We are in the situation of Theorem 1.4 with $L \subseteq \mathcal{S}_p$, a nonattractive and homogeneous set of equilibria. Indeed, for all $z^1 \in \mathcal{S}_p$, K_r is generated by $\{V^1, \dots, V^{p-1}\}$, $K_a = (K_r)^\perp$, J_+ is the matrix as aforesaid, and

$$J_-(z^1) = \begin{pmatrix} -2\lambda_p J(z^1) & 0 \\ 0 & J_- \end{pmatrix}.$$

To apply Theorem 1.4, it is enough to prove that the noise excitation is sufficient in the repulsive direction, i.e., with the same notations as in section 1.3, that

$$\liminf_n E(\|(\varepsilon_{n+1})^{(r)}\||\mathcal{F}_n) > 0.$$

For $1 \le k \le p-1$, a.s. on $\Gamma(L)$,

$$E([\langle \varepsilon^1_{n+1}, V^k\rangle - \langle (C_{n+1} - C)Z^1_n, V^k\rangle]^2|\mathcal{F}_n) \le K\langle Z^1_n, V^k\rangle^2,$$

and a.s., $\lim_n \langle Z^1_n, V^k\rangle = 0$. Hence

$$\lim_n E(\langle \varepsilon^1_{n+1}, V^k\rangle^2|\mathcal{F}_n) = \lim_n E([(V^k)^T X_{n+1} X^T_{n+1} Z^1_n - V^k C Z^1_n]^2|\mathcal{F}_n)$$

$$\lim_n E(\langle \varepsilon^1_{n+1}, V^k\rangle^2|\mathcal{F}_n) = E[\langle V^k, X_1\rangle^2 \langle X_1, V^p\rangle^2] > 0 \tag{35}$$

and

$$E(\|(\varepsilon^1_{n+1})^{(r)}\|^2|\mathcal{F}_n) = \sum_{k=1}^{p-1} \lim_n E(\langle \varepsilon^1_{n+1}, V^k\rangle^2|\mathcal{F}_n) > 0.$$

And since (ε_n) has a conditional moment with an order larger than 2, the excitation conditions are checked. $P(\Gamma(L)) = 0$ and the proposition is proved for $j = 1$.

(2) Assume that for $1 \le k \le j-1$, $i(k) = k$, and that $i(j) = p > j$ and $\mathcal{S}_p \ne \mathcal{S}_j$. We have to prove that $P(\Gamma(L)) = 0$.

Consider $\mathcal{M}$ provided with $\mathcal{B}_1 = \{M^{11} \dots M^{jd}\}$, where

$$M^{11} = [V^1 0 \dots 0], \dots, M^{1d} = [V^d 0 \dots 0], \qquad M^{21} = [0 V^1 0 \dots 0], \dots, M^{jd} = [0 \dots V^d].$$

Setting $Z = [Z^1 \dots Z^j] \in \mathcal{M}$, we denote $Z = \sum_{k=1}^j \sum_{m=1}^d z^{km} M^{km}$ and $Z^k = \sum_{m=1}^d z^{km} V^m$. If h^m_k designates the m-component of h_k in $\mathcal{B}$, we have

$$h^m_k(Z) = \lambda_m - \left(\sum_{n=1}^d \lambda_n (z^{kn})^2\right) z^{km} - 2\sum_{i=1}^{k-1} \left(\sum_{n=1}^d \lambda_n z^{kn} z^{in}\right) z^{im}.$$

Hence

$$\frac{\partial h^m_k}{\partial z^{km}}(Z) = \lambda_m - \sum_{n=1}^d \lambda_n (z^{kn})^2 - 2\lambda_m (z^{km})^2 - 2\sum_{i=1}^{k-1} \lambda_m (z^{im})^2, \tag{36}$$

$$\frac{\partial h^m_k}{\partial z^{kn}}(Z) = -2\lambda_n z^{kn} z^{km} - 2\sum_{i=1}^{k-1} \lambda_n z^{in} z^{im} \quad \text{if } n \ne m, \tag{37}$$

$$\frac{\partial h^m_k}{\partial z^{im}}(Z) = -2\lambda_m z^{km} z^{im} - 2\sum_{n=1}^{d} \lambda_n z^{kn} z^{in} \quad \text{for } 1 \le i \le k-1, \tag{38}$$

$$\frac{\partial h^m_k}{\partial z^{in}}(Z) = -2\lambda_n z^{kn} z^{im} \quad \text{if } n \ne m \text{ and } 1 \le i \le k-1, \tag{39}$$

$$\frac{\partial h^m_k}{\partial z^{in}}(Z) = 0 \quad \text{if } i > k. \tag{40}$$

For $z = [z^1 \dots z^{j-1} z^j]$, with $z^k \in \mathcal{S}_k$ for $1 \le k < j$ and $z^j \in \mathcal{S}_p$,

$$Dh(z) = \begin{pmatrix} \Delta_1 & . & . & . & . \\ \cdots & \Delta_2 & . & . & . \\ \cdots & . & . & . & . \\ \cdots & . & . & . & . \\ \cdots & . & . & . & \Delta_j \end{pmatrix}.$$

Denote by $0 < \alpha_\rho < \cdots < \alpha_1$ the distinct eigenvalues of C. By using the previous calculations, for $1 \le k \le j$, if $\lambda_k = \alpha_r$ and if $\nu(r)$ is the multiplicity order of α_r,

$$\Delta_k = \begin{pmatrix} -\lambda_1 - \lambda_k & . & . & . & . & . & . \\ . & . & . & . & . & . & . \\ . & . & -\alpha_{r-1} - \lambda_k & . & . & . & . \\ . & . & . & -2\lambda_k J(z^k) & . & . & . \\ . & . & . & . & \alpha_{r+1} - \lambda_k & . & . \\ . & . & . & . & . & . & . \\ . & . & . & . & . & . & \lambda_d - \lambda_k \end{pmatrix},$$

where $J(z^k)$ is a symmetric, semidefinite positive matrix $\nu(r) \times \nu(r)$ as $J(z^1)$.

So, for $1 \le k \le j-1$, all the matrices Δ_k have nonpositive eigenvalues. For $k = j$, only the first block of Δ_j has some positive eigenvalues and it doesn't depend on z.

$\{[z^1 \dots z^j] \in \mathcal{M};\ z^1 \in \mathcal{S}_1, \dots, z^{j-1} \in \mathcal{S}_{j-1}, z^j \in \mathcal{S}_p\}$ is a compact connected set of equilibria, homogeneous and nonattractive. K_r is generated by $\{M^{jj}, M^{j(j+1)}, \dots, M^{j(p-1)}\}$ and has a $(p-j)$-dimension, and $K_a = (K_r)^\perp$. About the noise excitation, $(\varepsilon_{n+1})^{(r)} = \sum_{k=j+1}^{p-1} M^{jk} (\varepsilon_{n+1})^T M^{jk}$, and by a similar calculation to (35), we obtain

$$E(\|(\varepsilon_{n+1})^{(r)}\|^2 | \mathcal{F}_n) = \sum_{k=j}^{p-1} E(\langle V^k, X_1 \rangle^2 \langle X_1, V^p \rangle^2) > 0.$$

So, by Theorem 1.4, $P(\Gamma(L)) = 0$. □

Step 3. *Proof of the a.s. convergence to a solution of the PCA*. Knowing that $d(Z_n^k, S_k) \to 0$, we have to show that, when λ_k is multiple, Z_n^k converges to a random vector of $\mathcal{S}_k$.

(a) For a Q matrix $d \times d$ and $Qx \ne 0$, if we set $\varphi(x) = \frac{Qx}{\|Qx\|}$, then

$$D\varphi(x) = \frac{Q}{\|Qx\|} - \frac{(Qx)^T (Qx) Q}{\|Qx\|^3}. \tag{41}$$

(b) For $z = [z^1 \dots z^d]$ such that, for $1 \le j \le d$, $d(z^j, \mathcal{S}_j) \le r$ and for r small enough, if P_j is the orthogonal projection on F_j, $[P_1(z^1) \dots P_d(z^d)]$ is nonsingular. We can perform a Gram–Schmidt orthonormalization on $[P_1(z^1) \dots P_d(z^d)]$:

$$z = [z^1 \dots z^d] \to [\varphi_1(z^1) \dots \varphi_d(z^1, \dots, z^d)] = \varphi(z).$$

We shall prove that $D\varphi(z) h(z) = 0$.

$$\begin{aligned} P_1 h_1(z^1) &= P_1 C z^1 - (z^1)^T C z^1 P_1 z^1 \\ &= (\lambda_1 - (z^1)^T C z^1) P_1 z^1, \end{aligned}$$

and by (41), with $Q = P_1$, $\frac{\partial}{\partial z^1} \varphi_1(z^1) h_1(z^1) = 0$.

Assume that for $1 \leq k < j$, $(z^1, \ldots, z^k) \to \varphi_k(z^1, \ldots, z^k)$ satisfies, for all $i \leq k$,

$$\frac{\partial}{\partial z^i}\varphi_k(z^1, \ldots, z^k)h_i(z^1, \ldots, z^i) = 0.$$

Let I be the set of i such as $\lambda_i = \lambda_j$ and $i < j$. Denote $P = P_j$ and $\varphi_i = \varphi(z^1, \ldots, z^i)$; then

$$\varphi_j(z^1, \ldots, z^j) = \frac{Pz^j - \sum_{i\in I}\langle \varphi_i, Pz^j\rangle \varphi_i}{\|Pz^j - \sum_{i\in I}\langle \varphi_i, Pz^j\rangle \varphi_i\|}.$$

Setting $Qx = Px - \sum_{i\in I}\langle Px, \varphi_i\rangle\varphi_i$ and using (41), we have

$$\varphi_j(z^1, \ldots, z^j) = \frac{Qz^j}{\|Qz^j\|},$$
$$\frac{\partial}{\partial z^j}\varphi_j(z^1, \ldots, z^j) = \frac{Q}{\|Qz^j\|} - \frac{Qz^j(Qz^j)^T P}{\|Qz^j\|^2}.$$

Now $Qx = Px - \sum_{i\in I}\langle Px, \varphi_i\rangle\varphi_i$, and for $k \in I$,

$$\begin{cases} Pz^k = \displaystyle\sum_{i\in I}\langle Pz^k, \varphi_i\rangle\varphi_i, \\ Qz^k = 0, \end{cases}$$

and for j, $Qz^j = Pz^j - \sum_{i\in I}\langle Pz^j, \varphi_i\rangle\varphi_i \in F_j$. Hence

$$\begin{aligned} Qh_j(z^1, \ldots, z^j) &= Q\left(Cz^j - (z^j)^T Cz^j z^j - \sum_{i<j}(z^i)^T C(z^j)z^i\right) \\ &= (\lambda_j - (z^j)^T Cz^j)z^j \end{aligned}$$

and

$$\frac{\partial}{\partial z^j}\varphi_j(z^1, \ldots, z^j)h_j(z^1, \ldots, z^j) = 0.$$

For $i < j$, $\frac{\partial}{\partial z^i}\varphi_j(z^1, \ldots, z^j) = \sum_{k\in I,\ k\geq i} A_k(\frac{\partial}{\partial z^i}\varphi_k(z^1, \ldots, z^k))$, where A_k is a matrix dependent on $z^1, \ldots, z^j$, but it is unnecessary to make it explicit because the recurrence assumption sets

$$\frac{\partial}{\partial z^i}\varphi_j(z^1, \ldots, z^j)h_i(z^1, \ldots, z^i) = 0.$$

We also proved that $D\varphi(z)h(z) = 0$.

(c) For all j,

$$\varphi_j(Z^1_{n+1}, \ldots, Z^j_{n+1}) - \varphi_j(Z^1_n, \ldots, Z^j_n) = \gamma_n \sum_{k=1}^{j}\frac{\partial}{\partial z^k}\varphi_j(Z^1_n, \ldots, Z^j_n)\varepsilon^k_{n+1} + \rho_{n+1};$$

the regressive series, with the general term $\gamma_n \sum_{k=1}^{j}\frac{\partial}{\partial z^k}\varphi_j(Z^1_n, \ldots, Z^j_n)\varepsilon^k_{n+1}$, converges, as does $\Sigma\rho_{n+1}$. It implies the a.s. convergence of $\varphi(Z_n)$ to $(W^1, \ldots, W^j)$, and thus by Proposition 3.3, of (Z_n) to $(W^1, \ldots, W^j)$. □

4. Appendices.

4.1. Appendix 1. Stochastic iterative inequality.

THEOREM 4.1 (of repulsion). *Set (ζ_n), a positive sequence, defined on a probability space $(\Omega, \mathcal{A}, \mathcal{P})$ provided with an increasing sequence of σ-fields $(\mathcal{F}_n)_{n\geq 0}$ and satisfying a.s. on an $\mathcal{F}_\infty$-measurable set $\Omega_0 \subseteq \Omega$,*

$$\zeta_{n+1} \geq (1+\lambda\gamma_n)\zeta_n + c_n(\varepsilon_{n+1} + r_{n+1}), \tag{42}$$

with $\lambda > 0$. We assume that

• *(ε_n) and (r_n) are real random sequences, defined on $(\Omega, \mathcal{A}, \mathcal{P})$, $(\mathcal{F}_n)$-measurable and satisfying (6) a.s on Ω_0, and*

$$\limsup_n E(\varepsilon_{n+1}^2|\mathcal{F}_n) < \infty \quad \textit{and} \quad \liminf_n E(|\varepsilon_{n+1}||\mathcal{F}_n) > 0; \tag{43}$$

• *(γ_n) and (c_n) are real nonnegative deterministic sequences satisfying (2) and (5).*

Then the event $\Omega_0 \bigcap \{\omega\ ;\ \zeta_n(\omega) \to 0\}$ has probability zero.

Proof. Step 1. It is sufficient to prove Theorem 4.1, assuming that a.s. on Ω,

$$E(\varepsilon_{n+1}|\mathcal{F}_n) = 0 \quad \text{and} \quad \limsup_n E(\varepsilon_{n+1}^2|\ \mathcal{F}_n) < \mathbf{C} < \infty, \tag{44}$$

$$\liminf_n E(|\varepsilon_{n+1}||\mathcal{F}_n) > \mathbf{C} > 0 \quad \text{and} \quad \Sigma r_n^2 < \mathbf{C} < \infty. \tag{45}$$

See [15] and [6, p. 401] for the way to achieve this simplification.

Step 2. Set $G = \Omega_0 \bigcap \{\omega\ ;\ \zeta_n(\omega) \to 0\}$. On G,

$$\zeta_{n+1} = (1+\lambda\gamma_n)\zeta_n + c_n(\varepsilon_{n+1} + r_{n+1}) + c_n U_{n+1}$$

with (U_n) a random positive real sequence that is $(\mathcal{F}_n)$-measurable.

Set

$$G_N = P(G|\mathcal{F}_N);$$

G is $\mathcal{F}_\infty$-measurable and (G_N) converges to $\mathbb{I}_G$ a.s. and in L^p for all $p \geq 1$. Thus

$$E((G_N - \mathbb{I}_G)^2) \to 0. \tag{46}$$

Setting $\beta_n = \prod_{j=0}^n (1+\gamma_j\lambda)$, we have

$$\zeta_n = \beta_n \left[\zeta_0 + \sum_{j=0}^n \frac{c_j}{\beta_j}(\varepsilon_{j+1} + r_{j+1} + U_{j+1}) \right].$$

Step 3. Prove that

$$E\left(\mathbb{I}_G \sum_{n=N}^\infty \frac{c_n}{\beta_n}\|U_n\| \right) = o\left(\left(\sum_{n=N}^\infty \frac{c_n^2}{\beta_n^2} \right)^{\frac{1}{2}} \right). \tag{47}$$

We have

$$\zeta_{N+n} = \beta_{N+n} \left[\frac{\zeta_N}{\beta_N} + \sum_{j=N}^{n+N} \frac{c_j}{\beta_j}(\varepsilon_{j+1} + r_{j+1} + U_{j+1}) \right],$$

and on G, $\zeta_{n+N} \to 0$ and $\beta_{N+n} \to \infty$. Hence on G,

$$-\frac{\zeta_N}{\beta_N} = \sum_{j=N}^{\infty} \frac{c_j}{\beta_j}(\varepsilon_{j+1} + r_{j+1} + U_{j+1})$$

and

$$\sum_{j=N}^{\infty} \frac{c_j}{\beta_j} U_{j+1} = -\frac{\zeta_N}{\beta_N} - \sum_{j=N}^{\infty} \frac{c_j}{\beta_j}(\varepsilon_{j+1} + r_{j+1}).$$

Thus

$$E\left[\mathbb{I}_G\left(\sum_{n=N}^{\infty} \frac{c_n}{\beta_n} U_{n+1}\right)\right] \le -E\left[\mathbb{I}_G \sum_{n=N}^{\infty} \frac{c_n}{\beta_n}(\varepsilon_{n+1} + r_{n+1})\right]$$

$$\le E\left[(G_N - \mathbb{I}_G) \sum_{n=N}^{\infty} \frac{c_n}{\beta_n}(\varepsilon_{n+1} + r_{n+1})\right] - E\left[G_N \sum_{n=N}^{\infty} \frac{c_n}{\beta_n}(\varepsilon_{n+1} + r_{n+1})\right]$$

$$\le [E((G_N - \mathbb{I}_G)^2)]^{\frac{1}{2}} \left[E\left(\sum_{n=N}^{\infty} \frac{c_n}{\beta_n}(\varepsilon_{n+1} + r_{n+1})^2\right)\right]^{\frac{1}{2}} + E\left(\sum_{n=N}^{\infty} \frac{c_n}{\beta_n}|r_{n+1}|\right)$$

$$\le \mathbf{C}[E((G_N - \mathbb{I}_G)^2)]^{\frac{1}{2}} \left(\sum_{n=N}^{\infty} \frac{c_n^2}{\beta_n^2}\right)^{\frac{1}{2}} + \left(E\left(\sum_{n=N}^{\infty} r_{n+1}^2\right)\right)^{\frac{1}{2}} \left(\sum_{n=N}^{\infty} \frac{c_n^2}{\beta_n^2}\right)^{\frac{1}{2}}$$

$$= o\left(\left(\sum_{n=N}^{\infty} \frac{c_n^2}{\beta_n^2}\right)^{\frac{1}{2}}\right).$$

So, by (44) and (46), (47) is proved.

We now use a theorem, proved in [6] (Theorem A in the appendix), that extends the framework of a result of Levy [18], Lai and Wei [15], and others about the sum of a convergent regressive series.

Here Theorem A of [6] applies with $H = G$, $c_n = \frac{c_n}{\beta_n}$, and $R_n = U_n$. So $P(G) = 0$. □

4.2. Appendix 2. An accompanying result. We use a version of a theorem of Benaïm and Hirsch [2], [10] which specifies the conditions under which any trajectory solution to (1) is a.s. asymptotic to a forward trajectory solution to ODE (3). From the study of Benaïm and Hirsch, we can claim the following result.

THEOREM 4.2. *Set* (1) *under Assumption* A1 *and the following assumptions:*

- *h is $\mathcal{C}^1$ on a neighborhood of L and*

$$\inf_{x \in L_1} \frac{1}{2} \lambda_{min}(Dh(x) + (Dh(x))^T) = -\mu, \tag{48}$$

where $L_1 \subset L$ is the closure of alpha and omega limit sets of points in L;

- *a.s. on $\Gamma(L)$, for $a > 2$,*

$$\limsup_n E(\|\varepsilon_{n+1}\|^a | \mathcal{F}_n) < \infty; \tag{49}$$

- *$\gamma_n = c_n = \frac{g}{n}$ $(g > 0)$ and $\frac{1}{2g} - \frac{1}{ag} > \max(0, \mu)$.*

Then, for any neighborhood W of L, there exist a random variable T and a random vector $Y \in W$, defined on $\Gamma(L)$, such that, a.s. on $\Gamma(L)$,

$$\limsup_n \frac{1}{s_{n-1}} \log(\|Z_n - z(s_{n-1} - T)\|) \leq -\left(\frac{1}{2g} - \frac{1}{ag}\right), \tag{50}$$

where $s_n = \sum_{j=0}^{n} \gamma_j$ and the function $t \to z(t)$ is the solution to the ODE (3), defined on $\mathbb{R}_+$, such that $z(0) = Y$, and whose orbit is in W.

Acknowledgments. I wish to thank Marie Duflo for her personal encouragements. I am particularly grateful to her for many remarks and fruitful ideas on the topics in this paper. I also thank the referee and Michel Benaïm for their judicious comments to ameliorate this work.

PARAMETER ESTIMATION IN ACOUSTIC MEDIA USING THE ADJOINT METHOD*

ELENA M. FERNÁNDEZ-BERDAGUER†

Abstract. We present an algorithm based on the adjoint method to locate points that provide an approximate solution to the parameter estimation problem for the acoustic model. The parameter belongs to infinite-dimensional sets. We prove the existence of the directional derivative of the solution with respect to the parameter in some dense set of directions of the set of parameters. This derivative is the solution of a differential boundary value problem. The adjoint problem is presented. A result on the convergence of the iterations is proved.

1. Introduction.

Algorithms to estimate coefficients in the acoustic problem have been discussed in detail in many works, but mostly in the case in which the coefficients are piecewise continuous; see, for example, [3, 4, 8, 9]. Here we consider more general sets of parameters: parameters in an infinite-dimensional space, of which the piecewise continuous case appears as a particular case.

Parameter estimation problems of the type considered here are typical of seismic exploration; they also appear in many different fields such as remote sensing, imaging, and nondestructive testing. The direct problem models the propagation of waves in acoustic media, and in the case of seismic exploration the parameter represents the bulk modulus of the media.

We will approach the estimation problem in the usual least squares sense, that is, as an optimization one. It consists of the minimization of a quadratic functional involving the observed data and a functional of the traces of the model.

Minimization problems where the model is a partial differential equation can be approached by discretizing the differential problem first and then applying optimization algorithms to the discretized version, or applying optimization algorithms to the continuous problem and discretizing as a final step. The first approach was the most commonly employed; among the many works using it we can mention as examples [2, 3, 4, 16, 17]. The second type of algorithm was used in applications in geophysics, mostly without rigorous proofs (see [19, 21, 20]), and more recently in several works, for example, [6, 15, 13, 8, 9].

We present an algorithm of the second type based on the adjoint method for a hyperbolic problem with absorbing boundary conditions. The method is used without a priori information on the parametrization of the function to be identified. Here we present the mathematical details of the differential equations involved, and the operators and conditions for the convergence of the method. The highlights of the method are the sensitivity equations (2.11)–(2.13) and the adjoint integral (3.10) that allow us to calculate the different steps by solving equations similar to the one for the direct model but with a different source function. Those features make the algorithm

*Received by the editors February 28, 1996; accepted for publication (in revised form) June 16, 1997; published electronically May 22, 1998.

†CONICET, Instituto de Cálculo FCEyN y Facultad de Ingenieria de la Universidad de Buenos Aires, Ciudad Universitaria, Pabellón II, Buenos Aires, Argentina (efernan@ulises.ic.fcen.uba.ar).

a fast one as needed for the application that we have in mind, which even in the layered case has a large number of parameters.

A similar algorithm that employs the sensitivity equations was used previously by us in the case of piecewise constant coefficients (this amounts to parameters in a finite-dimensional space) with very good numerical results (see [7, 8, 9]).

Basic questions when dealing with parameter estimation are those of existence and uniqueness of solutions of the inverse problem. Conditions for the existence of solutions to the estimation problem are known only for particular sets of parameters, mainly in the case where the parameter belongs to a space of finite dimension, as, for example, sets of piecewise constant functions. In general, inverse problems are ill posed since the solutions are very sensitive to changes in input data. An excellent discussion of the aforementioned problems can be found in the book by Banks and Kunisch [5]. Also, the identifiability problem, for systems different from those treated here, is clearly presented in the most recent articles by Giudici [10, 11]. For the particular problem presented in this work we refer the reader to the early publication of Bamberger, Chavent, and Lailly [1].

Here we do not address those problems; instead we present an algorithm which under conditions on the intervening operators converges to a critical point of the cost functional.

There is a vast body of research in the field of algorithms to identify parameters in problems governed by partial differential equations. A good update in the case of elliptic problems is the paper by Kunisch [14] and the bibliography therein.

The algorithm presented here does not include a regularization term. Our proofs on the differentiability with respect to the parameter suggest the use of an L^m-regularization term (with $m > 2$) instead of the usual L^2-norm term.

We use the customary notation as follows. Let $\Omega = (0,1)^n, n = 1, 2,$ or $3, \Gamma = \partial\Omega$. For all nonnegative integers s, let $(H^s(\Omega), \|\cdot\|_s)$ denote the usual Sobolev space. In particular, $H^0(\Omega) = L^2(\Omega)$ and $\|\|_0$ is the usual L^2-norm, with inner product

$$(v, w) = \int_\Omega v\, w\, dx.$$

For notational convenience, let

$$[v, w] = \int_\Gamma v\, w\, d\sigma$$

denote the inner product on Γ, with the associated norm denoted by $|\cdot|_0 = ([\cdot,\cdot])^{1/2}$, $d\sigma$ being the surface measure on Γ.

The following lemma about a trace inequality, for the particular domain with which we are dealing, will be needed. Its proof is given in the Appendix.

LEMMA 1.1. *Let $f \in H^1(\Omega)$ and m an integer such that $m \geq 2$. Then*

$$\|f\|^m_{L^m(\Gamma)} \leq C(\|f\|^m_{L^m(\Omega)} + \|f\|^{(m-1)}_{L^{2(m-1)}(\Omega)} \|f'\|_{L^2(\Omega)}).$$

Above, and in what follows, C stands for generic constants which may be different at different places.

The paper is organized as follows. In section 2 we present the direct model and state a theorem on the regularity of its solution. We set forth the inverse problem using the output least squares criterion. Also, we prove the existence of a continuous first

Gâteaux derivative of the solution of the direct model with respect to the parameter. We present the sensitivity equations for the derivatives. In section 3 we find an expression for the adjoint of the observation operator derivative. Finally, in section 4, we present an algorithm that under suitable hypotheses allows us to locate critical points of the cost functional.

2. The problem, the direct model, and the Gâteaux derivatives. The problem is to estimate the parameter $K(x)$ in the usual model for wave propagation in acoustic media:

$$\frac{1}{K}p_{tt}(K,x,t) - \nabla\cdot\left(\frac{1}{\rho}\nabla p(K,x,t)\right) = \frac{1}{K}S(x,t), \quad x\in\Omega, \quad t\in[0,T], \tag{2.1}$$

with initial condition

$$p(K,x,t=0) = p_t(K,x,t=0) = 0, \quad x\in\Omega, \tag{2.2}$$

and boundary condition

$$-\frac{1}{\rho(x)}\frac{\partial p(K,x,t)}{\partial \nu} = \frac{1}{\alpha(K,x)}p_t(K,x,t), \quad x\in\Gamma, \quad t\in[0,T], \tag{2.3}$$

where $\alpha(K,x) = \sqrt{K(x)\rho(x)}$. In seismic exploration, $p(K,x,t)$ represents the pressure, $K(x)$ the bulk modulus, and $\rho(x)$ the density of the medium. The function $S(x,t)$ in the right-hand side of (2.1) is the external source function, and equation (2.3) is an absorbing boundary condition so that waves arriving at Γ normally are absorbed completely; see [12, 18, 22].

We assume that $\rho(x)$ and $K(x)$ are measurable functions satisfying the following constraints that must be imposed from physical considerations:

$$\begin{array}{lccccc} \text{(i)} & \rho_* & \le & \rho(x) & \le & \rho^*, \\ \text{(ii)} & K_* & \le & K(x) & \le & K^*. \end{array} \tag{2.4}$$

Also, for the boundary condition (2.3) to make sense, we have to restrict K in a neighborhood of the boundary. For $0 < a_i < b_i < 1$, $i = 1,\dots,n$, let $S_n = \prod_{i=1}^n (a_i, b_i)$, $\tilde{S}_n = \Omega \setminus S_n$, and consider the space $\mathcal{A}$ spanned by a fixed set of continuous functions $g_1,\dots,g_\ell$ defined on $\tilde{S}_n$. A weaker condition could be imposed but we want $\mathcal{P}$ to be contained in a complete space. A similar condition must be imposed on ρ. The set of admissible parameters, denoted by $\mathcal{P}$, is given by

$$\mathcal{P} = \{K \text{ is measurable in } \Omega,\ K|_{\tilde{S}_n}\in\mathcal{A},\ K_*\le K(x)\le K^*,\ \text{a.e. in } \Omega\}.$$

The weak form of the direct problem (2.1)–(2.3) is: find $p(K,x,t)\in H^1(\Omega)$ such that

$$\left(\frac{1}{K}p_{tt}, v\right) + \left(\frac{1}{\rho}\nabla p, \nabla v\right) + \left[\frac{1}{\alpha}p_t, v\right] = \left(\frac{1}{K}S, v\right), \qquad v\in H^1(\Omega), \quad t\in[0,T]. \tag{2.5}$$

Let $\mathcal{V} = W^{1,\infty}(0,T,L^2(\Omega)) \cap L^\infty(0,T,H^1(\Omega))$. The following result on the solutions of (2.1)–(2.3) is proved in [9], so its proof is omitted here.

THEOREM 2.1. *Assume that ρ and K are measurable functions satisfying* (2.4)*, and that for an integer $q\ge 1$,*

$$\frac{\partial^{q-1}S}{\partial t^{q-1}} \in L^2(0,T,L^2(\Omega)).$$

Then the solution $p(K,x,t)$ *of* (2.5) *is such that*

$$\frac{\partial^{q-1}p(K,\cdot,\cdot)}{\partial t^{q-1}} \in \mathcal{V} \tag{2.6}$$

and satisfies the estimates

$$\left\|\frac{\partial^q p(K,\cdot,\cdot)}{\partial t^q}\right\|_{L^\infty(0,T,L^2(\Omega))} + \left\|\frac{\partial^{q-1}p(K,\cdot,\cdot)}{\partial t^{q-1}}\right\|_{L^\infty(0,T,H^1(\Omega))} \leq C\left\|\frac{\partial^{q-1}S}{\partial t^{q-1}}\right\|_{L^2(0,T,L^2(\Omega))},$$

where the positive constant C *depends only on the total time* T *and the upper and lower bounds for* $\rho(x)$ *and* $K(x)$.

We endow the set of admissible parameters with the $L^m(\Omega)\cap L^m(\Gamma)$-topology with $m=6$. The reason for the choice of the topology becomes clear in the proof of the differentiability in Theorem 2.4. We could have chosen the $H^1(\Omega)$-topology; but even in the case $n=1$ that choice overrides the space of piecewise constant functions. The choice of $\mathcal{P}$ as a subset of $H^1(\Omega)$ would have simplified many proofs. Also, the L^∞-topology is possible, but most regularization theorems require the parameter to belong to a reflexive space.

In [7] and [9] we have considered as the set of admissible parameters

$$\mathcal{Q}^N = \left\{ K:\ K(x) = \sum_{i=1}^{N} k_i \chi_{\Omega_i}(x), \quad K_* \leq k_i \leq K^* \right\};$$

there we estimated the parameters k_i while N and Ω_i were assumed to be fixed; in those cases we used the $L^2(\Omega)$-topology in the set of parameters. That was possible because the functions on the basis of the set of parameters were finite in number, then uniformly bounded.

Thus we endow the set $\mathcal{P}$ with the topology given by the norm

$$|||K|||_m = \|K\|_{L^m(\Omega)} + \|K\|_{L^m(\Gamma)}.$$

We assume that the observations are recorded at points x_{r_i} inside Ω, $1\leq i\leq N_r$, and denote by $p^{obs}\in L^2(0,T;R^{N_r})$ the vector of observations $p_i(t)=p^{obs}(x_{r_i},t)$, $1\leq i\leq N_r$, $t\in[0,T]$. We define the model for the observations as follows. For a given measurable set $E\subset R^n$, $|E|$ denotes the usual Lebesgue measure of E. Let B_i be the ball with center x_{r_i} and radius a, where a is small enough so that $B_i\cap B_j=\emptyset$ for $i\neq j$ and $B_i\subset\Omega$, $1\leq i,j\leq N_r$. The observation map $\Phi:\mathcal{P}\mapsto L^2(0,T;R^{N_r})$ is defined as the following nonlinear map:

$$\Phi(K)(t) = (\Phi_i(K)(t))_{1\leq i\leq N_r} \tag{2.7}$$

with

$$\Phi_i(K)(t) = \frac{1}{|B_i|}\int_{B_i} p(K,x,t)\,dx. \tag{2.8}$$

In the one-dimensional case, if the source function S satisfies $\partial S/\partial t\in L^2(0,T;L^2(\Omega))$, we can use point evaluation $p(K,x_{r_i},t)$, $i=1,\dots,N_r$, as the model for the observations because (Theorem 2.1) $p(K,\cdot,t)\in H^1(\Omega)$; therefore, for $n=1$, the function $p(K,\cdot,t)$ is absolutely continuous.

The estimation problem will be solved using the output least squares criterion. The problem is to minimize the functional

$$J(K) = \frac{1}{2} \left\| \Phi(K) - p^{obs} \right\|^2_{L^2(0,T;\mathbb{R}^{N_r})} \tag{2.9}$$

over the set $\mathcal{P}$.

A version of the next theorem, about the continuity of the solution of the direct model with respect to the parameter, was proved in [9] for the set $\mathcal{P}$ endowed with the $L^2(\Omega)$-topology. The difference is that here we show under additional hypotheses that the function p is Lipschitz continuous in the parameter K. A brief proof is given in the Appendix.

THEOREM 2.2. *Let $K_1(x), K_2(x) \in \mathcal{P}$, and $p(K_1, x, t)$, and $p(K_2, x, t)$ be the corresponding solutions of the direct problem* (2.1)–(2.3) *for $K = K_1$ and $K = K_2$, respectively. Set*

$$d(K_1, K_2, x, t) = p(K_1, x, t) - p(K_2, x, t),$$

and assume that for an integer $q \geq 1$,

$$\frac{\partial^{q+1} S}{\partial t^{q+1}}, \frac{\partial^{q+2} S}{\partial t^{q+2}} \in L^2(0, T, L^2(\Omega)).$$

Assume also that

(i) $\operatorname{supp}(K_1 - K_2) \cap \operatorname{supp} S(., t) = \emptyset$

or

(ii) $S \in L^2(0, T; L^3(\Omega))$.

Then $d(K_1, K_2, \cdot, \cdot) \in \mathcal{V}$. Moreover, d satisfies the estimate

$$\begin{aligned} &\left\| \frac{\partial^{q+1} d(K_1, K_2)}{\partial t^{q+1}} \right\|_{L^\infty(0,T,L^2(\Omega))} + \left\| \frac{\partial^q d(K_1, K_2)}{\partial t^q} \right\|_{L^\infty(0,T,H^1(\Omega))} \\ &\qquad \leq C \; |||K_1 - K_2|||_m , \end{aligned} \tag{2.10}$$

where $C = C(\Omega, T, \rho_*, \rho^*, K_*, K^*) C(S)$ with

$$C(S) = \left\| \frac{\partial^{q+1} S}{\partial t^{q+1}} \right\|_{L^2(0,T,L^2(\Omega))} + \left\| \frac{\partial^{q+2} S}{\partial t^{q+2}} \right\|_{L^2(0,T,L^2(\Omega))}$$

in case (i), *and*

$$C(S) = \|S\|_{L^2(0,T,L^3(\Omega))} + \left\| \frac{\partial^{q+1} S}{\partial t^{q+1}} \right\|_{L^2(0,T,L^2(\Omega))} + \left\| \frac{\partial^{q+2} S}{\partial t^{q+2}} \right\|_{L^2(0,T,L^2(\Omega))}$$

in case (ii).

COROLLARY 2.3. *The mapping*

$$\begin{array}{ccc} K & \longrightarrow & p(K, \cdot, \cdot), \\ \mathcal{P} & \longrightarrow & \mathcal{V} \end{array}$$

from the set $\mathcal{P}$ of parameters equipped with the $|||\cdot|||_m$-topology into $\mathcal{V}$ is continuous.

The following theorem will allow us to establish, in some cases, the existence of solutions of the output least squares problem.

THEOREM 2.4. *Let $\mathcal{Q} \subset \mathcal{P}$ be a compact set on $L^m(\Omega) \cap L^m(\Gamma)$; then the problem*

$$\text{minimize } J(K) \quad \text{over } \mathcal{Q}$$

has a solution.

Now we will prove that the function p has a Gâteaux derivative with respect to the parameter K for every $K \in \mathcal{P}$ and that this derivative is the solution of a differential problem.

Let $\mathcal{E}_0$ be a small neighborhood of the surface; for example, for $\eta \in (0,1)$, η small, we can choose the set $\mathcal{E}_0$ to be $[0,\eta]$ for $n=1$, $[0,\eta]\times[0,1]$ for $n=2$, and $[0,\eta]\times[0,1]\times[0,1]$ for $n=3$.

We choose as the space of perturbations for the parameter K one of the following subspaces of $L^m(\Omega) \cap L^m(\Gamma)$:

$$\mathcal{W}_0 = \{\delta K \in L^m(\Omega)\cap L^m(\Gamma),\ \delta K|_{\tilde{S}_n} \in \mathcal{A} \text{ and } \delta K(x) = 0 \text{ for } x \in \mathcal{E}_0\},$$

or

$$\mathcal{W} = \{\delta K \in L^m(\Omega)\cap L^m(\Gamma),\ \delta K|_{\tilde{S}_n} \in \mathcal{A}\}.$$

Since we can assume that we know the parameter K close to the surface, the condition $\delta K = 0$ in $\mathcal{E}_0$ is not an important restriction from the point of view of the application. We denote by Λ the quantity

$$\Lambda = \sum_{i=0}^{2} \left\| \frac{\partial^i S}{\partial t^i} \right\|_{L^2(0,T;L^2(\Omega))}.$$

The following theorem about the Gâteaux derivative of p with respect to K assumes different hypotheses depending on whether the perturbations belong to the set $\mathcal{W}_0$.

THEOREM 2.5. *Assume that the source function $S(x,t)$ is such that the quantity Λ is finite and that the parameter $K(x)$ in (1.1)–(1.3) belongs to the set $\mathcal{P}$. Assume also that either* (i) $\operatorname{supp} S \subset \mathcal{E}_0$ *and* $\delta K \in \mathcal{W}_0$ *or* (ii) $S \in L^2(0,T;L^3(\Omega))$ *and* $\delta K \in \mathcal{W}$. *Then the weak form of the problem*

$$\begin{aligned} &\frac{1}{K}(D'(K)\delta K)_{tt}(x,t) - \nabla\cdot\left(\frac{1}{\rho}\nabla D'(K)\delta K\right)(x,t) \\ &\qquad = \frac{\delta K(x)}{K^2(x)}\Big(p_{tt}(K,x,t) - S(x,t)\Big), \quad x\in\Omega, \quad t\in[0,T], \end{aligned} \tag{2.11}$$

with initial conditions

$$D'(K)\delta K(x,t=0) = (D'(K)\delta K)_t(x,t=0) = 0, \quad x\in\Omega, \tag{2.12}$$

and boundary conditions

$$-\frac{1}{\rho(x)}\frac{\partial D'(K)\delta K(x,t)}{\partial \nu} = \frac{(D'(K)\delta K)_t(x,t)}{\alpha(K,x)} - \frac{\delta K(x) p_t(K,x,t)}{2\sqrt{\rho(x)}K^{3/2}(x)}, \quad x\in\Gamma,\ t\in[0,T], \tag{2.13}$$

has a solution which satisfies the estimate

$$\|(D'(K)\delta K)_t\|^2_{L^\infty(0,T,L^2(\Omega))} + \|D'(K)\delta K\|^2_{L^\infty(0,T,H^1(\Omega))} \le C(\|\delta K\|^2_{L^m(\Omega)} + \|\delta K\|^2_{L^m(\Gamma)}), \tag{2.14}$$

where $C = C\,(K_*, K^*, \rho_*, \rho^*, T, \Omega, \Lambda)\, C(S)$, *with* $C(S)$ *as in Theorem* 2.2.

Moreover, if $\delta K \in L^\infty(\Omega)$, *the function* $D'(K)\delta K$ *is the Gâteaux derivative of* p (*the solution of* (2.5)) *with respect to* K *in the direction of* δK; *also, the limit*

$$\lim_{\lambda \to 0} \frac{p(K + \lambda \delta K, \cdot, \cdot) - p(K, \cdot, \cdot)}{\lambda}$$

exists in $\mathcal{V}$ *and is equal to* $D'(K)\delta K$.

Proof. The proof of (2.14) is a simplified version of the proof of the differentiability of p; thus we omit the former and we prove that for $D'(K)\delta K$ solution of (2.11)–(2.13), the function

$$\phi(K + \lambda \delta K, K, x, t) = D'(K)\delta K(x,t) - \frac{p(K + \lambda \delta K, x, t) - p(K, x, t)}{\lambda} \tag{2.15}$$

tends to zero in $\mathcal{V}$ as λ tends to zero.

We prove the theorem in case (i); case (ii) has extra terms that are treated as in the proof of Theorem 2.2.

First we prove the theorem for $\delta K \in L^\infty(\Omega)$. Let $\lambda_o = \frac{1}{2} K_* / \|\delta K\|_\infty$ and $|\lambda| \le \lambda_0$.

Now we use (2.5) for $K + \lambda \delta K$ and K, and the weak form of (2.11)–(2.13), in order to write the weak form for the differential problem for the function ϕ in (2.15).

Find $\phi \in H^1(\Omega)$ such that

$$\begin{aligned}
&\left(\frac{1}{K}\phi_{tt}, v\right) + \left(\frac{1}{\rho}\nabla\phi, \nabla v\right) + \left[\frac{1}{\alpha}\phi_t, v\right] \\
&\quad = \left(\frac{\lambda \delta K^2 p_{tt}(K + \lambda \delta K)}{K^2(K + \lambda \delta K)}, v\right) - \left(\frac{\delta K d_{tt}(K + \lambda \delta K, K)}{K^2}, v\right) \\
&\quad\quad + \left[\frac{\delta K}{\sqrt{\rho K}}\left(\frac{1}{K + \lambda\, K\, \delta K + \sqrt{K^2 + \lambda\, \delta K}} - \frac{1}{2K}\right) p_t(K + \lambda \delta K), v\right] \\
&\quad\quad - \left[\frac{\delta K d_t(K + \lambda \delta K, K)}{2\sqrt{\rho} K^{3/2}}, v\right], \qquad v \in H^1(\Omega), \quad t \in [0, T].
\end{aligned} \tag{2.16}$$

In the above formula, d is the difference function of Theorem 2.2.

In (2.16), choose $v = \phi_t$ to obtain

$$\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\left(\left\|\frac{\phi_t}{K^{1/2}}\right|_0^2 + \left\|\frac{\nabla\phi}{\rho^{1/2}}\right|_0^2\right) + \left[\frac{1}{\alpha(K)}\phi_t, \phi_t\right] \\
&\quad = \left(\frac{\lambda \delta K^2 p_{tt}(K + \lambda \delta K)^2}{K^2(K + \lambda \delta K)^2}, \phi_t\right) - \left(\frac{\delta K d_{tt}(K + \lambda \delta K, K)}{K^2}, \phi_t\right) \\
&\quad\quad + \left[\frac{\delta K}{\sqrt{\rho K}}\left(\frac{1}{K + \lambda\, K\, \delta K + \sqrt{K^2 + \lambda \delta K}} - \frac{1}{2K}\right) p_t(K + \lambda \delta K), \phi_t\right] \\
&\quad\quad - \left[\frac{\delta K d_t(K + \lambda \delta K, K)}{2\sqrt{\rho} K^{3/2}}, \phi_t\right], \qquad v \in H^1(\Omega), \quad t \in [0, T].
\end{aligned} \tag{2.17}$$

Adding the inequality

$$\frac{1}{2}\frac{d}{dt}\left(\left\|\frac{\phi}{\rho^{1/2}}\right\|_0^2\right) \le \left\|\frac{\phi}{\rho^{1/2}}\right\|_0^2 + C\left\|\frac{\phi_t}{K^{1/2}}\right\|_0^2$$

to (2.17), integrating the resulting inequality from 0 to t, and using the initial conditions, we have

$$\begin{aligned}
&\left\|\frac{\phi_t}{K^{1/2}}\right\|_0^2(t)+\left\|\frac{\phi}{\rho^{1/2}}\right\|_1^2(t)+2\int_0^t\left[\frac{1}{\alpha(K)}\phi_t,\phi_t\right](\tau)\,d\tau\\
&\le\left|\int_0^t\left(\frac{\lambda\delta K^2p_{tt}(K+\lambda\delta K)}{K^2(K+\lambda\delta K)^2},\phi_t\right)(\tau)\,d\tau\right|+\left|\int_0^t\left(\frac{\delta K\,d_{tt}(K+\lambda\delta K,K)}{K^2},\phi_t\right)(\tau)\,d\tau\right|\\
&\quad+C\int_0^t\left(\left\|\frac{\phi}{\rho^{1/2}}\right\|_0^2+\left\|\frac{\phi_t}{K^{1/2}}\right\|_0^2\right)(\tau)\,d\tau\\
&\quad+\left|\int_0^t\left[\frac{\delta K}{\sqrt{\rho K}}\left(\frac{1}{K+\lambda\delta K+\sqrt{K^2+\lambda\,\delta K}}-\frac{1}{2K}\right)p_t(K+\lambda\delta K),\phi_t\right](\tau)d\tau\right|\\
&\quad+\left|\int_0^t\left[\frac{\delta Kd_t(K+\lambda\delta K,K)}{2\sqrt{\rho}K^{3/2}},\phi_t\right](\tau)d\tau\right|\\
&=T_1+T_2+I+B_1+B_2.
\end{aligned}\tag{2.18}$$

We will bound each term T_1, T_2, B_1, B_2 on the right-hand side separately:

$$\begin{aligned}
|T_1|&=\left|\int_0^t\left(\frac{\lambda\delta K^2p_{tt}(K+\lambda\delta K)}{K^2(K+\lambda\delta K)^2},\phi_t\right)(\tau)\,d\tau\right|\\
&\le C\int_0^t\frac{\lambda^2}{K_*^6}\left\|p_{tt}(K+\lambda\delta K)\delta K^2\right\|_0^2(\tau)\,d\tau+\int_0^t\left\|\frac{\phi_t}{K^{1/2}}\right\|_0^2(\tau)\,d\tau\\
&\le C\lambda^2\int_0^t\left\|\delta K^4\right\|_{L^{\alpha'}(\Omega)}\left\|p_{tt}^2(K+\lambda\delta K)\right\|_{L^{\alpha}(\Omega)}(\tau)\,d\tau+\int_0^t\left\|\frac{\phi_t}{K^{1/2}}\right\|_0^2(\tau)\,d\tau\\
&=C\lambda^2\int_0^t\|\delta K\|_{L^{4\alpha'}(\Omega)}^4\|p_{tt}(K+\lambda\delta K)\|_{L^{2\alpha}(\Omega)}^2(\tau)\,d\tau+\int_0^t\left\|\frac{\phi_t}{K^{1/2}}\right\|_0^2(\tau)\,d\tau.
\end{aligned}$$

Sobolev's imbedding theorem implies that $L^{2\alpha}(\Omega)\subset H^1(\Omega)$ for $2\alpha\ge 2$ if $n=1$ or 2 and $2\le 2\alpha\le 6$ if $n=3$. Then using that and Theorem 2.1, we have

$$|T_1|\le C\lambda^2\left\|S_{tt}\right\|_{L^2(0,T;L^2(\Omega))}^2\|\delta K\|_{L^m(\Omega)}^4+\int_0^t\left\|\frac{\phi_t}{K^{1/2}}\right\|_0^2(\tau)\,d\tau.\tag{2.19}$$

Similarly, we have

$$\begin{aligned}
|T_2|&=\left|\int_0^t\left(\frac{\delta K\,d_{tt}(K+\lambda\delta K,K)}{K^2},\phi_t\right)(\tau)\,d\tau\right|\\
&\le C\int_0^t\|\delta K\|_{L^m(\Omega)}^2\,\|d_{tt}(K+\lambda\delta K,K)\|_1^2(\tau)\,d\tau+\int_0^t\left\|\frac{\phi_t}{K^{1/2}}\right\|_0^2(\tau)\,d\tau.
\end{aligned}\tag{2.20}$$

For the boundary terms we have

$$B_1=\int_0^t\left[\frac{\lambda\,\delta K^2\,(\lambda\delta K-3K)p_t(K+\lambda\delta K)}{\sqrt{\rho K}2K\left(\left(K+\sqrt{K^2+\lambda K\,\delta K}\right)^2-(\lambda\delta K)\right)},\phi_t\right](\tau)d\tau.$$

Integrating by parts in t and using that $K\in L^\infty(\Omega)$ we have

$$|B_1|\le C\lambda\left(\left[\delta K^2\,p_t(K+\lambda\delta K),\phi\right](t)+\int_0^t\left[\delta K^2p_{tt}(K+\lambda\delta K),\phi\right](\tau)d\tau\right).$$

By a similar argument to the one used for T_1, T_2 using Lemma 1.1, Sobolev's embedding theorem, and Theorem 2.1 we have

$$\begin{aligned}|B_1| &\le C\,\lambda\,\|\delta K\|^4_{L^m(\Gamma)}\left(\|p_t(K+\lambda\delta K)\|^2_1(t)+\int_0^t\|p_{tt}(K+\lambda\delta K)\|^2_1(\tau)d\tau\right)\\ &\quad+\frac{1}{4}\left\|\frac{\phi}{\rho^{1/2}}\right\|^2_1(t)+\int_0^t\left\|\frac{\phi}{\rho^{1/2}}\right\|^2_1(\tau)d\tau\\ &\le C\lambda\left(\|S_t\|_{L^2(0,T;L^2(\Omega))}+\|S_{tt}\|_{L^2(0,T;L^2(\Omega))}\right)+\frac{1}{4}\left\|\frac{\phi}{\rho^{1/2}}\right\|^2_1(t)\\ &\quad+\int_0^t\left\|\frac{\phi}{\rho^{1/2}}\right\|^2_1(\tau)d\tau.\end{aligned}\tag{2.21}$$

Finally,

$$\begin{aligned}|B_2| &\le C\|\delta K\|^4_{L^m(\Gamma)}\left(\|d_t(K+\lambda\delta K,K)\|^2_1(t)+\int_0^t\|d_{tt}(K+\lambda K,K)\|^2_1(\tau)d\tau\right)\\ &\quad+\frac{1}{4}\left\|\frac{\phi}{\rho^{1/2}}\right\|^2_1(t)+\int_0^t\left\|\frac{\phi}{\rho^{1/2}}\right\|^2_1(\tau)d\tau.\end{aligned}\tag{2.22}$$

Replacing (2.19)–(2.22) in (2.18) and using Gronwall's theorem, we obtain

$$\begin{aligned}\|\phi_t\|^2_{L^\infty(0,T;L^2(\Omega))}+\|\phi\|^2_{L^\infty(0,T;H^1(\Omega))} &\le C\lambda\sum_{i=0}^{2}\left\|\frac{\partial^i S}{\partial t^i}\right\|^2_{L^2(0,T,L^2(\Omega))}\\ &\quad+\|d_t(K+\lambda K,K)\|^2_{L^2(0,T,H^1(\Omega))}+\|d_{tt}(K+\lambda\delta K,K)\|^2_{L^2(0,T;H^1(\Omega))},\end{aligned}\tag{2.23}$$

where $C=C(K_*,K^*,\rho_*,\rho^*,T,\Omega)$. Now using Theorem 2.2 in (2.23), we have that for a given $\epsilon>0$ there is λ_0 such that if $\lambda<\lambda_0$

$$\|\phi_t\|_{L^\infty(0,T;L^2(\Omega))}+\|\phi\|_{L^\infty(0,T;H^1(\Omega))}\le\epsilon\Lambda.\tag{2.24}$$

Thus the theorem is proved for $\delta K\in L^\infty(\Omega)$. Now using Hahn–Banach's theorem and (2.14), the theorem holds for $\delta K\in\mathcal{W}_0$. ∎

As a consequence of Theorem 2.4, we have the following corollary.

COROLLARY 2.6. *Assume that the source function $S(x,t)$ satisfies the hypotheses of Theorem* 2.4. *Then the functional J has a Gâteaux derivative with respect to the parameter K and it is given by*

$$J'(K)\delta K=\int_0^T\left(\Phi'(K)\delta K,(\Phi(K)-p^{obs})(t)\right)dt,\tag{2.25}$$

where $\Phi'(K)\delta K(t)$ is the operator whose entries $(\Phi'(K)\delta K)_i(t)$, $1\le i\le N$, are given by

$$(\Phi'(K)\delta K)_i(t)=\frac{1}{|B_i|}\int_{B_i}D'(K)\delta K(x,t)\,dx,\tag{2.26}$$

and $D'(K)\delta K\in\mathcal{V}$ is the solution of (2.11)–(2.13).

Proof. Using (2.14) of Theorem 2.4 and Theorem 2.1, we have that

$$\begin{aligned}|J'(K)\delta K|^2 &\le C\,|||\delta K|||^2_m\int_0^T|\Phi(K)-p^{obs}|(t)dt\\ &\le C(\|S\|^2_{L^2(0,T;L^2(\Omega))}+\left\|p^{obs}\right\|_{L^2(0,T;\mathbb{R}^{N_r})})\,|||\delta K|||^2_m.\end{aligned}$$

∎

The following theorem about the continuity of $D'(K)\delta K$ with respect to K is necessary to prove the convergence of the algorithm.

THEOREM 2.7. *Let K_1, $K_2 \in \mathcal{P}$ and $\delta K \in \mathcal{W}_0$ $(\mathcal{W})$ and assume that the quantity Λ is finite; then*

$$\begin{aligned}\|(D'(K_1) - D'(K_2))\,\delta K\|_{L^\infty(0,T;L^2(\Omega))} + \|((D'(K_1) - D'(K_2))\,\delta K)_t\|_{L^\infty(0,T;H^1(\Omega))} \\ \leq C\Lambda\,|||K_1 - K_2|||_m\,.\end{aligned}$$

Proof. The technique of the proof is the same as the one of Theorem 2.4, thus we omit it here. ∎

3. The adjoint operator. To describe the algorithm we need the adjoint formulation of (2.25).

THEOREM 3.1. *Assume that the source function $S(x,t)$ satisfies the hypotheses of Theorem 2.4 and that the function f is such that*

$$f \in L^2(0,T,L^2(\Omega));$$

then

$$\begin{aligned}&\int_0^T \int_\Omega D'(K)\delta K(x,t) f(x,t)\,dx\,dt \\ &\quad = \int_\Omega \delta K(x) \int_0^T \frac{p_{tt}(K,x,t)}{K^2(x)} u(K,x,t)\,dt\,dx \\ &\qquad + \int_\Gamma \delta K(x) \int_0^T \frac{p_t(K,x,t)}{2\sqrt{\rho}K^{3/2}(x)} u(K,x,t)\,dt\,dx,\end{aligned} \tag{3.1}$$

where the function $u \in \mathcal{V}$ is defined as $u(K,x,t) = w(K,x,T-t)$ and w is the solution of: find $w(x,t) \in H^1(\Omega)$ such that

$$\left(\frac{1}{K} w_{tt}, v\right) + \left(\frac{1}{\rho}\nabla w, \nabla v\right) + \left[\frac{1}{\alpha} w_t, v\right] = \left(\check{f}, v\right), \qquad v \in H^1(\Omega), \quad t \in [0,T], \tag{3.2}$$

where $\check{f}(\cdot,t) = f(\cdot, T-t)$ and

$$w(K,x,t=0) = w_t(K,x,t=0) = 0. \tag{3.3}$$

Proof. Notice that under the hypotheses of the theorem, $w_{tt} \in \mathcal{V}$. Using $v = D'(K)\delta K(\cdot,t)$ in (3.2) and integrating in t from 0 to T,

$$\begin{aligned}&\int_0^T \left(\left(\frac{1}{K} w_{tt}, D'(K)\delta K\right)(t) + \left(\frac{1}{\rho}\nabla w, \nabla D'(K)\delta K\right)(t) + \left[\frac{1}{\alpha} w_t, D'(K)\delta K\right](t)\right) dt \\ &\quad = \int_0^T \left(f, D'(K)\delta K\right)(t)\,dt.\end{aligned} \tag{3.4}$$

Integrating the first and third integrals by parts in t and using that $w(K,x,T-t) = u(K,x,t)$, we have that

$$\begin{aligned}&\int_0^T \left(\left(\frac{1}{K}\left(D'(K)\delta K\right)_{tt}, u\right)(t) + \left(\frac{1}{\rho}\nabla D'(K)\delta K, \nabla u\right)(t) \right. \\ &\qquad \left. + \left[\frac{1}{\alpha}\left(D'(K)\delta K\right)_t, u\right](t)\right) dt = \int_0^T \left(f, D'(K)\delta K\right)(t)\,dt.\end{aligned} \tag{3.5}$$

Now integrating the weak form for $D'(K)\delta K$ (for $v = u$) from 0 to T we have

$$\begin{aligned}\int_0^T \left(\frac{1}{K}\left(D'(K)\delta K\right)_{tt}, u\right)(t)\,dt \\ + \int_0^T \left(\left(\frac{1}{\rho}\nabla D'(K)\delta K, \nabla u\right)(t) + \left[\frac{1}{\alpha}\left(D'(K)\delta K\right)_t, u\right](t)\right) dt \\ = \int_0^T \left(\frac{\delta K\, p_{tt}(K)}{K^2}, u\right)(t)\,dt + \int_0^T \left[\frac{\delta K\, p_t(K)}{2\sqrt{\rho}K^{3/2}}, u\right](t)\,dt.\end{aligned} \tag{3.6}$$

Finally, (3.1) follows from (3.5) and (3.6). ∎

COROLLARY 3.2. *Assume that the hypotheses on S of the theorem hold; then*

$$\begin{aligned}J'(K)\delta K = \int_\Omega \delta K(x) \int_0^T \frac{p_{tt}(K,x,t)\,u(K,x,t)}{K^2(x)}\,dt\,dx \\ + \int_\Gamma \delta K(x) \int_0^T \frac{p_t(K,x,t)\,u(K,x,t)}{2\sqrt{\rho(x)}K^{3/2}(x)}\,dt\,dx,\end{aligned} \tag{3.7}$$

where u is the solution of (3.2)–(3.3) *with*

$$f(x,t) = \sum_{i=1}^{N_r} \frac{\chi_{B_i}(x)}{|B_i|}(\Phi(K) - p^{\text{obs}})_i(t), \quad x \in \Omega, \quad t \in [0,T]. \tag{3.8}$$

Proof. First note that under the conditions on the source function S using Theorem 2.1, $f \in L^2(0,T,L^2(\Omega))$; then the result follows immediately from (3.1) and

$$\begin{aligned}J'(K)\delta K &= \int_0^T \Phi'(K)\delta K(t)(\Phi(K) - p^{\text{obs}})(t)\,dt \\ &= \int_0^T \sum_{i=1}^{N_r} \left(\frac{1}{|B_i|}\int_\Omega D'(K)\delta K(x,t)\chi_{B_i}(x)\,dx\right)(\Phi(K) - p^{\text{obs}})_i(t)\,dt. \quad ∎\end{aligned} \tag{3.9}$$

Remark. If for $n = 1$ we take point evaluations of p as the model for the measurements, $p(K, x_{r_i}, t)$, the function f in the right-hand side of (3.2), should be $\sum_{i=1}^{N_r} \delta(x - x_{r_i})(p_i - p_i^{\text{obs}})(x,t)$. In this particular case (which is not under the hypotheses of Theorem 3.1) the proof of the existence of solutions of (3.2)–(3.3) is done using energy estimates as in Theorem 2.1.

Consider the observation map Φ defined by (2.7)–(2.8); for $K \in \mathcal{P}$ the operator $\Phi'(K) \in \mathcal{B}(\mathcal{W}, L^2(0,T;\mathbb{R}^{Nr}))$ is given by

$$\Phi'(K)\delta K = \left(\frac{1}{|Bi|}\int_{Bi} D'(K)\,\delta K(x,t)dx\right)_{(1\le i\le Nr)}, \quad \delta K \in \mathcal{W}_o \quad (\mathcal{W}).$$

Thus the adjoint operator of $\Phi'(K)$ is a continuous operator from $L^2(0,T;\mathbb{R}^{Nr})$ into $\mathcal{W}_o$ $(\mathcal{W})$. Then we have the following theorem.

THEOREM 3.3. *Let $h \in L^2(0,T,R^{N_r})$; then the adjoint operator of $\Phi'(K)$ is given by*

$$\begin{aligned}\left([\Phi'(K)]^*\,h, \delta K\right) = \left(\int_0^T \frac{p_{tt}(K)u(K)}{K^2}(\cdot,t)\,dt, \delta K\right) \\ + \left[\int_0^T \frac{p_t(K)\,u(K)}{2\sqrt{\rho}K^{3/2}}(\cdot,t)\,dt, \delta K\right],\end{aligned} \tag{3.10}$$

where u is the solution of (3.2)–(3.3) *with*

$$f(x,t) = \sum_{i=1}^{N_r} \frac{\chi_{B_i}(x)}{|B_i|}\, h_i(t), \quad x \in \Omega, \quad t \in [0,T], \tag{3.11}$$

and the domain of $[\Phi'(K)]^*$ *is* $L^2(0,T;R^{N_r})$.

4. The inverse problem and the algorithm. We turn now to the iterative algorithm. Let $M(K) \in \mathcal{B}(\mathcal{W},\mathcal{W})$ be defined as

$$M(K)\, h(x) = [\Phi'(K)]^*\, \Phi'(K) h(x), \quad h \in \mathcal{W}. \tag{4.1}$$

For every $K \in \mathcal{W}$ for which the operator $M(K)$ is invertible let

$$f : \mathcal{P} \to \mathcal{W}$$

be defined as

$$f(K) = [M(K)]^{-1}\, [\Phi'(K)]^*\, (\Phi(K) - p^{\text{obs}}). \tag{4.2}$$

Note that in (4.1), $\Phi'(K)h \in L^2(0,T;\mathbb{R}^{N_r})$; also in (4.2), $\Phi(K) - p^{\text{obs}} \in L^2(0,T;\mathbb{R}^{N_r})$.

The algorithm is defined by the iteration

$$K^{n+1} = \begin{cases} K^n + f(K^n), & K_* \le K^n + f(K^n) \le K^*, \\ K^*, & K^* < K^n + f(K^n), \\ K_*, & K^n + f(K^n) < K_*. \end{cases} \tag{4.3}$$

Remarks. In practice a regularization term $N(K)$ with $N : \mathcal{Q} \to \mathbb{R}^+$ which is a weakly lower semicontinuous map satisfiying $\lim_{|x|\to\infty} N(x) = \infty$ is added to the cost functional $J(K)$. By choosing $N(K)$ adequately, the condition on the invertibility of the operator M is obtained.

The fact that we have to use in $\mathcal{P}$ the topology given by $|||\cdot|||_m$ with $m > 2$ suggests the use of a regularization term of the form $\left|||K - K^{ref}|||_m^m$ instead of the usual $\|K - K^{ref}\|_0^2$.

There are many different hypotheses under which algorithm (4.3) will converge. We prove the following classical result as an illustration of our particular problem.

THEOREM 4.1. *Assume that the hypotheses of Theorem* 2.5 *hold and that there is a* $K^c \in \mathcal{P}$ *such that* $J'(K^c) = 0$. *Also assume that* $M(K^c)$ *is invertible. Then* K^c *is a point of attraction of iteration* (4.6).

Proof. Since $\Phi'(K^c)$, $\Phi(K^c)$, and $[M(K^c)]^{-1}$ are bounded operators we have the inequality

$$\|[M(K^c)]^{-1}\|\, \|[\Phi'(K^c)]^*(\Phi(K^c) - p^{\text{obs}})\| \le C\|J'(K^c)\| = 0,$$

which implies that K^c is a fixed point for iteration (4.3).

The function $G(K)$,

$$G(K) = K - [M(K)]^{-1}[\Phi'(K)]^*(\Phi(K) - p^{\text{obs}}),$$

is well defined in a neighborhood of K^c as follows: if $M(K)$ satisfies

$$\|M(K) - M(K^c)\|\, \|M(K^c)\| < 1, \tag{4.4}$$

then $M(K)$ is one to one; moreover, $M(K)$ is one to one in a neighborhood of K^c.

Now let $\beta = \|[M(K^c)]^{-1}\|$ and let ϵ satisfy $0 < \epsilon < (2\beta)^{-1}$. Choose $\delta > 0$ so that the ball of center K^c and radius δ is contained in $\mathcal{P}$ and

$$\|M(K^c) - M(K)\| \le \epsilon \quad \text{for } K \in S.$$

Now for $K \in S$

$$\|[M(K)]^{-1}\| \le \beta + \epsilon\beta\|[M(K)]^{-1}\|.$$

Thus

$$\|[M(K)]^{-1}\| \le \beta/(1 - \epsilon\beta) \le 2\beta.$$

Since Φ is Gâteaux differentiable and Φ' is continuous as a function of K, Φ is Fréchet differentiable as follows:

$$\|\Phi(K + \delta K) - \Phi(K) - \Phi'(K)\,\delta K\| \le \sup_{\lambda} \|\Phi'(K + \lambda\,\delta K) - \Phi'(K)\|\,\|\delta K\| \le \epsilon\|\delta K\|.$$

Now we prove that the Fréchet derivative of $[\Phi'(K)]^*(\Phi(K) - p^{\text{obs}})$ at $K = K^c$ is $M(K^c)$.

$$\begin{aligned}\|[\Phi'(K)]^*(\Phi(K) - p^{\text{obs}}) - [\Phi'(K^c)]^*(\Phi(K^c) - p^{\text{obs}}) - M(K^c)(K - K^c)\| \\ \le \|[\Phi'(K)]^*\big((\Phi(K) - p^{\text{obs}}) - (\Phi(K^c) - p^{\text{obs}}) - \Phi'(K^c)(K - K^c)\big)\| \\ + \|[\Phi'(K)]^*\Phi'(K^c)(K - K^c) - M(K^c)(K - K^c)\| = T_1 + T_2.\end{aligned}$$

Using that Φ is Fréchet differentiable and the continuity of Φ with respect to K we have

$$T_1 \le \|[\Phi'(K)]^*\|\epsilon\|K - K^c\|.$$

Using the definition of M and the continuity of $[\Phi(K)]^*$ with respect to K,

$$T_2 \le \epsilon\|[\Phi'(K^c)]^*\|\,\|K - K^c\|.$$

Next we prove that the Fréchet derivative of G at $K = K^c$ is 0:

$$\begin{aligned}\|G(K) - G(K^c)\| &= \|K - [M(K)]^{-1}[\Phi'(K)]^*(\Phi(K) - p^{\text{obs}}) - K^c\| \\ &\le \|[M(K)]^{-1}(\Phi'(K)]^*(\Phi(K) - p^{\text{obs}}) - [\Phi'(K^c)]^*(\Phi(K^c) - p^{\text{obs}}) \\ &\quad - M(K^c)(K - K^c)\big)\| + \|[M(K)]^{-1}M(K^c)(K - K^c) + K - K^c\| \\ &\le 2\beta(\|[\Phi'(K)]^*\| + \|[\Phi'(K^c)]^*\|)\,\epsilon\,\|K - K^c\| \\ &\quad + \|[M(K)]^{-1}\|M(K^c) - M(K)\|\|K - K^c\| \le 2\beta C\,\epsilon\,\|K - K^c\|.\end{aligned}$$

Finally,

$$\|G(K) - G(K^c)\| = \|G(K) - K^c\| \le \epsilon\|K - K^c\|. \qquad \square$$

Appendix.

Proof of Lemma 1.1. Let $f \in C^1(\Omega)$. We distinguish two cases: $n = 1$ and $n = 2, 3$.

Case $n = 1$:

$$
\begin{aligned}
|f(0)|^m &= \left| f(x)^m - \int_0^x \frac{d}{ds}(f^m(s))\, ds \right| \\
&= \left| f(x)^m - m \int_0^x f^{m-1}(s)\, f'(s)\, ds \right| \\
&\le C(|f(x)|^m + \|f\|^{m-1}_{L^{2(m-1)}(\Omega)}\ \|f'\|_{L^2(\Omega)}).
\end{aligned} \tag{A1}
$$

A similar inequality holds for $|f(1)|^m$. Adding both and integrating from 0 to 1 we have

$$
\|f\|^m_{L^m(\Gamma)} \le C\left(\|f\|^m_{L^m(\Omega)} + \|f\|^{m-1}_{L^{2(m-1)}(\Omega)}\ \|f'\|_{L^2(\Omega)} \right). \tag{A2}
$$

Case $n = 2, 3$: Let $\tilde{x}_n = x_1$ if $n = 2$ and $\tilde{x}_n = (x_1, x_2)$ if $n = 3$:

$$
|f(\tilde{x}_n, 0)|^m = \left| f(\tilde{x}_n, x)^m - m \int_0^x f^{m-1}(\tilde{x}_n, s)\, f'(\tilde{x}_n, s)\, ds \right|. \tag{A3}
$$

Integrating in $\tilde{x}_n$ on $\widetilde{\Omega}_n = proj(\Omega)$ over $x_n = 0$ we have

$$
\begin{aligned}
\int_{\widetilde{\Omega}_n} |f(\tilde{x}_n, 0)|^m\ d\tilde{x}_n &\le C \int_{\widetilde{\Omega}_n} \left(|f(\tilde{x}_n, x)|^m + \int_0^x \left| f^{m-1}(\tilde{x}_n, s)\, f'(\tilde{x}_n, s) \right|\, ds \right) d\tilde{x}_n \\
&\le C \left(\int_{\widetilde{\Omega}_n} |f(\tilde{x}_n, x)|^m\ d\tilde{x}_n + \|f\|^{m-1}_{2(m-1)}(\Omega)\ \|f'\|_{L^2(\Omega)} \right).
\end{aligned}
$$

Integrating in x we have

$$
\int_{\widetilde{\Omega}_n} |f(\tilde{x}_n, 0)|^m\ d\tilde{x}_n \le C(\|f\|^m_{L^m(\Omega)} + \|f\|^{(m-1)}_{L^2(m-1)(\Omega)}\ \|f'\|_{L^2(\Omega)}).
$$

We have similar inequalities for each face of the cube. Adding them, inequality (A2) is obtained for $n = 2, 3$.

Proof of Theorem 2.2. We prove the theorem for $q = 0$. Let $d = d(K_1, K_2, x, t)$; d is the solution of the weak form: find $d \in H^1(\Omega)$ such that

$$
\begin{aligned}
&\left(\frac{1}{K_1} d_{tt}, v \right) + \left(\frac{1}{\rho} \nabla d, \nabla v \right) + \left[\left(\frac{1}{\alpha(K_1)} - \frac{1}{\alpha(K_2)} \right) d_t(K_2), v \right] \\
&\quad = \left(\frac{1}{K_1} - \frac{1}{K_2} S, v \right) + \left(\frac{1}{K_2} - \frac{1}{K_1} p_{tt}(K_2), v \right) - \left[\frac{\left(\sqrt{K_1} - \sqrt{K_2} \right) p_t(K_1)}{\rho \sqrt{K_1\, K_2}}, v \right], \\
&\qquad v \in H^1(\Omega), \quad t \in [0, T].
\end{aligned}
$$

Choosing $v = d_t$ and using the usual arguments we obtain the inequality

$$
\begin{aligned}
\left\| \frac{d_t}{K_1^{1/2}} \right\|_0^2 + \left\| \frac{d}{\rho^{1/2}} \right\|_1^2 &\le \int_0^t \left(\left\| \frac{d_t}{K_1^{1/2}} \right\|_0^2 + \left\| \frac{d}{\rho^{1/2}} \right\|_0^2 \right)(\tau)\, d\tau \\
&\quad + \int_0^t \left(\left(\frac{K_2 - K_1}{K_1\, K_2} p_{tt}(K_2), d_t \right)(\tau) + \left(\frac{K_2 - K_1}{K_1\, K_2} S, d_t \right)(\tau) \right) d\tau \\
&\quad + \int_0^t \left[\frac{\sqrt{K_2} - \sqrt{K_1}}{\sqrt{\rho\, K_1\, K_2}} p_t(K_2), d_t \right](\tau) d\tau \\
&= I + T_1 + T_2 + B.
\end{aligned} \tag{A4}
$$

We bound each term separately:

$$
\begin{aligned}
|T_1| &\le C \int_0^t \int_\Omega (K_1 - K_2)^2(x) \left| p_{tt}(K_2, x, \tau) \right|^2 d\tau + \int_0^t \left\| \frac{d_t}{K_1^{1/2}} \right\|_0^2 (\tau) d\tau \\
&\le C \left\| K_1 - K_2 \right\|_m^2 \int_0^T \left\| p_{tt} \right\|_{L^{2m/m-2}}^2 (\tau)\, d\tau + \int_0^t \left\| \frac{d_t}{K_1^{1/2}} \right\|_0^2 (\tau)\, d\tau \\
&\le C \left\| K_1 - K_2 \right\|_{L^m(\Omega)}^2 \left\| S_{tt} \right\|_{L^2(0,T;L^2(\Omega))} + \int_0^t \left\| \frac{d_t}{K_1^{1/2}} \right\|_0^2 (\tau)\, d\tau.
\end{aligned} \tag{A5}
$$

Similarly,

$$
\begin{aligned}
|T_2| &\le C \int_0^t \int_\Omega |K_1 - K_2|^2(x) |S|^2(x,\tau) dx\, d\tau + \int_0^t \left\| \frac{d_t}{K_1^{1/2}} \right\|_0^2 (\tau)\, d\tau \\
&\le C \left\| K_1 - K_2 \right\|_m^2 \left\| S \right\|_{L^2(0,T;L^{2m/m-2})}^2 + \int_0^t \left\| \frac{d_t}{K_1^{1/2}} \right\|_0^2 (\tau)\, d\tau.
\end{aligned} \tag{A6}
$$

Finally, for the boundary term, we have

$$
\begin{aligned}
|B| &\le C \left\| K_1 - K_2 \right\|_{L^m(\Gamma)}^2 \left(\left\| p_t \right\|_{L^\infty(0,T;H^1(\Omega))}^2 + \left\| p_{tt} \right\|_{L^\infty(0,T;H^1(\Omega))}^2 \right) \\
&\quad + \frac{1}{4} \left\| \frac{d}{\rho^{1/2}} \right\|_1^2 (t) + \int_0^T \left\| \frac{d}{\rho^1/2} \right\|_1^2 (\tau) d\tau \\
&\le C \left\| K_1 - K_2 \right\|_{L^m(\Gamma)}^2 \left(\left\| S_t \right\|_{L^2(0,T;L^2(\Omega))}^2 + \left\| S_{tt} \right\|_{L^2(0,T;L^2(\Omega))} \right) \\
&\quad + \int_0^T \left\| \frac{d}{\rho^1/2} \right\|_1^2 (\tau) d\tau + \frac{1}{4} \left\| \frac{d}{\rho^{1/2}} \right\|_1^2 (t) \left\| S_{tt} \right\|_{L^2(0,T;L^2(\Omega))}.
\end{aligned} \tag{A7}
$$

Replacing (A2)–(A4) in (A1) and using Gronwall's inequality we obtain the conclusion of the theorem.

Acknowledgment. I thank Prof. E. Lami Dozo for many useful discussions.

SIMPLIFYING OPTIMAL STRATEGIES IN STOCHASTIC GAMES*

J. FLESCH†, F. THUIJSMAN†, AND O. J. VRIEZE†

Abstract. We deal with zero-sum limiting average stochastic games. We show that the existence of arbitrary optimal strategies implies the existence of stationary ε-optimal strategies, for all $\varepsilon > 0$, and the existence of Markov optimal strategies. We present such a construction for which we do not even need to know these optimal strategies. Furthermore, an example demonstrates that the existence of stationary optimal strategies is not implied by the existence of optimal strategies, so the result is sharp.

More generally, one can evaluate a strategy π for the maximizing player, player 1, by the reward $\phi_s(\pi)$ that π guarantees to him when starting in state s. A strategy π is called nonimproving if $\phi_s(\pi) \geq \phi_s(\pi[h])$ for all s and for all finite histories h with final state s, where $\pi[h]$ is the strategy π conditional on the history h. Using the evaluation ϕ, we may define the relation "ε-better" between strategies. A strategy π^1 is called ε-better than π^2 if $\phi_s(\pi^1) \geq \phi_s(\pi^2) - \varepsilon$ for all s. We show that for any nonimproving strategy π, for all $\varepsilon > 0$, there exists an ε-better stationary strategy and a (0-)better Markov strategy as well. Since all optimal strategies are nonimproving, this result can be regarded as a generalization of the above result for optimal strategies.

Finally, we briefly discuss some other extensions. Among others, we indicate possible simplifications of strategies that are only optimal for particular initial states by "almost stationary" ε-optimal strategies, for all $\varepsilon > 0$, and by "almost Markov" optimal strategies. We also discuss the validity of the above results for other reward functions. Several examples clarify these issues.

Key words. stochastic games, limiting average rewards, optimality, Markov strategies, stationary strategies

1. Introduction.

A zero-sum stochastic game Γ can be described by a state space $S := \{1, \ldots, z\}$ and a corresponding collection $\{M_1, \ldots, M_z\}$ of matrices, where matrix M_s has size $m_s^1 \times m_s^2$ and, for $i_s \in I_s := \{1, \ldots, m_s^1\}$ and $j_s \in J_s := \{1, \ldots, m_s^2\}$, entry (i_s, j_s) of M_s consists of a payoff $r(s, i_s, j_s) \in \mathbb{R}$ and a probability vector $p(s, i_s, j_s) = (p(1|s, i_s, j_s), \ldots, p(z|s, i_s, j_s))$. The elements of S are called states and for each state $s \in S$ the elements of I_s and J_s are called the actions of player 1 and player 2 in state s. The game is to be played at stages in $\mathbb{N}$ in the following way. The play starts at stage 1 in an initial state, say, in state $s^1 \in S$, where, simultaneously and independently, both players are to choose an action: player 1 chooses an $i_{s^1}^1 \in I_{s^1}$, while player 2 chooses a $j_{s^1}^1 \in J_{s^1}$. These choices induce an immediate payoff $r(s^1, i_{s^1}^1, j_{s^1}^1)$ from player 2 to player 1. Next, the play moves to a new state according to the probability vector $p(s^1, i_{s^1}^1, j_{s^1}^1)$, say, to state s^2. At stage 2 new actions $i_{s^2}^2 \in I_{s^2}$ and $j_{s^2}^2 \in J_{s^2}$ are to be chosen by the players in state s^2. Then player 1 receives payoff $r(s^2, i_{s^2}^2, j_{s^2}^2)$ from player 2 and the play moves to some state s^3 according to the probability vector $p(s^2, i_{s^2}^2, j_{s^2}^2)$, and so on.

The sequence $(s^1, i_{s^1}^1, j_{s^1}^1; \ldots; s^{n-1}, i_{s^{n-1}}^{n-1}, j_{s^{n-1}}^{n-1}; s^n)$ is called the history up to stage n. The players are assumed to have complete information and perfect recall.

A mixed action for a player in state s is a probability distribution on the set of his actions in state s. Mixed actions in state s will be denoted by x_s for player 1 and

†Department of Mathematics, University of Maastricht, P.O. Box 616, 6200 MD Maastricht, the Netherlands (flesch@math.unimaas.nl, frank@math.unimaas.nl, oj.vrieze@math.unimaas.nl).

by y_s for player 2, and the sets of mixed actions in state s by X_s and Y_s, respectively. A strategy is a decision rule that prescribes a mixed action for any finite history of the play. Such general strategies, so-called behavior strategies, will be denoted by π for player 1 and by σ for player 2, and $\pi(h)$ and $\sigma(h)$ will denote the mixed actions for history h. We use the notations Π and Σ, respectively, for the behavior strategy spaces of players 1 and 2. If for all finite histories, the mixed actions prescribed by a strategy only depend on the current stage and state, then the strategy is called Markov, while if they only depend on the state then the strategy is called stationary. Thus the stationary strategy spaces are $X := \times_{s\in S} X_s$ for player 1 and $Y := \times_{s\in S} Y_s$ for player 2, while the Markov strategy spaces are $F := \times_{n\in\mathbb{N}} X$ for player 1 and $G := \times_{n\in\mathbb{N}} Y$ for player 2. We will use the respective notations x and y for stationary strategies and f and g for Markov strategies for players 1 and 2. A stationary strategy is called pure if, for each state, it specifies one "pure" action to be used. Hence the spaces of pure stationary strategies are $I := \times_{s\in S} I_s$ for player 1 and $J := \times_{s\in S} J_s$ for player 2. Pure stationary strategies will be denoted by i and j, respectively.

Let H denote the set of finite histories, $H(\alpha,\omega)$ the set of finite histories with initial state α and final state ω, $H(\alpha,\cdot)$ the set of finite histories with initial state α, and $H(\cdot,\omega)$ the set of finite histories with final state ω. For any strategy π and for any given history $h \in H(\cdot,\omega)$, we can define the strategy $\pi[h]$ which prescribes a mixed action $\pi[h](\bar{h})$ to each history $\bar{h} \in H(\omega,\cdot)$ as if h had happened before $\bar{h}$, i.e., $\pi[h](\bar{h}) = \pi(h\bar{h})$, where $h\bar{h}$ is the history consisting of h concatenated with $\bar{h}$.

Payoffs and transition probabilities can be naturally extended to mixed actions as well. For $x_s \in X_s$ and $y_s \in Y_s$ let

$$r(s,x_s,y_s) := \sum_{i_s\in I_s,\, j_s\in J_s} x_s(i_s)\, y_s(j_s)\cdot r(s,i_s,j_s),$$

$$p(t|s,x_s,y_s) := \sum_{i_s\in I_s,\, j_s\in J_s} x_s(i_s)\, y_s(j_s)\cdot p(t|s,i_s,j_s).$$

For $x \in X,\ y \in Y$ we will also use the vector notation

$$r(x,y) := (r(s,x_s,y_s))_{s\in S}.$$

A pair of strategies (π,σ) with an initial state $s \in S$ determines a stochastic process on the payoffs. The sequences of payoffs are evaluated by the limiting average reward and by the β-discounted reward, $\beta \in (0,1)$, given by

$$\gamma(s,\pi,\sigma) := \liminf_{N\to\infty} \mathbb{E}_{s\pi\sigma}\left(\frac{1}{N}\sum_{n=1}^{N} r_n\right) = \liminf_{N\to\infty} \mathbb{E}_{s\pi\sigma}\left(R_N\right),$$

$$\gamma^{\beta}(s,\pi,\sigma) := \mathbb{E}_{s\pi\sigma}\left((1-\beta)\sum_{n=1}^{\infty}\beta^{n-1} r_n\right),$$

where r_n is the random variable for the payoff at stage $n \in \mathbb{N}$, and R_N for the average payoff up to stage N. We also use the vector notations

$$\gamma(\pi,\sigma) := (\gamma(s,\pi,\sigma))_{s\in S}, \qquad \gamma^{\beta}(\pi,\sigma) := \left(\gamma^{\beta}(s,\pi,\sigma)\right)_{s\in S}.$$

A pair of stationary strategies (x, y) determines a Markov chain with transition matrix P_{xy} on S, where entry (s,t) of P_{xy} is $p(t|s, x_s, y_s)$. With respect to this Markov chain, we can speak of transient and recurrent states (a state is called recurrent if, when starting there, it will be visited infinitely often with probability 1; otherwise the state is called transient). We can group the recurrent states into minimal closed sets, and into so-called ergodic sets (an ergodic set is a collection E of recurrent states with the property that, when starting in one of the states in E, all states in E will be visited and the play will remain in E with probability 1). Let

$$Q_{xy} := \lim_{N\to\infty} \frac{1}{N} \sum_{n=1}^{N} (P_{xy})^n;$$

the limit is known to exist (cf. Doob [1953, Theorem 2.1, p. 175]). Entry (s,t) of the stochastic matrix Q_{xy}, denoted by $q(t|s,x,y)$, is the expected average number of stages the process is in state t when starting in s. The matrix Q_{xy} has the well-known properties (cf. Doob [1953]) that

$$Q_{xy} = Q_{xy}\, P_{xy} = P_{xy}\, Q_{xy}, \qquad Q_{xy}^2 = Q_{xy}. \tag{1.1}$$

By its definition, for the limiting average reward we have

$$\gamma(x,y) = Q_{xy}\, r(x,y), \tag{1.2}$$

hence by (1.1) we also obtain

$$\gamma(x,y) = Q_{xy}\, r(x,y) = Q_{xy}^2\, r(x,y) = Q_{xy}\, \gamma(x,y). \tag{1.3}$$

Against a fixed stationary strategy y there always exists a pure stationary best reply i of player 1 (cf. Hordijk, Vrieze, and Wanrooij [1983]); i.e.,

$$\gamma(i,y) \geq \gamma(\pi, y) \qquad \forall \pi.$$

Obviously a similar statement holds for the best replies of player 2.

For the limiting average reward, Mertens and Neyman [1981] showed that

$$\sup_{\pi} \inf_{\sigma} \gamma(s,\pi,\sigma) = \inf_{\sigma} \sup_{\pi} \gamma(s,\pi,\sigma) =: v_s \qquad \forall s \in S. \tag{1.4}$$

Here $v := (v_s)_{s\in S}$ is called the limiting average value and v is known to satisfy the following equations:

$$v_s = \mathrm{Val}\,(A_s) \qquad \forall s \in S, \tag{1.5}$$

where

$$A_s := \left[\sum_{t\in S} p(t|s, i_s, j_s)\, v_t\right]_{i_s\in I_s, j_s\in J_s} \tag{1.6}$$

and Val stands for the matrix game value. The sets of optimal mixed actions in A_s, for any $s \in S$, are nonempty polytopes. A strategy π of player 1 is called optimal for initial state $s \in S$ if

$$\gamma(s,\pi,\sigma) \geq v_s \quad \forall \sigma \in \Sigma,$$

and ε-optimal for initial state $s \in S$, $\varepsilon > 0$ if

$$\gamma(s, \pi, \sigma) \geq v_s - \varepsilon \quad \forall \sigma \in \Sigma.$$

If a strategy of player 1 is optimal or ε-optimal for all initial states in S, then the strategy is called optimal or ε-optimal, respectively. Optimality for strategies of player 2 is analogously defined. Although for all $\varepsilon > 0$, by (1.4), there exist ε-optimal strategies for both players, the famous example of Gillette [1957], the Big Match, examined by Blackwell and Ferguson [1968], demonstrates that in general the players need not have optimal strategies, and for achieving ε-optimality, behavior strategies are indispensable.

For the β-discounted reward, $\beta \in (0, 1)$, using a fixed-point argument, Shapley [1953] showed that

$$\sup_{\pi} \inf_{\sigma} \gamma^{\beta}(s, \pi, \sigma) = \inf_{\sigma} \sup_{\pi} \gamma^{\beta}(s, \pi, \sigma) =: v_s^{\beta} \qquad \forall s \in S.$$

Here $v^{\beta} := (v_s^{\beta})_{s \in S}$ is called the β-discounted value. Optimality can be similarly defined as for the limiting average reward. Stationary β-discounted optimal strategies always exist, and x is β-discounted optimal if and only if

$$v_s^{\beta} \leq (1 - \beta)\, r(s, x_s, y_s) + \beta \sum_{t \in S} p(t|s, x_s, y_s)\, v_t^{\beta} \qquad \forall y_s \in Y_s,\ \forall s \in S.$$

We will also make use of the N-stage game Γ^N, $N \in \mathbb{N}$, which is played up to stage N and where the reward is defined by the expected average payoff up to stage N. The N-stage game Γ^N, $N \in \mathbb{N}$, is known to have a value v^N, and both players have N-stage Markov optimal strategies. Bewley and Kohlberg [1976] showed, using Puiseux series, that both $\lim_{\beta \uparrow 1} v^{\beta}$ and $\lim_{N \to \infty} v^N$ exist and

$$\lim_{\beta \uparrow 1} v^{\beta} = \lim_{N \to \infty} v^N,$$

while Mertens and Neyman [1981] proved that the limiting average value is equal to the limit of the β-discounted values, i.e.,

$$v = \lim_{\beta \uparrow 1} v^{\beta}.$$

Although both the β-discounted value and the limiting average value exist, they cannot usually be easily calculated. In general, only iterative algorithms are available. We refer to Raghavan and Filar [1991] for a survey on algorithms.

We will often deal with specific restricted games derived from Γ. Assume that $S' \subset S$ is a nonempty set of states and $X_s' \subset X_s$, $Y_s' \subset Y_s$ are nonempty polytopes for all $s \in S'$. If all pairs of mixed actions in $X_s' \times Y_s'$, for all $s \in S'$, only induce transitions to states in S', then we may define a restricted game Γ', derived from Γ, where the state space is S' and the players are restricted to use strategies that only prescribe mixed actions in X_s' and Y_s' if the play is in state $s \in S'$. Let $\Pi' \subset \Pi$ and $\Sigma' \subset \Sigma$ denote the sets of these strategies. Clearly, the stationary strategy spaces in Γ' are $X' := \times_{s \in S'} X_s'$ and $Y' := \times_{s \in S'} Y_s'$. For the restricted game Γ', with respect to the β-discounted reward, $\beta \in (0, 1)$, similar results can be shown by using a fixed-point argument as for the original game Γ. Thus

$$\sup_{\pi \in \Pi'} \inf_{\sigma \in \Sigma'} \gamma^{\beta}(s, \pi, \sigma) = \inf_{\sigma \in \Sigma'} \sup_{\pi \in \Pi'} \gamma^{\beta}(s, \pi, \sigma) =: v_s'^{\beta} \qquad \forall s \in S'.$$

Here $v'^{\beta} := (v'^{\beta}_s)_{s\in S'}$ is called the β-discounted value for Γ'. Stationary β-discounted optimal strategies in Γ' always exist and $x \in X'$ is β-discounted optimal if and only if

$$v'^{\beta}_s \le (1-\beta)\, r(s, x_s, y_s) + \beta \sum_{t\in S'} p(t|s, x_s, y_s)\, v'^{\beta}_t \qquad \forall y_s \in Y'_s,\ \forall s \in S'. \tag{1.7}$$

The results of Bewley and Kohlberg [1976] apply for Γ' as well, so $\lim_{\beta\uparrow 1} v'^{\beta}$ and $\lim_{N\to\infty} v'^{N}$ exist and

$$v'^{1} := \lim_{\beta\uparrow 1} v'^{\beta} = \lim_{N\to\infty} v'^{N}. \tag{1.8}$$

Note that we do not claim that v'^{1} is the limiting average value of Γ', for even though the players only observe pure actions, these do not correspond one-to-one to extreme points of the restricted spaces of mixed actions. However, one can show, by using an appropriate sequence of discount factors as in Mertens and Neyman [1981], that, against any fixed strategy in Π', for any $\varepsilon > 0$ player 2 can make sure that player 1's limiting average reward is at most $v'^{1} + \varepsilon$; i.e.,

$$\sup_{\pi\in\Pi'} \inf_{\sigma\in\Sigma'} \gamma(s, \pi, \sigma) \le v'^{1}_s \qquad \forall s \in S'. \tag{1.9}$$

From now on, when we speak of rewards, values, or optimal strategies, we will always have the limiting average reward in mind, unless mentioned otherwise.

The organization of the paper is as follows. In section 2 we will deal with optimal strategies. We show that the existence of arbitrary optimal strategies implies the existence of stationary ε-optimal strategies, for all $\varepsilon > 0$, and the existence of Markov optimal strategies. We give such a construction for which we do not even need to know any optimal strategy. This remarkable result should not only be regarded as a simplification of optimal strategies, but also as a sufficient condition for the existence of stationary ε-optimal strategies or Markov optimal strategies. For many classes of stochastic games, where on the payoff or transition structures special conditions are imposed, stationary ε-optimal strategies exist, for all $\varepsilon > 0$, while about sufficient conditions for the existence of Markov optimal strategies, comparatively little is known. Here, instead of providing such structural conditions, the existence of optimal strategies will be proven to be sufficient. Moreover, an example will be provided to show that the existence of stationary optimal strategies is not implied by the existence of optimal strategies, so the result is sharp.

In section 3 we show that simplification of strategies can also be employed for a class of strategies, containing the optimal ones, in view of the rewards they guarantee. For this purpose we will evaluate a strategy π by the reward $\phi_s(\pi)$ that π guarantees when starting in state $s \in S$. A strategy π is called "nonimproving" if $\phi_s(\pi) \ge \phi_s(\pi[h])$ for all s and for all finite histories h with final state s, where $\pi[h]$ is the strategy π conditional on the history h, as defined above. Intuitively, a nonimproving strategy, for any state, cannot guarantee a larger reward conditional on any past history than initially. Using the evaluation ϕ, we may naturally define the relation "ε-better" between strategies. A strategy π^1 is called ε-better than π^2 if $\phi_s(\pi^1) \ge \phi_s(\pi^2) - \varepsilon$ for all $s \in S$. We show that for any nonimproving strategy π, for all $\varepsilon > 0$, there exists an ε-better stationary strategy and a (0-)better Markov strategy as well. Optimal strategies are clearly nonimproving, since they guarantee the value and more cannot be guaranteed; hence this result implies the above result for optimal strategies.

In section 4 we briefly discuss some extensions of the above results. We indicate possible simplifications of strategies that are only optimal for particular initial

states by "almost stationary" ε-optimal strategies and by "almost Markov" optimal strategies. We also discuss the validity of the results when other rewards are used to evaluate the long-term average payoffs. Some remarks concerning the proofs and some consequences are mentioned.

2. Optimal strategies. In this section we show the following result.

THEOREM 2.1. *If player* 1 *has an optimal strategy then, for all* $\varepsilon > 0$*, player* 1 *has stationary* ε*-optimal strategies and Markov optimal strategies as well.*

The proof will be constructive. We present such a construction for which we do not even need to know the optimal strategy.

For $s \in S$ let

$$X_s^* := \left\{ x_s \in X_s | \sum_{t \in S} p(t|s, x_s, y_s)\, v_t \geq v_s \ \ \forall y_s \in Y_s \right\}, \qquad X^* := \times_{s \in S} X_s^*,$$

so X_s^* is the set of optimal mixed actions for player 1 in the matrix game A_s (cf. (1.6)). The sets X_s^* are nonempty polytopes. For $s \in S$ let

$$Y_s^* := \left\{ y_s \in Y_s | \sum_{t \in S} p(t|s, x_s, y_s)\, v_t = v_s \ \ \forall x_s \in X_s^* \right\}, \qquad Y^* := \times_{s \in S} Y_s^*;$$

the sets Y_s^*, called the equalizers in the corresponding matrix games, are nonempty polytopes (in fact, by (1.5) all optimal mixed actions of player 2 in A_s belong to Y_s^*). Note the asimilarity in the definitions of X_s^* and Y_s^*, $s \in S$. It is easy to verify that, for any $s \in S$, there exists a $J_s^* \subset J_s$ such that $Y_s^* = \text{conv}(J_s^*)$, where conv stands for the convex hull of a set. Let

$$J^* := \times_{s \in S} J_s^*.$$

As described in the Introduction, we may define a restricted game Γ^*, derived from Γ, where the state space is S and the players are restricted to use strategies that only prescribe mixed actions in X_s^* and Y_s^* if the play is in state $s \in S$. The sets of these strategies are denoted by Π^* and Σ^*. Let $v^{*\beta}$ denote the β-discounted value for Γ^*, and let $v^{*1} := \lim_{\beta \uparrow 1} v^{*\beta}$.

By the finiteness of the state and action spaces there exists a countable subset of discount factors $\mathcal{B} \subset (0,1)$ such that 1 is a limit point of $\mathcal{B}$ and there are stationary β-discounted optimal strategies $x^\beta \in X^*$ in the restricted game Γ^* such that the sets $\{i_s \in I_s | \, x_s^\beta(i_s) > 0\}$, $s \in S$, are independent of $\beta \in \mathcal{B}$. In the sequel each time that we are dealing with discount factors, discounted optimal strategies, or limits when the discount factors converge to 1, we will have such a subset of discount factors $\mathcal{B}$ in mind.

The following lemma clarifies why the sets X^* and Y^* play an important role when player 1 has an optimal strategy in the original game Γ. This lemma states that if π is an optimal strategy for player 1 in Γ then, for any history with a positive occurrence probability with respect to (π, σ) for some $\sigma \in \Sigma^*$, the strategy π prescribes a mixed action belonging to X^*. In other words, if player 2 uses a strategy $\sigma \in \Sigma^*$ then the optimal strategy π will behave as a strategy in Π^*.

LEMMA 2.2. *Let* $\pi \in \Pi$ *be an optimal strategy for player* 1 *in the game* Γ*. Then for all* $h \in H(\alpha, \omega)$*, for any* $\alpha, \omega \in S$*, we have* $\pi(h) \in X_\omega^*$ *if* $\mathbb{P}_{\alpha\pi\sigma}(h) > 0$ *for some* $\sigma \in \Sigma^*$*. Here* $\mathbb{P}_{\alpha\pi\sigma}(h)$ *denotes the probability that the finite history* h *occurs when the strategies* π *and* σ *are played and the initial state is* α*.*

Proof. Suppose the opposite. Then there exists a shortest history $\bar{h}^n \in H(\alpha,\omega)$, say, with length n, for some $\alpha,\omega \in S$, and a $\sigma \in \Sigma^*$ with $\mathbb{P}_{\alpha\pi\sigma}(\bar{h}^n) > 0$ such that $\pi(\bar{h}^n) \notin X^*_\omega$. Since $\pi(\bar{h}^n) \notin X^*_\omega$ there exists a $j_\omega \in J_\omega$ such that

$$\tau := v_\omega - \sum_{s\in S} p(s|\omega,\pi(\bar{h}^n),j_\omega)\, v_s > 0.$$

Let $s^1 := \alpha$, let s^k, $k \geq 2$, denote the random variable for the state at stage k, and let h^k denote the history up to stage $k \in \mathbb{N}$. Let

$$\delta \in \left(0, \mathbb{P}_{s^1\pi\sigma}(\bar{h}^n)\cdot\tau\right).$$

Let $\sigma^\delta \in \Sigma$ be the strategy that prescribes to play as follows: play σ for the first $n-1$ stages and then, if $h^n = \bar{h}^n$, play j_ω, while if $h^n \neq \bar{h}^n$ then play an optimal mixed action in the matrix game A_{s^n}; and finally, play a δ-optimal strategy afterwards. Note that

$$\mathbb{P}_{s^1\pi\sigma^\delta}(\bar{h}^n) = \mathbb{P}_{s^1\pi\sigma}(\bar{h}^n) > 0.$$

Since we have chosen a shortest history $\bar{h}^n$ with the above property, by the definitions of X^* and Y^* we have

$$\mathbb{E}_{s^1\pi\sigma^\delta}\left(v_{s^n}\right) = v_{s^1},$$

and by the used mixed actions at stage n

$$\mathbb{E}_{s^1\pi\sigma^\delta}\left(v_{s^{n+1}}\right) \leq \mathbb{E}_{s^1\pi\sigma^\delta}\left(v_{s^n}\right) - \mathbb{P}_{s^1\pi\sigma^\delta}(\bar{h}^n)\cdot\tau.$$

From stage $n+1$, player 2 plays a δ-optimal strategy, so the choice of δ yields

$$\begin{aligned}\gamma(s^1,\pi,\sigma^\delta) &\leq \mathbb{E}_{s^1\pi\sigma^\delta}\left(v_{s^{n+1}}\right) + \delta \leq \mathbb{E}_{s^1\pi\sigma^\delta}\left(v_{s^n}\right) - \mathbb{P}_{s^1\pi\sigma^\delta}(\bar{h}^n)\cdot\tau + \delta \\ &= v_{s^1} - \mathbb{P}_{s^1\pi\sigma}(\bar{h}^n)\cdot\tau + \delta < v_{s^1},\end{aligned}$$

which contradicts the optimality of π. □

Based on the fact that any optimal strategy of player 1 in Γ guarantees the value v and, in view of the previous lemma, it only prescribes mixed actions in X^*_s, if the play is in state s, against any strategy of player 2 in Σ^*, we show that player 1 can guarantee at least v in the restricted game Γ^*. On the other hand, as discussed in (1.9), player 1 cannot guarantee more than the limit of the β-discounted values in Γ^*.

LEMMA 2.3. *Suppose that player* 1 *has an optimal strategy* $\pi \in \Pi$. *Then*

$$v_s \leq \sup_{\pi^*\in\Pi^*}\inf_{\sigma^*\in\Sigma^*}\gamma(s,\pi^*,\sigma^*) \leq v^{*1}_s \qquad \forall s \in S.$$

Proof. The second inequality follows from (1.9), so we only have to show the first one. For $\alpha,\omega \in S$ let

$$\bar{H}(\alpha,\omega) := \{h \in H(\alpha,\omega) |\, \mathbb{P}_{\alpha\pi\sigma^*}(h) > 0 \text{ for some } \sigma^* \in \Sigma^*\}.$$

Take an arbitrary $x \in X^*$. Using Lemma 2.2 we may define a strategy $\pi^* \in \Pi^*$ as follows: for $h \in H(\alpha,\omega)$ let

$$\pi^*(h) := \begin{cases} \pi(h) & \text{if } h \in \bar{H}(\alpha,\omega), \\ x_\omega & \text{otherwise.}\end{cases}$$

Then, by the optimality of π and by the definition of π^*, we have

$$v_s \le \gamma(s,\pi,\sigma^*) = \gamma(s,\pi^*,\sigma^*) \qquad \forall \sigma^* \in \Sigma^*,\ \forall s \in S,$$

which implies the first inequality. □

The next result shows the effectiveness of the β-discounted optimal strategies in the restricted game Γ^*.

LEMMA 2.4. *Let $\varepsilon > 0$. For $\beta \in \mathcal{B}$, let $x^\beta \in X^*$ be a β-discounted optimal strategy of player 1 in Γ^*, and let $y \in Y^*$. Suppose that $E \subset S$ is a closed set of states with respect to (x^β, y) for all $\beta \in \mathcal{B}$. Then, for large $\beta \in \mathcal{B}$,*

$$\gamma(s,x^\beta,y) \ge \min_{t\in E} v_t^{*1} - \varepsilon \qquad \forall s \in E.$$

Proof. Using inequality (1.7) for Γ^* we have

$$(1-\beta)\, r(x^\beta,y) + \beta\, P_{x^\beta y}\, v^{*\beta} \ge v^{*\beta} \qquad \forall \beta \in \mathcal{B}.$$

By (1.1), multiplying this inequality with $Q_{x^\beta y}$ yields

$$Q_{x^\beta y}\, r(x^\beta,y) \ge Q_{x^\beta y}\, v^{*\beta} \qquad \forall \beta \in \mathcal{B}.$$

The closedness of E implies that, for any $s \in E$, if $q(t|s,x^\beta,y) > 0$ then $t \in E$. Hence for all $s \in E$ and for large $\beta \in \mathcal{B}$, using (1.2), we have

$$\begin{aligned}\gamma(s,x^\beta,y) &= \sum_{t\in E} q(t|s,x^\beta,y)\, r(t,x_t^\beta,y_t) \ge \sum_{t\in E} q(t|s,x^\beta,y)\, v_t^{*\beta} \\ &\ge \sum_{t\in E} q(t|s,x^\beta,y)(v_t^{*1}-\varepsilon) \ge \min_{t\in E} v_t^{*1} - \varepsilon,\end{aligned}$$

so the proof is complete. □

Next we discuss some properties of stationary strategies belonging to X^* or to $\mathrm{Relint}(X^*)$, where $\mathrm{Relint}(X^*)$ stands for the relative interior of the polytope X^* and is defined as the set of points in X^* which can be written as a convex combination of all the extreme points of X^* with only strictly positive coefficients.

LEMMA 2.5. *Let $x \in X^*$ and $y \in Y$. Suppose E is an ergodic set with respect to (x,y). Then $v_s = v_t$ for all $s,t \in E$. Furthermore, if $x \in \mathrm{Relint}(X^*)$, then necessarily $y_s \in Y_s^*$ for all $s \in E$.*

Proof. By $x \in X^*$ we obtain

$$\sum_{t\in E} p(t|s,x_s,y_s)\, v_t \ge v_s \qquad \forall s \in E.$$

Let $\bar{E} := \{s \in E |\, v_s = \max_{t\in E} v_t\}$. The above inequalities imply that $\bar{E}$ is a closed set of states for (x,y), so since E is an ergodic set for (x,y) (minimal closed set of states), we have $\bar{E} = E$. Therefore, $v_s = v_t =: v_E$ for all $s,t \in E$.

