$

where the final two estimates above are consequences of (2.3), assumption (A2), and, recalling our findings in section 2, the fact that under the present assumptions $\|\overline{u}(t)\|$ is bounded for $t \in [0, \infty)$.

It follows from (3.28), together with the bounded convergence theorem, that the term involving the integral in the final estimate in (3.32) tends to zero as $n \to \infty$. Moreover, from the fact that $w - \lim_{n\to\infty} r(t_n) = r_\infty$, it also follows that $\overline{\lim_{n\to\infty}} | \int_{t_n}^{t_n+\epsilon} \langle B(\overline{u}(\tau))^* r_\infty, \tilde{\varphi} \rangle d\tau | \le \frac{\delta}{2}$, which contradicts (3.30).

Now (2.18), assumption (A3), and the Cauchy–Schwarz inequality imply that

$$\begin{aligned}\left\| \int_{t_{n_k}}^{t_{n_k}+\epsilon} B(\overline{u}(\tau))^* r(\tau) d\tau \right\|_* &= \left\| e(t_{n_k}) - e(t_{n_k}+\epsilon) - \int_{t_{n_k}}^{t_{n_k}+\epsilon} A e(\tau) d\tau \right\|_* \\ &\le K|e(t_{n_k})| + K|e(t_{n_k}+\epsilon)| + \alpha\sqrt{\epsilon}\sqrt{\int_{t_{n_k}}^{t_{n_k}+\epsilon} \|e(\tau)\|^2 d\tau},\end{aligned}$$

which, together with Theorem 3.2 and Lemma 3.1, yields that

$$\lim_{n\to\infty} \left\| \int_{t_{n_k}}^{t_{n_k}+\epsilon} B(\overline{u}(\tau))^* r(\tau) d\tau \right\|_* = 0. \tag{3.33}$$

Also, recalling the estimate (3.10), using (2.3) and assumption (A2), we find that

$$\begin{aligned}&\left| \left| \int_{t_{n_k}}^{t_{n_k}+\epsilon} \langle B(\overline{u}(\tau))^* r(\tau), \tilde{\varphi} \rangle d\tau \right| - \left| \int_{t_{n_k}}^{t_{n_k}+\epsilon} \langle B(\overline{u}(\tau))^* r(t_{n_k}), \tilde{\varphi} \rangle d\tau \right| \right| \\ &\le \left| \int_{t_{n_k}}^{t_{n_k}+\epsilon} \langle B(\overline{u}(\tau))^* \{r(\tau) - r(t_n)\}, \tilde{\varphi} \rangle d\tau \right| \\ &= \left| \int_{t_{n_k}}^{t_{n_k}+\epsilon} \langle A_1(r(\tau) - r(t_{n_k}))\overline{u}(\tau), \tilde{\varphi} \rangle d\tau \right| \\ &\le \alpha_1 \|\tilde{\varphi}\| \int_{t_{n_k}}^{t_{n_k}+\epsilon} |r(\tau) - r(t_{n_k})|_Q \|\overline{u}(\tau)\| d\tau \\ &\le \alpha_1 \|\tilde{\varphi}\| \gamma(\overline{u}) \sqrt{\epsilon} \sqrt{\int_{t_{n_k}}^{t_{n_k}+\epsilon} \|e(\tau)\|^2 d\tau} \int_{t_{n_k}}^{t_{n_k}+\epsilon} \|\overline{u}(\tau)\| d\tau.\end{aligned}$$

The fact that $\|\overline{u}(t)\|$ is bounded on $[0, \infty)$ (see section 2) and Lemma 3.1 then imply that

$$\lim_{k\to\infty} \left| \left| \int_{t_{n_k}}^{t_{n_k}+\epsilon} \langle B(\overline{u}(\tau))^* r(\tau), \tilde{\varphi} \rangle d\tau \right| - \left| \int_{t_{n_k}}^{t_{n_k}+\epsilon} \langle B(\overline{u}(\tau))^* r(t_{n_k}), \tilde{\varphi} \rangle d\tau \right| \right| = 0. \tag{3.34}$$

But (3.33) implies that

$$\lim_{k\to\infty} \left| \int_{t_{n_k}}^{t_{n_k}+\epsilon} \langle B(\overline{u}(\tau))^* r(\tau), \tilde{\varphi} \rangle d\tau \right| \le \lim_{k\to\infty} \left\| \int_{t_{n_k}}^{t_{n_k}+\epsilon} B(\overline{u}(\tau))^* r(\tau) d\tau \right\|_* \|\tilde{\varphi}\| = 0. \tag{3.35}$$

Combining (3.34) and (3.35) we obtain a contradiction to (3.31), and the theorem is proven. □

Theorem 3.7 yields the following corollary. Its proof, which is omitted, is exactly the same as the one given to verify Theorem 4.4 in [2] (see also [30]).

COROLLARY 3.8. *Under the same assumptions required to establish Theorem* 3.7, *we have* $\lim_{t\to\infty} w - \operatorname{dist}(q(t), \hat{P} \cap B_{\overline{\xi}}) = 0$, *where* $\overline{\xi} = \sqrt{\xi} + |\overline{q}|_Q$ *and* $\hat{P}$ *is the linear variety in* Q *given by* $\hat{P} = \overline{q} + \hat{Q}$. *Moreover* $w - \lim_{t\to\infty} q(t) = \overline{p} + P_{\hat{Q}} q(0)$, *where* $P_{\hat{Q}}$ *is the orthogonal projection of* Q *onto the closed linear subspace* $\hat{Q}$, *and* $\overline{p} = \overline{q} - P_{\hat{Q}}\overline{q}$ *is the unique element of minimum norm in* $\hat{P}$ (*see, for example,* [21]).

Note that the fact that $\hat{Q}$ is closed follows from the assumption that $(\overline{q}, \overline{u})$ is a plant.

If $\hat{Q} = \{0\}$, we shall say that the plant $(\overline{q}, \overline{u})$ is *weakly persistently excited*. When this is the case, we obtain weak parameter convergence. Indeed, Corollary 3.8 implies that $w - \lim_{t\to\infty} q(t) = \overline{q}$.

It is also possible to obtain what we shall call *weak partial parameter convergence* when the plant $(\overline{q}, \overline{u})$ is only partially weakly persistently excited. Suppose that $Q = Q_1 \oplus Q_1^{\perp}$ with $Q_1 \subset \hat{Q}^{\perp}$. Then Corollary 3.8 implies that $w - \lim_{t\to\infty} P_1 q(t) = P_1\overline{p} + P_1 P_{\hat{Q}} q(0) = P_1\overline{q} - P_1 P_{\hat{Q}}\overline{q} = P_1\overline{q}$, where P_1 denotes the orthogonal projection of Q onto Q_1. Thus if the plant $(\overline{q}, \overline{u})$ is weakly persistently excited with respect to some of the unknown parameters, the estimates for those parameters, $P_1 q(t)$, will converge weakly to the corresponding true plant parameters, $P_1\overline{q}$. An illustration of this phenomenon can be found in [8]. Note that when, as is frequently the case, Q is finite dimensional, the weak convergence discussed above becomes strong convergence.

Finally we note that persistence of excitation is sufficient to establish an identifiability result similar to the one in [5].

THEOREM 3.9. *If the plant* $(\overline{q}, \overline{u})$ *is persistently excited, then the parameter* $\overline{q}$ *is identifiable.*

Proof. Suppose not. That is, there exists $\overline{q}_1, \overline{q}_2 \in Q$ such that $\overline{u}$ is a solution to the initial value problem (2.5), (2.6) with either $q = \overline{q}_1$ or $q = \overline{q}_2$. Subtraction then yields that $\langle A_1(\overline{q}_1 - \overline{q}_2)\overline{u}(t), \varphi\rangle = 0$, a.e. $t > 0$, $\varphi \in V$, or, in light of (2.3), that $B(\overline{u}(t))^*\{\overline{q}_1 - \overline{q}_2\} = 0$, a.e. $t > 0$. This clearly contradicts Definition 3.3 unless $\overline{q}_1 = \overline{q}_2$, and the theorem is proven. ∎

4. Approximation theory. The estimator (2.13)–(2.15) is infinite dimensional. Its implementation requires finite-dimensional approximation. We consider Galerkin approximation and establish a convergence result.

For each $n = 1, 2, \ldots$, let H^n be a finite-dimensional subspace of H with $H^n \subset V$, and let Q^n be a finite-dimensional subspace of Q. The Galerkin equations corresponding to (2.13)–(2.15) are given by

$$\begin{aligned}\langle D_t u^n(t), \varphi^n\rangle + \langle Au^n(t), \varphi^n\rangle + \langle B(\overline{u}(t))^* q^n(t), \varphi^n\rangle = \langle f(t), \varphi^n\rangle \\ + \langle A\overline{u}(t), \varphi^n\rangle - \langle A_2\overline{u}(t), \varphi^n\rangle, \quad \varphi^n \in H^n, \text{ a.e. } t > 0,\end{aligned} \tag{4.1}$$

$$\begin{aligned}\langle D_t q^n(t), \psi^n\rangle_Q - \langle B(\overline{u}(t))u^n(t), \psi^n\rangle_Q \\ = -\langle B(\overline{u}(t))\overline{u}(t), \psi^n\rangle_Q, \ \psi^n \in Q^n, \text{ a.e. } t > 0,\end{aligned} \tag{4.2}$$

$$u^n(0) \in H^n, \qquad q^n(0) \in Q^n. \tag{4.3}$$

An argument similar to the one outlined previously in section 2 for the initial value problem (2.13)–(2.15) can be used to establish the existence of a unique solution, (q^n, u^n), to the initial value problem (4.1)–(4.3) for each $T > 0$ with $u^n \in H^1(0, T; H^n)$ and $q^n \in H^1(0, T; Q^n)$.

In order to establish convergence we require the following assumption:

(A5) For each fixed $T > 0$ and (q, u) the solution to the initial value problem (2.13)–(2.15), there exist functions $u_n \in H^1(0, T; H^n)$ and $q_n \in H^1(0, T; Q^n)$

such that $\lim_{n\to\infty} u_n = u$ in $L_2(0,T;V)$ and $C(0,T;H)$, $\lim_{n\to\infty} q_n = q$ in $C(0,T;Q)$, $\lim_{n\to\infty} D_t u_n = D_t u$ in $L_2(0,T;V^*)$, and $\lim_{n\to\infty} D_t q_n = D_t q$ in $L_2(0,T;Q)$.

THEOREM 4.1. *Assume that assumption* (A5) *holds, let* (q^n, u^n) *be the solution to the initial value problem* (4.1)–(4.3) *with* $u^n(0) = u_n(0)$ *and* $q^n(0) = q_n(0)$*, and let* (q,u) *be the solution to the initial value problem* (2.13)–(2.15)*. Then for each* $T > 0$*,* $\lim_{n\to\infty} u^n = u$ *in* $L_2(0,T;V)$ *and* $C(0,T;H)$ *and* $\lim_{n\to\infty} q^n = q$ *in* $C(0,T;Q)$*.*

Proof. Assumption (A5) and the triangle inequality imply that we need only show that

$$\lim_{n\to\infty} \int_0^T \|u_n(t) - u^n(t)\|^2 dt = 0, \qquad \lim_{n\to\infty} \sup_{t\in[0,T]} |u_n(t) - u^n(t)| = 0,$$

$$\text{and} \qquad \lim_{n\to\infty} \sup_{t\in[0,T]} |q_n(t) - q^n(t)|_Q = 0.$$

Toward this end, let $w^n = u^n - u_n$ and $p^n = q^n - q_n$. Then, using the fact that (q^n, u^n) satisfies (4.1), (4.2), and (q,u) satisfies (2.13), (2.14), we obtain the identity

$$\begin{aligned}
&D_t\{|w^n(t)|^2 + |p^n(t)|_Q^2\} = 2\mathrm{Re}\,\{\langle D_t w^n(t), w^n(t)\rangle + \langle D_t p^n(t), p^n(t)\rangle_Q\}\\
&= 2\mathrm{Re}\,\{-\langle A w^n(t), w^n(t)\rangle + \langle A\{u(t) - u_n(t)\}, w^n(t)\rangle\\
&+\langle B(\overline{u}(t))^*\{q(t) - q_n(t)\}, w^n(t)\rangle + \langle D_t\{u(t) - u_n(t)\}, w^n(t)\rangle\\
&+\langle B(\overline{u}(t))\{u_n(t) - u(t)\}, p^n(t)\rangle_Q + \langle D_t\{q(t) - q_n(t)\}, p^n(t)\rangle_Q\}, \qquad \text{a.e.} \quad t > 0.
\end{aligned}$$

Assumptions (A3) and (A4), the fact that $(\overline{q}, \overline{u})$ is a plant, and the well-known inequality

$$ab \le \frac{\epsilon}{2}a^2 + \frac{b^2}{2\epsilon}, \qquad a, b \in R,\ \epsilon > 0, \tag{4.4}$$

then yield that

$$\begin{aligned}
&D_t\{|w^n(t)|^2 + |p^n(t)|_Q^2\}\\
&\le -2\beta\|w^n(t)\|^2 + \frac{\alpha^2}{\epsilon}\|u(t) - u_n(t)\|^2 + \frac{\gamma(\overline{u})^2}{\epsilon}|q(t) - q_n(t)|_Q^2\\
&\quad + \frac{1}{\epsilon}\|D_t u(t) - D_t u_n(t)\|_*^2 + \gamma(\overline{u})^2\|u_n(t) - u(t)\|^2 + |D_t q(t) - D_t q_n(t)|_Q^2\\
&\quad + 3\epsilon\|w^n(t)\|^2 + 2|p^n(t)|_Q^2, \qquad \text{a.e.} \quad t > 0.
\end{aligned}$$

Choosing $\epsilon < \frac{2}{3}\beta$ and integrating from 0 to t, we obtain

$$\delta \int_0^t \|w^n(s)\|^2 ds + |w^n(t)|^2 + |p^n(t)|_Q^2 \le z^n(t) + 2\int_0^t |w^n(s)|^2 + |p^n(s)|_Q^2 ds, \tag{4.5}$$

where $\delta = 2\beta - 3\epsilon > 0$ and

$$\begin{aligned}
z^n(t) = \int_0^t &\left\{\frac{\alpha^2}{\epsilon} + \gamma(\overline{u})^2\right\}\|u_n(s) - u(s)\|^2 + \frac{1}{\epsilon}\|D_s u_n(s) - D_s u(s)\|_*^2\\
&+\frac{\gamma(\overline{u})^2}{\epsilon}|q_n(s) - q(s)|_Q^2 + |D_s q_n(s) - D_s q(s)|_Q^2 ds.
\end{aligned}$$

It follows from assumption (A5) that $\lim_{n\to\infty} z^n(t) = 0$ uniformly on $[0,T]$ for each $T > 0$. An application of the Gronwall lemma to the estimate (4.5) above yields the desired result. □

Since the state of the plant at each time t, $\overline{u}(t)$, is also in the infinite-dimensional space V, from an implementation point of view (i.e., sensor requirements), it may be desirable to replace $\overline{u}$ in (4.1)–(4.3) with a finite-dimensional approximation, $\overline{u}_n$. To establish a convergence result similar to the one given in Theorem 4.1 above, we require the following additional assumption.

(A6) For each fixed $T > 0$ and for the plant $(\overline{q}, \overline{u})$, there exists $\overline{u}_n \in C(0, T; H^n)$ such that $\overline{u}_n \to \overline{u}$ in $C(0, T; V)$.

THEOREM 4.2. *Assume that assumptions* (A5) *and* (A6) *hold, let* (q^n, u^n) *be the solution to the initial value problem* (4.1)–(4.3) *with* $u^n(0) = u_n(0)$ *and* $q^n(0) = q_n(0)$ *and* $\overline{u}$ *replaced by* $\overline{u}_n$*, and let* (q, u) *be the solution to the initial value problem* (2.13)–(2.15). *Then for each* $T > 0$, $\lim_{n\to\infty} u^n = u$ *in* $L_2(0, T; V)$ *and* $C(0, T; H)$ *and* $\lim_{n\to\infty} q^n = q$ *in* $C(0, T; Q)$.

Proof. Once again, letting $w^n = u^n - u_n$ and $p^n = q^n - q_n$, we show that $\lim_{n\to\infty} w^n = 0$ in $L_2(0, T; V)$ and $C(0, T; H)$ and that $\lim_{n\to\infty} p^n = 0$ in $C(0, T; Q)$. Using (2.13), (2.14), (4.1), (4.2), and (2.3) we obtain the identity

$$
\begin{aligned}
&D_t\{|w^n(t)|^2 + |p^n(t)|_Q^2\} = 2\mathrm{Re}\,\{\langle D_t w^n(t), w^n(t)\rangle + \langle D_t p^n(t), p^n(t)\rangle_Q\}\\
&= 2\mathrm{Re}\,\{-\langle Aw^n(t), w^n(t)\rangle + \langle A\{u(t) - u_n(t)\}, w^n(t)\rangle + \langle A_1(q(t) - q_n(t))\overline{u}_n(t), w^n(t)\rangle\\
&\qquad + \langle A_1(q(t))\overline{u}(t) - \overline{u}_n(t), w^n(t)\rangle + \langle A\{\overline{u}_n(t) - \overline{u}(t)\}, w^n(t)\rangle\\
&\qquad + \langle A_2\{\overline{u}_n(t) - \overline{u}(t)\}, w^n(t)\rangle + \overline{\langle A_1(p^n(t))\overline{u}_n(t), u_n(t) - u(t)\rangle}\\
&\qquad + \overline{\langle A_1(p^n(t))\overline{u}_n(t) - \overline{u}(t), u(t)\rangle} + \overline{\langle A_1(p^n(t))\overline{u}_n(t), \overline{u}(t) - \overline{u}_n(t)\rangle}\\
&\qquad + \overline{\langle A_1(p^n(t))\overline{u}(t) - \overline{u}_n(t), \overline{u}(t)\rangle} + \langle D_t\{u(t) - u_n(t)\}, w^n(t)\rangle\\
&\qquad + \langle D_t\{q(t) - q_n(t)\}, p^n(t)\rangle_Q\}, \qquad \text{a.e. } t > 0.
\end{aligned}
$$

Assumptions (A2), (A3), (A4), and (A6) then yield that

$$
\begin{aligned}
&D_t\{|w^n(t)|^2 + |p^n(t)|_Q^2\}\\
&\le -2\{\beta\|w^n(t)\|^2 + \alpha\|u(t) - u_n(t)\|\|w^n(t)\| + \alpha_1|q(t) - q_n(t)|_Q\|\overline{u}_n(t)\|\|w^n(t)\|\\
&\qquad + \alpha_1|q(t)|_Q\|\overline{u}(t) - \overline{u}_n(t)\|\|w^n(t)\| + \alpha\|\overline{u}_n(t) - \overline{u}(t)\|\|w^n(t)\|\\
&\qquad + \alpha_2\|\overline{u}_n(t) - \overline{u}(t)\|\|w^n(t)\| + \alpha_1|p^n(t)|_Q\|\overline{u}_n(t)\|\|u_n(t) - u(t)\|\\
&\qquad + \alpha_1|p^n(t)|_Q\|\overline{u}_n(t) - \overline{u}(t)\|\|u(t)\| + \alpha_1|p^n(t)|_Q\|\overline{u}_n(t)\|\|\overline{u}(t) - \overline{u}_n(t)\|\\
&\qquad + \alpha_1|p^n(t)|_Q\|\overline{u}(t) - \overline{u}_n(t)\|\|\overline{u}(t)\| + \|D_t\{u(t) - u_n(t)\}\|_*\|w^n(t)\|\\
&\qquad + |D_t\{q(t) - q_n(t)\}|_Q|p^n(t)|_Q\}, \qquad \text{a.e. } t > 0.
\end{aligned}
$$

Applying the inequality (4.4) and gathering like terms, we obtain that

$$
\begin{aligned}
&D_t\{|w^n(t)|^2 + |p^n(t)|_Q^2\}\\
&\le \{-2\beta + 6\epsilon\}\|w^n(t)\|^2 + \left\{\frac{\alpha_1^2}{\epsilon} + \alpha_1^2\|\overline{u}_n(t)\|^2\right\}\|u_n(t) - u(t)\|^2\\
&+ \left\{\frac{\alpha_1^2|q(t)|_Q^2}{\epsilon} + \frac{\alpha^2}{\epsilon} + \alpha_2^2 + \alpha_1^2\{\|u(t)\|^2 + \|\overline{u}_n(t)\|^2 + \|\overline{u}(t)\|^2\}\right\}\|\overline{u}(t) - \overline{u}_n(t)\|^2\\
&+ \frac{\alpha_1^2\|\overline{u}_n(t)\|^2}{\epsilon}|q(t) - q_n(t)|_Q^2 + \frac{1}{\epsilon}\|D_t\{u(t) - u_n(t)\}\|_*^2 + |D_t\{q(t) - q_n(t)\}|_Q^2 + 5|p^n(t)|_Q^2
\end{aligned}
$$

for a.e. $t > 0$. Choosing $\epsilon > 0$ so that $\epsilon < \frac{1}{3}\beta$ and then integrating both sides of the above estimate from 0 to t, we obtain

$$\delta \int_0^t \|w^n(s)\|^2 ds + |w^n(t)|^2 + |p^n(t)|_Q^2 \le z^n(t) + 5\int_0^t |w^n(s)|^2 + |p^n(s)|_Q^2 ds, \tag{4.6}$$

where $\delta = \beta - 3\epsilon > 0$ and

$$\begin{aligned} z^n(t) &= \int_0^t \left\{ \frac{\alpha^2}{\epsilon} + \alpha_1^2 \|\overline{u}_n(s)\|^2 \right\} \|u_n(s) - u(s)\|^2 \\ &+ \left[\frac{\alpha_1^2 |q(s)|_Q^2}{\epsilon} + \frac{\alpha^2}{\epsilon} + \alpha_2^2 + \alpha_1^2 \left(\|u(s)\|^2 + \|\overline{u}_n(s)\|^2 + \|\overline{u}(s)\|^2 \right) \right] \|\overline{u}(s) - \overline{u}_n(s)\|^2 \\ &+ \frac{\alpha_1^2 \|\overline{u}_n(s)\|^2}{\epsilon} |q(s) - q_n(s)|_Q^2 + \frac{\|D_s\{u(s) - u_n(s)\}\|_*^2}{\epsilon} + |D_s\{q(s) - q_n(s)\}|_Q^2 ds. \end{aligned}$$

Assumptions (A5) and (A6) imply that $\lim_{n\to\infty} z^n(t) = 0$, uniformly on $[0, T]$, for each fixed $T > 0$. Consequently, an application of the Gronwall lemma to the estimate (4.6) yields the desired result. □

5. Second-order systems. It is possible to use the framework developed in the previous three sections to identify unknown parameters in certain classes of strongly damped second-order, or abstract hyperbolic, systems on-line. We briefly outline the essential features of the requisite theory below. However, a more general and more versatile treatment of second-order systems can be found in [7] and [28].

Let H_0 be a Hilbert space with inner product $\langle \cdot, \cdot \rangle_0$ and V_0 be a reflexive Banach space with norm denoted by $\| \cdot \|_0$. We assume that V_0 is densely and continuously embedded in H_0. Let Q be a Hilbert space with inner product $\langle \cdot, \cdot \rangle_Q$, and for $i = 1, 2$, let $a^i(\cdot; \cdot, \cdot) : Q \times V_0 \times V_0 \to \mathbf{C}$ be a form satisfying the following assumptions:

(A7) (Q-linearity and symmetry) The map $q \to a^i(q; \cdot, \cdot)$ is linear from Q into the space of conjugate symmetric sesquilinear forms on V_0.

(A8) ($V_0 \times V_0$-boundedness) There exists $\alpha^i > 0$ for which

$$|a^i(q; \varphi, \psi)| \le \alpha^i |q|_Q \|\varphi\|_0 \|\psi\|_0, \quad \varphi, \psi \in V_0, \quad q \in Q.$$

(A9) (V_0-coercivity) There exists a subset $\tilde{Q} \subset Q$ such that for each $q^* \in \tilde{Q}$ there exists $\beta^i(q^*) > 0$ such that $a^i(q^*\varphi, \varphi) \ge \beta^i(q^*) \|\varphi\|_0^2$, $\varphi \in V_0$.

For $q \in Q$ and $i = 1, 2$, let $A^i(q) : V_0 \to V_0^*$ be the linear operator on V_0 determined by the form $a^i(q; \cdot, \cdot)$ via $\langle A^i(q)\varphi, \psi \rangle_0 = a^i(q; \varphi, \psi)$, $\varphi, \psi \in V_0$. Let $w_0 \in V_0$ and $w_1 \in H_0$, let $g \in L_2(0, T; V_0^*)$ for all $T > 0$, and for each $q \in Q$ consider the abstract second-order initial value problem given by

$$D_t^2 w(t) + A^2(q) D_t w(t) + A^1(q) w(t) = g(t), \qquad \text{a.e. } t > 0, \tag{5.1}$$

$$w(0) = w_0, \ \ D_t w(0) = w_1. \tag{5.2}$$

By a solution to the initial value problem (5.1), (5.2) on the interval $[0, T]$ for some $T > 0$, we mean a function $w \in L_2(0, T; V_0)$ with $D_t w \in L_2(0, T; V_0)$ and $D_t^2 w \in L_2(0, T; V_0^*)$ which satisfies (5.1) on a.e. $(0, T)$ as well as (5.2).

To apply the abstract theory developed in sections 2, 3, and 4 above, we effectively rewrite the initial value problem (5.1), (5.2) as an equivalent first-order system. Let

$q^* \in \tilde{Q}$ be fixed but arbitrary and H be the Hilbert space defined by $H = V_0 \times H_0$ with inner product given by

$$\langle \varphi, \psi \rangle = a^1(q^*; \varphi_1, \psi_1) + \langle \varphi_2, \psi_2 \rangle_0 \tag{5.3}$$

for $\varphi = (\varphi_1, \varphi_2)$, $\psi = (\psi_1, \psi_2) \in H$. Let V be the reflexive Banach space defined by $V = V_0 \times V_0$ with norm given by $\|\varphi\| = \left\{ \|\varphi_1\|_0^2 + \|\varphi_2\|_0^2 \right\}^{\frac{1}{2}}$ for $\varphi = (\varphi_1, \varphi_2) \in V$, and for $q \in Q$ define the operator $A_0(q) : V \to V^*$ by $\langle A_0(q)\varphi, \psi \rangle = -a^1(q^*; \varphi_2, \psi_1) + a^1(q; \varphi_1, \psi_2) + a^2(q; \varphi_2, \psi_2)$ for $\varphi = (\varphi_1, \varphi_2) \in V$ and $\psi = (\psi_1, \psi_2) \in V$. Assumptions (A7) and (A9) imply that the expression given in (5.3) is in fact an inner product on H. Assumption (A7) implies that for each $q \in Q$, the operator $A_0(q)$ satisfies assumption (A1) with the operator $A_1(q) : V \to V^*$ given by $\langle A_1(q)\varphi, \psi \rangle = a^1(q; \varphi_1, \psi_2) + a^2(q; \varphi_2, \psi_2)$ and the operator $A_2 : V \to V^*$ in assumption (A1) given by $\langle A_2\varphi, \psi \rangle = -a^1(q^*; \varphi_2, \psi_1)$. Assumption (A8) implies that assumption (A2) is satisfied with $\alpha_1 = 2\max\{\alpha^1, \alpha^2\}$ and $\alpha_2 = \alpha^1|q^*|_Q$. For any $\lambda > 0$, defining $A \in \mathcal{L}(V, V^*)$ by $\langle A\varphi, \psi \rangle = \langle A_0(q^*)\varphi + \lambda\varphi, \psi \rangle$, $\varphi, \psi \in V$, assumption (A8) implies that assumption (A3) holds, and assumption (A9) implies that assumption (A4) holds with $\beta = \min\{\lambda\beta^1(q^*), \beta^2(q^*)\}$.

For $\varphi \in V$, defining the operator $B(\varphi) : V \to Q$ as it was in (2.3) and setting $u_0 = (w_0, w_1) \in H$ and $f = (0, g) \in L_2(0, T; V^*)$, the second-order system (5.1), (5.2) and the first-order system (2.5), (2.6) are considered to be equivalent to $u \sim (w, D_t w)$.

For $\varphi = (\varphi_1, \varphi_2) \in V$, the operator $B(\varphi) : V \to Q$ defined in (2.3) is given by

$$\langle B(\varphi)\psi, q \rangle_Q = \overline{\langle A_1(q)\varphi, \psi \rangle} = \overline{a^1(q; \varphi_1, \psi_2)} + \overline{a^2(q; \varphi_2, \psi_2)}$$

for $q \in Q$ and $\psi = (\psi_1, \psi_2) \in V$. It then follows from Definition 2.1 that a pair $(\overline{q}, \overline{w})$ with $\overline{q} \in Q$ and $\overline{w}$ a solution to the initial value problem (5.1), (5.2) with $q = \overline{q}$ is a *plant* if there exists a constant $\gamma_0 = \gamma_0(\overline{w})$ such that

$$|\langle A^1(q)\overline{w}(t), \varphi \rangle_0 + \langle A^2(q) D_t \overline{w}(t), \varphi \rangle_0| \leq \gamma_0(\overline{w}) |q|_Q \|\varphi\|_0, \qquad \text{a.e. } t > 0,\ \varphi \in V_0.$$

It also follows from Definition 3.3 that the condition for a plant, $(\overline{q}, \overline{w})$, to be *persistently excited* is for there to exist T_0, δ_0, $\epsilon_0 > 0$ such that for each $q \in Q$ with $|q|_Q = 1$ and each $t > 0$ sufficiently large, there exists a $\tilde{t} \in [t, t + T_0]$ such that

$$\left\| \int_{\tilde{t}}^{\tilde{t}+\delta_0} A^1(q)\overline{w}(\tau) + A^2(q) D_\tau \overline{w}(\tau) d\tau \right\|_{V_0^*} \geq \epsilon_0.$$

The convergence results given in section 3 take the form $\lim_{t\to\infty} \|u_1(t) - \overline{w}(t)\|_0 = 0$, $\lim_{t\to\infty} |u_2(t) - D_t\overline{w}(t)|_0 = 0$, and if, in addition, the plant $(\overline{q}, \overline{w})$ is persistently excited, then $\lim_{t\to\infty} |q(t) - \overline{q}|_Q = 0$, where (q, u) with $u = (u_1, u_2)$ is the solution to the initial value problem (2.13)–(2.15).

It is also possible to restate our *partial persistence of excitation* and *partial* parameter convergence results, Theorem 3.7 and Corollary 3.8, in the context of second-order systems. In particular, note that the set $\hat{Q}$ takes the form

$$\hat{Q} = \left\{ q \in Q : \lim_{t\to\infty} \left| \int_t^{t+L} \langle A^1(q)\overline{w}(\tau) + A^2(q) D_\tau \overline{w}(\tau), \varphi \rangle_0 d\tau \right| = 0,\ \varphi \in V_0,\ L > 0 \right\}.$$

Finally we note that the appropriate modifications to the approximation theory presented in section 4 (i.e., assumptions (A5) and (A6) and Theorems 4.1 and 4.2), required to restate it in the context of second-order systems, should also be immediately clear.

6. Examples and numerical results. In this section we present and discuss a number of examples illustrating the application of the on-line estimation theory which was developed in the previous sections. We consider the estimation of both constant and functional (i.e., spatially varying) parameters in one-dimensional heat or diffusion equations, the estimation of constant damping and stiffness parameters in a one-dimensional wave equation with Kelvin–Voigt viscoelastic damping, and the estimation of the nonlinearity in a one-dimensional quasi-linear heat equation in which the thermal diffusivity is a function of the temperature gradient. The numerical studies for each example presented below were carried out via simulation of the plant. We also did not attempt to construct input signals which necessarily resulted in a persistently excited plant. Our concern here was to simply illustrate the feasibility of our approach. A detailed and complete numerical study of persistence of excitation and its effect on convergence has been carried out and is reported on elsewhere (see [8]). For simplicity, in the examples to follow, we have chosen all of the Hilbert and Banach spaces, H, V, and Q, to be real.

All of the computations described below were carried out on either a SUN SPARC-system 600 or a SPARCstation 10 in the Department of Mathematics at the University of Southern California. The finite-dimensional estimator equations, (4.1)–(4.3), were integrated using the stiff ODE solver from the Numerical Algorithms Group (NAG) Library, routine D02NBF. All required integrals were computed numerically via a composite two-point Gauss–Legendre quadrature rule.

6.1. Example 1. We consider the estimation of the parameters q_1, q_2, and q_3 in the one-dimensional heat or diffusion equation (with convective or advective and decay or growth terms) given by

$$\frac{\partial u}{\partial t}(t,x) = q_1 \frac{\partial^2 u}{\partial x^2}(t,x) - q_2 \frac{\partial u}{\partial x}(t,x) - q_3 u(t,x) + f(t,x), \quad t > 0,\ 0 < x < 1,$$

together with the Dirichlet boundary conditions $u(t,0) = 0 = u(t,1)$, $t > 0$. In this case we have $H = L_2(0,1)$ and $V = H_0^1(0,1)$ endowed with the usual inner products and corresponding induced norms. The embedding constant is $K = \pi^{-1}$ (see, for example, [29]). We take $Q = \mathbf{R}^3$ endowed with the weighted Euclidean inner product $\langle q, p\rangle = q^T \Omega p$, q, $p \in \mathbf{R}^3$, where Ω is the 3×3 diagonal matrix given by $\Omega = \text{Diagonal}(\omega_1, \omega_2, \omega_3)$, with $\omega_1, \omega_2, \omega_3 > 0$. We note that the weights ω_1, ω_2, and ω_3 serve as so-called *adaptive gains* or *tuning parameters* in the estimator. For $q \in Q$, the operator $A_0(q) = A_1(q) \in \mathcal{L}(V, V^*)$ is given by

$$\langle A_0(q)\varphi, \psi\rangle = q_1 \int_0^1 D\varphi(x) D\psi(x)dx + q_2 \int_0^1 D\varphi(x)\psi(x)dx + q_3 \int_0^1 \varphi(x)\psi(x)dx, \quad \varphi, \psi \in H_0^1(0,1).$$

It is easily verified that assumptions (A1) and (A2) are satisfied.

For the estimator dynamics, $A \in \mathcal{L}(V, V^*)$, we set $A = A_0(q^*)$ for an *appropriate* choice of $q^* \in Q$. It is immediately clear that $q^* \in Q$ can be chosen so that assumptions (A3) and (A4) hold. For example, let $q^* = (q_1^*, q_2^*, q_3^*)$, with $q_2^* = 0$, $q_1^* > 0$, and $q_3^* \geq 0$.

We approximate using linear B-splines. For $n = 1, 2, \ldots$, let $\{\varphi_j^n\}_{j=0}^n$ be the standard linear B-splines on the interval $[0,1]$ defined with respect to the uniform

mesh $\{0, \frac{1}{n}, \frac{2}{n}, \ldots, 1\}$. That is, for $i = 0, 1, 2, \ldots, n$

$$\varphi_i^n(x) = \begin{cases} 1 - |nx - i|, & x \in [\frac{i-1}{n}, \frac{i+1}{n}], \\ 0 & \text{elsewhere on } [0,1]. \end{cases} \tag{6.1}$$

Set $H^n = \operatorname{span}\{\varphi_j^n\}_{j=1}^{n-1}$. Since Q is finite dimensional, we simply set $Q^n = Q$, $n = 1, 2, \ldots$. For each $n = 1, 2, \ldots$, let P^n denote the orthogonal projection of H onto H^n, and setting $u_n = P^n u$, standard approximation results for spline functions (see [29]) can be used to establish that assumption (A5) is satisfied. For $n = 1, 2, \ldots$, let P_n denote the orthogonal projection of $V = H_0^1(0,1)$ onto H^n (with respect to the standard H_0^1 inner product), and set $\overline{u}_n = P_n \overline{u}$. If $\overline{u}$ is sufficiently smooth, it is not difficult to establish that assumption (A6) is satisfied as well. Thus the conclusions of Theorem 4.1 and Theorem 4.2 hold.

There is a practical advantage to using the V projection, P_n, to finite dimensionalize the plant. Indeed, if

$$\overline{u}_n(t) = P_n \overline{u}(t) = \sum_{j=1}^{n-1} \overline{U}_n(t)_j \varphi_j^n \tag{6.2}$$

(i.e., let $\overline{U}_n(t) \in \mathbf{R}^{n-1}$ be the coordinate vector for $\overline{u}_n(t)$ with respect to the basis $\{\varphi_j^n\}_{j=1}^{n-1}$), then

$$\overline{U}_n(t) = (K^n)^{-1} h_n(\overline{u}(t)), \tag{6.3}$$

where for $\varphi \in V$, $h_n(\varphi) \in \mathbf{R}^{n-1}$ is given by $h_n(\varphi)_j = \int_0^1 D\varphi(x) D\varphi_j^n(x)dx$, $j = 1, 2, \ldots, n-1$, and $K^n \in \mathbf{R}^{(n-1)\times(n-1)}$ is given by

$$K^n = \left[K_{ij}^n\right] = \left[\int_0^1 D\varphi_i^n(x) D\varphi_j^n(x)dx\right] = n \begin{bmatrix} 2 & -1 & 0 & & & 0 \\ -1 & 2 & \cdot & & & \\ 0 & \cdot & \cdot & \cdot & & \\ & & \cdot & \cdot & \cdot & 0 \\ & & & \cdot & \cdot & -1 \\ 0 & & & 0 & -1 & 2 \end{bmatrix}. \tag{6.4}$$

It is easily verified that for $\varphi \in V$

$$h_n(\varphi)_j = -n\Delta_{\frac{1}{n}}^2 \varphi(\frac{j-1}{n}) = -n\left\{\varphi\left(\frac{j+1}{n}\right) - 2\varphi\left(\frac{j}{n}\right) + \varphi\left(\frac{j-1}{n}\right)\right\}, \quad j = 1, \ldots, n-1.$$

Thus the approximating estimator (i.e., (4.1)–(4.3) with $\overline{u}$ replaced by $\overline{u}_n$) does not require spatially distributed data. For a given value of n, $\overline{u}$ need only be spatially sampled at the $n-1$ nodal points $\frac{1}{n}, \frac{2}{n}, \ldots, \frac{n-1}{n}$.

Let $U^n(t) \in \mathbf{R}^{n-1}$ be the coordinate vector for $u^n(t)$. That is,

$$u^n(t) = \sum_{j=1}^{n-1} U^n(t)_j \varphi_j^n. \tag{6.5}$$

Let M^n denote the Gram matrix corresponding to the basis $\{\varphi_j^n\}_{j=1}^{n-1}$. We have

$$M^n = \left[M_{ij}^n\right] = \left[\int_0^1 \varphi_i^n(x)\varphi_j^n(x)dx\right] = \frac{1}{6n} \begin{bmatrix} 4 & 1 & 0 & & & 0 \\ 1 & 4 & 1 & & & \\ 0 & \cdot & \cdot & \cdot & & \\ & & \cdot & \cdot & \cdot & 0 \\ & & & \cdot & \cdot & 1 \\ 0 & & & 0 & 1 & 4 \end{bmatrix}. \tag{6.6}$$

Also, let L^n be the $(n-1)\times(n-1)$ matrix given by

$$L^n = \left[L^n_{ij}\right] = \left[\int_0^1 \varphi_i^n(x) D\varphi_j^n(x)dx\right] = \frac{1}{2}\begin{bmatrix} 0 & 1 & 0 & & & 0 \\ -1 & 0 & 1 & & & \\ 0 & \cdot & \cdot & \cdot & & \\ & & \cdot & \cdot & \cdot & 0 \\ & & & \cdot & \cdot & 1 \\ 0 & & & 0 & -1 & 0 \end{bmatrix}.$$

The matrix form of the approximating estimator ((4.1)–(4.3) with $\overline{u}$ replaced by $\overline{u}_n$) is then given by

$$\begin{aligned} M^n\dot{U}^n(t) &+ q_1^* K^n U^n(t) + q_2^* L^n U^n(t) + q_3^* M^n U^n(t) \\ &+ q_1(t)K^n\overline{U}_n(t) + q_2(t)L^n\overline{U}_n(t) + q_3(t)M^n\overline{U}_n(t) \\ &= q_1^* K^n\overline{U}_n(t) + q_2^* L^n\overline{U}_n(t) + q_3^* M^n\overline{U}_n(t) + F^n(t), \quad t>0, \\ \omega_1\dot{q}_1^n(t) &+ \overline{U}_n(t)^T K^n\left\{\overline{U}_n(t) - U^n(t)\right\} = 0, \qquad t>0, \\ \omega_2\dot{q}_1^n(t) &+ \overline{U}_n(t)^T L^n\left\{\overline{U}_n(t) - U^n(t)\right\} = 0, \qquad t>0, \\ \omega_3\dot{q}_1^n(t) &+ \overline{U}_n(t)^T M^n\left\{\overline{U}_n(t) - U^n(t)\right\} = 0, \qquad t>0, \end{aligned}$$

where for $t>0$

$$F^n(t)_j = \int_0^1 f(t,x)\varphi_j^n(x)dx, \qquad j=1,2,\ldots,n-1. \tag{6.7}$$

To carry out our numerical studies, we set $\overline{q} = (\overline{q}_1,\overline{q}_2,\overline{q}_3)^T = (.1,0,.8)^T$ and let

$$f(t,x) = \left\{\sin(4\pi t) + 10^{-3}t^2\right\}\chi_{[.215,.315]}(x), \quad t>0, \quad 0<x<1, \tag{6.8}$$

where $\chi_{[a,b]}$ denotes the characteristic function corresponding to the interval $[a,b]$. We assume that the plant was initially at rest (i.e., $u_0=0$). Since $\overline{q}_2=0$, the mode shapes of the plant are $\varphi_j(x)=\sin(j\pi x)$, $j=1,2,\ldots$. To simulate the plant we used an N-dimensional truncated modal model with $N=65$. We set $q_1^*=.01$, $q_2^*=0$, and $q_3^*=0$. We also set $\omega_1=\omega_2=\omega_3=1.0$. We took the state estimate to be initially at rest and set $q_1^n(0)=0$, $q_2^n(0)=.25$, and $q_3^n(0)=-.15$, for all n. We integrated the estimator from $t=0$ to $t=100$. Our results for $n=4,8,16$, and 32 are plotted in Figures 6.1, 6.2, and 6.3. The estimates for q_1 are plotted in Figure 6.1; for q_2, in Figure 6.2; and for q_3, in Figure 6.3. The dotted line in each of the figures is the value for $\overline{q}_1$, $\overline{q}_2$, or $\overline{q}_3$.

It is clear from the figures that the asymptotic limits (with respect to time as opposed to n) of the approximating estimates for the unknown parameters approach the true values of the parameters as n increases. However, it is worth noting that reasonably good estimates are obtained for rather low values of n. This is valuable from a practical point of view. Indeed, the implication is that fewer data are required and that the estimator will be of relatively low dimension. Consequently fewer sensors are required, and the approximating estimator can be integrated more rapidly.

The oscillations which appear in the trajectories of the parameter estimates are a result of the relative levels of input excitation (i.e., f) and dissipation (i.e., q^*). The other tuning parameters (i.e., ω_i, $i=1,2,3$) also play a role in either amplifying or attenuating these oscillations. For an analysis and numerical study of these phenomena, see [8].

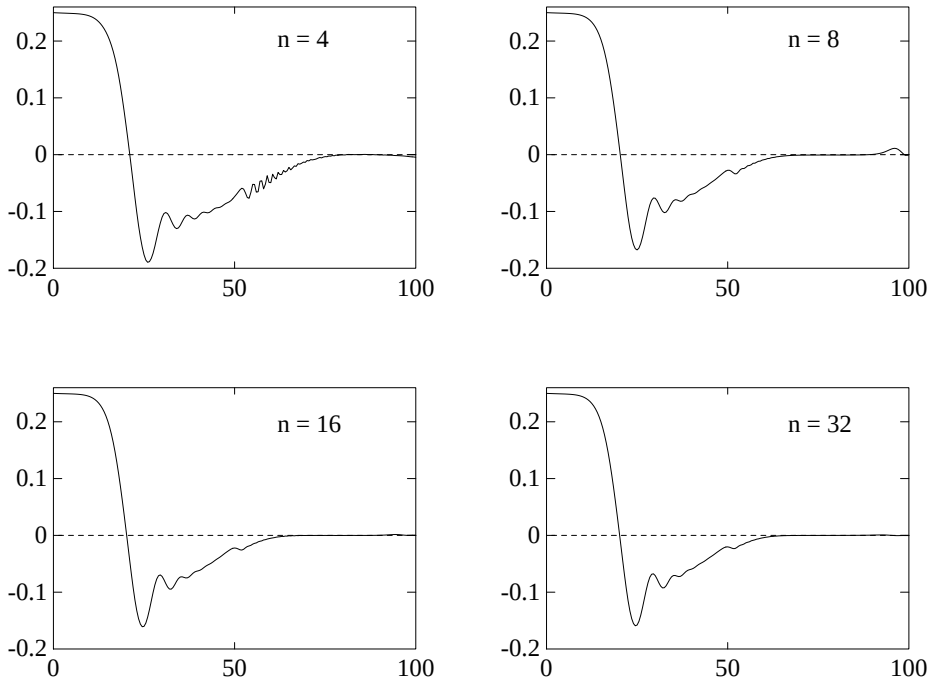

FIG. 6.2. *Estimates for* $\overline{q}_2$ *for* $n = 4, 8, 16, 32$.

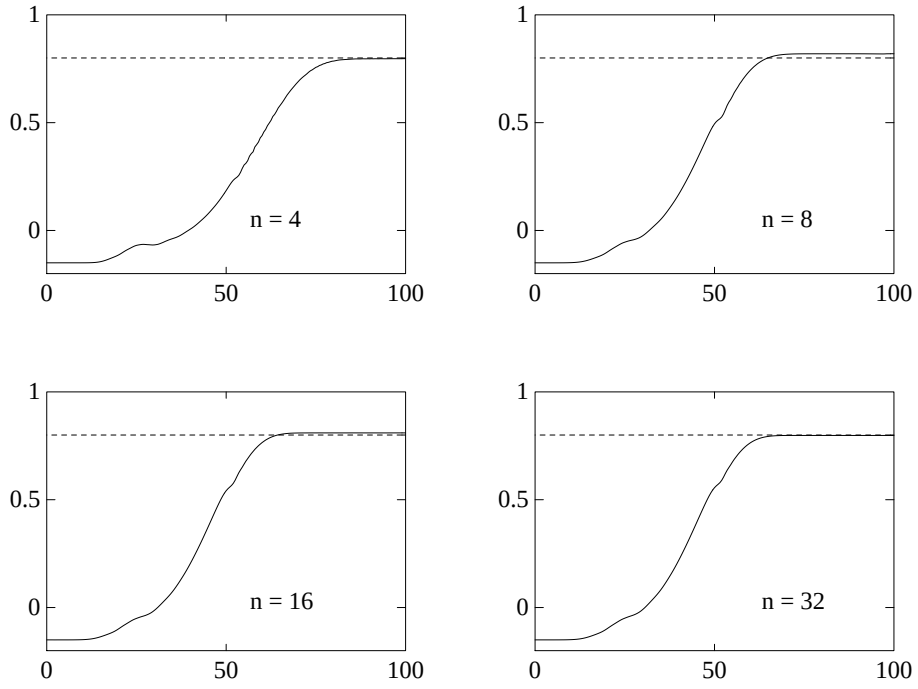

FIG. 6.3. *Estimates for $\overline{q}_3$ for $n = 4, 8, 16, 32$.*

6.2. Example 2. In this example we consider the estimation of the functional parameter q in the one-dimensional heat or diffusion equation

$$\frac{\partial u}{\partial t}(t,x) = \frac{\partial}{\partial x}\left\{q(x)\frac{\partial u}{\partial x}(t,x)\right\} + f(t,x), \quad t > 0, \quad 0 < x < 1,$$

together with the Dirichlet boundary conditions $u(t,0) = 0 = u(t,1)$, $t > 0$. Once again we set $H = L_2(0,1)$ and $V = H_0^1(0,1)$, each endowed with its usual inner product and corresponding induced norm. We let $Q = H^1(0,1)$ and take it to be endowed with the weighted inner product

$$\langle q, p\rangle_Q = \omega_1 \int_0^1 q(x)p(x)dx + \omega_2 \int_0^1 Dq(x)Dp(x)dx, \qquad p, q \in H^1(0,1),$$

where the weights ω_1 and ω_2 are assumed to be positive. When $\omega_2 = 0$, it is equivalent to taking $Q = L_2(0,1)$. For $q \in Q$, the operator $A_0(q) = A_1(q) \in \mathcal{L}(V, V^*)$ is given by

$$\langle A_0(q)\varphi, \psi\rangle = \int_0^1 q(x)D\varphi(x)D\psi(x)dx, \qquad \varphi, \psi \in H^1(0,1).$$

It is easily verified that assumptions (A1) and (A2) are satisfied.

Once again we choose the estimator dynamics $A \in \mathcal{L}(V, V^*)$, to be $A = A_0(q^*)$, for an appropriate choice of $q^* \in Q$. In particular for $x \in [0,1]$, we let $q^*(x) = q^* > 0$ (i.e., a constant function). For such a $q^* \in Q$, assumptions (A3) and (A4) are satisfied.

For $n = 1, 2, \ldots$, we choose the approximating subspaces for the state estimator, H^n, as they were in the previous example. We also use linear B-splines to discretize

the parameter space Q. For each $m = 1, 2, \ldots$, we set $Q^m = \text{span}\{\varphi_j^m\}_{j=0}^m$, where the linear spline basis, $\{\varphi_j^m\}_{j=0}^m$ is given by (6.1) with n replaced by m. Note that dim $H^n = n-1$ and dim $Q^m = m+1$. Consequently the dimension of the approximating estimator is $n-1+m+1 = n+m$.

Once again standard approximation results for linear splines yield that assumption (A5) is satisfied and consequently that the conclusion of Theorem 4.1 holds. If $\omega_2 > 0$, it is also easily verified that assumption (A6) is satisfied and therefore that the conclusion of Theorem 4.2 holds as well.

Define the family of $(n-1)\times(n-1)$ matrices $\{K_k^{n,m}\}_{k=0}^m$ by

$$K_k^{n,m} = [K_k^{n,m}]_{ij} = \int_0^1 \varphi_k^m(x) D\varphi_i^n(x) D\varphi_j^n(x)dx,$$
$$i,j = 0,1,\ldots,n-1, \qquad k = 0,1,\ldots,m.$$

It then follows that the matrix K^n given in (6.4) is given by $K^n = \sum_{k=0}^m K_k^{n,m}$. Let $p^m(t) = [p_0^m(t),\ldots,p_m^m(t)]^T \in \mathbf{R}^{m+1}$ denote the coordinate vector for the approximating estimate $q^m(t)$ with respect to the basis $\{\varphi_j^m\}_{j=0}^m$. That is, $q^m(t) = \sum_{j=0}^m p_j^m(t)\varphi_j^m$, $t > 0$. Taking, for simplicity, the tuning parameter $q^*(x) = q^*$, $x \in [0,1]$, to be constant, the matrix form of the approximating estimator (4.1)–(4.3) with $\overline{u}$ replaced by $\overline{u}_n$ ($\overline{u}_n$ as it was defined in the previous example) is given by

$$M^n\dot{U}^n(t) + q^*K^nU^n(t) + \sum_{k=0}^m p_k^m(t)K_k^{n,m}\overline{U}_n(t) = F^n(t) + q^*K^n\overline{U}_n(t), \qquad t > 0,$$

$$[\Omega^m\dot{p}^m(t)]_k + \overline{U}_n(t)^TK_k^{n,m}\left\{\overline{U}_n(t) - U^n(t)\right\} = 0, \qquad t > 0,\ k = 0,1,2,\ldots,m,$$

where the matrices M^n and K^n are given by (6.6) and (6.4), respectively, U^n is as defined in (6.5), $\overline{U}_n$ is as defined in (6.2) and (6.3), F^n is as given in (6.7), and the $(m+1)\times(m+1)$ matrix Ω^m is given by

$$\Omega^m = [\Omega^m]_{ij} = \frac{\omega_1}{6m}\begin{bmatrix} 2 & 1 & 0 & & & 0 \\ 1 & 4 & \cdot & & & \\ 0 & \cdot & \cdot & \cdot & & \\ & & \cdot & \cdot & \cdot & 0 \\ & & & \cdot & 4 & 1 \\ 0 & & & 0 & 1 & 2 \end{bmatrix} + \omega_2 m \begin{bmatrix} 1 & -1 & 0 & & & 0 \\ -1 & 2 & \cdot & & & \\ 0 & \cdot & \cdot & \cdot & & \\ & & \cdot & \cdot & \cdot & 0 \\ & & & \cdot & 2 & -1 \\ 0 & & & 0 & -1 & 1 \end{bmatrix}.$$

We set $\overline{q}(x) = .1 - .05\sin\{2\pi(x-.25)\}$, $0 < x < 1$, and took f to be as defined in (6.8). We assumed that the plant was initially at rest. To simulate the plant, we used a finite difference–based integrator for parabolic systems from the NAG Library, routine D03PAF. We set $q^* = .01$, $\omega_1 = 1$, and $\omega_2 = 0$. We note that strictly speaking assumption (A6) is not satisfied when $\omega_2 = 0$ (or equivalently when $Q = L_2(0,1)$). Therefore, in this case, Theorem 4.2 does not, in fact, apply. But nevertheless, we were still able to achieve convergence using approximating plant data.

We took the state estimator to be initially at rest and set $q(0,x) = .1$, $0 < x < 1$. In Figure 6.4 we plot estimate time trajectories for q for various values of n and m. The function $\overline{q}$ has also been plotted on the same sets of axes with a solid line. (The initial guess, $q(0,\cdot)$, is also plotted with a solid line.) Once again, reasonably accurate estimates are obtained with relatively low values of n and m. In Figure 6.5 we plot the approximating estimates of $\overline{q}$ at time $t = 100$ for $n = 64$ and $m = 8, 16, 24,$

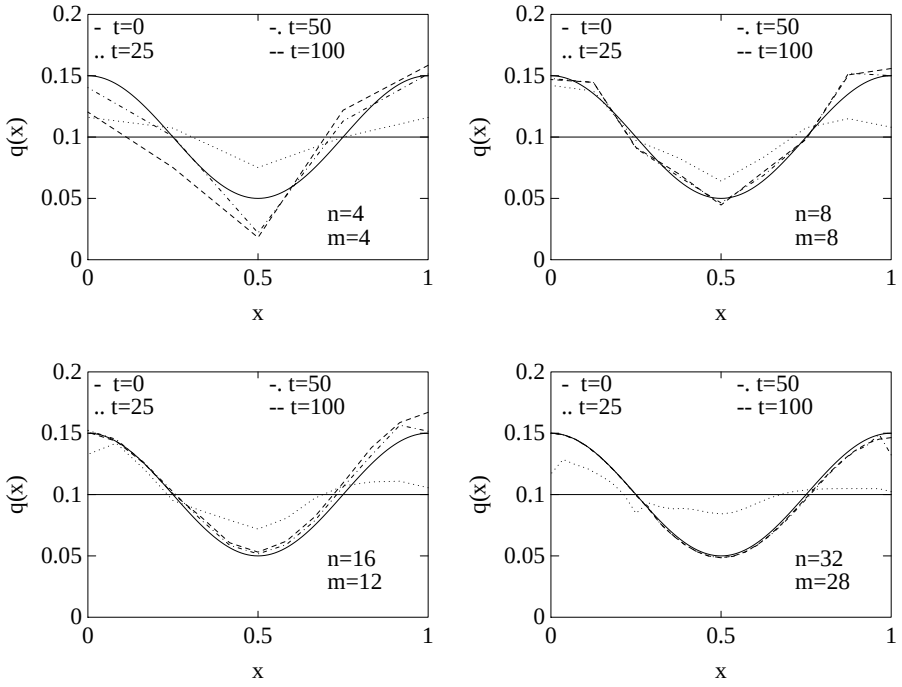

FIG. 6.4. *Estimate trajectories for $\overline{q}$ for various values of n and m.*

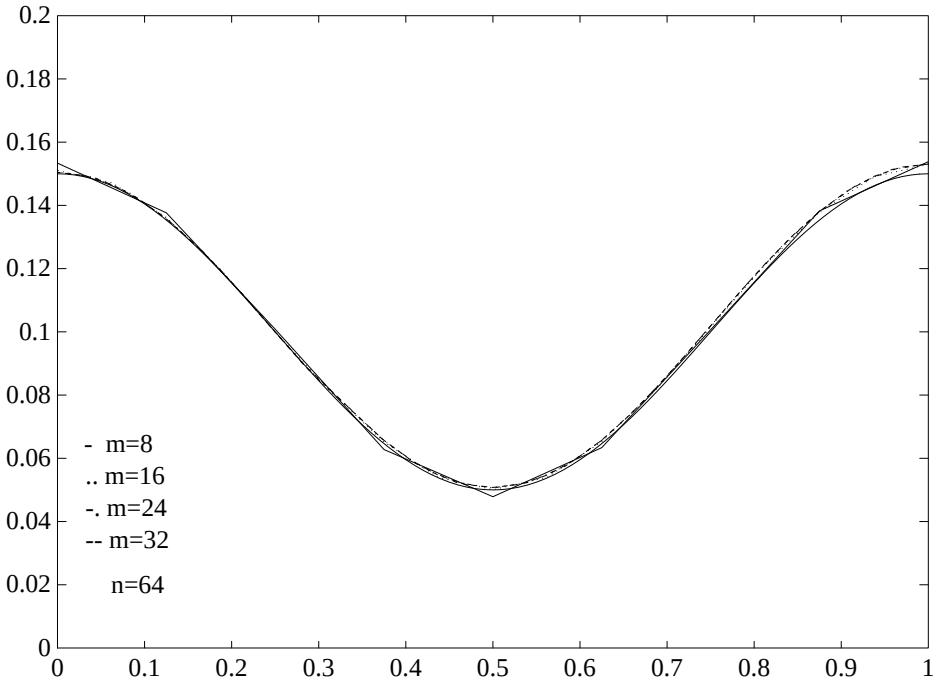

FIG. 6.5. *Estimate for $\overline{q}$ at time $t = 100$ with $n = 64$, $m = 8, 16, 24, 32$.*

and 32. Note that in the last case the dimension of the approximating estimator is $(n-1)+(m+1) = (64-1)+(32+1) = 96$. It is worth noting the high degree of stability exhibited by the scheme. Indeed, the problem of estimating functional coefficients in partial differential equations is well known to be, in general, ill posed. (see, for example, [2]). The instability usually becomes apparent as the value of m increases. For large values of n, we observed no evidence of instability until the value of m started to approach the value of n. We checked this for values of n as large as 64.

6.3. Example 3. In this example we consider the simultaneous estimation of constant stiffness and damping parameters in the one-dimensional wave equation with Kelvin–Voigt viscoelastic damping given by

$$\frac{\partial^2 w}{\partial t^2}(t,x) - q_2 \frac{\partial^2}{\partial x^2}\frac{\partial w}{\partial t}(t,x) - q_1 \frac{\partial^2 w}{\partial x^2} = g(t,x), \qquad t>0,\ 0<x<1, \tag{6.9}$$

with the Dirichlet (fixed endpoint) boundary conditions

$$w(t,0) = 0 = w(t,1), \qquad t>0. \tag{6.10}$$

Applying the theory developed in section 5, we set $H_0 = L_2(0,1)$ and $V_0 = H_0^1(0,1)$, each endowed with its respective usual inner product and corresponding induced norm. We let $Q = \mathbf{R}^2$ with the weighted inner product given by $\langle q,p\rangle = q^T\Omega p$, $q,p \in \mathbf{R}^2$, where Ω is the 2×2 diagonal matrix given by $\Omega = \text{Diagonal}(\omega_1,\omega_2)$, with $\omega_1,\omega_2>0$.

For $q=(q_1,q_2)^T \in Q$ and $i=1,2$, we define the forms $a^i(q;\cdot,\cdot): V_0\times V_0 \to R$ by

$$a^i(q;\varphi,\psi) = q_i \int_0^1 D\varphi(x) D\psi(x)dx, \qquad \varphi,\psi \in H_0^1(0,1).$$

Once again it is easily verified that assumptions (A7)–(A9) are satisfied for $i=1,2$, with the subset $\tilde{Q}$ of Q being the positive orthant of $\mathbf{R}^2$. That is, $\tilde{Q} = \{(q_1^*,q_2^*) \in \mathbf{R}^2 : q_i^*>0, i=1,2\}$.

We again approximate the state estimator using the linear spline basis given by (6.1). Let $H_0^n = \text{span}\{\varphi_j^n\}_{j=1}^{n-1}$, and set $u_1^n(t) = \sum_{j=1}^{n-1} U_1^n(t)_j \varphi_j^n$, $t\ge 0$, and $u_2^n(t) = \sum_{j=1}^{n-1} U_2^n(t)_j\varphi_j^n$, $t\ge 0$. Furthermore, let $\overline{W}_n(t) \in \mathbf{R}^{n-1}$ be the coordinate vector with respect to the basis $\{\varphi_j^n\}_{j=1}^{n-1}$ for the approximating plant $\overline{w}_n(t) = P_n\overline{w}(t)$, where P_n is the orthogonal projection of V_0 onto H_0^n with respect to $V_0 = H_0^1(0,1)$ inner product. The matrix form of the corresponding estimator is then given by

$$q_1^* K^n \dot{U}_1^n(t) - q_1^* K^n U_2^n(t) + \lambda q_1^* K^n U_1^n(t) = \lambda q_1^* K^n \overline{W}_n(t), \qquad t>0,$$

$$\begin{aligned} M^n\dot{U}_2^n(t) &+ q_2^* K^n U_2^n(t) + q_1^* K^n U_1^n(t) + \lambda M^n U_2^n(t) \\ &\quad + q_2^n(t) K^n \dot{\overline{W}}_n(t) + q_1^n(t) K^n \overline{W}_n(t) \\ &= q_2^* K^n \dot{\overline{W}}_n(t) + q_1^* K^n \overline{W}_n(t) + \lambda M^n \dot{\overline{W}}_n(t) + G^n(t), \qquad t>0, \end{aligned}$$

$$\omega_1 \dot{q}_1^n(t) + \overline{W}(t)^T K^n \left(\dot{\overline{W}}_n(t) - U_2^n(t)\right) = 0, \qquad t>0,$$

$$\omega_2 \dot{q}_1^n(t) + \dot{\overline{W}}(t)^T K^n \left(\dot{\overline{W}}_n(t) - U_2^n(t)\right) = 0, \qquad t>0,$$

where the matrices M^n and K^n are given by (6.6) and (6.4), respectively, $q_1^*, q_2^*, \lambda > 0$, and G^n is given by $G^n(t)_j = \int_0^1 g(t,x)\varphi_j^n(x)dx$, $j=1,2,\ldots,n-1$.

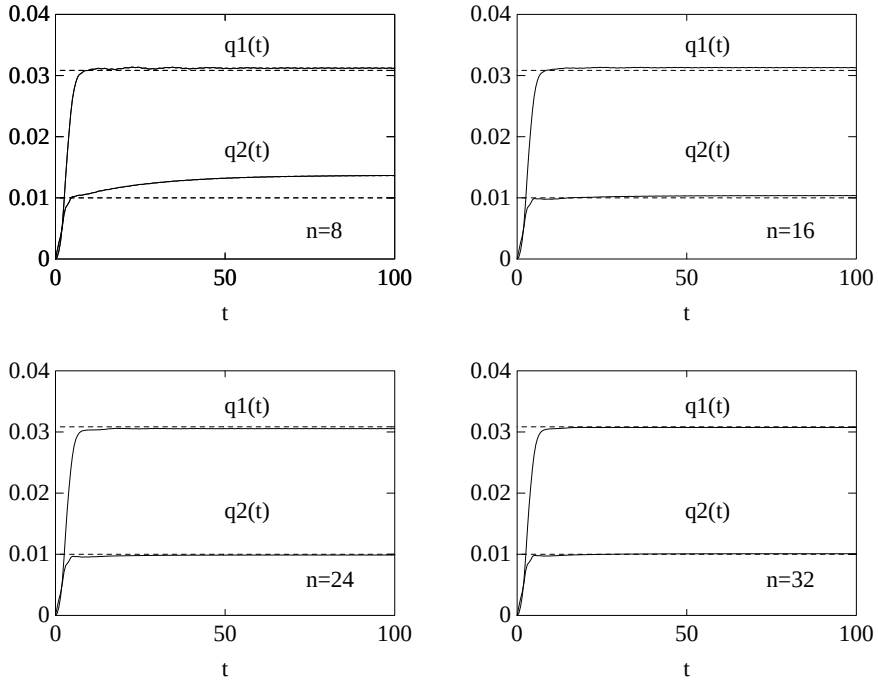

FIG. 6.6. *Estimator trajectories for* $\overline{q}_1$ *and* $\overline{q}_2$ *for* $n = 8, 16, 24,$ *and* 32.

To generate the numerical results that we present below, we set $\overline{q} = (\overline{q}_1, \overline{q}_2)^T = (.0308, .01)^T$, and let $g(t,x) = \{4\sin(4\pi t) + \cos(\pi t) + 2\}\,\chi_{[.215,.315]}(x)$, $t > 0$, $0 < x < 1$. We assumed that the plant was initially at rest and used the IMSL routine DMOLCH (a cubic Hermite polynomial method of lines solver for systems of partial differential equations) to integrate (6.9), (6.10) (together with zero initial data) with $q_i = \overline{q}_i$, $i = 1, 2$, to obtain $\overline{w}(t)$ and $\dot{\overline{w}}(t)$, for $t > 0$. We set $q_1^* = 2 \times 10^{-4}$, $q_2^* = .5$, $\omega_1 = \omega_2 = 53.334$, and $\lambda = 1$. We took the state estimator to be initially at rest and set $q_1^n(0) = q_2^n(0) = 0$ for all n. We integrated the estimator from $t = 0$ to $t = 100$. Our results for $n = 8, 16, 24,$ and 32 are plotted in Figure 6.6. The true values of the parameters, $\overline{q}_1$ and $\overline{q}_2$, are also plotted on the same axes with a dashed line. In Figure 6.7 we plot the Euclidean norm of the parameter error, $|r^n(t)| = \left\{(q_1^n(t) - \overline{q}_1)^2 + (q_2^n(t) - \overline{q}_2)^2\right\}^{\frac{1}{2}}$, from $t = 0$ to $t = 100$, for $n = 8, 16, 24,$ and 32. That convergence is achieved is immediately clear.

6.4. Example 4. In this example we consider the estimation of the thermal conductivity in a one-dimensional nonlinear (strictly speaking, quasi-linear) heat equation. More precisely, we consider the identification of the thermal conductivity, q, in the one-dimensional quasi-linear heat equation

$$\frac{\partial u}{\partial t}(t,x) - \frac{\partial}{\partial x}\left\{q\left(\left|\frac{\partial u}{\partial x}(t,x)\right|\right)\frac{\partial u}{\partial x}(t,x)\right\} = f(t,x), \qquad 0 < x < 1,\ t > 0, \tag{6.11}$$

together with the Dirichlet boundary conditions

$$u(t,0) = 0 \qquad \text{and} \qquad u(t,1) = 0, \qquad t > 0, \tag{6.12}$$

and the initial conditions

$$u(0,x) = u_0(x), \qquad 0 \le x \le 1. \tag{6.13}$$

We assume that $u_0 \in L_2(0,1)$ and $f(t,\cdot) \in L_2(0,1)$ for $t \ge 0$.

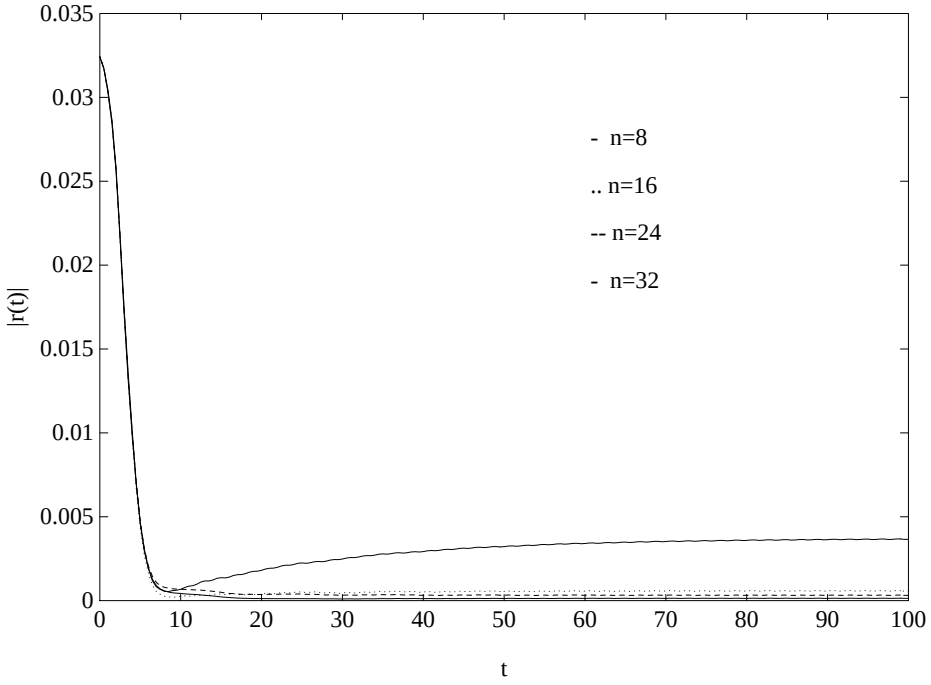

FIG. 6.7. *Euclidean norm of the parameter error for* $n = 8, 16, 24,$ *and* 32.

Let $H = L_2(0,1)$ be endowed with the standard inner product, let $V = H_0^1(0,1)$ be endowed with the usual norm, $\|\varphi\| = \{\int_0^1 |D\varphi(x)|^2 dx\}^{\frac{1}{2}}$, $\varphi \in H_0^1(0,1)$, and define the Hilbert space Q as follows. Let $\hat{Q} = \{\varphi : \varphi \in H^1_{Loc}(\mathbf{R}^+)$ and $\varphi, D\varphi \in L_\infty(\mathbf{R}^+)\}$. Define the inner product, $\langle \cdot, \cdot \rangle_Q$, on $\hat{Q}$ by

$$\langle \varphi, \psi \rangle_Q = \int_0^\infty \omega_0(\theta)\varphi(\theta)\psi(\theta)d\theta + \int_0^\infty \omega_1(\theta)D\varphi(\theta)D\psi(\theta)d\theta, \quad \varphi, \psi \in \hat{Q}, \tag{6.14}$$

where $\omega_0, \omega_1 \in L_1(\mathbf{R}^+)$ are positive weighting functions. Let $|\cdot|_Q$ denote the norm induced by the inner product given in (6.14), and define the Hilbert space Q to be the completion of the inner product space $\{\hat{Q}, \langle \cdot, \cdot \rangle_Q, |\cdot|_Q\}$. For $q \in Q$, let $A_0(q) : V \to V^*$ be given by

$$\langle A_0(q)\varphi, \psi \rangle = \int_0^1 q(|D\varphi(x)|)D\varphi(x)D\psi(x)dx, \qquad \varphi, \psi \in V.$$

It is not difficult to verify that assumptions (A1) and (A2) are satisfied.

For our estimator dynamics, we use a linear constant coefficient heat conduction operator with Dirichlet boundary conditions. That is, we define $A \in \mathcal{L}(V, V^*)$ by

$$\langle A\varphi, \psi \rangle = \alpha \int_0^1 D\varphi(x)D\psi(x)dx, \qquad \varphi, \psi \in V,$$

where $\alpha > 0$. It follows that for $\varphi, \psi \in V$ we have $|\langle A\varphi, \psi \rangle| \leq \alpha\|\varphi\|\|\psi\|$, and $\langle A\varphi, \varphi \rangle \geq \beta\|\varphi\|^2$, with $\beta = \alpha$. Consequently, assumptions (A3) and (A4) are satisfied.

We again approximate the state space using linear B-spline functions. Set $H^n = \text{span}\{\varphi_j^n\}_{j=1}^{n-1}$, where for each $n = 2, 3, \ldots$ and $j = 1, 2, \ldots n-1$, φ_j^n is given by (6.1). We again assume that (6.5) holds and that the plant, $\overline{u}$, is discretized as in (6.2).

We also use linear B-splines to discretize the parameter space Q. For each $m = 1, 2, \ldots$, and each $r > 0$, let $\{\hat{\psi}_j^{m,r}\}_{j=0}^m$ be the standard linear B-splines on the interval $[0, r]$ defined with respect to the uniform mesh $\{0, \frac{r}{m}, \frac{2r}{m}, \ldots, r\}$. Let $Q^{m,r} = \text{span}\{\psi_j^{m,r}\}_{j=0}^m$, where

$$\psi_j^{m,r} = \begin{cases} \hat{\psi}_j^{m,r}, & j = 0, 1, 2, \ldots, m-1, \\ \hat{\psi}_m^{m,r} + \chi_{[r,\infty)}, & j = m, \end{cases}$$

with χ_J denoting the characteristic function for the interval J. If we let $P_Q^{m,r}$ denote the orthogonal projection of Q onto $Q^{m,r}$, the requisite strong convergence to the identity which will ensure that assumption (A5) is satisfied can be demonstrated. Consequently, let $\Omega^{m,r}$ denote the $(m+1) \times (m+1)$ Gram matrix corresponding to the basis $\{\psi_j^{m,r}\}_{j=0}^m$. That is,

$$\Omega^{m,r} = [\Omega_{m,r}]_{i,j}$$

$$= \langle \psi_i^{m,r}, \psi_j^{m,r} \rangle_Q = \int_0^\infty \omega_0(\theta) \psi_i^{m,r}(\theta) \psi_j^{m,r}(\theta) d\theta + \int_0^\infty \omega_1(\theta) D\psi_i^{m,r}(\theta) D\psi_j^{m,r}(\theta) d\theta.$$

For $t \geq 0$, let $p^{m,r}(t) = [p^{m,r}(t)_0, \ldots, p^{m,r}(t)_m]^T \in \mathbf{R}^{m+1}$ denote the coordinate vector for the approximating parameter estimate $q^{m,r}(t)$ with respect to the basis $\{\psi_j^{m,r}\}_{j=0}^m$. That is, $q^{m,r}(t) = \sum_{j=0}^m p^{m,r}(t)_j \psi_j^{m,r}$, $t \geq 0$.

For each $t \geq 0$, define the $(n-1) \times (m+1)$ matrix $B^{n,m,r}(t)$ by

$$[B^{n,m,r}(t)]_{i,j}$$

$$= \int_0^1 \psi_j^{m,r}(|D_x \overline{u}_n(t,x)|) D_x \overline{u}_n(t,x) D\varphi_i^n(x) dx, \quad j = 0, 1, \ldots, m, \;\; i = 1, \ldots, n-1.$$

Using the fact that $\overline{u}_n(t) \in \text{span}\{\varphi_j^n\}_{j=1}^{n-1}$ and the fact that $D\varphi_j^n$ is piecewise constant, and adopting the convention that $\overline{U}_n(t)_0 = \overline{U}_n(t)_n = 0$, we obtain that

$$\begin{aligned} [B^{n,m,r}(t)]_{i,j} = {} & n\psi_j^{m,r}(n\{\overline{U}_n(t)_i - \overline{U}_n(t)_{i-1}\})\{\overline{U}_n(t)_i - \overline{U}_n(t)_{i-1}\} \\ & - n\psi_j^{m,r}(n\{\overline{U}_n(t)_{i+1} - \overline{U}_n(t)_i\})\{\overline{U}_n(t)_{i+1} - \overline{U}_n(t)_i\}, \\ & i = 1, 2, \ldots, n-1, \;\; j = 0, 1, \ldots, m. \end{aligned}$$

The matrix form of the approximating estimator, (4.1)–(4.3), is then given by

$$M^n \dot{U}^n(t) + K^n U^n(t) + B^{n,m,r}(t) p^{m,r}(t) = F^n(t) + K^n \overline{U}_n(t), \qquad t > 0, \tag{6.15}$$

$$\Omega^{m,r} \dot{p}^{m,r}(t) - B^{n,m,r}(t)^T U_n(t) = -B^{n,m,r}(t)^T \overline{U}_n(t), \qquad t > 0, \tag{6.16}$$

$$U_n(0) = (M^n)^{-1} U_0^n, \qquad p^{m,r}(0) = (\Omega^{m,r})^{-1} p_0^{m,r}, \tag{6.17}$$

where the $(n-1)$-vector U_0^n and the $(m+1)$-vector $p_0^{m,r}$ are given by

$$[U_0^n]_i = \int_0^1 u_0(x) \varphi_i^n(x) dx, \qquad i = 1, 2, \ldots, n-1,$$

and

$$[p_0^{m,r}]_i = \langle q_0, \psi_i^{m,r} \rangle_Q$$

$$= \int_0^\infty \omega_0(\theta) q_0(\theta) \psi_i^{m,r}(\theta) d\theta + \int_0^\infty \omega_1(\theta) Dq_0(\theta) D\psi_i^{m,r}(\theta) d\theta, \qquad i = 0, 1, 2, \ldots, m,$$

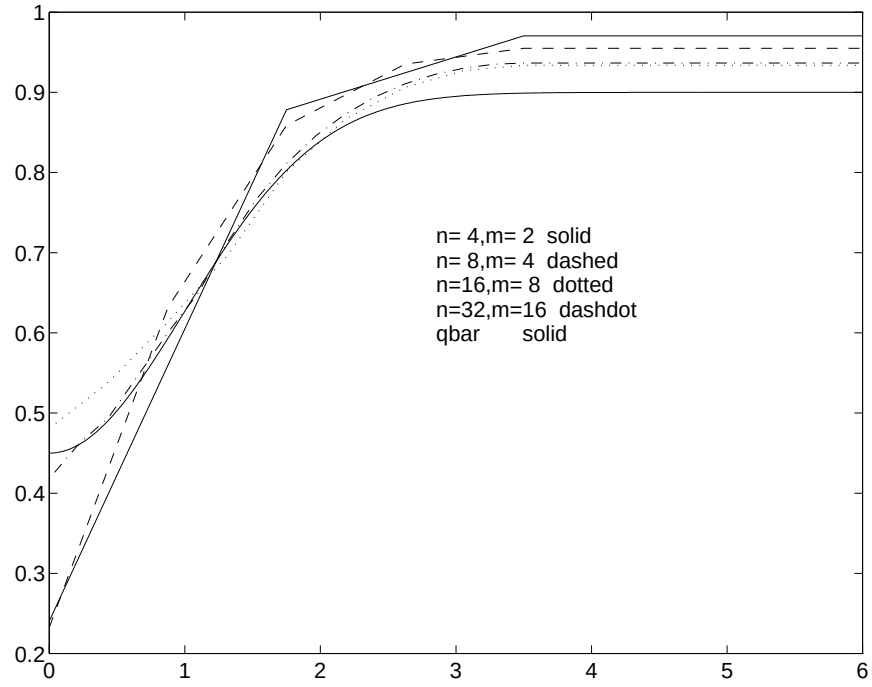

FIG. 6.8. *Final* ($t = 100$) *estimates for* $\overline{q}$ *for* $n = 2^{j+1}$, $m = 2^j$ *for* $j = 1, 2, 3, 4$.

respectively; F^n is given by (6.7); and the $(n-1) \times (n-1)$ matrices M^n and K^n are given by (6.6) and (6.4), respectively.

We set $\overline{q}(\theta) = .9(1 - \frac{1}{2}e^{-\frac{1}{2}\theta^2})$, $\theta \geq 0$, we let f be as it was given in (6.8), $f(t,x) = \{\sin(4\pi t) + 10^{-3}t^2\}\chi_{[.215,.315]}(x)$, $0 < x < 1$, $t > 0$, and set $\overline{u}_0(x) = 0$, $0 < x < 1$. We then proceeded to simulate the plant (i.e., (6.11)–(6.13)) using the IMSL routine DMOLCH, a double-precision Hermite polynomial–based method-of-lines partial differential equation solver. In our estimator, we set $\alpha = 10^{-2}$, $r = 3.5$,

$$\omega_0(\theta) = \omega_1(\theta) = \begin{cases} 1, & 0 \leq \theta < r, \\ \frac{1}{2}e^{-20\theta}, & r < \theta < \infty, \end{cases}$$

$u_0(x) = 0$, $0 < x < 1$, and $q_0(\theta) = 1$, $0 < \theta < \infty$. In Figure 6.8 we have plotted our final (i.e., at time $t = 100$) estimates for $\overline{q}$ for various values of n and m obtained by integrating the approximating estimator equations (6.15)–(6.17). In Figure 6.9 we have plotted the estimates for $\overline{q}$ at various times. These estimates were generated with $n = 32$ and $m = 16$.

7. Summary and concluding remarks. In this paper we have developed, analyzed, and tested an on-line, or adaptive, parameter identification scheme for abstract linear and nonlinear dynamical systems. Our estimator takes the form of an infinite–dimensional linear evolution system whose states consist of a state estimator and a parameter estimator. Using a standard Lyapunov estimate–based argument involving a variation of Barbălat's lemma, we were able to establish convergence of the state estimator. Under the additional assumption that the plant is sufficiently rich, or persistently excited, we were able to argue parameter convergence as well. Equivalently, when the plant is persistently excited, we were able to show that the

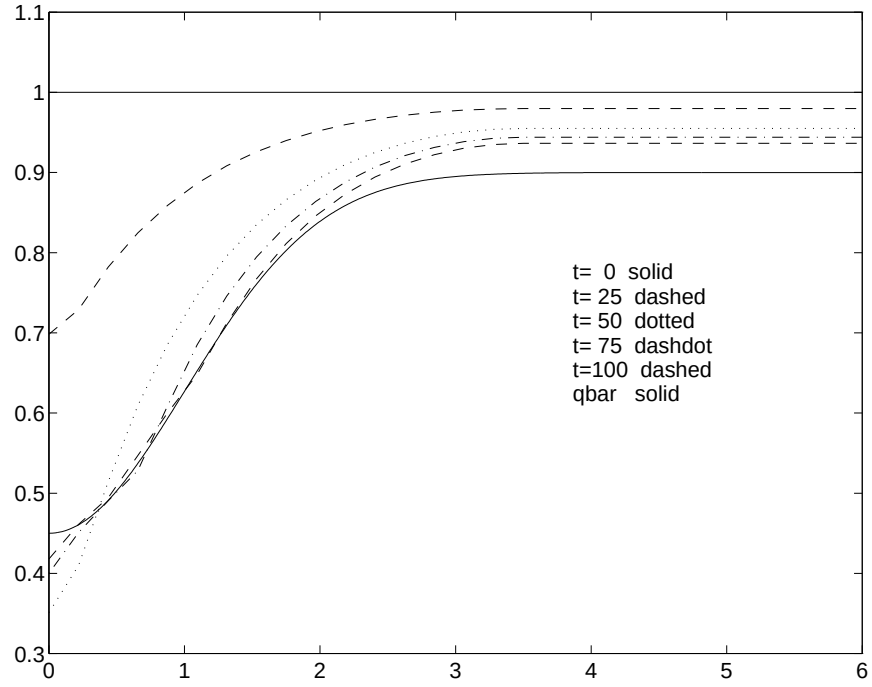

FIG. 6.9. *Estimates for $\bar{q}$ at various times generated with $n = 32$ and $m = 16$.*

solution to the error equations corresponding to the plant dynamics and the estimator with arbitrary initial data tends to the trivial solution as time tends to infinity. Our approach here represents an infinite-dimensional analogue, or extension, of some of the ideas and techniques found in the finite-dimensional treatment in [22]. We also developed a rather complete finite-dimensional approximation theory and established corresponding convergence results. We have considered the application of our general framework to certain classes of second-order systems and presented a number of examples (both first and second order, both linear and nonlinear, and involving both finite- and infinite-dimensional parameter spaces) and corresponding numerical results to demonstrate the feasibility of our schemes.

There are a number of significant extensions and applications of the results that we have presented here that we are currently pursuing. These include the development of a similar estimation theory for more general classes of distributed parameter systems, in particular, delay or hereditary systems and infinite-dimensional systems most appropriately formulated in a Banach space rather than Hilbert space setting. We are currently developing a rather general framework based upon either a single Hilbert space formulation (as opposed to the Gelfand triple approach taken here) or a Banach space formulation, which should be able to handle a significantly wider class of problems than does the treatment presented here. Extending our schemes to parameter estimation problems involving stochastic elements would also be quite useful. For example, these stochastic elements might take the form of noise in the plant measurement or the inclusion of a noise term in the plant dynamics.

A further and more significant extension of our results would involve the introduction of an observer for the purpose of eliminating the requirement that the full state be measured at each time. A modification of our scheme which does not require the entire state but rather only the output of a (finite rank) observation operator,

would represent a significant and valuable improvement. Indeed, even with the recent developments in sensor technology (for example, piezoceramics, fiber optics, and laser scanners) measuring the full state of an infinite-dimensional, or distributed, plant continues to present a substantial and, most likely, costly challenge. On the other hand, the analysis of a scheme such as ours coupled with an observer, is likely to present a significant mathematical challenge. This is because the observer would almost certainly destroy the overall linearity of the estimator. Consequently, a nonlinear stability and convergence analysis would now be required.

Finally, we are interested in using our on-line parameter estimator as a component in an indirect adaptive control algorithm for distributed parameter systems. For example, one approach that we are currently looking at involves using the evolving identified model (i.e., the output from the parameter estimator at any time instant) to design a linear quadratic controller. Such a treatment would be similar in spirit to the approach taken in [9], [10], [11], [12], [13], and [25] using either least squares or maximum likelihood estimators for the unknown parameters. A complete analysis of such a scheme is likely to be a nontrivial exercise as well.

ASYMPTOTICALLY EFFICIENT ADAPTIVE CHOICE OF CONTROL LAWS IN CONTROLLED MARKOV CHAINS*

TODD L. GRAVES† AND TZE LEUNG LAI‡

Abstract. We consider a controlled Markov chain on a general state space whose transition probabilities are parameterized by an unknown parameter belonging to a compact metric space. There is a one-step reward associated with each pair of control and the following state of the process. Given a finite set of stationary control laws, under each of which the Markov chain is uniformly recurrent, an optimal control law in this set is one that maximizes the long-run average reward. In ignorance of the parameter value, we construct an adaptive control rule which uses the optimal control law(s) at a relative frequency of $1-O(n^{-1}\log n)$ and show that this relative frequency gives an asymptotically optimal balance between the control objective and the amount of information needed to learn about the unknown parameter. The basic idea underlying this construction is to introduce suitable "uncertainty adjustments" via sequential testing theory into the certainty-equivalence rule, thus resolving the apparent dilemma between control and information.

Key words. adaptive control of Markov chains, martingales, likelihood ratios, stationary distributions, certainty equivalence, sequential testing, multiarmed bandits

1. Introduction and background.

We consider here a controlled Markov chain $\{X_n, n \geq 0\}$ on a measurable state space $(S, \mathcal{A})$, with a general control set U and a parametric family of transition density functions $p(x, y; u, \theta)$ with respect to some measure M on S, where θ is an unknown parameter taking values in a compact metric space Θ. Thus the transition probability measure under control action u and parameter θ is given by $P_\theta^u(X_{n+1} \in A | X_n = x) = \int_A p(x, y; u, \theta) dM(y)$. The initial distribution of X_0 under P_θ^u is also assumed to be absolutely continuous with respect to M. Let $G = \{g_1, \ldots, g_L\}$ be a finite set of stationary control laws $g_j : S \to U$ such that for every $g \in G$, the transition probability function $\{P_\theta^{g(x)}(x, A) : x \in S, A \in \mathcal{A}\}$ is irreducible with respect to some maximal irreducibility measure and has stationary distribution $\{\pi_\theta^g(A) : A \in \mathcal{A}\}$. Let $r(X_t, u_t)$ represent the one-step reward at time t, where $r : S \times U \to \mathbf{R}$, and define the long-run average reward

$$\mu_\theta(g) = \int r(x, g(x)) d\pi_\theta^g(x), \tag{1.1}$$

which will be assumed to be finite. If θ were known, then one would use the stationary control law $g_{j(\theta)}$ such that

$$\mu_\theta^* := \max_{g \in G} \mu_\theta(g) = \mu_\theta(g_{j(\theta)}). \tag{1.2}$$

In ignorance of θ, a certainty-equivalence control rule is to use the control law $g_{j(\hat{\theta}_t)}$ at time t, where $\widehat{\theta}_t$ is an estimate of θ based on the observed data $X_0, u_0, \ldots, X_{t-1}, u_{t-1}, X_t$ (in chronological order).

For the case of a finite state space S, Mandl [18] studied this certainty-equivalence rule in which $\widehat{\theta}_t$ is a minimum contrast estimate and showed that $\widehat{\theta}_t$ converges almost surely (a.s.) to θ under a restrictive "identifiability condition" and some other regularity conditions. Borkar and Varaiya [6] removed this identifiability condition and showed that when Θ is finite, the maximum likelihood estimate $\widehat{\theta}_t$ converges a.s. to a random variable θ^* such that

$$p(x, y; g_{j(\theta^*)}(x), \theta^*) = p(x, y, g_{j(\theta^*)}(x), \theta) \tag{1.3}$$

for all $x, y \in S$ (finite). They also gave an example for which $\theta^* \neq \theta$ with positive probability, showing that the certainty-equivalence rule can prematurely converge to a wrong parameter value so that it eventually uses only the suboptimal stationary control law $g_j(\theta^*)$ to the exclusion of other control laws.

In view of this difficulty with the certainty-equivalence rule, various modifications of the rule have appeared in the literature. Kumar [11] and Kumar and Varaiya [12] have provided comprehensive surveys of the developments up to the mid-1980s, which include (i) forced choice schemes that reserve some prespecified sparse set of times for experimentation with all stationary control laws in G, (ii) randomization schemes for which every $g \in G$ has a positive probability, whose value is to be determined adaptively from the past data, of being applied at each time, and (iii) using penalized (cost-biased) maximum likelihood estimators $\widehat{\theta}_t$.

1.1. Ideas from bandit theory. The past decade has witnessed other developments in a classical example of adaptive choice from a finite set of control actions, namely, the multiarmed bandit problem. In its simplest form, the problem can be described as follows. There are L statistical populations $\Pi_1, \ldots, \Pi_L$ with univariate density functions $p(y; \theta_1), \ldots, p(y; \theta_L)$ with respect to some measure M. At each time t we can sample from one of these populations, and the reward is the sampled value X_t. Thus the control set U is $\{1, \ldots, L\}$, where control action j refers to sampling from Π_j. An adaptive sampling rule consists of a sequence of random variables $u_1, u_2, \ldots$ taking values in $\{1, \ldots, k\}$ such that the event $\{u_t = j\}$ ("X_{t+1} is sampled from Π_j") belongs to the σ-field generated by $u_0, X_1, u_1, \ldots, X_{t-1}, u_{t-1}, X_t$. Let $\theta = (\theta_1, \ldots, \theta_L)$. If θ were known, then we would sample from the population $\Pi_{j(\theta)}$ with the largest mean; i.e., $\mu_\theta^* := \max_{1 \le j \le L} \mu_\theta(j) = \mu_\theta(j(\theta))$, where $\mu_\theta(j) = \int y p(y; \theta_j) dM(y)$ is assumed to be finite. In ignorance of θ, the problem is to sample $X_1, X_2, \ldots$ sequentially from the k populations to maximize $E_\theta(\sum_{i=1}^n X_i)$, or equivalently to minimize the regret

$$R_n(\theta) = n\mu_\theta^* - E_\theta\left(\sum_{i=1}^n X_i\right) = \sum_{j:\mu_\theta(j)<\mu_\theta^*} (\mu_\theta^* - \mu_\theta(j)) E_\theta T_n(j) \tag{1.4}$$

as $n \to \infty$, where $T_n(j) = \sum_{t=1}^n I_{\{u_{t-1}=j\}}$ and $I_A = 1$ if A occurs, $I_A = 0$ otherwise. Lai and Robbins [16] showed how to construct sampling rules for which $R_n(\theta) = O(\log n)$ at every θ. These rules are called "uniformly good." They also developed asymptotic lower bounds for the regret $R_n(\theta)$ of uniformly good rules and showed that the rules constructed actually attain these asymptotic lower bounds and are therefore asymptotically efficient. Specifically, they showed that under certain

regularity conditions

$$\liminf_{n\to\infty} R_n(\theta)/\log n \geq c(\theta) \tag{1.5}$$

for uniformly good rules and gave an explicit formula for $c(\theta)$ in terms of $\mu_\theta^* - \mu_\theta(j)$ and certain Kullback–Leibler information numbers. A more general representation of the lower bound $c(\theta)$ is given in section 2, where we extend this result on the multiarmed bandit problem to the general setting of adaptive choice of stationary control laws in controlled Markov chains.

Anantharam, Varaiya, and Walrand [5] generalized the results of [16] to the multiarmed bandit problem in which each Π_j represents an aperiodic, irreducible Markov chain on a finite state space S so that successive observations from Π_j are no longer independent but are governed by the Markov transition density $p(x, y; \theta_j)$. Assuming the successive observations from Π_j to be independent with a common density function $p(y; \theta_j)$, Agrawal, Hedge, and Teneketzis [1] incorporated an additional switching cost and showed that the sampling rules of [16] can be modified by sampling in blocks so that the asymptotic lower bound in (1.5) is still attained and the cumulative switching cost up to time n is of the order $o(\log n)$ when no more than one population has the largest mean μ_θ^*.

For the problem of adaptive choice of stationary control laws in controlled Markov chains, switching costs are particularly relevant since it usually takes time to change from a new control strategy to another. We shall assume no switching cost for switching among the (typically equivalent) optimal stationary control laws that attain the maximum in (1.2) and a cost $a(\theta)$ for each switch from one $g \in G$ to another $g' \in G$ when g and g' are not both optimal. An *adaptive control rule* ϕ is a sequence of random variables $\phi_1, \phi_2, \ldots$ taking values in G such that $\{\phi_t = g\} \in \mathcal{F}_t$ for all $g \in G$ and $t \geq 0$, where

$$\mathcal{F}_t = \sigma\text{-field generated by } X_0, \phi_0, \ldots, X_{t-1}, \phi_{t-1}, X_t. \tag{1.6}$$

Defining $\mu_\theta(g)$ and μ_θ^* by (1.1) and (1.2), we generalize (1.4) to controlled Markov chains by letting

$$R_n(\theta) = \sum_{g\in G:\mu_\theta(g)<\mu_\theta^*} (\mu_\theta^* - \mu_\theta(g)) E_\theta T_n(g), \text{ with } T_n(g) = \sum_{i=0}^{n-1} I_{\{\phi_i = g\}}. \tag{1.7}$$

In view of the additional switching cost $a(\theta)$ for each switch between two control laws in G, not both optimal, we define the overall regret to be $R_n(\theta) + a(\theta)S_n(\theta)$, where

$$S_n(\theta) = E_\theta \left(\sum_{i=1}^{n} I_{\{\phi_i \neq \phi_{i-1}, \min(\mu_\theta(\phi_i), \mu_\theta(\phi_{i-1})) < \mu_\theta^*\}} \right). \tag{1.8}$$

An adaptive control rule ϕ is said to be *uniformly good* if

$$R_n(\theta) = O(\log n) \text{ and } S_n(\theta) = o(\log n) \text{ for every } \theta \in \Theta. \tag{1.9}$$

In section 2 we develop an asymptotic lower bound for $R_n(\theta)$ among all uniformly good rules, and in section 3 we construct adaptive control rules that attain this lower bound. These results therefore generalize those of [16] on the multiarmed bandit problem to the setting of adaptive choice of control laws in controlled Markov chains.

A major technical difficulty in this generalization is that unlike Markovian bandit processes in which the state of Π_j is "frozen" until a new observation is sampled from Π_j, for controlled Markov chains X_{t+1} is governed by the immediately preceding state X_t and control action $\phi_t(X_t)$ irrespective of whether $\phi_{t+1} = \phi_t$ or not. We resolve this difficulty by using certain change-of-measure arguments in section 2 and some limit theorems for controlled Markov chains developed in section 4.

This difficulty disappears in the special case where the controlled Markov chain $\{X_t, t \geq 1\}$ is a sequence of independent random variables so that the conditional density of X_{t+1} given $u_t = u$ is $p(y; u, \theta)$. Assuming U and Θ to be finite, Agrawal, Teneketzis, and Anantharam [3] studied this special case by regarding each control action $u \in U$ as an arm and $r(X_1, u_1), r(X_2, u_2), \ldots$ as a sequence of rewards obtained by choosing the arms $u_1, u_2, \ldots$. They noted, however, another difficulty in reducing this problem to the multiarmed bandit problem because of the differences in how the parameter space Θ is defined in the two problems. In the controlled independent sequence problem, θ parameterizes all the arms $u \in U$, whereas in the multiarmed bandit problem $\theta = (\theta_1, \ldots, \theta_k)$ with each θ_j parameterizing the individual arm Π_j. They circumvented this difficulty by making use of the finiteness of Θ and introducing a finite set $B(\theta)$ of "bad" parameter values associated with θ. They thereby obtained an asymptotic lower bound for the regret (1.7) of uniformly good control rules and developed a rule that attains this bound. In section 2, without assuming Θ to be finite, we define the bad set $B(\theta)$ in the setting of controlled Markov chains with general state and parameter spaces. When the state space S, the control set U, and the parameter space Θ are all finite, Agrawal, Teneketzis, and Ananthanam [4] developed a "translation scheme" which together with the construction of an "extended probability space" enabled them to solve the controlled Markov chain problem by converting it to a form similar to that for the controlled independent sequence problem in [3]. This ingenious idea of translation schemes, however, depends heavily on the finiteness of S. Our development of an asymptotic lower bound for (1.7) in section 2 uses a different approach which involves large deviation probabilities for controlled Markov chains on general state spaces S satisfying certain uniform recurrence assumptions.

As a consequence of the translation scheme under their finiteness assumptions, Agrawal, Teneketzis, and Ananthanam [4] obtained the approximation

$$E_\theta \left\{ \sum_{i=0}^{n-1} r(X_i, \phi_i(X_i)) \right\} = \sum_{g \in G} \mu_\theta(g) E_\theta T_n(g) + O(1) \text{ as } n \to \infty. \tag{1.10}$$

Hence in this case (1.7) can be expressed as

$$R_n(\theta) = \widetilde{R}_n(\theta) + O(1), \text{ where } \widetilde{R}_n(\theta) = n\mu_\theta^* - E_\theta \left\{ \sum_{i=0}^{n-1} r(X_i, \phi_i(X_i)) \right\}. \tag{1.11}$$

Note that $\widetilde{R}_n(\theta)$ is the shortfall between the long-run cumulative reward using the optimal stationary control law $g_{j(\theta)}$ and the cumulative reward of the adaptive control rule ϕ. Moreover, by making use of the translation scheme in the development of their asymptotic lower bound for $R_n(\theta)$, Agrawal, Teneketzis, and Ananthanam [4] did not need to impose the constraint on the expected number of switches in (1.9) for uniformly good rules. However, for general state spaces, (1.10) and (1.11) need no longer hold, and there may even exist adaptive control rules for which $\lim_{n\to\infty} \widetilde{R}_n(\theta) = -\infty$ at certain values of θ. This difficulty arises because in the absence of (1.10), the long-run average optimality property (1.2) of the stationary control law $g_{j(\theta)}$ no longer

ensures it to be asymptotically optimal among adaptive control rules that can switch freely among stationary control laws in G. Note that G does not contain such adaptive control rules which are not stationary. We therefore have to put some constraint on the expected number of switches in the adaptive control rules to compare them with the optimal stationary control law $g_{j(\theta)}$ (which makes no switch in G). This can be regarded as a "complexity constraint," consistent with our basic assumption of a *finite* set of *stationary* control policies to reduce the complexity of the Markov control problem. Under the switching constraint that $S_n(\theta) = o(\log n)$ and assuming the transition probability function $\{P_\theta^{g(x)}(x, A) : x \in S, A \in \mathcal{A}\}$ to be uniformly recurrent for every $g \in G$, it is shown in [14] that the "reward regret" $\widetilde{R}_n(\theta)$ is asymptotically equivalent to the more tractable weighted sum (1.7) of expected frequencies of using suboptimal stationary control laws; i.e.,

$$\widetilde{R}_n(\theta) = R_n(\theta) + o(\log n) \text{ as } n \to \infty. \tag{1.12}$$

The constraint on $S_n(\theta)$ in (1.9) relates only to switches between two stationary control laws which are not both optimal when θ is the true parameter. We do not impose the $o(\log n)$ constraint on the expected number of switches between two optimal stationary control laws. In fact, since one cannot infer from the past data which of these optimal stationary control laws is significantly inferior, one is expected to keep switching among them to learn their performance, as in [16] for the multiarmed bandit problem.

1.2. Uncertainty adjustments to the certainty-equivalence rule via sequential testing theory. Lai [13] pointed out the usefulness of sequential testing theory in making uncertainty adjustments of the certainty-equivalence rule, leading to asymptotically optimal rules when the control set is finite. To illustrate this, he considered the following bivariate bandit problem. Let Π_1, Π_2, Π_3 be three bivariate normal populations with respective mean vectors $(\mu_1, \xi), (\mu_2, \mu_3)$, and $(\mu_3, \mu_2 + \xi)$ and with a common known covariance matrix which is equal to the identity matrix. Here $\theta = (\mu_1, \mu_2, \mu_3, \xi)$ is the unknown parameter vector and the problem is to sample $X_1, X_2, \ldots$ sequentially from the three populations in order to maximize the expected value of the first component of $\sum_{i=1}^n X_i$ as $n \to \infty$. The relevant information we need for optimal control can be represented by the three hypotheses $H_j : \mu_j = \max(\mu_1, \mu_2, \mu_3),\ j = 1, 2, 3$. In other words, we do not need to know the actual values of μ_1, μ_2, μ_3, ξ but need only to determine which of μ_1, μ_2, μ_3 is the largest. While information about μ_1 can only be obtained by sampling from Π_1, information about μ_2 and μ_3 can be obtained by sampling from Π_2 alone or from Π_3 and Π_1. Using results from sequential testing theory, Lai [13] constructed an asymptotically optimal rule whose regret (1.7) satisfies $R_n(\theta) = O(1)$ if $\mu_1 = \max(\mu_2, \mu_3)$ and $R_n(\theta) \sim c(\theta) \log n$ otherwise, where

$$\begin{aligned} c(\theta) &= 2/\{\mu_1 - \max(\mu_2, \mu_3)\} \text{ if } \mu_1 > \max(\mu_2, \mu_3) \\ &= 2/(\mu_2 - \mu_1) \text{ if } \mu_2 > \max(\mu_1, \mu_3) \\ &= 2/(\mu_3 - \mu_1) \text{ if } \mu_3 = \mu_2 > \mu_1 \text{ or } \mu_3 > \mu_1 \geq \mu_2 \\ &= 2/(\mu_3 - \mu_1) + 2/(\mu_3 - \mu_2) - 2(\mu_3 - \mu_2)/(\mu_3 - \mu_1)^2 \text{ if } \mu_3 > \mu_2 > \mu_1. \end{aligned}$$

In section 3 we use sequential testing theory to construct asymptotically efficient adaptive control rules in controlled Markov chains. These rules are considerably

simpler than those in [4] which require finiteness of S and Θ for their implementation and for the analysis that shows their regret $R_n(\theta)$ to be of the order $O(\log n)$. The rules in section 3 are applicable to general state spaces S and compact metric spaces Θ, and we prove in section 4 that they attain the asymptotic lower bound $(c(\theta)+o(1))\log n$ for the regret established in section 2.

In summary, by making use of bandit theory and sequential testing methodology, we generalize herein previous work of Agrawal, Tenektetzis, and Ananthanam [4] from the case of finite Θ and S to compact Θ and general state spaces S while still assuming finiteness of G, which is crucial for both the asymptotic lower bound in section 2 and the rules proposed in section 3. This generalization requires certain constraints on the expected number of switches among the stationary control laws in G and uniform recurrence assumptions on the transition probability functions. We construct in section 3 adaptive control rules with regret $R_n(\theta)$ having the asymptotically minimal order $c(\theta)\log n$, where the constant $c(\theta)$ is given in section 2. Using nonparametric sequential testing theory instead of the parametric likelihood ratio approach here and assuming G to be countable instead of finite, Lai and Yakowitz [17] removed the parametric and related assumptions herein and developed adaptive control rules with regret $R_n(\theta)=O(\alpha_n\log n)$ for any given nondecreasing sequence of positive numbers $\alpha_n\to\infty$ and $\alpha_{2n}=O(\alpha_n)$. Earlier, Agrawal and Teneketzis [2] also used a nonparametric approach to construct adaptive control rules with regret $R_n(\theta)=O((\log n))^{1+\delta})$ for any given $\delta>0$ in the case of finite G, Θ, and S so that the translation scheme of Agrawal, Teneketzis, and Ananthanam [4] is applicable.

2. Decomposition of the parameter space and an asymptotic lower bound for the regret of uniformly good rules. Using the same notation as that introduced at the beginning of section 1, define for $g\in G$ the Kullback–Leibler information number

$$I^g(\theta,\lambda)=\int\int\left\{\log\frac{p(x,y;g(x),\theta)}{p(x,y;g(x),\lambda)}\right\}p(x,y;g(x),\theta)dM(y)d\pi_\theta^g(x), \tag{2.1}$$

which will be assumed to be finite for all $\theta,\lambda\in\Theta$. We shall decompose Θ as the union of L subsets: $\Theta=\Theta_1\cup\cdots\cup\Theta_L$, where

$$\Theta_j=\{\theta\in\Theta:\mu_\theta(g_j)=\max_{g\in G}\mu_\theta(g)\}; \tag{2.2}$$

i.e., g_j is an optimal stationary control law if $\theta\in\Theta_j$. For $\theta\in\Theta$, let

$$J(\theta)=\{1\le j\le L:\mu_\theta(g_j)=\max_{g\in G}\mu_\theta(g)(=\mu_\theta^*)\}, \tag{2.3}$$

$$B(\theta)=\left\{\lambda\in\Theta:\ \lambda\notin\bigcup_{j\in J(\theta)}\Theta_j \text{ and } I^{g_j}(\theta,\lambda)=0 \text{ for all } j\in J(\theta)\right\}, \tag{2.4}$$

(2.5)

$$c(\theta)=\inf\left\{\sum_{j\notin J(\theta)}c_j[\mu_\theta^*-\mu_\theta(g_j)]:c_j\in[0,\infty),\ \inf_{\lambda\in B(\theta)}\sum_{j\notin J(\theta)}c_jI^{g_j}(\theta,\lambda)\ge 1\right\}(\inf\emptyset=\infty).$$

Thus, $\{g_j, j\in J(\theta)\}$ is the set of all optimal stationary control laws when θ is the true parameter value, and $B(\theta)$ consists of all "bad" parameter values $\lambda\notin\cup_{j\in J(\theta)}\Theta_j$

which are statistically indistinguishable from θ if one only uses the optimal control laws $g_j, j \in J(\theta)$, because $I^{g_j}(\theta, \lambda) = 0$. Theorem 1 below shows that under certain regularity conditions $(c(\theta) + o(1)) \log n$ is an asymptotic lower bound for the regret (1.7) of uniformly good rules. Note that (2.5) can also be expressed as

(2.6)
$$c(\theta) = \inf \left\{ \frac{\sum_{j \notin J(\theta)} \alpha_j [\mu_\theta^* - \mu_\theta(g_j)]}{\inf_{\lambda \in B(\theta)} \sum_{j \notin J(\theta)} \alpha_j I^{g_j}(\theta, \lambda)} \ : \ \alpha_j \geq 0, \ \sum_{j \notin J(\theta)} \alpha_j = 1 \right\} \ (\inf \emptyset = \infty).$$

This alternative form of the asymptotic lower bound of $R_n(\theta)/\log n$ was obtained by Agrawal, Teneketzis, and Ananthanam [4] when the state space S and the parameter space Θ are finite. Theorem 1 uses a different argument which involves the equivalent form (2.5) of (2.6) to establish the result for general state spaces and compact parameter spaces. We first give some examples to illustrate the computation of $c(\theta)$.

Example 1. Consider the multiarmed bandit problem of section 1.1. Here $\theta = (\theta_1, \cdots, \theta_L)$, $g_j = j$ ("sample from Π_j") and $I^j(\theta, \lambda) = I(\theta_j, \lambda_j)$, where

$$I(a, b) = \int p(y; a) \log[p(y; a)/p(y; b)] dM(y), \ \mu(a) = \int y p(y; a) dM(y). \tag{2.7}$$

Assume that $I(a, b) < \infty$ and that $I(a, b) = 0$ iff $\mu(a) = \mu(b)$, analogous to the assumptions (1.6) and (1.7) of Lai and Robbins [16].

(i) Suppose $L = 2, \Theta = \{(\alpha, \beta), (\beta, \alpha)\}$, and $\mu(\alpha) \neq \mu(\beta)$. Thus, it is known that one population has a specified parameter value α and the other has parameter value β, but it is not known whether Π_1 or Π_2 is associated with α. This is the two-armed bandit problem studied by Feldman [7]. Here $I^1((\alpha, \beta), (\beta, \alpha)) = I(\alpha, \beta) > 0, I^2((\alpha, \beta), (\beta, \alpha)) = I(\beta, \alpha) > 0$, and therefore $B(\theta) = \emptyset, c(\theta) = 0$ for $\theta \in \Theta$. In fact, Feldman's procedure has regret $R_n(\theta) = O(1)$. Lai and Robbins [15] considered more general k-armed bandit problems in which $B(\theta) = \emptyset$ for all $\theta \in \Theta$ and developed sampling rules with $R_n(\theta) = O(1)$.

(ii) Suppose $\Theta = \Delta^L$, where Δ is a compact metric space. For $\theta = (\theta_1, \ldots, \theta_L)$, let $\theta^* \in \{\theta_1, \ldots, \theta_L\}$ be such that $\mu(\theta^*) = \max_{1 \leq i \leq L} \mu(\theta_i)$. Then $J(\theta) = \{1 \leq j \leq L : \mu(\theta_j) = \mu(\theta^*)\}$ and

(2.8)
$$B(\theta) = \left\{ (\lambda_1, \ldots, \lambda_L) \in \Theta : \mu(\lambda_j) = \mu(\theta^*) \text{ for all } j \in J(\theta), \max_{1 \leq i \leq L} \mu(\lambda_i) > \mu(\theta^*) \right\}$$

since $I(a, b) = 0$ iff $\mu(a) = \mu(b)$ by assumption. Assume as in (1.7) of [16] that

$$I(\theta_j, b) \to I(\theta_j, \theta^*) \quad \text{as} \quad \mu(b) \downarrow \mu(\theta^*). \tag{2.9}$$

Consider the minimization problem in (2.5) which reduces here to finding nonnegative numbers $c_j, j \notin J(\theta)$, to minimize $\sum_{j \notin J(\theta)} c_j(\mu(\theta^*) - \mu(\theta_j))$ subject to the constraints

$$\inf_{\lambda \in B_i(\theta)} \sum_{j \notin J(\theta)} c_j I(\theta_j, \lambda_j) \geq 1, \ \ i \notin J(\theta), \tag{2.10}$$

where $B_i(\theta) = \{\lambda \in B(\theta) : \mu(\lambda_i) = \max_{1 \leq s \leq L} \mu(\lambda_s)\}$. For fixed $i \notin J(\theta)$, since $(\theta_1, \ldots, \theta_{i-1}, b, \theta_{i+1}, \ldots, \theta_L) \in B_i(\theta)$ for any $b \in \Delta$ with $\mu(b) > \mu(\theta^*)$, (2.9) and

(2.10) imply that $c_i \geq 1/I(\theta_i, \theta^*)$. Hence $c(\theta) \geq \sum_{j \notin J(\theta)} (\mu(\theta^*) - \mu(\theta_j))/I(\theta_j, \theta^*)$, which is the asymptotic lower bound for $R_n(\theta)/\log n$ given in [16], where sampling rules that attain this lower bound are also constructed for certain parametric families having the monotonicity property

$$I(a, b) \geq I(a, \theta^*) \quad \text{whenever} \quad \mu(b) \geq \mu(\theta^*) \geq \mu(a). \tag{2.11}$$

Under (2.11), $I(\theta_i, \lambda_i)/I(\theta_i, \theta^*) \geq 1$ for all $\lambda \in B_i(\theta)$, and therefore the constraint (2.10) holds with $c_j = 1/I(\theta_j, \theta^*)$, $j \notin J(\theta)$. This choice of c_j therefore solves the minimization problem in (2.5) under the assumptions (2.9) and (2.11), yielding $c(\theta) = \sum_{j \notin J(\theta)} (\mu(\theta^*) - \mu(\theta_j))/I(\theta_j, \theta^*)$.

Example 2. Consider the following variant of Example 1. Let Π_1, Π_2, Π_3 be three univariate normal populations with respective means $\gamma, \xi + 1$, and ξ^2 and common variance 1, where γ and ξ are unknown parameters. Here $\Theta = \{\theta = (\gamma, \xi) : -\infty < \gamma < \infty, -\infty < \xi < \infty\}$, and the problem is to sample $X_1, X_2, \ldots$ sequentially from the three populations to maximize the expected value of $\sum_{i=1}^n X_i$ as $n \to \infty$. Therefore, as in Example 1, $g_j = j$ ("sample from Π_j"), $I^1((\gamma, \xi), (\widetilde{\gamma}, \widetilde{\xi})) = (\gamma - \widetilde{\gamma})^2/2, I^2((\gamma, \xi), (\widetilde{\gamma}, \widetilde{\xi})) = (\xi - \widetilde{\xi})^2/2, I^3((\gamma, \xi), (\widetilde{\gamma}, \widetilde{\xi})) = (\xi^2 - \widetilde{\xi}^2)^2/2$, and

$$\begin{aligned} B(\gamma, \xi) &= \{(\widetilde{\gamma}, \widetilde{\xi}) : \max(\widetilde{\xi} + 1, \widetilde{\xi}^2) > \gamma\} \text{ if } \gamma > \max(\xi + 1, \xi^2) \\ &= \{(\widetilde{\gamma}, \xi) : \widetilde{\gamma} > \xi + 1\} \text{ if } \xi + 1 > \max(\gamma, \xi^2) \\ &= \{(\widetilde{\gamma}, \widetilde{\xi}) : |\widetilde{\xi}| = |\xi|, \max(\widetilde{\gamma}, \widetilde{\xi} + 1) > \xi^2\} \text{ if } \xi^2 > \max(\gamma, \xi + 1). \end{aligned}$$

To compute $c(\theta)$, we can use arguments similar to those in Example 1 to show that

$$c(\gamma, \xi) = 2/(\xi + 1 - \gamma) \text{ if } \xi + 1 > \max(\gamma, \xi^2). \tag{2.12}$$

The case $\gamma > \max(\xi + 1, \xi^2)$ is considerably more complicated, and it is more convenient to use the representation (2.6), which reduces to

$$c(\gamma, \xi) = \inf_{0 \leq \pi \leq 1} \frac{\pi(\gamma - \xi - 1) + (1 - \pi)(\gamma - \xi^2)}{\inf_{\widetilde{\xi}: \widetilde{\xi} + 1 > \gamma \text{ or } \widetilde{\xi}^2 > \gamma} \pi(\xi - \widetilde{\xi})^2/2 + (1 - \pi)(\xi^2 - \widetilde{\xi}^2)^2/2}. \tag{2.13}$$

To solve the minimization problem in (2.13), first fix $\pi \in [0, 1]$ and find $\widetilde{\xi}_\pi$ to minimize $\psi_\pi(\widetilde{\xi}) := \pi(\xi - \widetilde{\xi})^2/2 + (1 - \pi)(\xi^2 - \widetilde{\xi}^2)^2/2$ subject to $\widetilde{\xi} \geq \gamma - 1$ or $|\widetilde{\xi}| \geq \sqrt{\gamma}$. Then find $\pi(\gamma, \xi) \in [0, 1]$ that minimizes $\{\pi(\gamma - \xi - 1) + (1 - \pi)(\gamma - \xi^2)\}/\psi_\pi(\widetilde{\xi}_\pi)$. Note that $d\psi_\pi/d\widetilde{\xi} = -(\xi - \widetilde{\xi})\{\pi + 2(1 - \pi)\widetilde{\xi}(\xi + \widetilde{\xi})\}$, which has zeroes at $\widetilde{\xi} = \xi$ and $\widetilde{\xi} = \frac{1}{2}\{-\gamma + [\gamma^2 - 2\pi/(1 - \pi)]^{1/2}\}$. For example, if $(\gamma, \xi) = (1.69, -1)$, then $\pi(\gamma, \xi) = 0.112$. This is in sharp contrast to (2.12) or Example 1, for which the optimizing π is always 0 or 1 if we use the representation (2.6) to evaluate $c(\theta)$. In section 3 we shall consider the case $\xi^2 > \max(\gamma, \xi + 1)$.

In the following theorem we use the same notation as that introduced at the beginning of section 1. We shall assume that the transition probability function $\{P_\theta^{g(x)}(x, A) : x \in S, A \in \mathcal{A}\}$ is uniformly recurrent for every $\theta \in \Theta$ and $g \in G$; i.e., there exist positive constants $a_\theta^g < b_\theta^g$ such that

$$a_\theta^g \leq p(x, y; g(x), \theta) \leq b_\theta^g \text{ for almost every (with respect to } M) \ x \text{ and } y \tag{2.14}$$

(cf. [9]). This implies that for every $g \in G, \theta \in \Theta$, and $\lambda \in B(\theta)$, there exist positive constants $\alpha_{\theta,\lambda}^g < \beta_{\theta,\lambda}^g$ such that

$$\alpha_{\theta,\lambda}^g \leq p(x, y; g(x), \theta)/p(x, y; g(x), \lambda) \leq \beta_{\theta,\lambda}^g \text{ for } (M\text{-})\text{almost every } x \text{ and } y. \tag{2.15}$$

We consider situations where there are switching costs, for which "uniformly good" rules are defined by (1.9). The following theorem gives an asymptotic lower bound for the regret (1.7) of uniformly good rules.

THEOREM 1. *Under* (2.14), *for any uniformly good rule* ϕ,

$$\liminf_{n\to\infty} \sum_{j\notin J(\theta)} I^{g_j}(\theta,\lambda) E_\theta T_n(g_j)/\log n \geq 1 \text{ for every } \lambda \in B(\theta) \tag{2.16}$$

and therefore

$$\liminf_{n\to\infty} R_n(\theta)/\log n \geq c(\theta) \tag{2.17}$$

for every $\theta \in \Theta$.

Proof. Since $R_n(\theta) = \sum_{j\notin J(\theta)} [\mu_\theta^* - \mu_\theta(g_j)] E_\theta T_n(g_j)$ by (1.7), (2.17) follows from (2.5) and (2.16) (writing $E_\theta T_n(g_j) = c_{j,n} \log n$ and noting that $\inf \emptyset = \infty$). To prove (2.16), it suffices to show that for every $\lambda \in B(\theta)$ and $\epsilon > 0$,

$$\lim_{n\to\infty} P_\theta \left\{ \sum_{j\notin J(\theta)} I^{g_j}(\theta,\lambda) T_n(g_j) \geq (1-\epsilon)\log n \right\} = 1. \tag{2.18}$$

The proof of (2.18) uses a change-of-measure argument similar to that in the proof of Theorem 2 of Lai and Robbins [16] on the multiarmed bandit problem. Since $\lambda \in B(\theta)$, $\lambda \notin \cup_{j\in J(\theta)} \Theta_j$ and therefore $J(\lambda) \cap J(\theta) = \emptyset$. Since ϕ is uniformly good, $E_\lambda\{n - \sum_{i\in J(\lambda)} T_n(g_i)\} = O(\log n)$ by (1.9). For $g \in G$, if

$$0 = I^g(\theta,\lambda) = \int\int p(x,y;g(x),\theta) \log[p(x,y;g(x),\theta)/p(x,y;g(x),\lambda)] dM(y) d\pi_\theta^g(x), \tag{2.19}$$

then $p(x,y;g(x),\theta) = p(x,y;g(x),\lambda)$ for M-almost everywhere (a.e.) x and y (noting that $d\pi_\theta^g/dM > 0$ a.e.$[M]$ by (2.14)), and therefore $\mu_\theta(g) = \mu_\lambda(g)$. Since $\lambda \in B(\theta), \mu_\lambda^* > \mu_\lambda(g_i)$ and $I^{g_i}(\theta,\lambda) = 0$ for all $i \in J(\theta)$. Hence $\mu_\theta(g_i) = \mu_\lambda(g_i) < \mu_\lambda^*$ for all $i \in J(\theta)$, implying that $\mu_\lambda^* > \mu_\theta^*$. For $j \in J(\lambda), \mu_\lambda(g_j) = \mu_\lambda^* > \mu_\theta^* \geq \mu_\theta(g_j)$ and therefore $I^{g_j}(\theta,\lambda) > 0$. It then follows that for all large n,

$$\begin{aligned}
&P_\lambda \left\{ \sum_{j\notin J(\theta)} I^{g_j}(\theta,\lambda) T_n(g_j) < (1-\epsilon)\log n \right\} \\
&\leq P_\lambda \left\{ \sum_{j\in J(\lambda)} I^{g_j}(\theta,\lambda) T_n(g_j) < (1-\epsilon)\log n \right\} \\
&\leq P_\lambda \left\{ \sum_{j\in J(\lambda)} T_n(g_j) \leq n/2 \right\} = P_\lambda \left\{ n - \sum_{j\in J(\lambda)} T_n(g_j) \geq n/2 \right\} \\
&\leq 2n^{-1} E_\lambda \left\{ n - \sum_{j\in J(\lambda)} T_n(g_j) \right\} = O(n^{-1}\log n).
\end{aligned} \tag{2.20}$$

Let $L_n = \sum_{i=0}^{n-1} \log[p(X_i, X_{i+1}, \phi_i(X_i), \theta)/p(X_i, X_{i+1}; \phi_i(X_i), \lambda)]$ and let $0 < \delta < \epsilon/2$. Note that

(2.21)
$$\begin{aligned} &P_\lambda \left\{ \sum_{j \notin J(\theta)} I^{g_j}(\theta, \lambda) T_n(g_j) < (1-\epsilon)\log n, L_n \le (1-\delta)\log n \right\} \\ &= \int_{\left\{\sum_{j \notin J(\theta)} I^{g_j}(\theta,\lambda) T_n(g_j) < (1-\epsilon)\log n, L_n \le (1-\delta)\log n\right\}} e^{-L_n} dP_\theta \\ &\ge e^{-(1-\delta)\log n} P_\theta \left\{ \sum_{j \notin J(\theta)} I^{g_j}(\theta, \lambda) T_n(g_j) < (1-\epsilon)\log n, L_n \le (1-\delta)\log n \right\}. \end{aligned}$$

Combining (2.20) and (2.21) yields

$$\lim_{n\to\infty} P_\theta \left\{ \sum_{j \notin J(\theta)} I^{g_j}(\theta, \lambda) T_n(g_j) < (1-\epsilon)\log n, L_n \le (1-\delta)\log n \right\} = 0. \tag{2.22}$$

Let $h_g(x, y) = \log[p(x, y; g(x), \theta)/p(x, y; g(x), \lambda)]$. For $-\infty < \alpha < \infty$, define the measure

$$\widehat{P}_{x,\alpha,g}(A) = \int_A e^{\alpha h_g(x,y)} p(x, y; g(x), \theta) M(dy), \quad A \in \mathcal{A},$$

and define the linear operator $\widehat{P}_g(\alpha)$ on the space of bounded measurable functions $f : S \to \mathbf{R}$ by $\widehat{P}_g(\alpha) f(x) = \int f(y) \widehat{P}_{x,\alpha,g}(dy)$. In view of (2.14) and (2.15), $\widehat{P}_g(\alpha)$ has a maximal simple real eigenvalue $\rho_g(\alpha)$, with associated right eigenfunction $r_g(\cdot; \alpha) : S \to (0, \infty)$ and left eigenmeasure $\ell_g(\cdot; \alpha) : \mathcal{A} \to [0, \infty)$ normalized so that $\int r_g(x; \alpha) \ell_g(dx; \alpha) = 1$; moreover, $r_g(\cdot; \alpha)$ is bounded and uniformly positive for every fixed α (cf. [10]). For $j \in J(\theta)$, since $\lambda \in B(\theta)$, it follows that $I^{g_j}(\theta, \lambda) = 0$, and therefore by (2.19), $p(x, y; g_j(x), \theta) = p(x, y; g_j(x), \lambda)$; i.e., $h_g(x, y) = 0$, for M-a.e. x and y. Hence

$$L_n = \sum_{i=0}^{n-1} I_{\{\phi_i \notin G_J\}} \log[p(X_i, X_{i+1}; \phi_i(X_i), \theta)/p(X_i, X_{i+1}; \phi_i(X_i), \lambda)] \quad \text{a.s. } [P_\theta],$$

where $G_J = \{g_j : j \in J(\theta)\}$, recalling that the initial distribution of X_0 under P_θ is assumed to be absolutely continuous with respect to M.

Let $\Lambda_g(\alpha) = \log \rho_g(\alpha)$ and define a new probability measure Q_α on the controlled Markov chain by the "twisting" transformation (cf. [9], [10]):

$$Q_\alpha(B) = E_\theta \left\{ I_B \prod_{0 \le i < n : \phi_i \notin G_J} \frac{r_{\phi_i}(X_{i+1}; \alpha)}{r_{\phi_i}(X_i; \alpha)} e^{-\Lambda_{\phi_i}(\alpha) + \alpha h_{\phi_i}(X_i, X_{i+1})} \right\}, \quad B \in \mathcal{F}_n,$$

where $\Pi_{i \in \emptyset} = 1$ and $\mathcal{F}_n$ is the σ-field defined in (1.6). Letting

$$\begin{aligned} B = \Bigg\{ &\sum_{j \notin J(\theta)} I^{g_j}(\theta, \lambda) T_n(g_j) < (1-\epsilon)\log n, \quad L_n > (1-\delta)\log n, \text{ and} \\ &\sum_{i=1}^{n} I_{\{\phi_i \ne \phi_{i-1}, \phi_i \notin G_J\}} \le \delta \log n \Bigg\}, \end{aligned} \tag{2.23}$$

and noting that $L_n = \sum_{0\le i<n:\phi_i\notin G_J} h_{\phi_i}(X_i, X_{i+1})$, it then follows that for $\alpha > 0$,

(2.24)
$$\begin{aligned} &P_\theta(B) \\ &= \int_B \left\{ \prod_{0\le i<n:\phi_i\notin G_J} \frac{r_{\phi_i}(X_i;\alpha)}{r_{\phi_i}(X_{i+1};\alpha)} \right\} \exp\left\{ -\alpha L_n + \sum_{0\le i<n:\phi_i\notin G_J} \Lambda_{\phi_i}(\alpha) \right\} dQ_\alpha \\ &\le e^{-\alpha(1-\delta)\log n} \int_B \left\{ \prod_{0\le i<n:\phi_i\notin G_J} \frac{r_{\phi_i}(X_i;\alpha)}{r_{\phi_i}(X_{i+1};\alpha)} \right\} \exp\left\{ \sum_{j\notin J(\theta)} \Lambda_{g_j}(\alpha) T_n(g_j) \right\} dQ_\alpha \end{aligned}$$

since $L_n > (1-\delta)\log n$ on B. For $j \notin J(\theta)$,

$$\Lambda_{g_j}(0) = 0,\ (d\Lambda_{g_j}/d\alpha)(0) = \int\int h_{g_j}(x,y) p(x,y;g_j(x),\theta) M(dy) \pi_\theta^{g_j}(dx) = I^{g_j}(\theta,\lambda).$$

Therefore, we can choose $\alpha > 0$ sufficiently small so that $\Lambda_{g_j}(\alpha)/\alpha \le (1+\epsilon/2) I^{g_j}(\theta,\lambda)$. Since $\sum_{j\notin J(\theta)} I^{g_j}(\theta,\lambda) T_n(g_j) < (1-\epsilon)\log n$ on B, it then follows that

$$\sum_{j\notin J(\theta)} \Lambda_{g_j}(\alpha) T_n(g_j) < \alpha(1+\epsilon/2)(1-\epsilon)\log n < \alpha(1-\epsilon/2)\log n \text{ on } B. \tag{2.25}$$

Noting that $C := \max_{g\in G} \sup_{x\in S} r_g(x;\alpha) < \infty, D := \min_{g\in G} \inf_{x\in S} r_g(x;\alpha) > 0$ and that $\sum_{i=1}^n I_{\{\phi_i\ne\phi_{i-1},\phi_i\notin G_J\}} \le \delta \log n$ on B, we obtain that

$$\prod_{0\le i<n:\phi_i\notin G_J} \{r_{\phi_i}(X_i,\alpha)/r_{\phi_i}(X_{i+1},\alpha)\} \le (C/D)^{\delta\log n+1} \quad \text{on} \quad B. \tag{2.26}$$

Indeed, letting $i_1 < \cdots < i_m$ denote the elements of $\{1 \le i \le n : \phi_i \ne \phi_{i-1}, \phi_i \notin G_J\}$, we have $\phi_0 = \phi_1 = \cdots = \phi_{i_1-1}, \phi_{i_1} = \phi_{i_1+1} = \cdots = \phi_{i_2-1}, \ldots, \phi_{i_m} = \phi_{i_m+1} = \cdots = \phi_n$, and therefore the left-hand side of (2.26) can be expressed as

$$\{r_{\phi_0}(X_0,\alpha)/r_{\phi_{n-1}}(X_n,\alpha)\} \prod_{t=1}^m \{r_{\phi_{i_t}}(X_{i_t},\alpha)/r_{\phi_{i_t-1}}(X_{i_t},\alpha)\},$$

from which (2.26) follows since $m \le \delta \log n$ on B.

From (2.24)–(2.26), it follows that by choosing δ sufficiently small,

(2.27)
$$P_\theta(B) \le CD^{-1} \exp(\{-\alpha(1-\delta) + \alpha(1-\epsilon/2) + \delta\log(C/D)\}\log n) \to 0 \text{ as } n\to\infty.$$

Since ϕ is uniformly good, (1.9) yields that

(2.28)
$$\begin{aligned} &P_\theta\left\{ \sum_{i=1}^n I_{\{\phi_i\ne\phi_{i-1},\phi_i\notin G_J\}} > \delta\log n \right\} \\ &\le E_\theta\left(\sum_{i=1}^n I_{\{\phi_i\ne\phi_{i-1},\phi_i\notin G_J \text{ or } \phi_{i-1}\notin G_J\}} \right) / (\delta\log n) \to 0 \end{aligned}$$

as $n\to\infty$. From (2.22), (2.23), (2.27), and (2.28), the desired conclusion (2.18) follows.

3. Construction of asymptotically efficient rules. The main idea behind the adaptive control rule ϕ^* presented in this section is to introduce suitable "uncertainty adjustments" into the certainty-equivalence rule that uses the control law $g_{j(\widehat{\theta}_t)}$ at time t, where $j(\theta)$ is defined in (1.2) and $\widehat{\theta}_n$ is the following weighted maximum likelihood estimate of θ at time n:

$$\widehat{\theta}_n = \arg\max_{\theta\in\Theta} L_n(\theta),$$
$$L_n(\theta) = \sum_{g\in G}(T_n(g))^{-1} \sum_{1\le t\le n, \phi^*_{t-1}=g} \log p(X_{t-1}, X_t; g(X_{t-1}), \theta), \tag{3.1}$$

if the maximizer in (3.1) exists, as is the case when p is a continuous function of θ, since Θ is assumed to be compact. If the maximizer in (3.1) does not exist, then we define $\widehat{\theta}_n$ as an ϵ_n-maximizer of $L_n(\theta)$ in the sense that $L_n(\widehat{\theta}_n) \ge \sup_{\theta\in\Theta} L_n(\theta) - \epsilon_n$, where ϵ_n are positive numbers such that $\lim_{n\to\infty}\epsilon_n = 0$. The asymptotic lower bounds in section 2 provide valuable insights into how the uncertainty adjustments should be made and quantify the need for experimentation with the inferior control laws. In particular, they suggest that the total amount of experimentation with an inferior control law g_j up to time n should be at least of the order $\{c_j(\theta)+o(1)\}\log n$, where the $c_j(\theta)$ solve the minimization problem that defines $c(\theta)$ in (2.5); i.e.,

$$c(\theta) = \sum_{j\notin J(\theta)} c_j(\theta)[\mu^*_\theta - \mu_\theta(g_j)] \text{ and } \inf_{\lambda\in B(\theta)} \sum_{j\notin J(\theta)} c_j(\theta) I^{g_j}(\theta,\lambda) = 1 \text{ if } B(\theta)\neq\emptyset, \tag{3.2}$$
$$c_j(\theta) = 0 \text{ for all } j\notin J(\theta) \text{ if } B(\theta)=\emptyset.$$

Example 1 (continuation). We have shown in the multiarmed bandit problem of Example 1(ii) that $c_j(\theta) = 1/I(\theta_j,\theta^*)$ if $j\notin J(\theta)$. This suggests that to achieve the asymptotic lower bound $(c(\theta)+o(1))\log n$ for the regret, the sampling rule should take $(1/I(\theta_j,\theta^*)+o(1))\log n$ observations, up to stage n, from an inferior population Π_j to determine whether it is indeed inferior. If the sampling rule should indeed attain the asymptotic lower bound, then it would take $n - O(\log n)$ observations, up to stage n, from the population with mean $\mu(\theta^*)$, so we can regard the value of $\mu(\theta^*)$ as known with relatively negligible uncertainty in this case. The problem of determining whether Π_j has a larger mean than $\mu(\theta^*)$ then becomes that of testing the null hypothesis $H_j : \mu(\theta_j) > \mu(\theta^*)$. The theory of optimal stopping and sequential analysis shows that subject to the constraint that the probability of rejecting H_j when it is true be $\le\alpha$, the expected number of observations from Π_j of a sequential test under the alternative hypothesis is at least $\{1/I(\theta_j,\theta^*)+o(1)\}|\log\alpha|$ as $\alpha\to 0$, and there are sequential tests based on generalized likelihood ratio statistics or mixture likelihood ratio statistics that attain this asymptotic lower bound for the expected sample size. The construction of asymptotically efficient sampling rules in section 4 of [16] uses this sequential testing theory, with $|\log\alpha| \sim |\log n|$, although the procedure is described there in terms of certain "upper confidence bounds."

Example 2 (continuation). Here the $c_j(\theta)$ are considerably more complicated than those in Example 1. The means of the normal populations Π_1,Π_2,Π_3 are $\gamma, \xi+1$, and ξ^2, involving only two unknown parameters γ (which has to be learned from Π_1) and ξ (which can be learned from Π_2 or Π_3). If $\xi+1>\gamma$ and $\xi+1\ge\xi^2$, sampling from the superior population Π_2 would give information about the means of both Π_2 and Π_3, and therefore the same argument as that in Example 1 yields $c_1(\gamma,\xi) = 2/(\xi+1-\gamma)^2$, $c_3(\gamma,\xi)=0$, which in turn gives (2.12) as the solution of the minimization problem (2.5).

In the case $\xi^2 > \gamma$ and $\xi^2 \geq \xi+1$, sampling from the superior population Π_3 would give information about $|\xi|$ but not about the sign of ξ, which has to be learned from Π_2. If $\xi^2 \geq \xi + 1$ and $\xi^2 \geq -\xi + 1$ or, equivalently, if $\xi \notin ((-1-\sqrt{5})/2, (1-\sqrt{5})/2)$, then $B(\gamma,\xi) = \{(\widetilde{\gamma},\widetilde{\xi}) : |\widetilde{\xi}| = |\xi|, \max(\widetilde{\gamma},\widetilde{\xi}+1) > \xi^2\} = \{(\widetilde{\gamma},\xi) : \widetilde{\gamma} > \xi^2\}$, and the same argument as in Example 1 yields $c(\gamma,\xi) = 2/(\xi^2-\gamma)$, $c_1(\gamma,\xi) = 2/(\xi^2-\gamma)^2$, $c_2(\gamma,\xi) = 0$. On the other hand, if $-\xi+1 > \xi^2$, then $B(\gamma,\xi) = \{(\widetilde{\gamma},\widetilde{\xi}) : |\widetilde{\xi}| = |\xi|, \widetilde{\gamma} > \xi^2$ or $\widetilde{\xi}+1 > \xi^2\}$, and putting this in (2.5) yields

$$c_1(\gamma,\xi) = \frac{1}{(\xi^2-\gamma)^2/2}, \quad c_2(\gamma,\xi) = \frac{1}{(2\xi)^2/2}, \quad c(\gamma,\xi) = \frac{2}{\xi^2-\gamma} + \frac{\xi^2-\xi-1}{2\xi^2}. \tag{3.3}$$

In the case $\gamma > \max(\xi+1, \xi^2)$, (2.13) yields

$$c_2(\gamma,\xi) = \pi(\gamma,\xi)/\psi_{\pi(\gamma,\xi)}(\widetilde{\xi}_{\pi(\gamma,\xi)}), \quad c_3(\gamma,\xi) = (1-\pi(\gamma,\xi))/\psi_{\pi(\gamma,\xi)}(\widetilde{\xi}_{\pi(\gamma,\xi)}), \tag{3.4}$$

where $\psi_\pi(\widetilde{\xi})$, $\widetilde{\xi}_\pi$, and $\pi(\gamma,\xi)$ are defined in the two sentences following (2.13). For the case $\gamma = \xi + 1 \geq \xi^2$, sampling from Π_2 will give information about ξ, from which one can learn that Π_3 has mean ξ^2, and $B(\gamma,\xi) = \emptyset$ in this case. If $\gamma = \xi^2 \geq \xi + 1$ with $\xi \notin (-(1-\sqrt{5})/2, (1-\sqrt{5})/2)$, then $\xi^2 \geq \xi + 1$ and $\xi^2 \geq -\xi + 1$, and knowledge of ξ^2 will show that Π_2 does not have a larger mean than Π_3, so $B(\gamma,\xi) = \emptyset$ in this case. If $\gamma = \xi^2 > \xi + 1$ and $(-1-\sqrt{5})/2 < \xi < (1-\sqrt{5})/2$, then $-\xi + 1 > \xi^2$ and $B(\gamma,\xi) = \{(\gamma,-\xi)\}$, so putting this in (2.5) yields

$$J(\gamma,\xi) = \{1,3\}, \quad c_2(\gamma,\xi) = 2/(2\xi)^2, \quad c(\gamma,\xi) = (\xi^2-\xi-1)/(2\xi^2). \tag{3.5}$$

The main idea behind the uncertainty adjustments, presented below, to certainty-equivalence rules in controlled Markov chains is to apply sequential testing theory to assess whether an inferior-looking control law is indeed inferior on the basis of all the current and past observations. We shall use sequential likelihood ratio tests of composite hypotheses in general stochastic systems to test the null hypothesis that θ belongs to Θ_i, with prescribed error probability of wrongly rejecting the null hypothesis when it is true and with asymptotically minimal expected waiting time to reject the null hypothesis when it is false. In the present context, the "waiting time" has to be interpreted broadly as a weighted sum of the number of times that an inferior control law g_j is used. Because of switching costs and because of the technical difficulties in controlled Markov chains due to the change of the transition probability function P^g whenever the control law is changed, we shall designate blocks of successive times to use control law g_j for an entire block if the sequential likelihood ratio test performed at the beginning of the block does not reject the hypothesis that θ belongs to Θ_j.

Since θ is unknown, it is natural to replace $c_j(\theta)$ by $c_j(\widehat{\theta}_t)$, where $\widehat{\theta}_t$ is the weighted maximum likelihood estimate defined in (3.1), as in the "certainty-equivalent" testing phase of the control scheme described below. This certainty equivalence approach raises the question concerning how well $c_j(\widehat{\theta}_t)$ approximates $c_j(\theta)$. When one does not have enough information to estimate θ well, an alternative approach is to ignore the constants $c_j(\theta)$ and to experiment equally with each stationary control law, as is done in the following control scheme during its "evenly allocated" testing phase. The control scheme takes an integer $a \geq 2$ and initializes with a common control law for times $1, \ldots, a$.

Outline of control scheme between times a^i and a^{i+1}. Let n_i be positive integers such that

$$n_i \sim i/\log i \quad \text{as} \quad i \to \infty. \tag{3.6}$$

For fixed i, we now describe our control scheme at times $n \in \{a^i+1, \ldots, a^{i+1}\}$, which we partition into $m(i) := [(a^{i+1}-a^i)/n_i]$ blocks of consecutive integers, each block of length n_i except possibly the last one whose length may range from n_i to $2n_i - 1$. Label these blocks as $B^i_1, \ldots, B^i_{m(i)}$ so that the mth block begins at time $\nu_i(m) := a^i + 1 + (m-1)n_i$ for $1 \le m \le m(i)$. To begin with, at time a^i compute the weighted maximum likelihood estimate $\widehat{\theta}_{a^i}$ of θ. To this estimate corresponds a set $\{g_j : j \in J(\widehat{\theta}_{a^i})\}$ of apparently optimal stationary control laws, where $J(\theta)$ is defined in (2.3). We use $c_j(\widehat{\theta}_{a^i})$ to define below the "certainty-equivalent" testing phase (during the period from time a^i+1 to a^{i+1}), whose objective is to test sequentially whether $\theta \notin \cup_{j \in J(\widehat{\theta}_{a^i})} \Theta_j$. The certainty-equivalent testing phase is continued until we either (i) switch to the "evenly allocated" testing phase or (ii) terminate testing and use the same (apparently optimal) stationary control law up to time a^{i+1}. This adaptive control rule will be denoted by ϕ^*. Let $\mathcal{C}_i$ denote the set of times belonging to all those blocks B^i_m that begin with certainty-equivalent testing (at $\nu_i(m)$). Let

$$\mathcal{C} = \bigcup_{s=1}^{\infty} \mathcal{C}_s, \quad \tau_n(g) = \sum_{t=0}^{n-1} I_{\{t \in \mathcal{C}, \phi^*_t = g\}} \quad \text{for} \quad g \in G. \tag{3.7}$$

Thus, $\tau_n(g)$ is the total number of times $t < n$, within these certainty-equivalent-tested blocks, that use the control law $g \in G$. For $t \in \mathcal{C}$, let

$$\widehat{G}_{J,t} = \{g_j : j \in J(\widehat{\theta}_{a^s})\} \quad \text{if} \quad t \in \mathcal{C}_s, \tag{3.8}$$

which is the set of apparently optimal stationary control laws used for the certainty-equivalent test (3.11) below.

The certainty-equivalent testing phase. During the first L or fewer blocks of the certainty-equivalent testing phase, we use in succession the stationary control laws $g_j (j \in L)$ with $\tau_{a^i}(g_j) < n_i$. Suppose $\{1 \le j \le L : j \notin J(\widehat{\theta}_{a^i})$ and $\tau_{a^i}(g_j) < (\log a^i)[c_j(\widehat{\theta}_{a^i}) \wedge \log i]\} = \{j_1, \ldots, j_N\}$. The next blocks of stages use g_{j_1} until time $\nu_i(m_1) - 1$ and then use g_{j_2} until time $\nu_i(m_2) - 1$, etc., where

$$m_k = \inf\{m > m_{k-1} : \tau_{\nu_i(m)}(g_{j_k}) \ge (\log a^i)[c_{j_k}(\widehat{\theta}_{a^i}) \wedge \log i]\}, \quad k = 1, \ldots, N. \tag{3.9}$$

For $m \ge m_N$, alternate using the stationary control laws g_j (one for each block of consecutive times) that satisfy either (i) $j \notin J(\widehat{\theta}_{a^i})$ and

$$\tau_{\nu_i(m)}(g_j) \le (2\log a^i)\{c_j(\widehat{\theta}_{a^i}) \wedge \log i\} + n_i \ \text{ and } \ g_j \ \text{ has not been eliminated} \tag{3.10a}$$

or (ii) $j \in J(\widehat{\theta}_{a^i})$ and

$$\tau_{\nu_i}(m)(g_j) \le (2\log a^i)\log i + n_i. \tag{3.10b}$$

Sequential testing of the hypotheses $H_j : \theta \in \Theta_j$, $j \notin J(\widehat{\theta}_{a^i})$, is performed at times $\nu_i(m)$ with $m \ge m_N$, and we eliminate g_j from further use through time a^{i+1} once the hypothesis H_j is rejected. Rejection of H_j occurs at the first time $n = \nu_i(m)$ with $m \ge m_N$ when

$$\inf_{\lambda \in \Theta_j} \max \left\{ \frac{\int \Pi_{1 \le t \le n, t-1 \in \mathcal{C}, \phi^*_{t-1} \notin \widehat{G}_{J,t}} p(X_{t-1}, X_t; \phi^*_{t-1}(X_{t-1}), \theta) dF(\theta)}{\Pi_{1 \le t \le n, t-1 \in \mathcal{C}, \phi^*_{t-1} \notin \widehat{G}_{J,t}} p(X_{t-1}, X_t; \phi^*_{t-1}(X_{t-1}), \lambda)}, \right.$$
$$\left. \frac{\int \Pi_{1 \le t \le n, T_{t-1}(\phi^*_{t-1}) \ge a^{i-1}/L} \, p(X_{t-1}, X_t; \phi^*_{t-1}(X_{t-1}), \theta) dF(\theta)}{\Pi_{1 \le t \le n, T_{t-1}(\phi^*_{t-1}) \ge a^{i-1}/L} \, p(X_{t-1}, X_t; \phi^*_{t-1}(X_{t-1}), \lambda)} \right\} \ge ia^i, \tag{3.11}$$

where $\inf \emptyset = \infty$, $\Pi_{t=\emptyset} = 1$, F is a probability measure on Θ such that $F(A) > 0$ for all open subsets A of Θ, and $\mathcal{C}$ and $\widehat{G}_{J,t}$ are defined in (3.7) and (3.8). Certainty-equivalent testing is terminated when (3.10a) fails for all $j \notin J(\widehat{\theta}_{a^i})$. If only one stationary control law g_{j^*} is not eliminated at the termination of certainty-equivalent testing, we use g_{j^*} up to time a^{i+1}. Otherwise we switch to the evenly allocated testing phase.

The evenly allocated testing phase. This testing phase does not use the maximum likelihood estimate $\widehat{\theta}_{a^i}$, its associated set $J(\widehat{\theta}_{a^i})$, and the estimates $c_j(\widehat{\theta}_{a^i})$ that have been used in (3.9)–(3.11). Sequential testing of the hypotheses $H_j : \theta \in \Theta_j$ is performed at the times $\nu_i(m)$ for those g_j not yet eliminated (during the times $\nu_i(m')$ between a^i and a^{i+1} with $m' < m$, which include the times of certainty-equivalent testing) in succession in ascending order of j, and we eliminate g_j from further use through time a^{i+1} once the hypothesis H_j is rejected. We reject H_j at the test time $n = \nu_i(m)$ if

$$\inf_{\lambda\in\Theta_j} \max\left\{ \frac{\int \Pi_{1\le t\le n,\phi^*_{t-1}=g_j} p(X_{t-1},X_t;\phi^*_{t-1}(X_{t-1}),\theta)dF(\theta)}{\Pi_{1\le t\le n,\phi^*_{t-1}=g_j} p(X_{t-1},X_t;\phi^*_{t-1}(X_{t-1}),\lambda)}\right. , \tag{3.12}$$

$$\left. \frac{\int \Pi_{1\le t\le n,T_{t-1}(\phi^*_{t-1})\ge a^{i-1}/L}\ p(X_{t-1},X_t;\phi^*_{t-1}(X_{t-1}),\theta)dF(\theta)}{\Pi_{1\le t\le n,T_{t-1}(\phi^*_{t-1})\ge a^{i-1}/L}\ p(X_{t-1},X_t;\phi^*_{t-1}(X_{t-1}),\lambda)} \right\} \ge ia^i.$$

The "even" allocation rule alternates using the stationary control laws that have not been eliminated, one for each block B^i_m of consecutive times. The testing phase terminates as soon as all except one stationary control law have been eliminated, and we use the remaining stationary control law up to time a^{i+1}. For example, a typical pattern of the evenly allocated phase, sampling from four control laws labeled $1, 2, 3, 4$, is

$$1\cdots1\ 2\cdots2\ 3\cdots3\ 4\cdots4\ 1\cdots1\ 2\cdots2_{\uparrow}3\cdots3\ 4\cdots4\ 1\cdots1\ 3\cdots3\ 4\cdots4_{\downarrow}1\cdots1\ 3\cdots3\ 1\cdots1_{*},$$

where $\uparrow$ denotes the time at which 2 is eliminated, $\downarrow$ denotes the time at which 4 is eliminated, and $*$ denotes the time at which the testing phase terminates with the elimination of 1, leaving behind only the control law 3.

In the certainty-equivalent testing phase, we consider the maximum of two mixture likelihood ratio statistics instead of combining them into a single mixture likelihood ratio because we have different roles in mind for the two statistics. One of them has the form

$$\frac{\int \prod_{1\le t\le n,T_{t-1}(\phi^*_{t-1})\ge a^{i-1}/L} p(X_{t-1},X_t;\phi^*_{t-1}(X_{t-1}),\theta)dF(\theta)}{\prod_{1\le t\le n,T_{t-1}(\phi^*_{t-1})\ge a^{i-1}/L} p(X_{t-1},X_t;\phi^*_{t-1}(X_{t-1}),\lambda)}. \tag{3.13}$$

Controls from G that have been used most often as in (3.13) would thus provide accurate information about many of the characteristics of the unknown parameter but are incapable of distinguishing the true parameter θ_0 from the candidate values in $B(\theta_0)$, and therefore may not be able to settle whether $H_j : \theta \in \Theta_j$ is true. The controls in the complement of $\widehat{G}_{J,t}$, which make up the other mixture likelihood ratio statistic, are therefore needed to distinguish θ_0 from $B(\theta_0)$, but they would be used relatively infrequently. Similar reasoning has led us to replace the usual maximum likelihood estimate by a weighted version with weights $(T_n(g))^{-1}$ in (3.1). Since $\inf_{\lambda\in\Theta_j} = 1/\sup_{\lambda\in\Theta_j}$, the $\inf_{\lambda\in\Theta_j}$ in (3.11) is essentially tantamount to taking the

supremum of the denominator of (3.13) over $\lambda \in \Theta_j$, which is typically done in generalized likelihood ratio tests of the composite null hypothesis $H_j : \theta \in \Theta_j$. Our modification of the usual generalized likelihood ratio statistics consists of replacing $\sup_{\theta\in\Theta}$ by an integral with respect to a probability measure on Θ in the numerator of (3.13) and replacing a single likelihood ratio statistic by the maximum of two likelihood ratio statistics. The evenly allocated testing phase does not make use of $\widehat{\theta}_{a^i}$ and $\widehat{G}_{J,t}$. To test $H_j : \theta \in \Theta_j$, it uses the maximum of (3.13) and another mixture likelihood ratio statistic, which has the form (3.13) but with $T_{t-1}(\phi^*_{t-1}) \geq a^{i-1}/L$ replaced by $\phi^*_{t-1} = g_j$ and which is therefore based on data generated by the stationary control law g_j. For the special case of controlled independently and identically distributed (i.i.d.) processes, further details of the statistical ideas behind the modifications (3.11) and (3.12) of the classical generalized likelihood ratio statistics, together with illustrative examples and some variants of the adaptive control rule ϕ^*, are given in [8].

Throughout what follows we shall let θ_0 denote the true value of the unknown parameter. We shall also let $\mathbf{E}^\phi_x$ denote expectation under the probability measure $\mathbf{P}^\phi_x$ of the controlled Markov chain starting at x and using control rule ϕ, assuming the true value θ_0 of the parameter. Theorem 2 below shows that the regret $R_n(\theta_0)$ of ϕ^* satisfies

$$R_n(\theta_0) \sim \sum_{j\notin J(\theta_0)} c_j(\theta_0)[\mu^*_{\theta_0} - \mu_{\theta_0}(g_j)] \log n \tag{3.14}$$

under regularity conditions (C1)–(C5) in addition to those assumed at the beginning of section 1. Although we still use the notations (2.1)–(2.4) and define the $c_j(\theta)$ by (3.2) in Theorem 2, we do not assume condition (2.14) of Theorem 1. Our objective here is to establish (3.14), irrespective of whether it is an asymptotic lower bound for the regret of uniformly good rules. For $\delta > 0$, let $B_\delta(\theta_0)$ denote the open δ-neighborhood of $B(\theta_0)$; i.e., $B_\delta(\theta_0) = \{\theta \in \Theta : \inf_{\lambda\in B(\theta_0)} \rho(\theta, \lambda) < \delta\}$ ($B_\delta(\theta_0) = \emptyset$ if $B(\theta_0) = \emptyset$), where ρ denotes the metric of the compact metric space Θ.

(C1) For every $\epsilon > 0$, there exists $\delta > 0$ such that if $\rho(\theta_0, \theta) \leq \delta$ then $J(\theta) \subset J(\theta_0)$ and $\max_{j\notin J(\theta_0)} |c_j(\theta) - c_j(\theta_0)| < \epsilon$. Moreover, there exist ξ and $\delta^* > 0$ such that $\max_{j\notin J(\theta)} |c_j(\theta)| \leq \xi$ if $\rho(\theta_0, \theta) \leq \delta^*$.

(C2) $I^g(\theta_0, \theta)$ is a continuous function of θ for every $g \in G$.

(C3) $\max_{g\in G} I^g(\theta_0, \lambda) > 0$ for all $\lambda \in \cup_{j\in J(\theta_0)}\Theta_j - \{\theta_0\}$, $\inf_{\lambda\in\Theta_i\cap B(\theta_0)} I^{g_i}(\theta_0, \lambda) > 0$ and $\inf_{\lambda\in\Theta_i\setminus B_\delta(\theta_0)} \max_{j\in J(\theta_0)} I^{g_j}(\theta_0, \lambda) > 0$ for all $i \notin J(\theta_0)$ and $\delta > 0$ ($\inf \emptyset = \infty$).

(C4) For every $\theta \in \Theta$ and $g \in G$, there exist $\delta_\theta > 0$ and $r_\theta > 2$ such that

$$\sup_{x\in S} \mathbf{E}^g_x \left\{ \sup_{\lambda:\rho(\theta,\lambda)\leq\delta_\theta} \left| \log \frac{p(x, X_1; g(x), \theta_0)}{p(x, X_1; g(x), \lambda)} \right|^{r_\theta} \right\} < \infty$$

and, as $\delta \to 0$,

$$\sup_{x\in S} \mathbf{P}^g_x \left\{ \sup_{\lambda:\rho(\theta,\lambda)\leq\delta} \left| \frac{p(x, X_1; g(x), \theta)}{p(x, X_1; g(x), \lambda)} - 1 \right| \geq \epsilon \right\} \to 0 \text{ for all } \epsilon > 0.$$

(C5) For every $\theta \in \Theta$ and $g \in G$, as $n \to \infty$,

$$\sup_{x\in S} \left| \mathbf{E}^g_x \left\{ \frac{1}{n} \sum_{i=1}^n \log \frac{p(X_{t-1}, X_t; g(X_{t-1}), \theta_0)}{p(X_{t-1}, X_t; g(X_{t-1}), \theta)} \right\} - I^g(\theta_0, \theta) \right| \to 0.$$

Conditions (C1) and (C2) are continuity assumptions on $c_j(\theta)$ at $\theta = \theta_0$ and on $I^g(\theta_0, \theta)$. (C3) ensures that under ϕ^* one can estimate θ_0 consistently by the method of maximum likelihood, as will be shown in the proof of Theorem 2. From the definition (2.4) of $B(\theta_0)$, it follows that $\max_{j\in J(\theta_0)} I^{g_j}(\theta_0, \lambda) > 0$ if $\lambda \notin B(\theta_0) \cup (\cup_{j\in J(\theta_0)}\Theta_j)$, and the last inequality of (C3) requires this to be uniformly bounded away from zero for $\lambda \in \Theta_i \backslash B_\delta(\theta_0)$ with $i \notin J(\theta_0)$. Conditions (C4) and (C5) are natural moment and ergodicity assumptions on the log-likelihood ratio statistics. The uniformity over $x \in S$ in these assumptions enables us to get around difficulties with controlled Markov chains whose transition probability function $P_\theta^{g(x)}(x, A)$ is changed when the control law is changed. In section 4 we make use of martingale theory and uniform integrability to analyze the adaptive control rule ϕ^* in the proof of the following.

THEOREM 2. *Under* (C1)–(C5), *for every* $x \in S$ *and* $j \notin J(\theta_0)$,

$$\lim_{n\to\infty} \mathbf{E}_x^{\phi^*}(T_n(g_j))/\log n = c_j(\theta_0),$$

and therefore the regret $R_n(\theta_0)$ *of the rule* ϕ^* *satisfies* (3.14). *Moreover,* $S_n(\theta_0) = o(\log n)$, *where* $S_n(\theta_0)$ *is the expected number* (1.8) *of times that* ϕ^* *switches from one control law in* G *to another, not both optimal, up to stage* n.

The $c_j(\theta)$ are obtained by solving a constrained optimization problem in (3.2), which may be quite difficult in certain cases. Although the certainty-equivalent testing phase involves $J(\theta)$ and $c_j(\theta)$, these quantities are not used in the evenly allocated testing phase. In cases where the $c_j(\theta)$ are difficult to determine or fail to satisfy the continuity assumption (C1), an obvious modification of the adaptive control rule ϕ^* is to abandon the certainty-equivalent testing phase. Thus, partitioning $\{a^i + 1, \ldots, a^{i+1}\}$ into $m(i)$ blocks of consecutive integers so that the mth block B_m^i begins at time $\nu_i(m) := a^i + 1 + (m-1)n_i$, this modified rule $\widetilde{\phi}$ performs sequential testing of the hypotheses $H_j : \theta \in \Theta_j$ at the times $\nu_i(m)$ for those g_j not yet eliminated (during the times $\nu_i(m')$ with $m' < m$), in succession in ascending order of j, and eliminates g_j from further use through time a^{i+1} once the hypothesis H_j is rejected. Rejection of H_j occurs at the test time $n = \nu_i(m)$ if (3.12) holds. The rule $\widetilde{\phi}$ alternates using the stationary control laws that have not been eliminated, one for each block B_m^i of consecutive times. If all except one stationary control law have been eliminated, then $\widetilde{\phi}$ uses the remaining stationary control law up to time a^{i+1}. The following theorem shows that although this simpler rule $\widetilde{\phi}$ may be less efficient than ϕ^*, which attains the asymptotic lower bound $(c(\theta_0) + o(1))\log n$ for the regret, $\widetilde{\phi}$ still has a regret of the order $O(\log n)$.

THEOREM 3. *Under* (C2)–(C5), *the rule* $\widetilde{\phi}$ *satisfies* $R_n(\theta_0) = O(\log n)$ *and* $S_n(\theta_0) = o(\log n)$.

4. Martingale inequalities, uniform integrability, and proof of Theorems 2 and 3. We first consider some simple implications of conditions (C1)–(C5). Let $\epsilon > 0$ and take $2 < r'_\theta < r_\theta$. By (C2) together with (C4) for every $\theta \in \Theta$ we can choose $0 < \delta'_\theta \le \delta_\theta$ such that

$$\sup_{\lambda:\rho(\theta,\lambda)\le\delta'_\theta} |I^g(\theta_0, \theta) - I^g(\theta_0, \lambda)| < \epsilon \text{ for all } g \in G \text{ and} \tag{4.1}$$

$$\sup_{x\in S, g\in G} \mathbf{E}_x^g \left\{ \sup_{\lambda:\rho(\theta,\lambda)\le\delta'_\theta} \left| \log \frac{p(x, X_1; g(x), \theta_0)}{p(x, X_1; g(x), \lambda)} - \log \frac{p(x, X_1; g(x), \theta_0)}{p(x, X_1; g(x), \theta)} \right|^{r'_\theta} \right\} \le \epsilon^{r'_\theta}, \tag{4.2}$$

as will be explained in the next paragraph. Since Θ is compact, there exist finitely many points $\theta_1, \ldots, \theta_K$ such that

$$\Theta = \cup_{k=0}^{K} \{\lambda : \rho(\theta_k, \lambda) < \delta'_{\theta_k}\}. \tag{4.3}$$

By (C5) we can choose a positive integer D large enough so that

(4.4)

$$\sup_{x \in S, g \in G, k \le K} \left| \mathbf{E}_x^g \left\{ \frac{1}{n} \sum_{t=1}^{n} \log \frac{p(X_{t-1}, X_t; g(X_{t-1}), \theta_0)}{p(X_{t-1}, X_t; g(X_{t-1}), \theta_k)} \right\} - I^g(\theta_0, \theta_k) \right| \le \epsilon \text{ for all } n \ge D.$$

Concerning (4.2), first note that by (C4), $\sup_{x \in S} \mathbf{P}_x^g(\Omega(\delta, \eta; x)) \to 0$ as $\delta \to 0$ for every fixed $\eta > 0$, where $\Omega(\delta, \eta; x) = \{\sup_{\lambda : \rho(\theta, \lambda) \le \delta} |p(x, X_1; g(x), \theta)/p(x, X_1; g(x), \lambda) - 1| \ge \eta\}$. For sufficiently small η, $|\log y| < 2\eta$ if $|y - 1| < \eta$, and therefore, for $0 < \delta < \delta_\theta$,

$$\begin{aligned}
&\sup_{x \in S} \mathbf{E}_x^g \left\{ \sup_{\lambda : \rho(\theta, \lambda) \le \delta} \left| \log \frac{p(x, X_1; g(x), \theta)}{p(x, X_1; g(x), \lambda)} \right|^{r'_\theta} \right\} \\
&\le (2\eta)^{r'_\theta} + \sup_{x \in S} \mathbf{E}_x^g \left\{ \sup_{\lambda : \rho(\theta, \lambda) \le \delta} \left| \log \frac{p(x, X_1; g(x), \theta)}{p(x, X_1; g(x), \lambda)} \right|^{r'_\theta} I_{\Omega(\delta, \eta; x)} \right\} \\
&\le (2\eta)^{r'_\theta} \\
&\quad + \sup_{x \in S} \left\{ \mathbf{E}_x^g \left[\sup_{\lambda : \rho(\theta, \lambda) \le \delta_\theta} \left| \log \frac{p(x, X_1; g(x), \theta_0)}{p(x, X_1; g(x), \lambda)} - \log \frac{p(x, X_1; g(x), \theta_0)}{p(x, X_1; g(x), \theta)} \right|^{r_\theta} \right] \right\}^{r'_\theta / r_\theta} \\
&\quad \times \{\mathbf{P}_x^g(\Omega(\delta, \eta; x))\}^{1 - r'_\theta / r_\theta} \le (2\eta)^{r'_\theta} + o(1) \text{ as } \delta \to 0
\end{aligned}$$

by (C4), where we have used Hölder's inequality to obtain the second inequality.

We next make use of martingale theory to analyze the log-likelihood ratio statistics from the controlled Markov chain using the adaptive control rule ϕ^*. For $t \ge 0$, let $\mathcal{F}_t$ be the σ-field defined by (1.6). The control rule ϕ^* uses the same stationary control law for an entire block of stages $\nu_i(m), \ldots, \nu_i(m+1) - 1$, with the choice of the control law determined at the beginning of the block. Define a sequence of positive integers h_s such that $D \le h_s - h_{s-1} \le 2D - 1$ for $s > 1$ and all the $\nu_i(m)$ with $i \ge D$ belong to the sequence, where D is given by (4.4). For example, take $h_0 = 0, h_1 = a^D$, and for $s > 1$ let $h_s = h_{s-1} + D$ except when $h_s = \nu_i(m)$, for which we may change the above recursive definition of h_s to $h_s = h_{s-1} + D + r$, with $0 \le r < D$ being the remainder obtained when $\nu_i(m) - \nu_i(m-1)$ is divided by D. Since ϕ^* uses the same stationary control law for $h_{s-1}, \ldots, h_s - 1$ on the basis of observations prior to h_{s-1}, it follows that for $h_{s-1} < t \le h_s$ and $g \in G$, $\{\phi^*_{t-1} = g\} \in \mathcal{F}_{h_{s-1}}$. Therefore, by (4.4),

(4.5)

$$\begin{aligned}
\sup_{n \ge 1, g \in G, k \le K} \Bigg| &\frac{1}{T_{h_n}(g)} \sum_{s=1}^{n} \sum_{h_{s-1} < t \le h_s} \mathbf{E}_x^{\phi^*} \left\{ \log \frac{p(X_{t-1}, X_t; \phi^*_{t-1}(X_{t-1}), \theta_0)}{p(X_{t-1}, X_t; \phi^*_{t-1}(X_{t-1}), \theta_k)} \middle| \mathcal{F}_{h_{s-1}} \right\} \\
&\cdot I_{\{\phi^*_{t-1} = g\}} - I^g(\theta_0, \theta_k) \Bigg| I_{\{T_{h_n}(g) \ge D\}} \le \epsilon,
\end{aligned}$$

noting that $T_{h_n}(g) = \sum_{s=1}^{n} \sum_{h_{s-1} \le i < h_s} I_{\{\phi_i^* = g\}}$ and

$$\sum_{t=h_{s-1}+1}^{h_s} \mathbf{E}_x^{\phi^*} \left\{ \log \frac{p(X_{t-1}, X_t; \phi_{t-1}^*(X_{t-1}), \theta_0)}{p(X_{t-1}, X_t; \phi_{t-1}^*(X_{t-1}), \theta_k)} \middle| \mathcal{F}_{h_{s-1}} \right\} I_{\{\phi_{t-1}^* = g\}} \tag{4.6}$$

$$= \mathbf{E}_y^g \left\{ \sum_{t=1}^{h_s - h_{s-1}} \log \frac{p(X_{t-1}, X_t; g(X_{t-1}), \theta_0)}{p(X_{t-1}, X_t; g(X_{t-1}), \theta_k)} \right\} \text{ on } \{\phi_{h_{s-1}}^* = g, X_{h_{s-1}} = y\}.$$

Let

$$\ell_t(\theta) = \log[p(X_{t-1}, X_t; \phi_{t-1}^*(X_{t-1}), \theta_0) / p(X_{t-1}, X_t; \phi_{t-1}^*(X_{t-1}), \theta)]. \tag{4.7}$$

Lemma 1 states a result of [14], and Lemmas 2, 3, and 4 use it to approximate $\sum_{t=1}^{h_n} \ell_t(\theta)\ \chi_t$, where the χ_t are indicator variables (taking values in $\{0, 1\}$).

LEMMA 1. *Let $\{Z_n\}$ be a martingale difference sequence with respect to an increasing sequence of σ-fields $\{\mathcal{B}_n\}$ such that $\sup_n E(|Z_n|^\beta | \mathcal{B}_{n-1}) \le C$ a.s. for some nonrandom constants $\beta > 2$ and $C < \infty$. Let χ_n be $\mathcal{B}_{n-1}$-measurable variables taking values in $\{0, 1\}$ and let $\#_n = \sum_{t=1}^{n} \chi_t$. Then there exists a universal constant A depending only on C and β (and not on the distribution of $\{(\chi_n, Z_n) : n \ge 1\}$) such that for any $\eta > 0$ and $m \ge 1$,*

$$P\left\{ \sup_{n: \#_n \ge m} \left| \sum_{t=1}^{n} Z_t \chi_t \right| / \#_n > \eta \right\} \le A\{m^{-(\beta-1)} \eta^{-\beta} + (\eta^2 m)^{-(\beta-1)}\},$$

$$P\left\{ \max_{1 \le n \le m} \left| \sum_{t=1}^{n} Z_t \chi_t \right| > \eta m \right\} \le A\{m^{-(\beta-1)} \eta^{-\beta} + (\eta^2 m)^{-(\beta-1)}\}.$$

LEMMA 2. *Let $\beta = \min_{0 \le k \le K} r'_{\theta_k} (> 2)$, where the r'_θ are given by (4.2). Define $\ell_t(\theta)$ by (4.7) and $\mathcal{C}, \tau_n(g)$ by (3.7). Then for any $g \in G$ and $0 \le k \le K$,*

$$\mathbf{P}_x^{\phi^*} \left\{ \sup_{n: T_{h_n}(g) \ge m} \left| (T_{h_n}(g))^{-1} \sum_{t=1}^{h_n} \ell_t(\theta_k) I_{\{\phi_{t-1}^* = g\}} - I^g(\theta_0, \theta_k) \right| > 2\epsilon \right\} = O(m^{-(\beta-1)}),$$

$$\mathbf{P}_x^{\phi^*} \left\{ \sup_{n: \tau_{h_n}(g) \ge m} \left| (\tau_{h_n}(g))^{-1} \sum_{t=1}^{h_n} \ell_t(\theta_k) I_{\{t-1 \in \mathcal{C}, \phi_{t-1}^* = g\}} - I^g(\theta_0, \theta_k) \right| > 2\epsilon \right\}$$
$$= O(m^{-(\beta-1)}).$$

Proof. Let $Z_s = \sum_{h_{s-1} < t \le h_s} \ell_t(\theta_k) - \mathbf{E}_x^{\phi^*} \{\sum_{h_{s-1} < t \le h_s} \ell_t(\theta_k) | \mathcal{F}_{h_{s-1}}\}$. Then $\{Z_s, \mathcal{B}_s, s \ge 1\}$ is a martingale difference sequence, where $\mathcal{B}_s = \mathcal{F}_{h_s}$. Moreover, since $h_s - h_{s-1} \le 2D - 1$,

$$\sup_{s \ge 1} \mathbf{E}_x^{\phi^*} (|Z_s|^\beta | \mathcal{B}_{s-1}) \le A_{\beta, D} \sup_{y \in S, g \in G} \sum_{t=1}^{2D-1} \mathbf{E}_y^g |\ell_t(\theta_k)|^\beta$$

for some positive constant $A_{\beta,D}$ that depends only on β and D. For fixed $g \in G$, let $\chi_s = I_{\{\phi_{h_{s-1}}^* = g\}}$, which is $\mathcal{B}_{s-1}$ measurable, and note that

$$\sum_{h_{s-1} < t \le h_s} \ell_t(\theta_k) I_{\{\phi_{t-1}^* = g\}} = \chi_s \sum_{h_{s-1} < t \le h_s} \ell_t(\theta_k), \tag{4.8}$$

since ϕ^* uses the same stationary control law at the times $h_{s-1}, \ldots, h_s - 1$. Moreover,

$$D\sum_{s=1}^{n}\chi_s \le \sum_{s=1}^{n}(h_s - h_{s-1})\chi_s = T_{h_n}(g) \le (2D-1)\sum_{s=1}^{n}\chi_s.$$

Therefore it follows from Lemma 1 that

$$\mathbf{P}_x^{\phi^*}\left\{\sup_{n:T_{h_n}(g)\ge m}\left|\sum_{s=1}^{n} Z_s\chi_s\right| / T_{h_n}(g) > \epsilon\right\} = O(m^{-(\beta-1)}). \tag{4.9}$$

Since $\sum_{t=1}^{h_n}\ell_t(\theta_k)I_{\{\phi^*_{t-1}=g\}} = \sum_{s=1}^{n} Z_s\chi_s + \sum_{s=1}^{n}\sum_{h_{s-1}<t\le h_s}\mathbf{E}_x^{\phi^*}\{\ell_t(\theta_k)|\mathcal{F}_{h_{s-1}}\}I_{\{\phi^*_{t-1}=g\}}$ by (4.8), the desired conclusion for $T_{h_n}(g)$ follows from (4.5) and (4.9). The conclusion for $\tau_{h_n}(g)$ can be proved similarly, noting that for $h_{s-1} < t \le h_s$, $\{t-1 \in \mathcal{C}, \phi^*_{t-1} = g\} \in \mathcal{F}_{h_{s-1}}$.

LEMMA 3. *With β defined in Lemma 2 and δ'_θ given by (4.1) and (4.2), let χ_n be $\mathcal{F}_{n-1}$-measurable random variables taking values in $\{0,1\}$ and let $\#_n = \sum_{t=1}^{n}\chi_t$. Then for any $0 \le k \le K$,*

$$\mathbf{P}_x^{\phi^*}\left\{\sup_{n:\#_n\ge m}\left[\sup_{\theta:\rho(\theta_k,\theta)\le\delta'_{\theta_k}}\sum_{t=1}^{n}|\ell_t(\theta)-\ell_t(\theta_k)|\chi_t\right]/\#_n > 2\epsilon\right\} = O(m^{-(\beta-1)}).$$

Proof. Let $\Gamma_k = \{\theta : \rho(\theta_k,\theta) \le \delta'_{\theta_k}\}$. In view of (C4), applying Lemma 1 to $Z_t = \sup_{\theta\in\Gamma_k}|\ell_t(\theta)-\ell_t(\theta_k)| - \mathbf{E}_x^{\phi^*}\{\sup_{\theta\in\Gamma_k}|\ell_t(\theta)-\ell_t(\theta_k)||\mathcal{F}_{t-1}\}$ yields

$$\mathbf{P}_x^{\phi^*}\left\{\sup_{n:\#_n\ge m}\left(\sum_{t=1}^{n} Z_t\chi_t\right)/\#_n > \epsilon\right\} = O(m^{-(\beta-1)}). \tag{4.10}$$

Moreover, by (4.2),

$$\begin{aligned}\sum_{t=1}^{n}\chi_t\mathbf{E}_x^{\phi^*}&\left\{\sup_{\theta\in\Gamma_k}|\ell_t(\theta)-\ell_t(\theta_k)|\,\middle|\,\mathcal{F}_{t-1}\right\}\\ &\le\left(\sum_{t=1}^{n}\chi_t\right)\sup_{y\in S,g\in G}\mathbf{E}_y^g\left(\sup_{\lambda\in\Gamma_k}|\ell_t(\lambda)-\ell_t(\theta_k)|\right)\\ &\le\epsilon\#_n.\end{aligned} \tag{4.11}$$

Since $\sup_{\theta\in\Gamma_k}\sum_{t=1}^{n}|\ell_t(\theta)-\ell_t(\theta_k)|\chi_t \le \sum_{t=1}^{n} Z_t\chi_t + \sum_{t=1}^{n}\chi_t\mathbf{E}_x^{\phi^*}\{\sup_{\theta\in\Gamma_k}|\ell_t(\theta)-\ell_t(\theta_k)||\mathcal{F}_{t-1}\}$, the desired conclusion follows from (4.10) and (4.11).

LEMMA 4. *With the same notation as in Lemma 3, for any $0 \le k \le K$,*

$$\mathbf{P}_x^{\phi^*}\left\{\max_{1\le n\le m}\sup_{\theta:\rho(\theta_k,\theta)\le\delta'_{\theta_k}}\sum_{t=1}^{n}|\ell_t(\theta)-\ell_t(\theta_k)|\chi_t > 2\epsilon m\right\} = O(m^{-(\beta-1)}).$$

Moreover, for any $g \in G$ and $0 \le k \le K$,

$$\sup_{\tau\in\mathcal{T}}\mathbf{P}_x^{\phi^*}\left\{\max_{1\le n\le m}\left|\sum_{t=1}^{h_n}(\ell_t(\theta_k)-I^g(\theta_0,\theta_k))I_{\{t>\tau,\phi^*_{t-1}=g\}}\right| > 3\epsilon h_m\right\} = O(m^{-(\beta-1)}),$$

where $\mathcal{T}$ denotes the class of all stopping times (with respect to $\{\mathcal{F}_n\}$).

Proof. By using the second instead of the first inequality of Lemma 1, we can proceed as in the proof of Lemma 3 to obtain the first conclusion. To prove the second conclusion, let τ be a stopping time and let $\sigma = \inf\{s : h_s \geq \tau\}$. Define Z_s and $\mathcal{B}_s$ as in the proof of Lemma 2 but change the definition of χ_s there to $\chi_s = I_{\{\phi^*_{h_{s-1}}=g, s>\sigma\}}$. Since

$$\{s > \sigma\} = \{s - 1 \geq \sigma\} = \{h_{s-1} \geq \tau\} \in \mathcal{F}_{h_{s-1}} = \mathcal{B}_{s-1},$$

χ_s is $\mathcal{B}_{s-1}$ measurable. Therefore, by Lemma 1 there exists a constant A (which does not depend on σ) such that, for all $m \geq 1$,

$$\mathbf{P}_x^{\phi^*}\left\{\max_{1\leq n\leq m}\left|\sum_{s=1}^{n} Z_s\chi_s\right| > \epsilon m\right\} \leq A\{m^{-(\beta-1)}\epsilon^{-\beta} + (\epsilon^2 m)^{-(\beta-1)}\}.$$

Note that for $n \geq \sigma$, $\sum_{t=1}^{h_n} \ell_t(\theta_k) I_{\{\phi^*_{t-1}=g, t>\tau\}}$ can be written as

$$\sum_{\tau+1\leq t\leq h_\sigma} \ell_t(\theta_k) I_{\{\phi^*_{t-1}=g\}} + \sum_{s=1}^{n} \chi_s \mathbf{E}_x^{\phi^*}\left\{\sum_{h_{s-1}<t\leq h_s} \ell_t(\theta_k)\,\middle|\, \mathcal{F}_{h_{s-1}}\right\} + \sum_{s=1}^{n} Z_s\chi_s.$$

Since $h_s - h_{s-1} \geq D$, it follows from (4.4) that

$$\max_{1\leq s\leq m}\left|\sum_{s=1}^{n} \chi_s \sum_{h_{s-1}<t\leq h_s} \{\mathbf{E}_x^{\phi^*}[\ell_t(\theta_k)|\mathcal{F}_{h_{s-1}}] - I^g(\theta_0,\theta_k)\}\right| \leq \epsilon h_m.$$

Since $h_{\sigma-1} < \tau \leq h_\sigma$ and $h_\sigma - h_{\sigma-1} \leq 2D - 1$, the strong Markov property implies that

$$\mathbf{E}_x^{\phi^*}\left\{\left(\sum_{\tau+1\leq t\leq h_\sigma} |\ell_t(\theta_k)| I_{\{\phi^*_{t-1}=g\}}\right)^{\beta}\,\middle|\, \mathcal{F}_\tau\right\} \leq A_{\beta,D} \sup_{y\in S} \sum_{t=1}^{2D-1} \mathbf{E}_y^g |\ell_t(\theta_k)|^\beta$$

for some positive constant $A_{\beta,D}$ that depends only on β and D. Hence by the Markov inequality

$$\mathbf{P}_x^{\phi^*}\left\{\sum_{\tau+1\leq t\leq h_\sigma} |\ell_t(\theta_k)| I_{\{\phi^*_{t-1}=g\}} > \epsilon m\right\} \leq C\epsilon^{-\beta} m^{-\beta},$$

where $C = A_{\beta,D} \sup_{y\in S} \sum_{t=1}^{2D-1} \mathbf{E}_y^g |\ell_t(\theta_k)|^\beta < \infty$. Since the same constants A and C in the above probability bounds hold for all stopping times τ, these bounds yield the second conclusion of the lemma.

We shall make use of Lemmas 2–4 to prove the following two lemmas from which Theorems 2 and 3 follow easily. Recall that $G_J = \{g_j : j \in J(\theta_0)\}$.

LEMMA 5. *With $\beta > 2$ defined in Lemma 2, for every $\eta > 0$,*

$$\mathbf{P}_x^{\phi^*}\{\rho(\theta_0, \widehat{\theta}_{h_n}) \geq \eta \text{ for some } h_n \geq a^i\} = O((i/\log i)^{-(\beta-1)}). \tag{4.12}$$

Moreover, for any $j \notin J(\theta_0)$, as $n \to \infty$,

$$T_n(g_j)/\log n \to c_j(\theta_0),\ \sum_{i=1}^{n} I_{\{\phi_i^* \neq \phi_{i-1}^*, \phi_i^* \notin G_J \text{ or } \phi_{i-1}^* \notin G_J\}}/\log n \to 0 \text{ a.s. } [\mathbf{P}_x^{\phi^*}]. \tag{4.13}$$

LEMMA 6. *For any $j \notin J(\theta_0)$, $\{T_n(g_j)/\log n, n \geq 2\}$ is uniformly integrable under $\mathbf{P}_x^{\phi^*}$ or $\mathbf{P}_x^{\hat{\phi}}$.*

Proof of Theorem 2. From (4.13) and Lemma 6, it follows that $\mathbf{E}_x^{\phi^*} T_n(g_j)/\log n \to c_j(\theta_0)$ for any $j \notin J(\theta_0)$. This and (3.2) imply (3.14). The uniform integrability of

$$\sum_{i=1}^{n} I_{\{\phi_i^* \neq \phi_{i-1}^*, \phi_i^* \notin G_J \text{ or } \phi_{i-1}^* \notin G_J\}}/\log n,$$

which is $\leq 2\{1 + \sum_{j \notin J(\theta_0)} T_n(g_j)\}/\log n$, follows from Lemma 6. Therefore $S_n(\theta_0) = o(\log n)$ by (4.13).

Proof of Theorem 3. The desired conclusion on $R_n(\theta_0)$ follows from Lemma 6, and that on $S_n(\theta_0)$ can be proved by an argument similar to the proof of the second convergence in (4.13) and the associated uniform integrability in Theorem 2.

The proof of Lemmas 5 and 6 makes use of the following lemma, which applies martingale inequalities to analyze boundary crossing probabilities associated with (3.11) and (3.12).

LEMMA 7. *As in* (3.11) *and* (3.12), *let F be a probability measure on Θ such that $F(A) > 0$ for all open subsets A of Θ. For $a^i < n \leq a^{i+1}$, let*

$$U_n(\lambda) = \frac{\int \prod_{1 \leq t \leq n, t-1 \in \mathcal{C}, \phi_{t-1}^* \notin \hat{G}_{J,t}} p(X_{t-1}, X_t; \phi_{t-1}^*(X_{t-1}), \theta) dF(\theta)}{\prod_{1 \leq t \leq n, t-1 \in \mathcal{C}, \phi_{t-1}^* \notin \hat{G}_{J,t}} p(X_{t-1}, X_t; \phi_{t-1}^*(X_{t-1}), \lambda)}, \tag{4.14}$$

$$\widetilde{W}_{n,j}(\lambda) = \frac{\int \prod_{1 \leq t \leq n, \phi_{t-1}^* = g_j} p(X_{t-1}, X_t; \phi_{t-1}^*(X_{t-1}), \theta) dF(\theta)}{\prod_{1 \leq t \leq n, \phi_{t-1}^* = g_j} p(X_{t-1}, X_t; \phi_{t-1}^*(X_{t-1}), \lambda)}, \tag{4.15}$$

$$W_n(\lambda) = \frac{\int \prod_{1 \leq t \leq n, T_{t-1}(\phi_{t-1}^*) \geq a^{i-1}/L} p(X_{t-1}, X_t; \phi_{t-1}^*(X_{t-1}), \theta) dF(\theta)}{\prod_{1 \leq t \leq n, T_{t-1}(\phi_{t-1}^*) \geq a^{i-1}/L} p(X_{t-1}, X_t; \phi_{t-1}^*(X_{t-1}), \lambda)}. \tag{4.16}$$

If $\theta_0 \in \Theta_j$, then

$$\mathbf{P}_x^{\phi^*}\left\{\inf_{\lambda \in \Theta_j} \max(U_n(\lambda), W_n(\lambda)) \geq ia^i \text{ for some } n > a^i\right\} \leq 2(ia^i)^{-1},$$

$$\mathbf{P}_x^{\phi^*}\left\{\inf_{\lambda \in \Theta_j} \max(\widetilde{W}_{n,j}(\lambda), W_n(\lambda)) \geq ia^i \text{ for some } n > a^i\right\} \leq 2(ia^i)^{-1}.$$

Proof. Note that $\{t-1 \in \mathcal{C}, \phi_{t-1}^* \notin \widehat{G}_{J,t}\} \in \mathcal{F}_{t-1}$ by (3.7) and (3.8). Hence $U_n(\theta_0), W_n(\theta_0)$ and $\widetilde{W}_{n,j}(\theta_0), n > a^i$, are nonnegative martingales with common mean 1. Therefore, if $\theta_0 \in \Theta_j$, then

$$\begin{aligned}
&\mathbf{P}_x^{\phi^*}\left\{\inf_{\lambda \in \Theta_j} \max(U_n(\lambda), W_n(\lambda)) \geq ia^i \text{ for some } n > a^i\right\} \\
&\leq \mathbf{P}_x^{\phi^*}\{U_n(\theta_0) \geq ia^i \text{ for some } n > a^i\} + \mathbf{P}_x^{\phi^*}\{W_n(\theta_0) \geq ia^i \text{ for some } n > a^i\} \\
&\leq \{EU_{a^i+1}(\theta_0) + EW_{a^i+1}(\theta_0)\}/(ia^i).
\end{aligned}$$

Replacing $U_n(\lambda)$ by $\widetilde{W}_{n,j}(\lambda)$ in the above argument proves the second inequality.

Proof of Lemma 5. We first prove (4.12). By Lemma 3 (with $\chi_t = I_{\{\phi_{t-1}^* = g\}}$), for every $g \in G$ and $0 \leq k \leq K$,

(4.17)
$$\mathbf{P}_x^{\phi^*}\left\{\sup_{\theta\in\Gamma_k}\sum_{t=1}^{n}|\ell_t(\theta)-\ell_t(\theta_k)|I_{\{\phi^*_{t-1}=g\}}\ge 2\epsilon T_n(g)\text{ for some }T_n(g)\ge m\right\}=O(m^{-(\beta-1)}).$$

From (4.17) and Lemma 2, it follows that

(4.18)
$$\mathbf{P}_x^{\phi^*}\left\{\inf_{\theta\in\Gamma_k}(T_{h_n}(g))^{-1}\sum_{t=1}^{h_n}\ell_t(\theta)I_{\{\phi^*_{t-1}=g\}}\ge I^g(\theta_0,\theta_k)-4\epsilon\text{ for all }T_{h_n}(g)\ge m\right.$$
$$\left.\text{and every } g\in G \text{ and } 0\le k\le K\right\}\ge 1-O(m^{-(\beta-1)}).$$

By (4.1) and the compactness of Θ, for every $\epsilon>0$, there exists $\delta>0$ such that

(4.19)
$$\sup_{g\in G}|I^g(\theta_0,\lambda)-I^g(\theta_0,\lambda')|<\epsilon \text{ if } \rho(\lambda,\lambda')\le\delta.$$

For $i\notin J(\theta_0)$, since $\inf_{\lambda\in\Theta_i\cap B(\theta_0)}I^{g_i}(\theta_0,\lambda)>0$ by (C3), it follows from (4.19) (with ϵ sufficiently small) that $\inf_{\lambda\in\Theta_i\cap B_\delta(\theta_0)}I^{g_i}(\theta_0,\lambda)>0$ for some $\delta>0$. This and (C3) imply that $\max_{g\in G}I^g(\theta_0,\lambda)>0$ for all $\lambda\ne\theta_0$. Hence given $\eta>0$, we can choose ϵ sufficiently small so that

(4.20)
$$\max_{g\in G}I^g(\theta_0,\theta)\ge 5L\epsilon \quad\text{if}\quad \rho(\theta_0,\theta)\ge\eta,$$

in view of (C2) and the compactness of Θ. Since

$$L_n(\theta_0)-L_n(\theta)=\sum_{g\in G}(T_n(g))^{-1}\sum_{t=1}^{n}\ell_t(\theta)I_{\{\phi^*_{t-1}=g\}}$$

by (3.1), and since $\ell_t(\theta_0)=0$ and $I^g(\theta_0,\lambda)\ge 0$ for all $g\in G$ and $\lambda\in\Theta$, it follows from (4.18) and (4.20) that

(4.21)
$$\mathbf{P}_x^{\phi^*}\left\{\sup_{\theta:\rho(\theta_0,\theta)\ge\eta}L_{h_n}(\theta)<L_{h_n}(\theta_0)-\epsilon\text{ for all }h_n\ge a^i\right\}\ge 1-O((i^{-1}\log i)^{\beta-1}),$$

noting that $T_{a^i}(g)\ge\tau_{a^i}(g)\ge n_{i-1}(\sim i/\log i)$ because at least n_{i-1} stages in the certainty-equivalent testing phase between the times a^{i-1} and a^i use g if $\tau_{a^{i-1}}(g)<n_{i-1}$ for every $g\in G$. From (4.21), (4.12) follows.

Combining (4.12) with (C1) yields $\mathbf{P}_x^{\phi^*}(\cap_{i\ge t}A_i)\ge 1-O((t^{-1}\log t)^{\beta-1})$, where

(4.22)
$$A_i=\left\{J(\widehat{\theta}_{a^i})\subset J(\theta_0),\ \max_{j\notin J(\theta_0)}|c_j(\widehat{\theta}_{a^i})-c_j(\theta_0)|<\epsilon,\ \max_{j\in J(\theta_0)-J(\widehat{\theta}_{a^i})}|c_j(\widehat{\theta}_{a^i})|\le\xi\right\}.$$

Let $\Gamma_k=\{\theta:\rho(\theta_k,\theta)\le\delta'_{\theta_k}\}$ and $w_k=F(\Gamma_k)(>0)$ for $0\le k\le K$. By Lemma 3, $\mathbf{P}_x^{\phi^*}(\cap_{i\ge t}C_i)\ge 1-O((t^{-1}\log t)^{\beta-1})$, where

(4.23)
$$C_i=\left\{\max_{0\le k\le K}\sup_{\theta\in\Gamma_k}\sum_{t=1}^{n}|\ell_t(\theta)-\ell_t(\theta_k)|I_{\{t-1\in\mathcal{C},\phi^*_{t-1}=g\}}\le 2\epsilon\tau_n(g)\right.$$
$$\left.\text{for all } a^i<n\le a^{i+1}\text{ and } g\in G\right\},$$

since $\tau_{a^i}(g) \geq n_{i-1} \sim i/\log i$ for every $g \in G$. Note that $\ell_t(\theta_0) = 0$ and that

$$\begin{aligned}
&\int \prod_{1\leq t\leq n, t-1\in\mathcal{C}, \phi^*_{t-1}\notin \widehat{G}_{J,t}} p(X_{t-1}, X_t; \phi^*_{t-1}(X_{t-1}), \theta) dF(\theta) \\
&\geq \left\{ \prod_{1\leq t\leq n, t-1\in\mathcal{C}, \phi^*_{t-1}\notin \widehat{G}_{J,t}} p(X_{t-1}, X_t; \phi^*_{t-1}(X_{t-1}), \theta_0) \right\} \\
&\quad \cdot w_0 \inf_{\theta\in\Gamma_0} \exp\left(- \sum_{1\leq t\leq n, t-1\in\mathcal{C}, \phi^*_{t-1}\notin \widehat{G}_{J,t}} \ell_t(\theta) \right).
\end{aligned} \tag{4.24}$$

Suppose $\Theta_j \cap B_\delta(\theta_0) \neq \emptyset$. Let $\chi_t = I_{\{t-1\in\mathcal{C}, \phi^*_{t-1}\notin \widehat{G}_{J,t}\}}$. On $A_i \cap C_i$, if $a^i < n \leq a^{i+1}$, then

$$\inf_{\lambda\in\Gamma_k} \exp\left(\sum_1^n \chi_t \ell_t(\lambda) \right) \geq \exp\left\{ \sum_1^n \chi_t \ell_t(\theta_k) - 2\epsilon \sum_1^n \chi_t \right\},$$

$$\inf_{\lambda\in\Gamma_0} \exp\left(-\sum_1^n \chi_t \ell_t(\lambda) \right) \geq \exp\left(-2\epsilon \sum_1^n \chi_t \right),$$

so it follows from (4.7), (4.14), and (4.24) that

$$\inf_{\lambda\in\Theta_j\cap B_\delta(\theta_0)} U_n(\lambda) \geq w_0 \exp\left\{ \inf_{0\leq k\leq K:\Gamma_k\cap\Theta_j\cap B_\delta(\theta_0)\neq\emptyset} \sum_{t=1}^n (\ell_t(\theta_k) - 4\epsilon)\chi_t \right\}. \tag{4.25}$$

Since $\tau_{a^i}(g) \geq n_{i-1}$, it follows from Lemma 2 that $\mathbf{P}_x^{\phi^*}(\cap_{i\geq t} D_i) \geq 1 - O((t^{-1}\log t)^{\beta-1})$, where

$$\begin{aligned}
D_i = \Bigg\{ &\max_{g\in G} \max_{0\leq k\leq K} \left| (\tau_{h_n}(g))^{-1} \sum_{t=1}^{h_n} \ell_t(\theta_k) I_{\{t-1\in\mathcal{C}, \phi^*_{t-1}=g\}} - I^g(\theta_0, \theta_k) \right| \leq 2\epsilon \\
&\text{for all } a^i < h_n \leq a^{i+1} \Bigg\}.
\end{aligned} \tag{4.26}$$

Let $\Omega = \cup_{t=1}^\infty \cap_{i\geq t} (A_i \cap C_i \cap D_i)$. Then $\mathbf{P}_x^{\phi^*}(\Omega) = \lim_{t\to\infty} \mathbf{P}_x^{\phi^*}\{\cap_{i\geq t}(A_i\cap C_i\cap D_i)\} = 1$. On Ω, for all large i and at the times h_n during the certainty-equivalent testing phase of ϕ^* between a^i and a^{i+1}, it follows from (3.9), (3.10a), and (4.22) that $J(\widehat{\theta}_{a^i}) \subset J(\theta_0)$ and

$$(\log a^i)(c_\ell(\theta_0) - \epsilon) \leq \tau_{h_n}(g_\ell) \leq (2\log a^i)(c_\ell(\theta_0) + \epsilon) + 3n_i \text{ if } \ell \notin J(\theta_0), \tag{4.27}$$

$$\tau_{h_n}(g_\ell) \leq 3\xi \log a^i \text{ if } \ell \in J(\theta_0) - J(\widehat{\theta}_{a^i}), \tag{4.28}$$

and from (4.25), (4.26), and (4.28) that

(4.29)
$$\inf_{\lambda\in\Theta_j\cap B_\delta(\theta_0)} \log U_{h_n}(\lambda)$$
$$\geq \inf_{0\leq k\leq K:\Gamma_k\cap\Theta_j\cap B_\delta(\theta_0)\neq\emptyset} \sum_{\ell\notin J(\theta_0)} \{I^{g_\ell}(\theta_0,\theta_k)-6\epsilon\}\tau_{h_n}(g_\ell) - 6L\epsilon(3\xi\log a^i)+O(1),$$

noting that $I^g(\theta_0,\lambda)\geq 0$ for all $g\in G$ and $\lambda\in\Theta$. From (4.1) and (4.29), it follows that on Ω

(4.30)
$$\begin{aligned}&\inf_{\lambda\in\Theta_j\cap B_\delta(\theta_0)} \log U_{h_n}(\lambda)\\ &\geq \inf_{\lambda\in\Theta_j\cap B_\delta(\theta_0)} \sum_{\ell\notin J(\theta_0)} \{I^{g_\ell}(\theta_0,\lambda)-7\epsilon\}\tau_{h_n}(g_\ell) - 6L\epsilon(3\xi\log a^i)+O(1)\end{aligned}$$

at the times h_n during the certainty-equivalent phase of ϕ^* between a^i and a^{i+1} for all large i.

In view of (3.11), (3.12), and Lemma 7, for every $\ell\in J(\theta_0)$,

(4.31) $\mathbf{P}_x^{\phi^*}\{g_\ell \text{ is eliminated at some testing time between } a^i \text{ and } a^{i+1}\}\leq 4(ia^i)^{-1}$.

Hence by the Borel–Cantelli lemma, $\mathbf{P}_x^{\phi^*}\{\Omega_i \text{ for all large } i\}=1$, where

(4.32)
$$\begin{aligned}&\Omega_i\\ &=\{g_\ell \text{ is not eliminated during all test times between } a^{i-2} \text{ and } a^{i+1},\ \text{for all } \ell\in J(\theta_0)\}.\end{aligned}$$

In the event Ω_i, since $1-a^{-2}\geq 3/4$ and $3/5>a^{-1}$, we have the following for all sufficiently large i:

(4.33) $$T_{a^i-1}(g_\ell)\geq (4/5)\{(a^i-1-a^{i-2})/L\}>a^{i-1}/L \text{ for all } \ell\in J(\theta_0).$$

Note that $\{T_{t-1}(g)\geq a^{i-1}/L\}=\{t-1\geq\tau^{(i)}\}=\{t>\tau^{(i)}\}$, where $\tau^{(i)}=\inf\{s: T_s(g)\geq a^{i-1}/L\}$ is a stopping time. Let $N_n(g)=\sum_{t=1}^n I_{\{T_{t-1}(g)\geq a^{i-1}/L,\phi^*_{t-1}=g\}}$, and define

(4.34)
$$\begin{aligned}\Lambda_i=\Bigg\{&\max_{0\leq k\leq K}\sup_{\theta\in\Gamma_k}\sum_{t=1}^{h_n}|\ell_t(\theta)-\ell_t(\theta_k)|I_{\{T_{t-1}(g)\geq a^{i-1}/L,\phi^*_{t-1}=g\}}\leq 2\epsilon a^{i+1} \text{ and}\\ &\max_{0\leq k\leq K}\left|\sum_{t=1}^{h_n}\ell_t(\theta_k)I_{\{T_{t-1}(g)\geq a^{i-1}/L,\phi^*_{t-1}=g\}}-I^g(\theta_0,\theta_k)N_{h_n}(g)\right|\leq 2\epsilon a^{i+1}\\ &\text{for all } a^i<h_n\leq a^{i+1} \text{ and all } g\in G\Bigg\}.\end{aligned}$$

Letting Λ^c denote the complement of an event Λ, it follows from Lemma 4 that

(4.35) $$\mathbf{P}_x^{\phi^*}(\Lambda_i^c)=O(a^{-i(\beta-1)}).$$

Therefore by the Borel–Cantelli lemma, $\mathbf{P}_x^{\phi^*}\{\Lambda_i \text{ for all large } i\}=1$.

Suppose $\Theta_j \backslash B_\delta(\theta_0) \neq \emptyset$. Then we can use (4.33) and an argument similar to that leading to (4.25) and (4.30) to show that, for all large i, on $\Omega_i \cap \Lambda_i$,

$$\begin{aligned} &\min_{1\le m\le m(i)} \inf_{\lambda\in\Theta_j\backslash B_\delta(\theta)} \log W_{\nu_i(m)}(\lambda) \\ &\ge \inf_{\lambda\in\Theta_j\backslash B_\delta(\theta_0)} \sum_{\ell\in J(\theta_0)} I^{g_\ell}(\theta_0,\lambda) a^{i-1}/L - 7\epsilon a^{i+1} + \log w_0, \end{aligned} \tag{4.36}$$

noting that $I^g(\theta_0,\lambda) \ge 0$. Let $\Omega_* = \cup_{t=1}^\infty \cap_{i\ge t} (\Omega_i \cap \Lambda_i)$. Since

$$K := \inf_{\lambda\in\Theta_j\backslash B_\delta(\theta_0)} \sum_{\ell\in J(\theta_0)} I^{g_\ell}(\theta_0,\lambda) > 0$$

by (C3), (4.36) with $\epsilon > 0$ sufficiently small implies that on Ω_*, for all large i and $a^i < h_n \le a^{i+1}$,

$$\inf_{\lambda\in\Theta_j\backslash B_\delta(\theta_0)} \log W_{h_n}(\lambda) > K a^{i-1}/(2L). \tag{4.37}$$

Note that

$$\inf_{\lambda\in\Theta_j} \max\{U_{h_n}(\lambda), W_{h_n}(\lambda)\} \ge \min\{\inf_{\lambda\in\Theta_j\cap B_\delta(\theta_0)} U_{h_n}(\lambda), \inf_{\lambda\in\Theta_j\backslash B_\delta(\theta_0)} W_{h_n}(\lambda)\}.$$

By (4.19), for sufficiently small ϵ,

$$0 \le \inf_{\lambda\in\Theta_j\cap B(\theta_0)} \sum_{\ell\notin J(\theta_0)} c_\ell(\theta_0) I^{g_\ell}(\theta_0,\lambda) - \inf_{\lambda\in\Theta_j\cap B_\delta(\theta_0)} \sum_{\ell\notin J(\theta_0)} c_\ell(\theta_0) I^{g_\ell}(\theta_0,\lambda) \le \epsilon^{3/4}. \tag{4.38}$$

From (4.27), (4.30), (4.37), and (4.38) with ϵ sufficiently small, it follows that on $\Omega\cap\Omega_*$, for all large i, the certainty-equivalent testing phase between times a^i and a^{i+1} rejects H_j at time $\nu_i(m)$ with $(c_j(\theta_0)-\epsilon)\log a^i \le \tau_{\nu_i(m)}(g_j) \le (c_j(\theta_0)+\sqrt{\epsilon})\log a^i$ for every $j \notin J(\theta_0)$ (or equivalently $\theta_0 \notin \Theta_j$). In particular, the upper bound for $\tau_{\nu_i(m)}(g_j)$ follows from the lower bound in (4.27) together with (3.11), (4.37), and (4.30), noting that the $\epsilon^{3/4}$ in (4.38) is much smaller than $\sqrt{\epsilon}$ if ϵ is sufficiently small and that $\inf_{\lambda\in\Theta_j\cap B(\theta_0)} \sum_{\ell\notin J(\theta_0)} c_\ell(\theta_0) I^{g_\ell}(\theta_0,\lambda) \ge 1$ if $B(\theta_0) \neq \emptyset$ by (3.2). Hence on $\Omega\cap\Omega_*$, for all large i, the evenly allocated testing phase between times a^i and a^{i+1} is applied only to controls g_ℓ with $\ell \in J(\theta_0)$. Since ϵ can be arbitrarily small, this implies that $T_n(g_j) = \tau_n(g_j) + O(1)$ and that $T_n(g_j)/\log n \to c_j(\theta_0)$ a.s. $[\mathbf{P}_x^{\phi^*}]$ for every $j \notin J(\theta_0)$. This also implies that with probability 1, for all large i, ϕ^* only uses rules from G_J after certainty-equivalent testing between times a^i and a^{i+1}. Hence in view of (4.27) and the use of the same stationary control law for an entire block (of stages) B_m^i, of size $\ge n_i \sim i/\log i$, the desired conclusion on $\sum_1^n I_{\{\phi_i^*\neq\phi_{i-1}^*, \phi_i^*\notin G_J \text{ or } \phi_{i-1}^*\notin G_J\}}$ follows.

Proof of Lemma 6. Fix $j \notin J(\theta_0)$. The evenly allocated testing phase of ϕ^*, which was shown to use eventually only controls from G_J in the proof of the a.s. convergence of $T_n(g_j)/\log n$ in Lemma 5, will play a crucial role here in establishing uniform integrability of $T_n(g_j)/\log n$. Also the assumption $\beta > 2$ will be important here. Let $\tau_t = \tau_{a^{t+1}}(g_j)$ and $\widetilde{\tau}_t = T_{a^{t+1}}(g_j) - \tau_t$. It suffices to show that

$$\{\tau_t/t, t\ge 1\} \text{ and } \{\widetilde{\tau}_t/t, t\ge 1\} \text{ are uniformly integrable under } \mathbf{P}_x^{\phi^*}. \tag{4.39}$$

Take any $\epsilon > 0$ and define A_i as in (4.22). In the line above (4.22) we have shown that

$$\mathbf{P}_x^{\phi^*}(\Delta_t) \geq 1 - O(t^{-(\beta-1)}(\log t)^{2\beta}), \text{ where } \Delta_t = \cap_{i \geq [t/\log t]} A_i. \tag{4.40}$$

From the constraint (3.10a) or (3.10b) in the certainty-equivalent testing phase, it follows that

$$\tau_t \leq (2 \log a^t) \log t + 3n_t. \tag{4.41}$$

Moreover, in view of (4.41) together with (3.10a,b) and (4.22) we have, for all large t,

$$\tau_{[t/\log t]} < 3t \log a \text{ and } \tau_i < 3t(c_j(\theta_0) + \epsilon) \log a \text{ for all } [t/\log t] < i \leq t \text{ on } \Delta_t.$$

Hence for all large t,

$$\tau_t/t \leq (3 \log a)(\log t) I_{\Delta_t^c} + (3 \log a)(c_j(\theta_0) + \epsilon) I_{\Delta_t}. \tag{4.42}$$

Since $\mathbf{P}_x^{\phi^*}(\Delta_t^c) = O(t^{-(\beta-1)}(\log t)^{2\beta})$ by (4.40), the uniform integrability of $\{\tau_t/t, t \geq 1\}$ follows from (4.42).

Labeling the elements of $\{\nu_i(m) : i \geq 1, 1 \leq m \leq m(i)\}$ as $s_1 < s_2 < \cdots$ (test times), define

$$\sigma_t = \sup \left\{ s_n \leq a^{t+1} : \inf_{\lambda \in \Theta_j \cap B_\delta(\theta_0)} \widetilde{W}_{s_n,j}(\lambda) < t a^t \right\}, \quad \#_{t,1} = T_{\sigma_t}(g_j), \tag{4.43}$$

$$\#_{t,2} = \sum_{i=1}^{t} I_{\Omega_i \cap \Lambda_i} \sum_{m=1}^{m(i)} 2n_i I_{\{\inf_{\lambda \in \Theta_j \setminus B_\delta(\theta_0)} W_{\nu_i(m)}(\lambda) < i a^i\}}, \tag{4.44}$$

$$\#_{t,3} = \sum_{i=1}^{t} (a^{i+1} - a^i)(I_{\Omega_i^c} + I_{\Lambda_i^c}), \tag{4.45}$$

where Ω_i and Λ_i are defined in (4.32) and (4.34). Since $\nu_i(m) - \nu_i(m-1) \leq 2n_i$ and since

$$\inf_{\lambda \in \Theta_j} \max(\widetilde{W}_{n,j}(\lambda), W_n(\lambda)) \geq \min \left\{ \inf_{\lambda \in \Theta_j \cap B_\delta(\theta_0)} \widetilde{W}_{n,j}(\lambda), \inf_{\lambda \in \Theta_j \setminus B_\delta(\theta_0)} W_n(\lambda) \right\},$$

it follows from (3.12), (4.15), and (4.16) that

$$\widetilde{\tau}_t (= T_{a^{t+1}}(g_j) - \tau_t) \leq \#_{t,1} + \#_{t,2} + \#_{t,3}. \tag{4.46}$$

By (4.31) and (4.35) with $\beta > 2$, $\mathbf{E}_x^{\phi^*}(\#_{t,3}) = \sum_{i=1}^{t} O(i^{-1}) = O(\log t)$. Since $\#_{t,3} \geq 0$ and $\mathbf{E}_x^{\phi^*}(t^{-1}\#_{t,3}) \to 0$ as $t \to \infty$, it follows that $\{\#_{t,3}/t, t \geq 1\}$ is uniformly integrable under $\mathbf{P}_x^{\phi^*}$.

To prove that $\{\#_{t,1}/t, t \geq 1\}$ is uniformly integrable under $\mathbf{P}_x^{\phi^*}$, take $\epsilon > 0$, choose δ by (4.19) and define $\theta_1, \ldots, \theta_K$ as in (4.3). Letting $\Gamma_k = \{\theta : \rho(\theta_k, \theta) \leq \delta'_{\theta_k}\}$, we shall modify the use of (4.23) and (4.26) in the proof of Lemma 5 by introducing

$$\begin{aligned} \sigma^* = \sup \left\{ T_{s_n}(g_j) : \max_{0 \leq k \leq K} \sup_{\theta \in \Gamma_k} \sum_{s=1}^{s_n} |\ell_s(\theta) - \ell_s(\theta_k)| I_{\{\phi^*_{s-1} = g_j\}} > 2\epsilon T_{s_n}(g_j) \right\} \\ \vee \sup \left\{ T_{s_n}(g_j) : \max_{0 \leq k \leq K} \left| (T_{s_n}(g_j))^{-1} \sum_{s=1}^{s_n} \ell_s(\theta_k) I_{\{\phi^*_{s-1} = g_j\}} - I^{g_j}(\theta_0, \theta_k) \right| > 2\epsilon \right\}. \end{aligned} \tag{4.47}$$

For $T_{s_n}(g_j) > \sigma^*$, we have

$$\max_{0\le k\le K} \sup_{\theta\in\Gamma_k} \sum_{s=1}^{s_n} |\ell_s(\theta) - \ell_s(\theta_k)| I_{\{\phi^*_{s-1}=g_j\}} \le 2\epsilon T_{s_n}(g_j)$$

and

$$\max_{0\le k\le K} \left| T_{s_n}(g_j))^{-1} \sum_{s=1}^{s_n} \ell_s(\theta_k) I_{\{\phi^*_{s-1}=g_j\}} - I^{g_j}(\theta_0,\theta_k) \right| \le 2\epsilon.$$

Hence an argument similar to that used to derive (4.25) and (4.30) can be used to show that if $T_{s_n}(g_j) > \sigma^*$ then

$$\inf_{\lambda\in\Theta_j\cap B_\delta(\theta_0)} \log \widetilde{W}_{s_n,j}(\lambda) \ge \left\{ \inf_{\lambda\in\Theta_j\cap B_\delta(\theta_0)} I^{g_j}(\theta_0,\lambda) - 7\epsilon \right\} T_{s_n}(g_j) + \log w_0, \tag{4.48}$$

where $w_0 = F(\Gamma_0)$. From (4.48) and (4.43) it follows that

$$\#_{t,1}(= T_{\sigma_t}(g_j)) \le \max\{\sigma^*, 1 + \log(ta^t/w_0)/[\inf_{\lambda\in\Theta_j\cap B_\delta(\theta_0)} I^{g_j}(\theta_0,\lambda) - 7\epsilon]\}, \tag{4.49}$$

noting that $\inf_{\lambda\in\Theta_j\cap B_\delta(\theta_0)} I^{g_j}(\theta_0,\lambda) - 7\epsilon > 0$ by (C3) and (4.19), provided that ϵ is chosen sufficiently small. By (4.47) and Lemmas 2 and 3, $\sum_{m=1}^\infty \mathbf{P}_x^{\phi^*}\{\sigma^* \ge m\} = \sum_{m=1}^\infty O(m^{-(\beta-1)}) < \infty$ since $\beta > 2$. Therefore $\mathbf{E}_x^{\phi^*}(\sigma^*) < \infty$ and the uniform integrability of $\{\#_{t,1}/t, t \ge 1\}$ follows from (4.49).

To prove the uniform integrability of $\{\#_{t,2}/t, t \ge 1\}$ under $\mathbf{P}_x^{\phi^*}$, recall that (4.36) holds on $\Omega_i \cap \Lambda_i$ for all large i. By (C3) and choosing ϵ sufficiently small, this implies that $\{\#_{t,2}, t \ge 1\}$ is uniformly bounded by some constant.

The case where ϕ^* is replaced by $\widetilde{\phi}$ is even simpler and is similar to the preceding proof of the uniform integrability of $\{\widetilde{\tau}_t/t,\ t \ge 1\}$.

BLOCK TRIANGULAR DECOUPLING FOR LINEAR SYSTEMS OVER PRINCIPAL IDEAL DOMAINS*

NAOHARU ITO† AND HIROSHI INABA†

Abstract. This paper studies in the framework of the so-called geometric approach the block triangular decoupling problem with state feedback for linear systems defined over a principal ideal domain with identity. First, various properties of feedback reachability submodules are discussed, and then under certain assumptions necessary and sufficient conditions for its solvability are obtained. Further, the pole assignability for decoupled systems is investigated. Finally, a simple example is given to illustrate the results.

Key words. block triangular decoupling, linear systems over rings, feedback reachability submodules, pole assignability

1. Introduction.

In the so-called geometric approach, various block decoupling problems for linear systems over the field of real numbers were first studied in [9] and [13]. In particular, they studied the block decoupling problem with certain assumptions [13] as well as the block triangular decoupling problem [9] and obtained necessary and sufficient conditions for each problem to be solvable. The results were given in terms of the largest elements in some families of reachability subspaces satisfying certain conditions.

It seems quite interesting and useful to investigate the corresponding decoupling problems for systems over rings also in the framework of the geometric approach because systems over rings are a natural generalization of systems over the field of real numbers and are used as abstract descriptions of, for instance, systems with parameters or with time-delay operators. In fact, such systems have been extensively studied in the last two decades (see, e.g., [1], [3], [7], [11], and [10]).

The present authors [6] and with Munaka [5] have already shown that the results for the block decoupling problem given in [13] are essentially valid for the corresponding problem for systems over principal ideal domains. So, the purpose of the present investigation is to discuss the corresponding triangular decoupling problem for systems over principal ideal domains and to present necessary and sufficient conditions for the problem to be solvable. Although this problem brings a number of new difficulties to be resolved, it turns out that the results obtained in [9] are still essentially valid for this new problem. Furthermore, the pole assignability of decoupled systems is also studied in some detail.

The outline of the paper is as follows. Section 2 gives preliminaries and notions of reachability submodules and their important properties. In section 3, the block triangular decoupling problem is formulated in the framework of the geometric approach, and necessary and sufficient conditions for its solvability are obtained. Section 4 con-

siders the pole assignability of a decoupled system and shows that the reachability of the original system implies the pole assignability. In section 5 an example is presented to demonstrate our results, and finally in section 6 some concluding remarks are given.

2. Preliminaries and reachability submodules. Throughout this paper we consider a system (A, B, C) over a commutative principal ideal domain $\boldsymbol{\mathcal{K}}$ with the identity 1, where $A \in \boldsymbol{\mathcal{K}}^{n\times n}$, $B \in \boldsymbol{\mathcal{K}}^{n\times m}$, and $C \in \boldsymbol{\mathcal{K}}^{l\times n}$ denote the system matrix, the input matrix, and the output matrix, respectively. When the output matrix C is immaterial, we will simply write (A, B). Let $X := \boldsymbol{\mathcal{K}}^n$, $U := \boldsymbol{\mathcal{K}}^m$, and $Y := \boldsymbol{\mathcal{K}}^l$ be free $\boldsymbol{\mathcal{K}}$-modules. Then, system (A, B, C) defines a discrete-time system described by

$$x(t+1) = Ax(t) + Bu(t), \quad y(t) = Cx(t), \tag{2.1}$$

where $x(t) \in X$, $u(t) \in U$, and $y(t) \in Y$ are the state, the input, and the output, respectively. For a given input sequence $u = (u(t))_{t=0}^{\infty}$ and an initial state $x(0) = x_0 \in X$, we denote by $x(t; x_0, u)$ the state at time t resulting via (2.1). The triple (A, B, C) may also be considered to represent a continuous-time system of the form

$$\frac{dx(t)}{dt} = Ax(t) + Bu(t), \quad y(t) = Cx(t) \tag{2.2}$$

provided that the derivative $dx(t)/dt$ can be suitably defined. However, the development to follow in this paper does not depend on whether system (A, B, C) represents a discrete-time or a continuous-time system, so we may simply consider it as a discrete-time system. Throughout this paper, the field of real numbers will be denoted by $\boldsymbol{R}$.

Systems over principal ideal domains can describe various systems appearing applications, such as parametrized systems, systems over the integer ring, time-delay systems, etc.; see, e.g., [1], [7], [11], [10].

Example 2.1. Linearize around the equilibrium point $(x_1, x_2) = (\lambda, 0)$ the nonlinear system over $\boldsymbol{R}$ given by

$$\left\{ \begin{array}{rcl} x_1(t+1) & = & x_1(t) + x_1^2(t) + u_1(t), \\ x_2(t+1) & = & 2x_2(t) + u_2(t), \\ y(t) & = & x_1(t)x_2(t) + x_1(t), \end{array} \right. \tag{2.3}$$

where λ is an arbitrary real constant number. Then, the resulting linearized system is described by

$$x(t+1) = A(\lambda)x(t) + B(\lambda)u(t), \quad y = C(\lambda)x(t), \tag{2.4}$$

where

$$A(\lambda) = \begin{bmatrix} 1 & \lambda^2 \\ 0 & 2 \end{bmatrix}, \quad B(\lambda) = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}, \quad C(\lambda) = \begin{bmatrix} 1 & \lambda \end{bmatrix},$$

which are considered to be matrices over $\boldsymbol{R}[\lambda]$, the ring of polynomials in the indeterminate λ with coefficients in $\boldsymbol{R}$. Since $\boldsymbol{R}[\lambda]$ is a principal ideal domain, the triple $(A(\lambda), B(\lambda), C(\lambda))$ of (2.4) is regarded as a linear system over the principal ideal domain $\boldsymbol{R}[\lambda]$. □

Example 2.2. Consider the linear time-delay system described by

$$\frac{dx(t)}{dt} = \sum_{i=0}^{p} A_i x(t - ih) + \sum_{i=0}^{q} B_i u(t - ih), \quad y(t) = \sum_{i=0}^{r} C_i x(t - ih), \tag{2.5}$$

where h is a fixed positive number, A_i, B_i, and C_i are $n \times n, n \times m$, and $l \times n$ matrices over $\boldsymbol{R}$, respectively. Now, let σ denote the time-delay operator defined by $(\sigma x)(t) := x(t-h)$. Then (2.5) can be written in the form

$$\frac{dx}{dt} = A(\sigma)x + B(\sigma)u, \qquad y(t) = C(\sigma)x, \tag{2.6}$$

where $A(\sigma), B(\sigma)$, and $C(\sigma)$ are $n \times n, n \times m$, and $l \times n$ matrices over $\boldsymbol{R}[\sigma]$. Thus system (2.6) can be described as a linear system over the principal ideal domain $\boldsymbol{R}[\sigma]$. □

Consider a system (A, B) over $\boldsymbol{\mathcal{K}}$ with $A \in \boldsymbol{\mathcal{K}}^{n\times n}$ and $B \in \boldsymbol{\mathcal{K}}^{n\times m}$. As in the case of systems over $\boldsymbol{R}$ [12], the *reachable submodule* for system (A, B) is given by

$$\langle A|\operatorname{Im} B\rangle := \operatorname{Im} B + A(\operatorname{Im} B) + \cdots + A^{n-1}(\operatorname{Im} B) \subset X,$$

where $\operatorname{Im} B$ stands for the image of B. That $\langle A|\operatorname{Im} B\rangle$ is called the reachable submodule comes from the fact that for every $\tilde{x} \in \langle A|\operatorname{Im} B\rangle$ there exist a time $T \geq 0$ and an input u such that $x(T; 0, u) = \tilde{x}$. Thus, the pair (A, B) is called *reachable* if $\langle A|\operatorname{Im} B\rangle = X$.

The following definition gives the basic notions in the geometric approach for linear systems [13], [12].

DEFINITION 2.3. *Let φ be a submodule of X.*

(i) *φ is said to be* (A, B)-invariant *if $A\varphi \subset \varphi + \operatorname{Im} B$.*

(ii) *φ is said to be* feedback (A, B)-invariant *if there exists $F \in \boldsymbol{\mathcal{K}}^{m\times n}$ such that $(A + BF)\varphi \subset \varphi$. The set of all those F's satisfying such inclusion is denoted by $\mathbf{F}(\varphi; A, B)$. (Note that φ is feedback (A, B)-invariant if and only if $\mathbf{F}(\varphi; A, B) \neq \emptyset$.)* □

An (A, B)-invariant submodule φ has the property that for every $x(0) \in \varphi$ there exists an input sequence u such that $x(t; x(0), u) \in \varphi$ for $t = 0, 1, 2, \ldots$. A feedback (A, B)-invariant submodule φ has the property that there exists a matrix $F \in \boldsymbol{\mathcal{K}}^{m\times n}$ such that by defining an input sequence $u := (Fx(t))_{t=0}^{\infty}$ for every $x(0) \in \varphi$, $x(t; x(0), u)$ belongs to φ for $t = 0, 1, 2, \ldots$.

A submodule $\varphi \subset X$ is called a *direct summand* of X if there exists a submodule $\psi \subset X$ such that $X = \varphi + \psi$ and $\varphi \cap \psi = \{0\}$. Then we write $X = \varphi \oplus \psi$. We remark that subspaces of a linear space are always direct summands but submodules are not necessarily. As will be seen later, this difference causes the main difficulty in studying systems over $\boldsymbol{\mathcal{K}}$. So the following notion plays an important role in what follows.

DEFINITION 2.4. *Let $\psi \subset \varphi$ be submodules of X. The* closure $\operatorname{Cl}_\varphi(\psi)$ *of ψ in φ is defined to be the submodule given by*

$$\operatorname{Cl}_\varphi(\psi) := \{x \in \varphi \text{ such that } ax \in \psi \text{ for some nonzero } a \in \boldsymbol{\mathcal{K}}\}.$$

ψ is said to be closed *in φ if* $\operatorname{Cl}_\varphi(\psi) = \psi$. □

Remark 2.5. From [1] and [4] we recall the following facts.

(i) A submodule of X is closed in X if and only if it is a direct summand of X.

(ii) If a submodule of X is feedback (A, B)-invariant, then so is its closure in X. However, (A, B)-invariance does not necessarily imply (A, B)-invariance of its closure.

(iii) Feedback (A, B)-invariance implies (A, B)-invariance, but the converse is not generally true.

(iv) The sum of two (A, B)-invariant submodules is again an (A, B)-invariant submodule. Therefore, the family of all (A, B)-invariant submodules contained in

a given submodule has a unique largest (A, B)-invariant submodule. However, this property does not hold true for the case of feedback (A, B)-invariant submodules.

(v) The largest (A, B)-invariant submodule contained in a given closed submodule of X is feedback (A, B)-invariant if and only if it is closed in X. □

Now, the following two notions of reachability submodules are introduced.

DEFINITION 2.6. *Let φ be a submodule of X.*

(i) *φ is said to be a* reachability submodule *for (A, B) if for each $\tilde{x} \in \varphi$ there exist a time $T \geq 0$ and an input sequence $u = \{u(t)\}_{t=0}^{\infty}$ such that $x(t; 0, u)$ belongs to φ for $t = 0, 1, 2, \ldots$ and $x(T; 0, u) = \tilde{x}$.*

(ii) *φ is called a* feedback reachability submodule *for (A, B) if there exist $F \in \boldsymbol{\mathcal{K}}^{m\times n}$ and $G \in \boldsymbol{\mathcal{K}}^{m\times m}$ such that $\varphi = \langle A + BF | \operatorname{Im}(BG)\rangle$.* □

Remark 2.7. What was called a reachability submodule in the papers [6] and [5] is renamed in this paper a *feedback reachability submodule*. Conte and Perdon [2] introduced the notion of precontrollability submodules for linear systems over a commutative ring. It is possible to verify that this notion is equivalent to that of reachability submodules given in Definition 2.6. □

A feedback reachability submodule φ for (A, B) is the reachable submodule for the new system $(A + BF, BG)$ resulting from applying a state feedback of the form $u(t) = Fx(t) + Gv(t)$ to (2.1), where v denotes the new input. In other words, for each $\tilde{x} \in \varphi$ there exist a time $T \geq 0$ and an input sequence $v = (v(t))_{t=0}^{\infty}$ such that, defining an input sequence $u := (Fx(t) + Gv(t))_{t=0}^{\infty}$, we have $x(t; 0, u) \in \varphi$ for $t = 0, 1, 2, \ldots$ and $x(T; 0, u) = \tilde{x}$. Therefore, if a submodule of X is a feedback reachability submodule then it is a reachability submodule. However, a reachability submodule is not necessarily a feedback reachability submodule (see Remark 2.11), although these two notions are equivalent for linear systems over the field $\boldsymbol{R}$. In fact, Conte and Perdon [2] showed that a submodule is a feedback reachability submodule if and only if it is a reachability submodule and a feedback (A, B)-invariant submodule.

For feedback reachability submodules, the following lemma can be proved in the same manner as in [13], except for the sufficiency part of (i).

LEMMA 2.8. *Let φ be a submodule of X.*

(i) *φ is a feedback reachability submodule for (A, B) if and only if there exists $F \in \boldsymbol{\mathcal{K}}^{m\times n}$ such that $\varphi = \langle A + BF | \operatorname{Im} B \cap \varphi\rangle$.*

(ii) *If φ is a feedback reachability submodule for (A, B), then*

$$\varphi = \langle A + BF | \operatorname{Im} B \cap \varphi\rangle$$

for all $F \in \mathbf{F}(\varphi; A, B)$.

Proof. Only a proof of the sufficiency of (i) will be given. Since $\operatorname{Im} B \cap \varphi$ is a submodule of the free $\boldsymbol{\mathcal{K}}$-module X, it is free. Hence, if the rank of $\operatorname{Im} B \cap \varphi$ is p, there is a basis $\{b_1, b_2, \ldots, b_p\} \subset X$ of $\operatorname{Im} B \cap \varphi$. For each b_i $(i = 1, 2, \ldots, p)$ there exists $u_i \in U$ $(i = 1, 2, \ldots, p)$ such that $b_i = Bu_i$. Defining $G := [u_1, \ldots, u_p, 0, \ldots, 0] \in \boldsymbol{\mathcal{K}}^{m\times m}$, we obtain $\operatorname{Im} B \cap \varphi = \operatorname{Im}(BG)$, showing that φ is a feedback reachability submodule for (A, B). □

It should be remarked that if φ is a feedback reachability submodule, then φ is feedback (A, B)-invariant and hence the set $\mathbf{F}(\varphi; A, B)$ is not empty. Furthermore, a feedback reachability submodule is not necessarily closed in X, and the closure of a feedback reachability submodule is not always a feedback reachability submodule, as is seen from the following example.

Example 2.9. Let $\boldsymbol{\mathcal{K}}:=\boldsymbol{R}[\sigma]$ and $X := \boldsymbol{\mathcal{K}}^2$, and set

$$A := \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix}, \quad B := \begin{bmatrix} \sigma & 0 \\ 0 & 1 \end{bmatrix}, \quad \varphi := \operatorname{Im} \begin{bmatrix} \sigma \\ 0 \end{bmatrix}.$$

Then, it is easy to see that φ is A-invariant and $\varphi \cap \operatorname{Im} B = \varphi$. Therefore, $\varphi = \langle A | \operatorname{Im} B \cap \varphi \rangle$, and hence φ is a feedback reachability submodule for (A, B) by Lemma 2.8. The closure is given by

$$\operatorname{Cl}_X(\varphi) = \operatorname{Im} \begin{bmatrix} 1 \\ 0 \end{bmatrix} \neq \varphi,$$

and hence φ is not closed in X. Moreover, $\operatorname{Cl}_X(\varphi)$ is not a feedback reachability submodule for (A, B). In fact, since $\operatorname{Cl}_X(\varphi)$ is A-invariant and hence satisfies $0 \in \mathbf{F}(\operatorname{Cl}_X(\varphi); A, B)$, Lemma 2.8 and the relation

$$\langle A | \operatorname{Im} B \cap \operatorname{Cl}_X(\varphi) \rangle = \operatorname{Im} \begin{bmatrix} \sigma \\ 0 \end{bmatrix} \neq \operatorname{Cl}_X(\varphi)$$

imply that $\operatorname{Cl}_X(\varphi)$ is not a feedback reachability submodule. □

It is well known that for systems over $\boldsymbol{R}$ the sum of two feedback reachability subspaces is again a feedback reachability subspace. However, this statement is not true for systems over $\boldsymbol{\mathcal{K}}$. Thus there is no guarantee that a largest feedback reachability submodule in the family of feedback reachability submodules contained in a given submodule exists. The next example demonstrates that the sum of two feedback reachability submodules is not a feedback reachability submodule.

Example 2.10. Let $\boldsymbol{\mathcal{K}}:=\boldsymbol{R}[\sigma]$ and $X := \boldsymbol{\mathcal{K}}^3$, and set

$$A := \begin{bmatrix} 1 & 1 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}, \quad B := \begin{bmatrix} \sigma & 0 & 0 \\ 0 & \sigma & 0 \\ 0 & 1 & 1 \end{bmatrix},$$

$$\varphi_1 := \operatorname{Im} \begin{bmatrix} 0 \\ \sigma \\ 1 \end{bmatrix}, \quad \varphi_2 := \operatorname{Im} \begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix}.$$

Then, it can easily be checked that $\varphi_1 \cap \operatorname{Im} B = \varphi_1$ and $\varphi_2 \cap \operatorname{Im} B = \varphi_2$, and hence that $\langle A + BF_1 | \varphi_1 \cap \operatorname{Im} B \rangle = \varphi_1$ and $\langle A + BF_2 | \varphi_2 \cap \operatorname{Im} B \rangle = \varphi_2$, where

$$F_1 = \begin{bmatrix} 0 & 0 & -1 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \in \mathbf{F}(\varphi_1; A, B), \qquad F_2 = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \in \mathbf{F}(\varphi_2; A, B).$$

Therefore, by Lemma 2.8 φ_1 and φ_2 are feedback reachability submodules. On the other hand, the closure of the submodule $\varphi_1 + \varphi_2$, i.e., the closed submodule

$$\operatorname{Cl}_X(\varphi_1 + \varphi_2) = \operatorname{Im} \begin{bmatrix} 0 & 0 \\ 1 & 0 \\ 0 & 1 \end{bmatrix},$$

is not (A, B)-invariant because for $[0\ 1\ 0]^\top \in \operatorname{Cl}_X(\varphi_1 + \varphi_2)$

$$A \begin{bmatrix} 0 \\ 1 \\ 0 \end{bmatrix} = \begin{bmatrix} 1 \\ 1 \\ 0 \end{bmatrix} \notin \operatorname{Cl}_X(\varphi_1 + \varphi_2) + \operatorname{Im} B = \operatorname{Im} \begin{bmatrix} \sigma & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}.$$

Thus, by virtue of Remark 2.5, $\mathrm{Cl}_X(\varphi_1+\varphi_2)$ is not feedback (A,B)-invariant, and hence $\varphi_1+\varphi_2$ is not feedback (A,B)-invariant. Therefore, $\varphi_1+\varphi_2$ is not a feedback reachability submodule for (A,B). □

Remark 2.11. In Example 2.10, $\varphi_1+\varphi_2$ is a reachability submodule for (A,B) but not a feedback reachability submodule for (A,B). □

As will be seen later, in investigating systems over $\boldsymbol{\mathcal{K}}$ it is vital to look for conditions under which the largest feedback reachability submodule contained in a given submodule exists. To this purpose, we first introduce the following algorithm.

ALGORITHM 2.12. For a given submodule ψ of X, compute the sequence $(R^{(i)})$ of submodules of X for (A,B) as

$$\begin{cases} R^{(0)}(\psi) := 0, \\ R^{(i)}(\psi) := \psi \cap (AR^{(i-1)}(\psi) + \operatorname{Im} B) \quad (i = 1,2,\ldots). \end{cases} \tag{2.7}$$

Then, it is obvious that the sequence $(R^{(i)})$ is nondecreasing. Thus, since $\boldsymbol{\mathcal{K}}$ is a principal ideal domain, there exists an integer $q \geq 0$ such that $R^{(i)}(\psi) = R^{(i+1)}(\psi)$ for $i \geq q$. So set $\mathcal{R}(\psi) := R^{(q)}(\psi)$. □

Now, the following proposition will be proved.

PROPOSITION 2.13. *Let S be a submodule of X and V^*, the largest (A,B)-invariant submodule contained in S. If $\mathcal{R}(V^*)$ is feedback (A,B)-invariant, then $\mathcal{R}(V^*)$ is the largest feedback reachability submodule for (A,B) contained in S, and it is given as*

$$\mathcal{R}(V^*) = \langle A + BF | \operatorname{Im} B \cap V^* \rangle,$$

where F is an arbitrary element in $\mathbf{F}(\mathcal{R}(V^*); A, B)$.

Proof. Assume that $\mathcal{R}(V^*)$ is feedback (A,B)-invariant. Hence, it follows from Definition 2.3 that $\mathbf{F}(\mathcal{R}(V^*); A, B) \neq \emptyset$. Then, it is claimed that for any $F \in \mathbf{F}(\mathcal{R}(V^*); A, B)$

$$R^{(i)}(V^*) = \sum_{j=1}^{i} (A+BF)^{j-1}(V^* \cap \operatorname{Im} B) \quad (i = 1,2,\ldots). \tag{2.8}$$

To verify this claim, first notice that

$$(A+BF)R^{(i)}(V^*) \subset \mathcal{R}(V^*) \subset V^* \quad (i = 1,2,\ldots). \tag{2.9}$$

It is clear that (2.8) is true for $i = 1$. Next, assuming that (2.8) holds true for $i = p$, and using (2.9) and (2.7), one obtains

$$\begin{aligned} \sum_{j=1}^{p+1} (A+BF)^{j-1}(V^* \cap \operatorname{Im} B) &= V^* \cap \operatorname{Im} B + (A+BF)R^{(p)}(V^*) \\ &= V^* \cap [(A+BF)R^{(p)}(V^*) + \operatorname{Im} B] \\ &= V^* \cap (AR^{(p)}(V^*) + \operatorname{Im} B) \\ &= R^{(p+1)}(V^*). \end{aligned}$$

Thus (2.8) is true for all i, and hence the claim is verified.

Now, it is easily seen from (2.8) and the Cayley–Hamilton theorem that

$$\mathcal{R}(V^*) = R^{(n)}(V^*) = \langle A + BF | \operatorname{Im} B \cap V^* \rangle.$$

As in the proof of the sufficiency of (i) of Lemma 2.8, it is possible to construct a matrix $G \in \mathcal{K}^{m\times m}$ such that $\operatorname{Im} B \cap V^* = \operatorname{Im}(BG)$. Hence, $\mathcal{R}(V^*)$ is a feedback reachability submodule for (A, B). Moreover, it follows from Algorithm 2.12 and the inclusion $V^* \subset S$ that

$$\mathcal{R}(V^*) = R^{(n)}(V^*) \subset V^* \subset S.$$

Therefore, $\mathcal{R}(V^*)$ is a feedback reachability submodule for (A, B) contained in S.

To see that $\mathcal{R}(V^*)$ is the largest feedback reachability submodule contained in S, let φ be any feedback reachability submodule for (A, B) contained in S. First, note that $\mathbf{F}(\varphi; A, B) \neq \emptyset$ because φ is feedback (A, B)-invariant, and so take any $F \in \mathbf{F}(\varphi; A, B)$. Then, it is claimed that

$$R^{(i)}(\varphi) = \sum_{j=1}^{i} (A + BF)^{j-1}(\varphi \cap \operatorname{Im} B) \quad (i = 1, 2, \ldots). \tag{2.10}$$

In fact, this can be shown in the same manner as verifying (2.8). Further, it is easily seen from (2.10) and the Cayley–Hamilton theorem that

$$R^{(n)}(\varphi) = \langle A + BF | \operatorname{Im} B \cap \varphi \rangle = \varphi.$$

Now, since φ is an (A, B)-invariant submodule contained in S, one has $\varphi \subset V^*$, and hence

$$\varphi = R^{(n)}(\varphi) \subset R^{(n)}(V^*) = \mathcal{R}(V^*),$$

showing that $\mathcal{R}(V^*)$ is the largest feedback reachability submodule for (A, B) contained in S. □

COROLLARY 2.14. *Let S be a submodule of X and V^* be the largest (A, B)-invariant submodule contained in S. If V^* is closed in X, then $\mathcal{R}(V^*)$ is the largest feedback reachability submodule for (A, B) contained in S, and it is given as*

$$\mathcal{R}(V^*) = \langle A + BF | \operatorname{Im} B \cap V^* \rangle,$$

where F is an arbitrary element in $\mathbf{F}(\mathcal{R}(V^*); A, B)$. Furthermore, the inclusion $\mathbf{F}(V^*; A, B) \subset \mathbf{F}(\mathcal{R}(V^*); A, B)$ is satisfied.

Proof. First, we will show that V^* is feedback (A, B)-invariant. Since V^* is closed in X, there exists a basis $\{x_1, x_2, \ldots, x_n\}$ of X such that $\{x_1, x_2, \ldots, x_r\}$ is a basis of V^*, where $r(\leq n)$ is the rank of V^*. Further, since V^* is (A, B)-invariant, there exist $z_1, z_2, \ldots, z_r \in V^*$ and $u_1, u_2, \ldots, u_r \in U := \mathcal{K}^m$ such that

$$Ax_i = z_i - Bu_i \quad (i = 1, 2, \ldots, r).$$

Now, letting $T := [x_1, x_2, \ldots, x_n]$ and defining

$$F := [u_1, u_2, \ldots, u_r, 0_{m\times(n-r)}]T^{-1},$$

where $0_{m\times(n-r)}$ denotes the $m \times (n-r)$ zero matrix, it is easily seen that $(A+BF)x \in V^*$ for all $x \in V^*$. Thus, V^* is feedback (A, B)-invariant and $F \in \mathbf{F}(V^*; A, B)$.

Next, take any $F \in \mathbf{F}(V^*; A, B)$. Then for any $x \in \mathcal{R}(V^*) \subset V^*$ one has $(A + BF)x \in V^*$, and further

$$(A + BF)x = Ax + BFx \in A\mathcal{R}(V^*) + \operatorname{Im} B.$$

Thus, with the help of Algorithm 2.12,

$$(A+BF)x \in V^* \cap (A\mathcal{R}(V^*) + \operatorname{Im} B) = \mathcal{R}(V^*),$$

which shows that $\mathcal{R}(V^*)$ is feedback (A,B)-invariant and that

$$\mathbf{F}(V^*;A,B) \subset \mathbf{F}(\mathcal{R}(V^*);A,B).$$

Therefore, it follows from Proposition 2.13 that $\mathcal{R}(V^*)$ is the largest feedback reachability submodule for (A,B) contained in S, and it is given as

$$\mathcal{R}(V^*) = \langle A+BF|\operatorname{Im} B \cap V^*\rangle,$$

where F is an arbitrary element in $\mathbf{F}(\mathcal{R}(V^*);A,B)$. □

3. Block triangular decoupling. Consider a system (A,B,C) over $\boldsymbol{\mathcal{K}}$, and suppose that the output matrix C is partitioned into k blocks as

$$C = \begin{bmatrix} C_1 \\ C_2 \\ \vdots \\ C_k \end{bmatrix},$$

where $C_i \in \boldsymbol{\mathcal{K}}^{l_i \times n}$ and $l_1 + l_2 + \cdots + l_k = l$. Then, system (A,B,C) is represented as $(A,B,\{C_i\}_{i=1}^k)$, which defines the following system:

$$\begin{cases} x(t+1) &= Ax(t) + Bu(t), \\ y_i(t) &= C_i x(t) \quad (i = 1,2,\ldots,k). \end{cases}$$

Now, apply to this system a state feedback control of the form

$$u(t) = Fx(t) + \sum_{i=1}^{k} G_i v_i(t), \tag{3.1}$$

where $F \in \boldsymbol{\mathcal{K}}^{m\times n}$, $G_i \in \boldsymbol{\mathcal{K}}^{m\times m}$, and $v_i(t)$ are the new inputs. Then, the resulting closed loop system is easily seen to be $(A+BF, B[G_1,G_2,\ldots,G_k], \{C_i\}_{i=1}^k)$; i.e.,

$$\begin{cases} x(t+1) &= (A+BF)x(t) + \sum_{i=1}^{k} BG_i v_i(t), \\ y_i(t) &= C_i x(t) \quad (i = 1,2,\ldots,k). \end{cases}$$

Accordingly, the feedback reachability submodule φ_i generated by the input v_i is given by

$$\varphi_i = \langle A+BF|\operatorname{Im}(BG_i)\rangle.$$

Roughly speaking, the *block triangular decoupling problem* for $(A,B,\{C_i\}_{i=1}^k)$ can be stated as follows [9]: find a state feedback (3.1) such that the resulting closed loop system $(A+BF, B[G_1,G_2,\ldots,G_k], \{C_i\}_{i=1}^k)$ should control the output $y_1, y_2, \ldots, y_k$ sequentially; that is to say, v_1 controls y_1, possibly changing the values of $y_2, y_3, \ldots, y_k$, then v_2 controls y_2, possibly changing the values of $y_3, y_4, \ldots, y_k$ without allowing influence on y_1, and so forth, with v_k controlling y_k without allowing influence on

$y_1, y_2, \ldots, y_{k-1}$. As in the case of the field $\boldsymbol{R}$ [9], this problem can be described more precisely as follows: given system $(A, B, \{C_i\}_{i=1}^k)$, the problem is to find, if possible, $F \in \boldsymbol{\mathcal{K}}^{m\times n}$ and $G_i \in \boldsymbol{\mathcal{K}}^{m\times m}$ $(i = 1, 2, \ldots, k)$ such that the feedback reachability submodules given by

$$\varphi_i = \langle A + BF | \operatorname{Im}(BG_i) \rangle \quad (i = 1, 2, \ldots, k) \tag{3.2}$$

satisfy the following two conditions: the first is

$$\varphi_1 \subset X =: \Omega_1, \tag{3.3}$$

$$\varphi_i \subset \bigcap_{j=1}^{i-1} \operatorname{Ker} C_j =: \Omega_i \quad (i = 2, 3, \ldots, k), \tag{3.4}$$

which requires that v_i does not affect the outputs $y_1, \ldots, y_{i-1}$, where $\operatorname{Ker} C_j$ stands for the kernel of C_j, and the second is

$$\varphi_i + \operatorname{Ker} C_i = X \quad (i = 1, 2, \ldots, k), \tag{3.5}$$

which requires that v_i controls the corresponding output y_i completely. Furthermore, using Lemma 2.8, this problem can be rephrased in a more compact form as follows.

Problem 3.1. Given system $(A, B, \{C_i\}_{i=1}^k)$ over $\boldsymbol{\mathcal{K}}$, the block triangular decoupling problem is to find, if possible, a set $\{\varphi_1, \varphi_2, \ldots, \varphi_k\}$ of feedback reachability submodules for (A, B) such that

$$\bigcap_{i=1}^{k} \mathbf{F}(\varphi_i; A, B) \neq \emptyset, \tag{3.6}$$

$$\varphi_i \subset \Omega_i, \tag{3.7}$$

$$\varphi_i + \operatorname{Ker} C_i = X \quad (i = 1, 2, \ldots, k). \tag{3.8}$$

Such a set $\{\varphi_1, \varphi_2, \ldots, \varphi_k\}$ is called a *solution* of the problem. □

For systems over the field $\boldsymbol{R}$ of real numbers, this problem was first studied by Morse and Wonham [9] where it was shown that necessary and sufficient conditions for its solvability are given by

$$\varphi_i^* + \operatorname{Ker} C_i = X \quad (i = 1, 2, \ldots, k), \tag{3.9}$$

where φ_i^* is the largest feedback reachability subspace contained in Ω_i, and further that in this case $\{\varphi_1^*, \varphi_2^*, \ldots, \varphi_k^*\}$ is a solution of the problem. Accordingly, if Problem 3.1 with $\boldsymbol{\mathcal{K}} = \boldsymbol{R}$ is solvable then $\{\varphi_1^*, \varphi_2^*, \ldots, \varphi_k^*\}$ is always a solution of it, and vice versa. Of course, it does not mean that $\{\varphi_1^*, \varphi_2^*, \ldots, \varphi_k^*\}$ is the only solution. Although the largest feedback reachability subspaces φ_i^* always exist for systems over $\boldsymbol{R}$, this property does not hold in general for systems over $\boldsymbol{\mathcal{K}}$ as stated earlier. However, Proposition 2.13 and Corollary 2.14 give some sufficient conditions for existence of such largest submodules for systems over $\boldsymbol{\mathcal{K}}$.

Therefore, in investigating Problem 3.1 in the geometric approach, it is inevitable to make the assumption that such largest submodules exist, and our main concern is whether (3.9) also gives necessary and sufficient conditions for Problem 3.1 to be solvable under this assumption. The answer is yes. However, its proof involves a number of detailed technical verifications which are not needed for the case of systems over the field $\boldsymbol{R}$. First, we make the following assumption.

Assumption 3.2. For system $(A, B, \{C_i\}_{i=1}^k)$ over $\boldsymbol{\mathcal{K}}$, it is assumed that there exists the largest feedback reachability submodule φ_i^* for (A, B) contained in Ω_i $(i = 1, 2, \ldots, k)$. □

It should be remarked from Corollary 2.14 and Proposition 2.13 that this assumption is satisfied either if every largest (A, B)-invariant submodule V_i^* contained in Ω_i is closed in X or if each submodule $\mathcal{R}(V_i^*)$ is feedback (A, B)-invariant. Further, it should be remarked that $\varphi_i^* = \mathcal{R}(V_i^*)$ if Assumption 3.2 is satisfied. Finally, we note that $\varphi_1^*, \varphi_2^*, \ldots, \varphi_k^*$ satisfy

$$\varphi_k^* \subset \varphi_{k-1}^* \subset \cdots \subset \varphi_1^*. \tag{3.10}$$

Before proving our main theorem, the following lemma will be shown.

LEMMA 3.3. *If $\varphi \subset X$ is a feedback (A, B)-invariant submodule, then*

$$\mathbf{F}(\varphi; A, B) \subset \mathbf{F}(\mathrm{Cl}_X(\varphi); A, B).$$

Proof. Take any $F \in \mathbf{F}(\varphi; A, B)$. Then, for any $x \in \mathrm{Cl}_X(\varphi)$ there exists a nonzero element $\alpha \in \boldsymbol{\mathcal{K}}$ such that $\alpha x \in \varphi$, and hence $\alpha(A + BF)x = (A + BF)(\alpha x) \in \varphi$. Therefore, one has $(A + BF)x \in \mathrm{Cl}_X(\varphi)$, showing $F \in \mathbf{F}(\mathrm{Cl}_X(\varphi); A, B)$. □

Now, we are ready to prove our main theorem.

THEOREM 3.4. *Suppose that system $(A, B, \{C_i\}_{i=1}^k)$ satisfies Assumption* 3.2. *Then the block triangular decoupling Problem* 3.1 *is solvable if and only if*

$$\varphi_i^* + \mathrm{Ker}\, C_i = X \quad (i = 1, 2, \ldots, k). \tag{3.11}$$

Moreover, in this case the set $\{\varphi_1^*, \varphi_2^*, \ldots, \varphi_k^*\}$ is a solution of the problem.

Proof. First, the sufficiency will be proved. So assume that (3.11) is satisfied. Then the definition of φ_i^* and (3.11) imply that the set $\{\varphi_1^*, \varphi_2^*, \ldots, \varphi_k^*\}$ satisfies (3.7) and (3.8) with φ_i replaced by φ_i^*. Therefore, if $\{\varphi_1^*, \varphi_2^*, \ldots, \varphi_k^*\}$ is shown to satisfy (3.6), then it is a solution of the problem; hence both the sufficiency and the second assertion in the theorem are proved simultaneously.

To verify that $\{\varphi_1^*, \varphi_2^*, \ldots, \varphi_k^*\}$ satisfies (3.6), first recall the relation of (3.10), and choose submodules $N_0, N_1, \ldots, N_k$ through the equations

$$\begin{aligned} &X = N_0 \oplus \mathrm{Cl}_X(\varphi_1^*), \\ &\mathrm{Cl}_X(\varphi_i^*) = N_i \oplus \mathrm{Cl}_X(\varphi_{i+1}^*) \quad (i = 1, \ldots, k-1), \\ &N_k := \mathrm{Cl}_X(\varphi_k^*). \end{aligned} \tag{3.12}$$

Then it is easy to obtain the relation

$$X = N_0 \oplus N_1 \oplus \cdots \oplus N_k. \tag{3.13}$$

Since each N_i is free, it has a basis $\{x_{i1}, x_{i2}, \ldots, x_{ir_i}\}$, where r_i denotes the rank of N_i. So, if matrices $T_i \in \boldsymbol{\mathcal{K}}^{n \times r_i}$ and $T \in \boldsymbol{\mathcal{K}}^{n \times n}$ are defined by

$$\begin{aligned} T_i &:= [x_{i1}, x_{i2}, \ldots, x_{ir_i}] \quad (i = 0, 1, \ldots, k), \\ T &:= [T_0, T_1, \ldots, T_k], \end{aligned}$$

then it is easy to see from (3.13) that T is invertible over $\boldsymbol{\mathcal{K}}$.

Next, since each φ_i^* is a feedback reachability submodule for (A, B), it is feedback (A, B)-invariant and hence satisfies

$$\mathbf{F}(\varphi_i^*; A, B) \neq \emptyset.$$

So, choosing an $F_i \in \mathbf{F}(\varphi_i^*; A, B)$ and defining $F \in \boldsymbol{\mathcal{K}}^{m\times n}$ by

$$F := [0_{m\times r_0}, F_1T_1, F_2T_2, \ldots, F_kT_k]T^{-1},$$

it is claimed that $F \in \bigcap_{i=1}^{k} \mathbf{F}(\varphi_i^*; A, B)$, i.e., that $\{\varphi_1^*, \varphi_2^*, \ldots, \varphi_k^*\}$ satisfies (3.6). To verify this, introduce the following feedback reachability submodules for (A, B):

$$\widetilde{\varphi}_i := \langle A + BF | \operatorname{Im} B \cap \varphi_i^* \rangle \quad (i = 1, 2, \ldots, k), \tag{3.14}$$

and we will first show that

$$\widetilde{\varphi}_i \subset \Omega_i \quad (i = 1, 2, \ldots, k). \tag{3.15}$$

To show (3.15), first notice that

$$F = \begin{cases} 0 & \text{on} \quad N_0, \\ F_i & \text{on} \quad N_i \end{cases} \quad (i = 1, 2, \ldots, k) \tag{3.16}$$

and further that by Lemma 3.3

$$F_i \in \mathbf{F}(\operatorname{Cl}_X(\varphi_i^*); A, B). \tag{3.17}$$

Now, (3.12), (3.16), and (3.17) imply that

$$(A + BF)\operatorname{Cl}_X(\varphi_k^*) = (A + BF_k)\operatorname{Cl}_X(\varphi_k^*) \subset \operatorname{Cl}_X(\varphi_k^*), \tag{3.18}$$

showing $F \in \mathbf{F}(\operatorname{Cl}_X(\varphi_k^*); A, B)$. Next, suppose that for some j $(2 \le j \le k)$

$$F \in \mathbf{F}(\operatorname{Cl}_X(\varphi_j^*); A, B),$$

or equivalently

$$(A + BF)\operatorname{Cl}_X(\varphi_j^*) \subset \operatorname{Cl}_X(\varphi_j^*). \tag{3.19}$$

Then, it follows from (3.12), (3.16), (3.17), and (3.19) that

$$\begin{aligned} (A + BF)\operatorname{Cl}_X(\varphi_{j-1}^*) &= (A + BF)(N_{j-1} + \operatorname{Cl}_X(\varphi_j^*)) \\ &\subset (A + BF_{j-1})N_{j-1} + (A + BF)\operatorname{Cl}_X(\varphi_j^*) \\ &\subset \operatorname{Cl}_X(\varphi_{j-1}^*) + \operatorname{Cl}_X(\varphi_j^*) \\ &= \operatorname{Cl}_X(\varphi_{j-1}^*). \end{aligned} \tag{3.20}$$

Hence, (3.20) together with (3.18) and (3.19) implies that

$$(A + BF)\operatorname{Cl}_X(\varphi_i^*) \subset \operatorname{Cl}_X(\varphi_i^*) \quad (i = 1, 2, \ldots, k).$$

Thus, noticing that $\varphi_i^* \subset \Omega_i$ and that Ω_i are closed in X, one obtains

$$\begin{gathered} (A + BF)^{j-1}\varphi_i^* \subset (A + BF)^{j-1}\operatorname{Cl}_X(\varphi_i^*) \subset \operatorname{Cl}_X(\Omega_i) = \Omega_i, \\ (j = 1, 2, \ldots, n; i = 1, 2, \ldots, k), \end{gathered}$$

which together with (3.14) imply that (3.15) holds.

Next, we will prove equalities $\varphi_i^* = \widetilde{\varphi}_i$ $(i = 1, 2, \ldots, k)$. First, note that since $\widetilde{\varphi}_i$ is a feedback reachability submodule contained in Ω_i and φ_i^* is the largest feedback reachability submodule in Ω_i, one has

$$\widetilde{\varphi}_i \subset \varphi_i^* \quad (i = 1, 2, \ldots, k). \tag{3.21}$$

To show the converse inclusion, fix i $(1 \leq i \leq k)$ and suppose that for some j $(1 \leq j \leq n-1)$

$$(A+BF_i)^{j-1}(\operatorname{Im} B \cap \varphi_i^*) \subset \widetilde{\varphi}_i. \tag{3.22}$$

Then,

$$\begin{aligned}(A+BF_i)^{j}(\operatorname{Im} B \cap \varphi_i^*) &\subset (A+BF_i)\widetilde{\varphi}_i \\ &= [A+BF+B(F_i-F)]\widetilde{\varphi}_i \\ &\subset (A+BF)\widetilde{\varphi}_i + B(F_i-F)\widetilde{\varphi}_i. \end{aligned} \tag{3.23}$$

Now, for $x \in \widetilde{\varphi}_i$ one has

$$B(F_i-F)x \in \operatorname{Im} B$$

and furthermore by noticing $F_i \in \mathbf{F}(\varphi_i^*; A, B)$ and using (3.21)

$$\begin{aligned} B(F_i-F)x &= (A+BF_i)x - (A+BF)x \\ &\in \varphi_i^* + \widetilde{\varphi}_i = \varphi_i^*, \end{aligned} \tag{3.24}$$

and hence $B(F_i-F)\widetilde{\varphi}_i \subset \operatorname{Im} B \cap \varphi_i^*$. Thus, it follows from (3.23) and (3.14) that

$$(A+BF_i)^{j}(\operatorname{Im} B \cap \varphi_i^*) \subset (A+BF)\widetilde{\varphi}_i + \operatorname{Im} B \cap \varphi_i^* \subset \widetilde{\varphi}_i.$$

Hence, it has been shown that (3.22) holds true for all $j = 1, 2, \ldots, n$ because by (3.14) the inclusion (3.22) is satisfied for $j = 1$. Now, using Lemma 2.8 one has

$$\begin{aligned}\varphi_i^* &= \langle A+BF_i | \operatorname{Im} B \cap \varphi_i^* \rangle \\ &= \sum_{j=1}^{n} (A+BF_i)^{j-1}(\operatorname{Im} B \cap \varphi_i^*) \subset \widetilde{\varphi}_i \quad (i = 1, 2, \ldots, k),\end{aligned}$$

which together with (3.21) yields the desired result

$$\varphi_i^* = \widetilde{\varphi}_i \ (i = 1, \ldots, k). \tag{3.25}$$

Now, (3.14) and (3.25) lead us to the identities

$$\varphi_i^* = \langle A+BF | \operatorname{Im} B \cap \varphi_i^* \rangle \quad (i = 1, 2, \ldots, k),$$

which imply that

$$F \in \bigcap_{i=1}^{k} \mathbf{F}(\varphi_i^*; A, B).$$

Thus, $\{\varphi_1^*, \varphi_2^*, \ldots, \varphi_k^*\}$ satisfies (3.6).

Finally, to prove the necessity of the theorem, assume Problem 3.1 is solvable and let $\{\varphi_1, \varphi_2, \ldots, \varphi_k\}$ be an arbitrary solution of the problem. Then, since every feedback reachability submodule φ_i satisfies (3.7), one has

$$\varphi_i \subset \varphi_i^* \quad (i = 1, 2, \ldots, k).$$

Hence, this inclusion with (3.8) implies that

$$X = \varphi_i + \operatorname{Ker} C_i \subset \varphi_i^* + \operatorname{Ker} C_i \subset X \quad (i = 1, 2, \ldots, k),$$

showing that (3.11) holds true. This completes the proof of Theorem 3.4. □

4. Pole assignability. The present section deals with the pole assignability problem for decoupled systems. As in the case of systems over $\boldsymbol{R}$, a system (A, B) over $\boldsymbol{\mathcal{K}}$ is said to be *pole assignable* if for any $\beta_1, \ldots, \beta_n \in \boldsymbol{\mathcal{K}}$ there exists an $F \in \boldsymbol{\mathcal{K}}^{m\times n}$ such that

$$\det(sI_n - A - BF) = \prod_{i=1}^{n}(s - \beta_i),$$

where I_n is the $n \times n$ identity matrix and $\det(\cdot)$ means determinant. It is well known [8] that a principal ideal domain is a pole-assignable ring; that is to say, (A, B) is pole assignable if and only if (A, B) is reachable.

It is also well known [12, Theorem 5.1] that if (A, B) is a system over $\boldsymbol{R}$ and if φ is a feedback reachability subspace for (A, B) with dimension $r \geq 1$ then for an arbitrary symmetric set $\{\beta_1, \ldots, \beta_r\}$ of complex numbers there exists an $F \in \mathbf{F}(\varphi; A, B)$ such that

$$\det(sI_r - (A + BF)|\varphi) = \prod_{i=1}^{r}(s - \beta_i),$$

where $(A + BF)|\varphi$ denotes the restriction of $A + BF$ onto φ as mappings. However, this fact does not hold true for systems over $\boldsymbol{\mathcal{K}}$ as seen from the following simple example.

Example 4.1. Take $\boldsymbol{\mathcal{K}}{:=}\boldsymbol{R}[\sigma]$, $X := \boldsymbol{\mathcal{K}}^2$, and

$$A := \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix}, \quad B := \begin{bmatrix} 1 & 0 \\ 1 & \sigma \end{bmatrix}, \quad \varphi = \operatorname{Im} \begin{bmatrix} 0 \\ \sigma \end{bmatrix}.$$

Then, it is easy to check that system (A, B) is reachable and that φ is not closed. Simple computation shows that φ is feedback (A, B)-invariant and any $F \in \mathbf{F}(\varphi; A, B)$ must have the form

$$F := \begin{bmatrix} f_1 & -1 \\ f_2 & f_3 \end{bmatrix}, \quad f_i \in \boldsymbol{\mathcal{K}} \ (i = 1, 2, 3).$$

Furthermore, it is not difficult to verify the relation $\langle A + BF | \operatorname{Im} B \cap \varphi \rangle = \varphi$, which together with Lemma 2.8 implies that φ is a feedback reachability submodule.

Now, since

$$A + BF = \begin{bmatrix} f_1 + 1 & 0 \\ f_1 + \sigma f_2 & \sigma f_3 \end{bmatrix},$$

it follows that $(A + BF)|\varphi = \sigma f_3$. Therefore, there is no $F \in \mathbf{F}(\varphi; A, B)$ such that $\det(sI_1 - (A + BF)|\varphi) = s + 1$, showing that -1 cannot be assigned as a pole. □

Before going into the detailed discussion, some remarks are in order. First, the meaning of restriction $(A + BF)|\varphi$ needs to be made more precise. Let $H \in \boldsymbol{\mathcal{K}}^{n\times n}$ and $\psi \subset X := \boldsymbol{\mathcal{K}}^n$ be an H-invariant submodule with rank $r \geq 1$. Then, the matrix representation H_0 of $H|\psi$ with respect to a basis $\{w_1, w_2, \ldots, w_r\}$ of ψ is given to be the matrix $H_0 \in \boldsymbol{\mathcal{K}}^{r\times r}$ uniquely determined through the equation $H[w_1\ w_2\ \cdots\ w_r] = [w_1\ w_2\ \cdots\ w_r]H_0$. Next, matrices over $\boldsymbol{\mathcal{K}}$ and various matrix operations in $\boldsymbol{\mathcal{K}}$ may be considered to be those in the quotient field of $\boldsymbol{\mathcal{K}}$ whenever it is necessary and allowable.

First, the following two lemmas are proved, which will play vital roles in what follows.

LEMMA 4.2. *Let $\varphi \subset X$ be a feedback (A,B)-invariant submodule with rank $r \geq 1$. Then, for any $F \in \mathbf{F}(\varphi; A, B)$,*

$$\det(sI_r - (A+BF)|\varphi) = \det(sI_r - (A+BF)|\operatorname{Cl}_X(\varphi)).$$

Proof. Take a basis $\{x_1, \ldots, x_r, x_{r+1}, \ldots, x_n\}$ of X and a set $\{\alpha_1, \alpha_2, \ldots, \alpha_r\} \subset \boldsymbol{\mathcal{K}}$ with $\alpha_i \neq 0$ $(i = 1, 2, \ldots, r)$ such that $\{\alpha_1 x_1, \alpha_2 x_2, \ldots, \alpha_r x_r\}$ and $\{x_1, x_2, \ldots, x_r\}$ are bases of φ and $\operatorname{Cl}_X(\varphi)$, respectively. Then for $F \in \mathbf{F}(\varphi; A, B)$, the matrix representation of $(A+BF)|\varphi$ with respect to the basis $\{\alpha_1 x_1, \alpha_2 x_2, \ldots, \alpha_r x_r\}$ is characterized by

$$(A+BF)[\alpha_1 x_1, \ldots, \alpha_r x_r] = [\alpha_1 x_1, \ldots, \alpha_r x_r](A+BF)|\varphi.$$

Now, considering all matrices over $\boldsymbol{\mathcal{K}}$ and matrix operations in $\boldsymbol{\mathcal{K}}$ as those in the quotient field of $\boldsymbol{\mathcal{K}}$, one obtains

$$\begin{aligned}
&(A+BF)[x_1, \ldots, x_r] \\
&= [x_1, \ldots, x_r] \begin{bmatrix} \alpha_1 & & 0 \\ & \ddots & \\ 0 & & \alpha_r \end{bmatrix} (A+BF)|\varphi \begin{bmatrix} \alpha_1^{-1} & & 0 \\ & \ddots & \\ 0 & & \alpha_r^{-1} \end{bmatrix},
\end{aligned}$$

which leads to the matrix representation

$$(A+BF)|\operatorname{Cl}_X(\varphi) = \begin{bmatrix} \alpha_1 & & 0 \\ & \ddots & \\ 0 & & \alpha_r \end{bmatrix} (A+BF)|\varphi \begin{bmatrix} \alpha_1^{-1} & & 0 \\ & \ddots & \\ 0 & & \alpha_r^{-1} \end{bmatrix}.$$

So, finally one obtains the desired result as follows:

$$\begin{aligned}
&\det(sI_r - (A+BF)|\operatorname{Cl}_X(\varphi)) \\
&= \det\left(sI_r - \begin{bmatrix} \alpha_1 & & 0 \\ & \ddots & \\ 0 & & \alpha_r \end{bmatrix} (A+BF)|\varphi \begin{bmatrix} \alpha_1^{-1} & & 0 \\ & \ddots & \\ 0 & & \alpha_r^{-1} \end{bmatrix} \right) \\
&= \det\left(\begin{bmatrix} \alpha_1 & & 0 \\ & \ddots & \\ 0 & & \alpha_r \end{bmatrix} (sI_r - (A+BF)|\varphi) \begin{bmatrix} \alpha_1^{-1} & & 0 \\ & \ddots & \\ 0 & & \alpha_r^{-1} \end{bmatrix} \right) \\
&= \det(sI_r - (A+BF)|\varphi). \qquad \square
\end{aligned}$$

LEMMA 4.3. *Let $\varphi \subset X$ be a feedback (A,B)-invariant submodule with its rank $r \geq 1$. If for arbitrary $\beta_1, \beta_2, \ldots, \beta_r \in \boldsymbol{\mathcal{K}}$ there exists $F \in \mathbf{F}(\varphi; A, B)$ such that*

$$\det(sI_r - (A+BF)|\varphi) = \prod_{i=1}^{r} (s - \beta_i), \tag{4.1}$$

then both φ and $\operatorname{Cl}_X(\varphi)$ are feedback reachability submodules for (A,B).

Proof. First, we will show that under the given hypothesis φ is a feedback reachability submodule for (A,B). Choose an $F_0 \in \mathbf{F}(\varphi; A, B)$ and a basis $\{x_1, x_2, \ldots, x_r\}$ of φ, and set $A_0 := (A+BF_0)|\varphi$, or equivalently, let A_0 be the $r \times r$ matrix over $\boldsymbol{\mathcal{K}}$ determined by

$$(A+BF_0)[x_1, x_2, \ldots, x_r] = [x_1, x_2, \ldots, x_r]A_0. \tag{4.2}$$

Further, letting $\widehat{B} \in \boldsymbol{\mathcal{K}}^{n\times m}$ be such that $\operatorname{Im}\widehat{B} = \operatorname{Im} B \cap \varphi$, define $B_0 \in \boldsymbol{\mathcal{K}}^{r\times m}$ so as to satisfy

$$\widehat{B} = [x_1, x_2, \ldots, x_r]B_0.$$

Now, note that $B(F - F_0)\varphi \subset \operatorname{Im} B \cap \varphi$ for any $F \in \mathbf{F}(\varphi; A, B)$. Hence, for each $F \in \mathbf{F}(\varphi; A, B)$ there exists an $F_1 \in \boldsymbol{\mathcal{K}}^{m\times r}$ such that

$$B(F - F_0)[x_1, x_2, \ldots, x_r] = \widehat{B}F_1 = [x_1, x_2, \ldots, x_r]B_0F_1. \tag{4.3}$$

Thus, (4.2) and (4.3) lead to

$$\begin{aligned}(A + BF)[x_1, x_2, \ldots, x_r] &= ((A + BF_0) + B(F - F_0))[x_1, x_2, \ldots, x_r]\\ &= [x_1, x_2, \ldots, x_r]A_0 + [x_1, x_2, \ldots, x_r]B_0F_1\\ &= [x_1, x_2, \ldots, x_r](A_0 + B_0F_1),\end{aligned}$$

showing that the matrix representation of $(A+BF)|\varphi$ is given by $A_0+B_0F_1$. Therefore, (4.1) implies that for arbitrary $\beta_1, \beta_2, \ldots, \beta_r \in \boldsymbol{\mathcal{K}}$ there exists an $F_1 \in \boldsymbol{\mathcal{K}}^{m\times r}$ such that

$$\det(sI_r - (A_0 + B_0F_1)) = \prod_{i=1}^{r}(s - \beta_i).$$

Therefore, the system (A_0, B_0) with its state module $\boldsymbol{\mathcal{K}}^r$ is reachable; that is,

$$\langle A_0 | \operatorname{Im} B_0\rangle = \boldsymbol{\mathcal{K}}^r.$$

Now, using (4.2) one obtains

$$\begin{aligned}&\langle A + BF_0 | \operatorname{Im} B \cap \varphi\rangle\\ &= \operatorname{Im}\widehat{B} + (A + BF_0)(\operatorname{Im}\widehat{B}) + \cdots + (A + BF_0)^{n-1}(\operatorname{Im}\widehat{B})\\ &= [x_1, \ldots, x_r](\operatorname{Im} B_0) + (A + BF_0)[x_1, \ldots, x_r](\operatorname{Im} B_0) + \cdots\\ &\qquad +(A + BF_0)^{n-1}[x_1, \ldots, x_r](\operatorname{Im} B_0)\\ &= [x_1, \ldots, x_r](\operatorname{Im} B_0) + [x_1, \ldots, x_r]A_0(\operatorname{Im} B_0) + \cdots\\ &\qquad +[x_1, \ldots, x_r]A_0^{n-1}(\operatorname{Im} B_0)\\ &= [x_1, \ldots, x_r]\langle A_0 | \operatorname{Im} B_0\rangle\\ &= \varphi.\end{aligned}$$

So, it follows from Lemma 2.8 that φ is a feedback reachability submodule for (A, B).

Next, to show that $\mathrm{Cl}_X(\varphi)$ is a feedback reachability submodule for (A, B), first note from Lemma 4.2 that $\det(sI_r - (A + BF)|\varphi) = \det(sI_r - (A + BF)|\mathrm{Cl}_X(\varphi))$. Therefore, replacing φ with $\mathrm{Cl}_X(\varphi)$ in the previous proof easily leads to the desired conclusion. □

The next theorem will play a key role to study the pole assignability problem for decoupled systems.

THEOREM 4.4. *Let φ be a feedback reachability submodule for (A, B) with its rank $r \geq 1$. Then for arbitrary $\beta_1, \beta_2, \ldots, \beta_r \in \boldsymbol{\mathcal{K}}$ there exists an $F \in \mathbf{F}(\varphi; A, B)$ such that*

$$\det(sI_r - (A + BF)|\varphi) = \prod_{i=1}^{r}(s - \beta_i) \tag{4.4}$$

if and only if $\mathrm{Cl}_X(\varphi)$ is a feedback reachability submodule for (A, B).

Proof. The necessity follows from a direct application of Lemma 4.3, and therefore only the sufficiency will be proved. First choose an $F_0 \in \mathbf{F}(\varphi; A, B)$. Then Lemmas 2.8 and 3.3 imply that there exist $G,\ \widehat{G} \in \boldsymbol{\mathcal{K}}^{m\times m}$ such that

$$\begin{aligned}\varphi &= \langle A + BF_0 | \operatorname{Im}(BG)\rangle,\\ \operatorname{Cl}_X(\varphi) &= \langle A + BF_0 | \operatorname{Im}(B\widehat{G})\rangle.\end{aligned}$$

Since $\operatorname{Cl}_X(\varphi)$ is closed in X, there exists a basis $\{x_1, \dots, x_r, x_{r+1}, \dots, x_n\}$ of X such that $\{x_1, \dots, x_r\}$ is a basis of $\operatorname{Cl}_X(\varphi)$. Noticing that $(A + BF_0)\operatorname{Cl}_X(\varphi) \subset \operatorname{Cl}_X(\varphi)$ and $\operatorname{Im}(B\widehat{G}) \subset \operatorname{Cl}_X(\varphi)$, introduce the matrices $A_0 \in \boldsymbol{\mathcal{K}}^{r\times r}$ and $B_0 \in \boldsymbol{\mathcal{K}}^{r\times m}$ uniquely determined by

$$(A + BF_0)[x_1, \dots, x_r] = [x_1, \dots, x_r]A_0, \quad B\widehat{G} = [x_1, \dots, x_r]B_0.$$

Then,

$$\begin{aligned}\operatorname{Cl}_X(\varphi) &= \langle A + BF_0 | \operatorname{Im}(B\widehat{G})\rangle\\ &= \operatorname{Im}(B\widehat{G}) + (A + BF_0)(\operatorname{Im}(B\widehat{G})) + \cdots\\ &\qquad +(A + BF_0)^{n-1}(\operatorname{Im}(B\widehat{G}))\\ &= [x_1, \dots, x_r](\operatorname{Im} B_0) + (A + BF_0)[x_1, \dots, x_r](\operatorname{Im} B_0) + \cdots\\ &\qquad +(A + BF_0)^{n-1}[x_1, \dots, x_r](\operatorname{Im} B_0)\\ &= [x_1, \dots, x_r](\operatorname{Im} B_0) + [x_1, \dots, x_r]A_0(\operatorname{Im} B_0) + \cdots\\ &\qquad +[x_1, \dots, x_r]A_0^{n-1}(\operatorname{Im} B_0)\\ &= [x_1, \dots, x_r]\langle A_0 | \operatorname{Im} B_0\rangle.\end{aligned}$$

Therefore, noticing that $\{x_1, x_2, \dots, x_r\}$ is a basis of $\operatorname{Cl}_X(\varphi)$ one sees that

$$\langle A_0 | \operatorname{Im} B_0\rangle = \boldsymbol{\mathcal{K}}^r$$

and hence that the system (A_0, B_0) with its state module $\boldsymbol{\mathcal{K}}^r$ is reachable. So, for any $\beta_1, \beta_2, \dots, \beta_r \in \boldsymbol{\mathcal{K}}$ there exists an $F_1 \in \boldsymbol{\mathcal{K}}^{r\times r}$ such that

$$\det(sI_r - A_0 - B_0F_1) = \prod_{i=1}^{r}(s - \beta_i). \tag{4.5}$$

Next, let matrices $T_1 \in \boldsymbol{\mathcal{K}}^{n\times r}$ and $T \in \boldsymbol{\mathcal{K}}^{n\times n}$ be given by

$$T_1 := [x_1, \dots, x_r], \quad T := [x_1, \dots, x_r, x_{r+1}, \dots, x_n],$$

respectively, and noticing that T is invertible over $\boldsymbol{\mathcal{K}}$, define

$$F := F_0 + G[F_1, 0_{n\times(n-r)}]T^{-1}.$$

Then, we claim that this F satisfies (4.4). To clarify this, first notice that $F_0 \in \mathbf{F}(\varphi; A, B)$ and $\operatorname{Im}(BG) \subset \varphi$ and hence that

$$(A + BF)\varphi \subset (A + BF_0)\varphi + BG[F_1, 0_{n\times(n-r)}]T^{-1}\varphi \subset \varphi.$$

Further, noticing that

$$\begin{aligned}(A + BF)T_1 &= ((A + BF_0) + B\widehat{G}[F_1, 0_{n\times(n-r)}]T^{-1})T_1\\ &= (A + BF_0)T_1 + B\widehat{G}F_1\\ &= T_1A_0 + T_1B_0F_1\\ &= T_1(A_0 + B_0F_1),\end{aligned}$$

one obtains the equality $(A+BF)|\mathrm{Cl}_X(\varphi) = A_0 + B_0F_1$. Therefore, (4.5) implies that

$$\det(sI_r - (A+BF)|\,\mathrm{Cl}_X(\varphi)) = \prod_{i=1}^{r}(s-\beta_i).$$

Finally, by virtue of Lemma 4.2 this F satisfies (4.4). This completes the proof of Theorem 4.4. □

Now, we are ready to show the pole assignability of block triangular decoupled systems.