Now suppose that $x \in \mathrm{Relint}(X^*)$. Then $(\bar{x}_s, y_s)$ only induces transitions to states in E for any $\bar{x}_s \in X_s^*$, $s \in E$; hence

$$\sum_{t\in S} p(t|s,\bar{x}_s,y_s)\, v_t = \sum_{t\in E} p(t|s,\bar{x}_s,y_s)\, v_E = v_E = v_s \quad \forall \bar{x}_s \in X_s^*,\ \forall s \in E,$$

which implies that $y_s \in Y_s^*$ for all $s \in E$. □

An important property of convex combinations of stationary strategies is stated in the next lemma.

LEMMA 2.6. *For $\tau \in (0,1)$, $x^1, x^2 \in X$ let $x^\tau := \tau x^1 + (1-\tau)x^2$. Suppose that E is an ergodic set with respect to (x^τ, y) for some $y \in Y$. Let $\varepsilon > 0$ and $d \in \mathbb{R}$. If*

$$\gamma(s, x^1, y) \geq d \qquad \forall s \in E,$$

then for sufficiently large τ

$$\gamma(s, x^\tau, y) \geq d - \varepsilon \qquad \forall s \in E.$$

Proof. Let $\delta \in (0,1)$. Since

$$\gamma(s, x^1, y) \geq d \qquad \forall s \in E,$$

there exists a K^δ satisfying

$$\mathbb{E}_{sx^1y}(R_N) \geq d - \delta \qquad \forall N \geq K^\delta,\ \forall s \in E,$$

where R_N denotes the average payoff up to stage N. Choose $\tau \in (0,1)$ such that

$$\tau^{K^\delta} \geq 1 - \delta.$$

The strategy x^τ can be interpreted as playing x^1 with probability τ and x^2 with probability $1-\tau$ at each stage, so the last inequality means that x^1 will be played at each K^δ consecutive stages with probability at least $1-\delta$. Hence, with probability at least $1-\delta$, the expected average of the payoffs will be at least $d-\delta$ for any K^δ consecutive stages. Let r denote the smallest payoff in the game. Then if δ is small, by the law of large numbers we have

$$\gamma(s, x^\tau, y) \geq (1-\delta)(d-\delta) + \delta r \geq d - \varepsilon \qquad \forall s \in E,$$

so the proof is complete. □

The next lemma will enable us to construct Markov optimal strategies from stationary ε-optimal strategies which prescribe optimal mixed actions in the matrix games A_s, $s \in S$ (cf. (1.6)). Here we present a short proof, which uses some arguments of Bewley and Kohlberg [1978] on so-called irreducible games.

LEMMA 2.7. *Suppose that for all $\varepsilon > 0$ player 1 has a stationary ε-optimal strategy $x^\varepsilon \in X^*$ in Γ. Then player 1 also has a Markov optimal strategy f in Γ.*

Proof. Consider the restricted game $\Gamma^*(1)$, derived from Γ, where player 1 is restricted to use strategies that only prescribe mixed actions in X_s^*, if the play is in state $s \in S$. As before, Π^* will denote the set of these strategies for player 1. (Note that here only player 1 is restricted, in contrast with the game Γ^*, where both players have a restriction.) Let $v^{*\beta}(1)$ denote the β-discounted value in $\Gamma^*(1)$ and let $v^{*1}(1) := \lim_{\beta \uparrow 1} v^{*\beta}(1)$. Let $v^{*N}(1)$ denote the value of the N-stage game $\Gamma^{*N}(1)$, and let f^N be an N-stage Markov optimal strategy in $\Gamma^{*N}(1)$. Using the assumption that $x^\varepsilon \in X^*$ is ε-optimal in Γ for all $\varepsilon > 0$ and using (1.9) and (1.8), we obtain

$$v_s \leq \sup_{\pi \in \Pi^*} \inf_{\sigma \in \Sigma} \gamma(s, \pi, \sigma) \leq v_s^{*1}(1) = \lim_{N \to \infty} v_s^{*N}(1) \qquad \forall s \in S. \tag{2.1}$$

Let f be the Markov strategy of player 1 which prescribes to play as follows: at stage 1, play f^1; at the next two stages, play f^2; at the next three stages, play f^3; and so

on. We show that f is optimal. Let s^1 be the initial state and let s^N, $N \geq 2$, denote the state for the first stage when f^N is to be played. Take an arbitrary $\sigma \in \Sigma$. Notice that $f \in \Pi^*$, hence by the definition of X^*,

$$\mathbb{E}_{s^1 f\sigma}(v_{s^N}) \geq v_{s^1} \qquad \forall N \in \mathbb{N}.$$

Thus using the N-stage optimality of f^N and (2.1), for any $\delta > 0$ if N is large, then

$$\mathbb{E}_{s^1 f\sigma}(R^N) \geq \mathbb{E}_{s^1 f\sigma}\left(v^{*N}_{s^N}(1)\right) \geq \mathbb{E}_{s^1 f\sigma}\left(v_{s^N}\right) - \delta \geq v_{s^1} - \delta, \tag{2.2}$$

where R^N denotes the average payoff for those N consecutive stages when f^N is played. Let $\phi(K)$ be such that $f^{\phi(K)}$ is to be played at stage K. Observe that

$$\lim_{K\to\infty}\left[\frac{\sum_{N<\phi(K)} N}{K}\right] = 1, \qquad \lim_{K\to\infty}\left[\frac{K - \sum_{N<\phi(K)} N}{K}\right] = 0,$$

so if R_K denotes the average payoff up to stage K and r denotes the smallest payoff in the game, then (2.2) gives

$$\begin{aligned}
\gamma(s^1, f, \sigma) &= \liminf_{K\to\infty} \mathbb{E}_{s^1 f\sigma}\left(R_K\right) \\
&\geq \liminf_{K\to\infty} \mathbb{E}_{s^1 f\sigma}\left(\frac{\sum_{N<\phi(K)} N\cdot R^N + \left[K - \sum_{N<\phi(K)} N\right]\cdot r}{K}\right) \\
&= \liminf_{K\to\infty} \frac{\sum_{N<\phi(K)} N\cdot \mathbb{E}_{s^1 f\sigma}\left(R^N\right)}{K} \\
&\geq v_{s^1},
\end{aligned}$$

which implies that f is optimal in Γ. □

Now we are ready to prove Theorem 2.1.

Proof of Theorem 2.1. We show the existence of stationary ε-optimal strategies for all $\varepsilon > 0$, and then the existence of Markov optimal strategies follows from Lemma 2.7.

For $\beta \in \mathcal{B}$, let $x^\beta \in X^*$ be a β-discounted optimal strategy of player 1 in Γ^* and let $x \in \text{Relint}(X^*)$. For all $\tau \in (0,1)$ and $\beta \in \mathcal{B}$ let

$$x^{\tau\beta} := \tau x^\beta + (1-\tau)x.$$

By the convexity of X^* and by $x \in \text{Relint}(X^*)$ we have $x^{\tau\beta} \in \text{Relint}(X^*)$ for all $\tau \in (0,1)$ and $\beta \in \mathcal{B}$.

We show that, for any $\varepsilon > 0$, for large $\tau \in (0,1)$ and for large $\beta \in \mathcal{B}$ the strategy $x^{\tau\beta}$ is ε-optimal. Let $\varepsilon > 0$. Since against a stationary strategy there always exists a pure stationary best reply, and there are only finitely many pure stationary strategies, it suffices to show that, for all $j \in J$, if $\tau \in (0,1)$ and $\beta \in \mathcal{B}$ are large, then

$$\gamma(x^{\tau\beta}, j) \geq v - \varepsilon\, 1_z,$$

where $1_z = (1,\ldots,1) \in \mathbb{R}^z$. Take a $j \in J$ and let $E \subset S$ be an arbitrary ergodic set with respect to $(x^{\tau\beta}, j)$. We start with showing that for large $\tau \in (0,1), \beta \in \mathcal{B}$ we have

$$\gamma(s, x^{\tau\beta}, j) \geq v_s - \varepsilon \qquad \forall s \in E. \tag{2.3}$$

Since $x^{\tau\beta} \in \text{Relint}(X^*)$, by Lemma 2.5 we obtain $v_s = v_t := v_E$ for all $s, t \in E$ and $j_s \in J_s^*$ for all $s \in E$. Let $j_s^* := j_s$ for all $s \in E$ and let $j_s^* \in J_s^*$ for all $s \notin E$; so $j^* \in J^*$. By the definition of $x^{\tau\beta}$ and by the properties of $\mathcal{B}$, the set of states E is closed with respect to (x^β, j) for all $\beta \in \mathcal{B}$, so with respect to (x^β, j^*) for all $\beta \in \mathcal{B}$ as well. Thus, applying Lemma 2.4 for Γ^* and using Lemma 2.3 yields that for large $\beta \in \mathcal{B}$

$$\gamma(s, x^\beta, j) = \gamma(s, x^\beta, j^*) \geq \min_{t \in E} v_t^{*1} - \frac{1}{2}\varepsilon \geq \min_{t \in E} v_t - \frac{1}{2}\varepsilon = v_E - \frac{1}{2}\varepsilon \qquad \forall s \in E.$$

Now Lemma 2.6 yields that for large $\tau \in (0,1)$ and for large $\beta \in \mathcal{B}$

$$\gamma(s, x^{\tau\beta}, j) \geq v_E - \varepsilon = v_s - \varepsilon \qquad \forall s \in E,$$

which proves (2.3).

Using that $x^{\tau\beta} \in X^*$ we have

$$P_{x^{\tau\beta} j}\, v \geq v,$$

therefore

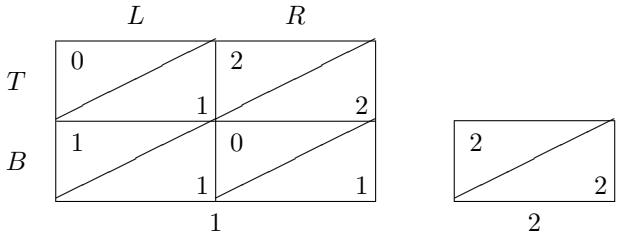
$$Q_{x^{\tau\beta} j}\, v \geq v.$$

For any $s \in S$, $q(t|s, x^{\tau\beta}, j) > 0$ implies that $t \in E$ for some ergodic set E with respect to $(x^{\tau\beta}, j)$; hence by (1.3) and (2.3), for large $\tau \in (0,1)$ and $\beta \in \mathcal{B}$, we obtain

$$\gamma(x^{\tau\beta}, j) = Q_{x^{\tau\beta} j}\, \gamma(x^{\tau\beta}, j) \geq Q_{x^{\tau\beta} j}\, (v - \varepsilon\, 1_z) = Q_{x^{\tau\beta} j}\, v - \varepsilon\, 1_z \geq v - \varepsilon\, 1_z,$$

which completes the proof. □

Example 1.



Here player 1 chooses rows and player 2 chooses columns. In each entry, the corresponding payoff is placed in the upper-left corner, while the transition is placed in the bottom-right corner. In this game each transition is represented by the number of the state to which transition should occur with probability 1. Notice that state 2 is absorbing. The value of this game is $v = (1, 2)$. It is not hard to show that there are optimal strategies for player 1 (later we will construct optimal Markov strategies). Following the construction for stationary ε-optimal strategies, we have $X^* = X$, $Y_1^* = \{(1,0)\}$, $Y_2^* = \{(1)\}$. Now the β-discounted optimal strategy of player 1 in Γ^* is $x^\beta = ((0,1),(1))$ for all $\beta \in (0,1)$. Take a strategy $x \in \text{Relint}(X^*)$, for example, $x = ((\frac{1}{2}, \frac{1}{2}), (1))$. Then for $\tau, \beta \in (0,1)$,

$$x^{\tau\beta} = \tau \cdot x^\beta + (1-\tau) \cdot x = \left(\left(\frac{1}{2} - \frac{1}{2}\tau, \frac{1}{2} + \frac{1}{2}\tau \right), (1) \right),$$

so $x^{\tau\beta}$ is ε-optimal for large τ and β (the strategies $((p,1-p),(1))$ are ε-optimal for $p \in (0,\varepsilon]$). Note that player 1 has no stationary optimal strategy in this game.

Also, a Markov optimal strategy can be constructed as in Lemma 2.7. In this game $X = X^*$, hence the restricted game $\Gamma^*(1)$ is just the original game Γ. The one-stage Markov optimal strategy and the one-stage value are

$$f^1 = \left(\left(\frac{1}{3},\frac{2}{3}\right),(1)\right), \qquad v^1 = v^{*1}(1) = \left(\frac{2}{3},2\right);$$

the two-stage Markov optimal strategy and the two-stage value are

$$f^2 = \left(\left(\left(\frac{3}{13},\frac{10}{13}\right),(1)\right);\left(\left(\frac{1}{3},\frac{2}{3}\right),(1)\right)\right), \qquad v^2 = v^{*2}(1) = \left(\frac{28}{39},2\right);$$

and so on. So, as shown before, the Markov strategy f which prescribes to play f^1 at the first stage, then f^2 at the next two stages, f^3 at the next three stages, and so on, is optimal.

3. Nonimproving strategies. It is in the spirit of zero-sum games to evaluate a strategy π of player 1 by the reward $\phi(\pi)$ it guarantees against any strategy of the opponent. For a strategy $\pi \in \Pi$ let

$$\phi_s(\pi) := \inf_{\sigma} \gamma(s,\pi,\sigma) \quad \forall s \in S, \qquad \phi(\pi) := (\phi_s(\pi))_{s\in S}\,.$$

Using this evaluation ϕ we may naturally define the relation "ε-better" between strategies of player 1. A strategy π^1 is called ε-better than π^2 if $\phi_s(\pi^1) \geq \phi_s(\pi^2) - \varepsilon$ holds for all $s \in S$. 0-better strategies will simply be called better. We will call a strategy π nonimproving if for any state $s \in S$ and for any history $h \in H(\cdot,s)$ we have

$$\phi_s(\pi) \geq \phi_s(\pi[h]).$$

Intuitively, a nonimproving strategy, for any state, cannot guarantee a larger reward conditional on any past history than initially. Obviously, all stationary strategies are nonimproving strategies. Also, optimal strategies are always nonimproving, since they guarantee the value, and no higher reward can be guaranteed.

In this section we will indicate how the following result, which is a generalization of Theorem 2.1, can be shown by using similar techniques as in section 2.

THEOREM 3.1. *For any nonimproving strategy, for any $\varepsilon > 0$, there exists an ε-better stationary strategy and a better Markov strategy as well.*

First we focus on the proof for the existence of ε-better stationary strategies, $\varepsilon > 0$, and afterwards we explain how the existence of a better Markov strategy will follow. Let π denote a fixed nonimproving strategy and let

$$w := \phi(\pi).$$

For $s \in S$ let

$$B_s := \left[\sum_{t\in S} p(t|s,i_s,j_s)\, w_t\right]_{i_s\in I_s,\, j_s\in J_s}, \qquad W_s := \mathrm{Val}\,(B_s),$$

where Val stands for the matrix game value. By using the nonimprovingness of π we obtain

$$\begin{aligned} w_s = \phi_s(\pi) &\leq \sum_{t\in S}\sum_{i_s\in I_s} \pi(s)(i_s)\, p(t|s,i_s,j_s)\cdot \phi_s(\pi[s,i_s,j_s,t]) \\ &\leq \sum_{t\in S}\sum_{i_s\in I_s} \pi(s)(i_s)\, p(t|s,i_s,j_s)\cdot w_t = \sum_{t\in S} p(t|s,\pi(s),j_s)\, w_t \qquad \forall j_s \in J_s,\ \forall s \in S, \end{aligned}$$

hence

$$w_s \le W_s = \mathrm{Val}\,(B_s) \qquad \forall s \in S. \tag{3.1}$$

This is the counterpart of (1.5), however, for w equality does not hold as for the value v, which causes some additional difficulties. We will define a restricted game here as well, but this restricted game will only be defined on a set of states s where $w_s = W_s$, so that we can use similar arguments as in section 2. Let

$$\tilde{X}_s := \left\{ x_s \in X_s | \sum_{t\in S} p(t|s,x_s,y_s)\, w_t \ge w_s \ \ \forall y_s \in Y_s \right\}, \qquad \tilde{X} := \times_{s\in S}\tilde{X}_s,$$

so the set $\tilde{X}_s$, which is a polytope, is the set of mixed actions of player 1 in state s which assure that after transition w will not decrease in expectation. The inequalities (3.1) imply that, for any state $s \in S$, all optimal mixed actions of player 1 in the matrix game B_s belong to $\tilde{X}_s$, which also means that the sets $\tilde{X}_s$ are nonempty.

Fix an arbitrary $x \in \mathrm{Relint}(\tilde{X})$. For a pure stationary strategy $j \in J$ let $R(j)$ denote the set of recurrent sets with respect to (x, j). Let

$$S' := \cup_{j\in J} R(j).$$

For $s \in S'$ let

$$J'_s := \cup_{j\in J,\, s\in R(j)}\{j_s\}, \quad Y'_s := \mathrm{conv}(J'_s), \quad Y' := \times_{s\in S'} Y'_s,$$

where conv stands for the convex hull of a set. Notice that the sets $R(j), S', J'_s, Y'_s, Y'$ are independent of the choice of $x \in \mathrm{Relint}(\tilde{X})$ and also that the sets Y'_s are nonempty polytopes. One can verify that all states $s \in S'$ are recurrent with respect to (x, y), if $y \in Y$ satisfies $y_s \in \mathrm{Relint}(Y'_s)$ for all $s \in S'$. If E is an ergodic set with respect to (x, y) with $y_s \in \mathrm{Relint}(Y'_s)$ for all $s \in S'$, then, as in Lemma 2.5, one can show that $w_s = w_t$ for all $s, t \in E$. Since $x \in \mathrm{Relint}(\tilde{X})$, this also yields that $w_s = W_s$ for all $s \in S'$, so w_s has a similar property as v_s in (1.5). The sets S' and Y' also have the property that, for any $y \in Y$, if $s \in S$ is recurrent with respect to (x, y), then $s \in S'$ and $y_s \in Y'_s$. Let

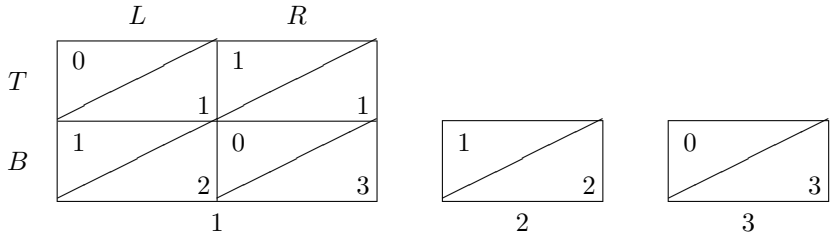
$$X' := \times_{s\in S'}\tilde{X}_s.$$

Let Γ' be the restricted game, derived from Γ, where the state space is S' and the players are restricted to using strategies that only prescribe mixed actions in X'_s and Y'_s, respectively, if the play is in state $s \in S'$. Note that, by the above property of S' and Y', if player 1 uses mixed actions in $\mathrm{Relint}(X'_s)$, $s \in S'$, then whatever stationary strategy y player 2 uses, the play will eventually reach an ergodic set $E \subset S'$ in such a way that w does not decrease in expectation, and $y_s \in Y'_s$ for all $s \in E$, so intuitively the play will eventually proceed in Γ'. Now, using $w_s = W_s$ for all $s \in S'$, for the restricted game Γ', similar results can be shown as for the restricted game in section 2, which completes the proof for the existence of ε-better stationary strategies.

Now the existence of better Markov strategies can be shown along similar lines as the proof of Lemma 2.7. One has to define a restricted game $\Gamma'(1)$, derived from Γ, where player 1 is restricted to use strategies that only prescribe mixed actions in X'_s if the play is in state $s \in S$. Notice that $\Gamma'(1)$ is the counterpart of $\Gamma^*(1)$ defined in the proof of Lemma 7 and also that the above constructed ε-better stationary strategies

belong to X', hence player 1 may use these strategies in the restricted game $\Gamma'(1)$ as well. Now in the game $\Gamma'(1)$, analogous equalities and inequalities can be derived as for $\Gamma^*(1)$ in the proof of Lemma 2.7, but w has to be used instead of v, which leads to the conclusion that better Markov strategies indeed exist.

Example 2.



This example, known as the Big Match (cf. Gillette [1957], Blackwell and Ferguson [1968]), clarifies that, although optimality implies nonimprovingness, improving strategies are indispensable for achieving ε-optimality. The notation is the same as in Example 1. Notice that states 2 and 3 are absorbing. For initial state 1, the limiting average value is $v_1 = \frac{1}{2}$ and player 1 has neither optimal strategies nor stationary ε-optimal strategies for small $\varepsilon > 0$, but for any $N \in \mathbb{N}$ player 1 can guarantee $\frac{1}{2} - \frac{1}{2(N+1)}$ by playing the following strategy π^N: for any history h without absorption, if $k(h)$ denotes the number of stages where player 2 has chosen action R minus the number of stages where player 2 has chosen action L, player 1 has to play the mixed action

$$\pi^N(h) := \left(1 - \frac{1}{(k(h)+N+1)^2}, \frac{1}{(k(h)+N+1)^2}\right).$$

This strategy π^N is clearly improving, since for the history $h = (1, T, R, 1)$ we have $\pi^N[h] = \pi^{N+1}$. Note that, in fact, all strategies that are ε-optimal for small $\varepsilon > 0$ must be improving; otherwise, by Theorem 3.1, player 1 would have stationary ε-optimal strategies (and Markov optimal strategies as well).

4. Concluding remarks. Finally we discuss some consequences. For the sake of simplicity, we only focus on the results of section 2 here.

Remarks on the restricted game Γ^*. In Lemma 2.3 we showed that $v_s^{*1} \geq v_s$ for all $s \in S$. In fact, this is the only statement for which we needed the condition that player 1 has an optimal strategy. Therefore, if in a zero-sum game $v_s^{*1} \geq v_s$ holds for all $s \in S$, then stationary ε-optimal strategies, $\varepsilon > 0$, and Markov optimal strategies can be constructed exactly as in section 2. It also means that $v_s^{*1} \geq v_s$ for all $s \in S$ holds if and only if player 1 has an optimal strategy.

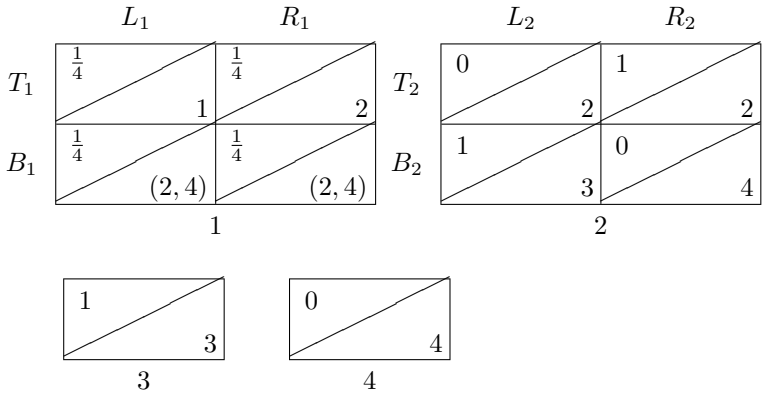
We also remark that, even if player 1 has an optimal strategy, one can find examples where $v_s^{*1} > v_s$ for some state s. However, if E is an ergodic set with respect to some $(x, y) \in \text{Relint}(X^*) \times \text{Relint}(Y^*)$, then there exists a state $s \in E$ such that $v_s^{*1} = v_E$ (recall that the value v is a constant on E by Lemma 2.5). To see this one can argue as follows. Suppose to the contrary that $v_s^{*1} \geq v_E + \mu$ for all $s \in E$, where $\mu > 0$. Let $x^{\tau\beta} \in \text{Relint}(X^*)$ be defined as in the proof of Theorem 2.1. Then Lemmas 2.4 and 2.6 imply that for large τ and β we have

$$\gamma(s, x^{\tau\beta}, j) \geq \min_{t \in E} v_t^{*1} - \frac{\mu}{2} \geq v_E + \frac{\mu}{2} \qquad \forall s \in E,\ \forall j \in J^*. \tag{4.1}$$

Here we used that there are only finitely many pure stationary strategies. Let player 1 play the strategy π^δ, $\delta > 0$, which prescribes to play as follows: play $x^{\tau\beta}$ as long as player 2 chooses actions in J_s^*, $s \in E$, and start playing a δ-optimal strategy as soon as player 2 chooses an action in $J_s \setminus J_s^*$ in some state $s \in E$. Note that if player 2 always chooses actions in J_s^*, $s \in E$, then (4.1) assures that the reward is at least $v_E + \frac{\mu}{2}$ (recall that against a stationary strategy there always exists a pure stationary best reply). On the other hand, if player 2 chooses an action in $J_s \setminus J_s^*$ in some state $s \in E$, then one can show that $x_s^{\tau\beta} \in \mathrm{Relint}(X_s^*)$ yields that the original value v increases in expectation by at least some $\nu > 0$, so if $\delta \in (0, \frac{\nu}{2})$, by the definition of π^δ, the reward is at least $v_E + \frac{\nu}{2}$ in this case. Therefore, π^δ, with $\delta \in (0, \frac{\nu}{2})$, guarantees a reward of at least $v_E + \frac{1}{2}\min(\mu, \nu) > v_E$, which contradicts the definition of the value. So we have shown that $v_s^{*1} = v_E$ holds for some state $s \in E$.

Optimal strategies for particular initial states. We briefly discuss a generalization of the results of section 2, which concerns strategies that are only optimal for particular initial states. Let $\tilde{S}$ denote the set of states for which player 1 has an optimal strategy. First note that in each stochastic game there always exists at least one initial state for which player 1 has optimal strategies (cf. Thuijsman and Vrieze [1991]), so the set $\tilde{S}$ is always nonempty. Using similar techniques as in section 2, one can show that, for any $\varepsilon > 0$, player 1 has a strategy ξ^ε which for all initial states $\alpha \in \tilde{S}$ satisfies the following criteria: (i) ξ^ε is ε-optimal, (ii) ξ^ε is stationary until leaving $\tilde{S}$, (iii) there exist stationary best replies of player 2 against ξ^ε, (iv) the probability of ever leaving $\tilde{S}$ is zero with respect to $(\alpha, \xi^\varepsilon, \sigma)$, if σ is a best reply. The difference between this result and the corresponding result of section 2 is mainly due to the fact that stationary strategies are not effective in states outside $\tilde{S}$, so player 1 may have to start playing a behavior δ-optimal strategy if the play leaves $\tilde{S}$, for some $\delta > 0$. Furthermore, one can also show that player 1 has a strategy χ which for all initial states $\alpha \in \tilde{S}$ satisfies the following criteria: (v) χ is optimal, (vi) χ is Markov until leaving $\tilde{S}$, (vii) there exist Markov best replies of player 2 against χ, (viii) the probability of ever leaving $\tilde{S}$ is zero with respect to (α, χ, σ), if σ is a best reply. We remark here that Markov best replies do not necessarily exist against a Markov strategy, but a Markov strategy χ can be constructed so that (vii) holds.

Example 3.



This example clarifies the existence of such "almost stationary" ε-optimal strategies and "almost Markov" optimal strategies for initial states in $\tilde{S}$. The notation is the same as in Example 1 except for two "mixed" transition vectors in entries (B_1, L_1) and (B_1, R_1), which lead to state 2 with probability $\frac{1}{2}$ and to state 4 with probability

$\frac{1}{2}$. For the sake of simplicity, we only focus on the possible simplifications by "almost stationary" ε-optimal strategies. Notice that if the initial state is state 2, then this game reduces to Example 2. So here the value is $v = (\frac{1}{4}, \frac{1}{2}, 1, 0)$. As mentioned, for initial state 2, player 1 has no optimal strategy, so $\tilde{S} = \{1, 3, 4\}$. Since initial states $3, 4 \in \tilde{S}$ are trivial, we assume the initial state to be $1 \in \tilde{S}$. Consider the strategy ξ for player 1 which prescribes playing action T_1 as long as the play is in state 1, and as soon as the play visits state 2 then prescribes starting to play a behavior $\frac{1}{8}$-optimal strategy. This strategy ξ is optimal and clearly satisfies properties (i), (ii), (iii), and (iv). Note that switching to a behavior strategy when entering state 2 is crucial, because by stationary strategies player 1 could only guarantee 0 for initial state 2. Note also that the use of action B_1 would violate property (iv).

An alternative proof for Lemma 2.7. We wish to remark that, under the condition of Lemma 2.7, other Markov optimal strategies exist as well . Let ε_n be a positive sequence converging to zero. One can show that the Markov strategy which prescribes x^{ε_1} for the first N_1 stages, x^{ε_2} for the next N_2 stages, and so on, is optimal for a well-chosen increasing sequence N_n.

Subgame optimality. Note that the Markov strategy f, constructed in section 2, is "subgame optimal"; namely, the strategy $f[h]$ is optimal for any finite history h.

Alternative rewards and optimality. It is worthwhile to mention that sometimes other rewards are used to evaluate the long-term average payoffs. The most common rewards are the following ones:

$$\gamma^1(s,\pi,\sigma) = \mathbb{E}_{s\pi\sigma}\left(\liminf_{N\to\infty} R_N\right), \qquad \gamma^2(s,\pi,\sigma) = \liminf_{N\to\infty} \mathbb{E}_{s\pi\sigma}\left(R_N\right),$$

$$\gamma^3(s,\pi,\sigma) = \limsup_{N\to\infty} \mathbb{E}_{s\pi\sigma}\left(R_N\right), \qquad \gamma^4(s,\pi,\sigma) = \mathbb{E}_{s\pi\sigma}\left(\limsup_{N\to\infty} R_N\right),$$

where R_N is the random variable for the average payoff up to stage $N \in \mathbb{N}$. It holds that $\gamma^1 \le \gamma^2 \le \gamma^3 \le \gamma^4$. Notice that we have used $\gamma = \gamma^2$ so far. Mertens and Neyman [1981] showed that the value is the same for all these rewards. Optimality and ε-optimality can be defined with respect to any of these four rewards. Sometimes a fifth alternative is to require uniformity from the optimal strategy; i.e., π is uniformly optimal for state $s \in S$ if

$$\forall \delta > 0\ \exists N^\delta\colon\ \mathbb{E}_{s\pi\sigma}\left(R_N\right) \ge v_s - \delta \quad \forall N \ge N^\delta,\ \forall \sigma \in \Sigma.$$

The definition of uniform ε-optimality is similar.

Focussing only on section 2 again, we briefly examine the validity of the results for all these criteria. First notice that it makes no difference in our results in which way the strategy of player 1 is optimal. Furthermore, for stationary strategy pairs, all the above optimality criteria are known to be equivalent (for example, cf. Bewley and Kohlberg [1978]), so the simplifications by stationary strategies remain valid with respect to all these alternatives. For Markov strategies, however, it is somewhat different. Notice first that the Markov strategy constructed in section 2 is uniformly optimal (see the proof of Lemma 2.7). Since $\gamma^2 \le \gamma^3 \le \gamma^4$ we have that this Markov strategy is also optimal for rewards γ^3, γ^4. However, when player 1 has an optimal strategy, the existence of Markov optimal strategies for reward γ^1 is not straightforward, not even by using an approach as in the alternative proof for Lemma 2.7.

A VISCOSITY APPROACH TO INFINITE-DIMENSIONAL HAMILTON–JACOBI EQUATIONS ARISING IN OPTIMAL CONTROL WITH STATE CONSTRAINTS*

MACIEJ KOCAN† AND PIERPAOLO SORAVIA‡

Abstract. We consider nonlinear optimal control problems with state constraints and nonnegative cost in infinite dimensions, where the constraint is a closed set possibly with empty interior for a class of systems with a maximal monotone operator and satisfying certain stability properties of the set of trajectories that allow the value function to be lower semicontinuous. We prove that the value function is a viscosity solution of the Bellman equation and is in fact the minimal nonnegative supersolution.

Key words. viscosity solutions, nonlinear semigroups, accretive operators, dynamic programming, optimal control with state constraints, optimality principles

1. Introduction. We study optimal control infinite horizon problems with state constraints in infinite dimensions. Let H be a real Hilbert space and let A be a maximal monotone operator in H, possibly nonlinear and multivalued. Let U be a Hilbert space and let $f\colon \overline{D(A)} \times U \to H$; the precise assumptions on f are stated in section 2. For $x \in \overline{D(A)}$ (where $D(A)$ denotes the domain of A) and $u \in L^2 \equiv L^2(0,\infty;U)$ let $y(\cdot) = y(\cdot,x,u) \in C([0,\infty);H)$ be the mild solution of the state equation

$$\begin{cases} y'(t) + Ay(t) \ni f(y(t),u(t)) & \text{for} \quad t \geq 0, \\ y(0) = x. \end{cases} \tag{1.1}$$

Given a lower semicontinuous function $g\colon \overline{D(A)} \to [0,+\infty]$, we seek to minimize the cost functional

$$J(x,u) = \int_0^\infty \left(g(y(t)) + \tfrac{1}{2}\|u(t)\|^2 \right) dt \tag{1.2}$$

over all controls $u \in L^2$, where $y(\cdot) = y(\cdot,x,u)$ is a trajectory of the system (1.1).

The value function $V\colon \overline{D(A)} \to [0,+\infty]$ associated with this problem is

$$V(x) = \inf \left\{ J(x,u)\colon\ u \in L^2(0,\infty;U) \right\}. \tag{1.3}$$

Our choice of the running cost g forces a state constraint on the trajectories of the system (1.1). Namely, let K denote the closure of $\mathrm{dom}(g) = \{x\colon\ g(x) \text{ is finite}\}$; we

remark that K may have an empty interior (with respect to $\overline{D(A)}$). Then clearly $V(x) = +\infty$ for $x \in \overline{D(A)} \setminus K$, so that $\mathrm{dom}(V) \subset K$. Observe that for $x \in \mathrm{dom}(V)$ in (1.3) it is enough to take the infimum over all controls $u \in \mathcal{U}(x)$, where

$$\mathcal{U}(x) = \left\{u \in L^2(0,\infty;U): \quad J(x,u) < +\infty\right\}, \tag{1.4}$$

and we can write

$$V(x) = \inf\left\{J(x,u):\ u \in \mathcal{U}(x)\right\} \quad \text{for} \quad x \in \mathrm{dom}(V) \subset K. \tag{1.5}$$

In particular, for every $x \in \mathrm{dom}(V)$ there exists a control $u \in L^2$ such that $g(y(t))$ is finite for almost all $t \geq 0$; that is, u is admissible for the state constraint K and satisfies

$$y(t,x,u) \in K \quad \text{for all} \quad t \geq 0.$$

We refer to M. Soner [20] for sufficient conditions for existence of admissible controls at all points in the finite-dimensional case and to P. Cannarsa, F. Gozzi, and M. Soner [6] for infinite-dimensional systems. We also recall I. Capuzzo-Dolcetta and P. L. Lions [7] for a general study of constrained viscosity solutions in finite dimensions. In our study we do not require the condition $\mathcal{U}(x) \neq \emptyset$ for $x \in K$ and thus $\mathrm{dom}(V)$ may be strictly contained in K.

As usual, following the dynamic programming approach, the value function V is expected to solve in some weak sense the associated Bellman equation

$$\langle Ax, DV\rangle + \sup_{u\in U}\left\{-\langle f(x,u), DV\rangle - \tfrac{1}{2}\|u\|^2\right\} = g(x) \quad \text{in} \quad \overline{D(A)}. \tag{1.6}$$

In particular, note that for $f(x,u) = Bu$, where $B \in \mathcal{L}(U,H)$ is bounded linear, (1.6) becomes

$$\langle Ax, DV\rangle + \tfrac{1}{2}\|B^*DV\|^2 = g(x) \quad \text{in} \quad \overline{D(A)}. \tag{1.7}$$

The main technical problems in proving (1.6) are due to the fact that K, and, consequently, $\mathrm{dom}(V)$, may have an empty interior. A suitable concept of solution, taking into account this and the singularity of the Hamiltonian outside $\mathrm{dom}(g)$, is introduced in section 3. It is clear that even if $\mathrm{dom}(V) = \overline{D(A)}$, solutions of (1.6) are never unique, and this ill-posedness of the problem may not be fixed by prescribing solutions to vanish at a particular point; see the paper by the second author [22] for some examples.

A finite horizon version of the control problem we study, for a linear system, linear operator A and convex cost g, and the time-dependent version of (1.7) associated with it, were studied by P. Cannarsa and G. Di Blasio in [5]. In [5] the authors assume that $\mathcal{U}(x) \neq \emptyset$ for $x \in K$ and define weak solutions of the evolution equation corresponding to (1.7) as pointwise limits of increasing sequences of strong solutions of approximate equations that are associated with unconstrained convex control problems. Strong solutions are meant in the sense of convex control theory; see V. Barbu and G. Da Prato [3].

Our approach is different. We directly define solutions of (1.6) as viscosity solutions in the spirit of D. Tataru [24], [25] and M. G. Crandall and P. L. Lions [15], modifying their definition to take into account the failure of comparison between super- and subsolutions of (1.6) and to cope with extended real-valued solutions. This

idea allows us to eliminate the convexity assumption and to extend the framework of [5] to include certain nonlinear systems; see sections 2 and 6 for precise assumptions and examples. On the other hand we do not prove general explicit formulas for the optimal feedback law, as in [5]. This kind of result remains for now a peculiarity of convex control, where more regular (e.g., convex) value functions are available. We refer the reader also to [3] for these results in the case of unconstrained control problems. We prove that the value function in (1.5) is the minimal nonnegative viscosity supersolution of (1.6). To this end we extend to infinite-dimensional systems certain optimality principles for viscosity supersolutions and subsolutions proved by the second author in [21] and [22] in finite dimensions.

Our techniques have a broader scope. We decided to treat the infinite horizon problem without discount factor and the stationary problem (1.6) here because of the additional technical difficulties it poses, namely, the lack of comparison for viscosity solutions of the Bellman equation. In the case of the finite horizon problem and the infinite horizon problem with a positive discount factor, appropriate analogues of our main result hold and are in fact easier to obtain. When g is Lipschitz, the corresponding Hamilton–Jacobi equations do satisfy comparison and have unique solutions, as is known from Crandall and Lions [15], which can be used to simplify our proofs. However, if g is merely extended real-valued and lower semicontinuous, one only expects uniqueness results in the spirit of our Proposition 2.5.

The plan of the paper is as follows. Our assumptions and statements are discussed in section 2. The definitions and references for the theory of viscosity solutions, as well as some preliminary lemmas, are given in section 3. In section 4 we study the relationship between Hamilton–Jacobi–Bellman equations and value functions of control problems. In section 5 we complete the proof of our main result. Finally, in section 6 we present some examples of systems and constraints satisfying our assumptions.

2. Preliminaries: Assumptions and statements. H is a fixed real Hilbert space and A a maximal monotone (equivalently, m-accretive) operator in H. Then $-A$ generates a strongly continuous semigroup $S(t)$ of contractions on $\overline{D(A)}$; we refer the reader to V. Barbu [1] or H. Brézis [4] for the theory of nonlinear semigroups.

The function f in the state equation (1.1) will always satisfy

$$\text{(2.1)}\qquad \begin{cases} f\colon \overline{D(A)} \times U \to H \quad \text{is continuous and} \\ \text{there exist } L>0, q\in[1,2) \text{ such that for all } x,z\in\overline{D(A)}, u\in U, \\ \|f(x,u)-f(z,u)\| \le L\|x-z\| \quad \text{and} \quad \|f(x,u)\| \le L\left(1+\|x\|+\|u\|^q\right). \end{cases}$$

Note that from (2.1) and Hölder's inequality, for every $x,z\in\overline{D(A)}$, $u\in L^2$, and $t>0$,

$$\begin{aligned} \|y(t,z,u)-x\| &\le \|y(t,z,u)-S(t)z\| + \|S(t)z-S(t)x\| + \|S(t)x-x\| \\ &\le \int_0^t \|f(y(s,z,u),u(s))\|ds + \|z-x\| + \|S(t)x-x\| \\ &\le L\int_0^t \left(1+\|y(s,z,u)\|+\|u(s)\|^q\right)ds + \|z-x\| + \|S(t)x-x\| \\ &\le Lt + L\|u\|^q_{L^2(0,t;U)}t^{1-\frac{q}{2}} + \|z-x\| + \|S(t)x-x\| \\ &\quad + L\int_0^t \|y(s,z,u)\|ds, \end{aligned} \qquad \text{(2.2)}$$

and then by Gronwall's lemma $\|y(t,z,u)\|$ stays bounded for t bounded, uniformly in u bounded in L^2 and z bounded in $\overline{D(A)}$. Using (2.2) again we deduce

$$y(t,z,u) \to x \ \text{ as } \ t \downarrow 0 \ \text{ and } \ z \to x, \ \text{uniformly for } u \text{ bounded in } L^2(0,T;U), \ T>0. \tag{2.3}$$

Our most restrictive, although natural, assumption on the system is one of the following two stability conditions:

$$\text{(W)} \qquad \begin{cases} \text{if } u_n \rightharpoonup u \text{ in } L^2(0,T;U) \text{ for some } T>0 \text{ and } x_n \rightharpoonup x \text{ in } \overline{D(A)}, \\ \text{then for every } t \in (0,T),\ y(t,x_n,u_n) \rightharpoonup y(t,x,u) \text{ in } H, \end{cases}$$

or

$$\text{(S)} \qquad \begin{cases} \text{if } u_n \rightharpoonup u \text{ in } L^2(0,T;U) \text{ for some } T>0 \text{ and } x_n \to x \text{ in } \overline{D(A)}, \\ \text{then for every } t \in (0,T),\ y(t,x_n,u_n) \to y(t,x,u) \text{ in } H. \end{cases}$$

Conditions (W) and (S) are not directly comparable. Note however that by (2.1) and Gronwall's inequality we have that

$$\|y(t,z,u) - y(t,x,u)\| \le \|z-x\| e^{Lt},$$

and therefore (S) is equivalent to its version with $x_n \equiv x \in \overline{D(A)}$. Moreover, the condition that $y(\cdot,x,u_n)$ converges pointwise to $y(\cdot,x,u)$ in (S) is equivalent to uniform convergence in $C([0,T];U)$; see Theorem 2.3.1 in Vrabie [26].

It is well known (and can be easily deduced from the Duhamel principle) that the weak condition (W) holds if the operator A is linear and $f(x,u) = Bu$, where $B \in \mathcal{L}(U,H)$. In particular, our framework extends that in [5]. If instead $-A$ generates a compact semigroup, then the strong condition (S) is satisfied when $f(x,u) = f_1(x) + f_2(x)u$ and f_i, $i = 1,2$ are Lipschitz; see Proposition 2.7 and Remark 2.8 below. The condition (S) is also satisfied if $f(x,u) = Bu$, $B \in \mathcal{L}(U,H)$ is compact, and A generates a weakly equicontinuous semigroup; see Remark 2.10 at the end of this section.

Remark 2.1. All the results we present in this paper hold with trivial changes even if we require the controls to satisfy the condition $u(t) \in C \subset U$ for a.e. $t \ge 0$, where $C \ni 0$ is such that $L^2(0,T;C)$ is weakly closed in $L^2(0,T;U)$ for $T>0$, for example, if C is closed and convex. For previous results on convex control problems with control constraints see also Di Blasio [17].

In what follows, $LSC(\Omega)$, $USC(\Omega)$, $w\text{-}LSC(\Omega)$, and $w\text{-}USC(\Omega)$ will stand for the spaces of all lower semicontinuous, upper semicontinuous, sequentially weakly lower semicontinuous, sequentially weakly upper semicontinuous (possibly extended real-valued) functions on Ω, respectively.

We will always assume that

$$g\colon \overline{D(A)} \to [0,+\infty] \tag{2.4}$$

is at least lower semicontinuous and denote

$$K = \overline{\operatorname{dom}(g)} \subseteq \overline{D(A)}.$$

One can impose state constraints on the system (1.1) on given closed set K by starting off with any $g\colon \overline{D(A)} \to [0,+\infty)$ and setting $g \equiv +\infty$ off K, so that the value

function V associated with such a running cost satisfies $\mathrm{dom}(V) \subset K$. Obviously $g \in LSC(\overline{D(A)})$ if and only if $g_{|K} \in LSC(K)$, and asking for $g \in w\text{-}LSC(\overline{D(A)})$ roughly amounts to $g_{|K} \in w\text{-}LSC(K)$ and the set K to be weakly closed.

We state the main result of the paper, which says that the value function V given by (1.3) can be uniquely characterized as the minimal nonnegative lower semicontinuous supersolution of (1.6). For the definition of viscosity solutions we refer to the next section. Recall that $V\colon \overline{D(A)} \to [0, +\infty]$ satisfies $\mathrm{dom}(V) \subset K$ and is given by (1.3).

THEOREM 2.2. *Assume* (2.1) *and* (2.4). *Suppose that* $g \in w\text{-}LSC(\overline{D(A)})$ ($g \in LSC(\overline{D(A)})$, *respectively*). *If* (W) ((S), *respectively*) *holds, then* V *is a viscosity solution of* (1.6) *and it is the minimal nonnegative, sequentially weakly lower semicontinuous (strongly lower semicontinuous, respectively) extended real-valued viscosity supersolution of* (1.6).

Theorem 2.2 will follow from the following series of propositions. The first statement is about the regularity of the value function. Note that the proof we give also shows existence of optimal controls for our problem; see section 5.

PROPOSITION 2.3. *Assume* (2.4) *and suppose that* (1.1) *has a unique mild solution for any* $u \in L^2(0, \infty; U)$ *and* $x \in \overline{D(A)}$. *Suppose that* $g \in w\text{-}LSC(\overline{D(A)})$ (*respectively,* $g \in LSC(\overline{D(A)})$). *If* (W) ((S), *respectively*) *holds then* $V \in w\text{-}LSC(\overline{D(A)})$ ($V \in LSC(\overline{D(A)})$, *respectively*).

The second statement relates the value function to the Hamilton–Jacobi equation.

PROPOSITION 2.4. *Assume* (2.1) *and* (2.4) *and suppose that* $g \in LSC(\overline{D(A)})$. *Then the value function* V *is a viscosity solution of* (1.6).

The third statement characterizes the value function through the equation.

PROPOSITION 2.5. *Assume* (2.1) *and* (2.4). *Suppose that* $g \in w\text{-}LSC(\overline{D(A)})$ (*respectively,* $g \in LSC(\overline{D(A)})$) *and* (W) ((S), *respectively*) *holds. Suppose that* $w \in w\text{-}LSC(\overline{D(A)})$ ($w \in LSC(\overline{D(A)})$, *respectively*) *is a nonnegative, extended real-valued viscosity supersolution of* (1.6). *Then* $w \geq V$ *on* $\overline{D(A)}$, *where* V *is the value function given by* (1.5).

We will prove more than the statement of Proposition 2.5, namely, an optimality principle for supersolutions of (1.6). We refer to section 5 for the actual statement of this result, see Lemma 5.5, and to [21] and [22] for similar results in the finite-dimensional case. Note in particular that from Proposition 2.5 it follows that there exists a viscosity supersolution of (1.6) which is finite at x if and only if $V(x)$ is finite and, therefore, if and only if there is at least one control providing a finite cost at x, i.e., $\mathcal{U}(x) \neq \emptyset$.

Remark 2.6. If A is linear, $-A$ generates a compact semigroup, $f(x, u) = Bu$, where $B \in \mathcal{L}(U, H)$, and (2.1) and (2.4) hold, then the following holds true (note that it is stronger than both (W) and (S)):

$$\begin{cases} \text{if } u_n \rightharpoonup u \text{ in } L^2(0, T; U) \text{ for some } T > 0 \text{ and } x_n \rightharpoonup x \text{ in } \overline{D(A)}, \\ \text{then for every } t \in (0, T),\ y(t, x_n, u_n) \to y(t, x, u) \text{ in } H. \end{cases}$$

Then statements a little bit stronger than the ones above hold; e.g., $g \in LSC(\overline{D(A)})$ implies that $V \in w\text{-}LSC(\overline{D(A)})$, etc.

We continue this section by proving the sufficient condition for (S) that we mentioned above.

PROPOSITION 2.7. *Suppose that* $f(y, u) = f_1(y) + f_2(y)u$, *where* $f_1\colon \overline{D(A)} \to H$ *and* $f_2\colon \overline{D(A)} \to \mathcal{L}(U, H)$ *are Lipschitz. If* $-A$ *generates a compact semigroup then* (S) *holds.*

Proof. Fix $T > 0$ and $\hat{x} \in \overline{D(A)}$ and suppose that $u_n \rightharpoonup u_\infty$ in $L^2(0,T;U)$. Then $\{u_n\}$ is bounded in $L^2(0,T;U)$. For $n = 1, 2, \dots, \infty$ and $w \in C([0,T];H)$ denote by $E_n[w](\cdot)$ the mild solution $y(\cdot)$ of

$$\begin{cases} y' + Ay \ni f_1(w) + f_2(w)u_n & \text{in} \quad [0,T], \\ y(0) = \hat{x}. \end{cases}$$

Then for every $0 < t \le T$, $E_n : C([0,t];H) \to C([0,t];H)$ and we claim that with respect to the sup-norm in $C([0,t];H)$ the map

$$E_n^k \quad \text{is} \quad \frac{L^k(\sqrt{T}+C)^k t^{k/2}}{\sqrt{k!}} - \text{Lipschitz} \quad \text{for every} \quad k = 1, 2, \dots, \tag{2.5}$$

where L denotes a Lipschitz constant for f_1 and f_2, and $C = \max_n\{\|u_n\|_{L^2(0,T;U)}\}$.

If $w_1, w_2 \in C([0,t];H)$ then for every $t \in [0,T]$,

$$\begin{aligned} &\|E_n[w_1] - E_n[w_2]\|_{L^\infty(0,t;H)} \\ &\quad \le \int_0^t (\|f_1(w_1(s)) - f_1(w_2(s))\| + \|f_2(w_1(s)) - f_2(w_2(s))\|\|u_n(s)\|)\, ds \\ &\quad \le L(t + C\sqrt{t})\|w_1 - w_2\|_{L^\infty(0,t;H)} \le L\sqrt{t}(\sqrt{T}+C)\|w_1 - w_2\|_{L^\infty(0,t;H)}, \end{aligned}$$

and (2.5) holds if $k = 1$. Suppose that (2.5) holds for $k \ge 1$. Then

$$\begin{aligned} \|E_n^{k+1}[w_1] - E_n^{k+1}[w_2]\|_{L^\infty(0,t;H)} &\le \int_0^t \|f_1(E_n^k[w_1](s)) - f_1(E_n^k[w_2](s))\| ds \\ &\quad + \int_0^t \|f_2(E_n^k[w_1](s)) - f_2(E_n^k[w_2](s))\|\|u_n(s)\| ds \\ &\le \int_0^t L\frac{L^k(\sqrt{T}+C)^k s^{k/2}}{\sqrt{k!}}(1 + \|u_n(s)\|) \\ &\quad \cdot \|w_1 - w_2\|_{L^\infty(0,s;H)} ds \\ &\le \frac{L^{k+1}(\sqrt{T}+C)^{k+1} t^{(k+1)/2}}{\sqrt{(k+1)!}}\|w_1 - w_2\|_{L^\infty(0,t;H)}, \end{aligned}$$

since

$$\int_0^t s^{k/2}(1 + \|u_n(s)\|) ds \le \tfrac{2}{k+2} t^{k/2+1} + \tfrac{1}{\sqrt{k+1}} t^{(k+1)/2}\|u_n\|_{L^2(0,T;U)}.$$

Then (2.5) follows by induction.

In particular, E_n^k is a contraction for big k. Note that $y' + Ay \ni f_1(y) + f_2(y)u_n$ if and only if y is a fixed point of E_n: $y = E_n[y]$. For $n = 1, 2, \dots, \infty$ denote $y_n(\cdot) = y(\cdot, \hat{x}, u_n)$. Then by (2.5) y_n can be obtained as a limit of iterations, starting from the constant function 0

$$y_n = \lim_{k\to\infty} E_n^k[0].$$

We claim that

$$\|y_n - E_n^k[0]\|_{L^\infty(0,T;H)} \le \Big(T\|f_1(0)\| + C\sqrt{T}\|f_2(0)\| + \sup_{s\in[0,T]}\|S(s)\hat{x}\|\Big)\sum_{i=k}^{\infty}\tfrac{(L(T+C\sqrt{T}))^i}{\sqrt{i!}}. \tag{2.6}$$

From (2.5) for any $m > k$,

$$\begin{aligned}\|E_n^m[0] - E_n^k[0]\|_{L^\infty(0,T;H)} &\le \sum_{i=k}^{m-1} \|E_n^{i+1}[0] - E_n^i[0]\|_{L^\infty(0,T;H)} \\ &\le \|E_n[0]\|_{L^\infty(0,T;H)} \sum_{i=k}^{m-1} \tfrac{(L(T+C\sqrt{T}))^i}{\sqrt{i!}}.\end{aligned} \tag{2.7}$$

Since

$$\begin{aligned}\|E_n[0]\|_{L^\infty(0,T;H)} &\le \|E_n[0] - S(\cdot)\hat{x}\|_{L^\infty(0,T;H)} + \sup_{s\in[0,T]} \|S(s)\hat{x}\| \\ &\le \int_0^T \|f_1(0) + f_2(0)u_n(s)\|ds + \sup_{s\in[0,T]} \|S(s)\hat{x}\|,\end{aligned}$$

letting $m \to \infty$ in (2.7) and Hölder's inequality give (2.6).

We will prove that

$$\lim_{n\to\infty} \|y_n - y_\infty\|_{L^\infty(0,T;H)} = 0. \tag{2.8}$$

Since for every $k \ge 1$,

$$y_\infty - y_n = \big(y_\infty - E_\infty^k[0]\big) + \big(E_\infty^k[0] - E_n^k[0]\big) + \big(E_n^k[0] - y_n\big)$$

and from (2.6) $y_\infty - E_\infty^k[0]$ and $E_n^k[0] - y_n$ go to 0 in $L^\infty(0,T;H)$ as $k \to \infty$, uniformly in n, to prove (2.8) it is enough to show that

$$\lim_{n\to\infty} \|E_\infty^k[0] - E_n^k[0]\|_{L^\infty(0,T;H)} = 0 \quad \text{for every} \quad k \ge 1. \tag{2.9}$$

Since $u_n \to u_\infty$ weakly in $L^2(0,T;H)$, it follows that $f_1(0) + f_2(0)u_n \to f_1(0) + f_2(0)u_\infty$ weakly in $L^1(0,T;H)$, and then $E_n[0] \to E_\infty[0]$ uniformly on $[0,T]$ as $n \to \infty$ by the Baras theorem; see, e.g., Corollary 2.3.1 in [26]. Thus (2.9) holds for $k = 1$. Suppose that (2.9) is proved for $k \ge 1$. Then $f_i(E_n^k[0])$, $i = 1, 2$, uniformly converge to $f_i(E_\infty^k[0])$ and then $f_1(E_n^k[0]) + f_2(E_n^k[0])u_n \to f_1(E_\infty^k[0]) + f_2(E_\infty^k[0])u_\infty$ weakly in $L^1(0,T;H)$, and using the Baras theorem again gives (2.9) for $k+1$. Therefore, (2.9) is proved by induction, and consequently (2.8) is satisfied, and the proof of the proposition is complete, since, as observed above, (S) is equivalent to its version with $x_n = \hat{x}$. □

Remark 2.8. The result of Proposition 2.7 has independent interest. However, since the proof of the main result of this paper requires condition (2.1) on the vector field f, there are really two cases where we can apply Proposition 2.7. Either $f_2 \equiv B \in \mathcal{L}(U,H)$ is constant, or we choose our controls in the restricted set $L^2(0,+\infty;C)$, where C is convex, closed, and bounded in U; see Remark 2.1. Note also that the proof of Proposition 2.7 shows existence and uniqueness of mild solutions of $y' + Ay \ni f_1(y) + f_2(y)u$ for any maximal monotone operator A.

Remark 2.9. Let $\Phi\colon H \to \mathbb{R} \cup \{+\infty\}$ be a lower semicontinuous and convex function $\mathrm{dom}(\Phi) \ne \emptyset$. Then its subgradient $\partial\Phi$ is an example of a multivalued, maximal monotone operator. Note that for our purposes it is not restrictive to assume that $\Phi \ge 0$. In fact, if $(x_0, p_0) \in \partial\Phi$, then defining

$$\tilde{\Phi}(x) = \Phi(x) - \Phi(x_0) - \langle p_0, x - x_0\rangle,$$

we get $\tilde{\Phi}(x_0) = 0$ and $(x_0, 0) \in \partial\tilde{\Phi}$. In particular $\partial\tilde{\Phi} = \partial\Phi - p_0$ and $\tilde{\Phi} \geq 0$, since $\tilde{\Phi}$ is convex. Therefore, for $A = \partial\tilde{\Phi}$ the properties of the system (1.1) are unaffected.

Assume now that Φ satisfies the following coercivity condition, namely, $\mathrm{dom}(\Phi) \subset V \subset H$, where V is a Hilbert space compactly and algebraically imbedded into H, and there are two functions $\omega, \rho\colon [0, +\infty) \to [0, +\infty)$, ρ nondecreasing, such that

$$\omega(\|y\|_V) \leq \rho(\|y\|) + \Phi(y) \quad \text{and} \quad \lim_{r\to+\infty} \omega(r) = +\infty.$$

Then for all $\lambda \geq 0$ the sublevel set $\{y \in H\colon \|y\|^2 + \Phi(y) \leq \lambda\}$ is bounded in V and is hence compact in H. This means that Φ is of compact type, which is equivalent to saying that $-\partial\Phi$ generates a compact semigroup; see [26, Proposition 2.2.2].

The situation we just described appears in the so-called abstract parabolic variational inequalities, where we are given an operator in H of the form $A = (\tilde{A} + \partial\varphi) \cap H \times H$. The operator $\tilde{A}$ is supposed linear, bounded, and symmetric; $\tilde{A}\colon V \to V'$; $V \subset H \subset V'$; V is a Hilbert space compactly and algebraically imbedded into H; V dense in H. Moreover, $\tilde{A}$ satisfies for $a > 0$, $b \in \mathbb{R}$,

$$\langle \tilde{A}y, y\rangle \geq a\|y\|_V^2 + b\|y\|^2, \quad y \in V.$$

The function $\varphi\colon H \to \mathbb{R} \cup \{+\infty\}$ is supposed to be nonnegative, lower semicontinuous and convex, $\mathrm{dom}(\varphi) \neq \emptyset$. For simplicity of notation we suppose $\tilde{A}$ monotone (otherwise $b < 0$ and one has to consider $\tilde{A} - bI$ in the following). Then by defining $\Phi\colon H \to \mathbb{R} \cup \{+\infty\}$,

$$\Phi(y) = \begin{cases} \frac{1}{2}\langle \tilde{A}y, y\rangle + \varphi(y), & y \in V, \\ +\infty & y \in H\backslash V, \end{cases}$$

we get $\partial\Phi = \tilde{A} + \partial\varphi$ and we fall into the situation above, namely, the operator $-A = -\partial\Phi$ generates a compact semigroup, and Proposition 2.7 applies.

Remark 2.10. Other situations are known in the literature where our condition (S) is satisfied. We can consider systems of the form

$$y'(t) + Ay(t) \ni Bu(t),$$

where $-A$ generates a weakly equicontinuous semigroup, $B \in \mathcal{L}(U, H)$ is compact, and our set of admissible controls is restricted to $L^2(0, +\infty; B_R^U)$ for some $R > 0$. For the proof of this statement, see [26, Theorem 2.9.2]. See also Remark 2.1 and section 6 for an explicit example.

3. Viscosity solutions. Over the last decade substantial progress in the theory of Hamilton–Jacobi–Bellman–Isaacs equations in infinite-dimensional spaces has been made due to the introduction of the notion of viscosity solution. In particular, very general results have been obtained for equations with unbounded terms; see, e.g. [18], [24], [15], and [25].

We seek to solve the partial differential equation

$$\langle Ax, Du\rangle + F(x, u(x), Du) = 0 \quad \text{in} \quad \Omega, \tag{3.1}$$

where $\Omega \subseteq \overline{D(A)}$. Whenever the function u is regular enough, the derivative Du is understood in the sense of Fréchet and is identified with an element of H. Thus $F\colon \Omega \times \mathbb{R} \times H \to \mathbb{R}$ is appropriate. However, in general our solutions will not be smooth in the above sense and we need to relax the concept of solution. In case of a

bounded A (see [10], [11], [12]) the theory of viscosity solutions for (3.1) is not much different from the finite-dimensional one for which we refer the reader to [8]. For an unbounded A one additional difficulty is in the interpretation of the term $\langle A\hat{x}, Du(\hat{x})\rangle$ when $\hat{x} \notin D(A)$. The classical approach (see, e.g., work of Barbu and Da Prato [3]) is restricted to equations with convex and Lipschitz ingredients and linear A. Crandall and Lions [13], [14], [16] introduced a notion of viscosity solution suitable for a linear A and more general nonlinearities F. Ishii [18] deals with the case of $A = \partial h$, where h is convex and lower semicontinuous. The definition of solution suitable for (3.1) with no additional assumptions on A besides maximal monotonicity has been introduced by Tataru [24] and later refined by Crandall and Lions [15] and Tataru [25]. Here we will follow Crandall–Lions's approach [15].

As explained in [24], for $\varphi \in C^1(H)$ it is natural to interpret the unbounded term $\langle Ax, D\varphi\rangle$ in terms of the derivatives of φ along the trajectories of $S(t)$. This motivates the following definition.

DEFINITION 3.1. *For a function* $\Phi\colon \overline{D(A)} \to \mathbb{R}$ *and* $\hat{x} \in \overline{D(A)}$ *define*

$$D_A^-\Phi(\hat{x}) = \liminf_{\substack{x\to\hat{x}\\ h\downarrow 0}} \frac{\Phi(x) - \Phi\left(S(h)x\right)}{h} \quad \textit{and} \quad D_A^+\Phi(\hat{x}) = \limsup_{\substack{x\to\hat{x}\\ h\downarrow 0}} \frac{\Phi(x) - \Phi\left(S(h)x\right)}{h}.$$

We refer to [15] and [19] for basic properties of these operators. Next we introduce "test functions." $Lip(\Omega)$ will denote the space of all Lipschitz continuous functions on Ω. Given $\psi \in Lip(\Omega)$, $L(\psi)$ will denote its best Lipschitz constant. Hereafter we denote with P the projection of H onto $\overline{D(A)}$.

DEFINITION 3.2. *We will say that* $\Phi = \varphi + \psi \in C^1(H) + Lip(H)$ *is a subtest (supertest, respectively) function if*

$$\varphi(Px) \le \varphi(x) \quad \textit{and} \quad \psi(Px) \le \psi(x) \quad \textit{for} \quad x \in H, \tag{3.2}$$

$$\left(\varphi(Px) \ge \varphi(x) \quad \textit{and} \quad \psi(Px) \ge \psi(x) \quad \textit{for} \quad x \in H, \quad \textit{respectively}\right). \tag{3.3}$$

Remark 3.3. As explained in [15], the restrictions on ψ in (3.2) and (3.3) are made only for notational convenience. Since only the values of ψ on $\overline{D(A)}$ matter, one can always extend ψ from $\overline{D(A)}$ to all of H via $\psi(x) = \psi(Px)$ without increasing its Lipschitz constant to guarantee that (3.2) and (3.3) hold.

The notion of viscosity solution we are about to introduce is specific for equations of the form (1.6) but trivially adapts to include more general equations arising in optimal control and differential games. The technical reasons for introducing a new concept instead of following [15] exactly are presented in Remark 3.7 below along with comments explaining the relationship between this notion and the one due to Tataru and Crandall–Lions.

Given an extended real-valued function w on $\overline{D(A)}$, we denote by w^* and w_* its upper and lower semicontinuous envelopes, respectively; i.e., for $x \in \overline{D(A)}$,

$$w^*(x) = \limsup_{\overline{D(A)}\ni y\to x} w(y), \quad w_*(x) = \liminf_{\overline{D(A)}\ni y\to x} w(y).$$

DEFINITION 3.4. *Suppose that* (2.1) *holds and let* g *as in* (2.4) *be lower semicontinuous. Then* $w \in USC(\overline{D(A)})$ *(*$w \in LSC(\overline{D(A)})$*, respectively) is a viscosity subsolution (respectively, supersolution) of* (1.6) *if for every subtest (respectively, supertest) function* $\Phi = \varphi + \psi \in C^1(H) + Lip(H)$ *and a local maximum (respectively,*

minimum) $\hat{x} \in \mathrm{dom}(w)$ *of* $w - \Phi$ *relative to* $\overline{D(A)}$ *we have*

$$D_A^- \Phi(\hat{x}) + \sup_{u \in U} \left\{ -\langle f(\hat{x}, u), D\varphi(\hat{x}) \rangle - L(\psi) \| f(\hat{x}, u) \| - \tfrac{1}{2} \|u\|^2 \right\} \leq g^*(\hat{x}), \tag{3.4}$$

$$\left(D_A^+ \Phi(\hat{x}) + \sup_{u \in U} \left\{ -\langle f(\hat{x}, u), D\varphi(\hat{x}) \rangle + L(\psi) \| f(\hat{x}, u) \| - \tfrac{1}{2} \|u\|^2 \right\} \geq g(\hat{x}) \right). \tag{3.5}$$

A function w *(not necessarily continuous) defined on* $\overline{D(A)}$ *is a solution of* (1.6) *if* w^* *is a subsolution and* w_* *is a supersolution of* (1.6).

In the following we write $B_r(x)$ for the closed ball in H of radius r centered at x. Note that in both (3.4) and (3.5) one can replace $L(\psi)$ by a local Lipschitz constant for ψ. Indeed, suppose that ψ is $L-$Lipschitz on $B_r(\hat{x})$. Let Q denote the (orthogonal) projection onto $B_r(\hat{x}) \cap \overline{D(A)}$ and put $\tilde{\psi}(x) = \psi(QPx)$. Then $\tilde{\psi}(Px) = \tilde{\psi}(x)$ for all x, $\tilde{\psi}$ is $L-$Lipschitz on H and coincides with ψ near $\hat{x}$ on $\overline{D(A)}$, and therefore can be used in place of ψ. Also by modifying φ away from $\hat{x}$ using an appropriate cut-off technique one can achieve that it is not restrictive to suppose $\varphi \in Lip(H)$; this can be done without destroying the subtest (or supertest) property.

Remark 3.5. Note that if u is a solution of (1.6) then the supersolution condition (3.5) may have to be checked at all points $\hat{x} \in \mathrm{dom}(w_*)$, even for $\hat{x} \in \mathrm{dom}(w_*) \setminus \mathrm{dom}(g)$, while the subsolution condition (3.4) is meaningful only at points $\hat{x} \in \overline{D(A)}$ such that both w and g are locally bounded from above near $\hat{x}$ on $\overline{D(A)}$, since otherwise either $\hat{x} \notin \mathrm{dom}(w^*)$ or $g^*(\hat{x}) = +\infty$ and (3.4) is trivially satisfied. In particular, it follows that (3.4) trivializes unless $\hat{x} \in \mathrm{dom}(g^*) \subset \mathrm{int}(K)$ (the interior is taken with respect to $\overline{D(A)}$). This shows that in our problem, at least when K has an empty interior, the role of subsolutions is neither particularly meaningful nor helpful. We considered the Hamilton–Jacobi–Bellman equation (1.6) for our problem in the whole of $\overline{D(A)}$ only for notational convenience. As a matter of fact the supersolution condition really plays a role only in $K = \overline{\mathrm{dom}(g)}$, as the following result shows.

PROPOSITION 3.6. *Let* $\Omega \subset \overline{D(A)}$ *be relatively open and* $u \in LSC(\overline{D(A)})$ *be bounded from below. Then* u *is a supersolution of*

$$\langle Ax, Du \rangle = +\infty \quad \text{in} \quad \Omega \tag{3.6}$$

if and only if $u \equiv +\infty$ *in* Ω.

In the proof of Proposition 3.6 (and also in the proof of Lemma 5.5 below) we will use a perturbed optimization technique due to Tataru (see [25] and also Crandall–Lions [15]). For $x, y \in \overline{D(A)}$ define the Tataru distance d by

$$d(x, y) = \inf_{t \geq 0} \{ t + \|x - S(t)y\| \};$$

d is almost a metric (it lacks symmetry). In [25] Tataru proved a version of the classical Ekeland ε-variational principle with d in place of the norm. Subsequently, this optimization technique was successfully employed in proofs of comparison and uniqueness of viscosity solutions by Tataru and then Crandall and Lions; see [24], [15], [25], and the proof of Lemma 5.5.

Proof of Proposition 3.6. Of course we only need to show the necessary part. Suppose that $u(z) < +\infty$, $z \in \Omega$. Choose $r > 0$ such that $\overline{B_{2r}(z)} \cap \overline{D(A)} \subset \Omega$ and pick any $y \in B_r(z) \cap D(A)$. Since u is bounded from below, by choosing sufficiently large $M > 0$ we can guarantee that

$$g(z) + \sigma < \inf \{ g(x) \colon\ x \in \overline{D(A)},\ \|x - z\| = 2r \}, \tag{3.7}$$

where $\sigma > 0$ and $g(x) = u(x) + M\|x-y\|^2$ ($\inf \emptyset = +\infty$). For $\epsilon > 0$ use Tataru's perturbed optimization (see [25]) to find $\hat{x} \in \overline{B_{2r}(z)} \cap \overline{D(A)}$ such that the mapping $x \mapsto g(x) + \epsilon\, d(x, \hat{x})$ has at $\hat{x}$ finite minimum over $\overline{B_{2r}(z)} \cap \overline{D(A)}$. From (3.7) it follows that if ϵ is sufficiently small then $\|\hat{x} - z\| < 2r$ and, consequently, $u(x) + M\|x-y\|^2 + \epsilon\, d(x, \hat{x})$ has at $\hat{x}$ local minimum relative to Ω. Denoting $\Phi(x) = -M\|x-y\|^2 - \epsilon\, d(x, \hat{x})$, Φ is a supertest function and

$$D_A^+\Phi(\hat{x}) \le -2M\langle A^\circ y, \hat{x} - y\rangle + \epsilon < +\infty$$

(see Lemma 2.2 in [15]), which contradicts (3.6). □

Remark 3.7. We recall here the definition of solution employed by Crandall and Lions in [15] and compare it with ours. In order to interpret the term "$D\psi$" for merely Lipschitz ψ in the general case of (3.1), for $(x, r, p) \in \Omega \times \mathbb{R} \times H$ and $\lambda > 0$, they introduce the notation

$$F_\lambda(x, r, p) = \inf\,\{F(x, r, p + q):\ q \in H,\ \|q\| \le \lambda\}$$

and

$$F^\lambda(x, r, p) = \sup\,\{F(x, r, p + q):\ q \in H,\ \|q\| \le \lambda\}\,.$$

A function $u \in USC(\Omega)$ ($u \in LSC(\Omega)$, respectively) is a CL-viscosity subsolution (respectively, CL-supersolution) of (3.1) with a continuous F if for every subtest (respectively, supertest) function $\Phi = \varphi + \psi \in C^1(H) + Lip(H)$ and a local maximum (respectively, minimum) $\hat{x} \in \mathrm{dom}(u)$ of $u - \Phi$ relative to Ω, we have

$$D_A^-\Phi(\hat{x}) + F_{L(\psi)}(\hat{x}, u(\hat{x}), D\varphi(\hat{x})) \le 0,$$
$$\Big(D_A^+\Phi(\hat{x}) + F^{L(\psi)}(\hat{x}, u(\hat{x}), D\varphi(\hat{x})) \ge 0, \quad \text{respectively}\Big).$$

These definitions still make sense for extended real-valued F. In this case, as well as in the case of discontinuous F, the definitions of sub- and supersolutions have to be modified in a usual way by inserting appropriate semicontinuous envelopes (e.g., F_* for the subsolution condition and F^* for supersolutions).

Note that if $F(x, r, p) = \sup_{u \in U}\left\{-\langle f(x, u), p\rangle - \frac{1}{2}\|u\|^2\right\} - g(x)$ is as in (1.6) then both notions of supersolutions clearly coincide, while the notion of Crandall–Lions' subsolution is stronger than the one given in Definition 3.4. The reason for introducing a new concept of solution as in Definition 3.4 is to eliminate "error terms" which appear while proving that the value function of a control problem or a differential game solves the associated Hamilton–Jacobi equation; see, e.g., the proof in the next section and also [12], [24], and [19]. Such error terms can be eliminated by means of comparison principle if it holds for the equation under consideration; see [12] and [19] for the appropriate argument. Problems of type (1.6) that we study here fail to have unique solutions and we dispense with error terms by relaxing the notion of solution. We observe however that our notion applied to Hamiltonians satisfying typical conditions required to carry out the proof of uniqueness of viscosity solutions yields the same unique solution as the one in [15].

Next two auxiliary lemmas on change of variables will be used in the proof of the main result in section 5. For convenience, Lemmas 3.8 and 3.9 are stated for general Hamiltonians and Crandall–Lions's notion of supersolution. We will apply them to Hamiltonians as in (1.6), recalling that in this case, by Remark 3.7, the two notions of supersolutions as given in [15] and in Definition 3.4 are equivalent.

LEMMA 3.8. *Suppose that* $w:\Omega \to [0,+\infty]$ *is a CL-supersolution of*

$$\langle Ax, Dw\rangle + F(x,Dw) = 0 \quad \text{in} \quad \Omega, \tag{3.8}$$

where $\Omega \subseteq \overline{D(A)}$ *and* $F:\Omega \times H \to \mathbb{R}$ *is upper semicontinuous and locally uniformly continuous in its second variable. Then* $W(x) = 1 - e^{-w(x)}$ *is a CL-supersolution of*

$$\langle Ax, DW\rangle + \overline{F}(x,W(x),DW) = 0 \quad \text{in} \quad \Omega \cap \{x: W(x) < 1\} = \Omega \cap \mathrm{dom}(w), \tag{3.9}$$

where $\overline{F}(x,r,p) = (1-r)F\left(x, p/(1-r)\right)$.

Proof. For $r \in \mathbb{R} \cup \{+\infty\}$ put $\rho(r) = 1 - e^{-r}$, where $\rho(+\infty) = 1$; then $W = \rho(w)$ and $0 \le W \le 1$, but $W < 1$ on $\mathrm{dom}(w)$. Let $\Phi = \varphi + \psi$ be a supertest function and suppose that $W - \Phi$ has a local minimum (relative to $\Omega \cap \mathrm{dom}(w)$) at $\hat{x} \in \Omega \cap \mathrm{dom}(w)$, so $W(\hat{x}) < 1$. Without loss of generality we may assume that

$$\varphi(\hat{x}) = W(\hat{x}), \quad \psi(\hat{x}) = 0, \quad \varphi + \psi < 1, \quad \varphi < 1 \quad \text{on} \quad H. \tag{3.10}$$

Locally near $\hat{x}$ on $\Omega \cap \mathrm{dom}(w)$,

$$W \ge \varphi + \psi = \rho(\tilde{\varphi}) + e^{-\tilde{\varphi}} e^{\tilde{\varphi}} \psi = \rho\left(\tilde{\varphi} + \rho^{-1}\left(e^{\tilde{\varphi}}\psi\right)\right),$$

with equality at $\hat{x}$, where $\tilde{\varphi} = \rho^{-1}(\varphi) = -\ln(1-\varphi)$. It follows that $w - \tilde{\varphi} - \tilde{\psi}$ has a local minimum relative to Ω at $\hat{x}$, where $\tilde{\psi} = \rho^{-1}(e^{\tilde{\varphi}}\psi) = -\ln(1 - \frac{\psi}{1-\varphi})$. We will show that $\tilde{\varphi} + \tilde{\psi}$ is a supertest function. Clearly $\tilde{\varphi}(Px) \ge \tilde{\varphi}(x)$ for all x, $\tilde{\varphi} \in C^1(H)$ and $D\tilde{\varphi}(\hat{x}) = D\varphi(\hat{x})/(1 - W(\hat{x}))$. Formally (but strictly a.e. in every direction)

$$D\tilde{\psi}(x) = \frac{(1-\varphi(x))D\psi(x) + \psi(x)D\varphi(x)}{(1-\varphi(x))(1-\varphi(x)-\psi(x))} \to \frac{D\psi(\hat{x})}{1 - W(\hat{x})} \quad \text{as} \quad x \to \hat{x}.$$

Therefore,

$$L(\tilde{\psi}_{|B_r(\hat{x})}) \le \frac{L(\psi)}{1 - W(\hat{x})} + o(1) \quad \text{as} \quad r \downarrow 0,$$

and from (3.8) and the locally uniform continuity of H

$$D_A^+(\tilde{\varphi} + \tilde{\psi})(\hat{x}) + F^{\frac{L(\psi)}{1-W(\hat{x})}}\left(\hat{x}, D\varphi(\hat{x})/(1 - W(\hat{x}))\right) \ge 0. \tag{3.11}$$

Now note that for any $y \in \overline{D(A)}$ and $h > 0$, from the mean value theorem

$$\begin{aligned}
&\tilde{\varphi}(y) + \tilde{\psi}(y) - \tilde{\varphi}\left(S(h)y\right) - \tilde{\psi}\left(S(h)y\right) \\
&\quad = \ln\left(1 - \varphi\left(S(h)y\right) - \psi\left(S(h)y\right)\right) - \ln(1 - \varphi(y) - \psi(y)) \\
&\quad = \tfrac{1}{\alpha}\left(\varphi(y) + \psi(y) - \varphi\left(S(h)y\right) - \psi\left(S(h)y\right)\right)
\end{aligned}$$

for some number α between $1 - \varphi\left(S(h)y\right) - \psi\left(S(h)y\right)$ and $1 - \varphi(y) - \psi(y)$. From (3.10) $\alpha \to 1 - W(\hat{x})$ as $y \to \hat{x}$ and $h \downarrow 0$ and consequently

$$D_A^+(\tilde{\varphi} + \tilde{\psi})(\hat{x}) \le \frac{1}{1 - W(\hat{x})} D_A^+(\varphi + \psi)(\hat{x}).$$

Combining this with (3.11) gives

$$D_A^+(\varphi + \psi)(\hat{x}) + \overline{F}^{L(\psi)}(\hat{x}, W(\hat{x}), D\varphi(\hat{x})) \ge 0$$

and (3.9) follows. ∎

LEMMA 3.9. *Let $\Omega \subseteq \overline{D(A)}$ and $F\colon \overline{D(A)} \times [0,1] \times H \to \mathbb{R} \cup \{+\infty\}$ be upper semicontinuous. Suppose that $W\colon \Omega \to [0,1)$ is a CL-supersolution of*

$$\langle Ax, DW\rangle + F(x, W(x), DW) = 0 \quad in \quad \Omega.$$

Define

$$\widetilde{W}(x) = \begin{cases} W(x) & if \quad x \in \Omega, \\ 1 & if \quad x \in \overline{D(A)}\backslash\Omega. \end{cases}$$

If $F(x,1,0) \geq 0$ for $x \in \overline{D(A)}\backslash\Omega$ and $\widetilde{W} \in LSC(\overline{D(A)})$, then it is a CL-supersolution of

$$\langle Ax, D\widetilde{W}\rangle + F(x, \widetilde{W}(x), D\widetilde{W}) \geq 0 \quad in \quad \overline{D(A)}.$$

Proof. Suppose that $\widetilde{W} - \Phi$ has a local minimum relative to $\overline{D(A)}$ at $\hat{x} \in \overline{D(A)}$. If $\hat{x} \in \Omega$ there is nothing to show. Otherwise, since Φ is a supertest function, it follows that

$$\Phi(\hat{x}) - \Phi(x) \geq \Phi(\hat{x}) - \Phi(Px) \geq \widetilde{W}(\hat{x}) - \widetilde{W}(Px) = 1 - \widetilde{W}(Px) \geq 0,$$

provided $x \in H$ is sufficiently close to $\hat{x}$, so Φ has a local maximum relative to H at $\hat{x}$ and therefore $\|D\varphi(\hat{x})\| \leq L(\psi)$. Moreover,

$$D_A^+\Phi(\hat{x}) \geq \limsup_{h\downarrow 0} \frac{\Phi(\hat{x}) - \Phi\left(S(h)\hat{x}\right)}{h} \geq 0$$

and then

$$D_A^+\Phi(\hat{x}) + F^{L(\psi)}\left(\hat{x}, \widetilde{W}(\hat{x}), D\varphi(\hat{x})\right) \geq F(\hat{x}, 1, 0) \geq 0. \qquad \square$$

4. Value functions, dynamic programming principle and Hamilton–Jacobi equations. In this section we develop the dynamic programming approach for the value function in (1.3) and an auxiliary value function which will be helpful in the proof of the main result. Let f and g be as in (2.1) and (2.4), respectively. In the following for $t, \lambda > 0$, $x \in \overline{D(A)}$, $u \in L^2$, and $w\colon \overline{D(A)} \to \mathbb{R}$, we denote

$$J(t,x,u) = \int_0^t \left(g(y(s)) + \tfrac{1}{2}\|u(s)\|^2\right) ds$$

and

$$J^\lambda(t,x,u,w) = \int_0^t e^{-\lambda s - J(s,x,u)} \left(g(y(s)) + \tfrac{1}{2}\|u(s)\|^2\right) ds + e^{-\lambda t - J(t,x,u)} w(y(t)), \tag{4.1}$$

where $y(\cdot, x, u)$ is the trajectory of the system (1.1) corresponding to the choice of control $u(\cdot)$ and initial point $x \in \overline{D(A)}$.

We start considering the value function V given by (1.3),

$$V(x) = \inf_{u \in L^2(0,+\infty;U)} \int_0^\infty \left(g(y(t)) + \tfrac{1}{2}\|u(t)\|^2\right) dt$$

and improve the representation formula in (1.5).

LEMMA 4.1. *Assume that $V(x)$ is finite. Then there is $M_x > 0$ such that*

$$V(x) = \inf\{J(x,u):\ u \in \mathcal{U}(x),\ \|u\|_2 \le M_x\}.$$

Proof. The proof is immediate if we observe that by the assumption and the fact that g is nonnegative for all ϵ-optimal controls u for $V(x)$ with $\epsilon \le 1$, we have $\frac{1}{2}\|u\|_2^2 < V(x) + \epsilon$, and then we can take, e.g., $M_x = \sqrt{2(V(x)+1)}$. □

As a consequence the following dynamic programming principle holds.

LEMMA 4.2. *Assume that $V(x)$ is finite. Then there is a constant $M_x > 0$ such that the constrained value function V satisfies, for all $t \ge 0$,*

$$V(x) = \inf\{J(t,x,u) + V(y(t,x,u)):\ u \in \mathcal{U}(x),\ \|u\|_2 \le M_x\} \quad \textit{for} \quad x \in \mathrm{dom}(V).$$

Proof. If $x \in \mathrm{dom}(V)$, the proof of the fact that

$$V(x) = \inf_{u \in \mathcal{U}(x)} \{J(t,x,u) + V(y(t,x,u))\}$$

is completely standard and we skip it. Since V is nonnegative by definition, the rest of the statement follows by the same argument as in the proof of Lemma 4.1. □

We now proceed with the proof of Proposition 2.4. We start recalling a preliminary technical lemma, which is based on ideas of Tataru, see [24] and [25], but for this particular version of it we refer the reader to the paper by the authors and Święch [19].

LEMMA 4.3. *Let Φ be a subtest function, $\hat{x} \in \overline{D(A)}$, and $D_A^-\Phi(\hat{x}) < +\infty$. Then there exists a modulus ρ (i.e., $\rho\colon [0,+\infty) \to [0,+\infty)$ is continuous, nondecreasing and $\rho(0) = 0$) such that if $v \in L^1(0,t;H)$ and $y(\cdot)$ solves*

$$\begin{cases} y'(s) + Ay(s) \ni v(s) & \textit{for} \quad 0 \le s \le t, \\ y(0) = \hat{y}, \end{cases} \tag{4.2}$$

then

$$\begin{aligned} \Phi(y(t)) - \Phi(\hat{y}) \le -tD_A^-\Phi(\hat{x}) + \int_0^t \langle D\varphi(y(s)), v(s)\rangle ds + L(\psi)\int_0^t \|v(s)\|ds \\ + t\rho\Big(\int_0^t \|v(s)\|ds + \sup_{s\in[0,t]} \|S(t)\hat{x} - \hat{x}\|\Big) \end{aligned} \tag{4.3}$$

for all $0 \le t < \bar{t}$, uniform for v bounded in $L^1(0,\bar{t};H)$ and $\hat{y}$ sufficiently close to $\hat{x}$.

Observe that a supertest version of the previous lemma holds as well by replacing Φ with $-\Phi$. To make the proof of Proposition 2.4 below self-contained we don't assume the lower semicontinuity of V (Proposition 2.3), and this is being taken care of in the course of the proof by introducing V_*. The proof simplifies somewhat if Proposition 2.3 is proved first.

Proof of Proposition 2.4. 1. We start with the supersolution case. Suppose that $V_* - \Phi$ has a local minimum at $\hat{x} \in \mathrm{dom}(V_*) \subset K$ and $V_*(\hat{x}) = \Phi(\hat{x})$. We start proving that

$$D_A^+\Phi(\hat{x}) > -\infty. \tag{4.4}$$

As we mentioned above, it is not restrictive to assume that Φ is Lipschitz. Let $\varepsilon \in (0,1]$ be fixed and $h > 0$ be sufficiently small. Let $x_n \to \hat{x}$ be such that $V(x_n) \to V_*(\hat{x})$.

From the proof of the dynamic programming principle Lemma 4.2 we can find a control u_n^h with $\|u_n^h\|_{L^2(0,h)} \le M_{\hat{x}}$ depending only on $\hat{x}$ such that

$$\varepsilon h + V(x_n) \ge \int_0^h \left(g(y(s,x_n,u_n^h)) + \tfrac{1}{2}\|u_n^h(s)\|^2\right) ds + V(y(h,x_n,u_n^h)),$$

and then as in (2.2), since g is nonnegative,

$$\begin{aligned}
\tfrac{1}{2}\int_0^h \|u_n^h(s)\|^2 ds &\le V(x_n) - V_*(\hat{x}) + V_*(\hat{x}) - V_*(y(h,x_n,u_n^h)) + \varepsilon h \\
&\le V(x_n) - V_*(\hat{x}) + \Phi(\hat{x}) - \Phi(y(h,x_n,u_n^h)) + \varepsilon h \\
&\le V(x_n) - V_*(\hat{x}) + \Phi(\hat{x}) - \Phi(S(h)\hat{x}) + \epsilon h \\
&\quad + L(\Phi)\|S(h)\hat{x} - y(h,x_n,u_n^h)\| \\
&\le V(x_n) - V_*(\hat{x}) + \Phi(\hat{x}) - \Phi(S(h)\hat{x}) + C_{\hat{x}}h + L(\Phi)Lh^{1-q/2}\|u_n^h\|^q_{L^2(0,h)} \\
&\quad + L(\Phi)\|x_n - \hat{x}\|,
\end{aligned}$$

where we put $C_{\hat{x}}$ to emphasize the dependence on $\hat{x}$. Rearranging the terms we can find $M > 0$ depending only on L, $L(\Phi)$, and q such that

$$V(x_n) - V_*(\hat{x}) + L(\Phi)\|x_n - \hat{x}\| + \Phi(\hat{x}) - \Phi(S(h)\hat{x}) + C_{\hat{x}}h \ge h\left(\tfrac{1}{2}r_n^2 - L(\Phi)Lr_n^q\right) \ge -Mh,$$

where $r_n = \|u_n^h\|_{L^2(0,h)}/\sqrt{h}$, and then, letting $n \to +\infty$ first, (4.4) follows.

We now argue by contradiction and suppose that

$$D_A^+\Phi(\hat{x}) + \sup_{u\in U}\{-\langle f(\hat{x},u), D\varphi(\hat{x})\rangle + L(\psi)\|f(\hat{x},u)\| - \tfrac{1}{2}\|u\|^2\} - g(\hat{x}) < -2\theta < 0.$$

That is, for all $u \in L^2(0,+\infty;U)$ and $t \ge 0$ we have

$$D_A^+\Phi(\hat{x}) - \langle f(\hat{x},u(t)), D\varphi(\hat{x})\rangle + L(\psi)\|f(\hat{x},u(t))\| - \tfrac{1}{2}\|u(t)\|^2 - g(\hat{x}) < -2\theta < 0.$$

Observe that for $x_n \to \hat{x}$ and $V(x_n) \to V_*(\hat{x})$, by the proof of Lemma 4.2, the constants $M_{x_n}, M_{\hat{x}}$ can be chosen uniformly bounded in n, say, by M. From (2.2), (2.3), and the assumptions on g, for every sufficiently small $t > 0$ and all $u \in \mathcal{U}(x_n)$, $\|u\|_{L^2} \le M$, we then have

$$D_A^+\Phi(\hat{x}) - \langle f(y_n(s),u(s)), D\varphi(y_n(s))\rangle + L(\psi)\|f(y_n(s),u(s))\| - \tfrac{1}{2}\|u(s)\|^2 - g(y_n(s)) < -\theta$$

for all $s \in [0,t]$, where $y_n(\cdot) = y(\cdot,x_n,u)$. Integrating from 0 to t gives

$$\begin{aligned}
t\left(D_A^+\Phi(\hat{x}) + \theta\right) &\le \int_0^t \left(\langle f\left(y_n(s),u(s)\right), D\varphi(y_n(s))\rangle - L(\psi)\|f(y_n(s),u(s))\|\right) ds \\
&\quad + \int_0^t \left(g\left(y_n(s)\right) + \tfrac{1}{2}\|u(s)\|^2\right) ds
\end{aligned}$$

for every $u \in \mathcal{U}(x_n)$, $\|u\|_2 \le M$, and thus

$$\begin{aligned}
t\left(D_A^+\Phi(\hat{x}) + \theta\right) \le \inf_{u\in\mathcal{U}(x_n),\|u\|_2\le M} \Big\{ &\int_0^t \left(g\left(y_n(s)\right) + \tfrac{1}{2}\|u(s)\|^2\right) ds \\
&+ \int_0^t \left(\langle f\left(y_n(s),u(s)\right), D\varphi(y_n(s))\rangle - L(\psi)\|f(y_n(s),u(s))\|\right) ds \Big\}.
\end{aligned}$$

We now use the dynamic programming principle Lemma 4.2, Lemma 4.3 (its supertest version), and (2.3) and get, for $t > 0$ sufficiently small,

$$\begin{aligned} t\theta &\le \inf_{u\in\mathcal{U}(x_n),\|u\|_2\le M}\Big\{\int_0^t (g(y_n(s))+\tfrac{1}{2}\|u(s)\|^2)ds + \Phi(y_n(s)) - \Phi(x_n)\Big\} \\ &\quad + t\rho(o(1)+\|x_n-\hat{x}\|) \\ &\le \inf_{u\in\mathcal{U}(x_n),\|u\|_2\le M}\Big\{\int_0^t (g(y_n(s))+\tfrac{1}{2}\|u(s)\|^2)ds + V(y_n(s)) - V_*(\hat{x})\Big\} \\ &\quad + \Phi(\hat{x}) - \Phi(x_n) + t\rho(o(1)+\|x_n-\hat{x}\|) \\ &= V(x_n) - V_*(\hat{x}) + \Phi(\hat{x}) - \Phi(x_n) + t\rho(o(1)+\|x_n-\hat{x}\|), \end{aligned}$$

where $o(1)$ is independent of n. Hence a contradiction as $n \to +\infty$ first and $t \downarrow 0$ next.

2. We now turn to the proof that V is a subsolution. Let Φ be a Lipschitz continuous subtest function and assume that $V^* - \Phi$ attains a maximum at $\hat{x} \in \mathrm{dom}(V^*)$; of course this implies that $\hat{x} \in \mathrm{int}(\mathrm{dom}(V^*)) \subset \mathrm{int}(K)$ as V is nonnegative. Moreover, it is not restrictive to assume $V^*(\hat{x}) = \Phi(\hat{x})$.

First we will prove that $D_A^-\Phi(\hat{x}) < +\infty$. Choose $x_n \to \hat{x}$ such that $V(x_n) \to V^*(\hat{x})$. We may also suppose that $\hat{x} \in \mathrm{dom}(g^*)$, as otherwise (3.4) is automatically satisfied. Then for sufficiently small $t > 0$ and large n, the control $u(s) \equiv 0$ for $s \in [0,t]$ and suitably defined afterward is an admissible element of $\mathcal{U}(x_n)$. Note to this end that V is locally bounded at $\hat{x}$; hence $\mathcal{U}(x) \neq \emptyset$ for x close to $\hat{x}$. From $\hat{x} \in \mathrm{dom}(g^*)$ and (2.3) it follows that $g(y(s,x_n,u))$ stay bounded uniformly in t small and n big. Denote this upper bound by $C_{\hat{x}}$; then by Lemma 4.2 we have

$$V(x_n) - V(y(t,x_n,u)) \le \int_0^t g(y(s,x_n,u))ds \le C_{\hat{x}}t.$$

Letting $n \to \infty$ and proceeding as in (2.2) gives, for t sufficiently small,

$$\begin{aligned} C_{\hat{x}}t &\ge V^*(\hat{x}) - V^*(y(t,\hat{x},u)) \ge \Phi(\hat{x}) - \Phi(y(t,\hat{x},u)) \\ &\ge \Phi(\hat{x}) - \Phi(S(t)\hat{x}) - L(\Phi)b\|y(t,\hat{x},u) - S(t)\hat{x}\| \ge \Phi(\hat{x}) - \Phi(S(t)\hat{x}) - L(\Phi)Ct, \end{aligned}$$

with some constant $C > 0$, which implies that $D_A^-\Phi(\hat{x}) < +\infty$.

We now again argue by contradiction and suppose that

$$D_A^-\Phi(\hat{x}) + \sup_{u\in U}\big\{-\langle f(\hat{x},u), D\varphi(\hat{x})\rangle - L(\psi)\|f(\hat{x},u)\| - \tfrac{1}{2}\|u\|^2\big\} - g^*(\hat{x}) > 2\theta > 0.$$

Then there is $u^* \in U$ such that

$$D_A^-\Phi(\hat{x}) - \langle f(\hat{x},u^*), D\varphi(\hat{x})\rangle - L(\psi)\|f(\hat{x},u^*)\| - g^*(\hat{x}) - \tfrac{1}{2}\|u^*\|^2 > 2\theta.$$

Let $x_n \to \hat{x}$ be such that $V(x_n) \to V^*(\hat{x})$. By the proof of Lemma 4.2 we can choose the constants $M_{x_n}, M_{\hat{x}}$ uniformly bounded, say, by M. Note that from $\hat{x} \in \mathrm{int}(\mathrm{dom}(V^*))$ and by (2.3), for a sufficiently small $t > 0$ and then for n large, we can find an admissible control $u^t \in \mathcal{U}(x_n)$ satisfying $u^t(s) = u^*$ for $s \in [0,t]$ (we can suitably extend it outside $[0,t]$). Denoting $y_n(\cdot) = y(\cdot,x_n,u^t)$ from (2.1) and (2.3) there exists $t > 0$ such that, for $s \in [0,t]$ and large n,

$$\begin{aligned} D_A^-\Phi(\hat{x}) &- \langle f(y_n(s),u^t(s)), D\varphi(y_n(s))\rangle \\ &- L(\psi)\|f(y_n(s),u^t(s))\| - g(y_n(s)) - \tfrac{1}{2}\|u^t(s)\|^2 > \theta. \end{aligned} \tag{4.5}$$

Integrating from 0 to t gives

$$t\left(D_A^-\Phi(\hat{x})-\theta\right)\geq\int_0^t\left(\langle f(y_n(s),u^t(s)),D\varphi(y_n(s))\rangle+L(\psi)\|f(y_n(s),u^t(s))\|\right)ds + \int_0^t\left(g(y_n(s))+\tfrac{1}{2}\|u^t(s)\|^2\right)ds$$

and consequently, denoting $y(\cdot)=y(\cdot,x_n,u)$ for a general $u\in\mathcal{U}(x_n)$,

$$t\left(D_A^-\Phi(\hat{x})-\theta\right)\geq\inf_{u\in\mathcal{U}(x_n),\|u\|_2\leq M}\Big\{\int_0^t\left(\langle f(y(s),u(s)),D\varphi(y(s))\rangle + L(\psi)\|f(y(s),u(s))\|\right)ds+\int_0^t\left(g(y(s))+\tfrac{1}{2}\|u(s)\|^2\right)ds\Big\}. \tag{4.6}$$

From this, using Lemma 4.3, we get

$$\begin{aligned}-t\theta&\geq\inf_{u\in\mathcal{U}(x_n),\|u\|_2\leq M}\Big\{\int_0^t\left(g(y(s))+\tfrac{1}{2}\|u(s)\|^2\right)ds+\Phi(y(t))-\Phi(x_n)\Big\}\\&\quad-t\rho_{\hat{x}}(o(1)+\|x_n-\hat{x}\|)\\&\geq\inf_{u\in\mathcal{U}(x_n),\|u\|_2\leq M}\Big\{\int_0^t\left(g(y(s))+\tfrac{1}{2}\|u(s)\|^2\right)ds+V^*(y(t))\Big\}-V^*(\hat{x})\\&\quad+\Phi(\hat{x})-\Phi(x_n)-t\rho_{\hat{x}}(o(1)+\|x_n-\hat{x}\|)\\&\geq V(x_n)-V^*(\hat{x})+\Phi(\hat{x})-\Phi(x_n)-t\rho_{\hat{x}}(o(1)+\|x_n-\hat{x}\|),\end{aligned}$$

where $o(1)$ does not depend on n as $t\downarrow 0$. Letting $n\to+\infty$ we then obtain $-t\theta\geq o(t)$, and this finally leads to a contradiction. ∎

In the rest of this section, we proceed with some results concerning an auxiliary problem we will need in the proof of Proposition 2.5, and for $\lambda>0$ and $w\colon\overline{D(A)}\to\mathbb{R}$ consider the value function

$$v^\lambda(x)=\inf_{u\in L^2}\sup_{t\geq 0}J^\lambda(t,x,u,w)\quad\text{for}\quad x\in\overline{D(A)}. \tag{4.7}$$

The function v^λ is known as the value of a stopping time control problem with stopping cost w.

LEMMA 4.4. *Let $g,w\colon\overline{D(A)}\to\mathbb{R}$ satisfy $0\leq g\leq C$ and $0\leq w\leq 1-\epsilon$ for some $\epsilon,C>0$. Then for every $\lambda>0$ we have $0\leq w\leq v^\lambda\leq(C/(\lambda+C))\wedge(1-\epsilon)<1$.*

Proof. Taking $t=0$ shows that $v^\lambda\geq w$. On the other hand, with the choice of $u(\cdot)\equiv 0$ we get

$$\begin{aligned}v^\lambda(x)&\leq\sup_{t\geq 0}\Big\{1-e^{-\lambda t-\int_0^t g(y(s))ds}(1-w(y(t)))-\lambda\int_0^t e^{-\lambda s-\int_0^s g(y(\sigma))d\sigma}ds\Big\}\\&\leq\sup_{t\geq 0}\Big\{1-\epsilon e^{-\lambda t-\int_0^t g(y(s))ds}-\lambda\int_0^t e^{-(\lambda+C)s}ds\Big\}\\&\leq\sup_{t\geq 0}\Big\{1-\epsilon e^{-(\lambda+C)t}+\tfrac{\lambda}{\lambda+C}\left(e^{-(\lambda+C)t}-1\right)\Big\},\end{aligned}$$

and then we easily reach the conclusion. ∎

LEMMA 4.5. *Under the assumptions and using the notation of Lemma* 4.4*, for a fixed* $\lambda > 0$ *there are* $T, K > 0$ *independent of* $x \in \overline{D(A)}$ *such that*

$$v^\lambda(x) = \inf_{\|u\|_{L^2(0,T)} \le K} \sup_{t \ge 0} J^\lambda(t, x, u, w).$$

Proof. By definition of v^λ, since g and w are nonnegative, we immediately obtain

$$v^\lambda(x) \ge \inf_{u \in L^2} \sup_{t \ge 0} e^{-\lambda t} \rho\Big(\int_0^t \tfrac{1}{2} \|u(s)\|^2 ds \Big),$$

where we recall that $\rho(r) = 1 - e^{-r}$. Therefore, for any ϵ-optimal control u for $v^\lambda(x)$ with $\epsilon \le \bar{\epsilon}$ independent of x, from Lemma 4.4 we have that

$$1 > M \ge v^\lambda(x) + \epsilon \ge e^{-\lambda t} \rho\Big(\int_0^t \tfrac{1}{2} \|u(s)\|^2 ds \Big) \quad \text{for all} \quad t \ge 0.$$

Therefore, if $T > 0$ is sufficiently small we get

$$\rho\Big(\int_0^t \tfrac{1}{2} \|u(s)\|^2 ds \Big) \le M e^{\lambda t} \le M e^{\lambda T} < 1 \quad \text{for all} \quad t \le T$$

and the conclusion by definition of ρ. ∎

As a consequence of the previous two lemmas, the following dynamic programming principle holds for the auxiliary value function v^λ defined by (4.7).

LEMMA 4.6. *Under the assumptions and using the notation of Lemma* 4.4*, for all* $x \in \overline{D(A)}$ *and* $t \ge 0$ *we have that*

$$v^\lambda(x) \ge \inf_{\|u\|_{L^2(0,T) \le K}} J^\lambda(t, x, u, v^\lambda). \tag{4.8}$$

If moreover $(v^\lambda)^*(x) > w^*(x)$*, there is* $\epsilon > 0$ *such that for* $z \in \overline{D(A)}$*,* $\|z - x\| < \epsilon$*, and* $|v^\lambda(z) - (v^\lambda)^*(x)| < \epsilon$*, we have*

$$v^\lambda(z) = \inf_{\|u\|_{L^2(0,T) \le K}} J^\lambda(t, z, u, v^\lambda) \quad \textit{for every } 0 \le t \le \epsilon.$$

Proof. The first part of the statement follows easily from the definition of $v^\lambda(x)$, Lemma 4.5, and the usual dynamic programming principle arguments, and we skip its proof.

We now assume that $x \in \overline{D(A)}$ and $(v^\lambda)^*(x) > w^*(x)$. If the statement was false, we could find sequences $x_n \in \overline{D(A)}$ and $0 < \delta_n, t_n < 1/n$ such that $\|x_n - x\| < 1/n$, $|v^\lambda(x_n) - (v^\lambda)^*(x)| < 1/n$, and

$$v^\lambda(x_n) > \inf_{\|u\|_{L^2(0,T) \le K}} J^\lambda(t_n, x_n, u, v^\lambda) + \delta_n. \tag{4.9}$$

By definition of $v^\lambda(x_n)$, for large n, $1/n \le T$, we can choose a control $u_n \in L^2$, $\|u_n\|_{L^2(0,T)} \le K$, such that

$$J^\lambda(t_n, x_n, u_n, v^\lambda) < v^\lambda(x_n) - \delta_n < \sup_{t \ge 0} J^\lambda(t, x_n, u_n, w),$$

and then using the definition of v^λ and J^λ, we can modify the control u_n off $[0,t_n]$ (we still use the same notation however) in such a way that by a change of variables in the integrals on the left-hand side we get

$$\sup_{t\geq t_n} J^\lambda(t,x_n,u_n,w) < v^\lambda(x_n)-\delta_n < \sup_{t\geq 0} J^\lambda(t,x_n,u_n,w).$$

Hence there is a sequence $s_n\in[0,t_n]$ such that

$$J^\lambda(s_n,x_n,u_n,w)\geq v^\lambda(x_n)-\delta_n. \tag{4.10}$$

By the uniform L^2 estimate on the controls u_n, i.e., $\|u_n\|_{L^2(0,s_n)}\leq K$, the definition of J^λ and by (2.3), we know that

$$\sup_{t\in[0,s_n]}\|y(t,x_n,u_n)-x\|\leq o(1)\quad\text{as}\quad n\to+\infty.$$

Therefore, as $n\to\infty$ in (4.10) we obtain

$$w^*(x)\geq (v^\lambda)^*(x),$$

and then we have a contradiction. □

Given Lemma 4.6, with a proof similar to the one of Proposition 2.4 we can show the following result.

PROPOSITION 4.7. *Under the assumptions of Lemma* 4.4*, if* $w,g\in LSC(\overline{D(A)})$*, for any* $\lambda>0$ *the value function* v^λ *is a viscosity solution of*

$$\begin{aligned}\lambda v^\lambda(x)+\min\Big\{&\langle Ax,Dv^\lambda\rangle+\sup_{u\in U}\left\{-\langle f(x,u),Dv^\lambda\rangle+(v^\lambda(x)-1)(\tfrac12\|u\|^2+g(x))\right\},\\ &v^\lambda(x)-(1+\lambda)w\Big\}=0\quad in\quad \overline{D(A)},\end{aligned} \tag{4.11}$$

where solutions of (4.11) *are defined by adapting Definition* 3.4 *in an obvious way.*

It is well known that stopping time control problems give rise to "quasi-variational inequalities" of the form (4.11); see [23] and the references therein.

5. Regularity and optimality principle. In the course of the proof of our main result we will use inf-convolutions to regularize various functions, including g. For $h\colon H\to\mathbb{R}\cup\{+\infty\}$ and $\epsilon>0$ put

$$h_\epsilon(x)=\inf_{y\in H}\left\{h(y)+\tfrac{1}{2\epsilon}\|x-y\|^2\right\}.$$

If h is lower semicontinuous and bounded from below then h_ϵ converge to h pointwise from below as $\epsilon\downarrow 0$. It is also known that if h is bounded or uniformly continuous then h_ϵ is globally Lipschitz. Moreover, if h is weakly lower semicontinuous then so is h_ϵ; see [9]. Therefore, combining inf-convolutions with an appropriate cut-off technique, for any bounded from below, (weakly) lower semicontinuous function $h\colon\overline{D(A)}\to\mathbb{R}\cup\{+\infty\}$ one can construct a sequence $h_1\leq h_2\leq\cdots\leq h_n\leq\cdots$ of bounded, globally Lipschitz (weakly) lower semicontinuous functions on H such that $h=\sup_n h_n$ on $\overline{D(A)}$.

In what follows we will frequently rely on the following well-known simple fact. X is going to be H equipped with either weak or strong topology.

LEMMA 5.1. *Suppose that X is a topological space and let $\phi, \phi_n : X \to \mathbb{R} \cup \{+\infty\}$ be sequentially lower semicontinuous. If $\phi_1 \le \phi_2 \le \cdots \le \phi_n \le \cdots$ and $\phi = \sup_n \phi_n$ then*

$$\liminf_{n\to\infty} \phi_n(x_n) \ge \phi(x) \quad \text{whenever} \quad x_n \to x \quad \text{in} \quad X. \tag{5.1}$$

Proof. For every $N \ge 1$,

$$\liminf_{n\to\infty} \phi_n(x_n) \ge \liminf_{n\to\infty} \phi_N(x_n) \ge \phi_N(x),$$

and taking a supremum over N gives (5.1). ∎

The following lemma guarantees the existence of optimal controls in the problems we consider and relies on one of the crucial assumptions (W) or (S) (see also Theorem 3.4 in [17]).

LEMMA 5.2. *Assume that* (1.1) *has a unique mild solution for any $u \in L^2(0,\infty;U)$ and $x \in \overline{D(A)}$. Suppose that $g, g_n, \phi, \phi_n \in$ w-LSC($\overline{D(A)}$) (LSC($\overline{D(A)}$), respectively), $0 \le \phi_1 \le \phi_2 \le \cdots \le \phi_n \le \cdots$, $0 \le g_1 \le g_2 \le \cdots \le g_n \le \cdots$, $\sup_n \phi_n = \phi$ and $\sup_n g_n = g$. If* (W) ((S), *respectively*) *holds and*

$$C \equiv \sup_{n\ge 1} \inf_{u\in L^2} \sup_{t\ge 0} \left\{ \int_0^t \left(g_n(y(s)) + \tfrac{1}{2}\|u(s)\|^2 \right) ds + \phi_n(y(t)) \right\},$$

where $y(\cdot) = y(\cdot, x, u)$ is the mild solution of (1.1) *and $x \in \overline{D(A)}$ is fixed, then there exists $u^\# \in L^2$ such that*

$$C = \sup_{t\ge 0} \left\{ \int_0^t \left(g(y(s,x,u^\#)) + \tfrac{1}{2}\|u^\#(s)\|^2 \right) ds + \phi(y(t,x,u^\#)) \right\}. \tag{5.2}$$

Proof. It is clear by definition that C is smaller than the right-hand side of (5.2) for any choice of $u^\# \in L^2$. To prove the opposite inequality, we may assume that $C < +\infty$. For every n there exists $u_n \in L^2$ such that for every $t \ge 0$

$$C + \tfrac{1}{n} \ge \int_0^t \left(g_n(y_n(s)) + \tfrac{1}{2}\|u_n(s)\|^2 \right) ds + \phi_n(y_n(t)) \ge \int_0^t \tfrac{1}{2}\|u_n(s)\|^2 ds.$$

Hence u_n are uniformly bounded in L^2, and one can find $u^\# \in L^2$ such that $u_n \rightharpoonup u^\#$ weakly in $L^2(0,T;U)$ for every $T > 0$ (passing to a subsequence if necessary). By the stability assumption $y_n(s) \equiv y(s,x,u_n)$ converges to $y^\#(s) \equiv y(s,x,u^\#)$ weakly (respectively, strongly) in H for every $s > 0$. Using the lower semicontinuity of ϕ_n's, g_n's, and the norm, from Lemma 5.1 and Fatou's lemma we deduce

$$\begin{aligned} \liminf_{n\to\infty} &\int_0^t \left(g_n(y_n(s)) + \tfrac{1}{2}\|u_n(s)\|^2 \right) ds + \phi_n(y_n(t)) \\ &\ge \int_0^t \left(g(y^\#(s)) + \tfrac{1}{2}\|u^\#(s)\|^2 \right) ds + \phi(y^\#(t)) \end{aligned}$$

for every $t \ge 0$ and the result follows. ∎

COROLLARY 5.3. *Under the assumptions of Proposition* 2.3 *the value function V in* (1.5), *i.e.,*

$$V(x) = \inf_{u\in L^2} \int_0^\infty \left(g(y(s)) + \tfrac{1}{2}\|u(s)\|^2 \right) ds = \inf_{u\in L^2} \sup_{t\ge 0} \left\{ \int_0^t \left(g(s) + \tfrac{1}{2}\|u(s)\|^2 \right) ds \right\}$$

has optimal controls.

Proof. Apply Lemma 5.2 with $g_n \equiv g$ and $\phi_n \equiv 0$. ∎

Given existence of optimal controls, we show that V is lower semicontinuous.

Proof of Proposition 2.3. Suppose for instance that $g \in w\text{-}LSC(\overline{D(A)})$ and that (W) holds (the other case follows similarly). Let $x_n \rightharpoonup x$, $x_n, x \in \overline{D(A)}$. We may assume that $\liminf_{n\to\infty} V(x_n) < +\infty$, and, passing to a subsequence, that $V(x_n)$ converges to $\liminf_{n\to\infty} V(x_n)$. From Corollary 5.3 for every n there exists $u_n \in L^2$ an optimal control for $V(x_n)$; that is,

$$V(x_n) \geq \int_0^t \left(g(y(s, x_n, u_n)) + \tfrac{1}{2}\|u_n(s)\|^2\right) ds \quad \text{for every} \quad t \geq 0. \tag{5.3}$$

Then $\|u_n\|_2$ are uniformly bounded and there is $u^\# \in L^2$ such that $u_n \rightharpoonup u^\#$ weakly in $L^2(0,T;U)$ for all $T > 0$ (passing to a subsequence if necessary), and then by (W) $y(s, x_n, u_n) \rightharpoonup y^\#(s) \equiv y(s, x, u^\#)$ weakly in H for every $s > 0$. Taking $\liminf$ as $n \to \infty$ in (5.3) yields, as in the proof of Lemma 5.2,

$$\liminf_{n\to\infty} V(x_n) \geq \int_0^t \left(g(y^\#(s)) + \tfrac{1}{2}\|u^\#(s)\|^2\right) ds$$

for every $t > 0$ and therefore $\liminf_{n\to\infty} V(x_n) \geq V(x)$. ∎

Proposition 2.5 is contained in the statement of Lemma 5.5 below, which is an optimality principle for viscosity supersolutions of equation (1.6). First, however, we prove the following elementary statement.

LEMMA 5.4. *Let $F\colon \overline{D(A)} \times H \times \mathbb{R} \times [0,1) \to \mathbb{R}$ be defined by*

$$F(x,p,r,s) = \sup_{u\in U} \left\{-\langle f(x,u), p\rangle + \|f(x,u)\| r - \tfrac{1}{2}\|u\|^2(1-s)\right\},$$

where f satisfies (2.1). Then for all $R > 0$ and $k \in (0,1)$ there is $C = C(R,k) > 0$ such that if $x \in \overline{D(A)}$, $\|p\|, |r| \leq R$ and $s \in [0, 1-k]$ then $\|u^*\| \leq C(1 + \sqrt{\|x\|})$ for any $u^* \in U$ satisfying

$$F(x,p,r,s) - 1 \leq -\langle f(x,u^*), p\rangle + \|f(x,u^*)\| r - \tfrac{1}{2}\|u^*\|^2(1-s).$$

Proof. Observe that by the assumption (2.1), $F(x,p,r,s)$ is finite for all $(x,p,r,s) \in \overline{D(A)} \times H \times \mathbb{R} \times [0,1)$. From one side, by choosing $u = 0$ we have by (2.1)

$$F(x,p,r,s) - 1 \geq -1 - L(1 + \|x\|)(\|p\| + |r|) \geq -1 - 2LR(1 + \|x\|),$$

for $x \in \overline{D(A)}$, $\|p\|, |r| \leq R$, and $s \in [0,1)$. On the other hand, if $x \in \overline{D(A)}$, $\|p\|, |r| \leq R$, and $s \in [0, 1-k]$ then, again by (2.1), we have for all $u \in U$,

$$\begin{aligned} -\langle f(x,u), p\rangle + \|f(x,u)\| r - \tfrac{1}{2}\|u\|^2(1-s) &\leq L(1 + \|x\| + \|u\|^q)(\|p\| + |r|) - \tfrac{1}{2}k\|u\|^2 \\ &\leq 2LR(1 + \|x\| + \|u\|^q) - \tfrac{1}{2}k\|u\|^2. \end{aligned}$$

Therefore, to reach the conclusion it is enough to consider only u's such that

$$\|u\|^q - \tfrac{k}{4LR}\|u\|^2 \geq -2(1 + \|x\|) - \tfrac{1}{2LR}. \tag{5.4}$$

We will use the elementary fact that for every $q \in [1,2)$ there is a constant C depending only on q (namely, $C = (\frac{q}{2})^{q/(2-q)} - (\frac{q}{2})^{2/(2-q)}$) such that

$$s^q \leq \epsilon s^2 + C\left(\tfrac{1}{\epsilon}\right)^{q/(2-q)} \quad \text{for all} \quad \epsilon > 0,\ s \geq 0.$$

(One quick way to prove this is to realize that it is equivalent to proving $\psi(s\epsilon^{1/(2-q)}) \geq -C$ for $\psi(r) = r^2 - r^q$.) Taking $\epsilon = \frac{k}{8LR}$ from (5.4) it follows that only u's satisfying

$$-\tfrac{1}{2LR} - 2(1 + \|x\|) \leq -\tfrac{k}{8LR}\|u\|^2 + C(\tfrac{8LR}{k})^{q/(2-q)}$$

or equivalently

$$\|u\|^2 \leq \tfrac{16LR}{k}(1 + \|x\|) + C(\tfrac{8LR}{k})^{2/(2-q)} + \tfrac{4}{k}$$

are of interest, from which the conclusion follows easily. □

We are now left with the most delicate step of the proof.

LEMMA 5.5. *Assume* (2.1) *and* (2.4). *Suppose that* $g \in w\text{-}LSC(\overline{D(A)})$ ($g \in LSC(\overline{D(A)})$) *and* (W) ((S), *respectively*) *holds. Suppose that* $w \in w\text{-}LSC(\overline{D(A)})$ ($w \in LSC(\overline{D(A)})$, *respectively*) *is a nonnegative extended real-valued viscosity supersolution of* (1.6). *Then*

$$w(x) = \inf_{u\in L^2} \sup_{t\geq 0} \left\{ \int_0^t \left(g(y(s)) + \tfrac{1}{2}\|u(s)\|^2\right) ds + w(y(t)) \right\} \quad \text{for all} \quad x \in \overline{D(A)}. \tag{5.5}$$

In particular $w \geq V$.

Proof. We treat the weakly lower semicontinuous case, the other case being similar.

1. Suppose that $w \in w\text{-}LSC(\overline{D(A)})$ is a nonnegative supersolution of (1.6). Construct two increasing sequences $0 \leq g_1 \leq g_2 \leq \cdots$ and $0 \leq w_1 \leq w_2 \leq \cdots$ of bounded, globally Lipschitz and weakly lower semicontinuous functions defined on H such that on $\overline{D(A)}$ $g = \sup_n g_n$ and $w = \sup_n w_n$, as at the beginning of this section. For every n put $W_n(x) = 1 - e^{-w_n(x)} \equiv \rho(w_n(x))$; $0 \leq W_n < 1$. Note that from (2.1) the Hamiltonian $H_n(x,p) = \sup_{u\in U}\{-\langle f(x,u),p\rangle - \frac{1}{2}\|u\|^2\} - g_n(x)$ is uniformly continuous on bounded subsets of $\overline{D(A)} \times H$ and therefore from Lemma 3.8 for every $\lambda > 0$ and $n \in \mathbb{N}$, $W = \rho(w)$ is a CL-supersolution of

$$\lambda W(x) + \langle Ax, DW\rangle + \sup_{u\in U}\left\{-\langle f(x,u), DW\rangle + (W(x)-1)(g_n(x) + \tfrac{1}{2}\|u\|^2)\right\} = 0$$

on $\{x \in \overline{D(A)}\colon W(x) < 1\} = \mathrm{dom}(w)$. We extend W by 1 off $\mathrm{dom}(w)$ (we still call this extended function W). Since $W \in w\text{-}LSC(\overline{D(A)})$, by Lemma 3.9 W is a CL-supersolution of

$$\lambda W(x) + \min\left\{\langle Ax, DW\rangle + \overline{H}_n(x, W(x), DW),\ W(x) - (1+\lambda)W_n(x)\right\} = 0 \quad \text{in} \quad \overline{D(A)}, \tag{5.6}$$

where for $(x,r,p) \in \overline{D(A)} \times [0,1] \times H$ we denote

$$\overline{H}_n(x,r,p) = \sup_{u\in U}\left\{-\langle f(x,u),p\rangle + \tfrac{1}{2}(r-1)\|u\|^2\right\} + (r-1)g_n(x).$$

Observe that $\overline{H}_n(x,1,p)$ may be infinite, but $\overline{H}_n(x,1,0) = 0$ so that $\overline{H}_n^*(x,1,0) \geq 0$ and the proof of Lemma 3.9 applies. Also note that from Lemma 5.4 one can easily show that $\overline{H}_n$ is uniformly continuous on bounded closed subsets of $\overline{D(A)} \times [0,1) \times H$. By Remark 3.7, W is a supersolution of (5.6) in the sense of Definition 3.4.

2. For $n \in \mathbb{N}$ and $x \in \overline{D(A)}$ let $U(x) = \inf_{u\in L^2} \sup_{t\geq 0} J_n^\lambda(t,x,u,W_n)$ be as in (4.7) and (4.1) with $g \equiv g_n$. By Lemma 4.4 there is $\kappa > 0$ such that $0 \leq U \leq 1-2\kappa$. Moreover, U^* is a subsolution of (5.6) by Proposition 4.7. We will show that

$$U^* \leq W \quad \text{on} \quad \overline{D(A)}. \tag{5.7}$$

The proof of (5.7) follows along the lines of the standard comparison theorem despite the Hamiltonian in (5.6) being possibly discontinuous and extended real valued, and we will only highlight the main points. To show (5.7) we argue by contradiction and suppose that $U^*(\hat z) - W(\hat z) \equiv 2\gamma > 0$ for some $\hat z \in \overline{D(A)}$.

We first make the following general remark. Let $\Psi\colon H\times H \to \mathbb{R}$, $\Psi = \varphi + \psi$, be a nonnegative subtest function for the operator $A \times A$ on $\overline{D(A)} \times \overline{D(A)}$. Assume that $U^*(x) - W(y) - \Psi(x,y)$ attains a maximum point at $(\hat x, \hat y)$ and $U^*(\hat x) - W(\hat y) - \Psi(\hat x, \hat y) > 0$. In particular we get

$$0 \leq W(\hat y) \leq U^*(\hat x) \leq 1 - 2\kappa.$$

Hence $(\hat y, W(\hat y)) \in \operatorname{dom}(w) \times [0, 1-2\kappa]$ and at $\hat x$, $\hat y$ we can use the equations for U^*, W, respectively, and the uniform continuity of $\overline{H}_n$ on the bounded subsets of $\overline{D(A)} \times [0,1-2\kappa] \times H$. It follows that with such test functions the proof of the doubling Theorem 3.1 in [15] can be applied (no matter if we use the notion of solution introduced in Definition 3.4 instead of the one employed in [15]).

3. For the sake of simplicity we start assuming that $(0,0) \in A$, so that $\varphi(x) = \|x\|^2$ is a subtest function and $D_A^- \varphi \geq 0$, as easily checked. For $\alpha, \delta > 0$ and $x, y \in \overline{D(A)}$ let

$$\Phi(x,y) = U^*(x) - W(y) - \tfrac{\alpha}{2}\|x-y\|^2 - \delta\|x\|^2 - \delta\|y\|^2;$$

note that $\Phi \leq 1 - 2\kappa$ and, for sufficiently small δ,

$$\sup \Phi \geq U^*(\hat z) - W(\hat z) - 2\delta\|\hat z\|^2 \geq \gamma.$$

For every $\epsilon > 0$ use perturbed optimization with Tataru's distance to find $\hat x, \hat y \in \overline{D(A)}$ such that $\Phi(\hat x, \hat y) \geq \sup\Phi - \epsilon$ and the map $\Phi(x,y) - \epsilon d(x,\hat x) - \epsilon d(y,\hat y)$ has a strict global maximum at $(\hat x, \hat y)$. Note that

$$\sup\{\Phi(x,y) - \epsilon d(x,\hat x) - \epsilon d(y,\hat y)\} = \Phi(\hat x, \hat y) \geq \gamma - \epsilon \geq \frac{\gamma}{2} > 0 \tag{5.8}$$

for small ϵ.

Consider two cases. If $U^*(\hat x) \leq W_n(\hat x)$ then

$$U^*(\hat x) - W(\hat y) \leq W_n(\hat x) - W_n(\hat y). \tag{5.9}$$

Otherwise, as we mentioned above, we can apply the doubling theorem in [15] to obtain

$$\begin{aligned}
&\lambda(U^*(\hat x) - W(\hat y)) - 2\epsilon \\
&\quad\leq \sup_{u\in U}\Big\{ -\langle f(\hat y,u), \alpha(\hat x - \hat y) - 2\delta\hat y\rangle + \epsilon\|f(\hat y,u)\| + (W(\hat y)-1)(\tfrac12\|u\|^2 + g_n(\hat y))\Big\} \\
&\qquad - \sup_{u\in U}\Big\{ -\langle f(\hat x,u), \alpha(\hat x - \hat y) + 2\delta\hat x\rangle - \epsilon\|f(\hat x,u)\| + (U^*(\hat x)-1)(\tfrac12\|u\|^2 + g_n(\hat x))\Big\}.
\end{aligned}$$

Note that from (5.8) $W(\hat{y}) \le U^*(\hat{x})$. By standard arguments (see, e.g., Lemma 3.2 in [15]), we can show that

$$\limsup_{\alpha\to\infty} \limsup_{\delta\downarrow 0} \limsup_{\epsilon\downarrow 0} \left(\alpha\|\hat{x}-\hat{y}\|^2 + \delta\|\hat{x}\|^2 + \delta\|\hat{y}\|^2\right) = 0. \tag{5.10}$$

Moreover, since Φ decays quadratically at infinity, for α and δ fixed, $\hat{x}$ and $\hat{y}$ remain bounded uniformly in $\epsilon \downarrow 0$. Therefore, letting $\epsilon \downarrow 0$ and using Lemma 5.4 gives

$$\begin{aligned} &\limsup_{\epsilon\downarrow 0} \lambda(U^*(\hat{x}) - W(\hat{y})) \\ &\le \limsup_{\epsilon\downarrow 0} \left(\overline{H}_n(\hat{y}, U^*(\hat{x}), \alpha(\hat{x}-\hat{y}) - 2\delta\hat{y}) - \overline{H}_n(\hat{x}, U^*(\hat{x}), \alpha(\hat{x}-\hat{y}) + 2\delta\hat{x})\right). \end{aligned} \tag{5.11}$$

Let $R > 0$ and suppose that $x \in \overline{D(A)}$, $\|p\| + \delta\|x\| \le R$, and $0 \le r \le 1 - \frac{1}{R}$. By Lemma 5.4 we can find $C = C(R)$ such that

$$\overline{H}_n(x,r,p) = \sup_{\|u\| \le C(1+\sqrt{\|x\|})} \left\{-\langle f(x,u), p\rangle + \tfrac{1}{2}(r-1)\|u\|^2\right\} + (r-1)g_n(x).$$

From (2.1) we then get

$$\begin{aligned} |\overline{H}_n(x,r,p+\delta x) - \overline{H}_n(x,r,p)| &\le \delta\|x\| L\left(1 + \|x\| + C^q(1+\sqrt{\|x\|})^q\right) \\ &\le \delta\|x\| L\left(1 + \|x\| + (2C)^q\left(1 + \|x\|^{\frac{q}{2}}\right)\right) \to 0, \quad \text{if} \quad \delta + \delta\|x\|^2 \to 0, \end{aligned} \tag{5.12}$$

uniformly for $\delta\|x\| + \|p\| \le R$, $0 \le r \le 1 - \frac{1}{R}$.

From (5.11), (5.12), and (2.1), by letting $\delta \to 0$,

$$\begin{aligned} &\limsup_{\delta\downarrow 0} \limsup_{\epsilon\downarrow 0} \lambda(U^*(\hat{x}) - W(\hat{y})) \\ &\le \limsup_{\delta\downarrow 0} \limsup_{\epsilon\downarrow 0} \left(\overline{H}_n(\hat{y}, U^*(\hat{x}), \alpha(\hat{x}-\hat{y})) - \overline{H}_n(\hat{x}, U^*(\hat{x}), \alpha(\hat{x}-\hat{y}))\right) \\ &\le \limsup_{\delta\downarrow 0} \limsup_{\epsilon\downarrow 0} \left(L\alpha\|\hat{x}-\hat{y}\|^2 + |g_n(\hat{y}) - g_n(\hat{x})|\right), \end{aligned} \tag{5.13}$$

and finally taking lim sup as $\alpha \to \infty$ and using (5.10) and the uniform continuity of g_n yields

$$\limsup_{\alpha\to\infty} \limsup_{\delta\downarrow 0} \limsup_{\epsilon\downarrow 0} (U^*(\hat{x}) - W(\hat{y})) \le 0.$$

The same inequality also holds in the first case because of (5.9) and $\|\hat{x}-\hat{y}\| \to 0$, and then (5.8) yields a contradiction.

If $(0,0) \notin A$ then one replaces $\delta\|x\|^2$ by $\delta\|x-\bar{x}\|^2$ for any fixed $\bar{x} \in D(A)$. As $D_A^-\|x-\bar{x}\|^2 \ge 2\langle A^\circ\bar{x}, x-\bar{x}\rangle$, additional terms of the form $2\delta\langle A^\circ\bar{x}, \hat{x}-\bar{x}\rangle$ appear, but they will vanish when $\delta \downarrow 0$.

4. Thus (5.7) is proved and for every $\lambda > 0$ and $n \ge 1$,

$$W(x) \ge \inf_{u\in L^2} \sup_{t\ge 0} J_n^\lambda(t,x,u,W_n) \quad \text{for} \quad x \in \overline{D(A)}. \tag{5.14}$$

Fix $x \in \overline{D(A)}$. Letting $\lambda \downarrow 0$ in (5.14) we obtain for every fixed $T > 0$,

$$\begin{aligned} W(x) &\ge \inf_{u\in L^2} \sup_{t\in[0,T]} \left\{1 - e^{-\int_0^t (g_n(y(s)) + \frac{1}{2}\|u(s)\|^2)ds}(1 - W_n(y(t)))\right\} \\ &= \inf_{u\in L^2} \sup_{t\in[0,T]} \left\{1 - e^{-\int_0^t (g_n(y(s)) + \frac{1}{2}\|u(s)\|^2)ds - w_n(y(t))}\right\} \\ &= \rho\left(\inf_{u\in L^2} \sup_{t\in[0,T]} \left\{\int_0^t (g_n(y(s)) + \tfrac{1}{2}\|u(s)\|^2)ds + w_n(y(t))\right\}\right), \end{aligned}$$

which implies, for all $n \geq 1$ and $T > 0$,

$$w(x) \geq \inf_{u \in L^2} \sup_{t \in [0,T]} \left\{ \int_0^t (g_n(y(s)) + \tfrac{1}{2}\|u(s)\|^2) ds + w_n(y(t)) \right\}. \tag{5.15}$$

Sending $n \to \infty$ in (5.15) as in Lemma 5.2 (hence here we finally use the assumption (W)), we get, for every $x \in \overline{D(A)}$,

$$w(x) \geq \inf_{u \in L^2} \sup_{t \in [0,T]} \left\{ \int_0^t \left(g(y(s)) + \tfrac{1}{2}\|u(s)\|^2\right) ds + w(y(t)) \right\}. \tag{5.16}$$

In order to pass to the limit as $T \to \infty$ in (5.16) we proceed as follows. For given $\varepsilon > 0$, we apply (5.16) with $T = 1$ and find $u_1 \in L^2$ such that

$$w(x) + \tfrac{\varepsilon}{2} \geq \int_0^t \left(g(y(s, x, u_1)) + \tfrac{1}{2}\|u_1(s)\|^2\right) ds + w(y(t, x, u_1))$$

for $t \in [0, 1]$. Then we apply (5.16) again at $y(1, x, u_1)$ with $T = 1$ and find $u_2 \in L^2$ such that

$$w(y(1, x, u_1)) + \tfrac{\varepsilon}{2^2} \geq \int_0^t \left(g(y(s, y(1, x, u_1), u_2)) + \tfrac{1}{2}\|u_2(s)\|^2\right) ds + w(y(t, y(1, x, u_1), u_2))$$

for $t \in [0, 1]$, and so forth. We proceed recursively and define $u(t) = u_{[t]+1}(t - [t])$ for $t \geq 0$, where $[t]$ denotes the largest integer in $[0, t]$. It then follows that

$$w(x) + \varepsilon \geq \int_0^t \left(g(y(s, x, u)) + \tfrac{1}{2}\|u(s)\|^2\right) ds + w(y(t, x, u)) \quad \text{for all} \quad t \geq 0;$$

therefore, in particular $u \in L^2$ since g and w are nonnegative and $u \in \mathcal{U}(x)$. Since ϵ was arbitrary we obtain for all $x \in \overline{D(A)}$,

$$w(x) \geq \inf_{u \in L^2} \sup_{t \geq 0} \left\{ \int_0^t (g(y(s)) + \tfrac{1}{2}\|u(s)\|^2) ds + w(y(t)) \right\},$$

which concludes the proof since the other inequality follows immediately by choosing $t = 0$ on the right-hand side. ∎

6. Examples. In this section we will quickly present some examples of nonlinear systems satisfying the strong stability condition (S) to which the results of this paper can be applied. These examples are meant to show that the condition is quite natural and is known to be satisfied in many interesting instances. More examples of nonlinear partial differential equations leading to systems of the form (1.1) with $-A$ generating a compact semigroup on a Hilbert space, e.g., reaction-diffusion systems, can be found in [26] and [2]. We do not present examples with a linear operator A that, as we mentioned above, satisfy the weak stability condition (W), but instead we refer the reader to [5].

Example 6.1 (p-Laplace operator). Let Ω be a bounded domain in $\mathbb{R}^n$, $n \geq 1$, with smooth boundary Γ, and let $p \geq 2$. For $\lambda \geq 0$ consider the nonlinear parabolic

equation with distributed parameters

$$\text{(6.1)}\qquad \begin{cases} \dfrac{\partial y}{\partial t} - \displaystyle\sum_{i=1}^{n} \frac{\partial}{\partial x_i}\left(\left| \frac{\partial y}{\partial x_i} \right|^{p-2} \frac{\partial y}{\partial x_i} \right) + \lambda y|y|^{p-2} = f(y,u) \\ \qquad \text{for} \quad (t,x) \in (0,T)\times\Omega, \\ -\displaystyle\sum_{i=1}^{n} \left| \frac{\partial y}{\partial x_i} \right|^{p-2} \frac{\partial y}{\partial x_i} \cdot n_i \in \partial\phi(y) \quad \text{for} \quad (t,x) \in (0,T)\times\Gamma, \\ y(0,x) = y_0(x) \quad \text{for} \quad x \in \Omega. \end{cases}$$

Here $n = (n_1, \dots, n_n)$ denotes the outward normal to Γ and $\phi\colon \mathbb{R} \to [0, +\infty]$ is lower semicontinuous and convex, $\phi(0) = 0$. Then (6.1) gives rise to a system of the form (1.1) in $H = L^2(\Omega)$ with a maximal monotone A, which is in fact the subgradient of a lower semicontinuous and convex function on H and such that $-A$ generates a compact semigroup in H; see [26, Remark 2.2.5]. If f in (6.1) satisfies the assumptions of Proposition 2.7, then (S) holds.

In the previous example, by choosing specific functions ϕ we obtain a number of physical models interesting for the applications; see [2, section 4.3].

Example 6.2. Let Ω be a bounded domain in $\mathbb{R}^n$, $n \geq 2$, with smooth boundary Γ. Consider the boundary value problem

$$\text{(6.2)}\qquad \begin{cases} \dfrac{\partial y}{\partial t} - \Delta y + y^3 = f(y,u) \quad \text{for} \quad (t,x) \in (0,T)\times\Omega, \\ \alpha y(t,x) + \beta \dfrac{\partial y}{\partial n}(t,x) = 0 \quad \text{for} \quad (t,x) \in (0,T)\times\Gamma, \\ y(0,x) = y_0(x) \quad \text{for} \quad x \in \Omega, \end{cases}$$

where $\alpha, \beta \geq 0$ and $\alpha + \beta > 0$. Then again (6.2) can be written in the form (1.1) in $H = L^2(\Omega)$ with a nonlinear maximal monotone A, $D(A) \subset H^2(\Omega)$; see, e.g., [2, p. 256]. From the compact embedding theorem it follows that $-A$ generates a compact semigroup and Proposition 2.7 applies.

In the previous example, the nonlinear perturbation y^3 of the Laplacian is the derivative of a convex function. Such example therefore falls into the class of problems that can be described by means of abstract parabolic variational inequalities; see Remark 2.9. As a matter of fact, the term y^3 can be replaced by any subgradient of a lower semicontinuous and convex function $\phi\colon \mathbb{R} \to \mathbb{R} \cup \{+\infty\}$. When ϕ has nontrivial domain then the corresponding operator is apparently multivalued and our generality is motivated. We will now describe a more explicit and specific example which is a special case of the one-phase Stefan problem; see [2, p. 279].

Example 6.3 (parabolic variational inequalities). Let Ω be a bounded domain in $\mathbb{R}^n$, $n \geq 2$, with smooth boundary Γ. Consider the boundary value problem

$$\text{(6.3)}\qquad \begin{cases} \dfrac{\partial y}{\partial t} - \Delta y \geq f(y,u) \quad \text{for} \quad (t,x) \in (0,T)\times\Omega, \\ \dfrac{\partial y}{\partial t} - \Delta y = f(y,u) \quad \text{if} \quad y(t,x) > 0, \\ y \geq 0, \\ \alpha y(t,x) + \beta \dfrac{\partial y}{\partial n}(t,x) = 0 \quad \text{for} \quad (t,x) \in (0,T)\times\Gamma, \\ y(0,x) = y_0(x) \quad \text{for} \quad x \in \Omega, \end{cases}$$

where $\alpha, \beta \geq 0$ and $\alpha + \beta > 0$. Here again $H = L^2(\Omega)$. In this example, we are in the situation described in Remark 2.9, where $V = H^1(\Omega)$ (or $V = H_0^1(\Omega)$ is $\beta = 0$) and

the operator $\tilde{A} \in \mathcal{L}(V, V')$ (for $\beta \neq 0$) is defined by the position

$$\langle \tilde{A}y, z\rangle = \int_\Omega Dy \cdot Dz \, dx + \tfrac{\alpha}{\beta} \int_{\partial\Omega} yz \, d\sigma.$$

Moreover, the function $\varphi\colon H \to \mathbb{R} \cup \{+\infty\}$ is the indicator function of the set $\{y \in V\colon y \geq 0\}$. Note that a state constraint ($y \geq 0$) appears in the formulation of the problem (6.3), but it is included here in the abstract definition of the operator rather than in the cost g.

We end this section by presenting an example that can be described in abstract form with a noncompact semigroup but still satisfies our stability condition (S); see Remark 2.10. For other examples of this sort, again we refer to [26].

Example 6.4 (nonlinear hyperbolic equations). Let Ω be a bounded domain in $\mathbb{R}^n$, $n \geq 2$, with smooth boundary Γ. Consider the boundary value problem

$$\text{(6.4)} \qquad \begin{cases} \dfrac{\partial^2 y}{\partial t^2} - \Delta y + \beta\left(\dfrac{\partial y}{\partial t}\right) = \displaystyle\sum_{i=1}^{k} w_i(x) u_i(t) \quad \text{for} \quad (t,x) \in (0,T) \times \Omega, \\ y(t,x) = 0 \quad \text{for} \quad (t,x) \in (0,T) \times \Gamma, \\ y(0,x) = y_0(x) \quad \text{for} \quad x \in \Omega, \\ \dfrac{\partial y}{\partial t}(0,x) = y_1(x) \quad \text{for} \quad x \in \Omega. \end{cases}$$

Here $w_i \in L^2(\Omega)$, the control set $B_R^U \subset U = \mathbb{R}^k$ is finite dimensional, so the linear operator defined by the right-hand side of (6.4) has finite-dimensional range, and $\beta\colon \mathbb{R} \to \mathbb{R}$ is continuous, nondecreasing, and of linear growth. One has to check that (6.4) can be described in an abstract form with an operator $-A$ in $H = L^2(\Omega) \times H_0^1(\Omega)$ generating a weakly equicontinuous semigroup, and for this purpose we refer to [26, Theorem 2.9.4]; see also Remark 2.10.

In all the examples above, there are many standard state constraints K that are of interest for the applications. Some instances are described by one of the conditions $\|y\|_{L^2(\Omega)} \leq R$, $y \geq 0$, $\|y\|_{L^\infty(\Omega)} \leq R$. Note that the last two define subsets of $L^2(\Omega)$ with empty interior. Any lower semicontinuous function $l\colon \overline{D(A)} \to [0, +\infty)$ could be combined with the indicator function of K,

$$I_K(y) = \begin{cases} 0, & y \in K, \\ +\infty, & y \notin K, \end{cases}$$

to provide a running cost acceptable for our statements, namely, $g = l + I_K$. An example, for $H = L^2(\Omega)$, which leads to a nonconvex cost is the integral of a w-shaped potential, e.g.,

$$g(y) = \int_\Omega (|y(x)|^2 - 1)^2 \, dx + I_{B_1^{L^\infty(\Omega)}}(y), \quad y \in H.$$

Note that again $\mathrm{dom}(g) = B_1^{L^\infty(\Omega)}$ has an empty interior. In some cases, if $y \equiv 1$ and $y \equiv -1$ are solutions of the parabolic equation with a given control $u(\cdot)$, such control can be proven to produce trajectories fulfilling the constraint for any initial condition in $\mathrm{dom}(g)$ by the maximum principle.

Acknowledgment. The authors wish to thank one of the referees for suggesting some examples of systems that satisfy the abstract assumptions of the paper.

UNIFORM STABILIZABILITY OF A FULL VON KARMAN SYSTEM WITH NONLINEAR BOUNDARY FEEDBACK*

IRENA LASIECKA†

Abstract. Full von Karman system accounting for in-plane accelerations and describing the transient deformations of a thin, elastic plate subject to edge loading is considered. The energy dissipation is introduced via the nonlinear velocity feedback acting on a part of the edge of the plate. It is known [J. Puel and M. Tucsnak, *SIAM J. Control Optim.*, 33 (1995), pp. 255–273] that in the case of *linear* dissipation and "star-shaped" domains, boundary velocity feedback with the tangential derivatives of horizontal displacements leads to the exponential decay rates for the energy of the resulting closed loop system. The main goal of the paper is to derive the *uniform* energy decay rates valid for the model without the above-mentioned restrictions. In particular, it is shown that simple, monotone *nonlinear* feedback (without the tangential derivatives of the horizontal displacements) provides the uniform decay rates for the energy in the absence of *geometric hypotheses* imposed on the controlled part of the boundary. This is accomplished by establishing, among other things, "sharp" regularity results valid for the boundary traces of solutions corresponding to this nonlinear model and by employing a Holmgren-type uniqueness result proved recently in [V. Isakov, *J. Differential Equations*, 97 (1997), pp. 134–147] for the dynamical systems of elasticity which are overdetermined on the boundary.

1. Introduction.

We consider a model of dynamic nonlinear plate that is referred to as the *full von Karman* system and is introduced in [11]. We associate with this model a nonlinear damping represented by moments and shears applied to the edge of the plate. Here the variables w and $u = (u_1, u_2)$ represent, respectively, the vertical and in-plane displacement of a thin plate occupying a two-dimensional domain Ω with sufficiently smooth boundary $\Gamma = \Gamma_0 \cup \Gamma_1$. We shall assume that $\Gamma_0 \cap \Gamma_1 = \emptyset$. The governing equations are given by

$$\begin{aligned} u_{tt} + b_1 u_t - \operatorname{div}[\mathcal{C}[\boldsymbol{\epsilon}(u) + f(\nabla w)]] &= 0 \text{ in } \Omega \times (0,\infty), \\ [I - \gamma\Delta]w_{tt} + b_2 w_t + D\Delta^2 w - \operatorname{div}[\mathcal{C}[\boldsymbol{\epsilon}(u) + f(\nabla w)]\nabla w] &= 0 \text{ in } \Omega \times (0,\infty) \end{aligned} \tag{1.1}$$

with Dirichlet boundary conditions on the "uncontrolled part" of the boundary Γ_0,

$$u = w = \nabla w = 0 \text{ on } \Gamma_0 \times (0,\infty).$$

The dissipative boundary conditions on the "controlled part" of the boundary Γ_1 are given by

$$\begin{aligned} \mathcal{C}[\boldsymbol{\epsilon}(u) + f(\nabla w)]\nu &= -g(u_t), \\ D[\Delta w + (1-\mu)B_1 w] &= -h_1(D_n w_t), \\ D[D_n \Delta w + (1-\mu)B_2 w] - \gamma D_n w_{tt} - [\mathcal{C}[\boldsymbol{\epsilon}(u) + f(\nabla w)]\nu \cdot \nabla w] & \\ = -D_\tau h_2(D_\tau w_t). & \end{aligned} \tag{1.2}$$

http://www.siam.org/journals/sicon/36-4/30190.html

†Department of Applied Mathematics, University of Virginia, Charlottesville, VA 22901 (il2v@virginia.edu).

With (1.1) and (1.2) we associate the initial conditions

$$u(0) = u_0, u_t(0) = u_1, w(0) = w_0, w_t(0) = w_1 \text{ in } \Omega. \tag{1.3}$$

The vector ν represents an outward normal and τ represents the tangential direction. D_n (resp., D_τ) stand for the normal and tangential derivatives. D represents the flexural rigidity, the constant $0 < \mu < 1/2$ is Poisson's modulus, and a positive constant γ is proportional to the thickness of the plate.

The fourth-order tensor $\mathcal{C}$ is defined by

$$\mathcal{C}(\boldsymbol{\epsilon}) \equiv \frac{E}{(1-2\mu)(1+\mu)}[\mu \; trace \; \boldsymbol{\epsilon} \; I + (1-2\mu)\boldsymbol{\epsilon}],$$

where $\boldsymbol{\epsilon}(u) \equiv 1/2(\nabla u + \nabla^T u)$. It can be easily verified that the tensor $\mathcal{C}$ is symmetric and strictly positive. The function f is given by

$$f(s) \equiv (1/2)s \times s, \; s \in R^2,$$

and the boundary operators are defined by

$$B_1 \equiv 2\nu_1\nu_2 D^2_{x,y} - \nu_1^2 D^2_{y,y} - \nu_2^2 D^2_{x,x},$$

$$B_2 \equiv D_\tau[(\nu_1^2 - \nu_2^2)D^2_{x,y} + \nu_1\nu_2(D^2_{y,y} - D^2_{x,x})] + lI.$$

The dissipation in the system is represented by a nonlinear vector function g and scalar functions h_i, which are assumed continuous, monotone increasing, zero at the origin, and of linear growth at infinity.

The following well-posedness/regularity results are proved for this model (see the Appendix).

PROPOSITION 1.1.

(1) Regular solutions. *We assume that* $h_1, h_2 \in C^1(R), g \in C^1(R^2)$ *are monotone, increasing functions with* $h_i{}'$ *(resp.,* g'*)* $\in L_\infty(R)$ *(resp.,* $L_\infty(R^2)$*). For any initial data*

$$u_0, u_1 \in [H^2(\Omega)]^2 \times [H^1(\Omega)]^2, \quad w_0, w_1 \in H^3(\Omega) \times H^2(\Omega)$$

subject to the compatibility conditions satisfied on the boundary Γ*,*

$$\begin{aligned} u_0 = w_0 = \nabla w_0 = w_1 = \nabla w_1 = 0 \quad & on \; \Gamma_0 \times (0,\infty), \\ \mathcal{C}[\boldsymbol{\epsilon}(u_0) + f(\nabla w_0)]\nu = -g(u_1) \quad & on \; \Gamma_1 \times (0,\infty), \\ D[\Delta w_0 + (1-\mu)B_1 w_0] = -h_1(D_n w_1) \quad & on \; \Gamma_1 \times (0,\infty), \end{aligned} \tag{1.4}$$

there exists a unique, global solution

$$(u,w) \in C(0,T;[H^2(\Omega)]^2 \times H^3(\Omega)), \quad (u_t, w_t) \in C(0,T;[H^1(\Omega)]^2 \times H^2(\Omega)),$$

where $T > 0$ *is arbitrary.*

(2) Weak solutions. *In the case of linear damping (i.e.,* $g'(s) = g_0 > 0, h_i{}'(s) = h_{i,0} > 0$*), there exist a* unique*, global solution of finite energy. This is to say that for any initial data*

$$u_0, u_1 \in [H^1(\Omega)]^2 \times [L_2(\Omega)]^2, \quad w_0, w_1 \in H^2(\Omega) \times H^1(\Omega),$$

subject to the boundary conditions satisfied on the boundary Γ_0*,*

$$u_0 = w_0 = \nabla w_0 = w_1 = 0 \quad on \; \Gamma_0 \times (0,\infty), \tag{1.5}$$

there exists a unique solution

$$(u,w)\in C(0,T;[H^1(\Omega)]^2\times H^2(\Omega)),\quad (u_t,w_t)\in C(0,T;[L_2(\Omega)]^2\times H^1(\Omega)),$$

where $T>0$ is arbitrary.

REMARK 1.1. *The existence of regular solutions, the result stated in the first part of Proposition* 1.1*, is proved in the appendix by using the nonlinear Galerkin method. It can also be proved by the same arguments (based on an application of Shaffer's theorem) as those used in* [3] *for the modified von Karman system with* nonlinear *dissipation.*

The uniqueness of regular solutions follows from a rather standard energy type argument which is given in section 7.2.

For the case of linear dissipation, the existence and uniqueness of strong solutions was proved in [23]*. (However, the techniques of* [23] *are not readily extendible for treating nonlinear boundary feedback.)*

In the case of linear damping the existence of weak *solutions (i.e.,* $(u,w)\in C(0,\infty;[H^1(\Omega)]^2\times H^2(\Omega));\ (u_t,w_t)\in C(0,\infty;[L_2(\Omega)]^2\times H^1(\Omega))$ *follows from the usual Galerkin-type argument. The uniqueness of weak solutions was recently proved in* [24] *for the case of Dirichlet boundary conditions and with* $\gamma=0$*. In section* 7.3 *we adopt Sedenko's method to prove the uniqueness of weak solutions for the model of interest (i.e., Proposition* 1.1(2)*). We also note that the uniqueness of weak solutions for the modified von Karman equations was proved recently in* [3]*. However, the arguments employed in* [3] *and based on sharp regularity of the Airy stress function are not applicable here.*

The main goal of this paper is to show that the solutions decay to zero at the uniform rate. To state this result, we recall that the energy functional associated with the plate model (1.1) is given by

$$E(t)=E_k(t)+E_p(t) \tag{1.6}$$

with the kinetic energy

$$E_k(t)=\int_\Omega |u_t|^2+w_t^2+\gamma|\nabla w_t|^2 d\Omega \tag{1.7}$$

and the potential energy

$$E_p(t)=a(w,w)+\int_\Omega [\mathcal{C}N(u,w)\cdot N(u,w)]\,d\Omega, \tag{1.8}$$

where the bilinear form $a(w,z)$ is defined by

$$\begin{aligned}a(w,z)\equiv D\int_\Omega [&w_{x,x}z_{x,x}+w_{y,y}z_{y,y}+\mu w_{x,x}z_{y,y}+\mu w_{y,y}z_{x,x}\\ &+2(1-\mu)w_{x,y}z_{x,y}]d\Omega+l\int_{\Gamma_1} wz d\Gamma_1,\end{aligned}$$

and the stress resultants $N(u,w)$ are given by

$$N(u,w)\equiv \boldsymbol{\epsilon}(u)+f(\nabla w).$$

It is well known that $E_p(t)$ is topologically equivalent to $H^2(\Omega)\times[H^1(\Omega)]^2$ topology.

To formulate our result we introduce the following functions:

$$\mathcal{H}_0(s) \equiv \mathcal{G}(s) + \mathcal{H}1(s) + \mathcal{H}2(s),$$

where the functions $\mathcal{G}, \mathcal{H}1, \mathcal{H}2$ are concave, strictly increasing functions, zero at the origin and such that the following inequalities are satisfied for $|s| \leq 1$

$$\mathcal{G}(\vec{s}g(\vec{s})) \geq |\vec{s}|^2 + |g(\vec{s})|^2, \quad \vec{s} \in R^2,$$

$$\mathcal{H}1(sh_1(s)) \geq s^2 + h_1^2(s), \quad s \in R,$$

$$\mathcal{H}2(sh_2(s)) \geq s^2 + h_2^2(s), \quad s \in R.$$

Due to the assumed monotonicity of the nonlinear functions g, h_i, one can easily construct functions $\mathcal{G}, \mathcal{H}1, \mathcal{H}2$ with the properties listed above (see [19]).

We are ready to state the main result of this paper. To this end we introduce the following hypothesis which will be assumed throughout the paper.

ASSUMPTION 1.

(1) *Let* $\boldsymbol{h}(x)$ *be a vector field defined by*

$$\boldsymbol{h}(x) \equiv x - x_0, \textit{where} \quad x_0 \in R^2.$$

We assume that

$$\boldsymbol{h}\nu \leq 0 \textit{ on } \Gamma_0. \tag{1.9}$$

(2) *There exist positive constants* $0 < m \leq M$ *such that for* $|s| \geq R$ *with a constant* R *sufficiently large, we have*

$$m|s|^2 \leq (g(s), s)_{R^2} \leq M|s|^2, \quad ms^2 \leq h_i(s)s \leq Ms^2, \quad i = 1, 2. \tag{1.10}$$

(3) *The "coefficients"* $b_1, b_2 \in \mathcal{L}(L_2(\Omega))$ *representing a potential "light damping" are assumed to satisfy* $(b_1 u, u)_{[L_2(\Omega)]^2} \geq 0$, $(b_2 w, w)_{L_2(\Omega)} \geq 0$ *for all* $u \in [L_2(\Omega)]^2$ *and* $w \in L_2(\Omega)$.

THEOREM 1.2. *Let* u, w *be a strong solution to the original system* (1.1) *and let us assume that either* $l > 0$ *or* $\Gamma_0 \neq \emptyset$.

Part I. *In addition to Assumption* 1 *we make Assumption* 2 *as follows.*

ASSUMPTION 2. *Either* b_1 *or* b_2 *are injective or* Ω *is star-shaped.*

Then there exists a constant $T_0 > 0$ *such that the following estimate holds*

$$E(t) \leq C(E(0))s(t/T_0 - 1)), \quad t \geq T_0, \tag{1.11}$$

where a real variable function $s(t)$ *converges to zero as* $t \to \infty$ *and it obeys the ordinary differential equation*

$$s_t(t) + q(s(t)) = 0, \quad s(0) = E(0). \tag{1.12}$$

The (nonlinear), monotone increasing function $q(s)$ *is determined entirely from the behavior at the origin of the nonlinear functions* g, h_i, *and it is given by the following algorithm:*

$$q \equiv I - (I + p)^{-1}, \tag{1.13}$$

$$p \equiv (kI + \mathcal{H})^{-1}, \tag{1.14}$$

$$\mathcal{H} \equiv \mathcal{H}_0(\cdot/mes\Sigma_1), \tag{1.15}$$

where the constant k is proportional to $\frac{1}{mes\Sigma_1}(m^{-1}+M)$ with $\Sigma_1 \equiv \Gamma_1 \times (0,T)$.

Part II. *If Assumption* 2 *does not hold, then the conclusion of Part* I *holds for all initial data incrementally more regular, i.e.,*

$$u_0 \in H^{1+\epsilon}(\Omega), \quad w_0 \in H^{2+\epsilon}(\Omega),$$

where $\epsilon > 0$ is arbitrary and the constant C in (1.11) *may depend on the norms of these data, i.e.,*

$$C = C(|u_0|_{H^{1+\epsilon}(\Omega)}, \quad |w_0|_{H^{2+\epsilon}(\Omega)}, E(0)).$$

REMARK 1.2. *If the nonlinear functions g, h_1, h_2 are bounded from below by a linear function, then it can be shown that the decay rates predicted by Theorem* 1.2 *are exponential. This is to say that there exist positive constants C, ω possibly depending on $E(0)$ and such that*

$$E(t) \leq Ce^{-\omega t} \quad for\ t > T_0.$$

If instead these functions have a polynomial growth at the origin, then the decay rates are algebraic (see [19]*).*

REMARK 1.3. *The light damping terms represented by the coefficients b_1, b_2 correspond, typically, to a possibility of having small viscous damping. We note that this damping alone (even if it is fully active, i.e., b_1 and b_2 are uniformly positive on Ω) will not cause a uniform decay for the energy (it may, at most, cause the strong stability of the solutions). For the former, the presence of the boundary dissipation or of a much stronger viscous damping is necessary. From the mathematical point of view, the presence of light damping is beneficial at the level of eliminating lower-order terms from the appropriate inequalities (see section* 5*) which is done by using the new uniqueness result due to Isakov* [9]*. Indeed, the application of this uniqueness result requires sufficient regularity of solutions to the linearized equations. This, in turn, can be established if one of the b_i's is injective or Ω is star-shaped. In the general case, however, the needed regularity can be shown provided we start off with minimally more regular initial data (see Part* II *of Theorem* 1.2*). At this point, it is not known whether this regularity requirement is necessary for the result to hold.*

REMARK 1.4. *The decay rates guaranteed in Part* II *of Theorem* 1.2 *can be extended to hold for all $H^{1+\epsilon}(\Omega) \times H^{2+\epsilon}(\Omega)$ solutions with ϵ arbitrary small. Indeed, this can be done by applying the usual density argument* [11] *combined with the uniqueness result stated in the Appendix. Similarly, in view of the uniqueness result valid for weak solutions in the case of linear dissipation, the result of Part* I *of Theorem* 1.2 *could be extended to all such weak solutions.*

Literature relevant to the problem. Problems related to boundary stabilization of von Karman equations have attracted considerable attention in recent years. Indeed, starting with [11] and followed by papers [6], [7] uniform decay properties for the energy of the *modified* von Karman system with boundary dissipation were established. As it is well known, the *modified* von Karman system does not account for in-plane accelerations and, therefore, it can be "almost" decoupled via the Airy stress function. This is in contrast to the *full* von Karman system, where the nonlinear coupling is strong. Moreover, the additional difficulty (in the case of the two-dimensional model) results from the unboundedness of nonlinear terms in the topology induced by the energy functional.

Energy decay rates for the one-dimensional full von Karman model were first derived in [14]. The two-dimensional version of this model has been subsequently treated

in [13], where the uniform decay rates were proved for a combination of static/dynamic models with a nonlinear boundary dissipation of a linear growth at the infinity and of a polynomial growth at the origin. A fully dynamic von Karman system accounting for in-plane accelerations (as considered in this paper) was treated in [22]. The model considered in [22], and inspired by [13], accounts for the *linear* boundary dissipation of the form

$$\begin{aligned} \mathcal{C}[\epsilon(u) + f(\nabla w)]\nu &= -a(\boldsymbol{h}\cdot\nu)u_t - b(D_\tau u_2, -D_\tau u_1), \\ D[\Delta w + (1-\mu)B_1 w] &= -a(\boldsymbol{h}\cdot\nu)D_n w_t, \\ D[D_n\Delta w + (1-\mu)B_2 w] - \gamma D_n w_{tt} - [\mathcal{C}[\epsilon(u) + f(\nabla w)]\nu\cdot\nabla w] & \\ = a(h\cdot\nu)w_t + a(D_\tau(h\cdot\nu)D_\tau w_t), & \end{aligned} \tag{1.16}$$

where the constants a, b are *strictly positive*. The exponential decay rates obtained in [22] for this model above hold under the following conditions: (i) *geometric star-shaped conditions* are assumed also on the *controlled* portion of the boundary Γ_1; (ii) the constant "b" in (1.16) is *strictly positive* but suitably *small*. This "smallness" requirement is dictated by the existence theory presented in [23].

Putting aside, for a moment, questions related to unjustified, on physical grounds, geometric conditions imposed on the *controlled* portion of the boundary and the linear nature of boundary dissipation, the major somewhat disappointing feature of this result is the fact that while the decay rates derived in [22] depend critically on the positivity of the constant b in (1.16) (in fact, they go to zero when b tends to zero), the very same constant needs to be assumed small in order to guarantee the existence of the solutions (see [23]). Moreover, since the estimates break down when $b = 0$, the authors in [22] suggest the necessity of these tangential components of vector u in the structure of the stabilizing feedback. This leads to an unpleasant dichotomy where the "factotum/savior" for the stabilization result is "knocked down" by the existence theory. It was precisely this aspect of the problem that provided the main motivation for gaining a better understanding and searching for more powerful techniques adequate for studying this nonlinear problem. Thus, the main question being asked is, can we obtain the uniform decay rates for the energy *without* the additional tangential components of the horizontal displacement u present in the structure of the feedback? (For example, can the constant b in (1.16) be equal to zero?)

This paper provides an affirmative answer to the above question. In fact, the results stated in Theorem 1.2 yield the uniform decay rates for the model *without* the additional component of the boundary feedback corresponding to the b term in (1.16) (contrary to the authors' conjecture in [22]). Moreover, our feedback is *nonlinear* and without any assumptions on the growth at the origin. Finally, the result of Theorem 1.2 does not require any geometric hypotheses on the controlled portion of the boundary Γ_1, which is in agreement with the physical understanding of propagations.

Let us state at the outset that the technique employed in [22], and based on a combination of multipliers and the Lyapunov method (used earlier also in [13], [12]) cannot be extended to treat the problem at hand. Instead, our main strategy is to obtain a certain nonlinear algebraic relation for the energy function which then leads, via suitable comparison argument, to the ordinary differential equation describing the decay rates for the solutions. This approach, very different from the Lyapunov function approach used by many authors (including [22]), has been introduced in [19] in a context of the wave equation. The main advantage of this technique is its flexibility in handling various "unstructured" terms of the equation (in contrast to the Lyapunov function method which is very sensitive to the structure of the

problem). However, the main new ingredients critical to the proof of Theorem 2.1 are (i) appropriate "sharp" trace estimates for the solutions to the nonlinear system (1.1) and (ii) a Holmgren-type uniqueness result valid for the nonlinear system which is overdetermined on the boundary.

Indeed, as to the point in (i), these "trace" estimates are responsible for handling the geometrical conditions as well as for showing the decay rates *without* the additional tangential boundary terms present in (1.16). We note that a version of sharp trace estimates was used before in [21], [6] for the purpose of eliminating geometric conditions in the context of wave and plate equations. However, in the present case, the situation is more complicated due to strong and nonlinear coupling of the equations.

A unique continuation result (point (ii) above) is needed at the level of absorbing lower-order terms. We show the validity of this unique continuation property by applying a new uniqueness result due to Isakov [9]. However, in order to do this, we need to establish a priori the regularity of the "overdetermined" solutions. This, in turn, can be proved for all finite energy solutions, provided, however, there is some light damping in the system (see Part I of Theorem 1.2). In the general case, however, we need to assume an incremental a priori smoothness of the initial data. (See Part II.) We note that this is in contrast with a modified von Karman system where one can show that the solutions overdetermined on the boundary display (without any interior damping) an arbitrary level of regularity. Proof of this "smoothing" property, carried out in [17], is based on sharp regularity of the Airy stress function established in [3]. Unfortunately, we do not have an analogue of this property valid for the present model.

2. Preliminary results and trace regularity. In this section we shall formulate and prove several preliminary estimates which deal with the trace regularity of solutions to the nonlinear equations given by (1.1). These results, while important in proving the main theorem, are also of independent interest in their own right.

2.1. Dissipativity equality. A starting point is, as usual, the dissipativity equality which states that the energy of the entire system is nonincreasing. This fact alone does not prove, of course, that the energy is decaying, but it is a necessary preliminary step of stability analysis.

LEMMA 2.1. *Let u, w be a finite energy solution of system* (1.1). *Then, for any $s \le t$,*

$$E(t) + 2\int_s^t \int_{\Gamma_1} [g(u_t)\cdot u_t + h_1(D_n w_t) D_n w_t + h_2(D_\tau w_t) D_\tau w_t] d\Gamma_1 dt + 2\int_s^t \int_\Omega [b_1 u_t \cdot u_t + b_2 w_t w_t] d\Omega dt = E(s). \tag{2.1}$$

Proof. The proof is standard and it follows by the classical energy type of argument (we multiply (1.1) by u_t, w_t, integrate over $\Omega \times (s,t)$, and apply the divergence theorem first to smooth solutions and then we extend it by density to all weak solutions). □

the corresponding trace estimates valid for (i) the linear model of dynamic elasticity and (ii) the linear Kirchhoff model obtained by methods of microlocal analysis in [5] and [21], respectively. Here the main idea is to obtain the estimates for the tangential derivatives on the boundary in terms of the velocity traces and lower-order terms. To formulate these results we introduce some notation. Let $T > 0$ be fixed. In fact, from now on we shall assume that T is sufficiently large and greater than the finite speed of propagation corresponding to equation (1.1). We denote $Q \equiv [0,T]\times\Omega$, $\Sigma_\alpha \equiv [\alpha, T-\alpha]\times\Gamma_1$, where $\alpha < T/2$. We also have that $\Sigma_1 \equiv [0,T]\times\Gamma_1$, $\Sigma_0 \equiv [0,T]\times\Gamma_0$, $\Sigma \equiv [0,T]\times\Gamma$.

We shall also use the following notation for Sobolev norms:

$$|u|_{\alpha,\Omega} \equiv |u|_{H^\alpha(\Omega)},\ |u|_{\alpha,\Gamma} \equiv |u|_{H^\alpha(\Gamma)}$$

and for the inner products

$$(u,v)_\Omega \equiv (u,v)_{L_2(\Omega)};\ \langle u,v\rangle_\Gamma \equiv (u,v)_{L_2(\Gamma)}.$$

Using the same symbol we shall also denote norms/inner products of two copies of L_2 or H^α spaces. This should not create any confusion, since the meaning will be clear from the context.

The constant C is a generic constant, different in various occurrences. $C(E(0))$ denotes the quantities bounded in terms of $E(0)$.

LEMMA 2.2. *Let u, w be a finite energy solution corresponding to the system (1.1). Then, for any $\epsilon < 1/4$, there exists a constant $C(E(0))$ such that the following trace regularity takes place:*

$$\begin{aligned}\int_{\Sigma\alpha} |\nabla u|^2 d\Sigma_\alpha \le C \int_{\Sigma_1} [|u_t|^2 + |g(u_t)|^2] dxdt \\ +C(E(0)) \int_0^T [|w|^2_{2-\epsilon,\Omega} + |u|^2_{1-\epsilon,\Omega}] dt. \end{aligned} \tag{2.2}$$

REMARK 2.1. *Notice that the regularity of the trace of ∇u proclaimed by Lemma 2.2 (see also Lemma 2.5 below) does not follow from the standard interior regularity of finite energy solutions via the trace theory. These are independent regularity results that rely heavily on microlocal arguments applied to both the dynamic system of elasticity and the dynamic Kirchhoff plate.*

Proof.

Step 1. We shall begin with the following trace regularity result valid [5] for the linear model of dynamic elasticity (see also [20] where the analogous result was proved for the wave equation). Define

$$F(x,y,t) \equiv \mathrm{div}[\mathcal{C}f(\nabla w(x,y,t))], \tag{2.3}$$

where w is a finite energy solution corresponding to the system (1.1). Then the solution u satisfies the following "linear" system of dynamic elasticity

$$u_{tt} + b_1 u_t - \mathrm{div}\mathcal{C}[\boldsymbol{\epsilon}(u)] = F \text{ in } Q. \tag{2.4}$$

According to [5], [28] for all $\epsilon < 1/2$, we have the estimate

$$\int_{\Sigma_\alpha} |\nabla u \cdot \tau|^2 d\Sigma_\alpha \le C \int_0^T [|u_t|^2_{0,\Gamma_1} + |\boldsymbol{\epsilon}(u)\cdot\nu|^2_{0,\Gamma_1} + |F|^2_{-1/2,\Omega} + |u|^2_{1-\epsilon,\Omega}] dt \tag{2.5}$$

and using the boundary conditions satisfied on Γ_1 we have

$$\int_{\Sigma_\alpha} |\nabla u \cdot \tau|^2 d\Sigma_\alpha \le C \int_0^T [|u_t|^2_{0,\Gamma_1} + |g(u_t)|^2_{0,\Gamma_1} + |f(\nabla w)|^2_{0,\Gamma_1} + |F|^2_{-1/2,\Omega} + |u|^2_{1-\epsilon,\Omega}]dt. \tag{2.6}$$

REMARK 2.2. *The estimate in inequality* (2.6), *when applied to the homogeneous system of dynamic elasticity, states that the traces of the tangential derivatives of* u *are bounded by the traces of velocity modulo lower-order terms. A result of similar nature was obtained first for the classical wave equation in* [20].

Step 2. We shall estimate the fourth term on the right-hand side of the inequality in (2.6).

PROPOSITION 2.3. *Let* $\epsilon < 1/2$. *Then the function* F *defined in* (2.3) *satisfies, for all* $t \ge 0$,

$$|F(t)|_{-1/2,\Omega} \le C|w(t)|_{2,\Omega}|w(t)|_{2-\epsilon,\Omega}. \tag{2.7}$$

Proof. Let $\phi \in H^{1/2}(\Omega)$. Direct computations give

$$(F,\phi)_{0,\Omega} = (\mathrm{div}[\mathcal{C}f(\nabla w)],\phi)_{0,\Omega} \le C|w|_{2,\Omega}|Dw\phi|_{0,\Omega}, \tag{2.8}$$

where D stands for a first-order differential operator. But

$$|Dw\phi|_{0,\Omega} \le C|w|_{W^1_{2p}(\Omega)}|\phi|_{L_{2q}(\Omega)},$$

where $1/p + 1/q = 1$. By Sobolev's embedding

$$H^{2-\epsilon}(\Omega) \subset W^1_4(\Omega), \quad H^{1/2}(\Omega) \subset L_4(\Omega)\ \epsilon \le 1/2 \tag{2.9}$$

we obtain

$$|Dw\phi|_{0,\Omega} \le C|w|_{2-\epsilon,\Omega}|\phi|_{1/2,\Omega}, \tag{2.10}$$

and going back to (2.8) we obtain

$$|(F,\phi)_{0,\Omega}| \le C|w|_{2,\Omega}|w|_{2-\epsilon,\Omega}|\phi|_{1/2,\Omega}, \tag{2.11}$$

which, via duality, proves the assertion in the proposition. □

Step 3. We shall next estimate the normal derivatives of the vector u.

PROPOSITION 2.4. *For all* $\epsilon < 1/4$ *we have*

$$\int_{\Sigma_\alpha} |\nabla u \cdot \nu|^2 d\Sigma_1 \le C \int_{\Sigma_\alpha} [|g(u_t)|^2 + |\nabla u \cdot \tau|^2] d\Sigma_\alpha + C(E(0)) \int_\alpha^{T-\alpha} |w|^2_{2-\epsilon,\Omega} dt. \tag{2.12}$$

Proof. Reading off the boundary conditions for the variable u we obtain the relation

$$\boldsymbol{\epsilon}(u) \cdot \nu = \vec{g}, \tag{2.13}$$

where we introduce the variable

$$\vec{g} \equiv -\mathcal{C}^{-1} g(u_t) - f(\nabla w) \cdot \nu,$$

where $\vec{g}$ satisfies the estimate

$$|\vec{g}|^2_{L_2(\Sigma_\alpha)} \le C[|g(u_t)|^2_{L_2(\Sigma_\alpha)} + |(\nabla w)^2|^2_{L_2(\Sigma_\alpha)}]$$
$$\le C\left[|g(u_t)|^2_{L_2(\Sigma_\alpha)} + |w|^2_{L_\infty(0,T;W_4^1(\Gamma_1))}\int_\alpha^{T-\alpha} |w(t)|^2_{W_4^1(\Gamma_1)}\right]$$
$$\le C|g(u_t)|^2_{L_2(\Sigma_\alpha)} + C(E(0))\int_\alpha^{T-\alpha} |w|^2_{2-\epsilon,\Omega} \tag{2.14}$$

and where we have used the estimate

$$|(\nabla w)^2|^2_{L_2(\Sigma_\alpha)} \le C\int_\alpha^{T-\alpha} |\nabla w(t)|^4_{L_4(\Gamma)}dt \le CE(0)\int_\alpha^{T-\alpha} |w(t)|^2_{2-\epsilon,\Omega}dt. \tag{2.15}$$

This last estimate follows, in turn, from the trace theorem, the dissipativity equality (2.1), and the following Sobolev embedding:

$$H^{3/2-\epsilon}(\Gamma) \subset W_4^1(\Gamma), \quad \epsilon \le 1/4. \tag{2.16}$$

On the other hand, denoting

$$\vec{d} \equiv \nabla u \cdot \tau$$

and writing

$$\boldsymbol{\epsilon}(u) \cdot \nu = \vec{g}, \tag{2.17}$$

$$\nabla u \cdot \tau = \vec{d}, \tag{2.18}$$

leads to the algebraic linear system of the form

$$A\vec{u} = [\vec{g}, \vec{d}]^T,$$

where $\vec{u} \equiv [u_{1,x}, u_{1,y}, u_{2,x}, u_{2,y}]$ and the determinant of the matrix A is equal to $-1/2$. Solving the above system pointwise and integrating the result over Σ_α yields the inequality

$$\int_{\Sigma_\alpha} [|D_x u|^2 + |D_y u|^2]d\Sigma_\alpha \le C\int_{\Sigma_\alpha} [|\vec{g}|^2 + |\vec{d}|^2]d\Sigma_\alpha. \tag{2.19}$$

The above estimate together with (2.14) leads to the result in (2.12). □

Step 4. Collecting the results of the estimates (2.6), (2.12), (2.7) we obtain

$$\int_{\Sigma\alpha} |\nabla u|^2 d\Sigma_\alpha \le C\int_{\Sigma_1} [|u_t|^2 + |g(u_t)|^2 + |f(\nabla w)|^2]dxdt$$
$$+C(E(0))\int_0^T \left[|w(t)|_{2-\epsilon,\Omega}dt + \int_0^T |u(t)|_{1-\epsilon}\right]dt. \tag{2.20}$$

Estimating the term $|f(\nabla w)|^2_{0,\Sigma_1}$ once more and using the inequality in (2.15) leads us to the desired result in Lemma 2.2. □

Our next result deals with the improved trace regularity for the vertical displacement w.

LEMMA 2.5. *Let u, w be a finite energy solution to* (1.1) *with the boundary conditions* (1.2). *Then*

$$\int_{\Sigma\alpha} [|D_n^2 w|^2 + |D_\tau^2 w|^2 + |D_n D_\tau w|^2]d\Sigma_\alpha \le C_T\int_{\Sigma_1} [|\nabla w_t|^2$$
$$+|h_1(D_n w_t)|^2 + |h_2(D_\tau w_t)|^2 + C(E(0))|u_t|^2]d\Sigma + C_T(E(0))\int_0^T |w|^2_{2-\epsilon,\Omega}dt. \tag{2.21}$$

Proof.
Step 1. Define

$$F \equiv \operatorname{div}[\mathcal{C}[\boldsymbol{\epsilon}(u) + f(\nabla w)]\nabla w];$$

then w satisfies the following equation of linear Kirchhoff plate

$$[I - \gamma\Delta]w_{tt} + b_2 w_t + D\Delta^2 w = F \text{ in } Q. \tag{2.22}$$

According to the estimates in Theorem 2.1 in [21] the following improved trace regularity is valid for (2.22)

$$\begin{aligned}\int_{\Sigma\alpha}[|D_n^2 w|^2 + |D_\tau^2 w|^2 + |D_n D_\tau w|^2]d\Sigma_\alpha \\ \leq C_T \int_{\Sigma_1}[|\nabla w_t|^2 \\ +|h_1(D_n w_t)|^2 + |h_2(D_\tau w_t)|^2]d\Sigma_1 \\ + \int_0^T [|\mathcal{C}[\boldsymbol{\epsilon}(u) + f(\nabla w)]\nu \cdot \nabla w|^2_{-1,\Gamma_1} \\ +|F(t)|^2_{(H^{3/2}(\Omega))'} + C|w(t)|^2_{2-\epsilon,\Omega}]dt \\ \leq C_T \int_{\Sigma_1}[|\nabla w_t|^2 + |h_1(D_n w_t)|^2 \\ +|h_2(D_\tau w_t)|^2]d\Sigma_1 \\ +C_T \int_0^T [|g(u_t)\cdot\nabla w|^2_{-1,\Gamma_1} + |F(t)|^2_{(H^{3/2}(\Omega))'} + |w(t)|^2_{2-\epsilon,\Omega}]dt,\end{aligned} \tag{2.23}$$

where we used the boundary conditions for the "u" equation.

Step 2. We shall estimate first the contribution of the term F in (2.23). This is accomplished by the proposition below.

PROPOSITION 2.6. *For all $\epsilon < 1/2$ the following estimates hold:*

$$|F(t)|_{(H^{3/2}(\Omega))'} \leq C[|N(u(t), w(t))|_{0,\Omega}|w(t)|_{2-\epsilon,\Omega} + |u_t(t)|_{0,\Gamma_1}|w(t)|_{2-\epsilon,\Omega}]. \tag{2.24}$$

Hence

$$\int_0^T |F(t)|^2_{(H^{3/2}(\Omega))'}dt \leq C(E(0))\int_0^T [|w(t)|^2_{2-\epsilon,\Omega} + |u_t(t)|^2_{0,\Gamma_1}]dt. \tag{2.25}$$

Proof. Let $\phi \in H^{3/2}(\Omega)$. Applying the divergence theorem and accounting for the boundary conditions we obtain

$$\begin{aligned}(F,\phi)_{0,\Omega} = (\operatorname{div}[\mathcal{C}[\boldsymbol{\epsilon}(u) + f(\nabla w)]\nabla w], \phi)_{0,\Omega} = -(\mathcal{C}[\boldsymbol{\epsilon}(u) + f(\nabla w)]\nabla w, \nabla\phi)_{0,\Omega} \\ +(\mathcal{C}[\boldsymbol{\epsilon}(u) + f(\nabla w)]\nu\cdot\nabla w, \phi)_{0,\Gamma_1} \\ = (\mathcal{C}[\boldsymbol{\epsilon}(u) + f(\nabla w)], \nabla\phi\times\nabla w)_{0,\Omega} + (g(u_t)\nabla w, \phi)_{0,\Gamma_1}.\end{aligned} \tag{2.26}$$

The first interior term in (2.26) is estimated as follows:

$$\begin{aligned}(\mathcal{C}[\boldsymbol{\epsilon}(u) + f(\nabla w)], \nabla\phi\times\nabla w)_{0,\Omega} \leq C|N(u,w)|_{0,\Omega}|\nabla w\times\nabla\phi|_{0,\Omega} \\ \leq C|N(u,w)|_{0,\Omega}|\nabla w|_{L_4(\Omega)}|\nabla\phi|_{L_4(\Omega)} \leq C|N(u,w)|_{0,\Omega}|w|_{2-\epsilon,\Omega}|\phi|_{3/2,\Omega},\end{aligned} \tag{2.27}$$

where we have used Sobolev's embedding (2.9).

To estimate the boundary term that appeared in (2.26) we proceed as follows:

$$(g(u_t)\nabla w, \phi)_{0,\Gamma_1} \le |g(u_t)|_{0,\Gamma_1} |\nabla w \phi|_{0,\Gamma_1}$$
$$\le C|u_t|_{0,\Gamma_1}|w|_{1,\Gamma_1}|\phi|_{1,\Gamma_1} \le C|u_t|_{0,\Gamma_1}|w|_{3/2,\Omega}|\phi|_{3/2,\Omega}. \tag{2.28}$$

Combining inequalities in (2.26)–(2.28) leads to the result stated in the first part of the proposition. The second inequality follows simply by integrating the first part and taking into account the dissipativity property (2.1). □

Step 3.

PROPOSITION 2.7. *We have*

$$\int_0^T |g(u_t)\nabla w|^2_{-1,\Gamma_1} dt \le CE(0)|u_t|^2_{0,\Sigma_T}. \tag{2.29}$$

Proof. As a bypass of the computations in (2.28) we obtain

$$|g(u_t)\nabla w|_{-1,\Gamma_1} \le C|u_t|_{0,\Gamma_1}|w|_{1,\Gamma_1} \le C|u_t|_{0,\Gamma_1}|w|_{2-\epsilon,\Omega}.$$

Integrating the above inequality with respect to time and recalling the dissipativity property we obtain the result claimed in Proposition 2.7. □

Step 4. Complete the proof of Lemma 2.5.

Combining the results of both propositions together with inequality (2.23) leads to the final conclusion of Lemma 2.5. □

3. Stabilizability estimate. The main aim in this section is to prove the following stabilizability estimate in Lemma 3.1.

LEMMA 3.1. *Let u, w be a regular solution to* (1.1). *Assume the geometric condition on* Γ_0 (1.9). *Then there exists T large enough such that for any constant $\epsilon < 1/4$ the following estimate takes place:*

$$E(0) + E(T) + \int_0^T E(t)dt \le C_T(E(0)) \int_{\Sigma_1} [|u_t|^2 + |\nabla w_t|^2 + |g(u_t)|^2 + |h_1(D_n w_t)|^2$$
$$+|h_2(D_\tau w_t)|^2]d_{\Sigma_1} + C\int_0^T [(b_1 u_t, u_t)_\Omega + (b_2 w_t, w_t)_\Omega]dt + C_T(E(0))lot(u,w), \tag{3.1}$$

where we have used the notation for the lower-order terms (lot(u,w))

$$lot(u,w) \equiv \int_0^T [|u(t)|^2_{1-\epsilon,\Omega} + |w(t)|^2_{2-\epsilon,\Omega}]dt. \tag{3.2}$$

The estimate of Lemma 3.1, critical to the proof of the main stabilizability result, is an inverse type of estimate. Indeed, it allows us to reconstruct the energy of the system, modulo lower-order terms, from the measurements of velocities on the boundary. The remainder of this section is devoted to the proof of Lemma 3.1. Here, the strategy used for the proof is to first apply the usual " multipliers" method (for an exposition of this method see the books [15], [11], [10] and references therein), which leads to the estimate for the energy in terms of *all* boundary traces and lower-order terms. The next crucial step is to eliminate the "unwanted" boundary traces by using sharp trace regularity results presented in section 2.

REMARK 3.1. *The result of Lemma* 3.1 *can be extended to hold for all finite energy (weak) solutions. Indeed, this can be accomplished by applying a special "regularization" argument as in* [19]. *In order to avoid the additional technical complications and for the sake of clarity of exposition we shall not do this here, and for details we refer the reader to* [19], [6], [7].

3.1. Variational formulation and preliminary identities. We shall begin by writing system (1.1) in a variational form. To this end let us have two test functions $\phi \in H^1(\Omega) \times H^1(\Omega)$ and $\psi \in H^2(\Omega)$. The von Karman system admits the following variational form:

$$(u_{tt}, \phi)_\Omega + (b_1 u_t, \phi)_\Omega + (\mathcal{C}[\boldsymbol{\epsilon}(u) + f(\nabla w)], \boldsymbol{\epsilon}(\phi))_\Omega + \langle g(u_t), \phi \rangle_{\Gamma_1} - \langle \mathcal{C}\boldsymbol{\epsilon}(u)\nu, \phi \rangle_{\Gamma_0} = 0, \tag{3.3}$$

$$\begin{aligned}(w_{tt}, \psi)_\Omega + \gamma(\nabla w_{tt}, \nabla\psi)_\Omega + a(w, \psi) + (b_2 w_t, \psi)_\Omega + (\mathcal{C}[\boldsymbol{\epsilon}(u) + f(\nabla w)], \nabla\psi \times \nabla w)_\Omega \\ + \langle h_1(D_n w_t), D_n\psi \rangle_{\Gamma_1} + \langle h_2(D_\tau w_t), D_\tau \psi \rangle_{\Gamma_1} - \langle \Delta w, D_n \psi \rangle_{\Gamma_0} = 0.\end{aligned} \tag{3.4}$$

Note that we have used the boundary conditions satisfied on Γ.

We shall apply this variational form with various choices of test functions ϕ and ψ. In order to facilitate verification of rather tedious computations below, we will provide a few elementary tensor identities.

In what follows the vector field $\boldsymbol{h}$ always denotes the radial vector field

$$\boldsymbol{\epsilon}(\boldsymbol{h}\nabla u) = \boldsymbol{\epsilon}(u) + M, \tag{3.5}$$

where the tensor M is given by

$$M \equiv \begin{bmatrix} D^2_{x_1,x_i} u_1 \boldsymbol{h}_i & 1/2[D^2_{x_2,x_i} u_1 \boldsymbol{h}_i + D^2_{x_1,x_i} u_2 \boldsymbol{h}_i] \\ 1/2[D^2_{x_2,x_i} u_1 \boldsymbol{h}_i + D^2_{x_1,x_i} u_2 \boldsymbol{h}_i] & D^2_{x_2,x_i} u_2 \boldsymbol{h}_i \end{bmatrix}, \tag{3.6}$$

and we have adopted double index notation to indicate the summation of the terms. If A is any symmetric fourth-order tensor identified by its coefficients $a_{i,j}$,

$$A \equiv \{a_{i,j}\},$$

then it is straightforward to show that

$$A \cdot M = a_{k,j} D^2_{x_k,x_i} u_j \boldsymbol{h}_i, \tag{3.7}$$

$$\nabla(\nabla w \boldsymbol{h}) = \nabla w + [w_{x_1,x_i} \boldsymbol{h}_i, w_{x_2,x_i} \boldsymbol{h}_i], \tag{3.8}$$

and

$$\nabla(\nabla w \boldsymbol{h}) \times \nabla w = \nabla w \times \nabla w + \nabla w \times [w_{x_1,x_i} \boldsymbol{h}_i, w_{x_2,x_i} \boldsymbol{h}_i], \tag{3.9}$$

$$A \cdot (\nabla(\nabla w \boldsymbol{h}) \times \nabla w) = A \cdot \nabla w \times \nabla w + a_{k,j} w_{x_j} w_{x_k,x_i} \boldsymbol{h}_i. \tag{3.10}$$

Let B be another symmetric tensor such that

$$a_{j,i} = c_{j,l} b_{l,i}$$

with constant and symmetric coefficients $c_{j,i}$. Then

$$\operatorname{div}[A \cdot B\boldsymbol{h}] = 2A \cdot B + c_{i,l} D_{x_k} b_{l,j} b_{i,j} \boldsymbol{h}_k = 2A \cdot B + 2a_{j,i} D_{x_k} b_{j,i} \boldsymbol{h}_k. \tag{3.11}$$

In the particular case when the tensors A and B are given by

$$A = \mathcal{C}[\boldsymbol{\epsilon}(u) + f(\nabla w)],$$

$$B = \boldsymbol{\epsilon}(u) + f(\nabla w),$$

the formula above reads

$$\begin{aligned}\operatorname{div}[\mathcal{C}[\boldsymbol{\epsilon}(u) + f(\nabla w)] \cdot [\boldsymbol{\epsilon}(u) + f(\nabla w)]\boldsymbol{h}] = 2\mathcal{C}[\boldsymbol{\epsilon}(u) + f(\nabla w)] \cdot [\boldsymbol{\epsilon}(u) + f(\nabla w)] \\ + 2a_{i,j}[D^2_{x_k,x_j} u_i + w_{x_j} D^2_{x_i,x_k} w]\boldsymbol{h}_k.\end{aligned} \tag{3.12}$$

3.2. First estimate. In this subsection we shall prove a preliminary estimate which shows that the energy of the system is bounded by the boundary traces modulo the lower-order terms. Computations carried below, based on the "multiplier's method," are reminiscent of those performed earlier in [13], [12], and later in [22].

LEMMA 3.2. *Let u, w be a regular solution to* (1.1). *Assume the geometric condition* (1.9) *holds on Γ_0. Then there exists T large enough such that for any constant $\epsilon < 1/4$ the following estimate takes place:*

$$E(T) + \int_0^T E(t)dt \le C_T(E(0)) \int_{\Sigma_1} [|u_t|^2 + |\nabla w_t|^2 + |g(u_t)|^2 + |h_1(D_n w_t)|^2 + |h_2(D_\tau w_t)|^2]d\Sigma_1 + C \int_{\Sigma_1} [|\nabla u|^2 + |D_n^2 w|^2 + |D_n D_\tau w|^2 + |D_\tau^2 w|^2]d\Sigma_1 + C \int_0^T [(b_1 u_t, u_t)_\Omega + (b_2 w_t, w_t)_\Omega]dt + C_T(E(0)) lot(u, w). \tag{3.13}$$

Proof.

Step 1. We use $\phi \equiv \nabla u \boldsymbol{h}$ as a test function in the first variational equality. By the virtue of (3.5), (3.7) applied with

$$A \equiv \mathcal{C}[\boldsymbol{\epsilon}(u) + f(\nabla w)],$$

we obtain

$$(\mathcal{C}[\boldsymbol{\epsilon}(u) + f(\nabla w)], \epsilon(\nabla u \boldsymbol{h})) = (\mathcal{C}[\boldsymbol{\epsilon}(u) + f(\nabla w)], \epsilon(u)) + (a_{i,j}, D^2_{x_k,x_j} u_i \boldsymbol{h}_k) \tag{3.14}$$

and integrating over Q

$$(u_t, \boldsymbol{h}\nabla u)_\Omega|_0^T + \int_0^T (b_1 u_t, \boldsymbol{h}\nabla u)_\Omega dt - 1/2 \int_\Sigma |u_t|^2 \boldsymbol{h} \cdot \nu d\Sigma + \int_{Q_T} |u_t|^2 dQ + \int_0^T [(\mathcal{C}[\boldsymbol{\epsilon}(u) + f(\nabla w)], \epsilon(u))_\Omega + (a_{i,j}, D^2_{x_k,x_j} u_i \boldsymbol{h}_k)_\Omega + \langle g(u_t), \boldsymbol{h}\nabla u\rangle_{\Gamma_1} - \langle \mathcal{C}\boldsymbol{\epsilon}(u), \epsilon(u)\nu h\rangle_{\Gamma_0}]dt = 0, \tag{3.15}$$

where we have used the fact that u vanishes on Γ_0 and, therefore,

$$\mathcal{C}\boldsymbol{\epsilon}(u)\nu\nabla u\boldsymbol{h} = \mathcal{C}\boldsymbol{\epsilon}(u) \cdot \boldsymbol{\epsilon}(u)\nu\boldsymbol{h} \text{ on } \Gamma_0. \tag{3.16}$$

To see (3.16), it suffices to notice the following identities taking place on Γ_0

$$\nabla u\boldsymbol{h} = D_n u \nu \boldsymbol{h}, \ \textit{trace}\ \boldsymbol{\epsilon}(u) = D_n u \nu,$$
$$\boldsymbol{\epsilon}(u)\nu = [D_n u_1 \nu_1^2, D_n u_2 \nu_2^2] + (1/2)\nu^T (D_n u \nu^T),$$
$$\boldsymbol{\epsilon}(u) \cdot \boldsymbol{\epsilon}(u) = D_n u_i^2 \nu_i^2 + (1/2)(D_n u \nu^T)^2.$$

Hence

$$\boldsymbol{\epsilon}(u)\nu\nabla u\boldsymbol{h} = \{[D_n u_1 \nu_1^2, D_n u_2 \nu_2^2] + (1/2)\nu^T (D_n u \nu^T)\} D_n u \nu \boldsymbol{h} = (D_n u_i^2 \nu_i^2 + (1/2)(D_n u \nu^T)^2)\nu\boldsymbol{h} = \boldsymbol{\epsilon}(u) \cdot \boldsymbol{\epsilon}(u))\nu\boldsymbol{h}. \tag{3.17}$$

Similarly

$$\textit{trace}\ (\boldsymbol{\epsilon}(u))I\nu\nabla u\boldsymbol{h} = (D_n u\nu)^2 \nu\boldsymbol{h} = \textit{trace}\ \boldsymbol{\epsilon}(u) I \cdot \boldsymbol{\epsilon}(u)\nu\boldsymbol{h}. \tag{3.18}$$

The identity in (3.16) follows now from (3.17) and (3.18) and the definition of the tensor $\mathcal{C}$.

To obtain appropriate estimates for the second variable we apply the variational form with the test function $\psi \equiv \nabla w \boldsymbol{h}$. From (3.10) we have

$$(\mathcal{C}[\boldsymbol{\epsilon}(u) + f(\nabla w)], \nabla(\nabla w \boldsymbol{h}) \times \nabla w) = 2(\mathcal{C}\boldsymbol{\epsilon}(u) + f(\nabla w), f(\nabla w)) + (a_{i,j} w_{x_j}, D^2_{x_i,x_k} w \boldsymbol{h}_k). \tag{3.19}$$

Integrating the result over Q we have

$$\begin{aligned}(w_t, \boldsymbol{h}\nabla w)_\Omega|_0^T + \gamma(\nabla w_t, \nabla(\boldsymbol{h}\nabla w))_\Omega|_0^T + \int_0^T [|w_t|^2_{0,\Omega} + (b_2 w_t, \boldsymbol{h}\nabla w)_\Omega + a(w,w) \\ +2(\mathcal{C}[\epsilon(u) + f(\nabla w)], f(\nabla w))_\Omega + (a_{i,j} w_{x_j}, D^2_{x_i,x_k} w \boldsymbol{h}_k)_\Omega] dt \\ = 1/2 \int_{\Sigma_1} [|w_t|^2 + \gamma|\nabla w_t|^2 - D/2[w^2_{x,x} + w^2_{y,y} + 2\nu w_{x,x} w_{y,y} + 2(1-\mu) w^2_{x,y}] \boldsymbol{h}\nu \\ +h_1(D_n w_t) D_n(\boldsymbol{h}\nabla w) + h_2(D_\tau w_t, D_\tau \boldsymbol{h}\nabla w)] d\Sigma_1 - D/2 \int_{\Sigma_0} |\Delta w|^2 \boldsymbol{h}\nu d\Sigma_0.\end{aligned} \tag{3.20}$$

Adding inequalities in (3.15) and (3.20) yields

$$\begin{aligned}\int_0^T [|u_t|^2_{0,\Omega} + |w_t|^2_{0,\Omega} + a(w,w) + (\mathcal{C}N(u,w), N(u,w))_\Omega + (\mathcal{C}N(u,w), f(\nabla w))_\Omega \\ +(a_{i,j}, [D^2 x_k, x_j u_i + w_{x_j} D^2_{x_j,x_k} w] \boldsymbol{h}_k)_\Omega] dt \le C[E(0) + E(T)] \\ +1/2 \int_{\Sigma_1} [|u_t|^2 + g(u_t) \boldsymbol{h}\nabla u + |w_t|^2 + \gamma|\nabla w_t|^2 + h_1(D_n w_t) D_n(\boldsymbol{h}\nabla w) \\ +h_2(D_\tau w_t) D_\tau(\boldsymbol{h}\nabla w) - D/2[w^2_{x,x} + w^2_{y,y} + 2\nu w_{x,x} w_{y,y} + 2(1-\nu) w^2_{x,y}] \boldsymbol{h}\nu] d\Sigma_1 \\ + \int_0^T [(b_1 u_t, \boldsymbol{h}\nabla u)_\Omega + (b_2 w_t, \boldsymbol{h}\nabla w)_\Omega] dt + \int_{\Sigma_0} [\mathcal{C}(\boldsymbol{\epsilon}(u)) \nu \boldsymbol{h}\nabla u + |\Delta w|^2 \boldsymbol{h}\nu] d\Sigma_0.\end{aligned} \tag{3.21}$$

Using the relations (3.12) in (3.21), applying the divergence theorem, and recalling (3.16) yields

$$\begin{aligned}\int_0^T [|u_t|^2_{0,\Omega} + |w_t|^2_{0,\Omega} + a(w,w) + (\mathcal{C}N(u,w), f(\nabla w))_\Omega] dt \le C[E(0) + E(T)] \\ +1/2 \int_{\Sigma_1} [|u_t|^2 + g(u_t) \boldsymbol{h}\nabla u + |w_t|^2 + \gamma|\nabla w_t|^2 + h_1(D_n w_t) D_n(\boldsymbol{h}\nabla w) \\ +h_2(D_\tau w_t) D_\tau(\boldsymbol{h}\nabla w) - D/2[w^2_{x,x} + w^2_{y,y} + 2\nu w_{x,x} w_{y,y} + 2(1-\nu) w^2_{x,y}] \boldsymbol{h}\nu] d\Sigma_1 \\ + \int_{\Sigma_0} [1/2 \mathcal{C}(\boldsymbol{\epsilon}(u)) \nu \boldsymbol{h}\nabla u + |\Delta w|^2 \boldsymbol{h}\nu] d\Sigma_0 - 1/2 \int_{\Sigma_1} \mathcal{C}N(u,w) \cdot N(u,w) \boldsymbol{h}\nu d\Sigma_1 \\ + \int_0^T [(b_1 u_t, \boldsymbol{h}\nabla u)_\Omega + (b_2 w_t, \boldsymbol{h}\nabla w)_\Omega] dt.\end{aligned} \tag{3.22}$$

On the other hand,

$$\int_{\Sigma_1} |N(u,w)|^2 d\Sigma_1 \le C \int_{\Sigma_1} |\nabla u|^2_{0,\Gamma_1} d\Sigma_1 + C(E(0)) \int_0^T |w|_{2-\epsilon,\Omega} dt, \tag{3.23}$$

$$(b_1 u_t, \boldsymbol{h}\nabla u)_\Omega \le \epsilon_1 |b_1^{*1/2} (\boldsymbol{h}\nabla u)|^2_{0,\Omega} + C_{\epsilon_1}(b_1 u_t, u_t)_\Omega \le \epsilon_0 |u|^2_{1,\Omega} + C_{\epsilon_0}(b_1 u_t, u_t)_\Omega, \tag{3.24}$$

$$(b_2 w_t, \boldsymbol{h}\nabla w)_\Omega \le \epsilon_1 |b_2^{*1/2} (\boldsymbol{h}\nabla w)|^2_{0,\Omega} + C_{\epsilon_1}(b_2 w_t, w_t)_\Omega \le \epsilon_0 |w|^2_{1,\Omega} + C_{\epsilon_0}(b_2 w_t, w_t)_\Omega. \tag{3.25}$$

Combining with (3.22) we obtain

$$\int_0^T [|u_t|^2_{0,\Omega} + |w_t|^2_{0,\Omega} + a(w,w) + (\mathcal{C}N(u,w), f(\nabla w))_\Omega]dt \le C[E(0) + E(T)$$
$$+1/2 \int_{\Sigma_1} [|u_t|^2 + g(u_t)\boldsymbol{h}\nabla u + |w_t|^2 + \gamma|\nabla w_t|^2 + h_1(D_n w_t)D_n(\boldsymbol{h}\nabla w) + h_2(D_\tau w_t)$$
$$\cdot D_\tau(\boldsymbol{h}\nabla w)]d\Sigma_1 - \int_{\Sigma_1} D/2[w^2_{x,x} + w^2_{y,y} + 2\nu w_{x,x}w_{y,y} + 2(1-\nu)w^2_{x,y}]\boldsymbol{h}\nu d\Sigma_1$$
$$+ \int_{\Sigma_0} [1/2\mathcal{C}(\boldsymbol{\epsilon}(u))\nu\boldsymbol{h}\nabla u + |\Delta w|^2\boldsymbol{h}\nu]d\Sigma_0 + \int_{\Sigma_1} |\nabla u|^2_{0,\Gamma_1} d\Sigma_1 + C(E(0)) \int_0^T |w|_{2-\epsilon,\Omega}dt$$
$$+C_{\epsilon_0} \int_0^T [(b_1 u_t, u_t)_\Omega + (b_2 w_t, w_t)_\Omega]dt + \epsilon_0 \int_0^T |u|^2_{1,\Omega}dt. \tag{3.26}$$

REMARK 3.2. *Note that in a special case when the geometric conditions are assumed also on* Γ_1*, then the last three boundary integrals in* (3.26) *can be discarded.*

Step 2. We apply the variational equality with the following test functions: $\phi = u$, $\psi = w$. We have

$$(u_t, u)_\Omega|_0^T + \int_0^T [(\mathcal{C}N(u,w), \boldsymbol{\epsilon}(u))_\Omega - |u_t|^2_{0,\Omega} + (b_1 u_t, u)_\Omega + \langle g(u_t), u\rangle_{\Gamma_1}$$
$$-\langle \mathcal{C}\boldsymbol{\epsilon}(u)\nu, u\rangle_{\Gamma_0}]dt = 0, \tag{3.27}$$

$$(w_t, w)_\Omega|_0^T + \gamma(\nabla w_t, \nabla w)_\Omega|_0^T + \int_0^T [a(w,w) + (b_2 w_t, w)_\Omega + (\mathcal{C}N(u,w), \nabla w \times \nabla w)_\Omega$$
$$-|w_t|^2_{0,\Omega} - \gamma|\nabla w_t|^2_{0,\Omega} - \langle h_1(D_n w_t), D_n w\rangle_{\Gamma_1} + \langle h_2(D_\tau w_t), D_\tau w\rangle_{\Gamma_1}]dt = 0. \tag{3.28}$$

Here we took into account the boundary conditions on Γ_0 for the variable w.

Multiplying equality (3.27) by a positive constant A, multiplying equality (3.28) by a negative constant B, adding the result to the inequality (3.26), and accounting for a correct sign of the boundary terms on Γ_0 yields

$$\int_0^T [|u_t|^2_{0,\Omega} + |w_t|^2_{0,\Omega} + a(w,w) + (\mathcal{C}N(u,w), f(\nabla w))_\Omega$$
$$+A\{(\mathcal{C}N(u,w), \boldsymbol{\epsilon}(u))_\Omega - |u_t|^2_{0,\Omega}\}$$
$$+B\{a(w,w) + 2(\mathcal{C}N(u,w), f(\nabla w))_\Omega - |w_t|^2_{0,\Omega} - \gamma|\nabla w_t|^2_{0,\Omega}\}]dt$$
$$\le C[E(0) + E(T)] + C \int_{\Sigma_1} [|u_t|^2 + g(u_t)\boldsymbol{h}\nabla u + |w_t|^2 + \gamma|\nabla w_t|^2 + h_1(D_n w_t)D_n(\boldsymbol{h}\nabla w)$$
$$+h_2(D_\tau w_t)D_\tau(\boldsymbol{h}\nabla w) - D/2[w^2_{x,x} + w^2_{y,y} + 2\nu w_{x,x}w_{y,y} + 2(1-\nu)w^2_{x,y}]\boldsymbol{h}\nu$$
$$-|\nabla u|^2]d\Sigma_1 + C \int_0^T [\langle g(u_t), u\rangle_{\Gamma_1} + \langle h_1(D_n w_t), D_n w\rangle_{\Gamma_1} + \langle h_2(D_\tau w_t), D_\tau w\rangle_{\Gamma_1}$$
$$+C_{\epsilon_0}((b_1 u_t, u_t)_\Omega + (b_2 w_t, w_t)_\Omega) + (b_1 u_t, u)_\Omega + (b_2 w_t, w)_\Omega + \epsilon_0|u|^2_{1,\Omega}$$
$$+C_\epsilon(E(0))|w|^2_{2-\epsilon,\Omega}]dt. \tag{3.29}$$

Selecting constants $A = 1/2, B = -1/4$ and upper bounding the boundary terms by

the trace theorem yields

$$\int_0^T [|u_t|^2_{0,\Omega} + |w_t|^2_{0,\Omega} + \gamma|\nabla w_t|^2_{0,\Omega} + a(w,w) + (\mathcal{C}N(u,w), N(u,w))_\Omega]dt$$
$$\leq C[E(0)+E(T)] + C\int_{\Sigma_1} [|u_t|^2 + |g(u_t)|^2 + |w_t|^2 + \gamma|\nabla w_t|^2 + |h_1(D_n w_t)|^2$$
$$+|h_2(D_\tau w_t)|^2 + |\nabla u|^2 + |D_n^2 w|^2 + |D_n D_\tau w|^2 + |D_\tau^2 w|^2]d\Sigma_1$$
$$+\int_0^T [C_{\epsilon_0}((b_1 u_t, u_t)_\Omega + (b_2 w_t, w_t)_\Omega) + \epsilon_0 |u|^2_{1,\Omega}]dt + C(E(0))\int_0^T [|w|^2_{2-\epsilon,\Omega} + |u|^2_{1-\epsilon,\Omega}]dt. \tag{3.30}$$

Recalling the definition of the energy together with the coercivity of E_p in $H^2(\Omega) \times H^1(\Omega)$ and taking ϵ_0 small enough yields

$$1/2TE(T) + 1/2\int_0^T E(t)dt \leq CE(T)$$
$$+C\int_{\Sigma_1} [|u_t|^2 + |g(u_t)|^2 + |w_t|^2 + \gamma|\nabla w_t|^2 + |h_1(D_n w_t)|^2$$
$$+|h_2(D_\tau w_t)|^2 + |\nabla u|^2 + |D_n^2 w|^2 + |D_n D_\tau w|^2 + |D_\tau^2 w|^2]d\Sigma_1$$
$$+C\int_0^T [(b_1 u_t, u_t)_\Omega + (b_2 w_t, w_t)_\Omega]dt + C(E(0))\int_0^T [|w|^2_{2-\epsilon,\Omega} + |u|^2_{1-\epsilon,\Omega}]dt. \tag{3.31}$$

Taking T large enough (note that the constant C in front of the term $E(T)$ is independent on T) yields the conclusion of Lemma 3.2 □

REMARK 3.3. *We note that the proof carried above provides a (new?) uniqueness result for the problem which is overdetermined on the boundary and defined on the star-shaped domain. Indeed, in the special case when the geometric conditions are satisfied also on* Γ_1,$b_1 = b_2 = 0$, *and solutions are required to have zero velocity traces on the boundary for* $t \in [0,T]$, *with* T *sufficiently large, the argument above gives*

$$E(t) \equiv 0.$$

Indeed, applying inequalities (3.22), (3.27), (3.28) *to the case considered above gives*

$$\int_0^T [|u_t|^2_{0,\Omega} + |w_t|^2_{0,\Omega} + a(w,w) + (\mathcal{C}N(u,w), f(\nabla w))_\Omega]dt \leq C[E(0)+E(T)], \tag{3.32}$$

$$(u_t, u)_\Omega|_0^T + \int_0^T [(\mathcal{C}N(u,w), \boldsymbol{\epsilon}(u))_\Omega - |u_t|^2_{0,\Omega}]dt = 0, \tag{3.33}$$

$$(w_t, w)_\Omega|_0^T + \gamma(\nabla w_t, \nabla w)_\Omega|_0^T + \int_0^T [a(w,w) + (\mathcal{C}N(u,w), \nabla w \times \nabla w)_\Omega$$
$$-|w_t|^2_{0,\Omega} - \gamma|\nabla w_t|^2_{0,\Omega}]dt = 0. \tag{3.34}$$

Multiplying equality (3.33) *by a positive constant* A, *multiplying equality* (3.34) *by a negative constant* B, *and adding the result to the inequality* (3.32) *yields*

$$\int_0^T [|u_t|^2_{0,\Omega} + |w_t|^2_{0,\Omega} + a(w,w) + (\mathcal{C}N(u,w), f(\nabla w))_\Omega$$
$$+A\{(\mathcal{C}N(u,w), \boldsymbol{\epsilon}(u))_\Omega - |u_t|^2_{0,\Omega}\}$$
$$+B\{a(w,w) + 2(\mathcal{C}N(u,w), f(\nabla w))_\Omega - |w_t|^2_{0,\Omega} - \gamma|\nabla w_t|^2_{0,\Omega}\}]dt$$
$$\leq C[E(0)+E(T)]. \tag{3.35}$$

Selecting constants $A = 1/2, B = -1/4$ *yields*

$$\int_0^T [|u_t|^2_{0,\Omega} + |w_t|^2_{0,\Omega} + \gamma|\nabla w_t|^2_{0,\Omega} + a(w,w) + (\mathcal{C}N(u,w), N(u,w))_\Omega]dt \leq C[E(0) + E(T)]. \tag{3.36}$$

Since, in our case, $E(t) = E(T)$, (3.36) *gives*

$$TE(T) = \int_0^T E(t)dt \leq CE(T) \tag{3.37}$$

and taking T *large enough we conclude* $E(t) \equiv 0$. *Hence* $u = w \equiv 0$, *which is the desired uniqueness result for the nonlinear problem at hand.*

3.3. Absorption of boundary traces and completion of the proof of Lemma 3.1. In this subsection we shall show that the boundary traces involving the second-order derivatives of w and the first-order derivatives of u are redundant. This will be done with the help of trace regularity results formulated in section 2.