THEOREM 4.5. *Suppose that system* $(A, B, \{C_i\}_{i=1}^k)$ *satisfies Assumption* 3.2 *and is reachable and further that the block triangular decoupling Problem* 3.1 *is solvable. Then, the decoupled system is pole assignable; in other words, for arbitrary* $\beta_1, \beta_2, \ldots, \beta_n \in \boldsymbol{\mathcal{K}}$ *there exists an* $F \in \bigcap_{i=1}^k \mathbf{F}(\varphi_i^*; A, B)$ *such that*

$$\det(sI_n - A - BF) = \prod_{i=1}^{n}(s-\beta_i) \tag{4.6}$$

if and only if all φ_i^* *are closed in* X.

Proof. First, notice that since $\{\varphi_1^*, \varphi_2^*, \ldots, \varphi_k^*\}$ is a solution of Problem 3.1 by Theorem 3.4, for any $F \in \bigcap_{i=1}^k \mathbf{F}(\varphi_i^*; A, B)$ there exist $G_1, G_2, \ldots, G_k \in \boldsymbol{\mathcal{K}}^{m\times m}$ such that the state feedback control law $(F, \{G_i\}_{i=1}^k)$ of (3.1) achieves the block triangular decoupling.

To prove the necessity, fix $i \in \{1, 2, \ldots, k\}$ and take a basis $\{x_1, x_2, \ldots, x_r, \ldots, x_n\}$ of X such that $\{x_1, x_2, \ldots, x_r\}$ is a basis of $\mathrm{Cl}_X(\varphi_i^*)$, where r is the rank of $\mathrm{Cl}_X(\varphi_i^*)$. Note that the matrix $T := [x_1, \ldots, x_n]$ is invertible over $\boldsymbol{\mathcal{K}}$. Let $\beta_1, \beta_2, \ldots, \beta_n \in \boldsymbol{\mathcal{K}}$ be arbitrary, and choose $F \in \bigcap_{i=1}^k \mathbf{F}(\varphi_i^*; A, B)$ to satisfy (4.6). Then, since by Lemma 3.3 $F \in \mathbf{F}(\mathrm{Cl}_X(\varphi_i^*); A, B)$, one obtains

$$A + BF = T \begin{bmatrix} (A+BF)|\,\mathrm{Cl}_X(\varphi_i^*) & * \\ 0 & * \end{bmatrix} T^{-1},$$

where $*$ indicates a suitable matrix. Hence, there exists a subset $\{q(1), \ldots, q(r)\} \subset \{1, 2, \ldots, n\}$ such that

$$\det(sI_r - (A+BF)|\,\mathrm{Cl}_X(\varphi_i^*)) = \prod_{j=1}^{r}(s-\beta_{q(j)}).$$

Since $\{\beta_1, \beta_2, \ldots, \beta_n\}$ was arbitrary, Lemmas 4.2 and 4.3 imply that $\mathrm{Cl}_X(\varphi_i^*)$ is a feedback reachability submodule for (A, B). Moreover, noticing that Ω_i is closed and $\varphi_i^* \subset \Omega_i$, one has

$$\varphi_i^* \subset \mathrm{Cl}_X(\varphi_i^*) \subset \mathrm{Cl}_X(\Omega_i) = \Omega_i.$$

Since $\mathrm{Cl}_X(\varphi_i^*)$ is a feedback reachability submodule contained in Ω_i, the supremality of φ_i^* implies $\mathrm{Cl}_X(\varphi_i^*) \subset \varphi_i^*$. Therefore, $\mathrm{Cl}_X(\varphi_i^*) = \varphi_i^*$, showing that φ_i^* is closed in X.

Next, to show the sufficiency of the theorem, first recall the relation $\varphi_1^* \supset \varphi_2^* \supset \cdots \supset \varphi_k^*$ of (3.10). Noticing that each φ_i^* is closed by the hypothesis, introduce submodules M_i of X such that

$$\begin{aligned} &\varphi_i^* = M_i \oplus \varphi_{i+1}^* \quad (i = 1, 2, \ldots, k-1), \\ &M_k := \varphi_k^*. \end{aligned}$$

Since (A, B) is reachable and φ_i^* is supremal, one has $\varphi_1^* = X$ and hence

$$X = M_1 \oplus M_2 \oplus \cdots \oplus M_k.$$

Each M_i is free, so that there exists a basis $\{x_{i1}, x_{i2}, \ldots, x_{ir_i}\}$ of M_i, where r_i denotes the rank of M_i. Now, define

$$\begin{aligned} T_i &:= [x_{i1}, x_{i2}, \ldots, x_{ir_i}] \quad (i = 1, 2, \ldots, k), \\ T &:= [T_1, T_2, \ldots, T_k], \end{aligned}$$

and note that T is invertible over $\boldsymbol{\mathcal{K}}$ and $r_1 + \cdots + r_k = n$. Recall $\bigcap_{i=1}^k \mathbf{F}(\varphi_i^*; A, B) \neq \emptyset$ because $\{\varphi_1^*, \ldots, \varphi_k^*\}$ is a solution of Problem 3.1. So choose any $F_0 \in \bigcap_{i=1}^k \mathbf{F}(\varphi_i^*; A, B)$ and set $A_0 := A + BF_0$. Then, by Lemma 2.8 there exists $G_i \in \boldsymbol{\mathcal{K}}^{m \times m}$ such that

$$\varphi_i^* = \langle A_0 | \operatorname{Im}(BG_i) \rangle \quad (i = 1, 2, \ldots, k),$$

and hence the resulting closed loop system $(A_0, B[G_1, G_2, \ldots, G_k], \{C_i\}_{i-1}^k)$ is a triangularly decoupled system as desired.

As the next step, we will show that the decoupled system $(A_0, B[G_1, G_2, \ldots, G_k], \{C_i\}_{i=1}^k)$ is arbitrarily pole assignable without destroying its decoupledness. To show this, first note that matrices $T^{-1}A_0T$ and $T^{-1}BG_i$ have the following forms:

$$T^{-1}A_0T = \begin{bmatrix} A_1 & 0 & \cdots & 0 \\ * & A_2 & \ddots & \vdots \\ \vdots & \ddots & \ddots & 0 \\ * & \cdots & * & A_k \end{bmatrix},$$

$$T^{-1}BG_i = \begin{bmatrix} 0_{(r_1 + \cdots + r_{i-1}) \times m} \\ B_i \\ *_{(r_{i+1} + \cdots + r_k) \times m} \end{bmatrix} \quad (i = 1, 2, \ldots, k),$$

where $A_i \in \boldsymbol{\mathcal{K}}^{r_i \times r_i}$, $B_i \in \boldsymbol{\mathcal{K}}^{r_i \times m}$, and $*_{(r_{i+1} + \cdots + r_k) \times m}$ denotes a suitable $(r_{i+1} + \cdots + r_k) \times m$ matrix. Since $F_0 \in \bigcap_{i=1}^k \mathbf{F}(\varphi_i^*; A, B)$, the system $(T^{-1}A_0T, T^{-1}B[G_1, \ldots, G_k], \{C_iT\}_{i=1}^k)$ is also block triangularly decoupled, and hence each subsystem (A_i, B_i) with its state module $\boldsymbol{\mathcal{K}}^{r_i}$ $(i = 1, \ldots, k)$ is reachable. Therefore, letting $\{\beta_1, \ldots, \beta_n\} \subset \boldsymbol{\mathcal{K}}$ be an arbitrary set and dividing the set into k subsets $\{\beta_{i1}, \ldots, \beta_{ir_i}\}$ $(i = 1, \ldots, k)$ in an arbitrary way, there exist $F_i \in \boldsymbol{\mathcal{K}}^{m \times r_i}$ such that

$$\det(sI_{r_i} - (A_i + B_iF_i)) = \prod_{j=1}^{r_i} (s - \beta_{ij}) \quad (i = 1, 2, \ldots, k).$$

Now, define

$$F := F_0 + [G_1F_1, G_2F_2, \ldots, G_kF_k]T^{-1}. \tag{4.7}$$

Then one obtains

$$\begin{aligned} (A + BF)\varphi_i^* &= (A + BF_0)\varphi_i^* + B[G_1F_1, G_2F_2, \ldots, G_kF_k]T^{-1}\varphi_i^* \\ &\subset \varphi_i^* + \operatorname{Im}(BG_i) \subset \varphi_i^* \quad (i = 1, 2, \ldots, k), \end{aligned}$$

and hence $F \in \bigcap_{i=1}^{k} \mathbf{F}(\varphi_i^*; A, B)$, implying that $(A+BF, B[G_1, G_2, \ldots, G_k], \{C_i\}_{i=1}^k)$ is still decoupled as desired. Further, since

$$
\begin{aligned}
&T^{-1}(A+BF)T \\
&= T^{-1}(A+BF_0)T + T^{-1}B[G_1F_1, G_2F_2, \ldots, G_kF_k] \\
&= \begin{bmatrix} A_1 & 0 & \cdots & 0 \\ * & A_2 & \ddots & \vdots \\ \vdots & \ddots & \ddots & 0 \\ * & \cdots & * & A_k \end{bmatrix} + \begin{bmatrix} B_1F_1 & 0 & \cdots & 0 \\ * & B_2F_2 & \ddots & \vdots \\ \vdots & \ddots & \ddots & 0 \\ * & \cdots & * & B_kF_k \end{bmatrix} \\
&= \begin{bmatrix} A_1+B_1F_1 & & & 0 \\ * & A_2+B_2F_2 & & \\ \vdots & \ddots & \ddots & \\ * & \cdots & * & A_k+B_kF_k \end{bmatrix},
\end{aligned}
$$

one obtains that

$$
\begin{aligned}
\det(sI_n - (A+BF)) &= \det(sI_n - T^{-1}(A+BF)T) \\
&= \prod_{i=1}^{k} \det(sI_{r_i} - (A_i + B_iF_i)) \\
&= \prod_{i=1}^{k} \prod_{j=1}^{r_i} (s - \beta_{ij}) \\
&= \prod_{i=1}^{n} (s - \beta_i).
\end{aligned}
$$

Therefore, the matrix F given by (4.7) satisfies (4.6), and hence the decoupled system is arbitrarily pole assignable. This completes the proof of the theorem. □

COROLLARY 4.6. *Suppose that system* $(A, B, \{C_i\}_{i=1}^k)$ *satisfies Assumption* 3.2 *and the reachable submodule* $\langle A|\operatorname{Im} B\rangle$ *has its rank* $r < n$ *and further that the block triangular decoupling Problem* 3.1 *is solvable. Then* r *poles of the decoupled system corresponding to the solution* $\{\varphi_1^*, \varphi_2^*, \ldots, \varphi_k^*\}$ *are arbitrarily assignable; in other words, for arbitrary* $\beta_1, \beta_2, \ldots, \beta_r \in \boldsymbol{\mathcal{K}}$ *there exists an* $F \in \bigcap_{i=1}^{k} \mathbf{F}(\varphi_i^*; A, B)$ *such that*

$$
\det(sI_r - (A+BF)|\langle A|\operatorname{Im} B\rangle) = \prod_{i=1}^{r} (s - \beta_i)
$$

if and only if all φ_i^* *are closed in* X.

Proof. This corollary easily follows from Theorems 4.5 and 4.4. In fact, for the sufficiency, noticing from the hypothesis that $\varphi_1^* = \langle A|\operatorname{Im} B\rangle$ is closed in X, consider the reachable subsystem of $(A, B, \{C_i\}_{i=1}^k)$ and apply Theorem 4.5 to this subsystem to complete the proof. For the necessity, first use Theorem 4.4 to see that $\mathrm{Cl}_X(\langle A|\operatorname{Im} B\rangle) = \mathrm{Cl}_X(\varphi_1^*)$ is a feedback reachability submodule, and then noticing that $\mathrm{Cl}_X(\varphi_1^*) \subset \Omega_1 = X$ and φ_1^* is the largest feedback reachability submodule in Ω_1, conclude that $\mathrm{Cl}_X(\varphi_1^*) = \varphi_1^*$; i.e., φ_1^* is closed in X. Finally, again considering the reachable subsystem, apply Theorem 4.5 to this subsystem to show that all φ_i^* are closed in X. □

5. Example. As an illustrative example, we will consider block triangular decoupling in Problem 3.1 for the following simple system $(A, B, \{C_i\}_{i=1}^2)$ over $\boldsymbol{\mathcal{K}} := \boldsymbol{R}[\lambda]$:

$$A := \begin{bmatrix} 0 & \lambda & -1 & 0 \\ 0 & -1 & 1 & 1 \\ 0 & -1 & 1 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix}, \quad B := \begin{bmatrix} 0 & 0 \\ 0 & 0 \\ 1 & 0 \\ 0 & 1 \end{bmatrix},$$

$$C_1 := \begin{bmatrix} 1 & 0 & 0 & 0 \end{bmatrix}, \quad C_2 := \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}.$$

By simple computation, we see that the system (A, B) is reachable, and that the largest (A, B)-invariant submodules ψ_1^* and ψ_2^* contained, respectively, in $\Omega_1 = \boldsymbol{\mathcal{K}}^4$ and $\Omega_2 = \operatorname{Ker} C_1$ are given as

$$\psi_1^* = \boldsymbol{\mathcal{K}}^4, \quad \psi_2^* = \operatorname{Im} \begin{bmatrix} 0 & 0 \\ 0 & 1 \\ 0 & \lambda \\ 1 & 0 \end{bmatrix}.$$

Clearly ψ_1^* and ψ_2^* are closed in $\boldsymbol{\mathcal{K}}^4$, and hence by Corollary 2.14 this system satisfies Assumption 3.2; that is, there exist the largest feedback reachability submodules φ_1^* and φ_2^* contained, respectively, in Ω_1 and Ω_2. Using Algorithm 2.12, they can be computed as

$$\varphi_1^* = \mathcal{R}(\psi_1^*) = \psi_1^*, \quad \varphi_2^* = \mathcal{R}(\psi_2^*) = \psi_2^*.$$

Furthermore, it is easy to check that $\{\varphi_1^*, \varphi_2^*\}$ satisfies (3.11) of Theorem 3.4 and, hence, that the given system $(A, B, \{C_i\}_{i=1}^2)$ can be block triangularly decoupled. Next, a decoupling state feedback $(F_0, \{G_i\}_{i=1}^2)$ of the form

$$u(t) = F_0 x(t) + \sum_{i=1}^{2} G_i v_i(t)$$

will be computed. First, it is not difficult to see that such an $F_0 \in \mathbf{F}(\varphi_1^*; A, B) \cap \mathbf{F}(\varphi_2^*; A, B)$ can be chosen as

$$F_0 := \begin{bmatrix} 0 & \lambda^2 - 2\lambda + 1 & 0 & \lambda \\ 0 & 0 & 0 & 0 \end{bmatrix},$$

and as in the proof of (i) of Lemma 2.8, matrices $G_i \in \boldsymbol{\mathcal{K}}^{2\times 2}$ satisfying $\varphi_i^* = \langle A + BF_0 | \operatorname{Im}(BG_i) \rangle$ $(i = 1, 2)$ can be computed as

$$G_1 := \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}, \quad G_2 := \begin{bmatrix} 0 & 0 \\ 0 & 1 \end{bmatrix}.$$

Now, note that the characteristic polynomial for the block triangularly decoupled system is

$$\det(sI_4 - A - BF_0) = s^2(s - \lambda + 1)(s + \lambda - 1).$$

So, following the proof of the sufficiency of Theorem 4.5, all the poles for the block triangularly decoupled system will be assigned to -1. First, note that a submodule $M_1 \subset X$ satisfying $\varphi_1^* = M_1 \oplus \varphi_2^*$ is given by

$$M_1 := \mathrm{Im} \begin{bmatrix} 1 & 0 \\ 0 & 0 \\ 0 & 1 \\ 0 & 0 \end{bmatrix}.$$

Further, set $M_2 := \varphi_2^* = \psi_2^*$. Then clearly $\boldsymbol{\mathcal{K}}^4 = M_1 \oplus M_2$. Now, defining

$$T := \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 1 & 0 & \lambda \\ 0 & 0 & 1 & 0 \end{bmatrix},$$

one easily obtains

$$T^{-1}(A + BF_0)T = \left[\begin{array}{cc|cc} 0 & -1 & 0 & 0 \\ 0 & -\lambda+1 & 0 & 0 \\ \hline 0 & 0 & 0 & 0 \\ 0 & 1 & 1 & \lambda-1 \end{array}\right],$$

$$T^{-1}BG_1 = \left[\begin{array}{cc} 0 & 0 \\ 1 & 0 \\ \hline 0 & 1 \\ 0 & 0 \end{array}\right], \quad T^{-1}BG_2 = \left[\begin{array}{cc} 0 & 0 \\ 0 & 0 \\ \hline 0 & 1 \\ 0 & 0 \end{array}\right].$$

Based on this equivalence transformation, introduce the two subsystems (A_1, B_1) and (A_2, B_2), where

$$A_1 := \begin{bmatrix} 0 & -1 \\ 0 & -\lambda+1 \end{bmatrix}, \quad A_2 := \begin{bmatrix} 0 & 0 \\ 1 & \lambda-1 \end{bmatrix},$$

$$B_1 := \begin{bmatrix} 0 & 0 \\ 1 & 0 \end{bmatrix}, \quad B_2 := \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix}.$$

Then since (A_1, B_1) and (A_2, B_2) are reachable, we can construct matrices F_i satisfying $\det(sI_2 - A_i - B_iF_i) = (s+1)^2$ as

$$F_1 := \begin{bmatrix} 1 & \lambda-3 \\ 0 & 0 \end{bmatrix}, \quad F_2 := \begin{bmatrix} 0 & 0 \\ -\lambda-1 & -\lambda^2 \end{bmatrix}.$$

Finally, using (4.7) a desired matrix $F \in \mathbf{F}(\varphi_1^*; A, B) \cap \mathbf{F}(\varphi_2^*; A, B)$ can be obtained as

$$F := F_0 + [G_1F_1, G_2F_2]T^{-1} = \begin{bmatrix} 1 & \lambda+1 & \lambda-3 & \lambda \\ 0 & -\lambda^2 & 0 & -\lambda-1 \end{bmatrix},$$

which gives $\det(sI_4 - A - BF) = (s+1)^4$. Hence, $(F, \{G_i\}_{i=1}^2)$ is a desired state feedback control law that achieves block triangular decoupling and simultaneously assigns all the poles of the decoupled system to be -1.

6. Conclusions. This paper studied in the framework of geometric approach the block triangular decoupling problem for linear systems defined over principal ideal domains. First, various properties of feedback reachability submodules were given, and then necessary and sufficient conditions for the problem to be solvable were obtained under the assumption that the largest feedback reachability submodules contained in some given submodules exist. Finally, the pole assignability for block triangularly decoupled systems was investigated.

Acknowledgments. The authors thank the referees for their helpful remarks.

CONFIGURATION CONTROLLABILITY OF SIMPLE MECHANICAL CONTROL SYSTEMS*

ANDREW D. LEWIS† AND RICHARD M. MURRAY†

Abstract. In this paper we present a definition of "configuration controllability" for mechanical systems whose Lagrangian is kinetic energy with respect to a Riemannian metric minus potential energy. A computable test for this new version of controllability is derived. This condition involves an object which we call the *symmetric product*. Of particular interest is a definition of "equilibrium controllability" for which we are able to derive computable sufficient conditions. Examples illustrate the theory.

Key words. mechanics, Riemannian geometry, controllability, symmetric product

1. Introduction.

Mechanical systems form a large subset of control systems which have many diverse applications. These systems are characterized by a rich structure which has been underexploited in the current controls literature. In this paper we utilize the structure of a specific class of mechanical systems to obtain controllability results which are meaningful for these systems. These results are important in two respects. First, they identify the structure of mechanical systems which lends to controllability of these systems. Second, the results provide computable checks for useful notions of controllability. One important aspect of our work is that the computations for checking controllability are performed on the configuration space and not on the phase space. This is important since the phase space has twice the dimension of the configuration space for mechanical systems.

Much of the previous work in the area of mechanical control systems has relied on specific structure of these systems. Bloch and Crouch [2] study mechanical systems on Riemannian manifolds. Under suitable hypotheses on the inputs and assuming some group symmetries for the systems under investigation, the authors are able to use a result of San Martin and Crouch [10] to arrive at a controllability result. Mechanical systems with nonholonomic constraints are studied by Bloch, Reyhanoglu, and McClamroch [3]. In this paper the authors are able to show that the systems considered are controllable if the inputs span a complement to the constraint forces. In both of the above papers, the results are limited by the hypotheses placed on the system: symmetries in the first case, and constraints in the second. In this paper we attempt to develop control theoretic tools for *mechanical* control systems. We emphasize mechanical because it is our intent to use the mechanical structure to advantage in the control problem rather than any additional structure imposed on the system.

In section 2 we motivate the development of the paper by posing various controllability questions for a simple example. In this section we also preview the results of the paper by stating a simplified form of the most general results. In section 3 we present enough background from the theory of free Lie algebras and Riemannian

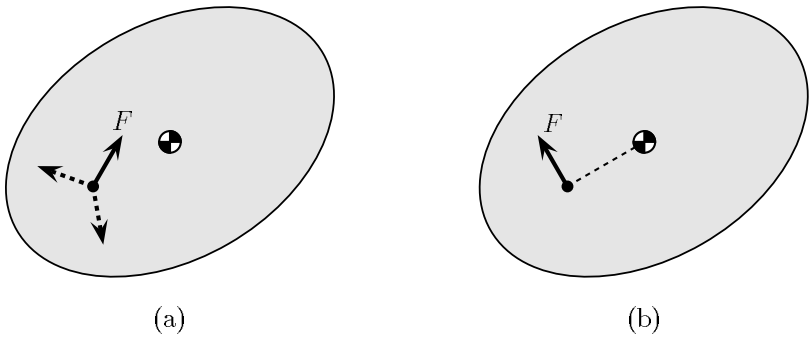

FIG. 1. *A planar rigid body with a variable direction thruster* (a) *and a fixed directional thruster* (b).

geometry that we can use these ideas in section 5. In section 3.2 we introduce the notion of a symmetric algebra which is new and will be particularly interesting to us. The *symmetric product* is defined in section 3.3. This is an interesting object whose geometric meaning is not fully utilized in this paper. However, it proves to be a useful computational tool for expressing our controllability results. In section 4 we state a result of Sussmann [13] which we shall use to prove some controllability results in section 5. The main results of the paper are stated in section 5. Illustrative examples are given in section 6.

2. Preliminary statement of results. It is possible to state a subset of the results of the paper without going through all of the formality needed to state the most general results. In this section we give some idea of the questions that we answer in the paper as well as state the results in the case when no potential energy is present.

Consider the planar rigid body system of Figure 1. On this body we consider two possible sets of forces. In one case we are able to apply a force in any direction to the body at a point away from the center of mass (case (a) in the figure). In the other case, we can apply a force which only is in a direction perpendicular to the line joining the point of application of the force with the center of mass (case (b) in the figure). The reader may wish to consider the former case as corresponding to having a thruster on the body whose direction may be varied, while in the second case the thruster can only provide thrust in one direction. In each of these cases one may ask certain questions about the controllability of this system. We list some of these questions below and in parentheses give the name of the general notion corresponding to this question.

(1) Starting from rest at a given configuration, is it possible to reach an open set of configurations? (local configuration accessibility)

(2) Starting from rest in a given configuration, is it possible to reach a neighborhood of the initial configuration? (local configuration controllability)

(3) Is it possible to get to these configurations with zero velocity? (equilibrium controllability)

It is exactly these questions which we address in this paper. Observe that the above controllability questions have the feature that the initial velocity is assumed to be zero. This turns out to greatly simplify the controllability computations. We observe that for this example the linearization is not controllable, so if the system is controllable, nonlinear tools must be employed.

Although we delay answering the above questions for the planar rigid body until section 6.2, we may state general results for a class of systems smaller than the general class we consider in the sequel. Let us consider, for the moment, mechanical systems whose Lagrangian is kinetic energy with respect to a Riemannian metric g on the configuration manifold Q. Suppose that the inputs are modeled by vector fields $\mathcal{Y} = \{Y_1, \dots, Y_m\}$. We may define the *symmetric product* between two vector fields on Q by

$$\langle X : Y \rangle = \nabla_X Y + \nabla_Y X,$$

where $\nabla_X Y$ is the *covariant derivative* of Y with respect to X. If $\mathfrak{X}(Q)$ denotes the set of vector fields on Q and if $\mathcal{V} \subset \mathfrak{X}(Q)$, we denote by $\overline{\text{Sym}}(\mathcal{V})$ the set of vector fields on Q obtained by taking iterated symmetric products of vector fields from $\mathcal{V}$. The usual involutive closure of $\mathcal{V}$ will be denoted $\overline{\text{Lie}}(\mathcal{V})$. We shall say that a symmetric product from $\overline{\text{Sym}}(\mathcal{Y})$ is *bad* if it contains an even number of each of the vector fields in $\mathcal{Y}$. Otherwise we shall call a symmetric product from $\overline{\text{Sym}}(\mathcal{Y})$ *good*. The *degree* of an iterated symmetric product of factors from $\mathcal{Y}$ will denote the total number of factors.

Notice that with the Lagrangian given by just kinetic energy, all configurations with zero velocity are equilibrium points for the unforced mechanical system. We shall say the system is *locally configuration accessible* at $q \in Q$ if the set of points reachable starting from q at zero velocity is open in Q. We shall say the system is *equilibrium controllable* if, starting from a given configuration at zero velocity, we can reach an open set of final configurations at zero velocity. Now we may state two results.

THEOREM 2.1. *Consider the mechanical control system on the configuration manifold Q whose Lagrangian is the kinetic energy with respect to a Riemannian metric g and whose input vector fields are $\mathcal{Y} = \{Y_1, \dots, Y_m\}$. Then*

(i) *the system is locally configuration accessible at q if the distribution defined by $\overline{\text{Lie}}(\overline{\text{Sym}}(\mathcal{Y}))$ has maximal rank at q;*

(ii) *the system is equilibrium controllable if it is locally configuration accessible and if every bad symmetric product is a linear combination of good symmetric products of lower degree.*

To prove this result, one basically proceeds as follows. Compute the accessibility distribution on TQ for the mechanical control system and evaluate at zero velocity. This will describe the set of *states* accessible from points of zero velocity. However, since we are interested in controllability of the *configurations*, we can project the accessibility distribution to Q with $T\tau_Q$, the derivative of the tangent bundle projection. It turns out that this is exactly the distribution $\overline{\text{Lie}}(\overline{\text{Sym}}(\mathcal{Y}))$. In this way we see that the conditions in (i) give local configuration accessibility. To prove (ii), we appeal to the controllability results of Sussmann [13] on local controllability. An application of Sussmann's results to the systems we are considering yields (ii).

The sections which follow formalize the above definitions and results and also generalize them to the case where the system has potential energy.

3. Mathematical preliminaries. In this section we present the necessary mathematical ideas that we shall need for our exposition of section 5.

3.1. Free Lie algebras and families of vector fields. In this section we recall some ideas for Lie algebras as presented by Serre [11]. These ideas will be important in our adaptation of Sussmann's conditions for small-time local controllability [13] as well as for some bracket calculations in section 5.1.

Let X be a set and let $A(X)$ be the free algebra of associative but not necessarily commutative products of elements in X. Let I be the two-sided ideal of $A(X)$ generated by elements of the form $a \cdot a$ and $a \cdot (b \cdot c) + c \cdot (a \cdot b) + b \cdot (c \cdot a)$. The algebra $L(X) = A(X)/I$ is called the *free Lie algebra* generated by X. The inherited product on this algebra satisfies the usual Lie bracket properties of a Lie algebra. We denote by $\mathrm{Br}(X)$ the subset of $L(X)$ consisting of brackets whose elements are in X. This subset generates $L(X)$ as a real vector space. In fact, the following proposition, whose proof may be found in Jacobson [6], gives a subset of $\mathrm{Br}(X)$ which generates $L(X)$.

PROPOSITION 3.1. *Every element of $L(X)$ is a linear combination of repeated brackets of the form*

$$[X_k, [X_{k-1}, [\ldots, [X_2, X_1], \ldots]]] \tag{1}$$

where $X_i \in X, i = 1, \ldots, k$.

We will need the notion of what we shall call the components of an element $u \in L(X)$. Every such element u has a unique decomposition as $u = [u_1, u_2]$. In turn, each of u_1 and u_2 may be uniquely expressed as $u_1 = [u_{11}, u_{12}]$ and $u_2 = [u_{21}, u_{22}]$. This process may be continued until we end up with elements which are not decomposable. All such elements $u_{i_1,\ldots,i_m}$, $i_a \in \{1, 2\}$, shall be called *components* of u.

If $\boldsymbol{X} = \{X_0, \ldots, X_l\}$, for $B \in \mathrm{Br}(\boldsymbol{X})$ we define $\delta_a(B)$, $a = 0, \ldots, l$, to be the number of times that X_a occurs in B. The sum of the δ_a's we shall call the *degree* of B.

Given a family of vector fields on a manifold M, $\mathcal{V} \subset \mathfrak{X}(M)$, we may define a distribution on M by

$$D_{\mathcal{V}}(x) = \mathrm{span}_{\mathbb{R}}\{X(x) \mid \quad X \in \mathcal{V}\}.$$

Since $\mathfrak{X}(M)$ is a Lie algebra, we may ask for the smallest Lie subalgebra of $\mathfrak{X}(M)$ which contains a family of vector fields $\mathcal{V}$. It is convenient to describe this subalgebra using the ideas from free Lie algebras presented above.

Let X be a set which is bijective to $\mathcal{V}$ with bijection ϕ. Thus, with each element of X we associate a vector field in $\mathcal{V}$. We establish a Lie algebra homomorphism, $\mathrm{Ev}(\phi) : L(X) \to \mathfrak{X}(M)$, in a natural manner. Thus we define $\mathrm{Ev}(\phi)$ so that $[\mathrm{Ev}(\phi)(B_1), \mathrm{Ev}(\phi)(B_2)] = \mathrm{Ev}(\phi)([B_1, B_2])$ for $B_1, B_2 \in \mathrm{Br}(X)$ and then extend this to $L(X)$ by $\mathbb{R}$-linearity. The smallest Lie subalgebra of $\mathfrak{X}(M)$ which contains $\mathcal{V}$ may now be stated in a simple manner. It is simply the image of $L(X)$ under the homomorphism $\mathrm{Ev}(\phi)$. We shall denote this subalgebra by $\overline{\mathrm{Lie}}(\mathcal{V})$ and call it the *involutive closure* of $\mathcal{V}$.

For $x \in M$ we define the map $\mathrm{Ev}_x(\phi) : L(X) \to T_xM$ by

$$\mathrm{Ev}_x(\phi)(u) = (\mathrm{Ev}(\phi)(u))(x).$$

We shall say that $\mathcal{V}$ satisfies the *Lie algebra rank condition* (LARC) at x if $\mathrm{Ev}_x(\phi)(L(X)) = T_xM$.

It is possible to talk about the involutive closure and the LARC without using free Lie algebras. However, since we will have to use free Lie algebras later in the paper, using them here provides us an opportunity to introduce the ideas in a more straightforward setting.

3.2. Symmetric algebra. As far as we know, the idea of a symmetric algebra does not appear in the literature. However, the concept is a natural one and shall be useful to us. A *symmetric algebra* is an algebra, A, where the multiplication (which

we shall denote by $(u, v) \mapsto \langle u : v \rangle$) satisfies $\langle u : v \rangle = \langle v : u \rangle$ for $u, v \in A$. A map $\sigma : A \to A'$ between symmetric algebras is called a *symmetric algebra homomorphism* if $\sigma(\langle u : v \rangle) = \langle \sigma(u) : \sigma(v) \rangle$ for each $u, v \in A$.

We now construct a symmetric algebra which is generated by a given set X. To construct this algebra, let X be a set, and recall that $A(X)$ is the free algebra on X. The *free symmetric algebra* on X, denoted $S(X)$, is the quotient algebra obtained by taking the quotient of $A(X)$ by the two-sided ideal generated by all elements of the form $a \cdot b - b \cdot a$, where $a, b \in A(X)$. We shall denote the product in $S(X)$ by $\langle u : v \rangle$. Note that, by construction, $\langle u : v \rangle = \langle v : u \rangle$ for every $u, v \in S(X)$. We denote by $\mathrm{Pr}(X)$ the subset of $S(X)$ consisting of the symmetric products whose elements are in X.

As with free Lie algebras, the finitely generated case is the most interesting to us. Let $\boldsymbol{Y} = \{X_1, \ldots, X_{l+1}\}$ (the reason for the slightly unusual enumeration will become clear in section 5.5). For $P \in \mathrm{Pr}(\boldsymbol{Y})$ define $\gamma_a(P)$ to be the number of times the element X_a occurs in $P \in \mathrm{Pr}(\boldsymbol{Y})$ for $a = 1, \ldots, l+1$. We shall call the sum of the γ_a's the *degree* of P.

3.3. Some Riemannian geometry. The kinetic energy of a mechanical system may be regarded as being determined by a *Riemannian metric* on the configuration space. A Riemannian metric g on a manifold M is simply a smooth assignment of an inner product for each tangent space of the manifold. In a set of coordinates $(x^1, \ldots, x^n)$ for M, the components of the metric are given by $g_{ij} = g(\frac{\partial}{\partial x^i}, \frac{\partial}{\partial x^j})$. For each $x \in M$, we may define isomorphisms $\sharp$: $T_x^*M \to T_xM$ and $\flat$: $T_xM \to T_x^*M$ in the usual manner (see [7]). These maps naturally extend to isomorphisms from $\mathfrak{X}(M)$, the set of vector fields on M, to $\Omega^1(M)$, the set of one-forms on M. In this case, given a function $f \in C^\infty(M)$, we define $\mathrm{grad} f = (\boldsymbol{d}f)^\sharp$.

A Riemannian manifold is endowed with a unique *affine connection* (called the Levi–Cività connection), which is characterized by being torsion free and by its parallel transportation being metric preserving (see [7]). This affine connection defines $\nabla_X Y$, which is called the *covariant derivative* of Y with respect to X. In coordinates we have

$$\nabla_X Y = \left(\frac{\partial Y^i}{\partial x^j} X^j + \Gamma^i_{jk} X^j Y^k \right) \frac{\partial}{\partial x^i}.$$

The Γ^i_{jk} are the *Christoffel symbols* and are given by

$$\Gamma^i_{jk} = \frac{1}{2} g^{il} \left(\frac{\partial g_{lj}}{\partial x^k} + \frac{\partial g_{lk}}{\partial x^j} - \frac{\partial g_{jk}}{\partial x^l} \right).$$

Here g^{ij} is the inverse of the matrix g_{ij}. On TM we may define a second-order vector field called the *geodesic spray*, which we denote by Z_g. This vector field is characterized by the fact that the projection to M of the integral curves of Z_g by the tangent bundle projection are *geodesics*. In coordinates we have

$$Z_g = v^i \frac{\partial}{\partial x^i} - \Gamma^i_{jk} v^j v^k \frac{\partial}{\partial v^i}.$$

Here we are denoting by $(x^1, \ldots, x^n, v^1, \ldots, v^n)$ the natural coordinates for TM corresponding to coordinates $(x^1, \ldots, x^n)$ for M.

We shall need the concept of a "symmetric subalgebra" of $\mathfrak{X}(M)$, which is generated by a family of vector fields $\mathcal{V} \subset \mathfrak{X}(M)$. This construction relies on the covariant

derivative discussed above. We may make $\mathfrak{X}(M)$ into a symmetric algebra by defining the symmetric product

$$\langle X : Y \rangle = \nabla_X Y + \nabla_Y X.$$

We remark that this product first appeared in the work of Crouch [4] on gradient dynamical systems. Let $\mathcal{V}$ be a family of vector fields on M and X be a set which is bijective to $\mathcal{V}$ with bijection ψ: $X \to \mathcal{V}$. As in section 3.2, let $S(X)$ be the free symmetric algebra on X and $\mathrm{Pr}(X)$ be the symmetric products with elements in X. We may define a symmetric algebra homomorphism from $S(X)$ to $\mathfrak{X}(M)$ by extending ψ in the natural way much as we did for Lie brackets in section 3.1. We denote the resulting map from $S(X)$ to $\mathfrak{X}(M)$ by $\mathrm{Ev}(\psi)$. We also define $\mathrm{Ev}_x(\psi)(P) = (\mathrm{Ev}(\psi)(P))(x)$ for $x \in M$. We denote by $\overline{\mathrm{Sym}}(\mathcal{V})$ the image of $S(X)$ under this homomorphism and call this the *symmetric closure* of $\mathcal{V}$.

4. Sufficient conditions for small-time local controllability. Sussmann [13] gives a general result concerning so-called small-time local controllability. We are interested in a version of Sussmann's result and so will present only as much background as is necessary to state this result. We consider control systems of the form

$$\dot{x} = X(x) + u^a Y_a(x) \tag{2}$$

on a manifold M, where $X, Y_1, \ldots, Y_m$ are analytic. (Here and in what follows, when we write $u^a Y_a$, there will be an implied sum over a from 1 to m.) We shall consider inputs from the set $\mathcal{U}$ of piecewise constant inputs. Let $x_0 \in M$, let V be a neighborhood of x_0, and let $T > 0$. We denote by $\mathcal{R}^V(x_0, T)$ the set of points which can be reached from x_0 in time T while remaining in V using inputs from $\mathcal{U}$. We also denote $\mathcal{R}^V(x_0, \leq T) = \cup_{t=0}^{T} \mathcal{R}^V(x_0, t)$. We say that the system (2) is *locally accessible* at x_0 if $\mathcal{R}^V(x_0, \leq T)$ contains an open subset of M for each V and for each T sufficiently small. Furthermore, we say that (2) is *small-time locally controllable* (STLC) if it is locally accessible and if x_0 is in the interior of $\mathcal{R}^V(x_0, \leq T)$ for each V and for each T sufficiently small.

Let $\boldsymbol{X} = \{X_0, \ldots, X_m\}$. An element $B \in \mathrm{Br}(\boldsymbol{X})$ is said to be *bad* if $\delta_0(B)$ is odd and $\delta_a(B)$ is even for each $a = 1, \ldots, m$. A bracket is *good* if it is not bad. Let S_m denote the permutation group on m symbols. For $\pi \in S_m$ and $B \in \mathrm{Br}(\boldsymbol{X})$, define $\bar{\pi}(B)$ to be the bracket obtained by fixing X_0 and sending X_a to $X_{\pi(a)}$ for $a = 1, \ldots, m$. Now define

$$\beta(B) = \sum_{\pi \in S_m} \bar{\pi}(B).$$

We may state sufficient conditions for STLC.

THEOREM 4.1 (see Sussmann [13]). *Consider the bijection ϕ: $\boldsymbol{X} \to \{X, Y_1, \ldots, Y_m\}$ which sends X_0 to X and X_a to Y_a for $a = 1, \ldots, m$. Suppose that* (2) *is such that every bad bracket $B \in \mathrm{Br}(\boldsymbol{X})$ has the property that*

$$\mathrm{Ev}_x(\phi)(\beta(B)) = \sum_{a=1}^{m} \xi^a \mathrm{Ev}_x(\phi)(C_a),$$

where C_a are good brackets in $\mathrm{Br}(\boldsymbol{X})$ of lower degree than B and $\xi^a \in \mathbb{R}$ for $a = 1, \ldots, m$. Also suppose that (2) *satisfies the LARC at x. Then* (2) *is STLC at x.*

Sussmann [13] gives this result as a corollary of a special case originally conjectured by Hermes [5] and proven by Sussmann [12].

5. Controllability of simple mechanical control systems. In this section we present the main results of the paper. First we make explicit the class of control systems that we are considering. All problem data will be assumed to be analytic so that we may use piecewise constant inputs. The data for the systems that we consider are an n-dimensional configuration manifold Q; a Riemannian metric g on Q, which represents the kinetic energy; an $\mathbb{R}$-valued function V on Q, which represents the potential energy; and m linearly independent one-forms, $F^1, \dots, F^m$, on Q, which represent the input forces for the system. We call a system described by this data a *simple mechanical control system*. Although the one-forms $F^1, \dots, F^m$ describe the forces for the problem, it is the vector fields $Y_a = (F^a)^\sharp$, $a = 1, \dots, m$, which will appear in the computations. Nevertheless, it is the one-forms which are basic in the problem description.

Given a vector field X on Q, we define the *vertical lift* (see [1]) of X as the vector field on TQ defined by

$$X^{lift}(v) = \left.\frac{d}{dt}\right|_{t=0} v + tX(\tau_Q(v))$$

for $v \in TQ$ and where $\tau_Q\colon TQ \to Q$. If $(q^1, \dots, q^n)$ are coordinates for Q, we shall denote the corresponding natural coordinates for TQ by $(q^1, \dots, q^n, v^1, \dots, v^n)$. In coordinates we have

$$X^{lift}(v_q) = X^i(q)\frac{\partial}{\partial v^i}$$

for $v_q \in T_qQ$. We may now define the vector field X_L on TQ by $X_L = Z_g - \mathrm{grad}V^{lift}$, where we recall that Z_g is the geodesic spray introduced in section 3.3. With this notation, the Euler–Lagrange equations for the forced system may be shown to be equivalent to the first-order system

$$\dot{v} = X_L + u^a Y_a^{lift} \tag{3}$$

on TQ. Thus the *drift vector field* for the system is X_L, and the control vector fields are $Y_1^{lift}, \dots, Y_m^{lift}$. It is this first-order affine control system which we study in this section. We are particularly interested in the following problem.

Problem Statement. *Describe the set of configurations reachable from a given configuration when starting at rest.*

Observe that we place no restriction on the final velocities of the system. The reader will further observe that this problem statement involves only *configurations* and not velocities. It would be desirable, therefore, to derive an answer to this problem in terms of quantities on the *configuration space*. As we shall see, this can in fact be done and is one of the more compelling aspects of this approach.

Since the computations in this section are quite involved, let us outline them here before we begin. The main goal of the computations is to describe the accessibility distribution for (3) at points of zero velocity in TQ. Thus we need to compute the involutive closure of the family of vector fields $\mathcal{V}' = \{X_L, Y_1^{lift}, \dots, Y_m^{lift}\}$. Observe that since $X_L = Z_g - \mathrm{grad}V^{lift}$, we may write vector fields in $\overline{\mathrm{Lie}}(\mathcal{V}')$ as $\mathbb{R}$-linear combinations of vector fields in $\mathcal{V} = \{Z_g, Y_1^{lift}, \dots, Y_m^{lift}, \mathrm{grad}V^{lift}\}$. This is made precise by using free Lie algebras in section 5.1. When we evaluate the brackets which are used in the computation of the accessibility distribution at zero velocity, only a small number of them make a contribution, and the rest vanish. The brackets which

vanish do so in one of two ways. Either they are identically zero or they are polynomial in the velocity coordinates and so go to zero when the velocity goes to zero. Therefore, we have three possible classes of brackets: one class which is nonzero when the velocity is zero, one class which is identically zero, and one class which is not identically zero but is zero when the velocity is zero. In section 5.1 we categorize these three types of brackets. There we shall see that the brackets which make a contribution to the accessibility distribution at zero velocity may be written as linear combinations of special brackets which we call *primitive* brackets. The computations in section 5.1 are done at the level of free Lie algebras since this provides a rigorous way to perform the necessary computations. In section 5.2 we give expressions for primitive brackets in terms of the geometry of the problem. It is here that the symmetric product introduced in section 3.3 makes its appearance. In section 5.3 we assemble the results of sections 5.1 and 5.2 to arrive at the form of the accessibility distribution for (3) at points of zero velocity. In section 5.4 we provide a precise statement of the types of controllability we consider, and in section 5.5 we provide computable conditions for these versions of controllability.

We remark that most of the complexity of this section is a consequence of including potential energy in the formulation. In [9] the authors provide sufficient conditions for controllability when there is no potential energy function. Due to space considerations, some of the free Lie algebra proofs from section 5.1 are omitted. We refer the reader to the dissertation [8] for these proofs.

5.1. Computations with free Lie algebras. In this section we perform some calculations with a pair of free Lie algebras which are suited to our purposes. Rather than just using a generating set which is in one-to-one correspondence with the set $\mathcal{V}' = \{X_L, Y_1^{lift}, \ldots, Y_m^{lift}\}$ of control vector fields and the drift vector field, we also use a generating set which is in one-to-one correspondence with the set $\mathcal{V} = \{Z_g, Y_1^{lift}, \ldots, Y_m^{lift}, \mathrm{grad}V^{lift}\}$. The reason for this is that vector fields in $\mathcal{V}'$ are $\mathbb{R}$-linear combinations of vector fields in $\mathcal{V}$, and as we shall see in section 5.3, it is comparatively easy to describe the involutive closure of $\mathcal{V}$.

Let $\boldsymbol{X} = \{X_0, \ldots, X_{m+1}\}$, and let $L(\boldsymbol{X})$ be the free Lie algebra generated by the set $\boldsymbol{X}$. We can simplify many of our computations for the controllability analysis of (3) by making simplifications to a set of generators for $L(\boldsymbol{X})$. We first need some notation. Let

$$\mathrm{Br}^k(\boldsymbol{X}) = \{B \in \mathrm{Br}(\boldsymbol{X}) \mid \text{ the degree of } B \text{ is } k\},$$

$$\mathrm{Br}_k(\boldsymbol{X}) = \left\{ B \in \mathrm{Br}(\boldsymbol{X}) \mid \ \delta_0(B) - \sum_{a=1}^{m+1} \delta_a(B) = k \right\}.$$

We shall see in section 5.2 that, when we restrict ourselves to zero velocities, only a small subset of $\mathrm{Br}(\boldsymbol{X})$ will evaluate to something nonzero. In turn, these brackets will be seen to be linear combinations of a special class of brackets which we shall call *primitive* brackets. Recall from section 3.1 the notion of components in $L(\boldsymbol{X})$.

DEFINITION 5.1. *Let $B \in \mathrm{Br}_0(\boldsymbol{X}) \cup \mathrm{Br}_{-1}(\boldsymbol{X})$, and let $B_1, B_2, B_{11}, B_{12}, B_{21}, B_{22}, \ldots$ be the decomposition of B into its components. We shall say that B is* primitive *if each of its components is in $\mathrm{Br}_{-1}(\boldsymbol{X}) \cup \mathrm{Br}_0(\boldsymbol{X}) \cup \{X_0\}$.*

The relevant observations that need to be made regarding primitive brackets are as follows:

Prim1. If $B \in \mathrm{Br}_{-1}(\boldsymbol{X})$ is primitive, then, up to sign, we may write $B = [B_1, B_2]$ with $B_1 \in \mathrm{Br}_{-1}(\boldsymbol{X})$ and $B_2 \in \mathrm{Br}_0(\boldsymbol{X})$ both primitive.

Prim2. If $B \in \mathrm{Br}_0(\boldsymbol{X})$ is primitive, then, up to sign, B may have one of two forms. Either $B = [X_0, B_1]$ with $B_1 \in \mathrm{Br}_{-1}(\boldsymbol{X})$ primitive or $B = [B_1, B_2]$ with $B_1, B_2 \in \mathrm{Br}_0(\boldsymbol{X})$ both primitive.

Using these two rules, it is possible to construct primitive brackets of any degree. For example, the primitive brackets of degrees one through four are, up to sign,

$$\begin{aligned}
&\text{Degree 1}: \ \{X_a \mid \ a = 1, \dots, m\},\\
&\text{Degree 2}: \ \{[X_0, X_a] \mid \ a = 1, \dots, m\},\\
&\text{Degree 3}: \ \{[X_a, [X_0, X_b]] \mid \ a, b = 1, \dots, m\},\\
&\text{Degree 4}: \ \{[X_0, [X_a, [X_0, X_b]]] \mid \ a, b = 1, \dots, m\}\\
&\qquad\qquad \cup \{[[X_0, X_a], [X_0, X_b]] \mid \ a, b = 1, \dots, m\}.
\end{aligned}$$

From Proposition 3.1 we know that to generate $L(\boldsymbol{X})$ we need only look at brackets of the form

$$[X_{a_k}, [X_{a_{k-1}}, \dots, [X_{a_2}, X_{a_1}]]], \tag{4}$$

where $a_i \in \{0, \dots, m+1\}$ for $i = 1, \dots, k$. We shall see in section 5.2 that brackets from $\mathrm{Br}_j(\boldsymbol{X})$, where $j \geq 1$ or $j \leq -2$, will not be of interest to us. In particular, we shall see that when $j \leq -2$ these brackets evaluate identically to zero. Therefore, in this section we concentrate our attention on brackets in $\mathrm{Br}_0(\boldsymbol{X}) \cup \mathrm{Br}_{-1}(\boldsymbol{X})$ which satisfy certain requirements. We state the form of these brackets in the following lemma.

LEMMA 5.2. *Let us impose the condition on elements of* $\mathrm{Br}(\boldsymbol{X})$ *that we shall consider a bracket to be zero if any of its components is in* $\mathrm{Br}_{-j}(\boldsymbol{X})$ *for* $j \geq 2$. *Let* $B \in \mathrm{Br}_0(\boldsymbol{X}) \cup \mathrm{Br}_{-1}(\boldsymbol{X})$. *Then we may write* B *as a finite sum of primitive brackets.*

The inductive proof is straightforward, and we refer the interested reader to [8]. However, in lieu of a proof an example is illustrative.

Example 5.3. Consider the bracket $B = [X_{m+1}, [X_0, [X_0, X_a]]] \in \mathrm{Br}_0(\boldsymbol{X})$. This bracket is in $\mathrm{Br}_0(\boldsymbol{X})$ but is not primitive. However, by Lemma 5.2, we may write B as a finite sum of primitive brackets. Indeed, by Jacobi's identity we have

$$\begin{aligned}
B &= [X_{m+1}, [X_0, [X_0, X_a]]] = -[[X_0, X_a], [X_{m+1}, X_0]] - [X_0, [[X_0, X_a], X_{m+1}]]\\
&= [[X_0, X_a], [X_0, X_{m+1}]] + [X_0, [X_{m+1}, [X_0, X_a]]].
\end{aligned}$$

The proof of Lemma 5.2 is essentially a generalization of this example.

Now we relate the free Lie algebra $L(\boldsymbol{X})$ with a free Lie algebra which corresponds to the set $\mathcal{V}' = \{X_L, Y_1^{lift}, \dots, Y_m^{lift}\}$. As we mentioned above, the reason why we wish to do this is that the vector fields in $\mathcal{V}'$ are $\mathbb{R}$-linear combinations of vector fields in $\mathcal{V} = \{Z_g, Y_1^{lift}, \dots, Y_m^{lift}, \mathrm{grad} V^{lift}\}$, the latter family of vector fields being bijective with the set $\boldsymbol{X}$. Let $\boldsymbol{X}' = \{X_0', \dots, X_m'\}$. We formally set $X_0' = X_0 - X_{m+1}$ and $X_a' = X_a$ for $a = 1, \dots, m$. We may now write brackets in $\mathrm{Br}(\boldsymbol{X}')$ as linear combinations of brackets in $\mathrm{Br}(\boldsymbol{X})$ by $\mathbb{R}$-linearity of the bracket. We may, in fact, be even more precise about this.

Let $B' \in \mathrm{Br}(\boldsymbol{X}')$. We define a subset $\boldsymbol{S}(B')$ of $\mathrm{Br}(\boldsymbol{X})$ by saying that $B \in \boldsymbol{S}(B')$ if each occurrence of X_a' in B' is replaced with X_a for $a = 1, \dots, m$ and if each occurrence of X_0' in B' is replaced with *either* X_0 *or* X_{m+1}. An example is illustrative. Suppose that

$$B' = [[X_0', X_1'], [X_2', [X_0', X_3']]].$$

Then

$$\boldsymbol{S}(B') = \{[[X_0, X_1], [X_2, [X_0, X_3]]], [[X_0, X_1], [X_2, [X_{m+1}, X_3]]], \\ [[X_{m+1}, X_1], [X_2, [X_0, X_3]]], [[X_{m+1}, X_1], [X_2, [X_{m+1}, X_3]]]\}.$$

Now we may precisely state how we write brackets in $\mathrm{Br}(\boldsymbol{X}')$.

LEMMA 5.4. *Let $B' \in \mathrm{Br}(\boldsymbol{X}')$. Then*

$$B' = \sum_{B \in \boldsymbol{S}(B')} (-1)^{\delta_{m+1}(B)} B.$$

The proof is by induction and may be found in [8].

We shall be interested only in terms in the above decomposition of B' which are in $\mathrm{Br}_0(\boldsymbol{X}) \cup \mathrm{Br}_{-1}(\boldsymbol{X})$ since, as we shall see in section 5.2, these are the only ones which will contribute to $\mathrm{Ev}_{0_q}(\phi')(B')$. Here 0_q is the zero vector in T_qQ.

5.2. Distribution computations for simple mechanical control systems. In this section we use the simplifications of section 5.1 to get a complete description of the brackets which contribute to the accessibility distribution for (3) restricted to $Z(TQ)$, the zero section of TQ. Note that we restrict ourselves to $Z(TQ)$ because we are interested in determining the reachable points starting with zero initial velocity. To make the correspondence between the free Lie algebra $L(\boldsymbol{X})$ used in section 5.1 and the accessibility algebra for (3), we use the family of vector fields $\mathcal{V} = \{Z_g, Y_1^{lift}, \ldots, Y_m^{lift}, \mathrm{grad} V^{lift}\}$ and establish a bijection ϕ from $\boldsymbol{X}$ to $\mathcal{V}$ by mapping X_0 to X_L, X_a to Y_a^{lift} for $a = 1, \ldots, m$, and X_{m+1} to $\mathrm{grad}\, V^{lift}$. Please note that $\mathcal{V}$ is *not* the family of vector fields which generates the accessibility algebra. The accessibility algebra is generated by the family $\mathcal{V}' = \{X_L, Y_1^{lift}, \ldots, Y_m^{lift}\}$. We establish a bijection ϕ' from $\boldsymbol{X}'$ to $\mathcal{V}'$ by mapping X_0' to X_L and X_a' to Y_a^{lift} for $a = 1, \ldots, m$. By Lemma 5.4, each vector field in $\overline{\mathrm{Lie}}(\mathcal{V}')$ is a $\mathbb{R}$-linear sum of vector fields in $\overline{\mathrm{Lie}}(\mathcal{V})$. That lemma also completely describes the sum.

Now we shall show that it is possible to compute the brackets from $\mathrm{Br}(\boldsymbol{X})$ in terms of the problem data. We first present a lemma which gives the basic structure of primitive brackets. In this lemma we see that a large number of brackets are computable in terms of quantities defined on Q. This is worth noting since the vector fields themselves are defined on TQ. Of particular interest in the lemma is the appearance of the symmetric product which was introduced in section 3.3.

We need to say a few words about the structure of TQ. We denote by $Z(TQ)$ the zero section of TQ. Since Q is naturally diffeomorphic to $Z(TQ)$, there is a natural inclusion of T_qQ into $T_{0_q}TQ$ for each $q \in Q$. We shall call the image of this inclusion in $T_{0_q}TQ$ the *horizontal subspace*. We shall call the subspace of $T_{0_q}TQ$ which is tangent to the fiber of TQ at q the *vertical subspace* and denote it by $V_{0_q}TQ$. We have $T_{0_q}TQ = T_qQ \oplus V_{0_q}TQ$ for each $q \in Q$. We mention that this notion of vertical is valid at any point in TQ. However, the definition of horizontal is valid only on $Z(TQ)$.

LEMMA 5.5. *Suppose that $B \in \mathrm{Br}^k(\boldsymbol{X})$ is primitive.*

(i) *If $B \in \mathrm{Br}_{-1}(\boldsymbol{X})$, then $\mathrm{Ev}(\phi)(B)$ is the vertical lift of a vector field on Q.*

(ii) *If $B \in \mathrm{Br}_0(\boldsymbol{X})$, then $U = \mathrm{Ev}(\phi)(B)$ has the property that, when expressed in a local chart, the vertical components of U are linear in the fiber coordinates v and the horizontal components are independent of v. In particular, we may define a vector field on Q by $U_Q \colon q \mapsto U(0_q) \in T_qQ \subset T_{0_q}TQ$. There are two cases to consider.*

(a) *$B = [X_0, B_1]$ with $B_1 \in \mathrm{Br}_{-1}(\boldsymbol{X})$: Define U_1 to be the vector field on Q such that $\mathrm{Ev}(\phi)(B_1) = U_1^{lift}$. Then $U(0_q) = \mathrm{Ev}(\phi)(B)(0_q) = -U_1(q)$. Let $U_2 \in \mathfrak{X}(Q)$. Then $[U_2^{lift}, U] = (\nabla_{U_1} U_2 + \nabla_{U_2} U_1)^{lift}$.*

(b) *$B = [B_1, B_2]$ with $B_1, B_2 \in \mathrm{Br}_0(\boldsymbol{X})$: Define $U_{1,Q}, U_{2,Q}$ to be the vector fields on Q corresponding to $\mathrm{Ev}(\phi)(B_1), \mathrm{Ev}(\phi)(B_2)$, respectively. Then $\mathrm{Ev}(\phi)(B)(0_q) = [U_{1,Q}, U_{2,Q}](q)$.*

Proof. The proof is by induction on k. The result is true for $k = 1$ trivially. If X and Y are vector fields on Q, it is a straightforward coordinate computation to show that

$$[X^{lift}, Y^{lift}] = 0.$$

If X is a vector field on Q, we compute

$$[Z_g, X^{lift}] = -Y^i \frac{\partial}{\partial q^i} + \left(\frac{\partial Y^i}{\partial q^j} v^j + \Gamma^i_{jk} Y^j v^k + \Gamma^i_{kj} v^k Y^j \right) \frac{\partial}{\partial v^i}. \tag{5}$$

Inspecting (5) shows that $[Z_g, X^{lift}](0_q) = -X(q)$. Now let $Y \in \mathfrak{X}(Q)$. We compute

$$[Y^{lift}, [Z_g, X^{lift}]] = \left(\frac{\partial Y^i}{\partial q^j} X^j + \frac{\partial X^i}{\partial q^j} Y^j + 2\Gamma^i_{jk} X^j Y^k \right) \frac{\partial}{\partial v^i}, \tag{6}$$

which is the coordinate representation of $(\nabla_X Y + \nabla_Y X)^{lift}$. This shows that the lemma is true for $k = 2$.

Now suppose that the lemma is true for $k = 1, \ldots, l$ for $l \geq 2$, and let $B \in \mathrm{Br}^{l+1}(\boldsymbol{X})$ be primitive.

(i) Suppose that $B \in \mathrm{Br}_{-1}(\boldsymbol{X})$. Without loss of generality (by Prim1) we may suppose that $B = [B_1, B_2]$ with $B_1 \in \mathrm{Br}_{-1}(\boldsymbol{X})$ and $B_2 \in \mathrm{Br}_0(\boldsymbol{X})$. Then, by the induction hypotheses, we have

$$\mathrm{Ev}(\phi)(B_1) = \alpha^i(q) \frac{\partial}{\partial v^i}, \qquad \mathrm{Ev}(\phi)(B_2) = \lambda^i(q) \frac{\partial}{\partial q^i} + \mu^i_j(q) v^j \frac{\partial}{\partial v^i}.$$

Now we compute

$$\mathrm{Ev}(\phi)([B_1, B_2]) = \left(\mu^i_j \alpha^j - \frac{\partial \alpha^i}{\partial q^j} \lambda^j \right) \frac{\partial}{\partial v^i}.$$

Note that the components in the q-direction are zero and the components in the v-direction are only functions of q. This means that this vector field is the vertical lift of a vector field on Q. This proves (i).

(ii) Suppose that $B \in \mathrm{Br}_0(\boldsymbol{X})$. Without loss of generality (by Prim2) we may suppose that either (a) $B = [X_0, B_1]$ with $B_1 \in \mathrm{Br}_{-1}(\boldsymbol{X})$ or (b) $B = [B_1, B_2]$ with $B_1, B_2 \in \mathrm{Br}_0(\boldsymbol{X})$. Let us deal with the first case. Equation (5) gives $\mathrm{Ev}(B)(\phi)(0_q) = -U_1(q)$, where U_1 is the vector field on Q so that $\mathrm{Ev}(\phi)(B_1) = U_1^{lift}$. (Such a vector field exists by (i).) For every vector field U_2 on Q we have $[U_2^{lift}, [Z_g, U_1^{lift}]] = (\nabla_{U_1} U_2 + \nabla_{U_2} U_1)^{lift}$ by (6). This proves (ii(a)).

Now suppose that we have $B_1, B_2 \in \mathrm{Br}_0(\boldsymbol{X})$. Then, by the induction hypotheses, we have

$$\mathrm{Ev}(\phi)(B_1) = \alpha^i(q) \frac{\partial}{\partial q^i} + \beta^i_j(q) v^j \frac{\partial}{\partial v^i}, \qquad \mathrm{Ev}(\phi)(B_2) = \lambda^i(q) \frac{\partial}{\partial q^i} + \mu^i_j(q) v^j \frac{\partial}{\partial v^i}.$$

We compute

$$\begin{aligned}\mathrm{Ev}(\phi)([B_1,B_2]) = &\left(\frac{\partial\lambda_i}{\partial q^j}\alpha^j - \frac{\partial\alpha^i}{\partial q^j}\lambda^j\right)\frac{\partial}{\partial q^i}\\ &+\left(\frac{\partial\mu^i_k}{\partial q^j}\alpha^j v^k + \mu^i_j\beta^j_k v^k - \frac{\partial\beta^i_k}{\partial q^j}\lambda^j v^k - \beta^i_j\mu^j_k v^k\right)\frac{\partial}{\partial v^i}.\end{aligned}$$

The components have the order in v specified by the lemma. Also, it is clear that the vector fields on Q defined by B_1 and B_2 are

$$U_{1,Q} = \alpha^i(q)\frac{\partial}{\partial q^i} \qquad \text{and} \qquad U_{2,Q} = \lambda^i(q)\frac{\partial}{\partial q^i},$$

respectively. It is easy to see that $\mathrm{Ev}(\phi)(B)(0_q) = [U_{1,Q}, U_{2,Q}](q)$. This completes the proof of the lemma. □

This lemma provides us with a positive step toward computing the value of all primitive brackets when evaluated using $\mathrm{Ev}(\phi)$. The following lemma shows that these are the *only* brackets that we need to consider.

LEMMA 5.6. (i) *Let $l \geq 1$ be an integer, and let $B \in \mathrm{Br}_l(\boldsymbol{X})$. Then $\mathrm{Ev}(\phi)(B)(0_q) = 0$ for each $q \in Q$.*

(ii) *Let $l \geq 2$ be an integer, and let $B \in \mathrm{Br}^k(\boldsymbol{X}) \cap \mathrm{Br}_{-l}(\boldsymbol{X})$ for $k \geq 2$. Then $\mathrm{Ev}(\phi)(B) = 0$.*

The proof of this lemma may be found in [8]. It goes very much like the proof of Lemma 5.5.

Let us summarize what we have done in this section. First we obtained a characterization of primitive brackets in $\boldsymbol{X}$ when we evaluate them in $\mathcal{V}$ via $\mathrm{Ev}(\phi)$. This characterization involved Lie brackets and covariant derivatives of the vector fields $Y_1, \ldots, Y_m, \mathrm{grad}V$. Then we showed in Lemma 5.6 that primitive brackets are the only ones that we need be concerned with if we are evaluating the vector fields on the zero section of TQ.

5.3. The form of the accessibility distribution restricted to $Z(TQ)$ for simple mechanical control systems. In this section we compute the accessibility distribution for (3) restricted to the zero section of TQ. By Lemma 5.4 we know that we may write the vector fields in the accessibility distribution in terms of vector fields in $\overline{\mathrm{Lie}}(\mathcal{V})$. In section 5.2 we saw some hints that we might be able to write vector fields in $\overline{\mathrm{Lie}}(\mathcal{V})$ in terms of covariant derivatives and Lie brackets of the input vector fields and grad$V$. First we resolve this issue by saying exactly what the vector fields in $\overline{\mathrm{Lie}}(\mathcal{V})$ look like when we restrict them to $Z(TQ)$. We denote by $D_{\overline{\mathrm{Lie}}(\mathcal{V})}$ the distribution defined by

$$D_{\overline{\mathrm{Lie}}(\mathcal{V})}(v) = \mathrm{span}_{\mathbb{R}}\{U(v) \mid \ U \in \overline{\mathrm{Lie}}(\mathcal{V})\}.$$

The reader will also wish to recall the ideas from symmetric algebras presented in section 3.3. We denote $\mathcal{Y} = \{Y_1, \ldots, Y_m\}$.

The following lemma describes the horizontal and vertical parts of the involutive closure of $\mathcal{V}$ restricted to $Z(TQ)$. The reader may wish to recall our remarks about the structure of the tangent bundle preceding Lemma 5.5.

LEMMA 5.7. *Let $q \in Q$. Then*

$$D_{\overline{\mathrm{Lie}}(\mathcal{V})}(0_q) \cap V_{0_q}TQ = (D_{\overline{\mathrm{Sym}}(\mathcal{Y}\cup\{\mathrm{grad}\,V\})}(q))^{lift}$$

and

$$D_{\overline{\mathrm{Lie}}(\mathcal{V})}(0_q) \cap T_qQ = D_{\overline{\mathrm{Lie}}(\overline{\mathrm{Sym}}(\mathcal{Y} \cup \{\operatorname{grad} V\}))}(q).$$

Proof. From Lemma 5.6 we know that the only brackets from $\mathrm{Br}(\boldsymbol{X})$ which we need to consider are the primitive brackets. From Lemma 5.5 we know that the brackets which are in $\mathrm{Br}_{-1}(\boldsymbol{X})$ will generate the vertical directions, and the brackets which are in $\mathrm{Br}_0(\boldsymbol{X})$ will generate the horizontal directions.

First we show that $(D_{\overline{\mathrm{Sym}}(\mathcal{Y} \cup \{\operatorname{grad} V\})}(q))^{lift} \subset D_{\overline{\mathrm{Lie}}(\mathcal{V})}(0_q)$. This may be done inductively. Define $\mathrm{Sym}^{(1)}(\mathcal{Y} \cup \{\operatorname{grad} V\}) = \mathcal{Y} \cup \{\operatorname{grad} V\}$, and inductively define

$$\mathrm{Sym}^{(k)}(\mathcal{Y} \cup \{\operatorname{grad} V\} = \{\langle U_1 : U_2 \rangle \mid U_i \in \mathrm{Sym}^{(k_i)}(\mathcal{Y} \cup \{\operatorname{grad} V\}), k_1 + k_2 = k\}.$$

Clearly

$$\overline{\mathrm{Sym}}(\mathcal{Y} \cup \{\operatorname{grad} V\}) = \bigcup_{k \in \mathbb{Z}^+} \mathrm{Sym}^{(k)}(\mathcal{Y} \cup \{\operatorname{grad} V\}).$$

It is trivially true that $(\mathrm{Sym}^{(1)}(\mathcal{Y} \cup \{\operatorname{grad} V\}))^{lift} \subset \overline{\mathrm{Lie}}(\mathcal{V})$. Now suppose that $(\mathrm{Sym}^{(k)}(\mathcal{Y} \cup \{\operatorname{grad} V\}))^{lift} \subset \overline{\mathrm{Lie}}(\mathcal{V})$ for $k = 1, \ldots, l$ for $l \geq 1$. We see that $(\mathrm{Sym}^{(l+1)}(\mathcal{Y} \cup \{\operatorname{grad} V\}))^{lift} \subset \overline{\mathrm{Lie}}(\mathcal{V})$ since we may generate all elements of $(\mathrm{Sym}^{(l+1)}(\mathcal{Y} \cup \{\operatorname{grad} V\}))^{lift}$ by considering brackets of the form $[U_1^{lift}, [Z_g, U_2^{lift}]]$, where $U_i \in \mathrm{Sym}^{(l_i)}(\mathcal{Y}, V)$ and $l_1 + l_2 = l + 1$. This follows from (6). This shows that $(D_{\overline{\mathrm{Sym}}(\mathcal{Y} \cup \{\operatorname{grad} V\})}(q))^{lift} \subset D_{\overline{\mathrm{Lie}}(\mathcal{V})}(0_q)$.

Now we show that $D_{\overline{\mathrm{Lie}}(\mathcal{V})}(0_q) \subset (D_{\overline{\mathrm{Sym}}(\mathcal{Y} \cup \{\operatorname{grad} V\})}(q))^{lift}$. To do this we must show that the image under $\mathrm{Ev}(\phi)$ of all primitive brackets in $\mathrm{Br}_{-1}(\boldsymbol{X})$ may be written as a linear combination of vector fields in $\overline{\mathrm{Sym}}(\mathcal{Y} \cup \{\operatorname{grad} V\})$. A primitive bracket in $\mathrm{Br}_{-1}(\boldsymbol{X})$ may be written as $B = [B_1, B_2]$ with $B_1 \in \mathrm{Br}_{-1}(\boldsymbol{X})$ and $B_2 \in \mathrm{Br}_0(\boldsymbol{X})$ both being primitive. Therefore, either $B_2 = [X_0, B_2']$ with B_2' primitive and in $\mathrm{Br}_{-1}(\boldsymbol{X})$ or $B_2 = [B_2', B_2'']$ with $B_2', B_2'' \in \mathrm{Br}_0(\boldsymbol{X})$ both primitive. In the first case $\mathrm{Ev}(\phi)(B) \in \mathrm{Sym}^{(k)}\mathcal{Y} \cup \{\operatorname{grad} V\})$ for some k by (6). In the second case we may use Jacobi's identity to obtain

$$B = -[B_2'', [B_1, B_2']] + [B_2', [B_1, B_2'']].$$

We may apply the above argument to the terms $[B_1, B_2']$ and $[B_1, B_2'']$, repeatedly using (6) until they are expressed in terms of covariant derivatives. When this is done, $\mathrm{Ev}(\phi)(B)$ will then be a $\mathbb{R}$-linear combination of elements in $\overline{\mathrm{Sym}}(\mathcal{Y} \cup \{\operatorname{grad} V\})$. This shows that $D_{\overline{\mathrm{Lie}}(\mathcal{V})}(0_q) \subset (D_{\overline{\mathrm{Sym}}(\mathcal{Y} \cup \{\operatorname{grad} V\})}(q))^{lift}$.

To demonstrate the proposed form of $D_{\overline{\mathrm{Lie}}(\mathcal{V})} \cap T_qQ$, by Lemma 5.5 (ii(b)) we need only show that $\overline{\mathrm{Sym}}(\mathcal{Y} \cup \{\operatorname{grad} V\})(q) \subset D_{\overline{\mathrm{Lie}}(\mathcal{V})}(0_q)$. But this is clear from Lemma 5.5 (ii(a)). This completes the proof of the lemma. ∎

Remark 5.8. Note that the constructions in the above lemma depend only upon $\{Y_1, \ldots, Y_m, \operatorname{grad} V\}$. The effects of the geodesic spray do not appear explicitly. However, its contribution is obviously important in the computations performed in section 5.2.

From Lemmas 5.4 and 5.7 we know that the vector fields which contribute to $\overline{\mathrm{Lie}}(\mathcal{V}')$ when we evaluate on $Z(TQ)$ will be $\mathbb{R}$-linear combinations of vector fields from $\overline{\mathrm{Lie}}(\overline{\mathrm{Sym}}(\mathcal{Y} \cup \{\operatorname{grad} V\}))$. Thus, to compute these vector fields, we need to figure out which vector fields need to be "removed" from $\overline{\mathrm{Lie}}(\overline{\mathrm{Sym}}(\mathcal{Y} \cup \{\operatorname{grad} V\}))$. We present an

ALGORITHM 7.1.

      end
    end
  end
END

FIG. 2. *Algorithm for computing* $\overline{\mathrm{Lie}}(\mathcal{V}') \mid Z(TQ)$.

algorithm which we shall prove determines exactly which $\mathbb{R}$-linear combinations from $\overline{\mathrm{Lie}}(\overline{\mathrm{Sym}}(\mathcal{Y} \cup \{\mathrm{grad}\, V\}))$ we need to compute. We define *two* sequences of families of vector fields on Q, which we shall denote by $\mathcal{C}_{ver}^{(k)}(\mathcal{Y}, V)$ and $\mathcal{C}_{hor}^{(k)}(\mathcal{Y}, V)$ where $k \in \mathbb{Z}^+$. In Figure 2 the algorithm is presented for computing these families. When we have computed these sequences we define

$$\mathcal{C}_{ver}(\mathcal{Y}, V) = \bigcup_{k \in \mathbb{Z}^+} \mathcal{C}_{ver}^{(k)}(\mathcal{Y}, V), \qquad \mathcal{C}_{hor}(\mathcal{Y}, V) = \bigcup_{k \in \mathbb{Z}^+} \mathcal{C}_{hor}^{(k)}(\mathcal{Y}, V).$$

The distributions defined by these families of vector fields shall be denoted $C_{ver}(\mathcal{Y}, V)$ and $C_{hor}(\mathcal{Y}, V)$, respectively.

We may now state the form of the accessibility distribution $\overline{\mathrm{Lie}}(\mathcal{V}')$ for (3) when restricted to the zero section of TQ.

PROPOSITION 5.9. *Let $q \in Q$. Then*

$$D_{\overline{\mathrm{Lie}}(\mathcal{V}')}(0_q) \cap V_{0_q}TQ = (C_{ver}(\mathcal{Y}, V)(q))^{lift}$$

and

$$D_{\overline{\mathrm{Lie}}(\mathcal{V}')}(0_q) \cap T_qQ = C_{hor}(\mathcal{Y}, V)(q).$$

Proof. Studying the algorithm that we have used to compute $\mathcal{C}_{ver}(\mathcal{Y}, V)$ and $\mathcal{C}_{hor}(\mathcal{Y}, V)$, the reader will note that we have exactly taken each primitive bracket $B \in \mathrm{Br}(\boldsymbol{X})$ and computed which $\mathbb{R}$-linear combinations from $\mathrm{Br}(\boldsymbol{X})$ appear along with B in the decomposition of some $B' \in \mathrm{Br}(\boldsymbol{X}')$ given by Lemma 5.4. Since it is only these primitive brackets which appear in $\overline{\mathrm{Lie}}(\mathcal{V}') \mid Z(TQ)$, this will, by construction, generate $D_{\overline{\mathrm{Lie}}(\mathcal{V}')} \mid Z(TQ)$.

We need to prove that, as stated in the first step of the algorithm, if $\delta_{m+1}(B) = 0$, then $\mathrm{Ev}_{0_q}(\phi)(B) \in D_{\overline{\mathrm{Lie}}(\mathcal{V}')}(0_q)$. To show that this is in fact the case, let $B' \in \mathrm{Br}(\boldsymbol{X}')$ be the bracket obtained by replacing X_a with X'_a for $a = 0, \ldots, m$. We claim that the only bracket in $\boldsymbol{S}(B')$ which contributes to $\mathrm{Ev}(\phi')(B')$ is B. This is true since any other brackets in $\boldsymbol{S}(B')$ are obtained by replacing X_0 in B with X_{m+1}. Such a replacement will result in a bracket which has at least one component which is in $\mathrm{Br}_{-l}(\boldsymbol{X})$ for $l \geq 2$. These brackets evaluate to zero by Lemma 5.6(ii).

We also need to show that if B has components of the form $[X_0, X_{m+1}]$, then it will not contribute to $\overline{\mathrm{Lie}}(\mathcal{V}') \mid Z(TQ)$. This is clear since, when constructing B' in the algorithm, the component $[X_0, X_{m+1}]$ will become $[X'_0, X'_0]$, which means that B' will be identically zero. □

It is perhaps useful to construct a few of the families $\mathcal{C}^{(k)}_{ver}(\mathcal{Y}, V)$ and $\mathcal{C}^{(k)}_{hor}(\mathcal{Y}, V)$ to show how the algorithm works. We shall do this for $k = 1, 2$. Our notation in these calculations follows that in the algorithm.

Let $i = 1$. The only primitive brackets in $\mathrm{Br}^{(1)}(\boldsymbol{X})$ are $X_1, \ldots, X_{m+1}$. For the brackets $B = X_a$, $a = 1, \ldots, m$, $\delta_{m+1}(B) = 0$. Note that $\mathrm{Ev}(\phi)(B) = Y_a^{lift}$ so $Y_a \in \mathcal{C}^{(1)}_{ver}(\mathcal{Y}, V)$ for $a = 1, \ldots, m$. The bracket X_{m+1} has no components of the form $[X_0, X_{m+1}]$, so it is a candidate for providing an element of $\mathcal{C}^{(1)}_{ver}(\mathcal{Y}, V)$. If $B = X_{m+1}$, we compute $B' = X'_0$. Therefore, $\boldsymbol{S}(B') = \{X_0, X_{m+1}\}$. The only element in $\boldsymbol{S}(B')$ which is in $\mathrm{Br}_{-1}(\boldsymbol{X}) \cup \mathrm{Br}_0(\boldsymbol{X})$ is X_{m+1}. Therefore, $B'' = -X_{m+1}$. We then see that $\mathrm{Ev}(\phi)(B'') = -\mathrm{grad}\, V^{lift}$, from which we conclude that $\mathrm{grad}\, V \in \mathcal{C}^{(1)}_{ver}(\mathcal{Y}, V)$. In summary,

$$\mathcal{C}^{(1)}_{ver}(\mathcal{Y}, V) = \{Y_1, \ldots, Y_m, \mathrm{grad}\, V\}.$$

Now we look at the case when $i = 2$. The primitive brackets in $\mathrm{Br}^{(2)}(\boldsymbol{X})$ are $\{[X_0, X_1], \ldots, [X_0, X_{m+1}]\}$. The brackets $B = [X_0, X_a]$, $a = 1, \ldots, m$, have the property that $\delta_{m+1}(B) = 0$. We compute $\mathrm{Ev}_{0_q}(\phi)(B) = -Y_a(q)$ and so conclude that $Y_a \in \mathcal{C}^{(1)}_{hor}(\mathcal{Y}, V)$. The bracket $[X_0, X_{m+1}]$ is not a candidate for providing an element of $\mathcal{C}^{(1)}_{hor}(\mathcal{Y}, V)$, so we have

$$\mathcal{C}^{(1)}_{hor}(\mathcal{Y}, V) = \{Y_1, \ldots, Y_m\}.$$

In a similar manner we may compute

$$\mathcal{C}^{(2)}_{ver}(\mathcal{Y}, V) = \{\langle Y_a : Y_b\rangle \mid \ a, b = 1, \ldots, m\} \cup \{\langle Y_a : \mathrm{grad}\, V\rangle \mid \ a = 1, \ldots, m\}$$

and

$$\mathcal{C}^{(2)}_{hor}(\mathcal{Y},V) = \mathcal{C}^{(2)}_{ver}(\mathcal{Y},V) \cup \{[Y_a,Y_b] \mid \ a,b=1,\dots,m\}$$
$$\cup \{2\langle Y_a : \operatorname{grad} V\rangle + [Y_a, \operatorname{grad} V] \mid \ a=1,\dots,m\}.$$

To compute the terms $2\langle Y_a : \operatorname{grad} V\rangle + [Y_a, \operatorname{grad} V]$ in $\mathcal{C}^{(2)}_{hor}(\mathcal{Y},V)$, we have used the computations of Example 5.3.

It would be interesting to be able to derive an inductive formula for computing the families $\mathcal{C}^{(k)}_{ver}(\mathcal{Y},V)$ and $\mathcal{C}^{(k)}_{hor}(\mathcal{Y},V)$. However, such an inductive formula appears to be quite complex.

There are some important statements which can easily be made regarding the distributions $C_{hor}(\mathcal{Y},V)$ and $C_{ver}(\mathcal{Y},V)$.

Remark 5.10.

(1) The generators that we have written for $\mathcal{C}^{(k)}_{ver}(\mathcal{Y},V)$ and $\mathcal{C}^{(k)}_{hor}(\mathcal{Y},V)$ are not linearly independent. Thus one should be able to generate these families with fewer calculations than are necessary to compute the generators we give. One way to do this is to choose a Philip Hall basis for $L(\boldsymbol{X}')$ and compute the image of these brackets under $\operatorname{Ev}(\phi')$. This will work for any given example. However, we are unable to give the general form for the image of a Philip Hall basis under $\operatorname{Ev}(\phi')$.

(2) We claim that $C_{hor}(\mathcal{Y},V)$ is involutive. Let $B_1', B_2' \in \operatorname{Br}(\boldsymbol{X}')$ be brackets which, when evaluated under $\operatorname{Ev}_{0_q}(\phi')$, give vector fields $U_1, U_2 \in \mathcal{C}_{hor}(\mathcal{Y},V)$. Then the decomposition of B_i given by Lemma 5.4 has the form $B_i' = B_i + \tilde{B}_i$, where $B_i \in \operatorname{Br}_0(\boldsymbol{X})$ and $\tilde{B}_i$ is a sum of brackets in $\operatorname{Br}_j(\boldsymbol{X})$ for $j \geq 2$. Therefore, $[B_1', B_2'] = [B_1, B_2] + B''$, where B'' is a sum of brackets in $\operatorname{Br}_j(\boldsymbol{X})$ for $j \geq 2$. This shows that $[U_1, U_2] \in \mathcal{C}_{hor}(\mathcal{Y},V)$. Here we have imposed the condition that brackets in $\operatorname{Br}_{-j}(\boldsymbol{X})$ are taken to be zero for $j \geq 2$ (see Lemma 5.2).

(3) An interesting special case, and one that we shall see in the examples in section 6, is that when $V = 0$. In this case we have $\mathcal{C}_{ver}(\mathcal{Y},V) = \overline{\operatorname{Sym}}(\mathcal{Y})$ and $\mathcal{C}_{hor}(\mathcal{Y},V) = \overline{\operatorname{Lie}}(\overline{\operatorname{Sym}}(\mathcal{Y}))$. This is easily seen in the algorithm by following the path when $\delta_{m+1}(B) = 0$.

(4) The calculations of this section and section 5.2 remain valid if we replace $\operatorname{grad} V$ with an arbitrary vector field on Q.

5.4. Controllability definitions for simple mechanical control systems. It is possible to simply adopt the controllability definitions from nonlinear control theory since our system may be written as a standard control system on TQ. However, since we are dealing with simple control mechanical systems, it is of more interest to us to know what is happening to the *configurations*. A good example of a question of interest in mechanics is, "What is the set of configurations which are reachable from a given configuration if we start at rest?" This is in fact exactly the question that we pose.

DEFINITION 5.11. *A* solution *of* (3) *is a pair,* (c,u)*, where* $c : [0,T] \to Q$ *is a piecewise smooth curve and* $u \in \mathcal{U}$ *such that* (c',u) *satisfies the first-order control system* (3)*.*

Note that since X_L is a second-order vector field on TQ, every solution of the control system (3) will be of the form (c',u) for some curve c on Q. We refer the reader to [1] for a discussion of second-order, and particularly Lagrangian, vector fields.

Let $q_0 \in Q$ and let U be a neighborhood of q_0. We define

$$\mathcal{R}^U_Q(q_0,T) = \{q \in Q \mid \ \text{there exists a solution } (c,u) \text{ of (3)}$$
$$\text{such that } c'(0) = 0_{q_0}, c(t) \in U \text{ for } t \in [0,T], \text{ and } c'(T) \in T_qQ\}$$

and denote $\mathcal{R}^U_Q(q_0, \leq T) = \cup_{t=0}^T \mathcal{R}^U_Q(q_0, t)$. Note that our definitions for reachable configurations do not require us to get to a point in the reachable set at *zero* velocity. They merely ask that we be able to reach that point at *some* velocity. It is, however, required that the initial velocity be zero.

We shall say that $q \in Q$ is an *equilibrium point* for L if $X_L(0_q) = 0$. Let $\mathfrak{E}(L)$ denote the set of equilibrium points for L.

We now introduce our notions of controllability.

DEFINITION 5.12. *We shall say that* (3) *is* locally configuration accessible *at $q_0 \in Q$ if there exists $T > 0$ such that $\mathcal{R}^U_Q(q_0, \leq t)$ contains a nonempty open set of Q for all neighborhoods U of q_0 and all $0 < t \leq T$. If this holds for any $q_0 \in Q$, then the system is called* locally configuration accessible.

We say that (3) *is* small-time locally configuration controllable (STLCC) *at q_0 if it is locally configuration accessible at q_0 and if there exists $T > 0$ such that q_0 is in the interior of $\mathcal{R}^U_Q(q_0, \leq t)$ for every neighborhood U of q_0 and $0 < t \leq T$. If this holds for any $q_0 \in Q$, then the system is called STLCC.*

We shall say that (3) *is* equilibrium controllable *if, for $q_1, q_2 \in \mathfrak{E}(L)$, there exists a solution (c, u) of* (3)*, where $c : [0, T] \to Q$ is such that $c(0) = q_1$, $c(T) = q_2$, and both $c'(0)$ and $c'(T)$ are zero.*

Note that these definitions may be made to apply to any control system which evolves on TQ.

5.5. Conditions for controllability of simple mechanical control systems. In [9] the authors present sufficient conditions for local configuration accessibility in the absence of potential energy. Here, since we have a complete description of $\overline{\text{Lie}}(\mathcal{Y}') \mid Z(TQ)$, we can give stronger results.

THEOREM 5.13. *The control system* (3) *is locally configuration accessible at q if $C_{hor}(\mathcal{Y}, V)(q) = T_qQ$.*

Proof. Let C denote the accessibility distribution. Since $C_{hor}(\mathcal{Y}, V)(q) \subset C(0_q)$ by Proposition 5.9 and $C_{hor}(\mathcal{Y}, V)(q) = T_qQ$ by hypothesis, $Z(TQ)$ must be an integral manifold of C. Let Λ be the maximal integral manifold which contains $Z(TQ)$. Since C is the accessibility distribution, Λ must be invariant under the system (3) and the system must be locally accessible when restricted to Λ. Thus the set $\mathcal{R}^{\tilde{U}}(0_q, \leq T)$ is open in Λ for every neighborhood $\tilde{U} \subset \Lambda$ of 0_q and for every T sufficiently small. Now let U be a neighborhood of q, and define a neighborhood of 0_q in Λ by $\tilde{U} = \tau_Q^{-1}(U) \cap \Lambda$. The set $\tau_Q(\mathcal{R}^{\tilde{U}}(0_q, \leq T))$ is open in Q for T sufficiently small since τ_Q is an open mapping. This proves the theorem. □

We also have a partial converse to Theorem 5.13 in the case when there is no potential energy.

THEOREM 5.14. *Suppose that $V = 0$ and* (3) *is locally configuration accessible. Then $C_{hor}(\mathcal{Y}, V)(q) = T_qQ$ for q in an open dense subset of Q.*

Proof. First note that if $C_{hor}(\mathcal{Y}, V)(q_0) = T_{q_0}Q$, then $C_{hor}(\mathcal{Y}, V)(q) = T_qQ$ in a neighborhood of q_0. This proves that the set of points q where $C_{hor}(\mathcal{Y}, V)(q) = T_qQ$ is open. Now suppose that $C_{hor}(\mathcal{Y}, V)(q) \subsetneq T_qQ$ in an open subset U of Q. Then there exists an open subset $\bar{U} \subset U$ so that $\text{rank}(C_{hor}(\mathcal{Y}, V)(q)) = k < n$ for all $q \in \bar{U}$. However, this contradicts local configuration accessibility. Therefore, there can be no open subset of Q on which $C_{hor}(\mathcal{Y}, V)(q) \subsetneq T_qQ$. Thus the set of points q where $C_{hor}(\mathcal{Y}, V)(q) = T_qQ$ is dense. This completes the proof. □

We may also prove an easy statement about STLCC. We need to say a few things about "good" and "bad" symmetric products. Let $\boldsymbol{Y} = \{X_1, \ldots, X_{m+1}\}$, and establish a bijection $\psi : \boldsymbol{Y} \to \mathcal{Y} \cup \{\text{grad}\, V\}$ by asking that $\psi(X_a) = Y_a$ for

$a = 1, \ldots, m$ and $\psi(X_{m+1}) = \operatorname{grad} V$. If $P \in \Pr(\boldsymbol{Y})$, we shall say that P is *bad* if $\gamma_a(P)$ is even for each $a = 1, \ldots, m$. We say that P is *good* if it is not bad. Let S_m denote the permutation group on m symbols. For $\pi \in S_m$ and $P \in \Pr(\boldsymbol{Y})$ define $\bar{\pi}(P)$ to be the bracket obtained by fixing X_{m+1} and sending X_a to $X_{\pi(a)}$ for $a = 1, \ldots, m$. Now define

$$\rho(P) = \sum_{\pi \in S_m} \bar{\pi}(P).$$

We may now state the sufficient conditions for STLCC.

THEOREM 5.15. *Suppose that* $\mathcal{Y} \cup \{\operatorname{grad} V\}$ *is such that every bad symmetric product in* $\Pr(\boldsymbol{Y})$ *has the property that*

$$\operatorname{Ev}_{0_q}(\psi)(\rho(P)) = \sum_{a=1}^{m} \xi_a \operatorname{Ev}_{0_q}(\psi)(C_a),$$

where C_a *are good symmetric products in* $\Pr(\boldsymbol{Y})$ *of lower degree than* P *and* $\xi_a \in \mathbb{R}$ *for* $a = 1, \ldots, m$. *Also, suppose that* (3) *is locally configuration accessible at* q. *Then* (3) *is STLCC at* q.

Proof. First recall from the proof of Theorem 5.13 that if (3) is locally configuration accessible at q, then $Z(TQ)$ is an integral manifold for the accessibility distribution. We let Λ be the maximal integral manifold for the accessibility distribution which contains $Z(TQ)$. Restricted to Λ, (3) is locally accessible. To show that (3) is STLCC at q, it clearly suffices to show that (3) is STLC at 0_q when restricted to Λ. We do this by showing that (3) satisfies the hypotheses of Theorem 4.1 if it satisfies the stated hypotheses on the symmetric products. To do this we shall show that there is a one-to-one correspondence between bad brackets in $\operatorname{Br}(\boldsymbol{X}')$ and bad symmetric products in $\Pr(\boldsymbol{Y})$ and good brackets in $\operatorname{Br}(\boldsymbol{X}')$ and good symmetric products in $\Pr(\boldsymbol{Y})$.

Suppose that $B' \in \operatorname{Br}(\boldsymbol{X}')$ is bad. Thus $\delta_a(B')$ is even for $a = 1, \ldots, m$ and $\delta_0(B')$ is odd. When we evaluate $\operatorname{Ev}_{0_q}(\phi')(B')$, the only terms that will remain in the decomposition of $\operatorname{Ev}(\phi')(B')$ given by Lemma 5.4 are the terms obtained from brackets in $\boldsymbol{S}(B')$ which are in $\operatorname{Br}_0(\boldsymbol{X}) \cup \operatorname{Br}_{-1}(\boldsymbol{X})$. Since B' is bad, we must have $\delta_a(B)$ even and $\delta_0(B) + \delta_{m+1}(B)$ odd for each $B \in \boldsymbol{S}(B')$. If $\delta_0(B)$ is odd, then $\delta_{m+1}(B)$ must be even. In this case we get $\sum_{a=1}^{m+1} \delta_a(B)$ as even and $\delta_0(B)$ as odd. Thus the only brackets in $\boldsymbol{S}(B')$ which contribute to $\operatorname{Ev}(\phi')(B')$ must be in $\operatorname{Br}_{-1}(\boldsymbol{X})$. This will give us a vector in $V_{0_q}TQ$ which comes from a symmetric product which is bad. Now suppose that $\delta_0(B)$ is even for $B \in \boldsymbol{S}(B')$. Then $\delta_{m+1}(B)$ must be odd. In this case $\sum_{a=1}^{m+1} \delta_a(B)$ is odd and $\delta_0(B)$ is even, and again, the only brackets in $\boldsymbol{S}(B')$ which contribute to $\operatorname{Ev}(\phi')(B')$ must be in $\operatorname{Br}_{-1}(\boldsymbol{X})$. We then conclude that $\operatorname{Ev}_{0_q}(\phi')(B')$ must be of the form $(\operatorname{Ev}_q(\psi)(P))^{lift}$, where $P \in \Pr(\boldsymbol{Y})$ is bad.

Now suppose that $B' \in \operatorname{Br}(X')$ is good. It is clear that if $\delta_a(B')$ is odd for any $a = 1, \ldots, m$, then B' cannot give rise to a bad symmetric product. Thus we may suppose that $\delta_a(B')$ is even for each $a = 0, \ldots, m$. Now let's look at what the brackets look like from $\boldsymbol{S}(B')$ which contribute to $\operatorname{Ev}(\phi')(B')$. Let B be such a bracket. We must have $\delta_a(B)$ even for $a = 1, \ldots, m$ and $\delta_0(B) + \delta_{m+1}(B)$ even. If $\delta_0(B)$ is odd, then $\delta_{m+1}(B)$ must be odd. Since B is primitive, this means that $\sum_{a=1}^{m+1} \delta_a(B)$ and $\delta_0(B)$ are odd. Therefore, B must be in $\operatorname{Br}_0(\boldsymbol{X})$. Now suppose that $\delta_0(B)$ is even. Then $\delta_{m+1}(B)$ must also be even. Thus $\sum_{a=1}^{m+1} \delta_a(B)$ and $\delta_0(B)$ are

even and so $B \in \mathrm{Br}_0(\boldsymbol{X})$. Therefore, good brackets from $\mathrm{Br}(\boldsymbol{X}')$ do not generate any bad symmetric products. □

Since the system restricted to the integral manifold Λ in the proof of the above theorem is STLC, the hypotheses of the theorem imply more than STLCC. In fact, the following corollary is easily seen to be true.

COROLLARY 5.16. *Suppose that the hypotheses of Theorem* 5.15 *hold for each* $q \in Q$. *Then the system* (3) *is equilibrium controllable.*

Remark 5.17.

(1) We have shown that it is not necessary to be able to generate *all* directions on TQ to obtain controllability in the configuration variables. Indeed, the only vertical directions that we generate are $C_{ver}(\mathcal{Y}, V)$ which need not span $V_{0_q}TQ$. This means that the notion of configuration controllability is genuinely weaker than are the standard notions of controllability if we are to simply regard the system (3) as a typical nonlinear control system.

(2) Corollary 5.16 may be made even stronger if we allow a point $q \in Q$ to be an equilibrium point if $\operatorname{grad} V(q)$ is in the span of the inputs at q.

6. Examples of mechanical control systems. In this section we present some examples. The examples are rather simple and are intended to illustrate the concepts put forward by the theory. One of the advantages of the conditions for local configuration accessibility given in Theorem 5.13 is that it lends itself to symbolic computation. Indeed, a Mathematica package was written to facilitate the computations in this section.

6.1. The robotic leg. This example, although simple, exhibits much of the subtle behavior that makes the study of mechanical systems interesting. The example is a rigid body with inertia J which is pinned to ground at its center of mass. The body has attached to it an extensible massless leg, and the leg has a point mass with mass m at its tip. The coordinate θ will describe the angle of the body, and ψ will describe the angle of the leg from an inertial reference frame. The coordinate r will describe the extension of the leg. Thus the configuration space for this problem is $Q = \mathbb{T}^2 \times \mathbb{R}^+$. See Figure 3. In the coordinates (θ, ψ, r) the Riemannian metric for the robotic leg is

$$g = Jd\theta \otimes d\theta + mr^2 d\psi \otimes d\psi + mdr \otimes dr,$$

the input one-forms are $F^1 = d\theta - d\psi$ and $F^2 = dr$, and the potential energy function is zero. We may compute the input vector fields to be

$$Y_1 = \frac{1}{J}\frac{\partial}{\partial\theta} - \frac{1}{mr^2}\frac{\partial}{\partial\psi}, \qquad Y_2 = \frac{1}{m}\frac{\partial}{\partial r}.$$

Since there is no potential energy present, the distribution $C_{hor}(\mathcal{Y}, V)$ is simply generated by the vector fields $\overline{\mathrm{Lie}}(\overline{\mathrm{Sym}}(\mathcal{Y}))$.

We will find the following computations to be sufficient:

$$\langle Y_1 : Y_1 \rangle = -\frac{2}{m^2 r^3}\frac{\partial}{\partial r}, \qquad \langle Y_1 : Y_2 \rangle = 0, \qquad \langle Y_2 : Y_2 \rangle = 0,$$

$$[Y_1, Y_2] = -\frac{2}{m^2 r^3}\frac{\partial}{\partial\psi}, \qquad [Y_1, \langle Y_1 : Y_1 \rangle] = \frac{4}{m^3 r^6}\frac{\partial}{\partial\psi}.$$

The controllability results for the robotic leg are displayed in Table 1.

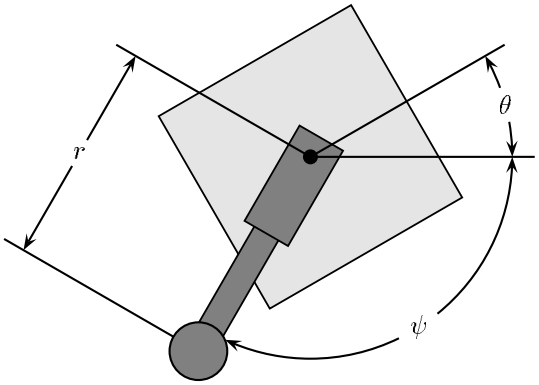

FIG. 3. *The robotic leg.*

TABLE 1

Controllability results for the robotic leg. The first column displays which inputs are present, the second column indicates whether the system is locally configuration accessible with these inputs, the third column indicates whether the system with these inputs satisfies the sufficient conditions of Theorem 5.15 *for STLCC, and the last column indicates whether the system with these inputs is actually STLCC.*

Inputs	Locally configuration accessible?	Satisfies sufficient conditions for STLCC?	STLCC?
Y_1 (torque)	yes	no	no
Y_2 (extension)	no	no	no
Y_1 and Y_2	yes	yes	yes

Remark 6.1.

(1) The linearization of this system at points of zero velocity is not controllable with any combination of inputs, so the controllability does not follow from linear results.

(2) When only the input Y_2 is present, the equations are

$$\ddot{r} - r\dot{\psi}^2 = \frac{1}{m}u_1,$$
$$\ddot{\theta} = 0,$$
$$\ddot{\psi} + \frac{2}{r}\dot{r}\dot{\psi} = 0.$$

Note that when the initial velocity is zero, the top equation decouples from the bottom two equations. Physically this means that we are simply moving the leg back and forth with no effect on the configuration of the body since the initial velocity is zero.

(3) Although the system only violates the *sufficient* conditions for STLCC with the input Y_1, one may easily see by looking at the r-component of the equations of motion that the system is, in fact, not STLCC. The reason for this is that, since $\ddot{r} \geq 0$, r will always increase no matter what happens to the other variables. Thus our initial configuration will never be in the interior of the set of reachable configurations.

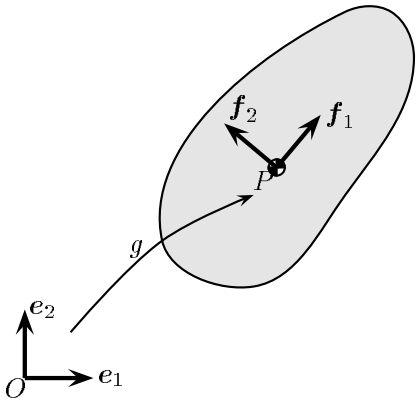

FIG. 4. *The configuration of a planar rigid body as an element of SE*(2).

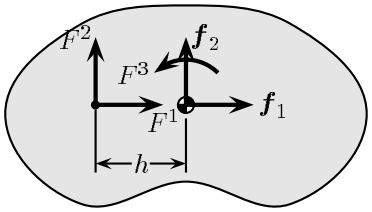

FIG. 5. *Positions for application of forces on a planar rigid body after simplifying assumptions.*

6.2. The forced planar rigid body. In this section we study the planar rigid body discussed in the introduction with various combinations of forces and torques. The configuration space for the system is the Lie group $SE(2)$. To establish the correspondence between the configuration of the body and $SE(2)$, fix a point $O \in \mathbb{R}^2$ and let $\{\boldsymbol{e}_1 = \frac{\partial}{\partial x}, \boldsymbol{e}_2 = \frac{\partial}{\partial y}\}$ be the standard orthonormal frame at that point. Let $\{\boldsymbol{f}_1, \boldsymbol{f}_2\}$ be an orthonormal frame attached to the body at its center of mass. The configuration of the body is determined by the element $g \in SE(2)$ which maps the point O with its frame $\{\boldsymbol{e}_1, \boldsymbol{e}_2\}$ to the position, P, of the center of mass of the body with its frame $\{\boldsymbol{f}_1, \boldsymbol{f}_2\}$. See Figure 4. The inputs for this problem consist of forces applied at an arbitrary point and a torque about the center of mass. Without loss of generality (by redefining our body reference frame $\{\boldsymbol{f}_1, \boldsymbol{f}_2\}$) we may suppose that the point of application of the force is a distance h along the $\boldsymbol{f}_1$ body-axis from the center of mass. The situation is illustrated in Figure 5.

With this convention fixed, we shall use coordinates (x, y, θ) for the planar rigid body, where (x, y) describe the position of the center of mass and θ describes the orientation of the frame $\{\boldsymbol{f}_1, \boldsymbol{f}_2\}$ with respect to the frame $\{\boldsymbol{e}_1, \boldsymbol{e}_2\}$. In these coordinates, the Riemannian metric for the system is

$$g = m dx \otimes dx + m dy \otimes dy + J d\theta \otimes d\theta.$$

Here m is the mass of the body and J is its moment of inertia about the center of mass. The inputs are described by the one-forms

$$F^1 = \cos\theta dx + \sin\theta dy, \qquad F^2 = -\sin\theta dx + \cos\theta dy - h d\theta, \qquad F^3 = d\theta,$$

TABLE 2

Controllability results for the planar rigid body. The first column displays which inputs are present, the second column indicates whether the system is locally configuration accessible with these inputs, the third column indicates whether the system with these inputs satisfies the sufficient conditions of Theorem 5.15 *for STLCC, and the last column indicates whether the system with these inputs is actually STLCC.*

Inputs	Locally configuration accessible?	Satisfies sufficient conditions for STLCC?	STLCC?
Y_1 (force at CM)	no	no	no
Y_2 (force $\perp$ to CM)	yes	no	no
Y_3 (torque)	no	no	no
Y_1 and Y_2	yes	yes	yes
Y_1 and Y_3	yes	yes	yes
Y_2 and Y_3	yes	no	yes

from which we compute the input vector fields as

$$Y_1 = \frac{\cos\theta}{m}\frac{\partial}{\partial x} + \frac{\sin\theta}{m}\frac{\partial}{\partial y},$$

$$Y_2 = -\frac{\sin\theta}{m}\frac{\partial}{\partial x} + \frac{\cos\theta}{m}\frac{\partial}{\partial y} - \frac{h}{J}\frac{\partial}{\partial\theta}, \qquad Y_3 = \frac{1}{J}\frac{\partial}{\partial\theta}.$$

Again, as with the robotic leg, there is no potential energy, so the distribution $C_{hor}(\mathcal{Y}, V)$ may be computed by calculating $\overline{\mathrm{Lie}}(\overline{\mathrm{Sym}}(\mathcal{Y}))$.

The following computations are sufficient to obtain the results that we desire:

$$\langle Y_1 : Y_1\rangle = 0, \qquad \langle Y_1 : Y_2\rangle = \frac{h\sin\theta}{mJ}\frac{\partial}{\partial x} - \frac{h\cos\theta}{mJ}\frac{\partial}{\partial y},$$

$$\langle Y_1 : Y_3\rangle = -\frac{\sin\theta}{mJ}\frac{\partial}{\partial x} + \frac{\cos\theta}{mJ}\frac{\partial}{\partial y}, \qquad \langle Y_2 : Y_2\rangle = \frac{2h\cos\theta}{mJ}\frac{\partial}{\partial x} + \frac{2h\sin\theta}{mJ}\frac{\partial}{\partial y},$$

$$\langle Y_2 : Y_3\rangle = -\frac{\cos\theta}{mJ}\frac{\partial}{\partial x} - \frac{\sin\theta}{mJ}\frac{\partial}{\partial y}, \qquad \langle Y_3 : Y_3\rangle = 0,$$

$$[Y_1, Y_2] = -\frac{h\sin\theta}{mJ}\frac{\partial}{\partial x} + \frac{h\cos\theta}{mJ}\frac{\partial}{\partial y}, \qquad [Y_1, Y_3] = \frac{\sin\theta}{mJ}\frac{\partial}{\partial x} - \frac{\cos\theta}{mJ}\frac{\partial}{\partial y},$$

$$[Y_2, Y_3] = \frac{\cos\theta}{mJ}\frac{\partial}{\partial x} + \frac{\sin\theta}{mJ}\frac{\partial}{\partial y}, \qquad [Y_2, \langle Y_2 : Y_2\rangle] = \frac{2h^2\sin\theta}{mJ^2}\frac{\partial}{\partial x} - \frac{2h^2\cos\theta}{mJ^2}\frac{\partial}{\partial y}.$$

With the computations done, we may proceed to determine configuration controllability for the planar rigid body with various combinations of inputs. The results are displayed in Table 2.

Remark 6.2.

(1) The linearization of this system around points of zero velocity is not controllable so the cases where the system is STLCC do not follow from the linear calculations.

(2) In this example, in the cases when the system fails to satisfy the sufficient conditions for STLCC of Theorem 5.15, we are not able to say whether the system is,

in fact, not STLCC. In fact, when the inputs Y_2 and Y_3 are present, even though the system does not satisfy the sufficient conditions of Theorem 5.15, it is easy to see that it *is* STLCC. Recent work, beyond the scope of this paper, shows that when only the input Y_2 is present, the system is not STLCC.

(3) In the case when only the input Y_1 is present, it is illustrative to represent the equations in the coordinates $(\xi, \eta, \psi) = (x\cos\theta + y\sin\theta, -x\sin\theta + y\cos\theta, \theta)$. In these coordinates the equations have the form

$$\begin{aligned}
&\ddot{\xi} + 2\left(\frac{m\eta^2}{J} - \frac{J + m\eta^2}{J}\right)\dot{\eta}\dot{\psi} + \left(\frac{m\xi\eta^2}{J} - \frac{\xi J + m\xi\eta^2}{J}\right)\dot{\psi}^2 \\
&\qquad = \left(\frac{J + m\eta^2}{J} - \frac{\eta^2}{J}\right)u_1, \\
&\ddot{\eta} + 2\left(\frac{J + m\xi^2}{J} - \frac{m\xi^2}{J}\right)\dot{\xi}\dot{\psi} + \left(\frac{m\eta\xi^2}{J} - \frac{\eta J + m\eta\xi^2}{J}\right)\dot{\psi}^2 = 0, \\
&\ddot{\psi} = 0.
\end{aligned}$$

Note that the top equation decouples from the last two equations when the initial velocity is zero. Since Y_1 is directed toward the center of mass, applying this input will cause the body to move in this direction and none of the other degrees of freedom are affected.

(4) In the case when the input Y_3 is present, the equations have the form

$$\begin{aligned}
\ddot{\theta} &= \frac{1}{J}u_3, \\
\ddot{x} &= 0, \\
\ddot{y} &= 0.
\end{aligned}$$

Again, the top equation decouples from the bottom two equations. This time the coupling is true for all initial velocities, not just zero initial velocity. In this case we see that the input simply causes a rotation of the body about its center of mass. The position of the center of mass is not affected if the initial velocity is zero.

6.3. The pendulum on a cart. To illustrate the effects of potential energy, consider the problem of a pendulum suspended from a cart. The configuration manifold for the system is $Q = \mathbb{R} \times \mathbb{S}^1$. As coordinates we shall use (x, θ) as shown in Figure 6. In this case the Riemannian metric for the system is

$$g = (M + m)dx \otimes dx + ml\cos\theta dx \otimes d\theta + ml\cos\theta d\theta \otimes dx + ml^2 d\theta \otimes d\theta.$$

Here M is the mass of the cart and m is the mass of the pendulum. The potential energy is

$$V = ma_g l(1 - \cos\theta),$$

where a_g is the acceleration due to gravity. The input is given by the one-form

$$F^1 = dx.$$

The input vector field is then readily computed to be

$$Y_1 = \frac{ml^2}{m^2l^2 + Mml^2 - m^2l^2\cos^2\theta}\frac{\partial}{\partial x} + \frac{ml\cos\theta}{m^2l^2 + Mml^2 - m^2l^2\cos^2\theta}\frac{\partial}{\partial\theta}.$$

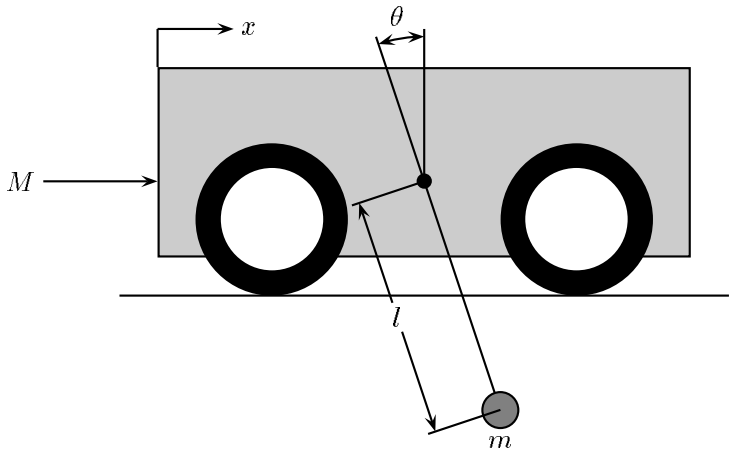

FIG. 6. *Pendulum suspended from a cart.*

To compute $C_{hor}(\mathcal{Y}, V)$ we need the following computations:

$$\langle Y_1 : Y_1 \rangle = \frac{16m\cos^2\theta\sin\theta}{l(m+2M-m\cos 2\theta)^3}\frac{\partial}{\partial x} + \frac{8(M+m)\sin\theta}{l^2(m\cos 2\theta - m - 2M)^3}\frac{\partial}{\partial\theta},$$

$$\begin{aligned}\langle Y_1 : \mathrm{grad}V \rangle = {} & \frac{4a_g m\cos\theta(m - m\cos 2\theta - 2M\cos 2\theta)}{l(m\cos 2\theta - m - 2M)^3}\frac{\partial}{\partial x} \\ & + \frac{4a_g(2M^2\cos 2\theta + 3Mm\cos 2\theta + m^2\cos 2\theta - Mm - m^2)}{l^2(m\cos 2\theta - m - 2M)^3}\frac{\partial}{\partial\theta}.\end{aligned}$$

Note that at all points $q \in Q$ except those where $\theta \in \{0, \pi\}$, the vector fields $\{Y_1, \langle Y_1 : Y_1 \rangle\}$ generate the tangent space at q. This means that the system is locally configuration accessible at these points. Also, at these points the bad symmetric product $\langle Y_1 : Y_1 \rangle$ is not a multiple of Y_1, so the system may not be STLCC at these points. At points where $\theta \in \{0, \pi\}$, the vector fields $\{Y_1, \langle Y_1 : \mathrm{grad}\, V \rangle\}$ span T_qQ, and so the system is also locally configuration accessible at these points. Most important, however, the bad symmetric product vanishes at these two points so the system is STLCC at these equilibria. This must be so as, at these two points, the linearized system is controllable.

7. Conclusions and future work. In this paper we have outlined what we regard as a *beginning* of a thorough program for analysis and synthesis for simple mechanical control systems. The first part of such a program is to determine the pertinent versions of controllability (local configuration accessibility and STLCC) and determine algebraic tests for these notions of controllability. The conditions that we present for checking our versions of controllability involve only computations on the configuration space. In determining these conditions, the symmetric product proved to play an important role. As we have presented it, the symmetric product is a useful computational tool. Our recent work provides a fairly complete description of the geometric role of the symmetric product in the control of mechanical systems. This will be the subject of an upcoming paper.

In the examples in section 6 some interesting circumstances may be observed. The most interesting of these is a comparison of the robotic leg with input Y_2 and

the planar rigid body with the inputs Y_2 and Y_3. In the former case the system does not satisfy the sufficient conditions for STLCC and may be shown to indeed not be STLCC. However, in the latter case, even though the sufficient conditions for STLCC are not met, the system *is* STLCC. It would be interesting to better understand why this happens, and perhaps arrive at a stronger condition for STLCC.

Finally we mention that, from a practical point of view, perhaps the most useful contribution is that of the notion, mentioned in section 5.4, of equilibrium controllability. If a system satisfies the hypotheses of Theorem 5.15 at each configuration, it would be interesting to determine a means of generating paths which connect points in the configuration manifold at zero velocity. Such an algorithm may involve a deeper understanding of the symmetric product.

In summary, we feel that this paper provides an effective initial understanding of mechanical control systems, and we hope that it will prove to be a useful foundation for further work in the area of mechanical control theory.

Acknowledgments. We would like to thank Jerry Marsden and Jim Ostrowski for helpful conversations. The anonymous reviewers were also very helpful in improving the presentation of the paper during the review process.

WEIGHTED SENSITIVITY MINIMIZATION FOR CAUSAL, LINEAR, DISCRETE TIME–VARYING SYSTEMS*

MICHEL VERHAEGEN†

Abstract. The weighted sensitivity minimization problem for discrete time–varying systems is treated in a state space framework. Given a controllable and causal (stable) state space realization of the plant to be controlled, the *first* step in the solution is the computation of an outer-inner factorization of the plant. The key algorithmic step here is the solution of a Lyapunov type of equation running backward in time. Based on the part of the realization of the inner (isometric) factor related to its output state space we then formulate and solve a Nevanlinna–Pick interpolation problem. This *second* step is also characterized by a Lyapunov equation. It is shown that the solution to the sensitivity minimization problem exists when the solution to this Lyapunov equation is positive definite for all time instances. Finally, we pay special attention to the minimal disturbance attenuation level when the latter is assumed to be equal to a constant scalar for all time instances as well as to a square root implementation of the recursive equations.

Key words. discrete time–varying systems, Nevanlinna–Pick interpolation, outer-inner factorization, Lyapunov equations

1. Introduction.

The sensitivity minimization problem was introduced by Zames in [1]. This type of problem constitutes a fundamental problem in the area of robust (H_∞) control.

So far, only a limited number of papers have appeared addressing the problem in a time-varying context. For discrete periodic time-varying systems, we mention the work of [2] and [3], which presents an algorithm for the operator theoretic solution outlined in [2]. Basically, this solution is characterized by "lifting up" the periodic time-variant system into a time-invariant system of big state dimension and then solving the problem using standard tools developed for time-invariant systems.

This approach fails when the system varies arbitrarily in time. Recently, based on [7], the sensitivity minimization problem for discrete time–varying systems was formulated and solved as a Nevanlinna–Pick interpolation (NPI) problem in [8]. In this way, this approach follows the original strategy of the solution presented in [10].

To formulate the NPI problem in [8], it was assumed that the inverse of the plant to be controlled is given into a simple partial fraction expansion format. Furthermore, that paper is restricted to systems of constant state, input, and output dimension. Both conditions will hamper the application of the outlined solution to practical circumstances. In a more realistic environment, the starting point in the controller design is a state space description of the plant P to be controlled. Therefore, the computation of the specific partial fraction expansion still needs to be performed. In [11], a procedure has been developed to calculate a state space realization of the required anticausal part of P^{-1}. This solution requires solving a Riccati equation, and also it is restricted to the case of constant state dimensions.

It has been observed that in realistic circumstances as reported in [13], the state dimension can change. Other examples include mechanical systems, such as a robot arm, where the degrees of freedom may change during operation. This in combination with the important class of problems related to multirate sampled data systems requires the treatment of time-varying systems exhibiting nonconstant state, input, and output dimensions.

To overcome the above drawbacks of existing methods, we present a solution to the weighted sensitivity minimization problem for discrete time–varying systems based on the inner-outer factorization technique developed in [15]. This solution only requires a state space realization of the plant P and allows varying state, input, and output dimensions. The key algorithmic steps are two recursive Lyapunov equations, both running backward in time.

An alternative to the interpolation approach in tackling robust control problems is the so-called "Riccati" approach, outlined in [9] for the continuous time–invariant case. Recently, this "standard" robust control problem has been extended to the continuous time–variant case with constant system dimensions in [4] and to the discrete time–variant case with varying system dimensions in [5].

Reformulating the sensitivity minimization problem as a standard robust control problem and solving the latter problem has two major drawbacks:

(1) The reformulation of the sensitivity minimization problem, precisely defined later on in section 3 (Problem 1), to a standard robust control problem is pictured in Figure 1. Here we adopt the standard notation such as used in [9]. This "standard" formulation does, however, violate one of the standard assumptions, namely that (one of) the diagonal operators of the feedthrough operator of the generalized plant G is nonzero. Making this formulation of the sensitivity minimization problem conformal to the standard assumptions substantially complicates the formulas which arise in the solution to the standard problem under standard assumptions [9].

(2) Even when one is willing to invest the energy in reformulating the sensitivity minimization problem as a standard robust control problem, the solution remains characterized by recursive Riccati equations. In [14], it is shown that the numerical solution of these recursive Riccati equations may diverge due to the accumulation of round-off errors. Coping with this phenomenon again requires additional precautions which complicate the overall solution.

In this paper, we overcome both drawbacks by tackling the sensitivity minimization problem for discrete time–varying systems with varying system dimensions in a more direct way. This direct route shows that the solution to this problem only requires the solution of two (recursive) Lyapunov equations instead of two (recursive) Riccati equations. These Lyapunov equations do not suffer from the divergence problems related to the Riccati equations. Both the direct way of addressing the problem and the solution of the problem via Lyapunov equations make the solution derived in this paper more robust and elegant compared with existing solutions in a time-variant context.

The outline of the paper is as follows. After reviewing the nomenclature of linear time-varying (LTV) systems in section 2, we formulate the sensitivity minimization problem in section 3. The reformulation of this problem as a NPI problem is done in section 4. In section 5, we briefly review its solution and mainly focus on the different viewpoint taken in this paper compared with that in [7]. These include (a) the formulation of the sensitivity minimization problem without making use of the generalized point evaluation map as done in [7, 8] and (b) the treatment of varying

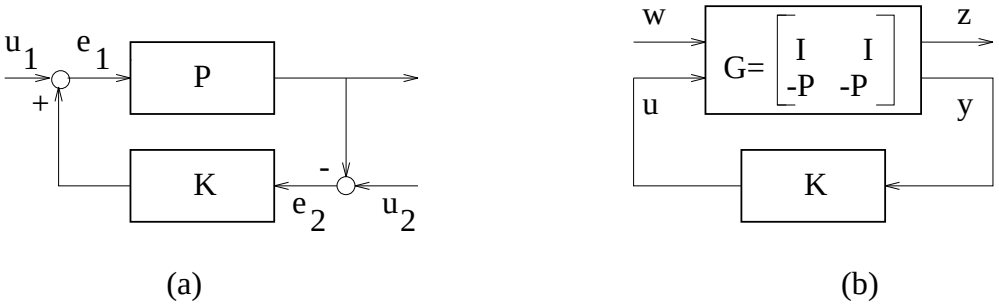

FIG. 1. (a) *The closed-loop configuration in the sensitivity minimization problem and* (b) *the closed-loop configuration in the formulation of the sensitivity minimization problem as a standard robust control problem.*

system dimensions. A summary of the numerical procedure and a brief highlight of some computational aspects are given in section 6. Finally section 7 concludes with some remarks.

2. Preliminaries. In this section, we introduce the notation used in representing LTV systems and collect the basic results from [15] about outer-inner factorization.

A state space realization of the LTV system P to be controlled is denoted on a local time scale as

$$\begin{aligned} x_{k+1} &= x_k A_k + u_k B_k, \\ y_k &= x_k C_k + u_k D_k, \end{aligned} \tag{1}$$

where x_k, u_k, and y_k are (finite-dimensional) row vectors in, respectively, $\mathbb{C}^{N_k}, \mathbb{C}^{M_k}$, and $\mathbb{C}^{L_k}$ and the matrices $\{A_k, B_k, C_k, D_k\}$ are bounded matrices of appropriate dimensions. Remark that this notation is compatible with the earlier work on LTV systems as reported in [16, 17, 18, 19].

To denote the state space representation more compactly, we introduce, as in [16, 17, 18, 19], the dimension space sequences $\mathcal{B}$:

$$\mathcal{B} = \cdots \times \boxed{\mathcal{B}_0} \times \mathcal{B}_1 \times \cdots,$$

where $\mathcal{B}_k = \mathbb{C}^{N_k}$ and the square box identifies the space of the zeroth entry. In a similar way, we introduce the dimension space sequence $\mathcal{M}$ and $\mathcal{N}$ from the integer sequences $\{M_k\}$ and $\{L_k\}$. It is allowed that some integers in these sequences are zero. The space of sequences in $\mathcal{B}$ with finite 2-norm will be denoted by $\ell_2^{\mathcal{B}}$. Next we stack the sequence of state vectors x_k, input vectors u_k, and output vectors y_k into ∞-dimensional row vectors x, u, and y, denoted explicitly for the state vector sequence as

$$x = \begin{bmatrix} \cdots & x_{-1} & \boxed{x_0} & x_1 & \cdots \end{bmatrix},$$

where the square identifies the position of the zeroth entry. Let $\mathcal{B}^{(-1)}$ denote the shifted dimension space sequence of $\mathcal{B}$, i.e.,

$$\mathcal{B}^{(-1)} = \cdots \times \boxed{\mathcal{B}_1} \times \mathcal{B}_2 \times \cdots,$$

and let $\mathcal{D}(\mathcal{M},\mathcal{N})$ denote the Hilbert space of bounded diagonal operators $\ell_2^{\mathcal{M}} \to \ell_2^{\mathcal{N}}$. Then we can stack the system operators A_k, B_k, C_k, and D_k into the diagonal

operators A, B, C, and D as (denoted only explicitly for A)

$$A = \operatorname{diag}\left[\begin{array}{ccccc} \cdots & A_{-1} & \boxed{A_0} & A_1 & \cdots \end{array}\right] \in \mathcal{D}(\mathcal{B}, \mathcal{B}^{(-1)}), \qquad \begin{array}{rcl} C & \in & \mathcal{D}(\mathcal{B}, \mathcal{N}), \\ B & \in & \mathcal{D}(\mathcal{M}, \mathcal{B}^{(-1)}), \\ D & \in & \mathcal{D}(\mathcal{M}, \mathcal{N}). \end{array}$$

Let the causal bilateral shift operator on sequences be denoted by Z such that

$$\left[\begin{array}{ccccc} \cdots & x_{-1} & \boxed{x_0} & x_1 & \cdots \end{array}\right] Z = \left[\begin{array}{ccccc} \cdots & x_{-2} & \boxed{x_{-1}} & x_0 & \cdots \end{array}\right];$$

then a compact notation on a global time scale of the state space representation (1) is

$$\begin{array}{rcl} xZ^{-1} & = & xA + uB, \\ y & = & xC + uD, \end{array} \quad \text{also denoted as} \quad \mathbf{P} = \left[\begin{array}{cc} A & C \\ B & D \end{array}\right]. \tag{2}$$

With this notation it is possible to represent an LTV system as an operator. Let the transition operator $\Phi(j,k)$ of the system with state space representation (2) be defined as

$$\Phi(j,k) = \begin{cases} A_k A_{k+1} \cdots A_{j-1}, & j > k, \\ I, & j = k, \\ \text{undefined}, & j < k, \end{cases}$$

and let $\lim_{j\to\infty} \Phi(j,k) = 0 \ \forall k < \infty$; then the inverse of the operator $(I - AZ)$ exists and is in $\mathcal{U}$, and the operator representation of the (*asymptotically stable*) LTV system P becomes

$$P = D + BZ(I - AZ)^{-1}C. \tag{3}$$

This transfer operator is *upper* triangular and in general the Hilbert space of bounded upper operators acting from $\ell_2^{\mathcal{M}}$ to $\ell_2^{\mathcal{N}}$ is denoted by $\mathcal{U}(\mathcal{M}, \mathcal{N})$ or denoted in short by $\mathcal{U}$. When the dimension N_k of the state vector is finite $\forall\ k$, then the operator represented as in (3) is *locally finite*. In the same way as $\mathcal{U}$, we denote the space of bounded operators by $\mathcal{X}(\mathcal{M}, \mathcal{N})$ and the space of bounded *lower* triangular operators by $\mathcal{L}(\mathcal{M}, \mathcal{N})$. A specific operator in $\mathcal{D}(\mathcal{M}, \mathcal{M})$ is the identity operator denoted by $I_{\mathcal{M}}$.

We also need the Hilbert–Schmidt space $\mathcal{U}_2$ and $\mathcal{D}_2$, which consists of those elements of $\mathcal{U}$ (respectively, $\mathcal{D}$) with square summable norms of their entries.

With the operator representation of P in (3), the closure of the output state space [20], denoted by $\overline{\mathcal{H}}_o(P)$, equals

$$\overline{\mathcal{H}}_o(P) = \mathcal{D}_2(\mathcal{B}, \mathcal{B})(I - AZ)^{-1}C \subset \mathcal{U}.$$

An operator $P_O \in \mathcal{U}$ is *left outer* if

$$\overline{\mathcal{U}_2 P_O} = \mathcal{U}_2,$$

and an operator $P_I \in \mathcal{U}$ is a *right isometry* if

$$P_I P_I^* = I,$$

where P_I^* denotes the adjoint of P_I.

Given a *causal* or upper operator P, the existence of an *outer-inner* factorization was first established by Arveson in [21]. Later, van der Veen [15], continuing in this work, devised a numerical procedure to calculate a realization of the inner and outer factor given a state realization of P.

Let us recall the existence theorem of the outer-inner factorization, given by Theorem 5 in [15].

THEOREM 2.1 (see [15, Theorem 5]). *Let $P \in \mathcal{U}(\mathcal{M},\mathcal{N})$. Then P has a factorization*

$$P = P_O P_I,$$

where $P_I \in \mathcal{U}(\mathcal{M}_I,\mathcal{N})$ is a right isometry, $P_O \in \mathcal{U}(\mathcal{M},\mathcal{M}_I)$ is outer, and $\mathcal{M}_I \subset \mathcal{M}$ (entrywise).

The key part of the algorithm to compute the inner-outer factorization is summarized in Proposition 6 of [15]. In the present paper, we state its dual variant, as this is required in solving the weighted sensitivity minimization problem and considers the outer-inner factorization. Due to their close relationship, the latter variant is stated without proof.

PROPOSITION 2.2 (Dual of Proposition 6 in [15]). *Let $P \in \mathcal{U}$ be a locally finite transfer operator, let $P = \{A, B, C, D\}$ be a controllable realization of P, and assume that the realization is asymptotically stable. Let P_I be a right isometric factor of P so that $P_O = PP_I^*$ is left outer. Then the pair (A_I, C_I) that defines an orthonormal basis for $\overline{\mathcal{H}_o}(P_I)$ satisfies*

$$\begin{array}{ll} \text{(i)} & Y = AY^{(-1)}A_I^* + CC_I^*, \\ \text{(ii)} & 0 = BY^{(-1)}A_I^* + DC_I^*, \\ \text{(iii)} & I = A_I A_I^* + C_I C_I^*, \\ \text{(iv)} & \ker(Y.) = \emptyset, \end{array}$$

where Y is some bounded diagonal operator and $Y^{(-1)} = ZYZ^{-1}$. Conversely, all solutions (A_I, C_I) of these equations give a basis representation of $\overline{\mathcal{H}_o}(P_I)$.

The computational scheme that can be derived from Proposition 2.2 (see section 6) returns a *uniformly observable* [23] and asymptotically stable pair (A_I, C_I).

Finally we end this section with the definition of the notion of uniform positivity of an Hermitian operator.

An Hermitian operator X is uniformly positive, denoted by $X \gg 0$, if

$$\exists\, \epsilon > 0 : \quad \| uXu^* \| > \epsilon \| uu^* \| \quad \forall\, u \in \ell_2\,.$$

If X is uniformly positive, then it is boundedly invertible.

3. The sensitivity minimization problem. Assume the feedback configuration in Figure 1(a). The plant P is assumed to be in $\mathcal{U}(\mathcal{M},\mathcal{N})$ and to be given by the following finite-dimensional LTV state space representation:

$$\mathbf{P} = \begin{bmatrix} A & C \\ B & D \end{bmatrix}, \qquad \begin{array}{ll} A \in \mathcal{D}(\mathcal{B},\mathcal{B}^{(-1)}), & C \in \mathcal{D}(\mathcal{B},\mathcal{N}), \\ B \in \mathcal{D}(\mathcal{M},\mathcal{B}^{(-1)}), & D \in \mathcal{D}(\mathcal{M},\mathcal{N}). \end{array}$$

The closed-loop system in Figure 1(a) is described by the systems of equations

$$\begin{cases} e_1 &= u_1 + e_2 K, \\ e_2 &= u_2 - e_1 P. \end{cases}$$

The overall closed-loop system is assumed to be *well posed*; that is, we can solve the above system of equations for the internal signals $[e_1,\ e_2]$ in terms of the input, respectively, disturbance signals $[u_1,\ u_2]$. This is indeed the case in which the operator $(I + PK)$ has a bounded inverse and then the map H from $[u_1,\ u_2]$ to $[e_1,\ e_2]$ is in $\mathcal{X}(\mathcal{M} \oplus \mathcal{N}, \mathcal{M} \oplus \mathcal{N})$ and given by

$$H = \begin{bmatrix} (I+PK)^{-1} & -P(I+KP)^{-1} \\ K(I+PK)^{-1} & (I+KP)^{-1} \end{bmatrix}.$$

An important notion of the closed-loop system is *internal stability*. This is defined next.

DEFINITION 3.1. *The system P in Figure* 1(a) *is internally stabilized by the controller K if and only if H is causal; that is, $H \in \mathcal{U}(\mathcal{M} \oplus \mathcal{N}, \mathcal{M} \oplus \mathcal{N})$.* ∎

The sensitivity map S is defined as the map from u_2 to e_2; that is,

$$S = (I + KP)^{-1}. \tag{4}$$

We are now in a position to state the sensitivity minimization problem.

Problem 1. For a given disturbance attenuation level $\Gamma \in \mathcal{D}$ with $\Gamma^*\Gamma > 0$ and an outer weighting map $W \in \mathcal{U}(\mathcal{N},\mathcal{N})$ $(W^{-1} \in \mathcal{U}(\mathcal{N},\mathcal{N}))$ with given state space realization

$$W = D_w + B_w Z(I - A_w Z)^{-1} C_w, \tag{5}$$

find a compensator K (if any exist) such that

$$\begin{aligned} &\text{(i)} \quad \text{the closed-loop system } H \text{ is internally stable,} \\ &\text{(ii)} \quad \|W S \Gamma^{-1}\| < 1, \end{aligned} \tag{6}$$

where $\|W S \Gamma^{-1}\|$ is the norm of $W S \Gamma^{-1}$ as a bounded operator on $\mathcal{N}$.

Remark 1. An extension of the above problem is treated in section 6. Here we do not assume the disturbance attenuation level to be specified but additionally consider the problem of determining the optimal (minimal) Γ for the special case $\Gamma = \gamma I$, where γ is a positive real constant.

4. An NPI problem. In this section, we formulate the sensitivity minimization Problem 1 as an NPI problem. For that purpose, we need the Youla parametrization of all internally stabilizing controllers in the present time-varying context. That this parametrization is valid in this context is stated in our first theorem. Since it is a special case of Theorem 11 of [6], we state it without proof.

THEOREM 4.1. *Let the plant $P \in \mathcal{U}(\mathcal{M},\mathcal{N})$; then a controller K internally stabilizes H if and only if there exists a $Q \in \mathcal{U}(\mathcal{N},\mathcal{M})$ such that*

$$K = (I - QP)^{-1} Q. \tag{7}$$

With the parametrization of K in (7), the sensitivity map S becomes

$$S = I - QP. \tag{8}$$

Suppose that in addition to the stability of P, P has an outer-inner factorization

$$P = P_O P_I. \tag{9}$$

Then we have

$$WS = W(I - QP)$$

from (8), and hence

$$W(I - S) = WQP \quad \in \mathcal{U}(\mathcal{N}, \mathcal{N}). \tag{10}$$

Using the expression for P in (9), we can state that when

$$W(I - S)P_I^* = WQP_O \quad \in \mathcal{U}(\mathcal{N}, \mathcal{M}_I), \tag{11}$$

we have found, since $W^{-1} \in \mathcal{U}$, a $Q \in \mathcal{U}$ that parametrizes an internally stabilizing controller K.

Now we first decompose the product WP_I^* into a component in $\mathcal{U}$ and one in $\mathcal{L}Z^{-1}$. This is done in our first lemma.

LEMMA 4.2. *Let the input-output map $W \in \mathcal{U}$ be given as in* (5)*, and let the input-output map $P_I \in \mathcal{U}(\mathcal{M}_I, \mathcal{N})$ be given as*

$$P_I = B_I Z(I - A_I Z)^{-1} C_I,$$

with A_I and A_w both asymptotically stable. Then

$$\exists! X_w, Y_w \in \mathcal{D} : WP_I^* = \underbrace{B_w Y_w^{(-1)} B_I^* + B_w Z(I - A_w Z)^{-1} X_w B_I^*}_{\in \mathcal{U}} + \underbrace{(D_w C_I^* + B_w Y_w^{(-1)} A_I^*)(I - Z^* A_I^*)^{-1} Z^* B_I^*}_{\in \mathcal{L}Z^{-1}},$$

with X_w and Y_w satisfying

$$C_w C_I^* = Y_w - A_w Y_w^{(-1)} A_I^*,$$
$$X_w = A_w Y_w^{(-1)}.$$

Proof. With the expressions for W and P_I in Lemma 4.2, WP_I^* becomes

$$WP_I^* = D_w C_I^* (I - Z^* A_I^*)^{-1} Z^* B_I^* + B_w Z \left[\; (I - A_w Z)^{-1} C_w C_I^* (I - Z^* A_I^*)^{-1} Z^* \; \right] B_I^*. \tag{12}$$

It is shown next that there exist operators $X_w, Y_w \in \mathcal{D}$ such that the term between square brackets can be decomposed as

$$\left[(I - A_w Z)^{-1} X_w + Y_w (I - Z^* A_I^*)^{-1} Z^* \right]. \tag{13}$$

To find these operators X_w and Y_w, multiply the left- and right-hand sides of both terms between square brackets by $(I - A_w Z)$ and $Z(I - Z^* A_I^*)$, respectively. This yields the following sequence of results:

$$\begin{aligned} C_w C_I^* &= X_w Z(I - Z^* A_I^*) + (I - A_w Z) Y_w \\ &= X_w Z - X_w A_I^* + Y_w - A_w Y_w^{(-1)} Z \\ &= (X_w - A_w Y_w^{(-1)}) Z + (Y_w - X_w A_I^*). \end{aligned}$$

Since X_w and Y_w are diagonal operators, we have that

$$X_w = A_w Y_w^{(-1)},$$
$$C_w C_I^* = Y_w - X_w A_I^*.$$

When we combine these expressions, we conclude that the Y_w operator satisfies

$$C_w C_I^* = Y_w - A_w Y_w^{(-1)} A_I^*.$$

This Stein equation has a unique and bounded solution since A_I (and A_w) are asymptotically stable. Therefore both X_w and Y_w are in $\mathcal{D}$. Replacing the term between square brackets in (12) with the one obtained in (13) yields

$$WP_I^* = D_w C_I^*(I - Z^* A_I^*)^{-1} Z^* B_I^* + B_w Z(I - A_w Z)^{-1} X B_I^* + B_w Z Y_w (I - Z^* A_I^*)^{-1} Z^* B_I^*.$$

Since the last term in this expression is equal to

$$B_w Y_w^{(-1)} B_I^* + B_w Y_w^{(-1)} A_I^* (I - Z^* A_I^*)^{-1} Z^* B_I^*,$$

the result of Lemma 4.2 is proved. □

With the result of Lemma 4.2, (11) can be written as

$$\begin{aligned} &\left(B_w Y_w^{(-1)} B_I^* + B_w Z(I - A_w Z)^{-1} X_w B_I^* \right) \\ &\quad + \left(D_w C_I^* + B_w Y_w^{(-1)} A_I^*) - (WS\Gamma^{-1})\Gamma C_I^* \right) (I - Z^* A_I^*)^{-1} Z^* B_I^* \in \mathcal{U}. \end{aligned}$$

Therefore, since the first term of the summation is in $\mathcal{U}$, (11) reduces to

$$\left((D_w C_I^* + B_w Y_w^{(-1)} A_I^*) - (WS\Gamma^{-1})\Gamma C_I^* \right) (I - Z^* A_I^*)^{-1} Z^* B_I^* \in \mathcal{U}.$$

Introduce the operator $J \in \mathcal{D}^2$ equal to $\begin{pmatrix} I_{\mathcal{N}} & \\ & -I_{\mathcal{N}} \end{pmatrix}$; then the Hermitian transpose of this last relationship can also be denoted as

$$B_I Z(I - A_I Z)^{-1} \begin{bmatrix} C_I \Gamma^* & C_I D_w^* + A_I Y_w^{*(-1)} B_w^* \end{bmatrix} J \begin{bmatrix} \Gamma^{-*} S^* W^* \\ I \end{bmatrix} \in \mathcal{L}.$$

The above exposure shows that the sensitivity minimization problem can be formulated as an NPI problem.

Problem 2. Find the weighted sensitivity map $\overline{S} = (WS\Gamma^{-1}) \in \mathcal{U}(\mathcal{N}, \mathcal{N})$ such that

$$\text{(14) (i)} \quad B_I Z(I - A_I Z)^{-1} \begin{bmatrix} C_I \Gamma^* & C_I D_w^* + A_I Y_w^{*(-1)} B_w^* \end{bmatrix} J \begin{bmatrix} \overline{S}^* \\ I \end{bmatrix} \in \mathcal{L}(\mathcal{M}_I, \mathcal{N}),$$

$$\text{(15) (ii)} \quad \|\overline{S}\| < 1.$$

Once the weighted sensitivity map $\overline{S}$ has been determined, the controller K directly follows from (4) and is given by

$$K = (\Gamma^{-1} \overline{S}^{-1} W - I) P^{-1}. \tag{16}$$

It should be remarked that this controller need not be causal.

5. Solving the NPI problem. NPI problems in the context of discrete time–varying systems have been studied and solved in [7]. That paper formulates and treats the NPI problem based on the so-called generalized "point evaluation map." In the present paper we take a different viewpoint. Instead we formulate the interpolation condition as in (14). As such we do not require the calculation of generalized points

as in [7], but we directly operate on the state space matrices of the given plant, its inner factor of an outer-inner factorization, and the given weighting. The calculation of these generalized points from the state space representation of the given plant P is still an unresolved problem. This alternative viewpoint leads to an immediate identification of the output state space of the J-isometric operator to be constructed in solving the NPI problem. This is highlighted in Lemma 5.2. A further generalization of the treatment given in [7] is that we allow the system dimensions to vary in time. Despite this more general context, a number of the key results derived in [7] simply carry over with minor modifications. As a consequence, we do not include proofs of the results requiring minor modifications and prove only the lemma's addressing the different viewpoint.

As outlined in [7], the solution of NPI problems requires the construction of a J-inner operator. In the present context of varying system dimension we focus on the construction of an operator $\Theta \in \mathcal{U}(\mathcal{M}_1 \oplus \mathcal{N}, \mathcal{N} \oplus \mathcal{N})$ which is J-isometric in the following generalized sense [19]:

$$\Theta J \Theta^* = J\prime = \begin{bmatrix} I_{\mathcal{M}_1} & \\ & -I_{\mathcal{N}} \end{bmatrix}, \tag{17}$$

where the dimension space sequence $\mathcal{M}_1$ still needs to be determined and which satisfies the interpolation condition

$$B_I Z (I - A_I Z)^{-1} \begin{bmatrix} C_I \Gamma^* & C_I D_w^* + A_I Y^{*(-1)} B_w^* \end{bmatrix} J\Theta^* \in \mathcal{L}(\mathcal{M}_I, \mathcal{M}_1 \oplus \mathcal{N}) \tag{18}$$

The following series of lemmas list a number of properties of J-isometric operators which are important in solving the NPI problem 2. In these lemmas we assume the operator Θ to be partitioned as

$$\Theta = \begin{bmatrix} \Theta_{11} & \Theta_{12} \\ \Theta_{21} & \Theta_{22} \end{bmatrix}, \qquad \begin{matrix} \Theta_{11} \in \mathcal{U}(\mathcal{M}_1, \mathcal{N}), & \Theta_{12} \in \mathcal{U}(\mathcal{M}_1, \mathcal{N}), \\ \Theta_{21} \in \mathcal{U}(\mathcal{N}, \mathcal{N}), & \Theta_{22} \in \mathcal{U}(\mathcal{N}, \mathcal{N}), \end{matrix}$$

and have the following state space realization:

$$\boldsymbol{\Theta} = \begin{bmatrix} A_\Theta & C_\Theta \\ B_\Theta & D_\Theta \end{bmatrix} = \begin{bmatrix} A_\Theta & C_1 & C_2 \\ B_1 & D_{11} & D_{12} \\ B_2 & D_{21} & D_{22} \end{bmatrix}. \tag{19}$$

As in [7], the state space realization $\boldsymbol{\Theta}$ of a J-isometric operator Θ satisfies the following condition.

LEMMA 5.1. *Let Θ be an operator in $\mathcal{U}^2$ with state space realization as given in* (19)*, and let the following relationship hold for some Hermitian operator $Q \in \mathcal{D}$:*

$$\boldsymbol{\Theta} \begin{bmatrix} Q^{(-1)} & \\ & J \end{bmatrix} \boldsymbol{\Theta}^* = \begin{bmatrix} Q & \\ & J\prime \end{bmatrix}; \tag{20}$$

then Θ is J-isometric in the generalized sense given in (17).

The identification of the output state space of the operator Θ by the interpolation condition (18) is stated in the following lemma.

LEMMA 5.2. *Let Θ be an operator in $\mathcal{U}^2$ with state space realization* (19)*, and let* (20) *hold for some Hermitian operator $Q \in \mathcal{D}$; then*

$$\mathcal{D}(I - A_\Theta Z)^{-1} C_\Theta J \Theta^* \in \mathcal{L}^2 Z^{-1}.$$

Proof. Since $\Theta \in \mathcal{U}^2$, its state space realization given in (19) allows us to express Θ as

$$\Theta = D_\Theta + B_\Theta Z(I - A_\Theta Z)^{-1} C_\Theta.$$

Hence,

$$(I - A_\Theta Z)^{-1} C_\Theta J \Theta^* = (I - A_\Theta Z)^{-1} C_\Theta J (D_\Theta^* + C_\Theta^* (I - Z^* A_\Theta^*)^{-1} Z^* B_\Theta^*).$$

Using (20), the right-hand side equals

$$\begin{aligned}
&= (I - A_\Theta Z)^{-1}(-A_\Theta Q^{(-1)} + (Q - A_\Theta Q^{(-1)} A_\Theta^*)(I - Z^* A_\Theta^*)^{-1} Z^*) B_\Theta^* \\
&= (I - A_\Theta Z)^{-1}(-A_\Theta Q^{(-1)} Z(I - Z^* A_\Theta^*) + Q - A_\Theta Q^{(-1)} A_\Theta^*)(I - Z^* A_\Theta^*)^{-1} Z^*) B_\Theta^* \\
&= (I - A_\Theta Z)^{-1}(-A_\Theta Q^{(-1)} Z + A_\Theta Q^{(-1)} A_\Theta^* + Q - A_\Theta Q^{(-1)} A_\Theta^*)(I - Z^* A_\Theta^*)^{-1} Z^* B_\Theta^* \\
&= (I - A_\Theta Z)^{-1}(-A_\Theta Z + I) Q (I - Z^* A_\Theta^*)^{-1} Z^* B_\Theta^* \\
&= Q(I - Z^* A_\Theta^*)^{-1} Z^* B_\Theta^* \quad \in \mathcal{L}^2 Z^{-1}. \qquad \square
\end{aligned}$$

The key condition on the J-isometric operator solving the NPI Problem 2 is stipulated in Lemma 5.5. Prior to stating that lemma, we have the following definition and lemma.

DEFINITION 5.3. *The pair* (A, C) *is uniformly detectable if and only if there exists a bounded operator* $K \in \mathcal{D}(\mathcal{N}, \mathcal{B}^{(-1)})$ *such that the state space model* $xZ^{-1} = x(A + CK)$ *is asymptotically stable.*

LEMMA 5.4. *Suppose the pair* (A, C) *is uniformly detectable. Then if there exists a solution* $X \in \mathcal{D}(\mathcal{B}, \mathcal{B})$ *and* $X \geq 0$ *of*

$$AX^{(-1)}A^* + CC^* = X, \tag{21}$$

then the state space model $xZ^{-1} = xA$ *is asymptotically stable. Conversely, if the state space model* $xZ^{-1} = xA$ *is asymptotically stable, then there exists a unique bounded solution* $X \geq 0$ *of* (21).

LEMMA 5.5. *Let* Θ *be an operator in* $\mathcal{U}^2$ *with state space realization* (19), *let* (20) *hold for a uniformly positive operator* $Q \in \mathcal{D}$, *and let the pair* (A_Θ, C_2) *be uniformly detectable; then*

(i) $\Theta_{22}^{-1} \in \mathcal{U}(\mathcal{N}, \mathcal{N})$,
(ii) $\Theta_{22}^{-1}\Theta_{21} \in \mathcal{U}(\mathcal{N}, \mathcal{N})$ *and* $\|\Theta_{22}^{-1}\Theta_{21}\| < 1$.

Proof. (i) From the state space realization of Θ given in the right-hand side in (19), the state space realization of Θ_{22} is

$$\Theta_{22} = \begin{bmatrix} A_\Theta & C_2 \\ B_2 & D_{22} \end{bmatrix}.$$

When the conditions

(a) D_{22} is invertible,

(b) the operator $(A_\Theta - C_2 D_{22}^{-1} B_2)$ is asymptotically stable

hold, then since the state space realization of Θ_{22}^{-1} equals

$$\begin{bmatrix} A_\Theta - C_2 D_{22}^{-1} B_2 & -C_2 D_{22}^{-1} \\ D_{22}^{-1} B_2 & D_{22}^{-1} \end{bmatrix},$$

we have that item (i) of the lemma is proved. We now prove both conditions (a) and (b), making use of the following relationships derived from (20):

$$A_\Theta Q^{(-1)} A_\Theta^* + C_1 C_1^* - C_2 C_2^* = Q, \tag{22}$$

$$B_2 Q^{(-1)} A_\Theta^* + D_{21} C_1^* - D_{22} C_2^* = 0, \tag{23}$$

$$B_2 Q^{(-1)} B_2^* + D_{21} D_{21}^* - D_{22} D_{22}^* = -I. \tag{24}$$

For condition (a), (24) shows that

$$D_{22} D_{22}^* = I + D_{21} D_{21}^* + B_2 Q^{(-1)} B_2^*.$$

Since $Q \gg 0$ it follows that $D_{22} D_{22}^* \gg 0$ and D_{22} is invertible.

For condition (b), consider the product of operators

$$(A_\Theta - C_2 D_{22}^{-1} B_2) Q^{(-1)} (A_\Theta - C_2 D_{22}^{-1} B_2)^*.$$

Using (23)–(24), this product can be written as

$$\begin{aligned} &= A_\Theta Q^{(-1)} A_\Theta^* - C_2 C_2^* \\ &\quad - \left[C_2 D_{22}^{-1} D_{22}^{-*} C_2^* + C_2 D_{22}^{-1} D_{21} D_{21}^* D_{22}^{-*} C_2^* - C_2 D_{22}^{-1} D_{21} C_1^* - C_1 D_{21}^* D_{22}^{-*} C_2^* \right]. \end{aligned}$$

And, therefore, using (22) we obtain the following Lyapunov equation:

$$\begin{aligned} &(A_\Theta - C_2 D_{22}^{-1} B_2) Q^{(-1)} (A_\Theta - C_2 D_{22}^{-1} B_2)^* + (C_1 - C_2 D_{22}^{-1} D_{21})(C_1 - C_2 D_{22}^{-1} D_{21})^* \\ &\qquad + C_2 D_{22}^{-1} D_{22}^{-*} C_2^* = Q. \end{aligned} \tag{25}$$

Since the pair $(A_\Theta,\ C_2)$ is uniformly detectable, also the pair $(A_\Theta - C_2 D_{22}^{-1} B_2,\ \left[C_1 - C_2 D_{22}^{-1} D_{21} \quad C_2 D_{22}^{-1}\right])$ is uniformly detectable. Therefore, since $Q \gg 0$, equation (25) and Lemma 5.4 show that condition (b) holds and therefore item (i) is proved.

(ii) Lemma 5.1 shows that

$$\Theta J \Theta^* = J\prime$$

and, therefore,

$$\Theta_{21} \Theta_{21}^* - \Theta_{22} \Theta_{22}^* = -I.$$

This shows that

$$\Theta_{22} \Theta_{22}^* = I + \Theta_{21} \Theta_{21}^* \gg 0;$$

since Θ_{22}^{-1} exists this last equation shows that

$$I - \Theta_{22}^{-1} \Theta_{22}^{-*} = \Theta_{22}^{-1} \Theta_{21} \Theta_{21}^* \Theta_{22}^{-*}$$

and therefore $\|\Theta_{22}^{-1} \Theta_{21}\| < 1$. Since $\Theta_{22}^{-1} \in \mathcal{U}$ and $\Theta_{21} \in \mathcal{U}$, it follows that $\Theta_{22}^{-1} \Theta_{21} \in \mathcal{U}$. □

Lemmas 5.1, 5.2, and 5.5 are used in the next section to calculate a state space realization of Θ that solves the interpolation condition (18).

In the remaining part of this section, we assume that such a Θ has been calculated and demonstrate how this Θ allows us to parametrize, as in [7], all solutions to the NPI Problem 2.

The first step in the parametrization is to observe that for $G_1 \in \mathcal{U}(\mathcal{N}, \mathcal{M}_1)$ and $G_2 \in \mathcal{U}(\mathcal{N}, \mathcal{N})$, equation (18) shows that

$$B_I Z(I - A_I Z)^{-1} \begin{bmatrix} C_I \Gamma^* & C_I D_w^* + A_I Y^{*(-1)} B_w^* \end{bmatrix} J \begin{bmatrix} \Theta_{11}^* & \Theta_{21}^* \\ \Theta_{12}^* & \Theta_{22}^* \end{bmatrix} \begin{bmatrix} G_1^* \\ G_2^* \end{bmatrix} \in \mathcal{L},$$

and hence the solution to the interpolation condition (14) requires G_1 and G_2 to be selected such that

$$\begin{bmatrix} \overline{S} & I \end{bmatrix} = \begin{bmatrix} G_1 & G_2 \end{bmatrix} \begin{bmatrix} \Theta_{11} & \Theta_{12} \\ \Theta_{21} & \Theta_{22} \end{bmatrix}. \tag{26}$$

From this relationship we parametrize all solutions $\overline{S}$ to Problem 2 as shown in the following two theorems. These theorems correspond to Theorems 3.2 and 3.3 of [7], adapted to the present context of nonconstant state, input and output dimensions. Since only minor adaptations are required, we state both modifications without proof.

THEOREM 5.6. *Let Θ be an operator in $\mathcal{U}^2$ satisfying the interpolation condition* (18). *Then $\overline{S}$ satisfies the interpolation condition* (14) *if and only if $\overline{S}$ has a representation of the form*

$$\overline{S} = (G_1\Theta_{12} + G_2\Theta_{22})^{-1}(G_1\Theta_{11} + G_2\Theta_{21})$$

for some pair of upper triangular operators $G_1 \in \mathcal{U}$ and $G_2 \in \mathcal{U}$ such that $(G_1\Theta_{12} + G_2\Theta_{22})$ is invertible with inverse again in $\mathcal{U}$.

THEOREM 5.7. *Let Θ be an operator in $\mathcal{U}^2$ satisfying the interpolation condition* (18). *Let Θ be partitioned as*

$$\Theta = \begin{bmatrix} \Theta_{11} & \Theta_{12} \\ \Theta_{21} & \Theta_{22} \end{bmatrix}$$

and have a state space realization as in (19) *such that* (20) *is satisfied for $Q \gg 0$. Then*

(1) *there exist solutions $\overline{S} \in \mathcal{U}$ to the NPI Problem* 2*;*

(2) *any solution $\overline{S}$ is given by*

$$\overline{S} = (S_L\Theta_{12} + \Theta_{22})^{-1}(S_L\Theta_{11} + \Theta_{21})$$

with $S_L \in \mathcal{U}(\mathcal{N}, \mathcal{M}_1)$ satisfying $\|S_L\| < 1$.

6. Calculation of a state space realization of Θ and a particular $\overline{S}$. Lemma 5.2 shows that the interpolation condition (18) fixes the pair $(A_\Theta,\ C_\Theta)$ of the state space realization of Θ, namely,

$$\begin{bmatrix} A_\Theta & C_\Theta \end{bmatrix} = \begin{bmatrix} A_I & C_I\Gamma^* & C_I D_w^* + A_I Y^{*(-1)} B_w^* \end{bmatrix}. \tag{27}$$

Computing the remaining part $(B_\Theta,\ D_\Theta)$ of the state space representation of Θ is done in such a way that (20) is satisfied for a uniformly positive diagonal operator Q. With the specification of $(A_\Theta,\ C_\Theta)$ as in (27), the relationships to be satisfied then are

$$\begin{bmatrix} A_I & C_I\Gamma^* & G \\ B_1 & D_{11} & D_{12} \\ B_2 & D_{21} & D_{22} \end{bmatrix} \begin{bmatrix} Q^{(-1)} & & \\ & I_{\mathcal{N}} & \\ & & -I_{\mathcal{N}} \end{bmatrix} \begin{bmatrix} A_I^* & B_1^* & B_2^* \\ \Gamma C_I^* & D_{11}^* & D_{21}^* \\ G^* & D_{12}^* & D_{22}^* \end{bmatrix} = \begin{bmatrix} Q & & \\ & J_{\mathcal{I}} & \end{bmatrix}, \tag{28}$$

where G equals $C_I D_w^* + A_I Y^{*(-1)} B_w^*$.

The relationships to compute $\boldsymbol{\Theta}$, which can directly be derived from (28), can be divided in two parts. One part is the following Lyapunov equation:

$$A_I Q^{(-1)} A_I^* + C_I \Gamma^* \Gamma C_I^* - GG^* = Q. \tag{29}$$

From this equation the operator Q can be calculated. The other part is the set of equations

$$\begin{bmatrix} B_1 & D_{11} & D_{12} \\ B_2 & D_{21} & D_{22} \end{bmatrix} \begin{bmatrix} Q^{(-1)} & & \\ & I_{\mathcal{N}} & \\ & & -I_{\mathcal{N}} \end{bmatrix} \begin{bmatrix} A_I^* \\ \Gamma C_I^* \\ G^* \end{bmatrix} = 0, \tag{30}$$

$$\begin{bmatrix} B_1 & D_{11} & D_{12} \\ B_2 & D_{21} & D_{22} \end{bmatrix} \begin{bmatrix} Q^{(-1)} & & \\ & I_{\mathcal{N}} & \\ & & -I_{\mathcal{N}} \end{bmatrix} \begin{bmatrix} B_1^* & B_2^* \\ D_{11}^* & D_{21}^* \\ D_{12}^* & D_{22}^* \end{bmatrix} = J\imath, \tag{31}$$

from which we determine the system matrices $\begin{pmatrix} B_1 & D_{11} & D_{12} \\ B_2 & D_{21} & D_{22} \end{pmatrix}$, given the solution Q to (29).

6.1. Selecting the minimal scalar γ when $\boldsymbol{\Gamma = \gamma I}$ in solving for the operator $\boldsymbol{Q}$. Consider the following two Lyapunov equations:

$$A_I Q_1^{(-1)} A_I^* + \gamma^2 C_I C_I^* = Q_1, \tag{32}$$

$$A_I Q_2^{(-1)} A_I^* - GG^* = Q_2. \tag{33}$$

Since A_I is asymptotically stable both equations have a unique solution. In addition $Q_1 \gg 0$, since the pair $(A_I \;\; C_I)$ is uniformly detectable. We now consider the scaled Lyapunov equations

$$A_I \overline{Q}_1^{(-1)} A_I^* + C_I C_I^* = \overline{Q}_1,$$

$$A_I \overline{Q}_2^{(-1)} A_I^* + GG^* = \overline{Q}_2.$$

And the relation between the solution of both pairs of Lyapunov equations is

$$Q_1 = \gamma^2 \overline{Q}_1, \quad Q_2 = -\overline{Q}_2.$$

In this way $\overline{Q}_2$ is semipositive definite. Furthermore, let $\overline{Q}_1 = S_1 S_1^*$ and $\overline{Q}_2 = S_2 S_2^*$; then we can easily construct the following square root update mechanisms for the above Lyapunov equations:

$$\begin{bmatrix} A_I S_1^{(-1)} & C_I \end{bmatrix} T_1 = \begin{bmatrix} S_1 & 0 \end{bmatrix},$$

$$\begin{bmatrix} A_I S_2^{(-1)} & G \end{bmatrix} T_2 = \begin{bmatrix} S_2 & 0 \end{bmatrix},$$

with both T_1 and T_2 diagonal unitary operators satisfying $T_1 T_1^* = T_2 T_2^* = I$. The actual solution to the original Lyapunov equation (29) can be derived from these two square roots and reads

$$Q = \left(\gamma^2 S_1 S_1^* - S_2 S_2^*\right).$$

Since $Q_1 \gg 0$, S_1 is invertible and we have that

$$Q = S_1 \left(\gamma^2 I - S_1^{-1} S_2 S_2^* S_1^{-*}\right) S_1^*. \tag{34}$$

Therefore, let $\mathbf{sv}(M)$ denote the singular values of the operator M; then

$$Q \gg 0 \quad \Leftrightarrow \gamma > \min \ \mathbf{sv}(S_1^{-1} S_2),$$

and we see that we can compute the minimal γ directly from the square roots S_1 and S_2. We also observe that as in the time-invariant case approaching the optimal γ leads to a singular solution of the Lyapunov equation. A close approximation of the minimal scalar disturbance attenuation level γ may be taken as

$$\widetilde{\gamma_{opt}} = \min \ \mathbf{sv}(S_1^{-1} S_2) + \epsilon,$$

where ϵ is a small positive real number.

Remark 2. In the present time-varying context, there is no need to fix Γ to γI. The diagonal operator Γ may have varying entries along its diagonal. However, determining such an optimal time-varying disturbance attenuation level is a very complex problem even when we assume Γ_k to be equal to $\gamma_k I$, for γ_k scalar. This is because a particular choice of such a γ_k at a local time instance k has a global effect on the solution (32), with γ replaced by γ_k. In addition this global effect of γ_k on $Q_{1,j}$ for $j \leq k$ is implicit rather than explicit. □

6.2. Completing the state space realization of Θ. We demonstrate in this section that the solution presented in [7] to complete the state space realization of $\boldsymbol{\Theta}$ using the solution of the Lyapunov equation (29) still holds when the system dimensions are time variant. In addition we present a square root solution. The solution is discussed on a local time scale.

Let $A_{I,k} \in \mathbb{R}^{N_k \times N_{k+1}}$ and $C_{I,k} \in \mathbb{R}^{N_k \times L_k}$; then the Lyapunov equation (29) with $Q_k > 0$ shows that [12]

$$N_k \leq N_{k+1} + L_k.$$

Furthermore, equation (29) shows that the rows of the matrix $\begin{bmatrix} A_{I,k} & \gamma_k C_{I,k} & G_k \end{bmatrix} \in \mathbb{R}^{N_k \times (N_{k+1}+2L_k)}$ are independent, and so are the columns of the matrix

$$\begin{bmatrix} Q_{k+1} & & \\ & I_{L_k} & \\ & & -I_{L_k} \end{bmatrix} \begin{bmatrix} A_{I,k}^* \\ \gamma_k C_{I,k}^* \\ G_k^* \end{bmatrix}.$$

Therefore, we can always find a matrix $V_k \in \mathbb{R}^{(N_{k+1}-N_k+2L_k)\times(N_{k+1}+2L_k)}$ with independent rows such that

$$V_k \begin{bmatrix} Q_{k+1} & & \\ & I_{L_k} & \\ & & -I_{L_k} \end{bmatrix} \begin{bmatrix} A_{I,k}^* \\ \gamma_k C_{I,k}^* \\ G_k^* \end{bmatrix} = 0.$$

The compound matrix $\begin{bmatrix} A_{I,k} & \gamma_k C_{I,k} & G_k \\ & V_k & \end{bmatrix}$ is square and of full rank, as is shown in the following theorem.

THEOREM 6.1. *Let* $V_k \in \mathbb{R}^{(N_{k+1}-N_k+2L_k)\times(N_{k+1}+2L_k)}$ *have independent rows, and let the following relationship hold:*

$$\underbrace{\begin{bmatrix} A_{I,k} & \gamma_k C_{I,k} & G_k \\ & V_k & \end{bmatrix}}\begin{bmatrix} Q_{k+1} & & \\ & I_{L_k} & \\ & & -I_{L_k} \end{bmatrix}\begin{bmatrix} A_{I,k}^* & & \\ \gamma_k C_{I,k}^* & & V_k^* \\ G_k^* & & \end{bmatrix} = \begin{bmatrix} Q_k & 0 \\ 0 & J'' \end{bmatrix}, \tag{35}$$

with both Q_k *and* Q_{k+1} *positive definite, then the underbraced matrix has full rank.*

Proof. The underbraced matrix is square since $V_k \in \mathbb{R}^{(N_{k+1}-N_k+2L_k)\times(N_{k+1}+2L_k)}$ and the matrix $\begin{bmatrix} A_{I,k} & \gamma_k C_{I,k} & G_k \end{bmatrix} \in \mathbb{R}^{N_k\times(N_{k+1}+2L_k)}$. Now suppose that this matrix is not invertible; i.e.,

$$\exists \begin{bmatrix} x_1 & x_2 \end{bmatrix} \neq 0 : \begin{bmatrix} x_1 & x_2 \end{bmatrix}\begin{bmatrix} A_{I,k} & \gamma_k C_{I,k} & G_k \\ & V_k & \end{bmatrix} = 0.$$

However, from (35) we derive that

$$\begin{bmatrix} x_1 & x_2 \end{bmatrix}\begin{bmatrix} A_{I,k} & \gamma_k C_{I,k} & G_k \\ & V_k & \end{bmatrix}\begin{bmatrix} Q_{k+1} & & \\ & I_{L_k} & \\ & & -I_{L_k} \end{bmatrix}\begin{bmatrix} A_{I,k}^* & & \\ \gamma_k C_{I,k}^* & & \\ G_k^* & & \end{bmatrix} = x_1 Q_k.$$

Since Q_k is nonsingular, $x_1 = 0$ and, as a consequence since V_k has independent rows, $x_2 = 0$. This is a contradiction and the theorem is proved. □

This theorem allows us to determine the inertia of the matrix J''. Let $\#_+(M_k)$ denote the number of $+$'s in the inertia of M_k, and similarly let $\#_-(M_k)$ denote the number of $-$'s; then (35) and Theorem 6.1 show that

$$\begin{aligned} N_{k+1} + L_k &= N_k + \#_+(J''), \\ L_k &= \#_-(J''). \end{aligned} \tag{36}$$

Let $\#_+(J'') = \alpha_k$; then we complete the calculation of the state space realization of Θ by computing the following factorization:

$$V_k \begin{bmatrix} Q_{k+1} & & \\ & I_{L_k} & \\ & & -I_{L_k} \end{bmatrix} V_k^* = J'' = U_k \begin{bmatrix} I_{\alpha_k} & \\ & -I_{L_k} \end{bmatrix} U_k^*. \tag{37}$$

Such a factorization with U_k invertible always exists. As a consequence the pair $\begin{bmatrix} B_\Theta & D_\Theta \end{bmatrix}$ now follows as

$$\begin{bmatrix} B_\Theta & D_\Theta \end{bmatrix} = U_k^{-1} V_k. \tag{38}$$

We end this section by presenting a square root variant to compute U_k directly from the square roots $S_{1,k}$ and $S_{2,k}$.

First note that with an additional singular value decomposition (SVD) of the matrix $S_{1,k+1}^{-1} S_{2,k+1}$ given as

$$S_{1,k+1}^{-1} S_{2,k+1} = U_{S,k+1} \Sigma_{S,k+1} V_{S,k+1}^*,$$

we can write (34) on the time instance $k+1$ as

$$Q_{k+1} = S_{1,k+1} U_{S,k+1} (\gamma^2 I - \Sigma_{S,k+1}^2)^{\frac{1}{2}} (\gamma^2 I - \Sigma_{S,k+1}^2)^{\frac{*}{2}} U_{S,k+1}^* S_{1,k+1}^*.$$

Let us denote the square root of Q_{k+1} by $S_{Q,k+1}$; then we can read off this quantity from the above expression.

We partition the matrix V_k as $\begin{bmatrix} V_{1,k} & V_{2,k} \end{bmatrix}$ with $V_{1,k} \in \mathbb{R}^{(N_{k+1}-N_k+2L_k)\times(N_{k+1}+L_k)}$ and the matrix U_k as $\begin{bmatrix} U_{1,k} & U_{2,k} \end{bmatrix}$ with $U_{1,k} \in \mathbb{R}^{(N_{k+1}-N_k+2L_k)\times\alpha_k}$ in addition to defining $V'_{1,k}$ as $V_{1,K}\begin{bmatrix} S_{Q,k+1} & \\ & I_{L_k} \end{bmatrix}$; then we can alternatively denote (37) as

$$V'_{1,k}V'^{*}_{1,k} - V_{2,k}V^{*}_{2,k} = U_{1,k}U^{*}_{1,k} - U_{2,k}U^{*}_{2,k}. \tag{39}$$

Finally, consider the generalized SVD [22] of the matrix pair $\left(V'_{1,k}, V_{2,k}\right)$, and denote this decomposition as

$$V'_{1,k} = X_k\Sigma_{V_1,k}U^{*}_{V_1,k}, \qquad V_{2,k} = X_k\Sigma_{V_2,k}U^{*}_{V_2,k},$$

where X_k is a square nonsingular $(L_k+\alpha_k)\times(L_k+\alpha_k)$ matrix, $\Sigma_{V_j,k}$ for $j=1,2$ is a diagonal matrix with positive or zero entries, and $U_{V_j,k}$ for $j=1,2$ are orthogonal square matrices. Based on this decomposition the left-hand side of (39) can be written as

$$V'_{1,k}V'^{*}_{1,k} - V_{2,k}V^{*}_{2,k} = X_k\left(\Sigma^2_{V_1,k} - \Sigma^2_{V_2,k}\right)X^{*}_k.$$

From this equation we can read off the required factors $U_{1,k}$ and $U_{2,k}$.

6.3. The state space realization for a particular $\overline{S}$. From Theorem 5.7 we recall that a particular solution $\overline{S}$ to the NPI Problem 2 is

$$\overline{S} = \Theta_{22}^{-1}\Theta_{21}.$$

With the state space representation for Θ calculated in the previous subsection, the latter two operators are determined as follows:

$$\begin{aligned}\Theta_{21} &= D_{21} + B_2Z(I - A_IZ)^{-1}C_I\Gamma^{*},\\ \Theta_{22} &= D_{22} + B_2Z(I - A_IZ)^{-1}G.\end{aligned}$$

Hence, because of Lemma 5.5,

$$\Theta_{22}^{-1} = D_{22}^{-1} - D_{22}^{-1}B_2Z(I - (A_I - GD_{22}^{-1}B_2)Z)^{-1}GD_{22}^{-1} \quad \text{exists and is} \quad \in \mathcal{U},$$

and the product $\Theta_{22}^{-1}\Theta_{21}(\in\mathcal{U})$ has the state following state space representation:

$$\begin{bmatrix} (A_I - GD_{22}^{-1}B_2) & -GD_{22}^{-1}B_2 & -GD_{22}^{-1}D_{21} \\ 0 & A_I & C_I\Gamma^{*} \\ D_{22}^{-1} & D_{22}^{-1}B_2 & D_{22}^{-1}D_{21} \end{bmatrix}.$$

Consider the following constant similarity transformation:

$$\begin{bmatrix} I & I & 0 \\ 0 & I & 0 \\ 0 & 0 & I \end{bmatrix}\begin{bmatrix} (A_I - GD_{22}^{-1}B_2) & -GD_{22}^{-1}B_2 & -GD_{22}^{-1}D_{21} \\ 0 & A_I & C_I\Gamma^{*} \\ D_{22}^{-1}B_2 & D_{22}^{-1}B_2 & D_{22}^{-1}D_{21} \end{bmatrix}\begin{bmatrix} I & -I & 0 \\ 0 & I & 0 \\ 0 & 0 & I \end{bmatrix}$$

$$= \begin{bmatrix} (A_I - GD_{22}^{-1}B_2) & 0 & C_I\Gamma^{*} - GD_{22}^{-1}D_{21} \\ 0 & A_I & C_I\Gamma^{*} \\ D_{22}^{-1}B_2 & 0 & D_{22}^{-1}D_{21} \end{bmatrix};$$

then $\Theta_{22}^{-1}\Theta_{21}$ is given as

$$\Theta_{22}^{-1}\Theta_{21} = D_{22}^{-1}D_{21} + D_{22}^{-1}B_2(I - (A_I - GD_{22}^{-1}B_2)Z)^{-1}(C_I\Gamma^{*} - GD_{22}^{-1}D_{21}). \tag{40}$$

6.4. Summary of the computational scheme. The analysis made in the previous sections can readily be summarized in a computational scheme to solve the weighted sensitivity minimization problem. In this section, we restrict ourselves to summarizing the key numerical equations. These are the following recursive equations, which are all of Lyapunov type running backwards in time:

(a) The computation of the part of the outer-inner factorization of the given plant P necessary in solving the sensitivity minimization problem is highlighted in Proposition 2.2. The equations in this proposition are reordered such that the sequential calculations occur from top to bottom. This results on a local time scale in the following equations:

$$\begin{array}{lcl} \left[\begin{array}{cc} B_k Y_{k+1} & D_k \end{array}\right] \left[\begin{array}{c} A^*_{I,k} \\ C^*_{I,k} \end{array}\right] & = & 0, \\ A_{I,k}A^*_{I,k} + C_{I,k}C^*_{I,k} & = & I, \\ A_k Y_{k+1} A^*_{I,k} + C_k C^*_{I,k} & = & Y_k. \end{array}$$

(b) In formulating the interpolation condition (14) for the weighted sensitivity minimization problem, the quantity $Y_{w,k}$ is required. According to Lemma 4.2, $Y_{w,k}$ satisfies

$$C_{w,k}C^*_{I,k} + A_{w,k}Y_{w,k+1}A^*_{I,k} \quad = \quad Y_{w,k}.$$

(c) Finally, the key equation in solving the NPI problem is the Lyapunov equation (29). This equation on a local time scale reads

$$A_{I,k}Q_{k+1}A^*_{I,k} + C_{I,k}\Gamma^*_k\Gamma_k C^*_{I,k} - G_k G^*_k \quad = \quad Q_k.$$

All other quantities that are computed in the course of solving the sensitivity minimization problem satisfy local expressions, making use of the solutions of the above recursive equations. For that reason, these three groups of recursive equations constitute the heart of the computational procedure. The actual solution of these equations requires the specification of end conditions. These end conditions can be calculated with a time-invariant solution to the sensitivity minimization problem for the case the plant becomes time-invariant from a particular time-instant on.

This situation occurs, e.g., in practical engineering problems when changing the stationary operation condition of industrial plants. Generally, in these operation conditions the system accurately behaves as a linear time-invariant system. Furthermore, the transition between operation conditions can often be approximated by a linear time-varying system.

7. Concluding remarks. The solution presented in this paper to the weighted sensitivity minimization problem is characterized by recursive calculations involving the system matrices of the given state space model of the plant to be controlled. The latter is assumed to be controllable and stable.

The key recursive equations are Lyapunov equations which run backward in time. For the special case the system becomes time-invariant from a specific point in time; it is possible to find initial conditions for both Lyapunov recursions making use of standard solutions for time-invariant systems.

The solution presented in this paper is computationally more efficient and elegant compared with both the lifting approach presented in [3] when the linear system is periodic as well as the time-varying solution in [4], [5]. Furthermore, the approach

outlined in this paper is capable of treating varying input and output dimensions. As a consequence the important class of problems of multirate sampled data systems also fits within the constructed framework.

Continued research on the extension of the present approach to treat unstable plants is currently under way. Here we will also consider the problem of making the disturbance attenuation level time-varying.

Acknowledgment. The author acknowledges Prof. H. Dym of the Weizmann Institute for fruitful discussions related to Theorem 6.1.

OUTPUT-INDUCED SUBSPACES, INVARIANT DIRECTIONS, AND INTERPOLATION IN LINEAR DISCRETE-TIME STOCHASTIC SYSTEMS*

ANDERS LINDQUIST† AND GYÖRGY MICHALETZKY‡

Abstract. In this paper we analyze the structure of the class of discrete-time linear stochastic systems in terms of the geometric theory of stochastic realization. We discuss the role of invariant directions, zeros of spectral factors, and output-induced subspaces in determining the systems-theoretical properties of the stochastic systems. A prototype interpolation problem for recovering lost state information is discussed, and it is shown how it can be solved via Kalman filtering recursions tying together the state processes of a family of totally ordered splitting subspaces.

Key words. invariant directions, zero dynamics, discrete-time stochastic systems, splitting subspaces

1. Introduction.

It is a somewhat surprising fact that, in the discrete-time case, the family of minimal state-space representations

$$\begin{cases} x(t+1) = Ax(t) + Bu(t), \\ y(t) = Cx(t) + Du(t) \end{cases} \tag{1.1}$$

of a stationary stochastic vector process $\{y(t); t \in \mathbb{Z}\}$ with a rational spectral density exhibits a remarkably rich structure, affecting the implementation of most estimation algorithms, and that much of this structure is not present in the corresponding continuous-time setting. This diversity is also reflected in the structure of the corresponding family of matrix Riccati equations, studied in detail in [22] in the context of invariant directions of matrix Riccati equations [5, 25, 26], a phenomenon that is not present in the continuous-time case.

As usual, $\{u(t); t \in \mathbb{Z}\}$ is a vector-valued white noise process which, passed through a stable filter with transfer function

$$W(z) = C(zI - A)^{-1}B + D \tag{1.2}$$

beginning at the remote past, produces the output process $\{y(t); t \in \mathbb{Z}\}$, say, of dimension m and with an $m \times m$ spectral density $\Phi(z) = W(z)W(1/z)'$. (Here $'$ denotes transpose, and the white noise u is a zero-mean process such that $\mathrm{E}\{u(t)u(s)'\} = I\delta_{ts}$.)

The output process y is of course purely nondeterministic, and we assume that its spectral density Φ is full rank. The representation (1.1) is a minimal realization in the sense that the *state process* x has as few components as possible.

Obviously W is a rational spectral factor having all its poles strictly inside the unit circle, implying that the same holds for the eigenvalues of A. Note that we are not confining ourselves to square spectral factors W, since the dimension p of the input noise process could be larger than m. In particular, this implies that the state vector may not be expressible in terms of the output process $y(t), t \in \mathbb{Z}$, alone but that it depends on some unobserved exogenous noise also. Another consequence is that the number of zeros of W may be fewer than the number of poles of W, even if D is full rank.

Part of this paper is devoted to the following prototype *interpolation problem*, which is of a somewhat different type from the interpolation problem considered in [23, 24]. Suppose that we observe the state x as well as the output y on some finite or infinite interval except that there is a blackout of state information on some finite subinterval (t_0, t_1). Then the problem is to reconstruct the lost state information in the least squares sense, given the noisy output and the remaining states information. This problem provides a framework for studying many important questions concerning the structure of discrete-time linear stochastic systems.

This interpolation problem is preferably studied in the context of the geometric theory of stochastic realization (see [17, 18, 14, 15] and references therein), in which the properties of the state representation (1.1) are expressed in terms of the *minimal Markovian splitting subspace*

$$X = \{a'x(0) \mid a \in \mathbb{R}^n\}, \tag{1.3}$$

where $n := \dim X$ is the number of components of $x(0)$ so that $x(0)$ forms a basis in X. Due to stationarity, it is sufficient to study $\{x(t); t \in \mathbb{Z}\}$ at time $t = 0$. The family of such X corresponding to a given y will be denoted $\mathcal{X}$. It is known that $\mathcal{X}$ is endowed with a certain partial ordering. This ordering, reviewed in section 2, will play an important role in this paper.

A basic tool in the analysis of the interpolation problem and, more generally, the structural properties of the family $\mathcal{X}$ of state-space representations is a pair $(\sigma, \bar{\sigma})$ of shift operators on $\mathcal{X}$, which given any $X \in \mathcal{X}$ produces a family $\{X^{(k)} \mid k \in \mathbb{Z}\}$ of totally ordered splitting subspaces. We show that these splitting subspaces are tied together by Kalman filtering recursions in the sense that we can pass from one state process $x^{(k)}$ to the next by (forward or backward) Kalman filtering, a remarkable fact that enables us actually to compute these spaces.

These sequences of splitting subspaces provide a deeper insight into the structure of the related discrete-time matrix Riccati difference equation. In fact, the corresponding sequence of state covariance matrices constitutes a solution of this Riccati equation. It is well known that the limits at $-\infty$ and at ∞ are solutions of the steady-state (algebraic) Riccati equation, but our procedure also enables us to study the transient behavior of these equations. This should be compared with the corresponding continuous-time results in [13].

The interpolation estimate of $x(t)$ on the interval (t_0, t_1) turns out to be a linear combination of $x^{(t_0-t)}(t)$ and $x^{(t_1-t)}(t)$, the state processes of $X^{(t_0-t)}$ and $X^{(t_1-t)}$, respectively, in a certain uniform choice of coordinates, enabling us to use these Kalman recursions to determine the estimate. As $t_0 \to -\infty$ and $t_1 \to \infty$, we obtain the corresponding prototype *smoothing problem*, and the structure of the solution is similar to those presented in [3] and in [18].

We show that the computational burden of determining the interpolation estimates depends on the dimension of the *internal subspace* $X \cap H_0$ of the splitting

subspace, where H_0 is the closure, in the inner product $\langle \xi, \eta \rangle := \mathrm{E}\{\xi, \eta\}$, of all random variables

$$\{y_i(t) \mid i = 1, 2, \dots, m;\ t \in \mathbb{Z}\}$$

of the output process. In fact, we show that if $\dim X \cap H_0 = n - \nu$, we need only solve matrix Riccati equations of dimension at most $\nu \times \nu$ rather than $n \times n$ to compute the appropriate filter estimates. Sometimes, however, we need an initial number of time steps to achieve this reduction and to understand this better we need to study the structure of the internal subspace $X \cap H_0$.

In this paper we show among other things that the internal subspace has the direct sum decomposition

$$X \cap H_0 = X \cap \{y(-1), \dots, y(-n)\} + Y^* + X \cap \{y(0), \dots, y(n-1)\},$$

where the subspace Y^* can be determined by algorithms akin to the one used to compute the maximal output-nulling subspace in geometric control theory [31]. This decomposition and the theoretical framework in which it is developed give a considerable amount of information about the structure of the discrete-time linear stochastic system (1.1).

First, if the *predictable subspace* $X \cap \{y(-1), \dots, y(-n)\}$ is nontrivial, there is an $a \in \mathbb{R}^n$ such that

$$a'x(t) \in \{y(t-1), y(t-2), \dots, y(t-n)\},$$

and consequently the *usual* Kalman filtering problem of estimating $x(t)$ given the data $y(t-1), y(t-2), \dots, y(0)$ reaches steady state in a finite number of steps in the direction a. An analogous statement holds for the initial point smoothing problem and the *smoothable subspace* $X \cap \{y(0), \dots, y(n-1)\}$. Nontrivial such directions a are known as *invariant directions* and have been studied extensively in the literature [5, 25, 26, 22], but the connections to the geometric theory of Markovian splitting subspaces are presented here for the first time.

Second, the basic reason why discrete-time models (1.1) are more complicated, and the study of them is more challenging, than in the continuous-time case is that DD' varies over $\mathcal{X}$. If $DD' > 0$ for all $X \in \mathcal{X}$, the results and the analysis of the (coercive) continuous-time case generally carry over verbatim. This is known as the *regular case*. In the regular case there are no invariant directions and $Y^* = X \cap H_0$. In this paper we give several geometric characterizations of regularity and investigate the fine structure of the nonregular case.

Third, the zero structure of the transfer function (1.2) plays an important role in the analysis of the interpolation problem, and it can be studied in terms of *output-induced subspaces*, i.e., subspaces of $X \cap H_0$ with certain invariance properties to be specified below. The output-induced subspaces also provide a link between stochastic realization theory and geometric control theory [31, 4] (see Remark 7.3). This program was initiated in [18, 19] and was continued in [13] and [29], where, in particular, the connections to geometric control theory are discussed in great detail in continuous and discrete time, respectively. In this paper we introduce the concept of *strictly output-induced subspaces*, a refinement needed to study the discrete-time case. In particular, Y^* is the maximal strictly output-induced subspace, which plays the role of $X \cap H_0$ in the nonregular case. The zero structure also provides information about the possible reduction of the Riccati recursions in the interpolation problem.

The paper is organized as follows. Section 2 is devoted to preliminaries on the geometric theory of stochastic realization theory and to notations. In section 3 we introduce the operators σ and $\bar{\sigma}$, characterize regularity in terms of them, and establish the properties of the family $\{X^{(k)}|k \in \mathbb{Z}\}$, and in section 4 we introduce the interpolation problem and relate it to the results in section 3. Section 5 is about the zero structure of $\{X^{(k)}|k \in \mathbb{Z}\}$ in the regular case. In section 6 we discuss output-induced subspaces, and in section 7 the role of invariant directions is investigated and the algorithm for determining Y^* is given. Finally, in section 8, the change in zero structure when applying σ and $\bar{\sigma}$ is discussed, and the connections to the zero dynamics operators and the reduction of the Riccati equations in the interpolation problem are explained.

2. Preliminaries and notations. Given a stationary purely nondeterministic m-dimensional stochastic process $\{y(t); t \in \mathbb{Z}\}$, any stochastic realization (1.1) of y may be represented in a coordinate-free manner by a triplet (X, H, U), where X is given by (1.3), underscoring the fact that two representations (1.1) are considered identical if they differ only by the choice of coordinates in X. Here H is the Hilbert space generated by the random variables

$$\{u_i(t) \mid i = 1, 2, \dots, p;\ t \in \mathbb{Z}\}$$

with inner product

$$\langle \xi, \eta \rangle = \mathrm{E}\{\xi, \eta\},$$

and the unitary operator $U : H \to H$ is the shift determined by

$$Uu_i(t) = u_i(t+1).$$

Then U acts as the shift for all processes in the system, i.e., $Uy_i(t) = y_i(t+1)$ and $Ux_i(t) = x_i(t+1)$. We always assume that the matrix $\begin{bmatrix} B \\ D \end{bmatrix}$ has linearly independent columns so that H is generated also by

$$\{y_i(t), x_j(t) \mid i = 1, \dots, m;\ j = 1, \dots, n;\ t \in \mathbb{Z}\}.$$

The Hilbert space H so defined is called the *ambient space* of X.

For any subspace $Y \subset H$ we shall write $\mathrm{E}^Y \lambda$ to denote the orthogonal projection of $\lambda \in H$ onto Y. Occasionally we shall misuse notations somewhat by writing $\mathrm{E}^Y z$ when z is a random vector to denote the vector with components $\{\mathrm{E}^Y z_i\}$. By $\mathrm{E}^Y Z$ we shall mean the closure of $\{\mathrm{E}^Y \zeta \mid \zeta \in Z\}$. For any pair of subspaces Y and Z we write $Y + Z$ to denote direct sum (implying that $Y \cap Z = 0$), $Y \oplus Z$ for orthogonal direct sum, and $Y \vee Z$ for the vector sum in the general case, i.e., for closure$\{\eta + \zeta \mid \eta \in Y, \zeta \in Z\}$. Moreover, we write $Z^\perp$ to denote the orthogonal complement $H \ominus Z$ of Z in the ambient space H. Finally, we write $Z \perp Y \mid X$ to denote that Z and Y are *conditionally orthogonal* given X, i.e., that

$$\langle \eta - E^X \eta, \zeta - E^X \zeta \rangle = 0 \quad \text{for all } \eta \in Y,\ \zeta \in Z.$$

There are some important subspaces related to the given process y, which are subspaces of H for each representation (X, H, U) and which are considered fixed in this analysis. Define the *past space* H^- as the subspace generated by the random variables

$$\{y_i(t) \mid i = 1, 2, \dots, m;\ t = -1, -2, -3, \dots\}$$

and the *future space* H^+ as the subspace generated by

$$\{y_i(t) \mid i = 1, 2, \dots, m;\ t = 0, 1, 2, \dots\},$$

and let

$$H_0 := H^- \vee H^+ \subset H \tag{2.1}$$

be the space generated by all random variables in y. We shall also consider finite-dimensional subspaces $\{y(j), \dots, y(k)\}$ spanned by the components of the random vectors depicted inside the curly brackets. We shall also use the shorthand notation H_{t-1}^- and H_t^+ for $U^t H^-$ and $U^t H^+$, respectively, the past and future spaces shifted to time t. Then $H_{-1}^- = H^-$ and $H_0^+ = H^+$, which is consistent with the asymmetric definition of past and future.

It is well known that X is a minimal Markovian splitting subspace [17, 18] and that it can be represented *uniquely* in terms of a pair $(S, \bar{S})$ of subspaces such that

$$S \supset H^- \quad \text{and} \quad \bar{S} \supset H^+, \tag{2.2}$$

$$U^{-1}S \subset S \quad \text{and} \quad U\bar{S} \subset \bar{S}, \tag{2.3}$$

and

$$H = \bar{S}^\perp \oplus X \oplus S^\perp. \tag{2.4}$$

Consequently, S and $\bar{S}$ may be regarded as extensions of the past space H^- and future space H^+, respectively, inheriting their invariance properties, and they intersect perpendicularly so that

$$X = S \cap \bar{S} = \mathrm{E}^S \bar{S} = \mathrm{E}^{\bar{S}} S. \tag{2.5}$$

Conversely, S and $\bar{S}$ can be recovered from X in terms of

$$\begin{cases} S &= H^- \vee X^-, \\ \bar{S} &= H^+ \vee X^+, \end{cases} \tag{2.6}$$

where $X^- := \bigvee_{t=-\infty}^{0} U^t X$ and $X^+ := \bigvee_{t=0}^{\infty} U^t X$. We shall write $X \sim (S, \bar{S})$ to exhibit the one-to-one correspondence between X and $(S, \bar{S})$.

Clearly, the ambient space has the representation

$$H = S \vee \bar{S}, \tag{2.7}$$

and $S \perp \bar{S} \mid X$, which is equivalent to

$$\mathrm{E}^S \lambda = \mathrm{E}^X \lambda \quad \text{for } \lambda \in \bar{S} \tag{2.8}$$

and to

$$\mathrm{E}^{\bar{S}} \lambda = \mathrm{E}^X \lambda \quad \text{for } \lambda \in S. \tag{2.9}$$

In particular, $H^- \perp H^+ \mid X$; i.e., X is a *splitting subspace*.

We recall that $X \sim (S, \bar{S})$ is *minimal* both in the sense of subspace inclusion and in the sense of dimension, two concepts of minimality which can be shown to be equivalent, if and only if

$$\bar{S} = H^+ \vee S^\perp \tag{2.10}$$

and

$$S = H^- \vee \bar{S}^\perp \tag{2.11}$$

[17, 18]. Condition (2.10) is equivalent to $X \cap (H^+)^\perp = 0$, i.e., to X being *observable*, and (2.11) to $X \cap (H^-)^\perp = 0$, i.e., to X being *constructible*. Therefore, in view of (2.5), we have

$$X = \mathrm{E}^S H^+ = \mathrm{E}^{\bar{S}} H^- \tag{2.12}$$

whenever X is minimal.

The space S is actually identical to the subspace generated by the past of the driving white noise u in (1.1), so u can be constructed from S by Wold decomposition [14, 15]. Analogously, $\bar{S}$ corresponds to another white noise process $\{\bar{u}(t); t \in \mathbb{Z}\}$, the future space of which coincides with $\bar{S}$, and, passed through an antistable filter with transfer function

$$\bar{W}(z) = z\bar{C}(I - zA')^{-1}\bar{B} + \bar{D} \tag{2.13}$$

from the remote future, $\bar{u}$ produces a backward realization of y, namely,

$$\begin{cases} \bar{x}(t-1) = A'\bar{x}(t) + \bar{B}\bar{u}(t-1), \\ y(t-1) = \bar{C}\bar{x}(t) + \bar{D}\bar{u}(t-1). \end{cases} \tag{2.14}$$

Here $\bar{x}(0)$ is just another basis in X such that

$$\bar{x}(t) = P^{-1}x(t), \tag{2.15}$$

where P is the state covariance

$$P = \mathrm{E}\{x(0)x(0)'\}. \tag{2.16}$$

The ambient space H will of course vary over the family $\mathfrak{X}$ of minimal Markovian splitting subspaces. If $X \subset H_0$, then $H = H_0$ and we say that X is *internal*. We write $\mathfrak{X}_0$ to denote the subclass of internal $X \in \mathfrak{X}$.

The family $\mathfrak{X}$ is endowed with a natural partial ordering [18]. We say that $X_1 \leq X_2$ if

$$\|\mathrm{E}^{X_1}\lambda\| \leq \|\mathrm{E}^{X_2}\lambda\| \quad \text{for all } \lambda \in H^+$$

or, equivalently,

$$\|\mathrm{E}^{X_2}\lambda\| \leq \|\mathrm{E}^{X_1}\lambda\| \quad \text{for all } \lambda \in H^-.$$

In this ordering the *predictor space* $X_- := \mathrm{E}^{H^-}H^+$ is the minimal element in $\mathfrak{X}$ and $X_+ := \mathrm{E}^{H^+}H^-$ is the maximal element, i.e.,

$$X_- \leq X \leq X_+ \quad \text{for all } X \in \mathfrak{X}. \tag{2.17}$$

Obviously, both $X_- \sim (S_-, \bar{S}_-)$ and $X_+ \sim (S_+, \bar{S}_+)$ are internal.

This ordering can be used to introduce a *uniform choice of bases* (or coordinates) in all $X \in \mathcal{X}$. In fact, let $x_+(0)$ be an arbitrary choice of basis in X_+, and define

$$x(0) = \mathrm{E}^X x_+(0) \tag{2.18}$$

for all $X \in \mathcal{X}$. This will ensure the invariance of the matrices A and C over the class of forward minimal realizations (1.1). In the same way, we define

$$\bar{x}(0) = \mathrm{E}^X \bar{x}_-(0), \tag{2.19}$$

where $\bar{x}_-(0) = P_-^{-1} x_-(0)$, $x_-(0)$ being formed via (2.18) for $X = X_-$ and P_- being the corresponding state covariance (2.16). Then $\bar{C}$ and A' will be invariant over the set of backward realizations (2.14).

Introducing coordinates in this uniform fashion, we can also parameterize the family $\mathcal{X}$ in terms of the corresponding class $\mathcal{P}$ of state covariances (2.16). The usual partial ordering of these positive definite matrices reflects the partial ordering of splitting subspaces in $\mathcal{X}$ introduced above. Consequently, in this parameterization (2.17) becomes

$$P_- \leq P \leq P_+ \quad \text{for all } P \in \mathcal{P} \tag{2.20}$$

(cf. [8]). In the same way, we can parameterize $\mathcal{X}$ in terms of the family $\bar{\mathcal{P}}$ of covariance matrices

$$\bar{P} := \mathrm{E}\{\bar{x}(0)\bar{x}(0)'\} = P^{-1} \tag{2.21}$$

of the backward realizations (2.14). Then (2.17) becomes

$$\bar{P}_+ \leq \bar{P} \leq \bar{P}_- \quad \text{for all } \bar{P} \in \bar{\mathcal{P}}. \tag{2.22}$$

3. An ordered family of splitting subspaces. A fact of central importance in this paper is that each splitting subspace $X \in \mathcal{X}$ can be naturally imbedded in a doubly infinite sequence of elements in $\mathcal{X}$, which contains finitely many different splitting subspaces if and only if $X \in \mathcal{X}_0$; i.e., X is internal. To see this, define operators σ and $\bar{\sigma}$ on $\mathcal{X}$ so that, for $X \sim (S, \bar{S})$,

$$\sigma X = \mathrm{E}^{H^- \vee (U^{-1}S)} X, \tag{3.1}$$

$$\bar{\sigma} X = \mathrm{E}^{H^+ \vee (U\bar{S})} X. \tag{3.2}$$

Observe that the operator σ is the geometric counterpart of a one-step-ahead state predictor given past output and state information. Our first result states, among other things, that σX is itself a splitting subspace so that $\sigma X \in \mathcal{X}$. Remarkably, as we shall see in section 4, the states corresponding to $\{\sigma^k X\}$ are actually generated by a Kalman filter. Analogous statements hold for $\bar{\sigma}$ with respect to the backward setting.

THEOREM 3.1. *Let $X \sim (S, \bar{S})$ be a minimal Markovian splitting subspace. Then*

(i) *σX and $\bar{\sigma} X$ are minimal Markovian splitting subspaces and*

$$\sigma X \leq X \leq \bar{\sigma} X. \tag{3.3}$$

Moreover, they have the same ambient spaces, namely, $S \vee \bar{S}$.

(ii) $\sigma X = X$ *if and only if*

$$UX \subset X \vee \{y(0)\}, \tag{3.4}$$

and $\bar{\sigma} X = X$ *if and only if*

$$U^{-1}X \subset X \vee \{y(-1)\}. \tag{3.5}$$

(iii) *The fixed points of* σ *and* $\bar{\sigma}$ *are internal minimal Markovian splitting subspaces.*

Proof. We prove all statements involving σ. Then those involving $\bar{\sigma}$ follow by symmetry, replacing H^-, S, and U^{-1} with H^+, $\bar{S}$, and U. Since $X \sim (S, \bar{S})$ is a minimal Markovian splitting subspace, S is U^{-1}-invariant and $X = \mathrm{E}^S H^+$. Obviously $S^{(-1)} := H^- \vee (U^{-1}S)$ is also U^{-1}-invariant and $S^{(-1)} \subset S$. Therefore

$$\sigma X = \mathrm{E}^{S^{(-1)}} \mathrm{E}^S H^+ = \mathrm{E}^{S^{(-1)}} H^+$$

is an observable Markovian splitting subspace. Since, in addition, $S^{(-1)} \subset S \perp H^+ \cap (H^-)^\perp$, σX is minimal [18, Theorem 4.10]. Since

$$\mathrm{E}^{S^{(-1)}} \mathrm{E}^S \lambda = \mathrm{E}^{S^{(-1)}} \lambda \quad \text{for each } \lambda \in H^+,$$

the splitting property (2.8) and the fact that $\|\mathrm{E}^{S^{(-1)}} \xi\| \leq \|\xi\|$ imply that $\sigma X \leq X$. Since X and σX are finite dimensional and hence proper [17, 18], their ambient spaces are $\bigvee_{t=0}^{\infty} U^t S$ and $\bigvee_{t=0}^{\infty} U^t S^{(-1)}$, which must coincide in view of the fact that

$$U^{-1}S \subset S^{(-1)} \subset S.$$

In the same way we show that X and $\bar{\sigma} X$ have the same ambient space. This proves (i).

Next, we show that if $\sigma X = X$, then $X \subset H_0$. Now, $\sigma X = X$ is equivalent to $X \subset H^- \vee U^{-1}S$ and hence to $UX \subset S \vee \{y(0)\}$. However, $S = X \oplus \bar{S}^\perp$ and $\{y(0)\} \subset H^+ \subset \bar{S} \perp \bar{S}^\perp$, so

$$UX \subset [X \vee \{y(0)\}] \oplus \bar{S}^\perp.$$

Since $UX \perp U\bar{S}^\perp \supset \bar{S}^\perp$ we have thus established that $\sigma X = X$ if and only if

$$UX \subset X \vee \{y(0)\}, \tag{3.6}$$

which is the first part of (ii). A symmetric argument yields the second part.

Finally, to prove (iii), we note that (3.6) implies that

$$U\mathrm{E}^{H_0^\perp} X \subset \mathrm{E}^{H_0^\perp} X.$$

But the subspace $\mathrm{E}^{H_0^\perp} X$ is finite dimensional. Since U is a bilateral shift, it has no eigenvalues [30] and hence cannot have a nontrivial finite-dimensional invariant subspace. Consequently we must have $X \subset H_0$. ∎

COROLLARY 3.2. *Let* $X \in \mathcal{X}$ *and* $X \sim (S, \bar{S})$. *Then*

$$X^{(k)} = \begin{cases} \sigma^{-k} X & \text{for } k = 0, -1, -2, \dots, \\ \bar{\sigma}^k X & \text{for } k = 0, 1, 2, \dots \end{cases} \tag{3.7}$$

defines a sequence $\{X^{(k)} \mid k \in \mathbb{Z}\}$ *of elements in* $\mathfrak{X}$ *which have the same ambient space and which are totally ordered with* $X^{(0)} = X$. *More precisely,*

$$\cdots \leq X^{(-2)} \leq X^{(-1)} \leq X \leq X^{(1)} \leq X^{(2)} \leq \cdots .$$

Moreover, for each $k \in \mathbb{Z}$, $X^{(k)} \sim (S^{(k)}, \bar{S}^{(k)})$, *where*

$$S^{(k)} = H^- \vee U^k S, \quad \bar{S}^{(k)} = H^+ \vee \left[S^{(k)}\right]^\perp \quad \text{for } k \leq 0$$

and

$$\bar{S}^{(k)} = H^+ \vee U^k \bar{S}, \quad S^{(k)} = H^- \vee \left[\bar{S}^{(k)}\right]^\perp \quad \text{for } k \geq 0.$$

Here the orthogonal complement $^\perp$ *is taken with respect to the common ambient space* $S \vee \bar{S}$.

Proof. This corollary follows from the proof of Theorem 3.1, (2.10), and (2.11). In fact, it follows by induction that $\sigma^k X$ is also a minimal Markovian splitting subspace and that

$$\sigma^k X = \mathrm{E}^{S^{(-k)}} X \quad \text{for } k = 0, 1, 2, \ldots,$$

where $S^{(-k)} := H^- \vee U^{-k} S$. The statement about $\bar{\sigma}$ follows by symmetry. □

Next we show that the sequence $\{X^{(k)} \mid k \in \mathbb{Z}\}$ can be extended to include limits $X^{(-\infty)}$ and $X^{(\infty)}$.

THEOREM 3.3. *The limits* $\lim_{k\to-\infty} E^{S^{(k)}}\xi$ *and* $\lim_{k\to\infty} E^{\bar{S}^{(k)}}\xi$ *exist for all* $\xi \in X$, *and the spaces*

$$X^{(-\infty)} := \left\{ \lim_{k\to-\infty} E^{S^{(k)}}\xi \mid \xi \in X \right\}, \tag{3.8}$$

$$X^{(\infty)} := \left\{ \lim_{k\to\infty} E^{\bar{S}^{(k)}}\xi \mid \xi \in X \right\} \tag{3.9}$$

are internal minimal Markovian splitting subspaces. Moreover, the sequences of splitting subspaces $\{X^{(-k)} \mid k = 0, 1, 2, \ldots\}$ *and* $\{X^{(k)} \mid k = 0, 1, 2, \ldots\}$ *converge in a finite number of steps if and only if* X *is internal. In that case the number of steps is no greater than* $\dim X$.

Proof. Since $\{S^{(-k)} \mid k = 0, 1, 2, \ldots\}$ is a nonincreasing sequence of subspaces, i.e.,

$$S \supset S^{(-1)} \supset S^{(-2)} \supset S^{(-3)} \supset \cdots , \tag{3.10}$$

it is well known [6, p. 24] that $\xi_{-\infty} = \lim_{k\to\infty} \mathrm{E}^{S^{(-k)}}\xi$ exists for all $\xi \in X$ and that $\xi_{-\infty} = \mathrm{E}^{S^{(-\infty)}}\xi$, where $S^{(-\infty)} = \bigcap_{k=0}^{\infty} S^{(-k)}$. Thus $X^{(-\infty)}$ is well defined, and since $X = \mathrm{E}^S H^+$,

$$X^{(-\infty)} = \mathrm{E}^{S^{(-\infty)}} H^+.$$

Therefore, since $S^{(-\infty)}$ is U^{-1}-invariant, $X^{(-\infty)}$ is an observable Markovian splitting subspace. But $S^{(-\infty)} \subset S \perp H^+ \cap (H^-)^\perp$, and hence $X^{(-\infty)}$ is minimal. It remains to show that $X^{(-\infty)}$ is internal. In view of Theorem 3.1, this would follow if $X^{(-\infty)}$ were a fixed point for σ. Next, we prove that this is in fact the case.

Consequently we want to prove that $\sigma X^{(-\infty)} = X^{(-\infty)}$, which follows from

$$H^- \vee U^{-1}S^{(-\infty)} = S^{(-\infty)}. \tag{3.11}$$

Let us prove (3.11). Since $S^{(-\infty)} = \bigcap_{k=0}^{\infty} S^{(-k)}$, $U^{-1}S^{(-k)} \subset S^{(-k)}$, and $H^- \subset S^{(-k)}$, it is trivial that

$$H^- \vee U^{-1}S^{(-\infty)} \subset S^{(-\infty)}.$$

It remains to prove the converse. To this end, note that

$$H^- \vee U^{-1}S^{(-k)} = \{y(-1)\} \vee U^{-1}S^{(-k)}.$$

This sum is in general not direct, so we want to reformulate it into such a sum. Therefore, observe that $\{y(-1)\} \cap U^{-1}S^{(k)}$ is nonincreasing in k and finite dimensional and thus there is a k_0 such that

$$\{y(-1)\} \cap U^{-1}S^{(k)} = \{y(-1)\} \cap U^{-1}S^{(k_0)} \quad \text{for } k \geq k_0.$$

Let V be a complement of $\{y(-1)\} \cap U^{-1}S^{(k_0)}$ in $\{y(-1)\}$. Then, for $k \geq k_0$,

$$H^- \vee U^{-1}S^{(-k)} = V + U^{-1}S^{(-k)} \tag{3.12}$$

is a direct sum. Now, if $\xi \in S^{(-\infty)} = \bigcap_{k=0}^{\infty}(H^- \vee U^{-1}S^{(-k)})$, then

$$\xi = v_k + \eta_k$$

with $v_k \in V$ and $\eta_k \in U^{-1}S^{(-k)}$ is a unique representation for each $k \geq k_0$. Therefore, since (3.12) is nonincreasing, $v_k = v \in V$ and $\eta_k = \eta \in \bigcap_{k=0}^{\infty} U^{-1}S^{(-k)} = U^{-1}S^{(-\infty)}$ for $k \geq k_0$. Hence

$$\xi = v + \eta \in V \vee U^{-1}S^{(-\infty)} \subset H^- \vee U^{-1}S^{(-\infty)},$$

proving that $X^{(-\infty)}$ is a fixed point.

Next, we assume that X is noninternal and prove that, in this case, all elements of the sequences $\{X^{(-k)} \mid k = 0, 1, 2, \dots\}$ and $\{X^{(k)} \mid k = 0, 1, 2, \dots\}$ are noninternal and that consequently these sequences cannot converge in a finite number of steps, the limits being internal. To see this, take a $\xi \in S$ such that $\xi \neq H_0$. Then $U^{-k}\xi \in S^{(-k)}$ but $U^{-k}\xi \notin H_0$, showing that $X^{(-k)}$ is noninternal for $k = 0, 1, 2, \dots$. A symmetric argument involving $\bar{S}$ shows that $X^{(k)}$ is also noninternal for $k = 0, 1, 2, \dots$.

To prove the converse, first recall that, for any internal $X \sim (S, \bar{S})$,

$$X = (X \cap X_-) \vee (X \cap X_+) \tag{3.13}$$

and that $S = H^- \vee X$. Relation (3.13) is proven in the same way as Lemma 2.9 in [13] and can also be found in [21]. Hence,

$$S = H^- \vee (X \cap X_+). \tag{3.14}$$

Since $X = \mathrm{E}^S H^+$, the subspace $X \cap X_+$ thus uniquely determines the internal splitting subspace X. In view of (3.14), (3.10) implies that the sequence $\{X^{(-k)} \cap X_+ \mid k = 0, 1, 2, \dots\}$ of finite-dimensional subspaces is nonincreasing. Therefore, it must converge in a finite number of steps which cannot be larger than $\dim X$, implying via (3.14) that the same holds for the sequence $\{X^{(-k)} \mid k = 0, 1, 2, \dots\}$. ∎

We remark that this proof also shows that, if X is internal, the whole sequence $\{X^{(k)} \mid k \in \mathbb{Z}\}$ cannot have more than $\dim X + 1$ different elements.

As pointed out in the end of the proof of Theorem 3.3, an internal X is completely characterized by its intersection $X \cap X_+ = X \cap H^+$ with the future via (3.14). In the same way,

$$\bar{S} = H^+ \vee (X \cap X_-), \tag{3.15}$$

so $X \in \mathfrak{X}_0$ is also characterized by its intersection $X \cap X_- = X \cap H^-$ with the past. In particular, we have the following characterizations of σX_+ and $\bar{\sigma} X_-$. Similar characterizations for arbitrary X are given in section 8.

PROPOSITION 3.4. *The intersection of σX_+ with the past H^- is described by*

$$(\sigma X_+) \cap X_- = (X_+ \cap X_-) \vee (\{y(-1)\} \cap X_-), \tag{3.16}$$

and the intersection of $\bar{\sigma} X_-$ with the future H^+ is described by

$$(\bar{\sigma} X_-) \cap X_+ = (X_- \cap X_+) \vee (\{y(0)\} \cap X_+). \tag{3.17}$$

Proof. First observe that (3.16) is equivalent to

$$\bar{S}_+^{(-1)} = H^+ \vee (\{y(-1)\} \cap X_-). \tag{3.18}$$

In fact, that (3.18) implies (3.16) follows from the facts that

$$\bar{S}_+^{(-1)} \cap X_- = (\sigma X_+) \cap X_-$$

and

$$\left[H^+ \vee (\{y(-1)\} \cap X_-)\right] \cap X_- = (X_+ \cap X_-) \vee (\{y(-1)\} \cap X_-),$$

while the opposite implication follows from the fact that

$$\bar{S}_+^{(-1)} = H^+ \vee \left[(\sigma X_+) \cap X_-\right].$$

Next let us prove (3.18). We have

$$\begin{aligned}
\bar{S}_+^{(-1)} &= H^+ \vee (S_+^{(-1)})^\perp = H^+ \vee (H^- \vee U^{-1} S_+)^\perp \\
&= H^+ \vee \left[(H^-)^\perp \cap (U^{-1} H^+) \cap (U^{-1} H^-)^\perp\right] \\
&= H^+ \vee \left[(H^-)^\perp \cap (U^{-1} H^+)\right] \\
&= H^+ \vee \left[(H^-)^\perp \cap (H^+ \vee \{y(-1)\})\right],
\end{aligned}$$

where in the third step we have used the fact that $S_+^\perp = H^+ \cap (H^-)^\perp$. (See, for example, [18, Example 4.4].) Now suppose that $\xi \in (H^-)^\perp \cap (H^+ \vee \{y(-1)\})$. Then $\xi = \alpha + \beta$, where $\alpha \in H^+$ and $\beta \in \{y(-1)\} \subset H^-$. But $\alpha + \beta \perp H^-$, and consequently

$$\beta = -\mathrm{E}^{H^-} \alpha \in \mathrm{E}^{H^-} H^+ = X_-$$

so that $\beta \in \{y(-1)\} \cap X_-$. Hence $\bar{S}_+^{(-1)} \subset H^+ \vee (\{y(-1)\} \cap X_-)$.

Conversely, if $\beta \in \{y(-1)\} \cap X_-$, there is an $\alpha \in H^+$ such that $\beta = -\mathrm{E}^{H^-} \alpha$, which implies that $\alpha + \beta \perp H^-$ and that $\alpha + \beta \in (H^+ \vee \{y(-1)\})$. Hence

$$\{y(-1)\} \cap X_- \subset H^+ \vee \left[(H^-)^\perp \cap (H^+ \vee \{y(-1)\})\right],$$

which concludes the proof of (3.16) and (3.18).

The proof of the dual statement is completely symmetric, using the fact that

$$S_-^{(1)} = H^- \vee (\{y(0)\} \cap X_+) \tag{3.19}$$

is equivalent to (3.17). □

Since a minimal internal splitting subspace is completely characterized by its intersection with X_- via (3.15) and by its intersection with X_+ via (3.14), Proposition 3.4 has the following corollary, which we shall need later.

COROLLARY 3.5. *The splitting subspace X_+ is a fixed point of the operator σ if and only if $X_- \cap \{y(-1)\} = 0$. Likewise, X_- is a fixed point of the operator $\bar{\sigma}$ if and only if $X_+ \cap \{y(0)\} = 0$.*

The proof of Proposition 3.4 is easily modified to yield the following amplification, describing the chains of splitting subspaces $\{X_+^{(k)}\}$ and $\{X_-^{(k)}\}$.

PROPOSITION 3.6. *For $k = 1, 2, 3, \dots$, we have*

$$(\sigma^k X_+) \cap X_- = (X_+ \cap X_-) \vee (\{y(-1), \dots, y(-k)\} \cap X_-) \tag{3.20}$$

or, equivalently,

$$\bar{S}_+^{(-k)} = H^+ \vee (\{y(-1), \dots, y(-k)\} \cap X_-); \tag{3.21}$$

and

$$(\bar{\sigma}^k X_-) \cap X_+ = (X_- \cap X_+) \vee (\{y(0), \dots, y(k-1)\} \cap X_+) \tag{3.22}$$

or, equivalently,

$$S_-^{(k)} = H^- \vee (\{y(0), \dots, y(k-1)\} \cap X_+). \tag{3.23}$$

We shall now characterize the fixed points of the operators σ and $\bar{\sigma}$ in terms of the matrices D and $\bar{D}$ in equations (1.1) and (2.14), respectively.

COROLLARY 3.7. *Let $X \in \mathfrak{X}$ and let D and $\bar{D}$ be the corresponding matrices in the models* (1.1) *and* (2.14). *Then $\sigma X = X$ if and only if $\ker D' = 0$ and $\bar{\sigma} X = X$ if and only if $\ker \bar{D}' = 0$.*

Proof. Given (1.1) an elementary calculation yields

$$x(1) = Ax(0) + BD'(DD')^\sharp [y(0) - Cx(0)] + B_2 u(0),$$

where $B_2 := B - BD'(DD')^\sharp D$ and $(DD')^\sharp$ is a pseudoinverse of DD'. In particular, this implies that

$$\mathrm{E}\{B_2 u(0) y(0)'\} = BD' - BD'(DD')^\sharp DD' = 0.$$

Since therefore the components of $B_2 u(0)$ are orthogonal to those of both $x(0)$ and $y(0)$, (3.4) is equivalent to $B_2 = 0$, which in turn is equivalent to

$$\begin{bmatrix} B \\ D \end{bmatrix} [I - D'(DD')^\sharp D] = 0.$$

But the columns of $\begin{bmatrix} B \\ D \end{bmatrix}$ are—according to our assumption—linearly independent so (3.4) is equivalent to $D'(DD')^\sharp D = I$, which holds if and only if DD' is full rank, i.e.,

if $(DD')^{-1}$ exists. Then the first statement follows from Theorem 3.1(ii). The second statement follows by symmetry. □

Remark 3.8. In view of Corollary 3.7 we have another proof of the fact that any fixed point of σ is internal. In fact, we established in the proof above that (3.4) is equivalent to $B_2 = 0$, which in the case when DD' is full rank implies that the transfer function (1.2) of (1.1) must be a square spectral factor and thus correspond to an internal realization [16, Theorem 5.2].

Theorem 3.1 and Corollary 3.7 give characterizations of precisely which internal X are fixed points of σ and $\bar{\sigma}$. It follows trivially from the definitions (3.1) and (3.2) that

$$\sigma X_- = X_- \quad \text{and} \quad \bar{\sigma} X_+ = X_+,$$

which, by Corollary 3.7, implies that D_- and $\bar{D}_+$ are always full rank, a well-known property of the innovations models. The following proposition together with Corollary 3.7 gives a more global picture on this question. (Also see [14].)

PROPOSITION 3.9. *Let $X \in \mathcal{X}$, and let D and $\bar{D}$ be the corresponding matrices in the models* (1.1) *and* (2.14). *Then*

$$\dim \ker D' = \dim(X \cap \{y(0)\}) \leq \dim(X_+ \cap \{y(0)\}) = \dim \ker D'_+ \tag{3.24}$$

and

$$\dim \ker \bar{D}' = \dim(X \cap \{y(-1)\}) \leq \dim(X_- \cap \{y(-1)\}) = \dim \ker \bar{D}'_-. \tag{3.25}$$

Proof. Let $a \in \ker D'$. Then $a'D = 0$ so that $a'y(0) \in X$. Conversely, suppose that $a'y(0) \in X$. Then, since $a'Cx(0) \in X$, we must have $a'Du(0) \in X \perp \{u(0)\}$, implying that $a'D = 0$. This proves the equalities in (3.24). To prove the inequality, note that

$$X \cap X_+ \cap \{y(0)\} = X \cap H^+ \cap \{y(0)\} = X \cap \{y(0)\}.$$

A symmetric argument yields (3.25). □

COROLLARY 3.10. *The splitting subspace X_+ is a fixed point of the operator σ if and only if $X_+ \cap \{y(0)\} = 0$. Likewise, X_- is a fixed point of the operator $\bar{\sigma}$ if and only if $X_- \cap \{y(-1)\} = 0$.*

Proof. In view of Corollary 3.7, this follows from the last equalities in (3.24) and (3.25), respectively. □

Comparing Corollaries 3.5 and 3.10, we can now see that the two conditions $X_+ \cap \{y(0)\} = 0$ and $X_- \cap \{y(-1)\} = 0$ are actually equivalent. We shall refer to the situation when they are satisfied as the *regular case*. From Proposition 3.9 and Corollary 3.7 it readily follows that, in the regular case and only in the regular case, *all* $X \in \mathcal{X}_0$ are fixed points of *both* σ and $\bar{\sigma}$. All this could also have been shown without using Corollary 3.5 by instead invoking the fact, proven in [14, Theorem 10.2], that D_+ has full rank if and only if $\bar{D}_-$ has.

The fact that $\sigma X_+ = X_+$ and $\bar{\sigma} X_- = X_-$ are the critical conditions in this analysis is also reflected in the ordering of covariances. In fact,

$$DD' = \Lambda_0 - CPC' \geq \Lambda_0 - CP_+C' = D_+D'_+$$

for all $P \leq P_+$ so that regularity is equivalent to

$$\Lambda_0 - CPC' > 0 \quad \text{for all } P \in \mathcal{P}$$

and analogous in the backward setting. This is also equivalent to all minimal spectral factors having zeros neither at zero nor at infinity.

We collect the regularity conditions in the following proposition. Some other characterizations can be found in [22, Theorem 3.2].

PROPOSITION 3.11. *The following regularity conditions are equivalent.*

(i) $\Lambda_0 - CP_+C' > 0$.
(ii) $\Lambda_0 - \bar{C}\bar{P}_-\bar{C}' > 0$.
(iii) $X_+ \cap \{y(0)\} = 0$.
(iv) $X_- \cap \{y(-1)\} = 0$.
(v) $\sigma X_+ = X_+$.
(vi) $\bar{\sigma} X_- = X_-$.

Clearly regularity is a property of the output process y. Therefore, we introduce the following definition.

DEFINITION 3.12. *The process y is* regular *if the conditions of Proposition* 3.11 *are satisfied.*

The regularity conditions can also be stated in terms of the whole family of minimal realizations.

PROPOSITION 3.11′. *Each of the following regularity conditions is equivalent to those in Proposition* 3.11.

(i)′ $\Lambda_0 - CPC' > 0$ *for all* $P \in \mathcal{P}$.
(ii)′ $\Lambda_0 - C\bar{P}C' > 0$ *for all* $\bar{P} \in \bar{\mathcal{P}}$.
(iii)′ $X \cap \{y(0)\} = 0$ *for all* $X \in \mathcal{X}$.
(iv)′ $X \cap \{y(-1)\} = 0$ *for all* $X \in \mathcal{X}$.
(v)′ $\sigma X = X$ *for all* $X \in \mathcal{X}_0$.
(vi)′ $\bar{\sigma} X = X$ *for all* $X \in \mathcal{X}_0$.

We shall next prove that the operators σ and $\bar{\sigma}$ are invertible in the regular case and that $\bar{\sigma} = \sigma^{-1}$. In fact, as we shall see in Theorem 3.13 and Corollary 3.14 below, this property characterizes the regularity of the process y. In section 6 we study the nonregular case and give a more complete description of the subspaces σX, $\bar{\sigma} X$ for any $X \in \mathcal{X}$.

In view of Proposition 3.4, a straightforward calculation based on (3.18) shows that

$$\bar{\sigma}\sigma X_+ = X_+ \quad \text{and} \quad \sigma\bar{\sigma} X_- = X_-. \tag{3.26}$$

A natural question is under what conditions these fixed-point properties can be generalized to arbitrary $X \in \mathcal{X}$.

THEOREM 3.13. *Let $X \in \mathcal{X}$. Then*

$$\sigma\bar{\sigma} X \leq X \leq \bar{\sigma}\sigma X \tag{3.27}$$

and

$$\bar{\sigma}\sigma X = X \Longleftrightarrow \{y(0)\} \cap X = \{y(0)\} \cap X_+. \tag{3.28}$$

Symmetrically,

$$\sigma\bar{\sigma} X = X \Longleftrightarrow \{y(-1)\} \cap X = \{y(-1)\} \cap X_-. \tag{3.29}$$

Proof. We prove (3.29) and the first inequality in (3.27). Then, the rest follows by symmetry. First observe that, since $X \cap H^- = X \cap X_- \subset X_-$ and $\{y(-1)\} \subset H^-$, it always holds that

$$\{y(-1)\} \cap X \subset \{y(-1)\} \cap X_-.$$

In view of Corollary 3.2, $\bar{\sigma}X \sim (S^{(1)}, \bar{S}^{(1)})$, where

$$\begin{aligned}\bar{S}^{(1)} &= H^+ \vee U\bar{S},\\ S^{(1)} &= H^- \vee (\bar{S}^{(1)})^\perp = H^- \vee \left[(H^+)^\perp \cap (U\bar{S}^\perp)\right].\end{aligned}$$

Then apply σ to $\bar{\sigma}X$ to obtain

$$H^- \vee U^{-1}S^{(1)} = H^- \vee U^{-1}H^- \vee \left[(U^{-1}H^+)^\perp \cap \bar{S}^\perp\right].$$

Since $U^{-1}H^- \subset H^-$ and $U^{-1}H^+ = \{y(-1)\} \vee H^+$, we have

$$H^- \vee U^{-1}S^{(1)} = H^- \vee \left[\bar{S}^\perp \cap \{y(-1)\}^\perp\right] \subset S, \tag{3.30}$$

the last of which is a consequence of the condition $S = H^- \vee \bar{S}^\perp$. Hence $\sigma\bar{\sigma}X \leq X$. To find a condition under which $\sigma\bar{\sigma}X = X$, we need to characterize the converse inequality. To this end, we consider the converse inclusion of (3.30) and take orthogonal complements in it to obtain

$$(H^-)^\perp \cap (\bar{S} \vee \{y(-1)\}) \subset (H^-)^\perp \cap \bar{S}. \tag{3.31}$$

Now, let ξ be an element in the subspace on the left side of (3.31). Then, $\xi = \alpha + \beta$, where $\alpha \in \bar{S}$ and $\beta \in \{y(-1)\} \subset H^-$, and $\xi \perp H^-$. Consequently,

$$\beta = -\mathrm{E}^{H^-}\alpha \in \mathrm{E}^{H^-}\bar{S} = X_-,$$

and hence $\beta \in \{y(-1)\} \cap X_-$. So if $\{y(-1)\} \cap X = \{y(-1)\} \cap X_-$ holds, $\beta \in \{y(-1)\} \cap X \subset \bar{S}$. Therefore, since $\alpha \in \bar{S}$, we have $\beta \in \bar{S}$, and hence (3.31) holds.

Conversely, suppose that (3.31) holds. Consider a $\beta \in \{y(-1)\} \cap X_-$. Then, there is an $\alpha \in \bar{S}$ such that $\beta = -\mathrm{E}^{H^-}\alpha$ so that

$$\alpha + \beta \in (H^-)^\perp \cap (\bar{S} \vee \{y(-1)\}).$$

Using condition (3.31), we obtain $\alpha + \beta \in \bar{S}$. But $\alpha \in \bar{S}$, and hence $\beta \in \bar{S}$. In other words, (3.31) implies that $\{y(-1)\} \cap X_- \subset \bar{S}$, and consequently

$$\{y(-1)\} \cap X_- = \{y(-1)\} \cap X_- \cap \bar{S} \subset \{y(-1)\} \cap X,$$

since $X_- \cap \bar{S} = X_- \cap S \cap \bar{S} = X_- \cap X$. But the converse inclusion has already been proven above. Hence we have established (3.29). □

COROLLARY 3.14. *In the regular case the operators σ and $\bar{\sigma}$ are invertible and*

$$\bar{\sigma} = \sigma^{-1}. \tag{3.32}$$

Proof. This follows from regularity condition (iii) in Proposition 3.11 and (3.28) in Theorem 3.13. □

In particular Corollary 3.14 implies that relations (3.7) can be extended so that

$$X^{(j)} = \sigma^{j-k}X^{(k)} = \bar{\sigma}^{k-j}X^{(k)} \quad \text{for all } j, k \in \mathbb{Z}. \tag{3.33}$$

4. An interpolation problem. The ordered family of splitting subspaces introduced in section 3 is intimately connected to the following estimation problem. Given a minimal stochastic system

$$\begin{cases} x(t+1) = Ax(t) + Bu(t), \\ y(t) = Cx(t) + Du(t) \end{cases} \tag{4.1}$$

of the type defined in section 2 and integers t_0, t_1 such that $t_0 < t_1$, find, for each time t between t_0 and t_1, the linear least squares estimate[1]

$$\hat{x}(t \mid t_0, t_1) = \mathrm{E}\{x(t) \mid y(s), s \in \mathbb{Z}; x(\tau), \tau \in \mathbb{Z} \setminus \{t_0 + 1, \dots, t_1 - 1\}\} \tag{4.2}$$

of the state $x(t)$ given the whole output process y and the whole state process x except for times τ such that $t_0 < \tau < t_1$.

This interpolation problem is a prototype of an estimation problem of the following type. The state of a linear stochastic system is being observed both directly and through a noisy channel. During an interval of time (t_0, t_1) the direct state information is lost, and the problem is to estimate the lost states from the noisy observations and the remaining state information. Letting $t_0 \to -\infty$ and $t_1 \to \infty$, we obtain a *smoothing problem.* In a practical situation one would of course expect the information to be given on a finite interval containing $[t_0, t_1]$ and not on all of $\mathbb{Z}$ as here. However, as will be seen in Theorem 4.6 below, our solution will depend only on data from the interval $[t_0, t_1]$ and hence applies also to this situation, a remarkable fact that derives from the Markov property and allows us to use Kalman filtering. Nevertheless, it is convenient to formulate the problem in terms of infinite data.

In the more compact notation of section 2, the interpolation estimate may be written

$$\hat{x}(t \mid t_0, t_1) = \mathrm{E}^{H_0 \vee (U^{t_0} X^-) \vee (U^{t_1} X^+)} x(t), \tag{4.3}$$

where X is the splitting subspace corresponding to (4.3) and X^- and X^+ are the past and future of X as defined after (2.6). Now, one of the main results of this section is that the estimate (4.3) can be represented as a linear combination of the two estimates

$$x^{(t_0 - t)}(t) = \mathrm{E}^{H^-_{t-1} \vee (U^{t_0} X^-)} x(t), \tag{4.4}$$

based on the past information, and

$$x^{(t_1 - t)}(t) = \mathrm{E}^{H^+_t \vee (U^{t_1} X^+)} x(t), \tag{4.5}$$

based on the future information. As we demonstrate below, this is due to the fact that $x^{(t_0 - t)}$ and $x^{(t_1 - t)}$ are state processes of minimal realizations of y, the splitting subspaces of which bound X from below and from above in the ordering defined in section 2. In fact, $x^{(t_0 - t)}(t) = U^t x^{(t_0 - t)}(0)$ and $x^{(t_1 - t)}(t) = U^t x^{(t_1 - t)}(0)$, where

$$x^{(-k)}(0) = \mathrm{E}^{H^- \vee U^{-k} X^-} x(0) \tag{4.6}$$

[1] Clearly $\mathrm{E}\{\cdot \mid \cdot\}$ denotes *wide sense* conditional expectation unless the system is assumed to be Gaussian.

and

$$x^{(k)}(0) = \mathrm{E}^{H^+ \vee U^k X^+} x(0) \tag{4.7}$$

are defined for $k = 0, 1, 2, \dots$. Obviously $x^{(0)} = x$ by both formulas. This relates the estimates (4.4) and (4.5) to the operators σ and $\bar{\sigma}$ defined in section 3.

PROPOSITION 4.1. *The family of subspaces* $\{X^{(k)} \mid k \in \mathbb{Z}\}$, *defined in terms of* (4.6) *and* (4.7) *by*

$$X^{(k)} = \{a' x^{(k)}(0) \mid a \in \mathbb{R}^n\}, \tag{4.8}$$

is a family of minimal Markovian splitting subspaces such that

$$X^{(-k)} = \sigma^k X \quad \textit{and} \quad X^{(k)} = \bar{\sigma}^k X \tag{4.9}$$

for $k = 0, 1, 2, \dots$, *where* $X = \{a' x(0) \mid a \in \mathbb{R}^n\}$ *and* $\sigma, \bar{\sigma}$ *are the operators defined by* (3.1) *and* (3.2). *Moreover, for each* $k \in \mathbb{Z}$, $x^{(k)}(0)$ *is the basis in* $X^{(k)}$ *in the same uniform choice of coordinates as* $x(0)$.

Proof. Let $X \sim (S, \bar{S})$. Then $S = H^- \vee X^-$ and $\bar{S} = H^+ \vee X^+$ and so, since $U^{-1}S \subset S$ and $U\bar{S} \subset \bar{S}$,

$$x^{(k)}(0) = \begin{cases} \mathrm{E}^{H^- \vee U^k S} x(0) = \mathrm{E}^{S^{(k)}} x(0) & \text{for } k \le 0, \\ \mathrm{E}^{H^+ \vee U^k \bar{S}} x(0) = \mathrm{E}^{\bar{S}^{(k)}} x(0) & \text{for } k \ge 0, \end{cases} \tag{4.10}$$

where $S^{(k)}$ and $\bar{S}^{(k)}$ are defined as in Corollary 3.2. Then the first statement is an immediate consequence of (4.10) and Corollary 3.2. Moreover, since $S^{(k)} \subset S$ for $k \le 0$,

$$x^{(k)}(0) = \mathrm{E}^{S^{(k)}} x(0) = \mathrm{E}^{S^{(k)}} \mathrm{E}^{S} x_+(0) = \mathrm{E}^{S^{(k)}} x_+(0)$$

for the appropriate choice of basis in X_+. Similarly, for $k \ge 0$, $\bar{S}^{(k)} \subset \bar{S}$ so that

$$\bar{x}^{(k)}(0) = \mathrm{E}^{\bar{S}^{(k)}} \bar{x}(0) = \mathrm{E}^{\bar{S}^{(k)}} \mathrm{E}^{\bar{S}} \bar{x}_-(0) = \mathrm{E}^{\bar{S}^{(k)}} \bar{x}_-(0),$$

where $\bar{x}_-(0) = P_-^{-1} x_-(0)$ and $x_-(0) = \mathrm{E}^{X_-} x_+(0)$, and this proves the second statement. □

Consequently, we have established that

$$\hat{x}(0 \mid t_0, t_1) = \mathrm{E}^{S^{(t_0 - t)} \vee \bar{S}^{(t_1 - t)}} x(0), \tag{4.11}$$

where $X^{(t_0 - t)} \sim (S^{(t_0 - t)}, \bar{S}^{(t_0 - t)})$ and $X^{(t_1 - t)} \sim (S^{(t_1 - t)}, \bar{S}^{(t_0 - t)})$ are elements in $\mathfrak{X}$ such that

$$X^{(t_0 - t)} \le X \le X^{(t_1 - t)} \tag{4.12}$$

and such that $S^{(t_0 - t)} \subset S$ and $\bar{S}^{(t_1 - t)} \subset \bar{S}$. The following chain of lemmas deals with this setup and leads to the first main result of this section.

LEMMA 4.2. *Let* $X \sim (S, \bar{S})$, $X_1 \sim (S_1, \bar{S}_1)$, *and* $X_2 \sim (S_2, \bar{S}_2)$ *be minimal Markovian splitting subspaces such that* $S_1 \subset S$ *and* $\bar{S}_2 \subset \bar{S}$. *Then* $X_1 \le X \le X_2$ *and*

$$x_1(0) = E^{X_1} x_2(0) \tag{4.13}$$

for any uniform choice $x_1(0), x_2(0)$ *of bases in* X_1 *and* X_2.

Proof. Since $\bar{S}_2 \subset \bar{S}$, we have

$$\bar{S}_2 \cap (H^-)^\perp \subset \bar{S} \cap (H^-)^\perp.$$

Since X and X_2 are minimal, this is equivalent to $S_2^\perp \subset S^\perp$ [18, Corollary 4.5] or, equivalently,

$$(\bar{S}_2 \vee S_2) \ominus S_2 \perp S. \tag{4.14}$$

In fact, $\bar{S}_2 \vee S_2$ is the ambient space of X_2. But (4.14) is equivalent to $\bar{S}_2 \perp S \mid S_2$ [18, Proposition 2.1] and also to

$$\mathrm{E}^S\lambda = \mathrm{E}^S\mathrm{E}^{S_2}\lambda \quad \text{for all } \lambda \in \bar{S}_2. \tag{4.15}$$

Apply E^{X_1} to this. Since $X_1 \subset S_1 \subset S$ and $H^+ \subset \bar{S}_2$, we obtain in particular

$$\mathrm{E}^{X_1}\lambda = \mathrm{E}^{X_1}\mathrm{E}^{S_2}\lambda \quad \text{for all } \lambda \in H^+.$$

But X_2 is a splitting subspace, so $\mathrm{E}^{S_2}\lambda = \mathrm{E}^{X_2}\lambda$ for all $\lambda \in H^+$ and $X_+ \subset H^+$. Consequently

$$\mathrm{E}^{X_1}\lambda = \mathrm{E}^{X_1}\mathrm{E}^{X_2}\lambda \quad \text{for all } \lambda \in X^+.$$

Hence, for an arbitrary choice of basis $x_+(0)$ in X_+, we have

$$\mathrm{E}^{X_1}x_+(0) = \mathrm{E}^{X_1}\mathrm{E}^{X_2}x_+(0),$$

which is equivalent to (4.13) with $x_1(0)$ and $x_2(0)$ being the corresponding bases in X_1 and X_2. The fact that $X_1 \le X$ follows immediately from $\mathrm{E}^{S_1} = \mathrm{E}^{S_1}\mathrm{E}^S$ and [18, Lemma 6.7]. The relation $X \le X_2$ follows analogously from $\bar{S}_2 \subset \bar{S}$. □

LEMMA 4.3. *Let $X \sim (S, \bar{S})$, $X_1 \sim (S_1, \bar{S}_1)$, and $X_2 \sim (S_2, \bar{S}_2)$ be minimal Markovian splitting subspaces such that $S_1 \subset S$, and $\bar{S}_2 \subset \bar{S}$. Then*

$$E^{S_1 \vee \bar{S}_2}X \subset X_1 \vee X_2. \tag{4.16}$$

Proof. Applying the projection operator E^S to $H^+ \subset \bar{S}_2 \subset \bar{S}$ we obtain

$$\mathrm{E}^S H^+ \subset \mathrm{E}^S\bar{S}_2 \subset \mathrm{E}^S\bar{S} = X.$$

But since X is observable, $X = \mathrm{E}^S H^+$, and therefore

$$X = \mathrm{E}^S\bar{S}_2. \tag{4.17}$$

Moreover, since $S_1 \subset S$, we have $\mathrm{E}^{S_1}H^+ = \mathrm{E}^{S_1}\mathrm{E}^S H^+$, and therefore, since X_1 and X are both observable,

$$X_1 = \mathrm{E}^{S_1}X, \tag{4.18}$$

which together with (4.17) yields

$$X_1 = \mathrm{E}^{S_1}\bar{S}_2. \tag{4.19}$$

Now, it is well known and easy to check that the orthogonal decomposition

$$A = (\mathrm{E}^A B) \oplus (A \cap B^\perp) \tag{4.20}$$

holds for all pairs of subspaces A, B. Therefore, in view of (4.19), we have

$$S_1 = X_1 \oplus (S_1 \cap \bar{S}_2^{\perp}). \tag{4.21}$$

A completely symmetric argument yields

$$\bar{S}_2 = X_2 \oplus (\bar{S}_2 \cap S_1^{\perp}). \tag{4.22}$$

Therefore, since $X_1 \perp S_1^{\perp}$ and $X_2 \perp \bar{S}_2^{\perp}$, we have

$$S_1 \vee \bar{S}_2 = (S_1 \cap \bar{S}_2^{\perp}) \oplus (X_1 \vee X_2) \oplus (\bar{S}_2 \cap S_1^{\perp}). \tag{4.23}$$

To prove (4.16), take any $\xi \in X$. Then

$$\xi - \mathrm{E}^{S_1}\xi \perp S_1 \supset S_1 \cap \bar{S}_2^{\perp}$$

and, by (4.18) and (4.21),

$$\mathrm{E}^{S_1}\xi \in X_1 \perp S_1 \cap \bar{S}_2^{\perp}.$$

Consequently, $\xi \perp S_1 \cap \bar{S}_2^{\perp}$. In the same way we show that $\xi \perp \bar{S}_2 \cap S_1^{\perp}$, and therefore it follows from (4.23) that

$$\mathrm{E}^{S_1 \vee \bar{S}_2}\xi \in X_1 \vee X_2,$$

establishing (4.16). □

LEMMA 4.4. *Let $X \sim (S, \bar{S})$, $X_1 \sim (S_1, \bar{S}_1)$, and $X_2 \sim (S_2, \bar{S}_2)$ be minimal Markovian splitting subspaces such that $S_1 \subset S$ and $\bar{S}_2 \subset \bar{S}$, and let $x(0)$, $x_1(0)$, and $x_2(0)$ be a uniform choice of bases in X, X_1, and X_2 with covariances P, P_1, and P_2, respectively. Then*

$$E^{X_1 \vee X_2}x(0) = (I - L)x_1(0) + Lx_2(0) \tag{4.24}$$

for any $n \times n$ matrix solution L of the linear system of equations

$$P - P_1 = L(P_2 - P_1). \tag{4.25}$$

Proof. Setting $\hat{x}(0) := \mathrm{E}^{X_1 \vee X_2}x(0)$, we have

$$\hat{x}(0) = Kx_1(0) + Lx_2(0) \tag{4.26}$$

for some $n \times n$ matrices K and L. By construction, $a'[x(0) - \hat{x}(0)] \perp X_1 \vee X_2$ for all $a \in \mathbb{R}^n$, which in particular implies that

(i) $a'[x(0) - \hat{x}(0)] \perp X_1$ for all $a \in \mathbb{R}^n$,
(ii) $a'[x(0) - \hat{x}(0)] \perp X_2$ for all $a \in \mathbb{R}^n$.

Condition (i) together with (4.26) yields

$$\mathrm{E}\{x(0)x_1(0)'\} - KP_1 - L\mathrm{E}\{x_2(0)x_1(0)'\} = 0.$$

But from Lemma 4.2 it follows that

$$\mathrm{E}\{x_2(0)x_1(0)'\} = P_1 \quad \text{and} \quad \mathrm{E}\{x(0)x_1(0)'\} = P_1,$$

and therefore, since P_1 is nonsingular,

$$K = I - L. \tag{4.27}$$

In the same way, condition (ii) implies that

$$P = KP_1 + LP_2, \tag{4.28}$$

where again we have used Lemma 4.2 to see that

$$\mathrm{E}\{x(0)x_2(0)'\} = P \quad \text{and} \quad \mathrm{E}\{x_1(0)x_2(0)'\} = P_1.$$

Then (4.24) and (4.25) follow from (4.26)–(4.28).

To show that any solution L of (4.25) yields the same estimate $\hat{x}(0)$, let L_1 and L_2 be any two such solutions and let $\hat{x}_1(0)$ and $\hat{x}_2(0)$ be the corresponding estimates (4.26). Then

$$(L_1 - L_2)(P_2 - P_1) = 0 \tag{4.29}$$

and

$$\hat{x}_1(0) - \hat{x}_2(0) = (L_1 - L_2)\,[x_2(0) - x_1(0)]\,. \tag{4.30}$$

Equating the covariances of each side in (4.30), equation (4.29) implies that $\hat{x}_1(0) = \hat{x}_2(0)$, as claimed. □

This immediately yields the following representation formula for the interpolation estimate.

THEOREM 4.5. *Given the stochastic system* (4.1) *and* $t_0, t_1 \in \mathbb{Z}$ *such that* $t_0 < t_1$, *the state estimate*

$$\hat{x}(t \mid t_0, t_1) = E\{x(t) \mid y(s), s \in \mathbb{Z}; x(\tau), \tau \in (-\infty, t_0] \vee [t_1, \infty)\} \tag{4.31}$$

is given by

$$\hat{x}(t \mid t_0, t_1) = [I - L(t_0 - t, t_1 - t)]\, x^{(t_0 - t)}(t) + L(t_0 - t, t_1 - t) x^{(t_1 - t)}(t), \tag{4.32}$$

where $\{x^{(k)} \mid k \in \mathbb{Z}\}$ *is the estimation sequence* (4.6)–(4.7) *corresponding to* x *with covariances* $\{P^{(k)} \mid k \in \mathbb{Z}\}$ *and* $L(\tau, s)$ *is an arbitrary solution of*

$$P - P^{(\tau)} = L(\tau, s)\left[P^{(s)} - P^{(\tau)}\right]. \tag{4.33}$$

It remains to design a procedure for determining the estimation sequence $\{x^{(k)} \mid k \in \mathbb{Z}\}$. We shall address this question next. For this we need the following important consequence of the Markov property.

THEOREM 4.6. *The state estimate* (4.31) *depends only on the data from the interval* $[t_0, t_1]$ *or, more precisely, on* $x(t_0)$, $x(t_1)$, *and* $y(t)$, $t = t_0, t_0 + 1, \ldots, t_1$. *In particular,*

$$x^{(t_0 - t)}(t) := E\{x(t) \mid x(t_0), y(t_0), \ldots, y(t-1)\} \quad \textit{for } t > t_0, \tag{4.34}$$

$$x^{(t_1 - t)}(t) := E\{x(t) \mid y(t), \ldots, y(t_1), x(t_1)\} \quad \textit{for } t \le t_1, \tag{4.35}$$

where $\{x^{(k)}; k \in \mathbb{Z}\}$ *is the sequence of estimation processes defined by* (4.6) *and* (4.7).

Proof. Let $X \sim (S, \bar{S})$ be the splitting subspace corresponding to the state process x. In view of the definition (4.4), the first statement (4.34) is equivalent to

$$\mathrm{E}^{H^-_{k-1}(y) \vee X^-} \xi = \eta \quad \text{for all } \xi \in U^k X \text{ and } k \ge 0, \tag{4.36}$$

where

$$\eta := \mathrm{E}^{\{y(0),\dots,y(k-1)\}\vee X}\xi.$$

The original statement is obtained from (4.36) by merely applying the shift U^{t_0}. To prove (4.36) first note that, since $S = H^- \vee X^-$,

$$\begin{aligned} H_{k-1}^- \vee X^- &= \{y(0),\dots,y(k-1)\} \vee S \\ &= [\{y(0),\dots,y(k-1)\} \vee X] \oplus [S \ominus X]\,. \end{aligned}$$

To see this, note that $\{y(0),\dots,y(k-1)\} \subset H^+ \subset \bar{S} \perp S \ominus X$. Moreover, $\xi \in U^k X \subset U^k \bar{S} \subset \bar{S}$, and hence $\xi \perp S \ominus X$, which implies (4.36). A completely symmetric argument yields (4.35). □

Note that (4.34) and (4.35) are really forward and backward Kalman estimates initiated at $x(t_0)$ and $x(t_1)$, respectively, enabling us to use Kalman filtering techniques to generate them. Due to the fact that the initial conditions are states, these Kalman filters will have some remarkable properties, especially in the regular case when the reversibility condition (3.32) holds. This will be further discussed below.

The estimate (4.34) is generated by the recursion

$$\text{(4.37)}\quad \begin{cases} x^{(t_0-t)}(t) = Ax^{(t_0-t+1)}(t-1) + K^{(t_0-t)}\left[y(t-1) - Cx^{(t_0-t+1)}(t-1)\right], \\ x^{(0)}(t_0) = x(t_0), \end{cases}$$

where

$$K^{(-k)} = (\bar{C}' - AP^{(-k)}C')(\Lambda_0 - CP^{(-k)}C')^\sharp.$$

Here $^\sharp$ denotes pseudoinverse, and the state covariance

$$P^{(-k)} = \mathrm{E}\{x^{(-k)}(0)x^{(-k)}(0)'\}$$

is given by the matrix Riccati equation

$$\text{(4.38)}\quad \begin{cases} P^{(-k-1)} = AP^{(-k)}A' + (\bar{C}' - AP^{(-k)}C')(\Lambda_0 - CP^{(-k)}C')^\sharp(\bar{C}' - AP^{(-k)}C')', \\ P^{(0)} = P. \end{cases}$$

Note that this is the (invariant) formulation of the Kalman filter used in stochastic realization theory [1, 8, 16].

In the same way, the estimate (4.35) can be generated by a backward Kalman filter applied to the backward model

$$\text{(4.39)}\quad \begin{cases} \bar{x}(t-1) = A'\bar{x}(t) + \bar{B}\bar{u}(t-1), \\ y(t-1) = \bar{C}\bar{x}(t) + \bar{D}\bar{u}(t-1) \end{cases}$$

of X. Using a similar calculation as that in the forward direction, it is not hard to see that the process $\bar{x}^{(k)}(t) = [P^{(k)}]^{-1}x^{(k)}(t)$ is the solution of the backward Kalman filter

$$\text{(4.40)}\quad \begin{cases} \bar{x}^{(t_1-t)}(t) = A'\bar{x}^{(t_1-t-1)}(t+1) + \bar{K}^{(t_1-t-1)}\left[y(t) - \bar{C}\bar{x}^{(t_1-t-1)}(t)\right], \\ \bar{x}^{(0)}(t_1) = x(t_1), \end{cases}$$

where

$$\bar{K}^{(k)} = (C' - A'\bar{P}^{(k)}\bar{C}')(\Lambda_0 - \bar{C}\bar{P}^{(k)}\bar{C}')^\sharp$$

and the backward covariance matrix $\bar{P}^{(k)} = (P^{(k)})^{-1}$ is given by the matrix Riccati equation

$$\begin{cases} \bar{P}^{(k+1)} = A'\bar{P}^{(k)}A + (C' - A'\bar{P}^{(k)}\bar{C}')(\Lambda_0 - \bar{C}\bar{P}^{(k)}\bar{C}')^\sharp(C' - A'\bar{P}^{(k)}\bar{C}')', \\ \bar{P}^{(0)} = P^{-1}. \end{cases} \tag{4.41}$$

Then the process $x^{(t_1-t)}$ is given by

$$x^{(t_1-t)}(t) = (\bar{P}^{(t_1-t)})^{-1}\bar{x}^{(t_1-t)}(t),$$

defining $x^{(k)}$ for $k \geq 0$.

At least in the regular case, the inverse $(\Lambda_0 - CP^{(-k)}C')^{-1}$ will exist for all $k \in \mathbb{Z}$ (Proposition 3.11) and the pseudoinverses can be replaced with inverses. In the regular case we also have the reversibility property $\bar{\sigma} = \sigma^{-1}$ (Corollary 3.14) leading to (3.33). This useful property can be expressed in terms of estimation processes as

$$\mathrm{E}\{x(t) \mid H_{[t,t_1]}(y), x^{(t_0-t_1)}(t_1)\} = \mathrm{E}\{x(t) \mid H_{[t_0,t-1]}(y), x(t_0)\} = x^{(t_0-t)}(t), \tag{4.42}$$

i.e., tying together forward and backward estimation. This relation illustrates an important property of the Kalman recursions (4.37) and (4.40), namely, that a consecutive application of forward and backward Kalman filtering brings us back through the same sequence of state processes of totally ordered stochastic realizations. This remarkable fact, which is due to the invertibility of the operator σ, can also be justified by elementary calculations expressing $x^{(t_0-t+1)}(t-1)$ in terms of $x^{(t_0-t)}(t)$ and $y(t-1)$ in (4.37), leading to a backward Kalman filter which is an extension of (4.40) for negative $k = t_0 - t$. Similarly (4.40) can be reversed to give a forward Kalman filter identical to (4.37) for positive $k = t_1 - t$.

Given a stochastic realization (4.1) of y and a corresponding splitting subspace $X \sim (S, \bar{S})$, we have thus constructed a sequence of splitting subspaces $\{X^{(k)}; k \in \mathbb{Z}\}$ with bases

$$x^{(k)}(0) = \begin{cases} \mathrm{E}^{H^- \vee (U^k S)}x(0), & k \leq 0, \\ P^{(k)}P^{-1}\mathrm{E}^{H^+ \vee (U^k \bar{S})}x(0), & k \geq 0, \end{cases} \tag{4.43}$$

which are tied together by the Kalman filtering recursions (4.37) and (4.40). Each such basis vector defines a vector process

$$x^{(k)}(t) = U^k x^{(k)}(0),$$

which is the state process of a (forward) realization

$$\begin{cases} x^{(k)}(t+1) = Ax^{(k)}(t) + B^{(k)}u^{(k)}(t), \\ y(t) = Cx^{(k)}(t) + D^{(k)}u^{(k)}(t) \end{cases} \tag{4.44}$$

connected with a spectral factor

$$W^{(k)}(z) = C(zI - A)^{-1}B^{(k)} + D^{(k)}. \tag{4.45}$$

It is a manifestation of the fact that (4.43) is a uniform choice of bases for the splitting subspaces $\{X^{(k)} \mid k \in \mathbb{Z}\}$ in the sense defined in section 2, and it is also easy to check that the system matrices A and C remain constant for all $k \in \mathbb{Z}$, while $B^{(k)}$, $D^{(k)}$, and $P^{(k)}$ will vary. We shall not need to determine $\{B^{(k)}\}$ and $\{D^{(k)}\}$, but we note that this is easy to do either from the Riccati equation (4.37) or by means of a "fast algorithm" formulated directly in terms of $\{B^{(k)}, D^{(k)}\}$ as reported in Badawi [2].

Remark 4.7. Let us point out that the Riccati equation (4.38) can be written in the following form:

$$P^{(-k-1)} = P^{(-k)} - B^{(-k)}\{I - (D^{(-k)})'[D^{(-k)}(D^{(-k)})']^{\sharp}D^{(-k)}\}(B^{(-k)})'.$$

The last term is nothing other than the covariance matrix of that part of the noise in the state-space equation, i.e., of $B^{(-k)}u^{(-k)}$, which cannot be explained using the noise in the corresponding observation equation, i.e., via $D^{(-k)}u^{(-k)}$.

A similar statement can be formulated for the Riccati equation (4.41).

In the next section we show that, in the regular case, all spectral factors $\{W^{(k)} \mid k \in \mathbb{Z}\}$ have the same zeros, and in section 8 we demonstrate that this is no longer the case in the nonregular case.

5. The zero structure of the estimation sequence in the regular case. Let us recall that $\lambda \in \mathbb{C}$ is an *(invariant) zero* of a spectral factor

$$W(z) = C(zI - A)^{-1}B + D$$

if there are row vectors a and b so that

$$\begin{bmatrix} a & b \end{bmatrix} \begin{bmatrix} A - \lambda I & B \\ C & D \end{bmatrix} = 0$$

or, in other words,

$$\begin{bmatrix} a & b \end{bmatrix} \begin{bmatrix} A & B \\ C & D \end{bmatrix} = \begin{bmatrix} \lambda a & 0 \end{bmatrix}. \tag{5.1}$$

Here a is called a *zero direction* (of order one) of W. In the regular case, when $DD' > 0$, we may eliminate b in these equations to obtain

$$\begin{cases} a\Gamma = \lambda a, \\ aB_2 = 0, \end{cases}$$

where

$$\begin{aligned} \Gamma &:= A - BD'(DD')^{-1}C, \\ B_2 &:= B - BD'(DD')^{-1}D, \end{aligned}$$

showing that a is perpendicular to the reachability space

$$\langle \Gamma \mid B_2 \rangle = \operatorname{Im}(B_2, \Gamma B_2, \Gamma^2 B_2, \dots).$$

More generally, the zero directions (of any order) of W are defined using the Jordan structure of Γ. Then it can be proven that the orthogonal complement $\langle \Gamma \mid B_2 \rangle^{\perp}$ of this space in $\mathbb{R}^n$ is spanned by the *zero directions* of W. Hence, if Π is a matrix whose rows form a basis in $\langle \Gamma \mid B_2 \rangle^{\perp}$, i.e.,

$$\ker \Pi = \langle \Gamma \mid B_2 \rangle, \tag{5.2}$$

then there is a matrix Λ such that

$$\begin{cases} \Pi\Gamma = \Lambda\Pi, \\ \Pi B_2 = 0. \end{cases} \tag{5.3}$$

Conversely, if Π is a matrix satisfying (5.3), then

$$\ker \Pi \supset \langle \Gamma \mid B_2 \rangle. \tag{5.4}$$

This fact can also be expressed in terms of a generalization of (5.1): Relation (5.4) is equivalent to the existence of matrices Λ and M so that

$$\begin{bmatrix} \Pi & -M \end{bmatrix} \begin{bmatrix} A & B \\ C & D \end{bmatrix} = \begin{bmatrix} \Lambda\Pi & 0 \end{bmatrix}. \tag{5.5}$$

The row vectors of the maximal solution Π satisfying (5.2) (in the sense of having maximal rank) are the generalized zero directions, and the eigenvalues of the corresponding matrix Λ are of course precisely the finite zeros of W.

Remark 5.1. The matrix equation (5.5) is the appropriate generalization of (5.6) also in the nonregular case to be discussed in sections 7 and 8; see [20]. Note, however, that W may have zeros at infinity in the nonregular case, so the eigenvalues of Λ corresponding to the maximal solution of (5.5) are here the *finite* zeros of W.

The following lemma enables us to characterize the zero directions in terms of a connection between the state x and the output y.

LEMMA 5.2. *A matrix* Π *satisfies* (5.3) *if and only if there are matrices* Λ *and* M *such that*

$$\Pi x(t+1) = \Lambda\Pi x(t) + My(t). \tag{5.6}$$

We shall here give a proof which exhibits the connection between the Γ-matrix and the zero directions and which works in the present regular case. In section 8, we shall provide an alternative proof which also works in the nonregular case—in fact, even when the Γ-matrix cannot be defined.

Proof. As mentioned in the proof of Corollary 3.7, the state equation can be reformulated in the form

$$x(t+1) = \Gamma x(t) + BD'(DD')^{-1}y(t) + B_2u(t), \tag{5.7}$$

which, in the present regular case, is a unique decomposition of $x(t+1)$ in terms of $x(t)$, $y(t)$ and $B_2u(t)$. Hence

$$\Pi x(t+1) = \Pi\Gamma x(t) + \Pi BD'(DD')^{-1}y(t) + \Pi B_2u(t)$$

so that if Π satisfies (5.3), then (5.6) is also satisfied with $M = \Pi BD'(DD')^{-1}$. Conversely, if there are Λ and M so that (5.6) holds, then the uniqueness of decomposition (5.7) implies that (5.3) holds. ∎

Remark 5.3. Since Λ has no zero eigenvalues in the regular case, (5.6) may be written

$$\Pi P\bar{x}(t-1) = \Lambda^{-1}\Pi P\bar{x}(t) - \Lambda^{-1}My(t-1),$$

showing that the zeros of $\bar{W}(z^{-1})$ are precisely the eigenvalues of Λ^{-1}. Consequently, the forward and the backward models have the same zeros although the zero directions are transformed by the covariance matrix P. In fact, introducing the matrix

$$\bar{\Gamma} = A' - \bar{B}\bar{D}'(\bar{D}\bar{D}')^{-1}\bar{C},$$

the zeros of $\bar{W}$ are connected to the reciprocals of the eigenvalues of $\bar{\Gamma}$ in a manner analogous to (5.3).

Let us note the similarity between (5.6) and (3.4). In Theorem 3.1 we proved that (3.4) implies that $X \subset H_0$. In view of this, it is not surprising that (5.6) characterizes the subspace $X \cap H_0$. Recall that

$$X \cap H_0 = (X \cap X_-) \vee (X \cap X_+), \tag{5.8}$$

where the sum is direct if and only if $H^- \cap H^+ = 0$, i.e., if and only if

$$P_+ - P_- > 0 \tag{5.9}$$

[13, Lemma 2.9]. We note that $X \cap X_-$ is connected to the stable zeros of W (including the zeros on the unit circle) and that $X \cap X_+$ is connected to the antistable zeros (again including the zeros on the unit circle). If (5.9) holds, these sets of zeros are disjoint, there being no zeros on the unit circle.

As explained in [13], the subspaces $\ker(P - P_-)$ and $\ker(P_+ - P)$ are isomorphic to the subspaces $X \cap X_-$ and $X \cap X_+$, respectively, under the bijection $a \mapsto a'x(0)$. Based on these observations it can be proven that the zeros of W form a subset of those of W_- and $\bar{W}_+$. Let us collect the statements about the zeros of W in the following theorem. Proofs can be found in [13, 19, 29].

THEOREM 5.4. *The subspace* $\ker(P-P_-)$ *is invariant under* Γ'_- *and* Γ'. *Moreover,*

$$\Gamma'|_{\ker(P-P_-)} = \Gamma'_-|_{\ker(P-P_-)}. \tag{5.10}$$

The stable zeros of W *and* $\bar{W}$ *(including the ones on the unit circle) are the eigenvalues of* (5.10)*, and the corresponding zero directions of* W *span the subspace* $\ker(P - P_-)$. *Similarly,* $\ker(\bar{P} - \bar{P}_+)$ *is invariant under* $\bar{\Gamma}'_+$ *and* $\bar{\Gamma}'$. *Moreover,*

$$\bar{\Gamma}'|_{\ker(\bar{P}-\bar{P}_+)} = \bar{\Gamma}'_+|_{\ker(\bar{P}-\bar{P}_+)}. \tag{5.11}$$

The antistable zeros of W *and* $\bar{W}$ *(including the ones on the unit circle) are the reciprocals of the eigenvalues of* (5.11)*, and the corresponding zero directions of* $\bar{W}$ *span the subspace* $\ker(\bar{P} - \bar{P}_+)$.

Note that in the nonregular case, to be considered in sections 7 and 8, the matrix Γ may not be well defined for all X. Nevertheless all other statements of the theorem remain true.

To obtain coordinate-free versions of Γ' and $\bar{\Gamma}'$ we first observe that, in the regular case and with Π maximal so that $\ker \Pi = \langle \Gamma \mid B_2 \rangle$, (5.6) is equivalent to

$$U(X \cap H_0) \subset X \cap H_0 + \{y(0)\}, \tag{5.12}$$

where the sum is direct because of the regularity condition (iii)$'$ of Proposition 3.11. Similarly,

$$U^{-1}(X \cap H_0) \subset X \cap H_0 + \{y(-1)\}. \tag{5.13}$$

Now, following [13], let us introduce the *zero dynamics operators* in the regular case.

DEFINITION 5.5 (regular case). *Let the operators* $G : X \cap H_0 \to X \cap H_0$ *and* $\bar{G} : X \cap H_0 \to X \cap H_0$ *be defined as*

$$G = \pi U|_{X \cap H_0} \tag{5.14}$$

and

$$\bar{G} = \bar{\pi} U^{-1}|_{X \cap H_0}, \tag{5.15}$$

where $\pi : (X \cap H_0) + \{y(0)\} \to X \cap H_0$ *and* $\bar{\pi} : (X \cap H_0) + \{y(-1)\} \to X \cap H_0$ *are the oblique projectors projecting parallel to* $\{y(0)\}$ *and* $\{y(-1)\}$*, respectively.*

In view of Definition 5.5, (5.10) and (5.11) may be written

$$G|_{X \cap X_-} = G_-|_{X \cap X_-}$$

and

$$\bar{G}|_{X \cap X_+} = \bar{G}_+|_{X \cap X_+},$$

respectively. Moreover, $X \cap X_-$ is invariant under both G and G_-, and $X \cap X_+$ under both $\bar{G}$ and $\bar{G}_+$. In the nonregular case, the operators G and $\bar{G}$ may not be defined on all of $X \cap H_0$ but only on a subset of it, a circumstance manifest in the fact that Γ and $\bar{\Gamma}$ cannot be defined as above. However, G_- and $\bar{G}_+$ are always defined as in the regular case. This will be further discussed in section 7.

Let us now return to the estimation sequence $\{x^{(k)} \mid k \in \mathbb{Z}\}$. The following theorem ensures that no zeros are being lost when we move along the sequence $\{W^{(k)}\}$ from $k = 0$ through negative k.

THEOREM 5.6. *If* Π *is a matrix of zero directions of* $W^{(k)}$*, it is also a matrix of zero directions for* $W^{(k-j)}$ *for* $j = 0, 1, 2, \ldots$*. Moreover, the zeros are preserved.*

Proof. Since Π is a zero direction of $W^{(k)}$, there is a matrix Λ such that

$$\Pi\Gamma^{(k)} = \Lambda\Pi,$$

and therefore, in view of (5.7),

$$\Pi x^{(k)}(t) - \Lambda\Pi x^{(k)}(t-1) - \Pi K^{(k)} y(t-1) = 0, \tag{5.16}$$

because $B^{(k)}(D^{(k)})'[D^{(k)}(D^{(k)})']^{-1} = K^{(k)}$. Consequently, by (4.37),

$$\begin{aligned}
&\Pi x^{(k-1)}(t+1) - \Lambda\Pi x^{(k-1)}(t) - \Pi K^{(k-1)} y(t) \\
&\quad = \Pi\Gamma^{(k)} x^{(k)}(t) - \Lambda\Pi\Gamma^{(k)} x^{(k)}(t-1) - \Lambda\Pi K^{(k)} y(t-1) \\
&\quad = \Lambda \left[\Pi x^{(k)}(t) - \Lambda K^{(k)}(t-1) - \Pi K^{(k)} y(t-1) \right],
\end{aligned}$$

which is zero by (5.16). This together with (5.16) establishes that not only the zero directions but also the zeros are preserved, since the same matrix Λ can be used in each step. ∎

By symmetry we also have the following theorem.

THEOREM 5.6′. *If* $\bar{\Pi}$ *is a matrix of zero directions of* $W^{(k)}$*, it is also a matrix of zero directions for* $\bar{W}^{(k+j)}$ *for* $j = 0, 1, 2, \ldots$*. Moreover, the zeros are preserved.*

We observe that $W^{(k)}$ and $\bar{W}^{(k)}$ have the same zeros in view of Remark 5.3. Theorems 5.6 and 5.6′ show that there is no loss of zeros when we apply a forward or

backward Kalman filter step in (4.37) or (4.40). By the invertibility condition (3.32), all the elements in the sequence $\{W^{(k)} \mid k \in \mathbb{Z}\}$ must then have the *same* zeros. It is also easy to see that the zero directions are being preserved.

These results illustrate the fact that, in the regular case, all internal minimal splitting subspaces are fixed points of the operators σ and $\bar{\sigma}$. In fact, if X is internal, then so are σX and $\bar{\sigma} X$ by construction. Hence they have square spectral factors [16], which, by Theorems 5.6 and 5.6′, have the same zeros. Hence X, σX, and $\bar{\sigma} X$ must be the same. This analysis and the fact that in general there may be $X \in \mathfrak{X}_0$ which are not fixed points show that, in the nonregular case, the zeros may change as you move along the estimation sequence. The precise manner in which this happens is the topic of section 8.

Remark 5.7. Note that Theorem 5.6 and 5.6′ imply that in the regular case the stable and unstable zero directions, i.e., the subspaces $\ker(P^{(-k)} - P_-)$, $\ker(P_+ - P^{(-k)})$ and $\ker(\bar{P}^{(k)} - \bar{P}_+)$, $\ker(\bar{P}_+ - \bar{P}^{(k)})$, remain unchanged as k tends to ∞ in the forward and backward Riccati equations (4.38) and (4.41). In other words, the solutions of the Riccati recursions remain constant in the zero directions, providing a possibility of reducing the size of the Riccati equation. In fact, choosing coordinates so that the last basis vectors span

$$\ker(P^{(-k)} - P_-) \vee \ker(P_+ - P^{(-k)}) \subset \mathbb{R}^n,$$

the matrices $\{P^{(-k)}\}$ in the solution of the Riccati recursion (4.38) take the form

$$P^{(-k)} = \begin{bmatrix} P_{11}^{(-k)} & P_{12} \\ P_{12}' & P_{22} \end{bmatrix}, \tag{5.17}$$

where only the upper left matrix block varies with k. Then, substituting (5.17) into (4.38) we obtain a reduced-order Riccati equation of dimension $\nu \times \nu$ where $\nu = n - \dim(X \cap H_0)$. A completely symmetric argument can be applied to the backward Riccati recursion (4.41).

6. Output-induced subspaces. We have just seen that the matrices Γ and $\bar{\Gamma}$ play an important role in the analysis of the estimation sequence $x^{(k)}$. We have also pointed out that they are easily defined only in the regular case. Therefore, in this section we shall consider only their coordinate-free versions, G and $\bar{G}$, which have natural definitions in the general case.

In the regular case, considered in section 5, the zero dynamics operators G and $\bar{G}$ of a splitting subspace $X \in \mathfrak{X}$ were defined on all of its internal subspace $X \cap H_0$. This is possible due to the direct sum decompositions (5.12) and (5.13). In the nonregular case these decompositions will fail to exist as we demonstrate in section 7. Therefore, we must shrink the domains of the zero dynamics operators.

As demonstrated in [29], G can always be defined on $X \cap X_-$, yielding only the stable zeros (including those on the unit circle), and $\bar{G}$ can always be defined on $X \cap X_+$, producing only the antistable zeros (including those on the unit circle and those at infinity). In fact, this can also be seen from the following representations. (Also see [29, Lemma 5.1].)

LEMMA 6.1. *Let* $X \in \mathfrak{X}$. *Then*

$$U^{-1}(X \cap X_+) \subset (X \cap X_+) + \{y(-1)\} \tag{6.1}$$

and

$$U(X \cap X_-) \subset (X \cap X_-) + \{y(0)\}. \tag{6.2}$$

Proof. We prove (6.2). Then (6.1) follows by symmetry. Obviously,

$$U(X \cap X_-) \subset UX_- \subset H^- \vee \{y(0)\}.$$

Also $X \cap X_- \subset \bar{S} \cap \bar{S}_-$, which is U-invariant. Therefore,

$$U(X \cap X_-) \subset (H^- \vee \{y(0)\}) \vee (\bar{S} \cap \bar{S}_-).$$

But $\{y(0)\} \subset H^+ \subset \bar{S} \cap \bar{S}_-$ and $H^- \cap \bar{S} \cap \bar{S}_- = X \cap X_-$, implying (6.2). ∎

In this paper, however, we would like to define G and $\bar{G}$ on the largest possible spaces. We show that this can be done in such a way that the eigenvalues of G are precisely the finite zeros of X, and the eigenvalues of $\bar{G}$ are the reciprocals of the nonzero zeros of X (using the definition $1/\infty = 0$). Moreover, we want to know on which subspaces G and $\bar{G}$ are invertible so that they can be directly related to each other. This leads to the topic of *output-induced subspaces*, introduced in [13] in the continuous-time setting. We now define it in the discrete-time case. Since, in the nonregular discrete-time case, the covariance matrix of the observation noise of the model (4.1) may be singular, the definition used in the continuous-time case must be somewhat modified.

DEFINITION 6.2. *Let X be a Markovian splitting subspace. A subspace $Y \subset X$ is called* output induced *if*

(i) $Y \subset H_0$,

(ii) $UY \subset Y \vee \{y(0), y(1), \dots, y(k)\}$ *for some* $k \geq 0$,

(iii) $U^{-1}Y \subset Y \vee \{y(-1), y(-2), \dots, y(-k-1)\}$ *for some* $k \geq 0$.

We say that Y is strictly output induced *if it is output induced and k can be chosen to be zero in* (ii) *and* (iii).

The following proposition is an immediate consequence of the definition and the finite dimension of X.

PROPOSITION 6.3. *The sum of two output-induced (strictly output-induced) subspaces is also output induced (strictly output induced). There exist a maximal output-induced (strictly output-induced) subspace in the sense of subspace inclusion.*

Since any output-induced subspace Y satisfies

$$Y \subset X \cap H_0 = (X \cap X_-) \vee (X \cap X_+),$$

let us first consider the subspaces $X \cap X_-$ and $X \cap X_+$. These, of course, trivially satisfy condition (i), and, by Lemma 6.1, they also satisfy one of the conditions (ii) and (iii) with $k = 0$, as required in the definition of being strictly output induced. Next, we show that these subspaces also satisfy the remaining condition so that they are output induced, and we investigate under what conditions they are actually strictly output induced.

THEOREM 6.4. *Let $X \in \mathcal{X}$. Then the subspaces $X \cap X_+$ and $X \cap X_-$ are output induced. Moreover, $X \cap X_+$ is strictly output induced if and only if*

$$(\sigma X) \cap X_+ = X \cap X_+, \tag{6.3}$$

and $X \cap X_-$ is strictly output induced if and only if

$$(\bar{\sigma} X) \cap X_- = X \cap X_-. \tag{6.4}$$

Proof. First we prove that $X \cap X_+$ is output induced. To this end, in view of (6.1), it is enough to check that there exists a $k \leq \dim X$ such that

$$U(X \cap X_+) \subset (X \cap X_+) \vee \{y(0), y(1), \dots, y(k)\}. \tag{6.5}$$

Since

$$X \cap X_+ = X_{0-} \cap X_+,$$

where X_{0-} is the tightest lower internal bound [18, 13], we may without loss of generality assume that X is internal. By Theorem 3.3, there is a $k \leq \dim X$ such that

$$\sigma^k X = \sigma^{k+1} X.$$

Consequently,

$$U^{-k} S \subset S^{(-k)} \subset S^{(-k-1)} = H^- \vee (U^{-(k+1)} S),$$

from which we have

$$US \subset S \vee U^{k+1} H^-.$$

Taking intersection with H^+ in both sides and noting that $U(S \cap H^+) \subset (US) \cap H^+$, we have

$$\begin{aligned} U(S \cap H^+) &\subset [S \vee \{y(0), \dots, y(k)\}] \cap H^+ \\ &= (S \cap H^+) \vee \{y(0), \dots, y(k)\}. \end{aligned}$$

Then (6.5) follows from the fact that $X \cap X_+ = S \cap H^+$. In the same way, we prove that there is an $\ell \leq \dim X$ such that

$$U^{-1}(X \cap X_-) \subset (X \cap X_-) \vee \{y(-1), y(-2), \dots, y(-\ell - 1)\}, \tag{6.6}$$

implying together with (6.2) that $X \cap X_-$ is output induced.

To characterize the strictly output-induced property we prove that

$$(\sigma X) \cap X_+ = (X \cap X_+) \cap \left[\{y(-1)\} \vee U^{-1}(X \cap X_+)\right] \tag{6.7}$$

and that

$$(\bar{\sigma} X) \cap X_- = (X \cap X_-) \cap \left[\{y(0)\} \vee U(X \cap X_-)\right]. \tag{6.8}$$

To this end, let $X \sim (S, \bar{S})$, and note that $S^{(-1)} := H^- \vee U^{-1} S \subset S$. Hence

$$\begin{aligned} (\sigma X) \cap X_+ &= S^{(-1)} \cap X_+ = S^{(-1)} \cap S \cap X_+ \\ &= S^{(-1)} \cap X \cap X_+ = \left[\{y(-1)\} \vee U^{-1} S\right] \cap X \cap X_+ \end{aligned}$$

But since $U^{-1} S = U^{-1} X \oplus U^{-1} \bar{S}^\perp$ and $\{y(-1)\} \subset U^{-1} \bar{S} \perp U^{-1} \bar{S}^\perp$,

$$\begin{aligned} (\sigma X) \cap X_+ &= \left[(\{y(-1)\} \vee U^{-1} X) \oplus U^{-1} \bar{S}^\perp\right] \cap X \cap X_+ \\ &= (\{y(-1)\} \vee U^{-1} X) \cap X \cap X_+, \end{aligned}$$

because $X_+ \subset \bar{S} \subset U^{-1} \bar{S} \perp U^{-1} \bar{S}^\perp$. Moreover, if $\xi \in (\{y(-1)\} \vee U^{-1} X) \cap X_+$, then $\xi = \alpha + \beta$, where $\alpha \in \{y(-1)\} \subset U^{-1} H^+$ and $\beta \in U^{-1} X$. Since $\xi \in H^+ \subset U^{-1} H^+$, we must have $\beta \in U^{-1} H^+$ so that $\beta \in U^{-1}(X \cap H^+) = U^{-1}(X \cap X_+)$. Therefore (6.7) follows. A symmetric argument yields (6.8).

Now, (6.7) and (6.8) immediately imply that

$$(\sigma X) \cap X_+ = X \cap X_+ \iff U(X \cap X_+) \subset (X \cap X_+) \vee \{y(0)\} \tag{6.9}$$

and

$$(\bar{\sigma} X) \cap X_- = X \cap X_- \iff U^{-1}(X \cap X_-) \subset (X \cap X_-) \vee \{y(-1)\}, \tag{6.10}$$

concluding the proof. □

COROLLARY 6.5. *The subspace $X \cap H_0$ is the maximal output-induced subspace of $X \in \mathcal{X}$.*

Proof. This follows immediately from Theorem 6.4 and (5.8). □

COROLLARY 6.6. *The subspace $X_- \cap X_+$ is always strictly output induced.*

Proof. This follows either from Lemma 6.1 or from (6.3) and the fact that $\sigma X_- = X_-$. □

We are now in a position to connect the concept strictly output-induced subspaces to fixed points of σ and $\bar{\sigma}$.

COROLLARY 6.7. *An $X \in \mathcal{X}_0$ is a fixed point of σ if and only if $X \cap X_+$ is strictly output induced. Likewise, $X \in \mathcal{X}_0$ is a fixed point of $\bar{\sigma}$ if and only if $X \cap X_-$ is strictly output induced.*

Proof. In the end of the proof of Theorem 3.3 we pointed out that the internal Markovian splitting subspaces are uniquely determined by $X \cap X_+$. Observe that if $X \in \mathcal{X}_0$, then $\sigma X \in \mathcal{X}_0$. Consequently, Theorem 6.4 implies that $\sigma X = X$ if and only if $X \cap X_+$ is strictly output induced, and the rest follows by a symmetric argument. □

As we shall see in section 8, these conditions can be formulated in terms of the stable and unstable zeros of the spectral factor (1.2) corresponding to the splitting subspace X.