LEMMA 3.3. *Under the assumptions of Lemma* 3.2 *we have*

$$E(T) + \int_0^T E(t)dt \leq C_T(E(0)) \int_{\Sigma_1} [|u_t|^2 + |\nabla w_t|^2 + |g(u_t)|^2 + |h_1(D_n w_t)|^2 + |h_2(D_\tau w_t)|^2]d_{\Sigma_1} + C\int_0^T [(b_1 u_t, u_t)_\Omega + (b_2 w_t, w_t)_\Omega]dt + C_{T,\epsilon}(E(0))lot(u,w). \tag{3.38}$$

Proof. From the result of Lemma 3.2 applied to the interval $[\alpha, T-\alpha]$ we obtain

$$\begin{aligned}\int_\alpha^{T-\alpha} E(t)dt &\leq C_T(E(0)) \int_{\Sigma_\alpha} [|u_t|^2 + |\nabla w_t|^2 + |g(u_t)|^2 + |h_1(D_n w_t)|^2 \\ &+|h_2(D_\tau w_t)|^2]d_{\Sigma_\alpha} + C\int_{\Sigma_\alpha} [|\nabla u|^2 + |D_n^2 w|^2 + |D_n D_\tau w|^2 + |D_\tau^2 w|^2]d\Sigma_\alpha \\ &+C\int_0^T [(b_1 u_t, u_t)_\Omega + (b_2 w_t, w_t)_\Omega]dt + C_T(E(0))lot(u,w).\end{aligned} \tag{3.39}$$

Here we took advantage of the dissipativity property in Lemma 2.1 which allows us to upper bound $E(\alpha)$ by $E(0)$. On the other hand, from regularity results stated in Lemmas 2.2 and 2.5 we infer the estimates

$$\begin{aligned}&\int_{\Sigma\alpha} [|\nabla u|^2 + |D_n^2 w|^2 + |D_\tau^2 w|^2 + |D_n D_\tau w|^2]d\Sigma_\alpha \\ &\leq C\int_{\Sigma_1} [|u_t|^2 + |g(u_t)|^2 + |\nabla w_t|^2 + h_1(D_n w_t)|^2 + |h_2(D_\tau w_t|^2 \\ &+C(E(0))|u_t|^2]d\Sigma_1 + C(E(0))\int_0^T [|w|^2_{2-\epsilon,\Omega} + |u|^2_{1-\epsilon,\Omega}]dt.\end{aligned} \tag{3.40}$$

Combining (3.39) and (3.40) and recalling, again, the dissipativity equality in Lemma

2.1 gives

$$E(T-\alpha)+\int_{\alpha}^{T-\alpha}E(t)dt\le C_T(E(0))\int_{\Sigma_1}[|u_t|^2+|\nabla w_t|^2+|g(u_t)|^2$$
$$+|h_1(D_nw_t)|^2+|h_2(D_\tau w_t)|^2]d_{\Sigma_1}+C\int_0^T[(b_1u_t,u_t)_\Omega+(b_2w_t,w_t)_\Omega]dt$$
$$+C(E(0))\int_0^T[|w|^2_{2-\epsilon,\Omega}+|u|^2_{1-\epsilon,\Omega}]dt. \tag{3.41}$$

To complete the proof of the lemma we need to estimate the contribution of the energy on the subintervals $[0,\alpha]$ and $[T-\alpha,T]$. To accomplish this we denote the right-hand side of (3.41) by $\mathcal{F}$. From dissipativity relation (2.1) and (3.41) we have, for all $t\in[0,T]$,

$$E(t)\le E(T-\alpha)+2\int_{\Sigma_1}[|u_t|^2+|\nabla w_t|^2+|g(u_t)|^2+|h_1(D_nw_t)|^2$$
$$+|h_2(D_\tau w_t)|^2]d\Sigma_1\le C\mathcal{F} \tag{3.42}$$

and by (3.41)

$$\int_0^{\alpha}E(t)dt+\int_{T-\alpha}^{T}E(t)dt\le C\mathcal{F}, \tag{3.43}$$

which completes the proof of the Lemma 3.3. □

Lemma 3.1 follows from Lemma 3.3 and from the dissipativity equality in Lemma 2.1. □.

4. Absorption of lower-order terms. Our next step is to eliminate lower-order terms from the inequality in Lemma 3.1. This is done by applying an appropriate compactness/uniqueness argument where a critical role is played by a recent uniqueness result due to Isakov which applies to domains with C^4 boundaries and with star-shaped unobserved portions of the boundaries (see [9, Remark 1.2], and [8, p. 750], where the geometry of the domains of unique continuation is explicitly described).

LEMMA 4.1. *Let u,w be a solution to* (1.1). *Then, there exist $T>0$ large enough so that the following parts hold.*

Part I. *Under Assumption* 2 (*in Theorem* 1.2) *we have*

$$lot(u,w)\equiv\int_0^T[|u(t)|^2_{1-\epsilon,\Omega}+|w(t)|^2_{2-\epsilon,\Omega}]dt\le C_T(E(0))\left[\int_{\Sigma_1}[|u_t|^2+|\nabla w_t|^2+|g(u_t)|^2\right.$$
$$\left.+|h_1(D_nw_t)|^2+|h_2(D_\tau w_t)|^2\right]d_{\Sigma_1}+C\int_0^T[(b_1u_t,u_t)_\Omega+(b_2w_t,w_t)_\Omega]dt. \tag{4.1}$$

Part II. *If the above assumption fails, then the constant C_T in* (4.1) *depends on*

$$E_\alpha(0)\equiv E(0)+|u_0|^2_{1+\alpha,\Omega}+|w_0|^2_{2+\alpha,\Omega},$$

where α can be taken to be arbitrarily small.

Proof. We argue by contradiction. Let u_n,w_n be a pair of solutions to (1.1) such that

$$\frac{lot(u_n,w_n)}{P(u_n,w_n)}\to\infty \text{ when } n\to\infty, \tag{4.2}$$

where

$$P(u,w) \equiv \int_{\Sigma_1} [|u_t|^2 + |\nabla w_t|^2 + |g(u_t)|^2 + |h_1(D_n w_t)|^2$$
$$+|h_2(D_\tau w_t)|^2]d_{\Sigma_1} + \int_0^T [(b_1 u_t, u_t)_\Omega + (b_2 w_t, w_t)_\Omega]dt. \tag{4.3}$$

From the boundedness of the initial energy ($E(0) \leq M$) we conclude that the sequence u_n, w_n satisfies

$$E_n(t) \leq M,$$

where E_n denotes $E(u_n, w_n)$.

Hence, on a subsequence,

$$\begin{aligned} u_n &\to u \text{ in } L_\infty(0,T;[H^1(\Omega)]^2) \text{ weakly}^\star, \\ u_{n,t} &\to u_t \text{ in } L_\infty(0,T;[L_2(\Omega)]^2) \text{ weakly}^\star, \\ w_n &\to w \text{ in } L_\infty(0,T;H^2(\Omega)) \text{ weakly}^\star, \\ w_{n,t} &\to w_t \text{ in } L_\infty(0,T;H^1(\Omega)) \text{ weakly}^\star. \end{aligned} \tag{4.4}$$

Thus, by the compactness of the lower-order terms (with respect to the topology induced by the energy) we conclude that

$$lot(u_n, w_n) \to lot(u, w). \tag{4.5}$$

We shall consider two separate cases.

Case 1. We have that

$$lot(u,w) \neq 0.$$

Then, $P(u_n, w_n) \to 0$ and

$$\begin{aligned} u_{n,t} &\to 0 \text{ in } [L_2(\Sigma)]^2, \\ \nabla w_{n,t} &\to 0 \text{ in } L_2(\Sigma), \\ g(u_{n,t}) &\to 0 \text{ in } [L_2(\Sigma)]^2, \\ h_1(D_n w_{n,t}) &\to 0 \text{ in } L_2(\Sigma), \\ h_2(D_\tau w_{n,t}) &\to 0 \text{ in } L_2(\Sigma), \\ b_1 u_{n,t} &\to 0 \text{ in } [L_2(\Omega)]^2, \\ b_2 w_{n,t} &\to 0 \text{ in } L_2(\Omega). \end{aligned} \tag{4.6}$$

Passing with the limit as $n \to \infty$ on the original equation (this is straightforward due to weak continuity of the nonlinear terms) we deduce that the limit functions u, w satisfy the original equations

$$\begin{aligned} u_{tt} + b_1 u_t - \operatorname{div}[\mathcal{C}[\boldsymbol{\epsilon}(u) + f(\nabla w)]] &= 0 \text{ in } \ Q, \\ [I - \gamma\Delta]w_{tt} + b_2 w_t + D\Delta^2 w - \operatorname{div}[\mathcal{C}[\boldsymbol{\epsilon}(u) + f(\nabla w)]\nabla w] &= 0 \ \text{ in } \ Q, \end{aligned} \tag{4.7}$$

$$\begin{aligned} \mathcal{C}[\boldsymbol{\epsilon}(u) + f(\nabla w)]\nu &= 0 \text{ in } \ \Sigma_1, \\ D[\Delta w + (1-\mu)B_1 w] &= 0 \text{ in } \ \Sigma_1, \\ D[D_n \Delta w + (1-\mu)B_2 w] &= 0 \text{ in } \ \Sigma_1, \\ u = w = \nabla w &= 0 \text{ in } \ \Sigma_0 \end{aligned} \tag{4.8}$$

with the overdetermined boundary conditions

$$u_t = 0, \nabla w_t = 0 \text{ on } \Sigma, \tag{4.9}$$

and

$$b_1 u_t = 0, b_2 w_t = 0 \text{ in } Q.$$

Denoting

$$\tilde{u} \equiv u_t, \quad \tilde{w} \equiv w_t,$$

we obtain the following system statisfied by the new variables

$$\begin{aligned} \tilde{u}_{tt} + b_1 \tilde{u}_t - \text{div}\mathcal{C}[\boldsymbol{\epsilon}(\tilde{u})] = L_1(\tilde{w}, w) \text{ in } \ Q, \\ [I - \gamma\Delta]\tilde{w}_{tt} + b_2\tilde{w}_t + D\Delta^2\tilde{w} = L_2(\tilde{u}, u, \tilde{w}, w) = 0 \ \text{ in } \ Q \end{aligned} \tag{4.10}$$

with the overdetermined boundary conditions on the boundary Γ

$$\tilde{u} = \nabla\tilde{w} = 0 \text{ on } \Sigma, \ \ \boldsymbol{\epsilon}(\tilde{u})\nu = 0 \text{ on } \Sigma_1, \ \ \Delta\tilde{w} = 0, \ D_n\Delta\tilde{w} = 0 \text{ on } \Sigma_1,$$

where we have used the notation

$$L_1(w, \tilde{w}) \equiv 1/2 \ \text{div}\mathcal{C}[\nabla\tilde{w} \times \nabla w] + 1/2 \ \text{div}\mathcal{C}[\nabla w \times \nabla\tilde{w}], \tag{4.11}$$

$$\begin{aligned} L_2(\tilde{u}, u, \tilde{w}, w) \equiv \text{div}[\mathcal{C}(\boldsymbol{\epsilon}(\tilde{u}))\nabla w + \mathcal{C}(\epsilon(u))\nabla\tilde{w} \\ + 1/2\mathcal{C}(\nabla\tilde{w} \times \nabla w)\nabla w + 1/2\mathcal{C}(\nabla w \times \nabla\tilde{w})\nabla w + \mathcal{C}f(\nabla w)\nabla\tilde{w}]. \end{aligned} \tag{4.12}$$

Our goal is to show that

$$u \equiv 0, \quad w \equiv 0 \text{ in } Q. \tag{4.13}$$

We shall treat separately cases considered in Parts I and II of Lemma 4.1. Let us notice first that in the case when the geometric conditions on the controlled portion of the boundary Γ_1 are satisfied (i.e., Ω is star-shaped), the conclusion in (4.13) follows at once from the uniqueness of solutions to the original equations (4.7), (4.8), (4.9) (see Remark 3.3). Thus, under the assumptions of Part I it suffices to consider the cases when either b_1 or b_2 are injective. Let us assume first that b_1 is injective. Then, we have $u_t \equiv 0$ and consequently

$$\begin{aligned} \text{div}\mathcal{C}N(u, w) = 0 \text{ in } \Omega, \\ N(u, w)\nu = 0 \text{ on } \Gamma_1, \ \ u = w = \nabla w = 0 \text{ on } \Gamma_0, \end{aligned} \tag{4.14}$$

which, in turn, implies

$$\text{div}\frac{d}{dt}\mathcal{C}(f(\nabla w)) = 0 \text{ in } Q. \tag{4.15}$$

Since a priori $f(\nabla w)\epsilon H^{1-\epsilon}(\Omega), \text{div} f(\nabla w) \in C(0, T; H^{-\epsilon}(\Omega))$ we obtain $\text{div}\mathcal{C}\epsilon(u) \in C(0, T; H^{-\epsilon}(\Omega))$ and by (4.14) $\epsilon(u) \cdot \nu|_{\Gamma_1} \in C(0, T; H^{1/2-\epsilon}(\Gamma_1))$. From elliptic regularity, we conclude the improved regularity for the variable u, i.e.,

$$u \in C(0, T; H^{2-\epsilon}(\Omega)). \tag{4.16}$$

Going back to the equation satisfied by w, denoting by $H(w)$ the matrix of the second derivatives of w (i.e., Hessian), and taking into account (4.14) we infer

$$\begin{aligned} [I - \gamma\Delta]w_{tt} + b_2 w_t + D\Delta^2 w = \mathcal{C}N(u, w) \cdot H(w) \text{ in } Q_T, \\ D[\Delta w + (1 - \mu)B_1 w] = 0 \text{ in } \ \Sigma_1, \\ D[D_n\Delta w + (1 - \mu)B_2 w] = 0 \text{ in } \ \Sigma_1, \end{aligned} \tag{4.17}$$

and the zero clamped boundary conditions on Γ_0. Differentiating (in the sense of distributions) the above equation in time yields

$$\begin{aligned}[I-\gamma\Delta]\tilde{w}_{t,t}+b_2\tilde{w}_t+D\Delta^2\tilde{w}=\mathcal{C}N(u,w)H(\tilde{w})+\mathcal{C}[1/2(\nabla\tilde{w}\times\nabla w)\\ +1/2(\nabla w\times\nabla\tilde{w})]H(w) \text{ in } Q,\\ D[\Delta\tilde{w}+(1-\mu)B_1\tilde{w}]=0 \text{ in } \Sigma_1,\\ D[D_n\Delta\tilde{w}+(1-\mu)B_2\tilde{w}]=0 \text{ in } \Sigma_1\end{aligned} \tag{4.18}$$

with the overdetermined boundary conditions on Γ_1

$$w=\nabla w=0 \text{ on } \Sigma.$$

Equation (4.18) is a linear equation in the variable $\tilde{w}$ with the coefficients depending on u, w. Therefore, provided that these coefficients are smooth enough and the solution itself is regular enough (and this is established in section 6, Theorem 6.2), we are in a position to apply the uniqueness result due to Isakov [9, Theorem 1.2], valid for the Kirchhoff plate, which gives

$$\tilde{w}=w_t=0 \text{ in } Q.$$

Thus, we have $u_t=0, w_t=0$ in Q. With this information we go back to the original equation (4.7), which now reads

$$\begin{aligned}\operatorname{div}\mathcal{C}N(u,w)=0 \text{ in } \Omega,\\ \mathcal{C}N(u,w)\nu=0 \text{ on } \Gamma_1, \quad u=0 \text{ on } \Gamma_0,\\ D\Delta^2 w-\operatorname{div}\mathcal{C}[N(u,w)\nabla w]=0 \text{ in } \Omega,\\ D[\Delta\tilde{w}+(1-\mu)B_1\tilde{w}]=0 \text{ on } \Gamma_1,\\ D[D_n\Delta w+(1-\mu)B_2 w]=0 \text{ on } \Gamma_1\end{aligned} \tag{4.19}$$

and the zero clamped boundary conditions on Γ_0. Multiplying the first equation by u, multiplying the second by $(1/2)w_t$, integrating over Ω, and adding the results yields

$$N(u,w)\equiv 0, \quad a(w,w)\equiv 0;$$

hence $w\equiv 0$ and $\epsilon(u)\equiv 0$. This combined with $\epsilon(u)\nu=0$ on Γ_1 and $u=0$ on Γ_0 gives $u\equiv 0, w\equiv 0$ as desired. Thus we have proved the assertion (4.13) when b_1 is injective.

We shall examine next the case when b_2 is injective. In this case we obtain that $w_t=\tilde{w}\equiv 0$ in Q. Therefore, $L_1(w,\tilde{w})\equiv 0$ and the variable $\tilde{u}$ satisfies

$$\tilde{u}_{tt}+b_1\tilde{u}_t-\operatorname{div}[\mathcal{C}\boldsymbol{\epsilon}(\tilde{u})]=0 \text{ in } Q, \tag{4.20}$$

$$\tilde{u}=0 \text{ on } \Sigma, \quad \boldsymbol{\epsilon}(\tilde{u})\nu=0 \text{ on } \Sigma_1. \tag{4.21}$$

The Holmgren type of uniqueness result for the elastic system (see, for instance, more precise results given in Theorem 1.2 and [8]) with the overdetermined boundary values gives that $\tilde{u}=0$ in Q_T. This, in turn, implies that both u_t and w_t are identically zero. As a result, we obtain the same static problem as in (4.19), which then yields the conclusion $u\equiv 0$ and $w\equiv 0$ as desired. Thus, the assertion (4.13) has been proved under the assumption of Part I of Lemma 4.1.

For Part II, the situation is more complicated and the assumption in Part II of Lemma 4.1 is also required. This is due to the fact that, in this case, our proof relies on an application of a new uniqueness result due to Isakov [9] in the context of a fully

dynamic von Karman system. This, in turn, requires the additional smoothness of the solutions and the coefficients corresponding to the system (4.10). The required regularity follows from Theorem 6.5 in section 6, which is proved under the additional assumption: $u_0 \in H^{1+\alpha}(\Omega), w_0 \in H^{2+\alpha}(\Omega)$ for $\alpha > 0$. Therefore, Theorem 1.3 in [9] applies to the linearized equation (4.10) and gives

$$\tilde{u} = \tilde{w} = 0.$$

Hence, u, w satisfy the static equation in (4.19) and we have $u = w = 0$. Thus we have established that under the assumptions of Parts I or II of Lemma 4.1 we always have $u = w = 0$. But this is a contradiction with the assumption made for Case 1. We shall next proceed to Case 2.

Case 2. $lot(u, w) = 0$. In this case, we do not need to distinguish between the Part I and Part II.

We define new variables

$$\hat{u}_n \equiv \frac{u_n}{c_n}, \quad \hat{w}_n \equiv \frac{w_n}{c_n},$$

where

$$c_n{}^2 \equiv lot(u_n, w_n) \to 0.$$

Thus we have

$$lot(\hat{u}_n, \hat{w}_n) = 1, \quad (1/c_n^2)P(u_n, w_n) \to 0, \tag{4.22}$$

which in turn implies

$$\begin{aligned} \hat{u}_{n,t} &\to 0 \text{ in } L_2(\Sigma), \\ \nabla \hat{w}_{n,t} &\to 0 \text{ in } L_2(\Sigma), \\ (1/c_n)g(u_{n,t}) &\to 0 \text{ in } L_2(\Sigma), \\ (1/c_n)h_1(D_n \hat{w}_{n,t}) &\to 0 \text{ in } L_2(\Sigma), \\ (1/c_n)h_2(D_\tau \hat{w}_{n,t}) &\to 0 \text{ in } L_2(\Sigma). \end{aligned} \tag{4.23}$$

Also, it is straightforward to verify that the new variables $\hat{u_n}, \hat{w_n}$ satisfy the system

$$\begin{aligned} &\hat{u}_{n,tt} + b_1 \hat{u}_t - \operatorname{div}[\mathcal{C}[\boldsymbol{\epsilon}(\hat{u}_n) + (1/c_n)f(\nabla w_n)]] = 0 \text{ in } \ Q, \\ &[I - \gamma\Delta]\hat{w}_{n,tt} + b_2 \hat{w}_t + D\Delta^2 \hat{w}_n - \operatorname{div}[\mathcal{C}[\boldsymbol{\epsilon}(\hat{u}_n) + (1/c_n)f(\nabla w_n)]\nabla w_n] = 0 \text{ in } \ Q \end{aligned} \tag{4.24}$$

with the Dirichlet boundary conditions on the uncontrolled part of the boundary Γ_0

$$\hat{u}_n = \hat{w}_n = \nabla \hat{w}_n = 0 \ \text{ on } \Sigma_0$$

and the dissipative boundary conditions on the controlled part of the boundary Γ_1

$$\begin{aligned} \mathcal{C}[\boldsymbol{\epsilon}(\hat{u}_n) + (1/c_n)f(\nabla w_n)]\nu &= -(1/c_n)g(u_{n,t}) \text{ in } \ \Sigma_1, \\ D[\Delta \hat{w}_n + (1-\mu)B_1 \hat{w}_n] &= -(1/c_n)h_1(D_n w_{n,t}) \text{ in } \ \Sigma_1, \\ D[D_n \Delta \hat{w}_n + (1-\mu)B_2 \hat{w}_n] - \gamma D_n \hat{w}_{n,tt} - [\mathcal{C}[\boldsymbol{\epsilon}(\hat{u}_n) + (1/c_n)f(\nabla w_n)]\nu \cdot \nabla w_n] & \\ = -(1/c_n)D_\tau h_2(D_\tau w_{n,t}). & \end{aligned} \tag{4.25}$$

Denoting

$$E_n \equiv E(u_n, w_n)$$

and recalling the stabilizability estimate in Lemma 3.1 together with (4.22) gives

(4.26)
$$(1/c_n^2)\left[E_n(0)+E_n(T)+\int_0^T E_n(t)dt\right]\le C(E_n(0))[(1/c_n^2)P(u_n,w_n)+lot(\hat{u}_n,\hat{w}_n)]\le M.$$

Elementary calculations show that (4.26) implies

$$\begin{aligned}|\hat{u}_n(t)|_{1,\Omega}&\le C,\\ |\hat{u}_{n,t}(t)|_{0,\Omega}&\le C,\\ |\hat{w}_n(t)|_{2,\Omega}&\le C,\\ |\hat{w}_{n,t}(t)|_{1,\Omega}&\le C.\end{aligned}\tag{4.27}$$

Hence, on a subsequence,

$$\hat{u}_n\to\hat{u}\text{ in }L_\infty(0,T;H^1(\Omega))\text{ weakly}\star,\tag{4.28}$$

$$\hat{u}_{n,t}\to\hat{u}_t\text{ in }L_\infty(0,T;L_2(\Omega))\text{ weakly}\star,\tag{4.29}$$

$$\hat{w}_n\to\hat{w}\text{ in }L_\infty(0,T;H^2(\Omega))\text{ weakly}\star,\tag{4.30}$$

$$\hat{w}_{n,t}\to\hat{w}_t\text{ in }L_\infty(0,T;H^1(\Omega))\text{ weakly}\star.\tag{4.31}$$

By the compactness of the lower-order term *lot* and (4.22) we infer that

$$lot(\hat{u}_n,\hat{w}_n)\to lot(\hat{u},\hat{w})=1.\tag{4.32}$$

We also notice that due to the uniform boundedness in (4.27)

$$w_n=\hat{w}_nc_n\to 0\text{ in }L_\infty(0,T;H^2(\Omega)).\tag{4.33}$$

Therefore, passing on the limit in the equation for $\hat{u}_n,\hat{w}_n$ (via routine arguments), using (4.31), (4.33), (4.23), and

$$|(1/c_n)f(\nabla w_n)|_{L_2(\Omega)}\le C|\nabla\hat{w}_n|_{L_4(\Omega)}|\nabla w_n|_{L_4(\Omega)}\to 0\tag{4.34}$$

leads to a decoupled system

$$\begin{aligned}\hat{u}_{tt}+b_1\hat{u}_t-\operatorname{div}[\mathcal{C}[\boldsymbol{\epsilon}(\hat{u})]&=0\text{ in }\ Q,\\ [I-\gamma\Delta]\hat{w}_{tt}+b_2\hat{w}_t+D\Delta^2\hat{w}&=0\ \text{ in }\ Q\end{aligned}\tag{4.35}$$

with Dirichlet/clamped boundary conditions on the uncontrolled part of the boundary Γ_0

$$\hat{u}=\hat{w}=\nabla\hat{w}=0\ \text{ on }\Sigma_0,$$

homogeneous boundary conditions on the controlled part of the boundary Γ_1

$$\begin{aligned}\mathcal{C}[\boldsymbol{\epsilon}(\hat{u})]\nu&=0\text{ in }\Sigma_1,\\ D[\Delta\hat{w}+(1-\mu)B_1\hat{w}]&=0\text{ in }\ \Sigma_1,\\ D[D_n\Delta\hat{w}+(1-\mu)B_2\hat{w}]&=0\ \text{ in }\ \Sigma_1,\end{aligned}\tag{4.36}$$

and the overdetermined boundary conditions

$$\hat{u}_t=0,\nabla\hat{w}_t=0\text{ on }\Sigma.$$

Denoting

$$\tilde{u} \equiv \hat{u}_t, \quad \tilde{w} \equiv \hat{w}_t,$$

we obtain that $\tilde{u}, \tilde{w}$ satisfy the same equation (4.35) with the boundary conditions

$$\tilde{u} = \tilde{w} = \nabla\tilde{w} = 0 \text{ on } \Sigma, \tag{4.37}$$

$$D_n\tilde{u} = \Delta\tilde{w} = D_n\Delta\tilde{w} = 0 \text{ on } \Sigma_1. \tag{4.38}$$

A standard Holmgren-type uniqueness result valid for these linear equations (see also [9]) yields

$$\tilde{u} \equiv 0, \quad \tilde{w} \equiv 0,$$

and going back to the static equation (4.19) we obtain

$$\hat{u} = 0, \quad \hat{w} = 0.$$

This is a contradiction of (4.32). The proof is thus completed. □

5. Completion of the proof of Theorem 1.2. By combining the results of Lemmas 3.1 and 4.1 we obtain Lemma 5.1.

LEMMA 5.1. *Let u, w be a regular solution to the original system. Then there exists a constant $T_0 > 0$ such that for any $T > T_0$,*

$$E(0) + E(T) + \int_0^T E(t)dt \le C_T(E(0)) \int_{\Sigma_1} [|u_t|^2 + |\nabla w_t|^2 + |g(u_t)|^2$$

$$+|h_1(D_n w_t)|^2 + |h_2(D_\tau w_t)|^2]d\Sigma_1 + \int_0^T [(b_1 u_t, u_t)_\Omega + (b_2 w_t, w_t)_\Omega]dt. \tag{5.1}$$

In what follows we shall denote

$$\Sigma_A \equiv \{(t,x) \in \Sigma_1 : |u_t| \le 1\}$$

and

$$\Sigma_B \equiv \Sigma_1 - \Sigma_A.$$

Recalling the definition of the function $\mathcal{G}$ we obtain

$$\int_{\Sigma_1} [|u_t|^2 + |g(u_t)|^2]d\Sigma_1 \le \int_{\Sigma_A} \mathcal{G}(u_t, g(u_t))d\Sigma_A + C\int_{\Sigma_B} g(u_t)u_t d\Sigma_B$$

$$\le \int_{\Sigma_1} [\mathcal{G}(u_t, g(u_t)) + Cu_t g(u_t)]d\Sigma_1. \tag{5.2}$$

A similar argument applies to the remaining feedback terms:

$$\int_{\Sigma_1} [|\nabla w_t|^2 + |h_1(D_n w_t)|^2 + |h_2(D_\tau w_t)|^2]d\Sigma_1 \le \int_{\Sigma_1} [C[D_n w_t h_1(D_n w_t)$$

$$+D_\tau w_t, h_2(D_\tau w_t)] + \mathcal{H}1(D_n w_t, h_1(D_n w_t)) + \mathcal{H}2(D_\tau w_t, h_2(D_\tau w_t))]d\Sigma_1. \tag{5.3}$$

Using Jensen's inequality we infer

$$\int_{\Sigma_1} [|u_t|^2 + |\nabla w_t|^2 + |g(u_t)|^2 + |h_1(D_n w_t)|^2 + |h_2(D_\tau w_t)|^2]d\Sigma_1$$

$$\le [CI + \mathcal{H}] \int_{\Sigma_1} [u_t g(u_t) + h_1(D_n w_t)D_n w_t + h_2(D_\tau w_t)D_\tau w_t]d\Sigma_1. \tag{5.4}$$

Denoting by

$$\mathcal{F} \equiv \int_{\Sigma_1} [u_t g(u_t) + h_1(D_n w_t) D_n w_t + h_2(D_\tau w_t) D_\tau w_t] d\Sigma_1 + \int_0^T [(b_1 u_t, u_t)_\Omega + (b_2 w_t, w_t)_\Omega] dt \tag{5.5}$$

we have that the inequality in (5.1) reads

$$E(0) + E(T) + \int_0^T E(t)dt \le C_T(E(0))[\mathcal{F} + \mathcal{H}(\mathcal{F})]. \tag{5.6}$$

Since the function $\mathcal{H} + \mathcal{I}$ is monotone, we can write

$$[I + \mathcal{H}]^{-1} E(T)/C_T(E(0)) \le \mathcal{F} = E(0) - E(T), \tag{5.7}$$

which in turn gives

$$p(E(T)) + E(T) \le E(0), \tag{5.8}$$

where the monotone function p is defined in section 1. Thus we have proved Lemma 5.2.

LEMMA 5.2. *Let u, w be a solution to the original equation. Then there exists a constant $T > 0$ such that*

$$p(E(T)) + E(T) \le E(0), \tag{5.9}$$

where the monotone function p is defined in section 1.

The final conclusion of Theorem 1.2 follows now from (5.9) and Lemma 3 in [19]. □

6. Regularity of the problem which is overdetermined on the boundary. We recall that for the proof of Lemma 4.1 in section 4 we have used the unique continuation results due to Isakov, which, however, require an additional regularity of the solutions to (4.14), (4.18), and (4.10). The purpose of this section is to establish the needed regularity. In fact, we shall show that solutions to these overdetermined on the boundary problems display an arbitrary level of smoothness. We shall begin our analysis with a simpler case of a semidynamic problem consisting of the system of equations given by (4.14), (4.18). (See the proof of Part I in Lemma 4.1.) Thus we are led to consider the following problem:

$$[I - \gamma\Delta]\tilde{w}_{tt} + b_2\tilde{w}_t + D\Delta^2\tilde{w} = L(u, \tilde{w}, w) \text{ in } Q \tag{6.1}$$

with the homogeneous boundary conditions on the boundary Γ

$$\nabla\tilde{w} = 0 \text{ on } \Gamma, \quad \Delta\tilde{w} = 0, \ D_n\Delta\tilde{w} = 0 \text{ on } \Gamma_1, \tag{6.2}$$

where we have used the notation

$$L(u, \tilde{w}, w) \equiv \mathcal{C}N(u, w)H(\tilde{w}) + 1/2\mathcal{C}(\nabla\tilde{w} \times \nabla w)H(w) + 1/2\mathcal{C}(\nabla w \times \nabla\tilde{w})H(w). \tag{6.3}$$

We know a priori (see (4.16)) that for any $\epsilon > 0$,

$$\begin{aligned} &u \in C(0, T; H^{2-\epsilon}(\Omega)), \quad w \in C(0, T; H^2(\Omega)), \quad \tilde{w} \in C(0, T; H^1(\Omega)), \\ &\tilde{w}_t \in C(0, T; L_2(\Omega)). \end{aligned} \tag{6.4}$$

Our first result follows in Lemma 6.1.

LEMMA 6.1. *Let $\tilde{w}$ be the solution to* (6.1) *with regularity specified above and the overdetermined boundary conditions given in* (6.2). *Then*

$$\tilde{w} \in C(0,T;H^2(\Omega)) \cap C^1(0,T;H^1(\Omega)). \tag{6.5}$$

Proof. The idea is to use Carleman's estimates, which are derived from [27] (see also [26]) and applied to equation (6.1). However, in order to do this we need to consider smoother solution than the ones given a priori. Therefore, we take a sequence of the initial data

$$\tilde{w}_{n,0} \in H_0^2(\Omega), \quad \tilde{w}_{n,1} \in H_0^1(\Omega)$$

such that

$$w_{n,0} \to \tilde{w}(0) \ \text{ in } \ H^1(\Omega), w_{n,1} \to \tilde{w}_t(0) \ \text{ in } \ L_2(\Omega). \tag{6.6}$$

Accounting for the regularity of the right-hand side in equation (6.1), i.e., term L which satisfies the estimate

$$|L(u,\tilde{w},w)|_{[H^1(\Omega)]'} \le C|\tilde{w}|_{2,\Omega}[|u|_{2-\epsilon,\Omega} + |w|^2_{2,\Omega}],$$

we infer by standard perturbation argument in linear semigroup theory that the solutions corresponding to the regularized initial data and denoted by $\tilde{w}_n(t)$ satisfy

$$\tilde{w}_n \in H_0^2(\Omega), \quad \tilde{w}_{n,t} \in H_0^1(\Omega), \tag{6.7}$$

$$\tilde{w}_n \to \tilde{w}(t) \ \text{ in } \ H^1(\Omega), \ \ \tilde{w}_{n,t} \to \tilde{w}_t(t) \ \text{ in } \ L_2(\Omega). \tag{6.8}$$

Since the term $L(u,w,\tilde{w}_n) \in C(0,T;H^{-1}(\Omega))$ we are in a position to apply Carleman's estimates in [27] to equation (6.1) satisfied by $\tilde{w}_n$. To do this, we need to introduce some notation. Let ϕ denotes a pseudoconvex function with respect to the real characteristics of the differential operator associated with the elastic and Kirchhoff system. In particular one can take

$$\phi(x) = |x - x_0|^2 - c(t - T/2)^2,$$

where the constant c is suitably small (see [27]). Let ψ be a nonnegative nondecreasing smooth real function with the following properties:

$$\psi(0) = 0, \quad \psi(x) > 0 \text{ for } x > 0, \tag{6.9}$$

$$\psi^{'}\psi^k/\psi \text{ is bounded on } R^+ \text{ for } k = 1,2,3. \tag{6.10}$$

We define

$$z \equiv \psi(\phi).$$

Applying the estimate of Theorem 2 in [27] (with $p = -1$) and noting that the anisotropic norms in the normal direction are irrelevant due to the zero overdetermined boundary conditions gives

$$\int_0^T |ze^{\tau\phi}\tilde{w}_{n,t}|^2_{1,\Omega} + |ze^{\tau\phi}\tilde{w}_n|^2_{2,\Omega}dt$$

$$\le C/\tau \int_0^T |ze^{\tau\phi}L(\tilde{w}_n,u,w)|^2_{-1,\Omega}dt + M_\tau(u,w,\tilde{w}_n), \tag{6.11}$$

where the constant τ can be arbitrarily large. The term $M_\tau(u, w, \tilde{w})$ is bounded by the a priori regularity of u, w, and, moreover, depends linearly on the lower-order norms of $\tilde{w}_n$, i.e.,

$$M_\tau(u, w, \tilde{w}_n) \leq M_{\tau,u,w} \int_0^T |\tilde{w}_n|^2_{1,\Omega} + |\tilde{w}_{n,t}|^2_{0,\Omega} dt. \tag{6.12}$$

Estimating the right-hand side of (6.11) gives

$$\begin{aligned} &\int_0^T |ze^{\tau\phi}\tilde{w}_{n,t}|^2_{1,\Omega} + |ze^{\tau\phi}\tilde{w}_n|^2_{2,\Omega} dt \\ &\leq C/\tau \int_0^T |ze^{\tau\phi}\tilde{w}_n|^2_{2,\Omega} dt [|w|^2_{L_\infty(0,T;H^2(\Omega))} + |u|_{L_\infty(0,T;H^{2-\epsilon}(\Omega))}] \\ &\qquad + M_\tau(u, w, \tilde{w}_n). \end{aligned} \tag{6.13}$$

Taking the constant τ to be large enough and recalling the a priori regularity in (6.4) gives

$$\int_0^T [|ze^{\tau\phi}\tilde{w}_{n,t}|^2_{1,\Omega} + |ze^{\tau\phi}\tilde{w}_n|^2_{2,\Omega}] dt \leq M_\tau(u, w, \tilde{w}_n). \tag{6.14}$$

Since ψ can be selected in such a way that

$$ze^{\tau\phi} \geq 1 \text{ on } [t_0, t_1] \in [0, T],$$

the inequality in (6.14) gives

$$\int_{t_0}^{t_1} |\tilde{w}_{n,t}|^2_{1,\Omega} + |\tilde{w}_n|^2_{2,\Omega} dt \leq M_\tau(u, w, \tilde{w}_n). \tag{6.15}$$

Define

$$\tilde{E}_n(t) \equiv |\tilde{w}_{n,t}(t)|^2_{1,\Omega} + |\tilde{w}_n(t)|^2_{2,\Omega}.$$

Noting that

$$\begin{aligned} &\int_s^{t_1} |L(w, u, \tilde{w}_n)|^2_{-1,\Omega} dt \\ &\leq C \int_s^{t_1} [|\tilde{w}_n|^2_{2,\Omega}] dt [|w|^2_{L_\infty(0,T);H^2(\Omega)} + |u|^2_{L_\infty(0,T);H^{2-\epsilon}(\Omega)}] + M_\tau(u, w, \tilde{w}_n), \end{aligned} \tag{6.16}$$

applying standard energy inequality to equation (6.1), and accounting for (6.15), we obtain for $t_0 \leq s \leq t_1$,

$$\begin{aligned} \tilde{E}_n(t_1) &\leq C\tilde{E}_n(s) + C \int_s^{t_1} |L(w, u\tilde{w}_n)|^2_{-1,\Omega} \\ &\leq C\tilde{E}_n(s) + M_\tau(u, w, \tilde{w}_n) + C \int_s^{t_1} \tilde{E}_n(t) dt \leq C\tilde{E}_n(s) + CM_\tau(u, w, \tilde{w}_n). \end{aligned} \tag{6.17}$$

Integrating the above inequality with respect to s yields

$$(t_1 - t_0)\tilde{E}_n(t_1) \leq C \int_{t_0}^{t_1} \tilde{E}_n(s) ds + CTM_\tau(u, w, \tilde{w}). \tag{6.18}$$

From (6.15) and (6.18) we infer

$$\tilde{E}_n(t_1) \leq C_T M_\tau(u, w, \tilde{w}_n). \tag{6.19}$$

Since the problem is linear in the variable $\tilde{w}$ and the term $M_\tau(u, w, \tilde{w}_n)$ depends on the lower-norm estimates for $\tilde{w}_n$, see (6.12), we apply the same argument to the sequence $\tilde{w}_n - \tilde{w}_m$. From (6.8) and (6.12) it follows that

$$M_\tau(u, w, \tilde{w}_n - \tilde{w}_m) \to 0. \tag{6.20}$$

Passing through the limit on the right-hand side of (6.19) (this time written for the difference between the two solutions) and accounting for (6.20) we conclude that $\tilde{w}_n(t_1), \tilde{w}_{n,t}(t_1)$ is a Cauchy sequence in $H^2(\Omega) \times H^1(\Omega)$ and it converges to $\tilde{w}(t_1), \tilde{w}_t(t_1)$. Standard semigroup argument yields the improved regularity for $\tilde{w}$:

$$\tilde{w} \in C(0, T; H^2(\Omega)), \tag{6.21}$$

$$\tilde{w}_t \in C(0, T; H^1(\Omega)). \qquad \square \tag{6.22}$$

In order to apply Isakov's uniqueness result in the context of equation (4.18), one needs to assert the regularity of solutions as well as the regularity of the coefficients of equation (4.18), which, in our case, amounts to the regularity of u, w. Since the variables $\tilde{u}, \tilde{w}$ are nothing but time derivatives of u, w, we have so far obtained

$$w_t \in C(0, T; H^2(\Omega)), \quad w_{tt} \in C(0, T; H^1(\Omega)). \tag{6.23}$$

In order to obtain a higher spatial regularity, we return to the original equation satisfied by u, w. Recalling the fact that the traces of velocities of u's and ∇w's are zero on Γ_1, we obtain

$$\begin{aligned}
\mathrm{div}\mathcal{C}[\boldsymbol{\epsilon}(u) + f(\nabla w)] &= 0 \text{ in } Q,\\
D\Delta^2 w = -[I - \gamma\Delta]w_{tt} - b_2 w_t + \mathrm{div}[\mathcal{C}[\boldsymbol{\epsilon}(u) + f(\nabla w)]\nabla w] &\text{ in } Q,\\
u = w = \nabla w &= 0 \text{ on } \Sigma_0,\\
\mathcal{C}[\boldsymbol{\epsilon}(u) + f(\nabla w)]\nu &= 0 \text{ in } \Sigma_1,\\
D[\Delta w + (1-\mu)B_1 w] &= 0 \text{ in } \Sigma_1,\\
D[D_n \Delta w + (1-\mu)B_2 w] &= 0 \text{ in } \Sigma_1.
\end{aligned} \tag{6.24}$$

By straightforward calculations and accounting for the result of Lemma 6.1 we infer that

$$\mathrm{div}[\mathcal{C} f(\nabla w)] \in C(0, T; H^{-\epsilon}(\Omega)), \tag{6.25}$$

$$[I - \gamma\Delta]w_{tt} + b_2 w_t + \mathrm{div}[\mathcal{C}[\boldsymbol{\epsilon}(u) + f(\nabla w)]\nabla w] \in C(0, T; H^{-1-\epsilon}(\Omega)). \tag{6.26}$$

From the regularity of the biharmonic problem, we further infer that

$$w \in C(0, T; H^{3-\epsilon}(\Omega)).$$

Hence,

$$f(\nabla w) \in C(0, T; H^1(\Omega)),$$

and going back to (6.24) we have that

$$\mathrm{div}[\mathcal{C} f(\nabla w)] \in C(0, T; L_2(\Omega)), \tag{6.27}$$

$$[I - \gamma\Delta]w_{tt} + \mathrm{div}[\mathcal{C}[\boldsymbol{\epsilon}(u) + f(\nabla w)]\nabla w] \in C(0, T; H^{-1}(\Omega)). \tag{6.28}$$

Since

$$f(\nabla w)|_{\Gamma_1} \in C(0,T;H^{1/2}(\Gamma_1)),$$

by reading off the boundary conditions in (6.24) we also obtain that

$$\mathcal{C}[\boldsymbol{\epsilon}(u)]|_{\Gamma_1} \in C(0,T;H^{1/2}(\Gamma_1)).$$

We are now in a position to apply elliptic estimates to the problem (6.24) and conclude that

$$u \in C(0,T;H^2(\Omega)), \quad w \in C(0,T;H^3(\Omega)). \tag{6.29}$$

Differentiating in time equation (6.1) and reiterating the same argument over and over we arrive at the conclusion that

$$u, w, \tilde{u}, \tilde{w} \in C^\infty(Q).$$

Thus we have obtained Theorem 6.2.

THEOREM 6.2. *Let u, w be a finite energy solution to the system* (4.7), (4.8) *with the overdetermined boundary data* (4.9) *such that $u_t \equiv 0$. Then*

$$u, w \in C^\infty(Q).$$

This gives us the improved regularity of the coefficients and of the solutions to equation (4.18), which, in turn, justifies the application, in section 4, of Isakov's Theorem 3 in [9]. From Theorem 3 in [9] we infer that the solution to (4.18) is identically zero, proving Corollary 6.3.

COROLLARY 6.3. *Let u, w be a finite energy solution to the system* (4.7), (4.8) *with the overdetermined boundary data* (4.9) *such that $u_t \equiv 0$. Then*

$$u, w \equiv 0 \text{ in } Q.$$

Now we consider the more difficult case, when Isakov's uniqueness property is used in the context of proving Lemma 4.1 under the assumptions of Part II. Application of Isakov's result requires that we show that the solutions and the coefficients of a fully dynamic system (4.10) are sufficiently smooth. Under the assumption of Part II, we have $E_\alpha \leq M$, which leads us to the limit solutions with the incrementally improved regularity (see [18]). This is to say that in equation (4.10) the coefficients u, w are in $C(0,T;H^{1+\alpha}(\Omega) \times H^{2+\alpha}(\Omega))$, where the parameter α may be arbitrarily small. Our goal is to show that this incremental improvement of regularity of the initial data implies that the solution to the problem (4.10) with the zero overdetermined boundary data is $C^\infty(Q)$. Thus we are led to consider the following problem. Let u, w be a finite energy solution corresponding to the original system with the additional regularity specified below, i.e., we assume the following.

ASSUMPTION 3. *We have that*

$$u \in C(0,T;H^{1+\alpha}(\Omega)), \quad w \in C(0,T;H^{2+\alpha}(\Omega)). \tag{6.30}$$

We consider the coupled system (see (4.10))

$$\begin{aligned} \tilde{u}_{tt} + b_1\tilde{u}_t - \operatorname{div}[\mathcal{C}[\boldsymbol{\epsilon}(\tilde{u})] &= L_1(\tilde{w}, w) \text{ in } Q, \\ [I - \gamma\Delta]\tilde{w}_{tt} + b_2\tilde{w}_t + D\Delta^2\tilde{w} &= L_2(\tilde{u}, u, \tilde{w}, w) \text{ in } Q, \end{aligned} \tag{6.31}$$

with the homogeneous boundary conditions on the boundary Γ

$$\tilde{u} = \nabla\tilde{w} = 0 \ \text{ on } \Gamma, \quad \Delta\tilde{w} = 0, \ D_n\Delta\tilde{w} = 0 \text{ on } \Gamma_1,$$

where we have used the notation

$$L_1(w,\tilde{w}) \equiv 1/2\mathrm{div}[\nabla\tilde{w}\times\nabla w] + 1/2\mathrm{div}[\nabla w\times\nabla\tilde{w}], \tag{6.32}$$

$$L_2(\tilde{u},u,\tilde{w},w) \equiv \mathrm{div}[\mathcal{C}(\boldsymbol{\epsilon}(\tilde{u}))\nabla w + \mathcal{C}(\epsilon(u))\nabla\tilde{w}$$

$$+1/2\mathcal{C}(\nabla\tilde{w}\times w)\nabla w + 1/2\mathcal{C}(\nabla w\times\nabla\tilde{w})\nabla w + \mathcal{C}f(\nabla w)\nabla\tilde{w}]. \tag{6.33}$$

Our result follows in Lemma 6.4.

LEMMA 6.4. *Under Assumption* 3, *stated above, any solution* $\tilde{u},\tilde{w}$ *to the problem* (6.31) *with the zero overdetermined boundary conditions*

$$\nabla\tilde{u} = 0, \ \nabla\tilde{w} = 0, \quad \Delta\tilde{w} = D_n\Delta\tilde{w} = 0 \text{ on } \Gamma_1$$

and such that a priori $\tilde{u},\tilde{w} \in C(0,T;L_2(\Omega)\times H^1(\Omega))$ *satisfies*

$$\tilde{u},\tilde{w} \in C(0,T;H^1(\Omega)\times H^2(\Omega)) \cap C^1(0,T;L_2(\Omega)\times H^1(\Omega)). \tag{6.34}$$

Proof. As before, the key idea is to use Carleman's estimates applied to the "regularized" problem, i.e., with "smooth" initial conditions such that (6.6) holds and, moreover,

$$\tilde{u}_{n,0} \in H_0^1(\Omega), \quad \tilde{u}_{n,1} \in L_2(\Omega), \tag{6.35}$$

$$\tilde{u}_{n,0} \to \tilde{u}(0) \text{ in } L_2(\Omega), \ \tilde{u}_{n,1} \to \tilde{u}_t(0) \text{ in } H^{-1}(\Omega). \tag{6.36}$$

In this case, the corresponding solutions $\tilde{u}_n,\tilde{w}_n$ satisfy (6.7), (6.8) and, moreover,

$$\tilde{u}_n(t) \in H_0^1(\Omega), \quad \tilde{u}_{n,t}(t) \in L_2(\Omega), \tag{6.37}$$

$$\tilde{u}_n(t) \to \tilde{u}(t) \text{ in } L_2(\Omega), \quad \tilde{u}_{n,t}(t) \to \tilde{u}_t(t) \text{ in } H^{-1}(\Omega). \tag{6.38}$$

With the improved regularity of regularized solutions and by virtue of Assumption 3 we easily verify that

$$L_1(w,\tilde{w}_n) \in C(0,T;L_2(\Omega)), \quad L_2(u,\tilde{u}_n,w,\tilde{w}_n) \in C(0,T;H^{-1}(\Omega)).$$

The above regularity allows us to apply Carleman's estimates given in [27]. Indeed, Theorem 2 in [27] applied separately to the Kirchhoff plate (6.31) and also to the system of elasticity (after decoupling into two wave equations and applying the estimates for the wave equation with $p=-1$ [25]) yields the following inequalities that are valid with any large constant τ:

$$\int_0^T |ze^{\tau\phi}\tilde{u}_{n,t}|^2_{0,\Omega} + |ze^{\tau\phi}\tilde{u}_n|^2_{1,\Omega}dt$$

$$\le C/\tau\int_0^T |ze^{\tau\phi}L_1(\tilde{w}_n,w)|^2_{0,\Omega}dt + M_\tau(u,w,\tilde{u}_n,\tilde{w}_n), \tag{6.39}$$

$$\int_0^T |ze^{\tau\phi}\tilde{w}_{n,t}|^2_{1,\Omega} + |ze^{\tau\phi}\tilde{w}_n|^2_{2,\Omega}dt$$

$$\le C/\tau\int_0^T |ze^{\tau\phi}L_2(\tilde{u}_n,\tilde{w}_n,u,w)|^2_{-1,\Omega}dt + M_\tau(u,w,\tilde{u}_n,\tilde{w}_n), \tag{6.40}$$

where the constant $M_\tau(u,w,\tilde{u},\tilde{w})$ is bounded by the a priori regularity of the solution $\tilde{u},\tilde{w}$ and u,w. More precisely,

$$M_\tau(u,w,\tilde{u}_n,\tilde{w}_n) \le M_{\tau,u,w}\int_0^T [|\tilde{u}_n|^2_{0,\Omega}+|\tilde{w}_n|^2_{1,\Omega}+|\tilde{w}_{n,t}|^2_{0,\Omega}]dt. \tag{6.41}$$

Estimating the terms on the right-hand sides of these two inequalities leads to

$$\begin{aligned}
&\int_0^T |ze^{\tau\phi}\tilde{u}_{n,t}|^2_{0,\Omega}+|ze^{\tau\phi}\tilde{u}_n|^2_{1,\Omega}dt \\
&\le C/\tau\int_0^T |ze^{\tau\phi}\tilde{w}_n|^2_{2,\Omega}dt|w|^2_{L_\infty(0,T);H^{2+\epsilon}(\Omega)}+M_\tau(u,w,\tilde{u}_n,\tilde{w}_n), \qquad (6.42)\\
&\int_0^T |ze^{\tau\phi}\tilde{w}_{n,t}|^2_{1,\Omega}+|ze^{\tau\phi}\tilde{w}_n|^2_{2,\Omega}dt \le C/\tau\int_0^T [|ze^{\tau\phi}\boldsymbol{\epsilon}(\tilde{u}_n)\nabla w|^2_{0,\Omega}+|ze^{\tau\phi}\epsilon(u)\nabla\tilde{w}_n|^2_{0,\Omega}\\
&\quad +|ze^{\tau\phi}(\nabla\tilde{w}_n\times\nabla w)\nabla w|^2_{0,\Omega}+|ze^{\tau\phi}(\nabla w\times\nabla w)\nabla\tilde{w}_n|^2_{0,\Omega}]dt+M_\tau(u,w,\tilde{u}_n,\tilde{w}_n)\\
&\le C/\tau\int_0^T [|ze^{\tau\phi}\tilde{u}_n|^2_{1,\Omega}+|ze^{\tau\phi}\tilde{w}_n|^2_{2,\Omega}]dt|w|^2_{L_\infty(0,T);H^{2+\epsilon}(\Omega)}\\
&\quad +\int_0^T |ze^{\tau\phi}\tilde{w}_n|^2_{2,\Omega}dt|u|^2_{L_\infty(0,T);H^{1+\epsilon}(\Omega)}+M_\tau(u,w,\tilde{u}_n,\tilde{w}_n). \qquad (6.43)
\end{aligned}$$

Combining (6.42) and (6.43) gives

$$\begin{aligned}
&\int_0^T |ze^{\tau\phi}\tilde{u}_{n,t}|^2_{0,\Omega}+|ze^{\tau\phi}\tilde{u}_n|^2_{1,\Omega}dt+\int_0^T |ze^{\tau\phi}\tilde{w}_{n,t}|^2_{1,\Omega}+|ze^{\tau\phi}\tilde{w}_n|^2_{2,\Omega}dt\\
&\le C(u,w)/\tau\left[\int_0^T |ze^{\tau\phi}\tilde{w}_n|^2_{2,\Omega}+|ze^{\tau\phi}\tilde{u}_n|^2_{1,\Omega}\right]dt+M_\tau(u,w,\tilde{u}_n,\tilde{w}_n). \qquad (6.44)
\end{aligned}$$

Taking the constant τ large enough gives

$$\int_0^T [|ze^{\tau\phi}\tilde{u}_{n,t}|^2_{0,\Omega}+|ze^{\tau\phi}\tilde{u}_n|^2_{1,\Omega}dt+|ze^{\tau\phi}\tilde{w}_{n,t}|^2_{1,\Omega}+|ze^{\tau\phi}\tilde{w}_n|^2_{2,\Omega}]dt \le M_\tau(u,w,\tilde{u}_n,\tilde{w}_n). \tag{6.45}$$

Since ψ can be selected in such a way that

$$ze^{\tau\phi}\ge 1 \text{ on } [t_0,t_1]\in[0,T],$$

the inequality in (6.45) gives

$$\int_{t_0}^{t_1} |\tilde{u}_{n,t}|^2_{0,\Omega}+|\tilde{u}_n|^2_{1,\Omega}dt+|\tilde{w}_{n,t}|^2_{1,\Omega}+|\tilde{w}_n|^2_{2,\Omega}dt \le CM_\tau(u,w,\tilde{u}_n,\tilde{w}_n). \tag{6.46}$$

Next define

$$\tilde{E}_n(t)\equiv |\tilde{u}_{n,t}(t)|^2_{0,\Omega}+|\tilde{u}_n(t)|^2_{1,\Omega}dt+|\tilde{w}_{n,t}(t)|^2_{1,\Omega}+|\tilde{w}_n(t)|^2_{2,\Omega}.$$

Noting that

$$\begin{aligned}
&\int_s^{t_1} |L_1(w,\tilde{w}_n)|^2_{0,\Omega}+|L_2(\tilde{u}_n,\tilde{w}_n,u,w)|^2_{-1,\Omega}]dt \\
&\le C\int_s^{t_1}[|\tilde{u}_n|^2_{1,\Omega}+|\tilde{w}_n|^2_{2,\Omega}]dt[|w|^2_{L_\infty(0,T);H^{2+\epsilon}(\Omega)}+|u|^2_{L_\infty(0,T);H^{1+\epsilon}(\Omega)}]+M_\tau(u,w,\tilde{u}_n,\tilde{w}_n), \qquad (6.47)
\end{aligned}$$

applying the standard energy inequality to equation (6.31), and accounting for (6.47) we obtain that

$$\tilde{E}_n(t_1) \leq C\tilde{E}_n(s) + C\int_s^{t_1} |L_1(w,\tilde{w}_n)|^2_{0,\Omega} + |L_2(\tilde{u}_n,\tilde{w}_n,u,w)|^2_{-1,\Omega}]dt$$

$$\leq C\tilde{E}_n(s) + CM_\tau(u,w,\tilde{u}_n,\tilde{w}_n) + C_{u,w}\int_s^{t_1} \tilde{E}_n(t)dt. \tag{6.48}$$

Integrating the above inequality with respect to s yields

$$(t_1-t_0)\tilde{E}_n(t_1) \leq C\int_{t_0}^{t_1} \tilde{E}_n(s)ds + CT\left[M_\tau(u,w,\tilde{u}_n,\tilde{w}_n) + \int_{t_0}^{t_1} \tilde{E}_n(t)dt\right]. \tag{6.49}$$

From (6.46) and (6.49) we infer that

$$\tilde{E}_n(t_1) \leq CM_\tau(u,w,\tilde{u}_n,\tilde{w}_n). \tag{6.50}$$

Applying the same argument to the difference of solutions $\tilde{u}_n - \tilde{u}_m,\ \tilde{w}_n - \tilde{w}_m$ and taking advantage of (6.38), (6.8), (6.41) we conclude that

$$\tilde{u}_n(t_1), \tilde{u}_{n,t}(t_1), \tilde{w}_n(t_1), \tilde{w}_{n,t}(t_1)$$

are Cauchy sequences in

$$H^1(\Omega) \times L_2(\Omega) \times H^2(\Omega) \times H^1(\Omega).$$

This leads, via standard semigroup argument, to the improved regularity for $\tilde{u}, \tilde{w}$:

$$\tilde{u} \in C(0,T;H^1(\Omega)), \quad \tilde{w} \in C(0,T;H^2(\Omega)), \tag{6.51}$$

$$\tilde{u}_t \in C(0,T;L_2(\Omega)), \quad \tilde{w}_t \in C(0,T;H^1(\Omega)). \qquad \square \tag{6.52}$$

In order to apply Isakov's uniqueness result, in the context of equation (4.10) we need to assert the regularity of solutions as well as the regularity of the coefficients of the equation, which, in our case, amounts to the regularity of u, w. Since the variables $\tilde{u}, \tilde{w}$ are the time derivatives of u, w, we have so far obtained

$$u_t \in C(0,T;H^1(\Omega)), \quad w_t \in C(0,T;H^2(\Omega)), \tag{6.53}$$

$$u_{tt} \in C(0,T;L_2(\Omega)), \quad w_{tt} \in C(0,T;H^1(\Omega)). \tag{6.54}$$

In order to obtain a higher spatial regularity, we return to the original equation satisfied by u, w. Recalling the fact that the traces of velocities of $u, \nabla w$ are zero on Γ_1, we obtain

$$\begin{aligned}
\operatorname{div}[\mathcal{C}[\boldsymbol{\epsilon}(u)]] &= u_{tt} + b_1u_t - \operatorname{div}[\mathcal{C}f(\nabla w)] \text{ in } Q,\\
D\Delta^2 w = -[I-\gamma\Delta]w_{tt} - b_2w_t + \operatorname{div}[\mathcal{C}[\boldsymbol{\epsilon}(u) + f(\nabla w)]\nabla w] &\text{ in } Q,\\
u = w = \nabla w &= 0 \text{ on } \Sigma_0,\\
\mathcal{C}[\boldsymbol{\epsilon}(u) + f(\nabla w)]\nu &= 0 \text{ in } \Sigma_1,\\
D[\Delta w + (1-\mu)B_1 w] &= 0 \text{ in } \Sigma_1,\\
D[D_n\Delta w + (1-\mu)B_2 w] &= 0 \text{ in } \Sigma_1.
\end{aligned} \tag{6.55}$$

By straightforward calculations and accounting for the result of Lemma 6.4 we infer that

$$u_{tt} + b_1u_t - \operatorname{div}[\mathcal{C}f(\nabla w)] \in C(0,T;H^{-\epsilon}(\Omega)), \tag{6.56}$$

$$[I-\gamma\Delta]w_{tt} + b_2w_t + \operatorname{div}[\mathcal{C}[\boldsymbol{\epsilon}(u) + f(\nabla w)]\nabla w] \in C(0,T;H^{-1-\epsilon}(\Omega)), \tag{6.57}$$

and from the regularity of the biharmonic problem we then infer that

$$w \in C(0,T;H^{3-\epsilon}(\Omega)).$$

Hence,

$$f(\nabla w) \in C(0,T;H^1(\Omega)),$$

and going back to (6.55) we have that

$$u_{tt} + b_1 u_t - \operatorname{div}[\mathcal{C} f(\nabla w)] \in C(0,T;L_2(\Omega)), \tag{6.58}$$

$$[I - \gamma\Delta]w_{tt} + b_2 w_t + \operatorname{div}[\mathcal{C}[\boldsymbol{\epsilon}(u) + f(\nabla w)]\nabla w] \in C(0,T;H^{-1}(\Omega)). \tag{6.59}$$

Since

$$f(\nabla w)|_{\Gamma_1} \in C(0,T;H^{1/2}(\Gamma_1)),$$

hence

$$\mathcal{C}[\boldsymbol{\epsilon}(u)]|_{\Gamma_1} \in C(0,T;H^{1/2}(\Gamma_1)).$$

We are now in a position to apply elliptic estimates to the problem (6.55), and we conclude that

$$u \in C(0,T;H^2(\Omega)), \quad w \in C(0,T;H^3(\Omega)). \tag{6.60}$$

Differentiating in time equation (6.31) and reiterating the same argument over and over we arrive at the conclusion that

$$u, w, \tilde{u}, \tilde{w} \in C^\infty(Q).$$

Thus we have proved Theorem 6.5.

THEOREM 6.5. *Let u, w be a finite energy solution of the system* (4.7), (4.8) *with the overdetermined boundary conditions* (4.9) *and such that*

$$|u(t)|_{1+\alpha,\Omega} + |w(t)|_{2+\alpha,\Omega} \leq \infty,$$

where $\alpha > 0$ can be arbitrary small. Then

$$u, w \in C^\infty(Q).$$

This gives us the improved regularity of the coefficients and solutions to equation (4.10) which is, in turn, required for the application of Theorem 3 in [9] in the context of the proof of Part II of Lemma 4.1. Theorem 3 in [9] then implies that the solution to (4.10) is identically zero, which proves Corollary 6.6.

COROLLARY 6.6. *Under the assumptions of Theorem* 6.5 *we have*

$$u, w \equiv 0 \text{ in } Q.$$

7. Appendix. Proof of Proposition 1.1.

7.1. Existence of regular solutions: Proof of Part 1 of Proposition 1.1. We shall use the nonlinear Galerkin method. Indeed, let h denote a parameter tending to zero and let $\mathcal{U}_h$ (resp., $\mathcal{W}_h$) be a finite-dimensional subspace of $H^2_{\Gamma_0}(\Omega)$ (resp., $H^3_{\Gamma_0}(\Omega)$), where the subindex Γ_0 indicates that the functions are subject to zero boundary conditions (see (1.1)) on Γ_0. We then denote

$$U_h \equiv \mathcal{U}_h \times \mathcal{U}_h, \quad V_h \equiv U_h \times W_h.$$

We consider the following semidiscrete approximation of the original problem (1.1), (1.2).

Given $(u_{h,0}, w_{h,0}, u_{h,1}, w_{h,1}) \in V_h \times V_h$, find $(u_h(t), w_h(t)) \in V_h$ such that $u_h(0) = u_{h,0}, w_h(0) = w_{h,0}, u_{h,t}(0) = u_{h,1}, w_{h,t}(0) = w_{h,1}$, and

$$(u_{h,tt}, \phi)_\Omega + (b_1 u_{h,t}, \phi)_\Omega + (\mathcal{C}N(u_h, w_h), \epsilon(\phi))_\Omega + \langle g(u_{h,t}), \phi\rangle_{\Gamma_1} = 0, \tag{7.1}$$
$$(w_{h,tt}, \psi)_\Omega + \gamma(\nabla w_{h,tt}, \nabla\psi)_\Omega + a(w_h, \psi) + (b_2 w_{h,t}, \psi)_\Omega$$

$$+(\mathcal{C}N(u_h, w_h), \nabla\psi \times \nabla w_h)_\Omega + \langle h_1(D_n w_{h,t}), D_n\psi\rangle_{\Gamma_1} + \langle h_2(D_\tau w_{h,t}), D_\tau\psi\rangle_{\Gamma_1} = 0 \tag{7.2}$$

for all $(\phi, \psi) \in V_h$.

Global existence and uniqueness of semidiscrete solutions follows from the fact that nonlinear terms are locally Lipschitz on V_h together with a standard a priori bound

$$E_h(t) \le E_h(0), \tag{7.3}$$

where

$$E_h(t) \equiv \int_\Omega |u_{h,t}|^2 + |w_{h,t}|^2 + \gamma|\nabla w_{h,t}|^2 d\Omega + a(w_h(t), w_h(t))$$
$$+ \int_\Omega [\mathcal{C}N(u_h(t), w_h(t)) \cdot N(u_h(t), w_h(t))]\, d\Omega. \tag{7.4}$$

Moreover, the solutions $(u_h(t), w_h(t))$ are $C^\infty([0, T_0), V_h)$ for some $T_0 > 0$. We shall show that Galerkin approximations defined by (7.2) are stable in higher norms. Indeed, differentiating (7.2) in time and denoting

$$\bar{u} \equiv u_{h,t}, \quad \bar{w} \equiv w_{h,t}, \quad N_t(u_h, w_h) \equiv \frac{d}{dt} N(u_h, w_h) = \epsilon(\bar{u}) + \frac{d}{dt} f(\nabla w_h)$$

we obtain the following equation satisfied for the new variables:

$$(\bar{u}_{tt}, \phi)_\Omega + (b_1\bar{u}_t, \phi)_\Omega + (\mathcal{C}N_t(u_h, w_h), \epsilon(\phi))_\Omega + \langle g'(u_{h,t})\bar{u}_t, \phi\rangle_{\Gamma_1} = 0, \tag{7.5}$$
$$(\bar{w}_{tt}, \psi)_\Omega + \gamma(\nabla\bar{w}_{tt}, \nabla\psi)_\Omega + a(\bar{w}_h, \psi) + (b_2\bar{w}_t, \psi)_\Omega + (\mathcal{C}N_t(u_h, w_h), \nabla\psi \times \nabla w_h)_\Omega$$
$$+(\mathcal{C}N(u_h, w_h), \nabla\psi \times \nabla\bar{w})_\Omega + \langle {h_1}'(D_n w_{h,t}) D_n\bar{w}_t, D_n\psi\rangle_{\Gamma_1}$$
$$+\langle {h_2}'(D_\tau w_{h,t}) D_\tau\bar{w}_t, D_\tau\psi\rangle_{\Gamma_1} = 0 \tag{7.6}$$

for all $(\phi, \psi) \in V_h$.

Taking $\phi = \bar{u}_t, \psi = \bar{w}_t$ yields

$$1/2\frac{d}{dt}[|\bar{u}_t|^2_\Omega + (\mathcal{C}N_t(u_h, w_h), N_t(u_h, w_h))_\Omega + |\bar{w}_t|^2_\Omega + \gamma|\nabla\bar{w}_t|^2_\Omega + a(\bar{w}, \bar{w})]$$
$$+(b_2\bar{w}_t, \bar{w}_t)_\Omega + (b_1\bar{u}_t, \bar{u}_t)_\Omega + \langle g'(u_{h,t})\bar{u}_t, \bar{u}_t\rangle_{\Gamma_1} + \langle {h_1}'(D_n w_{h,t}) D_n\bar{w}_t, D_n\bar{w}_t\rangle_{\Gamma_1}$$
$$+\langle {h_2}'(D_\tau w_{h,t}) D_\tau\bar{w}_t, D_\tau\bar{w}_t\rangle_{\Gamma_1}$$
$$= (\mathcal{C}N_t(u_h, w_h), \nabla\bar{w} \times \nabla\bar{w})_\Omega - (\mathcal{C}N(u_h, w_h), \nabla\bar{w}_t \times \nabla\bar{w})_\Omega = 0. \tag{7.7}$$

We denote

$$\bar{E}(t) \equiv |\bar{u}_t(t)|^2_\Omega + (\mathcal{C}N_t(u_h(t), w_h(t)), N_t(u_h(t), w_h(t)))_\Omega + |\bar{w}_t(t)|^2_\Omega + \gamma|\nabla\bar{w}_t(t)|^2_\Omega$$
$$+a(\bar{w}(t), \bar{w}(t)). \tag{7.8}$$

It is straightforward to verify that $\bar{E}(t)$ is bounded from above and below by the expression $C(|\bar{u}|_{1,\Omega}, |\bar{u}_t|_{0,\Omega}, |\bar{w}|_{2,\Omega}, |\bar{w}_t|_{1,\Omega})$. This fact will be used frequently without further mention.

Integrating (7.7) from 0 to t, integrating by parts the last term in (7.7), and recalling the monotonicity of boundary feedback yields the inequality

$$\bar{E}(t) \leq \bar{E}(0) + 6\int_0^t (\mathcal{C}N_t(u_h, w_h), f(\nabla \bar{w}))_\Omega dt - 2(\mathcal{C}N(u_h, w_h), f(\nabla \bar{w}))_\Omega|_0^t. \tag{7.9}$$

By Sobolev's embedding $L_4(\Omega) \subset H^{1/2}(\Omega)$ and the classical interpolation inequality $|w|^2_{1/2,\Omega} \leq C|w|_{1,\Omega}|w|_{0,\Omega}$, we obtain

$$|f(\nabla \bar{w})|_{0,\Omega} \leq C|\bar{w}|_{2,\Omega}|w_{h,t}|_{1,\Omega} \leq C[E_h(0)]^{1/2}|\bar{w}|_{2,\Omega}, \tag{7.10}$$

where in the last step we have used the a priori bound in (7.3). Combining (7.9) with (7.10) and using, again, the a priori bound in (7.3) gives

$$\begin{aligned} \bar{E}(t) &\leq \bar{E}(0) + CE_h(0)\int_0^t |N_t(u_h, w_h)|_{0,\Omega}|\bar{w}|_{2,\Omega}dt + \epsilon|\bar{w}(0)|^2_{2,\Omega} \\ &+\epsilon|\bar{w}(t)|^2_{2,\Omega} + C_\epsilon E_h(0)[|N(u_h(0), w_h(0))|^2_{0,\Omega} + |N(u_h(t), w_h(t))|^2_{0,\Omega}] \\ &\leq C\bar{E}(0) + CE_h(0)\int_0^t |N_t(u_h, w_h)|_{0,\Omega}|\bar{w}|_{2,\Omega}dt + \epsilon|\bar{w(t)}|^2_{2,\Omega} + C_\epsilon E_h(0)^3. \end{aligned} \tag{7.11}$$

Taking ϵ small enough, recalling the definition of $\bar{E}$, and applying Gronwall's inequality yields

$$\bar{E}(t) \leq C_T(E_h(0))[\bar{E}(0) + [E_h(0)]^3], \quad t \leq T, \tag{7.12}$$

where C_T does not depend on h.

In order to provide an effective estimate (independent on h) of the right side of inequality (7.12) we need to estimate $\bar{E}(0), E_h(0)$. To this end we make the following natural approximation/stability properties imposed on our approximating spaces. We assume that the following conditions hold.

(i) For any $u \in H^s_{\Gamma_0}(\Omega)$, there exists $\phi \in \mathcal{U}_h$ such that

$$|u - \phi|_{s,\Omega} \to 0 \text{ when } h \to 0, s \leq 2.$$

(ii) For any $w \in H^s_{\Gamma_0}(\Omega)$, there exist $\psi \in \mathcal{W}_h$ such that

$$|w - \psi|_{s,\Omega} \to 0 \text{ when } h \to 0, s \leq 3.$$

Moreover, there exist $p > 0$ such that the following "inverse approximation properties" hold

(iii)

$$|\phi|_{0,\Gamma} \leq Ch^{-p}|\phi|_{0,\Omega}, \quad |\nabla\psi|_{0,\Gamma} \leq Ch^{-p}|\psi|_{1,\Omega} \quad \text{for } \phi, \psi \in V_h,$$

(iv)

$$|D_1[u - \phi]|_{L_2(\Gamma)} \leq Ch^p|u|_{2,\Omega}, \quad |D_l[w - \psi]|_{L_2(\Gamma)} \leq Ch^p|w|_{l+1,\Omega}, \quad l = 1, 2,$$

where by D_i we have denoted the differential operator of order i.

We note that the approximation properties listed above are the standard ones for a variety of approximating subspaces including cubic splines defined on quasi-uniform

mesh. (This last property is guaranteed by the inverse approximation properties. In this case we have $p = 1/2$.)

Let us denote by C_0 a constant which depends on $|w_0|_{2,\Omega}, |w_1|_{1,\Omega}, |u_0|_{1,\Omega}, |u_1|_{0,\Omega}$ and by C_1 a constant depending on the higher-order norms of the initial data, i.e., $|w_0|_{3,\Omega}, |w_1|_{2,\Omega}, |u_0|_{2,\Omega}, |u_1|_{1,\Omega}$.

Now, we assume that $u_{h,0}, u_{h,1}, w_{h,0}, w_{h,1}$ are "good" approximations of the initial data; i.e., the approximation properties listed above are satisfied and, in particular,

$$\begin{aligned} &|u_0 - u_{h,0}|_{2,\Omega} \to 0 \ \text{ when } h \to 0, \ |u_1 - u_{h,1}|_{1,\Omega} \to 0 \ \text{ when } h \to 0, \\ &|w_0 - w_{h,0}|_{3,\Omega} \to 0 \ \text{ when } h \to 0, \ |w_1 - w_{h,1}|_{2,\Omega} \to 0 \ \text{ when } h \to 0. \end{aligned} \tag{7.13}$$

By stability of the estimates resulting from (7.13) and the regularity of the initial conditions we obtain

$$E_h(0) \le C_0.$$

Moreover, since $\bar{u}(0) = u_{h,1}, \bar{w}(0) = w_{h,1}$, we also have

$$|\bar{u}(0)|_{1,\Omega} \le |u_1|_{1,\Omega} \le C_1, |\bar{w}(0)|_{2,\Omega} \le |w_1|_{2,\Omega} \le C_1. \tag{7.14}$$

In order to estimate $|\bar{u}_t(0)|_{0,\Omega}$ we shall use the compatibility conditions. In fact from (7.2) we have

$$\begin{aligned} (\bar{u}_t(0), \phi)_{0,\Omega} \le |&(b_1 u_{h,1}, \phi)_\Omega + (\mathrm{div}\mathcal{C}N(u_{h,0}, w_{h,0}), \phi)_{0,\Omega} \\ &-\langle \mathcal{C}N(u_{h,0}, w_{h,0})\nu + g(u_{h,1}), \phi\rangle_{\Gamma_1}| \text{ for all } \phi \in U_h. \end{aligned} \tag{7.15}$$

Hence

$$\begin{aligned} (\bar{u}_t(0), \phi)_{0,\Omega} &\le C[|u_{h,0}|_{2,\Omega} + |w_{h,0}|_{3,\Omega} + |u_{h,1}|_{0,\Omega}]|\phi|_{0,\Omega} \\ &+C|N(u_{h,0}, w_{h,0})\nu + g(u_{h,1}) - N(u_0, w_0)\nu - g(u_1)|_{0,\Gamma_1}|\phi|_{0,\Gamma_1}, \end{aligned} \tag{7.16}$$

where we have used the compatibility relations (1.4) for the first equation. By Lipschitz continuity of the feedback g and the inverse approximation properties listed in (iii), (iv) we obtain

$$\begin{aligned} &|N(u_{h,0}, w_{h,0})\nu + g(u_{h,1}) - N(u_0, w_0)\nu - g(u_1)|_{0,\Gamma_1}|\phi|_{0,\Gamma_1} \\ &\le C[|u_{h,0} - u_0|_{1,\Gamma_1} + C_1|\nabla[w_{h,0} - w_0]|_{0,\Gamma_1} + |u_{h,1} - u_1|_{0,\Gamma}]h^{-p}||\phi|_{0,\Omega} \\ &\le C[|u_0|_{2,\Omega} + C_1|w_0|_{2,\Omega} + |u_1|_{1,\Omega}]h^p h^{-p}||\phi|_{0,\Omega} \le C[C_1 + C_1C_0]|\phi|_{0,\Omega}. \end{aligned} \tag{7.17}$$

Since ϕ is arbitrary in U_h, we obtain

$$|\bar{u}_t(0)|_{0,\Omega} \le C_1 + C_1C_0 \tag{7.18}$$

providing a desired an a priori bound for the initial datum $\bar{u}_t(0)$. In the same manner we obtain an a priori bound for the second variable, i.e.,

$$|\bar{w}_t(0)|_{1,\Omega} \le C_1 + C_0 + C_0C_1 = C(C_0, C_1). \tag{7.19}$$

Indeed,

$$\begin{aligned} (\bar{w}_t(0), \psi)_{1,\Omega} &= (\bar{w}_t(0), \psi)_\Omega + \gamma(\nabla\bar{w}_t(0), \nabla\psi)_\Omega \\ &= -a(w_h(0), \psi) - (b_2 w_{h,t}(0), \psi)_\Omega - (\mathcal{C}[N(u_h(0), w_h(0))\nabla w_h(0)], \nabla\psi)_\Omega \\ &\quad -\langle h_1(D_n\bar{w}(0)), D_n\psi\rangle_{\Gamma_1} - \langle h_2(D_\tau\bar{w}(0)), D_\tau\psi\rangle_{\Gamma_1}. \end{aligned} \tag{7.20}$$

Application of the first Green formula together with compatibility conditions (1.4) yield

$$(\bar{w}_t(0),\psi)_{1,\Omega} = a_1(w_h(0),\psi) - (b_2 w_{h,t}(0),\psi)_\Omega - (\mathcal{C}[N(u_h(0),w_h(0))\nabla w_h(0)],\nabla\psi)_\Omega \\ -\langle h_2(D_\tau\bar{w}(0)), D_\tau\psi\rangle_{\Gamma_1} + X = 0, \tag{7.21}$$

where we have denoted

$$X \equiv \langle D[\Delta w_h(0)+(1-\mu)B_1 w_h(0)-\Delta w_0-(1-\mu)B_1 w_0]-h_1(D_n w_{h,1})+h_1(D_n w_1), D_n\psi\rangle_{\Gamma_1}$$

and $a_1(w,\psi)\le C|w|_{3,\Omega}|\psi|_{1,\Omega}$. By using approximation properties listed in (iii), (iv), in the same manner as before, together with Lipschitz continuity of h_1 we obtain

$$|X| \le Ch^p|w_0|_{3,\Omega}h^{-p}|\psi|_{1,\Omega} + Ch^p|w_1|_{2,\Omega}h^{-p}|\psi|_{1,\Omega} \\ \le C_1|\psi|_{1,\Omega}. \tag{7.22}$$

A priori bounds in (7.14) together with the estimate (7.22) and the fact that h_2 is bounded from $H^{1/2}(\Gamma_1)$ into itself yield

$$(\bar{w}_t(0),\psi)_{1,\Omega} \le C_1|\psi|_{1,\Omega} + C[|w_h(0)|_{3,\Omega}|\psi|_{1,\Omega} + |\bar{w}(0)|_{0,\Omega}|\psi|_{0,\Omega} \\ +(|u_h(0)|_{2,\Omega}+|w_h(0)|_{2,\Omega})|w_h(0)|_{2,\Omega}|\psi|_{1,\Omega} + |h_2(D_\tau\bar{w}(0))|_{1/2,\Gamma_1}|D_\tau\psi|_{-1/2,\Gamma_1}] \\ \le C_1|\psi|_{1,\Omega} + C[|w_h(0)|_{3,\Omega}|\psi|_{1,\Omega} + |\bar{w}(0)|_{0,\Omega}|\psi|_{0,\Omega} \\ +(|u_h(0)|_{2,\Omega}+|w_h(0)|_{2,\Omega})|w_h(0)|_{2,\Omega}|\psi|_{1,\Omega} + |(D_\tau\bar{w}(0))|_{1/2,\Gamma_1}|D_\tau\psi|_{-1/2,\Gamma_1}] \\ \le C[|w_h(0)|_{3,\Omega}|\psi|_{1,\Omega} + |\bar{w}(0)|_{0,\Omega}|\psi|_{0,\Omega} + (|u_h(0)|_{2,\Omega}+|w_h(0)|_{2,\Omega})|w_h(0)|_{2,\Omega}|\psi|_{1,\Omega} \\ +|\bar{w}(0)|_{2,\Omega}|\psi|_{1/2,\Gamma_1} + C_1|\psi|_{1,\Omega} \le C[C_1+C_0+C_1C_0]|\psi|_{1,\Omega}. \tag{7.23}$$

This gives the desired result in (7.19).

Collecting (7.14), (7.18), (7.19) we conclude that $\bar{E}(0)\le C(C_0,C_1)$, and by (7.12)

$$\bar{E}(t)\le C(C_0,C_1).$$

Hence the a priori bounds

$$|u_{h,t}(t)|_{1,\Omega} + |u_h(t)|_{1,\Omega} + |u_{h,tt}(t)|_{0,\Omega} + |w_{h,t}(t)|_{2,\Omega} + |w_h(t)|_{2,\Omega} + |w_{h,tt}(t)|_{1,\Omega} \le C \tag{7.24}$$

hold uniformly in h for all $t<T$ where T is arbitrary.

We can now extract convergent subsequences (denoted by the same symbol) such that

$$u_h \to u \text{ weakly}^\star \text{ in } L_\infty(0,T;H^1(\Omega)), u_{h,t}\to u_t \text{ weakly}^\star \text{ in } L_\infty(0,T;H^1(\Omega)), \\ u_{h,tt}\to u_{tt} \text{ weakly}^\star \text{ in } L_\infty(0,T;L_2(\Omega)), \\ w_h \to w \text{ weakly}^\star \text{ in } L_\infty(0,T;H^2(\Omega)), w_{h,t}\to w_t \text{ weakly}^\star \text{ in } L_\infty(0,T;H^2(\Omega)), \\ w_{h,tt}\to w_{tt} \text{ weakly}^\star \text{ in } L_\infty(0,T;H^1(\Omega)). \tag{7.25}$$

Now, we can pass with the limit on the original semidiscrete form of equation (7.2). Indeed, this is possible due to weak continuity of the von Karman nonlinearity and due to the fact that from (7.25) we have the *strong* convergence of the boundary traces

$$u_{h,t}|_\Gamma \to u_t|_\Gamma, \quad \nabla w_{h,t}|_\Gamma \to \nabla w_t|_\Gamma \quad \text{strongly in } L_\infty(0,T;H^{1/2-\epsilon}(\Gamma)). \tag{7.26}$$

Thus, the assumption imposed on nonlinear feedback, which implies the continuity of g, h_i from $L_\infty(0,T;H^\alpha(\Gamma_1)), \alpha \le 1/2$ into itself, allows us to conclude that

$$g(u_{h,t}) \to g(u_t),$$
$$h_1(D_n w_{h,t}) \to h_1(D_n w_t);\ h_2(D_\tau w_{h,t}) \to h_2(D_\tau w_t) \text{ strongly in } L_2(\Sigma). \tag{7.27}$$

Passing through the limit we conclude that u, w satisfy the weak form of the original equation (1.1) and, moreover, they display the regularity

$$u \in C(0,T;H^1(\Omega)), u_t \in C(0,T;H^1(\Omega)), u_{tt} \in L_\infty(0,T;L_2(\Omega)),$$
$$w \in C(0,T;H^2(\Omega)), w_t \in C(0,T;H^2(\Omega)), w_{tt} \in L_\infty(0,T;H^1(\Omega)). \tag{7.28}$$

In order to obtain higher regularity in the space variable, we proceed as usual by reading off the elliptic regularity. Indeed, from (7.28) for each $0 \le t \le T$ we now have

(7.29)
$$\operatorname{div}[\mathcal{C}N(u,w)] \in L_2(\Omega), u_t|\Gamma_1 \in H^{1/2}(\Gamma_1), f(\nabla w) \in H^{1-\epsilon}(\Omega), f(\nabla w)|_{\Gamma_1} \in H^{1/2-\epsilon}(\Gamma_1).$$

Hence

(7.30)
$$\operatorname{div}[\mathcal{C}\boldsymbol{\epsilon}(u)] \in H^{-\epsilon}(\Omega), \mathcal{C}[\boldsymbol{\epsilon}(u)]\nu = -f(\nabla w)\nu - g(u_t) \in H^{1/2-\epsilon}(\Gamma_1), u = 0 \text{ on } \Gamma_0.$$

By standard elliptic theory we conclude that

$$u(t) \in C(0,T;H^{2-\epsilon}(\Omega)). \tag{7.31}$$

As for the variable w we shall use standard, by now, semigroup formulation of the underlying PDE. Indeed, we rewrite (see [4], [1]) the original equation for w as

(7.32)
$$\mathcal{A}w = -[I + \gamma A_N]w_{tt} - b_2 w_t - \mathcal{A}G_1 h_1(D_n w_t) - \mathcal{A}G_2 D_\tau h_2(D_\tau w_t) + F(u,w),$$

where we have used the following operators:

$$\mathcal{A}w = D\Delta^2 w, w \in D(\mathcal{A}),$$
(7.33)
$$D(\mathcal{A}) = \{w \in H^4_{\Gamma_0}; [\Delta w + (1-\mu)B_1 w] = 0, [D_n \Delta w + (1-\mu)B_2 w] = 0 \text{ on } \Gamma_1\},$$
$$G_i : L_2(\Gamma_1) \to L_2(\Omega) \text{ are given by}$$
$$\Delta^2 G_i g = 0 \text{ in } \Omega,\ G_i g = 0, D_n G_i g = 0 \text{ on } \Gamma_0, \tag{7.34}$$
$$[\Delta + (1-\mu)B_1]G_1 g = g \text{ on } \Gamma_1,\ [D_n\Delta + (1-\mu)B_2]G_1 g = 0 \text{ on } \Gamma_1,$$
$$[\Delta + (1-\mu)B_1]G_2 g = 0 \text{ on } \Gamma_1,\ [D_n\Delta + (1-\mu)B_2]G_2 g = g \text{ on } \Gamma_1, \tag{7.35}$$
$$A_N w = -\Delta w,\ w \in D(A_N) = \left\{ w \in H^2_{\Gamma_0}(\Omega); w = 0, \frac{\partial w}{\partial \nu} = 0;\ \text{on } \Gamma_1 \right\}, \tag{7.36}$$
$$F(u,w) = \operatorname{div}\mathcal{C}N(u,w)\nabla w + \mathcal{A}G_2 \mathcal{C}N(u,w)\nu\nabla w. \tag{7.37}$$

Taking advantage of the improved regularity for u (see (7.31)) we obtain

$$N(u,w)\nabla w \in H^{1-\epsilon}(\Omega); N(u,w)\nabla w|_{\Gamma_1} \in H^{1/2-\epsilon}(\Gamma_1). \tag{7.38}$$

By elliptic regularity we have

$$G_2 : H^{1/2-4\epsilon}(\Gamma_1) \to H^{4-4\epsilon}(\Omega) \subset D(\mathcal{A}^{7/8-\epsilon}).$$

Thus,

$$F(u,w) \in H^{-\epsilon}(\Omega) + D(\mathcal{A}^{1/8+\epsilon})' \subset D(\mathcal{A}^{1/4})' \sim D({A_N}^{1/2})'. \tag{7.39}$$

We write $w = w_1 + w_2$, where

$$\mathcal{A}w_1 = -[I + \gamma A_N]w_{tt} - b_2 w_t + F(u,w), \tag{7.40}$$

$$\mathcal{A}w_2 = -\mathcal{A}G_1 h_1(D_n w_t) - \mathcal{A}G_2 D_\tau h_2(D_\tau w_t). \tag{7.41}$$

By (7.39) and the fact that $w_{tt} \in H^1(\Omega) = D({A_N}^{1/2})$, $A_N w_{tt} \in D({A_N}^{1/2})' = D(\mathcal{A}^{1/4})'$, we conclude that $\mathcal{A}w_1 \in D(\mathcal{A}^{1/4})'$. Hence,

$$w_1 \in D(\mathcal{A}^{3/4}) \in H^3(\Omega). \tag{7.42}$$

On the other hand, $w_2 = -G_1 h_1(D_n w_t) - G_2 D_\tau h_2(D_\tau w_t)$. By the regularity of Green's maps G_i together with the fact that $h_1(D_n w_t) \in H^{1/2}(\Gamma_1), D_\tau h_2(D_\tau w_t) \in H^{-1/2}(\Gamma_1)$ we also have

$$G_1 h_1(D_n w_t) + G_2 D_\tau h_2(D_\tau w_t) \in H^3(\Omega). \tag{7.43}$$

Hence

$$w_2(t) \in H^4(\Omega) \oplus H^3(\Omega) \in H^3(\Omega). \tag{7.44}$$

Combining (7.42) and (7.44) gives the desired assertion

$$w \in C(0,T,H^3(\Omega)),$$

and going back to (7.28) we further improve the regularity by ϵ, obtaining $u \in C(0,T;H^2(\Omega))$, as desired for the proof of the existence of regular solutions. ∎

7.2. Uniqueness of regular solutions. To complete the proof of the first part of Proposition 1.1, we need to establish the uniqueness of the solutions. The proof of the uniqueness is standard, and it relies on the fact that nonlinear terms are locally Lipschitz with respect to the topology considered for regular solutions. In fact, one can prove an even stronger uniqueness result which is stated below.

LEMMA 7.1. *The solutions are unique in the space*

$$X_\epsilon \equiv C(0,T;H^{1+\epsilon}(\Omega)) \cap C^1(0,T;L_2(\Omega)) \times C(0,T;H^{2+\epsilon}(\Omega)) \cap C^1(0,T;H^1(\Omega)),$$

where ϵ is an arbitrary positive number.

Proof. Let $\tilde{u} \equiv u_1 - u_2, \tilde{w} \equiv w_1 - w_2$ with $(u_1,w_1),(u_2,w_2)$ be two potential solutions living in the space X_ϵ. Then $\tilde{u},\tilde{w}$ satisfy the system of equations

$$\begin{aligned}(\tilde{u}_{tt},\phi)_\Omega + (b_1 u_t,\phi)_\Omega + (\mathcal{C}[\boldsymbol{\epsilon}(\tilde{u})],\epsilon(\phi))_\Omega + \langle g(u_{1,t}) - g(u_{2,t}),\phi\rangle_{\Gamma_1} \\ = -(\mathcal{C}[f(\nabla w_1) - f(\nabla w_2)],\boldsymbol{\epsilon}(\phi))_\Omega\end{aligned} \tag{7.45}$$

$$\begin{aligned}(\tilde{w}_{tt},\psi)_\Omega + \gamma(\nabla\tilde{w}_{tt},\nabla\psi)_\Omega + a(\tilde{w},\psi) + (b_2\tilde{w}_t,\psi)_\Omega \\ +\langle(h_1(D_n w_{1,t}) - (h_1(D_n w_{2,t})), D_n\psi\rangle_{\Gamma_1} + \langle(h_2(D_\tau w_{1,t}) - (h_2(D_\tau w_{2,t})), D_\tau\psi\rangle_{\Gamma_1} \\ = -(\mathcal{C}[\boldsymbol{\epsilon}(u_1) + f(\nabla w_1)]\nabla w_1 - \mathcal{C}[\boldsymbol{\epsilon}(u_2) + f(\nabla w_2)]\nabla w_2,\nabla\psi)_\Omega\end{aligned} \tag{7.46}$$

for all $\phi \in [H^1(\Omega)]^2; \psi \in H^1(\Omega)$.

The following regularity can be easily shown:

$$|f(\nabla w_1) - f(\nabla w_2)|_{0,\Omega} \le C|\tilde{w}|_{1,\Omega}[|w_1|_{2+\epsilon_1,\Omega} + |w_2|_{2+\epsilon_1,\Omega}] \tag{7.47}$$

and

$$\left|\frac{d}{dt}[f(\nabla w_1)-f(\nabla w_2)]\right|_{0,\Omega}\le C|\tilde{w}_t|_{1,\Omega}[|w_1|_{2+\epsilon_1,\Omega}+|w_2|_{2+\epsilon_1,\Omega}]. \tag{7.48}$$

Integration by parts gives

$$\begin{aligned}\int_0^t(\mathcal{C}[f(\nabla w_1)-f(\nabla w_2)],\boldsymbol{\epsilon}(\tilde{u}_s))_\Omega ds&=(\mathcal{C}[f(\nabla w_1)-f(\nabla w_2)],\boldsymbol{\epsilon}(\tilde{u}_t))_\Omega|_0^t\\&\quad-\int_0^t\left(\frac{d}{ds}\mathcal{C}[f(\nabla w_1)-f(\nabla w_2)],\boldsymbol{\epsilon}(\tilde{u})\right)_\Omega ds.\end{aligned} \tag{7.49}$$

From (7.48)

$$\begin{aligned}\int_0^t\left(\frac{d}{ds}\mathcal{C}[f(\nabla w_1)-f(\nabla w_2)],\boldsymbol{\epsilon}(\tilde{u})\right)_\Omega ds&\le C\int_0^t|\tilde{u}|^2_{1,\Omega}ds+\int_0^t|\tilde{w}_t|^2_{1,\Omega}[|w_1|_{2+\epsilon_1,\Omega}\\&\quad+|w_2|_{2+\epsilon_1,\Omega)}]^2ds.\end{aligned} \tag{7.50}$$

On the other hand

$$(\mathcal{C}[f(\nabla w_1)-f(\nabla w_2)],\boldsymbol{\epsilon}(\tilde{u}_t))_\Omega|_0^t\le\epsilon_0|\tilde{u}(t)|^2_{1,\Omega}+C_{\epsilon_0}|f(\nabla w_1(t))-f(\nabla w_2(t)|^2_{0,\Omega}. \tag{7.51}$$

But

$$\begin{aligned}|f(\nabla w_1(t,x))-f(\nabla w_2(t,x))|&\le C|\nabla\tilde{w}(t,x)||\nabla w_i(t,x)|\\&=C\left|\int_0^t\nabla\tilde{w}_t(t,x)ds\right|[|\nabla w_1(t,x)|+|\nabla w_2(t,x)|]\\&\le C_T\left[\int_0^t|\nabla\tilde{w}_t(s,x)|^2ds\right]^{1/2}[|w_1(t)|_{2+\epsilon_1,\Omega}+|w_2(t)|_{2+\epsilon_1,\Omega}].\end{aligned} \tag{7.52}$$

Hence

$$|f(\nabla w_1(t))-f(\nabla w_2(t))|^2_{0,\Omega}\le C_T\int_0^t|\tilde{w}_s|^2_{1,\Omega}ds[|w_1(t)|^2_{2+\epsilon_1,\Omega}+|w_2(t)|^2_{2+\epsilon_1,\Omega}]. \tag{7.53}$$

Combining (7.51), (7.53) gives

$$\begin{aligned}(\mathcal{C}[f(\nabla w_1)-f(\nabla w_2)],\boldsymbol{\epsilon}(\tilde{u}_t))_\Omega|_0^t&\le\epsilon_0|\tilde{u(t)}|^2_{1,\Omega}+C_{\epsilon_0,T}\int_0^t|\tilde{w}_s|^2_{1,\Omega}ds[|w_i(t)|^2_{2+\epsilon_1,\Omega}]\\&\quad+[|w_i(t)|^2_{2+\epsilon_1,\Omega}].\end{aligned} \tag{7.54}$$

Setting in (7.45) $\phi\equiv\tilde{u_t}$, taking advantage of inequalities in (7.50), (7.54), and recalling the monotonicity of g yields

$$|\tilde{u}_t|^2_{0,\Omega}+|\tilde{u}|^2_{1,\Omega}\le C_{\epsilon_0,T}\int_0^t|\tilde{w}_t|^2_{1,\Omega}[|w_1|^2_{2+\epsilon,\Omega}+|w_2|^2_{2+\epsilon,\Omega}]+|\tilde{u}|^2_{1,\Omega}ds+\epsilon_0|\tilde{u}|^2_{1,\Omega}. \tag{7.55}$$

Similarly,

$$\begin{aligned}|[\boldsymbol{\epsilon}(u_1)-\boldsymbol{\epsilon}(u_2)]\nabla w_1|_{0,\Omega}&\le C|\tilde{u}|_{1,\Omega}|w_1|_{2+\epsilon},\\|\boldsymbol{\epsilon}(u_2)[\nabla w_1-\nabla w_2]|_{0,\Omega}&\le C|\tilde{w}|_{2,\Omega}|u|_{W^{1,\infty}(\Omega)}\le C|\tilde{w}|_{2,\Omega}|u_2|_{1+\epsilon,\Omega},\end{aligned} \tag{7.56}$$

$$|[f(\nabla w_1)\nabla w_1 - f(\nabla w_2)\nabla w_2]|_{0,\Omega} \le C|\tilde{w}|_{2,\Omega}[|w_1|^2_{2+\epsilon,\Omega} + |w_2|^2_{2+\epsilon,\Omega}]. \tag{7.57}$$

From (7.46) (where we set $\psi = \tilde{w}_t$) and (7.57) and accounting for the monotonicity of h_i we obtain the estimate

$$|\tilde{w}_t|^2_{1,\Omega} + |\tilde{w}|^2_{2,\Omega} \le C\int_0^t |\tilde{w}|^2_{2,\Omega}[|u_2|_{1+\epsilon,\Omega} + |\tilde{u}|_{1,\Omega}|w_1|_{2+\epsilon,\Omega}]dt. \tag{7.58}$$

Combining Gronwall's lemma gives $\tilde{u} \equiv 0, \tilde{w} \equiv 0$, as desired. □

7.3. Uniqueness of weak solutions: Proof of Part II of Proposition 1.1. Here we adapt the method proposed in [24] where Marguerre–Vlasov equations were considered with the zero Dirichlet boundary data. We note that the presence of the damping on the boundary as well as the fact that the boundary conditions are dynamic and of the higher order (as treated in this paper) add substantial technical difficulties with respect to the homogeneous Dirichlet case.

To begin with, let us introduce the operators providing for the semigroup representation of the part of the system corresponding to the longitudinal displacements u. Indeed, let A_0 be the generator corresponding to the system of elasticity, and let G_0 be the corresponding Green map defined as below:

$$A_0 u \equiv -\mathrm{div}\mathcal{C}\boldsymbol{\epsilon}(u); D(A_0) = \{u \in H^2_{\Gamma_0}(\Omega); \mathcal{C}\boldsymbol{\epsilon}(u)\nu = 0 \text{ on } \Gamma_1\},$$

$$G_0 g \equiv g \text{ iff } \mathrm{div}\mathcal{C}\boldsymbol{\epsilon}(v) = 0 \text{ in } \Omega,\ v = 0 \text{ on } \Gamma_0,\ \mathcal{C}\epsilon(v)\nu = g \text{ on } \Gamma_1.$$

Let $\tilde{u} \equiv u_1 - u_2, \tilde{w} \equiv w_1 - w_2$, where u_1, w_1 and u_2, w_2 are two potential solutions of finite energy (i.e., weak solutions). Using the definitions of operators A_0, G_0 given above and $M, \mathcal{A}, G_i$ introduced in the previous section we rewrite the original PDE as an abstract second-order system defined on $[D(A_0)]' \times [D(\mathcal{A})]'$ (see [1], [4], [16]):

$$\begin{aligned} &\tilde{u}_{tt} + b_1\tilde{u}_t + A_0\tilde{u} + A_0G_0(G_0^*A_0\tilde{u}_t) = f_1(\tilde{w}, w_i),\\ &M\tilde{w}_{tt} + b_2\tilde{w}_t + \mathcal{A}\tilde{w} + \mathcal{A}G_1(G_1^*\mathcal{A}\tilde{w}_t) + \mathcal{A}G_2(D_\tau^2 G_2^*\mathcal{A}\tilde{w}_t) = f_2(\tilde{u}, \tilde{w}, u_i, w_i), \end{aligned} \tag{7.59}$$

where the forcing terms f_i are defined as follows:

$$\begin{aligned} f_1(\tilde{w}, w_i) &\equiv \mathrm{div}\mathcal{C}[f(\nabla w_1) - f(\nabla w_2)] - A_0G_0G_0^*A_0\mathcal{C}[f(\nabla w_1) - f(\nabla w_2)]\nu,\\ f_2(\tilde{u}, \tilde{w}, u_i, w_i) &\equiv \mathrm{div}[\mathcal{C}N(u_1, w_1)\nabla w_1 - \mathcal{C}N(u_2, w_2)\nabla w_2]\\ &\quad + \mathcal{A}G_2G_2^*\mathcal{A}[\mathcal{C}N(u_1, w_1)\nabla w_1 - \mathcal{C}N(u_2, w_2)\nabla w_2]\nu. \end{aligned} \tag{7.60}$$

Since the damping is linear, we have assumed, without the loss of generality, that $g_0, h_{i0} = 1; i = 1, 2$.

Denoting

$$A_1 \equiv \begin{bmatrix} 0 & I \\ -A_0 & -A_0G_0G_0^*A_0 - b_1 \end{bmatrix}, \tag{7.61}$$

$A_1 : H_1 \to H_1$ with $H_1 \equiv [D({A_0}^{1/2})]^2 \times [L_2(\Omega)]^2$,

$$D(A_1) = \{(u_1, u_2) \in [D({A_0}^{1/2})]^2 \times [D({A_0}^{1/2})]^2; u_1 + G_0G_0^*A_0u_2 \in D(A_0)\},$$

$$A_2 \equiv \begin{bmatrix} 0 & I \\ -M^{-1}\mathcal{A} & -M^{-1}(\mathcal{A}G_1G_1^*\mathcal{A} + \mathcal{A}G_2D_\tau^2G_2^*\mathcal{A}_0 + b_2) \end{bmatrix}, \tag{7.62}$$

$A_2 : H_2 \to H_2$ with $H_2 \equiv D(\mathcal{A}^{1/2}) \times D(A_N)^{1/2}$,

$$D(A_2) = \{(w_1, w_2) \in D(\mathcal{A}^{1/2}) \times D(\mathcal{A}^{1/2}); \mathcal{A}(w_1 + G_1 G_1^* \mathcal{A} w_2 + G_2 D_\tau^2 G_2^* \mathcal{A} \tilde{w}_2) \in [D(A_N{}^{1/2})]'\}, \tag{7.63}$$

we rewrite (7.59) as

$$\begin{pmatrix} \tilde{u}(t) \\ \tilde{u}_t(t) \end{pmatrix}_t = A_1 \begin{pmatrix} \tilde{u}(t) \\ \tilde{u}_t(t) \end{pmatrix} + \begin{pmatrix} 0 \\ f_1(\tilde{w}, w_i) \end{pmatrix}, \tag{7.64}$$

$$\begin{pmatrix} \tilde{w}(t) \\ \tilde{w}_t(t) \end{pmatrix}_t = A_2 \begin{pmatrix} \tilde{w}(t) \\ \tilde{w}_t(t) \end{pmatrix} + \begin{pmatrix} 0 \\ M^{-1} f_2(\tilde{u}, \tilde{w}, u_i, w_i) \end{pmatrix}. \tag{7.65}$$

It is well known that the operators A_1, (resp., A_2) are generators of a contraction semigroup on the spaces $[D(A_0{}^{1/2})]^2 \times [L_2(\Omega)]^2$ and $D(\mathcal{A}^{1/2}) \times D(A_N{}^{1/2})$, respectively. By the standard semigroup argument we also know that these operators generate strongly continuous semigroups on the dual spaces $[D(A_1^*)]'$ and $[D(A_2^*)]'$, respectively, where the duality is, as usual, with respect to the H_1, H_2 topology. This implies the following negative norm estimates:

$$\begin{aligned} |(\tilde{u}, \tilde{u}_t)|_{[D(A_1^*)]'} &\le C \int_0^t |(0, f_1)|_{[D(A_1^*)]'} dt, \\ |(\tilde{w}, \tilde{w}_t)|_{[D(A_2^*)]'} &\le C \int_0^t |(0, M^{-1} f_2)|_{[D(A_1^*)]'} dt. \end{aligned} \tag{7.66}$$

On the other hand, by direct computations of $[A_i^*]^{-1}$ we obtain

$$\begin{aligned} |(u_1, u_2)|^2_{[D(A_1^*)]'} &= |u_1|^2_{0,\Omega} + |A_0{}^{-1/2} u_2 + A_0{}^{1/2} G_0 G_0^* A_0^* u_1|^2_{0,\Omega}, \\ |(w_1, w_2)|^2_{[D(A_2^*)]'} &= |M^{1/2} w_1|^2_{0,\Omega} + |\mathcal{A}^{-1/2} M w_2 + \mathcal{A}^{1/2} [G_1 G_1^* \mathcal{A} w_1 + G_2 D_\tau^2 G_2^* \mathcal{A} w_1]|^2_{0,\Omega}. \end{aligned} \tag{7.67}$$

Thus, in particular,

$$\begin{aligned} |\tilde{u}(t)|^2_{0,\Omega} &\le C \int_0^t |A_0^{-1/2} f_1|^2_{0,\Omega} dt, \\ |\tilde{w}(t)|^2_{1,\Omega} &\le C \int_0^t |\mathcal{A}^{-1/2} f_2|^2_{0,\Omega} dt. \end{aligned} \tag{7.68}$$

Inequalities in (7.68) form the basis for subsequent analysis.

Let $\phi \in [L_2(\Omega)]^2$. We compute

$$(A_0^{-1/2} f_1, \phi)_{0,\Omega} = -(\mathcal{C}[f(\nabla w_1) - f(\nabla w_2)], \boldsymbol{\epsilon}(A_0^{-1/2} \phi))_{0,\Omega}. \tag{7.69}$$

Hence,

$$|A_0^{-1/2} f_1|_{0,\Omega} \le C |f(\nabla w_1) - f(\nabla w_2)|_{0,\Omega}. \tag{7.70}$$

Let P_n be the orthogonal projection on the subspace spanned by n eigenvectors of $\mathcal{A}$ and let $Q_n = I - P_n$. (One could also take a projection on the subspace spanned by the eigenvectors of the biharmonic operator with clamped boundary conditions; this particular choice is not critical for the arguments.) The following "logarithmic"

estimate resulting from Sobolev's embedding and the Holder inequality is known [24], [2]:

$$|(P_n f)g|_{0,\Omega} \le C\mathrm{lg}(1+\lambda_n)^{1/2}|f|_{0,\Omega}|g|_{1,\Omega}, \tag{7.71}$$

where λ_n is an eigenvalue of $\mathcal{A}$ and the constant C is independent of n. Applying (7.71) and abusing notation slightly by using the projection operator applied to a vector function (meaning the projection is applied to each component) we obtain

$$\begin{aligned}|(f(\nabla w_1)-f(\nabla w_2))|_{0,\Omega} &\le C|\nabla\tilde{w}\times\nabla(w_1+w_2)|_{0,\Omega} \le C|(P_n\nabla\tilde{w})\times\nabla(w_1+w_2)|_{0,\Omega}\\ &+|(Q_n\nabla\tilde{w})\times\nabla(w_1+w_2)|_{0,\Omega} \le C\mathrm{lg}(1+\lambda_n)^{1/2}|\tilde{w}|_{1,\Omega}[|w_1|_{2,\Omega}+|w_2|_{2,\Omega}]\\ &+C|Q_n\nabla\tilde{w}|_{\epsilon,\Omega}[|w_1|_{2,\Omega}+|w_2|_{2,\Omega}].\end{aligned} \tag{7.72}$$

On the other hand we have

$$\begin{aligned}|Q_n\nabla\tilde{w}|_{\epsilon,\Omega} &\le C|\mathcal{A}^{1/4\epsilon}Q_n\nabla\tilde{w}|_{0,\Omega} \le C|\mathcal{A}^{1/4(\epsilon-\beta_0)}Q_n|_{\mathcal{L}(\mathcal{L}_2(\Omega))}|\nabla\tilde{w}|_{\beta_0,\Omega}\\ &\le C{\lambda_n}^{1/4(\epsilon-\beta_0)}|\nabla\tilde{w}|_{\beta_0,\Omega}| \le C{\lambda_n}^{1/4(\epsilon-\beta_0)}|\tilde{w}|_{3/2,\Omega},\end{aligned} \tag{7.73}$$

where $\beta_0 < 1/2$.

Combining (7.72), (7.73), (7.70) gives

$$\begin{aligned}|(A_0^{-1/2}f_1|_{0,\Omega} &\le C|(f(\nabla w_1)-f(\nabla w_2)|_{0,\Omega}\\ &\le C[\mathrm{lg}(1+\lambda_n)^{1/2}|\tilde{w}|_{1,\Omega}+{\lambda_n}^{-\beta}][|w_1|_{2,\Omega}+|w_2|_{2,\Omega}]\\ &\le C(E(0))\mathrm{lg}(1+\lambda_n)^{1/2}|\tilde{w}|_{1,\Omega}+C(E(0)){\lambda_n}^{-\beta},\end{aligned} \tag{7.74}$$

where $\beta < 1/8$ and $E(0)$ denotes the initial energy of weak solutions. The estimate for f_2 is carried out next. With $\psi \in L_2(\Omega)$ we have

$$(\mathcal{A}^{-1/2}f_2,\psi)_{0,\Omega} = (\mathcal{C}N(u_1,w_1)\nabla w_1 - \mathcal{C}N(u_2,w_2)\nabla w_2, \nabla\mathcal{A}^{-1/2}\psi)_{0,\Omega}. \tag{7.75}$$

We shall compute the right-hand side of (7.75). By using (7.71) we obtain

$$\begin{aligned}(\boldsymbol{\epsilon}(u_2)\nabla\tilde{w},\nabla\mathcal{A}^{-1/2}\psi)_{0,\Omega} &\le C|u_2|_{1,\Omega}|\nabla\tilde{w}\times\nabla\mathcal{A}^{-1/2}\psi|_{0,\Omega}\\ \le C|u_2|_{1,\Omega}[\log(1+\lambda_n)^{1/2}|\tilde{w}|_{1,\Omega}|\nabla\mathcal{A}^{-1/2}\psi|_{1,\Omega} &+ {\lambda_n}^{-\beta}[|w_1|_{2,\Omega}+|w_2|_{2,\Omega}]|\nabla\mathcal{A}^{-1/2}\psi|_{1,\Omega}]\\ &\le C[\mathrm{lg}(1+\lambda_n)^{1/2}|\tilde{w}|_{1,\Omega}+{\lambda_n}^{-\beta}[|w_1|_{2,\Omega}+|w_2|_{2,\Omega}]]|u_2|_{1,\Omega}|\psi|_{0,\Omega}].\end{aligned} \tag{7.76}$$

By the divergence theorem we have

$$\begin{aligned}(\boldsymbol{\epsilon}(\tilde{u})\nabla w_1,\nabla\mathcal{A}^{-1/2}\psi)_{0,\Omega} &= \langle\tilde{u},(1/2\nabla w_1\times\nabla\mathcal{A}^{-1/2}\psi)+(1/2\nabla w_1\times\nabla\mathcal{A}^{-1/2}\psi)^T\nu\rangle_{0,\Gamma_1}\\ &-(\tilde{u},\mathrm{div}((1/2\nabla w_1\times\nabla\mathcal{A}^{-1/2}\psi)+(1/2\nabla w_1\times\nabla\mathcal{A}^{-1/2}\psi)^T))_\Omega.\end{aligned} \tag{7.77}$$

Define

$$K \equiv 1/2\nabla w_1\times\nabla\mathcal{A}^{-1/2}\psi + (1/2\nabla w_1\times\nabla\mathcal{A}^{-1/2}\psi)^T.$$

Simple calculations and (7.71) imply

$$\begin{aligned}|(\tilde{u},\mathrm{div}K)_{0,\Omega}| &\le |(P_n\tilde{u},\mathrm{div}K)_{0,\Omega}+(Q_n\tilde{u},\mathrm{div}K)_{0,\Omega}]\\ \le C[|\tilde{u}|_{0,\Omega}\mathrm{lg}(1+\lambda_n)^{1/2}|w_1|_{2,\Omega}|\nabla\mathcal{A}^{-1/2}\psi|_{1,\Omega} &+ |\tilde{u}|_{1,\Omega}{\lambda_n}^{-\beta}|w_1|_{2,\Omega}|\nabla\mathcal{A}^{-1/2}\psi|_{1,\Omega}]\\ &\le C[|\tilde{u}|_{0,\Omega}\mathrm{lg}(1+\lambda_n)^{1/2}+|\tilde{u}|_{1,\Omega}{\lambda_n}^{-\beta}]|w_1|_{2,\Omega}|\psi|_{0,\Omega}.\end{aligned} \tag{7.78}$$

Also, by the trace theorem we have

$$\langle \tilde{u}, K\nu\rangle_\Gamma \le C|\tilde{u}|_{0,\Gamma_1}|K|_{1/2+\epsilon,\Omega} \le C|\tilde{u}|_{0,\Gamma_1}|w_1|_{2,\Omega}|\psi|_{0,\Omega}. \tag{7.79}$$

The crucial boundary term $|\tilde{u}|_{0,\Gamma_1}$ will be estimated later.

Finally the term $(f(\nabla w_1)\nabla w_1 - f(\nabla w_2)\nabla w_2, \nabla\mathcal{A}^{-1/2}\psi)_{0,\Omega}$ is estimated directly as

$$(f(\nabla w_1)\nabla w_1 - f(\nabla w_2)\nabla w_2, \nabla\mathcal{A}^{-1/2}\psi)_{0,\Omega} \le C|\tilde{w}|_{1,\Omega}[|w_1|^2_{2,\Omega} + |w_1|^2_{2,\Omega}]|\psi|_{0,\Omega}. \tag{7.80}$$

Collecting (7.75)–(7.80) yields

$$\begin{aligned}(\mathcal{A}^{-1/2}f_2,\psi)_{0,\Omega} &\le C\lg(1+\lambda_n)^{1/2}[|\tilde{u}|_{0,\Omega} + |\tilde{w}|_{1,\Omega}]\\ &\cdot[|w_1|_{2,\Omega} + |w_2|_{2,\Omega} + |u_2|_{1,\Omega} + |u_1|_{1,\Omega} + |w_1|^2_{2,\Omega} + |w_2|^2_{2,\Omega}]|\psi|_{0,\Omega}\\ &+C|\tilde{u}|_{0,\Gamma_1}|w_1|_{2,\Omega}|\psi|_{0,\Omega} + C{\lambda_n}^{-\beta}[|w_1|^2_{2,\Omega} + |w_2|^2_{2,\Omega} + |u_2|^2_{1,\Omega} + |u_1|^2_{1,\Omega}]|\psi|_{0,\Omega}.\end{aligned} \tag{7.81}$$

Hence

$$\begin{aligned}\int_0^t |\mathcal{A}^{-1/2}f_2|^2_{0,\Omega}ds &\le C(E(0))\lg(1+\lambda_n)\int_0^t [|\tilde{u}|^2_{0,\Omega} + |\tilde{u}|^2_{0,\Gamma_1} + |\tilde{w}|^2_{1,\Omega}]ds\\ &+C(E(0))\int_0^t |\tilde{u}|^2_{0,\Gamma_1}ds + {\lambda_n}^{-2\beta}C_T(E(0)).\end{aligned} \tag{7.82}$$

The crucial next step is to prove the following trace estimate

$$\int_0^t |\tilde{u}|^2_{0,\Gamma_1}ds \le C(E(0))\lg(1+\lambda_n)\int_0^t |\tilde{w}|^2_{1,\Omega}ds + C_T(E(0)){\lambda_n}^{-2\beta}. \tag{7.83}$$

To prove (7.83), the idea is to use the energy estimates for a new variable u^* defined as

$$u^*(t) \equiv \int_0^t \tilde{u}ds.$$

Denoting

$$\tilde{f} \equiv \mathcal{C}[f(\nabla w_1) - f(\nabla w_2)], \quad f^*(t) \equiv \int_0^t \tilde{f}ds,$$

we obtain the following equation satisfied by the new variable u^*:

$${u^*}_{tt} + A_0u^* + b_1u^*_t + A_0G_0(G_0^*A_0u^*_t) = \mathrm{div}f^* - A_0G_0G_0^*A_0f^*\nu. \tag{7.84}$$

Multiplying this equation by u^*_t and integrating by parts yield

$$|u^*_t(t)|^2_{0,\Omega} + |u^*(t)|^2_{1,\Omega} + \int_0^t |u^*_t(s)|^2_{0,\Gamma_1}ds \le C_T\int_0^t (f^*, \boldsymbol{\epsilon}(u^*_t))_{0,\Omega}ds. \tag{7.85}$$

When we integrate by parts in time the last term in the above inequality yields

$$|u^*_t(t)|^2_{0,\Omega} + |u^*(t)|^2_{1,\Omega} + \int_0^t |u^*_t(s)|^2_{0,\Gamma_1}ds \le C\left[\int_0^t |f^*_t|_{0,\Omega}|u^*|_{1,\Omega}ds + |f^*(t)|_{0,\Omega}|u^*(t)|_{1,\Omega}\right]. \tag{7.86}$$

Hence, in particular,

$$\int_0^t |\tilde{u}(s)|^2_{0,\Gamma_1} = \int_0^t |u_t^*(s)|^2_{0,\Gamma_1} ds \le C_T \left[\int_0^t |f_t^*|^2_{0,\Omega} ds + |f^*(t)|^2_{0,\Omega} \right]. \tag{7.87}$$

On the other hand,

$$\begin{aligned} \int_0^t |f_t^*|^2_{0,\Omega} ds &= \int_0^t |\tilde{f}|^2_{0,\Omega} d \le C \int_0^t |\nabla \tilde{w} \times \nabla w_i|^2_{0,\Omega} ds \\ &\le C \int_0^t |P_n \nabla \tilde{w} \times \nabla w_i|^2_{0,\Omega} + |Q_n \nabla \tilde{w} \times \nabla w_i|^2_{0,\Omega} ds \\ &\le C \lg(1+\lambda_n) \int_0^t |\tilde{w}|^2_{1,\Omega} |w_i|^2_{2,\Omega} ds + C {\lambda_n}^{-2\beta} \int_0^t |\tilde{w}|^2_{2,\Omega} |w_i|^2_{2,\Omega} ds. \end{aligned} \tag{7.88}$$

Similarly,

$$\begin{aligned} |f^*(t)|^2_{0,\Omega} &\le C_T \int_0^t |\tilde{f}|^2_{0,\Omega} ds \\ &\le C \lg(1+\lambda_n) \int_0^t |\tilde{w}|^2_{1,\Omega} |w_i|^2_{2,\Omega} ds + C {\lambda_n}^{-2\beta} \int_0^t |\tilde{w}|^2_{2,\Omega} |w_i|^2_{2,\Omega} ds. \end{aligned} \tag{7.89}$$

Collecting (7.87)–(7.89) leads to the desired conclusion in (7.83). From (7.82) and (7.83) we conclude

$$\int_0^t |\mathcal{A}^{-1/2} f_2|^2_{0,\Omega} ds \le C(E(0)) \lg(1+\lambda_n) \int_0^t [|\tilde{u}|^2_{0,\Omega} + + |\tilde{w}|^2_{1,\Omega}] ds + {\lambda_n}^{-2\beta} C(E(0)). \tag{7.90}$$

From (7.74) and (7.90) we obtain

$$\begin{aligned} \int_0^t [|\mathcal{A}^{-1/2} f_2|^2_{0,\Omega} + |{A_0}^{-1/2} f_1|^2_{0,\Omega}] ds \le C(E(0)) [\lg(1+\lambda_n)] \int_0^t [|\tilde{u}|^2_{0,\Omega} + |\tilde{w}|^2_{1,\Omega}] \\ + {\lambda_n}^{-\beta} C_T(E(0)), \end{aligned} \tag{7.91}$$

and combining this with (7.68) and Gronwall's inequality, we have

$$|\tilde{u}(t)|^2_{0,\Omega} + |\tilde{w}(t)|^2_{1,\Omega} \le C_T(E(0)) {\lambda_n}^{-2\beta} (1+\lambda_n)^{C(E(0))t}. \tag{7.92}$$

Taking $t < T_0$, where T_0 is sufficiently small yields the conclusion of the lemma for $t < T_0$. Applying the "boost trap" argument completes the proof of the second part of Proposition 1.1. □

APPROXIMATE FILTER FOR THE CONDITIONAL LAW OF A PARTIALLY OBSERVED PROCESS IN NONLINEAR FILTERING*

A. GEGOUT-PETIT†

Abstract. We study a problem of singular perturbations for a special class of nonlinear filtering problems in which the dimension of the signal process is 2 and only one of the two components of this process is observed. We propose an approximate filter of finite dimension for the observed part. Using this filter, we construct an approximate filter of infinite dimension for the nonobserved part. This filter solves a Zakai-type equation whose spatial variable dimension is 1 even though the spatial variable dimension of the Zakai equation solved by the exact filter is 2. The method used gives the order of the approximation error.

Key words. nonlinear filtering, singular perturbations, partially observed process, Zakai's equation

Introduction. This paper considers an asymptotic problem in nonlinear filtering when the signal observes only one component of X. In recent years, nonlinear filtering with high signal-to-noise ratio has been studied in numerous publications, some of whose fundamental results we will now recall before presenting our work.

Consider the following filtering problem:

$$\begin{cases} X_t = X_0 + \displaystyle\int_0^t f(X_s)ds + \int_0^t g(X_s)dV_s, \\ Y_t = \displaystyle\int_0^t h(X_s)ds + \varepsilon W_t, \end{cases} \tag{1}$$

where X_t is a nonobserved vectorial process and Y_t is the observation.

The filtering problem consists of computing the best approximation of the law of X_t using the observation of Y up to instant t: it is the conditional law of X_t given $\mathcal{Y}_t = \sigma\{Y_s, 0 \le s \le t\}$. In the nonlinear case, the solution of this problem has infinite dimension. Indeed, the unnormalized conditional law of X_t given $\mathcal{Y}_t$ satisfies a parabolic partial differential equation (PDE) called Zakai's equation (see Zakai [16] or Pardoux [5], [6]). As is often the case in practice, we will suppose throughout our work that ε is small. We are therefore dealing with the case of high signal-to-noise ratio.

We will often use the notation $\hat{X}_t \stackrel{\Delta}{=} E[X_t/\mathcal{Y}_t]$.

Filtering with high signal-to-noise ratio.

Case where h is one to one. When $\varepsilon = 0$, $dY_t = h(X_t)dt$, and if h is one to one, X is perfectly observed. We expect that X_t is "almost $\mathcal{Y}_t$-measurable" when ε is small in the sense that $(X_t - E[X_t/\mathcal{Y}_t])$ is small in the L^p-norm. In fact, suppose

$\hat{X}_t - X_t = O(\varepsilon^k)$ (we will define the meaning of $O(\varepsilon^k)$ rigorously in Definition 1.2). For any function φ smooth enough, we have

$$\varphi(X_t) = \varphi(\hat{X}_t) + \varphi'(\hat{X}_t)(X_t - \hat{X}_t) + \frac{1}{2}\varphi''(\xi_t)(X_t - \hat{X}_t)^2$$

with $\xi_t \in [X_t, \hat{X}_t]$. Taking the conditional expectation of this expression, we get

$$E[\varphi(X_t)/\mathcal{Y}_t] = \varphi(\hat{X}_t) + O(\varepsilon^{2k}). \tag{2}$$

In this case we see that if we have a good approximation of $\hat{X}_t$, we also get a good estimation of the whole conditional law since it is "concentrated" around $\hat{X}_t$ and the filtering problem is considerably simplified as there is no need to compute the whole conditional law of X_t given $\mathcal{Y}_t$ (i.e., $E[\varphi(X_t)/\mathcal{Y}_t]$ with φ varying in a large class of functions) but merely an approximation of $\hat{X}_t$. We will therefore try to find an approximate filter for $\hat{X}_t$. There is an extensive literature on the existence of approximate filters of finite dimension in the case of a high signal-to-noise ratio, and the list of articles referenced in this paper is far from exhaustive. We have mostly used the following papers by Picard: [7], [8], [9], [10].

An approximate filter is a $\mathcal{Y}_t$-measurable process here denoted by M_t, defined by a finite number of equations. We will use only first-order filters here, but it is possible to define second-order filters like the extended Kalman filter, which uses an approximation of the conditional variance $E[(X_t - \hat{X}_t)^2/\mathcal{Y}_t]$, or third-order filters [12]. For example, under sufficient assumptions, the process M_t defined below is an approximate filter of the process X_t defined in (1):

$$M_t = m_0 + \int_0^t f(M_s)ds + \int_0^t \frac{1}{\varepsilon}(h')^{-1}(h'gg^*h'^*)^{\frac{1}{2}}(M_s)(dY_s - h(M_s)ds), \tag{3}$$

and we get the following result:

$$X_t - M_t = O(\sqrt{\varepsilon}). \tag{4}$$

This estimation is easily established (we will give the proof for a particular case in the proof of Lemma 1.3), and we deduce immediately that

$$\hat{X}_t - M_t = O(\sqrt{\varepsilon}), \tag{5}$$

which can be improved to get

$$\hat{X}_t - M_t = O(\varepsilon). \tag{6}$$

This new estimation is much more difficult to establish than the previous one: it will require techniques of time reversal of diffusion processes (Picard [7]), techniques of derivation with respect to the initial condition or derivation in the Wiener space (Picard [9]), or fine techniques of PDEs (Bensoussan [1]). (In some particular cases, such as the semilinear case, or for higher-order filters, we get estimations of order $\varepsilon^{\frac{3}{2}}$ or even of order ε^2 (Picard [7], [10])). For regular φ functions we can then, using (2), estimate $E[\varphi(X_t)/\mathcal{Y}_t]$ by $\varphi(M_t)$ and the error is of order ε.

Case where h is not one to one. The function h can be locally, but not globally, one to one. In this work we will consider the case where h is not one to one because it observes only some of the components of X. As expected, the components of X which are nonobserved are not $\mathcal{Y}_t$-measurable when $\varepsilon = 0$. We distinguish two different cases.

1) The case where the conditional variance of any component of X converges to 0 with ε. Therefore, there exist approximate filters for X. The process X is said to be observable.

2) The case where X is not perfectly observed when $\varepsilon = 0$. In this case, we can construct approximate filters for the observed components of X, but no approximate filter can exist for the other components.

Zeitouni and Dembo [17] give cases of observability of the system. Picard [11] shows that the detectability of the system is a sufficient criterion for the conditional variance to converge to 0 with ε. Except for the linear detectable case where the terms of the conditional variance matrix can be estimated (the variance satisfies a Riccati equation; see [6]), it seems that the only method to prove the convergence of the variance to 0 with ε is to construct an approximate filter for X. In [15] using a formal asymptotic development for the conditional law, Yaesh, Bobrovsky, and Schuss give detectability criteria when the dimension of X is 2 and when Y, whose dimension is 1, observes only a component of X. Approximate filters are given for the observed part of X.

In the case 2) (we can suppose without restriction that X^1 is the observed part of X, and X^2 the nonobserved one), Takeuchi and Akashi [14], using a theorem of martingale convergence, prove that $E[\varphi(X_t)/\mathcal{Y}_t]$ converges in probability to $E[\varphi(X_t)/\mathcal{X}_t^1]$ ($\mathcal{X}_t^1 = \sigma(X_s^1, 0 \le s \le t)$) when ε converges to 0. Sachs [13] obtains the same result in the linear case. In particular, $E[\varphi(X_t^2)/\mathcal{Y}_t]$ converges to $E[\varphi(X_t^2)/\mathcal{X}_t^1]$. When $\varepsilon = 0$, X^1 is perfectly observed and the conditional law of X^2 given $\mathcal{X}_t^1$ satisfies the associated Zakai equation. This equation is a parabolic PDE whose partial variable dimension is the dimension of X^2. As seen above, approximate filters of finite dimension do not exist for X^2, but we can expect that there exists an approximate filter which satisfies a Zakai-type equation whose spatial variable has dimension smaller than that of the exact Zakai equation satisfied by $E[\varphi(X_t)/\mathcal{Y}_t]$. The advantage of this filter is that the numerical computations of the Zakai equation are easier.

In this work, we give such an approximate filter for X^2 in the case $\dim(X^1) = \dim(X^2) = \dim(Y) = 1$. To define it, we use an approximate filter of finite dimension for X^1. The idea is to replace X^1 by M in the Zakai equation satisfied by $E[\varphi(X_t^2)/\mathcal{X}_t^1]$ (which is equal to $E[\varphi(X_t^2)/\mathcal{Y}_t]$ when $\varepsilon = 0$). The method shows that the rate of convergence is of order ε.

This paper is organized as follows: in section 1, we give the assumptions and we define the approximate filter for X^1 as well as the approximate filter for X^2 and the Zakai-type equation it satisfies. In section 2, we give an expression for the difference between the exact and the approximate filters as a function of $(X^1 - M)$. In section 3, we recall results about the rate of convergence of M. We deduce the order of the rate of convergence of our problem.

1. Approximate filters definitions.

1.1. Assumptions. Let $(\Omega, \mathcal{F}, (\mathcal{F}_t)_{t\ge 0}, P)$ be a filtered probability space. All the filtrations we are using here are completed and right-continuous. If $(X_t)_{t\ge 0}$ is a

process, we call $\mathcal{X}_t$ its natural completed filtration $\mathcal{X}_t = \sigma(X_s, 0 \le s \le t)$.

We consider the filtering problem:

$$\begin{cases} X_t^1 = X_0^1 + \displaystyle\int_0^t f_1(X_s^1, X_s^2)ds + V_t^1, \\ X_t^2 = X_0^2 + \displaystyle\int_0^t f_2(X_s^1, X_s^2)ds + V_t^2, \\ Y_t = \displaystyle\int_0^t h(X_s^1)ds + \varepsilon W_t, \end{cases} \tag{7}$$

where X^1, X^2, and Y are scalar. We note that the observation-function h only depends on X^1.

Assumptions.

H.1. V_t^1, V_t^2, and W_t are scalar-independent Wiener processes.

H.2. X_0^1 is deterministic.

H.3. X_0^2 is independent of V_t^1, V_t^2, and W_t.

H.4. f_1 and f_2 are bounded and have derivatives of order 3 which are bounded.

H.5. Let $g(x^1, x^2) = \int_0^{x^1} f_1(u, x^2)du$. We suppose that g and its derivatives are bounded. (This is true if, for example, the support of f_1 relative to x^1 is compact.)

H.6. h is C_b^2 and there exists $0 < \alpha < \delta$ such that $\forall x \in \mathbb{R},\ 0 < \alpha < h'(x) < \delta$.

1.2. An approximate filter for X^1. We define a new process $(M_t, 0 \le t < \infty)$ which is an approximate filter for X_t^1 (cf. Lemma 1.3):

$$\begin{cases} M_0 = X_0^1, \\ dM_t = \dfrac{1}{\varepsilon}(dY_t - h(M_t)dt). \end{cases} \tag{8}$$

REMARK 1.1. *The filtrations $\mathcal{Y}_t$ and $\mathcal{M}_t$ are equal $\forall t \ge 0$. We will use the two notations interchangeably.*

We will see that $(X^1 - M)$ is of order $\sqrt{\varepsilon}$, but only on each time interval $[t_0, \infty]$. This is why we give the following definition.

DEFINITION 1.2. *Let Z_t be an adapted process defined on Ω. Let us suppose that Z depends on ε. We say that Z is of order ε^k (and note that $Z_t = O(\varepsilon^k)$) if there exist $\varepsilon_0 > 0$ and $r \in \mathbb{R}$ (r could be negative) such that $\forall t_0 > 0$ and $1 \le q < \infty$, $\exists C > 0$ such that for all $\varepsilon < \varepsilon_0$,*

$$\sup_{t_0 \le t < \infty} \|Z_t\|_q \le C\varepsilon^k \quad \text{and} \quad \sup_{0 \le t < \infty} \|Z_t\|_q \le C\varepsilon^r. \tag{9}$$

Let us denote by $\| \ \|_p$ the norm of $L^p(\Omega, \mathcal{F}, P)$. Likewise we will say that Z_t is of order ε^k under the probability $\tilde{P}$ (introduced at (10)) if (9) is true for $\| \ \|_p^{\sim}$, the norm of $L^p(\Omega, \mathcal{F}, \tilde{P})$.

We will see later that M is an approximate filter of order ε for X^1. For the moment, we only use the following result, whose proof is easier.

LEMMA 1.3. *Under the probability P we have the following two assertions:*

i) $(X_t^1 - M_t) = O(\sqrt{\varepsilon})$,

ii) $E[X_t^1/\mathcal{Y}_t] - M_t = O(\sqrt{\varepsilon})$.

Proof. The conditional expectation is an L^p-contraction, so i) implies ii). Using assumption H.6, i) is equivalent to $h(X_t^1) - h(M_t) = O(\sqrt{\varepsilon})$. Using Itô's formula, we obtain

$$d(h(X_t^1) - h(M_t)) = -\frac{h'(M_t)}{\varepsilon}(h(X_t^1) - h(M_t))dt + h'(X_t^1)dV_t^1 - h'(M_t)dW_t + \left(f_1(X_t^1, X_t^2)h'(X_t^1) + \frac{1}{2}(h''(X_t^1) - h''(M_t))\right)dt,$$

$$\begin{aligned} h(X_t^1) - h(M_t) = {} & \exp\left(-\frac{1}{\varepsilon}\int_0^t h'(M_s)ds\right)(h(X_0^1) - h(M_0)) \\ & + \int_0^t e^{-\frac{1}{\varepsilon}\int_s^t h'(M_r)dr}\left(f_1(X_s^1, X_s^2)h'(X_s^1) + \frac{1}{2}(h''(X_s^1) - h''(M_s))\right)ds \\ & + \int_0^t e^{-\frac{1}{\varepsilon}\int_s^t h'(M_r)dr}(h'(X_s^1)dV_s^1 - h'(M_s)dW_s). \end{aligned}$$

Again using H.6 ($h'(x) > \alpha$), the first term is of order $e^{-\frac{c}{\varepsilon}}$ for $t \geq t_0$, the second is of order ε, and the last is of order $\sqrt{\varepsilon}$. □

REMARK 1.4. *We will need later the fact that X_0^1 is deterministic. In the last equation, we see that we do not need the assumption $M_0 = X_0^1$ to establish Lemma* 1.3. *The error at time $t = 0$ disappears because of the exponential function. The filter therefore has a "short memory."*

1.3. Change of probability. Let $\Gamma_t = \exp(\int_0^t f_1(X_s^1, X_s^2)dX_s^1 - \frac{1}{2}\int_0^t (f_1(X_s^1, X_s^2))^2 ds)$. We can define a new probability $\tilde{P}$ on $\mathcal{F}_t$ by

$$\left.\frac{d\tilde{P}}{dP}\right|_{\mathcal{F}_t} = \Gamma_t^{-1}. \tag{10}$$

Under $\tilde{P}$, X_t^1 is a Wiener process which does not depend on $\mathcal{V}^2 \vee \mathcal{W}$.

If we define

$$g(x^1, x^2) = \int_0^{x_1} f_1(u, x^2)du \tag{11}$$

and apply Itô's formula to the process $g(X_t^1, X_t^2)$, Γ_t can be rewritten in the following way:

$$\begin{aligned} \Gamma_t = \exp\Bigg(& g(X_t^1, X_t^2) - g(X_0^1, X_0^2) - \int_0^t [\mathcal{L}_{(X_s^1)}g(X_s^1, .)](X_s^2)ds \\ & - \frac{1}{2}\int_0^t \frac{\partial f_1}{\partial x_1}(X_s^1, X_s^2)ds - \int_0^t \frac{\partial g}{\partial x_2}(X_s^1, X_s^2)dV_s^2 \\ & - \frac{1}{2}\int_0^t (f_1(X_s^1, X_s^2))^2 ds\Bigg), \end{aligned} \tag{12}$$

with

$$\mathcal{L}_{(y)}\varphi(x) = \frac{1}{2}\varphi''(x) + \varphi'(x)f_2(y, x). \tag{13}$$

Under this new expression of Γ we see that we can "freeze" X^1 in the Γ_t definition. For a function $x \in \mathcal{C}([0,t])$, let us define

$$X_t^2(x) \triangleq X_0^2 + \int_0^t f_2(x_s, X_s^2(x))ds + V_t^2,$$

$$\begin{aligned}\Gamma_t(x) = \exp\Bigg(& g(x_t, X_t^2(x)) - g(x_0, X_0^2) - \int_0^t \mathcal{L}_{(x_s)} g(x_s, .)(X_s^2(x))ds \\ & - \frac{1}{2}\int_0^t \frac{\partial f_1}{\partial x_1}(x_s, X_s^2(x))ds - \int_0^t \frac{\partial g}{\partial x_2}(x_s, X_s^2(x))dV_s^2 \\ & - \frac{1}{2}\int_0^t (f_1(x_s, X_s^2(x)))^2 ds\Bigg). \end{aligned} \tag{14}$$

The assumptions on f_1 will make Γ_t bounded in the L^p norm. We deduce that the order of a process (in the sense of Definition 1.2) is the same under the two probabilities P and $\tilde{P}$.

LEMMA 1.5. *Under the assumptions of the Introduction, for a fixed $T > 0$, $\forall p \in \mathbb{R}$, there exists $c(p)$ such that $\forall t \leq T$ and $\forall x \in \mathcal{C}([0,T])$,*

$$E[(\Gamma_t(x))^p] \leq c(p). \tag{15}$$

Proof. We use H.4 and H.5 to show that the first exponential below is bounded for all $x \in \mathcal{C}([0,T])$:

$$\begin{aligned}(\Gamma_t(x))^p = \exp p\Bigg(& g(x_t, X_t^2(x)) - g(x_0, X_0^2) - \int_0^t \mathcal{L}_{(x_s)} g(x_s, .)(X_s^2(x))ds \\ & - \frac{1}{2}\int_0^t \frac{\partial f_1}{\partial x_1}(x_s, X_s^2(x))ds - \frac{1}{2}\int_0^t (f_1(x_s, X_s^2(x)))^2 ds \\ & + \frac{p}{2}\int_0^t \left(\frac{\partial g}{\partial x_2}(x_s, X_s^2(x))\right)^2 ds\Bigg) \\ & \times \exp\left(-p\int_0^t \frac{\partial g}{\partial x_2}(x_s, X_s^2(x))dV_s^2 - \frac{p^2}{2}\int_0^t \left(\frac{\partial g}{\partial x_2}(x_s, X_s^2(x))\right)^2 ds\right) \\ \leq c(p,T)\exp & \left(-p\int_0^t \frac{\partial g}{\partial x_2}(x_s, X_s^2(x))dV_s^2 - \frac{p^2}{2}\int_0^t \left(\frac{\partial g}{\partial x_2}(x_s, X_s^2(x))\right)^2 ds\right). \end{aligned} \tag{16}$$

$c(p,T)$ does not depend on the function x. The last term is an exponential martingale whose expectation is equal to 1. ∎

LEMMA 1.6. *Let $(Z_t)_{t\leq 0}$ be a process defined on Ω, $T > 0$. The following two properties are equivalent:*

i) $\forall t \leq T, \quad Z_t = O(\varepsilon^k)$ *under* P,

ii) $\forall t \leq T, \quad Z_t = O(\varepsilon^k)$ *under* $\tilde{P}$.

Proof of Lemma 1.6. We use Lemma 1.5:

$$\begin{aligned} E[(Z_t)^p] &= \tilde{E}[(Z_t)^p \Gamma_t] \\ &\le \sqrt{\tilde{E}[(Z_t)^{2p}]}\sqrt{\tilde{E}[(\Gamma_t)^2]} \\ &\le \sqrt{\tilde{E}[(Z_t)^{2p}]}\sqrt{E[(\Gamma_t)]} \\ &\le c(T)\varepsilon^{kp} \end{aligned}$$

for t large enough. □

REMARK 1.7. *The results of Lemma* 1.3 *are true under the probability* $\tilde{P}$. *From now on, when we say that a process is of order* ε^k, *we mean under both* P *and* $\tilde{P}$.

1.4. An approximate filter for X^2.

1.4.1. Definition. Let us consider the filtering problem (7) at the limit case $\varepsilon = 0$. Because h is one to one relative to X^1, X^1 is perfectly observed and (7) is reduced to the filtering problem when X^1 is the observation and X^2 the nonobserved process. The last change of probability now becomes natural because we need to work under the probability which makes the observation (X^1 if $\varepsilon = 0$) a Brownian motion.

Under the classical filtering results (see [16] and [6]), for a function $\varphi \in C_b^2(\mathbb{R})$, the process $\tilde{E}[\varphi(X_t^2)\Gamma_t/\mathcal{X}_t^1]$ satisfies the well-known Zakai equation

(17)
$$\begin{aligned} &\tilde{E}[\varphi(X_t^2)\Gamma_t/\mathcal{X}_t^1] \\ &\quad = E[\varphi(X_0^2)] + \int_0^t \tilde{E}[\mathcal{L}_{(X_s^1)}\varphi(X_s^2)\Gamma_s/\mathcal{X}_s^1]ds + \int_0^t \tilde{E}[(\varphi(X_s^2)f_1(X_s^1, X_s^2))\Gamma_s/\mathcal{X}_s^1]dX_s^1. \end{aligned}$$

To give a heuristic explanation about the method we use to construct the approximate filter $\mu_t(\varphi)$ for $E[\varphi(X_t^2)/\mathcal{Y}_t]$, we can say that, when ε is small, by the results [13], [14] explained in the Introduction, we can expect $\tilde{E}[\varphi(X_t^2)\Gamma_t/\mathcal{X}_t^1]$ and an unnormalized version of $E[\varphi(X_t^2)/\mathcal{Y}_t]$ to be close. This leads us to replace X^1 by M in $\tilde{E}[\varphi(X_t^2)\Gamma_t/\mathcal{X}_t^1]$ in order to define the filter. Because of a sort of continuity of $\tilde{E}[\varphi(X_t^2)\Gamma_t/\mathcal{X}_t^1]$ relative to X^1 the process obtained will converge to the unnormalized version of $E[\varphi(X_t^2)/\mathcal{Y}_t]$.

Let us define

$$\breve{X}_t^2 \triangleq X^2(M), \tag{18}$$

$$\breve{\Gamma}_t \triangleq \exp\left(\int_0^t f_1(M_s, \breve{X}_s^2)dM_s - \frac{1}{2}\int_0^t (f_1(M_s, \breve{X}_s^2))^2 ds\right). \tag{19}$$

Applying Itô's formula to $g(M_t, \breve{X}_t^2)$ as in (12), we see from (14) that $\breve{\Gamma}_t = \Gamma_t(M_t)$.

Let φ be a function from $\mathbb{R}$ to $\mathbb{R}$ and

$$\mu_t(\varphi) \triangleq \frac{\tilde{E}[\varphi(\breve{X}_t^2)\breve{\Gamma}_t/\mathcal{M}_t]}{\tilde{E}[\breve{\Gamma}_t/\mathcal{M}_t]}. \tag{20}$$

We will show that $\mu_t(\varphi)$ is an approximate filter for $E[\varphi(X_t^2)/\mathcal{Y}_t]$.

1.4.2. Equation satisfied by the filter μ_t. When φ is twice-differentiable, the process $\mu_t(\varphi)$ satisfies the Kushner–Stratonovitch-type equation, as in the following proposition.

PROPOSITION 1.8. *For $\varphi \in \mathcal{C}_b^2(\mathbb{R})$,*

$$\mu_t(\varphi) = E[X_0^2] + \int_0^t \mu_s(\mathcal{L}_{(M_s)}\varphi)ds + \int_0^t [\mu_s(f_1(M_s,.)\varphi) - \mu_s(f_1(M_s,.))\mu_s(\varphi)][dM_s - \mu_s(f_1(M_s,.))ds], \tag{21}$$

where $\mathcal{L}$ is as defined in (13).

REMARK 1.9. *As mentioned in the Introduction, this equation no longer depends on X^1, although the Kushner–Stratonovitch equation for the exact filter $E[\varphi(X_t^2)/\mathcal{Y}_t]$ is coupled with $E[\varphi(X_t^1)/\mathcal{Y}_t]$.*

Proof. We first derive the associated Zakai-type equation using the two following lemmas.

LEMMA 1.10. *Let $\sigma_t(\varphi) = \tilde{E}[\varphi(\breve{X}_t^2)\breve{\Gamma}_t/\mathcal{M}_t]\ \forall \varphi \in \mathcal{C}_b^2(\mathbb{R})$. Then*

$$\sigma_t(\varphi) = \sigma_0(\varphi) + \int_0^t \sigma_s(\mathcal{L}_{(M_s)}\varphi)ds + \int_O^t \sigma_s(f_1(M_s,.)\varphi)dM_s. \tag{22}$$

REMARK 1.11. *Equation* (22) *is identical to* (17)*, with X^1 replaced by M.*

Proof of Lemma 1.10. As for the proof of the exact Zakai equation (see Pardoux [6, Theorem 2.3.3]), by Itô's formula we have

$$\breve{\Gamma}_t\varphi(\breve{X}_t^2) = \varphi(X_0^2) + \int_0^t \mathcal{L}_{(M_s)}\varphi(\breve{X}_s^2)\breve{\Gamma}_s ds + \int_0^t \breve{\Gamma}_s\varphi'(\breve{X}_s^2)dV_s^2 + \int_0^t \varphi(\breve{X}_s^2)\breve{\Gamma}_s f_1(M_s,\breve{X}_s^2)dM_s.$$

We take the conditional expectation $\tilde{E}[\dots/\mathcal{Y}_t]$ of this equation. We use the result (see, for example, [6, Lemma 2.2.4]) to pass the conditional expectation through the integral. We obtain

—$\tilde{E}[\int_0^t \varphi(\breve{X}_s^2)\breve{\Gamma}_s f_1(M_s,\breve{X}_s^2)dM_s/\mathcal{Y}_t] = \int_0^t \tilde{E}[\varphi(\breve{X}_s^2)\breve{\Gamma}_s f_1(M_S,\breve{X}_s^2)/\mathcal{Y}_t]dM_s$ because of Remark 1.1;

—$\tilde{E}[\int_0^t \varphi'(\breve{X}_s^2)\breve{\Gamma}_s dV_s^2/\mathcal{Y}_t] = 0$, using the independence of V^2 and Y_t under $\tilde{P}$;

—$\tilde{E}[\int_0^t \mathcal{L}_{(M_s)}\varphi\breve{\Gamma}_s ds/\mathcal{Y}_t] = \int_0^t \tilde{E}[\mathcal{L}_{(M_s)}\varphi\breve{\Gamma}_s/\mathcal{Y}_t]ds$.

The proof of Lemma 1.10 will be completed if we can replace $\mathcal{Y}_t$ and $\mathcal{Y}_s$ in the conditional expectations. Unlike the proof of the exact Zakai equation, we do not work here under the probability $\tilde{P}$ which turns Y_t into a Brownian motion. The filtration $\mathcal{Y}_t$ does not satisfy $\mathcal{Y}_t = \mathcal{Y}_s \vee \mathcal{Y}_s^t$, where $\mathcal{Y}_s$ and $\mathcal{Y}_s^t$ are independent ($\mathcal{Y}_s^t = \sigma\{Y_r - Y_s,\ s \le r \le t\}$). However, we have the following lemma.

LEMMA 1.12. *For any map $F : \mathbb{R}^2 \to \mathbb{R}$, we have*

$$\tilde{E}[F(M_s,\breve{X}_s^2)\breve{\Gamma}_s/\mathcal{Y}_t] = \tilde{E}[F(M_s,\breve{X}_s^2)\breve{\Gamma}_s/\mathcal{Y}_s].$$

Proof of Lemma 1.12. $F(M_t,\breve{X}_t^2)\breve{\Gamma}_t$ depends only on $\sigma(X_0^2, V_s^2\ s \le t)$ and $\mathcal{Y}_t$. Using the independence of these two filtrations under $\tilde{P}$, the properties of the conditional expectation allow us to write

$$\tilde{E}[F(M_s,\breve{X}_s^2)\breve{\Gamma}_s/\mathcal{Y}_t] = \tilde{E}[F(x_s, X_s^2(x))\Gamma_s(x)]|_{(x=M)} = \tilde{E}[F(M_s,\breve{X}_s^2)\breve{\Gamma}_s/\mathcal{Y}_s].$$

$\breve{\Gamma}_s = \Gamma_s(M)$ is justified by (14). □

To show Proposition 1.8, we only need to normalize the above process as is done for the exact Kushner–Stratonovitch equation (see [6, Theorem 2.3.7]), and we get (21). □

2. $\mu_t(\varphi) - E[\varphi(X_t^2)/\mathcal{Y}_t]$ as a function of $(X^1 - M)$. We need to show the convergence of $\mu_t(\varphi)$ to $E[\varphi(X_t^2)/\mathcal{Y}_t]$. We first prove that the processes $\mu_t(\varphi) - E[\varphi(X_t^2)/\mathcal{Y}_t]$ and $\tilde{E}[\varphi(X_t^2)\Gamma_t/\mathcal{Y}_t] - \tilde{E}[\varphi(\breve{X}_t^2)\breve{\Gamma}_t/\mathcal{Y}_t]$ have the same rate of convergence.

PROPOSITION 2.1. *Let $T < \infty$. Let us suppose that $\forall t \le T$ and for any function $\varphi \in \mathcal{C}_b^2(\mathbb{R})$, $\exists k$ such that the following assertion holds:*

$$\tilde{E}[\varphi(X_t^2)\Gamma_t/\mathcal{Y}_t] - \tilde{E}[\varphi(\breve{X}_t^2)\breve{\Gamma}_t/\mathcal{Y}_t] = O(\varepsilon^k).$$

Then, $\forall \varphi \in \mathcal{C}^2(\mathbb{R})$, we have

$$\mu_t(\varphi) - E[\varphi(X_t^2)/\mathcal{Y}_t] = O(\varepsilon^k).$$

Proof. We will use the Kallianpur–Striebel formula [6]:

$$\begin{aligned}
&E[|E[\varphi(X_t^2)/\mathcal{Y}_t] - \mu_t(\varphi)|^p] \\
&\quad = E\left[\left|\frac{\tilde{E}[\varphi(X_t^2)\Gamma_t/\mathcal{Y}_t]}{\tilde{E}[\Gamma_t/\mathcal{Y}_t]} - \frac{\tilde{E}[\varphi(\breve{X}_t^2)\breve{\Gamma}_t/\mathcal{Y}_t]}{\tilde{E}[\breve{\Gamma}_t/\mathcal{Y}_t]}\right|^p\right] \\
&\quad \le KE\left[\left|\frac{\tilde{E}[\varphi(X_t^2)\Gamma_t/\mathcal{Y}_t] - \tilde{E}[\varphi(\breve{X}_t^2)\breve{\Gamma}_t/\mathcal{Y}_t]}{\tilde{E}[\Gamma_t/\mathcal{Y}_t]}\right|^p\right] \\
&\qquad + KE\left[\left|\frac{\tilde{E}[\varphi(\breve{X}_t^2)\breve{\Gamma}_t/\mathcal{Y}_t]}{\tilde{E}[\breve{\Gamma}_t/\mathcal{Y}_t]}\frac{1}{\tilde{E}[\Gamma_t/\mathcal{Y}_t]}(\tilde{E}[\Gamma_t/\mathcal{Y}_t] - \tilde{E}[\breve{\Gamma}_t/\mathcal{Y}_t])\right|^p\right]. \qquad (23)
\end{aligned}$$

The first term of this expression is bounded by the Cauchy–Schwarz inequality:

$$\begin{aligned}
&E\left[\left|\frac{\tilde{E}[\varphi(X_t^2)\Gamma_t/\mathcal{Y}_t] - \tilde{E}[\varphi(\breve{X}_t^2)\breve{\Gamma}_t/\mathcal{Y}_t]}{\tilde{E}[\Gamma_t/\mathcal{Y}_t]}\right|^p\right] \\
&\quad \le \sqrt{E\left[\left(\frac{1}{\tilde{E}[\Gamma_t/\mathcal{Y}_t]}\right)^{2p}\right]}\sqrt{E[(\tilde{E}[\varphi(X_t^2)\Gamma_t/\mathcal{Y}_t] - \tilde{E}[\varphi(\breve{X}_t^2)\breve{\Gamma}_t/\mathcal{Y}_t])^{2p}]} \\
&\quad = O(\varepsilon^{kp}).
\end{aligned}$$

Indeed, the last equality is true because of the Jensen inequality applied to the convex function $x \to (\frac{1}{x})^{1-2p}$ on $\mathbb{R}^+$. We get

$$\begin{aligned}
E\left[\left(\frac{1}{\tilde{E}[\Gamma_t/\mathcal{Y}_t]}\right)^{2p}\right] &= \tilde{E}\left[\Gamma_t(\tilde{E}[\Gamma_t/\mathcal{Y}_t])^{-2p}\right] \\
&= \tilde{E}[(\tilde{E}[\Gamma_t/\mathcal{Y}_t])^{1-2p}] \\
&\le \tilde{E}[(\Gamma_t)^{1-2p}] \\
&= E[(\Gamma_t)^{-2p}],
\end{aligned}$$

and the last expression does not depend on ε.

Remarking that

$$\frac{\tilde{E}[\varphi(\breve{X}_t^2)\breve{\Gamma}_t/\mathcal{Y}_t]}{\tilde{E}[\breve{\Gamma}_t/\mathcal{Y}_t]} \leq \|\varphi\|_\infty,$$

we obtain in the same way the order of the second term of (23). The proof is now complete. □

In order to compute the rate of convergence of $\mu_t(\varphi)$ to $E[\varphi(X_t^2)/\mathcal{Y}_t]$, we will express $\tilde{E}[\varphi(X_t^2)\Gamma_t/\mathcal{Y}_t]-\tilde{E}[\varphi(\breve{X}_t^2)\breve{\Gamma}_t/\mathcal{Y}_t]$ as a function of (X^1-M). To give the general idea of the proof without using computations that are too big, let us first establish this expression for the process $\tilde{E}[X_t^2 - \breve{X}_t^2/\mathcal{Y}_t]$ (in this case the computations are easier). We will later give an expression for $\tilde{E}[\Gamma_t-\breve{\Gamma}_t/\mathcal{Y}_t]$, and finally for $\tilde{E}[\varphi(X_t^2)\Gamma_t-\varphi(\breve{X}_t^2)\breve{\Gamma}_t/\mathcal{Y}_t]$.

2.1. Order of $\tilde{E}[X_t^2 - \breve{X}_t^2/\mathcal{Y}_t]$.

LEMMA 2.2. *Let $T>0$. Then, $\forall 0 \leq t \leq T$, we have the estimation*

$$X_t^2 - \breve{X}_t^2 = O(\sqrt{\varepsilon}).$$

Proof. We use assumption H.4, Gronwall's lemma, and Lemma 1.3. □

This first estimation shows that $\breve{X}_t^2$ converges to X_t^2 when ε converges to 0. But we will see that if we condition by $\mathcal{Y}_t$, the rate of convergence will be better.

Let us define the following directional derivative by

$$Z_t^2(x,y) = \lim_{\lambda\to 0} \frac{X_t^2(x+\lambda y) - X_t^2(x)}{\lambda}. \tag{24}$$

We have an exact formula for $Z_t^2(x,y)$, given in Lemma 2.3.

LEMMA 2.3.

$$Z_t^2(x,y) = \int_0^t \exp\left(\int_s^t \frac{\partial f_2}{\partial x_2}(x_u, X_u^2(x))du\right) \frac{\partial f_2}{\partial x_1}(x_s, X_s^2(x))y_s ds. \tag{25}$$

Proof. As there is no λ in the stochastic integral, the computations are easy:

$$\begin{aligned} Z_t^2(x,y) &= \lim_{\lambda\to 0} \int_0^t \frac{f_2(x_s+\lambda y_s, X_s^2(x+\lambda y)) - f_2(x_s, X_s^2(x))}{\lambda} ds \\ &= \int_0^t \frac{\partial f_2}{\partial x_1}(x_s, X_s^2(x))y_s + \frac{\partial f_2}{\partial x_2}(x_s, X_s^2(x)) Z_s^2(x,y) ds. \end{aligned}$$

We have

$$\frac{d}{dt} Z_t^2(x,y) = \frac{\partial f_2}{\partial x_1}(x_t, X_t^2(x))y_t + \frac{\partial f_2}{\partial x_2}(x_t, X_t^2(x)) Z_t^2(x,y),$$

and the result follows. □

Using Lemma 1.3 and the exact formula for Z_t^2, we can deduce the following corollary.

COROLLARY 2.4. *Let $T>0$. Then, $\forall t \leq T$ and $\lambda \in [0,1]$, we have*

$$Z_t^2(M + \lambda(X^1 - M), X^1 - M) = O(\sqrt{\varepsilon}).$$

To make the computations simpler, let us note that

$$L_{(s,t)}(x) = \exp\left(\int_s^t \frac{\partial f_2}{\partial x_2}(x_u, X_u^2(x))du\right). \tag{26}$$

For $x,\ y \in \mathcal{C}([0,T],\ \mathbb{R})$ and $\lambda \in [0,1]$, let us note that $\rho_t(\lambda) = X_t^2(y + \lambda(x-y))$; the difference $X_t^2(x) - X_t^2(y)$ can be written as

$$\begin{aligned} X_t^2(x) - X_t^2(y) &= X_t^2(y + (x-y)) - X_t^2(y) \\ &= \rho_t(1) - \rho_t(0) \\ &= \int_0^1 \rho_t'(\lambda)d\lambda \\ &= \int_0^1 Z_t^2(y + \lambda(x-y), (x-y))d\lambda \end{aligned}$$

because $\rho_t'(\lambda) = Z_t^2(y + \lambda(x-y), x-y)$.

LEMMA 2.5. *Let $x,\ y \in \mathcal{C}([0,T],\ \mathbb{R})$. We have*

$$|Z_t^2(x + \lambda y, y) - Z_t^2(x,y)| \le c(T)\left(\int_0^t (y_s)^2 ds + \left(\int_0^t |y_s|ds\right)^2\right).$$

Proof. Let $x,\ y$ be two functions of $\mathcal{C}([0,T],\ \mathbb{R})$ and let us denote $\gamma_t(l) \triangleq Z_t^2(x + ly, y)$. Rolle's theorem (or the Taylor–Lagrange theorem) gives

$$Z_t^2(x + \lambda y, y) - Z_t^2(x,y) = \gamma_t(\lambda) - \gamma_t(0) = \lambda\, \gamma_t'(l)$$

with $l \in [0, \lambda]$. We have

$$\begin{aligned} |\gamma_t'(l)| = \Bigg| &\int_0^t \left(\int_s^t \left[\frac{\partial^2 f_2}{\partial x_1 \partial x_2}(x_u + ly_u, X_u^2(x+ly))y_u + \frac{\partial^2 f_2}{\partial^2 x_2}(\ldots)Z_u^2(x+ly, y)\right]du\right) \\ &\times L_{(s,t)}(x+ly)\frac{\partial f_2}{\partial x_1}(x_s + ly_s, X_s^2(x+ly))y_s ds \\ &+ \int_0^t L_{(s,t)}(x+ly)\left(\frac{\partial^2 f_2}{\partial x_1^2}(\ldots)y_s + \frac{\partial^2 f_2}{\partial x_1 \partial x_2}(\ldots)Z_s^2(x+ly, y)\right)y_s ds\Bigg| \\ \le c(T)&\left(\int_0^t (y_s)^2 ds + \left(\int_0^t |y_s|ds\right)^2\right). \qquad \square \end{aligned} \tag{27}$$

Lemmas 1.3 and 2.5 imply the following result.

LEMMA 2.6. *Let $T > 0$. Then, $\forall t \le T$, we have*

$$Z_t^2(M + \lambda(X^1 - M), X^1 - M) = Z_t^2(M, X^1 - M) + O(\varepsilon).$$

PROPOSITION 2.7. *Let $T > 0$. $\forall t \le T$,*

$$\begin{aligned} &\tilde{E}[X_t^2 - \breve{X}_t^2/\mathcal{Y}_t] \\ &\quad = \tilde{E}\left[\int_0^t L_{(s,t)}(M)\frac{\partial f_2}{\partial x_1}(M_s, X_s^2(M))(X_s^1 - M_s)ds/\mathcal{Y}_t\right] + O(\varepsilon). \end{aligned} \tag{28}$$

Proof.

$$\begin{aligned}
&\tilde{E}[X_t^2 - \breve{X}_t^2/\mathcal{Y}_t] \\
&\quad = \tilde{E}\left[\int_0^1 Z_t^2(M + \lambda(X^1 - M), X^1 - M)d\lambda/\mathcal{Y}_t\right] \\
&\quad = \tilde{E}[Z_t^2(M, X^1 - M)/\mathcal{Y}_t] + O(\varepsilon) \\
&\quad = \tilde{E}\left[\int_0^t L_{(s,t)}(M)\frac{\partial f_2}{\partial x_1}(M_s, X_s^2(M))(X_s^1 - M_s)ds/\mathcal{Y}_t\right] + O(\varepsilon).
\end{aligned}$$

Using Lemma 1.3, we see that $\tilde{E}[X_t^2 - \breve{X}_t^2/\mathcal{Y}_t]$ is of order $\sqrt{\varepsilon}$. We will later improve this estimation and see that the rate of convergence is of order ε. □

2.2. Order of $\tilde{E}[\Gamma_t - \breve{\Gamma}_t/\mathcal{Y}_t]$. As seen above, $\Gamma_t - \breve{\Gamma}_t = \Gamma_t(X^1) - \breve{\Gamma}_t(M)$. $\Gamma_t(x)$ depends on x directly and via X_t^2 (see (14)). One can, however, write

$$\begin{aligned}
\Gamma_t(x) - \Gamma_t(y) &= \Gamma_t(y + (x - y)) - \Gamma_t(y) \\
&= \sigma_t(1) - \sigma_t(0) \\
&= \int_0^1 \sigma_t'(\lambda)d\lambda \qquad (29)
\end{aligned}$$

with

$$\sigma_t(\lambda) = \Gamma_t(y + \lambda(x - y)). \qquad (30)$$

We need to differentiate $\Gamma_t(y + \lambda(x - y))$ with respect to λ. We have already noticed the differentiability of X_t^2. The problem will come from the stochastic integral, but using the Kunita method we can show the following result.

PROPOSITION 2.8. *For $\lambda \in]-1, 1[$, the derivative of the stochastic integral*

$$\int_0^t \frac{\partial g}{\partial x_2}(x_s^1 + \lambda y_s, X_s^2(x + \lambda y))dV_s^2$$

with respect to λ exists and is given by

$$\frac{\partial}{\partial\lambda}\left(\int_0^t \frac{\partial g}{\partial x_2}(x_s^1 + \lambda y_s, X_s^2(x + \lambda y))dV_s^2\right) = \int_0^t \frac{\partial}{\partial\lambda}\left(\frac{\partial g}{\partial x_2}(x_s^1 + \lambda y_s, X_s^2(x + \lambda y))\right)dV_s^2.$$

This result is proposed in an exercise in Kunita ([3, exercise 3.1.5]) and is proved in our specific case in Gégout-Petit [2, Part I, Appendix]. We don't give the proof here.

Then

$$\sigma_t'(\lambda) = \Gamma_t(y + \lambda(x - y))\frac{\partial}{\partial\lambda}\log(\Gamma_t(y + \lambda(x - y))). \qquad (31)$$

Write

$$\begin{aligned}
\psi^1(x, y) &= -\left(\frac{1}{2}\frac{\partial^2 f_1}{\partial x_2^2} + \frac{\partial f_1}{\partial x_2}f_2 + \frac{\partial g}{\partial x_2}\frac{\partial f_2}{\partial x_1} + \frac{1}{2}\frac{\partial^2 f_1}{\partial x_1^2} + \frac{\partial f_1}{\partial x_1}f_1\right)(x, y), \\
\psi^2(x, y) &= -\left(\frac{1}{2}\frac{\partial^3 g}{\partial x_2^3} + \frac{\partial^2 g}{\partial x_2^2}f_2 + \frac{\partial g}{\partial x_2}\frac{\partial f_2}{\partial x_2} + \frac{1}{2}\frac{\partial^2 f_1}{\partial x_1\partial x_2} + \frac{\partial f_1}{\partial x_2}f_1\right)(x, y).
\end{aligned}$$

We obtain

$$\begin{aligned}
&\frac{\partial}{\partial\lambda}\Big(\log(\Gamma_t(y+\lambda(x-y)))\Big)\\
&\quad=-f_1(y_0+\lambda(x_0-y_0),X_0^2)(x_0-y_0)\\
&\qquad+f_1(y_t+\lambda(x_t-y_t),X_t^2(y+\lambda(x-y)))(x_t-y_t)\\
&\qquad+\frac{\partial g}{\partial x_2}(y_t+\lambda(x_t-y_t),X_t^2(y+\lambda(x-y)))\\
&\qquad\times Z_t^2(y+\lambda(x-y),x-y)\\
&\qquad+\int_0^t\psi_1(y_s+\lambda(x_s-y_s),X_s^2(y+\lambda(x-y)))(x_s-y_s)ds\\
&\qquad+\int_0^t\psi_2(y_s+\lambda(y_s-y_s),X_s^2(y+\lambda(x-y)))\\
&\qquad\times Z_s^2(y+\lambda(x-y),x-y)ds\\
&\qquad+\int_0^t\frac{\partial f_1}{\partial x_2}(y_s+\lambda(x_s-y_s),X_s^2(y+\lambda(x-y)))(x_s-y_s)dV_s^2\\
&\qquad-\int_0^t\frac{\partial^2 g}{\partial x_2^2}(y_s+\lambda(x_s-y_s),X_s^2(y+\lambda(x-y)))\\
&\qquad\times Z_s^2(y+\lambda(x-y),x-y)dV_s^2.
\end{aligned}$$

LEMMA 2.9. *Let us note that*

(32)

$$\begin{aligned}
&\Psi^{1,t,\lambda}(y,x-y)\\
&\quad=(f_1(y_t+\lambda(x_t-y_t),X_t^2(y+\lambda(x-y)))-f_1(y_t,X_t^2(y)))(x_t-y_t)\\
&\qquad+\frac{\partial g}{\partial x_2}(y_t+\lambda(x_t-y_t),X_t^2(y+\lambda(x-y)))Z_t^2(y+\lambda(x-y),x-y)\\
&\qquad-\frac{\partial g}{\partial x_2}(y_t,X_t^2(y))Z_t^2(y,x-y)\\
&\qquad+\int_0^t(\psi_1(y_s+\lambda(x_s-y_s),X_s^2(y+\lambda(x-y)))-\psi_1(y_s,X_s^2(y)))(x_s-y_s)ds\\
&\qquad+\int_0^t\psi_2(y_s+\lambda(x_s-y_s),X_s^2(y+\lambda(x-y)))Z_s^2(y+\lambda(x-y),x-y)\\
&\qquad-\psi_2(y_s,X_s^2(y))Z_s^2(y,x-y)ds\\
&\qquad+\int_0^t\left(\frac{\partial f_1}{\partial x_2}(y_s+\lambda(x_s-y_s),X_s^2(y+\lambda(x-y)))-\frac{\partial f_1}{\partial x_2}(y_s,X_s^2(y))\right)\\
&\qquad\times(x_s-y_s)dV_s^2\\
&\qquad-\int_0^t\left(\frac{\partial^2 g}{\partial x_2^2}(y_s+\lambda(x_s-y_s),X_s^2(y+\lambda(x-y)))Z_s^2(y+\lambda(x-y),x-y)\right.\\
&\qquad\qquad\left.-\frac{\partial^2 g}{\partial x_2^2}(y_s,X_s^2(y))Z_s^2(y,x-y)\right)dV_s^2.
\end{aligned}$$

For $\lambda \in [0,1]$ the following equality holds:

$$\begin{aligned}
&\frac{\partial}{\partial\lambda}\Big(\log(\Gamma_t(y+\lambda(x-y)))\Big)\\
&\quad= f_1(y_0+\lambda(x_0-y_0),X_0^2)(x_0-y_0)\\
&\qquad+ f_1(y_t,X_t^2(y))(x_t-y_t)+\frac{\partial g}{\partial x_2}(y_t,X_t^2(y))Z_t^2(y,x-y)\\
&\qquad+\int_0^t \psi_1(y_s,X_s^2(y))(x_s-y_s)ds+\int_0^t \psi_2(y_s,X_s^2(y))Z_s^2(y,x-y)ds\\
&\qquad+\int_0^t \frac{\partial f_1}{\partial x_2}(y_s,X_s^2(y))(x_s-y_s)dV_s^2\\
&\qquad-\int_0^t \frac{\partial^2 g}{\partial x_2^2}(y_s,X_s^2(y))Z_s^2(y,x-y)dV_s^2\\
&\qquad+\Psi^{1,t,\lambda}(y,x-y).
\end{aligned}$$

Thanks to Rolle's theorem, there exists

$$\Theta_y^{\lambda(x-y)} \in [\log(\Gamma_t(y+\lambda(x-y))),\log(\Gamma_t(y))] \tag{33}$$

such that

$$\Gamma_t(y+\lambda(x-y)) = \Gamma_t(y)+\exp(\Theta_y^{\lambda(x-y)})[\log(\Gamma_t(y+\lambda(x-y)))-\log(\Gamma_t(y))]. \tag{34}$$

REMARK 2.10. *Thanks to* (33) *and Lemma* 1.5 *we can claim that for a fixed $T>0$, $\forall p\in\mathbb{R}$, there exists $c(p)$ such that $\forall t\le T$ and $\forall x\in\mathcal{C}([0,T])$,*

$$E[(\exp(\Theta_y^{\lambda(x-y)}))^p] \le c(p). \tag{35}$$

We now use (29), (31), Lemma 2.9, and (34) in the case $x=X^1$ and $y=M$ to write $\Gamma_t-\breve{\Gamma}_t$ in the following way:

(36)

$$\begin{aligned}
&\Gamma_t-\breve{\Gamma}_t\\
&\quad=\Gamma_t(M+(X^1-M))-\Gamma_t(M)\\
&\quad=\int_0^1 \Gamma_t(M+\lambda(X^1-M))\frac{\partial}{\partial\lambda}\log(\Gamma_t(M+\lambda(X^1-M)))d\lambda\\
&\quad=-\Gamma_t(M+\lambda(X^1-M))f_1(M_0\lambda+(X_0^1-M_0),X_0^2)(X_0^1-M_0)\\
&\qquad+\Gamma_t(M)f_1(M_t,X_t^2(M))(X_t^1-M_t)\\
&\qquad+\Gamma_t(M)\frac{\partial g}{\partial x_2}(M_t,X_t^2(M))Z_t^2(M,(X^1-M))\\
&\qquad+\Gamma_t(M)\int_0^t \psi_1(M_s,X_s^2(M))(X_s^1-M_s)+\psi_2(M_s,X_s^2(M))Z_s^2(M,X^1-M)ds\\
&\qquad+\int_0^1 [\exp(\Theta_M^{\lambda(X^1-M)})[\log(\Gamma_t(M+\lambda(X^1-M)))-\log(\Gamma_t(M))]]\\
&\qquad\times\Big[f_1(M_t,X_t^2(M))(X_t^1-M_t)+\frac{\partial g}{\partial x_2}(M_t,X_t^2(M))Z_t^2(M,X^1-M)
\end{aligned}$$

$$
\begin{aligned}
&+ \int_0^t \psi_1(M_s, X_s^2(M))(X_s^1 - M_s) + \psi_2(M_s, X_s^2(M)) Z_s^2(M, X^1 - M) ds \\
&+ \int_0^t \left[\frac{\partial f_1}{\partial x_2}(M_s, X_s^2(M))(X_s^1 - M_s) \right. \\
&\qquad \left. - \frac{\partial^2 g}{\partial x_2^2}(M_s, X_s^2(M)) Z_s^2(M, X^1 - M) \right] dV_s^2 \Bigg] d\lambda \\
&+ \Gamma_t(M) \times \int_0^t \left[\frac{\partial f_1}{\partial x_2}(M_s, X_s^2(M))(X_s^1 - M_s) \right. \\
&\qquad \left. - \frac{\partial^2 g}{\partial x_2^2}(M_s, X_s^2(M)) Z_s^2(M, X^1 - M) \right] dV_s^2 \\
&+ \int_0^1 \Gamma_t(M + \lambda(X^1 - M)) \Psi_t^{1,t,\lambda}(X^1, X^1 - M) d\lambda.
\end{aligned}
$$

We now take the $\mathcal{Y}_t$-conditional expectation of this formula and then propose to show that all the terms of $\tilde{E}[\Gamma_t - \breve{\Gamma}_t / \mathcal{Y}_t]$ are small because $(X_t^1 - M_t)$ is small with ε (Lemma 1.3). Without assumption H.2 and equation (8), the first term need not be small. We group the terms of order ε, using the following estimations.

LEMMA 2.11. *Fix $T < \infty$. $\forall t < T$, $\forall \lambda \in [0,1]$, we have*

$$
\kappa_t^\lambda \triangleq \log(\Gamma_t(M + \lambda(X^1 - M))) - \log(\Gamma_t(M)) = O(\sqrt{\varepsilon}) \tag{37}
$$

and

$$
\Psi_t^{1,t,\lambda}(X^1, X^1 - M) = O(\varepsilon). \tag{38}
$$

Sketch of the proof. We use the following results:

—$X^1 - M = O(\sqrt{\varepsilon})$ (Lemma 1.3);

—$Z_t^2(M + \lambda(X^1 - M), X^1 - M) = O(\sqrt{\varepsilon})$ (Corollary 2.4);

—For all F from $\mathbb{R}^2$ into $\mathbb{R}$, bounded with bounded derivatives, $F(X_t^1, X_t^2) - F(M_t, \breve{X}_t^2) = O(\sqrt{\varepsilon})$.

All the terms of $\Psi_t^{1,t,\lambda}(X^1, X^1 - M)$ (see (32)) are products of two terms of order $\sqrt{\varepsilon}$, and by Lemma 2.6, $Z_t^2(M + \lambda(X^1 - M), X^1 - M) - Z_t^2(M, X^1 - M) = O(\varepsilon)$. □

Some terms of (36) are clearly of order ε. Indeed, if we use Jensen's and Cauchy–Schwarz's inequalities, we get

$$
\begin{aligned}
&\tilde{E}[|\tilde{E}[\exp(\Theta_M^{\lambda(X^1 - M)})(\log(\Gamma_t(M + \lambda(X^1 - M))) - \log(\Gamma_t(M))) \\
&\qquad \times f_1(M_t, X_t^2(M))(X_t^1 - M_t)/\mathcal{Y}_t]|^p] \\
&\quad = \tilde{E}[|\tilde{E}[\exp(\Theta_M^{\lambda(X^1 - M)}) \kappa_t^\lambda f_1(M_t, X_t^2(M))(X_t^1 - M_t)/\mathcal{Y}_t]|^p] \\
&\quad \le (\tilde{E}[(\exp(\Theta_M^{\lambda(X^1 - M)}) \kappa_t^\lambda f_1(M_t, X_t^2(M)))^{2p}])^{\frac{1}{2}} (\tilde{E}[(X_t^1 - M_t)^{2p}])^{\frac{1}{2}}.
\end{aligned}
$$

Also, using Lemma 2.11 and Remark 2.10, we get

$$
\int_0^1 \tilde{E}[\exp(\Theta_M^{\lambda(X^1 - M)}) \kappa_t^\lambda f_1(M_t, X_t^2(M))(X_t^1 - M_t)/\mathcal{Y}_t] d\lambda = O(\varepsilon).
$$

By the same method we get

$$\begin{aligned}\int_0^1 \tilde{E}\Big[&\exp(\Theta_M^{\lambda(X^1-M)})\kappa_t^\lambda \times \Big(\frac{\partial g}{\partial x_2}(M_t, X_t^2(M))Z_t^2(M, X^1-M)\\ &+ \int_0^t \psi_1(M_s, X_s^2(M))(X_s^1 - M_s) + \psi_2(M_s, X_s^2(M))Z_s^2(M, X^1-M)ds\\ &+ \int_0^t \frac{\partial f_1}{\partial x_2}(M_s, X_s^2(M))(X_s^1 - M_s)\\ &- \frac{\partial^2 g}{\partial x_2^2}(M_s, X_s^2(M))Z_s^2(M, X^1-M)dV_s^2\Big)/\mathcal{Y}_t\Big]d\lambda\\ &= O(\varepsilon)\end{aligned}$$

and

$$\tilde{E}\left[\int_0^1 \Gamma_t(M + \lambda(X^1 - M))\Psi_t^{1,t,\lambda}(X^1, X^1 - M)d\lambda/\mathcal{Y}_t\right] = O(\varepsilon).$$

PROPOSITION 2.12. *For a fixed $T > 0$ and $\forall t \le T$ we have*

$$\begin{aligned}&\tilde{E}[\Gamma_t - \breve{\Gamma}_t/\mathcal{Y}_t]\\ &\quad= \tilde{E}[\Gamma_t(M)f_1(M_t, X_t^2(M))(X_t^1 - M_t)|\mathcal{Y}_t]\\ &\quad+ \tilde{E}\left[\Gamma_t(M)\int_0^t \psi_1(M_s, X_s^2(M))(X_s^1 - M_s)ds/\mathcal{Y}_t\right]\\ &\quad+ \tilde{E}\left[\Gamma_t(M)\int_0^t \psi_2(M_s, X_s^2(M))\int_0^s L_{(u,t)}(M)\frac{\partial f_2}{\partial x_1}(M_u, X_u^2(M))(X_u^1 - M_u)duds/\mathcal{Y}_t\right]\\ &\quad+ \tilde{E}\left[\Gamma_t(M)\frac{\partial g}{\partial x_2}(M_t, X_t^2(M))\int_0^t L_{(s,t)}(M)\frac{\partial f_2}{\partial x_1}(M_s, X_s^2(M))(X_s^1 - M_s)ds/\mathcal{Y}_t\right]\\ &\quad+ \tilde{E}\Big[\Gamma_t(M)\int_0^t \frac{\partial f_1}{\partial x_2}(M_s, X_s^2(M))(X_s^1 - M_s)\\ &\qquad- \frac{\partial^2 g}{\partial x_2^2}(M_s, X_s^2(M))Z_s^2(M, X^1 - M)dV_s^2/\mathcal{Y}_t\Big]\\ &\quad+ O(\varepsilon).\end{aligned}$$

COROLLARY 2.13.

$$\tilde{E}[\Gamma_t - \breve{\Gamma}_t/\mathcal{Y}_t] = O(\sqrt{\varepsilon}).$$

2.3. Order of $\tilde{E}[\varphi(X_t^2)\Gamma_t - \varphi(\breve{X}_t^2)\breve{\Gamma}_t/\mathcal{Y}_t]$.

PROPOSITION 2.14. *Let $\varphi \in \mathcal{C}_b^2(\mathbb{R})$. For a fixed $T > 0$ and $\forall t \le T$, we have the following expression for the difference between the two filters:*

$$\begin{aligned}&\tilde{E}[\varphi(X_t^2)\Gamma_t - \varphi(\breve{X}_t^2)\breve{\Gamma}_t/\mathcal{Y}_t]\\ &\quad= \tilde{E}[\varphi(X_t^2(M))\Gamma_t(M)f_1(M_t, X_t^2(M))(X_t^1 - M_t)/\mathcal{Y}_t] \qquad (39)\\ &\quad+ \tilde{E}\left[\varphi(X_t^2(M))\Gamma_t(M)\int_0^t \psi_1(M_s, X_s^2(M))(X_s^1 - M_s)ds/\mathcal{Y}_t\right] \qquad (40)\end{aligned}$$

$$+\tilde{E}\left[\varphi(X_t^2(M))\Gamma_t(M)\int_0^t \psi_2(M_s,X_s^2(M))\right.$$

$$\left.\times\int_0^s L_{(u,s)}(M)\frac{\partial f_2}{\partial x_1}(M_u,X_u^2(M))(X_u^1-M_u)duds/\mathcal{Y}_t\right] \tag{41}$$

$$+\tilde{E}\left[\Gamma_t(M)\left(\varphi(X_t^2(M))\frac{\partial g}{\partial x_2}(M_t,X_t^2(M))+\varphi'(X_t^2(M))\right)\right.$$

$$\left.\times\int_0^t L_{(s,t)}(M)\frac{\partial f_2}{\partial x_1}(M_s,X_s^2(M))(X_s^1-M_s)ds/\mathcal{Y}_t\right] \tag{42}$$

$$+\tilde{E}\left[\Gamma_t(M)\varphi(X_t^2(M))\int_0^t\left[\frac{\partial f_1}{\partial x_2}(M_s,X_s^2(M))(X_s^1-M_s)\right.\right.$$

$$\left.\left.-\frac{\partial^2 g}{\partial x_2^2}(M_s,X_s^2(M))Z_s^2(M,X^1-M)\right]dV_s^2\right] \tag{43}$$

$$+O(\varepsilon).$$

Proof. By the method used in the previous section, we write

$$\Gamma_t(x)\varphi(X_t^2(x))-\Gamma_t(y)\varphi(X_t^2(y))=\nu_t(1)-\nu_t(0)$$
$$=\int_0^1\nu_t'(\lambda)d\lambda$$

with

$$\nu_t(\lambda)=\Gamma_t(y+\lambda(x-y))\varphi(X_t^2(y+\lambda(x-y))), \tag{44}$$

with σ defined by (30):

$$\nu_t'(\lambda)=\Gamma_t(y+\lambda(x-y))\varphi'(X_t^2(y+\lambda(x-y)))Z_t^2(y+\lambda(x-y),x-y)$$
$$+\sigma_t'(\ldots)\varphi(X_t^2(\ldots)).$$

If we proceed as in the previous sections, we get the required result. □

All the terms of the difference in Proposition 2.14 are clearly of order $\sqrt{\varepsilon}$. In order to give a finer estimation of the rate of convergence we now recall other results about filtering.

3. Rate of convergence of $\mu_t(\varphi)$ to $E[\varphi(X_t^2)/\mathcal{Y}_t]$.

3.1. M_t, approximate filter of order ε. If we study our system under the probability $\tilde{P}$, we have

$$\begin{cases}X_t^1,\\ Y_t=\displaystyle\int_0^t h(X_s^1)ds+\varepsilon W_t,\end{cases} \tag{45}$$

where X_t^1 is a Wiener process independent of W. The drift is therefore "erased" and X^1 no longer depends on X^2. So, h being one to one in X^1, we can apply Picard's results [9, Main Theorem of section 2] and we have the following proposition.

PROPOSITION 3.1. *In the sense of Definition* 1.2 *we have*

$$\tilde{E}[X_t^1/\mathcal{Y}_t]-M_t^1=O(\varepsilon). \tag{46}$$

REMARK 3.2. *The proof of this result is more difficult than the case* $\sqrt{\varepsilon}$. *As seen in the proof of Lemma* 1.3, *to show* $\sqrt{\varepsilon}$ *order we first show that* $(X^1 - M) = O(\sqrt{\varepsilon})$ *and, by contraction, the same estimation for* $\tilde{E}[X_t^1/\mathcal{Y}_t] - M_t^1$ *follows. By computing the conditional variance of* X^1 *(in the linear detectable case, the computations are explicit; for the nonlinear case, see Picard* [7]*), we notice that the order of convergence for* $X^1 - M$ *is exactly* $\sqrt{\varepsilon}$. *The conditional expectation improves the convergence, but makes the majoration more difficult. The method used in* [9] *uses techniques of differentiation on a Wiener space.*

As seen in Definition 1.2, the convergence is not good when t is near 0. Even in the case when X_0^1 is deterministic and $X_0^1 = M_0$, this problem remains. But as Picard remarked it [9] (see the discussion after the main theorem of section 2), the proof of his main theorem applied to the case $X_0^1 = M_0$ gives estimates of $\tilde{E}[X_t^1/\mathcal{Y}_t] - M_t$ for small t. Indeed, we have the following result.

PROPOSITION 3.3. *In the case when* $X_0^1 = M_0$ $\forall q \geq 1$, $\exists C > 0$ *such that*

$$\sup_{0\leq t\leq\sqrt{\varepsilon}} \|\tilde{E}[X_t^1/\mathcal{Y}_t] - M_t\|_q \leq C\sqrt{\varepsilon}, \qquad \sup_{\sqrt{\varepsilon}\leq t<\infty} \|\tilde{E}[X_t^1/\mathcal{Y}_t] - M_t\|_q \leq C\varepsilon. \tag{47}$$

3.2. Order of convergence of filter. We can now estimate all the terms obtained for $\tilde{E}[\varphi(X_t^2)\Gamma_t - \varphi(\check{X}_t^2)\check{\Gamma}_t/\mathcal{Y}_t]$ in Proposition 2.14. We will deal separately with (i) term (39), which is a special case, (ii) the Lebesgue integrals (40), (41), and (42), and (iii) the stochastic integrals (43).

We will use the results of the previous section. An important property used in the proofs below is the fact that $\mathcal{V}^2$ and $\mathcal{X}^1 \vee \mathcal{Y}$ are independent under $\tilde{P}$.

Estimation of term (39).

PROPOSITION 3.4. *In the sense of Definition* 1.2 *we have*

$$\tilde{E}[\varphi(X_t^2(M))\Gamma_t(M)f_1(M_t, X_t^2(M))(X_t^1 - M_t)/\mathcal{Y}_t] = O(\varepsilon).$$

Proof.

$$\begin{aligned}
&\tilde{E}[\varphi(X_t^2(M))\Gamma_t(M)f_1(M_t, X_t^2(M))(X_t^1 - M_t)/\mathcal{Y}_t] \\
&\quad = \tilde{E}[\tilde{E}[\varphi(X_t^2(M))\Gamma_t(M)f_1(M_t, X_t^2(M))/\mathcal{X}_t^1 \vee \mathcal{Y}_t](X_t^1 - M_t)/\mathcal{Y}_t] \\
&\quad = \Phi_t^1(M)\tilde{E}[(X_t^1 - M_t)|\mathcal{Y}_t].
\end{aligned}$$

The fact that $\mathcal{V}_t^2$ and $\mathcal{X}_t^1 \vee \mathcal{Y}_t$ are independent allows us to write

$$\tilde{E}[\varphi(X_t^2(M))\Gamma_t(M)f_1(M_t, X_t^2(M))/\mathcal{X}_t^1 \vee \mathcal{Y}_t] = \Phi_t^1(M), \tag{48}$$

$$\Phi_t^1(M) = \tilde{E}[\Gamma_t(x)f_1(x, X_t^2(x))]|_{x=M}. \tag{49}$$

Using Lemma 1.5 and the Cauchy–Schwarz inequality we get, $\forall x \in \mathcal{C}([0,t],\ \mathbb{R})$, $\forall p \geq 1$,

$$\begin{aligned}
\tilde{E}[|\Gamma_t(M)f_1(M, X_t^2(M))|^p] &\leq \sqrt{\tilde{E}[f_1^{2p}(M, X_t^2(M))]}\sqrt{\tilde{E}[(\Gamma_t(M))^{2p}]} \\
&\leq c'(p).
\end{aligned} \tag{50}$$

(50) and (47) allow us to conclude the proof. □

REMARK 3.5. *The law of* V^2 *being the same under* P *and under* $\tilde{P}$, *we can also take the expectation under* P *in* (49).

3.2.1. Estimation of the Lebesgue integrals.

Estimation of terms (40), (42). These two terms are a priori not the same because of the non-$\mathcal{F}_s$-measurability of $L_{(s,t)}(x)$ in (42). Using (26) we can note, however, that

$$L_{(s,t)}(x) = \exp\left(\int_s^t \frac{\partial f_2}{\partial x_2}(x_u, X_u^2(x))du\right) = L_{(0,t)}(x)(L_{(0,s)}(x))^{-1}.$$

The two terms can then be represented by

$$\tilde{E}[\Phi_t(M_\cdot, X_\cdot^2(M)) \int_0^t \Psi(M_s, X_s^2(M))(X_s^1 - M_s)ds/\mathcal{Y}_t],$$

where Φ_t looks like $\Gamma_t(M)$. In other words, Φ_t is a function of the paths of M and $X^2(M)$ from 0 to t, bounded either in L^∞ or in all L^p with $1 \le p < \infty$. The function Ψ is $\mathcal{F}_s$-measurable and bounded.

Let us first study the convergence of $\tilde{E}[X_s^1/\mathcal{Y}_t]$ to M_s. We have $(X_s^1 - M_s^1) = O(\sqrt{\varepsilon})$, which implies $\tilde{E}[X_s^1/\mathcal{Y}_t] - M_s^1 = O(\sqrt{\varepsilon})$. It seems that the order $\sqrt{\varepsilon}$ cannot be improved.[1]

Nevertheless, when we integrate $X^1 - M$ from 0 to t, we get a term of order ε. We obtain

$$\tilde{E}\left[\int_0^t (X_s^1 - M_s^1)ds/\mathcal{Y}_t\right] = O(\varepsilon).$$

We will not show this result but a stronger one because of Φ and Ψ, which appear in term 2.

PROPOSITION 3.6. *For all $0 \le t \le T$, we have*

$$\tilde{E}\left[\Phi_t(M_\cdot, X_\cdot^2(M)) \int_0^t \Psi(M_s, X_s^2(M))(X_s^1 - M_s)ds/\mathcal{Y}_t\right] = O(\varepsilon). \tag{51}$$

Proof.

$$\tilde{E}\left[\left|\tilde{E}\left[\Phi_t(M_\cdot, X_\cdot^2(M)) \int_0^t \Psi(M_s, X_s^2(M))(X_s^1 - M_s)ds/\mathcal{Y}_t\right]\right|^p\right]$$

$$\le \left(\tilde{E}\left[\left|\Phi_t(M_\cdot, X_\cdot^2(M))\right|^{2p}\right]\right)^{\frac{1}{2}} \left(\tilde{E}\left[\left|\int_0^t \Psi(M_s, X_s^2(M))(X_s^1 - M_s)ds\right|^{2p}\right]\right)^{\frac{1}{2}}. \tag{52}$$

The first square root is bounded.

Let us assume for a moment the following proposition.

PROPOSITION 3.7. *When $(F_s)_{0\le s\le t}$ is adapted to the filtration $\mathcal{Y}_s \vee \mathcal{V}_s^2$ and in L^p for $1 \le p < \infty$, then in the sense of Definition* 1.2 *we have*

$$\int_0^s F_s(X_s^1 - M_s)ds = O(\varepsilon).$$

[1] This conjecture is due to J. Picard (private communication) and is based on the following considerations (the first one is proved and the last two are heuristic).

1) The order of $X_s^1 - E[X_s^1/\mathcal{Y}_s]$ is exactly $O(\sqrt{\varepsilon})$ (Picard [7, Corollary 6.2]).

2) The information given by the future after s is not better than that given by the past, so as in 1) we have $E[X_s^1/\mathcal{Y}_s] - E[E[X_s^1/\mathcal{Y}_s]/\mathcal{Y}_s^t] = O(\sqrt{\varepsilon})$.

3) Since $\mathcal{Y}_s^t$ and $\mathcal{Y}_s$ are independent given Y_s and $\mathcal{Y}_t = \mathcal{Y}_s \vee \mathcal{Y}_s^t$, we can conjecture that $\tilde{E}[X_s^1/\mathcal{Y}_s]$ and $E[E[X_s^1/\mathcal{Y}_s]/\mathcal{Y}_s^t]$ are very closed and that $\tilde{E}[X_s^1/\mathcal{Y}_t] - \tilde{E}[X_s^1/\mathcal{Y}_s] = O(\sqrt{\varepsilon})\ \forall t > s$.

It follows that the second square root of (52) is of order ε. This shows Proposition 3.6. □

Proof of Proposition 3.7. We write the Taylor formula at point M_s for $h(X_s^1)$ and we get

$$h(X_s^1) - h(M_s) = (X_s^1 - M_s)h'(M_s) + \frac{1}{2}h''(\theta_s)(X_s^1 - M_s)^2 \quad \text{with } \theta_s \in [X_s^1, M_s],$$

$$(X_s^1 - M_s) = \frac{1}{h'(M_s)}(h(X_s^1) - h(M_s)) + \frac{h''(\theta_s)}{2h'(M_s)}(X_s^1 - M_s)^2. \tag{53}$$

By assumption H.6 and Lemma 1.3, we have

$$\frac{h''(\theta_s)}{2h'(M_s)}(X_s^1 - M_s)^2 = O(\varepsilon).$$

Then

$$(X_s^1 - M_s) - \frac{1}{h'(M_s)}(h(X_s^1) - h(M_s)) = O(\varepsilon). \tag{54}$$

The proof of Lemma 1.3 shows that the estimation is good for all $s \geq 0$. Taking the conditional expectation given $\mathcal{Y}_s$ under $\tilde{P}$ in equation (53), we also have

$$\tilde{E}[h(X_s^1)/\mathcal{Y}_s] - h(M_s) = h'(M_s)(\tilde{E}[X_s^1/\mathcal{Y}_s] - M_s) + O(\varepsilon).$$

By Proposition 3.3 and assumption H.6, we have $\tilde{E}[X_s^1/\mathcal{Y}_s] - M_s = O(\varepsilon)$, which implies

$$h(M_s) = \tilde{E}[h(X_s^1)/\mathcal{Y}_s] + O(\varepsilon). \tag{55}$$

We have seen (Proposition 3.3) that the expectation of $|h(M_s) - \tilde{E}[h(X_s^1)/\mathcal{Y}_s]|^p$ is not bounded by $C\varepsilon^p$ for $s \geq 0$ but only for $s \geq \sqrt{\varepsilon}$. For $s \leq \sqrt{\varepsilon}$, it is bounded by $C(\sqrt{\varepsilon})^p$. We integrate an error $\sqrt{\varepsilon}$ during a time $\sqrt{\varepsilon}$. We thus get an error of order ε. By (54) and (55) we have

$$\begin{aligned}
&\int_0^t F_s(X_s^1 - M_s)ds \\
&\quad = \int_0^t \frac{F_s}{h'(M_s)}[(h(X_s^1) - \tilde{E}[h(X_s^1)/\mathcal{Y}_s])ds + \varepsilon dW_s] - \underbrace{\int_0^t \frac{F_s}{h'(M_s)}\varepsilon dW_s}_{=O(\varepsilon)} + O(\varepsilon) \\
&\quad = \int_0^t \frac{F_s}{h'(M_s)}(dY_s - \tilde{E}[h(X_s^1)/\mathcal{Y}_s]ds) + O(\varepsilon). \qquad (56)
\end{aligned}$$

We have used the assumptions on F_s and the fact that

$$\frac{F_s}{h'(M_s)} \in L^p \quad \text{for } 1 \leq p < \infty.$$

In filtering theory, the process $I_t \overset{\Delta}{=} Y_t - \int_0^t \tilde{E}[h(X_s^1)/\mathcal{Y}_s]ds$ is called the innovation process, and under the probability P, $(\frac{I_t}{\varepsilon})_{0 \leq t \leq T}$ is a $\mathcal{Y}_t$-Wiener process (Pardoux [6]). Again using the fact that $\mathcal{Y} \vee \mathcal{X}^1$ and $\mathcal{V}^2$ are independent under $\tilde{P}$, we get without difficulty the following proposition.

PROPOSITION 3.8. *Under* $\tilde{P}$, $(\frac{I_t}{\varepsilon})_{0\le t\le T}$ *is a* $\mathcal{Y}_t \vee \mathcal{V}_t^2$ *Brownian motion.*
The process

$$\frac{F_s}{h'(M_s)}$$

being $\mathcal{Y}_s \vee \mathcal{V}_s^2$ measurable, then

$$\int_0^t \frac{F_s}{h'(M_s)} dI_s$$

is a stochastic integral. We can therefore use the Burkholder–Davis–Gundy inequalities:

$$\begin{aligned}\tilde{E}\left[\left|\int_0^t \frac{F_s}{h'(M_s)} dI_s\right|^p\right] &\le c(p)\tilde{E}\left[\left(\int_0^t \left(\frac{F_s}{h'(M_s)}\right)^2 \varepsilon^2 ds\right)^{\frac{p}{2}}\right] \\ &\le c'(p)\varepsilon^p.\end{aligned}$$

The result follows. □

REMARK 3.9. *In the study of* (39) *the conditioning by* $\mathcal{Y}_t$ *is indispensable in obtaining the order* ε. *For* (40) *and* (42), *it is not necessary.*

Estimation of term (41). Again using $L_{(u,s)} = L_{(0,s)}(L_{(u,s)})^{-1}$, we can write (41) as

$$\tilde{E}\left[\Phi_t(M_\cdot, X_\cdot^2(M)) \int_0^t \Psi(M_s, X_s^2(M)) \int_0^s \psi(M_u, X_u^2(M))(X_u^1 - M_u) du ds / \mathcal{Y}_t\right].$$

Φ is bounded in L^p, and Ψ and ψ are bounded. This term is also of order ε.

We use the same techniques as for the computation of terms (40) and (42). By Hölder's and Jensen's inequalities,

$$\begin{aligned}&\tilde{E}\left[\left|\Phi_t(M_\cdot, X_\cdot^2(M)) \int_0^t \Psi(M_s, X_s^2(M)) \int_0^s \psi(M_u, X_u^2(M))(X_u^1 - M_u) du ds\right|^p\right] \\ &\le c(p,t)\tilde{E}\left[\int_0^t |\Phi_t(M_\cdot, X_\cdot^2(M))\Psi(M_s, X_s^2(M)) \int_0^s \psi(M_u, X_u^2(M))(X_u^1 - M_u) du|^p ds\right] \\ &\le \left(\tilde{E}\left[\int_0^t |\Phi_t(M_\cdot, X_\cdot^2(M))\Psi(M_s, X_s^2(M))|^{2p} ds\right]\right)^{\frac{1}{2}} \\ &\qquad \times \left(\int_0^t \tilde{E}\left[\left|\int_0^s \psi(M_u, X_u^2(M))(X_u^1 - M_u) du\right|^{2p} ds\right]\right)^{\frac{1}{2}}.\end{aligned}$$

The first square root is bounded and, using Proposition 3.7, the second one is bounded by $C\varepsilon^p$.

3.2.2. Estimation of the stochastic integrals.
PROPOSITION 3.10.

$$\begin{aligned}&\tilde{E}\left[\Gamma_t(M) \int_0^t \frac{\partial f_1}{\partial x_2}(M_s, X_s^2(M))(X_s^1 - M_s) dV_s^2 / \mathcal{Y}_t\right] \\ &\quad - \tilde{E}\left[\Gamma_t(M) \int_0^t \frac{\partial^2 g}{\partial x_s^2}(M_s, X_s^2(M)) Z_s^2(M, X^1 - M) dV_s^2 / \mathcal{Y}_t\right] = O(\varepsilon).\end{aligned}$$

Proof. We use here the techniques of differentiation on the Wiener space (Malliavin calculus). Let us denote by D_s the operator of differentiation with respect to the perturbation of the Brownian motion, V_s^2. We can apply an integration-by-parts formula thanks again to the fact that $\mathcal{Y}_t$ and $\mathcal{V}_t^2$ are independent. (See Ocone [4] or Pardoux [6, chapter 5.])

$$\begin{aligned}&\tilde{E}\left[\Gamma_t(M)\int_0^t \frac{\partial f_1}{\partial x_2}(M_s, X_s^2(M))(X_s^1 - M_s)dV_s^2/\mathcal{Y}_t\right]\\ &\quad = \tilde{E}\left[\int_0^t D_s\Gamma_t(M)\frac{\partial f_1}{\partial x_2}(M_s, X_s^2(M))(X_s^1 - M_s)ds/\mathcal{Y}_t\right]. \qquad (57)\end{aligned}$$

Let us write the expressions for $D_sX_t^2$ and $D_s\Gamma_t(M)$. Using (18), we get

$$D_s\breve{X}_t^2 = \exp\left(\int_s^t \frac{\partial f_2}{\partial x_s}(M_u, \breve{X}_u^2)du\right). \qquad (58)$$

Using (19), we also have

$$\begin{aligned}D_s\Gamma_t(M) = \Gamma_t(M)(D_0\breve{X}_s^2)^{-1}&\left[\int_0^t \left(\frac{\partial f_1}{\partial x_2}(M_u, \breve{X}_u^2) - f_1\frac{\partial f_1}{\partial x_2}(M_u, \breve{X}_u^2)\right)D_0\breve{X}_u^2 dM_u\right.\\ &\left. - \int_0^s \left(\frac{\partial f_1}{\partial x_2}(M_u, \breve{X}_u^2) - f_1\frac{\partial f_1}{\partial x_2}(M_u, \breve{X}_u^2)\right)D_0\breve{X}_u^2 dM_u\right]. \qquad (59)\end{aligned}$$

(57) now becomes

(60)

$$\begin{aligned}&\tilde{E}\left[\Gamma_t(M)\int_0^t \frac{\partial f_1}{\partial x_2}(M_s, X_s^2(M))(X_s^1 - M_s)dV_s^2/\mathcal{Y}_t\right]\\ &= \tilde{E}\left[\Gamma_t(M)\left(\int_0^t \left(\frac{\partial f_1}{\partial x_2}(M_u, \breve{X}_u^2) - f_1\frac{\partial f_1}{\partial x_2}(M_u, \breve{X}_u^2)\right)D_0\breve{X}_u^2 dM_u\right)\right.\\ &\qquad \left.\times \int_0^t (D_0\breve{X}_s^2)^{-1}\frac{\partial f_1}{\partial x_2}(M_s, X_s^2(M))(X_s^1 - M_s)ds/\mathcal{Y}_t\right]\\ &\quad - \tilde{E}\left[\Gamma_t(M)\int_0^t (D_0\breve{X}_s^2)^{-1}\left(\int_0^s \left(\frac{\partial f_1}{\partial x_2}(M_u, \breve{X}_u^2) - f_1\frac{\partial f_1}{\partial x_2}(M_u, \breve{X}_u^2)\right)D_0\breve{X}_u^2 dM_u\right)\right.\\ &\qquad \left.\times \frac{\partial f_1}{\partial x_2}(M_s, X_s^2(M))(X_s^1 - M_s)ds/\mathcal{Y}_t\right].\end{aligned}$$

Except for $(X_s^1 - M_s)$, this expression is only a function on M and V^2. Provided the dM_u-integrals in (60) are bounded in L^p, the terms of this equation look like the Lebesgue integrals estimated in the previous section. $\tilde{E}[\Gamma_t(M)\int_0^t \frac{\partial f_1}{\partial x_2}(M_s, X_s^2(M))(X_s^1 - M_s)dV_s^2/\mathcal{Y}_t]$ will be of order ε if we show the following lemma holds.

LEMMA 3.11. *Let v be a bounded function from $\mathbb{R}^2$ to $\mathbb{R}$. Let us suppose that its derivative with respect to the second variable is bounded. There exists $\varepsilon_0 > 0$ such that*

$$\forall 0 \le t \le T,\ \forall p \ge 1,\ \exists C_p \text{ such that } \forall \varepsilon < \varepsilon_0, \quad \tilde{E}\left[\left|\int_0^t v(M_s, \breve{X}_s^2)dM_s\right|^p\right] \le C_p.$$

Proof of Lemma 3.11. Let us define $\Upsilon(x_1,x_2)=\int_0^{x_1} v(u,x_2)du$. By Itô's formula,

$$\int_0^t v(M_s,\breve{X}_s^2)dM_s=\Upsilon(M_t,\breve{X}_t^2)-\Upsilon(X_0^1,X_0^2)-\int_0^t\frac{\partial\Upsilon}{\partial x_2}(M_s,\breve{X}_s^2)dX_s^2,$$

we obtain

$$\begin{aligned}
&\tilde{E}\left[\left|\int_0^t v(M_s,\breve{X}_s^2)dM_s\right|^p\right]\\
&\le c(p)\left(\tilde{E}[|\Upsilon(M_t,\breve{X}_t^2)|^p]+\tilde{E}[|\Upsilon(X_0^1,X_0^2)|^p+\int_0^t\tilde{E}\left[\left|\frac{\partial\Upsilon}{\partial x_2}(M_s,\breve{X}_s^2)f_2(M_s,\breve{X}_s^2)\right|^p\right]ds\right.\\
&\qquad\left.+\tilde{E}\left[\left|\int_0^t\frac{\partial\Upsilon}{\partial x_2}(M_s,\breve{X}_s^2)dV_s^2\right|^p\right]\right)\\
&\le c(p)\left(\tilde{E}[|\Upsilon(M_t,\breve{X}_t^2)|^p]+\tilde{E}[|\Upsilon(X_0^1,X_0^2)|^p+\int_0^t\tilde{E}\left[\left|\frac{\partial\Upsilon}{\partial x_2}(M_s,\breve{X}_s^2)f_2(M_s,\breve{X}_s^2)\right|^p\right]ds\right.\\
&\qquad\left.+c'(p)\tilde{E}\left[\left|\int_0^t\left(\frac{\partial\Upsilon}{\partial x_2}(M_s,\breve{X}_s^2)\right)^2ds\right|^{\frac{p}{2}}\right]\right).\qquad(61)
\end{aligned}$$

We have used the Burkholder–Davis–Gundy inequalities.

Using Lemma 1.3, we also have

$$\begin{aligned}
\tilde{E}[|\Upsilon(M_t,\breve{X}_t^2)|^p]&\le\|v\|_\infty^p\tilde{E}[|M_t|^p]\\
&\le c(p)\|v\|_\infty^p(\tilde{E}[|M_t-X_t^1|^p]+\tilde{E}[|X_t^1|^p])\\
&\le C(p)(C(\varepsilon_0)+\tilde{E}[\sup_{0\le t\le T}|X_t^1|^p]).\qquad(62)
\end{aligned}$$

The parameter ε_0 is the parameter which appears in Definition 1.2. X_t^1 being a Brownian motion under probability $\tilde{P}$, $\tilde{E}[\sup_{0\le t\le T}|X_t^1|^p]$ no longer depends on ε. By the same method, we show the existence of a constant $C(\varepsilon_0,p,T)$ such that

$$\forall\varepsilon<\varepsilon_0,\ \forall 0\le t\le T,\quad\tilde{E}\left[\left|\frac{\partial\Upsilon}{\partial x_2}(M_t,\breve{X}_t^2)\right|^p\right]\le C(\varepsilon_0,p,T).\qquad(63)$$

f_2 being bounded (see H.5), we find that

$$\tilde{E}\left[\left|\int_0^t v(M_s,\breve{X}_s^2)dM_s\right|^p\right]\le c(\varepsilon_0,p,T).\qquad\square$$

By the same method we find

$$\tilde{E}\left[\Gamma_t(M)\int_0^t\frac{\partial^2 g}{\partial x_2^2}(M_s,X_s^2(M))Z_s^2(M,X^1-M)dV_s^2/\mathcal{Y}_t\right]=O(\varepsilon).$$

Proposition 3.10 is thus proved. $\square$

We can now conclude with the following theorem.

THEOREM 3.12. *Under the assumptions of section* 1.1, $\forall\varphi\in\mathcal{C}_b^2(\mathbb{R})$, *we have*

$$\tilde{E}[\varphi(X_t^2)\Gamma_t-\varphi(\breve{X}_t^2)\breve{\Gamma}_t|\mathcal{Y}_t]=O(\varepsilon).\qquad(64)$$

COROLLARY 3.13. *Under the assumptions of section* 1.1, $\forall\varphi\in\mathcal{C}_b^2(\mathbb{R})$, *we have*

$$\mu_t(\varphi)-E[\varphi(X_t^2)/\mathcal{Y}_t]=O(\varepsilon).\qquad(65)$$

The corollary is the direct consequence of Theorem 3.12 and Proposition 2.1.

4. Conclusion. In this work we have used a method which gives an approximation of the order of convergence between the approximate filter and the exact filter. The main element used to obtain this approximation is the integration by parts of section 1.3, which makes it possible to express $\mu_t(\varphi) - E[\varphi(X_t^2)/\mathcal{Y}_t]$ as a function of $(X^1 - M)$. It is easy to notice that the method extends without difficulty to the case where there is a coefficient of diffusion $\sigma(X^1)$ in front of dV^1 and a coefficient $\sigma(X^2)$ in front of dV^2. We can also generalize this result to the case where the dimension of X^2 is greater than 1, but where f_1 is a potential in X^2.

In the case when the integration by parts is not valid (in particular, the case when the dimension of X^1 is greater than 1, which would be useful for numerical applications), it seems possible to construct an approximate filter for the conditional law of X^2 given $\mathcal{Y}_t$ of the same type as μ_t, and it is very likely that this filter converges when ε tends to 0. However, the method used in this paper to compute the rate of convergence of such an approximate filter cannot be used. It remains an open problem to prove the convergence.

Acknowledgments. Proposition 3.7, which improves the order of convergence, is due to J. Picard. This work is part of a Ph.d. Thesis under the direction of E. Pardoux at the Université de Provence (France).

APPROXIMATION OF INFINITE-DIMENSIONAL LINEAR PROGRAMMING PROBLEMS WHICH ARISE IN STOCHASTIC CONTROL*

MARTA SUSANA MENDIONDO† AND RICHARD H. STOCKBRIDGE†

Abstract. We study a general approximation scheme for infinite-dimensional linear programming (LP) problems which arise naturally in stochastic control. We prove that the optimal value of the approximating problems converges to the value of the original LP problem. For the controls, we show that if the approximating optimal controls converge, the limiting control is an optimal control for the original LP problem.

As an application of this theory, we present numerical approximations to the LP formulation of stochastic control problems in continuous time. We study long-term average and discounted control problems. For the example for which the theoretical solution is known, our approximation results are very accurate.

Key words. linear programming, stochastic control, numerical approximation, long-term average criterion, discounted criterion

1. Introduction.

This paper addresses the task of solving linear programming problems of the following form:

$$P_0: \quad \begin{cases} \text{minimize} \displaystyle\int c(x,u)\,\mu(dx\times du) \\ \text{subject to} \displaystyle\int Af(x,u)\mu(dx\times du)=0 \quad \forall f\in\mathcal{D}(A), \\ \qquad\qquad \mu \text{ is a probability measure,} \end{cases}$$

where c denotes the cost function, A is an operator on functions f, and $\mathcal{D}(A)$ denotes the domain of the operator. (Refer to section 2 for a formal definition of P_0.) Observe that optimization occurs over the space of measures satisfying the given constraints, which is typically infinite-dimensional. Often explicit solutions are difficult to determine due to this infinite-dimensionality. For such problems, it is necessary to make some reduction to finite dimensions.

This paper considers a general approach to approximating P_0 by a sequence of linear programs:

$$P_n: \quad \begin{cases} \text{minimize} \displaystyle\int c_n(x,u)\,\mu_n(dx\times du) \\ \text{subject to} \displaystyle\int A_nf_n(x,u)\mu_n(dx\times du)=0 \quad \forall f_n\in\mathcal{D}(A_n), \\ \qquad\qquad \mu_n \text{ is a probability measure} \end{cases}$$

*Received by the editors December 9, 1996; accepted for publication (in revised form) October 7, 1997; published electronically May 28, 1998. This research was partially supported by NSF grant DMS-9404990.

where the function f_n approximates f, the operator A_n approximates the operator A, the cost function c_n is related to the original cost function c, and $\mathcal{D}(A_n)$ denotes the domain of the operator A_n. The optimal values of the approximating problems P_n will be shown to be approximately optimal for the original problem P_0. The application of the general approximation scheme will be to obtain linear programming problems P_n which are finite-dimensional and hence accessible to computational solutions.