The notion of strictly output-induced subspaces enables us in some cases to characterize the limits $X^{(-\infty)}$ and $X^{(\infty)}$ of the sequence $\{X^{(k)} \mid k \in \mathbb{Z}\}$ defined in section 3. To this end, let us recall [18] that the *tightest internal bounds*, X_{0-} and X_{0+}, are the closest internal X such that

$$X_{0-} \leq X \leq X_{0+}.$$

More precisely,

$$X_{0-} := \sup\{X_0 \in \mathcal{X}_0 \mid X_0 \leq X\}$$

and

$$X_{0+} := \inf\{X_0 \in \mathcal{X}_0 \mid X \leq X_0\}.$$

COROLLARY 6.8. *Let $X \in \mathcal{X}$, and let X_{0-} and X_{0+} be its tightest internal bounds. Then*

$$X^{(-\infty)} = X_{0-}$$

if and only if $X \cap X_+$ is strictly output induced, and

$$X^{(\infty)} = X_{0+}$$

if and only if $X \cap X_-$ is strictly output induced.

Proof. Let us first recall that

$$S_{0-} = S \cap H_0 = H^- \vee (X \cap X_+)$$

(cf. [18, Lemma 6.11], [13]). Therefore Theorem 6.4 implies that X_{0-} is the lower tightest internal bound of σX also if and only if $X \cap X_+$ is strictly output induced. By induction, we then have that $\sigma^{-k}X \geq X_{0-}$ for $k = 0, 1, 2, \dots$ and hence that $X^{(-\infty)} \geq X_{0-}$. But $X^{(-\infty)} \in \mathfrak{X}_0$ (Theorem 3.3), and consequently $X^{(-\infty)} = X_{0-}$ follows from the tightness of the bound. The proof for the upper bound is analogous. □

Another consequence of Theorem 6.4 is that the splitting subspaces in the sequence $\{X^{(k)} \mid k \in \mathbb{Z}\}$ have the same tightest local frame [18] if and only if the internal subspace $X \cap H_0$ is strictly output induced. As we shall see in the next section, this is only true in the regular case.

COROLLARY 6.9. *A necessary and sufficient condition for all splitting subspaces in the family $\{X^{(k)} \mid k \in \mathbb{Z}\}$ to have the same tightest internal bounds is that $X \cap H_0$ is strictly output induced.*

Proof. The proof follows immediately from Corollary 6.8, Proposition 6.3, and (5.8). □

Theorem 6.4 also yields the following alternative characterizations of regularity.

COROLLARY 6.10. *The following conditions are equivalent to the regularity conditions of Propositions* 3.11 *and* 3.11′.

(vii) *X_+ is strictly output induced.*
(viii) *X_- is strictly output induced.*
(vii)′ *$X \cap X_+$ is strictly output induced for all $X \in \mathfrak{X}_0$.*
(viii)′ *$X \cap X_-$ is strictly output induced for all $X \in \mathfrak{X}_0$.*
(ix)′ *All $X \in \mathfrak{X}_0$ are strictly output induced.*
(x)′ *The internal subspace $X \cap H_0$ is strictly output induced for all $X \in \mathfrak{X}$.*

Proof. By Corollary 6.7, (vii)′ and (viii)′ are equivalent to conditions (v)′ and (vi)′ of Proposition 3.11′, and (vii) and (viii) are equivalent to conditions (v) and (vi) of Proposition 3.11. In view of Proposition 6.3, (ix)′ follows from (vii)′, (viii)′ and (3.13), and (x)′ follows from (vii)′, (viii)′, and (5.8). Clearly either (vii) or (viii) implies (ix)′ and (x)′. □

7. Invariant directions and the maximal strictly output-induced subspace. Proposition 6.3 states that, to each $X \in \mathfrak{X}$, there exists a maximal strictly output-induced subspace Y^*. In this section we construct Y^* explicitly. Let us recall that $Y \subset X \cap H_0$ is said to be strictly output induced if

$$UY \subset Y \vee \{y(0)\} \tag{7.1}$$

and

$$U^{-1}Y \subset Y \vee \{y(-1)\}. \tag{7.2}$$

To determine Y^*, we first construct the subspaces $Y, \bar{Y} \subset X \cap H_0$ satisfying (7.1) and (7.2), respectively, which are maximal in the sense of subspace inclusion and show that Y^* is precisely the intersection of these.

To this end, we design a procedure which is akin to the one used in geometric control theory [31] to construct the maximal output-nulling subspace. More precisely, define two sequences of subspaces $\{Y_0, Y_1, Y_2, \dots\}$ and $\{\bar{Y}_0, \bar{Y}_1, \bar{Y}_2, \dots\}$ by

$$Y_k = (\sigma^k X) \cap X \cap H_0 \tag{7.3}$$

and

$$\bar{Y}_k = (\bar{\sigma}^k X) \cap X \cap H_0 \tag{7.4}$$

and show that they converge monotonically to Y and $\bar{Y}$, respectively, in finitely many steps. As will be seen below these are precisely the largest spaces on which the zero dynamics operators may be defined. Obviously, $Y_0 = \bar{Y}_0 = X \cap H_0$. We now give alternative characterizations of these sequences and obtain iterative solutions of (7.1) and (7.2), respectively.

LEMMA 7.1. *For each $k = 1, 2, 3, \ldots$ the subspaces* (7.3) *and* (7.4) *can be written*

$$Y_k = \{\xi \in X \cap H_0 \mid U^k \xi \in (X \cap H_0) \vee \{y(0), \ldots, y(k-1)\}\} \tag{7.5}$$

and

$$\bar{Y}_k = \{\xi \in X \cap H_0 \mid U^{-k} \xi \in (X \cap H_0) \vee \{y(-1), \ldots, y(-k)\}\}, \tag{7.6}$$

respectively. Moreover, the sequences $\{Y_k\}$ and $\{\bar{Y}_k\}$ satisfy the recursions

$$Y_{k+1} = \{\xi \in Y_k \mid U\xi \in Y_k \vee \{y(0)\}\} \tag{7.7}$$

and

$$\bar{Y}_{k+1} = \{\xi \in \bar{Y}_k \mid U^{-1}\xi \in \bar{Y}_k \vee \{y(-1)\}\} \tag{7.8}$$

for $k = 1, 2, 3, \ldots$.

Proof. We prove only (7.5) and (7.7), (7.6) and (7.8) following by a symmetric argument.

To prove (7.5), observe that

$$\sigma^k X = \mathrm{E}^{(U^{-k}S) \vee H^-} X \subset U^{-k} X \vee \{y(-1), \ldots, y(-k)\} \tag{7.9}$$

in view of the decomposition

$$(U^{-k}S) \vee H^- = \left[(U^{-k}X) \vee \{y(-1), \ldots, y(-k)\}\right] \oplus U^{-k}\bar{S}^\perp$$

and the fact that $U^{-k}\bar{S}^\perp \subset \bar{S}^\perp \perp X$.

Consequently, if $\xi \in Y_k$, then $\xi \in X \cap H_0$ and

$$U^k \xi \in [X \vee \{y(0), \ldots, y(k-1)\}] \cap H_0 = (X \cap H_0) \vee \{y(0), \ldots, y(k-1)\}.$$

Conversely, if $\xi \in X \cap H_0$ and $U^k \xi \in (X \cap H_0) \vee \{y(0), \ldots, y(k-1)\}$, then

$$\mathrm{E}^{(U^{-k}S) \vee H^-} \xi = \mathrm{E}^{(U^{-k}X) \vee \{y(-1), \ldots, y(-k)\}} \xi = \xi,$$

proving that $\xi \in \sigma^k X$ so that $\xi \in Y_k$.

Concerning the proof of (7.7), first consider a $\xi \in Y_k$ such that $U\xi \in Y_k \vee \{y(0)\}$. By (7.5) we have

$$\begin{aligned} U^{k+1}\xi = U^k(U\xi) &\in U^k Y_k \vee \{y(k)\} \\ &\subset (X \cap H_0) \vee \{y(0), \ldots, y(k)\}, \end{aligned}$$

proving that $\xi \in Y_{k+1}$, as can be seen from (7.5).

Conversely, if $\xi \in Y_{k+1}$, then (7.5) implies that $U^{k+1}\xi$ has the representation

$$U^{k+1}\xi = \zeta + \lambda_0 + \lambda_1,$$

where $\zeta \in X \cap H_0$, $\lambda_0 \in \{y(0), \dots, y(k-1)\}$ and $\lambda_1 \in \{y(k)\}$. We want to prove that $U\xi - U^{-k}\lambda_1 \in Y_k$, which implies (7.7). To this end, we note that

$$U\xi - U^{-k}\lambda_1 = U^{-k}\zeta + U^{-k}\lambda_0.$$

The left member of this belongs to $\bar{S}$, while the right member belongs to S, implying that they are in X and hence in $X \cap H_0$. Moreover, in view of (7.5), the identity

$$U^k(U\xi - U^{-k}\lambda_1) = \zeta + \lambda_0$$

implies that $U\xi - U^{-k}\lambda_1 \in Y_k$ concluding the proof of (7.7). □

An immediate consequence of Lemma 7.1 is that

$$X \cap H_0 = Y_0 \supset Y_1 \supset Y_2 \supset \cdots \tag{7.10}$$

and that

$$UY_{k+1} \subset Y_k \vee \{y(0)\}. \tag{7.11}$$

Dually, we also have

$$X \cap H_0 = \bar{Y}_0 \supset \bar{Y}_1 \supset \bar{Y}_2 \supset \cdots \tag{7.12}$$

and

$$U^{-1}\bar{Y}_{k+1} \subset \bar{Y}_k \vee \{y(-1)\}. \tag{7.13}$$

Since $X \cap H_0$ is finite dimensional, the chain of inclusions (7.10) implies that there is a $k \leq \dim(X \cap H_0)$ such that $Y_{k+1} = Y_k$. Then (7.7) implies that $Y_\ell = Y_k$ for all $\ell \geq k$. Since $\dim(X \cap H_0) \leq \dim X := n$, we may refer to this subspace as Y_n. Clearly

$$UY_n \subset Y_n \vee \{y(0)\}.$$

Similarly, $\bar{Y}_n$ is the limit of $\{\bar{Y}_k\}$ and satisfies

$$U^{-1}\bar{Y}_n \subset \bar{Y}_n \vee \{y(-1)\}.$$

THEOREM 7.2. *The subspace Y_n is the maximal subspace of $X \cap H_0$ with the property*

$$UY \subset Y \vee \{y(0)\}, \tag{7.14}$$

and $\bar{Y}_n$ is the maximal subspace in $X \cap H_0$ such that

$$U^{-1}\bar{Y} \subset \bar{Y} \vee \{y(-1)\}. \tag{7.15}$$

In the regular case, $Y_n = \bar{Y}_n = X \cap H_0$.

Proof. We have already proved that Y_n and $\bar{Y}_n$ satisfy (7.14) and (7.15), respectively. To prove maximality, consider a $Y \subset X \cap H_0 = Y_0$ satisfying (7.14). We prove

by induction that $Y \subset Y_k$ for $k = 0, 1, 2, \ldots$. To this end, assume that $Y \subset Y_i$ and show that $Y \subset Y_{i+1}$. If $\xi \in Y$, then

$$U\xi \in Y \vee \{y(0)\} \subset Y_i \vee \{y(0)\}.$$

Consequently, in view of (7.7), $\xi \in Y_{i+1}$, as claimed. The maximality of $\bar{Y}_n$ is proven in the same way. The last statement follows from (5.12) and (5.13). □

Remark 7.3. Applying the orthogonal projection operator E^X to (7.14), we obtain

$$FY \subset Y \vee \mathrm{E}^X\{y(0)\}, \tag{7.16}$$

where F is the compressed shift operator $F := \mathrm{E}^X U|_X$. From the systems equations (1.1) one can infer that F has the matrix representations A' in the corresponding basis and that $\mathrm{E}^X\{y(0)\}$ has the matrix representations C'. Therefore, analogously to the continuous-time case [13], (7.16) is a stochastic version of (A', C')-invariance in geometric control theory [31, 4]. This connection to geometric control theory is elaborated upon in [29]. In this context, we note that a similar application of E^X to (7.11) yields

$$FY_{k+1} \subset Y_k \vee \mathrm{E}^X\{y(0)\},$$

which should be compared to the algorithm in geometric control theory to determine the maximal output-nulling subspace $\mathcal{V}^*$.

Now, referring back to the regular case and (5.12) and (5.13), we recall that, in this case, $X \cap H_0$ satisfies (7.14) and (7.15) with direct sum. This enabled us to define the operators G and $\bar{G}$. In the general case $X \cap H_0 \cap \{y(0)\}$ and $X \cap H_0 \cap \{y(-1)\}$ may be nontrivial subspaces. Nevertheless, as we will prove below, Y_n and $\bar{Y}_n$ satisfy (7.14) and (7.15) with direct sum decomposition in the right member. This requires a deeper analysis of so-called *invariant directions* of a system representation (1.1) of X [5, 25, 26, 22].

More precisely, there are two kinds of invariant directions. An $a \in \mathbb{R}^n$ is a *predictable direction* if there is a positive integer k such that

$$a'x(0) \in \{y(-1), y(-2), \ldots, y(-k)\}. \tag{7.17}$$

The smallest k with this property is called the *order* of the invariant direction a. If a satisfies (7.17), the Kalman filter estimate $\hat{x}$ takes the form

$$a'\hat{x}(t) = a'x(t) = \sum_{i=1}^{r} c_i' y(t-i)$$

in that direction so that the estimation error becomes zero. This manifests itself in that the filtering Riccati equation can be reduced in dimension after a finite number of steps. A similar reduction occurs in the fast filtering algorithm [11]; see in particular [12]. It can be shown [22] that a is a predictable direction if and only if, for some $k \geq 0$,

$$a \in \ker(\Gamma_-')^k \cap \ker(P - P_-). \tag{7.18}$$

Dually, $a \in \mathbb{R}^n$ is a *smoothable direction* if there is a positive integer k such that

$$a'\bar{x}(0) \in \{y(0), y(1), \ldots, y(k-1)\}, \tag{7.19}$$

causing a reduction in the backward Kalman filtering algorithms. Again the smallest k with this property is the order of the invariant direction a, and

$$a \in \ker(\bar{\Gamma}'_+)^k \cap \ker(P_+ - P) \tag{7.20}$$

for some k is a necessary and sufficient condition for a to be a smoothable direction.

It can be seen from (7.18) and (7.20) that the order of an invariant direction cannot be larger than the dimension of X. Although the definition of invariant directions depends on the particular choice of coordinates in X, $a'x(0)$ and $a'\bar{x}(0)$ in the definitions (7.17) and (7.19) are independent of the coordinate system. Therefore we shall refer to these elements of X as the invariant directions of X.

Now, let $H^\square$ be the *frame space*

$$H^\square = X_- \vee X_+, \tag{7.21}$$

i.e., the closed linear hull of all internal subspaces $X \cap H_0$ as X ranges over $\mathfrak{X}$, and define the subspace

$$H_{0+} = H^\square \cap \{y(-n), \dots, y(n-1)\}.$$

In analogy with the continuous-time case [7], H_{0+} is called the *germ space* [22], since it contains all differences of y up to order n at $t = 0$.

PROPOSITION 7.4. *The germ space has the direct sum decomposition*

$$H_{0+} = X_- \cap \{y(-1), \dots, y(-n)\} + X_+ \cap \{y(0), \dots, y(n-1)\}. \tag{7.22}$$

Moreover, X_- contains no smoothable and X_+ no predictable directions.

Proof. The inclusion $\supset$ is trivial. To prove the other direction, note that, since y is purely nondeterministic, the two terms in (7.22) have a zero intersection, and every $\xi \in H_{0+}$ has a unique representation $\xi = \xi_- + \xi_+$ such that $\xi_- \in \{y(-1), \dots, y(-n)\} \subset H^-$ and $\xi_+ \in \{y(0), \dots, y(n-1)\} \subset H^+$. But in view of decomposition (4.20), ξ_- has an orthogonal decomposition $\xi_- = \hat{\xi}_- + \tilde{\xi}_-$ such that $\hat{\xi}_- \in X_-$ and $\tilde{\xi}_- \in H^- \cap (H^+)^\perp$, and ξ_+ can be written $\xi_+ = \hat{\xi}_+ + \tilde{\xi}_+$, where $\hat{\xi}_+ \in X_+$ and $\tilde{\xi}_+ \in H^+ \cap (H^-)^\perp$. Therefore, since

$$H_0 = \left[H^- \cap (H^+)^\perp\right] \oplus H^\square \oplus \left[H^+ \cap (H^-)^\perp\right],$$

the fact that $\xi = \tilde{\xi}_- + (\hat{\xi}_- + \hat{\xi}_+) + \tilde{\xi}_+ \in H^\square$ shows that $\tilde{\xi}_- = \tilde{\xi}_+ = 0$. Hence $\xi_- \in X_-$ and $\xi_+ \in X_+$, establishing the inclusion $\subset$. □

Consequently, the germ space is spanned by the predictable invariant directions in X_- and the smoothable invariant directions in X_+. Moreover, y is regular if and only if it has a trivial germ space.

PROPOSITION 7.5. *Let $X \in \mathfrak{X}$. Then*

$$X \cap H_{0+} = X \cap \{y(-1), \dots, y(-n)\} + X \cap \{y(0), \dots, y(n-1)\}; \tag{7.23}$$

i.e., $X \cap H_{0+}$ is spanned by the invariant directions of X. Moreover,

$$X \cap \{y(-1), \dots, y(-n)\} \subset X_- \cap \{y(-1), \dots, y(-n)\} \tag{7.24}$$

and

$$X \cap \{y(0), \dots, y(n-1)\} \subset X_+ \cap \{y(0), \dots, y(n-1)\}. \tag{7.25}$$

Proof. Let $X \sim (S, \bar{S})$. Relations (7.24) and (7.25) follow from the fact that $X \cap H^- = X \cap X_-$ and that $X \cap H^+ = X \cap X_+$, respectively. In view of this and Proposition 7.4, the inclusion $\supset$ in (7.23) is immediate. To prove $\subset$, take $\xi \in X \cap H_{0+}$. By Proposition 7.4, there is a unique decomposition $\xi = \xi_- + \xi_+$ such that $\xi_- \in X_- \cap \{y(-1), \dots, y(-n)\}$ and $\xi_+ \in X_+ \cap \{y(0), \dots, y(n-1)\}$. Hence it just remains to prove that $\xi_- \in X$ and $\xi_+ \in X$. To this end, note that $\xi_- \in H^- \subset S$ and $\xi \in X \subset S$, so we must have $\xi_+ \in S$. But $\xi_+ \in H^+ \subset \bar{S}$, so $\xi_+ \in S \cap \bar{S} = X$. Since $\xi \in X$, we must have $\xi_- \in X$ also. ∎

We have thus proved that all invariant directions of X_- are predictable and all the invariant directions of X_+ are smoothable, while an arbitrary X can have invariant directions of either kind. In view of (7.18), the predictable directions of X are also among the predictable directions of X_-. In the same way, (7.20) implies that the smoothable directions of X form a subspace of the smoothable directions of X_+ [22]. We call $X \cap \{y(-1), \dots, y(-n)\}$ the *predictable subspace* and $X \cap \{y(0), \dots, y(n-1)\}$ the *smoothable subspace* of X.

THEOREM 7.6. *Let $X \in \mathfrak{X}$. Then we have the following.*

(i) *The internal subspace $X \cap H_0$ of X has the direct-sum decomposition*

$$X \cap H_0 = Y_n + X \cap \{y(0), \dots, y(n-1)\}. \tag{7.26}$$

Moreover,

$$X \cap X_- \subset Y_n. \tag{7.27}$$

In particular, Y_n contains the predictable directions $X \cap \{y(-1), \dots, y(-n)\}$ of X.

(ii) *The internal subspace $X \cap H_0$ of X has the direct-sum decomposition*

$$X \cap H_0 = \bar{Y}_n + X \cap \{y(-1), \dots, y(-n)\}. \tag{7.28}$$

Moreover,

$$X \cap X_+ \subset \bar{Y}_n. \tag{7.29}$$

In particular, $\bar{Y}_n$ contains the smoothable directions $X \cap \{y(0), \dots, y(n-1)\}$ of X.

(iii) *The maximal strictly output-induced subspace of X is given by*

$$Y^* = Y_n \cap \bar{Y}_n. \tag{7.30}$$

Moreover,

$$Y_n = Y^* + X \cap \{y(-1), \dots, y(-n)\} \tag{7.31}$$

and

$$\bar{Y}_n = Y^* + X \cap \{y(0), \dots, y(n-1)\}. \tag{7.32}$$

In the regular case, $Y^* = X \cap H_0$ for all $X \in \mathfrak{X}$.

This theorem, the proof of which we defer to the end of the section, shows in particular that the internal subspace $X \cap H_0$ can be decomposed as

$$X \cap H_0 = X \cap \{y(-1), \dots, y(-n)\} + Y^* + X \cap \{y(0), \dots, y(n-1)\}, \tag{7.33}$$

i.e., as the direct sum of the subspace of predictable directions, the maximal strictly output-induced subspace, and the subspace of smoothable directions of X. In view

of Proposition 7.5, $X \cap H_0$ is also the direct sum of Y^* and the germ subspace of X, i.e.,

$$X \cap H_0 = Y^* + X \cap H_{0+}. \tag{7.34}$$

This has the following consequence.

COROLLARY 7.7. *The process y is regular if and only if no $X \in \mathfrak{X}$ has invariant directions.*

Remark 7.8. An immediate consequence of the definitions of Y_n, $\bar{Y}_n$, and Y^* is that

$$Y^* \subset Y_n \subset (\sigma^k X) \cap H_0 \quad \text{and} \quad Y^* \subset \bar{Y}_n \subset (\bar{\sigma}^k X) \cap H_0$$

for all $k = 0, 1, 2, \dots$, showing that the maximal strictly output-induced subspace of any $X \in \mathfrak{X}$ is contained in each of the internal subspaces of the corresponding sequence of splitting subspaces $\{X^{(k)}; k \in \mathbb{Z}\}$.

From Theorems 7.2 and 7.6(i) we also have the following corollary.

COROLLARY 7.9. *The following inclusions hold:*

$$UY_n \subset Y_n + \{y(0)\}, \tag{7.35}$$

$$U^{-1}\bar{Y}_n \subset \bar{Y}_n + \{y(-1)\}. \tag{7.36}$$

Let us recall that, in the regular case, (5.12) and (5.13) enabled us to define the zero dynamics operators G and $\bar{G}$ on all of the internal subspace $X \cap H_0$ of $X \in \mathfrak{X}$. In the general case, Corollary 7.9 provides the appropriate counterparts of (5.12) and (5.13).

DEFINITION 7.10 (general case). *Let the zero dynamics operators $G : Y_n \to Y_n$ and $\bar{G} : \bar{Y}_n \to \bar{Y}_n$ be defined as*

$$G = \pi U|_{Y_n} \tag{7.37}$$

and

$$\bar{G} = \bar{\pi} U^{-1}|_{\bar{Y}_n}, \tag{7.38}$$

where $\pi : Y_n + \{y(0)\} \to Y_n$ and $\bar{\pi} : \bar{Y}_n + \{y(-1)\} \to \bar{Y}_n$ are the oblique projectors projecting parallel to $\{y(0)\}$ and $\{y(-1)\}$, respectively.

Note that in the regular case the definitions of π and $\bar{\pi}$ coincide with that of section 4. In fact, we recall from Theorem 7.2 that $Y_n = \bar{Y}_n = X \cap H_0$ in this case. Consequently, the present definitions of G and $\bar{G}$ are merely straightforward generalizations of those in section 4.

THEOREM 7.11. *The maximal strictly output-induced subspace Y^* is both G- and $\bar{G}$-invariant. Also $G|_{Y^*}$ is invertible, and its inverse is $\bar{G}|_{Y^*}$. Furthermore, the subspaces $X \cap \{y(-1)\}$ and $X \cap \{y(0)\}$ are the null spaces of G and $\bar{G}$, respectively. More generally,*

$$\ker G^k = X \cap \{y(-1), \dots, y(-k)\} \quad \textit{for } k = 1, 2, 3, \dots$$

and

$$\ker \bar{G}^k = X \cap \{y(0), \dots, y(k)\} \quad \textit{for } k = 1, 2, 3, \dots.$$

In particular, $\ker G^n$ *is the space of predictable and* $\ker \bar{G}^n$ *the space of smoothable invariant directions.*

Proof. The fact that Y^* is strictly output induced and thus satisfies

$$UY^* \subset Y^* + \{y(0)\} \quad \text{and} \quad U^{-1}Y^* \subset Y^* + \{y(-1)\}$$

implies that Y^* is both G- and $\bar{G}$-invariant. To prove the last statement, take $\xi \in Y^*$. Then

$$U\xi = G\xi + \lambda,$$

where $G\xi \in Y^*$ and $\lambda \in \{y(0)\}$, and therefore $U^{-1}G\xi = \xi - U^{-1}\lambda$. Consequently, since $U^{-1}\lambda \in \{y(-1)\}$,

$$\bar{G}G\xi = \xi,$$

proving that $G|_{Y^*} = \left[\bar{G}|_{Y^*}\right]^{-1}$. To prove the statement concerning the kernel of G, observe that $\xi \in \ker G$ if and only if $\xi \in Y_n$ and $U\xi \in \{y(0)\}$. Therefore, since $\{y(-1)\} \cap X \subset Y_n$, $\ker G = X \cap \{y(-1)\}$. Similar arguments prove the rest. ∎

This again illustrates the fact that G and $\bar{G}$ are defined and invertible on all of $X \cap H_0$ in the regular case and only in the regular case. The following theorem, the proof of which is deferred to Appendix A, gives an upper bound for the number of invariant directions of any $X \in \mathcal{X}$. This is a generalization of Theorem 3.8 in [22], which deals with the internal case.

THEOREM 7.12. *The space of predictable directions in* X_- *has the same dimension* μ *as the space of smoothable directions in* X_+*, i.e.,*

$$\mu := \dim(X_- \cap \{y(-1), \dots, y(-n)\}) = \dim(X_+ \cap \{y(0), \dots, y(n-1)\}).$$

Moreover, the dimension of the space of invariant directions of any $X \in \mathcal{X}$ *is no larger than* μ*, i.e.,*

$$\dim(X \cap \{y(-1), \dots, y(-n)\} + X \cap \{y(0), \dots, y(n-1)\}) \leq \mu.$$

If X *is internal, there is equality in this relation.*

Proof of Theorem 7.6. We first prove (i). In the same way as in the proof of Theorem 3.3 we observe that

$$S^{(-k)} \cap H_0 = H^- \vee (X^{(-k)} \cap X_+),$$

formed analogously to (3.14), and that $X^{(-k)} \cap X_+$ converges in a finite number of steps which cannot exceed n. Consequently,

$$S^{(-n)} \cap H_0 = S^{(-2n)} \cap H_0.$$

Therefore, since $S^{(-k)} = (U^{-k}S) \vee H^-$ by definition, we obtain

$$(U^n S) \cap H_0 \subset (S \cap H_0) \vee U^{2n}H^- = (S \cap H_0) \vee \{y(0), \dots, y(2n-1)\}.$$

Now, taking the intersection with H^+ and using the shift invariance of H^+, we see that

$$U^n(S \cap H^+) \subset (U^n S) \cap H^+ \subset (S \cap H^+) \vee \{y(0), \dots, y(2n-1)\},$$

i.e.,

$$U^n(X \cap X_+) \subset (X \cap X_+) \vee \{y(0), \dots, y(2n-1)\}. \tag{7.39}$$

At the same time, (6.2) in Lemma 6.1 implies that

$$U^n(X \cap X_-) \subset (X \cap X_-) \vee \{y(0), \dots, y(n-1)\},$$

which together with (7.39) and (5.8) yields

$$U^n(X \cap H_0) \subset (X \cap H_0) \vee \{y(0), \dots, y(2n-1)\}.$$

Consequently,

$$X \cap H_0 \subset \big[U^{-n}(X \cap H_0) \vee \{y(-1), \dots, y(-n)\}\big] \vee \{y(0), \dots, y(n-1)\}, \tag{7.40}$$

where the first summand is a subspace of S, while the second is contained in $H^+ \subset \bar{S}$. Now, observing that

$$\big[U^{-n}(X \cap H_0) \vee \{y(-1), \dots, y(-n)\}\big] \cap \bar{S} \subset S \cap H_0 \cap \bar{S} \subset X \cap H_0,$$

(7.5) implies that the left member equals Y_n. Therefore, taking the intersection with $\bar{S}$ in (7.40), we obtain

$$X \cap H_0 \subset Y_n \vee \{y(0), \dots, y(n-1)\},$$

which after intersection with X yields

$$X \cap H_0 = Y_n \vee (X \cap \{y(0), \dots, y(n-1)\}),$$

the opposite inclusion being trivial. It remains to show that this is a direct sum. To see this, consider a $\xi \in Y_n \cap X \cap \{y(0), \dots, y(n-1)\}$. Then, by (7.5), $U^n\xi$ has the representation

$$U^n\xi = \zeta + \lambda, \tag{7.41}$$

where $\zeta \in X \cap H_0$ and $\lambda \subset \{y(0), \dots, y(n-1)\}$. Therefore,

$$\zeta = U^n\xi - \lambda \in X \cap \{y(0), \dots, y(2n-1)\}$$

is a smoothable direction of X, so we have that $\zeta \in X \cap \{y(0), \dots, y(n-1)\}$. Consequently, by (7.41), $U^n\xi \in \{y(0), \dots, y(n-1)\}$. However, by assumption, $U^n\xi \in \{y(n), \dots, y(2n-1)\}$, which, by virtue of the strictly nondeterministic property of y, implies that $\xi = 0$, concluding the proof (7.26). Since $X \cap X_-$ satisfies (7.14) (Lemma 6.1), the maximality of Y_n implies that $X \cap X_- \subset Y_n$. The last statement now follows from the fact that $X \cap H^- = X \cap X_-$. This concludes the proof of (i). A symmetric argument yields (ii).

Next we prove that Y^* defined by (7.30) satisfies the inclusion

$$UY^* \subset Y^* + \{y(0)\}. \tag{7.42}$$

To this end, consider a $\xi \in Y^*$. In view of Lemma 7.1, using the fact $Y_n = Y_{n+1}$, ξ is seen to have the two representations

$$\xi = U^{-n-1}\zeta + \lambda = U^n\bar{\zeta} + \bar{\lambda},$$

where $\zeta, \bar{\zeta} \in X \cap H_0$, $\lambda \in \{y(-1), \dots, y(-n-1)\}$, and $\bar{\lambda} \in \{y(0), \dots, y(n)\}$. Consequently,

$$U\xi = U^{-n}\zeta + \lambda_1 + \lambda_0,$$

where $\lambda_0 \in \{y(0)\}$ and $\lambda_1 \in \{y(-1), \dots, y(-n)\}$ and $\lambda_1 + \lambda_0 = U\lambda$. We prove that $U^{-n}\zeta + \lambda_1 \in Y^*$, thereby proving (7.42). Since for Y_n the inclusion (7.11) holds and $\xi \in Y_n$, we obtain that

$$U^{-n}\zeta + \lambda_1 \in Y_n.$$

On the other hand,

$$U^{-n}\zeta + \lambda_1 = U^{2n+1}\bar{\zeta} + U\bar{\lambda} - \lambda_0 \in U^{2n+1}(X \cap H_0) \vee \{y(0), \dots, y(n)\},$$

which, in view of Lemma 7.1, gives

$$U^{-n}\zeta + \lambda_1 \in Y_n,$$

concluding the proof of (7.42).

A similar argument shows that

$$U^{-1}Y^* \subset Y^* + \{y(-1)\}. \tag{7.43}$$

Equations (7.42) and (7.43) establish that Y^* is a strictly output-induced subspace. Since the maximality of Y_n and that of $\bar{Y}_n$ imply that any strictly output-induced subspace must be included in both Y_n and $\bar{Y}_n$, the intersection Y^* is the maximal strictly output-induced subspace.

Taking intersections with $\bar{Y}_n$ on both sides in (7.26) and observing that $X \cap \{y(0), \dots, y(n-1)\} \subset \bar{Y}_n$ by (ii), we immediately obtain (7.32).

In the same way, (7.31) follows by intersecting (7.28) with Y_n and observing the fact that $X \cap \{y(-1), \dots, y(-n)\} \subset Y_n$ by (i). □

8. The change of zero dynamics under σ and $\bar{\sigma}$. In Definition 7.10 we assigned to each $X \in \mathcal{X}$ two operators G and $\bar{G}$, defined on the appropriate subspaces of X. Now we will relate the eigenvalues of G and $\bar{G}$ to the zeros of W and $\bar{W}$, the spectral factors corresponding to X, justifying the name zero dynamics operators. Next we analyze the connections between the zero dynamics operators belonging to different splitting subspaces. Finally, using these operators, we describe completely the change in the zero structure when applying the prediction operators σ and $\bar{\sigma}$.

To this end, we recall from [20] that the finite zeros of W and the corresponding zero directions are characterized by the solutions of (5.5), i.e.,

$$\begin{bmatrix} \Pi & -M \end{bmatrix} \begin{bmatrix} A & B \\ C & D \end{bmatrix} = \begin{bmatrix} \Lambda\Pi & 0 \end{bmatrix}, \tag{8.1}$$

in the sense that the eigenvalues of Λ are zeros of W and the rows of Π span the subspace of the corresponding generalized zero directions. In order to describe all finite zeros we need to consider a maximal solution of (8.1) in the sense that Π has maximal rank or in the sense that the subspace generated by the row vectors of Π is maximal.

We now give an alternative proof of a generalization of Lemma 5.2 which also works in the nonregular case.

LEMMA 8.1. *A matrix* Π *satisfies* (8.1) *if and only if there are matrices* Λ *and* M *such that*

$$\Pi x(t+1) = \Lambda\Pi x(t) + My(t). \tag{8.2}$$

Proof. Equation (8.1) is equivalent to

$$\begin{bmatrix}\Pi & -M\end{bmatrix}\begin{bmatrix}A & B\\ C & D\end{bmatrix}\begin{bmatrix}x(t)\\ u(t)\end{bmatrix} = \begin{bmatrix}\Lambda\Pi & 0\end{bmatrix}\begin{bmatrix}x(t)\\ u(t)\end{bmatrix},$$

where x is the state process and u is the driving noise of the stochastic model (1.1). This is seen by observing that the covariance matrix of $\begin{bmatrix}x(t)\\ u(t)\end{bmatrix}$ is full rank. Together with the systems equations (1.1) this yields (8.2). □

A coordinate-free version of (8.2) is provided by

$$UY \subset Y \vee \{y(0)\}, \tag{8.3}$$

where Y consists of the random variables of the form $b'\Pi x(0)$. This observation allows us to characterize the zeros of W in terms of the eigenvalues of G.

PROPOSITION 8.2. *The eigenvalues of* G *are precisely the finite zeros of* W. *Similarly, the eigenvalues of* $\bar{G}$ *are the finite zeros of* $\bar{W}(z^{-1})$.

Proof. Consider the maximal solution of (8.1). Then the eigenvalues of Λ are the finite zeros of W. Moreover, since Y_n is the maximal subspace satisfying (8.3) (Theorem 7.2), $z := \Pi x(0)$ is a basis in Y_n, the space on which G is defined. It then follows from (8.2) that

$$Gz_i = \sum_j \Lambda_{ij} z_j,$$

and consequently Λ' is a matrix representation of G in the basis of z, thus having the same eigenvalues. This concludes the proof of the first statement. The second statement follows by symmetry. □

This together with Theorem 7.11 illustrates that we have zeros at zero and/or infinity precisely in the nonregular case and that such zeros are connected to invariant directions. More precisely, predictable directions correspond to zeros at zero and smoothable directions to zeros at infinity.

It was proven in [20] and [29], independently and with different methods, that W and $\bar{W}$ have the same zeros also in the nonregular case. (A modification of the argument in Remark 5.3 could also be used to see this.) Therefore, any statement about the zeros of W also holds for $\bar{W}$, and vice versa.

Recall that

$$X \cap H_0 = (X \cap X_-) \vee (X \cap X_+), \tag{8.4}$$

where the sum is direct if and only if $X_- \cap X_+ = 0$ or, equivalently, $H^- \cap H^+ = 0$. Only in the regular case can we define G and $\bar{G}$ on all of $X \cap H_0$, but in view of Theorem 7.6(i), $X \cap X_-$ is always contained in the domain of G and $X \cap X_+$ in the domain of $\bar{G}$.

THEOREM 8.3. *Let* G_- *be the* G*-operator of* X_- *and* $\bar{G}_+$ *be the* $\bar{G}$*-operator of* X_+. *Let* $(W, \bar{W})$ *be the spectral factors of* $X \in \mathfrak{X}$. *Then*

$$G|_{X\cap X_-} = G_-|_{X\cap X_-} \tag{8.5}$$

and

$$\bar{G}|_{X\cap X_+} = \bar{G}_+|_{X\cap X_+}. \tag{8.6}$$

Consequently, the eigenvalues of $G|_{X\cap X_-}$ *are the stable zeros of* W *(including those on the unit circle) and that the eigenvalues of* $\bar{G}|_{X\cap X_+}$ *are the reciprocals of the antistable zeros (including those on the unit circle and at infinity). Finally,*

$$G|_{X_-\cap X_+} = \left[\bar{G}|_{X_-\cap X_+}\right]^{-1}, \tag{8.7}$$

and its eigenvalues are precisely the zeros on the unit circle.

Proof. Referring to (6.2) we see that $X \cap X_-$ is invariant under both G and G_- and hence (8.5) follows. In the same way, (6.1) implies that $X \cap X_+$ is invariant under both $\bar{G}$ and $\bar{G}_+$, implying (8.6). This is in harmony with Theorem 5.4 and implies the statements on stable and unstable zeros. Finally, by Corollary 6.6, $X_- \cap X_+$ is strictly output induced and is thus contained in Y^*, on which space G is invertible (Theorem 7.6). Consequently, the last statement follows. ∎

In particular, we have the following observation, which was previously reported in [10] and [9]. (In the latter paper the proof is somewhat incomplete, since the multiplicities are not counted properly.)

COROLLARY 8.4. *All minimal spectral factors have the same number of zeros on the unit circle* (*counting multiplicity*)*, namely,* $\dim X_- \cap X_+ = \dim H^- \cap H^+$.

In section 5 we showed that in the regular case, the zeros, as well as the zero directions, are preserved as the operators σ and $\bar{\sigma}$ are applied. In general this is not true in the nonregular case. In view of Theorem 8.3, the following two theorems, relating σ and $\bar{\sigma}$ to the operators G and $\bar{G}$, show what happens.

THEOREM 8.5. *Let* $X \in \mathfrak{X}$. *Then*

$$(\sigma X) \cap X_+ = \bar{G}_+(X \cap X_+) = \bar{G}(X \cap X_+) \tag{8.8}$$

and

$$(\bar{\sigma} X) \cap X_- = G_-(X \cap X_-) = G(X \cap X_-). \tag{8.9}$$

Proof. We prove only (8.8). Then a symmetric argument yields (8.9). First we show that

$$\sigma X \subset \{y(-1)\} \vee U^{-1}X. \tag{8.10}$$

To this end, observe that $H^- \vee U^{-1}S = \{y(-1)\} \vee U^{-1}S$, which, in view of the fact that $\{y(-1)\} \subset U^{-1}H^+ \subset U^{-1}\bar{S}$, equals $(\{y(-1)\} \vee U^{-1}X) \oplus U^{-1}\bar{S}^\perp$. However, $X \perp \bar{S}^\perp \supset U^{-1}\bar{S}^\perp$, and consequently (8.10) follows from the definition (3.1). Now, consider $\zeta \in (\sigma X) \cap X_+$. In view of (8.10), we have the representation

$$\zeta = \eta + U^{-1}\xi,$$

where $\eta \in \{y(-1)\}$ and $\xi \in X$. On the other hand, since $U^{-1}\xi = \zeta - \eta \in U^{-1}H^+$, we see that $\xi \in H^+ \cap X = X \cap X_+$. From the definition of the operator $\bar{G}_+$, we have

$$\zeta = \bar{G}_+\xi, \quad \text{where } \xi \in X \cap X_+.$$

Conversely, if $\xi \in X \cap X_+$, $\bar{G}_+\xi \in X_+$ and $\bar{G}_+\xi - U^{-1}\xi \in \{y(-1)\}$, implying that $\bar{G}_+\xi \in H^- \vee U^{-1}S = S^{(-1)}$. Hence,

$$\bar{G}_+\xi \in (\sigma X) \cap X_+,$$

which together with (8.6) concludes the proof of the theorem. ∎

THEOREM 8.6. *Let $X \in \mathcal{X}$. Then*

$$(\sigma X) \cap X_- = \{\xi \in X_- \mid G_-\xi \in X \cap X_-\} \tag{8.11}$$

and

$$(\bar{\sigma} X) \cap X_+ = \{\xi \in X_+ \mid \bar{G}_+\xi \in X \cap X_+\}. \tag{8.12}$$

Proof. We prove (8.11); then (8.12) follows by symmetry. Let $\xi \in X_-$. Since $\mathrm{E}^{H^-}X = X_-$ [18, Lemma 4.6 and Theorem 4.10] and $\ker \mathrm{E}^{H^-}|_X = X \cap (H^-)^\perp = 0$ (see section 2), there is a unique $\zeta \in X$ such that $\xi = \mathrm{E}^{H^-}\zeta$. By the definition of G_-,

$$U\xi = G_-\xi + \eta,$$

where $\eta \in \{y(0)\}$, and therefore

$$U(\zeta - \xi) = U\zeta - \eta - G_-\xi.$$

Since $G_-\xi \in X_- \subset S$, $U\zeta \in U\bar{S} \subset \bar{S}$, and $\eta \in H^+ \subset \bar{S}$, the splitting property (2.8) yields

$$\mathrm{E}^S U(\zeta - \xi) = \mathrm{E}^X(U\zeta - \eta) - G_-\xi. \tag{8.13}$$

Now, suppose $\xi \in (\sigma X) \cap X_-$. Then by definition (3.1), $\xi = \mathrm{E}^{H^- \vee U^{-1}S}\lambda$ for some $\lambda \in X$. But then, since $\xi \in H^-$, $\xi = \mathrm{E}^{H^-}\lambda$, so by uniqueness we must have $\lambda = \zeta$. Consequently, $\zeta - \xi \perp H^- \vee U^{-1}S$, which in particular implies that $U(\zeta - \xi) \perp S$. Hence, it follows from (8.13) that $G_-\xi \in X$, proving that $G_-\xi \in X \cap X_-$.

Conversely, suppose that $G_-\xi \in X \cap X_-$. Then, by (8.13),

$$\mathrm{E}^S U(\zeta - \xi) \in X. \tag{8.14}$$

But, since $\xi = \mathrm{E}^{H^-}\zeta$,

$$U(\zeta - \xi) \perp UH^- \supset H^-. \tag{8.15}$$

Therefore, since $S = H^- \oplus S \cap (H^-)^\perp$ by (4.20), we have

$$\mathrm{E}^S U(\zeta - \xi) = \mathrm{E}^{S \cap (H^-)^\perp} U(\zeta - \xi) \in S \cap (H^-)^\perp. \tag{8.16}$$

Since $X \cap S \cap (H^-)^\perp = X \cap (H^-)^\perp = 0$ (see section 2), it follows from (8.14) and (8.16) that $\mathrm{E}^S U(\zeta - \xi) = 0$, and hence

$$U(\zeta - \xi) \perp S,$$

which together with (8.15) yields

$$\zeta - \xi \perp H^- \vee U^{-1}S.$$

Consequently, $\xi = \mathrm{E}^{H^- \vee U^{-1}S}\zeta \in \sigma X$, and so $\xi \in (\sigma X) \cap X_-$ as claimed. ∎

In particular, Theorems 8.5 and 8.6 show that

$$(\bar{\sigma} X) \cap X_- \subset X \cap X_- \subset (\sigma X) \cap X_-; \tag{8.17}$$

i.e., stable zeros may be lost as we apply $\bar{\sigma}$ and gained as we apply σ. In the same way,

$$(\sigma X) \cap X_+ \subset X \cap X_+ \subset (\bar{\sigma} X) \cap X_+, \tag{8.18}$$

showing that antistable zeros may be lost when applying σ and gained when applying $\bar{\sigma}$. This is in agreement with Proposition 3.4 and formulas (6.7) and (6.8).

To determine what zeros are being lost and gained under these operations, we observe from Theorems 8.5 and 8.6 that the subspaces being added or subtracted from $X \cap X_-$ and $X \cap X_+$ must be contained in the kernel of some G- or $\bar{G}$-operator. Consequently, by Theorem 7.11, the corresponding zero directions are invariant directions.

We may therefore formulate an amplification of statement (8.17), namely, that zeros at zero together with the corresponding predictable directions may be gained when applying σ and lost when applying $\bar{\sigma}$. In the same way, (8.18) and Theorem 7.11 show that zeros at infinity together with the corresponding smoothable directions may be lost when applying σ and gained when applying $\bar{\sigma}$.

The following corollary is an immediate consequence of Theorems 8.5 and 8.6.

COROLLARY 8.7. *Let $X \in \mathcal{X}$, and let Y_n and $\bar{Y}_n$ be defined as in section 7. Then*

$$\begin{aligned}(\sigma^k X) \cap H_0 &= Y_n \vee \{\textit{predictable directions in } X_-\} \\ &= Y^* + \{\textit{predictable directions in } X_-\}\end{aligned}$$

and

$$\begin{aligned}(\bar{\sigma}^k X) \cap H_0 &= \bar{Y}_n \vee \{\textit{smoothable directions in } X_+\} \\ &= Y^* + \{\textit{smoothable directions in } X_+\}\end{aligned}$$

for $k = n, n+1, \ldots$.

Remark 8.8. Theorem 7.11, Remark 7.8, and Corollary 8.7 enable us to generalize the statement in Remark 5.7 to the nonregular case. The same construction that was used in this remark to reduce the Riccati equations can be applied here with modifications which take into account the fact that the internal subspace $X^{(k)} \cap H_0$ is no longer constant along the sequence of splitting subspaces $\{X^{(k)}\}$ in the nonregular case. In view of Remark 7.8, the solutions of the Riccati recursions are constant from the start in the zero directions of Y_n, while they become constant only after a finite number of steps in the remaining predictable directions by Corollary 8.7. Consequently, after a finite number of steps the size of the reduced Riccati equations is $\nu \times \nu$ where $\nu = n - \dim(\sigma^n X) \cap H_0$. In view of Corollary 8.7 and Theorem 7.12, the backward Riccati equation can be reduced to the same size.

9. Conclusions. In this paper we discuss the very rich and intricate structure of discrete-time linear stochastic systems in the context of an interpolation-type problem, namely, to reconstruct lost state information on a finite interval using the whole history of the output process and the remaining state information. We show that, at each time, the (least squares) state estimate can be written as a linear combination of two filter estimates, which are generated by (forward respectively backward) Kalman filtering-type recursions with the initial condition being itself a state. Remarkably, these Kalman filtering recursions generate sequences of state processes from different stochastic realizations which are totally ordered. When $k \to \infty$ and when $k \to -\infty$, the sequence of splitting subspaces $X^{(k)}$ converge to limits which are internal splitting

subspaces. These limits are determined by the zero structure of the spectral factor (1.2).

In the regular case, when there are no zeros at the origin and at infinity, the set of zeros and zero directions of the spectral factors $W^{(k)}$ corresponding to the splitting subspaces $X^{(k)}$ remain invariant during these recursions giving a set of invariants. We show that in the nonregular case the whole set of zeros is no longer invariant but the finite zeros with finite reciprocals still are.

We have shown that the computational burden of determining the interpolation estimate depends on the dimension of the internal subspace $X \cap H_0$, i.e., on the number of zeros. This leads to the study of output-induced and strictly output-induced subspaces and zero dynamics operators. In particular, if $a'x(0) \in X \cap H_0$, then, in the regular case, the solutions of the Riccati equations (4.38) and (4.41) for the interpolation problem becomes constant in the direction a, allowing for a reduction in size of the Riccati equations. In fact, if $\dim X \cap H_0 = n - \nu$, we need only to solve Riccati equations of dimension $\nu \times \nu$ rather than $n \times n$ in the regular case (Remark 5.7). In the nonregular case the reduction may be even larger after a finite number of steps (Remark 8.8).

What makes the discrete-time case more complicated than the continuous-time case is the possibility that the *predictable subspace* $X \cap \{y(-1), \dots, y(-n)\}$ and the *smoothable subspace* $X \cap \{y(0), \dots, y(n-1)\}$ are nontrivial. In fact, if these spaces are zero spaces (the regular case), the structure of the problem is very much like the continuous-time coercive case, studied in [13], and $X \cap H_0$ is itself strictly output induced. If they are not, the matrix D will lose rank, and the matrix Riccati equations of forward and backward Kalman filtering will become constant in the directions a for which $a'x(0)$ is an element of these spaces, thus influencing the implementation of the filtering algorithms, as explained above. These a are called *invariant directions*. Nonregularity, and hence invariant directions, are connected with zeros at zero and at infinity.

In particular, we have demonstrated that $X \cap H_0$ can be decomposed as a direct sum of the predictable subspace, the smoothable subspace and the maximal strictly output-induced subspace, corresponding to the zeros at zero, the zeros at infinity, and the remaining zeros, respectively. The maximal strictly output-induced subspace Y^* equals $X \cap H_0$ in the regular case and plays the role of $X \cap H_0$ in the nonregular case. We have given several geometric characterizations of regularity (Propositions 3.11 and 3.11′ and Corollaries 6.10 and 7.7). We have also shown that Y^* can be determined by algorithms akin to that used in geometric control theory for determining the maximal output-nulling subspace.

On the maximal strictly output-induced subspace Y^* the forward and backward zero dynamics operators G and $\bar{G}$, respectively, are inverses of each other. The eigenvalues are the finite zeros with finite reciprocals. The operators G and $\bar{G}$ can be separately extended to a larger subspace. On these subspaces (in the nonregular case) these operators are in general singular and the invariant directions determine the kernel of these operators.

Appendix A. Proof of Theorem 7.12.

Let us denote by $I_p(X)$ the predictable directions in $X \in \mathfrak{X}$ under the natural isomorphism $a \mapsto a'x(0)$ and by $I_s(X)$ the smoothable directions under the same isomorphism. Then Theorem 7.11 implies that

$$I_p(X) = \ker(P - P_-) \cap \ker(\Gamma'_-)^n \quad \text{and} \quad I_s(X) = \ker(P_+ - P) \cap \ker P_+^{-1}(\bar{\Gamma}'_+)^n P_+.$$

In particular,

$$I_p(X_-) = \ker(\Gamma'_-)^n \quad \text{and} \quad I_s(X_+) = \ker P_+^{-1}(\bar{\Gamma}'_+)^n P_+.$$

As in [28, p. 53], a straightforward but somewhat tedious calculation yields the identity

$$\bar{\Gamma}_+ P_+^{-1}(P_+ - P_-) = P_+^{-1}(P_+ - P_-)\Gamma'_-. \tag{A.1}$$

First, we prove that

$$\dim I_p(X_-) = \dim I_s(X_+).$$

To this end, observe that (A.1) implies that

$$(P_+ \bar{\Gamma}_+^n P_+^{-1})(P_+ - P_-) = (P_+ - P_-)(\Gamma'_-)^n. \tag{A.2}$$

Since it follows from Theorem 8.3 that $\ker(P_+ - P_-) \cap \ker \Gamma'_- = 0$, we obtain that if $\xi \in \ker(\Gamma'_-)^n$ is nonzero, then $(P_+ - P_-)\xi \neq 0$. Thus

$$(P_+ - P_-) I_p(X_-) \subset \ker P_+^{-1}(\bar{\Gamma}_+)^n P_+,$$

implying that

$$\dim I_p(X_-) \leq \dim I_s(X_+).$$

A symmetric argument yields the reverse inequality, proving the first statement in the theorem and also that

$$\ker P_+^{-1}(\bar{\Gamma}_+)^n P_+ = (P_+ - P_-) I_p(X_-).$$

Consequently, $Y := \operatorname{Im} P_+^{-1}(\bar{\Gamma}'_+)^n P_+$, the counterpart of the maximal strictly output-induced subspace Y^* of X_+ under the natural isomorphism, is the orthogonal complement of $(P_+ - P_-) I_p(X_-)$, i.e.,

$$Y = \{a \in \mathbb{R}^n \mid a'(P_+ - P_-)b = 0 \quad \text{for} \quad b \in I_p(X_-)\}.$$

Thus, again invoking that $(P_+ - P_-)$ is nonsingular on $I_p(X_-)$, we obtain the direct-sum decomposition

$$I_p(X_-) + Y = \mathbb{R}^n,$$

where the two summands are "orthogonal" in the inner product defined by $(P_+ - P_-)$. In view of the direct-sum decomposition

$$I_s(X_+) + Y = \mathbb{R}^n \tag{A.3}$$

we see that both the predictable directions and the smoothable directions under the natural isomorphisms are mapped to subspaces which are complementary to Y.

Now observe that if $a \in \ker(P - P_-)$ and $b \in \ker(P_+ - P)$, then $a'(P_+ - P_-)b = 0$, i.e., $\ker(P - P_-)$ and $\ker(P_+ - P)$, are also orthogonal in the inner product determined by $(P_+ - P_-)$. This inner product is nonsingular on $I_p(X_-)$, so we can consider a $(P_+ - P_-)$-orthogonal complement Z of $I_p(X)$ in $I_p(X_-)$, i.e.,

$$I_p(X) + Z = I_p(X_-). \tag{A.4}$$

Then the $(P_+ - P_-)$-orthogonal complement of $I_p(X)$ in $\mathbb{R}^n$ is $Z + Y$, the latter obviously containing $\ker(P_+ - P)$. Consequently

$$I_s(X) \subset (Z + Y) \cap I_s(X_+). \tag{A.5}$$

In the internal case we have equality in this inclusion. Now, the identity (A.3) implies that

$$\dim(Z + Y) \cap I_s(X_+) = \dim Z,$$

which together with (A.4) and (A.5) yields

$$\dim I_p(X) + \dim I_s(X) \leq \dim I_p(X_-) = \mu$$

with equality in the internal case, concluding the proof of the theorem.

Appendix B. Zero direction of σX and $\bar{\sigma} X$.

Theorems 8.5 and 8.6 can be reformulated in terms of (generalized) zero directions.

THEOREM B.1. *The antistable zero directions of σX are described by*

$$(\sigma X) \cap X_+ = \{a' \bar{x}_+(0) \mid a = \bar{\Gamma}'_+ b, \text{ where } b \in \ker(\bar{P} - \bar{P}_+)\}. \tag{B.1}$$

Similarly, the stable zero directions of $\bar{\sigma} X$ are given by

$$(\bar{\sigma} X) \cap X_- = \{a' \bar{x}_-(0) \mid a = \bar{\Gamma}'_- b, \text{ where } b \in \ker(P - P_-)\}. \tag{B.2}$$

THEOREM B.2. *The stable zero directions of σX are described by*

$$(\sigma X) \cap X_- = \{a' x_-(0) \mid a \in \mathbb{R}^n, \Gamma'_- a \in \ker(P - P_-)\}. \tag{B.3}$$

Similarly, the antistable zero directions of $\bar{\sigma} X$ are given by

$$(\bar{\sigma} X) \cap X_+ = \{a' \bar{x}_+(0) \mid a \in \mathbb{R}^n, \bar{\Gamma}'_+ a \in \ker(\bar{P} - \bar{P}_+)\}. \tag{B.4}$$

These theorems follow directly from Theorems 8.5 and 8.6, identifying G_- and $\bar{G}_+$ with Γ'_- and $\bar{\Gamma}'_+$ and $X \cap X_-$ and $X \cap X_+$ with $\ker(P - P_-)$ and $\ker(\bar{P} - \bar{P}_+)$, respectively. (Also see [13].) However, we also have the following independent coordinate-dependent proofs.

Proof of Theorem B.1. We prove (B.1). Then (B.2) follows by symmetry. The proof of this theorem runs parallel to that of Theorem 8.6. In view of the definition (3.1) of σX, we need to characterize all $\xi \in X$ such that

$$\mathrm{E}^{H^- \vee U^{-1} S} \xi = \mathrm{E}^{\{y(-1)\} \vee U^{-1} X} \xi \in X_+,$$

or, in other words, $\xi = d' \bar{x}_+(0)$ such that

$$\mathrm{E}^{\{y(-1)\} \vee U^{-1} X} d' \bar{x}(0) = c' y(-1) + b' \bar{x}(-1) = a' \bar{x}_+(0)$$

for appropriate vectors a, b, c, and d. The equations connecting a, b, c, and d are

$$d' \begin{bmatrix} \bar{P}\bar{C}' & \bar{P}A \end{bmatrix} = \begin{bmatrix} c' & b' \end{bmatrix} \begin{bmatrix} \Lambda_0 & C \\ C' & P \end{bmatrix}, \tag{B.5}$$

$$\begin{bmatrix} c' & b' \end{bmatrix} \begin{bmatrix} \bar{C} \\ A' \end{bmatrix} = a', \tag{B.6}$$

and

$$\begin{bmatrix} c' & b' \end{bmatrix} \begin{bmatrix} \Lambda_0 & C \\ C' & P \end{bmatrix} = a' \bar{P}_+ a. \tag{B.7}$$

Here the first two equations are projection formulas projecting ξ onto $\{y(-1)\} \vee U^{-1}X$ and $c'y(-1) + b'\bar{x}(-1)$ onto X_+, respectively, and the third equation expresses that in the latter projection the error is zero. Now, insert (B.6) into (B.7) and rearrange terms to obtain

$$\begin{bmatrix} c' & b' \end{bmatrix} \begin{bmatrix} \Lambda_0 - \bar{C}\bar{P}_+\bar{C}' & C - \bar{C}\bar{P}_+A \\ C' - A'\bar{P}_+\bar{C}' & \bar{P} - A'\bar{P}_+A \end{bmatrix} \begin{bmatrix} c \\ b \end{bmatrix} = 0.$$

Using the facts that $\Lambda_0 - \bar{C}\bar{P}_+\bar{C}' = \bar{D}_+\bar{D}'_+$, $C - \bar{C}\bar{P}_+A = \bar{D}_+\bar{B}'_+$, and also $\bar{P} - A'\bar{P}_+A = \bar{B}_+\bar{B}'_+ + (\bar{P} - \bar{P}_+)$, we obtain

$$\begin{bmatrix} c' & b' \end{bmatrix} \begin{bmatrix} \bar{D}_+\bar{D}'_+ & \bar{D}_+\bar{B}'_+ \\ \bar{B}_+\bar{D}'_+ & \bar{B}_+\bar{B}'_+ + (\bar{P} - \bar{P}_+) \end{bmatrix} \begin{bmatrix} c \\ b \end{bmatrix} = 0.$$

Since $\bar{P} \geq \bar{P}_+$, this is clearly a positive semidefinite quadratic form, and therefore

$$\begin{bmatrix} \bar{D}_+\bar{D}'_+ & \bar{D}_+\bar{B}'_+ \\ \bar{B}_+\bar{D}'_+ & \bar{B}_+\bar{B}'_+ + (\bar{P} - \bar{P}_+) \end{bmatrix} \begin{bmatrix} c \\ b \end{bmatrix} = 0.$$

The first block equation together with the fact that $\bar{D}_+\bar{D}'_+$ is invertible yields

$$c = -(\bar{D}_+\bar{D}'_+)^{-1}\bar{D}_+\bar{B}'_+ b. \tag{B.8}$$

Inserting this into the second block equation we get

$$(\bar{P} - \bar{P}_+)b = 0.$$

This shows that, if $a'\bar{x}_+(0) \in (\sigma X) \cap X_+$, then there is a $b \in \mathbb{R}^n$ such that $b \in \ker(\bar{P} - \bar{P}_+)$ and $a = \bar{\Gamma}'_+ b$. Conversely, assume that this is satisfied, define c by (B.8), and set $d := a$. Now straightforward calculations show that (B.5), (B.6), and (B.7) are satisfied. □

Proof of Theorem B.2. We prove (B.3); then (B.4) follows by symmetry. Recall that $\sigma X = \mathrm{E}^{H^- \vee U^{-1}S}X$. Therefore, if $a'x_-(0) \in (\sigma X) \cap X_-$, there exists a $\xi \in X$ such that

$$\mathrm{E}^{H^- \vee U^{-1}S}\xi = a'x_-(0).$$

Apply E^{H^-} to this to see that $\mathrm{E}^{H^-}\xi = a'x_-(0)$. Hence, by uniqueness of the uniform choice of bases, $\xi = a'x(0)$. On the other hand,

$$H^- \vee U^{-1}S = \{y(-1)\} \vee U^{-1}S = (\{y(-1)\} \vee U^{-1}X) \oplus U^{-1}\bar{S}^\perp,$$

since $\{y(-1)\} \in U^{-1}H^+ \subset U^{-1}\bar{S} \perp U^{-1}\bar{S}^\perp$ and $S = X \oplus \bar{S}^\perp$. Hence, since $\xi \in X \perp \bar{S}^\perp \supset U^{-1}\bar{S}^\perp$,

$$\mathrm{E}^{H^- \vee U^{-1}S}\xi = \mathrm{E}^{\{y(-1)\} \vee U^{-1}X}\xi.$$

But $a'x(0) - a'x_-(0) \perp H^- \supset \{y(-1)\}$, so the space $(\sigma X) \cap X_-$ is completely characterized by the condition

$$a'x(0) - a'x_-(0) \perp \{x(-1)\},$$

or, in other words,

$$\mathrm{E}\{[a'x(0) - a'x_-(0)]x(-1)'\} = 0. \tag{B.9}$$

To compute this covariance, note that the error process $x(t) - x_-(t)$ satisfies the forward state equation

$$x(t+1) - x_-(t+1) = \Gamma_-[x(t) - x_-(t)] + (B - B_-D_-^{-1}D)u(t)$$

so that

$$\mathrm{E}\{[x(0) - x_-(0)][x(-1) - x_-(-1)]'\} = \Gamma_-(P - P_-).$$

However, since $x_-(0) = \mathrm{E}^{H^-}x(0)$ and $a'x_-(-1) \in H^-$, (B.9) yields $a'\Gamma_-(P-P_-) = 0$ as claimed. □

ON THE PUISEUX SERIES EXPANSION OF THE LIMIT DISCOUNT EQUATION OF STOCHASTIC GAMES*

W. W. SZCZECHLA†, S. A. CONNELL‡, J. A. FILAR‡, AND O. J. VRIEZE§

Abstract. In this paper we give a new proof of the existence of Puiseux series expansion of the limit discount equation of finite state stochastic games. Unlike the original proof, due to Bewley and Kohlberg [*Math. Oper. Res.*, 3 (1976), pp. 197–208], our proof is not algebraic and does not invoke Tarski's principle. Instead we use only the theory of functions of complex variables and complex analytic varieties.

Key words. stochastic games, Puiseux series, limit discount equation

AMS subject classification. 90D15

Introduction. Perhaps the first minimax theorem of modern game theory is due to von Neumann in 1928 (see [5]). In that classical paper it is shown that a matrix game possesses a "value": an optimal gain/loss for players I and II when they are playing in an antagonistic (zero-sum) fashion. In 1950 Weyl (see [8]) simplified von Neumann's proof and demonstrated that if the entries of a matrix game belong to an ordered field, then the value belongs to the same ordered field.

An important generalization to the infinite horizon dynamic case was proposed in 1953 by Shapley (see [6]). Shapley established the existence of the value vector in a class of games analogous to what are now called discounted stochastic games. In these games the rewards at future stages are discounted by a factor $\beta \in [0, 1)$. Shapley also observed that even when all of the data of these games lie in the field of rational numbers, the entries of the value need not be in the same field.

The asymptotic behavior of the value vector as $\beta \nearrow 1$ has been studied by a number of authors. In an important contribution Bewley and Kohlberg [1] viewed Shapley's "optimality condition" as an elementary sentence in formal logic over the closed ordered field of real Puiseux series. These authors invoke a powerful theorem from mathematical logic, known as Tarski's principle, to conclude that in some neighborhood of $\beta = 1$, the value vector belongs to the field of real Puiseux series. The essentially algebraic nature of Bewley and Kohlberg's approach and the use of Tarski's principle, while ingenious, do not give insight into the manner in which fractional power series solutions arise naturally in this problem. Arguably, this has proved to be a difficulty for researchers in stochastic games, because Bewley and Kohlberg's result has become an important building block in subsequent developments. For instance, Mertens and Neyman [4] used it to prove the existence of the value vector in the limiting average stochastic games.

In this paper we offer an alternative proof of the Puiseux series expansion of the value vector of discounted stochastic games. Our approach is based on the fact that Shapley's optimality equation can be viewed as a system of polynomial equations in several variables. Solution sets of such systems of equations, over the complex numbers, are called complex analytic varieties. We exploit the geometric structure of the variety that arises in our case, thereby enabling us to reduce the polynomial system to one where each polynomial is in the form to which a classical result of Puiseux (see [2]) can be applied. In this way we obtain the desired fractional power series expansion. In our approach the Puiseux series play only an auxiliary role, being used mainly to translate our results on varieties into the language of Bewley and Kohlberg's paper [1]. In particular, note that the existence of the limit of the value vector as $\beta \nearrow 1$ is now proven as a consequence of the geometric structure of the varieties and without invoking the Puiseux series expansion. This may be the first use of techniques from the theory of several complex variables to solve a problem in game theory. As such, considerable preparation is still required to follow the proof. However, we believe that our approach is more natural and may shed light on as yet unsolved problems. In fact Theorem 5.2 already extends Bewley and Kohlberg's result to every point in the entire interval $[0, 1]$, and Theorem 4.3 contains geometric insight that is not apparent in an application of Tarski's principle.

1. Definitions and preliminaries of matrix games. Any $m \times n$ real matrix $A = (a_{ij})_{i,j=1}^{m,n}$ can be regarded as a two-person, zero-sum *matrix game* with a_{ij} denoting the amount player II will pay player I if II chooses an action $j \in \{1, 2, \ldots, n\}$ and I chooses an action $i \in \{1, 2, \ldots, m\}$. A *mixed* (or *randomized*) *strategy* for player I (II) in such a game is an $m(n)$-component probability vector $x(y)$ whose ith (jth) entry $x_i(y_j)$ denotes the probability that player I (II) will choose an action $i(j)$. It was von Neumann [5] who proved the celebrated "minimax theorem" for matrix games. It is a consequence of this theorem that there always exists a strategy pair (x^o, y^o) satisfying

$$x^T A y^o \leq (x^o)^T A y^o \leq (x^o)^T A y \tag{1.1}$$

for all mixed strategies $x(y)$ of player I (II). The strategies x^o, y^o are then called *optimal strategies*, and the real number $\mathrm{val}(A) := (x^o)^T A y^o$ is called the *value* of the matrix game A. It is well known that if $b_{ij} = ka_{ij} + c$, for all $i, j,\ k > 0$, and $B = (b_{ij})_{i,j=1}^{m,n}$, then $\mathrm{val}B = \mathrm{val}A + c$.

A matrix game A is called *completely mixed* if all of its optimal strategies are strictly positive in every component. Extending earlier results of Kaplansky [3], Shapley and Snow [7] have demonstrated the following result.

PROPOSITION 1.1. *If A is a matrix game and* $\mathrm{val}\, A \neq 0$, *then A has a square invertible submatrix $\overline{A}$, called a Shapley–Snow kernel, such that*

(K1) $\mathrm{val}\, \overline{A} = \mathrm{val}\, A = \det \overline{A} / \sum_{ij} \overline{A}^{ij} = (\mathbf{1}^T \overline{A}^{-1} \mathbf{1})^{-1}$, *where $\overline{A}^{ij}$ denotes the (i, j)th cofactor of $\overline{A}$.*

(K2) *There is a pair (x^0, y^0) of strategies for $\overline{A}$ which is optimal for A (after inserting zeroes) and satisfies*

$$(x^0)^T = (\mathrm{val}\, A)\mathbf{1}^T \overline{A}^{-1} \quad \textit{and} \quad y^0 = (\mathrm{val}\, A)\overline{A}^{-1}\mathbf{1},$$

where $\mathbf{1} = (1, \ldots, 1)^T$.

LEMMA 1.2. *If A is a matrix game and* $\mathrm{val}\, A \neq 0$, *then A has a square invertible submatrix $\overline{A}$, which will be called a* cmv-kernel, *such that*

(K0) *The matrix game* $\overline{A}$ *is completely mixed, and* $\overline{A}$ *satisfies condition* (K1) *of Proposition* 1.1.

Proof. Among the submatrices X of A satisfying $\mathrm{val}X = \mathrm{val}A$, let $\overline{A}$ be minimal with respect to matrix inclusion. First note that $\overline{A}$ is completely mixed. Indeed, if (p, q) is a nonmixed pair of optimal strategies for $\overline{A}$, then the matrix A', corresponding to the strictly positive entries of p and q, is a proper submatrix of $\overline{A}$. By the minimax condition (1.1), (p, q) is optimal for A'. Hence $\mathrm{val}A' = p^T A' q = p^T \overline{A} q = \mathrm{val}\overline{A}$, which contradicts the minimality of $\overline{A}$.

Since the matrix game $\overline{A}$ is completely mixed, Proposition 1.1 (K2) implies that it has a unique Shapley–Snow kernel equal to $\overline{A}$. Hence (K1) follows. □

By the above proof the cmv-kernels are simply the minimal "value-wise Shapley–Snow kernels." Their utility comes from the fact, proved in Lemma 1.3 below, that the completely mixed matrix games form an open set in the space of the entries. In particular the single algebraic formula $\mathrm{val}(M) = (\mathbf{1}M^{-1}\mathbf{1})^{-1}$ is insensitive to small perturbations of a completely mixed matrix game M. This fact will be used in the proof of Lemma 4.1.

LEMMA 1.3. *Let* M *be a completely mixed matrix game. Then every matrix game of the same size whose entries are sufficiently close to the corresponding entries of* M*, is also completely mixed.*

Proof. Suppose that (M_i) is a sequence of not completely mixed matrix games of the same size, whose entries converge to the corresponding entries of M. For every i choose a pair of nonmixed optimal strategies for M_i and extract a subsequence converging to a pair of vectors (p, q). Since the set of all probability vectors (of a suitable dimension) having a zero in some entry is closed, and since the minimax condition is closed, then (p, q) is nonmixed and optimal for M, which is a contradiction. □

2. Discounted stochastic games.

2.1. Definitions and preliminaries of stochastic games. A *stochastic game* as formulated by Shapley [6] is played in stages. At each stage, the game is in one of finitely many *states*, $s = 1, 2, \ldots, N$, in which players I and II are obliged to play a matrix game $R(s) = (r(s, a, b))_{a,b=1}^{m_s,n_s}$, once. The "law of motion" is defined by the probabilities $p(s'|s, a, b)$, where the event $\{s'|s, a, b\}$ is the event that the game will enter state s' at the next stage given that at the current stage the state of the game is s, and that players I and II choose the ath row and the bth column of $R(s)$, respectively.

In general, players' strategies will depend on complete past histories. In this paper, however, we shall only be concerned with *stationary strategies*. We may represent a typical stationary strategy μ for player I by a "composite" vector, $\mu = (\mu(1), \mu(2), \ldots, \mu(N))$, where each $\mu(s)$ is a probability distribution on $\{1, 2, \ldots, m_s\}$. Player II's stationary strategies ν are similarly defined.

It should be clear that once we specify the initial state s and a strategy pair (μ, ν) for players I and II, we implicitly define a probability distribution over all sequences of states and actions which can occur during the game and consequently over all sequences of payoffs to player I. In particular, if the random variable $\mathcal{R}_t$ denotes the payoff to player I for stage t, then the expected value of $\mathcal{R}_t$ given s and (μ, ν)

$$E_{\mu\nu s}(\mathcal{R}_t) := E\{\mathcal{R}_t|\mu, \nu, s\}$$

is well defined. The *β-discounted stochastic game* Γ_β is then the game in which the overall payoff, normalized by a factor of $1 - \beta$, resulting from the strategy pair (μ, ν)

and a starting state s is evaluated according to

$$v_\beta(\mu,\nu,s) := \sum_{t=1}^{\infty} \beta^{t-1}(1-\beta)E_{\mu\nu s}(\mathcal{R}_t),$$

where $\beta \in (0,1)$ is called the *discount factor*. A number $v_s(\beta)$ is called the *value* of the game Γ_β starting in state s if $v_s(\beta) = \sup_\mu \inf_\nu v_\beta(\mu,\nu,s) = \inf_\nu \sup_\mu f_\beta(\mu,\nu,s)$. The vector $\mathbf{v}(\beta) = (v_1(\beta), v_2(\beta), \ldots, v_N(\beta))$ is called the *value vector*. Furthermore, the pair (μ^o, ν^o) is called an *optimal strategy pair* for players I and II if

$$v_s(\beta) = v_\beta(\mu^o, \nu^o, s).$$

The existence of the value vector and of a pair of *optimal stationary strategies* was proved in 1953 in Shapley's seminal paper on the subject [6]. A key element in Shapley's proof was the construction of N auxiliary matrix games $R_\beta(s,\mathbf{u})$ that depend on an arbitrary vector $\mathbf{u} = (u_1, u_2, \ldots, u_N) \in \mathbf{R^N}$ according to

$$R_\beta(s,\mathbf{u}) = \left[(1-\beta)r(s,a,b) + \beta \sum_{s'=1}^{N} p(s'|s,a,b)u_{s'}\right]_{a,b=1}^{m_s,n_s}. \tag{2.1}$$

In view of the fact that the value of a matrix game always exists, it is possible to define, for each $\beta \in (0,1)$, an operator $T_\beta : \mathbf{R^N} \to \mathbf{R^N}$, the sth component of which is given by

$$[T_\beta(\mathbf{u})]_s := \mathrm{val}[R_\beta(s,\mathbf{u})]. \tag{2.2}$$

This operator is a contraction operator in the sup-norm with contraction constant $\leq \beta$; see [6]. It therefore follows from Banach's fixed-point theorem that there exists a unique fixed point $\mathbf{v}(\beta)$ of T_β; that is,

$$\mathbf{v}(\beta) = T_\beta(\mathbf{v}(\beta)). \tag{2.3}$$

This can be shown to be an equivalent definition of the value vector $\mathbf{v}(\beta)$ introduced above. Also, any optimal strategy pairs for $R_\beta(s,\mathbf{v}(\beta))$ can be shown to form an optimal strategy pair for Γ_β.

Since $\{T_\beta\}$ is a continuous family of contractions we have the following result.

LEMMA 2.1. *The function $\beta \mapsto \mathbf{v}(\beta)$ is bounded and continuous on $[0,1)$.*

Proof. To prove boundedness, note that if $M_1 \leq r(s,i,j) \leq M_2$ for all s, i, and j, then T_β maps the hypercube $K = [M_1, M_2]^N$ into itself. Hence T_β has a fixed point in K, which must be $\mathbf{v}(\beta)$.

To prove continuity of $\mathbf{v}(\beta)$ at β_0, let $\beta' < \beta_0 < \beta'' < 1$ (for $\beta_0 \neq 0$; if $\beta_0 = 0$, then $\beta' = \beta_0$) and note that for all $\beta \in [\beta', \beta'']$ the map T_β is a contraction with a constant β''. Now for any $\epsilon > 0$ take the closed ball $\overline{B}(\epsilon) = \overline{B}(\mathbf{v}(\beta_0), \epsilon)$ in $\mathbf{R}^N$, and observe that T_{β_0} maps $\overline{B}(\epsilon)$ into itself. Moreover,

$$T_\beta(\overline{B}(\epsilon)) \subseteq \overline{B}\left(T_\beta(\mathbf{v}(\beta_0)), \beta''\epsilon\right) \tag{2.4}$$

for all $\beta \in [\beta', \beta'']$. By the continuous dependence of val$M$ on the entries of matrix M the map

$$\beta \mapsto T_\beta(\mathbf{v}(\beta_0))$$

(which moves the center of $\overline{B}(\epsilon)$) is continuous. This and (2.4) imply that, for all β close enough to β_0, T_β maps $\overline{B}(\epsilon)$ into itself (just like T_{β_0} does). Hence, for all β close enough to β_0, both T_β and T_{β_0} have their fixed points in $\overline{B}(\epsilon)$. Since those fixed points are $\mathbf{v}(\beta)$ and $\mathbf{v}(\beta_0)$ and since $\epsilon > 0$ is arbitrary, this implies that $\mathbf{v}$ is continuous at β_0. □

Assuming $v_s(\beta) \neq 0$ for all β and s, in view of Lemma 1.3 we know that for each fixed $\beta \in (0,1)$ and each $\mathbf{u}$ close enough to $\mathbf{v}(\beta)$ there exist cmv-kernels $\overline{R_\beta(s,\mathbf{u})}$ such that the fixed-point equation above locally reduces to

$$v_s(\beta) = \frac{|\overline{R_\beta(s,\mathbf{v}(\beta))}|}{\sum_i \sum_j \left[\overline{R_\beta(s,\mathbf{v}(\beta))}\right]_{ij}} \quad \text{for each } s = 1,2,\ldots,N,$$

where $[V]_{ij}$ denotes the (i,j)th cofactor of a matrix V.

If we now transform the above equations to

$$v_s(\beta)\left\{\sum_i \sum_j \left[\overline{R_\beta(s,\mathbf{v}(\beta))}\right]_{ij}\right\} - |\overline{R_\beta(s,\mathbf{v}(\beta))}| = 0 \quad \forall s = 1,2,\ldots,N, \tag{2.5}$$

then for each fixed combination of the locations of these kernels we can regard this system as being a system of polynomials in the variables $x_0 := \beta, x_1 := v_1(\beta), x_2 := v_2(\beta), \ldots, x_N := v_N(\beta)$ of the form

$$\begin{aligned} f_1(x_0,\ldots,x_N) &= 0, \\ &\vdots \\ f_N(x_0,\ldots,x_N) &= 0. \end{aligned} \tag{2.6}$$

2.2. Asymptotic result of Bewley and Kohlberg. The behavior of the value vector $\mathbf{v}(\beta)$ as $\beta \nearrow 1$ is extremely important in the analysis of the so-called *limiting-average stochastic game* Γ_α, where the overall payoff resulting from the strategy pair (μ,ν) and starting state s is evaluated according to

$$v_\alpha(\mu,\nu,s) := \liminf_{\tau\to\infty}\left(\frac{1}{\tau+1}\right)\sum_{t=o}^{\tau} E_{\mu\nu s}(R_t).$$

In particular, the limit of $\mathbf{v}(\beta)$ as $\beta \nearrow 1$ is the natural candidate for the value vector of Γ_α. Indeed, this was proved by Mertens and Neyman [4], who exploited an interesting characteristic of $\mathbf{v}(\beta)$ due to Bewley and Kohlberg [1]. We give a direct proof of the existence of this limit in section 5.

The result of Bewley and Kohlberg [1] can be interpreted as saying that *the solutions to the system of equations* (2.5) *are given by Puiseux series over the field of real numbers* (see section 3.1 below). As mentioned earlier, for β sufficiently near 1, their proof relies on a result in formal logic known as Tarski's principle (see [1]). However, systems of polynomial equations such as (2.6) are precisely the objects of study in the field of algebraic geometry. This is an old branch of mathematics, and it is in this setting that Puiseux series originally arose. In fact the use of fractional power series goes back to Newton. One would therefore expect that the tools of algebraic geometry would allow a "natural" proof of Bewley and Kohlberg's theorem. This indeed turns out to be the case. However, in order to do this some results from algebraic geometry will be needed.

3. Puiseux series and systems of polynomial equations.

3.1. Puiseux series. *Puiseux series* over a field $\mathbf{K}$, equal to either $\mathbf{R}$ or $\mathbf{C}$, are "fractional power series" of the form $\sum_{\nu=k}^{\infty} c_\nu z^{\nu/m}$, where $c_\nu \in \mathbf{K}$, $k \in \mathbf{Z}$, $m \in \mathbf{N}\setminus\{0\}$, and the series converges in some annulus, $\{z \in \mathbf{K} | 0 < |z| < R,\ R > 0\}$. The Puiseux series over K form a field (in fact the Puiseux series over $\mathbf{R}$ form an ordered field). Puiseux series over $\mathbf{C}$ are simply called Puiseux series. They arise as the solutions of particular polynomial equations. Specifically, there is the following classical result due to Puiseux (see [2, Chapter 1, Theorem 8.14]).

THEOREM 3.1 (Puiseux). *Let $\mathbf{C}\{\{z\}\}$ be the field of all Laurent series with finite principal part*

$$\phi(z) = \sum_{\nu=k}^{\infty} c_\nu z^\nu, \quad k \in \mathbf{Z}, \quad c_\nu \in \mathbf{C},$$

converging on some punctured disc $\{z \in \mathbf{C} : 0 < |z| < r\}$, where r may depend on the element $\phi \in \mathbf{C}\{\{z\}\}$. Let

$$F(z, w) = w^n + a_1(z)w^{n-1} + \cdots + a_n(z)$$

be a polynomial in w of degree n which is irreducible over the field $\mathbf{C}\{\{z\}\}$. Then there exists a Laurent series

$$\phi(\zeta) = \sum_{\nu=k}^{\infty} c_\nu \zeta^\nu \in \mathbf{C}\{\{\zeta\}\}$$

such that

$$F(\zeta^n, \phi(\zeta)) = 0$$

as an element of $\mathbf{C}\{\{\zeta\}\}$. In other words the equation

$$F(z, w) = 0$$

can be solved by a Puiseux series

$$w = \phi(z^{1/n}) = \sum_{\nu=k}^{\infty} c_\nu z^{\nu/n},$$

where $z^{1/n}$ is a branch of the nth root function.

The case where $F(z, w)$ is not necessarily irreducible over $\mathbf{C}\{\{z\}\}$ is covered by the following result. This result also states that locally *all* solutions to $F(z, w) = 0$ are given by Puiseux series.

COROLLARY 3.2. *Let*

$$F(z, t) = z^m + \sum_{k=0}^{m-1} z^k g_k(t),$$

where the g_k are holomorphic (resp., meromorphic) in a disc $D(0, r')$. Then there is $r \in (0, r')$, a positive integer M, and functions $\varphi_1, \ldots, \varphi_m$ holomorphic (resp., meromorphic) in $D(0, r^{1/M})$ such that

$$F(z, t^M) = \prod_{k=1}^{m} z - \varphi_k(t).$$

Note. Only the holomorphic variant will be used.

Proof. It suffices to prove the meromorphic version. Indeed, for each fixed t, the $\varphi_k(t)$ are roots of the monic polynomial $F(z, t^M)$. If the coefficients g_k are holomorphic near $t = 0$, they are bounded, and hence the roots stay in a bounded set; it follows that each φ_k has a removable singularity at 0.

We will write $\mathcal{M}$ for $\mathbf{C}\{\{t\}\}$. Each g_k will be regarded as an element of $\mathcal{M}$. Thus F is a polynomial over the field $\mathcal{M}$, that is, $F \in \mathcal{M}[z]$. Note that $\mathcal{M}$ (and $\mathbf{C}\{\{t\}\}$) can also be identified with the field $\mathcal{M}_0$ of germs of meromorphic functions at 0.

Observe that if $F = F_1F_2$, where $F_1, F_2 \in \mathcal{M}[z]$ are nonconstant monic polynomials satisfying the assertion with

$$F_j\left(z, t^{M_j}\right) = \prod_{k=1}^{m_j}(z - \varphi_{j,k}(t)) \quad (j = 1, 2),$$

then F also satisfies the assertion, since

$$F\left(z, t^{M_1M_2}\right) = \prod_{k=1}^{m_1}\left(z - \varphi_{1,k}\left(t^{M_2}\right)\right)\prod_{k=1}^{m_2}\left(z - \varphi_{2,k}\left(t^{M_1}\right)\right).$$

Also observe that, if the assertion is valid for the polynomial $F(z, t^n)$, where n is a positive integer, then it is also valid for $F(z, t)$, since

$$F\left(z, t^{M_n}\right) = \prod_{k=1}^{m}\left(z - \varphi_k\left(t^M\right)\right).$$

We will use induction with respect to the degree of F, the assertion being trivial if $\deg F = 1$. Let $G \in \mathcal{M}[z]$ be an irreducible factor of F. Theorem 3.1 says that the polynomial $G(z, t^n) \in \mathcal{M}[z]$, where $n = \deg G$, has a root $\varphi \in \mathcal{M}$. Hence $F(z, t^n) = (z - \varphi(t))F_1(z, t)$, where $F_1 \in \mathcal{M}[z]$. Since F_1 is a monic polynomial of degree $n - 1 < \deg F$, it satisfies the assertion. By the previous observations, the assertion is satisfied by $F(z, t^n)$ and hence by F. □

Remark. Another way of stating Puiseux's theorem is to say that the field of *real* Puiseux series is *real closed* (that is, no proper algebraic extension of the field of real Puiseux series is ordered). This is precisely the condition Bewley and Kohlberg needed in order to apply Tarski's principle and show that the value of a discounted, two-person, zero-sum stochastic game is given by a Puiseux series over $\mathbf{R}$ (see [1, section 10]).

As it stands, Puiseux's theorem does not apply to the system (2.6) for several reasons. First, (2.6) is a system of equations over $\mathbf{R}$ and not $\mathbf{C}$. Second, Puiseux's theorem applies to polynomial equations of a very special form, and there is no guarantee that the polynomials in (2.6) will have this form. In particular Puiseux's theorem involves *two* variables z and w, whereas the system (2.6) involves $N + 1$ variables $\beta, v_1(\beta), \ldots, v_N(\beta)$. Finally, the form of the polynomial system (2.6) depends on the location of the kernels and hence may be different for different values of β. Of these problems, the last two can be helped to be overcome by invoking a more general point of view, namely, that of algebraic geometry.

3.2. Algebraic and analytic varieties. Generally speaking, algebraic geometry over a field $\mathbf{F}$ (usually taken to be $\mathbf{R}$ or $\mathbf{C}$) is the study of the solution sets of

systems of polynomial equations of the form

$$\begin{aligned} f_1(z_0,\dots,z_N) &= 0,\\ &\vdots\\ f_k(z_0,\dots,z_N) &= 0, \end{aligned} \tag{3.1}$$

where, for $i = 1,\dots,k$, f_i is a polynomial of degree d_i over $\mathbf{F}$ and $(z_0,\dots,z_N) \in \mathbf{F}^{N+1}$. The solution set of (3.1) is called an *algebraic variety* over $\mathbf{F}$. Only the case $\mathbf{F} = \mathbf{C}$ will concern us at this stage. In this case the variety V defined by (3.1) will be a subset of $\mathbf{C}^{\mathbf{N+1}}$. The study of algebraic varieties over $\mathbf{C}$ uses powerful tools from both abstract algebra and complex analysis. The problem at hand will require the use of complex analytic methods. In particular the *local* properties of holomorphic functions are exploited.

A few preliminary definitions and results will be needed. Most of the definitions and theorems in this section are taken from [9]. A subset V of $\mathbf{C}^{N+1}$ is *analytic near* a point $p \in \mathbf{C}^{N+1}$ or is a *variety near* p if there is a neighborhood U of p and functions $f_1,\dots,f_k$ holomorphic on U such that $V \cap U$ is the zero set of these functions. If V is analytic near each of its points, then V is called *locally analytic* or a *local variety*. If H is open in $\mathbf{C}^{N+1}$ and $V \subseteq H$ is a local variety, then V is called a *variety in* H if V is closed in H (that is, if V is a variety near every point of H). If V and V' are local varieties such that $V' \subseteq V$ and V' is closed in V, then V' is called a *subvariety* of V (that is, V' is a variety near every point of V). Note that V is a variety in an open set H iff V is a subvariety of H. (Compare [9, Chapter 2, section 1].) We will be mainly interested in the case $H = \mathbf{C}^{N+1}$.

It is easy to see that any intersection or union of a family of varieties in H (or subvarieties of V) is also a variety in H (resp., subvariety of V), provided that the family is locally finite in H (resp., in V).

A point p of a local variety V is called a *regular* or *smooth point* of V of *dimension* d if V is a submanifold of dimension d near p. That is, if V is given in some neighborhood of p by the zero set of a collection of holomorphic functions $f_1,\dots,f_k$ whose Jacobian matrix has rank k; in this case $d = n - k$. The set of regular points of V of dimension d is denoted $\operatorname{Reg}_d V$, where $d = 0, 1, 2, \dots$. The set of regular points of any dimension is denoted $\operatorname{Reg} V$. It follows from Proposition 3.3 below that $\operatorname{Reg} V$ is dense in V. The *dimension* of V is defined by

$$\dim V = \max\{d : \operatorname{Reg}_d V \neq \emptyset\}.$$

If $\operatorname{Reg}_d V = \operatorname{Reg} V$ then we say that V is *purely d-dimensional* (or of *constant dimension* d) and write $\dim V \equiv d$ (see [9, Chapter 2, section 2]).

A local variety V is *irreducible* if it cannot be written as the union of two local varieties neither of which is equal to V. Proposition 3.3 below shows how every local variety can be written as a union of its irreducible subvarieties.

PROPOSITION 3.3 (see [9, Chapter 3, Theorem 1G]). *Let V be a local variety, let $M_1, M_2, \dots$ be the connected pieces of $\operatorname{Reg} V$, and let V_i denote the V-closure of M_i. Then V is the union of the V_i. Also*

(a) *each V_i is an irreducible subvariety of V of constant dimension equal to $\dim M_i$.*
(b) *the V_i form a locally finite collection of sets in V (i.e., any point $p \in V$ has a neighborhood in $\mathbf{C}^{N+1}$ which intersects only finitely many V_i's).*

The varieties V_i are called the *irreducible components* or *ircomps* of V. We will be mostly interested in the 1-dimensional ircomps. Also note that every 0-dimensional

local variety consists of isolated points (that is, $V = \mathrm{Reg}_0 V$). Indeed, the connected pieces of $\mathrm{Reg}_0 V$ are single isolated points, hence their closures are single isolated points and, by Proposition 3.3, their union is V.

PROPOSITION 3.4. *If $X = \bigcup_\alpha V_\alpha$, where the V_α are purely 1-dimensional varieties in $\mathbf{C}^{N+1}$ and the union is locally finite in $\mathbf{C}^{N+1}$, then X is a purely 1-dimensional variety in $\mathbf{C}^{N+1}$.*

Proof. This follows from [9, Chapter 2, Lemma 9J] since, by the local finiteness, the union is countable and X is locally analytic and closed in $\mathbf{C}^{N+1}$. □

PROPOSITION 3.5. *If V and W are varieties in $\mathbf{C}^{N+1}$, V is irreducible 1-dimensional, and V is not contained in W, then the set $V \cap W$ is discrete (or empty) in $\mathbf{C}^{N+1}$.*

Proof. The set $V \cap W$ is analytic in $\mathbf{C}^{N+1}$. Since $V \cap W$ is a proper subvariety of V, [9, Chapter 3, Theorem 1J] states that $\dim V \cap W < \dim V$. Hence $V \cap W$ is either (-1)-dimensional (that is, empty) or 0-dimensional, in which case it consists of isolated points. It is also closed in $\mathbf{C}^{N+1}$. □

It is convenient to introduce some notation to be used throughout the rest of the paper. For any $c \in \mathbf{C}$ define

$$H_c := \left\{(z_0, \ldots, z_N) \in \mathbf{C}^{N+1} : z_0 = c\right\}.$$

This is a hyperplane (dimension N variety) in $\mathbf{C}^{N+1}$. It is in the case $W = H_c$ that Proposition 3.6 will be applied.

The next result is essential in our approach to the connection with Puiseux series. It is known in the literature as the Remmert–Stein representation theorem (see [9, Chapter 3, section 3]). The 1-dimensional case of this theorem states that if a local variety V has constant dimension 1 and $p \in V$, then V can be locally represented by a set of equations to which Puiseux's theorem is applicable. However, V is not arbitrary: near p it must have a "good" location in the system of coordinates. Our formulation will follow [9, Theorems 3A(c) and 3D(a)].

PROPOSITION 3.6. *Let V be a local variety of constant dimension 1, and let $p = (c_0, \ldots, c_N) \in V$. Also, suppose that p is isolated in $V \cap H_{c_0}$. Then we may find*

(1) *a neighborhood $U = D_0 \times \cdots \times D_N$ of p, where the D_j are open discs;*
(2) *positive integers m_j;*
(3) *holomorphic functions $f_{j,k} : D_0 \to \mathbf{C}$,*

with the following property: for every point $(z_0, \ldots, z_N) \in V \cap U$ one has

$$z_j^{m_j} + \sum_{k=0}^{m_j - 1} z_j^k f_{j,k}(z_0) = 0 \quad \text{for} \quad j = 1, \ldots, N. \tag{3.2}$$

Proof. We may assume that p is the origin 0 since we can replace z_j with $z_j + c_j$ without affecting the leading term $z_i^{m_j}$ in (3.2). Thus, $0 \in V$ is isolated in $V \cap \mathbf{C}^N$ but is not isolated in $V \cap \mathbf{C}^{N+1}$ because $0 \notin \mathrm{Reg}_0 V = \emptyset$ (by 1-dimensionality). Now the proposition follows from [9, Chapter 2, Theorem 7A(b)] (with $n = N + 1$ and $\kappa = N$). □

The following result reinterprets the preceding proposition in terms of Puiseux series.

PROPOSITION 3.7. *Let V be a local variety of constant dimension 1, and let $p = (c_0, \ldots, c_N) \in V$. Also, suppose that p is isolated in $V \cap H_{c_0}$. Then there are a disc $D_0' = D(c_0, r)$, a positive integer M, and a finite set $\mathcal{S}$ of functions holomorphic in the disc $D(0, r^{1/M})$ with the following property. If*

$$(c_0 + t^M, z_1, \ldots, z_N) \in V \cap (D_0' \times D_1 \times \cdots \times D_N),$$

then for each $j = 1, \dots, N$ there is $\varphi \in \mathcal{S}$ such that

$$z_j = \varphi(t).$$

Proof. Use Proposition 3.6 and Corollary 3.2 for each j with $z = z_j$, $t = z_0 - c_0$ and $g_k(t) = f_{j,k}(z_0)$ to find corresponding integers M_j and sets $\mathcal{S}_j$. Then set $M = \prod M_j$ and

$$\mathcal{S} = \bigcup_j \left\{ \varphi(t^{M/M_j}) : \ \varphi \in \mathcal{S}_j \right\}. \qquad \square$$

4. Proof of main results.

4.1. Outline. Briefly, our approach is as follows. (Detailed proofs of statements below will be given in subsequent sections.) We want to use the Shapley–Snow equations to define a finite collection of varieties V_j in $\mathbf{C}^{N+1}$, each corresponding to one location of N square submatrices in the N $m_s \times n_s$ matrices $R(s, \mathbf{v}(\beta))$. Since equations (2.6) are polynomial, each such variety V_j is a variety in $\mathbf{C}^{N+1}$. The existence of the cmv-kernels implies that for each β there is j such that $(\beta, \mathbf{v}(\beta)) \in V_j$. Next, using the contraction property of the Shapley operator for the stochastic game, restricted to the cmv-kernels of the games $R_\beta(s, \mathbf{v}(\beta))$, we show that in fact $(\beta, \mathbf{v}(\beta)) \in \mathrm{Reg}_1 V_j$ ($j = j(\beta)$). We let V be the union of the closures of those connected components of the $\mathrm{Reg}_1 V_j$, which contain a corresponding point of the form $(\beta, \mathbf{v}(\beta))$; then, by Proposition 3.4, V is a variety in $\mathbf{C}^{N+1}$ of constant dimension 1. By Proposition 3.5, the set where V meets the hyperplane $H_c = \{(z_0, \dots, z_N) \in \mathbf{C}^{N+1} | z_0 = c\}$ is discrete (for all $c \in \mathbf{C}$). For $c = 1$ this, together with continuity of $\mathbf{v}$, directly implies the existence of $\lim_{\beta \to 1} \mathbf{v}(\beta)$. This also makes it possible to apply Proposition 3.7 which, along with the Puiseux theorem, readily implies that $\mathbf{v}$ has one-sided Puiseux series developments at every point of the closed interval $[0, 1]$. (In particular, it is analytic on $[0, 1]$ except for a finite set.)

Next we use the fact that whether a given submatrix is a Shapley–Snow kernel is determined by a finite number of inequalities involving meromorphic functions of the entries. This fact, along with Puiseux developments of $\mathbf{v}$, implies that Shapley–Snow kernels of $R_\beta(s, \mathbf{v}(\beta))$ can be selected piecewise constant on the interval $[0, 1]$. Therefore, by Proposition 1.1 (K2), optimal strategies can be selected to have one-sided Puiseux developments near all points of the interval $[0, 1]$.

4.2. Algebraic varieties and stochastic games. Since we want to compute the components of $\mathbf{v}(\beta)$ using the cmv-kernels, we need the condition

$$\operatorname{val} R_\beta(s, \mathbf{v}(\beta)) \neq 0 \quad (\beta \in (0, 1), \quad s = 1, \dots, N). \tag{4.1}$$

This can be achieved, without loss of generality, by replacing every reward $r(s, i, j)$ with $r'(s, i, j) = r(s, i, j) + r$, where r is large enough. Since $\mathbf{v}(\beta)$ is a bounded function of β (by Lemma 2.1), if r is large enough, we have $v_s'(\beta) > 0$ for all s and β. Moreover, adding the constant r does not affect the existence of $\lim_{\beta \to\ 1} \mathbf{v}(\beta)$ or of the Puiseux series expansion. In what follows we assume that Γ itself satisfies (4.1).

Consider any fixed collection of nonempty subsets of actions $K_s \subseteq \{1, \dots, m_s\}$ and $L_s \subseteq \{1, \dots, n_s\}$ such that $\operatorname{card} K_s = \operatorname{card} L_s$ for all $s = 1, \dots, N$. Thus we have a finite sequence of sets $\kappa = (K_1, L_1, \dots, K_N, L_N)$. By restricting the players' actions in each state s to K_s and L_s, we obtain a discounted stochastic game, $\Gamma_{\beta,\kappa}$ with auxiliary Shapley games

$$R_{\beta,\kappa}(s,\mathbf{x}) = [R_\beta(s,\mathbf{x})_{ij}]_{i\in K_s, j\in L_s}\,.$$

Let $T_{\beta,\kappa}:\mathbf{R}^N\to\mathbf{R}^N$ denote the Shapley operator (2.2) for $\Gamma_{\beta,\kappa}$.

In the original game Γ_β, for each β and $\mathbf{x}$ such that for each s $\operatorname{val}R_\beta(s,\mathbf{x})\neq 0$ select some cmv-kernel of each matrix game $R_\beta(s,\mathbf{x})$, given by

$$\overline{R_\beta(s,\mathbf{x})} = [R_\beta(s,\mathbf{x})_{ij}]_{i\in K_s(\beta,\mathbf{x}),\ j\in L_s(\beta,\mathbf{x})}\,,$$

where $K_s(\beta,\mathbf{x})\subseteq\{1,\dots,m_s\}$ and $L_s(\beta,\mathbf{x})\subseteq\{1,\dots,n_s\}$. Recall that $\overline{R_\beta(s,\mathbf{x})}$ are completely mixed square matrix games. By (4.1) and by Lemma 1.2, these kernels are defined in particular, for all those $(\beta,\mathbf{x})$ lying on the graph of $\mathbf{v}$. Also, let

$$\kappa(\beta) = (K_1(\beta,\mathbf{v}(\beta)), L_1(\beta,\mathbf{v}(\beta)),\dots,K_N(\beta,\mathbf{v}(\beta)), L_N(\beta,\mathbf{v}(\beta)))\,.$$

In other words $\kappa(\beta)$ correspond to the cmv-kernels of $R_\beta(s,\mathbf{v}(\beta))$.

Now, for a fixed κ, consider the following four systems of N equations in the $N+1$ variables $\beta,x_1,\dots,x_N$:

(V0) $x_s = \operatorname{val}R_\beta(s,x_1,\dots,x_N)\quad(s=1,\dots,N)$,

(V1) $x_s = \operatorname{val}R_{\beta,\kappa}(s,x_1,\dots,x_N)\quad(s=1,\dots,N)$,

(V2) $x_s = \frac{\det R_{\beta,\kappa}(s,x_1,\dots,x_N)}{\sum_{ij}R^{ij}_{\beta,\kappa}(s,x_1,\dots,x_N)}\quad(s=1,\dots,N)$,

(V3) $x_s\sum_{ij}R^{ij}_{\beta,\kappa}(s,x_1,\dots,x_N) - \det R_{\beta,\kappa}(s,x_1,\dots,x_N) = 0\ (s=1,\dots,N)$,

where the R^{ij} denote cofactors. To begin with, we make some simple observations concerning these systems.

(i) The systems $(V0)$ and $(V1)$ are defined in $(0,1)\times\mathbf{R}^N$. (V0) is a reformulation of $\mathbf{x}=T_\beta(\mathbf{x})$, and (V1) is a reformulation of $\mathbf{x}=T_{\beta,\kappa}(\mathbf{x})$. Let $CMV_\kappa\subseteq(0,1)\times\mathbf{R}^N$ be the set of parameters $(\beta,\mathbf{x})$, where $R_{\beta,\kappa}(s,\mathbf{x}) = \overline{R_\beta(s,\mathbf{x})}$. Then (V0) and (V1) are equivalent on CMV_κ.

(ii) The system (V2) is defined and analytic in an open subset $U_\kappa\subseteq\mathbf{C}^{N+1}$. Let $CM^+_\kappa\subseteq(0,1)\times\mathbf{R}^N$ denote the set of parameters $(\beta,\mathbf{x})$, where all the matrix games $R_{\beta,\kappa}(s,x_1,\dots,x_N)$ $(s=1,\dots,N)$ are completely mixed and have a nonzero value. Then

$$CMV_\kappa\subseteq CM^+_\kappa\subseteq U_\kappa.$$

Also, on CM^+_κ, (V2) is a simple restatement of (V1), for, by Proposition 1.1 (K2), on CM^+_κ each matrix $R_{\beta,\kappa}(s,\mathbf{x})$ is a Shapley–Snow kernel of itself and hence (K1) can be applied with $A=\overline{A}=R_{\beta,\kappa}(s,\mathbf{x})$.

(iii) The system (V3) is defined and analytic (in fact, algebraic) in $\mathbf{C}^{N+1}$. It thus defines an analytic variety in $\mathbf{C}^{N+1}$. Call this variety V_κ. Clearly, (V3) is equivalent to (V2) whenever the denominators in (V2) are nonzero.

From Lemma 1.3 it follows that CM^+_κ is an open subset of $(0,1)\times\mathbf{R}^N$.

Note that the CMV_κ are not necessarily open (or closed). However, for all $\beta\in(0,1)$ we have, by definition,

$$(\beta,\mathbf{v}(\beta))\in CMV_{\kappa(\beta)}$$

and hence

$$\bigcup_\beta(\beta,\mathbf{v}(\beta))\subseteq\bigcup_\kappa V_\kappa.$$

LEMMA 4.1. *If $p \in V_\kappa \cap CM_\kappa^+$, then $p \in \mathrm{Reg}_1 V_\kappa$. Moreover, in some neighborhood of p in $\mathbf{C}^{N+1}$, the variety V_κ is the graph of a holomorphic function from an open subset of $\mathbf{C}$ into $\mathbf{C}^N$.*

Proof. We use the fact that $T_{\beta,\kappa}$ is a contraction in $\mathbf{R}^N$. Let $p = (\beta^0, x_1^0, \dots, x_N^0)$. Near p, namely, in the set U_κ—which is a neighborhood of p as $p \in CM_\kappa^+ \subseteq U_\kappa$—the variety V_κ is, in view of remark (iii) above, defined by the system (V2). First rewrite (V2) directly in the form

$$F_\kappa(\beta, x_1, \dots, x_N) - (x_1, \dots, x_N) = 0.$$

Thus, $F_\kappa : U_\kappa \to \mathbf{C}^N$ is an analytic (in fact, rational) function, and by remark (ii) above,

$$F_\kappa(\beta, \cdot) \equiv T_{\beta,\kappa}(\cdot) \qquad \text{for} \qquad (\beta, \cdot) \in CM_\kappa^+. \tag{4.2}$$

By the complex implicit function theorem it is enough to show that the $N \times N$ complex matrix

$$D^{\mathbf{C}}_{x_1,\dots,x_N} F_\kappa(\beta^0, x_1^0, \dots, x_N^0) - I \tag{4.3}$$

is nonsingular, where $D^{\mathbf{C}}_{x_1,\dots,x_N}$ denotes complex differentiation along the complex hyperplane $H_0 = \{(x_0, \dots, x_N) \in \mathbf{C}^{N+1} | x_0 = 0\}$. By (4.2), the map $F_\kappa(\beta^0, \cdot)$ is a contraction (in the real sup-norm) from the set $\{\mathbf{x} : (\beta^0, \mathbf{x}) \in CM_\kappa^+\} \subseteq \mathbf{R}^N$ into $\mathbf{R}^N$. Let $D^{\mathbf{R}}$ denote differentiation along the real directions (and here, as the target-space is $\mathbf{R}^N$, this is equivalent to real differentiation). Since CM_κ^+ is open, and since $p \in CM_\kappa^+$, it follows that $D^{\mathbf{R}}_{x_1,\dots,x_N} F_\kappa(p)$ is also a contraction, and hence the matrix

$$D^{\mathbf{R}}_{x_1,\dots,x_N} F_\kappa(\beta^0, x_1^0, \dots, x_N^0) - I$$

is nonsingular over $\mathbf{R}$. But since F_κ is a holomorphic extension of a real function and $p \in \mathbf{R}^{N+1}$, we have $D^{\mathbf{C}} F_\kappa(p) = D^{\mathbf{R}} F_\kappa(p)$. (Alternatively, it is enough to note that, since F_κ is a rational function, both Jacobians can be computed algebraically in the same way.) Since a real nonsingular matrix is also nonsingular as a complex matrix, we find that (4.3) is indeed nonsingular and the proof is complete. □

We now prove that $(\beta, \mathbf{v}(\beta))$ lies in the 1-dimensional regular part of V_κ (for a suitable κ).

LEMMA 4.2. *For all $\beta \in (0,1)$ we have $(\beta, \mathbf{v}(\beta)) \in \mathrm{Reg}_1 V_{\kappa(\beta)}$, with $\kappa(\beta)$ defined above, corresponding to some arbitrarily selected cmv-kernels of $R_\beta(s, \mathbf{v}(\beta))$. More precisely, $\mathrm{Reg}_1 V_{\kappa(\beta)}$ meets the hyperplane H_β transversally at the point $(\beta, \mathbf{v}(\beta))$.*

Proof. By Lemma 4.1 it is enough to show that $(\beta, \mathbf{v}(\beta)) \in V_{\kappa(\beta)} \cap CM^+_{\kappa(\beta)}$. Since $\kappa(\beta)$ corresponds to the cmv-kernels, we have $(\beta, \mathbf{v}(\beta)) \in CMV_{\kappa(\beta)} \subseteq CM^+_{\kappa(\beta)}$. To see that $(\beta, \mathbf{v}(\beta)) \in V_{\kappa(\beta)}$, recall that by (i), (ii), (iii) on $CMV_{\kappa(\beta)}$, (V3) is equivalent to (V0) which, evaluated at $(\beta, \mathbf{v}(\beta))$, has the form

$$\mathbf{v}(\beta) = T_\beta(\mathbf{v}(\beta)), \tag{4.4}$$

which is true by definition. The fact that $\mathrm{Reg}_1 V_{\kappa(\beta)}$ meets H_β transversally at $(\beta, \mathbf{v}(\beta))$ follows from the second statement of Lemma 4.1. □

We are now in a position to define a variety V associated to a discounted stochastic game.

THEOREM 4.3. *There exists a variety $V = V(\Gamma)$ in $\mathbf{C}^{N+1}$ with the following properties*

(a) *V has constant dimension* 1.
(b) *For every $c \in \mathbf{C}$ the intersection of V with the hyperplane $H_c = \{(z_0, \ldots, z_N) \in \mathbf{C}^{N+1} | z_0 = c\}$ is a discrete subset of $\mathbf{C}^{N+1}$.*
(c) *For every $\beta \in (0,1)$ we have $(\beta, \mathbf{v}(\beta)) = (\beta, v_1(\beta), \ldots, v_N(\beta)) \in V$.*

Proof. By Lemma 4.2, for every $\beta \in (0,1)$ there is $\kappa(\beta)$ such that $(\beta, \mathbf{v}(\beta)) \in \mathrm{Reg}_1 V_{\kappa(\beta)}$. Let V_β be the closure of the connected component of $\mathrm{Reg}_1 V_{\kappa(\beta)}$, containing the point $(\beta, \mathbf{v}(\beta))$. (Note that it may frequently happen that $V_{\beta'} = V_{\beta''}$ with $\beta \neq \beta''$.) Then, by Proposition 3.3(a), V_β is an irreducible purely 1-dimensional variety in $\mathbf{C}^{N+1}$. Also, V_β is not contained in H_c; otherwise $c = \beta$, but in this case the transversality property in Lemma 4.2 leads to a contradiction. Since H_c is a variety in $\mathbf{C}^{N+1}$ (defined by the equation $x_0 = c$), Proposition 3.5 states that the set $H_c \cap V_\beta$ is discrete. Let $V = V(\Gamma)$ be defined by

$$V = \bigcup_{\beta \in (0,1)} V_\beta.$$

By construction, V is a union of certain 1-dimensional ircomps of the V_κ. By Proposition 3.3(b), and since there are only a finite number of κ's, the union is locally finite. Hence, Proposition 3.4 implies that V is a purely 1-dimensional variety in $\mathbf{C}^{N+1}$. Also, by local finiteness the set $H_c \cap V$ is discrete. ∎

Remark. The variety V constructed in Theorem 4.3 may not necessarily be unique since it may depend on the choice of $\kappa(\beta)$. However, this fact is not relevant to the application of Theorem 4.3. The notation $V = V(\Gamma)$ is therefore a little misleading. This can be easily remedied if we define $V(\Gamma)$ as the smallest V satisfying Theorem 4.3. In fact it can be shown that the intersection of all the V's satisfying Theorem 4.3 also satisfies that theorem.

THEOREM 4.4. *The value vector $\mathbf{v}(\beta)$ converges in $\mathbf{C}^N$ as $\beta \nearrow 1$.*

Proof. Let $V = V(\Gamma)$ and H_1 be as in Theorem 4.3 (i.e., $H_1 = H_c$, where $c = 1$). Since $\mathbf{v}$ is a bounded function of β (by Lemma 2.1), take a compact set $K \subseteq \mathbf{C}^{N+1}$ such that $(\beta, \mathbf{v}(\beta)) \in K$ for every β. Then, by Theorem 4.3(b), the set $P = H_1 \cap V \cap K$ is discrete in $\mathbf{C}^{N+1}$. Also, since K is compact, P is finite. Let $P = \{p_1, p_2, \ldots p_r\}$.

Next, we claim that

$$\mathrm{dist}((t,x), P) \to 0 \quad \text{as} \quad (t,x) \in V \cap K, \quad t \to 1 \quad \text{and} \quad x \in \mathbf{C}^N. \tag{4.5}$$

Suppose that it is not so. Then there exist $\delta > 0$ and a sequence $(a_k) \equiv (t_k, x_k)$ with $t_k \to 1$ and $a_k \in V \cap K$ such that $\mathrm{dist}(a_k, P) > \delta$ for each k. There is a subsequence of (t_k, x_k) converging to a point $p = (1, x_\infty)$, and $p \in V \cap K$ since V and K are closed. It follows that $p \in N$. Thus, δ cannot exist.

From (4.5) and Theorem 4.3(c) it follows that

$$\mathrm{dist}((\beta, \mathbf{v}(\beta)), P) \to 0 \quad \text{as} \quad \beta \to 1. \tag{4.6}$$

In particular, this implies that P is not empty.

Now, since P is finite, take a fixed $\epsilon > 0$ such that the balls $B_j = B(p_j, \epsilon)$ are disjoint. By (4.6), there exists $c < 1$ such that for all $\beta > c$, $(\beta, \mathbf{v}(\beta)) \in B_k$ for some $k = k(\beta)$. But since $\mathbf{v}(\beta)$ is continuous on the interval $(c, 1)$ (Lemma 2.1), $k(\beta)$ must be the same for all $\beta > c$; otherwise the preimages under the continuous function $\beta \mapsto (\beta, \mathbf{v}(\beta))$ of the B_k would partition the interval (c,1) into at least two disjoint nonempty open sets. Thus it follows from (4.6) that $\lim_{\beta \to 1} \mathbf{v}(\beta) = p_k$. ∎

COROLLARY 4.5. *The function $\mathbf{v}$ can be extended continuously over the interval $[0,1]$. Also, $(\beta, \mathbf{v}(\beta)) \in V(\Gamma)$ for all $\beta \in [0,1]$.*

Proof. The first assertion follows directly from Theorem 4.4 (having Lemma 2.1 in mind). The second follows from Theorem 4.4 and the fact that $V(\Gamma)$ is closed. □

4.3. The connection with Puiseux series. We are now in a position to apply Proposition 3.7 to the variety V at the point $p = (1, v_1(1), \dots, v_N(1))$. In fact we prove a slightly more general result.

THEOREM 4.6. *There is a finite set $\mathcal{N} \subseteq [0,1]$ such that $\mathbf{v}$ is analytic on $[0,1]\backslash\mathcal{N}$ and develops (component-wise) into a real Puiseux series in one-sided neighborhoods of each point of $\mathcal{N}$.*

More precisely, for any $c_0 \in (0,1]$ there exist $\epsilon > 0$ and $M \in \mathbf{N}$ such that each v_j is an analytic function of $u = \sqrt[M]{c_0 - \beta}$ for $\beta \in (c_0 - \epsilon, c_0]$, and a similar statement holds for each $c_0 \in [0,1)$, $u = \sqrt[M]{\beta - c_0}$, and $\beta \in [c_0, c_0 + \epsilon)$.

Proof. It is sufficient to prove the second part of the theorem. The fact that V is analytic outside a finite set $\mathcal{N}$ can be deduced from this second part by selecting a suitable finite subcover of $[0,1]$ and noting that a Puiseux function is analytic except at the base point. Let $V = V(\Gamma)$ be as in Theorem 4.3. Let $c_0 \in [0,1]$ be fixed, and denote

$$p := (c_0, \mathbf{v}(\beta)) = (c_0, v_1(c_0), \dots, v_N(c_0)) = (c_0, c_1, \dots, c_N).$$

By Theorem 4.3(b) the set $V \cap H_{c_0}$ is discrete. (In fact, $V \cap H_c$ is discrete for every $c \in \mathbf{C}$.) Hence p is isolated in $V \cap H_{c_0}$. Hence Proposition 3.7 is applicable, and we will follow its notation.

Since $\mathbf{v}$ is continuous at c_0, there is $\epsilon_1 > 0$ such that if $\beta \in [0,1]$ and $|\beta - c_0| < \epsilon_1$, then $(\beta, \mathbf{v}(\beta)) \in V \cap (D_0' \times \cdots \times D_N)$.

Let $t = \alpha u$, where α is chosen so that $t^M = \beta - c_0$; say, $\alpha = 1$ if we consider $\beta \geq c_0$ and $\alpha = e^{2\pi i/M}$ if we consider $\beta \leq c_0$. Thus, by Proposition 3.7, for any $j \in \{1, \dots, N\}$ we have

$$\text{if } |t^M| < \epsilon_1, \text{ then } (\exists \varphi \in \mathcal{S}) \quad v_j(c_0 + t^M) = \varphi(t) = \varphi(\alpha u). \tag{4.7}$$

Since the elements of $\mathcal{S}$ are holomorphic, the zero set of $\varphi - \phi$, where $\varphi, \phi \in \mathcal{S}$ and $\varphi \not\equiv \phi$, cannot have 0 as a limit point. Hence, there is $\epsilon_2 > 0$ with $\epsilon_2 \leq \epsilon_1$ such that

$$\text{if } \varphi, \phi \in \mathcal{S} \text{ and } \varphi \not\equiv \phi \text{ and } 0 < |t^M| < \epsilon_2, \text{ then } \varphi(t) \neq \phi(t) \tag{4.8}$$

By the continuity of v_j and of the $\varphi \in \mathcal{S}$, it follows that for each j the choice of the function $\varphi \in \mathcal{S}$ in (4.7) must be locally constant for $|t^M| \in (0, \epsilon_2)$. It follows that the choice of φ must be constant for $\beta \in I^+ = (c_0, c_0 + \epsilon_2) \cap [0,1]$ and for $\beta \in I^- = (c_0 - \epsilon_2, c_0) \cap [0,1]$, because the intervals I^+ and I^- are connected. Thus, by (4.7),

$$v_j(\beta) = f(u) \quad \text{on } I^+, \tag{4.9}$$

where $f(x) = \varphi(\alpha x)$ and φ is a fixed element of $\mathcal{S}$. An analogous result holds on I^-. However, the choice of φ (a fixed element of $\mathcal{S}$) may be different on I^-. It suffices to consider the case where $I^+ \neq \emptyset$ (resp., $I^- \neq \emptyset$). Since v_j is real valued on I^+ (resp., I^-), the power series of f has real coefficients. By continuity, (4.9) holds for $u = 0$ as well. By formula (4.9) the theorem is proven. □

5. Connection with analytic matrix games, Shapley–Snow kernels, and optimal strategies. In this subsection we derive from Theorem 4.6 some results on Shapley–Snow kernels and optimal strategies. First we present a lemma on analytic matrix games.

LEMMA 5.1. *Let $A(t)$ $(-r \le t \le r)$ be a family of nonzero-value matrix games of constant dimension $m \times n$, whose entries are holomorphic in the disc $D(0, r')$ with $r' > r$. Then it is possible to choose a Shapley–Snow kernel of $A(t)$ for each $t \in [-r, r]$ so that the location of the kernels is piecewise constant.*

More precisely, there exist a finite partition $[-r, r] = \cup_k I_k$, where the I_k are open or degenerate disjoint intervals, and sets $K_k \subseteq \{1, \dots, m\}$ and $L_k \subseteq \{1, \dots, n\}$ such that $[A(t)_{ij}]_{i \in K_k, j \in L_k}$ is a Shapley–Snow kernel of $A(t)$ for all $t \in I_k$.

Proof. Let $A(t) = [a_{ij}(t)]_{i,j=1}^{m,n}$ and consider any submatrix $B(t) = [a_{ij}(t)]_{i \in K, j \in L}$, where the sets K and L are fixed. The necessary and sufficient conditions for $B(t)$ to be a Shapley–Snow kernel of $A(t)$ are the following:

$$\begin{aligned} &\det B(t) \neq 0, \mathbf{1}^T B(t)^{-1} \mathbf{1} \neq 0, \text{ and} \\ &(p(t)^o, q(t)^o) \text{ is a pair of optimal strategies for } A(t), \end{aligned} \tag{5.1}$$

where

$$p(t) = \frac{\mathbf{1}^T B(t)^{-1}}{\mathbf{1}^T B(t)^{-1} \mathbf{1}} \text{ and } q(t) = \frac{B(t)^{-1} \mathbf{1}}{\mathbf{1}^T B(t)^{-1} \mathbf{1}} \tag{5.2}$$

and x^o denotes a vector of dimension m or n obtained by inserting zeroes in entries that do not appear in x. (Then one also automatically has val $A(t) =$ val $B(t) = (\mathbf{1}^T B(t)^{-1} \mathbf{1})^{-1}$.)

The conditions of (5.1) are equivalent to

$$\begin{aligned} &\det B(t) \neq 0, \mathbf{1}^T B(t)^{-1} \mathbf{1} \neq 0, \\ &p_i(t) \ge 0 \text{ and } q_j(t) \ge 0 \quad (i = 1, \dots, m, j = 1, \dots, n), \text{ and} \\ &e_i A(t) q(t)^o \le p(t)^o A(t) q(t)^o \le p(t)^o A(t) e_j \quad (i = 1, \dots, m, j = 1, \dots, n), \end{aligned} \tag{5.3}$$

where the e_k are unit coordinate vectors of appropriate dimension. (One also automatically has $\sum_i p_i(t) = \sum_j q_j(t) = 1$ by (5.2).)

We may leave out the case where $\det B(t) \equiv 0$ on $D(0, r')$. Then the entries of $B(t)^{-1}$ are meromorphic on $D(0, r')$. Hence the formulae in (5.4) involve functions meromorphic in $t \in D(0, r')$. Consequently, each of these formulas becomes an equality either for all $t \in [-r, r]$ or at most for a finite number of values of $t = t_0, \dots, t_M \in [-r, r]$, and we may assume $-r = t_0 < \cdots < t_M = r$. On each interval (t_k, t_{k+1}) these functions are continuous, so the relations in (5.3) become $>$ or $<$ or $=$ and are fixed.

Consequently, if $B(t)$ is a Shapley–Snow kernel for some $t \in (t_k, t_{k+1})$, then it is so for all $t \in (t_k, t_{k+1})$. Since a Shapley–Snow kernel exists for each $t \in [-r, r]$ (by Proposition 1.1), if we set $I_0 = \{t_0\}$, $I_1 = (t_0, t_1)$, $I_2 = \{t_1\}$, $I_3 = (t_1, t_2)$, etc., then the submatrices $K_k \times L_k$ can be found. ∎

THEOREM 5.2. *There is a finite partition of the interval $[0, 1]$ into subintervals I_k, open or degenerate, such that the Shapley–Snow kernels of the matrix games $R_\beta(s, \mathbf{v}(\beta))$ can be chosen for each $\beta \in [0, 1]$ in such a way that the location of these kernels is constant on each I_k.*

Proof. By Theorem 4.6 and by compactness, the interval $[0, 1]$ can be divided into subintervals $I_k = [t_k, t_{k+1}]$ $(0 = t_0 < \cdots < t_s = 1)$ so that the entries of the

$R_\beta(s, \mathbf{v}(\beta))$ are given by analytic functions of $u = \sqrt[M]{\beta - t_k}$ or $u = \sqrt[M]{t_{k+1} - \beta}$, having holomorphic extensions over a disc $D(0, r')$ with $r' > \sqrt[M]{t_{k+1} - t_k}$. By Lemma 5.1, the interval $[0, \sqrt[M]{t_{k+1} - t_k}]$ has the desired partition, which can be pulled back to I_k as the real Mth root function $\sqrt[M]{}$ is increasing. Now it is enough to use these partitions, letting each t_k form a degenerated interval. □

COROLLARY 5.3. *One can choose some optimal stationary strategy pair* $(u^0(\beta), v^0(\beta))$ *of* Γ_β *for each* $\beta \in [0, 1)$ *in such a way that there exists a set* $\{c_k\}_{k=0}^n$, $0 = c_0 < \cdots < c_n = 1$, *satisfying the following:*

(i) *For* $\beta \in [0, 1] \backslash \{c_k\}_{k=0}^n$, u^0 *and* v^0 *are analytic functions of* β.
(ii) *For all* $k = 1, \ldots, n$, *there exists* $\epsilon > 0$ *such that for* $\beta \in (c_k - \epsilon, c_k)$ *each component of* u^0 *and* v^0 *is a real Puiseux function of* $c_k - \beta$.
(iii) *For all* $k = 0, \ldots, n-1$, *there exists* $\epsilon > 0$ *such that for* $\beta \in (c_k, c_k + \epsilon)$ *each component of* u^0 *and* v^0 *is a real Puiseux function of* $\beta - c_k$.

Proof. Let a set $\{c_0, \ldots, c_M\}$ with $0 = c_0 < \cdots < c_n = 1$ contain all the partition points implied by Theorems 5.2 and 4.6. Let $A(s, \beta)$ denote some corresponding Shapley–Snow kernels of $R_\beta(s, v(\beta))$, whose location, by Theorem 5.2, may be assumed to be constant on each (c_k, c_{k+1}).

By subsection 2.1, a pair $(u^0(\beta), v^0(\beta))$ will be optimal for Γ_β if

$$u^0(\beta) = (p(1, \beta), \ldots, p(N, \beta)) \text{ and } v^0(\beta) = (q(1, \beta), \ldots, q(N, \beta)),$$

where each $(p(s, \beta), q(s, \beta))$ is an optimal strategy pair for $R_\beta(s, v(\beta))$.

By Proposition 1.1 we can put

$$p(s, \beta) = \mathbf{1}^T A(s, \beta)^{-1} \mathrm{val} A(s, \beta),$$

$$q(s, \beta) = A(s, \beta)^{-1} \mathbf{1} \mathrm{val} A(s, \beta), \tag{5.4}$$

$$\text{where } \mathrm{val} A(s, \beta) = (\mathbf{1}^T A(s, \beta)^{-1} \mathbf{1})^{-1}.$$

For $\beta \in (c_k, c_{k+1})$ the entries of $A(s, \beta)$ depend analytically on β (since $\mathbf{v}(\beta)$ does, by Theorem 4.6). For $\beta \in (c_k - \epsilon, c_k)$ $(k = 1, \ldots, n)$ or $\beta \in (c_k, c_k + \epsilon)$ $(k = 0, \ldots, n-1)$ the entries of $A(s, \beta)$ are Puiseux functions of $|\beta - c_k|$ (by the same Theorem 4.6). By the formulas in (5.4), the same can be said about $p(s, \beta)$ and $q(s, \beta)$. In addition, here all functions are real. □

CONSTRAINED REGULAR LQ-CONTROL PROBLEMS*

G. STEFANI† AND P. ZEZZA‡

Abstract. In this paper we give a complete description of how the Jacobi theory of conjugate points can be extended to a regular linear-quadratic control problem where the state end-points are jointly constrained to belong to a subspace of $\mathbf{R}^n \times \mathbf{R}^n$ and there is a linear pointwise state-control constraint. We introduce also the definition of semiconjugate point which describes a distinctive feature of these problems and state the corresponding necessary and sufficient conditions for the quadratic form to be nonnegative or coercive. In the case in which the constraints and the costs act separately on the initial and final points we give equivalent characterizations of the coercivity of the quadratic form by means of the solutions of an associated Riccati equation in both the controllable and uncontrollable case.

Key words. linear-quadratic problems, conjugate points, end-point constraints, pointwise state-control constraints, necessary and sufficient conditions, Riccati equation

1. Introduction.

Although linear-quadratic (LQ) problems have been studied since the birth of control theory, there are still interesting questions which wait for a complete answer. This is the case for the problem we analyze in this paper. It is an LQ-control problem whose main features are that the state end-points are jointly constrained to belong to a subspace of $\mathbf{R}^n \times \mathbf{R}^n$ and that there is a linear pointwise state-control constraint. These kinds of problems arise while studying second-order optimality conditions in nonlinear problems with mixed state-control constraints of both equality and inequality type. Second-order conditions are needed in nonlinear problems both when the candidate solution is not unique (see [13] for a numerical example) and when an existence theorem cannot be applied (see Example 4.4 and [13] for numerical examples).

The aim of this paper is to give a complete description of how the Jacobi theory of conjugate points can be extended to this kind of regular LQ-control problems with a possibly indefinite cost; here, regular means that a suitable version of the Legendre condition is fulfilled. We are then able to state necessary and sufficient conditions for the quadratic form to be nonnegative or coercive. This issue is interesting because these problems have properties different from the usual ones. For this reason we introduce the definition of semiconjugate point because the points which characterize the coercivity and the nonnegativity of the quadratic form are different when the problem is not controllable or when it does not have at least one fixed end-point.

In the case when the constraints and the costs act separately on the initial and final points we give an equivalent characterization of the coercivity of the quadratic form by means of the solutions of the associated Riccati equation in both the controllable and the uncontrollable case. In the case of controllable systems the result is sharper, and it allows us to solve the associated affine problem; see [22]. These

Riccati-type conditions can be applied also to problems with boundary conditions given jointly on both end-points, for example, periodic, by transforming the problem into another one in double dimension. Here we give a sufficient condition which can be simply stated and proved.

The previous results, together with the results in [23] (announced in [18]), give necessary and/or sufficient conditions for a constrained nonlinear optimal control problem to have a weak local minimum. For a survey, see [21].

Our results extend to the control, setting some classical results for problems in the calculus of variations, where an important role is played by the Legendre and Jacobi conditions. They concern the quadratic form obtained as the second variation of a nonlinear problem. The original results are about the simplest problem in the calculus of variations, where both end-points are fixed (Jacobi, 1837), and they have been generalized by Kneser, 1896, to the case of one fixed end-point. The statements are based on the definition of conjugate (both fixed end-points) or focal point (one fixed end-point). Until the crucial work by Hestenes [7] and Morse [17], the improvements concerned only the regularity of the data and of the optimal solution while they developed an index theory for quadratic forms in Hilbert spaces, and they explain the connection between the index of the quadratic form and the conjugate (or focal) points.

Conjugate points and the Riccati equation have been widely studied in connection with regular LQ problems, especially for problems with at least one end-point fixed. It is impossible to quote all the results published since the seminal papers by Kalman [9] and Hestenes [7]. Here we mention the contributions in [5, 6, 8] and [15], where the Hestenes approach has been used to consider optimal control problems; those in [3, 10], where the classical approach has been extended to the optimal control setting but in a rather informal and nonrigorous approach; and those in [4, 16], where an approach to the Riccati equation closer to ours is used.

As far as conjugate points are concerned, the problem when both end-points are variable has been analyzed in [26, 27], where, under suitable controllability assumptions, the authors introduce the concept of coupled point, and they state the corresponding necessary conditions. The calculus of variations case with separate end-point conditions is studied in [24], where necessary and sufficient conditions for the coercivity of the quadratic form are given by means of coupled points and, equivalently, by the properties of a solution of the Riccati equation. In [28] the author gives necessary and sufficient conditions for the case of joint end-points constraints, still with suitable controllability assumptions.

LQ problems with constraints can be seen as those defining the accessory minimization problem associated with nonlinear optimization problems with state-control and end-point equality and inequality constraints. There is a large amount of literature on these problems; for some recent results see, for example, [14, 19, 23, 25] and the references therein.

In [25], while studying a nonlinear control problem with state-control pure inequality constraints and with fixed initial point, Zeidan analyzes the accessory LQ problem, assuming that the linearized system is controllable. Zeidan gives necessary conditions for the nonnegativity of the quadratic form by means of conjugate points and sufficient conditions for its coercivity by the existence of a solution of the Riccati equation satisfying certain boundary conditions.

In the appendix we summarize an example of an application to an economic model (Example 4.4). Techniques similar to those that we study here are used in [13], and

in other papers by the same authors, to analyze some applied examples. The results we state in this paper widen the class of problems to which these techniques can be applied and allow us to use either conjugate points or Riccati-type results to check both necessary and sufficient conditions.

In [29] an abstract Jacobi theory has been presented. We are going to use the results therein to develop a conjugate point approach to LQ problems in the presence of constraints. The abstract theory points out that the different definitions of conjugate, focal, and coupled point can be seen as corresponding to the same object in different situations. For this reason we go back to the original name of conjugate point, including in this definition all the previously mentioned cases. To take into account the situation related to the existence of a focal interval or table we introduce the definition of semiconjugate point.

The abstract theory analyzes the sign of a form J on an Hilbert space H by means of its restriction to a family of subspaces depending on a parameter c. The changes of the index or the nullity of the form are investigated through a value function V which is the minimum of the form J on a level set of a weakly continuous positive quadratic form in a subspace belonging to the family. A kind of "continuation principle" is given in the sense that, roughly speaking, the Jacobi condition states that if V is positive at level $c = 0$ and it does not become zero along the family, then at the final level, which corresponds to the whole space, it is still positive and hence the form is coercive. Analogously, if the function V is nonnegative at level $c = 0$ and it does not change sign, then the form is nonnegative. A detailed analysis is needed to characterize these points by the properties of the solutions of the Jacobi system.

The Hilbert space we consider is given by the couples made by the initial state and the control which satisfy the constraints; this is because the initial condition plays the role of a further control. From this point of view it is quite natural to consider the family of subspaces obtained by taking as parameter c the time and by setting the control equal to a reference one after c. This reference control is chosen in a feed-back form such that the state-control constraint is satisfied for every initial point. With this choice the subspace at level $c = 0$ is finite dimensional so that it is easy to check if the form is nonnegative there. This approach leads to the definition of semiconjugate point which can usually be given through the solutions of the Jacobi system and through the transversality conditions which can be obtained by setting the first derivative of the form constrained to the subspace equal to zero. The transversality conditions include an extra term which does not appear when the moving end-point is constrained to be zero. Let us remark that here we consider as fixed the left end-point of the time interval $t = 0$, and we take the other one as a parameter. We could very well do the opposite, doubling all the statements and obtaining symmetric results.

Differently from previous works, we do not assume any kind of controllability with respect to the boundary conditions here, but we need a surjectivity assumption on the state-control constraint (Assumption 2.2) and a suitable version of the Legendre–Clebsch condition (Assumption 2.3) which allows us to give the Jacobi system only by means of the trajectory and the adjoint covector. Theorems 2.5 and 2.6 give a complete characterization of the coercivity and of the nonnegativity of the studied quadratic form by means of semiconjugate and conjugate points, including and extending all the previous results on the subject. Preliminary results has been announced in [20].

These results concerning conjugate points are crucial in proving the necessary and sufficient conditions in the framework of Riccati theory. Here we fully analyze only the case when costs and boundary conditions are given separately on the two end-points.

Theorem 2.9 states that the coercivity of the form plus a controllability assumption is equivalent to the existence of a solution of the Riccati equation on the half open interval $(0,T]$ with suitable boundary conditions. While, without any controllability assumption, Theorem 2.10 states the equivalence between the coercivity of the form and the existence of a solution of the Riccati equation on the closed interval $[0,T]$ with suitable inequality-type boundary conditions. Under stronger controllability assumptions it is possible to characterize also the nonnegativity of the quadratic form by a solution of the Riccati equation, Theorem 2.11. These theorems include and extend the previous results on the subject.

For the case of joint costs and boundary conditions we give here only some simple, partial results in Theorem 2.12 and Corollary 2.13; a complete description will be the subject of a forthcoming paper. The plan of the paper is the following. In section 2 we describe the main assumptions and results. Subsection 2.1 is dedicated to the conjugate points, and subsection 2.2 concerns the Riccati equation. All the proofs and all the needed lemmas are in section 3. In the appendix there are some related results and examples.

2. Statement of the problem and main results. On a given compact interval $[0,T]$ we consider the quadratic form

$$\begin{aligned} I(\eta,u) &= \frac{1}{2}(\eta^\top(0),\eta^\top(T))\Gamma\begin{pmatrix}\eta(0)\\ \eta(T)\end{pmatrix} \\ &+\frac{1}{2}\int_0^T \left\{\eta^\top(s)P(s)\eta(s)+2u^\top(s)Q(s)\eta(s)+u^\top(s)R(s)u(s)\right\}ds, \end{aligned} \tag{2.1}$$

defined on the subspace of $AC([0,T],\mathbf{R}^n)\times L^2([0,T],\mathbf{R}^m)$ of the couples (η,u) satisfying

$$\dot\eta(t)=A(t)\eta(t)+B(t)u(t) \text{ almost everywhere (a.e.) } t\in[0,T]. \tag{2.2}$$

This subspace is an Hilbert space since it can be identified with

$$U=\mathbf{R}^n\times L^2([0,T],\mathbf{R}^m)$$

by $(\eta,u)\mapsto(\eta(0),u)$. We study the restriction of the quadratic form I to the closed subspace K of U given by two different types of constraints. The first one is a boundary condition on the state end-points

$$N\begin{pmatrix}\eta(0)\\ \eta(T)\end{pmatrix}=0, \tag{2.3}$$

whereas the second one is a pointwise state-control constraint which is an infinite dimensional constraint

$$C(t)\eta(t)+D(t)u(t)=0 \text{ a.e. } t\in[0,T]. \tag{2.4}$$

Γ is a symmetric matrix in $M_{2n\times 2n}$, $N\in M_{p\times 2n}$. We assume that the data satisfy the following standard minimal assumptions

$$\begin{gathered} A,P\in L^1([0,T],M_{n\times n}),\ B\in L^2([0,T],M_{n\times m}),\ Q\in L^2([0,T],M_{m\times n}),\\ R\in L^\infty([0,T],M_{m\times m}),\ C\in L^2([0,T],M_{k\times n}),\ D\in L^\infty([0,T],M_{k\times m}) \end{gathered}$$

and that $P(t)$ and $R(t)$ are symmetric matrices. When any of this time-dependent matrix acts on a function, it becomes an operator between L^p spaces, which will be denoted by the same capital letter. In the following all the equalities between L^p functions are assumed to hold a.e.

If the quadratic form describes an accessory minimization problem coming from inequality constraint, then the set of active constraint depends on t. To include this possibility we have to allow the ranges of the maps C, D to change. This can be done by assuming the following.

Assumption 2.1. There exists $\delta_i \in L^\infty([0,T],\mathbf{R})$, $\delta_i(t) \in \{0,1\}, i = 1,\dots,k$, such that the orthogonal projection defined by $\Delta(t) = \operatorname{diag}\{\delta_1(t),\delta_2(t),\dots,\delta_k(t)\}$ satisfies

$$\Delta C = C \quad \text{and} \quad \Delta D = D.$$

Our aim is to give necessary and sufficient conditions for the quadratic form to be coercive or nonnegative on K. Combining these results with those in [23], we obtain a complete set of necessary and sufficient conditions for a weak local minimum in presence of equality-type constraints.

Besides the above regularity assumptions on the data, we make two main assumptions which have been considered by several authors also in the nonlinear case [11, 12]. The first one concerns the regularity of the infinite-dimensional constraint (2.4). By Assumption 2.1, the map $(\eta(0),u) \mapsto C\eta + Du$ is a map from U into Range $\Delta \subset L^2([0,T],\mathbf{R}^k)$, and it is onto if and only if the following assumption is satisfied (see Lemma 4.1 in the Appendix). An analogous result has been proved in [19] for the L^∞ case.

Assumption 2.2. There is $h > 0$ such that

$$D\,D^\top + (Id - \Delta) \geq h\,Id.$$

Under this assumption we can define the operator $D^\sharp \in L^\infty([0,T], M_{m\times k})$:

$$D^\sharp \equiv D^\top (DD^\top + (Id - \Delta))^{-1}.$$

Since Δ is an orthogonal projection, Assumption 2.1 yields

$$(Id - \Delta)(DD^\top + (Id - \Delta))^{-1} = (Id - \Delta);$$

hence

$$D\,D^\sharp = \Delta. \tag{2.5}$$

The maps

$$\Pi_1 = Id - D^\sharp D, \quad \Pi_2 = D^\sharp D$$

are orthogonal projections in $L^2([0,T],\mathbf{R}^m)$, and they give an orthogonal decomposition of U:

$$U_1 = \mathbf{R}^n \times \operatorname{Range}\Pi_1,\ U_2 = \{0\} \times \operatorname{Ker}\Pi_1.$$

The other main assumption we are going to make is a suitable version of the strengthened Legendre–Clebsch condition on K; see also [15].

Assumption 2.3. The quadratic form I satisfies the strengthened Legendre–Clebsch condition on K; that is, one of the following equivalent statements holds:

$$\text{there are } h_0, h_1 > 0 \text{ such that } R + h_1\Pi_2 \geq h_0\, Id, \tag{2.6}$$

$$\text{there is } h > 0 \text{ such that } \Pi_1 R \Pi_1 + \Pi_2 \geq h\, Id, \tag{2.7}$$

$$\text{there is } h > 0 \text{ such that } \Pi_1 R \Pi_1 \geq h\Pi_1. \tag{2.8}$$

The proof of the equivalence among the statements is in Lemma 4.2 in the appendix. Notice that when the number of active constraints is equal to the number of controls, then $\Pi_1 \equiv 0$ and Assumption 2.3 is empty.

In what follows we use a natural generalization of the definition of controllability for the linear system (2.2) constrained by (2.4); namely, we will say the following.

DEFINITION 2.1. *The constrained system* (2.2) *and* (2.4) *is* N*-controllable at time* t_1 *if the map*

$$(x, u) \mapsto N \begin{pmatrix} \eta(0) \\ \eta(t_1) \end{pmatrix}$$

is onto Range N*, where* η *is the solution of* (2.2) *corresponding to* u*, with* $\eta(0) = x$ *and* (η, u) *satisfying* (2.4)*. For*

$$N = \begin{pmatrix} L & 0 \\ 0 & Id \end{pmatrix},$$

the above definition coincides with the usual definition of controllability from a subspace, and we say that the constrained system (2.2) *and* (2.4) *is controllable from* Ker L *at time* t_1.

By Assumption 2.1, if we take controls of the form

$$u = \Pi_1 u + \Pi_2 u = \Pi_1 u - D^\sharp C\eta,$$

then the constraint (2.4) is verified independently from the starting point of the trajectory. Thus the solutions of the constrained control system (2.2) and (2.4) correspond to the solutions of

$$\dot{\xi}(t) = \bar{A}(t)\xi + B(t)\Pi_1(t)u(t), \tag{2.9}$$

where

$$\bar{A} \equiv A - BD^\sharp C. \tag{2.10}$$

This is because if (η, u) is a solution of (2.2) and (2.4), then $\xi = \eta$ is a solution of (2.9) with control $\Pi_1 u$; see the beginning of section 3 for a detailed analysis.

Remark 2.1. By the above properties we can give an equivalent definition of N-controllability without a direct reference to the constraint (2.4). In fact, the system (2.2) and (2.4) is N-controllable at time t_1 if and only if the system (2.9) is N-controllable at time t_1.

We can now describe how the Jacobi theory of conjugate points can be extended to these problems. Following [29] we define the conjugate points by means of a family of problems which are parametrized by the time $c \in [0, T]$. This family is obtained by considering the restriction of the functional I to a family of subspaces of K increasing with c. They are defined by establishing the control values on the interval $[c, T]$ to be

equal to the feedback control (2.11) which is taken as reference one for system (2.2). Hence a special role is played by the solutions of (2.2) corresponding to the feedback control

$$u = -D^\sharp C\eta, \tag{2.11}$$

which are the solutions of (2.9) corresponding to the null control; they can be described through the solution $\Phi(t,c)$ of the matrix equation

$$\dot\Phi(t) = \bar A(t)\Phi(t)\ ,\ \Phi(c) = Id.$$

Since the control values are fixed on the interval $[c,T]$, then the problems of the family can be considered as problems on $[0,c]$ with new boundary conditions and end-point cost at time c given by

$$N_c = N\begin{pmatrix} Id & 0 \\ 0 & \Phi(T,c)\end{pmatrix},$$

$$\Gamma_c = \begin{pmatrix} Id & 0 \\ 0 & \Phi^\top(T,c)\end{pmatrix}\Gamma\begin{pmatrix} Id & 0 \\ 0 & \Phi(T,c)\end{pmatrix} + \begin{pmatrix} 0 & 0 \\ 0 & \displaystyle\int_c^T \Phi^\top(s,c)\bar P(s)\Phi(s,c)ds\end{pmatrix}, \tag{2.12}$$

where

$$\bar P \equiv P - C^\top(D^\sharp)^\top Q - Q^\top D^\sharp C + C^\top(D^\sharp)^\top R D^\sharp C. \tag{2.13}$$

We consider also the case $c=0$ that is the restriction of the quadratic functional I to the subspace of K corresponding to the control which is feedback on the whole $[0,T]$. This subspace can be identified with the subspace of $\mathbf{R}^n$ given by

$$K_0 \equiv \left\{ x\in\mathbf{R}^n : N_0\begin{pmatrix} x \\ x\end{pmatrix} = 0\right\}.$$

Notice that K_0 may be nontrivial if no end-point is fixed. The restriction of I to K_0 can be written as a finite-dimensional quadratic form on K_0:

$$I_0 : x \mapsto \frac{1}{2}(x^\top, x^\top)\Gamma_0\begin{pmatrix} x \\ x\end{pmatrix}.$$

We are going to define an Hamiltonian which differs from the usual one because we have to take into account the functional constraint (2.4). Let us emphasize that the Hamiltonian is the same for all the problems in the family because the new boundary conditions, N_c, and the new cost, Γ_c, on the state end-points do not play any role in its definition. Thanks to Assumption 2.3, define

$$S = \Pi_1(\Pi_1 R\Pi_1 + \Pi_2)^{-1}\Pi_1, \tag{2.14}$$

which plays the role usually played by R^{-1}, and set

$$\bar Q \equiv Q - RD^\sharp C, \tag{2.15}$$

$$E = \bar Q^\top S\bar Q - \bar P\ ,\ F = \bar A - BS\bar Q\ ,\ G = -BSB^\top.$$

The *true* (minimized) Hamiltonian $\mathcal{H} : \mathbf{R}\times(\mathbf{R}^n)^*\times\mathbf{R}^n \to \mathbf{R}$ is given by

$$\mathcal{H}(t,\gamma,x) \equiv -\frac{1}{2}x^\top E(t)x + \gamma F(t)x + \frac{1}{2}\gamma G(t)\gamma^\top. \tag{2.16}$$

Notice that the presence of extra terms in the Hamiltonian depends on the pointwise constraint on the state; in fact, they disappear if $C = 0$. Two systems are associated with the Hamiltonian $\mathcal{H}$: the Jacobi system on $\mathbf{R}^n \times (\mathbf{R}^n)^*$

$$\begin{aligned} \dot{\zeta}(t) &= F(t)\zeta(t) + G(t)\lambda^\top(t), \\ \dot{\lambda}(t) &= \zeta^\top(t)E(t) - \lambda(t)F(t), \end{aligned} \tag{2.17}$$

and the corresponding matrix system

$$\begin{aligned} \dot{Z}(t) &= F(t)Z(t) + G(t)\Lambda^\top(t), \\ \dot{\Lambda}(t) &= Z^\top(t)E(t) - \Lambda(t)F(t). \end{aligned} \tag{2.18}$$

The solutions of the Jacobi system which satisfy appropriate transversality conditions describe the extremals, and they correspond to the critical points of the problems in the family; see Lemma 3.8. Let us introduce the following.

DEFINITION 2.2. *For $c \in [0, T]$, an arc ζ is called a c-transversal extremal if there exists an arc λ such that*

$$(\zeta, \lambda) : [0, T] \to \mathbf{R}^n \times (\mathbf{R}^n)^*$$

is a solution of the Jacobi system (2.17) *satisfying the following transversality conditions:*

$$N_c \begin{pmatrix} \zeta(0) \\ \zeta(c) \end{pmatrix} = 0,$$

$$(-\lambda(0), \lambda(c)) = (\zeta^\top(0), \zeta^\top(c))\Gamma_c + \sigma N_c \text{ for some } \sigma \in (\mathbf{R}^p)^*.$$

Notice that this definition is given also for $c = 0$, and it corresponds to the existence of a critical point $x = \zeta(0)$ of I_0 restricted to K_0. $\lambda(0)$ is the associated Lagrange multiplier; see Lemma 3.8.

Remark 2.2. Differently from other authors in the literature, we do not define the extremals as the solutions of the Jacobi system because there can exist a nontrivial solution of the Jacobi system corresponding to the zero extremal without any controllability assumption, as is shown by Example 4.1. There is a one-to-one correspondence between c-transversal extremals and c-transversal solutions of the Jacobi system if and only if the system (2.9) is N_c-controllable at time c; see Lemmas 3.8 and 3.9.

The existence of nontrivial c-transversal extremals which are also solutions of (2.2) corresponding to the feedback control is typical of control problems with nonzero boundary conditions; hence, we need the following definition which characterizes them (see also Remark 2.3).

DEFINITION 2.3. *A c-transversal extremal ζ is said to be degenerate on the interval $[\alpha, \beta]$ containing c if*

$$\Pi_1(t)(\bar{Q}(t)\zeta(t) + B^\top(t)\lambda^\top(t)) = 0, \quad t \in [\alpha, \beta],$$

or, equivalently, for $t \in [\alpha, \beta]$

$$\begin{aligned} \dot{\zeta}(t) &= \bar{A}(t)\zeta(t), \\ \dot{\lambda}(t) &= -\lambda(t)\bar{A}(t) - \zeta^\top(t)\bar{P}(t). \end{aligned}$$

2.1. Conjugate points. This subsection contains our main results concerning the extension of the Jacobi theory of conjugate points to our problem. Let us first introduce the definitions of conjugate and semiconjugate points. This distinction is needed because of the existence of c-transversal degenerate extremals.

DEFINITION 2.4. *A point $c \in [0,T]$ is called semiconjugate with zero if there exists a nontrivial c-transversal extremal. A point $c \in [0,T)$ will be called conjugate with zero if there exists a nontrivial c-transversal extremal which is not degenerate on $[c,\beta]$, $c < \beta \leq T$.*

Remark 2.3. When $I_0 \geq 0$ on K_0, the interval between the first semiconjugate point and the first conjugate point has been called a focal interval in [15] or a table in [5]. Degenerate extremals do not exist when the right end-point is fixed and the linear system (2.9) is controllable from $\{0\}$ on any subinterval (see Lemma 3.10). In this last case the semiconjugate points are also conjugate and the focal interval (if it exists) reduces to a point. Recall that the controllability assumption is always satisfied in the calculus of variations problems.

We are now able to state our main results concerning conjugate points which correspond to the classical Jacobi necessary and sufficient conditions. Under Assumptions 2.2 and 2.3 the following theorems hold.

THEOREM 2.5. *The quadratic form I is nonnegative if and only if I_0 is nonnegative on K_0 and there is no point $c \in [0,T)$ conjugate with zero.*

THEOREM 2.6. *The quadratic form I is coercive if and only if I_0 is positive on K_0 and there is no point $c \in (0,T]$ semiconjugate with zero.*

These definitions naturally generalize the previous ones of conjugate and focal point, while the definition of a point coupled with zero, which has been introduced in [26] for the calculus of variations and in [27] for an optimal control problem under controllability assumptions, in our setting can be generalized by the following.

DEFINITION 2.7. *A point $c \in (0,T]$ is coupled with zero if there exists a nontrivial c-transversal extremal which is not degenerate on $[c,T]$. This last condition is empty when $c = T$.*

Because we want to emphasize the point of view of index theory, we prefer Definition 2.4, since a conjugate point corresponds to the point where the index increases while a semiconjugate point corresponds to an arc in the nullity.

Lemma 3.13 shows that the existence of a coupled point on the half-closed interval $(0,T]$ is equivalent to the existence of a semiconjugate point on the same interval. This is analogous for the existence of coupled points and conjugate points on the open interval $(0,T)$. Thus Theorems 2.5 and 2.6 could have been stated by means of coupled points.

COROLLARY 2.8. *The quadratic form I is nonnegative (coercive) if and only if I_0 is nonnegative (positive) on K_0 and there is no point $c \in [0,T)$ ($c \in (0,T]$) coupled with zero.*

This result includes the previous results stated by means of coupled points, in particular those in [25] where necessary conditions for the nonnegativity of the quadratic form I are given under controllability assumptions and with fixed initial point.

2.2. The Riccati equation. This section contains our main results concerning Riccati-type results for our problem. The following classical Riccati differential equation is associated with the Hamiltonian $\mathcal{H}$:

$$\dot{W}(t) = -W(t)F(t) - F^{\top}(t)W(t) - W(t)G(t)W(t) + E(t). \tag{2.19}$$

Notice that when the number of active constraints is equal to the number of controls then $G(t) \equiv 0$ and the Riccati equation becomes linear.

To obtain Riccati-type results for our problem, we consider first the problem with separate costs and end-points constraints; i.e., we set

$$N = \begin{pmatrix} N_0 & 0 \\ 0 & N_T \end{pmatrix}, \qquad \Gamma = \begin{pmatrix} \Gamma_0 & 0 \\ 0 & \Gamma_T \end{pmatrix}.$$

Later, we will state some results for the general case. Let us assume, without loss of generality, that N_0, N_T are orthogonal projections in $\mathbf{R^n}$.

Let (Z_0, Λ_0) be the solution of (2.18) defined by the initial conditions

$$Z_0(0) = Id - N_0, \qquad \Lambda_0(0) = -(Id - N_0)\Gamma_0(Id - N_0) + N_0. \tag{2.20}$$

Our main results relate the existence of a solution of the Riccati equation to the coercivity of I, and they correspond to Theorem 2.6, while there is no analogue to Theorem 2.5 in the general case. Under Assumptions 2.2 and 2.3 the following hold.

THEOREM 2.9. *The following statements are equivalent:*

(1) *I is coercive on K and the system* (2.9) *is controllable for every $c > 0$ from* Ker N_0.

(2) *$I_0 > 0$ on K_0 and there is a symmetric solution W of the Riccati equation* (2.19) *on $(0, T]$ such that*

$$\lim_{t \to 0^+} W(t)Z_0(t) = -(Id - N_0)\Gamma_0(Id - N_0) + N_0 \tag{2.21}$$

and

$$\Gamma_T - W(T) > 0 \text{ on } \operatorname{Ker} N_T. \tag{2.22}$$

In the case of unconstrained initial point (i.e., $N_0 = 0$), the controllability assumption is always satisfied and W is defined on $[0, T]$, so that the limit condition (2.21) *becomes*

$$W(0) = -\Gamma_0.$$

It is also possible to state necessary and sufficient conditions without any controllability hypothesis.

THEOREM 2.10. *The following statements are equivalent:*

(1) *The quadratic form I is coercive on K.*

(2) *There is a symmetric solution W of* (2.19) *on $[0, T]$ and $\beta \in \mathbf{R}$ such that*

$$W(0) = -\Gamma_0 - \beta N_0 \quad \text{and} \quad \Gamma_T - W(T) > 0 \text{ on } \operatorname{Ker} N_T.$$

(3) *There is a symmetric solution W of* (2.19) *on $[0, T]$ such that*

$$W(0) + \Gamma_0 > 0 \quad \text{on} \quad \operatorname{Ker} N_0 \quad \text{and} \quad \Gamma_T - W(T) > 0 \text{ on } \operatorname{Ker} N_T.$$

Let us remark that when an end-point is fixed, the corresponding inequality condition for the solution of the Riccati equation is empty.

The existence of a solution of the Riccati equation (or Riccati inequality) has been used to prove sufficient conditions for the nonlinear problem [25, 14].

Although general results for the nonnegativity of I on K cannot be stated, we can prove the following theorem in the case when the are no degenerate c-transversal extremals.

THEOREM 2.11. *Assume that the system* (2.9) *is controllable from* $\{0\}$ *on each subinterval and that the right end-point is fixed; then the following statements are equivalent:*

(1) *I is nonnegative on K.*

(2) $I_0 > 0$ *on* K_0, *and there is a symmetric solution* W *of the Riccati equation* (2.19) *on* $(0,T)$ *such that*

$$\lim_{t\to 0^+} W(t)Z_0(t) = -(Id - N_0)\Gamma_0(Id - N_0) + N_0.$$

(3) *There is a symmetric solution* W *of* (2.19) *on* $[0,T)$ *and* $\beta \in \mathbf{R}$ *such that*

$$W(0) = -\Gamma_0 - \beta N_0.$$

(4) *There is a symmetric solution* W *of* (2.19) *on* $[0,T)$ *such that*

$$W(0) + \Gamma_0 \geq 0 \text{ on } \operatorname{Ker} N_0.$$

Theorem 2.11 is of some interest because it includes the well-studied case of problems in the calculus of variations with one fixed end-point. The analogue of statement (3) in Theorem 2.10 does not hold with strict inequality, as is shown by Example 4.3.

The previous theorems are stated for the case when the boundary conditions and the costs are given separately on the initial and final points. They can be applied also to problems with boundary conditions given jointly on both end-points, periodic, for example, by transforming the problem into another one in double dimension. This can be done by considering an extended system (ξ, ν), where ν satisfies $\dot\nu(t) = 0$ subject to the constraint $\xi(0) = \nu(0)$. Then any condition involving $\xi(0)$ may be imposed on $\nu(T)$, so that the original cost and constraint are imposed on the final values of the extended system, while the new boundary conditions involve only the initial point. These necessary and sufficient conditions are stated by means of a $2n \times 2n$ solution W of a Riccati equation in double dimension,

$$W = \begin{pmatrix} W_{11} & W_{12} \\ W_{12}^\top & W_{22} \end{pmatrix}.$$

The three matrices are a solution of a cascade of differential equations given by a Riccati differential equation, a linear equation, and an integrator. The properties of this system will be described in a forthcoming paper. Here we give a sufficient condition which has a simple formulation and proof. It is not a necessary condition, as is shown by Example 4.2 in the appendix.

THEOREM 2.12. *If there is a symmetric solution* W *of* (2.19) *on* $[0,T]$ *such that*

$$\Gamma + \begin{pmatrix} W(0) & 0 \\ 0 & -W(T) \end{pmatrix} > 0 \text{ on } \operatorname{Ker} N, \tag{2.23}$$

then the quadratic form I *is coercive on the subspace* K.

Of some interest is the case of periodic boundary conditions, i.e., $N = (Id, -Id)$, when the end-point cost can be imposed on one of the end-points, i.e., $\Gamma = \begin{pmatrix} \Gamma_0 & 0 \\ 0 & 0 \end{pmatrix}$. From Theorem 2.12 we obtain the following.

COROLLARY 2.13. *If there is a symmetric solution* W *of* (2.19) *on* $[0,T]$ *such that*

$$\Gamma_0 + W(0) - W(T) > 0,$$

then the quadratic form I *is coercive on the subspace* K *defined by* $\eta(0) = \eta(T)$ *and by* (2.4).

3. Proofs of the results. As we said in section 2, we consider the quadratic form I acting on the Hilbert space U of the couples $(x,u) = (\textit{initial state}, \textit{control})$.

Thanks to Assumptions 2.1 and 2.2, our problem can be equivalently written in a simpler form. Let us consider a couple (x,u) such that (η,u) satisfies (2.2) and (2.4). From Assumption 2.2 and by (2.5) we deduce that

$$u = \Pi_1 u + \Pi_2 u = \Pi_1 u - D^\sharp C\eta.$$

Thus η solves also (2.9) with $\xi(0) = \eta(0)$, as it can be checked by direct substitution, and we can write $u = \Pi_1 u - D^\sharp C\xi$. For the quadratic form J defined by

$$J(x,u) = \frac{1}{2}(x^\top, \xi^\top(T))\Gamma\begin{pmatrix} x \\ \xi(T)\end{pmatrix}$$
$$+\frac{1}{2}\int_0^T \left\{\xi^\top(s)\bar{P}(s)\xi(s) + 2u^\top(s)\Pi_1(s)\bar{Q}(s)\xi(s) + u^\top(s)\Pi_1(s)R(s)\Pi_1(s)u(s)\right\} ds, \tag{3.1}$$

where $\bar{A}$, $\bar{P}$, $\bar{Q}$ are defined, respectively, in (2.10), (2.13), (2.15), we obtain that

$$I(x,u) = J(x,u) \text{ on } K. \tag{3.2}$$

Instead of studying the quadratic form I on K we study the quadratic form J on the closed subspace H of U defined by

$$N\begin{pmatrix} x \\ \xi(T)\end{pmatrix} = 0, \tag{3.3}$$

$$Du \equiv 0. \tag{3.4}$$

The equivalence between these two problems is stated in the following.

LEMMA 3.1. *The quadratic form I is coercive (nonnegative) on K if and only if the quadratic form J is coercive (nonnegative) on H.*

Proof. Since $J(x,u) = J(x,\Pi_1 u)$, the statement on nonnegativity is straightforward from (3.2). To prove the statement relative to the coercivity, by (3.2) it is sufficient to prove that J coercive on H implies that there exists $k > 0$ such that

$$J(x,u) \geq k(||x||^2 + ||\Pi_1 u||^2 + ||D^\sharp C\xi||^2).$$

It is not difficult to see that the linear map $\Xi : U_1 \to L^2([0,T],\mathbf{R}^m)$ defined as $(x,\Pi_1 u) \mapsto D^\sharp C\xi$, where ξ is the solution of (2.9) such that $\xi(0) = x$, is continuous. The result follows from standard computations. □

In the following we use some general properties of quadratic forms on Hilbert spaces stated in [7]. We recall first the basic definition of the *Legendre* form, sometimes called *elliptic* [15].

DEFINITION 3.2. *The quadratic form J is said to be Legendre on H if it is weakly lower semicontinuous on H and if, for every sequence $\{h_n\}$ which converges weakly to $h \in H$ and such that $\{J(h_n)\}$ converges to $J(h)$, $\{h_n\}$ converges strongly to $h \in H$.*

In order to prove Theorems 2.5 and 2.6 we use the results in [29], which we briefly recall. The results concern a Legendre quadratic form J defined on an Hilbert space H and a family of closed subspaces with some continuity properties by which it is possible to define a Jacobi-type condition.

DEFINITION 3.3. *A one-parameter family $\{H_c\}$, $c \in [0,T]$, of closed subspaces of H is said to be continuous if it has the following properties:*

(1) *for $0 \leq c_1 \leq c_2 \leq T$, $\quad H_{c_1} \subset H_{c_2}$ and $H_T = H$.*

(2) *for* $c_0 \in (0,T]$, cl $(\bigcup_{0\le c<c_0} H_c) = H_{c_0}$.
(3) *for* $c_0 \in [0,T)$, $\quad \bigcap_{c_0<c\le T} H_c = H_{c_0}$.

For a given continuous family H_c and for a positive weakly continuous quadratic form $\mathcal{K}$ define

$$\Omega_c = \{e \in H_c : \mathcal{K}(e) = 1\}.$$

The study of a Legendre form J can be pursued through the following "value function" $V : [0,T] \to (-\infty, +\infty]$ defined as

$$V(c) = \min_{e\in\Omega_c} J(e),$$

as usually $V(c) = +\infty$ if $\Omega_c = \emptyset$. The use of the min operator instead of the infimum in the definition of the function V is possible because a Legendre form attains its minimum on Ω_c and hence we have

- J is coercive on $H_c \iff V(c) > 0$,
- J is nonnegative on $H_c \iff V(c) \ge 0$.

The main result which summarizes the properties of the function V is the following [29].

THEOREM 3.4. *Assume that J is Legendre on H. The function V is nonincreasing and continuous as an extended-real-valued function*

$$V : [0,T] \to \mathbf{R} \cup \{+\infty\}.$$

Remark 3.1. For an optimal control problem we can choose $\mathcal{K}(x,u) = \|x\|^2 + \|\omega\|_2^2$, where $w : t \mapsto \int_0^t u(s)ds$. This choice is the usual one in the calculus of variations and leads us to characterize $V(c)$ as the first eigenvalue of the associated Euler–Lagrange differential operator.

From the properties of the function V we can deduce that J is coercive on H if and only if J is positive on H_0 and there is no point $c \in (0,T]$ at which V becomes zero. Moreover, J is nonnegative on H if and only if J is nonnegative on H_0 and there is no point $c \in [0,T)$ at which V changes sign. In our case, using a suitable family of subspaces, we can link the existence of such points with semiconjugate and conjugate points.

To apply the above theory it is convenient to see the Hilbert space H as the Kernel of the linear operator $\Sigma : U_1 \to \mathbf{R}^p$, defined by

$$\Sigma(x,u) = N\begin{pmatrix} x \\ \xi(T) \end{pmatrix},$$

where ξ is the solution of equation (2.9) with initial condition $\xi(0) = x$.

As a first step we show that our quadratic form is Legendre.

THEOREM 3.5. *Under Assumption* 2.2*, the quadratic form J is Legendre on H if and only if Assumption* 2.3 *is satisfied.*

Proof. Let

$$E(x,u) = \|x\|^2 + \int_0^T u^\top(s)\Pi_1(s)R(s)\Pi_1(s)u(s)ds.$$

The quadratic form J can be written as the sum of a weakly continuous form $J - E$ plus the form E. $J - E$ is weakly continuous because of the compactness of the solution operator associated to a linear differential equation. By Theorem 11.5 in [7] the quadratic form J is Legendre on H if and only if the form E is Legendre on H. On

the other hand the orthogonal complement of $H = \operatorname{Ker}\Sigma$ in U_1 is finite dimensional as the range of Σ; therefore it follows from Theorem 11.4 in [7] that E is Legendre on H if and only if it is on U_1. It is clear that the strengthened Legendre–Clebsch condition implies that the form E is coercive and hence Legendre on U_1.

Let us prove the converse. If E is Legendre on U_1, by Theorem 5.2 in [7] its nullity and index are finite. Since it is nonnegative, the index must be zero. But, for this particular form, the nullity also has to be zero because if $E(x,u) = 0$, then for all $\phi \in C([0,T],\mathbf{R})$ also $E(\|\phi\|x, \phi u) = 0$; hence the form E is positive on U_1. By Theorem 11.1 in [7] this yields that it is coercive, so that (2.8) holds. □

In order to define the family of subspaces $\{H_c\}$ for our problem let us introduce the following notation. For $c \in [0,T]$ set

$$U_c = \{(x,u) \in U_1 : u(t) \equiv 0 \ \text{ for } \ t \in [c,T]\},$$

and consider the following one-parameter family of subspaces:

$$H_c = U_c \bigcap \operatorname{Ker}\Sigma.$$

A subspace H_c is isomorphic to a subspace of $\mathbf{R}^n \times L^2([0,c],\mathbf{R}^m)$; in particular, H_0 can be identified with the subspace K_0 of $\mathbf{R}^n$ defined in section 1 and, moreover, $H_T = H$.

Since we do not have any controllability assumption on the system (2.9),

$$\mathcal{R}_c \equiv \Sigma\,(U_c)$$

need not be the whole space $\mathbf{R}^p$. Notice that for $(x,u) \in U_c$ we have that

$$\Sigma(x,u) = N\begin{pmatrix} x \\ \xi(T) \end{pmatrix} = N_c\begin{pmatrix} x \\ \xi(c) \end{pmatrix},$$

and hence, with these notations, the system (2.9) is N_c-controllable at time c if and only if $\mathcal{R}_c = \operatorname{Range} N$.

The following lemma describes a property of $\mathcal{R}_c$ which is crucial to prove the continuity of the family $\{H_c\}$.

LEMMA 3.6. *Under Assumption* 2.2*, there is a finite partition* $c_0 = 0 < c_1 < \cdots < c_s = T$ *such that* $\mathcal{R}_c$ *is constant for all* $c \in (c_i, c_{i+1}]$.

Proof. It follows immediately from the definition that the spaces U_c's have the following properties:

$$U_c \subseteq U_d,\ 0 \le c \le d \le T,\ \operatorname{cl}\left(\bigcup_{0\le c<c_0} U_c\right) = U_{c_0}.$$

Therefore, by the continuity of Σ the corresponding sets $\mathcal{R}_c$'s have the same properties as the sets U_c's, and since they also are finite dimensional, the statement follows immediately. □

We can now prove that the family $\{H_c\}$ satisfies the properties required by Definition 3.3.

LEMMA 3.7. *Under Assumption* 2.2 *the above-defined family* $\{H_c\}$ *is continuous.*

Proof. Properties 1 and 3 are immediate.

Property 2. Since H_{c_0} is a closed subspace, it is clear that $\operatorname{cl}\left(\bigcup_{0\le c<c_0} H_c\right) \subseteq H_{c_0}$; we have to prove the converse inclusion. Let $c_0 \in (0,T]$; by Lemma 3.6, there is $c_1 < c_0$

such that $\mathcal{R}_c = \mathcal{R}_{c_0}$ for all $c \in [c_1, c_0]$. Let $\Psi : \mathcal{R}_{c_0} \to U_{c_1}$ be the right inverse of $\Sigma : U_{c_1} \to \mathcal{R}_{c_1} = \mathcal{R}_{c_0}$. Choose a fixed $(x, u) \in H_{c_0}$. For $c_1 < c < c_0$ consider the truncation of the control u given by

$$u_c(t) = u(t) \text{ for } t \in [0, c] \text{ and } u_c(t) = 0 \text{ for } t \in [c, T].$$

(x, u_c) need not belong to H_c, but we can define

$$(x_c, v_c) = \Psi\, \Sigma(0, u_c - u) \in U_{c_1}$$

so that $\Sigma(x_c, v_c) = \Sigma(0, u_c - u)$ and hence

$$(y_c, w_c) = (x - x_c, u_c - v_c)$$

belongs to H_c. It is easy to see that as $c \to c_0$ then $(x_c, v_c) \to 0$ in H_{c_1}. Let us compute

$$\begin{aligned}\|(y_c, w_c) - (x, u)\|^2 &= \|x_c\|^2 + \|u_c - v_c - u\|^2 \\ &= \|x_c\|^2 + \int_0^c \|v_c(s)\|^2 ds + \int_c^{c_0} \|u(s)\|^2 ds\end{aligned}$$

so that $(y_c, w_c) \to (x, u)$ as $c \to c_0$, and the statement is proved. □

Since we have shown that the abstract theory in [29] applies to our case, we have now to determine the relation between the zeros of V and the semiconjugate and conjugate points. Let us consider the expression of the restriction of J to U_c written as a quadratic form on $[0, c]$. It will be denoted by J_c. For $(x, u) \in U_c$ we have

$$\begin{aligned}J(x, u) = J_c(x, u) = \frac{1}{2}(x^\top, \xi^\top(c))\Gamma_c \begin{pmatrix} x \\ \xi(c) \end{pmatrix} \\ + \frac{1}{2}\int_0^c \left\{\xi^\top(s)\bar{P}(s)\xi(s) + 2u^\top(s)\Pi_1(s)\bar{Q}(s)\xi(s) + u^\top(s)\Pi_1(s)R(s)\Pi_1(s)u(s)\right\} ds,\end{aligned}$$

where ξ is a solution of (2.9) and Γ_c is given by (2.12). Let us remark that $J_0 = I_0$.

LEMMA 3.8. *(x, u) is a critical point for J_c restricted to H_c if and only if there exists a c-transversal extremal ζ such that*

$$(x, u) = (\zeta(0), -S(\bar{Q}\zeta + B^\top\lambda^\top)) \quad \text{on} \quad [0, c]. \tag{3.5}$$

(ζ, λ) is uniquely determined if and only if the system (2.9) is N_c-controllable at time c. Moreover ζ is degenerate on $[\alpha, \beta]$ if and only if the corresponding control is identically zero on $[\alpha, \beta]$.

Proof. (x, u) is critical for J_c restricted to H_c if and only if $DJ_c(x, u)(y, v) = 0$ for all $(y, v) \in U_c$ such that $\Sigma(y, v) = 0$. For $c = 0$ the above extremality condition can be easily characterized by the usual Lagrange multiplier rule for a finite-dimensional problem. That is, there exists a multiplier $\sigma \in (\mathbf{R}^p)^*$ such that

$$(x^\top, x^\top)\Gamma_0 \begin{pmatrix} Id \\ Id \end{pmatrix} + \sigma N_0 \begin{pmatrix} Id \\ Id \end{pmatrix} = 0,$$

which can be equivalently written as

$$(x^\top, x^\top)\Gamma_0 + \sigma N_0 = (-y, y)$$

for some $y \in (\mathbf{R}^n)^*$, which is equivalent to the existence of a zero-transversal extremal with $\lambda(0) = y$.

Let us now examine the case $c > 0$. We can consider $\mathcal{R}_c$ as the range of Σ so that the constraint can be thought as regular and the above extremality condition is equivalent to the existence of a unique multiplier $\sigma \in (\mathcal{R}_c)^*$ which can be extended to a multiplier $\sigma \in (\mathbf{R}^p)^*$ such that $DJ_c(x,u) + \sigma\Sigma = 0$ on U_c. Such an extension is unique up to a component in the orthogonal of Range N if and only if $\mathcal{R}_c = \text{Range } N$. We can use an equivalent characterization of the critical points by means of the Hamiltonian $H : \mathbf{R} \times (\mathbf{R}^n)^* \times \mathbf{R}^n \times \mathbf{R}^m \to \mathbf{R}$:

$$\begin{aligned} H(t,\gamma,x,w) &\equiv \gamma(\bar{A}(t)x + B(t)\Pi_1(t)w) \\ &+ \frac{1}{2}(x^\top \bar{P}(t)x + 2w^\top \Pi_1(t)\bar{Q}(t)x + w^\top \Pi_1(t)R(t)\Pi_1(t)w); \end{aligned} \tag{3.6}$$

see, e.g., Lemma 5.5 in [23]. The couple (x,u) is a critical point of J_c restricted to H_c if and only if there exists a multiplier $\sigma \in (\mathbf{R}^p)^*$ and a solution of the adjoint equation

$$-\dot{\lambda}(t) = \lambda(t)\bar{A}(t) + \xi^\top(t)\bar{P}(t) + u^\top(t)\Pi_1(t)\bar{Q}(t)$$

satisfying the corresponding transversality conditions

$$(-\lambda(0), \lambda(c)) = (\xi^\top(0), \xi^\top(c))\Gamma_c + \sigma N_c$$

such that

$$\begin{aligned} &D_4 H(t, \lambda(t), \xi(t), \Pi_1(t)u(t)) \\ &= (u^\top(t)\Pi_1(t)R(t) + \lambda(t)B(t) + \xi^\top(t)\bar{Q}^\top(t))\Pi_1(t) \equiv 0. \end{aligned}$$

Since the operator S defined in (2.14) is such that

$$S_{|\text{Range}\,\Pi_1} = (\Pi_1 R \Pi_{1|\text{Range}\,\Pi_1})^{-1} \quad \text{and} \quad S\,\Pi_1 = \Pi_1 S = S,$$

we obtain

$$u = \Pi_1 u = -S(\bar{Q}\xi + B^\top \lambda^\top).$$

Substituting the above expression for u in the Hamiltonian H and in the equations defining ξ and λ, we obtain a solution of the Jacobi system satisfying the transversality conditions and hence a c-transversal extremal. Notice that two multipliers σ_1, σ_2 such that $\sigma_1 - \sigma_2 \in (\text{Range}\, N)^\perp$ identify the same λ, and hence if the system (2.9) is N_c-controllable at time c, then the extremal is uniquely determined.

Let us now prove that ζ is degenerate on $[\alpha,\beta]$ if and only if the corresponding control is identically zero on $[\alpha,\beta]$. Since S is invertible on Range Π_1, u is zero on $[\alpha,\beta]$ if and only if $\Pi_1(\bar{Q}\zeta + B^\top \lambda^\top) = 0$. □

Remark 3.2. By the strengthened Legendre–Clebsch condition, the Hamiltonian $\mathcal{H}$ in (2.16) can be obtained by minimization from the Hamiltonian H in (3.6). Namely,

$$\hat{w}(\gamma,x)(t) = -S(t)(\bar{Q}(t)x + B^\top(t)\gamma^\top) \tag{3.7}$$

is the unique minimizer of $H(t,\gamma,x,\cdot)$ and

$$\mathcal{H}(t,\gamma,x) \equiv H(t,\gamma,x,\hat{w}(\gamma,x)(t)) = \min_w H(t,\gamma,x,w). \tag{3.8}$$

LEMMA 3.9. *A c-transversal extremal ζ is trivial if and only if the corresponding couple (x,u) is zero. Moreover any nonzero c-transversal couple (ζ,λ) corresponds to a nontrivial c-transversal extremal if the system* (2.9) *is N_c-controllable at time c.*

Proof. If $(x,u)=(0,0)$, then ζ is identically zero. Conversely, let $\zeta=0$; then $\dot{\zeta}(t)=-B(t)S(t)B^\top(t)\lambda^\top(t)\equiv 0$ yields

$$\lambda(t)B(t)S(t)B^\top(t)\lambda^\top(t)\equiv 0.$$

From the properties of S we obtain that $\Pi_1 B^\top\lambda^\top\equiv 0$ and hence $SB^\top\lambda^\top=u=0$. By Lemma 3.8, the c-transversal extremal corresponding to $(0,0)$ is uniquely determined if and only if Σ is onto Range N; hence the only trivial c-transversal extremal is the one that is zero, if and only if Σ is onto Range N. ∎

LEMMA 3.10. *Assume that the right end-point is fixed, that is,* $N=\begin{pmatrix}\Gamma_0 & 0\\ 0 & Id\end{pmatrix}$, *and that the system* (2.9) *is controllable from* $\{0\}$ *on any subinterval. Then there are no degenerate c-transversal extremals.*

Proof. Assume that ζ is a c-transversal degenerate extremal. Since the right end-point is fixed, the transversality condition implies that $\zeta(c)=0$. From the characterization of degenerate extremal it follows that there exists an interval $[\alpha,\beta]$ containing c such that $\zeta(t)\equiv 0$ on $[\alpha,\beta]$ with a corresponding λ satisfying

$$\dot{\lambda}(t)=-\lambda(t)\bar{A},\qquad \Pi_1 B^\top\lambda^\top=0$$

on the same interval. By the controllability assumption λ has to be zero on that interval and hence the couple (ζ,λ) is trivial. ∎

LEMMA 3.11. *If* $V(c)=0$, *then there is a nontrivial c-transversal extremal.*

Proof. If $V(c)=0$, then 0 is the global minimum for J_c restricted to H_c and the minimum is attained at a nonzero (x,u). Lemmas 3.8 and 3.9 imply that there exists a nontrivial c-transversal extremal. ∎

LEMMA 3.12. *A* c_0*-transversal extremal* ζ *which is degenerate on* $[\alpha,\beta]$ *is a c-transversal extremal for every* $c\in[\alpha,\beta]$.

Proof. The proof can be carried out by direct computation, taking into account that for $c\in[\alpha,\beta]$ we have

$$\zeta(c)=\Phi(c,c_0)\zeta(c_0),$$
$$\lambda(c)=\lambda(c_0)\Phi(c_0,c)-\zeta^\top(c)\int_{c_0}^{c}\Phi^\top(s,c)\bar{P}(s)\Phi(s,c)\,ds.$$ ∎

We are now able to prove the main results.

Proof of Theorem 2.5. Assume that J_0 is nonnegative on H_0 (i.e., $V(0)\geq 0$) and that there is no point $c_0\in(0,T)$ conjugate with zero. We show the result by proving that there is no point $c_1\in[0,T]$ such that $V(c_1)<0$. Assume by contradiction that there is a point $c_1\in[0,T]$ such that $V(c_1)<0$; we can find a point c_0 at which V changes its sign. Since $V(c_0)=0$, then by Lemma 3.11 there exists a nontrivial c_0-transversal extremal. Since $V(c)<0$ for $c>c_0$, the index of the quadratic form J_c is positive. By Lemma 16.3 in [7] there exists a nontrivial critical point $(x,u)\in H_{c_0}$ which is not a critical point for $c>c_0$. By Lemma 3.12 the corresponding c_0-transversal extremal cannot be degenerate on $[c_0,\beta]$, with $\beta>c_0$; that is, c_0 is conjugate with zero yielding a contradiction.

Conversely, assume that the form J is nonnegative on H; then the function V is nonnegative on $[0,T]$. It is clear that J_0 is nonnegative on H_0. Let us show that there is no point $c_0\in[0,T)$ conjugate with zero. Assume by contradiction that $c_0\in[0,T)$ is conjugate with zero. By Lemma 3.8 it follows that J_{c_0} has a critical point in H_{c_0}, so that $V(c_0)\leq 0$. If $V(c_0)<0$ we have a contradiction. Otherwise $V(c_0)=0$ and hence any nontrivial c_0-transversal extremal ζ corresponds to a nonzero $(\bar{x},\bar{u})\in H_{c_0}$ which is a minimizer for J_{c_0}. It is clear that $J_T(\bar{x},\bar{u})=J_{c_0}(\bar{x},\bar{u})=0$, so that, since V

is identically zero on the interval $[c_0, T]$, $(\bar{x}, \bar{u})$ is a minimizer also for J_T. Therefore by Lemmas 3.8 and 3.9 ζ is degenerate on $[c_0, T]$, a contradiction. ∎

Proof of Theorem 2.6. Assume that J_0 is positive on H_0 (i.e., $V(0) > 0$) and that there is no point $c_0 \in (0, T]$ semiconjugate with zero. Let us show that there is no point $c \in (0, T]$ such that $V(c) = 0$. Assume by contradiction that $V(c) = 0$; then by Lemma 3.11, there exists a nontrivial c-transversal extremal, a contradiction.

Conversely, assume that the quadratic form J is coercive on H. Then the function V is strictly positive on $[0, T]$. This ensures that quadratic form J_c restricted to H_c does not have any nonzero critical point; by Lemmas 3.8 and 3.9 the statement follows. ∎

LEMMA 3.13. *There exists a point $c \in (0, T]$ coupled with zero if and only if there exists a point semiconjugate with zero on the same interval. There exists a point $c \in (0, T)$ coupled with zero if and only if there is a point conjugate with zero on the same interval.*

Proof. Assume that there exists a point $c \in (0, T]$ coupled with zero; then by definition there exists a point semiconjugate with zero. Conversely, if there exists a point $c \in (0, T]$ semiconjugate with zero, then there are two possibilities: either the extremal is not degenerate on $[c, T]$ and hence the point c is coupled with zero or it is degenerate until T and in this case T is coupled with zero.

Let us now prove the second statement. Assume that there exists a point $c \in (0, T)$ coupled with zero. Since the corresponding extremal is not degenerate until T, there exists a maximal interval $[c, c_1]$ with $c \le c_1 < T$ on which it is degenerate. By Lemma 3.12 it is a c_1-transversal extremal corresponding to a conjugate point. The converse follows immediately from the definitions. ∎

The proof of Corollary 2.8 is now straightforward.

Let us now prove the statements concerning the Riccati theory. For sake of completeness we prove some standard properties of the solutions of Jacobi system and Riccati equation. In the following we use the fact that if (ζ, λ) is a solution of (2.17), then ζ is a solution of (2.9) corresponding to the control $\hat{w}(\zeta, \lambda)$, where $\hat{w}$ is defined in (3.7). Set

$$g(t, x, w) = x^\top \bar{P}(t)x + 2w^\top \Pi_1(t)\bar{Q}(t)x + w^\top \Pi_1(t)R(t)\Pi_1(t)w.$$

LEMMA 3.14. *If (ζ, λ) is a solution of* (2.17)*, then the following equality holds:*

$$g(t, \zeta(t), \hat{w}(\zeta, \lambda)(t)) = -\frac{d(\lambda\zeta)}{dt}(t).$$

Proof. From the definition of the Hamiltonian H and its minimum property (3.8) it follows that

$$\begin{aligned} g(t, \zeta(t), \hat{w}(\zeta, \lambda)(t)) &= 2H(t, \lambda(t), \zeta(t), \hat{w}(\zeta, \lambda)(t)) - 2\lambda(t)\dot{\zeta}(t) \\ &= 2\mathcal{H}(t, \lambda(t), \zeta(t)) - 2\lambda(t)\dot{\zeta}(t). \end{aligned}$$

Moreover, since $\mathcal{H}$ is quadratic,

$$\begin{aligned} &g(t, \zeta(t), \hat{w}(\zeta, \lambda)(t)) \\ &= \lambda(t)\frac{\partial \mathcal{H}}{\partial \gamma}(t, \lambda(t), \zeta(t)) + \frac{\partial \mathcal{H}}{\partial x}(t, \lambda(t), \zeta(t))\,\zeta(t) - 2\lambda(t)\dot{\zeta}(t) \\ &= -\dot{\lambda}(t)\zeta(t) - \lambda(t)\dot{\zeta}(t). \end{aligned}$$

The statement is proved. ∎

LEMMA 3.15. *Let ξ be a solution of* (2.9) *corresponding to the control u and let W be a solution of the Riccati equation* (2.19) *on an interval $I \subseteq [0,T]$. Then*

$$g(t,\xi(t),u(t)) \geq -\frac{d\,(\xi^\top W\xi)}{dt}(t),\ t \in I.$$

Moreover, the equality holds if and only if

$$u = -S(\bar{Q} + B^\top W)\xi, \tag{3.9}$$

and this happens if and only if the couple $(\xi, \xi^\top W)$ is a solution of the Jacobi system (2.17).

Proof. Set $\lambda(t) = \xi^\top(t)W(t)$. Easy computations show that

$$-\frac{1}{2}\xi^\top(t)\dot{W}(t)\xi(t) = \mathcal{H}(t,\lambda(t),\xi(t)).$$

By the minimum properties of the Hamiltonian $\mathcal{H}$, (3.8), we have that

$$\frac{1}{2}g(t,\xi(t),u(t)) \geq \mathcal{H}(t,\lambda(t),\xi(t)) - \lambda(t)\dot{\xi}(t) = -\frac{1}{2}\frac{d\,(\xi^\top W\xi)}{dt}(t).$$

Since the Hamiltonian H attains its minimum in a unique point, the equality holds if and only if

$$u = -S(\bar{Q}\zeta + B^\top\lambda^\top) = -S(\bar{Q} + B^\top W)\xi.$$

A direct computation proves the last statement. □

LEMMA 3.16. *Let (Z_0,Λ_0) be the solution of* (2.18) *defined by the initial conditions* (2.20). *If $Z_0(t)$ is invertible for $t \in [a,b]$, then $W = \Lambda_0{}^\top Z_0^{-1}$ is a symmetric solution of the Riccati equation* (2.19) *on $[a,b]$.*

Proof. A direct computation proves that W is a solution of (2.19). Since the derivative of $\Lambda_0 Z_0 - Z_0{}^\top\Lambda_0{}^\top$ is zero, then from the symmetry of $\Lambda_0(0)Z_0(0)$, it follows that $\Lambda_0 Z_0 = Z_0{}^\top\Lambda_0{}^\top$. Multiplying the equality by $(Z_0{}^\top)^{-1}$ from the left and by Z_0^{-1} from the right, we obtain the statement. □

Proof of Theorem 2.9. Let (Z_0,Λ_0) be the solution of (2.18) defined by the initial conditions (2.20). It is easy to show that each solution (ζ,λ) of the Jacobi system (2.17) which satisfies the transversality conditions at $t=0$ can be uniquely expressed as $(\zeta,\lambda) = (Z_0 y, y^\top\Lambda_0),\ y \in \mathbf{R}^n$.

Let us now prove that $1 \Rightarrow 2$. If J is coercive, then clearly J_0 is positive on H_0. Let us prove that $Z_0(t)$ is invertible for $t \neq 0$. Let $(\zeta,\lambda) = (Z_0 y, y^\top\Lambda_0)\ ,\ y \in \mathbf{R}^n$. By Lemma 3.14 we obtain

$$J_c(\zeta(0),\hat{w}(\zeta,\lambda)) = y^\top(Z_0{}^\top(c)\Gamma_T^c - \Lambda_0(c))Z_0(c)y, \tag{3.10}$$

where

$$\Gamma_T^c = \Phi^\top(T,c)\Gamma_T\Phi(T,c) + \int_c^T \Phi^\top(s,c)\bar{P}(s)\Phi(s,c)ds.$$

Assume that $Z_0(c)y = 0$; then (3.10) yields $J_c(\zeta(0),\hat{u}(\zeta,\lambda)) = 0$ and hence from the coercivity assumption it follows that $(\zeta(0),\hat{u}(\zeta,\lambda)) = 0$ on $[0,c]$, and it corresponds to a global minimum for J_c. ζ is a c-transversal extremal for the problem with fixed right end-point, and by applying Lemma 3.9, whose controllability assumptions are

satisfied, we deduce that (ζ, λ) is identically zero on $[0, c]$. If we evaluate the initial conditions we obtain $\zeta(0) = (Id - N_0)y = 0$ and $0 = \lambda(0) = -y^\top(Id - N_0)\Gamma_0(Id - N_0) + y^\top N_0 = y^\top N_0$ and hence $y = 0$, so that $Z_0(c)$ is invertible. Let us define $W = \Lambda_0{}^\top Z_0^{-1}$, which is a symmetric solution of (2.19) by Lemma 3.16. The limit condition (2.21) is straightforward. Since $Z_0(T)$ is invertible, any $w \in \operatorname{Ker} N_T$ can be written as $w = Z_0(T)y$. From (3.10) evaluated at $c = T$, by the coercivity assumption on J, one obtains immediately (2.22).

Let us now prove that $2 \Rightarrow 1$. By contradiction assume that J is not coercive. Then from Theorem 2.6 there is a semiconjugate point $c \in (0, T]$ and by Lemma 3.8 there is a nonzero $(x, u) \in H_c$ such that

$$0 = J_c(x, u) = J(x, u) = \frac{1}{2}x^\top \Gamma_0 x + \frac{1}{2}\xi^\top(T)\Gamma_T \xi(T) + \frac{1}{2}\int_0^T g(s, \xi(s), u(s))\, ds.$$

ξ coincides with a c-transversal extremal on $[0, c]$ so that there exists $y \in \mathbf{R}^n$ such that $\xi = Z_0 y$ on $[0, c]$. From Lemma 3.15 it follows that

$$\begin{aligned} 0 &= J_c(x, u) \\ &\geq \frac{1}{2}x^\top \Gamma_0 x + \frac{1}{2}\xi^\top(T)\Gamma_T \xi(T) + \frac{1}{2}\lim_{t \to 0^+} y^\top Z_0{}^\top(t) W(t) Z_0(t) y - \frac{1}{2}\xi^\top(T) W(T) \xi(T) \\ &= \frac{1}{2}\xi^\top(T)(\Gamma_T - W(T))\xi(T) \geq 0. \end{aligned}$$

The two opposite inequalities yield $\xi(T) = 0$. Moreover, the above inequality is indeed an equality and Lemma 3.15 implies that the couple $(\xi, \xi^\top W)$ is a solution of (2.17). Since it has zero final value, it is the zero solution, a contradiction.

Let us now prove that statement 2 implies that $Z_0(c)$ is invertible for $c \in (0, T]$ and hence the constrained control system is controllable at any time c from $\operatorname{Ker} N_0$. For $c \in (0, T]$ and $y \in \mathbf{R}^n$, assume that $Z_0(c)y = 0$; hence the trajectory

$$\xi(t) = \begin{cases} Z_0(t)y & \text{if } t \in [0, c], \\ 0 & \text{if } t \in [c, T], \end{cases} \qquad u(t) = \begin{cases} \hat{u}(Z_0 y, y^\top \Lambda_0) & \text{if } t \in [0, c], \\ 0 & \text{if } t \in [c, T] \end{cases}$$

is admissible. Lemma 3.14 yields $J(\xi(0), u) = 0$, and since we have shown that the quadratic form is coercive, $Z_0(0)y = (Id - N_0)y = 0$. On the other hand, by Lemma 3.15 one obtains

$$0 = J(\xi(0), u) \geq \frac{1}{2}y^\top(Id - N_0)\Gamma_0(Id - N_0)y + \frac{1}{2}\lim_{t \to 0^+} y^\top Z_0{}^\top(t) W(t) Z_0(t) y = 0.$$

Hence, again from Lemma 3.15, since the equality holds, $(\xi, \xi^\top W)$ is a solution of (2.17) which has value zero at $t = c$. Therefore it is identically zero, so that $\lambda(0) = N_0 y = 0$ also and hence $y = 0$, which proves that $Z_0(c)$ is invertible.

In the case of unconstrained initial point, i.e., $N_0 = 0$, $Z_0(0) = Id$ is invertible; therefore $W = \Lambda_0{}^\top Z_0^{-1}$ exists on the whole interval and $W(0) = -\Gamma_0$. □

In the next proofs we will reduce our problem to one without boundary constraints. This can be done by applying Theorems 13.2 and 13.3 of [7] to obtain the following.

LEMMA 3.17. *Let J be a Legendre form and Q be a nonnegative w-continuous form such that J is coercive (nonnegative) where Q is zero; then there exists a constant $\beta > 0$ such that $J + \frac{1}{2}\beta Q$ is coercive (nonnegative) on the whole space.*

Proof of Theorem 2.10. We can apply Lemma 3.17 with

$$Q(x,u) = x^\top N_0 x + \xi^\top(T) N_T \xi(T),$$

which is a w-continuous form since it involves only the state end-points. If we apply Theorem 2.9 to this special case, we obtain the first formulation of the statement taking into account that $\Gamma_T + \beta N_T - W(T)$ is positive on $\mathbf{R}^n$ if and only if $\Gamma_T - W(T)$ is positive on Ker N_T. To prove the other equivalent form of the statement let us first notice that elementary results in perturbation theory yield that, for $\epsilon > 0$ sufficiently small, there exists a solution of the Riccati equation such that

$$W(0) + \Gamma_0 + \beta N_0 = \epsilon Id \text{ and } \Gamma_T - W(T) > 0 \text{ on } \operatorname{Ker} N_T.$$

To prove the converse statement it is sufficient to use Lemma 3.15 in a way analogous to the proof of Theorem 2.9. □

Proof of Theorem 2.11. It is a consequence of Lemma 3.10 that every semiconjugate point is also a conjugate point. Hence the function V changes sign at the point where it becomes zero. The form J is then nonnegative on H if and only if it is coercive on H_c for $c \in [0,T)$. The prove of the equivalence among the first three statements can be carried out as in the proofs of Theorems 2.9 and 2.10. Since statement 4 is an obvious consequence of statement 3, we need only to prove that if statement 4 holds then the form J is nonnegative on H. This can be done by direct computation on J_c using Lemma 3.15. Let us underline that the perturbation argument in Theorem 2.10 does not hold. □

Let us now go back to the case of mixed boundary conditions and cost.

Proof of Theorem 2.12. Let (x,u) belong to H; then the couple $(x,\xi(T)) \in \operatorname{Ker} N$ and by Lemma 3.15 we obtain

$$\begin{aligned} 2J(x,u) &\geq (x^\top, \xi^\top(T))\Gamma \begin{pmatrix} x \\ \xi(T) \end{pmatrix} + x^\top W(0) x - \xi^\top(T) W(T) \xi(T) \\ &= (x^\top, \xi^\top(T)) \left(\Gamma + \begin{pmatrix} W(0) & 0 \\ 0 & -W(T) \end{pmatrix} \right) \begin{pmatrix} x \\ \xi(T) \end{pmatrix} \geq 0. \end{aligned}$$

Let us now show that J is not semidefinite but indeed coercive. If $J(x,u) = 0$, then $(x,\xi(T)) = 0$. Moreover, again by Lemma 3.15, the equality holds if and only if $(\xi, \xi^\top W)$ is a solution of the Jacobi equation. Since it is zero at the initial point, it is identically zero. By (3.9) the couple (x,u) is also trivial; thus J is coercive on H. □

4. Appendix. This section contains two technical results we have been using and the examples.

Lemma 4.1 states that Assumption 2.2 is equivalent to the regularity of the infinite-dimensional constraint (2.4) under Assumption 2.1.

LEMMA 4.1. *Assume that Assumption* 2.1 *holds, and let the map* $\Psi : U \to W = \operatorname{Range} \Delta$ *be given by* $(x,u) \mapsto C\eta + Du$, *where* η *is the solution of* (2.2). Ψ *is onto if and only if Assumption* 2.2 *holds.*

Proof. Assume that Assumption 2.2 holds; the right inverse can be written explicitly through $D^\sharp$ as in [19], taking into account the presence of the projection. Assume that Ψ is onto. Since it is a map between Hilbert spaces this is equivalent to the existence of a continuous right inverse of Ψ denoted by $\Psi^\sharp$. Let us first prove that this

implies that there exists a positive constant h such that $\Psi\Psi^\top \geq h\, Id$. By contradiction assume that there exists a sequence $\{u_n\} \subset U$ such that

$$\|u_n\| = 1, \qquad \left\|\Psi^\top u_n\right\|^2 \to 0.$$

Hence

$$(\Psi^\sharp)^\top \Psi^\top u_n = (\Psi\Psi^\sharp)^\top u_n = u_n \xrightarrow{s} 0,$$

a contradiction. Easy computations show that the map $\Psi^\top : W \subset L^2([0,T], \mathbf{R}^k) \to U$ is given by $v \mapsto (\nu(0), B^\top\nu + D^\top v)$, where $\dot\nu(t) = -A^\top(t)\nu(t) - C^\top(t)v(t),\ \nu(T) = 0$. Hence

$$\left\|\Psi^\top v\right\|^2 = \nu(0)^\top\nu(0) + \int_0^T (\nu^\top BB^\top\nu + 2\nu^\top BD^\top v + v^\top DD^\top v)(s)\, ds.$$

All the addends where the state ν appears give weakly continuous quadratic forms; moreover $\Psi\Psi^\top$ is coercive and hence Legendre. By Theorem 11.5 in [7] the nonnegative quadratic form $Q : v \mapsto \left\|D^\top v\right\|^2$ is Legendre. The nullity of Q coincides with Dim Ker $D^\top$ and therefore is either 0 or $+\infty$. Since Q is Legendre its nullity is finite dimensional and hence it is 0; that is, Q is positive and hence coercive by Theorem 11.1 in [7]. Since Δ is an orthogonal projection, the quadratic form on $L^2([0,T], \mathbf{R}^k)$ given by

$$w \mapsto \left\|D^\top \Delta w\right\|^2 + \|(Id - \Delta)w\|^2$$

is coercive. Finally, by Theorem 4.4 in [7] we obtain Assumption 2.2. □

Lemma 4.2 shows that the three statements in Assumption 2.3 are equivalent.

LEMMA 4.2. *The three statements in Assumption* 2.3 *are equivalent.*

Proof. From (2.6) it follows that

$$u^\top \Pi_1 R \Pi_1 u \geq h_0 \|\Pi_1 u\|^2;$$

therefore, since the Π_i's are orthogonal projections,

$$u^\top(\Pi_1 R \Pi_1 u + \Pi_2 u) \geq h_0\|\Pi_1 u\|^2 + \|\Pi_2 u\|^2 \geq h\|u\|^2.$$

Hence (2.6) yields (2.7). (2.7) implies (2.8), obviously.

Let us now show that (2.8) implies (2.6). Let the L^∞ norm of the matrix $R(t)$ be bounded by M; from (2.8), by easy computations, we obtain that for all $h_0, h_1 > 0$

$$\begin{aligned} &u^\top(R + h_1\Pi_2 - h_0 Id)u \\ &= u^\top(\Pi_1 R\Pi_1 + \Pi_2 R\Pi_2 + 2\Pi_1 R\Pi_2 + h_1\Pi_2 - h_0 Id)u \\ &\geq u^\top(h\Pi_1 - M\Pi_2 + h_1\Pi_2 - h_0 Id)u - 2M\|\Pi_1 u\|\|\Pi_2 u\| \\ &= (h - h_0)\|\Pi_1\|^2 + (h_1 - h_0 - M)\|\Pi_2\|^2 - 2M\|\Pi_1 u\|\|\Pi_2 u\|. \end{aligned}$$

By a suitable choice of h_0, h_1 the sum in the brackets can be made nonnegative, proving (2.6). □

In the following example we have a coercive quadratic form with a nonzero c-transversal solution of the Jacobi system which corresponds to the zero extremal.

Example 4.1. Let us consider the quadratic form

$$I(u) = \frac{1}{2}\int_0^2 u^2(s)\, ds$$

on the subspace H of the controls u such that

$$\dot{\xi}(t) = b(t)u(t), \quad t \in [0,2],$$

$$\xi(0) = 0, \quad \xi(2) = 0,$$

where the function b is identically zero on $[0,1]$ and positive elsewhere.

I is clearly coercive on H and the solutions of the Jacobi system are given by

$$(\zeta(t), \lambda(t)) = \left(-\lambda_0 \int_0^t b^2(s)\, ds, \lambda_0 \right).$$

For any $c \in [0,1]$ we have nonzero c-transversal solutions (ζ, λ), but they correspond to the trivial c-transversal extremal so that c is not a point semiconjugate with zero.

The next example shows that the sufficient conditions in Theorem 2.11 are not necessary.

Example 4.2. Let us consider the quadratic form

$$I(x,u) = \xi(0)\xi(T) + \frac{1}{2}\int_0^T u^2(s)\, ds$$

on the subspace H of the couples (ξ, u) such that $\dot{\xi}(t) = 0$ and $\xi(0) = x$. The state is constant, and hence the form J is clearly coercive because it can be written as $I(x,u) = \|\xi(0)\|^2 + \frac{1}{2}\|u\|^2$, but the conditions of Theorem 2.12 are not satisfied. In fact the solutions of the Riccati equations are also constant, but there is no solution W which satisfies

$$\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} + \begin{pmatrix} W & 0 \\ 0 & -W \end{pmatrix} > 0 \text{ on } \mathbf{R}^2.$$

Let us remark that if we write

$$I(x,u) = \xi^2(0) + \frac{1}{2}\int_0^T u^2(s)\, ds,$$

which is clearly an equivalent expression for I on H, we can then apply Theorems 2.9 and 2.10, whose conditions are satisfied for $W = -\frac{1}{2}$.

The next example shows why in statement 4 of Theorem 2.11 we do not have strict inequality as in Theorem 2.10. The perturbation argument cannot be applied to a solution defined on a half-open interval $[0,T)$, and hence a solution of the Riccati equation satisfying $W(0) + \Gamma_0 > 0$ may not exist on the whole interval $[0,T)$.

Example 4.3. Let us consider the following form in the calculus of variations

$$I(x,\dot{\xi}) = \frac{1}{2}\xi^2(0) + \frac{1}{2}\int_0^{\frac{3\pi}{4}} \left\{ \dot{\xi}^2(s) - \xi(s) \right\} ds$$

with $\xi(T) = 0$. This form is positive semidefinite, and it has value zero along the arc $\xi(t) = \sin(t) + \cos(t)$. All the assumptions of Theorem 2.11 are satisfied, and there exists a solution of the corresponding Riccati equation which satisfies the suitable initial condition, namely $W(t) = \tan(t - \frac{\pi}{4})$, defined on the interval $[0, \frac{3\pi}{4})$. If we want $W(0) + \Gamma_0 > 0$ then we have to perturb the initial conditions by a positive constant ϵ. The solution becomes $W_\epsilon(t) = \tan(t - \frac{\pi}{4} + \epsilon)$, which does not exist on the whole interval $[0, \frac{3\pi}{4})$. Clearly if we want $W(0) + \Gamma_0 \geq 0$, it is enough to take $\epsilon = 0$.

We end this section with an example where these results have been applied to study an economic theory model (see [1, 2]).

Example 4.4. The model concerns the classical optimal saving problem for a consumer with increasing marginal utility in an economy characterized by irreversible investments. If the consumer has a quadratic utility function then the problem over a finite horizon can be seen as the following optimal control problem:

$$\text{Maximize } J_T(c) = \frac{1}{2}\int_0^T e^{-\rho s}c^2(s)\,ds,$$
$$\dot{k}(t) = \alpha k(t) - c(t), \quad k(0) = k_0 > 0,$$
$$0 \le c(t) \le \alpha k(t),$$

where

- c is consumption,
- k is capital,
- ρ is discount factor, $\rho > 0$,
- α is instantaneous rate of return, $0 \le \alpha \le 1$.

This example is of some interest because the usual existence theorems do not apply; hence the candidate optimal solution obtained by the Pontryagin maximum principle needs to be tested by second-order conditions in order to prove its optimality.

In [1] the following candidate optimal solution is singled out:

$$\hat{c}(t) = \begin{cases} 0, & t \in [0, t^*), \\ \alpha\hat{k}(t), & t \in [t^*,\ T], \end{cases} \qquad \hat{k}(t) = \begin{cases} k_0 e^{\alpha t}, & t \in [0, t^*), \\ k_0 e^{\alpha t^*}, & t \in [t^*,\ T], \end{cases}$$

where

$$t^* = \begin{cases} 0 & \text{if } \rho \ge 2\alpha \text{ or if } \rho < 2\alpha \text{ and } T \le \bar{t}, \\ T - \bar{t} & \text{if } \rho < 2\alpha \text{ and } T > \bar{t} \end{cases}$$

and

$$\bar{t} = \frac{1}{\rho}\ln\left(\frac{2\alpha}{2\alpha - \rho}\right).$$

By adding some extra controls this problem can be reduced to one with equality constraints. In [2] it is shown that there are no semiconjugate points in the accessory problem; therefore the candidate solution provides a local maximum which is also a global optimum.

The solution has an interesting economic meaning. If this *hedonistic* consumer has a discount rate that is small compared with the instantaneous rate of return, $\rho < 2\alpha$, and he/she has a long enough life, $T > \bar{t}$, then he or she accumulates the returns from investments during a certain period of time and afterwards he or she consumes all the surplus. Otherwise he or she will consume all the investment returns immediately. Hence a hedonistic consumer, i.e., with increasing marginal utility, might also be willing to save.

OPTIMAL CONTROL FOR HOLONOMIC AND NONHOLONOMIC MECHANICAL SYSTEMS WITH SYMMETRY AND LAGRANGIAN REDUCTION*

WANG-SANG KOON† AND JERROLD E. MARSDEN‡

Abstract. In this paper we establish necessary conditions for optimal control using the ideas of Lagrangian reduction in the sense of reduction under a symmetry group. The techniques developed here are designed for Lagrangian mechanical control systems with symmetry. The benefit of such an approach is that it makes use of the special structure of the system, especially its symmetry structure, and thus it leads rather directly to the desired conclusions for such systems.

Lagrangian reduction can do in one step what one can alternatively do by applying the Pontryagin maximum principle followed by an application of Poisson reduction. The idea of using Lagrangian reduction in the sense of symmetry reduction was also obtained by Bloch and Crouch [*Proc. 33rd CDC*, IEEE, 1994, pp. 2584–2590] in a somewhat different context, and the general idea is closely related to those in Montgomery [*Comm. Math. Phys.*, 128 (1990), pp. 565–592] and Vershik and Gershkovich [*Dynamical Systems* VII, V. Arnold and S. P. Novikov, eds., Springer-Verlag, 1994]. Here we develop this idea further and apply it to some known examples, such as optimal control on Lie groups and principal bundles (such as the ball and plate problem) and reorientation examples with zero angular momentum (such as the satellite with moveable masses). However, one of our main goals is to extend the method to the case of nonholonomic systems with a nontrivial momentum equation in the context of the work of Bloch, Krishnaprasad, Marsden, and Murray [*Arch. Rational Mech. Anal.*, (1996), to appear]. The snakeboard is used to illustrate the method.

1. Introduction.

Recently several papers have appeared exploring the symmetry reduction of optimal control problems on configuration spaces such as Lie groups and principal bundles. The mechanical systems which they have modeled vary widely, ranging from the falling cat and the rigid body with two oscillators to the plate-ball system as well as the (airport) landing tower problem. Since the Pontryagin maximum principle is such an important and powerful tool in optimal control theory, it is frequently employed as a first step in finding necessary conditions for the optimal controls. Finally, different variants of Poisson reduction on the cotangent bundle T^*Q of the configuration space Q are used to obtain the reduced equations of motion for the optimal trajectories.

This paper develops a Lagrangian alternative to the method of Pontryagin maximum principle and Poisson reduction used in many of the above studies. More importantly, our method can handle the optimal control of nonholonomic mechanical system such as the snakeboard, which has a nontrivial evolution equation for its nonholonomic momentum. Our key idea is to link the method of Lagrange multipliers with Lagrangian reduction. This procedure, which will be referred to as "reduced

Lagrangian optimization," is able to handle all the above cases, including the snakeboard. We hope that it will complement other existing methods and may also have the advantage that it is easier to use in many situations and can solve many new problems. In the optimal control problems we deal with in this paper, one encounters degenerate Lagrangians; fortunately this does not cause problems with the technique of Lagrangian reduction. For more information on these degeneracies, see Bloch and Crouch [1994].

Our objectives in this paper are limited to presenting reduced Lagrangian optimization in the context of both holonomic and nonholonomic systems that may have conservation laws or nontrival momentum equations. We use this approach as an alternative to the Pontryagin maximum principle and Poisson reduction. Although an assumption of controllability underlies most optimal control problems, we are concerned here with finding necessary conditions for optimality and so do not discuss controllability explicitly. We do not extensively develop the geometry of the situation in much detail, and we restrict our attention to regular extremals throughout the paper without explicit mention. Of course all of these points are of interest in themselves.

In the course of working on this paper, we have found some related ideas in Montgomery [1990], Vershik and Gershkovich [1994], Bloch and Crouch [1994, 1995], Kelly and Murray [1995], and Bloch, Crouch, and Ratiu [1994]. The paper by Bloch, Krishnaprasad, Marsden, and Murray [1996] provides a useful framework for the present work.

Outline of the paper. In section 2, we recall some basic facts about both holonomic and nonholonomic mechanical systems with symmetry. We set up a class of optimal control problems for holonomic mechanical systems on a (trivial) principal bundle as was done in Montgomery [1990, 1993] and in Krishnaprasad, Yang, and Dayawansa [1991]. We also set up the corresponding problems for nonholonomic systems. We will call these "Lagrangian optimal control problems."

In section 3 we review some aspects of the theory of Lagrangian reduction and use it to solve the Lagrangian optimal control problem in the holonomic case, showing that an optimal trajectory is a solution of Wong's equations (at least for regular extremals). This provides an alternative derivation to the approach (based on methods of sub-Riemannian geometry) in Montgomery [1990] and the approach (based on the Pontryagin maximum principle and Poisson reduction) in Krishnaprasad, Yang, and Dayawansa [1991].

In section 4 we generalize these results to the case of nonholonomic systems. Notice in particular that our techniques allow for nonzero values of the momentum map, which is interesting even for the holonomic case. In section 5 we consider a number of examples, such as the ball on a plate (as in Bloch, Krishnaprasad, Marsden, and Murray [1995]) and the snakeboard. We also consider optimal control problems for systems on Lie groups such as the landing tower problem (see Krishnaprasad [1993] and Walsh, Montgomery, and Sastry [1994]) and the plate-ball problem considered in Jurdjevic [1993, 1996].

In the conclusion, we give a few remarks on future research directions.

2. Lagrangian mechanical systems with symmetry. In this section we shall review, for the convenience of the reader, some notation and results for mechanical systems with symmetry. We will begin with the case of holonomic systems and then study the nonholonomic case.

2.1. Holonomic systems with symmetry.

Notation. A simple Lagrangian system with symmetry consists of a configuration manifold Q, a metric tensor (the mass matrix) $\langle\langle\, , \rangle\rangle$, a symmetry group G (a Lie group), and a Lagrangian L. Assume that G acts on Q by isometries and that the Lagrangian L is of the form kinetic minus potential energy; i.e.,

$$L(q,v) = \frac{1}{2}\|v\|_q^2 - V(q),$$

where $\|\cdot\|_q$ denotes the norm on T_qQ and V is a G-invariant potential. For more information, see, for example, Marsden [1992] and Marsden and Ratiu [1994]. Examples of such systems are the falling cat (Montgomery [1990, 1991]) and the rigid body with two oscillators (Krishnaprasad, Yang, and Dayawansa [1991]).

The associated equivariant momentum map $J : TQ \to \mathfrak{g}^*$ for a simple Lagrangian system with symmetry is given by

$$\langle J(q,v), \xi\rangle = \langle\langle v, \xi_Q(q)\rangle\rangle = \frac{\partial L}{\partial \dot{q}^i}(\xi_Q)^i, \tag{2.1}$$

where $\mathfrak{g}^*$ is the dual of the Lie algebra $\mathfrak{g}$ of G, ξ_Q is the infinitesimal generator of $\xi \in \mathfrak{g}$ on Q, and $\langle\, , \rangle$ is the pairing between $\mathfrak{g}^*$ and $\mathfrak{g}$ (other natural pairings between spaces and their duals are also denoted $\langle\, , \rangle$ in this paper).

Assume that G acts freely and properly on Q, so we can regard $Q \to Q/G$ as a principal G-bundle (Q, B, π, G), where $B = Q/G$ is called the base (or shape) space and $\pi : Q \to B$ is the bundle projection. On this bundle, we construct the mechanical connection $\mathcal{A}$ as follows: for each $q \in Q$, let the locked inertia tensor be the map $\mathbb{I}(q) : \mathfrak{g} \to \mathfrak{g}^*$ defined by

$$\langle \mathbb{I}(q)\eta, \xi\rangle = \langle\langle \eta_Q(q), \xi_Q(q)\rangle\rangle.$$

The terminology comes from the fact that for a coupled rigid body, particle, or elastic system, $\mathbb{I}(q)$ is the classical moment of inertia tensor of the instantaneous rigid system. The mechanical connection is the map $\mathcal{A} : TQ \to \mathfrak{g}$ that assigns to each (q,v) the "angular velocity of the locked system"

$$\mathcal{A}(q,v) = \mathbb{I}(q)^{-1} J(q,v). \tag{2.2}$$

When there is danger of confusion, we will write the mechanical connection as $\mathcal{A}^{\text{mec}}$ (additional connections will be introduced later in the paper). The map $\mathcal{A}$ is a connection on the principal G-bundle $Q \to Q/G$; that is, $\mathcal{A}$ is G-equivariant and satisfies $\mathcal{A}(\xi_Q(q)) = \xi$, both of which are readily verified. The horizontal space of the connection $\mathcal{A}$ is given by

$$\text{hor}_q = \{(q,v) \mid J(q,v) = 0\},$$

i.e., the space orthogonal to the G-orbits. The vertical space consists of vectors that are tangent to the group orbits; i.e.,

$$\text{ver}_q = T_q(\text{Orb}(q)) = \{\xi_Q(q) \mid \xi \in \mathfrak{g}\}.$$

For later use, we would like to say a few words about a general principal connection and its expression in a local trivialization. As stated above, a principal connection is

a $\mathfrak{g}$-valued one-form $\mathcal{A} : TQ \to \mathfrak{g}$ such that $\mathcal{A}(g \cdot v) = \mathrm{Ad}_g \mathcal{A}(v)$ and $\mathcal{A}(\xi_Q(q)) = \xi$ for each $\xi \in \mathfrak{g}$. For example, if $Q = G$, there is a canonical connection given by the right invariant one-form which equals the identity at $g = e$. That is, for $v \in T_gG$, we let $\mathcal{A}_G : TG \to \mathfrak{g}$, $\mathcal{A}_G(v) = TR_{g^{-1}} \cdot v$. In a local trivialization, where we can locally write $Q = B \times G$ and the action of G is given by left translation on the second factor, a connection $\mathcal{A}$ as a one-form has the form

$$\mathcal{A}(r, g) = \mathcal{A}_{\mathrm{loc}}(r, g)dr + \mathcal{A}_G$$

and

$$\mathcal{A}(r, g)(\dot{r}, \dot{g}) = \mathcal{A}_{\mathrm{loc}}(r, g)\dot{r} + \dot{g}g^{-1} = \mathrm{Ad}_g(\mathcal{A}_{\mathrm{loc}}(r, e)\dot{r} + g^{-1}\dot{g}),$$

where $(\dot{r}, \dot{g})$ is the tangent vector at each point $q = (r, g)$. With abuse of notation, we denote $\mathcal{A}_{\mathrm{loc}}(r, e) = \mathcal{A}_{\mathrm{loc}}(r)$. Hence, for a principal connection, we can write

$$\mathcal{A}(r, g)(\dot{r}, \dot{g}) = \mathrm{Ad}_g(g^{-1}\dot{g} + \mathcal{A}_{\mathrm{loc}}(r)\dot{r}). \tag{2.3}$$

Holonomic optimal control problems. Now we are ready to formulate an optimal control problem for a holonomic system on a trivial bundle $(B \times G, B, \pi, G)$. As in Montgomery [1990, 1991] and Krishnaprasad, Yang, and Dayawansa [1991], let us assume that the control is internal to the system, which leaves invariant the conserved momentum map J and that there is no drift; i.e., $\mu = J(q, v) = 0$. Assume further that the velocity $\dot{r}$ of the path in the base space B can be directly controlled; then an associated control problem can be set up as

$$\begin{cases} \dot{r} = u, \\ g^{-1}\dot{g} = -\mathcal{A}_{\mathrm{loc}}(r)u \end{cases} \tag{2.4}$$

because, from the results above, the constraint that $\mu = 0$ is nothing but $(\dot{r}, \dot{g}) \in \mathrm{hor}_{(r,g)}$, which is equivalent to $g^{-1}\dot{g} + \mathcal{A}_{\mathrm{loc}}(r)\dot{r} = 0$. Here $u(\cdot)$ is a vector-valued function.

Let C be a cost function which usually is a positive definite quadratic function in u and hence C can be written as the square of a metric on B. Then we can formulate an optimal control problem on $Q = B \times G$ as follows.

Optimal control problem for holonomic systems. *Given two points q_0, q_1 in Q, find the optimal controls $u(\cdot)$ which steer from q_0 to q_1 and minimize $\int_0^1 C(u)dt$ subject to the constraints $\dot{r} = u$, $g^{-1}\dot{g} = -\mathcal{A}_{\mathrm{loc}}(r)u$.*

Clearly the above optimal control problem is equivalent to the following constrained variational problem.

Constrained variational problem for holonomic systems. *Among all curves $q(t)$ such that $\dot{q}(t) \in \mathrm{hor}_{q(t)}$, $q(0) = q_0$, $q(1) = q_1$, find the optimal curves $q(t)$ such that $\int_0^1 C(\dot{r})dt$ is minimized, where $r = \pi(q)$.*

For example, Krishnaprasad, Yang, and Dayawansa [1991] considered a rigid body with two (driven) oscillators, which was used to model the drift observed in the Hubble Space Telescope due to thermoelastically driven shape changes of the solar panels arising from the day–night thermal cycling during orbit. The bundle used was $(\mathbb{R}^2 \times \mathrm{SO}(3), \mathbb{R}^2, \pi, \mathrm{SO}(3))$, and the corresponding optimal control problem was as follows.

Optimal control for a rigid body with two oscillators. *Find the control $u(\cdot) = (u^1(\cdot), u^2(\cdot))$ that minimizes $\int_0^1((u^1)^2 + (u^2)^2)dt$ subject to $\dot{r} = u$, $\dot{g} = -g\mathcal{A}_{\mathrm{loc}}(r)u$ for $r^1(0) = r^1(1) = r^2(0) = r^2(1) = 0$, $g(0) = g_0$, and $g(1) = g_1 \in \mathrm{SO}(3)$.*

For more details on the derivation of this model, see Krishnaprasad, Yang, and Dayawansa [1991]. Below we will take this optimal control problem as given and focus on finding the necessary conditions for its optimal trajectories; see Montgomery [1990, 1991] for additional examples.

2.2. Simple nonholonomic mechanical systems with symmetry. Next we recall some basic ideas and results from Bloch, Krishnaprasad, Marsden, and Murray [1995] which will help to set the overall context for the optimal control of a simple nonholonomic system. Assume that we have data as before, namely a configuration manifold Q, a Lagrangian of the form kinetic minus potential, and a symmetry group G that leaves the Lagrangian invariant. However, now we also assume we have a distribution $\mathcal{D}$ that describes the kinematic nonholonomic constraints. Thus, $\mathcal{D}$ is a collection of linear subspaces denoted $\mathcal{D}_q \subset T_qQ$, one for each $q \in Q$. We assume that G acts on Q by isometries and leaves the distribution invariant; i.e., the tangent of the group action maps $\mathcal{D}_q$ to $\mathcal{D}_{gq}$. Moreover, we assume that we are in the principal case where the constraints and the orbit directions span the entire tangent space to the configuration space: $\mathcal{D}_q + T_q(\mathrm{Orb}(q)) = T_qQ$ for each $q \in Q$.

As discussed in Bloch, Krishnaprasad, Marsden, and Murray [1996], the dynamics of a nonholonomically constrained mechanical system is governed by the Lagrange–d'Alembert principle. This principle states that (at least in the case of homogeneous linear constraints) the equations of motion of a curve $q(t)$ in configuration space are obtained by setting to zero the variations in the integral of the Lagrangian subject to variations lying in the constraint distribution and that the velocity of the curve $q(t)$ itself satisfies the constraints.

The momentum equation. In the case of a simple holonomic mechanical system, setting up an optimal control problem uses the momentum map J, the mechanical connection $\mathcal{A}$ as well as the reconstruction of path on Q given a path in Q/G. For the case of a simple nonholonomic mechanical system, we shall need similar notions, and they are recalled in the following discussion.

Let the intersection of the tangent to the group orbit and the distribution at a point $q \in Q$ be denoted

$$\mathcal{S}_q = \mathcal{D}_q \cap T_q(\mathrm{Orb}(q)).$$

Define, for each $q \in Q$, the vector subspace $\mathfrak{g}^q$ to be the set of Lie algebra elements in $\mathfrak{g}$ whose infinitesimal generators evaluated at q lie in $\mathcal{S}_q$:

$$\mathfrak{g}^q = \{\xi \in \mathfrak{g} : \xi_Q(q) \in S_q\}.$$

Then $\mathfrak{g}^{\mathcal{D}}$ is the corresponding bundle over Q whose fiber at the point q is given by $\mathfrak{g}^q$. The nonholonomic momentum map J^{nh} is the bundle map taking TQ to the bundle $(\mathfrak{g}^{\mathcal{D}})^*$ (whose fiber over the point q is the dual of the vector space $\mathfrak{g}^q$) that is defined by

$$\langle J^{\mathrm{nh}}(v_q), \xi\rangle = \frac{\partial L}{\partial \dot{q}^i}(\xi_Q)^i, \tag{2.5}$$

where $\xi \in \mathfrak{g}^q$.

As examples such as the snakeboard show, in general the tangent space to the group orbit through q intersects the constraint distribution at q nontrivially.

Notice that the nonholonomic momentum map may be viewed as giving just some of the components of the ordinary momentum map, namely along those symmetry directions that are consistent with the constraints.

It is proven in Bloch, Krishnaprasad, Marsden, and Murray [1996] that if the Lagrangian L is invariant under the group action and that if ξ^q is a section of the bundle $\mathfrak{g}^{\mathcal{D}}$, then any solution $q(t)$ of the Lagrange–d'Alembert equations for a nonholonomic system must satisfy, in addition to the given kinematic constraints, the momentum equation

$$\frac{d}{dt}\left(J^{\mathrm{nh}}(\xi^{q(t)})\right) = \frac{\partial L}{\partial \dot{q}^i}\left[\frac{d}{dt}(\xi^{q(t)})\right]_Q^i. \tag{2.6}$$

When the momentum map is paired with a section in this way, we will just refer to it as the momentum. Examples show that the nonholonomic momentum map may or may not be conserved.

The momentum equation in an orthogonal body frame. Let a local trivialization (r, g) be chosen on the principal bundle $\pi : Q \to Q/G$. Let $\eta \in \mathfrak{g}^q$ and $\xi = g^{-1}\dot{g}$. Since L is G invariant, we can define a new function l by writing $L(r, g, \dot{r}, \dot{g}) = l(r, \dot{r}, \xi)$. Define $J^{\mathrm{nh}}_{\mathrm{loc}} : TQ/G \to (\mathfrak{g}^{\mathcal{D}})^*$ by

$$\left\langle J^{\mathrm{nh}}_{\mathrm{loc}}(r, \dot{r}, \xi), \eta \right\rangle = \left\langle \frac{\partial l}{\partial \xi}, \eta \right\rangle.$$

As with connections, J^{nh} and its version in a local trivialization are related by the Ad map; i.e., $J^{\mathrm{nh}}(r, g, \dot{r}, \dot{g}) = \mathrm{Ad}^*_{g^{-1}} J^{\mathrm{nh}}_{\mathrm{loc}}(r, \dot{r}, \xi)$.

Choose a q-dependent basis $e_a(q)$ for the Lie algebra such that the first m elements span the subspace $\mathfrak{g}^q$. We require the basis to be such that the infinitesimal generators of the first m basis elements are orthogonal in the kinetic energy metric to the generators of the last $k - m$ basis elements. In a local trivialization, one chooses, for each r, such a basis at the identity element, and we denote it by

$$e_1(r), e_2(r), \ldots, e_m(r), e_{m+1}(r), \ldots, e_k(r).$$

Define the orthogonal body frame by

$$e_a(r, g) = \mathrm{Ad}_g \cdot e_a(r);$$

thus, by G invariance, the first m elements span the subspace $\mathfrak{g}^q$. In this basis, we have

$$\left\langle J^{\mathrm{nh}}(r, g, \dot{r}, \dot{g}), e_b(r, g) \right\rangle = \left\langle \frac{\partial l}{\partial \xi}, e_b(r) \right\rangle := p_b, \tag{2.7}$$

which defines p_b, a function of r, $\dot{r}$, and ξ. It is proven in Bloch, Krishnaprasad, Marsden, and Murray [1995] that in such an orthogonal body frame, the momentum equation can be written in the following form:

$$\dot{p} = \dot{r}^T H(r)\dot{r} + \dot{r}^T K(r)p + p^T D(r)p. \tag{2.8}$$

Note that in this body representation, the functions p_b are *invariant* rather than equivariant, as is usually the case with the momentum map, and the momentum equation is independent of, that is, decouples from, the group variables g.

The nonholonomic connection. Recall that in the case of holonomic mechanical systems, the mechanical connection $\mathcal{A}$ is defined by $\mathcal{A}(v_q) = \mathbb{I}(q)^{-1}J(v_q)$ or equivalently by the fact that its horizontal space at q is orthogonal to the group orbit at q. For the case of a simple nonholonomic mechanical system where the Lagrangian is of the form kinetic minus potential energy and G acts on Q by isometries and leaves $\mathcal{D}$ invariant, the result turns out to be quite similar.

As Bloch, Krishnaprasad, Marsden, and Murray [1996] point out, in the principal case where the constraints and the orbit directions span the entire tangent space to the configuration space (that is, $\mathcal{D}_q + T_q(\mathrm{Orb}(q)) = T_qQ$), the nonholonomic connection $\mathcal{A}^{\mathrm{nh}}$ is a principal connection on the bundle $Q \to Q/G$ whose horizontal space at the point $q \in Q$ is given by the orthogonal complement to the space $\mathcal{S}_q$ within the space $\mathcal{D}_q$. Moreover, Bloch, Krishnaprasad, Marsden, and Murray [1996] develop formulas for $\mathcal{A}^{\mathrm{nh}}$ similar to those for the mechanical connection; namely,

$$\mathcal{A}^{\mathrm{nh}}(v_q) = \mathbb{I}^{\mathrm{nh}}(q)^{-1}J^{\mathrm{nh}}(v_q), \tag{2.9}$$

where $\mathbb{I}^{\mathrm{nh}} : \mathfrak{g}^{\mathcal{D}} \to (\mathfrak{g}^{\mathcal{D}})^*$ is the locked inertia tensor defined in a way similar to that given above for holonomic systems. In an orthogonal body frame, (2.9) can be written as

$$\mathrm{Ad}_g(g^{-1}\dot{g} + \mathcal{A}^{\mathrm{nh}}_{\mathrm{loc}}(r)\dot{r}) = \mathrm{Ad}_g(\mathbb{I}^{\mathrm{nh}}_{\mathrm{loc}}(r)^{-1}p), \tag{2.10}$$

where $\mathcal{A}^{\mathrm{nh}}_{\mathrm{loc}}$ and $\mathbb{I}^{\mathrm{nh}}_{\mathrm{loc}}$ are the representations of $\mathcal{A}^{\mathrm{nh}}$ and $\mathbb{I}^{\mathrm{nh}}$ in a local trivialization. For simplicity in what follows, we shall omit the subscript "loc."

Control systems in momentum equation form. With the help of the momentum equations and the nonholonomic mechanical connection, Bloch, Krishnaprasad, Marsden, and Murray [1996] provide a framework for studying the general form of nonholonomic mechanical control systems with symmetry that may have a nontrivial evolution of their nonholonomic momentum. The dynamics of such a system can be described by a system of equations of the form of a reconstruction equation for a group element g, an equation for the nonholonomic momentum p (no longer conserved in the general case), and the equations of motion for the reduced variables r which describe the "shape" of the system. In terms of these variables, the equations of motion have the functional form

$$\begin{cases} g^{-1}\dot{g} = -\mathcal{A}^{\mathrm{nh}}(r)\dot{r} + \Gamma(r)p, \\ \dot{p} = \dot{r}^T H(r)\dot{r} + \dot{r}^T K(r)p + p^T D(r)p, \\ M(r)\ddot{r} = \delta(r,\dot{r},p) + \tau, \end{cases} \tag{2.11}$$

where $(\Gamma(r) = \mathbb{I}^{\mathrm{nh}}(r)^{-1})$.

The first equation describes the motion in the group variables as the flow of a left invariant vector field determined by the internal shape r, its velocity $\dot{r}$, as well as the generalized momentum p. The term $g^{-1}\dot{g} + \mathcal{A}^{\mathrm{nh}}(r)\dot{r} = \Gamma(r)^{-1}p$ is interpreted as the local representation of the body angular velocity. This is nothing more than the vertical part of the bundle velocity. The momentum equation describes the evolution of p and is bilinear in $(\dot{r}, p)$. Finally, the bottom (second-order) equation for $\ddot{r}$ describes the motion of the variables which describe the configuration up to a symmetry (i.e., the shape). The variable τ represents the external forces applied to the system, which we assume here only affect the shape variables; i.e., the external forces are G invariant. Note that the evolution of the momentum p and the shape r decouple from the group variables.

The optimal control problem for nonholonomic systems on a trivial bundle. Assume that we have a simple nonholonomic mechanical system with symmetry; thus, assume we have data $(Q, \mathcal{D}, \langle\langle\, , \rangle\rangle, G, L)$, where the Lagrangian L is G invariant and of the form kinetic minus potential energy, the distribution $\mathcal{D}$ is G invariant, and we are in the principal case where the constraints and the orbit directions span the tangent space to the configuration space. Let us also assume in this section that the principal bundle $\pi : Q \to Q/G$ is trivial; all the examples we consider (including the snakeboard) have a trivial principal bundle structure. We consider this simplification as a first step to the general case because in a local trivialization any principal bundle is a trivial bundle $(B \times G, B, \pi, G)$. Furthermore, we will assume the following.

(1) Any control forces applied to the system affect only the shape variables, which leaves the generalized momenta and the momentum equation unchanged. Indeed, such forces would be invariant under the action of the Lie group G and so would be annihilated by the variations taken to derive the momentum equation.
(2) We have full control of the shape variables; that is, the curve $r(t)$ in the shape space B can be specified arbitrarily using a suitable control force τ.

Given a cost function C which is a positive definite quadratic function of $\dot{r}(t)$ (so can be written as the square of a metric on the shape space B), we can formulate an optimal control problem on $Q = B \times G$ as follows.

OPTIMAL CONTROL PROBLEM FOR NONHOLONOMIC SYSTEMS. *Given two points $q_0, q_1 \in Q$, find the curves $r(t) \in B$ which steer the system from q_0 to q_1 and which minimize the total cost $\int_0^1 C(\dot{r})dt$, where $r = \pi(q)$, subject to the constraints $g^{-1}\dot{g} = -\mathcal{A}^{\rm nh}(r)\dot{r} + \Gamma(r)p$ and to the momentum equation $\dot{p} = \dot{r}^T H(r)\dot{r} + \dot{r}^T K(r)p + p^T D(r)p$.*

This optimal control problem is clearly equivalent to the following constrained variational problem.

CONSTRAINED VARIATIONAL PROBLEM FOR NONHOLONOMIC SYSTEMS. *Among all curves $q(t)$ with $q(0) = q_0, q(1) = q_1$ and satisfying $g^{-1}\dot{g} = -\mathcal{A}^{\rm nh}(r)\dot{r} + \Gamma(r)p$, where $\dot{p} = \dot{r}^T H(r)\dot{r} + \dot{r}^T K(r)p + p^T D(r)p$, find the curves $q(t)$ such that $\int_0^1 C(\dot{r})dt$ is minimized, where $r = \pi(q)$.*

Now we are ready to use the method of Lagrange multipliers and Lagrangian reduction to find necessary conditions for optimal trajectories.

3. Optimal control and Lagrangian reduction for holonomic systems.

In this section we consider reduced Lagrangian optimization in the context of holonomic systems.

3.1. A review of Lagrangian reduction.

We first recall some facts about Lagrangian reduction theory for systems with holonomic constraints (see Marsden and Scheurle [1993a, 1993b]).

Rigid body reduction. Let $R \in \mathrm{SO}(3)$ denote the time-dependent rotation that gives the current configuration of a rigid body. The body angular velocity Ω is defined in terms of R by

$$R^{-1}\dot{R} = \hat{\Omega},$$

where $\hat{\Omega}$ is the three-by-three skew matrix defined by $\hat{\Omega}v := \Omega \times v$. Denoting by I the (time-independent) moment of inertia tensor, the Lagrangian thought of as a function of R and $\dot{R}$ is given by $L(R, \dot{R}) = \frac{1}{2}\langle I\Omega, \Omega\rangle$, and when we think of it as a function of Ω alone, we write $l(\Omega) = \frac{1}{2}\langle I\Omega, \Omega\rangle$.

The following statements are equivalent.

(1) $(R, \dot{R})$ satisfies the Euler–Lagrange equations on SO(3) for L.
(2) Hamilton's principle on SO(3) holds:

$$\delta \int L\, dt = 0.$$

(3) Ω satisfies the Euler equations

$$I\dot{\Omega} = I\Omega \times \Omega.$$

(4) The reduced variational principle holds on $\mathbb{R}^3$:

$$\delta \int l\, dt = 0,$$

where variations in Ω are restricted to be of the form $\delta\Omega = \dot{\eta} + \eta \times \Omega$, with η an arbitrary curve in $\mathbb{R}^3$ satisfying $\eta = 0$ at the temporal endpoints.

An important point is that when one reduces the standard variational principle from SO(3) to its Lie algebra $\mathfrak{so}(3)$, one ends up with a variational principle in which the *variations are constrained*; that is, one has a principle of Lagrange–d'Alembert type. In this case, the term η represents the infinitesimal displacement of particles in the rigid body. Note that the same phenomenon of constrained variations occurs in the case of nonholonomic systems.

The Euler–Poincaré equations. Let $\mathfrak{g}$ be a Lie algebra and let $l : \mathfrak{g} \to \mathbb{R}$ be a given Lagrangian. Then the Euler–Poincaré equations are

$$\frac{d}{dt}\frac{\partial l}{\partial \xi} = \mathrm{ad}^*_\xi \frac{\partial l}{\partial \xi}$$

or, in coordinates,

$$\frac{d}{dt}\frac{\partial l}{\partial \xi^a} = C^b_{da}\xi^d \frac{\partial l}{\partial \xi^b},$$

where the structure constants are defined by $[\xi, \eta]^a = C^a_{de}\xi^d\eta^e$. If G is a Lie group with Lie algebra $\mathfrak{g}$, we let $L : TG \to \mathbb{R}$ be the left invariant extension of l and let $\xi = g^{-1}\dot{g}$. In the case of the rigid body, ξ is $\hat{\Omega}$, where Ω is the body angular velocity.

The basic fact regarding the Lagrangian reduction leading to these equations is as follows.

THEOREM 3.1 (Euler–Poincaré reduction). *A curve $(g(t), \dot{g}(t)) \in TG$ satisfies the Euler–Lagrange equations for L if and only if ξ satisfies the Euler–Poincaré equations for l.*

In this situation, the reduction is implemented by the map $(g, \dot{g}) \in TG \mapsto g^{-1}\dot{g} =: \xi \in \mathfrak{g}$.

One proof of this theorem is of special interest, as it shows how to drop variational principles to the quotient (see Marsden and Scheurle [1993b] and Bloch, Krishnaprasad, Marsden, and Ratiu [1996] for more details). Namely, we transform

$$\delta \int L\, dt = 0$$

under the map $(g, \dot{g}) \mapsto g^{-1}\dot{g}$ to give the reduced variational principle for the Euler–Poincaré equations: ξ satisfies the Euler–Poincaré equations if and only if

$$\delta \int l\, dt = 0,$$

where the variations are all those of the form

$$\delta\xi = \dot{\eta} + [\xi, \eta]$$

and where η is an arbitrary curve in the Lie algebra satisfying $\eta = 0$ at the endpoints. Variations of this form are obtained by calculating what variations are induced by variations on the Lie group itself.

One obtains the Lie–Poisson equations on $\mathfrak{g}^*$ by the Legendre transformation:

$$\mu = \frac{\partial l}{\partial \xi}, \quad h(\mu) = \mu \cdot \xi - l(\xi).$$

Dropping the variational principle this way is the analogue of Lie–Poisson reduction in which one drops the Poisson bracket from T^*G to the Lie–Poisson bracket on $\mathfrak{g}^*$.

The reduced Euler–Lagrange equations. The Euler–Poincaré equations can be generalized to the situation in which G acts freely on a configuration space Q to obtain the *reduced Euler–Lagrange equations*. This process starts with a G-invariant Lagrangian $L : TQ \to \mathbb{R}$, which induces a reduced Lagrangian $l : TQ/G \to \mathbb{R}$. The Euler–Lagrange equations for L induce the reduced Euler–Lagrange equations on TQ/G. To compute them in coordinates, it is useful to introduce a principal connection on the bundle $Q \to Q/G$. Although any can be picked, a common choice is the mechanical connection.

Thus, assume that the bundle $Q \to Q/G$ has a given (principal) connection $\mathcal{A}$. Divide variations into horizontal and vertical parts—this breaks up the Euler–Lagrange equations on Q into two sets of equations that we now describe. Let r^α be coordinates on shape space Q/G and Ω^a be coordinates for vertical vectors in a local bundle chart. Drop L to TQ/G to obtain a reduced Lagrangian $l : TQ/G \to \mathbb{R}$ in which the group coordinates are eliminated. We can represent this reduced Lagrangian in a couple of ways. First, if we choose a local trivialization as we have described earlier, we obtain l as a function of the variables $(r^\alpha, \dot{r}^\alpha, \xi^a)$. However, it will also be convenient to change variables from ξ^a to the local version of the locked angular velocity, i.e., the body angular velocity, namely $\Omega = \xi + \mathcal{A}_{\text{loc}}\dot{r}$, or in coordinates,

$$\Omega^a = \xi^a + \mathcal{A}^a_\alpha(r)\dot{r}^\alpha.$$

We will write $l(r^\alpha, \dot{r}^\alpha, \Omega^a)$ for the local representation of l in these variables.

THEOREM 3.2 (Lagrangian reduction theorem). *A curve $(q^i, \dot{q}^i) \in TQ$ satisfies the Euler–Lagrange equations if and only if the induced curve in TQ/G with coordinates given in a local trivialization by $(r^\alpha, \dot{r}^\alpha, \Omega^a)$ satisfies the reduced* Euler–Lagrange equations:

$$\frac{d}{dt}\frac{\partial l}{\partial \dot{r}^\alpha} - \frac{\partial l}{\partial r^\alpha} = \frac{\partial l}{\partial \Omega^a}\left(-\mathcal{B}^a_{\alpha\beta}\dot{r}^\beta + \mathcal{E}^a_{\alpha d}\Omega^d\right), \tag{3.1}$$

$$\frac{d}{dt}\frac{\partial l}{\partial \Omega^b} = \frac{\partial l}{\partial \Omega^a}(-\mathcal{E}^a_{\alpha b}\dot{r}^\alpha + C^a_{db}\Omega^d), \tag{3.2}$$

where

$$\mathcal{B}^b_{\alpha\beta} = \frac{\partial \mathcal{A}^b_\alpha}{\partial r^\beta} - \frac{\partial \mathcal{A}^b_\beta}{\partial r^\alpha} - C^b_{ac}\mathcal{A}^a_\beta\mathcal{A}^c_\alpha$$

are the coordinates of the curvature $\mathcal{B}$ of $\mathcal{A}$ and $\mathcal{E}^a_{\alpha d} = C^a_{bd}\mathcal{A}^b_\alpha$.

The first of these equations is similar to the Lagrange–d'Alembert equations for a nonholonomic system written in terms of the constrained Lagrangian, and the second is similar to the momentum equation. It is useful to note that the first set of equations results from Hamilton's principle by restricting the variations to be horizontal relative to the given connection.

If one uses the variables $(r^\alpha, \dot{r}^\alpha, p_a)$, where p is the body angular momentum, so that $p = \mathbb{I}_{\text{loc}}(r)\Omega = \partial l/\partial\Omega$, then the equations become (using the same letter l for the reduced Lagrangian, an admitted abuse of notation)

$$\frac{d}{dt}\frac{\partial l}{\partial \dot{r}^\alpha} - \frac{\partial l}{\partial r^\alpha} = p_a\left(-\mathcal{B}^a_{\alpha\beta}\dot{r}^\beta + \mathcal{E}^a_{\alpha d}I^{de}p_e\right) - p_d\frac{\partial I^{de}}{\partial r^\alpha}p_e, \tag{3.3}$$

$$\frac{d}{dt}p_b = p_a(-\mathcal{E}^a_{\alpha b}\dot{r}^\alpha + C^a_{db}I^{de}p_e), \tag{3.4}$$

where I^{de} denotes the inverse of the matrix I_{ab}.

Connections are also useful in control problems with feedback. For example, Bloch, Krishnaprasad, Marsden, and Sánchez de Alvarez [1992] found a feedback control that stabilizes rigid body dynamics about its middle axis using an internal rotor. This feedback controlled system can be described in terms of connections (Marsden and Sánchez de Alvarez [1996]); a shift in velocity (change of connection) turns the free Euler–Poincaré equations into the feedback-controlled Euler–Poincaré equations.

3.2. Reduced Lagrangian optimization for holonomic systems. Let us assume for the moment that we are dealing with a holonomic system on a trivial bundle and that the momentum map vanishes. Since we would like to use the method of Lagrange multipliers to relax the constraints, we define a new Lagrangian by $\mathcal{L}$:

$$\mathcal{L} = C(\dot{r}) + \langle\lambda(t), \xi + \mathcal{A}_{\text{loc}}(r)\dot{r}\rangle \tag{3.5}$$

for some $\lambda(t) \in \mathfrak{g}^*$, where $\xi = g^{-1}\dot{g} \in \mathfrak{g}$. Clearly $\mathcal{L}$ is G invariant and induces a function l on $(TQ/G) \times \mathfrak{g}^*$, where

$$l = C(\dot{r}) + \langle\lambda(t), \xi + \mathcal{A}_{\text{loc}}(r)\dot{r}\rangle \tag{3.6}$$

THEOREM 3.3 (reduced Lagrangian optimization for holonomic systems). *Assume that $q(t) = (r(t), g(t))$ is a (regular) optimal trajectory for the above optimal control problem; then there exists a $\lambda(t) \in \mathfrak{g}^*$ such that the reduced curve $(r(t), \dot{r}(t), \xi(t)) \in TQ/G$ with coordinates given by $(r^\alpha, \dot{r}^\alpha, \xi^a)$ satisfies the constraints $\xi = -\mathcal{A}_{\text{loc}}(r)\dot{r}$, as well as the reduced Euler–Lagrange equations*

$$\frac{d}{dt}\frac{\partial l}{\partial \dot{r}^\alpha} - \frac{\partial l}{\partial r^\alpha} = 0, \tag{3.7}$$

$$\frac{d}{dt}\frac{\partial l}{\partial \xi^b} = \frac{\partial l}{\partial \xi^a}C^a_{db}\xi^d, \tag{3.8}$$

where $l = C(\dot{r}) + \langle\lambda(t), \xi + \mathcal{A}_{\text{loc}}(r)\dot{r}\rangle$.

Proof. If $(r(t), g(t))$ is a (regular) optimal trajectory, then by the method of Lagrange multipliers, it solves the following variational problem:

$$\delta\int_0^1 \mathcal{L}dt = \delta\int_0^1 (C(\dot{r}) + \langle\lambda(t), \xi + \mathcal{A}_{\text{loc}}(r)\dot{r}\rangle)dt = 0$$

for some $\lambda(t) \in \mathfrak{g}^*$.

Since $B\times G \to B$ is trivial, we can put a trivial connection on this bundle and use it to split the variations into the horizontal and vertical parts. Then by the Lagrangian reduction method recalled above, the reduced curve $(r(t), \dot{r}(t), \xi(t)) \in TQ/G$ with coordinates given by $(r^\alpha, \dot{r}^\alpha, \xi^a)$ satisfies the reduced Euler–Lagrange equations stated above. (When using a trivial connection, the coefficients of $\mathcal{A}$ and $\mathcal{B}$ vanish and the reduced Euler–Lagrange equations are called Hamel's equations). □

Now we are ready to generalize one of the results in Krishnaprasad, Yang, and Dayawansa [1991]. Define the components $\mathcal{A}^a_\alpha$ of the mechanical connection by $\mathcal{A}_{\rm loc}(r)\dot{r} = \mathcal{A}^a_\alpha \dot{r}^\alpha e_a$, where $\{e_a\}$ is the basis of $\mathfrak{g}$ and $\{e^a\}$ is its dual basis. Here α runs from 1 to $n-k$ and a runs from 1 to k, where $n-k$ is the dimension of the base space B and k is the dimension of the Lie algebra $\mathfrak{g}$. The result deals with the following problem.

ISOHOLONOMIC PROBLEM FOR TRIVIAL BUNDLES. *Minimize* $\int_0^1 C(\dot{r})\,dt$, *subject to* $\dot{r} = u, \dot{g} = -g\mathcal{A}_{\rm loc}u = -g\mathcal{A}^a_\alpha(r)u^\alpha e_a$, *for given boundary conditions*

$$(r(0), g(0)) = (\mathbf{0}, g_0), \qquad (r(1), g(1)) = (\mathbf{0}, g_1).$$

COROLLARY 3.4. *Let the cost function C be quadratic in u, say,*

$$C = \sum_1^{n-k} c_\alpha (u^\alpha)^2.$$

If $(r(t), g(t))$ is a (regular) optimal trajectory with the control $\bar{u}(t)$ for the isoholonomic problem, then there exist $\rho(t) \in T^*B$ and $\lambda(t) \in \mathfrak{g}^*$ satisfying $\dot{r}^\alpha = \bar{u}^\alpha$, $\xi^a = -\mathcal{A}^a_\alpha(x)\bar{u}^\alpha$, and the following ordinary differential equations:

$$\dot{\rho}_\beta = \lambda_a \frac{\partial \mathcal{A}^a_\alpha}{\partial r^\beta}\bar{u}^\alpha,$$
$$\dot{\lambda}_b = -C^a_{db}\lambda_a \mathcal{A}^d_\alpha \bar{u}^\alpha,$$

where

$$\bar{u}_\beta = \frac{1}{2c_\beta}(\rho_\beta - \lambda_a \mathcal{A}^a_\beta)$$

with boundary conditions $r(0) = \mathbf{0}, g(0) = g_0, r(1) = \mathbf{0}, g(1) = g_1$.

Proof. According to Theorem 3.3, there exists some $\lambda(t) \in \mathfrak{g}^*$ such that the reduced curve $(r(t), \dot{r}(t), \xi(t))$ satisfies the reduced Euler–Lagrange equations for

$$l = c_\alpha(\dot{r}^\alpha)^2 + \langle \lambda_a e^a, (\xi^a + \mathcal{A}^a_\alpha \dot{r}^\alpha)e_a\rangle = c_\alpha(\dot{r}^\alpha)^2 + \lambda_a(\xi^a + \mathcal{A}^a_\alpha \dot{r}^\alpha).$$

After some computations, we find

$$\frac{\partial l}{\partial \dot{r}^\beta} = 2c_\beta \dot{r}^\beta + \lambda_a \mathcal{A}^a_\beta,$$
$$\frac{\partial l}{\partial r^\beta} = \lambda_a \frac{\partial \mathcal{A}^a_\alpha}{\partial r^\beta}\dot{r}^\alpha,$$
$$\frac{\partial l}{\partial \xi^b} = \lambda_b.$$

Now let

$$\rho_\beta = \frac{\partial l}{\partial \dot{r}^\beta} = 2c_\beta \dot{r}^\beta + \lambda_a \mathcal{A}^a_\beta$$

and solve for $\dot{r}$ to give

$$\dot{r}_\beta = \frac{1}{2c_\beta}(\rho_\beta - \lambda_a \mathcal{A}^a_\beta).$$

Moreover, the reduced Euler–Lagrange equations (3.7) and (3.8) give

$$\dot{\rho}_\beta = \frac{d}{dt}\frac{\partial l}{\partial \dot{r}^\beta} = \frac{\partial l}{\partial r^\beta} = \lambda_a \frac{\partial \mathcal{A}^a_\alpha}{\partial r^\beta}\dot{r}^\alpha,$$
$$\dot{\lambda}_b = \frac{d}{dt}\frac{\partial l}{\partial \xi^b} = \frac{\partial l}{\partial \xi^a} C^a_{db}\xi^d = C^a_{db}\lambda_a \xi^d.$$

After substituting

$$\dot{r}^\alpha = \bar{u}^\alpha \qquad \xi^d = -\mathcal{A}^d_\alpha \bar{u}^\alpha,$$

we get the desired equations. □

Remarks.

(1) This corollary generalizes the result of Krishnaprasad, Yang, and Dayawansa [1991] for the trivial principal bundle $(\mathbb{R}\times\mathbb{R}\times \mathrm{SO}(3), \mathbb{R}\times\mathbb{R}, \pi, \mathrm{SO}(3))$ (see Theorem 3.3 and Remark 3.2 in Krishnaprasad, Yang, and Dayawansa [1991]).

(2) The reduced equations of motion for ρ_β and λ_b can be written in intrinsic form as a special case of Wong's equations in r_β and λ_b (see the following subsection).

3.3. Optimal control of a holonomic system on a principal bundle. While the above method seems to work only for the case where the principle bundle is trivial, it can be easily generalized to an arbitrary principle bundle. In fact, the proof of the Lagrangian reduction theorem stated above provides all the necessary techniques. Recall that Marsden and Scheurle [1993b] arrived at the general reduced Euler–Lagrange equations in two steps:

(1) One first gets the Hamel equations in a local bundle trivialization:

$$\frac{d}{dt}\frac{\partial l}{\partial \dot{r}^\alpha} - \frac{\partial l}{\partial r^\alpha} = 0,$$

$$\frac{d}{dt}\frac{\partial l}{\partial \xi^b} = \frac{\partial l}{\partial \xi^a} C^a_{db}\xi^d.$$

(2) One introduces an arbitrary principal connection $\mathcal{A}$ (which is not necessarily the mechanical connection) to split the original variational principle intrinsically and globally relative to horizontal and vertical parts of the variation δq and derived the general form from the above form by means of a velocity shift replacing ξ by the vertical part relative to this connection:

$$\Omega^a = \mathcal{A}^a_\alpha \dot{r}^\alpha + \xi^a.$$

Here $\mathcal{A}^a_\alpha$ are the local coordinates of the connection $\mathcal{A}$. The resulting reduced Euler–Lagrange equations are then as given earlier.

Now we are ready to state a general theorem for the constrained variational problem on a principal bundle. This problem is as follows.

ISOHOLONOMIC PROBLEM FOR GENERAL BUNDLES (THE FALLING CAT PROBLEM). *Among all curves $q(t)$ such that $q(0) = q_0, q(1) = q_1$, and $\dot{q}(t) \in \mathrm{hor}_{q(t)}$*

(*horizontal with respect to the mechanical connection* $\mathcal{A}^{\text{mec}}$), *find the optimal curves* $q(t)$ *such that* $\int_0^1 C(\dot{r})dt$ *is minimized, where* $r = \pi(q)$.

Observe that although this problem is set up using the mechanical connection $\mathcal{A}^{\text{mec}}$, when applying the Lagrangian reduction theorem, one may use an arbitrary connection $\mathcal{A}$ to split the variational principle. This observation is used in the proof of the following result.

THEOREM 3.5. *If* $q(t)$ *is a* (*regular*) *optimal trajectory for the isoholonomic problem for general bundles, then there exists a* $\lambda(t) \in \mathfrak{g}^*$ *such that the reduced curve in* TQ/G *with coordinates given in a local trivialization by* $(r^\alpha, \dot{r}^\alpha, \Omega^\alpha)$ *satisfies the constraints* $\xi^a = -(\mathcal{A}^{\text{mec}})^a_\alpha \dot{r}^\alpha$ *as well as the reduced Euler–Lagrange equations* (3.1) *and* (3.2), *where*

$$l = C(\dot{r}) + \langle \lambda(t), \xi + \mathcal{A}_{\text{loc}}(r)\dot{r} \rangle$$

and

$$\Omega^a = \mathcal{A}^a_\alpha \dot{r}^\alpha + \xi^a.$$

Proof. The proof proceeds as in the proof in Marsden and Scheurle [1993b] in the present context. The needed modifications of what we have done before are minor and so are omitted. □

COROLLARY 3.6. *In Theorem* 3.5, *if we use the mechanical connection* $\mathcal{A}^{\text{mec}}$ *to split the variational principle, then the reduced Euler–Lagrange equations coincide with Wong's equations* (*see Montgomery* [1984, 1993] *and references therein*):

$$\begin{aligned} \dot{p}_\alpha &= -\lambda_a \mathcal{B}^a_{\alpha\beta} \dot{r}^\beta - \frac{1}{2} \frac{\partial g^{\beta\gamma}}{\partial r^\alpha} p_\beta p_\gamma, \\ \dot{\lambda}_b &= -\lambda_a C^a_{db} \mathcal{A}^d_\alpha \dot{r}^\alpha, \end{aligned}$$

where $g_{\alpha\beta}$ *is the local representation of the metric on the base space* Q/G, *that is,*

$$C(\dot{r}) = \frac{1}{2} g_{\alpha\beta} \dot{r}^\alpha \dot{r}^\beta,$$

$g^{\beta\gamma}$ *is the inverse of the matrix* $g_{\alpha\beta}$, *and* p_α *is defined by*

$$p_\alpha = \frac{\partial C}{\partial \dot{r}^\alpha} = g_{\alpha\beta} \dot{r}^\beta,$$

and where we write the components of $\mathcal{A}^{\text{mec}}$ *simply as* $\mathcal{A}^b_\alpha$ *and similarly for its curvature.*

Proof. Apply Theorem 3.5 to the function l, where

$$\begin{aligned} l &= C(\dot{r}) + \langle \lambda(t), \xi + A_{\text{loc}}(r)\dot{r} \rangle \\ &= C(\dot{r}) + \langle \lambda(t), \Omega \rangle \\ &= C(\dot{r}^\alpha) + \lambda_a \Omega^a. \end{aligned}$$

Clearly,

$$\begin{aligned} \frac{\partial l}{\partial \dot{r}^\alpha} &= \frac{\partial C}{\partial \dot{r}^\alpha} = g_{\alpha\beta} \dot{r}^\beta, \\ \frac{\partial l}{\partial r^\alpha} &= \frac{\partial C}{\partial r^\alpha} = \frac{1}{2} \frac{\partial g^{\beta\gamma}}{\partial r^\alpha} \dot{r}^\beta \dot{r}^\gamma, \\ \frac{\partial l}{\partial \Omega^a} &= \lambda_a. \end{aligned}$$

Since $\xi^a = -\mathcal{A}^a_\alpha \dot{r}^\alpha$ (the constraints) and $\Omega^a = \mathcal{A}^a_\alpha \dot{r}^\alpha + \xi^a$, we have $\Omega^a = 0$, and the reduced Euler–Lagrange equations become

$$\begin{aligned}\frac{d}{dt}\frac{\partial C}{\partial \dot{r}^\alpha} - \frac{\partial C}{\partial r^\alpha} &= -\lambda_a(\mathcal{B}^a_{\alpha\beta}\dot{r}^\beta),\\ \frac{d}{dt}\lambda_b &= -\lambda_a(\mathcal{E}^a_{\alpha b}\dot{r}^\alpha) = -\lambda_a C^a_{db}\mathcal{A}^d_\alpha \dot{r}^\alpha.\end{aligned}$$

But

$$\begin{aligned}\frac{d}{dt}\frac{\partial C}{\partial \dot{r}^\alpha} - \frac{\partial C}{\partial r^\alpha} &= \dot{p}_\alpha - \frac{1}{2}\frac{\partial g_{\beta\gamma}}{\partial r^\alpha}\dot{r}^\beta \dot{r}^\gamma\\ &= \dot{p}_\alpha + \frac{1}{2}\frac{\partial g^{\kappa\sigma}}{\partial r^\alpha} g_{\kappa\beta} g_{\sigma\gamma}\dot{r}^\beta \dot{r}^\gamma\\ &= \dot{p}_\alpha + \frac{1}{2}\frac{\partial g^{\kappa\sigma}}{\partial r^\alpha} p_\kappa p_\sigma\\ &= \dot{p}_\alpha + \frac{1}{2}\frac{\partial g^{\beta\gamma}}{\partial r^\alpha} p_\beta p_\gamma,\end{aligned}$$

and so we have the desired equations. □

Remark. Recall that in Corollary 3.4, we have the reduced equations

$$\begin{aligned}\dot{\rho}_\beta &= \lambda_a \frac{\partial \mathcal{A}^a_\alpha}{\partial r^\beta}\dot{r}^\alpha,\\ \dot{\lambda}_b &= -C^a_{db}\lambda_a \mathcal{A}^d_\alpha \dot{r}^\alpha.\end{aligned}$$

But $\rho_\beta = \lambda_a \mathcal{A}^a_\alpha + 2c_\beta \dot{r}^\beta$ and hence

$$\dot{\rho}_\beta = 2c_\beta \ddot{r}^\beta + \dot{\lambda}_a \mathcal{A}^a_\beta + \lambda_a \frac{\partial \mathcal{A}^a_\beta}{\partial r^\alpha}\dot{r}^\alpha = \lambda_a \frac{\partial \mathcal{A}^a_\alpha}{\partial r^\beta}\dot{r}^\alpha.$$

Therefore,

$$\begin{aligned}2c_\beta \ddot{r}^\beta &= \lambda_a \frac{\partial \mathcal{A}^a_\alpha}{\partial r^\beta}\dot{r}^\alpha - \lambda_a \frac{\partial \mathcal{A}^a_\beta}{\partial r^\alpha}\dot{r}^\alpha - (-C^a_{db}\lambda_a \mathcal{A}^d_\alpha \dot{r}^\alpha)\mathcal{A}^b_\beta\\ &= \lambda_a\left(\frac{\partial \mathcal{A}^a_\alpha}{\partial r^\beta} - \frac{\partial \mathcal{A}^a_\beta}{\partial r^\alpha} - C^a_{bd}\mathcal{A}^d_\alpha \mathcal{A}^b_\beta\right)\dot{r}^\alpha\\ &= -\lambda_a \mathcal{B}^a_{\beta\alpha}\dot{r}^\alpha.\end{aligned}$$

That is, the reduced equations in Corollary 3.4 (and those in Krishnaprasad, Yang, and Dayawansa [1991]) can be written intrinsically as Wong's equations after a change of variables. This should not surprise us, because Marsden and Scheurle derived the general reduced Euler–Lagrange equations from the Hamel equations using a suitable change of variables from local trivialization variables to those in which the Lie algebra variable is replaced by the vertical part of the bundle velocity.

4. Optimal control and Lagrangian reduction for nonholonomic systems. Now we are ready to use the method of Lagrange multipliers and Lagrangian reduction to find the necessary conditions for optimal trajectories of nonholonomic systems in the case of a trivial bundle.

4.1. The general theorem for optimization. In Bloch, Krishnaprasad, Marsden, and Murray [1996], the reconstruction process may be seen in a two-step fashion: given an initial condition and a path $r(t)$ in the base space, we first integrate the momentum equation to determine $p(t)$ for all time and then use $r(t)$ and $p(t)$ jointly to determine the motion $g(t)$ in the fiber. But in studying the optimal control problem, it is better to treat p as a set of independent variables and the momentum equation as an additional set of constraints. With this viewpoint, it is possible to write down the reduced equations of motion for the optimal trajectories.

Since we would like to use the method of Lagrange multipliers to relax the constraints, we define a new Lagrangian $\mathcal{L}$:

$$\begin{aligned}\mathcal{L} = C(\dot{r}) &+ \langle \lambda(t), \xi + \mathcal{A}(r)\dot{r} - \Gamma(r)p \rangle \\ &+ \left\langle \kappa(t), \dot{p} - \dot{r}^T H(r)\dot{r} - \dot{r}^T K(r)p - p^T D(r)p \right\rangle\end{aligned} \tag{4.1}$$

for some $\lambda(t) \in \mathfrak{g}^*$ and for some $\kappa(t) \in \mathbb{R}^m$, where m is the number of momentum functions p_b. For simplicity of notation we have written $\mathcal{A}$ for $\mathcal{A}^{\text{nh}}$. Clearly $\mathcal{L}$ is G invariant and induces a function on $(T(Q \times \mathbb{R}^m)/G) \times \mathfrak{g}^* \times \mathbb{R}^m$ which is also denoted $\mathcal{L}$.

We formulate the main problem to be studied as follows.

ISOHOLONOMIC PROBLEM FOR NONHOLONOMIC SYSTEMS. *Among all curves $q(t)$ such that $q(0) = q_0, q(1) = q_1$, $\dot{q}(t) \in \mathcal{D}_{q(t)}$ and in which $g^{-1}\dot{g} + \mathcal{A}(r)\dot{r} = \Gamma(r)p$ and the momentum equation, find the optimal curves $q(t)$ such that $\int_0^1 C(\dot{r})dt$ is minimized, where $r = \pi(q)$.*

Before we state the theorem and do some computations, we want to make sure that the readers understand the index convention used in this section.

(1) The first batch of indices is denoted $a, b, c, ...$ and range from 1 to k corresponding to the symmetry direction ($k = \dim \mathfrak{g}$).
(2) The second batch of indices will be denoted $i, j, k, ...$ and range from 1 to m corresponding to the symmetry direction along constraint space (m is the number of momentum functions).
(3) The indices $\alpha, \beta, ...$ on the shape variables r range from 1 to $n - k$ ($n - k = \dim (Q/G)$, i.e., the dimension of the shape space).

THEOREM 4.1 (reduced Lagrangian optimization for nonholonomic systems). *If $q(t) = (r(t), g(t))$ is a (regular) optimal trajectory for the above optimal control problem, then there exist a $\lambda(t) \in \mathfrak{g}^*$ and a $\kappa(t) \in \mathbb{R}^m$ such that the reduced curve $(r(t), \dot{r}(t), \xi(t)) \in TQ/G$ with coordinates $(r^\alpha, \dot{r}^\alpha, \xi^\alpha)$ satisfies the reduced Euler–Lagrange equations*

$$\begin{aligned}\frac{d}{dt}\frac{\partial \mathcal{L}}{\partial \dot{r}^\beta} - \frac{\partial \mathcal{L}}{\partial r^\beta} &= 0, \\ \frac{d}{dt}\frac{\partial \mathcal{L}}{\partial \xi^b} &= \frac{\partial \mathcal{L}}{\partial \xi^a} C^a_{db}\xi^d, \\ \frac{d}{dt}\frac{\partial \mathcal{L}}{\partial \dot{p}_j} - \frac{\partial \mathcal{L}}{\partial p_j} &= 0,\end{aligned}$$

as well as

$$\begin{aligned}\xi &= -\mathcal{A}(r)\dot{r} + \Gamma(r)p, \\ \dot{p} &= \dot{r}^T H(r)\dot{r} + \dot{r}^T K(r)p + p^T D(r)p.\end{aligned}$$

Here C^a_{db} are the structure coefficients of the Lie algebra $\mathfrak{g}$ and

$$\mathcal{L} = C(\dot r) + \langle \lambda(t), \xi + \mathcal{A}(r)\dot r - \Gamma(r)p\rangle + \left\langle \kappa(t), \dot p - \dot r^T H(r)\dot r - \dot r^T K(r)p - p^T D(r)p\right\rangle. \tag{4.2}$$

Proof. If $(r(t), g(t))$ is a (regular) optimal trajectory, then by the method of Lagrange multipliers it solves the following variational problem:

$$\delta \int_0^1 \mathcal{L} dt = 0$$

for some $\lambda(t) \in \mathfrak{g}^*$ and some $\kappa(t) \in \mathbb{R}^m$. Since the bundle is trivial, we can put a flat connection on this bundle and use it to split the variations into horizontal and vertical parts. Then by the Lagrange reduction theorem, the reduced curve $(r(t), \dot r(t), \xi(t)) \in TQ/G$ satisfies the reduced Euler–Lagrange equations stated above. ∎

4.2. The optimality conditions in coordinates. Now let us work out everything in detail in bundle coordinates. Since

$$\mathcal{L} = \frac{1}{2} C_\alpha (\dot r^\alpha)^2 + \lambda_a(\xi^a + \mathcal{A}^a_\alpha \dot r^\alpha - \Gamma^{ai} p_i) + \kappa^i(\dot p_i - H_{\alpha\gamma i}\dot r^\alpha \dot r^\gamma - K^l_{i\alpha}\dot r^\alpha p_l - D^{lk}_i p_l p_k), \tag{4.3}$$

we find after some computations that

$$\frac{\partial \mathcal{L}}{\partial \dot r^\beta} = C_\beta \dot r^\beta + \lambda_a \mathcal{A}^a_\beta - \kappa^i(2H_{\alpha\beta i}\dot r^\alpha + K^l_{i\beta} p_l),$$
$$\frac{\partial \mathcal{L}}{\partial r^\beta} = \lambda_a \left(\frac{\partial \mathcal{A}^a_\alpha}{\partial r^\beta}\dot r^\alpha - \frac{\partial \Gamma^{ai}}{\partial r^\beta} p_i\right) - \kappa^i \left(\frac{\partial H_{\alpha\gamma i}}{\partial r^\beta}\dot r^\alpha \dot r^\gamma + \frac{\partial K^l_{i\alpha}}{\partial r^\beta}\dot r^\alpha p_l + \frac{\partial D^{lk}_i}{\partial r^\beta} p_l p_k\right).$$

Also, we have

$$\frac{\partial \mathcal{L}}{\partial \xi^b} = \lambda_b,$$
$$\frac{\partial \mathcal{L}}{\partial \dot p_j} = \kappa^j,$$
$$\frac{\partial \mathcal{L}}{\partial p_j} = -\lambda_a \Gamma^{aj} - \kappa^i(K^j_{i\alpha}\dot r^\alpha + 2D^{lj}_i p_l).$$

By Theorem 4.1, we know that the reduced curve $(r(t), \dot r(t), \xi(t))$ must satisfy the following system of differential equations for the given boundary conditions $q(0) = (r_0, g_0), q(1) = (r_1, g_1)$:

$$\frac{d}{dt}[C_\beta \dot r^\beta + \lambda_a \mathcal{A}^a_\beta - \kappa^i(2H_{\alpha\beta i}\dot r^\alpha + K^l_{i\beta} p_l)] = \lambda_a \left(\frac{\partial \mathcal{A}^a_\alpha}{\partial r^\beta}\dot r^\alpha - \frac{\partial \Gamma^{ai}}{\partial r^\beta} p_i\right) - \kappa^i \left(\frac{\partial H_{\alpha\gamma i}}{\partial r^\beta}\dot r^\alpha \dot r^\gamma + \frac{\partial K^l_{i\alpha}}{\partial r^\beta}\dot r^\alpha p_l + \frac{\partial D^{lk}_i}{\partial r^\beta} p_l p_k\right)$$

and

$$\dot\kappa^j = -\lambda_a \Gamma^{aj} - \kappa^i(K^j_{i\alpha}\dot r^\alpha + 2D^{lj}_i p_l),$$
$$\dot\lambda_b = C^a_{db}\lambda_a \xi^d = C^a_{db}\lambda_a(-\mathcal{A}^d_\alpha \dot r^\alpha + \Gamma^{di} p_i),$$
$$\dot p_i = H_{\alpha\gamma i}\dot r^\alpha \dot r^\gamma + K^l_{i\alpha}\dot r^\alpha p_l + D^{lk}_i p_l p_k.$$

Remarks.

(1) The first set of equations can be simplified somewhat as follows:

$$\begin{aligned}\frac{d}{dt}&\left[C_\beta \dot{r}^\beta - \kappa^i(2H_{\alpha\beta i}\dot{r}^\alpha + K^l_{i\beta}p_l)\right]\\ &= \lambda_a \mathcal{B}^a_{\beta\alpha}\dot{r}^\alpha - \lambda_a\left(\frac{\partial \Gamma^{ai}}{\partial r^\beta} + C^a_{db}\mathcal{A}^b_\beta \Gamma^{di}\right)p_i\\ &\qquad -\kappa^i\left(\frac{\partial H_{\alpha\gamma i}}{\partial r^\beta}\dot{r}^\alpha\dot{r}^\gamma + \frac{\partial K^l_{i\alpha}}{\partial r^\beta}\dot{r}^\alpha p_l + \frac{\partial D^{lk}_i}{\partial r^\beta}p_l p_k\right),\end{aligned}$$

where $\mathcal{B}^a_{\beta\alpha}$ are the coordinates of the curvature $\mathcal{B}$ of the nonholonomic connection $\mathcal{A}$, which is used to set up the constrained variational problem. Clearly more work is needed to establish a better form of the first set of equations as well as the geometry behind them. However, for the snakeboard, the reduced equations of motion for the optimal trajectories turn out to be rather simple.

(2) In proving the above theorem, although variations with fixed endpoints for $r(t)$ can be used, we generally can only hold the initial endpoint fixed for the variations of $p(t)$ and leave their final endpoints free (which is called "free endpoint problem" in the language of calculus of variations). However, we will obtain the same system of differential equations (namely the reduced Euler–Lagrange equations) except the need to impose some kind of transversality condition at $t = 1$; e.g., in this case we need to have $\kappa(1) = 0$.

In the following section, we will apply the method of reduced Lagrangian optimization developed in this section to some examples, especially the snakeboard.

5. Examples.

5.1. Optimal control of a homogeneous ball on a rotating plate. Bloch, Krishnaprasad, Marsden, and Murray [1995] also study a well-known example, namely the model of a homogeneous ball on a rotating plate, and write down its equations of motion in a form that is suitable for the application of control theory. (For more information, also see Naimark and Fufaev [1972] and Yang [1992] for the affine case and Bloch and Crouch [1992], Brockett and Dai [1992], and Jurdjevic [1993] for the linear case.)

Fix coordinates in inertial space and let the plane rotate with constant angular velocity Ω about the z-axis. The configuration space of the sphere is $Q = \mathbb{R}^2 \times \mathrm{SO}(3)$, parameterized by $(x, y, g), g \in \mathrm{SO}(3)$, all measured with respect to the inertial frame. Let $\omega = (\omega_x, \omega_y, \omega_z)$ be the angular velocity vector of the sphere measured also with respect to the inertial frame, let m be the mass of the sphere and mk^2 its inertia about any axis, and let a be its radius.

The Lagrangian of the system is

$$L = \frac{1}{2}m(\dot{x}^2 + \dot{y}^2) + \frac{1}{2}mk^2({\omega_x}^2 + {\omega_y}^2 + {\omega_z}^2),$$

with the affine nonholonomic constraints

$$\begin{aligned}\dot{x} - a\omega_y &= -\Omega y,\\ \dot{y} + a\omega_x &= +\Omega x.\end{aligned}$$

Note that the Lagrangian here is a metric on Q which is bi-invariant on $\mathrm{SO}(3)$ as the ball is homogeneous. Note also that $\mathbb{R}^2 \times \mathrm{SO}(3)$ is a principal bundle over $\mathbb{R}^2$ with

respect to the right SO(3) action on Q given by

$$(x, y, g) \mapsto (x, y, gh)$$

for $h \in \mathrm{SO}(3)$. The action is on the *right* since the symmetry is a material symmetry.

After some computations, it can be shown (for details, see Bloch, Krishnaprasad, Marsden, and Murray [1996]) that the equations of motion are

$$\begin{aligned} \omega_x + \frac{1}{a}\dot{y} &= \frac{\Omega x}{a}, \\ \omega_y - \frac{1}{a}\dot{x} &= \frac{\Omega y}{a}, \\ \omega_z &= c, \end{aligned}$$

(where c is a constant), together with

$$\begin{aligned} \ddot{x} + \frac{k^2\Omega}{a^2 + k^2}\dot{y} &= 0, \\ \ddot{y} - \frac{k^2\Omega}{a^2 + k^2}\dot{x} &= 0. \end{aligned}$$

Notice that the first set of three equations has the form

$$\dot{g}g^{-1} = -\mathcal{A}_{\mathrm{loc}}(r)\dot{r} + \Gamma_{\mathrm{loc}}(r),$$

where

$$\mathcal{A}_{\mathrm{loc}} = \frac{1}{a}e_1 dy - \frac{1}{a}e_2 dx$$

and

$$\Gamma_{\mathrm{loc}} = \frac{\Omega}{a}xe_1 + \frac{\Omega}{a}ye_2 + ce_3.$$

Here, $r^1 = x, r^2 = y$, and e_1, e_2, e_3 is the standard basis of $so(3)_-$. Also, $\mathcal{A}_{\mathrm{loc}}$ is the expression of nonholonomic connection relative to the (global) trivialization, and Γ_{loc} is the expression of the affine piece of the constraints with respect to the same trivialization (see Bloch, Krishnaprasad, Marsden, and Murray [1995]).