Linear programming problems of the form P_0 arise as an equivalent formulation of stochastic control problems. The idea of reformulating problems in a space of measures was introduced by Young [23] for calculus of variations problems and has been applied to nonstochastic control problems by Rubio [17, 18]. The use of linear programming to solve stochastic control problems has been studied for more than three decades. Early work concentrated on control problems in a discrete setting: discrete state space, discrete control space, and/or discrete time (see, for example, [3, 4, 15, 21, 22]). Recently, Hernández-Lerma, Hennet, and Lasserre [11] considered discrete time Markov decision processes with Borel state and control spaces under a long-run expected average cost criterion. Working in continuous time, Kurtz [12] and Stockbridge [19] studied control problems when the state space E and control space U are allowed to be locally compact, complete, and separable metric spaces. Stockbridge showed that stochastic control problems involving the long-term average cost can be reformulated as LP problems. The equivalence depended upon the existence of stationary solutions but was limited in that the optimal control was not characterized. This equivalence has been improved in several ways independently by Bhatt and Borkar [2] and Kurtz and Stockbridge [13]. Both papers characterize the optimal control and also extend the LP formulation to infinite horizon discounted and finite horizon control problems. Kurtz and Stockbridge [13] also extend the results to first passage control problems, and Bhatt and Borkar [2] relax the local compactness of the state space.

An LP formulation has been used by Heinricher and Stockbridge [9] to solve a stochastic control problem for processes modeling the wear of a system. Also, Ghosh, Arapostathis, and Marcus [6] used an LP formulation to show existence of an optimal solution for the ergodic control problem but then used dynamic programming to express the solution in terms of the Hamilton–Jacobi–Bellman equation.

This paper studies a general approximation of these types of LP problems with the goal of providing numerical methods of solution. In our example, the reduction to finite dimensions uses the Markov chain approximations studied extensively by Kushner and Dupuis [14] and others. They use dynamic programming on these approximations to solve control problems, whereas our approach relies on linear programming methods. They justify the results using weak convergence techniques and work with measures on the space of stochastic processes, whereas our justification uses weak convergence directly on measures on the state and control spaces. Some other papers which study finite-dimensional approximations of linear programming problems are [20, 8].

The paper is organized as follows. In section 2 we show that, given a linear programming problem P_0, we can define approximating problems P_n, whose optimal solutions converge to the optimal solution for P_0. Convergence of the controls is also considered. Section 3 examines finite-dimensional LP approximations to the original infinite-dimensional LP problem for two examples. Both examples are modifications of the bounded follower problem studied by Beneš, Shepp, and Witsenhausen [1]. The first one uses a long-term average criterion for which the solution is known; the second

one uses an infinite horizon discounted cost criterion.

2. Mathematical formulations and theoretical results. This section is divided into three sections. Section 2.1 contains the formal definition of the linear programming problem P_0. Section 2.2 defines the approximating LP problems. Section 2.3 provides results about the existence of the solutions to the approximating linear programming problems P_n and their convergence to the solution of P_0. Section 2.3.1 deals with convergence of the values, while section 2.3.2 considers convergence of the controls.

2.1. The original LP problem. In this section we formally define the LP problem.

Denote the state space by E and the control space by U. We assume E and U are compact, metric spaces. We denote the distance between points in E and U by $|\cdot - \cdot|$ and on the product space by $d(\cdot,\cdot)$. Denote by $\mathcal{P}(E)$ and $\mathcal{P}(U)$ the space of probability measures on E and U, respectively. Also, let $C(E)$ and $C(E\times U)$ denote the spaces of continuous functions on E and $E\times U$, respectively, and let $M(E\times U)$ denote the space of measurable functions on $E\times U$.

Let $A : \mathcal{D}(A) \to C(E\times U)$, where $\mathcal{D}(A) \subset C(E)$ denotes the domain of the operator A.

2.1.1. Conditions on the generator A and cost function c. We assume that A satisfies the following conditions:

(C1) $\mathcal{D}(A)$ is an algebra which is dense in $C(E)$, and

(C2) there exists some reference measure π on $(E,\mathcal{B}(E))$ such that if $\mu\in\mathcal{P}(E\times U)$ satisfies the stationarity condition $\int_{E\times U} Af(x,u)\mu(dx\times du) = 0$ for each $f\in\mathcal{D}(A)$, $\mu_0(\cdot)=\mu(\cdot\times U)$ is absolutely continuous with respect to π.

Condition (C1) is used in [13] to prove that many stochastic control problems can be equivalently written as LP problems of the form P_0. Condition (C2) implies that any set that has π-measure zero also has μ_0-measure zero for each stationary distribution μ.

Let $c(x,u) : E\times U\to\mathbb{R}$ be a continuous function.

2.1.2. Statement of the original LP problem. We need to place one additional restriction on the optimization problem concerning the types of controls over which optimization occurs. In order to state the condition, we need the following observation and terminology.

Observe that, for any $\mu\in\mathcal{P}(E\times U)$, we can decompose μ as $\mu(dx\times du) = \eta(x,du)\mu_0(dx)$ in which μ_0 is the marginal of μ on E and η is the regular conditional distribution on U given x under μ_0. We refer to η as a relaxed control.

We make the following restriction. *The only relaxed controls η we consider for the optimization problem satisfy*

(R1) η, as a measure-valued function of the state, is continuous almost everywhere (in the Prohorov metric (see [5, section 3.1])) with respect to the reference measure π of (C2).

This is a continuity restriction about the relaxed controls and is necessary for the weak convergence arguments we use in this paper. From a practical point of view, (R1) is not a serious limitation. The measure π is typically absolutely continuous with respect to Lebesgue measure so sets of positive π measure will be uncountable. Implementation of controls having infinitely many discontinuities is impossible. In addition, it is often possible to show a priori that the optimal control for the unrestricted problem satisfies (R1). When this is so, there is no loss of generality.

Let $\mathcal{D}_\eta$ denote the set of $x \in E$ where $\eta(x, \cdot)$ is discontinuous as a function of x. We define the linear programming problem P_0 as

$$P_0: \begin{cases} \text{minimize } \displaystyle\int_{E\times U} c(x,u)\,\mu(dx\times du) \\ \\ \text{subject to } \displaystyle\int_{E\times U} Af(x,u)\mu(dx\times du) = 0 \quad \forall f \in \mathcal{D}(A), \\ \\ \qquad\qquad \mu \in \mathcal{P}(E\times U) \text{ satisfies (R1) for some cond. dist. } \eta. \end{cases}$$

To simplify notation, $\mu = \eta\mu_0$ is used to indicate $\mu(dx \times du) = \eta(x, du)\mu_0(dx)$, and for a function $g \in M(E \times U)$ and a probability measure $\mu \in \mathcal{P}(E \times U)$, let

$$\langle g, \mu\rangle = \int_{E\times U} g(x,u)\mu(dx\times du)\,.$$

We define feasibility and optimality as follows:
Feasibility: A probability measure $\mu \in \mathcal{P}(E\times U)$ is a feasible point for P_0 if $\langle Af, \mu\rangle = 0$ for each $f \in \mathcal{D}(A)$ and μ has decomposition $\eta\mu_0$ for some η satisfying (R1). We denote the set of P_0-feasible points by $\mathcal{A}$.
Optimality: μ^* is an optimal solution for P_0 if $\mu^* \in \mathcal{A}$ and for each $\mu \in \mathcal{A}$

$$\langle c, \mu^*\rangle \le \langle c, \mu\rangle.$$

Kurtz and Stockbridge [13] show that the conditional distribution $\eta^*(x, du)$ of an optimizing μ^* identifies an optimal control for the stochastic control problem.

2.2. The approximating LP problems. Throughout the remainder of this paper we adopt the following notation. For $n \ge 0$, let E_n and U_n be compact metric spaces. We assume that for each n there exist measurable functions

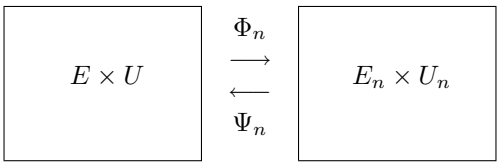
$$\psi_n^1 : E_n \to E, \qquad \psi_n^2 : U_n \to U,$$

$$\phi_n^1 : E \to E_n, \qquad \phi_n^2 : U \to U_n$$

such that

(C3) $\sup_{u\in U} \left|u - \psi_n^2\left(\phi_n^2(u)\right)\right| \to 0$ as $n \to \infty$ and
(C4) $\left|x - \psi_n^1\left(\phi_n^1(x)\right)\right| \to 0$ as $n \to \infty$ for each $x \in E$.
We denote

(2.1) $\Psi_n = (\psi_n^1, \psi_n^2) : E_n \times U_n \to E \times U$ and $\Phi_n = (\phi_n^1, \phi_n^2) : E \times U \to E_n \times U_n$:



For each n, we transfer the cost function c to the approximating space $E_n \times U_n$ by defining $c_n = c \circ \Psi_n$. Note that $c_n : E_n \times U_n \to \mathbb{R}$.

Given $\mu \in \mathcal{P}(E \times U)$, we define $\widehat{\mu}^n := \mu \circ \Phi_n^{-1}$, the distribution on $E_n \times U_n$ induced by Φ_n. Equivalently, $\widehat{\mu}^n$ can be defined as the distribution on $E_n \times U_n$ such that for each continuous h

$$\int_{E_n \times U_n} h(y,v)\widehat{\mu}^n(dy \times dv) = \int_{E \times U} h\left(\phi_n^1(x), \phi_n^2(u)\right) \mu(dx \times du)\,. \tag{2.2}$$

Similarly, given $\mu^n \in \mathcal{P}(E_n \times U_n)$, we define $\overline{\mu^n} := \mu^n \circ \Psi_n^{-1}$ as the distribution on $E \times U$ which satisfies

$$\int_{E \times U} h(x,u)\overline{\mu^n}(dx \times du) = \int_{E_n \times U_n} h\left(\psi_n^1(y), \psi_n^2(v)\right) \mu^n(dy \times dv) \tag{2.3}$$

for each $h \in C(E \times U)$.

The notation for the measures in this paper can at times appear quite cumbersome since we use the marginals of measures, measures on $E_n \times U_n$ induced by measures on $E \times U$, and measures on $E \times U$ induced by measures on $E_n \times U_n$ in various combinations. We have adopted the following conventions, hoping to aid the reader.

- For a measure μ on a product space, the marginal on the first component (E or E_n) is denoted μ_0.
- For a measure $\mu \in \mathcal{P}(E \times U)$, the induced measure on $E_n \times U_n$ is denoted by placing "$\widehat{\ }^n$" over the μ. The "hat" is to indicate that the measure "comes from" a measure on $E \times U$.
- For a measure $\mu \in \mathcal{P}(E_n \times U_n)$, the induced measure on $E \times U$ is denoted by placing "$\overline{\ }$" over the μ. The "bar" is to indicate that the measure "comes from" a measure on $E_n \times U_n$.
- The use of $*$ with a measure indicates that it is an optimal measure for the linear programming problem.

An example of this notation is $\widehat{\overline{\mu_0^n}}$, which represents the marginal of the measure $\widehat{\overline{\mu^n}}$ on $E \times U$, which is induced by the measure $\widehat{\mu}^n$ on $E_n \times U_n$, that is in turn induced by the measure μ on $E \times U$.

2.2.1. Definition of the approximating LP problem. Given E_n, U_n, and Ψ_n as defined above, for each $n \geq 1$, let

$$A_n : \mathcal{D}(A_n) \subset C(E_n) \to C(E_n \times U_n)$$

be such that, for each $f \in \mathcal{D}(A)$, there exists $f_n \in \mathcal{D}(A_n)$ satisfying

(C5) $\sup_{y \in E_n} \left|f_n(y) - f\left(\psi_n^1(y)\right)\right| \to 0$ as $n \to \infty$ and

(C6) $\sup_{(y,v) \in E_n \times U_n} |A_n f_n(y,v) - Af\left(\Psi_n(y,v)\right)| \to 0$ as $n \to \infty$.

We assume

(C7) for each n, for each relaxed control $\widehat{\eta}^n : E_n \times \mathcal{B}(U_n) \to [0,1]$, there exists a probability measure $\widehat{\mu}_0^n \in \mathcal{P}(E_n)$ such that

$$\int_{E_n} \int_{U_n} A_n f_n(y,v)\widehat{\eta}^n(y,dv)\widehat{\mu}_0^n(dy) = 0 \quad \forall f_n \in \mathcal{D}(A_n)\,;$$

i.e., each relaxed control induces some stationary distribution $\widehat{\mu}_0^n$ on the states.

In our application, the spaces E_n and U_n are a discretization of E and U, respectively, and the function Ψ_n is the embedding of $E_n \times U_n$ into $E \times U$. Φ_n maps intervals into a single point in the interval. Thus, conditions (C3) and (C4) are easily verified. As for conditions (C5), (C6), and (C7), we approximate a diffusion process by a finite-state Markov chain so these conditions can also be readily verified.

Another way of satisfying these conditions is to take $E_n = E$, $U_n = U$, Φ_n and Ψ_n to be the identity and $f_n = f$ and approximate the generator A uniformly by a sequence A_n. For example, if A is a diffusion operator, A_n can be an approximating diffusion in which the drift and diffusion coefficients uniformly approximate the corresponding coefficients of A.

The approximating LP problem is given by

$$P_n: \quad \begin{cases} \text{minimize } \langle c_n, \mu^n \rangle \\ \\ \text{subject to } \quad \langle A_n f_n, \mu^n \rangle = 0 \quad \forall f_n \in \mathcal{D}(A_n), \\ \\ \qquad\qquad \mu^n \in \mathcal{P}(E_n \times U_n). \end{cases}$$

As before, we say that a probability measure μ^n is P_n-feasible if $\langle A_n f_n, \mu^n \rangle = 0$ for each $f_n \in \mathcal{D}(A_n)$, and we denote the collection of P_n-feasible points by $\mathcal{A}_n$. We say $\overset{*n}{\mu}$ is P_n-optimal if $\overset{*n}{\mu} \in \mathcal{A}_n$ and $\langle c_n, \overset{*n}{\mu} \rangle \leq \langle c_n, \mu^n \rangle$ for each $\mu^n \in \mathcal{A}_n$.

2.3. Convergence results. In this section we state and prove the results that justify the use of the solution of P_n to approximate the solution of P_0. We first consider the convergence of the optimal values and then the convergence of the optimal controls.

2.3.1. Convergence of the values. In this section we show the following results. First, a convergent sequence of P_n-feasible points converges to a P_0-feasible point. Then, given any P_0-feasible point, we can construct a sequence of P_n-feasible points that converges to it, and finally, if those points are P_n-optimal solutions, any limit is P_0-optimal.

THEOREM 1. *Let $\{\mu^n\}$ be a sequence of P_n-feasible points. Define $\overline{\mu^n}(dx \times du) \in \mathcal{P}(E \times U)$ by* (2.3)*; i.e., for each continuous h*

$$\int_{E\times U} h(x,y)\overline{\mu^n}(dx \times dy) = \int_{E_n \times U_n} h\left(\psi_n^1(y), \psi_n^2(v)\right) \mu^n(dy \times dv).$$

If there exists a $\mu \in \mathcal{P}(E \times U)$ and some subsequence $\{n_k\}$ such that $\overline{\mu^{n_k}} \Rightarrow \mu$, then

$$\int_{E\times U} Af d\mu = 0 \quad \forall f \in \mathcal{D}(A)\,;$$

i.e., μ is P_0-feasible.

Proof. Let $f \in \mathcal{D}(A)$, and let μ be as in the statement of the theorem. Without loss of generality, assume the entire sequence converges in distribution to μ; i.e., $\overline{\mu^n} \Rightarrow \mu$. Observe that $\int A_n f_n d\mu^n = 0$ since μ^n is P_n-feasible, so

$$\int_{E\times U} Af(x,y)\mu(dx \times du) = \int_{E\times U} Af(x,u)\mu(dx \times du)$$
$$- \int_{E_n \times U_n} Af\left(\psi_n^1(y), \psi_n^2(v)\right) \mu^n(dy \times dv)$$

$$
\begin{aligned}
&+\int_{E_n\times U_n} Af\left(\psi_n^1(y),\psi_n^2(v)\right)\mu^n(dy\times dv)\\
&-\int_{E_n\times U_n} A_nf_n(y,v)\mu^n(dy\times dv)\\
&\quad=\left\{\int_{E\times U} Af(x,u)\mu(dx\times du)-\int_{E\times U} Af(x,u)\overline{\mu^n}(dx\times du)\right\}\\
&+\left\{\int_{E_n\times U_n}\left[Af\left(\psi_n^1(y),\psi_n^2(v)\right)-A_nf_n(y,v)\right]\mu^n(dy\times dv)\right\}.
\end{aligned}
$$

Since Af is (bounded and) continuous and $\overline{\mu^n}\Rightarrow\mu$, then

$$\int_{E\times U} Af(x,u)\mu(dx\times du)-\int_{E\times U} Af(x,u)\overline{\mu^n}(dx\times du)\to 0\,.$$

Also, by condition (C6),

$$\sup_{(y,v)\in E_n\times U_n}\left|Af\left(\psi_n^1(y),\psi_n^2(v)\right)-A_nf_n(y,v)\right|\to 0\,,$$

so

$$\int_{E_n\times U_n}\left[Af\left(\psi_n^1(y),\psi_n^2(v)\right)-A_nf_n(y,v)\right]\mu^n(dy\times dv)\to 0\,.$$

Therefore,

$$\int_{E\times U} Af(x,u)\mu(dx\times du)=0\,;$$

i.e., μ is P_0-feasible. □

The second theorem in this section shows that given any P_0-feasible point $\mu=\eta\mu_0$, there exists a distribution $\nu_0\in\mathcal{P}(E)$ and P_n-feasible points $\widehat{\mu}^n$ such that their induced measure $\widehat{\overline{\mu^n}}$ on $E\times U$ converges to $\eta\nu_0$. This result does not assume uniqueness of the stationary distribution on E for the control η. When the control η has a unique stationary distribution, then $\mu_0=\nu_0$ (see Corollary 3).

THEOREM 2. *Let μ be a P_0-feasible point having some decomposition $\mu(dx\times du)=\eta(x,du)\mu_0(dx)$ with η satisfying the restriction* (R1). *For each n, define the relaxed control $\widehat{\eta}^n:E_n\times\mathcal{B}(U_n)\to[0,1]$ satisfying*

$$\int_{U_n} h(v)\widehat{\eta}^n(y,dv)=\int_U h(\phi_n^2(u))\eta(\psi_n^1(y),du)\qquad\forall h\in C(U),$$

and let $\widehat{\mu}_0^n\in\mathcal{P}(E_n)$ be the stationary distribution satisfying condition (C7) *with control $\widehat{\eta}^n$. Then there exists a distribution $\nu_0\in\mathcal{P}(E)$ such that*

(i) *$\eta(x,du)\nu_0(dx)$ is P_0-feasible and*

(ii) *for each continuous function h on $E\times U$,*

$$\int_{E_n}\int_{U_n} h\left(\psi_n^1(y),\psi_n^2(v)\right)\widehat{\eta}^n(y,dv)\widehat{\mu}_0^n(dy)\to\int_E\int_U h(x,u)\eta(x,du)\nu_0(dx)\,.$$

Proof. Let μ, η, $\widehat{\eta}^n$, and $\widehat{\mu}_0^n$ be as in the statement of the theorem. Let

$$\widehat{\mu}^n(dy\times dv)=\widehat{\eta}^n(y,dv)\widehat{\mu}_0^n(dy),$$

and define $\overline{\widehat{\mu}^n} \in \mathcal{P}(E \times U)$ as in (2.3) so that for all $h \in C(E \times U)$,

$$\int_{E\times U} h(x,u)\overline{\widehat{\mu}^n}(dx \times du) = \int_{E_n \times U_n} h\left(\psi_n^1(y), \psi_n^2(v)\right) \widehat{\mu}^n(dy \times dv).$$

Let $\overline{\widehat{\mu}_0^n}(dx) = \overline{\widehat{\mu}^n}(dx \times U)$ be the state marginal of $\overline{\widehat{\mu}^n}$. Observe that

$$\begin{aligned}
\int_{E\times U} h(x,u)\overline{\widehat{\mu}^n}(dx \times du) &= \int_{E_n}\int_{U_n} h\left(\psi_n^1(y), \psi_n^2(v)\right) \widehat{\mu}^n(dy \times dv) \\
&= \int_{E_n}\int_{U_n} h\left(\psi_n^1(y), \psi_n^2(v)\right) \widehat{\eta}^n(y, dv)\widehat{\mu}_0^n(dy) \\
&= \int_{E_n}\int_{U} h\left(\psi_n^1(y), \psi_n^2(\phi_n^2(u))\right) \eta\left(\psi_n^1(y), du\right) \widehat{\mu}_0^n(dy) \\
&= \int_{E}\int_{U} h\left(x, \psi_n^2(\phi_n^2(u))\right) \eta(x, du)\overline{\widehat{\mu}_0^n}(dx)\,. \qquad (2.4)
\end{aligned}$$

Since $E \times U$ is compact, $\{\overline{\widehat{\mu}^n}\}$ is tight and hence relatively compact. Thus, there exists a subsequence $\{n_k\}$ and a $\nu \in \mathcal{P}(E \times U)$ such that $\overline{\widehat{\mu}^{n_k}} \Rightarrow \nu$; without loss of generality, we can assume that $\overline{\widehat{\mu}^n} \Rightarrow \nu$; i.e.,

$$\int_{E\times U} h(x,u)\overline{\widehat{\mu}^n}(dx \times du) \to \int_{E\times U} h(x,u)\nu(dx \times du)\,. \qquad (2.5)$$

Letting ν_0 denote the state marginal of ν, it immediately follows that $\overline{\widehat{\mu}_0^n} \Rightarrow \nu_0$. Since h is continuous on the compact set $E \times U$, given $\epsilon > 0$ $\exists \delta > 0$ such that $d\left((x_1, y_1), (x_2, y_2)\right) < \delta$ implies

$$|h(x_1, u_1) - h(x_2, u_2)| < \epsilon\,.$$

By condition (C3), $\left|u - \psi_n^2\left(\phi_n^2(u)\right)\right| \to 0$ uniformly as $n \to \infty$, so there exists $N > 0$ such that $\forall n \geq N$,

$$\left|u - \psi_n^2\left(\phi_n^2(u)\right)\right| < \delta\,.$$

Then $\forall n \geq N$,

$$\begin{aligned}
&\left|\int_E\int_U h\left(x, \psi_n^2\left(\phi_n^2(u)\right)\right) \eta(x, du)\overline{\widehat{\mu}_0^n}(dx) - \int_E\int_U h(x,u)\eta(x, du)\overline{\widehat{\mu}_0^n}(dx)\right| \\
&\leq \int_E\int_U \left|h\left(x, \psi_n^2\left(\phi_n^2(u)\right)\right) - h(x,u)\right| \eta(x, du)\overline{\widehat{\mu}_0^n}(dx) < \epsilon\,.
\end{aligned}$$

Since ϵ is arbitrary,

$$\lim_{n\to\infty}\left|\int_E\int_U h\left(x, \psi_n^2\left(\phi_n^2(u)\right)\right) \eta(x, du)\overline{\widehat{\mu}_0^n}(dx) - \int_E\int_U h(x,u)\eta(x, du)\overline{\widehat{\mu}_0^n}(dx)\right| = 0,$$

and so, by (2.4),

$$\lim_{n\to\infty}\left|\int_{E\times U} h(x,u)\overline{\widehat{\mu}^n}(dx \times du) - \int_E\int_U h(x,u)\eta(x, du)\overline{\widehat{\mu}_0^n}(dx)\right| = 0.$$

Then, by (2.5), we conclude that

$$\lim_{n\to\infty}\int_E\int_U h(x,u)\eta(x, dx)\overline{\widehat{\mu}_0^n}(dx) = \int_{E\times U} h(x,u)\nu(dx \times du)\,.$$

Recall, $\mathcal{D}_\eta$ is the set of discontinuity points of η. We claim that $\nu_0(\mathcal{D}_\eta) = 0$. To see this, let $f \in \mathcal{D}(A)$ be arbitrary but fixed, and let $h(x,u) = Af(x,u)$. Then

$$\int_{E_n}\int_{U_n} Af\left(\psi_n^1(y),\psi_n^2(v)\right)\widehat{\eta}^n(y,dv)\widehat{\mu}_0^n(dy) \to \int_E\int_U Af(x,u)\nu(dx\times du)\,. \tag{2.6}$$

Also, condition (C6) on the generators A_n implies

$$\int_{E_n}\int_{U_n} \left|Af\left(\psi_n^1(y),\psi_n^2(v)\right) - A_nf_n(y,v)\right|\widehat{\eta}^n(y,dv)\widehat{\mu}_0^n(dy) \to 0,$$

and so

$$\left|\int_{E_n}\int_{U_n} Af\left(\psi_n^1(y),\psi_n^2(v)\right)\widehat{\eta}^n(y,dv)\widehat{\mu}_0^n(dy) - \int_{E_n}\int_{U_n} A_nf_n(y,v)\widehat{\eta}^n(y,dv)\widehat{\mu}_0^n(dy)\right| \to 0.$$

Since $\widehat{\mu}_0^n$ is chosen so that the second term is zero, (2.6) implies

$$\int_E\int_U Af(x,u)\nu(dx\times du) = 0.$$

Thus, ν is P_0-feasible, and condition (C2) implies $\nu_0 \ll \pi$, and therefore $\nu_0(\mathcal{D}_\eta) = 0$, proving the claim.

The continuous mapping theorem [5, Corollary 3.1.9] implies

$$\begin{aligned}\int_E\int_U h(x,u)\eta(x,du)\nu_0(dx) &= \lim_{n\to\infty}\int_E\int_U h(x,u)\eta(x,du)\overline{\widehat{\mu}_0^n}(dx)\\ &= \int_{E\times U} h(x,u)\nu(dx\times du)\\ &= \int_E\int_U h(x,u)\overline{\eta}(x,du)\nu_0(dx)\,.\end{aligned}$$

Taking $h(x,u) = h_1(x)h_2(u)$, for $h_1 \in C(E)$ and $h_2 \in C(U)$,

$$\int_E h_1(x)\left(\int_U h_2(u)\eta(x,du)\right)\nu_0(dx) = \int_E h_1(x)\left(\int_U h_2(u)\overline{\eta}(x,du)\right)\nu_0(dx).$$

Since this is true for each $h_1 \in C(E)$, it follows that for each $h_2 \in C(U)$,

$$\int_U h_2(u)\eta(x,du) = \int_U h_2(u)\overline{\eta}(x,du) \text{ a.e. (almost everywhere) } \nu_0,$$

and thus

$$\eta(x,\cdot) = \overline{\eta}(x,\cdot) \text{ a.e. } \nu_0\,.$$

This shows that ν has decomposition

$$\nu(dx\times du) = \eta(x,du)\nu_0(dx). \tag{2.7}$$

From the definition of $\overline{\widehat{\mu}^n}$, (2.5), and (2.7), the result is established. □

Corollary 3. *Suppose η is a relaxed control satisfying restriction* (R1). *Suppose also there is a unique $\mu_0 \in \mathcal{P}(E)$ such that for each $f \in \mathcal{D}(A)$,*

$$\int_E\int_U Af(x,u)\,\eta(x,du)\,\mu_0(dx) = 0.$$

Define $\widehat{\eta}^n$ *and* $\widehat{\mu}_0^n$ *as in Theorem* 2. *Then*

$$\int_{E_n}\int_{U_n} h(\psi_n^1(y),\psi_n^2(v))\widehat{\eta}^n(y,dv)\widehat{\mu}_0^n(dy) \to \int_E\int_U h(x,u)\eta(x,du)\mu_0(dx).$$

Proof. The fact that μ_0 is unique implies that μ_0 is the ν_0 of Theorem 2. The result now follows from Theorem 2. □

Finally, we only need to show that the limit of optimal solutions in P_n is an optimal solution in P_0.

THEOREM 4. *Suppose* $\overset{*n}{\mu}$ *is an optimal solution for* P_n, *and as in* (2.3), *let* $\overline{\overset{*n}{\mu}} = \overset{*n}{\mu} \circ \Psi_n^{-1}$. *Suppose that, for each* η *satisfying* (R1), *there is a unique stationary distribution* μ_0 *such that* $\langle Af, \eta\mu_0\rangle = 0$ *for all* $f \in \mathcal{D}(A)$. *Then any* μ^* *which is a weak limit of* $\{\overline{\overset{*n_k}{\mu}}\}$ *for some subsequence* $\{n_k\}$ *is* P_0*-optimal.*

Proof. By Theorem 1, μ^* is a P_0-feasible point. Let μ be any other P_0-feasible point, and let $\{\widehat{\mu}^n = \widehat{\eta}^n\widehat{\mu}_0^n\}$ be the P_n-feasible points given in the statement of Theorem 2. By Corollary 3, the induced measures $\overline{\widehat{\mu}^n} \Rightarrow \mu$. By the Skorohod representation theorem, there exists a sequence of $E\times U$-valued random variables $\{(X_n,U_n)\}$ and an $E\times U$-valued random variable (X,U) such that $X_n \to X$ almost surely (a.s.) and $U_n \to U$ a.s. This implies that $\int c\, d\overline{\widehat{\mu}^n} \to \int c\, d\mu$. In a similar manner, it follows that $\int c\, d\,\overline{\overset{*n}{\mu}} \to \int c\, d\mu^*$. Thus,

$$\begin{aligned}
\int_{E\times U} c(x,u)\mu(dx\times du) &= \lim_{n\to\infty}\int_{E\times U} c(x,u)\overline{\widehat{\mu}^n}(dx\times du)\\
&= \lim_{n\to\infty}\int_{E_n\times U_n} c\left(\psi_n^1(y),\psi_n^2(v)\right)\widehat{\mu}^n(dy\times dv)\\
&\geq \lim_{n\to\infty}\int_{E_n\times U_n} c\left(\psi_n^1(y),\psi_n^2(v)\right)\ \overset{*n}{\mu}(dy\times dv)\\
&= \lim_{n\to\infty}\int_{E\times U} c(x,u)\ \overline{\overset{*n}{\mu}}(dx\times du)\\
&= \int_{E\times U} c(x,u)\mu^*(dx\times du)\,. \qquad \square
\end{aligned} \tag{2.8}$$

2.3.2. Convergence of controls. This section presents results concerning the controls. We show that, given any control $\eta \in \mathcal{P}(U)$ satisfying restriction (R1), the induced controls $\overline{\widehat{\eta}^n}$ converge in distribution to η for almost all x. We also show that a limit of P_n-optimal controls is a P_0-optimal control.

THEOREM 5. *Given any* $\eta : E\times\mathcal{B}(U) \to [0,1]$ *satisfying restriction* (R1), *define* $\widehat{\eta}^n : E_n\times\mathcal{B}(U_n) \to [0,1]$ *such that* $\forall g \in C(U)$,

$$\int_{U_n} g(v)\widehat{\eta}^n(y,dv) = \int_U g\left(\phi_n^2(u)\right)\eta\left(\psi_n^1(x),du\right),$$

and define $\overline{\widehat{\eta}^n} : E\times\mathcal{B}(U) \to [0,1]$ *such that* $\forall h \in C(U)$,

$$\int_U h(u)\overline{\widehat{\eta}^n}(x,du) = \int_{U_n} h\left(\psi_n^2(v)\right)\widehat{\eta}^n\left(\phi_n^1(x),dv\right).$$

Then

$$\overline{\widehat{\eta^n}}(x,\cdot) \Rightarrow \eta(x,\cdot) \qquad a.e.\ \pi.$$

Proof. Let $h \in C(U)$. Select $\epsilon > 0$ arbitrarily. Since h is continuous on a compact space, find $\delta > 0$ such that $|h(u_1) - h(u_2)| \le \epsilon/2$ whenever $|u_1 - u_2| \le \delta$. By condition (C3), find N_1 such that for all $n \ge N_1$, $|u - \psi_n^2(\phi_n^2(u))| \le \delta$. Then for all $n \ge N_1$,

$$\begin{aligned}
&\left| \int_U h(u) \overline{\widehat{\eta^n}}(x,du) - \int_U h(u)\eta(x,du) \right| \\
&= \left| \int_U h\left(\psi_n^2\left(\phi_n^2(u)\right)\right) \eta\left(\psi_n^1\left(\phi_n^1(x)\right), du\right) - \int_U h(u)\eta(x,du) \right| \\
&= \left| \int_U \left[h\left(\psi_n^2\left(\phi_n^2(u)\right)\right) - h(u)\right] \eta\left(\psi_n^1\left(\phi_n^1(x)\right), du\right) \right. \\
&\quad \left. + \int_U h(u)\eta\left(\psi_n^1\left(\phi_n^1(x)\right), du\right) - \int_U h(u)\eta(x,du) \right| \\
&\le \frac{\epsilon}{2} + \left| \int_U h(u)\eta\left(\psi_n^1\left(\phi_n^1(x)\right), du\right) - \int_U h(u)\eta(x,du) \right|.
\end{aligned}$$

By condition (C4), $\left|x - \psi_n^1\left(\phi_n^1(x)\right)\right| \to 0$ as $n \to \infty$. Letting $x_n = \psi_n^1\left(\phi_n^1(x)\right)$, we have $x_n \to x$. Since η is continuous a.e. π, $\eta(x_n,\cdot) \to \eta(x,\cdot)$ in the Prohorov metric for a.e. $x\,(d\pi)$. Therefore,

$$\eta(x_n,\cdot) \Rightarrow \eta(x,\cdot) \qquad \text{a.e. } \pi,$$

or equivalently,

$$\lim_{n\to\infty} \int_U h(u)\eta(x_n,du) = \int_U h(u)\eta(x,du) \qquad \text{a.e. } \pi\,.$$

So we can select N_2 such that $\forall n \ge N_2$,

$$\left| \int_U h(u)\eta(x_n,du) - \int_U h(u)\eta(x,du) \right| < \frac{\epsilon}{2}\,,$$

and taking $N = \max(N_1, N_2)$,

$$\left| \int_U h(u) \overline{\widehat{\eta^n}}(x,du) - \int_U h(u)\eta(x,du) \right| < \epsilon \quad \forall n \ge N.$$

Therefore,

$$\overline{\widehat{\eta^n}}(x,\cdot) \Rightarrow \eta(x,\cdot) \qquad \text{a.e. } \pi\,. \qquad \square \tag{2.9}$$

Next we show that a limit of the P_n-optimal controls is an optimal control for the P_0-problem.

THEOREM 6. *Let* $\overset{*n}{\eta} : E_n \times \mathcal{B}(U_n) \to [0,1]$ *be an optimal control for* P_n*, i.e., there exists some* $\overset{*n}{\mu_0} \in \mathcal{P}(E_n)$ *such that for each* $\mu^n \in \mathcal{A}_n$*,*

$$\int_{E_n} \int_{U_n} c_n(y,v)\ \overset{*n}{\eta}(y,dv)\, \overset{*n}{\mu_0}(dy) \le \int_{E_n \times U_n} c_n(y,v)\mu^n(dy \times dv).$$

Let $\overline{\overset{*n}{\eta}} : E \times \mathcal{B}(U) \to [0,1]$ *be the induced control satisfying*

$$\int_U h(u)\ \overline{\overset{*n}{\eta}}(x, du) = \int_{U_n} h\left(\psi_n^2(v)\right)\ \overset{*n}{\eta}\left(\phi_n^1(x), dv\right)$$

for each $h \in \overline{C}(U)$*, and let* $\overline{\overset{*n}{\mu_0}} \in \mathcal{P}(E)$ *be the induced measure satisfying*

$$\int_E h(x)\overline{\overset{*n}{\mu_0}}(dx) = \int_{E_n} h\left(\psi_n^1(y)\right)\ \overset{*n}{\mu_0}(dy)$$

for each $h \in \overline{C}(E)$*. Suppose there exists* $\eta : E \times \mathcal{B}(U) \to [0,1]$ *which, as a measure-valued function of* x*, is continuous a.e.* π*,* η *induces a unique stationary distribution* μ_0 *on the state space* E*, and* $\overline{\overset{*n}{\eta}}(x, \cdot) \Rightarrow \eta(x, \cdot)$ *for almost every* x *with respect to* π*. Then* $\overline{\overset{*n}{\mu_0}} \Rightarrow \mu_0$ *and* $\eta(x, du)\mu_0(dx)$ *is* P_0*-optimal.*

Proof. Define $\overline{\overset{*n}{\mu}}(dx \times du) = \overline{\overset{*n}{\eta}}(x, du)\overline{\overset{*n}{\mu_0}}(dx)$. Since $E \times U$ is compact, $\{\ \overline{\overset{*n}{\mu}}\ \}$ is tight, and hence $\overline{\overset{*n}{\mu}} \Rightarrow \tilde{\mu}$ along a subsequence for some $\tilde{\mu} \in \mathcal{P}(E \times U)$. Let $\tilde{\mu}_0$ be the marginal of $\tilde{\mu}$, and decompose $\tilde{\mu}$ as

$$\tilde{\mu}(dx \times du) = \tilde{\eta}(x, du)\tilde{\mu}_0(dx)$$

for some regular conditional distribution $\tilde{\eta}$ on U given x. Since $\tilde{\mu}$ is the limit of P_n-feasible solutions, it is P_0-feasible by Theorem 1.

Since by assumption $\tilde{\mu}_0 \ll \pi$, then $\tilde{\mu}_0(\mathcal{D}_\eta) = 0$. Using the argument which produces (2.7), $\eta(x, \cdot)$ is a version of $\tilde{\eta}(x, \cdot)$. Since $\tilde{\mu}$ is P_0-feasible and has decomposition $\tilde{\mu}(dx \times du) = \eta(x, du)\tilde{\mu}_0(dx)$, the uniqueness of the stationary distribution induced by η implies $\tilde{\mu}_0 = \mu_0$. Therefore, for each $h \in C(E \times U)$,

$$\int_E \int_U h(x, u)\ \overline{\overset{*n}{\eta}}(x, du)\overline{\overset{*n}{\mu_0}}(dx) \to \int_E \int_U h(x, u)\eta(x, du)\mu_0(dx)$$

along the subsequence. By Theorem 4, $\mu = \eta\mu_0$ is P_0-optimal. ∎

3. Numerical solutions using finite-dimensional LP approximations. In this section we approximate infinite-dimensional LP problems with finite-dimensional problems by approximating a jump-diffusion process with a sequence of finite state Markov chains. The convergence results of the previous section indicate that the optimal values for the approximations will be close to the optimal value of the original problem. In addition, the numerical results are consistent with convergence of the optimal controls.

3.1. The bounded follower problem. One of the stochastic control processes studied by Beneš, Shepp, and Witsenhausen [1] is the bounded follower problem. The state of this process is $x + w_t - \xi_t$, in which w is a Brownian motion process, $x + w_t$ gives the location in $\mathbb{R}^1$ at time t of an object, and ξ_t gives the location at time t of something which attempts to follow the object. In this, ξ is an absolutely continuous process whose rate of change is bounded between θ_0 and θ_1. The objective is to minimize the expected discounted square of the difference between the locations of the object and the follower:

$$E\left[\int_0^\infty e^{-\alpha t}(x + w_t - \xi_t)^2\, dt\right].$$

This problem has as its optimal control

$$\dot{\xi}_t = \begin{cases} \theta_0, & x + w_t - \xi_t < \delta, \\ \theta_1, & x + w_t - \xi_t \geq \delta, \end{cases}$$

where δ is determined from the parameters α, θ_0, and θ_1. We refer the reader to [1] for the specific expression for δ, but when $\theta_0 = -\theta_1$, the switch point δ equals 0.

For our examples we modify the stochastic process of the difference in locations $x - \xi + w$ by truncating the state space to an interval $[-b, b]$ and having the process stick at the boundary for an exponential (λ) amount of time, after which it jumps to zero. For simplicity, we take $b = 1$ and $\theta_0 = -1$ and $\theta_1 = 1$. Specifically, when the process is in the interval $(-1, 1)$, it follows the stochastic differential equation

$$dx_t = u_t dt + \sigma dw_t,$$

where w is a standard Brownian motion process and u is a nonanticipating process with $-1 \leq u_t \leq 1$.

3.2. Long-term average criterion. The first example we investigate uses a long-term average criterion for which the exact optimal control and optimal cost are known.

3.2.1. The original LP problem. The state space E, control space U, cost function c, and generator A are

$$E = [-1, 1], \qquad U = [-1, 1], \qquad c(x, u) = x^2, \text{ and}$$

$$Af(x, u) = \left[uf'(x) + \frac{\sigma^2}{2} f''(x) \right] I_{(-1,1)}(x) + \lambda \left[f(0) - f(x) \right] I_{\{\pm 1\}}(x), \tag{3.1}$$

where $\mathcal{D}(A) = C^2(E)$.

The original LP problem P_0 is

$$P_0 : \begin{cases} \text{minimize} & \displaystyle\int_{[-1,1]\times[-1,1]} x^2 \mu(dx \times du) \\ \text{subject to} & \displaystyle\int_{[-1,1]\times[-1,1]} \left\{ \left[uf'(x) + \frac{\sigma^2}{2} f''(x) \right] I_{(-1,1)}(x) \right. \\ & \left. \quad + \lambda \left[f(0) - f(x) \right] I_{\{\pm 1\}}(x) \right\} \mu(dx \times du) = 0 \quad \forall f \in C^2(E), \\ & \mu \in \mathcal{P}(E \times U). \end{cases}$$

Observe that each regular conditional distribution η on the control space specifies a nondegenerate diffusion. It is well known (see [7, section 18, Theorem 1]) that the stationary distribution of a nondegenerate diffusion (with η specified) is absolutely continuous with respect to Lebesgue measure. Thus, condition (C2) is satisfied in this example with the measure π consisting of Lebesgue measure on the interval $(-1, 1)$ and placing unit point masses at the endpoints $\{-1, 1\}$.

To verify the uniqueness of the stationary distribution μ_0 on the state for a given η, we display μ_0. The reader is referred to the appendix of [16] for the verification.

The measure μ_0 has the density in the interval $(-1,1)$

$$p(x) = \begin{cases} p_+(x), & x \geq 0, \\ p_-(x), & x < 0, \end{cases}$$

in which, letting $\overline{u}(x) = \int_U u\,\eta(x,du)$,

$$p_+(x) = \int_x^1 2\lambda K_1 e^{\int_y^x 2\overline{u}(r)dr} dy,$$

$$p_-(x) = \int_{-1}^x 2\lambda K_2 e^{\int_y^x 2\overline{u}(r)dr} dy.$$

In this the constant $K_1 = \frac{c_3}{c_1c_4+c_2c_3}$ and $K_2 = \frac{c_4}{c_1c_4+c_2c_3}$, where

$$c_1 = 1 + 2\lambda \int_{-1}^0 \int_{-1}^x e^{\int_y^x 2\overline{u}(r)dr} dydx,$$

$$c_2 = 1 + 2\lambda \int_0^1 \int_0^x e^{\int_y^x 2\overline{u}(r)dr} dydx,$$

$$c_3 = 2\lambda \int_{-1}^0 e^{\int_y^0 2\overline{u}(r)dr} dydx,$$

$$c_4 = 2\lambda \int_0^1 e^{\int_y^0 2\overline{u}(r)dr} dydx.$$

The masses of μ_0 at the endpoints $\{\pm 1\}$ are $\mu_0(\{-1\}) = K_2$ and $\mu_0(\{1\}) = K_1$.

3.2.2. The exact solution. Helmes and Stockbridge [10] have shown that this formulation is equivalent to the P_0 problem stated in section 3.1. They have also found that the exact optimal solution to this problem takes the form

$$u^*(x) = -\text{sign}(x) \quad \text{when} \quad \lambda < 5.55471$$

and for $\lambda \geq 5.55471$

$$u^*(x) = \begin{cases} -1, & -1 \leq x < -a, \\ 1, & -a \leq x < 0, \\ 0, & x = 0, \\ -1, & 0 \leq x < a, \\ 1, & a \leq x < 1, \end{cases} \tag{3.2}$$

where the switch point a is a function of λ and is the solution to the equation

$$a^2 + a + \left(r - \frac{1}{2}\right)(e^{2a} - 1) = 0,$$

where

$$r = \frac{\frac{1}{12}[-8a^3 - 6a^2 - 6a + 6a^2e^{(2a-2)} - 6ae^{(2a-2)} + 3e^{(2a-2)} + 3e^{2a} - 2] + \frac{1}{\lambda}}{\frac{1}{2}[-4a + e^{2a} + e^{(2a-2)}] + \frac{1}{\lambda}}.$$

Values of a for some selected values of λ are given in Table 1.

TABLE 1
Values of the switch point a.

λ	a
10	.88706
20	.80607
100	.72990
1000	.71066

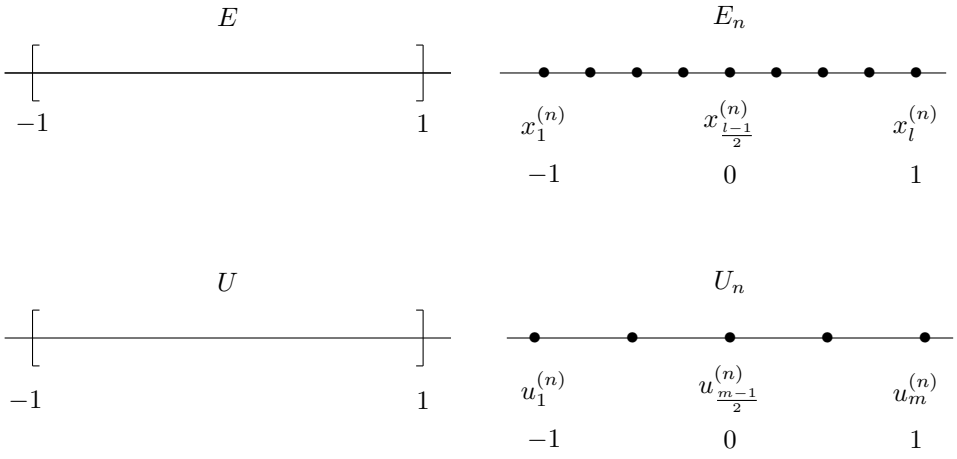
3.2.3. The approximating LP problems P_n. Let $l = l(n)$ and $m = m(n)$ be odd integers such that $l, m \to \infty$ as $n \to \infty$. (This allows different discretizations for the E and U spaces.) Let $h_l = 2/(l-1)$ and $h_m = 2/(m-1)$, and note that h_l and $h_m \to 0$ as $n \to \infty$. Define

$$x_1^{(n)} = -1, \quad x_i^{(n)} = -1 + (i-1)h_l \quad (i = 2, \ldots, l-1), \quad x_l^{(n)} = 1;$$

$$u_1^{(n)} = -1, \quad u_i^{(n)} = -1 + (i-1)h_m \quad (i = 2, \ldots, m-1), \quad u_m^{(n)} = 1,$$

and set

$$E_n = \left\{x_1^{(n)}, x_2^{(n)}, \ldots, x_l^{(n)}\right\} \qquad \text{and} \qquad U_n = \left\{u_1^{(n)}, u_2^{(n)}, \ldots, u_m^{(n)}\right\}.$$



Define

$$\phi_n^1(x) = x_i^{(n)} \quad \text{for } \left(x_i^{(n)} - \frac{1}{2}h_l\right) \le x < \left(x_i^{(n)} + \frac{1}{2}h_l\right), \ \ i = 1, 2, \ldots, l, \quad x \in E,$$

$$\phi_n^2(u) = u_i^{(n)} \quad \text{for } \left(u_i^{(n)} - \frac{1}{2}h_m\right) \le u < \left(u_i^{(n)} + \frac{1}{2}h_m\right), \ \ i = 1, 2, \ldots, m, \quad u \in U,$$

$$\psi_n^1\left(x_i^{(n)}\right) = x_i^{(n)} \quad \text{for } x_i^{(n)} \in E_n,$$

$$\psi_n^2\left(u_i^{(n)}\right) = u_i^{(n)} \quad \text{for } u_i^{(n)} \in U_n,$$

and $\Phi_n : E \times U \to E_n \times U_n$ and $\Psi_n : E_n \times U_n \to E \times U$ by (2.1). Note that Ψ_n is the identity and embeds $E_n \times U_n$ in $E \times U$. Since $c_n = c \circ \Psi_n$, then $c_n(x_i^{(n)}, u_j^{(n)}) = (x_i^{(n)})^2$. Also, for all n, define $f_n \equiv f|_{E_n}$ and $A_n f_n$ using the finite difference approximations for the derivatives of Af as in section 5.3 of Kushner and Dupuis [14],

$$\begin{aligned} A_n f_n(x_i^{(n)}, u_j^{(n)}) = \Bigg[& \frac{\sigma^2}{2} \frac{f_n\left(x_i^{(n)} + h_l\right) + f_n\left(x_i^{(n)} - h_l\right) - 2f_n\left(x_i^{(n)}\right)}{h_l^2} \\ & + u_j^{(n)^+} \left(f_n(x_i^{(n)} + h_l) - f_n(x_i^{(n)})\right)/h_l \\ & + u_j^{(n)^-} \left(f_n(x_i^{(n)}) - f_n(x_i^{(n)} - h_l)\right)/h_l \Bigg] I_{(-1,1)}(x_i^{(n)}) \\ & + \lambda \left[f_n(0) - f_n(x_i^{(n)})\right] I_{\{\pm 1\}}(x_i^{(n)}), \end{aligned} \tag{3.3}$$

where $u_j^{(n)^+} = u_j^{(n)} \vee 0$ and $u_j^{(n)^-} = -u_j^{(n)} \vee 0$.

The approximating LP problem P_n is therefore

$$P_n : \begin{cases} \text{minimize} & \displaystyle\sum_{i=1}^{l}\sum_{j=1}^{m} \left(x_i^{(n)}\right)^2 \mu^n(x_i^{(n)}, u_j^{(n)}) \\ \text{subject to} & \displaystyle 0 = \sum_{i=1}^{l}\sum_{j=1}^{m} \Bigg\{ \left(\frac{\sigma^2}{2h_l^2} + \frac{u_j^{(n)^+}}{h_l}\right) I_{(-1,1)}(x_i^{(n)}) f_n(x_i^{(n)} + h_l) \\ & \qquad + \left(\frac{\sigma^2}{2h_l^2} - \frac{u_j^{(n)^-}}{h_l}\right) I_{(-1,1)}(x_i^{(n)}) f_n(x_i^{(n)} - h_l) \\ & \qquad + \lambda I_{\{\pm 1\}}(x_i^{(n)}) f_n(0) \\ & \qquad - \Bigg[\left(\frac{\sigma^2}{h_l^2} + \frac{u_j^{(n)^+}}{h_l} - \frac{u_j^{(n)^-}}{h_l}\right) I_{(-1,1))}(x_i^{(n)}) \\ & \qquad\quad + \lambda I_{\{\pm 1\}}(x_i^{(n)}) \Bigg] f_n(x_i^{(n)}) \Bigg\} \mu^n(x_i^{(n)}, u_j^{(n)} \\ & \qquad\qquad \forall f_n \in \mathcal{D}(A_n), \\ & \mu^n \in \mathcal{P}(E_n \times U_n). \end{cases}$$

Conditions (C3)–(C6) are easily verified. In order to verify condition (C7), we rewrite the generator $A_n f_n$ in (12) as

$$\begin{aligned}A_n f_n(x_i^{(n)}, u_j^{(n)}) &= \left(\frac{\sigma^2}{2h_l^2} + \frac{u_j^{(n)^+}}{h_l}\right) I_{(-1,1)}(x_i^{(n)}) f_n(x_i^{(n)} + h_l) \\ &\quad + \left(\frac{\sigma^2}{2h_l^2} - \frac{u_j^{(n)^-}}{h_l}\right) I_{(-1,1)}(x_i^{(n)}) f_n(x_i^{(n)} - h_l) \\ &\quad + \lambda I_{\{\pm 1\}}(x_i^{(n)}) f_n(0) \\ &\quad - \left[\left(\frac{\sigma^2}{h_l^2} + \frac{u_j^{(n)^+}}{h_l} - \frac{u_j^{(n)^-}}{h_l} I_{(-1,1)}(x_i^{(n)})\right) + \lambda I_{\{\pm 1\}}(x_i^{(n)})\right] f_n(x_i^{(n)}).\end{aligned}$$

Let

$$\gamma(x_i^{(n)}) = \left(\frac{\sigma^2}{h_l^2} + \frac{u_j^{(n)^+}}{h_l} + \frac{u_j^{(n)^-}}{h_l}\right) I_{(-1,1)}(x_i^{(n)}) + \lambda I_{\{\pm 1\}}(x_i^{(n)}),$$

and define

$$\begin{aligned}P\left(x_{i+1}^{(n)} | x_i^{(n)}, u_j^{(n)}\right) &= \frac{\frac{\sigma^2}{2h_l^2} + \frac{u_j^{(n)^+}}{h}}{\gamma(x_i^{(n)})} I_{(-1,1)}(x_i^{(n)}), \\ P\left(x_{i-1}^{(n)} | x_i^{(n)}, u_j^{(n)}\right) &= \frac{\frac{\sigma^2}{2h_l^2} + \frac{u_j^{(n)^-}}{h}}{\gamma(x_i^{(n)})} I_{(-1,1)}(x_i^{(n)}), \\ P\left(0 | x_i^{(n)}, u_j^{(n)}\right) &= \frac{\lambda}{\gamma(x_i^{(n)})} I_{\{\pm 1\}}(x_i^{(n)}), \\ P\left(x_k^{(n)} | x_i^{(n)}, u_j^{(n)}\right) &= 0, \qquad k \neq i-1, i+1, \frac{l-1}{2}.\end{aligned}$$

Note that for each $x_i^{(n)}$, $u_j^{(n)}$,

$$P\left(x_k^{(n)} | x_i^{(n)}, u_j^{(n)}\right) \geq 0 \quad \forall k = 1, \ldots, l$$

and

$$\sum_{k=1}^{l} P\left(x_k^{(n)} | x_i^{(n)}, u_j^{(n)}\right) = 1,$$

and therefore we can write

$$A_n f_n(x_i^{(n)}, u_j^{(n)}) = \gamma(x_i^{(n)}) \sum_{k=1}^{l} \left[f_n(x_k^{(n)}) - f_n(x_i^{(n)})\right] P\left(x_k^{(n)} | x_i^{(n)}, u_j^{(n)}\right) \quad \forall x_i^{(n)}, u_j^{(n)}.$$

This has the form of a generator for a finite state, continuous time Markov chain. Since $\sigma^2 > 0$, the chain is irreducible for each fixed control η so there exists a unique stationary distribution on E, and condition (C7) is verified.

3.2.4. Reduction of the P_n-problem constraints. We now show that it is sufficient to consider a finite collection of indicator functions f_i, $i = 1, \ldots, l$. Let

$$g(x) = \begin{cases} (1-x^2)^3, & -1 \le x \le 1, \\ 0 & \text{otherwise}, \end{cases}$$

and define the collection of functions f_i in $\mathcal{D}(A)$ as

$$f_i(x) = g\left(\frac{x - x_i^{(n)}}{h_l/2}\right) \qquad \forall x \in [-1,1]\,.$$

Then $f_i(x) \in C^2(E)$ and $f_i(x)|_{E_n} = I_{\{x_i^{(n)}\}}(x)$ for $x \in E_n$. Denote the restriction of f_i to E_n by $f_i^{(n)}$. Since any function on E_n can be expressed as a linear combination of these indicator functions, it is sufficient to consider the stationarity constraints using only $f_i^{(n)}$, $i = 1, \ldots, l$. Thus, the constraints given in P_n reduce to

∘ For $f_i^{(n)}(x) = I_{\{x_i^{(n)}\}}(x)$ when $x_i^{(n)} \neq 1, -1, 0$,

$$0 = \sum_{j=1}^{m} \left[\left(\frac{\sigma^2}{2h_l^2} + \frac{u_j^{(n)^+}}{h_l} \right) \mu^n(x_{i-1}^{(n)}, u_j^{(n)}) + \left(\frac{\sigma^2}{2h_l^2} - \frac{u_j^{(n)^-}}{h_l} \right) \mu^n(x_{i+1}^{(n)}, u_j^{(n)}) \right.$$
$$\left. - \left(\frac{\sigma^2}{2h_l^2} + \frac{u_j^{(n)^+}}{h_l} - \frac{u_j^{(n)^-}}{h_l} \right) \mu^n(x_i^{(n)}, u_j^{(n)}) \right].$$

∘ For $f_i^{(n)}(x) = I_{\{x_i^{(n)}\}}(x)$, when $x_i^{(n)} = 0$,

$$0 = \sum_{j=1}^{m} \left[\left(\frac{\sigma^2}{2h_l^2} + \frac{u_j^{(n)^+}}{h_l} \right) \mu^n(x_{i-1}^{(n)}, u_j^{(n)}) + \left(\frac{\sigma^2}{2h_l^2} - \frac{u_j^{(n)^-}}{h_l} \right) \mu^n(x_{i+1}^{(n)}, u_j^{(n)}) \right.$$
$$- \left(\frac{\sigma^2}{2h_l^2} + \frac{u_j^{(n)^+}}{h_l} - \frac{u_j^{(n)^-}}{h_l} \right) \mu^n(x_i^{(n)}, u_j^{(n)}) + \lambda \mu^n(-1, u_j^{(n)})$$
$$\left. + \lambda \mu^n(1, u_j^{(n)}) \right].$$

∘ For $f_i^{(n)}(x) = I_{\{x_i^{(n)}\}}(x)$, when $x_i^{(n)} = -1$ (i.e., when $i = 1$),

$$0 = \sum_{j=1}^{m} \left[\left(\frac{\sigma^2}{2h_l^2} - \frac{u_j^{(n)^-}}{h_l} \right) \mu^n(x_{i+1}^{(n)}, u_j^{(n)}) - \lambda \mu^n(x_i^{(n)}, u_j^{(n)}) \right].$$

∘ For $f_i^{(n)}(x) = I_{\{x_i^{(n)}\}}(x)$, $x_i^{(n)} = 1$ (i.e., when $i = l$),

$$0 = \sum_{j=1}^{m} \left[\left(\frac{\sigma^2}{2h_l^2} + \frac{u_j^{(n)+}}{h_l} \right) \mu^n(x_{i-1}^{(n)}, u_j^{(n)}) - \lambda \mu^n(x_i^{(n)}, u_j^{(n)}) \right].$$

In addition to the constraints for stationarity, there is the constraint that μ^n be a probability measure:

$$\sum_{j=1}^{m}\sum_{i=1}^{l}\mu^n(x_i^{(n)},u_j^{(n)})=1 \qquad \text{and} \qquad \mu^n(x_i^{(n)},u_j^{(n)})\geq 0 \quad \forall i,j\,.$$

3.2.5. P_n-optimal solution. The P_n problem is solved using a program written in SAS which utilizes the LP procedure. Since in this example the optimal control only takes the values -1, 0 and 1 in U even when $h_m = 0.1$, all the numerical approximations presented here therefore use $h_m = 0.5$.

Figure 1 shows the optimal control obtained for the discretized problem P_n ($h_l = .10$, $\lambda = 100$) represented by the dots, and the induced control in the interval $[-1, 1]$ represented by the solid line.

Figures 2–4 illustrate how the optimal control changes as a function of λ. When $\lambda = 5$, the optimal control is $-\text{sign}(x)$, while for $\lambda = 20$ and $\lambda = 100$ the optimal control is of the form (3.2), where the switch location a depends on λ and a decreases as λ increases.

Table 2 gives the interval in which the positive "switch point" occurs for P_n. The results for the negative switch point follow by symmetry. Note that the P_0 switch point a falls within the switch interval for P_n.

TABLE 2
"Switch point" as a function of λ, $h = .01$.

		$\lambda = 10$	$\lambda = 20$	$\lambda = 100$	$\lambda = 1000$
P_n	$h_l = .05$	(.85, .90)	(.80, .85)	(.70, .75)	(.70, .75)
switch	$h_l = .02$	(.88, .90)	(.80, .82)	(.72, .74)	(.70, .72)
interval	$h_l = .01$	(.88, .89)	(.80, .81)	(.72, .73)	(.71, .72)
P_0	switch	.88706	.80607	.72990	.71066

TABLE 3
Optimal values for the long-term average cost.

		$\lambda = 5$	$\lambda = 10$	$\lambda = 100$
	$h_l = .20$	.218321	.173058	.113664
	$h_l = .10$	.208359	.167671	.118411
P_n	$h_l = .05$	.201667	.162920	.119131
	$h_l = .02$	.197067	.160184	.118735
	$h_l = .01$	.195432	.159153	.118452
P_0		.193746	.158037	.117969

The values for the cost function for three values of λ and five values of h_l are given in Table 3. Note that as the mesh size decreases, the P_n-optimal values well-approximate the P_0-optimal value.

3.3. Discounted cost criterion. For this example, we examine a discounted cost of the processes considered in the previous section. Note that this is the same cost criterion used by Beneš, Shepp, and Witsenhausen [1] in the bounded follower problem, though the dynamics have been modified. In this section, α denotes the discount rate.

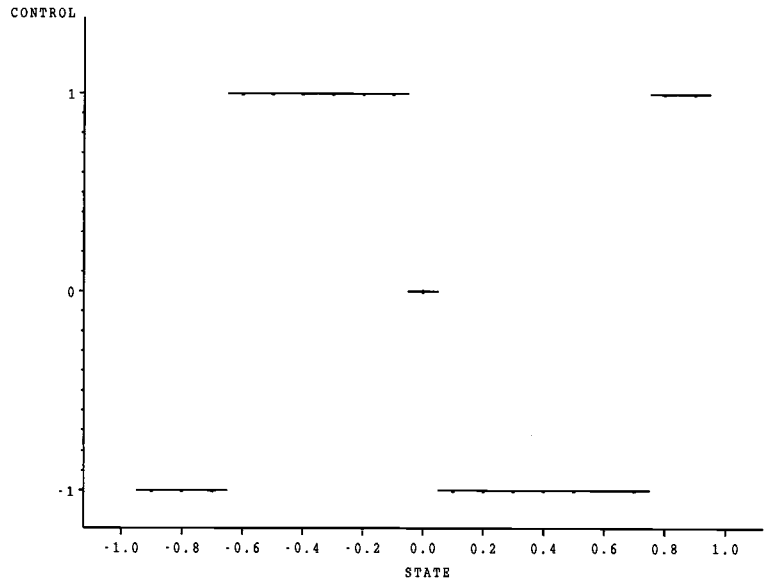


FIG. 1. *Long-term average (LTA) optimal control induced by* P_n, $h_l = .10$, $\lambda = 100$.

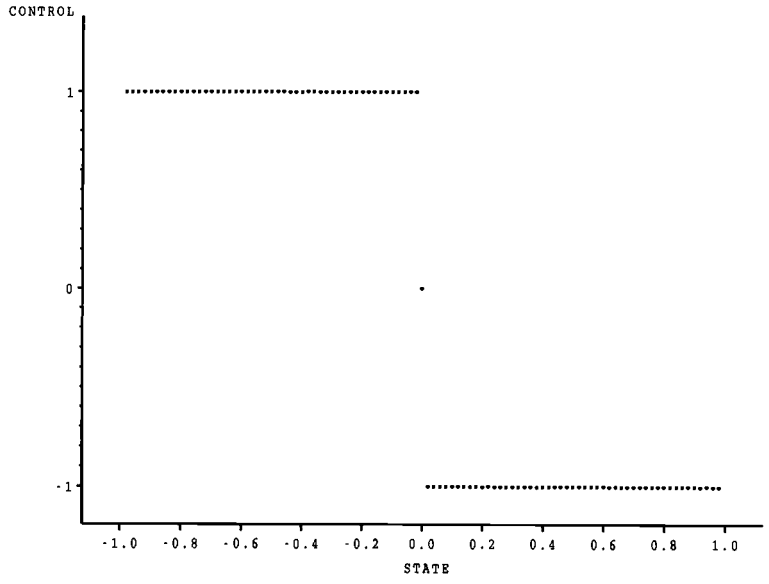

FIG. 2. P_n *optimal control for LTA,* $\lambda = 5$, $h = .02$.

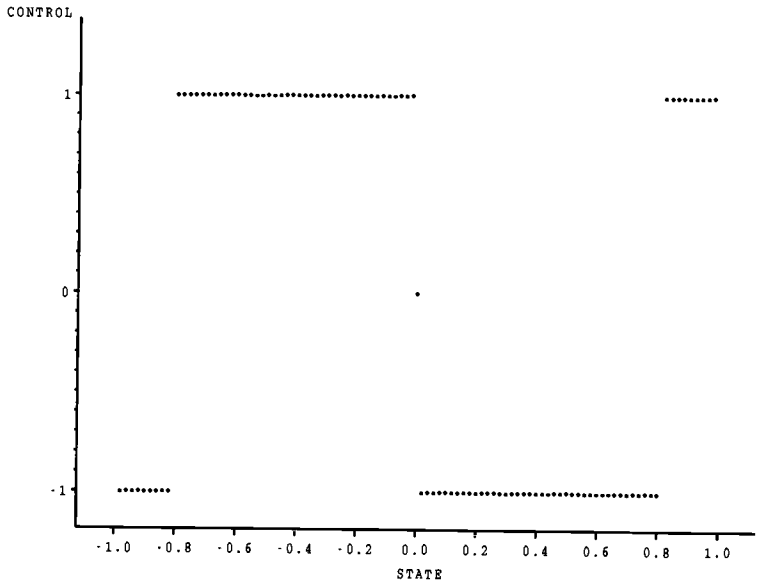

FIG. 3. *P_n optimal control for LTA, $\lambda = 20$, $h = .02$.*

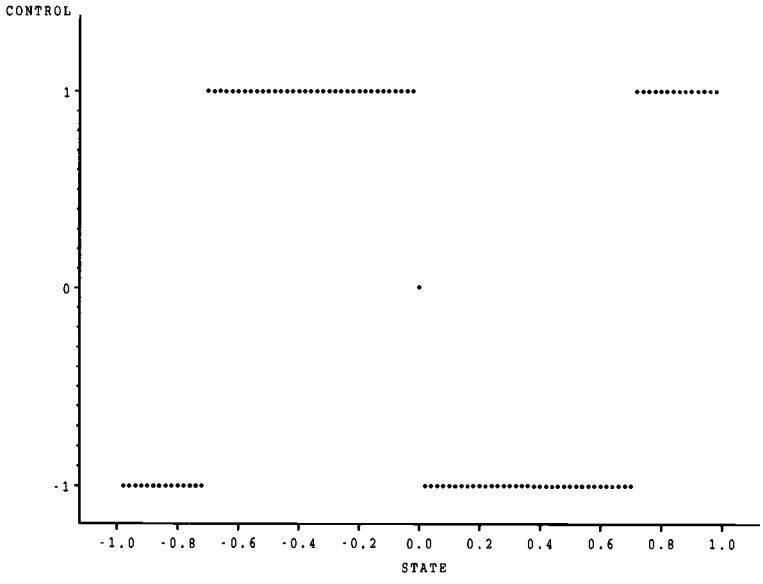

FIG. 4. *P_n optimal control for LTA, $\lambda = 1000$, $h = .02$.*

3.3.1. The original LP problem. Kurtz and Stockbridge [13] show that the LP formulation of the discounted control problem adjusts the cost by a factor of α and introduces a jump term into the generator of the process. The original LP problem P_0 is

$$P_0 : \begin{cases} \text{minimize} & \dfrac{1}{\alpha}\displaystyle\int_{[-1,1]\times[-1,1]} x^2 \mu(dx \times du) \\ \text{subject to} & \displaystyle\int_{[-1,1]\times[-1,1]} \left\{ \left[uf'(x) + \frac{\sigma^2}{2} f''(x) \right] I_{(-1,1)}(x) \right. \\ & \qquad + \lambda \left[f(0) - f(x) \right] I_{\{\pm 1\}}(x) \\ & \qquad \left. + \alpha \left[f(0) - f(x) \right] \right\} \mu(dx \times du) = 0 \\ & \qquad\qquad \forall f \in C^2(E), \\ & \mu \in \mathcal{P}(E \times U). \end{cases}$$

3.3.2. The approximating LP problem P_n. Using the same Markov chain approximations, we have

$$P_n : \begin{cases} \text{minimize} & \dfrac{1}{\alpha} \displaystyle\sum_{i=1}^{l} \sum_{j=1}^{m} \left(x_i^{(n)} \right)^2 \mu^n(x_i^{(n)}, u_j^{(n)}) \\ \text{subject to} & 0 = \displaystyle\sum_{i=1}^{l} \sum_{j=1}^{m} \left\{ \left(\frac{\sigma^2}{2h_l^2} + \frac{u_j^{(n)^+}}{h_l} \right) I_{(-1,1)}(x_i^{(n)}) f_n(x_i^{(n)} + h_l) \right. \\ & \qquad + \left(\dfrac{\sigma^2}{2h_l^2} - \dfrac{u_j^{(n)^-}}{h_l} \right) I_{(-1,1)}(x_i^{(n)}) f_n(x_i^{(n)} - h_l) \\ & \qquad + \lambda I_{\{\pm 1\}}(x_i^{(n)}) f_n(0) \\ & \qquad - \left[\left(\dfrac{\sigma^2}{h_l^2} + \dfrac{u_j^{(n)^+}}{h_l} - \dfrac{u_j^{(n)^-}}{h_l} \right) I_{(-1,1)}(x_i^{(n)}) \right. \\ & \qquad \left. + \lambda I_{\{\pm 1\}}(x_i^{(n)}) \right] f_n(x_i^{(n)}) \\ & \qquad \left. + \alpha \left[f_n(0) - f_n(x_i^{(n)}) \right] \right\} \mu^n(x_i^{(n)}, u_j^{(n)}) \quad \forall f_n \in \mathcal{D}(A_n), \\ & \mu^n \in \mathcal{P}(E_n \times U_n). \end{cases}$$

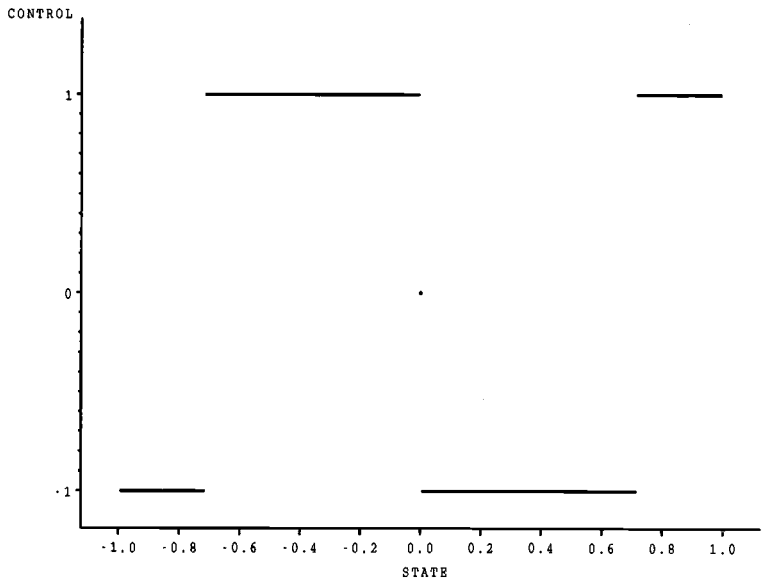

FIG. 5. *P_n optimal control for the discounted problem, $\lambda = 1000$, $\alpha = 0.3$, $h_l = .01$.*

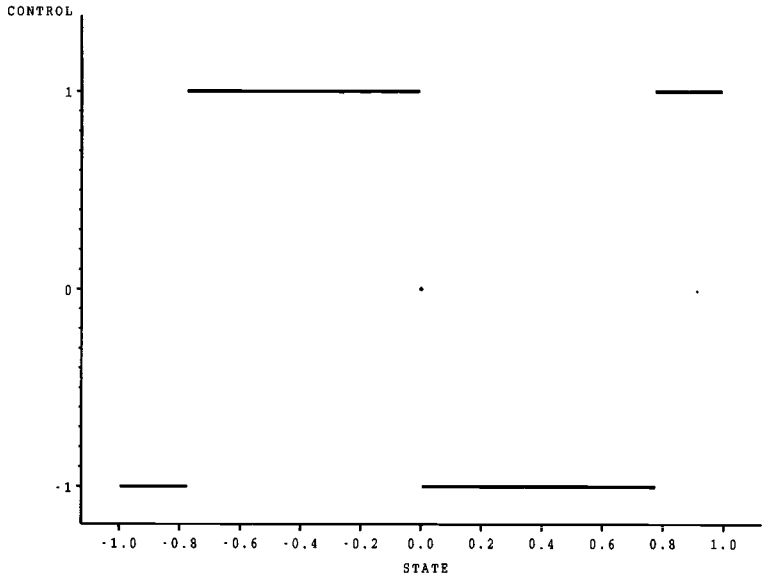

FIG. 6. *P_n optimal control for the discounted problem, $\lambda = 1000$, $\alpha = 20.0$, $h_l = .01$.*

The same reduction to a finite number of constraints can be adopted using the functions $\{f_i^{(n)}\}$ for the long-term average LP problem P_n.

3.3.3. P_n-optimal solutions. The numerical solution to the discounted problem takes the same form as the one for the long-term average problem. In the case of $\lambda \leq 5.55471$, the optimal control is the $u(x) = -\text{sign}(x)$ for every value of α.

Figures 5 and 6 illustrate the effect of α on the optimal control when $\lambda = 1000$. In these examples, $h_l = .01$ and α takes the values 0.3 and 20. Note that the "switch point" for the control that occurs in the (.71, .72) interval in Table 2 ($\alpha = 0$) does not change when α takes the value .3, but it changes to (.77, .78) when α takes the value 20. As the discount rate increases, the switch point moves closer to the boundary. It should be noted that a value of $\alpha = 0.3$ corresponds to an annual inflation rate of 35% and $\alpha = 20$ corresponds to a *daily* inflation rate of 5.6%.

One approach to solving long-term average control problems is to begin with the discounted problem, normalize the cost by multiplying by α, and let α go to zero. Table 4 gives the values of the α-normalized cost function for three values of λ. Note that as $\alpha \to 0$, the α-normalized cost function for the discounted problem converges to the cost function for the long-term average problem. (These values are calculated using $h = .01$.)

TABLE 4
α-normalized P_n-values.

	$\lambda = 5$	$\lambda = 10$	$\lambda = 1000$

DYNAMIC THICK RESTARTING OF THE DAVIDSON, AND THE IMPLICITLY RESTARTED ARNOLDI METHODS*

ANDREAS STATHOPOULOS†, YOUSEF SAAD†, AND KESHENG WU†

Abstract. The Davidson method is a popular preconditioned variant of the Arnoldi method for solving large eigenvalue problems. For theoretical as well as practical reasons the two methods are often used with restarting. Frequently, information is saved through approximated eigenvectors to compensate for the convergence impairment caused by restarting. We call this scheme of retaining more eigenvectors than needed "thick restarting" and prove that thick restarted, nonpreconditioned Davidson is equivalent to the implicitly restarted Arnoldi. We also establish a relation between thick restarted Davidson and a Davidson method applied on a deflated system. The theory is used to address the question of which and how many eigenvectors to retain and motivates the development of a dynamic thick restarting scheme for the symmetric case, which can be used in both Davidson and implicit restarted Arnoldi. Several experiments demonstrate the efficiency and robustness of the scheme.

Key words. Davidson method, Arnoldi method, Lanczos method, implicit restarting, deflation, eigenvalue, preconditioning

1. Introduction.

The computation of a few eigenpairs of large, sparse, eigenvalue problems $Ax = \lambda x$ is central to many scientific applications [19]. The Arnoldi method and its equivalent in the symmetric case, the Lanczos method, have been the traditional approach to solving these problems. Preconditioning, through some shift-and-invert technique [22], is frequently employed to improve robustness. A different approach is followed by the generalized Davidson (GD) method [8, 16, 6] which is a popular preconditioned variant of the Lanczos iteration. Instead of using a three-term recurrence to build an orthonormal basis for the Krylov subspace, the GD algorithm obtains the next basis vector by explicitly orthogonalizing the preconditioned residual $(M - \lambda I)^{-1}(A - \lambda I)x$ against the existing basis. A straightforward extension to the nonsymmetric case has also been studied in [21]. When $M = A$, the preconditioned residual yields back x, thus providing no improvement. The Jacobi–Davidson (JD) modification, proposed in [23], suggests that the proper way to precondition the residual is through an operator with range orthogonal to x. The GD and its JD modification can be regarded as two ways of improving convergence and robustness at the expense of a more complicated step.

Often, eigenvalue problems are very large and ill conditioned. As a result, eigenvalue methods require a large number of steps and need to save all the vector iterates for extracting the eigenvectors. Such cases exhibit overwhelming storage requirements. In addition, the Lanczos and Arnoldi processes, which traditionally had been considered without restarting, are plagued by orthogonality problems and spurious solutions. For the above reasons many restarting variants are used in practice [7, 18, 24, 2]. The GD method improves convergence and solves some of the aforementioned problems

through orthogonalization and preconditioning. However, the number of iterations can still grow very large and cause similar storage problems. The problem is actually aggravated in the symmetric case, where the better theoretical framework and software has led researchers to consider matrices of huge size that allow only a few vectors to be stored. The GD method also can be restarted every time the basis contains m vectors (GD(m)). If the l lowest eigenvalues are needed, the l lowest Ritz values are computed at the mth step, and their corresponding Ritz vectors are used as initial guesses for the restarted GD iteration.

Truncating the Krylov sequence is expected to impair the convergence rate of the method. There are two main reasons: the new vectors entering the basis repeat some of the information that was discarded when restarting, and the Rayleigh–Ritz procedure does not minimize over the whole Krylov subspace. There has been much discussion about the problems caused by restarted methods for both linear systems and eigenvalue problems [27, 20, 24]. Some methods tend to save additional information at each restart [14, 3, 11]. For the Davidson method, Murray, Racine, and Davidson [17] and Van Lenthe and Pulay [29] have proposed restarting with two vectors per required Ritz vector with some success. In an effort to minimize execution time, Crouzeix, Philippe, and Sadkane [6] have proposed a dynamically chosen size m.

Recently, "implicit restarting" has gained popularity as a means of improving convergence of the restarted Arnoldi procedure [24]. By using $p = m - k$ steps of the implicit QR algorithm on the Hessenberg matrix, the basis is truncated down to k vectors. It turns out that the k new basis vectors can be considered the Arnoldi vectors obtained from a polynomially transformed starting vector. This is the basis of the popular eigenvalue package ARPACK [13]. Preconditioners for eigenvalue problems usually vary between steps, in which case the implicitly restarted Arnoldi (IRA(k, m)) is not straightforward to apply. Further, in case of the GD(m) where the residual is preconditioned, the Ritz vectors cannot be described with a polynomial of A. Clearly, a new restarting scheme is needed.

In this paper, we study an extension to the IRA(k, m) technique for the GD(m), which we call "thick restarting" and denote by GD(k, m), and which depends on an integer parameter k. GD(k, m) restarts with k Ritz vectors instead of the l wanted ones, where $l \leq k < m$. The principle idea is mentioned by Kosugi in [11], Sleijpen and van der Vorst in [23], and Morgan in [15]. In the literature, the benefits of IRA(k, m) are studied in relation to the polynomially transformed initial vector. This paper addresses the question of which and how many Ritz vectors should be kept. The theory presented motivates a dynamic strategy of thick restarting that can be used in both IRA(k, m) and GD(k, m). Although the results are proved for the nonpreconditioned case, the idea of thick restarting is readily applicable to the preconditioned GD(k, m) and similar behavior is expected. Compared with IRA(k, m), GD(k, m) can also assume any number of initial guesses and/or enhancements of the basis through arbitrary vectors during the procedure.

After briefly presenting the IRA(k, m) and GD(k, m) algorithms in section 2, in section 3 we prove as an extension to [15] that in the absence of preconditioning, and for arbitrary targeting scheme of GD(k, m), the IRA(k, m) using the Ritz values as shifts and GD(k, m) are equivalent, in the sense that their basis vectors span exactly the same space. In section 4 a theorem is proved that relates the IRA(k, m), and thus GD(k, m), with an Arnoldi process applied on an approximately deflated initial vector. This extends the ideas that appeared recently in [28]. In section 5, a dynamic choice of k is derived for the symmetric case, where the rate of convergence is described

by well-known bounds. In section 6, numerical experiments on matrices from the Harwell–Boeing collection demonstrate the effectiveness of GD(k, m).

2. The restarted Arnoldi and Davidson methods. Throughout this paper we assume that the matrix A is diagonalizable, of order N, with eigenpairs (λ_i, x_i). We look for l outermost eigenpairs (e.g., lowest or highest in the symmetric case). The Arnoldi and Davidson methods use a basis size of $m > l$. The following descriptions of the algorithms serve for establishing the notation. For theoretical and implementation details refer to [24, 13, 8, 16, 6, 23]. For all quantities the superscripts in parentheses denote the corresponding restarting step. These superscripts are dropped whenever there is no ambiguity.

Restarted Arnoldi's method in its simplest form can be expressed as follows.

ALGORITHM 2.1 Restarted Arnoldi.

0. *Start: Choose initial unit vector* $v^{(0)}$
1. *For* $s = 0, 1, \ldots$ *Do*
2. $\quad v_1 = v^{(s)}$, $V_1^{(s)} = \{v_1\}$
3. $\quad$ *For* $j = 1, \ldots, m$ *Do*
4. $\quad\quad h_{ij} = (Av_j, v_i),\ i = 1, \ldots, j,$
5. $\quad\quad w_j = Av_j - \sum_{i=1}^{j} h_{ij} v_i$
6. $\quad\quad h_{j+1,j} = \|w_j\|_2$, *if* $h_{j+1,j} = 0$ *stop.*
7. $\quad\quad v_{j+1} = w_j / h_{j+1,j}$
8. $\quad$ *Enddo*
9. $\quad$ *Compute the wanted eigenpairs* $(\mu_i^{(s)}, y_i^{(s)})$ *of* $H_m^{(s)} = (h_{i,j})$
   $\quad$ *and the Ritz vectors* $x_i^{(s)} = V_m^{(s)} y_i^{(s)}$, *where* $V_m^{(s)} = \{v_1, \ldots, v_m\}$
10. $\quad v^{(s+1)} = \sum c_i x_i^{(s)}$, *for some* c_i, *and the wanted* $x_i^{(s)}$
11. *Enddo*

The algorithm builds a Hessenberg matrix, from which the approximate eigenpairs are extracted through the Rayleigh–Ritz procedure. For the symmetric case, $H_m^{(s)}$ is a tridiagonal matrix, and a three-term recurrence replaces the above orthogonalization step. A linear combination of the wanted Ritz vectors are used to restart the algorithm. Such a restarting strategy, however, may discard a lot of information and result in degradation of the convergence rate.

Implicitly restarted Arnoldi applies the implicit QR algorithm with the $m - l$ unwanted eigenvalues as shifts to the Hessenberg matrix and uses the generated orthogonal transformations to truncate the basis down to l vectors. Therefore, it avoids the need to restart with a single vector which captures the information for all l eigenvectors. The number of vectors in the new basis after restart may also be larger than l, say k. For the rest of the paper we assume that $l \le k < m$, $p = m - k$, and IRA(k, m) denotes the associated method. An outline of the IRA(k, m) algorithm follows.

ALGORITHM 2.2 Implicitly restarted Arnoldi.

0. *Start: Choose initial vector* $v_1^{(0)}$
1. *Build an initial Arnoldi iteration of* k *steps:* $(V_k^{(0)}, H_k^{(0)})$
2. *For* $s = 0, 1, \ldots$ *Do*
3. $\quad$ *Test for convergence*
4. $\quad$ *Extend* $V_k^{(s)}$ *to* $k + p$ *vectors, taking* p *more Arnoldi steps:* $(V_{k+p}^{(s)}, H_{k+p}^{(s)})$
5. $\quad$ *Choose shifts* $\mu_i,\ i = 1, \ldots, p$
6. $\quad H_{k+p} = Q^T H_{k+p}^{(s)} Q$, *with* Q *the orthogonal matrix obtained through*
   $\quad$ *the implicit QR algorithm with* $\mu_i, i = 1, \ldots, p$ *shifts*

7. *Define* $V_k^{(s+1)} = (V_{k+p}^{(s)} Q)\begin{pmatrix} I_k \\ 0 \end{pmatrix}$, *and*
8. $H_k^{(s+1)} = \begin{pmatrix} I_k & 0 \end{pmatrix} H_{k+p} \begin{pmatrix} I_k \\ 0 \end{pmatrix}$
9. *Enddo*

The power of the IRA(k, m) lies in the following two properties. First,

$$v_1^{(s+1)} = \psi(A) v_1^{(s)} = \prod_{i=1}^{p} (A - \mu_i I) v_1^{(s)}, \tag{2.1}$$

for any choice of shifts μ_i, not limited to the exact shifts (Ritz values), and thus the new Arnoldi iteration starts with a polynomially transformed initial vector. Second, the vectors $v_2^{(s+1)}, \ldots, v_k^{(s+1)}$ can be considered the Arnoldi vectors of the Arnoldi process started with $v_1^{(s+1)}$. Thus, no matrix–vector multiplications are needed for the first k Arnoldi vectors. Among various interpretations, IRA(k, m) can be considered a truncation of the QR algorithm for dense matrices as well as an efficient and robust implementation of the subspace iteration with polynomial transformations.

The Davidson method first appeared as a diagonally preconditioned version of the Lanczos method for the symmetric eigenproblem. Extensions, to both general preconditioners and to the nonsymmetric case, have been given since. The following describes the algorithm for the symmetric case. For the nonsymmetric case, line 5 should also include the computation of the last row of the projection matrix $T_j^{(s)}$. MGS denotes the modified Gram–Schmidt procedure.

ALGORITHM 2.3 Generalized Davidson.

0. *Choose initial unit vectors* $U_l^{(0)} = \{u_1^{(0)}, \ldots, u_l^{(0)}\}$
1. *For* $s = 0, 1, \ldots$ *Do*
2. $\quad w_i^{(s)} = A u_i^{(s)},\ i = 1, \ldots, l-1$
3. $\quad$ *For* $j = l, \ldots, m$ *Do*
4. $\quad\quad w_j^{(s)} = A u_j^{(s)}$.
5. $\quad\quad t_{i,j} = (w_j^{(s)}, u_i^{(s)}),\ i = 1, \ldots, j$, *the last column of* $T_j^{(s)}$
6. $\quad\quad$ *Compute some wanted eigenpair, say* (μ_1, z_1) *of* $T_j^{(s)}$.
7. $\quad\quad x_1 = U_j^{(s)} z_1$ *and* $r = Ax_1 - \mu_1 x_1$, *the Ritz vector and its residual*
8. $\quad\quad$ *Test* $\|r\|$ *for convergence. If satisfied target a new vector.*
9. $\quad\quad$ *Solve* $M_{(s,j)} t = r$, *for* t.
10. $\quad\quad b_{j+1}^{(s)} = MGS(U_j^{(s)}, t)$
11. $\quad$ *Enddo*
12. $\quad$ *Set* $U_k^{(s+1)} = \{x_1, \ldots, x_k\},\ k < m$, *and restart*
13. *Enddo*

The preconditioning is performed by solving the equation at step 9, with $M_{(s,j)}$ approximating $(A - \mu_1 I)$ in some sense. In [23] Sleijpen and van der Vorst show that for stability, robustness, as well as efficiency, the operator $M_{(s,j)}$ should have a range orthogonal to x. This is the Jacobi–Davidson (JD) method, and it solves approximately the projected correction equation ($\|x_1\|_2 = 1$)

$$(I - x_1 x_1^T)(A - \mu_1 I)(I - x_1 x_1^T)\ t = (I - x_1 x_1^T)(\mu_1 I - A) x_1 = -r.$$

The projections can be easily applied if an iterative linear solver is used. For preconditioners which approximate A directly, such as incomplete factorizations and approximate inverses, the above orthogonality condition is enforced through an equivalent formulation known as Olsen method. Since the purpose of this paper is the study of

restarting strategies, we use the general description of GD, and the results are valid whether step 9 is performed through JD or otherwise.

A Davidson step is more expensive than that of the Lanczos and Arnoldi algorithms, to allow for preconditioning. In addition, the Davidson algorithm can start with any number of initial vectors and include in the basis any extra information that can be available during the execution. The targeted eigenpair (i.e., the one chosen for preconditioning) may vary in different steps, allowing for a variable targeting scheme. Finally, it can restart with the approximate eigenvectors, so it does not share the problems of the original restarted Arnoldi. As in IRA(k,m), the Davidson method can also restart with more Ritz vectors than needed. This version is "thick restarting" and we denote it by GD(k,m), where l,k, and m are defined as in IRA(k,m). In the following section, we show that IRA(k,m) and GD(k,m) are equivalent in the nonpreconditioned case, but GD(k,m) offers all the aforementioned advantages and extensions.

3. Thick and implicit restarting. It is known that the Lanczos and the Davidson methods are equivalent when no preconditioning is used. However, this has been pointed out only for the nonrestarted case, where one eigenvalue is sought [16]. Recently, the equivalence of the IRA(k,m) with an Arnoldi method restarting with a Ritz vector and augmented by $k-1$ Ritz vectors has been shown [15]. In this section we prove that, in the nonpreconditioned case, if GD(k,m) and IRA(k,m) start with the same initial vector, they are equivalent for any targeting scheme of GD(k,m).

The first lemma is an extension of Lemma 3.10 in [24], and it is the basis for the equivalence proof. Note that the implicit QR algorithm is applied to any diagonalizable matrix H.

LEMMA 3.1. *Let $\lambda(H)=\{\lambda_1,\ldots,\lambda_k\}\cup\{\mu_1,\ldots,\mu_p\}$ be a disjoint partition of the eigenvalue set of a diagonalizable matrix H. Let $Q=Q_1Q_2\cdots Q_p$, where Q_i is the orthogonal matrix implicitly defined by the shift μ_i in the implicit QR algorithm on H. Then, the first k columns of Q span the same space as the k eigenvectors y_i of H associated with the eigenvalues $\lambda_i,\ i=1,\ldots,k$.*

Proof. After p steps of the implicit QR algorithm, it holds that

$$QR=Q_1Q_2\cdots Q_pR_p\cdots R_2R_1=\prod_{i=1}^{p}(H-\mu_i),$$

where Q_iR_i is the QR decomposition of $H_i-\mu_i$ at the ith step, and $R=(r_{ij})=R_p\cdots R_2R_1$ denotes an upper triangular matrix. Since the shifts $\mu_i,\ i=1,\ldots,p$, are eigenvalues of H, QR is a rank k matrix, and if the decompositions are performed with traditional column pivoting, $r_{ii}\neq 0,\ i=1,\ldots,k$, and $r_{ii}=0,\ i=k+1,\ldots,k+p$. For Hessenberg matrices it is shown in [24] that $q_1=Qe_1$ is in the span of $\{y_1,\ldots,y_k\}$. Using a similar argument, if $e_1=\sum_{j=1}^{k+p}\xi_jy_j$,

$$QRe_1=q_1r_{11}=\sum_{j=1}^{k}\xi_j\prod_{i=1}^{p}(\lambda_j-\mu_i)y_j,$$

and $q_1\in\operatorname{span}\{y_1,\ldots,y_k\}$. Inductively, let $q_1,\ldots,q_s\in\operatorname{span}\{y_1,\ldots,y_k\}$. If $e_{s+1}=\sum_{j=1}^{k+p}\xi_{s,j}y_j$,

$$QRe_{s+1}=\sum_{j=1}^{s}r_{j,s+1}q_j+r_{s+1,s+1}q_{s+1}=\sum_{j=1}^{k}\xi_{s,j}\prod_{i=1}^{p}(\lambda_j-\mu_i)y_j,$$

and since $r_{s+1,s+1} \neq 0$, $q_{s+1} \in \text{span}\{y_1, \ldots, y_k\}$. Since Q is an orthogonal matrix, its first k columns are independent and therefore $\text{span}\{q_1, \ldots, q_k\} = \text{span}\{y_1, \ldots, y_k\}$. ∎

In the special case where the matrix H is the Hessenberg matrix obtained from the Arnoldi procedure, an immediate consequence is the following.

LEMMA 3.2. *If at step s the basis vectors $U_m^{(s)}$ and $V_m^{(s)}$ of GD(k,m) and IRA(k,m), respectively, span the same space, then, after restarting both methods,*

$$\text{span}(V_k^{(s+1)}) = \text{span}(U_k^{(s+1)}).$$

Proof. From the assumption, the Ritz vectors are the same for both methods at the end of the sth step, and after restarting, $U_k^{(s+1)}$ contains the k chosen ones, say X_k. If $Q(1:k)$ are the first k columns of the orthogonal matrix of Lemma 3.1, we have $V_k^{(s+1)} = V_m^{(s)} Q(1:k) = V_m^{(s)} Y(1:k) C = X_k C$, where $Y(1:k)$ are the chosen k eigenvectors of the Hessenberg matrix H_m, and C is some $k \times k$ coefficient matrix. ∎

The above shows the equivalence of the two methods at restart. To conclude the proof we need the following proposition which describes the residuals of the Ritz vectors of the Arnoldi procedure [19].

PROPOSITION 3.3. *At the jth step of inner Arnoldi loop, let y_i be the ith eigenvector of H_j associated with the eigenvalue λ_i, and x_i be the Ritz approximate eigenvector $x_i = V_j y_i$. Then,*

$$(A - \lambda_i I) x_i = h_{j+1,j} e_j^H y_i \; v_{j+1}.$$

THEOREM 3.4. *If GD(k,m) without preconditioning and IRA(k,m) are executed with the same initial vector $v^{(0)}$, and at each restarting the p shifts used in IRA(k,m) are the Ritz values of the Ritz vectors discarded by GD(k,m), then the basis vectors produced by the two methods span the same space, for any targeting scheme of GD(k,m), and thus the methods are equivalent.*

Proof. If the two methods start with the same initial vector and no restarting is used, the vectors built are identical. This is an immediate consequence of Proposition 3.3, for any selection of targets in GD(k,m). This is well established in the literature (see [16, 21]).

For the general case, a simple induction on the number s of restarts is used. From the above, it follows that for $s = 0$, the bases built by IRA(k,m) and GD(k,m) satisfy $V_m^{(0)} = U_m^{(0)}$.

Let, for $s > 0$, $\text{span}(V_m^{(s)}) = \text{span}(U_m^{(s)})$. After restarting both methods, and from Lemma 3.2, $\text{span}(V_k^{(s+1)}) = \text{span}(U_k^{(s+1)})$. As a result, at this k step, the Ritz vectors for both methods are the same, and because of Proposition 3.3, the next expansion vectors for both methods are parallel. Thus it holds, $\text{span}(V_{k+1}^{(s+1)}) = \text{span}(U_{k+1}^{(s+1)})$, and inductively

$$\text{span}(V_m^{(s+1)}) = \text{span}(U_m^{(s+1)}). \qquad ∎$$

A few comments are in order. Lemma 3.1 can be applied to the Hessenberg matrices built by Krylov subspace methods, if these are diagonalizable. This assumption is always satisfied by the tridiagonal matrices built in the symmetric case. This justifies the use of this result in Lemma 3.2 for the nonpreconditioned case.

Further, Lemma 3.1 applies to any non-Hessenberg diagonalizable matrix, and although Lemma 3.2 discusses the IRA(k,m) method, it is true for all methods that

use an implicit restarting scheme. Consequently, implicit restarting can be applied to the projection, full matrix T obtained from the preconditioned basis vectors of GD(k,m). If exact shifts are used, it produces a sequence of vectors that span the same space with the required Ritz vectors. Several numerical examples, however, have shown that this can be an unstable process. The reason is traced back to the forward numerical instability of the QR process. Treatments of the problem have been developed [12], but we find it inexpensive and stable to thick restart with the orthogonal (or orthogonalized in the nonsymmetric case) Ritz vectors.

In the preconditioned case, the application of implicit restarting does not result in a polynomial transformation as in (2.1). Specifically, let $U = \{u_1^{(0)}, \ldots, u_m^{(0)}\}$ be the GD(k,m) basis before restarting, with decomposition $AU = UT + E$ and $U^H E = 0$. Following steps similar to Lemma 3.1 and to those in [24], the first basis vector $u_1^{(1)}$ after the implicit restarting can be expressed as $u_1^{(1)} = \psi(UU^H AUU^H)u_1^{(0)} = U\psi(T)U^H u_1^{(0)}$, where ψ is the polynomial having the implicit shifts as roots. The polynomial transformation involves the projected matrix on the space spanned by U and not the full rank matrix A. An arbitrary choice of shifts may lead to a different polynomial, but there are no clear advantages for doing so.

Finally, in the unlikely case where preconditioning produces a defective projection matrix, both implicit and thick restarting may fail as described earlier. Working with the Schur vectors rather than the Ritz vectors provides a stable solution to the problem. The algorithm has been proposed recently in [10] and consists of a slight modification to the GD(k,m): instead of finding the eigendecomposition of T, a Schur decomposition is computed and the diagonal elements of the upper triangular matrix are used as shifts in the implicit restarting procedure. In this way the algorithm computes a partial Schur decomposition of A. Note that thick restarting can still be applied keeping more Schur vectors than needed.

4. The deflation connection. Krylov methods for linear systems, such as conjugate gradient (CG) and GMRES, demonstrate a superlinear convergence at later iterations. One explanation of this phenomenon is the convergence of the outermost eigenpairs of the matrix, so that each method behaves as if deflation has occurred, resulting in faster convergence. Such observations have appeared as early as in [5], but actual quantification of the behavior appears in [20] and [27, 28]. In the latter papers, the optimality of the CG and GMRES polynomials is employed to relate each method after some iterations with a similar process of the same method on a deflated residual.

Results similar to [28] cannot be applied directly to the residual and eigenvalues in the nonsymmetric Arnoldi, since there is no optimality principle. In the following, we extend the results found in [28] to the Arnoldi method by considering the distance of some eigenvector from the Arnoldi–Krylov subspace. Again, preconditioning is not considered since the space that it creates is not a Krylov subspace. This general result is used later in the context of thick/implicit restarting to justify the expected benefits and to help provide a good choice of k.

For simplicity, let A be a diagonalizable matrix, $X^{-1}AX = \Lambda = \text{diag}(\lambda_i)$, of order N. The results in this section can be extended naturally to the Jordan form of A, following the methodology in [28]. However, the presentation is more involved. Let $v = X\xi$ be the expansion of the starting Arnoldi vector to the eigenvector basis. Also let $\mathcal{K}_k(v)$ be the Krylov subspace of dimension k generated by v. Define three numbers satisfying $l < k' \leq k$, where $k-1$ is the number of steps that a nonrestarted Arnoldi method takes starting from v. We can assume an eigenvalue ordering so that

the first l ones are wanted, and the eigenvalues $l+1,\ldots,k'$ are well approximated by the $k-1$ steps of Arnoldi. Let μ_i be the k Ritz values from this $\mathcal{K}_k(v)$ space. At this point we let the Arnoldi process take p more steps and build the space $\mathcal{K}_{k+p}(v)$. The following shows the ordering of these numbers:

Define $\mathcal{D}^{(k)}$ a diagonal matrix with elements

$$\mathcal{D}^{(k)}_{jj} = \begin{cases} 0, & \text{for } j = l+1,\ldots,k', \\ \prod_{i=l+1}^{k'} \frac{\lambda_j-\lambda_i}{\lambda_j-\mu_i}, & \text{for } j \le l \text{ or } j = k'+1,\ldots,N. \end{cases} \tag{4.1}$$

Assuming the above definitions we have the following theorem.

THEOREM 4.1. *Let x_j be an eigenvector to be approximated from the Krylov subspace $\mathcal{K}_{k+p}(v)$, and $\tilde{x}_j$ be the corresponding Ritz vector from $\mathcal{K}_k(v)$, whose components of $x_{l+1},\ldots,x_{k'}$ have been removed. If these Krylov subspaces can be built, then for any $j = 1,\ldots,l$*

$$\operatorname{dist}(x_j, \mathcal{K}_{k+p}(v)) \le |1 - \mathcal{D}^{(k)}_{jj}| + \|X\mathcal{D}^{(k)}X^{-1}\| \operatorname{dist}(x_j, \mathcal{K}_p(\tilde{x}_j)).$$

Proof. At step $k-1$ of the Arnoldi procedure, the Ritz vector x'_j from $\mathcal{K}_k(v)$ has the following expression:

$$x'_j = q_j(A)v/\|q_j(A)v\|, \quad \text{with}$$
$$q_j(t) = \prod_{i=1, i\ne j}^{k} (t-\mu_i).$$

We define $h(t)$ a polynomial of degree $k-1$ as

$$h(t) = \prod_{i=l+1}^{k'} \frac{(t-\lambda_i)}{(t-\mu_i)} q_j(t).$$

Note that the eigencomponents $l+1,\ldots,k'$ of the vector $h(A)v$ are annihilated. If $\tilde{\xi}_i = 0$ for $i = l+1,\ldots,k'$ and $\tilde{\xi}_i = \xi_i$ otherwise, then $\tilde{x}_j = \frac{1}{\phi} X q_j(\Lambda)\tilde{\xi}$, where ϕ is a normalization factor. Since any vector in $\mathcal{K}_{k+p}(v)$ can be expressed as a polynomial of A applied on v, if π^* is some polynomial of degree p, and e_j is the jth orthocanonical vector, we have

$$\begin{aligned} \operatorname{dist}(x_j, \mathcal{K}_{k+p}(v)) &= \min_{q, deg(q)=k+p-1} \|x_j - q(A)v\| \\ &\le \|x_j - \pi^*(A)h(A)X\xi\| \\ &= \|x_j - X\pi^*(\Lambda)\mathcal{D}^{(k)}q_j(\Lambda)\xi\| \\ &= \|x_j - X\mathcal{D}^{(k)}X^{-1}X\pi^*(\Lambda)q_j(\Lambda)\tilde{\xi}\| \\ &= \|x_j - X\mathcal{D}^{(k)}X^{-1}\pi^*(A)\phi\tilde{x}_j\| \\ &= \|x_j - X\mathcal{D}^{(k)}X^{-1}(Xe_j - Xe_j + \pi^*(A)\phi\tilde{x}_j)\| \\ &\le \|x_j - \mathcal{D}^{(k)}_{jj}x_j\| + \|X\mathcal{D}^{(k)}X^{-1}\|\|x_j - \pi^*(A)\phi\tilde{x}_j\|. \end{aligned} \tag{4.2}$$

The result follows by choosing $\pi^* = \frac{1}{\phi}\pi_d$, where π_d is the polynomial that minimizes the distance of x_j from $\mathcal{K}_p(\tilde{x}_j)$, and assuming $\|x_j\| = 1$. ∎

The term $\|X\mathcal{D}^{(k)}X^{-1}\|$ is bounded as follows [28]:

$$\|X\mathcal{D}^{(k)}X^{-1}\| < k_2(X) \max_{j \neq l+1,\ldots,k'} \prod_{i=l+1}^{k'} \frac{\lambda_j - \lambda_i}{\lambda_j - \mu_i} = k_2(X)F_k,$$

where $k_2(X) = \|X\|\|X^{-1}\|$ is the condition number of the matrix X. If k is large enough, then the approximations μ_i converge to λ_i for $i = 1, \ldots, k'$. Thus, $F_k \to 1$, and $|1 - \mathcal{D}_{jj}^{(k)}| \to 0$. Even when these are not accurately converged, provided that $\mathcal{O}(\text{dist}) < \mathcal{O}(|1-\mathcal{D}_{jj}^{(k)}|)$, the distance behaves similarly to the distance from a deflated Krylov subspace. It should be noted that the above bound is rather pessimistic, since $\mathcal{D}^{(k)}$ converges to a part of the identity matrix and thus $X\mathcal{D}^{(k)}X^{-1}$ converges to a spectral projector.

4.1. Deflation in IRA (k, m). Theorem 4.1 can be applied to the $k+p$ vectors at the end of an IRA(k, m) step. As previously, l eigenpairs are needed, k pairs are retained after each restart, and $p = m - k$ additional vectors are built. Theorem 4.1 applies with the same l, k, p, and $k' = k$:

$$\text{dist}(x_j, \mathcal{K}_{k+p}(v^{(s)})) \leq |1 - \mathcal{D}_{jj}^{(k,s)}| + \|X\mathcal{D}^{(k,s)}X^{-1}\| \text{ dist}(x_j, \mathcal{K}_p(\tilde{x}_j)).$$

Note that the space $\mathcal{K}_k(v^{(s)})$ contains exactly the wanted k Ritz vectors at the end of the previous $s-1$ step. From the comments in section 2, the Krylov space $\mathcal{K}_{k+p}(v^{(s)})$ is built implicitly by only p steps. Therefore, Theorem 4.1 relates the p steps of the deflated method, to p, rather than $k + p$ steps of the original method.

The diagonal elements of $\mathcal{D}^{(k,s)}$ depend on two parameters: k is the number of the initial Krylov steps, and s is the restarting step on which the theorem is applied. Since k in IRA(k, m) is bounded, the reason for convergence of $\mathcal{D}_{jj}^{(k,s)}$ is assumed by s, the step number. It has been proved for the symmetric case, and under certain assumptions for the nonsymmetric case [24], that the retained eigenpairs in IRA(k, m) converge. Thus, $F_k^{(s)} \to 1$ and $|1 - \mathcal{D}_{jj}^{(k,s)}| \to 0$, as $s \to \infty$. After several restarts, the IRA(k, m) method builds a space close to the one built by an IRA(k, m) applied on a system deflated from the eigencomponents $l + 1, \ldots, k$. Because of Theorem 3.4, the GD(k, m) performs in a similar way.

The above results suggest that there are advantages in keeping more vectors at each restart, i.e., using a thicker restart. If only the wanted eigenpairs $(1, \ldots, l)$ are retained at restart, the method does not demonstrate the deflation behavior for any other eigenpairs. At every restarting the current approximations of eigenpairs $(l + 1, \ldots, k + p)$ are annihilated, and thus they do not converge. Frequently, some eigenvalues close to the wanted ones or close to the other end of the spectrum are relatively well approximated before restarting, and if retained, they would have converged soon. Even more undesirable is the fact that these approximations will slowly reappear in the Krylov subspace, since their approximations are not accurate enough to completely annihilate the corresponding eigenvectors. Therefore, thick restarting should almost always be beneficial.

5. Dynamic thick restarting in the symmetric case. In this section we restrict the discussion to the symmetric case where explicit bounds for convergence rates are known. Two difficulties are associated with thick restarting: the choice of

which eigenpairs to retain and how many of them. It is well known that the Arnoldi method constructs vectors with strong components in the direction of the extreme eigenvectors (associated with extreme eigenvalues) and, therefore, close to the few wanted ones. Sleijpen and van der Vorst in [23] argue that the restarted Arnoldi method repeats the information for these extreme eigenpairs that are dispensed in previous iterations, and they propose keeping $l+1,\ldots,k$ eigenvalues closest to the wanted ones. A similar strategy is followed in the implicit restarting of the ARPACK code. We denote this special case of GD(k,m) as TR(k), implying the basis size m.

The preceding discussion suggests that thick restarting should aim at improving the convergence of the method through deflation. TR(k) attempts to increase the gap of the wanted eigenvalues from the rest of spectrum by keeping nearby eigenpairs. The same objective is followed by subspace iteration where the number of vectors determines the rate of convergence. Since IRA(k,m) can be interpreted as an efficient way to perform subspace iteration [12], similar restarting considerations hold. However, convergence depends on the gap ratios of the eigenvalues and, therefore, the other end of the spectrum is also of importance. A more general form of thick restarting would be TR(L,R), where L lowest (leftmost) and R highest (rightmost) eigenvectors are kept.

We need to address the issue of choosing optimal restarting parameters. In ARPACK, k is chosen dynamically, starting from a relatively small number and increasing it every time an eigenvalue converges. This attempts to maintain a "constant" gap, and it is slightly different from the strategy reported in [24], where values of k close to $m/2$ usually gave the best results.

Because of the deflation relation, the thicker the restarting, the larger the part of the spectrum that is deflated. However, the basis size m is limited, and if too many vectors are retained when restarting, the Lanczos process cannot effectively build additional basis vectors. A dynamic choice of the parameters L and R should be able to capture this trade-off. For the Lanczos procedure, convergence is governed by a term involving a Chebyshev polynomial. If p Lanczos steps are taken, the error of the ith eigenvalue involves the following term:

$$\frac{1}{T_p^2(1+2\gamma_i)}, \quad \text{with } \gamma_i = \frac{\lambda_i - \lambda_{i+1}}{\lambda_{i+1} - \lambda_N}.$$

γ_i is the gap ratio of the ith eigenvalue, and for small gap ratios (i.e., difficult problems) the above term behaves as

$$\frac{1}{T_p^2(1+2\gamma_i)} \approx 2e^{-2p\sqrt{\gamma_i}}. \tag{5.1}$$

The L and R thick restarting parameters should maximize the deflated gap ratio $\gamma_i = (\lambda_i - \lambda_{L+1})/(\lambda_{L+1} - \lambda_{N-R})$ and also maximize the number of new Lanczos steps $p = m - L - R$. The trade-off is captured by minimizing the error approximation equation (5.1). Since the actual eigenvalues are not known, the m approximate Ritz values (μ_i) before restarting should be used to estimate the spectrum. Thus, assuming the l lowest eigenpairs are sought, L and R are obtained dynamically by maximizing the following expression:

$$\max_{L=l,\ldots,m,\ R=0,\ldots,m-l,\ L+R<m} (m-L-R)\sqrt{\frac{\lambda_i - \lambda_{L+1}}{\lambda_{L+1} - \lambda_{m-R}}}.$$

We implement a combination of the dynamic restarting and the TR(L) schemes. Similarly to subspace iteration and ARPACK, we keep at least $L' > l$ vectors from the side of the required eigenpairs to guarantee an increased separation gap. In the experiments in the next section the value $L' = 10$ is chosen. The dynamic scheme is adopted for the rest of the vectors, maximizing the above expression for $L = L', \ldots, m$. In this way, we capture the benefits from both strategies. It has been observed that if some unwanted eigenvector has converged, it is usually beneficial to include it in restarting, since this information may be slowly repeated. We do not consider this option and let the dynamic choice of L and R take care of such cases.

For the nonsymmetric GD(k, m) a similar expression may be maximized, where the Ritz values are ordered according to the required objective, i.e., largest modulus, largest real part, etc. Often, this ordering corresponds to the outermost eigenvalues of the spectrum that the Arnoldi method approximates first, and thus similar deflation arguments can be made. However, this may not always be true, and the choice is more ad hoc because of lack of general expressions for convergence rates. The dynamic strategy can also be used in case of preconditioning, although its effects are expected to be less pronounced for two reasons. First, the spectrum of the varying operator is transformed by the preconditioners and, second, the preconditioning equation usually targets one specific eigenvector for correction, offering little improvement to the rest of the eigenvectors. Often, however, the use of less efficient preconditioners does not affect the eigenvalue order significantly, and thick restarting can perform as well in this case. Finally, dynamic thick restarting can be used in both GD(k, m) and in the IRA(k, m) of the ARPACK package.

6. Numerical experiments. In the first part of this section we give a small artificial example which demonstrates the increasing effect of deflation in thick restart TR(k). In the second part, we present results from a large number of tests on the symmetric matrices of the Harwell–Boeing collection [9]. The GD(k, m) code is based on a program published in [25] and the extensions proposed in [26]. It implements a variable block generalized Davidson method, using the reverse communication protocol for matrix–vector multiplication and preconditioning operations. Robust shifting and the Olsen strategy, which is equivalent to the Jacobi–Davidson approach in exact arithmetic [23], are adopted in preconditioning. In the third and fourth parts, the dynamic strategy is used to provide the shifts to the IRA(k, m) of the ARPACK implementation. Results from standard nonsymmetric cases are reported in the third part. In the last part, comparisons with the original ARPACK code, and with the ARPACK code using Leja shifts [2] in the symmetric case, facilitate a discussion on the effects of the basis size.

6.1. Deflation works. The GD(k, m) is applied on an artificially generated diagonal matrix of order 100 and elements:

$$A_{jj} = \begin{cases} j/55, & \text{for } j = 1, \ldots, 8, \\ 19/55 + j/55, & \text{for } j = 9, \ldots, 16, \\ j - 16, & \text{for } j = 17, \ldots, 100. \end{cases} \tag{6.1}$$

The lowest eigenvalues of this matrix are grouped in two clusters of eight equidistant eigenvalues each. The separation between the two groups is equal to the separation of the second group from eigenvalue 17. Figure 6.1 depicts the lowest part of this spectrum. We look for the lowest eigenvalue and allow for 20 basis vectors in all versions of GD(k, m). The history of the logarithm of the eigenvalue error is plotted in Figure 6.2 for various restarting thicknesses of TR(k).

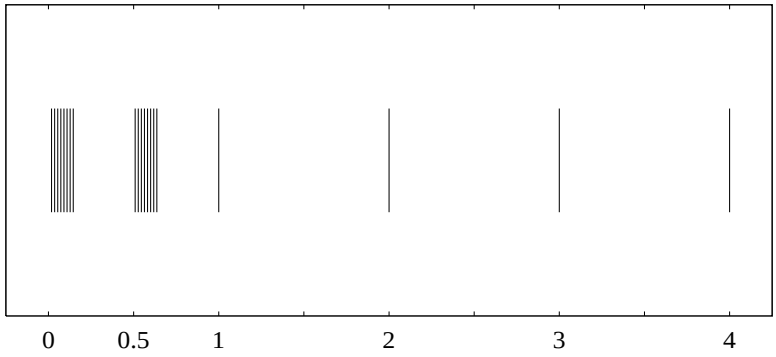

FIG. 6.1. *The lowest* 20 *eigenvalues of the* 100×100 *matrix. The first two clusters contain eight equidistant eigenvalues each. The rest of the* 80 *eigenvalues are the integers from* 5 *up to* 84.

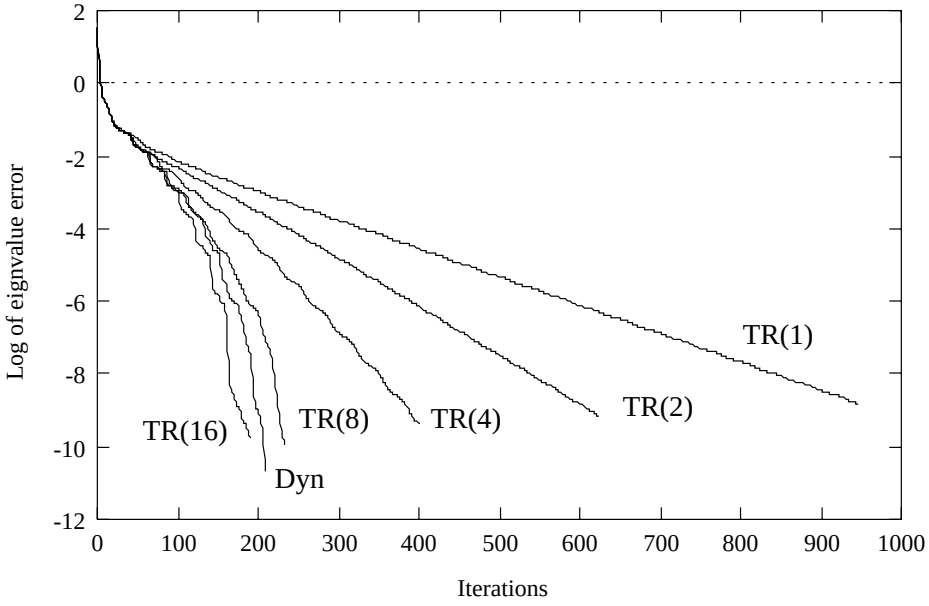

FIG. 6.2. *Effects of thick restarting to the convergence of the generalized Davidson. No preconditioning is used, and the lowest eigenvalue is sought. TR(k) denotes GD(k,*20*).*

As expected, the poor separation of the lowest eigenvalue results in a very slow original GD(20) (or TR(1)) method. A very good approximation of the second eigenvalue is available quite early, and thus when retained (TR(2)), the convergence rate improves by 30%, and similarly with TR(4) and TR(8). The superlinear convergence is more evident in TR(8). In early iterations, higher eigenvalues are not well approximated and TR(8) behaves similarly to TR(1) and TR(2). Later, as better approximations for eigenvalues 2–4 appear, TR(8) is similar to TR(4), and as higher eigenvalues settle down, TR(8) exhibits a concave convergence curve.

Methods TR(k), with $8 < k < 16$, are similar to TR(8) since there is no significant improvement to the deflated gap ratio. In theory, TR(16) should be different because of the large separation between eigenvalues 16 and 17. In practice, however, TR(16) does not perform significantly better than TR(8). The reason is that the Krylov

subspace is of dimension 20, and it is difficult for the 16th Ritz eigenvalue to converge. The dynamic thick restarting, shown as Dyn in the figure, takes advantage of both ends of the spectrum and performs better than TR(8) and close to TR(16), requiring no prior knowledge about the spectrum.

6.2. Harwell–Boeing tests. To confirm the theoretical benefits of thick and dynamic thick restarting, a wide variety of tests have been performed on the symmetric matrices from the Harwell–Boeing collection. This includes a set of 67 matrices with orders ranging from 48 to 15,439. Some of matrices have been derived from eigenvalue problems, but for almost all of them, the lowest end of the spectrum is very poorly conditioned, making them particularly hard test problems. The higher end of the spectrum usually consists of well separated, very large eigenvalues, providing a good test for easy or intermediate problems.

We have compared three different versions of GD(k, m) for both the lower and the higher part of the spectrum. Five eigenvalues are sought and the basis size m for all GD methods is 20. An eigenpair is considered converged when the norm of its residual is less than $10^{-12}\|A\|_F$, where $\|A\|_F$ is the Frobenius norm of its matrix. For the highest eigenvalues only the nonpreconditioned versions of GD(k, m) are considered, while for the lowest ones we consider diagonal and approximate inverse preconditioning. The former is computed at every step as $(\mathrm{diag}(A) - \mu)^{-1}$, and the latter is only computed once as the approximate inverse of A [4]. Since most of the matrices are positive definite, this is a relatively powerful preconditioner.

In Table 6.1, the results from the lower part of the spectrum are reported. A maximum number of 5000 matrix–vector multiplications is allowed. The table does not include any of the diagonal matrices. As it is easily seen, TR(11) outperforms the original Davidson method (TR(5)), except for BCSSTK22. It is usually several times faster, and offers better robustness, converging for six additional matrices. Further, dynamic thick restarting improves both the robustness and the speed in almost all cases. Sometimes the reduction in the matrix–vector multiplication number can be as high as 50 to 70% over TR(11). With diagonal preconditioning TR(11) still outperforms TR(5) in both convergence and robustness. Dynamic thick restarting improves convergence even further, although the improvements are not as impressive as in the nonpreconditioned case. On average, the approximate inverse preconditioner is better than the diagonal one but with several exceptions since it depends on the characteristics of the matrix. Dynamic thick restarting still performs much better than the original approach, and it is relatively faster and more robust than TR(12). However, as mentioned in the previous section, in those cases where approximate inverse works well, the differences between thick and dynamic thick restarting diminish because of the higher quality preconditioner.

Similar behavior of the methods is shown in Table 6.2, where the five largest eigenpairs are required. Dynamic thick restarting improves on the performance of TR(10) which in turn improves on the performance of TR(5). However, the few steps required for the problems in this table do not yield the same impressive improvements as in Table 6.1.

6.3. The effect of the basis size. The dynamic thick restarting strategy, developed for the GD(k, m), can also be used to provide the shifts to the ARPACK code through the supplied reverse communication protocol. Results from this implementation when seeking one lowest eigenpair of the Harwell–Boeing collection appear in Table 6.3. Two tests are performed, one with basis size of 25 and one with basis size of 10. The dynamic restarting significantly improves the speed and robustness of

TABLE 6.1

Comparison of thick (TR(L)) and dynamic thick restarting (Dyn) with original Davidson (TR(5)) on symmetric Harwell–Boeing matrices, with diagonal and approximate inverse preconditioners. The number of matrix–vector multiplications is reported, with a maximum of 5000. *Five smallest eigenvalues are sought. The GD codes use basis size of* 20.

+ denotes that one eigenpair has been skipped

the native restarting scheme of ARPACK, which for one eigenvalue is the equivalent with thick restart of half the basis size. What is more interesting is that dynamic restarting seems much less sensitive to reduction of the basis size. Similar insensitivity to the basis size has recently been demonstrated through the use of Leja points as shifts in IRA(k, m) [2]. We have implemented the Leja shifts restarting strategy as outlined in [2], and the results appear in Table 6.3. For the small basis size, dynamic thick restarting and Leja shifts are comparable. However, as the basis size increases, the dynamic strategy is more efficient and even more robust. Although Leja shifts may be better for extremely small spaces (less than five vectors), they are harder to implement and they are more expensive to compute.

Experience with the dynamic thick restarting has shown that most of the vectors are retained at every restart, and only three or four are annihilated. The range of the annihilated ones varies from step to step. Figure 6.3 shows the range of eigenvalues which the filtering polynomial covers, as well as the shifts of this polynomial, at every restart for a typical case. We have observed that it is important to have both a small degree polynomial at every restart (i.e., only few eigenvalues annihilated) and to also vary the range from where these shifts are chosen. Therefore, TR(16) does

TABLE 6.2

not perform as well as dynamic restarting, even though, on average, it retains the same number of vectors. Also, if we force the dynamic restarting to annihilate more than five or six shifts at every restart, the scheme does not perform as well either. The efficiency of the dynamic thick restarting may be attributed to the fact that the filtering polynomial is of low degree and seems to select the best region to dampen, without growing fast outside these regions. The efficient use of the Leja shifts in the ARPACK also exhibits analogous requirements.

Finally, we should point out that the above results compare the number of matrix–vector multiplications of the methods. This is an acceptable performance metric if the matrix–vector operation is expensive. Since, on average, thick restarting uses more vectors in the basis than the original Davidson, its Davidson step is also more expensive. Although improvements like the ones in Table 6.1 justify any increase in the expense of the Davidson step, for easier cases a less aggressive choice of restarting might be more effective.

6.4. Thick restarting in the nonsymmetric case. As in the symmetric case, we can likewise use the dynamic thick restarting scheme to provide the shifts to the nonsymmetric ARPACK code. Results from this implementation applied on the nonsymmetric matrices of the test matrix collection of eigenvalue problems of Bai et al. [1] appear in Table 6.4. All the matrices stem from standard eigenvalue problems, except ODEP400A which is included because it is close to symmetric. Since for almost all examples the rightmost eigenpairs are of interest, we look for five eigenpairs with largest real parts. The convergence threshold for ARPACK is set to 10^{-12}, and a maximum of 5000 matrix–vector multiplications is allowed.

The shifts for thick restarting are chosen similarly to the symmetric case. First, we order the Ritz values according to their real parts. The dynamic scheme works on

TABLE 6.3

these real parts, yielding the numbers L and R on the real axis. We then supply the corresponding Ritz values as shifts to ARPACK, requiring that conjugate Ritz values are either annihilated together or kept together.

The results show that the thick restarted versions improve efficiency and robustness of the native scheme of ARPACK, and that thicker restarting schemes achieve better efficiencies. This is expected by analogy with the subspace iteration method. The dynamic thick restarting is not uniformly better than the rest as in the symmetric case. In fact, it seems comparable to TR(20) which, on average, keeps the same number of vectors as the dynamic one. As mentioned in section 5, the extreme eigenpairs chosen by the dynamic scheme are based on the ordering of the real parts of the Ritz values and may not always represent the extreme eigenpairs approximated well by the Arnoldi method. In spite of this, dynamic thick restarting is still the most robust of the methods used and shows that the efficiency of the one-sided thick restarting can be improved.

7. Conclusions. Restarting is a necessary technique for solving large eigenvalue problems, which may cause significant convergence deterioration. In this paper we consider a class of restarting techniques which, at every restart, retain more Ritz vectors than needed, and we denote it as "thick restarting." The GD(k, m) and IRA(k, m) are proved to be equivalent in the absence of preconditioning and a relation is given between thick restarted Davidson and a Davidson method applied on a

deflated system. These theoretical results imply that retaining more outermost Ritz pairs can enhance convergence.

For the symmetric case, the results can be interpreted as an effort to increase the gap ratio for the required eigenvalues. Since the number of basis vectors is limited, the actual objective is to maximize the error reduction between restarts. This gives rise to a dynamic thick restarting technique which applies to IRA(k, m) and to the preconditioned GD(k, m). The extensive numerical experiments demonstrate the efficiency and robustness of the dynamic thick restarting and show that the robustness carries over to the nonsymmetric case. In addition, this scheme seems to be much less sensitive to smaller Krylov subspace dimensions and can be extremely beneficial in very large eigenvalue problems.

Acknowledgments. We are grateful to the referees and to H. A. van der Vorst whose insightful comments improved the presentation significantly. We also acknowledge R. B. Lehoucq for long, revealing discussions on implicit restarting, as well as E. Chow for kindly providing us with his approximate inverse preconditioning code.

CORRECTIONS TO "A TARGET RECOGNITION PROBLEM: SEQUENTIAL ANALYSIS AND OPTIMAL CONTROL"*

MARK H. A. DAVIS† AND MOHAMMAD FARID‡

Abstract. In the above-mentioned paper [*SIAM J. Control Optim.*, 34 (1996), pp. 2116–2132], despite the correct results, the proof of Theorem 4.6 has a subtle mistake. In the following paragraphs the correct proof, including Lemmas 4.7, 4.8, and 4.9, are given.

Key words. optimal control, viscosity solutions, variational inequality, dynamic programming

AMS subject classifications. 49J40, 49L25, 62C10, 62K05, 62L10, 93C15

PII. S0363012997320304

THEOREM 4.6. *Consider the following variational inequality for all* $(x,\pi) \in \mathbb{R}^n \times [0,1]$:

$$\max\left\{\sup_{u\in U}[-\ell(x,u) - g(x,u)\cdot D_x V(x,\pi)],\ V(x,\pi) - \psi(x,\pi)\right\} = 0, \tag{1}$$

and make all the assumptions of Theorem 4.2*; then if* $\psi(x,\pi) \geq 0\ \forall\ (x,\pi) \in \mathbb{R}^n \times [0,1]$ *there is at most one viscosity solution of* (1).

Without loss of generality we drop π in all the following arguments. We will need the following lemmas.

LEMMA 4.7. *Define* $H(x,p) := \sup_{u\in U}[-\ell(x,u) - g(x,u)\cdot p]$*; then* $H(x,p)$ *is a convex function with respect to* p.

Proof. This is easily verified. □

LEMMA 4.8. *Define*

$$\tilde{H}(x,r,p) := \max\{H(x,p),\ r - \psi(x)\},$$

where

$$\ell(x,u) \geq \delta > 0 \quad \forall\ (x,u) \in \mathbb{R}^n \times U,$$
$$\psi(x) \geq 0 \quad \forall\ x \in \mathbb{R}^n.$$

Then $\tilde{H}(x,V,DV)$ *has a strict subsolution* [BP88]*; i.e.,*

$$\exists w \in C^1(\mathbb{R}^n) \cap BUC(\mathbb{R}^n), B > 0, \quad \text{s.t. } \tilde{H}(x,w,Dw) \leq -\beta < 0 \quad \text{in } \mathbb{R}^n.$$

Proof. It is easily seen that $w(x) \equiv -\delta$ is a strict subsolution; i.e., $\max\{H(x,0),\ -\delta - \psi(x)\} \leq -\delta < 0$. □

LEMMA 4.9. *Assume that* $v_1(x)$ *is a viscosity subsolution of* $\tilde{H}(x,V,DV) = 0$. *Then* $v_\eta = \eta v_1 + (1-\eta)w$ *is a viscosity subsolution of*

$$\tilde{H}(x,V,DV) \leq -(1-\eta)\delta < 0, \tag{2}$$

*Received by the editors April 21, 1997; accepted for publication (in revised form) June 3, 1997; published electronically May 28, 1998.
http://www.siam.org/journals/sicon/36-4/32030.html
†Tokyo-Mitsubishi International Plc, 6 Broadgate, London EC2M 2AA, UK (mark.davis@t-mi.com).
‡Control Engineering Research Center, City University, London EC1V 0HB, UK (m.farid@city.ac.uk).

where $w(x)$ is a strict subsolution and $\eta \in (0,1)$.

Proof. v_1 is a viscosity subsolution of $\tilde{H}(x,V,DV)=0$, so for all $\varphi \in C^1(\mathbb{R}^n)$, if $v_1-\varphi$ attains a local maximum at $x_0 \in \mathbb{R}^n$, then

$$\tilde{H}(x_0, v_1(x_0), D\varphi(x_0)) \le 0.$$

When $v_1-\varphi$ attains a local maximum at x_0, so does $\eta v_1+(1-\eta)w-(\eta\varphi+(1-\eta)w)$ for $\eta \in (0,1)$. Here $w \in C^1(\mathbb{R}^n)$ is a strict subsolution of $\tilde{H}$. Now we show that $\eta v_1+(1-\eta)w$ is a strict viscosity subsolution of $\tilde{H}$:

$$\begin{aligned}
&\tilde{H}(x_0,\ \eta v_1(x_0)+(1-\eta)w(x_0),\ \eta D\varphi(x_0)+(1-\eta)Dw(x_0))\\
&\quad = \max\{H(x_0,\eta D\varphi(x_0)+(1-\eta)Dw(x_0)), \eta v_1(x_0)+(1-\eta)w(x_0)-\psi(x_0)\}\\
&\quad \le \max\{\eta H(x_0,D\varphi(x_0))+(1-\eta)H(x_0,Dw(x_0)), \eta v_1(x_0)+(1-\eta)w(x_0)-\psi(x_0)\}\\
&\quad \le \eta\max\{H(x_0,D\varphi(x_0)),\ v_1(x_0)-\psi(x_0)\}\\

&\quad \le -(1-\eta)\delta < 0,
\end{aligned}$$

because v_1 is a viscosity subsolution and w is a strict subsolution. ∎

Proof of Theorem 4.6. Consider the following auxiliary test function:

$$\Phi_{\epsilon,\alpha}(x,y) = v_\eta(x)-v_2(y)-\frac{|\,x-y\,|^2}{2\epsilon}-\frac{\alpha}{2}(|\,x\,|^2+|\,y\,|^2), \qquad \epsilon,\alpha>0,$$

where v_η and v_2 are a viscosity subsolution and a viscosity supersolution of (2) and (1), respectively. By definition, $v_\eta, v_2 \in BUC(\mathbb{R}^n)$. Let us define $M_\eta = \sup_{\mathbb{R}^n}(v_\eta - v_2)$; then if $M_{\epsilon,\alpha}$ denotes the maximum of $\Phi_{\epsilon,\alpha}$, one can prove the following properties (refer to Theorem 2.11 in [Bar94]).

- $M_{\epsilon,\alpha} \to M_\eta$ as $(\epsilon,\alpha)\to 0$.
- If $(x_{\epsilon,\alpha}, y_{\epsilon,\alpha})$ denotes the maximum point of $\Phi_{\epsilon,\alpha}$ then
  (a) $v_\eta(x_{\epsilon,\alpha})-v_2(y_{\epsilon,\alpha}) \to M_\eta$ when $(\epsilon,\alpha)\to 0$,
  (b) $\frac{|x_{\epsilon,\alpha}-y_{\epsilon,\alpha}|^2}{\epsilon} \to 0$ when $(\epsilon,\alpha)\to 0$,
  (c) $\alpha(|\,x_{\epsilon,\alpha}\,|^2+|\,y_{\epsilon,\alpha}\,|^2)\to 0$ when $(\epsilon,\alpha)\to 0$.

Thus one can conclude that $|\,x_{\epsilon,\alpha}-y_{\epsilon,\alpha}\,| \to 0$ and $\alpha x_{\epsilon,\alpha}, \alpha y_{\epsilon,\alpha} \to 0$ when $(\epsilon,\alpha)\to 0$. Define

$$w_1(x) = v_2(y_{\epsilon,\alpha})+\frac{|\,x-y_{\epsilon,\alpha}\,|^2}{2\epsilon}+\frac{\alpha}{2}(|\,x\,|^2+|\,y_{\epsilon,\alpha}\,|^2);$$

then obviously $w_1 \in C^\infty(\mathbb{R}^n)$ and $v_\eta - w_1$ attains its maximum at $x_{\epsilon,\alpha}$. According to Lemma 4.9 we have

$$\max\{H(x_{\epsilon,\alpha}, p_{\epsilon,\alpha}+\alpha x_{\epsilon,\alpha}),\ v_\eta(x_{\epsilon,\alpha})-\psi(x_{\epsilon,\alpha})\} \le -\delta_\eta < 0, \tag{3}$$

where $p_{\epsilon,\alpha} := (x_{\epsilon,\alpha}-y_{\epsilon,\alpha})/\epsilon$ and $\delta_\eta := (1-\eta)\delta$. Now define

$$w_2(y) = v_\eta(x_{\epsilon,\alpha})-\frac{|\,x_{\epsilon,\alpha}-y\,|^2}{2\epsilon}-\frac{\alpha}{2}(|\,x_{\epsilon,\alpha}\,|^2+|\,y\,|^2),$$

where $w_2 \in C^\infty(\mathbb{R}^n)$ and v_2-w_2 attains its minimum at $y_{\epsilon,\alpha}$, thus

$$\max\{H(y_{\epsilon,\alpha}, p_{\epsilon,\alpha}-\alpha y_{\epsilon,\alpha}),\ v_2(y_{\epsilon,\alpha})-\psi(y_{\epsilon,\alpha})\} \ge 0. \tag{4}$$

The inequality in (3) implies that

$$\begin{cases} H(x_{\epsilon,\alpha}, p_{\epsilon,\alpha} + \alpha x_{\epsilon,\alpha}) \le -\delta_\eta < 0 \\ v_\eta(x_{\epsilon,\alpha}) - \psi(x_{\epsilon,\alpha}) \le -\delta_\eta < 0 \end{cases} \qquad \forall \epsilon, \alpha > 0. \tag{5}$$

One can show that

$$\begin{aligned} |H(x_{\epsilon,\alpha},\ p_{\epsilon,\alpha} + \alpha x_{\epsilon,\alpha}) - H(y_{\epsilon,\alpha},\ p_{\epsilon,\alpha} - \alpha y_{\epsilon,\alpha})| \le\ & m_\ell(|x_{\epsilon,\alpha} - y_{\epsilon,\alpha}|) \\ & + K|x_{\epsilon,\alpha} - y_{\epsilon,\alpha}||p_{\epsilon,\alpha} + \alpha x_{\epsilon,\alpha}| \\ & + C\alpha|x_{\epsilon,\alpha} + y_{\epsilon,\alpha}|, \end{aligned}$$

where $m_\ell \in C([0,\infty))$ with $m_\ell(0) = 0$ (i.e., m_ℓ is the modulus of continuity for ℓ), K is the Lipschitz constant of g, and $C = \sup_{(x,u)} |g(x,u)|$. Finally taking the limit when $(\epsilon, \alpha) \to 0$ gives

$$\lim_{(\epsilon,\alpha)\to 0} |H(x_{\epsilon,\alpha}, p_{\epsilon,\alpha} + \alpha x_{\epsilon,\alpha}) - H(y_{\epsilon,\alpha}, p_{\epsilon,\alpha} - \alpha y_{\epsilon,\alpha})| = 0;$$

thus there exists $\epsilon_0, \alpha_0 > 0$ such that for all $0 < \epsilon < \epsilon_0$ and $0 < \alpha < \alpha_0$ we have (see the first inequality in (5))

$$H(y_{\epsilon,\alpha}, p_{\epsilon,\alpha} - \alpha y_{\epsilon,\alpha}) \le -\delta_\eta/2 < 0. \tag{6}$$

Using (4) and (6) one can easily conclude that

$$v_2(y_{\epsilon,\alpha}) - \psi(y_{\epsilon,\alpha}) \ge 0 \quad \forall\ 0 < \epsilon < \epsilon_0 \text{ and } 0 < \alpha < \alpha_0.$$

Since for all $x \in \mathbb{R}^n$, $\Phi_{\epsilon,\alpha}(x,x) \le \Phi_{\epsilon,\alpha}(x_{\epsilon,\alpha}, y_{\epsilon,\alpha})$, one can write

$$\begin{aligned} v_\eta(x) - v_2(x) - \alpha \mid x \mid^2 &\le v_\eta(x_{\epsilon,\alpha}) - v_2(y_{\epsilon,\alpha}) - \frac{|x_{\epsilon,\alpha} - y_{\epsilon,\alpha}|^2}{2\epsilon} \\ &\quad - \frac{\alpha}{2}(|x_{\epsilon,\alpha}|^2 + |y_{\epsilon,\alpha}|^2), \\ &= (v_\eta(x_{\epsilon,\alpha}) - \psi(x_{\epsilon,\alpha})) - (v_2(y_{\epsilon,\alpha}) - \psi(y_{\epsilon,\alpha})) \\ &\quad + (\psi(x_{\epsilon,\alpha}) - \psi(y_{\epsilon,\alpha})) - \frac{|x_{\epsilon,\alpha} - y_{\epsilon,\alpha}|^2}{2\epsilon} \\ &\quad - \frac{\alpha}{2}(|x_{\epsilon,\alpha}|^2 + |y_{\epsilon,\alpha}|^2), \\ &\le (\psi(x_{\epsilon,\alpha}) - \psi(y_{\epsilon,\alpha})) - \frac{|x_{\epsilon,\alpha} - y_{\epsilon,\alpha}|^2}{2\epsilon} \\ &\quad - \frac{\alpha}{2}(|x_{\epsilon,\alpha}|^2 + |y_{\epsilon,\alpha}|^2), \end{aligned}$$

where in the last inequality we have $0 < \epsilon < \epsilon_0$ and $0 < \alpha < \alpha_0$, so when $(\epsilon, \alpha) \to 0$ one gets $v_\eta(x) - v_2(x) \le 0$ or

$$v_\eta(x) \le v_2(x).$$

Now let $v_\eta(x) = \eta v_1(x) + (1-\eta)w(x)$, where v_1 is a viscosity subsolution and w is a strict subsolution (see Lemma 4.9); then we have

$$\eta v_1(x) + (1-\eta)w(x) \le v_2(x) \quad \forall x \in \mathbb{R}^n \text{ and } \eta \in (0,1).$$

Let $\eta \to 1$ and one finally gets

$$v_1(x) \leq v_2(x). \tag{7}$$

The inequality in (7) simply says that any viscosity subsolution is less than or equal to any viscosity supersolution. A viscosity solution is both a viscosity subsolution and a viscosity supersolution, so if V_1 and V_2 are two different viscosity solutions for (1), then by (7) we must have $V_1 \leq V_2$ and $V_1 \geq V_2$, which implies that $V_1 = V_2$. So there is at most one viscosity solution of (1). □

ASYMPTOTIC CONTROLLABILITY AND EXPONENTIAL STABILIZATION OF NONLINEAR CONTROL SYSTEMS AT SINGULAR POINTS*

LARS GRÜNE†

Abstract. We discuss the relation between exponential stabilization and asymptotic controllability of nonlinear control systems with constrained control range at singular points. Using a discounted optimal control approach, we construct discrete feedback laws minimizing the Lyapunov exponent of the linearization. Thus we obtain an equivalence result between uniform exponential controllability and uniform exponential stabilizability by means of a discrete feedback law.

Key words. stabilization, nonlinear control systems, singular points, Lyapunov exponents, discounted optimal control problems, discrete feedback control

1. Introduction.

In this paper we will present a technique for the exponential stabilization of nonlinear control systems with constrained control range at singular points. In particular we address the relation between asymptotic controllability and exponential stabilization and will derive an equivalence theorem. In our context a singular point is a fixed point for each admissible control value of the control system. Such singular situations do typically occur if the control enters in the parameters of an uncontrolled system at a fixed point, for instance, when the restoring force of a nonlinear oscillator is controlled. One example to which our results can be applied is the stabilization problem of an inverted pendulum for which the suspension point is moved up and down periodically and the period of this motion can be controlled; cf. [14]. The main tool used throughout this paper is the linearization of the nonlinear system which forms a semilinear system. For two-dimensional control affine systems this linearization approach has been carried out in [4], giving a characterization of feedback stabilizability by algebraic methods.

The approach we follow here is based on optimal control techniques. More precisely, we consider the Lyapunov exponents of the linearization and formulate a discounted optimal control problem in order to minimize these exponents—an idea that was first presented in [12]. Lyapunov exponents have recently turned out to be a suitable tool for the stability analysis of semilinear systems, see, e.g., [7] and [8], and also for their stabilization [11]. However, due to the fact that for discounted optimal control problems optimal feedback laws are in general not available, we modify the feedback concept and introduce *discrete feedback laws* that are based on a discrete time sampled approximation of the given continuous time system. Using this approach it could be shown in [11] that, for semilinear systems satisfying an accessibility condition, exponential null controllability is equivalent to exponential stabilizability by discrete feedback. Using a similar feedback concept, a result on the relation between

asymptotic null controllability and practical stabilization for nonlinear systems has been developed in [5] using Lyapunov functions.

This paper is organized into two parts. In the first part we will focus on semilinear systems and extend the results from [11] and [12]. In particular in section 3 we will discuss different null controllability concepts for semilinear systems and extend the approximation results from [12] to general semilinear systems without any accessibility assumptions. Then in section 4 we will use this result in order to construct a stabilizing discrete feedback law following the outline of [11].

In the second part we will apply this discrete feedback to a general nonlinear system at a singular point. For this purpose we will first prove a robustness property of the discrete feedback in section 5. Using this result we will present the main theorem in section 6, stating that (local) uniform exponential null controllability is equivalent to (local) exponential stabilizability by means of a discrete feedback.

2. Preliminaries. We are interested in the stabilization of nonlinear control systems on $\mathbb{R}^d \times M$ given by

$$\begin{aligned} \dot{x}(t) &= f(x(t), y(t), u(t)), \\ \dot{y}(t) &= g(y(t), u(t)), \end{aligned} \tag{2.1}$$

where $x \in \mathbb{R}^d$ and $y \in M$, M is some Riemannian manifold and f and g are vector fields which are C^2 in x, Lipschitz in y, and continuous in u. The control function $u(\cdot)$ may be chosen from the set $\mathcal{U} := \{u : \mathbb{R} \to U \,|\, u(\cdot) \text{ measurable}\}$, where $U \subset \mathbb{R}^m$ is compact, i.e., we have a constrained set of control values.

For each pair (x_0, y_0) of initial values, the trajectories of (2.1) will be denoted by the pair $(x(t, x_0, y_0, u(\cdot)),\ y(t, y_0, u(\cdot)))$ and we assume them to exist uniquely for all times.

Our interest lies in the stabilization of the x-component at a *singular point* x^*, i.e., a point where $f(x^*, y, u) = 0$ for all $(y, u) \in M \times U$. Throughout the paper we will assume $x^* = 0$.

Note that our general setup covers several models: the additional equation for y allows us to model systems where time varying parametric excitations governed by an additional (nonlinear) control or dynamical system enter the system to be stabilized. The case in which the control u does not enter explicitly in the function f and the case in which f does not depend on y occur as special situations in this setup; hence they are also covered.

Our main tool for the stabilization is the linearization of (2.1) at the singular point which is given by

$$\begin{aligned} \dot{z}(t) &= A(y(t), u(t))z(t), \\ \dot{y}(t) &= g(y(t), u(t)). \end{aligned} \tag{2.2}$$

Here $A(y, u) := \frac{\partial}{\partial x} f(x^*, y, u) \in \mathbb{R}^{d \times d}$ and $f(x, y, u) = A(y, u)x + \tilde{f}(x, y, u)$. Then for any given compact subset $K \subset M$ the differentiability assumption on f implies the inequality

$$\|\tilde{f}(x, y, u)\| \le C_f \|x\|^2 \tag{2.3}$$

which holds for some constant C_f for all $y \in K$ and all x in a neighborhood of x^*.

As above we denote the trajectories of (2.2) by $(z(t, z_0, y_0, u(\cdot)),\ y(t, y_0, u(\cdot)))$ for the pair of initial values $(z_0,\ y_0)$.

The first step is now to analyze and characterize the null controllability of (2.2).

3. Lyapunov exponents and their approximation. This section is concerned with the asymptotic null controllability of the semilinear system (2.2). From [7] it is known for bilinear systems that exponential null controllability of (2.2) can be characterized by certain Lyapunov exponents, provided an accessibility condition holds and the matrix A does not depend on y. These conditions will be dropped here and in addition we will show that the characterization is also valid if we replace *exponential* null controllability with *asymptotic* null controllability.

We will first introduce some concepts that will help us characterize the properties of (2.2); see [6] and [7] for more details. Afterwards we will show the relation between different concepts of null controllability and then use these results in order to extend the approximation results from [12].

In order to measure the exponential null controllability we define the Lyapunov exponent of a trajectory of (2.2) by

$$\lambda(z_0, y_0, u(\cdot)) := \limsup_{t\to\infty} \frac{1}{t} \ln \|z(t, z_0, y_0, u(\cdot)\|.$$

Clearly $\lambda(z_0, y_0, u(\cdot)) < 0$ iff the corresponding trajectory converges to the origin exponentially fast. For each pair of initial values we define the infimal Lyapunov exponent by

$$\lambda^*(z_0, y_0) := \inf_{u(\cdot)\in\mathcal{U}} \lambda(z_0, y_0, u(\cdot)).$$

From the linearity of (2.2) it follows that $\lambda(z_0, y_0, u(\cdot)) = \lambda(\alpha z_0, y_0, u(\cdot))$ for all $\alpha \in \mathbb{R} \setminus \{0\}$. Hence we can use the projection of the z component to the unit sphere $\mathbb{S}^{d-1}$ which is given by

$$\begin{aligned} \dot{s}(t) &= h(s(t), y(t), u(t)), \\ \dot{y}(t) &= g(y(t), u(t)), \end{aligned} \tag{3.1}$$

where $h(s, y, u) = [A(y, u) - s^T A(y, u)s, \mathrm{Id}]s$, where Id denotes the $d \times d$ identity matrix. Denoting the projected trajectory by $s(t, s_0, y_0, u(\cdot))$, it follows from the chain rule that for $s_0 = \frac{z_0}{\|z_0\|}$ the Lyapunov exponent can be written as

$$\lambda(s_0, y_0, u(\cdot)) = \limsup_{t\to\infty} \frac{1}{t} \int_0^t q(s(\tau, s_0, y_0, u(\cdot)),\, y(\tau, y_0, u(\cdot)), u(\tau))d\tau, \tag{3.2}$$

where $q(s, y, u) := s^T A(y, u)s$. This integral is also referred to as an *averaged functional*.

By defining the exponential growth rate in finite time t,

$$\lambda^t(z_0, y_0, u(\cdot)) := \frac{1}{t} \ln \frac{\|z(t, z_0, y_0, u(\cdot)\|}{\|z_0\|},$$

it is easily seen that

$$\|z(t, z_0, y_0, u(\cdot))\| = e^{t\lambda^t(z_0, y_0, u(\cdot))}\|z_0\|. \tag{3.3}$$

As above, this expression can be written in integral form using the projected system, i.e., for $s_0 = \frac{z_0}{\|z_0\|}$ we obtain

$$\lambda^t(s_0, y_0, u(\cdot)) = \frac{1}{t} \int_0^t q(s(\tau, s_0, y_0, u(\cdot)),\, y(\tau, y_0, u(\cdot)), u(\tau))d\tau.$$

In our definitions of null controllability we need the notion of a positively invariant set for the subsystem on M.

DEFINITION 3.1. *A subset $K \subseteq M$ is called positively invariant for the subsystem of* (2.2) *on M if for all $y_0 \in K$ and all control functions $u(\cdot) \in \mathcal{U}$ the corresponding trajectory satisfies $y(t, y_0, u(\cdot)) \in K$ for all $t > 0$.*

Now we can define the concepts of null controllability; cf. also the stability concepts in [15].

DEFINITION 3.2. *Let $K \subseteq M$ be a compact positively invariant set for the subsystem of* (2.2) *on M.*

(i) *The system* (2.2) *is called* asymptotically null controllable *over K if for any pair of initial values $(z_0, y_0) \in \mathbb{R}^d \times K$ there exists a control function $u(\cdot) \in \mathcal{U}$ such that*

$$\lim_{t \to 0} \|z(t, z_0, y_0, u(\cdot))\| = 0.$$

(ii) *The system* (2.2) *is called* exponentially null controllable *over K if λ^* satisfies* $\sup_{(z_0,y_0)\in\mathbb{R}^d\times K} \lambda^*(z_0, y_0) < 0$.

(iii) *The system* (2.2) *is called* uniformly exponentially null controllable *over K if there exist constants C, $\alpha > 0$, such that for any pair of initial values $(z_0, y_0) \in \mathbb{R}^d \times K$ there exists a control function $u_{(z_0,y_0)}(\cdot) \in \mathcal{U}$ with*

$$\|z(t, z_0, y_0, u_{(z_0,y_0)}(\cdot))\| \le Ce^{-\alpha t}\|z_0\|.$$

An immediate consequence from (3.3) is that (2.2) is uniformly exponentially null controllable over K iff there exists a time $T > 0$ and a constant $\sigma < 0$ such that for any pair of initial values $(z_0, y_0) \in \mathbb{R}^d \times K$ there exists a control function $u_{(z_0,y_0)}(\cdot) \in \mathcal{U}$ with

$$\lambda^t(z_0, y_0, u_{(z_0,y_0)}(\cdot)) \le \sigma < 0$$

for all $t \ge T$.

It is easily seen from this definition that (iii) $\Rightarrow$ (ii) $\Rightarrow$ (i). In fact the converse is also true, i.e., the definitions are equivalent as the following proposition shows.

PROPOSITION 3.3. *Let $K \subseteq M$ be a compact positively invariant set for the subsystem of* (2.2) *on M. Then for the system* (2.2)*, asymptotic null controllability over K implies uniform exponential null controllability over K.*

Proof. We will first show the following property: there exist $T > 0$ and $\sigma < 0$ such that for each $(z, y) \in \mathbb{R}^d \times K$ there exists a control function $u_{(z,y)}(\cdot) \in \mathcal{U}$ and a time $t_{(z,y)} \le T$ such that $\lambda^{t_{(z,y)}}(z, y, u_{(z,y)}(\cdot)) < \sigma$.

The asymptotic null controllability implies that for each $(\tilde{z}_0, \tilde{y}_0) \in \mathbb{R}^d \times K$ there exists a time $\tilde{t}_{(\tilde{z}_0,\tilde{y}_0)}$ and a control function $\tilde{u}_{(\tilde{z}_0,\tilde{y}_0)}(\cdot)$, such that

$$\|z(\tilde{t}_{(\tilde{z}_0,\tilde{y}_0)}, \tilde{z}_0, \tilde{y}_0, \tilde{u}_{(\tilde{z}_0,\tilde{y}_0)}(\cdot))\| < \frac{1}{3}\|\tilde{z}_0\|.$$

Considering only those $\tilde{z}_0$ with $\|\tilde{z}_0\| = 1$ (i.e., $\tilde{z}_0 \in \mathbb{S}^{d-1}$) and using the continuous dependence on the initial value, we find a neighborhood $U(\tilde{z}_0, \tilde{y}_0)$ in $\mathbb{S}^{d-1} \times K$ such that for each $(z, y) \in U(\tilde{z}_0, \tilde{y}_0)$ it holds that

$$\|z(\tilde{t}_{(\tilde{z}_0,\tilde{y}_0)}, z, y, \tilde{u}_{(\tilde{z}_0,\tilde{y}_0)}(\cdot))\| < \frac{1}{2}\|z\|.$$

Hence it follows that $\lambda^{\tilde{t}_{(\tilde{z}_0,\tilde{y}_0)}}(z,y,\tilde{u}_{(\tilde{z}_0,\tilde{y}_0)}(\cdot)) < \gamma_{(\tilde{z}_0,\tilde{y}_0)} < 0$, where

$$\gamma_{(\tilde{z}_0,\tilde{y}_0)} = \frac{\ln \frac{1}{2}}{\tilde{t}_{(\tilde{z}_0,\tilde{y}_0)}}.$$

By the compactness of $\mathbb{S}^{d-1} \times K$ we may pick a finite number of pairs $(\tilde{z}_0, \tilde{y}_0)$ such that the neighborhoods $U(\tilde{z}_0, \tilde{y}_0)$ cover $\mathbb{S}^{d-1} \times K$. Now the independence of λ^t from the norm of z yields the asserted property, where T is the maximum over all $\tilde{t}_{(\tilde{z}_0,\tilde{y}_0)}$ and $\sigma < 0$ the maximum over all $\gamma_{(\tilde{z}_0,\tilde{y}_0)}$.

Now pick an arbitrary pair (z_0, y_0) of initial values. We use the control $u_0(\cdot) := u_{(z_0,y_0)}(\cdot)$ from above up to the time $t_1 := t_{(z_0,y_0)} < T$ from above and end up at the point $(z_1, y_1) = (z(t_1, z_0, y_0, u_0(\cdot)), y(t_0, y_0, u_0(\cdot)))$. We continue iteratively by defining $t_{i+1} := t_i + t_{(z_i,y_i)}$ and $u_i(\cdot) := u_{(z_i,y_i)}(\cdot)$ and define a control function $u : \mathbb{R}^+ \to U$ by

$$u(t) := u_i(t - t_i),\ t \in [t_i, t_{i+1}]$$

for $i \in \mathbb{N}_0$, where $t_0 := 0$.

This yields $\lambda^{t_i}(z_0, y_0, u(\cdot)) < \sigma$ for all t_i, $i \in \mathbb{N}_0$, and since $t_i - t_{i-1} < T$, it follows that for any $t > 0$ there exists $t_i =: t_i(t)$ with $0 \le t - t_i(t) < T$. By the definition of λ^t we obtain

$$\lambda^t(z_0, y_0, u(\cdot)) = \frac{t_i(t)}{t}\lambda^{t_i(t)}(z_0, y_0, u(\cdot)) + \frac{t - t_i(t)}{t}\lambda^{t-t_i(t)}(z_i, y_i, u_i(\cdot))$$

which yields

$$\lambda^t(z_0, y_0, u(\cdot)) < \sigma + \varepsilon(t),$$

where

$$\varepsilon(t) = \frac{t - t_i(t)}{t}\big(\lambda^{t-t_i(t)}(z_i, y_i, u_i(\cdot)) - \lambda^{t_i(t)}(z_0, y_0, u(\cdot))\big),$$

implying $\varepsilon(t) \to 0$ for $t \to \infty$ independently from (z_0, y_0) since λ^t is uniformly bounded for all $t > 0$ and all $(z, y) \in \mathbb{R}^d \times K$. Hence there exists $\varepsilon > 0$ and a time $T > 0$ such that $\lambda^t(z_0, y_0, u(\cdot)) < \sigma + \varepsilon < 0$ for all $t \ge T$, and the assertion follows. □

Using essentially the same arguments as in the previous proof, we can also determine the uniform upper bound for the values of the λ^t.

PROPOSITION 3.4. *Let $K \subseteq M$ be a compact positively invariant set for the subsystem of (2.2) on M. Let $\sigma := \sup_{(z_0,y_0)\in\mathbb{R}^d\times K} \lambda^*(z_0, y_0)$. Then for each $\varepsilon > 0$ there exists a $T > 0$ such that for any $(z_0, y_0) \in \mathbb{R}^d \times K$ there exists a control function $u(\cdot) \in \mathcal{U}$ satisfying*

$$\lambda^t(z_0, y_0, u(\cdot)) < \sigma + \varepsilon$$

for all $t \ge T$.

Proof. For any pair $(\tilde{z}_0, \tilde{y}_0) \in \mathbb{R}^d \times K$ there exists a control function $\tilde{u}_{(\tilde{z}_0,\tilde{y}_0)}(\cdot)$ and a time $\tilde{t}_{(\tilde{z}_0,\tilde{y}_0)}$ such that

$$\lambda^{\tilde{t}_{(\tilde{z}_0,\tilde{y}_0)}}(\tilde{z}_0, \tilde{y}_0, \tilde{u}_{(\tilde{z}_0,\tilde{y}_0)}(\cdot)) < \sigma + \frac{\varepsilon}{3}.$$

As in the previous proof, continuous dependence and compactness implies that for any pair (z, y) there exist $t_{(z,y)}$ bounded by some $\tilde{T}$ and control functions $u_{(z,y)} \in \mathcal{U}$, such that

$$\lambda^{t_{(z,y)}}(z, y, u_{(z,y)}(\cdot)) < \sigma + \frac{\varepsilon}{2}.$$

Following the previous proof we can iteratively construct control functions satisfying

$$\lambda^{t}(z_0, y_0, u(\cdot)) < \sigma + \frac{\varepsilon}{2} + \varepsilon(t).$$

Again $\varepsilon(t)$ can be chosen independently from (z_0, y_0) and $\varepsilon(t) \to 0$ as $t \to \infty$; hence the assertion follows by choosing T such that $\varepsilon(t) < \frac{\varepsilon}{2}$ for all $t \geq T$. □

This result implies that the α in Definition 3.2 (iii) can be chosen arbitrarily close to the sup-inf Lyapunov exponent σ as defined in Proposition 3.4. This Lyapunov exponent therefore gives the characteristic value for the null controllability of (2.2).

The construction of the stabilizing discrete feedback in the next section — following the outline of [11] — is based on the minimization of the Lyapunov exponent. This is related to minimizing (3.2) which forms an average time optimal control problem, for which the construction of optimal feedback controls is still an unsolved problem.

Hence we will not approach this problem directly but will use the approximation of (3.2) by a *discounted functional* with *discount rate* $\delta > 0$ defined by

$$J_\delta(s_0, y_0, u(\cdot)) := \int_0^\infty e^{-\delta\tau} q(s(\tau, s_0, y_0, u(\cdot)),\, y(\tau, y_0, u(\cdot)), u(\tau)) d\tau. \tag{3.4}$$

The function

$$v_\delta(s_0, y_0) := \inf_{u(\cdot)\in\mathcal{U}} J_\delta(s_0, y_0, u(\cdot)) \tag{3.5}$$

is called the *optimal value function* of this discounted optimal control problem.

The relation between this problem and the minimization of (3.2) has been discussed in [12] for the case where (3.1) is locally accessible, exploiting the controllability properties of (3.1). Here we will use Proposition 3.4 in combination with a stronger version of the approximation theorems from [12] in order to show this relation without assuming local accessibility.

LEMMA 3.5 (approximation theorems). *Let $q : \mathbb{R} \to \mathbb{R}$ be a measurable function satisfying $|q(s)| < M_q$ for almost all $s \in \mathbb{R}$.*

(i) *Assume there exists a time $T > 0$ such that*

$$\frac{1}{t}\int_0^t q(\tau)d\tau < \sigma \text{ for all } t \geq T.$$

Then for any $\varepsilon > 0$ and all $0 < \delta < \frac{\varepsilon}{(M_q+\sigma+\varepsilon)T}$ the following inequality holds:

$$\delta \int_0^\infty e^{-\delta\tau} q(\tau)d\tau \leq \sigma + \varepsilon.$$

(ii) *Let $\delta > 0$ be arbitrary and let*

$$\delta \int_0^\infty e^{-\delta\tau} q(\tau)d\tau =: \sigma.$$

Then for any $\varepsilon > 0$ there exists a $T \in [\frac{\varepsilon}{(4M_q+4\sigma+\varepsilon)\delta}, -\frac{1}{\delta}\ln\frac{\varepsilon}{4M_q}]$ satisfying

$$\frac{1}{T}\int_0^T q(\tau)d\tau \le \sigma + \varepsilon.$$

(iii) *Let $\delta > 0$ be arbitrary and let $\sigma \in \mathbb{R}$ such that*

$$\delta \int_0^\infty e^{-\delta\tau} q(t+\tau)d\tau \le \sigma \text{ for all } t \ge 0.$$

Then

$$\limsup_{T\to\infty} \frac{1}{T}\int_0^T q(\tau)d\tau \le \sigma$$

Proof. The rather technical proof can be found in the appendix. ∎

Next we can formulate the consequence for the optimal value function.

THEOREM 3.6. *Let $K \subseteq M$ be a compact positively invariant set for the subsystem on M of (2.2). Then*

$$\lim_{\delta\to 0} \sup_{(s,y)\in\mathbb{S}^{d-1}\times K} \delta v_\delta(s,y) = \sup_{(s,y)\in\mathbb{S}^{d-1}\times K} \lambda^*(s,y).$$

Proof. Let $\sigma := \sup_{(s,y)\in\mathbb{S}^{d-1}\times K} \lambda^*(s,y)$ and $\varepsilon > 0$. By Proposition 3.4 there exists a time $T > 0$ such that for each pair $(s,y) \in \mathbb{S}^{d-1} \times K$ there exists a control function $u(\cdot) \in \mathcal{U}$ such that

$$\lambda^t(s,y,u(\cdot)) < \sigma + \frac{\varepsilon}{2}.$$

By Lemma 3.5 (i) this implies

$$\delta J_\delta(s,y,u(\cdot)) < \sigma + \varepsilon$$

for all sufficiently small $\delta > 0$. Since $\varepsilon > 0$ was arbitrary this implies

$$\limsup_{\delta\to 0} \sup_{(s,y)\in\mathbb{S}^{d-1}\times K} \delta v_\delta(s,y) \le \sigma.$$

Now assume $\liminf_{\delta\to 0} \sup_{(s,y)\in\mathbb{S}^{d-1}\times K} \delta v_\delta(s,y) = \gamma < \sigma$. Then there exists $\delta > 0$ such that by Bellman's optimality principle [19, Theorem 1.2] for each pair (s,y) there exists a control function $u(\cdot)$ satisfying

$$\delta J_\delta(s(t,s,y,u(\cdot)), y(t,y,u(\cdot)), u(t+\cdot)) < \tilde{\gamma} < \sigma$$

for all $t \ge 0$. Now by Lemma 3.5 (iii) it follows that $\lambda^*(s,y) \le \tilde{\gamma} < \sigma$ which contradicts the definition of σ. Hence the assertion follows. ∎

This theorem states that the Lyapunov exponent that gives the characteristic number for null controllability can be approximated by the value function of a discounted optimal control problem.

Since algorithms for the numerical computation of v_δ are known (cf., e.g., [9] and [13]) this theorem also lays the foundation for the numerical null controllability analysis of semilinear systems; see also [12]. This is of particular interest because the question of whether (2.2) is null controllable cannot in general be answered by analytical methods.

4. Construction of the discrete feedback. We will now present a feedback construction for the (approximately) optimal solution of the discounted optimal control problem defined by (3.4) and (3.5), which will then be stabilizing for (2.2).

In general the construction of optimal feedback laws for discounted optimal control problems is an unsolved problem. One of the main problems is that optimal feedbacks are typically discontinuous and hence properties such as the existence and uniqueness of the corresponding solutions are no longer guaranteed. Some effort has been made in order to take these difficulties into account, e.g., by using differential inclusions (see [10] and [1]). However, apart from the fact that this approach leads to a characterization of optimal trajectories rather than to a construction of a feedback law, from the stabilization (and application) point of view it seems desirable to preserve these properties. Furthermore we will need a certain robustness property, as discussed in section 5, in order to apply the feedback to the nonlinear system.

These considerations lead to a somewhat modified feedback concept which is based on an approximation of $\mathcal{U}$ as introduced in [11]. Theorem 3.6 yields the property needed for the construction of the stabilizing discrete feedback in sections 3 and 4 of [11] and our construction now follows this outline. We will therefore just give the idea of the construction and omit the proofs except for the concluding theorem.

We approximate $\mathcal{U}$ by

$$\mathcal{U}_h := \{u : \mathbb{R} \to U \mid u|_{[ih,(i+1)h)} \equiv u_i \text{ for all } i \in \mathbb{Z}\}$$

for some time step $h > 0$. This discretization for discounted optimal control problems bears some similarity to the discretization in [2] and [3]; in fact what we obtain is a discrete time system by the process of sampling (cf., [21, section 2.10]):

$$s_{i+1} = s(h, s_i, y_i, u_i),\ y_{i+1} = y(h, y_i, u_i), \tag{4.1}$$

where $(u_i)_{i\in\mathbb{Z}} \in U^{\mathbb{Z}}$.

Defining

$$v_\delta^h(s_0, y_0) := \inf_{u(\cdot)\in\mathcal{U}_h} J_\delta(s_0, y_0, u(\cdot)),$$

the approximation property

$$\|v_\delta - v_\delta^h\|_\infty \le Ch^{\frac{\gamma}{2}}$$

holds for $\gamma = \delta/L$ where L denotes the Lipschitz constant of (3.1); see [3].

Bellman's optimality principle [19, Theorem 1.2] yields

$$v_\delta^h(s_0, y_0) = \inf_{u\in U} \left\{ \int_0^h e^{-\delta\tau} q(s(\tau, s_0, y_0, u),\ y(\tau, y_0, u), u)d\tau + e^{-\delta h} v_\delta^h(s(h, s_0, y_0, u),\ y(h, y_0, u)) \right\}.$$

By the continuity of all functions involved and the compactness of U, we can now define a function $F : \mathbb{S}^{d-1} \times K \to U$ by choosing $F(s_0, y_0) := u \in U$ such that the infimum above is attained in u.

We may now apply F to (3.1) by

$$\begin{aligned} \dot{s}(t) &= h(s(t), y(t), F(s(\left[\tfrac{t}{h}\right] h), y(\left[\tfrac{t}{h}\right] h))), \\ \dot{y}(t) &= g(y(t), F(s(\left[\tfrac{t}{h}\right] h), y(\left[\tfrac{t}{h}\right] h))). \end{aligned} \tag{4.2}$$

We denote the solution trajectories of (4.2) by $(s_F(t, s_0, y_0), y_F(t, y_0))$.

Feedback laws of this kind can be found in the literature under the name of *modified feedback control* [16], [17], *sample-and-hold* control, or *sampled feedback* [20], [22], and *step-by-step control* [18]. Of particular interest in this context is the recent work [5] where a stabilization result using a "sampled feedback" control is presented. We will discuss the relation between this work and the present paper in section 6.

In our terminology we call F a "discrete" feedback control, a notion being motivated by the fact that F is indeed a feedback control for the discrete time system (4.1). From this interpretation the existence and uniqueness of the trajectories of (4.2) is immediately clear.

If we evaluate

$$J_\delta(s,y,F) := \int_0^\infty e^{-\delta\tau} q\left(s_F(\tau,s,y),\, y_F(\tau,y), F\left(s_F\left(\left[\frac{\tau}{h}\right]h, s, y\right),\, y_F\left(\left[\frac{\tau}{h}\right]h, y\right)\tau\right)\right) d\tau,$$

i.e., the discounted value along the trajectories of (4.2), it follows that $J_\delta(s,y,F) = v_\delta^h(s,y)$ for all initial values $(s,y) \in \mathbb{S} \times K$ ([11, Theorem 3.6]). Hence F forms an optimal discrete feedback for the discounted optimal control problem with respect to the discretized control functions from $\mathcal{U}_h$.

In the same way we define the averaged value along the trajectories by

$$\lambda^t(s,y,F) := \frac{1}{t}\int_0^t q\left(s_F(\tau,s,y),\, y_F(\tau,y), F\left(s_F\left(\left[\frac{\tau}{h}\right]h, s, y\right),\, y_F\left(\left[\frac{\tau}{h}\right]h, y\right)\tau\right)\right) d\tau.$$

By defining $F_{\mathbb{R}}(z,y) := F(z/\|z\|, y)$ we can apply $F_{\mathbb{R}}$ to the nonprojected system (2.2) by

$$\begin{aligned} \dot z(t) &= A(y(t), F_{\mathbb{R}}(s(\left[\tfrac{t}{h}\right]h), y(\left[\tfrac{t}{h}\right]h)))z(t), \\ \dot y(t) &= g(y(t), F_{\mathbb{R}}(z(\left[\tfrac{t}{h}\right]h), y(\left[\tfrac{t}{h}\right]h))). \end{aligned} \tag{4.3}$$

As above we denote the corresponding trajectories by $(x_{F_{\mathbb{R}}}(t, x_0, y_0), y_{F_{\mathbb{R}}}(t, y_0))$. Applying $F_{\mathbb{R}}$ this way we can state the following theorem.

THEOREM 4.1. *Let $K \subseteq M$ be a compact positively invariant set for the subsystem of* (2.2) *on M. Then* (2.2) *is asymptotically null controllable over K iff there exists a time step h and a discrete feedback law $F_{\mathbb{R}} : \mathbb{R} \times K \to U$ such that* (4.3) *is uniformly exponentially stable, i.e., there exists C, $\alpha > 0$ such that every trajectory of* (4.3) *satisfies the condition from Definition* 3.2 (iii).

Proof ("$\Rightarrow$"). Assume asymptotic null controllability of (2.2). By [11, Corollary 3.7], it follows that for any $\varepsilon > 0$ there exists $h > 0$ such that the discrete feedback as defined above satisfies

$$\delta J_\delta(s,y,F) < \delta v_\delta(s,y) + \varepsilon. \tag{4.4}$$

Choosing $\delta > 0$ sufficiently small, Proposition 3.3 implies that there exists $\sigma < 0$ such that $\delta J_\delta(s,y,F) < \sigma$, hence from Lemma 3.5 (ii) we can conclude that for any $\varepsilon > 0$ there exists a bounded time $t = t(\varepsilon) > 0$ such that $\lambda^t(s,y,F) < \sigma + \varepsilon$. Using [11, Lemma 4.1] we obtain estimate (4.4) for the next trajectory piece and can inductively obtain the assertion as in the proof of Proposition 3.3.

("$\Leftarrow$"). This direction is immediately clear. □

Note that this stabilizing discrete feedback law is numerically computable — at least for lower-dimensional systems — using the algorithm proposed in [11] and [13].

5. Robustness of the discrete feedback control. From the definition of the discrete feedback F and $F_{\mathbb{R}}$ it is obvious that these functions are typically discontinuous. Hence by applying this feedback law, continuous dependence of the trajectories on the initial value will in general not hold.

This gives rise to the question of the robustness of the optimal trajectories. More precisely: do optimal trajectories remain approximately optimal under small perturbations?

The answer is given in the following proposition and is essentially based on the Hölder continuity of v_δ^h which satisfies

$$|v_\delta^h(s,y) - v_\delta^h(\tilde{s},\tilde{y})| \le C(d_{\mathbb{S}}(s,\tilde{s}) + d_M(y,\tilde{y}))^\gamma,$$

where $\gamma = \delta/L$ and L is the Lipschitz constant of (3.1). For systems in $\mathbb{R}^n$ this immediately follows from [3, Lemma 4.1]; the proof is easily transferred to general manifolds. Here $d_{\mathbb{S}}$ and d_M denote some metrics on $\mathbb{S}$ and M, respectively.

In what follows we allow time varying perturbations of the following kind: assume that we have a time varying system on $\mathbb{S}^{d-1} \times K$ given by

$$\begin{aligned} \dot{s}(t) &= \tilde{h}(t, s(t), y(t), u(t)), \\ \dot{y}(t) &= \tilde{g}(t, y(t), u(t)), \end{aligned} \tag{5.1}$$

with trajectories $(\tilde{s}(t,t^*,s_0,y_0,u(\cdot)),\ \tilde{y}(t,t^*,y_0,u(\cdot)))$ using the initial time t^*. For some pair of initial values (s_0,y_0) and a discrete Feedback F with time step $h>0$, we denote the solution trajectories of (5.1) applying F with initial time $t^*=0$ by $(\tilde{s}_F(t,s_0,y_0),\tilde{y}_F(t,y_0))$. Using the abbreviations $t_i := ih$, $\tilde{s}_i := \tilde{s}_F(t_i,s_0,y_0)$, $\tilde{y}_i := \tilde{y}_F(t_i,y_0)$, and $u_i := F(\tilde{s}_i,\tilde{y}_i)$ we assume

$$d_{\mathbb{S}}(\tilde{s}(t,t_i,\tilde{s}_i,\tilde{y}_i,u_i), s(t,\tilde{s}_i,\tilde{y}_i,u_i)) + d_M(\tilde{y}(t,t_i,\tilde{y}_i,u_i), y(t,\tilde{y}_i,u_i)) < \varepsilon_i \tag{5.2}$$

for all $t\in[0,h]$, all $i\in\mathbb{N}$, and some sequence $(\varepsilon_i)_{i\in\mathbb{N}}$.

PROPOSITION 5.1. *Consider the system* (3.1)*, a time step h, the corresponding optimal value function v_δ^h, and the optimal discrete feedback F. Assume that a system* (5.1) *with the property* (5.2) *for some pair of initial values (s,y) is given and denote the trajectories of* (5.1) *with initial time $t^*=0$ and the discrete feedback F by $(\tilde{s}_F(t,s_0,y_0),\tilde{y}_F(t,y_0))$.*

Then for any $k\in\mathbb{N}$ the following inequality holds:

$$|v_\delta^h(s,y) - \tilde{J}_\delta(s,y,F)| < C\sum_{i=0}^{k-1} e^{-\delta h i}\varepsilon_i^\gamma + 2e^{-\delta hk}\frac{M_q}{\delta},$$

where

$$\tilde{J}_\delta(s,y,F) := \int_0^\infty e^{-\delta\tau} q\Big(\tilde{s}_F(\tau,s,y),\, \tilde{y}_F(\tau,y), F\Big(\tilde{s}_F\Big(\Big[\frac{\tau}{h}\Big]h,s,y\Big),\, \tilde{y}_F\Big(\Big[\frac{\tau}{h}\Big]h,y\Big)\tau\Big)\Big)\,d\tau$$

is the value along the discrete feedback controlled trajectory of (5.1) *and M_q is the bound of $|q|$ on $\mathbb{S}^{d-1}\times K$.*

Remark 5.2. Note that the right-hand side of this inequality becomes small if the ε_i are small for all sufficiently large $i\in\mathbb{N}$.

Proof. From the definition of F and the assumption (5.2) it follows that

$$\begin{aligned} v_\delta^h(s,y) &= \int_0^h q(s_F(\tau,s,y), y_F(\tau,y), F(s,y)) + e^{-\delta h} v_\delta^h(s_F(h,s,y), y_F(h,y)) \\ &= \int_0^h q(\tilde{s}_F(\tau,s,y), \tilde{y}_F(\tau,y), F(s,y)) + e^{-\delta h} v_\delta^h(\tilde{s}_F(h,s,y), \tilde{y}_F(h,y)) + \tilde{C}\varepsilon_0^\gamma, \end{aligned}$$

where $|\tilde{C}| < C$. On the other hand, we obtain

$$\tilde{J}_\delta(s,y,F) = \int_0^h q(\tilde{s}_F(\tau,s,y),\tilde{y}_F(\tau,y),F(s,y)) + e^{-\delta h}\tilde{J}_\delta(\tilde{s}_F(h,s,y),\tilde{y}_F(h,y),F).$$

This yields

$$\begin{aligned}&|v_\delta^h(s,y) - \tilde{J}_\delta(s,y,F)|\\ &\quad\le\quad e^{-\delta h}|v_\delta^h(\tilde{s}_F(h,s,y),\tilde{y}_F(h,y)) - \tilde{J}_\delta(\tilde{s}_F(h,s,y),\tilde{y}_F(h,y),F)| + C\varepsilon_0^\gamma.\end{aligned}$$

By observing that v_δ^h and $\tilde{J}_\delta$ are bounded by M_q/δ, the assertion follows by induction. □

This robustness property is the main tool for the linearization result in the next section.

6. Stabilization of the nonlinear system. We will now return to our original system (2.1). We recall the fact that $f(x,y,u) = A(y,u)x + \tilde{f}(x,y,u)$, where for y in a compact set $K \subset M$ the estimate $\|\tilde{f}(x,y,u)\| \le C_f\|x\|^2$ holds for all $x \in B_{\eta_f}(0)$, the ball with radius η_f around 0; cf. (2.3).

In analogy to Definition 3.2 we begin by defining the controllability concepts for system (2.1). Since we assume that the singular point x^* coincides with the origin we may again formulate these concepts in terms of null controllability. As in the semilinear case, we denote the exponential growth rates of a trajectory by

$$\lambda_f^t(x_0,y_0,u(\cdot)) := \frac{1}{t}\ln\frac{\|x(t,x_0,y_0,u(\cdot))\|}{\|x_0\|}$$

and

$$\lambda_f^*(x_0,y_0) := \inf_{u(\cdot)\in\mathcal{U}} \limsup_{t\to\infty} \lambda^t(x_0,y_0,u(\cdot)).$$

DEFINITION 6.1. *Let $K \subseteq M$ be a compact positively invariant set for the subsystem of* (2.1) *on M.*

(i) *The system* (2.1) *is called* (locally) asymptotically null controllable *over K if there exists a neighborhood $B(0)$ of 0 such that for any pair of initial values $(x_0,y_0) \in B(0)\times K$ there exists a control function $u(\cdot)\in\mathcal{U}$ with*

$$\lim_{t\to 0}\|x(t,z_0,y_0,u(\cdot))\| = 0.$$

(ii) *The system* (2.1) *is called* (locally) exponentially null controllable *over K if there exists a neighborhood $B(0)$ of 0 such that $\sup_{(x_0,y_0)\in B(0)\times K}\lambda_f^*(x_0,y_0) < 0$.*

(iii) *The system* (2.2) *is called* (locally) uniformly exponentially null controllable *over K if there exists a neighborhood $B(0)$ of 0 and constants C, $\alpha > 0$, such that for any pair of initial values $(x_0,y_0) \in B(0)\times K$ there exists a control function $u_{(x_0,y_0)}(\cdot)\in\mathcal{U}$ with*

$$\|z(t,x_0,y_0,u_{(x_0,y_0)}(\cdot))\| \le Ce^{-\alpha t}\|x_0\|.$$

As in the semilinear case, the implications (iii) ⇒ (ii) ⇒ (i) are obvious. However, for nonlinear systems the converse is not true, as the example below will show. Note

that frequently the notion of *exponential stability* already demands the uniformity as in (iii); cf., e.g., [23] or [24].

We will now first prove some a priori estimates for the solutions of (2.1) and (2.2).

LEMMA 6.2. *Abbreviate with* $(x(t), y(t))$ *and* $(z(t), y(t))$ *the solutions of the systems* (2.1) *and* (2.2) *for a pair of initial values* (x_0, y_0) *and a control function* $u(\cdot)$. *Let* $T > 0$ *be a given time.*

Then there exist constants α, β, $C > 0$, *and* $\eta(T) > 0$ *independent from* $u(\cdot)$ *such that for all* $t \in [0, T]$ *the following estimates hold:*

(i) $\|x(t)\| \in [e^{-\alpha t}\|x_0\|, e^{\alpha t}\|x_0\|]$ *for all* $x_0 \in B_{\eta(T)}(0)$,

(ii) $\|z(t)\| \in [e^{-\alpha t}\|x_0\|, e^{\alpha t}\|x_0\|]$ *for all* $x_0 \in \mathbb{R}^d$,

(iii) $\|x(t) - z(t)\| \le tCe^{\beta t}\|x_0\|^2$ *for all* $x_0 \in B_\eta(T)(0)$,

where $B_\eta(T)(0)$ *denotes the ball with radius* $\eta(T)$ *around the origin.*

Proof. (i) We show the estimate for the upper bound; the estimate for the lower bound follows from (ii) and (iii). From the linearization it follows that

$$x(t) = x_0 + \int_0^t A(y(\tau),\, u(\tau))x(\tau) + \tilde{f}(x(\tau), y(\tau), u(\tau))d\tau.$$

As long as $x(t) \in B_{\eta_f}(0)$, this implies

$$\|x(t)\| \le \|x_0\| + \int_0^t \alpha\|y(\tau)\|d\tau$$

for some constant $\alpha > 0$. This yields $\|x(t)\| \le e^{\alpha t}\|x_0\|$ as long as $e^{\alpha t}\|x_0\| \le \eta_f$ and hence the assertion follows with $\eta(T) = \eta_f/e^{\alpha T}$.

(ii) This is an easy consequence from the linearity of the system.

(iii) Define $m(t) := x(t) - z(t)$. From (i) and (ii) it follows that $\|m(t)\| \le e^{\alpha t}\|x_0\|$. Furthermore m is a solution of the differential equation

$$\dot{m}(t) = A(y(t),\, u(t))m(t) + \tilde{f}(y(s),\, m(t) + z(t),\, u(t)), \;\; z(0) = 0$$

and thus satisfies

$$\begin{aligned}
\|m(t)\| &\le \int_0^t \|A(y(\tau),\, u(\tau))m(\tau)\| + \|\tilde{f}(y(\tau),\, m(\tau) + z(\tau),\, u(\tau))\|d\tau \\
&\le \int_0^t \|A(y(\tau),\, u(\tau))m(\tau)\| + C_f(\|m(\tau)\|^2 + \|z(\tau)\|\|m(\tau)\| + \|z(\tau)\|^2)d\tau \\
&\le tC_f e^{2\alpha t}\|x_0\|^2 + \int_0^t \gamma\|m(s)\|ds
\end{aligned}$$

for some constant $\gamma > 0$. Now the Gronwall lemma yields

$$\|m(t)\| \le tC_f e^{2\alpha t}\|x_0\|^2 e^{\gamma t}$$

and thus the assertion. ∎

As in the semilinear case, we may now write the exponential growth rate in finite time in integral form

$$\lambda_f^t(x_0, y_0, u(\cdot)) = \frac{1}{t}\int_0^t q_f(x(\tau, x_0, y_0, u(\cdot)), y(\tau, y_0, u(\cdot)), u(\tau))d\tau,$$

where

$$q_f(x,y,u) = q\left(\frac{x}{\|x\|}, y, u\right) + \frac{x^t \tilde{f}(x,y,u)}{\|x\|^2}$$

which can be calculated using the chain rule.

A simple calculation shows that

$$\|x(t,x_0,y_0,u(\cdot))\| = \|x_0\| e^{t\lambda_f^t(x_0,y_0,u(\cdot))t}.$$

We can now apply the discrete feedback $F_{\mathbb{R}}$ from the previous sections to (2.1) by

$$\begin{aligned} \dot{x}(t) &= f(x(t),y(t),F_{\mathbb{R}}(x(\left[\tfrac{t}{h}\right]h), y(\left[\tfrac{t}{h}\right]h))), \\ \dot{y}(t) &= g(y(t),F_{\mathbb{R}}(x(\left[\tfrac{t}{h}\right]h), y(\left[\tfrac{t}{h}\right]h))), \end{aligned} \tag{6.1}$$

and denote the resulting trajectories by $(x_{F_{\mathbb{R}}}(t,x_0,y_0), y_{F_{\mathbb{R}}}(t,y_0))$.

Defining the growth rate of $\|x_{F_{\mathbb{R}}}(t,x_0,y_0)\|$ in finite time by

$$\lambda_f^t(x_0,y_0,F_{\mathbb{R}}) := \frac{1}{t}\ln\frac{\|x_{F_{\mathbb{R}}}(t,x_0,y_0)\|}{\|x_0\|},$$

we obtain the following estimate.

LEMMA 6.3. *Let δ, $h>0$ and let F be an optimal discrete feedback with respect to v_δ^h for the linearization* (2.2). *Let $\sigma := \sup_{(s,y)\in\mathbb{S}^{d-1}\times K}\delta v_\delta^h(x,y)$. Then for any $\varepsilon>0$ there exists an interval $[C_-(\varepsilon), C^-(\varepsilon)]$ and a constant $\eta(\varepsilon)>0$ such that for all pairs of initial values x_0, y_0 where $x_0 \in B_{\eta(\varepsilon)}(0)$ the estimate*

$$\lambda_f^t(x_0,y_0,F_{\mathbb{R}}) \le \sigma + \varepsilon$$

holds for some $t \in [C_-(\varepsilon), C^-(\varepsilon)]$.

Proof. For a fixed pair of initial values (x_0,y_0) and a control function $u(\cdot)\in\mathcal{U}$ we abbreviate $x(t) := x(t,x_0,y_0,u(\cdot))$ and define

$$\tilde{h}(t,s,y,u) = \frac{f(x(t),y,u)}{\|x(t)\|} - \left\langle \frac{f(x(t),y,u)}{\|x(t)\|}, s\right\rangle s$$

for $s\in\mathbb{S}^{d-1}$. With $s_0 := x_0/\|x_0\|$ and $\tilde{s}(t,s_0,y_0,u(\cdot)) := x(t)/\|x(t)\|$ it follows that

$$\dot{\tilde{s}}(t,s_0,y_0,u(\cdot)) = \tilde{h}(t,\tilde{s}(t,s_0,y_0,u(\cdot)), y(t,y_0,u(\cdot)), u(t));$$

hence the projection of the trajectory $x(t)$ onto $\mathbb{S}$ forms a solution trajectory of this time varying control system.

Now let $x_i := x_{F_{\mathbb{R}}}(ih,x_0,y_0)$. Using Lemma 6.2 we obtain

$$\left\| \frac{z(h,x_i,y_i,u)}{\|z(h,x_i,y_i,u)\|} - \frac{x(h,x_i,y_i,u)}{\|x(h,x_i,y_i,u)\|}\right\| \le hC_1\|x_i\|.$$

By Lemma 6.2, x_i can be made arbitrarily small for each fixed $i\in\mathbb{N}$ by choosing x_0 sufficiently small, and we can use Proposition 5.1 with $s = z/\|z\|$ and $\tilde{s} = x/\|x\|$ in order to obtain the estimate

$$\delta\tilde{J}_\delta(x_0,y_0,F) \le \sigma + \frac{\varepsilon}{4}$$

for all sufficiently small x_0.

From the linearization estimates we obtain

$$\left| \frac{x_i^t \tilde{f}(x_i, u)}{\|x_i\|^2} \right| \leq C_f \|x_i\| \leq C_f e^{\gamma t} \|x_0\|$$

for all sufficiently small $\|x_i\|$, i.e., all sufficiently small $\|x_0\|$.

Hence $\|q(x_{F_{\mathbb{R}}}(t, x_0, y_0), \cdot, \cdot)/\|x_{F_{\mathbb{R}}}(t, x_0, y_0)\| - q_f(x_{F_{\mathbb{R}}}(t, x_0, y_0), \cdot, \cdot)\|$ can be made arbitrarily small on each bounded time interval by choosing x_0 sufficiently close to the origin, and using [3, Lemma 4.1] we can conclude

$$\delta \int_0^\infty e^{-\delta\tau} q_f \left(x_{F_{\mathbb{R}}}(\tau, x, y),\, y_{F_{\mathbb{R}}}(\tau, y), F_{\mathbb{R}} \left(x_{F_{\mathbb{R}}} \left(\left[\frac{\tau}{h} \right] h, x, y \right),\, y_{F_{\mathbb{R}}} \left(\left[\frac{\tau}{h} \right] h, y \right) \right) \right) d\tau \leq \sigma + \frac{\varepsilon}{2}$$

for all sufficiently small $\|x_0\|$.

Now Lemma 3.5 (ii) yields the assertion. □

In order prove the stability of (6.1) the last thing that remains to do is putting together the trajectory pieces.

PROPOSITION 6.4. *Consider system* (2.1). *Let $K \subseteq M$ be a compact positively invariant set for the subsystem of* (2.1) *on M. Assume that the linearization* (2.2) *is asymptotically null controllable over K. Then there is $\delta > 0$ and $h > 0$ such that the system* (6.1) *with the discrete feedback $F_{\mathbb{R}}$ is uniformly exponentially stable in some neighborhood of the origin.*

Proof. From the assumptions on the linearization, Lemma 6.3 can be applied with $\sigma < 0$.

Hence for all sufficiently small initial values $\|x_0\|$ there exists a $t \in [C_-(\varepsilon), C^-(\varepsilon)]$ such that

$$\frac{1}{t} \ln \frac{\|x_{F_{\mathbb{R}}}(t, x_0, y_0)\|}{\|x_0\|} \leq \sigma + \varepsilon < 0.$$

Abbreviating $x_1 := x_{F_{\mathbb{R}}}(t, x_0, y_0)$, it holds that $\|x_1\| < \|x_0\|$. Thus we can proceed inductively as in the proof of Proposition 3.3 and the assertion follows. □

This proposition gives a characterization of exponential discrete feedback stabilizability by looking at its linearization. However, we would also like to have a characterization in terms of the nonlinear system itself. Clearly, since we are dealing with linearizations, asymptotic null controllability of the nonlinear system is not sufficient; see, e.g., [4, Example 15].

In fact, even exponential null controllability is not sufficient, as the following example shows. Consider

$$\dot{x} = \begin{pmatrix} -1 & 0 \\ 0 & 1 \end{pmatrix} x + u_1 \begin{pmatrix} -\frac{1}{2} & 0 \\ -\frac{1}{3} & \frac{1}{2} \end{pmatrix} x + u_2 \begin{pmatrix} -\frac{1}{2} & 0 \\ \frac{1}{3} & \frac{1}{2} \end{pmatrix} x + u_3 \begin{pmatrix} x_2^2 \\ 0 \end{pmatrix},$$

where $U = [-1, 1]^3$.

We claim that the linearized system is not asymptotically null controllable: looking at the initial values $z_0 = (0,\, z_2)^T$, $z_2 > 0$, it is easily seen that

$$A(u) z_0 = \begin{pmatrix} 0 \\ (1 + \frac{1}{2}u_1 + \frac{1}{2}u_2) z_2 \end{pmatrix}.$$

Denoting the solution by $z(t, x_0, u(\cdot)) = (z_1(t, z_0, u(\cdot)), z_2(t, z_0, u(\cdot)))^T$, we obtain $z_1(t, z_0, u(\cdot)) \equiv 0$ and $z_2(t, z_0, u(\cdot)) \geq z_2$ since $(1 + \frac{1}{2}u_1(t) + \frac{1}{2}u_2(t)) \geq 0$ for all $u(\cdot) \in U$ and all $t \geq 0$. Thus we can conclude that $\|z(t, z_0, u(\cdot))\| \geq \|z_2\|$ for all $u(\cdot) \in \mathcal{U}$, meaning that for all initial values z_0 of the considered form no possible trajectory converges to the origin, which implies our claim.

However, for any $x = (x_1, x_2)^T \in \mathcal{C}$, where $\mathcal{C}$ is the cone defined by

$$\mathcal{C} := \left\{ \begin{pmatrix} x_1 \\ x_2 \end{pmatrix} \in \mathbb{R}^2 \;\middle|\; \left|\frac{x_2}{x_1}\right| < \frac{1}{10} \right\},$$

we can choose the control $u_x = (u_{x1}, u_{x2}, u_{x3}) := (\frac{2x_2}{x_1/3 - x_2}, 0, 0) \in U$. Then a simple computation yields

$$f(x, u_x) = \left(-1 - \frac{1}{2}u_{x1}\right) x,$$

and since $u_{\alpha x} = u_x$ for all $\alpha \in \mathbb{R} \setminus \{0\}$ the solution for $u_x(\cdot) \equiv u_x$ satisfies

$$x(t, x, u_x(\cdot)) = e^{(-1 - \frac{1}{2}u_{x1})t} x.$$

Hence the corresponding trajectory satisfies $\|x(t, x, u_x)\| \leq e^{-\frac{1}{2}t}\|x\|$ and thus converges to the origin exponentially fast.

For all initial values $x_0 \in \mathbb{R}^2 \setminus \mathcal{C}$ we choose $u(t) \equiv (-1, -1, \operatorname{sgn}(x_1))$ (with the convention $\operatorname{sgn}(0) = 1$) as long as the corresponding trajectory stays outside $\mathcal{C}$ and switch to u_x from above once the trajectory reaches a point $x \in \mathcal{C}$.

Using this control function, any trajectory will enter the cone $\mathcal{C}$ in some finite time and then converge to the origin exponentially fast; thus the overall trajectory also converges to the origin exponentially fast. Hence the nonlinear system is exponentially null controllable, although the semilinear system is not even asymptotically null controllable. Thus exponential null controllability of the nonlinear system does not imply asymptotic null controllability of the linearized system.

In order to formulate the desired result we therefore need the notion of uniform exponential null controllability.

THEOREM 6.5. *Consider system* (2.1). *Let $K \subseteq M$ be a compact positively invariant set for the subsystem of* (2.1) *on M. Then the following properties are equivalent:*

(i) (2.1) *is (locally) uniformly exponentially null controllable over K.*
(ii) (2.2) *is asymptotically null controllable over K.*
(iii) *There is $h > 0$ and a discrete feedback that (locally) stabilizes* (2.1) *uniformly exponentially over K.*

Proof. "(ii)⇒(iii)" is Proposition 6.4; "(iii)⇒(i)" is immediately clear. It remains to show "(i)⇒(ii)":

Let $B(0)$ be the neighborhood in which uniform exponential null controllability holds. From (i) it follows that for any $\varepsilon > 0$ there exists a $T > 0$ such that for all $(x_0, y_0) \in B(0) \times K$ there exists a control function $u_{(x_0,y_0)}(\cdot) \in \mathcal{U}$ with

$$\lambda_f^T(x_0, y_0, u_{(x_0,y_0)}(\cdot)) < -\alpha + \varepsilon.$$

Using the estimates from the proof of Lemma 6.3, we obtain for the growth rate of (2.2),

$$\lambda^T(x_0, y_0, u_{(x_0,y_0)}(\cdot)) < -\alpha + 2\varepsilon$$

for x_0 sufficiently close to the origin. Due to the linearity of (2.2) this estimate holds for all $x_0 \in \mathbb{R}^d$. Now by induction we obtain the assertion as in the proof of Proposition 3.3. □

This theorem shows in particular that any attempt to stabilize (2.1) at a singular point by using its linearization must fail if uniform exponential controllability is not satisfied, because the linearized system will not even be asymptotically null controllable. Conversely, exponential discrete feedback stabilization is always possible under this condition. We have therefore obtained the strongest result possible within the linearization approach.

A related result has been developed in [5] using Lyapunov functions: it is shown that for nonlinear systems, asymptotic controllability to a (not necessarily singular) point x implies stabilizability by means of a discrete feedback, where in order to reach x the step size h must tend to 0. The result can therefore be interpreted as a kind of practical stabilization. In contrast to this practical stability here we obtain *exponential* stability using a discrete feedback with a *fixed* step size.

7. Conclusions. In this paper we developed results on the relation between null controllability and exponential stabilization by using a discrete feedback law for nonlinear systems at singular points. The construction of the feedback is obtained by minimizing the Lyapunov exponent of the linearized system, which forms a semilinear system. For semilinear systems, asymptotic null controllability and exponential stabilizability by a discrete feedback turned out to be equivalent. For general nonlinear systems the equivalence between uniform exponential controllability and uniform exponential stabilizability has been shown. An example illustrated that uniform exponential controllability is in fact a necessary condition for the applicability of linearization techniques.

8. Appendix: Proof of Lemma 3.5. (i) Fix $\varepsilon > 0$. We may assume $\sigma = -\varepsilon$; otherwise we use $q - \sigma - \varepsilon$ and $M_q + \sigma + \varepsilon$ instead of q and M_q. Hence there exists $0 \le T_0 < T$ such that

$$\int_0^{T_0} q(\tau)\,d\tau = -T_0\varepsilon \quad \text{and} \quad \int_0^{t} q(\tau)\,d\tau < -t\varepsilon \quad \text{for all } t > T_0. \tag{8.1}$$

This yields

$$\int_{T_0}^{t} q(\tau)\,d\tau < (t - T_0)(-\varepsilon) \quad \text{for all } t > T_0. \tag{8.2}$$

Since for all $y \in [0,1)$ the inequality $\ln(1-y) \le -y$ and hence $e^{-y} \ge 1 - y$ holds, we obtain

$$\begin{aligned}\left| \int_0^{T_0} q(\tau)\,d\tau - \int_0^{T_0} e^{-\delta t} q(\tau)\,d\tau \right| &\le T_0(1 - e^{-\delta T_0})M \\ &\le T(1 - e^{-\delta T})M \\ &\le \delta T^2 M.\end{aligned}$$

Thus the inequality in (8.1) implies for $\delta < \frac{\varepsilon}{MT} < \frac{\varepsilon}{MT_0}$

$$\delta \int_0^{T_0} e^{-\delta\tau} q(\tau)\,d\tau < \delta(-T_0\varepsilon + \delta T^2 M) < 0. \tag{8.3}$$

Now fix $\tilde{\varepsilon} > 0$. Since q is bounded there exists $T_1 > T_0$ such that

$$\left| \int_{T_0}^{\infty} e^{-\delta\tau} q(\tau)\, d\tau - \int_{T_0}^{T_1} e^{-\delta\tau} q(\tau)\, d\tau \right| \leq \tilde{\varepsilon}. \tag{8.4}$$

From estimate (8.2) choose $\gamma > 0$ maximal with the property

$$\int_{T_0}^{T_1} q^+(\tau)\, d\tau - \int_{T_0}^{T_1-\gamma} q^-(\tau)\, d\tau = 0, \tag{8.5}$$

where q^+ and q^- denote the positive and negative parts of q, respectively. Now we can define a monotonically decreasing sequence τ_i, $i \in \mathbb{N}$ by $\tau_1 := T_1,\ \tau_2 := T_1 - \gamma$, and

$$\tau_{i+1} := \min \left\{ t \in [T_0, \tau_i] \mid -\int_t^{\tau_i} q^-(\tau)\, d\tau + \int_{\tau_i}^{\tau_{i-1}} q^+(\tau)\, d\tau = 0 \right\}.$$

This sequence is well defined: assume that there exists τ_i for some $i \geq 2$. In the case $i > 2$ for all j with $i \geq j \geq 3$, the equality

$$-\int_{T_0}^{\tau_j} q^-(s)\, ds + \int_{\tau_j}^{\tau_{j-1}} q^+(s)\, ds = -\int_{T_0}^{\tau_{j-1}} q^-(s)\, ds + \int_{\tau_{j-1}}^{\tau_{j-2}} q^+(s)\, ds$$

holds, and by induction and the choice of γ in (8.5) it follows

$$-\int_{T_0}^{\tau_i} q^-(\tau)\, d\tau + \int_{\tau_i}^{\tau_{i-1}} q^+(\tau)\, d\tau = -\int_{T_0}^{T_1-\gamma} q^-(\tau)\, d\tau + \int_{T_1-\gamma}^{T_1} q^+(\tau)\, d\tau \ \leq 0.$$

This guarantees the existence of τ_{i+1}. Since (τ_i) is monotone and bounded, the sequence converges to some $\tilde{\tau} \geq T_0$. We claim $\tilde{\tau} = T_0$.

By the definition of τ_i it follows that $-\int_{\tau_{i+1}}^{T_1-\gamma} q^-(\tau)\, d\tau + \int_{\tau_i}^{T_1} q^+(\tau)\, d\tau = 0$. The convergence $\tau_i \to \tilde{\tau}$ yields the equality

$$-\int_{\tilde{\tau}}^{T_1-\gamma} q^-(\tau)\, d\tau + \int_{\tilde{\tau}}^{T_1} q^+(\tau)\, d\tau = 0.$$

This implies $\int_{T_0}^{\tilde{\tau}} q(\tau)\, d\tau = 0$, which shows the asserted equality using (8.2).

Hence we can choose $k \in \mathbb{N}$ such that $|\tau_{k-1} - T_0| \leq \tilde{\varepsilon}$ and replace τ_k by $\tau_k = T_0$. Thus we can estimate

$$\begin{aligned}
\int_{T_0}^{T_1} e^{-\delta\tau} q(\tau)\, d\tau &\leq \sum_{i=2}^{k-1} \left(-\int_{\tau_{i+1}}^{\tau_i} e^{-\delta\tau} q^-(\tau)\, d\tau + \int_{\tau_i}^{\tau_{i-1}} e^{-\delta\tau} q^+(\tau)\, d\tau \right) + M\tilde{\varepsilon} \\
&\leq \sum_{i=2}^{k-1} \underbrace{\left(-\int_{\tau_{i+1}}^{\tau_i} e^{-\delta\tau_i} q^-(\tau) d\tau + \int_{\tau_i}^{\tau_{i-1}} e^{-\delta\tau_i} q^+(\tau) d\tau \right)}_{=0} + M\tilde{\varepsilon} \\
&= M\tilde{\varepsilon}.
\end{aligned}$$

In connection with (8.3) and (8.4) this yields

$$\int_0^{\infty} e^{-\delta\tau} q(\tau)\, d\tau = \int_0^{T_0} e^{-\delta\tau} q(\tau)\, d\tau + \int_{T_0}^{T_1} e^{-\delta\tau} q(\tau)\, d\tau + \int_{T_1}^{\infty} e^{-\delta\tau} q(\tau)\, d\tau < 0 + M\tilde{\varepsilon} + \tilde{\varepsilon}.$$

Since $\tilde{\varepsilon} > 0$ was arbitrary this proves (i).

(ii) Assume the opposite: let

$$\frac{1}{t}\int_0^t q(\tau)d\tau > \sigma + \varepsilon \text{ for all } t \in \left[\frac{\varepsilon}{(4M+4\sigma+\varepsilon)\delta}, -\frac{\ln\frac{\varepsilon}{4M}}{\delta}\right].$$

We define $\tilde{q}$ via

$$\tilde{q}(\tau) := \begin{cases} q(\tau), & \tau \le -\frac{\ln\frac{\varepsilon}{4M}}{\delta}, \\ \sigma+\varepsilon, & \tau > -\frac{\ln\frac{\varepsilon}{4M}}{\delta}. \end{cases}$$

This yields

$$\frac{1}{t}\int_0^t \tilde{q}(\tau)d\tau > \sigma + \varepsilon \text{ for all } t \ge \frac{\varepsilon}{(4M+4\sigma+\varepsilon)\delta},$$

and by (i) (with opposite signs and inequalities) we obtain

$$\delta\int_0^\infty e^{-\delta\tau}\tilde{q}(\tau)d\tau \ge \sigma + \frac{3}{4}\varepsilon.$$

Hence

$$\begin{aligned}\delta\int_0^\infty e^{-\delta\tau}q(\tau)d\tau &= \delta\int_0^\infty e^{-\delta\tau}\tilde{q}(\tau)d\tau - \delta\int_{-\frac{\ln\frac{\varepsilon}{4M}}{\delta}}^\infty \tilde{q}(\tau) - q(\tau)d\tau \\ &\ge \sigma + \frac{3}{4}\varepsilon - \delta\int_{-\frac{\ln\frac{\varepsilon}{4M}}{\delta}}^\infty e^{-\delta\tau}2Md\tau \quad = \quad \sigma + \frac{1}{4}\varepsilon,\end{aligned}$$

which contradicts the assumption on this discounted integral.

(iii) By (ii) for any $\varepsilon > 0$ there exist times $\tau(t)$ bounded from below and above such that

$$\frac{1}{\tau(t)}\int_0^{\tau(t)} q(t+\tau)d\tau < \sigma + \varepsilon.$$

Hence $\tau_0 := 0$, $\tau_{i+1} = \tau_i + \tau(\tau_i)$ defines a monotonically increasing sequence diverging to infinity for which there exists $a \in \mathbb{R}$ such that $\tau_{i+1} - \tau_i < a$ for all $i \in \mathbb{N}$. For arbitrary $T > 0$ let $\tau_{i(T)}$ be the maximal element of this sequence satisfying $\tau_{i(T)} \le T$. Thus we obtain

$$\begin{aligned}\limsup_{T\to\infty}\frac{1}{T}\int_0^T q(\tau)d\tau &= \limsup_{T\to\infty}\frac{1}{T}\left(\sum_{j=0}^{i(T)}\int_{\tau_{j-1}}^{\tau_j} q(\tau)d\tau + \int_{\tau_{i(T)}}^T q(\tau)d\tau\right) \\ &\le \limsup_{T\to\infty}\left(\sigma+\varepsilon+\frac{aM}{T}\right) \quad = \quad \sigma+\varepsilon.\end{aligned}$$

Since $\varepsilon > 0$ was arbitrary the assertion follows. □

STOCHASTIC H^∞*

D. HINRICHSEN† AND A. J. PRITCHARD‡

Abstract. We consider stochastic linear plants which are controlled by dynamic output feedback and subjected to both deterministic and stochastic perturbations. Our objective is to develop an H^∞-type theory for such systems. We prove a bounded real lemma for stochastic systems with deterministic and stochastic perturbations. This enables us to obtain necessary and sufficient conditions for the existence of a stabilizing compensator which keeps the effect of the perturbations on the to-be-controlled output below a given threshhold $\gamma > 0$. In the deterministic case, the analogous conditions involve two uncoupled linear matrix inequalities, but in the stochastic setting we obtain coupled nonlinear matrix inequalities instead. The connection between H^∞ theory and stability radii is discussed and leads to a lower bound for the radii, which is shown to be tight in some special cases.

Key words. stochastic systems, state dependent noise, H^∞ control, bounded real lemma, matrix inequalities

1. Introduction.

The objective of this paper is to develop an H^∞-type theory over infinite time horizons for the disturbance attenuation of stochastic systems by dynamic output feedback. We consider systems Σ described by Ito stochastic differential equations of the form

$$
\begin{aligned}
(1) \qquad dx(t) &= Ax(t)dt + A_0x(t)dw_1(t) + B_0v(t)dw_2(t) + B_1v(t)dt + B_2u(t)dt,\\
z(t) &= C_1x(t) + D_{11}v(t) + D_{12}u(t),\\
y(t) &= C_2x(t) + D_{21}v(t),
\end{aligned}
$$

where w_i, $i = 1, 2$ are zero mean scalar Wiener processes, not necessarily independent. In applications, such models are often obtained by linearization, and then $x(t)$, $z(t)$, and $u(t)$ represent deviations from desired fixed values of the state, the output, and the control (for instance, in a tracking problem; see [30]). We view v as an *unknown* finite energy stochastic disturbance which adversely affects the to-be-controlled output z (whose desired value is represented by 0). The disturbing effect is to be ameliorated via control action u based on dynamic feedback from the measured output y. A feedback controller $K : y \mapsto u$ has to be chosen in such a way that the closed loop system Σ_{cl} is stabilized. The effect of the disturbances on the to-be-controlled output z of Σ_{cl} is then described by the perturbation operator $\mathbb{L}_{cl} : v \mapsto z$ of Σ_{cl} which (for zero initial state) maps finite energy disturbance signals v into the corresponding finite energy output signals z of the closed loop system. The size of this linear operator is measured by the induced norm. The larger that this norm is, the larger is the effect of the unknown disturbance v on the to-be-controlled output z *in the worst case.*

*Received by the editors April 1, 1996; accepted for publication (in revised form) September 5, 1997; published electronically June 2, 1998.

The problem is to determine whether or not for each $\gamma > 0$ there exists a stabilizing controller K achieving $\|\mathbb{L}_{cl}\| < \gamma$. Moreover, we want to know how such controllers, if they exist, can be constructed.

In the deterministic case, the norm $\|\mathbb{L}_{cl}\|$ is given by the H^∞-norm of the associated rational transfer matrix, and so the theory dealing with the above problem is known as H^∞-control theory. In the present stochastic context the term H^∞ control may be a misnomer, but we use it nevertheless to refer, in a succinct and suggestive way, to the above disturbance attenuation problem.

System (1) may be regarded as a perturbed version of the stochastic system

$$\begin{aligned} \dot{x}(t) &= (A + A_0\dot{w}_1(t))x(t) + B_2u(t), \\ z(t) &= C_1x(t) + D_{12}u(t), \\ y(t) &= C_2x(t), \end{aligned} \tag{2}$$

representing a linear time-invariant system with multiplicative white noise. Such systems are widely considered in the stochastic literature, especially in stochastic stability analysis; see [10, ch. 6], [1, ch. 11], and [4, ch. 11]. By adding unknown disturbances to this equation we lay the groundwork for an analysis of *robust stability* of these systems; see section 5.

The disturbance of the state equation in our model (1) is composed of two parts, $B_1v(t)dt$ and $B_0v(t)dw_2(t)$. Although v is in general a stochastic vector, we view the first term as the *deterministic* and the second as the *stochastic component* of the disturbance. To motivate this terminology, let $v = \Delta z$, where Δ is an unknown matrix, and assume that the two Wiener processes in (1) are equal: $w_1 = w_2 = w$. Then the state equation in (1) reads

$$dx(t) = (A + B_1\Delta C_1)x(t)dt + (A_0 + B_0\Delta C_1)x(t)dw(t) + B_2u(t)dt. \tag{3}$$

So the deterministic disturbance term $B_1\Delta C_1$ represents a perturbation of A, i.e., of the deterministic parameters, and the stochastic disturbance term $B_0\Delta C_1$ represents a perturbation of the stochastic parameters of the system. The presence of both types of disturbances in (1) is essential to obtain a full generalization of the H^∞-control problem to the stochastic context. As a special case, it contains, on the one hand, $(A_0 = 0, B_0 = 0)$, the general deterministic H^∞-control problem (without regularity assumptions) as stated, e.g., in [8], [9], [17], [25], and [26]. On the other hand, it also includes the "purely stochastic" case where $B_1 = 0$, see [16].