Now we are ready to apply reduced Lagrangian optimization to find the optimal trajectories for a homogeneous ball. Clearly the homogeneous ball on a rotating plate is a simple nonholonomic mechanical system with symmetry as defined earlier which also has a trivial principal bundle structure (except that the constraint is affine which can be dealt with in the same way). Also, we can assume that we have full control over the motion of the center of the ball, i.e., over the shape variables. Now let the cost function be $C(\dot{r}) = \frac{1}{2}[(\dot{x})^2 + (\dot{y}^2)]$ and set $a = 1$ for simplicity; then we can use the method of Lagrange multipliers and Lagrangian reduction to find the necessary conditions for the optimal trajectories of the following optimal control problem.

PLATE-BALL PROBLEM. *Given two points $q_0, q_1 \in \mathbb{R}^2 \times \mathrm{SO}(3)$, find the optimal control curves $(x(t), y(t)) \in \mathbb{R}^2$ that steer the system from q_0 to q_1 and minimize*

$$\int_0^1 \frac{1}{2}[(\dot{x})^2 + (\dot{y})^2]dt\,,$$

subject to the constraints

$$\dot{g}g^{-1} = -\dot{y}e_1 + \dot{x}e_2 + ce_3 + \Omega x e_1 + \Omega y e_2,$$

where, again, e_a is the standard basis of $so(3)_-$.

Following the reduced Lagrangian optimization method developed in the preceding section, we define a new Lagrangian $\mathcal{L}$ by

$$\mathcal{L} = \frac{1}{2}[(\dot{x})^2 + (\dot{y})^2] + \lambda_a \xi^a + \lambda_1 \dot{y} - \lambda_2 \dot{x} - \lambda_3 c - \Omega\lambda_1 x - \Omega\lambda_2 y,$$

where $\lambda(t) \in so(3)^*_-$. (Note that we use the negative Lie–Poisson structure because the right action is used.)

By Theorem 4.1, we know that any reduced optimal curve

$$(x(t), y(t), \dot{x}(t), \dot{y}(t), \xi^a(t))$$

must satisfy the reduced Euler–Lagrangian equations. Simple computations show that

$$\begin{aligned}
\frac{\partial \mathcal{L}}{\partial \dot{x}} &= \dot{x} - \lambda_2 = \rho_1, \\
\frac{\partial \mathcal{L}}{\partial x} &= -\Omega\lambda_1, \\
\frac{\partial \mathcal{L}}{\partial \dot{y}} &= \dot{y} + \lambda_1 = \rho_2, \\
\frac{\partial \mathcal{L}}{\partial y} &= -\Omega\lambda_2, \\
\frac{\partial \mathcal{L}}{\partial \xi^b} &= \lambda_b.
\end{aligned}$$

Therefore,

$$\begin{aligned}
\dot{\rho}_1 &= -\Omega\lambda_1, \\
\dot{\rho}_2 &= -\Omega\lambda_2,
\end{aligned}$$

and

$$\dot{\lambda}_b = C^a_{db}\lambda_a \xi^d;$$

that is,

$$\begin{aligned}
\dot{\lambda}_1 &= \lambda_3\xi^2 - \lambda_2\xi^3 = \lambda_3(\rho_1 + \lambda_2 + \Omega y) - c\lambda_2, \\
\dot{\lambda}_2 &= -\lambda_3\xi^1 + \lambda_1\xi^3 = \lambda_3(\rho_2 - \lambda_1 - \Omega x) + c\lambda_1, \\
\dot{\lambda}_3 &= \lambda_2\xi^1 - \lambda_1\xi^2 = -(\lambda_1\rho_1 + \lambda_2\rho_2) + \Omega(\lambda_2 x - \lambda_1 y).
\end{aligned}$$

In the special case where $c = 0$ (no drift) and $\Omega = 0$ (no rotation) studied in Jurdjevic [1993], we have

$$\begin{aligned}
\dot{\rho}_1 &= 0, \\
\dot{\rho}_2 &= 0, \\
\dot{\lambda}_1 &= \lambda_3(\rho_1 + \lambda_2), \\
\dot{\lambda}_2 &= \lambda_3(\rho_2 - \lambda_1), \\
\dot{\lambda}_3 &= -(\lambda_1\rho_1 + \lambda_2\rho_2),
\end{aligned}$$

which gives the same result as in Jurdjevic [1993] obtained through the application of the Pontryagin maximum principle.

5.2. Optimal control of the snakeboard. The snakeboard is a modified version of a skateboard in which the front and back pairs of wheels are independently actuated. The extra degree of freedom enables riders to generate forward motion by twisting their bodies back and forth, while simultaneously moving the wheels with the proper phase relationship. For details, see Bloch, Krishnaprasad, Marsden, and Murray [1996] and the references listed there. Here we will include the computations shown in that paper for completeness and to make concrete the nonholonomic theory.

The snakeboard is modeled as a rigid body (the board) with two sets of independently actuated wheels, one on each end of the board. The human rider is modeled as a momentum wheel which sits in the middle of the board and is allowed to spin about the vertical axis. Spinning the momentum wheel causes a counter torque to be exerted on the board. The configuration of the board is given by the position and orientation of the board in the plane, the angle of the momentum wheel, and the angles of the back and front wheels. Thus the configuration space is $Q = \mathrm{SE}(2) \times S^1 \times S^1 \times S^1$. Let (x, y, θ) represent the position and orientation of the center of the board, ψ the angle of the momentum wheel relative to the board, and ϕ_1 and ϕ_2 the angles of the back and front wheels, also relative to the board. Take the distance between the center of the board and the wheels to be r.

The Lagrangian for the snakeboard consists only of kinetic energy terms and can be written as

$$L(q, \dot{q}) = \frac{1}{2} m(\dot{x}^2 + \dot{y}^2) + \frac{1}{2} J\dot{\theta}^2 + \frac{1}{2} J_0(\dot{\theta} + \dot{\psi})^2 + \frac{1}{2} J_1(\dot{\theta} + \dot{\phi}_1)^2 + \frac{1}{2} J_2(\dot{\theta} + \dot{\phi}_2)^2,$$

where m is the total mass of the board, J is the inertia of the board, J_0 is the inertia of the rotor, and J_i, $i = 1, 2$, is the inertia corresponding to ϕ_i. The Lagrangian is independent of the configuration of the board and hence it is invariant to all possible group actions.

The rolling of the front and rear wheels of the snakeboard is modeled using nonholonomic constraints which allow the wheels to spin about the vertical axis and roll in the direction that they are pointing. The wheels are not allowed to slide in the sideways direction. This gives constraint one forms

$$\begin{aligned} \omega_1(q) &= -\sin(\theta + \phi_1)dx + \cos(\theta + \phi_1)dy - r\cos\phi_1 d\theta, \\ \omega_2(q) &= -\sin(\theta + \phi_2)dx + \cos(\theta + \phi_2)dy + r\cos\phi_2 d\theta. \end{aligned}$$

These constraints are invariant under the SE(2) action given by

$$(x, y, \theta, \psi, \phi_1, \phi_2) \mapsto (x\cos\alpha - y\sin\alpha + a, x\sin\alpha + y\cos\alpha + b, \theta + \alpha, \psi, \phi_1, \phi_2),$$

where $(a, b, \alpha) \in \mathrm{SE}(2)$. The constraints determine the kinematic distribution $\mathcal{D}_q$:

$$\mathcal{D}_q = \mathrm{span}\left\{ \frac{\partial}{\partial\psi}, \frac{\partial}{\partial\phi_1}, \frac{\partial}{\partial\phi_2}, a\frac{\partial}{\partial x} + b\frac{\partial}{\partial y} + c\frac{\partial}{\partial\theta} \right\},$$

where a, b, and c are given by

$$\begin{aligned} a &= -r(\cos\phi_1\cos(\theta + \phi_2) + \cos\phi_2\cos(\theta + \phi_1)), \\ b &= -r(\cos\phi_1\sin(\theta + \phi_2) + \cos\phi_2\sin(\theta + \phi_1)), \\ c &= \sin(\phi_1 - \phi_2). \end{aligned}$$

The tangent space to the orbits of the SE(2) action is given by

$$T_q(\mathrm{Orb}(q)) = \mathrm{span}\left\{\frac{\partial}{\partial x}, \frac{\partial}{\partial y}, \frac{\partial}{\partial \theta}\right\}.$$

The intersection between the tangent space to the group orbits and the constraint distribution is thus given by

$$\mathcal{D}_q \cap T_q(\mathrm{Orb}(q)) = a\frac{\partial}{\partial x} + b\frac{\partial}{\partial y} + c\frac{\partial}{\partial \theta}.$$

The momentum can be constructed by choosing a section of $\mathcal{D} \cap T\mathrm{Orb}$ regarded as a bundle over Q. Since $\mathcal{D}_q \cap T_q\mathrm{Orb}(q)$ is one dimensional, the section can be chosen to be

$$\xi_Q^q = a\frac{\partial}{\partial x} + b\frac{\partial}{\partial y} + c\frac{\partial}{\partial \theta},$$

which is invariant under the action of SE(2) on Q. The corresponding Lie algebra element in $\mathfrak{se}(2)$, ξ^q, is

$$\xi^q = (a + yc)e_x + (b - xc)e_y + ce_\theta,$$

where e_x is the basis element of the Lie algebra corresponding to translations in the x direction (and whose corresponding infinitesimal generator is $\partial/\partial x$), etc. The nonholonomic momentum map is thus given by

$$\begin{aligned} p = J^{\mathrm{nh}}(\xi^q) &= \frac{\partial L}{\partial \dot{q}^i}(\xi_Q^q)^i \\ &= ma\dot{x} + mb\dot{y} + Jc\dot{\theta} + J_0c(\dot{\theta} + \dot{\psi}) + J_1c(\dot{\theta} + \dot{\phi}_1) + J_2c(\dot{\theta} + \dot{\phi}_2). \end{aligned}$$

In Bloch, Krishnaprasad, Marsden, and Murray [1996] a simplification is made which we shall also assume in this paper, namely, $\phi_1 = -\phi_2$, $J_1 = J_2$. The parameters are also chosen such that $J + J_0 + J_1 + J_2 = mr^2$ (which eliminates some terms in the derivation but does not affect the essential geometry of the problem). Setting $\phi = \phi_1 = -\phi_2$, the constraints plus the momentum are given by

$$\begin{aligned} 0 &= -\sin(\theta + \phi)\dot{x} + \cos(\theta + \phi)\dot{y} - r\cos\phi\dot{\theta}, \\ 0 &= -\sin(\theta - \phi)\dot{x} + \cos(\theta - \phi)\dot{y} + r\cos\phi\dot{\theta}, \\ p &= -2mr\cos^2(\phi)\cos(\theta)\dot{x} - 2mr\cos^2(\phi)\sin(\theta)\dot{y} \\ &\quad + mr^2\sin(2\phi)\dot{\theta} + J_0\sin(2\phi)\dot{\psi}. \end{aligned}$$

Adding, subtracting, and scaling these equations, we can write (away from $\phi = \pi/2$)

$$\begin{bmatrix} \cos(\theta)\dot{x} + \sin(\theta)\dot{y} \\ -\sin(\theta)\dot{x} + \cos(\theta)\dot{y} \\ \dot{\theta} \end{bmatrix} + \begin{bmatrix} -\dfrac{J_0}{2mr}\sin(2\phi)\dot{\psi} \\ 0 \\ \dfrac{J_0}{mr^2}\sin^2(\phi)\dot{\psi} \end{bmatrix} = \begin{bmatrix} \dfrac{-1}{2mr}p \\ 0 \\ \dfrac{\tan\phi}{2mr^2}p \end{bmatrix}. \tag{5.1}$$

These equations have the form

$$g^{-1}\dot{g} + \mathcal{A}_{\mathrm{loc}}(r)\dot{r} = \Gamma(r)p,$$

where

$$\mathcal{A}_{\text{loc}} = -\frac{J_0}{2mr}\sin(2\phi)e_x\,d\psi + \frac{J_0}{mr^2}\sin^2(\phi)e_\theta\,d\psi,$$
$$\Gamma(r) = \frac{-1}{2mr}e_x + \frac{1}{2mr^2}\tan(\phi)\,e_\theta.$$

These are precisely the terms which appear in the nonholonomic connection relative to the (global) trivialization (r, g). The momentum equation, which governs the evolution of p, is given by

$$\begin{aligned}\dot{p} &= \frac{\partial L}{\partial \dot{q}^i}\left[\frac{d}{dt}\xi^q\right]_Q^i \\ &= 4mr\cos(\theta)\cos(\phi)\sin(\phi)\dot{x}\dot{\phi} + 4mr\sin(\theta)\cos(\phi)\sin(\phi)\dot{y}\dot{\phi} \\ &\quad +2J_0\cos(2\phi)\dot{\phi}\dot{\psi} + 2mr^2\cos(2\phi)\dot{\theta}\dot{\phi} \\ &\quad -2mr\cos(\theta)\cos^2(\phi)\dot{y}\dot{\theta} + 2mr\sin(\theta)\cos^2(\phi)\dot{x}\dot{\theta}.\end{aligned}$$

Solving for the group velocities $\dot{x}, \dot{y}, \dot{\theta}$ from the equations which define the nonholonomic connection, the momentum equation can be rewritten as

$$\dot{p} = 2J_0\cos^2(\phi)\,\dot{\phi}\dot{\psi} - \tan(\phi)\,p\dot{\phi}.$$

This version of the momentum equation corresponds to the coordinate form in body representation, but it contains no terms which are quadratic in p due to the fact that $\mathfrak{g}^q$ is one dimensional.

These equations describe how paths in the base space, parameterized by $r \in S^1 \times S^1 \times S^1$ (in fact, the base space is $S^1 \times S^1$ if we assume $\phi_1 = -\phi_2$), are lifted to the fiber SE(2). The utility of these equations is that they greatly simplify the process of solving for the motion of the system given the base space trajectory.

Now we are ready to apply the method of reduced Lagrangian optimization to find the optimal trajectories for the snakeboard. Clearly the snakeboard is a simple nonholonomic mechanical system with symmetry as defined earlier and which also has a trivial principal bundle structure. Moreover, the control forces are only applied to the shape variables for which we have full control. Let the cost function be $C(\dot{r}) = \frac{1}{2}[(\dot{\psi})^2 + (\dot{\phi})^2]$ for simplicity. We can use the method of Lagrange multipliers and Lagrangian reduction to find the necessary conditions for the optimal trajectories of the following optimal control problem.

Optimal control problem for the snakeboard. *Given two points $q_0, q_1 \in \text{SE}(2) \times S^1 \times S^1$, find the optimal control curves $(\psi(t), \phi(t)) \in S^1 \times S^1$ that steer from q_0 to q_1 and minimize $\int_0^1 \frac{1}{2}((\dot{\psi})^2 + (\dot{\phi})^2)dt$, subject to the constraints*

$$g^{-1}\dot{g} + \mathcal{A}_{\text{loc}}(r)\dot{r} = \Gamma(r)p,$$
$$\dot{p} = 2J_0\cos^2(\phi)\dot{\phi}\dot{\psi} - \tan(\phi)p\dot{\phi},$$

where

$$\mathcal{A}_{\text{loc}} = -\frac{J_0}{2mr}\sin(2\phi)e_x\,d\psi + \frac{J_0}{mr^2}\sin^2(\phi)e_\theta\,d\psi,$$
$$\Gamma(r) = \frac{-1}{2mr}e_x + \frac{1}{2mr^2}\tan(\phi)\,e_\theta.$$

Following the general procedures in the previous section, we define a new $\mathcal{L}$ by

$$\begin{aligned}\mathcal{L} = &\frac{1}{2}((\dot\psi)^2 + (\dot\phi)^2) + \lambda_a\xi^a - \frac{J_0}{2mr}\lambda_1 \sin(2\phi)\dot\psi + \frac{J_0}{mr^2}\lambda_3 \sin^2(\phi)\dot\psi \\ &+ \frac{1}{2mr}\lambda_1 p - \frac{1}{2mr^2}\lambda_3 \tan(\phi)p + \kappa\dot p - 2J_0\kappa\cos^2(\phi)\dot\phi\dot\psi + \kappa\tan(\phi)p\dot\phi,\end{aligned}$$

where $\xi = g^{-1}\dot g \in \mathfrak{g}$, $\lambda(t) \in \mathfrak{g}^*$, and $\kappa(t) \in \mathbb{R}^1$ are Lagrange multipliers. Here ξ^a and λ_a are the components of ξ and λ in the standard basis of $\mathfrak{se}(2)$ and $\mathfrak{se}(2)^*$, respectively.

By Theorem 4.1, we know that the reduced optimal curves

$$(\psi(t), \phi(t), \dot\psi(t), \dot\phi(t), \xi^a(t))$$

must satisfy the reduced Euler–Lagrangian equations for $\mathcal{L}$. After some computations, we find

$$\begin{aligned}\frac{\partial\mathcal{L}}{\partial\dot\psi} &= \dot\psi - \frac{J_0}{2mr}\lambda_1\sin(2\phi) + \frac{J_0}{mr^2}\lambda_3\sin^2(\phi) - 2J_0\kappa\cos^2(\phi)\dot\phi,\\
\frac{\partial\mathcal{L}}{\partial\psi} &= 0,\\
\frac{\partial\mathcal{L}}{\partial\dot\phi} &= \dot\phi - 2J_0\kappa\cos^2(\phi)\dot\psi + \kappa\tan(\phi)p,\\
\frac{\partial\mathcal{L}}{\partial\phi} &= -\frac{J_0}{mr}\lambda_1\cos(2\phi)\dot\psi + \frac{J_0}{mr^2}\lambda_3\sin(2\phi)\dot\psi - \frac{1}{2mr^2}\lambda_3\sec^2(\phi)p\\
&\quad +2J_0\kappa\sin(2\phi)\dot\phi\dot\psi + \kappa\sec^2(\phi)p\dot\phi,\\
\frac{\partial\mathcal{L}}{\partial\dot p} &= \kappa,\\
\frac{\partial\mathcal{L}}{\partial p} &= \frac{1}{2mr}\lambda_1 - \frac{1}{2mr^2}\lambda_3\tan(\phi) + \kappa\tan(\phi)\dot\phi,\\
\frac{\partial\mathcal{L}}{\partial\xi^b} &= \lambda_b.\end{aligned}$$

Substitute the above calculations into the reduced Euler–Lagrangian equations and simplify, giving

$$\begin{aligned}&\ddot\psi - \frac{J_0}{2mr}\dot\lambda_1\sin(2\phi) - \frac{J_0}{mr}\lambda_1\cos(2\phi)\dot\phi + \frac{J_0}{mr^2}\lambda_3\sin(2\phi)\dot\phi\\
&\quad + \frac{J_0}{mr^2}\dot\lambda_3\sin^2(\phi) - 2J_0\dot\kappa\cos^2\phi\,\dot\phi + 2J_0\kappa\sin(2\phi)(\dot\phi)^2 - 2J_0\kappa\cos^2(\phi)\ddot\phi = 0,\\
&\ddot\phi - 2J_0\dot\kappa\cos^2(\phi)\dot\psi - 2J_0\kappa\cos^2(\phi)\ddot\psi + \dot\kappa\tan(\phi)p + \kappa\tan(\phi)\dot p\\
&\qquad\qquad = -\frac{J_0}{mr}\lambda_1\cos(2\phi)\dot\psi + \frac{J_0}{mr^2}\lambda_3\sin(2\phi)\dot\psi - \frac{1}{2mr^2}\lambda_3\sec^2(\phi)p.\end{aligned}$$

Also, we have

$$\begin{aligned}\dot\kappa &= \frac{1}{2mr}\lambda_1 - \frac{1}{2mr^2}\lambda_3\tan(\phi) + \kappa\tan(\phi)\dot\phi,\\
\dot\lambda_1 &= \lambda_2\xi^3 = \lambda_2\left(-\frac{J_0}{mr^2}\sin^2(\phi)\dot\psi + \frac{1}{2mr^2}\tan(\phi)p\right),\end{aligned}$$

$$\dot{\lambda}_2 = -\lambda_1 \xi^3 = -\lambda_1 \left(-\frac{J_0}{mr^2} \sin^2(\phi)\dot{\psi} + \frac{1}{2mr^2} \tan(\phi) p \right),$$
$$\dot{\lambda}_3 = -\lambda_2 \xi^1 = -\lambda_2 \left(\frac{J_0}{2mr} \sin(2\phi)\dot{\psi} - \frac{1}{2mr} p \right),$$
$$\dot{p} = 2J_0 \cos^2(\phi)\ \dot{\phi}\dot{\psi} - \tan(\phi)\ p\dot{\phi}.$$

After eliminating $\dot{\lambda}_1, \dot{\lambda}_3, \dot{\kappa}$, and $\dot{p}$ from the first set of two equations, we finally obtain

$$\ddot{\psi} - \frac{J_0}{2mr}\lambda_1(1 + 3\cos(2\phi))\dot{\phi} + \frac{3J_0}{2mr^2}\lambda_3 \sin(2\phi)\dot{\phi} + J_0\kappa \sin(2\phi)(\dot{\phi})^2 - 2J_0\kappa \cos^2(\phi)\ddot{\phi} = 0,$$
$$\ddot{\phi} - \frac{J_0}{mr}\lambda_1 \sin^2\phi\ \dot{\psi} + \frac{1}{2mr}\lambda_1 \tan(\phi) p + \frac{1}{2mr^2}\lambda_3 p - \frac{J_0}{2mr^2}\lambda_3 \sin(2\phi)\dot{\psi} - 2J_0\kappa \cos^2(\phi)\ddot{\psi} = 0.$$

5.3. Optimal control on a Lie group. Krishnaprasad [1993] considered the following optimal control problem on a finite-dimensional Lie group G which has been used to model various problems in several other papers (e.g., the plate-ball problem in Jurdjevic [1993] and the landing tower problem in Walsh, Montgomery, and Sastry [1994]). While it is possible to model this class of problems as a special case of the optimal control of nonholonomic system on a trivial principal bundle and apply reduced Lagrangian optimization, it may be useful to provide in this section a more direct proof that uses simpler machinery.

OPTIMAL CONTROL PROBLEM FOR A LIE GROUP. *Given a left-invariant control system on G, $\dot{g} = g \cdot \xi_u$, where $\xi_u = e_0 + \sum_{i=1}^m u^i(t) e_i$, find the optimal controls $u(\cdot)$ that steer from g_0 to g_1 and minimize $\int_0^1 L(u)dt$.*

Here $\{e_0, e_1, \ldots, e_m\}$ spans an $(m+1)$-dimensional subspace of the whole Lie algebra $\mathfrak{g}$ of G; $m+1 \le n = \dim(\mathfrak{g})$; $u(\cdot)$ is a vector-valued control function with $u^i(t) \in \mathbb{R}$; L is a cost function on $\mathbb{R}^m$, which is the space of values of controls; and $L(u) = \frac{1}{2}\sum_{i=1}^m I_i (u^i)^2$ with $I_i > 0$.

To apply the method of Lagrangian reduction, we recast the above optimal control problem as a constrained variational problem. For simplicity of exposition, we will deal with the vector space case first, where there is no e_0 term, and will take up the affine case later.

Let $\mathcal{C}$ be the m-dimensional subspace of $\mathfrak{g}$ spanned by $\{e_1, \ldots, e_m\}$. We make the following points:

(i) $\xi_u = \sum_{i=1}^m u^i(t) e_i$ lies in $\mathcal{C}$.

(ii) If we define $L_1 = L \circ \phi$, where $L = \frac{1}{2}\sum_{i=1}^m I_i (u^i)^2$ with $I_i > 0$ and $\phi = (e^1, \ldots, e^m)$ with $\{e^1, \ldots, e^m\}$ as the dual basis of $\{e_1, \ldots, e_m\}$, then $L_1 : \mathcal{C} \to \mathbb{R}$ is nothing but one half of the square of a metric on $\mathcal{C}$ which is intrinsically defined and does not depend on the basis chosen.

(iii) We can extend L_1 to be half of the square of a metric $\bar{L}$ on $\mathfrak{g}$ such that $\bar{L} = L_1$ on $\mathcal{C}$. As we will see, the necessary conditions for an optimal control do not depend on how the extension is done.

(iv) For the affine case, we will simply set $\xi_u - e_0 = \sum_{i=1}^m u^i(t) e_i$.

Now it should be clear that the original problem is equivalent to the following constrained variational problem.

CONSTRAINED VARIATIONAL PROBLEM FOR OPTIMAL CONTROL ON LIE GROUPS. *Given an m-dimensional subspace $\mathcal{C}$ of $\mathfrak{g}$, find the optimal control curves $\xi - e_0 \in \mathcal{C}$ such that $g(0) = g_0$, $g(1) = g_1$ and minimize $\int_0^1 \bar{L}(\xi - e_0)\, dt$.*

Since we want to use the method of Lagrange multipliers to relax the constraint on the variations, we define a new Lagrangian

$$\mathcal{L} = \bar{L}(\xi - e_0) + \lambda(t)(\xi - e_0) = \tilde{L}(\xi) + \tilde{\lambda}(t)(\xi), \tag{5.2}$$

where $\lambda(t)$ lies in the annihilator $\mathcal{C}^0$ of $\mathcal{C}$; furthermore, $\tau(\xi) = \xi - e_0$, $\tilde{L} = \bar{L} \circ \tau$, and $\tilde{\lambda} = \lambda \circ \tau$.

THEOREM 5.1 (optimization theorem for nonholonomic systems on Lie groups). *If $\bar{\xi}$ is a (regular) optimal control curve in $\mathcal{C} + e_0 = \{\xi \in \mathfrak{g} : \xi = \xi_c + e_0, \xi_c \in \mathcal{C}\}$, then there exists a $\lambda(t) \in \mathfrak{g}^*$ such that $\bar{\xi}$ satisfies the Euler–Poincaré equation*

$$\frac{d}{dt}\left(\frac{\delta \tilde{L}}{\delta \xi} + \lambda\right) = \mathrm{ad}^*_\xi \left(\frac{\delta \tilde{L}}{\delta \xi} + \lambda\right). \tag{5.3}$$

Proof. If $\bar{\xi}(t)$ is an optimal control curve in $\mathcal{C} + e_0$, then by the Lagrangian reduction method, $\bar{\xi}(t)$ is a solution of the following variational problem:

$$\delta \int_0^1 \mathcal{L}(\xi) dt = \delta \int_0^1 (\tilde{L}(\xi) + \tilde{\lambda}(\xi)) dt = 0$$

for some $\lambda \in \mathfrak{g}^*$, where the variations take the form $\delta\xi = \dot{\Omega} + [\xi, \Omega]$ with $\Omega = g^{-1} \cdot \delta g$ arbitrary except vanishing at the endpoints. Since

$$\begin{aligned}
0 &= \delta \int_0^1 \left(\tilde{L}(\xi) + \tilde{\lambda}(\xi)\right) dt \\
&= \int_0^1 \left(\frac{\delta \tilde{L}}{\delta \xi} \delta\xi + \lambda\,(\delta\xi)\right) dt \\
&= \int_0^1 \left(\frac{\delta \tilde{L}}{\delta \xi} + \lambda\right) \left(\dot{\Omega} + [\xi, \Omega]\right) dt \\
&= \int_0^1 \left(-\frac{d}{dt}\left(\frac{\delta \tilde{L}}{\delta \xi} + \lambda\right) + \mathrm{ad}^*_\xi \left(\frac{\delta \tilde{L}}{\delta \xi} + \lambda\right)\right) \Omega dt,
\end{aligned}$$

we conclude that $\bar{\xi}(t)$ satisfies

$$\frac{d}{dt}\left(\frac{\delta \tilde{L}}{\delta \xi} + \lambda\right) = \mathrm{ad}^*_\xi \left(\frac{\delta \tilde{L}}{\delta \xi} + \lambda\right). \qquad \square$$

COROLLARY 5.2. *Given a left-invariant control system on G, $\dot{g} = g \cdot \xi_u$, where*

$$\xi_u = e_0 + \sum_{i=1}^m u^i(t) e_i.$$

If $\bar{u}(\cdot)$ is an optimal control, then

$$\bar{u}^i(t) = \frac{\mu_i(t)}{I_i},$$

where $i = 1, \ldots, m$ and μ_i, $i = 1, \ldots, m$ is the solution of the following system of differential equations:

$$\dot{\mu}_i = C^k_{ji} \mu_k \xi^j_u,$$

where $i, j, k = 0, \ldots, n-1$ and where C^k_{ij} are the structure constants of $\mathfrak{g}$.

Proof. Extend $\{e_0, e_1, \ldots, e_m\}$ to a basis $\{e_0, \ldots, e_{n-1}\}$, and let $\{e^0, \ldots, e^{n-1}\}$ be its dual basis.

(i) For $i = 1, \ldots, m$ and $\xi_u \in e_0 + \mathcal{C}$, we have

$$\frac{\delta \tilde{L}}{\delta \xi_u^i} = \frac{\partial L}{\partial u^i} = I_i u^i$$

because $\tilde{L}(\xi_u) = L \circ \phi \circ \tau(\xi_u) = L(u)$ and $\xi_u^i = u^i$; furthermore,

$$\lambda_i = 0, \qquad i = 1, \ldots, m$$

because λ lies in the annihilator $\mathcal{C}^0$.

(ii) If we set

$$\mu_i = \frac{\delta \tilde{L}}{\delta \xi_u^i}, \ i = 1, \ldots, m,$$

and

$$\mu_i = \frac{\delta \tilde{L}}{\delta \xi_u^i} + \lambda_i, \ i = m+1, \ldots, n-1, 0,$$

and write out the Euler–Poincaré equation using the above coordinates, we will get the desired system of differential equations. □

Remarks.

(1) From the above computations we can see that the necessary conditions for an optimal control $\bar{u}(\cdot)$ depend only on L and have nothing to do with how the extension is done, because not only $u^i(t) = \mu_i(t)/I_i$ but also $\dot{\mu}_i = C_{ji}^k \mu_k \xi_u^j$ do not depend on $\bar{L}$.

(2) The necessary conditions given in Corollary 5.2 are the same as those in Krishnaprasad [1993]:

$$u^i = \frac{\mu_i}{I_i}, \qquad i = 1, \ldots, m,$$
$$\dot{\mu}_i = -\mu_k C_{ij}^k \frac{\delta h}{\delta \mu_j}, \qquad i, j, k = 0, \ldots, n-1,$$

where

$$h = \mu_0 + \frac{1}{2} \sum_{i=1}^{m} \frac{\mu_i^2}{I_i}.$$

This is because $C_{ji}^k = -C_{ij}^k$ and

$$\frac{\delta h}{\delta \mu_j} = \left\{ \begin{array}{ll} 1, & j = 0, \\ \dfrac{\mu_j}{I_j} = u^j, & j = 1, \ldots, m, \\ 0, & j = m+1, \ldots, n-1 \end{array} \right\} = \xi_u^j.$$

Conclusions. We have found a procedure based on reduced Lagrangian optimization that can be used to directly establish results on

(1) optimal control for left-invariant systems on Lie group with velocity constraints,

(2) optimal control for holonomic systems on principal bundles with the constraint of the vanishing of the momentum map,

(3) optimal control for nonholonomic systems on (trivial) principal bundles that may have a nontrivial evolution of its nonholonomic momentum.

In fact, the first two results can be seen as special cases of the last result even though we have derived each of them in a parallel way. Recall that in the nonholonomic case, we have

$$\begin{aligned}\mathcal{L} = C(\dot{r}) &+ \langle \lambda(t), \xi + \mathcal{A}(r)\dot{r} - \Gamma(r)p \rangle \\ &+ \left\langle \kappa(t), \dot{p} - \dot{r}^T H(r)\dot{r} - \dot{r}^T K(r)p - p^T D(r)p \right\rangle .\end{aligned} \tag{5.4}$$

In the driftless holonomic case, $\mathcal{D}_q = T_q Q$ for each $q \in Q$, the momentum is conserved and assumed to be zero, so the above Lagrangian $\mathcal{L}$ reduces to

$$\mathcal{L} = C(\dot{r}) + \langle \lambda(t), \xi + \mathcal{A}(r)\dot{r} \rangle ,$$

which is exactly the same Lagrangian used in the second case. As for a system on Lie group G with velocity constraint (say, $g^{-1}\dot{g} = \sum_{i=1}^{m} u^i e_i$ for simplicity), it can be seen as a system on (trivial) principal bundle $G \times \mathbb{R}^m$ whose (nonholonomic) connection is independent of the shape variable r; i.e.,

$$\xi^a = \mathcal{A}^a_\alpha \dot{r}^\alpha,$$

where $\mathcal{A}^a_\alpha = 1$ and $\dot{r}^\alpha = u^\alpha$.

Topics for future work.

(1) In the nonholonomic case, we have stated only the result for the case of a trivial principal bundle. While it is true that all examples known to us have a trivial bundle structure, it is of interest to generalize the reduced Lagrangian optimization theorem to the case of an arbitrary principal bundle. Also, we need to understand better the geometry underlying this procedure. We hope to address all of these issues in a follow-up paper.

(2) We need to construct algorithms that can effectively find approximate solutions to the system of differential equations that are obtained through reduced Lagrangian optimization. For example, finite element techniques appear to be appropriate and will be explored.

INVESTIGATION OF THE DEGENERACY PHENOMENON OF THE MAXIMUM PRINCIPLE FOR OPTIMAL CONTROL PROBLEMS WITH STATE CONSTRAINTS*

ARAM V. ARUTYUNOV† AND SERGEI M. ASEEV‡

Abstract. In this paper we study the degeneracy phenomenon in optimal control problems with state constraints. It is shown that this phenomenon occurs because of the incompleteness of the standard variants of Pontryagin's maximum principle for problems with state constraints. A new maximum principle containing additional information about the behavior of the Hamiltonian at the endtimes is developed. We also obtain some sufficient and necessary conditions for nondegeneracy and pointwise nontriviality of the maximum principle. The results obtained pertain to optimal control problems with systems described by differential inclusions and ordinary differential equations.

Key words. optimal control, state constraints, maximum principle, degeneracy phenomenon, controllability conditions

1. The degeneracy phenomenon. To illustrate the degeneracy phenomenon, let us consider the "simplest" optimal control problem with state constraints:

$$\dot{x} = f(x,t,u), \qquad u \in U; \tag{1.1}$$

$$x(t_1) = x_1; \tag{1.2}$$

$$g(x(t)) \le 0 \quad \forall\, t \in [t_1, t_2]; \tag{1.3}$$

$$J(u(\cdot)) = k_0(x(t_2)) \to \min. \tag{1.4}$$

Here $x \in R^n$, $U \subset R^k$, the time interval $I = [t_1, t_2]$ is fixed, x_1 is a given initial point, and the right endpoint $x(t_2)$ is free. We suppose that the vector function f and the scalar functions g, k_0 are smooth and $\frac{\partial g}{\partial x}(x) \neq 0$ for all x such that $g(x) = 0$. The set of admissible controls consists of all bounded measurable functions u such that $u(t) \in U$ almost everywhere (a.e.) on I.

The problem (1.1)–(1.4) satisfies the hypotheses of several variants of Pontryagin's maximum principle (see [1], [2], [3], [4], [5], [6], [7]). Let us apply the standard one.

We define the Hamilton–Pontryagin function $\mathcal{H}$ and the Hamiltonian H as follows:

$$\mathcal{H}(x,t,u,\psi) = \langle \psi, f(x,t,u) \rangle,$$

$$H(x,t,\psi) = \sup_{u \in U} \mathcal{H}(x,t,u,\psi).$$

Let the pair x_0, u_0 solve the problem (1.1)–(1.4). Then Pontryagin's well-known maximum principle for problems with state constraints, proven by Dubovitskii and

Milutin [1], [3], [7], asserts that there exists a number $\lambda_0 \geq 0$, a left-continuous function ψ of bounded variation and a nonnegative bounded regular Borel measure η on I such that following conditions hold[1]:

$$\psi(t) = -\lambda_0 \frac{\partial k_0}{\partial x}(x_0(t_2)) + \int_t^{t_2} \frac{\partial \mathcal{H}}{\partial x}(x_0(s), s, u_0(s), \psi(s))\, ds \tag{1.5}$$

$$- \int_t^{t_2} \frac{\partial g}{\partial x}(x_0(s))\, d\eta \quad \forall\, t \in [t_1, t_2],$$

$$H(x_0(t), t, \psi(t)) = - \int_t^{t_2} \frac{\partial \mathcal{H}}{\partial t}(x_0(s), s, u_0(s), \psi(s))\, ds \tag{1.6}$$

$$+ H(x_0(t_2), t_2, \psi(t_2)) \quad \forall\, t > t_1,$$

$$\mathcal{H}(x_0(t), t, u_0(t), \psi(t)) \overset{\text{a.e.}}{=} H(x_0(t), t, \psi(t)), \tag{1.7}$$

$$\operatorname{supp} \eta \subset \{t :\ g(x_0(t)) = 0\}, \tag{1.8}$$

$$\lambda_0 + \|\eta\| + \sup_{t_1 \leq t \leq t_2} \|\psi(t)\| \neq 0. \tag{1.9}$$

Here,

$$\|\eta\| = \sup_{\|x\|_{C(I)}=1} \int_{t_1}^{t_2} x(s)\, d\eta.$$

Suppose now that the initial endpoint x_1 belongs to the boundary of the state constraints (1.3), i.e., $g(x_1) = 0$. Then the maximum principle (1.5)–(1.9) degenerates. This means that it is satisfied by a collection of Lagrange multipliers λ_0, ψ, η such that $\lambda_0 = 0$ and $\psi(t) = 0\ \forall\, t \in (t_1, t_2)$. (We shall call such a collection of Lagrange multipliers trivial.) Indeed, one can take $\lambda_0 = 0$; $\eta = \delta_{t_1}$, the Dirac measure concentrated at the point t_1; $\psi(t_1) = -\frac{\partial g}{\partial x}(x_1)$, $\psi(t) = 0\ \forall\, t \in (t_1, t_2]$. Obviously, in this case any admissible trajectory satisfies the maximum principle and hence we get no useful information. Applying to the problem (1.1)–(1.4) any of the above-cited variants of the maximum principle, we get the same result.

Note that in the general case when an optimal control problem incorporates a Bolza-type functional, free time, and full endpoint constraints, the maximum principle may degenerate if one end of an optimal trajectory belongs to the boundary of the state constraints. Degenerate multipliers exist in any problem with one end fixed on the state boundary. Moreover, there exist problems in which the trivial collection of Lagrange multipliers is the only one satisfying the maximum principle.

The following example is due to Dubovitskii and Dubovitskii [8].

[1] Putting

$$\hat{\psi}(t) = \psi(t) - \int_{[t_1, t)} \frac{\partial g}{\partial x}(x_0(s))\, d\eta,$$

one can rewrite the conditions (1.5)–(1.9) in terms of the absolutely continuous function $\hat{\psi}$.

Example 1. Consider the following problem:

$$\begin{aligned}
&\dot{x}_1 = tu, \qquad |u| \le 1;\\
&\dot{x}_2 = u;\\
&x_1(0) = 0, \qquad x_2(0) = 0;\\
&x_1(t) \ge 0 \quad \forall\, t \in I = [0,1];\\
&J(u(\cdot)) = x_2(1) \to \min.
\end{aligned}$$

It is not difficult to show that the unique solution of this problem is $x_0(t) \equiv 0$ and $u_0(t) = 0$ a.e. on I. Let λ_0, ψ, η be a collection of Lagrange multipliers corresponding to x_0. Then due to the maximum condition (1.7) we have

$$|t\psi_1(t) + \psi_2(t)| \overset{\text{a.e.}}{=} tu_0(t)\psi_1(t) + u_0(t)\psi_2(t) \overset{\text{a.e.}}{=} 0.$$

From the adjoint equation (1.5) we have $\psi_2(t) \equiv \psi_2(0)\ \forall\, t \in I$. Let $\psi_2(0) \neq 0$. Then $\psi_1(t) \overset{\text{a.e.}}{=} -\frac{\psi_2(0)}{t}$ fails to be a function of bounded variation. Thus, $\psi_2(t) \equiv 0$ and $\psi_1(t) = 0\ \forall\, t \in (0,1]$. Further, due to (1.5) $\lambda_0 = 0$. So, there is a unique (up to a positive multiplier) collection of Lagrange multipliers corresponding to the optimal pair in this example and it is trivial.

In the present paper we investigate the degeneracy phenomenon. Some results in this direction have been obtained earlier in [8], [9], [10], [11], [12], [13], [14], [15], [16], [17], [18] (see section 6). Our contribution to the subject is the following. We show that the degeneracy phenomenon arises due to the incompleteness of the standard variants of the maximum principle for problems with state constraints and develop a new version containing additional information about the Hamiltonian (a new jump condition at the endtimes). This condition enables one to investigate the degeneracy phenomenon.

The paper is organized as follows. In section 2 we state our main result—a new version of the maximum principle (as announced in [19], [20]). It is important to underline that the Hamiltonian plays the main role in our investigation. That is why we state the result in Hamiltonian form. In addition, the consideration of the problem in intrinsic form makes the presentation more descriptive. For simplicity we consider the problem on a fixed time interval (the free time problem can be investigated analogously [17], [19]). Section 3 contains the technical proof of the main result. In section 4 under some natural controllability assumptions we present sufficient conditions for nondegeneracy and pointwise nontriviality. In the case in which the state constraint set is regular at the endpoints, these conditions of controllability turn out to be precisely the ones necessary for the maximum principle to be informative. In section 5 we consider the free time classical optimal control problem and formulate the results applicable to it. Furthermore, sufficient conditions for the existence of at least one nontrivial collection of Lagrange multipliers corresponding to an optimal trajectory are obtained. Section 6 contains bibliographical comments.

2. The main result. Consider the optimal control problem with state constraints in intrinsic form:

$$\dot{x} \in F(x,t); \tag{2.1}$$

$$x(t_1) \in C_1, \qquad x(t_2) \in C_2; \tag{2.2}$$

$$x(t) \in G \quad \forall\, t \in [t_1, t_2]; \tag{2.3}$$

$$J(x(\cdot)) = k_0(x(t_1), x(t_2)) \to \min. \tag{2.4}$$

Here $x \in R^n$; C_1, C_2, G are nonempty closed subsets of R^n; the time interval $I = [t_1, t_2]$ is fixed; $k_0 : R^{2n} \to R^1$ is a locally Lipschitz function; and the multivalued mapping F is supposed to be locally Lipschitz with nonempty convex compact values. We assume also that Clarke's tangent cone $T_G(x)$ has a nonempty interior at any point $x \in G$ [2]. The class of admissible trajectories consists of all Lipschitz continuous functions x satisfying conditions (2.1)–(2.3).

Denote by $\partial f(x)$ Clarke's generalized gradient [2] of the locally Lipschitz function f at the point x, by $H(x,t,\psi) = \max_{f \in F(x,t)} \langle f, \psi \rangle$ the Hamiltonian of the system (2.1), and by $N_M(x)$ Clarke's normal cone to the set M at the point x [2]. Denote by $\hat{N}_M(x) = \limsup_{x_i \xrightarrow{M} x} \xi_i(x_i) = \{\xi \in R^n : \xi = \lim \xi_i(x_i)$ for some sequences $\xi_i(x_i)$ and $x_i \to x$ in $M\}$ the cone of limiting normals to M at x, where $\xi_i(x_i)$ is a proximal normal to M at x_i [2], [5], [21], [22], and by

$$\hat{\partial} f(x) = \{\xi \in R^n : (\xi, -1) \in \hat{N}_{epif}(x, f(x))\}$$

the set of limiting subgradients of the locally Lipschitz function f at x [5], [21], [22].

Our main result is the following.

THEOREM 1 (maximum principle). *Let x_0 be a solution of the problem (2.1)–(2.4). Then there exists a number $\lambda_0 \geq 0$, an absolutely continuous function ψ, and a bounded regular Borel vector measure η on I such that following conditions hold:*

(a) *The absolute continuity condition: the function $h(t) = H(x_0(t), t, \psi(t) + \int_{t_1}^{t} d\eta)$ is absolutely continuous on I;*

(b) *the jump condition:*

$$H\left(x_0(t), t, \psi(t) + \int_{t_1}^{t} d\eta\right) = H\left(x_0(t), t, \psi(t) + \int_{t_1}^{t} d\eta - \eta(t)\right) \quad \forall\, t \in I;$$

(c) *the measure sign condition: the measure η is nonpositive on the set of all continuous functions y with values in $T_G(x_0(t))$; i.e.,*

$$\int_{t_1}^{t_2} y(t)\, d\eta \leq 0 \quad \forall\, y \in C(I) :\ y(t) \in T_G(x_0(t)) \quad \forall\, t \in I;$$

(d) *the Hamiltonian inclusion:*

$$(-\dot{\psi}(t), \dot{h}(t), \dot{x}_0(t)) \overset{\text{a.e.}}{\in} \partial H\left(x_0(t), t, \psi(t) + \int_{t_1}^{t} d\eta\right);$$

(e) *the transversality condition:*

$$\left(\psi(t_1), -\psi(t_2) - \int_{t_1}^{t_2} d\eta\right) \in \lambda_0 \hat{\partial} k_0(x_0(t_1), x_0(t_2)) + \hat{N}_{C_1 \cap G}(x_0(t_1)) \times \hat{N}_{C_2 \cap G}(x_0(t_2));$$

(f) *the nontriviality condition:*

$$\lambda_0 + \|\psi(t_1)\| + \|\eta\| \neq 0.$$

Here $\eta(t)$ is the atomic component of the measure η at the point t.

The main distinction of the theorem formulated above from the other variants of the maximum principle consists of condition (b) at the endtimes t_1 and t_2, which is

crucial to the nondegeneracy conditions we derive below. Conditions (a) and (b) are not completely independent. For any $t > t_1$, condition (b) says $h(t) = h(t-0)$, which follows from (a). When $t = t_1$, however, condition (b) places a restriction on the atom $\eta(t_1)$. So, we shall prove condition (a) and then condition (b) at the point t_1. The sense of these two conditions is to take into consideration the energy conservation law.

We should note that the nontraditional transversality condition (e), in which the right side contains normal cones to intersections of endpoint sets C_1 and C_2 with the state constraint set G, appears to be essential to the validity of the jump condition (b) at the endpoints. Example 2 below shows that Theorem 1 may fail if (e) is replaced by a traditional transversality condition [2], [4].

Further, using the Radon–Nikodým theorem [23], one can show that there exist a bounded nonnegative regular scalar Borel measure ν and a ν-integrable function ζ on I such that the measure η is absolutely continuous with respect to ν and

$$\frac{d\eta}{d\nu} = \zeta(t), \qquad \zeta(t) \in N_G(x_0(t)) \quad \nu \text{ — a.e. on } I. \tag{2.5}$$

The inclusions

$$\operatorname{supp}\eta \subset \{t \in I : \ x(t) \in \partial G\}; \qquad \eta(t) \in N_G(x_0(t)) \quad \forall\, t \in I$$

are obvious consequences of the measure sign condition. Here ∂G designates the boundary of the set G.

The following example illustrates the correlation of the new transversality condition (e) and the jump condition (b) at the endtimes t_1, t_2.

Example 2. Consider the problem

$$\begin{aligned}
&\dot{x} \in F(x) = \{y \in R^1 : \ |y| \le 1\};\\
&x(0) \in C_1 = \{y \in R^1 : \ y \le 0\}, \qquad x(1) \in C_2 = R^1;\\
&x(t) \ge 0 \quad \forall\, t \in I = [0,1];\\
&J(x(\cdot)) = x(0) + x(1) \to \min.
\end{aligned}$$

Obviously, $x_0(t) \equiv 0$ is an optimal trajectory. In this example $H(x,t,\psi) = |\psi|$, $G = \{y \in R^1 : \ y \ge 0\}$. Due to the Hamiltonian inclusion we have $|\psi(t) + \int_{t_1}^{t} d\eta| = 0$ a.e. on I. Hence, $\psi(t) \equiv \psi(t_1) = -\eta(t_1)$ and $\eta = \eta(t_1)\delta_{t_1} + \eta(t_2)\delta_{t_2}$.

Consider the transversality condition (e). It gives

$$(-\eta(t_1), -\eta(t_2)) \in \lambda_0(1,1) + (\xi_1, \xi_2),$$

where $\xi_1 \in N_{C_1 \cap G} \Rightarrow \xi_1 \in R^1$; $\xi_2 \in N_{C_2 \cap G} \Rightarrow \xi_2 \le 0$. Due to the measure sign condition $\eta(t_1) \le 0$ and $\eta(t_2) \le 0$. Thus, $\eta(t_1) = -\lambda_0 - \xi_1 \le 0$, $\eta(t_2) = -\lambda_0 - \xi_2 \le 0$. Putting $\lambda_0 = 1$, $\xi_1 = \xi_2 = -1$, we can satisfy the jump conditions at the endtimes t_1, t_2: $\eta(t_1) = 0$, $\eta(t_2) = 0$.

Consider now the standard transversality condition [2], [4]:

$$\left(\psi(t_1), -\psi(t_2) - \int_{t_1}^{t_2} d\eta\right) \in \lambda_0 \partial k_0(x(t_1), x(t_2)) + N_{C_1}(x(t_1)) \times N_{C_2}(x(t_2)).$$

It gives

$$(-\eta(t_1), -\eta(t_2)) \in \lambda_0(1,1) + (\xi_1, \xi_2),$$

where $\xi_1 \in N_{C_1}(0) \Rightarrow \xi_1 \geq 0$; $\xi_2 \in N_{C_2}(0) \Rightarrow \xi_2 = 0$. Hence, we can satisfy the jump conditions at the endtimes t_1, t_2 only by putting $\lambda_0 = \xi_1 = \xi_2 = 0$. But in this case $\lambda_0 = 0$, $\psi(t) \equiv 0$, $\eta = 0$, which contradicts the nontriviality condition (f). Thus, the jump condition (b) at the endtimes cannot be added to the standard maximum principles [1], [2], [3], [4], [5], [6], [7].

3. Proof of Theorem 1. Let x_0 be an optimal trajectory, $\rho(x) = \min_{y \in G} \|y - x\|$ and $\rho_i(x) = \int_{R^n} \rho(x+y) w_i(y)\, dy$. Here w_i is a smooth probabilistic density such that $\operatorname{supp} w_i \subset \{x : \|x\| \leq \frac{1}{2^i}\}$, $i = 1, 2, \ldots$.

Consider now a sequence of auxiliary problems:

$$\dot{x} \in F(x,t), \tag{3.1}$$

$$x(t_1) \in C_1 \cap G, \qquad x(t_2) \in C_2 \cap G, \tag{3.2}$$

$$\|x(t_1) - x_0(t_1)\| \leq 1, \tag{3.3}$$

$$J_i(x(\cdot)) = k_0(x(t_1), x(t_2)) + \int_{t_1}^{t_2} \varphi_i(x,t)\, dt \to \min. \tag{3.4}$$

Here $\varphi_i(x,t) = i\rho_i(x) + \|x - x_0(t)\|^2$, $i = 1, 2, \ldots$.

By virtue of Filippov's existence theorem, for any $i = 1, 2, \ldots$ there exists a solution x_i of auxiliary problem (3.1)–(3.4), and the sequence $\{x_i\}$ is relatively compact in $C(I)$. Furthermore, any limit point $x_* = \lim_{i \to \infty} x_i$ is a trajectory of the differential inclusion (3.1).

LEMMA. *Let $\{x_i\}$ be a sequence of solutions of* (3.1)–(3.4). *Then $x_i \rightrightarrows x_0$ on I, $\dot{x}_i \to \dot{x}_0$ weakly in $L_1(I)$, and $i\rho_i(x_i(t)) \to 0$ a.e. on I, $i \to \infty$.*

Proof. Let x_* be some limit point of $\{x_i\}$ and $x_i \to x_*$ in $C(I)$, $i \to \infty$. Then due to the optimality of x_i we have

$$J_i(x_i(\cdot)) \leq J_i(x_0(\cdot)) \leq k_0(x_0(t_1), x_0(t_2)) + \frac{i}{2^i}(t_2 - t_1). \tag{3.5}$$

Thus, $\int_{t_1}^{t_2} \rho_i(x_i(t))\, dt \to 0$ and $x_*(t) \in G\ \forall\, t \in I$. So the trajectory x_* satisfies the state constraints (2.3) and the endpoint constraints (2.2). Hence, due to the optimality of x_0 we have

$$k_0(x_0(t_1), x_0(t_2)) \leq k_0(x_*(t_1), x_*(t_2)).$$

Substituting this inequality into (3.5), we obtain

$$k_0(x_i(t_1), x_i(t_2)) + \int_{t_1}^{t_2} \varphi_i(x_i(t), t)\, dt \leq k_0(x_*(t_1), x_*(t_2)) + \frac{i}{2^i}(t_2 - t_1).$$

Passing to the limit in the last inequality, we get

$$\int_{t_1}^{t_2} i\rho_i(x_i(t))\, dt \to 0, \qquad \int_{t_1}^{t_2} \|x_*(t) - x_0(t)\|^2\, dt = 0.$$

Hence, $i\rho_i(x_i(t)) \to 0$ a.e. on I, $i \to \infty$ and $x_*(t) \equiv x_0(t)$. The weak convergence of $\{\dot{x}_i\}$ to $\dot{x}_0$ in $L_1(I)$ is a consequence of the uniform convergence of $\{x_i\}$ to x_0 and of the uniform boundness of $\{\|\dot{x}_i(t)\|\}$. □

Due to the lemma above, the inequality in endpoint constraint (3.3) holds strictly for all sufficiently large numbers i. Hence, it may be neglected in the transversality conditions of the maximum principle for the problem (3.1)–(3.4). Thus, due to the Hamiltonian necessary conditions of optimality for the problems without state constraints [2][2] with transversality conditions suggested by Mordukhovich [21] (see [5] for details) we obtain that there exist an absolutely continuous function ψ_i and a number $\lambda_i \geq 0$ such that

$$(-\dot{\psi}_i(t), \dot{h}_i(t), \dot{x}_i(t)) \overset{\text{a.e.}}{\in} \partial H(x_i(t), t, \psi_i(t)) \tag{3.6}$$

$$-\lambda_i \left(i\frac{\partial \rho_i(x_i(t))}{\partial x} + 2(x_i(t) - x_0(t)), -2\langle x_i(t) - x_0(t), \partial x_0(t)\rangle, 0 \right),$$

$$(\psi_i(t_1), -\psi_i(t_2)) \in \lambda_i \hat{\partial} k_0(x_i(t_1), x_i(t_2)) + \hat{N}_{C_1 \cap G}(x_i(t_1)) \times \hat{N}_{C_2 \cap G}(x_i(t_2)), \tag{3.7}$$

$$\lambda_i + \|\psi_i(t_1)\| \neq 0. \tag{3.8}$$

Here $h_i(t) = H(x_i(t), t, \psi_i(t)) - \lambda_i \varphi_i(x_i(t), t)$,

$$\langle x_i(t) - x_0(t), \partial x_0(t)\rangle = \bigcup_{\xi \in \partial x_0(t)} \langle x_i(t) - x_0(t), \xi\rangle.$$

Further, introducing the absolutely continuous function

$$\tilde{\psi}_i = \psi_i(t) - \int_{t_1}^{t} i\lambda_i \frac{\partial \rho_i}{\partial x}(x_i(s))\, ds,$$

the conditions (3.6)–(3.8) can be rewritten as

$$(-\dot{\tilde{\psi}}_i(t), \dot{h}_i(t), \dot{x}_i(t)) \overset{\text{a.e.}}{\in} \partial H\left(x_i(t), t, \tilde{\psi}_i(t) + i\lambda_i \int_{t_2}^{t} \frac{\partial \rho_i}{\partial x}(x_i(s))\, ds \right) \tag{3.9}$$

$$-\lambda_i (2(x_i(t) - x_0(t)), -2\langle x_i(t) - x_0(t), \partial x_0(t)\rangle, 0),$$

$$\left(\tilde{\psi}_i(t_1), -\tilde{\psi}_i(t_2) - \int_{t_1}^{t_2} i\lambda_i \frac{\partial \rho_i}{\partial x}(x_i(s))\, ds \right) \in \lambda_i \hat{\partial} k_0(x_i(t_1), x_i(t_2)) \tag{3.10}$$

$$+\hat{N}_{C_1 \cap G}(x_i(t_1)) \times \hat{N}_{C_2 \cap G}(x_i(t_2)),$$

$$\lambda_i + \|\tilde{\psi}_i(t_1)\| \neq 0. \tag{3.11}$$

Let us normalize the multipliers λ_i, $\tilde{\psi}_i$ as follows:

$$\lambda_i + \|\tilde{\psi}_i(t_1)\| + i\lambda_i \int_{t_1}^{t_2} \left\| \frac{\partial \rho_i}{\partial x}(x_i(s)) \right\| ds = 1. \tag{3.12}$$

[2]Using the smooth approximation procedure [17], [24], it is possible to derive our main result directly from Pontryagin's maximum principle [25].

Then, passing to a subsequence, we have $\lambda_i \to \lambda_0 \geq 0$, $\tilde{\psi}_i(t_1) \to \psi_1$, and by virtue of Helly's theorem [26] the sequence $\{i\lambda_i \frac{\partial \rho_i}{\partial x}(x_i(\cdot))\}$ converges weakly to a bounded regular Borel vector measure η on I.

Further, due to the Hamiltonian inclusion (3.9) and Proposition 3.2.4(e) in [2] we have

$$\|\dot{\tilde{\psi}}_i(t)\| \leq \kappa_1(\|\tilde{\psi}_i(t)\| + 1) \text{ a.e. on } I.$$

Here and in what follows $\kappa_1, \kappa_2, \ldots$ denote positive constants. Hence, due to the Bellman–Gronwall inequality and (3.12) we can suppose $\tilde{\psi}_i \rightrightarrows \psi$ on I and $\dot{\tilde{\psi}}_i \to \dot{\psi}$ weakly in $L_1(I)$, $i \to \infty$, where ψ is a Lipschitz continuous vector function. So, $\psi(t_1) = \psi_1$.

Now we prove the measure sign condition (c). For this we show that for any continuous vector function y on I such that $y(t) \in T_G(x_0(t))\ \forall\, t \in I$ the following inequality holds:

$$\langle \eta, y \rangle = \int_{t_1}^{t_2} y(t)\, d\eta \leq 0.$$

Using the assumption $\operatorname{int} T_G(x_0(t)) \neq \emptyset\ \forall\, t \in I$ and Michael's continuous selection theorem [27], it is not difficult to prove that there is a sequence of continuous functions $\{y_i\}$ such that $y_i \rightrightarrows y$, $i \to \infty$ and $y_i(t) \in \operatorname{int} T_G(x_0(t))\ \forall\, t \in I$.

Hence, without loss of generality we can assume that there is $\delta > 0$ such that

$$y(t) \in N_\delta^*(t) \quad \forall\, t \in I. \tag{3.13}$$

Here $N_\delta(t) = \{\lambda y : \ \|y - x\| \leq \delta,\ x \in N_G(x_0(t)),\ \|x\| = 1,\ \lambda \geq 0\}$ is the conic δ-neighborhood of the normal cone $N_G(x_0(t))$ and $N_\delta^*(t)$ its adjoint.

Let us take an arbitrary point $\tau \in I$ and prove that there is $\varepsilon(\tau) > 0$ such that

$$\frac{\partial \rho_i}{\partial x}(x_i(t)) \in N_{\delta/2}(\tau) \tag{3.14}$$

for all large enough numbers i and all t such that $|t - \tau| \leq \varepsilon(\tau)$. Indeed, from the definition of the function ρ_i we have

$$\frac{\partial \rho_i}{\partial x}(x_i(t)) = \int \frac{\partial \rho}{\partial x}(x_i(t) + y) w_i(y)\, dy. \tag{3.15}$$

If $x_0(\tau) \in \operatorname{int} G$, then $N_G(x_0(\tau)) = \{0\}$ and (3.14) holds, obviously. Suppose that $x_0(\tau) \in \partial G$ and (3.14) is violated. Then there is a sequence $t_i \to \tau$, $i \to \infty$ such that $\frac{\partial \rho_i}{\partial x}(x_i(t_i)) \notin N_{\delta/2}(\tau)$. Due to (3.15) there is a sequence $y_i \to 0$, $i \to \infty$ such that

$$v_i = \frac{\partial \rho}{\partial x}(x_i(t_i) + y_i) \notin N_{\delta/2}(\tau). \tag{3.16}$$

According to the properties of the distance function ρ we have $\|v_i\| = 1$ and $v_i \in N_G(z_i)$, where $z_i \in G$ is a closest point to $x_i(t_i) + y_i$ (see Proposition 2.5.4 in [2]). Since x_i converges to x_0, the sequence $\{z_i\}$ converges to $x_0(\tau)$, $i \to \infty$.

Passing to a subsequence we obtain

$$v_i \to v \quad \text{as} \quad i \to \infty, \qquad \|v\| = 1.$$

Due to the upper semicontinuity of Clarke's normal cone $N_G(x)$ in the case in which $\operatorname{int} T_G(x) \neq \emptyset$ we obtain $v \in N_G(x_0(\tau))$, which contradicts (3.16). Thus, the inclusion (3.14) is proved.

Decreasing the number $\varepsilon > 0$ if necessary, due to (3.13) we get

$$y(t) \in N^*_{\delta/2}(\tau) \quad \forall\, t:\ |t-\tau| \leq \varepsilon.$$

This inclusion and (3.14) imply

$$\left\langle i\lambda_i \frac{\partial \rho_i}{\partial x}(x_i(t)), y(t) \right\rangle \leq 0 \quad \forall\, t \in I:\ |t-\tau| \leq \varepsilon$$

for all large enough numbers i.

From this fact and the definition of the measure η, we conclude that for any point $\tau \in I$ there is $\varepsilon(\tau)$ such that

$$\int_{I \cap [\tau-\varepsilon(\tau), \tau+\varepsilon(\tau)]} y(t)\, d\eta \leq 0,$$

from where it is not difficult to derive the desired inequality

$$\int_{t_1}^{t_2} y(t)\, d\eta \leq 0.$$

Let us prove the nontriviality condition (f); i.e.,

$$\lambda_0 + \|\psi(t_1)\| + \|\eta\| \neq 0.$$

Indeed, let us assume $\lambda_0 = 0$, $\|\psi(t_1)\| = 0$, $\|\eta\| = 0$. Then from (3.12),

$$i\lambda_i \int_{t_1}^{t_2} \Big\| \frac{\partial \rho_i(x_i(t))}{\partial x} \Big\|\, dt \to 1, i \to \infty. \tag{3.17}$$

Due to the condition $\operatorname{int} T_G(x_0(t)) \neq \emptyset$ there is a continuous vector function g on I and a number $\delta > 0$ such that $\|g(t)\| = 1$, $\{y:\ \|y - g(t)\| \leq 2\delta\} \subset T_G(x_0(t))\ \forall\, t \in I$. Then, obviously,

$$\langle g(t), y \rangle \leq -2\delta \|y\| \quad \forall\, y \in N_G(x_0(t)) \quad \forall\, t \in I. \tag{3.18}$$

We show now that

$$\int_{t_1}^{t_2} g(s)\, d\eta \leq -\frac{\delta}{2} < 0.$$

Let $\delta > 0$; then from (3.14) for any point $\tau \in I$ there is $\varepsilon(\tau) > 0$ such that

$$\frac{\partial \rho_i}{\partial x}(x_i(t)) \in N_{\delta/2}(\tau) \quad \forall\, t \in I \cap [\tau - \varepsilon(\tau), \tau + \varepsilon(\tau)]$$

for all large enough numbers i. Hence, $\forall\, t \in I \cap [\tau - \varepsilon(\tau), \tau + \varepsilon(\tau)]$ there exist $z(t) \in N_G(x_0(\tau))$ with $\|z(t)\| = 1$ and $\xi(t)$ with $\|\xi(t)\| \leq \delta/2$ such that

$$\frac{\partial \rho_i}{\partial x}(x_i(t)) = (z(t) + \xi(t)) \Big\| \frac{\partial \rho_i}{\partial x}(x_i(t)) \Big\|. \tag{3.19}$$

Due to the continuity of g and (3.18) and decreasing $\varepsilon(\tau) > 0$ if necessary, we get

$$\langle g(t), z\rangle \le -\delta\|z\| \quad \forall\, z \in N_G(x_0(\tau)) \quad \forall\, t \in I \cap [\tau - \varepsilon(\tau), \tau + \varepsilon(\tau)].$$

Thus, by (3.19) we obtain

$$\int_{\tau-\varepsilon(\tau)}^{\tau+\varepsilon(\tau)} \left\langle g(s), \frac{\partial \rho_i}{\partial x}(x_i(s))\right\rangle ds \le -\frac{\delta}{2}\int_{\tau-\varepsilon(\tau)}^{\tau+\varepsilon(\tau)} \left\|\frac{\partial \rho_i}{\partial x}(x_i(s))\right\| ds$$

for all large enough numbers i.

Using the compactness of the time interval I, it is not difficult to show the existence of the finite system of disjoint half-open intervals $\{I_j\}$, $j = 1, \dots, N$ such that $I = \cup_{j=1}^{N} I_j$ and for all large enough numbers i

$$\int_{I_j} \left\langle g(s), \frac{\partial \rho_i}{\partial x}(x_i(s))\right\rangle ds \le -\frac{\delta}{2}\int_{I_j} \left\|\frac{\partial \rho_i}{\partial x}(x_i(s))\right\| ds.$$

Hence,

$$\int_{t_1}^{t_2} \left\langle g(s), \frac{\partial \rho_i}{\partial x}(x_i(s))\right\rangle ds \le -\frac{\delta}{2}\int_{t_1}^{t_2} \left\|\frac{\partial \rho_i}{\partial x}(x_i(s))\right\| ds$$

for all large enough numbers i. According to the definition of the measure η and (3.17) we have

$$\int_{t_1}^{t_2} g(s)\, d\eta \le -\frac{\delta}{2} < 0.$$

The nontriviality condition (f) is proved.

Let us denote

$$p_i(t) = H\left(x_i(t), t, \tilde{\psi}_i(t) + \int_{t_1}^{t} i\lambda_i \frac{\partial \rho_i}{\partial x}(x_i(s))\, ds\right),$$

$$g_i(t) = i\lambda_i \rho_i(x_i(t)) + \lambda_i \|x_i(t) - x_0(t)\|^2.$$

Then $h_i(t) = p_i(t) - g_i(t)$ is an absolutely continuous function $\forall\, i = 1, 2, \dots$. Due to the endpoint constraints (3.2) we have

$$p_i(t_1) = H(x_i(t_1), t_1, \tilde{\psi}_i(t_1)) \to H(x_0(t_1), t_1, \psi(t_1)),$$

$$|g_i(t_1)| \le \lambda_i \left(\frac{i}{2^i} + \|x_i(t_1) - x_0(t_1)\|^2\right) \to 0.$$

So, the sequence $\{|h_i(t_1)|\}$ is bounded. Further, due to the Hamiltonian inclusion (3.9) and (3.12) we have $|\dot{h}_i(t)| \le \kappa_2$ $\forall\, t \in I$. Therefore, without loss of generality we can suppose $h_i \rightrightarrows h$ on I, $\dot{h}_i \to \dot{h}$ weakly in $L_1(I)$ as $i \to \infty$, where h is a Lipschitz continuous function on I.

Let $t_* < t_2$. Since

$$\int_{t_1}^{t} d\eta = \lim_{\varepsilon \to 0+} \lim_{i \to \infty} \int_{t_1}^{t+\varepsilon} i\lambda_i \frac{\partial \rho_i}{\partial x}(x_i(s))\, ds \quad \forall\, t < t_2$$

and $g_i(t) \to 0$ a.e. on I, $i \to \infty$ (see the lemma above), one can choose a sequence $\tau_i \to t_* + 0$, $i \to \infty$ such that, passing to a subsequence, we get

$$p_i(\tau_i) = H\biggl(x_i(\tau_i), \tau_i, \tilde{\psi}_i(\tau_i) + \int_{t_1}^{\tau_i} i\lambda_i \frac{\partial \rho_i}{\partial x}(x_i(s))\, ds\biggr)$$

$$\to H\biggl(x_0(t_*), t_*, \psi(t_*) + \int_{t_1}^{t_*} d\eta\biggr), \qquad g_i(\tau_i) \to 0.$$

Then

$$h(t_*) = \lim_{i\to\infty} h_i(\tau_i) = H\biggl(x_0(t_*), t_*, \psi(t_*) + \int_{t_1}^{t_*} d\eta\biggr).$$

Now let us consider the point t_2. Due to the endpoint constraints (3.2), $g_i(t_2) \to 0$, and according to the definition of η

$$h(t_2) = \lim_{i\to\infty} h_i(t_2) = H\biggl(x_0(t_2), t_2, \psi(t_2) + \int_{t_1}^{t_2} d\eta\biggr).$$

Thus, $H(x_0(t), t, \psi(t) + \int_{t_1}^{t} d\eta) = h(t)\ \forall t \in I$. Hence, the function $H(x_0(t), t, \psi(t) + \int_{t_1}^{t} d\eta)$ is absolutely continuous on I.

The jump condition (b) is a consequence of the continuity of h for any $t > t_1$. Let us prove the jump condition (b) for $t = t_1$. We have

$$h_i(t_1) = H(x_i(t_1), t_1), \tilde{\psi}_i(t_1)) - i\lambda_i \rho_i(x_i(t_1))$$

$$-\lambda_i \|x_i(t_1) - x_0(t_1)\|^2 \to H(x_0(t_1), t_1, \psi(t_1)).$$

On the other hand $h_i(t_1) \to h(t_1) = H(x_0(t_1), t_1, \psi(t_1) + \eta(t_1))$, $i \to \infty$. Thus, the jump condition (b) holds for $t = t_1$.

Let us prove the Hamiltonian inclusion (d). As we have proved above, $x_i \rightrightarrows x_0$, $\tilde{\psi}_i \rightrightarrows \psi$, $h_i \rightrightarrows h$ on I, and $\dot{x}_i \to \dot{x}_0$, $\dot{\tilde{\psi}}_i \to \dot{\psi}_i$, $\dot{h}_i \to \dot{h}$ weakly in $L_1(I)$. Due to the definition of the measure η we have

$$\int_{t_1}^{t} d\eta = \lim_{i\to\infty} i\lambda_i \int_{t_1}^{t} \frac{\partial \rho_i}{\partial x}(x_i(s))\, ds \quad \text{a.e. on } I.$$

Hence, due to the upper semicontinuity of Clarke's generalized gradient [2] we obtain

$$\partial H\biggl(x_0(t), t, \psi(t) + \int_{t_1}^{t} d\eta\biggr)$$

$$\supseteq \limsup_{i\to\infty} \partial H\biggl(x_i(t), t, \psi_i(t) + i\lambda_i \int_{t_1}^{t} \frac{\partial \rho_i}{\partial x}(x_i(s))\, ds\biggr) \quad \text{a.e. on } I.$$

Hence, due to the inclusion (3.9) and Mazur's theorem [1]

$$(-\dot{\psi}(t), \dot{h}(t), \dot{x}_0(t)) \in \partial H\biggl(x_0(t), t, \psi(t) + \int_{t_1}^{t} d\eta\biggr) \quad \text{a.e. on } I.$$

The property (d) is proved.

The transversality condition (e) follows directly from (3.10) and upper semicontinuity of the cone of limiting normals and of the set of limiting subgradients [5], [21], [22]. □

4. The conditions of nondegeneracy and pointwise nontriviality. The following notion of the controllability of the reference trajectory at the endpoints plays the central role in our study of the degeneracy phenomenon.

DEFINITION 1. *A trajectory x_0 of the control system* (2.1) *is called controllable at the endpoints (with respect to the state and endpoints constraints) if*

$$H(x_0(t_i), t_i, (-1)^i g) > 0 \tag{4.1}$$

$$\forall\, g \in N_G(x_0(t_i)) \cap [-\hat{N}_{C_i \cap G}(x_0(t_i))], \quad g \neq 0, \quad i = 1, 2.$$

The controllability condition (4.1) is a very natural one. Indeed, let the state constraint set G be regular at the endpoints x_1, x_2. This means that Clarke's tangent cone $T_G(x_i)$ coincides with the contingent cone $K_G(x_i)$, $i = 1, 2$ [2]. Let us suppose that there exists a trajectory x_0 of the control system (2.1) satisfying the state constraints (2.3) and transferring the point x_1 to the point x_2. Then

$$\limsup_{t \xrightarrow{I} t_i} \frac{x(t) - x_i}{t - t_i} \subseteq F(x_i, t_i) \cap (-1)^{i+1} K_G(x_i), \qquad i = 1, 2.$$

Hence, $H(x_i, t_i, (-1)^i g) \geq 0\ \forall\, g \in N_G(x_i)$, $i = 1, 2$. Obviously, if the set G is regular at the endpoints x_i, $i = 1, 2$ then the controllability condition (4.1) is the generic one. This means not only that if there is at least one admissible trajectory x_0 transferring the point x_1 to the point x_2 then using small perturbation $F_\varepsilon(x, t) = F(x, t) + \varepsilon B$, $\varepsilon > 0$ of the right-hand side of the system we can satisfy (4.1) but also that this condition is stable under all small enough perturbations of the right-hand side of the system. Here B denotes the closed unit ball with center at the origin.

THEOREM 2. *Let the trajectory x_0 satisfying the maximum principle* (*Theorem* 1) *be controllable at the endpoints. Then*

$$\lambda_0 + \operatorname{meas}\left\{t :\ \psi(t) + \int_{t_1}^{t} d\eta \neq 0\right\} > 0. \tag{4.2}$$

Proof. Let us suppose that

$$\lambda_0 = 0 \quad \text{and} \quad \psi(t) + \int_{t_1}^{t} d\eta = 0 \quad \text{a.e. on } I.$$

According to the Hamiltonian inclusion we have

$$\|\dot{\psi}(t)\| \leq \kappa_2 \left\| \psi(t) + \int_{t_1}^{t} d\eta \right\| \quad \text{a.e. on } I.$$

Hence, $\psi(t) \equiv \psi(t_1)$, measure η is equal to 0 on (t_1, t_2), and $h_0(t) \equiv 0$. Further, due to the measure sign condition $\eta(t_1) \in N_G(x_1)$. Hence, $\psi(t_1) = -\eta(t_1)$ and due to the transversality condition $\eta(t_1) \in N_G(x_1) \cap [-\hat{N}_{C_1 \cap G}(x_1)]$, where $x_i = x_0(t_1)$, $i = 1, 2$.

It follows from the jump condition that $H(x_1, t_1, -\eta(t_1)) = 0$. We have $\eta(t_1) = 0$ from the previous equality and controllability of the trajectory x_0 at the left endpoint.

Let us consider now the right endpoint. Then we obtain similarly that $\eta(t_2) \in N_G(x_2) \cap (-\hat{N}_{C_2 \cap G}(x_2))$ and $H(x_2, t_2, \eta(t_2)) = 0$. Hence, from the controllability of the trajectory x_0 at the right endpoint we have $\eta(t_2) = 0$.

Thus, $\lambda_0 = 0$, $\psi(t) \equiv 0$, and $\eta = 0$. But this contradicts the nontriviality condition. Hence, the condition (4.2) is proved. □

It turns out that in the case in which the set G is regular [2] at the endpoints, the controllability condition (4.1) is the necessary and sufficient one for the maximum principle (Theorem 1) to be informative.

THEOREM 3. *Let the set G be regular at the endpoints x_1, x_2 of the trajectory x_0 satisfying the maximum principle. Then the nondegeneracy condition* (4.2) *holds for all collections of Lagrange multipliers λ_0, ψ, η if and only if the trajectory x_0 is controllable at the endpoints.*

Proof. Due to Theorem 2 we need to prove only the necessity.

Suppose that there exists a vector $g \in N_G(x_1) \cap [-\hat{N}_{C_1 \cap G}(x_1)]$, $g \neq 0$ such that $H(x_1, t_1, -g) = 0$ (the case of the right endpoint is completely analogous). Then we put $\lambda_0 = 0$, $\psi(t) \equiv g$ and $\eta = -g\delta_{t_1}$. Obviously, all conditions of Theorem 1 are satisfied and $\lambda_0 + \operatorname{meas}\{t : \psi(t) + \int_{t_1}^{t} d\eta \neq 0\} = 0$. □

THEOREM 4. *Let a trajectory x_0 satisfying the maximum principle* (*Theorem* 1) *be controllable at the endpoints and*

$$H(x_0(t), t, (-1)^i g) > 0 \quad \forall\, g \in N_G(x_0(t)) :\ g \neq 0, \tag{4.3}$$

$$\forall\, t \in (t_1, t_2), \qquad i = 1, 2.$$

Then

$$\lambda_0 + \left\| \psi(t) + \int_{t_1}^{t} d\eta \right\| \neq 0 \quad \forall\, t \in (t_1, t_2). \tag{4.4}$$

Proof. Let us consider the set

$$T = \left\{ t \in (t_1, t_2) :\ \psi(t) + \int_{t_1}^{t} d\eta = 0 \right\}.$$

Suppose that (4.4) is violated. Then $\lambda_0 = 0$ and $T \neq \emptyset$. We prove first that T is open. Let $\tau \in T$. We show that there exists a right-half neighborhood O_τ^+ of the point τ such that $O_\tau^+ \subset T$. Let us denote $\xi(t) = \| \int_\tau^t d\eta \|$. Suppose that $\xi(t) \not\equiv 0$ in some right-half neighborhood of τ.

Since $\tau \in T$ and the Hamiltonian inclusion holds, we have

$$\|\dot{\psi}(t)\| \leq \kappa_3(\|\psi(t) - \psi(\tau)\| + \xi(t)),$$

$$|\dot{h}(t)| \leq \kappa_3(\|\psi(t) - \psi(\tau)\| + \xi(t))$$

for all $t \geq \tau$. Therefore, Bellman–Gronwall's inequality leads to

$$\|\psi(t) - \psi(\tau)\| \leq \kappa_4 \int_\tau^t \xi(s)\, ds, \qquad t \geq \tau. \tag{4.5}$$

The bounded function ξ is nonnegative. Hence

$$\int_\tau^\sigma \int_\tau^t \xi(s)\, ds dt \leq \int_\tau^\sigma \xi(s) ds \qquad \forall \sigma \in [\tau, \tau + 1].$$

Due to the assumption $\tau \in T$ we have $h(\tau) = 0$. Therefore, due to the absolute continuity of h, (4.5), and the above inequality we obtain

$$|h(t)| \leq \kappa_5 \int_\tau^t \xi(s)\, ds \qquad \forall\, t \geq \tau. \tag{4.6}$$

Now Bellman–Gronwall's inequality leads to the existence of a sequence $\{t_i\}:\ t_i \to \tau + 0$ as $i \to \infty$ such that

$$\xi(t_i) \neq 0; \qquad \xi(t_i)^{-1} \int_\tau^{t_i} \xi(s)\, ds \to 0, \qquad i \to \infty.$$

Hence, due to (4.5), (4.6) we obtain

$$\xi(t_i)^{-1} h(t_i) \to 0, \qquad \xi(t_i)^{-1} \|\psi(t_i) - \psi(\tau)\| \to 0, \qquad i \to \infty. \tag{4.7}$$

Further, due to the upper semicontinuity of the normal cone $N_G(x)$ and (2.5) there exists $g \in N_G(x_0(\tau))$, $\|g\| = 1$ such that, passing to a subsequence, we obtain

$$\xi(t_i)^{-1} \int_\tau^{t_i} d\eta \to g, \qquad i \to \infty.$$

Due to the assumption $\tau \in T$ we have

$$h(t_i) = H\bigg(x_0(t_i), t_i, \psi(t_i) - \psi(\tau) + \int_\tau^{t_i} d\eta\bigg).$$

Dividing both parts of this equality by $\xi(t_i)$ and passing to the limit, due to (4.7) we obtain

$$H(x_0(\tau), \tau, g) = 0.$$

Thus, we come to a contradiction with assumption (4.3) for $i = 2$.

This contradiction proves that $\xi(t) \equiv 0\ \forall\, t \in O_\tau^+$ for some right-half neighborhood O_τ^+ of τ. Due to (4.4) we have

$$\psi(t) \equiv \psi(\tau) \quad \forall\, t \in O_\tau^+ \Rightarrow \psi(t) + \int_{t_1}^t d\eta \equiv 0 \quad \forall\, t \in O_\tau^+.$$

Hence, $O_\tau^+ \subset T$. Using similar arguments, one can prove the existence of some left-half neighborhood O_τ^- of the point τ such that $O_\tau^- \subset T$.

So, we have proved that the set T is open. Now let us prove the closedness of the set T with respect to interval (t_1, t_2).

Indeed, let a sequence $\{t_i\}$ converge to $\tau \in (t_1, t_2)$, $t_i \in T$, $i = 1, 2, \ldots$. Without loss of generality we can consider two cases: $t_i \to \tau + 0$ and $t_i \to \tau - 0$.

Let $t_i \to \tau + 0$. Then due to the regularity of the measure η we obtain that the function $\psi(t) + \int_{t_1}^t d\eta$ is continuous from the right. Hence,

$$\psi(\tau) + \int_{t_1}^\tau d\eta = \lim_{i \to \infty} \bigg(\psi(t_i) + \int_{t_1}^{t_i} d\eta\bigg) = 0.$$

Thus, $\tau \in T$.

Let $t_i \to \tau - 0$. Then

$$\begin{aligned} \eta(\tau) &= \eta(\tau) + \lim_{i \to \infty} \bigg(\psi(t_i) + \int_{t_1}^{t_i} d\eta\bigg) \\ &= \eta(\tau) + \psi(\tau) + \int_{[t_1, \tau)} d\eta = \psi(\tau) + \int_{t_1}^\tau d\eta. \end{aligned}$$

Due to the continuity of the Hamiltonian $h(\tau) = \lim_{i\to\infty} h(t_i) = 0$. Hence,

$$H(x_0(\tau), \tau, \eta(\tau)) = H\left(x_0(\tau), \tau, \psi(\tau) + \int_{t_1}^{\tau} d\eta\right) = 0.$$

Due to the measure sign condition $\eta(\tau) \in N_G(x_0(\tau))$. Therefore, the condition (4.3) with $i = 1$ gives $\eta(\tau) = 0$. So $\psi(\tau) + \int_{t_1}^{\tau} d\eta = 0$ and $\tau \in T$.

Thus, we have proved that the set T is closed with respect to the interval (t_1, t_2). We have proved above that T is open. The interval (t_1, t_2) is an arcwise connected set. Hence, $T = (t_1, t_2)$. But this contradicts the statement of Theorem 2. Hence, (4.4) is proved. □

We should note that in the problem considered above in Example 2 the state constraint set G is regular at any point and $H(x, g) > 0 \ \forall\, g \neq 0$. Hence, according to Theorem 4 the pointwise nontriviality condition (4.4) holds for any solution of this problem.

5. The classical optimal control problem. Now let us consider the classical optimal control problem for systems described by ordinary differential equations with control parameters. This problem is formulated as follows:

$$\dot{x} = f(x, t, u), \qquad u \in U; \tag{5.1}$$

$$x(t_1) = x_1, \qquad x(t_2) = x_2, \qquad p = (t_1, t_2, x_1, x_2); \tag{5.2}$$

$$k_1(p) \leq 0, \qquad k_2(p) = 0; \tag{5.3}$$

$$g(x(t)) \leq 0 \quad \forall\, t \in I = [t_1, t_2]; \tag{5.4}$$

$$J(u, p) = k_0(p) \to \min. \tag{5.5}$$

Here $x \in R^n$; U is a given closed subset of R^k; smooth vector functions k_1, k_2, g take values in spaces of dimensions d_1, d_2, and m, respectively; and the scalar function k_0 is also supposed to be smooth. As usual, we assume that the set of admissible controls consists of all bounded measurable functions u, each of them defined on its own time interval I such that $u(t) \in U$ a.e. on I.

Before formulating the maximum principle for the problem (5.1)–(5.5) let us introduce some notations and assumptions.

We define the small Lagrangian l and Hamilton–Pontryagin's function $\mathcal{H}$ as follows:

$$l(p, \lambda) = \lambda_0 k_0(p) + \langle \lambda_1, k_1(p) \rangle + \langle \lambda_2, k_2(p) \rangle,$$

$$\mathcal{H}(x, t, u, \psi) = \langle f(x, t, u), \psi \rangle.$$

Here $\lambda = (\lambda_0, \lambda_1, \lambda_2) \in R^{d_1+d_2+1}$, $p = (t_1, t_2, x_1, x_2) \in R^{2n+2}$, $\psi \in R^n$.

The Hamiltonian associated with the control system (5.1) is defined by

$$H(x, t, \psi) = \sup_{u\in U} \langle f(x, t, u), \psi \rangle.$$

Let a pair x_0, u_0 be a solution of the problem (5.1)–(5.5) and $I_0 = [t_{1,0}, t_{2,0}]$, $p_0 = (t_{1,0}, t_{2,0}, x_{1,0}, x_{2,0})$ correspond to it. We suppose that $t_{1,0} < t_{2,0}$ and the following assumptions are fulfilled:

(H1) The vectors $\left\{\frac{\partial g_j(x_0(t))}{\partial x}\right\}_{j:\, g_j(x_0(t))=0}$ are linearly independent $\forall\, t \in I_0$; $g = (g_1, \dots, g_m)$.

(H2) rank $\frac{\partial k_2}{\partial p}(p_0) = d_2$.

$$\exists\, y \in R^{d_2} :\ \frac{\partial k_2}{\partial p}(p_0)y = 0, \qquad \left\langle \frac{\partial k_{1,i}}{\partial p}(p_0), y \right\rangle < 0,$$

where $k_{1,i}(p_0)$ are all the coordinates of the vector $k_1(p_0)$ such that $k_{1,i}(p_0) = 0$.

(H3) The state constraints (5.4) are in accordance with the endpoint constraints (5.3) in some neighborhood of the ends of x_0. This means that there exists $\varepsilon > 0$ such that

$$\{p :\ \|p - p_0\| \le \varepsilon,\ k_1(p) \le 0,\ k_2(p) = 0,\ k_0(p) \le k_0(p_0)\}$$

$$\subset \{p :\ g(x_1) \le 0,\ g(x_2) \le 0\}.$$

(H4) The sets $F(x,t) = \{f(x,t,u) :\ u \in U\}$ are convex for all x, t.

The main distinction of the problem (5.1)–(5.5) from (2.1)–(2.4) consists of the smooth parametric form of the differential, endpoint, and state constraints.

It follows from (H1) that the state constraints set $G = \{x \in R^n :\ g(x) \le 0\}$ is regular at $x_0(t)$ $\forall\, t \in I_0$ and

$$N_G(x_0(t)) = \operatorname{cone}\left\{\frac{\partial g_j}{\partial x}(x_0(t))\right\}_{j:\, g_j(x_0(t))=0} \qquad \forall\, t \in I_0.$$

Analogously, (H2) provides the regularity of the endpoint constraint set $P = \{p \in R^{2n+2} :\ k_1(p) \le 0,\ k_2(p) = 0\}$ at p_0 and

$$N_P(p_0) = \Bigg\{z \in R^{2n+2} :\ z = \sum_{i=1}^{d_1} \alpha_i \frac{\partial k_{1,i}(p_0)}{\partial p}$$

$$+ \sum_{i=1}^{d_2} \beta_i \frac{\partial k_{2,i}(p_0)}{\partial p},\ \beta \in R^1,\ \alpha_i \ge 0,\ \sum_{i=1}^{d_1} \alpha_i k_{1,i}(p_0) = 0\Bigg\}.$$

Note that (H3) holds automatically, if some neighborhood of p_0 in P is contained in $\{z = (t_1, t_2, x_1, x_2) \in R^{2n+2} :\ x_i \in G,\ i = 1, 2\}$. In this case the normal cones to the sets P and $P_G = \{p \in P :\ x_i \in G,\ i = 1, 2\}$ are the same.

The following result is the modified version of Pontryagin's maximum principle.

THEOREM 5 (maximum principle). *Let the pair x_0, u_0 solve the problem* (5.1)–(5.5). *Then there exist a vector $\lambda = (\lambda_0, \lambda_1, \lambda_2)$: $\lambda_0 \in R^1$, $\lambda_i \in R^{d_i}$, $i = 1, 2$; a left-continuous vector function ψ of bounded variation; and a bounded nonnegative m-dimensional regular Borel measure η on I_0 such that following conditions hold:*

(a) $$\psi(t) = -\frac{\partial l}{\partial x_2}(p_0, \lambda) + \int_t^{t_{2,0}} \frac{\partial \mathcal{H}}{\partial x}(x_0(s), s, u_0(s), \psi(s))\, ds$$

$$- \int_t^{t_{2,0}} \frac{\partial g}{\partial x}(x_0(s))\, d\eta \quad \forall\, t \in I_0;$$

(b) $\mathcal{H}(x_0(t), t, u_0(t), \psi_0(t)) = H(x_0(t), t, \psi(t))$ *a.e. on* I_0;

(c) *the function* $h(t) = H(x_0(t), t, \psi(t))$ *is absolutely continuous on* I_0 *and*

$$\frac{dh(t)}{dt} = \frac{\partial \mathcal{H}}{\partial t}(x_0(t), t, u_0(t), \psi(t)) \quad \textit{a.e. on } I_0;$$

(d) $H(x_0(t), t, \psi(t)) = H\left(x_0(t), t, \psi(t) + \dfrac{\partial g}{\partial x}(x_0(t))\eta(t)\right)\ \forall\, t \in I_0$;

(e) $\psi(t_{1,0}) = \dfrac{\partial l}{\partial x_1}(p_0, \lambda)$,

$$-h(t_{1,0}) = \frac{\partial l}{\partial t_1}(p_0, \lambda), \qquad h(t_{2,0}) = \frac{\partial l}{\partial t_2}(p_0, \lambda);$$

(f) $\operatorname{supp}\eta_i \subset \{t \in I_0 :\ g_i(x_0(t)) = 0\}$, $i = 1, 2, \dots, m$;
(g) $\lambda_0 \geq 0$, $\lambda_1 \geq 0$, $\langle k_1(p_0), \lambda_1\rangle = 0$;
(h) $\|\lambda\| + \|\eta\| \neq 0$.

Note that if assumption (H3) is violated, then the endpoint constraint set P should be considered in intrinsic form. In this case the assertion of Theorem 5 is valid with the transversality condition analogous to the one in Theorem 1 (see also [19]). The smooth nonautonomous problem with state constraint $g(x, t) \leq 0$ can be reduced to the autonomous one standardly [25] by introducing an additional variable $\dot{x}^{n+1} = 1$.

DEFINITION 2. *A trajectory* x_0 *is called controllable at the endpoints*[3] *(with respect to the state and endpoint constraints) if*

$$H(x_0(t_{i,0}), t_{i,0}, (-1)^i z_i) > 0$$

$$\forall\, z_i \neq 0 : \exists z = (z_1, z_2) \in N \cap D, \qquad i = 1, 2;$$

$$N = N_G(x_0(t_{1,0})) \times N_G(x_0(t_{2,0})), \qquad D = \Big\{(z_1, z_2) \in R^{2n} : (z_1, z_2)$$

$$= -\frac{\partial}{\partial(x_1, x_2)}(\langle\lambda_1, k_1(p_0)\rangle + \langle\lambda_2, k_2(p_0)\rangle),\ \lambda_i \in R^{d_i},\ i = 1, 2;\ \lambda_1 \geq 0\Big\}.$$

THEOREM 6. *Let pair* x_0, u_0 *satisfy the maximum principle. Then for all collections of Lagrange multipliers*

$$\lambda_0 + \operatorname{meas}\{t \in I_0 :\ \psi(t) \neq 0\} > 0$$

if and only if the trajectory x_0 *is controllable at the endpoints.*

THEOREM 7. *Let pair* x_0, u_0 *satisfy the maximum principle and the trajectory* x_0 *be controllable at the endpoints. Let* $\forall\, t \in (t_{1,0}, t_{2,0})\ \exists\, u_i(t) \in U$:

$$(-1)^i \left\langle \frac{\partial g_j}{\partial x}(x_0(t)), f(x_0(t), t, u_i(t)) \right\rangle > 0$$

$$\forall\, j :\ g_j(x_0(t)) = 0, \qquad i = 1, 2.$$

[3]This notion of controllability at the endpoints is a little bit weaker than the one introduced in [9].

Then

$$\lambda_0 + \|\psi(t)\| \neq 0 \quad \forall\, t \in (t_{1,0}, t_{2,0}).$$

The proofs of Theorems 5–7 are analogous to the ones of Theorems 1–4 above. Some details of these proofs concerning time-transversality conditions and problems formulated in the class of generalized controls can be found in [14].

Finally, let us consider the case in which maximum principle degenerates. In this case under some controllability conditions it is possible to guarantee the existence of at least one nontrivial collection of Lagrange multipliers.

THEOREM 8. *Let the pair x_0, u_0 satisfy the maximum principle* (*Theorem* 5) *and* $N = N_G(x_0(t_{1,0})) \times N_G(x_0(t_{2,0}))$. *Suppose that* $\forall\, z = (z_1, z_2) \in N \cap \operatorname{Im} \left[\frac{\partial k_2(p_0)}{\partial(x_1, x_2)}\right]^*$, $z \neq 0$ $\exists i = 1, 2$ *such that the following condition holds:*

$$H(x_0(t_{i,0}), t_{i,0}, (-1)^i z_i) > 0. \tag{5.6}$$

Then there exists at least one nontrivial collection of Lagrange multipliers λ, ψ, η (*i.e., such that* $\lambda_0 + \operatorname{meas}\{t :\ \psi(t) \neq 0\} > 0$) *corresponding to* x_0.

Proof. Let $\lambda = (\lambda_0, \lambda_1, \lambda_2)$, ψ, η be a collection of Lagrange multipliers corresponding to x_0.

If (4.2) holds, then λ, ψ, η are desired Lagrange multipliers.

Suppose now that $\lambda_0 = 0$, $\psi(t) = 0$ $\forall\, t \in (t_{1,0}, t_{2,0})$. Then $\eta = \eta_1 \delta_{t_{1,0}} + \eta_2 \delta_{t_{2,0}}$ ($\eta_j = \eta(t_{j,0})$, $j = 1, 2$) and the conditions of the maximum principle lead to

$$\frac{\partial l}{\partial x_j}(p_0, \lambda) = -\frac{\partial g}{\partial x}(x_0(t_{j,0}))\eta_j, \qquad j = 1, 2; \tag{5.7}$$

$$H(x_0(t_{j,0}), t_{j,0}, (-1)^j \frac{\partial g}{\partial x}(x_0(t_{j,0}))\eta_j) = 0, \qquad j = 1, 2. \tag{5.8}$$

Consider the following auxiliary mathematical programming problem:

$$\chi(p) = \langle g(x_1), \eta_1 \rangle + \langle g(x_2), \eta_2 \rangle \to \max,$$

$$k_0(p) \leq k_0(p_0), \qquad k_1(p) \leq 0, \qquad k_2(p) = 0.$$

Due to (H3) p_0 is a local solution of this problem. Hence, by virtue of the Lagrange multiplier rule there exist $\gamma \geq 0$, $\beta = (\beta_0, \beta_1, \beta_2) \in R^{d_1 + d_2 + 1}$ such that

$$\gamma \frac{\partial g}{\partial x}(x_{j,0})\eta_j = \frac{\partial l}{\partial x_j}(p_0, \beta), \qquad j = 1, 2;$$

$$\beta_0 \geq 0, \quad \beta_1 \geq 0, \quad \beta_0 k_0(p_0) = 0; \quad \langle \beta_1, k_1(p_0) \rangle = 0; \quad \gamma + \|\beta\| \neq 0.$$

If $\gamma = 0$, then $\beta \neq 0$ and, hence, p_0 satisfies the Lagrange multiplier rule for the problem

$$k_0(p) \to \min, \tag{5.9}$$

$$k_1(p) \leq 0, \qquad k_2(p) = 0. \tag{5.10}$$

In this case by virtue of (H2) $\beta_0 > 0$. Hence, $\tilde{\lambda} = (\beta_0, \beta_1, \beta_2)$, $\tilde{\psi}(t) = 0$, $\tilde{\eta} = 0$ is a nontrivial collection of Lagrange multipliers corresponding to x_0.

Suppose that $\gamma \neq 0$. Then, setting $\gamma = 1$, due to (5.7) we obtain

$$\frac{\partial g}{\partial x}(x_{j,0})\eta_j = \frac{\partial l}{\partial x_j}(p_0, \beta) = -\frac{\partial l}{\partial x_j}(p_0, \lambda), \qquad j = 1, 2. \tag{5.11}$$

Hence,

$$\frac{\partial l}{\partial x_j}(p_0, \lambda + \beta) = 0, \qquad j = 1, 2.$$

If $\lambda + \beta \neq 0$, then p_0 satisfy the Lagrange multipliers rule for (5.9), (5.10). Hence, due to (H2), $\beta_0 > 0$ and $\tilde{\lambda} = (\beta_0, \lambda_1 + \beta_1, \lambda_2 + \beta_2)$, $\tilde{\psi}(t) \equiv 0$, $\tilde{\eta} = 0$ is a nontrivial collection of Lagrange multipliers corresponding to x_0.

If $\lambda + \beta = 0$, then $\beta_0 = 0$, $\lambda_1 = -\beta_1 = 0$, $\lambda_2 = -\beta_2 \neq 0$. Hence, by (5.11) and (H2),

$$z = (z_1, z_2) = \left(\frac{\partial g}{\partial x}(x_{1,0})\eta_1, \frac{\partial g}{\partial x}(x_{2,0})\eta_2\right) = \left[\frac{\partial k_2(p_0)}{\partial(x_1, x_2)}\right]^* \beta_2 \neq 0.$$

Due to (5.8) this equality contradicts assumptions (5.6) of the theorem. □

Let us consider now the problem of Example 1. In this case the optimal trajectory $x_0(t) \equiv 0$ is not controllable at the left endpoint and any corresponding collection of Lagrange multipliers is trivial. The question arises as how to modify it to exhibit the degeneracy phenomenon. In our opinion, if the optimal trajectory fails to be controllable at the endpoints the class of admissible Lagrange multipliers should be generalized. Some results in this direction can be found in [15], [17]. Here we restrict ourselves to an illustrative example.

Example 3. Following a suggestion of Maurer we introduce a small parameter $\alpha < 0$ in the problem of Example 1:

$$\begin{aligned}
&\dot{x}_1 = tu, \qquad |u| \leq 1,\\
&\dot{x}_2 = u;\\
&x_1(0) = 0, \qquad x_2(0) = 0, \qquad x_1(1) \geq \alpha;\\
&x_1(t) \geq \alpha \quad \forall\, t \in [0, 1];\\
&J(u(\cdot)) = x_2(1) \to \min.
\end{aligned}$$

Then the optimal pair x^α, u^α is the following:

$$x_1^\alpha(t) = \begin{cases} -\dfrac{t^2}{2}, & t \in [0, \sqrt{-2\alpha}];\\ -\alpha, & t \in [\sqrt{-2\alpha}, 1]; \end{cases} \qquad x_2^\alpha(t) = \begin{cases} -t, & t \in [0, \sqrt{-2\alpha}];\\ -\sqrt{-2\alpha}, & t \in [\sqrt{-2\alpha}, 1]; \end{cases}$$

$$u^\alpha(t) = \begin{cases} -1 & \text{a.e. on } [0, \sqrt{-2\alpha}];\\ 0 & \text{a.e. on } [\sqrt{-2\alpha}, 1]. \end{cases}$$

Let us apply Theorem 5. The easy calculations give the Lagrange multipliers λ_0^α, λ_1^α,

ψ^α, η^α corresponding to x^α, u^α:

$$\lambda_0^\alpha = 1, \qquad \lambda_1^\alpha = 1;$$

$$\psi_1^\alpha(t) = \begin{cases} \dfrac{1}{\sqrt{-2\alpha}}, & t \in [0, \sqrt{-2\alpha}]; \\ 1/t, & t \in [\sqrt{-2\alpha}, 1]; \end{cases} \qquad \psi_2^\alpha(t) = -1;$$

$$d\eta^\alpha = 1/t^2 dt, \qquad t \in (\sqrt{-2\alpha}, 1];$$

$$\operatorname{supp} \eta^\alpha = (\sqrt{-2\alpha}, 1].$$

In the limit as $\alpha \to -0$, we obtain

$$\lambda_0^\alpha \to \lambda_0 = 1, \qquad \lambda_1^\alpha \to \lambda_1 = 1;$$

$$\psi^\alpha(t) \to \psi(t) = \left(\frac{1}{t}, -1\right) \quad \forall\, t \in (0, 1];$$

$$\eta^\alpha \to \eta : \ \operatorname{supp} \eta = (0, 1], \qquad d\eta = \frac{1}{t^2} dt.$$

The obtained collection λ_0, λ_1, ψ, η satisfies all the conditions of Theorem 5 except the conditions for ψ to be a function of bounded variation and the measure η to be bounded.

6. Bibliographical notes. The first version of Pontryagin's maximum principle for problems with state constraints was obtained by Gamkrelidze in 1959 (see [25], [28]) under a priori assumptions on an optimal trajectory. (It is supposed that the reference trajectory consists of the finite number of boundary and interior arcs and corresponding control is regular.) This maximum principle contains no measures and is the nondegenerate one.

The present paper deals with the degeneracy phenomenon arising in a framework of the Dubovitskii–Milutin version of Pontryagin's maximum principle proven in 1963 [29] for trajectories without any a priori assumptions (see also [1], [3]).

The first conditions which guarantee the nondegeneracy of this maximum principle for classical optimal control problem with state constraints were obtained in [16], [18], and [9]. A maximum principle with pointwise nontriviality conditions of the type as in Theorem 7 above was obtained in [16], [18] under a controllability assumption along the reference trajectory. The maximum principle with zero atomic components of the measure at the endpoints was obtained in [9] under the controllability condition at the endpoints similar to (4.1). These results showed the importance of assumptions of controllability and accordance of state and endpoint constraints for strengthened nontriviality conditions. We should note that the assumption of accordance for state and endpoint constraints were used but not formulated explicitly in [16].

The results obtained in [9], [16] were generalized and strengthened in [8], [10], [11], [14].

In [12], [13] the maximum principle with new time-transversality conditions was obtained. It was proved that this maximum principle holds with nontriviality condition (4.2) under controllability conditions at the endpoints similar to (4.1).

The results obtained in [12], [13] are close to the ones obtained in [8], [9], [10], but the methods used are essentially different. As in present paper a perturbation

technique is used in [12], [13] to derive a new version of the maximum principle without any controllability assumptions and then controllability conditions are used to prove the strengthened nontriviality conditions, whereas in [8], [9], [10] the controllability conditions are used from the beginning to obtain the nondegenerate maximum principle.

Nondegenerate first-order necessary optimality conditions for differential inclusions problem were obtained in [15] in the case when the support function of the right-hand side is smooth in x (these results are analogous to [12], [13]). Moreover, [15] contains the maximum principle with unbounded measures for trajectories which are weakly controllable at the endpoints. These results were generalized to a more natural class of problems with locally Lipschitz support function in [17] (this paper contains main technical devices used in present investigation).

The present paper summarizes and synthesizes the essence of previous works [8], [9], [10], [11], [12], [13], [14], [15], [16], [17], [18]. The principal distinction of the result obtained here is the following. The maximum principle for problems with state constraints is obtained with additional jump condition at the endtimes without any a priori assumptions. This condition is a new one (even in the smooth case of classical optimal control problem) and enables one to describe the degeneracy phenomenon.

The paper [30] deals with the degeneracy phenomenon for the classical optimal control problem on the fixed time interval $I = [t_1, t_2]$. The state constraint set is given by the time-dependent inequality $g(x,t) \le 0$, the left endpoint x_1 is fixed on the state boundary and the right endpoint constraint is given by the inequality. The right-hand side f of the control system satisfies (H4) and is measurable in t.

The main result of [30, Proposition 2.1] asserts that if there is an admissible control u' such that

$$\lim_{\varepsilon\to 0+} \operatorname*{ess\,sup}_{t_1\le s<t_1+\varepsilon} \left\langle \frac{\partial g}{\partial x}(x_1,t_1), (f(x_1,s,u'(s)) - f(x_1,s,u_0(s))) \right\rangle < 0, \tag{6.1}$$

then the maximum principle [2] holds with the following nontriviality condition:

$$\lambda_0 + \|\lambda_1\| + \left| \int_{(t_1,t_2]} d\eta \right| \ne 0. \tag{6.2}$$

Here u_0 is the optimal control; λ_0, λ_1 are the Lagrange multipliers corresponding to the functional and right endpoint inequality constraint, respectively; η is the measure arising in the maximum principle.

This assertion follows from [12], [13] (see Proposition), and also from Theorem 5 above if (H3) is valid and the function f is smooth in t. To our knowledge it is a new one in the measurable in t case.

Consider condition (6.1). If the function f is continuous in t uniformly in u, the state constraint is autonomous, and the left endpoint x_1 is fixed, then (6.1) is more restrictive than (4.1) for $i = 1$ (or similar controllability condition at the left endpoint introduced earlier in [9]). Indeed, (4.1) follows from (6.1) in this case. On the other hand (6.1) is an a priori assumption on the behavior of an optimal control u_0 near t_1 while (4.1) is an assumption on the controllability of the system at the endpoints and is the checkable one. Condition (6.1) is equivalent to (4.1) under the additional assumption that the reference trajectory lies on the state boundary in some right neighborhood $O^+_{t_1}$ of t_1 [30] or that the corresponding control u_0 is continuous on $O^+_{t_1}$.

Some normality conditions (normality means $\lambda_0 > 0$) are also suggested in [30]. Note that a sufficient condition for $\lambda_0 > 0$ has been obtained earlier by Maurer [31] by expressing a regularity condition in optimization in terms of control problems.

Acknowledgment. We are very grateful to the anonymous referees for helpful suggestions.

GENERALIZED CONTROLLED INVARIANCE FOR NONLINEAR SYSTEMS *

H. J. C. HUIJBERTS†, C. H. MOOG‡, AND R. ANDIARTI§

Abstract. A general setting is developed which describes controlled invariance for nonlinear control systems and which incorporates the previous approaches dealing with controlled invariant (co -) distributions. A special class of controlled invariant subspaces, called controllability cospaces, is introduced. These geometric notions are shown to be useful for deriving a (geometric) solution to the dynamic disturbance decoupling problem and for characterizing the so-called fixed dynamics for noninteracting control. These fixed dynamics are a central issue in studying noninteracting control with stability. The class of quasi-static state feedbacks is used.

Key words. nonlinear systems, controlled invariance, quasi-static state feedback

1. Introduction.

During the last two decades, nonlinear control theory was developed thanks to the increasing number of researchers involved in this area. A main goal of the research in the 1980s was the generalization of the so-called geometric approach which proved to be particularly efficient for linear time-invariant systems (see [48], [4] for an overview). In this linear theory, controlled invariance plays a fundamental role in both static and dynamic feedback control problems. The goal of generalizing the linear approach to the nonlinear case was only *partially* reached: the situation is quite well understood when regular static feedback synthesis problems are considered; limits of the standard (geometric) notions became clear at the end of the 1980s in the study of such problems as

- control problems involving dynamic feedback,
- the inversion of a nonlinear system, the definition of its rank, and so on.

Alternative (algebraic) tools have been developed from 1985 on [19] and a definition of the rank of a system was provided by a differential algebraic theory [20].

The goal of this paper is to introduce a generalized notion of controlled invariance. The motivation is to clarify the geometric structure of nonlinear systems and to develop a geometric framework to tackle synthesis problems via dynamic feedback. In particular, we answer the two following questions:

Question 1. Does there exist any *geometric* solution to the dynamic disturbance decoupling problem (DDDP)?

*Received by the editors August 17, 1995; accepted for publication (in revised form) April 1, 1996. This research was performed in part under the auspices of the GR Automatique of CNRS, France.

Question 2. Does there exist a *geometric* structure of nonlinear systems which displays the rank, the so-called decoupling zeros (under dynamic feedback), and the like?

The answer to such questions is of major importance since these questions motivate the search for geometric solutions to any other synthesis problem which involves dynamic feedback. Such solutions will contribute to the completion of the extension to nonlinear systems of the linear geometric theory [48], [4].

DDDP, considered in Question 1, is a special control problem involving dynamic feedback and was first stated and studied in [26], [25], [44], where an (algebraic) solution was provided based on the inversion algorithm. Also, a geometric interpretation was given by using (nonintrinsic) standard controlled invariant (co-)distributions on an extended state space and then projecting these (co-)distributions on the original state space to obtain intrinsic objects. Parallel results can be found in [42], [41], [27]. The generalization of controlled invariance which is introduced in this paper is shown to give a *natural* geometric solution to the DDDP, i.e., without taking recourse to nonintrinsic objects defined on an extended state space that are rendered intrinsic after projection. Of course, it goes without saying that the objects defined in this paper and the geometric objects defined in [26], [25], [44] carry the same information concerning the solvability of the DDDP. Recall that in the special case of linear systems, DDDP is equivalent to DDP (static feedback disturbance decoupling problem). The state of the art is summarized in Table 1, where notations are borrowed from [48], [29], [38].

One contribution of the paper is the completion of Table 1.

Question 2 originated in [30]. Standard controlled invariant distributions cannot be used to characterize the rank of a system in a straightforward manner. The rank was introduced in [19] based on a differential algebraic analysis. A geometric interpretation of the rank may be found in [45], based on controllability distributions defined on a certain extended state space. Contributions which parallel the geometric and algebraic approaches can be found in [49].

Generalized controlled invariance introduced in this paper is shown to give a natural and intrinsic geometric characterization of the rank. It further displays new (geometric) structures of a nonlinear system. We focus on the structure related to the so-called decoupling zeros (under quasi-static feedback [12], [13], [14]). We summarize once again the state of the art in Table 2, and we borrow the notations from the given references.

$u = \alpha(x, v, \dot{v}, \ldots, v^{(k)})$	?

In this paper, Table 2 is completed thanks to the controllability cospaces introduced in what follows. Moreover, throughout the text, the new geometric structures are compared with the standard ones. Both embody different and complementary properties.

The study of controlled invariance for nonlinear systems of the form

$$\dot{x} = f(x) + g(x)u, \tag{1}$$

where $x \in \mathbb{R}^n$, $u \in \mathbb{R}^m$ was initiated in [8]. In this paper invariants were sought under feedback transformations of the form

$$u = \alpha(x) + v. \tag{2}$$

Later on, controlled invariance was tackled by various authors [31], [24], [36], [37]. The group of feedback transformations acting on (1) was enlarged to transformations of the form

$$u = \alpha(x) + \beta(x)v, \tag{3}$$

where $\beta(x)$ is square and locally invertible. These works yielded the definition of a controlled invariant distribution. The key was found for the solution of synthesis problems, such as the disturbance decoupling problem and the noninteracting control problem, via regular (or invertible) static state feedback (see [29], [38] for an overview). The study of controlled invariance under the class of feedbacks (3) remains active; see [10], [22], [11], [43], [49] for recent contributions. A special class of controlled invariant distributions is given by controllability distributions [39], [33], [34]. They became a basic tool for solving the noninteracting control problem with or without stability. Indeed, the controllability distributions allow us to characterize the fixed dynamics of the decoupled system via static feedback [32].

In this paper, a generalized notion of controlled invariance is introduced by allowing an enlarged class of feedback transformations acting on (1), namely the class of quasi-static feedbacks $u = \alpha(x, v, \dot{v}, \ldots, v^{(k)})$. This class of feedbacks describes intrinsic properties of the system with respect to the solvability of synthesis problems via dynamic feedback as disturbance decoupling or noninteracting control. In this sense, quasi-static feedbacks are considered a mathematical tool rather than a new class of feedbacks to be used in practical applications. The various contributions to the study of controlled invariance are summarized in Table 3. This table will be completed in this paper. Preliminary results can be found in [28].

Quasi-static feedback has been used in [40] to derive canonical forms (see also [46]) and was formalized in [12], [13], [14], where the input-output decoupling problem under quasi-static state feedback was solved as well. Practical applications of quasi-static feedback can be found in [16].

In what follows we consider a nonlinear control system (1), where the entries of $f(x)$ and $g(x)$ are meromorphic functions from $\mathbb{R}^n$ to $\mathbb{R}$. Recall that a meromorphic function is the quotient of two analytic functions. This allows us to derive properties of the system under consideration on an open and dense subset of the state space. Different classes of systems can also be treated:

- C^∞ systems, where all results should be explicitly stated as local results, valid around a *regular* point, where regularity is to be defined in an appropriate way, depending on the problem under consideration;
- analytic systems, in which case the results are also valid on some open dense submanifold of the state space.

In the rest of this paper we use mainly a function field formalism. It is assumed that rank $g(x) = m$ and that $n \geq 1$.

The organization of the paper is as follows. In section 2 we define the generalized notion of invariance with respect to the dynamics (1). Section 3 is devoted to controlled invariance and related properties. A geometric necessary and sufficient condition for the existence of a solution to DDDP is obtained. Controllability cospaces and their applications as well as the fixed modes or decoupling zero dynamics under quasi-static feedback are treated in section 4.

2. Invariant subspaces. We follow the notations and setting of [18]. Let $\mathcal{K}$ denote the field of meromorphic functions of $\{x, u^{(k)}, k \geq 0\}$. $\mathcal{E}$ is the formal vector space spanned by $\{d\eta \mid \eta \in \mathcal{K}\}$ over $\mathcal{K}$. The notation dx stands for $\{dx_1, \ldots, dx_n\}$ and $du^{(k)}$ for $\{du_1^{(k)}, \ldots, du_m^{(k)}\}$. Let $\mathcal{X} := \text{span}_{\mathcal{K}}\{dx\}$ and $\mathcal{U} := \text{span}_{\mathcal{K}}\{du, d\dot{u}, \ldots, du^{(k)} \mid k \geq 0\}$.

Throughout this paper we employ the following terminology. A vector $\omega \subset \mathcal{E}$ is called *exact* if there exists a $\phi \in \mathcal{K}$ such that $\omega = d\phi$. A subspace $\Omega \subset \mathcal{E}$ of dimension r is called *exact* if there exist functions $\phi_1, \ldots, \phi_r \in \mathcal{K}$ such that $\Omega = \text{span}_{\mathcal{K}}\{d\phi_1, \ldots, d\phi_r\}$. Given subspaces $\Omega_1 \subset \Omega_2 \subset \mathcal{E}$, (Ω_2/Ω_1) is said to be *exact* if there exist functions $\phi_1, \ldots, \phi_d \in \mathcal{E}$, with $d = \dim(\Omega_2) - \dim(\Omega_1)$, such that $\Omega_2 = \Omega_1 \oplus \text{span}_{\mathcal{K}}\{d\phi_1, \ldots, d\phi_d\}$, or, in other words, (Ω_2/Ω_1) is isomorphic to an exact subspace of $\mathcal{E}$. Consider a subspace $\Omega \subset \mathcal{E}$. Then clearly $\{0\} \subset \Omega$ is exact. Furthermore, if $\Omega_1 \subset \Omega$, $\Omega_2 \subset \Omega$ are exact, then $\Omega_1 + \Omega_2 \subset \Omega$ is also exact. Hence there exists a unique maximal exact subspace in Ω.

Consider a subspace $\Omega \subset \mathcal{X}$. Define

$$\dot{\Omega} = \text{span}_{\mathcal{K}}\{\dot{\omega} \mid \omega \in \Omega\}, \tag{4}$$

where $\omega = \sum_{i=1}^n \omega_i(x, u, \dot{u}, \ldots, u^{(n-1)})dx_i$ and time derivation is defined by

$$\dot{\omega} = \sum_{i=1}^n (\omega_i d\dot{x}_i + \dot{\omega}_i dx_i).$$

Thus $\dot{\omega} \in \text{span}_{\mathcal{K}}\{dx, du\}$.

DEFINITION 2.1. *A subspace $\Omega \subset \mathcal{X}$ is said to be invariant with respect to* (1) *if*

$$\dot{\Omega} \subset \Omega + \text{span}_{\mathcal{K}}\{du\}. \tag{5}$$

Remark 2.2. Let $\mathcal{K}_k$ be the field of meromorphic functions of $x, u, \ldots, u^{(k)}$ and define

$$\mathcal{K}' = \bigcup_{k \in \mathbb{N}} \mathcal{K}_k.$$

Then (5) is equivalent to the statement that $(\Omega + \text{span}_{\mathcal{K}'}\{du^{(k)} \mid k \geq 0\})$ is a differential vector space, with the derivation defined above.

Example 2.3. Let Ω be an integrable invariant codistribution for (1) in the sense of, e.g., [29], [38], and let (x_1, x_2) be a local system of coordinates such that $\Omega = \text{span}\{dx_1\}$. Then in the coordinates (x_1, x_2), (1) takes the form (cf. [29], [38])

$$\begin{aligned} \dot{x}_1 &= f_1(x_1) + g_1(x_1)u, \\ \dot{x}_2 &= f_2(x_1, x_2) + g_2(x_1, x_2)u. \end{aligned} \tag{6}$$

Interpreting Ω as a subspace of $\text{span}_{\mathcal{K}}\{dx\}$, we then obtain

$$\dot{\Omega} = \text{span}_{\mathcal{K}}\{d\dot{x}_1\} = \text{span}_{\mathcal{K}}\{d(f_1(x_1) + g_1(x_1)u)\} \subset \Omega + \text{span}_{\mathcal{K}}\{du\}. \tag{7}$$

Hence Ω is invariant in the sense of Definition 2.1.

When a given subspace is not invariant, it is interesting to know whether or not there exists a feedback transformation that renders it invariant. This is the topic of the next section.

3. Controlled invariant subspaces. In this section we define and characterize the controlled invariance of subspaces $\Omega \subset \mathcal{X}$ under quasi-static state feedback. In subsection 3.1 we first define quasi-static state feedback, based on [12], [13], [14]. In subsection 3.2 we give a definition of controlled invariance under quasi-static state feedback. In subsection 3.3 some properties of controlled invariance under regular static state feedback (3) are given. Conditions for controlled invariance of subspaces $\Omega \subset \mathcal{X}$ under quasi-static state feedback are investigated in subsection 3.4. We make some remarks about the smallest controlled invariant subspace containing some given subspace in subsection 3.4.2. As shown in section 3.5, this subspace allows us to characterize the solvability conditions of the DDDP.

3.1. Quasi-static state feedback. Consider the nonlinear system (1). A *generalized static state feedback* for (1) is a feedback of the form

$$u = \phi(x, v, \ldots, v^{(r)}), \tag{8}$$

where $v \in \mathbb{R}^m$ denotes the new controls. Let $\mathcal{K}_v$ denote the field of meromorphic functions of $\{x, \{v^{(k)} \mid k \geq 0\}\}$, and define the formal vector space $\mathcal{E}_v := \text{span}_{\mathcal{K}_v}\{d\xi \mid \xi \in \mathcal{K}_v\}$. As in [12], [13], we define the following *filtrations* [3] of $\mathcal{E}_v$:

$$\begin{aligned} \mathcal{V}_{-1} &:= \text{span}_{\mathcal{K}_v}\{dx\}, \\ \mathcal{V}_k &:= \text{span}_{\mathcal{K}_v}\{dx, dv, \ldots, dv^{(k)}\} \quad (k \geq 0), \end{aligned} \tag{9}$$

$$\begin{aligned} \mathcal{U}_{-1} &:= \text{span}_{\mathcal{K}_v}\{dx\}, \\ \mathcal{U}_k &:= \text{span}_{\mathcal{K}_v}\{dx, d\phi, \ldots, d\phi^{(k)}\} \quad (k \geq 0). \end{aligned} \tag{10}$$

The filtrations $\mathcal{U}_k$ and $\mathcal{V}_k$ are said to have *bounded difference* [3] if there exists an $s \in \mathbb{N}$ such that for all $k \geq -1$

$$\begin{aligned} \mathcal{U}_k &\subset \mathcal{V}_{k+s}, \\ \mathcal{V}_k &\subset \mathcal{U}_{k+s}. \end{aligned} \tag{11}$$

DEFINITION 3.1 ([12], [13], [14]). *u given by* (8) *is said to be a* quasi-static state feedback *for* (1) *if the filtrations $\mathcal{U}_k$ and $\mathcal{V}_k$ have bounded difference.*

Remark 3.2. It is easily verified that a regular static state feedback (3) is a quasi-static state feedback.

The following result is also easily proven.

PROPOSITION 3.3. *Let u given by* (8) *be a quasi-static state feedback. Then there locally exists a function $\psi(x, u, \dots, u^{(r)})$ such that*

$$v = \psi(x, u, \dots, u^{(r)}). \qquad \square \tag{12}$$

Remark 3.4. In [17] a definition of quasi-static state feedback is given for generalized systems (systems of the form $\dot{x} = f(x, u, \dot{u}, \dots, u^{(s)})$, $y = h(x, u, \dot{u}, \dots, u^{(s)})$). This definition is the same as Definition 3.1 with the extra requirement that x is a state (in the sense of [17]) of the closed-loop system.

3.2. Controlled invariance. Consider the control system (1) together with a quasi-static state feedback (8) and define $\mathcal{V} := \operatorname{span}_{\mathcal{K}_v}\{dv^{(k)} \mid k \geq 0\}$. We denote by $\Theta^{(k)}$ the time derivative of order k of Θ along the trajectories of the system (1) and by $\Theta^{[k]}$ the time derivative of order k of Θ along the trajectories of the closed-loop system (1), (8). We will write $\dot{\Theta}$ for $\Theta^{(1)}$.

DEFINITION 3.5. *A subspace $\Omega \subset \mathcal{X}$ is said to be controlled invariant for* (1) *if there exists a quasi-static state feedback* (8) *such that for* (1), (8) *one has*

$$\Omega^{[1]} \subset \Omega + \mathcal{V}. \tag{13}$$

The definition of controlled invariance given in Definition 3.5 is in accordance with the well-known definition of a controlled invariant codistribution. Recall from [29], [38], e.g., that a codistribution Ω is controlled invariant if there exists a regular static state feedback (3) such that

$$\begin{aligned} \mathcal{L}_{f+g\alpha}\Omega &\subset \Omega, \\ \mathcal{L}_{(g\beta)_{*i}}\Omega &\subset \Omega \quad (i = 1, \dots, m). \end{aligned} \tag{14}$$

Let $\omega \in \Omega$. Then for (1), (3) we have

$$\omega^{[1]} = \mathcal{L}_{f+g\alpha}\omega + \sum_{i=1}^{m}(v_i \mathcal{L}_{(g\beta)_{*i}}\omega + \langle \omega, (g\beta)_{*i}\rangle dv_i) \in \Omega + \mathcal{V} \tag{15}$$

when we interpret Ω as a subspace of $\operatorname{span}_{\mathcal{K}}\{dx\}$.

Example 3.6. Consider a nonlinear system given by

$$\dot{x}_1 = u_1, \quad \dot{x}_2 = x_3 u_1 + x_2, \quad \dot{x}_3 = u_2.$$

Let $\Omega = \operatorname{span}_{\mathcal{K}}\{u_1 dx_3 + dx_2\}$ and

$$u_1 = v_1, \quad u_2 = (v_2 - x_3(\dot{v}_1 + v_1) - x_2)/v_1,$$

where $v = (v_1, v_2)^T$ is the new input. This is a quasi-static feedback since

$$v_1 = u_1, \quad v_2 = u_1 u_2 + x_3(\dot{u}_1 + u_1) + x_2.$$

This feedback renders Ω invariant, since we have

$$\Omega^{[1]} = \operatorname{span}_{\mathcal{K}_v}\{\dot{v}_1 dx_3 + v_1 d((v_2 - x_3(\dot{v}_1 + v_1) - x_2)/v_1) + d(x_3 v_1 + x_2)\} \subset \mathcal{V}.$$

The following theorem gives a necessary condition for controlled invariance. For (1), let $\mathcal{G}$ denote the distribution spanned by the input vector fields. Define the subspace $\mathcal{G}^\perp \subset \mathcal{X}$ by

$$\mathcal{G}^\perp = \{\omega \in \mathcal{X} \mid \langle \omega, g \rangle \equiv 0 \ \forall g \in \mathcal{G}\}. \tag{16}$$

THEOREM 3.7. *Let $\Omega \subset \mathcal{X}$. Then Ω is controlled invariant only if*

$$\widehat{(\dot{\Omega \cap \mathcal{G}^\perp})} \subset \Omega. \tag{17}$$

Proof. By definition of $\mathcal{G}^\perp$, $\widehat{(\dot{\Omega \cap \mathcal{G}^\perp})} \subset \mathcal{X}$. Controlled invariance of Ω then implies (17). □

Remark 3.8. Let Ω be an integrable codistribution. Using (15), it may be shown that (17) (with Ω interpreted as a subspace of $\mathcal{X}$) is equivalent to the well-known conditions $\mathcal{L}_f(\Omega \cap \mathcal{G}^\perp) \subset \Omega$, $\mathcal{L}_{g_i}(\Omega \cap \mathcal{G}^\perp) \subset \Omega \, (i = 1, \ldots, m)$ for controlled invariance of Ω (cf. [29], [38]).

3.3. Characterization of controlled invariant subspaces under regular static state feedback. In this subsection we investigate under what conditions a subspace $\Omega \subset \mathcal{X}$ is controlled invariant under regular static state feedback. Recall from subsection 3.2 that a regular static state feedback is a special sort of quasi-static state feedback. A first result is the following.

PROPOSITION 3.9. *Consider a d-dimensional subspace $\Omega \subset \mathcal{X}$. Assume that Ω is controlled invariant under a quasi-static state feedback of the form $u = \phi(x, v)$. Then Ω admits a basis $\omega_1, \ldots, \omega_d$ with*

$$\omega_i = \sum_{j=1}^{n} \omega_{ij}(x) dx_j. \tag{18}$$

Proof. Assume that $\Omega = \operatorname{span}_{\mathcal{K}}\{\tilde{\omega}_1, \ldots, \tilde{\omega}_d\}$, with

$$\tilde{\omega}_i = \sum_{j=1}^{n} \tilde{\omega}_{ij}(x, u) dx_j \qquad \square \tag{19}$$

Let $A(x, u)$ be the matrix with entries $\tilde{\omega}_{ij}$ $(i = 1, \ldots, d; j = 1, \ldots, n)$. Viewing Ω as a linear subspace (over $\mathcal{K}$) of $\mathcal{X} \oplus \operatorname{span}_{\mathcal{K}}\{du\}$, it may be characterized by

$$\Omega = \operatorname{rowspan}_{\mathcal{K}} \begin{pmatrix} A(x,u) & 0 \end{pmatrix}. \tag{20}$$

Similarly, $\Omega + \dot{\Omega}$ is characterized by

$$\Omega + \dot{\Omega} = \operatorname{rowspan}_{\mathcal{K}} \begin{pmatrix} A(x,u) & 0 \\ B(x,u,\dot{u}) & (Ag)(x,u) \end{pmatrix}, \tag{21}$$

where

$$B(x,u,\dot{u}) = \sum_{i=1}^{n} \frac{\partial A}{\partial x_i}(x,u)\dot{x}_i(x,u) + \sum_{j=1}^{m} \frac{\partial A}{\partial u_j}\dot{u}_j + A(x,u)\left(f_x(x) + \sum_{i=1}^{n} \frac{\partial g}{\partial x_i} u\right), \tag{22}$$

with f_x the Jacobian of f. Since Ω is rendered invariant via $u = \phi(x, v)$ there exist matrices $P(x, v, \dot{v})$ and $Q(x, v)$ such that

$$B(x, \phi, \dot{\phi})dx + (Ag)(x, \phi)d\phi = P(x, v, \dot{v})A(x, \phi)dx + Q(x, v)dv \tag{23}$$

or, equivalently,

$$\begin{aligned} B(x,\phi,\dot{\phi}) &= P(x,v,\dot{v})A(x,\phi) - (Ag)(x,\phi)\phi_x(x,v), \\ (Ag)(x,\phi)\phi_v(x,v) &= Q(x,v). \end{aligned} \tag{24}$$

Since $\phi_v(x,v)$ is invertible, this yields

$$B(x,\phi,\dot{\phi}) = P(x,v,\dot{v})A(x,\phi) - Q(x,v)\phi_v(x,v)^{-1}\phi_x(x,v). \tag{25}$$

Since $u = \phi(x,v)$ is a quasi-static state feedback, by Proposition 3.3 there locally exists a function $\psi(x,u)$ such that $\phi(x,\psi(x,u)) = u$. This yields in particular that

$$\psi_x(x,u) = -\phi_v(x,\psi(x,u))^{-1}\phi_x(x,\psi(x,u)).$$

Hence (25) yields

$$B(x,u,\dot{u}) = \tilde{P}(x,u,\dot{u})A(x,u) + \tilde{Q}(x,u)\psi_x(x,u), \tag{26}$$

where $\tilde{P}(x,u,\dot{u}) = P(x,\psi(x,u),\dot{\psi}(x,u,\dot{u}))$ and $\tilde{Q}(x,u) = Q(x,\psi(x,u))$. Taking partial derivatives with respect to $\dot{u}_i$, we obtain

$$\frac{\partial A}{\partial u_i} = \frac{\partial \tilde{P}}{\partial \dot{u}_i}A(x,u) \quad (i = 1,\dots,m). \tag{27}$$

Obviously,

$$\frac{\partial^2 \tilde{P}}{\partial \dot{u}_i \partial \dot{u}_j} = 0 \quad (i,j = 1,\dots,m).$$

Hence there exist matrices $R_i(x,u)$ $(i = 1,\dots,m)$ such that

$$\frac{\partial A}{\partial u_i} = R_i(x,u)A(x,u). \tag{28}$$

Using arguments from the theory of linear time-varying ordinary differential equations this yields that $A(x,u)$ is of the form

$$A(x,u) = \Phi(x,u)\Psi(x),$$

where $\Phi(x,u)$ is a square invertible matrix. Hence

$$\Omega = \mathrm{rowspan}_{\mathcal{K}}\,(A(x,u)\ \ 0) = \mathrm{rowspan}_{\mathcal{K}}\,(\Psi(x)\ \ 0)\,, \tag{29}$$

which establishes our claim. If $\Omega = \mathrm{rowspan}_{\mathcal{K}}\left(A(x,u,\dots,u^{(\ell)})\ \ 0\right)$ with $\ell > 1$, the claim is established by using the same arguments together with an induction argument. □

From the above proposition it follows that the set of subspaces $\Omega \subset \mathcal{X}$ that are controlled invariant under a quasi-static state feedback $u = \phi(x,v)$ may be identified with the set of "classical" controlled invariant codistributions. The following theorem gives a characterization of controlled invariance in our generalized framework.

THEOREM 3.10. *Let $\Omega \subset \mathcal{X}$ be a subspace such that*

$$(\Omega + \dot{\Omega})/\Omega \text{ is exact} \tag{30}$$

and admits a basis satisfying (18). *Then* Ω *is controlled invariant under a quasi-static state feedback* $u = \phi(x, v)$ *if and only if*

$$\widehat{(\dot{\Omega \cap \mathcal{G}^\perp})} \subset \Omega. \tag{31}$$

Moreover, if the conditions above are satisfied, then $\phi(x, v)$ *rendering* Ω *invariant may be chosen of the form* (3).

Proof. The necessity was proven in Theorem 3.7. To establish the sufficiency, assume that (31) holds. Note that $\Omega + \dot{\Omega} \subset \operatorname{span}_{\mathcal{K}}\{dx, du\}$. Let $\tilde{\Omega} \subset \mathcal{X}$ be such that $\Omega = (\Omega \cap \mathcal{G}^\perp) \oplus \tilde{\Omega}$. Assume that $\dot{\tilde{\Omega}} \cap \mathcal{X} \neq \{0\}$. This implies that there is an $\tilde{\omega} \in \tilde{\Omega}$, $\tilde{\omega} \neq 0$, such that $\dot{\tilde{\omega}} \in \mathcal{X}$ and hence $\tilde{\omega} \in (\Omega \cap \mathcal{G}^\perp)$, which gives a contradiction. Thus

$$\dot{\tilde{\Omega}} \cap \mathcal{X} = \{0\}. \tag{32}$$

By (30), there exists $v_1(x, u)$ such that

$$\Omega + \dot{\Omega} = \Omega \oplus \operatorname{span}_{\mathcal{K}}\{dv_1\}. \tag{33}$$

Since (31) and (32) hold, we must have that $(\partial v_1/\partial u)$ has full row rank. Then there exists a function $v_2(u)$ such that $(\partial v/\partial u)$ is square and invertible, where $v = (v_1^T\ v_2^T)^T$. By (33) we now have that

$$\Omega^{[1]} \subset \Omega + \mathcal{V}. \tag{34}$$

Moreover, since $(\partial v/\partial u)$ is invertible, there exists a $\psi(x, v)$ such that $u = \psi(x, v)$. Hence ψ defines a quasi-static state feedback and thus Ω can be rendered invariant via quasi-static state feedback. Since we are dealing with a control system (1) that is affine in u, it is easily seen that v can be taken affine in u and thus ψ can be taken affine in v. This implies that Ω can be rendered invariant via a static state feedback (3). □

Remark 3.11.

(i) If Ω is exact, then clearly also $(\Omega + \dot{\Omega})/\Omega$ is exact. Hence the set of subspaces $\Omega \subset \mathcal{X}$ such that $(\Omega + \dot{\Omega})/\Omega$ is exact incorporates the standard integrable codistributions.

(ii) The exactness of $(\Omega + \dot{\Omega})/\Omega$ is not necessary for controlled invariance. This can be seen from the following counter example. Take the system $\dot{x}_1 = u_1$, $\dot{x}_2 = u_2$, $\dot{x}_3 = 0$, and $\Omega = \operatorname{span}_{\mathcal{K}}\{dx_1 + x_2 dx_3\}$. It is straightforward to check that $\widehat{(\dot{\Omega \cap \mathcal{G}^\perp})} \subset \Omega$ and that $(\Omega + \dot{\Omega})/\Omega$ is not exact. However, with the regular static state feedback $u_1 = v_1 - x_3 v_2$, $u_2 = v_2$ we obtain

$$\dot{\Omega} = \operatorname{span}_{\mathcal{K}}\{dv_1 - x_3 dv_2\} \subset \Omega + \mathcal{V}$$

and hence Ω is controlled invariant.

3.4. Some characterizations of controlled invariance. In this subsection, conditions are derived for controlled invariance of a subspace under a quasi-static state feedback.

3.4.1. The general case: A sufficient condition. Let us consider a general subspace $\Omega \subset \mathcal{X}$. Define by induction

$$\begin{aligned} \hat{\Omega}_0 &:= 0, \\ \Omega_0 &:= \Omega, \\ \hat{\Omega}_{k+1} &:= \text{maximal exact subspace in } \frac{\Omega_k + \dot{\Omega}_k}{\Omega_k}, \\ \Omega_{k+1} &:= \Omega_k + \hat{\Omega}_{k+1}. \end{aligned}$$

Furthermore, define

$$k^* := \max\{k \geq 1 \mid \dim(\hat{\Omega}_k) > \dim(\hat{\Omega}_{k-1})\}.$$

THEOREM 3.12. *Let $\Omega \subset \mathcal{X}$. If*

(i) $(\widehat{\dot{\Omega \cap \mathcal{G}^\perp}}) \subset \Omega$,

(ii) $\dfrac{\Omega_{k^*-1} + \dot{\Omega}_{k^*-1}}{\Omega_{k^*-1}}$ *is exact,*

then Ω is controlled invariant for (1).

Proof. From the definition of k^* there exist vector-valued $dv_1, \ldots, dv_{k^*}$ in $\mathcal{E}$, where each dv_i is nonempty, such that

$$\begin{aligned}
\hat{\Omega}_1 &= \operatorname{span}_{\mathcal{K}}\{dv_1\} \subset \frac{\Omega_0 + \dot{\Omega}_0}{\Omega_0}, \\
\hat{\Omega}_2 &= \operatorname{span}_{\mathcal{K}}\{d\dot{v}_1, dv_2\} \subset \frac{\Omega_1 + \dot{\Omega}_1}{\Omega_1}, \\
&\vdots \\
\hat{\Omega}_{k^*} &= \operatorname{span}_{\mathcal{K}}\{dv_1^{(k^*-1)}, dv_2^{(k^*-2)}, \ldots, dv_{k^*}\} \subset \frac{\Omega_{k^*-1} + \dot{\Omega}_{k^*-1}}{\Omega_{k^*-1}}.
\end{aligned} \tag{35}$$

Note that from (ii) the last inclusion in (35) is in fact an equality. We now have

$$\begin{aligned}
\dot{\Omega} &\subset \Omega_0 + \hat{\Omega}_1 + \dot{\Omega}_0 + \dot{\hat{\Omega}}_1 = \Omega_1 + \dot{\Omega}_1 \subset \cdots \\
&\subset \Omega_{k^*-1} + \dot{\Omega}_{k^*-1} = \Omega_{k^*-1} + \operatorname{span}_{\mathcal{K}}\{dv_1^{(k^*-1)}, \ldots, dv_{k^*}\} \\
&\subset \Omega + \operatorname{span}_{\mathcal{K}}\{dv^{(k)} \mid k \geq 0\}.
\end{aligned} \tag{36}$$

It remains to be shown that v defines a quasi-static state feedback. From the above construction, one has

$$\begin{aligned}
v_1 &= \phi_1(x, u), \\
v_2 &= \phi_2(x, v_1, \dot{v}_1, u), \\
&\vdots \\
v_{k^*} &= \phi_{k^*}(x, \{v_i^{(j)} \mid 1 \leq i \leq k^* - 1, 0 \leq j \leq k^* - i\}, u).
\end{aligned} \tag{37}$$

From (i), $(\partial(\phi_1, \ldots, \phi_{k^*})/\partial u)$ has full row rank on an open and dense subset of $\mathbb{R}^n \times \mathbb{R}^{(k^*-1)(k^*-i+1)} \times \mathbb{R}^m$. By the implicit function theorem, for every point of this open and dense subset there exists a neighborhood of this point and a function ψ such that $u = \psi(x, v, \dot{v}, \ldots, v^{(k^*)})$. By applying this feedback, one has

$$\Omega^{[1]} \subset \Omega + \operatorname{span}_{\mathcal{K}}\{dv^{(k)} \mid k \geq 0\}. \qquad \square$$

Remark 3.13. Theorem 3.12 gives only sufficient conditions for the controlled invariance of a subspace $\Omega \subset \mathcal{X}$. In Theorem 3.7 it was shown that (i) is also a necessary condition. But the condition (ii) is not. This is shown by the following example.

Example 3.14 (see [30]). We consider a nonlinear system on $\mathbb{R}^4$ with three inputs u_1, u_2, u_3 given by

$$\dot{x}_1 = u_1, \quad \dot{x}_2 = x_4 + u_2, \quad \dot{x}_3 = x_3 u_1 + u_2, \quad \dot{x}_4 = u_3.$$

Let $\Omega = \text{span}_{\mathcal{K}}\{dx_1 - u_1 dx_3, dx_4\}$. Then Ω is not exact, and $\dot{\Omega}$ is given by

$$\dot{\Omega} = \text{span}_{\mathcal{K}}\{(1 - u_1 x_1)du_1 - u_1 du_2 - \dot{u}_1 dx_3 - u_1^2 dx_1, du_3\}.$$

Ω is rendered invariant by $u_1 = v_1$, $u_2 = -\frac{\dot{v}_1}{v_1^2}x_1 - v_1 x_1 + v_2$, and $u_3 = v_3$. One obtains $k^* = 1$, but $\frac{\Omega + \dot{\Omega}}{\Omega}$ is not exact.

3.4.2. The smallest controlled invariant subspace containing a given subspace. Given a subspace $\Pi \subset \mathcal{X}$, it is unclear whether (or under what conditions) there exists a smallest controlled invariant subspace containing Π. This is due to the fact that for two controlled invariant subspaces $\Omega_1, \Omega_2 \subset \mathcal{X}$, we do not necessarily have that $\Omega_1 \cap \Omega_2$ is controlled invariant, so that we cannot use the "standard" arguments (as in, e.g., [48], [29], [38]). In this subsection we will give some comments on this question.

We will use the following notation. Given a subspace $\Pi \subset \mathcal{X}$, we define

$$\Pi_* := \mathcal{X} \cap (\Pi + \Pi^{(1)} + \cdots + \Pi^{(n-1)}). \tag{38}$$

In what follows, we will need the following lemma.

LEMMA 3.15. *Consider a subspace $\Omega \subset \mathcal{X}$ satisfying $(\Omega \cap \mathcal{G}^{\perp}) = \{0\}$. Then we have for all $k \in \mathbb{N}$:*

$$\mathcal{X} \cap (\Omega^{(1)} + \cdots + \Omega^{(k)}) = \{0\}. \tag{39}$$

Proof. Let $d := \dim(\Omega)$, and let $\omega_1, \ldots, \omega_d$ be a basis of Ω, with

$$\omega_i = \sum_{j=1}^{n} \omega_{ij}(x, u, \ldots, u^{(r)})dx_j \quad (i = 1, \ldots, d). \tag{40}$$

Let $A(x, u, \ldots, u^{(r)})$ be the (d, n)-matrix with entries ω_{ij} $(i = 1, \ldots, d; j = 1, \ldots, n)$. Since $\omega_1, \ldots, \omega_d$ forms a basis of Ω, the matrix A has full row rank over $\mathcal{K}$. We may now characterize Ω by

$$\Omega = \text{rowspan}_{\mathcal{K}}(A(x, u, \ldots, u^{(r)})\ 0\ \cdots\ 0), \tag{41}$$

while $\Omega^{(k)}$ $(k = 1, 2, \ldots)$ may be characterized by

$$\Omega^{(k)} = \text{rowspan}_{\mathcal{K}}(X_{k0}\ X_{k1}\ \cdots\ X_{kk-1}\ (Ag)\ 0\ \cdots\ 0) \tag{42}$$

for certain matrices $X_{k0}, \ldots, X_{kk-1}$. Now assume that (Ag) is not right invertible over $\mathcal{K}$. This implies that there exists a nonzero row vector $\eta^T := (\eta_1 \cdots \eta_d)$ such that

$$\eta^T(Ag) = 0. \tag{43}$$

This gives that $\omega := \sum_{j=1}^{d} \eta_j \omega_j$ satisfies

$$\langle \omega, \tau \rangle = 0 \quad (\forall \tau \in \mathcal{G}), \tag{44}$$

which contradicts the fact that $(\Omega \cap \mathcal{G}^{\perp}) = \{0\}$. Hence we have that (Ag) is right invertible over $\mathcal{K}$. Next, let $\omega \in \mathcal{X} \cap (\Omega^{(1)} + \cdots + \Omega^{(k)})$ $(k \in \{1, 2, \ldots\})$. Since $\omega \in (\Omega^{(1)} + \cdots + \Omega^{(k)})$, we may represent ω by a row vector

$$(\eta_1^T\ \cdots\ \eta_k^T) \begin{pmatrix} X_{10} & (Ag) & 0 & \cdots & \cdots & 0 \\ X_{20} & X_{21} & (Ag) & \cdots & \cdots & 0 \\ \vdots & \vdots & \vdots & \ddots & & \vdots \\ \vdots & \vdots & \vdots & & \ddots & \vdots \\ X_{k0} & X_{k1} & X_{k2} & \cdots & X_{kk-1} & (Ag) \end{pmatrix}.$$

The fact that $\omega \in \mathcal{X}$ implies that necessarily

$$(\eta_1^T \ \cdots \ \eta_k^T) \begin{pmatrix} (Ag) & 0 & 0 & \cdots & \cdots & 0 \\ X_{21} & (Ag) & 0 & \cdots & \cdots & 0 \\ \vdots & \vdots & \vdots & \ddots & & \vdots \\ \vdots & \vdots & \vdots & & \ddots & \vdots \\ X_{k1} & X_{k2} & X_{k3} & \cdots & X_{kk-1} & (Ag) \end{pmatrix} = 0,$$

and thus

$$\eta_i^T (Ag) = 0,$$

which give $\eta_i^T = 0$, since (Ag) is right invertible. Thus $\omega = 0$, which establishes our claim. □

PROPOSITION 3.16. *Let $\Omega \subset \mathcal{X}$ be a subspace satisfying $(\widehat{\Omega \cap \mathcal{G}^\perp}) \subset \Omega$. Then*

$$\Omega_* = \Omega.$$

Proof. Let $\tilde{\Omega}$ be such that

$$\Omega = (\Omega \cap \mathcal{G}^\perp) \oplus \tilde{\Omega}. \tag{45}$$

By hypothesis we have

$$(\widehat{\Omega \cap \mathcal{G}^\perp}) \subset \Omega. \tag{46}$$

We now prove by induction that we have

$$(\Omega \cap \mathcal{G}^\perp)^{(k)} \subset \Omega + \tilde{\Omega}^{(1)} + \cdots + \tilde{\Omega}^{(k-1)} \quad (k = 1, 2, \ldots). \tag{47}$$

By (46), we have that (47) holds for $k = 1$. Next assume that (47) holds for $k = 1, \ldots, \ell - 1$. Then

$$\begin{aligned} (\Omega \cap \mathcal{G}^\perp)^{(\ell)} &= ((\Omega \cap \mathcal{G}^\perp)^{(\ell-1)})^{(1)} \overset{\text{IH}}{\subset} (\Omega + \tilde{\Omega}^{(1)} + \cdots + \tilde{\Omega}^{(\ell-2)})^{(1)} \\ &= (\Omega^{(1)} + \tilde{\Omega}^{(2)} + \cdots + \tilde{\Omega}^{(\ell-1)}) \overset{(45)}{=} ((\widehat{\Omega \cap \mathcal{G}^\perp}) + \tilde{\Omega}^{(1)} + \cdots + \tilde{\Omega}^{(\ell-1)}) \\ &\overset{(46)}{\subset} (\Omega + \tilde{\Omega}^{(1)} + \cdots + \tilde{\Omega}^{(\ell-1)}), \end{aligned}$$

which establishes (47). Using (47) and the modular distributive rule (see, e.g., [48, section 0.3]) we obtain

$$\begin{aligned} \Omega_* &= \mathcal{X} \cap (\Omega + \Omega^{(1)} + \cdots + \Omega^{(n-1)}) \\ &= \mathcal{X} \cap (\Omega + (\Omega \cap \mathcal{G}^\perp)^{(1)} + \tilde{\Omega}^{(1)} + \cdots + (\Omega \cap \mathcal{G}^\perp)^{(n-1)} + \tilde{\Omega}^{(n-1)}) \\ &\subset \mathcal{X} \cap (\Omega + \tilde{\Omega}^{(1)} + \cdots + \tilde{\Omega}^{(n-1)}) = \Omega + \mathcal{X} \cap (\tilde{\Omega}^{(1)} + \cdots + \tilde{\Omega}^{(n-1)}). \end{aligned} \tag{48}$$

Since by definition of $\tilde{\Omega}$ we have that $(\tilde{\Omega} \cap \mathcal{G}^\perp) = \{0\}$, we obtain from (48) and Lemma 3.15 that

$$\Omega_* \subset \Omega. \tag{49}$$

Furthermore, we have by definition of Ω_* that

$$\Omega \subset \Omega_*. \tag{50}$$

Hence we have that $\Omega_* = \Omega$, which establishes our claim. □

COROLLARY 3.17. *Consider a subspace $\Pi \subset \mathcal{X}$, and let $\Omega \subset \mathcal{X}$ be a controlled invariant subspace containing Π. Then $\Pi_* \subset \Omega$.*

Proof. Using the definition of Π_*, the fact that $\Pi \subset \Omega$ and combining the results of Theorem 3.7 and Proposition 3.16, we obtain

$$\Pi_* = \mathcal{X} \cap (\Pi + \Pi^{(1)} + \cdots + \Pi^{(n-1)}) \subset \mathcal{X} \cap (\Omega + \Omega^{(1)} + \cdots + \Omega^{(n-1)}) = \Omega_* = \Omega,$$

which establishes our claim. □

The subspace Π_* defined in (38) is, by Corollary 3.17, a candidate for being the smallest controlled invariant subspace containing Π. If Π is exact, it can be shown that indeed it *is*. This may be shown in the following way. Let $r = \dim \Pi$ and choose meromorphic functions $h_1(x), \ldots, h_r(x)$ such that $\Pi = \operatorname{span}_{\mathcal{K}}\{dh_1, \ldots, dh_r\}$. Next consider the system

$$\begin{aligned} \dot{x} &= f(x) + g(x)u, \\ y &= h(x). \end{aligned} \tag{51}$$

Then for this system, $\Pi_* = \mathcal{X} \cap \mathcal{Y}$, where $\mathcal{Y} = \operatorname{span}_{\mathcal{K}}\{dy, \ldots, dy^{(n-1)}\}$. (The subspace $\mathcal{X} \cap \mathcal{Y}$ was introduced in [9] for the study of the minimal order input-output decoupling problem.) If the system (51) is right invertible, one can construct a quasi-static state feedback which renders Π_* invariant by using the construction in [41]. If (51) is not right invertible, the same construction, together with Lemma 1 from [35], may be used to show that Π_* is controlled invariant. Summarizing, we have the following result.

THEOREM 3.18. *Consider a subspace $\Pi \subset \mathcal{X}$ which is exact. Then $\Pi_* := \mathcal{X} \cap (\Pi + \cdots + \Pi^{(n-1)})$ is the smallest controlled invariant subspace containing Π.* □

An application of the subspace $\Omega_* = \mathcal{X} \cap \mathcal{Y}$ is given in Section 3.5, where we consider the DDDP.

It has been shown that a "standard" controlled invariant codistribution is a controlled invariant subspace in the sense of Definition 3.5. If Δ^* denotes the largest controlled invariant distribution contained in $\ker dh$, then $\Delta^{*^\perp} \cap \mathcal{X}$ is a controlled invariant subspace containing the differential of the output. Since $\Omega_* = \mathcal{X} \cap \mathcal{Y}$ is the smallest controlled invariant subspace containing $\operatorname{span}_{\mathcal{K}}\{dy\}$, one has $\Delta^{*^\perp} \cap \mathcal{X} \supset \Omega_*$. These two different geometric structures are displayed in the lattice diagram in Figure 1.

In the special case of linear systems, this lattice diagram is simplified since $\Delta^{*^\perp} \cap \mathcal{X} = \Omega_*$.

3.4.3. A special case. Let us consider a subspace $\Omega \subset \mathcal{X}$ such that

$$\Omega = \Omega \cap \mathcal{G}^\perp + \Phi_*, \tag{52}$$

where Φ is an exact subspace of $\mathcal{X}$.

PROPOSITION 3.19. *Let $\Omega \subset \mathcal{X}$ satisfy* (52); *then Ω is controlled invariant if and only if*

$$\widehat{(\Omega \cap \mathcal{G}^\perp)^{\cdot}} \subset \Omega. \tag{53}$$

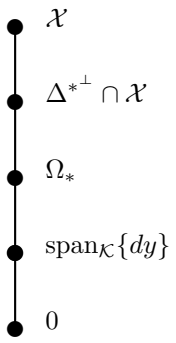

FIG. 1. *Lattice diagram: (geometric) structure of nonlinear systems.*

Proof. By Theorem 3.7 we only need to show the sufficiency. Clearly Φ_* is controlled invariant (see Theorem 3.18). Hence there exists a quasi-static feedback (8) such that

$$\Phi_*^{[1]} \subset \Phi_* + \mathcal{V}.$$

Now (53) implies that

$$\Omega^{[1]} \subset \Omega + \mathcal{V},$$

and hence Ω is controlled invariant. □

The following proposition gives conditions for the existence of a subspace $\Phi \subset \mathcal{X}$ such that (52) holds.

PROPOSITION 3.20. *Let $\Omega \subset \mathcal{X}$ be a subspace such that* (53) *holds. Then there exists an exact subspace $\Phi \subset \Omega$ satisfying* (52) *if and only if*

$$\Omega = \Omega \cap \mathcal{G}^\perp + \hat{\Phi}_*, \tag{54}$$

where $\hat{\Phi}$ is the largest exact subspace in Ω.

Proof. Assume that (54) holds. Taking $\Phi = \hat{\Phi}$, we then have (52). Conversely, assume that there exists an exact subspace $\Phi \subset \mathcal{X}$ such that (52) holds. Clearly $\Phi_* \subset \hat{\Phi}_*$. Now $\hat{\Phi} \subset \Omega$ implies by Proposition 3.16 that $\hat{\Phi}_* \subset \Omega$. Thus

$$\Omega = \Omega \cap \mathcal{G}^\perp + \Phi_* \subset \Omega \cap \mathcal{G}^\perp + \hat{\Phi}_* \subset \Omega.$$

Hence (54) is verified. □

3.5. Dynamic disturbance decoupling. A fundamental application of controlled invariance is disturbance decoupling [48], [29], [38]. In this section, generalized controlled invariance is shown to yield a geometric condition that characterizes the solvability of the dynamic feedback disturbance decoupling problem (DDDP). DDDP is stated as follows.

Consider a perturbed system Σ_q given by

$$\Sigma_q : \begin{cases} \dot{x} &= f(x) + g(x)u + p(x)q, \\ y &= h(x), \end{cases} \tag{55}$$

where q represents a disturbance. Find, if possible, a dynamic state feedback such that the disturbance q does not affect the output y.

Let $\mathcal{P}$ denote the distribution spanned by the disturbance vector fields. Define the subspace $\mathcal{P}^\perp$ by

$$\mathcal{P}^\perp = \{\omega \in \mathcal{X} \mid \langle \omega, p \rangle = 0 \ \forall p \in \mathcal{P}\}. \tag{56}$$

The following result gives a necessary and sufficient condition for DDDP to be solvable.

THEOREM 3.21. *DDDP is solvable if and only if there exists a controlled invariant subspace Ω such that*

$$\mathrm{span}_{\mathcal{K}}\{dy\} \subset \Omega \subset \mathcal{P}^\perp. \tag{57}$$

Proof. From Theorem 2.3 in [41] it follows that DDDP is solvable if and only if it is solvable by quasi-static state feedback. Thus, to prove Theorem 3.21, it suffices to show that the DDP is solvable by quasi-static state feedback.

Sufficiency. Controlled invariance of Ω implies that there exists a quasi-static state feedback $u = \phi(x, v, \ldots, v^{(r)})$ such that

$$\Omega^{[1]} \subset \Omega + \mathcal{V}. \tag{58}$$

By (57) and (58), one has

$$dy^{[k]} \subset \Omega + \mathcal{V} \quad \forall k \geq 0. \tag{59}$$

Thus in the closed loop system the output y is decoupled from the disturbance.

Necessity. Suppose that the quasi-static state feedback $u = \phi(x, v, \ldots, v^{(r)})$ solves the DDP. Then for the system Σ_q fed back with $u = \phi(x, v, \ldots, v^{(r)})$, one has

$$dy^{[k]} \subset \mathrm{span}_{\mathcal{K}_v}\{dx, dv, \ldots, dv^{(r+k-1)}\} \quad \forall k \geq 0. \tag{60}$$

Define the sequence Ω_μ as

$$\begin{aligned} \Omega_0 &= \mathcal{P}^\perp, \\ \Omega_{\mu+1} &= \{\omega \in \Omega_\mu \mid \omega^{[1]} \in \Omega_\mu + \mathcal{V}\} \quad \forall \mu \geq 1, \end{aligned} \tag{61}$$

and

$$\Omega = \lim_{\mu \to \infty} \Omega_\mu.$$

Obviously $\Omega^{[1]} \subset \Omega + \mathcal{V}$. Thus, Ω is a controlled invariant subspace. Since $\mathrm{span}_{\mathcal{K}}\{dy\} \subset \Omega$ and $\Omega \subset \mathcal{P}^\perp$, (57) also holds. □

Condition (57) in Theorem 3.21 is not constructive. The corresponding constructive condition is obtained when considering the smallest controlled invariant subspace containing the differential of the output Ω_*. From Theorem 3.18, Ω_* is given by $\mathcal{X} \cap \mathcal{Y}$. An immediate consequence of Theorem 3.21 is then as follows.

COROLLARY 3.22. *The DDDP is solvable if and only if*

$$\Omega_* \subset \mathcal{P}^\perp. \tag{62}$$ □

Remark 3.23. Theorem 3.21 gives the nonlinear feedback analogon of Theorem 4.2 in [48] for the linear (D)DDP. Also, it gives the dynamic feedback analogon of condition (3.1) in [29] and Proposition 7.8 in [38] for the nonlinear DDP. In this way

TABLE 4
(Geometric) solution to DDP (complete).

	Static feedback	Dynamic feedback
Linear systems	$\mathcal{P} \subset \mathcal{V}^*$	
Nonlinear systems	$\mathcal{P} \subset \Delta^*$	$\Omega_* \subset \mathcal{P}^\perp$

it is established that our generalized notion of controlled invariance is the natural generalization to the nonlinear dynamic feedback case of the linear notion of controlled invariance defined in [48]. It may be checked that condition (62) is equivalent to the geometric conditions (44) in [26] and (4.5) in [44]. Further, (62) is exactly the same as the condition for solvability of the DDDP derived in [41]. However, in [41] the concept of controlled invariance was missing.

Table 1, which displayed the various solutions of the DDP, is now completed in Table 4.

4. Controllability cospaces. In this section, we study controllability cospaces under quasi-static state feedback. These controllability cospaces form a special class of the controlled invariant subspaces defined previously. They parallel the dynamic controllability distributions [45]. In subsection 4.1 we first define controllability cospaces. An algorithm which characterizes these cospaces is then given in subsection 4.2, and some properties of these controllability cospaces are discussed. In subsection 4.3 we derive an algorithm computing the smallest controllability cospace containing a given exact subspace. Applications of controllability cospaces are treated in subsections 4.4 and 4.5. In particular, the fixed modes or decoupling zero dynamics under quasi-static feedback are characterized using controllability cospaces.

4.1. Definition of controllability cospaces. Controllability cospaces are vector spaces that are autonomous after having applied a certain quasi-static state feedback $u = \psi(x, v, \dots, v^{(r)})$ and zeroing certain input channels v_j, where $j \in \mathcal{J} \subset \{1, \dots, m\}$. Such nonregular transformations are not defined for every element in $\mathcal{K}_v$. One possibility to circumvent this problem is to consider the module $\mathrm{span}_{\mathcal{A}}\{dx\}$ over the ring of analytic functions rather than the linear space over the field of meromorphic functions. Another way is chosen here; it consists in taking a particular basis of a given subspace of $\mathrm{span}_{\mathcal{K}}\{dx\}$ so that its time derivative is well defined when applying nonregular feedback. Such a basis always exists. More precisely, let $\Theta \subset \mathcal{X}$ be a subspace which admits a basis $\theta_1, \dots, \theta_d$ with

$$\theta_i = \sum_{k=1}^{n} \frac{\alpha_{ik}(x, v, \dots, v^{(\nu)})}{\beta_{ik}(x, v, \dots, v^{(\nu)})} dx_i,$$

where α_{ik} and β_{ik} are in $\mathcal{A}$, the ring of analytic functions of $\{x, v^{(k)} \mid k \geq 0\}$. Obviously, we can choose another basis for Θ, $\tilde{\theta}_1, \dots, \tilde{\theta}_d$, in the module $\mathrm{span}_{\mathcal{A}}\{dx\}$ over the ring $\mathcal{A}$ by taking

$$\tilde{\theta}_i = \left(\prod_{k=1}^{n} \beta_{ik} \right) \theta_i.$$

DEFINITION 4.1. *A subspace $\mathcal{C} \subset \mathcal{X}$ is said to be a controllability cospace for* (1) *if there exist a quasi-static state feedback* (8) *and a set of integers $\mathcal{J} \subset \{1, \dots, m\}$ such that for* (1), (8) *one has*

$$\mathcal{C}^{[1]} \subset \mathcal{C} + \mathcal{V} \tag{63}$$

and

$$\mathcal{C} = \max\{\Theta \subset \mathcal{X} \mid \operatorname{span}_{\mathcal{K}}\{\tilde{\theta}_i^{[1]} \mid_{v_j=0, j\in\mathcal{J}}\} \subset \Theta\}, \tag{64}$$

where $\tilde{\theta}_i$ is defined as above.

This means that $\mathcal{C}$ is the largest autonomous subspace in $\mathcal{X}$ of the closed loop system. Moreover, by this definition, it is clear that a controllability cospace is controlled invariant. The following example illustrates the above definition.

Example 4.2. Consider again the nonlinear system given in Example 3.14. Let $\mathcal{C} = \operatorname{span}_{\mathcal{K}} \{dx_1, d(x_2 - x_3), dx_4 - u_1 dx_3\}$, and suppose that $u_1 = v_1 + c$, where c is a nonzero constant, $u_2 = v_2$ and $u_3 = v_3 + \dot{v}_1 x_3 + (v_1 + c)^2 x_3 + (v_1 + c)v_2$. This feedback is quasi-static since $v_1 = u_1 - c$ and $v_2 = u_2$ and $v_3 = u_3 - \dot{u}_1 x_3 - u_1^2 x_3 - u_1 u_2$.

From this, it is easy to show that

$$\mathcal{C}^{[1]} = \operatorname{span}_{\mathcal{K}}\{dv_1, dx_4 - u_1 dx_3, dv_3 + (x_3(v_1 + c) + v_2)dv_1 + x_3 d\dot{v}_1\} \subset \mathcal{C} + \mathcal{V}$$

and

$$\mathcal{C}^{[1]} \mid_{v_1=0, v_3=0} = \operatorname{span}_{\mathcal{K}}\{dx_4 - u_1 dx_3\} \subset \mathcal{C}.$$

Furthermore

$$\mathcal{C} = \max\{\Theta \subset \mathcal{X} \mid \Theta^{[1]} \mid_{v_1=0, v_3=0} \subset \Theta\}.$$

Hence $\mathcal{C}$ is a controllability cospace in the sense of Definition 4.1.

4.2. Controllability cospace algorithm. First of all, we give an algorithm characterizing controllability cospaces called *the controllability cospace algorithm*. Some properties of a general controllability cospace are then derived. Let $\mathcal{C}$ be a given subspace and define a sequence $\mathcal{S}_\mu$ according to

$$\begin{aligned} \mathcal{S}_0 &:= \mathcal{X}, \\ \mathcal{S}_{\mu+1} &:= \operatorname{span}_{\mathcal{K}}\{\omega \in \mathcal{S}_\mu \mid \dot{\omega} \in \mathcal{S}_\mu + \dot{\mathcal{C}}\} \quad (\mu \in \mathbb{N}). \end{aligned} \tag{65}$$

The sequence $\mathcal{S}_\mu$ is decreasing. Thus, there exists a $\mu^* \in \mathbb{N}$ such that $\mathcal{S}_{\mu^*} = \mathcal{S}_{\mu^*+k}$ for all $k \in \mathbb{N}$. Define $\mathcal{S}^* := \mathcal{S}_{\mu^*}$.

Algorithm (65) yields a necessary condition for a subspace $\mathcal{C}$ of $\mathcal{X}$ to be a controllability cospace. This is shown in the following lemma.

LEMMA 4.3. *Let $\mathcal{C} \subset \mathcal{X}$. If $\mathcal{C}$ is a controllability cospace, then $\mathcal{C} = \mathcal{S}^*$.*

Proof. Assume that $\mathcal{C}$ is a controllability cospace. Let $\{\tilde{\omega}_i\}$ be a basis for $\mathcal{C}$ in the module $\operatorname{span}_{\mathcal{A}}\{dx\}$ over the ring $\mathcal{A}$. Then by definition there exists a quasi-static state feedback (8) and a set of integers $\mathcal{J} \subset \{1, \ldots, m\}$ such that $\mathcal{C}^{[1]} \subset \mathcal{C} + \mathcal{V}$ and $\mathcal{C}^{[1]} = \operatorname{span}_{\mathcal{K}}\{\tilde{\omega}_i^{[1]} \mid_{v_j=0, j\in\mathcal{J}}\} \subset \mathcal{C}$. From (65), it follows that $\mathcal{S}^*$ satisfies

$$\mathcal{S}^* = \operatorname{span}_{\mathcal{K}}\{\omega \in \mathcal{X} \mid \dot{\omega} \in \mathcal{S}^* + \dot{\mathcal{C}}\}. \tag{66}$$

Let $\omega \in \mathcal{C}$. We have $\dot{\omega} \in \dot{\mathcal{C}}$ and hence $\omega \in \mathcal{S}^*$. This implies that $\mathcal{C} \subset \mathcal{S}^*$. Now, $\dot{\mathcal{S}}^* \subset \mathcal{S}^* + \dot{\mathcal{C}}$. By the feedback, which yields $\mathcal{C}^{[1]} \subset \mathcal{C}$, one has $\mathcal{S}^{*[1]} \subset \mathcal{S}^*$. Since $\mathcal{C}$ is the largest subspace in $\mathcal{X}$ such that $\mathcal{C}^{[1]} \subset \mathcal{C}$, one has $\mathcal{S}^* \subset \mathcal{C}$. □

In the next section, we give an algorithm computing the smallest controllability cospace containing a given subspace based on algorithm (65).

4.3. The smallest controllability cospace containing a given subspace. In general, the intersection of two controllability cospaces is not a controllability cospace. Thus it is unclear if there exists a smallest controllability cospace containing some given subspace. However, if an exact subspace $\Pi \subset \mathcal{X}$ is given, then there exists a smallest controllability cospace containing Π.

Consider a nonlinear system given by (1). By Theorem 3.18, Π_* is the smallest controlled invariant subspace containing Π. The next theorem will relate Π_* to the smallest controllability cospace containing Π.

THEOREM 4.4. *Define the sequence* $\mathcal{D}_\mu$ *by*

$$\begin{aligned} \mathcal{D}_0 &= \mathcal{X}, \\ \mathcal{D}_{\mu+1} &= \operatorname{span}_{\mathcal{K}}\{\omega \in \mathcal{D}_\mu \mid \dot{\omega} \in \mathcal{D}_\mu + \dot{\Pi}_*\} \quad (\mu \in \mathbb{N}). \end{aligned} \tag{67}$$

Then $\mathcal{D}_* = \lim_{\mu\to\infty} \mathcal{D}_\mu$ *is the smallest controllability cospace containing* Π.

Proof. Note that

$$\mathcal{D}_* = \operatorname{span}_{\mathcal{K}}\{\omega \in \mathcal{X} \mid \dot{\omega} \in \mathcal{D}_* + \dot{\Pi}_*\}. \tag{68}$$

Let $r = \dim\Pi$. The fact that Π is exact implies that there exist meromorphic functions $\varphi_1(x), \ldots, \varphi_r(x)$ such that $\Pi = \operatorname{span}_{\mathcal{K}}\{d\varphi_1, \ldots, d\varphi_r\}$. Consider the system (1) with a "dummy" output $\varphi = (\varphi_1, \ldots, \varphi_r)^T$. We decompose the output φ as $\varphi = (\tilde{\varphi}, \hat{\varphi})^T$ so that the system (1) with the output $\tilde{\varphi}$ is right invertible. Define $\rho := \dim(\tilde{\varphi})$.

Construct a quasi-static state feedback $u = \phi(x, v, \ldots, v^{(r)})$ by taking $v_i = \tilde{\varphi}_i^{(n_i')}$, where $\{n_i'\}$ is the set of orders of zeros at infinity [18] for $i = 1, \ldots, \rho$ and $v_i = w_i$ for $i = \rho + 1, \ldots, m$. This feedback always renders Π_* invariant. Thus, $\mathcal{D}_*$ is rendered invariant too; i.e., $\mathcal{D}_*^{[1]} \subset \mathcal{D}_* + \mathcal{V}$. Let now $\{\tilde{\omega}_i\}$ be a basis for $\mathcal{D}_*$ in the module $\operatorname{span}_{\mathcal{A}}\{dx\}$ over the ring $\mathcal{A}$. If we set $v_i = 0$ for $i = 1, \ldots, \rho$ one obtains

$$\mathcal{D}_*^{[1]} = \operatorname{span}_{\mathcal{K}}\{\tilde{\omega}_i^{[i]} \mid_{v_j=0, j=1,\cdots,\rho}\} \subset \mathcal{D}_*.$$

Hence $\mathcal{D}_*$ is a controllability cospace. In order to prove that $\mathcal{D}_*$ is the smallest controllability cospace containing Π, we consider another controllability cospace $\mathcal{D}$ such that $\mathcal{D} \supset \Pi$. By definition $\mathcal{D}$ is controlled invariant, and, according to Lemma 4.3, $\mathcal{D}$ satisfies

$$\mathcal{D} = \operatorname{span}_{\mathcal{K}}\{\omega \in \mathcal{X} \mid \dot{\omega} \in \mathcal{D} + \dot{\mathcal{D}}\}. \tag{69}$$

Since Π_* is the smallest controlled invariant subspace containing Π, this implies that $\mathcal{D} \supset \Pi_*$. From (68) and (69), one has $\mathcal{D}_* \subset \mathcal{D}$. ∎

COROLLARY 4.5. *Consider a nonlinear system of the form* (51). *Define the sequence* $\mathcal{C}_\mu$ *according to*

$$\begin{aligned} \mathcal{C}_0 &= \mathcal{X}, \\ \mathcal{C}_{\mu+1} &= \operatorname{span}_{\mathcal{K}}\{\omega \in \mathcal{C}_\mu \mid \dot{\omega} \in \mathcal{C}_\mu + \dot{\Omega}_*\} \quad (\mu \in \mathbb{N}). \end{aligned} \tag{70}$$

Then $\mathcal{C}_* = \lim_{\mu\to\infty} \mathcal{C}_\mu$ *is the smallest controllability cospace containing* $\operatorname{span}_{\mathcal{K}}\{dh(x)\}$.

Proof. Clearly, $\Omega_* = \mathcal{X} \cap \mathcal{Y}$ is the smallest controlled invariant subspace containing the differential of the outputs. The result then immediately follows from Theorem 4.4. ∎

Remark 4.6. When specialized to linear systems, the sequence $\mathcal{C}_\mu$ (70) turns out to be equal to the dual of the sequence $\mathcal{R}_\mu$ (the sequence computing the maximal

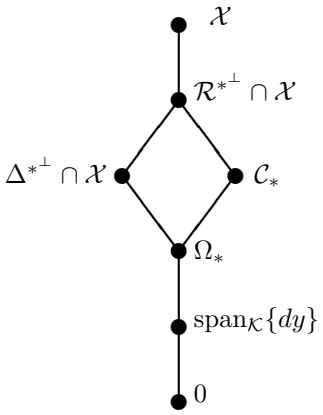

FIG. 2. *Lattice diagram: (Geometric) structure of nonlinear systems* (*continued; see Figure* 1).

controllability subspace in the kernel of the output mapping). A proof of this can be found in the appendix.

The geometric structure of a nonlinear system as presented in Figure 1 can now be completed. Let $\mathcal{R}^*$ be the largest controllability distribution contained in the kernel of the output. As an immediate consequence, $\mathcal{R}^{*^\perp} \cap \mathcal{X}$ is a controllability cospace in the sense of Definition 4.1. Figure 2 displays further geometric structures of nonlinear systems.

4.4. The block input-output decoupling problem. We now use the smallest controllability cospace $\mathcal{C}_*$, previously defined, to solve a quasi-static state feedback input-output decoupling problem. For this, we consider the system (1) together with the partitioned output blocks y_i for $i = 1, \ldots, k$, given by

$$y_i = h_i(x). \tag{71}$$

The problem can be stated as follows: find a quasi-static state feedback and a partition of the new control $v = (v_1^T, \ldots, v_k^T)^T$ such that the new input v_i affects only the output y_i.

Define $\mathcal{C}_{i*}$ and Ω_{i*} to be the smallest controllability cospace and the smallest controlled invariant subspace, respectively, both containing $\text{span}_{\mathcal{K}}\{dh_i(x)\}$.

First, let us give the following property which is derived from Theorem 5.1 in [42].

PROPERTY 4.7. *Consider system* (51)*, and assume that* $\dim(\mathcal{G}^\perp) = n - m$*. Let* ρ *be its differential output rank. Then*

$$\dim(\mathcal{G}^\perp + \Omega_*) = \dim(\mathcal{G}^\perp + \mathcal{C}_*) = (n - m + \rho). \tag{72}$$

Moreover, if the system (51) *is right invertible, then*

$$\dim(\mathcal{G}^\perp + \Omega_*) = \dim(\mathcal{G}^\perp + \mathcal{C}_*) = (n - m + p). \tag{73}$$

This property is a generalization of a known result on linear systems. It gives a geometric interpretation of the rank of a system. The property was also derived by Respondek in [45] using dynamic controllability distributions.

COROLLARY 4.8. *The block input-output decoupling problem via quasi-static (or dynamic) state feedback for the system* (1), (71) *is solvable if and only if*

$$\dim\left(\frac{\mathcal{G}^\perp + \mathcal{C}_*}{\mathcal{G}^\perp}\right) = \sum_{i=1}^{k} \dim\left(\frac{\mathcal{G}^\perp + \mathcal{C}_{i*}}{\mathcal{G}^\perp}\right). \tag{74}$$

Condition (74) coincides with the condition given by Di Benedetto, Grizzle, and Moog [18], in the case of the dynamic block decoupling problem. Indeed, if ρ denotes the rank of the system (1), (71) and ρ_i denotes the rank of the subsystem (1) with the output y_i, then by Property 4.7, (74) is equivalent to

$$\rho = \sum_{i=1}^{k} \rho_i. \tag{75}$$

By applying the structure algorithm to the system (1), (71), a quasi-static feedback which decouples the system is obtained [14].

Further, controllability cospaces also allow us to characterize the fixed dynamics with respect to any quasi-static feedback. This will be the topic of the next section.

4.5. Fixed modes by quasi-static state feedback. The problem of noninteraction with stability of nonlinear systems by means of static feedback has first been considered by Isidori and Grizzle [32]. They have shown that there exists a fixed internal dynamics called P^* *dynamics* whose stability is a necessary condition for solving the noninteracting control problem with stability via static feedback. In the case where the P^* dynamics are unstable, Wagner has shown [47] that there exists a well-defined dynamics called Δ_{mix} *dynamics* which cannot be eliminated by any regular dynamic feedback that renders the considered system noninteractive. The Δ_{mix} dynamics must then be asymptotically stable if noninteracting control with stability is to be achieved by means of dynamic state feedback. Glumineau, Moog, and Tarn [21] used a dynamic compensator to remove a one-dimensional interconnection zero dynamics and showed that such a compensator is able to cancel only the fixed dynamics which have a certain linearity property. A sufficient condition to solve the problem of noninteracting control with stability by means of dynamic state feedback was given in [5], [6], [7]. In these references, the problem of dynamic feedback noninteracting control with stability is solved if some regularity assumptions are satisfied, the Δ_{mix} dynamics are asymptotically stable and each decoupled subsystem is asymptotically stabilizable.

All results above are valid under the assumption that the decoupling matrix $A(x)$ is nonsingular. In the case where $A(x)$ is singular and the system is square and invertible, Zhan, Tarn, and Isidori [50] introduced the so-called canonical dynamic decoupling algorithm to construct a canonical dynamic extension (Σ_p). They have shown that the dynamically decoupled system is stable only if the Δ_{mix} dynamics of the canonical dynamic extension is stable, which is an intrinsic property of the given system. These different contributions are summarized in Table 2.

In this section, we investigate the case where the decoupling matrix is not necessarily invertible and study the noninteracting control problem with stability by means of quasi-static feedback. The goal is to show that the controllability cospaces introduced before are able to describe intrinsic geometric conditions with respect to quasi-static feedbacks, analogous to the above ones. Preliminary results may be found in [1].

Let us consider a square invertible nonlinear affine system (Σ) of the form

$$\Sigma : \begin{cases} \dot{x} &= f(x) + \displaystyle\sum_{i=1}^{m} g_i(x)u_i, \qquad x \in \mathbb{R}^n,\ u_i \in \mathbb{R}, \\ y_i &= h_i(x), \qquad i = 1, \ldots, m,\ y_i \in \mathbb{R}. \end{cases} \tag{76}$$

Let $\{n_i'\}$ be the set of orders of zeros at infinity [18], where $n_1' > n_2' > \cdots > n_m'$.

Permute if necessary y_i such that the corresponding order of zero at infinity is $n_i^{'}$. Let $\mathcal{C}_{i*}$ be the smallest controllability cospace containing $\text{span}_{\mathcal{K}}\{dh_i(x)\}$. A first result is the following.

LEMMA 4.9. *Suppose that the system* (76) *can be decoupled by a quasi-static state feedback* $u = \psi(x, v, \ldots, v^{(s)})$. *Then there always exist coordinates* $\xi = (\xi_0, \xi_1, \ldots, \xi_m, \hat{\xi})$ *such that the system* (76) *has the following form:*

$$
\begin{aligned}
\dot{\xi}_0 &= f_0(\xi_0), \\
\dot{\xi}_1 &= f_1(\xi_0, \xi_1, v_1), \\
&\vdots \\
\dot{\xi}_m &= f_m(\xi_0, \xi_m, v_m), \\
\dot{\hat{\xi}} &= \hat{f}(\xi, v, \dot{v}, \ldots, v^{(s)}), \\
y_i &= h_i(\xi_0, \xi_i). \qquad \square
\end{aligned} \tag{77}
$$

The system (77) will be referred to as a *standard decomposed system*, analogous to [23]. To prove Lemma 4.9, we first need the following property of $\mathcal{C}_{i*}$.

LEMMA 4.10. *For a scalar output* $y_i = h_i(x)$, $\mathcal{C}_{i*}$ *is an exact subspace.*

Proof. Let Ω_{i*} be the smallest controlled invariant subspace containing $\text{span}_{\mathcal{K}}\{dh_i\}$. If Δ_i^* is the maximal controlled invariant distribution in $\ker\{dh_i(x)\}$, we have $\Omega_{i*} = \Delta_i^{*\perp}$. Now let $\mathcal{R}_i^*$ be the maximal controllability distribution in $\ker\{dh_i(x)\}$. Clearly $\mathcal{R}_i^{*\perp}$ is a controllability cospace containing $\text{span}_{\mathcal{K}}\{dh_i(x)\}$, and thus $\mathcal{C}_{i*} \subset \mathcal{R}_i^{*\perp}$. From [29] we have

$$
\mathcal{R}_i^* = \Delta_i^* \cap \left([f, \mathcal{R}_i^*] + \sum_{j=1}^{m} [g_j, \mathcal{R}_i^*] + \mathcal{G} \right) \tag{78}
$$

and thus

$$
\begin{aligned}
\mathcal{R}_i^{*\perp} &= \Omega_{i*} + [f, \mathcal{R}_i^*]^\perp \cap \Big(\bigcap_{j=1}^{m} [g_j, \mathcal{R}_i^*]^\perp \Big) \cap \mathcal{G}^\perp \\
&= \{\omega \in \mathcal{X} \mid \exists \omega_1 \in \Omega_{i*}, \exists \omega_2 \in \mathcal{G}^\perp \text{ such that } \omega = \omega_1 + \omega_2 \\
&\qquad \text{and } (\forall \tau \in \mathcal{R}_i^*)(\forall \sigma \in \{f, g_1, \ldots, g_m\})(\langle [\sigma, \tau], \omega_2 \rangle = 0)\}.
\end{aligned} \tag{79}
$$

Let $\omega \in \mathcal{R}_i^{*\perp}$. Then there exist $\omega_1 \in \Omega_{i*}$ and $\omega_2 \in \mathcal{G}^\perp$ such that $\omega = \omega_1 + \omega_2$, and $\forall \tau \in \mathcal{R}_i^*, \forall \sigma \in \{f, g_1, \ldots, g_m\}$, one has $\langle [\sigma, \tau], \omega_2 \rangle = 0$. Compute

$$
\dot{\omega} = \dot{\omega}_1 + \dot{\omega}_2.
$$

Clearly $\dot{\omega}_1 \in \dot{\Omega}_{i*}$. Furthermore,

$$
\begin{aligned}
\dot{\omega}_2 &= \mathcal{L}_f \omega_2 + \sum_{j=1}^{m} (u_j \mathcal{L}_{g_j} \omega_2 + \langle \omega_2, g_j \rangle du_j) \\
&= \mathcal{L}_f \omega_2 + \sum_{j=1}^{m} u_j \mathcal{L}_{g_j} \omega_2.
\end{aligned} \tag{80}
$$

Now, let $\tau \in \mathcal{R}_i^*$ and $\sigma \in \{f, g_1, \ldots, g_m\}$. Then

$$
\begin{aligned}
\langle \tau, \mathcal{L}_\sigma \omega_2 \rangle &= \mathcal{L}_\sigma \langle \tau, \omega_2 \rangle - \langle [\sigma, \tau], \omega_2 \rangle \\
&= \mathcal{L}_\sigma \langle \tau, \omega_2 \rangle = \mathcal{L}_\sigma \langle \tau, (\omega - \omega_1) \rangle = 0,
\end{aligned} \tag{81}
$$

where the last equality follows from the fact that $\omega \in \mathcal{R}_i^{*\perp}$ and $\omega_1 \in \Omega_{i*} \subset \mathcal{R}_i^{*\perp}$. By (80), (81), we then have $\dot{\omega}_2 \in \mathcal{R}_i^{*\perp}$, and hence

$$\widehat{\dot{\mathcal{R}}_i^{*\perp}} \subset \dot{\Omega}_{i*} + \mathcal{R}_i^{*\perp}.$$

By construction, $\mathcal{C}_{i*}$ is the largest subspace in $\mathcal{X}$ which verifies $\dot{\mathcal{C}}_{i*} \subset \mathcal{C}_{i*} + \dot{\Omega}_{i*}$. This implies $\mathcal{R}_i^{*\perp} \subset \mathcal{C}_{i*}$. So $\mathcal{C}_{i*}$ is the annihilator of $\mathcal{R}_i^*$, which is defined to be involutive [39], [29]. Hence $\mathcal{C}_{i*}$ is exact, which establishes our claim. □

Proof of Lemma 4.9. By Lemma 4.10, $\mathcal{C}_{i*}$ is an exact subspace. Thus, $\dot{\mathcal{C}}_{i*}$ as well as $\sum_{j=0}^{n_i'-1} \mathcal{C}_{i*}^{(j)}$ is also exact. Let us define $\mathcal{C}_0$ as the uncontrollable subspace of (Σ) which is the subspace $\mathcal{H}_\infty$ introduced in [2]. It is obvious that for each $i = 1, \ldots, m$

$$\mathcal{C}_0 = \sum_{j=0}^{n_i'-1} \mathcal{C}_{i*}^{(j)} \cap \sum_{k=\neq i} \sum_{j=0}^{n_k'-1} \mathcal{C}_{k*}^{(j)}.$$

Let $\{d\xi_0\}$ be a basis of $\mathcal{C}_0$; thus $\dot{\xi}_0 = f_0(\xi_0)$. For an invertible system, we can construct a quasi-static state feedback which decouples system (Σ) by taking $v_i = y_i^{(n_i')}$. For $i = 1, \ldots, m$, choose $d\xi_i$ such that $\{d\xi_0, d\xi_i\}$ is a basis of $\sum_{j=0}^{n_i'-1} \mathcal{C}_{i*}^{(j)}$. Then one has

$$\dot{\xi}_i = f_i(\xi_0, \xi_i, v_i).$$

Complete the new coordinates by choosing $\hat{\xi}$ such that $\{d\xi_0, d\xi_1, \ldots, d\xi_m, d\hat{\xi}\}$ is linearly independent. Without loss of generality, $\hat{\xi}$ can be chosen so that $\operatorname{span}\{d\hat{\xi}\} \subset \mathcal{X}$. Thus, one has

$$\dot{\hat{\xi}} = \hat{f}(\xi, v, \dot{v}, \ldots, v^{(s)}),$$

and (77) is established. □

Now we may state the following theorem.

THEOREM 4.11. *For a square invertible nonlinear system, the dimension of the fixed dynamics with respect to any quasi-static state feedback is*

$$n - \dim \left(\mathcal{X} \cap \sum_{i=1}^{m} \sum_{j \geq 0} \mathcal{C}_{i*}^{(j)} \right). \tag{82}$$

Moreover, if the origin is an equilibrium point for Σ *and the quasi-static state feedback rendering* (76) *noninteractive preserves this equilibrium point, then the induced fixed dynamics are*

$$\dot{\hat{\xi}} = \hat{f}(0, \ldots, 0, \hat{\xi}, 0, \ldots, 0), \tag{83}$$

where $\hat{\xi}$ *is as defined in Lemma* 4.9.

Proof. From the proof of Lemma 4.9, the dimension of the fixed dynamics with respect to any quasi-static feedback which decouples the system is

$$n - \dim \left(\sum_{i=1}^{m} \sum_{j=0}^{n_i'-1} \mathcal{C}_{i*}^{(j)} \right). \tag{84}$$

From the definition of the structure at infinity, one gets

$$\dim\left(\sum_{i=1}^{m}\sum_{j=0}^{n_i'-1}\mathcal{C}_{i*}^{(j)}\right)=\dim\left(\mathcal{X}\cap\sum_{i=1}^{m}\sum_{j\geq 0}\mathcal{C}_{i*}^{(j)}\right). \tag{85}$$

Thus (82) is established. Once the system is in standard decomposed form (77), and analogously to [23], any decoupling quasi-static state feedback is of the form $v_i=\alpha_i(\xi_0,\xi_i,w_i,\ldots,w_i^{(\nu)})$. Hence, if the α_i's preserve the equilibrium, the second statement in Theorem 4.11 is immediate. □

The asymptotic stability of dynamics (83) is a necessary condition for noninteracting control with internal stability by quasi-static state feedback.

The next example illustrates Theorem 4.11.

Example 4.12. Let us consider a nonlinear system given by

$$\dot{x}_1=u_1,\quad \dot{x}_2=x_4+x_3u_1,\quad \dot{x}_3=x_3+x_4,\quad \dot{x}_4=u_2,\quad \dot{x}_5=x_1+x_2,$$
$$y_1=x_1,\qquad y_2=x_2.$$

We have $\{n_i'\}=\{2,1\}$. Permute then y_i, and thus $\mathcal{C}_{1*}=\{dx_2\}$ and $\mathcal{C}_{2*}=\{dx_1\}$. The quasi-static feedback which decouples the system is $u_1=v_1$ and $u_2=v_2-(x_3+x_4)v_1-x_3\dot{v}_1$, where (v_1,v_2) is a new input vector. It is clear that $\mathcal{C}_0=0$. We choose $d\xi_1=\{dx_2,d(x_4+x_3u_1)\}$ as a basis of $\{\mathcal{C}_{1*}+\dot{\mathcal{C}}_{1*}\}$, and thus

$$\dot{\xi}_1=\begin{pmatrix}\dot{\xi}_{11}\\ \dot{\xi}_{12}\end{pmatrix}=\begin{pmatrix}\xi_{12}\\ v_2\end{pmatrix}. \tag{86}$$

Now choose $\{d\xi_2\}=\{dx_1\}$ as a basis of $\mathcal{C}_{2*}$, and one has

$$\dot{\xi}_2=v_1. \tag{87}$$

We complete our coordinate transformation by taking

$$\hat{\xi}=\begin{pmatrix}\hat{\xi}_1\\ \hat{\xi}_2\end{pmatrix}=\begin{pmatrix}x_4\\ x_5\end{pmatrix}.$$

So in the new coordinates $(\xi_1,\xi_2,\hat{\xi})$, the considered system becomes

$$\begin{aligned}
\dot{\xi}_{11} &= \xi_{12},\\
\dot{\xi}_{12} &= v_2,\\
\dot{\xi}_2 &= v_1,\\
\dot{\hat{\xi}}_1 &= v_2-(\xi_{12}-\hat{\xi}_1)-\hat{\xi}_1v_1-(\xi_{12}-\hat{\xi}_1)\dot{v}_1/v_1,\\
\dot{\hat{\xi}}_2 &= \xi_2+\xi_{11},\\
y_1 &= \xi_2,\\
y_2 &= \xi_{11}.
\end{aligned} \tag{88}$$

Clearly, $\dim(\hat{\xi})=2=n-\dim(\mathcal{X}\cap(\sum_{i=1}^{m}\sum_{j\geq 0}\mathcal{C}_{i*}^{(j)}))=n-\dim(\mathrm{span}\{dx_1,dx_2,dx_4+u_1dx_3\})$. Thus, the dimension of the fixed dynamics equals two. Since the origin is an equilibrium point, the fixed dynamics are then

$$\begin{aligned}
\dot{\hat{\xi}}_1 &= \hat{\xi}_1,\\
\dot{\hat{\xi}}_2 &= 0.
\end{aligned} \tag{89}$$

TABLE 5
Decoupling zero structure (complete).

Feedback	$A(x)$ invertible	$A(x)$ noninvertible
(Quasi-) Static	dim $(\mathcal{P}^*)$ Isidori and Grizzle [32]	$n - \dim \left(\mathcal{X} \cap \left(\sum_{i=1}^{m} \sum_{j\geq 0} \mathcal{C}_i^{*(j)}\right)\right)$
Dynamic	dim (Δ_{mix}) Wagner [47]	dim $(\Delta_{mix}(\Sigma_p))$ Zhan, Tarn, and Isidori [50]

Similarly to Wagner's and Battilotti's results, in the case where no quasi-static state feedback can render the system simultaneously noninteractive and stable, a suitable dynamic feedback may still solve the problem. This reduces to the results in Zhan, Tarn, and Isidori [50].

Table 2, which displays the dimension of the various decoupling zero dynamics, is now completed in Table 5.

5. Conclusions. A generalized notion of controlled invariance under quasi-static state feedback for nonlinear systems was introduced. It was shown that this notion coincides with the standard notion of a controlled invariant distribution under regular static state feedback. Using the generalized notion of controlled invariance, a condition for the controlled invariance of not necessarily integrable codistributions was derived. For a subspace $\Omega \subset \mathcal{X}$, we gave sufficient conditions for controlled invariance under quasi-static state feedback. Furthermore, a necessary and sufficient condition for controlled invariance was also given for a special class of subspaces Ω. The generalized controlled invariance was applied to the DDP by dynamic feedback. A necessary and sufficient condition for solvability of this DDDP was obtained.

For a controllability cospace $\mathcal{C} \subset \mathcal{X}$, some properties were derived by means of the controllability cospace algorithm. Moreover, the smallest controllability cospace containing the differential of the output mapping allowed us to solve the block input-output decoupling problem. It also characterized the dimension of the fixed dynamics with respect to any quasi-static state feedback in the case of one to one decoupling.

This paper leaves some interesting open questions, which are topics for further research. A first question is related to necessary and sufficient conditions for controlled invariance for a general class of subspaces. A second question is whether (or under what conditions) there exists a smallest controlled invariant subspace containing some given subspace. It seems that for the answer to both questions a better understanding of quasi-static state feedback is needed.

Finally, let us remark that throughout the paper we have restricted ourselves to "Kalmanian" systems and to subspaces $\Omega \subset \mathcal{X}$. However, the definition of controlled invariance and the characterizations of controlled invariance in this paper can, mutatis mutandis, be translated to non-Kalmanian systems and subspaces $\Omega \subset \mathcal{X} \times \mathcal{U}$.

Appendix. According to Remark 4.6, we will prove that the sequence (70) computing $\mathcal{C}_*$ is the same as the one computing $\mathcal{R}^{*^\perp}$ (the dual of $\mathcal{R}^*$, the maximal controllability subspace in kernel of the output) for linear time-invariant systems. We proceed by induction. First, we recall some basic operations that we need.

Consider a linear system given by

$$\begin{aligned} \dot{x} &= Ax + Bu,\ x \in \mathbb{R}^n, u \in \mathbb{R}^m, \\ y &= Cx. \end{aligned} \tag{90}$$

Identify elements of $\mathbb{R}^n$ with column vectors while elements of $\mathbb{R}^{n^\perp}$, its dual, are identified with row vectors. Thus, $\omega = \sum_{i=1}^n \alpha_i dx_i \in \mathbb{R}^{n^\perp}$ is identified with the row vector $\alpha := (\alpha_1, \ldots, \alpha_n) \in \mathbb{R}^n$. With this notation,

$$\dot{\omega} = \alpha d\dot{x} = \alpha A dx + \alpha B du \in (\mathbb{R}^n \times \mathbb{R}^m)^\perp \tag{91}$$

is identified with the row vector $(\alpha A \ \alpha B)$.

Let a subspace $V \subset \mathbb{R}^n$ be given. Then

$$\begin{array}{rcl} (AV)^\perp & = & \{\omega \in \mathrm{span}\{dx\} \mid < \omega, Av >= 0 \, \forall v \in V\} \\ & = & \{\alpha \in \mathbb{R}^n \mid \alpha A v = 0, \forall v \in V\} = \{\alpha \in \mathbb{R}^n \mid \alpha A \in V^\perp\} \\ & =: & {}^{-1}AV^\perp \end{array} \tag{92}$$

if $\omega = \alpha dx \in (AV)^\perp \cap \mathcal{B}^\perp$, where $\mathcal{B} = \mathrm{Im}B$. Then

$$\dot{\omega} = \alpha A dx + \alpha B du = \alpha A dx \simeq \alpha A \in V^\perp. \tag{93}$$

The two sequences to be compared are

$$\left\{ \begin{array}{rcl} \mathcal{R}_0^\perp & := & \mathcal{X}, \\ \mathcal{R}_{\mu+1}^\perp & := & \mathcal{V}^{*^\perp} + {}^{-1}A\mathcal{R}_\mu^\perp \cap \mathcal{B}^\perp \quad (\mu \in \mathbb{N}) \end{array} \right. \tag{94}$$

and

$$\left\{ \begin{array}{rcl} \mathcal{C}_0 & := & \mathcal{X}, \\ \mathcal{C}_{\mu+1} & := & \{\omega \in \mathcal{C}_\mu \mid \dot{\omega} \in \mathcal{C}_\mu + \dot{\mathcal{V}}^{*^\perp}\} \ \ (\mu \in \mathbb{N}), \end{array} \right. \tag{95}$$

where $\mathcal{V}^*$ is the maximal controlled invariant subspace in $\mathrm{Ker}C$ for the system (90). For step 0, it is obvious that $\mathcal{R}_0^\perp = \mathcal{C}_0$. Suppose that $\mathcal{R}_\mu^\perp = \mathcal{C}_\mu$ for $\mu = 0, \ldots, \ell$. Let $\omega \in \mathcal{R}_{\ell+1}^\perp$, thus there exist $\omega_1 \in \mathcal{V}^{*^\perp}$ and $\omega_2 \in {}^{-1}A\mathcal{R}_\ell^\perp \cap \mathcal{B}^\perp$ such that $\omega = \omega_1 + \omega_2$. By (93), $\dot{\omega}_2 \in \mathcal{R}_\ell^\perp = \mathcal{C}_\ell$ and hence $\mathcal{R}_{\ell+1}^\perp \subset \mathcal{C}_{\ell+1}$. To show the other inclusion, let $\omega \in \mathcal{C}_{\ell+1}$; then

$$\dot{\omega} \in \mathcal{C}_\ell + \dot{\mathcal{V}}^{*^\perp} = \mathcal{R}_\ell^\perp + \dot{\mathcal{V}}^{*^\perp}. \tag{96}$$

Thus there exists $\omega_1 \in \mathcal{V}^{*^\perp}$ and $\omega_2 \in \mathcal{R}_\ell^\perp$ such that $\dot{\omega} = \dot{\omega}_1 + \omega_2$. Let now $\dot{\omega}_0 = \dot{\overbrace{\omega - \omega_1}} = \omega_2$. So $\dot{\omega}_0 \in \mathcal{R}_\ell^\perp$. This implies that

$$\begin{array}{rcl} \omega_0 & \in & \{\omega = \alpha dx \mid \dot{\omega} \in \mathcal{R}_\ell^\perp\} = \{\alpha dx \mid \alpha A dx + \alpha B du \in \mathcal{R}_\ell^\perp\} \\ & = & \{\alpha \mid \alpha A \in \mathcal{R}_\ell^\perp\} \cap \mathcal{B}^\perp = {}^{-1}A\mathcal{R}_\ell^\perp \cap \mathcal{B}^\perp. \end{array} \tag{97}$$

So $\omega = \omega_1 + \omega_0 \in \mathcal{R}_{\ell+1}^\perp$, which yields that $\mathcal{C}_{\ell+1} \subset \mathcal{R}_{\ell+1}^\perp$. Thus, we have that $\mathcal{C}_\mu = \mathcal{R}_\mu^\perp$ for all $\mu \in \mathbb{N}$, which establishes our claim. □

FINITE-DIMENSIONAL FILTERS. PART I: THE WEI–NORMAN TECHNIQUE*

M. COHEN DE LARA†

Abstract. This two-part paper deals with necessary or sufficient conditions for the existence of finite-dimensional filters. In this first part, we set the problem and propose a construction of such filters by the Wei–Norman technique. After having formulated the problem of finite-dimensional filters in terms of finite-dimensional realizations of input-output mappings, we specify the dependence with respect to the initial measure. We show how different notions of dependence imply different properties of the so-called estimation algebra $\mathcal{E}$: $\mathcal{E}$ is homomorphic to a Lie algebra of vector fields; $\mathcal{E}$ contains only operators of order less than or equal to two; $\mathcal{E}$ is finite dimensional and contains only operators of order less than or equal to two. These results depend on a precise definition of a finite-dimensional realization, especially on what concerns the domain of the output function. The last (and most stringent) condition on $\mathcal{E}$ will be shown to be almost sufficient to recover a family of finite-dimensional realizations thanks to the proof of a Baker–Campbell–Hausdorff formula which allows us to apply the Wei–Norman technique in a quite general setting.

Key words. finite-dimensional filter, estimation Lie algebra, bilinear stochastic partial differential equation, Baker–Campbell–Hausdorff formula.

1. Introduction.

The filtering problem for systems with correlated noises of the form (see [11, 48])

$$\begin{cases} dx_t = f(x_t)dt + g(x_t)dv_t + \tilde{g}(x_t)dy_t, & x_0 \rightsquigarrow \mu_0, \\ dy_t = h(x_t)dt + dw_t, & y_0 = 0, \end{cases} \tag{1}$$

where $x \in \mathbb{R}^n$, $f(x) \in \mathbb{R}^n$, $g(x) = (g_1(x), ..., g_m(x)) \in (\mathbb{R}^n)^m$, $\tilde{g}(x) = (\tilde{g}_1(x), ..., \tilde{g}_m(x)) \in (\mathbb{R}^n)^m$, $y \in \mathbb{R}^p$, $h(x) \in \mathbb{R}^p$ is the characterization of the conditional law Π_t of x_t knowing $\mathcal{Y}_t$, the σ-field generated by $\{y_s \,|\, 0 \le s \le t\}$, or at least of some statistics $\langle \Pi_t, \phi \rangle$ such as the conditional mean or variance.

Under quite general assumptions, the reference probability method allows us to define an unnormalized conditional law σ_t which satisfies a (generally) infinite-dimensional bilinear stochastic partial differential equation (PDE): the Duncan–Mortensen–Zakai equation (Zakai equation, for short) [47, 44, 15, 37]

$$\begin{aligned} d\sigma_t(\phi) = \sigma_t \left(\frac{1}{2} \sum_{k=1}^{m} L_{g_k}^2 \phi + L_f \phi - \frac{1}{2} \left(\|h\|^2 + \sum_{i=1}^{p} L_{\tilde{g}_i} h_i \right) \phi \right) dt \\ + \sum_{i=1}^{p} \sigma_t (L_{\tilde{g}_i} \phi + h_i \phi) \circ dy_t^i, \quad \sigma_0 = \mu_0. \end{aligned} \tag{2}$$

Remark. For any vector field X, we make use of the Lie derivative notation

$$L_X \phi(\xi) = X \cdot \phi(\xi) = \langle d\phi, X \rangle (\xi) = \lim_{t \to 0} \frac{\phi(\Phi_t^X(\xi)) - \phi(\xi)}{t}, \tag{3}$$

where Φ_t^X denotes the local flow generated by X. Of course, we have $L_X^k\phi = L_X(L_X^{k-1}\phi)\ \forall\ k \geq 1$ with the convention $L_X^0\phi = \phi$.

As was noticed by Brockett [9, 8], the solution of (2) usually defines an input output map

$$\mathcal{F}^{\mu_0} : \mathbb{R}_+ \times C^0(\mathbb{R}_+, \mathbb{R}^p) \to \mathbb{M}_+(\mathbb{R}^n), \tag{4}$$

where μ_0 is the initial law and $\mathbb{M}_+(\mathbb{R}^n)$ denotes the space of nonnegative bounded measures on $\mathbb{R}^n$. Then, in the spirit of system theory, we can define a finite-dimensional realization (FDR) of such an input-output map. This is just a specific way to formulate finite-dimensional filtering problems.

Such problems find their origin in the linear Gaussian case, where the solution σ_t of the Zakai equation evolves in the set of unnormalized Gaussian measures and where the corresponding finite number of parameters satisfies a stochastic differential equation, driven by the observations, on a finite-dimensional manifold. The extension of this property to nonlinear systems, or non-Gaussian initial laws, has given rise to the notion of finite-dimensional filters (FDFs). After the example of Beneš [3] a few others were discovered [5, 45, 39, 4, 28, 25, 14] and also [27, 13, 18] in a different setting. The estimation Lie algebra $\mathcal{E}$ associated with the Zakai equation [9, 10] plays a crucial role in the study, thus enhancing the existing links with geometric or algebraic methods [8, 10, 31, 29, 19]. Results of nonexistence are mostly obtained [34, 26], even in the case of the finite-dimensional computation of some statistics [11, 20, 21]. Nevertheless, whenever FDFs are known to exist, the estimation Lie algebra is a powerful tool in the computation of a solution [3, 34, 33, 45, 25, 46]. Other approaches use analytic methods [2, 35, 36], geometric tools [1, 26], classical probabilistic methods [28, 24], or Malliavin stochastic calculus of variations [30, 25, 32].

In this paper, we restrict ourselves to the problem of the existence of an FDF for the conditional law and more generally to the study of FDRs of bilinear stochastic PDEs very similar to equation (2) as in [26]. Our aim is to give tools for explicit computation of such realizations. We focus on the role of the initial measure to define specific families of FDRs $\{\mathcal{F}^{\mu_0} \mid \mu_0 \in \mathbb{M}_0\}$, parametrized by a set of initial measures $\mathbb{M}_0$. According to the more or less strong dependence of the elements of the FDR on $\mu_0 \in \mathbb{M}_0$, this yields a classification of estimation Lie algebras based on the following results.

1. A necessary condition for the existence of an FDR for one single initial law μ_0 is the existence of a nontrivial homomorphism from $\mathcal{E}$ to a Lie algebra of vector fields on a finite-dimensional manifold. This property, known as the conjecture of Brockett, has already been sketched out in the case of finite-dimensional statistics for the cubic sensor problem (section 3) [20, 21].

2. For bilinear stochastic bilinear PDEs admitting FDRs for every Dirac initial law with an additional regularity property (conic or regular FDR), we show in section 4 that $\mathcal{E}$ contains only operators of order less than or equal to two. The proof relies on a characterization of C^∞-differential operators satisfying the maximum principle to be found in [6] for instance. As was noticed in [26], $\mathcal{E}$ is generally infinite dimensional.

3. For bilinear stochastic bilinear PDEs admitting regular FDRs parametrized by Dirac measures and uniform with respect to the dynamics and initial condition (namely the same regular FDR holds for all Dirac initial law up to the output function), we show in section 5 that $\mathcal{E}$ is finite dimensional and has a basis consisting of one operator of order less than or equal to two and operators of order less than or equal to one. It turns out that such uniform realizations may generally be extended to many more initial laws than the Dirac ones.

4. In section 5, these results are used to compute FDRs uniform with respect to the dynamics and initial condition under additional regularity and algebraic assumptions. The key point is a extension of the Baker–Campbell–Hausdorff formula to linear partial differential operators, which is proved in the appendix.

In Part II, we shall propose another means of constructing FDRs by invariance group technique developed in [12], and we shall relate both methods.

2. Problem statement. Let $(y_t)_{t\geq 0}$ be a standard p-dimensional Brownian motion, and let $\circ dy_t$ denote its "Stratonovitch differential." For $\mu_0 \in \mathbb{M}_+(\mathbb{R}^n)$, the space of nonnegative bounded measures on $\mathbb{R}^n$, we consider the following stochastic bilinear PDE:

$$d\nu_t(\phi) = \nu_t(M_0\phi)dt + \sum_{i=1}^{p} \nu_t(M_i\phi) \circ dy_t^i \quad \forall\, \phi \in \mathcal{D}(\mathbb{R}^n), \quad \nu_0 = \mu_0. \tag{5}$$

Here $\mathcal{D}(\mathbb{R}^n)$ denotes the space of smooth functions on $\mathbb{R}^n$ with compact support, and $M_0, M_1, \ldots, M_p$ are the linear differential operators defined by

$$\begin{cases} M_0\phi = \mathcal{L}\phi + H\phi, \\ M_i\phi = L_{\tilde{g}_i}\phi + h_i\phi, \quad i = 1, \ldots, p \qquad \forall\, \phi \in \mathcal{D}(\mathbb{R}^n), \end{cases} \tag{6}$$

$\mathcal{L}$ being a smooth diffusion operator ($\mathcal{L}1 = 0$), $\tilde{g}_1, \ldots, \tilde{g}_p$ being smooth vector fields on $\mathbb{R}^n$, and $H, h_1, \ldots, h_p$ being smooth functions from $\mathbb{R}^n$ to $\mathbb{R}$.

Remark. In the filtering problem stated in the introduction, the Zakai equation is a particular case of equation (5) with

$$\mathcal{L}\phi = \frac{1}{2}\sum_{k=1}^{m} L_{g_k}^2\phi + L_f\phi \quad \text{and} \quad H = -\frac{1}{2}\left(\|h\|^2 + \sum_{i=1}^{p} L_{\tilde{g}_i}h_i\right). \tag{7}$$

Assumption 1. *For all $\mu_0 \in \mathbb{M}_+(\mathbb{R}^n)$, we assume that there exists an input-output map*

$$\mathcal{F}^{\mu_0} : \mathbb{R}_+ \times C^0(\mathbb{R}_+, \mathbb{R}^p) \to \mathbb{M}_+(\mathbb{R}^n) \tag{8}$$

which satisfies the following property: for all p-dimensional Brownian motion $(y_t)_{t\geq 0}$, equation (5) *has a unique solution $(\nu_t)_{t\geq 0}$ given by*

$$\text{with probability one } (w.p.1) \quad \forall\, t \geq 0, \quad \nu_t = \mathcal{F}^{\mu_0}(t; y_s, s \leq t). \tag{9}$$

In particular, uniqueness for the solution of equation (5) *is thus assumed.*

Remark. Other notions of input-output mappings can be considered, such as $\mathcal{F}^{\mu_0}(t; y_s, s \leq t) = \nu_t(\phi) \in \mathbb{R}$ (conditional statistics).

This input-output map $\mathcal{F}^{\mu_0}$ can be realized in finite dimension when it can be written $\nu_t = \theta(\xi_t)$, where ξ_t is driven by $(y_s)_{s\geq 0}$ and evolves on a finite-dimensional manifold M and θ is a nonnegative output function.

DEFINITION 2.1. *An* output function θ *on a finite-dimensional manifold M is a map*

$$\theta : \mathrm{Dom}(\theta) \to \mathcal{D}'(\mathbb{R}^n), \tag{10}$$

where $\mathrm{Dom}(\theta)$ *is an open set of M and $\mathcal{D}'(\mathbb{R}^n)$ is the space of distributions such that for every $\phi \in \mathcal{D}(\mathbb{R}^n)$ the function*

$$\begin{array}{rcl} \mathrm{Dom}(\theta) & \to & \mathbb{R}, \\ \xi & \mapsto & \langle \theta(\xi), \phi \rangle \end{array} \tag{11}$$

is of class C^∞ *(on the open set* $\mathrm{Dom}(\theta)$*) and has continuous partial derivatives of all order on* $\overline{\mathrm{Dom}(\theta)}$*. A* nonnegative output function *is an output function with values in* $\mathbb{M}_+(\mathbb{R}^n)$*.*

A well-known example of such an output function is given by the Gaussian family

$$\theta(m,\sigma) = \frac{1}{\sigma\sqrt{2\pi}} \exp\left(-\frac{(x-m)^2}{2\sigma^2}\right) dx \in \mathbb{M}_+(\mathbb{R}^n) \subset \mathcal{D}'(\mathbb{R})$$

with $\mathrm{Dom}(\theta) = \mathbb{R} \times (0,+\infty) \subset M = \mathbb{R}^2$ such that for every $\phi \in \mathcal{D}(\mathbb{R})$ the function

$$(m,\sigma) \mapsto \langle \theta(\xi),\, \phi\rangle = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{+\infty} \exp\left(-\frac{z^2}{2}\right) \phi(m+\sigma z)\, dz$$

is of class C^∞ and has continuous partial derivatives of all order on $\mathbb{R}^2$ (thus a fortiori on $\overline{\mathrm{Dom}(\theta)} = \mathbb{R} \times [0,+\infty)$).

DEFINITION 2.2. *An* FDR *of the input-output map* $\mathcal{F}^{\mu_0}$ *given by* (8) *consists of a collection* $(M,\, \xi_0,\, b_0,\, b_1,\, \ldots,\, b_p,\, \theta)$*, where*

1. M *is a smooth finite-dimensional manifold,*
2. $\xi_0 \in M$*,*
3. $b_0,\, b_1,\, \ldots,\, b_p$ *are smooth vector fields on* M*,*
4. θ *is a nonnegative output function on* M*,*

such that, if $(y_t)_{t\geq 0}$ *is a Brownian motion, the Stratonovitch stochastic differential equation*

$$d\xi_t = b_0(\xi_t)dt + \sum_{i=1}^{p} b_i(\xi_t) \circ dy_t^i, \quad \xi_{t\,|\,t=0} = \xi_0, \tag{12}$$

*is conservative (that is, w.p.*1 *has a solution for all time or w.p.*1 *has infinite explosion time) with a solution satisfying*

$$w.p.1 \quad \forall\, t > 0, \quad \xi_t \in \mathrm{Dom}(\theta)$$

and

$$w.p.1 \quad \forall\, t \geq 0, \quad \theta(\xi_t) = \mathcal{F}^{\mu_0}(t; y_s, s \leq t) = \nu_t. \tag{13}$$

We shall also say that system (1) *admits an* FDF *if the corresponding Zakai equation* (2) *admits an* FDR*.*

Remark. With the above definition, note that the deterministic point ξ_0 necessarily belongs to $\overline{\mathrm{Dom}(\theta)}$.

This definition can be extended to the case of a family of input-output maps, corresponding to the case where we want to specify the dependence with respect to the initial measure μ_0. Clearly, if $\{\mathcal{F}^{\mu_0} \mid \mu_0 \in \mathbb{M}_0\}$ is a given family of input-output maps, the corresponding family of FDRs, if it exists, is denoted by $(M^{\mu_0},\, \xi_0^{\mu_0},\, b_0^{\mu_0},\, b_1^{\mu_0},\, \ldots,\, b_p^{\mu_0},\, \theta^{\mu_0})$.

However, particular subclasses of families of stochastic realizations may be useful and will receive particular attention.

DEFINITION 2.3. *Given* $\mathbb{M}_0 \subset \mathbb{M}_+(\mathbb{R}^n)$ *and a family of input-output maps* $\{\mathcal{F}^{\mu_0} \mid \mu_0 \in \mathbb{M}_0\}$*, an FDR of* $\{\mathcal{F}^{\mu_0} \mid \mu_0 \in \mathbb{M}_0\}$*,* uniform with respect to the dynamics *(resp.,* to the dynamics and initial condition*), is a family of FDRs for which* $M^{\mu_0},\, b_0^{\mu_0},\, b_1^{\mu_0},\, \ldots,\, b_p^{\mu_0}$ *(resp.,* $M^{\mu_0},\, b_0^{\mu_0},\, b_1^{\mu_0},\, \ldots,\, b_p^{\mu_0}$*, and* $\xi_0^{\mu_0}$*) do not depend on* $\mu_0 \in \mathbb{M}_0$*.*

Of course, when a family of FDRs is uniform with respect to the dynamics and initial condition, then only the nonnegative output function θ may depend upon the initial law μ_0.

FDFs give rise to FDRs, and examples of FDRs, uniform with respect to the dynamics, are given by the Kalman–Bucy filter [23] and by Beneš [3], while examples of FDRs, uniform with respect to the dynamics and initial condition, are given by Beneš and Karatzas [5], Makowski [28], Wong [45], Lévine [25], and Yau [46].

An important tool in the study of FDRs is the following estimation Lie algebra.

DEFINITION 2.4. *The* estimation Lie algebra *of equation* (5)*, noted $\mathcal{E}$, is the* $\mathbb{R}$*-vector space of linear differential operators generated by $M_0, \ldots, M_p$ (defined by* (6)*) with respect to the Lie bracket defined by*

$$[N_1, N_2]\phi = N_1(N_2\phi) - N_2(N_1\phi) \quad \forall\, \phi \in \mathcal{D}(\mathbb{R}^n).$$

Let $x_0 \in \mathbb{R}^n$. If N is any smooth linear partial differential operator, $N(x_0)$ denotes the linear partial differential operator with constant coefficients, obtained by freezing at x_0 all the coefficients of N. $\mathcal{E}(x_0)$ denotes the vector space consisting of all partial differential operators with constant coefficients of the form $N(x_0)$ for $N \in \mathcal{E}$. If $N \in \mathcal{E}$, its dual operator $N^\star$ is given by $\langle \lambda, N\phi\rangle = \langle N^\star\lambda, \phi\rangle$ for all ϕ in $\mathcal{D}(\mathbb{R}^n)$ and $\lambda \in \mathcal{D}'(\mathbb{R}^n)$.

3. FDRs and the homomorphism property. The conjecture of Brockett is as follows: if the system (1) admits an FDF for the conditional law or for conditional statistics, there should exist a nontrivial Lie algebra homomorphism from the estimation Lie algebra to a Lie algebra of vector fields [8].

In this section, we assume that the input-output map $\mathcal{F}^{\mu_0}$ given by (8) admits an FDR given by Definition 2.2.

DEFINITION 3.1. *$\mathcal{B}$ denotes the Lie algebra of vector fields on M generated by the vector fields $b_0, \ldots, b_p$ given by Definition* 2.2*.*

Proofs of the conjecture of Brockett are discussed and outlined by Hazewinkel, Marcus, and Sussmann in [20] and also by Hijab [21] in the case of existence of FDFs for conditional statistics of the cubic sensor. It should be noted that the construction of the homomorphism is different according to both authors, especially because of the choice of various ideals of $\mathcal{B}$ used to quotient this latter algebra. However, both methods can be extended to other systems than the cubic sensor. The proof of the conjecture in [11] is quite different since it relies on a specific dependence of a family of FDRs upon Dirac initial measures.

In the spirit of these previous works, we shall exhibit an ideal $\mathcal{J}$ of $\mathcal{B}$ as well as a nontrivial Lie algebra homomorphism from $\mathcal{E}$ to a quotient $\mathcal{B} \setminus \mathcal{J}$ of $\mathcal{B}$. But here the definition of the set $\mathcal{J}$ is different from others and does not obviously imply that it is an ideal of $\mathcal{B}$. In fact, this latter property holds because we are dealing with *universal* FDRs (in the terminology of [11]), that is, the realizations of the process ν_t and not only of some statistics $\langle \nu_t, \phi\rangle$. This homomorphism will be useful in the next sections.

DEFINITION 3.2. *Let θ be an output function on a finite-dimensional manifold M and X be a smooth vector field on M. We define a new output function $L_X\theta$ by*

$$\langle L_X\theta(\xi)\,,\, \phi\rangle = L_X\left(\langle \theta(\cdot)\,,\, \phi\rangle\right)_{|\xi} \tag{14}$$

for all $\xi \in \mathrm{Dom}(\theta)$ and $\phi \in \mathcal{D}(\mathbb{R}^n)$.

Note that $L_X\theta$ indeed is an output function because $L_X\theta(\xi)$ is a weak limit of distributions.

PROPOSITION 3.3. *If the input-output map $\mathcal{F}^{\mu_0}$ given by* (8) *admits an FDR given by Definition* 2.2*, then the subset*

$$\mathcal{J} = \{\, j \in \mathcal{B} \mid w.p.1 \quad \forall\, t > 0, \quad L_j\theta(\xi_t) = 0 \,\} \tag{15}$$

is a Lie ideal of $\mathcal{B}$. Furthermore, there exists a surjective Lie algebras homomorphism from $\mathcal{E}$ to $\mathcal{B} \setminus \mathcal{J}$.

The proof relies on the following lemma which can be found in [26, proof of Theorem 3.1 and equations (12), (16), pp. 80–82].

LEMMA 3.4. *If the input-output map $\mathcal{F}^{\mu_0}$ given by* (8) *admits an FDR given by Definition* 2.2*, we have w.p.*1 *for all $t > 0$:*

$$\begin{aligned} M_i^\star\theta(\xi_t) &= L_{b_i}\theta(\xi_t), \quad i = 0, \ldots, p, \\ [M_j^\star, M_i^\star]\theta(\xi_t) &= L_{[b_i, b_j]}\theta(\xi_t), \quad i, j = 0, \ldots, p, \\ &\cdots = \cdots \end{aligned} \tag{16}$$

In these latter equalities,

- the left-hand side represents the differential operator (on $\mathbb{R}^n$) $M_i^\star$, or $[M_j^\star, M_i^\star]$, acting on the measure (on $\mathbb{R}^n$) $\theta(\xi_t)$;
- the right-hand side represents the derivative of the mapping $\xi \mapsto \theta(\xi)$ along the vector field b_i (see (14)) or along $[b_i, b_j]$, evaluated at the point $\xi = \xi_t$.

Since $\mathcal{B}$ is generated by linear combinations of iterated brackets of the vector fields $b_0, \ldots, b_p$ and $\mathcal{E}$ by linear combinations of iterated brackets of the operators $M_0, \ldots, M_p$, the following corollary of equations (16) is clear.

COROLLARY 3.5. *If the input-output map $\mathcal{F}^{\mu_0}$ given by* (8) *admits an FDR given by Definition* 2.2*, then for any $E \in \mathcal{E}$, there exists at least one $b \in \mathcal{B}$ such that*

$$w.p.1 \quad \forall\, t > 0, \quad L_b\theta(\xi_t) = E^\star\theta(\xi_t). \tag{17}$$

Conversely, for any $b \in \mathcal{B}$, there exists at least one $E \in \mathcal{E}$ such that equation (17) *is satisfied.*

The following remark will be quite useful in what follows.

Remark. By Definition 2.2 (and the remark following it), we know that the deterministic point ξ_0 belongs to $\overline{\mathrm{Dom}(\theta)}$.

Therefore, thanks to Definition 2.1 (the assumption that the mapping (11) has continuous partial derivatives of all order on $\overline{\mathrm{Dom}(\theta)}$), we can extend the equality (17) at $t = 0$. This provides the following deterministic relationship: if the input-output map $\mathcal{F}^{\mu_0}$ given by (8) admits an FDR given by Definition 2.2, then for any $E \in \mathcal{E}$, there exists at least one $b \in \mathcal{B}$ such that

$$L_b\theta(\xi_0) = E^\star\theta(\xi_0). \tag{18}$$

Conversely, for any $b \in \mathcal{B}$, there exists at least one $E \in \mathcal{E}$ such that equality (18) is satisfied.

Note that (18) is satisfied with $b = b_i$ and $E = M_i$ for $i = 0, \ldots, p$.

Now we turn to the proof of Proposition 3.3.

Proof of Proposition 3.3. Let $j \in \mathcal{J}$, $b \in \mathcal{B}$ be given. To prove that $\mathcal{J}$ is an ideal of $\mathcal{B}$, we shall show that

$$\text{w.p.1} \quad \forall\, t > 0, \quad L_{[b,\,j]}\theta(\xi_t) = L_bL_j\theta(\xi_t) \,-\, L_jL_b\theta(\xi_t) = 0. \tag{19}$$

First, we show that w.p.1 $\forall\, t > 0, L_bL_j\theta(\xi_t) = 0$. In [26], the Itô–Stratonovitch formula is applied to the semimartingale $L_j\theta(\xi_t)$ in the nuclear space of distributions

[42] as follows:

$$\text{w.p.1} \quad \forall\, t > 0, \quad dL_j\theta(\xi_t) = L_{b_0}L_j\theta(\xi_t)dt + \sum_{i=1}^{p} L_{b_i}L_j\theta(\xi_t) \circ dy_t^i \,. \tag{20}$$

But j belongs to $\mathcal{J}$, so that the semimartingale $L_j\theta(\xi_t)$ is zero. Therefore, so are the absolutely continous part and the martingale parts, and this gives

$$\text{w.p.1} \quad \forall\, t > 0, \quad L_{b_i}L_j\theta(\xi_t) = 0, \quad i = 0, \ldots, p \,. \tag{21}$$

Now, since $b \in \mathcal{B}$ can be written as a linear combination of iterated brackets of the vector fields $b_0, \ldots, b_p$, iterations of the Itô–Stratonovitch formula and proper linear combinations of the above equations provide the expected result:

$$\text{w.p.1} \quad \forall\, t > 0, \quad L_bL_j\theta(\xi_t) = 0 \,. \tag{22}$$

Second, we show that w.p.1 $\forall\, t > 0, L_jL_b\theta(\xi_t) = 0$, and this is not as straightforward here as above.

We know from Corollary 3.5 that there exists $E \in \mathcal{E}$ such that (17) is satisfied. Therefore, if we apply the Itô–Stratonovitch formula enough times to this latter equation, followed by appropriate linear combinations, we find that

$$\text{w.p.1} \quad \forall\, t > 0, \quad L_jL_b\theta(\xi_t) = L_jE^\star\theta(\xi_t).$$

We now show that the last term $L_jE^\star\theta(\xi_t)$ is zero.

On the one hand, by (14), we have the following for $\xi \in \mathrm{Dom}(\theta)$:

$$\begin{aligned} \forall\, \phi \in \mathcal{D}(\mathbb{R}^n), \quad \langle L_jE^\star\theta(\xi), \phi\rangle &= L_j\left(\langle E^\star\theta(.)\,,\, \phi\rangle\right)_{|\xi} \quad \text{by def. of } L_j \\ &= L_j\left(\langle \theta(.)\,,\, E\phi\rangle\right)_{|\xi} \quad \text{by duality} \\ &= \langle L_j\theta(\xi)\,,\, E\phi\rangle \quad \text{by def. of } L_j \\ &= \langle E^\star L_j\theta(\xi)\,,\, \phi\rangle \quad \text{by duality.} \end{aligned}$$

Thus, with $\xi = \xi_t$, we get

$$\text{w.p.1} \quad \forall\, t > 0, \quad L_jL_b\theta(\xi_t) = L_jE^\star\theta(\xi_t) = E^\star L_j\theta(\xi_t).$$

On the other hand, since $j \in \mathcal{J}$, we have

$$\text{w.p.1} \quad \forall\, t > 0, \quad L_j\theta(\xi_t) = 0,$$

so that for almost all $\omega \in \Omega$ and for all $t > 0$, the measure (on $\mathbb{R}^n$) $L_j\theta(\xi_t(\omega))$ is zero. Now, $E^\star$ is a differential operator on the state-space $\mathbb{R}^n$ (acting on measures on $\mathbb{R}^n$) and thus for almost all $\omega \in \Omega$ and for all $t > 0$ we have

$$E^\star L_j\theta(\xi_t) = E^\star 0 = 0.$$

Combining the last three equalities we get the expected result:

$$\text{w.p.1} \quad \forall\, t > 0, \quad L_jL_b\theta(\xi_t) = L_jE^\star\theta(\xi_t) = E^\star L_j\theta(\xi_t) = E^\star 0 = 0 \,.$$

To end the proof, we define the surjective homomorphism from $\mathcal{E}$ to $\mathcal{B} \setminus \mathcal{J}$ as follows:

$$\Upsilon(E) = \{\, b \in \mathcal{B} \,|\, \text{w.p.1} \;\; \forall\, t \;>\; 0, \; L_b\theta(\xi_t) = E^\star\theta(\xi_t) \,\}. \tag{23}$$

It is indeed easily seen that $\Upsilon(E)$ belongs to $\mathcal{B}\backslash\mathcal{J}$ and, by making use of Corollary 3.5, that Υ is a surjective homomorphism. □

COROLLARY 3.6. *If the input-output map $\mathcal{F}^{\mu_0}$ given by* (8) *admits an FDR given by Definition* 2.2 *such that $\theta(\xi_t)$ is not constant, then there exists a nontrivial Lie algebras homomorphism from the estimation Lie algebra to an algebra of vector fields on a finite-dimensional manifold.*

Proof. With the previous notations, we choose for manifold a leaf N of the foliation generated by the involutive distribution $\eta \to \mathcal{J}(\eta)$ (by the Frobenius theorem [22, p. 25], since this latter distribution is of fixed dimension if we restrict η to the open subset of M consisting of points η where the subspace $\mathcal{J}(\eta)$ of M has maximal dimension).

We now exhibit a Lie algebra homomorphism from $\mathcal{B} \setminus \mathcal{J}$ to the Lie algebra of vector fields on N.

Let $\eta_* \in N$ and $(\eta^1, \ldots, \eta^r)$ be a coordinate system on a neighborhood V of η_* such that $N = \{\, \eta \in V \mid \eta^1(\eta) = \eta^1(\eta_*), \ldots, \eta^k(\eta) = \eta^k(\eta_*) \,\}$. Thus, if j belongs to $\mathcal{J}$, we have

$$j = \sum_{i=1}^{k} j_i(\eta)\, \frac{\partial}{\partial \eta^i}.$$

Since $\mathcal{J}$ is an ideal, an easy computation provides for any $a \in \mathcal{B}$ [22, pp. 45–46]:

$$a = \sum_{i=1}^{k} a_i(\eta^1, \ldots, \eta^r)\, \frac{\partial}{\partial \eta^i} \; + \sum_{i=1}^{r-k} a_{k+i}(\eta^{k+1}, \ldots, \eta^r)\, \frac{\partial}{\partial \eta^{k+i}}.$$

Let C be a class of $\mathcal{B} \setminus \mathcal{J}$: there exists $c \in \mathcal{B}$ such that any $a \in C$ satisfies $c - a \in \mathcal{J}$. In coordinates, this means that there exist $r - k$ functions $c_{k+1}(\eta^{k+1}, \ldots, \eta^r)$, $\ldots$, $c_r(\eta^{k+1}, \ldots, \eta^r)$ on V such that any a in C can be written

$$a = \sum_{i=1}^{k} a_i(\eta^1, \ldots, \eta^r)\, \frac{\partial}{\partial \eta_i} \; + \sum_{i=1}^{r-k} c_{k+i}(\eta^{k+1}, \ldots, \eta^r)\, \frac{\partial}{\partial \eta^{k+i}}.$$

Thus $\overline{c} = \sum_{i=1}^{r-k} c_{k+i}(\eta^{k+1}, \ldots, \eta^r)\, \frac{\partial}{\partial \eta^{k+i}}$ is uniquely determined by the class C, and we can in this way assign $\overline{c}$ to C and thus define $\upsilon(C) = \overline{c}$.

It is easily seen that υ is a Lie algebras homomorphism from $\mathcal{B} \setminus \mathcal{J}$ to the Lie algebra of vector fields on the manifold N. On the other hand, υ is not trivial because $\upsilon = 0$ means that $\mathcal{B} \subset \mathcal{J}$, or equivalently that $\theta(\xi_t)$ is constant.

To end the proof, we note that since Υ in (23) is a surjective homomorphism from $\mathcal{E}$ to $\mathcal{B} \setminus \mathcal{J} \neq 0$, then $\Upsilon \circ \upsilon$ is a nontrivial homomorphism from $\mathcal{E}$ to the Lie algebra of vector fields on the manifold N. □

4. FDRs for Dirac initial laws. Although the estimation Lie algebra $\mathcal{E}$ of a system admitting an FDF is necessarily homomorphic to a Lie algebra of vector fields on a finite-dimensional manifold, it appears that, for all the known cases of systems admitting FDFs, the estimation Lie algebra $\mathcal{E}$ has much stronger properties: it is either both finite dimensional and made of operators of order less than or equal to two [23, 3, 5, 45, 4, 28, 14, 25, 41, 46] or made only of operators of order less than or equal to two [26].

We shall prove in this section and the following one that these last properties of $\mathcal{E}$ can be related to the existence of FDRs for the family $\{\mathcal{F}^{\mu_0} \mid \mu_0 \in \mathbb{D}_0\}$, where $\mathbb{D}_0$ is the set of Dirac measures.

First, a technical difficulty arises because Dirac measures are extremal measures in the cone of nonnegative measures. Indeed, we shall prove that, when an FDR exists, the parametrization of the nonnegative output function θ is almost always singular around any point ξ_0 such that $\theta(\xi_0) \in \mathbb{D}_0$.

LEMMA 4.1. *Let $x_0 \in \mathbb{R}^n$ be such that*

1. *the second-order part of the operator M_0 given in equation (6) is not zero at x_0, that is $M_0(x_0)$ is a constant linear differential operator of order equal to two (but may be degenerate),*
2. *$\mathcal{F}^{\delta_{x_0}}$, given by (8), admits an FDR.*

Then the initial point ξ_0 given in Definition 2.2 is necessarily a boundary point of the open domain $\mathrm{Dom}(\theta)$ of the nonnegative output function θ; that is, $\xi_0 \in \partial\mathrm{Dom}(\theta)$.

Proof. Let us note $M_0(x_0) = \sum_{i,j=1}^n s_{ij} \frac{\partial^2}{\partial x_i x_j} + \cdots$, where $S = (s_{ij})_{i,j=1,\ldots,n}$ is a nonnegative symmetric matrix. Let us choose $\phi \in \mathcal{D}(\mathbb{R}^n)$ nonnegative such that $\phi(x) = (x - x_0)' S (x - x_0)$ in a neighborhood of x_0. Since θ is a nonnegative output function and $\phi \geq 0$, we have $\langle \theta(\xi), \phi \rangle \geq 0$. On the other hand, we have $\langle \theta(\xi_0), \phi \rangle = \langle \delta_{x_0}, \phi \rangle = \phi(x_0) = 0$.

Now, assume that ξ_0 is not a boundary point of the open domain $\mathrm{Dom}(\theta)$. Therefore, all first-order partial derivatives of the mapping (11) are zero at ξ_0. In particular, we have $\langle L_{b_0} \theta(\xi_0), \phi \rangle = 0$, while on the other hand, we know from (16) that $M_0^\star \theta(\xi_0) = L_{b_0} \theta(\xi_0)$. Therefore,

$$(M_0\phi)(x_0) = \langle \delta_{x_0}, M_0\phi \rangle = \langle \theta(\xi_0), M_0\phi \rangle = \langle M_0^\star \theta(\xi_0), \phi \rangle = \langle L_{b_0}\theta(\xi_0), \phi \rangle = 0,$$

where ϕ is such that $(M_0\phi)(x_0) = \sum_{i,j=1}^n s_{ij}^2 > 0$, which contradicts the assumption on M_0. Thus, ξ_0 is a boundary point of the open domain $\mathrm{Dom}(\theta)$. □

In what follows, it appears that the shape of $\mathrm{Dom}(\theta)$ in the neighborhood of the boundary point ξ_0 is important to specify.

DEFINITION 4.2. *The* tangent cone *at ξ_0 is the cone of vectors v of the tangent space $T_{\xi_0}M$ at ξ_0 such that there exists a smooth path $\gamma : [0, T] \to M$ satisfying*

1. *$\gamma(0) = \xi_0$,*
2. *$T > 0$ and $\gamma(t) \in \mathrm{Dom}(\theta)$ for all $t \in (0, T]$,*
3. *$\gamma'(0) = v$.*

This indeed defines a cone (since v may be replaced by λv, $\lambda > 0$ by changing the path parametrization) that we note $K(\xi_0)$.

DEFINITION 4.3. *The FDR of Definition 2.2 is said to be*

- conic *if $b_0(\xi_0)$ belongs to the interior $\overset{\circ}{K}(\xi_0)$ of the tangent cone $K(\xi_0)$,*
- regular *if the tangent cone $K(\xi_0)$ contains an open half-space $T^+_{\xi_0}M$ and if $b_0(\xi_0)$ belongs to $T^+_{\xi_0}M$.*

With this definition, a regular FDR is conic.

The following proposition gives a necessary condition for $\mathcal{F}^{\delta_{x_0}}$ to have a conic or a regular FDR.

PROPOSITION 4.4. *Let $x_0 \in \mathbb{R}^n$ be such that the input-output map $\mathcal{F}^{\delta_{x_0}}$ given by (8) admits a conic FDR. Then $\mathcal{E}(x_0)$ contains no operators of order greater than two; that is,*

$$\mathcal{E}(x_0) \subset \mathbb{R} - \mathrm{span}\left\{ 1, \frac{\partial}{\partial x_i}, i = 1, \ldots, n, \frac{\partial^2}{\partial x_i \partial x_j}, i, j = 1, \ldots, n \right\}. \tag{24}$$

Moreover, if the FDR is not only conic but also regular, then

$$\mathcal{E}(x_0) \subset \mathbb{R}M_0(x_0) + \mathbb{R} - \mathrm{span}\left\{ 1, \frac{\partial}{\partial x_i}, i = 1, \ldots, n \right\}. \tag{25}$$

We need a lemma based on a characterization of the operators satisfying the maximum principle [6].

LEMMA 4.5. *Let R be a smooth differential operator on $\mathbb{R}^n$ such that for all smooth nonnegative function ϕ and for all $x_0 \in \mathbb{R}^n$, we have*

$$\phi(x_0) = 0 \Rightarrow (R\phi)(x_0) \geq 0 \,(resp., = 0). \tag{26}$$

Then R is a differential operator of order less than or equal to two (resp., of order less than or equal to one).

Proof. Let us write R under the form

$$R = \sum_{\alpha=(\alpha_1,\ldots,\alpha_n)\in\mathbb{N}^n} r_\alpha \frac{\partial^{\alpha_1+\cdots+\alpha_n}}{\partial x_1^{\alpha_1}\cdots\partial x_n^{\alpha_n}}. \tag{27}$$

Let $x_0 \in \mathbb{R}^n$ be given.

Let Q be a nonnegative symmetric matrix, let $\lambda \in \mathbb{R}$, and let $\beta = (\beta_1, \ldots, \beta_n) \in \mathbb{N}^n$ be such that $\mid \beta \mid = \beta_1 + \cdots + \beta_n > 2$. Then, let ϕ be a smooth nonnegative function such that in a neighborhood of x_0 we have

$$\phi(x) = \frac{(x-x_0)'Q(x-x_0)}{2} + \frac{\lambda}{\beta_1!\ldots\beta_n!}(x_1-(x_0)_1)^{\beta_1}\cdots(x_n-(x_0)_n)^{\beta_n}. \tag{28}$$

By (27) and (28) we have

$$(R\phi)(x_0) = \sum_{|\alpha|=2} r_\alpha(x_0)Q_\alpha + \lambda r_\beta(x_0).$$

In the notation Q_α, one has to understand the following: when $\mid \alpha \mid = 2$, there exists

- either $i \neq j$ such that $\alpha_i = \alpha_j = 1$ (and all others $\alpha_k = 0$) and then $Q_\alpha = Q_{i,j}$,
- or i such that $\alpha_i = 2$ (and all others $\alpha_k = 0$) and then $Q_\alpha = Q_{i,i}$.

Now, if $(R\phi)(x_0) \geq 0$, then

$$\sum_{|\alpha|=2} r_\alpha(x_0)Q_\alpha + \lambda r_\beta(x_0) \geq 0.$$

This inequality being true for all $\lambda \in \mathbb{R}$, we must have $r_\beta(x_0) = 0$ and this latter equality holds for all $\beta = (\beta_1, \ldots, \beta_n) \in \mathbb{N}^n$ such that $\mid \beta \mid = \beta_1 + \cdots + \beta_n > 2$. Thus, R is a differential operator of order less than or equal to two at x_0 (and then on all R^n since x_0 is arbitrary).

Now, if $(R\phi)(x_0) = 0$, we know that $r_\beta(x_0) = 0$ for all $\beta = (\beta_1, \ldots, \beta_n) \in \mathbb{N}^n$ such that $\mid \beta \mid = \beta_1 + \cdots + \beta_n > 2$. Thus, we simply have

$$\sum_{|\alpha|=2} r_\alpha(x_0)Q_\alpha = 0.$$

This equality being true for all Q nonnegative symmetric matrices, we must have $r_\alpha(x_0) = 0$ for all α such that $\mid \alpha \mid = 2$. Thus, R is a differential operator of order less than or equal to one at x_0 (and then on all R^n since x_0 is arbitrary). This ends the proof of Lemma 4.5. □

Proof of Proposition 4.4. Let $E \in \mathcal{E}$ be given and $b \in \mathcal{B}$ be such that (18) is satisfied by the remark following Corollary 3.5.

Assume that the FDR is conic. Since $b_0(\xi_0) \in \overset{\circ}{K}(\xi_0)$, there exists $\varepsilon \neq 0$ such that $b_0(\xi_0) + \varepsilon b(\xi_0) \in \overset{\circ}{K}(\xi_0)$. Let γ be a corresponding path in $\mathrm{Dom}(\theta)$ (apart from the starting point $\xi_0 \in \partial\mathrm{Dom}(\theta)$), with $\gamma'(0) = b_0(\xi_0) + \varepsilon b(\xi_0)$. We prove that

$$R = M_0 + \varepsilon E$$

and thus E itself is a differential operator of order less than or equal to two.

Let x_0 be given and let ϕ be a nonnegative smooth function such that $\phi(x_0) = 0$. By the remark following Corollary 3.5, we have both $(L_{b_0}\theta)(\xi_0) = M_0^\star\theta(\xi_0)$ and $(L_b\theta)(\xi_0) = E^\star\theta(\xi_0)$, so that

$$(R\phi)(x_0) = \langle L_{b_0+\varepsilon b}\theta(\xi_0), \phi\rangle\,.$$

We now prove that the above right-hand side is nonnegative.

The function

$$\varrho : t \in [0,T] \mapsto \langle \theta(\gamma(t)), \phi\rangle \in \mathbb{R}.$$

has the following properties:

1. It is smooth on $(0,T]$ with continous derivatives of all order on $[0,T]$.
2. It is nonnegative since ϕ is nonnegative.
3. It satisfies $\varrho(0) = 0$ since

$$\varrho(0) = \langle \theta(\gamma(0)), \phi\rangle = \langle \theta(\xi_0), \phi\rangle = \langle \delta_{x_0}, \phi\rangle = \phi(x_0) = 0.$$

By continuity of $\varrho'(t)$ at $t = 0$, we have

$$\langle L_{b_0+\varepsilon b}\theta(\xi_0), \phi\rangle \;=\; \left\langle L_{\gamma'(0)}\theta(\xi_0), \phi\right\rangle \;= \lim_{t\downarrow 0} \varrho'(t) = \lim_{t\downarrow 0} \frac{1}{t}\int_0^t \varrho'(s)ds.$$

We evaluate the last term sign by

$$\int_0^t \varrho'(s)ds = \lim_{\eta\downarrow 0}\int_\eta^t \varrho'(s)ds = \lim_{\eta\downarrow 0}(\varrho(t) - \varrho(\eta)) = \varrho(t) - 0 \geq 0.$$

Thus, we get $\langle L_{b_0+\varepsilon b}\theta(\xi_0), \phi\rangle \geq 0$.

We conclude that $R = M_0 + \varepsilon E$, and thus E itself is a differential operator of order less than or equal to two by Lemma 4.5.

Assume that the FDR is regular. Then there exists an open half-space $T^+_{\xi_0}M$ in the tangent space $T_{\xi_0}M$ of M at ξ_0 such that we can split

$$T_{\xi_0}M = T^+_{\xi_0}M \oplus T^0_{\xi_0}M \oplus T^-_{\xi_0}M,$$

where $T^+_{\xi_0}M = -T^-_{\xi_0}M$ and $T^0_{\xi_0}M = \partial T^+_{\xi_0}M = \overline{T^+_{\xi_0}M} \cap \overline{T^-_{\xi_0}M}$.

By symmetry ($a(\xi_0) \in T^+_{\xi_0}M \iff -a(\xi_0) \in T^-_{\xi_0}M$) and by continuity ($T^0_{\xi_0}M = \partial T^+_{\xi_0}M = \overline{T^+_{\xi_0}M} \cap \overline{T^-_{\xi_0}M}$), we get for all smooth function ϕ and for all $x_0 \in \mathbb{R}^n$ by the study here above,

$$\phi \geq \phi(x_0) = 0 \Rightarrow \begin{cases} \langle L_a\theta(\xi_0), \phi\rangle \;\geq\; 0 & \text{if } a(\xi_0) \in T^+_{\xi_0}M, \\ \langle L_a\theta(\xi_0), \phi\rangle \;\leq\; 0 & \text{if } a(\xi_0) \in T^-_{\xi_0}M, \\ \langle L_a\theta(\xi_0), \phi\rangle \;=\; 0 & \text{if } a(\xi_0) \in T^0_{\xi_0}M. \end{cases}$$

Now, since $b_0(\xi_0) \in T^+_{\xi_0}M$, there exists $\rho \in \mathbb{R}$ such that $\rho b_0(\xi_0) + b(\xi_0) \in T^0_{\xi_0}M$. Thus we have

$$\phi \geq \phi(x_0) = 0 \Rightarrow \langle L_{\rho b_0 + b}\theta(\xi_0), \phi\rangle \ = \ 0.$$

But by the remark following Corollary 3.5, we also have

$$((\rho M_0 + E)\phi)(x_0) = \langle L_{\rho b_0 + b}\theta(\xi_0), \phi\rangle .$$

We conclude that $R = \rho M_0 + E$ is a differential operator of order less than or equal to one by Lemma 4.5. Therefore, for any $E \in \mathcal{E}$ there exists a real ρ such that

$$E = \rho M_0 + \text{a first-order differential operator.}$$

This ends the proof of Proposition 4.4. □

The following proposition is an easy corollary.

PROPOSITION 4.6. *If the family of input-output maps* $\{\mathcal{F}^{\mu_0} \mid \mu_0 \in \mathbb{D}_0\}$*, given by* (8)*, admits a family of regular FDRs, then the estimation Lie algebra* $\mathcal{E}$ *contains only operators of order less than or equal to two. In particular, we have for all* x_0 *in* $\mathbb{R}^n$*,* $\dim \mathcal{E}(x_0) \leq \frac{(n+1)(n+2)}{2} < +\infty$.

Let us stress the fact that the assumption under which Proposition 4.6 holds differs from that of [11, p. 88], where it is assumed that the diffusion ξ_t depends on the point x_0 of $\mathbb{R}^n$ through a relationship of the form $\xi_0 = \psi(x_0)$. Moreover, this last result on $\dim \mathcal{E}(x_0)$ is to be compared with results in [11, 26] asserting that the estimation Lie algebra is finite dimensional when estimated on any point $x_0 \in \mathbb{R}^n$.

In [26], Lévine notices that estimation Lie algebras with this last property are not necessarily finite dimensional. The example given relies upon the use of the time-varying Kalman–Bucy filter, where the variable t is considered as a state variable (in fact, note that any estimation Lie algebra $\mathcal{E}$, where M_0 is a differential operator of order less than or equal to one is generally infinite dimensional, though finite dimensional when estimated on any point of $\mathbb{R}^n$ since it is made of operators of order less than or equal to one). Nevertheless this trick allows us to exhibit a class of systems (1) (and therefore of operators (6)) such that there exist FDFs for every Dirac initial law (and therefore FDRs for every Dirac measure) but that the estimation Lie algebra is not finite dimensional. Here is an example.

Consider the following system with state $z = (x, t) \in \mathbb{R}^2$ and observation $y \in \mathbb{R}$:

$$\left\{ \begin{array}{ll} dx_t \ = \ dv_t, & x_0 \,\text{deterministic,} \\ dt = dt, & t_0 \,\text{deterministic,} \\ dy_t \ = \ h(t)x_t dt \ + \ dw_t, & y_0 \ = \ 0. \end{array} \right. \tag{29}$$

It is clear that there exists for each Dirac initial law an FDF given by the (time-varying) Kalman–Bucy filter. On the other hand, the estimation Lie algebra is generally infinite dimensional. Indeed, we have

$$\left\{ \begin{array}{rcl} M_0 & = & \dfrac{1}{2}\dfrac{\partial^2}{\partial x^2} + \dfrac{\partial}{\partial t} - \dfrac{1}{2}h^2(t)x^2, \\ M_1 & = & h(t)x, \end{array} \right. \tag{30}$$

and it is easily seen that

$$[M_0, M_1] = h(t)\frac{\partial}{\partial x} + h'(t)x,$$

$$[[M_0, M_1], M_1] = h^2(t),$$

$$\mathrm{ad}_{M_0}([[M_0, M_1], M_1]) = [M_0, [[M_0, M_1], M_1]] = \frac{d}{dt}h^2(t),$$

$$\mathrm{ad}^2_{M_0}([[M_0, M_1], M_1]) = [M_0, \mathrm{ad}_{M_0}([[M_0, M_1], M_1])] = \frac{d^2}{dt^2}h^2(t).$$

Thus, a k-iterate Lie bracket as above is of the form

$$\mathrm{ad}^k_{M_0}([[M_0, M_1], M_1]) = [M_0, [M_0, [...[M_0, h^2(t)]...]] = \frac{d^k}{dt^k} h^2(t). \tag{31}$$

If we choose h such that all derivatives of h^2 are linearly independent, then the estimation Lie algebra is infinite dimensional.

Although such estimation Lie algebras have a certain finite-dimensional property, we shall see in the next chapter how to specify the dependency on the initial laws to have finite-dimensional estimation Lie algebras.

5. Uniform families of FDRs. In filtering theory it is remarkable that almost all the systems (except, for instance, those from [26] seen at the end of the previous section or the conditionally Gaussian processes of [18]) for which an FDF has been found have two particularities:

- they admit FDFs which depend on a broad class of initial measures only through the output function (any nonnegative measure in [28] or almost any nonnegative measure in [5] for linear systems, the domain of an operator of $L^1(\mathbb{R}^2)$ in [45], any probability measure in [25]),
- their estimation Lie algebra is finite dimensional (and contains only operators of order less than or equal to two).

It can be checked that all the FDFs in [45, 5, 28, 25] lead to families of FDRs for which the nonnegative output function θ^{μ_0} associated with the initial law μ_0 is of the form

$$\langle \theta^{\mu_0}, \phi \rangle = \int d\mu_0(x_0) \, \langle \theta^{\delta_{x_0}}, \phi \rangle, \tag{32}$$

where $\theta^{\delta_{x_0}}$ is the nonnegative output function of a family of FDRs, uniform with respect to the dynamics and initial condition. Indeed, in all these examples, the family of input-output maps $\{\mathcal{F}^{\mu_0} \mid \mu_0 \in \mathbb{M}_0\}$ is parametrized by a set $\mathbb{M}_0$ like $L^1(\mathbb{R}^n)$ which is too big to be parametrized by some finite-dimensional manifold (unlike the Dirac or the Gaussian measures), and then it is a reasonable choice to have the FDRs depend on μ through the nonnegative output function and not through the diffusion ξ_t by its starting point ξ_0 (like in the Kalman–Bucy filter or in [11]).

When $\mathbb{M}_0 = \mathbb{D}_0$, the set of Dirac measures, the following proposition yields the structure of the estimation Lie algebra.

PROPOSITION 5.1. *If the family of input-output maps $\{\mathcal{F}^{\mu_0} \mid \mu_0 \in \mathbb{D}_0\}$ given by* (8) *admits a regular FDR uniform with respect to the dynamics and initial condition, then $\mathcal{E}$ is finite dimensional and of the form*

$$\mathcal{E} = \mathbb{R}M_0 + \mathcal{R}, \tag{33}$$

where $\mathcal{R}$ is a finite-dimensional subalgebra of differential operators of order less than or equal to one.

Proof. Once we prove that $\mathcal{E}$ is finite dimensional, then it is clear that (33) holds by a straightforward application of Proposition 4.6.

Thus, to show that $\mathcal{E}$ is finite dimensional, we first exhibit a Lie ideal $\mathcal{J}$ of $\mathcal{B}$ such that $\mathcal{E}$ is isomorphic to $\mathcal{B} \setminus \mathcal{J}$, then show that this latter vector space is finite dimensional.

We introduce the following family of Lie ideals of $\mathcal{B}$ (Lie ideals by Proposition 3.3):

$$\mathcal{J}_{x_0} = \{\, j \in \mathcal{B} \,|\, \text{w.p.1} \;\; \forall\, t \geq 0, \; L_j \theta^{\delta_{x_0}}(\xi_t) = 0 \,\},$$

and we define the Lie ideal $\mathcal{J}$ of $\mathcal{B}$ by

$$\mathcal{J} = \bigcap_{x_0 \in \mathbb{R}^n} \mathcal{J}_{x_0}.$$

Now, we define a homomorphism Λ from $\mathcal{E}$ to $\mathcal{B} \setminus \mathcal{J}$ as follows. Let $E \in \mathcal{E}$. We can always write

$$E = \sum_{k \leq l} \sum_{i_1=0}^{p} \cdots \sum_{i_k=0}^{p} e_{i_1,\ldots,i_k} [\, M_{i_1}, [\ldots, M_{i_k}\,] \ldots]. \tag{34}$$

It is then clear by Lemma 3.4 that we have

$$\forall\, x_0 \in \mathbb{R}^n \quad \text{w.p.1} \quad \forall\, t \,>\, 0, \quad L_b \theta^{\delta_{x_0}}(\xi_t) = E^\star \theta^{\delta_{x_0}}(\xi_t), \tag{35}$$

where $b \in \mathcal{B}$ is defined by

$$b = \sum_{k \leq l} \sum_{i_1=0}^{p} \cdots \sum_{i_k=0}^{p} e_{i_1,\ldots,i_k} [\, b_{i_1}, [\ldots, b_{i_k}\,] \ldots]\,. \tag{36}$$

Thus, we can assign to $E \in \mathcal{E}$ a nonempty subset $\Lambda(E)$ of $\mathcal{B}$ by

$$\Lambda(E) = \{\, b \in \mathcal{B} \mid \text{w.p.1} \quad \forall\, t \,>\, 0, \quad L_b \theta^{\delta_{x_0}}(\xi_t) = E^\star \theta^{\delta_{x_0}}(\xi_t) \,\}\,. \tag{37}$$

What is more, it is easily seen that $\Lambda(E)$ belongs to $\mathcal{B} \setminus \mathcal{J}$.

The above-defined mapping Λ is one to one:

- Λ is injective because $\Lambda(E) = \mathcal{J}$ implies, by the definitions of $\Lambda(E)$ and $\mathcal{J}$, that for all $x_0 \in \mathbb{R}^n$, one has $E^\star \delta_{x_0} = 0$ and thus $E = 0$,
- Λ is onto, because for any $b \in \mathcal{B}$, we can always write it as in (36) and then $E \in \mathcal{E}$ given by (34) is such that $\Lambda(E)$ is the class of b.

Therefore, $\mathcal{E}$ is isomorphic to $\mathcal{B} \setminus \mathcal{J}$.

We now prove that $\mathcal{B} \setminus \mathcal{J}$ is finite dimensional. For this, we consider the following linear mapping ϖ:

$$\varpi \,:\, \mathcal{B} \to T_{\xi_0} M, \quad b \mapsto b(\xi_0)\,. \tag{38}$$

We study $\mathrm{Ker}\varpi$. Let $b \in \mathcal{B}$ such that $b(\xi_0) = 0$ and, since Λ is onto, let $E \in \mathcal{E}$ be such that $\Lambda(E)$ is the class of b. As a consequence of (37) for $t = 0$, E satisfies $L_b \theta^{\delta_{x_0}}(\xi_0) = E^\star \delta_{x_0}$ for all $x_0 \in \mathbb{R}^n$. Since $b(\xi_0) = 0$, then

$$\forall\, x_0 \in \mathbb{R}^n, \quad 0 = L_{b(\xi_0)} \theta^{\delta_{x_0}}(\xi_0) = L_b \theta^{\delta_{x_0}}(\xi_0) = E^\star \delta_{x_0}$$

and therefore $E = 0$. We have just shown that $\mathrm{Ker}\varpi \subset \Lambda(0) = \mathcal{J}$, and thus $\mathcal{B} \setminus \mathcal{J} \subset \mathcal{B} \setminus \mathrm{Ker}\varpi$.

Moreover, by (38), there exists an injection, derived from ϖ, from $\mathcal{B} \setminus \mathrm{Ker}\varpi$ to $T_{\xi_0} M$, and we obtain

$$\mathcal{E} \simeq \mathcal{B} \setminus \mathcal{J} \subset \mathcal{B} \setminus \mathrm{Ker}\varpi \hookrightarrow T_{\xi_0} M.$$

Since the last mapping is an injection, we finally get

$$\dim \mathcal{E} \leq \dim M \,<\, +\infty. \tag{39}$$

This ends the proof. □

Now we shall prove that the above necessary conditions of Proposition 5.1 for the existence of certain classes of FDRs are almost sufficient.

THEOREM 5.2. *Assume that*

1. $\mathcal{E}$ *is finite dimensional and given by* (33)*, where* $\mathcal{R}$ *is a finite-dimensional subalgebra of differential operators of order less than or equal to one,*

2. $\mathcal{E}$ *is a solvable Lie algebra, with a basis* $\{F_0, F_1, F_2, \ldots, F_q\}$ *such that* $F_0 = M_0$ *and* $\mathcal{F}_i = \mathbb{R} - \text{span}\{ F_i, \ldots, F_q \}$ *is a Lie ideal of* $\mathcal{F}_{i-1}$ *for* $i = 0, \ldots, q$*,*

3. *the first-order part of each operator* F_1*, ...,* F_q *defines a complete vector field on* $\mathbb{R}^n$*,*

4. *for all* $\phi \in \mathcal{D}(\mathbb{R}^n)$*, there exists a unique solution* $u \in C^\infty(]0, +\infty[\times\mathbb{R}^n) \cap C^0([0, +\infty[\times\mathbb{R}^n)$ *of the PDE*

$$\frac{\partial u}{\partial t} = M_0\, u, \quad u(0, x) = \phi(x). \tag{40}$$

Then the family of input-output maps $\{\mathcal{F}^{\mu_0} \mid \mu_0 \in \mathbb{D}_0\}$ *given by* (8) *admits a regular FDR, uniform with respect to the dynamics and initial condition.*

Remark. The Lie algebra $\mathcal{E}$ can be finite dimensional without being solvable, as is the case for $\mathcal{E} = \{\frac{d^2}{dx^2}, x^2\}_{\mathcal{L}.\mathcal{A}.}$. However, Tam, Wong, and Yau prove in [41] that finite-dimensional estimation algebra from filtering problems (without correlated noise) are solvable when the second-order part of the infinitesimal generator of the signal is the Laplacian on $\mathbb{R}^n$ and the drift is a gradient vector field.

First, we shall define the collection of output functions.

LEMMA 5.3. *Suppose that the assumptions of Theorem* 5.2 *are satisfied. Then there exists a family of nonnegative output functions* $\left(\theta^{\delta_{x_0}}\right)_{x_0 \in \mathbb{R}^n}$ *on* $\text{Dom}(\theta) =]0, +\infty[\times\mathbb{R}^q$ *which satisfy*

$$\left\langle \frac{\partial \theta^{\delta_{x_0}}}{\partial \xi^i}(\xi), \phi \right\rangle = \left\langle \theta^{\delta_{x_0}}(\xi), e^{-\xi^0\, ad_{F_0}} \cdots e^{-\xi^{i-1}\, ad_{F_{i-1}}} F_i \phi \right\rangle, \tag{41}$$

where $F_0 = M_0$*. Here,* $ad_M(N) = [M, N]$ *and* $e^{t\, ad_M}$ *is the linear operator* $e^{t\, ad_M} = \sum_{j=0}^{+\infty} \frac{t^j\, ad_M^j}{j!}$ *of the finite-dimensional Lie algebra* $\mathcal{E}$*.*

Proof. If $F_1 = X_1 + c_1, \ldots, F_q = X_q + c_q$ is a basis of $\mathcal{R}$, where $X_1, \ldots, X_q$ are (operators of order one identified with) complete vector fields and c_1, ..., c_q are smooth functions, then the evolution equations

$$\frac{\partial u}{\partial t} = F_i\, u = (X_i + c_i)u, \quad u(0, x) = \phi(x), \tag{42}$$

generate positive transition groups $(P_t^1)_{t\in\mathbb{R}}$, ..., $(P_t^q)_{t\in\mathbb{R}}$ on $C^\infty(\mathbb{R}^n)$ given by

$$P_t^i\, \phi\,(x) \,=\, \exp\left(\int_0^t c_i(\Phi_s^{X_i}(x))\, ds \right)\, \phi\,(\Phi_t^{X_i}(x))\,. \tag{43}$$

Moreover, if $(P_t^0)_{t\geq 0}$ is the transition semigroup on $\mathcal{D}(\mathbb{R}^n)$ generated by the evolution equation (40), let us define the map $\theta^{\delta_{x_0}}$ from $]0, +\infty[\times\mathbb{R}^q$ to $\mathbb{M}_+(\mathbb{R}^n)$ by

$$\left\langle \theta^{\delta_{x_0}}(\xi),\, \phi \right\rangle \,=\, \left(P_{\xi^q}^q \,\cdots\, (P_{\xi^0}^0\, \phi) \right)\, (x_0) \,=\, P_{\xi^q}^q \,\cdots\, P_{\xi^0}^0\, \phi\,(x_0). \tag{44}$$

The function $\left\langle \theta^{\delta_{x_0}}(\cdot),\, \phi \right\rangle$ is clearly continuous on $[0, +\infty[\times\mathbb{R}^q$ and smooth on $]0, +\infty[\times\mathbb{R}^q$ since it can be expressed by the formula

$$\begin{aligned}
&\left\langle \theta^{\delta_{x_0}}(\xi),\, \phi \right\rangle \\
&\quad = \exp\left(\int_0^{\xi^q} c_q(\Phi_s^{X_q}(x_0))\, ds \right) \times \cdots \times \exp\left(\int_0^{\xi^1} c_1(\Phi_s^{X_1} \circ \Phi_{\xi^2}^{X_2} \circ \cdots \circ \Phi_{\xi^q}^{X_q}(x_0))\, ds \right) \\
&\qquad \times\, (P_{\xi^0}^0 \phi)(\Phi_{\xi^1}^{X_1} \circ \cdots \circ \Phi_{\xi^q}^{X_q}(x_0))\,.
\end{aligned}$$

To prove (41), we put

$$\phi_0 = \phi \in \mathcal{D}(\mathbb{R}^n), \phi_1 = P^0_{\xi^0}\,\phi_0 \in C^\infty(\mathbb{R}^n), \ldots, \phi_q = P^q_{\xi^q}\,\phi_{q-1} \in C^\infty(\mathbb{R}^n)$$

so that if $\varepsilon_0, \ldots, \varepsilon_q$ is the canonical basis of $\mathbb{R}^{q+1}$, we have

$$\frac{\left\langle \theta^{\delta_{x_0}}(\xi),\, \phi \right\rangle - \left\langle \theta^{\delta_{x_0}}(\xi + t\varepsilon_i),\, \phi \right\rangle}{t} = \left(P^q_{\xi^q} \cdots P^i_{\xi^i}\, \frac{P^i_t\,\phi_i - \phi_i}{t} \right)(x_0).$$

When t tends to zero, this last term converges to $(P^q_{\xi^q} \cdots P^i_{\xi^i}\, F_i\phi_i)(x_0)$ since the operators P^1_t, …, P^q_t are easily seen to be continuous on $C^0(\mathbb{R}^n)$ for the pointwise convergence. Therefore, we have for $i = 0, \ldots, q$:

$$\left\langle \frac{\partial \theta^{\delta_{x_0}}}{\partial \xi^i}(\xi), \phi \right\rangle = \frac{\partial}{\partial \xi^i} \left\langle \theta^{\delta_{x_0}}(\cdot),\, \phi \right\rangle_{|\xi} = P^q_{\xi^q} \cdots P^i_{\xi^i}\, F_i\, \phi_i\,(x_0)\,. \tag{45}$$

By Theorem A.1 in the Appendix, the Baker–Campbell–Hausdorff formula (A.57) applies to $F_i\,\phi_i$ for $i = 1, \ldots, q$. Indeed, we have

$$\begin{aligned} F_1\,\phi_1 &= F_1\,P^0_{\xi^0}\,\phi_0 \\ &= P^0_{\xi^0}\,(e^{-\xi^0\,\mathrm{ad}_{F_0}} F_1\,\phi_0) \end{aligned}$$

since $\phi_0 = \phi$, $F_0\phi_0$, …, $F_q\phi_0$ all belong to $\mathcal{D}(\mathbb{R}^n)$ on which $P^0_{\xi^0}$ is defined (see Theorem A.1). Now, with $\phi_1, \ldots, \phi_q \in C^\infty(\mathbb{R}^n)$, we show in the same way for $i = 1, \ldots, q$,

$$\begin{aligned} F_i\,\phi_i &= F_i\,P^{i-1}_{\xi^{i-1}}\,\phi_{i-1} \\ &= P^{i-1}_{\xi^{i-1}}\,e^{-\xi^{i-1}\,\mathrm{ad}_{F_{i-1}}} F_i\,\phi_{i-1} \\ &= \cdots \\ &= P^{i-1}_{\xi^{i-1}} \cdots P^0_{\xi^0}\,e^{-\xi^0\,\mathrm{ad}_{F_0}} \cdots e^{-\xi^{i-1}\,\mathrm{ad}_{F_{i-1}}}\, F_i\phi\,. \end{aligned}$$

After reporting this last expression in (45), we find (41).

Now, there remains to prove that all partial derivatives of $\left\langle \theta^{\delta_{x_0}}(\xi),\, \phi \right\rangle$ have limits on $[0, +\infty[\times\mathbb{R}^q$ (see Definition 2.1). For this, we can notice that in (41) the term $e^{-\xi^0 \mathrm{ad}_{F_0}} \cdots e^{-\xi^{i-1} \mathrm{ad}_{F_{i-1}}} F_i$ is an analytic expression in $(\xi^0, \ldots, \xi^{i-1})$ since $\mathcal{E}$ is finite dimensional. Therefore, we can write

$$e^{-\xi^0\,\mathrm{ad}_{F_0}} \cdots e^{-\xi^{i-1}\,\mathrm{ad}_{F_{i-1}}}\, F_i = \sum_{j=0}^{q} \alpha_{ij}(\xi^0, \ldots, \xi^{i-1})\, F_j, \tag{46}$$

where α_{i0}, …, α_{iq} are analytic functions. As a consequence of (41), we have

$$\left\langle \frac{\partial \theta^{\delta_{x_0}}}{\partial \xi^i}(\xi),\, \phi \right\rangle = \sum_{j=0}^{q} \alpha_{ij}(\xi^0, \ldots, \xi^{i-1}) \left\langle \theta^{\delta_{x_0}}(\xi),\, F_j\,\phi \right\rangle$$

so that the first partial derivatives of $\left\langle \theta^{\delta_{x_0}}(\cdot)\,,\, \phi \right\rangle$ have limits on $[0, +\infty[\times\mathbb{R}^q$ since $\left\langle \theta^{\delta_{x_0}}(\cdot)\,,\, \phi \right\rangle$ is continuous on $[0, +\infty[\times\mathbb{R}^q$. If we iterate the procedure, we prove that this is the case for all partial derivatives, so that $\theta^{\delta_{x_0}}$ is an output function on $]0, +\infty[\times\mathbb{R}^q$. □

Proof of Theorem 5.2. If we show that there exist $p+1$ vector fields b_0, b_1, …, b_p on $\mathbb{R}^q$ such that equation (12) is conservative on $]0,+\infty[\times\mathbb{R}^q$ (with $\xi_{t\,|t=0}=0$) and that

$$\left\langle L_{b_i}\theta^{\delta_{x_0}}(\xi),\,\phi\right\rangle \,=\, \left\langle \theta^{\delta_{x_0}}(\xi),\,M_i\phi\right\rangle, \quad i=0,\dots,p, \tag{47}$$

then $(\mathbb{R}^{q+1},0,b_0,b_1,\dots,b_p,\theta^{\delta_{x_0}})_{x_0\in\mathbb{R}^n}$ is a family of regular FDRs, uniform with respect to the dynamics and initial condition, for the family of input-output maps $\{\mathcal{F}^{\mu_0}\mid\mu_0\in\mathbb{D}_0\}$ given by (8).

Indeed, it would only remain to show that $\left\langle\theta^{\delta_{x_0}}(\xi_t),\,\phi\right\rangle$ satisfies equation (5). But (47) and (12) provide the result thanks to the (ordinary) Itô–Stratonovitch formula since for all $\phi\in\mathcal{D}(\mathbb{R}^n)$, w.p.1, we have

$$\begin{aligned} d\left\langle\theta^{\delta_{x_0}}(\xi_t),\,\phi\right\rangle &= L_{b_0}\left\langle\theta^{\delta_{x_0}},\phi\right\rangle_{|\xi_t}dt \,+\, \sum_{i=1}^{p} L_{b_i}\left\langle\theta^{\delta_{x_0}},\phi\right\rangle_{|\xi_t}\circ dy_t^i \\ &= \left\langle L_{b_0}\theta^{\delta_{x_0}}(\xi_t),\phi\right\rangle dt \,+\, \sum_{i=1}^{p}\left\langle L_{b_i}\theta^{\delta_{x_0}}(\xi_t),\phi\right\rangle\circ dy_t^i \\ &= \left\langle\theta^{\delta_{x_0}}(\xi_t),M_0\phi\right\rangle dt \,+\, \sum_{i=1}^{p}\left\langle\theta^{\delta_{x_0}}(\xi_t),M_i\phi\right\rangle\circ dy_t^i. \end{aligned}$$

We define the vector fields b_0, …, b_p on $\mathbb{R}^{q+1}$ as images of left-invariant vector fields on a Lie group as follows.

Since the Lie algebra $\mathcal{E}$ is finite dimensional, then it is the Lie algebra of a simply connected Lie group G [17]. Moreover, if $\mathcal{G}$ denotes the Lie algebra of left-invariant vector fields of the Lie group G and T_eG the tangent space to G at the neutral element e of G, there is a series of isomorphisms

$$\mathcal{E}\simeq\mathcal{G}\simeq T_eG. \tag{48}$$

Let us denote by $\mathbf{g}_0,\dots,\mathbf{g}_q$ the images of F_0, …, F_q in $\mathcal{G}$. The exponential mapping from T_eG to G satisfies $\Phi_t^{\mathbf{g}}(\tau)=\tau\,e^{t\mathbf{g}(e)}$ for all $\tau\in G$ and $\mathbf{g}\in\mathcal{G}$. Denoting $g_i=\mathbf{g}_i(e)\in T_eG$, the following mapping Ψ from $\mathbb{R}^{q+1}$ to G is analytic:

$$\Psi(\xi^0,\dots,\xi^q)=e^{\xi^q g_q}\,\cdots\,e^{\xi^0 g_0}=\Phi_{\xi^q}^{\mathbf{g}_q}\cdots\Phi_{\xi^0}^{\mathbf{g}_0}(e)\,. \tag{49}$$

Moreover, since $\mathcal{E}$ is solvable, then G is also solvable and, thanks to the choice of the basis $\{F_0,F_1,\dots,F_q\}$, Ψ is shown to be one to one with analytic inverse [7, p. 240]. Then, to the vector fields $\mathbf{g}_0$, …, $\mathbf{g}_q$ we associate the following vector fields on $\mathbb{R}^{q+1}$: $a_0=\Psi_\star^{-1}(\mathbf{g}_0)$, …, $a_q=\Psi_\star^{-1}(\mathbf{g}_q)$. They satisfy

$$\left\langle L_{a_i}\theta^{\delta_{x_0}}(\xi),\,\phi\right\rangle \,=\, \left\langle\theta^{\delta_{x_0}}(\xi),\,F_i\,\phi\right\rangle \quad\forall\,\xi\in\,[0,+\infty[\times\mathbb{R}^q\,. \tag{50}$$

Indeed, for ξ in $]0,+\infty[\times\mathbb{R}^q$ and $i=0,\dots,p$, we have

$$\begin{aligned} \left\langle L_{a_i}\theta^{\delta_{x_0}}(\xi),\,\phi\right\rangle &= L_{a_i}\left\langle\theta^{\delta_{x_0}}(\cdot)\,,\,\phi\right\rangle_{|\xi} \\ &= L_{\Psi_\star^{-1}(\mathbf{g}_i)}\left\langle\theta^{\delta_{x_0}}(\cdot)\,,\,\phi\right\rangle_{|\xi} \\ &= L_{\mathbf{g}_i}\left\langle\theta^{\delta_{x_0}}\left(\Psi^{-1}(\cdot)\right),\,\phi\right\rangle_{|\Psi(\xi)} \\ &= \tfrac{d}{dt}_{|t=0}\left\langle\theta^{\delta_{x_0}}\left(\Psi^{-1}(\Phi_t^{\mathbf{g}_i}(\Psi(\xi)))\right),\,\phi\right\rangle. \end{aligned} \tag{51}$$

Now, since Ψ is an analytic diffeomorphism of $\mathbb{R}^{q+1}$, there exist analytic functions $r_0, \ldots, r_q$ (which depend on $\xi^0, \ldots, \xi^q$) such that for all t

$$\Phi_t^{\mathbf{g}_i}(\Psi(\xi)) = e^{\xi^q g_q} \cdots e^{\xi^0 g_0} e^{t g_i} = e^{(\xi^q + r_q(t)) g_q} \cdots e^{(\xi^0 + r_0(t)) g_0}. \tag{52}$$

Therefore, by (51) we have

$$\begin{aligned} \left\langle L_{a_i} \theta^{\delta_{x_0}}(\xi),\, \phi \right\rangle &= \frac{d}{dt}_{|t=0} \left\langle \theta^{\delta_{x_0}} \left(\xi^0 + r_0(t), \ldots, \xi^q + r_q(t)\right),\, \phi \right\rangle \\ &= \sum_{j=0}^{q} \frac{dr_j}{dt}(0) \left\langle \frac{\partial \theta^{\delta_{x_0}}}{\partial \xi^j}(\xi),\, \phi \right\rangle \\ &= \left\langle \theta^{\delta_{x_0}}(\xi),\, \widetilde{F}_i\, \phi \right\rangle, \end{aligned}$$

where

$$\widetilde{F}_i = \sum_{j=0}^{q} \frac{dr_j}{dt}(0)\, e^{-\xi^0 \operatorname{ad}_{F_0}} \cdots e^{-\xi^{j-1} \operatorname{ad}_{F_{j-1}}} F_j. \tag{53}$$

We now prove that $\widetilde{F}_i = F_i$ for $i = 0, \ldots, q$, and for this purpose we focus on equation (52), which defines the functions $r_0, \ldots, r_q$. Denoting $\tau = e^{\xi^q g_q} \cdots e^{\xi^0 g_0}$, we obtain the following equality:

$$\tau\, g_i = \sum_{j=0}^{q} e^{\xi^q g_q} \cdots e^{\xi^j g_j}\, \frac{dr_j}{dt}(0)\, g_j\, e^{\xi^{j-1} g_{j-1}} \cdots e^{\xi^0 g_0}$$

in the tangent space $T_\tau(G)$ after differentiation in t. Here, $g\, g_i$ denotes the tangent mapping at e, estimated on the tangent vector g_i, of the left action on the Lie group G: $h \mapsto g\, h$ (this notation is convenient because it allows easy and theoretically justified manipulations). Multiplying this last equation by $e^{-\xi^q g_q} \cdots e^{-\xi^1 g_1}$, we finally get

$$g_i = \sum_{j=0}^{q} \frac{dr_j}{dt}(0)\, e^{-\xi^0 g_0} \cdots e^{-\xi^{j-1} g_{j-1}}\, g_j\, e^{\xi^{j-1} g_{j-1}} \cdots e^{\xi^0 g_0},$$

where, as in any Lie group, $e^{-\xi^{j-1} g_{j-1}}\, g_j\, e^{\xi^{j-1} g_{j-1}} = e^{-\xi^{j-1} \operatorname{ad}_{g_{j-1}}}\, g_j$ [16, p. 175], so that

$$g_i = \sum_{j=0}^{q} \frac{dr_j}{dt}(0)\, e^{-\xi^0 \operatorname{ad}_{g_0}} \cdots e^{-\xi^{j-1} \operatorname{ad}_{g_{j-1}}} (g_j).$$

Therefore, by the Lie isomorphisms (48) and by comparing this latter equality with (53), this proves that $\widetilde{F}_i = F_i$.

Now, if $M_i = \sum_{j=0}^{q} f_{ij}\, F_j$, we define $p+1$ vector fields $b_0, \ldots, b_p$ on $\mathbb{R}^{q+1}$ by $b_i = \sum_{j=0}^{q} f_{ij}\, a_j$. By (50), the vector fields $b_0, \ldots, b_p$ satisfy (47).

Since $\mathbf{g}_0, \ldots, \mathbf{g}_q$ are left-invariant vector fields on the Lie group G, then the stochastic differential equation

$$dg_t = \left(\sum_{j=0}^{q} f_{0j} \mathbf{g}_j \right)(g_t)\, dt + \sum_{i=1}^{p} \left(\sum_{j=0}^{q} f_{ij} \mathbf{g}_j \right)(g_t)\, dy_t^i, \quad g_0 = e \tag{54}$$

is conservative [40]. It is easily seen that $\xi_t = \Psi^{-1}(g_t)$ is a solution of the stochastic differential equation (12), thus proving that it is conservative. Moreover, the solution ξ_t is of the form (t, η_t). Indeed, (49) implies that

$$\begin{aligned}\frac{\partial \Psi}{\partial \xi^j} &= e^{\xi^q g_q} \cdots e^{\xi^j g_j}\, g_j\, e^{\xi^{j-1} g_{j-1}} \cdots e^{\xi^0 g_0} \\ &= e^{\xi^q g_q} \cdots e^{\xi^0 g_0} e^{-\xi^0 g_0} \cdots e^{-\xi^{j-1} g_{j-1}}\, g_j\, e^{\xi^{j-1} g_{j-1}} \cdots e^{\xi^0 g_0} \\ &= e^{\xi^q g_q} \cdots e^{\xi^0 g_0} e^{-\xi^0 \operatorname{ad}_{g_0}} \cdots e^{-\xi^{j-1} \operatorname{ad}_{g_{j-1}}}(g_j) \\ &= \Psi(\xi^0, \ldots, \xi^q) e^{-\xi^0 \operatorname{ad}_{g_0}} \cdots e^{-\xi^{j-1} \operatorname{ad}_{g_{j-1}}}(g_j);\end{aligned}$$

that is,

$$\begin{aligned}\frac{\partial}{\partial \xi^0} &= \Psi_\star^{-1}(\mathbf{g}_0), \\ \frac{\partial}{\partial \xi^1} &= \Psi_\star^{-1}\left(e^{-\xi^0 \operatorname{ad}_{\mathbf{g}_0}}\, \mathbf{g}_1\right), \\ \cdots &= \cdots \\ \frac{\partial}{\partial \xi^q} &= \Psi_\star^{-1}\left(e^{-\xi^0 \operatorname{ad}_{\mathbf{g}_0}} \cdots e^{-\xi^{q-2} \operatorname{ad}_{\mathbf{g}_{q-2}}}\, \mathbf{g}_q\right).\end{aligned}$$

By the property of the basis $\{F_0, F_1, F_2, \ldots, F_q\}$ of the solvable Lie algebra $\mathcal{E}$ (see assumption 2 of Theorem 5.2), we have

$$b_i(\xi) \in \mathbb{R} - \operatorname{span}\left\{\frac{\partial}{\partial \xi^1}, \ldots, \frac{\partial}{\partial \xi^q}\right\} \quad \forall\, i = 1, \ldots, q. \tag{55}$$

Since $b_0 = a_0 = \frac{\partial}{\partial \xi^0}$, it is clear that ξ_t is of the form (t, η_t) so that the stochastic differential equation (12) is conservative on $]0, +\infty[\times\mathbb{R}^q$. □

Remarks.

• This uniform FDR is minimal in the sense that the dimension q of the manifold is minimal by the inequality (39).

• Under the assumptions of Theorem 5.2, let μ_0 in $\mathbb{M}_+(\mathbb{R}^n)$ be such that for all $\xi \in]0, +\infty[\times\mathbb{R}^q$ there exists a neighborhood V such that $x_0 \mapsto \sup_{\xi\in V} |\langle \theta^{\delta_{x_0}}(\xi),\, \phi\rangle|$ belongs to $L^1(\mu_0)$ for any ϕ in $\mathcal{D}(\mathbb{R}^n)$ (in order to apply Lebesgue's dominated convergence theorem). Then an easy extension of the proof provides an FDR for $\mathcal{F}^{\mu_0}$, where the nonnegative output function θ^{μ_0} is defined by

$$\langle \theta^{\mu_0}(\xi),\, \phi\rangle \;=\; \int_{\mathbb{R}^n} d\mu_0(x_0)\, \left\langle \theta^{\delta_{x_0}}(\xi),\, \phi\right\rangle.$$

• If M_0 is a first-order differential operator, everything remains valid with P_t^0 defined like $P_t^1, \ldots, P_t^q$.

Appendix A. A Baker–Campbell–Hausdorff formula. We are providing a variation of the Baker–Campbell–Hausdorff formula which gives, under proper assumptions, the exponential expression of a product of exponentials in a Lie group [7, sections 6, 7]. Our formulation is close to that of Wei and Norman [43] but in the field of semigroups of operators, namely a sort of exponential of differential operator. The proof of the formula does not appeal to functional spaces theory as in [33, 45] for the particular cases treated but does appeal to partial differential calculations as in [38].

THEOREM A.1. *Let Y and Z be two smooth linear differential operators on $\mathbb{R}^n$. Let D be a set of smooth functions ϕ such that the PDE*

$$\frac{\partial u}{\partial t} \;=\; Y\, u, \quad u(0, x) \;=\; \phi(x) \tag{A.56}$$

has a unique solution $u(t,x)$ *in* $C^\infty(I\times\mathbb{R}^n)$*, where* $I=]0,+\infty[$ *or* $I=\mathbb{R}$*. In such a case, we denote* $u(t,x)$ *by* $P_t\,\phi\,(x)$*.*

If the Lie algebra $\mathcal{O}$ *of differential operators generated by* Y *and* Z *is finite dimensional and if* $\mathcal{O}\,D\,\subset\,D$*, then we have the following relation:*

$$\forall\, t\in I,\quad \forall\,\phi\in D,\quad Z\,(P_t\,\phi)\;=\;P_t\,(e^{-t\,ad_Y}\,Z\,\phi). \tag{A.57}$$

Here, $ad_Y(Z)=[Y,Z]$ *and* $e^{t\,ad_Y}$ *is the linear operator* $e^{t\,ad_Y}=\sum_{j=0}^{+\infty}\frac{t^j\,ad_Y^j}{j!}$ *of the finite-dimensional Lie algebra* $\mathcal{O}$*.*

Proof. Suppose that for any $X\in\mathcal{O}$ we show that

$$\forall\, t\in I,\quad \forall\,\phi\,\in\,D,\quad e^{t\,\mathrm{ad}_Y}\,X\,(P_t\,\phi)\;=\;P_t\,(X\,\phi)\,. \tag{A.58}$$

Then, if we replace X by $e^{-t\,\mathrm{ad}_Y}Z$, the theorem is proved.

With the definition of D, equation (A.58) means that the function u defined by $u(t,x)=e^{t\,\mathrm{ad}_Y}X\,(P_t\,\phi)(x)$ satisfies (A.56) with initial condition $u(0,x)=X\phi$. Since this last property of u is straightforward, let us compute $\frac{\partial u}{\partial t}$. If $\{W_1,\,\ldots,\,W_q\}$ is a basis of $\mathcal{O}$, then $e^{-t\,\mathrm{ad}_Y}X$ can be written as $e^{t\,\mathrm{ad}_Y}X=\sum_{j=1}^q\,z_j(t)\,W_j$, where $z_1,\,\ldots,\,z_q$ are smooth functions of t and therefore

$$u(t,x)=\sum_{j=1}^{q}\,z_j(t)\,W_j(P_t\,\phi)(x). \tag{A.59}$$

The function u is smooth on $I\times\mathbb{R}^n$ and we have

$$\frac{\partial u}{\partial t}=\sum_{j=1}^{q}\,\frac{\partial}{\partial t}(z_j(t)\,W_j\,(P_t\,\phi))=\sum_{j=1}^{q}\,\frac{dz_j(t)}{dt}W_j\,(P_t\,\phi)\,+\,\sum_{j=1}^{q}\,z_j(t)\,\frac{\partial}{\partial t}(W_j\,P_t\,\phi).$$

Now, $P_t\,\phi\,(x)$ is smooth in both variables (t,x) so that we can swap the differentiations $\frac{\partial}{\partial t}$ in the variable t and W_j in the variable x to get

$$\frac{\partial u}{\partial t}=\sum_{j=1}^{q}\,\frac{dz_j(t)}{dt}W_j\,(P_t\,\phi)\,+\,\sum_{j=1}^{q}\,z_j(t)\,W_j\,\frac{\partial}{\partial t}(P_t\,\phi)\,.$$

To compute $\frac{dz_j(t)}{dt}$, note that $Z_t=e^{t\,\mathrm{ad}_Y}X$ is the solution of the linear differential equation $\frac{dZ_t}{dt}=[Y,\,Z_t]$, $Z_0=Z$ in the finite-dimensional real vector space $\mathcal{O}$, so that $\frac{dZ_t}{dt}=[Y,\,Z_t]=\sum_{j=1}^q\,z_j(t)\,[Y,\,W_j]$. Since $\frac{dZ_t}{dt}=\sum_{j=1}^q\,\frac{dz_j(t)}{dt}\,W_i$, we have

$$\sum_{j=1}^{q}\,\frac{dz_j(t)}{dt}\,W_j=\sum_{j=1}^{q}\,z_j(t)\,[Y,\,W_j].$$

Therefore,

$$\begin{aligned}\frac{\partial u}{\partial t}\;&=\;\sum_{j=1}^{q}\,z_j(t)\,[Y,\,W_j]\,(P_t\,\phi)\,+\,\sum_{j=1}^{q}\,z_j(t)\,W_j\,Y\,(P_t\,\phi)\\&=\;\sum_{j=1}^{q}\,z_j(t)\,Y\,W_j\,(P_t\,\phi)\\&=\;Y\,\left(\sum_{j=1}^{q}\,z_j(t)\,W_j\right)\,(P_t\,\phi)\\&=\;Y\,e^{t\,\mathrm{ad}_Y}X\,(P_t\,\phi)\;=\;Y\,u.\end{aligned}$$

This ends the proof. □

Acknowledgment. The author is indebted to Professor J. Lévine for fruitful discussions.

FINITE-DIMENSIONAL FILTERS. PART II: INVARIANCE GROUP TECHNIQUES*

M. COHEN DE LARA†

Abstract. This two-part paper deals with necessary or sufficient conditions for the existence of finite-dimensional filters. In the first part, we set the problem and proposed a construction of finite-dimensional filters by the Wei–Norman technique. In this second part, we show how geometric-methods offer another approach that is more powerful, as we shall see. The invariance group of a parabolic equation is introduced and its action on initial data enhanced. This is applied to the problem of finite-dimensional realization of bilinear stochastic PDEs and further simplified by the introduction of a Riemannian framework. We end by an analysis of partially observed systems having finite-dimensional filters, with emphasis on the case of systems with correlated noise.

Key words. finite-dimensional filter, estimation Lie algebra, bilinear stochastic partial differential equation, invariance group, Riemannian geometry

Notation.

$A(F)$: subgroup of the group $G(F)$ of (global) diffeomorphisms of $F = \mathbb{R} \times \mathbb{R}^n \times \mathbb{R}$, consisting of diffeomorphisms g of the form (26); that is, $g(s,x,u) = (\alpha(s), \beta(s,x), \delta(s,x)u)$.

$SA(F)$: semigroup of $A(F)$ consisting of diffeomorphisms g such that $g^{-1}(\mathbb{R}_+ \times \mathbb{R}^n \times (0,+\infty)) \subset \mathbb{R}_+ \times \mathbb{R}^n \times (0,+\infty)\}$; that is, $\alpha^{-1}(\mathbb{R}_+) \subset \mathbb{R}_+$ and $\delta > 0$.

$\mathcal{U}_P$: subset of $C^\infty(\mathbb{R}_+ \times \mathbb{R}^n)$, consisting of functions $u(t,x)$, solutions of $\frac{\partial u}{\partial t} = M_0^\star u$.

$SA_P(F)$: symmetry semigroup of $\mathcal{U}_P$, consisting of diffeomorphisms $g \in SA(F)$ such that for all $u \in \mathcal{U}_P$, $g \cdot u \in \mathcal{U}_P$:

$$SA_P(F) \subset SA(F) \subset A(F).$$

$\mathcal{A}^c(F)$: set of *complete* smooth vector fields Z on F of the form (37); that is, $Z = \zeta^0(s)\frac{\partial}{\partial s} + \sum_{i=1}^n \zeta^i(s,x)\frac{\partial}{\partial x_i} + \zeta^{n+1}(s,x)u\frac{\partial}{\partial u}$.

$\mathcal{SA}_P^c(F)$: set of complete infinitesimal symmetries of $\mathcal{U}_P$; that is, set of vector fields Z in $\mathcal{A}^c(F)$ such that Φ_r^Z belongs to $SA_P(F)$, for all $r \in \mathbb{R}$,

$$\mathcal{A}^c(F) \subset \mathcal{SA}_P^c(F) \subset \mathcal{X}^c(F) \subset \mathcal{X}(F).$$

1. Introduction.

In this second part we present geometric methods which are powerful to analyze a stochastic partial bilinear partial differential equation (PDE), such as the Zakai equation, and, should the occasion occur, to build a finite-dimensional realization (FDR). The range of application of such methods will be shown to be broader than the Wei–Norman techniques developed in Part I.

In section 2, we motivate the introduction of invariance groups by treating the case of the one-dimensional heat equation and, after stating the problem in section 3, we formalize in section 4 the notions behind the example developed above and introduce basic definitions, notations, and properties for the next sections. In section 5, we show how such invariance group techniques may bring an answer to the FDR problem and state our main result. In section 6, we compare main theorems from Parts I and II. A Riemannian geometric framework is introduced in section 7, which greatly simplifies

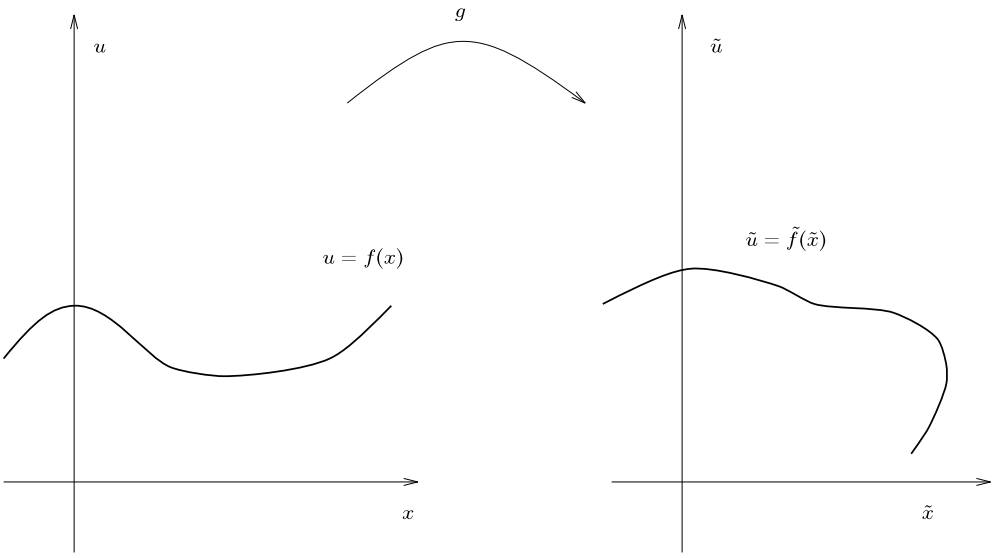

FIG. 1. *Action of a group transformation on a function.*

the analysis of the FDR problem. In section 8, a systematic treatment of the finite dimensional filter (FDF) problem by this latter technique is presented.

2. Motivation. The set of planar motions which keep a geometric figure invariant forms a group, the *symmetry group* of the figure (square, triangle, circle, etc.). In the case of an algebraic equation, a symmetry group or *invariance group* consists of transformations of the base space which permute solutions. (This is one of the basic concepts of Galois's theory.) In some cases, the knowledge of such a group may help solving the equation as in the classical example of the "bisquared" equation:

$$x^4 + bx^2 + c = 0 \iff z = x^2 \quad \text{and} \quad z^2 + bz + c = 0\,.$$

In the case of ordinary differential equations (ODEs), it was pointed out by Lie that all the special techniques to solve certain classes of ODEs had their origin in a general method related to the existence of a continuous invariance group for these ODEs (see the introduction of [16]). Basically, this (local) group consists of geometric transformations of the product space "independent variables" × "dependent variables," and its action on functions consists in transforming their graph as in Figure 1, these transformed graphs being graphs of solutions of the original ODE.

Continuous groups are interesting because they can be found by some calculation algorithms. It is indeed a crucial fact of Lie theory that "the nonlinear conditions expressing the invariance of a system of differential equations under the action of a group of transformations may, in the case of continuous groups, be replaced by *linear* but simpler equivalent conditions" [16]. The latter represent the infinitesimal invariance of the system under the action of the infinitesimal generators of the group.

All the Lie theory can be extended to PDEs [17, 16, 4]. The case of evolution equations, where the variable t plays a specific role, is particularly interesting to us.

Indeed, Rosencrans in [20] utilizes the invariance group of a linear evolution equation of the form $u_t = Au$, where A is a differential operator "acting on the space variables," not to find new solutions from one of them, but to exhibit solutions of

other evolution equations of the form $w_t = (A + P)w$. The set of possible operators P is shown to form a Lie algebra, called the *perturbation algebra*. We illustrate this in the case of the one-dimensional heat equation.

PROPOSITION 2.1. *Let $(g_{r,r'})_{(r,r')\in\mathbb{R}^2}$ be the family of two-parameter diffeomorphisms of $\mathbb{R}\times\mathbb{R}\times\mathbb{R}$ defined by*

$$g_{r,r'}(t,x,u) = (e^{-2r}t - r', e^{-r}x, u)\,. \tag{1}$$

The action of the diffeomorphism $g_{r,r'}$ on a function $u(t,x)$ defines a new function $g_{r,r'}\cdot u$ by the relation

$$g_{r,r'}(\mathit{graph}(u)) \supset \mathit{graph}(g_{r,r'}\cdot u) \tag{2}$$

(see Figure 1*), and its expression is given by*

$$(g_{r,r'}\cdot u)(t',x') = u(e^{2r}(t'+r'), e^r x')\,. \tag{3}$$

The family $(g_{r,r'})_{(r,r')\in\mathbb{R}^2}$ is actually a two-parameter group *of diffeomorphisms, and the mapping*

$$g_{r,r'} \mapsto g_{r,r'}\cdot u \tag{4}$$

defines a group action. Moreover, $(g_{r,r'})$ is an invariance group of the one-dimensional heat equation $u_t = u_{xx}$.

If u is a solution of the heat equation with initial data ϕ, then for $r\in\mathbb{R}$, $r'\geq 0$, $g_{r,r'}\cdot u$ is also a solution of the heat equation but with initial data $(g_{r,r'}\cdot u)(0,x') = u(e^{2r}r', e^r x')$. What is more, the group action (4) *of $g_{r,r'}$ for $r\in\mathbb{R}$, $r'\in\mathbb{R}_+$ induces a group action*

$$g_{r,r'} \mapsto \widehat{g}_{r,r'}\phi \tag{5}$$

by mapping the initial data ϕ to the latter initial data:

$$(\widehat{g}_{r,r'}\phi)(x') = (g_{r,r'}\cdot u)(0,x') = u(e^{2r}r', e^r x')\,. \tag{6}$$

To this group action corresponds a Lie infinitesimal action. The infinitesimal generators of the two-parameter group of diffeomorphisms $(g_{r,r'})_{(r,r')\in\mathbb{R}^2}$ form a Lie algebra generated by the vector fields $\frac{\partial}{\partial t}$ and $2t\frac{\partial}{\partial t} + x\frac{\partial}{\partial x}$. The one-parameter group of diffeomorphisms $\Phi_s^Z(t,x,u)$ generated by the vector field

$$Z = -a\frac{\partial}{\partial t} - b\left(2t\frac{\partial}{\partial t} + x\frac{\partial}{\partial x}\right) \tag{7}$$

belongs to the two-parameter group of diffeomorphisms $(g_{r,r'})_{(r,r')\in\mathbb{R}^2}$ and may be written

$$\Phi_s^Z(t,x,u) = \left(te^{-2bs} - a\frac{1-e^{-2bs}}{2b}, e^{-bs}x, u\right) = g_{r(s),r'(s)}(t,x,u)\,, \tag{8}$$

where $r(s) = bs$, $r'(s) = a(1-e^{-2bs})/2b$. Then, for $a\geq 0$, $(\widehat{g}_{r(s),r'(s)})_{s\geq 0}$ defines a semigroup of operators with infinitesimal generator

$$a\frac{d^2}{dx^2} + bx\frac{d}{dx}\,. \tag{9}$$

In particular, if $u(t,x)$ is the solution of the heat equation with initial data ϕ, then a solution to the Cauchy problem

$$\frac{\partial w}{\partial s} = a\frac{\partial^2 w}{\partial x^2} + bx\frac{\partial w}{\partial x}\,, \quad w(0,x) = \phi(x) \tag{10}$$

is given by

$$w(s,x) = u\left(a\frac{e^{2bs}-1}{2b}, e^{-bs}x\right)\,. \tag{11}$$

Proof. For a given function $u(t,x)$, we have

$$\begin{aligned} g_{r,r'}(\mathrm{graph}(u)) &= \{g_{r,r'}(t,x,u(t,x)) \mid (t,x) \in \mathrm{Dom}(u)\} \\ &= \{(e^{-2r}t - r', e^{-r}x, u(t,x)) \mid (t,x) \in \mathrm{Dom}(u)\} \\ &= \{(t',x',u(e^{2r}(t'+r'), e^r x')) \mid (t',x') \in g_{r,r'}\,(\mathrm{Dom}(u))\}. \end{aligned}$$

This justifies the expression of $(g_{r,r'}\cdot u)(t',x')$ in (3).

Note that the family $(g_{r,r'})_{r,r'\in\mathbb{R}^2}$ is generated by the subfamilies

$$g_{r,0}(t,x,u) = (e^{-2r}t, e^{-r}x, u) \quad \text{and} \quad g_{0,r'}(t,x,u) = (t-r',x,u) \tag{12}$$

since we have the relations

$$\begin{cases} g_{r,0}\circ g_{0,r'}(t,x,u) &= (e^{-2r}(t-r'), e^{-r}x, u) = g_{r,r'}(t,x,u), \\ g_{0,r'}\circ g_{r,0}(t,x,u) &= (e^{-2r}t - r', e^{-r}x, u) = g_{r,e^{2r}r'}(t,x,u)\,. \end{cases} \tag{13}$$

It is thus a two-parameter group of diffeomorphisms. The mapping (4) does define a group action since, on the one hand, we have

$$g_{q,q'}\,(g_{r,r'}(\mathrm{graph}(u))) \supset g_{q,q'}\,(\mathrm{graph}(g_{r,r'}\cdot u)) \supset \mathrm{graph}(g_{q,q'}\cdot(g_{r,r'}\cdot u))$$

and, on the other hand,

$$g_{q,q'}\,(g_{r,r'}(\mathrm{graph}(u))) = g_{q,q'}\circ g_{r,r'}\,(\mathrm{graph}(u)) \supset \mathrm{graph}\,((g_{q,q'}\circ g_{r,r'})\cdot u))$$

so that

$$g_{q,q'}\cdot(g_{r,r'}\cdot u) = (g_{q,q'}\circ g_{r,r'})\cdot u. \tag{14}$$

If $u_t = u_{xx}$, we deduce from (3) that

$$\frac{\partial g_{r,r'}\cdot u}{\partial t'}(t',x') = e^{2r}\frac{\partial^2 u}{\partial x^2}(e^{2r}(t'+r'), e^r x') = \frac{\partial^2 g_{r,r'}\cdot u}{\partial x'^2}(t',x')\,.$$

Therefore, the two-parameter group of diffeomorphisms $(g_{r,r'})_{r,r'\in\mathbb{R}^2}$ is an *invariance group* of the one-dimensional heat equation $u_t = u_{xx}$.

Let u be a function with domain $\mathrm{Dom}(u) = [0,+\infty)\times\mathbb{R}$. Its image $g_{r,r'}\cdot u$ by the diffeomorphism $g_{r,r'}$ has the domain $\mathrm{Dom}(g_{r,r'}\cdot u) = [-r',+\infty)\times\mathbb{R}$ by the formula (3). If u is solution of the heat equation with initial data $u(0,\cdot) = \phi$, then for $r\in\mathbb{R}$ and $r'\geq 0$, $g_{r,r'}\cdot u$ is also a solution of the heat equation, but for other initial data $(g_{r,r'}\cdot u)(0,x') = u(e^{2r}r', e^r x')$. The group action (4) of $g_{r,r'}$ for $r\in\mathbb{R}$, $r'\geq 0$, clearly induces a group action on the initial data.

To this group action corresponds a Lie infinitesimal action as follows. It is well known from elementary Lie group theory [16] that the infinitesimal generators of the two-parameter group of diffeomorphisms $(g_{r,r'})_{r,r'\in\mathbb{R}^2}$ form a Lie algebra generated by the vector fields

$$\left\{\begin{array}{rcl} \frac{\partial}{\partial r}_{|r=0} g_{r,0}(t,x,u) & = & (-2t,-x,0) = -2t\frac{\partial}{\partial t} - x\frac{\partial}{\partial x}, \\ \frac{\partial}{\partial r'}_{|r'=0} g_{0,r'}(t,x,u) & = & (-1,0,0) = -\frac{\partial}{\partial t}\,. \end{array}\right.$$

The one-parameter group of diffeomorphisms $\Phi_s^Z(t,x,u)$ generated by the vector field $Z = -a\frac{\partial}{\partial t} - b(2t\frac{\partial}{\partial t} + x\frac{\partial}{\partial x})$ is the flow of the differential equation

$$\frac{dt}{ds} = -a - 2bt\,, \quad \frac{dx}{ds} = -bx\,, \quad \frac{du}{ds} = 0\,. \tag{15}$$

One finds $t(s) = t(0)e^{-2bs} - a(1-e^{-2bs})/2b$, $x(s) = e^{-bs}x(0)$, $u(s) = u(0)$, hence the expression of $\Phi_s^Z(t,x,u)$ in (8). The comparison of (8) and (1) yields the expressions $r(s) = bs$ and $r'(s) = a(1-e^{-2bs})/2b$.

For $a \geq 0$ and $s \geq 0$, we have $r'(s) \geq 0$, and $(\widehat{g}_{r(s),r'(s)})_{s\geq 0}$ does define a semigroup of operators on the initial data since (5) is a group action ($(g_{r(s),r'(s)})_{s\geq 0}$ extends to the initial data its action on the solutions of the heat equation). If u is the solution of the heat equation with initial data ϕ, then the infinitesimal generator of this semigroup may be computed by

$$\begin{aligned} \frac{d}{ds}_{|s=0} \widehat{g}_{r(s),r'(s)}\phi(x') &= \frac{d}{ds}_{|s=0} u(e^{2r(s)}r'(s), e^{r(s)}x') \\ &= \frac{d}{ds}_{|s=0} u\left(ae^{2bs}\frac{1-e^{-2bs}}{2b}, e^{bs}x'\right) \\ &= \frac{d}{ds}_{|s=0} u\left(a\frac{e^{2bs}-1}{2b}, e^{bs}x'\right) \\ &= a\frac{\partial u}{\partial t}(0,x') + bx'\frac{\partial u}{\partial x}(0,x') \\ &= a\frac{\partial^2 u}{\partial x^2}(0,x') + bx'\frac{\partial u}{\partial x}(0,x') \\ &= a\frac{\partial^2 \phi}{\partial x^2}(x') + bx'\frac{\partial \phi}{\partial x}(x')\,. \end{aligned}$$

In particular, a solution of the Cauchy problem (10) is given by

$$\begin{aligned} w(s,x') &= \widehat{g}_{r(s),r'(s)}\phi(x') \\ &= g_{r(s),r'(s)}\cdot u(0,x) \\ &= u(e^{2r(s)}r'(s), e^{r(s)}x') \\ &= u\left(ae^{2bs}\frac{1-e^{-2bs}}{2b}, e^{bs}x'\right). \end{aligned}$$ □

The link between these techniques and the filtering problem appears when one writes the Zakai equation for the density as $dp_t = (M_0^\star + \sum_{i=1}^p M_i^\star \dot{y}_i(t))p_t dt$. Baras in [2] utilizes this form to define a notion of equivalence between two filtering problems. He gives general conditions, related to the existence of a common invariance group, under which the solution of a filtering problem may be computed from the solution of the other problem.

Here, we extend the method to the resolution of valued functions stochastic evolution equations. We first consider the unperturbed equation $dp_t = M_0^\star p_t dt$ (when $y_t \equiv 0$) and its invariance group. The generators of this latter group may be used to describe the deformations of solutions of the unperturbed equation for each trajectory of the process (y_t) and yield an accurate description of the structure of the resulting finite realization.

3. Problem statement. Let $(y_t)_{t\geq 0}$ be a standard p-dimensional Brownian motion and let $\circ dy_t$ denote its "Stratonovitch differential." For $p_0 \in C^\infty(\mathbb{R}^n)$, we consider the following stochastic bilinear PDE:

$$\text{with probability one (w.p.1) } \forall\, t \in \mathbb{R}_+\,, \quad dp_t = M_0^\star p_t dt + \sum_{i=1}^{p} M_i^\star p_t \circ dy_t^i\,, \quad p_{t|t=0} = p_0. \tag{16}$$

Here $\mathcal{D}(\mathbb{R}^n)$ denotes the space of smooth functions on $\mathbb{R}^n$ with compact support and M_0, M_1, ..., M_p are the linear differential operators defined by

$$\begin{cases} M_0\phi &= \mathcal{L}\phi + H\phi, \\ M_i\phi &= L_{\tilde{g}_i}\phi + h_i\phi\,, \quad i = 1,\ldots,p, \qquad \forall\, \phi \in \mathcal{D}(\mathbb{R}^n)\,, \end{cases} \tag{17}$$

$\mathcal{L}$ being a smooth diffusion operator ($\mathcal{L}1 = 0$), $\tilde{g}_1$, ..., $\tilde{g}_p$ smooth vector fields on $\mathbb{R}^n$ and H, h_1, ..., h_p smooth functions from $\mathbb{R}^n$ to $\mathbb{R}$.

Assumption 1. M_0 (or $\mathcal{L}$) is nondegenerate elliptic; that is, if

$$M_0 = \frac{1}{2}\sum_{i,j=1}^{n} a^{ij}(x)\frac{\partial^2}{\partial x_i \partial x_j} + \sum_{i=1}^{n} b^i(x)\frac{\partial}{\partial x_i} + H(x), \tag{18}$$

the symmetric matrix $(a^{ij}(x))_{i,j=1,\ldots,n}$ is positive definite for all $x \in \mathbb{R}^n$.

Remark. In the filtering problem stated in the introduction of Part I, the Zakai equation is a particular case of equation (16) with

$$\mathcal{L}\phi = \frac{1}{2}\sum_{k=1}^{m} L_{g_k}^2\phi + L_f\phi \quad \text{and} \quad H = -\frac{1}{2}\left(\|h\|^2 + \sum_{i=1}^{p} L_{\tilde{g}_i}h_i\right). \tag{19}$$

DEFINITION 3.1. *Let* Π *consist of all functions* $p_0 \in C^\infty(\mathbb{R}^n)$ *such that there exists an input-output map*

$$\mathcal{F}^{p_0} : \mathbb{R}_+ \times C^0(\mathbb{R}_+, \mathbb{R}^p) \to C^\infty(\mathbb{R}^n) \tag{20}$$

which satisfies the following property: for all $p_0 \in \Pi$ *and* p*-dimensional Brownian motion* $(y_t)_{t\in\mathbb{R}_+}$*, the stochastic bilinear PDE* (16) *has a unique solution* $(p_t)_{t\in\mathbb{R}_+}$ *in* $C^\infty(\mathbb{R}^n)$ *given by*

$$w.p.1 \quad \forall\, t \in \mathbb{R}_+\,, \quad p_t = \mathcal{F}^{p_0}(t; y_s, s \leq t)\,. \tag{21}$$

The definition of an FDR for the input-output map $\mathcal{F}^{p_0}$ is the same as in Part I except for the output function θ. Indeed, θ must be a smooth map from $\mathrm{Dom}(\theta) \subset M$ to $C^\infty(\mathbb{R}^n)$; that is, the following function $(\xi, x) \in \mathrm{Dom}(\theta) \times \mathbb{R}^n \mapsto \theta(\xi)(x) \in \mathbb{R}$ must be smooth.

DEFINITION 3.2. *An* FDR *of the input-output map* $\mathcal{F}^{p_0}$ *given by* (20) *consists of a collection* $(M, \xi_0, b_0, b_1, \ldots, b_p, \theta)$*, where*

1. *M is a smooth finite-dimensional manifold,*
2. *$\xi_0 \in M$,*
3. *b_0, b_1, ..., b_p are smooth vector fields on M,*
4. *θ is a smooth map from $\mathrm{Dom}(\theta) \subset M$ to $C^\infty(\mathbb{R}^n)$; that is, the following function $(\xi, x) \in \mathrm{Dom}(\theta) \times \mathbb{R}^n \mapsto \theta(\xi)(x) \in \mathbb{R}$ must be smooth,*

such that if $(y_t)_{t\geq 0}$ is a Brownian motion, the Stratonovitch stochastic differential equation (SDE)

$$d\xi_t = b_0(\xi_t)dt + \sum_{i=1}^{p} b_i(\xi_t) \circ dy_t^i\,, \quad \xi_{t\,|t=0} = \xi_0 \tag{22}$$

is conservative (that is, w.p.1 has a solution for all time or w.p.1 has infinite explosion time) with solution satisfying

$$w.p.1 \quad \forall\, t > 0\,, \quad \xi_t \in \mathrm{Dom}(\theta)$$

and

$$w.p.1 \quad \forall\, t \geq 0\,, \quad \theta(\xi_t) = \mathcal{F}^{p_0}(t; y_s, s \leq t) = \nu_t\,. \tag{23}$$

4. Symmetry semigroup and infinitesimal symmetries. In this section, we formalize the notions behind the example developed above and introduce basic definitions, notations, and properties for the next sections (see also [7]). The symmetry semigroup consists of a class of point transformations of

$$F = \mathbb{R} \times \mathbb{R}^n \times \mathbb{R} \tag{24}$$

which permute graphs of the solutions of the parabolic equation $u_t = M_0^\star u$. If symmetry groups commonly used in the study of symmetries of differential equations [17, 16, 4, 20] are *local*, we must consider here *global* groups because the Zakai equation is defined on all $\mathbb{R}^n$.

DEFINITION 4.1. *Let $\mathcal{D}(M_0^\star)$ be the subspace of $C^\infty(\mathbb{R}^n)$ consisting of functions p_0 such that the following PDE*

$$\frac{\partial u}{\partial t} = M_0^\star u\,, \quad u(0,\cdot) = p_0 \tag{25}$$

has a unique solution $u(t,x) \in C^\infty(\mathbb{R}_+ \times \mathbb{R}^n)$. Let $(P_t)_{t\in\mathbb{R}_+}$ be the nonnegative (since $M_0^\star$ is a second-order differential operator) semigroup on $\mathcal{D}(M_0^\star)$ generated by equation (25).

For $p_0 \in \mathcal{D}(M_0^\star)$, Pp_0 denotes the function $Pp_0(t,x) = (P_t p_0)(x)$ defined on $\mathbb{R}_+ \times \mathbb{R}^n$. The set of solutions of equation (25) is $\mathcal{U}_P \subset C^\infty(\mathbb{R}_+ \times \mathbb{R}^n)$, consisting of functions of the form Pp_0 for $p_0 \in \mathcal{D}(M_0^\star)$.

We now introduce groups and semigroups (that is, only stable by composition of diffeomorphisms, not by inversion) of F as follows.

DEFINITION 4.2. *Let $G(F)$ denote the group of (global) diffeomorphisms of $F = \mathbb{R} \times \mathbb{R}^n \times \mathbb{R}$, and let $A(F)$ be the subgroup of diffeomorphisms g of the form*

$$\begin{array}{rccc} g: & \mathbb{R} \times \mathbb{R}^n \times \mathbb{R} & \to & \mathbb{R} \times \mathbb{R}^n \times \mathbb{R}, \\ & (s,x,u) & \mapsto & (\alpha(s), \beta(s,x), \delta(s,x)u)\,. \end{array} \tag{26}$$

Let $SA(F) \subset A(F)$ be the semigroup defined by

$$SA(F) = \{g \in A(F) \mid g^{-1}(\mathbb{R}_+ \times \mathbb{R}^n \times (0,+\infty)) \subset \mathbb{R}_+ \times \mathbb{R}^n \times (0,+\infty)\}\,. \tag{27}$$

If g is given by (26)*, this can be rewritten as*

$$g \in SA(F) \iff g \in A(F) \quad \textit{and} \quad \alpha^{-1}(\mathbb{R}_+) \subset \mathbb{R}_+ \quad \textit{and} \quad \delta > 0\,. \tag{28}$$

We recall that a natural action of $SA(F)$ on $C^\infty(\mathbb{R}_+ \times \mathbb{R}^n)$ is given as in [16, 17]. For any function h, graph(h) will denote its graph.

PROPOSITION 4.3. *For any $u \in C^\infty(\mathbb{R}_+ \times \mathbb{R}^n)$ and $g \in SA(F)$, there exists a unique function $g{\cdot}u \in C^\infty(\mathbb{R}_+ \times \mathbb{R}^n)$ such that $g\,(graph(u)) \supset graph(g{\cdot}u)$. Moreover, if g_1 and g_2 belong to $SA(F)$, we have*

$$(g_1 \circ g_2){\cdot}u = g_1{\cdot}(g_2{\cdot}u). \tag{29}$$

If g is given by (26) *and m defined by $m(s,x) = (\alpha(s), \beta(s,x))$, we have*

$$g{\cdot}u\,(s,x) = (\delta \times u)(m^{-1}(s,x)) \quad \forall\ (s,x) \in \mathbb{R}_+ \times \mathbb{R}^n\,. \tag{30}$$

The symmetry semigroup $SA_P(F)$ *of $\mathcal{U}_P$ is defined by*

$$SA_P(F) = \{\, g \in SA(F) \mid \forall\, u \in \mathcal{U}_P\,,\ g{\cdot}u \in \mathcal{U}_P \,\}\,. \tag{31}$$

Example. For $r \in \mathbb{R}_+$, $\Phi_{-r}^{\frac{\partial}{\partial s}} \in SA(F)$ and we have

$$\Phi_{-r}^{\frac{\partial}{\partial s}}{\cdot}u\,(s,x) = u(s+r,x). \tag{32}$$

What is more, $\Phi_{-r}^{\frac{\partial}{\partial s}} \in SA_P(F)$ since, if u satisfies (25) with initial data $u(0,\cdot) = p_0$, then $\Phi_{-r}^{\frac{\partial}{\partial s}}{\cdot}u$ satisfies (25) with initial data $u(r,\cdot) = P_r p_0$.

Remark. In this formal definition of a symmetry semigroup, we are interested in *global* transformations of the state-space. For the *local* definition and results, we send the reader to [8]. (Some results are recalled in the appendix.)

It is easy to see that $SA_P(F)$ is a semigroup by equation (29). Moreover, it is noticed in [20] that since any function in $\mathcal{U}_P$ is characterized by its initial data $u(0,\cdot) \in \mathcal{D}(M_0^\star)$, then $SA_P(F)$ induces an action on $\mathcal{D}(M_0^\star)$ as follows.

PROPOSITION 4.4. *For any $p_0 \in \mathcal{D}(M_0^\star)$ and $g \in SA(F)$, let us define*

$$\widehat{g}{\cdot}p_0 = (g{\cdot}Pp_0)(0,\cdot) \in \mathcal{D}(M_0^\star). \tag{33}$$

If $g \in SA_P(F)$, then $\widehat{g}$ is a nonnegative linear endomorphism of $\mathcal{D}(M_0^\star)$. Moreover, if g_1 and g_2 belong to $SA_P(F)$, we have for all $p_0 \in \mathcal{D}(M_0^\star)$ the following homomorphism property:

$$\widehat{g_1 \circ g_2}{\cdot}p_0 = \widehat{g}_1{\cdot}(\widehat{g}_2{\cdot}p_0)\,. \tag{34}$$

Proof. If $g \in SA_P(F)$ and $p_0 \in \mathcal{D}(M_0^\star)$, then $g{\cdot}Pp_0$ belongs to $\mathcal{U}_P$; that is, $g{\cdot}Pp_0 = P\tilde{p}_0$ for some $\tilde{p}_0 \in \mathcal{D}(M_0^\star)$. But $\tilde{p}_0(x) = P\tilde{p}_0(0,x) = g{\cdot}Pp_0(0,x) = (\widehat{g}{\cdot}p_0)\,(x)$, so that $\widehat{g}{\cdot}p_0$ belongs to $\mathcal{D}(M_0^\star)$ and thus

$$\forall\, p_0 \in \mathcal{D}(M_0^\star)\,, \quad \forall\, g \in SA_P(F) \quad g{\cdot}(Pp_0) = P(\widehat{g}{\cdot}p_0)\,. \tag{35}$$

By (33), it is clear that $\widehat{g}{\cdot}p_0$ is linear in p_0, since each P_t is a linear operator, and nonnegative as soon as p_0 is nonnegative, since each P_t is a nonnegative linear operator (see Definition 4.1).

For g_1, $g_2 \in SA_P(F)$, we have by equation (29)

$$\widehat{g_1 \circ g_2}{\cdot}p_0 = ((g_1 \circ g_2){\cdot}Pp_0)\,(0,\cdot) = (g_1{\cdot}(g_2{\cdot}Pp_0))\,(0,\cdot)\,,$$

where $g_2 \cdot Pp_0 = P(\widehat{g_2} \cdot p_0)$ by (35), so that

$$\widehat{g_1 \circ g_2} \cdot p_0 = (g_1 \cdot P(\widehat{g_2} \cdot p_0))\,(0, \cdot) = \widehat{g_1} \cdot (\widehat{g_2} \cdot p_0). \qquad \square$$

Example. By the example following Proposition 4.3 and by (32), we have for $r \in \mathbb{R}_+$:

$$\Phi_{-r}^{\frac{\partial}{\partial s}} \in SA_P(F) \quad \text{and} \quad \forall\, p_0 \in \mathcal{D}(M_0^\star)\,, \widehat{\Phi_{-r}^{\frac{\partial}{\partial s}}} \cdot p_0 = P_r p_0. \tag{36}$$

Now we turn to infinitesimal aspects. Since we are interested in *global diffeomorphisms*, not all infinitesimal generators are to be considered but only those which are *complete* vector fields.

Let $\mathcal{X}(F)$ be the Lie algebra of smooth vector fields on $F = \mathbb{R} \times \mathbb{R}^n \times \mathbb{R}$ and $\mathcal{X}^c(F)$ be the set of complete smooth vector fields on F. We recall that a complete vector field is a vector field whose flow can be defined for all time (no explosion in finite time): if $Z \in \mathcal{X}^c(F)$, its global flow on F will be denoted $(\Phi_r^Z)_{r \in \mathbb{R}}$. The set $\mathcal{X}^c(F)$ is stable neither by addition, nor by Lie bracketing.

DEFINITION 4.5. *$\mathcal{A}^c(F) \subset \mathcal{X}^c(F)$ is the set of* complete *smooth vector fields Z on F of the form*

$$Z = \zeta^0(s)\frac{\partial}{\partial s} + \sum_{i=1}^{n} \zeta^i(s,x)\frac{\partial}{\partial x_i} + \zeta^{n+1}(s,x)u\frac{\partial}{\partial u}. \tag{37}$$

The vector field Z in $\mathcal{A}^c(F)$ of global flow $(\Phi_r^Z)_{r \in \mathbb{R}}$ is said to be a complete infinitesimal symmetry of $\mathcal{U}_P$ if Φ_r^Z belongs to $SA_P(F)$ for all $r \in \mathbb{R}$. We denote by $\mathcal{SA}_P^c(F)$ the set of complete infinitesimal symmetries of $\mathcal{U}_P$.

It should be noted that when $Z \in \mathcal{SA}_P^c(F)$, Φ_r^Z belongs to $SA_P(F)$ for all $r \in \mathbb{R}$ and not only for all $r \in \mathbb{R}_+$.

PROPOSITION 4.6. *Let Z be a complete infinitesimal symmetry of $\mathcal{U}_P$. If Z is given by* (37)*, then $\zeta^0(0) = 0$, and for any $p_0 \in \mathcal{D}(M_0^\star)$ and $x \in \mathbb{R}^n$ we have*

$$\frac{d}{dr}_{|r=0} \left(\widehat{\Phi_r^Z} \cdot p_0\right)(x) = -\sum_{i=1}^{n} \zeta^i(0,x)\frac{\partial p_0}{\partial x_i}(x) + \zeta^{n+1}(0,x)p_0(x) \stackrel{\text{def}}{=} \left(\widehat{Z}_0 p_0\right)(x). \tag{38}$$

Proof. If $\Phi_r^Z(s,x,u) = (\alpha_r(s), \beta_r(s,x), \delta_r(s,x)u)$, we have $\alpha_r^{-1}(\mathbb{R}_+) \subset \mathbb{R}_+$ and $\alpha_{-r}^{-1}(\mathbb{R}_+) \subset \mathbb{R}_+$ by (28) applied to Φ_r^Z and to Φ_{-r}^Z. Since $\alpha_{-r}^{-1} = \alpha_r$ by the group property, this implies that $\alpha_r(\mathbb{R}_+) = \mathbb{R}_+$. But α_r is a global diffeomorphism of $\mathbb{R}$, hence it is monotonous and therefore it is a strictly increasing function. Then, the relation $\alpha_r(\mathbb{R}_+) = \mathbb{R}_+$ implies that 0 is a fixed point of α_r, so that $\zeta^0(0) = \frac{d}{dr}_{|r=0}\alpha_r(0) = 0$. Now equation (38) comes from the classic computation (see [16, 17, 20])

$$\begin{aligned}
\left(\widehat{\Phi_r^Z} \cdot p_0\right)(x) &= \left(\Phi_r^Z \cdot p_0\right)(0,x) \\
&= (\delta_r \times Pp_0)\left(\alpha_r^{-1}(0), \beta_r(\alpha_r^{-1}(0), \cdot)^{-1}(x)\right) \quad \text{by (30)} \\
&= (\delta_r \times Pp_0)\,(0, \beta_{-r}(0,x)) \quad \text{since} \quad \alpha_{-r}(0) = 0 \\
&= \delta_r\,(0, \beta_{-r}(0,x)) \times p_0\,(\beta_{-r}(0,x)) \\
&= \left(1 + r\zeta^{n+1}(0,x) + o(r)\right) \\
&\quad \times p_0\left(x_1 - r\zeta^1(0,x) + o(r), \ldots, x_n - r\zeta^n(0,x) + o(r)\right) \\
&= p_0(x) + r\left(\zeta^{n+1}(0,x)p_0(x) - \sum_{i=1}^{n} \zeta^i(0,x) \cdot \frac{\partial p_0}{\partial x_i}(x)\right) + o(r). \qquad \square
\end{aligned}$$

5. Application to FDR. Unlike Part I, we are concerned here with FDRs of *mappings having values in a set of smooth functions* (densities) rather than measures (laws). We keep the same notations, however.

A general means of constructing FDRs is given by the following proposition (which will be further simplified in section 7).

PROPOSITION 5.1. *Assume that*

1. *there exist p complete infinitesimal symmetries* $Z^1, \ldots, Z^p$ *of* $\mathcal{U}_P$ *such that the first-order differential operators associated by* (38) *satisfy*

$$\forall\, p_0 \in \mathcal{D}(M_0^\star)\,, \quad \widehat{Z^1}_0 p_0 = M_1^\star p_0\,, \ldots,\, \widehat{Z^p}_0 p_0 = M_p^\star p_0; \tag{39}$$

2. *the subalgebra of* $\mathcal{X}(F)$ *generated by the vector fields* $Z^1, \ldots, Z^p$ *and* $\frac{\partial}{\partial s}$ *is finite dimensional.*

Then there exists an FDR, uniform with respect to the dynamics and initial condition, of the family of input-output maps $\{\mathcal{F}^{p_0} \mid p_0 \in \mathcal{D}(M_0^\star) \cap \Pi\}$.

Example. For the one-dimensional linear system ($dx_t = dv_t$, $dy_t = x_t + dw_t$) we have

$$M_0 = \frac{1}{2}\frac{d^2}{dx^2} - \frac{1}{2}x^2 (= M_0^\star) \quad \text{and} \quad M_1 = x (= M_1^\star).$$

If $Z = -s\frac{\partial}{\partial x} + xu\frac{\partial}{\partial u}$ we have

$$\Phi_r^Z(s,x,u) = \left(s, x - sr, u\exp(xr - sr^2/2)\right),$$

$$\Phi_r^Z \cdot u(s,x) = \exp(xr + sr^2/2) u(s, x + sr).$$

1. If u is solution of $\partial_t u - M_0^\star u = 0$, an easy computation shows that for all r, $v = \Phi_r^Z \cdot u$ is a solution of $\partial_t v - M_0^\star v = 0$; thus, Z is a complete infinitesimal symmetry of the PDE, $\partial_t u - M_0^\star u = 0$.

By (38), we have $\widehat{Z}_0 p_0 = x p_0 = M_1^\star p_0$.

2. Z and $\frac{\partial}{\partial s}$ generate a four-dimensional Lie algebra with basis: Z, $\frac{\partial}{\partial s}$, $\frac{\partial}{\partial x}$, $u\frac{\partial}{\partial u}$.

Proof of Proposition 5.1. First, let us define the manifold M of the FDR.

The manifold M is the subgroup of $G(F)$ generated by the global flows $(\Phi_r^{Z^1})_{r\in\mathbb{R}}$, $\ldots$, $(\Phi_r^{Z^p})_{r\in\mathbb{R}}$, and $(\Phi_r^{\frac{\partial}{\partial s}})_{r\in\mathbb{R}}$. By [18, pp. 99–105, Theorem VII], it can indeed be equipped with a unique manifold structure that makes it a Lie group since the vector fields $Z^1, \ldots, Z^p$ and $\frac{\partial}{\partial s}$ of $\mathcal{X}(F)$ are complete (by Assumption 1) and generate a finite-dimensional Lie algebra (by Assumption 2).

We denote by $\mathfrak{M}$ the finite-dimensional subalgebra of vector fields on F generated by the vector fields $Z^1, \ldots, Z^p$ and $\frac{\partial}{\partial s}$. The Lie group M is a Lie transformation group (in the terminology of [18, p. 99, Definition IV]), and thus there exists an isomomorphism $Z \mapsto Z^+$ from $\mathfrak{M}$ to the Lie algebra of right-invariant vector fields on the Lie group M: this isomomorphism is such that if $Z \in \mathfrak{M}$, then $\Phi_r^Z \in G(F)$ coincides with the exponential $\exp(rZ^+) \in M$. In particular, the following mapping is smooth:

$$r \in \mathbb{R} \mapsto \Phi_r^Z = \exp(rZ^+) \in M\,. \tag{40}$$

Second, let us define the output functions $(\theta^{p_0}, \mathrm{Dom}(\theta^{p_0}))$ of the FDR. We take

$$\mathrm{Dom}(\theta^{p_0}) = M \cap SA(F);$$

that is, all $g \in M$ such that $g^{-1}(\mathbb{R}_+ \times \mathbb{R}^n \times (0,+\infty)) \subset \mathbb{R}_+ \times \mathbb{R}^n \times (0,+\infty)$ (see Definition 4.2). The map θ^{p_0} is defined from $\mathcal{D}(M_0^\star)$ to $\mathcal{D}(M_0^\star)$ as follows (see (33)):

$$\forall\, p_0 \in \mathcal{D}(M_0^\star)\,, \quad \forall\, g \in \mathrm{Dom}(\theta^{p_0})\,, \quad \theta^{p_0}(g) = \widehat{g}\cdot p_0\,. \tag{41}$$

This map is smooth because by (33) and (30) we have, if g is given by (26),

$$(\widehat{g}\cdot p_0)(x) = (g\cdot Pp_0)(0,x) = (\delta \times Pp_0)(\alpha^{-1}(0), \beta(\alpha^{-1}(0),\cdot)^{-1}(x)),$$

where Pp_0 is smooth by assumption and where the following mapping is smooth by [18, p. 99, Definition IV]:

$$\begin{array}{rcl} M \times \mathbb{R} \times \mathbb{R}^n \times \mathbb{R} & \to & \mathbb{R} \times \mathbb{R}^n \times \mathbb{R}, \\ (g,s,x,u) & \mapsto & g(s,x,u) = (\alpha(s), \beta(s,x), \delta(s,x)u). \end{array} \tag{42}$$

Third, let us exhibit a conservative stochastic differential equation on M having values in $\mathrm{Dom}(\theta)$.

Let the vector fields b_0, b_1, …, b_p on M be given by

$$b_0 = \frac{\partial}{\partial s}^+, b_1 = Z^{1+}, \ldots, b_p = Z^{p+}\,.$$

The SDE

$$dg_t = \frac{\partial}{\partial s}^+ \cdot g_t\, dt + \sum_{i=1}^p Z^{i+}\cdot g_t \circ dy_t^i\,, \quad g_0 = \mathrm{Id}_F, \tag{43}$$

is conservative on M, since b_0, b_1, …, b_p are right-invariant vector fields on the Lie group M by [22, Lemma 2.2].

We now prove that the solution g_t belongs to $\mathrm{Dom}(\theta)$, that is, belongs to $SA(F)$. For this, we write $g_t(s,x,u) = (\alpha_t(s), \beta_t(s,x), \delta_t(s,x)u)$ and, by (28), we just have to show that $\alpha_t^{-1}(\mathbb{R}_+) \subset \mathbb{R}_+$ and that $\delta > 0$. It is clear that $\delta_t(s,x) > 0$ by continuity since $\delta_0(s,x) = 1$ and since $\delta_t(s,x) \neq 0$ (g_t belongs to a group, hence is invertible). Thus, we must study $\alpha_t(s)$.

Since the mapping (42) is smooth, so is the map $f_z(g) = g(z)$ for $z \in F$ and $g \in M$. By (40), we have for any $Z \in \mathfrak{M}$:

$$(Z^+ f_z)(g) = \frac{d}{dr}_{|r=0} f_z(\exp(rZ^+)\circ g) = \frac{d}{dr}_{|r=0} \Phi_t^Z(g(z)) = Z(g(z))\,.$$

Therefore, for any $z = (s,x,u) \in F$, we can apply the Itô–Stratonovitch formula to $f_z(g_t)$ to get w.p.1 for all $t \geq 0$:

$$\begin{aligned} dg_t(s,x,u) &= \left(\frac{\partial}{\partial s}^+ f_z\right)(g_t)\, dt + \sum_{i=1}^p (Z^{i+} f_z)(g_t) \circ dy_t^i \\ &= \frac{\partial}{\partial s}(g_t(s,x,u))\, dt + \sum_{i=1}^p Z^i(g_t(s,x,u)) \circ dy_t^i\,. \end{aligned}$$

Denoting, for $i = 1, \ldots, p$, $Z^j = \zeta_j^0(s)\frac{\partial}{\partial s} + \sum_{i=1}^n \zeta_j^i(s,x)\frac{\partial}{\partial x_i} + \zeta_j^{n+1}(s,x)u\frac{\partial}{\partial u}$, then $\alpha_t(s)$ satisfies

$$\begin{aligned} d\alpha_t(s) &= dt + \sum_{i=1}^p \zeta_i^0(\alpha_t(s)) \circ dy_t^i \\ &= dt + \frac{1}{2}\sum_{i=1}^p ((\zeta_i^0)'\zeta_i^0)(\alpha_t(s))dt + \sum_{i=1}^p \zeta_i^0(\alpha_t(s))\, dy_t^i\,, \quad \alpha_0(s) = s\,. \end{aligned}$$

By the diffeomorphism theorem [19, p. 139], the (Itô) SDE

$$d\alpha_t = dt + \frac{1}{2}\sum_{i=1}^{p}((\zeta_i^0)'\zeta_i^0)(\alpha_t)dt + \sum_{i=1}^{p}\zeta_i^0(\alpha_t)\,dy_t^i$$

generates a stochastic flow of diffeomorphisms and thus, in particular, we have $\alpha_t(\mathbb{R}) = \mathbb{R}$. On the other hand, we know from Proposition 4.6 that $\zeta_j^0(0) = 0$: therefore, when $\alpha_0(s) = s \geq 0$ (resp. $\alpha_0(s) = s \leq 0$), $\alpha_t(s)$ cannot escape from $\mathbb{R}_+$ (resp. $\mathbb{R}_-$) [11, p. 149]. Thus $\alpha_t(\mathbb{R}_+) \subset \mathbb{R}_+$ and $\alpha_t(\mathbb{R}_-) \subset \mathbb{R}_-$, so that $\alpha_t^{-1}(\mathbb{R}_+) \subset \mathbb{R}_+$.

Fourth, we prove that (23) is satisfied. For this, we start by showing that

$$\mathrm{Dom}(\theta^{p_0}) = M \cap SA(F) \subset SA_P(F),$$

which will allow us to use the homomorphism property (34). By Assumption 1 and the Definition 4.5 of complete infinitesimal symmetries of $\mathcal{U}_P$, the flows $(\Phi_r^{Z^1})_{r\in\mathbb{R}}$, …, $(\Phi_r^{Z^p})_{r\in\mathbb{R}}$ all belong to $SA_P(F)$. On the other hand, the whole flow $(\Phi_r^{\frac{\partial}{\partial s}})_{r\in\mathbb{R}}$ cannot belong to $SA_P(F)$ because for $r \in \mathbb{R}_+$, $\Phi_r^{\frac{\partial}{\partial s}} \notin SA(F)$. However, for $r \in \mathbb{R}_+$ we know by (36) that $\Phi_{-r}^{\frac{\partial}{\partial s}} \in SA_P(F)$. Therefore, $M \cap SA(F) \subset SA_P(F)$.

Now, we apply the Itô–Stratonovitch formula to $\theta^{p_0}(g_t)(x)$ (for notation reasons, we shall forget the term x in what follows):

$$\text{w.p.1} \quad \forall\, t \in \mathbb{R}_+\,, \quad d\theta^{p_0}(g_t) = \left(\frac{\partial}{\partial s}\cdot\theta^{p_0}\right)(g_t)\,dt + \sum_{i=1}^{p}\left(Z^i\cdot\theta^{p_0}\right)(g_t)\circ dy_t^i\,.$$

For $i = 1, \ldots, p$ we have by (34)

$$\theta^{p_0}(\Phi_r^{Z^i}(g)) = \theta^{p_0}(\Phi_r^{Z^i}\circ g) = \widehat{\Phi_r^{Z^i}\circ g}\cdot p_0 = \widehat{\Phi_r^{Z^i}}\cdot(\widehat{g}\cdot p_0) = \widehat{\Phi_r^{Z^i}}\cdot(\theta^{p_0}(g))$$

so that

$$\left(Z^i\cdot\theta^{p_0}\right)(g) = \frac{d}{dr}_{|r=0}\widehat{\Phi_r^{Z^i}}\cdot(\theta^{p_0}(g)) = \widehat{Z^i}_0(\theta^{p_0}(g)) = M_i^\star\theta^{p_0}(g)\,.$$

In the same way, (36) provides

$$\left(\frac{\partial}{\partial s}\cdot\theta^{p_0}\right)(g) = \frac{d}{dr}_{|r=0+}\widehat{\Phi_{-r}^{\frac{\partial}{\partial s}}}\cdot(\theta^{p_0}(g)) = \frac{d}{dr}_{|r=0+}P_r(\theta^{p_0}(g)) = M_0^\star\theta^{p_0}(g)$$

and therefore

$$\text{w.p.1} \quad \forall\, t \in \mathbb{R}_+\,, \quad d\theta^{p_0}(g_t) = M_0^\star\theta^{p_0}(g_t)dt + \sum_{i=1}^{p}M_i^\star\theta^{p_0}(g_t)\circ dy_t^i\,.$$

We conclude by uniqueness of smooth solutions of equation (16) for $p_0 \in \Pi$. □

The following theorem is the main result of Part II. (It will be compared with the main theorem of Part I.)

THEOREM 5.2. *Assume that*

1. *the estimation algebra is finite dimensional and can be written*

$$\mathcal{E} = \mathbb{R}M_0 + \mathcal{Q}, \tag{44}$$

where $\mathcal{Q}$ is a (finite-dimensional) subalgebra of differential operators on $\mathbb{R}^n$ of order less than or equal to one;

2. *the vector fields* $Z^1, \ldots, Z^p$ *on* $\mathbb{R} \times \mathbb{R}^n \times \mathbb{R}$ *defined hereafter*

$$Z^j = \zeta_j^0(s)\frac{\partial}{\partial s} + \sum_{i=1}^{n} \zeta_j^i(s,x)\frac{\partial}{\partial x_i} + \zeta_j^{n+1}(s,x)u\frac{\partial}{\partial u} \tag{45}$$

are complete. For each $j = 1, \ldots, p$ *the coefficients* $\zeta_j^0(s)$, $\zeta_j^1(s,x)$, $\ldots$, $\zeta_j^{n+1}(s,x)$ *are given by*

$$\exp(sad_{M_0})(M_j) = -\zeta_j^0(s)M_0 - \sum_{i=1}^{n}\zeta_j^i(s,x)\frac{\partial}{\partial x_i} + \zeta_j^{n+1}(s,x). \tag{46}$$

Then, there exists an FDR of $\{\mathcal{F}^{p_0} \mid p_0 \in \mathcal{D}(M_0^\star) \cap \Pi\}$*, uniform with respect to the dynamics and initial condition.*

Proof. It suffices to prove that the assumptions of Proposition 5.1 are satisfied. To begin with, note that the assumptions of the theorem may be rewritten as follows by taking the dual expressions of all equalities.

1. The estimation algebra is finite dimensional, and we have

$$\mathcal{E}^\star = \mathbb{R}M_0^\star + \mathcal{R}, \tag{47}$$

where $\mathcal{R}(= \mathcal{Q}^\star)$ is a (finite-dimensional) subalgebra of differential operators on $\mathbb{R}^n$ of order less than or equal to one.

2. The vector fields $T^1, \ldots, T^p$ on $\mathbb{R} \times \mathbb{R}^n \times \mathbb{R}$ defined hereafter

$$T^j = \zeta_j^0(s)\frac{\partial}{\partial s} - \sum_{i=1}^{n}\zeta_j^i(s,x)\frac{\partial}{\partial x_i} + \left(\zeta_j^{n+1}(s,x) + \sum_{i=1}^{n}\frac{\partial \zeta_j^i}{\partial x_i}(s,x)\right)u\frac{\partial}{\partial u} \tag{48}$$

are complete. For each $j = 1, \ldots, p$ the coefficients $\zeta_j^0(s)$, $\zeta_j^1(s,x)$, $\ldots$, $\zeta_j^{n+1}(s,x)$ are given by

$$\exp(s\mathrm{ad}_{M_0^\star})(M_j^\star) = -\zeta_j^0(s)M_0^\star + \sum_{i=1}^{n}\zeta_j^i(s,x)\frac{\partial}{\partial x_i} + \sum_{i=1}^{n}\frac{\partial \zeta_j^i}{\partial x_i}(s,x) + \zeta_j^{n+1}(s,x). \tag{49}$$

We shall point out why the vector fields $T^1, \ldots, T^p$ are complete. The equations of the flow of T^j are

$$\left\{\begin{array}{rcl} \dot{s} &=& \zeta_j^0(s), \\ \dot{x} &=& -\displaystyle\sum_{i=1}^{n}\zeta_j^i(s,x)\frac{\partial}{\partial x_i}, \\ \dot{u} &=& \left(\zeta_j^{n+1}(s,x) + \sum_{i=1}^{n}\frac{\partial \zeta_j^i}{\partial x_i}(s,x)\right)u, \end{array}\right.$$

and they generate a solution defined for all time, since this is the case for the following equations of the flow of Z^j (s is not changed, just invert time for x, u satisfies a linear equation):

$$\left\{\begin{array}{rcl} \dot{s} &=& \zeta_j^0(s), \\ \dot{x} &=& \displaystyle\sum_{i=1}^{n}\zeta_j^i(s,x)\frac{\partial}{\partial x_i}, \\ \dot{u} &=& \zeta_j^{n+1}(s,x)u. \end{array}\right.$$

For the proof, we then proceed as follows. We shall make use of some notions recalled in Appendix B, particularly the notion of *perturbation algebra* $\mathcal{P}_{M_0^\star}$ of $M_0^\star$ presented in Proposition B.1 (where A has to be replaced by $M_0^\star$).

1. We prove that the vector fields $T^1, \ldots, T^p$ are complete infinitesimal symmetries of $\mathcal{U}_P$, such that the first-order differential operators associated by (38) satisfy

$$\forall\, p_0 \in \mathcal{D}(M_0^\star)\,, \quad \widehat{T^1}_0 p_0 = M_1^\star p_0\,, \ldots, \widehat{T^p}_0 p_0 = M_p^\star p_0. \tag{50}$$

By (49) evaluated at $s = 0$, we have

$$\begin{aligned} M_j^\star &= \exp(0 \times \mathrm{ad}_{M_0^\star})(M_j^\star) \\ &= -\zeta_j^0(0) M_0^\star + \sum_{i=1}^n \zeta_j^i(0,x)\frac{\partial}{\partial x_i} + \sum_{i=1}^n \frac{\partial \zeta_j^i}{\partial x_i}(0,x) + \zeta_j^{n+1}(0,x) \\ &= \widehat{T^j}_0 \quad \text{by (38) and (48).} \end{aligned}$$

Now, we show that the vector fields $T^1, \ldots, T^p$ are complete infinitesimal symmetries of $\mathcal{U}_P$.

By Assumption 1 for each $i = 1, \ldots, p$ the Lie algebra generated by $M_0^\star$ and $M_i^\star$ is finite dimensional. Thus, by the characterization of the perturbation algebra in Proposition B.1 in the appendix, we see that $M_1^\star, \ldots, M_p^\star$ belong to $\mathcal{P}_{M_0^\star}$. Thus, by the above equalities we have

$$\widehat{T^1}_0 = M_1^\star \in \mathcal{P}_{M_0^\star}, \ldots, \widehat{T^p}_0 = M_p^\star \in \mathcal{P}_{M_0^\star}.$$

On the other hand, the equalities (48) and (49) may be rewritten, with the notation of (B.86),

$$\widehat{T^1}_t = \exp(t\mathrm{ad}_{M_0^\star})(M_1^\star), \ldots, \widehat{T^p}_t = \exp(t\mathrm{ad}_{M_0^\star})(M_p^\star).$$

These two latter equations precisely mean, by Proposition B.1 and especially (B.87), that the vector fields $T^1, \ldots, T^p$ are (local) infinitesimal symmetries of $\mathcal{U}_P$. Since, by completeness, $\Phi_r^{T^i}$ is a global diffeomorphism of $\mathbb{R}^n$ for all $r \in \mathbb{R}$, this implies that for all $u \in \mathcal{U}_P$, $\Phi_r^{T^i} \cdot u \in \mathcal{U}_P$. This means that $T^1, \ldots, T^p$ belong to $\mathcal{SA}_P^c(F)$. The first assumption of Proposition 5.1 is thus satisfied.

2. It remains to prove the second assumption of Proposition 5.1, namely that the subalgebra of $\mathcal{X}(F)$ generated by the vector fields $T^1, \ldots, T^p$ and $\frac{\partial}{\partial s}$ is finite dimensional. But $\frac{\partial}{\partial s}$ is an infinitesimal symmetry of $\mathcal{U}_P$ since $\partial_t - M_0^\star$ is invariant by time translations and the result then follows from Theorem 2.1 in [8]. (This result is recalled in Proposition B.1 in the appendix, where A has to be replaced by $M_0^\star$ and states that (nontrivial) infinitesimal symmetries form a finite-dimensional Lie algebra.)

The assumptions of Proposition 5.1 are thus satisfied and this completes the proof. □

6. Comparison between Part I and Part II main theorems. *Under the common assumption that M_0 is nondegenerate elliptic, Theorem* 5.2 *is stronger than the main theorem of Part* I *recalled here below.*

THEOREM 6.1. *Assume that*

1. *$\mathcal{E}$ is finite dimensional and given by*

$$\mathcal{E} = \mathbb{R}M_0 + \mathcal{R},$$

where $\mathcal{R}$ is a finite-dimensional subalgebra of differential operators of order less than or equal to one;

2. *$\mathcal{E}$ is a solvable Lie algebra, with a basis $\{F_0,F_1,F_2,\ldots,F_q\}$ such that $F_0 = M_0$ and $\mathcal{F}_i = \mathbb{R} - \mathrm{span}\{F_i,\ldots,F_q\}$ is a Lie ideal of $\mathcal{F}_{i-1}$ for $i = 0,\ldots,q$,*

3. *the first-order part of each operator F_1, ..., F_q defines a complete vector field on $\mathbb{R}^n$,*

4. *for all $\phi \in \mathcal{D}(\mathbb{R}^n)$, there exists a unique solution $u \in C^\infty(]0,+\infty[\times\mathbb{R}^n) \cap C^0([0,+\infty[\times\mathbb{R}^n)$ of the PDE*

$$\frac{\partial u}{\partial t} = M_0\, u\,, \quad u(0,x) = \phi(x)\,. \tag{51}$$

Then the family of input-output maps $\{\mathcal{F}^{\mu_0} \mid \mu_0 \in \mathbb{D}_0\}$ given by (20) admits a regular FDR, uniform with respect to the dynamics and initial condition.

If we suppose that the assumptions 1, 2, 3, and 4 of this latter theorem are satisfied, then the assumptions of Theorem 5.2 are automatically satisfied:

1. the estimation algebra $\mathcal{E}$ can be written as in (44), with $\mathcal{Q} = \mathcal{R}^\star$ by 1,
2. we have by 2 the following expression:

$$\exp(s\mathrm{ad}_{M_0})(M_j) = \sum_{i=1}^{q} \alpha_j^i(s) F_i = \sum_{i=1}^{q} \alpha_j^i(s) X_i + \sum_{i=1}^{q} \alpha_j^i(s) c_i \tag{52}$$

so that the vector fields Z^1, ..., Z^p are given by

$$Z^j = -\sum_{i=1}^{q} \alpha_j^i(s) X_i + \left(\sum_{i=1}^{q} \alpha_j^i(s) c_i(x)\right) u \frac{\partial}{\partial u}\,. \tag{53}$$

The equations of the flow of Z^j are therefore

$$\left\{\begin{array}{rcl} \dot{s} &=& 0, \\ \dot{x} &=& -\displaystyle\sum_{i=1}^{q} \alpha_j^i(s) X_i(x), \\ \dot{u} &=& \left(\displaystyle\sum_{i=1}^{q} \alpha_j^i(s) c_i(x)\right) u, \end{array}\right. \tag{54}$$

so that if $s(0) = s_0$, Z^j is complete on $\mathbb{R}\times\mathbb{R}^n\times\mathbb{R}$ as soon as the vector field $X = \sum_{i=1}^q \alpha_j^i(s_0) X_i(x)$ is complete on $\mathbb{R}^n$. By a theorem of Palais [18, Theorem III, pp. 91–97], X appears to be complete as the sum of complete vector fields generating a finite-dimensional Lie algebra of vector fields.

7. A Riemannian geometric point of view. In this section, we take advantage of the Riemannian structure induced by the operator M_0.

Thanks to the assumption that M_0 is nondegenerate elliptic, it is well known that we can introduce a Riemannian metric g on $\mathbb{R}^n$ as follows (see [17, 13, 15, 9]).

LEMMA 7.1. *If $(a_{ij}(x))_{i,j=1,\ldots,n}$ denotes the inverse matrix of $(a^{ij}(x))_{i,j=1,\ldots,n}$ in (18), then*

$$g = \sum_{i,j=1}^{n} a_{ij}(x) dx_i dx_j \tag{55}$$

defines a Riemannian metric g on $\mathbb{R}^n$, that we shall note $g = met(M_0)$. Moreover, if Δ_g is the Laplace–Beltrami operator (Laplacian) on the Riemannian manifold $(\mathbb{R}^n, g)$, then we can write

$$M_0 = \frac{1}{2}\Delta_g + B + H, \tag{56}$$

where B is a smooth vector field on $\mathbb{R}^n$ (which depends not only on $b^1, \ldots, b^n$ in (18) *but also on a^{ij}, $i, j = 1, \ldots, n$).*

The first assumption of Theorem 5.2 may be replaced by the equivalent formulation that $M_1, \ldots, M_p$ belong to the *perturbation algebra* $\mathcal{P}_{M_0}$ of M_0 (see Appendix B, where A has to be replaced by M_0). This is interesting since geometric characterizations of $\mathcal{P}_{M_0}$ may be found in [9]. This is the point of view that we develop here.

We utilize the geometric objects recalled in Appendix A (see also [9]). We identify a smooth differential operator of order less than or equal to one with the sum of a smooth vector field and of a smooth function.

PROPOSITION 7.2. *Assume that $(\mathbb{R}^n, g)$ is complete. Let us write $M_1 = X^1 + m^1$, $\ldots$, $M_p = X^p + m^p$. If*

$$X_0^1 = X^1 \in \mathcal{H}_g(\mathbb{R}^n), \ldots, X_0^p = X^p \in \mathcal{H}_g(\mathbb{R}^n) \tag{57}$$

and if there exist p sequences $(X_i^1)_{i\geq 1}$, $\ldots$, $(X_i^p)_{i\geq 1}$ in $\mathcal{I}_g(\mathbb{R}^n)$ such that

1. *for $j = 1, \ldots, p$,*

$$\begin{aligned} X_1^j &= K_{M_0} X_0^j + \nabla_g (m^j - g(X_0^j, B)) \\ (or &= -\eta_g(X_0^j) B + [B, X_0^j] + \nabla_g m^j), \end{aligned} \tag{58}$$

2. *for $j = 1, \ldots, p$,*

$$\begin{aligned} X_2^j &= K_{M_0} X_1^j + \frac{1}{2} \nabla_g (L_{X_0^j} H_{M_0} + \eta_g(X_0^j) H_{M_0}) \\ (or &= [B, X_1^j] + \nabla_g (g(X_1^j, B) + \tfrac{1}{2} L_{X_0^j} H_{M_0} + \tfrac{1}{2} \eta_g(X_0^j) H_{M_0})), \end{aligned} \tag{59}$$

3. *for $j = 1, \ldots, p$ and $i \geq 1$,*

$$\begin{aligned} X_{i+2}^j &= K_{M_0} X_{i+1}^j + \frac{1}{2} \nabla_g (L_{X_i^j} H_{M_0}) \\ (or &= [B, X_{i+1}^j] + \nabla_g (g(X_{i+1}^j, B) + \tfrac{1}{2} L_{X_i^j} H_{M_0})). \end{aligned} \tag{60}$$

Then, there exists an FDR of $\{\mathcal{F}^{p_0} \mid p_0 \in \mathcal{D}(M_0^\star) \cap \Pi\}$, uniform with respect to the dynamics and initial condition.

Proof. By Proposition 3.2 in [8] (recalled in Theorem B.3 in the appendix, where A has to be replaced by M_0), the above assumptions imply that $M_1, \ldots, M_p$ belong to the perturbation algebra $\mathcal{P}_{M_0}$ of M_0. Thus, the first assumption of Theorem 5.2 is satisfied by Proposition 3.1 in [8] (recalled in Proposition B.1).

By (B.97), the sequence $(X_i^j)_{i\geq 0}$ is such that

$$\mathrm{ad}_{M_0}^{i+1}(M^j) = \eta_g(X_i^j) M_0 + X_i^j + \text{function}.$$

Since $X_i^j \in \mathcal{I}_g(\mathbb{R}^n)$ for $i \geq 1$ and thus $\eta_g(X_i^j) = 0$, this implies that

$$\begin{aligned} \exp(s\mathrm{ad}_{M_0})(M_j) &= M_j + \sum_{i=0}^{+\infty} \frac{s^{i+1}}{(i+1)!} \mathrm{ad}_{M_0}^{i+1}(M^j) \\ &= s\eta_g(X_0^j) M_0 + X_j + \sum_{i=1}^{+\infty} \frac{s^{i+1}}{(i+1)!} X_i^j + \text{function}, \end{aligned}$$

so that by comparing with (46), we see that necessarily $\zeta_j^0(s,x) = s\eta_g(X_0^j) = s\lambda$. The flow of the vector field Z^j is thus given by

$$\left\{\begin{array}{rcl} \dot{s} &=& \lambda s, \\ \dot{x}_1 &=& \zeta^1(s,x), \\ & \cdots & \\ \dot{x}_n &=& \zeta^n(s,x), \\ \dot{u} &=& \zeta^{n+1}(s,x)u. \end{array}\right.$$

Thus, if $s(0) = s_0$, the vector field Z^j on $\mathbb{R} \times \mathbb{R}^n \times \mathbb{R}$ is complete as soon as the time-varying vector field $X = \sum_{k=1}^n \zeta^k(e^{\lambda t}s_0, x)\frac{\partial}{\partial x_k}$ on $\mathbb{R} \times \mathbb{R}^n$ is complete. But for each fixed t, X belongs to $\mathcal{H}_g(\mathbb{R}^n)$ and the result follows from Lemma C.1 in the appendix. □

COROLLARY 7.3. *Assume that $(\mathbb{R}^n, g)$ is complete and that $M_1 = h_1, \ldots, M_p = h_p$. If*

$$X_1^1 = \nabla_g h_1 \in \mathcal{P}_g(\mathbb{R}^n), \ldots, X_1^p = \nabla_g h_p \in \mathcal{P}_g(\mathbb{R}^n) \tag{61}$$

and if there exists p sequences $(X_i^1)_{i\geq 2}, \ldots, (X_i^p)_{i\geq 2}$ in $\mathcal{I}_g(\mathbb{R}^n)$ such that

1. *for $j = 1, \ldots, p$,*

$$\begin{array}{rcl} X_2^j &=& K_{M_0} X_1^j \\ (or &=& [B, \nabla_g h_j] + \nabla_g(L_B h_j)\,), \end{array} \tag{62}$$

2. *for $j = 1, \ldots, p$ and $i \geq 1$,*

$$\begin{array}{rcl} X_{i+2}^j &=& K_{M_0} X_{i+1}^j + \frac{1}{2}\nabla_g(L_{X_i^j} H_{M_0}) \\ (or &=& [B, X_{i+1}^j] + \nabla_g(g(X_{i+1}^j, B) + \frac{1}{2} L_{X_i^j} H_{M_0}\,). \end{array} \tag{63}$$

Then, there exists an FDR of $\{\mathcal{F}^{p_0} \mid p_0 \in \mathcal{D}(M_0^\star) \cap \Pi\}$, uniform with respect to the dynamics and initial condition.

8. Application to filtering. For the relation between FDFs and FDRs, we follow Part I. By Proposition 7.2 and Corollary 7.3, we see that the construction of FDRs by the methods developed above imposes strong constraints on the geometry of the Riemannian space $(\mathbb{R}^n, g)$, particularly on the Lie algebras $\mathcal{P}_g(\mathbb{R}^n)$ of *parallel vector fields* and $\mathcal{H}_g(\mathbb{R}^n)$ of *infinitesimal homothetic transformations*. For the sake of simplicity, we shall assume in this section that the Riemannian space $(\mathbb{R}^n, g)$ is complete.

Remark. Saying that the Riemannian space $(\mathbb{R}^n, g)$ is complete amounts to saying that $\mathbb{R}^n$ equipped with the distance

$$d(x,y) = \inf\left\{\int_0^1 \sqrt{g(\dot{\gamma}(s), \dot{\gamma}(s))}ds \mid \gamma : [0,1] \to \mathbb{R}^n\,,\ \gamma(0) = x\,,\ \gamma(1) = y\right\} \tag{64}$$

is complete or that any bounded closed subset of $(\mathbb{R}^n, d)$ is compact [14]. This latter property is satisfied as soon as there exists $k > 0$ such that

$$\forall\, z \in \mathbb{R}^n\,,\ \forall\, x \in \mathbb{R}^n\,, \quad \sum_{i,j=1}^n a_{ij}(x) z_i z_j \geq k\|z\|^2\,. \tag{65}$$

Indeed, for any path γ such that $\gamma(0) = x$ and $\gamma(1) = y$, we have

$$k\|x-y\| \leq \int_0^1 \|\dot{\gamma}(s)\| ds \leq \int_0^1 \sqrt{\sum_{i,j=1}^n a_{ij}(\gamma(s))\dot{\gamma}_i(s)\dot{\gamma}_j(s)} ds$$

so that, by taking the infimum on all such paths, we get

$$k\|x-y\| \leq d(x,y)\,. \tag{66}$$

Let K be a bounded closed subset of $(\mathbb{R}^n, d)$. The topologies of $(\mathbb{R}^n, d)$ and $(\mathbb{R}^n, \| \|)$ being the same [14], K also is a closed subset of $(\mathbb{R}^n, \| \|)$. By (66), K is a bounded closed subset of $(\mathbb{R}^n, \| \|)$ and thus a compact of $(\mathbb{R}^n, \| \|)$. It is also a compact of $(\mathbb{R}^n, d)$ since the topologies are the same.

It may be noted that the inequality (65) is "opposite" to the one expressing the uniform ellipticity of M_0 since (65) may be written as

$$\forall\, z \in \mathbb{R}^n\,,\ \forall\, x \in \mathbb{R}^n\,, \quad \sum_{i,j=1}^n a^{ij}(x) z_i z_j \leq k\|z\|^2\,. \tag{67}$$

8.1. The case without correlated noises. In this case, the operators M_1, $\ldots$, M_p are functions $h_1, \ldots, h_p$. By Corollary 7.3, the construction of FDRs by the methods developed above necessitates that their gradients should belong to the Lie algebra $\mathcal{P}_g(\mathbb{R}^n)$ of parallel vector fields of $(\mathbb{R}^n, g)$. Necessarily the Lie algebra $\mathcal{P}_g(\mathbb{R}^n)$ of parallel vector fields of $(\mathbb{R}^n, g)$ is not reduced to zero, and this is a strong condition as can be seen from Proposition B.4.

8.1.1. Flat metrics on $\mathbb{R}^n$ and gradient drifts. This case is particularly studied in [23, 10]. We shall omit the reference to the metrics g and note $\nabla_g = \nabla$ and $\Delta_g = \Delta$. Here, we have

$$\mathcal{P}_g(\mathbb{R}^n) = \mathbb{R} - \text{span}\{\nabla x_1, \ldots, \nabla x_n\},$$

that is, all the "constant" vector fields on $\mathbb{R}^n$. By Definition B.2, we have

$$\left\{ \begin{array}{rcl} M_0 & = & \frac{1}{2}\Delta + \nabla\varphi - \frac{1}{2}\sum_{i=1}^p h_i^2, \\ K_{M_0} & = & 0, \\ H_{M_0} & = & \Delta\varphi + \|\nabla\varphi\|^2 + \sum_{i=1}^p h_i^2. \end{array} \right.$$

The following class of systems having FDFs is already known [3, 23, 10].

PROPOSITION 8.1. *If $\Delta\varphi + \|\nabla\varphi\|^2$ is quadratic, then there exists an FDF to compute the unnormalized conditional density associated with a system of the form*

$$\left\{ \begin{array}{rcl} dx_t & = & \nabla\varphi(x_t)dt + dv_t\,, \quad x_0 \rightsquigarrow p_0(x)dx, \\ dy_t & = & (Cx_t + D)dt + dw_t \end{array} \right. \tag{68}$$

when the density p_0 of x_0 belongs to $\mathcal{D}(M_0^\star)$.

Proof. This is a straightforward application of Corollary 7.3 with

$$X_2^j = 0 \quad \text{and} \quad X_{i+2}^j = \frac{1}{2}\nabla_g(L_{X_i^j} H_{M_0}) \in \mathcal{P}_g(\mathbb{R}^n)$$

since H_{M_0} is quadratic and X_i^j is a constant vector field (that is, belongs to $\mathcal{P}_g(\mathbb{R}^n)$) as can be seen by induction. □

8.1.2. Flat metrics on $\mathbb{R}^n$ and other drifts. Here, we still have $\mathcal{P}_g(\mathbb{R}^n) = \mathbb{R} - \mathrm{span}\{\nabla x_1, \dots, \nabla x_n\}$, but we no longer have $K_{M_0} = 0$.

PROPOSITION 8.2. *Let K be a skew-symmetric matrix. If $\Delta\varphi + \|\nabla\varphi + Kx\|^2$ is quadratic, then there exists an FDF to compute the unnormalized conditional density associated with a system of the form*

$$\left\{ \begin{array}{rcl} dx_t &=& (\nabla^0\varphi(x_t) + Kx_t)dt + dv_t\,, \quad x_0 \rightsquigarrow p_0(x)dx, \\ dy_t &=& (Cx_t + D)dt + dw_t \end{array} \right. \tag{69}$$

when the density p_0 of x_0 belongs to $\mathcal{D}(M_0^\star)$.

Proof. We have by Definition B.2

$$\left\{ \begin{array}{rcl} M_0 &=& \frac{1}{2}\Delta + (Kx + \nabla\varphi) - \frac{1}{2}\sum_{i=1}^p h_i^2, \\ K_{M_0} &=& 2K, \\ H_{M_0} &=& \Delta\varphi + \|Kx + \nabla\varphi\|^2 + \sum_{i=1}^p h_i^2. \end{array} \right.$$

The proof is a straightforward application of Corollary 7.3 with

$$X_2^j = 2K\nabla h_j \in \mathcal{P}_g(\mathbb{R}^n) \quad \text{and} \quad X_{i+2}^j = 2KX_{i+1}^j + \frac{1}{2}\nabla_g(L_{X_i^j}H_{M_0}) \in \mathcal{P}_g(\mathbb{R}^n)$$

since H_{M_0} is quadratic and X_i^j is a constant vector field (that is, belongs to $\mathcal{P}_g(\mathbb{R}^n)$) as can be seen by induction. □

In the one-dimensional case, we do not find new finite filters (since all vector fields are gradients and $K = 0$). In the multidimensional case, the systems we find have already been studied by Yau in [25, Theorem 7] and by Haussmann and Pardoux in a more general setting with stochastic coefficients [12].

8.1.3. Other metrics. Here, we no longer have $\mathcal{P}_g(\mathbb{R}^n) = \mathbb{R} - \mathrm{span}\{\nabla x_1, \dots, \nabla x_n\}$. If $\mathcal{P}_g(\mathbb{R}^n)$ is not zero, it can be written as $\mathbb{R} - \mathrm{span}\{\nabla_g z_1, \dots, \nabla_g z_r\}$ by Proposition B.4.

PROPOSITION 8.3. *Assume that*

1. *$h_1, \dots, h_p$ belong to $\mathbb{R} - \mathrm{span}\{1, z_1, \dots, z_r\}$,*
2. *$\Delta\varphi + \|\nabla\varphi\|^2$ is quadratic in the variables $z_1, \dots, z_r$;*

then there exists an FDF to compute the unnormalized conditional density associated with a system of the form

$$\left\{ \begin{array}{rcl} x_t & \text{diffusion process with generator } \mathcal{L} = \frac{1}{2}\Delta_g + \nabla_g\varphi\,, & x_0 \rightsquigarrow p_0(x)dx, \\ dy_t = & h(x_t)dt + dw_t \end{array} \right. \tag{70}$$

when the density p_0 of x_0 belongs to $\mathcal{D}(M_0^\star)$.

Proof. We have by Definition B.2,

$$\left\{ \begin{array}{rcl} M_0 &=& \frac{1}{2}\Delta_g + \nabla_g\varphi - \frac{1}{2}\sum_{i=1}^p h_i^2, \\ K_{M_0} &=& 0, \\ H_{M_0} &=& \Delta_g\varphi + \|\nabla_g\varphi\|^2 + \sum_{i=1}^p h_i^2 \quad \text{is quadratic in} \quad z_1, \dots, z_r. \end{array} \right.$$

The proof follows that of Proposition 8.1. □

8.2. The case with correlated noises. Here, the operators $M_1 = L_{\tilde{g}_1} + h_1$, $\dots$, $M_p = L_{\tilde{g}_p} + h_p$ are not all functions, as was the case with uncorrelated noises, but some of them are differential operators of order equal to one. By Proposition 7.2,

the construction of FDRs by the methods developed here above necessitates that $\tilde{g}_1$, ..., $\tilde{g}_p$ should belong to the Lie algebra $\mathcal{H}_g(\mathbb{R}^n)$ of infinitesimal homothetic transformations of $(\mathbb{R}^n, g)$. The conditions for having $\mathcal{H}_g(\mathbb{R}^n) \neq 0$ are less restrictive than those for having $\mathcal{P}_g(\mathbb{R}^n) \neq 0$ since $\mathcal{P}_g(\mathbb{R}^n) \subset \mathcal{H}_g(\mathbb{R}^n)$. This is why this case is more favorable for the existence of FDFs.

8.2.1. Flat metrics on $\mathbb{R}^n$ and gradient drifts. Here, $\mathcal{H}(\mathbb{R}^n)$ consists of vector fields T of the form

$$T = \mu \sum_{i=1}^{n} \tilde{x}^i \frac{\partial}{\partial \tilde{x}^i} + \sum_{i=1}^{n} \left(\sum_{j=1}^{n} \alpha_{ij} \tilde{x}^j \right) \frac{\partial}{\partial \tilde{x}^i} + \sum_{i=1}^{n} \beta_i \frac{\partial}{\partial \tilde{x}^i},$$

where μ, β_1, ..., β_n belong to $\mathbb{R}$ and α is any skew-symmetric matrix. Moreover, we have by Definition B.2,

$$\left\{ \begin{array}{rcl} M_0 & = & \frac{1}{2}\Delta + \nabla\varphi - \frac{1}{2}\sum_{i=1}^{p} \left(h_i^2 + L_{\tilde{g}_i} h_i \right), \\ K_{M_0} & = & 0, \\ H_{M_0} & = & \Delta\varphi + \|\nabla\varphi\|^2 + \sum_{i=1}^{p} \left(h_i^2 + L_{\tilde{g}_i} h_i \right). \end{array} \right.$$

PROPOSITION 8.4. *Let*

1. *$\tilde{g}_1$, ..., $\tilde{g}_p$ be vector fields of the form*

$$\tilde{g}_j(x) = K_j x + G_j\,,\ K_j' = -K_j\,, \quad j = 1, \ldots, p\,, \tag{71}$$

2. *h_1, ..., h_p and φ be such that*

$$\Delta\varphi + \|\nabla\varphi\|^2 + \sum_{i=1}^{p} \left(h_i^2 + L_{\tilde{g}_i} h_i \right) \tag{72}$$

and $h_1(x) - L_{\tilde{g}_1}\varphi(x)$, ..., $h_p(x) - L_{\tilde{g}_p}\varphi(x)$ are all affine functions.
Then there exists an FDF to compute the unnormalized conditional density associated with a system of the form

$$\left\{ \begin{array}{rcl} dx_t & = & \nabla\varphi(x_t)dt + dv_t + \tilde{g}(x_t) \circ dy_t\,, \quad x_0 \rightsquigarrow p_0(x)dx, \\ dy_t & = & h(x_t)dt + dw_t \end{array} \right. \tag{73}$$

when the density p_0 of x_0 belongs to $\mathcal{D}(M_0^\star)$.

Proof. The proof is a straightforward application of Proposition 7.2 with $X_0^j = \tilde{g}_j \in \mathcal{I}_g(\mathbb{R}^n)$, $X_1^j = \nabla(h_i - L_{\tilde{g}_i}\varphi) \in \mathcal{P}_g(\mathbb{R}^n)$ and $X_{i+1}^j = \frac{1}{2}\nabla(L_{X_i^j} H_{M_0}) \in \mathcal{P}_g(\mathbb{R}^n)$ since H_{M_0} is affine and X_i^j is a linear vector field (as all infinitesimal homothetic transformations of $\mathbb{R}^n$). □

Remark. If $\tilde{g}_1(x) = G_1$, ..., $\tilde{g}_p(x) = G_p$, the previous result still holds when (72) is not affine but even quadratic.

8.2.2. Flat metrics on $\mathbb{R}^n$ and other drifts. Here, we no longer have $K_{M_0} = 0$.

PROPOSITION 8.5. *Let*

1. *$\tilde{g}_1$, ..., $\tilde{g}_p$ be constant vector fields,*
2. *K be a skew-symmetric matrix, h_1, ..., h_p and φ be such that*

$$\Delta\varphi + \|Kx + \nabla\varphi\|^2 + \sum_{i=1}^{p} \left(h_i^2 + L_{\tilde{g}_i} h_i \right) \tag{74}$$

is quadratic and that for all $i = 1$, ..., p, $h_i(x) - L_{\tilde{g}_i}\varphi(x)$ is an affine function.

Then there exists an FDF to compute the unnormalized conditional density associated with a system of the form

$$\left\{ \begin{array}{lcl} dx_t &=& (\nabla\varphi(x_t) + Kx_t)dt \,+\, dv_t \,+\, \tilde{g} \circ dy_t \,, \quad x_0 \rightsquigarrow p_0(x)dx, \\ dy_t &=& h(x_t)dt \,+\, dw_t \end{array} \right. \tag{75}$$

when the density p_0 of x_0 belongs to $\mathcal{D}(M_0^\star)$.

Proof. The proof is a straightforward application of Proposition 7.2 with $X_0^j = \tilde{g}_j \in \mathcal{P}_g(\mathbb{R}^n)$, $X_1^j = \nabla(h_i - L_{\tilde{g}_i}\varphi) \in \mathcal{P}_g(\mathbb{R}^n)$, and $X_{i+1}^j = \frac{1}{2}\nabla_g(L_{X_i^j}H_{M_0}) \in \mathcal{P}_g(\mathbb{R}^n)$ since H_{M_0} is quadratic and X_i^j is a constant vector field (that is, belongs to $\mathcal{P}_g(\mathbb{R}^n)$), as can be seen by induction. □

8.2.3. Other metrics. We shall not treat this case, which does not lead to amenable formulations for the results.

8.3. Examples of FDFs. The following examples are straightforward applications of Proposition 8.4 (and the remark following, for the first of them).

PROPOSITION 8.6. *If there exist δ, ϵ such that the function*

$$f'(x) + f^2(x) + (\delta x + \epsilon)f(x) \tag{76}$$

is quadratic, then there exists a finite filter for the system

$$\left\{ \begin{array}{ll} dx_t \,=\, f(x_t)dt \,+\, dv_t \,+\, dy_t \,, & x_0 \rightsquigarrow p_0(x)dx, \\ dy_t \,=\, (f(x_t) + \delta x_t + \epsilon)\, dt \,+\, dw_t \,, & y_0 \,=\, 0\,. \end{array} \right. \tag{77}$$

We do not detail this case since it can more or less be found in [26].

Remark. It can be easily seen that there is no quadratic f satisfying the above assumptions but that any affine function does. Setting $f(x) = ax + b + 1/u(x)$, we find a family of solutions

$$f(x) = ax + b + \frac{\exp(-(a+\epsilon/2)x^2 + (2b+\delta)x)}{c + \displaystyle\int_0^x \exp(-(a+\epsilon/2)z^2 + (2b+\delta)z)dz}\,.$$

For instance, there exists an FDF for the system

$$\left\{ \begin{array}{ll} dx_t \,=\, \dfrac{1}{e^{-x_t}+1}dt \,+\, dv_t \,+\, dy_t \,, & x_0 \rightsquigarrow p_0(x)dx \\ dy_t \,=\, -\dfrac{e^{-x_t}}{e^{-x_t}+1}dt \,+\, dw_t \,, & y_0 \,=\, 0\,. \end{array} \right. \tag{78}$$

PROPOSITION 8.7. *If there exist δ, ϵ such that the function*

$$(1+x^2)(f'(x) + f^2(x)) + x\,(2(\delta x + \epsilon) + 1)\, f(x) + \delta^2 x^2 \tag{79}$$

is an affine function, then there exists a finite filter for the system

$$\left\{ \begin{array}{ll} dx_t \,=\, f(x_t)dt \,+\, dv_t \,+\, x_t \circ dy_t \,, & x_0 \rightsquigarrow p_0(x)dx, \\ dy_t \,=\, (x_t f(x_t) + \delta x_t + \epsilon)\, dt \,+\, dw_t \,, & y_0 \,=\, 0\,. \end{array} \right. \tag{80}$$

Remark. Setting $f(x) = b + 1/u(x)$, it can be shown by computation that any $f(x)$ of the form

$$f(x) = -\delta + \frac{(1+x^2)^{-\epsilon-\frac{1}{2}} \exp(2\delta \arctan x)}{a + \displaystyle\int_0^x (1+z^2)^{-\epsilon-\frac{1}{2}} \exp(2\delta \arctan z) dz} \tag{81}$$

is such that (79) is quadratic.

For instance, there exists an FDF for the system

$$\begin{cases} dx_t = \dfrac{1}{(1+x_t^2)(\arctan x_t + a)} dt + dv_t + x_t \circ dy_t\,, & x_0 \rightsquigarrow p_0(x)dx, \\ dy_t = \left(\dfrac{x_t}{(1+x_t^2)(\arctan x_t + a)} - \dfrac{3}{2} \right) dt + dw_t\,, & y_0 = 0, \end{cases} \tag{82}$$

where $a \notin]-\pi/2, \pi/2[$, when $p_0 \in \mathcal{D}(M_0^\star)$.

Appendix A. On the Riemannian geometric framework. Here, we review the necessary mathematical background (our references are [14, 1]). We assume from now on that $\mathbb{R}^n$ is equipped with a Riemannian metric g.

DEFINITION A.1. *Let T be an r-form ($(0,r)$ tensor field), X, X_1, ..., X_r be vector fields and f a smooth function on $\mathbb{R}^n$. The* Lie derivation *(of tensors) L_X is characterized by the following relations.*

$$\begin{cases} L_X f = Xf = \langle df, X \rangle\,, \\ L_X X_1 = [X, X_1], \\ L_X(T(X_1, \ldots, X_r)) = (L_X T)(X_1, \ldots, X_r) + \displaystyle\sum_{i=1}^r T(X_1, \ldots, L_X X_i, \ldots, X_r). \end{cases}$$

The inner product *i_X is defined by*

$$(i_X T)(X_2, \ldots, X_r) = T(X, X_2, \ldots, X_r).$$

DEFINITION A.2. *Let X, Y, and Z be vector fields ($(1,0)$ tensor fields), ω be a one-form ($(0,1)$ tensor field), and f be a smooth function on $\mathbb{R}^n$.*

1. *D_Z denotes the covariant derivation and A_Z the derivation $A_Z = L_Z - D_Z$.*
2. *A_Z induces a $(1,1)$ tensor field by $A_Z X = -D_X Z$ whose adjoint $A_Z^\star$ is defined by $g(A_Z^\star X, Y) = g(X, A_Z Y)$.*
3. *Ω_g is the* volume form *on $(\mathbb{R}^n, g)$.*
4. *The* divergence *of X is the function $\mathrm{div}_g X$ which satisfies $L_X \Omega_g = \mathrm{div}_g X\, \Omega_g$.*
5. *$Z^\flat$ is the one-form defined by duality by $Z^\flat(X) = g(Z, X)$.*
6. *$\omega^\sharp$ is the vector field defined by duality by $g(\omega^\sharp, X) = \omega(X)$.*
7. *The* gradient *of f is the vector field $\nabla_g f = (df)^\sharp$ such that $g(\nabla_g f, X) = Xf$.*
8. *The* Laplacian (*or Laplace–Beltrami operator*) *Δ_g is given by $\Delta_g f = \mathrm{div}_g(\nabla_g f)$.*

DEFINITION A.3. *We note by $\mathcal{P}_g(\mathbb{R}^n)$ the Lie algebra of* parallel vector fields *of $(\mathbb{R}^n, g)$, namely,*

$$\begin{aligned} \mathcal{P}_g(\mathbb{R}^n) &= \{X \in \mathcal{X}(\mathbb{R}^n) \mid L_X g = 0 \quad \text{and} \quad dX^\flat = 0\} \\ &= \{X \in \mathcal{X}(\mathbb{R}^n) \mid A_X = 0\}. \end{aligned} \tag{A.83}$$

We note by $\mathcal{I}_g(\mathbb{R}^n)$ the Lie algebra of infinitesimal isometries *of $(\mathbb{R}^n, g)$, namely,*

$$\mathcal{I}_g(\mathbb{R}^n) = \{X \in \mathcal{X}(\mathbb{R}^n) \mid L_X g = 0\}. \tag{A.84}$$

We note by $\mathcal{H}_g(\mathbb{R}^n)$ *the Lie algebra of* infinitesimal homothetic transformations *of* $(\mathbb{R}^n, g)$*, namely,*

$$\mathcal{H}_g(\mathbb{R}^n) = \{X \in \mathcal{X}(\mathbb{R}^n) \mid \exists \lambda \in \mathbb{R}\,, \quad L_X g = \lambda g\}. \tag{A.85}$$

If $L_X g = \rho g$*, we note* $\rho = \eta_g(X)$*. It is clear that* $\mathcal{P}_g(\mathbb{R}^n) \subset \mathcal{I}_g(\mathbb{R}^n) \subset \mathcal{H}_g(\mathbb{R}^n)$*.*

Appendix B. Recalls on the perturbation algebra of a parabolic operator. In this section, we make a brief recall of the main results in [8], and we broaden their validity by relaxing an analyticity assumption in [8].

Let A be an elliptic operator, assumed to have smooth coefficients, and be non-degenerate elliptic:

$$A = \sum_{i,j=1}^{n} a^{ij}(x) \frac{\partial^2}{\partial x_i \partial x_j} + \sum_{i=1}^{n} b^i(x) \frac{\partial}{\partial x_i} + c(x).$$

Above in the paper, we make use of the following results with either $A = M_0$ or $A = M_0^\star$.

PROPOSITION B.1 (see [8]). *Let* $Z \in \mathfrak{X}(F)$ *be of the form* (37) *and let* $\widehat{Z}_t$ *be defined, for all* t*, as a smooth differential operator on* $\mathbb{R}^n$*: for all* $p \in C^\infty(\mathbb{R}^n)$*,*

$$\left(\widehat{Z}_t p\right)(x) = -Z^0(t) A p(x) - \sum_{i=1}^{n} Z^i(t,x) \frac{\partial p}{\partial x_i}(x) + Z^{n+1}(t,x) p(x). \tag{B.86}$$

Then, there exists a finite-dimensional Lie algebra $\mathcal{P}_A$*, the* perturbation algebra *of the parabolic operator* $\partial_t - A$*, of linear partial differential operators of order less than or equal to one on* $\mathbb{R}^n$ *such that* Z *is a (local) infinitesimal symmetry of the parabolic PDE* $\partial_t u - Au = 0$ *if and only if*

$$\widehat{Z}_0 \in \mathbb{R}A \oplus \mathcal{P}_A \quad \textit{and} \quad \forall\, t \in \mathbb{R}\,, \quad \widehat{Z}_t = \exp(t\, ad_A)(\widehat{Z}_0)\,. \tag{B.87}$$

Moreover, $\Lambda(Z) = \widehat{Z}_0$ *is an anti-isomorphism from the set of such (local) infinitesimal symmetries to* $\mathbb{R}A \oplus \mathcal{P}_A$*. In particular, (local) infinitesimal symmetries of the form* (37) *form a finite-dimensional Lie algebra.*

Let O *be linear partial differential operators of order less than or equal to one on* $\mathbb{R}^n$*. Then* $O \in \mathcal{P}_A$ *if and only if the Lie algebra* $\{A, O\}_{\mathcal{L}.\mathcal{A}.}$ *of smooth differential operators on* $\mathbb{R}^n$ *generated by* A *and* O *is of the form* $\{A, O\}_{\mathcal{L}.\mathcal{A}.} = \mathbb{R}A \oplus \mathcal{Q}$*, where* $\mathcal{Q}$ *is a finite-dimensional Lie algebra consisting of linear partial differential operators of order less than or equal to one on* $\mathbb{R}^n$*.*

Proof. We simply prove here that the assumption on the analyticity of the coefficients of A in [8] may be relaxed and replaced by the assumption that the coefficients of A are smooth.

This analyticity condition was used in the proof of Proposition 2.2 in [8], and we follow the notations of this proof.

Let $U^{(2)}$ be the second jet space of $\mathbb{R} \times \mathbb{R}^n$, with coordinates denoted by

$$u^{(2)} = (u, (u_t, u_{x_i},\ 1 \leq i \leq n), (u_{tt}, u_{tx_j},\ 1 \leq j \leq n, u_{x_i x_j},\ 1 \leq i \leq j \leq n)).$$

If $(t_0, x_0) \in \mathbb{R} \times \mathbb{R}^n$ and v is a smooth function on a neighborhood of (t_0, x_0), the two-jet of v (or second prolongation of v) at (t_0, x_0) is the collection $\mathrm{pr}^{(2)}[v](t_0, x_0)$ of partial derivatives of v at (t_0, x_0) up to order two.

Let Γ be the smooth map on $\mathbb{R} \times \mathbb{R}^n \times U^{(2)}$ given by

$$\Gamma(t,x,u^{(2)}) = u_t - \sum_{i,j=1}^{n} a^{ij}(x) u_{x_i x_j} - \sum_{i=1}^{n} b^i(x) u_{x_i} - c(x)u. \tag{B.88}$$

We have

$$\Gamma(t,x,\mathrm{pr}^{(2)}[v](t,x)) = (\partial_t - A)v(t,x).$$

Γ is of maximal rank and, to prove that it is *nondegenerate* in the sense of [16, Definition 2.70], it remains to be proven that it is *locally solvable* in the sense of [16, Definition 2.70]. This latter condition is satisfied if, for any $(t_0, x_0, u_0^{(2)}) \in \mathbb{R} \times \mathbb{R}^n \times U^{(2)}$ such that $\Gamma(t_0, x_0, u_0^{(2)}) = 0$, there exists a smooth function v on a neighborhood of (t_0, x_0) such that

$$\begin{cases} \Gamma(t,x,\mathrm{pr}^{(2)}[v](t,x)) &= 0 \text{ for all } (t,x) \text{ in a neighborhood of } (t_0,x_0) \\ & \quad (v \text{ is a solution of } (\partial_t - A)v = 0), \\ \Gamma(t_0,x_0,\mathrm{pr}^{(2)}[v](t_0,x_0)) &= u_0^{(2)}. \end{cases}$$

Let $(t_0, x_0, u_0^{(2)}) \in \mathbb{R} \times \mathbb{R}^n \times U^{(2)}$ be given and let us exhibit such a function v.

First, since the symmetric matrix $(a^{ij}(x_0))_{i,j=1,\ldots,n}$ is not degenerate, it is easily seen that there exists $f \in C^\infty(\mathbb{R}^n)$ whose derivatives up to four satisfy

$$\begin{cases} \mathrm{pr}^{(2)}[f](x_0) &= \left(u^0, (u^0_{x_i},\ 1\le i\le n), (u^0_{x_i x_j},\ 1\le i\le j\le n)\right), \\ (Af)(x_0) &= u^0_t, \\ (A^2 f)(x_0) &= u^0_{tt}, \\ (\partial_{x_j} Af)(x_0) &= u^0_{tx_j}, \quad j = 1,\ldots,n. \end{cases} \tag{B.89}$$

Second, given a smooth function ψ on $\mathbb{R}^n$ with compact support included in an open ball $\Omega = B(x_0, r)$ and having constant value one in a neighborhood of x_0, we exhibit (for $T > t_0$) a smooth function v in $C^\infty([t_0, T] \times \Omega)$ such that

$$(\partial_t - A)v(t,x) = 0 \quad \forall\ (t,x) \in]t_0, T[\times B(x_0, r), \tag{B.90}$$

$$v(t,x) = 0 \quad \forall\ (t,x) \in]t_0, T[\times S(x_0, r) =]t_0, T[\times \partial B(x_0, r), \tag{B.91}$$

$$v(t_0, x) = \psi(x) f(x) \quad \forall\ x \in B(x_0, r). \tag{B.92}$$

Indeed, the above problem has a unique solution $v \in C^\infty([t_0, T] \times \Omega)$ since the assumptions of [5, Theorem X.10] are satisfied:

- the smooth elliptic differential operator A is strictly elliptic on the bounded open set Ω: $\sum_{i,j=1}^n a_{ij}(x)\zeta_i\zeta_j \ge \alpha\|\zeta\|^2, x \in \Omega,\ \zeta \in \mathbb{R}^n,\ \alpha > 0$, because A is nondegenerate elliptic with smooth coefficients,
- the open set Ω is bounded and has a smooth frontier $\partial\Omega = S(x_0, r)$,
- a^{ij}, b^i, c, and $v(t_0, \cdot) = \psi f$ belong to $C^\infty(\overline{\Omega})$,
- the compatibility relations, $\forall\ k \in \mathbb{N}, A^k v(t_0, \cdot) = 0$ on $\partial\Omega$, are satisfied since $v(t_0, \cdot) = \psi f$ has compact support included in that of ψ, therefore in the open ball Ω, and is thus zero in a neighborhood of $\partial\Omega$.

Third, the function v answers the question since by (B.90) (extended down to $t = t_0$, since $v \in C^\infty([t_0, T] \times \Omega)$), by (B.89), and by (B.92) it satisfies

$$\left\{\begin{array}{rcl} v(t_0,x_0) & = & f(x_0) = u^0, \\ \partial_t v(t_0,x_0) & = & Av(t_0,x_0) = (Af)(x_0) = u^0_t, \\ \partial_{x_j} v(t_0,x_0) & = & \partial_{x_j} f(x_0) = u^0_{x_i}, \\ \partial^2_{tt} v(t_0,x_0) & = & \partial_t Av(t_0,x_0) = A\partial_t v(t_0,x_0) = (A^2 f)(x_0) = u^0_{tt}, \\ \partial^2_{tx_j} v(t_0,x_0) & = & \partial_{x_j}\partial_t v(t_0,x_0) = \partial_{x_j}(Af)(x_0) = u^0_{tx_j}, \\ \partial^2_{x_i x_j} v(t_0,x_0) & = & \partial^2_{x_i x_j} f(x_0) = u^0_{x_i x_j}\,. \end{array}\right.$$

This ends the proof by relaxing the analyticity assumption. □

We can characterize the perturbation algebra in geometric terms when A has the form

$$A = \frac{1}{2}\Delta_g + U + c, \tag{B.93}$$

where U is a smooth vector field on $\mathbb{R}^n$ and where c is a smooth function.

DEFINITION B.2. *If A is given by* (B.93)*, the skew-symmetric* $(1,1)$ *tensor field K_A and the function H_A are defined by*

$$K_A = A_U - A^\star_U \quad \textit{and} \quad H_A = \mathrm{div}_g U + g(U,U) - 2c. \tag{B.94}$$

If $U = \nabla_g \varphi$, then $K_A = 0$ and $H_A = \Delta_g \varphi + \|\nabla_g \varphi\|^2 - 2c$.

Remark. The case $U = \nabla_g \varphi$ is related to the so-called *exact estimation algebra* extensively studied in [24, 23, 10, 6].

We identify a smooth differential operator of order less than or equal to one with the sum of a smooth vector field and of a smooth function.

THEOREM B.3 (see [9]). *The operator $X + m \in \mathcal{X}(\mathbb{R}^n) \oplus C^\infty(\mathbb{R}^n)$ belongs to $\mathcal{P}_A$ if and only if there exists a sequence $(X_i)_{i\in\mathbb{N}}$ in $\mathcal{H}_g(\mathbb{R}^n)$ which satisfies one of the equivalent following inductions:*

$$\left\{\begin{array}{rcl} X_0 & = & X, \\ X_1 & = & K_A X_0 + \nabla_g(m - g(X_0,U)) \\ (or & = & -\eta_g(X_0)U + [U,X_0] + \nabla_g m\ ), \\ X_{i+2} & = & K_A X_{i+1} + \frac{1}{2}\nabla_g(L_{X_i} H_A + \eta_g(X_i) H_A) \\ (or & = & -\eta_g(X_{i+1})U + [U,X_{i+1}] + \nabla_g(g(X_{i+1},U) + \frac{1}{2}L_{X_i}H_A + \frac{1}{2}\eta_g(X_i)H_A)\ ) \end{array}\right. \tag{B.95}$$

or

$$\left\{\begin{array}{rcl} X_0 & = & X, \\ X_1^\flat & = & -i_{X_0}(dU^\flat) + d(m - g(X_0,U)), \\ X_{i+2}^\flat & = & -i_{X_{i+1}}(dU^\flat) + \frac{1}{2}d(L_{X_i}H_A + \eta_g(X_i)H_A), \end{array}\right. \tag{B.96}$$

where the skew-symmetric $(1,1)$ *tensor field K_A and the function H_A are defined in* (B.94)*. Moreover, we have*

$$ad_A^{k+1}(X+m) = \eta_g(X_k)A + X_{k+1} + \textit{function}. \tag{B.97}$$

PROPOSITION B.4. *Assume that $(\mathbb{R}^n, g)$ is complete. If $\mathcal{P}_A$ is not reduced to constants, then $\mathcal{H}_g(\mathbb{R}^n)$ is not trivial. If $\mathcal{P}_A$ contains a nonconstant function, then $\mathcal{P}_g(\mathbb{R}^n)$ is not trivial.*

If $\dim\mathcal{P}_g(\mathbb{R}^n) = r \neq 0$, there exist $\tilde{x}^1, \ldots, \tilde{x}^r$ smooth functions such that $\nabla\tilde{x}^1, \ldots, \nabla\tilde{x}^r$ is an orthonormal basis of $\mathcal{P}_g(\mathbb{R}^n)$. Let $h \in \mathcal{P}_A$.

1. *If $0 < r < n$, h necessarily is a linear combination of $1, \tilde{x}^1, \ldots, \tilde{x}^r$.*
2. *If $r = n$, h necessarily is a linear combination of $1, \tilde{x}^1, \ldots, \tilde{x}^n$ and $\|\tilde{x}\|^2$.*

Proof. If $\mathcal{P}_A$ is not reduced to constants, then either X_0 or X_1 in (B.95) is not zero, so that $\mathcal{H}_g(\mathbb{R}^n)$ is not trivial (this holds true even if $(\mathbb{R}^n, g)$ is not complete).

By Theorem B.3, we know that if $h \in \mathcal{P}_A$, then $X_0 = \nabla_g h \in \mathcal{H}_g(\mathbb{R}^n)$. Then, either $\mathcal{I}_g(\mathbb{R}^n) \subsetneq \mathcal{H}_g(\mathbb{R}^n)$ and then $\mathcal{P}_g(\mathbb{R}^n) \neq 0$ (since $(\mathbb{R}^n, g)$ is complete and by Lemma A.3 in [8]) or $\mathcal{I}_g(\mathbb{R}^n) = \mathcal{H}_g(\mathbb{R}^n)$ and then $\nabla_g h \in \mathcal{P}_g(\mathbb{R}^n)$ (since any gradient vector field T in $\mathcal{I}_g(\mathbb{R}^n)$ is in fact in $\mathcal{P}_g(\mathbb{R}^n)$ because we have both $A_T = A_T^\star$ and $A_T + A_T^\star = 0$ [8, 9]).

If $\dim\mathcal{P}_g(\mathbb{R}^n) = r \neq 0$, such $\tilde{x}^1, \ldots, \tilde{x}^r$ exist by Lemma A.3 in [8]. If $r < n$, then $\nabla_g h \in \mathcal{H}_g(\mathbb{R}^n) \iff \nabla_g h \in \mathcal{P}_g(\mathbb{R}^n)$ by the same argument as above, so that the result is clear. If $r = n$, then by Lemma A.3 in [8] $(\mathbb{R}^n, g)$ is isometric to $\mathbb{R}^n$ flat so that $\mathcal{H}_g(\mathbb{R}^n) = \mathcal{I}_g(\mathbb{R}^n) \oplus \mathbb{R}\nabla\|\tilde{x}\|^2$. This ends the proof. ∎

Appendix C. A lemma on completeness of time-varying vector fields. The following lemma is used in the proof of Proposition 7.2.

LEMMA C.1. *Assume that $(\mathbb{R}^n, g)$ is complete. Let $H_1, \ldots, H_k$ be a basis of $\mathcal{H}_g(\mathbb{R}^n)$ and $\alpha_1(t), \ldots, \alpha_k(t)$ be piecewise continuous functions. Then the ODE*

$$\dot{x}(t) = \sum_{l=1}^{k} \alpha_l(t) H_l(x(t)), \quad x(0) = x_0 \tag{C.98}$$

has a solution defined for all time t.

Proof. The sketch of the proof is as follows.

Let $T > 0$ and $C(T) = \sup_{l=1,\ldots,k} \sup_{0\leq t\leq T} |\alpha_l(t)|$.

1. When $\alpha_1(t), \ldots, \alpha_k(t)$ are constant functions, we know that (C.98) has a solution defined for all time t. We shall show that, for $0 \leq t \leq T$,

$$d(x_0, x(t)) \leq t e^{\gamma C(T) t} C(T) \phi(x_0), \tag{C.99}$$

where γ depends only on $H_1, \ldots, H_k$ and $\phi(x)$ depends only on the Riemannian structure.

2. We shall also prove that there exists $\lambda \geq 0$ (depending only on the structural constants of the Lie algebra $\mathcal{H}_g(\mathbb{R}^n)$) such that, for $0 \leq t \leq T$,

$$\phi(x(t)) \leq e^{t(\lambda+\gamma)C(T)} \phi(x_0). \tag{C.100}$$

3. When $\alpha_1(t), \ldots, \alpha_k(t)$ are piecewise constant functions, we know that (C.98) has a solution defined for all time t. We shall show that, for $0 \leq t \leq T$,

$$d(x_0, x(t)) \leq C(T) t e^{t(2\gamma+\lambda)C(T)} \phi(x_0)$$

4. When $\alpha_1(t), \ldots, \alpha_k(t)$ are piecewise continuous functions, we shall show that (C.98) has a solution defined at least up to time T.

Since $(\mathbb{R}^n, g)$ is complete, $\mathcal{H}_g(\mathbb{R}^n)$ consists of complete vector fields [14], and therefore (C.98) has a solution defined for all time t when $\alpha_1(t), \ldots, \alpha_k(t)$ are constant functions. What is more, we have

$$d(x_0, x(t)) \leq \int_0^t \sqrt{g(\dot{x}(s), \dot{x}(s))} ds,$$

where $g(\dot{x}(s), \dot{x}(s)) = g(\sum_{l=1}^k \alpha_l H_l(x(s)), \sum_{l=1}^k \alpha_l H_l(x(s))$ satisfies a linear differential equation in the variable s since $\sum_{l=1}^k \alpha_l H_l$ is an infinitesimal homothetic transformation. Thus

$$\begin{aligned} d(x_0, x(t)) &\leq \sqrt{g\left(\sum_{l=1}^k \alpha_l H_l(x_0), \sum_{l=1}^k \alpha_l H_l(x_0)\right)} \int_0^t e^{s\eta_g(\sum_{l=1}^k \alpha_l H_l)} ds \\ &\leq te^{t\gamma C(T)} C(T) \sqrt{\sum_{l,m=1}^k g(H_l, H_m)(x_0)} \end{aligned}$$

and the first point is proved with $\gamma = \sum_{l=1}^k |\eta_g(H_l)|$ and $\phi(x) = \sqrt{\sum_{l,m=1}^k g(H_l, H_m)(x)}$.

It is easy to see that the $g(H_l, H_m)(x(t))$ satisfy a linear differential system in the variable t whose coefficients depend linearly on $\eta_g(\sum_{l=1}^k \alpha_l H_l)$, on $\alpha_1, \ldots, \alpha_k$, and the structural constants of the Lie algebra $\mathcal{H}_g(\mathbb{R}^n)$. Thus, there exists $\lambda \geq 0$, depending only upon these structural constants, such that

$$\sum_{l,m=1}^k g(H_l, H_m)(x(t)) \leq e^{2t(\lambda+\gamma)C(T)} \sum_{l,m=1}^k g(H_l, H_m)(x_0).$$

This leads to $\phi(x(t)) \leq e^{t(\lambda+\gamma)C(T)} \phi(x_0)$ and the second point is proved.

Now, when $\alpha_1(t), \ldots, \alpha_k(t)$ are piecewise constant functions, we can piece together the previous inequalities as (C.99) obtained for $d(x(t_q), x(t_{q+1}))$ on each interval $[t_q, t_{q+1}]$, where $\alpha_1(t), \ldots, \alpha_k(t)$ are constant. This gives, for $0 \leq t \leq T$,

$$d(x_0, x(t)) \leq C(T) \sum_q (t_{q+1} - t_q) e^{\gamma C(T)(t_{q+1} - t_q)} \phi(x(t_q)).$$

Since by (C.100) an easy induction yields

$$\phi(x(t_q)) \leq e^{(\lambda+\gamma)C(T)(t_q - t_{q-1})} \phi(x(t_{q-1})) \leq e^{(\lambda+\gamma)C(T)t_q} \phi(x_0),$$

we obtain the following estimate for $0 \leq t \leq T$:

$$d(x_0, x(t)) \leq C(T) t e^{t(2\gamma+\lambda)C(T)} \phi(x_0).$$

The third point being proved, we turn to the last one. When $\alpha_1(t), \ldots, \alpha_k(t)$ are piecewise continuous functions, we know that (C.98) has a solution defined at least up to a positive time. Let $\tau > 0$ be the first time when $x(t)$ leaves the nonempty (when $C(T) > 0$) bounded open set

$$\Omega = \{x \in \mathbb{R}^n, d(x_0, x) < 2C(T) T e^{T(2\gamma+\lambda)C(T)} \phi(x_0)\}.$$

We shall prove that $\tau \geq T$. Indeed, by [21, p. 106], since Ω is included in a bounded closed set (hence compact on the complete Riemannian manifold $(\mathbb{R}^n, g)$ [14]), the whole trajectory $(x(t), 0 \leq t \leq \tau \wedge T)$ may be approximated by trajectories of (C.98) with $\alpha_1(t), \ldots, \alpha_k(t)$ being piecewise constant functions. Thus, for $0 \leq t \leq \tau \wedge T$, we have by continuity

$$d(x_0, x(t)) \leq C(T) t e^{t(2\gamma+\lambda)C(T)} \phi(x_0) \leq C(T) T e^{T(2\gamma+\lambda)C(T)} \phi(x_0).$$

If $\tau < T$, this leads to a contradiction with the definition of τ.

We have shown that, for any time $T > 0$, the ODE (C.98) has a solution defined at least up to time T. This proves the assertion of the lemma. □

OPTIMIZATION OF OBSERVATIONS: A STOCHASTIC CONTROL APPROACH*

BORIS M. MILLER† AND WOLFGANG J. RUNGGALDIER‡

Abstract. We study a stochastic control problem for the optimization of observations in a partially observable stochastic system. Using a method of discontinuous time transformation, we associate with the original problem with unbounded controls a problem that has bounded controls. This latter problem allows us to construct nearly optimal nonanticipative Lipschitz Markov controls with finite observation power for the original problem. Since the controlled observation equation may degenerate, we also derive a corresponding filtering result and show a separation property of the optimal controls.

Key words. partially observed stochastic systems, observation control, nonlinear filtering, separation principle, discontinuous time transformation

Introduction. The most common way to formulate a control problem is to let the control affect only the evolution of the state while possible partial observations of the state are supposed to be continuously available.

Many practical situations, however, lead to the possibility that the observations also can be controlled in a way that affects both their timing as well as their quality. This then leads to a control problem where one tries to choose the control in a way to maximize the information content of the observations regarding the state while at the same time also taking into account a possible penalization of the control effort. Since the information content of the observations can be measured by the state estimation covariance, maximization of the information content can be obtained by minimizing this estimation covariance.

Problems of optimization of observations were mainly studied in the East (see, e.g., [1], [2], [9], [11]); a first study in the West appears in [4]. In a stochastic context only the linear case has been studied so far. More precisely, in [9] the authors consider the following linear model:

$$dx_t = a_t x_t\,dt + b_t\,dw_t^{(1)}, \tag{0.1a}$$

$$dy_t = A_t(u_t)x_t\,dt + B_t\,dw_t^{(2)}, \tag{0.1b}$$

where u_t is the observation control and $(w_t^{(1)})$ and $(w_t^{(2)})$ are independent standard Wiener processes. In this linear case the estimation covariance γ does not depend on the observations and so the optimal control becomes a deterministic time function.

The purpose of this paper is an attempt to extend the investigations to the nonlinear case. As a first step in this direction we consider a model related to (0.1), where

the coefficients depend on an unknown parameter and the observation noise is more realistically considered as an endogenous noise induced by the observations themselves; the observation power is restricted to be finite at all times with bounded total observation energy. Contrary to the linear case, the observation covariance here depends on the observations and the control problem itself becomes a stochastic control problem.

The structure of the paper is as follows: in section 1 we present our control model and study the associated filter problem which, due to the possibility that the (controlled) observation equation may degenerate, cannot be approached directly by standard techniques. In section 2 we then formulate the full control problem and show a separation property, namely, that among the optimal controls there is one depending on the observations through the filter values. This control problem is a nonstandard nonlinear problem with finite but unbounded controls. In section 3, using a stochastic version of the so-called method of discontinuous time transformation (see [10] for a deterministic context), we therefore derive an auxiliary problem with bounded controls and study the relationship between the original and the auxiliary control problems. While the auxiliary problem can be shown to admit an optimal solution, for the original problem there may not exist an optimal nonanticipative solution. On the other hand, the auxiliary problem gives also the possibility to derive a nearly optimal nonanticipative Lipschitz Markov (feedback) control for the original problem. Finally, in the concluding remarks we recall some of the delicate points of our approach.

1. The model and the associated filter process.

1.1. The model. On a given finite time interval $[0, T]$ consider a partially observed process (x_t, y_t) that satisfies the following linear system, parametrized by an unknown parameter θ and with a control in the observations:

$$x_t = x_0 + \int_0^t a_s(\theta) x_s \, ds + \int_0^t b_s(\theta) \, dw_s^{(1)}, \tag{1.1a}$$

$$y_t = \int_0^t A_s(\theta) x_s \, dv_s + \eta_t. \tag{1.1b}$$

In this system, where for simplicity of presentation we consider all processes to be scalar valued, $(w_t^{(1)})$ is a standard Wiener process with respect to a given filtration $(\mathcal{F}_t)$ with $\mathcal{F}_t \supseteq \mathcal{F}_t^y := \sigma\{y_s,\, s \le t\}$; x_0 is $\mathcal{F}_0$-measurable with distribution $\mathcal{N}(m_0, \sigma_0)$ and independent of $(w_t^{(1)})$. The observation control process (v_t) is an $\mathcal{F}_t^y$-adapted absolutely continuous and almost surely (a.s.) nondecreasing process with $v_0 = 0$ that thus has almost everywhere (a.e.) a derivative $u_t = \dot{v}_t$ that we assume satisfies the restrictions

$$0 \le u_t < +\infty \qquad \text{(finite observation power)}, \tag{1.2a}$$

$$\int_0^T u_t dt = v_T \le M < +\infty \qquad \text{(finite observation energy)}. \tag{1.2b}$$

The additive observation disturbance consists of an endogenously induced noise, due to the observation itself and represented by the (conditionally) Gaussian $\mathcal{F}_t^y$-martingale (η_t), whose quadratic variation satisfies the compatibility condition

$$\langle \eta \rangle_t = B^2 \, v_t \qquad (B \neq 0) \tag{1.3}$$

and is independent of $(w_t^{(1)})$ and x_0. Although other reasonable models could possibly be posited, in this first approach to the control of the observations in the nonlinear stochastic case we assume a compatibility condition in the form of (1.3), which implicitly states that drift and noise in the observation equation are both linear in the control (see the ensuing equivalent representation of model (1.1) in (1.6) below). By considering more complex situations, the control may enter the diffusion term in a nonmultiplicative way so that the absolute continuity of the drift with respect to the quadratic variation of the noise in the observation equation may be lost with ensuing additional problems for the filter. Note also that we may let the constant B in (1.3) be substituted by a time function B_t; dividing the observations by the (known) function B_t then reduces this more general case to the one treated here.

As a consequence of (1.3), there exists an $\mathcal{F}_t$-standard Wiener process $(w_t^{(2)})$, independent of $(w_t^{(1)})$ and x_0, so that the following representation holds:

$$\eta_t = B \int_0^t (u_s)^{1/2} dw_s^{(2)}. \tag{1.4}$$

For this representation (1.4) and analogous ones later, as is usually done we implicitly assume that, where necessary, the underlying probability space is sufficiently enlarged to support all required Wiener processes. (For an explicit construction of such an enlargement see, e.g., section 1.4.4 in [5].)

The dependence of u_t on the observation history implies that (1.1b) is actually an equation in (y_t). To ensure that (1.1b) is well defined, we shall thus assume that u_t as a function of the observation history $y_0^t := \{y_s, s \le t\}$ is such that it satisfies a Lipschitz property in the sense that for a nondecreasing and right continuous function $K(t)$, $0 \le K(t) \le 1$, and some nonnegative constants L_1, L_2 we have for all $t \ge 0$

$$|u_t(y_0^t) - u_t(\tilde{y}_0^t)\,|^2 \le L_1 \int_0^t |y_s - \tilde{y}_s|^2 dK(s) + L_2 |y_t - \tilde{y}_t|^2. \tag{1.5}$$

Furthermore, taking the Bayesian point of view, the unknown parameter θ is considered an $\mathcal{F}_0$-measurable random variable, independent of $x_0, (w_t^{(1)})$, and (η_t) and taking a finite number of possible values $\theta^i\,(i = 1, \dots, k)$ with prior probabilities $p_i = P(\theta = \theta^i)$. Finally, $a_t(\theta), b_t(\theta)$, and $A_t(\theta)$ are continuous and bounded functions of t for all θ.

In the setting just described, system (1.1) can equivalently be represented as

$$dx_t = a_t(\theta) x_t\, dt + b_t(\theta)\, dw_t^{(1)}, \tag{1.6a}$$

$$dy_t = A_t(\theta) x_t u_t\, dt + B \cdot (u_t)^{1/2} dw_t^{(2)}, \quad y_0 = 0, \tag{1.6b}$$

$$d\theta = 0. \tag{1.6c}$$

Remark 1.1. Since the value of u_t corresponds to the power applied to the observation of the signal x_t, conditions (1.2) imply that we require this power to be finite at each t with bounded total observation energy, which indeed corresponds to the actual physical situation. The fact that the additive observation noise in (1.1b), or equivalently in (1.6b), is given by an endogenously generated noise due to the observation itself justifies the assumption of a compatibility condition such as (1.3). The Gaussian assumption for this noise can be justified for those cases when the power u_t,

applied for observing x_t, is sufficiently large; take, e.g., an optical noise that is Poisson with intensity proportional to the power of the observation so that for large values of this power it can be approximated by a Gaussian. In a sense, the observation noise in (1.1b) or (1.6b) is thus a minimum-level noise, to which some independent exogenous Gaussian noise could possibly be added as well. Note finally that the observation inaccuracy is due not only to the additive observation noise but also to the averaging of the signal x_t as implied by the first term on the right of the observation equation (1.1b) or (1.6b). The averaging due to the choice of v_t (equivalently of u_t) thus affects both the timing and the quality of the observations: in the limit, when the observation power tends to infinity, u_t tends to a δ-function thus determining only the timing of the observations with no averaging of the signal. Note also that the observation power may tend to infinity, while the total observation energy remains still bounded by M.

Before going on to describe the full control problem, we study the filter process associated with the given partially observed control model.

1.2. The filter process. For $i = 1, \dots, k$ consider

$$m_t^i := E\{x_t | \mathcal{F}_t^y, \theta^i\}, \tag{1.7a}$$

$$\gamma_t^i := E\{(x_t - m_t^i)^2 | \mathcal{F}_t^y, \theta^i\}, \tag{1.7b}$$

$$\pi_t^i := P\{\theta = \theta^i | \mathcal{F}_t^y\}, \tag{1.7c}$$

and let the "filter process" X_t be given by the following set of triplets:

$$X_t := \{m_t^i, \gamma_t^i, \pi_t^i\}_{i=1,\dots,k}. \tag{1.8}$$

The main purposes of this subsection are to derive a stochastic differential equation for X_t and to show that, under the assumptions of subsection 1.1, it has a unique solution. We point out that these results will not simply be a direct application of known filtering results since, due to the possibility that u_t may be equal to zero on intervals of positive length, the observation equation may degenerate. The main result of this section is the following theorem.

THEOREM 1.2. *The filter process* (X_t) *in* (1.8) *satisfies, for a given control* v_t *(equivalently* u_t*) and* $i = 1, \dots, k$,

$$dm_t^i = a_t(\theta^i) m_t^i dt + B^{-2} A_t(\theta^i) \gamma_t^i [dy_t - A_t(\theta^i) m_t^i dv_t], \quad m_0^i = m_0 = E(x_0), \tag{1.9a}$$

$$d\gamma_t^i = 2a_t(\theta^i)\gamma_t^i dt + b_t^2(\theta^i)dt - B^{-2}[A_t(\theta^i)\gamma_t^i]^2 dv_t, \quad \gamma_0^i = \sigma_0 = \mathrm{Cov}(x_0), \tag{1.9b}$$

$$d\pi_t^i = \pi_t^i \left[A_t(\theta^i) m_t^i - \sum_{j=1}^k \pi_t^j A_t(\theta^j) m_t^j \right] B^{-2} d\xi_t, \quad \pi_0^i = p_i, \tag{1.9c}$$

where

$$\xi_t := \int_0^t \left[dy_s - \sum_{j=1}^k \pi_s^j A_s(\theta^j) m_s^j dv_s \right] \tag{1.10}$$

is an $\mathcal{F}_t^y$-conditionally Gaussian martingale with quadratic variation

$$\langle \xi \rangle_t = v_t(y_0^t). \tag{1.11}$$

Furthermore, the system (1.9) *can be represented in compact form as*

$$dX_t = F_t(X_t)dt + B_t(X_t)u_t dt + G_t(X_t)u_t^{1/2} dw_t^X \tag{1.12}$$

for suitable functions F, B, and G related to the coefficients in (1.9) *and where (w_t^X) is an $\mathcal{F}_t$-standard Wiener process. Finally, for any given control (v_t) or (u_t), the solution of* (1.9) (*or* (1.12)) *is unique.*

To prove this theorem (the proof will be given below) we shall need an intermediate result for an auxiliary filtering problem that will allow us to cope with the possible degeneracy of the original (controlled) filtering model. To derive the auxiliary problem we use an absolutely continuous time transformation. More precisely, for a given control v_t (recall that $v_0 = 0$) let

$$\Gamma_t := v_t + \int_0^t I\{s : \dot{v}_s = 0\}\, ds, \tag{1.13}$$

which is an $\mathcal{F}_t^y$-adapted absolutely continuous process with strictly positive derivative and satisfying $\Gamma_T \le M + T$ (see (1.2)). On the interval $[0, \Gamma_T]$ it admits thus the inverse function

$$\nu_s = \inf\{\tau : \Gamma_\tau > s\} = \inf\{\tau : \Gamma_\tau = s\}, \tag{1.14}$$

which satisfies $0 \le \nu_s \le T$ and is absolutely continuous with

$$\dot{\nu}_s = \frac{1}{\dot{\Gamma}_{t\,|t=\nu_s}} = \frac{1}{(\dot{v}_t + I\{t : \dot{v}_t = 0\})_{|t=\nu_s}} > 0. \tag{1.15}$$

Furthermore, for each $s \in [0, T]$, ν_s is an $\mathcal{F}_t^y$-stopping time and, as a process, (ν_s) is adapted to $\mathcal{F}_{\nu_s}^y = \sigma\{y_\tau : 0 \le \tau \le \nu_s\}$. Consider now the time-transformed observation process

$$\bar{y}_s = y_{\nu_s}, \tag{1.16}$$

which by (1.1) satisfies

$$d\bar{y}_s = A_{\nu_s}(\theta)x_{\nu_s} dv_{\nu_s} + d\eta_{\nu_s}. \tag{1.17}$$

Note that (η_{ν_s}) is a continuous, $\mathcal{F}_{\nu_s}^y$–conditionally Gaussian martingale with quadratic variation $\langle \eta \rangle_{\nu_s} = B^2 v_{\nu_s}$ such that

$$\frac{d}{ds}\langle \eta \rangle_{\nu_s} = \frac{B^2 \dot{v}_{\nu_s}}{\dot{v}_{\nu_s} + I\{s : \dot{v}_{\nu_s} = 0\}} = B^2 I\{s : \dot{v}_{\nu_s} \ne 0\}. \tag{1.18}$$

The process (η_{ν_s}) may thus degenerate and so, using a regularization procedure, we define

$$\tilde{\eta}_s := \eta_{\nu_s} + B\int_0^s I\{\tau : \dot{v}_{\nu_\tau} = 0\}\, dw_\tau, \tag{1.19}$$

where (w_t) is an $\mathcal{F}_t$-standard Wiener process, independent of $(w_t^{(1)})$ and (η_t). This process $(\tilde{\eta}_t)$ is thus a conditionally Gaussian martingale with respect to $\mathcal{F}_{\nu_s}^y = \mathcal{F}_s^{\tilde{y}}$, that has continuous trajectories and nondegenerate quadratic variation

$$\begin{aligned}\langle\tilde{\eta}\rangle_s &= \langle\eta\rangle_{\nu_s} + B^2\int_0^s I\{\tau : \dot{v}_{\nu_\tau} = 0\}\,d\tau \\ &= B^2\int_0^s I\{\tau : \dot{v}_{\nu_\tau} \neq 0\}\,d\tau + B^2\int_0^s I\{\tau : \dot{v}_{\nu_\tau} = 0\}\,d\tau = B^2 s.\end{aligned} \tag{1.20}$$

Since $(\tilde{\eta}_s)$ is independent of $(w_s^{(1)})$, in what follows we shall consider an $\mathcal{F}_t$-Wiener process $(\tilde{w}_s^{(2)})$, independent of $(w_s^{(1)})$, and represent $(\tilde{\eta}_s)$ as $\tilde{\eta}_s = B\,\tilde{w}_s^{(2)}$. On the other hand, since for the process $(w_{\nu_s}^{(1)})$ we have $\langle w^{(1)}\rangle_{\nu_s} = \nu_s$, we may also consider an $\mathcal{F}_s$-standard Wiener process $(\tilde{w}_s^{(1)})$, independent of $(\tilde{w}_s^{(2)})$, and obtain $(w_{\nu_s}^{(1)})$ as

$$w_{\nu_s}^{(1)} = \int_0^s (\dot{\nu}_\tau)^{1/2} d\tilde{w}_\tau^{(1)}. \tag{1.21}$$

Defining finally for $s \le \Gamma_T$ (see (1.15))

$$\tilde{a}_s(\theta) := \frac{a_{\nu_s}(\theta)}{(\dot{v}_t + I\{t : \dot{v}_t = 0\})_{|t=\nu_s}} = a_{\nu_s}(\theta)\,\dot{\nu}_s, \tag{1.22a}$$

$$\tilde{b}_s(\theta) := b_{\nu_s}(\theta), \tag{1.22b}$$

$$\tilde{A}_s(\theta) := \frac{A_{\nu_s}(\theta)\,\dot{v}_{t\,|t=\nu_s}}{(\dot{v}_t + I\{t : \dot{v}_t = 0\})_{|t=\nu_s}} = A_{\nu_s}(\theta)\,I\{s : \dot{v}_{\nu_s} \neq 0\}, \tag{1.22c}$$

consider on $[0, T+M]$ the process-pair $(\tilde{x}_s, \tilde{y}_s)$ defined, for $0 \le s \le \Gamma_T$, by

$$d\tilde{x}_s = \tilde{a}_s(\theta)\tilde{x}_s ds + \tilde{b}_s(\theta)(\dot{\nu}_s)^{1/2} d\tilde{w}_s^{(1)}, \quad \tilde{x}_0 = x_0, \tag{1.23a}$$

$$d\tilde{y}_s = \tilde{A}_s(\theta)\tilde{x}_s ds + B\,d\tilde{w}_s^{(2)}, \quad \tilde{y}_0 = 0, \tag{1.23b}$$

$$d\theta = 0 \tag{1.23c}$$

and by putting $d\tilde{x}_s = d\tilde{y}_s = d\theta = 0$ for $\Gamma_T < s < T+M$. Note that from the foregoing we immediately have

$$\tilde{x}_s := x_{\nu_s}, \tag{1.24}$$

$$\bar{y}_s = \int_0^s I\{\tau : \dot{v}_{\nu_\tau} \neq 0\}\,d\tilde{y}_\tau \tag{1.25}$$

so that $\bar{y}_s$ defined in (1.16) is $\mathcal{F}_s^{\tilde{y}}$-measurable and therefore

$$\mathcal{F}_{\nu_s}^y = \mathcal{F}_s^{\bar{y}} \subseteq \mathcal{F}_s^{\tilde{y}}. \tag{1.26}$$

Analogously to (1.7) now consider

$$\tilde{m}_s^i := E\{\tilde{x}_s |\, \mathcal{F}_s^{\tilde{y}}, \theta^i\}, \tag{1.27a}$$

$$\tilde{\gamma}_s^i := E\{(\tilde{x}_s - \tilde{m}_s^i)^2 |\, \mathcal{F}_s^{\tilde{y}}, \theta^i\}, \tag{1.27b}$$

$$\tilde{\pi}_s^i := P\{\theta = \theta^i |\, \mathcal{F}_s^{\tilde{y}}\}. \tag{1.27c}$$

We have the following proposition.

PROPOSITION 1.3. *The process* $\tilde{X}_s := \{\tilde{m}_s^i, \tilde{\gamma}_s^i, \tilde{\pi}_s^i\}_{i=1,\dots,k}$ *satisfies on* $[0,T]$ *(for a given control)*

$$d\tilde{m}_s^i = \tilde{a}_s(\theta)\tilde{m}_s^i ds + B^{-2}\tilde{A}_s(\theta^i)\tilde{\gamma}_s^i\,[d\tilde{y}_s - \tilde{A}_s(\theta^i)\tilde{m}_s^i ds], \quad \tilde{m}_0^i = m_0^i = m_0, \tag{1.28a}$$

$$d\tilde{\gamma}_s^i = 2\tilde{a}_s(\theta^i)\tilde{\gamma}_s^i ds + \tilde{b}_s^2(\theta^i)\,\dot{\nu}_s ds - B^{-2}[\tilde{A}_s(\theta^i)\tilde{\gamma}_s^i]^2 ds, \quad \tilde{\gamma}_0^i = \gamma_0^i\sigma_0, \tag{1.28b}$$

$$d\tilde{\pi}_s^i = \pi_s^i \left[\tilde{A}_s(\theta^i)\tilde{m}_s^i - \sum_{j=1}^k \tilde{\pi}_s^j \tilde{A}_s(\theta^j)\tilde{m}_s^j\right] B^{-2} d\tilde{\xi}_t, \quad \tilde{\pi}_0^i = \pi_0^i = p_i, \tag{1.28c}$$

where

$$\tilde{\xi}_s := \int_0^s \left[dy_\tau - \sum_{j=1}^k \tilde{\pi}_\tau^j \tilde{A}_\tau(\theta^j)\tilde{m}_\tau^j d\tau\right]. \tag{1.29}$$

Remark 1.4. From (1.22c) and (1.25) we have

$$\int_0^s \tilde{A}_\tau(\theta^i)\tilde{m}_\tau^i d\tilde{y}_\tau = \int_0^s A_{\nu_\tau}(\theta^i)\tilde{m}_\tau^i d\bar{y}_\tau, \tag{1.30}$$

$$\int_0^s \tilde{A}_\tau(\theta^i)\tilde{\gamma}_\tau^i d\tilde{y}_\tau = \int_0^s A_{\nu_\tau}(\theta^i)\tilde{\gamma}_\tau^i d\bar{y}_\tau \tag{1.31}$$

so that, besides being $\mathcal{F}_s^{\tilde{y}}$-adapted, the process $\tilde{X}_s$ in Proposition 1.3 can also be considered $\mathcal{F}_s^{\bar{y}}$-adapted. Since

$$E\left\{\tilde{x}_s | \mathcal{F}_s^{\tilde{y}}\right\} = E\left\{E\left\{\tilde{x}_s | \mathcal{F}_s^{\tilde{y}}, \theta\right\} | \mathcal{F}_s^{\tilde{y}}\right\} = \sum_{i=1}^k \tilde{m}_s^i \tilde{\pi}_s^i, \tag{1.32}$$

it thus follows that (see (1.26))

$$E\left\{\tilde{x}_s | \mathcal{F}_s^{\bar{y}}\right\} = E\left\{E\left\{\tilde{x}_s | \mathcal{F}_s^{\tilde{y}}\right\} | \mathcal{F}_s^{\bar{y}}\right\} = E\left\{\tilde{x}_s | \mathcal{F}_s^{\tilde{y}}\right\}. \tag{1.33}$$

Proof of Proposition 1.3. Note that the partially observed system $(\tilde{x}_s, \tilde{y}_s)$ defined in (1.23) is nondegenerate and corresponds to the so-called "conditionally Gaussian" case. For the first two sets of components in (1.28) we may thus make use of Theorem 12.1 in [8], whose assumptions can easily be seen to be satisfied; in fact (see (1.22a))

$$\begin{aligned}\int_0^{T+M} |\tilde{a}_s(\theta)|\, I\{s : s \le \Gamma_T\} ds &= \int_0^{T+M} |a_{\nu_s}(\theta)|\, \dot{\nu}_s\, I\{s : s \le \Gamma_T\} ds \\ &= \int_0^T |a_s(\theta)| ds < +\infty,\end{aligned} \tag{1.34}$$

and analogously (see (1.22c))

$$\int_0^{T+M} \tilde{A}_s^2(\theta)\, I\{s : s \le \Gamma_T\} ds = \int_0^{T+M} A_{\nu_s}^2(\theta)\, I\{s : s \le \Gamma_T\} dv_{\nu_s} = \int_0^T A_s^2(\theta) dv_s < +\infty. \tag{1.35}$$

Furthermore, the function $\tilde{b}_s(\theta)$ is continuous and $(\dot{\nu}_s)^{1/2}$ is integrable.

For the components $(\tilde{\pi}_t^i)$ in (1.28) we make use of the general (innovations form) nonlinear filtering equation of Theorem 8.1 in [8], putting, for a generic $i \le k$ and all $t \ge 0$,

$$h_s = h_s(\theta) := I\{\theta = \theta^i\}. \tag{1.36}$$

The assumptions of Theorem 8.1 in [8] are satisfied, and equation (8.10) in [8] with $H = D = 0$ then leads to

$$\begin{aligned} d\tilde{\pi}_s^i = B^{-2} &\left[\pi_s\left(I\{\theta = \theta^i\}\tilde{A}_s(\theta)\tilde{x}_s\right) - \pi_s\left(I\{\theta = \theta^i\}\right)\pi_s\left(\tilde{A}_s(\theta)\tilde{x}_s\right)\right] \\ &\times \left[d\tilde{y}_s - \pi_s\left(\tilde{A}_s(\theta)\tilde{x}_s\right) ds\right], \end{aligned} \tag{1.37}$$

where $\pi_s(Z) := E(Z|\mathcal{F}_s^{\tilde{y}})$. Noting now that

$$\begin{aligned} &\pi_s\left(I\{\theta = \theta^i\}\tilde{A}_s(\theta)\tilde{x}_s\right) \\ &\quad = E\left\{E\left\{I\{\theta = \theta^i\}\tilde{A}_s(\theta)\tilde{x}_s|\mathcal{F}_s^{\tilde{y}}, \theta\right\}|\mathcal{F}_s^{\tilde{y}}\right\} = \tilde{A}_s(\theta^i)\tilde{m}_s^i\,\tilde{\pi}_s^i \end{aligned} \tag{1.38}$$

and analogously

$$\pi_s\left(\tilde{A}_s(\theta)\tilde{x}_s\right) = \sum_{j=1}^k \tilde{A}_s(\theta^j)\tilde{m}_s^j\,\tilde{\pi}_s^j, \tag{1.39}$$

it follows that (1.37) is exactly (1.28c). We are now in a position to come to the proof of Theorem 1.2.

Proof of Theorem 1.2. Note first that, by (1.16), (1.24), and (1.33),

$$m_t^i = E\left\{\tilde{x}_{\Gamma(t)}|\mathcal{F}_{\Gamma(t)}^{\bar{y}}, \theta^i\right\} = E\left\{\tilde{x}_{\Gamma(t)}|\mathcal{F}_{\Gamma(t)}^{\tilde{y}}, \theta^i\right\} = \tilde{m}_{\Gamma(t)}^i. \tag{1.40}$$

Analogously,

$$\gamma_t^i = \tilde{\gamma}_{\Gamma(t)}^i, \qquad \pi_t^i = \tilde{\pi}_{\Gamma(t)}^i. \tag{1.41}$$

From (1.40) and (1.28a) we obtain

$$m_t^i = \tilde{m}_{\Gamma(t)}^i = \tilde{m}_0^i + \int_0^{\Gamma(t)} \tilde{a}_s(\theta^i)\tilde{m}_s^i\, ds + B^{-2}\int_0^{\Gamma(t)} \tilde{A}_s(\theta^i)\tilde{\gamma}_s^i\,[d\tilde{y}_s - \tilde{A}_s(\theta^i)\tilde{m}_s^i\, ds]. \tag{1.42}$$

We now evaluate the integrals in this last expression, namely (see (1.22) and (1.16) with (1.25)),

$$\int_0^{\Gamma(t)} \tilde{a}_s(\theta^i)\tilde{m}_s^i\, ds = \int_0^{\Gamma(t)} a_{\nu_s}(\theta^i)\tilde{m}_s^i\,\dot{\nu}_s ds = \int_0^t a_\tau(\theta^i)m_\tau^i\, d\tau, \tag{1.43}$$

$$
\begin{aligned}
&\int_0^{\Gamma(t)} \tilde{A}_s(\theta^i)\tilde{\gamma}_s^i\,[d\tilde{y}_s - \tilde{A}_s(\theta^i)\tilde{m}_s^i\,ds] \\
&\qquad = \int_0^{\Gamma(t)} A_{\nu_s}(\theta^i)\tilde{\gamma}_s^i\,[A_{\nu_s}(\theta)\dot{v}_{\nu_s}\dot{\nu}_s\tilde{x}_s\,ds + d\eta_{\nu_s} - A_{\nu_s}(\theta^i)\dot{v}_{\nu_s}\dot{\nu}_s\tilde{m}_s^i\,ds] \\
&\qquad = \int_0^t A_\tau(\theta^i)\gamma_\tau^i\,[A_\tau(\theta)x_\tau\,dv_\tau + d\eta_\tau - A_\tau(\theta^i)m_\tau^i\,dv_\tau] \\
&\qquad = \int_0^t A_\tau(\theta^i)\gamma_\tau^i\,[dy - A_\tau(\theta^i)m_\tau^i\,dv_\tau].
\end{aligned} \tag{1.44}
$$

Substituting (1.43) and (1.44) into (1.42) we obtain (1.9a). The remaining equations for (γ_t^i) and (π_t^i) in (1.9) follow analogously.

Coming to the statement of Theorem 1.2 concerning the process (ξ_t) note that, according to Theorem 7.12 in [8], the process $(\tilde{y}_s)$ defined in (1.23) admits the representation

$$
\tilde{y}_s = \int_0^s E\left\{\tilde{A}_\tau(\theta)\tilde{x}_\tau|\mathcal{F}_\tau^{\tilde{y}}\right\}d\tau + \tilde{w}_s = \int_0^s \sum_{j=1}^k \tilde{A}_\tau(\theta^j)\,\tilde{m}_\tau^j\tilde{\pi}_\tau^j\,d\tau + \tilde{w}_s, \tag{1.45}
$$

where $(\tilde{w}_s)$ is an $\mathcal{F}_s^{\tilde{y}}$-standard Wiener process and the second equality follows from (1.39). As a consequence

$$
\tilde{w}_s = \int_0^s \left[d\tilde{y}_s - \sum_{j=1}^k \tilde{A}_\tau(\theta^j)\,\tilde{m}_\tau^j\tilde{\pi}_\tau^j\,d\tau\right]. \tag{1.46}
$$

On the other hand, from the definition of (ξ_t) in (1.10) and from (1.16), (1.15), (1.22), and (1.25), it then follows that

$$
\begin{aligned}
\xi_t &= \int_0^t \left[dy_s - \sum_{j=1}^k A_s(\theta^j)\,m_s^j\pi_s^j\,dv_s\right] \\
&= \int_0^{\Gamma(t)} \left[d\bar{y}_s - \sum_{j=1}^k \tilde{A}_{\nu_s}(\theta^j)\,\tilde{m}_s^j\tilde{\pi}_s^j\,I\{s:\dot{v}_{\nu_s}\neq 0\}ds\right] \\
&= \int_0^{\Gamma(t)} I\{s:\dot{v}_{\nu_s}\neq 0\}\left[d\tilde{y}_s - \sum_{j=1}^k \tilde{A}_{\nu_s}(\theta^j)\,\tilde{m}_s^j\tilde{\pi}_s^j\,ds\right] \\
&= \int_0^{\Gamma(t)} I\{s:\dot{v}_{\nu_s}\neq 0\}\,d\tilde{w}_s,
\end{aligned} \tag{1.47}
$$

from which

$$
\langle\xi\rangle_t = \int_0^{\Gamma(t)} I\{s:\dot{v}_{\nu_s}\neq 0\}ds = \int_0^{\Gamma(t)} dv_{\nu_s} = v_{\nu_{\Gamma(t)}} = v(t). \tag{1.48}
$$

It follows that there exists an $\mathcal{F}_t$-Wiener process (w_t^x) such that

$$
d\xi_t = u_t^{1/2}dw_t^x. \tag{1.49}
$$

On the other hand, the driving random process in (1.9a) can, using (1.10) and (1.49), be expressed as

$$
\begin{aligned}
&[dy_t - A_t(\theta^i) m_t^i dv_t] \\
&\quad = \left[dy_t - \sum_{j=1}^k \pi_t^j A_t(\theta^j) m_t^j dv_t \right] + \left[\sum_{j=1}^k \pi_t^j A_t(\theta^j) m_t^j - A_t(\theta^i) m_t^i \right] dv_t \\
&\quad = u_t^{1/2} dw_t^x + \left[\sum_{j=1}^k \pi_t^j A_t(\theta^j) m_t^j - A_t(\theta^i) m_t^i \right] u_t dt.
\end{aligned} \tag{1.50}
$$

Equation (1.12) now follows from (1.9), thus concluding the first part of the proof of the theorem.

Concerning the uniqueness, we start from the equation (1.9b) for (γ_t^i). Its solution is uniformly bounded, implying the local Lipschitzianity (with integrable Lipschitz constant) of the right-hand side in (1.9b). Coming to (1.9a) for (m_t^i), its uniqueness follows from the linearity in m_t^i of the right-hand side. Finally concerning the equation for (π_t^i), consider the auxiliary process $(\pi_{t\wedge t_n}^i)$, where

$$
t_n := \inf\{t : \max_i |m_t^i| = n\} \wedge T, \tag{1.51}
$$

for which it is easily seen that $t_n \uparrow T$. Due to the linearity of its right-hand side, the equation for $(\pi_{t\wedge t_n}^i)$ now admits a unique solution that coincides with (π_t^i) for $t \le t_n$. If, besides (π_t^i), there is also a solution $(\hat\pi_t^i)$, then $\pi_{t\wedge t_n}^i = \hat\pi_{t\wedge t_n}^i$ so that, by $t_n \uparrow T$ and the continuity of π_t^i, it follows that $\pi_t^i = \hat\pi_t^i \ \ \forall t \in [0,T]$.

2. The control problem.

2.1. Formulation of the control problem. The purpose of the control problem is to choose the control v_t, or equivalently u_t, in (1.1) to maximize the information content of the observations regarding the state. This information content can be measured by the precision of the estimation of x_t on the basis of the observation history $y_0^t := \{y_s;\, 0 \le s \le t\}$, which is given by the inverse of the conditional estimation covariance

$$
\begin{aligned}
\gamma_t = \mathrm{Cov}(x_t |\, \mathcal{F}_t^y) &= E\left\{ \left(x_t - \sum_{i=1}^k \pi_t^i m_t^i \right)^2 \mid \mathcal{F}_t^y \right\} \\
&= \sum_{i=1}^k \pi_t^i \left(\gamma_t^i + (m_t^i)^2 \right) - \left(\sum_{i=1}^k \pi_t^i m_t^i \right)^2 .
\end{aligned} \tag{2.1}
$$

The control objective can therefore be seen as minimizing γ_t for each t. More generally, taking into consideration also a possible penalization of the control effort, we shall consider as control objective the minimization of the following (finite-horizon) functional:

$$
J(u) = E\left\{ \int_0^T \left[f_t^0(\gamma_t) + f_t^1(\gamma_t) u_t \right] dt + \phi^0(\gamma_T) \right\}, \tag{2.2}
$$

where f^0, f^1, and ϕ^0 are continuous functions of polynomial growth in γ. Note that the filter components γ_t^i and π_t^i are uniformly bounded; on the other hand, by (1.10), equation (1.9a) can (see also the proof of Theorem 1.2) be rewritten as

(2.3)
$$dm_t^i = a_t(\theta^i)\, m_t^i\, dt + B^{-2} A_t(\theta^i)\gamma_t^i \left[\sum_{j=1}^k \pi_t^j A_t(\theta^j) m_t^j - A_t(\theta^i) m_t^i\right] u_t dt + B^{-2} A_t(\theta^i)\gamma_t^i d\xi_t,$$

from which it follows that, for a given control u_t, m_t^i possesses uniformly bounded moments of all orders. By (2.1) and the polynomial growth property of f^0, we thus have the existence of the expectation

(2.4)
$$E\{f_t^0(\gamma_t)\} = E\{E\{f_t^0(\gamma_t)|\mathcal{F}_t^y\}\} = E\left\{f_t^0\left(\sum_{i=1}^k \pi_t^i\,(\gamma_t^i + (m_t^i)^2) - \left(\sum_{i=1}^k \pi_t^i m_t^i\right)^2\right)\right\} := E\{F_t^0(X_t)\},$$

with X_t as in (1.8). Analogously, for the remaining two terms in (2.2) we have

$$E\left\{f_t^1(\gamma_t)u_t\right\} = E\left\{F_t^1(X_t)\, u_t\right\}, \tag{2.5}$$

$$E\left\{\phi^0(\gamma_T)\right\} = E\left\{\Phi^0(X_T)\right\}. \tag{2.6}$$

From (2.4)–(2.6), which implicitly define the functions F^0, F^1, and Φ^0, we have that the criterion function in (2.2) is well defined for any control (u_t) satisfying (1.2) and that $J(u)$ can equivalently be represented as

$$J'(u) = E\left\{\int_0^T \left[F_t^0(X_t) + F_t^1(X_t)u_t\right]\, dt + \Phi^0(X_T)\right\} \tag{2.7}$$

for suitable functions F^0, F^1, and Φ^0 that inherit the polynomial growth property of f^0, f^1, and ϕ^0 (the prime distinguishing the representation (2.3) from that in (2.2)).

2.2. The separation property. So far the admissible controls were assumed to be $\mathcal{F}_t^y$-adapted. In line with stochastic control under partial state observation one may investigate whether among the possible $\mathcal{F}_t^y$-adapted optimal controls there is one that is $\mathcal{F}_t^X$- adapted, namely, a function of the observations through the filter values. This is in fact so, and for this purpose consider the two classes of controls

(2.8)
$$\mathcal{L}_0 := \{u : u_t \text{ is } \mathcal{F}_t^y\text{-adapted, is Lipschitz in the sense of (1.5), and satisfies (1.2)}\},$$

$$\mathcal{L}_1 := \{u \in \mathcal{L}_0 : u_t \text{ is in particular } \mathcal{F}_t^X\text{-adapted}\}. \tag{2.9}$$

Given these two classes of controls and recalling (2.2) and (2.7), we have the following *separation theorem*, which allows us to consider, instead of the original control system (1.1) with admissible controls in $\mathcal{L}_0$ and criterion functional $J(u)$ according to (2.2),

the equivalent problem for the filter system (1.12), admissible controls in $\mathcal{L}_1$, and criterion functional $J'(u)$ (see (2.7).

THEOREM 2.1. *Let* $\gamma_0 = \mathrm{Cov}(x_0) > 0$ *and* $f_t^1(\gamma_t) \geq 0$. *Then the strong principle of separation holds, namely,*

$$\inf_{u\in\mathcal{L}_1} J'(u) = \inf_{u\in\mathcal{L}_0} J(u). \tag{2.10}$$

Proof. Since $\mathcal{L}_1 \subseteq \mathcal{L}_0$, we immediately have

$$\inf_{u\in\mathcal{L}_1} J'(u) \geq \inf_{u\in\mathcal{L}_0} J(u), \tag{2.11}$$

so we need to show only the opposite inequality. For this purpose, defining

$$N_A := \left\{ t : \sup_{i\leq k} |A_t(\theta^i)| = 0 \right\}, \tag{2.12}$$

consider the subclasses of controls

$$\bar{\mathcal{L}}_0 = \{u \in \mathcal{L}_0 : u_t = 0 \quad \text{for} \quad t \in N_A\}, \tag{2.13a}$$

$$\bar{\mathcal{L}}_1 = \{u \in \mathcal{L}_1 : u_t = 0 \quad \text{for} \quad t \in N_A\}. \tag{2.13b}$$

For $u \in \mathcal{L}_0$ let

$$\bar{u}_t := u_t\, I\{t \notin N_A\} \in \bar{\mathcal{L}}_0, \tag{2.14}$$

and we have

$$J(\bar{u}) \leq J(u). \tag{2.15}$$

Analogously for $u \in \mathcal{L}_1$. In fact, it is easily seen from (1.9) that $u(\cdot)$ and $\bar{u}(\cdot)$ generate the same process $X_t = \left\{m_t^i, \gamma_t^i, \pi_t^i\right\}_{i=1,\dots,k}$, while due to the nonnegativity of $f_t^1(\gamma)$ and of u_t, one has

$$\int_0^T f_t^1(\gamma_t)\bar{u}_t\, dt \leq \int_0^T f_t^1(\gamma_t)u_t\, dt. \tag{2.16}$$

It follows that

$$\inf_{u\in\bar{\mathcal{L}}_0} J(u) \leq \inf_{u\in\mathcal{L}_0} J(u), \tag{2.17}$$

and, since $\bar{\mathcal{L}}_0 \subseteq \mathcal{L}_0$, we have

$$\inf_{u\in\bar{\mathcal{L}}_0} J(u) = \inf_{u\in\mathcal{L}_0} J(u) \tag{2.18}$$

and, analogously,

$$\inf_{u\in\bar{\mathcal{L}}_1} J'(u) = \inf_{u\in\mathcal{L}_1} J'(u). \tag{2.19}$$

Now let $\bar{u}$ denote a control with $\bar{u}_t = 0$ for $t \in N_A$; in particular, we may think of $\bar{u} \in \bar{\mathcal{L}}_0$. Corresponding to any such given control $\bar{u}$, the σ-algebra $\mathcal{F}_t^y$ generated by

y_s for $0 \le s \le t$ is contained in that $\mathcal{F}_t^X$ generated by $X_s = \{m_s^i, \gamma_s^i, \pi_s^i\}_{i=1,\dots,k}$ for $0 \le s \le t$. In fact, since $\gamma_0 > 0$, passing to its inverse, we have from (1.9b) that $\gamma_t > 0$ for all $t \in [0,T]$. Furthermore, on the complement of N_A there exists at least one value of $i \in \{1,\dots,k\}$ for which $A_t(\theta^i)\gamma_t^i \neq 0$; consequently, taking into account the continuity of $A_t(\theta^i)\gamma_t^i$, one can choose a measurable function $i(t)$ with values in $\{1,\dots,k\}$ so that

$$A_t(\theta^{i(t)})\gamma_t^{i(t)} \neq 0 \qquad \text{for} \quad t \in \bar{N}_A, \tag{2.20}$$

where $\bar{N}_A$ denotes the complement of N_A. This set $\bar{N}_A$ can then be represented in the form $\bar{N}_A = \cup_{i=1}^k \bar{N}_i$, where

$$\bar{N}_i := \{t : i(t) = i\}, \quad i = 1,\dots,k, \tag{2.21}$$

with $A_t(\theta^i)\gamma_t^i \neq 0$ for $t \in \bar{N}_i$, and we have

$$I\{t \notin N_A\} = \sum_i I\{t \notin N_i\}. \tag{2.22}$$

Recalling then that $\bar{u}_t = 0$ for $t \in N_A$, for the observation process we have

$$y_t = \int_0^t I\{s \notin N_A\}\, dy_s = \sum_{i=1}^k \int_0^t I\{s \notin N_i\}\, dy_s. \tag{2.23}$$

On the other hand, from (1.9a) we obtain

$$\begin{aligned} &\int_0^t B^{-2} A_s(\theta^i)\gamma_s^i\, dy_s \\ &\qquad = \int_0^t \left(dm_s^i - a_s(\theta^i) m_s^i\, ds\right) + \int_0^t B^{-2} A_s^2(\theta^i)\gamma_s^i\, m_s^i\, \bar{u}_s\, ds. \end{aligned} \tag{2.24}$$

Multiplying the integrands by $\left(B^{-2}A_s(\theta^i)\gamma_s^i\right)^+ I\{s \notin N_i\}$, where $(\cdot)^+$ denotes the generalized inverse, it follows that

$$\begin{aligned} \int_0^t I\{s \notin N_i\}\, dy_s = &\int_0^t \left(B^{-2}A_s(\theta^i)\gamma_s^i\right)^+ I\{s \notin N_i\} \left[dm_s^i - a_s(\theta^i) m_s^i ds\right] \\ &+ \int_0^t I\{s \notin N_i\} A_s(\theta^i)\, m_s^i\, \bar{u}_s\, ds, \end{aligned} \tag{2.25}$$

from which, taking (2.23) into account, we obtain for y_t the following representation:

$$\begin{aligned} y_t = \sum_{i=1}^k \int_0^t I\{s \notin N_i\} \Big\{ &\left(B^{-2}A_s(\theta^i)\gamma_s^i\right)^+ \left[dm_s^i - a_s(\theta^i) m_s^i ds\right] \\ &+ A_s(\theta^i)\, m_s^i\, \bar{u}_s\, ds \Big\}. \end{aligned} \tag{2.26}$$

This representation shows that, given a control $\bar{u}$ with $\bar{u}_t = 0$ for $t \in N_A$, the process (y_t) is also $\mathcal{F}_t^X$-adapted and so $\mathcal{F}_t^y \subseteq \mathcal{F}_t^X$. As a consequence, we have that $\bar{\mathcal{L}}_0 \subseteq \bar{\mathcal{L}}_1$ so that by (2.18) and (2.19)

$$\inf_{u \in \mathcal{L}_1} J'(u) = \inf_{u \in \bar{\mathcal{L}}_1} J'(u) \le \inf_{u \in \bar{\mathcal{L}}_0} J(u) = \inf_{u \in \mathcal{L}_0} J(u), \tag{2.27}$$

which is the desired opposite inequality.

3. The auxiliary control problem and nearly optimal Lipschitz Markov controls. Our original control problem now consists of controlling the filter process

$$X_t = \left\{m_t^i, \gamma_t^i, \pi_t^i\right\}_{i=1,\dots,k}$$

evolving according to (1.12) in order to minimize (see (2.7))

$$J'(u) = E\left\{\int_0^T \left[F_t^0(X_t) + F_t^1(X_t)u_t\right]\, dt + \Phi^0(X_T)\right\}. \tag{3.1}$$

As follows from Theorem 2.1, we may limit ourselves to considering controls from the class $\mathcal{L}_1$ so that they satisfy also the constraints (1.2), i.e.,

$$\int_0^T u_t dt \le M < +\infty, \quad 0 \le u_t < +\infty. \tag{3.2}$$

It is a nonlinear control problem with unbounded controls, so an optimal solution may not exist. Using the so-called method of discontinuous time transformation (see [10] in a deterministic context, where it is used for the representation of generalized—in particular, discontinuous—solutions in problems with impulse control) next we transform this original problem into an auxiliary problem with bounded controls for which an optimal solution can be shown to exist.

3.1. Method of discontinuous time transformation. To describe the method, let $u \in \mathcal{L}_1$ and consider similarly to section 1.2 the function

$$\Gamma_t := t + \int_0^t u_s ds = t + v_t \tag{3.3}$$

as well as its inverse

$$\nu_s = \Gamma_s^{-1} = \inf\{\tau : \Gamma_\tau > s\}, \tag{3.4}$$

which is an $\mathcal{F}_{\nu_s}^X$-adapted process defined on $[0, \Gamma_T]$, where, due to (3.2), $\Gamma_T \le T + M$. Furthermore, it is absolutely continuous since, for any s_1, s_2 with $s_1 \le s_2$, we have

$$0 < \nu_{s_2} - \nu_{s_1} \le s_2 - s_1, \tag{3.5}$$

so it is almost everywhere differentiable on $[0, \Gamma_T]$ with derivative (see (3.3))

$$\dot\nu_s = \left[\dot\Gamma_t\right]^{-1}_{|t=\nu_s} = (1 + u_t)^{-1}_{|t=\nu_s}, \tag{3.6}$$

which is $\mathcal{F}_{\nu_s}^X$-adapted and satisfies

$$0 < \dot\nu_s \le 1. \tag{3.7}$$

Then considering the process-pair

$$Z_s := X_{\nu_s}, \qquad \mu_s := v_{\nu_s}, \tag{3.8}$$

where (see section 1.1)

$$v_t = \int_0^t u_\tau d\tau, \tag{3.9}$$

we have the following lemma.

LEMMA 3.1. *Let the process* (X_t) *satisfy* (1.12) *for some* $u \in \mathcal{L}_1$. *Then there exists an* $\mathcal{F}_{\nu_s}$*-Wiener process* (w_s^Z) *such that the process-triple* (Z_s, μ_s, ν_s) *satisfies, for* $s \in [0, \Gamma_T]$,

$$\begin{aligned} dZ_s &= \alpha_s F_{\nu_s}(Z_s)ds + (1-\alpha_s)B_{\nu_s}(Z_s)ds \\ &\quad + (1-\alpha_s)^{1/2} G_{\nu_s}(Z_s)dw_s^Z, \quad Z_0 = X_0, \end{aligned} \tag{3.10a}$$

$$d\mu_s = (1-\alpha_s)\, ds, \quad \mu_0 = 0, \tag{3.10b}$$

$$d\nu_s = \alpha_s ds, \quad \nu_0 = 0, \tag{3.10c}$$

where the functions F, B, *and* G *are as in* (1.12), *the control* α *is given by*

$$\alpha_s = \dot{\nu}_s, \tag{3.11}$$

and it is $\mathcal{F}_s^Z$*-adapted and satisfies* $0 < \alpha_s \le 1$. *Furthermore, the solution of* (3.10) *is unique.*

Proof. By (3.7) we have $0 < \alpha_s \le 1$. By (1.12) the process $Z_s = X_{\nu_s}$ satisfies

$$Z_s = X_{\nu_s} = X_0 + \int_0^{\nu_s} F_t(X_t)dt + \int_0^{\nu_s} B_t(X_t)u_t dt + \int_0^{\nu_s} G_t(X_t)u_t^{1/2} dw_t^X. \tag{3.12}$$

Taking into account the identities

$$\nu_{\Gamma_t} = t, \quad \Gamma_{\nu_s} = s \tag{3.13}$$

valid for $t \in [0,T]$ and $s \in [0, \Gamma_T]$, we derive next a representation for the integrals in the right-hand side of (3.12), namely, performing the change of variables $t = \nu_\tau$,

$$\int_0^{\nu_s} F_t(X_t)dt = \int_0^{\Gamma_{\nu_s}} F_{\nu_\tau}(X_{\nu_\tau})d\nu_\tau = \int_0^s F_{\nu_\tau}(X_{\nu_\tau})\, \alpha_\tau d\tau, \tag{3.14}$$

$$\begin{aligned} \int_0^{\nu_s} B_t(X_t)u_t dt &= \int_0^{\nu_s} B_t(X_t)\frac{u_t}{1+u_t}(1+u_t)\, dt \\ &= \int_0^{\Gamma_{\nu_s}} B_{\nu_\tau}(X_{\nu_\tau}) \left(1 - \frac{1}{1+u_t}\right)_{|t=\nu_\tau} d\Gamma_{\nu_\tau} \\ &= \int_0^s B_{\nu_\tau}(X_{\nu_\tau})\, (1-\alpha_\tau)\, d\tau, \end{aligned} \tag{3.15}$$

$$\int_0^{\nu_s} G_t(X_t)u_t^{1/2} dw_t^X = \int_0^{\Gamma_{\nu_s}} G_{\nu_\tau}(X_{\nu_\tau})\, u_{\nu_\tau}^{1/2} dw_{\nu_\tau}^X. \tag{3.16}$$

The process $w_{\nu_\tau}^X$ is an $\mathcal{F}_{\nu_\tau}^X$-adapted, conditionally Gaussian martingale with continuous trajectories and quadratic variation

$$\langle w^X \rangle_{\nu_\tau} = \nu_\tau = \int_0^\tau \alpha_u du. \tag{3.17}$$

There exists therefore an $\mathcal{F}_{\nu_s}$-Wiener process w_s^Z such that

$$w_{\nu_\tau}^X = \int_0^\tau (\alpha(u))^{1/2} dw_u^Z. \tag{3.18}$$

Substituting (3.18) into (3.16) we then obtain (see also (3.6) and (3.11))

$$\begin{aligned} \int_0^{\nu_s} G_t(X_t) u_t^{1/2} dw_t^X &= \int_0^s G_{\nu_\tau}(X_{\nu_\tau}) \left(\frac{u_{\nu_\tau}}{1+u_{\nu_\tau}}\right)^{1/2} dw_\tau^Z \\ &= \int_0^s G_{\nu_\tau}(X_{\nu_\tau}) (1-\alpha_\tau)^{1/2} dw_\tau^Z. \end{aligned} \tag{3.19}$$

Using (3.14), (3.15), and (3.19) in (3.12) we obtain (3.10a) for Z_s. Analogously, for the process μ_s we obtain

$$\begin{aligned} \mu_s = \int_0^{\nu_s} u_t dt &= \int_0^{\Gamma_{\nu_s}} u_{\nu_\tau} d\nu_\tau \\ &= \int_0^s \frac{u_{\nu_\tau}}{1+u_{\nu_\tau}} d\tau = \int_0^s (1-\alpha_\tau) d\tau. \end{aligned} \tag{3.20}$$

The uniqueness of a strong solution of (3.10) follows analogously to that of system (1.12) (see Theorem 1.2).

Next we shall establish a relationship converse to Lemma 3.1. Therefore consider (3.10) as a system controlled by a process α_s that is $\mathcal{F}_s^Z$-adapted and satisfies $0 < \alpha_s \le 1$ for $0 \le s \le S$, where S is an $\mathcal{F}_s^{Z,\mu}$-stopping time given by

$$S := S_\nu \wedge S_\mu, \tag{3.21}$$

with

$$S_\nu := \inf\{s : \nu_s = T\}, \tag{3.22a}$$

$$S_\mu := \inf\{s : \mu_s = M\}. \tag{3.22b}$$

By the fact that (see (3.10)) $\nu_s + \mu_s = s$, we have $S \le T + M$.

Define $\mathcal{A}$ as the class of $\mathcal{F}_s^Z$-adapted controls α satisfying $\alpha_s \in (0,1]$ for $s \in [0,S]$ and where, if $S = S_\mu$, we extend its definition, letting $\alpha_s = 1$ for $S_\mu < s \le T + M$. We then have the following lemma.

LEMMA 3.2. *Given* (3.10), *let* $\alpha \in \mathcal{A}$. *Then, putting* $\Gamma_t := \inf\{s : \nu_s > t\}$, *there exists an* $\mathcal{F}_{\Gamma_t}^{Z,\mu}$*-adapted control* (u_t) *satisfying* (1.2) (*see also* (3.2)) *and an* $\mathcal{F}_{\Gamma_t}^{Z,\mu}$*-Wiener process* (w_t^X) *such that, for* $t \le T$, *the processes*

$$X_t := Z_{\Gamma_t}, \quad v_t := \mu_{\Gamma_t} \tag{3.23}$$

satisfy (1.12) *with* $v_t = \int_0^t u_\tau d\tau$. *The control* (u_t) *is furthermore given by*

$$u_t = \dot{\Gamma}_t - 1 = \alpha_{\Gamma_t}^{-1} - 1 \tag{3.24}$$

and $\mathcal{F}_{\Gamma_t}^{Z,\mu} = \mathcal{F}_t^{X,v}$.

Proof. From its definition in (3.24), the control u_t is trivially $\mathcal{F}^{Z,\mu}_{\Gamma_t}$-adapted and satisfies (1.2a). Furthermore, under the assumptions of the lemma, we have

$$v_t = \int_0^t u_\tau d\tau = \int_0^t \left(\alpha_{\Gamma_t}^{-1} - 1\right) d\tau = \int_0^t \frac{1-\alpha_{\Gamma_\tau}}{\alpha_{\Gamma_\tau}} d\tau$$
$$= \int_0^t (1-\alpha_{\Gamma_\tau}) d\Gamma_\tau = \int_0^{\Gamma_\tau} (1-\alpha_s)\, ds = \mu_{\Gamma_\tau} \le M$$

so that (1.2b) also is satisfied and $v_t = \mu_{\Gamma_t}$. It remains to show that $X_t = Z_{\Gamma_t}$ satisfies (1.12). For this purpose note that, based on (3.14) and (3.15) as well as (3.24), we may write

$$\int_0^{\Gamma_t} F_{\nu_s}(Z_s)\, \alpha_s\, ds = \int_0^t F_\tau(Z_{\Gamma_\tau})\, d\tau, \tag{3.25}$$

$$\int_0^{\Gamma_t} B_{\nu_s}(Z_s)\, (1-\alpha_s)\, ds = \int_0^t B_\tau(Z_{\Gamma_\tau})\, u_\tau\, d\tau, \tag{3.26}$$

and, finally, based on (3.19)

$$\begin{aligned} \int_0^{\Gamma_t} G_{\nu_s}(Z_s)\, (1-\alpha_s)^{1/2}\, dw_s^Z &= \int_0^t G_\tau(Z_{\Gamma_\tau}) \left(\frac{u_\tau}{1+u_\tau}\right)^{1/2} dw^Z_{\Gamma_\tau} \\ &= \int_0^t G_\tau(Z_{\Gamma_\tau})\, u_\tau^{1/2} dw_\tau^X, \end{aligned} \tag{3.27}$$

where (see also (3.18) and (3.24))

$$w_t^X = \int_0^t \frac{dw^Z_{\Gamma_\tau}}{(1+u_\tau)^{1/2}} \tag{3.28}$$

is a continuous $\mathcal{F}^{Z,\mu}_{\Gamma_t} = \mathcal{F}^{X,v}_t$-martingale with quadratic variation

$$\langle w^X \rangle_t = \int_0^t \frac{d\Gamma_\tau}{1+u_\tau} = t,$$

and therefore an $\mathcal{F}^{X,v}_t$-Wiener process.

The results obtained in the two lemmas above allow us to consider, instead of the original controlled system (1.12) with unbounded controls, the system (3.10) where the controls are bounded. We are now going to define more precisely the control problem corresponding to this latter system, which we shall call the *auxiliary control problem.*

3.2. The auxiliary control problem. This auxiliary problem concerns the controlled system (Z_s, μ_s, ν_s) satisfying (3.10) with controls from an enlarged class $\mathcal{A}_0$ consisting of the controls in $\mathcal{A}$ (defined in Lemma 3.2), where we also allow the value $\alpha_s = 0$, i.e.,

$$\mathcal{A}_0 := \{\alpha \in \mathcal{A} \mid 0 \le \alpha_s \le 1\}. \tag{3.29}$$

This enlargement of the class of controls guarantees, as we shall see, the existence of an optimal solution for the auxiliary problem. On the other hand, through the

correspondence (3.24), this is equivalent to allowing unbounded controls in the original problem.

As a cost functional to be minimized we consider

$$J(\alpha) = E\left\{\int_0^S \left[\alpha_s F^0_{\nu_s}(Z_s) + (1-\alpha_s)F^1_{\nu_s}(Z_s)\right]\, ds + \bar{\Phi}^0_{\nu_S}(Z_S)\right\}, \tag{3.30}$$

where S is the $\mathcal{F}^{Z,\mu}_s$-stopping time defined in (3.21) and (3.22), F^0 and F^1 are as in (3.1) or (2.7), and the terminal cost function is given by

$$\bar{\Phi}^0_\nu(Z) = \begin{cases} \Phi^0(Z) & \text{if } S = S_\nu, \\ \Phi^0(\psi_T(\nu, Z)) + \int_\nu^T F^0_s(\psi_s(\nu, Z))\, ds & \text{if } S = S_\mu, \end{cases} \tag{3.31}$$

with $\psi_s(\nu, Z)$ being the solution on $[\nu, T]$ of the deterministic equation

$$\dot{\psi}_s = F_s(\psi_s), \tag{3.32}$$

having initial condition $\psi_\nu(\nu, Z) = Z$. F is as in (1.12) (see also (3.10a)), and F^0, F^1, and Φ^0 are the same as in $J'(u)$ (see (3.1) or (2.7)).

Remark 3.3. The function $\psi_s(\nu, Z)$ satisfies $\psi_\nu(\nu, Z) = Z$, is continuous in all variables, and has linear growth with respect to Z, since the function $F_s(X)$ is continuous and Lipschitz in X for each s.

3.3. Relationship between the original and auxiliary problems. In this section we will show the correspondence existing between the cost functionals $J'(u)$ in (3.1) and $J(\alpha)$ in (3.30). We have in fact the following proposition.

PROPOSITION 3.4. *If $u \in \mathcal{L}_1$ is given and α is according to* (3.11) *and* (3.6)*, or $\alpha \in \mathcal{A}$ is given, $S = S_\nu$, and u is according to* (3.24)*, then*

$$J'(u) = J(\alpha). \tag{3.33}$$

When $\alpha \in \mathcal{A}$ but $S = S_\mu$ so that $\nu_S < T$, then (3.33) *continues to hold with u according to* (3.24) *if (see the definition of the class $\mathcal{A}$ before Lemma* 3.2*) one puts $\alpha_s = 1$ for $S_\mu < s \le T + M$.*

Proof. For the first part of the statement note the following: given a control $u \in \mathcal{L}_1$ and letting (see (3.11)) $\alpha_s = \dot{\nu}_s$, then since (see (3.8) and (3.9)) $\mu_s = \int_0^{\nu_s} u_\tau\, d\tau$ and $u \in \mathcal{L}_1$ satisfies (3.2), we have $S = S_\nu = \Gamma_T$ with $\Gamma(\cdot)$ as in (3.3) or, equivalently, as in the statement of Lemma 3.2. As a consequence we have

$$\nu_S = T, \quad Z_S = X_T, \tag{3.34}$$

and, by considerations analogous to those leading to (3.14) and (3.15), we then obtain

$$\int_0^T F^0_t(X_t)\, dt = \int_0^S F^0_{\nu_s}(Z_s)\, \alpha_s\, ds, \tag{3.35}$$

$$\int_0^T F^1_t(X_t)\, u_t\, dt = \int_0^S F^1_{\nu_s}(Z_s)\, (1-\alpha_s)\, ds. \tag{3.36}$$

On the other hand, given a control $\alpha \in \mathcal{A}$, if $S = S_\nu$, the same relations (3.34)–(3.36) hold. Combining these considerations with Lemmas 3.1 and 3.2 we obtain the first part of the proposition. The second part follows immediately, taking (3.31) into account.

Remark 3.5. The previous equivalence considerations are valid for $\alpha \in \mathcal{A}$, i.e., such that $\alpha_s > 0$. For the purpose of obtaining existence of an optimal solution for the auxiliary problem, we shall allow also controls in $\mathcal{A}_0$ (see (3.29)) so that α_s might be equal to zero on some subintervals of $[0, S]$. Correspondingly, on these subintervals, ν_s will be constant implying that its inverse $\Gamma_t = \inf\{s : \nu_s > t\}$ jumps. Consequently also $X_t = Z_{\Gamma_t}$ and $v_t = \mu_{\Gamma_t}$ will jump and can therefore not be a solution of (1.12) for any measurable control. In other words, while the auxiliary control problem admits an optimal solution, there may not exist a corresponding optimal solution for the original problem. We shall therefore determine nearly optimal (ε-optimal) solutions for the original problem.

Letting

$$\mathcal{A}_0^L := \{\alpha \in \mathcal{A}_0 : \alpha_t = \alpha_t(Z_t, \mu_t) \text{ a Lipschitz function}\} \tag{3.37}$$

and, analogously, for $\mathcal{A}^L$, we first prove the following.

PROPOSITION 3.6. *For any control $\alpha \in \mathcal{A}_0^L$ there exists a sequence of controls $\alpha^k \in \mathcal{A}^L$ obtained as*

$$\alpha_s^k = \frac{1}{(k+1)} + \frac{k}{(k+1)}\alpha_s, \tag{3.38}$$

where $s \in [0, S]$ if $S = S_\nu$ and $s \in [0, T + M]$ if $S = S_\mu$, such that

$$\lim_{k\to\infty} J(\alpha^k) = J(\alpha). \tag{3.39}$$

Proof. Given $\alpha \in \mathcal{A}_0^L$, let S be the corresponding stopping time defined according to (3.21) and (3.22). Define the sequence $\alpha^k \in \mathcal{A}^L$ as in (3.38). Also let

$$S^k := S_\nu^k \wedge S_\mu^k, \tag{3.40}$$

where S_ν^k and S_μ^k are defined according to (3.22) with $\nu = \nu^k$ and $\mu = \mu^k$ that correspond to α^k via (3.10). The sequence α^k is monotonically decreasing and converges to α.

Let us first show that the sequence S^k converges for all ω to S. In fact, since $\alpha_s^k \geq \alpha_s$ and

$$\alpha_s^{k+1} - \alpha_s^k = \frac{(\alpha_s - 1)}{(k+1)(k+2)} \leq 0$$

for the stopping times $S_\nu^k = \inf\left\{s : \nu_s^k = \int_0^s \alpha_\tau^k d\tau = T\right\}$, we have

$$S_\nu^k \leq S_\nu^{k+1} \leq S_\nu, \tag{3.41}$$

and analogously for $S_\mu^k = \inf\left\{s : \mu_s^k = \int_0^s (1 - \alpha_\tau^k)\, d\tau = M\right\}$ we get

$$S_\mu \leq S_\mu^{k+1} \leq S_\mu^k. \tag{3.42}$$

We can now prove that $\lim_{k\to\infty} S_\nu^k = S_\nu$. From (3.41) the limit of S_ν^k exists and, denoting it by $\bar{S}_\nu$, we have $\bar{S}_\nu \leq S_\nu$. By the uniform convergence of α^k to α we have that ν_s^k converges to ν_s uniformly on compact subintervals of $[0, S_\nu]$, where, we recall, $S_\nu \leq T + M$. In addition

$$\nu_{S_\nu^k}^k = T, \quad \nu_{S_\nu} = T.$$

Let us determine the value of $\nu_{\bar{S}_\nu}$. From

$$\nu^k_{S^k_\nu} - \nu_{\bar{S}_\nu} = \nu^k_{S^k_\nu} - \nu_{S^k_\nu} + \nu_{S^k_\nu} - \nu_{\bar{S}_\nu},$$

the uniform convergence of ν^k_s to ν_s, and the continuity of ν_s it follows that

$$\nu_{\bar{S}_\nu} = \lim_{k\to\infty} \nu^k_{S^k_\nu} = T. \tag{3.43}$$

Now suppose that $\bar{S}_\nu < S_\nu$ for some ω; then (3.43) contradicts the definition of S_ν as the stopping time according to (3.22), and consequently $\lim_{k\to\infty} S^k_\nu = S_\nu$. Analogously we obtain $\lim_{k\to\infty} S^k_\mu = S_\mu$ and finally

$$\lim_{k\to\infty} S^k = \lim_{k\to\infty} \left(S^k_\nu \wedge S^k_\mu\right) = S_\nu \wedge S_\mu = S.$$

Consider next the sequence (Z^k_s), with Z^k_s obtained as solutions of (3.10) corresponding to $\alpha = \alpha^k$. For each given $N > 0$ determine the sequence of stopping times $\theta^{N,k} = \min\{S, S^k, \tau^N, \tau^{N,k}\}, k = 1, 2, \ldots,$ where

$$\tau^N = \inf\{s : ||Z_s|| = N\}, \tag{3.44a}$$

$$\tau^{N,k} = \inf\{s : ||Z^k_s|| = N\}. \tag{3.44b}$$

The properties of the coefficients in the right-hand side of (3.10) guarantee that the trajectories of Z^k_s are a.s. continuous so that, for any $\alpha \in \mathcal{A}^L_0$ and any k,

$$\tau^N,\ \tau^{N,k} \uparrow \infty \qquad \text{a.s. as} \quad N \to \infty. \tag{3.45}$$

Consider next the sequences of processes $Z^k_{s\wedge\theta^{N,k}}$ as well as $Z_{s\wedge\theta^{N,k}}$. By the continuity and the local Lipschitzianity with respect to Z of the functions in the right-hand side of (3.10) as well the uniform convergence of $\nu^k_s \to \nu_s$ and of $\alpha^k_s \to \alpha_s$ on compact subsets of $[0, S_\nu]$, we obtain

$$\begin{aligned} &\sup_{\tau\le s\wedge\theta^{N,k}} E\,||\,Z^k_{\tau\wedge\theta^{N,k}} - Z_{\tau\wedge\theta^{N,k}}\,||^2 \\ &\qquad \le C_1 \int_0^{s\wedge\theta^{N,k}} \sup_{\tau\le u} E\,||\,Z^k_{\tau\wedge\theta^{N,k}} - Z_{\tau\wedge\theta^{N,k}}\,||^2 du + C_2\varepsilon_k, \end{aligned} \tag{3.46}$$

where $\lim_{k\to\infty} \varepsilon_k = 0$. Applying the Gronwall–Bellman inequality to (3.45) we get for all $s \le S$

$$\lim_{k\to\infty} \sup_{\tau\le s\wedge\theta^{N,k}} E\,||\,Z^k_\tau - Z_\tau||^2 = 0. \tag{3.47}$$

Together with k now also let $N \uparrow \infty$; then $\theta^{N,k} \to S$ a.s., implying that for all $s < S$ we have the convergence in $\mathcal{L}^2$ of Z^k_s to Z_s and, by the continuity of Z^k_s in $s = S$, also of $Z^k_{S^k}$ to Z_S.

This convergence in turn implies the convergence in probability of Z^k_s to Z_s for all $s \in [0, S]$ as well as that of $Z^k_{S^k}$ to Z_S. In addition we have the uniform integrability of Z^k_s on $\Omega \times [0, T + M]$ and of $Z^k_{S^k}$ on Ω since, by the linear growth in Z of the functions in the right-hand side of (3.10), we have for $p \ge 1$

$$\int_0^{T+M} E\,||Z^k_s||^p ds \le L < \infty, \quad E\,||Z^k_{S^k}||^p \le L < \infty. \tag{3.48}$$

As a consequence, and due to the polynomial growth in Z of the functions F^0, F^1, and $\bar{\Phi}^0$, we may pass to the limit in (3.30), thus concluding the proof of the proposition.

Combining the result of Proposition 3.6 with that of Proposition 3.4 we immediately obtain the following corollary.

COROLLARY 3.7. *For any control $\alpha \in \mathcal{A}_0^L$ there exists a sequence of Lipschitz Markov (feedback) controls $u_t^k = u_t^k(X_t, v_t)$ satisfying* (1.2) *such that*

$$\lim_{k\to\infty} J'(u^k) = J(\alpha). \tag{3.49}$$

Proof. From (3.38) we immediately have that, if $\alpha_t = \alpha_t(Z_t, \mu_t)$ with $\alpha_t(\cdot)$ Lipschitz, α^k also is Lipschitz. Recall next that the u^k corresponding to α^k is defined by (3.24) and (see Lemma 3.2) satisfies (1.2). Using the relationship (3.23) as well as the fact that $\alpha_s^k \geq \frac{1}{1+k}$, for such a u^k we then have $u_t^k = u_t^k(X_t, v_t)$ with $u_t^k(\cdot)$ Lipschitz. The result then follows by combining the previous considerations with Proposition 3.4.

3.4. Nearly optimal Lipschitz Markov controls. In this section we study first the existence of an optimal solution for the auxiliary control problem in the class $\mathcal{A}_0$ as well as the existence of a nearly optimal Lipschitz Markov control for the original problem. We then return to the relationship between the original and the auxiliary control problems, showing the usefulness of the auxiliary problem to obtain a nearly optimal Lipschitz Markov control in the original problem.

For the first part we have the following theorem.

THEOREM 3.8. *In the class $\mathcal{A}_0$ there exists an optimal control for the auxiliary problem, and it is of the Markov (feedback) type*

$$\alpha_s^0 = \alpha_s^0(Z_s, \mu_s). \tag{3.50}$$

Furthermore, for any $\varepsilon > 0$ there exists a Lipschitz Markov control $\alpha_s^{0,\varepsilon}(Z_s, \mu_s) \in \mathcal{A}_0$ such that

$$J(\alpha^0) = \inf_{\alpha\in\mathcal{A}_0} J(\alpha) \geq J(\alpha^{0,\varepsilon}) - \varepsilon. \tag{3.51}$$

Proof. Concerning the existence of an optimal solution in $\mathcal{A}_0$ note first that, under our assumptions, the set

$$K(\nu, Z) = \left\{ \begin{array}{l} \alpha F + (1-\alpha)B, \quad 1-\alpha, \quad \alpha, \quad (1-\alpha)GG^T \\ \alpha F^0 + (1-\alpha)F^1 \end{array} \right\}_{|\alpha\in[0,1]} \tag{3.52}$$

is, for all (ν, Z), bounded, closed, and convex. This allows us to apply known results on the existence of optimal controls—in particular, Theorem 5.15 in [3]—since the functions F, B, GG^T, F^0, and F^1 satisfy the growth conditions required in that theorem and the admissible control set $\mathcal{A}_0$ is not empty. More precisely, according to Theorem 5.15 in [3] we have that in the auxiliary problem there exists an optimal control in the class $\mathcal{A}_0$ and it is furthermore of the Markov (feedback) type, namely, as in (3.50). The existence of a Lipschitz Markov control can be obtained by using, e.g., results in [7] (see also [6]).

Before coming to the main result of the second part of this section, for later convenience we state the following lemma, whose proof can be obtained via a truncation argument analogous to that used in the proof of Theorem 2.1 concerning the uniqueness of the solution of (1.9).

LEMMA 3.9. *Any Lipschitz Markov control* $u_t = u_t(X_t, v_t)$ *belongs to the class* $\mathcal{L}_1$*; in particular, as a function of* y_0^t *it is Lipschitz in the sense of* (1.5).

THEOREM 3.10. *The following equality holds between the optimal values of the original and the auxiliary control problems*

$$\inf_{u\in\mathcal{L}_0} J(u) = \inf_{u\in\mathcal{L}_1} J'(u) = \inf_{\alpha\in\mathcal{A}_0^L} J(\alpha) \tag{3.53}$$

with $\mathcal{A}_0^L$ *as defined in* (3.37).

Furthermore, given an ε*-optimal control* $\alpha^\varepsilon \in \mathcal{A}_0^L$*, let* k *be so large that for the control* $u^{k,\varepsilon}$*, obtained via* (3.24) *from a Lipschitz control* $\alpha^{k,\varepsilon} \in \mathcal{A}^L$ *that in turn is obtained from* α^ε *via* (3.38)*, we have*

$$J'(u^{k,\varepsilon}) \le J(\alpha^\varepsilon) + \varepsilon. \tag{3.54}$$

Then $u^{k,\varepsilon}$ *belongs to* $\mathcal{L}_1$ *and is a* 4ε*-optimal Lipschitz Markov control for the original problem.*

Proof. The first equality in (3.53) follows from Theorem 2.1. For the second equality note first that, letting u^ε be an ε-optimal control in $\mathcal{L}_1$, α^ε be the corresponding control in $\mathcal{A}_0$ obtained according to (3.11) and (3.6), and α^0 and $\alpha^{0,\varepsilon}$ be the optimal and nearly optimal controls of Theorem 3.8 and using Proposition 3.4 we obtain

$$\begin{aligned}\inf_{u\in\mathcal{L}_1} J'(u) &\ge J'(u^\varepsilon) - \varepsilon = J(\alpha^\varepsilon) - \varepsilon \ge \inf_{\alpha\in\mathcal{A}_0} J(\alpha) - \varepsilon \\ &= J(\alpha^0) - \varepsilon \ge J(\alpha^{0,\varepsilon}) - 2\varepsilon \ge \inf_{\alpha\in\mathcal{A}_0^L} J(\alpha) - 2\varepsilon.\end{aligned} \tag{3.55}$$

On the other hand let $\alpha^\varepsilon \in \mathcal{A}_0^L$ be ε-optimal. Starting from this α^ε, construct the Lipschitz control $\alpha^{k,\varepsilon} \in \mathcal{A}^L$ according to (3.38), and let $u^{k,\varepsilon}$ be the corresponding Lipschitz Markov control obtained according to (3.24). Then, using Corollary 3.7 and the fact that (see Lemma 3.9) if $u_t^{k,\varepsilon} = u_t^{k,\varepsilon}(X_t, v_t)$ is Lipschitz as a function of (X_t, v_t), then it is also in $\mathcal{L}_1$, we have for k sufficiently large

$$\inf_{\alpha\in\mathcal{A}_0^L} J(\alpha) \ge J(\alpha^\varepsilon) - \varepsilon \ge J'(u^{k,\varepsilon}) - 2\varepsilon \ge \inf_{u\in\mathcal{L}_1} J'(u) - 2\varepsilon. \tag{3.56}$$

Combining (3.55) with (3.56) one obtains

$$\inf_{u\in\mathcal{L}_1} J'(u) + 2\varepsilon \ge \inf_{\alpha\in\mathcal{A}_0^L} J(\alpha) \ge \inf_{u\in\mathcal{L}_1} J'(u) - 2\varepsilon, \tag{3.57}$$

from which, due to the arbitrariness of $\varepsilon > 0$, the second equality in (3.53) follows. From (3.55) and (3.56) one also obtains

$$J'(u^{k,\varepsilon}) \le \inf_{u\in\mathcal{L}_1} J'(u) + 4\varepsilon, \tag{3.58}$$

i.e., the 4ε-optimality of $u^{k,\varepsilon}$.

Concluding remarks. From Theorem 3.10 we have that the optimal value $\inf_{u\in\mathcal{L}_0} J(u)$ of the original control problem can be determined by solving the auxiliary problem. However, as mentioned in Remark 3.5, while the auxiliary problem admits an optimal control, there may not exists a control for the original problem for which the optimal value is achieved. There are essentially two reasons for this:

- The filter process X_t corresponding to the optimal solution of the auxiliary problem may jump, so it can be represented as solution of (1.12) only if we allow the control also to have infinite power.
- Even if we allow infinite control power, the representation of the possible jumps of the filter process by means of (1.22) may require anticipative impulse controls.

In fact, due to the linearity in the control α of the Hamilton–Jacobi–Bellman equation of the auxiliary control problem, there will be intervals on which the optimal control α_s^0 for this latter problem will be either zero or one.

If $\alpha_s^0 = 1$, for the corresponding control u_t^0 of the original problem, obtained from α^0 via (3.24), we have $u_t^0 = 0$, and this motivated the extended study of the filter problem in section 1.2.

If, however, $\alpha_s^0 = 0$ on some interval $[s_1, s_2]$, the corresponding ν_s^0 (see (3.10c)) is constant, implying a jump for the inverse function $\Gamma_t^0 = \inf\{s : \nu_s^0 > t\}$. Since (see Lemma 3.2) $X_t = Z_{\Gamma_t}$, $v_t = \mu_{\Gamma_t}$, this then implies that X_t and v_t also jump and can therefore be a solution of (1.12) only if we allow controls u_t with infinite power. This implies an impulse control for the original problem at the moment $t_1 = \nu_{s_1}$, leading (see (1.1b)) to a discrete observation with intensity (see the relation $v_t = \mu_{\Gamma_t}$ in (3.23)) $\Delta v_{t_1} = s_2 - s_1$. Since s_2 is $\mathcal{F}_{s_2}^{Z,\nu} = \mathcal{F}_{t_1^+}^{X,v}$-measurable, this Δv_{t_1} cannot be determined on the basis of the observations up to time t_1; i.e., the control would be anticipative.

Our approach, based on the search of a nearly optimal control, avoids this problem. In fact, the control $u^{k,\varepsilon} \in \mathcal{L}_1$ obtained according to Theorem 3.10 (namely, obtained via (3.24) from a nearly optimal control $\alpha^{k,\varepsilon}$ of the auxiliary problem that belongs to $\mathcal{A}^L$ and thus satisfies $\alpha^{k,\varepsilon} > 0$) has finite power, is $\mathcal{F}_t^{X,v}$-measurable, and allows us to approximate arbitrarily closely the optimal value $\inf_{u\in\mathcal{L}_0} J(u) = \inf_{u\in\mathcal{L}_1} J'(u)$ of the objective function of the original problem.

STATE MAPS FOR LINEAR SYSTEMS*

PAOLO RAPISARDA† AND J. C. WILLEMS‡

Abstract. Modeling of physical systems consists of writing the equations describing a phenomenon and yields as a result a set of differential-algebraic equations. As such, state-space models are not a natural starting point for modeling, while they have utmost importance in the simulation and control phase. The paper addresses the problem of computing state variables for systems of linear differential-algebraic equations of various forms. The point of view from which the problem is considered is the behavioral one, as put forward in [J. C. Willems, *Automatica J. IFAC*, 22 (1986), pp. 561–580; *Dynamics Reported*, 2 (1989), pp. 171–269; *IEEE Trans. Automat. Control*, 36 (1991), pp. 259–294].

1. Introduction.

The usual procedure in modeling consists of *tearing* and *zooming*: a system is viewed as an interconnection of subsystems, and modeling consists of describing the subsystems and the interconnection laws. This procedure is often executed hierarchically, with the subsystems in turn viewed as an interconnection. The net result of such a modeling procedure will be a model which involves *manifest* variables (often called *external* variables), which are the variables whose behavior we try to model, and *latent* variables (often called *internal* variables), which are the variables describing the subsystems. The formalization of this modeling procedure is the philosophy underlying the *behavioral* approach to systems theory. These ideas have been explained in detail in [8, 9, 10].

As should be apparent, the resulting model will typically involve many algebraic relations (for example, interconnection constraints, resistors laws, spring and damper characteristics, kinematic constraints), combined with differential equations. These may be first-order (for example, inductors, capacitors, the dynamics of dampers), second-order (for example, the dynamics of masses), or higher-order (for example, subsystems whose dynamic laws have been obtained from an identification procedure).

A state-space model is hence not the natural end result of the modeling phase, while its importance for simulation or for control design is undisputed. This is one of the reasons why the notion of state is one of the most investigated ones in system theory and why its characterization and construction have been the subject of many papers since the beginning of this discipline. The problem that we deal with in this paper is that of computing state variables, from which a state-space model is easily recovered, starting from an arbitrary set of linear differential-algebraic equations.

The paper is organized as follows. In section 2 a set of definitions and results pertaining to the behavioral framework is introduced. In section 3 the consequences of the property of Markovianity, the key to the notion of state, are worked out. In

section 4 the problem at hand is formally stated. In section 5 operators on polynomials are introduced which will be used in sections 6–9, in which state functions for systems of differential-algebraic equations are computed. As we shall see, the systems may be in kernel, in image, or in hybrid form.

The proofs and some of the notation are collected in the appendices.

2. The behavioral framework. In this section we give a brief introduction to behavioral system theory, with emphasis on the definitions and results pertaining to the problem at hand, referring the reader to [8, 9, 10] for a thorough exposition.

In the behavioral framework a *system* is defined as a triple $\Sigma = (T, W, \mathcal{B})$, with T the time set, W the signal space, and $\mathcal{B}$ the behavior of the system, $\mathcal{B} \subseteq W^T$.

Effectively, a system consists of a family of trajectories which take their value in the signal space. In this paper we consider continuous-time ($T = \mathbb{R}$) systems whose variables take values in a finite-dimensional real vector space, $W = \mathbb{R}^q$. A dynamical system will be called *linear* if $\mathcal{B}$ is a linear vector subspace of $(\mathbb{R}^q)^{\mathbb{R}}$, the latter equipped with the usual vector space structure induced by that of $\mathbb{R}^q$, and *time invariant* if the following holds $\forall\ t \in \mathbb{R}$:

$$(w(\cdot)\ \in\ \mathcal{B}) \Longrightarrow (w(\cdot + t)\ \in\ \mathcal{B}). \tag{2.1}$$

In many instances systems are described by differential equations, say,

$$f_1\left(w, \frac{d}{dt}w, \ldots, \frac{d^L}{dt^L}w\right) = f_2\left(w, \frac{d}{dt}w, \ldots, \frac{d^L}{dt^L}w\right). \tag{2.2}$$

A concrete representation of the behavior of a linear, time-invariant, continuous-time differential system $(\mathbb{R}, \mathbb{R}^q, \mathcal{B})$ is then given as the solution set of a system of linear, constant coefficient differential equations:

$$R_0 w + R_1 \frac{d}{dt}w + R_2 \frac{d^2}{dt^2}w + \cdots + R_L \frac{d^L}{dt^L}w = 0 \tag{2.3}$$

with constant matrices $R_i \in \mathbb{R}^{\bullet \times q}$. Equation (2.3) is what we call a *kernel representation* of such a system. A shorthand notation for (2.3) is

$$R\left(\frac{d}{dt}\right) w = 0, \tag{2.4}$$

where $R(\xi) := R_0 + R_1\xi + \cdots + R_L\xi^L \in \mathbb{R}^{\bullet \times q}[\xi]$. Note that (2.4) may involve algebraic equations in addition to ordinary differential equations.

The behavioral framework takes into account the nonuniqueness of the representation of behaviors. This is natural, given the connections between this approach and the actual procedure of modeling physical systems, in which different, although equivalent, sets of equations describing the same phenomenon may be produced.

The formalization of this equivalence concept is given as follows. Two kernel representations $R_1(\frac{d}{dt})w = 0$ and $R_2(\frac{d}{dt})w = 0$ with R_1, $R_2 \in \mathbb{R}^{\bullet \times q}[\xi]$ are *equivalent*—that is, the behaviors associated with them are the same—if and only if there exist polynomial matrices F_1, F_2 with a suitable number of columns such that $R_1 = F_1 R_2$ and $R_2 = F_2 R_1$; in particular, if R_1 and R_2 are of full row rank, this means that there exists a unimodular polynomial matrix F such that $R_1 = F R_2$ (see [10, p. 263]).

As already explained in the introduction, (2.4) is not the most natural result of a modeling process, since normally a number of auxiliary latent variables will have

been introduced. The natural counterpart of (2.4) to cope with this is

$$R\left(\frac{d}{dt}\right)w = M\left(\frac{d}{dt}\right)\ell, \tag{2.5}$$

where $M \in \mathbb{R}^{\bullet\times d}[\xi]$ and where $\ell \in (\mathbb{R}^d)^{\mathbb{R}}$ are the latent variables. The set of equations (2.5) is called a *latent variable* or a *hybrid representation* of the *latent variable system* $(\mathbb{R}, \mathbb{R}^q, \mathbb{R}^d, \mathcal{B}_f)$, where the *full behavior* $\mathcal{B}_f$ is composed of trajectories (w, ℓ) satisfying (2.5) and inducing the *external* or *manifest behavior* $\mathcal{B}_{ext} := \pi_w\mathcal{B}_f$ by projection on the external variables. Actually the external behavior induced by a latent variable system may be described (modulo some closedness problems pointed out in [6] and discussed in detail in the following) in terms of the external variables only by *eliminating the latent variable*, a procedure discussed in the following.

Of course the problem arises what sort of *solution* we want to use for (2.4) and (2.5). Restricting ourselves to $\mathcal{C}^\infty$ (infinitely differentiable signals) would leave out interesting functions such as steps, etc. The space of distributions is a bit too large, leaving us with the problem of defining the value of a solution at a point. The space $\mathcal{L}_1^{loc}$ of locally integrable functions is large enough to accommodate steps, ramps, and so on and still concrete enough to avoid the problems we would have with distributions. Therefore, in (2.4) and (2.5) *w and ℓ are to be intended in $\mathcal{L}_1^{loc}$ and equality in the sense of distributions.*

Let us focus now on the *elimination of the latent variable* from (2.5).

Hybrid representations involve two kind of variables, namely, the manifest and the latent variables; and associated with a hybrid representation are two behaviors, the full behavior $\mathcal{B}_f$, consisting of trajectories with both the latent and the external variables, and the external behavior $\mathcal{B}_{ext}$, composed of trajectories in the manifest variables only.

At the level of trajectories, the relationship between $\mathcal{B}_f$ and $\mathcal{B}_{ext}$ is the following: any trajectory in $\mathcal{B}_{ext}$ is induced by a trajectory in $\mathcal{B}_f$ via the projection operator $\pi_w((w, \ell)) = w$. At the level of representations and of the equations representing the behaviors, things are more complicated. Take a hybrid representation

$$R\left(\frac{d}{dt}\right)w = M\left(\frac{d}{dt}\right)\ell. \tag{2.6}$$

By premultiplication by a unimodular matrix U we can bring $(\,R \;\mid\; -M\,)$ to the form

$$U\,(\,R \;\mid\; -M\,) = \begin{pmatrix} R_1' & 0 \\ R_2' & -M_2' \end{pmatrix} \tag{2.7}$$

with M_2' of full row rank. Unimodularity of U implies that the full behavior represented by (2.6) is not altered by the change of representation and coincides with the behavior represented by

$$R_1'\left(\frac{d}{dt}\right)w = 0, \tag{2.8}$$

$$R_2'\left(\frac{d}{dt}\right)w = M_2'\left(\frac{d}{dt}\right)\ell. \tag{2.9}$$

A natural candidate for representing the external behavior corresponding to (2.6) would be $R_1'(\frac{d}{dt})w = 0$, since if $w \in \mathcal{B}_{ext}$ of (2.6), then $R_1'(\frac{d}{dt})w = 0$. In fact, for

discrete-time systems it has been shown in [10, p. 234] that the analogue of (2.8) in discrete time is indeed a kernel representation of the manifest behavior; this result is referred to in behavioral system theory as the *latent variable elimination theorem*. However, in the continuous-time case there are difficulties. Take, for example, the hybrid representation

$$\begin{aligned} w_1 &= w_2, \\ \frac{d}{dt} w_2 &= \ell. \end{aligned} \tag{2.10}$$

Note that the second equation imposes a smoothness requirement on w_2 not present in the first one: the external behavior does not coincide with the one described by $w_1 = w_2$. When situations like the one exemplified above do not occur, the latent variable ℓ is said to be *properly eliminable* (cf. [6]). Necessary and sufficient conditions for proper eliminability are given in [6].

If the latent variable is not properly eliminable, $\mathcal{B}_{ext}$ is described by $R_1'(\frac{d}{dt})w = 0$ of (2.8) along with some smoothness constraints. These constraints on w cannot be represented by equations involving w alone and the need to circumvent this difficulty arises. The most natural way to do this is to drop them, that is, to consider the closure of $\mathcal{B}_{ext}$ in the topology of $\mathcal{L}_1^{loc}$. This choice has much to recommend it besides its simplicity: it allows to keep $\mathcal{L}_1^{loc}$ as the natural function space in which to operate, and in this way the latent variable can always be eliminated. We summarize this in the following theorem.

THEOREM 2.1. *Let* (2.6) *be a hybrid representation. There exists a unimodular matrix* U *such that*

$$U \left(\begin{array}{c|c} R & -M \end{array} \right) = \begin{pmatrix} R_1' & 0 \\ R_2' & -M_2' \end{pmatrix} \tag{2.11}$$

with M_2' *of full row rank. Then*

$$\begin{aligned} \left\{ w \in \mathcal{L}_1^{loc}(\mathbb{R}; \mathbb{R}^q) \mid R_1' \left(\frac{d}{dt} \right) w = 0 \right\} &= \overline{\pi_w(\mathcal{B}_f)}^{closure} \\ &= \overline{\{w \mid \exists\ \ell\ s.t.\ (2.6)\ holds\}}^{closure} \end{aligned} \tag{2.12}$$

with the closure taken in the topology of $\mathcal{L}_1^{loc}(\mathbb{R}; \mathbb{R}^q)$.

Proof. See the appendix. □

In the following, unless otherwise stated, we will take (2.12) to be the manifest behavior induced by (2.6).

The important notions of controllability and observability emerge in the behavioral context as follows. The time-invariant system $(\mathbb{R}, \mathbb{R}^q, \mathcal{B})$ is said to be *controllable* if for all w_1, w_2 in $\mathcal{B}$, there exists a $T \geq 0$ and a $w \in \mathcal{B}$ such that $w(t) = w_1(t)$ for $t < 0$ and $w(t + T) = w_2(t)$ for $t \geq 0$. The notion of observability deals with latent variable systems and refers to the possibility of deducing the latent variables from the manifest ones. Thus (2.5) defines an *observable* system if there exists a map $F : (\mathbb{R}^q)^{\mathbb{R}} \mapsto (\mathbb{R}^d)^{\mathbb{R}}$ such that $((w, \ell) \in \mathcal{B}_f) \Longrightarrow (\ell = F(w))$. For linear latent variable systems this is equivalent to $((0, \ell) \in \mathcal{B}_f) \Longrightarrow (\ell = 0)$.

The question when a system (2.4) is controllable can be answered effectively in terms of R. Indeed, (2.4) is controllable if and only if $\operatorname{rank}(R(\lambda)) = \operatorname{rank}(R)$ for all $\lambda \in \mathbb{C}$, as shown in [9, p. 238]. (Here one should view $R(\lambda)$ as a matrix over the

field of complex numbers and R as a matrix over the field of real rational functions.) Analogously, (2.5) will be observable if and only if $M(\lambda)$ is right prime (equivalently, if and only if $M(\lambda)$ is of full column rank for all $\lambda \in \mathbb{C}$), as shown in [9, p. 239]. Actually, controllability can also be characterized in terms of (2.5). Take $R = I$ in (2.5), yielding

$$w = M\left(\frac{d}{dt}\right)\ell. \tag{2.13}$$

Let $\mathcal{B}$ be the manifest behavior of (2.13). (More precisely, in view of questions related to closedness, $\mathcal{B} = \overline{M(\frac{d}{dt})\mathcal{C}^\infty(\mathbb{R},\mathbb{R}^d)}^{closure}$, with the closure taken with respect to the topology of $\mathcal{L}_1^{loc}(\mathbb{R},\mathbb{R}^q)$.) This yields the dynamical system $(\mathbb{R},\mathbb{R}^q,\mathcal{B})$, and for obvious reasons we will call (2.13) an *image representation* of $\mathcal{B}$. By the already mentioned latent variable elimination theorem, $\mathcal{B}$ admits a kernel representation as (2.4). However, not every system (2.4) has an image representation. This is the case if and only if the system is controllable! (See [9, p. 238].)

Finally, let us introduce the notion of *input* and *output*. Consider a system (2.4) with $R(\xi)$ of full row rank. Possibly permuting the components of w, assume R partitioned as $R := (\,P \;\mid\; -Q\,)$, with P square, nonsingular, and $P^{-1}Q$ proper. Such a partition of R always exists and can be found as follows. By unimodular premultiplication by a suitable U, bring R in row reduced form (see [3, p. 382]). Let R'_{hc} be the highest row coefficient matrix of $R' := UR$. R'_{hc} has full row rank, and therefore there exists at least one $g \times g$ nonzero minor, corresponding to a choice of the k_1th, k_2th, $\ldots, k_g$th column of R_{hc}. The minor of R corresponding to this column selection is of maximal degree among the $g \times g$ minors of R. This implies that if we take P to be the matrix formed by the k_1th, k_2th, $\ldots, k_g$th column of R, P is nonsingular and $P^{-1}Q$ is proper, $-Q$ being the complementary matrix of P in R.

The partition of R induces a corresponding partition of w in (y,u) so that (2.4) may be rewritten as

$$P\left(\frac{d}{dt}\right)y = Q\left(\frac{d}{dt}\right)u. \tag{2.14}$$

This is an *input-output* representation of the behavior of (2.4), with y the *output* variables and u the *input* variables.

It is important to note that the selection of P and Q of (2.14) is not unique, in general. This implies that for a system whose behavior is described by (2.4), different selections of inputs and outputs can be given. This corresponds to different selections of R'_{hc} to form a nonzero minor in the procedure sketched above. Anyway, it is possible to prove (see [10, p. 243]) that the number of outputs, and consequently the number of inputs, in any representation (2.4) of the behavior of the system is unique and coincides with $\operatorname{rank}(R)$.

3. State, Markovianity, and first-order representations. Let $(\mathbb{R},\mathbb{R}^q,\mathcal{B})$ be a time-invariant dynamical system. We will call it *Markovian* if

$$(w_1, w_2 \in \mathcal{B}) \wedge (w_1, w_2 \text{ continuous at } 0) \wedge (w_1(0) = w_2(0)) \tag{3.1}$$

implies $((w_1 \wedge w_2)) \in \mathcal{B})$; $w_1 \wedge w_2$ stands for concatenation:

$$(f_1 \wedge f_2)(t) := \begin{cases} f_1(t), & t < 0, \\ f_2(t), & t \geq 0. \end{cases} \tag{3.2}$$

Thus in a Markovian system trajectories passing in a continuous way through the same point at $t = 0$ can be concatenated. The very much related notion of state refers to systems with latent variables. Thus let $(\mathbb{R}, \mathbb{R}^q, \mathbb{R}^d, \mathcal{B}_f)$ be a time-invariant latent variable system. Then it is a *state system* if

$$((w_1, \ell_1), (w_2, \ell_2) \in \mathcal{B}_f) \wedge (\ell_1(0) = \ell_2(0)) \wedge (\ell_1, \ell_2 \text{ continuous at } t = 0)$$
$$\implies ((w_1, \ell_1) \wedge (w_2, \ell_2)) \in \mathcal{B}_f). \tag{3.3}$$

We call (3.3) the *axiom of state*. If (3.3) holds, then the latent variable is called the *state*. Thus in a state model trajectories passing in a continuous way through the same state at $t = 0$ can be concatenated. The continuity requirement is inspired by the fact that we are dealing with solutions of (2.4) and (2.5) in $\mathcal{L}_1^{loc}$, in which case the simple requirement $\ell_1(0) = \ell_2(0)$ is of little consequence.

Usually a Markovian or a state variable is denoted by x. We will do so in the following discussion.

It is easy to prove that if the behavior is described by a set of first-order differential equations, as

$$f\left(x, \frac{d}{dt}x\right) = 0, \tag{3.4}$$

then it is Markovian; similarly, if it can be described by a set of differential equations which is first order in the latent variables and zeroth order in the manifest variables, as

$$f\left(w, x, \frac{d}{dt}x\right) = 0, \tag{3.5}$$

then it is a state model (see [9, p. 191]). For linear differential systems this is, in fact, necessary and sufficient, as shown by the following proposition.

PROPOSITION 3.1. *Let Σ_S be a system as in* (2.5). *Then it is a state-space system if and only if there exist matrices E, F, and G such that $\mathcal{B}_f$ has the kernel representation*

$$Gw + Fx + E\frac{d}{dt}x = 0. \tag{3.6}$$

Analogously, $(\mathbb{R}, \mathbb{R}^q, \mathcal{B})$ *as in* (2.4) *is Markovian if and only if there exist matrices E and F such that $\mathcal{B}$ has the kernel representation*

$$Fx + E\frac{d}{dt}x = 0. \tag{3.7}$$

Proof. See the appendix. □

Remark 3.1. The above proposition constitutes an example of application of the following fact. Equation (2.4) determines a representation of the behavior $\mathcal{B}$, but it is not the unique possible representation of $\mathcal{B}$. In fact, if U is a unimodular matrix, then UR determines the same behavior. This allows us to obtain representations which put certain properties in evidence, just like the state property above.

Remark 3.2. A state-space system induces, by projection of $\mathcal{B}_f$ on the external variable w, an external behavior $\mathcal{B} := \pi_w \mathcal{B}_f$. Therefore it will be called a *state-space representation* or a *state-space model* of $\mathcal{B}$.

Besides state-space models of $\mathcal{B}$ whose full behavior is described by equations of the form (3.6), *state-space models with driving variables* and *input/state/output models* can be defined.

A *state-space model with driving variables* is described by

$$\begin{aligned} \frac{d}{dt}x &= Ax + Bv, \\ w &= Cx + Dv, \end{aligned} \tag{3.8}$$

where x is a state variable for $\mathcal{B} = \{w \in \mathcal{L}_1^{loc} | \ \exists\ x \in \mathcal{L}_1^{loc}, v \in \mathcal{L}_1^{loc},$ s.t. (3.8) holds$\}$ and v is composed of free but latent variables which generate, together with the initial conditions, the state trajectory and the external signal. We call v the *driving variable*.

By integrating the state property and the input-output structure in the same representation, an *input/state/output representation* is obtained. It can be computed from a state representation (3.6) by partitioning the w variables in inputs u and outputs y and rearranging the equations (3.6) so that a representation

$$\begin{aligned} \frac{d}{dt}x &= Ax + Bu, \\ y &= Cx + Du \end{aligned} \tag{3.9}$$

is obtained.

Let $\Sigma_S = (\mathbb{R}, \mathbb{R}^q, \mathbb{R}^n, \mathcal{B}_f)$ be a state-space system and $(\mathbb{R}, \mathbb{R}^q, \mathcal{B})$ be its external (i.e., manifest) behavior. We will call Σ_s *minimal* if whenever $\Sigma_{S'} = (\mathbb{R}, \mathbb{R}^q, \mathbb{R}^{n'}, \mathcal{B}'_f)$ is another state-space model with the same external behavior $(\mathbb{R}, \mathbb{R}^q, \mathcal{B})$, then $n \leq n'$. It is possible to prove (see [10, p. 270]) that Σ_S is minimal if and only if it is *observable* (with the state viewed as the latent variable) and *state trim* (meaning that for all $x_0 \in \mathbb{R}^n$ there exists a $(w, x) \in \mathcal{B}_f \bigcap \mathcal{C}^\infty$ such that $x(0) = x_0$). Observability, in particular, implies that there then exists a $F \in \mathbb{R}^{n \times q}[\xi]$ such that $((w, x) \in \mathcal{B}_f) \Longrightarrow (x = F(\frac{d}{dt})w)$. Actually it can further be shown (see [10, p. 271]) that if Σ_S and $\Sigma_{S'} = (\mathbb{R}, \mathbb{R}^q, \mathbb{R}^{n'}, \mathcal{B}'_f)$ are two minimal state space systems with the same external behavior, then there exists a nonsingular matrix $S \in \mathbb{R}^{n \times n}$ such that

$$((w, x) \in \mathcal{B}_S \text{ and } (w, x') \in \mathcal{B}_{S'}) \Longrightarrow (x' = Sx). \tag{3.10}$$

4. Problem statement. The question arises of how to compute a set of state variables when a system is given either in kernel or in hybrid form.

This question may be stated as: *Given a set of equations in either kernel or hybrid form, how do we determine a* state map $X(\frac{d}{dt})$*?* More precisely, given R, determine the integer n and $X \in \mathbb{R}^{n \times q}[\xi]$ such that

$$R\left(\frac{d}{dt}\right) w = 0, \tag{4.1}$$

$$X\left(\frac{d}{dt}\right) w = x \tag{4.2}$$

defines a (minimal) state-space system with external behavior given by (4.1). The problem is to derive X from R. Similarly we want to derive a state map X for the external behavior of a system represented in hybrid form or image form. In this case, in view of the closedness problems discussed in the previous section, we will interpret

the external behavior associated with the hybrid or image representation under study, in the sense of Theorem 2.1.

Remark 4.1. It is of utmost importance at this point to note that the external behavior of the state-space system described by (4.1), (4.2) is assumed to be described by (4.1); that is, the equations (4.2) do not impose any smoothness constraint on the trajectories defined by (4.1). Therefore, when dealing with state-space representations of a given external behavior $\mathcal{B}$, we will consider the (latent) state variable x induced by the state map to be *properly eliminable.*

The next section introduces the tools that we will use to deal with the problem of computing state maps for the various sorts of representations introduced so far.

5. Operators on polynomials. The behavioral framework for linear differential systems is intimately connected to polynomial matrix algebra. These connections are also reflected in the results which will be presented in the following sections, related to the characterization of state maps.

This section is devoted to the introduction of some notational conventions related to polynomials and rational functions.

Any rational function can be written in a unique way as the sum of a polynomial and of a strictly proper rational function. That is, given $q \in \mathbb{R}(\xi)$, there exist unique $p \in \mathbb{R}[\xi]$ and $s \in \mathbb{R}_+(\xi)$, the set of strictly proper rational functions, such that $q = p + s$. Now define

$$(\ )_+ : \mathbb{R}(\xi) \mapsto \mathbb{R}[\xi] \tag{5.1}$$

as

$$(q(\xi))_+ := p(\xi). \tag{5.2}$$

On the set of rational functions in the indeterminate ξ, multiplication by ξ^{-1} defines a map $\xi^{-1} : \mathbb{R}(\xi) \mapsto \mathbb{R}(\xi)$ in the obvious way.

DEFINITION 5.1. *The* shift-and-cut *operator σ_+ is defined as*

$$\sigma_+ : \mathbb{R}(\xi) \mapsto \mathbb{R}[\xi],$$

$$\sigma_+ := (\ )_+ \circ \xi^{-1}. \tag{5.3}$$

The definition of σ_+ is extended to vectors and matrices of rational functions in a componentwise manner.

Iterated application of σ_+ will be considered in the following and denoted as

$$\sigma_+^k := \overbrace{\sigma_+ \circ \sigma_+ \circ \cdots \sigma_+}^{k-times}. \tag{5.4}$$

In the following, special importance will be given to the action of σ_+ on vector polynomials. Therefore, let us examine in detail what the result is of the application of σ_+ to a vector polynomial $p \in \mathbb{R}^{1\times q}[\xi]$. Write

$$p(\xi) := p_\delta \xi^\delta + p_{\delta-1}\xi^{\delta-1} + \cdots + p_1\xi + p_0. \tag{5.5}$$

Then

$$\sigma_+(p(\xi)) = p_\delta \xi^{\delta-1} + p_{\delta-1}\xi^{\delta-2} + \cdots + p_1; \tag{5.6}$$

that is,

$$\sigma_+(p(\xi)) = \xi^{-1}(p(\xi) - p_0). \tag{5.7}$$

Now let $R \in \mathbb{R}^{g\times q}[\xi]$ be given, and assume $R := R_0 + R_1\xi + \cdots + R_L\xi^L$. Define R^k, $k = 0, \ldots, L$, as $R^0 := R$ and $R^k := \sigma_+^k R = \sigma_+ R^{k-1}$, $k = 1, \ldots, L$. Define the Ξ-*matrix* R_Ξ as

$$R_\Xi := \operatorname{col}(R^k)_{k=1,\ldots,L} = \begin{pmatrix} R^1 \\ R^2 \\ \vdots \\ R^L \end{pmatrix}. \tag{5.8}$$

Connected to R_Ξ is the important notion of Ξ-space. Let $r_1, r_2, \ldots, r_g$ denote the rows of R. Then define the $\mathbb{R}$-vector space Ξ_R as

$$\Xi_R := \langle \sigma_+^k(r_i) \rangle, \quad k \in \mathbb{N},\ i = 1, \ldots, g, \tag{5.9}$$

where $\langle\ \rangle$ denotes the span over $\mathbb{R}$. The Ξ-space of R is most easily constructed as the $\mathbb{R}$-vector space generated by the rows of R_Ξ. Note that R_Ξ need not define a basis of the Ξ-space of R.

Introduce now on Ξ_R the equivalence relation $\overset{R}{\sim}$ defined as follows: $p, q \in \Xi_R$ are *equivalent modulo* R, written $p \overset{R}{\sim} q$, if and only if there exists $r(\xi) \in \mathbb{R}^{1\times g}[\xi]$ such that $p(\xi) - q(\xi) = r(\xi)R(\xi)$. It is easily verified that $\overset{R}{\sim}$ is indeed an equivalence relation.

Note that the vector space structure on Ξ_R induces a vector space structure on the set of equivalence classes induced by $\overset{R}{\sim}$ on Ξ_R. We will denote this set of equivalence classes as $\Xi_R \pmod R$. That is,

$$\Xi_R \pmod R = \{[p] \in 2^{\Xi_R} \mid q \in [p] \text{ iff } \exists\ r \in \mathbb{R}^{1\times g}[\xi] \text{ s.t. } p = q + rR\}. \tag{5.10}$$

The following example illustrates the above notions.

Example 5.1. Let

$$R := \begin{pmatrix} \xi^2 + 2\xi - 1 & \xi + 1 \\ \xi - 1 & \xi^2 - 3 \end{pmatrix}, \tag{5.11}$$

and consider its first row, $(\,\xi^2 + 2\xi - 1 \quad \xi + 1\,)$. The shift-and-cut operator acts on this row as

$$\sigma_+(\,\xi^2 + 2\xi - 1 \quad \xi + 1\,) = (\,\xi + 2 \quad 1\,). \tag{5.12}$$

The Ξ_R space is the vector space spanned by

$$(\,\xi + 2 \quad 1\,),\ (\,1 \quad 0\,),\ (\,1 \quad \xi\,),\ (\,0 \quad 1\,), \tag{5.13}$$

which actually form a basis for this space. It is easily verified that the vectors (5.13), interpreted as representing elements of $\Xi_R \pmod R$, are linearly independent as well, and therefore form a basis of $\Xi_R \pmod R$.

Note that selecting from the rows of R_Ξ a maximal set of linearly independent rows and considering these as representatives of elements of $\Xi_R \pmod R$ do not necessarily yield a basis for $\Xi_R \pmod R$, as made explicit by the following example.

Example 5.2. Let

$$R = \begin{pmatrix} 1 & 0 & -1 \\ 0 & 1 & \xi^3 \\ 0 & 0 & \xi \end{pmatrix}. \tag{5.14}$$

A maximal set of linearly independent rows of R_Ξ is

$$(\,0 \quad 0 \quad \xi^2\,),\ (\,0 \quad 0 \quad \xi\,),\ (\,0 \quad 0 \quad 1\,), \tag{5.15}$$

but the first and the second element of this set are equivalent to zero modulo R, since $(\,0 \quad 0 \quad \xi^2\,) = (\,0 \quad 0 \quad \xi\,)\,R$ and $(\,0 \quad 0 \quad \xi\,) = (\,0 \quad 0 \quad 1\,)\,R$.

Equipped with these notions, we are now ready to consider the problem of the determination of state-inducing maps for systems in kernel form.

6. State maps for systems in kernel form. The systems we will consider in this section are those described by equations (2.4). For some systems of this kind the problem of computing a state map is trivial, namely, those corresponding to a behavior coinciding with the zero trajectory only. These systems can be characterized as those corresponding to a right prime polynomial matrix R; this can be readily shown by resorting to the Smith form of R. In the following we assume that R is not right prime.

The main result of this section is a characterization of state-inducing polynomial matrices for systems in kernel form. As a preliminary result, we first consider the conditions under which a trajectory is concatenable with the zero one. These conditions correspond to a system of linear equations involving w and its derivatives and define a polynomial differential operator which, in fact, corresponds to a state map. As we will see, the rows of this polynomial matrix have a nice interpretation in terms of the shift-and-cut operator defined in the previous section.

Before stating Proposition 6.1, we observe the following smoothness result. Consider the polynomial matrices R^1, R^2, ..., and observe that if $w \in \mathcal{L}_1^{loc}$ is a solution of (2.4) in the sense of distributions, then

$$R^k\left(\frac{d}{dt}\right) w \tag{6.1}$$

is continuous for $k = 1, 2, \ldots$. In order to see this, let

$$R(\xi) = R_0 + R_1\xi + \cdots + R_L\xi^L; \tag{6.2}$$

then (2.4) implies

$$\frac{d}{dt}\left(R_1 + \cdots + R_L\frac{d^{L-1}}{dt^{L-1}}\right) w = -R_0 w. \tag{6.3}$$

Since the right-hand side is in $\mathcal{L}_1^{loc}$, this implies that

$$\left(R_1 + \cdots + R_L\frac{d^{L-1}}{dt^{L-1}}\right) w = R^1\left(\frac{d}{dt}\right) w \tag{6.4}$$

is absolutely continuous. Proceeding recursively yields the absolute continuity of (6.1). Note that this implies that $R_\Xi(\frac{d}{dt})w$ is also absolutely continuous.

PROPOSITION 6.1. *Let a kernel representation as in* (2.4) *be given, and let* $\mathcal{B}$ *be its behavior. A trajectory* $w \in \mathcal{B}$ *is concatenable with the zero trajectory; that is,* $0 \wedge w \ \in \mathcal{B}$ *if and only if*

$$\left(R_{\Xi}\left(\frac{d}{dt}\right) w\right)(0) = 0. \tag{6.5}$$

Proof. See the appendix. □

This yields the main result of this section.

THEOREM 6.2. *The polynomial matrix* $X \in \mathbb{R}^{\bullet \times q}[\xi]$ *defines a state-inducing map for* (2.4)*; i.e.,*

$$R\left(\frac{d}{dt}\right) w = 0,$$

$$X\left(\frac{d}{dt}\right) w = x \tag{6.6}$$

defines a state-space system with external behavior $\operatorname{Ker} R(\frac{d}{dt})$ *if and only if there exists a matrix* $A \in \mathbb{R}^{\bullet \times \bullet}$ *and a polynomial matrix* $B(\xi) \in \mathbb{R}^{\bullet \times \bullet}[\xi]$ *such that*

$$R_{\Xi}(\xi) = AX(\xi) + B(\xi)R(\xi) \tag{6.7}$$

and the latent variable x *is properly eliminable from the system with latent variable* (6.6).

Proof. See the appendix. □

Remark 6.1. Proper eliminability of $x = X(\frac{d}{dt})w$ in the system with latent variable (6.6) can be checked as follows (cf. [6, Theorem 2.5]). Without loss of generality, assume $R(\xi)$ to be of full row rank g, and let $X(\xi)$ have n rows. x is properly eliminable if and only if there exists an $(n+g) \times (n+g)$ submatrix of maximal determinantal degree of

$$\begin{pmatrix} R & 0_{g \times n} \\ X & -I_n \end{pmatrix}, \tag{6.8}$$

which includes the last n columns of (6.8).

Remark 6.2. In the discrete-time case, an analogue of Proposition 6.1 has been given in [7, p. 1075]. A necessary condition for a state map, analogous to (6.7), has been given in the continuous-time case (with a solution space other than $\mathcal{L}_1^{loc}$) in [5, p. 77]. In the context of discrete-time *output nulling representations*

$$x(k+1) = Ax(k) + Bw(k),$$

$$0 = Cx(k) + Dw(k), \tag{6.9}$$

a procedure similar to using the shift-and-cut operator to obtain R_{Ξ} from R has been used in [1, p. 3643].

Remark 6.3. If the rows of X of (6.7) are interpreted as representative of elements of $\Xi_R \pmod R$, Theorem 6.2 can be restated as follows: X defines a state-inducing map for (2.4) if and only if the span over $\mathbb{R}$ of its rows contains $\Xi_R \pmod R$ and the latent variable x is properly eliminable from (6.6). This, together with the smoothness result given at the beginning of this section, yields the following corollary of Theorem 6.2.

COROLLARY 6.3. *The polynomial matrix $X \in \mathbb{R}^{\bullet \times q}[\xi]$ defines a minimal state-inducing map for* (2.4) *if and only if its rows, considered as representative of elements of $\Xi_R \pmod R$, form a basis for $\Xi_R \pmod R$.*

Remark 6.4. Note that in the scalar case ($R \in \mathbb{R}[\xi]$, $R \neq 0$) the above theorem corresponds to the usual method of stacking the lower-order derivatives of each component to reduce a system of equations of high order to a system of equations of order one, as made explicit by the following example.

Example 6.1. Let $q = 1$ and a system be described by

$$p\left(\frac{d}{dt}\right) w = 0 \tag{6.10}$$

with

$$p(\xi) := p_0 + p_1\xi + \cdots + p_L\xi^L, \tag{6.11}$$

with $p_L \neq 0$.

The Ξ_p space is generated by

$$p_1 + p_2\xi + p_3\xi^2 + \cdots + p_L\xi^{L-1}, p_2 + p_3\xi + \cdots + p_L\xi^{L-2}, \ldots, p_{L-1} + p_L\xi, p_L, \tag{6.12}$$

which in fact constitutes a basis for the space; another basis for Ξ_p could be chosen as

$$\xi^{L-1}, \xi^{L-2}, \ldots, \xi, 1. \tag{6.13}$$

In fact, it can be verified that both (6.12) and (6.13) are bases of $\Xi_p \pmod p$. Therefore a minimal state is induced by the first $L-1$ derivatives of w, as made apparent by (6.13), or by the differential operators associated with the polynomials (6.12). That is, both

$$x := \begin{pmatrix} \frac{d^{L-1}}{dt^{L-1}} w \\ \frac{d^{L-2}}{dt^{L-2}} w \\ \vdots \\ \frac{d}{dt} w \\ w \end{pmatrix} \tag{6.14}$$

and

$$x := \begin{pmatrix} (p_1 + p_2\frac{d}{dt} + p_3\frac{d^2}{dt^2} + \cdots + p_L\frac{d^{L-1}}{dt^{L-1}})w \\ (p_2 + p_3\frac{d}{dt} + \cdots + p_L\frac{d^{L-2}}{dt^{L-2}})w \\ \vdots \\ (p_{L-1} + p_L\frac{d}{dt})w \\ p_L w \end{pmatrix} \tag{6.15}$$

define minimal state variables.

Remark 6.5. Note that computation of a first-order kernel representation of a state system is easy once the state map is given and amounts to solving a linear system of equations. In fact, once the polynomial matrix $X \in \mathbb{R}^{n \times q}[\xi]$ has been

computed, the equations may be recovered in the following way. Find matrices E, F in $\mathbb{R}^{(n+g)\times n}$, $G \in \mathbb{R}^{(n+g)\times q}$, and $T \in \mathbb{R}^{(n+g)\times g}[\xi]$ which solve the equation

$$(\xi E + F)X(\xi) + G = T(\xi)R(\xi). \tag{6.16}$$

An input/state/output representation is easily computed from the kernel representation of the state system obtained in this way. Note that for simple cases these computations can be done by inspection.

In the context of the nonuniqueness of representation of behaviors pointed out in section 2, a question arises with respect to Theorem 6.2. That is, given two equivalent kernel representations of the same system, which we assume to correspond to full row rank polynomial matrices, what relationships hold between the corresponding Ξ-spaces?

The following result holds.

PROPOSITION 6.4. *Let a kernel representation* (2.4) *be given with R of full row rank, and let an equivalent representation be obtained as UR, U unimodular. Then there exist a constant full column rank matrix A and a polynomial matrix B such that $(UR)_\Xi = AR_\Xi + BR$.*

Proof. See the appendix. ∎

COROLLARY 6.5. *Let a kernel representation* (2.4) *be given with R of full row rank, and let an equivalent representation be obtained as UR, U unimodular. For each polynomial matrix $\bar{\Xi}_{UR}$ whose rows form a basis of Ξ_{UR} and every polynomial matrix $\bar{\Xi}_R$ whose rows form a basis of Ξ_R there exists a polynomial matrix C and a constant nonsingular matrix T such that $\bar{\Xi}_{UR} = T\bar{\Xi}_R + CR$.*

Minimal (in the sense of the minimal possible dimension of the state space) states are induced by the choice of a polynomial matrix X whose rows form a basis of $\Xi_R \pmod R$. A natural question arises as to when minimality of the state space is already guaranteed by directly applying σ_+ to the equations describing the system. The following result holds.

PROPOSITION 6.6. *Let a kernel representation such as* (2.4) *be given. Then the nonzero rows of R_Ξ define a basis for $\Xi_R \pmod R$ if and only if R is in row reduced form. Whence if R is in row reduced form and X is composed of the nonzero rows of R_Ξ,*

$$R\left(\frac{d}{dt}\right)w = 0,$$

$$X\left(\frac{d}{dt}\right)w = x \tag{6.17}$$

defines a minimal state representation.

Proof. See the appendix. ∎

COROLLARY 6.7. *Let* (2.4) *be given with R of full row rank. The minimal dimension of the state space of the system associated to R equals the McMillan degree of R, i.e., the maximal degree of the* $\operatorname{rank}(R) \times \operatorname{rank}(R)$ *minors of R. In the row reduced case, this equals the sum of the row degrees of R.*

Let us now give two examples illustrating the procedure of state construction.

Example 6.2. Consider the system with behavior described by

$$\frac{d^n}{dt^n}w_1 + \cdots + p_1\frac{d}{dt}w_1 + p_0 w_1 = q_n\frac{d^n}{dt^n}w_2 + \cdots + q_1\frac{d}{dt}w_2 + q_0 w_2, \tag{6.18}$$

where w_i, $i = 1, 2$, are scalar functions. Defining

$$p^i := \sigma_+^i(p) = \xi^{n-i} + p_{n-1}\xi^{n-i-1} + \cdots + p_i \tag{6.19}$$

and analogously for q^i, it is easy to see that

$$f_i := \begin{pmatrix} p^i & -q^i \end{pmatrix} \tag{6.20}$$

$i = 1, \ldots, n$, form a basis for $\Xi_{\begin{pmatrix} p & -q \end{pmatrix}} \pmod{\begin{pmatrix} p & -q \end{pmatrix}}$. Stacking the f^i vectors yields a polynomial minimal state-inducing matrix.

Example 6.3. Let a system be described by

$$\frac{d^2}{dt^2}w_1 - \frac{d}{dt}w_2 = 0, \tag{6.21}$$

which corresponds to $R(\xi) = \begin{pmatrix} \xi^2 & -\xi \end{pmatrix}$. The space Ξ_R is generated by $\begin{pmatrix} \xi & -1 \end{pmatrix}$ and $\begin{pmatrix} 1 & 0 \end{pmatrix}$, as is easily seen applying the shift-and-cut operator to $R(\xi)$. Then a state is defined as

$$x := \begin{pmatrix} \frac{d}{dt}w_1 - w_2 \\ w_1 \end{pmatrix}, \tag{6.22}$$

which corresponds to the input/state/output equations

$$\frac{d}{dt}x = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix} x + \begin{pmatrix} 0 \\ 1 \end{pmatrix} w_2.$$

$$w_1 = x_2.$$

We summarize the above results in the following algorithms.

ALGORITHM 1 (Construction of a state map for a kernel representation).

Data: $R \in \mathbb{R}^{g\times q}[\xi]$, of degree L.

Output: $X \in \mathbb{R}^{\bullet\times q}[\xi]$ inducing, through $x = X(\frac{d}{dt})w$, a state for the system described by $R(\frac{d}{dt})w = 0$.

Step 1. Set $R^0 := R$ and compute $R^{k+1} := \sigma_+(R^k)$, for $k = 0, 1, \ldots, L-1$.

Step 2. Find $x_1, \ldots, x_n \in \mathbb{R}^{1\times q}[\xi]$ such that $\langle x_1, \ldots, x_n \rangle$ equals the space spanned by the rows of R_Ξ.

Step 3. $X = \operatorname{col}(x_1, \ldots, x_n)$.

Step 4. *Stop.*

ALGORITHM 2 (Construction of a minimal state map for a kernel representation).

Data: $R \in \mathbb{R}^{g\times q}[\xi]$, of degree L.

Output: $X \in \mathbb{R}^{\bullet\times q}[\xi]$ inducing, through $x = X(\frac{d}{dt})w$, a minimal state for the system described by $R(\frac{d}{dt})w = 0$.

Step 1. As in Algorithm 1.

Step 2. Find $x_1, \ldots, x_n$ forming a basis of $\Xi_R \pmod R$.

Comment: The computation of the vectors x_i can be accomplished by computing R_Ξ and reducing each of its rows modulo R with standard polynomial operations.

Step 3. $X := \operatorname{col}(x_k)_{k=1,\ldots,n}$.

Step 4. *Stop.*

ALGORITHM 3 (Verification of a state map).

Data: $R \in \mathbb{R}^{g\times q}[\xi]$, of degree L and $X \in \mathbb{R}^{n\times q}[\xi]$.

Output: *True* if X is a state map for the system described by R, *False* otherwise.

Step 1. Compute R_Ξ as in Algorithm 1.

Step 2. Find a constant matrix A and a polynomial matrix B such that $R_\Xi(\xi) = AX(\xi) + B(\xi)R(\xi)$.

Comment: The computation of A and B can be accomplished with standard polynomial operations.

Step 3. If A and B exists, then

Step 4. If x is properly eliminable from

$$R\left(\frac{d}{dt}\right) w = 0,$$

$$X\left(\frac{d}{dt}\right) w = x,$$

then Output:=*True* else Output:=*False*.

Comment: Proper eliminability can be checked as described in Remark 6.1.

Step 5. *Stop*.

Remark 6.6. The algorithms described above are of immediate interest for the simulation problem, where by "simulation" we mean a procedure for selecting an arbitrary element of the behavior $\mathcal{B}$, followed by an algorithm for computing it. Before getting to the simulation issue, let us describe how to construct a driving variables representation for a kernel description (2.4). Compute R_Ξ and consider the following set of equations in the unknowns A, B, C, D, $P \in \mathbb{R}^{\bullet\times g}[\xi]$, $P' \in \mathbb{R}^{q\times g}[\xi]$, $U \in \mathbb{R}^{\bullet\times q}[\xi]$:

$$\begin{aligned} \xi R_\Xi &= AR_\Xi + BU + PR, \\ I_q &= CR_\Xi + DU + P'R. \end{aligned} \tag{6.23}$$

Then the equations

$$\begin{aligned} \frac{d}{dt}x &= Ax + Bv, \\ w &= Cx + Dv \end{aligned} \tag{6.24}$$

represent the external behavior of (2.4) with a state-space model with driving variable v, as can be seen applying the latent-variables-elimination theorem. Note that A, B, C, D, U, P, and P' in (6.23) are easily obtained by inspection from R and R_Ξ.

Note that (6.24) leads to the following simulation procedure. Given R, compute (6.24) and choose a vector $x_0 \in \mathbb{R}^n$ and a $v \in \mathcal{L}_1^{loc}(\mathbb{R}, \mathbb{R}^m)$. Generate a trajectory x satisfying the first block of equations of (6.24) with the initial conditions $x(0) = x_0$. Then $w \in \mathcal{B}$ can be computed according to the second block of equations (6.24).

7. State maps for systems in hybrid form. As pointed out in the introduction, hybrid representations are the most natural result of a modeling process. Therefore the characterization of state maps for such representations which we give in this section is especially interesting for applications.

Following Theorem 2.1, given a hybrid representation (2.6), we will consider the problem of computing a state map for the closure of the external behavior described by (2.6). To this purpose, let us make some preliminary comments.

First, note that when considering the simulation or control of a system, the state variables will in general be chosen as function of both the external and the latent variables. In fact, although the former are the quantities we are interested in, in a hybrid representation the two kinds of variables enter the description of the system on an equal footing; this is exemplified by the fact that (2.6) can be considered as a kernel description of the full behavior.

Second, a characterization of w-induced state maps can be given as follows. As discussed in Theorem 2.1, the closure of the external behavior of (2.6) is described by (2.8). This implies that the computation of a w-induced state map for the closure of the external behavior of a hybrid representation (2.6) can be performed as follows. First, the ℓ variable is eliminated by computing a suitable unimodular matrix U such that premultiplying the equations by U yields (2.11). Then a set of generators of the Ξ-space of R_1' of (2.8) is computed, as discussed in section 6.

Note that the computation of w-induced state maps for the closure of the external behavior is obtained by elimination of the latent variables, therefore modifying the original equations. This modification is not a desirable feature of a state construction algorithm: the state variables should reflect as much as possible the physical structure of the system as put in evidence by the original equations.

These considerations motivate us to restrict our attention in the remainder of this section to the characterization of (w, ℓ)-induced state maps.

As a third consideration, note that there are hybrid representations for which the determination of a state variable is trivial, namely, the hybrid representations for which the closure of the external behavior corresponds to $\mathcal{L}_1^{loc}(\mathbb{R}, \mathbb{R}^q)$. These representations are characterized as follows. Note that $\forall\ w \in \mathcal{L}_1^{loc}(\mathbb{R}, \mathbb{R}^q)$ there exists an $\ell \in \mathcal{L}_1^{loc}(\mathbb{R}, \mathbb{R}^d)$ such that (2.6) holds if and only if $M(\xi)$ has full row rank. In the following we will implicitly assume that the systems we are dealing with are not of this kind, and that a nontrivial external behavior corresponds to (2.6).

As a fourth consideration, let us characterize the situations where a state variable for the closure of the external behavior is a state variable for the full behavior as well. This happens if and only if the dimension of the minimal state spaces for the closure of the external and the full behavior are the same. An efficient way of checking this is given in the following proposition.

PROPOSITION 7.1. *Let a system be described in hybrid form as in* (2.6)*, and let ℓ be observable from w. The dimensions of the minimal state spaces for the closure of the external and for the full behavior respectively are the same if and only if there exists an input-output selection in (w, ℓ) such that the variables ℓ are all outputs for the full behavior.*

Proof. See the appendix. □

Remark 7.1. The above proposition implies that if there exists an input-output selection on (w, ℓ) such that the latent variables can all be chosen as outputs, a polynomial differential operator X is a state map for the closure of the external behavior if and only if it is a state map for the full behavior.

Remark 7.2. Existence of an input-output selection on (w, ℓ) such that ℓ is entirely composed of outputs can be checked as follows. Assume that $(\ R \ \ | \ \ -M\ )$ has full row rank g. Then ℓ can be chosen as entirely composed of outputs for the full behavior if and only if one of the $\text{rank}((\ R \ \ | \ \ -M\ )) \times \text{rank}((\ R \ \ | \ \ -M\ ))$ minors of maximal degree among all such minors, contains $-M$ as a submatrix.

This procedure is summarized for future use in the following algorithm.

ALGORITHM ℓ-outputs (Verification if ℓ may be chosen as consisting entirely of outputs for the full system).

Data: $(\,R \quad | \quad -M\,) \in \mathbb{R}^{g\times(q+d)}[\xi]$ of full row rank.

Output: True if there exists an input-output partition such that ℓ is entirely composed of outputs, *False* otherwise.

Step 1. Compute n, the maximal degree of the nonzero $\operatorname{rank}((\,R \quad | \quad -M\,)) \times \operatorname{rank}((\,R \quad | \quad -M\,))$ minors of $(\,R \quad | \quad -M\,)$.

Step 2. For every subset P_i of columns of R such that $(\,P_i \quad | \quad -M\,)$ has $\operatorname{rank}((\,R \quad | \quad -M\,))$ columns, compute the maximal degree of its nonzero $\operatorname{rank}((\,R \quad | \quad -M\,)) \times \operatorname{rank}((\,R \quad | \quad -M\,))$ minors, let it be n_i.

Step 3. If there exists i such that $n_i = n$, then *True* else *False*.

Step 4. *Stop.*

Now assume that ℓ is observable but that in any selection of inputs and outputs for the full system some components of ℓ have to be chosen as inputs. Analogously to what has been done in section 6 for the case of kernel representations, we will first characterize the concatenability of external trajectories. Note that concatenability conditions that involve both w and ℓ are, in general, more restrictive than concatenability conditions involving the external variable only: even if a full trajectory cannot be concatenated with zero at $t = 0$, it could still be possible to concatenate the corresponding external trajectory with the zero one. Therefore, the idea that we pursue in the following is to derive the concatenability conditions for the external trajectories starting from the concatenability conditions for the full trajectories. According to Proposition 6.1, the concatenability conditions of full trajectories can be characterized using the matrix $(\,R \quad -M\,)_\Xi$. As we will see, to derive concatenability conditions for the external trajectory we project $(\,R \quad -M\,)_\Xi$ down with a suitably defined linear map. We call this process the *reduction* of $(\,R \quad -M\,)_\Xi$.

The reduction process involves introducing some new concepts.

Assume that the full row rank matrix $(\,R \quad | \quad -M\,)(\xi) = \sum_{j=0}^{L} (\,R_j \quad -M_j\,)\,\xi^j$ has g rows. Consider

$$\begin{pmatrix} (\,R \quad | \quad -M\,)_\Xi \\ 0_{g\times(d+q)} \end{pmatrix} = \operatorname{col}(\sigma_+^k((\,R \quad | \quad -M\,)))_{k=1,\dots,L+1} \tag{7.1}$$

and the matrix $T := \operatorname{col}(M_i)_{i=0,\dots,L}$.

Define $E := \{r \in \mathbb{R}^{1\times(L+1)g} \mid rT = 0\}$. E is the set of constant left annihilators of T; in fact, E is a vector space.

The following example clarifies the notions just introduced.

Example 7.1. Consider

$$(\,R \quad | \quad -M\,)(\xi) = \begin{pmatrix} \xi & 1 & | & -1 \\ \xi & \xi^2+1 & | & -\xi+1 \end{pmatrix}. \tag{7.2}$$

In this case

$$(\,R \quad | \quad -M\,)_\Xi = \begin{pmatrix} 1 & 0 & 0 \\ 1 & \xi & -1 \\ 0 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix} \tag{7.3}$$

and

$$T = \begin{pmatrix} 1 \\ -1 \\ 0 \\ 1 \\ 0 \\ 0 \end{pmatrix}. \tag{7.4}$$

The space E is obtained as

$$\begin{aligned} E = \langle &(0 \quad 0 \quad 1 \quad 0 \quad 0 \quad 0), (0 \quad 0 \quad 0 \quad 0 \quad 1 \quad 0), \\ &(0 \quad 0 \quad 0 \quad 0 \quad 0 \quad 1), (1 \quad 1 \quad 0 \quad 0 \quad 0 \quad 0), (1 \quad 0 \quad 0 \quad -1 \quad 0 \quad 0) \rangle. \end{aligned} \tag{7.5}$$

Let us now examine the conditions under which a trajectory $(w, \ell) \in \mathcal{B}_f$ is externally concatenable with zero; that is, $0 \wedge w \in \mathcal{B}_{ext}$. These conditions correspond to a system of linear equations involving w, ℓ, and their derivatives and define a polynomial differential operator which is in fact a state map. The rows of the corresponding polynomial matrix turn out, as stated in the following proposition, to have an interpretation in terms of a set of generators of E, and of the matrix

$$\begin{pmatrix} (R \quad | \quad -M)_{\Xi} \\ 0_{g \times (d+q)} \end{pmatrix}.$$

PROPOSITION 7.2. *Let an hybrid representation* (2.6) *be given with ℓ observable from w. Assume that for every input-output partition of (w, ℓ) there exists at least one component of ℓ chosen as input.*

A trajectory $(w, \ell) \in \mathcal{B}_f$ is externally concatenable with zero, that is, $0 \wedge w \in \mathcal{B}_{ext}$, if and only if given any set $\{v_1, \dots, v_s\}$ of generators of E, there holds

$$\left(v_i \begin{pmatrix} (R \quad | \quad -M)_{\Xi} \\ 0_{g \times (d+q)} \end{pmatrix} \begin{pmatrix} \frac{d}{dt} \end{pmatrix} \begin{pmatrix} w \\ \ell \end{pmatrix} \right)(0) = 0, \tag{7.6}$$

$i = 1, \dots, s$.

Proof. See the appendix. □

We can now state the main result regarding systems in hybrid form with ℓ observable from w.

THEOREM 7.3. *Let a system be described in hybrid form as in* (2.6)*, and let ℓ be observable from w. Assume that for every input-output partition of (w, ℓ) there exists at least one component of ℓ chosen as input. The matrix $X \in \mathbb{R}^{\bullet \times (q+d)}[\xi]$ defines a (w, ℓ)-induced state map for the closure of the external system corresponding to* (2.6)*; that is,*

$$\begin{aligned} (R \quad -M) \begin{pmatrix} \frac{d}{dt} \end{pmatrix} \begin{pmatrix} w \\ \ell \end{pmatrix} &= 0, \\ X \begin{pmatrix} \frac{d}{dt} \end{pmatrix} \begin{pmatrix} w \\ \ell \end{pmatrix} &= x \end{aligned} \tag{7.7}$$

define a state model for the closure of the external behavior corresponding to (2.6) *if and only if for each constant matrix V whose rows generate E there exist a constant matrix A and a polynomial matrix B such that*

$$V \begin{pmatrix} (R \quad | \quad -M)_{\Xi} \\ 0 \end{pmatrix} = AX + B (R \quad | \quad -M)$$

and the variable x does not impose smoothness constraints on the trajectories of the closure of the external behavior of (2.6).

Remark 7.3. To check whether x does not impose smoothness constraints on the trajectories of the closure of the external behavior, we can proceed as follows. Assume without loss of generality that $(\,R \quad -M\,)$ is of full row rank g, and note that by unimodular transformations (7.7) can be brought to the form

$$\begin{aligned} R_1'\left(\frac{d}{dt}\right)w &= 0,\\ R_2'\left(\frac{d}{dt}\right)w &= \ell,\\ X_1\left(\frac{d}{dt}\right)w &= -X_2\left(\frac{d}{dt}\right)\ell + x, \end{aligned} \tag{7.8}$$

where $R_1' \in \mathbb{R}^{g'\times q}$, $R_2' \in \mathbb{R}^{d\times q}$, $X_i \in \mathbb{R}^{n\times \bullet}$, $i = 1, 2$, $X = (\,X_1 \quad X_2\,)$, and $g = g' + d$. Again using unimodular transformations, we can modify this description to

$$R_1'\left(\frac{d}{dt}\right)w = 0, \tag{7.9}$$

$$R_2'\left(\frac{d}{dt}\right)w = \ell, \tag{7.10}$$

$$(X_1 + X_2R_2')\left(\frac{d}{dt}\right)w = x. \tag{7.11}$$

Note that, given (7.9), (7.11), proper eliminability of x could be checked following the procedure illustrated in Remark 6.1. However, this property can be checked on the basis of the original equations, since each $(g' + n) \times (g' + n)$ minor of

$$\begin{pmatrix} R_1' & 0\\ X_1 + X_2R_2' & -I_n \end{pmatrix} \tag{7.12}$$

corresponds uniquely to a $(g' + n + d) \times (g' + n + d)$ minor of

$$\begin{pmatrix} R_1' & 0 & 0\\ R_2' & -I_d & 0\\ X_1 & X_2 & -I_n \end{pmatrix} \tag{7.13}$$

and therefore to a $(g' + n + d) \times (g' + n + d)$ minor of

$$\begin{pmatrix} R & -M & 0\\ X_1 & X_2 & -I_n \end{pmatrix}, \tag{7.14}$$

obtained from a submatrix including the d columns corresponding to ℓ (that is, the columns of (7.14) from the $(q+1)$th up to the $(q+d)$th one). Therefore x is properly eliminable from the equations (7.7) if and only if among all $(g+n)\times(g+n)$ submatrices of (7.14) which include the d columns corresponding to ℓ (that is, the columns of (7.14) from the $(q+1)$th up to the $(q+d)$th one), there exists one of maximal determinantal degree which includes all columns corresponding to x (that is, the columns of (7.14) from the $(q + d + 1)$th up to the $(q + d + n)$th one).

Remark 7.4. Theorem 7.3 may be restated as follows: if no input-output partition of (w, ℓ) exists such that ℓ consists entirely of outputs for the full behavior, X defines a state-inducing map if and only if x does not impose any smoothness constraint on the trajectories of the closure of the external behavior, and the span over $\mathbb{R}$ of the rows of X contains the vector space

$$\left\{ r \begin{pmatrix} \mathrm{col}(\sigma_+^i (R \quad | \quad -M))_{i=1,\dots,L} \\ 0_{g\times(q+d)} \end{pmatrix} \quad | \quad r \in E \right\} \pmod{(R \quad | \quad -M)}, \tag{7.15}$$

defined as the set of equivalence classes determined by the equivalence $\overset{(R|-M)}{\sim}$ on the vector space

$$\left\{ r \begin{pmatrix} \mathrm{col}(\sigma_+^i (R \quad | \quad -M))_{i=1,\dots,L} \\ 0_{g\times(q+d)} \end{pmatrix} \quad | \quad r \in E \right\}. \tag{7.16}$$

This equivalent formulation, together with Proposition 7.1, yields the following characterization of minimality:

COROLLARY 7.4. *X defines a (w, ℓ)-induced minimal state map for the external system corresponding to* (2.6) *if and only if either* (1) *there exists an input-output selection in (w, ℓ) in which ℓ is entirely composed of outputs for the full behavior and the rows of X form a basis for $(R \quad | \quad -M)_\Xi \pmod{(R \quad -M)}$ or* (2) *the rows of X form a basis for the vector space*

$$\left\{ r \begin{pmatrix} \mathrm{col}(\sigma_+^i (R \quad | \quad -M))_{i=1,\dots,L} \\ 0_{g\times(q+d)} \end{pmatrix} \quad | \quad r \in E \right\} \pmod{(R \quad | \quad -M)}. \tag{7.17}$$

Remark 7.5. State-space equations are straightforwardly computed once the state map is given, analogously to the kernel representations case.

The results exposed up to this point suggest the following algorithm for the computation of a state map for a system in hybrid form with ℓ observable from w.

ALGORITHM 4 (Construction of a state map for the external behavior of a system in hybrid form with ℓ observable from w).

Data: $(R \quad | \quad -M) \in \mathbb{R}^{g\times(q+d)}[\xi]$, of degree L and full row rank, M right prime.

Output:] $X \in \mathbb{R}^{\bullet\times(d+q)}[\xi]$ inducing through $x = X(\frac{d}{dt})\binom{w}{\ell}$ a state for the external behavior of the system described in hybrid form by $(R \quad | \quad -M)$.

Step 1. Set $(R \quad | \quad -M)^0 := (R \quad | \quad -M)$ and compute $(R \quad | \quad -M)^{k+1} := \sigma_+^k (R \quad | \quad -M)$, $k = 1, \dots, L+1$.

Step 2. Invoke algorithm ℓ-outputs (cf. Remark 7.2).

Step 3. If *True* then

Step 4. $X := \mathrm{col}((R \quad | \quad -M)^k)_{k=1,\dots,L}$.

Step 5. *Stop.*

Step 6. Else

Step 7. Compute $v_1, \dots, v_s$ in $\mathbb{R}^{1\times g(L+1)}$ such that $\langle v_1, \dots, v_s \rangle$ equals the space $\{r \in \mathbb{R}^{1\times(L+1)g} \mid r\mathrm{col}(M_i)_{i=0\dots L} = 0\}$.

Step 8. $S := \mathrm{col}((R \quad | \quad -M)^k)_{k=1,\dots,L+1}$.

Step 9. $X := VS$.

Comment. Due to the smoothness result given at the beginning of section 6, X defines a properly eliminable latent variable.

Step 10. *Stop.*

The following example illustrates the construction of a state-inducing map for a hybrid representation with observable latent variables.

Example 7.2. Let

$$\begin{pmatrix} 0 & 1 & 1 \\ \frac{d}{dt}-1 & \frac{d}{dt}+1 & 1 \\ \frac{d}{dt} & \frac{d}{dt}-1 & \frac{d}{dt} \end{pmatrix} \begin{pmatrix} w_1 \\ w_2 \\ w_3 \end{pmatrix} = \begin{pmatrix} \frac{d}{dt}-1 & 0 \\ \frac{d}{dt} & 1 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} \ell_1 \\ \ell_2 \end{pmatrix} \tag{7.18}$$

be a hybrid representation of $\mathcal{B}_{ext}$. It is easy to see that ℓ_1 can be chosen as an output for the full system, but in any input-output partition of (w, ℓ), ℓ_2 has to be chosen as an input.

The matrix

$$S = \begin{pmatrix} (R & | & -M)_{\Xi} \\ & 0_{3\times 5} & \end{pmatrix}$$

is

$$S = \begin{pmatrix} 0 & 0 & 0 & -1 & 0 \\ 1 & 1 & 0 & -1 & 0 \\ 1 & 1 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{pmatrix}, \tag{7.19}$$

and the matrix T is

$$T = \begin{pmatrix} -1 & 0 \\ 0 & 1 \\ 0 & 1 \\ 1 & 0 \\ 1 & 0 \\ 0 & 0 \end{pmatrix}. \tag{7.20}$$

E can be computed as

$$\begin{aligned} E = \langle (0 \quad 1 \quad -1 \quad 0 \quad 0 \quad 0), (1 \quad 0 \quad 0 \quad 1 \quad 0 \quad 0), (0 \quad 0 \quad 0 \quad 1 \quad -1 \quad 0), \\ (0 \quad 0 \quad 0 \quad 0 \quad 0 \quad 1) \rangle, \end{aligned} \tag{7.21}$$

and this yields

$$X = \begin{pmatrix} 0 & 0 & 0 & -1 & 0 \\ 0 & 0 & -1 & -1 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{pmatrix} \tag{7.22}$$

as a state-inducing map for the external behavior of the system described by (7.18). By choosing X as $X = \left(\begin{smallmatrix} 0 & 0 & 0 & -1 & 0 \\ 0 & 0 & -1 & -1 & 0 \end{smallmatrix} \right)$ a minimal state is obtained.

Remark 7.6. The results exposed up to this point provide us with a technique for computing state maps for systems in hybrid form for which ℓ is not observable from w. For ease of exposition, we will limit the investigation to the case in which M is of full column rank d; the case in which M has column rank $d' < d$ can be dealt with similarly. Note that any non–right prime matrix M can be factored as $M = \bar{M}F$, with $\bar{M}$ a right prime matrix and F a full row rank matrix;. The following result holds.

PROPOSITION 7.5. *Let a hybrid representation of a latent variable system* (2.6) *be given. Let M be factored as $M = \bar{M}F$, with F a full row rank right divisor of M and $\bar{M}$ right prime. Then the closure of the external behavior of* (2.6) *and the closure of that of*

$$R\left(\frac{d}{dt}\right) w = \bar{M}\left(\frac{d}{dt}\right) \ell \tag{7.23}$$

are the same.

Proof. See the appendix. ∎

Let us examine the consequences of Proposition 7.5: given a system with ℓ nonobservable from w, factoring out of M an appropriate right divisor F yields a hybrid representation of a system which has the same external behavior of the original one (modulo the usual closedness issues) and the latent variable observable from the manifest ones. This provides us with a technique to tackle the problem of construction of state maps for nonobservable systems. The underlying idea is the following: given $(\, R \quad | \quad -M \,)$ with M non–right prime, extract a full row rank right factor G from M, getting a representation $(\, R \quad -\bar{M} \,)$ with the same external behavior and $\bar{M}$ right prime. Computation of a polynomial matrix X_{obs} that induces a state for this system can be accomplished according to Algorithm 4. Now partition X_{obs} as $X_{obs} := (\, X_w \quad X_\ell \,)$.

Now note that $\forall\ \bar{\ell} \in \mathcal{L}_1^{loc}(\mathbb{R}, \mathbb{R}^d)$ such that $(w, \bar{\ell})$ belongs to the full behavior associated with $(\, R \quad -\bar{M} \,)$ there exists $\ell \in \mathcal{L}_1^{loc}(\mathbb{R}, \mathbb{R}^d)$ such that $G(\frac{d}{dt})\ell = \bar{\ell}$. Moreover, $(w, \ell)^T \in \mathcal{B}_f((\, R \quad | \quad -M \,))$.

This suggests that

$$x := X_{obs}\left(\frac{d}{dt}\right)\begin{pmatrix} w \\ \bar{\ell} \end{pmatrix} = X_{obs}\left(\frac{d}{dt}\right)\begin{pmatrix} w \\ G(\frac{d}{dt})\ell \end{pmatrix} = (\, X_w \quad X_\ell G \,)\left(\frac{d}{dt}\right)\begin{pmatrix} w \\ \ell \end{pmatrix}$$

is a good candidate for a state for the closure of the external behavior of the system associated with $(\, R \quad | \quad -M \,)$.

PROPOSITION 7.6. *Let $(\, R \quad | \quad -M \,)$ be given, with M a non–right prime matrix of full column rank. Let $M = \bar{M}G$, with G a full row rank matrix and $\bar{M}$ right prime.*

Assume that $X_{obs} := (\, X_w \quad X_l \,)$ is a state-inducing map for the external behavior of the system in hybrid form associated with $(\, R \quad -\bar{M} \,)$. Then

$$X := (\, X_w \quad X_l G \,) \tag{7.24}$$

defines a state-inducing map for the closure of the external behavior of the system described in hybrid form by $(\, R \quad | \quad -M \,)$.

Proof. See the appendix. ∎

Remark 7.7. Minimal state maps are obtained by choosing X_{obs} to be a minimal state-inducing map for the system associated with $(\, R \quad -\bar{M} \,)$.

The above proposition is illustrated in the following example.

Example 7.3. Let the following system in hybrid form be given:

$$\begin{pmatrix} \frac{d}{dt} & 1 \\ \frac{d}{dt} & \frac{d}{dt}^3 + 1 \end{pmatrix} w = \begin{pmatrix} \frac{d}{dt} - 1 \\ \frac{d}{dt}^2 - \frac{d}{dt} \end{pmatrix} \ell. \tag{7.25}$$

The system has ℓ nonobservable from w, since $\xi - 1$ is a nontrivial greatest right factor for $M(\xi)$. The associated system with ℓ observable from w is

$$\begin{pmatrix} \frac{d}{dt} & 1 \\ \frac{d}{dt} & \frac{d}{dt}^3 + 1 \end{pmatrix} w = \begin{pmatrix} 1 \\ \frac{d}{dt} \end{pmatrix} \ell. \tag{7.26}$$

Computing a state-inducing map for the full system described by (7.26) yields

$$(R \quad | \quad -M)_{\Xi} = \begin{pmatrix} 1 & 0 & 0 \\ 1 & \xi^2 & -1 \\ 0 & 0 & 0 \\ 0 & \xi & 0 \\ 0 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix} \tag{7.27}$$

and the matrix T is

$$T = (1 \quad 0 \quad 0 \quad 1 \quad 0 \quad 0 \quad 0 \quad 0)^T. \tag{7.28}$$

T has left nullspace described by

$$\begin{pmatrix} 1 & 0 & 0 & -1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \end{pmatrix} \tag{7.29}$$

and therefore a (minimal) state-inducing map for the external observable behavior is obtained multiplying

$$\begin{pmatrix} (R \quad | \quad -M)_{\Xi} \\ 0_{2\times 5} \end{pmatrix}$$

on the left by the first three rows of (7.29), yielding

$$\begin{pmatrix} 1 & -\frac{d}{dt} & 0 \\ 1 & \frac{d^2}{dt^2} & -1 \\ 0 & 1 & 0 \end{pmatrix}. \tag{7.30}$$

The last column of this matrix corresponds to $X_{obs,\ell}$ as in Proposition 7.6. The state for the external behavior of the nonobservable system is therefore induced by

$$\begin{pmatrix} 1 & -\frac{d}{dt} & 0 \\ 1 & \frac{d^2}{dt^2} & -(\frac{d}{dt} - 1) \\ 0 & 1 & 0 \end{pmatrix}. \tag{7.31}$$

The following equations can be written for the state induced by the map in (7.31):

$$\begin{pmatrix} \frac{d}{dt} & 1 & 0 \\ 0 & \frac{d}{dt} & 0 \\ 1 & 0 & \frac{d}{dt} \\ 0 & 0 & 1 \end{pmatrix} x + \begin{pmatrix} -1 & 1 & 0 \\ 0 & 1 & 0 \\ -1 & 0 & 0 \\ 0 & -1 & 0 \end{pmatrix} \begin{pmatrix} w \\ \ell \end{pmatrix} = 0. \tag{7.32}$$

8. State maps for systems in image form. Image representations

$$w = M\left(\frac{d}{dt}\right)\ell, \tag{8.1}$$

where $w \in (\mathbb{R}^q)^{\mathbb{R}}$, $\ell \in (\mathbb{R}^d)^{\mathbb{R}}$, $M \in \mathbb{R}^{q\times d}[\xi]$, of the behavior of a linear time-invariant differential system have been introduced in section 2 in connection with the notion

of controllability: the behavior of a system has an image representation if and only if the system is controllable.

In this section we consider the determination of state maps for the external behavior of systems whose full behavior is described by (8.1). These may be considered to be a special case of systems representable in hybrid form, with $R = I_q$. Therefore, before stating the results pertaining to image representations, let us make some important considerations in the light of the results given in the previous section.

Let us restrict attention to the case in which $M(\xi)$ of (8.1) is right prime; i.e., the latent variable ℓ is observable from w. Note that in a system whose behavior is described by (8.1), the latent variables can be chosen as playing the role of outputs in the full behavior. This is most easily seen by considering that for full column rank M a suitable subset R_1 of the columns of the $q \times q$ identity matrix exists such that

$$(\,R_1 \quad M\,) \tag{8.2}$$

is nonsingular and, arranging the columns of a complementary canonical basis of R_1 in $\mathbb{R}^q$ in a matrix R_2, we have

$$(\,R_1 \quad M\,)^{-1} R_2 \tag{8.3}$$

proper. Then the external variables corresponding to R_2 can be chosen as inputs, while those corresponding to R_1 and the latent variable ℓ can be chosen as outputs for the full behavior.

This result, together with Proposition 7.1, allows us to conclude that for observable image representations the dimensions of the minimal state space for the closure of the external and for the full behavior are equal.

Consider now the problem of determining a state-inducing map for an observable image representation. The following theorem is an immediate consequence of the considerations made so far.

THEOREM 8.1. *Let a system be represented in image form with ℓ observable from w. A polynomial $\bullet \times (q+d)$ matrix X defines a state map for the system* (8.1) *(i.e., $w = M(\frac{d}{dt})\ell$, $x = X(\frac{d}{dt})\binom{w}{\ell}$ defines a state system) if and only if there exist a constant matrix $A \in \mathbb{R}^{\bullet\times\bullet}$ and a polynomial matrix $B \in \mathbb{R}^{\bullet\times q}$ such that $(\,I_q \quad -M\,)_\Xi = AX + B\,(\,I_q \quad -M\,)$ and the variable x is properly eliminable from*

$$(\,I_q \quad -M\,)\begin{pmatrix}\frac{d}{dt}\end{pmatrix}\begin{pmatrix} w \\ \ell \end{pmatrix} = 0, \qquad X\begin{pmatrix}\frac{d}{dt}\end{pmatrix}\begin{pmatrix} w \\ \ell \end{pmatrix} = x. \tag{8.4}$$

Note that $\sigma_+^k\,(\,I_q \quad | \quad -M\,) = (\,0_{q\times q} \quad -\sigma_+^k M\,)$, $k \in \mathbb{N}$, and therefore any state map for the system (8.1), after suitable rearrangement of the equations, may be considered to be ℓ induced. This suggests the following algorithm for the computation of a state map for the external behavior of the system described by (8.1). Note that it is effectively a restatement of Algorithm 4.

ALGORITHM 5 (Construction of a state map for the external behavior of a system in image form with ℓ observable from w).

Data: $M \in \mathbb{R}^{q\times d}[\xi]$, of degree L, M right prime.

Output: $X \in \mathbb{R}^{\bullet\times d}[\xi]$ inducing through $x = X(\frac{d}{dt})\ell$ a state for the external behavior of the system described in image form by (8.1).

Step 1. Set $M^0 := M$ and compute
$M^{k+1} := \sigma_+^k M$, $k = 1, \ldots, L$.

Step 2. $X := \operatorname{col}(M^k)_{k=1,\ldots,L}$.

Step 3. *Stop.*

Remark 8.1. The case in which M of (8.1) is not right prime, i.e., the case in which ℓ is not observable from w, can be dealt with in a manner completely analogous to that described in Remark 7.6.

As noted above, $\sigma_+^k \begin{pmatrix} I_q & | & -M \end{pmatrix} = \begin{pmatrix} 0_{q\times q} & -\sigma_+^k M \end{pmatrix}$, $k \in \mathbb{N}$, and therefore the structure of the space Ξ_M is particularly important for the determination of state maps. In view of the results exposed in the next section, let us pursue further investigation of the structure of the space Ξ_M. Without loss of generality (possibly, permuting the rows) consider $M(\xi)$ partitioned as

$$M = \begin{pmatrix} N \\ D \end{pmatrix} \tag{8.5}$$

with D nonsingular and ND^{-1} proper. Equivalently, choose D as a nonsingular $d \times d$ submatrix of M of maximal determinantal degree.

Let us state the following two propositions, which are of independent interest and yield the main result regarding the structure of the space Ξ_M.

PROPOSITION 8.2. *Let $N \in \mathbb{R}^{p\times d}[\xi]$, $D \in \mathbb{R}^{d\times d}[\xi]$, $\det(D) \neq 0$, be two polynomial matrices such that ND^{-1} is proper. Then $\Xi_N \subseteq \Xi_D$.*

Proof. See the appendix. □

PROPOSITION 8.3. *Let $D \in \mathbb{R}^{d\times d}[\xi]$ be a nonunimodular polynomial matrix with $\det(D) \neq 0$. Then $\Xi_D = \{r \in \mathbb{R}^{1\times d}[\xi] \mid rD^{-1}$ strictly proper$\}$.*

Proof. See the appendix. □

The next proposition states the main result regarding the structure of the space Ξ_M.

PROPOSITION 8.4. *$\Xi_M = \Xi_D = \{r \in \mathbb{R}^{1\times d}[\xi] \mid rD^{-1}$ is strictly proper$\}$.*

Proof. See the appendix. □

The interest in considering state maps for systems represented in image form arises not only from the controllability issue but also from the connections among image representations and the notion of transfer function as given in the behavioral framework. This is the subject of next section.

9. Transfer functions and state maps. The purpose of this section is to make contact with the algebraic approach to the realization problem, put forward in [4] and extensively studied by Fuhrmann [2].

Consider the input-output system

$$P\left(\frac{d}{dt}\right) y = Q\left(\frac{d}{dt}\right) u \tag{9.1}$$

with $P \in \mathbb{R}^{p\times p}[\xi]$, $Q \in \mathbb{R}^{p\times m}[\xi]$, $\det(P) \neq 0$, and $P^{-1}Q$ proper. The function $G := P^{-1}Q \in \mathbb{R}^{p\times m}(\xi)$ is called the *transfer function* of (9.1).

The latent variable system

$$\begin{aligned} u &= D\left(\frac{d}{dt}\right)\ell, \\ y &= N\left(\frac{d}{dt}\right)\ell \end{aligned} \tag{9.2}$$

with $D \in \mathbb{R}^{m\times m}[\xi]$, $N \in \mathbb{R}^{p\times m}[\xi]$, $\det(D) \neq 0$, and ND^{-1} proper defines an input-output system with transfer function $G = ND^{-1}$.

It can be shown that two systems have the same transfer function if and only if they have the same controllable part (see [9, p. 248]). The (unique) controllable

system which has a given transfer function $G \in \mathbb{R}_+^{p\times m}(\xi)$ can be obtained by making a left coprime factorization $G = P^{-1}Q$ of G and considering (9.1) or by making a right factorization $G = ND^{-1}$ and considering (9.2); if the latter factorization is right coprime, then (9.2) will be an observable image representation of the controllable system with transfer function G (see [9, pp. 249, 250]).

Note that the algorithms described in sections 6 and 8 can be directly applied in order to obtain a state-space realization of a system with a given transfer function.

Transfer functions play a prominent role in control theory, since they provide a natural framework in many engineering applications. The concept of realization as put forward in [4], associated with the notion of an input-output map, is intimately connected with the notion of transfer function. Not surprisingly, therefore, many formalizations of the notion of state starting from an input-output or transfer function point of view have been given in the past.

The algorithms proposed in our paper are very akin to those of Fuhrmann [2]. The module structure on which his approach is based, has many connections with left and right factorizations of transfer functions. In particular, the state space corresponding to a right factorization ND^{-1} of a transfer function is defined therein to be isomorphic to the vector space K_D defined as

$$K_D := \{f \in \mathbb{R}^{1\times d}[\xi] \mid fD^{-1} \in \mathbb{R}_+^{1\times d}(\xi)\} \tag{9.3}$$

(cf. [2, Lemma 2-15, p. 11, and Theorem 10-2, p. 41]). The connection with the result of Proposition 8.4 is evident.

10. Conclusions. In modeling physical systems the most natural way of proceeding is to write a set of high-order differential equations possibly with algebraic constraints among the variables. When it comes to simulation of the corresponding system, however, state-space equations are the most natural representation to use. Therefore the need arises to compute the latter from the former. In this paper a characterization of state-inducing maps has been given for systems given in kernel or in hybrid representations. This characterization suggests immediately algorithms to actually perform a computation of the state function from which state-space equations are easily recovered.

Appendix A. Notation.

$\mathbb{N}$ natural numbers (0 is not included).
$\mathbb{Z}_+$ nonnegative integers.
$\mathbb{R}$ real numbers.
2^A set whose members are the subsets of A.
$\mathbb{R}[\xi]$ polynomials with real coefficients.
$\mathbb{R}_+(\xi)$ proper rational functions.
e_i the ith vector of a canonical basis vector in $\mathbb{R}^{1\times\bullet}$.
$\mathbb{R}^{g\times q}$ $g \times q$ real matrices.
$\mathbb{R}^{\bullet\times q}$ real matrices with q columns.
$\operatorname{col}(r_1, \ldots, r_n)$ the matrix

$$\begin{pmatrix} r_1 \\ r_2 \\ \vdots \\ r_n \end{pmatrix}.$$

$\operatorname{diag}(x_k)_{k=1,\ldots,r}$ $r \times r$ diagonal matrix with diagonal elements x_k.

$\mathbb{R}^{g\times q}[\xi]$ $g\times q$ polynomial matrices in the indeterminate ξ.
$\mathbb{R}^{\bullet\times q}$ polynomial matrices in the indeterminate ξ with q columns.
$\mathbb{R}^{g\times q}_{+}(\xi)$ $g\times q$ matrices of strictly proper rational functions.
$(W)^T$ maps from W to T.
$\mathcal{C}^\infty(\mathbb{R},\mathbb{R}^q)$ infinitely differentiable functions from $\mathbb{R}$ to $\mathbb{R}^q$.
$\mathcal{L}_1^{loc}(\mathbb{R};\mathbb{R}^q)$ locally integrable functions from $\mathbb{R}$ to $\mathbb{R}^q$.
$\langle r_1,\dots,r_n\rangle$ space spanned by the vectors r_i.
π_w projection on the w variables: $\pi_w(w,\ell):=w$.
$\circ$ composition of maps.
$[p]$ equivalence class with representative p.

Appendix B. Proofs.

B.1. Proof of Theorem 2.1. That $w\in\overline{\pi_w(\mathcal{B}_f)}^{closure}$ implies $R_1'(\frac{d}{dt})w=0$ is easy to see. To prove the converse, let $\mathcal{B}_1$ be the behavior of $R_1'(\frac{d}{dt})w=0$, and observe that $\mathcal{B}_1\bigcap\mathcal{C}^\infty$ is dense in $\mathcal{B}_1$. Let $M_2'\in\mathbb{R}^{n_1\times n_2}[\xi]$. Obviously $M_2'(\frac{d}{dt})$ maps $\mathcal{C}^\infty(\mathbb{R},\mathbb{R}^{n_2})$ into $\mathcal{C}^\infty(\mathbb{R},\mathbb{R}^{n_1})$. Since M_2' is of full row rank, this map is surjective. (In order to see this, use the Smith form of M_2'.) Hence for all $w\in\mathcal{B}_1\bigcap\mathcal{C}^\infty$ there exists a $(w,\ell)\in\mathcal{B}_f\bigcap\mathcal{C}^\infty$. This shows $\mathcal{B}_1=\overline{\pi_w(\mathcal{B}_f)}^{closure}$. ∎

B.2. Proof of Proposition 3.1. We will prove only the Markovian case, the state-space case being entirely equivalent. The "if" part is trivial. To show the "only if" case, assume that (2.4) satisfies the concatenability condition. Without loss of generality we can assume that R has full row rank. Also, there exists a unimodular $U\in\mathbb{R}^{\bullet\times\bullet}[\xi]$ such that $R':=UR$ is in row reduced form, meaning that the matrix formed by the coefficients of the highest powers in ξ of the rows of $R'(\xi)$ has full row rank. It is easy to see that systems with kernel representations defined by R and R' are the same. We will now show that R' is a first order polynomial matrix. Assume the contrary. Write R' in input-output form:

$$P\left(\frac{d}{dt}\right)w_1=Q\left(\frac{d}{dt}\right)w_2 \tag{B.1}$$

with $\det(P)\neq 0$ and $P^{-1}Q$ proper. The assumption that R' is not first order implies that P is not. From the assumption that $R(\frac{d}{dt})w=0$ is Markovian, it follows that also $P(\frac{d}{dt})w_1=0$ is. Now let w_1', w_1'' be solutions of $P(\frac{d}{dt})w=0$ with $w_1'(0)=w_1''(0)$. Since $\det(P)\neq 0$, w_1' and w_1'' are also $\mathcal{C}^\infty$ and by the state property are concatenable. In order to obtain a contradiction it suffices therefore to prove Proposition 3.1 for autonomous systems. This, however, is an immediate consequence of the following lemma.

LEMMA B.1. *Let the autonomous system $R(\frac{d}{dt})w=0$ with $R\in\mathbb{R}^{q\times q}[\xi]$, $\det R\neq 0$, be Markovian. Then this system admits the kernel representation*

$$Fw+E\frac{d}{dt}w=0 \tag{B.2}$$

with E, $F\in\mathbb{R}^{q\times q}$ and $\det(E\xi+F)\neq 0$

Proof. Let $\mathcal{B}$ be the behavior of $R(\frac{d}{dt})w=0$. Let $P(\frac{d}{dt})w=0$ be the corresponding representation in row reduced form, as in the above proof. Write it as

$$P_0w+P_1\frac{d}{dt}w+\cdots+P_L\frac{d}{dt}w=0. \tag{B.3}$$

We need to prove that it is first order. Assume that this is not the case and that $P_L \neq 0$ and $L \geq 2$.

Denote with L_k, $k = 1, \ldots, q$, the highest order of differentiation of w_k in (B.3). Note that there is at least one $L_k \geq 2$. Introduce the auxiliary variables z_i^k defined as

$$z_i^k := \frac{d^i w_k}{dt^i}, \tag{B.4}$$

$k = 1, \ldots, q$, $i = 0, \ldots, L_k - 1$, and define

$$z := \begin{pmatrix} z_0^1 & z_1^1 & \ldots & z_{L_1-1}^1 & \ldots & z_0^q & \ldots & z_{L_q-1}^q \end{pmatrix}. \tag{B.5}$$

Now consider the system with latent variable z, described by the equations

$$\begin{aligned} \frac{d}{dt} z &= Fz, \\ w_k &= z_0^k, \quad k = 1, \ldots, q, \end{aligned} \tag{B.6}$$

where the entries of the $\sum_{k=1}^q L_k \times \sum_{k=1}^q L_k$ matrix F are determined from (B.3) and the definitions (B.4). Equations (B.6) represent a system in hybrid form with latent variable z; it external behavior coincides with that described by (B.3), as can be checked by applying the latent-variable-elimination theorem.

However, the external behavior of (B.6) does not enjoy the Markovianity property. In fact, (B.6) has exactly one solution (w, z) for each initial condition vector

$$\begin{pmatrix} z_0^1(0) & z_1^1(0) & \ldots & z_{L_1-1}^1(0) & \ldots & z_0^q(0) & \ldots & z_{L_q-1}^q(0) \end{pmatrix}. \tag{B.7}$$

This contradicts Markovianity, since two solutions (w, z), (w', z') of (B.6) with $z_0^k(0) = z_0'^k(0)$, $k = 1, \ldots, q$, cannot be concatenated unless also $z_j^k(0) = z_j'^k(0)$, $j = 1, \ldots, L_k - 1$, $k = 1, \ldots, q$. □

B.3. Proof of Proposition 6.1. The behavior described by $R(\frac{d}{dt})w(t) = 0$ with $w \in \mathcal{L}_1^{loc}$ is the set of all w for which

$$\int_{-\infty}^{+\infty} w^T(t) \left(R\left(-\frac{d}{dt}\right)^T \right) f(t) dt = 0 \tag{B.8}$$

for all testing functions $f(t)$ (that is, f is a $\mathcal{C}^\infty$ vector-valued function with compact support).

(Only if) Assume that $w \in \mathcal{B}$ and $0 \wedge w \in \mathcal{B}$. Define $R^k := \sigma_+^k(R)$. We will show that $(R^k(\frac{d}{dt})w)(0) = 0$ for $k = 1, 2, \ldots$. Consider

$$\int_{-\infty}^{+\infty} (0 \wedge w)^T(t) \left(R\left(-\frac{d}{dt}\right)^T \right) f(t) dt. \tag{B.9}$$

This obviously equals

$$\int_{0}^{+\infty} w^T(t) \left(R\left(-\frac{d}{dt}\right)^T \right) f(t) dt. \tag{B.10}$$

Since $R^k(\frac{d}{dt})w$ is locally integrable $\forall\ k = 1, \ldots, \deg(R)$, (B.10) may be integrated by parts and equals

$$\int_0^{+\infty} \left(R\left(\frac{d}{dt}\right) w(t) \right)^T f(t) dt + \sum_{k=1}^{L} \sum_{j=k}^{L} (-1)^{k-1} (w^{(j-k)}(0))^T R_j^T f^{(k-1)})(0). \tag{B.11}$$

But since $w \in \mathcal{B}$, the integral in (B.11) is zero. Since $0 \wedge w \in \mathcal{B}$, (B.9) and hence (B.11) are also zero, and therefore so is the double sum in (B.11). Hence, due to the arbitrariness of the testing function f,

$$\left(R^k\left(\frac{d}{dt}\right)w\right)(0) = 0 \tag{B.12}$$

$\forall\ k = 1, \ldots, \deg(R)$.

(If) Assume that $w \in \mathcal{B}$ satisfies $(R^k(\frac{d}{dt})w)(0) = 0$ for $k = 1, 2, \ldots$. We want to show that $0 \wedge w \in \mathcal{B}$. To prove this, we have to prove that the integral (B.9) is zero for all testing functions f. Proceeding as above, integrating by parts, (B.11) is obtained. Now the claim is obtained by noting that since $w \in \mathcal{B}$, $R(\frac{d}{dt})w = 0$ holds and therefore the integral is zero, while the double sum in (B.11) is zero by assumption. ∎

B.4. Proof of Theorem 6.2. Let us first prove the following

LEMMA B.2. *Let $\mathcal{B}$ be the behavior of* (2.4). *Let X_1, $X_2 \in \mathbb{R}^{\bullet\times q}[\xi]$. Assume that for all $w \in \mathcal{B} \bigcap \mathcal{C}^\infty(\mathbb{R}, \mathbb{R}^q)$ there holds*

$$\left\{\left(X_1\left(\frac{d}{dt}\right)w\right)(0) = 0\right\} \Longrightarrow \left\{\left(X_2\left(\frac{d}{dt}\right)w\right)(0) = 0\right\}. \tag{B.13}$$

Then there exist $A \in \mathbb{R}^{\bullet\times\bullet}$ and $B \in \mathbb{R}^{\bullet\times\bullet}[\xi]$ such that

$$X_2(\xi) = AX_1(\xi) + B(\xi)R(\xi). \tag{B.14}$$

Proof. We will prove this lemma only in the case that (2.4) defines a controllable system. The general case is left to the reader. Using the Smith form for R it follows that there exist unimodular matrices U and V such that $URV = (\,I \quad 0\,)$. Let $v := V^{-1}(\frac{d}{dt})w$. Then $w \in \mathcal{B}$ if and only if $(\,I \quad 0\,)v = 0$. Define $X_1' := X_1V$ and $X_2' := X_2V$. Partition v, X_1', and X_2' as $\binom{v_1}{v_2}$, $(\,X_{11}' \quad X_{12}'\,)$, $(\,X_{21}' \quad X_{22}'\,)$, with the partition induced by $(\,I \quad 0\,)$. Then for any $v_2 \in \mathcal{C}^\infty$ there holds

$$\left\{\left(X_{12}'\left(\frac{d}{dt}\right)v_2\right)(0) = 0\right\} \Longrightarrow \left\{\left(X_{22}'\left(\frac{d}{dt}\right)v_2\right)(0) = 0\right\}. \tag{B.15}$$

This implies that there exists a matrix $A \in \mathbb{R}^{\bullet\times\bullet}$ such that

$$X_{22}'\left(\frac{d}{dt}\right) = AX_{12}'\left(\frac{d}{dt}\right). \tag{B.16}$$

This yields that X_2' is of the form

$$X_2'(\xi) = AX_1'(\xi) + B(\xi)\,(\,I \quad 0\,). \tag{B.17}$$

Now postmultiply by V^{-1}. ∎

This lemma yields the claim of the theorem as follows.

(Only if) Assume that $X(\frac{d}{dt})$ is a state map. Then $x = X(\frac{d}{dt})w$ is properly eliminable from

$$\begin{aligned} R\left(\frac{d}{dt}\right)w &= 0, \\ X\left(\frac{d}{dt}\right)w &= x. \end{aligned} \tag{B.18}$$

Moreover, $(X(\frac{d}{dt})w)(0) = 0$ implies that w is concatenable with the zero trajectory. Proposition 6.1 states that concatenability with zero is equivalent to $(R_\Xi(\frac{d}{dt})w)(0) = 0$. One has to apply now the above lemma with $X_1 = X$ and $X_2 = R_\Xi$.

(If) Assume that (6.7) holds. Recall (cf. the beginning of section 6) that $R_\Xi(\frac{d}{dt})w$ is absolutely continuous. Now consider $w \in \mathcal{B}$ such that $X(\frac{d}{dt})w$ is continuous at $t = 0$. Then $R_\Xi = AX + BR$ implies that $(BR)(\frac{d}{dt})w$ is continuous at $t = 0$, so that $(R_\Xi(\frac{d}{dt})w)(0) = (AX(\frac{d}{dt})w)(0) + (BR(\frac{d}{dt})w)(0)$ and $(X(\frac{d}{dt})w)(0) = 0$ imply $(R_\Xi(\frac{d}{dt})w)(0) = 0$ since $(BR)(\frac{d}{dt})w = 0$ and $(BR)(\frac{d}{dt})w$ is continuous at $t = 0$. Therefore by Proposition 6.1 one concludes that $0 \wedge w \in \mathcal{B}$. By assumption, $x = X(\frac{d}{dt})w$ is properly eliminable from (B.18), and therefore (B.18) defines a state-space system with external behavior $\operatorname{Ker} R(\frac{d}{dt})$. ∎

B.5. Proof of Proposition 6.4. The claim follows directly by applying the second of the lemmas below. To get to that result, let us first consider the following lemma.

LEMMA B.3. *Let $p \in \mathbb{R}^{1\times q}[\xi]$, $R \in \mathbb{R}^{q\times g}[\xi]$. Then*

$$\sigma_+(pR) = (\sigma_+ p)R + p(0)(\sigma_+ R). \tag{B.19}$$

Proof. Let $p = (\,p_1 \quad \dots \quad p_q\,)$, $p_i = \sum_{j=0}^{n} p_{ji}\xi^j$, and $R = \operatorname{col}(R_i)_{i=1,\dots,q}$, $R_i \in \mathbb{R}^{1\times g}[\xi]$. Note that

$$pR = \sum_{i=1}^{q} \left(\sum_{j=0}^{n} p_{ji}\xi^j R_i \right) \tag{B.20}$$

and therefore that

$$\sigma_+(pR) = \sigma_+ \left(\sum_{i=1}^{q} \left(\sum_{j=0}^{n} p_{ji}\xi^j R_i \right) \right), \tag{B.21}$$

which is equivalent to $\sum_{i=1}^{q} \sigma_+(\sum_{j=0}^{n} p_{ji}\xi^j R_i)$. This is equivalent to

$$\sum_{i=1}^{q} \left(\sum_{j=1}^{n} p_{ji}\xi^{j-1} R_i + p_{0i}\sigma_+(R_i) \right), \tag{B.22}$$

which yields $\sum_{i=1}^{q} (\sigma_+ p_i)R_i + \sum_{i=1}^{q} p_{0i}(\sigma_+ R_i)$ and the claim. ∎

This lemma explains how σ_+ acts on vector multiples of a given matrix. The next one shows how σ_+ acts on unimodular matrix multiples.

LEMMA B.4. *Let R, R' be matrices related as*

$$R = UR' \tag{B.23}$$

for a unimodular U. Then

$$R_\Xi = VR'_\Xi + BR' \tag{B.24}$$

with V a constant full column rank matrix and B a polynomial matrix.

Proof. The proof follows trivially from Lemma B.3 and the fact that a unimodular matrix U has $\det(U(0)) \neq 0$. ∎

B.6. Proof of Proposition 6.6. Let us first prove that the nonzero rows of R_Ξ form a basis of Ξ_R if and only if R is in row reduced form.

Define R'_Ξ to be the submatrix of R_Ξ consisting of the nonzero rows of R_Ξ. Let us prove sufficiency. Assume that R'_Ξ has not full row rank. Then there exists at least one row which is a linear combination of the others. Since $R_\Xi := \mathrm{col}(R^k)_{k=1,\dots,L}$, the highest coefficient vector of this row is the same as that of the corresponding row of R, and is a linear combination of the highest coefficient vectors of the other rows of R. But this contradicts row reducedness. The proof of necessity goes along the same lines.

Note that the result just proven implies necessity of the claim of the proposition. Let us prove sufficiency. Let module(R) be the module of $R^{1\times q}[\xi]$ generated by the rows of R. We have to prove that the intersection of Ξ_R and module(R) consists of the zero vector only.

We prove this as follows. Let ν_i, $i = 1, \dots, g$, be the degree of the ith row R_i of R, and assume that the rows of R have been ordered so that $\nu_1 = \nu_2 = \cdots = \nu_{g'} > \nu_{g'+1} \geq \cdots \geq \nu_g$.

Let now $y \in \Xi_R \bigcap \mathrm{module}(R)$. Note first that, since $y \in \Xi_R$, $\deg(y) \leq \nu_1 - 1$. Then note that $y \in \mathrm{module}(R)$ implies $y = xR$ for some $x = (\, x_1, \dots, x_g\,) \in \mathbb{R}^{1\times g}[\xi]$. From the predictable degree property of R [3, p. 387], we conclude that $\deg(y) = \max_{1\leq i\leq g,\ x_i\neq 0}\{\deg(x_i) + \nu_i\}$ and therefore, since $\deg(y) \leq \nu_1 - 1$, that $x_i = 0$, $1 \leq i \leq g'$.

Assume now that $x_i = 0$ for $g' + 1 \leq i \leq \bar{g} < g$, $x_{\bar{g}+1} \neq 0$. By the predictable degree property of R, $\deg(y) \geq \nu_{\bar{g}+1}$. Since $y \in \Xi_R$, $y = \sum_{j=1}^{g}\sum_{i=1}^{\nu_j} \alpha_{ij}(\sigma_+^i R_j)$, for suitable scalars $\alpha_{ij} \in \mathbb{R}$. Since $\deg(y) \geq \nu_{\bar{g}+1}$, at least one of the α_{ij}'s with $1 \leq j \leq \bar{g}$ must be nonzero, since the only generators of Ξ_R of degree $\geq \nu_{\bar{g}+1}$ are to be found among the vectors $(\sigma_+^i R_j)$, $1 \leq j \leq \bar{g}$. This implies that the highest coefficient of y is a linear combination of the first $\bar{g}$ rows of R_{hc}, the highest row coefficient matrix of R. On the other hand, since $x_i = 0$ for $1 \leq i \leq \bar{g}$, and $x_{\bar{g}+1} \neq 0$, the highest coefficient of $y = xR$ is a linear combination of the last $g - \bar{g}$ rows of R_{hc}. But this implies that the first $\bar{g}$ and the last $g - \bar{g}$ rows of R_{hc} generate the same vector; this, by row reducedness, is possible if and only if this vector is zero. Therefore $x_i = 0$ for all i; that is, $y = 0$ as was to be proven. □

B.7. Proof of Proposition 7.1. The system represented by (2.6) has ℓ observable from w. Therefore it allows a representation of the form

$$N\left(\frac{d}{dt}\right) w = \ell,$$

$$R'_1\left(\frac{d}{dt}\right) w = 0, \tag{B.25}$$

with R'_1 of full row rank. Now partition R'_1 as $(\, P_1 \quad Q_1\,)$ with $P_1^{-1}Q_1$ proper. This induces a partition (y, u) on w in inputs u and outputs y. The proposition follows immediately from examining the minors of

$$\begin{pmatrix} P_1 & Q_1 & 0 \\ N_1 & N_2 & -I \end{pmatrix}. \tag{B.26}$$

In fact, sufficiency can be proven as follows. Since (y, ℓ) consists of outputs for the full system, it follows that

$$\begin{pmatrix} P_1 & 0 \\ N_1 & -I \end{pmatrix} \tag{B.27}$$

has maximal degree among the minors of (B.26). By Corollary 6.7 this implies that the minimal dimension of the state space for the full behavior equals $\deg(\det(\left(\begin{smallmatrix} P_1 & 0 \\ N_1 & -I \end{smallmatrix}\right))) = \deg(\det(P_1))$. Now note that $\deg(\det(P_1))$ equals the minimal dimension of the state space for the external behavior since $\det(P_1)$ has maximal degree among the minors of R_1'. This yields the claim.

As for necessity, note that if the minimal dimensions of the state space for the external and the full behavior are the same, $\deg(\det(P_1))$ equals the maximal degree of the minors of (B.26). Since $\det(\left(\begin{smallmatrix} P_1 & 0 \\ N_1 & -I \end{smallmatrix}\right))$ has degree $\deg(\det(P_1))$, it has maximal degree among the minors of (B.26) and therefore the corresponding partition of the (w, ℓ) variables, that is, (y, ℓ), is a set of outputs for the full system. □

B.8. Proof of Proposition 7.2. Before proving the proposition, let us point out the following general result. Assume that in a hybrid representation ℓ is observable from w; then $w(t) = 0 \ \forall \ t < 0$ implies $\ell(t) = 0 \ \forall \ t < 0$. This is proven as follows. Observability implies that there exists a polynomial differential operator $F(\frac{d}{dt})$ such that $F(\frac{d}{dt})w = \ell$; then for $t < 0$ $(F(\frac{d}{dt})w)(t) = (F(\frac{d}{dt})0)(t) = 0$.

Let us turn to the proof of the proposition.

(Only if) External concatenability with zero is equivalent to

$$\int_{-\infty}^{+\infty} \begin{pmatrix} 0 \wedge w \\ \ell \end{pmatrix}^T (t) \left(\begin{pmatrix} R & -M \end{pmatrix}^T \left(-\frac{d}{dt} \right) \right) f(t) dt = 0 \tag{B.28}$$

for every testing function f.

Observability of ℓ from w and the remark made above imply that integration can be considered in $[0, +\infty)$ only:

$$\int_{0}^{+\infty} \begin{pmatrix} w \\ \ell \end{pmatrix}^T (t) \left(\begin{pmatrix} R & -M \end{pmatrix}^T \left(-\frac{d}{dt} \right) \right) f(t) dt = 0. \tag{B.29}$$

Note that since ℓ is a locally integrable function, there exists an absolutely continuous function $\mathcal{L}$ such that $\frac{d}{dt}\mathcal{L} = \ell$ almost everywhere.

Then $R(\frac{d}{dt})w = M(\frac{d}{dt})\ell$ may be written as

$$R\left(\frac{d}{dt}\right) w = M\left(\frac{d}{dt}\right) \frac{d}{dt}\mathcal{L}, \tag{B.30}$$

and if

$$\begin{pmatrix} R & -M \end{pmatrix} = \begin{pmatrix} R_0 & -M_0 \end{pmatrix} + \begin{pmatrix} R_1 & -M_1 \end{pmatrix} \xi + \cdots + \begin{pmatrix} R_L & -M_L \end{pmatrix} \xi^L, \tag{B.31}$$

(B.30) corresponds to the polynomial matrix

$$\begin{aligned} \begin{pmatrix} R & -M \end{pmatrix}' := \begin{pmatrix} R_0 & 0 \end{pmatrix} + \begin{pmatrix} R_1 & -M_0 \end{pmatrix} \xi + \cdots \\ + \begin{pmatrix} R_L & -M_{L-1} \end{pmatrix} \xi^L + \begin{pmatrix} 0 & -M_L \end{pmatrix} \xi^{L+1}, \end{aligned} \tag{B.32}$$

which is more conveniently written as $\sum_{j=0}^{L+1} \begin{pmatrix} R_j & -M_{j-1} \end{pmatrix} \xi^j$, defining $M_{-1} := 0$, $R_{L+1} := 0$.

Equation (B.29) corresponds then to

$$\int_{0}^{+\infty} \begin{pmatrix} w \\ \mathcal{L} \end{pmatrix}^T (t) \left(\sum_{j=0}^{L+1} (-1)^j \begin{pmatrix} R_j & -M_{j-1} \end{pmatrix}^T \frac{d^j}{dt^j} f(t) \right) dt = 0. \tag{B.33}$$

Analogously to what has been done at the beginning of section 6 it is possible to prove that the Ξ-matrix of (B.32) induces an absolutely continuous function. It is then possible to integrate by parts the left-hand side of (B.33), and this yields

$$\begin{aligned}
&\int_0^{+\infty} \left(\sum_{j=0}^{L+1} \begin{pmatrix} R_j & -M_{j-1} \end{pmatrix} \begin{pmatrix} w \\ \mathcal{L} \end{pmatrix}^{(j)} (t) \right)^T f(t)dt \\
&- \sum_{j=1}^{L+1} \left(\left(\begin{pmatrix} R_j & -M_{j-1} \end{pmatrix} \begin{pmatrix} w \\ \mathcal{L} \end{pmatrix}^{(j-1)} \right)(0) \right)^T f(t) \\
&+ \sum_{j=2}^{L+1} \left(\left(\begin{pmatrix} R_j & -M_{j-1} \end{pmatrix} \begin{pmatrix} w \\ \mathcal{L} \end{pmatrix}^{(j-2)} \right)(0) \right)^T \frac{d}{dt} f(t) + \cdots \\
&+ (-1)^{L+1} \left(\begin{pmatrix} 0 & -M_L \end{pmatrix} \begin{pmatrix} w \\ \mathcal{L} \end{pmatrix}(0) \right)^T f^{(L)}(0), \qquad \text{(B.34)}
\end{aligned}$$

where $g^{(j)}$ denotes the jth derivative of a function g (and the function itself in case $j = 0$).

Equation (B.34) can be rewritten as

$$\begin{aligned}
&\int_0^{+\infty} \left(\sum_{j=0}^{L+1} \begin{pmatrix} R_j & -M_{j-1} \end{pmatrix} \begin{pmatrix} w \\ \mathcal{L} \end{pmatrix}^{(j)} (t) \right)^T f(t)dt \\
&+ \sum_{k=1}^{L+1} \left(\sum_{j=k}^{L+1} (-1)^k \left(\begin{pmatrix} R_j & -M_{j-1} \end{pmatrix} \begin{pmatrix} w \\ \mathcal{L} \end{pmatrix}^{(j-k)} (0) \right)^T \right) f^{(k-1)}(0). \qquad \text{(B.35)}
\end{aligned}$$

Since $(0 \wedge w, \ell) \in \mathcal{B}_f$, (B.35) equals zero for all testing functions f. Now note that the integral in (B.35) is zero, since $(w, \ell) \in \mathcal{B}_f$. Therefore $(0 \wedge w, \ell) \in \mathcal{B}_f$ implies

$$\sum_{k=1}^{L+1} \left(\sum_{j=k}^{L+1} (-1)^k \left(\begin{pmatrix} R_j & -M_{j-1} \end{pmatrix} \begin{pmatrix} w \\ \mathcal{L} \end{pmatrix}^{(j-k)} (0) \right)^T \right) f^{(k-1)}(0) = 0. \qquad \text{(B.36)}$$

Arbitrariness of the testing function f then yields the set of equations

$$\sum_{j=k}^{L+1} (-1)^k \left(\begin{pmatrix} R_j & -M_{j-1} \end{pmatrix} \begin{pmatrix} w \\ \mathcal{L} \end{pmatrix}^{(j-k)} \right)(0) = 0, \qquad \text{(B.37)}$$

$k = 1, \ldots, L+1$, which is more conveniently written as

$$\begin{aligned}
&\sum_{j=k}^{L} \left(\begin{pmatrix} R_j & -M_j \end{pmatrix} \begin{pmatrix} w \\ \ell \end{pmatrix}^{(j-k)} \right)(0) = M_{k-1}\mathcal{L}(0), \quad k = 1, \ldots, L, \\
&0 = M_L \mathcal{L}(0). \qquad \text{(B.38)}
\end{aligned}$$

In matrix form, (B.38) reads as

$$\left(\left(\begin{pmatrix} R & -M \\ & 0 \end{pmatrix}_\Xi \right) \left(\frac{d}{dt} \right) \begin{pmatrix} w \\ \ell \end{pmatrix} \right)(0) = \begin{pmatrix} M_0 \\ M_1 \\ \vdots \\ M_L \end{pmatrix} \mathcal{L}(0). \qquad \text{(B.39)}$$

Now let $V := \mathrm{col}(v_1, \ldots, v_s)$, with $\{v_i\}_{i=1,\ldots,s}$ a set of generators of E. Multiply both sides of (B.39) by V. This yields

$$V\left(\begin{pmatrix} R & -M \end{pmatrix}_{\Xi}\begin{pmatrix} \frac{d}{dt} \end{pmatrix}\begin{pmatrix} w \\ \ell \end{pmatrix}\right)(0) = \left(\left(V\begin{pmatrix} R & -M \end{pmatrix}_{\Xi}\right)\begin{pmatrix} \frac{d}{dt} \end{pmatrix}\begin{pmatrix} w \\ \ell \end{pmatrix}\right)(0) = 0, \tag{B.40}$$

which is the claim of the proposition.

(If) Assume that

$$\left(\left(V\begin{pmatrix} R & -M \end{pmatrix}_{\Xi}\begin{pmatrix} \frac{d}{dt} \end{pmatrix}\right)\begin{pmatrix} w \\ \ell \end{pmatrix}\right)(0) = 0, \tag{B.41}$$

where V is a set of generators of E.

Then in particular

$$\left(V\begin{pmatrix} R & -M \end{pmatrix}_{\Xi}\begin{pmatrix} \frac{d}{dt} \end{pmatrix}\begin{pmatrix} w \\ \ell \end{pmatrix}\right)(0) = V\begin{pmatrix} M_0 \\ M_1 \\ \vdots \\ M_L \end{pmatrix}\mathcal{L}(0), \tag{B.42}$$

with $\mathcal{L}$ such that $\frac{d}{dt}\mathcal{L} = \ell$ almost everywhere. Equation (B.42) is equivalent to

$$V\left(\left(\left(\begin{pmatrix} R & -M \end{pmatrix}_{\Xi}\begin{pmatrix} \frac{d}{dt} \end{pmatrix}\begin{pmatrix} w \\ \ell \end{pmatrix}\right)(0) - \begin{pmatrix} M_0 \\ M_1 \\ \vdots \\ M_L \end{pmatrix}\mathcal{L}(0)\right)\right) = 0 \tag{B.43}$$

and therefore

$$\left(\left(\begin{pmatrix} R & -M \end{pmatrix}_{\Xi}\begin{pmatrix} \frac{d}{dt} \end{pmatrix}\begin{pmatrix} w \\ \ell \end{pmatrix}\right)(0) - \begin{pmatrix} M_0 \\ M_1 \\ \vdots \\ M_L \end{pmatrix}\mathcal{L}(0)\right) \tag{B.44}$$

belongs to the vector space generated by the columns of

$$\begin{pmatrix} M_0 \\ \vdots \\ M_L \end{pmatrix};$$

that is, there exist $\alpha_i \in \mathbb{R}$, $i = 1, \ldots, d$, such that (B.44) equals

$$\begin{pmatrix} M_0 \\ M_1 \\ \vdots \\ M_L \end{pmatrix}\begin{pmatrix} \alpha_1 \\ \vdots \\ \alpha_d \end{pmatrix}. \tag{B.45}$$

Consider now the function $\bar{\mathcal{L}}$ defined as follows: $\bar{\mathcal{L}}(t) := \mathcal{L}(t)\ \forall t \neq 0$ and

$$\bar{\mathcal{L}}(0) := \mathcal{L}(0) + \begin{pmatrix} \alpha_1 \\ \vdots \\ \alpha_d \end{pmatrix}.$$

Then $\frac{d}{dt}\bar{\mathcal{L}} = \ell$ almost everywhere and

$$\left(\begin{pmatrix} (\,R & -M\,)_{\Xi} \\ & 0 \end{pmatrix}\begin{pmatrix} d/dt \end{pmatrix}\begin{pmatrix} w \\ \ell \end{pmatrix}\right)(0) - \begin{pmatrix} M_0 \\ M_1 \\ \vdots \\ M_L \end{pmatrix}\bar{\mathcal{L}}(0) = 0. \tag{B.46}$$

Now consider $(0 \wedge w, 0 \wedge \ell)$. To show that it belongs to the full behavior, we prove that

$$R\left(\frac{d}{dt}\right)(0 \wedge w) = M\left(\frac{d}{dt}\right)\frac{d}{dt}(0 \wedge \bar{\mathcal{L}}). \tag{B.47}$$

Using the notation introduced in (B.32), note that (B.47) holds if and only if

$$\int_{-\infty}^{+\infty}\begin{pmatrix} 0 \wedge w \\ 0 \wedge \bar{\mathcal{L}} \end{pmatrix}^T(t)\left(\sum_{j=0}^{L+1}(-1)^j\,(\,R_j \quad -M_{j-1}\,)^T\frac{d^j f}{dt^j}(t)\right)dt = 0, \tag{B.48}$$

that is, if and only if

$$\int_{0}^{+\infty}\begin{pmatrix} w \\ \bar{\mathcal{L}} \end{pmatrix}^T(t)\left(\sum_{j=0}^{L+1}(-1)^j\,(\,R_j \quad -M_{j-1}\,)^T\frac{d^j f}{dt^j}(t)\right)dt = 0. \tag{B.49}$$

The Ξ-matrix of (B.32) induces an absolutely continuous function. Therefore (B.49) can be integrated by parts and, with manipulations completely analogous to those of the necessity part of the proof, this yields

$$\begin{aligned}&\int_{0}^{+\infty}\left(\sum_{j=0}^{L+1}(\,R_j \quad -M_{j-1}\,)\begin{pmatrix} w \\ \bar{\mathcal{L}} \end{pmatrix}^{(j)}(t)\right)^T f(t)dt \\ &+\sum_{k=1}^{L+1}\left(\sum_{j=k}^{L+1}(-1)^k\left((\,R_j \quad -M_{j-1}\,)\begin{pmatrix} w \\ \bar{\mathcal{L}} \end{pmatrix}^{(j-k)}(0)\right)^T\right)f^{(k-1)}(0).\end{aligned} \tag{B.50}$$

The integral is zero, since $\frac{d}{dt}\bar{\mathcal{L}} = \ell$ and $(w, \ell) \in \mathcal{B}_f$ by assumption. The double sum is zero, since by assumption each addendum of the outermost sum is zero (cf. (B.46)). The claim follows. □

B.9. Proof of Theorem 7.3. Note first that Lemma B.2 holds also for the kernel representation $(\,R \quad -M\,)\left(\frac{d}{dt}\right)\binom{w}{\ell} = 0$ of the full behavior. Let us now prove necessity. If $X(\frac{d}{dt})$ is a (w, ℓ)-induced state map for the external behavior, then x is properly eliminable, and $(X(\frac{d}{dt})\binom{w}{\ell})(0) = 0$ implies external concatenability with zero. Proposition 7.2 states that external concatenability with zero is equivalent to

$$\left(V\begin{pmatrix} (\,R & -M\,)_{\Xi} \\ & 0 \end{pmatrix}\begin{pmatrix} d/dt \end{pmatrix}\begin{pmatrix} w \\ \ell \end{pmatrix}\right)(0) = 0.$$

Now apply Lemma B.2 with $X_1 = X$ and

$$X_2 = V\begin{pmatrix} (\,R & -M\,)_{\Xi} \\ & 0 \end{pmatrix}.$$

Sufficiency is proven as follows.

$$\left(V\left(\begin{pmatrix} R & -M \\ & 0 \end{pmatrix}_{\Xi}\right)\right)\left(\frac{d}{dt}\right)\begin{pmatrix} w \\ \ell \end{pmatrix}$$

is an absolutely continuous function (cf. the remark made at the beginning of section 6). Since

$$\left(V\left(\begin{pmatrix} R & -M \\ & 0 \end{pmatrix}_{\Xi}\right)\right)\left(\frac{d}{dt}\right) = AX\left(\frac{d}{dt}\right) + B\begin{pmatrix} R & -M \end{pmatrix}\left(\frac{d}{dt}\right), \tag{B.51}$$

for each $(w,\ell) \in \mathcal{B}_f$ such that $(X(\frac{d}{dt})\binom{w}{\ell})(0) = 0$ and such that $X(\frac{d}{dt})\binom{w}{\ell}$ is continuous at $t = 0$,

$$\left(V\left(\begin{pmatrix} R & -M \\ & 0 \end{pmatrix}_{\Xi}\right)\right)\left(\frac{d}{dt}\right)\begin{pmatrix} w \\ \ell \end{pmatrix}(0) = 0$$

holds, since

$$B\begin{pmatrix} R & -M \end{pmatrix}\left(\frac{d}{dt}\right)\begin{pmatrix} w \\ \ell \end{pmatrix} = V\left(\begin{pmatrix} R & -M \\ & 0 \end{pmatrix}_{\Xi}\right)\left(\frac{d}{dt}\right)\begin{pmatrix} w \\ \ell \end{pmatrix} - AX\left(\frac{d}{dt}\right)\begin{pmatrix} w \\ \ell \end{pmatrix}$$

is continuous at $t = 0$. Then Proposition 7.2 can be applied, and external concatenability with zero follows. Moreover, since x is properly eliminable, the external behavior of the state-space representation is the same as that of the original hybrid representation. This concludes the proof. □

B.10. Proof of Proposition 7.5. Consider the system described by (2.6). Following Theorem 2.1, computation of a kernel description of (the closure of) its external behavior is done by determining a unimodular matrix U such that $UM = \binom{0}{M_2'}$, with M_2' of full row rank. Partitioning U, R, and M according to the number of rows of M_2' as

$$U := \begin{pmatrix} U_{11} & U_{12} \\ U_{21} & U_{22} \end{pmatrix}, \quad M := \begin{pmatrix} M_1 \\ M_2 \end{pmatrix}, \quad R := \begin{pmatrix} R_1 \\ R_2 \end{pmatrix}, \tag{B.52}$$

the description of the external behavior is given as $R_1'(\frac{d}{dt})w = 0$, with $R_1' = U_{11}R_1 + U_{12}R_2$.

Now assume $M = \bar{M}F$, with F a full row rank right factor of M. Note that

$$0 = U_{11}M_1 + U_{12}M_2 = U_{11}\bar{M}_1F + U_{12}\bar{M}_2F = (U_{11}\bar{M}_1 + U_{12}\bar{M}_2)F \tag{B.53}$$

if and only if $U_{11}\bar{M}_1 + U_{12}\bar{M}_2 = 0$ by the fact that F has full row rank. Therefore U eliminates the latent variable in the description $R(\frac{d}{dt})w = \bar{M}(\frac{d}{dt})\ell$, and $R_1'(\frac{d}{dt})w = 0$ describes the closure of the external behavior of this system as well. □

B.11. Proof of Proposition 7.6. G is a nonsingular $d \times d$ matrix and therefore $\forall\ \bar{\ell} \in \mathcal{L}_1^{loc}(\mathbb{R};\mathbb{R}^d)\ \exists\ \ell \in \mathcal{L}_1^{loc}(\mathbb{R};\mathbb{R}^d)$ such that $\bar{\ell} = G(\frac{d}{dt})\ell$. Therefore

$$\begin{aligned}\left(X_{obs}\left(\frac{d}{dt}\right)\begin{pmatrix} w \\ \bar{\ell} \end{pmatrix}\right)(0) = 0 &\iff \left(X_{obs}\left(\frac{d}{dt}\right)\begin{pmatrix} w \\ G\left(\frac{d}{dt}\right)\ell \end{pmatrix}\right)(0) = 0 \\ &\iff \left(\begin{pmatrix} X_{obs,w} & X_{obs,l}G \end{pmatrix}\left(\frac{d}{dt}\right)\begin{pmatrix} w \\ \ell \end{pmatrix}\right)(0) = 0.\end{aligned}$$

Since X_{obs} induces a state map, $(X_{obs}(\frac{d}{dt})\binom{w}{\bar{\ell}})(0) = 0$ implies that $(w, \bar{\ell})$ is externally concatenable with zero; moreover, external concatenability in zero for $(w, \bar{\ell})$ is equivalent to external concatenability in zero for (w, ℓ), as $\bar{\ell} = G(\frac{d}{dt})\ell$. Let us now prove that $x = X(\frac{d}{dt})\binom{w}{\ell}$ does not impose additional smoothness constraints on the trajectories of the external behavior of $(\,R \quad -M\,)(\frac{d}{dt})\binom{w}{\ell} = 0$. By unimodular transformations, which preserve the proper eliminability of a latent variable, we can bring the equations

$$\begin{aligned} R\left(\frac{d}{dt}\right) w &= M\left(\frac{d}{dt}\right) \ell, \\ X_w\left(\frac{d}{dt}\right) &= -(X_\ell G)\left(\frac{d}{dt}\right) \ell + x \end{aligned} \tag{B.54}$$

to the form

$$\begin{aligned} R_1'\left(\frac{d}{dt}\right) w &= 0, \\ R_2'\left(\frac{d}{dt}\right) w &= G\left(\frac{d}{dt}\right) \ell, \\ X_w\left(\frac{d}{dt}\right) &= -(X_\ell G)\left(\frac{d}{dt}\right) \ell + x \end{aligned} \tag{B.55}$$

and, again by unimodular operations, to

$$\begin{aligned} R_1'\left(\frac{d}{dt}\right) w &= 0, \\ R_2'\left(\frac{d}{dt}\right) w &= G\left(\frac{d}{dt}\right) \ell, \\ (X_w + X_\ell R_2')\left(\frac{d}{dt}\right) w &= x. \end{aligned} \tag{B.56}$$

Observe that $x = (X_w + X_\ell R_2')(\frac{d}{dt})w$ is a state variable for the behavior Ker $R_1'(\frac{d}{dt})$ and therefore that it is properly eliminable from

$$\begin{aligned} R_1'\left(\frac{d}{dt}\right) w &= 0, \\ (X_w + X_\ell R_2')\left(\frac{d}{dt}\right) w &= x; \end{aligned} \tag{B.57}$$

the claim follows. □

B.12. Proof of Proposition 8.2. Let N_i be the ith row of N. Since $N_i D^{-1}$ is proper, there exists a rational vector $n_i := \sum_{k=0}^{\infty} n_{ik}\xi^{-k}$ such that $N_i D^{-1} = n_i$. Write $D = D_0 + D_1\xi + \cdots + D_L\xi^L$ and $N_i = N_{i0} + N_{i1}\xi + \cdots + N_{iL'}$, $L' \le L$. $N_i = n_i D$ yields the following equalities:

$$\begin{aligned} N_{i0} &= n_{i0}D_0 + n_{i1}D_1 + \cdots + n_{iL}D_L, \\ N_{i1} &= n_{i0}D_1 + n_{i1}D_2 + \cdots + n_{iL-1}D_L, \\ &\vdots \\ N_{iL'} &= n_{i0}D_{L'} + n_{i1}D_{L'+1} + \cdots + n_{iL-L'}D_L. \end{aligned} \tag{B.58}$$

These equalities imply $N_i = n_{i0}D + n_{i1}\sigma_+(D) + \cdots + n_{iL}\sigma_+^L(D)$ and therefore $\sigma_+(N_i) = n_{i0}\sigma_+(D) + n_{i1}\sigma_+^2(D) + \cdots + n_{iL-1}\sigma_+^L(D)$. Then $\sigma_+(N_i) \in \Xi_D$, and the same holds for $\sigma_+^2(N_i)$, $\sigma_+^3(N_i), \ldots$. This yields the claim. ∎

B.13. Proof of Proposition 8.3. The inclusion $\Xi_D \subseteq \{r \mid rD^{-1}$ is strictly proper$\}$ can be proven as follows. Let D_i be the ith row of D, $D_i = \sum_{k=0}^{L} D_{ik}\xi^L$. Then $\sigma_+ D_i = \xi^{-1}D_i - \xi^{-1}D_{i0}$, and therefore $\sigma_+ D_i D^{-1} = \xi^{-1}e_i - \xi^{-1}D_{i0}D^{-1} \in \mathbb{R}_+^{1\times d}(\xi)$. Analogously, $\sigma_+^2 D_i = \xi^{-2}D_i - \xi^{-2}D_{i0} - \xi^{-1}D_{i1}$ and therefore $\sigma_+^2 D_i D^{-1} = \xi^{-2}e_i - \xi^{-2}D_{i0}D^{-1} - \xi^{-1}D_{i1}D^{-1} \in \mathbb{R}_+^{1\times d}(\xi)$ and similarly for all iterations of σ_+ and for all rows of D.

The opposite inclusion may be proven as follows. Take $r \in \{r' \mid r'D^{-1}$ is strictly proper$\}$. Then there exists $n \in \mathbb{R}_+^{1\times d}(\xi)$ such that $r = nD$. Write

$$n = \sum_{k=1}^{\infty} n_k \xi^{-k}, \tag{B.59}$$

$n_k \in \mathbb{R}^{1\times d}$, and denote

$$D := D_0 + D_1\xi + \cdots + D_L\xi^L \tag{B.60}$$

and

$$r := r_0 + r_1\xi + \cdots + r_{L'}\xi^{L'}, \tag{B.61}$$

where without loss of generality we can assume $L' \leq L - 1$. $r = nD$ yields, equating powers of ξ,

$$\begin{aligned} r_0 &= n_1 D_1 + n_2 D_2 + \cdots + n_L D_L, \\ r_1 &= n_1 D_2 + n_2 D_3 + \cdots + n_{L-1} D_L, \\ &\vdots \\ r_j &= n_1 D_{j+1} + n_2 D_{j+2} + \cdots + n_{L-j} D_L, \\ &\vdots \end{aligned} \tag{B.62}$$

and this implies

$$r = n_1\sigma_+(D) + n_2\sigma_+^2(D) + \cdots + n_L\sigma_+^L(D) \tag{B.63}$$

and therefore that $r \in \Xi_D$, as we were to prove. ∎

B.14. Proof of Proposition 8.4. The first equality follows from the fact that $\Xi_M = \Xi_N + \Xi_D$ and from Proposition 8.2. The second equality can be proven by applying Proposition 8.3. ∎

MIN-MAX CHARACTERIZATION OF A SMALL NOISE LIMIT ON RISK-SENSITIVE CONTROL*

A. BENSOUSSAN† AND H. NAGAI‡

Abstract. Stochastic control problems on a finite horizon with exponential cost criteria are considered. By taking a kind of singular limit a Hamilton–Jacobi–Isaacs equation is obtained. Its solution is characterized as the lower value function of a deterministic differential game related to robust control of nonlinear systems.

Key words. risk-sensitive control, small noise limit, H_∞-control, Hamilton–Jacobi–Isaacs equation, differential game

Introduction. The large deviation treatment for risk-sensitive control problems has been considered by several authors (cf. [2], [9], [10], [11], [13], [14], [15]) in relation to H_∞-control theory since Whittle's works [22] and [23]. It has been noticed that the large deviation theory of Freidlin–Wentzell in stochastic control problems with the criterion function of the exponential of an additive cost function may link with deterministic control problems called H_∞- or robust-control. In the case of finite-time horizon with full observation, Fleming and McEneaney [9] and, independently, James [13] have given rigorous treatment to the problem. However, those cases are limited by growth conditions which do not cover the linear exponential quadratic Gaussian (LEQG) model. The case has been treated directly. The infinite-horizon case has been considered by Fleming and McEneaney [10] and Fleming and James [11]. By taking a small noise limit, they obtained a deterministic differential game related to H_∞-control theory.

In the present paper we deal with the case of finite-time horizon and relax the growth conditions assumed in [9], [13], [15] so that the LEQG model can be included. We shall comment on this point further in discussion of the assumption (1.14) at the end of subsection 1.2.

Our research is based on [18], where risk-sensitive control problems for nonlinear systems, including the LEQG case, have been treated in a rather general setting, and no breakdown problems and large time asymptotics of the value function have been considered.

More precisely, we consider the controlled stochastic differential equation (SDE) with a small parameter $\epsilon > 0$:

$$\begin{cases} dX_s = \sqrt{\epsilon}\sigma(X_s)dB_s + b(X_s)ds + c(X_s, z_s)ds, \\ X_0 = x \end{cases} \tag{0.1}$$

and take up the following value function of a risk-sensitive control problem:

$$J_\epsilon^*(t,x;T,\theta) = \inf_{z.} E_x\left[\exp\left(\frac{\theta}{\epsilon}\Phi_{T-t}\right)\right], \quad 0 \le t \le T, \tag{0.2}$$

where

$$\Phi_s = \int_0^s \{V(X_\tau) + \phi(X_\tau, z_\tau)\}d\tau. \tag{0.3}$$

The Bellman equation of J^* can be formally written as

$$\begin{cases} \mathcal{L}^\epsilon J_\epsilon + \inf\limits_{z\in Z}\left\{c^i(x,z)D_iJ_\epsilon + \dfrac{\theta}{\epsilon}(V(x)+\phi(x,z))\right\} = 0, \ [0,T)\times R^N, \\ J_\epsilon(T,x) = 1, \end{cases} \tag{0.4}$$

where

$$\mathcal{L}^\epsilon J_\epsilon = \frac{\partial J_\epsilon}{\partial t} + \frac{\epsilon}{2}a^{ij}D_{ij}J_\epsilon + b^iD_iJ_\epsilon.$$

Taking a transformation $J_\epsilon = \exp(\frac{\theta}{\epsilon}w_\epsilon)$, we obtain

$$\begin{cases} \mathcal{L}^\epsilon w_\epsilon + Q_0(x,\nabla w_\epsilon) + V(x) = 0, \\ w_\epsilon(T,x) = 0, \end{cases} \tag{0.5}$$

where

$$\begin{aligned} Q_0(x,p) &\equiv Q_0(x,p;\theta) \\ &= \frac{\theta}{2}a^{ij}p_ip_j + \inf_{z\in Z}\{c^i(x,z)p_i + \phi(x,z)\}. \end{aligned}$$

The existence of a nonnegative solution of (0.5) has been shown under the main assumption (1.14), which indicates the condition on a risk-sensitive parameter for no breakdown. In the present paper we first consider the asymptotic behavior of the solution w_ϵ of (0.5) as $\epsilon \to 0$. To this end, as was done in [9], [13], [15], we employ viscosity methods introduced by Crandall and Lions and developed recently to a large extent (cf. [3], [4], [5], [7], [8], and references therein). Owing to a stability theorem on viscosity solutions, a limit nonlinear equation is obtained by obtaining estimates independent of ϵ on w_ϵ and its first derivatives (cf. section 2). It is to be noted that we cannot expect that w_ϵ is globally Lipshitz, which comes from the fact that we cover the case of polynomial growth $V(x)$, and we utilize some techniques used in [18] to get the estimates.

There are some difficulties in characterizing the limit value, which comes from the fact that the control region is noncompact and the cost functions are unbounded. Those assumptions are necessary to include the LEQG case. We shall take up a more specialized case (cf. section 2.1) than that of section 1 and show that the limit value is characterized as the lower value function of a differential game whose Hamilton–Jacobi–Bellman equation is written as

$$\begin{cases} \dfrac{\partial w}{\partial t} + b^iD_iw + Q_0(x,\nabla w) + V = 0, \\ w(T,x) = 0. \end{cases} \tag{0.6}$$

Following Varaiya [21], Roxin [19], Elliott and Kalton [6], we have formulated a deterministic differential game and shown that the lower value function of the game formulated in this way is the unique nonnegative viscosity solution of (0.6) along the line of Evans and Souganidis [8]. However, because of the noncompactness of the control region and the unboundedness of the cost functions, the finiteness of the lower value function is nontrivial. We need assumption (2.5) (a counterpart of (1.14) for the specialized case) to show it. Moreover, to prove that the lower value function satisfies (0.6) in a viscosity sense, we shall obtain some hitting time estimates on controlled dynamics and develop some technical tricks to show its continuity. We refer to [16], [17], [20], and the references therein, where viscosity solutions of Hamilton–Jacobi–Isaacs equations are directly considered.

1. A small noise limit on risk-sensitive control.

1.1. Setting up. We shall formulate a risk-sensitive control problem depending on a parameter $\epsilon > 0$ and then consider a problem taking a limit as $\epsilon \to 0$. Let $(\Omega, \mathcal{F}, P)$ be a probability space with filtration $\mathcal{F}_t$, $t \geq 0$, B_t a standard N-dimensional $\mathcal{F}_t$ Brownian motion process, and z_t a progressively measurable process taking its value on a Borel subset Z of R^{N_1}. We consider the following SDE with a parameter $\epsilon > 0$:

$$\begin{cases} dX_s^i = \sqrt{\epsilon}\sigma_j^i(X_s)dB_s^j + b^i(X_s)ds + c^i(X_s, z_s)ds, \quad i = 1, ..., N, \\ X_0 = x. \end{cases} \tag{1.1}$$

We then introduce the value function J_ϵ^* with a risk-sensitive parameter $\theta > 0$ as follows:

$$J_\epsilon^*(t, x; T, \theta) = \inf_{\mathcal{A}_{T-t}^0} E_x \left[\exp\left(\frac{\theta}{\epsilon} \Phi_{T-t} \right) \right], \quad 0 \leq t \leq T, \tag{1.2}$$

where

$$\Phi_s = \int_0^s \{V(X_\tau) + \phi(X_\tau, z_\tau)\} d\tau \tag{1.3}$$

and $\mathcal{A}_{T-t}^0$ is the totality of $(\Omega, \mathcal{F}, \mathcal{F}_s, P, B_s, z_s)_{0 \leq s < T-t}$ such that (1.1) has a unique solution for $0 \leq s < T - t$. Note that in this paper we employ the summation convention that if the same indices appear twice in a term, then the symbol of summation is omitted. We assume the following conditions:

(1.4) $\sigma, b, c, V,$ and ϕ are smooth;

(1.5) σ and b satisfy a global Lipshitz condition;

(1.6) $\sigma, b,$ and V and all their derivatives are dominated by $M(1 + |x|^2)^m$ for some $m > 0, M > 0$;

(1.7) $|c(x, z)| \leq c_0(z)$ for some locally bounded function $c_0(z)$;

(1.8) $V(x) \geq 0$ and $\lim_{|x| \to \infty} V(x) = \infty$;

(1.9) $\phi(x, z) \geq 0, \quad \lim_{|z| \to \infty} \phi(x, z) = \infty, \quad \lim_{|z| \to \infty} \dfrac{|c(x, z)|}{\phi(x, z)} = 0,$ uniformly in x;

(1.10) $a^{ij}\xi_i\xi_j \geq \nu|\xi|^2, \quad \xi \in R^N, \quad \exists \nu > 0,$

where $a^{ij} = (\sigma\sigma^*)^{ij}$ and σ^* stands for a transposed matrix of the matrix σ. The above-defined value function J^* is considered to satisfy formally the following Bellman equation:

$$\begin{cases} \mathcal{L}^\epsilon J_\epsilon + \inf_{z\in Z}\left\{c^i(x,z)D_iJ_\epsilon + \dfrac{\theta}{\epsilon}(V(x)+\phi(x,z))\right\} = 0,\ [0,T)\times R^N, \\ J_\epsilon(T,x) = 1, \end{cases} \tag{1.11}$$

where

$$\mathcal{L}^\epsilon J_\epsilon = \frac{\partial J_\epsilon}{\partial t} + \frac{\epsilon}{2}a^{ij}D_{ij}J_\epsilon + b^iD_iJ_\epsilon$$

and $D_i = \frac{\partial}{\partial x^i}$, $D_{ij} = \frac{\partial^2}{\partial x^i \partial x^j}$. Then, by taking a transformation $J_\epsilon = e^{\frac{\theta}{\epsilon}w_\epsilon}$, we obtain the equation

$$\begin{cases} \mathcal{L}^\epsilon w_\epsilon + Q_0(x,\nabla w_\epsilon) + V(x) = 0, \\ w_\epsilon(T,x) = 0, \end{cases} \tag{1.12}$$

where

$$\begin{aligned} Q_0(x,p) &\equiv Q_0(x,p;\theta) \\ &= \frac{\theta}{2}a^{ij}p_ip_j + \inf_{z\in Z}\{c^i(x,z)p_i + \phi(x,z)\}. \end{aligned} \tag{1.13}$$

We furthermore assume that

$$-\frac{k_1}{2}a^{ij}p_ip_j \le Q_0(x,p) \le -\frac{k_2}{2}a^{ij}p_ip_j, \quad p\in R^N, \tag{1.14}$$

for some k_1, $k_2 > 0$ and

$$\left|\frac{\partial Q_0(x,p)}{\partial p}\right| \le M_1|p| + M_2, \quad \left|\frac{\partial Q_0(x,p)}{\partial x}\right| \le M_1|p|^2 + M_2 \tag{1.15}$$

for some locally bounded functions M_1 and M_2. For examples satisfying conditions (1.14) and (1.15) we refer to [18, section 1.5]. Note that according to [18] we have the following theorem.

THEOREM 1.0 (see [18]). *Under the assumptions* (1.4)–(1.10), (1.14), *and* (1.15) *the equation* (1.12) *has a nonnegative solution* $w_\epsilon \in C^{1+\frac{\alpha}{2},2+\alpha}([0,T)\times R^N)\cap C([0,T]\times R^N)$. *Moreover, under those conditions the value function* J_ϵ^* *defined by* (1.2) *has a finite value.*

We shall consider the limit equation of (1.12) as ϵ tends to zero. It can be formally written as

$$\begin{cases} \dfrac{\partial w}{\partial t} + b^iD_iw + Q_0(x,\nabla w) + V = 0, \\ w(T,x) = 0. \end{cases} \tag{1.16}$$

To deduce the equation as the limit of (1.12) we employ viscosity methods (cf. [4], [7], [12]) and then obtain the following theorem.

THEOREM 1.1. *Let* w_ϵ *be a nonnegative solution of* (1.12) *obtained by Theorem* 1.0. *Then there exists a subsequence of* $\{w_\epsilon\}$ *converging uniformly on each compact set to a continuous function* $w(t,x)$, *which is a viscosity solution of equation* (1.16).

Discussion on assumption (1.14). We address here assumption (1.14) and compare it with the literature. Suppose that we are in the LEQG case, where (1.4) to (1.10) and (1.15) are satisfied. Assumption (1.14) remains a restriction which is to be interpreted as a smallness condition on θ. Such a restriction is unavoidable. Indeed, we consider the case where $N = 1$, $Z = R^1$, $\sigma \equiv 1$, $b(x) \equiv 0$, $c(x,z) = z$, $V(x) = \frac{1}{2}x^2$, and $\phi(x,z) = \frac{1}{2}z^2$, namely the case

$$X_s = x + \sqrt{\epsilon}B_s + z_s,$$
$$\Phi_s = \int_0^s \frac{1}{2}(X_s^2 + z_s^2)ds.$$

In this case $Q_0(x,p)$ turns out to be $Q_0(x,p) = -\frac{1-\theta}{2}p^2$, and assumption (1.14) is reduced to the form

$$\theta < 1. \tag{1.14$'$}$$

Moreover, the Bellman equation (1.12) reads

$$\begin{cases} \dfrac{\partial w_\epsilon}{\partial t} + \dfrac{\epsilon}{2}\dfrac{\partial^2 w_\epsilon}{\partial x^2} - \dfrac{1-\theta}{2}\left|\dfrac{\partial w_\epsilon}{\partial x}\right|^2 + \dfrac{1}{2}x^2 = 0, \\ w_\epsilon(T,x) = 0. \end{cases} \tag{1.12$'$}$$

Note that the solution to (1.12$'$) has the following explicit form:

$$w_\epsilon(t,x) = \frac{1}{2}P(t)x^2 + \frac{\epsilon}{2}\int_t^T P(s)ds,$$

provided that the Riccati equation

$$\frac{dP}{dt} - (1-\theta)P^2 + 1 = 0, \quad P(T) = 0, \tag{P}$$

has a solution on $[0,T]$. However, if $\theta > 1$, there may appear a conjugate point (a finite escape time) of T in the equation. In fact, the solution $P(t)$ to (P) is nothing but

$$P(t) = \frac{1}{\sqrt{\theta-1}}\tan(\sqrt{\theta-1}(T-t)),$$

and t_0 satisfying $\sqrt{\theta-1}(T-t_0) = \frac{\pi}{2}$ is the finite escape time. Thus we see that (P) has no solution on $[0,T]$ for T such that $T > \frac{\pi}{2\sqrt{\theta-1}}$ if $\theta > 1$ and the condition (1.14$'$) is to be expected. Such an assumption is unnecessary when V and ϕ are bounded or have linear growth (these are the assumptions in [9], [13], [15]) since the value function (1.2) never diverges in that case and equation (1.12) has a solution regardless of the size of θ. We furthermore consider the case where the controlled process is defined by

$$dX_s = \sqrt{\epsilon}dB_s - \alpha X_s + z_s, \quad X_0 = x,$$

with $\alpha > 0$. Here it remains the case that $N = 1$ and $Z = R^1$. Besides, if $V(x)$ and $\phi(x,z)$ are same as above, then the size of the risk-sensitive parameter ensuring the existence of the solution of the Bellman equation becomes larger than the above; indeed, we can see that it is $\theta < 1 + \alpha^2$. However, our theorem deals with the case of polynomial growth $V(x)$. So, if the growth of $V(x)$ is faster than the quadratic growth, then the effect of such $b(x) = -\alpha x$ disappears and we still need assumption (1.14).

1.2. Proof of Theorem 1.1. We first give an L^∞_{loc} estimate for a solution w_ϵ of (1.12) by using the Feynman–Kac formula. Namely, we shall prove the following.

LEMMA 1.2. *Let w_ϵ be a nonnegative solution of* (1.12) *given by Theorem* 1.0*; then $0 \le w_\epsilon(t,x) \le c_{R,T}$ on $[0,T] \times B_R$ for each $R > 0$, where $c_{R,T}$ is a constant independent of ϵ and $B_R = \{x; |x| < R\}$.*

Proof. Let $\psi_\epsilon(t,x)$ be a solution of the following linear equation:

$$\begin{cases} \mathcal{L}^\epsilon \psi_\epsilon - \dfrac{k_2}{\epsilon} V \psi_\epsilon = 0, \\ \psi_\epsilon(T,x) = 1. \end{cases} \tag{1.17}$$

It is easy to see that $\psi_\epsilon(t,x) \ge 0$, and therefore we may set

$$\tilde{w}_\epsilon(t,x) = -\frac{\epsilon}{k_2} \log \psi_\epsilon(t,x).$$

Then $\tilde{w}_\epsilon(t,x)$ satisfies the following nonlinear equation:

$$\begin{cases} \mathcal{L}^\epsilon \tilde{w}_\epsilon - \dfrac{k_2}{2} a^{ij} D_i \tilde{w}_\epsilon D_j \tilde{w}_\epsilon + V(x) = 0, \\ \tilde{w}_\epsilon(T,x) = 0. \end{cases} \tag{1.18}$$

Because of (1.14), we see that $\tilde{w}_\epsilon(t,x)$ is a supersolution of (1.12) and dominates its solution $w_\epsilon(t,x)$ (cf. the proof of Theorem 1.1 in [18]). Hence we obtain

$$\begin{aligned} w_\epsilon(t,x) &\le \tilde{w}_\epsilon(t,x) \\ &= -\frac{\epsilon}{k_2} \log E_x \left[\exp\left(-\frac{k_2}{\epsilon} \int_0^{T-t} V(Y_s) ds \right) \right] \end{aligned} \tag{1.19}$$

by the Feynman–Kac formula, where Y_s is a solution of the SDE

$$\begin{cases} dY_s = \sqrt{\epsilon}\sigma(Y_s) dB_s + b(Y_s) ds, \\ Y_0 = x. \end{cases} \tag{1.20}$$

Jensen's inequality and (1.19) imply that

$$w_\epsilon(t,x) \le E_x \left[\int_0^{T-t} V(Y_s) ds \right]. \tag{1.21}$$

Standard moment estimates for the solution of the SDE (1.20) give an L^∞_{loc} estimate of the right-hand side of (1.21) because of the assumptions (1.5) and (1.6). Thus we obtain the estimate $0 \le w_\epsilon(t,x) \le c_{R,T}$ on $[0,T] \times B_R$, where $c_{R,T}$ is independent of ϵ such that $0 \le \epsilon \le 1$. □

The following lemma, obtained by using the gradient estimate for a solution w_ϵ of (1.12), plays a key role in the proof of Theorem 1.1.

LEMMA 1.3. *Let w_ϵ be a solution of* (1.12) *given by Theorem* 1.0 *for each $\epsilon > 0$; then $\{w_\epsilon(t,x)\}_{1 \ge \epsilon > 0}$ are equicontinuous on $[0,T] \times B_R$ for each $R > 0$.*

Proof. For the proof of this lemma we note that the following estimates are valid for $u_\epsilon(t,x) = w_\epsilon(T-t,x)$:

$$\frac{\partial u_\epsilon}{\partial t} \ge 0, \tag{1.22}$$

$$t\left(|\nabla u_\epsilon|^2 + \gamma \frac{\partial u_\epsilon}{\partial t} \right) \le t K_{R,\gamma} + L_{R,\gamma} \quad [0,T] \times B_R, \quad \gamma > \frac{2}{k_2 \nu}, \tag{1.23}$$

where $K_{R,\gamma}$ and $L_{R,\gamma}$ are constants independent of ϵ.

Estimate (1.22) is obtained in [18]. As for (1.23), we can follow the proof of Lemma 1.5 in [18]. In fact, we set

$$\Gamma(F) = \frac{\epsilon}{2}a^{ij}D_{ij}F + \frac{\partial Q}{\partial p_i}(x, \nabla u)D_iF - \frac{\partial F}{\partial s} + \frac{F}{s}, \tag{1.24}$$

where $F = t(|\nabla u_\epsilon|^2 + \gamma\frac{\partial u_\epsilon}{\partial t})$ and $Q(x,p) = b^i p_i + Q_0(x,p)$, perform the same procedure as the proof of Lemma 1.5 in [12], and obtain the estimate (1.23). Now we shall complete the proof of Lemma 1.3. We have $0 \le u_\epsilon(t,x) \le E_x[\int_0^t V(Y_s)ds]$ by (1.21), and, consequently, standard moment estimates for the solution of the SDE imply that for each $\eta > 0$ there exists δ_R such that $E_x[\int_0^t V(Y_s)ds] < \eta$ for $t < 2\delta_R$, $x \in B_R$. Take (t_1, x_1) and (t_2, x_2) such that

$$|x_1 - x_2| + |t_1 - t_2| < \eta, \quad |t_1 - t_2| < \delta_R, \quad (t_i, x_i) \in [0,T] \times B_R, \quad i = 1, 2.$$

Then, if $t_1 < \delta_R$ or $t_2 < \delta_R$, we have

$$|u_\epsilon(t_1, x_1) - u_\epsilon(t_2, x_2)| \le 2E_x\left[\int_0^{2\delta_R} V(Y_s)ds\right] \le 2\eta.$$

If $t_1, t_2 > \delta_R$, then from the estimates (1.22) and (1.23) it follows that $|u_\epsilon(t_1, x_1) - u_\epsilon(t_2, x_2)| \le c_R^{'}\eta$ for some constant $c_R^{'}$. □

Proof of Theorem 1.1. Lemmas 1.1 and 1.2 and the Ascoli–Arzelà theorem imply that there exists a subsequence $\{w_{\epsilon_k}\}$ of $\{w_\epsilon\}$ converging uniformly on each compact set to a continuous function $w(t,x)$. Moreover, the stability theorem on viscosity solutions (cf. [4]) asserts that $w(t,x)$ is a viscosity solution of (1.16), since the classical solution $w_\epsilon(t,x)$ of (1.12) is obviously that of viscosity sense. □

2. Interpretation of the limit.

2.1. Differential games. We are going to characterize the solution $w(t,x)$ of the limit equation (1.16) as the lower value function of a differential game. To this end we confine ourselves to the case where $Z = R^{N_1}$:

$$c^i(x,z) = B_k^i(x)z^k, \quad \phi(x,z) = \frac{1}{2}S_{ij}z^i z^j, \tag{2.1}$$

where (S_{ij}) is a symmetric smooth matrix such that

$$S_{ij}(x)\xi^i\xi^j \ge \mu|\xi|^2 \quad \forall \xi \in R^N, \quad \mu > 0, \tag{2.2}$$

and $(B_k^i(x))$ is a bounded and smooth $N \times N_1$ matrix. We assume also (1.4)–(1.6), (1.8), and (1.10). In this case $Q_0(x,p)$ has the following form:

$$\begin{aligned} Q_0(x,p) &= \frac{\theta}{2}a^{ij}p_ip_j + \inf_{z\in R^N}\left\{B_k^i z^k p_i + \frac{1}{2}S_{ij}z^i z^j\right\} \\ &= \frac{\theta}{2}a^{ij}p_ip_j - \frac{1}{2}(BS^{-1}B^*)^{ij}p_ip_j, \end{aligned} \tag{2.3}$$

where B^* stands for the transposed matrix of B. Then equation (1.16) reads

$$\begin{cases} \dfrac{\partial w}{\partial t} + b^i D_i w - \dfrac{1}{2}(BS^{-1}B^* - \theta a)^{ij}D_iwD_jw + V = 0, \\ w(T,x) = 0. \end{cases} \tag{2.4}$$

Moreover, we assume that

$$k_2 a^{ij} p_i p_j \leq (BS^{-1}B^* - \theta a)^{ij} p_i p_j \quad \forall p \in R^N. \tag{2.5}$$

Then conditions (1.14) and (1.15) are satisfied under these assumptions. Thus we see that Theorem 1.1 applies to the present case. Following Varaiya [21], Roxin [19], and Elliot and Kalton [6], we shall formulate a differential game. Let $\mathcal{A}_t$ be the set of all measurable functions $z_1(\cdot) : [0,t] \rightsquigarrow R^N$ such that

$$\int_0^t |z_1(s)|^2 \, ds < \infty, \tag{2.6}$$

and let $\mathcal{B}_t$ be the one of all measurable functions $z_2(\cdot) : [0,t] \rightsquigarrow R^{N_1}$ satisfying (2.6) replaced by $z_2(s)$. Let U be a map $U : \mathcal{A}_t \rightsquigarrow \mathcal{B}_t$ such that whenever for each $0 \leq \sigma \leq t$ and $z_1, \tilde{z}_1 \in \mathcal{A}_t$, $z_1(s) = \tilde{z}_1(s)$ almost everywhere (a.e.) on $0 \leq s \leq \sigma$, then $(Uz_1)(s) = (U\tilde{z}_1)(s)$ a.e. on $0 \leq s \leq \sigma$. The totality of such maps is denoted by Γ_t. We consider the criterion

$$I(t,x;T;z_1,Uz_1) = \int_0^{T-t} \Psi(X(s), z_1(s), (Uz_1)(s)) ds \tag{2.7}$$

for $z_1 \in \mathcal{A}_{T-t}$ and $U \in \Gamma_{T-t}$, where

$$\Psi(x,z_1,z_2) = -\frac{1}{2\theta} z_1^* a^{-1}(x) z_1 + \frac{1}{2} z_2^* S(x) z_2 + V(x) \tag{2.8}$$

and $X(s)$ is the solution of the ordinary differential equation (ODE)

$$\begin{cases} dX(s) = \{b(X(s)) + z_1(s) + B(X(s))(Uz_1)(s)\} ds, \\ X(0) = x. \end{cases} \tag{2.9}$$

We define the lower value function $\underline{w}(t,x)$ by

$$\underline{w}(t,x) = \inf_{U \in \Gamma_{T-t}} \sup_{z_1 \in \mathcal{A}_{T-t}} I(t,x;T;z_1,Uz_1). \tag{2.10}$$

We regard $Q_0(x,p)$ as

$$Q_0(x,p) = \sup_{z_1 \in R^N} \left\{ z_1 \cdot p - \frac{1}{2\theta} z_1^* a^{-1} z_1 \right\} + \inf_{z_2 \in R^{N_1}} \left\{ (Bz_2) \cdot p + \frac{1}{2} z_2^* S z_2 \right\} \tag{2.11}$$

and equation (1.16) as the Hamilton–Jacobi equation associated with the differential game (2.10), where we denote by $z_1 \cdot p$ the inner product of z_1 and p. Then we have the following theorem.

THEOREM 2.1. *We assume* (1.5), (1.6), (1.8), *and* (1.10). *Let* $\underline{w}(t,x)$ *be the lower value function of a differential game defined by* (2.10). *Then* $\underline{w}(t,x)$ *is the unique nonnegative viscosity solution of equation* (2.4).

As a corollary of Theorem 1.1 and 2.1 we have the following.

COROLLARY. *Let* $w_\epsilon(t,x)$ *be a nonnegative solution of* (1.12) *with* $Q_0(x,p)$ *defined by* (2.3) *whose existence is assured by Theorem* 1.0*; then* $w_\epsilon(t,x)$ *converges uniformly on each compact set to the lower value function* $\underline{w}(t,x)$ *of the differential game defined by* (2.10) *as* ϵ *tends to zero.*

2.2. Finiteness of the lower value function. We first prove the following lemma.

LEMMA 2.1. *The lower value function* $\underline{w}(t,x)$ *defined by* (2.10) *has a nonnegative finite value.*

Proof. Note that $V(x) \le M(1+|x|^2)^m$ by assumption (1.6), and set

$$\chi(x) = |x|^{2l}, \tag{2.12}$$

where $l > \max\{\frac{m+1}{2}, 1\}$. Then there exists a constant c such that

$$b \cdot \nabla\chi - \frac{1}{2}(\nabla\chi)^*(BS^{-1}B^* - \theta a)\nabla\chi + V \le c \quad \forall x \in R^N \tag{2.13}$$

since

$$-\frac{1}{2}(\nabla\chi)^*(BS^{-1}B^* - \theta a)\nabla\chi \le -\frac{k_2}{2}(\nabla\chi)^* a \nabla\chi \le -2k_2\nu l^2|x|^{4l-2}$$

because of (2.5) and (1.10). Therefore, for each $z_1 \in R^N$,

$$b \cdot \nabla\chi + z_1 \cdot \nabla\chi - \frac{1}{2\theta} z_1^* a^{-1} z_1 - \frac{1}{2}(\nabla\chi)^* BS^{-1}B^*\nabla\chi + V \le c. \tag{2.14}$$

For each control $z_1(\cdot) \in \mathcal{A}_{T-t}$ we consider the ODE

$$\begin{cases} dX(s) = \{b(X(s)) + z_1(s) - BS^{-1}B^*\nabla\chi(X(s))\}ds, \\ X(0) = x. \end{cases} \tag{2.15}$$

Since b and $BS^{-1}B^*\nabla\chi$ are smooth, (2.15) has a local solution $X(s)$. We shall see that the solution is a global one up to $T-t$ and that $\hat{U}$ defined by

$$\hat{U}z_1(s) = -S^{-1}B^*\nabla\chi(X(s)) \tag{2.16}$$

belongs to Γ_{T-t}. Set

$$\zeta_R = \inf\{s : X(s) \notin B_R\} \tag{2.17}$$

for the local solution $X(s)$ of (2.15). Then

$$\begin{aligned} &\chi(X(s\wedge\zeta_R)) - \chi(x) \\ &= \int_0^{s\wedge\zeta_R} \{b\cdot\nabla\chi + z_1(\tau)\cdot\nabla\chi - (\nabla\chi)^* BS^{-1}B^*\nabla\chi\}(X_\tau)d\tau \\ &\le \int_0^{s\wedge\zeta_R} \left(|b||\nabla\chi| + \frac{1}{2\theta} z_1^* a^{-1} z_1\right) d\tau \\ &\quad - \int_0^{s\wedge\zeta_R} \left\{\frac{1}{2}(\nabla\chi)^*(BS^{-1}B^* - \theta a)\nabla\chi + \frac{1}{2}(\nabla\chi)^* BS^{-1}B^*\nabla\chi\right\}(X(\tau))d\tau \\ &\le \int_0^{s\wedge\zeta_R} \left(c_1(1+|X_\tau|)|\nabla\chi|(X(\tau)) + \frac{\nu}{2\theta}|z_1(\tau)|^2\right) d\tau \\ &\quad - \nu\left(k_2 + \frac{\theta}{2}\right)\int_0^{s\wedge\zeta_R} |\nabla\chi|^2(X(\tau))d\tau \end{aligned} \tag{2.18}$$

for some positive constant c_1. Thus we obtain the following inequality

$$c_2 \int_0^{s\wedge\zeta_R} |X(\tau)|^{4l-2} d\tau \le \chi(x) + \frac{\nu}{2\theta} \int_0^s |z_1(\tau)|^2 d\tau + c_3 s \tag{2.19}$$

for some positive constants c_2 and c_3, from which

$$\int_0^{T-t} |X(\tau)|^{4l-2} d\tau < \infty \tag{2.20}$$

follows, by letting R tend to ∞ and s tend to $T-t$, since $z_1(\cdot) \in \mathcal{A}_{T-t}$. It implies that $\int_0^{T-t} |(\hat{U}z_1)(s)|^2 ds < \infty$ and that (2.15) has a global solution up to $T-t$. Now from (2.14) it follows that

$$\begin{aligned} &\chi(X(T-t)) - \chi(x) \\ &= \int_0^{T-t} \{b \cdot \nabla\chi + z_1(s) \cdot \nabla\chi - (\nabla\chi)^* B S^{-1} B^* \nabla\chi\}(X(s)) ds \\ &\le \int_0^{T-t} \frac{1}{2\theta} z_1^*(s) a^{-1} z_1(s) - \frac{1}{2} (\nabla\chi)^* B S^{-1} B^* \nabla\chi(X(s)) ds \\ &\quad - \int_0^{T-t} V(X(s)) ds + c(T-t), \end{aligned} \tag{2.21}$$

which implies that

$$\int_0^{T-t} \Psi(X(s), z_1(s), \hat{U}z_1(s)) ds \le \chi(x) + c(T-t) \tag{2.22}$$

for each $z_1(\cdot) \in \mathcal{A}_{T-t}$. Hence we obtain our present lemma, since $\underline{w}(t,x)$ is obviously nonnegative. □

2.3. Dynamic programming principle. We shall prove the following lemma.

LEMMA 2.2. *For each $0 \le t_0 < t < T$, $x \in R^N$, and $R > 0$,*

$$\begin{aligned} &\underline{w}(t_0, x_0) \\ &= \inf_{U \in \Gamma_{t-t_0}} \sup_{z_1 \in \mathcal{A}_{t-t_0}} \left\{ \int_0^{t_R - t_0} \Psi(X(s), z_1(s), Uz_1(s)) ds \; + \underline{w}(t_R, X(t_R - t_0)) \right\}, \end{aligned} \tag{2.23}$$

where $\tau_R = \inf\{s; |X(s) - x_0| \ge R\}$ and $t_R = t_0 + (t - t_0) \wedge \tau_R$.

Proof. For each δ there exists $U \in \Gamma_{T-t_0}$ such that

$$\sup_{z_1 \in \mathcal{A}_{T-t_0}} I(t_0, x_0; T; z_1, Uz_1) \le \underline{w}(t_0, x_0) + \delta. \tag{2.24}$$

Note that $\underline{w}(t_0, x_0) < \infty$ for each $(t_0, x_0) \in [0,T] \times R^N$ by Lemma 2.1. Denote the right-hand side of (2.23) by $\tilde{w}(t_0, x_0)$; then by definition for each $U \in \Gamma_{T-t_0}$ satisfying (2.24) we have

$$\tilde{w}(t_0, x_0) \le \sup_{z_1 \in \mathcal{A}_{t-t_0}} \left\{ \int_0^{t_R - t_0} \Psi(X(s), z_1(s), Uz_1(s)) ds \; + \; \underline{w}(t_R, X(t_R - t_0)) \right\}, \tag{2.25}$$

and consequently there exists $\hat{z}_1 \in \mathcal{A}_{t-t_0}$ such that

$$\tilde{w}(t_0,x_0) \le \int_0^{t_R-t_0} \Psi(X(s),\hat{z}_1(s),U\hat{z}_1(s))ds \ + \ \underline{w}(t_R,X(t_R-t_0)) + \delta. \tag{2.26}$$

For each $\tilde{z}_1 \in \mathcal{A}_{T-t_R}$ define $z_1 \in \mathcal{A}_{T-t_0}$ by

$$z_1(s) = \begin{cases} \hat{z}_1(s), & 0 \le s \le (t-t_0)\wedge\tau_R, \\ \tilde{z}_1(s-(t-t_0)\wedge\tau_R), & (t-t_0)\wedge\tau_R \le s \le T-t_0, \end{cases} \tag{2.27}$$

and then define $\tilde{U}$ by

$$\tilde{U}\tilde{z}_1(s) = Uz_1((t-t_0)\wedge\tau_R+s), \quad 0 \le s \le T-t_R. \tag{2.28}$$

Then

$$\underline{w}(t_R,X(t_R-t_0)) \le \sup_{\tilde{z}_1\in\mathcal{A}_{T-t_R}} \int_0^{T-t_R} \Psi(\tilde{X}(s),\tilde{z}_1(s),\tilde{U}\tilde{z}_1(s))ds, \tag{2.29}$$

where $\tilde{X}(s)$ is governed by the ODE

$$\begin{cases} d\tilde{X}(s) = (b(\tilde{X}(s)) + \tilde{z}_1(s) + B\tilde{U}\tilde{z}_1(s))ds, \\ \tilde{X}(0) = X(t_R-t_0) \end{cases} \tag{2.30}$$

and $X(s)$ is the solution of

$$\begin{cases} dX(s) = (b(X(s)) + z_1(s) + BUz_1(s))ds, \quad 0 \le s \le t-t_0, \\ X(0) = x_0. \end{cases} \tag{2.31}$$

The right-hand side of (2.29) is finite because of (2.24) and Lemma 2.1, and there exists $\tilde{z}_1^0 \in \mathcal{A}_{T-t_R}$ such that

$$\underline{w}(t_R,X(t_R-t_0)) \le \int_0^{T-t_R} \Psi(\tilde{X}(s),\tilde{z}_1^0(s),\tilde{U}\tilde{z}_1^0(s))ds + \delta. \tag{2.32}$$

Define $z_1^0 \in \mathcal{A}_{T-t_0}$ by

$$z_1^0(s) = \begin{cases} \hat{z}_1(s), \quad 0 \le s \le (t-t_0)\wedge\tau_R, \\ \tilde{z}_1^0(s-(t-t_0)\wedge\tau_R), \quad (t-t_0)\wedge\tau_R \le s \le T-t_0. \end{cases}$$

Then from (2.26) and (2.32) it follows that

$$\tilde{w}(t_0,x_0) \le \int_0^{T-t_0} \Psi(X^0(s),z_1^0(s),Uz_1^0(s))ds + 2\delta, \tag{2.33}$$

where $X^0(s)$ denotes the trajectory associated with z_1^0 and Uz_1^0, and so (2.24) implies that

$$\tilde{w}(t_0,x_0) \le \ \underline{w}(t_0,x_0) + 3\delta \tag{2.34}$$

for each $\delta > 0$. Hence $\tilde{w}(t_0,x_0) \le \underline{w}(t_0,x_0)$.

Now let us prove the converse inequality. For each $(t_1, x) \in [t_0, T] \times R^N$ and $\delta > 0$ there exists $U^{(t_1,x)} \in \Gamma_{T-t_1}$ such that

$$\sup_{\tilde{z}_1 \in \mathcal{A}_{T-t_1}} I(t_1, x; T; \tilde{z}_1, U^{(t_1,x)}\tilde{z}_1) \leq \underline{w}(t_1, x) + \delta. \tag{2.35}$$

Furthermore, there exists $U^0 \in \Gamma_{t-t_0}$ such that

$$\begin{aligned} \sup_{z_1 \in \mathcal{A}_{t-t_0}} \left\{ \int_0^{t_R - t_0} \Psi(X(s), z_1(s), U^0 z_1(s))ds \ + \ \underline{w}(t_R, X(t_R - t_0)) \right\} \\ \leq \tilde{w}(t_0, x_0) + \delta. \end{aligned} \tag{2.36}$$

For $\hat{z}_1 \in \mathcal{A}_{T-t_0}$ define z_1 and $\tilde{z}_1$ by

$$z_1(s) = \hat{z}_1(s), \quad 0 \leq s \leq t - t_0, \tag{2.37}$$

and

$$\tilde{z}_1(s) = \hat{z}_1((t - t_0) \wedge \tau_R + s), \quad 0 \leq s \leq T - t_R, \tag{2.38}$$

where τ_R is defined by $\tau_R = \inf\{s; |X(s) - x_0| \geq R\}$ and $X(s)$ is a solution of the ODE

$$\begin{cases} dX(s) = (b(X(s)) + \hat{z}_1(s) + BU^0\hat{z}_1(s))ds, \\ X(0) = x_0 \end{cases} \tag{2.39}$$

for $U^0 \in \Gamma_{t-t_0}$. Define $U \in \Gamma_{T-t_0}$ by

$$U\hat{z}_1(s) = \begin{cases} U^0 z_1(s), & 0 \leq s \leq t_R - t_0, \\ U^{(t_R, X(t_R - t_0))}\tilde{z}_1(s - (t_R - t_0)), & t_R - t_0 \leq s \leq T - t_0. \end{cases} \tag{2.40}$$

In (2.35) we set $t_1 = t_R$ and $x = X((t - t_0) \wedge \tau_R)$; then

$$\sup_{\tilde{z}_1 \in \mathcal{A}_{T-t_R}} \int_0^{T-t_R} \Psi(\tilde{X}(s), \tilde{z}_1(s), U^{(t_R,x)}\tilde{z}_1(s))ds \ \leq \underline{w}(t_R, x) + \delta, \tag{2.41}$$

where $x = X(t_R - t_0)$ and $\tilde{X}(s)$ is a solution of

$$\begin{cases} d\tilde{X}(s) = (b(\tilde{X}(s)) + \tilde{z}_1(s) + BU^{(t_R,x)}\tilde{z}_1(s))ds, \\ \tilde{X}(0) = X((t - t_0) \wedge \tau_R). \end{cases} \tag{2.42}$$

Define $\hat{X}(s)$ by

$$\hat{X}(s) = \begin{cases} X(s), & 0 \leq s \leq t_R - t_0, \\ \tilde{X}(s - (t_R - t_0)) & t_R - t_0 \leq s \leq T - t_0. \end{cases} \tag{2.43}$$

Then (2.36) and (2.41) imply that

$$\tilde{w}(t_0, x_0) + \delta \geq \int_0^{T-t_0} \Psi(\hat{X}(s), \hat{z}_1(s), U\hat{z}_1(s))ds - \delta \tag{2.44}$$

for each δ, and therefore we obtain

$$\begin{aligned} \tilde{w}(t_0, x_0) + 2\delta &\geq \sup_{\hat{z}_1 \in \mathcal{A}_{T-t_0}} \int_0^{T-t_0} \Psi(\hat{X}(s), \hat{z}_1(s), U\hat{z}_1(s))ds \\ &\geq \underline{w}(t_0, x_0) \end{aligned} \tag{2.45}$$

for all $\delta > 0$. Hence, the other inequality $\tilde{w}(t_0, x_0) \geq \underline{w}(t_0, x_0)$ holds. □

2.4. Continuity of the lower value function. Let $\mathcal{A}_{T-t}(L)$ be a set defined by

$$\mathcal{A}_{T-t}(L) = \left\{ z_1 \in \mathcal{A}_{T-t} : \int_0^{T-t} |z_1(s)|^2 ds \le L \right\}; \tag{2.46}$$

then we have the following lemma.

LEMMA 2.3. *For each R there exists a constant $L = L(R)$ such that*

$$\underline{w}(t,x) = \inf_{U \in \Gamma_{T-t}} \sup_{z_1 \in \mathcal{A}_{T-t}(L)} \int_0^{T-t} \Psi(X(s), z_1(s), Uz_1(s)) ds \tag{2.47}$$

for $x \in B_R$, $0 \le t \le T$.

Proof. For each control $z_1 \in \mathcal{A}_{T-t}$, we consider the solution of the ODE (2.15) and define $\hat{U}$ by (2.16). Then we have

$$\begin{aligned} &\chi(X(T-t)) - \chi(x) \\ &\le \int_0^{T-t} \left\{ c_1(1+|X(s)|)|\nabla\chi|(X(s)) + \frac{1}{2\theta} z_1^* a^{-1} z_1 - \frac{1}{2}(\hat{U}z_1)^* S \hat{U} z_1 \right\} ds \\ &\quad - \frac{1}{2} \int_0^{T-t} (\nabla\chi)^* (BS^{-1}B^* - \theta a) \nabla\chi(X(s)) ds \\ &\le \int_0^{T-t} \left\{ \frac{1}{2\theta} z_1^* a^{-1} z_1 - \frac{1}{2}(\hat{U}z_1)^* S \hat{U} z_1 \right\} ds \\ &\quad - \frac{k'}{2} \int_0^{T-t} |X(s)|^{4l-2} ds + c'(T-t) \end{aligned} \tag{2.48}$$

for some positive constants k', $c' > 0$. Note that

$$\begin{aligned} \int_0^{T-t} V(X(s)) ds &\le M \int_0^{T-t} (1+|X(s)|^2)^m ds \\ &\le c''(T-t) + \frac{k''}{2} \int_0^{T-t} |X(s)|^{4l-2} ds \end{aligned}$$

hold for some constants $c'' > 0$ and $0 < k'' < k'$ since $l > \frac{m+1}{2}$. Therefore, from (2.48) it follows that

$$\begin{aligned} &\int_0^{T-t} \left\{ -\frac{1}{2\theta} z_1^* a^{-1} z_1 + \frac{1}{2}(\hat{U})^* S \hat{U} z_1 + V(X(s)) \right\} ds \\ &\qquad \le \chi(x) + (c'+c'')(T-t) - \frac{k'-k''}{2} \int_0^{T-t} |X(s)|^{4l-2} ds. \end{aligned}$$

In case

$$\chi(x) + (c'+c'')(T-t) < \frac{k'-k''}{2} \int_0^{T-t} |X(s)|^{4l-2} ds, \tag{2.49}$$

we have

$$\int_0^{T-t} \Psi(X(s), z_1(s), \hat{U}z_1(s)) ds < 0. \tag{2.50}$$

On the other hand, if (2.49) does not hold, then setting $\lambda = \|BS^{-1}B^*\|$

$$\begin{aligned}(2.51)\quad &\int_0^{T-t} \Psi(X(s), z_1(s), \hat{U}z_1(s))ds \\ &\leq \int_0^{T-t} \left\{ -\frac{1}{2\theta\nu}|z_1(s)|^2 + \left(4l^2\lambda + \frac{k''}{2}\right)|X(s)|^{4l-2}ds + c''(T-t) \right\} \\ &\leq -\frac{1}{2\theta}\int_0^{T-t} |z_1(s)|^2 ds + \frac{(8l^2\lambda + k'')}{k' - k''}(\chi(x) + (c' + c'')(T-t)) + c''(T-t).\end{aligned}$$

Therefore, if we take $-\frac{1}{2\theta}\int_0^{T-t}|z_1(s)|^2ds$ so large that the right-hand side of (2.51) becomes negative for all $x \in B_R$, then (2.50) always holds. Thus we obtain our present lemma, since $\underline{w}(t,x) \geq 0$. □

Let $K = K(R)$ be a constant defined by

$$(2.52)\qquad K = \frac{1}{\mu}\sup_{x\in B_R}(\chi(x) + cT),$$

where c is the constant that appeared in (2.13). Define a set $\Gamma_{T-t}(K)$ by

$$(2.53)\qquad \Gamma_{T-t}(K) = \left\{ U \in \Gamma_{T-t} : \sup_{z_1 \in \mathcal{A}_{T-t}(L)} \int_0^{T-t} \left(\frac{1}{2}|Uz_1(s)|^2 - \frac{\nu}{2\mu\theta}|z_1(s)|^2 \right) ds \leq K \right\}.$$

Then we have the following lemma.

LEMMA 2.4. *For $x \in B_R$, $0 \leq t \leq T$,*

$$(2.54)\qquad \underline{w}(t,x) = \inf_{U\in\Gamma_{T-t}(K)} \sup_{z_1\in\mathcal{A}_{T-t}(L)} \int_0^{T-t} \Psi(X(s), z_1(s), Uz_1(s))ds.$$

Proof. If $U \in \Gamma_{T-t} \cap \Gamma_{T-t}(K)^c$, then there exists $z_1 \in \mathcal{A}_{T-t}(L)$ such that

$$\begin{aligned}(2.55)\qquad \int_0^{T-t} \left\{ \frac{1}{2}|Uz_1(s)|^2 - \frac{\nu}{2\mu\theta}|z_1(s)|^2 \right\} ds &> K(R) \\ &\geq \frac{1}{\mu}(\chi(x) + cT).\end{aligned}$$

Therefore

$$\begin{aligned}(2.56)\qquad &\int_0^{T-t} \Psi(X(s), z_1(s), Uz_1(s))ds \\ &\geq -\frac{\nu}{2\theta}\int_0^{T-t} |z_1(s)|^2 ds + \frac{\mu}{2}\int_0^{T-t} |Uz_1(s)|^2 ds \\ &> \chi(x) + cT.\end{aligned}$$

Since $\underline{w}(t,x) \leq \chi(x) + c(T-t)$ by (2.22) we obtain our lemma. □

Now we can see the continuity of the lower value function.

LEMMA 2.5. *The lower value function $\underline{w}(t,x)$ is Hölder continuous on $[0,T] \times R^N$.*

Proof. Let us take $x \in B_R$, $z_1 \in \mathcal{A}_{T-t}(L)$, and $U \in \Gamma_{T-t}(K)$ and consider the following equation:

$$\begin{cases} dX(s) = (b(X(s)) + z_1(s) + BUz_1(s))ds, \\ X(0) = x. \end{cases}$$

Then we have

$$\begin{aligned} |X(s) - x| &\le M \int_0^s |X(s) - x| ds + c_1 s + \int_0^s (|z_1(s)| + |BUz_1(s)|) ds \\ &\le M \int_0^s |X(s) - x| ds + c_2 s^{\frac{1}{2}}, \quad 0 \le s \le T - t, \end{aligned}$$

for some positive constants c_1 and c_2 since

$$\int_0^{T-t} |Uz_1(s)|^2 ds \le 2K + \frac{\nu}{\mu\theta} \int_0^{T-t} |z_1(s)|^2 ds \le 2K + \frac{\nu L}{\mu\theta}.$$

Standard arguments using the Gronwall inequality imply that

$$|X(s) - x| \le c_3 s^{\frac{1}{2}}, \quad 0 \le s \le T - t. \tag{2.57}$$

Let us choose x_1, $x_2 \in B_R$, $0 \le t_1 < t_2 \le T$, such that $|x_1| + c_3|t_2 - t_1|^{\frac{1}{2}} < R$. For each $\epsilon > 0$ there exists $\hat{U} \in \Gamma_{T-t_2}(K)$ such that

$$\underline{w}(t_2, x_2) + \epsilon > \sup_{\tilde{z}_1 \in \mathcal{A}_{T-t_2}} I(t_2, x_2; T; \tilde{z}_1, \hat{U}\tilde{z}_1). \tag{2.58}$$

For each $z_1 \in \mathcal{A}_{T-t_1}(L)$ define $\hat{z}_1 \in \mathcal{A}_{T-t_2}(L)$ by

$$\hat{z}_1(s) = z_1(t_2 - t_1 + s), \quad 0 \le s \le T - t_2,$$

and for some $y_0 \in R^{N_1}$ define $U \in \Gamma_{T-t_1}(K)$ by

$$Uz_1(s) = \begin{cases} y_0, & 0 \le s \le t_2 - t_1, \\ \hat{U}\hat{z}_1(s - (t_2 - t_1)), & t_2 - t_1 \le s \le T - t_1. \end{cases}$$

Let $X_1(s)$ be the solution of

$$\begin{cases} dX_1(s) = (b(X_1(s)) + z_1(s) + BUz_1(s))ds, \quad 0 \le s \le T - t_1, \\ X_1(0) = x_1, \end{cases}$$

and let $X_2(s)$ be the solution of

$$\begin{cases} dX_2(s) = (b(X_2(s)) + \hat{z}_1(s) + B\hat{U}\hat{z}_1(s))ds, \quad 0 \le s \le T - t_2, \\ X_2(0) = x_2. \end{cases}$$

Then we have

$$\begin{aligned} |X_2(s) - X_1(t_2 - t_1 + s)| &\le c_4 |x_2 - X_1(t_2 - t_1)| \\ &\le c_5(|x_2 - x_1| + |t_2 - t_1|^{\frac{1}{2}}), \quad 0 \le s \le T - t_2, \end{aligned} \tag{2.59}$$

because $\hat{z}_1(s) = z_1(t_2 - t_1 + s)$ and $\hat{U}\hat{z}_1(s) = Uz_1(t_2 - t_1 + s)$ for $0 \le s \le T - t_2$. Since for each $\epsilon > 0$ there exists $z_1 \in \mathcal{A}_{T-t}(L)$ such that

$$\underline{w}(t_1, x_1) \le I(t_1, x_1; T, z_1, Uz_1) + \epsilon,$$

we obtain by (2.58)

$$\begin{aligned}\underline{w}(t_1, x_1) - \underline{w}(t_2, x_2) &\le I(t_1, x_1; T; z_1, Uz_1) - I(t_2, x_2; T; \hat{z}_1, \hat{U}\hat{z}_1) + 2\epsilon \\ &= \int_0^{T-t_2} \{\Psi(X_1(t_2 - t_1 + s), \hat{z}_1(s), \hat{U}\hat{z}_1(s)) - \Psi(X_2(s), \hat{z}_1(s), \hat{U}\hat{z}_1(s))\} ds \\ &\quad + \int_0^{t_2-t_1} \Psi(X_1(s), z_1(s), Uz_1(s)) ds + 2\epsilon \\ &\le c_6(|x_2 - x_1| + |t_2 - t_1|^{\frac{1}{2}}) + 2\epsilon.\end{aligned}$$

On the other hand, for each $\epsilon > 0$ there exists $U \in \Gamma_{T-t_1}(K)$ such that

$$\underline{w}(t_1, x_1) + \epsilon > \sup_{z_1 \in \mathcal{A}_{T-t_1}} I(t_1, x_1; T; z_1, Uz_1). \tag{2.60}$$

For each $\hat{z}_1 \in \mathcal{A}_{T-t_2}$ and some $z_0 \in R^N$ define $z_1 \in \mathcal{A}_{T-t_1}$ by

$$z_1(s) = \begin{cases} z_0, & 0 \le s \le t_2 - t_1, \\ \hat{z}_1(s - (t_2 - t_1)), & t_2 - t_1 \le s \le T - t_1. \end{cases}$$

Now define $\hat{U} \in \Gamma_{T-t_2}$ by

$$\hat{U}\hat{z}_1(s) = (Uz_1)(s + t_2 - t_1).$$

Let $X_1(s)$ be the solution of

$$\begin{cases} dX_1(s) = (b(X_1(s)) + z_1(s) + BUz_1(s))ds, & 0 \le s \le T - t_1, \\ X_1(0) = x_1, \end{cases}$$

and let $X_2(s)$ be the solution of

$$\begin{cases} dX_2(s) = (b(X_2(s)) + \hat{z}_1(s) + B\hat{U}\hat{z}_1(s))ds, & 0 \le s \le T - t_2, \\ X_2(0) = x_2. \end{cases}$$

Then we obtain (2.59) for these $X_1(s)$ and $X_2(s)$ in the same way as above. Since for each $\epsilon > 0$ there exists $\hat{z}_1 \in \mathcal{A}_{T-t_2}$ such that

$$\underline{w}(t_2, x_2) \le I(t_2, x_2; T : \hat{z}_1, \hat{U}\hat{z}_1) + \epsilon,$$

we have by (2.60)

$$\begin{aligned}\underline{w}(t_2, x_2) - \underline{w}(t_1, x_1) &\le I(t_2, x_2; T; \hat{z}_1, \hat{U}z_1) - I(t_1, x_1; T; z_1, Uz_1) + 2\epsilon \\ &\le \int_0^{T-t_2} \{\Psi(X_2(s), \hat{z}_1(s), Uz_1(s)) - \Psi(X_1(t_2 - t_1 + s), \hat{z}_1(s), \hat{U}\hat{z}_1(s))\} ds \\ &\quad - \int_0^{t_2-t_1} \Psi(X_1(s), z_1(s), Uz_1(s)) ds + 2\epsilon \\ &\le c_7(|x_2 - x_1| + |t_2 - t_1|^{\frac{1}{2}}) + 2\epsilon.\end{aligned}$$

Thus we see that $\underline{w}(t, x)$ is Hölder continuous. □

2.5. Viscosity solution.

PROPOSITION 2.6. *The lower value function* $\underline{w}(t,x)$ *defined by* (2.10) *is a viscosity solution of* (2.4).

Proof. Let $\phi \in C^\infty((0,T)\times R^N)$ be a function such that $\underline{w}-\phi$ attains its maximum at (t_0,x_0). Then we shall prove that

$$\frac{\partial\phi}{\partial t}(t_0,x_0)+H(x_0,\nabla\phi(t_0,x_0))\geq 0, \tag{2.61}$$

where $H(x,p)=b\cdot p+Q_0(x,p)+V(x)$, $p\in R^N$. Suppose that (2.61) does not hold. Then there exists $\delta>0$ such that

$$\frac{\partial\phi}{\partial t}(t_0,x_0)+H(x_0,\nabla\phi(t_0,x_0))\leq -\delta<0,$$

and so in a neighborhood G of (t_0,x_0),

$$\frac{\partial\phi}{\partial t}(t_0+s,x)+H(x,\nabla\phi(t_0+s,x))\leq -\frac{\delta}{2}<0,\quad (t_0+s,x)\in G. \tag{2.62}$$

Therefore, for each $z_1\in R^N$,

$$\begin{aligned}\frac{\partial\phi}{\partial t}&+b\cdot\nabla\phi+z_1\cdot\nabla\phi-\frac{1}{2\theta}z_1^*a^{-1}z_1-\frac{1}{2}(\nabla\phi)^*BS^{-1}B^*\nabla\phi+V\\&\leq -\frac{\delta}{2}-\frac{1}{2\theta}(z_1-\theta a\nabla\phi)^*a^{-1}(z_1-\theta a\nabla\phi)<0,\quad (t_0+s,x)\in G.\end{aligned} \tag{2.63}$$

Let $X(s)$ be the solution of the ODE

$$\begin{cases} dX(s)=(b(X(s))+z_1(s)-BS^{-1}B^*\nabla\phi(t_0+s,X(s)))ds,\\ X(0)=x_0,\end{cases} \tag{2.64}$$

and set

$$Uz_1(s)=-S^{-1}B^*\nabla\phi(t_0+s,X(s)) \tag{2.65}$$

and

$$f(x,z_1,z_2)=b(x)+z_1+Bz_2,\quad z_1\in R^N,\quad z_2\in R_1^N. \tag{2.66}$$

Then by (2.63) we have

$$\begin{aligned}&\frac{\partial\phi}{\partial t}(t_0+s,X(s))+f(X(s),z_1(s),Uz_1(s))\cdot\nabla\phi(t_0+s,X(s))\\&\quad+\Psi(X(s),z_1(s),Uz_1(s))\\&\leq -\frac{1}{2\theta}(z_1(s)-\theta a\nabla\phi(t_0+s,X(s)))^*a^{-1}(z_1(s)-\theta a\nabla\phi(t_0+s,X(s)))-\frac{\delta}{2},\\&\quad(t_0+s,x)\in G.\end{aligned} \tag{2.67}$$

Take t and R such that $G_0=[t_0,t)\times B_R(x_0)\subset G$, and set

$$\xi(s,x)=\frac{1}{2}|x-x_0|^2+(s-t_0) \tag{2.68}$$

and

$$\tau = \inf\{s : (t_0 + s, X(s)) \notin G_0\} \equiv (t - t_0) \wedge \tau_R. \tag{2.69}$$

Then for each $z_1(s)$

$$\begin{aligned}
\xi(t_0 + \tau, X(\tau)) &= \int_0^\tau \left\{ \frac{\partial \xi}{\partial s}(t_0 + s, X(s)) + f(X, z_1, Uz_1) \cdot \nabla \xi(t_0 + s, X(s)) \right\} ds \\
&= \tau + \int_0^\tau (z_1(s) - \theta a \nabla \phi) \cdot \nabla \xi(t_0 + s, X(s)) ds \\
&\quad + \int_0^\tau (b + \theta a \nabla \phi - BS^{-1}B^* \nabla \phi) \cdot \nabla \xi(t_0 + s, X(s)) ds \\
&\leq c_1 \tau + \frac{1}{2\theta} \int_0^\tau (z_1(s) - \theta a \nabla \phi)^* a^{-1} (z_1(s) - \theta a \nabla \phi)(t_0 + s, X(s)) ds \\
&\quad + \frac{\theta}{2} \int_0^\tau (\nabla \xi)^* a \nabla \xi(t_0 + s, X(s)) ds \\
&\leq c_2 \left(\frac{\delta}{2} \tau + \frac{1}{2\theta} \int_0^\tau (z_1(s) - \theta a \nabla \phi)^* a^{-1} (z_1(s) - \theta a \nabla \phi)(t_0 + s, X(s)) ds \right)
\end{aligned}$$

for some positive constants c_1 and c_2 since b, a, $\nabla \phi$, $BS^{-1}B^*$, and $\nabla \xi$ are bounded in G. Now from $\xi(t_0 + \tau, X(\tau)) \geq (t - t_0) \wedge \frac{R^2}{2}$ we obtain

$$c_2^{-1}(t - t_0) \wedge \frac{R^2}{2} \leq \frac{\delta}{2} \tau + \frac{1}{2\theta} \int_0^\tau (z_1(s) - \theta a \nabla \phi)^* a^{-1} (z_1(s) - \theta a \nabla \phi)(t_0 + s, X(s)) ds \tag{2.70}$$

for each $z_1(s)$, which implies that

$$0 < \inf_{z_1 \in \mathcal{A}_{t-t_0}} \left[\frac{\delta}{2} \tau + \frac{1}{2\theta} \int_0^\tau (z_1(s) - \theta a \nabla \phi)^* a^{-1} (z_1(s) - \theta a \nabla \phi)(t_0 + s, X(s)) ds \right]. \tag{2.71}$$

Thus from (2.67) it follows that

$$\sup_{z_1 \in \mathcal{A}_{t-t_0}} \int_0^\tau \left\{ \frac{\partial \phi}{\partial t} + f(X, z_1, Uz_1) \cdot \nabla \phi(t_0 + s, X(s)) + \Psi(X, z_1, Uz_1) \right\} ds < 0. \tag{2.72}$$

Hence

$$\inf_{U \in \Gamma_{t-t_0}} \sup_{z_1 \in \mathcal{A}_{t-t_0}} \int_0^\tau \left\{ \frac{\partial \phi}{\partial s} + f(X, z_1, Uz_1) \cdot \nabla \phi + \Psi(X, z_1, Uz_1) \right\} ds < 0. \tag{2.73}$$

On the other hand, $\underline{w} - \phi$ attains its local maximum at (t_0, x_0), and we have

$$\underline{w}(t_0, x_0) - \phi(t_0, x_0) \geq \underline{w}(t_0 + \sigma, X(\sigma)) - \phi(t_0 + \sigma, X(\sigma)) \tag{2.74}$$

for sufficiently small σ. Therefore, by (2.23) in section 2.3,

$$\inf_{U \in \Gamma_{t-t_0}} \sup_{z_1 \in \mathcal{A}_{t-t_0}} \left[\int_0^\tau \Psi(X, z_1, Uz_1) ds + \phi(t_0 + \tau, X(\tau)) - \phi(t_0, x_0) \right] \geq 0, \tag{2.75}$$

which means

$$\inf_{U\in\Gamma_{t-t_0}}\sup_{z_1\in\mathcal{A}_{t-t_0}}\int_0^\tau\left\{\frac{\partial\phi}{\partial s}+f(X,z_1,Uz_1)\cdot\nabla\phi+\Psi(X,z_1,Uz_1)\right\}ds\geq 0. \tag{2.76}$$

It contradicts (2.73).

On the other hand, let $\phi\in C^\infty((0,T)\times R^N)$ be a function such that $\underline{w}-\phi$ attains its local minimum at (t_0,x_0). Then we shall prove that

$$\frac{\partial\phi}{\partial t}(t_0,x_0)+H(x_0,\nabla\phi(t_0,x_0))\leq 0. \tag{2.77}$$

Suppose that (2.77) fails to hold. Then there exists $\delta>0$ such that

$$\frac{\partial\phi}{\partial t}(t_0,x_0)+H(x_0,\nabla\phi(t_0,x_0))>\delta>0. \tag{2.78}$$

Then in a neighborhood G of (t_0,x_0),

$$\frac{\partial\phi}{\partial t}(t_0+s,x)+H(x,\nabla\phi(t_0+s,x))>\frac{\delta}{2},\quad (t_0+s,x)\in G. \tag{2.79}$$

Since

$$\sup_{z_1\in R^N}\left\{z_1\cdot\nabla\phi-\frac{1}{2\theta}z_1^*a^{-1}z_1\right\}=\frac{\theta}{2}(\nabla\phi)^*a\nabla\phi, \tag{2.80}$$

$$\inf_{z_2\in R^{N_1}}\left\{(Bz_2)\cdot\nabla\phi+\frac{z_2^*Sz_2}{2}\right\}=-\frac{1}{2}(\nabla\phi)^*BS^{-1}B^*\nabla\phi, \tag{2.81}$$

and $\frac{\theta}{2}(\nabla\phi)^*a\nabla\phi$ is continuous, there exists $\hat{z}_1\in R^N$ and a neighborhood $\hat{G}\subset G$ of (t_0,x_0) such that

$$\begin{aligned}&\frac{\partial\phi}{\partial t}+b\cdot\nabla\phi+\hat{z}_1\cdot\nabla\phi-\frac{1}{2\theta}\hat{z}_1^*a^{-1}\hat{z}_1+(Bz_2)\dot{\nabla}\phi+\frac{1}{2}z_2^*Sz_2+V\\&\qquad\geq\frac{\delta}{4}+\frac{1}{2}(z_2+S^{-1}B^*\nabla\phi)^*S(z_2+S^{-1}B^*\nabla\phi)>0\quad\text{ in }\hat{G}\end{aligned} \tag{2.82}$$

for each $z_2\in R^{N_1}$. Take a control $\hat{z}_1(s)\equiv\hat{z}_1$ and consider the ODE

$$\begin{cases}d\hat{X}(s)=(b(\hat{X}(s))+\hat{z}_1+BU\hat{z}_1)ds,\\ \hat{X}(0)=x_0\end{cases} \tag{2.83}$$

for $U\in\Gamma_{t-t_0}$. Then

$$\begin{aligned}&\frac{\partial\phi}{\partial t}+f(\hat{X},\hat{z}_1,U\hat{z}_1)\cdot\nabla\phi+\Psi(\hat{X},\hat{z}_1,U\hat{z}_1)\\&\geq\frac{\delta}{4}+\frac{1}{2}(U\hat{z}_1+S^{-1}B^*\nabla\phi)^*S(U\hat{z}_1+S^{-1}B^*\nabla\phi),\quad(t_0+s,\hat{X}(s))\in\hat{G}\end{aligned} \tag{2.84}$$

for each $U\in\Gamma_{t-t_0}$. Define $G_0=[t_0,t)\times B_R(x_0)\subset\hat{G}$, and let $\tau=\inf\{s:(t_0+$

$s, \hat{X}(s)) \notin G_0\}$. Take a function ξ defined by (2.68); then

(2.85)
$$\begin{aligned}\xi(t_0+\tau,\hat{X}(\tau)) &= \int_0^\tau \left\{\frac{\partial \xi}{\partial s} + f(\hat{X},\hat{z}_1,U\hat{z}_1)\cdot\nabla\xi(t_0+s,\hat{X}(s))\right\}ds \\ &= \int_0^\tau \{1 + b\cdot\nabla\xi + \hat{z}_1\cdot\nabla\xi + (BU\hat{z}_1)\cdot\nabla\xi\}ds \\ &\le c_1\left(\tau + \int_0^\tau |U\hat{z}_1 + S^{-1}B^*\nabla\phi|ds\right) \\ &\le c_2\left(\frac{\delta}{4}\tau + \frac{1}{2}\int_0^\tau (U\hat{z}_1 + S^{-1}B^*\nabla\phi)^* S(U\hat{z}_1 + S^{-1}B^*\nabla\phi)ds\right)\end{aligned}$$

for some positive constants c_1 and c_2. Thus we see in the same way as above

$$\begin{aligned}&\inf_{U\in\Gamma_{t-t_0}}\left(\frac{\delta}{4}\tau + \frac{1}{2}\int_0^\tau (U\hat{z}_1 + S^{-1}B^*\nabla\phi)^* S(U\hat{z}_1 + S^{-1}B^*\nabla\phi)ds\right) \\ &> c_2^{-1}(t-t_0)\wedge\frac{R^2}{2} > 0.\end{aligned} \tag{2.86}$$

Hence,

$$\inf_{U\in\Gamma_{t-t_0}}\sup_{z_1\in\mathcal{A}_{t-t_0}}\int_0^\tau\left\{\frac{\partial\phi}{\partial s} + f(X,z_1,Uz_1)\cdot\nabla\phi + \Psi(X,z_1,Uz_1)\right\}ds > 0. \tag{2.87}$$

Since $\underline{w} - \phi$ attains its local minimum at (t_0, x_0),

$$\underline{w}(t_0,x_0) - \phi(t_0,x_0) \le \underline{w}(t_0+\sigma, X(\sigma)) - \phi(t_0+\sigma, X(\sigma))$$

for sufficiently small σ. Therefore from (2.23) it follows that

$$\begin{aligned}0 &\ge \inf_{U\in\Gamma_{t-t_0}}\sup_{z_1\in\mathcal{A}_{t-t_0}}\left[\int_0^\tau \Psi(X,z_1,Uz_1)ds + \phi(t_0+\tau,X(\tau)) - \phi(t_0,x_0)\right] \ge 0 \\ &= \inf_{U\in\Gamma_{t-t_0}}\sup_{z_1\in\mathcal{A}_{t-t_0}}\int_0^\tau\left\{\frac{\partial\phi}{\partial s} + f(X,z_1,Uz_1)\cdot\nabla\phi + \Psi(X,z_1,Uz_1)\right\}ds,\end{aligned}$$

which contradicts (2.87). □

2.6. Uniqueness of the positive solution. Let us set

$$\Lambda^{ij} = (BS^{-1}B^* - \theta a)^{ij}; \tag{2.88}$$

then there exist positive constants k_1, $k_2 > 0$, such that

$$k_2|\xi|^2 \le \Lambda^{ij}\xi_i\xi_j \le k_1|\xi|^2 \quad \forall \xi \in R^N \tag{2.89}$$

by our assumptions. Equation (2.4) reads

$$\begin{cases}\dfrac{\partial w}{\partial t} + b\cdot\nabla w - \dfrac{1}{2}(\nabla w)^*\Lambda\nabla w + V(x) = 0, \\ w(T,x) = 0.\end{cases} \tag{2.90}$$

Let $w(t,x)$ be a nonnegative viscosity solution of (2.90), and set

$$w_R(t,x) = \inf_{z\in\mathcal{A}_{T-t}} \left[\int_0^{\tilde{t}_R - t} \left\{ \frac{1}{2} z(s)^* \Lambda^{-1} z(s) + V(X(s)) \right\} ds + w(\tilde{t}_R, X(\tilde{t}_R - t)) \right], \tag{2.91}$$

where $\tilde{t}_R = t + (T-t) \wedge \zeta_R$ and $X(s)$ is the solution of

$$\begin{cases} dX(s) = (b(X(s)) + z(s))ds, \\ X(0) = x \end{cases} \tag{2.92}$$

for $z \in \mathcal{A}_{T-t}$.

LEMMA 2.7. *For each R $w_R(t,x) = w(t,x)$.*

Proof. It is easy to see that w_R is a viscosity solution of the Dirichlet problem

$$\begin{cases} \dfrac{\partial w_R}{\partial t} + b \cdot \nabla w - \dfrac{1}{2} (\nabla w_R)^* \Lambda \nabla w_R + V = 0 \quad \text{in } (0,T) \times B_R, \\ w_R(t,x) = w(t,x), \quad x \in \partial B_R, \quad 0 < t < T, \\ w_R(T,x) = 0, \end{cases} \tag{2.93}$$

and the proof is seen in Fleming and Soner [12, cf. Theorems 7.1 and 16.1, Chapter II]. Since it is known that the viscosity solution of (2.93) is unique (cf. [4]), we see that $w_R(t,x) = w(t,x)$ for each R. □

LEMMA 2.8. *Let $X(s)$ be a solution of* (2.92)*; then*

$$|X(s)|^2 \le c_1 |x|^2 + c_2 |T-t| + c_3 \int_0^s |z(\zeta)|^2 d\zeta, \quad 0 \le s \le T-t, \tag{2.94}$$

where c_1, c_2, and c_3 are positive constants.

Proof.

$$\begin{aligned} |X(s)|^2 - |X(0)|^2 &= 2 \int_0^s \{ b(X(\zeta)) \cdot X(\zeta) + z(\zeta) \cdot X(\zeta) \} d\zeta \\ &\le 2M \int_0^s (1 + |X(\zeta)|) |X(\zeta)| d\zeta + \int_0^s (|z(\zeta)|^2 + |X(\zeta)|^2) d\zeta \\ &\le Ms + \int_0^s |z(\zeta)|^2 d\zeta + (3M+1) \int_0^s |X(\zeta)|^2 d\zeta. \end{aligned} \tag{2.95}$$

Set $m(s) = |X(s)|$; then standard arguments using the Gronwall inequality for $m(s)$ imply our present lemma. □

PROPOSITION 2.9. *A nonnegative viscosity solution of* (2.90) *is unique.*

Proof. By Lemma 2.7 for each R

$$w(t,x) = \inf_{z\in\mathcal{A}_{T-t}} \left[\int_0^{\tilde{t}_R - t} \left\{ \frac{1}{2} z(s)^* \Lambda z(s) + V(X(s)) \right\} ds + w(\tilde{t}_R, X(\tilde{t}_R - t)) \right]. \tag{2.96}$$

Fix (t,x) and take R sufficiently large such that

$$w(t,x) < \frac{1}{2k_1 c_3} (R^2 - c_1 |x|^2 - c_2 (T-t)).$$

Suppose that $\sup_{0\le s\le T-t}|X(s)|\ge R$; then by Lemma 2.8

$$c_3^{-1}(R^2-c_1|x|^2-c_2(T-t))\le\int_0^{\zeta_R}|z(s)|^2ds$$

and consequently

$$\begin{aligned}(2.97)\qquad &\int_0^{\tilde t_R-t}\left\{\frac{1}{2}z(s)^*\Lambda^{-1}z(s)+V(X(s))\right\}ds+w(\tilde t_R,X(\tilde t_R-t))\\ &\ge\int_0^{\tilde t_R-t}\frac{1}{2}z(s)^*\Lambda^{-1}z(s)\ge\frac{1}{2k_1c_3}(R^2-c_1|x|^2-c_2(T-t))\\ &>w(t,x).\end{aligned}$$

Thus we have

$$(2.98)\qquad w(t,x)=\inf_{z\in\mathcal{A}_{T-t}}\int_0^{T-t}\left\{\frac{1}{2}z(s)^*\Lambda^{-1}z(s)+V(X(s))\right\}ds,$$

which implies uniqueness of a viscosity solution of (2.90). □

Theorem 2.1 is a direct consequence of Propositions 2.6 and 2.9.

FINITE-DIMENSIONAL FILTERS WITH NONLINEAR DRIFT VII: MITTER CONJECTURE AND STRUCTURE OF η^*

JIE CHEN† AND STEPHEN S.-T. YAU‡

Abstract. The concept of estimation algebra introduced independently by Brockett and Mitter has been playing a fundamental role in the investigation of finite-dimensional nonlinear filters. Mitter conjectured that the observation terms $h_i(x)$ are polynomials of degree one if the corresponding estimation algebra is finite dimensional. Chiou, Leung, and the present authors classify all finite-dimensional estimation algebra of maximal rank with dimension of the state space less than or equal to three. In this paper, we prove the Mitter conjecture for finite-dimensional estimation algebra of maximal rank with arbitrary state space dimension. In the course of our proof, we show that the $\Omega = (\frac{\partial f_j}{\partial x_i} - \frac{\partial f_i}{\partial x_j})$ matrix, where f denotes the drift term, has special linear structure which generalizes our previous result in [J. Chen and S. S.-T. Yau, *Math. Control Signals Systems*, 9 (1996), to appear]. We also give a structure theorem for $\eta = \sum_{i=1}^n \frac{\partial f_i}{\partial x_i} + \sum_{i=1}^n f_i^2 + \sum_{i=1}^m h_i^2$.

Key words. finite-dimensional nonlinear filter, Mitter conjecture, estimation algebras

1. Introduction.

The idea of using estimation algebras to construct finite-dimensional nonlinear filters was first proposed in Brockett and Clark [Br–Cl], Brockett [Br], and Mitter [Mi]. The concept of estimation algebras has proved to be an invaluable tool in the study of nonlinear filtering problems. In 1983, Brockett proposed classifying all finite-dimensional estimation algebras. As a first step to attack this problem, Mitter conjectured that the observation terms $h_i(x)$ are affine polynomials. In [Ch2–Ya], Chiou and Yau first introduced the concept of estimation algebra of maximal rank. The purpose of this paper is to show that Mitter conjecture is true for all finite-dimensional estimation algebras of maximal rank. In [Wo], the concept of Ω is introduced, defined as the matrix whose (i,j) entry is $\frac{\partial f_j}{\partial x_i} - \frac{\partial f_i}{\partial x_j}$, where f is the drift term of the state evolution equation. Recently, Yau [Ya] has studied a filtering system such that all entries of Ω are constants. He was able to classify all finite-dimensional estimation algebras of maximal rank and proved Mitter conjecture for such a filtering system. If the dimension of the state space is two or three, then Chiou and Yau [Ch2–Ya] and Chen, Leung, and Yau [C–L–Y] have shown, respectively, that all entries of Ω are constants as long as the estimation algebra is of maximal rank and finite dimensional. Thus finite-dimensional estimation algebra of maximal rank is completely classified if the dimension of the state space is at most three.

In [Ch1–Ya], we have shown that Ω is an affine matrix in the sense that every entry in Ω is an affine polynomial if the estimation algebra is of maximal rank and finite-dimensional. This is a fundamental step in classifying finite-dimensional estimation of maximal rank. In fact we proved that Ω has a special affine structure. The purpose of this paper is to give affirmative solution to Mitter conjecture for finite-dimensional estimation algebra of maximal rank. The following is our main theorem.

MAIN THEOREM. *Let E be a finite-dimensional estimation algebra of maximal rank. Let k be the quadratic rank of E (cf. Definition 2.2 below). Then*

(1) *the observation terms $h_i(x)$, $1 \le i \le m$, are affine polynomials.*

(2) (a) *ω_{ij}, for $1 \le i \le k$ or $1 \le j \le k$, are constants*

(b) *ω_{ij}, for $k+1 \le i, j \le n$, are degree-one polynomials in $x_{k+1}, \dots, x_n$.*

(3) *$\eta = \sum_{i=1}^n \frac{\partial f_i}{\partial x_i} + \sum_{i=1}^n f_i^2 + \sum_{i=1}^m h_i^2$ is a homogeneous polynomial of degree four. Moreover, η_4 (homogeneous polynomial of degree-four part of η) depends only on $x_{k+1}, \dots, x_n$ variables.*

Notice that in our previous paper, we proved only that ω_{ij} for $1 \le i \le k$ or $1 \le j \le k$ are affine polynomials in $x_1, \dots, x_k$. It is precisely the improvement of the result on ω_{ij} for $1 \le i \le k$ or $1 \le j \le k$ that allows us to solve the Mitter conjecture affirmatively. This paper is, in essence, a continuation of [Ch1–Ya], and we strongly recommend that readers familiarize themselves with the results in [Ch1–Ya]. However, every effort will be made to make this paper as self-contained as possible without too much duplication of the previous paper.

2. Basic concepts. The filtering problem here is based on the following signal observation model:

$$\begin{cases} dx(t) = f\big(x(t)\big)dt + g\big(x(t)\big)dv(t), & x(0) = x_0, \\ dy(t) = h\big(x(t)\big)dt + dw(t), & y(0) = 0, \end{cases} \tag{2.1}$$

in which x, v, y, and w are, respectively, $\mathbb{R}^n$-, $\mathbb{R}^p$-, $\mathbb{R}^m$-, and $\mathbb{R}^m$-valued processes and v and w have components which are independent, standard Brownian process. We further assume that $n = p$, f, h are C^∞ smooth and that g is an orthogonal matrix. We shall refer to $x(t)$ as the state of the system at time t and $y(t)$ as the observation at time t. $\rho(t,x)$, the conditional probability density of the state, $x(t)$, given the observation $\big\{y(s) : 0 \le s \le t\big\}$ is determined by the Duncan–Mortensen–Zakai equation, which in the unnormalized form is given by (see [Da–Ma], for example)

$$\frac{d}{dt}\sigma(t,x) = L_0\sigma(t,x)dt + \sum_{i=1}^m L_i\sigma(t,x)dy_i(t), \quad \sigma(0,x) = \sigma_0, \tag{2.2}$$

where

$$L_0 = \frac{1}{2}\sum_{i=1}^n \frac{\partial^2}{\partial x_i^2} - \sum_{i=1}^n f_i\frac{\partial}{\partial x_i} - \sum_{i=1}^n \frac{\partial f_i}{\partial x_i} - \frac{1}{2}\sum_{i=1}^m h_i^2$$

and for $i = 1, \dots, m$, L_i is the zero-degree differential operator of multiplication by h_i. (If a is a vector, we use the notation a_i to represent the ith component of a.) σ_0 is the probability density of the initial point x_0. When the observation is absent—that is, $h = 0$—then (2.2) is simply the Kolmogorov equation.

It is important to find efficient ways to solve (2.2), which is the subject of many research studies in nonlinear filtering theory. For this purpose, we need to introduce the following definition.

DEFINITION 2.1. *The estimation algebra E of a filtering system* (2.1) *is defined to be the Lie algebra generated by $\{L_0, L_1, \dots, L_m\}$. E is said to be an estimation algebra of maximal rank if for every $1 \le i \le n$ there exists a constant c_i such that $x_i + c_i$ is in E.*

In [Wo], the concept of Ω is introduced, defined as the matrix whose (i,j) element ω_{ij} is $\frac{\partial f_j}{\partial x_i} - \frac{\partial f_i}{\partial x_j}$.

Define

$$D_i = \frac{\partial}{\partial x_i} - f_i$$

and

$$\eta = \sum_{i=1}^{n} \frac{\partial f_i}{\partial x_i} + \sum_{i=1}^{n} f_i^2 + \sum_{i=1}^{m} h_i^2.$$

Then

$$L_0 = \frac{1}{2}\left(\sum_{i=1}^{n} D_i^2 - \eta\right).$$

Recall here that the assumption of maximal rank on E implies that E contains all affine polynomial and the operations $D_1, \ldots, D_n$. This follows from the fact that $D_j = [L_0, x_j + c_j]$ and $1 = [D_j, x_j + c_j]$.

The following theorem proved in [Ya] plays a fundamental roles in Mitter conjecture as well as the classification of finite-dimensional estimation algebra.

THEOREM 2.1. *Let E be a finite-dimensional estimation algebra of* (2.1) *such that $\omega_{ij} = \frac{\partial f_j}{\partial x_i} - \frac{\partial f_i}{\partial x_j}$ are constant functions. Then $h_i(x)$, $1 \le i \le m$, are affine polynomials. If in addition, E is of maximal rank, then E is a real vector space of dimension $2n+2$ with basis given by $1, x_1, x_2, \ldots, x_n, D_1, \ldots, D_n$ and L_0.*

We need the following basic result [Oc] for later discussion.

THEOREM 2.2 (Ocone). *Let E be a finite-dimensional estimation algebra. If φ is a function in E, then φ is a polynomial of degree at most two.*

In our previous paper [Ch1–Ya], we have introduced the following important concepts and notations. Let Q be the space of quadratic forms in n variables, i.e., real vector space spanned by $x_i x_j$, with $1 \le i \le j \le n$. Let $X = (x_1, \ldots, x_n)^T$. For any quadratic form $p \in Q$, there exists a symmetric matrix A such that $p(x) = X^T A X$. The rank of the quadratic form p is denoted by $\mathrm{rk}(p)$ and is defined to be the rank of the matrix A.

DEFINITION 2.2. *A fundamental quadratic form of the estimation algebra E is an element $p_0 \in E \cap Q$ with the greatest positive rank, i.e., $\mathrm{rk}(p_0) \ge \mathrm{rk}(p)$ for any $p \in E \cap Q$. The quadratic rank of the estimation algebra E is defined to be $\mathrm{rk}(p_0)$.*

After an orthogonal transformation on x, p_0 can be written as

$$p_0(x) = c_1 x_1^2 + c_2 x_2^2 + \cdots + c_k x_k^2, \tag{2.3}$$

where $c_i \neq 0$, $1 \le i \le k$, and k is the quadratic rank of E. From $p_0(x)$, we can construct a sequence of quadratic forms in $E \cap Q$ as follows:

$$q_0 = p_0,$$
$$q_j = \big[[L_0, q_{j-1}], q_0\big] = \sum_{i=1}^{k} 4^j c_i^{j+1} x_i^2.$$

In view of the invertibility of the Vandermonde matrix, we can assume that

$$p_0(x) = x_1^2 + x_2^2 + \cdots + x_k^2 \in E. \tag{2.4}$$

The following results were proven in [Ch1–Ya].

LEMMA 2.3. *Let k be the quadratic rank of the estimation algebra E with fundamental quadratic form $p_0(x) = x_1^2 + \cdots + x_k^2$. Then $p(x)$ is independent of $x_{k+1}, x_{k+2}, \ldots, x_n$ for any quadratic form $p(x)$ in E.*

Let $p_1(x)$ be a quadratic form in E with least positive rank, i.e., $\mathrm{rk}(p_1) \le \mathrm{rk}(q)$ for any $q(x) \in E \cap Q$. After an orthogonal transform on X which fixes $x_{k+1}, \ldots, x_n$ (i.e., an orthogonal transform on $x_1, x_2, \ldots, x_k$) and the Vandermonde matrix procedure as before, we can assume

$$p_1(x) = \sum_{i=1}^{k_1} x_i^2 \in E, \quad 1 \le k_1 \le k. \tag{2.5}$$

Note that the orthogonal transform on $x_1, \ldots, x_k$ leaves $p_0(x)$ invariant. By definition, $p_0(x) = \sum_{i=1}^{k} x_i^2$ has the greatest positive rank and $p_1(x) = \sum_{i=1}^{k_1} x_i^2$ has the least positive rank. Define

$$S_1 = \{1, 2, \ldots, k_1\} \subseteq S = \{1, 2, \ldots, k\}, \tag{2.6}$$

$$Q_1 = \text{ real vector space spanned by } \{x_i x_j : k_1 + 1 \le i \le j \le k\} \subseteq Q. \tag{2.7}$$

If $k_1 < k$, then $Q_1 \cap E$ is a nontrivial space since $p_1(x) - p_0(x) \in E \cap Q_1$. In a procedure similar to that above, there exists

$$p_2(x) = \sum_{i=k_1+1}^{k_2} x_i^2 \in E \cap Q_1 \tag{2.8}$$

with the least positive rank in $E \cap Q_1$. By induction, we can construct a series of S_i, Q_i, and $p_i(x)$ such that

$$S_i = \{k_{i-1} + 1, \ldots, k_i\}, \quad k_0 = 0, \quad k_i \le k, \tag{2.9}$$

$$Q_i = \text{ linear span } \{x_i x_j : k_i + 1 \le i \le j \le k\}, \tag{2.10}$$

$$p_i(x) = \sum_{j=k_{i-1}+1}^{k_i} x_j^2 = \sum_{j \in S_i} x_j^2, \quad i > 0, \tag{2.11}$$

and $p_i(x)$ has the least rank in $E \cap Q_{i-1}$.

LEMMA 2.4. *If $p(x) \in E \cap Q$, then*

$$p(0, \ldots, 0, x_{k_{i-1}+1}, \ldots, x_{k_i}, 0, \ldots, 0) = \lambda p_i(x) \quad \textit{for } i > 0,$$
$$p(x_1, \ldots, x_{k_{i-1}}, 0, \ldots, 0, x_{k_i+1}, \ldots, x_k) \in E \quad \textit{for } i > 0.$$

PROPOSITION 2.5. *Suppose that $p(x)$ is a quadratic form in E of the following form, which depends on $\{x_i \ i \in S_{\ell_1} \cup S_{\ell_2}\}$:*

$$p(x) = \left(X_{\ell_1}^T, X_{\ell_2}^T\right) \begin{pmatrix} 0 & A \\ A^T & 0 \end{pmatrix} \begin{pmatrix} X_{\ell_1} \\ X_{\ell_2} \end{pmatrix},$$

where $X_i = \left(x_{k_{i-1}+1}, \ldots, x_{k_i}\right)^T$, i.e., $p(x) = \sum_{i \in S_{\ell_1}} \sum_{j \in S_{\ell_2}} 2a_{ij} x_i x_j$. Suppose that $\ell_1 < \ell_2$. Then $|S_{\ell_1}| = |S_{\ell_2}|$ and $A = bT$, where b is a constant and T is an orthogonal matrix.

THEOREM 2.6. *Suppose that E is a finite-dimensional estimation algebra of maximal rank. Then $\omega_{ij} = \frac{\partial f_j}{\partial x_i} - \frac{\partial f_i}{\partial x_j}$, $1 \le i, j \le n$, are polynomials of degree at most one.*

Notation. From now on we shall write $\omega_{ij} = \beta_{ij} + \gamma_{ij}$, where β_{ij} is the linear part of ω_{ij} while γ_{ij} is the constant part of ω_{ij}.

PROPOSITION 2.7. *Suppose that E is a finite-dimensional estimation algebra of maximal rank. With the same notation as before, if $\ell_1 \neq \ell_2$ and $i \in S_{\ell_1}$, $j \in S_{\ell_2}$, then $\beta_{ij} = 0$; i.e., ω_{ij} is a constant.*

THEOREM 2.8. *Suppose that E is a finite-dimensional estimation algebra of maximal rank. Let k be the quadratic rank of E. With the same notation as before, then*

(i) *for $j \in S_\ell$*

$$\begin{pmatrix} \beta_{jk_{\ell-1}+1} \\ \vdots \\ \beta_{jk_\ell} \end{pmatrix} = A_1^{j,\ell} X_\ell \qquad \text{with} \quad A_1^{j,\ell} = -(A_1^{j,\ell})^T,$$

where $X_\ell = \left(x_{k_{\ell-1}+1}, \dots, x_{k_\ell}\right)$ and $A_1^{j,\ell}$ is a $(k_\ell - k_{\ell-1}) \times (k_\ell - k_{\ell-1})$ matrix;

(ii) *for $j > k$*

$$\begin{pmatrix} \beta_{jk_{\ell-1}+1} \\ \vdots \\ \beta_{jk_\ell} \end{pmatrix} = \lambda_{j,\ell} X_\ell + A_2^{j,\ell} \widetilde{X_\ell},$$

where $\widetilde{X_\ell}$ denote the complementary variable vector of X_ℓ in $(x_1, \dots, x_k)^T$, i.e., $\widetilde{X_\ell} = \left(x_1, \dots, x_{k_{\ell-1}}, x_{k_\ell+1}, \dots, x_k\right)^T$, and $A_2^{j,\ell}$ is a $k_\ell \times (k - k_\ell)$ matrix.

THEOREM 2.9. *Suppose that E is a finite-dimensional estimation algebra of maximal rank. With the same notation as before, then $A_1^{j,\ell} = 0$ in* (i) *of Theorem* 2.8. *This means that $\beta_{ij} = 0$ for $i, j \in S_\ell = \left\{k_{\ell-1} + 1, \dots, k_\ell\right\}$; i.e., $\omega_{ij} =$* constant *for $i, j \in S_\ell$.*

PROPOSITION 2.10. *Suppose that E is a finite-dimensional estimation algebra of maximal rank. Then*

(i) *ω_{ij} is a degree-one polynomial in $x_1, \dots, x_k$ for $1 \le i \le k$ or $1 \le j \le k$;*

(ii) *ω_{ij} is a degree-one polynomial in $x_{k+1}, \dots, x_n$ for $k + 1 \le i, j \le n$.*

It follows from Theorem 2.6, Proposition 2.7, Theorem 2.9, and Proposition 2.10 that we have the following theorem.

THEOREM 2.11. *Let E be a finite-dimensional estimation algebra of maximal rank and k be the quadratic rank of E. Then all the entries $\omega_{ij} = \frac{\partial f_j}{\partial x_i} - \frac{\partial f_i}{\partial x_j}$ of Ω are degree-one polynomials. In fact, for $1 \le i, j \le k$, ω_{ij} are constants; for $1 \le i \le k$ or $1 \le j \le k$, ω_{ij} are degree-one polynomials in $x_1, \dots, x_k$; and for $k + 1 \le i, j \le n$, ω_{ij} are degree-one polynomials in $x_{k+1}, \dots, x_n$.*

For the sake of convenience to the readers, we also provide the following lemma without proof. The proof can be found in [Ya].

LEMMA 2.12. (i) *$[XY, Z] = X[Y, Z] + [X, Z]Y$, where X, Y, and Z are differential operators.*

(ii) *$[gD_i, h] = g\frac{\partial h}{\partial x_i}$, where $D_i = \frac{\partial}{\partial x_i} - f_i$ and g and h are functions defined on $\mathbb{R}^n$.*

(iii) *$[gD_i, hD_j] = -gh\omega_{ij} + g\frac{\partial h}{\partial x_i} D_j - h\frac{\partial g}{\partial x_j} D_i$, where $\omega_{ji} = [D_i, D_j] = \frac{\partial f_i}{\partial x_j} - \frac{\partial f_j}{\partial x_i}$.*

(iv) *$[gD_i^2, h] = 2g\frac{\partial h}{\partial x_i} D_i + g\frac{\partial^2 h}{\partial x_i^2}$.*

(v) $[D_i^2, hD_j] = 2\frac{\partial h}{\partial x_i}D_iD_j - 2h\omega_{ij}D_i + \frac{\partial^2 h}{\partial x_i^2}D_j - h\frac{\partial \omega_{ij}}{\partial x_i}$.

(vi) $[D_i^2, D_j^2] = 4\omega_{ji}D_jD_i + 2\frac{\partial \omega_{ji}}{\partial x_j}D_i + 2\frac{\partial \omega_{ji}}{\partial x_i}D_j + \frac{\partial^2 \omega_{ji}}{\partial x_i \partial x_j} + 2{\omega_{ji}}^2$.

(vii) $[D_k^2, hD_iD_j] = 2\frac{\partial h}{\partial x_k}D_kD_iD_j + 2h\omega_{jk}D_iD_k + 2h\omega_{ik}D_kD_j + \frac{\partial^2 h}{\partial x_k^2}D_iD_j + 2h\frac{\partial \omega_{jk}}{\partial x_i}D_k + h\frac{\partial \omega_{jk}}{\partial x_k}D_i + h\frac{\partial \omega_{ik}}{\partial x_k}D_j + h\frac{\partial^2 \omega_{jk}}{\partial x_i \partial x_k}$.

(viii) $[gD_iD_j, hD_k] = g\frac{\partial h}{\partial x_j}D_iD_k + g\frac{\partial h}{\partial x_i}D_jD_k + gh\omega_{kj}D_i + gh\omega_{ki}D_j + g\frac{\partial^2 h}{\partial x_i \partial x_j}D_k + gh\frac{\partial \omega_{kj}}{\partial x_i} - h\frac{\partial g}{\partial x_k}D_iD_j$.

3. Structure of second-order operators and special linear structure of Ω. Building on our previous results in [Ch1–Ya], in this section, we shall prove that Ω has very special linear structure. It is exactly this result which allows us to prove Mitter conjecture for maximal rank finite-dimensional estimation algebra. To begin with, we need some results on second-order operator in E.

Consider the polynomial algebra $C^\infty(\mathbb{R}^n)[D_1, \dots, D_n]$ in variables $D_1, \dots, D_n$ with coefficients in $C^\infty(\mathbb{R}^n)$ modulo the relations $D_iD_j = D_jD_i + \omega_{ji}$ and $D_ia = aD_i + \frac{\partial a}{\partial x_i}$, where $C^\infty(\mathbb{R}^n)$ is the ring of all C^∞ functions on $\mathbb{R}^n$ and a is a C^∞ function. Every element $A \in C^\infty(\mathbb{R}^n)[D_1, \dots, D_n]$ has a representation in the following:

$$A = \sum a_{i_1 \cdots i_n}(x) D_1^{i_1} \cdots D_n^{i_n}, \tag{3.1}$$

i.e., a polynomial in D_i with coefficients in $C^\infty(\mathbb{R}^n)$. Since $D_iD_j = D_jD_i + \omega_{ji}$, $C^\infty(\mathbb{R}^n)[D_1, \dots, D_n]$ is not a commutative algebra. It is clear that every element of E has a representation of (3.1). For any $A \in E$, let P_A be the principal part of A, i.e., the highest homogeneous part of A in $D_1, \dots, D_n$. For example, for $L_0 \in E$, $P_{L_0} = \frac{1}{2}(D_1^2 + \cdots + D_n^2)$.

LEMMA 3.1. *If $\frac{\partial a}{\partial x_j}(x) \neq 0$, then the principal part of $\left[D_j^\ell, a(x)D_1^{i_1} \cdots D_n^{i_n}\right]$ is given by*

$$P_{\left[D_j^\ell, a(x)D_1^{i_1} \cdots D_n^{i_n}\right]} = \ell \frac{\partial a}{\partial x_j}(x) D_1^{i_1} \cdots D_j^{i_j + \ell - 1} \cdots D_n^{i_n}. \tag{3.2}$$

Proof. If $\ell = 1$, then (3.2) is trivial. Suppose that (3.2) is true for $\ell - 1$; then

$$\begin{aligned} &\left[D_j^\ell, a(x)D_1^{i_1} \cdots D_n^{i_n}\right] \\ &= D_j\left[D_j^{\ell-1}, a(x)D_1^{i_1} \cdots D_n^{i_n}\right] + \left[D_j, a(x)D_1^{i_1} \cdots D_n^{i_n}\right]D_j^{\ell-1}. \end{aligned} \tag{3.3}$$

Hence

$$\begin{aligned} P_{\left[D_j^\ell, a(x)D_1^{i_1} \cdots D_n^{i_n}\right]} &= P_{D_j\left[D_j^{\ell-1}, a(x)D_1^{i_1} \cdots D_n^{i_n}\right]} + P_{\left[D_j, a(x)D_1^{i_1} \cdots D_n^{i_n}\right]D_j^{\ell-1}} \\ &= (\ell - 1)\frac{\partial a}{\partial x_j}(x) D_1^{i_1} \cdots D_j^{i_j + \ell - 1} \cdots D_n^{i_n} \\ &\quad + \frac{\partial a}{\partial x_j}(x) D_1^{i_1} \cdots D_j^{i_j + \ell - 1} \cdots D_n^{i_n} \\ &= \ell \frac{\partial a}{\partial x_j}(x) D_1^{i_1} \cdots D_j^{i_j + \ell - 1} \cdots D_n^{i_n}. \end{aligned}$$

□

PROPOSITION 3.2. *If the principal part of A is of the form*

$$P_A = \sum a_{i_1 \cdots i_n}(x) D_1^{i_1} \cdots D_n^{i_n},$$

where for some $(i_1, \dots, i_n)$ *and* j, $\frac{\partial a_{i_1 \cdots i_n}}{\partial x_j}(x) \neq 0$, *then the principal part of* $[L_0, A]$ *is given by*

$$P_{[L_0,A]} = \sum_j \sum_{i_1 \cdots i_n} \frac{\partial a_{i_1 \cdots i_n}}{\partial x_j}(x) D_1^{i_1} \cdots D_j^{i_j+1} \cdots D_n^{i_n}.$$

Proof. The proposition follows immediately when Lemma 3.1 is applied repeatedly. □

THEOREM 3.3. *Let* E *be a finite-dimensional estimation algebra. Suppose that* A *is a second order in* E *with principal part* $P_A = \sum_{i \leq j} a_{ij}(x) D_i D_j$. *Then* $\frac{\partial a_{ii}}{\partial x_i}(x) = 0$.

Proof. Without loss of generality, we can assume $i = 1$. a_{11} must be a polynomial; otherwise E would be infinite dimensional. If $\frac{\partial a_{11}}{\partial x_1}(x) \neq 0$, then there exists a positive integer ℓ such that

$$\frac{\partial^{\ell+1} a_{11}}{\partial x_1^{\ell+1}}(x) = 0 \quad \text{and} \quad \frac{\partial^{\ell} a_{11}}{\partial x_1^{\ell}}(x) \neq 0.$$

This is true because $a_{11}(x)$ is a polynomial in view of a result of [Wo]. By Proposition 3.2, we have

$$P_{[L_0,A]} = \frac{\partial a_{11}}{\partial x_1}(x) D_1^3 + \text{lower-order term in } D_1.$$

Hence if we let $Ad_{L_0} A = [L_0, A]$ and $Ad_{L_0}^m A = \big[L_0, Ad_{L_0}^{m-1} A\big]$, then

$$P_{Ad_{L_0}^{\ell} A} = \frac{\partial^{\ell} a_{11}}{\partial x_1^{\ell}}(x) D_1^{\ell+2} + \text{lower-order term in } D_1.$$

Let $B = Ad_{L_0}^{\ell-1} A$ (for $\ell = 1$, take $B = A$). Then

$$\begin{aligned} P_{Ad_B^s L_0} =& (-1)^s (\ell+1)(\ell+2)(2\ell+2)(3\ell+2) \cdots ((s-1)\ell+2) \Big(\frac{\partial^{\ell} a_{11}}{\partial x_1^{\ell}}(x) \Big)^s D_1^{s\ell+2} \\ &+ \text{lower-order term in } D_1. \end{aligned}$$

We have produced an infinite sequence of independent elements $\big\{ Ad_B^s L_0 : s = 1, 2, \dots \big\}$ in E. This contradicts our assumption that E is finite dimensional. □

THEOREM 3.4. *Let* E *be a finite-dimensional estimation algebra and* A *be an element in* E *with principal part of* $P_A = \sum_{i \leq j} a_{ij}(x) D_i D_j$. *Suppose that* $\frac{\partial a_{ii}}{\partial x_j}(x) = \frac{\partial a_{jj}}{\partial x_i}(x) = 0$. *Then* $\frac{\partial a_{ij}}{\partial x_i}(x) = \frac{\partial a_{ij}}{\partial x_j}(x) = 0$.

Proof. Without loss of generality, we shall assume $i = 1$ and $j = 2$. Suppose to the contrary that either $\frac{\partial a_{12}}{\partial x_1}(x) \neq 0$ or $\frac{\partial a_{12}}{\partial x_2}(x) \neq 0$. Then

$$P_{[L_0,A]} = \frac{\partial a_{12}}{\partial x_1}(x) D_1^2 D_2 + \frac{\partial a_{12}}{\partial x_2}(x) D_1 D_2^2 + \text{ terms in degree } D_1, D_2 \text{ lower than 3.}$$

If $\frac{\partial a_{12}}{\partial x_1}(x) \neq 0$, then there exists a positive integer ℓ such that

$$\frac{\partial^{\ell} a_{12}}{\partial x_1^{\ell}}(x) \neq 0 \quad \text{and} \quad \frac{\partial^{\ell+1} a_{12}}{\partial x_1^{\ell+1}}(x) = 0.$$

Let $B = Ad_{L_0}^{\ell-1} A \in E$. Then

$$P_B = \frac{\partial^{\ell-1} a_{12}}{\partial x_1^{\ell-1}}(x) D_1^{\ell} D_2 + \text{other terms.}$$

Hence

$$P_{Ad_B^s L_0} = a\Big(\frac{\partial^\ell a_{12}}{\partial x_1^\ell}(x)\Big)^s D_1^{\ell+s} D_2 + \text{other terms},$$

where a is a nonzero constant. So we have produced an infinite sequence $\{Ad_B^s L_0 \in E : s = 1, 2, \dots\}$ of linearly independent elements in E. This contradicts to our hypothesis that $\dim E < \infty$. Therefore we conclude that $\frac{\partial a_{12}}{\partial x_1}(x) = 0$. Similarly, we can prove $\frac{\partial a_{12}}{\partial x_2}(x) = 0$. □

We are now ready to prove the special linear structure of Ω.

THEOREM 3.5. *Suppose that E is a finite-dimensional estimation algebra of maximal rank. Let k be the quadratic rank of E. With the same notation as before let β_{ij} be the linear part of ω_{ij}. Then*

$$\begin{pmatrix} \beta_{jk_{\ell-1}+1} \\ \vdots \\ \beta_{jk_\ell} \end{pmatrix} = A_2^{j,\ell} \widetilde{X_\ell} \qquad \text{for } \ j > k,$$

where $\widetilde{X_\ell} = \big(x_1, \dots, x_{k_{\ell-1}}, x_{k_\ell+1}, \dots, x_k\big)^T$ and $A_2^{j,\ell}$ is a $k_\ell \times (k - k_\ell)$ matrix.

Proof. In view of part (ii) of Theorem 2.8, we have, for $j > k$,

$$\begin{pmatrix} \beta_{jk_{\ell-1}+1} \\ \vdots \\ \beta_{jk_\ell} \end{pmatrix} = \lambda_{j,\ell} X_\ell + A_2^{j,\ell} \widetilde{X_\ell},$$

where $X_\ell = \big(x_{k_{\ell-1}+1}, \dots, x_{k_\ell}\big)^T$. To prove the theorem, we need to prove $\lambda_{j,\ell} = 0$. For this purpose, we need only to prove that $\omega_{mk_{\ell-1}+1}$ does not depend on $x_{k_{\ell-1}+1}$. Since $p_\ell(x) = x_{k_{\ell-1}+1}^2 + \cdots + x_{k_\ell}^2 = \sum_{j \in S_\ell} x_j^2 \in E$, we have

$$\begin{aligned}
\big[L_0, p_\ell\big] \in E &\Longrightarrow \sum_{j \in S_\ell} x_j D_j \in E, \\
\Big[L_0, \sum_{j \in S_\ell} x_j D_j\Big] &= \frac{1}{2} \sum_{i=1}^n \sum_{j \in S_\ell} \big[D_i^2, x_j D_j\big] - \frac{1}{2} E_{k_\ell}(\eta) \\
&= \sum_{i=1}^n \sum_{j \in S_\ell} \left(\delta_{ij} D_i D_j - x_j \omega_{ij} D_i - \frac{1}{2} x_j \frac{\partial \omega_{ij}}{\partial x_i} \right) - \frac{1}{2} E_{k_\ell}(\eta),
\end{aligned}$$

where $E_{k_\ell} = \sum_{j \in S_\ell} x_j \frac{\partial}{\partial x_j}$. Since E is of maximal rank and ω_{ij} is an affine function, we deduce that

$$Z_1 = \sum_{j \in S_\ell} D_j^2 - \sum_{i=1}^n \sum_{j \in S_\ell} x_j \omega_{ij} D_i - \frac{1}{2} E_{k_\ell}(\eta) \in E.$$

It follows from Lemma 2.12 that

$$\begin{aligned}
P_{[L_0, Z_1]} &= P_{\left[\frac{1}{2}\sum_{i=1}^n D_i^2, \sum_{j \in S_\ell} D_j^2\right]} + P_{\left[\frac{1}{2}\sum_{i=1}^n D_i^2, -\sum_{r=1}^n \sum_{j \in S_\ell} x_j \omega_{rj} D_r\right]} \\
&= \sum_{i=1}^n \sum_{j \in S_\ell} 2\omega_{ji} D_j D_i - \sum_{i=1}^n \sum_{r=1}^n \sum_{j \in S_\ell} \frac{\partial (x_j \omega_{rj})}{\partial x_i} D_i D_r.
\end{aligned}$$

Since $\omega_{k_{\ell-1}+1,k_{\ell-1}+1}=0$, the coefficient of $D^2_{k_{\ell-1}+1}$ in $P_{[L_0,Z_1]}$ is

$$-\sum_{j\in S_\ell}\frac{\partial(x_j\omega_{k_{\ell-1}+1,j})}{\partial x_{k_{\ell-1}+1}}=0$$

in view of Theorem 2.9. Similarly, for $m>k=$ quadratic rank of E, we can see that the coefficient of D^2_m is

$$-\sum_{j\in S_\ell}\frac{\partial(x_j\omega_{mj})}{\partial x_m}=0$$

in view of Proposition 2.10. Now the coefficient of $D_{k_{\ell-1}+1}D_m$ is

$$\begin{aligned}
&2\omega_{k_{\ell-1}+1,m}-\sum_{j\in S_\ell}\Big[\frac{\partial(x_j\omega_{k_{\ell-1}+1,j})}{\partial x_m}+\frac{\partial(x_j\omega_{mj})}{\partial x_{k_{\ell-1}+1}}\Big]\\
&=2\omega_{k_{\ell-1}+1,m}-\sum_{j\in S_\ell}\frac{\partial(x_j\omega_{mj})}{\partial x_{k_{\ell-1}+1}}\quad\text{in view of Theorem 2.11}\\
&=3\omega_{k_{\ell-1}+1,m}-\sum_{j\in S_\ell}x_j\frac{\partial\omega_{mj}}{\partial x_{k_{\ell-1}+1}}\\
&=3\omega_{k_{\ell-1}+1,m}-x_{k_{\ell-1}+1}\frac{\partial\omega_{mk_{\ell-1}+1}}{\partial x_{k_{\ell-1}+1}}
\end{aligned}$$

in view of part (ii) of Theorem 2.8. By Theorem 3.4, we know that the coefficient of $D_{k_{\ell-1}+1}D_m$ is independent of $x_{k_{\ell-1}+1}$. This simply means that

$$3\omega_{mk_{\ell-1}+1}+x_{k_{\ell-1}+1}\frac{\partial\omega_{mk_{\ell-1}+1}}{\partial x_{k_{\ell-1}+1}}$$

is independent of $x_{k_{\ell-1}+1}$. Hence $\omega_{mk_{\ell-1}+1}$ does not depend on $x_{k_{\ell-1}+1}$. □

THEOREM 3.6. *With the same hypothesis and notation as in Theorem* 3.5*, then* $A_2^{j,\ell}=0$*, i.e.,* $\beta_{ij}=0$ *for* $i\le k$ *(quadratic rank of* E*)* $<j$.

Proof. Since $[[L_0,p_\ell(x)],D_j]\in E$, we have $\sum_{i\in S_\ell}x_i\beta_{ji}\in E$. Theorem 3.5 says that

$$\begin{pmatrix}\beta_{jk_{\ell-1}+1}\\ \vdots\\ \beta_{jk_\ell}\end{pmatrix}=A_2^{j,\ell}\widetilde{X_\ell},$$

where $\widetilde{X_\ell}=\big(x_1,\dots,x_{k_{\ell-1}},x_{k_\ell+1},\dots,x_k\big)^T$. In view of Lemma 2.3, $X_\ell^TA_2^{j,\ell}\widetilde{X_\ell}=\sum_{i\in S_\ell}x_i\beta_{ji}\in E$ is independent of the $x_{k+1},\dots,x_n$ variable. Hence

$$A_2^{j,\ell}=\big(B_1^{j,\ell},B_2^{j,\ell},\dots\big),$$

where $B_1^{j,\ell},B_2^{j,\ell},\dots$ are constant multiples of some orthogonal matrices by Proposition 2.5. So we have

$$\begin{pmatrix}\beta_{jk_{\ell-1}+1}\\ \vdots\\ \beta_{jk_\ell}\end{pmatrix}=A_2^{j,\ell}\widetilde{X_\ell}=B_1^{j,\ell}X_1+\cdots+B_{\ell-1}^{j,\ell}X_{\ell-1}+B_{\ell+1}^{j,\ell}X_{\ell+1}+\cdots.$$

In order to make clear what our strategy is, in the following we shall list several of these equations explicitly:

$$\begin{pmatrix}\beta_{j1}\\ \vdots\\ \beta_{jk_1}\end{pmatrix} = A_2^{j,1}\widetilde{X_1} = B_2^{j,1}X_2 + B_3^{j,1}X_3 + B_4^{j,1}X_4 + B_5^{j,1}X_5 + \cdots,$$

$$\begin{pmatrix}\beta_{jk_1+1}\\ \vdots\\ \beta_{jk_2}\end{pmatrix} = A_2^{j,2}\widetilde{X_2} = B_1^{j,2}X_1 + B_3^{j,2}X_3 + B_4^{j,2}X_4 + B_5^{j,2}X_5 + \cdots,$$

$$\begin{pmatrix}\beta_{jk_2+1}\\ \vdots\\ \beta_{jk_3}\end{pmatrix} = A_2^{j,3}\widetilde{X_3} = B_1^{j,3}X_1 + B_2^{j,3}X_2 + B_4^{j,3}X_4 + B_5^{j,3}X_5 + \cdots,$$

$$\begin{pmatrix}\beta_{jk_3+1}\\ \vdots\\ \beta_{jk_4}\end{pmatrix} = A_2^{j,4}\widetilde{X_4} = B_1^{j,4}X_1 + B_2^{j,4}X_2 + B_3^{j,4}X_3 + B_5^{j,4}X_5 + \cdots,$$

$$\vdots$$

We first claim that $B_m^{j,\ell} = \big(B_\ell^{j,m}\big)^T$. To see this, we observe that from the cyclic relation $\frac{\partial\omega_{j\ell}}{\partial x_m} + \frac{\partial\omega_{\ell m}}{\partial x_j} + \frac{\partial\omega_{mj}}{\partial x_\ell} = 0$ we deduce that

$$\frac{\partial\beta_{j\ell}}{\partial x_m} + \frac{\partial\beta_{\ell m}}{\partial x_j} + \frac{\partial\beta_{mj}}{\partial x_\ell} = 0.$$

If we take $m, \ell \le k =$ quadratic rank of $E < j$, then $\frac{\partial\beta_{\ell m}}{\partial x_j} = 0$ in view of Theorem 2.11. Therefore the above equation implies

$$\frac{\partial\beta_{j\ell}}{\partial x_m} = \frac{\partial\beta_{jm}}{\partial x_\ell},$$

from which we deduce easily that $B_m^{j,\ell} = \big(B_\ell^{j,m}\big)^T$.

Now we prove $B_1^{j,\ell} = 0$ for $\ell \ge 2$. Since $\sum_{i\in S_\ell} x_i\beta_{ji} = X_\ell^T A_2^{j,\ell}\widetilde{X_\ell} = X_\ell^T B_1^{j,\ell}X_1 + \cdots + X_\ell^T B_{\ell-1}^{j,\ell}X_{\ell-1} + X_\ell B_{\ell+1}^{j,\ell}X_{\ell+1} + \cdots \in E$, we conclude from Lemma 2.4 that $X_\ell^T B_1^{j,\ell}X_1 \in E$. Let $B_1^{j\ell} = \big(b_{ir}^{j\ell}\big), k_{\ell-1}+1 \le i \le k_\ell, 1 \le r \le k_1$. Then

$$\begin{aligned}\big[L_0, X_\ell^T B_1^{j\ell}X_1\big] &= \Big[\frac{1}{2}\sum_{m=1}^n D_m^2, \sum_{i\in S_\ell}\sum_{r\in S_1} x_i b_{ir}^{j\ell}x_r\Big]\\ &= \sum_{m=1}^n\sum_{i\in S_\ell}\sum_{r\in S_1}\big(b_{ir}^{j\ell}x_r\delta_{im}D_m + b_{ir}^{j\ell}x_i\delta_{mr}D_m + b_{ir}^{j\ell}\delta_{im}\delta_{rm}\big)\\ &= \sum_{i\in S_\ell}\sum_{r\in S_1} b_{ir}^{j\ell}x_r D_i + \sum_{i\in S_\ell}\sum_{r\in S_1} b_{ir}^{j\ell}x_i D_r\\ &= \sum_{i\in S_\ell}\sum_{r\in S_1} b_{ir}^{j\ell}\big(x_r D_i + x_i D_r\big) \in E,\end{aligned}$$

$$
\begin{aligned}
W_1 :=& \Big[L_0, \big[L_0, X_\ell^T B_1^{j\ell} X_1\big]\Big] \\
=& \Big[\frac{1}{2}\sum_{m=1}^{n} D_m^2 - \frac{1}{2}\eta, \sum_{i\in S_\ell}\sum_{r\in S_1} b_{ir}^{j\ell}\big(x_r D_i + x_i D_r\big)\Big] \\
=& \frac{1}{2}\sum_{m=1}^{n}\sum_{i\in S_\ell}\sum_{r\in S_1} b_{ir}^{j\ell}\big[D_m^2, x_r D_i + x_i D_r\big] + \text{ function} \\
=& \sum_{m=1}^{n}\sum_{i\in S_\ell}\sum_{r\in S_1} b_{ir}^{j\ell}\big(\delta_{mr} D_m D_i - x_r\omega_{mi} D_m + \delta_{mi} D_m D_r - x_i\omega_{mr} D_m\big) \\
&+ \text{ function} \\
=& 2\sum_{i\in S_\ell}\sum_{r\in S_1} b_{ir}^{j\ell} D_r D_i - \sum_{m=1}^{n}\sum_{i\in S_\ell}\sum_{r\in S_1} b_{ir}^{j\ell}\big(x_r\omega_{mi} + x_i\omega_{mr}\big) D_m \\
&+ \text{ function,} \\
[L_0, W_1] =& \Big[\sum_{m=1}^{n} D_m^2, \sum_{i\in S_\ell}\sum_{r\in S_1} b_{ir}^{j\ell} D_i D_r\Big] \\
&- \Big[\frac{1}{2}\sum_{v=1}^{m} D_v^2, \sum_{m=1}^{n}\sum_{i\in S_\ell}\sum_{r\in S_1} b_{ir}^{j\ell}\big(x_r\omega_{mi} + x_i\omega_{mr}\big) D_m\Big] \\
&+ \text{ first-order term} \\
=& 2\sum_{m=1}^{n}\sum_{i\in S_\ell}\sum_{r\in S_1} b_{ir}^{j\ell}\big(\omega_{rm} D_i D_m + \omega_{im} D_m D_r\big) \\
&- \sum_{v=1}^{n}\sum_{m=1}^{n}\sum_{i\in S_\ell}\sum_{r\in S_1} b_{ir}^{j\ell}\frac{\partial(x_r\omega_{mi} + x_i\omega_{mr})}{\partial x_v} D_v D_m \\
&+ \text{ first-order term.}
\end{aligned}
$$

The coefficient of D_1^2 in $[L_0, W_1]$ is

$$
2\sum_{i\in S_\ell} b_{ir}^{j\ell}\omega_{i1} - \sum_{i\in S_\ell}\sum_{r\in S_1} b_{ir}^{j\ell}\frac{\partial(x_r\omega_{1i} + x_i\omega_{1r})}{\partial x_1} = \sum_{i\in S_\ell} b_{i1}^{j\ell}\omega_{i1},
$$

which is a constant in view of Theorem 2.11.

On the other hand, the coefficient of D_j^2 in $[L_0, W_1]$ for $j > k =$ quadratic rank of E is

$$
-\sum_{i\in S_\ell}\sum_{r\in S_1} b_{ir}^{j\ell}\frac{\partial(x_r\omega_{ji} + x_i\omega_{jr})}{\partial x_j},
$$

which is a zero in view of Theorem 2.11.

We deduce from Theorem 3.4 that the coefficient of $D_1 D_j$ in $[L_0, W_1]$ is independent of x_1 and x_j variables. However, the coefficient of $D_1 D_j$ in $[L_0, W_1]$ is given by

$$
\begin{aligned}
&2\sum_{i\in S_\ell} b_{i1}^{j\ell}\omega_{ij} - \sum_{i\in S_\ell}\sum_{r\in S_1} b_{ir}^{j\ell}\Big(\frac{\partial(x_r\omega_{ji}+x_i\omega_{jr})}{\partial x_1}+\frac{\partial(x_r\omega_{1i}+x_i\omega_{1r})}{\partial x_j}\Big)\\
&= 2\sum_{i\in S_\ell} b_{i1}^{j\ell}\omega_{ij} - \sum_{i\in S_\ell}\sum_{r\in S_1} b_{ir}^{j\ell}\Big(\delta_{1r}\omega_{ji}+x_r\frac{\partial\omega_{ji}}{\partial x_1}+x_i\frac{\partial\omega_{jr}}{\partial x_1}\Big) \text{ in view of Theorem 2.11}\\
&= 2\sum_{i\in S_\ell} b_{i1}^{j\ell}\omega_{ij} - \sum_{i\in S_\ell} b_{i1}^{j\ell}\omega_{ji} - \sum_{i\in S_\ell}\sum_{r\in S_1} b_{ir}^{j\ell}\Big(x_r\frac{\partial\omega_{ji}}{\partial x_1}+x_i\frac{\partial\omega_{jr}}{\partial x_1}\Big)\\
&= 3\sum_{i\in S_\ell} b_{i1}^{j\ell}\omega_{ij} - \sum_{i\in S_\ell}\sum_{r\in S_1} b_{ir}^{j\ell}x_r\frac{\partial\omega_{ji}}{\partial x_1} \quad \text{by Theorem 3.5}\\
&= -3\sum_{i\in S_\ell} b_{i1}^{j\ell}\omega_{ji} - \sum_{i\in S_\ell} b_{i1}^{j\ell}x_1\frac{\partial\omega_{ji}}{\partial x_1} + \text{other terms not involving } x_1\\
&= -3\Big(b_{k_{\ell-1}+1,1}^{j\ell}\omega_{jk_{\ell-1}+1}+b_{k_{\ell-1}+2,1}^{j\ell}\omega_{jk_{\ell-1}+2}+\cdots+b_{k_\ell,1}^{j\ell}\omega_{jk_\ell}\Big)\\
&\quad -\Big(b_{k_{\ell-1}+1,1}^{j\ell}x_1\frac{\partial\omega_{jk_{\ell-1}+1}}{\partial x_1}+b_{k_{\ell-1}+2,1}^{j\ell}x_1\frac{\partial\omega_{jk_{\ell-1}+2}}{\partial x_1}+\cdots+b_{k_\ell,1}^{j\ell}x_1\frac{\partial\omega_{jk_\ell}}{\partial x_1}\Big)\\
&\quad + \text{ other terms not involving } x_1\\
&= -3\Big\{\Big[\Big(b_{k_{\ell-1}+1,1}^{j\ell}\Big)^2x_1+\cdots\Big]+\Big[\Big(b_{k_{\ell-1}+2,1}^{j\ell}\Big)^2x_1+\cdots\Big]+\cdots+\Big[\Big(b_{k_\ell,1}^{j\ell}\Big)^2x_1+\cdots\Big]\Big\}\\
&\quad -\Big[\Big(b_{k_{\ell-1}+1,1}^{j\ell}\Big)^2x_1+\Big(b_{k_{\ell-1}+2,1}^{j\ell}\Big)^2x_1+\cdots+\Big(b_{k_\ell,1}^{j\ell}\Big)^2x_1\Big]\\
&\quad + \text{ other terms not involving } x_1\\
&= -4\sum_{i\in S_\ell}\big(b_{i1}^{j\ell}\big)^2x_1 + \text{other terms not involving } x_1.
\end{aligned}
$$

Therefore we conclude that

$$\sum_{i\in S_\ell}\big(b_{i1}^{j\ell}\big)^2 = 0.$$

This implies that the first column of the matrix $B_1^{j\ell} = \big(b_{ir}^{j\ell}\big)$, $k_{\ell-1}+1 \le i \le k_\ell$, $1 \le r \le k_1$, is a zero vector. Recall that $B_1^{j\ell}$ is either zero or nonsingular. We deduce that $B_1^{j\ell} = 0$ for any $j > k =$ quadratic rank of E and $\ell \ge 2$. By $B_m^{j\ell} = \big(B_\ell^{jm}\big)^T$, we conclude further that

$$
\begin{aligned}
&\begin{pmatrix}\beta_{j1}\\ \vdots\\ \beta_{jk_1}\end{pmatrix} = A_2^{j,1}\widetilde{X_1} = 0,\\
&\begin{pmatrix}\beta_{jk_1+1}\\ \vdots\\ \beta_{jk_2}\end{pmatrix} = A_2^{j,2}\widetilde{X_2} = B_3^{j2}X_3 + B_4^{j2}X_4 + B_5^{j2}X_5 + \cdots,\\
&\begin{pmatrix}\beta_{jk_2+1}\\ \vdots\\ \beta_{jk_3}\end{pmatrix} = A_2^{j,3}\widetilde{X_3} = B_2^{j3}X_2 + B_4^{j3}X_4 + B_5^{j3}X_5 + \cdots,
\end{aligned}
$$

$$\begin{pmatrix} \beta_{jk_3+1} \\ \vdots \\ \beta_{jk_4} \end{pmatrix} = A_2^{j,4}\widetilde{X_4} = B_2^{j4}X_2 + B_3^{j4}X_3 + B_5^{j4}X_5 + \cdots,$$

$$\vdots$$

Similarly, by considering an element in E of the form $\sum_{i\in S_\ell} x_i\beta_{ji} = X_\ell^T A_2^{j,\ell}\widetilde{X_\ell}$ for $\ell \geq 3$, we can prove that $B_2^{j,\ell} = 0$ for $\ell \geq 3$. As before, we deduce $A_2^{j,2} = 0$ in view of $B_m^{j\ell} = \left(B_\ell^{jm}\right)^T$. Hence Theorem 3.6 follows easily by induction. □

As a consequence of Theorem 3.6 and Theorem 2.11, we have proved the following theorem.

THEOREM 3.7. *Let E be a finite-dimensional estimation algebra of maximal rank and k be the maximal rank of quadratic forms in E. Then* (1) *ω_{ij} are constants for $1 \leq i \leq k$ or $1 \leq j \leq k$;* (2) *ω_{ij} are affine polynomials in $x_{k+1}, \ldots, x_n$ for $k+1 \leq i, j \leq n$.*

4. Structure of η. In this section, we shall study the possible structure of η, where

$$\eta = \sum_{i=1}^{n} \frac{\partial f_i}{\partial x_i} + \sum_{i=1}^{n} f_i^2 + \sum_{i=1}^{m} h_i^2. \tag{4.1}$$

LEMMA 4.1. *Let E be a finite-dimensional estimation algebra of maximal rank. Then η is a polynomial of degree at most four.*

Proof. Since E is a finite-dimensional estimation algebra with maximal rank for any $1 \leq i \leq n$, there exists constant c_i such that $x_i + c_i$ is in E. Observe that

$$\begin{aligned} &[L_0, x_j + c_j] = D_j \in E, \\ &[D_j, x_j + c_j] = 1 \in E, \\ &[L_0, D_j] = \sum_{i=1}^{n} \left(\omega_{ji}D_i + \frac{1}{2}\frac{\partial \omega_{ji}}{\partial x_i}\right) + \frac{1}{2}\frac{\partial \eta}{\partial x_j} \in E. \end{aligned}$$

Since ω_{ji}, $1 \leq i, j \leq n$, are polynomial of degree at most one, we deduce that

$$Y_j := \sum_{i=1}^{n} \omega_{ji}D_i + \frac{1}{2}\frac{\partial \eta}{\partial x_j} \in E. \tag{4.2}$$

As

$$[Y_j, D_m] = \sum_{i=1}^{n} \left(\omega_{ji}\omega_{mi} - \frac{\partial \omega_{ji}}{\partial x_m}D_i\right) - \frac{1}{2}\frac{\partial^2 \eta}{\partial x_m \partial x_j} \in E,$$

we deduce that

$$\sum_{\ell=1}^{n} \omega_{j\ell}\omega_{\ell m} + \frac{1}{2}\frac{\partial^2 \eta}{\partial x_m \partial x_j} \in E \tag{4.3}$$

for all $1 \leq j, m \leq n$. Hence $\frac{\partial^2 \eta}{\partial x_m \partial x_j}$ for $1 \leq j, m \leq n$ are polynomials of degree at most two in view of Ocone's theorem. It follows that η is a polynomial of degree at most four. □

Notation. η_4 is denoted the homogeneous part of degree four of η.

PROPOSITION 4.2. *Let E be a finite-dimensional estimation algebra of maximal rank. Then η_4 does not contain $x_{i_1}x_{i_2}x_jx_m$ for $i_1 \le k < i_2$, where k is the quadratic rank of E.*

Proof. Let us assume that this is false. From (4.3), we have

$$\sum_{\ell=1}^{n} \omega_{i_1\ell}\omega_{\ell m} + \frac{1}{2}\frac{\partial^2 \eta}{\partial x_m \partial x_{i_1}} \in E. \tag{4.4}$$

Recall that $\omega_{i_1\ell},\ 1 \le \ell \le n$, are constants, while $\omega_{\ell m},\ 1 \le \ell \le n$, are polynomials of degree one in $x_{k+1}, \dots, x_n$ by Theorem 3.7. Equation (4.4) says that E contains a quadratic form with term of the form $x_{i_2}x_j$. This contradicts Lemma 2.3. □

The following proposition also follows immediately from Theorem 3.7.

PROPOSITION 4.3. *Let E be a finite-dimensional estimation algebra of maximal rank with quadratic rank k. If $i \le k < j$, then $\sum_{\ell=1}^{n} \omega_{i\ell}\omega_{\ell j}$ is a degree-one polynomial in $x_{k+1}, \dots, x_n$.*

THEOREM 4.4. *Let E be a finite-dimensional estimation algebra of maximal rank with quadratic rank k. Then η_4 is an homogeneous polynomial of degree four depending only on $x_{k+1}, \dots, x_n$ variables.*

Proof. Since $p_0(x) = x_1^2 + \cdots + x_k^2 \in E$ by (2.4), we have

$$[L_0, p_0] \in E \Rightarrow \widetilde{E_k} := \sum_{i=1}^{k} x_i D_i \in E.$$

Let $E_k = \sum_{i=1}^{k} x_i \frac{\partial}{\partial x_i}$. Then in view of (4.2), we have

$$\begin{aligned}
[\widetilde{E_k}, Y_j] &= \Big[\sum_{i=1}^{k} x_i D_i, \sum_{i=1}^{k} \omega_{j\ell} D_\ell + \frac{1}{2}\frac{\partial \eta}{\partial x_j}\Big] \\
&= \sum_{i=1}^{k}\sum_{\ell=1}^{n} [x_i D_i, \omega_{j\ell} D_\ell] + \frac{1}{2} E_k\left(\frac{\partial \eta}{\partial x_j}\right) \\
&= \sum_{i=1}^{k}\sum_{\ell=1}^{n} \left(-x_i\omega_{j\ell}\omega_{i\ell} + x_i \frac{\partial \omega_{j\ell}}{\partial x_i} D_\ell - \omega_{j\ell}\delta_{i\ell} D_i\right) + \frac{1}{2} E_k\left(\frac{\partial \eta}{\partial x_j}\right) \\
&= \sum_{\ell=1}^{n} E_k(\omega_{j\ell}) D_\ell - \sum_{i=1}^{k} \omega_{ji} D_i + \frac{1}{2} E_k\left(\frac{\partial \eta}{\partial x_j}\right) - \sum_{\ell=1}^{n}\sum_{i=1}^{k} x_i \omega_{j\ell}\omega_{i\ell} \\
&\in E.
\end{aligned} \tag{4.5}$$

Recall that $\omega_{j\ell},\ 1 \le j, \ell \le n$, are polynomials depending only on $x_{k+1}, \dots, x_n$. So $E_k(\omega_{j\ell}) = 0$ for $1 \le j, \ell \le n$. Since $\omega_{ji},\ 1 \le i \le k$, are constants and $D_i, 1 \le i \le k$, are in E, we deduce from (4.5) that

$$\frac{1}{2} E_k\left(\frac{\partial \eta}{\partial x_j}\right) - \sum_{i=1}^{k} x_i \Big(\sum_{\ell=1}^{n} \omega_{j\ell}\omega_{i\ell}\Big) \in E. \tag{4.6}$$

The second term in (4.6) is a polynomial of degree at most two by Proposition 4.3. This implies that

$$E_k\left(\frac{\partial \eta_4}{\partial x_j}\right) = 0, \qquad 1 \le j \le n, \tag{4.7}$$

because $E_k\left(\frac{\partial \eta_4}{\partial x_j}\right)$ is a polynomial of degree three. By Proposition 4.2, we have

$$\eta_4(x_1, \dots, x_n) = \eta_4^1(x_1, \dots, x_k) + \eta_4^2(x_{k+1}, \dots, x_n),$$

where η_4^1 and η_4^2 are homogeneous polynomials of degree four. Equation (4.7) is equivalent to

$$E_k\left(\frac{\partial \eta_4^1}{\partial x_j}\right) = 0, \qquad 1 \le j \le k. \tag{4.8}$$

Since

$$E_k\left(\frac{\partial \eta_4^1}{\partial x_j}\right) = 3\frac{\partial \eta_4^1}{\partial x_j}, \qquad 1 \le j \le k,$$

we deduce easily that $\eta_4^1(x_1, \dots, x_k) = 0$. So η_4 depends only on $x_{k+1}, \dots, x_n$ variables. □

5. Mitter conjecture. If E is a finite-dimensional estimation algebra, Ocone's theorem says that h_i, $1 \le i \le m$, are polynomials of degree at most two. Mitter conjecture asserts that h_i has to be affine (i.e., degree-one polynomial). In this section, we shall prove the Mitter conjecture for finite-dimensional estimation algebras of maximal rank. For this purpose, let us first recall the following theorem proven in [Ya].

THEOREM 5.1. *Let $F(x_1, \dots, x_n)$ be a polynomial on $\mathbb{R}^n$. Suppose that there exists a polynomial path $c : \mathbb{R} \to \mathbb{R}^n$ such that $\lim_{t\to\infty} \|c(t)\| = \infty$ and $\lim_{t\to\infty} F \circ c(t) = -\infty$. Then there are no c^∞ functions $f_1, \dots, f_n$ on $\mathbb{R}^n$ satisfying the equation*

$$\sum_{i=1}^n \frac{\partial f_i}{\partial x_i} + \sum_{i=1}^n f_i^2 = F.$$

THEOREM 5.2. *If E is a finite-dimensional estimation algebra of maximal rank, then h_i, $1 \le i \le m$, are degree-one polynomials.*

Proof. For $1 \le i \le m$, let $h_i(x) = q_i(x) + \ell_i(x)$, where $q_i(x)$ is a homogeneous degree-two polynomial, while $\ell_i(x)$ is a degree-one polynomial. Since $h_i \in E$ by definition, we deduce that $q_i(x)$ is also in E for all $1 \le i \le m$ by the maximal rank condition of E. In view of Lemma 2.3, we conclude that q_i depends only on $x_1, x_2, \dots, x_k$ variables for all $1 \le i \le m$. Hence

$$h_i(x) = q_i(x_1, \dots, x_k) + \ell_i(x), \qquad 1 \le i \le m.$$

On the other hand, Theorem 4.4 tells us that

$$\sum_{i=1}^n \frac{\partial f_i}{\partial x_i} + \sum_{i=1}^n f_i^2 + \sum_{i=1}^m h_i^2 = \eta_4(x_{k+1}, \dots, x_n) + \text{ polynomial of degree three},$$

which implies

$$\begin{aligned} &\sum_{i=1}^n \frac{\partial f_i}{\partial x_i} + \sum_{i=1}^n f_i^2 \\ &= -\sum_{i=1}^m \big(q_i(x_1, \dots, x_k)\big)^2 + \eta_4(x_{k+1}, \dots, x_n) + \text{ polynomial of degree three}. \end{aligned}$$

The above equation and Theorem 5.1 imply that $q_i(x_i, \dots, x_k) = 0$ for all $1 \le i \le m$; i.e., $h_i(x)$, $1 \le i \le m$, are degree-one polynomials. □

FINITE-DIMENSIONAL FILTERS WITH NONLINEAR DRIFT VIII: CLASSIFICATION OF FINITE-DIMENSIONAL ESTIMATION ALGEBRAS OF MAXIMAL RANK WITH STATE-SPACE DIMENSION 4*

JIE CHEN†, STEPHEN S.-T. YAU†, AND CHI-WAH LEUNG‡

Abstract. The idea of using estimation algebra to construct finite-dimensional nonlinear filters was first proposed independently by Brockett and Mitter. Estimation algebra turns out to be a useful concept in the investigation of finite-dimensional nonlinear filters. In his talk at the International Congress of Mathematics in 1983, Brockett proposed classifying all finite-dimensional estimation algebras. Chiou and the present authors classify all finite-dimensional estimation algebras of maximal rank with dimension of the state space less than or equal to three. In this paper, we succeed in classifying all finite-dimensional estimation algebras of maximal rank with state-space dimension equal to four. In fact our method gives classification of all finite-dimensional algebras of maximal rank with state-space dimension equal to or less than four.

Key words. finite-dimensional filter, estimation algebra of maximal rank, nonlinear drift, state-space dimension 4

1. Introduction.

In the 1960s and early 1970s, the basic approach to nonlinear filtering theory was via the "innovation methods" originally proposed by Kailath and subsequently rigorously developed by Fujisaki, Kallianpur, and Kunita [FKK] in 1972. As pointed out by Mitter [Mi], the difficulty with this approach is that the innovation process is not, in general, explicitly computable (except in the well-known Kalman–Bucy case). In the late 1970s, Brockett and Clark [BrCl], Brockett [Br], and Mitter [Mi] proposed the idea of using estimation algebras to construct a finite-dimensional nonlinear filter. The advantage of this finite-dimensional nonlinear filter is the same as the Kalman–Bucy filter. Moreover it avoids the disadvantages of the Kalman–Bucy filter such as the Gaussian initial condition as well as linearity assumption of the drift term. For more detail, we refer the readers to [TWY], [Ya], and the very interesting Ph.D. thesis by M. Cohen de Lara [La], in which the links between finite-dimensional estimation algebras and finite-dimensional filters were discussed. In [Ya], Yau has studied the general class of nonlinear filtering systems which included both Kalman–Bucy and Benes filtering systems as special cases. He gives necessary and sufficient conditions for an estimation algebra of such filtering systems to be finite dimensional. Using the Wei–Norman approach, he constructed explicitly finite-dimensional recursive filters for such a nonlinear filtering systems.

In his talk at the International Congress of Mathematics in 1983, Brockett proposed classifying all finite-dimensional estimation algebras. Since then, the concept of estimation algebra has been proven to be an invaluable tool in the study of nonlinear filtering problems. If the drift term of the nonlinear filtering system has a

potential function (i.e., drift term is a gradient vector field), then the corresponding estimation algebra is called exact. In [TWY], Tam, Wong, and Yau have classified all finite-dimensional exact estimation algebras of maximal rank with arbitrary state-space dimension. In [ChYa], Chiou and Yau are able to classify all finite-dimensional estimation algebras of maximal rank with state-space dimension less than or equal to two. The novelty of their theorem is that there is no assumption on the drift term of the nonlinear filtering system. In [CLY], Chen, Leung, and Yau classify all finite-dimensional estimation algebras of maximal rank with state-space dimension equal to 3 (without any assumption on the drift term). This paper is a natural continuation of [ChYa] and [CLY]. The following is our main theorem.

MAIN THEOREM. *Suppose that the state space of the filtering system* (2.1) *is of dimension* $n \leq 4$. *If* E *is the finite-dimensional estimation algebra of maximal rank, then the drift term* f *must be a linear vector field (i.e., each component is a polynomial of degree one) plus a gradient vector field and* E *is a real vector space of dimension* $2n + 2$ *with basis given by* $1, x_1, \ldots, x_n, D_1, \ldots, D_n$ *and* L_0. *Moreover* η *is a degree* 2 *polynomial.*

This kind of nonlinear filtering system was studied by Yau [Ya]. Therefore, from Lie algebraic point of view, we have shown that the finite-dimensional filters considered in [Ya] are the most general finite-dimensional filters (cf. [Ch] for a nice review of the Yau filter).

Let $\omega_{ij} = \frac{\partial f_j}{\partial x_i} - \frac{\partial f_i}{\partial x_j}$, which was first introduced by Wong [Wo3]. Our strategy is to prove ω_{ij} constant for all i, j. Then we can apply the result of [Ya] to finish the proof. This involves two steps. The first step is to prove that ω_{ij} is a degree-one polynomial. Let n be the dimension of the state space. In the case $n = 3$ there are three unknowns: ω_{12}, ω_{13}, and ω_{23}. It is easy to see that they are all degree-two polynomials in view of Ocone's theorem. In [YaLe], Leung and Yau showed that the coefficients of the quadratic parts of ω_{12}, ω_{13}, and ω_{23} have to satisfy 90 quadratic equations. It was shown in that paper that the 90 quadratic equations have only a trivial solution. Hence the proof of the first step is completed in this case. Obviously, this approach encounters difficulty when n is greater than 3. Fortunately, Chen and Yau [ChYa1] were able to prove that ω_{ij} is a degree-one polynomial for arbitrary n by means of their new algebraic technique. The second step is to prove that ω_{ij} is actually a constant. This is the hard part of the problem of classification of finite-dimensional estimation algebras of maximal rank. The purpose of this paper is to deal with the hard part of the problem by proving ω_{ij} constant for $n \leq 4$. We introduce a new matrix equation. The key point of this paper is to show that this matrix has no nontrivial solution. The advantage of our new technique is not only that we can obtain entirely new results for $n = 4$ but also that we have simple uniform proof of our previous results for $n \leq 3$.

The paper is in essence a continuation of [Ya], [ChYa], [CLY], [ChYa1], [ChYa2], and we strongly recommend that readers familiarize themselves with the results in [Ya], [ChYa1], [ChYa2]. However, every effort will be made to make this paper as self-contained as possible, with minimal duplication of the previous papers.

2. Basic concepts. In this section, we shall recall some basic concepts and results from [Ya] and [ChYa]. Consider a filtering problem based on the following observation model:

$$\begin{cases} dx(t) = f(x(t))dt + g(x(t))dv(t), & x(0) = x_0, \\ dy(t) = h(x(t))dt + dw(t), & y(0) = 0, \end{cases} \tag{2.1}$$

in which x, v, y, and w are, respectively, $\mathbb{R}^n$-, $\mathbb{R}^p$-, $\mathbb{R}^m$-, and $\mathbb{R}^m$-valued processes and v and w have components which are independent, standard Brownian processes. We further assume that $n = p, f, h$ are C^∞ smooth and that g is an orthogonal matrix. We shall refer to $x(t)$ as the state of the system at time t and to $y(t)$ as the observation at time t.

Let $\rho(t, x)$ denote the conditional density of the state given the observation $\{y(s) : 0 \le s \le t\}$. It is well known (see [DaMa], for example) that $\rho(t, x)$ is given by normalizing a function, $\sigma(t, x)$, which satisfies the Duncan–Mortensen–Zakai equation:

$$d\sigma(t,x) = L_0\sigma(t,x)dt + \sum_{i=1}^{m} L_i\sigma(t,x)dy_i(t), \qquad \sigma(0,x) = \sigma_0, \tag{2.2}$$

where

$$L_0 = \frac{1}{2}\sum_{i=1}^{n}\frac{\partial^2}{\partial x_i^2} - \sum_{i=1}^{n} f_i\frac{\partial}{\partial x_i} - \sum_{i=1}^{n}\frac{\partial f_i}{\partial x_i} - \frac{1}{2}\sum_{i=1}^{m} h_i^2$$

and for $i = 1, \dots, m$, L_i is the zero-degree differential operator of multiplication by h_i, σ_0 is the probability density of the initial point x_0. In this paper, we will assume σ_0 is a C^∞ function.

Equation (2.2) is a stochastic partial differential equation. The stochastic differential is a Stratonovich one and not an Ito one. In real applications, we are interested in constructing state estimators from observed sample paths with some property of robustness. Based on Rozovsky's transformation [Ro],

$$\xi(t,x) = \exp\Big(-\sum_{i=1}^{m} h_i(x)y_i(t)\Big)\sigma(t,x),$$

Davis [Da] proposed studying the following robust Duncan–Mortensen–Zakai equation:

$$\begin{aligned} &\frac{\partial\xi}{\partial t}(t,x) = L_0\xi(t,x) + \sum_{i=1}^{m} y_i(t)[L_0, L_i]\xi(t,x) + \frac{1}{2}\sum_{i,j=1}^{m} y_i(t)y_j(t)[[L_0, L_i], L_j]\xi(t,x), \\ &\xi(0,x) = \sigma_0, \end{aligned} \tag{2.3}$$

which is a time-varying partial differential equation. Here we have used the following notation.

DEFINITION 1. *If X and Y are differential operators, the Lie bracket of X and Y, $[X, Y]$, is defined by $[X, Y]\phi = X(Y\phi) - Y(X\phi)$ for any C^∞ function ϕ.*

DEFINITION 2. *The estimation algebra E of a filtering problem* (2.1) *is defined to be the Lie algebra generated by $\{L_0, L_1, \dots, L_m\}$. E is said to be an estimation algebra of maximal rank if for any $1 \le i \le n$ there exists a constant c_i such that $x_i + c_i$ is in E.*

Most of the known finite-dimensional estimation algebras are maximal. For example, if (2.1) is linear, i.e., $f(x) = Ax$, $g(x) = B$, and $h(x) = Cx$, and if (A, B, C)

also is minimal, then the corresponding estimation algebra is maximal [Ha]. We need the following basic result for later discussion.

THEOREM 2.1 (Ocone). *Let E be a finite-dimensional estimation algebra. If a function ξ is in E, then ξ is a polynomial of degree at most two.*

In [Wo3], the concept of Ω is introduced, defined as the matrix whose (i,j)-element ω_{ij} is $\frac{\partial f_j}{\partial x_i} - \frac{\partial f_i}{\partial x_j}$. Define

$$D_i = \frac{\partial}{\partial x_i} - f_i$$

and

$$\eta = \sum_{i=1}^{n} \frac{\partial f_i}{\partial x_i} + \sum_{i=1}^{n} f_i^2 + \sum_{i=1}^{m} h_i^2.$$

Then

$$L_0 = \frac{1}{2}\left(\sum_{i=1}^{n} D_i^2 - \eta\right).$$

The following theorem proved in [Ya] plays a fundamental role in the classification of finite-dimensional estimation algebras.

THEOREM 2.2 (Yau). *Let E be a finite-dimensional estimation algebra of* (2.1) *such that $\omega_{ij} = \frac{\partial f_j}{\partial x_i} - \frac{\partial f_i}{\partial x_j}$ are constant functions. If E is of maximal rank, then E is a real vector space of dimension $2n+2$ with basis given by $1, x_1, x_2, \dots, x_n, D_1, D_2, \dots, D_n$ and L_0.*

Recently, Chen and Yau [ChYa1] have made important progress in the program of classification of finite-dimensional estimation algebras of maximal rank. Namely, they have shown that Ω matrix is linear in the sense that all ω_{ij} are degree-one polynomials. More recently, in order to prove the Mitter conjecture for finite-dimensional estimation algebra of maximal rank, Chen and Yau [ChYa2] have sharpened the above result. To describe this new result, let us first recall some important concepts and notations introduced in [ChYa1].

Let Q be the space of quadratic forms in n variables, i.e., real vector space spanned by $x_i x_j$, with $1 \le i \le j \le n$. Let $X = (x_1, \dots, x_n)^T$. For any quadratic form $p \in Q$, there exists a symmetric matrix A such that $p(x) = X^T A X$. The rank of the quadratic form p is denoted by $\mathrm{rk}(p)$ and is defined to be the rank of the matrix A.

DEFINITION 3. *A fundamental quadratic form of the estimation algebra E is an element $p_0 \in E \cap Q$ with the greatest positive rank, i.e.,* $\mathrm{rk}(p_0) \ge \mathrm{rk}(p)$ *for any $p \in E \cap Q$. The quadratic rank of the estimation algebra E is defined to be* $\mathrm{rk}(p_0)$. *The following Theorem* 2.3 *and Proposition* 2.4 *are proved in* [ChYa2].

THEOREM 2.3. *Let E be a finite-dimensional estimation algebra of maximal rank. Let k be the quadratic rank of E. Then*

(1) *the observation terms $h_i(x), 1 \le i \le m$, are affine polynomials.*

(2) (a) *ω_{ij}, for $1 \le i \le k$ or $1 \le j \le k$, are constants.*

(b) *ω_{ij}, for $k+1 \le i, j \le n$, are degree-one polynomials in $x_{k+1}, \dots, x_n$.*

(3) *$\eta = \sum_{i=1}^{n} \frac{\partial f_i}{\partial x_i} + \sum_{i=1}^{n} f_i^2 + \sum_{i=1}^{m} h_i^2$ is a homogeneous polynomial of degree four. Moreover, η_4 (homogeneous polynomial of degree-four part of η) depends only on $x_{k+1}, \dots, x_n$ variables.*

PROPOSITION 2.4. *Let E be a finite-dimensional estimation algebra of maximal rank. Let k be the quadratic rank of E. Then η is a polynomial of degree at most four, and any homogeneous polynomial of degree two in E depends only on $x_1, x_2, \dots, x_k$.*

Finally, we need to recall the following theorem proved in [Ya].

THEOREM 2.5. *Let $F(x_1, \dots, x_n)$ be a polynomial on $\mathbb{R}^n$. Suppose that there exists a polynomial path $c : \mathbb{R} \to \mathbb{R}^n$ such that $\lim_{t\to\infty}||c(t)|| = \infty$ and $\lim_{t\to\infty}F(c(t)) = -\infty$. Then there are no C^∞ functions $f_1, \dots, f_n$ on $\mathbb{R}^n$ satisfying the equations*

$$\sum_{i=1}^{n} \frac{\partial f_i}{\partial x_i} + \sum_{i=1}^{n} f_i^2 = F.$$

3. Proof of the main theorem. From Yau's theory [Ya], to classify all finite-dimensional estimation algebras of maximal rank, we need only to prove that the ω_{ij}'s corresponding to these estimation algebras of maximal rank are automatically constants.

We first introduce a new matrix equation which turns out to play an important role in classification of finite-dimensional estimation algebras of maximal rank.

THEOREM 3.1. *Suppose that η_4 is a homogeneous polynomial of degree four in n variables. If $n \le 4$ and $\triangle$ is an antisymmetric matrix with each entry a homogeneous polynomial of degree one such that*

$$\triangle\triangle^T = \frac{1}{2}H(\eta_4), \tag{3.1}$$

where $H(\eta_4) = (\frac{\partial^2\eta_4}{\partial x_i \partial x_j})$ is the Hessian matrix of η_4, then $\triangle = 0$.

Proof. Write

$$\triangle = \sum_{i=1}^{n} A_i x_i, \tag{3.2}$$

$$\frac{1}{2}H(\eta_4) = \sum_{i\le j} H_{ij} x_i x_j, \tag{3.3}$$

where A_i's are real $n \times n$ antisymmetric matrices and H_{ij}'s are real $n \times n$ symmetric matrices, i.e.,

$$A_i = -A_i^T, \tag{3.4}$$

$$H_{ij} = H_{ij}^T. \tag{3.5}$$

Then (3.1) implies

$$A_i^2 = -H_{ii}, \tag{3.6}$$

$$A_iA_j + A_jA_i = -H_{ij}. \tag{3.7}$$

Denote the (i, j) entry of the matrix M by $M(i, j)$. For $i > j$, we let $H_{ij} = H_{ji}$. Note that

$$\frac{\partial^2(x_i^2x_j^2)}{\partial x_i^2} = 2x_j^2, \qquad \frac{\partial^2(x_i^2x_j^2)}{\partial x_j^2} = 2x_i^2, \quad \text{and} \qquad \frac{\partial^2(x_i^2x_j^2)}{\partial x_i\partial x_j} = 4x_ix_j. \tag{3.8}$$

From (3.3) and (3.8), we get

$$2H_{ii}(j, j) = 2H_{jj}(i, i) = H_{ij}(i, j) \quad \text{for } i \ne j. \tag{3.9}$$

Hence, for $i \neq j$, (3.6), (3.7), and (3.9) imply

$$\sum_l A_i(j,l)A_i(l,j) = \sum_l A_j(i,l)A_j(l,i) = \frac{1}{2}\sum_l \big[A_i(i,l)A_j(l,j) + A_j(i,l)A_i(l,j)\big]. \tag{3.10}$$

Recall that each A_i is an antisymmetric matrix. So (3.10) is reduced to the following equation:

$$\sum_l \big[A_i(j,l)\big]^2 = \sum_l \big[A_j(i,l)\big]^2 = \frac{1}{2}\sum_l \big[A_i(i,l)A_j(j,l) + A_j(i,l)A_i(j,l)\big]. \tag{3.11}$$

In view of the Schwarz inequality, we have

$$\begin{aligned} 2\sum_l \big[A_i(j,l)\big]^2 + 2\sum_l \big[A_j(i,l)\big]^2 &= 2\sum_l A_i(i,l)A_j(j,l) + 2\sum_l A_j(i,l)A_i(j,l) \\ &\le \sum_{l\neq i,j} \big[A_i(i,l)\big]^2 + \sum_{l\neq i,j} \big[A_j(j,l)\big]^2 + \sum_{l\neq i,j} \big[A_j(i,l)\big]^2 \\ &\quad + \sum_{l\neq i,j} \big[A_i(j,l)\big]^2. \end{aligned} \tag{3.12}$$

This implies

$$\begin{aligned} &\sum_l \big[A_i(j,l)\big]^2 + \sum_l \big[A_j(i,l)\big]^2 + \sum_{l=i,j} \big[A_j(i,l)\big]^2 + \sum_{l=i,j} \big[A_i(j,l)\big]^2 \\ &\qquad \le \sum_{l\neq i,j} \big[A_i(i,l)\big]^2 + \sum_{l\neq i,j} \big[A_j(j,l)\big]^2. \end{aligned} \tag{3.13}$$

Taking the sum of left-hand side of (3.13) over $i < j$, we get

$$\begin{aligned} &\sum_{i<j}\sum_{l=1}^n \big[A_i(j,l)\big]^2 + \sum_{i<j}\sum_{l=1}^n \big[A_j(i,l)\big]^2 + \sum_{i<j} \big[A_j(i,j)\big]^2 + \sum_{i<j} \big[A_i(j,i)\big]^2 \\ &\quad = \sum_{i<j}\sum_{l=1}^n \big[A_i(j,l)\big]^2 + \sum_{j<i}\sum_{l=1}^n \big[A_j(i,l)\big]^2 + \sum_{i<j} \big[A_j(i,j)\big]^2 + \sum_{j<i} \big[A_j(i,j)\big]^2 \\ &\quad = \sum_{i\neq l, i\neq j} \big[A_i(j,l)\big]^2 + 2\sum_{i\neq l} \big[A_i(i,l)\big]^2. \end{aligned} \tag{3.14}$$

On the other hand, by taking the sum of right-hand side of (3.13) over $i < j$, we get

$$\begin{aligned} &\sum_{i<j}\sum_{l\neq i,j} \big[A_i(i,l)\big]^2 + \sum_{i<j}\sum_{l\neq i,j} \big[A_j(j,l)\big]^2 \\ &\quad = \sum_{i<j}\sum_{l\neq i,j} \big[A_i(i,l)\big]^2 + \sum_{j<i}\sum_{l\neq i,j} \big[A_i(i,l)\big]^2 \\ &\quad = (n-2)\sum_{i\neq l} \big[A_i(i,l)\big]^2. \end{aligned} \tag{3.15}$$

Comparing (3.14) and (3.15), we get

$$\sum_{i\neq l, i\neq j} \big[A_i(j,l)\big]^2 = (n-4)\sum_{i\neq l} \big[A_i(i,l)\big]^2. \tag{3.16}$$

When $n = 4$, we see from (3.16) that

$$\sum_{i\neq l, i\neq j} \big[A_i(j,l)\big]^2 = 0;$$

hence

$$A_i(j,l) = 0 \quad \text{for } i \neq j \quad \text{and } i \neq l. \tag{3.17}$$

Using (3.17) in (3.10) gives

$$\big[A_i(i,j)\big]^2 = \big[A_j(j,i)\big]^2. \tag{3.18}$$

Note that for $i < j$

$$\frac{\partial^2 x_i^3 x_j}{\partial x_i \partial x_j} = 3x_i^2 \quad \text{and} \quad \frac{\partial^2 x_i^3 x_j}{\partial x_i^2} = 6x_i x_j. \tag{3.19}$$

From (3.3) and (3.19), we get

$$2H_{ij}(i,i) = H_{ii}(i,j). \tag{3.20}$$

In view of (3.6), (3.7), and (3.20), we have

$$2\sum_l A_i(i,l)A_j(l,i) = \sum_l A_i(i,l)A_i(l,j). \tag{3.21}$$

Using (3.17) in (3.21) gives

$$A_i(i,j)A_j(j,i) = 0. \tag{3.22}$$

In view of (3.18) and (3.22), we get

$$A_i(i,j) = 0 \quad \text{for all } i,j. \tag{3.23}$$

Therefore $A_1 = A_2 = A_3 = A_4 = 0$ by (3.17) and (3.23). This simply means that $\triangle = 0$. □

PROPOSITION 3.2. *Let E be a finite-dimensional estimation algebra of maximal rank associated with the filtering system* (2.1). *Then E contains the real vector space spanned by $1, x_1, \ldots, x_n, D_1, \ldots, D_n$ and L_0.*

Proof. Since E is a finite-dimensional estimation algebra with maximal rank, there are constants c_i's such that $x_i + c_i$ is in E for $1 \leq i \leq n$:

$$[L_0, x_j + c_j] = \frac{1}{2}\left[\sum_{i=1}^n D_i^2 - \eta, x_j\right] = \frac{1}{2}\sum_{i=1}^n \big[D_i^2, x_j\big] = D_j \in E,$$
$$[D_j, x_j + c_j] = 1 \in E.$$

Hence $x_1, \ldots, x_n \in E$. □

We are now ready to prove the main theorem of this paper stated in section 1. By Theorem 2.3, we know that ω_{ij}'s are constants for $1 \le i \le k$ or $1 \le j \le k$, where k is the quadratic rank of E. We also know that ω_{ij}'s are degree-one polynomials in $x_{k+1}, \dots, x_n$ variables for $k+1 \le i, j \le n$. We are going to prove that ω_{ij}'s are indeed constants for $k+1 \le i, j \le n$ and $n \le 4$. Observe that

$$\begin{aligned}\big[[L_0, D_j], D_l\big] &= \left[\sum_{i=1}^{n}\left(\omega_{ji}D_i + \frac{1}{2}\frac{\partial \omega_{ji}}{\partial x_i}\right) + \frac{1}{2}\frac{\partial \eta}{\partial x_j}, D_l\right] \\ &= \sum_{i=1}^{n}\left(\omega_{ji}\omega_{li} - \frac{\partial \omega_{ji}}{\partial x_l}D_i\right) - \frac{1}{2}\sum_{i=1}^{n}\frac{\partial^2 \omega_{ji}}{\partial x_l \partial x_i} - \frac{1}{2}\frac{\partial^2 \eta}{\partial x_l \partial x_j} \\ &\in E.\end{aligned}$$

In view of Theorem 2.3 and Proposition 3.2, we deduce that

$$\sum_{i=1}^{n}\omega_{ji}\omega_{li} - \frac{1}{2}\frac{\partial^2 \eta}{\partial x_l \partial x_j} \in E. \tag{3.24}$$

Let η_m be the homogeneous polynomial of the degree-m part of η and β_{ij} be the homogeneous polynomial of the degree-one part of ω_{ij}. Then in view of Theorem 2.3 and Proposition 3.2, we have

$$\sum_{i=k+1}^{n}\beta_{ji}\beta_{li} - \frac{1}{2}\frac{\partial^2 \eta_4}{\partial x_l \partial x_j} \in E \tag{3.25}$$

for $k+1 \le l, j \le n$. Observe that $\sum_{i=k+1}^{n}\beta_{ji}\beta_{li} - \frac{1}{2}\frac{\partial^2 \eta}{\partial x_l \partial x_j}$ is a homogeneous polynomial of degree two in E which depends only on $x_1, \dots, x_k$ variables because k is the quadratic rank of E. On the other hand η_4, β_{ji}, and β_{li}, for $k+1 \le i, j, l \le n$, depend only on $x_{k+1}, \dots, x_n$ variables by Theorem 2.3. So the left-hand side of (3.25) depends only on $x_{k+1}, \dots, x_n$. Therefore we deduce that

$$\sum_{i=k+1}^{n}\beta_{ji}\beta_{li} - \frac{1}{2}\frac{\partial^2 \eta}{\partial x_l \partial x_j} = 0 \qquad \text{for } k+1 \le j, l \le n. \tag{3.26}$$

Let $\triangle = (\beta_{ij})$, $k+1 \le i, j \le n$, be an $(n-k) \times (n-k)$ antisymmetric matrix. Then we have

$$\triangle\triangle^T = \frac{1}{2}H(\eta_4), \tag{3.27}$$

where $H(\eta_4) = (\frac{\partial^2 \eta_4}{\partial x_i \partial x_j})$, $k+1 \le i, j \le n$, stands for the Hessian matrix for η_4. In view of Theorem 3.1, we have $\triangle = 0$. So we have shown that ω_{ij}'s are constants for $1 \le i, j \le n$. By Theorem 2.2 of Yau, E is a real vector space of dimension $2n+2$ with basis given by $1, x_1, x_2, \dots, x_n, D_1, D_2, \dots, D_n$ and L_0.

Since $\triangle = 0$, (3.27) implies $\eta_4 = 0$. So

$$\sum_{i=1}^{n}\frac{\partial f_i}{\partial x_i} + \sum_{i=1}^{n}f_i^2 + \sum_{i=1}^{m}h_i^2 = \eta_0 + \eta_1 + \eta_2 + \eta_3,$$

which implies

$$\sum_{i=1}^{n} \frac{\partial f_i}{\partial x_i} + \sum_{i=1}^{n} f_i^2 = \eta_0 + \eta_1 + \eta_2 - \sum_{i=1}^{m} h_i^2 + \eta_3. \tag{3.28}$$

By Theorem 2.3, $\tilde{F} = \eta_0 + \eta_1 + \eta_2 - \sum_{i=1}^{m} h_i^2$ is at most a polynomial of degree two. If η_3 is not identically zero, then we can choose a polynomial path $c : \mathbb{R} \to \mathbb{R}^n$ such that $\lim_{t\to\infty} ||c(t)|| = \infty$ and $\lim_{t\to\infty} F(c(t)) = -\infty$. This is not possible in view of Theorem 2.5. So we conclude that $\eta_3 = 0$; i.e., η is a polynomial of degree two.

PROXIMAL MINIMIZATION METHODS WITH GENERALIZED BREGMAN FUNCTIONS*

KRZYSZTOF C. KIWIEL†

Abstract. We consider methods for minimizing a convex function f that generate a sequence $\{x^k\}$ by taking x^{k+1} to be an approximate minimizer of $f(x)+D_h(x,x^k)/c_k$, where $c_k>0$ and D_h is the D-function of a Bregman function h. Extensions are made to B-functions that generalize Bregman functions and cover more applications. Convergence is established under criteria amenable to implementation. Applications are made to nonquadratic multiplier methods for nonlinear programs.

Key words. convex programming, nondifferentiable optimization, proximal methods, Bregman functions, B-functions

1. Introduction.

We consider the convex minimization problem

$$f_* = \inf\{\, f(x) : x \in X \,\}, \tag{1.1}$$

where $f : \mathbb{R}^n \to (-\infty,\infty]$ is a closed proper convex function and X is a nonempty closed convex set in $\mathbb{R}^n$. One method for solving (1.1) is the proximal point algorithm (PPA) [Mar70, Roc76b], which generates a sequence

$$x^{k+1} = \arg\min\{\, f(x) + |x-x^k|^2/2c_k : x \in X \,\} \quad \text{for } k = 1,2,\dots, \tag{1.2}$$

starting from any point $x^1 \in \mathbb{R}^n$, where $|\cdot|$ is the Euclidean norm and $\{c_k\}$ is a sequence of positive numbers. The convergence and applications of the PPA are discussed in, e.g., [Aus86, CoL93, EcB92, GoT89, Gül91, Lem89, Roc76a, Roc76b].

Several proposals have been made for replacing the quadratic term in (1.2) with other distancelike functions [BeT94, CeZ92, ChT93, Eck93, Egg90, Ius95, IuT93, Teb92, TsB93]. In [CeZ92], (1.2) is replaced by

$$x^{k+1} = \arg\min\{\, f(x) + D_h(x,x^k)/c_k : x \in X \,\}, \tag{1.3}$$

where $D_h(x,y) = h(x) - h(y) - \langle \nabla h(y), x-y\rangle$ is the D-function of a Bregman function h [Bre67, CeL81], which is continuous, strictly convex, and differentiable in the interior of its domain; here $\langle\cdot,\cdot\rangle$ is the usual inner product and ∇h is the gradient of h. Accordingly, this is called *Bregman proximal minimization* (BPM). The convergence of the BPM method is discussed in [CeZ92, ChT93, Eck93, Ius95, TsB93], a generalization for finding zeros of monotone operators is given in [Eck93], and applications to convex programming are presented in [Cha94, Eck93, Ius95, NiZ92, NiZ93a, NiZ93b, Teb92, TsB93].

This paper discusses convergence of the BPM method using the *B-functions* of [Kiw97] that generalize Bregman functions, being possibly nondifferentiable and infinite on the boundary of their domains (cf. section 2; another recent generalization of

†Systems Research Institute, Newelska 6, 01–447 Warsaw, Poland (kiwiel@ibspan.waw.pl).

Bregman functions is given in [BaB97] for convex feasibility problems). Then (1.3) involves $D_h^k(x, x^k) = h(x) - h(x^k) - \langle \gamma^k, x - x^k \rangle$, where γ^k is a subgradient of h at x^k. We establish for the first time convergence of versions of the BPM method that relax the requirement for exact minimization in (1.3). (The alternative approach of [Flå94], being restricted to Bregman functions with Lipschitz continuous gradients, cannot handle the applications of sections 7–9.) We note that in several important applications, strictly convex problems of the form (1.3) may be solved by dual ascent methods; cf. references in [Kiw97, Tse90].

The application of the BPM method to the dual functional of a convex program yields nonquadratic multiplier methods [Eck93, Teb92]. By allowing h to have singularities, we extend this class of methods to include, e.g., *shifted* Frish and Carroll barrier function methods [FiM68]. We show that our criteria for inexact minimization can be implemented similarly as in the nonquadratic multiplier methods of [Ber82, Chap. 5]. Our convergence results extend those in [Eck93, TsB93] to quite general *shifted penalty functions*, including twice continuously differentiable ones.

We add that the continuing interest in nonquadratic modified Lagrangians stems from the fact that, in contrast with the quadratic one, they are twice continuously differentiable, and this facilitates their minimization [Ber82, BTYZ92, BrS93, BrS94, CGT92, CGT94, GoT89, IST94, JeP94, Kiw96, NPS94, Pol92, PoT97, Teb92, TsB93]. By the way, our convergence results seem stronger than ones in [IST94, PoT97] for *modified barrier functions*, resulting from a dual application of (1.3) with $D_h^k(x, x^k)$ replaced by an entropylike ϕ-divergence.

The paper is organized as follows. In section 2 we recall several elementary properties of B-functions. In section 3 we present an inexact BPM method. Its global convergence under various conditions is established in sections 4 and 5. In section 6 we show that the exact BPM method converges finitely when (1.1) enjoys a sharp minimum property. Applications to multiplier methods are given in section 7. Convergence of general multiplier methods is studied in section 8, while section 9 focuses on two classes of shifted penalty methods. Additional aspects of multiplier methods are discussed in section 10. The appendix contains proofs of certain technical results.

Our notation is fairly standard. $\mathbb{R}_+$ and $\mathbb{R}_>$ are the nonnegative and positive reals, respectively. For any set C in $\mathbb{R}^n$, $\operatorname{cl} C$, $\overset{\circ}{C}$, $\operatorname{ri} C$, and ∂C denote the closure, interior, relative interior, and boundary of C, respectively. The *indicator* function of C is denoted by $\imath_C$ ($\imath_C(x) = 0$ if $x \in C$, ∞ otherwise), and its *support* function by $\imath_C^*(\cdot) = \sup_{x \in C} \langle \cdot, x \rangle$.

2. *B*-functions. We first recall some useful concepts from convex analysis (see, e.g., [Roc70]).

For any proper convex function h on $\mathbb{R}^n$, $\mathcal{D}_h = \{x : f(x) < \infty\}$ denotes its *effective domain*, $\partial_\epsilon h(\cdot) = \{p : h(y) \geq h(\cdot) + \langle p, y - \cdot \rangle - \epsilon \ \forall y\}$ its *ϵ-subdifferential* for each $\epsilon \geq 0$, $\partial h = \partial_0 h$ its *subdifferential*, and $h'(x; d) = \lim_{t \downarrow 0} [h(x + td) - h(x)]/t$ its *derivative* in any direction d at a point x where h is finite. By [Roc70, Thm. 23.2],

$$h'(x; d) \geq \imath^*_{\partial h(x)}(d) = \sup\{\langle g, d \rangle : g \in \partial h(x)\}. \tag{2.1}$$

The *domain* and *range* of ∂h are denoted by $\mathcal{D}_{\partial h}$ and $\operatorname{im} \partial h$, respectively. If h is proper, then $\operatorname{ri} \mathcal{D}_h \subset \mathcal{D}_{\partial h} \subset \mathcal{D}_h$ [Roc70, Thm. 23.4]. h is called *cofinite* when its *conjugate* $h^*(\cdot) = \sup_x \langle \cdot, x \rangle - h(x)$ is real valued. If h is closed proper convex, its *recession* function $h0^+(\cdot) = \lim_{t \to \infty} [h(x + t\cdot) - h(x)]/t$ ($\forall x \in \mathcal{D}_h$) is positively homogeneous [Roc70, Thm. 8.5]. h is called *essentially strictly convex* if h is strictly convex on

every convex subset of $\mathcal{D}_{\partial h}$. A proper convex function h is called *essentially smooth* if $\mathcal{D}_{\nabla h} = \mathring{\mathcal{D}}_h \neq \emptyset$ and $|\nabla h(x^k)| \to \infty$ whenever $\{x^k\} \subset \mathring{\mathcal{D}}_h$, $x^k \to x \in \partial\mathcal{D}_h$.

FACT 2.1 (see [Roc70, Thm. 23.5]). *If h is closed proper convex, then the following are equivalent*: $g \in \partial h(x)$, $x \in \partial h^*(g)$, $x \in \operatorname{Arg\,min}\{h(\cdot) - \langle g, \cdot\rangle\}$, $h(x) + h^*(g) = \langle g, x\rangle$.

FACT 2.2 (see [Roc70, Thms. 25.1 and 25.5]). *If h is proper convex, then ∇h is continuous on $\mathcal{D}_{\nabla h} \subset \mathring{\mathcal{D}}_h$, and $x \in \mathcal{D}_{\nabla h}$, i.e., h is differentiable at x, iff $\partial h(x) = \{\nabla h(x)\}$.*

FACT 2.3 (see [Roc70, Thms. 26.1 and 26.3]). *Suppose that h is closed proper convex. Then*

(i) *h is essentially smooth iff $\partial h(x) = \{\nabla h(x)\}$, $\forall x \in \mathring{\mathcal{D}}_h$, and $\partial h(x) = \emptyset$, $\forall x \in \partial\mathcal{D}_h$.*

(ii) *h is essentially strictly convex iff h^* is essentially smooth.*

For any proper convex function h on $\mathbb{R}^n$, we define its *difference functions*:

$$\begin{aligned} D_h^\flat(x,y) &= h(x) - h(y) - \imath^*_{\partial h(y)}(x-y) \quad \forall x, y \in \mathcal{D}_h, \\ D_h^\sharp(x,y) &= h(x) - h(y) + \imath^*_{\partial h(y)}(y-x) \quad \forall x, y \in \mathcal{D}_h. \end{aligned} \tag{2.2}$$

By convexity (cf. (2.1)), $h(x) \geq h(y) + \imath^*_{\partial h(y)}(x-y)$ and

$$0 \leq D_h^\flat(x,y) \leq h(x) - h(y) - \langle \gamma, x-y\rangle \leq D_h^\sharp(x,y) \quad \forall x, y \in \mathcal{D}_h, \gamma \in \partial h(y). \tag{2.3}$$

$D_h^\flat$ and $D_h^\sharp$ generalize the usual *D-function* of h [Bre67, CeL81], defined by

$$D_h(x,y) = h(x) - h(y) - \langle \nabla h(y), x-y\rangle \quad \forall x \in \mathcal{D}_h,\ y \in \mathcal{D}_{\nabla h}, \tag{2.4}$$

since

$$D_h(x,y) = D_h^\flat(x,y) = D_h^\sharp(x,y) \quad \forall x \in \mathcal{D}_h,\ y \in \mathcal{D}_{\nabla h}. \tag{2.5}$$

DEFINITION 2.4 (see [Kiw97]). *A closed proper (possibly nondifferentiable) convex function h is called a B-*function (generalized Bregman function) *if*

(i) *h is strictly convex on $\mathcal{D}_h$.*

(ii) *h is continuous on $\mathcal{D}_h$.*

(iii) *For every $\alpha \in \mathbb{R}$ and $x \in \mathcal{D}_h$, the set $\mathcal{L}_h^\flat(x,\alpha) = \{y \in \mathcal{D}_{\partial h} : D_h^\flat(x,y) \leq \alpha\}$ is bounded.*

(iv) *For every $\alpha \in \mathbb{R}$ and $x \in \mathcal{D}_h$, if $\{y^k\} \subset \mathcal{L}_h^\flat(x,\alpha)$ is a convergent sequence with limit $y^* \in \mathcal{D}_h \setminus \{x\}$, then $D_h^\sharp(y^*, y^k) \to 0$.*

Remarks 2.5.

(i) $D_f^\flat$ and $D_f^\sharp$ are used like distances, because for $x \in \mathcal{D}_f$ and $y \in \mathcal{D}_{\partial f}$, $0 \leq D_f^\flat(x,y) \leq D_f^\sharp(x,y)$, and $D_f^\flat(x,y) = 0 \iff D_f^\sharp(x,y) = 0 \iff x = y$ by strict convexity.

(ii) Our generalization of Bregman functions [CeL81] has two components. First, we allow singularities of h at $\partial\mathcal{D}_h$ to cover more examples. Second, handling nondifferentiable functions only requires slightly more complex notation. In many cases h will be essentially smooth, so $D_h = D_h^\flat = D_h^\sharp$ on $\mathcal{D}_h \times \mathring{\mathcal{D}}_h$ (Fact 2.3(i) and (2.5)).

(iii) Several results of [Kiw97] help in checking if a given function is a B-function. We only recall the following results and examples from [Kiw97].

LEMMA 2.6 (see [Kiw97, Lem. 2.8]). *Let $h = \sum_{i=1}^k h_i$, where $h_1, \ldots, h_k$ are closed proper convex functions such that (s.t.) $h_{j+1}, \ldots, h_k$ ($j \geq 0$) are polyhedral and*

$\cap_{i=1}^{j} \operatorname{ri}(\mathcal{D}_{h_i}) \cap_{i=j+1}^{k} \mathcal{D}_{h_i} \neq \emptyset$. *If* h_1 *is a B-function,* $h_2, \ldots, h_j$ *are continuous on* $\mathcal{D}_h = \cap_{i=1}^{k} \mathcal{D}_{h_i}$ *and satisfy condition* (iv) *of Definition* 2.4, *then* h *is a B-function. In particular,* h *is a B-function if* $h_1, \ldots, h_j$ *are.*

LEMMA 2.7 (see [Kiw97, Lems. 2.10 and 2.11]).

(i) *Let* h *be a proper convex function on* $\mathbb{R}$. *Then* h *is a B-function iff* h *is closed and essentially strictly convex and* $\mathcal{D}_{h^*} = \mathring{\mathcal{D}}_{h^*}$.

(ii) *Let* $h_1, \ldots, h_n$ *be B-functions on* $\mathbb{R}$. *Then* $h(x) = \sum_{i=1}^{n} h_i(x_i)$ *is a B-function.*

Examples 2.8 (see [Kiw97, Exs. 2.12]). If $h(x) = \sum_{i=1}^{n} h_i(x_i)$ with $h_i : \mathbb{R} \to (-\infty, \infty]$, then $h^*(y) = \sum_i h_i^*(y_i)$ and $D_h(x, y) = \sum_i D_{h_i}(x_i, y_i)$, so we consider only $n = 1$. In each example, it can be verified that h is an essentially smooth B-function.

(1 [Eck93]). $h(x) = |x|^\alpha/\alpha$ on $\mathcal{D}_h = \mathbb{R}$ for $\alpha > 1$. Then $h^*(\cdot) = |\cdot|^\beta/\beta$ with $\alpha + \beta = \alpha\beta$ (cf. [Roc70, sect. 12]). For $\alpha = 2$, $h(x) = |x|^2/2$ and $D_h(x, y) = |x - y|^2/2$.

(2) $h(x) = -x^\alpha/\alpha$ on $\mathcal{D}_h = \mathbb{R}_+$ with $\alpha \in (0, 1)$. Then $h^*(y) = -(-y)^\beta/\beta$ on $\mathcal{D}_{h^*} = (-\infty, 0)$ with $\alpha + \beta = \alpha\beta$. For $h(x) = (\alpha x - x^\alpha)/(1 - \alpha)$ [Teb92], $h^*(y) = (1 + y/\beta)^\beta$ on $\mathcal{D}_h^* = (-\infty, -\beta)$. For $\alpha = \frac{1}{2}$, $D_h(x, y) = (x^{1/2} - y^{1/2})^2/y^{1/2}$.

(3 ("$x \log x$"-entropy) [Bre67]) $h(x) = x \ln x$ on $\mathcal{D}_h = \mathbb{R}_+$ ($0 \ln 0 = 0$). Then $h^*(y) = \exp(y - 1)$ on $\mathcal{D}_{h^*} = \mathbb{R}$ and $D_h(x, y) = x \ln(x/y) + y - x$ (the Kullback–Leibler entropy). For $h(x) = x \ln x - x$ (Boltzmann–Shannon), $h^*(y) = \exp y$ and D_h is the same.

(4 (Burg's entropy) [CDPI91]) $h(x) = -\ln x$ on $\mathcal{D}_h = \mathbb{R}_>$. Then $h^*(y) = -\ln(-y) - 1$ on $\mathcal{D}_{h^*} = (-\infty, 0)$, and $D_h(x, y) = -\ln(x/y) + x/y - 1$.

(5 (Hellinger)) $h(x) = -\sqrt{1 - x^2}$ on $\mathcal{D}_h = [-1, 1]$. Then $h^*(y) = \sqrt{1 + y^2}$ on $\mathcal{D}_{h^*} = \mathbb{R}$ and $D_h(x, y) = (1 - xy)/\sqrt{1 - y^2} - \sqrt{1 - x^2}$ on $[-1, 1] \times (-1, 1)$. For $h(x) = -\sqrt{x(1 - x)}$ on $\mathcal{D}_h = [0, 1]$, $h^*(y) = \frac{1}{2}(y + \sqrt{1 + y^2})$.

(6 (Fermi–Dirac)) $h(x) = x \ln x + (1 - x) \ln(1 - x)$ on $\mathcal{D}_h = [0, 1]$. Then $h^*(y) = \ln(1 + \exp y)$ on $\mathcal{D}_{h^*} = \mathbb{R}$.

(7) $h(x) = -\ln x - \ln(1 - x)$ on $\mathcal{D}_h = [0, 1]$. Then $h^*(y) = \frac{1}{2}[(y^2 + 4)^{1/2} + y - 2] + \ln[(y^2 + 4)^{1/2} - 2] - \ln y^2$ for $y \neq 0$, $h^*(0) = -\ln 4$, $\mathcal{D}_{h^*} = \mathbb{R}$.

We now provide a dual complement of Lemma 2.7(i).

LEMMA 2.9.

(i) *If* ψ *is a B-function on* $\mathbb{R}$, *then* ψ^* *is essentially smooth and* $\mathcal{D}_{\psi^*} = \mathring{\mathcal{D}}_{\psi^*}$.

(ii) *If* $\phi : \mathbb{R} \to (-\infty, \infty]$ *is closed proper convex essentially smooth and* $\mathcal{D}_\phi = \mathring{\mathcal{D}}_\phi$, *then* ϕ^* *is a B-function with* $\operatorname{ri} \mathcal{D}_{\phi^*} \subset \operatorname{im} \nabla\phi \subset \mathcal{D}_{\phi^*}$.

Proof. (i) This follows from Definition 2.4, Fact 2.3(ii), and Lemma 2.7(i). (ii) By Facts 2.1 and 2.3, $\operatorname{ri} \mathcal{D}_{\phi^*} \subset \mathcal{D}_{\partial\phi^*} = \operatorname{im} \partial\phi = \operatorname{im} \nabla\phi \subset \mathcal{D}_{\phi^*}$ and ϕ^* is closed proper essentially strictly convex with $\phi^{**} = \phi$ [Roc70, Thm. 12.2]. The conclusion follows from Lemma 2.7(i). ∎

We need the following consequence of [Kiw97, Lems. 2.15 and 2.16] formulated in terms of

$$0 \leq D'_h(x, y) := h(x) - h(y) - h'(y; x - y) \leq D_h^\flat(x, y) \quad \forall x, y \in \mathcal{D}_h. \tag{2.6}$$

LEMMA 2.10. *Let* h *be a B-function on* $\mathbb{R}^n$. *Then*

(i) *If* $\{x^k\}$ *is a sequence in* $\mathcal{L}_h^\flat(x, \alpha)$ *for some* $x \in \mathcal{D}_h$, $\alpha \in \mathbb{R}$, *then* $\{x^k\}$ *is bounded and every limit point of* $\{x^k\}$ *is in* $\mathcal{D}_h$.

(ii) *If* $\{x^k\} \subset \mathcal{D}_h$ *is bounded and* $D'_h(x, x^k) \to 0$ *for some* x, *then* $x^k \to x$.

3. The BPM method. We make the following standing assumptions about problem (1.1) and the algorithm.

Assumption 3.1.
(i) f is a closed proper convex function.
(ii) X is a nonempty closed convex set.
(iii) h is a (possibly nonsmooth) B-function.
(iv) $\mathcal{D}_{f_X} \cap \mathcal{D}_h \neq \emptyset$, where $f_X = f + \imath_X$ is the *essential objective* of (1.1).
(v) $\{c_k\}$ is a sequence of positive numbers satisfying $\sum_{k=1}^{\infty} c_k = \infty$.
(vi) $\{\epsilon_k\}$ is a sequence of nonnegative numbers satisfying

$$\lim_{l\to\infty} \sum_{k=1}^{l} c_k\epsilon_k / \sum_{k=1}^{l} c_k = 0.$$

Consider the following *inexact BPM method*. At iteration $k \geq 1$, having

$$x^k \in \mathcal{D}_{f_X} \cap \mathcal{D}_{\partial h}, \tag{3.1}$$

$$\gamma^k \in \partial h(x^k), \tag{3.2}$$

$$D_h^k(x, x^k) = h(x) - h(x^k) - \langle \gamma^k, x - x^k \rangle \quad \forall x, \tag{3.3}$$

find x^{k+1}, γ^{k+1}, and p^{k+1} satisfying

$$\gamma^{k+1} \in \partial h(x^{k+1}), \tag{3.4}$$

$$c_k p^{k+1} + \gamma^{k+1} - \gamma^k = 0, \tag{3.5}$$

$$p^{k+1} \in \partial_{\epsilon_k} f_X(x^{k+1}), \tag{3.6}$$

$$f_X(x^{k+1}) \leq f_X(x^k). \tag{3.7}$$

We note that $x^{k+1} \approx \arg\min\{f_X + D_h^k(\cdot, x^k)/c_k\}$ with

$$0 \leq D_h^\flat(\cdot, x^k) \leq D_h^k(\cdot, x^k) \leq D_h^\sharp(\cdot, x^k) \tag{3.8}$$

by (2.2), (2.3), (3.2), and (3.3); in fact x^{k+1} is an ϵ_k-minimizer of

$$\phi_k(x) = f_X(x) + D_h^k(x, x^k)/c_k, \tag{3.9}$$

as shown after the following (well-known) technical result (cf. [Roc70, Thm. 27.1]).

LEMMA 3.2. *A closed proper and strictly convex function ϕ on $\mathbb{R}^n$ has a unique minimizer iff ϕ is inf-compact, i.e., the α-level set $\mathcal{L}_\phi(\alpha) = \{x : \phi(x) \leq \alpha\}$ is bounded for any $\alpha \in \mathbb{R}$, and this holds iff $\mathcal{L}_\phi(\alpha)$ is nonempty and bounded for one $\alpha \in \mathbb{R}$.*

Proof. If $x \in \operatorname{Arg\,min} \phi$, then by strict convexity of ϕ, $\mathcal{L}_\phi(\phi(x)) = \{x\}$ is bounded, so ϕ is inf-compact (cf. [Roc70, Cor. 8.7.1]). If for some $\alpha \in \mathbb{R}$, $\mathcal{L}_\phi(\alpha) \neq \emptyset$ is bounded, then it is closed (cf. [Roc70, Thm. 7.1]) and contains $\operatorname{Arg\,min} \phi \neq \emptyset$ because ϕ is closed. ∎

LEMMA 3.3. *Under the above assumptions, we have the following:*
(i) *ϕ_k is closed proper and strictly convex.*
(ii) *$\phi_k(x^{k+1}) \leq \inf \phi_k + \epsilon_k$ (i.e., $0 \in \partial_{\epsilon_k}\phi_k(x^{k+1})$).*
(iii) *If $f_* = \inf_X f > -\infty$, then ϕ_k is inf-compact.*
(iv) *ϕ_k is inf-compact if $(\gamma^k - c_k \operatorname{im} \partial f_X) \cap \operatorname{im} \partial h \neq \emptyset$, where $\operatorname{im} \partial h = \mathring{\mathcal{D}}_{h^*}$, so that $\operatorname{im} \partial h = \mathbb{R}^n$ iff h is cofinite. In particular, ϕ_k is inf-compact if $(\gamma^k - c_k \operatorname{ri} \mathcal{D}_{f_X^*}) \cap \operatorname{ri} \mathcal{D}_{h^*} \neq \emptyset$.*

(v) *If ϕ_k is inf-compact and either* $\operatorname{ri}\mathcal{D}_{f_X}\cap\operatorname{ri}\mathcal{D}_h\neq\emptyset$, *or* $\mathcal{D}_{f_X}\cap\operatorname{ri}\mathcal{D}_h\neq\emptyset$ *and f_X is polyhedral, then there exist* $\hat{x}^{k+1}=\arg\min\phi_k$, $\hat{p}^{k+1}\in\partial f_X(\hat{x}^{k+1})$, *and* $\hat{\gamma}^{k+1}\in\partial h(\hat{x}^{k+1})$ *s.t.* $f_X(\hat{x}^{k+1})+D_h^k(\hat{x}^{k+1},x^k)/c_k\le f_X(x^k)$ *and* $c_k\hat{p}^{k+1}+\hat{\gamma}^{k+1}-\gamma^k=0$; *also* $\hat{x}^{k+1}\in\mathring{\mathcal{D}}_h$ *if* $\mathcal{D}_{\partial f_X}\subset\mathring{\mathcal{D}}_h$ *or* $\mathcal{D}_{\partial h}=\mathring{\mathcal{D}}_h$; *e.g., h is essentially smooth.*

(vi) *The assumptions of* (v) *hold if either* $\operatorname{ri}\mathcal{D}_{f_X}\subset\mathring{\mathcal{D}}_h$ *and* $\inf_X f>-\infty$, *or* $\mathcal{D}_{\partial f_X}\subset\mathring{\mathcal{D}}_h$ *and* $\operatorname{im}\partial h=\mathbb{R}^n$.

Proof. (i) Since f, $\imath_X$, and h are closed proper convex, so are $f_X=f+\imath_X$, $D_h^k(\cdot,x^k)$ and $\phi_k=f_X+D_h^k(\cdot,x^k)/c_k$ (cf. [Roc70, Thm. 9.3]), having nonempty domains $\mathcal{D}_f\cap X$, $\mathcal{D}_h$, and $\mathcal{D}_{f_X}\cap\mathcal{D}_h$ respectively (cf. Assumption 3.1(iv)). $D_h^k(\cdot,x^k)$ and ϕ_k are strictly convex, since so is h (cf. Definition 2.4(i)).

(ii) For any x, add the inequality (cf. (3.3), (3.4)) $D_h^k(x,x^k)\ge D_h^k(x^{k+1},x^k)+\langle\gamma^{k+1}-\gamma^k,x-x^{k+1}\rangle$ divided by c_k to $f_X(x)\ge f_X(x^{k+1})+\langle p^{k+1},x-x^{k+1}\rangle-\epsilon_k$ (cf. (3.6)) and use (3.5) to get $\phi_k(x)\ge\phi_k(x^{k+1})-\epsilon_k$.

(iii) By part (i), $\psi=D_h^k(\cdot,x^k)$ is closed proper strictly convex, and $\mathcal{L}_\psi(0)=\{x^k\}$ by strict convexity of h (cf. Definition 2.4(i), (2.3), and (2.6)), so ψ is inf-compact (cf. Lemma 3.2). Let $\beta=\inf\phi_k$. Since $\psi\ge0$ (cf. (3.8)), $\beta\ge f_*$ and $\emptyset\neq\mathcal{L}_{\phi_k}(\beta+1)\subset\mathcal{L}_\psi(c_k(\beta-f_*+1))$ (cf. (3.9)). The last set is bounded, since ψ is inf-compact, so ϕ_k is inf-compact by part (i) and Lemma 3.2.

(iv) Let $\hat{y}\in\mathcal{D}_{\partial f_X}$, $\hat{\gamma}\in\partial f_X(\hat{y})$, $\tilde{x}\in\mathcal{D}_{\partial h}$, and $\tilde{\gamma}\in\partial h(\tilde{x})$ satisfy $\gamma^k-c_k\hat{\gamma}=\tilde{\gamma}$. Then $\tilde{\psi}(\cdot)=f_X(\hat{y})+\langle\hat{\gamma},\cdot-\hat{y}\rangle+D_h^k(\cdot,x^k)/c_k$ is closed proper and strictly convex (as is $D_h^k(\cdot,x^k)$; cf. part (i)), and $\tilde{x}=\arg\min\tilde{\psi}$ because $0\in\partial\tilde{\psi}(\tilde{x})=\hat{\gamma}+(\partial h(\tilde{x})-\gamma^k)/c_k$ (cf. [Roc70, Thm. 23.8]). Hence $\tilde{\psi}$ is inf-compact (cf. Lemma 3.2), and so is ϕ_k, since $\phi_k\ge\tilde{\psi}$ from $f_X(\cdot)\ge f_X(\hat{y})+\langle\hat{\gamma},\cdot-\hat{y}\rangle$. By strict convexity of h (cf. Definition 2.4(i)) and Facts 2.1 and 2.3, $\operatorname{im}\partial h=\mathcal{D}_{\partial h^*}=\mathring{\mathcal{D}}_{h^*}$. Of course, $\mathring{\mathcal{D}}_{h^*}=\mathbb{R}^n$ iff $\mathcal{D}_{h^*}=\mathbb{R}^n$, i.e., iff h is cofinite. The second assertion follows from $\operatorname{ri}\mathcal{D}_{f_X^*}\subset\mathcal{D}_{\partial f_X^*}=\operatorname{im}\partial f_X$.

(v) By part (i) and Lemma 3.2, $\hat{x}^{k+1}=\arg\min\phi_k$ is well defined. The rest follows from $D_h^k(\cdot,x^k)\ge0$ (cf. (3.8)), the fact $0\in\partial\phi_k(\hat{x}^{k+1})=\partial f(\hat{x}^{k+1})+c_k[\partial h(\hat{x}^{k+1})-\gamma^k]$ due to our assumptions on $\mathcal{D}_{f_X}$ and $\operatorname{ri}\mathcal{D}_h$ (cf. [Roc70, Thm. 23.8]), and Fact 2.3(i).

(vi) If $\inf_X f>-\infty$ or $\operatorname{im}\partial h=\mathbb{R}^n$, then ϕ_k is inf-compact by parts (iii) and (iv). If $\operatorname{ri}\mathcal{D}_{f_X}\subset\mathring{\mathcal{D}}_h$ then $\operatorname{ri}\mathcal{D}_{f_X}\cap\operatorname{ri}\mathcal{D}_h=\operatorname{ri}\mathcal{D}_{f_X}\neq\emptyset$, since $\mathcal{D}_{f_X}\neq\emptyset$ (cf. Assumption 3.1(iv)). □

Remark 3.4. Lemma 3.3(v) and (vi) state conditions under which the *exact* BPM method (with $x^{k+1}=\hat{x}^{k+1}=\arg\min\phi_k$ and $\epsilon_k=0$ in (3.6)) is well defined. Our conditions are slightly weaker than those in [Eck93, Thm. 5], which correspond to $\operatorname{ri}\mathcal{D}_{f_X}\subset\mathring{\mathcal{D}}_h$, and either $\operatorname{cl}\mathcal{D}_{f_X}\subset\mathring{\mathcal{D}}_h$ and $\operatorname{im}\partial h=\mathbb{R}^n$ or, f being finite, continuous and bounded below on X.

Example 3.5. Let $X=\{x\ge0:Ax=b\}$, $f=\langle\hat{c},\cdot\rangle+\imath_X$, and $h(x)=-\sum_{i=1}^n\ln x_i$, where $A\in\mathbb{R}^{m\times n}$, $b\in\mathbb{R}^m$, and $\hat{c}\in\mathbb{R}^n$. Suppose $f_*>-\infty$ and $Ax=b$ for some $x>0$. Since $\mathring{\mathcal{D}}_h=\{x:x>0\}$, Lemma 3.3(iii) and (v) implies that $\hat{x}^{k+1}$ is well defined.

Example 3.6. Let $n=1$, $X=\mathbb{R}$, $f(x)=-x$, and $h(x)=e^{-x}+x$. Then $f^*=\imath_{\{-1\}}$, $\operatorname{ri}\mathcal{D}_{f^*}=\operatorname{im}\partial f=\{-1\}$, $\mathring{\mathcal{D}}_{h^*}=\operatorname{im}\partial h=(-\infty,1)$, and $\operatorname{ri}\mathcal{D}_{f^*}\cap\mathring{\mathcal{D}}_{h^*}\neq\emptyset$. Clearly, $\phi_k(x)=e^{-x}+x(e^{-x^k}-1)+\text{const}$ for $c_k=1$, so $\arg\min\phi_k\neq\emptyset$ iff $x^k<0$. Although h is not a Bregman function, this is a counterexample to [Teb92, Thm. 3.1].

4. Convergence of the BPM method. We first derive a global convergence rate estimate for the BPM method. We follow the analysis of [ChT93], which generalized that in [Gül91]. Let $s_k=\sum_{j=1}^k c_j$ for all k.

LEMMA 4.1. *For all $x \in \mathcal{D}_h$ and $k \le l$, we have*

$$D_h^{k+1}(x,x^{k+1}) + D_h^k(x^{k+1},x^k) - D_h^k(x,x^k) = \langle \gamma^k - \gamma^{k+1}, x - x^{k+1}\rangle \le c_k[f_X(x) - f_X(x^{k+1})] + c_k\epsilon_k, \tag{4.1}$$

$$D_h^{k+1}(x,x^{k+1}) \le D_h^k(x,x^k) - D_h^k(x^{k+1},x^k) + c_k\epsilon_k \quad \text{if} \quad f_X(x) \le f_X(x^{k+1}), \tag{4.2}$$

$$s_l[f_X(x^{l+1}) - f_X(x)] \le D_h^1(x,x^1) - D_h^{l+1}(x,x^{l+1}) - \sum_{k=1}^{l} D_h^k(x^{k+1},x^k) + \sum_{k=1}^{l} c_k\epsilon_k, \tag{4.3}$$

$$f_X(x^{l+1}) - f_X(x) \le D_h^1(x,x^1)/s_l + \sum_{k=1}^{l} c_k\epsilon_k/s_l. \tag{4.4}$$

Proof. The equality in (4.1) follows from (3.3), and the inequality from $\gamma^k - \gamma^{k+1} = c_k p^{k+1}$ (cf. (3.5)) and $p^{k+1} \in \partial_{\epsilon_k} f_X(x^{k+1})$ (cf. (3.6)), i.e., $\langle p^{k+1}, x - x^{k+1}\rangle \le f_X(x) - f_X(x^{k+1}) + \epsilon_k$, since $c_k > 0$. (4.2) is a consequence of (4.1). Summing (4.1) over $k = 1{:}\,l$ we obtain

$$D_h^{l+1}(x,x^{l+1}) - D_h^1(x,x^1) + \sum_{k=1}^{l} D_h^k(x^{k+1},x^k) \le s_l f_X(x) - \sum_{k=1}^{l} c_k f_X(x^{k+1}) + \sum_{k=1}^{l} c_k\epsilon_k. \tag{4.5}$$

Use $f_X(x^{l+1}) \le f_X(x^k)$ for $k = 1{:}\,l$ (cf. (3.7)) in (4.5) to get (4.3). Equation (4.4) follows from (4.3) and the fact $D_h^k(\cdot,x^k) \ge 0$ for all k (cf. (3.8)). ∎

By (2.6) and (3.8), for all k

$$0 \le D_h'(\cdot,x^k) \le D_h^\flat(\cdot,x^k) \le D_h^k(\cdot,x^k) \le D_h^\sharp(\cdot,x^k). \tag{4.6}$$

LEMMA 4.2. *If $\sum_{k=1}^{\infty} c_k\epsilon_k < \infty$ and $x \in \mathcal{D}_h$ is s.t. $f_X(x^k) \ge f_X(x)$ for all k, then*

(i) *$\{x^k\}$ is bounded and $\{x^k\} \subset \mathcal{L}_h^\flat(x,\alpha)$, where $\alpha = D_h^1(x,x^1) + \sum_{k=1}^{\infty} c_k\epsilon_k$.*

(ii) *every limit point of $\{x^k\}$ is in $\mathcal{D}_h$.*

(iii) *$\{x^k\}$ converges to some $x^\infty \in \mathcal{D}_{f_X} \cap \mathcal{D}_h$ s.t. $f_X(x^k) \ge f_X(x^\infty)$ for all k.*

Proof. (i) We have $D_h^l(x,x^l) \le D_h^1(x,x^1) + \sum_{k=1}^{l-1} c_k\epsilon_k \le \alpha$ for all l (cf. (4.2), (4.6)) and $\{x^k\} \subset \mathcal{D}_{\partial h}$ (cf. (3.1)), so $\{x^k\} \subset \mathcal{L}_h^\flat(x,\alpha)$, a bounded set (cf. Definition 2.4(iii)).

(ii) Since $\{x^k\} \subset \mathcal{L}_h^\flat(x,\alpha)$ by part (i), this follows from Lemma 2.10(i).

(iii) By parts (i) and (ii), a subsequence $\{x^{l_j}\}$ converges to some $x^\infty \in \mathcal{D}_h$. Suppose $x^\infty \ne x$. Since $\{x^k\} \subset \mathcal{L}_h^\flat(x,\alpha)$, $D_h^\sharp(x^\infty,x^{l_j}) \to 0$ (cf. Definition 2.4(iv)) and $D_h^{l_j}(x^\infty,x^{l_j}) \to 0$ (cf. (4.6)). But $f_X(x^k) \ge f_X(x^\infty)$ for all k, since $x^{l_j} \to x^\infty$, $f_X(x^{k+1}) \le f_X(x^k)$ (cf. (3.7)) and f_X is closed (cf. Assumption 3.1(i), (ii)). Hence for $l > l_j$, $D_h^l(x^\infty,x^l) \le D_h^{l_j}(x^\infty,x^{l_j}) + \sum_{k=l_j}^{l-1} c_k\epsilon_k$ (cf. (4.2)) with $\sum_{k=l_j}^{\infty} c_k\epsilon_k \to 0$ as $j \to \infty$ yield $D_h^l(x^\infty,x^l) \to 0$ as $l \to \infty$. Thus $D_h'(x^\infty,x^k) \to 0$ (cf. (4.6)) and $x^k \to x^\infty$ by Lemma 2.10(ii). Finally, if $x^\infty = x$ but $\{x^k\}$ does not converge, it has a limit point $x' \in \mathcal{D}_h \setminus \{x\}$ (cf. parts (i) and (ii)), and replacing x^∞ by x' in the preceding argument yields a contradiction. ∎

We may now prove our main result for the inexact BPM descent method (3.1)–(3.7).

THEOREM 4.3. *Suppose that Assumption* 3.1(i), (ii), (iv), (v) *holds with h closed proper convex.*

(i) *If* $\lim_{l\to\infty} \sum_{k=1}^{l} c_k\epsilon_k / \sum_{k=1}^{l} c_k = 0$, *then*

$$f_X(x^k) \downarrow \inf_{\mathcal{D}_h} f_X = \inf_{\mathrm{cl}(\mathcal{D}_h \cap \mathcal{D}_{f_X})} f.$$

Hence $f_X(x^k) \downarrow \inf_X f$ *if* $\mathcal{D}_{f_X} \subset \mathcal{D}_h$. *If* $\mathrm{ri}\,\mathcal{D}_h \cap \mathrm{ri}\,\mathcal{D}_{f_X} \neq \emptyset$ (*e.g.*, $\mathring{\mathcal{D}}_h \cap \mathcal{D}_{f_X} \neq \emptyset$), *then* $\inf_{\mathcal{D}_h} f_X = \inf_{(\mathrm{cl}\,\mathcal{D}_h)\cap(\mathrm{cl}\,\mathcal{D}_{f_X})} f = \inf_{\mathrm{cl}\,\mathcal{D}_h} f_X$. *If* $\mathrm{ri}\,\mathcal{D}_{f_X} \subset \mathrm{cl}\,\mathcal{D}_h$ (*e.g.*, $\mathcal{D}_{\partial f_X} \subset \mathrm{cl}\,\mathcal{D}_h$), *then* $\mathrm{cl}\,\mathcal{D}_h \supset \mathrm{cl}\,\mathcal{D}_{f_X}$ *and* $\mathrm{Arg\,min}_X f \subset \mathrm{cl}\,\mathcal{D}_h$.

(ii) *If h is a B-function,* $f_X(x^k) \to \inf_{\mathcal{D}_h} f_X$, $\sum_{k=1}^{\infty} c_k\epsilon_k < \infty$, *and* $X_* = \mathrm{Arg\,min}_{\mathcal{D}_h} f_X$ *is nonempty, then* $\{x^k\}$ *converges to some* $x^\infty \in X_*$, *and*

$$x^\infty \in \mathrm{Arg}\min_X f \qquad \textit{if} \qquad \mathcal{D}_{f_X} \subset \mathcal{D}_h.$$

(iii) *If* $f_X(x^k) \to \inf_{\mathcal{D}_h} f_X$, $\mathcal{D}_{f_X} \subset \mathcal{D}_h$, *and* $X_* = \emptyset$, *then* $|x^k| \to \infty$.

Proof. (i) For any $x \in \mathcal{D}_h$, taking the limit in (4.4) yields $\lim_{l\to\infty} f_X(x^l) \leq f_X(x)$, using $f_X(x^{l+1}) \leq f_X(x^l)$ (cf. (3.7)), $s_l \to \infty$ (Assumption 3.1(v)), and $\sum_{k=1}^{l} c_k\epsilon_k/s_l \to 0$. Hence $f_X(x^k) \to \inf_{\mathcal{D}_h} f_X = \inf_{\mathcal{D}_h\cap\mathcal{D}_{f_X}} f = \inf_{\mathrm{cl}(\mathcal{D}_h\cap\mathcal{D}_{f_X})} f$ (cf. [Roc70, Cor. 7.3.2]). If $\mathrm{ri}\,\mathcal{D}_h \cap \mathrm{ri}\,\mathcal{D}_{f_X} \neq \emptyset$ (e.g., $\mathring{\mathcal{D}}_h \cap \mathcal{D}_{f_X} \neq \emptyset$; cf. [Roc70, Cor. 6.3.2]), then $\mathrm{cl}(\mathcal{D}_h \cap \mathcal{D}_{f_X}) = \mathrm{cl}(\mathcal{D}_h) \cap \mathrm{cl}(\mathcal{D}_{f_X})$ (cf. [Roc70, Thm. 6.5]) and $\inf_{\mathcal{D}_h} f_X = \inf_{(\mathrm{cl}\,\mathcal{D}_h)\cap(\mathrm{cl}\,\mathcal{D}_{f_X})} f \leq \inf_{\mathcal{D}_{f_X}\cap\mathrm{cl}\,\mathcal{D}_h} f = \inf_{\mathrm{cl}\,\mathcal{D}_h} f_X$, so $\inf_{\mathcal{D}_h} f_X = \inf_{\mathrm{cl}\,\mathcal{D}_h} f_X$. If $\mathrm{ri}\,\mathcal{D}_{f_X} \subset \mathrm{cl}\,\mathcal{D}_h$, then $\mathrm{cl}\,\mathcal{D}_{f_X} \subset \mathrm{cl}\,\mathcal{D}_h$ (cf. [Roc70, Thm. 6.5]).

(ii) If $x \in X_*$, then $f_X(x^k) \to f_X(x)$. But $f_X(x^k) \geq f_X(x)$ for all k (cf. (3.1)), so $x^k \to x^\infty \in \mathcal{D}_{f_X} \cap \mathcal{D}_h$ and $\lim_{k\to\infty} f_X(x^k) \geq f_X(x^\infty)$ by Lemma 4.2, and thus $x^\infty \in X_*$.

(iii) If $|x^k| \not\to \infty$, $\{x^k\}$ has a limit point x with $f_X(x) \leq \inf_{\mathcal{D}_h} f_X \leftarrow f_X(x^k)$ (f_X is closed; cf. Assumption 3.1(i), (ii)), so $\mathcal{D}_{f_X} \subset \mathcal{D}_h$ yields $x \in \mathcal{D}_h \cap X_*$, i.e., $X_* \neq \emptyset$. ∎

Remark 4.4. For the exact BPM method (with $\epsilon_k \equiv 0$), Theorem 4.3(i), (ii) subsume [ChT93, Thm. 3.4], which assumes $\mathrm{ri}\,\mathcal{D}_{f_X} \subset \mathring{\mathcal{D}}_h$ and $\mathcal{D}_h = \mathrm{cl}\,\mathcal{D}_h$. Theorem 4.3(ii), (iii) strengthen [Eck93, Thm. 5], which shows only that $\{x^k\}$ is unbounded if $\mathrm{cl}\,\mathcal{D}_{f_X} \subset \mathring{\mathcal{D}}_h$ and $X_* = \emptyset$. Theorem 4.3(i), (ii) and Lemma 3.3 subsume [Ius95, Thm. 4.1], which assumes that h is essentially smooth, f is continuous on $\mathcal{D}_f$, $\mathcal{D}_f \cap \mathring{\mathcal{D}}_h \neq \emptyset$, $X = \mathrm{cl}\,\mathcal{D}_h$, $\mathrm{Arg\,min}_X f \neq \emptyset$, and $\inf_k c_k > 0$.

For choosing $\{\epsilon_k\}$ (cf. Assumption 3.1(vi)), one may use the following simple result.

LEMMA 4.5.

(i) *If* $\epsilon_k \to 0$, *then* $\sum_{k=1}^{l} c_k\epsilon_k/s_l \to 0$ *as* $l \to \infty$.

(ii) *If* $\sum_{k=1}^{\infty} \epsilon_k < \infty$ *and* $\{c_k\} \subset (0, c_{\max}]$ *for some* $c_{\max} < \infty$, *then* $\sum_{k=1}^{\infty} c_k\epsilon_k < \infty$.

Proof. (i) For any $\epsilon > 0$, pick $\bar{k}$ and $\bar{l} > \bar{k}$ s.t. $\epsilon_k \leq \epsilon$ for all $k \geq \bar{k}$ and $\sum_{k=1}^{\bar{k}} c_k\epsilon_k/s_l \leq \epsilon$ for all $l \geq \bar{l}$; then

$$\sum_{k=1}^{l} c_k\epsilon_k/s_l \leq \sum_{k=1}^{\bar{k}} c_k\epsilon_k/s_l + \epsilon \sum_{k=\bar{k}+1}^{l} c_k / \sum_{k=1}^{l} c_k \leq 2\epsilon$$

for all $l \geq \bar{l}$.

(ii) We have $\sum_{k=1}^{\infty} c_k\epsilon_k \leq c_{\max} \sum_{k=1}^{\infty} \epsilon_k < \infty$. ∎

5. Convergence of a nondescent BPM method. In certain applications (cf. section 7) it may be difficult to satisfy the descent requirement (3.7). Hence we now consider a *nondescent BPM method*, in which (3.7) is replaced by

$$f_X(x^{k+1}) + D_h^k(x^{k+1}, x^k)/c_k \le f_X(x^k) + \epsilon_k. \tag{5.1}$$

By Lemma 3.3(ii), (5.1) holds *automatically*, since it means $\phi_k(x^{k+1}) \le \phi_k(x^k) + \epsilon_k$.

LEMMA 5.1. *For all $x \in \mathcal{D}_h$ and $k \le l$, we have*

$$f_X(x^{k+1}) \le f_X(x^k) + \epsilon_k, \tag{5.2}$$

$$s_l[f_X(x^{l+1}) - f_X(x)] \le D_h^1(x, x^1) - D_h^{l+1}(x, x^{l+1}) - \sum_{k=1}^{l}(s_k/c_k)D_h^k(x^{k+1}, x^k) + \sum_{k=1}^{l} s_k\epsilon_k, \tag{5.3}$$

$$f_X(x^{l+1}) - f_X(x) \le D_h^1(x, x^1)/s_l + \sum_{k=1}^{l} s_k\epsilon_k/s_l. \tag{5.4}$$

Proof. Equations (4.1) and (4.2) still hold. Equation (5.2) follows from $D_h^k(x^{k+1}, x^k) \ge 0$ (cf. (3.8)) and (cf. (5.1)) $f_X(x^k) - f_X(x^{k+1}) \ge D_h^k(x^{k+1}, x^k)/c_k - \epsilon_k$. Multiplying this inequality by $s_{k-1} = s_k - c_k$ and summing over $k = 1{:}\, l$ yield

$$-s_l f_X(x^{l+1}) + \sum_{k=1}^{l} c_k f_X(x^{k+1}) \ge \sum_{k=1}^{l}(s_{k-1}/c_k)D_h^k(x^{k+1}, x^k) - \sum_{k=1}^{l} s_{k-1}\epsilon_k. \tag{5.5}$$

Subtract (5.5) from (4.5) and rearrange, using $s_k = s_{k-1} + c_k$, to get (5.3). Equation (5.4) follows from (5.3) and the fact $D_h^k(\cdot, x^k) \ge 0$ for all k (cf. (3.8)). ∎

THEOREM 5.2. *Suppose that Assumption* 3.1(i)–(ii), (iv)–(v) *holds with h closed proper convex.*

(i) *If $\sum_{k=1}^{l} s_k\epsilon_k/s_l \to 0$ (see Lemma* 5.3 *for sufficient conditions), then*

$$f_X(x^k) \to \inf_{\mathcal{D}_h} f_X.$$

Hence the assertions of Theorem 4.3(i) *hold.*

(ii) *If h is a B-function, $f_X(x^k) \to \inf_{\mathcal{D}_h} f_X$, $\sum_{k=1}^{\infty} c_k\epsilon_k < \infty$, and $X_* = \operatorname{Arg\,min}_{\mathcal{D}_h} f_X$ is nonempty then $\{x^k\}$ converges to some $x^\infty \in X_*$, and*

$$x^\infty \in \operatorname*{Arg\,min}_X f \qquad \text{if} \qquad \mathcal{D}_{f_X} \subset \mathcal{D}_h.$$

(iii) *If $f_X(x^k) \to \inf_{\mathcal{D}_h} f_X$, $\mathcal{D}_{f_X} \subset \mathcal{D}_h$, and $X_* = \emptyset$, then $|x^k| \to \infty$.*

Proof. (i) The upper limit in (5.4) for any $x \in \mathcal{D}_h$ yields $\limsup_{l\to\infty} f_X(x^l) \le \inf_{\mathcal{D}_h} f_X$, using $\sum_{k=1}^{l} s_k\epsilon_k/s_l \to 0$. But $\{x^k\} \subset \mathcal{D}_h$ (cf. (3.1)), so $\liminf_{l\to\infty} f_X(x^l) \ge \inf_{\mathcal{D}_h} f_X$.

(ii) If $x \in X_*$, then $f_X(x^k) \to f_X(x)$ and $f_X(x^k) \ge f_X(x)$ for all k (cf. (3.1)). Assertions (i)–(iii) of Lemma 4.2 still hold, since the proofs of (i)–(ii) remain valid, whereas in the proof of (iii) we have $x^\infty \in \mathcal{D}_h$ and $f_X(x^\infty) \le \lim_{j\to\infty} f_X(x^{l_j}) = f_X(x)$ (f_X is closed), so $x^\infty \in X_*$ and $f_X(x^k) \ge f_X(x^\infty)$ for all k as before yield $x^k \to x^\infty$.

(iii) Use the proof of Theorem 4.3(iii). ∎

LEMMA 5.3.

(i) *Let $\{\alpha_k\}$, $\{\beta_k\}$, and $\{\varepsilon_k\}$ be sequences in $\mathbb{R}$ s.t. $0 \le \alpha_{k+1} \le (1-\beta_k)\alpha_k + \varepsilon_k$, $\alpha_1 \ge 0$, $0 < \beta_k \le 1$, $\varepsilon_k \ge 0$ for $k = 1, 2, \ldots$, $\sum_{k=1}^{\infty} \beta_k = \infty$, and $\lim_{k\to\infty} \varepsilon_k/\beta_k = 0$. Then $\lim_{k\to\infty} \alpha_k = 0$.*

(ii) *If* $\sum_{l=1}^{\infty} c_l/s_l = \infty$ *and* $\lim_{k\to\infty} \epsilon_k s_k/c_k = 0$, *then* $\lim_{l\to\infty} \sum_{k=1}^{l} s_k\epsilon_k/s_l = 0$.

(iii) *If* $\{c_k\} \subset [c_{\min}, c_{\max}]$ *for some* $0 < c_{\min} \le c_{\max}$ *and* $k\epsilon_k \to 0$, *then* $\sum_{k=1}^{l} s_k\epsilon_k/s_l \to 0$.

Proof. (i) See, e.g., [Pol83, Lem. 2.2.3].

(ii) Use part (i) with $\alpha_l = \sum_{k=1}^{l} s_k\epsilon_k/s_l$, $s_l = \sum_{k=1}^{l} c_k$, and $\alpha_{l+1} = (1 - c_{l+1}/s_{l+1})\alpha_l + \epsilon_{l+1}$.

(iii) Use part (ii) with $c_l/s_l \in [c_{\min}/lc_{\max}, c_{\max}/lc_{\min}]$ for all l. □

6. Finite termination for sharp minima. We now extend to the exact BPM method the finite convergence property of the PPA in the case of sharp minima (cf. [Fer91, Roc76b, BuF93]).

THEOREM 6.1. *Let* f *have a sharp minimum on* X, *i.e.,* $X_* = \operatorname{Arg\,min}_X f \ne \emptyset$, *and there exists* $\alpha > 0$ *s.t.* $f_X(x) \ge \min_X f + \alpha \min_{y\in X_*} |x - y|$ *for all* x. *Consider the exact BPM method applied to* (1.1) *with a B-function* h *s.t.* $\mathcal{D}_{f_X} \subset \mathcal{D}_{\nabla h}$, $\epsilon_k \equiv 0$, *and* $\inf_k c_k > 0$. *Then there exists* k *s.t.* $p^k = 0$ *and* $x^k \in X_*$.

Proof. By Theorem 4.3, $x^k \to x^\infty \in X_*$, so $x^\infty \in \mathcal{D}_{\nabla h}$, $\gamma^k = \nabla h(x^k) \to \nabla h(x^\infty)$ (cf. (3.2) and Fact 2.2) and $\partial f_X(x^k) \ni p^k = (\gamma^{k-1} - \gamma^k)/c_{k-1} \to 0$ (cf. (3.5), (3.6)). But if $x \notin X_*$ and $p \in \partial f_X(x)$, then $|p| \ge \alpha$ (cf. [Ber82, sect. 5.4]) (since for $y = \arg\min_{y\in X_*} |x - y|$, $\min_X f = f_X(y) \ge f_X(x) + \langle p, y - x\rangle$ yields $|p||x - y| \ge \langle p, x - y\rangle \ge \alpha|x - y|$). Hence for some k, $|p^k| < \alpha$ implies $p^k = 0$ and $x^k \in X_*$. □

We note that piecewise linear programs have sharp minima, if any (cf. [Ber82, section 5.4]).

7. Inexact multiplier methods. Following [Eck93, Teb92], this section considers the application of the BPM method to dual formulations of convex programs of the form presented in [Roc70, sect. 28]:

$$\text{minimize} \quad f(x) \quad \text{subject to} \quad g_i(x) \le 0,\ i = 1\colon m, \tag{7.1}$$

under the following

Assumption 7.1. f, $g_1, \dots, g_m$ are closed proper convex functions on $\mathbb{R}^n$ with $\mathcal{D}_f \subset \bigcap_{i=1}^m \mathcal{D}_{g_i}$ and $\operatorname{ri}\mathcal{D}_f \subset \bigcap_{i=1}^m \operatorname{ri}\mathcal{D}_{g_i}$.

Letting $g(\cdot) = (g_1(\cdot), \dots, g_m(\cdot))$, we define the *Lagrangian* of (7.1):

$$L(x,\pi) = \begin{cases} f(x) + \langle \pi, g(x)\rangle & \text{if } x \in \mathcal{D}_f \text{ and } \pi \in \mathbb{R}^m_+, \\ -\infty & \text{if } x \in \mathcal{D}_f \text{ and } \pi \notin \mathbb{R}^m_+, \\ \infty & \text{if } x \notin \mathcal{D}_f, \end{cases}$$

and the *dual functional* $d(\pi) = \inf_x L(x,\pi)$. Then $d(\pi) = -\infty$ if $\pi \notin \mathbb{R}^m_+$. Assume that $d(\pi) > -\infty$ for some π. The *dual problem* to (7.1) is to maximize d, or equivalently to minimize $q(\pi)$ over $\pi \ge 0$, where $q = -d$ is a closed proper convex function. We will apply the BPM method to this problem, using some B-function h on $\mathbb{R}^m$.

We assume that $\mathbb{R}^m_> \subset \mathcal{D}_h$, so that $h_+ = h + \iota_{\mathbb{R}^m_+}$ is a B-function (cf. Lemma 2.6). The *monotone conjugate* of h (cf. [Roc70, p. 111]) defined by $h^+(\cdot) = \sup_{\pi\ge 0}\{\langle \pi, \cdot\rangle - h(\pi)\}$ is *nondecreasing* (i.e., $h^+(u) \le h^+(u')$ if $u \le u'$, since $\langle \pi, u\rangle \le \langle \pi, u'\rangle$ $\forall \pi \ge 0$) and coincides with the convex conjugate h^*_+ of h_+, since $h^+(\cdot) = \sup_\pi\{\langle \pi, \cdot\rangle - h_+(\pi)\} = h^*_+(\cdot)$. We need the following variation on [Eck93, Lem. A3]. Its proof is given in the appendix.

LEMMA 7.2. *If* h *is a closed proper essentially strictly convex function on* $\mathbb{R}^m$ *with* $\mathbb{R}^m_+ \cap \operatorname{ri}\mathcal{D}_h \ne \emptyset$, *then* h^+ *is closed proper convex and essentially smooth,* $\partial h^+(u) = \{\nabla h^+(u)\}$ *for all* $u \in \mathcal{D}_{\partial h^+}$, $\partial h^+ = (\partial h_+)^{-1}$, *and* ∇h^+ *is continuous on* $\mathcal{D}_{\partial h^+} =$

$\mathring{\mathcal{D}}_{h^+} = \operatorname{im}\partial h_+$. *Further,* $\mathcal{D}_{h^+} = \mathcal{D}_{h^+} - \mathbb{R}^m_+$, $\mathring{\mathcal{D}}_{h^+} = \mathring{\mathcal{D}}_{h^+} - \mathbb{R}^m_+$, $\partial h_+ = \partial h + N_{\mathbb{R}^m_+}$, *and* $\nabla h^+ = \nabla h^+ \circ (I + N_{\mathbb{R}^m_+} \circ \nabla h^+)$, *where* I *is the identity operator and* $N_{\mathbb{R}^m_+} = \partial \imath_{\mathbb{R}^m_+}$ *is the normal cone operator of* $\mathbb{R}^m_+$, *i.e.,* $N_{\mathbb{R}^m_+}(\pi) = \{\gamma \le 0 : \langle \gamma, \pi\rangle = 0\}$ *if* $\pi \ge 0$, $N_{\mathbb{R}^m_+}(\pi) = \emptyset$ *if* $\pi \not\ge 0$. *If additionally* $\operatorname{im}\partial h \supset \mathbb{R}^m_>$, *then* h_+ *is cofinite,* $\mathcal{D}_{h^+} = \mathbb{R}^m$, *and* h^+ *is continuously differentiable.*

Since $\mathbb{R}^m_> \subset \mathcal{D}_{h_+} \subset \mathbb{R}^m_+$, to find $\inf_{\pi\ge 0} q(\pi)$ via the BPM method we replace in (3.1)–(3.6) f, X, h, and x^k by q, $\mathbb{R}^m$, h_+, and π^k, respectively. Given $\pi^k \in \mathcal{D}_q \cap \mathcal{D}_{\partial h_+}$ and $\gamma^k \in \partial h_+(\pi^k)$, our *inexact multiplier method* requires finding π^{k+1} and x^{k+1} s.t.

$$L(x^{k+1}, \pi^{k+1}) \le \inf_x L(x, \pi^{k+1}) + \epsilon_k = d(\pi^{k+1}) + \epsilon_k, \tag{7.2}$$

$$\pi^{k+1} = \nabla h^+(\gamma^k + c_k g(x^{k+1})) \tag{7.3}$$

with

$$p^{k+1} \in \partial_{\epsilon_k} q(\pi^{k+1}), \tag{7.4}$$

$$\gamma^{k+1} = \gamma^k - c_k p^{k+1} \in \partial h_+(\pi^{k+1}) \tag{7.5}$$

for some p^{k+1} and γ^{k+1}. Note that (7.2) implies

$$-g(x^{k+1}) \in \partial_{\epsilon_k} q(\pi^{k+1}) = \partial_{\epsilon_k} q(\pi^{k+1}) + \partial \imath_{\mathbb{R}^m_+}(\pi^{k+1}), \tag{7.6}$$

since $-d = q \ge \tilde{q} := -f(x^{k+1}) - \langle \cdot, g(x^{k+1})\rangle = \tilde{q}(\pi^{k+1}) + \langle -g(x^{k+1}), \cdot - \pi^{k+1}\rangle$ and $\mathcal{D}_q \subset \mathbb{R}^m_+$ from $q = \sup_x -L(x,\cdot)$, and $\tilde{q}(\pi^{k+1}) \ge q(\pi^{k+1}) - \epsilon_k$ (cf. (7.2)). Next, (7.3) gives $\pi^{k+1} \in \mathcal{D}_{\partial h_+} \subset \mathcal{D}_{h_+} \subset \mathbb{R}^m_+$, whereas $q(\pi^{k+1}) \le q(\pi^k) + \epsilon_k$ (cf. (5.1)) yields $\pi^{k+1} \in \mathcal{D}_q$. By (7.6), (7.4) and (7.5) hold if we take $p^{k+1} = (\gamma^k - \gamma^{k+1})/c_k$ and

$$\gamma^{k+1} = \gamma^k + c_k g(x^{k+1}) - \tilde{\gamma}^{k+1} \in \partial h_+(\pi^{k+1}) \quad \text{with} \quad \tilde{\gamma}^{k+1} \in N_{\mathbb{R}^m_+}(\pi^{k+1}), \tag{7.7}$$

since then

$$p^{k+1} = -g(x^{k+1}) + \tilde{\gamma}^{k+1}/c_k \in \partial_{\epsilon_k} q(\pi^{k+1}). \tag{7.8}$$

Using (7.3) and $(\partial h_+)^{-1} = \nabla h^+$ (Lemma 7.2), we have

$$\gamma^k + c_k g(x^{k+1}) \in \partial h_+(\pi^{k+1}) = \partial h(\pi^{k+1}) + N_{\mathbb{R}_+}(\pi^{k+1}), \tag{7.9}$$

so we may take $\tilde{\gamma}^{k+1} = 0$; other choices will be discussed later.

Further insight may be gained as follows. Rewrite (7.3) as

$$\pi^{k+1} = \nabla P_k(g(x^{k+1})), \tag{7.10}$$

where

$$P_k(u) = h^+(\gamma^k + c_k u)/c_k \quad \forall u \in \mathbb{R}^m. \tag{7.11}$$

Let

$$L_k(x) = f(x) + \frac{1}{c_k}[h^+(\gamma^k + c_k g(x)) - h^+(\gamma^k)] \tag{7.12}$$

if $x \in \mathcal{D}_f$ ($\subset \mathcal{D}_g = \bigcap_{i=1}^m \mathcal{D}_{g_i}$; cf. Assumption 7.1), $L_k(x) = \infty$ otherwise.

LEMMA 7.3. *Suppose* $\inf_{\mathcal{D}_f} \max_{i=1}^m g_i \le 0$, *e.g., the* feasible set $C_0 = \{x \in \mathcal{D}_f : g(x) \le 0\}$ *of* (7.1) *is nonempty. Then* L_k *is a proper convex function and*

$$\partial L_k(x) = \partial f(x) + \sum_{i=1}^m [\nabla P_k(g(x))]_i \partial g_i(x) \quad \forall x \in \mathcal{D}_{L_k} \supset \mathcal{D}_{\partial L_k}. \tag{7.13}$$

If $\partial L_k(x) \neq \emptyset$, *then* $\pi = \nabla P_k(g(x))$ *is well defined,* $\pi \geq 0$, *and* $\partial L_k(x) = \partial_x L(x,\pi)$, *where*

$$\partial_x L(x,\pi) = \partial f(x) + \sum_{i=1}^{m} \pi_i \partial g_i(x) \quad \forall x \in \mathbb{R}^n, \forall \pi \in \mathbb{R}^m_+. \tag{7.14}$$

If $\hat{x} \in \operatorname{Arg\,min} L_k$ *then* $\hat{x} \in \operatorname{Arg\,min}_x L(x,\hat{\pi})$ *for* $\hat{\pi} = \nabla P_k(g(\hat{x}))$. *The preceding assertions hold when* $\inf_{\mathcal{D}_f} \max_{i=1}^m g_i > 0$ *but* $\mathcal{D}_{h^+} = \mathbb{R}^m$, *e.g., if* $\operatorname{im} \partial h \supset \mathbb{R}^m_>$ (*cf. Lemma* 7.2).

Proof. Using $\gamma^k \in \partial h_+(\pi^k) \subset \mathring{\mathcal{D}}_{h^+}$ (cf. Lemma 7.2) and $\mathring{\mathcal{D}}_{P_k} = (\mathring{\mathcal{D}}_{h^+} - \gamma^k)/c_k$, pick $\tilde{u} \in \mathcal{D}_{P_k} \cap \mathbb{R}^m_>$ and $\tilde{x} \in \mathcal{D}_f$ s.t. $g(\tilde{x}) < \tilde{u}$. Then, since P_k is nondecreasing (as is h^+) and $\operatorname{ri} \mathcal{D}_f \subset \bigcap_i \operatorname{ri} \mathcal{D}_{g_i}$ (cf. Assumption 7.1), Lemma A.1 in the appendix yields $\operatorname{im} \partial P_k \subset \mathbb{R}^m_+$ and (7.13), using $\partial P_k = \{\nabla P_k\}$ (cf. Lemma 7.2). Hence if $\partial L_k(x) \neq \emptyset$, then $\pi = \nabla P_k(g(x)) \geq 0$, so $\operatorname{ri} \mathcal{D}_f \subset \bigcap_i \operatorname{ri} \mathcal{D}_{g_i}$ implies (cf. [Roc70, Thm. 23.8]) $\partial_x L(x,\pi) = \partial f(x) + \sum_i \pi_i \partial g_i(x) = \partial L_k(x)$. If $\hat{x} \in \operatorname{Arg\,min} L_k$, then $0 \in \partial L_k(\hat{x}) = \partial_x L(\hat{x},\hat{\pi})$ for $\hat{\pi} = \nabla P_k(g(\hat{x}))$ yields $\hat{x} \in \operatorname{Arg\,min}_x L(x,\hat{\pi})$. Finally, when $\mathcal{D}_{h^+} = \mathbb{R}^m$, then for any $\tilde{x} \in \mathcal{D}_f$ we may pick $\tilde{u} \in \mathcal{D}_{P_k}$ with $g(\tilde{x}) < \tilde{u}$, since $\mathcal{D}_f \subset \bigcap_i \mathcal{D}_{g_i}$ (Assumption 7.1) and $\mathcal{D}_{P_k} = \mathbb{R}^m$. □

The *exact* multiplier method of [Eck93, Thm. 7] takes $x^{k+1} \in \operatorname{Arg\,min} L_k$ and $\pi^{k+1} = \nabla P_k(g(x^{k+1}))$, assuming h is smooth, $\mathring{\mathcal{D}}_h \supset \mathbb{R}^m_>$ and $\operatorname{im} \nabla h \supset \mathbb{R}^m_>$. Then (7.2) holds with $\epsilon_k = 0$ (cf. Lemma 7.3). Our inexact method requires only that $x^{k+1} \tilde{\in} \operatorname{Arg\,min} L_k$ in the sense that (7.2) holds for a given $\epsilon_k \geq 0$. Thus we have derived the following algorithm.

ALGORITHM 7.4. At iteration $k \geq 1$, having $\pi^k \in \mathcal{D}_q$ and $\gamma^k \in \partial h_+(\pi^k)$, find

$$\begin{aligned} x^{k+1} &\tilde{\in} \operatorname{Arg\,min}_{x \in \mathcal{D}_f} \left\{ f(x) + \frac{1}{c_k} h^+(\gamma^k + c_k g(x)) \right\}, \\ \pi^{k+1} &= \nabla h^+(\gamma^k + c_k g(x^{k+1})) \end{aligned}$$

s.t. (7.2) holds, choose γ^{k+1} satisfying (7.7), and set $p^{k+1} = (\gamma^k - \gamma^{k+1})/c_k$.

Remark 7.5. To find x^{k+1} as in [Ber82, sect. 5.3], suppose that f is *strongly convex*, i.e.,

$$\exists \breve{\alpha} > 0 \quad \text{s.t.} \quad f(x) \geq f(\bar{x}) + \langle \gamma, x - \bar{x} \rangle + \breve{\alpha}|x - \bar{x}|^2/2 \quad \forall x, \bar{x}, \forall \gamma \in \partial f(\bar{x}). \tag{7.15}$$

Adding subgradient inequalities of g_i, $i = 1\colon m$, and using (7.14) yield for all x

$$L(x,\pi^{k+1}) \geq L(x^{k+1},\pi^{k+1}) + \langle \gamma, x - x^{k+1} \rangle + \breve{\alpha}|x - x^{k+1}|^2/2 \quad \forall \gamma \in \partial_x L(x^{k+1},\pi^{k+1}). \tag{7.16}$$

Assuming $\partial L_k(x^{k+1}) \neq \emptyset$ and $\partial_x L(x^{k+1},\pi^{k+1}) = \partial L_k(x^{k+1})$ (e.g., $C_0 \neq \emptyset$ or $\mathcal{D}_{h^+} = \mathbb{R}^m$; cf. Lemma 7.3), let $\Delta_x L_k(x^{k+1}) = \arg\min_{\gamma \in \partial L_k(x^{k+1})} |\gamma|$. Minimization in (7.16) yields

$$d(\pi^{k+1}) \geq L(x^{k+1},\pi^{k+1}) - |\Delta_x L_k(x^{k+1})|^2/2\breve{\alpha}, \tag{7.17}$$

so (7.2) holds if

$$|\Delta_x L_k(x^{k+1})|^2/2\breve{\alpha} \leq \epsilon_k. \tag{7.18}$$

Thus, as in the multiplier methods of [Ber82, sect. 5.3], one may use any algorithm for minimizing L_k that generates a sequence $\{z^j\}$ such that $\liminf_{j\to\infty} |\Delta_x L_k(z^j)| = 0$, setting $x^{k+1} = z^j$ when (7.18) occurs. (If $\breve{\alpha}$ is unknown, it may be replaced in (7.18) by any fixed $\bar{\alpha} > 0$; this only scales $\{\epsilon_k\}$.) Of course, the strong convexity assumption

is not necessary if one can employ the direct criterion (7.2), i.e., $L(z^j,\pi)\le d(\pi)+\epsilon_k$ with $\pi=\nabla P_k(g(z^j))$ (cf. (7.10)), where $d(\pi)$ may be computed with an *error* that can be absorbed in ϵ_k.

Some examples are now in order. We start with three quite abstract examples: the first one treats general separable penalties, whereas the next two employ different assumptions on the behavior of ∇h near $\partial\mathbb{R}^m_>$ (this aspect will be studied in sections 8 and 9). They are followed by four examples of more concrete methods.

Example 7.6. Suppose that $h(\pi)=\sum_{i=1}^m h_i(\pi_i)$, where h_i are B-functions on $\mathbb{R}$ with $\mathcal{D}_{h_i}\supset\mathbb{R}_>$, $i=1\!:\!m$ (cf. Lemma 2.7(ii)). For each i, let $\bar u_i=h_i'(0;1)$ if $0\in\mathcal{D}_{h_i}$ and $\bar u_i=-\infty$ if $0\notin\mathcal{D}_{h_i}$ so that (cf. [Eck93, Ex. 6]) $h_i^+(u_i)=h_i^*(\max\{u_i,\bar u_i\})$ and $\nabla h_i^+(u_i)=\max\{0,\nabla h_i^*(u_i)\}$. Using (7.9) and "maximal" γ^{k+1} in (7.7), Algorithm 7.4 may be written as

$$x^{k+1}\ \tilde\in\ \operatorname{Arg\,min}_x\left\{f(x)+\frac{1}{c_k}\sum_{i=1}^m h_i^*(\max\{\bar u_i,\gamma_i^k+c_kg_i(x)\})\right\},\tag{7.19a}$$

$$\pi_i^{k+1}=\max\{0,\nabla h_i^*(\gamma_i^k+c_kg_i(x^{k+1})\},\quad i=1\!:\!m,\tag{7.19b}$$

$$\gamma_i^{k+1}=\max\{\bar u_i,\gamma_i^k+c_kg_i(x^{k+1})\},\quad i=1\!:\!m.\tag{7.19c}$$

Remark 7.7. To justify (7.19c), note that if we had $\gamma^k<\bar u\in\mathbb{R}^m$, then (7.19a) would not penalize constraint violations $g_i(x)\in(0,(\bar u_i-\gamma_i^k)/c_k]$. An *ordinary* penalty method (cf. [Ber82, p. 354]) would use (7.19a) and (7.19b) with $\gamma^k\equiv\bar u$ and $c_k\uparrow\infty$. Thus (7.19) is a *shifted* penalty method in which the *shifts* γ^k should ensure convergence even for $\sup_k c_k<\infty$, thus avoiding the ill-conditioning of ordinary penalty methods.

Example 7.8. Suppose that $\mathcal{D}_{\partial h}\cap\mathbb{R}^m_+=\mathcal{D}_{\nabla h}\cap\mathbb{R}^m_+$ so that $\partial h_+=\nabla h+\partial\imath_{\mathbb{R}^m_+}$ from $\mathbb{R}^m_>\subset\mathcal{D}_h$ (cf. [Roc70, Thm. 23.8] and Fact 2.2). Then we may use $\gamma^k=\nabla h(\pi^k)$ for all k, since the maximal shift $\gamma^{k+1}=\nabla h(\pi^{k+1})$ satisfies (7.7) due to (7.9). Thus Algorithm 7.4 becomes

$$\begin{aligned}&x^{k+1}\ \tilde\in\ \operatorname{Arg\,min}_x\left\{f(x)+\frac{1}{c_k}h^+(\nabla h(\pi^k)+c_kg(x))\right\},\\&\pi^{k+1}=\nabla h^+(\nabla h(\pi^k)+c_kg(x^{k+1})).\end{aligned}$$

In the separable case of Example 7.6, the formulas specialize to

$$\begin{aligned}&x^{k+1}\ \tilde\in\ \operatorname{Arg\,min}_x\left\{f(x)+\frac{1}{c_k}\sum_{i=1}^m h_i^*(\max\{\bar u_i,\nabla h_i(\pi_i^k)+c_kg_i(x)\})\right\},\\&\pi_i^{k+1}=\max\{0,\nabla h_i^*(\nabla h_i(\pi_i^k)+c_kg_i(x^{k+1}))\},\quad i=1\!:\!m,\end{aligned}$$

where $\bar u_i=\nabla h_i(0)$ if $0\in\mathcal{D}_{\partial h_i}$, $\bar u_i=-\infty$ if $0\notin\mathcal{D}_{\partial h_i}$, $i=1\!:\!m$.

Example 7.9. Let $h(\pi)=\sum_{i=1}^m\psi(\pi_i)$, where ψ is a B-function on $\mathbb{R}$ with $\mathcal{D}_{\nabla\psi}\supset\mathbb{R}_>$. Let $\bar v=\psi'(0;1)$ if $0\in\mathcal{D}_\psi$ and $\bar v=-\infty$ if $0\notin\mathcal{D}_\psi$. Then $\partial\psi_+(t)=\{\psi'(t;1)\}$ for $t>0$, $\partial\psi_+(0)=(-\infty,\bar v]$ if $\bar v>-\infty$, $\partial\psi_+(0)=\emptyset$ if $\bar v=-\infty$. Using (7.7) and (7.9) as in Example 7.6, we may let $\gamma_i^{k+1}=\psi'(\pi_i^{k+1};1)$, $i=1\!:\!m$. Thus Algorithm 7.4 becomes

$$\begin{aligned}&x^{k+1}\ \tilde\in\ \operatorname{Arg\,min}_x\left\{f(x)+\frac{1}{c_k}\sum_{i=1}^m\psi^+(\psi'(\pi_i^k;1)+c_kg_i(x))\right\},\\&\pi_i^{k+1}=\nabla\psi^+(\psi'(\pi_i^k;1)+c_kg_i(x^{k+1})),\quad i=1\!:\!m,\end{aligned}\tag{7.20}$$

i.e.,

$$\begin{aligned} x^{k+1} &\tilde{\in} \operatorname{Arg\,min}_x \left\{ f(x) + \frac{1}{c_k} \sum_{i=1}^{m} \psi^*(\max\{\bar{v}, \psi'(\pi_i^k; 1) + c_k g_i(x)\}) \right\}, \\ \pi_i^{k+1} &= \max\{0, \nabla\psi^*(\psi'(\pi_i^k; 1) + c_k g_i(x^{k+1}))\}, \quad i = 1{:}\, m. \end{aligned} \tag{7.21}$$

Example 7.10. For $\psi(t) = |t|^\alpha/\alpha$ with $\alpha > 1$ and $\beta = \alpha/(\alpha - 1)$ (cf. Example 2.8(1)), (7.21) becomes

$$x^{k+1} \tilde{\in} \operatorname{Arg\,min}_x \left\{ f(x) + \frac{1}{\beta c_k} \sum_{i=1}^{m} \max\{0, (\pi_i^k)^{1/(\beta-1)} + c_k g_i(x)\}^\beta \right\}, \tag{7.22a}$$

$$\pi_i^{k+1} = \max\{0, (\pi_i^k)^{1/(\beta-1)} + c_k g_i(x^{k+1})\}^{\beta-1}, \quad i = 1{:}\, m. \tag{7.22b}$$

Even if f and all g_i are smooth, for $\beta = 2$ the objective of (7.22a) is, in general, only once continuously differentiable. This is a well-known drawback of quadratic augmented Lagrangians (cf. [Ber82, TsB93]). However, for $\beta = 3$ we obtain a *cubic multiplier method* [Kiw97] with a *twice* continuously differentiable objective.

Example 7.11 (see [Eck93, Ex. 7]). For $\psi(t) = t \ln t - t$ (cf. Example 2.8(3)), (7.21) reduces to

$$\begin{aligned} x^{k+1} &\tilde{\in} \operatorname{Arg\,min}_x \left\{ f(x) + \frac{1}{c_k} \sum_{i=1}^{m} \pi_i^k \exp[c_k g_i(x)] \right\}, \\ \pi_i^{k+1} &= \pi_i^k \exp[c_k g_i(x^{k+1})], \quad i = 1{:}\, m, \end{aligned} \tag{7.23}$$

i.e., to an inexact *exponential multiplier method* (cf. [Ber82, sect. 5.1.2; TsB93]).

Example 7.12. For $\psi(t) = -\ln t$ (cf. Example 2.8(4)), (7.21) reduces to

$$\begin{aligned} x^{k+1} &\tilde{\in} \operatorname{Arg\,min}_x \left\{ f(x) - \frac{1}{c_k} \sum_{i=1}^{m} \ln[1/\pi_i^k - c_k g_i(x)] \right\}, \\ \pi_i^{k+1} &= \pi_i^k / [1 - c_k \pi_i^k g_i(x^{k+1})], \quad i = 1{:}\, m, \end{aligned}$$

i.e., to an inexact *shifted logarithm barrier method* (which was also derived heuristically in [Cha94, Ex. 4.2]). This method is related, but not identical, to ones in [CGT92, GMSW88]; cf. [CGT94].

Example 7.13. If $\psi(t) = -t^\alpha/\alpha$, $\alpha \in (0, 1)$ (cf. Example 2.8(2)), (7.21) reduces to

$$\begin{aligned} x^{k+1} &\tilde{\in} \operatorname{Arg\,min}_x \left\{ f(x) - \frac{1}{\beta c_k} \sum_{i=1}^{m} [(\pi_i^k)^{1/(\beta-1)} - c_k g_i(x)]^\beta \right\}, \\ \pi_i^{k+1} &= [(\pi_i^k)^{1/(\beta-1)} - c_k g_i(x^{k+1})]^{\beta-1}, \quad i = 1{:}\, m, \end{aligned}$$

where $\beta = \alpha/(\alpha - 1)$; $\beta = -1$ corresponds to a *shifted Carroll barrier method*.

8. Convergence of multiplier methods. Ideally, the sequences $\{x^k\}$ and $\{\pi^k\}$ generated by Algorithm 7.4 should solve the primal and dual problems asymptotically. Convergence of $\{\pi^k\}$ may be studied in the framework of section 5, but that of $\{x^k\}$ will require more work. For the framework of section 5, in addition to Assumption 7.1, we make the following standing assumptions.

Assumption 8.1.

(i) h_+ is a B-function s.t. $\mathcal{D}_{h_+} \supset \mathbb{R}^m_>$ (e.g., so is h; cf. Lemma 2.6).

(ii) Either $\mathcal{D}_q \cap \mathbb{R}^m_> \neq \emptyset$ or $\emptyset \neq \mathcal{D}_q \subset \mathcal{D}_{h_+}$, where $-q = d = \inf_x L(x,\cdot)$.

(iii) $\{c_k\}$ is a sequence of positive numbers s.t. $s_k = \sum_{j=1}^k c_j \to \infty$.

Remark 8.2. Under Assumption 8.1, q is closed proper convex, $\mathring{\mathcal{D}}_{h_+} = \mathbb{R}^m_> \subset \mathcal{D}_{h_+} \subset \mathbb{R}^m_+$, $\operatorname{cl}\mathcal{D}_{h_+} = \mathbb{R}^m_+ \supset \mathcal{D}_q$, $\mathcal{D}_q \cap \mathring{\mathcal{D}}_{h_+} \neq \emptyset$ if $\mathcal{D}_q \cap \mathbb{R}^m_> \neq \emptyset$, and $\inf_{\mathcal{D}_{h_+}} q = \inf q = \inf_{\operatorname{cl}\mathcal{D}_{h_+}} q$. Hence for the BPM method applied to the dual problem $\sup d = -\inf q$ with a B-function h_+ we may invoke the results of sections 3–6 (replacing f, X, and h with q, $\mathbb{R}^m$, and h_+, respectively).

We first translate Theorem 5.2 for the dual variables $\{\pi^k\}$ of Algorithm 7.4.

THEOREM 8.3. *If* $\sum_{j=1}^k s_j\epsilon_j/s_k \to 0$ (*cf. Lemma* 5.3), *then* $d(\pi^k) \to \sup d$. *If* $d(\pi^k) \to \sup d$, $\mathcal{D}_{h_+} \cap \operatorname{Arg\,max} d \neq \emptyset$, *and* $\sum_{k=1}^\infty c_k\epsilon_k < \infty$, *then* $\pi^k \to \pi^\infty \in \operatorname{Arg\,max} d$. *If* $d(\pi^k) \to \sup d$, $\mathcal{D}_q \subset \mathcal{D}_{h_+}$ *and* $\operatorname{Arg\,max}_{\mathcal{D}_{h_+}} d = \emptyset$ (*e.g.*, $\mathcal{D}_{h_+} = \mathbb{R}^m_+$ *and* $\operatorname{Arg\,max} d = \emptyset$), *then* $|\pi^k| \to \infty$.

Proof. This follows from Remark 8.2 and Theorem 5.2, since $\mathcal{D}_{h_+} \cap \operatorname{Arg\,max} d \subset \operatorname{Arg\,max}_{\mathcal{D}_{h_+}} d \subset \operatorname{Arg\,max} d$ if $\mathcal{D}_{h_+} \cap \operatorname{Arg\,max} d \neq \emptyset$. ∎

Thanks to Bregman proximal regularization, $\{\pi^k\}$ in Theorem 8.3 may converge to a particular dual solution even when $\operatorname{Arg\,max} d$ is not a singleton. Since the primal subproblems of Algorithm 7.4 are not regularized, convergence of $\{x^k\}$ will require additional assumptions (cf. Remark 8.5). We start with the "standard" case of $\mathcal{D}_{\nabla h} \supset \mathbb{R}^m_+$ (as in Example 7.10).

THEOREM 8.4. *Let* $\mathcal{D}_{\nabla h} \supset \mathbb{R}^m_+$, $\gamma^k = \nabla h(\pi^k)$ *for all* k (*cf. Example* 7.8) *and* $\sum_{j=1}^k s_j\epsilon_j/s_k \to 0$. *Then* $d(\pi^k) \to \sup d$. *If* $\operatorname{Arg\,max} d \neq \emptyset$ *and* $\sum_{k=1}^\infty c_k\epsilon_k < \infty$, *then* $\pi^k \to \pi^\infty \in \operatorname{Arg\,max} d$, *and if* $\inf_k c_k > 0$, *then*

$$\limsup_{k\to\infty} f(x^k) \le \sup_\pi d(\pi) \quad \textit{and} \quad \limsup_{k\to\infty} g_i(x^k) \le 0, \quad i = 1\colon m, \tag{8.1}$$

and every limit point of $\{x^k\}$ *solves* (7.1). *If* $\operatorname{Arg\,max} d = \emptyset$, *then* $|\pi^k| \to \infty$.

Proof. Since $\mathcal{D}_h \supset \mathcal{D}_{\nabla h} \supset \mathbb{R}^m_+$, the assertions about $\{\pi^k\}$ follow from Theorem 8.3. Suppose $\pi^k \to \pi^\infty \in \operatorname{Arg\,max} d$, $\inf_k c_k > 0$. Since $p^k = (\gamma^{k-1} - \gamma^k)/c_{k-1}$ with $p^k + g(x^k) \in N_{\mathbb{R}^m_+}(\pi^k)$ (cf. Example 7.8), we have (cf. Lemma 7.2) $\langle \pi^k, g(x^k)\rangle = -\langle \pi^k, p^k\rangle$ and $g(x^k) \le -p^k$ $\forall k > 1$, with $p^k \to 0$, since $\pi^k \to \pi^\infty$, ∇h is continuous on $\mathbb{R}^m_+$, and $c_k \ge c_{\min}$ $\forall k$. Hence $\langle \pi^k, g(x^k)\rangle \to 0$ and $\limsup_{k\to\infty} g_i(x^k) \le 0$ $\forall i$. Since $L(x^k,\pi^k) \le \inf_x L(x,\pi^k) + \epsilon_{k-1}$ (cf. (7.2)) means $f(x^k) + \langle \pi^k, g(x^k)\rangle \le f(x) + \langle \pi^k, g(x)\rangle + \epsilon_{k-1}$ for any x, in the limit $\limsup_k f(x^k) \le L(x,\pi^\infty)$ ($\epsilon_k \to 0$), so $\limsup_k f(x^k) \le d(\pi^\infty)$. Suppose $x^k \xrightarrow{K} x^\infty$ for some x^∞ and $K \subset \{1,2,\ldots\}$. By (8.1), $f(x^\infty) \le \sup d$ and $g(x^\infty) \le 0$ (f and g are closed), so by weak duality, $f(x^\infty) \ge \sup d$, $f(x^\infty) = \max d$, and x^∞ solves (7.1). ∎

Remark 8.5. Let C_* denote the optimal solution set for (7.1). If (7.1) is consistent (i.e., $C_0 \neq \emptyset$), then C_* is nonempty and compact iff f and g_i, $i = 1\colon m$, have no common direction of recession [Ber82, sect. 5.3], in which case (8.1) implies that $\{x^k\}$ is bounded and hence has limit points. In particular, if $C_* = \{x^*\}$, then $x^k \to x^*$ in Theorem 8.4.

Remark 8.6. Theorems 8.3 and 8.4 subsume [Eck93, Thm. 7], which additionally requires that $\epsilon_k \equiv 0$, $\operatorname{im}\nabla h \supset \mathbb{R}^m_>$ and each g_i is continuous on $\mathcal{D}_f$.

We now establish finite convergence of an exact version of Algorithm 7.4 (with $\epsilon_k \equiv 0$) in the case of a dual sharp minimum (cf. [Ber82, sect. 5.4] and [BuF93]).

THEOREM 8.7. *Let* (7.1) *be s.t.* $q = -d$ *has a sharp minimum. Let* $\mathcal{D}_{\nabla h} \supset \mathbb{R}^m_+$, $\inf_k c_k > 0$, $\epsilon_k = 0$, *and* $\gamma^k = \nabla h(\pi^k)$ (*cf. Example* 7.8) *for all* k. *Then there exists* k *s.t.* $p^k = 0$, $\pi^k \in \operatorname{Arg\,max} d$, *and* x^k *solves* (7.1).

Proof. Using the proof of Theorem 6.1 with $\pi^k \to \pi^\infty \in \operatorname{Arg\,max} d \subset \mathcal{D}_{\nabla h}$ and $\gamma^k = \nabla h(\pi^k) \to \nabla h(\pi^\infty)$, we get k s.t. $\pi^k \in \operatorname{Arg\,max} d$ and $p^k = 0$; the conclusion follows from the proof of Theorem 8.4. ∎

Remark 8.8. Results on finite convergence of other multiplier methods are restricted to only once continuously differentiable augmented Lagrangians [Ber82, sect. 5.4], whereas Theorem 8.7 covers Example 7.10 also with $\beta > 2$. Applications include polyhedral programs.

We shall need the following result, similar to ones in [Ber82, sect. 5.3] and [TsB93].

LEMMA 8.9. *With $u^{k+1} := g(x^{k+1})$, for each k, we have*

$$L(x^{k+1}, \pi^{k+1}) = L_k(x^{k+1}) + D_{h^+}(\gamma^k, \gamma^k + c_k u^{k+1})/c_k \geq L_k(x^{k+1}), \tag{8.2}$$

$$L_k(x^{k+1}) = L(x^{k+1}, \pi^k) + D_{h^+}(\gamma^k + c_k u^{k+1}, \gamma^k)/c_k \geq L(x^{k+1}, \pi^k), \tag{8.3}$$

$$\begin{aligned} L(x^{k+1}, \pi^{k+1}) - L(x^{k+1}, \pi^k) &= \left\langle \pi^{k+1} - \pi^k, u^{k+1} \right\rangle \\ &= \left\langle \nabla h^+(\gamma^k + c_k u^{k+1}) - \nabla h^+(\gamma^k), u^{k+1} \right\rangle \geq 0, \end{aligned} \tag{8.4}$$

$$d(\pi^k) \leq L(x^{k+1}, \pi^k) \leq L_k(x^{k+1}) \leq L(x^{k+1}, \pi^{k+1}) \leq d(\pi^{k+1}) + \epsilon_k. \tag{8.5}$$

Proof. As for (8.2), use (7.12), (7.3), (2.4), and convexity of h^+ to develop

$$\begin{aligned} L(x^{k+1}, \pi^{k+1}) - L_k(x^{k+1}) &= \left\langle \pi^{k+1}, u^{k+1} \right\rangle - [h^+(\gamma^k + c_k u^{k+1}) - h^+(\gamma^k)]/c_k \\ &= [h^+(\gamma^k) - h^+(\gamma^k + c_k u^{k+1}) \\ &\qquad - \left\langle \nabla h^+(\gamma^k + c_k u^{k+1}), -c_k u^{k+1} \right\rangle]/c_k \\ &= D_{h^+}(\gamma^k, \gamma^k + c_k u^{k+1})/c_k \geq 0. \end{aligned}$$

Since $\nabla h^+ = (\partial h_+)^{-1}$ (cf. Lemma 7.2) and $\gamma^k \in \partial h_+(\pi^k)$ (cf. (7.5)), $\pi^k = \nabla h^+(\gamma^k)$, so

$$\begin{aligned} L_k(x^{k+1}) - L(x^{k+1}, \pi^k) &= [h^+(\gamma^k + c_k u^{k+1}) - h^+(\gamma^k)]/c_k - \left\langle \pi^k, u^{k+1} \right\rangle \\ &= [h^+(\gamma^k + c_k u^{k+1}) - h^+(\gamma^k) - \left\langle \nabla h^+(\gamma^k), c_k u^{k+1} \right\rangle]/c_k \\ &= D_{h^+}(\gamma^k + c_k u^{k+1}, \gamma^k)/c_k \geq 0 \end{aligned}$$

yields (8.3), and (8.4) holds with $\left\langle \nabla h^+(\gamma^k + c_k u^{k+1}) - \nabla h^+(\gamma^k), c_k u^{k+1} \right\rangle / c_k \geq 0$ by the convexity of h^+. Equation (8.5) follows from (8.2)–(8.4) and (7.2). ∎

Theorem 8.4 covers only methods with $\mathcal{D}_{\nabla h} \supset \mathbb{R}^m_+$, such as Example 7.10. To handle other examples in section 9, we shall use the following abstraction of the ergodic framework of [TsB93]. For each k, define the aggregate primal solution

$$\breve{x}^{k+1} = \sum_{j=1}^{k} c_j x^{j+1}/s_k, \quad \text{where} \quad s_k = \sum_{j=1}^{k} c_j. \tag{8.6}$$

Since g is convex and $c_j g(x^{j+1}) \leq -c_j p^{j+1} = \gamma^{j+1} - \gamma^j$ for $j = 1\colon k$ by (7.7) and (7.8),

$$g(\breve{x}^{k+1}) \leq \sum_{j=1}^{k} c_j g(x^{j+1})/s_k \leq (\gamma^{k+1} - \gamma^1)/s_k. \tag{8.7}$$

LEMMA 8.10. *Suppose that $\sup_{i,k} \gamma_i^k < \infty$, $\epsilon_k \to 0$, $\left\langle \pi^k, u^k \right\rangle \to 0$, and $d(\pi^k) \to d^\infty < \infty$. Then*

$$\limsup_{k\to\infty} f(\breve{x}^k) \leq d^\infty \quad \textit{and} \quad \limsup_{k\to\infty} g_i(\breve{x}^k) \leq 0, \quad i = 1\colon m. \tag{8.8}$$

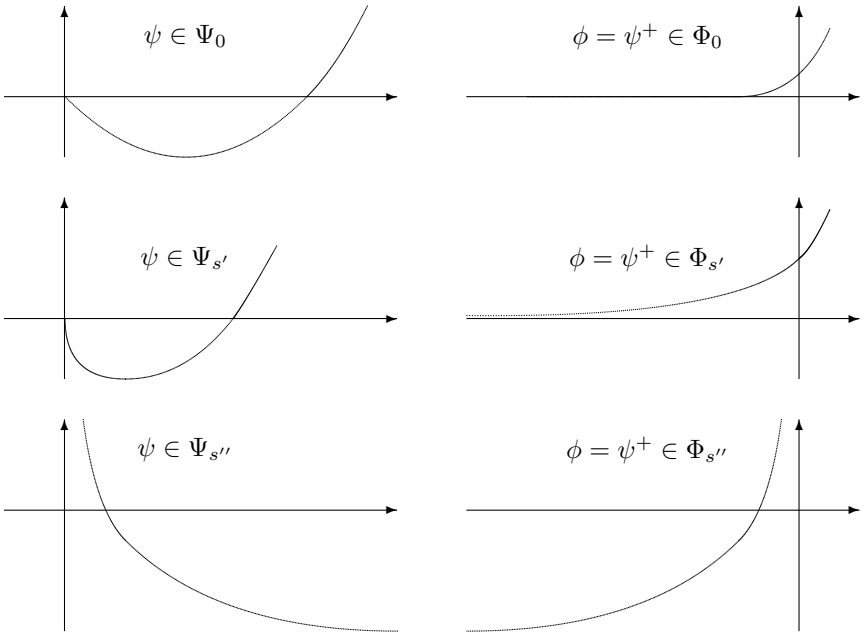

FIG. 9.1. *Examples of B-functions and corresponding penalty functions.*

If $\{\breve{x}^k\}$ *has a limit point* x^∞ (*e.g.,* $C_* \neq \emptyset$ *is bounded; cf. Remark* 8.11), *then* x^∞ *solves* (7.1), $f(x^\infty) = d^\infty = \max d$, *and each limit point of* $\{\pi^k\}$ *maximizes* d.

Proof. By (8.7), $\limsup_k g_i(\breve{x}^k) \leq 0\ \forall i$, since $s_k \to \infty$. By (8.6) and convexity of f, $f(\breve{x}^{k+1}) \leq \sum_{j=1}^k c_j f(x^{j+1})/s_k$, while $f(x^k) = L(x^k, \pi^k) - \langle \pi^k, u^k \rangle \to d^\infty$ from (8.5), so $\limsup_k f(\breve{x}^k) \leq d^\infty$. Suppose $\breve{x}^k \xrightarrow{K} x^\infty$. By (8.8), $f(x^\infty) \leq d^\infty$ and $g(x^\infty) \leq 0$ (f and g are closed). Hence by weak duality, $f(x^\infty) \geq d^\infty \leftarrow d(\pi^k)$, $f(x^\infty) = d^\infty = \max d$, and x^∞ solves (7.1). Since $d(\pi^k) \to d^\infty$ and d is closed, each cluster of $\{\pi^k\}$ maximizes d. ∎

Remark 8.11. If $C_* \neq \emptyset$ is bounded, then (8.8) implies that $\{\breve{x}^k\}$ is bounded (cf. Remark 8.5). In particular, if $C_* = \{x^*\}$, then $\breve{x}^k \to x^*$ in Lemma 8.10.

9. Classes of penalty functions. Examples 7.11–7.13 stem from B-functions of the form $h(\pi) = \sum_{i=1}^m \psi(\pi_i)$, where ψ is a B-function on $\mathbb{R}$ s.t. $\psi_+ = \psi$. Since $\psi_+ = (\psi^+)^*$, such examples may also be derived by choosing suitable penalty functions ϕ on $\mathbb{R}$ and letting $\psi = \phi^*$ (cf. Lemma 2.9). Let us first define several useful classes of B-functions and penalty functions.

DEFINITION 9.1. *We say that* $\psi \in \Psi$ *iff* ψ *is a B-function on* $\mathbb{R}$ *with* $\mathcal{D}_\psi \supset \mathbb{R}_>$. *Let* $\tilde{\Psi} = \{\psi \in \Psi : \mathcal{D}_{\nabla\psi} \supset \mathbb{R}_>\}$, $\Psi_0 = \{\psi \in \tilde{\Psi} : \mathcal{D}_{\partial\psi} \supset \mathbb{R}_+\}$, $\Psi_s = \{\psi \in \tilde{\Psi} : \mathcal{D}_{\partial\psi} = \mathbb{R}_>\}$, $\Psi_{s'} = \{\psi \in \Psi_s : 0 \in \mathcal{D}_\psi\}$, $\Psi_{s''} = \{\psi \in \Psi_s : 0 \notin \mathcal{D}_\psi\}$ (*cf. Fig.* 9.1).

Remark 9.2. We have $\tilde{\Psi} = \Psi_0 \cup \Psi_s$, $\Psi_0 = \{\psi \in \tilde{\Psi} : 0 \in \mathcal{D}_{\partial\psi}\}$, $\Psi_s = \{\psi \in \tilde{\Psi} : 0 \notin \mathcal{D}_{\partial\psi}\}$ (since $\mathcal{D}_{\partial\psi} \supset \mathcal{D}_{\nabla\psi} \supset \mathbb{R}_>$ if $\psi \in \tilde{\Psi}$) and $\psi_+ = \psi$ if $\psi \in \Psi_s$ (from $\mathcal{D}_\psi \subset \operatorname{cl} \mathcal{D}_{\partial\psi} = \mathbb{R}_+$).

DEFINITION 9.3. *We say that* $\phi \in \Phi$ *iff* $\phi : \mathbb{R} \to (-\infty, \infty]$ *is closed proper convex essentially smooth,* $\mathring{\mathcal{D}}_\phi = \mathcal{D}_\phi$, *and* $\mathbb{R}_> \subset \operatorname{im} \nabla\phi \subset \mathbb{R}_+$. *Let* $t_\phi = \sup_{t \in \mathcal{D}_\phi} t$, $t_\phi^0 = \sup_{\nabla\phi(t)=0} t$, $\Phi_s = \{\phi \in \Phi : \phi$ *is strictly convex*$\}$, $\Phi_0 = \{\phi \in \Phi : \phi$ *is strictly convex on* $(t_\phi^0, t_\phi), t_\phi^0 > -\infty\}$, $\Phi_{s'} = \{\phi \in \Phi_s : \inf \phi > -\infty\}$, $\Phi_{s''} = \{\phi \in \Phi_s : \inf \phi = -\infty\}$, $\tilde{\Phi} = \Phi_0 \cup \Phi_s$.

Remark 9.4. If $\phi \in \Phi$, then ϕ is nondecreasing ($\operatorname{im}\nabla\phi \subset \mathbb{R}_+$), $\mathcal{D}_\phi = (-\infty, t_\phi)$, $t_\phi^0 = -\infty$ iff $\operatorname{im}\nabla\phi = \mathbb{R}_>$, $\phi \in \Phi_s$ iff $\nabla\phi$ is increasing, $\phi \in \Phi_0$ iff $\nabla\phi$ is increasing on (t_ϕ^0, t_ϕ), and $t_\phi^0 > -\infty$ (cf. [Roc70, p. 254]). Also $\phi \in \Phi$ iff ϕ is closed proper convex, $\mathcal{D}_{\nabla\phi} = \mathring{\mathcal{D}}_\phi = \mathcal{D}_\phi$ (cf. Fact 2.3(i)), and $\mathbb{R}_> \subset \operatorname{im}\nabla\phi \subset \mathbb{R}_+$.

We now discuss duality relations between Definitions 9.1 and 9.3.

LEMMA 9.5. *If $\phi \in \Phi$, then ϕ^* is a B-function with $\mathbb{R}_> \subset \mathcal{D}_{\phi^*} \subset \mathbb{R}_+$, $(\phi^*)^+ = \phi^{**} = \phi$, $\lim_{t\downarrow-\infty}\nabla\phi(t) = 0$, $\lim_{t\uparrow t_\phi}\nabla\phi(t) = \lim_{t\uparrow t_\phi}\phi(t) = \infty$, and $\phi 0^+ = \imath^*_{\mathbb{R}_+}$. If $\phi \in \Phi_s$, then ϕ^* is essentially smooth, $\nabla\phi^* = (\nabla\phi)^{-1}$, and $\mathcal{D}_{\partial\phi^*} = \mathcal{D}_{\nabla\phi^*} = \mathbb{R}_>$. If $\phi \in \Phi_0$, then $\nabla\phi^* = (\nabla\phi)^{-1}$, $\mathcal{D}_{\nabla\phi^*} = \mathbb{R}_>$ and $\partial\phi^*(0) = (-\infty, t_\phi^0]$.*

Proof. By Definition 9.3 and Lemma 2.9, $\mathbb{R}_> \subset \operatorname{im}\nabla\phi \subset \mathbb{R}_+$ and ϕ^* is a B-function with $\operatorname{ri}\mathcal{D}_{\phi^*} \subset \operatorname{im}\nabla\phi \subset \mathcal{D}_{\phi^*}$, so $\mathbb{R}_> \subset \mathcal{D}_{\phi^*} \subset \mathbb{R}_+$. $\mathcal{D}_{\phi^*} \subset \mathbb{R}_+$ yields $(\phi^*)^+ = \phi^{**} = \phi$. Since $\mathbb{R}_> \subset \operatorname{im}\nabla\phi \subset \mathbb{R}_+$ and $\nabla\phi$ is nondecreasing, $\lim_{t\downarrow-\infty}\nabla\phi(t) = 0$ and $\lim_{t\uparrow t_\phi}\nabla\phi(t) = \infty$. Since ϕ is closed and proper, $\phi 0^+ = \imath^*_{\mathcal{D}_{\phi^*}}$ [Roc70, Thm. 13.3] with $\imath^*_{\mathcal{D}_{\phi^*}} = \imath^*_{\operatorname{cl}\mathcal{D}_{\phi^*}}$ and $\operatorname{cl}\mathcal{D}_{\phi^*} = \mathbb{R}_+$ from $\mathbb{R}_> \subset \mathcal{D}_{\phi^*} \subset \mathbb{R}_+$. If $t_\phi < \infty$, then $\lim_{t\uparrow t_\phi}\phi(t) = \infty$ from $t_\phi \notin \mathcal{D}_\phi$ and closedness of ϕ; otherwise $\lim_{t\uparrow t_\phi}\phi(t) = \infty$ from $\infty = \phi 0^+(1) = \lim_{t\uparrow\infty}[\phi(t) - \phi(0)]/t$ [Roc70, Thm. 8.5]. If $\phi \in \Phi_s$, then ϕ^* is essentially smooth, $\nabla\phi^* = (\nabla\phi)^{-1}$, and $\mathcal{D}_{\nabla\phi^*} = \mathcal{D}_{\partial\phi^*} = \mathring{\mathcal{D}}_{\phi^*} = \mathbb{R}_>$ (Facts 2.1 and 2.3). If $\phi \in \Phi_0$, then $\partial\phi^* = (\partial\phi)^{-1} = \{(\nabla\phi)^{-1}\}$ (Facts 2.1 and 2.3(i)) yields $\partial\phi^*(0) = \{t : \nabla\phi(t) = 0\} = (-\infty, t_\phi^0]$ ($0 \le \nabla\phi(t) \le \nabla\phi(t_\phi^0)\ \forall t \le t_\phi^0$), whereas $\nabla\phi$ is increasing on (t_ϕ^0, t_ϕ) (Remark 9.4), so $\partial\phi^* = \{(\nabla\phi)^{-1}\}$ is single valued on $\mathbb{R}_> = (\nabla\phi(t_\phi^0), \infty) \subset \operatorname{im}\nabla\phi$, and hence $\partial\phi^* = \{\nabla\phi^*\}$ on $\mathbb{R}_>$ (Fact 2.2). ∎

LEMMA 9.6. *Let ψ be a B-function on $\mathbb{R}$ s.t. $\mathcal{D}_\psi \supset \mathbb{R}_>$. Then $\psi^+ \in \Phi$. Suppose that $\mathcal{D}_{\nabla\psi} \supset \mathbb{R}_>$. If $\partial\psi(0) = \emptyset$ (i.e., $0 \notin \mathcal{D}_\psi$ or $\psi'(0;1) = -\infty$), then ψ_+ is essentially smooth and $\psi^+ \in \Phi_s$. If $\partial\psi(0) \ne \emptyset$ (i.e., $\psi'(0;1) > -\infty$), then $\psi^+ \in \Phi_0$ with $t^0_{\psi^+} = \psi'(0;1)$, and there exists a B-function $\breve{\psi}$ s.t. $\psi_+ = \breve{\psi}_+$, $\psi^+ = \breve{\psi}^+$, $\mathcal{D}_{\nabla\breve{\psi}} \supset \mathbb{R}_+$, and $\nabla\breve{\psi}(0) = t^0_{\psi^+}$.*

Proof. $\psi_+ = \psi + \imath_{\mathbb{R}_+}$ is a B-function (Lemma 2.6) and $\psi^+ = \psi^*_+$, so $\mathcal{D}_{\psi^+} = \mathring{\mathcal{D}}_{\psi^+}$ (Lemma 2.9(i)). Also ψ^+ is nondecreasing and essentially smooth (Lemma 7.2), so $\operatorname{im}\nabla\psi^+ \subset \mathbb{R}_+$, whereas $\mathbb{R}_> \subset \mathcal{D}_{\psi_+}$ yields $\mathbb{R}_> \subset \mathring{\mathcal{D}}_{\psi_+} \subset \mathcal{D}_{\partial\psi_+} = \operatorname{im}\partial\psi^+ = \operatorname{im}\nabla\psi^+$. Suppose $\mathcal{D}_{\nabla\psi} \supset \mathbb{R}_>$. By strict convexity of ψ (cf. Definition 2.4(i)), $\nabla\psi_+ = \nabla\psi$ is increasing on $\mathbb{R}_>$, so $\nabla\psi^+ = (\nabla\psi_+)^{-1}$ is increasing on $(t^0, \infty) \cap \mathcal{D}_{\psi^+}$ with $t^0 = \lim_{t\downarrow 0}\nabla\psi(t)$, and hence ψ^+ is strictly convex on (t^0, ∞) (cf. [Roc70, p. 254]). If $\partial\psi(0) = \emptyset$, then $t^0 = -\infty$, $\psi^+ \in \Phi_s$, and ψ_+ is essentially smooth (Fact 2.3(ii)). Otherwise, $t^0 = \psi'(0;1) = t^0_{\psi^+}$. Let $\breve{\psi}(t) = \psi(t)\ \forall t \ge 0$, and let $\breve{\psi}(t)$ for $t \le 0$ be a strictly convex quadratic function s.t. $\breve{\psi}(0) = \psi(0)$ and $\breve{\psi}'(0;-1) = -\psi'(0;1)$. Then $\breve{\psi}_+ = \psi_+$ and $\nabla\breve{\psi}(0) = t^0_{\psi^+}$. ∎

Remark 9.7. Lemmas 9.5 and 9.6 imply the following duality relations: $\Phi^* = \Psi_+$, $\tilde{\Phi}^* = \tilde{\Psi}_+$, $\Phi_s^* = \Psi_s$, $\Phi_{s'}^* = \Psi_{s'}$, $\Phi_{s''}^* = \Psi_{s''}$, $\Phi_0^* = \Psi_{0+}$, using $\Psi_+ = \{\psi_+ : \psi \in \Psi\} = \{\psi \in \Psi : \psi_+ = \psi\}$ and $\Psi_{s+} = \Psi_s$ (cf. Remark 9.2). (If $\psi \in \Psi_+$, then $\psi^* = \psi_+^* = \psi^+ \in \Phi$ (Lemma 9.6) and $\psi = \psi^{**} \in \Phi^*$; use $\inf\psi^* = -\psi(0)$ for the remaining "$\supset$" inclusions.) Similarly, $\Psi^+ = \Phi$, $\tilde{\Psi}^+ = \tilde{\Phi}$, $\Psi_s^+ = \Phi_s$, $\Psi_{s'}^+ = \Phi_{s'}$, $\Psi_{s''}^+ = \Phi_{s''}$, $\Psi_0^+ = \Phi_0$. (If $\phi \in \Phi$, then $\phi^* \in \Psi$ and $\phi = (\phi^*)^+ \in \Psi^+$ by Lemma 9.5; use $\inf\phi = -\phi^*(0)$ for the remaining "$\supset$" inclusions.)

We now extend Theorems 8.4 and 8.7 to Example 7.9 with $\psi \in \Psi_0$ (allowing $\mathcal{D}_{\nabla\psi} \not\supset \mathbb{R}_+$).

COROLLARY 9.8. *If $\psi \in \Psi_0$ (e.g., $\psi = \phi^*$ with $\phi \in \Phi_0$; cf. Lemma 9.5), then the method of Example 7.9 coincides with that of Example 7.8 with $h(\pi) = \sum_{i=1}^m \breve{\psi}(\pi_i)$,*

where $\breve{\psi}$ is the smooth extension of ψ described in Lemma 9.6*, so that $\mathcal{D}_{\nabla h} \supset \mathbb{R}^m_+$ and Theorems* 8.4 *and* 8.7 *apply.*

Proof. Use $\psi^+ = \breve{\psi}^+$ and $\psi'(t,1) = \nabla\breve{\psi}(t)\ \forall t \geq 0$ (cf. Lemma 9.6) in Example 7.9. ∎

Remarks 9.9.

(i) Example 7.9 with $\psi \in \Psi_0$ has $\mathcal{D}_{\partial\psi} \supset \mathbb{R}_+$ and $\bar{v} = \psi'(0;1) > -\infty$. It is not changed if we replace ψ with $\tilde{\psi} = \psi_+$ (since $\tilde{\psi}^+ = \psi^+$); e.g., use ϕ^* with $\phi = \psi^+ \in \Phi_0$ (Lemma 9.6), since $\phi^* = (\psi^+)^* = (\psi^*_+)^* = \psi_+$.

(ii) In terms of $\phi \in \Phi_0$, the method of Example 7.9 with $\psi = \phi^*$ becomes

$$x^{k+1} \in \operatorname{Arg\,min}_x \left\{ f(x) + \frac{1}{c_k}\sum_{i=1}^m \phi\left(\phi^{*'}(\pi_i^k;1) + c_k g_i(x)\right) \right\},$$
$$\pi_i^{k+1} = \nabla\phi\left(\phi^{*'}(\pi_i^k;1) + c_k g_i(x^{k+1})\right), \quad i = 1\!:\!m,$$

where $\phi^{*'}(\pi_i^k;1) = (\nabla\phi)^{-1}(\pi_i^k)$ if $\pi_i^k > 0$, $\phi^{*'}(\pi_i^k;1) = t^0_\phi$ if $\pi_i^k = 0$ (cf. Lemma 9.5).

In view of Corollary 9.8, we restrict attention to Example 7.9 with $\psi \in \Psi_s$.

Remark 9.10. Choosing $\psi \in \Psi_s$ corresponds to using $\psi = \phi^*$ with $\phi \in \Phi_s$ (Remark 9.7).

Example 9.11. Choosing $\phi \in \Phi_s$ and $\psi = \phi^*$ in Example 7.9 yields the method

$$x^{k+1} \in \operatorname{Arg\,min}_x \left\{ f(x) + \frac{1}{c_k}\sum_{i=1}^m \phi\left((\nabla\phi)^{-1}(\pi_i^k) + c_k g_i(x)\right) \right\},$$
$$\pi_i^{k+1} = \nabla\phi\left((\nabla\phi)^{-1}(\pi_i^k) + c_k g_i(x^{k+1})\right), \quad i = 1\!:\!m,$$

with $\gamma_i^k = (\nabla\phi)^{-1}(\pi_i^k)$, $\pi_i^k = \nabla\phi(\gamma_i^k)$, $i = 1\!:\!m$, for all k. (Indeed, $\psi^+ = \phi$, $\mathcal{D}_{\nabla\psi} = \mathbb{R}_>$ and $\nabla\psi = (\nabla\phi)^{-1}$ (Lemma 9.5), while $\pi^k = \nabla h^+(\gamma^k)$ yields $\pi_i^k = \nabla\psi^+(\gamma_i^k) = \nabla\phi(\gamma_i^k) > 0$ (Remark 9.2), $i = 1\!:\!m$.) Note that $\phi(t) = e^t$ for Example 7.11, $\phi(t) = -1 - \ln(-t)$ $(t < 0)$ for Example 7.12, $\phi(t) = -(-t)^\beta/\beta$ $(t < 0,\ \beta < 0)$ for Example 7.13.

We now explore a forcing property of $\phi \in \Phi_s$ needed by Lemma 9.16 below to ensure that $\langle \pi^k, u^k \rangle \to 0$ in Example 9.11, as required in Lemma 8.10.

DEFINITION 9.12. *We say that $\phi \in \Phi$ is* forcing *on $[t'_\phi, t''_\phi]$ if $[\phi'(t'_k) - \phi'(t''_k)](t'_k - t''_k) \to 0$ implies $\phi'(t''_k)(t'_k - t''_k) \to 0$ for any sequences $\{t'_k\}, \{t''_k\} \subset [t'_\phi, t''_\phi] \cap \mathcal{D}_\phi$, where $\phi' = \nabla\phi$.*

LEMMA 9.13. *If $\phi \in \Phi_s$, $\inf\phi > -\infty$, and $t''_\phi \in \mathcal{D}_\phi$, then ϕ is forcing on $[-\infty, t''_\phi]$.*

Proof. Replace ϕ with $\phi - \inf\phi$ so that $\inf\phi = 0$. Since $\phi' = \nabla\phi$ is positive and increasing (cf. Remark 9.4), so is ϕ. Let $[\phi'(t'_k) - \phi'(t_k)]\tau_k \to 0$, $\tau_k > 0$, $t'_k = t_k + \tau_k \leq t''_\phi$. If $\phi'(t_k)\tau_k \not\to 0$, there are $\epsilon > 0$ and $K \subset \{1, 2, \ldots\}$ s.t. $\phi'(t_k)\tau_k \geq \epsilon\ \forall k \in K$, so $\frac{\phi'(t'_k)}{\phi'(t_k)} \xrightarrow{K} 1$. Since $\phi'(t_k) < \phi'(t''_\phi)$ and $\phi(t'_k) \geq \phi(t_k) + \phi'(t_k)\tau_k \geq \epsilon$, $\tau_k \geq \epsilon/\phi'(t''_\phi)$ and $t'_k \geq \phi^{-1}(\epsilon)\ \forall k \in K$. Pick t_∞ and $K' \subset K$ s.t. $t'_k \xrightarrow{K'} t_\infty$. Then $t_k + \epsilon/2\phi'(t''_\phi) \leq t_\infty$ and $\phi'(t_k) \leq \phi'(t_\infty - \epsilon/2\phi'(t''_\phi)) < \phi'(t_\infty) = \lim_{k\in K'} \phi'(t'_k)$ for large $k \in K'$ contradict $\frac{\phi'(t'_k)}{\phi'(t_k)} \xrightarrow{K} 1$. Therefore, $\phi'(t_k)\tau_k \to 0$; i.e., ϕ is forcing. ∎

Example 9.14. The following functions are forcing on $[-\infty, t''_\phi]$: $\phi_1(t) = e^t$ with $t''_\phi \in \mathbb{R}$, $\phi_2(t) = -1 - \ln(-t)$ $(t < 0)$ with $t''_\phi \leq 0$, $\phi_3(t) = -(-t)^\beta/\beta$ $(t < 0,\ \beta < 0)$ with $t''_\phi < 0$. Indeed, let $\phi = \phi_2$. Suppose $\frac{\phi'(t_k+\tau_k) - \phi'(t_k)}{\phi'(t_k)}\phi'(t_k)\tau_k \to 0$. Since

$\phi'(t_k)\tau_k = -\tau_k/t_k$ and $\frac{\phi'(t_k+\tau_k)-\phi'(t_k)}{\phi'(t_k)} = \frac{-1}{1+t_k/\tau_k}$, $\phi'(t_k)\tau_k \to 0$; i.e., ϕ is forcing. Invoke Lemma 9.13 for ϕ_1 and ϕ_3.

Example 9.15. Let $\phi \in \Phi_s$ be s.t. $\phi(t) = -\frac{(-t)^\beta - 1}{\beta}$ for $t < -\frac{1}{2}$, $\beta \in (0,1)$. Let $t_k = -k$, $\tau_k = 1/\phi'(t'_k)$. Then $[\phi'(t_k+\tau_k) - \phi'(t_k)]\tau_k = (1-k^{-\beta})^{\beta-1} - 1 \to 0$, but $\phi'(t_k)\tau_k \to 1$; i.e., ϕ is not forcing on $[-\infty,-1]$, although $\lim_{\beta\downarrow 0} -\frac{(-t)^\beta-1}{\beta} = -\ln(-t)$ is (cf. Example 9.14).

LEMMA 9.16. *Suppose that in Example* 9.11 $\phi \in \Phi_s$ *is forcing on* $(-\infty, t_\gamma]$ *with* $t_\gamma = \sup_{i,k}\gamma_i^k$, $c_k \geq c_{\min} > 0$ *for all* k, *and* $\langle \pi^{k+1} - \pi^k, u^{k+1}\rangle \to 0$. *Then* $\langle \pi^k, u^k\rangle \to 0$.

Proof. Since $\nabla\phi$ is nondecreasing and $h^+(u) = \sum_i \phi(u_i)$, we deduce from (8.4) that

$$
\begin{aligned}
0 \leftarrow \langle \pi^{k+1} - \pi^k, u^{k+1}\rangle &= \sum_{i=1}^m [\phi'(\gamma_i^k + c_k u_i^{k+1}) - \phi'(\gamma_i^k)]u_i^{k+1} \\
&\geq \sum_{i=1}^m [\phi'(\gamma_i^k + c_{\min} u_i^{k+1}) - \phi'(\gamma_i^k)]u_i^{k+1} \geq 0
\end{aligned} \tag{9.1}
$$

and $[\phi'(\gamma_i^k + c_{\min}u_i^{k+1}) - \phi'(\gamma_i^k)]c_{\min}u_i^{k+1} \to 0$, $i = 1\colon m$. But $\gamma^{k+1} = \gamma^k + c_k u^{k+1}$ for all k (cf. Example 9.11) yields $\sup_{i,k}\{\gamma_i^k + c_{\min}u_i^{k+1}\} \leq t_\gamma$, so the preceding relation and the forcing property of ϕ give $\pi_i^k u_i^{k+1} = \phi'(\gamma_i^k)u_i^k \to 0\ \forall i$; hence $\langle \pi^{k+1}, u^{k+1}\rangle \to 0$ by (9.1). ∎

The following result relates the quantity t_γ of Lemma 9.16 with boundedness of $\{\pi^k\}$.

LEMMA 9.17. *Consider Example* 9.11 *with* $\phi \in \Phi_s$, $t_\phi = \sup_{t\in\mathcal{D}_\phi} t$, *and* $t_\gamma = \sup_{i,k}\gamma_i^k$. *Then* $t_\gamma \leq t_\phi$ (*so that* $t_\gamma < \infty$ *if* $t_\phi < \infty$). *In general,* $t_\gamma < t_\phi$ *iff* $\{\pi^k\}$ *is bounded.*

Proof. This follows from the facts $\pi_i^k = \nabla\phi(\gamma_i^k) \geq 0$, $\gamma_i^k \in \mathcal{D}_\phi = (-\infty, t_\phi)$, $\lim_{t\uparrow t_\phi}\nabla\phi(t) = \infty$ and monotonicity of $\nabla\phi$; cf. Remark 9.4, Lemma 9.5, and Example 9.11. ∎

We may now establish ergodic convergence of Example 9.11 with $\phi \in \Phi_{s'}$ (cf. Definition 9.3).

THEOREM 9.18. *Consider Example* 9.11 *with* $\phi \in \Phi_s$ *s.t.* $\inf\phi > -\infty$. *Suppose* $\operatorname{Arg\,max} d \neq \emptyset$, $\sum_{j=1}^k s_j\epsilon_j/s_k \to 0$, $\sum_{k=1}^\infty c_k\epsilon_k < \infty$, *and* $\inf_k c_k > 0$. *Then* $\pi^k \to \pi^\infty \in \operatorname{Arg\,max} d$, $d(\pi^k) \to d^\infty = d(\pi^\infty)$ *and* (8.8) *holds. If* $\{\breve{x}^k\}$ *has a limit point* x^∞ (*e.g.,* $C_* \neq \emptyset$ *is bounded; cf. Remark* 8.11), *then* x^∞ *solves* (7.1) *and* $f(x^\infty) = d^\infty$.

Proof. Let $\psi = \phi^*$. We have $\psi(0) = -\inf\phi < \infty$, $\mathcal{D}_\psi = \mathbb{R}_+$ (cf. Lemma 9.5), $\mathcal{D}_{\psi_+} = \mathbb{R}_+$, and $\mathcal{D}_{h_+^*} = \mathbb{R}_+^m$, so the assertions about $\{\pi^k\}$ follow from Theorem 8.3. Then $t_\gamma = \sup_{i,k}\gamma_i^k < t_\phi$ by Lemma 9.17 ($\{\pi^k\}$ is bounded), so ϕ is forcing on $[-\infty, t_\gamma]$ (Lemma 9.13). Since $d(\pi^k) \to d^\infty < \infty$ and $0 \leq \epsilon_k \leq \sum_{j=1}^k s_j\epsilon_j/s_k \to 0$, (8.4) and (8.5) yield $\langle \pi^{k+1} - \pi^k, u^{k+1}\rangle \to 0$. Then $\langle \pi^k, u^k\rangle \to 0$ by Lemma 9.16. The conclusion follows from Lemma 8.10. ∎

Remarks 9.19.

(i) For the exponential multiplier method (Example 7.11 with $\phi(t) = e^t$), Theorems 8.3 and 9.18 subsume [TsB93, Prop. 3.1] (in which $\operatorname{Arg\,max} d \neq \emptyset$, $C_* \neq \emptyset$ is bounded, $\epsilon_k \equiv 0$) and [IST94, Thm. 7.3] (in which $x^k \to x^\infty$ implies $\breve{x}^k \to x^\infty$).

(ii) Theorem 9.18 holds for Example 7.9 with $\psi \in \Psi_{s'}$, since $\Psi_{s'} = \Phi_{s'}^*$ (Remark 9.7).

For $\psi \in \Psi_0 \cup \Psi_{s'}$, Corollary 9.8 and Theorem 9.18 hinge on $\pi^k \to \pi^\infty \in \operatorname{Arg\,max} d \subset \mathcal{D}_{h^+} = \mathbb{R}^m_+$. Since $\mathcal{D}_h = \mathbb{R}^m_>$ for $\psi \in \Psi_{s''}$, we now present another approach.

THEOREM 9.20. *Consider Example* 9.11 *with* $\phi \in \Phi_s$ *forcing on* $(-\infty, t_\phi) \neq \mathbb{R}$ *(e.g.,* $\phi(t) = -1 - \ln(-t)$*; cf. Example* 9.14*). Suppose* $\epsilon_k \to 0$, $\inf_k c_k > 0$, *and* $d(\pi^k) \to d^\infty < \infty$. *Then* (8.8) *holds. If* $\{\breve{x}^k\}$ *has a limit point* x^∞ *(e.g.,* $C_* \neq \emptyset$ *is bounded; cf. Remark* 8.11*), then* x^∞ *solves* (7.1), $f(x^\infty) = d^\infty = \max d$, *and each limit point of* $\{\pi^k\}$ *maximizes* d.

Proof. By Lemma 9.17, $t_\gamma = \sup_{i,k} \gamma^k_i \leq t_\phi$, so ϕ is forcing on $(-\infty, t_\gamma]$. Since $d(\pi^k) \to d^\infty < \infty$ and $\epsilon_k \to 0$, (8.4) and (8.5) yield $\langle \pi^{k+1} - \pi^k, u^{k+1} \rangle \to 0$. Then $\langle \pi^k, u^k \rangle \to 0$ by Lemma 9.16. Since $t_\gamma \leq t_\phi < \infty$, the conclusion follows from Lemma 8.10. ∎

Remark 9.21. Suppose $\sum_{k=1}^\infty \epsilon_k < \infty$. Then $d^{k+1} \geq d^k - \epsilon_k \; \forall k$ (cf. (8.4)) yields $d(\pi^k) \to d^\infty \in (\infty, \infty]$ (cf. [Pol83, Lem. 2.2.3]). If $d^\infty = \infty$, then $C_0 = \emptyset$ by weak duality. If $d^\infty < \infty$, then $\{\pi^k\}$ is bounded if $\operatorname{Arg\,max} d \neq \emptyset$ is (cf. [Roc70, Cor. 8.7.1]), whereas if $C_0 \neq \emptyset$, then $\operatorname{Arg\,max} d \neq \emptyset$ is bounded iff Slater's condition holds, i.e., $g(x) < 0$ for some $x \in \mathcal{D}_f$ [GoT89, Thm. 1.3.4]. This observation may be used in Lemma 8.10 and Theorem 9.20.

The following two results use Slater's condition to complement Theorems 9.18 and 9.20.

THEOREM 9.22. *Consider Example* 9.11 *with* $\phi \in \Phi_s$ *s.t.* $\inf \phi > -\infty$. *Suppose* $g(x) < 0$ *for some* $x \in \mathcal{D}_f$, $\sum_{k=1}^\infty \epsilon_k < \infty$, *and* $\inf_k c_k > 0$. *Then* $d(\pi^k) \to d^\infty < \infty$ *and* (8.8) *holds. If* $\{\breve{x}^k\}$ *has a limit point* x^∞ *(e.g.,* $C_* \neq \emptyset$ *is bounded; cf. Remark* 8.11*), then* x^∞ *solves* (7.1), $f(x^\infty) = d^\infty = \max d$, *and each limit point of* $\{\pi^k\}$ *maximizes* d. *If* $d^\infty = \sup d$ *and* $\sum_{k=1}^\infty c_k \epsilon_k < \infty$, *then* $\pi^k \to \pi^\infty \in \operatorname{Arg\,max} d$.

Proof. Since $\epsilon_k \to 0$, $d(\pi^k) \to d^\infty < \infty$, $\{\pi^k\}$ and $\operatorname{Arg\,max} d \neq \emptyset$ are bounded (Remark 9.21), we get, as in the proof of Theorem 9.18, $\mathcal{D}_{h_+} = \mathbb{R}^m_+$, $t_\gamma < t_\phi$, and $\langle \pi^k, u^k \rangle \to 0$. Hence the first two assertions follow from Lemma 8.10, and the third one from Theorem 8.3. ∎

THEOREM 9.23. *Consider Example* 9.11 *with* $\phi \in \Phi_s$ *forcing on* $(-\infty, t''_\phi] \; \forall t''_\phi \in \mathbb{R}$. *Suppose that* $g(x) < 0$ *for some* $x \in \mathcal{D}_f$, $\sum_{k=1}^\infty \epsilon_k < \infty$, *and* $\inf_k c_k > 0$. *Then* $d(\pi^k) \to d^\infty < \infty$ *and* (8.8) *holds. If* $\{\breve{x}^k\}$ *has a limit point* x^∞ *(e.g.,* $C_* \neq \emptyset$ *is bounded; cf. Remark* 8.11*), then* x^∞ *solves* (7.1), $f(x^\infty) = d^\infty = \max d$, *and each limit point of* $\{\pi^k\}$ *maximizes* d. *If* $d^\infty = \sup d$, $\operatorname{Arg\,max} d \cap \mathcal{D}_{h_+} \neq \emptyset$, *and* $\sum_{k=1}^\infty c_k \epsilon_k < \infty$, *then* $\pi^k \to \pi^\infty \in \operatorname{Arg\,max} d$.

Proof. Use the proof of Theorem 9.22, without asserting that $\mathcal{D}_{h_+} = \mathbb{R}^m_+$. ∎

Remark 9.24. It is easy to see that we may replace $\phi \in \Phi_s$ with $\phi \in \Phi_0$ and Example 9.11 with Example 7.9 with $\psi = \phi^*$ in Lemmas 9.13, 9.16, and 9.17 and Theorems 9.18, 9.20, 9.22, and 9.23. (In the proof of Lemma 9.13, $t_\infty \geq \psi^{-1}(\epsilon) > t^0_\phi$, since ϕ' and ϕ are positive and increasing on (t^0_ϕ, t_ϕ); in the proof of Lemma 9.16, use $\gamma^{k+1} \geq \gamma^k + c_k u^{k+1}$ (cf. (7.7)); in proving Lemma 9.17, recall Remark 9.9(ii).) Such results complement Theorems 8.4 and 8.7; cf. Corollary 9.8.

10. Additional aspects of multiplier methods. Modified barrier functions can be extrapolated quadratically to facilitate their minimization; cf. [BTYZ92, BrS93, BrS94, NPS94, PoT97]. We now extend such techniques to our penalty functions, starting with a technical result.

LEMMA 10.1. *Let* $\phi_1, \phi_2 \in \Phi$ *be s.t. for some* $t_s \in (t^0_{\phi_1}, t_{\phi_1})$, $\phi_1(t_s) = \phi_2(t_s)$, $\phi'_1(t_s) = \phi'_2(t_s)$, ϕ_1 *is forcing on* $(-\infty, t_s]$, *and* ϕ_2 *is forcing on* $[t_s, t''_{\phi_2}]$ *with* $t''_{\phi_2} \in$

$[t_s, t_{\phi_2}]$. *Let* $\phi(t) = \phi_1(t)$ *if* $t \le t_s$, $\phi(t) = \phi_2(t)$ *if* $t > t_s$. *Then* ϕ *is forcing on* $(-\infty, t''_{\phi_2}]$. *If* $\phi_2 \in \Phi_s \cup \Phi_0$, *then* $\phi \in \Phi_s$ *iff* $\phi_1 \in \Phi_s$ *and* $\phi \in \Phi_0$ *iff* $\phi_1 \in \Phi_0$.

Proof. Suppose $[\phi'(t''_k) - \phi'(t'_k)](t''_k - t'_k) \to 0$ with $t'_k \le t_s \le t''_k \le t''_{\phi_2}$ (other cases being trivial). Since ϕ'_1 and ϕ'_2 are nondecreasing, so is ϕ'; therefore, all terms in

$$\begin{aligned}[\phi'(t''_k) - \phi'(t'_k)](t''_k - t'_k) &\ge [\phi'(t''_k) - \phi'(t_s)](t''_k - t_s) + [\phi'(t_s) - \phi'(t'_k)](t_s - t'_k)\\ &= [\phi'_2(t''_k) - \phi'_2(t_s)](t''_k - t_s) + [\phi'_1(t_s) - \phi'_1(t'_k)](t_s - t'_k)\end{aligned}$$

are nonnegative and tend to zero. Thus $\phi'_2(t_s)(t''_k - t_s) \to 0$ and $\phi'_1(t_s)(t_s - t'_k) \to 0$ (Definition 9.12). Hence $t'_k, t''_k \to t_s$ ($\phi'_2(t_s) = \phi'_1(t_s) > 0$), $\phi'(t''_k)(t''_k - t'_k) \to \phi'(t_s)0$, and $\phi'(t'_k)(t''_k - t'_k) \to 0$ yield the first assertion. For the second one, use Definition 9.3 and Remark 9.4. ∎

Examples 10.2. Using the notation of Lemma 10.1, we add the condition $\phi''_1(t_s) = \phi''_2(t_s)$ to make ϕ twice continuously differentiable. In each example, $\phi \in \Phi_s \cup \Phi_0$ is forcing on $(-\infty, t''_\phi]$ $\forall t''_\phi \in \mathbb{R}$; cf. Remark 9.4, Lemma 9.13, Example 9.14, and Remark 9.24.

(1 (cubic-quadratic)) $\phi(t) = \frac{\max\{0, t+t_s\}^3}{12 t_s} - \frac{t_s^2}{6}$ if $t \le t_s$, $\phi(t) = \frac{\max\{0,t\}^2}{2} = \phi_2(t)$ if $t > t_s$, $t_s > 0$. This ϕ grows only as fast as ϕ_2 in Example 7.10 with $\beta = 2$ but is smoother.

(2 (exponential-quadratic)) $\phi(t) = e^t$ if $t \le t_s > 0$, $\phi(t) = e^{t_s}(\frac{t^2}{2} + (1 - t_s)t + 1 - t_s - \frac{t_s^2}{2})$ if $t > t_s$, $\phi_2(\cdot) = a \max\{0, \cdot - t^0_{\phi_2}\}^2 + b$. This ϕ does not grow as fast as e^t in Example 7.11.

(3 (log-quadratic)) $\phi(t) = -\ln(-t) - 1 = \phi_1(t)$ if $t \le t_s < 0$, $\phi(t) = \frac{t^2}{2t_s^2} - \frac{2t}{t_s} + \frac{1}{2} - \ln(-t_s)$ if $t > t_s$. This ϕ allows arbitrarily large infeasibilities, in contrast to ϕ_1 in Example 7.12.

(4 (hyperbolic-quadratic)) $\phi(t) = -\frac{1}{t} = \phi_1(t)$ if $t \le t_s < 0$, $\phi(t) = \frac{t^2}{|t_s|^3} + \frac{3t}{t_s^2} - \frac{3}{t_s}$ if $t > t_s$. Again, this ϕ has $\mathcal{D}_\phi = \mathbb{R}$, in contrast to ϕ_1 in Example 7.13.

(5 (hyperbolic-log-quadratic)) $\phi(t) = \frac{-4t'_s}{-t'_s - t} - 2 - \ln(-t'_s)$ if $t \le t'_s < 0$, $\phi(t) = -\ln(-t)$ if $t'_s \le t \le t_s < 0$, $\phi(t) = \frac{t^2}{2t_s^2} - \frac{2t}{t_s} + \frac{3}{2} - \ln(-t_s)$ if $t > t_s$.

Remark 10.3. Other smooth penalty functions (e.g., cubic-log-quadratic) are easy to derive. Such functions are covered by the various results of section 9. Their properties, e.g., $\inf \phi > -\infty$, may also have practical significance; this should be verified experimentally.

The following result (inspired by [Ber82, Prop. 5.7]) shows that minimizing L_k (cf. (7.12)) in Algorithm 7.4 is well posed under mild conditions (see the appendix for its proof).

LEMMA 10.4. *Let* $h(\pi) = \sum_{i=1}^m \psi(\pi_i)$, *where* ψ *is a B-function with* $\mathcal{D}_\psi \supset \mathbb{R}_>$. *Suppose that* $L_k \not\equiv \infty$ (*e.g.,* $\inf_{\mathcal{D}_f} \max_{i=1}^m g_i \le 0$). *Then* $\operatorname{Arg\,min} L_k$ *is nonempty and compact iff* f *and* $g_1, \dots, g_m$ *have no common direction of recession, and if* $C_0 \ne \emptyset$, *then this is equivalent to* (7.1) *having a nonempty and compact set of solutions.*

We now consider a variant of condition (7.18), inspired by one in [Ber82, p. 328].

LEMMA 10.5. *Under the strong convexity assumption* (7.15), *consider* (7.17) *with*

$$|\Delta_x L_k(x^{k+1})|^2 \le \eta_k [L(x^{k+1}, \pi^{k+1}) - L_k(x^{k+1})] \tag{10.1}$$

and $\epsilon_k = |\Delta_x L_k(x^{k+1})|^2 / 2\breve{\alpha}$ *replacing* (7.18), *where* $\eta_k \ge 0$. *Then*

$$L(x^{k+1}, \pi^{k+1}) - d(\pi^{k+1}) \le \epsilon_k \le \frac{\eta_k}{2\breve{\alpha}} [L(x^{k+1}, \pi^{k+1}) - L_k(x^{k+1})], \tag{10.2}$$

$$d(\pi^k) \le L(x^{k+1}, \pi^k) \le L_k(x^{k+1}) \le d(\pi^{k+1}) \quad \text{if} \quad \eta_k \le 2\breve{\alpha}, \tag{10.3}$$

$$\epsilon_k \le \frac{\eta_k}{\breve{\alpha}}[d(\pi^{k+1}) - d(\pi^k)] \le d(\pi^{k+1}) - d(\pi^k) \quad \text{if} \quad \eta_k \le \breve{\alpha}. \tag{10.4}$$

Next, suppose $\eta_k \to 0$ *in* (10.1). *Then* $d(\pi^k) \to d^\infty \in (-\infty, \infty]$. *If* $d^\infty < \infty$, *then* $\sum_{k=1}^\infty \epsilon_k < \infty$, $\epsilon_k \to 0$, $\sum_{j=1}^k c_j\epsilon_j/s_k \to 0$; *further,* $\sum_{k=1}^\infty c_k\epsilon_k < \infty$ *if* $\{c_k\eta_k\}$ *is bounded.*

Proof. By (7.17) and (10.1), (10.2) holds with $L(x^{k+1}, \pi^{k+1}) \ge L_k(x^{k+1})$ by (8.2). Thus $\eta_k \le 2\breve{\alpha}$ yields $L_k(x^{k+1}) \le d(\pi^{k+1})$ and (10.3) follows from (8.5). Similarly, $L(x^{k+1}, \pi^{k+1}) - d(\pi^{k+1}) \le \frac{1}{2}[L(x^{k+1}, \pi^{k+1}) - L_k(x^{k+1})]$ for $\eta_k \le \breve{\alpha}$ yields $L(x^{k+1}, \pi^{k+1}) - L_k(x^{k+1}) \le 2[d(\pi^{k+1}) - L_k(x^{k+1})]$, so (10.4) follows from (10.2) and $d(\pi^k) \le L_k(x^{k+1})$ (cf. (10.3)). Next, let $\eta_k \to 0$. Pick $\bar{k}$ s.t. $\eta_k \le \breve{\alpha}$ $\forall k \ge \bar{k}$. Equations (10.3)–(10.4) yield $d(\pi^k) \to d^\infty$, $\sum_{k=\bar{k}}^\infty \epsilon_k \le [d^\infty - d(\pi^{\bar{k}})]$, $\sum_{k=\bar{k}}^\infty c_k\epsilon_k \le \sup_k \frac{c_k\eta_k}{\breve{\alpha}}[d^\infty - d(\pi^{\bar{k}})]$. If $d^\infty < \infty$, then $\epsilon_k \to 0$ gives $\sum_{j=1}^k c_j\epsilon_j/s_k \to 0$ (Lemma 4.5(i)). ∎

Remark 10.6. In view of Lemma 10.5, suppose in the strongly convex case of (7.15), (10.1) is used with $\eta_k \to 0$. Since $q(\pi^{k+1}) \le q(\pi^k)$ for all large k (cf. (10.3)), the results of sections 8 and 9 may invoke, instead of Theorem 5.2 with $\sum_{j=1}^k s_j\epsilon_j/s_k \to 0$, Theorem 4.3 with $\sum_{j=1}^k c_j\epsilon_j/s_k \to 0$. The latter condition holds automatically if $\lim_{k\to\infty} d(\pi^k) < \infty$, e.g., $\sup d < \infty$. Thus we may drop the conditions

$$\sum_{j=1}^k s_j\epsilon_j/s_k \to 0$$

from Theorems 8.3, 8.4, and 9.18, $\epsilon_k \to 0$ from Lemma 8.10 and Theorem 9.20, and $\sum_{k=1}^\infty \epsilon_k < \infty$ from Theorems 9.22 and 9.23. Instead of $\sum_{k=1}^\infty c_k\epsilon_k < \infty$, we may assume that $\{c_k\eta_k\}$ is bounded in Theorems 8.3, 8.4, 9.18, 9.22, and 9.23.

Condition (10.1) can be implemented as in [Ber82, Prop. 5.7(b)].

LEMMA 10.7. *Suppose that* f *is strongly convex,* $\inf_{\mathcal{D}_f} \max_{i=1}^m g_i \le 0$, *and* g *is continuous on* $\mathcal{D}_f$. *Consider iteration* k *of Example* 7.6 *with* $h(\pi) = \sum_{i=1}^m \psi(\pi_i)$, *where* ψ *is a B-function s.t.* $\mathcal{D}_{\nabla\psi} \supset \mathbb{R}_>$. *If* $\eta_k > 0$, π^k *is not a Lagrange multiplier of* (7.1), $\{z^j\}$ *is a sequence converging to* $\hat{x} = \arg\min L_k$, *and* $\Delta_x L_k(z^j) \to 0$, *then there exists* $x^{k+1} \in \{z^1, z^2, \ldots\}$ *satisfying the stopping criterion* (10.1).

Proof. By Lemmas 9.5 and 9.6, Example 7.6 has $\bar{u}_i = t_\phi^0$, $\pi_i^k = \nabla\phi(\gamma_i^k)$, $\gamma_i^k \ge t_\phi^0$, $i = 1{:}\,m$, $h^+(u) = \sum_{i=1}^m \phi(u_i)$, where $\phi = \psi^+ \in \Phi_s \cup \Phi_0$. Let $\hat{u} = g(\hat{x})$ and $\hat{\pi} = \nabla h^+(\gamma^k + c_k\hat{u})$. Then, as in (8.2),

$$L(\hat{x}, \hat{\pi}) - L_k(\hat{x}) = D_{h^+}(\gamma^k, \gamma^k + c_k\hat{u})/c_k \ge 0. \tag{10.5}$$

Suppose that $L(\hat{x}, \hat{\pi}) = L_k(\hat{x})$. By (10.5), (2.4), and convexity of h^+, $\phi(\gamma_i^k) - \phi(\gamma_i^k + c_k\hat{u}_i) - \nabla\phi(\gamma_i^k + c_k\hat{u}_i)(-c_k\hat{u}_i) = 0$, $i = 1{:}\,m$. Therefore, since ϕ is strictly convex on $[t_\phi^0, t_\phi)$ with $\nabla\phi(t) = 0$ iff $t \le t_\phi^0$ (Definition 9.3), and $\gamma_i^k \ge t_\phi^0$, for each i, either $\gamma_i^k + c_k\hat{u}_i = \gamma_i^k > t_\phi^0$ yields $\hat{u}_i = 0$ and $\hat{\pi}_i = \pi_i^k = \nabla\phi(\gamma_i^k)$ or $\gamma_i^k + c_k\hat{u}_i \le t_\phi^0 = \gamma_i^k$ yields $\hat{u}_i \le 0$ and $\hat{\pi}_i = \pi_i^k = \nabla\phi(\gamma_i^k) = 0$. Hence $\hat{\pi} = \pi^k$, $\hat{u} \le 0$ and $\langle\hat{\pi}, \hat{u}\rangle = 0$. Combining this with $0 \in \partial L_k(\hat{x}) = \partial_x L(\hat{x}, \hat{\pi})$ (Lemma 7.3), we see (cf. [Roc70, Thm. 28.3]) that π^k is a Lagrange multiplier, a contradiction. Therefore, we must have strict inequality in (10.5). Since $g(z^j) \to \hat{u}$ and $D_{h^+}(\gamma^k, \gamma^k + c_k g(z^j)) \to D_{h^+}(\gamma^k, \gamma^k + c_k\hat{u}) > 0$ by continuity, whereas $\eta_k > 0$ and $\Delta_x L_k(z^j) \to 0$, the stopping criterion will be satisfied for sufficiently large j. ∎

Appendix A. We now give proofs of certain technical results.

Proof of Lemma 7.2. $\mathbb{R}^m_+ \cap \operatorname{ri} \mathcal{D}_h \neq \emptyset$ implies $\partial h_+ = \partial h + \partial \iota_{\mathbb{R}^m_+}$ [Roc70, Thm. 23.8], so $\mathcal{D}_{\partial h_+} = \mathcal{D}_{\partial h} \cap \mathbb{R}^m_+$ and h_+ is essentially strictly convex. Hence $h^+ = h^*_+$ is closed proper essentially smooth (Fact 2.3(ii)), $\partial h^+(u) = \{\nabla h^+(u)\}\ \forall u \in \mathring{\mathcal{D}}_{h^+} = \mathcal{D}_{\partial h^+}$ (Fact 2.3(i)), ∇h^+ is continuous on $\mathring{\mathcal{D}}_{h^+}$ (Fact 2.2), $\partial h^*_+ = (\partial h_+)^{-1}$, and $\operatorname{im} \partial h_+ = \mathcal{D}_{\partial h^+}$ (Fact 2.1). Since h^+ is nondecreasing, $\mathcal{D}_{h^+} = \mathcal{D}_{h^+} - \mathbb{R}^m_+$, so $\mathring{\mathcal{D}}_{h^+} = \mathring{\mathcal{D}}_{h^+} - \mathbb{R}^m_+$ as the union of open sets. That $N_{\mathbb{R}^m_+}(\pi) = \{\gamma \leq 0 : \langle \gamma, \pi \rangle = 0\}$ for $\pi \geq 0$ is elementary (cf. [Roc70, p. 226]). If $\pi = \nabla h^+(\gamma)$ and $\tilde{\gamma} \in N_{\mathbb{R}^m_+}(\pi)$, then $\gamma \in \partial h_+(\pi)$ and $\gamma + \tilde{\gamma} \in \partial h_+(\pi)$, so $\pi = \nabla h^+(\gamma + \tilde{\gamma})$. If $\operatorname{im} \partial h \supset \mathbb{R}^m_>$ and $u \in \mathbb{R}^m$, then $-h^+(u) = \inf \phi$, where $\phi = h_+ - \langle u, \cdot \rangle$ is inf-compact. Indeed, pick $\tilde{\pi}$ and $\tilde{u} \in \partial h(\tilde{\pi})$ s.t. $\tilde{u} > u$. Then $\tilde{\phi}(\pi) = h(\tilde{\pi}) + \langle \tilde{u}, \pi - \tilde{\pi} \rangle - \langle u, \pi \rangle \leq \phi(\pi)$ for all $\pi \geq 0$, and if $\{\pi^k\} \subset \mathbb{R}^m_+$, $|\pi^k| \to \infty$, then $\tilde{\phi}(\pi^k) \to \infty$ since $\tilde{u} - u > 0$. Hence ϕ is inf-compact and $u \in \mathcal{D}_{h^+}$, so $\mathcal{D}_{h^+} = \mathbb{R}^m$. ∎

We need the following slightly sharpened version of [GoT89, Thm. 1.5.4].

LEMMA A.1 (subdifferential chain rule). *Let $f_1, \ldots, f_m$ be proper convex functions on $\mathbb{R}^n$ with $\bigcap_{i=1}^m \operatorname{ri} \mathcal{D}_{f_i} \neq \emptyset$. Let $f(\cdot) = (f_1(\cdot), \ldots, f_m(\cdot))$ and $\mathcal{D}_f = \bigcap_{i=1}^m \mathcal{D}_{f_i}$. Let ϕ be a proper convex nondecreasing function on $\mathbb{R}^m$ s.t. $f(\tilde{x}) < \tilde{y}$ for some $\tilde{x} \in \mathcal{D}_f$ and $\tilde{y} \in \mathcal{D}_\phi$. Let $\psi(x) = \phi(f(x))$ if $x \in \mathcal{D}_f$, $\psi(x) = \infty$ if $x \notin \mathcal{D}_f$. Then ψ is proper convex, $\operatorname{im} \partial \phi \subset \mathbb{R}^m_+$, and for each $\bar{x} \in \mathcal{D}_f$ and $\bar{y} = f(\bar{x})$*

$$\partial \psi(\bar{x}) = \bigcup \{ \sum_{i=1}^m \gamma_i \partial f_i(\bar{x}) : \gamma \in \partial \phi(\bar{y}) \}. \tag{A.1}$$

Proof. For any $x^1, x^2 \in \mathcal{D}_f$ and $\lambda \in [0,1]$, $f(\lambda x^1 + (1-\lambda)x^2) \leq \lambda f(x^1) + (1-\lambda) f(x^2)$ and hence $\psi(\lambda x^1 + (1-\lambda)x^2) \leq \phi(\lambda f(x^1) + (1-\lambda) f(x^2)) \leq \lambda \psi(x^1) + (1-\lambda)\psi(x^2)$, so ψ is convex. Since $\psi(x) > -\infty$ for all x, ψ is proper. Let $Q = \bigcup_{\gamma \in \partial \phi(\bar{y})} \sum_{i=1}^m \gamma_i \partial f_i(\bar{x})$. Let $\gamma \in \partial \phi(\bar{y})$, $\gamma^i \in \partial f_i(\bar{x})$, $i = 1\colon m$, $\Gamma = [\gamma^1, \ldots, \gamma^m]^T$. For any x, $f(x) \geq f(\bar{x}) + \Gamma(x - \bar{x})$ yields $\psi(x) \geq \phi(f(\bar{x}) + \Gamma(x - \bar{x})) \geq \psi(\bar{x}) + \gamma^T \Gamma(x - \bar{x})$, i.e., $\Gamma^T \gamma \in \partial \psi(\bar{x})$, so $Q \subset \partial \psi(\bar{x})$. To prove the opposite inclusion, let $\bar{\gamma} \in \partial \psi(\bar{x})$. Consider the convex program

$$\text{minimize} \quad \phi(y) - \langle \bar{\gamma}, x \rangle \ \text{ s.t. } f(x) - y \leq 0,\ x \in \mathcal{D}_f,\ y \in \mathcal{D}_\phi. \tag{A.2}$$

By the monotonicity of ϕ and the definition of subdifferential, $(\bar{x}, \bar{y})$ solves (A.2), which satisfies Slater's condition (cf. $f(\tilde{x}) < \tilde{y}$), so (cf. [Roc70, Cor. 28.2.1]) it has a Kuhn–Tucker point $\bar{\pi} \in \mathbb{R}^m_+$ s.t. (cf. [Roc70, Thm. 28.3])

$$\phi(y) - \langle \bar{\gamma}, x \rangle + \langle \bar{\pi}, f(x) - y \rangle \geq \phi(\bar{y}) - \langle \bar{\gamma}, \bar{x} \rangle + \langle \bar{\pi}, f(\bar{x}) - \bar{y} \rangle \quad \forall x \in \mathcal{D}_f, y \in \mathcal{D}_\phi.$$

Then $\phi(y) \geq \phi(\bar{y}) + \langle \bar{\pi}, y - \bar{y} \rangle\ \forall y$ yields $\bar{\pi} \in \partial \phi(\bar{y})$, whereas $\langle \bar{\pi}, f(x) \rangle \geq \langle \bar{\pi}, f(\bar{x}) \rangle + \langle \bar{\gamma}, x - \bar{x} \rangle\ \forall x$ yields $\bar{\gamma} \in \partial(\sum_{i=1}^m \bar{\pi}_i f_i)(\bar{x}) = \sum_{i=1}^m \bar{\pi}_i \partial f_i(\bar{x})$ from $\bigcap_{i=1}^m \operatorname{ri} \mathcal{D}_{f_i} \neq \emptyset$ (cf. [Roc70, Thm. 23.8]). Thus $\partial \psi(\bar{x}) \subset Q$, i.e., $\partial \psi(\bar{x}) = Q$. To see that $\operatorname{im} \partial \phi \subset \mathbb{R}^m_+$, note that if $\gamma \in \partial \phi(y^1)$, then $\phi(y^1) \geq \phi(y^2) \geq \phi(y^1) + \langle \gamma, y^2 - y^1 \rangle$ for all $y^2 \leq y^1$ implies $\gamma \geq 0$. ∎

Proof of Lemma 10.4. Let $\phi_i(x) = \psi^+(\gamma^k_i + c_k g_i(x))$ if $x \in \mathcal{D}_{g_i}$, $\phi_i(x) = \infty$ if $x \notin \mathcal{D}_{g_i}$, $i = 1\colon m$. Each ϕ_i is closed: for any $\alpha \in \mathbb{R}$, $\{t : \psi^+(t) \leq \alpha\} = (-\infty, \beta]$ for some $\beta < \infty$ (ψ^+ is closed nondecreasing and $\lim_{t \uparrow t_{\psi^+}} \psi^+(t) = \infty$ by Lemmas 9.5 and 9.6) and $\{x : \phi_i(x) \leq \alpha\} = \{x : g_i(x) \leq (\beta - \gamma^k_i)/c_k\}$ is closed (as is g_i). We have $L_k = f + \frac{1}{c_k} \sum_{i=1}^m [\phi_i - \psi^+(\gamma^k_i)]$ with f and ϕ_i closed proper and $L_k \not\equiv \infty$, so L_k is closed and $L_k 0^+ = f 0^+ + \frac{1}{c_k} \sum_{i=1}^m \phi_i 0^+$ [Roc70, Thm. 9.3]. Suppose that $g_i 0^+(y) \leq 0$. Since $L_k \not\equiv \infty$, $\mathcal{D}_{\psi^+} = (-\infty, t_{\psi^+})$ (cf. Lemma 9.6 and Definition 9.3),

and g_i is closed, there is $x \in \operatorname{ri} \mathcal{D}_{g_i}$ s.t. $\gamma_i^k + c_k g_i(x) \in \mathcal{D}_{\psi^+}$. Let $\gamma \in \partial g_i(x)$. Then $g_i(x)+t\,\langle \gamma, y\rangle \le g_i(x+ty) \le g_i(x)\ \forall t \ge 0$, so $\langle \gamma, y\rangle \le 0$ and, since ψ^+ is nondecreasing, $\psi^+(\gamma_i^k + c_k[g_i(x)+t\,\langle \gamma, y\rangle]) \le \psi^+(\gamma_k^k + c_k g_i(x+ty)) \le \psi^+(\gamma_i^k + c_k g_i(x))\ \forall t \ge 0$. Hence $\psi^+0^+(c_k\,\langle \gamma, y\rangle) \le \phi_i 0^+(y) \le 0$, so $\langle \gamma, y\rangle \le 0$ and $\psi^+0^+ = \imath^*_{\mathbb{R}_+}$ (cf. Lemmas 9.5 and 9.6) yield $\phi_i 0^+(y) = 0$. Now suppose $g_i 0^+(y) > 0$. Pick $\bar t > 0$ and $\bar\alpha > 0$ s.t. $[g_i(x+ty) - g_i(x)]/t \ge \bar\alpha\ \forall t \ge \bar t$. Then

$$\begin{aligned}
\phi_i 0^+(y) &= \lim_{t\uparrow\infty}[\psi^+(\gamma_i^k + c_k g_i(x+ty)) - \psi^+(\gamma_i^k + c_k g_i(x))]/t \\
&\ge \lim_{t\uparrow\infty}[\psi^+(\gamma_i^k + c_k (g_i(x) + t\bar\alpha)) - \psi^+(\gamma_i^k + c_k g_i(x))]/t \\
&= \psi^+0^+(c_k\bar\alpha) = \infty
\end{aligned}$$

from $\psi^+0^+ = \imath^*_{\mathbb{R}_+}$. Thus $\phi_i 0^+(y) = 0$ if $g_i 0^+(y) \le 0$, $\phi_i 0^+(y) = \infty$ if $g_i 0^+(y) > 0$. Therefore, $L_k 0^+(y) = f 0^+(y)$ if $g_i 0^+(y) \le 0$ for $i = 1{:}\,m$, $L_k 0^+(y) = \infty$ otherwise. The proof may be finished as in [Ber82, sect. 5.3]. □

TURNPIKE PROPERTY OF OPTIMAL SOLUTIONS OF INFINITE-HORIZON VARIATIONAL PROBLEMS*

A. J. ZASLAVSKI†

Dedicated to Valery L. Makarov on his 60th birthday.

Abstract. Given $x_0 \in R^n$ we study the infinite-horizon problem of minimizing the expression $\int_0^T f(x(t), x'(t))dt$ as T grows to infinity, where a function $x\colon [0,\infty) \to R^n$ is absolutely continuous and satisfies the initial condition $x(0) = x_0$ and $f = f(x,u)$ is an integrand. We study the structure of (f)-weakly optimal solutions and establish the turnpike property for a generic integrand f.

Key words. infinite horizon, weakly optimal function, good function, turnpike property

AMS subject classification. 49J99

1. Introduction.

In this paper we consider a special class of extremals, the so-called *weakly optimal solutions* of infinite-horizon autonomous variational problems with vector-valued functions.

Given $x_0 \in R^n$ we study the infinite-horizon problem of minimizing the expression $\int_0^T f(x(t), x'(t))dt$ as T grows to infinity, where a function $x\colon [0,\infty) \to R^n$ is absolutely continuous (a.c.) and satisfies the initial condition $x(0) = x_0$ and $f = f(x,u)$ is an integrand.

The study of variational and optimal control problems defined on infinite intervals has recently been a rapidly growing area of research. These problems arise in engineering (see Anderson and Moore [1], Artstein and Leizarowitz [2], Leizarowitz [14]), in models of economic growth (see Rockafellar [18], Brock and Haurie [3], Leizarowitz [12], Haurie [10], Carlson [5]), and in theory of thermodynamical equilibrium for materials (see Leizarowitz and Mizel [16], Coleman, Marcus, and Mizel [8], Zaslavski [23, 24]).

The following notion, known as *the overtaking optimality criterion*, was introduced in the economics literature by Gale [9] and von Weizsacker [20] and has been used in control theory by Artstein and Leizarowitz [2]; Brock and Haurie [3]; Carlson [5]; Carlson, Haurie, and Jabrane [6]; and Carlson, Haurie, and Leizarowitz [7].

An a.c. function $x\colon [0,\infty) \to R^n$ is called (f)-*overtaking optimal* if, for any a.c. function $y\colon [0,\infty) \to R^n$ satisfying $y(0) = x(0)$,

$$\limsup_{T\to\infty} \int_0^T [f(x(t), x'(t)) - f(y(t), y'(t))]\, dt \le 0.$$

Various existence results of overtaking optimal functions are nicely collected in Carlson, Haurie, and Leizarowitz [7]. The most typical infinite-horizon optimization problem for which the existence of overtaking optimal function has been established is an autonomous variational problem with a convex integrand $\int_0^T f(x(t),\ x'(t))dt$, studied by Rockafellar [18], Brock and Haurie [3], and Leizarowitz [12].

For convex integrands the existence of overtaking optimal solutions may follow from the fact that all good trajectories converge to a unique steady state (Brock and

*Received by the editors July 24, 1995; accepted for publication April 24, 1996.
http://www.siam.org/journals/sicon/35-4/28935.html.
†Department of Mathematics, Technion-Israel Institute of Technology, Haifa 32000, Israel (mar9319@technion.technion.ac.il).

Haurie [3], Leizarowitz [12]). For nonconvex integrands the existence of overtaking optimal solutions is not guaranteed, and in this situation we look for *weakly optimal solutions*.

In this paper we employ the following weakened version of the overtaking optimality criterion.

An a.c. function $x\colon [0,\infty) \to R^n$ is called (f)-*weakly optimal* if, for any a.c. function $y\colon [0,\infty) \to R^n$ satisfying $y(0) = x(0)$,

$$\liminf_{T\to\infty} \int_0^T [f(x(t), x'(t)) - f(y(t), y'(t))]\, dt \le 0.$$

The first existence result of weakly optimal solutions without convexity assumptions was obtained by Carlson [4] for autonomous optimal control problems with vector-valued functions. Under the assumptions posed in Carlson [4] for every (f)-good trajectory $x(\cdot)$ defined on $[0,\infty)$ the following holds:

$$\tau^{-1} \int_0^\tau x(t)\, dt \to \bar{x} \quad \text{as } \tau \to \infty,$$

where $\bar{x}$ is a unique steady state. Using this fact Carlson established the existence of weakly optimal solutions.

In a general situation, when we do not have any kind of a convergence property of all good trajectories to a unique steady state, our consideration can be based on the following observation, which was described in Leizarowitz [15]: *For every initial state there exists a weakly optimal solution if all good trajectories have the same limit point set.*

Recently this was used by Zaslavski [25] to establish, for a class of variational problems described below, the existence of weakly optimal solutions for a generic integrand and any initial state.

Denote by $|\cdot|$ the Euclidean norm in R^n, and denote by $\mathfrak{A}$ the set of continuous functions $f\colon R^n \times R^n \to R^1$ which satisfy the following assumptions.

Assumption A.

(i) For each $x \in R^n$ the function $f(x,\cdot)\colon R^n \to R^1$ is convex.

(ii) $f(x,u) \ge \sup\{\psi(|x|), \psi(|u|)|u|\} - a$ for each $(x,u) \in R^n \times R^n$, where $a > 0$ is a constant and $\psi\colon [0,\infty) \to [0,\infty)$ is an increasing function such that $\psi(t) \to +\infty$ as $t \to \infty$ (here a and ψ are independent on f).

(iii) For each $M, \varepsilon > 0$ there exist $\Gamma, \delta > 0$ such that

$$|f(x_1,u_1) - f(x_2,u_2)| \le \varepsilon \sup\{f(x_1,u_1), f(x_2,u_2)\}$$

for each $u_1, u_2, x_1, x_2 \in R^n$ which satisfy

$$|x_i| \le M, \quad |u_i| \ge \Gamma \quad (i = 1,2), \quad \sup\{|x_1 - x_2|, |u_1 - u_2|\} \le \delta.$$

It is an elementary exercise to show that an integrand $f = f(x,u) \in C^1(R^{2n})$ belongs to $\mathfrak{A}$ if f satisfies assumptions A(i) and A(ii) with a constant $a > 0$ and a function $\psi\colon [0,\infty) \to [0,\infty)$ and there exists an increasing function $\psi_0\colon [0,\infty) \to [0,\infty)$ such that for each $x, u \in R^n$

$$\sup\{|\partial f/\partial x(x,u)|, \ \ |\partial f/\partial u(x,u)|\} \le \psi_0(|x|)(1 + \psi(|u|)|u|).$$

For the set $\mathfrak{A}$ we consider the uniformity which is determined by the following base:

$$E(N,\varepsilon,\lambda)=\{(f,g)\in\mathfrak{A}\times\mathfrak{A}:\ \ |f(x,u)-g(x,u)|\le\varepsilon\ \ (u,x\in R^n,\ \ |x|,|u|\le N),$$
$$(|f(x,u)|+1)(|g(x,u)|+1)^{-1}\in[\lambda^{-1},\lambda]\ (x,u\in R^n,\ |x|\le N)\},$$

where $N>0$, $\varepsilon>0$, $\lambda>1$ (see Kelley [11]).

It was shown in Zaslavski [25] that the uniform space $\mathfrak{A}$ is metrizable and complete. We consider functionals of the form

$$I^f(T_1,T_2,x)=\int_{T_1}^{T_2}f(x(t),\ x'(t))\,dt, \tag{1.1}$$

where $f\in\mathfrak{A}$, $0\le T_1<T_2<+\infty$ and $x\colon [T_1,T_2]\to R^n$ is an a.c. function.

For $f\in\mathfrak{A}$, y, $z\in R^n$, and numbers T_1,T_2 satisfying $0\le T_1<T_2$ we set

$$U^f(T_1,T_2,y,z)=\inf\{I^f(T_1,T_2,x)\colon x\colon[T_1,T_2]\to R^n \text{ is an a.c. function}$$
$$\text{satisfying } x(T_1)=y,\ x(T_2)=z\}. \tag{1.2}$$

It is easy to see that $-\infty<U^f(T_1,T_2,y,z)<+\infty$ for each $f\in\mathfrak{A}$, each $y,z\in R^n$, and each numbers T_1,T_2 satisfying $0\le T_1<T_2$.

Let $f\in\mathfrak{A}$. For any a.c. function $x\colon[0,\infty)\to R^n$ we set

$$J(x)=\liminf_{T\to\infty}T^{-1}I^f(0,T,x). \tag{1.3}$$

Of special interest is the *minimal long-run average cost growth rate*

$$\mu(f)=\inf\{J(x)\colon x\colon[0,\infty)\to R^n \text{ is an a.c. function}\}. \tag{1.4}$$

Clearly $-\infty<\mu(f)<+\infty$. Here we follow Leizarowitz [13] in defining "good functions" for the infinite-horizon variational problem with the integrand f.

An a.c. function $x\colon[0,\infty)\to R^n$ is called an *(f)-good function* if the function $\Phi_x^f\colon T\to I^f(0,T,x)-\mu(f)T$, $T\in(0,\infty)$ is bounded.

Propositions 1.1 and 3.1 in Zaslavski [25] imply the following result.

PROPOSITION 1.1. *For any a.c. function $x\colon[0,\infty)\to R^n$ either*

$$I^f(0,T,x)-T\mu(f)\to+\infty \text{ as } T\to\infty$$

or

$$\sup\{|I^f(0,T,x)-T\mu(f)|\colon T\in(0,\infty)\}<\infty.$$

Moreover any (f)-good function $x\colon[0,\infty)\to R^n$ is bounded.

We denote $d(x,B)=\inf\{|x-y|\colon\ y\in B\}$ for $x\in R^n$, $B\subset R^n$. Denote by $\operatorname{dist}(A,B)$ the Hausdorff metric for two sets $A\subset R^n$, $B\subset R^n$. For every bounded a.c. function $x\colon[0,\infty)\to R^n$ define

$$\Omega(x)=\{y\in R^n\colon\text{there exists a sequence } (t_i)_{i=0}^{\infty}\subset(0,\infty) \text{ for which}$$
$$t_i\to\infty,\ x(t_i)\to y \text{ as } i\to\infty\}. \tag{1.5}$$

We say that an integrand $f\in\mathfrak{A}$ has Property B if $\Omega(v_2)=\Omega(v_1)$ for each (f)-good functions $v_i\colon[0,\infty)\to R^n$, $i=1,2$.

In Zaslavski [25, Theorem 2.1] we established the following result, which describes the limit behavior of (f)-good functions for a generic $f \in \mathfrak{A}$.

THEOREM 1.1. *There exists a set $\mathcal{F} \subset \mathfrak{A}$ which is a countable intersection of open everywhere dense subsets of $\mathfrak{A}$ and such that each $f \in \mathcal{F}$ has Property* B.

Moreover, it was shown in [25, Theorem 2.2] that for each integrand $f \in \mathfrak{A}$ which has Property B and each initial condition $x_0 \in R^n$ there exists an (f)-weakly optimal function $x\colon [0,\infty) \to R^n$ satisfying $x(0) = x_0$.

Since there exists an example of a function $f \in \mathfrak{A}$ which does not have Property B (see [25, sect. 14]) it is very important for applications to know that Property B, which provides the existence of a weakly optimal solution with any initial value, holds for "almost all" integrands $f \in \mathfrak{A}$.

Consider any $f \in \mathfrak{A}$. In analyzing the infinite-horizon variational problem with the integrand f in [25] we studied the function $U^f(T_1,\ T_2,\ y,\ z)$ $(T_2 > T_1 \geq 0,\ y,\ z \in R^n)$ defined by (1.2). By a simple modification of the proof of Proposition 4.4 in Leizarowitz and Mizel [16] (see [25, Theorems 8.1 and 8.2]) we established the representation formula

$$U^f(0,T,x,y) = T\mu(f) + \pi^f(x) - \pi^f(y) + \bar{\theta}^f_T(x,y), \qquad x,y \in R^n, T \in (0,\infty), \tag{1.6}$$

where $\pi^f\colon\ R^n \to R^1$ is a continuous function and $(T,x,y) \to \bar{\theta}^f_T(x,y) \in R^1$ is a continuous nonnegative function defined for $T > 0$, $x,\ y \in R^n$,

$$\begin{aligned}\pi^f(x) = \inf\{\liminf_{T\to+\infty}[I^f(0,T,v) - \mu(f)T]\colon v\colon\ [0,\infty) \to R^n \text{ is an a.c. function}\\ \text{satisfying } v(0) = x\}, \qquad x \in R^n,\end{aligned} \tag{1.7}$$

and for every $T > 0$, every $x \in R^n$ there is $y \in R^n$ satisfying $\bar{\theta}^f_T(x,y) = 0$.

Assume that there exists a compact set $H(f) \subset R^n$ such that $\Omega(v) = H(f)$ for each (f)-good function $v\colon\ [0,\infty) \to R^n$. (By Theorem 1.1 this assumption holds for a generic $f \in \mathfrak{A}$).

By Theorems 8.3 and 8.4 in [25] for every $x \in R^n$ there exists an (f)-good function $v\colon\ [0,\infty) \to R^n$ such that $v(0) = x$ and the relation

$$I^f(T_1,T_2,v) = (T_2 - T_1)\mu(f) + \pi^f(v(T_1)) - \pi^f(v(T_2)) \tag{1.8}$$

holds for each $T_1 \in [0,\infty)$, $T_2 \in (T_1,\infty)$, and moreover, each a.c. function $v\colon\ [0,\infty) \to R^n$ such that (1.8) holds for each $T_1 \in [0,\infty)$, $T_2 \in (T_1,\infty)$ is an (f)-weakly optimal function.

Denote by $\mathcal{A}(f)$ the set of all a.c. functions $v\colon\ [0,\infty) \to R^n$ which satisfy (1.8) for each $T_1 \in [0,\infty)$, $T_2 \in (T_1,\infty)$.

For a given $x_0 \in R^n$ we can construct a function $x \in \mathcal{A}(f)$, which is (f)-weakly optimal and satisfies initial condition $x(0) = x_0$, using the following scheme.

Let $x_0 \in R^n$. We fix a positive number T and obtain $\mu(f)$ by (1.4), $U^f(0,T,y,z)$ $(y,z \in R^n)$ by (1.2), $\pi^f(y)(y \in R^n)$ by (1.7), and $\bar{\theta}^f_T(y,z)(y,z \in R^n)$ by (1.6). By the properties of the functions $\bar{\theta}^f_T$ we define a sequence $\{x_i\}_{i=0}^{\infty} \subset R^n$ such that $\bar{\theta}^f_T(x_i,x_{i+1}) = 0$, $i = 0,1,\ldots$. Then we construct an a.c. function $x\colon\ [0,\infty) \to R^n$ for which

$$x(iT) = x_i, \quad I^f(iT,(i+1)T,x) = U^f(0,T,x_i,x_{i+1}), \quad i = 0,1,\ldots.$$

It follows from this construction that $x \in \mathcal{A}(f)$ and it is an (f)-weakly optimal function. Since the above construction uses the set $\mathcal{A}(f)$, the function π^f, and the

minimal long-run average cost growth rate $\mu(f)$, and since we are not aware of any other way of constructing weakly optimal solutions, it follows that these concepts are of great importance for us.

In this paper we will establish the following propositions for any integrand f which has Property B:

(a) f is a continuity point of the mapping $g \to (\mu(g), \pi^g) \in R^1 \times C(R^n)$, $g \in \mathfrak{A}$, where $C(R^n)$ is the space of all continuous functions $\phi\colon R^n \to R^1$ with the topology of the uniform convergence on bounded subsets.

(b) Given any $\varepsilon > 0$ there exist numbers ℓ, $\delta > 0$ such that for each $v \in \mathcal{A}(f)$ satisfying $d(v(0), H(f)) \le \delta$ and each $T \ge 0$

$$\operatorname{dist}(H(f), \quad \{v(t)\colon t \in [T, T+\ell]\}) \le \varepsilon. \tag{1.9}$$

(c) For each ε, $K > 0$ there exist numbers ℓ, $Q > 0$ such that for each $v \in \mathcal{A}(f)$ satisfying $|v(0)| \le K$ relation (1.9) holds for each $T \ge Q$.

Assume that we have some algorithm to calculate $\mu(f)$ and π^f. Indeed using this algorithm, instead of f, we deal with a function g, which is an approximation of f. Proposition (a) shows that if g is close enough to f, then the results we obtain are a good approximation of $\mu(f)$, π^f. Propositions (b) and (c) establish the turnpike property, which is well known in mathematical economics (see [7], [17], and survey [19]) for (f)-weakly optimal solutions $v \in \mathcal{A}(f)$. In [25, Theorem 2.4] a weak version of the turnpike property was established. For an optimal solution $v \in \mathcal{A}(f)$ Theorem 2.4 in [25] implies that relation (1.9), with ℓ which depends on ε and $|v(0)|$, holds for all $t \in [0, \infty) \backslash E$, where $E \subset [0, \infty)$ is a measurable subset and the Lebesgue measure of E does not exceed a constant which depends on ε and $|v(0)|$. Clearly Propositions (b) and (c) are an essential improvement of Theorem 2.4 in [25] for optimal solutions $v \in \mathcal{A}(f)$.

Propositions (b) and (c) are also important for applications. Suppose that we know (f)-weakly optimal solutions $x_i \in \mathcal{A}(f), i = 1, \dots, q$, with initial conditions $x_i(0) \in \{z \in R^n\colon |z| \le K\}$, where K is a positive constant. Therefore we know the turnpike $H(f)$, or at least its approximation, and the constant Q (see Proposition (c)) which is an estimate for the time period required to reach the turnpike. This information can be useful if we need to find an (f)-weakly optimal solution with a new initial value from the set $\{z \in R^n\colon |z| \le K\}$.

Propositions (a), (b), and (c) are extensions of the main results in Zaslavski [22] which were established for discrete-time control systems. In the approach used in [21, 22] the following property played a crucial role.

Property C. In the space of integrands (or cost functions) there exists an everywhere dense subset E such that for each $f \in E$ there exists an (f)-good periodic trajectory.

This approach was also used in Zaslavski [24] for a class of one-dimensional variational problems arising in continuum mechanics which was discussed in Leizarowitz and Mizel [16] and Coleman, Marcus, and Mizel [8]. It is not clear whether Property C holds in general. In the present paper we develop a more general approach based on the following idea which arose in our discussions with Moshe Marcus.

The validity of Property B for an integrand $f \in \mathfrak{A}$ (namely, if all (f)-good trajectories have the same limit point set) implies that f has the additional interesting properties: for any initial condition there exists an (f)-weakly optimal solution; the turnpike property holds for optimal functions $v \in \mathcal{A}(f)$; f is a continuity point of the mapping $g \to (\mu(g), \pi^g)$, $g \in \mathfrak{A}$.

We hope that this approach is universal and can be applied to various classes of variational and optimal control problems, in particular when Property C does not hold.

2. Main results. For each function $f \in \mathfrak{A}$ denote by $\mathcal{A}(f)$ the set of all a.c. functions $v\colon [0,\infty) \to R^n$ which satisfy (1.8) for each $T_1 \in [0,\infty)$, $T_2 \in (T_1,\infty)$. It follows from Theorem 8.3 in [25] that for every $f \in \mathfrak{A}$ and every $x \in R^n$ there exists an (f)-good function $v \in \mathcal{A}(f)$ satisfying $v(0) = x$.

If $f \in \mathfrak{A}$ and for each (f)-good function $v_i\colon [0,\infty) \to R^n$, $i = 1, 2$,

$$\Omega(v_2) = \Omega(v_1),$$

then by Theorem 8.4 in [25] any function $v \in \mathcal{A}(f)$ is an (f)-weakly optimal function.

We will establish the following results.

THEOREM 2.1. *Assume that $f \in \mathfrak{A}$ and there exists a compact set $H(f) \subset R^n$ such that $\Omega(v) = H(f)$ for each (f)-good function $v\colon [0,\infty) \to R^n$. Then f is a continuity point of the mapping $g \to (\mu(g), \pi^g) \in R^1 \times C(R^n)$, $g \in \mathfrak{A}$, where $C(R^n)$ is the space of all continuous functions $\phi\colon R^n \to R^1$ with the topology of the uniform convergence on bounded subsets.*

Theorems 2.2 and 2.3 establish the turnpike property for a generic $f \in \mathfrak{A}$.

THEOREM 2.2. *Assume that $f \in \mathfrak{A}$ and there exists a compact set $H(f) \subset R^n$ such that $\Omega(v) = H(f)$ for each (f)-good function $v\colon [0,\infty) \to R^n$. Let ε be a positive number. Then there exist numbers $L, \delta > 0$ and a neighborhood $\mathcal{U}$ of f in $\mathfrak{A}$ such that for each $g \in \mathcal{U}$, each $v \in \mathcal{A}(g)$ satisfying $d(v(0), H(f)) \le \delta$, and each $T \in [0,\infty)$*

$$\operatorname{dist}(H(f),\ \{v(t)\colon t \in [T, T+L]\}) \le \varepsilon. \tag{2.1}$$

THEOREM 2.3. *Assume that $f \in \mathfrak{A}$ and there exists a compact set $H(f) \subset R^n$ such that $\Omega(v) = H(f)$ for each (f)-good function $v\colon [0,\infty) \to R^n$. Let ε and K be positive numbers. Then there exist numbers $L, Q > 0$ and a neighborhood $\mathcal{U}$ of f in $\mathfrak{A}$ such that for each $g \in \mathcal{U}$, each $v \in \mathcal{A}(g)$ satisfying $|v(0)| \le K$ relation (2.1) holds for all $T \in [Q,\infty)$.*

For each $f \in \mathfrak{A}$ denote by $\mathcal{B}(f)$ the set of all a.c. functions $v\colon R^1 \to R^n$ such that (1.8) holds for each $T_1 \in R^1$, $T_2 \in (T_1,\infty)$, and $\liminf_{t\to-\infty} |v(t)| < \infty$.

THEOREM 2.4. *Assume that $f \in \mathfrak{A}$ and there exists a compact set $H(f) \subset R^n$ such that $\Omega(v) = H(f)$ for each (f)-good function $v\colon [0,\infty) \to R^n$. Then the following properties hold:*

(1) *for each $h \in H(f)$ there exists $v \in \mathcal{B}(f)$ satisfying $v(0) = h$;*

(2) *for each $v \in \mathcal{B}(f)$ the relation $v(t) \in H(f)$ holds for all $t \in R^1$;*

(3) *for each $\varepsilon > 0$ there exists $L > 0$ such that (2.1) holds for each $v \in \mathcal{B}(f)$ and each $T \in R^1$.*

3. Auxiliary results. In [25] we established the following results.

PROPOSITION 3.1 ([25, Proposition 3.1]). *For each $f \in \mathfrak{A}$ there exists a neighborhood $\mathcal{U}$ of f in $\mathfrak{A}$ and a number $M > 0$ such that, for each $g \in \mathcal{U}$ and each (g)-good function $x\colon [0,\infty) \to R^n$,*

$$\limsup_{t\to\infty} |x(t)| < M.$$

PROPOSITION 3.2 ([25, Proposition 3.2]). *Let $f \in \mathfrak{A}$ and $M_1,\ M_2,\ c > 0$. Then there exist a neighborhood $\mathcal{U}$ of f in $\mathfrak{A}$ and $S > 0$ such that for each $g \in \mathcal{U}$, each $T_1 \in [0,\infty)$, and each $T_2 \in [T_1 + c, \infty)$ the following property holds: for each*

x, $y \in R^n$ satisfying $|x|, |y| \le M_1$ and each a.c. function $v\colon [T_1, T_2] \to R^n$ satisfying $v(T_1) = x, v(T_2) = y, I^g(T_1, T_2, v) \le U^g(T_1, T_2, x, y) + M_2$, the relation $|v(t)| \le S$ $(t \in [T_1, T_2])$ holds.

PROPOSITION 3.3 ([25, Proposition 3.3]). *Let $f \in \mathfrak{A}$, $0 < c_1 < c_2 < \infty, M, \varepsilon > 0$. Then there exists $\delta > 0$ such that for each $T_1, T_2 \ge 0$ satisfying $T_2 - T_1 \in [c_1, c_2]$ and each $y_1, y_2, z_1, z_2 \in R^n$ satisfying $|y_i|, |z_i| \le M (i = 1, 2)$, $\sup\{|y_1 - y_2|, |z_1 - z_2|\} \le \delta$ the relation $|U^f(T_1, T_2, y_1, z_1) - U^f(T_1, T_2, y_2, z_2)| \le \varepsilon$ holds.*

PROPOSITION 3.4 ([25, Proposition 3.4]). *Assume that $f \in \mathfrak{A}, M_1 > 0$, $0 \le T_1 < T_2, x_i\colon [T_1, T_2] \to R^n, i = 1, 2, \ldots,$ is a sequence of a.c. functions such that $I^f(T_1, T_2, x_i) \le M_1, i = 1, 2, \ldots$. Then there exist a subsequence $\{x_{i_k}\}_{k=1}^{\infty}$ and an a.c. function $x\colon [T_1, T_2] \to R^n$ such that $I^f(T_1, T_2, x) \le M_1, x_{i_k}(t) \to x(t)$ as $k \to \infty$ uniformly in $[T_1, T_2]$ and $x'_{i_k} \to x'$ as $k \to \infty$ weakly in $L^1(R^n; (T_1, T_2))$.*

PROPOSITION 3.5 ([25, Proposition 3.5]). *For each $f \in \mathfrak{A}$, each number T_1, T_2 satisfying $0 \le T_1 < T_2$, and each z_1, $z_2 \in R^n$ there is an a.c. function $x\colon [T_1, T_2] \to R^n$ such that $x(T_i) = z_i$, $i = 1, 2$, $I^f(T_1, T_2, x) = U^f(T_1, T_2, z_1, z_2)$.*

PROPOSITION 3.6 ([25, Proposition 3.7]). *Let $f \in \mathfrak{A}, 0 < c_1 < c_2 < \infty, c_3 > 0$. Then there exists a neighborhood $\mathcal{U}$ of f in $\mathfrak{A}$ such that the set $\{U^g(T_1, T_2, z_1, z_2)\colon g \in \mathcal{U}, T_1 \in [0, \infty), T_2 \in [T_1 + c_1, T_1 + c_2], z_1, z_2 \in R^n, |z_1| \le c_3 (i = 1, 2)\}$ is bounded.*

PROPOSITION 3.7 ([25, Proposition 3.8]). *Let $f \in \mathfrak{A}, 0 < c_1 < c_2 < \infty, D, \varepsilon > 0$. Then there is a neighborhood V of f in $\mathfrak{A}$ such that for each $g \in V$, each T_1, $T_2 \ge 0$ satisfying $T_2 - T_1 \in [c_1, c_2]$, and each a.c. function $x\colon [T_1, T_2] \to R^n$ satisfying $\inf\{I^f(T_1, T_2, x), I^g(T_1, T_2, x)\} \le D$ the relation $|I^f(T_1, T_2, x) - I^g(T_1, T_2, x)| \le \varepsilon$ holds.*

PROPOSITION 3.8 ([25, Proposition 3.9]). *Let $f \in \mathfrak{A}, 0 < c_1 < c_2 < \infty, c_3, \varepsilon > 0$. Then there exists a neighborhood V of f in $\mathfrak{A}$ such that for each $g \in V$, each T_1, $T_2 \ge 0$ satisfying $T_2 - T_1 \in [c_1, c_2]$, and each z, $y \in R^n$ satisfying $|y|, |z| \le c_3$ the relation $|U^f(T_1, T_2, y, z) - U^g(T_1, T_2, y, z)| \le \varepsilon$ holds.*

PROPOSITION 3.9 ([25, Theorem 5.1]). *Assume that $f \in \mathfrak{A}$ and there exists a compact set $H(f) \subset R^n$ such that $\Omega(v) = H(f)$ for each (f)-good function $v\colon [0, \infty) \to R^n$. Let ε be a positive number. Then there exists an integer $L \ge 1$ such that for each (f)-good function $v\colon [0, \infty) \to R^n$*

$$\operatorname{dist}(H(f), \quad \{v(t)\colon\ t \in [T, T + L]\}) \le \varepsilon \quad \text{for all large } T.$$

PROPOSITION 3.10 ([25, Theorem 6.1]). *Assume that $f \in \mathfrak{A}$. Then the mapping $(T_1, T_2, x, y) \to U^f(T_1, T_2, x, y)$ is continuous for $T_1 \in [0, \infty), T_2 \in (T_1, \infty), x, y \in R^n$.*

PROPOSITION 3.11 ([25, Theorem 8.3]). *For each $f \in \mathfrak{A}$ and each $x \in R^n$ there exists an (f)-good function $v \in \mathcal{A}(f)$ satisfying $v(0) = x$.*

PROPOSITION 3.12 ([25, Theorem 8.4]). *Assume that $f \in \mathfrak{A}$ and there exists a compact set $H(f) \in R^n$ such that $\Omega(x) = H(f)$ for each (f)-good function $x\colon [0, \infty) \to R^n$. Then each $v \in \mathcal{A}(f)$ is an (f)-weakly optimal function.*

PROPOSITION 3.13 ([25, Theorem 2.3]). *Assume that $f \in \mathfrak{A}$ and there exists a compact set $H(f) \subset R^n$ such that $\Omega(v) = H(f)$ for each (f)-good function $v\colon [0, \infty) \to R^n$. Let ε be a positive number. Then there exist an integer $L \ge 1$ and a neighborhood $\mathcal{U}$ of f in $\mathfrak{A}$ such that for each $g \in \mathcal{U}$ and each (g)-good function $v\colon [0, \infty) \to R^n$*

$$\operatorname{dist}(H(f), \quad \{v(t)\colon\ t \in [T, T + L]\}) \le \varepsilon \quad \text{for all large } T.$$

Theorem 8.1, equation (8.2), and Proposition 7.3 in [25] imply the following result.

PROPOSITION 3.14. *Let $f \in \mathfrak{A}$. Then $\pi^f(x) \to +\infty$ as $|x| \to \infty$.*

4. Proof of Theorems 2.1–2.3. Assume that $f \in \mathfrak{A}$ and $H(f) \subset R^n$ is a compact set such that $\Omega(v) = H(f)$ for each (f)-good function $v\colon [0,\infty) \to R^n$.

In [25] we established the following results.

LEMMA 4.1 ([25, Lemma 10.2]). *Let $\varepsilon_0 \in (0,1)$, $K_0, M_0 > 0$, and let ℓ be a positive integer such that, for each (f)-good function $x\colon [0,\infty) \to R^n$,*

$$\operatorname{dist}(H(f), \{x(t)\colon t \in [T, T+\ell]\}) \le 8^{-1}\varepsilon_0 \tag{4.1}$$

for all large T (the existence of ℓ follows from Proposition 3.9). Then there exist an integer $N \ge 10$ and a neighborhood $\mathcal{U}$ of f in $\mathfrak{A}$ such that for each $g \in \mathcal{U}$, each $S \in [0,\infty)$, and each a.c. function $x\colon [S, S+N\ell] \to R^n$ satisfying

$$|x(S)|, \quad |x(S+N\ell)| \le K_0, \quad I^g(S, S+N\ell, x) \le U^g(S, S+N\ell, x(S), x(S+N\ell)) + M_0$$

there exists an integer $i_0 \in [0, N-8]$ such that for all $T \in [S+i_0\ell, S+(i_0+7)\ell]$

$$\operatorname{dist}(H(f), \{x(t)\colon t \in [T, T+\ell]\}) \le \varepsilon_0.$$

LEMMA 4.2 ([25, Lemma 10.3]). *Let $\varepsilon > 0$. Then there exists $\delta > 0$ such that, for each $x_1, x_2 \in R^n$ which satisfy $d(x_i, H(f)) \le \delta$, $i = 1, 2$, there exists an a.c. function $v\colon [0,T] \to R^n$ for which*

$$T \ge 1, \quad v(0) = x_1, \quad v(T) = x_2, \quad I^f(0,T,v) - \pi^f(x_1) + \pi^f(x_2) - T\mu(f) \le \varepsilon.$$

LEMMA 4.3 ([25, Lemma 10.4]). *Let $\varepsilon \in (0,1)$ and let L be a positive integer such that for each (f)-good function $v\colon [0,\infty) \to R^n$*

$$\operatorname{dist}(H(f), \{v(t)\colon t \in [S, S+L]\}) \le \varepsilon \tag{4.2}$$

for all large S (the existence of L follows from Proposition 3.9).

Then there exists $\delta > 0$ such that for each $T \in [L, \infty)$ and each a.c. function $v\colon [0,T] \to R^n$ which satisfies

$$d(v(0), H(f)) \le \delta, \quad d(v(T), H(f)) \le \delta, \quad I^f(0,T,v) - T\mu(f) - \pi^f(v(0)) + \pi^f(v(T)) \le \delta$$

relation (4.2) holds for every $S \in [0, T-L]$.

Lemma 4.1 and Proposition 3.2 imply the following.

LEMMA 4.4. *Let $\varepsilon_0 \in (0,1)$, $K_0, M_0 > 0$, and let ℓ be a positive integer such that each (f)-good function $x\colon [0,\infty) \to R^n$ satisfies (4.1) for all large T. Then there exist an integer $N \ge 10$, a neighborhood $\mathcal{U}$ of f in $\mathfrak{A}$, and a number $M_1 > 0$ such that for each $g \in \mathcal{U}$, each $T_1 \ge 0, T_2 \ge T_1 + N\ell$, and each a.c. function $x\colon [T_1, T_2] \to R^n$ which satisfies*

$$|x(T_i)| \le K_0, \quad i = 1, 2, \quad I^g(T_1, T_2, x) \le U^g(T_1, T_2, x(T_1), x(T_2)) + M_0$$

the following properties hold: $|x(t)| \le M_1$ for all $t \in [T_1, T_2]$; for each $S \in [T_1, T_2 - N\ell]$ there exists an integer $i_0 \in [0, N-8]$ such that

$$\operatorname{dist}(H(f), \{x(t)\colon t \in [T, T+\ell]\}) \le \varepsilon_0 \quad \textit{for all } T \in [S+i_0\ell, S+(i_0+7)\ell].$$

Set

$$D_f = \sup\{|h|\colon\ h \in H(f)\}. \tag{4.3}$$

For each $g \in \mathfrak{A}$ denote by $\mathcal{A}(g)$ the set of all a.c. functions $v\colon [0,\infty) \to R^n$ such that for each $T_1 \in [0,\infty), T_2 \in (T_1,\infty)$

$$I^g(T_1,T_2,v) = (T_2-T_1)\mu(g) + \pi^g(v(T_1)) - \pi^g(v(T_2)). \tag{4.4}$$

For $K,\tau > 0$ and $g \in \mathfrak{A}$ we define

$$\ell(g,K,\tau) = \inf\{U^g(0,\tau,x,y) - \pi^f(x) + \pi^f(y)\colon x,y \in R^n, |x|,|y| \le K\}. \tag{4.5}$$

It follows from the representation formula (see (1.6), (1.7)), Proposition 3.11, that

$$\ell(f,K,\tau) = \mu(f)\tau, \qquad \tau > 0, \quad K > D_f. \tag{4.6}$$

Equations (4.5), (4.6), and Proposition 3.8 imply the following result.

LEMMA 4.5. *Let $K > D_f, 0 < \tau_1, \tau_2, \delta > 0$. Then there exists a neighborhood $\mathcal{U}$ of f in $\mathfrak{A}$ such that $|\ell(g,K,\tau) - \mu(f)\tau| \le \delta$ for each $g \in \mathcal{U}$ and each $\tau \in [\tau_1,\tau_2]$.*

LEMMA 4.6. *Let $h \in H(f)$. Then there exists an (f)-good function $v\colon [0,\infty) \to H(f)$ such that $v \in \mathcal{A}(f)$ and $v(0) = h$.*

Proof. By Proposition 3.14 there exists an (f)-good function $u \in \mathcal{A}(f)$. We may assume that

$$d(u(t),H(f)) \le 1 \ \text{ for all } \ t \in [0,\infty). \tag{4.7}$$

There exists a sequence of positive numbers $\{T_p\}_{p=0}^{\infty}$ such that

$$T_{p+1} \ge T_p + 1, \quad p = 0,1,\ldots, \quad u(T_p) \to h \quad \text{as } p \to \infty. \tag{4.8}$$

For every integer $p \ge 1$ we set

$$v_p(t) = u(t+T_p), \qquad t \in [0,\infty). \tag{4.9}$$

By Proposition 3.4, (4.9), and (4.7) there exist a subsequence $\{v_{p_j}\}_{j=1}^{\infty}$ and an a.c. function $v\colon [0,\infty) \to R^n$ such that for every integer $N \ge 1$

$$v_{p_j}(t) \to v(t) \text{ as } j \to \infty \text{ uniformly in } [0,N], \tag{4.10}$$

$$I^f(0,N,v) \le \liminf_{j\to\infty} I^f(0,N,v_{p_j}). \tag{4.11}$$

Since $\Omega(u) = H(f)$, it follows from (4.9) and (4.10) that $v(t) \in H(f)$ for all $t \in [0,\infty)$. By (4.8)–(4.10) $v(0) = h$. Since $u \in \mathcal{A}(f)$, it follows from (4.9)–(4.11) that for each integer $N \ge 1$

$$\begin{aligned} I^f(0,N,v) &\le \liminf_{j\to\infty} I^f(T_{p_j}, T_{p_j}+N, u) \\ &\le \liminf_{j\to\infty} [N\mu(f) + \pi^f(u(T_{p_j})) - \pi^f(u(T_{p_j}+N))] \\ &= N\mu(f) + \pi^f(v(0)) - \pi^f(v(N)). \end{aligned}$$

Together with the representation formula (see (1.6), (1.7)) this implies that $v \in \mathcal{A}(f)$. The lemma is proven.

LEMMA 4.7. *Let $\varepsilon \in (0,1)$ and $K > D_f + 1$. Then there exists a neighborhood $\mathcal{U}$ of f in $\mathfrak{A}$ such that for each $g \in \mathcal{U}$ and each number $T \ge 1$ there exists an a.c. function $x\colon [0,T] \to R^n$ such that $x(0), x(T) \in H(f)$,*

$$I^g(0,T,x) - \pi^f(x(0)) + \pi^f(x(T)) \le \ell(g,K,T) + \varepsilon. \tag{4.12}$$

Proof. By Lemma 4.6 there exists an (f)-good function

$$v_0 : [0,\infty) \to H(f) \text{ such that } v_0 \in \mathcal{A}(f). \tag{4.13}$$

By Proposition 3.2 there exists a neighborhood $\mathcal{U}_1$ of f in $\mathfrak{A}$ and $M_1 > 0$ such that for each $g \in \mathcal{U}_1$, each $T_1 \in [0,\infty), T_2 \in [T_1 + 8^{-1}, \infty)$, and each a.c. function x: $[T_1, T_2] \to R^n$ which satisfies

$$|x(T_i)| \le K, \quad i = 1,2, \quad I^g(T_1, T_2, x) \le U^g(T_1, T_2, x(T_1), x(T_2)) + 1 \tag{4.14}$$

the following relation holds:

$$|x(t)| \le M_1, \qquad t \in [T_1, T_2]. \tag{4.15}$$

By Proposition 3.10 there exists a number

$$\delta \in (0, 8^{-1}\varepsilon) \tag{4.16}$$

such that for each $y_1, y_2, z_1, z_2 \in R^n$ which satisfy

$$|y_i|, |z_i| \le M_1 + 2K + 1, \quad i = 1,2, \quad |y_i - z_i| \le 4\delta, \quad i = 1,2, \tag{4.17}$$

the following relations hold:

$$|U^f(0,1,y_1,y_2) - U^f(0,1,z_1,z_2)| \le 2^{-6}\varepsilon, \quad |\pi^f(y_i) - \pi^f(z_i)| \le 2^{-6}\varepsilon, \quad i = 1,2. \tag{4.18}$$

By Proposition 3.9 there exists an integer $L \ge 1$ such that for each (f)-good function v: $[0,\infty) \to R^n$

$$\operatorname{dist}(H(f), \{v(t):\ t \in [T, T+L]\}) \le 8^{-1}\delta \tag{4.19}$$

for all large T.

By Lemma 4.4 and the definition of L there exist an integer $N_1 \ge 10$ and a neighborhood $\mathcal{U}_2$ of f in $\mathfrak{A}$ such that for each $g \in \mathcal{U}_2$, each $T_1 \ge 0$, $T_2 \ge T_1 + N_1 L$, each a.c. function x: $[T_1, T_2] \to R^n$ which satisfies (4.14), and each $S \in [T_1, T_2 - N_1 L]$ there exists an integer $i_0 \in [0, N_1 - 8]$ such that for all $T \in [S + i_0 L, S + (i_0 + 7)L]$

$$\operatorname{dist}(H(f), \{x(t):\ t \in [T, T+L]\}) \le \delta. \tag{4.20}$$

Since $\Omega(v_0) = H(f)$ it follows from (4.13) that there exist integers

$$N_2 \ge 4N_1 L + 4, \qquad N_3 \ge 8 \tag{4.21}$$

such that

$$\begin{aligned} &\operatorname{dist}(H(f), (v_0(t):\ t \in [0, N_2 L]\}) \le 8^{-1}\delta, \\ &\operatorname{dist}(H(f), \{v_0(t):\ t \in [8(N_2+1)L, 8(N_2+1)L + N_3 L]\}) \le 8^{-1}\delta. \end{aligned} \tag{4.22}$$

Fix an integer

$$N_0 \ge 8L(N_1 + N_2 + N_3 + 4). \tag{4.23}$$

By Proposition 3.8 there exists a neighborhood $\mathcal{U}_3$ of f in $\mathfrak{A}$ such that for each $g \in \mathcal{U}_3$ and each z, $y \in R^n$ which satisfy $|y|$, $|z| \le 4M_1 + 4K + 4$ the following relation holds:

$$|U^f(0,1,y,z) - U^g(0,1,y,z)| \le 2^{-6}\varepsilon. \tag{4.24}$$

By Proposition 3.7 there exists a neighborhood $\mathcal{U}_4$ of f in $\mathfrak{A}$ such that for each $g \in \mathcal{U}_4$, each $T_1 \geq 0$, $T_2 \in [T_1+1, T_1+N_0+1]$, and each a.c. function $x\colon [T_1, T_2] \to R^n$ which satisfies

$$\inf\{I^f(T_1,T_2,x), I^g(T_1,T_2,x)\} \leq N_0(|\mu(f)|+1)+2\sup\{|\pi^f(h)|\colon\ h \in H(f)\} \tag{4.25}$$

the following relation holds:

$$|I^f(T_1,T_2,x) - I^g(T_1,T_2,x)| \leq 2^{-6}\varepsilon. \tag{4.26}$$

By Lemma 4.5 there exists a neighborhood $\mathcal{U}_5$ of f in $\mathfrak{A}$ such that for each $g \in \mathcal{U}_5$ and each $\tau \in [1, 8(N_0+1)]$

$$|\ell(g,K,\tau) - \mu(f)\tau| \leq 2^{-6}\varepsilon. \tag{4.27}$$

Set

$$\mathcal{U} = \bigcap_{i=1}^{5} \mathcal{U}_i. \tag{4.28}$$

Let $g \in \mathcal{U}$ and a number $T \geq 1$. There are two cases: (i) $T \leq N_0$; (ii) $T > N_0$.

Consider the case (i). Set

$$x(t) = v_0(t), \qquad t \in [0,T]. \tag{4.29}$$

It follows from (4.13) and the definition of $\mathcal{A}(f)$ (see (4.4)) that

$$I^f(0,T,x) \leq N_0|\mu(f)| + 2\sup\{|\pi^f(h)|\colon\ h \in H(f)\}.$$

By this relation and the definition of $\mathcal{U}_4$ (see (4.26))

$$|I^f(0,T,x) - I^g(0,T,x)| \leq 2^{-6}\varepsilon. \tag{4.30}$$

By the definition of $\mathcal{U}_5$ (see (4.27))

$$|\ell(g,K,T) - \mu(f)T| \leq 2^{-6}\varepsilon. \tag{4.31}$$

Combining (4.30), (4.29), and (4.13) we obtain that

$$\begin{aligned} I^g(0,T,x) - \pi^f(x(0)) + \pi^f(x(T)) &\leq I^f(0,T,v_0) - \pi^f(v_0(0)) + \pi^f(v_0(T)) + 2^{-6}\varepsilon \\ &\leq \mu(f)T + 2^{-6}\varepsilon \leq \ell(g,K,T) + 2^{-5}\varepsilon. \end{aligned}$$

Therefore in the case (i) the assertion of the lemma is valid.

Consider the case (ii). Then

$$T > N_0. \tag{4.32}$$

There exists an a.c. function $y\colon [0,T] \to R^n$ such that

$$|y(0)|, |y(T)| \leq K, \qquad I^g(0,T,y) - \pi^f(y(0)) + \pi^f(y(T)) \leq \ell(g,K,T) + 16^{-1}\delta. \tag{4.33}$$

Clearly

$$I^g(0,T,y) \leq U^g(0,T,y(0),y(T)) + 16^{-1}\delta.$$

By this relation, (4.33), (4.32), (4.23), and the definition of N_1, $\mathcal{U}_2$ (see (4.20)) there exist integers i_1, $i_2 \in [0, N_1 - 8]$ such that

$$\operatorname{dist}(H(f), \{y(t)\colon t \in [S, S+L]\}) \le \delta \tag{4.34}$$

for each

$$S \in [i_1 L, (i_1+7)L] \cup [T - 2N_1 L + i_2 L, \quad T - 2N_1 L + (i_2+7)L]. \tag{4.35}$$

It follows from (4.34), (4.35), and (4.22) that there exist

$$t_1 \in [8(N_2+1)L, 8(N_2+1)L + N_3 L], \qquad t_2 \in [0, N_2 L] \tag{4.36}$$

for which

$$|y(i_1 L+1) - v_0(t_1)| \le \delta + 4^{-1}\delta, \quad |y(T - 2N_1 L + i_2 L + 1) - v_0(t_2)| \le \delta + 4^{-1}\delta. \tag{4.37}$$

By Proposition 3.5, (4.13), (4.36), (4.21), (4.32), and (4.23) there exists an a.c. function $x\colon [0,T] \to R^n$ such that

$$x(t) = v_0(t + t_1 - i_1 L - 1), \quad t \in [0, i_1 L + 1), \quad x(t) = y(t), \quad t \in [i_1 L + 2, T - 2N_1 L + i_2 L],$$

$$x(t) = v_0(t + t_2 - (T - 2N_1 L + i_2 L + 1)), \qquad t \in [T - 2N_1 L + i_2 L + 1, T],$$

$$I^g(\tau, \tau+1, x) = U^g(0, 1, x(\tau), x(\tau+1)), \quad \tau = i_1 L + 1, \quad T - 2N_1 L + i_2 L. \tag{4.38}$$

For each a.c. function $u\colon [0,T] \to R^n$ and each $r_1, r_2 \in [0,T]$ satisfying $r_1 < r_2$ we set

$$\sigma(r_1, r_2, u) = I^g(r_1, r_2, u) - \pi^f(u(r_1)) + \pi^f(u(r_2)). \tag{4.39}$$

Set

$$\tau_0 = 0, \quad \tau_1 = i_1 L + 1, \quad \tau_2 = i_1 L + 2, \quad \tau_3 = T - 2N_1 L + i_2 L,$$
$$\tau_4 = T - 2N_1 L + i_2 L + 1, \qquad \tau_5 = T. \tag{4.40}$$

It follows from (4.38)–(4.40) that

$$\sigma(0, T, x) - \sigma(0, T, y) = \sum_{i=0}^{1} [\sigma(\tau_i, \tau_{i+1}, x) - \sigma(\tau_i, \tau_{i+1}, y)]$$
$$+ \sum_{i=3}^{4} [\sigma(\tau_i, \tau_{i+1}, x) - \sigma(\tau_i, \tau_{i+1}, y)]. \tag{4.41}$$

Analogously to the case (i) we can show that

$$\sigma(t_1 - i_1 L - 1, t_1, v_0) \le \ell(g, K, i_1 L + 1) + 2^{-5}\varepsilon,$$
$$\sigma(t_2, t_2 + 2N_1 L + i_2 L + 1, v_0) \le \ell(g, K, 2N_1 L + i_2 L + 1) + 2^{-5}\varepsilon.$$

Together with (4.38)–(4.40) this implies that

$$\sigma(\tau_i, \tau_{i+1}, x) \le \ell(g, K, \tau_{i+1} - \tau_i) + 2^{-5}\varepsilon, \qquad i = 0, 4. \tag{4.42}$$

By (4.40), (4.33), (4.37), (4.16), and (4.13)

$$\sigma(\tau_i, \tau_{i+1}, y) \geq \ell(g, K, \tau_{i+1} - \tau_i), \qquad i = 0, 4. \tag{4.43}$$

It follows from (4.38)–(4.40) that for $i = 1, 3$

$$\begin{aligned}\sigma(\tau_i, \tau_{i+1}, x) - \sigma(\tau_i, \tau_{i+1}, y) &\leq U^g(0, 1, x(\tau_i), x(\tau_{i+1})) - \pi^f(x(\tau_i)) + \pi^f(x(\tau_{i+1}))\\ &\quad -[U^g(0, 1, y(\tau_i), y(\tau_{i+1})) - \pi^f(y(\tau_i)) + \pi^f(y(\tau_{i+1}))].\end{aligned} \tag{4.44}$$

It follows from (4.33) and the definition of $\mathcal{U}_1, M_1$ (see (4.14), (4.15)) that

$$|y(t)| \leq M_1, \qquad t \in [0, T]. \tag{4.45}$$

By (4.40), (4.38), (4.37), (4.13), and the definition of δ (see (4.16)–(4.18)) for $i = 1, 3$

$$|\pi^f(x(\tau_{i+1})) - \pi^f(x(\tau_i)) - (\pi^f(y(\tau_{i+1})) - \pi^f(y(\tau_i)))| \leq 2^{-6}\varepsilon. \tag{4.46}$$

It follows from (4.40), (4.38), (4.45), (4.13), the definition of $\mathcal{U}_3$ (see (4.24)), the definition of δ (see (4.16)–(4.18)), and (4.37) that for $i = 1, 3$

$$\begin{aligned}&|U^g(0, 1, x(\tau_i), x(\tau_{i+1})) - U^g(0, 1, y(\tau_i), y(\tau_{i+1}))|\\ &\quad \leq\ 2^{-5}\varepsilon + |U^f(0, 1, x(\tau_i), x(\tau_{i+1})) - U^f(0, 1, y(\tau_i), y(\tau_{i+1}))| \leq 2^{-4}\varepsilon.\end{aligned}$$

Together with (4.44) and (4.46) this implies that for $i = 1, 3$

$$\sigma(\tau_i, \tau_{i+1}, x) - \sigma(\tau_i, \tau_{i+1}, y) \leq 2^{-3}\varepsilon.$$

By this relation and (4.41)–(4.43), $\sigma(0, T, x) - \sigma(0, T, y) \leq 2^{-1}\varepsilon$. Together with (4.39), (4.33), and (4.16) this implies (4.12). This completes the proof of the lemma.

LEMMA 4.8. *Let $\varepsilon \in (0, 1)$ and $K > D_f + 1$. Then there exists a neighborhood $\mathcal{U}$ of f in $\mathfrak{A}$ such that for each $g \in \mathcal{U}$, each $h \in H(f)$, and each number $T \geq 1$ there exists an a.c. function $x\colon [0, T] \to R^n$ for which*

$$x(0) = h, \qquad x(T) \in H(f), \tag{4.47}$$

$$I^g(0, T, x) - \pi^f(x(0)) + \pi^f(x(T)) \leq \ell(g, K, T) + \varepsilon. \tag{4.48}$$

Proof. By Proposition 3.2 there exist a neighborhood $\mathcal{U}_1$ of f in $\mathfrak{A}$ and $M_1 > 2K + 1$ such that for each $g \in \mathcal{U}_1$, each $T_1 \in [0, \infty), T_2 \in [T_1 + 8^{-1}, \infty)$, and each a.c. function $x\colon [T_1, T_2] \to R^n$ which satisfies

$$|x(T_i)| \leq K, \quad i = 1, 2, \quad I^g(T_1, T_2, x) \leq U^g(T_1, T_2, x(T_1), x(T_2)) + 1 \tag{4.49}$$

the following relation holds:

$$|x(t)| \leq M_1, \qquad t \in [T_1, T_2]. \tag{4.50}$$

By Lemma 4.7 there exists a neighborhood $\mathcal{U}_2$ of f in $\mathfrak{A}$ such that for each $g \in \mathcal{U}_2$ and each number $T \geq 1$ there exists an a.c. function $x\colon [0, T] \to R^n$ such that

$$\begin{aligned}&x(0), \quad x(T) \in H(f),\\ &I^g(0, T, x) - \pi^f(x(0)) + \pi^f(x(T)) \leq \ell(g, M_1, T) + 2^{-6}\varepsilon.\end{aligned} \tag{4.51}$$

By Proposition 3.10 there exists a number

$$\delta \in (0, 8^{-1}\varepsilon) \tag{4.52}$$

such that for each $y_1, y_2, z_1, z_2 \in R^n$ which satisfy

$$|y_i|, |z_i| \le 2M_1 + 4, \quad i = 1, 2, \quad |y_i - z_i| \le 4\delta, \quad i = 1, 2 \tag{4.53}$$

the following relations hold:

$$|U^f(0, 1, y_1, y_2) - U^f(0, 1, z_1, z_2)| \le 2^{-6}\varepsilon, \quad |\pi^f(y_i) - \pi^f(z_i)| \le 2^{-6}\varepsilon, \quad i = 1, 2. \tag{4.54}$$

By Proposition 3.8 there exists a neighborhood $\mathcal{U}_3$ of f in $\mathfrak{A}$ such that for each $g \in \mathcal{U}_3$ and each z, $y \in R^n$ which satisfy $|y|$, $|z| \le 2M_1 + 4$ the following relation holds:

$$|U^f(0, 1, y, z) - U^g(0, 1, y, z)| \le 2^{-6}\varepsilon. \tag{4.55}$$

By Lemma 4.6 there exists an (f)-good function

$$v_0\colon [0, \infty) \to H(f) \quad \text{such that } v_0 \in \mathcal{A}(f). \tag{4.56}$$

Since $\Omega(v_0) = H(f)$, it follows from (4.56) that there exist integers N_1, $N_2 \ge 8$ for which

$$\begin{aligned} &\operatorname{dist}(H(f), \{v_0(t)\colon\ t \in [4, N_1 + 4]\}) \le 8^{-1}\delta, \\ &\operatorname{dist}(H(f), \{v_0(t)\colon\ t \in [2N_1 + 16, 2N_1 + 16 + N_2]\}) \le 8^{-1}\delta. \end{aligned} \tag{4.57}$$

Fix an integer

$$N_0 \ge 8(N_1 + N_2 + 20). \tag{4.58}$$

By Proposition 3.7 there exists a neighborhood $\mathcal{U}_4$ of f in $\mathfrak{A}$ such that for each $g \in \mathcal{U}_4$, each $T_1 \ge 0$, $T_2 \in [T_1 + 1, T_1 + N_0]$, and each a.c. function $x\colon [T_1, T_2] \to R^n$ which satisfies

$$\inf\{I^f(T_1, T_2, x), I^g(T_1, T_2, x)\} \le N_0|\mu(f)| + 2\sup\{|\pi^f(z)|\colon\ z \in H(f)\} \tag{4.59}$$

the following relation holds:

$$|I^f(T_1, T_2, x) - I^g(T_1, T_2, x)| \le 2^{-6}\varepsilon. \tag{4.60}$$

By Lemma 4.5 there exists a neighborhood $\mathcal{U}_5$ of f in $\mathfrak{A}$ such that for each $g \in \mathcal{U}_5$ and each $T \in [1, 2N_0 + 8]$

$$|\ell(g, M_1, T) - \mu(f)T| \le 2^{-6}\varepsilon. \tag{4.61}$$

Set

$$\mathcal{U} = \bigcap_{i=1}^{5} \mathcal{U}_i. \tag{4.62}$$

Let $g \in \mathcal{U}$, $h \in H(f)$, and a number $T \ge 1$. There are two cases: (i) $T \le N_0$; (ii) $T > N_0$. Consider the case (i). By Lemma 4.6 there exists an (f)-good function

$$x\colon [0, \infty) \to H(f) \quad \text{such that } x \in \mathcal{A}(f), \quad x(0) = h.$$

Analogously to the case (i) in the proof of Lemma 4.7 we can show that relation (4.48) holds. Therefore in the case (i) the assertion of the lemma is valid.

Consider the case (ii). Then

$$T > N_0. \tag{4.63}$$

It follows from the definition of $\mathcal{U}_2$ (see (4.51)), (4.63), and (4.58) that there exists an a.c. function $u\colon [0, T - 4(N_1 + N_2 + 5)] \to R^n$ such that

$$u(0),\ u(T - 4(N_1 + N_2 + 5)) \in H(f), \tag{4.64}$$

$$\begin{aligned} &I^g(0, T - 4(N_1 + N_2 + 5), u) - \pi^f(u(0)) + \pi^f(u(T - 4(N_1 + N_2 + 5))) \\ &\le\ \ell(g, M_1, T - 4(N_1 + N_2 + 5)) + 2^{-6}\varepsilon. \end{aligned} \tag{4.65}$$

By (4.57) and (4.64) there exist

$$t_1,\ t_3 \in [4, N_1 + 4], \qquad t_2 \in [2N_1 + 16, 2N_1 + 16 + N_2] \tag{4.66}$$

for which

$$\begin{aligned} &|h - v_0(t_1)| \le 4^{-1}\delta, \quad |u(0) - v_0(t_2)| \le 4^{-1}\delta, \\ &|u(T - 4(N_1 + N_2 + 5)) - v_0(t_3)| \le 4^{-1}\delta. \end{aligned} \tag{4.67}$$

By Proposition 3.5, (4.66), (4.63), and (4.58) there exists an a.c. function $x\colon [0, T] \to R^n$ such that

$$\begin{aligned} x(0) &= h, \quad x(t) = v_0(t + t_1), \quad t \in [1, t_2 - t_1 - 1], \\ x(t) &= u(t - t_2 + t_1), \\ &\quad t \in [t_2 - t_1, T - 4(N_1 + N_2 + 5) + t_2 - t_1], \\ x(t) &= v_0(t + t_3 - (T - 4(N_1 + N_2 + 5) + t_2 - t_1)), \\ &\quad t \in [T - 4(N_1 + N_2 + 5) + t_2 - t_1 + 1, T], \\ I^g(\tau, \tau + 1, x) &= U^g(0, 1, x(\tau), x(\tau + 1)), \\ &\quad \tau = 0, t_2 - t_1 - 1, T - 4(N_1 + N_2 + 5) + t_2 - t_1. \end{aligned} \tag{4.68}$$

Clearly (4.47) holds. We will show that (4.48) holds.

For each a.c. function $v\colon [0, T] \to R^n$ and each $r_1, r_2 \in [0, T]$ satisfying $r_1 < r_2$ we set

$$\sigma(r_1, r_2, v) = I^g(r_1, r_2, v) - \pi^f(v(r_1)) + \pi^f(v(r_2)). \tag{4.69}$$

Set

$$\begin{aligned} &\tau_0 = 0, \quad \tau_1 = 1, \quad \tau_2 = t_2 - t_1 - 1, \quad \tau_3 = t_2 - t_1, \\ &\tau_4 = T - 4(N_1 + N_2 + 5) + t_2 - t_1, \\ &\tau_5 = T - 4(N_1 + N_2 + 5) + t_2 - t_1 + 1, \qquad \tau_6 = T. \end{aligned} \tag{4.70}$$

There exists an a.c. function $y\colon [0, T] \to R^n$ such that

$$|y(0)|,\ |y(T)| \le K, \qquad \sigma(0, T, y) \le \ell(g, K, T) + 2^{-6}\varepsilon. \tag{4.71}$$

It follows from (4.71) and the definition of $\mathcal{U}_1$, M_1 (see (4.49), (4.50)) that

$$|y(t)| \le M_1, \qquad t \in [0,T]. \tag{4.72}$$

Equations (4.69) and (4.70) imply that

$$\sigma(0,T,x) - \sigma(0,T,y) = \sum_{i=0}^{5} [\sigma(\tau_i, \tau_{i+1}, x) - \sigma(\tau_i, \tau_{i+1}, y)]. \tag{4.73}$$

By (4.72) and (4.69)

$$\sigma(\tau_i, \tau_{i+1}, y) \ge \ell(g, M_1, \tau_{i+1} - \tau_i), \qquad i = 0, \dots, 5. \tag{4.74}$$

It follows from (4.70), (4.68), (4.69), and (4.65) that

$$\sigma(\tau_3, \tau_4, x) \le \ell(g, M_1, \tau_4 - \tau_3) + 2^{-6}\varepsilon. \tag{4.75}$$

Analogously to (4.42) (see the proof of Lemma 4.7) we can show that

$$\sigma(\tau_i, \tau_{i+1}, x) \le \ell(g, M_1, \tau_{i+1} - \tau_i) + 2^{-5}\varepsilon, \qquad i = 1, 5. \tag{4.76}$$

By (4.68)–(4.70), the definition of $\mathcal{U}_3$ (see (4.55)), (4.64), and (4.56) for $i = 0, 2, 4$

$$\begin{aligned} \sigma(\tau_i, \tau_{i+1}, x) &= U^g(0, 1, x(\tau_i), x(\tau_{i+1})) - \pi^f(x(\tau_i)) + \pi^f(x(\tau_{i+1})) \\ &\le U^f(0, 1, x(\tau_i), x(\tau_{i+1})) - \pi^f(x(\tau_i)) + \pi^f(x(\tau_{i+1})) + 2^{-6}\varepsilon. \end{aligned} \tag{4.77}$$

We set

$$\gamma_0 = t_1, \quad \gamma_2 = t_2 - 1, \quad \gamma_4 = t_3. \tag{4.78}$$

Equations (4.78), (4.70), (4.68), and (4.67) imply that for $i = 0, 2, 4$

$$|x(\tau_i) - v_0(\gamma_i)|, |x(\tau_i + 1) - v_0(\gamma_i + 1)| \le 4^{-1}\delta. \tag{4.79}$$

It follows from (4.77), (4.70), (4.79), and (4.56) and the definition of δ (see (4.52)–(4.54)) that for $i = 0, 2, 4$

$$\begin{aligned} \sigma(\tau_i, \tau_{i+1}, x) &\le U^f(0, 1, x(\tau_i), x(\tau_i + 1)) - \pi^f(x(\tau_i)) + \pi^f(x(\tau_i + 1)) + 2^{-6}\varepsilon \\ &\le U^f(0, 1, v_0(\gamma_i), v_0(\gamma_i + 1)) - \pi^f(v_0(\gamma_i)) + \pi^f(v_0(\gamma_i + 1)) \\ &\quad + 2^{-4}\varepsilon = \mu(f) + 2^{-4}\varepsilon. \end{aligned}$$

By this relation and the definition of $\mathcal{U}_5$ for $i = 0, 2, 4$

$$\sigma(\tau_i, \tau_{i+1}, x) \le \ell(g, M_1, \tau_{i+1} - \tau_i) + 2^{-4}\varepsilon + 2^{-6}\varepsilon.$$

Combining this relation and (4.73)–(4.76) we obtain that

$$\sigma(0,T,x) - \sigma(0,T,y) \le 2^{-6}\varepsilon + 2^{-4}\varepsilon + 3(2^{-6}\varepsilon + 2^{-4}\varepsilon) \le 2^{-1}\varepsilon.$$

Together with (4.69) and (4.71) this implies (4.48). This completes the proof of the lemma.

LEMMA 4.9. *Let $\varepsilon \in (0,1)$, $K > D_f + 1$, and let L be a positive integer such that for each (f)-good function $v\colon [0,\infty) \to R^n$*

$$\operatorname{dist}(H(f), \{v(t):\ t \in [T, T+L]\}) \le 8^{-1}\varepsilon \tag{4.80}$$

for all large T (the existence of L follows from Proposition 3.9).

Then there exist a neighborhood $\mathcal{U}$ of f in $\mathfrak{A}$ and $\delta \in (0,1)$ such that for each $g \in \mathcal{U}$, each $T \in [L, \infty)$, and each a.c. function v: $[0,T] \to R^n$ which satisfies

$$d(v(0), H(f)) \le \delta, \qquad d(v(T), H(f)) \le \delta, \tag{4.81}$$

$$I^g(0,T,v) - \pi^f(v(0)) + \pi^f(v(T)) \le \ell(g,K,T) + \delta \tag{4.82}$$

the relation

$$\operatorname{dist}(H(f), \{v(t):\ t \in [S, S+L]\}) \le \varepsilon \tag{4.83}$$

holds for every $S \in [0, T-L]$.

Proof. By Lemma 4.3 there exists

$$\delta_1 \in (0, \varepsilon) \tag{4.84}$$

such that for each $T \in [L, \infty)$ and each a.c. function v: $[0,T] \to R^n$ which satisfies

$$\begin{aligned} &d(v(0), H(f)),\ d(v(T), H(f)) \le \delta_1, \\ &I^f(0,T,v) - T\mu(f) - \pi^f(v(0)) + \pi^f(v(T)) \le \delta_1 \end{aligned} \tag{4.85}$$

relation (4.83) holds for every $S \in [0, T-L]$. Fix a number

$$\delta \in (0, 8^{-1}\delta_1). \tag{4.86}$$

By Proposition 3.9 there exists an integer $L_1 \ge 1$ such that for each (f)-good function v: $[0,\infty) \to R^n$

$$\operatorname{dist}(H(f),\ \{v(t):\ t \in [T, T+L_1]\}) \le 8^{-1}\delta \tag{4.87}$$

for all large T. We may assume that

$$L_1 \ge 10L + 24. \tag{4.88}$$

By Lemma 4.4 there exist an integer $N_1 \ge 10$ and a neighborhood $\mathcal{U}_1$ of f in $\mathfrak{A}$ such that for each $g \in \mathcal{U}_1$, each $T_1 \ge 0$, $T_2 \ge T_1 + N_1 L_1$, each a.c. function x: $[T_1, T_2] \to R^n$ which satisfies

$$|x(T_i)| \le K, \quad i = 1,2, \quad I^g(T_1, T_2, x) \le U^g(T_1, T_2, x(T_1), x(T_2)) + 1, \tag{4.89}$$

and each $S \in [T_1, T_2 - N_1 L_1]$ there exists an integer $i_0 \in [0, N_1 - 8]$ such that for all $T \in [S + i_0 L_1, S + (i_0 + 7)L_1]$

$$\operatorname{dist}(H(f), \{x(t):\ t \in [T, T+L_1]\}) \le \delta. \tag{4.90}$$

By Lemma 4.8 there exists a neighborhood $\mathcal{U}_2$ of f in $\mathfrak{A}$ such that for each $g \in \mathcal{U}_2$, each $h \in H(f)$, and each $T \ge 1$ there exists an a.c. function x: $[0,T] \to R^n$ for which

$$\begin{aligned} &x(0) = h, \qquad x(T) \in H(f), \\ &I^g(0,T,x) - \pi^f(x(0)) + \pi^f(x(T)) \le \ell(g,K,T) + 8^{-1}\delta. \end{aligned} \tag{4.91}$$

Choose an integer

$$N_0 \geq 100 L_1 N_1. \tag{4.92}$$

By Lemma 4.5 there exists a neighborhood $\mathcal{U}_3$ of f in $\mathfrak{A}$ such that for each $g \in \mathcal{U}_3$ and each $\tau \in [1, N_0]$

$$|\ell(g, K, \tau) - \mu(f)\tau| \leq 4^{-1}\delta. \tag{4.93}$$

By Proposition 3.7 there exists a neighborhood $\mathcal{U}_4$ of f in $\mathfrak{A}$ such that for each $g \in \mathcal{U}_4$, each $T_1 \geq 0, T_2 \in [T_1+1, T_1+2N_0+1]$, and each a.c. function $x\colon [T_1, T_2] \to R^n$ which satisfies

$$\begin{aligned} &\inf\{I^f(T_1, T_2, x), I^g(T_1, T_2, x)\} \\ &\quad \leq 2N_0|\mu(f)| + 4 + 2\sup\{|\pi^f(h)|\colon\ h \in R^n,\ |h| \leq K+2\} \end{aligned} \tag{4.94}$$

the following relation holds:

$$|I^f(T_1, T_2, x) - I^g(T_1, T_2, x)| \leq \delta. \tag{4.95}$$

Set

$$\mathcal{U} = \bigcap_{i=1}^{4} \mathcal{U}_i. \tag{4.96}$$

Assume that $g \in \mathcal{U}$, $T \geq L$, and an a.c. function $v\colon\ [0, T] \to R^n$ satisfies (4.81) and (4.82). There are two cases: (i) $T \leq N_0$; (ii) $T > N_0$.

Consider case (i). It follows from (4.82), the definition of $\mathcal{U}_3$ (see (4.93)) that

$$I^g(0, T, v) - \pi^f(v(0)) + \pi^f(v(T)) \leq |\mu(f)|T + 2\delta. \tag{4.97}$$

By this relation and the definition of $\mathcal{U}_4$ (see (4.94), (4.95)) and (4.81)

$$|I^f(0, T, v) - I^g(0, T, v)| \leq \delta.$$

Together with (4.97), (4.81), and (4.86) this implies (4.85). It follows from (4.85) and the definition of δ_1 (see (4.84)) that (4.83) holds for all $S \in [0, T-L]$. Therefore in case (i) the assertion of the lemma is valid.

Consider case (ii). Then

$$T > N_0. \tag{4.98}$$

It follows from (4.81), (4.82), (4.98), (4.91) and the definition of N_1 and $\mathcal{U}_1$ (see (4.89), (4.90)) that there exists a sequence of numbers $\{T_i\}_{i=0}^q$ such that

$$\begin{aligned} &T_0 = 0, \quad T_q = T, \quad T_{i+1} - T_i \in [2L_1, 2(2N_1 - 6)L_1], \\ &\qquad i = 0, \dots, q-1, \\ &d(v(T_i), H(f)) \leq \delta, \qquad i = 0, \dots, q. \end{aligned} \tag{4.99}$$

For each a.c. function $y\colon [0, T] \to R^n$ we define

$$\sigma(r_1, r_2, y) = I^g(r_1, r_2, y) - \pi^f(y(r_1)) + \pi^f(y(r_2)) \tag{4.100}$$

for each $r_1, r_2 \in [0,T]$ satisfying $r_1 < r_2$ and set

$$\sigma(r,r,y) = 0 \tag{4.101}$$

for each $r \in [0,T]$. We set

$$\ell(g,K,0) = 0. \tag{4.102}$$

Let integers $j, p \in [0,q], j < p$. We will estimate

$$\sigma(T_j, T_p, v) - \ell(g, K, T_p - T_j).$$

By the definition of $\mathcal{U}_2$ (see 4.91)) and (4.99)–(4.102) there exists an a.c. function y: $[0,T] \to R^n$ such that

$$y(T_i) \in H(f), \quad i = 0, j, p, q, \quad \sigma(0, T_j, y) \le \ell(g, K, T_j) + 8^{-1}\delta,$$
$$\sigma(T_j, T_p, y) \le \ell(g, K, T_p - T_j) + 8^{-1}\delta, \qquad \sigma(T_p, T_q, y) \le \ell(g, K, T_q - T_p) + 8^{-1}\delta.$$

It follows from this relation, (4.82), and (4.99)–(4.102) that

$$\begin{aligned}\delta \ge \sigma(0,T,v) - \sigma(0,T,y) &= [\sigma(0,T_j,v) - \sigma(0,T_j,y)] + [\sigma(T_j,T_p,v) - \sigma(T_j,T_p,y)] \\ &\quad + [\sigma(T_p,T_q,v) - \sigma(T_p,T_q,y)] \\ &\ge \sigma(T_j,T_p,v) - \sigma(T_j,T_p,y) - 4^{-1}\delta, \\ \sigma(T_j,T_p,v) &\le \delta + 4^{-1}\delta + \ell(g,K,T_p - T_j) + 8^{-1}\delta. \end{aligned} \tag{4.103}$$

We have shown that (4.103) holds for each integer $j, p \in [0,q]$ satisfying $j < p$.

Let $S \in [0, T-L]$. By (4.99) and (4.88) there exist integers $j, p \in [0,q]$ such that

$$j < p, \quad S \in [T_j, T_p - L], \quad T_p - T_j \in [2L_1, 8N_1L_1]. \tag{4.104}$$

Evidently (4.103) holds. By (4.103), (4.100), (4.104), (4.92), and the definition of $\mathcal{U}_3$ (see (4.93))

$$I^g(T_j, T_p, v) - \pi^f(v(T_j)) + \pi^f(v(T_p)) \le \mu(f)(T_p - T_j) + 2\delta.$$

By this relation, the definition of $\mathcal{U}_4$ (see (4.94), (4.95)), (4.99), (4.104), and (4.92)

$$|I^f(T_j, T_p, v) - I^g(T_j, T_p, v)| \le \delta,$$
$$I^f(T_j, T_p, v) - \pi^f(v(T_j)) + \pi^f(v(T_p)) \le \mu(f)(T_p - T_j) + 3\delta.$$

It follows from these relations, (4.99), (4.88), (4.86), and the definition of δ_1 (see (4.84)) that (4.83) holds. This completes the proof of the lemma.

LEMMA 4.10. *Let $\varepsilon \in (0,1), K > D_f + 4$, and let $L \ge 1$ be an integer such that for each (f)-good function v: $[0,\infty) \to R^n$*

$$\operatorname{dist}(H(f), \{v(t):\ t \in [T, T+L]\}) \le 8^{-1}\varepsilon$$

for all large T (the existence of L follows from Proposition 3.9).

Then there exists a neighborhood $\mathcal{U}$ of f in $\mathfrak{A}$ such that for each $g \in \mathcal{U}$ and each $h \in H(f)$ there exists an a.c. function x: $[0,\infty) \to R^n$ such that $x(0) = h$;

$$\operatorname{dist}(H(f), \{x(t):\ t \in [S, S+L]\}) \le \varepsilon \tag{4.105}$$

for all $S \in [0, \infty)$*;*

$$I^g(0,T,x) - \pi^f(x(0)) + \pi^f(x(T)) \le \ell(g,K,T) + \varepsilon \tag{4.106}$$

for each $T \ge 1$*;*

$$I^g(t_1,t_2,x) - \pi^f(x(t_1)) + \pi^f(x(t_2)) \le \ell(g,K,t_2-t_1) + \varepsilon \tag{4.107}$$

for each $t_1 \ge 1, t_2 \ge t_1 + 1$.

Proof. By Lemma 4.9 there exist a neighborhood $\mathcal{U}_1$ of f in $\mathfrak{A}$ and

$$\delta_1 \in (0, 8^{-1}\varepsilon) \tag{4.108}$$

such that for each $g \in \mathcal{U}_1$, each $T \in [L, \infty)$, and each a.c. function $v\colon [0,T] \to R^n$ which satisfies

$$\begin{aligned} d(v(0), H(f)) \le \delta_1, \qquad d(v(T), H(f)) \le \delta_1, \\ I^g(0,T,v) - \pi^f(v(0)) + \pi^f(v(T)) \le \ell(g,K,T) + \delta_1 \end{aligned} \tag{4.109}$$

relation (4.105) holds for all $S \in [0, T-L]$.

By Lemma 4.8 there exists a neighborhood $\mathcal{U}_2$ of f in $\mathfrak{A}$ such that for each $g \in \mathcal{U}_2$, each $h \in H(f)$, and each $T \ge 1$ there exists an a.c. function $v\colon [0,T] \to R^n$ for which

$$\begin{aligned} v(0) = h, \qquad v(T) \in H(f), \\ I^g(0,T,v) - \pi^f(v(0)) + \pi^f(v(T)) \le \ell(g,K,T) + 8^{-1}\delta_1. \end{aligned} \tag{4.110}$$

Set

$$\mathcal{U} = \mathcal{U}_1 \cap \mathcal{U}_2. \tag{4.111}$$

Assume that $g \in \mathcal{U}$ and $h \in H(f)$. By the definition of $\mathcal{U}_2$ (see (4.110)) for each $N \ge 1$ there exists an a.c. function $x_N\colon [0,N] \to R^n$ such that (4.110) holds with $T = N$, $v = x_N$. It follows from the definition of $\mathcal{U}_1$ and δ_1 (see (4.109)) that for each integer $N \ge L$ and each number $S \in [0, N-L]$

$$\operatorname{dist}(H(f), \{x_N(t)\colon\ t \in [S, S+L]\}) \le \varepsilon. \tag{4.112}$$

Let $N \ge L$ be an integer. For each a.c. function $y\colon [0,N] \to R^n$ and each number $r_1, r_2 \in [0,N]$ satisfying $r_1 < r_2$ we define $\sigma(r_1,r_2,y)$ by (4.100). Assume that an integer $q \in \{2,3,4\}$, $\{t_i\}_{i=0}^q \subset [0,N]$, $t_0 = 0$, $t_q = N$, $t_{i+1} - t_i \ge 1$, $i = 0, \dots, q-1$. Equation (4.112), which holds for each $S \in [0, N-L]$, implies that

$$\sigma(t_i, t_{i+1}, x_N) \ge \ell(g,K,t_{i+1}-t_i), \qquad i = 0, \dots, q-1. \tag{4.113}$$

By the definition of $\mathcal{U}_2$ (see (4.110)) there exists an a.c. function $y\colon [0,N] \to R^n$ for which

$$y(t_i) \in H(f), \quad i = 0, \dots, q, \quad \sigma(t_i, t_{i+1}, y) \le \ell(g,K,t_{i+1}-t_i) + 8^{-1}\delta_1, \quad i = 0, \dots, q-1.$$

Together with (4.110), which holds with $T = N$, $v = x_N$, and (4.113), this implies that for each $j \in [0, q-1]$

$$\begin{aligned} 8^{-1}\delta_1 \ge \sigma(0,N,x_N) - \sigma(0,N,y) &= \sum_{i=0}^{q-1} [\sigma(t_i,t_{i+1},x_N) - \sigma(t_i,t_{i+1},y)] \\ &\ge \sigma(t_j,t_{j+1},x_N) - \ell(g,K,t_{j+1}-t_j) - 8^{-1}\delta_1 q. \end{aligned}$$

This implies that for each integer $N \geq L+3$ and each $\tau_1 \in \{0\} \cup [1, N-2]$, $\tau_2 \in [\tau_1 + 1, N-1]$

$$I^g(\tau_1, \tau_2, x_N) - \pi^f(x_N(\tau_1)) + \pi^f(x_N(\tau_2)) \leq \ell(g, K, \tau_2 - \tau_1) + 3 \cdot 4^{-1}\delta_1. \tag{4.114}$$

By this relation, (4.112), which holds for each $N \geq L$ and each number $S \in [0, N-L]$, and by Proposition 3.4 there exist a subsequence $\{x_{N_p}\}_{p=1}^{\infty}$ and an a.c. function $x\colon [0,\infty) \to R^n$ such that for each integer $N \geq 1$

$$x_{N_p}(t) \to x(t) \quad \text{as } p \to \infty \text{ uniformly in } [0, N] \tag{4.115}$$

and

$$I^g(T_1, T_2, x) \leq \liminf_{p\to\infty} I^g(T_1, T_2, x_{N_p}) \tag{4.116}$$

for each $T_1 \in [1,\infty) \cup \{0\}$, $T_2 \geq T_1 + 1$.

Equation (4.110), which holds with $T = N$, $v = x_N$, and (4.115), implies that $x(0) = h$. Equations (4.112) and (4.115) imply (4.105) for all $S \in [0,\infty)$. Equations (4.114)–(4.116) and (4.108) imply (4.106) for each $T \geq 1$ and (4.107) for each $t_1 \geq 1$, $t_2 \geq t_1 + 1$. This completes the proof of the lemma.

LEMMA 4.11. $\sup\{\pi^f(h)\colon\ h \in H(f)\} = 0$.

Proof. There exists $h_0 \in H(f)$ for which

$$\pi^f(h_0) \geq \pi^f(h), \qquad h \in H(f). \tag{4.117}$$

Let $v\colon [0,\infty) \to R^n$ be an a.c. function,

$$v(0) = h_0. \tag{4.118}$$

We will show that $\liminf_{T\to\infty}[I^f(0, T, v) - T\mu(f)] \geq 0$.

By Proposition 1.1 we may assume that v is an (f)-good function. Then $\Omega(v) = H(f)$. It follows from this relation, the representation formula (see (1.6)), (4.117), and (4.118) that

$$\liminf_{T\to\infty}[I^f(0, T, v) - T\mu(f)] \geq \liminf_{T\to\infty}[\pi^f(v(0)) - \pi^f(v(T))] \geq 0.$$

This implies that $\pi^f(h_0) \geq 0$. By Proposition 3.11 there exists an (f)-good function $u \in \mathcal{A}(f)$ satisfying $u(0) = h_0$. It is easy to see that $\Omega(u) = H(f)$,

$$\liminf_{T\to\infty}[I^f(0, T, u) - T\mu(f)] = \liminf_{T\to\infty}[\pi^f(u(0)) - \pi^f(u(T))] = 0.$$

This completes the proof of the lemma.

LEMMA 4.12. *Let $\varepsilon \in (0,1)$. Then there exists a neighborhood $\mathcal{U}$ of f in $\mathfrak{A}$ such that $|\mu(f) - \mu(g)| \leq \varepsilon$ for each $g \in \mathcal{U}$.*

Proof. By Proposition 3.1 there exists a neighborhood $\mathcal{U}_1$ of f in $\mathfrak{A}$ and $M_0 > 0$ such that for each $g \in \mathcal{U}_1$ and each (g)-good function $x\colon [0,\infty) \to R^n$

$$\limsup_{t\to\infty} |x(t)| < M_0. \tag{4.119}$$

Set

$$M_1 = \sup\{|U^f(0, 1, x, y)|\colon\ x, y \in R^n,\ |x|, |y| \leq 2M_0 + 2\}. \tag{4.120}$$

By Proposition 3.7 there is a neighborhood $\mathcal{U}_2$ of f in $\mathfrak{A}$ such that for each $g \in \mathcal{U}_2$, each $T \geq 0$, and each a.c. function y: $[T, T+1] \to R^n$ satisfying

$$\inf\{I^f(T, T+1, y), I^g(T, T+1, y)\} \leq 2M_1 + 4$$

the following relation holds:

$$|I^f(T, T+1, y) - I^g(T, T+1, y)| \leq 8^{-1}\varepsilon. \tag{4.121}$$

By Proposition 3.8 there exists a neighborhood $\mathcal{U}_3$ of f in $\mathfrak{A}$ such that for each $g \in \mathcal{U}_3$ and each $x, y \in R^n$ satisfying $|y|$, $|x| \leq 2M_0 + 2$ the following relation holds:

$$|U^f(0, 1, x, y) - U^g(0, 1, x, y)| \leq 16^{-1}\varepsilon. \tag{4.122}$$

Set

$$\mathcal{U} = \bigcap_{i=1}^{3} \mathcal{U}_i. \tag{4.123}$$

Let $g_1, g_2 \in \mathcal{U}$. Consider a (g_1)-good function x: $[0, \infty) \to R^n$. We have

$$\sup\{|I^{g_1}(0, T, x) - T\mu(g_1)|\colon\ T \in (0, \infty)\} < \infty. \tag{4.124}$$

By the definition of $\mathcal{U}_1, M_0$ (see (4.119)) we may assume that

$$|x(t)| \leq M_0, \qquad t \in [0, \infty). \tag{4.125}$$

By Proposition 1.1 we may assume without loss of generality that

$$I^{g_1}(T, T+1, x) \leq U^{g_1}(0, 1, x(T), x(T+1)) + 4^{-1} \quad \text{for all } T \in [0, \infty).$$

It follows from this relation, (4.125), the definition of $\mathcal{U}_3$ (see (4.122)), and (4.120) that

$$I^{g_1}(T, T+1, x) \leq M_1 + 2^{-1} \quad \text{for all } T \in [0, \infty).$$

By this relation and the definition of $\mathcal{U}_2$, for each $T \in [0, \infty)$,

$$\begin{aligned} &|I^f(T, T+1, x) - I^{g_1}(T, T+1, x)| \leq 8^{-1}\varepsilon, \\ &\quad I^f(T, T+1, x) \leq M_1 + 1, \\ &|I^f(T, T+1, x) - I^{g_2}(T, T+1, x)| \leq 8^{-1}\varepsilon, \\ &\quad |I^{g_1}(T, T+1, x) - I^{g_2}(T, T+1, x)| \leq 4^{-1}\varepsilon. \end{aligned} \tag{4.126}$$

Equations (4.124) and (4.126) imply that

$$\sup\{|I^{g_2}(0, N, x) - N4^{-1}\varepsilon - N\mu(g_1)|\colon\ N = 1, 2, \dots, \} < \infty.$$

Together with Proposition 1.1, this implies that $\mu(g_2) \leq \mu(g_1) + 4^{-1}\varepsilon$. This completes the proof of the lemma.

LEMMA 4.13. *Let $K > D_f + 1$. Then there exists a neighborhood $\mathcal{U}$ of f in $\mathfrak{A}$ such that $\ell(g, K, \tau) \leq \tau\mu(g)$ for each $g \in \mathcal{U}$ and each $\tau > 0$.*

Proof. By Proposition 3.13 there exists a neighborhood $\mathcal{U}$ of f in $\mathfrak{A}$ such that for each $g \in \mathcal{U}$ and each (g)-good function $x\colon [0,\infty) \to R^n$

$$\limsup_{t\to\infty} |x(t)| < K.$$

Let $g \in \mathcal{U}$, $\tau > 0$. Consider any (g)-good function $x\colon [0,\infty) \to R^n$. We may assume that

$$|x(t)| \le K, \qquad t \in [0,\infty). \tag{4.127}$$

It follows from (4.127) that for each integer $N \ge 1$

$$\begin{aligned} I^g(0,N\tau,x) - \pi^f(x(0)) + \pi^f(x(N\tau)) &= \sum_{i=0}^{N-1} [I^g(i\tau,(i+1)\tau,x) \\ &\qquad - \pi^f(x(i\tau)) + \pi^f(x((i+1)\tau))] \\ &\ge N\ell(g,K,\tau), \\ I^g(0,N\tau,x) &\ge N\ell(g,K,\tau) + 2\sup\{|\pi^f(z)|\colon\ z \in R^n,\ |z| \le K\}. \end{aligned}$$

Since x is a (g)-good function, we have

$$\sup\{N\ell(g,K,\tau) - N\tau\mu(g)\colon\ N = 1,2,\ldots\} < \infty.$$

This completes the proof of the lemma.

There exists

$$h_* \in H(f) \quad \text{such that } \pi^f(h_*) \ge \pi^f(h),\ h \in H(f). \tag{4.128}$$

LEMMA 4.14. *Let $\varepsilon \in (0,1)$ and $K > D_f + 4$. Then there exist a neighborhood $\mathcal{U}$ of f in $\mathfrak{A}$ and an integer $L \ge 1$ such that for each $g \in \mathcal{U}$ and each $h \in H(f)$ there exists a (g)-good function $v\colon [0,\infty) \to R^n$ such that*

$$v(0) = h; \tag{4.129}$$

$$\operatorname{dist}(H(f), \{v(t)\colon\ t \in [T,T+L]\}) \le \varepsilon \tag{4.130}$$

for all $T \in [0,\infty)$;

$$I^g(T_1,T_2,v) - \pi^f(v(T_1)) + \pi^f(v(T_2)) \le \ell(g,K,T_2-T_1) + \varepsilon \tag{4.131}$$

for each $T_1 \in \{0\} \cup [1,\infty), T_2 \ge T_1 + 1$;

$$|I^g(0,T,v) - \pi^f(v(0)) + \pi^f(v(T)) - T\mu(g)| \le \varepsilon \tag{4.132}$$

for each $T \in [1,\infty)$;

$$|\liminf_{T\to\infty} [I^g(0,T,v) - T\mu(g)] - \pi^f(h)| \le 2\varepsilon. \tag{4.133}$$

Proof. By Lemma 4.6 and (4.128) there exists an (f)-good function $v_0\colon [0,\infty) \to H(f)$ for which

$$v_0 \in \mathcal{A}(f), \qquad v_0(0) = h_*. \tag{4.134}$$

By Proposition 3.10 there exists a number

$$\delta \in (0, 2^{-8}\varepsilon) \tag{4.135}$$

such that for each $y_1, y_2, z_1, z_2 \in R^n$ which satisfy $|y_i|, |z_i| \le 2K+8, i = 1, 2, |y_i - z_i| \le 4\delta, i = 1, 2$, the following relations hold:

(4.136)

$$|U^f(0, 1, y_1, y_2) - U^f(0, 1, z_1, z_2)| \le 2^{-8}\varepsilon, \quad |\pi^f(y_i) - \pi^f(z_i)| \le 2^{-8}\varepsilon, \quad i = 1, 2.$$

By Proposition 3.8 there exists a neighborhood $\mathcal{U}_1$ of f in $\mathfrak{A}$ such that for each $g \in \mathcal{U}_1$ and each $z, y \in R^n$ which satisfy $|y|, |z| \le 2K + 8$ the following relation holds:

$$|U^f(0, 1, y, z) - U^g(0, 1, y, z)| \le 2^{-4}\delta. \tag{4.137}$$

Since $\Omega(v_0) = H(f)$, there exist integers $N_1, N_2 \ge 10$ for which

$$\begin{aligned} &\operatorname{dist}(H(f), \{v_0(t):\ t \in [0, N_1]\}) \le 2^{-4}\delta, \\ &\operatorname{dist}(H(f), \{v_0(t):\ t \in [4N_1, 4N_1 + N_2]\}) \le 2^{-4}\delta. \end{aligned} \tag{4.138}$$

By Proposition 3.9 there exists an integer $L \ge 1$ such that for each (f)-good function $v\colon [0, \infty) \to R^n$

$$\operatorname{dist}(H(f), \{v(t):\ t \in [T, T + L]\}) \le 2^{-4}\delta \tag{4.139}$$

for all large T.

By Lemma 4.10 there exists a neighborhood $\mathcal{U}_2$ of f in $\mathfrak{A}$ such that for each $g \in \mathcal{U}_2$ and each $h \in H(f)$ there exists an a.c. function $v\colon [0, \infty) \to R^n$ satisfying (4.129) and such that for each $T \in [0, \infty)$

$$\operatorname{dist}(H(f), \{v(t):\ t \in [T, T + L]\}) \le \delta, \tag{4.140}$$

$$I^g(T_1, T_2, v) - \pi^f(v(T_1)) + \pi^f(v(T_2)) \le \ell(g, K, T_2 - T_1) + \delta \tag{4.141}$$

for each $T_1 \in \{0\} \cup [1, \infty), T_2 \ge T_1 + 1$.

By Lemma 4.13 there exists a neighborhood $\mathcal{U}_3$ of f in $\mathfrak{A}$ such that for each $g \in \mathcal{U}_3$ and each $T > 0$

$$\ell(g, K, T) \le T\mu(g). \tag{4.142}$$

By Lemma 4.12 there exists a neighborhood $\mathcal{U}_4$ of f in $\mathfrak{A}$ such that for each $g \in \mathcal{U}_4$

$$|\mu(g) - \mu(f)| \le 2^{-8}\delta(8N_1 + 8N_2)^{-1}. \tag{4.143}$$

By Proposition 3.7 there exists a neighborhood $\mathcal{U}_5$ of f in $\mathfrak{A}$ such that for each $g \in \mathcal{U}_5$, each $T_1 \ge 0$, $T_2 \in [T_1 + 1, T_1 + 8(N_1 + N_2)]$, and each a.c. function $v\colon [T_1, T_2] \to R^n$ which satisfies

$$\begin{aligned} &\inf\{I^f(T_1, T_2, v), I^g(T_1, T_2, v)\} \\ &\quad \le (8N_1 + 8N_2)|\mu(f)| + 4 + 2\sup\{|\pi^f(z)|:\ z \in R^n, |z| \le 2K + 2\} \end{aligned} \tag{4.144}$$

the following relation holds:

$$|I^f(T_1, T_2, v) - I^g(T_1, T_2, v)| \le 2^{-8}\delta. \tag{4.145}$$

Set

$$\mathcal{U} = \bigcap_{i=1}^{5} \mathcal{U}_i. \tag{4.146}$$

Let $g \in \mathcal{U}$ and $h \in H(f)$. It follows from the definition of $\mathcal{U}_2$ that there exists an a.c. function $v\colon [0,\infty) \to R^n$ such that (4.129) holds, relation (4.140) holds for each $T \in [0,\infty)$, and relation (4.141) holds for each $T_1 \in \{0\} \cup [1,\infty), T_2 \ge T_1 + 1$. By (4.141), which holds for $T_1 = 0$ and each $T_2 \ge 1$, and the definition of $\mathcal{U}_3$ (see (4.142)) v is a (g)-good function.

Fix a number $T \ge 1$. We will establish (4.132). It follows from (4.140) and (4.138) that there exist

$$t_1 \in [0, N_1], \qquad t_2 \in [4N_1, 4N_1 + N_2] \tag{4.147}$$

for which

$$|v(T) - v_0(t_1)| \le \delta + 8^{-1}\delta, \qquad |h - v_0(t_2)| \le \delta + 8^{-1}\delta. \tag{4.148}$$

By Proposition 3.5 there exists an a.c. function $x\colon [0, T + t_2 - t_1] \to R^n$ such that

$$\begin{aligned}
&x(t) = v(t), \quad t \in [0,T], \quad x(t) = v_0(t + t_1 - T),\\
&t \in [T+1, T + t_2 - t_1 - 1],\\
&x(T + t_2 - t_1) = h, \quad I^g(S, S+1, x) = U^g(0, 1, x(S), x(S+1)),\\
&S = T, \quad T + t_2 - t_1 - 1.
\end{aligned} \tag{4.149}$$

Equations (4.149) and (4.129) imply that

$$I^g(0, T + t_2 - t_1, x) \ge \mu(g)(T + t_2 - t_1). \tag{4.150}$$

Equation (4.149) implies that

$$\begin{aligned}
&I^g(T, T + t_2 - t_1, x) - \pi^f(x(T)) + \pi^f(x(T + t_2 - t_1))\\
&\quad = U^g(0, 1, x(T), x(T+1)) - \pi^f(x(T))\\
&\qquad + \pi^f(x(T+1)) + I^g(t_1 + 1, t_2 - 1, v_0)\\
&\qquad - \pi^f(v_0(t_1 + 1)) + \pi^f(v_0(t_2 - 1))\\
&\qquad + U^g(0, 1, x(T + t_2 - t_1 - 1), x(T + t_2 - t_1))\\
&\qquad - \pi^f(x(T + t_2 - t_1 - 1)) + \pi^f(x(T + t_2 - t_1)).
\end{aligned} \tag{4.151}$$

Analogously to the proof of the case (i) in Lemma 4.7 (see (4.30) and (4.31)) we can show by using (4.134), (4.147), and the definition of $\mathcal{U}_5$ (see (4.145)) that

$$I^g(t_1+1, t_2-1, v_0) - \pi^f(v_0(t_1+1)) + \pi^f(v_0(t_2-1)) \le 2^{-8}\delta + \mu(f)(t_2 - t_1 - 2). \tag{4.152}$$

Set

$$S_1 = T, \quad S_2 = T + t_2 - t_1 - 1, \quad r_1 = t_1, \quad r_2 = t_2 - 1. \tag{4.153}$$

It follows from this relation; (4.149); the definition of $\mathcal{U}_1, \delta$ (see (4.135)–(4.137)); (4.140), which holds for each $T \geq 0$; and (4.134) that for $i = 1, 2$

$$\begin{aligned} &U^g(0,1,x(S_i),x(S_i+1)) - \pi^f(x(S_i)) + \pi^f(x(S_i+1)) \\ &\quad \leq U^f(0,1,x(S_i),x(S_i+1)) - \pi^f(x(S_i)) + \pi^f(x(S_i+1)) + 2^{-4}\delta \\ &\quad \leq U^f(0,1,v_0(r_i),v_0(r_i+1)) - \pi^f(v_0(r_i)) + \pi^f(v_0(r_i+1)) + 2^{-6}\varepsilon \\ &\quad \leq \mu(f) + 2^{-6}\varepsilon. \end{aligned}$$

By this relation, (4.151)–(4.153), the definition of $\mathcal{U}_4$ (see (4.143)), and (4.147)

$$\begin{aligned} &I^g(T, T+t_2-t_1, x) - \pi^f(x(T)) + \pi^f(x(T+t_2-t_1)) \\ &\quad = 2\mu(f) + 2^{-5}\varepsilon + \mu(f)(t_2-t_1-2) + 2^{-8}\varepsilon \\ &\quad \leq 2^{-5}\varepsilon + \mu(g)(t_2-t_1) + 2^{-7}\varepsilon. \end{aligned} \tag{4.154}$$

It follows from this relation, (4.150), (4.149), and (4.129) that

$$I^g(0,T,v) - \pi^f(v(0)) + \pi^f(v(T)) \geq \mu(g)T - 2^{-4}\varepsilon.$$

This relation; (4.141), which holds with $T_1 = 0, T_2 = T$; and (4.142) imply (4.132). Therefore we have shown that (4.132) holds for each $T \in [1, \infty)$. Together with (4.129), this implies that

$$\varepsilon \geq |\liminf_{T\to\infty}[I^g(0,T,v) - T\mu(g)] - \liminf_{T\to\infty}[\pi^f(h) - \pi^f(v(T))]|. \tag{4.155}$$

By (4.140), which holds for each $T \in [0, \infty)$, and the definition of δ (see (4.135), (4.136))

$$|\liminf_{T\to\infty}[\pi^f(h) - \pi^f(v(T))] - [\pi^f(h) - \sup\{\pi^f(z):\ z \in H(f)\}]| \leq 2^{-8}\varepsilon.$$

Equation (4.133) now follows from this relation, (4.155), and Lemma 4.11. The lemma is proven.

LEMMA 4.15. *Let $\varepsilon \in (0,1)$. Then there exist $\delta \in (0, \varepsilon)$ and a neighborhood $\mathcal{U}$ of f in $\mathfrak{A}$ such that for each $g \in \mathcal{U}$, each $h \in H(f)$, and each $y \in R^n$ satisfying $|y - h| \leq \delta$ the relation $|\pi^g(y) - \pi^f(h)| \leq \varepsilon$ holds.*

Proof. Fix

$$K > D_f + 4. \tag{4.156}$$

By Proposition 3.10 there exists a number

$$\delta \in (0, 8^{-1}\varepsilon) \tag{4.157}$$

such that for each $x_1, x_2, y_1, y_2 \in R^n$ which satisfy

$$|x_i|, |y_i| \leq K+2, \quad i = 1,2, \quad |x_i - y_i| \leq 8\delta, \quad i = 1,2, \tag{4.158}$$

the following relations hold:

$$|U^f(0,1,x_1,x_2) - U^f(0,1,y_1,y_2)| \leq 2^{-8}\varepsilon, \ \ |\pi^f(x_i) - \pi^f(y_i)| \leq 2^{-8}\varepsilon, \ \ i = 1,2. \tag{4.159}$$

By Proposition 3.8 there exists a neighborhood $\mathcal{U}_1$ of f in $\mathfrak{A}$ such that for each $g \in \mathcal{U}_1$ and each $y_1, y_2 \in R^n$ which satisfy $|y_i| \leq 2K+2, i = 1,2$,

$$|U^f(0,1,y_1,y_2) - U^g(0,1,y_1,y_2)| \leq 2^{-8}\varepsilon. \tag{4.160}$$

By Lemma 4.14 there exist a neighborhood $\mathcal{U}_2$ of f in $\mathfrak{A}$ and an integer $L \geq 1$ such that for each $g \in U_2$ and each $h \in H(f)$ there exists a (g)-good function v: $[0,\infty) \to R^n$ such that $v(0) = h$;

$$\operatorname{dist}(H(f), \{v(t):\ t \in [T, T+L]\}) \leq 2^{-6}\delta \tag{4.161}$$

for all $T \in [0,\infty)$;

$$I^g(T_1, T_2, v) - \pi^f(v(T_1)) + \pi^f(v(T_2)) \leq \ell(g, K, T_2 - T_1) + 2^{-6}\delta \tag{4.162}$$

for each $T_1 \in \{0\} \cup [1,\infty), T_2 \geq T_1 + 1$;

$$|I^g(0, T, v) - \pi^f(v(0)) + \pi^f(v(T)) - T\mu(g)| \leq 2^{-6}\delta \tag{4.163}$$

for each $T \in [1,\infty)$;

$$|\liminf_{T\to\infty}[I^g(0, T, v) - T\mu(g)] - \pi^f(h)| \leq 2^{-6}\delta. \tag{4.164}$$

By Lemmas 4.13 and 4.12 there exist a neighborhood $\mathcal{U}_3$ of f in $\mathfrak{A}$ such that for each $g \in \mathcal{U}_3$ and each $T \in (0,\infty)$

$$|\mu(g) - \mu(f)| \leq 2^{-6}\varepsilon, \qquad \ell(g, K, T) \leq T\mu(g). \tag{4.165}$$

By Proposition 3.13 there exist an integer $L_1 \geq 1$ and a neighborhood $\mathcal{U}_4$ of f in $\mathfrak{A}$ such that for each $g \in \mathcal{U}_4$ and each (g)-good function v: $[0,\infty) \to R^n$

$$\operatorname{dist}(H(f), \quad \{v(t):\quad t \in [T, T+L_1]\}) \leq 2^{-8}\delta \tag{4.166}$$

for all large T. Set

$$\mathcal{U} = \bigcap_{i=1}^{4} \mathcal{U}_i. \tag{4.167}$$

Assume that

$$g \in \mathcal{U}, \quad h \in H(f), \quad y \in R^n, \quad |y - h| \leq \delta. \tag{4.168}$$

By the definition of $\mathcal{U}_2, L$ and (4.168) there exists a (g)-good function v: $[0,\infty) \to R^n$ such that $v(0) = h$, (4.161) holds for each $T \geq 0$, (4.162) holds for each $T_1 \in \{0\} \cup [1,\infty)$ and each $T_2 \geq T_1 + 1$, and (4.163) holds for each $T \in [1,\infty)$. Together with (4.165) this implies that

$$0 \leq T\mu(g) - \ell(g, K, T) \leq 2^{-5}\delta \quad \text{for all } T \in [1,\infty). \tag{4.169}$$

Consider any (g)-good function u: $[0,\infty) \to R^n$ for which $u(0) = y$. By the definition of $\mathcal{U}_4, L_1$, (4.168) holds with $v = u$ for all large T. Together with (4.169) and (4.168), this implies that

$$\begin{aligned} \liminf_{T\to\infty}[I^g(0, T, u) - T\mu(g)] &\geq \liminf_{T\to\infty}[I^g(0, T, u) - \ell(g, K, T)] - 2^{-5}\delta \\ &\geq \liminf_{T\to\infty}[\pi^f(y) - \pi^f(u(T))] - 2^{-5}\delta. \end{aligned} \tag{4.170}$$

It follows from (4.166), which holds with $v = u$ for all large T; (4.170); (4.168); the definition of δ (see (4.157)–(4.159)); and Lemma 4.1 that

$$\begin{aligned}\liminf_{T\to\infty}[\pi^f(y) - \pi^f(u(T))] &\geq \pi^f(h) - 2^{-8}\varepsilon - \limsup_{T\to\infty}\pi^f(u(T))\\ &\geq \pi^f(h) - 2^{-8}\varepsilon - \sup\{\pi^f(z)\colon z \in H(f)\} - 2^{-8}\varepsilon\\ &\geq \pi^f(h) - 2^{-7}\varepsilon.\end{aligned}$$

Together with (4.170) and (4.157) this implies that

$$\liminf_{T\to\infty}[I^g(0,T,u) - T\mu(g)] \geq \pi^f(h) - \varepsilon.$$

Therefore

$$\pi^g(y) \geq \pi^f(h) - \varepsilon. \tag{4.171}$$

We will show that $\pi^g(y) \leq \pi^f(h) + \varepsilon$. By Lemma 4.6 there exists an (f)-good function

$$v_0\colon [0,\infty) \to H(f) \quad \text{such that } v_0 \in \mathcal{A}(f),\ v_0(0) = h. \tag{4.172}$$

By the definition of $\mathcal{U}_2$ and L and (4.172) there exists a (g)-good function $v_1\colon [0,\infty) \to R^n$ such that

$$v_1(0) = v_0(1), \tag{4.173}$$

(4.161) holds with $v = v_1$ for each $T \in [0,\infty)$; (4.162) holds with $v = v_1$ for each $T_1 \in \{0\} \cup [1,\infty)$, $T_2 \geq T_1 + 1$; (4.163) holds with $v = v_1$ for each $T \in [1,\infty)$; and (4.164) holds with $v = v_1$, $h = v_0(1)$.

By Proposition 3.5 there exists an a.c. function $w\colon [0,\infty) \to R^n$ such that

(4.174)

$$w(0) = y, \quad w(t) = v_1(t-1), \quad t \in [1,\infty), \quad I^g(0,1,w) = U^g(0,1,w(0),w(1)).$$

Equations (4.173), (4.174), and (4.164), which holds with $v = v_1$, $h = v_0(1)$, imply that

$$\begin{aligned}\pi^g(y) &\leq \liminf_{T\to\infty}[I^g(0,T,w) - T\mu(g)] = U^g(0,1,y,v_0(1)) - \mu(g)\\ &\quad + \liminf_{T\to\infty}[I^g(0,T,v_1) - T\mu(g)]\\ &= U^g(0,1,y,v_0(1)) - \mu(g) + \pi^f(v_0(1)) + 2^{-6}\delta. \qquad (4.175)\end{aligned}$$

It follows from (4.168), (4.156), (4.172), the definition of $\mathcal{U}_1$ (see (4.160)), and the definition of δ (see (4.157)–(4.159)) that

$$\begin{aligned}U^g(0,1,y,v_0(1)) &\leq U^g(0,1,y,v_0(1)) + 2^{-8}\varepsilon \leq 2^{-8}\varepsilon + U^f(0,1,v_0(0),v_0(1)) + 2^{-8}\varepsilon\\ &= 2^{-7}\varepsilon + \pi^f(h) - \pi^f(v_0(1)) + \mu(f).\end{aligned}$$

Together with (4.175) and (4.165) this implies that $\pi^g(y) \leq 2^{-7}\varepsilon + 2^{-5}\varepsilon + \pi^f(h) \leq \pi^f(h) + \varepsilon$. This completes the proof of the lemma.

There exists $h_f \in H(f)$ such that

$$\pi^f(h_f) \geq \pi^f(h), \qquad h \in H(f). \tag{4.176}$$

LEMMA 4.16. *Let $\varepsilon \in (0,1)$, $K > D_f + 4$. Then there exist a neighborhood $\mathcal{U}$ of f in $\mathfrak{A}$ and integers $Q_1 \geq 8$, $Q_2 \geq 8 + Q_1$ such that, for each $g \in \mathcal{U}$ and each $x \in R^n$ satisfying $|x| \leq K$,*

$$\pi^g(x) = \inf\{\liminf_{T\to\infty}[I^g(0,T,v) - T\mu(g)]\colon\ v\colon\ [0,\infty) \to R^n \text{ is an a.c. function},$$

$$v(0) = x,\ \inf\{|v(t) - h_f|\colon\ t \in [Q_1, Q_2]\} \leq \varepsilon\}. \tag{4.177}$$

Proof. By Proposition 3.13 there exist an integer $L \geq 1$ and a neighborhood $\mathcal{U}_1$ of f in $\mathfrak{A}$ such that, for each $g \in \mathcal{U}_1$ and each (g)-good function $v\colon\ [0,\infty) \to R^n$,

$$\operatorname{dist}(H(f),\ \{v(t)\colon\ t \in [T, T+L]\}) \leq 16^{-1}\varepsilon \tag{4.178}$$

for all large T.

By Lemma 4.4 and the definition of L there exist an integer $N \geq 10$ and a neighborhood $\mathcal{U}_2$ of f in $\mathfrak{A}$ such that for each $g \in \mathcal{U}_2$, each $T_1 \geq 0$, $T_2 \geq T_1 + NL$, each a.c. function $v\colon\ [T_1, T_2] \to R^n$ which satisfies

$$|v(T_i)| \leq K, \quad i = 1,2, \quad I^g(T_1, T_2, v) \leq U^g(T_1, T_2, v(T_1), v(T_2)) + 4, \tag{4.179}$$

and each $S \in [T_1, T_2 - NL]$ there exists an integer $i_0 \in [0, N-8]$ such that, for all $T \in [S + i_0 L, S + (i_0 + 7)L]$,

$$\operatorname{dist}(H(f), \{v(t)\colon\ t \in [T, T+L]\}) \leq 2^{-1}\varepsilon. \tag{4.180}$$

Set

$$\mathcal{U} = \mathcal{U}_1 \cap \mathcal{U}_2, \quad Q_1 = NL, \quad Q_2 = 2NL. \tag{4.181}$$

Assume that

$$g \in \mathcal{U}, \quad x \in R^n, \quad |x| \leq K.$$

Denote by E the set of all (g)-good functions $v\colon\ [0,\infty) \to R^n$ for which

$$v(0) = x, \qquad \liminf_{T\to\infty}[I^g(0,T,v) - T\mu(g)] \leq \pi^g(x) + 1. \tag{4.182}$$

It is easy to see that

$$\pi^g(x) = \inf\{\liminf_{T\to\infty}[I^g(0,T,v) - T\mu(g)]\colon\ v \in E\}. \tag{4.183}$$

Consider any $v \in E$. By the definition of $\mathcal{U}_1, L$

$$|v(t)| \leq K \text{ for all large } t. \tag{4.184}$$

Equation (4.182) implies that

$$I^g(0,T,v) \leq U^g(0,T,v(0),v(T)) + 2, \quad \text{for all } T \in [1,\infty).$$

It follows from this relation, (4.184), (4.181), and the definition of $N, \mathcal{U}_2$ (see (4.179), (4.180)) that $\inf\{|v(t) - h_f|\colon t \in [Q_1, Q_2]\} \le \varepsilon$. This completes the proof of the lemma.

Proof of Theorem 2.1. By Lemma 4.12 f is a continuity point of the mapping $g \to \mu(g)$, $g \in \mathfrak{A}$. We will show that f is a continuity point of the mapping $g \to \pi^g$, $g \in \mathfrak{A}$.

Assume that $\varepsilon \in (0,1), K > D_f + 4$. By Lemma 4.15 there exist a neighborhood $\mathcal{U}_1$ of f in $\mathfrak{A}$ and

$$\delta \in (0, 16^{-1}\varepsilon) \tag{4.185}$$

such that, for each $g \in \mathcal{U}_1$, each $h \in H(f)$, and each $y \in R^n$ satisfying $|y - h| \le \delta$, the following relation holds:

$$|\pi^g(y) - \pi^f(h)| \le 16^{-1}\varepsilon. \tag{4.186}$$

By Lemma 4.16 there exist a neighborhood $\mathcal{U}_2$ of f in $\mathfrak{A}$ and integers $Q_1 \ge 8$, $Q_2 \ge 8 + Q_1$ such that for each $g \in \mathcal{U}_2$ and each $x \in R^n$ satisfying $|x| \le K$, relation (4.177) holds with $\varepsilon = 8^{-1}\delta$. By Lemma 4.12 and Proposition 3.8 there exists a neighborhood $\mathcal{U}_3$ of f in $\mathfrak{A}$ such that

$$|\mu(g) - \mu(f)| \le (16(Q_1 + Q_2))^{-1}\varepsilon \quad \text{for each } g \in \mathcal{U}_3, \tag{4.187}$$

$$|U^f(0,\tau,x,y) - U^g(0,\tau,x,y)| \le 16^{-1}\varepsilon \tag{4.188}$$

for each $g \in \mathcal{U}_3$, each $\tau \in [1, 2Q]$, and each $x, y \in R^n$ which satisfy $|x|, |y| \le 2K + 2$. Set

$$\mathcal{U} = \bigcap_{i=1}^{3} \mathcal{U}_i.$$

It follows from the definition of $\mathcal{U}_2$, Q_1, Q_2, and (4.177) that for each $g \in \mathcal{U}$ and each $x \in R^n$ satisfying $|x| \le K$

$$\pi^g(x) = \inf\{U^g(0,T,x,y) - T\mu(g) + \pi^g(y)\colon\ t \in [Q_1, Q_2], y \in R^n, |y - h_f| \le 8^{-1}\delta\}.$$

By this relation, (4.187), (4.188), and the definition of $\mathcal{U}_1, \delta$ (see (4.185) and (4.186)), for each $g \in \mathcal{U}$ and each $x \in R^n$ satisfying $|x| \le K$,

$$\begin{aligned}|\pi^g(x) - \inf\{U^f(0,T,x,y) - T\mu(f) + \pi^f(h_f)\colon\ T \in [Q_1, Q_2],\ y \in R^n,\ |y - h_f| \le 8^{-1}\delta\}| \\ \le\ 16^{-1}\varepsilon + 8^{-1}\varepsilon + 16^{-1}\varepsilon \le 4^{-1}\varepsilon.\end{aligned}$$

This implies that for each g_1, $g_2 \in \mathcal{U}$ and each $x \in R^n$ satisfying $|x| \le K$

$$|\pi^{g_1}(x) - \pi^{g_2}(x)| \le 2^{-1}\varepsilon.$$

Therefore f is a continuity point of the mapping $g \to \pi^g$, $g \in \mathfrak{A}$. The theorem is proven.

Proof of Theorem 2.2. Let $\varepsilon \in (0,1)$. By Proposition 3.9 there exists an integer $L \ge 1$ such that for each (f)-good function $v\colon\ [0,\infty) \to R^n$

$$\operatorname{dist}(H(f), \{v(t)\colon\ t \in [T, T + L]\}) \le 2^{-8}\varepsilon \tag{4.189}$$

for all large T. By Lemma 4.9 there exist a neighborhood $\mathcal{U}_1$ of f in $\mathfrak{A}$ and

$$\delta_0 \in (0, 8^{-1}\varepsilon) \tag{4.190}$$

such that for each $g \in \mathcal{U}_1$, each $T \in [L, \infty)$, and each a.c. function $v\colon [0,T] \to R^n$ which satisfies

$$\begin{aligned} &d(v(0), H(f)) \le \delta_0, \qquad d(v(T), H(f)) \le \delta_0, \\ &I^g(0,T,v) - \pi^f(v(0)) + \pi^f(v(T)) \le \ell(g, D_f + 4, T) + \delta_0 \end{aligned} \tag{4.191}$$

the relation

$$\operatorname{dist}(H(f), \{v(t)\colon\ t \in [S, S+L]\}) \le \varepsilon \tag{4.192}$$

holds for all $S \in [0, T-L]$.

By Lemma 4.8 there exists a neighborhood $\mathcal{U}_2$ of f in $\mathfrak{A}$ such that for each $g \in \mathcal{U}_2$, each $h \in H(f)$, and each $T \ge 1$ there exists an a.c. function $v\colon [0,T] \to R^n$ for which

(4.193)

$$v(0) = h, \quad v(T) \in H(f), \quad I^g(0,T,v) - \pi^f(v(0)) + \pi^f(v(T)) \le \ell(g, D_f + 4, T) + 8^{-1}\delta_0.$$

Clearly there exists

$$\delta \in (0, 2^{-6}\delta_0) \tag{4.194}$$

such that, for each $x, y \in R^n$ satisfying $|x - y| \le \delta$ and $|x|, |y| \le D_f + 4$,

$$|\pi^f(x) - \pi^f(y)| \le 2^{-4}\delta_0. \tag{4.195}$$

By Theorem 2.1 there exists a neighborhood $\mathcal{U}_3$ of f in $\mathfrak{A}$ such that for each $g \in \mathcal{U}_3$ and each $x \in R^n$ satisfying $|x| \le D_f + 4$

$$|\pi^f(x) - \pi^g(x)| \le 2^{-4}\delta_0. \tag{4.196}$$

By Proposition 3.13 there exist an integer $L_0 \ge 1$ and a neighborhood $\mathcal{U}_4$ of f in $\mathfrak{A}$ such that for each $g \in \mathcal{U}_4$ and each (g)-good function $v\colon [0, \infty) \to R^n$

$$\operatorname{dist}(H(f),\ \{v(t)\colon\ t \in [T, T + L_0]\}) \le \delta \tag{4.197}$$

for all large T.

We may assume that $L_0 \ge L$. Set

$$\mathcal{U} = \bigcap_{i=1}^{4} \mathcal{U}_i.$$

Assume that

$$g \in \mathcal{U}, \quad v \in \mathcal{A}(g), \quad d(v(0), H(f)) \le \delta. \tag{4.198}$$

It follows from (4.198) and Proposition 3.14 that v is a (g)-good function. By the definition of $\mathcal{U}_4$ and L_0 there exists a number $T_0 > 0$ such that (4.197) holds for each $T \ge T_0$.

Let $T \geq T_0 + L$. There exists

$$\tau \in [T + L_0, T + 2L_0] \quad \text{such that } |v(\tau) - h_f| \leq \delta \tag{4.199}$$

(recall h_f in (4.176)). We will show that

$$I^g(0, \tau, v) - \pi^f(v(0)) + \pi^f(v(\tau)) \leq \ell(g, D_f + 4, \tau) + \delta_0. \tag{4.200}$$

It follows from (4.198), (4.199), and the definition of $\mathcal{U}_3$ (see (4.196)) that

$$\begin{aligned} \ell(g, D_f + 4, \tau) &\leq I^g(0, \tau, v) - \pi^f(v(0)) + \pi^f(v(\tau)) \\ &\leq I^g(0, \tau, v) - \pi^g(v(0)) + \pi^g(v(\tau)) + 2^{-3}\delta_0 \\ &= \tau\mu(g) + 2^{-3}\delta_0. \end{aligned} \tag{4.201}$$

By the definition of $\mathcal{U}_2$ (see (4.193)) there exists an a.c. function $u\colon [0, \tau] \to R^n$ such that

$$u(0), u(\tau) \in H(f), \qquad I^g(0, \tau, u) - \pi^f(u(0)) + \pi^f(u(\tau)) \leq \ell(g, D_f + 4, \tau) + 8^{-1}\delta_0.$$

It follows from these relations, the definition of $\mathcal{U}_3$ (see (4.196)), and the representation formula (1.6) that

$$\ell(g, D_f + 4, \tau) + 8^{-1}\delta_0 \geq I^g(0, \tau, u) - \pi^g(u(0)) + \pi^g(u(\tau)) - 2^{-3}\delta_0 \geq \tau\mu(g) - 2^{-3}\delta_0.$$

Together with (4.201) this implies (4.200). By (4.198)–(4.200) and the definition of $\mathcal{U}_1$, (4.192) holds for all $S \in [0, \tau - L]$. This completes the proof of the theorem.

Proof of Theorem 2.3. Let $\varepsilon \in (0, 1)$ and $K > D_f + 4$. By Theorem 2.2 there exist $\delta \in (0, \varepsilon)$, $L > 0$, and a neighborhood $\mathcal{U}_1$ of f in $\mathfrak{A}$ such that, for each $g \in \mathcal{U}_1$, each $v \in \mathcal{A}(g)$ satisfying $d(v(0), H(f)) \leq \delta$, and each $T \geq 0$,

$$\operatorname{dist}(H(f),\ \{v(t)\colon\ t \in [T, T + L]\}) \leq \varepsilon. \tag{4.202}$$

By Proposition 3.13 there exist an integer $L_0 \geq 1$ and a neighborhood $\mathcal{U}_2$ of f in $\mathfrak{A}$ such that for each $g \in \mathcal{U}_2$ and each (g)-good function $v\colon [0, \infty) \to R^n$

$$\operatorname{dist}(H(f),\ \{v(t)\colon\ t \in [T, T + L_0]\}) \leq 8^{-1}\delta \tag{4.203}$$

for all large T.

By Lemma 4.4 there exists an integer $N \geq 10$ and a neighborhood $\mathcal{U}_3$ of f in $\mathfrak{A}$ such that, for each $g \in \mathcal{U}_3$; each $T_1 \geq 0$, $T_2 \geq T_1 + NL_0$; each a.c. function $v\colon [T_1, T_2] \to R^n$ which satisfies

$$|v(T_i)| \leq K + 8, \quad i = 1, 2, \quad I^g(T_1, T_2, v) \leq U^g(T_1, T_2, v(T_1), v(T_2)) + 4; \tag{4.204}$$

and each $S \in [T_1, T_2 - NL_0]$, there exists an integer $i_0 \in [0, N - 8]$ such that for all $T \in [S + i_0L_0, S + (i_0 + 7)L_0]$

$$\operatorname{dist}(H(f), \{v(t)\colon\ t \in [T, T + L_0]\}) \leq \delta. \tag{4.205}$$

Set

$$\mathcal{U} = \bigcap_{i=1}^{3} \mathcal{U}_i, \qquad Q = NL_0. \tag{4.206}$$

Assume that

$$g \in \mathcal{U}, \quad v \in \mathcal{A}(g), \quad |v(0)| \le K. \tag{4.207}$$

Equation (4.207) and Proposition 3.14 imply that v is a (g)-good function. Therefore by the definition of $\mathcal{U}_2$

$$|v(t)| \le K + 1 \quad \text{for all large } t.$$

It follows from this relation, (4.207), (4.206), and the definition of $\mathcal{U}_3$, N that there exists $\tau \in [0, Q]$ for which $d(v(\tau), H(f)) \le \delta$. By this relation, (4.207), and the definition of $\mathcal{U}_1$, δ, L, relation (4.202) holds for each $T \ge \tau$. This completes the proof of the theorem.

5. Proof of Theorem 2.4.

LEMMA 5.1. *Assume that $f \in \mathfrak{A}, x\colon [0,\infty) \to R^n$ is an (f)-good function and $h \in \Omega(x)$. Then there exists an a.c. function $v\colon R^1 \to \Omega(x)$ such that $v \in \mathcal{B}(f)$, $v(0) = h$.*

Proof. By Proposition 3.1 the function x is bounded. It is easy to see that the following property holds:

(a) for each $\varepsilon > 0$ there exists $T(\varepsilon) > 0$ such that for each $T_1 \ge T(\varepsilon), T_2 > T_1$

$$I^f(T_1, T_2, x) - \pi^f(x(T_1)) + \pi^f(x(T_2)) - (T_2 - T_1)\mu(f) \le \varepsilon.$$

There exists a sequence of numbers $\{T_p\}_{p=0}^{\infty}$ such that

$$T_{p+1} \ge T_p + 1, \quad p = 0, 1, \ldots, \quad x(T_p) \to h \quad \text{as } p \to \infty. \tag{5.1}$$

For every integer $p \ge 1$ we set

$$v_p(t) = x(t + T_p), \qquad t \in [-T_p, \infty). \tag{5.2}$$

By Proposition 3.4, the boundness of x, (5.1), and (5.2) there exists a subsequence $\{v_{p_j}\}_{j=1}^{\infty}$ and an a.c. function $v\colon R^1 \to R^n$ such that for each integer $N \ge 1$

$$v_{p_j}(t) \to v(t) \quad \text{as } j \to \infty \text{ uniformly in } [-N, N],$$

$$I^f(-N, N, v) \le \liminf_{j \to \infty} I^f(-N, N, v_{p_j}). \tag{5.3}$$

Equations (5.1)–(5.3) imply that $v(0) = h$ and $v(t) \in \Omega(x), t \in R^1$. It follows from property (a), (5.3), and (5.2) that $v \in \mathcal{B}(f)$. The lemma is proven.

Propositions 3.1, 3.2, and 3.14 imply the following result.

LEMMA 5.2. *Assume that $f \in \mathfrak{A}$ and $v \in \mathcal{B}(f)$. Then* $\sup\{|v(t)|\colon t \in R^1\} < \infty$.

Assertion (1) of Theorem 2.4 follows from Lemma 5.1. Assertion (2) of Theorem 2.4 follows from Lemma 5.2 and Theorem 2.3. Assertion (3) of Theorem 2.4 follows from assertion (2) and Theorem 2.4.

Lemma 5.1 implies the following result.

PROPOSITION 5.1. *Assume that $f \in \mathfrak{A}$ and there exists a compact set $H(f) \subset R^n$ such that for each $v \in \mathcal{B}(f)$ the following relations hold:*

$$v(t) \in H(f), \qquad t \in R^1,$$

$$\{y \in R^n\colon \text{ there exists a sequence } \{t_i\}_{i=0}^{\infty} \subset [0,\infty) \text{ for which } t_i \to \infty, v(t_i) \to y \text{ as } i \to \infty\} = H(f).$$

Then $\Omega(u) = H(f)$ for each (f)-good function $u\colon [0,\infty) \to R^n$.

6. Examples. Fix a constant $a > 0$ and set $\psi(t) = t (t \in [0, \infty))$. Consider the complete metric space $\mathfrak{A}$ of integrands $f\colon R^n \times R^n \to R^1$ defined in the introduction.

Example 1. Consider an integrand $f(x, u) = |x|^2 + |u|^2, x, u \in R^n$. It is easy to see that $f \in \mathfrak{A}$. We can show (see [25, sect. 14]) that $\Omega(v) = \{0\}$ for every (f)-good function $v\colon [0, \infty) \to R^n$.

Example 2. Fix a number $q > 0$, and consider an integrand $g(x, u) = q|x|^2|x - e|^2 + |u|^2 (x, u \in R^n)$, where $e = (1, 1, \ldots, 1) \in R^n$. It is easy to see that $g \in \mathfrak{A}$ if the constant a is large enough. Clearly the functions $v_1(t) = 0$ and $v_2(t) = e$ $(t \in [0, \infty))$ are (g)-good and g does not have property B.

Acknowledgment. The author thanks A. Leizarowitz and M. Marcus for helpful discussions.

AN ABSTRACT BANG-BANG PRINCIPLE AND TIME-OPTIMAL BOUNDARY CONTROL OF THE HEAT EQUATION*

VICTOR J. MIZEL† AND THOMAS I. SEIDMAN‡

Abstract. A principal technical result of this paper is that the one-dimensional heat equation with boundary control is exactly null-controllable with control restricted to an arbitrary set $\mathcal{E} \subset [0,T]$ of positive measure. A general abstract argument is presented to show that, in contrast to previous results, this implies the bang-bang property for time-optimal controls—i.e., such a control can take only extreme values of (the hull of) the constraint set—without imposing any condition regarding the target state.

Key words. partial differential equation, bang-bang control, nullcontrol, reachability

1. Introduction. Our principal concern will be with the bang-bang property for time-optimal boundary control of the one-dimensional heat equation

$$\begin{aligned} &u_t = u_{xx} \qquad (0 < t < T,\ 0 < x < 1),\\ &u(\cdot,0) = \varphi = \text{ control}, \qquad u(\cdot,1) = 0,\\ &u(0,\cdot) = \omega_0 \in \mathcal{X}_0 = L^2(0,1). \end{aligned} \tag{1.1}$$

(Here we will assume a pointwise control constraint and then will say that φ has the bang-bang property if it takes only extremal values.) We note at this point (cf. Remark 4.1) that the previously known results [12], [8] on the bang-bang property for time-optimal control of (1.1) are incomplete in that their hypotheses impose conditions on the target state which turn out to be extraneous for the bang-bang property per se; our focal goal will be the removal of such restrictions.

To this end, we will introduce an abstract formulation of the problem, following [14] in spirit if not quite in detail, and will prove a general abstract result (Theorem 2) which, in the context of (1.1), reduces the problem to a question of independent interest: *exact nullcontrollability for* (1.1) *when* φ *is restricted to* $L^\infty(\mathcal{E})$ *for an arbitrary set* $\mathcal{E}$ *of positive measure in* $[0,T]$. The argument for the latter (Theorem 5) is based on a recent result in nonharmonic analysis by Borwein and Erdélyi [2], [3].

We begin with the observation that there are really two quite distinct versions of the time-optimality problem in control theory:

- immediately initiate control so as to reach the goal as early as possible;
- reach the goal by a fixed time T while delaying initiation of active control to as late as possible.

The first of these is usually taken as the standard statement of the problem, but, much as in [14], it will be more convenient here to use the second version for our

‡Department of Mathematics and Statistics, University of Maryland–Baltimore County, Baltimore, MD 21250 (seidman@math.umbc.edu).

abstract formulation. We do observe that the two versions are clearly equivalent when the problem is autonomous (with suitable initial conditions). It is also worth emphasizing that (still when the problem is autonomous) the construction used in the proof of the abstract bang-bang principle, Theorem 2 below, could be used equally well directly for a proof of the bang-bang property in the context of version 1, with no restriction on the initial data.

In the context of version 2, we adjoin to (1.1) the target condition that the profile at time T belongs to a prescribed set

$$u(T,\cdot) \in \mathcal{S}_T \tag{1.2}$$

and formulate the time-optimality problem as finding a pair (φ, τ) which maximizes τ subject to the *admissibility constraints* that, for a given set-valued function $A : [0,T] \to 2^{\mathbb{R}}$, one has

$$\begin{aligned} &\text{(i)} \quad \varphi(t) = \varphi_*(t) = \text{given} \qquad \text{for } 0 \le t < \tau, \\ &\text{(ii)} \quad \varphi(t) \in A(t) \qquad \text{for } \tau \le t \le T, \\ &\text{(iii)} \quad \text{the solution } u \text{ of (1.1) using this control } \varphi \text{ satisfies (1.2).} \end{aligned} \tag{1.3}$$

We interpret φ_* as a trivial or passive control (e.g., $\varphi_* \equiv 0$), so τ represents the time at which we initiate active control and maximizing τ is just minimizing the duration $(T-\tau)$ of the actively controlled interval. (If $\omega_0 = 0$, $\varphi_* \equiv 0$, then (1.1) gives $u(\tau,\cdot) = 0$. So, if $A(t)$ were also independent of t, we could translate $[\tau, T]$ to $[0, T-\tau]$ to get the usual earliest arrival (version 1) for this autonomous problem.) Concerning the set function $A(\cdot)$, we assume that

$$\begin{gathered} a(t), b(t) \in A(t) \text{ and } a(\cdot), b(\cdot) \in L^\infty(0,T) \\ \text{for } a(t) := \min\{A(t)\}, \quad b(t) := \max\{A(t)\}. \end{gathered} \tag{1.4}$$

We emphasize that to obtain the bang-bang property *we need impose no hypotheses whatsoever on the data* $\{\omega_0, T, \mathcal{S}_T, \varphi_*\}$ *beyond the implicit assumption that such a time-optimal control does exist.* We do note that the usual argument gives existence of an optimizer in the setting above with $\mathcal{S}_T = \{\omega_T\}$, provided only that the data are *compatible* (i.e., there is some control satisfying (1.3)), and this reachability is the *only* restriction to be imposed regarding the target state ω_T in $\mathcal{X}_T = L^2(0,1)$.

For (1.1), (1.2) with $\mathcal{S}_T = \{\omega_T\}$, (1.3ii) with (1.4), we will show that *pointwise almost everywhere (a.e.) on* $[\tau, T]$*, the values of any time-optimal control* φ *must be either* $\varphi(t) = a(t)$ *or* $\varphi(t) = b(t)$*, with* a, b *as in* (1.4) and that this time-optimal control φ is unique. Note that in this situation the control φ is a *scalar* function of t and this strongly affects the ease with which we can use Theorems 1 and 2 to obtain such a bang-bang property. We will, however, comment in section 4 on the related situation in which one has control at both ends of the interval so

$$u\Big|_{x=0} = \varphi_1, \qquad u\Big|_{x=1} = \varphi_2, \tag{1.5}$$

and the control $\varphi := (\varphi_1, \varphi_2)$ is then an $\mathbb{R}^2$-valued function on $[0,T]$.

2. Evolutionary abstract control systems. We begin by recalling from [14], in slightly modified form, the notion of an *evolutionary abstract control system.* Consider $\mathcal{I}_0 := [0,T]$ as an order category; i.e., writing $\mathcal{I} = \mathcal{I}'\mathcal{I}''$ for $\mathcal{I} = [r,t]$ means

$\mathcal{I}'' = [r,s]$, $\mathcal{I}' = [s,t]$ with $0 \le r \le s \le t \le T$. Let $(\mathcal{X}, \mathbf{E})$ be a functor from $\mathcal{I}_0$ to the category of Banach spaces and continuous linear maps so $\mathcal{I} = [r,t]$ gives $\mathbf{E}_{\mathcal{I}} : \mathcal{X}_r \to \mathcal{X}_t$ with $\mathcal{I} = \mathcal{I}'\mathcal{I}''$ implying $\mathbf{E}_{\mathcal{I}} = \mathbf{E}_{\mathcal{I}'} \circ \mathbf{E}_{\mathcal{I}''}$; i.e.,

$$\mathbf{E}_{r,t} = \mathbf{E}_{s,t}\mathbf{E}_{r,s} : \mathcal{X}_r \to \mathcal{X}_s \to \mathcal{X}_t \quad \text{for } r \le s \le t. \tag{2.1}$$

In general, $\mathbf{E}_{\cdot\cdot}$ represents uncontrolled system evolution for a possibly nonautonomous well-posed problem. Next we associate *control spaces* $\mathcal{U}_{\mathcal{I}} = \mathcal{U}_{r,t}$ with the intervals $\mathcal{I} = [r,t] \subset \mathcal{I}_0$. We always think of each $\mathcal{U}_{\mathcal{I}}$ as a space of functions defined on $\mathcal{I}$, e.g., $\mathcal{U}_{\mathcal{I}} = L^2(\mathcal{I})$, so when $\mathcal{I} = \mathcal{I}'\mathcal{I}''$ we may decompose $\varphi \in \mathcal{U}_{\mathcal{I}}$ into a pair of functions (φ', φ'') defined on $\mathcal{I}'$ and $\mathcal{I}''$, respectively, by restriction maps $\mathbf{\Omega}'$, $\mathbf{\Omega}''$. We then ask that $\varphi' = \mathbf{\Omega}'\varphi \in \mathcal{U}_{\mathcal{I}'}$ and $\varphi'' = \mathbf{\Omega}''\varphi \in \mathcal{U}_{\mathcal{I}''}$. The control maps $\mathbf{C}_{r,t} : \mathcal{U}_{r,t} \to \mathcal{X}_t$ must satisfy the obvious identity

$$\mathbf{C}_{r,t} = \mathbf{C}_{s,t}\mathbf{\Omega}'_s + \mathbf{E}_{s,t}\mathbf{C}_{r,s}\mathbf{\Omega}''_s \tag{2.2}$$

for any such decomposition (any choice of $s \in [r,t]$).

Given any Banach space $\mathcal{V}$ with an injection $\mathbf{I}_{\mathcal{V}} : \mathcal{V} \to \mathcal{U}_{\mathcal{I}}$ — so we may think of $\mathcal{V}$ as consisting of functions with support in (some specified subset of) $\mathcal{I} = [t,T]$ — we say that $\mathcal{V}$ has the *nullcontrollability property* and write $\mathcal{V} \in \mathcal{NC}_{t,T}$ if there is a nullcontrol $v \in \mathcal{V}$ for each initial state in $\mathcal{X}_t$; i.e., if

$$\begin{gathered} \textit{for each } x = x_t \in \mathcal{X}_t \ \textit{ there is some } v \in \mathcal{V} \textit{ such that} \\ \mathbf{E}_{t,T}x + \mathbf{C}_{\mathcal{V}}v = 0 \quad (\mathbf{C}_{\mathcal{V}} := \mathbf{C}_{t,T}\mathbf{I}_{\mathcal{V}})\,. \end{gathered} \tag{2.3}$$

(Clearly, if $\mathcal{V} \in \mathcal{NC}_{t,T}$ for some $\mathcal{V} \hookrightarrow \mathcal{U}_{\mathcal{I}}$, then $\mathcal{U}_{\mathcal{I}} \in \mathcal{NC}_{t,T}$. We recall Theorem 1 of [14]: If $\mathcal{U}_{t,T} \in \mathcal{NC}_{t,T}$, then $\mathcal{K}_s = \mathcal{K}_t^0$ for all $s \le t$, where $\mathcal{K}_s := \mathcal{R}(\mathbf{E}_{s,T}) + \mathcal{R}(\mathbf{C}_{s,T})$ and $\mathcal{K}_s^0 := \mathcal{R}(\mathbf{C}_{s,T})$.) Slightly more delicate than (2.3), but useful later, is the *restricted nullcontrollability property*: we write $\mathcal{V} \in \mathcal{NC}_{t,T}^r$ if

$$\begin{gathered} \textit{for each } x \in \overline{\mathcal{R}(\mathbf{C}_{0,t})} \subset \mathcal{X}_t \ \textit{ there is some } v \in \mathcal{V} \textit{ such that} \\ \mathbf{E}_{t,T}x + \mathbf{C}_{\mathcal{V}}v = 0; \end{gathered} \tag{2.4}$$

i.e., we are restricting initial states in (2.3) to $\overline{\mathcal{R}(\mathbf{C}_{0,t})}$.

We will need the following result, which we present in full although the argument is already known in somewhat different contexts.

THEOREM 1. *If $\mathcal{V} \in \mathcal{NC}_{t,T}$ (respectively, $\mathcal{V} \in \mathcal{NC}_{t,T}^r$), then there is a constant $K_{\mathcal{V}}$ such that v in* (2.3) (*respectively,* (2.4)) *may be chosen with $\|v\|_{\mathcal{V}} \le K\|x\|_{\mathcal{X}_t}$ for any $K > K_{\mathcal{V}}$. Dually, if $\mathcal{V} \in \mathcal{NC}_{t,T}$, one has*

$$\|\mathbf{E}_{t,T}^*\,\xi\|_{\mathcal{X}_t^*} \le K_{\mathcal{V}}\|\mathbf{C}_{\mathcal{V}}^*\,\xi\| \tag{2.5}$$

for $\xi \in \mathcal{X}_T^*$ with the $\mathcal{V}^*$-norm on the right. Conversely, if $\mathcal{V}$ contains a dual space $(\mathcal{W}^* \subset \mathcal{V})$ and $\mathbf{C}_{\mathcal{V}}^*\,\xi \in \mathcal{W}$ for a dense set $\mathcal{D}$ of $\xi \in \mathcal{X}_T^*$, then (2.5)*, using the $\mathcal{W}$-norm on the right for $\xi \in \mathcal{D}$, implies that $\mathcal{V} \in \mathcal{NC}_{t,T}$.*

Proof. For brevity we now simply write $\mathbf{E}$ for $\mathbf{E}_{t,T}$ and $\mathbf{C}$ for $\mathbf{C}_{\mathcal{V}} := \mathbf{C}_{t,T}\mathbf{I}_{\mathcal{V}}$. Clearly, $\mathcal{V} \in \mathcal{NC}_{t,T}$ is equivalent to range containment:

$$\mathcal{R}(\mathbf{E}) \subset \mathcal{R}(\mathbf{C}) =: \mathcal{K}^0(\mathcal{V}) \subset \mathcal{X}_T.$$

Set $\hat{\mathcal{V}} := \mathcal{V}/\mathcal{N}(\mathbf{C})$ with an injective induced map $\hat{\mathbf{C}} : \hat{\mathcal{V}} \to \mathcal{X}_T$ (i.e., $\hat{\mathbf{C}}v = \mathbf{C}_{\mathcal{V}}\hat{v}$ for $v \in \hat{v} \in \hat{\mathcal{V}}$), and let

$$\Gamma := \{(x, \hat{v}) : \mathbf{E}x + \hat{\mathbf{C}}\hat{v} = 0\} \ \subset \ \mathcal{X}_t \times \hat{\mathcal{V}}.$$

Note that Γ is a subspace and is the graph of a linear map $\mathbf{L} = \mathbf{L}_{\mathcal{V}} : \mathcal{X}_t \to \hat{\mathcal{V}}$ which is well defined on all of $\mathcal{X}_t$ by (2.3) and the injectivity of $\hat{\mathbf{C}}$. Since Γ is closed (as $\mathbf{E}, \hat{\mathbf{C}}$ are continuous), it follows that $\mathbf{L}_{\mathcal{V}}$ is bounded, by the closed graph theorem, and the bound on $\|v\|$ with $K_{\mathcal{V}} = \|\mathbf{L}\|$ follows from the definition of the quotient space norm on $\hat{\mathcal{V}}$. Simply replacing $\mathcal{X}_t$ by $\overline{\mathcal{R}(\mathbf{C}_{0,t})}$ in the argument above now gives the bound when $\mathcal{V} \in \mathit{NC}^r_{t,T}$. To obtain (2.5) when $\mathcal{V} \in \mathit{NC}_{t,T}$, we note that the construction of $\mathbf{L}$ gives

$$\mathbf{E} = -\hat{\mathbf{C}}\mathbf{L} \quad \text{so, dually,} \quad \mathbf{E}^* = -\mathbf{L}^*\hat{\mathbf{C}}^*$$

with $\mathbf{L}^* : \hat{\mathcal{V}}^* \to {\mathcal{X}_t}^*$. We then have $\|\mathbf{L}^*\| = \|\mathbf{L}\| =: K_{\mathcal{V}}$ and, since $\langle \hat{\mathbf{C}}^*\xi, \hat{v}\rangle = \langle \mathbf{C}^*\xi, v\rangle$ for $v \in \hat{v} \in \hat{\mathcal{V}}$ and $\xi \in {\mathcal{X}_T}^*$, this gives (2.5).

For the converse, consider any $\eta \in \mathbf{C}^*\mathcal{D}$, i.e., $\eta = \mathbf{C}^*\,\xi$ for some $\xi \in \mathcal{D} \subset \mathcal{X}_T^*$, we can set $\zeta := -\mathbf{E}^*\xi$, noting that if ξ is nonunique (so also $\eta = \mathbf{C}\xi'$ with $\xi' \in \mathcal{D}$), then (2.5) ensures that $\|\mathbf{E}^*(\xi - \xi')\| = 0$, so ζ is well defined. Now, arbitrarily fixing $x = x_t \in \mathcal{X}_t$, we consider

$$\Phi : \eta \longmapsto \langle x, \zeta\rangle = -\langle x, \mathbf{E}^*\xi\rangle$$

for such η. It is clear that the functional Φ is linear on $\mathbf{C}^*\mathcal{D} \subset \mathcal{W}$ and that

$$|\langle \Phi, \eta\rangle| = |\langle x, \zeta\rangle| \le \|x\|\|\zeta\| \le \|x\|K\|\eta\|.$$

Thus, Φ extends by continuity to the $\mathcal{W}$-closure $\overline{\mathbf{C}^*\mathcal{D}}$ and then, by the Hahn–Banach theorem, to a linear functional v on $\mathcal{W}$ (i.e., $v \in \mathcal{W}^* \subset \mathcal{V}$) without increase of norm, so $\|v\| \le K_{\mathcal{V}}\|x\|$. Since

$$\langle \mathbf{C}v, \xi\rangle = \langle v, \mathbf{C}^*\xi\rangle = -\langle x, \mathbf{E}^*\xi\rangle = \langle -\mathbf{E}x, \xi\rangle$$

for ξ dense in ${\mathcal{X}_T}^*$, it follows that $\mathbf{E}x + \mathbf{C}v = 0$ and $v \in \mathcal{V}$ is a nullcontrol for x. As $x \in \mathcal{X}_t$ was arbitrary, we have (2.3), so $\mathcal{V} \in \mathit{NC}_{t,T}$ as asserted. ∎

3. Time-optimality. We now turn to formulation of the abstract time-optimality problem. It will be convenient here to abuse notation slightly by thinking of $\mathcal{U} = \mathcal{U}_{0,T}$ as the common domain of the control maps $\mathbf{C}_{s,t} : \mathcal{U} \to \mathcal{X}_t$, omitting explicit indication of the $\mathbf{\Omega}$ operators; note that we think of $\mathbf{C}_{s,t}\varphi$ as depending only on the part of φ between s and t, so $\mathcal{N}(\mathbf{C}_{s,t}) \supset \mathcal{N}(\mathbf{\Omega}_{[s,t]})$, where, in the obvious notation,

$$\mathbf{\Omega}_{[s,t]} := \mathbf{\Omega}'_{s,[0,t]}\mathbf{\Omega}''_{t,[0,T]} = \mathbf{\Omega}''_{t,[s,T]}\mathbf{\Omega}'_{s,[0,T]}.$$

Fixing the *passive control* $\varphi_* \in \mathcal{U}$, a basic assumption is that for each $s \in (0,T)$ we have

$$\varphi \in \mathcal{U} \Rightarrow \mathbf{P}_s\varphi := \begin{cases} \varphi_* & \text{on } [0,s) \\ \varphi & \text{on } [s,T] \end{cases} \in \mathcal{U} \tag{3.1}$$

or, more formally, $\mathbf{\Omega}'_s\mathbf{P}_s\varphi = \mathbf{\Omega}'_s\varphi$ and $\mathbf{\Omega}''_s\mathbf{P}_s\varphi = \mathbf{\Omega}''_s\varphi_*$; note that $\mathbf{P}_s$ will not generally be linear unless $\varphi_* \equiv 0$. We impose the continuity condition that

$$\mathbf{C}_{r,t}\mathbf{P}_s\varphi \to \mathbf{C}_{r,t}\varphi \text{ as } s \searrow r \tag{3.2}$$

for $0 \le r < t \le T$, which just says that changing φ on the vanishingly small interval $[r,s]$ has vanishingly small control effect at any $t > r$.

The data for the time-optimality problem will be

$$x_0 \in \mathcal{X}_0, \qquad \varphi_* \in \mathcal{U}, \qquad \mathcal{A} \subset \mathcal{U}, \qquad \mathcal{S}_T \subset \mathcal{X}_T, \tag{3.3}$$

where x_0 is an *initial state*, φ_* is the passive control, $\mathcal{A}$ is a *constraint set*, and $\mathcal{S}_T$ is the *target set*. We will require, to simplify our statement rather than to restrict $\mathcal{A}$, that $\varphi \in \mathcal{A}$ implies $\mathbf{P}_s\varphi \in \mathcal{A}$ for each s. The set of *admissible pairs* $\mathcal{P} = \mathcal{P}(\mathcal{A}, \mathcal{S}_T; x_0, \varphi_*)$ is then defined as

$$\mathcal{P} := \{(\varphi, \tau) \in \mathcal{A} \times [0,T] : \varphi = \mathbf{P}_\tau\varphi, [\mathbf{E}_{0,T}x_0 + \mathbf{C}_{0,T}\varphi] \in \mathcal{S}_T\}, \tag{3.4}$$

and we say that a control $\bar{\varphi}$ or, more precisely, an admissible pair $(\bar{\varphi}, \bar{\tau}) \in \mathcal{P}$ is *time-optimal* (with respect to these data) if it maximizes τ over $(\varphi, \tau) \in \mathcal{P}$.

We will say that $\varphi \in \mathcal{U}$ is *slack with respect to* $(\mathcal{A}, \mathcal{V})$ (for a Banach space $\mathcal{V}$ with $\mathbf{I}_\mathcal{V} : \mathcal{V} \to \mathcal{U}$) if there is some $\varepsilon > 0$ such that

$$[\varphi + \mathbf{I}_\mathcal{V} v] \in \mathcal{A} \ \textit{ for all } v \in \mathcal{V} \textit{ with } \|v\|_\mathcal{V} < \varepsilon. \tag{3.5}$$

At this point we may state and prove our abstract bang-bang principle.

THEOREM 2. *Suppose that $\varphi \in \mathcal{U}$ is slack with respect to $(\mathcal{A}, \mathcal{V})$ for some $\mathcal{V} \in \mathcal{NC}^r_{t,T}$. Then (φ, τ) with $\tau < t$ cannot be time-optimal with respect to any data set $(\mathcal{A}, \mathcal{S}_T; x_0, \varphi_*)$ involving this $\mathcal{A}$.*

Proof. Note that, while we have written simply $\mathbf{I}_\mathcal{V} : \mathcal{V} \to \mathcal{U}$, the condition $\mathcal{V} \in \mathcal{NC}^r_{t,T}$ includes the implication that $\mathcal{R}(\mathbf{I}_\mathcal{V})$ is actually in $\mathcal{U}_{t,T}$, so for $s \le t$ one has

$$\mathbf{P}_s\varphi_s = \varphi_s \ \text{ for } \varphi_s := \mathbf{P}_s(\varphi + \mathbf{I}_\mathcal{V} v) \qquad (\text{any } v \in \mathcal{V}). \tag{3.6}$$

Now let K^r be as $K_\mathcal{V}$ in Theorem 1 applied to this $\mathcal{V} \in \mathcal{NC}^r_{t,T}$ and let $\varepsilon > 0$ be as in (3.5). In view of (3.2) with $r = \tau < t$, we may choose $s =: \hat{\tau}$ close enough to τ (with $\tau < \hat{\tau} < t$) that

$$\tilde{x} := \mathbf{C}_{\tau,t}\left[\mathbf{P}_{\hat{\tau}}\varphi - \varphi\right] \ \textit{ gives } \ \|\tilde{x}\| < \varepsilon / K^r, \tag{3.7}$$

noting that $\tilde{x} \in \mathcal{R}(\mathbf{C}_{0,t}) \subset \mathcal{X}_t$. By Theorem 1 we may then choose $v \in \mathcal{V}$ such that

$$\mathbf{E}_{t,T}\tilde{x} + \mathbf{C}_{t,T}v = 0 \text{ and } \|v\|_\mathcal{V} < \varepsilon. \tag{3.8}$$

Now set

$$\hat{\varphi} := \mathbf{P}_{\hat{\tau}}\left(\varphi + \mathbf{I}_\mathcal{V} v\right); \quad \text{i.e., } \ \hat{\varphi} = \begin{cases} \varphi_* & \text{on } [0,\tau), \\ \mathbf{P}_{\hat{\tau}}\varphi & \text{on } [\tau,t), \\ \varphi + \mathbf{I}_\mathcal{V} v & \text{on } [t,T]. \end{cases} \tag{3.9}$$

Since $\|v\|_\mathcal{V} < \varepsilon$, we have $[\varphi + \mathbf{I}_\mathcal{V} v] \in \mathcal{A}$ by (3.5) and also $\hat{\varphi} \in \mathcal{A}$; we have $\mathbf{P}_{\hat{\tau}}\hat{\varphi} = \hat{\varphi}$ by (3.6). Using (2.2) twice (splitting $[0,T]$ at τ and at t), we have

$$\begin{aligned} \mathbf{C}_{0,T}\varphi &= \mathbf{E}_{\tau,T}\mathbf{C}_{0,\tau}\varphi_* + \mathbf{C}_{\tau,T}\varphi \\ &\qquad\qquad \text{as } \varphi = \varphi_* \text{ on } [0,\tau) \\ &= \mathbf{E}_{\tau,T}\mathbf{C}_{0,\tau}\varphi_* + \mathbf{E}_{t,T}\mathbf{C}_{\tau,t}\varphi + \mathbf{C}_{t,T}\varphi, \end{aligned} \tag{3.10}$$

and, similarly, we have

$$\mathbf{C}_{0,T}\hat{\varphi} = \mathbf{E}_{\tau,T}\mathbf{C}_{0,\tau}\varphi_* + \mathbf{E}_{t,T}\mathbf{C}_{\tau,t}\mathbf{P}_{\hat{\tau}}\varphi + \mathbf{C}_{t,T}\left[\varphi + \mathbf{I}_\mathcal{V} v\right] \tag{3.11}$$

using (3.9). Comparing (3.11) with (3.10) gives (with $\mathbf{C}_{\mathcal{V}} := \mathbf{C}_{t,T}\mathbf{I}_{\mathcal{V}}$ as before)

$$\begin{aligned} \mathbf{C}_{0,T}\hat{\varphi} - \mathbf{C}_{0,T}\varphi &= \mathbf{E}_{t,T}\mathbf{C}_{\tau,t}\left[\mathbf{P}_{\hat{\tau}}\varphi - \varphi\right] + \mathbf{C}_{\mathcal{V}}v \\ &= \mathbf{E}_{t,T}\tilde{x} + \mathbf{C}_{\mathcal{V}}v = 0 \end{aligned} \tag{3.12}$$

by (3.7) and (3.8).

It follows that $(\hat{\varphi}, \hat{\tau}) \in \mathcal{P} = \mathcal{P}(\mathcal{A}, \mathcal{S}_T; x_0, \varphi_*)$ for any data, which gives $(\varphi, \tau) \in \mathcal{P}$: if $\mathbf{E}_{0,T}x_0 + \mathbf{C}_{0,T}\varphi =: x_T \in \mathcal{S}_T$, then also $\mathbf{E}_{0,T}x_0 + \mathbf{C}_{0,T}\hat{\varphi} = x_T$ for the very same $x_T \in \mathcal{S}_T$. Since $\hat{\tau} > \tau$, it would then be impossible for τ to be maximal and φ could not be a time-optimal control. □

To see why we refer to Theorem 2 as an abstract bang-bang principle, we note our motivating consequence. Observe, first, that in considering scalar controls with a uniform pointwise bound as in (1.4), there is some arbitrariness about the specification of the control space $\mathcal{U}$. We will, somewhat arbitrarily, take $\mathcal{U} := L^p(0,T)$ for some finite $p > 1$ (so, in particular, $\mathcal{U}$ is reflexive) and assume that each of the operators $\mathbf{E}_{s,t}$, $\mathbf{C}_{s,t}$ is continuous for this choice of $\mathcal{U}$.

THEOREM 3. *Consider a time-optimality problem, as above, with $\mathcal{S}_T$ closed and convex in $\mathcal{X}_T$, scalar control (say, $\mathcal{U} = L^p(0,T)$ for some $p \geq 1$), and $\mathcal{A}$ of the form*

$$\mathcal{A} := \{\varphi \in \mathcal{U} : \varphi(t) \in A(t) \text{ a.e. on } [0,T]\} \tag{3.13}$$

with $A(\cdot)$ as in (1.4) *and $\varphi_* \in \mathcal{A}$. Assume*

$$\begin{gathered} \text{for each } t \in (0,T), \text{ each set } \mathcal{E} \subset (t,T) \text{ of positive measure,} \\ \text{one has } L^\infty(\mathcal{E}) \in \mathcal{NC}^r_{t,T}. \end{gathered} \tag{3.14}$$

Then there is a unique time-optimal control $\bar{\varphi}$, and this necessarily has the bang-bang property:

$$[\varphi(t) = a(t) \text{ or } \varphi(t) = b(t)] \quad \text{a.e. on } [\tau, T], \tag{3.15}$$

with a, b as in (1.4).

The key to this is that for (3.15) to fail one must have

$$a(t) + \varepsilon \leq \varphi(t) \leq b(t) - \varepsilon \quad \text{for } t \in \mathcal{E} \tag{3.16}$$

for some $\varepsilon > 0$ and some set $\mathcal{E}$ of positive measure in $[\tau, T]$, perhaps restricting to an intersection. We may assume that this set $\mathcal{E}$ is actually contained in some $[\bar{t}, T]$ with $\bar{t} > \tau$. We do note that the very existence of a time-optimal control is not immediately clear at this point, since we have not even assumed that $A(t)$ should be a closed set.

Proof. We first consider the situation with $\mathcal{A}$ replaced by $\mathcal{A}_*$, where

$$\mathcal{A}_* := \{\varphi \in \mathcal{U} : \varphi(t) \in [a(t), b(t)] =: A_*(t) \text{ a.e. on } [0,T]\}.$$

As $\mathcal{A}_*$ is bounded, closed, and convex (hence weakly compact in $\mathcal{U} = L^p(0,T)$), the usual argument gives existence of a time-optimal control: let (φ_ν) be an optimizing sequence so we may assume $\varphi_\nu \rightharpoonup \bar{\varphi}$ with $\tau_\nu \nearrow \tau$. Noting that $\mathbf{C}_{0,T}\varphi_\nu \rightharpoonup \mathbf{C}_{0,T}\bar{\varphi}$, we must have $\mathbf{E}_{0,T}x_0 + \mathbf{C}_{0,T}\bar{\varphi} \in \mathcal{S}_T$, whence $(\bar{\varphi}, \tau)$ is admissible and so is time-optimal. By (3.14) and Theorem 2, we see that $\bar{\varphi}$ cannot be slack with respect to $(\mathcal{A}_*, \mathcal{V})$ for any $\mathcal{V} = L^\infty(\mathcal{E})$ with $\mathcal{E}$ of positive measure in $(\bar{t}, T)$, $\bar{t} > \tau$. On the other hand, we have already noted that a failure of (3.15) would give (3.16), which would imply

such slackness and give a contradiction. Hence, $\bar{\varphi}$ must satisfy (3.15). So by (1.4) we have $\bar{\varphi} \in \mathcal{A}$, and this pair $(\bar{\varphi}, \tau)$ is also admissible for the original problem. Since the problem using $\mathcal{A}_*$ is a relaxed version of that, $(\bar{\varphi}, \tau)$ must be time-optimal for the original problem.

To see uniqueness, note that if $(\hat{\varphi}, \tau)$ were a different time-optimal pair for the original problem (necessarily with the same τ), then we could set $\tilde{\varphi} := (\bar{\varphi} + \hat{\varphi})/2$. Note also that $(\tilde{\varphi}, \tau)$ is an admissible pair for the problem using $\mathcal{A}_*$, since the system is linear and $\mathcal{A}_*, \mathcal{S}_T$ are convex. Whether or not $\hat{\varphi}$ satisfies (3.15), it is clear that (3.15) cannot hold for $\tilde{\varphi}$ on the (assumed nonnull) set, where $\hat{\varphi} \neq \bar{\varphi}$. As above, we then see that $(\tilde{\varphi}, \tau)$ cannot be time-optimal for that problem, contradicting the assumed maximality of τ. Thus, $\bar{\varphi}$ is the unique optimal control for the original problem. ∎

For the finite-dimensional case (state space $\mathbb{R}^n$) we see that the hypotheses above are easily established for control systems governed by

$$\dot{x} = Ax + \varphi \mathbf{b} \qquad x(0) = x_0. \tag{3.17}$$

COROLLARY 4. *The results of Theorem* 3 *apply to finite-dimensional time-optimality problems of the indicated form for* (3.17)*, provided that* $A(\cdot)\,, \mathbf{b}(\cdot)$ *are real-analytic on* $[0, T]$ *when this is nonautonomous.*

Proof. We need only verify the hypothesis (3.14), and for this it is convenient to take $\mathcal{X}_t := \mathcal{R}(\mathbf{C}_{0,t})$ for $t \in [0, T]$, so, in particular, $\mathbf{C} = \mathbf{C}_{0,T}$ is surjective to $\mathcal{X}_T$. The choice of control space $\mathcal{U}$ is not very significant, and we take, e.g., $\mathcal{U} := L^2(0, T)$. One easily verifies that the adjoint map $\mathbf{C}^*$ is given for $\eta \in \mathcal{X}_T^*$ $(\subset \mathbb{R}^n)$ by $\mathbf{C}^* : \eta \mapsto \langle \mathbf{b}, y \rangle \in L^2(0, T)$, where

$$-\dot{y} = A^* y, \qquad y(T) = \eta. \tag{3.18}$$

The range $\mathcal{R}(\mathbf{C}^*) = \{\langle \mathbf{b}, y \rangle\}$ is then finite dimensional: indeed, as $\mathbf{C}$ is surjective, it follows that $\mathbf{C}^*$ is injective and $\dim \mathcal{R}(\mathbf{C}^*) = \dim \mathcal{X}_T^* = \dim \mathcal{X}_T \leq n$. The analyticity assumptions on $A(\cdot)$, $\mathbf{b}(\cdot)$ ensure that y and $\langle \mathbf{b}, y \rangle$ are real analytic on $[0, T]$. Hence, if $\langle \mathbf{b}, y \rangle = 0$ on any set $\mathcal{E}$ of positive measure, one must have $\langle \mathbf{b}, y \rangle \equiv 0$ on $[0, T]$. Thus, the map $\mathbf{L}_{\mathcal{E}} : \eta \mapsto \langle \mathbf{b}, y \rangle|_{\mathcal{E}} : \mathcal{X}_T^* \to \mathcal{R}(\mathbf{C}) \to \hat{\mathcal{W}}$ (where $\hat{\mathcal{W}}$ consists of the restrictions to $\mathcal{E}$ of functions in $\mathcal{R}(\mathbf{C}^*)$) is injective and so invertible. Since $\hat{\mathcal{W}}$ is finite dimensional, $[\mathbf{L}_{\mathcal{E}}]^{-1}$ is continuous, with $\hat{\mathcal{W}}$ normed as a subspace of $\mathcal{W} := L^1(\mathcal{E})$ (so $\mathcal{V} := L^\infty(0, T)$ is just $\mathcal{W}^*$), and (2.5) holds, giving (3.14) by Theorem 1. The conclusion is now immediate from Theorem 3. ∎

This argument seems new, even for the finite-dimensional case; we do note that it does not seem to be usefully related to the usual characterization of time-optimal controls as in the Pontryagin maximum principle.

4. Boundary control of the heat equation. In this section we return to consideration of (1.1) as an example of the abstract formulation of sections 2 and 3. Our principal new result is exact boundary nullcontrollability from measurable sets—more precisely, that $L^\infty(\mathcal{E}) \in \mathcal{NC}_{t,T}$ for any set $\mathcal{E}$ of positive measure in $[t, T]$. This is just (3.14)—one notes that $\mathcal{NC}_{t,T}$ and $\mathcal{NC}_{t,T}^r$ are equivalent here—so Theorem 3 then gives the desired bang-bang property for time-optimal boundary control of (1.1).

We will take $\mathcal{X}_t = \mathcal{X} := L^2(0, 1)$ for each $t \in [0, T]$ and will, e.g., take $\mathcal{U} = L^2(0, T)$, so $\mathcal{U}_{\mathcal{I}} = L^2(\mathcal{I})$ with the obvious interpretations of the $\mathbf{\Omega}$ operators by restriction. For this autonomous situation one has $\mathbf{E}_{r,t} = \mathbf{S}(t - r)$, where $\mathbf{S}(\cdot)$ is the semigroup on $L^2(0, 1)$ corresponding to (1.1) with homogeneous boundary conditions.

Then $\mathbf{C}_{s,t}$ is the control effect (so $\mathbf{C}_{s,t} : \varphi \mapsto u(t,\cdot)$, where u satisfies the first two lines of (1.1) with $u(s,\cdot) = 0$), and it is standard (cf., e.g., [10]) that each $\mathbf{C}_{s,t}$ is continuous, indeed compact, from $L^2(s,t)$ to $\mathcal{X} = L^2(0,1)$. (We note in passing that there is a well-known explicit representation for this control mapping associated with (1.1), using convolution with a fundamental solution, expressible in terms of a theta function; cf., e.g., [5, p. 171].) The identities (2.1), (2.2) are clear in this context. For this $\mathcal{U}$ there is no difficulty in defining $\mathbf{P}_s$, and the continuity condition (3.2) here follows a fortiori from the stronger fact that $\mathbf{P}_s \to \mathbf{P}_r$ (strongly on $\mathcal{U} = L^2(0,T)$) as $s \to r$.

To compute the adjoint maps $\mathbf{E}^*_{\bar{t},T}$, $\mathbf{C}^*_{\bar{t},T}$ we consider u satisfying (1.1) for $\bar{t} < t \le T$ with $u(\bar{t},\cdot) \equiv 0$ and y satisfying

$$\begin{aligned} &-y_t = y_{xx} \qquad (0 < t < T,\ 0 < x < 1),\\ &y(T,\cdot) = \eta \in \mathcal{X}^*_T = L^2(0,1),\\ &y(\cdot,0) \equiv 0 \equiv y(\cdot,1). \end{aligned} \tag{4.1}$$

A simple computation involving (1.1) with $u(\bar{t},\cdot) = 0$, (4.1), and an integration by parts gives the identity

$$\int_0^1 uy\,dx\Big|_{t=T} = \int_{\bar{t}}^T \varphi\,[y_x(\cdot,0)]\,dt,$$

and, since $u(T,\cdot) = \mathbf{C}_{\bar{t},T}\varphi$ here, this gives

$$\begin{aligned} \mathbf{C}^*_{\bar{t},T} :&\quad \mathcal{X}^*_T \to L^2(\bar{t},T) \subset L^2(0,T)\\ :&\quad \eta \longmapsto \psi := y_x(\cdot,0)\Big|_{[\bar{t},T]}. \end{aligned} \tag{4.2}$$

Even more simply, (4.1) gives

$$\mathbf{E}^*_{\bar{t},T} : \mathcal{X}^*_T \to \mathcal{X}^*_{\bar{t}} = L^2(0,1) : \eta \longmapsto y(\bar{t},\cdot). \tag{4.3}$$

It will be necessary to represent y in terms of the eigenfunctions and eigenvalues

$$\eta_k(x) := \sqrt{2}\sin\sqrt{\lambda_k}x, \qquad \lambda_k := k^2\pi^2, \tag{4.4}$$

so that

$$\eta = \sum_k c_k\eta_k \ \text{ gives } \ \begin{cases} y = \displaystyle\sum_k c_k e^{-\lambda_k(T-t)}\eta_k,\\ \psi = \displaystyle\sum_k \left[\sqrt{2\lambda_k}\,c_k\right] e^{-\lambda_k(T-t)}. \end{cases} \tag{4.5}$$

Our immediate observation is that

$$\eta \in \mathcal{D} := \text{ span}\,\{\eta_k\} \quad \Rightarrow \quad \mathbf{C}^*_{\bar{t},T}\eta = \psi \in \mathcal{M} = \mathcal{M}(\Lambda) := \text{ span}\,\{e^{-\lambda_k(T-t)}\},$$

where $\Lambda := \{\lambda_k : k = 1,2,\ldots\}$ with, looking to a somewhat more general setting, $0 < \lambda_1 < \lambda_2 < \cdots$ such that $\Sigma_k 1/\lambda_k$ is convergent, as is obviously the case here.

Our starting point will be an inequality

$$\|y(0,\cdot)\|_{L^2(0,1)} \le M_{\bar{t}}\|y_x(\cdot,0)\|_{L^2(0,\bar{t})} \tag{4.6}$$

for solutions of (4.1); it is sufficient to consider this only for $\eta \in \mathcal{D}$. We recognize this as (2.5), giving (2.3) by Theorem 1, corresponding to having $\mathcal{U}_{0,\bar{t}} \in \mathit{NC}_{0,\bar{t}}$, replacing T by $\bar{t}$ here. We will take this nullcontrollability as well known, but note that essentially this inequality (with time reversed and an interchange of Dirichlet and Neumann conditions) was the principal result of [11], with the nullcontrollability form given in [4]). From (4.6) with time reversed, one sees clearly the interpretation of (2.5) as asserting *well-posed observability*: predicting the terminal state from (boundary) observations without knowing the initial state.

Our major new resource is an inequality recently obtained by Borwein and Erdélyi; this is Theorem 5.6 of [2], but see also [1], [3].

THEOREM (BE). *Assume* $\Sigma_k 1/\lambda_k < \infty$, *etc. Then, for every* $q > 0$, $s > 0$, $\rho \in (0,1)$, *there is a constant* $c = c_q(s,\rho,\Lambda)$ *such that*

$$\text{for every set } \mathcal{A} \subset [\rho,1] \text{ with } \operatorname{meas} \mathcal{A} \geq s \text{ one has}$$

$$\|p\|_{L^\infty(0,\rho)} \leq c\|p\|_{L^q(\mathcal{A})} \tag{4.7}$$

$$\text{for every polynomial } p \in \mathcal{M}_0 = \mathcal{M}_0(\Lambda) := \{\Sigma_k a_k x^{\lambda_k}\}.$$

For our present purposes, we make the substitution $x = e^{-(T-t)}$ and set $\rho = e^{-(T-\bar{t})}$ so $t \in [0,\bar{t}]$, $[\bar{t},T]$, $\mathcal{E}$ correspond, respectively, to $x \in [e^{-T},\rho] \subset [0,\rho]$, $[\rho,1]$, $\mathcal{A}$ and $\mathcal{M}$ corresponds to $\mathcal{M}_0$. Noting that meas $\mathcal{A} \geq \rho \operatorname{meas} \mathcal{E}$ for $\mathcal{E} \subset [\bar{t},T]$, one easily sees that, specializing to $q = 1$, (4.7) gives just the inequality we will need

$$\|\tilde{\psi}\|_{L^2(0,\bar{t})} \leq \tilde{c}\|\tilde{\psi}\|_{L^1(\mathcal{E})} \qquad \text{for } \tilde{\psi} \in \mathcal{M} \tag{4.8}$$

with $\tilde{c} = \sqrt{\bar{t}}\, c_1(\rho \operatorname{meas} \mathcal{E}, \rho, \Lambda)$ for any set $\mathcal{E}$ of positive measure in $[\bar{t},T]$.

At this point we are in a position to state and prove our second principal result, on exact boundary nullcontrollability of the one-dimensional heat equation from arbitrary sets of positive measure.

THEOREM 5. *Let* $T > 0$ *and suppose that* $\mathcal{E} \subset [0,T]$ *has positive measure. Then there is a constant* K *such that*

for every $\omega_0 \in \mathcal{X} = L^2(0,1)$ *there is a control* φ *such that*

$|\varphi(t)| \leq K\|\omega_0\|_{\mathcal{X}}$ *for* $t \in \mathcal{E}$, $\qquad \varphi(t) = 0$ *for* $t \notin \mathcal{E}$,

and the solution u *of* (1.1), *using* φ, *has* $u(T,\cdot) = 0$.

Proof. This follows directly from the results we have already developed. Choose any $\bar{t} > 0$ such that $\hat{\mathcal{E}} \cap [\bar{t},T]$ has positive measure, set $\mathcal{W} := L^1(\hat{\mathcal{E}})$, and $\mathcal{V} := \mathcal{W}^* = L^\infty(\hat{\mathcal{E}})$. Consider $y(0,\cdot) = \mathbf{E}^*_{0,T}\eta$ and $\tilde{\psi} = \psi = \mathbf{C}^*_{0,T}\eta$ for $\eta \in \mathcal{D}$. Then (4.6) and (4.8) with $\mathcal{E}$ replaced by $\hat{\mathcal{E}}$ give $\|y(0,\cdot)\|_{L^2(0,1)} \leq M_{\bar{t}}\tilde{c}\|\psi\|_{L^1(\hat{\mathcal{E}})}$ or, equivalently,

$$\|\mathbf{E}^*_{0,T}\eta\|_{\mathcal{X}^*} \leq K_{\mathcal{V}}\|\mathbf{C}^*_{\mathcal{V}}\eta\|_{\mathcal{W}},$$

which we recognize as (2.5). The second part of Theorem 1 then gives $\mathcal{V} \in \mathit{NC}_{\bar{t},T}$ which, since $\hat{\mathcal{E}} \subset \mathcal{E}$ so $\mathcal{V} \hookrightarrow L^\infty(\mathcal{E})$, gives precisely the conclusion of the present theorem. ∎

COROLLARY 6. *The results of Theorem* 3 *apply to the time-optimality problem for* (1.1).

Proof. Theorem 5 just gives the hypothesis (3.14) in this context so Theorem 3 applies. ∎

The argument in Theorem 5 establishing that for each $\mathcal{E}$ in $[t,T]$ of positive measure one has $L^\infty(\mathcal{E})$ in NC^r and hence that Theorem 3 applies shows (cf. Theorem V 1.1 of [7]) that the vector measure

$$m : B[0,T] \to \mathcal{X}_T = L^2(0,1) : \mathcal{E} \mapsto C_{0,T}(\chi_{\mathcal{E}})$$

is a *Liapunov measure*; i.e., for each Borel set $\mathcal{F} \subset [0,T]$ of positive measure, the set $\{m(\mathcal{E}) : \mathcal{E} \subset \mathcal{F}\}$ is a convex, weakly compact subset of L^2. The control-theoretic implications of this property of m are discussed in Chapters V and IX of [7].

Remark 4.1. We remark that the bang-bang property for time-optimal controls is classical for the finite-dimensional case but has previously been shown in the context of boundary controls of the heat equation only with the imposition of a slackness condition on the target state: the control constraint has the form $|\varphi| \le M$, where it is to be known that the target is actually reachable (in *some* time) subject to $|\varphi| \le M'$ with the slackness consisting of asking that $M > M'$. Some years ago, when [12] appeared, we felt that this condition might be an artifact of the proof technique, and we attempted to demonstrate the bang-bang property without it, i.e., for arbitrary (reachable) targets. We failed at that time. The gap in our argument was the need for an estimate such as (4.7), and it is the recent availability of the result by Borwein and Erdélyi [1] which has enabled us now to return successfully to the problem at least for one dimension.

It should be noted that a newer proof of the bang-bang property was presented in Krabs's book [8], but this proof also imposes an auxiliary condition on the target state ω_T. The result, Theorem 2.4.13 of [8], is formulated in terms of a moment problem, so some translation is necessary for comparison. He requires that $\mathbf{c} \in W$, where $\mathbf{c} = (c_k)$ is the sequence of Fourier coefficients of the target u_* and the space W is such that this requirement is equivalent to asking that u_* is a limit—in the sense that differences are reachable by controls with L^∞-norm approaching zero—of targets of the special form $\tilde{u}(\varepsilon, \cdot)$ for $\varepsilon > 0$ and $\tilde{u}$ satisfying the equation $\tilde{u}_t = \tilde{u}_{xx}$ with control vanishing on $[T-\varepsilon, T]$. Certainly the special targets then have $\tilde{u}(\varepsilon, x) = 0$ at $x = 0, 1$, so this, in particular, will also be true in the limit, i.e., for the targets to which Krabs's Theorem 2.4.13 would apply. Krabs also provides Theorem 2.4.14, explicitly following ideas of [12], giving the conclusion with essentially the same slackness condition mentioned earlier; this condition certainly implies that $|\tilde{u}(0)| \le M' < M$. Thus, neither of these theorems would apply to use as target, e.g., the trivially reachable state obtained by taking $\varphi \equiv M$ on $[0, T_*]$. In comparison, we emphasize that we have imposed *no* requirement on the target to get the bang-bang property for a time-optimal control except as is implicit in the very existence of such a control.

The paper [12] considers the n-dimensional case (a bounded spatial region $\Omega \subset \mathbb{R}^n$ with control φ on $[0,T] \times \partial\Omega$) subject to a constraint of the form

$$|\varphi(t,x)| \le M \qquad \text{a.e. for } 0 \le t \le T,\ x \in \partial\Omega. \tag{4.9}$$

To use our present approach to prove the strong form of the bang-bang property, that $|\varphi^*| = M$ a.e. on $[0,T^*] \times \partial\Omega$, would require an n-dimensional form of Theorem 5, showing exact nullcontrollability with controls in $L^\infty(\mathcal{E})$, where $\mathcal{E}$ is now an arbitrary subset of positive measure in $[0,T^*] \times \partial\Omega$. This seems well out of reach by currently available ideas; indeed, even the nullcontrollability from a patch ($\mathcal{E} = [0,T^*] \times \mathcal{P}$ with $\mathcal{P} \subset \partial\Omega$ open but small) has only recently been demonstrated ([9], cf. [13]). On the other hand, it seems to be a tractable open problem to show the weaker bang-bang property that $\|\varphi^*(t,\cdot)\|_{L^\infty(\partial\Omega)} = M$ a.e. on $[0,T^*]$ by showing nullcontrollability from $L^\infty(\mathcal{E} \times \partial\Omega)$ with $\mathcal{E}$ of positive measure in $[0,T^*]$ as earlier.

Note that each of the results above obtains the bang-bang property by way of the adjoint characterization: $\varphi = \{M \text{ where } v_x \ge M; -M \text{ where } v_x \le -M\}$ for some solution v of the adjoint problem. A plausible conjecture is that the additional

restriction on the target state might be significant to ensure this characterization (so there might conceivably be examples for which this characterization fails in the absence of some such slackness condition; this could be a subject for future investigation), although we have seen that it is not necessary for the bang-bang property itself.

Remark 4.2. An essentially identical argument works if we replace the heat equation in (1.1) by

$$u_t = (pu_x)_x - qu \tag{4.10}$$

and/or replace the Dirichlet boundary conditions there by some alternative type of boundary control. For this case we let $\{\lambda_k, z_k\}$ be the eigenvalues and eigenfunctions of the Sturm–Liouville operator $\mathbf{A} : z \mapsto -(pz')' + qz$ whose (homogeneous) boundary conditions are those of the new form of boundary control.

Similarly, one could consider the problem with scalar control in the equation itself:

$$u_t = (pu_x)_x - qu + \varphi(t)b \tag{4.11}$$

for some specified $b(\cdot) \in \mathcal{X}$, using homogeneous boundary condition. In this connection one might note Henry's example [6] of a problem with time-optimal control not of bang-bang form, as in (4.10), but effectively considering version 1 of the time-optimality problem with time-dependent constraints, so it does not correspond to the situation we have analyzed.

Remark 4.3. We may consider the problem with a nonscalar control: $\boldsymbol{\varphi} = [\varphi_0, \varphi_1]$ so the boundary conditions in (1.1) are replaced by

$$u(\cdot, 0) = \varphi_1 \qquad u(\cdot, 1) = \varphi_2 \tag{4.12}$$

and in (1.3) we take $A(t) = \mathcal{K} \subset \mathbb{R}^2$, where $\mathcal{K}$ is a closed, bounded, convex set. Here we may distinguish two forms of the bang-bang property:

weak: *a.e. on* $[0, T^*]$ *one has* $\boldsymbol{\varphi}(t) \in \partial\mathcal{K}$,

strong: *a.e. on* $[0, T^*]$ *one has* $\boldsymbol{\varphi}(t)$ *an extreme point of* $\mathcal{K}$.

The weak form is immediate from the previous arguments: if there were $\mathcal{E} \subset [0, T]$ with positive measure for which $\boldsymbol{\varphi}$ remained in the interior, then we could obtain a contradiction as in the proof of Theorem 2, perturbing only the component φ_0 as there. For the strong form one needs a modification of this to avoid the possibility that $\boldsymbol{\varphi}$ might remain interior to some face within $\partial\mathcal{K}$ so that one must consider perturbations with a linear restriction: $\tilde{\varphi}(t) = \hat{\varphi}(t)\mathbf{c}$ for some nonzero $\mathbf{c} \in \mathbb{R}^2$. What would be needed then is the appropriate modification of the inequality (4.6), obtainable along similar lines.

To illustrate the situation, consider first $\mathcal{K} = [0, 1] \times [0, 1]$. Any case where $\boldsymbol{\varphi}$ is weakly optimal but not strongly optimal can be reduced to the following: for a set E of positive measure in $[\tau, T]$ and some $\varepsilon > 0$, one has $\varphi_1(t) \in (\varepsilon, 1-\varepsilon)$ with $\varphi_2(t) \in \{0, 1\}$ for all $t \in \mathcal{E}$. By selecting $\hat{\tau} > \tau$ but close, we can ensure that $\mathcal{E}' = E \cap [\tau, T]$ has positive measure and that the state $\omega'_{\hat{\tau}}$ produced at $\hat{\tau}$ by use of the modified controls $\varphi'_i(t) = \{\varphi_i(t)$ for $t < \tau$; $= 0$ for $t \in [\tau, \hat{\tau}]\}$ differs from the state $\omega_{\hat{\tau}}$ produced by the original $\boldsymbol{\varphi} = (\varphi_1, \varphi_2)$ by less than ε/K^r, i.e., $\|\omega'_{\hat{\tau}} - \omega_{\hat{\tau}}\| < \varepsilon/K^r$. Consequently, by modifying φ'_1 by v supported on $\mathcal{E}'$ and of sup norm$< \varepsilon$, we obtain, as in the proof of Theorem 2, that $(\varphi'_1 + v, \varphi'_2)$ attains the same target ω_T as $\boldsymbol{\varphi}$ yet with τ replaced by

the larger $\hat{\tau}$, contradicting the assumed optimality of τ. On the other hand, if we take $\mathcal{K} = \{(x, y) : x, y \geq 0,\ x + y \leq 1\}$, it is clear that such an argument is only available if one knows that pairs with $\varphi_1 + \varphi_2 = 0$ on $\mathcal{E}$ are available as nullcontrols for the state perturbation. Such "odd" control pairs only produce corresponding odd states and so can only compensate for odd state perturbations. Hence our argument cannot be expected to work in this setting, although we cannot on this basis conclude that the bang-bang property fails.

Similar considerations apply if one would generalize (4.11) to

$$u_t = (pu_x)_x - qu + \Sigma_j \varphi_j(t) b_j \tag{4.13}$$

with pointwise constraints imposed on the vector control $\boldsymbol{\varphi} = [\varphi_1, \ldots, \varphi_J]$.

Remark 4.4. There is little difficulty in generalizing the abstract Theorem 3 to treat state-dependent constraints. It is convenient to take a space $\boldsymbol{\mathcal{X}} = \{x(\cdot)\}$ of "controlled trajectories," where the state trajectory is defined by $x(t) := \mathbf{C}_{0,t}\varphi$ for $t \in [0, T]$, $\varphi \in \mathcal{U}$; we assume the topology imposed on $\boldsymbol{\mathcal{X}}$ is such that the linear map $\mathbf{X} : \varphi \mapsto x(\cdot) : \mathcal{U} \to \boldsymbol{\mathcal{X}}$ is continuous. By a state-dependent constraint we mean a set-valued function

$$(t, x) \longmapsto A(t, x) \subset \mathbb{R} \qquad \text{for } t \in [0, T], x \in \boldsymbol{\mathcal{X}}, \tag{4.14}$$

so the control restriction (1.3ii) becomes

$$\varphi \in \mathcal{A} := \{\varphi \in \mathcal{U} : \varphi(t) \in A(t, \mathbf{X}\varphi) \text{ a.e. on } [0, T]\}. \tag{4.15}$$

We continue to take $\mathcal{U} = L^p(0, T)$ and to assume (1.4), now also writing $a(t) = a(t, x)$, $b(t) = b(t, x)$; we will further assume that one has uniform bounds: $a \leq a(t, x) \leq b(t, x) \leq b$ for all $x \in \boldsymbol{\mathcal{X}}$. Finally, we need a mild continuity condition[1]

$$\begin{aligned} &\varphi_n \rightharpoonup \bar{\varphi} \textit{(weak convergence in } \mathcal{U}\textit{) with } (4.15) \textit{ for each } n \\ &\textit{implies} \qquad a(t, \mathbf{X}\bar{\varphi}) \leq \bar{\varphi}(t) \leq b(t, \mathbf{X}\bar{\varphi}) \textit{ a.e. on } [0, T]. \end{aligned} \tag{4.16}$$

We may then argue much as in the proof of Theorem 3. If φ_n is an optimizing sequence for the time-optimality problem given by (4.15), we have $\varphi_n \rightharpoonup \bar{\varphi}$, using our assumptions on $A(\cdot\cdot)$ and extracting a subsequence if necessary, so we may set $A_*(t) := [a(t, \mathbf{X}\bar{\varphi}), b(t, \mathbf{X}\bar{\varphi})]$ and have $\bar{\varphi}(t) \in A_*(t)$ a.e. on $[0, T]$. As in the proof of Theorem 3, we consider the time-optimality problem using A_* for $\mathcal{A}$ to obtain a (unique) time-optimal control $\hat{\varphi}$. As there, $\hat{\varphi}$ has the bang-bang property and so is also admissible for the original problem, whence the control times τ are the same and we can conclude that $\hat{\varphi} = \bar{\varphi}$ so that this is the unique time-optimal control for the original problem.

Acknowledgments. The first author wishes to express his appreciation to Peter Borwein for informing him of the recent results achieved by Borwein and Erdélyi in [1] and to Greg Knowles for very stimulating discussions on this topic several years ago.

[1]For example, it is not hard to see that (4.16) will hold if one can take $\boldsymbol{\mathcal{X}}$ compact in $C([0, T] \to \mathcal{X})$ and if, with $A(t) = A(t, x(t))$ so $A : [0, T] \times \mathcal{X} \to 2^{\mathbb{R}}$, one has

$$r_n \to \bar{r}, z_n \to \bar{z}, r_n \in A(t, z_n) \qquad \Rightarrow \qquad a(t, \bar{z}) \leq \bar{r} \leq b(t, \bar{z}).$$

$\mathcal{H}_\infty$ CONTROL AND ESTIMATION PROBLEMS WITH DELAYED MEASUREMENTS: STATE-SPACE SOLUTIONS*

KRISHAN M. NAGPAL† AND R. RAVI‡

Abstract. Most physical processes exhibit transport delay in the measured output, and it is well known that this can have disastrous effects on system stability and performance if it is not accounted for. In this paper, we give necessary and sufficient conditions for existence of estimators and controllers that achieve the desired $\mathcal{H}_\infty$ performance criterion when such a measurement delay is present. We also give the complete characterization of all controllers and estimators that achieve the desired performance criterion. The necessary and sufficient conditions are easy to check and are given in terms of the familiar pair of algebraic Riccati equations that appear in the nondelay versions of the corresponding $\mathcal{H}_\infty$ problems, along with an additional Riccati differential equation. Explicit state-space formulas for the controllers and estimators are also obtained. They have a linear periodic structure and are easily implementable. To obtain these results, we first obtain state-space results for a "modified" Nehari problem, which may be of independent interest (see Problem 5 in section 2).

1. Introduction.

The problem of controller and estimator design for finite-dimensional systems with the $\mathcal{H}_\infty$ performance criterion is by now fairly well understood (see, for example, [3] and [8] and the references therein). In several practical situations, one encounters systems whose models are distributed or infinite dimensional. Flexible beams or systems involving delay are examples of such systems. An interesting area of work in control has been the extension of finite-dimensional results to infinite-dimensional systems. The aim of the present paper is to provide state space solutions to several commonly encountered control and estimation problems for finite-dimensional linear systems when there is a delay present in the measurements. Our optimality criterion is the minimization of the $\mathcal{L}_2$-induced norm (or the $\mathcal{H}_\infty$ norm) and the approach is based on time domain techniques.

Some early results obtained for $\mathcal{H}_\infty$ control of certain classes of distributed plants using various operator-theoretic ideas are, for example, [4], [11], [10], [12], and [17]. These approaches are usually based on the commutant lifting methods or the skew Toeplitz theory. The approach we adopt here is time domain in nature and follows such recent approaches as [2], [13], [14], and [15]. Tadmor in [15] presents state-space solutions to the $\mathcal{H}_\infty$ problem for general linear system. However, because of the presence of delay, direct application of his results would involve Riccati equations that are in operator form and to which solutions may not be easy to compute. *Since the underlying system is finite dimensional, we have tried as much as possible to stick to finite-dimensional techniques in the paper and obtain solutions that would be*

similar and comparable with the solutions when there is no delay in the measurements. Consequently, our results show that the extra price one has to pay for tolerating the delay, as compared with the case where there is no delay, is the solution of an *additional* Riccati differential equation defined over the duration of the delay. The approach adopted here uses lifting ideas that have also been used for some sampled data control problems (see, for example, [1]). Some aspects of two of the problems considered here—namely, the problems of state feedback control and output feedback control with measurement delay—have also been addressed in [2] using game theory ideas. The problem of prediction with an $\mathcal{H}_\infty$ criterion has not been previously addressed in the literature. Crucial to the results outlined here are the results of a "modified" Nehari problem which may be of independent interest.

The paper is organized as follows. In section 2 we describe the problems considered in this paper, and the main results are given in section 3. Some preliminary results are presented in section 4, and section 5 contains the proofs of the main results. A summary and some concluding remarks are contained in section 6.

We end this introduction with some remarks on the notation. Let $\mathcal{R}$ denote the set of real numbers, $\mathcal{R}^n$ denote the n-dimensional Euclidean space (identified with $n \times 1$ vectors of real numbers), and $\mathcal{R}^{n\times m}$ be the set of all $n \times m$ real matrices. We will use A' (or v') to denote the transpose of the matrix A (or vector v) and $\rho(A) := \max_i |\lambda_i(A)|$ to denote the spectral radius. A square matrix A is called stable if all its eigenvalues are in the open left half plane. The following norms will be used: $\|\eta\| := (\sum_1^n |\eta_i|^2)^{1/2}$ for $\eta \in \mathcal{R}^n$; $\|z\|_{[a,b]} := (\int_a^b \|z(t)\|^2 dt)^{1/2}$, and $\langle z_1, z_2\rangle_{[a,b]}$ will denote the norm and the inner product in $\mathcal{L}_2^n[a,b]$. Whenever there is no ambiguity about the interval of interest, we ignore the subscript $[a,b]$ in the definition of the norm and the inner product. The map from w to z is denoted by T_{zw}, and its $\mathcal{L}_2$-induced norm is denoted as $\|T_{zw}\|$ and its adjoint as T_{zw}^*. The map T_{zw} is said to be causal if $z(t) = f(w(s)),\ 0 \le s \le t$, and anticausal if $z(t) = f(w(s)),\ s \ge t$. If T_{zw} admits a state-space representation as follows,

$$\begin{aligned} \dot{x} &= A(t)x + B(t)w, \\ z &= C(t)x + D(t)w, \end{aligned}$$

then we will use the following *packed matrix* abbreviation to describe T_{zw}:

$$T_{zw} = \left[\begin{array}{c|c} A & B \\ \hline C & D \end{array}\right].$$

We now briefly describe the notation used for lifting. Let $l_{\mathcal{L}_2[0,h]}$ be the space of sequences where each element is in $\mathcal{L}_2[0,h]$; i.e.,

$$l_{\mathcal{L}_2[0,h]} := \{\{q_i\} : q_i \in \mathcal{L}_2[0,h]\ \forall i \ge 0\},$$

with the norm defined as

$$\|\{q_i\}\| = \left[\sum_0^\infty \|q_i\|^2\right]^{\frac{1}{2}},$$

where $\|q_i\|$ is the $\mathcal{L}_2[0,h]$ norm of q_i. The lifting operation is defined as $W : \mathcal{L}_2[0,\infty) \to l_{\mathcal{L}_2[0,h]}$, where

$$\{q_i\} = Wq, \quad q_i(t) = q(ih+t) \ \text{ for } 0 \le t \le h. \tag{1}$$

The lifting map W can be visualized as breaking up a signal q defined for $t \geq 0$ into an infinite number of pieces where each piece is an identical copy of q restricted to an interval of length h. It is easily seen that W is a one-to-one, invertible isometry between $\mathcal{L}_2[0,\infty)$ and $l_{\mathcal{L}_2[0,h]}$. A map $\Theta : l_{\mathcal{L}_2[0,h]} \to l_{\mathcal{L}_2[0,h]}$ is called causal if $W^{-1}\Theta W : \mathcal{L}_2[0,\infty) \to \mathcal{L}_2[0,\infty)$ is causal.

2. Problem definitions. In this section we describe the problems that are addressed in this paper. The first four concern delay systems and the fifth one is a "modified" Nehari problem. In Problems 1 to 4, we will limit ourselves to finite-dimensional linear time-invariant systems. Because of the time-domain techniques employed in the proofs, most of the results are easily generalizable to linear time-varying systems as well. Some of the issues in Problem 1 have also been discussed in [17], and some aspects of Problems 2 and 4 also appear in [2].

Problem 1 (*the basic delay problem*). Given are a real number $h \geq 0$ (representing delay) and a finite-dimensional linear system G (not necessarily stable) with a realization as follows:

$$G \left\{ \begin{array}{rcl} \dot{x} & = & Ax + Bw,\ t \in [0,\infty),\ x(0) = 0, \\ z & = & Cx. \end{array} \right. \tag{2}$$

The estimate of $z(t)$ denoted by $\hat{z}(t)$ is generated by a causal operator $f(\cdot)$ that has available to it all $w(s)$ with $s \leq t - h$; i.e.,

$$\hat{z}(t) = f(w(s)),\ s \leq t - h.$$

The problem is then one of determining conditions for a causal operator $f(\cdot)$ to exist so that

$$\sup_w \frac{\|z - \hat{z}\|^2}{\|w\|^2} < 1.$$

Moreover, if the above problem is solvable, we would like to characterize all such causal operators $f(\cdot)$ that achieve the above performance bound.

(In the frequency domain terminology, if the system G is stable ($G \in \mathcal{H}_\infty$), the above problem is equivalent to determining conditions for existence of an operator $Q \in \mathcal{H}_\infty$ such that

$$\inf_{Q \in \mathcal{H}_\infty} \|G - Qe^{-hs}\| < 1,$$

and if such a system exists, to obtain the set of all such Q.)

Problem 2 (*full information control problem with delay*). Given are a real number $h \geq 0$ and a finite-dimensional linear time-invariant system G_{fi}:

$$G_{fi} \left\{ \begin{array}{rcl} \dot{x} & = & Ax + B_1 w + B_2 u,\ t \in [0,\infty),\ x(0) = 0, \\ z & = & C_1 x + D_{12} u, \\ y & = & \begin{pmatrix} x \\ w \end{pmatrix}. \end{array} \right. \tag{3}$$

We would like to determine conditions for a controller $f(\cdot)$ to exist such that with

$$u(t) = f(y(s)) \text{ with } s \leq t - h,$$

$\|T_{zw}\| < 1$ and the feedback system is internally stable. Note that the measurements y are available to the controller only after a time delay of h units. Again, we seek a parameterization of all controllers $f(\cdot)$ that achieve $\|T_{zw}\| < 1$.

Problem 3 (*prediction problem*). Given are a real number $h \geq 0$ and a finite-dimensional linear time-invariant system G_p:

$$G_p \begin{cases} \dot{x} &= Ax + B_1 w,\ t \in [0,\infty),\ x(0) = 0, \\ z &= C_1 x, \\ y &= C_2 x + D_{21} w. \end{cases} \tag{4}$$

We would like to determine conditions under which we can construct an estimator for z to achieve a desired $\mathcal{H}_\infty$ bound, given measurements delayed by h time units. In other words we would like to find a function $f(\cdot)$ so that with

$$\hat{z}(t) = f(y(s)),\ s \leq t - h,$$

$\|T_{ew}\| < 1$, where $e := z - \hat{z}$ is the estimation error. We also seek to parameterize the set of all predictors $f(\cdot)$ that achieve $\|T_{ew}\| < 1$.

Problem 4 (*output feedback control problem with delay*). Given are a real number $h \geq 0$ and a finite-dimensional linear time-invariant system G_{of}:

$$G_{of} \begin{cases} \dot{x} &= Ax + B_1 w + B_2 u,\ t \in [0,\infty),\ x(0) = 0, \\ z &= C_1 x + D_{12} u, \\ y &= C_2 x + D_{21} w. \end{cases} \tag{5}$$

We would like to determine conditions for a controller $f(\cdot)$ to exist so that with

$$u(t) = f(y(s)) \text{ with } s \leq t - h,$$

$\|T_{zw}\| < 1$ and the feedback system is internally stable. Again, we seek a parameterization of all $f(\cdot)$ that achieve this performance bound.

Problem 5 (*modified Nehari problem*). Given are the following two finite-dimensional linear (possibly time-varying) *anti-causal systems* $\Sigma_1 : w_1 \to y_1$ and $\Sigma_2 : w_2 \to y_2$:

$$\Sigma_1 \begin{cases} \dot{x}_1 &= F_1 x_1 + G_1 w_1,\ t \in [0,T],\ x_1(T) = 0, \\ y_1 &= H_1 x_1; \end{cases} \tag{6}$$

$$\Sigma_2 \begin{cases} \dot{x}_2 &= F_2 x_2 + G_2 w_2,\ t \in [0,T],\ x_2(T) = 0, \\ y_2 &= H_2 x_2 + w_2. \end{cases} \tag{7}$$

We would like to determine conditions for a *causal function* $f(\cdot)$ to exist so that with

$$\hat{y}_1(t) = f(w(s)) \text{ with } 0 \leq s \leq t$$

the following holds:

$$\sup_{w_1} \frac{\|\Sigma_2(\Sigma_1 w_1 - \hat{y}_1)\|^2}{\|w_1\|^2} < 1.$$

Again, we seek a parameterization of all $f(\cdot)$ that achieve this performance bound.

The last problem described above reduces to the standard (finite-horizon version) Nehari problem when $\Sigma_2 = I$, where I is the identity operator. State-space results for the standard Nehari problem have been obtained for both time-invariant and time-varying systems by various authors (see, for example, [6] and [16]). Problem 5 stated above can be viewed as a generalization of the standard Nehari problem because it allows one to also include a "weighting filter" Σ_2. The results that we obtain can be easily generalized to the infinite-horizon version of the above problem, but we consider the finite-horizon version simply because of its relevance to the first four delay problems presented in this section.

3. Main results. We will first present the results of the modified Nehari problem since the results of the other problems rely quite critically on its solution.

THEOREM 3.1. *Given are two anticausal linear systems Σ_1 and Σ_2 as described in equations* (6) *and* (7). *There exists a causal system $f(\cdot)$ such that with $\hat{y}_1(t) = f(w(s))$, where $0 \le s \le t$,*

$$\sup_{w_1} \frac{\|\Sigma_2(\Sigma_1 w_1 - \hat{y}_1)\|^2}{\|w_1\|^2} < 1$$

if and only if

$$\lambda_{max}(P(t)Q(t)) < 1 \quad \forall t \in [0,T],$$

where λ_{max} denotes the largest eigenvalue and

$$\begin{aligned} -\dot{Q} &= \bar{F}'Q + Q\bar{F} - \bar{H}'\bar{H}, \quad Q(0) = 0, \\ \dot{P}_1 &= F_1P_1 + P_1F_1' - G_1G_1', \quad P_1(T) = 0, \\ \dot{P}_2 &= (F_2 - G_2H_2)P_2 + P_2(F_2 - G_2H_2)' - G_2G_2', \quad P_2(T) = 0, \\ P &= \begin{bmatrix} P_1 & 0 \\ 0 & -P_2 \end{bmatrix}, \end{aligned} \tag{8}$$

where $\bar{F}$ and $\bar{H}$ are defined as

$$\bar{F} = \begin{bmatrix} F_1 & 0 \\ G_2H_1 & F_2 \end{bmatrix}, \qquad \bar{H} = \begin{bmatrix} H_1 & H_2 \end{bmatrix}.$$

Moreover, if $\lambda_{max}(P(t)Q(t)) < 1$ then the set of all causal operators $f : w_1 \to \hat{y}_1$ that achieve the desired bound are given by

$$\begin{aligned} \dot{q} &= -(\tilde{F}' + N(t)Q(t)\tilde{G}_1\tilde{G}_1')q + N(t)Q(t)\tilde{G}_1w_1 - N(t)[\bar{H}' - Q(t)\tilde{G}_2]v, \ q(0) = 0, \\ \hat{y}_1(t) &= -[\bar{H}P(t) - \tilde{G}_2']q - v, \\ \eta(t) &= w_1(t) - \tilde{G}_1'q, \\ v(t) &= \Theta\eta, \ \textit{where } \Theta \textit{ is causal, and } \|\Theta\| < 1, \end{aligned} \tag{9}$$

where

$$\tilde{F} = \begin{bmatrix} F_1 & 0 \\ 0 & F_2 - G_2H_2 \end{bmatrix}, \ \tilde{G}_1 = \begin{bmatrix} G_1 \\ 0 \end{bmatrix}, \ \tilde{G}_2 = \begin{bmatrix} 0 \\ G_2 \end{bmatrix}, \quad N(t) = (I - Q(t)P(t))^{-1}.$$

For convenience in describing the results of the other problems, we will use the following notation to describe the system given in (9):

$$\mathcal{N}^1_{[\Sigma_1,\Sigma_2,T,\Theta]} : w_1 \to \hat{y}_1 := \text{ the corresponding map described by (9)}, \tag{10}$$

$$\mathcal{N}^2_{[\Sigma_1,\Sigma_2,T,\Theta]} : w_1 \to \eta := \text{ the corresponding map described by (9)}. \tag{11}$$

The next theorem gives the result for the basic delay problem or Problem 1 of the previous section. Before presenting the result, we will describe some notation that appears in the statement of the next theorem. Let $X(t)$ be the solution to the Riccati

differential equation defined in (22). Also, let $\Psi(\cdot,\cdot)$ denote the transition matrix of $A + BB'X$, and let $\bar{B}(\tau)$ be defined as follows:

(12)
$$\frac{d\Psi(\tau,s)}{d\tau} = (A + BB'X(\tau))\Psi(\tau,s), \quad \Psi(s,s) = I, \quad \bar{B}(\tau) = e^{A\tau}\Psi(h,\tau)B \text{ for } \tau \in [0,h].$$

Let $S(t)$ be the solution of the following Riccati equation defined over the interval $[0,h]$:

$$-\dot{S} = -(A + BB'X)S - S(A + BB'X)' - SC'CS + BB', \quad S(0) = 0. \tag{13}$$

We now define four operators from $\mathcal{L}_2[0,h]$ to $\mathcal{L}_2[0,h]$, where G_0 and G_2 are causal while G_1 and G_3 are anticausal. With the notation $G_i : f \to g$ for $0 \le i \le 3$, the state-space realizations of these systems are

$$G_0 \left\{ \begin{array}{rcl} \dot{x}_0(\tau) &=& Ax_0(\tau) + Bf(\tau),\ \tau \in [0,h],\ x_0(0) = 0, \\ g(\tau) &=& f(\tau) - B'X(\tau)x_0(\tau); \end{array} \right. \tag{14}$$

$$G_1 \left\{ \begin{array}{rcl} \dot{x}_1(\tau) &=& Ax_1(\tau) + \bar{B}(\tau)f(\tau),\ \tau \in [0,h],\ x_1(h) = 0, \\ g(\tau) &=& -Cx_1(\tau); \end{array} \right. \tag{15}$$

$$G_2 \left\{ \begin{array}{rcl} \dot{x}_2(\tau) &=& (A + BB'X(\tau))x_2(\tau) + Bf(\tau),\ \tau \in [0,h],\ x_2(0) = 0, \\ g(\tau) &=& Cx_2(\tau); \end{array} \right. \tag{16}$$

$$G_3 \left\{ \begin{array}{rcl} \dot{x}_3(\tau) &=& -(A + BB'X(\tau))'x_3 - C'f(\tau),\ \tau \in [0,h],\ x_3(h) = 0, \\ g(\tau) &=& -CS(\tau)x_3(\tau) + f(\tau). \end{array} \right. \tag{17}$$

Let $\{w_i\}, \{r_i\}, \{z_{1i}\}, \{z_{2i}\} \in l_{\mathcal{L}_2[0,h]}$ be defined as follows (recall that W is the lifting operator defined in (1)):

$$\{w_i\} = Ww, \tag{18}$$

$$r_i = G_0 w_i, \quad i \ge 0, \tag{19}$$

$$z_{10} = 0, \quad z_{1i} = G_1 r_{i-1} \text{ for } i \ge 1, \tag{20}$$

$$z_{20} = 0, \quad z_{2i} = G_2 r_i \text{ for } i \ge 1, \tag{21}$$

where the systems G_0, G_1, and G_2 are as defined in (14), (15), and (16). Also define

$$\tilde{F}_d(t) := \begin{bmatrix} A & 0 \\ 0 & -(A + BB'X(t))' - C'CS(t) \end{bmatrix}, \quad \tilde{G}_{1d}(t) := \begin{bmatrix} \bar{B}(t) \\ 0 \end{bmatrix},$$

$$\tilde{G}_{2d} := \begin{bmatrix} 0 \\ -C' \end{bmatrix}, \quad t \in [0,h];$$

$$\bar{F}_d(t) = \begin{bmatrix} A & 0 \\ C'C & -(A + BB'X(t))' \end{bmatrix}, \ \bar{H}_d(t) = -\begin{bmatrix} C & CS(t) \end{bmatrix}, \quad t \in [0,h].$$

$$\begin{array}{rcl} -\dot{Q}_d(t) &=& \bar{F}_d'(t)Q(t) + Q(t)\bar{F}_d(t) - \bar{H}_d'(t)\bar{H}_d(t), \quad t \in [0,h],\ Q_d(0) = 0, \\ \dot{P}_{1d}(t) &=& AP_1(t) + P_1(t)A' - \bar{B}'(t)\bar{B}(t), \quad t \in [0,h],\ P_{1d}(h) = 0, \\ \dot{P}_{2d} &=& -(A' + X(t)BB' + C'CS(t))P_{2d}(t) - P_{2d}(t)(A' + X(t)BB' + C'CS(t))' \\ && -C'C, \quad t \in [0,h],\ P_{2d}(h) = 0, \\ P_d(t) &=& \begin{bmatrix} P_{1d} & 0 \\ 0 & -P_{2d} \end{bmatrix}, \\ N_d(t) &=& (I - Q_d(t)P_d(t))^{-1}, \quad t \in [0,h]. \end{array}$$

We now present the main result for the basic delay problem.

THEOREM 3.2. *Given are a causal linear system G described by equation* (2) *and a positive real number h representing the delay. There exists a causal system $f(\cdot)$ such that with*

$$\hat{z}(t) = f(w(s)), \quad 0 \le s \le t-h,$$

the following holds:

$$\sup_w \frac{\|z-\hat{z}\|^2}{\|w\|^2} < 1$$

if and only if there exists a matrix function $X(t)$ for $t \in [0,h]$ that satisfies the following (Riccati) differential equation:

$$-\dot{X} = A'X + XA + XBB'X + C'C, \quad X(h) = 0. \tag{22}$$

Moreover, if the above condition holds, then the set of all $f : w \to \hat{z}$ that achieve the desired performance is of the form

$$\begin{aligned} \hat{z}(t) &= 0, \quad 0 \le t \le h, \\ \hat{z}(ih+t) &= C\{e^{A(t+h)}x((i-1)h) + e^{At}\textstyle\int_0^t \Psi(h,s)Br_{i-1}(s)ds\} + \hat{\hat{z}}_i(t), \\ &\quad 0 \le t \le h, \ i \ge 1, \end{aligned} \tag{23}$$

where r_i and $\Psi(\cdot,\cdot)$ are defined in the equations (19) *and* (12)*, respectively, and $\hat{\hat{z}}_i \in l_{\mathcal{L}_2[0,h]}$ is obtained as follows:*

$$\begin{aligned} w_{10} &= r_0; \quad w_{1i} = r_i - G_2^*(z_{1i} - \hat{\hat{z}}_i) \ \text{ for } i \ge 1, \\ \dot{q}_i(t) &= -[\tilde{F}_d' + N_d(t)Q_d(t)\tilde{G}_{1d}(t)\tilde{G}_{1d}'(t)]q_i(t) + N_d(t)Q_d(t)\tilde{G}_{1d}(t)w_{1i}(t) \\ &\quad -N_d(t)[\bar{H}_d'(t) - Q_d(t)\tilde{G}_{2d}]v_i(t), \quad q_i(0) = 0, \ t \in [0,h], \ i \ge 0, \\ \hat{y}_{i+1}(t) &= -[\bar{H}_d P_d(t) - \tilde{G}_{2d}']q_i(t) - v_i(t), \quad t \in [0,h], \ i \ge 0, \\ \eta_i(t) &= w_{1i}(t) - \tilde{G}_{1d}'q_i(t), \ t \in [0,h], \quad i \ge 0, \\ \{v_i\} &= \Theta\{\eta_i\}, \ \text{where } \Theta \text{ is causal and } \|\Theta\| < 1, \\ \hat{\hat{z}}_0 &= 0, \quad \hat{\hat{z}}_{i+1}(t) = (G_1G_2^*(z_{1i} - \hat{\hat{z}}_i))(t) + \hat{y}_{i+1}(t), \quad t \in [0,h], \ i \ge 0. \end{aligned} \tag{24}$$

Remark 1. To emphasize the connection between the above result and the modified Nehari problem and for the reader's convenience, the above equations are also summarized below:

$$\begin{aligned} \{w_i\} &= Ww, \\ r_i &= G_0 w_i, \quad i \ge 0, \\ z_{10} &= 0, \quad z_{1i} = G_1 r_{i-1} \text{ for } i \ge 1, \\ w_{10} &= 0, w_{1i} = r_i - G_2^*(z_{1i} - \hat{\hat{z}}_i), \\ \hat{y}_{i+1} &= \mathcal{N}^1_{[G_1,G_3,h,\Theta]}(w_{1i}), \quad i \ge 0, \\ \eta_i &= \mathcal{N}^2_{[G_1,G_3,h,\Theta]} : (w_{1i}), \quad i \ge 0, \\ \hat{\hat{z}}_0 &= 0, \quad \hat{\hat{z}}_{i+1} = \hat{y}_{i+1} + G_1G_2^*(z_{1i} - \hat{\hat{z}}_i), \quad i \ge 0, \\ \hat{z}(ih+t) &= C\{e^{A(t+h)}x((i-1)h) + e^{At}\textstyle\int_0^t \Psi(h,s)Br_{i-1}(s)ds\} + \hat{\hat{z}}_i(t), \\ &\quad 0 \le t \le h, \ i \ge 1, \end{aligned}$$

where the maps $\mathcal{N}^1$ and $\mathcal{N}^2$ are as defined in (10) and (11).

For convenience in describing the results of Problems 2 through 5, we will use the following notation to characterize the set $\Omega : w \to \hat{z}$ of all admissible functions that solve the basic delay problem (Problem 1) described in the Theorem 3.2; i.e.,

(25)
$$\mathcal{D}_{[A,B,C,h]} := \{\Omega : \text{ where } \Omega : w \to \hat{z} \text{ admits a realization of the form given by (23) and (24)}\}.$$

For the full information control problem, we will make the following standard assumptions:

A1: (A, B_1, C_1) is stabilizable and detectable; (A, B_2) is stabilizable;
A2: $D_{12}'[C_1 \ D_{12}] = [0 \ I]$.

THEOREM 3.3. *For the linear system G_{fi} with a realization as described in (3), there exists a controller $f(\cdot)$ so that with $u(t) = f(y(s))$, $0 \le s \le t - h$, the feedback system is internally stable and*

$$\sup_w \frac{\|z\|^2}{\|w\|^2} < 1$$

if and only if the following conditions hold.

(1) *There exists a positive semidefinite matrix $X \ge 0$ that is a stabilizing solution of the following algebraic Riccati equation:*

$$A'X + XA + X(B_1B_1' - B_2B_2')X + C_1'C_1 = 0. \tag{26}$$

(2) *There exists a positive semidefinite matrix function $S_1(t)$ for $t \in [0, h]$ that satisfies the following Riccati equation:*

(27)
$$-\dot{S}_1 = (A + B_1B_1'X)'S_1 + S_1(A + B_1B_1'X) + S_1B_1B_1'S_1 + XB_2B_2'X, \quad S_1(h) = 0.$$

If the above conditions hold, then the set of all controllers that achieve the desired performance can be represented as

$$u(t) = 0, \quad t \in [0, h),$$

$$u(t) = -B_2'Xx_2(t) + (\Omega \ w)(t), \quad t \ge h,$$

where $\Omega \in \mathcal{D}_{[A+B_1B_1'X, B_1, -B_2'X, h]}$ (where this set is as defined in (25)) and x_2 is obtained as follows:

$$\dot{x}_2 = (A + B_1B_1'X)x_2 + B_2u, \quad x_2(0) = 0.$$

Remark 2. Condition 2 of the above theorem can equivalently be written as follows: there exists positive semidefinite matrix function $Q(t)$ defined over $[0, h]$ that satisfies

$$-\dot{Q} = A'Q + QA + QB_1B_1'Q + C_1'C_1, \ Q(h) = X.$$

This is easily verified by noting that $Q(t) := S_1(t) + X$ satisfies the above equation.

Next we turn to the prediction problem, for which we will make the following assumptions:

A3: (A, B_1, C_1) is stabilizable and detectable; (A, C_2) is detectable;
A4: $D_{21}[B_1' \ D_{21}'] = [0 \ I]$.

THEOREM 3.4. *Given the linear system G_p described in* (4)*, there exists a predictor $\hat{z}(t) = f(y(s))$ with $0 \le s \le t-h$ that achieves*

$$\sup_w \frac{\|z-\hat{z}\|^2}{\|w\|^2} < 1$$

if and only if the following conditions hold.

(1) *There exists a positive semidefinite matrix $Y \ge 0$ that is a stabilizing solution of the following algebraic Riccati equation:*

$$AY + YA' + Y(C_1'C_1 - C_2'C_2)Y + B_1B_1' = 0. \tag{28}$$

(2) *There exists a positive semidefinite matrix function $S_2(t)$ for $t \in [0,h]$ that satisfies the following Riccati equation:*

$$-\dot{S}_2 = (A + YC_1'C_1)'S_2 + S_2(A + YC_1'C_1) + S_2YC_2'C_2Y_2S_2 + C_1'C_1, \quad S_2(h) = 0. \tag{29}$$

Let p be defined as an output of the following system:

$$\begin{aligned} \dot{x}_1 &= (A + YC_1'C_1 - YC_2'C_2)x_1 + YC_2'y - YC_1'\hat{z}, \quad x_1(0) = 0, \\ p &= -C_2x_1 + y. \end{aligned}$$

Then the set of all predictors that achieve the desired performance can be represented as

$$\hat{z}(t) = 0, \quad t \in [0,h),$$
$$\hat{z}(t) = C_1x_2(t) - (\Omega\ p)(t), \quad t \ge h,$$

where $\Omega \in \mathcal{D}_{[(A+YC_1'C_1),YC_2',-C_1,h]}$ (where this set is as defined in (25)*) and x_2 is obtained as follows:*

$$\dot{x}_2 = (A + YC_1'C_1)x_2 - YC_1'\hat{z}, \quad x_2(0) = 0.$$

For the output feedback control problem with delay, we will make the following assumptions:

A5: (A, B_1, C_1) and (A, B_2, C_2) are stabilizable and detectable,
A6: $D_{21}[B_1'\ D_{21}'] = [0\ I]$,
A7: $D_{12}'[C_1\ D_{12}] = [0\ I]$.

THEOREM 3.5. *For the linear system G_{of} described in* (5)*, there exists a controller $f(\cdot)$ so that with $u(t) = f(y(s)), 0 \le s \le t-h$, the feedback system is internally stable and*

$$\sup_w \frac{\|z\|^2}{\|w\|^2} < 1$$

if and only if the following conditions hold.

(1) *There exists a positive semidefinite matrix $X \ge 0$ that is a stabilizing solution of the following algebraic Riccati equation:*

$$A'X + XA + X(B_1B_1' - B_2B_2')X + C'C = 0. \tag{30}$$

(2) *There exists a positive semidefinite matrix $Y \ge 0$ that is a stabilizing solution of the following algebraic Riccati equation:*

$$AY + YA' + Y(C_1'C_1 - C_2'C_2)Y + B_1B_1' = 0. \tag{31}$$

(3)

$$\rho(YX) < 1. \tag{32}$$

(4) *With Z defined as $Z := X(I - YX)^{-1}$, there exists a positive semidefinite matrix function $S_3(t)$ for $t \in [0, h]$ that satisfies the following Riccati equation:*

$$\begin{aligned} -\dot{S}_3 &= (A + YC_1'C_1 + YC_2C_2'YZ)'S_3 + S_3(A + YC_1'C_1 + YC_2C_2'YZ) \\ &\quad + S_3YC_2'C_2YS_3 + ZB_2B_2'Z, \quad S_3(h) = 0. \end{aligned} \tag{33}$$

Let r be defined as an output of the following system

$$\begin{aligned} \dot{x}_1 &= (A + YC_1'C_1 - YC_2C_2')x_1 + YC_2'y + B_2u, \quad x_1(0) = 0, \\ r &= -C_2(I + YZ)x_1 + y. \end{aligned}$$

Then the set of all controllers that achieve the desired performance can be represented as

$$u(t) = 0, \quad t \in [0, h),$$

$$u(t) = -B_2'Zx_2(t) + (\Omega r)(t), \quad t \geq h,$$

where $\Omega \in \mathcal{D}_{[(A+YC_1'C_1+YC_2C_2'YZ),YC_2',-B_2'Z,h]}$ (where this set is as defined in (25)*) and x_2 is given by*

$$\dot{x}_2 = (A + YC_1'C_1 + YC_2C_2'YZ)x_2 + B_2u, \quad x_2(0) = 0.$$

Remark 3. Condition 4 of the necessity in the above equation is equivalent to the existence of positive semidefinite matrix function $Q(t)$ defined over $[0, h]$ that satisfies

$$-\dot{Q} = A'Q + QA + QB_1B_1'Q + C_1'C_1, \; Q(h) = X$$

with an additional spectral radius condition of $\rho(YQ(0)) < 1$.

4. Preliminary results. In this section we present some preliminary results that will be used in the proofs of the main results considered here. All the results that are well known in the literature are presented without proofs.

LEMMA 4.1. *Define $P(t)$ to be the solution of*

$$\dot{P} = AP + PA' + BB', \quad P(0) = 0. \tag{34}$$

If (A, B) is controllable, then for the system described in equation (2)

$$\inf_w \left\{ \|w\|^2_{[0,\tau]} : x(0) = 0, x(\tau) = x_\tau \right\} = x_\tau' P(\tau)^{-1} x_\tau. \tag{35}$$

When (A, B) is not controllable, the statement of the above lemma is still valid for all x_τ that are reachable with the given initial condition with $P(\tau)^{-1}$ replaced by the pseudoinverse of $P(\tau)$. The following lemma follows from the standard factorization results for finite horizon linear regulator theory, but for completeness we give a brief proof for it.

LEMMA 4.2. *Let G_2 and G_3 be the systems defined in* (16) *and* (17)*, respectively. Then,*

$$I + G_2G_2^* = G_3^*G_3.$$

Proof. The system $G_2^* : f_a \to g_a$, the adjoint of the system G_2, has a state-space realization

$$\begin{aligned} \dot{x}_{2a}(\tau) &= -(A + BB'X(\tau))'x_{2a}(\tau) - C'f_a(\tau),\ \tau \in [0,h],\ x_{2a}(h) = 0, \\ g_a(\tau) &= B'x_{2a}(\tau). \end{aligned}$$

If S satisfies the differential equation described in (13), then it is easily verified that

$$\frac{d}{dt}(x'_{2a}(t)S(t)x_{2a}(t)) = -x'_{2a}(t)BB'x_{2a}(t) - f'_a(t)f_a + [f_a - CS(t)x_{2a}(t)]'[f_a - CS(t)x_{2a}(t)].$$

Integrating the above from 0 to h and noting that the boundary conditions drop out because of the boundary conditions on S and x_a, one obtains

$$\|f_a\|^2_{[0,h]} + \|g_a\|^2_{[0,h]} = \|f_a - CSx_{2a}\|^2_{[0,h]}.$$

Thus, for any $f_a \in \mathcal{L}_2[0,h]$,

$$\langle (I + G_2G_2^*)f_a, f_a\rangle_{[0,h]} = \|f_a\|^2_{[0,h]} + \|g_a\|^2_{[0,h]} = \|f_a - CSx_{2a}\|^2_{[0,h]} = \|G_3f_a\|^2_{[0,h]} \qquad \square$$

The next lemma is the so-called Redheffer's lemma [3, Lemma 15] and plays a crucial role in several $\mathcal{H}_\infty$ optimization problems. Most of the subsequent results are from [3] (or easily obtained from the results therein), where they are proven for finite-dimensional linear time-invariant systems. However, they can be generalized to infinite-dimensional systems, as for example in [15].

LEMMA 4.3. *Let P be a system partitioned as*

$$P = \begin{bmatrix} P_{11} & P_{12} \\ P_{21} & P_{22} \end{bmatrix},$$

and let Q be another system connected to P as in Figure 1. *Suppose that P has an exponentially stable realization and that Q is any linear operator. In addition, suppose that the closed loop system is also stabilizable and detectable (from w and z, respectively). Let P be isometric (i.e., $\|w\|^2 + \|v\|^2 = \|z\|^2 + \|r\|^2\ \forall v, w \in \mathcal{L}_2$), and let P_{21}^{-1} exist and be stable. Then the closed loop system is exponentially stable and $||T_{zw}|| < 1$ if and only if Q is exponentially stable and $||Q|| < 1$, where T_{zw} is the closed loop input-output operator mapping w to z.*

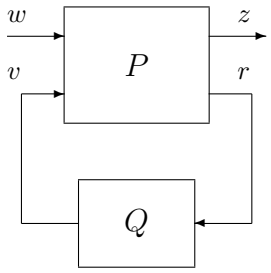

FIG. 1.

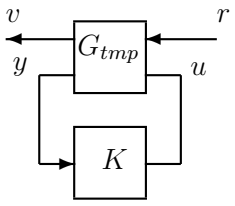
The next result introduces a transformation that is by now standard in this field (see for example [3, Lemma 9]).

LEMMA 4.4. *Let assumptions* A1–A2 *hold and suppose that X as defined in* (26) *exists. A controller K stabilizes G_{of} defined in* (5) *and achieves $\|T_{zw}\| < 1$ if and*

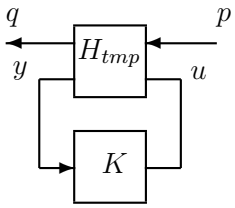


$$G_{tmp} \sim \left[\begin{array}{c|cc} A + B_1 B_1' X & B_1 & B_2 \\ \hline B_2' X & 0 & I \\ C_2 & D_{21} & 0 \end{array}\right]$$

FIG. 2.

only if K stabilizes the system G_{tmp} and achieves $\|T_{vr}\| < 1$ for the system G_{tmp} described in Figure 2.

The next result that we will state requires an additional auxiliary system, H_{tmp}, which we interconnect with a controller K as in Figure 3. This result is the dual of Lemma 9 in [3] or, equivalently, the dual of the lemma stated above.



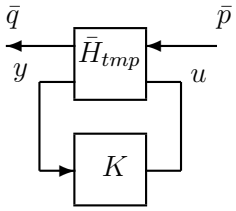
$$H_{tmp} \sim \left[\begin{array}{c|cc} A + Y C_1' C_1 & Y C_2' & B_2 \\ \hline C_1 & 0 & D_{12} \\ C_2 & I & 0 \end{array}\right]$$

FIG. 3.

LEMMA 4.5. *Let assumptions* A5–A7 *hold and suppose that Y as defined in* (31) *exists. A controller K stabilizes the system G_{of} defined in* (5) *and achieves $\|T_{zw}\| < 1$ if and only if K stabilizes H_{tmp} and achieves $\|T_{qp}\| < 1$ for the system H_{tmp}.*

The next result is obtained by combining the previous two lemmas. Even though its proof is straightforward, we provide a brief sketch of it since this transformation is not often used in the literature (a closely related observation appears in the work of Tadmor [15, Proposition 3.5.1]).

LEMMA 4.6. *Let assumptions* A5–A7 *hold. Let X and Y satisfy equations* (30), (31), *and* (32), *and let $Z := X(I - YX)^{-1}$. A controller K internally stabilizes the system G_{of} defined in* (5) *and achieves $\|T_{zw}\| < 1$ if and only if K stabilizes $\bar{H}_{tmp}$ (as defined in Figure* 4) *and achieves $\|T_{\bar{q}\bar{p}}\| < 1$.*



$$\bar{H}_{tmp} \sim \left[\begin{array}{c|cc} A + Y C_1' C_1 + Y C_2' C_2 Y Z & Y C_2' & B_2 \\ \hline B_2' Z & 0 & I \\ C_2(I + YZ) & I & 0 \end{array}\right]$$

FIG. 4.

Proof. It can be easily verified that if X and Y satisfy the given conditions, then $Z := X(I - YX)^{-1}$ is positive semidefinite and satisfies the algebraic Riccati equation

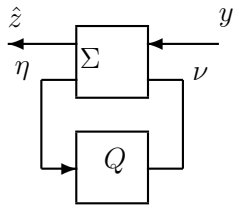
$$(A + Y C_1' C_1)' Z + Z(A + Y C_1' C_1) + Z(Y C_2' C_2 Y - B_2 B_2') Z + C_1' C_1 = 0,$$

where $A + Y C_1' C_1 + (Y C_2' C_2 Y - B_2 B_2') Z$ is stable. From Lemma 4.5, a controller

K solves the $\mathcal{H}_\infty$ control problem for the system G_{of} defined in (5) if and only if K stabilizes H_{tmp} and achieves $\|T_{qp}\|_\infty < 1$. Now treating the system H_{tmp} as the system G_{of} and applying the Lemma 4.4 to it, one obtains the above Lemma 4.6. □

The following result is from [5] and gives a parameterization of all causal estimators that achieve $\|T_{ew}\| < 1$ for the estimation problem.

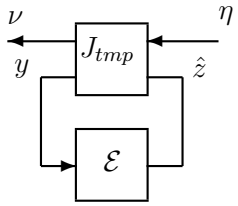
LEMMA 4.7. *Let assumptions* A3, A4 *hold and let* Y *satisfy* (28). *Any causal estimator* $\mathcal{E} : y \to \hat{z}$ *that solves the estimation problem for the system* G_p *defined in* (4) *and achieves* $\|T_{ew}\| < 1$ *(where* $e = z - \hat{z}$*) can be represented as in Figure* 5, *where* Q *is a causal operator with* $\|Q\| < 1$.



$$\Sigma \sim \left[\begin{array}{c|cc} A - YC_2'C_2 & YC_2' & YC_1' \\ \hline C_1 & 0 & -I \\ -C_2 & I & 0 \end{array}\right]$$

FIG. 5.

The following lemma states that a causal estimator for the system G_p defined in (4) achieves $\|T_{ew}\| < 1$ if and only if it achieves $\|T_{\nu\eta}\| < 1$ for the system described in Figure 6. This result follows immediately from the above parameterization of causal estimators.



$$J_{tmp} \sim \left[\begin{array}{c|cc} A + YC_1'C_1 & YC_2' & -YC_1' \\ \hline C_1 & 0 & -I \\ C_2 & I & 0 \end{array}\right]$$

FIG. 6.

LEMMA 4.8. *Let assumptions* A3, A4 *hold and let* Y *satisfy* (28). *A causal estimator* $\mathcal{E} : y \to \hat{z}$ *solves the estimation problem for the system* G_p *defined in* (4) *and achieves* $\|T_{ew}\| < 1$ *if and only if* $\|T_{\nu\eta}\|_\infty < 1$ *for the system described in Figure* 6.

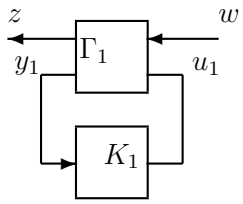
Proof. Let $\hat{x}$ be the state of the system Σ described in the Figure 5. Then the system Σ can be redescribed as

$$\dot{\hat{x}} = (A + YC_1'C_1)\hat{x} + YC_2\eta - YC_1'\hat{z},$$

$$y = C_2\hat{x} + \eta, \quad \hat{z} = \mathcal{E}y, \quad \nu = C_1\hat{x} - \hat{z}.$$

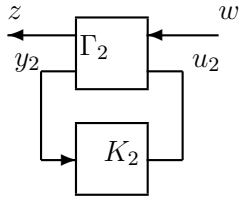
The above is nothing but the description of the system J_{tmp}. Now the conclusion of the above lemma follows immediately from Lemma 4.7 since the estimator $\mathcal{E}$ achieves the desired performance if and only if $\|T_{\nu\eta}\| < 1$. □

The following lemma, a proof of which is contained in [3, Propositions 3 and 4], is fairly straightforward. To state the result, we need to describe the feedback connection of systems and controllers shown below in Figures 7 and 8.



$$\Gamma_1 \sim \left[\begin{array}{c|cc} A & B_1 & B_2 \\ \hline C_1 & 0 & D_{12} \\ 0 & I & 0 \end{array}\right]$$

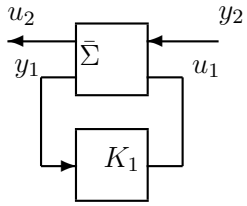
FIG. 7.



$$\Gamma_2 \sim \left[\begin{array}{c|cc} A & B_1 & B_2 \\ \hline C_1 & 0 & D_{12} \\ C_2 & I & 0 \end{array}\right]$$

FIG. 8.

LEMMA 4.9. *Let $A-B_1C_2$ be stable and the controller K_1 be such that it internally stabilizes the feedback system shown in Figure* 7*. If the controller $K_2 : y_2 \to u_2$ can be represented as in Figure* 9*, then the feedback system represented in Figure* 8 *is internally stable. Moreover, if K_2 can be represented as in Figure* 9*, then the closed loop map from w to z for the two feedback systems described in Figures* 7 *and* 8 *is identical.*



$$\bar{\Sigma} \sim \left[\begin{array}{c|cc} A - B_1C_2 & B_1 & B_2 \\ \hline 0 & 0 & I \\ -C_2 & I & 0 \end{array}\right]$$

FIG. 9.

Let $\mathcal{K}_1$ be the set of all controllers that internally stabilize the feedback system shown in Figure 7 *and render $\|T_{zw}\| < 1$. If $A - B_1C_2$ is stable, then any controller K_2 that internally stabilizes the feedback system shown in the Figure* 8 *and renders $\|T_{zw}\| < 1$ can be represented as in Figure* 9*, where $K_1 \in \mathcal{K}_1$.*

5. Proofs.

Proof of Theorem 3.1: *The modified Nehari problem.*

Necessity. Here we show that if there exists a causal system f that achieves the desired performance, then $\lambda_{max}(P(t)Q(t)) < 1 \, \forall t \in [0, T]$. For clarity of exposition, we will make a simplifying assumption that (F_1, G_1) and (F_2, G_2) are controllable (all the subsequent arguments go through if this is not the case by replacing matrix inverses by their pseudoinverses). Let the observability grammian Q defined in (8) be partitioned as

$$Q := \begin{bmatrix} Q_{11} & Q_{12} \\ Q_{12}' & Q_{22} \end{bmatrix}. \tag{36}$$

We will show that if the problem is solvable then with P_1 and P_2 as defined in (8),

$$P_1^{-1}(t) - Q_{11}(t) + Q_{12}(t)(P_2^{-1}(t) + Q_{22}(t))^{-1}Q_{12}'(t) > 0 \quad \forall t \in (0,T). \tag{37}$$

Let x_1 be the state of Σ_1, x_2 be the state of Σ_2, and $\hat{y}_1 = f(w_1)$, where $f(\cdot)$ is a given causal function. Then the system can be written in state-space form as

$$\begin{bmatrix} \dot{x}_1 \\ \dot{x}_2 \end{bmatrix} = \begin{bmatrix} F_1 & 0 \\ G_2H_1 & F_2 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} + \begin{bmatrix} G_1 \\ 0 \end{bmatrix} w_1 - \begin{bmatrix} 0 \\ G_2 \end{bmatrix} \hat{y}_1, \quad x_1(T) = x_2(T) = 0,$$

$$e = \begin{bmatrix} H_1 & H_2 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} - \hat{y}_1, \quad \text{where } e := \Sigma_2(\Sigma_1 w_1 - \hat{y}_1).$$

Fix a $\tau \in (0,T)$ and a nonzero vector $x_{1\tau}$. Let w_1 be such that $w_1(s) = 0$ for all $s < \tau$, and for $t \in [\tau, T]$ let w_1 be the minimum norm input such that $x_1(\tau) = x_{1\tau}$ for the system (6). Then from Lemma 4.1 (note that the system here is anticausal),

$$\|w\|_{[0,T]}^2 = \|w\|_{[\tau,T]}^2 = x_{1\tau}' P_1^{-1}(\tau) x_{1\tau}.$$

Since $w_1(s) = 0$ for all $0 < s < \tau$ and $\hat{y}_1$ is causally generated from w_1, $\hat{y}_1(s) = 0$ for all $0 < s < \tau$. Thus for $0 < s < \tau$,

$$\begin{bmatrix} \dot{x}_1 \\ \dot{x}_2 \end{bmatrix} = \begin{bmatrix} F_1 & 0 \\ G_2H_1 & F_2 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix}, \quad e = \begin{bmatrix} H_1 & H_2 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix},$$
$$\text{and } \|e\|_{[0,\tau]}^2 = x'(\tau) Q(\tau) x(\tau),$$

where

$$x := \begin{bmatrix} x_1 \\ x_2 \end{bmatrix}.$$

Since $e := \Sigma_2(\Sigma_1 w_1 - \hat{y}_1)$, the dynamics of system Σ_2 can also be written as (with x_2 as the state of Σ_2)

$$\dot{x}_2 = (F_2 - G_2H_2)x_2 + G_2 e, x_2(T) = 0.$$

Suppose there exists a causal $f(\cdot)$ that achieves the desired performance for the given problem. Then for this $f(\cdot)$ and the given choice of w_1, we have the following series of inequalities, where the fourth step follows from application of Lemma 4.1 to the above equation for x_2:

$$\begin{aligned}
0 &< \|w\|_{[0,T]}^2 - \|e\|_{[0,T]}^2 \\
&= \|w\|_{[\tau,T]}^2 - \|e\|_{[0,\tau]}^2 - \|e\|_{[\tau,T]}^2 \\
&= x_{1\tau}' P_1^{-1}(\tau) x_{1\tau} - x'(\tau) Q(\tau) x(\tau) - \|e\|_{[\tau,T]}^2 \\
&\le x_{1\tau}' P_1^{-1}(\tau) x_{1\tau} - \inf_{x_2(\tau)} \left\{ x'(\tau) Q(\tau) x(\tau) + \inf_e \left\{ \|e\|_{[\tau,T]}^2 \right\} \right\} \\
&= x_{1\tau}' P_1^{-1}(\tau) x_{1\tau} - \inf_{x_2(\tau)} \left\{ x'(\tau) Q(\tau) x(\tau) + x_2(\tau)' P_2^{-1}(\tau) x_2(\tau) \right\} \\
&= x_{1\tau}' P_1^{-1}(\tau) x_{1\tau} - x_{1\tau}' [Q_{11}(\tau) - Q_{12}(\tau)(P_2^{-1}(\tau) + Q_{22}(\tau))^{-1} Q_{12}'(\tau)] x_{1\tau},
\end{aligned}$$

where in obtaining the last step we have used the fact that if $M > 0$, then

$$\begin{aligned}\inf_{x_2}\left\{\begin{bmatrix} x_2' & x_1' \end{bmatrix}\begin{bmatrix} M & S \\ S' & N \end{bmatrix}\begin{bmatrix} x_2 \\ x_1 \end{bmatrix}\right\} \\ = \inf_{x_2}\left\{\|M^{1/2}(x_2 + M^{-1}Sx_1)\|^2 + x_1'(N - S'M^{-1}S)x_1\right\} \\ = x_1'(N - S'M^{-1}S)x_1.\end{aligned}$$

Since the above inequality is true for all $\tau \in (0,T)$ and for all $x_{1\tau}$ we see that (37) holds. This implies that the matrix $P^{-1}(\tau) - Q(\tau)$ is invertible for all $\tau \in (0,T)$, or equivalently that $\lambda_{max}(P(\tau)Q(\tau)) < 1 \ \ \forall \tau \in [0,T]$.

Sufficiency. Here we first show that any causal $f : w_1 \to \hat{y}_1$ that is of the form (9) achieves $\sup_{w_1} \frac{\|\Sigma_2(\Sigma_1 w_1 - \hat{y}_1)\|^2}{\|w_1\|^2} < 1$. With x as defined above, the composite state-space expression for the system Σ_1, Σ_2 and the operator $f(\cdot)$ defined in (9) can be written as

$$\begin{aligned}\dot{\eta} &= \check{F}\eta + \check{G}\nu, \\ \begin{bmatrix} e \\ \eta \end{bmatrix} &= \check{H}\eta + \begin{bmatrix} I & 0 \\ 0 & I \end{bmatrix}\nu,\end{aligned} \tag{38}$$

where

$$\eta = \begin{bmatrix} x \\ q \end{bmatrix}, \quad \nu = \begin{bmatrix} v \\ w_1 \end{bmatrix}, \quad \check{F} = \begin{bmatrix} \bar{F} & \tilde{G}_2(\bar{H}P - \tilde{G}_2') \\ 0 & -\tilde{F}' - NQ\tilde{G}_1\tilde{G}_1' \end{bmatrix}, \tag{39}$$

$$\check{G} = \begin{bmatrix} \tilde{G}_2 & \tilde{G}_1 \\ N(Q\tilde{G}_2 - \bar{H}') & NQ\tilde{G}_1 \end{bmatrix}, \quad \check{H} = \begin{bmatrix} \bar{H} & \bar{H}P - \tilde{G}_2' \\ 0 & -\tilde{G}_1' \end{bmatrix}. \tag{40}$$

With

$$\check{X} := \begin{bmatrix} Q & -(I - QP) \\ -(I - PQ) & -(I - PQ)P \end{bmatrix} = \begin{bmatrix} Q & -N^{-1} \\ -N^{-T} & -N^{-T}P \end{bmatrix}, \tag{41}$$

one can verify by straightforward though tedious algebra that the following hold:

$$\begin{aligned}-\frac{d\check{X}}{dt} &= \check{F}'\check{X} + \check{X}\check{F} - \check{H}'\check{H}, \\ \check{G}'\check{X} &= \check{H}.\end{aligned}$$

From (38) and above, one notes that

$$\frac{d(\eta'\check{X}\eta)}{dt} = \eta'\left[\check{F}'\check{X} + \check{X}\check{F} + \frac{d(\check{X})}{dt}\right]\eta + \eta'\check{X}\check{G}\nu + \nu'\check{G}'\check{X}\eta = \left[\nu + \check{H}\eta\right]'\left[\nu + \check{H}\eta\right] - \nu'\nu.$$

Integrating $\frac{d(\eta'\check{X}\eta)}{dt}$ from 0 to T one obtains (the boundary terms drop out because of boundary conditions on x, q, Q, and P)

$$\|w_1\|^2 + \|v\|^2 = \|\eta\|^2 + \|e\|^2. \tag{42}$$

Since $\|\Theta\| < 1$, there exists an $\epsilon > 0$ such that $\|\eta\|^2 - \|v\|^2 \geq \epsilon\|\eta\|^2$. Thus

$$\|w_1\|^2 - \|e\|^2 \geq \epsilon\|\eta\|^2 \geq \frac{\epsilon}{\|T_{w_1\eta}\|}\|w_1\|^2.$$

To complete the proof, it remains to be shown that any causal $f : w_1 \to \hat{y}_1$ that achieves the desired performance admits a representation as described in (9) for some Θ with $\|\Theta\| < 1$. This will now be shown using Lemma 4.3. Let $f : w_1 \to \hat{y}_1$ be a causal operator that achieves $\sup_{w_1} \frac{\|\Sigma_2(\Sigma_1 w_1 - \hat{y}_1)\|^2}{\|w_1\|^2} < 1$. Define $v := \hat{y}_1 - [\bar{H}P - \tilde{G}_2']q$, where q satisfies the differential equation described in (9). Then

$$P : \begin{bmatrix} w_1 \\ v \end{bmatrix} \to \begin{bmatrix} e \\ \eta \end{bmatrix}$$

is described by the system (38). As observed above, P is isometric (i.e., $\|w_1\|^2 + \|v\|^2 = \|\eta\|^2 + \|e\|^2$). It is also easily seen that the map from w_1 to η is invertible (i.e., P_{21}^{-1} exists), and since the problem is defined over a finite interval, P and P_{21}^{-1} are stable. Thus from Lemma 4.3 we conclude that $\|T_{ew_1}\| < 1$ if and only if $\|T_{v\eta}\| < 1$. Moreover, since the map $f(\cdot)$ is required to be causal, from (9) we observe that so must be $T_{v\eta}$. The required result follows by noting $\Theta := T_{v\eta}$. □

Before proceeding to the proof of the next theorem, we state the following lemma, the proof of which is implicit in the necessity proof of the modified Nehari problem, and thus we state it without proof. For any given $\tau \in [0, T]$, let $\mathcal{W}_\tau$ and $\mathcal{Y}_\tau$ be defined as

$$\mathcal{W}_\tau := \{w_1 \in L_2[0,T] : w_1(s) = 0 \ \forall\ 0 \le s < \tau\},$$
$$\mathcal{Y}_\tau := \{\hat{y}_1 \in L_2[0,T] : \hat{y}_1(s) = 0 \ \forall\ 0 \le s < \tau\}.$$

LEMMA 5.1. *Let Σ_1 and Σ_2 be anticausal systems described in equations* (6) *and* (7)*, respectively. The given modified Nehari problem* (*Problem* 5 *in section* 2) *is solvable* (*i.e., there exists a causal $f : w_1 \to \hat{y}_1$ that achieves* $\sup_{w_1} \frac{\|\Sigma_2(\Sigma_1 w_1 - \hat{y}_1)\|^2}{\|w_1\|^2} < 1$) *if and only if there exists an $\epsilon > 0$ so that*

$$\inf_{w_1 \in \mathcal{W}_\tau} \sup_{\hat{y}_1 \in \mathcal{Y}_\tau} \{\|w_1\|^2 - \|\Sigma_2(\Sigma_1 w_1 - \hat{y}_1)\|^2\} \ge \epsilon \|w_1\|^2$$

holds for all $\tau \in (0, T)$.

Proof of Theorem 3.2: *The basic delay problem.*

Necessity. Here we show that if there exists a causal operator $f(\cdot)$ that achieves the desired performance bound, then the Riccati differential equation described in (22) admits a solution. Since the information available to any admissible f about w is delayed by h units, for $t \in [0, h)$ it has no information and thus $\hat{z}(t) = 0$ for $t \in [0, h]$. Thus an existence of an admissible f so that $\sup_w \frac{\|z - \hat{z}\|^2}{\|w\|^2} < 1$ implies that, for some $\epsilon > 0$,

$$\|w\|_{[0,h]}^2 - \|Cx\|_{[0,h]}^2 \ge \epsilon \|w\|_{[0,h]}^2$$

for the system G defined in (2). It is well known (see, for example, [7]) that the above requirement is equivalent to the existence of a solution to the Riccati differential equation described by (22).

Sufficiency. The proof is somewhat long and hence we will break it down into smaller steps.

(1) Here we rewrite Cx, the signal to be estimated for the system (2), as a sum of three parts. The first part is predictable with the information available to the estimator, i.e., with knowledge of w with a delay of h units. For easier reading, we

rewrite some of the notation described previously.

$$\frac{d\Psi(\tau,s)}{d\tau} = (A + BB'X(\tau))\Psi(\tau,s), \quad \Psi(s,s) = I, \quad \bar{B}(\tau) = e^{A\tau}\Psi(h,\tau)B \text{ for } \tau \in [0,h],$$

$$\{w_i\} = Ww,$$

$$r_i = G_0 w_i, \quad i \geq 0,$$

$$z_{10} = 0, \quad z_{1i} = G_1 r_{i-1} \text{ for } i \geq 1,$$

$$z_{20} = 0, \quad z_{2i} = G_2 r_i \text{ for } i \geq 1,$$

where the systems G_0, G_1, and G_2 are as defined in (14), (15), and (16), respectively. From the above equations it is easily verified that, for all $\tau \in [0,h]$ and $i \geq 1$,

$$z_{2i}(\tau) = C\int_0^\tau \Psi(\tau,s)Br_i(s)ds = C\int_0^\tau e^{A(\tau-s)}Bw_i(s)ds,$$

$$\begin{aligned} z_{1i}(\tau) &= -C\int_h^\tau e^{A(\tau-s)}\bar{B}(s)r_{i-1}(s)ds \\ &= C\int_\tau^h e^{A(\tau-s)}e^{As}\Psi(h,s)Br_{i-1}(s)ds = Ce^{A\tau}\int_\tau^h \Psi(h,s)Br_{i-1}(s)ds, \end{aligned}$$

where the second equality of the first equation above follows from the fact that $G_2G_0 = G$. Again using the fact that $G_2G_0 = G$ and from (2), we have that, for any $\tau \in [0,h]$ and for any integer $i \geq 1$,

$$\begin{aligned} x(ih+\tau) &= e^{A\tau}x(ih) + \int_0^\tau e^{A(\tau-s)}Bw_i(s)ds \\ &= e^{A\tau}\left[e^{Ah}x((i-1)h) + \int_0^h \Psi(h,s)Br_{i-1}(s)ds\right] + \int_0^\tau e^{A(\tau-s)}Bw_i(s)ds \\ &= \left[e^{A(\tau+h)}x((i-1)h) + e^{A\tau}\int_0^\tau \Psi(h,s)Br_{i-1}(s)ds \ \right] \\ &\quad + e^{A\tau}\int_\tau^h \Psi(h,s)Br_{i-1}(s)ds + \int_0^\tau \Psi(\tau,s)Br_i(s)ds. \end{aligned}$$

From the above and definitions of z_{1i} and z_{2i} as defined in (20) and (21), one obtains

$$\begin{aligned} z(ih+\tau) &= Cx(ih+\tau) \\ &= C\left[e^{A(\tau+h)}x((i-1)h) + e^{A\tau}\int_0^\tau \Psi(h,s)Br_{i-1}(s)ds\right] \quad (\text{“term 1”}) \\ &\quad + Ce^{A\tau}\int_\tau^h \Psi(h,s)Br_{i-1}(s)ds + C\int_0^\tau \Psi(\tau,s)Br_i(s)ds \\ &= \text{“term 1”} + G_1 r_{i-1}(\tau) + G_2 r_i(\tau) = \text{“term 1”} + z_{1i}(\tau) + z_{2i}(\tau). \end{aligned} \tag{43}$$

The “term 1” depends only on $w(s)$ for $s \leq (i-1)h + \tau$ and thus is completely obtainable at $t = ih + \tau$ with knowledge of w with h units' delay. Note also that the

first term in the estimate $\hat{z}$ of z in the statement of Theorem 3.2 is nothing but the "term 1." With the following notation of $\{\hat{\hat{z}}_i\} \in l_{\mathcal{L}_2[0,h]}$,

$$\begin{aligned}
&\hat{\hat{z}}_0 = 0,\\
&\hat{\hat{z}}_i(\tau) := \hat{z}(ih+\tau) - C\left\{e^{A(\tau+h)}x((i-1)h) + e^{A\tau}\int_0^\tau \Psi(h,s)Br_{i-1}(s)ds\right\} \quad \text{for } i \geq 1\\
&(44) \quad = \hat{z}(ih+\tau) - \text{"term 1,"}
\end{aligned}$$

and the above decomposition of Cx, it follows that to show that the $\hat{z} = f(w)$ achieves the desired performance, we have to show that

$$\sup_w \frac{\|Cx\|^2_{[0,h]} + \|\{z_{1i} + z_{2i} - \hat{\hat{z}}_i\}\|^2}{\|w\|^2} < 1, \tag{45}$$

where $\hat{\hat{z}}_i$ is as defined in (44). Thus the given problem is solvable if and only if there exists a function $\hat{f} : \mathcal{L}_2 \to l_{\mathcal{L}_2[0,h]}$ so that with $\hat{\hat{z}}_0 = 0$, $\hat{\hat{z}}_i(\tau) = \hat{f}(w(s))(\tau)$, where $0 \leq s \leq (i-1)h + \tau$, $\tau \in [0,h]$, the above inequality holds.

(2) Here we obtain an expression for

$$\|w\|^2 - \|Cx\|^2_{[0,h]} - \|\{z_{1i} + z_{2i} - \hat{\hat{z}}_i\}\|^2$$

for any given $\{\hat{\hat{z}}_i\} \in l_{\mathcal{L}_2[0,h]}$ such that $\hat{\hat{z}}_0 = 0$. The expression we obtain not only is an important step in the proof but also may provide an insight into the structure of the problem and how $\hat{\hat{z}}_i$ must be chosen so as to satisfy (45).

Noting that $G_2G_0 = G$, one can write the expressions for r_i and z_{2i} defined in (19) and (21) using a single differential equation as

$$\begin{aligned}
\dot{x}_0(\tau) &= Ax_0(\tau) + Bw_i(\tau),\ \tau \in [0,h],\ x_0(0) = 0,\\
r_i(\tau) &= w_i(\tau) - B'X(\tau)x_0(\tau),\\
z_{2i}(\tau) &= Cx_0(\tau).
\end{aligned}$$

Integrating $\frac{d(x_0'Xx_0)}{dt}$ from 0 to h, where X satisfies (22), one obtains that

$$\|w_i\|^2 - \|z_{2i}\|^2 = \|r_i\|^2.$$

Similarly one can show that $\|w_0\|^2 - \|Cx\|^2_{[0,h]} = \|r_0\|^2$. From the above equation we have that for any $\{\hat{\hat{z}}_i\}$ such that $\hat{\hat{z}}_0 = 0$,

$$\begin{aligned}
&(46)\quad \|w\|^2 - \|Cx\|^2_{[0,h]} - \|\{z_{1i} + z_{2i} - \hat{\hat{z}}_i\}\|^2\\
&= \|r_0\|^2 + \textstyle\sum_{i\geq 1}\left[\{\|w_i\|^2 - \|z_{2i}\|^2\} - 2\langle z_{1i} - \hat{\hat{z}}_i, z_{2i}\rangle_{[0,h]} - \|z_{1i} - \hat{\hat{z}}_i\|^2\right]\\
&= \|r_0\|^2 + \textstyle\sum_{i\geq 1}\left[\|r_i\|^2 - 2\langle z_{1i} - \hat{\hat{z}}_i, G_2r_i\rangle_{[0,h]} - \|z_{1i} - \hat{\hat{z}}_i\|^2\right]\\
&= \|r_0\|^2 + \textstyle\sum_{i\geq 1}\left[\|r_i\|^2 - 2\langle G_2^*(z_{1i} - \hat{\hat{z}}_i), r_i\rangle_{[0,h]} - \|z_{1i} - \hat{\hat{z}}_i\|^2\right]\\
&= \|r_0\|^2 + \textstyle\sum_{i\geq 1}\left[\|r_i - G_2^*(z_{1i} - \hat{\hat{z}}_i)\|^2 - \langle (I + G_2G_2^*)(z_{1i} - \hat{\hat{z}}_i), (z_{1i} - \hat{\hat{z}}_i)\rangle_{[0,h]}\right]\\
&= \|r_0\|^2 + \textstyle\sum_{i\geq 1}\left[\|r_i - G_2^*(z_{1i} - \hat{\hat{z}}_i)\|^2 - \|G_3(z_{1i} - \hat{\hat{z}}_i)\|^2\right].
\end{aligned}$$

The last equality stems from Lemma 4.2. Noticing the way $\{w_{1i}\} \in l_{\mathcal{L}_2[0,h]}$ is defined in the theorem statement ($w_{10} = r_0$ and $w_{1i} = r_i - G_2^*(z_{1i} - \hat{\hat{z}}_i)$ for $i \geq 1$) and using the definition of z_{1i} ($z_{1i} = G_1 r_{i-1}$), the above equation can be rewritten as

$$\begin{aligned} &\|w\|^2 - \|Cx\|^2_{[0,h]} - \textstyle\sum_{i\geq 1} \|z_{1i} + z_{2i} - \hat{\hat{z}}_i\|^2 \\ &= \textstyle\sum_{i\geq 0} \left[\|w_{1i}\|^2 - \|G_3(z_{1(i+1)} - \hat{\hat{z}}_{i+1})\|^2\right] \\ &= \textstyle\sum_{i\geq 0} \left[\|w_{1i}\|^2 - \|G_3(G_1 w_{1i} + \nu_i - \hat{\hat{z}}_{i+1})\|^2\right], \end{aligned} \tag{47}$$

where $\{\nu_i\} \in l_{\mathcal{L}_2[0,h]}$ is defined as

$$\nu_i := G_1 G_2^*(z_{1i} - \hat{\hat{z}}_i), \quad i \geq 0.$$

(3) In this part we will show that a certain modified Nehari problem admits a solution. Based on this modified Nehari problem and (47), we will qualitatively outline the structure of all admissible $f : w \to \hat{z}$ (or equivalently, $\hat{f} : w \to \hat{\hat{z}}$) that achieve the desired performance bound.

The signal z_{1i} ($z_{1i} = G_{1i} r_{i-1}$) depends only on $w(s)$, $0 \leq s \leq ih$. Because of the presence of delay, for all admissible $\hat{f} : w \to \hat{\hat{z}}$, $\hat{\hat{z}}_i$ also depends only on $w(s)$, $0 \leq s \leq ih$. Thus both of the signals z_{1i} and $\hat{\hat{z}}_i$ are known if one knows $w(s)$ for all $0 \leq s \leq t = ih$. Thus the signal $\nu_i = G_1 G_2^*(z_{1i} - \hat{\hat{z}}_i)$ is also known if one knows $w(s)$ for all $0 \leq s \leq t = ih$. Treating ν_i as a known signal, each of the terms in the summation in (47) can be viewed as a modified Nehari problem (problem 5 in the problem definition section) if one makes the following association with the terminology of the modified Nehari problem (note that both G_1 and G_3 are anticausal systems):

$$\Sigma_1 \leftarrow G_1, \quad \Sigma_2 \leftarrow G_3, \quad w_1 \leftarrow w_{1i}, \quad \hat{y}_1 \leftarrow \hat{\hat{z}}_{i+1} - \nu_i, \quad T \leftarrow h.$$

It is shown in the appendix that if the Riccati differential equation (22) admits a solution, then indeed the above modified Nehari problem is solvable.

We now briefly outline how $\hat{\hat{z}}_{i+1}$ is chosen from the solution of the above modified Nehari problem. Let us make the following association with the notation adopted in the modified Nehari problem:

$$\Sigma_1 \leftarrow G_1, \quad \Sigma_2 \leftarrow G_3, \quad w_1 \leftarrow w_{1i}, \quad T \leftarrow h, \; \hat{y}_1 \leftarrow \hat{y}_{i+1}, \quad v \leftarrow v_i, \quad \eta \leftarrow \eta_i.$$

It follows from equation (42) of the modified Nehari problem proof that for all integers $i \geq 0$

$$\|w_{1i}\|^2 - \|G_3(G_1 w_{1i} - \hat{y}_{i+1})\|^2 = \|\eta_i\|^2 - \|v_i\|^2.$$

If $\hat{\hat{z}}_{i+1}$ is chosen as $\hat{\hat{z}}_{i+1} = \hat{y}_{i+1} + G_1 G_2^*(z_{1i} - \hat{\hat{z}}_i) = \hat{y}_{i+1} + \nu_i$, then it follows from the above that

$$\|w_{1i}\|^2 - \|G_3(G_1 w_{1i} + G_1 G_2^*(z_{1i} - \hat{\hat{z}}_i) - \hat{\hat{z}}_{i+1})\|^2 = \|\eta_i\|^2 - \|v_i\|^2 \quad \forall i \geq 0.$$

Summing the above for all $i \geq 0$, one observes that

$$P : \begin{bmatrix} \{w_{1i}\} \\ \{v_i\} \end{bmatrix} \to \begin{bmatrix} \{G_3(G_1 w_{1i} + G_1 G_2^*(z_{1i} - \hat{\hat{z}}_i) - \hat{\hat{z}}_{i+1})\} \\ \{\eta_i\} \end{bmatrix} \text{ is isometric.} \tag{48}$$

Thus $\|\{w_1\}\|^2 + \|\{v_i\}\|^2 = \|\{\eta_i\}\|^2 + \|\{G_3(G_1 w_{1i} + G_1 G_2^*(z_{1i} - \hat{\hat{z}}_i) - \hat{\hat{z}}_{i+1})\}\|^2$. If additionally $\|\{\eta_i\}\|^2 > \|\{v_i\}\|^2$, then the right-hand side of (47) would be greater than or equal to zero and thus the required performance bound would be achieved.

Because of the presence of delay, one also needs to show that for any $\tau \in [0, h]$, $\hat{\hat{z}}_{i+1}(\tau)$ chosen as above depends only on $w(s)$ for $0 \le s \le ih + \tau$. Let $i \ge 1$ be any given integer. We have already established that ν_i depends only on $w(s)$ for $s \le ih$. Also, $\hat{\hat{z}}_{i+1} = \hat{y}_{i+1} + \nu_i$ where $\hat{y}_{i+1}$ is the estimate for the modified Nehari problem. From the definition of modified Nehari problem, for any $\tau \in [0, h]$, $\hat{y}_{i+1}(\tau)$ is generated causally from w_{1i} and thus depends only on $w_{1i}(s)$ for $0 \le s \le \tau$. From the definition of w_{1i} it then follows that $\hat{y}_{i+1}(\tau)$ depends only on $w(s)$ for $0 \le s \le ih + \tau$. Thus $\hat{\hat{z}}_{i+1}(\tau) = y_{i+1}(\tau) + \nu_i(\tau)$ depends only on $w(s)$ for $0 \le s \le ih + \tau$.

(4) In this part we complete the proof of the "sufficiency" along the lines outlined in the previous subsection. For convenience, the set of all estimators described in (24) is reproduced below:

$$\begin{aligned}
\hat{y}_{i+1} &= \mathcal{N}^1_{[G_1, G_3, h, \Theta]}(w_{1i}), \quad i \ge 0, \\
\eta_i &= \mathcal{N}^2_{[G_1, G_3, h, \Theta]} : (w_{1i}), \quad i \ge 0, \\
\hat{\hat{z}}_{i+1} &= \hat{y}_{i+1} + G_1 G_2^*(z_{1i} - \hat{\hat{z}}_i), \quad i \ge 0, \\
\{v_i\} &= \Theta\{\eta_i\}, \quad \text{where } \|\Theta\| < 1.
\end{aligned}$$

From (48) and (47) it follows that

$$\begin{aligned}
& \|w\|^2 - \|Cx\|^2_{[0,h]} - \textstyle\sum_{i \ge 1} \|z_{1i} + z_{2i} - \hat{\hat{z}}_i\|^2 \\
= \;& \textstyle\sum_{i \ge 0} \left[\|\eta_i\|^2 - \|v_i\|^2 \right] \\
\ge \;& \gamma \|\{\eta_i\}\|^2 \quad (\text{for some } \gamma > 0 \text{ since } \|\Theta\| < 1) \qquad (49) \\
\ge \;& \epsilon_1 \gamma \|\{w_{1i}\}\|^2 \quad (\text{for some } \epsilon_1 > 0) \\
\ge \;& \epsilon_2 \epsilon_1 \gamma \|\{w_i\}\|^2 = \epsilon \|w\|^2 \quad (\text{for some } \epsilon_2 > 0, \text{ and thus } \epsilon = \epsilon_2 \epsilon_1 \gamma > 0),
\end{aligned}$$

where the third from last inequality follows from the fact that $\|\Theta\| < 1$, where $\Theta : \{\eta_i\} \to \{v_i\}$. The second from last inequality follows from the fact that with $\{v_i\} = \Theta\{\eta_i\}$, the map from $\{\eta_i\}$ to $\{w_{1i}\}$ is bounded. The last inequality is a consequence of the fact that the map from $\{w_{1i}\}$ to $\{w_i\}$ is bounded.

The above inequality, together with the fact that it is enough to show (45), leads to the conclusion that the maps $f : w \to \hat{z}$ described in (24) achieve the desired performance bound.

(5) Next we show that any $f : w \to \hat{z}$ that is admissible and achieves the desired performance bound, admits a realization as in the theorem statement with some causal Θ such that $\|\Theta\| < 1$. This is shown as in the proof of the modified Nehari problem. Let $f : w \to \hat{z}$ be admissible and achieve the desired performance bound. For this f, let the operator $\hat{f}$ be defined as $\hat{f} : w \to \hat{\hat{z}}$, where $\hat{\hat{z}}_i$ is as defined in (44). Then from (45) one notes that there exists an $\epsilon > 0$ such that

$$\|w\|^2 - \|Cx\|^2_{[0,h]} - \|\{z_{1i} + z_{2i} - \hat{\hat{z}}_i\}\|^2 \ge \epsilon \|w\|^2.$$

Since $z_{1i} = G_1 G_0 w_{i-1}$ and $z_{2i} = G_2 G_0 w_i$, $\|\{z_{1i}\}\| \le \|G_1 G_0\| \|w\|$ and $\|\{z_{2i}\}\| \le \|G_2 G_0\| \|w\|$, where both $\|G_1 G_0\|$ and $\|G_2 G_0\|$ are bounded, since these operators are defined over a finite interval. From this together with the fact that the above inequality

holds, one concludes that there exists an $M < \infty$ such that $\|\{\hat{\hat{z}}_i\}\| \le M\|w\|$. Since $w_{1i} = r_i - G_2^*(z_{1i} - \hat{\hat{z}}_i)$, $\|\{w_{1i}\}\| < \gamma\|w\|$ for some $\gamma < \infty$. Thus for this $\hat{f} : w \to \hat{\hat{z}}$ that is admissible and achieves the desired performance, from the above equation and (47),

$$\begin{aligned}&\|w\|^2 - \|Cx\|^2_{[0,h]} - \textstyle\sum_{i\ge1} \|z_{1i} + z_{2i} - \hat{\hat{z}}_i\|^2\\ &= \textstyle\sum_{i\ge0} \left[\|w_{1i}\|^2 - \|e_i\|^2\right] \ge \epsilon_1 \|\{w_{1i}\}\|^2,\end{aligned}$$

where $\epsilon_1 = \frac{\epsilon}{\gamma} > 0$ and

$$e_i := G_3(G_1 w_{1i} + G_1 G_2^*(z_{1i} - \hat{\hat{z}}_i) - \hat{\hat{z}}_{i+1}).$$

For this function $\hat{f}$, let $\{v_i\} \in l_{\mathcal{L}_2[0,h]}$ be defined as $v_i := G_1 G_2^*(z_{1i} - \hat{\hat{z}}_i) - [\bar{H}_d P_d - \tilde{G}'_{2d}]q_i - \hat{\hat{z}}_{i+1}$, where q_i is the solution of the differential equation described in (24). Also, let η_i be as defined in (24). The map from w_{1i} to η_i is invertible and bounded (since the system is defined over a finite interval). Now from (48) and Lemma 4.3 we conclude that $\|T_{\{e_i\}\{w_{1i}\}}\| < 1$ if and only if $\|T_{\{v_i\}\{\eta_i\}}\| =: \|\Theta\| < 1$. Next we argue that Θ must also be causal. Because of the delay, for any $\tau \in [0,h]$, $\hat{\hat{z}}_{i+1}(\tau)$ should depend only on $w_{1j},\ j < i$, and $w_{1i}(s),\ 0 \le s \le \tau$. It is easily observed from (24) that this is the case if and only if $v_i(s)$ depends only on $w_{1j},\ j < i$, and $w_{1i}(s),\ 0 \le s \le \tau$. This is the case if and only if $\Theta = T_{\{v_i\}\{\eta_i\}}$ is causal. □

Proof of Theorem 3.3: *Full information control problem with delay.*

The proof of the Theorem 3.3 proceeds by converting the original problem to one that is equivalent to a basic delay problem using Lemma 4.4 adapted to the system G_{fi}.

Necessity. Here we show that conditions (1) and (2) of Theorem 3.3 must be satisfied for there to exist a controller which stabilizes the system and achieves $\|T_{zw}\| < 1$. Condition 1 is a necessary condition for the existence of controllers that achieve the desired performance even in the absence of delay (see, for example, [3]). Thus it must also be a necessary condition when the measurements are available with a delay.

From the full information (full information is used to denote complete information about the state and the exogenous signal) equivalent to Lemma 4.4 (see, for example, [3]), one concludes that if there exists a controller K that achieves $\|T_{zw}\| < 1$ for the system G_{fi}, then for the same controller $\|T_{vr}\| < 1$ for the following system:

$$\begin{aligned}\dot{x} &= (A + B_1 B_1' X)x + B_1 r + B_2 u,\ t \in [0,\infty),\ x(0) = 0,\\ v &= B_2' X x + u,\\ y &= \begin{bmatrix} x \\ r \end{bmatrix},\\ u(t) &= f(y(s)) \text{ with } s \le t - h,\end{aligned} \tag{50}$$

where the function $f(\cdot)$ defines the controller. Since for $t \in [0,h)$ the controller has no information, $u(t) = 0$ for $t \in [0,h)$. Thus if $\|T_{vr}\| < 1$, there exists an $\epsilon > 0$ such that

$$\|r\|^2_{[0,h]} - \|B_2' X x\|^2_{[0,h]} \ge \epsilon \|r\|^2_{[0,h]}$$

for the system given by the equation (50) with $u(t) = 0$ for $t \in [0,h)$. A necessary and sufficient condition for this to hold is nothing but condition (2) of Theorem 3.3.

Sufficiency. Here we show that all the controllers that achieve the desired performance are as described in the statement of Theorem 3.3. Because of Lemma 4.4, it is enough to show that all such controllers are the ones that achieve $\|T_{vr}\| < 1$ for the system described by (50).

The state x of the system described in equation (50) can be written as the sum of two states, one driven by the input u and the other by the exogenous signal r:

$$\begin{aligned} \dot{x_1} &= (A + B_1 B_1' X)x_1 + B_1 r,\ t \in [0,\infty),\ x_1(0) = 0, \\ \dot{x_2} &= (A + B_1 B_1' X)x_2 + B_2 u,\ t \in [0,\infty),\ x_2(0) = 0, \\ x &= x_1 + x_2, \\ v &= B_2' X(x_1 + x_2) + u. \end{aligned}$$

At any time t, $x_2(t)$ is known since it is generated by past inputs which are known. Thus x_2 can be treated as a deterministic/known signal. Let $\bar{u} := u + B_2' X x_2$. Thus a given controller $K : r \to u$ achieves the desired performance if and only if with $\bar{u} := u + B_2' X x_2$, $\|T_{vr}\| < 1$ for the following system:

$$\begin{aligned} \dot{x_1} &= (A + B_1 B_1' X)x_1 + B_1 r,\ t \in [0,\infty),\ x_1(0) = 0, \\ v &= B_2' X x_1 + \bar{u}, \\ \bar{u}(t) &= \bar{f}(r(s)) \text{ with } 0 \le s \le t - h. \end{aligned} \tag{51}$$

We now note that for the above system, the problem of determining $\bar{u}$ so as to achieve $\|T_{vr}\| < 1$ is nothing but a basic delay problem (Problem 1) if one makes the following association with the terminology of the basic delay problem:

$$A \leftarrow A + B_1 B_1' X, \quad B \leftarrow B_1, \quad C \leftarrow -B_2' X, \quad \hat{z} \leftarrow \bar{u}.$$

From Theorem 3.2 one concludes that the above basic delay problem is solvable because of condition (2) of Theorem 3.3. Let $\Omega : r \to \bar{u}$, where $\Omega \in \mathcal{D}_{[A+B_1B_1'X, B_1, -B_2'X, h]}$; i.e., Ω solves the basic delay problem for the system described in (51) and achieves $\|T_{vr}\| < 1$. Then from the above arguments it follows that $u = \bar{u} - B_2' X x_2$ achieves $\|T_{vr}\| < 1$ for the system given by (50). It is easily verified that all controllers presented in Theorem 3.3 are of this form.

Next we show that any controller that achieves $\|T_{vr}\| < 1$ for the system described in equation (50) admits a realization as described in Theorem 3.3. Let the controller $K : r \to u$ be admissible and achieve $\|T_{vr}\| < 1$ for the system described by (50). Define $\bar{u} := u + B_2' X x_2$, where x_2 is as defined above and in the theorem statement. For this controller K, let $\bar{K} : r \to \bar{u}$ be the corresponding map from r to $\bar{u}$. Then using the above decomposition of x, one concludes that $\bar{K}$ solves the basic delay problem for the system described in (51) and achieves $\|T_{vr}\| < 1$ or, equivalently, $\bar{K} \in \mathcal{D}_{[A+B_1B_1'X, B_1, -B_2'X, h]}$. □

Proof of Theorem 3.5: *Output feedback control problem with delay.*

The proof of Theorem 3.5 proceeds by converting the original problem to one that is equivalent to a basic delay problem using Lemmas 4.6 and 4.9.

Necessity. Here we show that conditions (30), (31), (32), and (33) of Theorem 3.5 must be satisfied for there to exist a controller which stabilizes the system and achieves $\|T_{zw}\| < 1$. Conditions (30), (31), and (32) are necessary conditions for existence of controllers that achieve the desired performance even in the absence of delay (see, for example, [3]). Thus they must also necessarily hold when the measurements are available with a delay.

From Lemma 4.6 one concludes that if there exists a controller K that achieves $\|T_{zw}\| < 1$, then for the same controller, $\|T_{\bar{q}\bar{p}}\| < 1$ for the following system:

$$
\begin{array}{rcl}
\dot{x} & = & (A + YC_1'C_1 + YC_2'C_2YZ)x + YC_2'\bar{p} + B_2u,\ t \in [0,\infty),\ x(0) = 0, \\
\bar{q} & = & B_2'Zx + u, \\
y & = & C_2(I + YZ)x + \bar{p}, \\
u(t) & = & f(y(s)) \text{ with } 0 \le s \le t - h,
\end{array} \tag{52}
$$

where the function $f(\cdot)$ defines the controller. Since for $t \in [0, h)$ the controller has no information, $u(t) = 0$ for $t \in [0, h)$. Thus if $\|T_{\bar{q}\bar{p}}\| < 1$, there exists an $\epsilon > 0$ such that

$$\|\bar{p}\|^2_{[0,h]} - \|B_2'Zx\|^2_{[0,h]} \ge \epsilon\|\bar{p}\|^2_{[0,h]}$$

for the system described by (52) with $u(t) = 0$ for $t \in [0, h)$. A necessary and sufficient condition for this to hold is nothing but the condition (33) of the theorem statement.

Sufficiency. Here we show that all the controllers that achieve the desired performance are as described in the statement of Theorem 3.5. From the Lemma 4.6, all controllers that achieve the desired performance are the ones that achieve $\|T_{\bar{q}\bar{p}}\| < 1$ for the system described by (52).

Consider the following system, which has the same dynamics as the system (52), but now the controller has delayed measurements of $\bar{p}$ instead of $C_2(I + YZ)x + \bar{p}$; i.e.,

$$
\begin{array}{rcl}
\dot{x} & = & (A + YC_1'C_1 + YC_2'C_2YZ)x + YC_2'\bar{p} + B_2u,\ t \in [0,\infty),\ x(0) = 0, \\
\bar{q} & = & B_2'Zx + u, \\
y_2 & = & \bar{p}, \\
u(t) & = & g(y_2(s)) \text{ with } 0 \le s \le t - h.
\end{array} \tag{53}
$$

For the system described by (53), the problem of obtaining $g(\cdot)$ so that $\|T_{\bar{q}\bar{p}}\| < 1$ is of the same type as was encountered in equation (50) in the proof of Theorem 3.3. As in the proof of Theorem 3.3, one concludes that the above problem is solvable because of condition 4 of Theorem 3.5. One now proceeds exactly as before in the proof of Theorem 3.3 to conclude that any controller that achieves the desired performance $\|T_{\bar{q}\bar{p}}\| < 1$ for the system (53) has a realization of the following form:

$$
K_\Omega \left\{ \begin{array}{rcl}
\dot{x_2} & = & (A + YC_1'C_1 + YC_2'C_2YZ)x_2 + B_2u,\ t \in [0,\infty),\ x_2(0) = 0, \\
u(t) & = & 0, \quad t \in [0, h), \\
u(t) & = & -B_2'Zx_2 + (\Omega\bar{p})(t) \quad t \ge h,
\end{array} \right.
$$

where $\Omega \in \mathcal{D}_{[(A+YC_1'C_1+YC_2C_2'YZ),YC_2',-B_2'Z,h]}$. Let us define the above controller as $K_\Omega : \bar{p} \to u$.

Note that from condition 2 of Theorem 3.5, $A + YC_1'C_1 - YC_2C_2'$ is stable. From Lemma 4.9 it follows that all controllers that achieve $\|T_{\bar{q}\bar{p}}\| < 1$ for system (52) are of the form

$$
\begin{array}{rcl}
\dot{x_1} & = & (A + YC_1'C_1 - YC_2'C_2)x_1 + YC_2'y + B_2u,\ t \in [0,\infty),\ x_1(0) = 0, \\
r & = & -C_2(I + YZ)x_1 + y, \\
u & = & K_\Omega r.
\end{array}
$$

It is easily verified that the controllers described in Theorem 3.5 that achieve the desired performance are of the above form. □

Proof of Theorem 3.4: *Prediction problem.*

The proof of Theorem 3.4 proceeds by converting the original problem to one that is equivalent to a basic delay problem using Lemma 4.8. From Lemma 4.8 one concludes that if there exists a predictor $\mathcal{E}$ that achieves $\|T_{ew}\| < 1$, then for the same predictor $\|T_{\nu\eta}\| < 1$ for the following system:

$$\begin{aligned} \dot{x} &= (A + YC_1'C_1)x + YC_2'\eta - YC_1'\hat{z},\ t \in [0,\infty),\ x(0) = 0, \\ \nu &= C_1x - \hat{z}, \\ y &= C_2x + \eta, \\ \hat{z}(t) &= f(y(s)) \text{ with } 0 \le s \le t - h, \end{aligned} \tag{54}$$

where the function $f(\cdot)$ defines the predictor. This problem is completely analogous to (52), discussed in the proof of Theorem 3.5, and the proof proceeds along the same lines if one makes the following association with the terminology in (52):

$$(A + YC_1'C_1 + YC_2'C_2YZ) \leftarrow (A + YC_1'C_1),\quad YC_2' \leftarrow YC_2',\quad B_2 \leftarrow YC_1',$$

$$B_2'Z \leftarrow C_1,\quad C_2(I + YZ) \leftarrow C_2,\quad \bar{p} \leftarrow \eta,\quad \bar{q} \leftarrow \nu,\quad u \leftarrow -\hat{z}. \qquad \square$$

6. Summary. In this paper we have presented state-space solutions to $\mathcal{H}_\infty$ control and estimation problems when there is a delay present in the measurements or implementation of control. The necessary and sufficient conditions are given in terms of finite-dimensional algebraic and differential Riccati equations. Using the solutions to these Riccati equations, one can obtain explicit state-space realizations for the controllers and predictors. The "central" solution for the controllers/estimators is a linear periodic system, with the period being the amount of delay present. Though the approach presented here may provide some new insight about how "lifting" type techniques can be used for such problems, it is not clear if these ideas are generalizable to a wider class of problems, such as ones involving multiple delays in dynamics or measurements.

Appendix. Here we show that if the Riccati differential equation (22) admits a solution, then the modified Nehari problem with the following association with the terminology of the modified Nehari problem is solvable:

$$\Sigma_1 \leftarrow G_1, \quad \Sigma_2 \leftarrow G_3, \quad T \leftarrow h.$$

In the discussions that follow, τ is a fixed number in the interval $\tau \in (0, h)$. Recall that $\{w_i\} = Ww$ and $r_i = G_0w_i$. Let $\mathcal{W}_\tau$, $\mathcal{Z}_\tau$, and $\mathcal{R}_\tau$ be defined as follows:

$$\begin{aligned} \mathcal{W}_\tau &:= \{w_0 \in L_2[0,h] : w_0(s) = 0\ \forall\ 0 \le s < \tau\}, \\ \mathcal{Z}_\tau &:= \{\hat{z}_1 \in L_2[0,h] : \hat{z}_1(s) = 0\ \forall\ 0 \le s < \tau\}, \\ \mathcal{R}_\tau &:= \{r_0 \in L_2[0,h] : r_0(s) = 0\ \forall\ 0 \le s < \tau\}. \end{aligned} \tag{55}$$

Since $r_0 = G_0w_0$ and G_0 is causal and invertible, $r_0 \in \mathcal{R}_\tau$ if and only if $w_0 \in \mathcal{W}_\tau$. From (43) one notes that for any $w_0 \in \mathcal{W}_\tau$, $z = Cx$ for the system (2) in the interval $[h, 2h]$ can be written as

$$Cx(h + t) = z_{11}(t) + z_{12}(t),\ t \in [0,h], \tag{56}$$

where $z_{11}(t) = G_1 r_0(t)$ and $z_{21}(t) = G_2 r_1(t)$, since the "term 1" here is 0 because $x(0) = 0$ and $r_0(s) = 0,\ 0 \le s < \tau$.

It is well known that existence of a solution to the Riccati differential equation described by (22) implies that, for some $\epsilon > 0$,

$$\|w\|^2_{[0,h]} - \|Cx\|^2_{[0,h]} \ge \epsilon \|w\|^2_{[0,h]} \quad \forall w \in L_2[0,h] \tag{57}$$

for the system G defined in (2). The following observation follows immediately from the above inequality: for any $w \in L_2[0,2h]$ for which $w_0 \in \mathcal{W}_\tau$,

$$\begin{aligned} &\sup_q \{\|w\|^2_{[\tau,2h]} - \|Cx\|^2_{[\tau,\tau+h]} - \|Cx - q\|^2_{[\tau+h,2h]}\} \\ &= \{\|w\|^2_{[\tau,\tau+h]} - \|Cx\|^2_{[\tau,\tau+h]}\} + \|w\|^2_{[\tau+h,2h]} \\ &\quad \text{(with } q \text{ chosen as } q(t) = Cx(t),\ t \in [\tau+h, 2h]) \\ &\ge \epsilon \|w\|^2_{[\tau,\tau+h]} \quad \text{(from (57) and the fact that } x(\tau) = 0 \text{ since } w_0 \in \mathcal{W}_\tau). \end{aligned} \tag{58}$$

Moreover, if $w_0 \in \mathcal{W}_\tau$, the following holds for any choice of $\hat{\hat{z}}_1$:

$$\begin{aligned} &\|w\|^2_{[0,2h]} - \|Cx\|^2_{[0,h]} - \|Cx - \hat{\hat{z}}_1\|^2_{[h,2h]} \\ &= \|w_0\|^2_{[\tau,h]} + \|w_1\|^2 - \|Cx\|^2_{[\tau,h]} - \|Cx - \hat{\hat{z}}_1\|^2_{[h,2h]} \quad (\text{since } w_0 \in \mathcal{W}_\tau) \\ &= \|w_0\|^2_{[\tau,h]} + \|w_1\|^2 - \|Cx\|^2_{[\tau,h]} - \|z_{11} + z_{21} - \hat{\hat{z}}_1\|^2 \quad (\text{from (56)}) \\ &= \|r_0\|^2_{[\tau,h]} + \|r_1 - G^*_{2i}(z_{11} - \hat{\hat{z}}_1)\|^2 - \|G_3(z_{11} - \hat{\hat{z}}_1)\|^2 \quad (\text{from (46)}). \end{aligned}$$

From the above identity and (58) it follows that for any $r_1 \in L_2[0,h]$ and $r_0 \in \mathcal{R}_\tau$,

$$\sup_{\hat{\hat{z}}_1 \in \mathcal{Z}_\tau} \{\|r_0\|^2_{[\tau,h]} + \|r_1 - G^*_{2i}(z_{11} - \hat{\hat{z}}_1)\|^2 - \|G_3(z_{11} - \hat{\hat{z}}_1)\|^2\} \ge \epsilon \|w\|^2_{[\tau,\tau+h]} \ge \rho \|r_0\|^2_{[\tau,h]}$$

for some $\rho > 0$. Since the above holds for all r_1, it also holds for $r_1 = G^*_{2i}(z_{11} - \hat{\hat{z}}_1)$. Thus

$$\inf_{r_0 \in \mathcal{R}_\tau} \sup_{\hat{\hat{z}}_1 \in \mathcal{Z}_\tau} \{\|r_0\|^2_{[\tau,h]} - \|G_3(G_1 r_0 - \hat{\hat{z}}_1)\|^2\} \ge \rho \|r_0\|^2_{[\tau,h]},$$

where we have used the fact that $z_{11} = G_1 r_0$. Since the above holds for any $\tau \in (0,h)$, we conclude from Lemma 5.1 that the given modified Nehari problem is solvable.

CONSTRAINED H_∞ OPTIMAL CONTROL OVER AN INFINITE HORIZON*

ATHANASIOS SIDERIS† AND HÉCTOR ROTSTEIN‡

Abstract. It has been recently shown in [*Automatica J. IFAC*, 29 (1993), pp. 969–983; *IEEE Trans. Automat. Control*, 39 (1994), pp. 762–779] that time-domain constraints can be incorporated *explicitly* into H_∞ optimal control problems over a finite horizon. In this paper, we construct a sequence of such finite-horizon constrained H_∞ optimization problems and show that their solutions converge to the solution of the infinite-horizon H_∞ optimization. We prove that convergence is uniform in the H_∞ norm and that the optimal solution to the infinite-horizon problem is unique.

Key words. H_∞ optimal control, time-domain constraints

AMS subject classifications. 93C05, 93C80, 49N05

1. Introduction.

It has been recently shown that time-domain constraints can be incorporated *explicitly* into the H_∞ optimal control problems over a finite horizon. More specifically in [10, 8], the problem of minimizing the H_∞ norm of a closed-loop transfer function of a discrete-time system subject to convex constraints on the time responses of several closed-loop responses to given test signals such as steps, impulses, etc. imposed over a *finite* horizon is solved exactly.

These results allow significantly more insight into the properties of the constrained optimal systems and offer certain computational advantages over pure convex programming approaches for constrained control problems [4, 6, 2, 5]. These results are outlined in section 2.

In the approach in [10, 8], one perhaps expects that the decay of the time-domain responses implied by the asymptotic stability of the closed-loop system, along with the constraints over the finite horizon, produce a desirable time-domain behavior over the infinite horizon. However, constrained H_∞ optimal solutions may exhibit undesirable time-domain behavior *immediately* after the finite horizon, regardless of how long this horizon is extended.

This behavior is essentially caused because constrained H_∞ optimal solutions over a finite horizon are allpass, while such solutions over an infinite horizon are not necessarily so. Section 3 illustrates this point by a simple design example.

Given this situation, the following questions arise. What is the optimal constrained H_∞ norm, μ_∞, for the infinite-horizon problem? Is μ_∞ achieved, and if yes, what are the properties of the constrained optimal solution t^*? How can this solution be obtained or approximated? It is shown in [9] that under certain assumptions t^* exists, and a sequence of finite-horizon solutions t^n obtained by extending the horizon converges to t^* in the so-called normal sense; that is, there exists a subsequence t^{n_k} of t^n that converges to t^* uniformly on compact sets of $\mathcal{D}^c \doteq \{z \in \mathcal{C} \ / \ |z| > 1\}$ [1]. However, in the approach of [9] an approximating sequence is difficult to construct.

In this note, we take a different approach to the infinite-horizon constrained H_∞ problem. As is observed in [10], one can sacrifice optimality in the finite-horizon H_∞ optimization problems in order to obtain good behavior of the tail response. This is achieved in [10] by placing the closed-loop poles inside a disk $\mathcal{D}_{1/\rho}$ of radius $1/\rho$, $\rho > 1$, instead of the unit disk by means of a scaling $z \longleftarrow \rho \cdot z$, which is undone once the transfer function of the controller has been obtained. A similar device, although in a different setting, has been recently used in [11]. Examples in [10] show that extending the horizon coupled with such a ρ-scaling is very effective in producing a response that satisfies the constraints over the infinite horizon. However, no analysis has been given relating the solutions obtained in this manner to the optimal constrained H_∞ solution over the infinite horizon. The main result of this paper is to show that by taking the limit $\rho \to 1$ and by extending the time horizon *appropriately*, a sequence of real rational solutions is obtained that converges *uniformly* to the constrained optimal solution which is shown to be *unique*. Thus, we obtain complete answers to the questions raised above and most importantly a constructive procedure to approximate the optimal constrained H_∞ norm and solution by rational transfer functions. These results are obtained under certain assumptions on the given time-domain constraints which are easily satisfied in practice and can be readily checked. Section 4 contains our main results, while the most technical proofs are relegated to the appendix.

Our results are illustrated by a simple design example in section 5, and section 6 contains the conclusions.

Notation. L_∞ denotes the Lebesgue space of complex-valued functions which are essentially bounded on the unit circle, with norm $\|g\|_\infty \doteq \text{ ess } \sup_{\theta\in[0,2\pi]} |g(e^{j\theta})|$. By H_∞ we denote the set of functions $g(z) \in L_\infty$ that are analytic outside the closed unit disk and bounded on the unit circle. The H_∞ norm is defined as

$$\|g\|_\infty \doteq \text{ ess } \sup_{|z|>1} |g(z)|.$$

Under this definition, z^{-1} represents the unit delay operator. Finally, we define $g^\sim(z) \doteq g(1/z)$.

2. Problem formulation. Let $p(z)$ be the nominal plant, $k(z)$ be the controller to be designed, and $t(z) \doteq p(z)k(z)[1 + p(z)k(z)]^{-1}$ be the complementary sensitivity transfer function which represents the command response transfer function in the closed-loop system of $p(z)$ and $k(z)$. As $t(z)$ must be stable, it has an expansion

$$t(z) = \sum_{i=0}^{\infty} t_i z^{-i}.$$

The problem studied in this paper is the following.

PROBLEM 1 (H_∞ optimization with time-domain constraints over an infinite horizon). *Given two sequences* $\{ub_i\} = \{ub_0, ub_1, ub_2, \ldots\}$ *and* $\{lb_i\} = \{lb_0, lb_1, lb_2, \ldots\}$, *design a controller* $k(z)$ *such that*

(a) $k(z)$ *is internally stabilizing;*

(b) *the constraints*

$$lb_i \le t_i \le ub_i \qquad \forall\ i \ge 0$$

are satisfied; and

(c) $\|t\|_\infty$ *is minimized.* □

In [10, 8], the following problem is solved instead.

PROBLEM 2 (H_∞ optimization with time-domain constraints over a finite horizon). *Given two finite sequences* $\{ub_i\} = \{ub_0, ub_1, ub_2, \dots, ub_{n-1}\}$ *and* $\{lb_i\} = \{lb_0, lb_1, lb_2, \dots, lb_{n-1}\}$, *design a controller* $k(z)$ *such that*

(a) $k(z)$ *is internally stabilizing;*

(b) *the constraints*

$$lb_i \le t_i \le ub_i \qquad \forall\ i = 0, \dots, n-1$$

are satisfied; and

(c) $\|t\|_\infty$ *is minimized.* ∎

As observed in [10] and the introduction, as the horizon length $n \to \infty$, then the solutions will not in general converge in the H_∞-norm sense to a solution of the infinite-horizon problem [9]. Also we should point out that this form of the time-domain constrained H_∞ optimal control problem is considered here mainly for simplicity; the general version of the theory which requires a more elaborated notation and is technically more involved is treated in [8].

3. The finite-horizon case. In this section we summarize the solution of Problem 2 from [10]. By the well-known Youla parametrization lemma (see, e.g. [3]), the set of all admissible (i.e., resulting from internally stabilizing controllers) closed-loop transfer functions $t(z)$ can be expressed in the form

$$t(z) = u(z) - v(z)q(z),$$

where u is stable and v can be selected to be inner, i.e., stable and such that $v^\sim(z)v(z) = 1$ for $|z| = 1$ and both are determined from the problem data, while $q(z)$ is any stable transfer function $q(z)$ (the Youla parameter). Then the minimization of $\|t\|_\infty$ is easily seen to be equivalent to the minimization of $\|r - q\|_\infty$, where $r(z) = v^\sim(z)u(z)$ is real-rational and antistable (i.e., all its poles lie outside the unit disk). Let $u(z) = \sum_{i=0}^{\infty} u_i z^{-i}$, $v(z) = \sum_{i=0}^{\infty} v_i z^{-i}$, and $q(z) = \sum_{i=0}^{\infty} q_i z^{-i}$. Let $\mathbf{t_n} \doteq [t_0\ \cdots\ t_{n-1}]$, $\mathbf{u_n} \doteq [u_0\ \cdots\ u_{n-1}]$, $\mathbf{v_n} \doteq [v_0\ \cdots\ v_{n-1}]$, and

$$\mathbf{q_n} = [q_0 \cdots q_{n-1}].$$

Then it is easy to see that

$$t_i = u_i - \sum_{j=0}^{i} v_{i-j} q_j,$$

or in matrix notation,

$$\mathbf{t_n} = \mathbf{u_n} - \mathbf{q_n} V_n,$$

where

$$V_n = \begin{bmatrix} v_0 & v_1 & \cdots & v_{n-1} \\ 0 & v_0 & \cdots & v_{n-2} \\ \vdots & \vdots & \ddots & \vdots \\ 0 & \cdots & \cdots & v_0 \end{bmatrix}.$$

Introducing the additional notation

$$\mathbf{lb_n} \doteq [lb_0\ lb_1\ \cdots\ lb_{n-1}],$$
$$\mathbf{ub_n} \doteq [ub_0\ ub_1\ \cdots\ ub_{n-1}],$$

it is clear that the constraints up to the nth sample may be written as

$$\mathbf{lb_n} - \mathbf{u_n} \leq -\mathbf{q_n} V_n \leq \mathbf{ub_n} - \mathbf{u_n}.$$

Therefore, under the assumption that constraints are enforced only over a finite horizon, the time-domain constrained H_∞ problem may be formulated as

$$\mu_n = \min_{\substack{q \in H_\infty \\ \mathbf{lb_n} - \mathbf{u_n} \leq -\mathbf{q_n} V_n \leq \mathbf{ub_n} - \mathbf{u_n}}} \|r - q\|_\infty. \tag{1}$$

3.1. Summary of the solution in the finite-horizon case. It is convenient to replace r by its conjugate $g \doteq r^\sim$. The transfer function g is then stable and can be assumed to be strictly proper without loss of generality, by redefining q_0 if necessary. $g(z)$ has a minimal state-space realization

$$g = \left(\begin{array}{c|c} A & b \\ \hline c & 0 \end{array} \right).$$

Let W_c and W_o denote the controllability and observability Gramians of g, respectively, satisfying the discrete-time Lyapunov equations

$$W_c = A W_c A^t + b b^t,$$

$$W_o = A^t W_o A + c^t c,$$

and let w_c and w_o denote positive square roots of W_c and W_o. Then we have the following result.

THEOREM 1. *The solution to Problem* 1 *is obtained as*

$$q^*(z) = \sum_{i=0}^{n-1} q_i^* z^{-i} + z^{-n} q_{tail}^*(z),$$

where $\mathbf{q_n^*} \doteq [q_0^* \cdots q_{n-1}^*]$ *solves the convex minimization problem*

$$\mu_n = \min_{\substack{\mathbf{q_n} \\ \mathbf{lb_n} - \mathbf{u_n} \leq -\mathbf{q_n} V_n \leq \mathbf{ub_n} - \mathbf{u_n}}} \overline{\sigma}\left[W_n(\mathbf{q_n})\right]$$

with

$$W_n(\mathbf{q_n}) = \begin{bmatrix} w_o A^n w_c & w_o A^{n-1} b & \cdots & w_o A b & w_o b \\ c A^{n-1} w_c & c A^{n-2} b & \cdots & w_o b & -q_0 \\ \vdots & \vdots & & \vdots & \vdots \\ c A w_c & c w_c & \cdots & -q_{n-3} & -q_{n-2} \\ c w_c & -q_0 & \cdots & -q_{n-2} & -q_{n-1} \end{bmatrix}$$

and q_{tail}^* *the solution of the standard* H_∞ *optimization problem*

$$\|z^n \left[r - \sum_{i=0}^{n-1} q_i^* z^{-i} \right] - q_{tail}\|_\infty.$$

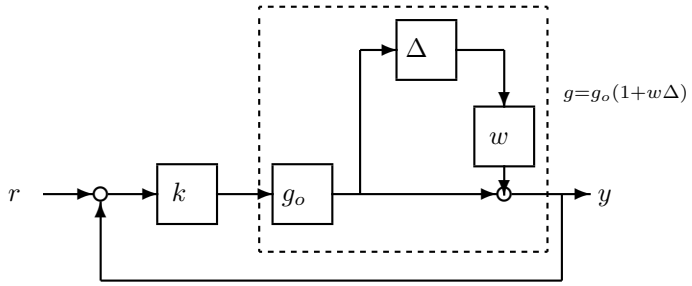

FIG. 1. *A simple design example.*

Proof. See [10]. ∎

A state-space procedure for computing $q(z)$ is given in [8]. It is a well-known fact that the solution to (1) is unique if no constraint is active at the optimum, since in that case the solution is given by the Nehari theorem (see, e.g., [3]).

It can be shown that this is the case even when a finite number of constraints are active, and therefore, the following result is true.

THEOREM 2 (see [9]). *Problem* 2 *has a unique solution.* ∎

3.2. A simple design example. Consider the system of Fig. 1. The nominal plant is given by $g_0(z) = \frac{z+0.2}{z^2-0.6z-1.12}$. We assume multiplicative model uncertainty of the form $g = g_o(1 + w\Delta)$, where $\Delta \in \mathcal{H}_\infty$ and the weighting function $w(z) = 0.3705\frac{z+0.986}{z+0.4682}$. We consider the following design specifications.

(1) The nominal closed-loop system should be asymptotically stable.
(2) For r a unit impulse at $i = 0$, y has a settling time of 10 samples for the nominal system, with a maximum peak of 0.6.
(3) The robustness of the closed-loop system is maximized for the multiplicative model uncertainty considered, i.e.,

$$\min_{k(z)\ \text{stab.}} \|w\ t\|_\infty$$

with $t(z) = \frac{k(z)g_o(z)}{1+k(z)g_o(z)} \equiv \sum_{i=0}^{\infty} t_i z^{-i}$.

As remarked previously, the formulation of Problems 1 and 2 can be easily extended to allow the use of weighting functions such as w above or even to impose time domain constraints on more than one, possibly different transfer functions than the ones involved in the $\mathcal{H}_\infty$ optimization [10, 8].

Standard H_∞ theory gives an optimal H_∞ norm of 0.66 but an impulse response that violates the second specification (Fig. 2). When we apply the method of constrained H_∞ optimization over finite horizons of lengths 30, 59, and 250 samples, we obtain the results depicted in Figs. 3, 4, and 5, respectively. These results clearly show that the oscillations immediately after the horizon cannot be controlled by simply extending the horizon.

4. Main results. In this section, we obtain a sequence of suboptimal solutions to finite-horizon constrained H_∞ optimal control problems that converges *uniformly* to the solution of the infinite horizon constrained H_∞ optimal control problem (Problem 1).

In proving the results of the paper, we make certain assumptions on the time-domain constraints. We collect these assumptions in the following subsection.

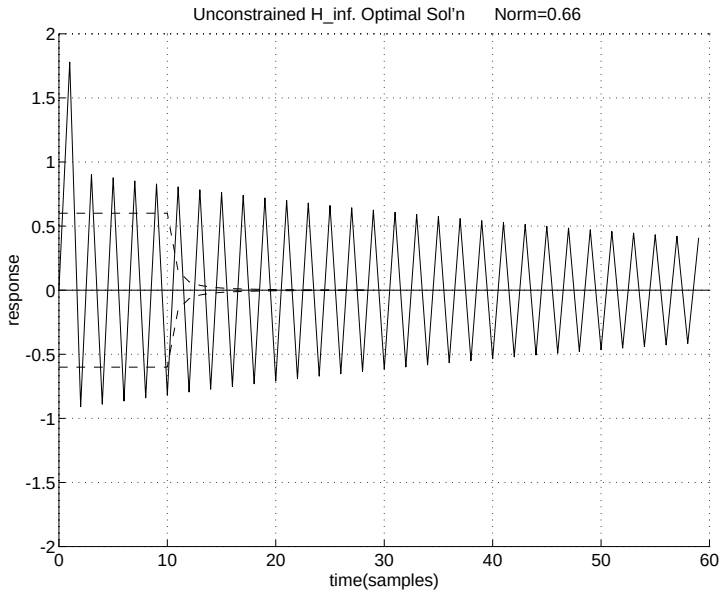

FIG. 2.

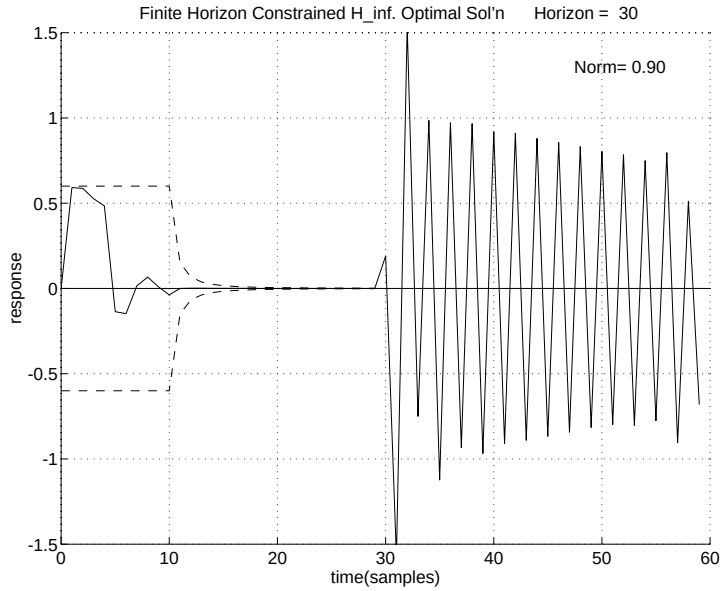

FIG. 3.

4.1. Assumptions on the time-domain constraints.

Assumption 1. The sequences $\{lb_i\}$ and $\{ub_i\}$ that define the time-domain constraints satisfy

$$\sum_{i=0}^{\infty} |lb_i - t_\infty| < \infty, \qquad \sum_{i=0}^{\infty} |ub_i - t_\infty| < \infty,$$

where $t_\infty \doteq \lim_{i\to\infty} t_i$ is the desired asymptotic value for t_i. ∎

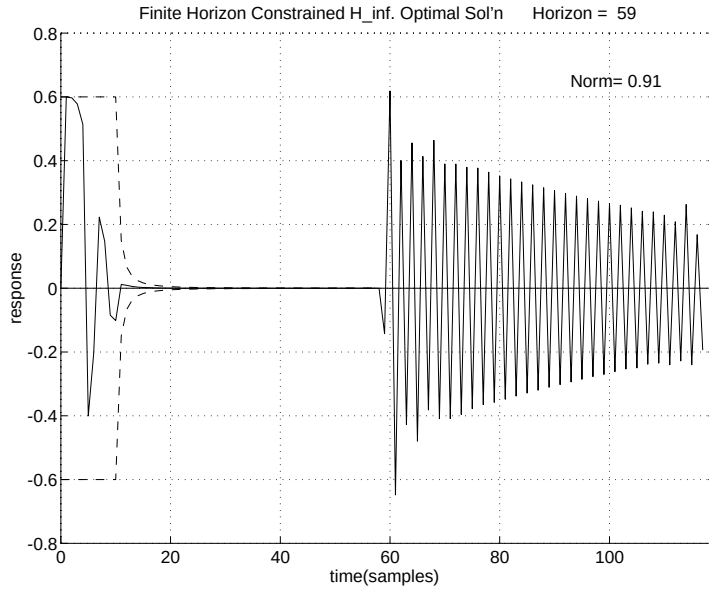

FIG. 4.

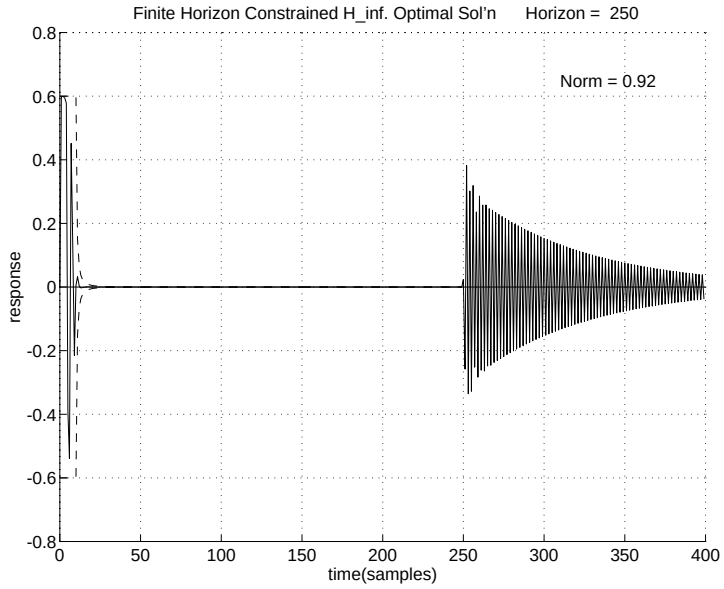

FIG. 5.

Assumption 2. There exists N_1 so that the time-domain constraints satisfy

$$lb_i \leq t_\infty \leq ub_i, \quad i \geq N_1,$$

where t_∞ is the desired asymptotic value for t_i. □

Assumption 3. The sequences $\{lb_i\}$ and $\{ub_i\}$ that define the time-domain constraints satisfy

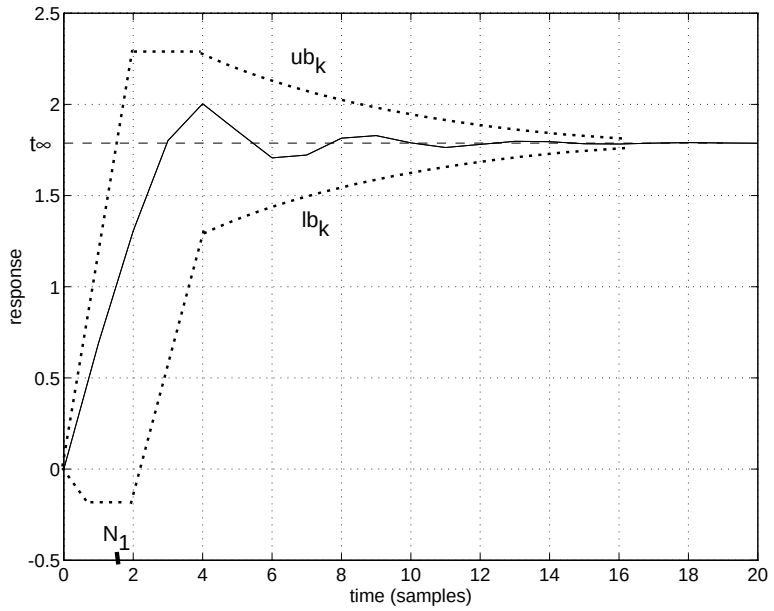

FIG. 6.

$$\sum_{i=0}^{\infty} \alpha^{-i} |lb_i - t_\infty| = \infty, \quad \sum_{i=0}^{\infty} \alpha^{-i} |ub_i - t_\infty| = \infty$$

for all $\alpha \in (0\ 1)$ and where t_∞ is the desired asymptotic value for t_i. □

The above assumptions are easily satisfied in all cases of practical interest.

This is illustrated by the typical step response bounds depicted in Fig. 6.

We also remark that Assumptions 1 to 3 are expressed in terms of the *given time response bounds*, that is, in terms of the problem data. Assumption 1 combined with Assumption 3 ensures that the sequences $\{ub_i\}$ and $\{lb_i\}$ converge to t_∞ but not exponentially fast. Assumption 2 requires that $\{ub_i\}$ and $\{lb_i\}$ converge to t_∞ from above and below, respectively.

Next, let Ω^n be the set of H_∞ functions that satisfy the time-domain constraints over the finite horizon of length n *and* the interpolation constraints necessary for nominal closed-loop stability. Each of the latter takes the form

$$\sum_{i=0}^{\infty} t_i w_k^{-i} = v_k, \quad k = 1, \ldots, r, \tag{2}$$

where w_k is plant pole or zero in $\mathcal{D}^c$ and $v_k = 1$ or 0, respectively (assuming for simplicity that w_k is of multiplicity one) [12]. Ω^n is then the feasible set for Problem 2. Similarly, Ω^∞ is the feasible set for Problem 1 and consists of the H_∞ functions satisfying the time-domain constraints over the infinite horizon and the stability interpolation constraints. We remark that Ω^∞ will generically either be empty or contain more than one point. Indeed, the case that Ω^∞ contains only one point is obtained when the hyperplane of the interpolation constraints (see (2)) intersects the set of the time-domain constraints only at one of its extreme points.

We also require the following assumption.

Assumption 4. *Ω^∞ contains a point $t^{FD}(z) = \sum_{i=0}^{L-1} t_i^{FD} z^{-i}$ of finite duration.*

Assumption 4 may appear at first to be restrictive. However, Lemma 1 of the next subsection shows that Assumption 4 is generically equivalent with the condition that Ω^∞ is not empty, that is, the existence of feasible solutions for Problem 1. Assumption 4 can be verified in practice by solving a linear programming problem. Consequently, Lemma 1 also gives a finite procedure to verify that Ω^∞ is not empty.

4.2. Preliminary results. In the remainder of the paper, we assume for simplicity that the asymptotic value $t_\infty = 0$ ($t_\infty = \lim_{i\to\infty} lb_i \equiv \lim_{i\to\infty} ub_i$ and, therefore, is a part of the problem data).

This is the case, for example, when t is the impulse response of a closed-loop rational transfer function. However, in case that $t_\infty \neq 0$, one should consider $t(z) - t_\infty$, $lb_k - t_\infty$, $ub_k - t_\infty$ in place of $t(z)$, lb_k, and ub_k, respectively, as well as $v_k - t_\infty$ in place of v_k in the interpolation constraints (2).

The following lemma provides justification for Assumption 4.

LEMMA 1. *Assume that the time-domain constraints satisfy Assumptions* 1–3 *and that t_∞, the desired asymptotic value for the solution, is zero. Then Ω^∞ is empty or it generically contains a point $t^{FD}(z) = \sum_{i=0}^{L-1} t_i^{FD} z^{-i}$ of finite duration.*

Proof. If Ω^∞ is empty, there is nothing to prove. Therefore, let us assume that Ω^∞ is not empty. By the previous discussion, Ω^∞ generically contains two functions $t(z)$, $s(z)$ such that $t(z) \neq s(z)$. Define

$$e(z) \doteq t(z) - s(z) = \sum_i e_i z^{-i},$$

and consider the stability interpolation constraints (2), assuming for ease of exposition that $w_k \in \mathbb{R}$, $k = 1, \ldots, r$. Then, e has at least $r+1$ nonzero coefficients. Indeed, let $e_i \neq 0$ for $i_1, \ldots, i_l$ (by hypothesis $l \geq 1$). It holds that

$$[e_{i_1} \;\; e_{i_2} \;\; \cdots \;\; e_{i_l}] \underbrace{\begin{bmatrix} 1 & 1 & \cdots & 1 \\ w_1^{-i_1} & w_2^{-i_1} & \cdots & w_r^{-i_1} \\ w_1^{-i_2} & w_2^{-i_2} & \cdots & w_r^{-i_2} \\ \vdots & \vdots & \vdots & \vdots \\ w_1^{-i_l} & w_2^{-i_l} & \cdots & w_r^{-i_l} \end{bmatrix}}_{\mathbf{W_r}} = [0 \;\; 0 \;\; \cdots \;\; 0].$$

Since $\mathbf{W_r}$ is full rank for $l < r+1$, it should be $l \geq r+1$.

Next, take

$$\hat{t}(z) \doteq \lambda t(z) + (1-\lambda) s(z)$$

for some $0 < \lambda < 1$. Clearly, $\hat{t}(z)$ satisfies the interpolation constraints, and moreover

$$lb_{i_j} \leq \min\{t_{i_j}, s_{i_j}\} < \hat{t}_{i_j} < \max\{t_{i_j}, s_{i_j}\} \leq ub_{i_j}.$$

Let $\epsilon = \min_{j=1,\ldots,r} \left\{ \hat{t}_{i_j} - lb_{i_j},\ ub_{i_j} - \hat{t}_{i_j} \right\} > 0$. This means that the coefficients $\hat{t}_{i_j}$, $j = 1, \ldots, r$ can be changed by ϵ without violating the time domain constraints. By Assumption 2, it holds that $lb_i \leq 0 \leq ub_i$ for some $i > N_1$. We next determine $L > N_1$ such that after dropping from $\hat{t}$ the tail

$$\hat{t}^{tail}(z) = \sum_{i=L}^{\infty} \hat{t}_i z^{-i} = z^{-L} \sum_{i=0}^{\infty} \hat{t}_{i+L} z^{-i},$$

$\hat{t}_{i_j},\ j=1,\dots,r$, in $\hat{t}^{FD}(z)=\sum_{i=0}^{L-1}\hat{t}_i z^{-i}$ can be modified by no more than ϵ to have $\hat{t}^{FD}(z)$ satisfy the stability interpolation constraints.

Since

$$\left|\hat{t}^{tail}(w_k)\right| = |w_k|^{-L}\left|\sum_{i=0}^{\infty}\hat{t}_{i+L}w_k^{-i}\right| \le |w_k|^{-L}\,\|\hat{t}\|_1,$$

choose L such that

$$|w_k|^{-L}\,\|\hat{t}\|_1 < \epsilon/\left\|\mathbf{W}\mathbf{r}^{-1}\right\|_1,$$

and compute

$$[\Delta_1\ \ \Delta_2\ \ \cdots\ \ \Delta_r] = [\hat{t}^{tail}(w_1)\ \ \hat{t}^{tail}(w_2)\ \ \cdots\ \ \hat{t}^{tail}(w_r)]\mathbf{W}\mathbf{r}^{-1}.$$

It follows that $|\Delta_i| \le \left\|\mathbf{W}\mathbf{r}^{-1}\right\|_1 \cdot \max_{j=1,\dots,r}\left\{|\hat{t}^{tail}(w_j)|\right\} < \epsilon$. Finally, define

$$t_i^{FD} = \begin{cases} \hat{t}_i, & 0\le i<L,\ i\ne i_1,\dots,i_r,\\ \hat{t}_i+\Delta_i, & i=i_1,\dots,i_r,\\ 0, & i\ge L,\end{cases}$$

and $t^{FD}=\sum_{i=0}^{\infty}t_i^{FD}z^{-i}$.

It is clear by construction that $t^{FD}\in\Omega^\infty$, and the proof is complete. ∎

We also have the following corollary to Lemma 1.

COROLLARY 1. *Consider Assumptions 1–4, and let $t\in\Omega^\infty$. Then there exists a sequence $\hat{t}^n\in\Omega^\infty$, $n=1,2,\dots$, of finite duration functions that converges uniformly to t.*

Proof. In the proof of Lemma 1, take $s(z)$ to be the finite duration point of Assumption 4, and let λ be sufficiently close to unity, so that $\|t-\hat{t}\|_\infty \le 1/(2n)$. Pick $\epsilon_1=\min\{\epsilon,1/(2nr)\}$ and L such that

$$|w_k|^{-L}\,\|\hat{t}\|_1 < \epsilon_1/\left\|\mathbf{W}\mathbf{r}^{-1}\right\|_1.$$

Then $|\Delta_i|<\epsilon$ and $\sum_{j=1}^{r}|\Delta_i|\le 1/(2n)$. It follows that $\left\|\hat{t}-t^{FD}\right\|_\infty \le \left\|\hat{t}-t^{FD}\right\|_1 \le 1/(2n)$ and $\|t-t^{FD}\|_\infty < 1/n$. Identify $\hat{t}^n$ with t^{FD}, and the proof is complete. ∎

Next, consider the disk of radius $1/\rho$

$$D_{1/\rho} = \{z\ /\ |z|<1/\rho\},\qquad \rho>1, \tag{3}$$

and let $t(z)$ have its poles inside $D_{1/\rho}$. We define the $\rho\infty$-norm of t as

$$\|t\|_{\rho\infty} \doteq \sup_{-\pi\le\theta\le\pi}\left|t\left(\frac{1}{\rho}e^{j\theta}\right)\right|. \tag{4}$$

LEMMA 2. *Let $t(z)=\sum_{k=0}^{\infty}t_k z^{-k}$ have its poles in $D_{1/\rho}$, and assume that the $\rho\infty$-norm of t satisfies*

$$\|t\|_{\rho\infty}\le M$$

for some constant M. Then

$$|t_k|\le M\rho^{-k}\quad\forall\ k.$$

Proof. It is well known that

$$t_k = \frac{1}{2\pi j} \oint_C t(z) z^{(k-1)} dz,$$

where C is a closed curve inside the region of convergence. Since all the singularities of $t(z)$ are confined inside a disk of radius $1/\rho$,

$$t_k = \frac{1}{2\pi} \int_{-\pi}^{\pi} t(e^{j\theta}/\rho) \rho^{-k} e^{jk\theta} d\theta.$$

This implies $|t_k| \le M\rho^{-k}$, and the result follows. ∎

4.3. Construction of suboptimal solutions in Ω^∞. We next describe a procedure to construct suboptimal solutions to Problem 1 which are in Ω^∞; that is, they satisfy the time-domain constraints over the infinite horizon. This is achieved by obtaining solutions to Problem 2 that have poles inside $D_{1/\rho}$ (see (3)) for $\rho > 1$ and for a horizon length n_ρ which is defined later. The construction is given in the following theorem.

THEOREM 3. *Assume that the time-domain constraints satisfy Assumptions* 1–4. *Fix* $\rho_o > 1$, *and let* $\rho_o > \rho > 1$.

Define

$$\hat{t}(z) \doteq t(\rho z) = \sum_{k=0}^{\infty} \underbrace{(t_k \rho^{-k})}_{\hat{t}_k} z^{-k}. \tag{5}$$

Also define an "equivalent" constraint set $\hat{\Omega}^n$ *for* $\hat{t}(z)$ *defined by bounds* $\hat{lb}_k$ *and* $\hat{ub}_k$ *derived from*

$$lb_k \le t_k \le ub_k \iff \underbrace{lb_k \rho^{-k}}_{\hat{lb}_k} \le \hat{t}_k \le \underbrace{ub_k \rho^{-k}}_{\hat{ub}_k}, \qquad k = 0, 1, \ldots, n-1,$$

and by the scaled interpolation constraints

$$\sum_{i=0}^{\infty} \hat{t}_i \underbrace{\left(\frac{w_k}{\rho}\right)}_{\hat{w}_k}^{-i} = v_k.$$

Let $\hat{t}^n$ *be the unique solution of the finite-horizon constrained* $\mathcal{H}_\infty$ *optimization problem*

$$\min_{\hat{t} \in \hat{\Omega}^n} \|\hat{t}\|_\infty,$$

and define

$$t^n(z) \doteq \hat{t}(z/\rho).$$

Then $t^n(z)$ *has the following properties.*

(1) t^n *is feasible over the finite horizon of length* n.

(2) t^n *has its poles inside* $D_{1/\rho} = \{z \ / \ |z| < 1/\rho\}$.

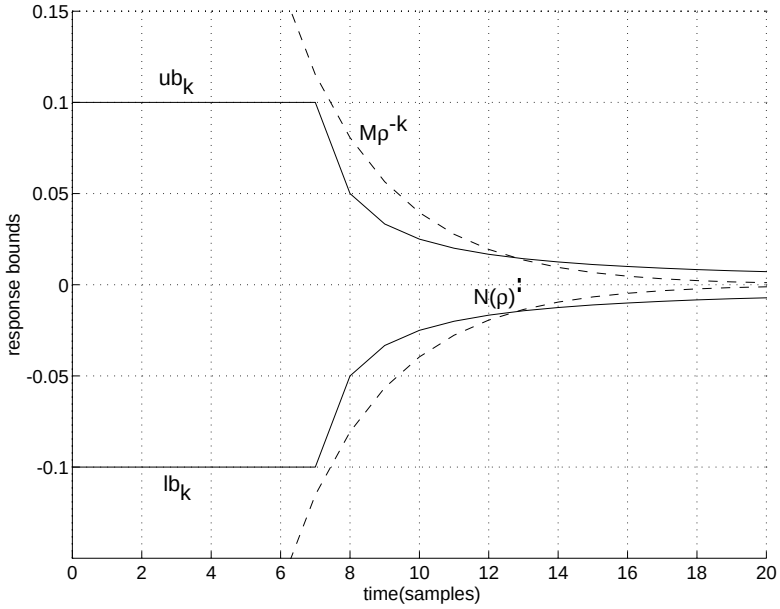

FIG. 7.

(3) *The $\rho\infty$-norm of t^n (see (4)) satisfies*

$$\|t\|_{\rho\infty} < M \quad \forall\ 1 < \rho < \rho_o,$$

where M is some constant depending only on the problem data and independent of both ρ and n.

(4) *There exists a horizon length n_ρ such that $t^{n_\rho} \in \Omega^\infty$; i.e., t^{n_ρ} is a feasible point for Problem* 1.

Proof. The first assertion follows from the construction of the set $\hat{\Omega}^n$. The second assertion is true because of the ρ-scaling in (5) and since $\hat{t}^n$ has its poles inside the unit disk. To show the third assertion consider the finite duration feasible point $t^{FD}(z)$ of Assumption 4 and let $M = \|t^{FD}\|_{\rho_o\infty}$. Then note that

$$\|t^n\|_{\rho\infty} \le \|t^{FD}\|_{\rho\infty} \le M \quad \forall\ \rho < \rho_o,$$

where the first inequality follows by the fact that t^{FD} is a feasible solution of Problem 2 for every ρ and t^n minimizes $\|t\|_{\rho\infty}$ over all $t \in \Omega^n$ by construction, and the second inequality follows by the maximum modulus principle. The last part of the proof is obtained by noting that t^n satisfies the assumptions of Lemma 2, and therefore it holds that

$$|t_k^n| \le M\rho^{-k} \quad \forall\ k \tag{6}$$

independently of the horizon length n. From Assumption 3, the bounds on the time-domain response converge to the steady-state value t_∞ less rapidly than the exponential decay prescribed by (6), and from Assumption 2, they remain on different sides of t_∞ after some $i > N_1$. Therefore, there is a time n_ρ after which the time-domain constraints are automatically satisfied by t^n (see Fig. 7). □

We are now in a position to state the main result of the paper.

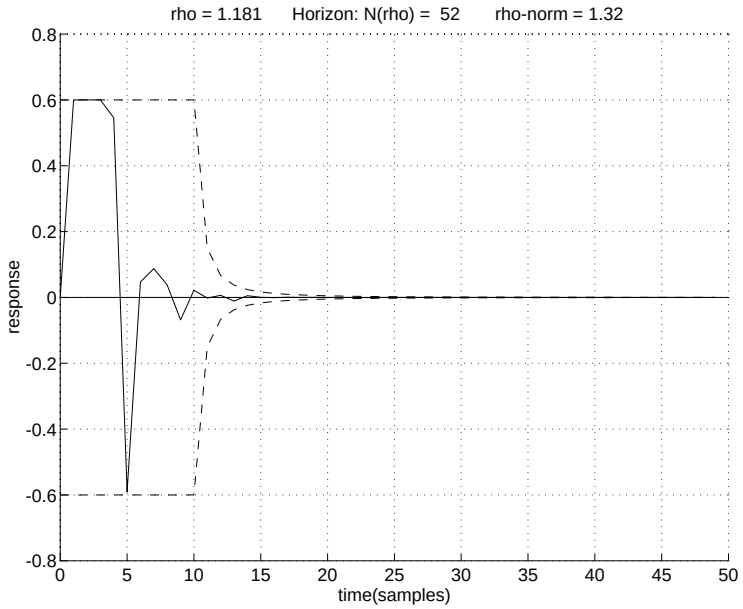

FIG. 8.

THEOREM 4. *Assume that the time-domain constraints satisfy Assumptions* 1–4. *Consider a sequence* ρ_n *such that* $\rho_n > 1 \ \forall \ n$ *and* $\rho_n \downarrow 1$ *as* $n \to \infty$ (*for example,* $\rho_n = 1 + \frac{1}{n}$). *Consider also* t^n *obtained from Theorem* 3 *for* $\rho = \rho_n$. *Then the following hold.*

(1) t^n *is feasible and unique for all* n.

(2) $\|t^n\|_{\rho_n \infty}$ *is monotonically decreasing and converges to* μ_∞, *the optimal constrained* H_∞ *norm over* Ω^∞.

(3) *The optimal norm in Problem* 1 *is achieved by a unique solution* t^*.

(4) $t^n \to t^*$ *uniformly.*

Proof. The proof of this result is rather technical and is included in the appendix. □

To illustrate Theorem 4 and the procedure of approximating the optimal solution, we apply it to the example of section 3.2. The results for different values of ρ are shown in Figs. 8–13. On top of each figure, we give the value of the ρ-scaling used, the horizon length n_ρ of Theorem 3, and the ρ-norm achieved by t_n—an upper bound on μ_∞.

We remark that it is also possible to derive a sequence of lower bounds converging to μ_∞ and thus obtain a meaningful stopping criterion based on the difference between the sequences of lower and upper bounds. Indeed, the H_∞-norm of the solution of Problem 2 for a horizon of length n_ρ and without the scaling of Theorem 3 gives such a sequence of lower bounds (see Figs. 3–5).

5. Conclusions. Theorem 4 resolves Problem 1 in a most satisfactory way. Under the mild Assumptions 1–4 on the time-domain constraints, Theorem 4 guarantees the existence of a unique optimal solution that can be approximated uniformly (that is, with approximation error measured in terms of the H_∞-norm) by rational functions. Furthermore, Theorem 4 gives a constructive procedure to obtain such approximations by solving finite-horizon problems. We remark that the horizon in each of these

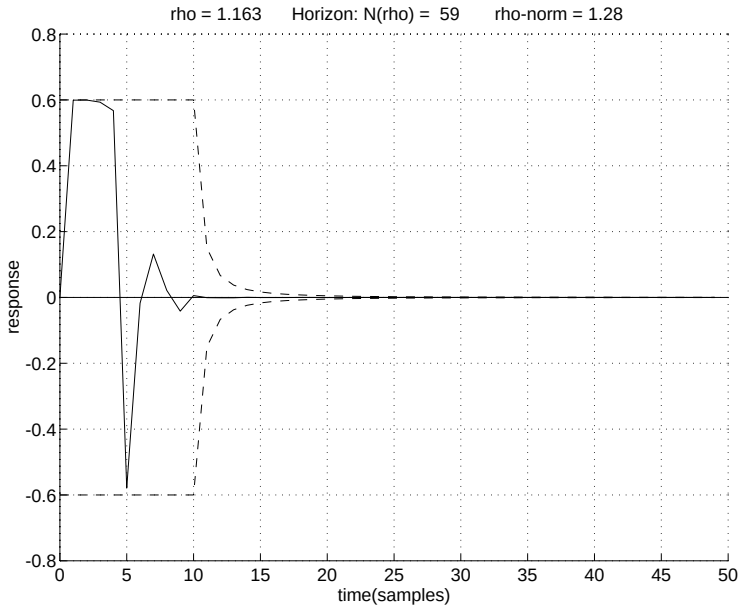

FIG. 9.

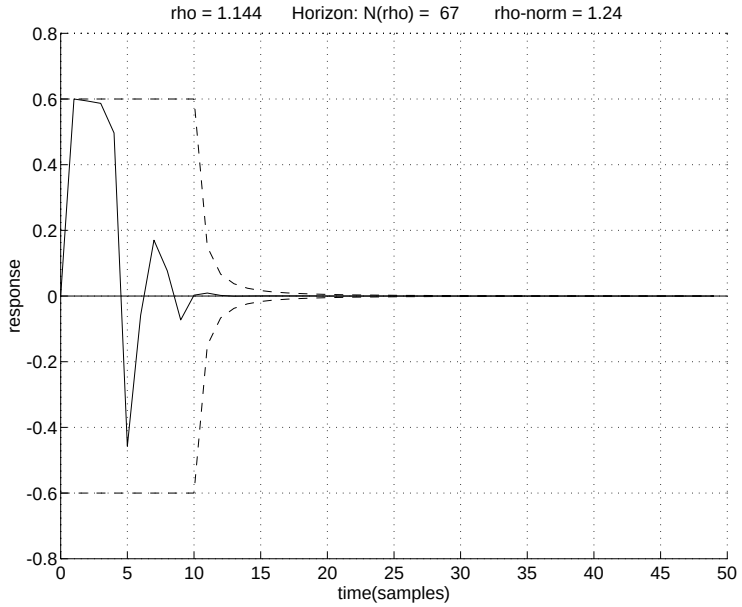

FIG. 10.

problems is determined from the given time-domain constraints and does not depend on the solution of the problem.

Although the basic concepts and some of the analysis used here carry through in the multivariable case, the latter apparently requires a different treatment. The main complications in the multivariable case arise from the nonuniqueness of the solution of

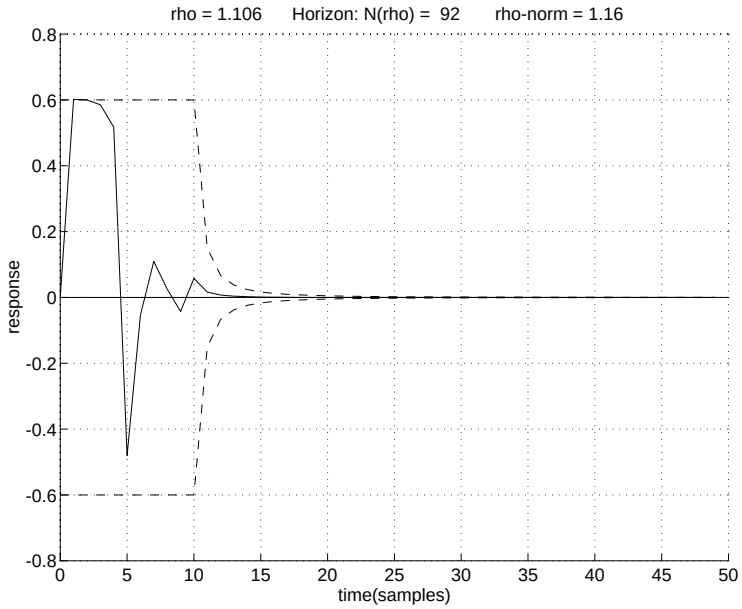

FIG. 11.

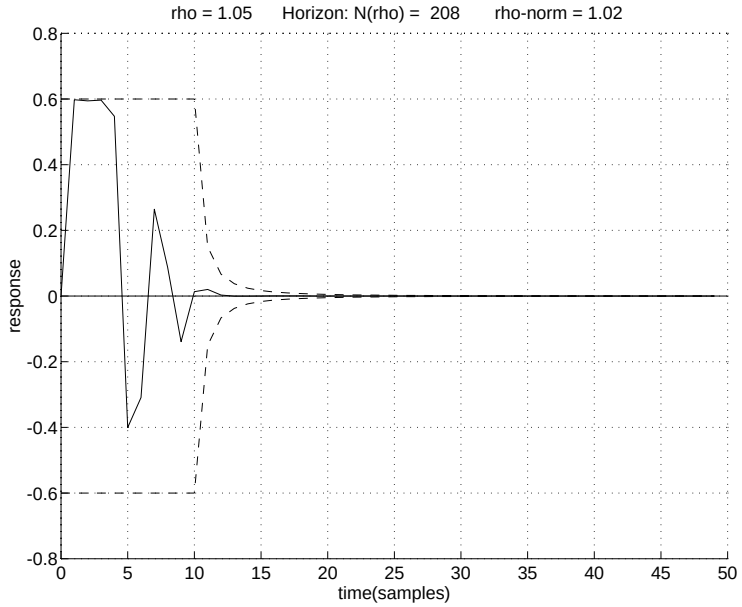

FIG. 12.

Problem 2 and the less straightforward representation of the interpolation constraints. One can equivalently pose the problem in terms of $Q \in H_\infty$, the Youla parameter of the Q-parametrization of all feedback stabilizing controllers. In this manner, the interpolation constraints are automatically satisfied but the time-domain constraints as reflected on Q are more complicated than the bound constraints assumed on t

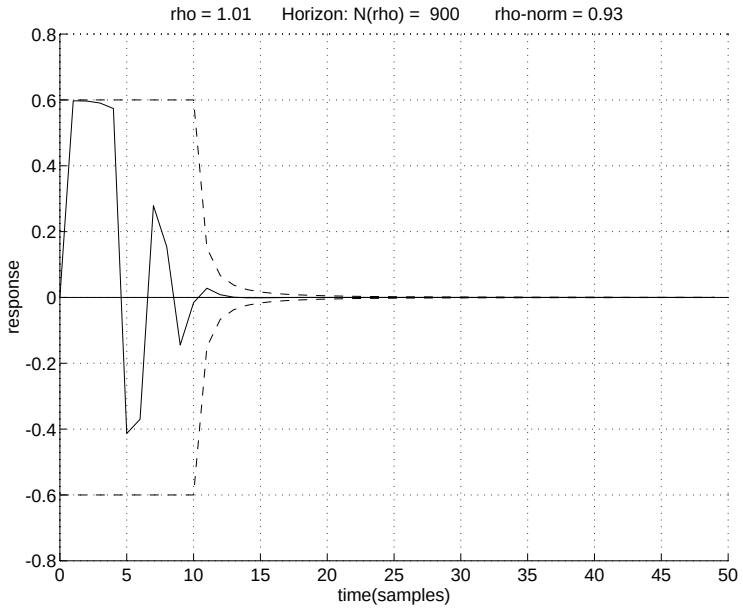

FIG. 13.

(see section 3 and [8]). However, experimentation with computer simulations in the multivariable case shows that the technique of ρ-scaling produces constrained solutions that satisfy the time-domain constraints over the infinite horizon and suggests that similar results with the ones obtained here for the SISO case are to be expected in the multivariable case also.

Appendix A. Proof of Theorem 4.

The proof of Theorem 4 is based on the following lemmas.

LEMMA 3. *Under Assumption* 1, Ω^∞ *is compact in the* ∞*-norm sense.*

Proof. Compactness of Ω^∞ is shown in [7]. We include the proof here for the reader's convenience. It is first shown that Ω^∞ is compact as a subset of the space l_1. Then Lemma [3] follows since the l_1 norm bounds the H_∞ norm.

Consider the set $\bar{\Omega}^\infty \subset l_1$ defined only by the time-domain constraints. The space l_1 is complete and $\bar{\Omega}^\infty$ is closed, and hence it suffices to show that for every $\epsilon > 0$ it is possible to cover $\bar{\Omega}^\infty$ with a finite number of balls in l_1 with radius ϵ. So let $\epsilon > 0$ be given. By Assumption 1, there exists N such that

$$\sum_{i=N}^{\infty} |lb_i - t_\infty| < \epsilon/4, \tag{7}$$

$$\sum_{i=N}^{\infty} |ub_i - t_\infty| < \epsilon/4, \tag{8}$$

implying $\sum_{i=N}^{\infty} |t_i - t_\infty| < \sum_{i=N}^{\infty} |lb_i - t_\infty| + \sum_{i=N}^{\infty} |ub_i - t_\infty| \le \epsilon/2 \ \forall\, t = \sum_{i=0}^{\infty} t_i z^{-i} \in \bar{\Omega}^\infty$. Now consider the set

$$\bar{\Omega}^N \doteq \{[t_0\ t_1\ \cdots\ t_{N-1}] \in \mathcal{R}^N \text{ s.t. } lb_i \le t_i \le ub_i\}.$$

$\bar{\Omega}^N$ is a closed and bounded set in $\mathcal{R}^N$ and hence there exists a finite number of balls

$\mathcal{B}(\hat{t}^k, \epsilon/2)$, centered at $\hat{t}^k \doteq [t_0^k \; t_1^k \; \cdots \; t_{N-1}^k]$ and of radius $\epsilon/2$ that cover $\bar{\Omega}^N$. Define

$$t^k \doteq [t_0^k \; t_1^k \; \cdots \; t_{N-1}^k \; t_\infty \; t_\infty \; \cdots],$$

and consider the balls $\mathcal{B}(t^k, \epsilon) \subset l_1$. Consider now any $t \in \bar{\Omega}^\infty$. By construction, there exist a k such that $\sum_{i=0}^{N-1} |t_i - t_i^k| < \epsilon/2$, and thus

$$\|t - t^k\|_1 \leq \sum_{i=0}^{N-1} |t_i - t_i^k| + \sum_{i=N}^{\infty} |t_i - t_\infty|, \tag{9}$$

$$\|t - t^k\|_1 < \epsilon/2 + \epsilon/2 = \epsilon. \tag{10}$$

Since the finite number of balls $\mathcal{B}(t^k, \epsilon)$ cover $\bar{\Omega}^\infty$, the set is compact.

Next, note that $\Omega^\infty \equiv \bar{\Omega}^\infty \cap \mathcal{I}$, where $\mathcal{I} \subset l_1$ is the set of functions satisfying the interpolation constraints (2). Since $\mathcal{I}$ is closed, it follows that Ω^∞ is also compact. □

The next lemma is instrumental in establishing uniqueness of the optimal solution in Problem 1.

LEMMA 4. *Let P be a continuous functional defined on a compact subset $\mathcal{B}$ of a Banach space, and consider the minimization*

$$\min_{x \in \mathcal{B}} P(x).$$

Suppose that x^* achieves the minimum $v^* = P(x^*)$ and that x^* is the unique minimizer. Then, given $\epsilon > 0$, there exists $\delta > 0$ such that if x_1, $x_2 \in \mathcal{B}$ with $v_1 = P(x_1)$, $v_2 = P(x_2)$ satisfying $|v_1 - v^*| \leq \delta$ and $|v_2 - v^*| \leq \delta$, it holds that $\|x_1 - x_2\| \leq \epsilon$.

Proof. Let us define the set $E_\delta = \{x \in \mathcal{B} / |P(x) - v^*| \leq \delta\}$, and let $d(\delta)$ be defined as

$$d(\delta) = \max_{x \in E_\delta} \|x - x^*\|.$$

Note that $d(\delta)$ is an increasing function of δ. We claim that $d(\delta) \to 0$ as $\delta \to 0$; that is, given ϵ, there exists δ such that $x \in E_\delta \implies d(\delta) \leq \epsilon$. Indeed, suppose that the last assertion is not true. Then for all δ, there exists $x_\delta \in \mathcal{B}$ such that $|P(x_\delta) - v^*| \leq \delta$ and $\|x_\delta - x^*\| > \epsilon$. Consider a sequence $\delta_n \to 0$ as $n \to \infty$ and the corresponding vectors $x_n \equiv x_{\delta_n}$. Since $\mathcal{B}$ is compact, $\{x_n\}$ has a convergence subsequence $y_n \equiv \{x_{n_k}\} \longrightarrow y^* \in \mathcal{B}$. Note that $\|y^* - x^*\| > \epsilon$ and the continuity of P implies $P(y^*) = \lim_{n \to \infty} P(y_n) = v^*$. This contradicts the hypothesis that x^* is the unique minimizer of P, and therefore, $d(\delta) \to 0$ as $\delta \to 0$ follows. Now given $\epsilon > 0$, let δ be such that $d(\delta) \leq \epsilon/2$, and assume that $|v_1 - v^*|$, $|v_2 - v^*| \leq \delta$. But then x_1, $x_2 \in E_\delta$ implying $\|x_1 - x_2\| \leq \|x_1 - x^*\| + \|x_2 - x^*\| \leq 2d(\delta) \leq \epsilon$, and the proof is complete. □

Next, we prove Theorem 4.

Proof of Part (1). The feasibility of t^n over the infinite horizon follows from Theorem 3, part (4). The uniqueness of t^n follows from Theorem 2. □

Proof of Part (2). Let $\mu_n \equiv \|t^n\|_{\rho_n \infty} \doteq \max_{|z| = \frac{1}{\rho_n}} |t^n(z)|$, and consider $1 < \rho_{n_2} < \rho_{n_1}$. Then it holds that

$$\mu_{n_2} = \max_{|z| = \frac{1}{\rho_{n_2}}} |t^{n_2}(z)| \leq \max_{|z| = \frac{1}{\rho_{n_2}}} |t^{n_1}(z)| \leq \max_{|z| = \frac{1}{\rho_{n_1}}} |t^{n_1}(z)| = \mu_{n_1},$$

where the first inequality above follows from the optimality of t^{n_2} and the fact that both t^{n_1} and t^{n_2} are feasible over the infinite horizon, and the second inequality follows from the maximum modulus principle. Since μ_n is monotone decreasing and bounded below, it converges to a number μ^*. Furthermore, since each t^n is feasible for the constrained H_∞ minimization over Ω^∞, it holds that

$$\mu_\infty \leq \|t^n\|_\infty \leq \mu_n.$$

Thus, we have

$$\mu_\infty \leq \mu^*. \tag{11}$$

Next, we show that the reverse inequality is true. Lemma 3 guarantees that μ_∞ in Problem 1 is achieved by some optimal solution $t^* = \sum_{i=0}^{\infty} t_i^* z^{-i}$.

Consider the sequence in Corollary 1, of finite-duration functions $\hat{t}^n \in \Omega^\infty$ that converges uniformly to t^*. By the optimality of t^n it holds that $\|\hat{t}^n\|_{\rho\infty} \geq \|t^n\|_{\rho\infty}\ \forall\ n$. Also by the maximum modulus principle, we have

$$\epsilon_n \doteq \|\hat{t}^n\|_{\rho\infty} - \|\hat{t}^n\|_\infty \geq 0. \tag{12}$$

Thus, we obtain

$$\|\hat{t}^n\|_\infty \geq \|t^n\|_{\rho\infty} - \epsilon_n. \tag{13}$$

Now note that $\epsilon_n \to 0$ as $n \to \infty$. (All functions $\hat{t}^n$ are uniformly bounded, and therefore they define an equicontinuous family of functions [1, p. 224]. Thus, given ϵ there exists δ such that

$$|z_1 - z_2| \leq \delta \implies |\hat{t}^n(z_1) - \hat{t}^n(z_2)| \leq \epsilon \quad \forall n. \tag{14}$$

Now take ϵ, let δ so that (14) holds, and consider N such that for $n \geq N$ it holds that $\rho_n \leq \frac{1}{1-\delta}$.

Then (14) implies

$$\left|\hat{t}^n\left(\frac{1}{\rho_n}e^{j\theta}\right) - \hat{t}^n(e^{j\theta})\right| \leq \epsilon \ \ \forall\theta \in [-\pi\ \pi] \quad n \geq N$$
$$\implies \left|\|\hat{t}^n\|_{\rho\infty} - \|\hat{t}^n\|_\infty\right| \leq \epsilon \quad n \geq N,$$

and $\epsilon_n \to 0$ follows from (12).)

By taking the limit in (13), we obtain

$$\mu_\infty \geq \mu^*, \tag{15}$$

and from (11) and (15) we obtain $\mu_\infty = \mu^*$. □

Proof of Part (3). To prove the uniqueness of t^*, let us assume that there exist t^{1*} and t^{2*} in Ω^∞ achieving μ_∞.

Next from Corollary 1, consider sequences $\hat{t}^{1n} \in \Omega^\infty$ and $\hat{t}^{2n} \in \Omega^\infty$ of finite-duration functions, converging uniformly to t^{1*} and t^{2*}, respectively Now note that $\|\cdot\|_{\rho\infty}$ is continuous, Ω^∞ is compact by Lemma 3, and the minimum of the finite-horizon constrained H_∞ optimization problem is unique by Theorem 2 and achieved by t^n. Therefore, Lemma 4 applies, and given ϵ, let δ be as in Lemma 4. From (12) we have $\|\hat{t}^{in}\|_{\rho\infty} - \|\hat{t}^{in}\|_\infty \to 0$, $i = 1, 2$, and from uniform convergence $\|\hat{t}^{in}\|_\infty \to$

$\|t^{i*}\|_\infty = \mu_\infty$, $i = 1, 2$. On the other hand, by parts (1) and (2), $\|t^n\|_{\rho\infty} \doteq \mu_n \to \mu^* \equiv \mu_\infty$. Therefore, there exists N_1 so that $\left|\|\hat{t}^{in}\|_{\rho\infty} - \mu_n\right| \leq \delta$, $i = 1, 2$ for $n \geq N_1$. From Lemma 4, we conclude

$$\|\hat{t}^{1n} - \hat{t}^{2n}\|_\infty \leq \epsilon \quad \forall\ n \geq N_1, \tag{16}$$

and from the uniform convergence of $\hat{t}^{1n}$ and $\hat{t}^{2n}$ to t^1 and t^2, respectively, there exists N_2 so that

$$\|\hat{t}^{in} - t^{i*}\|_\infty \leq \epsilon \quad \forall\ n \geq N_2, \quad i = 1, 2. \tag{17}$$

But then with $n \geq \max\{N_1,\ N_2\}$, (16) and (17) imply

$$\|t^{1*} - t^{2*}\|_\infty \leq 3\epsilon \quad \forall\ \epsilon;$$

i.e., $t^1 \equiv t^2$ and thus the optimal solution of Problem 1 over $\mathcal{S}$ is unique. □

Proof of Part (4). Let us apply Lemma 4 to $\hat{t}^n \doteq \hat{t}^{1n} \equiv \hat{t}^{2n}$ and t^n. With ϵ and δ as in Lemma 4, there exists N such that $|\|\hat{t}^n\|_\infty - \mu_\infty| \leq \delta$ and $|\|t^n\|_\infty - \mu_\infty| \leq \delta$ for $n \geq N_1$ (see the argument in the proof of part (3)). Since t^* is the unique minimizer of $\|\cdot\|_\infty$ over Ω^∞ by part (3), Lemma 4 implies

$$\|\hat{t}^n - t^n\|_\infty \leq \epsilon, \quad n \geq N_1. \tag{18}$$

On the other hand, $\hat{t}^n$ converges uniformly to t^*; therefore, there exists N_2 such that

$$\|\hat{t}^n - t^*\|_\infty \leq \epsilon, \quad n \geq N_2. \tag{19}$$

From (18) and (19), we conclude

$$\|t^n - t^*\|_\infty \leq 2\epsilon, \quad n \geq N = \max\{N_1,\ N_2\};$$

that is, t^n converges uniformly to t^*. □

EXPERIMENTAL CONFIRMATION OF A PDE-BASED APPROACH TO DESIGN OF FEEDBACK CONTROLS*

H. T. BANKS†, RALPH C. SMITH‡, D. E. BROWN§, R. J. SILCOX¶, AND VERN L. METCALF‖

Abstract. Issues regarding the experimental implementation of PDE-based controllers are discussed in this work. While the motivating application involves the reduction of vibration levels for a circular plate through excitation of surface-mounted piezoceramic patches, the general techniques described here will extend to a variety of applications. The initial step is the development of a PDE model which accurately captures the physics of the underlying process. This model is then discretized to yield a vector-valued initial value problem. Optimal control theory is used to determine continuous-time voltages to the patches, and the approximations needed to facilitate discrete-time implementation are addressed. Finally, experimental results demonstrating the control of both transient and steady-state vibrations through these techniques are presented.

Key words. feedback control, piezoceramic actuators, PDE model

1. Introduction.

An increasingly popular method for controlling structural vibrations is through the use of piezoceramic patches bonded to or embedded in the structure. These patches exhibit the piezoelectric property that inplane strains are generated in response to an applied voltage. Depending upon the geometry of patch placement, location with respect to the structure's neutral surface, and the method of excitation, this provides a mechanism for generating both inplane forces and/or bending moments in the underlying structure.

The advantage of using such patches as actuators in many applications is due to the fact that they are lightweight, space efficient, and relatively inexpensive and provide a means of obtaining structural control without significantly changing the passive structural dynamics. (They do not mass load the structure in the manner of a shaker or proof mass actuator.) Due to their ceramic nature, they can also be molded in a variety of shapes so as to fit the structure under consideration. Moreover, rigid body torques and spillover effects are minimized due to the fact that they are fully self-contained and distributed in nature. Finally, they also exhibit the inverse piezoelectric property and therefore generate a voltage in response to strains in the material. Hence a single patch or patch pair can be used for either sensing or actuation. This contributes to their efficiency and application in "smart material" structures.

In addition to their utility in purely structural applications, the patches are also finding increasing use in structural acoustic and fluid/structure applications. Again, their advantage lies in the fact that they provide an efficient means of controlling the structure without significantly altering its passive dynamics. Through consideration of the coupling between the structure and the adjacent media, this provides a means of controlling acoustic sound pressure levels or adjacent flow dynamics.

A great deal of research in the last several years has been directed at questions regarding the modeling of piezoceramic patch interactions with underlying structures (see [16] and the references therein), strategies for determination of optimal patch location and number, and control techniques which utilize the patches as sensors and actuators. Due to the steady-state periodic nature of the dynamics in many structural and structural acoustic systems, a large number of the current control methods are based upon frequency response input/output analysis. For example, Fuller, Gibbs, and Silcox have employed a feedforward filtered X version of an adaptive least mean squares algorithm to control flexural and extensional beam vibrations using piezoceramic actuators [25]. While such techniques have proven quite successful for controlling steady-state vibrations, they do not have the capability for direct control of transient responses. Other successfully implemented methods employing piezoelectric actuators to actively control structural vibrations include feedthrough techniques [24] and velocity feedback techniques [1, 32]. In general, these methods are based upon modal techniques and are designed to control purely steady-state responses. An exception to this is the experimental results reported in [32] in which transient plate vibrations, generated by an impact hammer, were reduced using an analog velocity feedback circuit.

Similar studies have demonstrated the experimental success of using surface-mounted piezoceramic patches to reduce structure-borne noise in structural acoustic systems [26, 27]. The emphasis in these studies was again on using frequency input/output analysis to control steady-state dynamics.

An alternative approach to controlling structural vibrations and sound pressure levels in structural acoustic systems is through the use of PDE-based feedback control methods. Analysis and numerical studies demonstrating these techniques for structural applications can be found in [7, 8, 9, 17] with corresponding results for structural acoustic systems given in [4, 6, 13]. These techniques start with an infinite-dimensional PDE model for the system under consideration. When developing such models, care should be taken to incorporate not only the contributions due to the piezoceramic patches but also dynamics due to inexact boundary conditions [18] coupling with adjacent acoustic fields [6], as well as any other physical phenomena which affect the dynamics of the structure. In this setting, mathematical issues such as model well-posedness and approximation issues concerning simulations, parameter estimation, and control can be addressed.

By approaching the problems in this manner, one can address the difficulties caused in purely modal methods by patch contributions, coupling between components, and inexact boundary conditions. Moreover, by combining the PDE model with appropriate time-dependent feedback control theory, one obtains a method which is equally applicable for controlling transient or steady-state vibrations.

There are several important features and benefits of a PDE-based approach. First, such an approach entails correct modeling based on physics. This facilitates treatment of actuator *loading* (passive) with respect to mass, stiffness, damping, geometry, etc., as well as the form of the actuator input. Of equal importance, the approach permits

the correct choice of an approximation framework so that computed quantities (which are suboptimal for the original infinite-dimensional system problem), such as states, feedback and compensator gains, and controls, actually converge to optimal quantities for the infinite-dimensional system, i.e., the actual physical model.

The choice of approximations is a *delicate* matter. It is known [11, 22] that failure to choose approximating elements "appropriately" in infinite-dimensional problems can yield poorly (weakly) convergent or even nonconvergent controls. "Appropriately" has been rather well documented in the PDE control research literature (e.g., see [3, 10, 28]) and involves concepts such as "costate or adjoint convergence" and "preservation of exponential stabilizability" (POES) or uniform stabilization under approximation (see Chapter 7 of [19] for a survey of some of the extensive theoretical literature on this subject). These theoretical concepts play a fundamental role in the practical choice of approximation schemes and associated computational algorithms.

For the problems and implementations addressed in this paper (including linear quadratic Gaussian (LQG) compensator and feedback design for unbounded input systems with periodic exogenous excitation), the theory is essentially complete if one combines and extends slightly the results in the literature (e.g., see [7, 23, 30, 35, 36]). A complete approximation and convergence analysis for the MinMax formulation is still under development, but the difficult points of the theory and their solution are basically resolved. We chose not to implement the MinMax design on the plate vibration problem described below since extensive computations [5] comparing the LQG and MinMax design suggested little advantage of the MinMax formulation for problems of the type considered in this paper.

In this paper, the experimental implementation of such a PDE-based control method is considered. While the motivating application involves the control of vibration levels for a circular plate through the excitation of surface-mounted piezoceramic patches, the general techniques described here will extend to a variety of applications. Following a brief discussion regarding the model and a Fourier–Galerkin scheme used to discretize it, relevant feedback control theory is discussed. In the discussion of the continuous- and discrete-time control results, two cases are considered; namely, the control of plate vibrations in the absence of a primary input force and the control of a plate driven by a periodic exogenous force. Implementation issues such as the effects of phase shifts and delays due to hardware are discussed, and the experimental setup is briefly described. Finally, experimental results demonstrating the transient and steady-state control results are presented. These demonstrate the effectiveness of the PDE-based controller for this system and indicate the potential of these control techniques for reducing transient and steady-state dynamics in other structural and structural acoustic systems.

Finally, we offer comments on the nature of our contributions here to the literature. This paper does *not* contain any new *theoretical* results; it reports on our successful use of PDE-based methods in experiments at NASA Langley Research Center. The methods (which *are* theoretically sound) for parameter estimation and feedback control are based on approximation theory developed (by us and many others in the PDE control community) during the past several decades. All necessary theorems on convergence of finite-dimensional parameter estimates, gains, filters, controls, observers, tracking variables, et cetera, needed for the examples treated here either have appeared or will soon appear in the research literature. Many of these theoretical results on PDE-based control have been largely viewed (especially in the engineering community) as nonimplementable and, hence, as somewhat irrelevant to

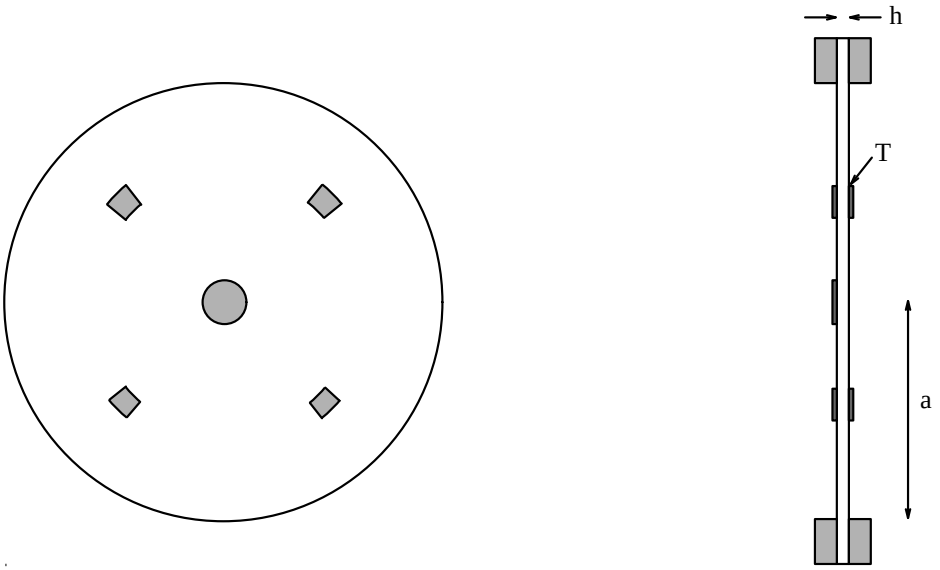

FIG. 2.1. *Thin circular plate with surface-mounted piezoceramic patches.*

applied scientists and engineers. The present manuscript refutes this notion and validates the practicality and importance of much of the theoretical efforts over the past years on PDE-based control. Our group is the first, to our knowledge, to provide substantial evidence that one can start from basic physical laws, derive careful infinite-dimensional distributed parameter or PDE control models, and successfully implement PDE control methods (with the approximations necessary to obtain finite-dimensional controls) which behave as theory and simulations predict.

2. Circular plate model. The structure under consideration is a thin circular plate with s sets of piezoceramic patches of thickness T bonded to the plate either singly or in pairs as depicted in Figure 2.1. Throughout this discussion, the radius and thickness of the plate are denoted by a and h, respectively. The density, Young's modulus, Poisson ratio, and Kelvin–Voigt damping parameters for the plate are given by $\rho_p, E_p, \nu_p, \hat{c}_{D_p}$, respectively, while similar parameters for the patches and bonding layer are denoted by $E_{pe}, \nu_{pe}, \nu_{pe}, \hat{c}_{D_{pe}}$ and $E_{b\ell}, \nu_{b\ell}, \nu_{b\ell}, \hat{c}_{D_{b\ell}}$, respectively. Moreover, μ, w, and $\tilde{g}$ are used to denote the air damping coefficient, transverse displacement, and external force on the plate. Finally, the region occupied by the unstrained neutral surface of the plate is indicated by Γ_0.

We point out that using current technology, piezoceramic patches can be cut to a variety of shapes. This includes circular and sectoral patches appropriate for the circular plate geometry considered here. From a modeling perspective, alignment of patch edges with coordinate axes is unnecessary when employing a weak form of the model; variations in shape simply affect the characteristic functions used to isolate the patch contributions. With regards to performance, experience indicates that while patch size, number, and placement strongly affect the ultimate control performance, slight variations in shape have minimal effect on the attenuation achieved using piezoceramic actuators.

Equations of motion for the plate can be determined from both Newtonian (force and moment balancing) and Hamiltonian (energy formulation) principles, and we

summarize both approaches here. The presentation will be for a general Kirchhoff plate with potentially nonaxisymmetric responses.

2.1. Strong form of plate model. Considering first the model which derives from Newtonian principles, we let $M_r, M_\theta, M_{r\theta}$ denote internal moments and $(M_r)_{pe}, (M_\theta)_{pe}$ denote external moments generated by the piezoceramic patches. As detailed in [12, 39], for a structure with s patch pairs, the internal moments are given by

$$\begin{aligned} M_r &= DK_r + \tilde{D}K_\theta + c_D\dot{K}_r + \tilde{c}_D\dot{K}_\theta, \\ M_\theta &= DK_\theta + \tilde{D}K_r + c_D\dot{K}_\theta + \tilde{c}_D\dot{K}_r, \\ M_{r\theta} &= M_{\theta r} = \frac{D}{2}\tau - \frac{\tilde{D}}{2}\tau + \frac{c_D}{2}\dot{\tau} - \frac{\tilde{c}_D}{2}\dot{\tau}, \end{aligned}$$

where

$$K_r = -\frac{\partial^2 w}{\partial r^2}, \quad K_\theta = -\frac{1}{r}\frac{\partial w}{\partial r} - \frac{1}{r^2}\frac{\partial^2 w}{\partial \theta^2}, \quad \tau = -\frac{2}{r}\frac{\partial^2 w}{\partial r \partial \theta} + \frac{2}{r^2}\frac{\partial w}{\partial \theta}.$$

The global flexural rigidity parameters D and $\tilde{D}$ and Kelvin–Voigt damping parameters c_D and $\tilde{c}_D$ are given by

$$\begin{aligned} D(r,\theta) &= \frac{E_p h^3}{12(1-\nu_p^2)} + \frac{2}{3}\sum_{i=1}^{s}\left[\frac{E_{pe}a_{3pe}}{1-\nu_{pe}^2} + \frac{E_{b\ell}a_{3b\ell}}{1-\nu_{b\ell}^2}\right]\chi_i(r,\theta), \\ \tilde{D}(r,\theta) &= \frac{E_p h^3 \nu_p}{12(1-\nu_p^2)} + \frac{2}{3}\sum_{i=1}^{s}\left[\frac{E_{pe}a_{3pe}\nu_{pe}}{1-\nu_{pe}^2} + \frac{E_{b\ell}a_{3b\ell}\nu_{b\ell}}{1-\nu_{b\ell}^2}\right]\chi_i(r,\theta), \\ c_D(r,\theta) &= \frac{\hat{c}_{D_p} h^3}{12(1-\nu_p^2)} + \frac{2}{3}\sum_{i=1}^{s}\left[\frac{\hat{c}_{D_{pe}}a_{3pe}}{1-\nu_{pe}^2} + \frac{\hat{c}_{D_{b\ell}}a_{3b\ell}}{1-\nu_{b\ell}^2}\right]\chi_i(r,\theta), \\ \tilde{c}_D(r,\theta) &= \frac{\hat{c}_{D_p} h^3 \nu_p}{12(1-\nu_p^2)} + \frac{2}{3}\sum_{i=1}^{s}\left[\frac{\hat{c}_{D_{pe}}a_{3pe}\nu_{pe}}{1-\nu_{pe}^2} + \frac{\hat{c}_{D_{b\ell}}a_{3b\ell}\nu_{b\ell}}{1-\nu_{b\ell}^2}\right]\chi_i(r,\theta). \end{aligned} \tag{2.1}$$

Here $a_{3b\ell} = (h/2+T_{b\ell})^3 - (h/2)^3$ and $a_{3pe} = (h/2+T_{b\ell}+T)^3 - (h/2+T_{b\ell})^3$ arise from integration through the bonding layer and patch thickness while $\chi_i(r,\theta)$ denotes the characteristic function which has a value of 1 in the region covered by the ith patch and is 0 elsewhere. A similar definition is used for the density which also exhibits a piecewise constant nature due to the presence of the patches. These definitions can be adapted to the case of a single patch that is bonded to the plate by replacing the 2/3 by 1/3. We point out that if the plate, patches, and bonding layers have the same Poisson ratios ($\nu_p = \nu_{pe} = \nu_{b\ell} = \nu$), then the internal moment expressions reduce to the familiar relations for a thin plate. For example, M_r in this case is given by

$$M_r = -D\left(\frac{\partial^2 w}{\partial r^2} + \frac{\nu}{r}\frac{\partial w}{\partial r} + \frac{\nu}{r^2}\frac{\partial^2 w}{\partial \theta^2}\right) - c_D\left(\frac{\partial^3 w}{\partial r^2 \partial t} + \frac{\nu}{r}\frac{\partial^2 w}{\partial r \partial t} + \frac{\nu}{r^2}\frac{\partial^3 w}{\partial \theta^2 \partial t}\right),$$

with D and c_D defined in (2.1).

The external moments generated by the patches in response to an applied voltage (out-of-phase for the patch pair) are given by

$$(M_r)_{pe} = (M_\theta)_{pe} = -\sum_{i=1}^{s} \mathcal{K}_i^B u_i(t)\chi_i(r,\theta),$$

where $u_i(t)$ is the voltage into the ith patch and $\mathcal{K}_i^B$ is a parameter which depends on the geometry, piezoceramic material properties, and piezoelectric strain constants (see [16] for details).

The internal and external moments can then be combined to yield the general plate moments

$$\begin{aligned} \mathcal{M}_r &= M_r - (M_r)_{pe}, \\ \mathcal{M}_\theta &= M_\theta - (M_\theta)_{pe}, \\ \mathcal{M}_{r\theta} &= M_{r\theta}. \end{aligned}$$

For a clamped plate with initial displacement $w_0(r,\theta)$ and velocity $w_1(r,\theta)$, force and moment balancing yield the equations

$$\begin{cases} \rho h \dfrac{\partial^2 w}{\partial t^2} + \mu \dfrac{\partial w}{\partial t} - \dfrac{\partial^2 \mathcal{M}_r}{\partial r^2} - \dfrac{2}{r}\dfrac{\partial \mathcal{M}_r}{\partial r} + \dfrac{1}{r}\dfrac{\partial \mathcal{M}_\theta}{\partial r} & 0 < \theta \le 2\pi, \\ \quad -\dfrac{2}{r}\dfrac{\partial^2 \mathcal{M}_{r\theta}}{\partial r \partial \theta} - \dfrac{2}{r^2}\dfrac{\partial \mathcal{M}_{r\theta}}{\partial \theta} - \dfrac{1}{r^2}\dfrac{\partial^2 \mathcal{M}_\theta}{\partial \theta^2} = \tilde{g}(t,r,\theta), & 0 \le r < a; \end{cases}$$

$$\text{(2.2)} \quad \begin{cases} w(t,a,\theta) = \dfrac{\partial w}{\partial r}(t,a,\theta) = 0; \end{cases}$$

$$\begin{cases} w(0,r,\theta) = w_0(r,\theta), \qquad \dfrac{\partial w}{\partial t}(0,r,\theta) = w_1(r,\theta) \end{cases}$$

as the strong form of the plate model (see [12, 37] for details). From an applications perspective, the following observations can be made regarding this model.

(1) It is first noted that in many applications, it is nearly impossible to maintain the truly fixed (zero displacement and slope) boundary conditions specified in the model (2.2). For the experimental plate which we used, parameter estimation results indicated minimal energy loss through the boundary conditions, and an adequate fit of the model (2.2) was obtained (see the identification results in [2, 15]). For plates in which the boundary clamping is less secure, a model for imperfectly clamped boundaries such as that presented in [18] should be used in order to obtain a model fit which is adequate for control applications.

(2) As discussed in [16] and noted in the model, the plate parameters ρ, D, ν, and c_D are discontinuous due to the presence and differing material properties of the patches. Moreover, while "handbook" values can be determined for ρ, D, and ν for a plate which is devoid of patches, those values usually cannot be used in the final system model with any accuracy due to nonuniformities in the plate and boundary conditions, variations in materials, and contributions due to the presence of the patches. In applications, such as that in this paper, these parameters are estimated using fit-to-data techniques (see [2, 15] for the parameter estimation results pertaining to the plate used here).

(3) The input parameters $\mathcal{K}_i^B$ are discontinuous since they are nonzero only over the regions of the patches. While expressions for these constants are derived in [16],

they too must be estimated in applications due to manufacturing variations in the patches.

It is readily noted in the strong form of the modeling equations that the discontinuous plate parameters and patch input terms are differentiated, thus leading to derivatives of the Dirac δ "function." The difficulties associated with this formulation are avoided in the weak form of the modeling equations which is presented in the next section.

2.2. Weak form of plate model. To provide a framework which facilitates analysis, approximation, and implementation, it is advantageous to consider a weak form of the modeling equations. Such a formulation can be determined directly from Hamiltonian (energy) principles and is equivalent to that obtained by integration by parts after multiplication of the strong form by suitably smooth test functions.

For the plate problem under consideration, a suitable space V of test functions is the subset of the Sobolev space $H^2(\Gamma_0)$ which satisfies the essential boundary conditions $w = \partial w/\partial r = 0$ at $r = a$. As detailed in [12, 39], a weak or variational form of the equations of motion for the plate is

$$\int_{\Gamma_0} \rho h \frac{\partial^2 w}{\partial t^2}\overline{\eta} d\gamma + \int_{\Gamma_0} \mu \frac{\partial w}{\partial t}\overline{\eta} d\gamma - \int_{\Gamma_0} M_r \overline{\frac{\partial^2 \eta}{\partial r^2}} d\gamma - \int_{\Gamma_0} \frac{1}{r^2} M_\theta \left[r\overline{\frac{\partial \eta}{\partial r}} + \overline{\frac{\partial^2 \eta}{\partial \theta^2}} \right] d\gamma$$
$$-2\int_{\Gamma_0} \frac{1}{r^2} M_{r\theta} \left[r\overline{\frac{\partial^2 \eta}{\partial r \partial \theta}} - \overline{\frac{\partial \eta}{\partial \theta}} \right] d\gamma = \int_{\Gamma_0} \sum_{i=1}^{s} \mathcal{K}_i^B u_i(t) \chi_i(r,\theta) \overline{\nabla^2 \eta} d\gamma + \int_{\Gamma_0} \tilde{g}\overline{\eta} d\gamma \tag{2.3}$$

for all $\eta \in V$. The overbar here denotes complex conjugation and the differential is $d\gamma = r d\theta dr$. It is easily noted that in this form, derivatives that were originally applied to moments have been transferred onto test functions. This eliminates the difficulties associated with differentiating the piecewise constant parameters ρ, D, ν, and c_D found in the internal moments as well as the discontinuous input parameters $\mathcal{K}_1^B, \ldots, \mathcal{K}_s^B$.

2.3. State approximation. As discussed in [12, 39], an appropriate choice for the basis and Fourier–Galerkin expansion of the plate displacement, when considering clamped boundary conditions, is $B_k^{\mathcal{N}}(r,\theta) = r^{|\hat{m}|} B_n^m(r) e^{im\theta}$ and

$$w^{\mathcal{N}}(t,r,\theta) = \sum_{m=-M}^{M} \sum_{n=1}^{N^m} w_{mn}^{\mathcal{N}}(t) r^{|\hat{m}|} B_n^m(r) e^{im\theta} = \sum_{k=1}^{\mathcal{N}} w_k^{\mathcal{N}}(t) B_k^{\mathcal{N}}(r,\theta). \tag{2.4}$$

Here $B_n^m(r)$ is the nth modified cubic spline satisfying $B_n^m(a) = \frac{dB_n^m(a)}{dr} = 0$, with the condition $\frac{dB_n^m(0)}{dr} = 0$ being enforced when $m = 0$ (this latter condition guarantees differentiability at the origin and implies that

$$N^m = \begin{cases} N, & m = 0, \\ N+1, & m \neq 0, \end{cases}$$

where N denotes the number of modified cubic splines). The total number of plate basis functions is $\mathcal{N} = (2M+1)(N+1) - 1$. As discussed in [12, 39], the inclusion of the weighting term $r^{|\hat{m}|}$ with

$$\hat{m} = \begin{cases} 0, & m = 0, \\ 1, & m \neq 0, \end{cases}$$

is motivated by the asymptotic behavior of the Bessel functions, which make up the analytic plate solution as $r \to 0$. It also serves to ensure the uniqueness of the solution at the origin. The Fourier coefficient in the weight is truncated to control the conditioning of the mass and stiffness matrices (see the examples in [12]).

To obtain a matrix system (again, see [12, 39] for a careful derivation with complete details), the $\mathcal{N}$-dimensional approximating subspace is taken to be $H^{\mathcal{N}} = \text{span}\{B_k^{\mathcal{N}}\}$ and the product space for the usual corresponding first-order vector system is $\mathcal{H}^{\mathcal{N}} \times \mathcal{H}^{\mathcal{N}}$. The restriction of the first-order form for the infinite-dimensional system (2.3) to the space $\mathcal{H}^{\mathcal{N}} \times \mathcal{H}^{\mathcal{N}}$ then yields the matrix equation

$$\begin{bmatrix} K_D^{\mathcal{N}} & 0 \\ 0 & M^{\mathcal{N}} \end{bmatrix} \begin{bmatrix} \dot{\vartheta}^{\mathcal{N}}(t) \\ \ddot{\vartheta}^{\mathcal{N}}(t) \end{bmatrix} = \begin{bmatrix} 0 & K_D^{\mathcal{N}} \\ -K_D^{\mathcal{N}} & -K_{c_D}^{\mathcal{N}} \end{bmatrix} \begin{bmatrix} \vartheta^{\mathcal{N}}(t) \\ \dot{\vartheta}^{\mathcal{N}}(t) \end{bmatrix} + \begin{bmatrix} 0 \\ \tilde{B}^{\mathcal{N}} \end{bmatrix} u(t) + \begin{bmatrix} 0 \\ \hat{g}^{\mathcal{N}}(t) \end{bmatrix},$$

$$\begin{bmatrix} K_D^{\mathcal{N}} & 0 \\ 0 & M^{\mathcal{N}} \end{bmatrix} \begin{bmatrix} \vartheta^{\mathcal{N}}(0) \\ \dot{\vartheta}^{\mathcal{N}}(0) \end{bmatrix} = \begin{bmatrix} g_1^{\mathcal{N}} \\ g_2^{\mathcal{N}} \end{bmatrix},$$

where $\vartheta^{\mathcal{N}}(t) = [w_1^{\mathcal{N}}(t), w_2^{\mathcal{N}}(t), \ldots, w_{\mathcal{N}}^{\mathcal{N}}(t)]^T$ denotes the column $\mathcal{N}$ vector containing the approximate state coefficients (see (2.4)). For the case in which $\nu_p = \nu_{pe} = \nu_{b\ell} = \nu$, the component matrices and vectors are given by

$$\begin{aligned}
&K_D^{\mathcal{N}} = K_{D1} + K_{D2} + K_{D3} + K_{D4} + K_{D5}, \\
&K_{c_D}^{\mathcal{N}} = K_{c_D1} + K_{c_D2} + K_{c_D3} + K_{c_D4} + K_{c_D5} + \int_{\Gamma_0} \mu B_k^{\mathcal{N}} \overline{B_\ell^{\mathcal{N}}} \, d\gamma, \\
&\left[M^{\mathcal{N}}\right]_{\ell,k} = \int_{\Gamma_0} \rho h B_k^{\mathcal{N}} \overline{B_\ell^{\mathcal{N}}} \, d\gamma, \qquad (2.5) \\
&\left[\hat{g}^{\mathcal{N}}(t)\right]_\ell = \int_{\Gamma_0} \tilde{g} \overline{B_\ell^{\mathcal{N}}} \, d\gamma, \quad \left[\tilde{B}^{\mathcal{N}}\right]_{\ell,j} = \int_{j^{th}patch} \mathcal{K}_j \overline{\nabla^2 B_\ell^{\mathcal{N}}} \, d\gamma, \\
&\left[g_1^{\mathcal{N}}\right]_\ell = \left\langle w_0, B_\ell^{\mathcal{N}} \right\rangle_V, \quad \left[g_2^{\mathcal{N}}\right]_\ell = \left\langle w_0, B_\ell^{\mathcal{N}} \right\rangle_H,
\end{aligned}$$

where

$$\begin{aligned}
[K_{D1}]_{\ell,k} &= \int_{\Gamma_0} D \left[\frac{\partial^2 B_k^{\mathcal{N}}}{\partial r^2} + \frac{\nu}{r} \frac{\partial B_k^{\mathcal{N}}}{\partial r} + \frac{\nu}{r^2} \frac{\partial^2 B_k^{\mathcal{N}}}{\partial \theta^2} \right] \frac{\partial^2 \overline{B_\ell^{\mathcal{N}}}}{\partial r^2} \, d\gamma, \\
[K_{D2}]_{\ell,k} &= \int_{\Gamma_0} D \left[\frac{1}{r^2} \frac{\partial B_k^{\mathcal{N}}}{\partial r} + \frac{1}{r^3} \frac{\partial^2 B_k^{\mathcal{N}}}{\partial \theta^2} + \frac{\nu}{r} \frac{\partial^2 B_k^{\mathcal{N}}}{\partial r^2} \right] \frac{\partial \overline{B_\ell^{\mathcal{N}}}}{\partial r} \, d\gamma, \\
[K_{D3}]_{\ell,k} &= \int_{\Gamma_0} D \left[\frac{1}{r^3} \frac{\partial B_k^{\mathcal{N}}}{\partial r} + \frac{1}{r^4} \frac{\partial^2 B_k^{\mathcal{N}}}{\partial \theta^2} + \frac{\nu}{r^2} \frac{\partial^2 B_k^{\mathcal{N}}}{\partial r^2} \right] \frac{\partial^2 \overline{B_\ell^{\mathcal{N}}}}{\partial \theta^2} \, d\gamma, \\
[K_{D4}]_{\ell,k} &= 2 \int_{\Gamma_0} D(1-\nu) \left[\frac{1}{r^2} \frac{\partial^2 B_k^{\mathcal{N}}}{\partial r \partial \theta} - \frac{1}{r^3} \frac{\partial B_k^{\mathcal{N}}}{\partial \theta} \right] \frac{\partial^2 \overline{B_\ell^{\mathcal{N}}}}{\partial r \partial \theta} \, d\gamma, \\
[K_{D5}]_{\ell,k} &= 2 \int_{\Gamma_0} D(1-\nu) \left[-\frac{1}{r^3} \frac{\partial^2 B_k^{\mathcal{N}}}{\partial r \partial \theta} + \frac{1}{r^4} \frac{\partial B_k^{\mathcal{N}}}{\partial \theta} \right] \frac{\partial \overline{B_\ell^{\mathcal{N}}}}{\partial \theta} \, d\gamma,
\end{aligned}$$

with D defined in (2.1) (similar expressions arise in the more general case of differing Poisson ratios). The index ranges here are $k, \ell = 1, \ldots, \mathcal{N}$. The matrices $K_{c_D1} - K_{c_D5}$ are defined similarly with the inclusion of the parameter c_D in the various integrals. Finally, we remind the reader that ρ, D, ν, and c_D are piecewise constant in these definitions due to the presence of the patches.

For application purposes, it is useful to note that the matrix system for the plate can thus be written as the Cauchy system

$$\begin{aligned} \dot{y}^{\mathcal{N}}(t) &= A^{\mathcal{N}} y^{\mathcal{N}}(t) + B^{\mathcal{N}} u(t) + g^{\mathcal{N}}(t), \\ y^{\mathcal{N}}(0) &= y_0^{\mathcal{N}}, \end{aligned} \tag{2.6}$$

where $y^{\mathcal{N}}(t) = [\vartheta^{\mathcal{N}}(t), \dot{\vartheta}^{\mathcal{N}}(t)]^T = [w_1^{\mathcal{N}}(t), \ldots, w_{\mathcal{N}}^{\mathcal{N}}(t), \dot{w}_1^{\mathcal{N}}(t), \ldots, \dot{w}_{\mathcal{N}}^{\mathcal{N}}(t)]^T$ denotes the column $2\mathcal{N}$ vector containing the generalized Fourier coefficients for the approximate displacement and velocity. In this form, the control problem can be readily discussed.

3. Continuous-time control problem. In the preceding discussion leading from the infinite-dimensional PDE model to the finite-dimensional matrix approximation, the superscript $\mathcal{N}$ was used to denote the level of discretization; i.e., the number of Fourier/spline basis elements used to approximate the state. This notation is standard in the theory of finite-element and spline approximations of infinite-dimensional systems. In finite-dimensional control theory, however, the level of discretization is typically fixed, and these superscript $\mathcal{N}$'s are usually omitted to simplify notation. We will do the same in this and subsequent sections so as to remain consistent with standard control notation.

3.1. Initial displacement and velocity—LQG control law. We consider first the $\mathcal{N}$-dimensional systems

$$\begin{aligned} \dot{y}(t) &= Ay(t) + Bu(t), \quad y(0) = y_0, \\ y_{ob}(t) &= Cy(t), \\ z(t) &= Hy(t) + Gu(t), \end{aligned} \tag{3.1}$$

where y_{ob} denotes observations in $\mathbb{R}^P$ and C is a $P \times \mathcal{N}$ observation matrix whose structure is determined by the manner and number of observations being used (the specific C matrix used in the plate experiments is described in section 4.2). Moreover, $z \in \mathbb{R}^r$ denotes the performance output obtained under the assumption that G and H are time-invariant matrices satisfying $H^T G = 0$. In the event that $P = \mathcal{N}$ and C is an identity, the optimal control u can be obtained from standard linear quadratic regulator (LQR) optimal control theory. The number of observations P is usually limited, however, and we concentrate instead on the case $P < \mathcal{N}$ which occurs when the full state is unavailable and must be reconstructed using a compensator (e.g., see [33]).

The general control problem for this case consists of determining the voltage u which minimizes the performance index (or cost functional)

$$\begin{aligned} J(u) &= \int_0^\infty |z(t)|^2 \, dt \\ &= \int_0^\infty \{\langle Qy(t), y(t)\rangle + \langle Ru(t), u(t)\rangle\} \, dt \end{aligned}$$

subject to (3.1). The $\mathcal{N} \times \mathcal{N}$ matrix Q can be chosen to satisfy various design criteria including frequency windowing, the weighting of various state components, or minimization of certain energy measures. The Q matrix used here was chosen using energy considerations, and construction details can be found in section 4.2. The $s \times s$ matrix R weights the voltages to the various patches or patch pairs.

Because full state information is not available in most applications, the state must be estimated or reconstructed from observations before a controlling voltage can be determined. We consider here a full order compensator or observer of Luenberger type [33] and refer the reader to [21, 30] for details on reduced order observers.

The compensator or reconstructed state satisfies the matrix system

$$\begin{aligned} \dot{y}_c(t) &= Ay_c(t) + Bu(t) + F\left[y_{ob}(t) - Cy_c(t)\right], \\ y_c(0) &= y_{c_0}, \end{aligned}$$

with the optimal voltage

$$u(t) = -Ky_c(t),$$

where F and K denote the compensator and feedback gains, respectively. We note that K and F are chosen so that the reconstruction error $|y(t) - y_c(t)| \to 0$ as $t \to \infty$. Under usual observability and controllability hypotheses (see [33]), the optimal feedback and compensator gains are given by

$$\begin{aligned} K &= R^{-1}B^T\Pi, \\ F &= PC^T\tilde{R}^{-1}, \end{aligned} \tag{3.2}$$

where Π and P are unique nonnegative-definite solutions to the following feedback (regulator) and compensator (observer) algebraic Riccati equations

$$\begin{aligned} \Pi A + A^T\Pi - \Pi BR^{-1}B^T\Pi + Q &= 0, \\ PA^T + AP - PC^T\tilde{R}^{-1}CP + \tilde{Q} &= 0, \end{aligned} \tag{3.3}$$

respectively. As was the case with the matrices Q and R, the matrices $\tilde{Q}$ and $\tilde{R}$ are design criteria for the specific control application under consideration (specific choices used in the plate experiments are summarized in section 4.2). We point out that in terms of the component matrices and control voltage, the compensator can be expressed as

$$\dot{y}_c(t) = \left[A - BR^{-1}B^T\Pi\right] y_c(t) + PC^T\tilde{R}^{-1}C\left[y(t) - y_c(t)\right].$$

The control law just described must be implemented in real time in order to be a viable method for reducing vibrations in physical structures. To facilitate implementation, it is prudent to calculate offline as many components as possible and then treat those precalculated components as filters when performing online computations. The method for continuous-time implementation is summarized, and offline and online components are categorized in Algorithm 3.1.

We note that the expensive (time-consuming) calculation of the component matrices A, B, Q, R, C, $\tilde{Q}$, and $\tilde{R}$ and Riccati solutions Π, P is performed offline, with the results loaded into the control code as datafiles. This leaves the integration of the system $\dot{y}_c(t) = A_c y_c(t) + F y_{ob}(t)$ as the primary computation to be performed during implementation. Issues regarding the numerical integration of the system as well as the effects of discrete-time calculations will be discussed in section 4, and a discrete version of Algorithm 3.1 is summarized in Algorithm 4.1.

While this compensator does provide the desired performance, it may lack robustness in some applications. In cases where added robustness with regard to certain types of system or observation noise and modeling errors is required, an H^∞/MinMax compensator of the type described in the next section can be used.

ALGORITHM 3.1. *Continuous time control of initial displacement and velocity.*

Offline	(i)	**Construct matrices** $A, B, C, Q, R, \tilde{Q}, \tilde{R}$
	(ii)	**Solve Riccati equations (3.3) for** Π **and** P
	(iii)	**Construct** $K = R^{-1}B^T\Pi$ **and** $F = PC^T\tilde{R}^{-1}$
Online	(i)	**Collect data** $y_{ob}(t) = Cy(t)$
	(ii)	**Solve the ODE system** $\dot{y}_c(t) = [A - BK - FC]\, y_c(t) + Fy_{ob}(t) = A_c y_c(t) + Fy_{ob}(t)$
	(iii)	**Calculate the voltage** $u(t) = -Ky_c(t)$

3.2. Initial displacement and velocity—H^∞/MinMax control law. We consider now the design of a dynamic compensator which is robust with respect to certain types of state and measurement uncertainties or disturbances (see [20] for details). To incorporate such uncertainties, we let $w(t) \in \mathbb{R}^q$ denote input and output disturbances. The system, with no exogenous force, is then given by

$$\begin{aligned}\dot{y}(t) &= Ay(t) + Bu(t) + Dw(t),\\ y_{ob}(t) &= Cy(t) + Ew(t),\\ z(t) &= Hy(t) + Gu(t).\end{aligned}$$

For this discussion, we assume that the input and output disturbances are independent and hence $DE^T = 0$. This is a matter of convenience, and the dependent case can be handled similarly after slight modifications are made (see [20]).

In this case, the MinMax optimization problem leading to the controller consists of finding a controller $u^* \in U \equiv L^2(0,\infty;\mathbb{R}^s)$ and disturbance $w^* \in W \equiv L^2(0,\infty;\mathbb{R}^q)$ such that

$$J_\gamma^* = \inf_{u\in U}\sup_{w\in W} J_\gamma(u,w) = J_\gamma(u^*,w^*)$$

for the disturbance-augmented functional

$$\begin{aligned}J_\gamma(u,w) &= \int_0^\infty \left\{|z(t)|^2 - \gamma^2\,|w(t)|^2\right\} dt\\ &= \int_0^\infty \left\{\langle Qy(t),y(t)\rangle + \langle Ru(t),u(t)\rangle - \gamma^2\,\langle w(t),w(t)\rangle\right\} dt.\end{aligned}$$

As noted in [17, 20], the results from this optimization problem yield a bound γ for the H^∞ norm of the transfer function from disturbance $\mathcal{L}(w)$ to the performance output $\mathcal{L}(z)$ where $\mathcal{L}$ denotes the Laplace transform.

Under the assumption that the pair (A,B) is stabilizable, (A,C) is detectable, (A,G) is controllable, and (A,H) is observable, one can prove the existence of (minimal) positive definite solutions Π and P to the algebraic Riccati equations

$$\begin{aligned}\Pi A + A^T\Pi - \Pi\left[BR^{-1}B^T - \gamma^{-2}\tilde{Q}\right]\Pi + Q = 0,\\ PA^T + AP - P\left[C^T\tilde{R}^{-1}C - \gamma^{-2}Q\right]P + \tilde{Q} = 0\end{aligned}$$

for a given attenuation $\gamma > 0$. Moreover, if the spectral radius ρ of $P\Pi$ satisfies the condition

$$\rho(P\Pi) < \gamma^2 \quad \text{or} \quad \Pi - \gamma^2 P^{-1} < 0,$$

then there exists a unique optimal controller

$$u^*(t) = -R^{-1}B^T\Pi y_c(t).$$

The state estimator $y_c(t) \in \mathbb{R}^{\mathcal{N}}$ satisfies

$$\begin{aligned}\dot{y}_c(t) &= A_c y_c(t) + F y_{ob}(t),\\ y_c(0) &= y_{c_0},\end{aligned}$$

where

$$\begin{aligned}A_c &= A - BK - FC + \gamma^{-2}\tilde{Q}\Pi,\\ F &= \left[I - \gamma^{-2}P\Pi\right]^{-1} PC^T\tilde{R}^{-1}.\end{aligned}$$

The implementation issues concerning the method are similar to those discussed in the algorithm for the LQG controller, but determination of the Riccati solutions Π, P and filter F are complicated by the fact that a suitable design value of γ must be determined before matrix calculations can proceed. Fortunately, these calculations can be performed offline and resulting matrices input as data files for the online computations. Hence the actual online controller can run at the same rate as that obtained using the LQG methodology.

3.3. Periodic primary excitation. For the case in which a periodic exogenous force drives the system, knowledge of that force can be used to extend previously discussed results to include the effects of periodicity. The $\mathcal{N}$-dimensional system in this case is

$$\begin{aligned}&\dot{y}(t) = Ay(t) + Bu(t) + g(t), \quad y(0) = y(\tau),\\ &y_{ob}(t) = Cy(t),\end{aligned} \tag{3.4}$$

where $g(t) \in \mathbb{R}^{\mathcal{N}}$ is periodic with period τ. That periodicity is then reflected in the performance index

$$J(u) = \int_0^\tau \left\{\langle Qy(t), y(t)\rangle + \langle Ru(t), u(t)\rangle\right\} dt$$

which is minimized subject to (3.4).

With K and F defined in (3.2), the reconstructed state in this case satisfies the system

$$\begin{aligned}&\dot{y}_c(t) = Ay_c(t) + Bu(t) + F\left[y_{ob}(t) - Cy_c(t)\right] + g(t),\\ &y_c(0) = y_c(\tau),\end{aligned} \tag{3.5}$$

with the optimal voltage given by

$$u(t) = -Ky_c(t) + R^{-1}B^T r(t). \tag{3.6}$$

Here r is a tracking variable defined by the system

$$\begin{aligned}&\dot{r}(t) = -\left[A - BK\right]^T r(t) + \Pi g(t),\\ &r(0) = r(\tau),\end{aligned} \tag{3.7}$$

where Π solves the first of the algebraic Riccati equations (3.3). We point out that in this case, the voltage contains two contributions. The first incorporates transient

ALGORITHM 3.2. *Continuous-time control with periodic exogenous force.*

Offline	(i)	**Construct matrices** $A, B, C, Q, R, \tilde{Q}, \tilde{R}$
	(ii)	**Solve Riccati equations (3.3) for** Π **and** P
	(iii)	**Construct** $K = R^{-1}B^T\Pi$ **and** $F = PC^T\tilde{R}^{-1}$
Online	(i)	**Collect data** $y_{ob}(t) = Cy(t)$ **and force measurements** $g(t)$
	(ii)	**Solve the ODE systems**
		$\dot{r}(t) = -[A - BK]^T r(t) + \Pi g(t)$
		$= A_{tr} r(t) + \hat{g}(t)$
		$\dot{y}_c(t) = [A - BK - FC]\, y_c(t) + F y_{ob}(t) + BR^{-1}B^T r(t) + g(t)$
		$= A_c y_c(t) + F y_{ob}(t) + A_r r(t) + g(t)$
	(iii)	**Calculate the voltage** $u(t) = -Ky_c(t) + R^{-1}B^T r(t)$

information by feeding back state estimates while the tracking component incorporates information regarding the periodic force.

Combining (3.5) and (3.6) yields the single expression

$$\begin{aligned} &\dot{y}_c(t) = [A - BK]\, y_c(t) + FC\,[y(t) - y_c(t)] + BR^{-1}B^T r(t) + g(t), \\ &y_c(0) = y_c(\tau) \end{aligned} \tag{3.8}$$

for the state estimator in terms of the tracking variable. The state estimate at time t is then obtained by integrating (3.7) and (3.8) after solving the necessary Riccati equations.

As was the case when considering control of the unforced system with initial displacement and velocity, the computations can be categorized with respect to those which can be performed offline and those which must be done online. Algorithm 3.2 summarizes the continuous-time control method for periodic excitation and categorizes the offline and online components. In this case, the tracking equation $\dot{r}(t) = A_{tr} r(t) + \hat{g}(t)$ must be solved before the state can be estimated by integrating the system $\dot{y}_c(t) = A_c y_c(t) + F y_{ob}(t) + A_r r(t) + g(t)$.

Expressions similar to those in section 3.2 arise when an H^∞/MinMax compensator is considered for the problem. For this case, the reader is referred to [4], where details concerning the design of an H^∞/MinMax compensator for a structural acoustic system that is subjected to a periodic exogenous force is considered.

4. Discrete-time control problem. The control laws summarized in the last section were derived under the assumption of continuous-time sampling of observed state and force data. Hence it was assumed that $y_{ob}(t)$ and $g(t)$ were available for all t within the temporal interval of interest. Moreover, it was assumed that $y(t), y_c(t)$, and $r(t)$ could be obtained through exact integration of the state, state estimator, and tracking equations. When implementing the method, however, one has available only discrete data values and the differential estimator and tracking equations must be numerically approximated at discrete-time values. The manner in which the control laws are implemented in discrete time and the influence of this discretization on the overall performance are discussed in this section.

In the last section, it was demonstrated that in the case with no primary exogenous force, the state equation, state estimator, and controlling voltage for the LQG and H^∞/MinMax problems had the form summarized in column 1 of Table 4.1. The corresponding quantities for a system subjected to a periodic exogenous force are summarized in the second column. Details regarding the component matrices can be found in the previous section.

TABLE 4.1
State, state estimator, and controlling voltage for the systems with no primary input and a periodic exogenous force.

	No primary input	Periodic exogenous force
State equation	$\dot{y}(t) = Ay(t) + Bu(t),\ y(0) = y_0,$ $y_{ob}(t) = Cy(t)$	$\dot{y}(t) = Ay(t) + Bu(t) + g(t),\ y(0) = y(\tau),$ $y_{ob}(t) = Cy(t)$
State estimator	$\dot{y}_c(t) = A_c y_c(t) + F y_{ob}(t),$ $y_c(0) = y_{c_0}$	$\dot{y}_c(t) = A_c y_c(t) + F y_{ob}(t) + A_r r(t) + g(t),$ $y_c(0) = y_c(\tau)$
Tracking equation		$\dot{r}(t) = A_{tr} r(t) + \hat{g}(t),$ $r(0) = r(\tau)$
Control voltage	$u(t) = -R^{-1} B^T \Pi y_c(t)$	$u(t) = -R^{-1} B^T \Pi y_c(t) + R^{-1} B^T r(t)$

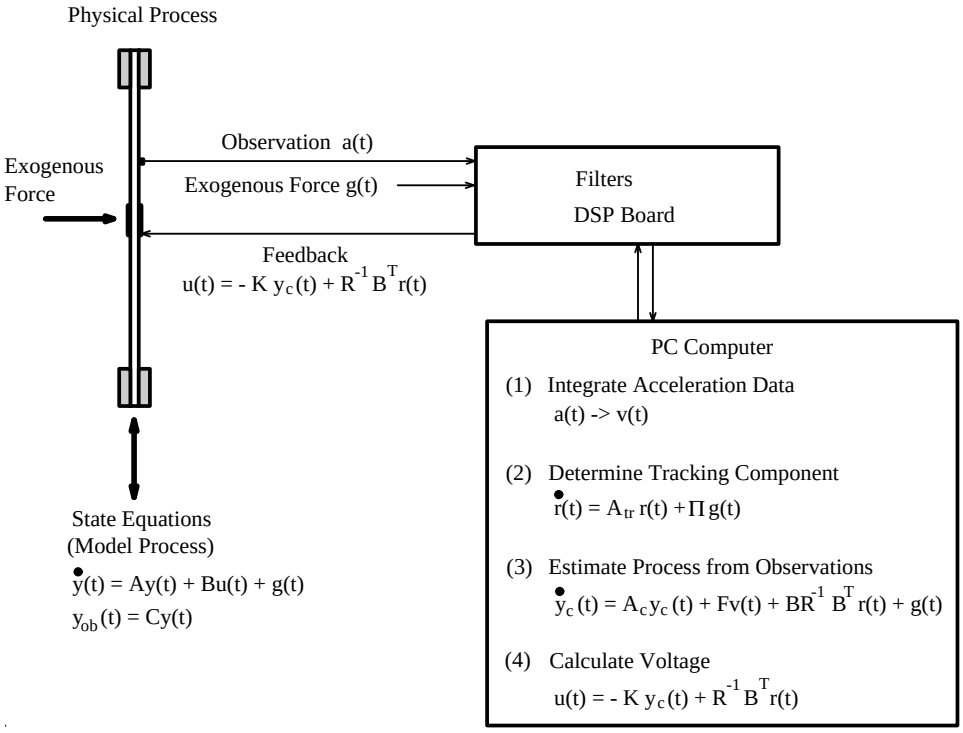

FIG. 4.1. *Experimental plate setup, modeling equations, and computations necessary for determination of controlling voltage.*

The relationship of these components to the experimental plate setup, driven by a periodic exogenous force, is illustrated in Figure 4.1. For that setup, the physical process consists of the clamped circular plate with attached piezoceramic patches. The state equations represent the spatial discretization of a PDE model of the process with physical parameters estimated using experimental data so that the model accurately captures the plate dynamics.

We point out that when modeling the process or performing simulations, the observations $y_{ob}(t)$ are obtained from the approximate state through the relation $y_{ob}(t) = Cy(t)$, where C is the matrix observation operator. When experimentally implementing the method, temporal data from the process are used to determine the observations $y_{ob}(t)$. This often requires processing either through digital or analog filters or in the software. In the circular plate experiments, accelerometer data $a(t)$ were integrated to yield velocity measurements $v(t)$ to be used for the observations $y_{ob}(t)$ (see the final subsection of this section for details). Once $y_{ob}(t)$ has been obtained, the state is estimated by numerically integrating the estimator equation and a controlling voltage is calculated. This voltage is then fed back to the process.

Because data is processed in a digital manner, the observations y_{ob} and force measurements g are obtained only at discrete times t_j. The rate at which these data can be sampled is governed by the data acquisition system, the software being used, and the number of calculations required between samples. In particular, the tracking component $r(t_j)$, state estimate $y_c(t_j)$, and voltage $u(t_j)$ must be calculated before the arrival of data at time t_{j+1}. While details regarding these calculations are postponed until section 4.1, it is noted here that the system sizes must be minimized in order to permit real-time approximation of the estimation equation. This is a major motivation for choosing appropriate, accurate approximation techniques to spatially discretize the modeling PDEs.

As indicated previously, the open and closed loop process dynamics can be simulated by using the state equations to model the plate. The state estimate and state are then approximated by simultaneously integrating the corresponding equations. The integration of the state equation can be performed using any sufficiently accurate ODE routine which is efficient for the system under consideration; for example, a variable order, variable stepsize method was used to solve the stiff system which arose when simulating plate dynamics. If simulations demonstrating the levels of control that can be obtained under "optimal" conditions are desired, the estimator equation can be integrated using the same high-order routine. On the other hand, simulations representing the attenuation levels that can be expected under "implementation" conditions can be obtained by incorporating values of y_{ob} and g calculated at discrete times and approximating $y_c(t_j)$ using the techniques employed when implementing the method. Simulation results using both techniques can be found in [14].

4.1. Approximation of the estimator and tracking equations. In order to obtain tracking values and state estimates to be used when calculating controlling voltages, the solution to the tracking and state estimator equations must be numerically approximated. If the goal is solely to perform simulations, this can be easily accomplished using the same ODE solver used to integrate the state equation (indeed, the state and estimator equations can be combined into a single system and integrated simultaneously). This is not practical when experimentally implementing the method, however, and one must typically perform the work subject to the following criteria. The method must be sufficiently efficient so as to facilitate real-time implementation and sufficiently accurate so as to resolve system dynamics. The systems are quite often stiff, which implies that either a-stability or α-stability is important. Finally, the difficulties in storing past data make it prohibitive to use many popular multistep methods.

For the experiments performed with the circular plate, the sample rate was sufficiently fast (and hence Δt was sufficiently small) that a modified backward Euler

ALGORITHM 4.1. *Discrete-time control of initial displacement and velocity.*

	(iv)	**Calculate the voltage** $u(t_j) = -K y_{c_j}$

or trapezoidal method produced adequate results. We illustrate here such a modified backward Euler method.

4.1.1. Initial displacement and velocity. Considering first the compensator/estimator system with no primary exogenous force, we find that the modified Euler approximate to the solution at time t_{j+1} is given by

$$\begin{aligned} y_{c_{j+1}} &= (I - \Delta t A_c)^{-1} y_{c_j} + (I - \Delta t A_c)^{-1} F y_{ob}(t_j) \\ &= \mathcal{A}_c y_{c_j} + \mathcal{F}_c y_{ob}(t_j). \end{aligned}$$

The method is modified in the sense that current observation values $y_{ob}(t_j)$ are used as input since futures values at t_{j+1} are unknown. The time step Δt is dictated by the sample rate. We point out that the matrix $\mathcal{A}_c = (I - \Delta t A_c)^{-1}$ and vector $\mathcal{F}_c = (I - \Delta t A_c)^{-1} F$ can be computed offline and then loaded as datafiles for the online computations. Hence the implicit nature of the method, which is necessary to ensure stability, does not slow the implementation. The discrete-time implementation of the method is summarized in Algorithm 4.1. The definitions of the component matrices can be found in section 3, and Algorithm 4.1 can be compared with the corresponding continuous-time Algorithm 3.1 given in that section.

4.1.2. Periodic exogenous force. The application of these control techniques to systems with both transient and steady-state behavior involves the approximation of both the tracking and the state estimator equations before a control input is calculated. While a variety of techniques and strategies can be used to obtain approximate values of $r(t_j)$, which are then used when computing $y(t_j)$, these calculations must ultimately be performed in real time when implementing the method. In the experiments involving the circular plate, the exogenous force was measured for several periods and the solutions to the tracking equation were approximated and stored over a time period commensurate with the driving frequency. These stored tracking values were then used as a filter when approximating the estimated state during the remainder of the experiment.

Illustrating with the backward Euler discretization, the approximate to the tracking solution was determined from the difference equation

$$\begin{aligned} r_{j+1} &= (I - \Delta t A_{tr})^{-1} r_j + (I - \Delta t A_{tr})^{-1} \hat{g}(t_j) \\ &= \mathcal{A}_{tr} r_j + \mathcal{A}_{tr} \hat{g}(t_j) \end{aligned}$$

ALGORITHM 4.2. *Discrete-time control of periodic excitation.*

Offline	(i)	**Construct matrices** $A, B, C, Q, R, \tilde{Q}, \tilde{R}$
	(ii)	**Solve Riccati equations (3.3) for** Π **and** P
	(iii)	**Construct** $K = R^{-1}B^T\Pi$ $F = PC^T\tilde{R}^{-1}$ $A_c = A - BK - FC$ $A_{tr} = -[A - BK]^T$
	(iv)	**Choose appropriate** Δt **(determined by sample rate)**
	(v)	**Construct** $\mathcal{A}_c = (I - \Delta t A_c)^{-1}$ $\mathcal{A}_r = (I - \Delta t A_c)^{-1} A_r$ $\mathcal{A}_{tr} = (I - \Delta t A_{tr})^{-1}$ $\mathcal{F}_c = (I - \Delta t A_c)^{-1} F$
Online	(i)	**Collect acceleration data** $a(t_j)$
	(ii)	**Integrate to obtain** $y_{ob}(t_j) = v(t_j)$
	(iii)	**Approximate and store tracking values** $r_{j+1} = \mathcal{A}_{tr} r_j + \mathcal{A}_{tr}\hat{g}(t_j)$ $r(\tau) = 0$
	(iii)	**Time step the discrete estimator system** $y_{c_{j+1}} = \mathcal{A}_c y_{c_j} + \mathcal{F}_c y_{ob}(t_j) + \mathcal{A}_r r_j + \mathcal{A}_c g(t_j)$ $y_c(k\tau) = 0$
	(iv)	**Calculate the voltage** $u(t_j) = -Ky_{c_j} + R^{-1}B^T r_j$

subject to the final condition $r(\tau) = 0$. (When implementing the method, one can simply search for a "suitable" zero crossing to start the approximation.)

This approximation was continued throughout several periods of the driving force, with r_j being stored in a circular buffer. This buffer was then treated as a filter when estimating the state using the difference equations

$$\begin{aligned} y_{c_{j+1}} &= (I - \Delta t A_c)^{-1} y_{c_j} + (I - \Delta t A_c)^{-1} F y_{ob}(t_j) + (I - \Delta t A_c)^{-1} A_r r_j \\ &\quad + (I - \Delta t A_c)^{-1} g(t_j) \\ &= \mathcal{A}_c y_{c_j} + \mathcal{F}_c y_{ob}(t_j) + \mathcal{A}_r r_j + \mathcal{A}_c g(t_j). \end{aligned}$$

As indicated in Algorithm 4.2, the time-intensive calculations involving matrix construction, solution of the Riccati equations, and matrix inversion were performed offline prior to the experiments, and the matrices $\mathcal{A}_{tr}, \mathcal{A}_c, \mathcal{A}_r$ and vector $\mathcal{F}_c$ were simply loaded as datafiles. This, combined with the solution of the tracking filter before state estimation, yielded an algorithm which was sufficiently fast for implementation. Current efforts are aimed toward the simultaneous approximation of the tracking and state estimator equations during implementation.

4.1.3. Higher-order approximations. In the previous discussion, a modified backward Euler method was used to discretize the state estimator and tracking equations. As indicated, by numerical simulations reported in [14] and experimental results in the next section, for small Δt, this provides sufficient accuracy to calculate an effective feedback voltage. If more accuracy is needed, a trapezoid rule or hybrid method of the nature discussed on page 225 of [34] can be used. These provide increased accuracy without adding complexity during implementation since the components $\mathcal{A}_{tr}, \mathcal{A}_c, \mathcal{A}_r$, and $\mathcal{F}_c$ can still be computed offline.

TABLE 4.2
System and control matrices used in the circular plate experiments.

Component	Size	Comments
$A = \begin{bmatrix} 0 & I \\ -(M^{\mathcal{N}})^{-1} K_D^{\mathcal{N}} & -(M^{\mathcal{N}})^{-1} K_{c_D}^{\mathcal{N}} \end{bmatrix}$	32×32	The elements composing the 16×16 matrices $M^{\mathcal{N}}, K_D^{\mathcal{N}}$, and $K_{c_D}^{\mathcal{N}}$ are summarized in (2.5)
$B = \begin{bmatrix} 0 \\ (M^{\mathcal{N}})^{-1} \tilde{B}^{\mathcal{N}} \end{bmatrix}$	32×1	See (2.5) for the description of $\tilde{B}^{\mathcal{N}}$
$g(t) = \begin{bmatrix} 0 \\ \hat{g}^{\mathcal{N}}(t) \end{bmatrix}$	32×1	The elements of $\hat{g}^{\mathcal{N}}(t)$ are detailed in (2.5)
$C = \left[\begin{array}{c\|c} 0, \cdots, 0 & B_1^{\mathcal{N}}(r_1, \theta_1), \cdots, B_{\mathcal{N}}^{\mathcal{N}}(r_1, \theta_1) \\ \vdots & \vdots \\ 0, \cdots, 0 & B_1^{\mathcal{N}}(r_p, \theta_p), \cdots, B_{\mathcal{N}}^{\mathcal{N}}(r_p, \theta_p) \end{array}\right]$	$p \times 32$	In the experiments, acceleration data were integrated to obtain velocity values which are the second-state values in the second-order formulation. Since one accelerometer was used, $p = 1$. See Example 2 of section 4.3 for a discussion regarding the duality between control and observation.

4.2. Example 1—matrix construction. The control discussion thus far has been general in the sense that it holds for general systems of the form

$$\begin{aligned} \dot{y}(t) &= Ay(t) + Bu(t), \\ y_{ob}(t) &= Cy(t), \end{aligned} \quad \text{or} \quad \begin{aligned} \dot{y}(t) &= Ay(t) + Bu(t) + g(t), \\ y_{ob}(t) &= Cy(t) \end{aligned}$$

as long as the pair (A, B) is stabilizable and (A, C) is detectable. Moreover, the cost functional matrices Q, R and observation matrices $\tilde{Q}, \tilde{R}$ have been treated as general design criteria to be specified according to the application under consideration. In this example, we illustrate explicitly the matrices and filters used when implementing these control techniques for a vibrating circular plate.

We first note that $16 (= N)$ modified cubic splines (see (2.4)) were sufficient for resolving the plate dynamics in the frequency range under consideration. Due to the axisymmetric excitation and response of the plate, the Fourier limit $M = 0$ was used in all calculations. Hence a total of $\mathcal{N} = 16$ basis functions were used, which led to 32 coefficients in the vector y.

The formulation and sizes of all components in the control system for the circular plate are summarized in Tables 4.2 and 4.3. The component matrices and vectors are then employed in Algorithm 4.1 or 4.2 to create the implementation matrices and filters which were ultimately used in the experiments.

4.3. Example 2—duality between control and observation. The duality between control and observation can be noted by considering the form of the control matrix B and observation matrix C. Illustrating with the case in which s patch pairs are used for control, the $2\mathcal{N} \times s$ control matrix has the form

$$B = \begin{bmatrix} 0 \\ (M^{\mathcal{N}})^{-1} \tilde{B}^{\mathcal{N}} \end{bmatrix},$$

TABLE 4.3

Control and observation matrices used in the circular plate experiments. The experimental results in section 5.1 *demonstrate control of transient dynamics, while the periodic case is illustrated in section* 5.2.

Component	Size	Comments
$Q = \begin{bmatrix} d_1 I^{\mathcal{N}} & 0 \\ 0 & d_2 I^{\mathcal{N}} \end{bmatrix} \begin{bmatrix} K_D^{\mathcal{N}} & 0 \\ 0 & M^{\mathcal{N}} \end{bmatrix}$	32×32	A weighted mass matrix was used for the penalty term Q. As discussed in [6], this provides a means of weighting the kinetic and potential energy of the plate. Section 5.1: $d_1 = d_2 = 1$. Section 5.2: $d_1 = d_2 = 5$.
$R = \begin{bmatrix} R_{11} & & \\ & \ddots & \\ & & R_{ss} \end{bmatrix}$	$s \times s$	In the plate experiments, one controlling patch was used, so $s = 1$. Section 5.1: $R_{11} = 10^{-7}$. Section 5.2: $R_{11} = 10^{-10}$.
$\tilde{Q} = \begin{bmatrix} c_1 I^{\mathcal{N}} & 0 \\ 0 & c_2 I^{\mathcal{N}} \end{bmatrix}$	32×32	For the plate experiments, $\tilde{Q}$ was treated solely as a design parameter as compared with the choice in [4], where physical arguments were used to construct the matrix. The identity weights were taken to be $c_1 = c_2 = 1$ in the experiments.
$\tilde{R} = \begin{bmatrix} \tilde{R}_{11} & & \\ & \ddots & \\ & & \tilde{R}_{pp} \end{bmatrix}$	$p \times p$	In the experiments, $p = 1$ since one accelerometer was used for data collection. The weight was taken to be $\tilde{R}_{11} = 1$.

where the $\mathcal{N} \times s$ matrix $\tilde{B}^{\mathcal{N}}$ has elements

$$\begin{aligned} \left[\tilde{B}^{\mathcal{N}}\right]_{\ell,j} &= \int_{\Gamma_0} \mathcal{K}_j \overline{\nabla^2 B_\ell^{\mathcal{N}}} \chi_j(r,\theta)\, d\gamma \\ &= \int_{jth\ patch} \mathcal{K}_j \overline{\nabla^2 B_\ell^{\mathcal{N}}}\, d\gamma \end{aligned}$$

(here $\chi_j(r,\theta)$ denotes the characteristic function over the jth patch).

When data from accelerometers located at the points $(r_1,\theta_1),\ldots,(r_p,\theta_p)$ are integrated to obtain velocity values, the $p \times 2\mathcal{N}$ observation matrix is given by

$$C = [0 \quad 1] \begin{bmatrix} \tilde{C} & 0 \\ 0 & \tilde{C} \end{bmatrix},$$

where, using the $2-D$ Dirac delta notation δ,

$$\begin{aligned} \left[\tilde{C}\right]_{j,\ell} &= \int_{\Gamma_0} B_\ell^{\mathcal{N}} \delta(r - r_j, \theta - \theta_j)\, d\gamma \\ &= B_\ell^{\mathcal{N}}(r_j, \theta_j). \end{aligned}$$

With C thus defined, it can immediately be noted that

$$\begin{aligned} y_{ob}(t) &= Cy(t) \\ &= \sum_{k=1}^{\mathcal{N}} \dot{w}_k(t) B_k^{\mathcal{N}}(r_j, \theta_j) \end{aligned}$$

denotes the physical value of the velocity at the point (r_j, θ_j) given by the state equations at time t. This is an approximation (to within modeling and processing error) of the actual plate plate velocity $v(t)$ which is measured in experiments.

Similarly, multiplication of the state estimator coefficients y_c by C produces an estimate of the velocity which is then compared with the measured plate velocity when integrating the state estimator equation

$$\dot{y}_c(t) = \left[A - BR^{-1}B^T\Pi\right] y_c(t) + PC^T\tilde{R}^{-1}\left[v(t) - Cy_c(t)\right].$$

It should be noted that as the state estimates approach the measured plate values, the estimator equation approaches the state equation

$$\dot{y}(t) = Ay(t) - BR^{-1}B^T\Pi y_c(t),$$

which is used to model the plate dynamics.

4.4. Integration of experimental data. For the experiments involving the control of circular plate vibrations, data consisted of acceleration measurements obtained from one or more accelerometers on the plate. It was then necessary to approximately integrate these data to obtain velocity values so as to have a state variable for control calculations. An issue which turns out to be crucial when approximately integrating experimental data concerns the robustness of the integrator with respect to inexact initial conditions and DC gains or biases (added constants or offsets) in the data. The inexact initial conditions can be due to unknown system contributions, static shocks during system connections, et cetera. While careful calibration can alleviate some of the uncertainty in initial conditions, it cannot fully eliminate the problem. The problem of gains or biases due to small DC voltages in the system can also be minimized but never fully eliminated. Hence an integrator which is minimally affected by uncertain initial conditions and DC offsets in the data is crucial for success when approximately integrating data.

Here we consider two techniques for approximately integrating acceleration data to obtain velocity values in accordance with the relation

$$\dot{v}(t) = a(t).$$

Essentially, the idea is to replace the integration by either the first-order differential equation

$$\dot{v} + \Omega v = \frac{1}{RC} a \tag{4.1}$$

or the second-order equation

$$\ddot{v} + \Omega\dot{v} + \Omega^2 v = \frac{1}{RC}\dot{a} \tag{4.2}$$

(see [29]). The design parameters Ω and RC are frequency and time constants, respectively, which are chosen so that $RC = 1$ and $\omega > 6\Omega$, where ω is the smallest

observed frequency. For solution, (4.2) is written as the first-order system

$$\begin{aligned} \begin{bmatrix} \dot{v} \\ \dot{e} \end{bmatrix} &= \begin{bmatrix} -\Omega & \Omega \\ -\Omega & 0 \end{bmatrix} \begin{bmatrix} v \\ e \end{bmatrix} + \begin{bmatrix} \frac{a(t)}{RC} \\ 0 \end{bmatrix} \\ &\Rightarrow \dot{z} = Az + f, \end{aligned} \tag{4.3}$$

where $\dot{e} = -\Omega v$. The integration of (4.3) is subject to the initial conditions

$$\begin{bmatrix} v(0) \\ e(0) \end{bmatrix} = \begin{bmatrix} v_0 \\ e_0 \end{bmatrix}. \tag{4.4}$$

As will be detailed in the subsequent discussion, the first-order integrator (4.1) is robust with respect to inexact initial conditions but propagates DC offsets in the data. In the second-order integrator (4.2), or system (4.3), both disturbance in initial conditions and DC offsets in acceleration data are exponentially attenuated. Moreover, the frequency response of this approximator is very close to that in the original signal for $\omega > 6\Omega$. Hence this latter method provides an accurate and robust means of approximately integrating experimental data.

4.4.1. First-order approximate integrator. Here we examine the properties of the first-order approximate integrator (4.1). We consider first the case in which the exact initial condition v_0 is known and the acceleration $a(t)$ is free from DC gains or biases (added constants). If we let $V(s) = \mathcal{L}\{v(t)\}$ and $A(s) = \mathcal{L}\{a(t)\}$, then Laplace transformation of the system (4.1) yields

$$V(s) = \frac{1}{s+\Omega} v_0 + \frac{1}{s+\Omega} \cdot \frac{1}{RC} A(s).$$

Hence the approximate integrator (4.1) is a single pole filter. Inverse transformation then yields

$$v(t) = e^{-\Omega t} v_0 + \frac{1}{RC} \int_0^t e^{-\Omega(t-s)} a(s) ds \tag{4.5}$$

as the solution to (4.1).

Similarly, if $\tilde{v}_0$ denotes a perturbed initial condition and a DC gain $\tilde{g}_a$ is present in the data, then the solution is given by

$$\tilde{v}(t) = e^{-\Omega t} \tilde{v}_0 + \frac{1}{RC} \int_0^t e^{-\Omega(t-s)} \left[a(s) + \tilde{g}_a \right] ds.$$

It follows immediately that

$$\tilde{v}(t) = v(t) + e^{-\Omega t} \left(\tilde{v}_0 - v_0 - \frac{\tilde{g}_a}{RC\Omega} \right) + \frac{\tilde{g}_a}{RC\Omega}.$$

It is first noted that the perturbations in initial conditions exponentially decay with the rate of decay influenced by the magnitude of the parameter Ω. DC gains of the order $\tilde{g}_a/(RC\Omega)$ remain, however, thus leading to difficulties when such biases are present in the data. Both properties are numerically illustrated through examples in [14].

The manner through which the solution (4.5) approximates the solution to the original relation $\dot{v}(t) = a(t)$ can be illustrated with a simple example. Consider $a(t) = 120\pi\cos(120\pi t)$. The solution to (4.1) for this acceleration is

$$v(t) = \frac{1}{RC}\cdot\frac{120\pi}{\Omega^2+(120\pi)^2}\left[\Omega\cos(120\pi t)+120\pi\sin(120\pi t)\right]-\frac{1}{RC}\cdot\frac{120\pi\Omega}{\Omega^2+(120\pi)^2}e^{-\Omega t},$$

which reduces to the solution of the original relation with $\Omega = 0$ and $RC = 1$. For $\Omega = 16\pi$, the solution v still provides an adequate approximation to the original, whereas it is a very poor approximation with $\Omega = 120\pi$. This phenomenon is illustrated in [14].

4.4.2. Second-order approximate integrator. The second-order approximate integrator (4.2), or equivalent system (4.3), eliminates the difficulties associated with both inexact initial conditions and DC gains or biases in the data. The elimination of constants in the data can heuristically be attributed to the differentiation of the acceleration data. This can be made rigorous by analytically solving the problem.

We again let $V(s) = \mathcal{L}\{v(t)\}$ and $A(s) = \mathcal{L}\{a(t)\}$ and let v_0, v_1, and a_0 denote initial conditions. Transformation of (4.2) yields

$$\left[s^2V(s)-sv_0-v_1\right]+\Omega\left[sV(s)-v_0\right]+\Omega^2V(s)=\frac{1}{RC}\left[sA(s)-a_0\right],$$

from which it follows that

$$V(s)=\frac{s+\Omega}{s^2+\Omega s+\Omega^2}v_0+\frac{(v_1-a_0/RC)}{s^2+\Omega s+\Omega^2}+\frac{s}{s^2+\Omega s+\Omega^2}\cdot\frac{1}{RC}A(s).$$

Inverse transformation then yields the solution

$$\begin{aligned}v(t) = e^{-\Omega t/2}&\left[\cos\left(\sqrt{3}\Omega t/2\right)v_0+\frac{1}{\sqrt{3}}\sin\left(\sqrt{3}\Omega t/2\right)v_0\right.\\&\left.+\frac{2}{\sqrt{3}\Omega}\sin\left(\sqrt{3}\Omega t/2\right)\left(v_1-\frac{a_0}{RC}\right)\right]\\+\frac{1}{RC}\int_0^t e^{-\Omega(t-s)/2}&\left[\cos\left(\sqrt{3}\Omega(t-s)/2\right)-\frac{1}{\sqrt{3}}\sin\left(\sqrt{3}\Omega(t-s)/2\right)\right]a(s)ds.\end{aligned}$$

As in the discussion of (4.1), we then consider the corresponding solution with perturbed initial conditions $\tilde{v}_0, \tilde{v}_1$, and $\tilde{a}_0$ and DC gain $\tilde{g}_a$. In this case, the perturbed solution $\tilde{v}(t)$ is given by

$$\begin{aligned}\tilde{v}(t) = v(t)&+e^{-\Omega t/2}\left[\cos\left(\sqrt{3}\Omega t/2\right)+\frac{1}{\sqrt{3}}\sin\left(\sqrt{3}\Omega t/2\right)\right]\left[\tilde{v}_0-v_0\right]\\&+e^{-\Omega t/2}\cdot\frac{2}{\sqrt{3}\Omega}\sin\left(\sqrt{3}\Omega t/2\right)\left[\left(\tilde{v}_1-\frac{\tilde{a}_0}{RC}\right)-\left(v_1-\frac{a_0}{RC}\right)\right]\\&+e^{-\Omega t/2}\cdot\frac{2\tilde{g}_a}{\sqrt{3}RC\Omega}.\end{aligned}$$

Here both the perturbations in initial conditions and the added constants in the data exponentially decay with the rate of decay dependent on the magnitude of Ω. This is illustrated in examples given in [14]. We reiterate that while increased values of Ω lead to more rapid decay of perturbations and biases, the solution to the differential equation less accurately approximates the true velocity. This, in combination with the goal of accurately preserving signal frequencies, leads to the condition $\Omega < \omega/6$.

4.4.3. Numerical approximation. Because of the potential for problems involving DC gains with the first-order formulation (4.1), we concentrate primarily on the second-order filter (4.2) and the corresponding system (4.3). We note that similar scalar techniques can be used to approximate the solution to (4.1). In considering numerical techniques for integrating (4.3), emphasis was placed on using a technique which could easily be implemented in real time. The two methods considered here are Euler's method and a backward Euler's method. The two are summarized below.

Euler's method.

$$z(t_{k+1}) = [I + \Delta t A]\, z(t_k) + \Delta t f(t_k)$$
$$\Rightarrow \begin{bmatrix} v \\ e \end{bmatrix}(t_{k+1}) = \begin{bmatrix} 1 - \Delta t\Omega & \Delta t\Omega \\ -\Delta t\Omega & 1 \end{bmatrix} \begin{bmatrix} v \\ e \end{bmatrix}(t_k) + \begin{bmatrix} \Delta t \dfrac{a(t_k)}{RC} \\ 0 \end{bmatrix}.$$

Backward Euler's method.

$$z(t_k) = [I - \Delta t A]^{-1} z(t_{k-1}) + [I - \Delta t A]^{-1} \Delta t f(t_{k-1}),$$

where

$$[I - \Delta t A]^{-1} = \begin{bmatrix} \dfrac{1}{1 + \Delta t\Omega + (\Delta t\Omega)^2} & \dfrac{\Delta t\Omega}{1 + \Delta t\Omega + (\Delta t\Omega)^2} \\ \dfrac{-\Delta t\Omega}{1 + \Delta t\Omega + (\Delta t\Omega)^2} & \dfrac{1 + \Delta t}{1 + \Delta t\Omega + (\Delta t\Omega)^2} \end{bmatrix},$$

$$\Delta t\, [I - \Delta t A]^{-1} f(t_{k-1}) = \begin{bmatrix} \dfrac{(\Delta t/RC) a(t_{k-1})}{1 + \Delta t\Omega + (\Delta t\Omega)^2} \\ \dfrac{(-(\Delta t)^2\Omega/RC) a(t_{k-1})}{1 + \Delta t\Omega + (\Delta t\Omega)^2} \end{bmatrix}.$$

The advantage of the backward Euler's method over Euler's method is its stability properties, with slightly more involved matrices being the disadvantage. Numerical examples demonstrating both methods with a variety of exogenous forces can be found in [14].

5. Experimental results. Experimental results demonstrating both the transient and steady-state capabilities of the control methodology are presented in this section. The circular plate used in these experiments had a radius of 9 inches (.2276m) and a thickness of .05 inch (.00127m). A pair of piezoceramic patches having radius .75 inch (.01905m) and thickness .007 inch (.0001778m) was bonded to the center of the plate. In both the transient and the steady-state experiments, only one patch was used for control. In the steady-state experiments, the opposite patch was used to drive the plate while it was allowed to remain uncharged in the transient case. The plate was mounted in a wooden frame by a circular aluminum collar which provided boundary conditions which were sufficiently close to clamped (zero displacement and slope).

The first step in the process was the estimation of physical parameters through fit-to-data techniques. As detailed in [2, 15], transient plate vibrations were excited though an impact hammer strike or the input of a voltage spike to the patches, and acceleration data were measured. The parameter values summarized in Table 5.1 were obtained through a least squares minimization of the difference between the model response and the measured data. These values were then employed when constructing the component matrices A, B, and Q (see Table 4.2) used during the experimental implementation of the controller.

5.1. Transient control. To investigate the capabilities of the method for controlling transient vibrations, decaying plate responses generated by an impact hammer strike were considered. In each case, the strike was directed to the center of the plate and hence the plate response was axisymmetric. In the first set of experiments, data were collected from an accelerometer located at the plate center on the side opposite from the hammer impact; thus $P_1 = (r_1, \theta_1) = (0, 0)$ in the construction of the observation matrix C described in Table 4.2. The experiments were then repeated with the accelerometer placed at the off-center point $P_2 = (r_1, \theta_1) = (2'', 0)$ to illustrate that collocation between the sensor and actuator is unnecessary in this control method (see Figure 5.1 for sensor, actuator, and impact locations). The results obtained with the off-center accelerometer are presented here, and the reader is referred to [14] for a discussion of the transient control results obtained with observations from the centered accelerometer.

Since no exogenous force was applied to the plate, the state estimator and control law summarized in Algorithm 4.1 were used to compute the controlling voltage to the patch. The component matrices as well as the cost functional and observation parameters used in these experiments are summarized in Tables 4.2 and 4.3.

Data acquisition and processing were performed with a PC-based Texas Instruments TMS 320-C30 digital signal processing (DSP) board. A schematic of the amplifiers, filters, DSP configuration and PC algorithm is given Figure 5.2. In the experiments, the accelerometer voltage was initially boosted by a factor of 10 and then reduced by 5 dB before reaching the DSP board. The controlling voltage output from the DSP was also boosted by an amplifier before input to the patches. This was necessary since the maximum voltage output by the DSP is 2.5 V whereas $60-70$ V were needed at the patch. The reader is also referred to Figure 4.1 for an illustration of the experimental process and to [14] for details regarding the implementation process. We point out that the ratio $\frac{2048}{2.5V}$, illustrated in the A/D conversion, results when the voltage range -2.5 to 2.5 is discretized into 4096 possible digital values. The reciprocal process occurs when digital values are converted to analog voltages in the D/A converter.

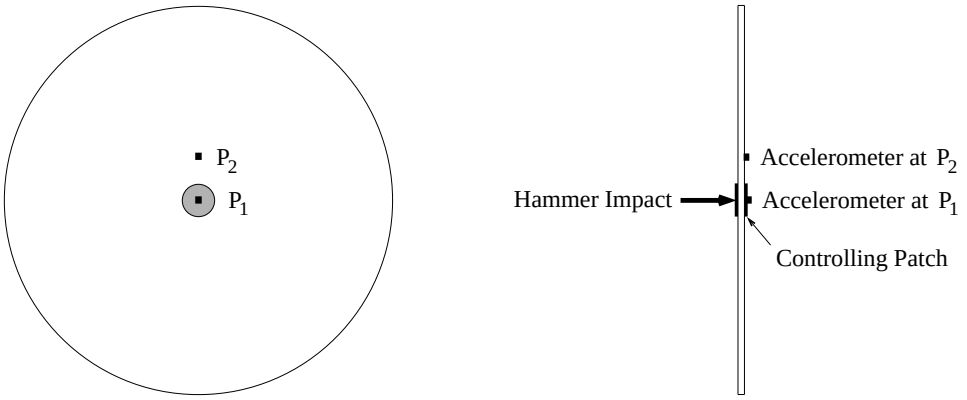

FIG. 5.1. *Patch, accelerometer, and impact locations for the experiments involving control of transient vibrations.*

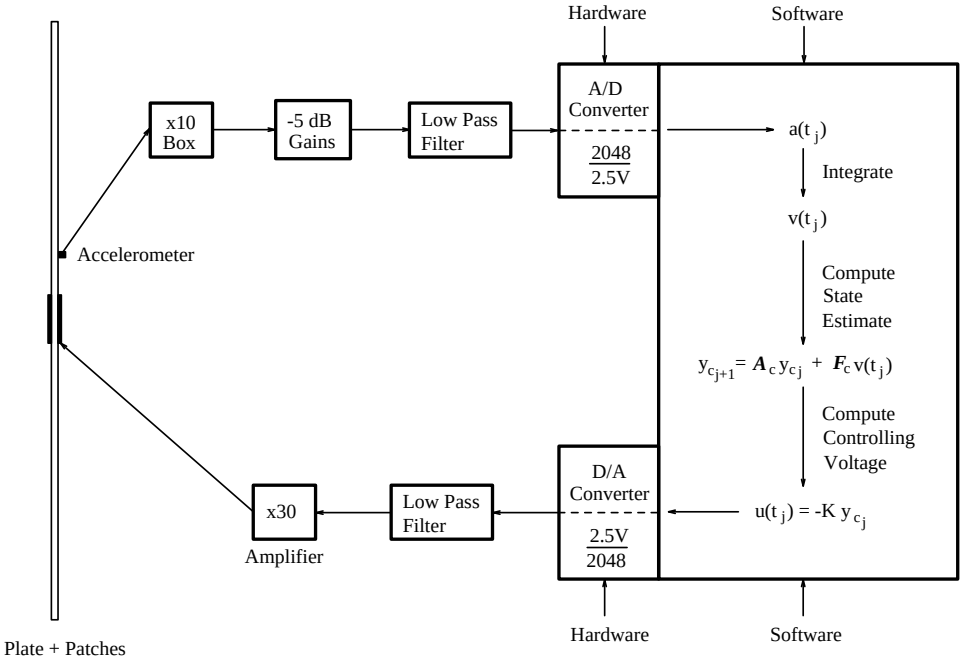

FIG. 5.2. *Amplifiers, DSP configuration, and PC Algorithm* 4.1 *for controlling a plate excited by an initial impact. Component matrices are defined in Figures* 4.2 *and* 4.3.

The control code was written in assembler in order to attain sufficiently fast sample rates for resolving transient frequencies excited by the hammer impact. While the code ran at rates greater than 7 KHz, a sample rate of 3.5 KHz was used in the experiments. This proved to be sufficient for resolving the three axisymmetric modes (with frequencies of 60 Hz, 227 Hz, and 512 Hz) excited in the experiments.

Representative plots of the plate velocity (integrated from the data) at the off-center point P_2 in the uncontrolled and controlled cases are given in Figure 5.3, with reduction levels at times $t = 0.5, 1.0, 1.5$ sec summarized in Table 5.2. The percentage

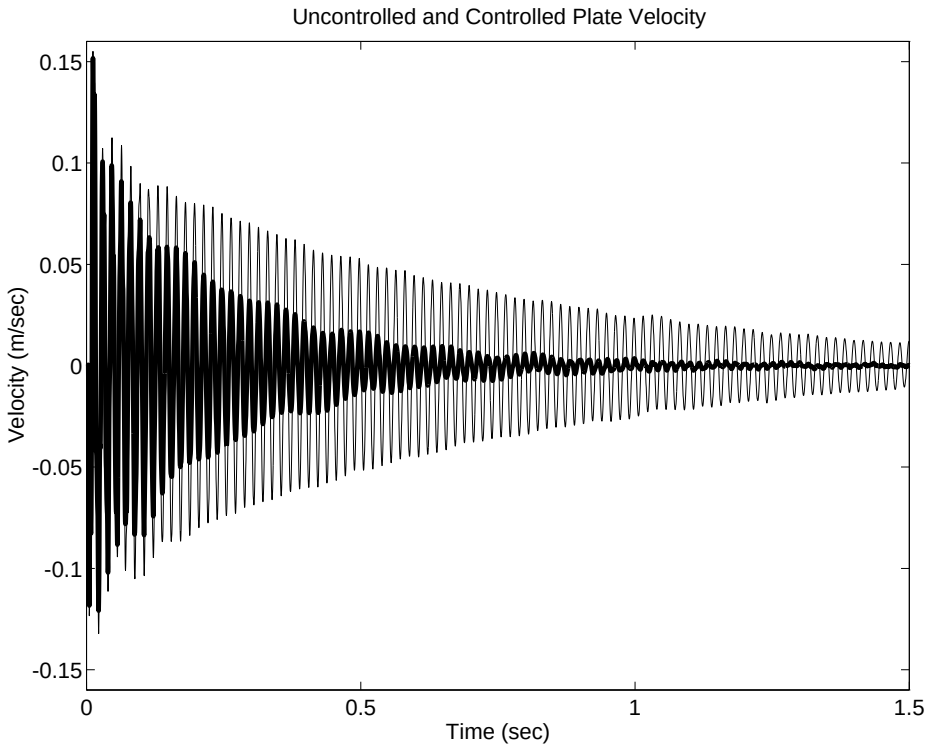

FIG. 5.3. *Uncontrolled and controlled plate vibrations at* $(2'', 0)$ *in response to an impact hammer hit:* —— *(uncontrolled),* ▬▬ *(controlled).*

TABLE 5.2
The percent reductions in acceleration and velocity levels at the point $P_2 = (2'', 0)$ *when feedback control is implemented.*

Time	Acceleration	Velocity
.5 sec	69.5	68.2
1 sec	88.9	84.7
1.5 sec	93.8	97.8

reductions were calculated by determining the ratio between the maximum values of the controlled and uncontrolled trajectories through one period containing the time point of interest. As illustrated by the results in Table 5.2 and Figure 5.3, the velocity level in the controlled case has been reduced by 50% before .5 sec and is essentially fully attenuated by 1.5 sec. We reiterate that these results were obtained with data obtained from an accelerometer at $(2'', 0)$ and a centered actuating patch, thus illustrating that collocation is unnecessary for this control method.

The voltage $u(t_j) = -Ky_{c_j}$ was recorded in each experiment and that voltage yielding the control results reported here is plotted in Figure 5.4. It is noted that the voltage has a maximum magnitude of 70 V. In practice, it has been observed that the patches can be used for extended periods at the frequencies of interest without damage or degradation of performance if the voltage levels are maintained below 8–10 rms V/mil [38]. Hence control voltage levels required for control of the transient vibrations is well within the tolerance of the 7-mil patches used in the experiments.

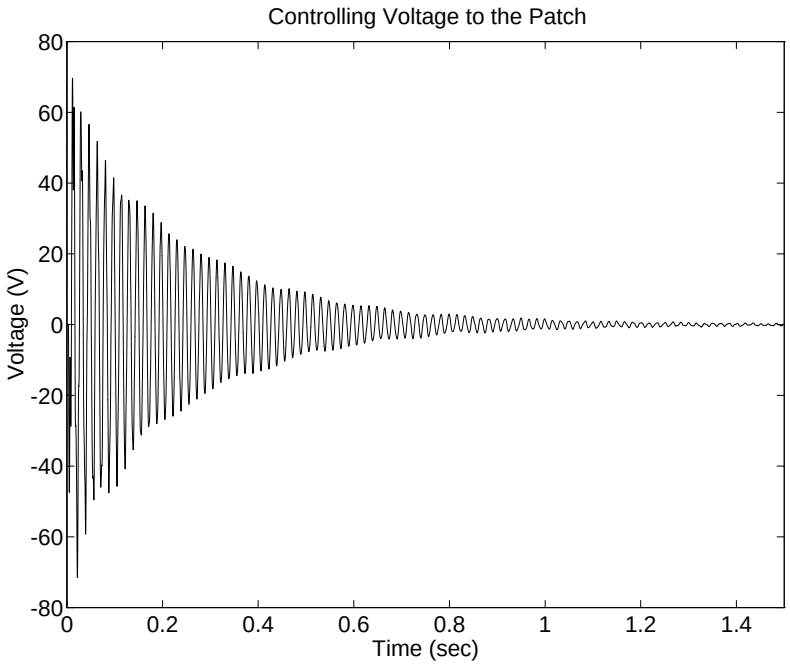

FIG. 5.4. *The controlling voltage for acceleration data observed at* $(2'', 0)$.

Finally, the force delivered by the hammer impact in the uncontrolled and controlled cases is plotted in Figure 5.5 so as to provide a means of testing the equity of excitation levels in the uncontrolled and controlled experiments (the initial velocities in the two cases can also be compared to determine whether the same level of energy is being delivered in each experiment). As indicated by the results in this latter figure, the force delivered in the two cases is nearly identical (a slight double hit was always present when an impact hammer was used to excite the axisymmetric modes).

5.2. Control of a periodic exogenous force. A second problem under consideration concerns the control of plate vibrations when the plate is driven by a periodic exogenous force. To demonstrate the control capabilities in this case, a periodic driving voltage was supplied to one centered patch on the plate, and the patch on the opposite side of the plate was used as the control actuator. Experimental tests indicated that a 350-Hz driving voltage produced a strong plate response and all tests were conducted with the exogenous voltage at that frequency.

Two sources were used to generate this exogenous signal: namely, an external oscillator and the PC running the control algorithm. As reported under Case 1 below, a purely steady-state response could be considered with the oscillator-generated exogenous force since the plate was driven to steady state before the control program was initiated. Both a transient and steady-state response were noted in the PC-generated signal since the input of the exogenous force to the plate began at the same time that the control algorithm was started. This latter means of excitation is considered in Case 2.

Since the system was driven by a periodic exogenous force, the discrete-time Algorithm 4.2 (corresponding to continuous-time Algorithm 3.2) was used to calculate the controlling voltage to the actuating patch. Again, component matrices as well as control and observation parameters are summarized in Tables 4.2 and 4.3.

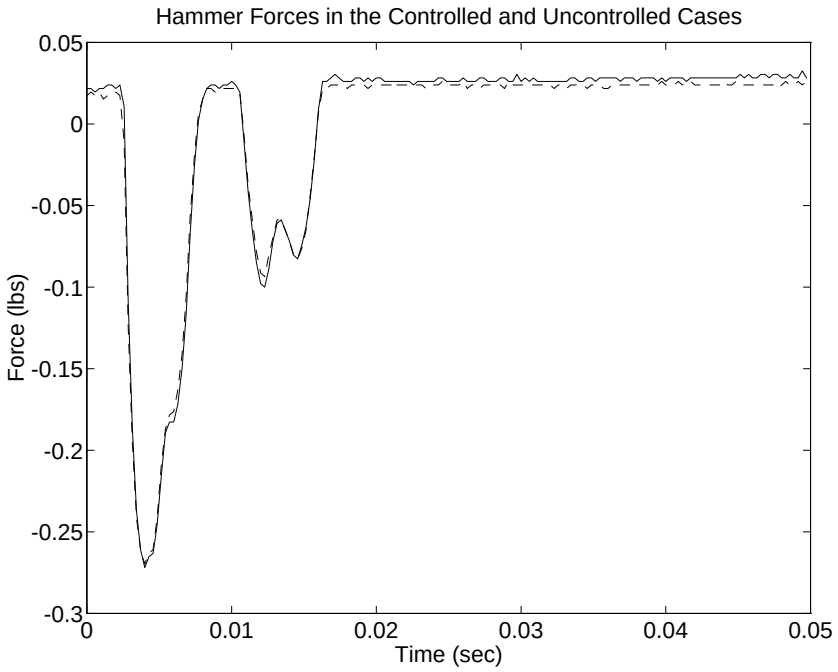

FIG. 5.5. *The force delivered by the impact hammer in the uncontrolled and controlled cases:* ——– *(controlled case),* – – – *(uncontrolled case).*

For the off-center results reported here, velocity observation values were obtained by integrating data from an off-center accelerometer located at the point $P_2 = (2'', 0)$ as depicted in Figure 5.1. The second input to the algorithm consisted of measurements $g(t_j)$ of the force driving the plate. We point out that when implementing this control method, both phase and magnitude information for the driving force were required, as compared with many other methods (e.g., feedforward) which require only phase information.

In these experiments, the tracking components r_j were calculated first and stored in a circular buffer. These values were then used when calculating the state estimates y_j and voltages $u(t_j)$. While the implementation in this manner facilitated running the algorithm with sample rates on the order of 7 KHz (again, the algorithm was coded in assembler), it limits the robustness of the method with respect to changes and variations in the driving force. Current efforts are directed toward simultaneous solution of the tracking and estimator difference equations.

A crucial issue when implementing the method concerns the handling of delays and phase shifts produced by the filters, A/D and D/A conversions, computation of the control voltages, et cetera. While the amount of delay and phase shift is frequency dependent, experiments indicated that at 350 Hz, 30°–40° phase shifts were introduced by the hardware. This was sufficient to destabilize the controller if left uncompensated. In the experiments, we compensated by first conducting an offline, numerical "identification" to determine the amount of added delay necessary for stabilizing the controller in the presence of phase shifts of the order introduced by the experimental hardware. A summary of these results can be found in [14]. This is analogous to the online tuning or phase locking which is necessary for ensuring stability in other control methods. The numerical tests, summarized in [14],

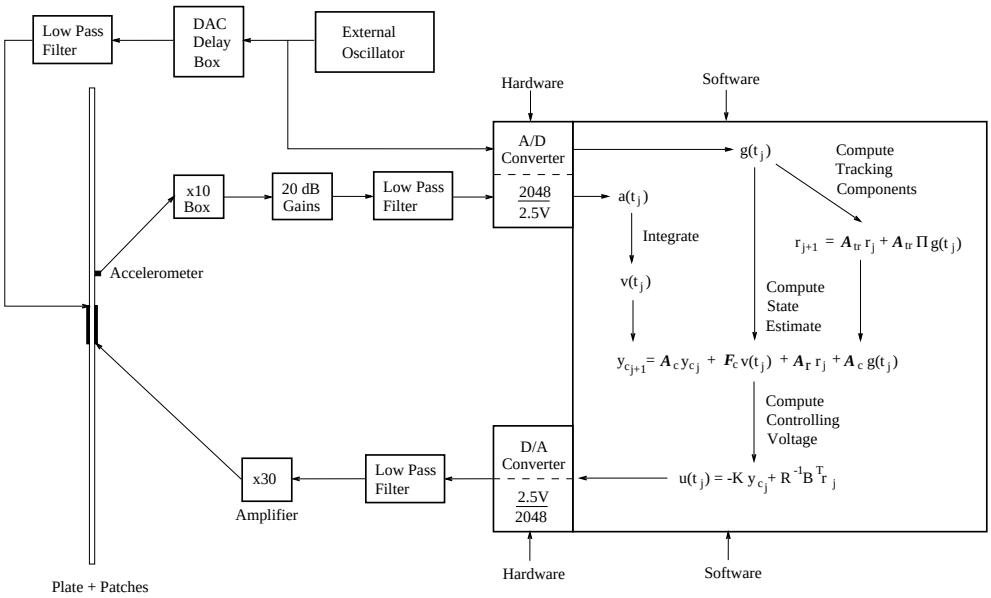

FIG. 5.6. *Amplifiers, DSP configuration, and PC Algorithm* 4.2 *for controlling a plate driven by a periodic exogenous force. Component matrices are defined in Tables* 4.2 *and* 4.3.

indicated that the introduction of a 216° delay in accelerometer or exogenous force data would stabilize the systems, and this was implemented in the experiments by using a DAC delay box. The compensation for phase delays in this manner provides merely a first step toward optimal implementation of the method, and one aspect of current research efforts is directed toward online compensation in the algorithm.

Data acquisition and processing was again performed with a PC-based Texas Instruments TMS 320-C30 board. A schematic of the setup is given in Figure 5.6.

Case 1. Oscillator-generated driving signal. For the results described here, the signal to the driving patch was generated by an external oscillator. The plate was allowed to reach steady state, and then the control program was initiated. Acceleration levels measured by the accelerometer located at $P_2 = (2'', 0)$ and integrated velocity values for the uncontrolled and controlled cases are plotted in Figure 5.7. As noted from the controlled trajectories in that figure, it takes the algorithm approximately 0.06 sec to calculate and store a sufficient number of tracking components r_j. During that time interval, no voltage is fed to the actuating patch. Once the tracking calculations are completed, state estimation begins and the controlling voltage is computed and fed back into the system. The vibration levels decay for approximately 0.3 sec and then are maintained at levels that are approximately 15% of those for the uncontrolled case for the remainder of the time interval. This corresponds to a $20\log(a_{con}/a_{uncon}) \approx -16.5$ dB reduction in acceleration levels.

While the magnitude of the controlling voltage is dependent upon the amplitude of the driving signal, magnitudes less than 40 V (28.3 V rms) were required to attain the levels reported here. At 350 Hz, this was well within the range (56 V–70 V rms in this case) that was considered to be safe for the patch being used (see section 5.1 for further discussion regarding the voltage levels at which the patches can be driven without damage or degradation in performance).

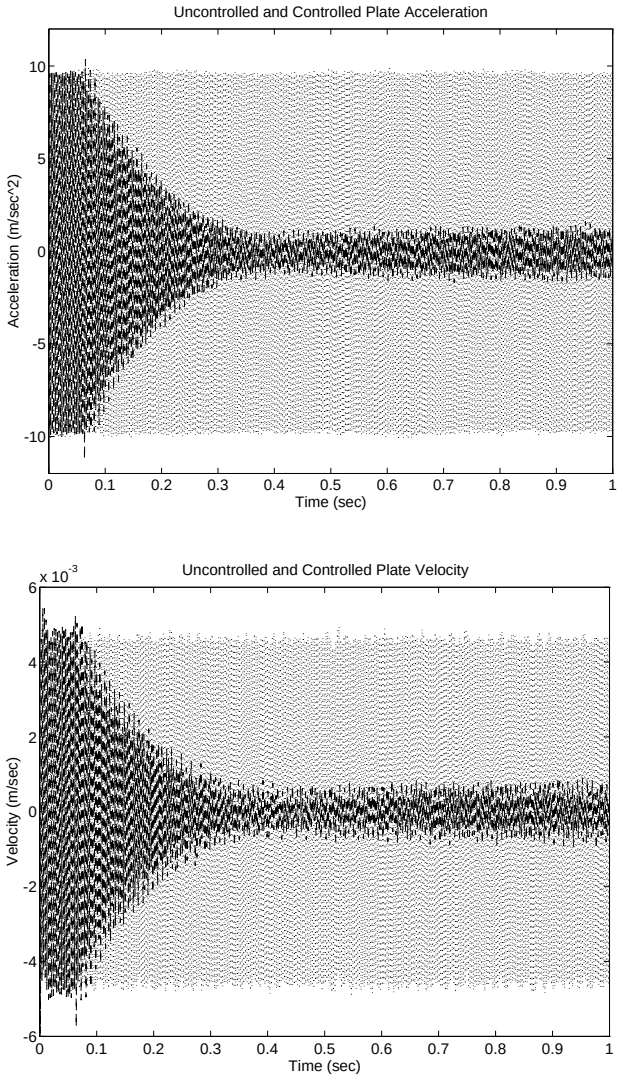

FIG. 5.7. *Uncontrolled and controlled plate acceleration and velocity at* $(2, 0)$ *for system driven by periodic exogenous force:* ——— *(uncontrolled),* ▬▬ *(controlled).*

The results in this experiment demonstrate the effectiveness of the algorithm for controlling a system that has reached steady state. Hence one is not required to start the control with a system at rest.

Case 2. PC-generated driving signal. A second mechanism for generating the driving signal is with the PC that is used to process data and run the control algorithm. Acceleration and velocity plots of the uncontrolled and controlled plate vibrations excited in this manner are given in Figure 5.8. It can be seen that in this case, the plate starts from rest and is still being driven through a transient stage when the tracking calculations are completed and control begins. At that point, the controlled trajectories are reduced to the levels noted in the purely steady-state case, whereas the uncontrolled trajectories are driven to steady state. Here, an 82% (15 dB) reduction in levels is noted at time $T = 1$ sec. This was obtained with a controlling

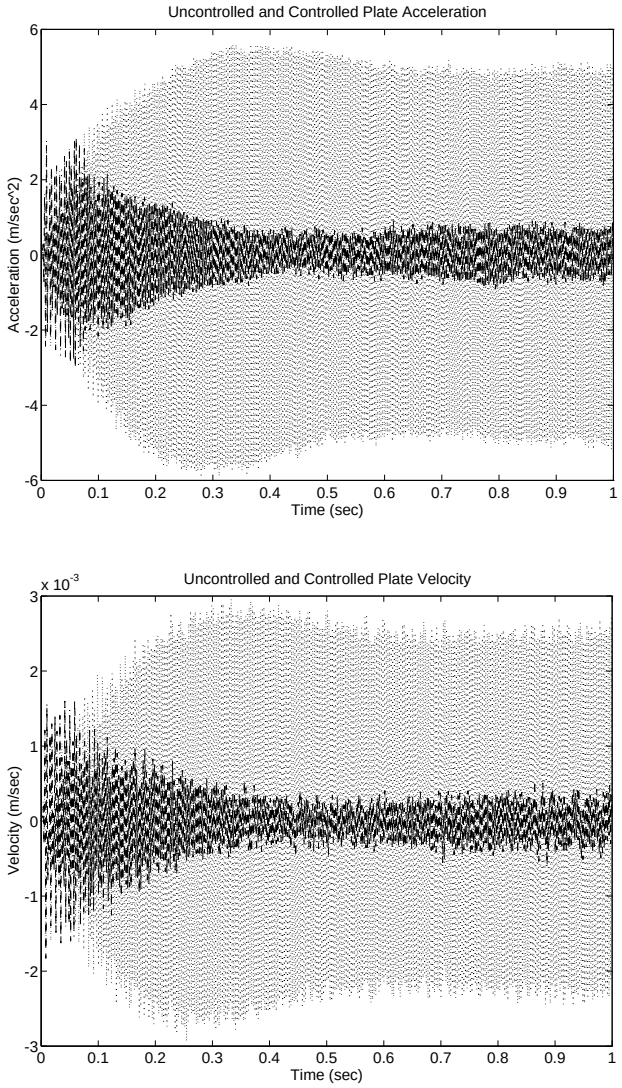

FIG. 5.8. *Uncontrolled and controlled plate acceleration and velocity at* $(2, 0)$ *for system driven by periodic exogenous force:* —— *(uncontrolled),* ▬▬ *(controlled).*

voltage of magnitude $12\,\mathrm{V}_{max}$ $(8.5\,\mathrm{V}_{rms})$. These results demonstrate the effectiveness of the control algorithm for a system undergoing transient oscillations before reaching steady state in response to a periodic driving force.

6. Conclusions. In this work, the experimental implementation of a PDE-based controller was considered. While the motivating application involves the control of vibration levels for a circular plate through the excitation of surface-mounted piezoceramic patches, the general techniques described here will extend to a variety of applications.

For such control techniques, the first step is the derivation of a PDE model which accurately describes the dynamics of the system under consideration. Physical parameters in these models must typically be estimated through fit-to-data techniques be-

fore control applications can be considered. Following a brief discussion regarding the strong and weak forms of a thin plate model with a discontinuous control input term (due to the piecewise constant nature of the piezoceramic patches), continuous-time LQG and H^∞ methods for systems with no exogenous force or a periodic exogenous force were discussed. The discrete-time approximations necessary for implementing the methods with digital measurements were also presented. A crucial step when implementing the discrete-time controllers involves the approximate integration of data (e.g., accelerometer data integrated to obtain velocity state values), and first- and second-order filters for accomplishing this were discussed. Without such filters, DC biases, which are always present in the data, would render the integrated values useless.

Experimental results demonstrating the control of transient and steady-state vibrations were then presented. One advantage of the PDE-based controllers over standard frequency response input/output techniques is the capability for direct control of transient responses, and this was demonstrated in the first set of examples. A centered hammer impact was used to excite the plate, and integrated data from an off-center accelerometer were used to reconstruct the state. The results demonstrate that attenuation levels on the order of 95% reduction can be attained by 1.5 sec using the PDE-based controller.

The second example demonstrates the control of transient and steady-state responses when the plate was driven by a periodic exogenous voltage to a secondary piezoceramic patch. These results demonstrate that, after accounting for hardware delays, attenuation levels on the order of 85% were attained when control was implemented. While implementation techniques are still being refined, these results demonstrate the effectiveness of the PDE-based controller for this system and indicate the potential of these control techniques for reducing transient and steady-state dynamics in other structural and structural acoustic systems.

Acknowledgments. The authors extend their sincere thanks to Yun Wang, Brooks Air Force Base, for substantial collaboration throughout the duration of this work.