It may seem odd that we use the same disturbance vector v in both the deterministic and stochastic disturbance terms. But this is in fact more general since distinct disturbance vectors v_0 and v_1 can be accounted for by setting $B_0 = [B_0^0\ 0]$, $B_1 = [0\ B_1^1]$, and $v = \left[\begin{smallmatrix} v_0 \\ v_1 \end{smallmatrix}\right]$. Similarly, it would simplify the situation if we assumed that the two Wiener processes w_1 and w_2 are independent. But we avoid this assumption in order to derive formulae which are equally applicable to the case where, e.g., $w_1 = w_2 = w$; see (3).

In order to keep the notational burden as low as possible, we do not deal with more general models or more general multiperturbation structures, where the single stochastic terms in (1) are replaced by sums of similar terms. In section 6 we make some comments about the extension of our results to such systems.

The main complication in the H^∞-control problem studied here is due to the presence of both deterministic and stochastic perturbations terms in (1). In the case of purely stochastic disturbances, the problem has been solved in [16]. The key result

on which the general solution will be based is the Stochastic Bounded Real Lemma which will be proved in the next section. This result states necessary and sufficient conditions for a given stochastic system to be stable with $\|\mathbb{L}\| < \gamma$. It is of independent interest, because it allows one to determine $\|\mathbb{L}\|$ which measures the influence of the disturbances in the worst case scenario. The centerpiece of our conditions is no longer a Riccati-type equation or the corresponding matrix inequality (as in the deterministic case) but is a rational matrix equation which appears to be new. For the associated matrix inequality we could not find existence results in the literature. Our proof proceeds—as in the theory of algebraic Riccati equations—via the study of a finite time optimization problem which, due to the structure of our disturbance model, has a number of subtleties.

While section 2 deals with a problem of system analysis (under which conditions does the input output operator $\mathbb{L}$ of a stable stochastic system have a norm $\|\mathbb{L}\| < \gamma$?) the synthesis problem of H^∞-control will be treated in section 3. Here we follow the linear matrix inequalities (LMI) approach developed for deterministic systems; see [8], [17]. The idea is to apply the Stochastic Bounded Real Lemma to the compensated system Σ_{cl} in such a way that the matrices of compensator parameters, which achieve stability and $\|\mathbb{L}_{cl}\| < \gamma$, are characterized by a linear matrix inequality. Then, applying the projection lemma [8] we are able to obtain necessary and sufficient conditions in terms of the given data. The result is a characterization in terms of a pair of matrix inequalities. But in contrast to the deterministic case the two matrix inequalities are coupled and nonlinear. Specializing to the case $A_0 = B_0 = 0$, however, the inequalities are linear and decoupled, and we regain the deterministic results as given in [8].

In section 4 we deal with the so-called regular case. The matrix inequalities—although still coupled and nonlinear—are greatly simplified via the regularity assumptions, and it is possible to derive explicit formulae for full order suboptimal compensators. In the deterministic context, this was the case for which the H^∞-control problem was first resolved via a pair of Riccati equations [5]. In the stochastic context, we do not obtain an analogous pair of rational matrix *equations*. In fact it has been shown for the special case $A_0 = B_1 = 0$ that, in general, it is not possible to replace the two inequalities by equalities; see [16]. Therefore, even for regular data, matrix *in*equalities seem to be indispensable tools of an H^∞-type optimal control theory in the stochastic context. For the deterministic case $A_0 = B_0 = 0$, however, our conditions reduce to the well-known Riccati inequalities from which the results in [5] follow via standard theorems about the relationship between Riccati inequalities and equations.

In section 5, we consider stability radii for a nominal system where all direct input output couplings are zero (a singular problem). If (2) is stable, $u = 0$, and $v = \Delta z$, the associated stability radius is the maximum ρ such that all the perturbed systems with $\|\Delta\| < \rho$ are stable. We will use the results of section 2 to obtain a lower bound for the radius. In the deterministic case there is a close relationship between the singular H^∞-control problem and the problem of maximizing the stability radius of a given system by state or dynamic output feedback; see [13]. We will use this relationship to show how the radius may be enhanced by feedback. However, we do not determine precise formulae for the stability radius or for the supremal stability radius achievable by feedback. The general problem of characterizing and maximizing stability radii of stochastic systems of the form (1) is still open.

In some concluding remarks (section 6) we will comment on further open problems and possible extensions of our work.

The stabilization of stochastic systems with multiplicative noise has been studied since the late sixties, particularly in the context of linear quadratic optimal control; see, e.g., [20], [27], and [29]. The subject of robust stabilization is of more recent vintage. An early reference is [28], where the problem is considered in an almost disturbance decoupling framework. More recently, a number of papers have been published which deal with robust stability and robust stabilization problems in the spirit of H^∞-control or the stability radius approach. In [6], El Ghaoui describes how the maximization of an estimate for the stability radius by state feedback can be formulated—for general multi noise structures—as a convex optimization problem over linear matrix inequalities. In [22], the norm of the perturbation operator of a time-varying stable linear system with state dependent noise ($B_0 = 0, B_1 = 0$) is related to a parametrized Riccati equation. Formulae for stability radii and supremal stability radii of stochastic systems have been obtained for various special cases. The first formula was derived for the case $A_0 = 0$, $B_1 = 0$ in [2]. Morozan [21] extended this formula to the case where $B_1 = 0$ and the nominal system contains a sum of white noise terms. The maximization of stability radii via state feedback was first considered in [13]. A full H^∞ and stability radius theory for stochastic multiperturbations of a deterministic system was developed in [16]. *However, all these characterizations of stability radii apply only to the special case of purely stochastic parameter disturbances* ($B_1 = 0$). First results concerning stability radii subjected to simultaneous deterministic and stochastic parameter perturbations have been presented in [15]. These are improved in the present paper. However, our main intention is to develop a counterpart of H^∞-control for linear stochastic systems. The conceptual difference between H^∞-control theory and the theory of stability radii, which has been blurred by the fact that they yield similar results for deterministic time-invariant linear systems, stands out more clearly in the stochastic context.

2. A stochastic version of the bounded real lemma. The main tool that we will use in our analysis of the stochastic disturbance attenuation problem is an extension of the bounded real lemma to stochastic systems. This result is of independent interest and, in fact, we regard it as the main result of this paper. In order to describe it we consider the following system

$$\begin{aligned} dx(t) &= Ax(t)dt + A_0x(t)dw_1(t) + B_0v(t)dw_2(t) + Bv(t)dt, \\ z(t) &= Cx(t) + Dv(t), \end{aligned} \tag{4}$$

where

(5)

$$(A, A_0, B_0, B, C, D) \in \mathbb{K}^{n\times n} \times \mathbb{K}^{n\times n} \times \mathbb{K}^{n\times \ell} \times \mathbb{K}^{n\times \ell} \times \mathbb{K}^{q\times n} \times \mathbb{K}^{q\times \ell}, \qquad \mathbb{K} = \mathbb{R} \text{ or } \mathbb{C}.$$

w_1, w_2 are zero mean real scalar Wiener processes on a probability space $(\Omega, \mathcal{F}, \mu)$ relative to an increasing family $(\mathcal{F}_t)_{t\in\mathbb{R}_+}$ of σ-algebras $\mathcal{F}_t \subset \mathcal{F}$. We assume that

$$\mathcal{E}((w_i(t) - w_i(s))(w_j(t) - w_j(s))) = q_{ij}(t - s), \quad i, j = 1, 2, \quad t, s \in \mathbb{R}_+, \quad t > s.$$

So $Q = (q_{ij})$ is the incremental covariance matrix of the two-dimensional Wiener process

$$\begin{bmatrix} w_1(t) \\ w_2(t) \end{bmatrix}.$$

In (4), the input process $v(t)$ is viewed as a stochastic disturbance and the output process $z(t)$ is viewed as a vector of the to-be-controlled variables. The system equation contains multiplicative state and input dependent noise terms which may be interpreted as white noise parameter perturbations of the following matrices A and B:

$$dx(t) = (A + A_0\dot{w}_1(t))x(t)dt + (B + B_0\dot{w}_2(t))v(t)dt.$$

In this paper, we provide all spaces $\mathbb{K}^k$, $k \geq 1$ with the usual inner product $\langle \cdot, \cdot \rangle$ and the corresponding 2-norm $\| \cdot \|$. Let $L^2(\Omega, \mathbb{K}^k)$ denote the space of square-integrable $\mathbb{K}^k$-valued functions (modulo equivalence) on the probability space $(\Omega, \mathcal{F}, \mu)$. For any $0 < T \leq \infty$, we write $[0, T]$ for the closure of the open interval $(0, T)$ in $\mathbb{R}$ and denote by $L^2_w([0, T]; L^2(\Omega, \mathbb{K}^k))$ the space of nonanticipative stochastic processes $y(\cdot) = (y(t))_{t\in[0,T]}$ with respect to $(\mathcal{F}_t)_{t\in[0,T]}$ (see, e.g., [7]) satisfying

$$\|y(\cdot)\|^2_{L^2_w} = \mathcal{E}\left(\int_0^T \|y(t)\|^2 dt\right) = \int_0^T \mathcal{E}(\|y(t)\|^2)dt < \infty. \tag{6}$$

For arbitrary $0 < T < \infty$ and $(v, x^0) \in L^2_w([0, T]; L^2(\Omega, \mathbb{K}^\ell)) \times \mathbb{K}^n$, there exists a unique solution $x(\cdot) = x(\cdot, v, x^0) \in L^2_w([0, T]; L^2(\Omega, \mathbb{K}^n))$ of (4) with $x(0) = x^0$ [18], i.e., $x(\cdot)$ is a continuous nonanticipative stochastic process satisfying the Ito integral equation

(7)

$$x(t) = x^0 + \int_0^t (Ax(s) + Bv(s))ds + \int_0^t [A_0x(s)\ B_0v(s)]d\begin{bmatrix} w_1(s) \\ w_2(s) \end{bmatrix}, \quad t \in [0, T].$$

Moreover, $x(\cdot)$ has bounded second moments on $[0, T]$.

Definition 2.1. *The system* (4) *is called* internally stable *if there exists a constant $c > 0$ such that*

$$\mathcal{E}\int_0^\infty \|x(t)\|^2 dt \leq c\|x^0\|^2, \qquad x^0 \in \mathbb{K}^n,$$

where $x(\cdot) = x(\cdot; 0, x^0)$ is the free *trajectory of* (7) *starting at x^0 (i.e., $v = 0$).*

It has been shown (see [4]) that an equivalent condition is that there exist constants $M \geq 1$, $\omega > 0$ such that

$$\mathcal{E}\|x(t; 0, x^0)\|^2 \leq Me^{-\omega t}\|x^0\|^2 \quad \text{for all } x^0 \in \mathbb{K}^n, \quad t \geq 0.$$

Let $\mathcal{H}_n(\mathbb{K})$ denote the set of Hermitian matrices in $\mathbb{K}^{n\times n}$. It is known [4] that (4) is stable in the above sense if and only if there exists $P \in \mathcal{H}_n(\mathbb{K})$, $P \prec 0$ such that

$$PA + A^*P + q_{11}A_0^*PA_0 = I_n. \tag{8}$$

It is easily seen that in this stability criterion the identity matrix (on the right-hand side of (8)) may be replaced by any other positive definite matrix $Q_0 \in \mathcal{H}_n(\mathbb{K})$.

The following definition generalizes the concept of finite gain L^2 stability from deterministic input output systems to stochastic systems of the form (4).

Definition 2.2. *The system* (4) *is said to be* externally stable *or* L^2 input-output stable *if, for every $v(\cdot) \in L^2_w(\mathbb{R}_+; L^2(\Omega, \mathbb{K}^\ell))$,*

$$z(\cdot) = Cx(\cdot, v, 0) + Dv(\cdot) \in L^2_w(\mathbb{R}_+; L^2(\Omega, \mathbb{K}^q)),$$

and there exists a constant $\gamma \geq 0$ *such that*

$$\|z(\cdot)\|_{L_w^2(\mathbb{R}_+;L^2(\Omega,\mathbb{K}^q))} \leq \gamma \|v(\cdot)\|_{L_w^2(\mathbb{R}_+;L^2(\Omega,\mathbb{K}^\ell))}, \qquad v \in L_w^2(\mathbb{R}_+;L^2(\Omega,\mathbb{K}^\ell)). \tag{9}$$

DEFINITION 2.3. *Suppose that* (4) *is externally stable. The operator*

$$\mathbb{L} : L_w^2(\mathbb{R}_+;L^2(\Omega,\mathbb{K}^\ell)) \to L_w^2(\mathbb{R}_+;L^2(\Omega,\mathbb{K}^q)),$$

defined by

$$(\mathbb{L}v)(t) = Cx(t,v,0) + Dv(t), \quad t \geq 0, \quad v(\cdot) \in L_w^2(\mathbb{R}_+;L^2(\Omega,\mathbb{K}^\ell)), \tag{10}$$

is called the perturbation operator *of* (4). *Its norm is defined as the minimal* $\gamma \geq 0$ *such that* (9) *is satisfied, i.e.,*

$$\|\mathbb{L}\| = \sup_{v \in L_w^2(\mathbb{R}_+;L^2(\Omega,\mathbb{K}^\ell)), v \neq 0} \frac{\|Cx(\cdot,v,0) + Dv(\cdot)\|_{L_w^2(\mathbb{R}_+;L^2(\Omega,\mathbb{K}^q))}}{\|v(\cdot)\|_{L_w^2(\mathbb{R}_+;L^2(\Omega,\mathbb{K}^\ell))}}. \tag{11}$$

$\|\mathbb{L}\|$ *is a measure of the worst effect the stochastic disturbance* $v(\cdot)$ *may have on the to-be-controlled output* $z(\cdot)$ *of the system. Therefore it is important to find a way of determining the norm* $\|L\|$. *The stochastic bounded real lemma which we will derive in this section provides a method for computing* $\|\mathbb{L}\|$.

We proceed by associating a finite time quadratic cost functional with the problem

$$J_T^{\gamma^2}(x^0,v) = \int_0^T \mathcal{E}[\gamma^2\|v(t)\|^2 - \|z(t)\|^2]dt = \int_0^T \mathcal{E}[\gamma^2\|v(t)\|^2 - \|Cx(t) + Dv(t)\|^2]dt, \tag{12}$$

where $x(\cdot) = x(\cdot,v,x^0)$ denotes the solution of (4) with $x(0) = x^0$ and $v(\cdot) \in L_w^2 = L_w^2([0,T];L^2(\Omega,\mathbb{K}^\ell))$, and $z(\cdot) = z(\cdot,v,x^0)$ is the corresponding output. We will see that the problem of minimizing this functional will lead us to a solution of the supremum problem on the right-hand side of (11). Formally, the problem of minimizing $J_T^{\gamma^2}(x^0,v)$ has the form of an optimal control problem and so in our development in this section we will refer to the disturbance v as a "control." Our first step is to show that an internally stable system (4) is also externally stable. For every $P \in \mathcal{H}_n(\mathbb{K})$, we set

$$M(P) = \begin{bmatrix} PA + A^*P + q_{11}A_0^*PA_0 - C^*C & PB + q_{12}A_0^*PB_0 - C^*D \\ B^*P + q_{12}B_0^*PA_0 - D^*C & \gamma^2 I_\ell + q_{22}B_0^*PB_0 - D^*D \end{bmatrix}. \tag{13}$$

LEMMA 2.4. *Suppose* $P(\cdot) : [0,T] \mapsto \mathcal{H}_n(\mathbb{K})$ *is continuously differentiable,* $T > 0$. *Then for every* $x^0 \in \mathbb{K}^n, v(\cdot) \in L_w^2$,

$$\begin{aligned} J_T^{\gamma^2}(x^0,v) &= \langle x^0, P(0)x^0\rangle - \mathcal{E}\langle x(T), P(T)x(T)\rangle \\ &\quad + \int_0^T \mathcal{E}\left(\langle x(t), \dot{P}(t)x(t)\rangle + \left\langle \begin{bmatrix} x(t) \\ v(t) \end{bmatrix}, M(P(t)) \begin{bmatrix} x(t) \\ v(t) \end{bmatrix} \right\rangle\right) dt, \end{aligned} \tag{14}$$

where $M(P)$ *is defined by* (13) *and* $x(\cdot) = x(\cdot,v,x^0)$.

Proof. Let $x^0 \in \mathbb{K}^n$, $v(\cdot) \in L^2_w$, and let $x(\cdot) = x(\cdot, v, x^0)$ denote the corresponding solution of (4). Then the vector function $\varphi(s) = (Ax(s) + Bv(s))$ and the $n \times 2$ matrix function $\Phi(s) = [A_0 x(s)\ B_0 v(s)]$ satisfy the conditions of Ito's lemma (see [4, ch. 4, section 5]) and, by (7),

$$x(t) = x^0 + \int_0^t \varphi(s)ds + \int_0^t \Phi(s)d \begin{bmatrix} w_1(s) \\ w_2(s) \end{bmatrix}, \qquad t \in [0, T].$$

Applying Ito's formula to $F(t, x(t)) = \langle x(t),\ P(t)x(t)\rangle$ and taking expectations we obtain, for every $T > 0$.

$$\begin{aligned}
\mathcal{E}\langle x(T), P(T)x(T)\rangle - \langle x^0, P(0)x^0\rangle &= \mathcal{E}\int_0^T \langle x(t), \dot{P}(t)x(t)\rangle dt \\
&+ \mathcal{E}\int_0^T 2\mathrm{Re}\left\langle P(t)x(t), \Phi(t)d \begin{bmatrix} w_1(s) \\ w_2(s) \end{bmatrix} \right\rangle \\
&+ \mathcal{E}\int_0^T 2\mathrm{Re}\langle P(t)x(t), Ax(t) + Bv(t)\rangle dt \\
&+ \mathcal{E}\int_0^T \mathrm{tr}\{P(t)[A_0x(t)\ B_0v(t)]Q[A_0x(t)\ B_0v(t)]^*\}dt,
\end{aligned}$$

where tr denotes the trace. We first prove (14) under the condition that $v(\cdot) \in L^2_w$ is bounded, i.e.,

$$\exists c > 0 : \qquad \|v(t, \omega)\|_{\mathbb{K}^\ell} \le c, \quad (t, \omega) \in [0, T] \times \Omega.$$

Applying an estimate for the moments of $x(\cdot)$ (see [19, p. 81, Corollary 6]) there exist constants $c_0, c_1 > 0$ such that

$$\mathcal{E}\|x(t, v, x^0)\|^2_{\mathbb{K}^n} \le c_0\|x^0\|^2_{\mathbb{K}^n} + c_1\mathcal{E}\int_0^t \|v(s)\|^2_{\mathbb{K}^\ell} ds. \tag{15}$$

Hence, $\mathcal{E}\|x(t, v, x^0)\|^2_{\mathbb{K}^n}$ is bounded on $[0, T]$ and therefore,

$$\begin{aligned}
\mathcal{E}\int_0^T \left\langle P(t)x(t), \Phi(t)d \begin{bmatrix} w_1(s) \\ w_2(s) \end{bmatrix} \right\rangle &= \mathcal{E}\int_0^T \langle P(t)x(t), A_0x(t)\rangle dw_1(t) \\
&+ \mathcal{E}\int_0^T \langle P(t)x(t), B_0v(t)\rangle dw_2(t) = 0.
\end{aligned}$$

Now

$$\begin{aligned}
&\mathrm{tr}\{P(t)[A_0x(t)\ B_0v(t)]Q[A_0x(t)\ B_0v(t)]^*\} \\
&= \mathrm{tr}\left\{ \begin{bmatrix} x(t)^*A_0^* \\ v(t)^*B_0^* \end{bmatrix} P(t)[A_0x(t)\ B_0v(t)]Q \right\} \\
&= \mathrm{tr}\left\{ \begin{bmatrix} x(t)^*A_0^*P(t)A_0x(t) & x(t)^*A_0^*P(t)B_0v(t) \\ v(t)^*B_0^*P(t)A_0x(t) & v(t)^*B_0^*P(t)B_0v(t) \end{bmatrix} \begin{bmatrix} q_{11} & q_{12} \\ q_{12} & q_{22} \end{bmatrix} \right\} \\
&= \left\langle \begin{bmatrix} x(t) \\ v(t) \end{bmatrix}, \begin{bmatrix} q_{11}A_0^*P(t)A_0 & q_{12}A_0^*P(t)B_0 \\ q_{12}B_0^*P(t)A_0 & q_{22}B_0^*P(t)B_0 \end{bmatrix} \begin{bmatrix} x(t) \\ v(t) \end{bmatrix} \right\rangle.
\end{aligned}$$

Hence,

$$
\begin{aligned}
&J_T^{\gamma^2}(x^0,v)+\mathcal{E}\langle x(T),P(T)x(T)\rangle-\langle x^0,P(0)x^0\rangle\\
&\quad=\ \mathcal{E}\int_0^T\Bigg\{\langle x(t),\dot P(t)x(t)\rangle+\gamma^2\|v(t)\|^2-\|Cx(t)+Dv(t)\|^2\\
&\qquad+\langle P(t)x(t),Ax(t)+Bv(t)\rangle+\langle Ax(t)+Bv(t),P(t)x(t)\rangle\\
&\qquad+\left\langle\begin{bmatrix}x(t)\\v(t)\end{bmatrix},\begin{bmatrix}q_{11}A_0^*P(t)A_0 & q_{12}A_0^*P(t)B_0\\ q_{12}B_0^*P(t)A_0 & q_{22}B_0^*P(t)B_0\end{bmatrix}\begin{bmatrix}x(t)\\v(t)\end{bmatrix}\right\rangle\Bigg\}dt\\
&\quad=\ \mathcal{E}\int_0^T\Bigg\{\langle x(t),\dot P(t)x(t)\rangle\\
&\qquad+\left\langle\begin{bmatrix}x(t)\\v(t)\end{bmatrix},\begin{bmatrix}P(t)A+A^*P(t)-C^*C & P(t)B-C^*D\\ B^*P(t)-D^*C & \gamma^2I-D^*D\end{bmatrix}\begin{bmatrix}x(t)\\v(t)\end{bmatrix}\right\rangle\\
&\qquad+\left\langle\begin{bmatrix}x(t)\\v(t)\end{bmatrix},\begin{bmatrix}q_{11}A_0^*P(t)A_0 & q_{12}A_0^*P(t)B_0\\ q_{12}B_0^*P(t)A_0 & q_{22}B_0^*P(t)B_0\end{bmatrix}\begin{bmatrix}x(t)\\v(t)\end{bmatrix}\right\rangle\Bigg\}dt\\
&\quad=\ \int_0^T\mathcal{E}\left\{\langle x(t),\dot P(t)x(t)\rangle+\left\langle\begin{bmatrix}x(t)\\v(t)\end{bmatrix},M(P(t))\begin{bmatrix}x(t)\\v(t)\end{bmatrix}\right\rangle\right\}dt.
\end{aligned}
$$

This proves (14) for all bounded $v(\cdot)\in L_w^2$ and $x^0\in\mathbb{K}^n$. Now consider the linear maps

$$
\begin{aligned}
L_w^2\times\mathbb{K}^n\to L_w^2([0,T];L^2(\Omega,\mathbb{K}^n)),\qquad (v,x^0)\mapsto x(\cdot,v,x^0),\\
L_w^2\times\mathbb{K}^n\to L^2(\Omega,\mathbb{K}^n),\qquad (v,x^0)\mapsto x(T,v,x^0),
\end{aligned}
$$

where we endow $L_w^2\times\mathbb{K}^n$ with the norm $\|(v,x^0)\|=(\|x^0\|_{\mathbb{K}^n}^2+\|v(\cdot)\|_{L_w^2}^2)^{1/2}$. By the estimate (15), these are bounded linear operators. As a consequence, for any fixed $x^0\in\mathbb{K}^n$ the left- and right-hand sides of (12) depend continuously on $v\in L_w^2$. They coincide on the linear subspace L_b^2 of bounded $v\in L_w^2$ which is dense in L_w^2. Therefore (12) holds for all $v\in L_w^2$, $x^0\in\mathbb{K}^n$. ∎

PROPOSITION 2.5. *Suppose* (4) *is internally stable. Then* (4) *is externally stable. Moreover, there exist* $\gamma>0$ *and* $P\in\mathcal{H}_n(\mathbb{K})$, $P\prec 0$ *such that*

(16)
$$
M(P)=\begin{bmatrix}PA+A^*P+q_{11}A_0^*PA_0-C^*C & PB+q_{12}A_0^*PB_0-C^*D\\ B^*P+q_{12}B_0^*PA_0-D^*C & \gamma^2I_\ell+q_{22}B_0^*PB_0-D^*D\end{bmatrix}\succ 0,
$$

and, for each pair $(\gamma,P)\in(0,\infty)\times\mathcal{H}_n(\mathbb{K})$ *satisfying* (16) *and* $P\prec 0$, *we have* $\|\mathbb{L}\|<\gamma$.

Proof. Since (4) is internally stable, there exists $P\in\mathcal{H}_n(\mathbb{K})$, $P\prec 0$ such that

$$
PA+A^*P+q_{11}A_0^*PA_0-C^*C\succ 0. \tag{17}
$$

For any Hermitian block matrix $M=\left[\begin{smallmatrix}M_{11} & M_{12}\\ M_{21} & M_{22}\end{smallmatrix}\right]\in\mathbb{K}^{(n+\ell)\times(n+\ell)}$, we have the well-known definiteness criterion

$$
M\succ 0\quad\Leftrightarrow\quad(M_{22}\succ 0\text{ and }M_{11}-M_{12}M_{22}^{-1}M_{21}\succ 0). \tag{18}
$$

Applying this criterion to $M(P)$ (with the above P) we see that, for γ sufficiently large, $M(P) \succ 0$. Hence, there exists a pair $(\gamma, P) \in (0,\infty) \times \mathcal{H}_n(\mathbb{K})$ satisfying (16) and $P \prec 0$.

Now assume that $(\gamma, P) \in (0,\infty) \times \mathcal{H}_n(\mathbb{K})$ is any pair satisfying (16) and $P \prec 0$. Choose $\varepsilon > 0$ sufficiently small such that $M(P) \succeq \varepsilon^2 I$. Then, setting $P(t) = P$ and $x^0 = 0$ in (14), we obtain for all $v(\cdot) \in L^2_w(\mathbb{R}_+; L^2(\Omega, \mathbb{K}^\ell))$ and all $T > 0$,

$$J_T^{\gamma^2}(0, v) = \int_0^T \mathcal{E}[\gamma^2 \|v(t)\|^2 - \|z(t)\|^2] dt \geq \varepsilon^2 \int_0^T \mathcal{E}\|v(t)\|^2 dt, \tag{19}$$

since $P \prec 0$. It follows that $z(\cdot) = z(\cdot, v, 0) \in L^2_w(\mathbb{R}_+; L^2(\Omega, \mathbb{K}^q))$ and

$$\|\mathbb{L}v\|^2_{L^2_w(\mathbb{R}_+; L^2(\Omega,\mathbb{K}^q))} = \int_0^\infty \mathcal{E}\|z(t)\|^2 dt \leq (\gamma^2 - \varepsilon^2) \int_0^\infty \mathcal{E}\|v(t)\|^2 dt$$

for all $v(\cdot) \in L^2_w(\mathbb{R}_+; L^2(\Omega, \mathbb{K}^\ell))$. This concludes the proof. ∎

Remark 2.6. (i) By setting $C = I_n$ and $D = 0$, we see that $x(\cdot, v, 0) \in L^2_w(\mathbb{R}_+; L^2(\Omega, \mathbb{K}^n))$ for $v(\cdot) \in L^2_w(\mathbb{R}_+; L^2(\Omega, \mathbb{K}^\ell))$, and since $x(t, v, x^0) = x(t, 0, x^0) + x(t, v, 0)$, we conclude that $x(\cdot, v, x^0) \in L^2_w(\mathbb{R}_+; L^2(\Omega, \mathbb{K}^n))$ for all $(v(\cdot), x^0) \in L^2_w \times \mathbb{K}^n$.

(ii) Suppose that $M(P) \succ 0$ for some $\gamma > 0$ and $P \in \mathcal{H}_n(\mathbb{K})$ with $P \prec 0$ (as in Proposition 2.5). Then there exists $\delta > 0$ such that $P \preceq -\delta^2 I$, and by (14),

$$\begin{aligned}\gamma^2 \int_0^\infty \mathcal{E}\|v(t)\|^2 dt \geq J_T^{\gamma^2}(x^0, v) &\geq \langle x^0, Px^0\rangle - \mathcal{E}\langle x(T), Px(T)\rangle \\ &\geq \langle x^0, Px^0\rangle + \delta^2 \mathcal{E}\|x(T)\|^2, \qquad T > 0.\end{aligned}$$

It follows that $\mathcal{E}\|x(t, v, x^0)\|^2$ is bounded in $t \in \mathbb{R}_+$, for all $(v(\cdot), x^0) \in L^2_w \times \mathbb{K}^n$.

COROLLARY 2.7. *Suppose that* (16) *holds for some pair* $(\gamma, P) \in (0,\infty) \times \mathcal{H}_n(\mathbb{K})$ *with* $P \prec 0$. *Then* (4) *is internally stable and* $\|\mathbb{L}\| < \gamma$.

Proof. Suppose that (16) holds. Since (16) implies (17), system (4) is internally stable. Hence, $\|\mathbb{L}\| < \gamma$ follows from the previous proposition. ∎

We will now show the converse of Corollary 2.7, i.e., we will prove the following characterization of the norm of the perturbation operator which can be viewed as a stochastic version of the bounded real lemma.

THEOREM 2.8 (stochastic bounded real lemma). *For any set of data* (5) *and any positive real number* γ, *the following statements are equivalent:*

(i) *The system* (4) *is internally stable and* $\|\mathbb{L}\| < \gamma$.

(ii) *There exists* $P \in \mathcal{H}_n(\mathbb{K})$ *such that* (16) *is satisfied.*

It remains to prove that (i) implies (ii). In order to do this we need a number of lemmata. Using the notation

$$H^{\gamma^2}(P) = \gamma^2 I_\ell + q_{22} B_0^* P B_0 - D^* D \in \mathcal{H}_\ell(\mathbb{K}), \quad K(P) = PB + q_{12} A_0^* P B_0 - C^* D \in \mathbb{K}^{n\times\ell},$$

we can write $M(P)$, defined by (13), in the following way:

$$M(P) = \begin{bmatrix} PA + A^*P + q_{11}A_0^*PA_0 - C^*C & K(P) \\ K(P)^* & H^{\gamma^2}(P) \end{bmatrix} \succ 0. \tag{20}$$

LEMMA 2.9. *Suppose* $F(\cdot) \in C([0,T], \mathbb{K}^{\ell\times n})$ *and* $P_F^{\gamma^2}(\cdot)$ *satisfies the linear differential matrix equation*

$$\begin{aligned}&\dot X(t) + X(t)(A + BF(t)) + (A + BF(t))^* X(t) + q_{11}A_0^* X(t) A_0 \\ &\quad + q_{22} F(t)^* B_0^* X(t) B_0 F(t) + q_{12} A_0^* X(t) B_0 F(t) \\ &\quad + q_{12} F(t)^* B_0^* X(t) A_0 + \gamma^2 F(t)^* F(t) - (C + DF(t))^*(C + DF(t)) = 0,\end{aligned} \tag{21}$$

with $P_F^{\gamma^2}(T) = 0$. *Then if* $v(\cdot) \in L_w^2([0,T]; L^2(\Omega, \mathbb{K}^\ell))$, *we have*

$$\begin{aligned} J_T^{\gamma^2}(x^0, v + Fx_F) &= \langle x^0, P_F^{\gamma^2}(0)x^0\rangle \\ &\quad + \int_0^T \mathcal{E}[\langle v, Nx_F\rangle + \langle Nx_F, v\rangle + \langle v, H^{\gamma^2}(P_F^{\gamma^2})v\rangle]dt, \end{aligned} \tag{22}$$

where $x_F(\cdot) = x_F(\cdot, v(\cdot), x^0) = x(\cdot, F(\cdot)x_F(\cdot) + v(\cdot), x^0)$ *is the solution of*

$$\begin{aligned} dx_F(t) &= (A + BF(t))x_F(t)dt + A_0x_F(t)dw_1(t) + B_0F(t)x_F(t)dw_2(t) \\ &\quad + B_0v(t)dw_2(t) + Bv(t)dt, \end{aligned} \tag{23}$$

with $x_F(0) = x^0$ *and* $N(t) = K(P_F^{\gamma^2}(t))^* + H^{\gamma^2}(P_F^{\gamma^2}(t))F(t)$. *In particular, if* $v = 0$, *then*

$$J_T^{\gamma^2}(x^0, Fx_F) = \langle x^0, P_F^{\gamma^2}(0)x^0\rangle. \tag{24}$$

Proof. The left-hand side of (21) can be written as

$$\dot{X}(t) + \begin{bmatrix} I \\ F(t) \end{bmatrix}^* \begin{bmatrix} X(t)A + A^*X(t) + q_{11}A_0^*X(t)A_0 - C^*C & X(t)B + q_{12}A_0^*X(t)B_0 - C^*D \\ B^*X(t) + q_{12}B_0^*X(t)A_0 - D^*C & \gamma^2 I + q_{22}B_0^*X(t)B_0 - D^*D \end{bmatrix} \begin{bmatrix} I \\ F(t) \end{bmatrix}.$$

Hence, $P_F^{\gamma^2}(t)$ satisfies

$$\dot{X}(t) + [I \quad F^*(t)]M(X(t)) \begin{bmatrix} I \\ F(t) \end{bmatrix} = 0, \qquad X(T) = 0. \tag{25}$$

Therefore, applying Lemma 2.4 with $P(\cdot) = P_F^{\gamma^2}(\cdot)$ and $F(\cdot)x_F(\cdot) + v(\cdot)$ for $v(\cdot)$, we obtain that $J_T^{\gamma^2}(x^0, Fx_F + v)$ is equal to

$$\begin{aligned} &\langle x^0, P_F^{\gamma^2}(0)x^0\rangle + \mathcal{E}\int_0^T \left\{ \langle x_F(t), \dot{P}_F^{\gamma^2}(t)x_F(t)\rangle \right. \\ &\qquad \left. + \begin{bmatrix} x_F(t) \\ F(t)x_F(t) + v(t) \end{bmatrix}^* M(P_F^{\gamma^2}(t)) \begin{bmatrix} x_F(t) \\ F(t)x_F(t) + v(t) \end{bmatrix} \right\} dt \\ &= \langle x^0, P_F^{\gamma^2}(0)x^0\rangle + \mathcal{E}\int_0^T [\langle v(t), N(t)x_F(t)\rangle \\ &\qquad + \langle N(t)x_F(t), v(t)\rangle + \langle v(t), H^{\gamma^2}(P_F^{\gamma^2}(t))v(t)\rangle]dt. \end{aligned}$$

Hence, (22) holds. Setting $v = 0$ in (22), we obtain (24). ∎

LEMMA 2.10. *Suppose* (4) *is internally stable and* $\|\mathbb{L}\| < \gamma$. *Then there exists* $c > 0$ *such that*

$$J_T^{\gamma^2}(x^0, v) \geq -c\|x^0\|^2, \quad x^0 \in \mathbb{K}^n, \quad v(\cdot) \in L^2_w([0,T]; L^2(\Omega, \mathbb{K}^\ell)), \quad T > 0. \tag{26}$$

Proof. Denote by $X_T(t)$ the solution of (21) with $F(t) \equiv 0$ and final value $X_T(T) = 0$, i.e., $X_T(t)$ solves

$$\dot{X}(t) + X(t)A + A^*X(t) + q_{11}A_0^*X(t)A_0 - C^*C = 0, \qquad X(T) = 0.$$

By time invariance, $X_T(t) = X_{T-t}(0)$. By linearity, we have $x(t, v, x^0) = x(t, 0, x^0) + x(t, v, 0)$. Applying (22) with $F(t) \equiv 0$, we get

$$\begin{aligned} J_T^{\gamma^2}(x^0, v) - J_T^{\gamma^2}(0, v) &= \langle x^0, X_T(0)x^0\rangle \\ &\quad + \mathcal{E}\int_0^T [\langle v(t), N_T(t)x(t,0,x^0)\rangle + \langle N_T(t)x(t,0,x^0), v(t)\rangle]dt, \end{aligned}$$

where $N_T(t) = K(X_T(t))^*$. Let $0 < \varepsilon^2 < \gamma^2 - \|\mathbb{L}\|^2$. Then,

$$\begin{aligned} J_T^{\gamma^2}(0, v) &\geq \gamma^2\|\bar{v}\|^2_{L^2_w([0,\infty];L^2(\Omega,\mathbb{K}^\ell))} - \|(\mathbb{L}\bar{v}\|^2_{L^2_w([0,\infty];L^2(\Omega,\mathbb{K}^\ell))}, \\ &\geq \varepsilon^2\|\bar{v}\|^2_{L^2_w([0,\infty];L^2(\Omega,\mathbb{K}^\ell))} = \varepsilon^2\|v\|^2_{L^2_w([0,T];L^2(\Omega,\mathbb{K}^\ell))}, \end{aligned}$$

where $\bar{v}$ denotes the extension of v from $[0, T]$ to $\mathbb{R}_+$ by 0. Hence,

$$\begin{aligned} J_T^{\gamma^2}(x^0, v) &\geq \langle x^0, X_T(0)x^0\rangle + \int_0^T \mathcal{E}[\varepsilon^2\langle v(t), v(t)\rangle + \langle v(t), N_T(t)x(t,0,x^0)\rangle \\ &\qquad + \langle N_T(t)x(t,0,x^0), v(t)\rangle]dt \\ &= \langle x^0, X_T(0)x^0\rangle + \int_0^T \mathcal{E}[\|\varepsilon v(t) + \varepsilon^{-1}N_T(t)x(t,0,x^0)\|^2 \\ &\qquad - \|\varepsilon^{-1}N_T(t)x(t,0,x^0)\|^2]dt \\ &\geq \langle x^0, X_T(0)x^0\rangle - \int_0^T \mathcal{E}\|\varepsilon^{-1}N_T(t)x(t,0,x^0)\|^2 dt. \end{aligned} \tag{27}$$

Since (4) is stable, there exists $c_0 > 0$ such that

$$\int_0^\infty \mathcal{E}\|x(t,0,x^0)\|^2 dt \leq c_0\|x^0\|^2.$$

Hence, by (24) there exist constants $c_1, c_2 > 0$ independent on T such that

$$\begin{aligned} 0 \geq \langle x^0, X_T(t)x^0\rangle &= \langle x^0, X_{T-t}(0)x^0\rangle = J^{\gamma^2}_{T-t}(x^0, 0) \\ &\geq -\int_0^\infty \mathcal{E}\|Cx(s,0,x^0)\|^2 ds \geq -c_1\|x^0\|^2 \end{aligned}$$

and

$$\|N_T(t)\| = \|X_T(t)B + q_{12}A_0^*X_T(t)B_0 - C^*D\| \leq c_2, \quad t \in [0,T], \quad T > 0.$$

Thus, by (27)

$$J_T^{\gamma^2}(x^0, v) \geq -c_1\|x^0\|^2 - c_2^2\varepsilon^{-2}c_0\|x^0\|^2, \qquad T > 0.$$

This concludes the proof. □

LEMMA 2.11. *Suppose* (4) *is internally stable,* $\|\mathbb{L}\| < \gamma$, $F(\cdot) \in C([0,T], \mathbb{K}^{\ell\times n})$, $T > 0$, *and* $P_F^{\gamma^2}(\cdot)$ *satisfies* (21) *with* $P_F^{\gamma^2}(T) = 0$. *Then,*

$$\gamma^2 I - D^*D \succ 0 \quad \textit{and} \quad H^{\gamma^2}(P_F^{\gamma^2}(t)) \succeq (\gamma^2 - \|\mathbb{L}\|^2)I_\ell, \qquad t \in [0,T]. \tag{28}$$

Proof. We will first prove that $H^{\gamma^2}(P_F^{\gamma^2}(t)) \succeq 0$. Suppose this is false and there exists $\hat{t} \in [0,T]$, $u \in \mathbb{K}^\ell$, $\|u\| = 1$ such that $\langle u, H^{\gamma^2}(P_F^{\gamma^2}(\hat{t}\,))u\rangle \leq -\eta$ for some $\eta > 0$. Assume $\hat{t} < T$. Then, for $\delta > 0$ sufficiently small,

$$\langle u, H^{\gamma^2}(P_F^{\gamma^2}(t))u\rangle \leq -\eta/2, \qquad t \in [\hat{t}, \hat{t}+\delta] \subset [0,T].$$

Define

$$v(t) = \begin{cases} 0 & \text{if} \quad t \in [0,\hat{t}\,) \cup (\hat{t}+\delta, \infty), \\ u & \text{if} \quad t \in [\hat{t}, \hat{t}+\delta]. \end{cases}$$

Now apply Lemma 2.9 to this $v(\cdot)$ and $x^0 = 0$. Then, $x_F(t) = x_F(t, v(\cdot), 0) = 0$ for $t \in [0,t]$, and

$$\begin{aligned}
\mathcal{E}\int_0^\infty \left[\gamma^2\|v(t)\|^2 - \|Cx_F(t) + Dv(t)\|^2\right] dt &\leq \mathcal{E}\int_0^T \left[\gamma^2\|v(t)\|^2 - \|Cx_F(t) + Dv(t)\|^2\right] dt \\
&= \int_0^T \mathcal{E}[\langle v(t), N(t)x_F(t)\rangle + \langle N(t)x_F(t), v(t)\rangle + \langle v(t), H^{\gamma^2}(P_F^{\gamma^2}(t))v(t)\rangle]dt \\
&\leq \int_{\hat{t}}^{\hat{t}+\delta} (2\|N(t)^*u\|\,\|\mathcal{E}x_F(t)\| - \eta/2)dt.
\end{aligned}$$

Choosing $\delta > 0$ sufficiently small, the integrand becomes negative, since $\mathcal{E}x_F(t)$ is continuous and $\mathcal{E}x_F(\hat{t}\,) = 0$. This yields a contradiction whence $H^{\gamma^2}(P_F^{\gamma^2}(t)) \succeq 0$. If $\hat{t} = T$, a similar proof applies, replacing the interval $[\hat{t}, \hat{t}+\delta]$ by $[T-\delta, T]$.

Now let ε be any positive number such that $\|\mathbb{L}\|^2 < \gamma^2 - \varepsilon^2$. Applying the previous step with $\tilde{\gamma} = (\gamma^2 - \varepsilon^2)^{1/2}$ instead of γ we obtain, for the corresponding solution $P_F^{\tilde{\gamma}^2}(t)$ of (21) (with $\tilde{\gamma}$ instead of γ), $H^{\tilde{\gamma}^2}(P_F^{\tilde{\gamma}^2}(t)) \succeq 0$. For any $t_0 \in [0,T)$, define $F_{t_0}(t) = F(t+t_0)$, $t \in [0, T-t_0]$. Let $P_{F_{t_0}}^{\tilde{\gamma}^2}(t)$ be the solution of (21) with γ replaced by $\tilde{\gamma}$ and F replaced by F_{t_0} on the interval $[0, T-t_0]$ such that $P_{F_{t_0}}^{\tilde{\gamma}^2}(T-t_0) = 0$. Then,

$$P_{F_{t_0}}^{\tilde{\gamma}^2}(t) = P_F^{\tilde{\gamma}^2}(t+t_0), \qquad t \in [0, T-t_0].$$

Hence by (24), for any $t_0 \in [0,T)$, $x^0 \in \mathbb{K}^n$,

$$\begin{aligned}
\langle x^0, P_F^{\tilde{\gamma}^2}(t_0)x^0\rangle = \langle x^0, P_{F_{t_0}}^{\tilde{\gamma}^2}(0)x^0\rangle &= J_{T-t_0}^{\tilde{\gamma}^2}(x^0, F_{t_0}x_{F_{t_0}}) \\
&\leq J_{T-t_0}^{\gamma^2}(x^0, F_{t_0}x_{F_{t_0}}) = \langle x^0, P_F^{\gamma^2}(t_0)x^0\rangle,
\end{aligned}$$

and so $H^{\gamma^2-\varepsilon^2}(P_F^{\gamma^2}(t_0)) \succeq H^{\gamma^2-\varepsilon^2}(P_F^{\tilde{\gamma}^2}(t_0)) \succeq 0$, i.e., $H^{\gamma^2}(P_F^{\gamma^2}(t)) \succeq \varepsilon^2 I$ for all $t \in [0,T]$ (by continuity). Since this holds for arbitrary $\varepsilon^2 < \gamma^2 - \|\mathbb{L}\|^2$, (28) follows, and

$$\gamma^2 I - D^*D = H^{\gamma^2}(P_F^{\gamma^2}(T)) \succ 0.$$

This completes the proof. □

We will now study the matrix differential equation

(29)

$$\dot{X} + XA + A^*X + q_{11}A_0^*XA_0 - C^*C - K(X)H^{\gamma^2}(X)^{-1}K(X)^* = 0, \qquad X(T) = 0.$$

The function

$$f(X) = XA + A^*X + q_{11}A_0^*XA_0 - C^*C - K(X)H^{\gamma^2}(X)^{-1}K(X)^*$$

is continuously differentiable on its domain of definition $D_f = \{X \in \mathcal{H}_n(\mathbb{K}); \det(H^{\gamma^2}(X)) \neq 0\}$ in the real vector space $\mathcal{H}_n(\mathbb{K})$. For every $T > 0$, there exists a (unique) solution of (29) backwards in time on a maximal interval $(t_-(T), T]$. The following proposition shows, in particular, that $t_-(T) < 0$ for all $T > 0$.

PROPOSITION 2.12. *Suppose* (4) *is internally stable and* $\|\mathbb{L}\| < \gamma$. *Then* (29) *has a unique solution* $P_T(\cdot)$ *on* $[0,T]$ *for every* $T > 0$. *Moreover, the feedback control*

$$v_T(t) = F_T(t)x_{F_T}(t), \qquad F_T(t) = -H^{\gamma^2}(P_T(t))^{-1}K(P_T(t))^*, \tag{30}$$

where $x_{F_T}(\cdot)$ *satisfies*

$$\begin{aligned} dx_{F_T}(t) = {} & (A + BF_T(t))x_{F_T}(t)dt + A_0x_{F_T}(t)dw_1(t) \\ & + B_0F_T(t)x_{F_T}(t)dw_2(t), \qquad x_{F_T}(0) = x^0, \end{aligned}$$

minimizes $J_T^{\gamma^2}(x^0, v)$, *and the optimal cost is*

$$\min_{v \in L_w^2} J_T^{\gamma^2}(x^0, v) = \langle x^0, P_T(0)x^0 \rangle. \tag{31}$$

Proof. Since (29) is time invariant, we have

$$P_T(t) = P_{T-t}(0), \quad t \in (t_-(T), T] \quad \text{and} \quad t_-(T-\tau) = t_-(T) - \tau, \quad \tau \in \mathbb{R}. \tag{32}$$

Let $\tilde{T} = \inf\{T \geq 0; t_-(T) \geq 0\}$. Then $\tilde{T} > 0$, and $t_-(\tilde{T}) = 0$ if $\tilde{T} < \infty$. For every $T < \tilde{T}$, we have $t_-(T) < 0$, and $P_T(\cdot)$ is continuously differentiable on $[0,T]$. Setting $F(t) = F_T(t)$, $t \in [0,T]$ in (25), we get from (20) and (30)

$$\begin{aligned} & \dot{P}_T + \begin{bmatrix} I \\ F_T \end{bmatrix}^* M(P_T) \begin{bmatrix} I \\ F_T \end{bmatrix} \\ & = \dot{P}_T + \begin{bmatrix} I \\ F_T \end{bmatrix}^* \begin{bmatrix} P_TA + A^*P_T + q_{11}A_0^*P_TA_0 - C^*C & K(P_T) \\ K(P_T)^* & H^{\gamma^2}(P_T) \end{bmatrix} \begin{bmatrix} I \\ F_T \end{bmatrix} \\ & = \dot{P}_T + P_TA + A^*P_T + q_{11}A_0^*P_TA_0 - C^*C - K(P_T)H^{\gamma^2}(P_T)^{-1}K(P_T)^* = 0. \end{aligned}$$

Hence $P_T(\cdot)$ satisfies (25), or equivalently (21), with $F(t) = F_T(t)$ on $[0,T]$ for all $T < \tilde{T}$, i.e.,

$$P^{\gamma^2}_{F_T}(t) = P_T(t), \qquad t \in [0,T].$$

Moreover, with this choice of $F(t)$,

$$N(t) = K(P_T(t))^* + H^{\gamma^2}(P_T(t))F_T(t) = 0,$$

and so Lemma 2.9 implies that

$$J^{\gamma^2}_T(x^0, v + F_T x) = \langle x^0, P_T(0)x^0\rangle + \int_0^T \mathcal{E}[\langle v(t), H^{\gamma^2}(P_T(t))v(t)\rangle]dt.$$

But by Lemma 2.11,

$$H^{\gamma^2}(P_T(t)) = H^{\gamma^2}(P^{\gamma^2}_{F_T}(t)) \succeq (\gamma^2 - \|\mathbb{L}\|^2)I_\ell \succ 0, \qquad t \in [0,T]. \tag{33}$$

Hence, the control $v_T(t) = F_T(t)x(t)$ minimizes $J^{\gamma^2}_T(x^0, v)$ and the optimal costs are given by (31), for all $T < \tilde{T}$. As a consequence, we obtain

$$\langle x^0, P_T(\tau)x^0\rangle = \langle x^0, P_{T-\tau}(0)x^0\rangle = J^{\gamma^2}_{T-\tau}(x^0, v_{T-\tau}) \le J^{\gamma^2}_{T-\tau}(x^0, 0) \le 0, \qquad \tau \in [0,T].$$

On the other hand,

$$\langle x^0, P_T(\tau)x^0\rangle = J^{\gamma^2}_{T-\tau}(x^0, v_{T-\tau}) \ge -c\|x^0\|^2, \quad x^0 \in \mathbb{K}^n, \quad \tau \in [0,T],$$

for all $T < \tilde{T}$ by Lemma 2.10. Hence,

$$-cI_n \preceq P_T(t) \preceq 0, \qquad t \in [0,T], \quad T < \tilde{T}. \tag{34}$$

Now, suppose $\tilde{T} < \infty$ so that $t_-(\tilde{T}) = 0$. Then $-cI \preceq P_{\tilde{T}}(t) \preceq 0$ for all $t \in (0, \tilde{T}]$ and hence, the solution $P_{\tilde{T}}(t)$ of (29) (with $T = \tilde{T}$) cannot escape to ∞ as $t \downarrow 0$. It follows that there exists a boundary point $P^0 \in \mathcal{H}_n(\mathbb{K})$, $\det(H^{\gamma^2}(P^0)) = 0$ of the domain D_f which is a limit point of $P_{\tilde{T}}(t)$ as $t \downarrow 0$. But this contradicts the fact that by (33), $H^{\gamma^2}(P_{\tilde{T}}(t)) = H^{\gamma^2}(P_{\tilde{T}-t}(0)) \succeq (\gamma^2 - \|\mathbb{L}\|^2)I_\ell$ for all $t \in (0, \tilde{T})$. Thus, $\tilde{T} = \infty$ and the proposition is proved. □

Now we examine what happens as $T \to \infty$.

LEMMA 2.13. *Suppose* (4) *is internally stable and* $\|\mathbb{L}\| < \gamma$. *Then* $P_T(t)$ *decreases as* T *increases for each* $t \in [0,T]$.

Proof. Suppose $T' > T, t \in [0,T]$, and $x^0 \in \mathbb{K}^n$. Let v_{T-t} be optimal for x^0 on $[0, T-t]$, and set $v(\tau) = v_{T-t}(\tau)$ for $\tau \in [0, T-t]$ and $v(\tau) = 0$ for $\tau \in (T-t, T'-t]$. Then,

$$\begin{aligned}\langle x^0, P_{T'}(t)x^0\rangle &\le J_{T'-t}(x^0, v) = J_{T-t}(x^0, v_{T-t}) - \int_{T-t}^{T'-t} \mathcal{E}\|z(s)\|^2 ds \\ &\le J_{T-t}(x^0, v_{T-t}) = \langle x^0, P_T(t)x^0\rangle. \qquad \square\end{aligned}$$

We are now in a position to prove Theorem 2.8.

Proof of Theorem 2.8. By Corollary 2.7, it only remains to prove that (i) implies (ii). Assume (i), i.e., (4) is internally stable and $\|\mathbb{L}\| < \gamma$. Using (34), it follows from

Lemma 2.13 that $P_T(t)$ converges as $T \to \infty$ for any $t \geq 0$. But $P_T(t) = P_{T-t}(0)$, so the limit $\lim_{T\to\infty} P_T(t) = \lim_{T\to\infty} P_T(0) = P$ is constant. It follows from (34) and (33) that P satisfies

$$P \preceq 0 \quad \text{and} \quad H^{\gamma^2}(P) \succ 0 \tag{35}$$

and is a solution of the rational matrix equation

$$PA + A^*P + q_{11}A_0^*PA_0 - C^*C - K(P)H^{\gamma^2}(P)^{-1}K(P)^* = 0. \tag{36}$$

Now replace C by $C_\delta = \left[\begin{smallmatrix} C \\ \delta I \end{smallmatrix}\right]$ and D by $D_\delta = \left[\begin{smallmatrix} D \\ 0 \end{smallmatrix}\right]$ in Definition 2.3 to obtain the perturbation operator $\mathbb{L}_\delta$ for the modified data. Then $\|\mathbb{L}_\delta\| < \gamma$ for sufficiently small $\delta > 0$, and so applying the above result to the modified data we find that there exists $P_\delta \in \mathcal{H}_n(\mathbb{K})$, $P_\delta \preceq 0$ satisfying

(37)

$$P_\delta A + A^*P_\delta + q_{11}A_0^*P_\delta A_0 - C^*C - \delta^2 I - K(P_\delta)H^{\gamma^2}(P_\delta)^{-1}K(P_\delta)^* = 0, \qquad H^{\gamma^2}(P_\delta) \succ 0.$$

By stability, $P_\delta \prec 0$, and the above equation implies

$$P_\delta A + A^*P_\delta + q_{11}A_0^*P_\delta A_0 - C^*C - K(P_\delta)H^{\gamma^2}(P_\delta)^{-1}K(P_\delta)^* \succ 0, \qquad H^{\gamma^2}(P_\delta) \succ 0.$$

Applying the definiteness criterion (18), we get that $M(P_\delta) \succ 0$, and (ii) is proved. ∎

For later use we add the following consequence of Theorem 2.8.

COROLLARY 2.14. *For any set of data* (5)*, the following conditions are equivalent:*

(a) *The system* (4) *is internally stable and* $\|\mathbb{L}\| < \gamma$.

(b) *There exist* $\delta > 0$ *and* $P_\delta \prec 0$ *satisfying* (37).

(c) *There exist* $P \in \mathcal{H}_n(\mathbb{K}), P \prec 0$ *such that*

$$\begin{bmatrix} PA + A^*P + q_{11}A_0^*PA_0 & PB + q_{12}A_0^*PB_0 & C^* \\ B^*P + q_{12}B_0^*PA_0 & \gamma^2 I + q_{22}B_0^*PB_0 & D^* \\ C & D & I \end{bmatrix} \succ 0. \tag{38}$$

Proof. In the above proof, we have shown that (a) implies (b) and (b) implies condition (ii) of Theorem 2.8 (hence (a)). So it remains to show the equivalence of conditions (ii) and (c). This follows from the equality

$$\begin{bmatrix} I & 0 & -C^* \\ 0 & I & -D^* \\ 0 & 0 & I \end{bmatrix} \begin{bmatrix} PA + A^*P + q_{11}A_0^*PA_0 & PB + q_{12}A_0^*PB_0 & C^* \\ B^*P + q_{12}B_0^*PA_0 & \gamma^2 I + q_{22}B_0^*PB_0 & D^* \\ C & D & I \end{bmatrix} \begin{bmatrix} I & 0 & 0 \\ 0 & I & 0 \\ -C & -D & I \end{bmatrix}$$

$$= \begin{bmatrix} PA + A^*P + q_{11}A_0^*PA_0 - C^*C & PB + q_{12}A_0^*PB_0 - C^*D & 0 \\ B^*P + q_{12}B_0^*PA_0 - D^*C & \gamma^2 I + q_{22}B_0^*PB_0 - D^*D & 0 \\ 0 & 0 & I \end{bmatrix}$$

$$= \begin{bmatrix} M(P) & 0 \\ 0 & I \end{bmatrix}. \qquad \blacksquare$$

The following scalar example illustrates the above results.

Example 2.15. Consider the following system of the form (4), with $n = 1$, $\mathbb{K} = \mathbb{R}$, and $D = 0$:

$$dx(t) = ax(t)dt + a_0x(t)dw_1(t) + b_0v(t)dw_2(t) + bv(t)dt, \qquad y(t) = cx(t), \tag{39}$$

where $a, a_0, b, b_0, c \in \mathbb{R}$ and $w_1(t)$, $w_2(t)$ are Wiener processes, as before. Equation (16) is equivalent to

$$2pa + q_{11}a_0^2p - c^2 - (b + q_{12}a_0b_0)^2p^2/(\gamma^2 + q_{22}b_0^2p) > 0, \qquad \gamma^2 + q_{22}b_0^2p > 0. \tag{40}$$

Suppose $a = -1$, $a_0 = b = b_0 = c = 1$, and assume first that $w_1 = w_2 = q_{11} = q_{12} = q_{22} = 1$. The inequalities (40) become

$$-p - 1 - 4p^2/(\gamma^2 + p) > 0, \qquad \gamma^2 + p > 0,$$

and these in turn are equivalent to

$$0 > 5p^2 + (1 + \gamma^2)p + \gamma^2 \quad \text{and} \quad \gamma^2 + p > 0. \tag{41}$$

The first inequality holds if and only if

$$(9 + \sqrt{80} < \gamma^2 \text{or } \gamma^2 < 9 - \sqrt{80}\,) \quad \text{and} \quad 10p < -(1 + \gamma^2) + (\gamma^4 - 18\gamma^2 + 1)^{1/2}.$$

So

$$10(\gamma^2 + p) < (\gamma^4 - 18\gamma^2 + 1)^{1/2} + 9\gamma^2 - 1.$$

Hence, the constraint $\gamma^2 + p > 0$ requires $\gamma^2 \geq 1/9 > 9 - \sqrt{80}$ which excludes the alternative $\gamma^2 < 9 - \sqrt{80}$. Therefore, $9 + \sqrt{80} < \gamma^2$ is a necessary and sufficient condition for (41) to have a joint negative solution p. Thus, $\|\mathbb{L}\|^2 = 9 + \sqrt{80}$.

We will now analyze what happens if the incremental covariance matrix of the system is changed. Let $q_{11} = 1$, $q_{12} = q_{22} = 0$ so that the stochastic perturbation term $v(t)dw_2(t)$ is absent from (39). In this case, the inequalities (40) reduce to

$$-p - 1 - p^2/\gamma^2 > 0.$$

This inequality has a negative solution p if and only if $\gamma^2 > 4$. Hence $\|\mathbb{L}\| = 2$. □

3. Resolution of the general disturbance attenuation problem. We will study the H^∞-type disturbance attenuation problem for stochastic systems of the form

$$\Sigma: \begin{aligned} dx(t) &= Ax(t)dt + A_0x(t)dw_1(t) + B_0v(t)dw_2(t) + B_1v(t)dt + B_2u(t)dt, \\ z(t) &= C_1x(t) + D_{11}v(t) + D_{12}u(t), \\ y(t) &= C_2x(t) + D_{21}v(t), \end{aligned} \tag{42}$$

where

$$(A, A_0, B_0, B_1, B_2) \in \mathbb{K}^{n\times n} \times \mathbb{K}^{n\times n} \times \mathbb{K}^{n\times \ell} \times \mathbb{K}^{n\times \ell} \times \mathbb{K}^{n\times m},$$
$$(C_1, C_2, D_{11}, D_{12}, D_{21}) \in \mathbb{K}^{q\times n} \times \mathbb{K}^{p\times n} \times \mathbb{K}^{q\times l} \times \mathbb{K}^{q\times m} \times \mathbb{K}^{p\times \ell},$$

and w_1, w_2 are as in the previous section. There are two vector valued input variables u, v and two vector valued output variables y, z. v represents an unknown stochastic disturbance signal, u the control, z the vector of the to-be-controlled variables,

and y the measurements. As compensator we choose—as usual in H^∞-theory—a finite-dimensional time-invariant deterministic linear system which is driven by the measurement process $y(\cdot)$ of Σ and produces the (random) control values $u(t)$:

$$\Sigma_K : d\hat{x}(t) = A_K\hat{x}(t)dt + B_K y(t)dt, \qquad u(t) = C_K\hat{x}(t) + D_K y(t), \tag{43}$$

where $(A_K, B_K, C_K, D_K) \in \mathbb{K}^{\hat{n}\times\hat{n}} \times \mathbb{K}^{\hat{n}\times p} \times \mathbb{K}^{m\times\hat{n}} \times \mathbb{K}^{m\times p}$ and the dimension $\hat{n} \geq 0$ is arbitrary. If $\hat{n} = 0$, the state equation of Σ_K vanishes and we obtain $u(t) = D_K y(t)$, i.e., a static linear output feedback control law. For arbitrary $\hat{n} \geq 0$, let

$$M_K = \begin{bmatrix} A_K & B_K \\ C_K & D_K \end{bmatrix}.$$

The resulting closed loop system is

$$\Sigma_{cl} \ : \ \begin{aligned} d\bar{x}(t) &= A_{cl}\bar{x}(t)dt + A^0_{cl}\bar{x}(t)dw_1(t) + B^0_{cl}v(t)dw_2(t) + B_{cl}v(t)dt, \\ z(t) &= C_{cl}\bar{x}(t) + D_{cl}v(t), \end{aligned} \tag{44}$$

where

$$\bar{x} = \begin{bmatrix} x \\ \hat{x} \end{bmatrix}, \quad A_{cl} = \begin{bmatrix} A + B_2D_KC_2 & B_2C_K \\ B_KC_2 & A_K \end{bmatrix}, \quad A^0_{cl} = \begin{bmatrix} A_0 & 0 \\ 0 & 0 \end{bmatrix},$$

$$B^0_{cl} = \begin{bmatrix} B_0 \\ 0 \end{bmatrix} \quad B_{cl} = \begin{bmatrix} B_1 + B_2D_KD_{21} \\ B_KD_{21} \end{bmatrix}, \tag{45}$$

$$C_{cl} = [C_1 + D_{12}D_KC_2, \quad D_{12}C_K], \quad D_{cl} = D_{11} + D_{12}D_KD_{21}.$$

Suppose (44) is internally stable in the sense of the previous section, and the linear operator

$$\mathbb{L}_{cl} : L^2_w(\mathbb{R}_+; L^2(\Omega, \mathbb{K}^\ell)) \to L^2_w(\mathbb{R}_+; L^2(\Omega, \mathbb{K}^q)),$$

is defined by

$$(\mathbb{L}_{cl}v)(t) = C_{cl}\bar{x}(t, v, 0) + D_{cl}v(t), \qquad t \geq 0, \qquad v(\cdot) \in L^2_w(\mathbb{R}_+; L^2(\Omega, \mathbb{K}^\ell)), \tag{46}$$

where $\bar{x}(t, v, \bar{x}^0)$ is the solution of (44) with $\bar{x}(0) = \bar{x}^0$, for every $v(\cdot) \in L^2_w(\mathbb{R}_+; L^2(\Omega, \mathbb{K}^\ell))$. $\mathbb{L}_{cl}$ describes the effect of the disturbance signal $v(\cdot)$ on the to-be-controlled output vector $z(\cdot)$ of the closed loop system. Given $\gamma > 0$, our aim is to determine whether or not there is a compensator (43) which stabilizes system (42) internally and achieves $\|\mathbb{L}_{cl}\| < \gamma$. Such controllers will be called *suboptimal* of level γ. In case of existence, we want to know how these compensators M_K can be constructed.

Remark 3.1. In the linear quadratic Gaussian control problem, additive noise terms are present in the basic model and one may ask why we have excluded them here. Consider the following model with additive white noise in the state and the measurement equations:

$$\begin{aligned} dx(t) &= Ax(t)dt + A_0x(t)dw_1(t) + B_0v(t)dw_2(t) + B_1v(t)dt + B_2u(t)dt + E_1dw_3(t), \\ z(t) &= C_1x(t) + D_{11}v(t) + D_{12}u(t), \\ dy(t) &= C_2x(t)dt + D_{21}v(t)dt + E_2dw_3(t), \end{aligned}$$

where $(E_1, E_2) \in \mathbb{K}^{n\times r} \times \mathbb{K}^{p\times r}$, and w_3 is a vector of r scalar Wiener processes. Suppose the compensator has the form

$$d\hat{x}(t) = A_K\hat{x}(t)dt + B_K dy(t), \qquad u(t) = C_K\hat{x}(t).$$

Then the closed loop system is

$$\begin{aligned} d\bar{x}(t) &= A_{cl}\bar{x}(t)dt + A^0_{cl}\bar{x}(t)dw_1(t) + B^0_{cl}v(t)dw_2(t) + B_{cl}v(t)dt + E_{cl}dw_3(t),\\ z(t) &= C_{cl}\bar{x}(t) + D_{cl}v(t), \end{aligned}$$

where $\bar{x} = \left[\begin{smallmatrix} x \\ \hat{x}\end{smallmatrix}\right]$, $A_{cl}, A^0_{cl}, B^0_{cl}, C_{cl}, D_{cl}$ are as in (45) with $D_K = 0$ and $E_{cl} = \left[\begin{smallmatrix} E_1 \\ B_K E_2\end{smallmatrix}\right]$. In order for the H^∞ problem to make sense over infinite time horizons, the map from v to z (with initial state $\bar{x}(0) = 0$) must be linear or must at least map the zero input onto the zero output. For the preceding closed loop system, this will only be the case if the additive noise term w_3 is completely decoupled from z. In the case where the diffusion term is absent in the nominal system equation ($A_0 = 0$), this would require that the kernel of C_{cl} must contain the smallest A_{cl}-invariant subspace generated by the range of E_{cl}. Thus, the presence of additive white noise would impose an additional, very restrictive, condition on the controllers. In fact, it is our opinion that adding a specific white noise term is not really appropriate in an H^∞-type disturbance attenuation problem. In this framework, measurement and state disturbances are modelled by the *unknown* random process v (so that, e.g., measurement noise is represented by the term $D_{21}v(t)$ in the second output equation. □

We will show that the above disturbance attenuation problem can be solved via the resolution of matrix inequalities. Our approach follows the one developed by Gahinet and Apkarian for the deterministic case [8]. The key tool which makes this possible is the stochastic version of the bounded real lemma derived in the previous section. From deterministic H^∞-control theory, we will need the following so-called projection lemma. A proof of this lemma can be found in [8].

LEMMA 3.2 (projection lemma). *Suppose* $N \in \mathbb{K}^{\ell\times m}, M \in \mathbb{K}^{n\times m}$, *and* $H \in \mathcal{H}_m(\mathbb{K})$. *Then the linear matrix inequality*

$$H + N^*X^*M + M^*XN \succ 0$$

has a solution $X \in \mathbb{K}^{n\times\ell}$ *if and only if* H *is positive definite on* $\ker N$ *and* $\ker M$.

To simplify the presentation, the following notations will be used:

$$A^0 = \begin{bmatrix} A & 0 \\ 0 & 0_{\hat{n}\times\hat{n}}\end{bmatrix}, \quad B^0 = \begin{bmatrix} B_1 \\ 0_{\hat{n}\times\ell}\end{bmatrix}, \quad C^0 = [C_1, 0_{q\times\hat{n}}], \quad D^0_{12} = [0_{q\times\hat{n}}, D_{12}],$$

$$B^I = \begin{bmatrix} 0 & B_2 \\ I_{\hat{n}} & 0\end{bmatrix}, \quad C^I = \begin{bmatrix} 0 & I_{\hat{n}} \\ C_2 & 0\end{bmatrix}, \quad D^0_{21} = \begin{bmatrix} 0_{\hat{n}\times\ell} \\ D_{21}\end{bmatrix}.$$

Then the closed loop matrices can be written as

$$\begin{aligned} &A_{cl} = A^0 + B^I M_K C^I, \quad B_{cl} = B^0 + B^I M_K D^0_{21}, \quad C_{cl} = C^0 + D^0_{12} M_K C^I,\\ &D_{cl} = D_{11} + D^0_{12} M_K D^0_{21}, \qquad A^0_{cl}, B^0_{cl} \quad \text{as in (45)}. \end{aligned} \tag{47}$$

In order to save space we will not write out the upper triangle of large Hermitian matrices but will use a $\star$ notation.

THEOREM 3.3. *For any system of the form* (42) *and* $\gamma > 0$, *the following conditions are equivalent:*

(i) *There exists a compensator* (43) *of dimension* $\hat{n}$ *such that the resulting closed loop system* (44) *is internally stable and* $\|\mathbb{L}_{cl}\| < \gamma$.

(ii) *There exists a* $P_{cl} \in \mathcal{H}_{n+\hat{n}}(\mathbb{K})$, $P_{cl} \prec 0$ *such that the matrix* $\Phi_{P_{cl}} = \Phi_{P_{cl}}^*$ *is positive definite on* $\ker U$ *and* $\Psi_{P_{cl}} = \Phi_{P_{cl}}^*$ *is positive definite on* $\ker V$, *where*

$$\Psi_{P_{cl}} = \begin{bmatrix} (A^0)^* P_{cl} + P_{cl} A^0 + q_{11}(A_{cl}^0)^* P_{cl} A_{cl}^0 & \star & \star \\ (B^0)^* P_{cl} + q_{12}(B_{cl}^0)^* P_{cl} A_{cl}^0 & \gamma I_\ell + q_{22}(B_{cl}^0)^* P_{cl} B_{cl}^0 & \star \\ C^0 & D_{11} & I_q \end{bmatrix},$$

$$\Phi_{P_{cl}} = \begin{bmatrix} P_{cl}^{-1} & 0 & 0 \\ 0 & I_\ell & 0 \\ 0 & 0 & I_q \end{bmatrix} \Psi_{P_{cl}} \begin{bmatrix} P_{cl}^{-1} & 0 & 0 \\ 0 & I_\ell & 0 \\ 0 & 0 & I_q \end{bmatrix},$$

and

$$U = [(B^I)^*, 0_{(\hat{n}+m)\times\ell}, (D_{12}^0)^*], \qquad V = [C^I, D_{21}^0, 0_{(\hat{n}+p)\times q}]. \tag{48}$$

Proof. Applying Corollary 2.14 with $A = A_{cl}$, $A_0 = A_{cl}^0$, etc. we see that (i) is equivalent to the existence of $P_{cl} \prec 0$ such that

$$\begin{bmatrix} (A_{cl})^* P_{cl} + P_{cl} A_{cl} + q_{11}(A_{cl}^0)^* P_{cl} A_{cl}^0 & \star & \star \\ (B_{cl})^* P_{cl} + q_{12}(B_{cl}^0)^* P_{cl} A_{cl}^0 & \gamma^2 I_\ell + q_{22}(B_{cl}^0)^* P_{cl} B_{cl}^0 & \star \\ C_{cl} & D_{cl} & I_q \end{bmatrix} \succ 0.$$

Substituting for A_{cl}, B_{cl}^0, etc. the expressions in (47), we obtain that this is equivalent to

$$\begin{bmatrix} (A^0 + B^I M_K C^I)^* P_{cl} + P_{cl}(A^0 + B^I M_K C^I) + q_{11}(A_{cl}^0)^* P_{cl} A_{cl}^0 & \star & \star \\ ((B^0)^* + (D_{21}^0)^* M_K^* (B^I)^*) P_{cl} + q_{12}(B_{cl}^0)^* P_{cl} A_{cl}^0 & \gamma^2 I_\ell + q_{22}(B_{cl}^0)^* P_{cl} B_{cl}^0 & \star \\ C^0 + D_{12}^0 M_K C^I & D_{11} + D_{12}^0 M_K D_{21}^0 & I_q \end{bmatrix} \succ 0.$$

Or, separating the data and the design parameters,

$$\Psi_{P_{cl}} + \begin{bmatrix} P_{cl} B^I \\ 0_{\ell\times(\hat{n}+\ell)} \\ D_{12}^0 \end{bmatrix} M_K [C^I, D_{21}^0, 0_{(\hat{n}+p)\times q}]$$

$$+ \begin{bmatrix} (C^I)^* \\ (D_{21}^0)^* \\ 0_{q\times(\hat{n}+p)} \end{bmatrix} M_K^* [(B^I)^* P_{cl},\ 0_{(\hat{n}+\ell)\times\ell}, (D_{12}^0)^*] \succ 0.$$

That is,

$$\Psi_{P_{cl}} + U_{P_{cl}}^* M_K V + V^* M_K^* U_{P_{cl}} \succ 0, \tag{49}$$

where $U_{P_{cl}} = [(B^I)^* P_{cl},\ 0_{(\hat{n}+m)\times\ell},\ (D_{12}^0)^*]$ and V is defined as in (48).

Applying the projection lemma, we conclude that (i) is equivalent to $\Psi_{P_{cl}}$ being positive definite on $\ker V$ and $\ker U_{P_{cl}}$. To complete the proof, note that

$$U_{P_{cl}} = U \begin{bmatrix} P_{cl} & 0 & 0 \\ 0 & I_\ell & 0 \\ 0 & 0 & I_q \end{bmatrix}. \qquad \square$$

The characterization in the above theorem is awkward since it involves both P_{cl} and its inverse. However, a simpler form can be obtained by partitioning P_{cl}. To achieve this, the following lemma will be useful; see Lemma 7.5 in [23].

LEMMA 3.4. *Let $n, \hat{n} \geq 1$. Suppose $P \in \mathcal{H}_{n+\hat{n}}(\mathbb{K})$ and its inverse P^{-1} are partitioned as follows:*

$$P = \begin{bmatrix} S & N \\ N^* & Q \end{bmatrix}, \qquad P^{-1} = \begin{bmatrix} R & M \\ M^* & T \end{bmatrix}, \qquad R, S \in \mathcal{H}_n(\mathbb{K}), \tag{50}$$

and $P \prec 0$, then

$$S \preceq R^{-1} \prec 0 \quad \text{and} \quad \operatorname{rank}[R^{-1} - S] \leq \hat{n}. \tag{51}$$

Conversely, if $R, S \in \mathcal{H}_n(\mathbb{K})$ are given such that (51) is satisfied, then there exists $P \in \mathcal{H}_{n+\hat{n}}(\mathbb{K})$, $P \prec 0$ such that P and its inverse can be partitioned as in (50) (with suitable N, Q, M, T).

THEOREM 3.5. *For any system of the form (42) and $\gamma > 0$, the following conditions are equivalent:*

(i) *There exists a stabilizing compensator (43) of dimension $\hat{n}$ such that $\|\mathbb{L}_{cl}\| < \gamma$.*

(ii) *There exists $(R, S) \in \mathcal{H}_n(\mathbb{K}) \times \mathcal{H}_n(\mathbb{K})$ such that*

$$S \preceq R^{-1} \prec 0, \quad \operatorname{rank}(R^{-1} - S) \leq \hat{n} \quad \text{and} \quad \Pi_\gamma(S) = \gamma^2 I_\ell + q_{22} B_0^* S B_0 \succ 0, \tag{52}$$

$$\begin{bmatrix} AR + RA^* + q_{11} RA_0^* S A_0 R & RC_1^* \\ C_1 R & I_\ell \end{bmatrix} - \begin{bmatrix} B_1 + q_{12} RA_0^* S B_0 \\ D_{11} \end{bmatrix} \Pi_\gamma(S)^{-1} \begin{bmatrix} B_1 + q_{12} RA_0^* S B_0 \\ D_{11} \end{bmatrix}^* \succ 0 \quad \text{on } \ker [B_2^* D_{12}^*] \tag{53}$$

and

$$\begin{bmatrix} SA + A^* S + q_{11} A_0^* S A_0 & SB_1 + q_{12} A_0^* S B_0 \\ B_1^* S + q_{12} B_0^* S A_0 & \Pi_\gamma(S) \end{bmatrix} - \begin{bmatrix} C_1^* \\ D_{11}^* \end{bmatrix} \begin{bmatrix} C_1^* \\ D_{11}^* \end{bmatrix}^* \succ 0 \quad \text{on } \ker [C_2 \ D_{21}]. \tag{54}$$

Proof. By Theorem 3.3, (i) is equivalent to the existence of $P_{cl} \in \mathcal{H}_{n+\hat{n}}(\mathbb{K})$, $P_{cl} \prec 0$ such that the matrix $\Phi_{P_{cl}}$ is positive definite on $\ker U$ and $\Psi_{P_{cl}}$ is positive definite on $\ker V$. If we partition

$$P_{cl} = \begin{bmatrix} S & N \\ N^* & Q \end{bmatrix}, \quad P_{cl}^{-1} = \begin{bmatrix} R & M \\ M^* & T \end{bmatrix}, \quad R, S \in \mathcal{H}_n(\mathbb{K}),$$

we obtain from the preceding lemma that

$$S \preceq R^{-1} \prec 0 \quad \text{and} \quad \text{rank } [R^{-1} - S] \leq \hat{n}.$$

Let us first consider the condition that $\Psi_{P_{cl}}$ is positive definite on $\ker V$. Since, by definition (48),

$$V = \begin{bmatrix} 0 & I_{\hat{n}} & 0 & 0_{\hat{n}\times q} \\ C_2 & 0 & D_{21} & 0_{p\times q} \end{bmatrix},$$

$\ker V$ can be represented as

$$\ker V = \text{Im} \begin{bmatrix} V_1 & 0 \\ 0 & 0 \\ V_2 & 0 \\ 0 & I_q \end{bmatrix},$$

where $\begin{bmatrix} V_1 \\ V_2 \end{bmatrix}$ is a basis matrix for $\ker [C_2, D_{21}]$. Partitioning $\Psi_{P_{cl}}$ accordingly, a straightforward calculation yields

$$\Psi_{P_{cl}} = \begin{bmatrix} SA + A^*S + q_{11}A_0^*SA_0 & \star & \star & \star \\ N^*A & 0 & \star & \star \\ B_1^*S + q_{12}B_0^*SA_0 & B_1^*N & \Pi_\gamma(S) & \star \\ C_1 & 0 & D_{11} & I_q \end{bmatrix}.$$

Now,

$$\begin{bmatrix} V_1^* & 0 & V_2^* & 0 \\ 0 & 0 & 0 & I_q \end{bmatrix} \begin{bmatrix} SA + A^*S + q_{11}A_0^*SA_0 & A^*N & SB_1 + q_{12}A_0^*SB_0 & C_1^* \\ N^*A & 0 & N^*B_1 & 0 \\ B_1^*S + q_{12}B_0^*SA_0 & B_1^*N & \Pi_\gamma(S) & D_{11}^* \\ C_1 & 0 & D_{11} & I_q \end{bmatrix} \begin{bmatrix} V_1 & 0 \\ 0 & 0 \\ V_2 & 0 \\ 0 & I_q \end{bmatrix}$$

$$= \begin{bmatrix} [V_1^* \;\; V_2^*] \begin{bmatrix} SA + A^*S + q_{11}A_0^*SA_0 & SB_1 + q_{12}A_0^*SB_0 \\ B_1^*S + q_{12}B_0^*SA_0 & \Pi_\gamma(S) \end{bmatrix} \begin{bmatrix} V_1 \\ V_2 \end{bmatrix} & [V_1^* \;\; V_2^*] \begin{bmatrix} C_1^* \\ D_{11}^* \end{bmatrix} \\ [C_1 \;\; D_{11}] \begin{bmatrix} V_1 \\ V_2 \end{bmatrix} & I_q \end{bmatrix}.$$

Using (18), it follows therefore that $\Psi_{P_{cl}}$ is positive definite on $\ker V$ if and only if

$$\begin{bmatrix} SA + A^*S + q_{11}A_0^*SA_0 & SB_1 + q_{12}A_0^*SB_0 \\ B_1^*S + q_{12}B_0^*SA_0 & \Pi_\gamma(S) \end{bmatrix} - \begin{bmatrix} C_1^* \\ D_{11}^* \end{bmatrix} [C_1 \;\; D_{11}] \succ 0 \quad \text{on ker } [C_2 \;\; D_{21}],$$

i.e., if and only if (54) is satisfied.

The condition that the matrix $\Phi_{P_{cl}}$ is positive definite on $\ker U$ can be analyzed in a similar way. Since, by definition (48),

$$U = \begin{bmatrix} 0 & I_{\hat{n}} & 0_{\hat{n}\times\ell} & 0 \\ B_2^* & 0 & 0_{m\times\ell} & D_{12}^* \end{bmatrix},$$

$\ker U$ can be represented by

$$\ker U = \operatorname{Im} \begin{bmatrix} U_1 & 0 \\ 0 & 0 \\ 0 & I_\ell \\ U_2 & 0 \end{bmatrix},$$

where $\left[\begin{smallmatrix} U_1 \\ U_2 \end{smallmatrix}\right]$ is a basis for $\ker [B_2^* \ D_{12}^*]$. Partitioning $\Phi_{P_{cl}}$ accordingly, we obtain by a straightforward calculation that

$$\Phi_{P_{cl}} = \begin{bmatrix} AR + RA^* + q_{11}RA_0^*SA_0R & \star & \star & \star \\ (AM + q_{11}RA_0^*SA_0M)^* & q_{11}M^*A_0^*SA_0M & \star & \star \\ (B_1 + q_{12}RA_0^*SB_0)^* & q_{12}B_0^*SA_0M & \Pi_\gamma(S) & \star \\ C_1R & C_1M & D_{11} & I_q \end{bmatrix}.$$

Now,

$$\begin{bmatrix} U_1^* & 0 & 0 & U_2^* \\ 0 & 0 & I_\ell & 0 \end{bmatrix} \begin{bmatrix} AR + RA^* + q_{11}RA_0^*SA_0R & \star & \star & \star \\ (AM + q_{11}RA_0^*SA_0M)^* & q_{11}M^*A_0^*SA_0M & \star & \star \\ (B_1 + q_{12}RA_0^*SB_0)^* & q_{12}B_0^*SA_0M & \Pi_\gamma(S) & \star \\ C_1R & C_1M & D_{11} & I_q \end{bmatrix} \begin{bmatrix} U_1 & 0 \\ 0 & 0 \\ 0 & I_\ell \\ U_2 & 0 \end{bmatrix}$$

$$= \begin{bmatrix} [U_1^* \ U_2^*] \begin{bmatrix} AR + RA^* + q_{11}RA_0^*SA_0R & RC_1^* \\ C_1R & I_q \end{bmatrix} \begin{bmatrix} U_1 \\ U_2 \end{bmatrix} & [U_1^* \ U_2^*] \begin{bmatrix} B_1 + q_{12}RA_0^*SB_0 \\ D_{11} \end{bmatrix} \\ \begin{bmatrix} B_1 + q_{12}RA_0^*SB_0 \\ D_{11} \end{bmatrix}^* \begin{bmatrix} U_1 \\ U_2 \end{bmatrix} & \Pi_\gamma(S) \end{bmatrix}.$$

Hence, again using (18), $\Phi_{P_{cl}}$ is positive definite on $\ker U$ if and only if $\Pi_\gamma(S) \succ 0$ and (53) hold. Altogether we see that (i) implies (ii).

Conversely, suppose $(R, S) \in \mathcal{H}_n(\mathbb{K}) \times \mathcal{H}_n(\mathbb{K})$, $R \prec 0$, $S \prec 0$ satisfy the conditions in (ii). Applying Lemma 3.4, we obtain that there exist N, $M \in \mathbb{K}^{n\times\ell}$, Q, $T \in \mathcal{H}_\ell(\mathbb{K})$ such that

$$P_{cl} := \begin{bmatrix} S & N \\ N^* & Q \end{bmatrix} \prec 0, \qquad P_{cl}^{-1} = \begin{bmatrix} R & M \\ M^* & T \end{bmatrix}.$$

Now define $\Psi_{P_{cl}}$, $\Phi_{P_{cl}}$ as in Theorem 3.3. We have just proved that (53) and (54) imply that the matrix $\Phi_{P_{cl}}$ is positive definite on $\ker U$ and $\Psi_{P_{cl}}$ is positive definite on $\ker V$. But this is equivalent to (i). □

Let γ_{opt} be the optimal value of our H^∞-control problem, i.e.,

(55)

$$\gamma_{\text{opt}} = \inf\{\gamma \geq 0; \exists \text{ compensator (43) s.t. (44) is internally stable and } \|\mathbb{L}_{cl}\| < \gamma\}.$$

By the previous theorem, γ_{opt} is the infimum of all $\gamma \geq 0$ for which there exist $(R, S) \in \mathcal{H}_n(\mathbb{K}) \times \mathcal{H}_n(\mathbb{K})$ such that (52), (53), and (54) are satisfied. Now the condition $\text{rk}(R^{-1} - S) \leq \hat{n}$ is automatically satisfied for $\hat{n} \geq n$ and conditions (53), (54) do not depend on $\hat{n}$. Therefore we obtain, as a consequence of the previous theorem, that for every $\gamma > \gamma_{\text{opt}}$ there exists a stabilizing controller (43) *of dimension* $\leq n$ such that $\|\mathbb{L}_{cl}\| < \gamma$.

Remark 3.6. (i) In the deterministic case ($A_0 = 0, B_0 = 0$), we have $\Pi_\gamma(S) = \gamma^2 I$ and so (53) and (54) become

$$\begin{bmatrix} AR + RA^* - B_1 B_1^*/\gamma^2 & RC_1^* - B_1 D_{11}^*/\gamma^2 \\ C_1 R - D_{11} B_1^*/\gamma^2 & I - D_{11} D_{11}^*/\gamma^2 \end{bmatrix} \succ 0, \quad \text{on ker } [B_2^* \;\; D_{12}^*], \tag{56}$$

$$\begin{bmatrix} SA + A^* S - C_1^* C_1 & SB_1 - C_1^* D_{11} \\ B_1^* S - D_{11}^* C_1 & \gamma^2 I - D_{11}^* D_{11} \end{bmatrix} \succ 0, \quad \text{on ker } [C_2 \;\; D_{21}]. \tag{57}$$

These, together with

$$S \preceq R^{-1} \prec 0, \qquad \text{rank } (R^{-1} - S) \leq \hat{n},$$

are precisely the LMI solvability conditions for the suboptimal H^∞ synthesis problem as stated in [8].

(ii) Suppose R, S satisfying the conditions in part (ii) of the previous theorem have been found for a given value of γ. Then, stabilizing compensators that achieve $\|\mathbb{L}_{cl}\| < \gamma$ can be constructed just as for deterministic systems [8]. First, one constructs P_{cl}, followed by $\Psi_{P_{cl}}$ and $\Phi_{P_{cl}}$, and then one solves (49) for M_K. An explicit construction will be given in the next section for the regular case.

(iii) Comparing (53), (54) with (56), (57), we see that the presence of multiplicative state and control dependent noise leads to nonlinear instead of linear matrix inequalities and to a one-sided coupling of "controller" and "observer" matrix inequalities. Note, however, that the "observer" inequality (54) is still linear and independent of (53) so that it can be considered separately. Its solutions then have to be fed into the controller inequality (53) which is a quadratic matrix inequality in R. □

We can replace inequalities (53), (54) by inequalities on the whole space at the sake of introducing scalar parameters. Namely, (53) is equivalent to the existence of $\alpha > 0$ such that

$$\begin{aligned} &\begin{bmatrix} AR + RA^* + q_{11} RA_0^* S A_0 R & RC_1^* \\ C_1 R & I \end{bmatrix} \\ &- \begin{pmatrix} B_1 + q_{12} RA_0^* S B_0 \\ D_{11} \end{pmatrix} \Pi_\gamma(S)^{-1} \begin{pmatrix} B_1 + q_{12} RA_0^* S B_0 \\ D_{11} \end{pmatrix}^* \\ &+ \alpha^2 \begin{bmatrix} B_2 \\ D_{12} \end{bmatrix} [B_2^* \; D_{12}^*] \succ 0, \end{aligned} \tag{58}$$

and (54) is equivalent to the existence of $\beta > 0$ such that

$$\begin{aligned}&\begin{bmatrix} SA + A^*S + q_{11}A_0^*SA_0 & SB_1 + q_{12}A_0^*SB_0 \\ B_1^*S + q_{12}B_0^*SA_0 & \Pi_\gamma(S) \end{bmatrix} \\ &\quad - \begin{bmatrix} C_1^* \\ D_{11}^* \end{bmatrix} \begin{bmatrix} C_1^* \\ D_{11}^* \end{bmatrix}^* + \beta^2 \begin{bmatrix} C_2^* \\ D_{21}^* \end{bmatrix} [C_2 \ D_{21}] \succ 0.\end{aligned} \tag{59}$$

Furthermore, we can replace the above inequalities with lower-dimensional ones. In fact, applying (18), (58) is equivalent to $I + \alpha^2 D_{12}D_{12}^* - D_{11}\Pi_\gamma(S)^{-1}D_{11}^* \succ 0$ and

$$\begin{aligned}&AR + RA^* + q_{11}RA_0^*SA_0R \\ &\quad - (B_1 + q_{12}RA_0^*SB_0)\Pi_\gamma(S)^{-1}(B_1 + q_{12}RA_0^*SB_0)^* + \alpha^2 B_2B_2^* \\ &\quad - \left[RC_1^* - (B_1 + q_{12}RA_0^*SB_0)\Pi_\gamma(S)^{-1}D_{11}^* + \alpha^2 B_2D_{12}^*\right] \\ &\qquad \left[I + \alpha^2 D_{12}D_{12}^* - D_{11}\Pi_\gamma(S)^{-1}D_{11}^*\right]^{-1} \\ &\quad \times \left[RC_1^* - (B_1 + q_{12}RA_0^*SB_0)\Pi_\gamma(S)^{-1}D_{11}^* + \alpha^2 B_2D_{12}^*\right]^* \succ 0.\end{aligned} \tag{60}$$

Similarly, we obtain that (59) is equivalent to $\Pi_\gamma(S) + \beta^2 D_{21}^*D_{21} - D_{11}^*D_{11} \succ 0$ and

(61)

$$\begin{aligned}&SA + A^*S + q_{11}A_0^*SA_0 - C_1^*C_1 + \beta^2 C_2^*C_2 \\ &\quad - \left[SB_1 + q_{12}A_0^*SB_0 - C_1^*D_{11} + \beta^2 C_2^*D_{21}\right] \\ &\quad \times \left[\Pi_\gamma(S) + \beta^2 D_{21}^*D_{21} - D_{11}^*D_{11}\right]^{-1}\left[SB_1 + q_{12}A_0^*SB_0 - C_1^*D_{11} + \beta^2 C_2^*D_{21}\right]^* \succ 0.\end{aligned}$$

Thus, we have the following corollary.

COROLLARY 3.7. *For any system of the form* (42) *and any* $\gamma > 0$*, the following conditions are equivalent:*

(i) *There exists a stabilizing compensator* (43) *of dimension* $\hat{n}$ *such that* $\|\mathbb{L}_{cl}\| < \gamma$.

(ii) *There exist* $(R, S) \in \mathcal{H}_n(\mathbb{K}) \times \mathcal{H}_n(\mathbb{K}), \alpha > 0, \beta > 0$*, such that*

$$\begin{aligned}&S \preceq R^{-1} \prec 0, \quad \operatorname{rk}(R^{-1} - S) \le \hat{n}, \quad \Pi_\gamma(S) = \gamma^2 I + q_{22}B_0^*SB_0 \succ 0, \\ &I + \alpha^2 D_{12}D_{12}^* - D_{11}\Pi_\gamma(S)^{-1}D_{11}^* \succ 0, \qquad \Pi_\gamma(S) + \beta^2 D_{21}^*D_{21} - D_{11}^*D_{11} \succ 0,\end{aligned}$$

and (60), (61) *hold.*

We conclude this section with a brief discussion of the *state feedback case*, where $C_2 = I_n$ and $D_{21} = 0$. Then (54) is equivalent to

$$\Pi_\gamma(S) - D_{11}^*D_{11} = \gamma^2 I + q_{22}B_0^*SB_0 - D_{11}^*D_{11} \succ 0.$$

The following corollary determines what can be achieved by static state feedback:

$$u(t) = Fx(t), \qquad F \in \mathbb{K}^{m\times n}. \tag{62}$$

COROLLARY 3.8. *There exists a stabilizing static state feedback controlled* (62) *such that* $\|\mathbb{L}_{cl}\| < \gamma$ *if and only if there exists* $R \in \mathcal{H}_n(\mathbb{K})$, $R \prec 0$ *satisfying*

$$\Pi_\gamma(R^{-1}) - D_{11}^*D_{11} = \gamma^2 I + q_{22}B_0^*R^{-1}B_0 - D_{11}^*D_{11} \succ 0 \tag{63}$$

and

$$\begin{bmatrix} AR + RA^* + q_{11}RA_0^*R^{-1}A_0R & RC_1^* \\ C_1R & I \end{bmatrix}$$

$$- \begin{bmatrix} B_1 + q_{12}RA_0^*R^{-1}B_0 \\ D_{11} \end{bmatrix} \Pi_\gamma(R^{-1})^{-1} \begin{bmatrix} B_1 + q_{12}RA_0^*R^{-1}B_0 \\ D_{11} \end{bmatrix}^* \succ 0 \tag{64}$$

$$\text{on } \ker \begin{bmatrix} B_2^* & D_{12}^* \end{bmatrix}.$$

Proof. In the static state feedback case, we have $\hat{n} = 0$ and hence (52) implies $S = R^{-1}$. But with $S = R^{-1}$, (53) and (54) are equivalent to (64) and (63), respectively. Thus the statement follows from Theorem 3.5. ∎

An interesting question is whether or not lower levels of γ can be achieved by employing *dynamic state feedback*. This has been answered in the negative for the deterministic case $A_0 = 0$, $B_0 = 0$, (see, e.g., [26]) and for the special stochastic case $A_0 = 0$, $B_1 = 0$, see Proposition 5.6 in [16]. The following corollary generalizes these results to the general stochastic case where the nominal system's noise $w_1(t)$ and the perturbation noise $w_2(t)$ are independent.

COROLLARY 3.9. *For any system of the form* (42) *with* $q_{12} = 0$ *and any* $\gamma > 0$, *the following conditions are equivalent:*

(i) *There exists a stabilizing static state feedback controller* (62) *such that* $\|\mathbb{L}_{cl}\| < \gamma$.

(ii) *There exists a stabilizing dynamic state feedback controller of dimension* $\hat{n} \geq 0$ (*i.e.,* (43) *with* $y(t) = x(t)$) *such that* $\|\mathbb{L}_{cl}\| < \gamma$.

Proof. Only the implication (ii) $\Rightarrow$ (i) needs to be proved. Assume (ii); then by Theorem 3.5 there exists $(R, S) \in \mathcal{H}_n(\mathbb{K}) \times \mathcal{H}_n(\mathbb{K})$, such that $S \preceq R^{-1} \prec 0$, and the following inequalities are satisfied:

$$\begin{bmatrix} AR + RA^* + q_{11}RA_0^*SA_0R & RC_1^* \\ C_1R & I \end{bmatrix}$$

$$- \begin{bmatrix} B_1 \\ D_{11} \end{bmatrix} \Pi_\gamma(S)^{-1} \begin{bmatrix} B_1 \\ D_{11} \end{bmatrix}^* \succ 0 \quad \text{on } \ker \begin{bmatrix} B_2^* & D_{12}^* \end{bmatrix},$$

$$\Pi_\gamma(S) - D_{11}^*D_{11} = \gamma^2 I + q_{22}B_0^*SB_0 - D_{11}^*D_{11} \succ 0.$$

But since $S \preceq R^{-1} \prec 0$, it follows that $0 \prec \Pi_\gamma(S) \preceq \Pi_\gamma(R^{-1})$ and $q_{11}RA_0^*SA_0R \preceq q_{11}RA_0^*R^{-1}A_0R$. Hence, the previous two inequalities hold with S replaced by R^{-1}. Therefore (i) follows from Corollary 3.8. ∎

4. The regular case. In this section we consider the so-called regular case and make the following usual assumptions [5]:

$$D_{11} = 0, D_{12}^*D_{12} = I, \quad D_{21}D_{21}^* = I, \quad D_{12}^*C_1 = 0, \quad D_{21}B_1^* = 0. \tag{65}$$

Then (60) becomes

$$\begin{aligned} &AR + RA^* + q_{11}RA_0^*SA_0R \\ &\quad - (B_1 + q_{12}RA_0^*SB_0)\Pi_\gamma(S)^{-1}(B_1 + q_{12}RA_0^*SB_0)^* + \alpha^2 B_2B_2^* \\ &\quad - (RC_1^* + \alpha^2 B_2D_{12}^*)(I + \alpha^2 D_{12}D_{12}^*)^{-1}(RC_1^* + \alpha^2 B_2D_{12}^*)^* \succ 0. \end{aligned}$$

By (65),

$$(I+\alpha^2 D_{12}D_{12}^*)^{-1}D_{12} = (1+\alpha^2)^{-1}D_{12}, \qquad (I+\alpha^2 D_{12}D_{12}^*)^{-1}C_1 = C_1,$$

and hence

$$RC_1^*(I+\alpha^2 D_{12}D_{12}^*)^{-1}(RC_1^*+\alpha^2 B_2 D_{12}^*)^* = RC_1^*C_1R.$$

Therefore, (60) is equivalent to

$$\begin{aligned} AR+RA^*+q_{11}RA_0^*SA_0R-(B_1+q_{12}RA_0^*SB_0)\Pi_\gamma(S)^{-1}(B_1+q_{12}RA_0^*SB_0)^* \\ +\alpha^2 B_2B_2^*-RC_1^*C_1R-\alpha^4 B_2D_{12}^*(I+\alpha^2D_{12}D_{12}^*)^{-1}D_{12}B_2^* \succ 0. \end{aligned}$$

Now $D_{12}^*(I+\alpha^2 D_{12}D_{12}^*)^{-1}D_{12} = (1+\alpha^2)^{-1}I$, so (60) is equivalent to

(66)
$$\begin{aligned} AR+RA^*+q_{11}RA_0^*SA_0R-(B_1+q_{12}RA_0^*SB_0)\Pi_\gamma(S)^{-1}(B_1+q_{12}RA_0^*SB_0)^* \\ +\alpha^2(1+\alpha^2)^{-1}B_2B_2^*-RC_1^*C_1R \succ 0. \end{aligned}$$

Equation (61) becomes

$$\begin{aligned} &SA+A^*S+q_{11}A_0^*SA_0-C_1^*C_1+\beta^2C_2^*C_2 \\ &-(SB_1+q_{12}A_0^*SB_0+\beta^2C_2^*D_{21})(\Pi_\gamma(S)+\beta^2D_{21}^*D_{21})^{-1} \\ &(SB_1+q_{12}A_0^*SB_0+\beta^2C_2^*D_{21})^* \succ 0. \end{aligned}$$

Suppose, in addition, that $D_{21}B_0^* = 0$, then after similar calculation to the ones above we obtain the equivalent inequality

(67)
$$\begin{aligned} SA+A^*S+q_{11}A_0^*SA_0-C_1^*C_1+\beta^2\gamma^2(\beta^2+\gamma^2)^{-1}C_2^*C_2 \\ -(SB_1+q_{12}A_0^*SB_0)\Pi_\gamma(S)^{-1}(SB_1+q_{12}A_0^*SB_0)^* \succ 0. \end{aligned}$$

If (66), (67) are satisfied for some given α, $\beta > 0$, they are also satisfied for all larger values. Taking limits as $\alpha \to \infty$, $\beta \to \infty$, we see that (66) and (67) are equivalent, respectively, to

$$\begin{aligned} &AR+RA^*+q_{11}RA_0^*SA_0R+B_2B_2^*-RC_1^*C_1R \\ &\quad -(B_1+q_{12}RA_0^*SB_0)\Pi_\gamma(S)^{-1}(B_1+q_{12}RA_0^*SB_0)^* \succ 0, \\ &SA+A^*S+q_{11}A_0^*SA_0-C_1^*C_1+\gamma^2C_2^*C_2 \\ &\quad -(SB_1+q_{12}A_0^*SB_0)\Pi_\gamma(S)^{-1}(SB_1+q_{12}A_0^*SB_0)^* \succ 0. \end{aligned} \tag{68}$$

Setting $R^{-1} = P$, the first inequality is equivalent to

$$\begin{aligned} &PA+A^*P+q_{11}A_0^*SA_0+PB_2B_2^*P-C_1^*C_1 \\ &\quad -(PB_1+q_{12}A_0^*SB_0)\Pi_\gamma(S)^{-1}(PB_1+q_{12}A_0^*SB_0)* \succ 0. \end{aligned} \tag{69}$$

Altogether we have derived the following consequence of Corollary 3.7.

PROPOSITION 4.1. *Suppose the regularity conditions* (65) *and* $D_{21}B_0^* = 0$. *Then the following statements are equivalent:*

(i) *There exists a stabilizing compensator* (43) *of dimension* $\hat{n}$ *such that* $\|\mathbb{L}_{cl}\| < \gamma$.

(ii) *There exist* $P, S \in \mathcal{H}_n(\mathbb{K})$ *such that* $S \preceq P \prec 0$, $\operatorname{rank}(P-S) \le \hat{n}$, $\gamma^2 I + q_{22} B_0^* S B_0 \succ 0$ *and* (68), (69) *hold.*

We now show how to explicitly calculate a compensator in the special case that $\hat{n} = n$. Suppose that condition (ii) of the previous proposition is satisfied with $\hat{n} = n$. Then there exist $P, S \in \mathcal{H}_n(\mathbb{K})$ such that $S \prec P \prec 0$, $\gamma^2 I + q_{22} B_0^* S B_0 \succ 0$, and $\Pi_S \succ 0$, $\Pi_P \succ 0$, where

$$\begin{aligned}\Pi_S &= SA + A^*S + q_{11}A_0^*SA_0 - C_1^*C_1 + \gamma^2 C_2^*C_2 \\ &\quad -(SB_1 + q_{12}A_0^*SB_0)\Pi_\gamma(S)^{-1}(SB_1 + q_{12}A_0^*SB_0)^*, \\ \Pi_P &= PA + A^*P + q_{11}A_0^*SA_0 + PB_2B_2^*P - C_1^*C_1 \\ &\quad -(PB_1 + q_{12}A_0^*SB_0)\Pi_\gamma(S)^{-1}(PB_1 + q_{12}A_0^*SB_0)^*.\end{aligned}$$

Define

$$B_K = \gamma^2(P-S)^{-1}C_2^*, \quad C_K = B_2^*P, \quad D_K = 0, \tag{70}$$

then,

$$A_{cl} = \begin{bmatrix} A & B_2B_2^*P \\ \gamma^2(P-S)^{-1}C_2^*C_2 & A_K \end{bmatrix}, \quad A_{cl}^0 = \begin{bmatrix} A_0 & 0 \\ 0 & 0 \end{bmatrix}, \quad B_{cl}^0 = \begin{bmatrix} B_0 \\ 0 \end{bmatrix},$$

$$B_{cl} = \begin{bmatrix} B_1 \\ \gamma^2(P-S)^{-1}C_2^*D_{21} \end{bmatrix}, \quad C_{cl} = [C_1 \;\; D_{12}B_2^*P], \quad D_{cl} = 0.$$

So condition (ii) of Theorem 2.8 is equivalent to the existence of $P_{cl} \prec 0$ such that

(71)

$$\begin{aligned}\Pi &:= P_{cl}A_{cl} + A_{cl}^*P_{cl} + q_{11}A_{cl}^{0*}P_{cl}A_{cl}^0 - C_{cl}^*C_{cl} \\ &\quad -(P_{cl}B_{cl} + q_{12}A_{cl}^{0*}P_{cl}B_{cl}^0)(\gamma^2 I + q_{22}B_{cl}^{0*}P_{cl}B_{cl}^0)^{-1}(P_{cl}B_{cl} + q_{12}A_{cl}^{0*}P_{cl}B_{cl}^0)^* \succ 0.\end{aligned}$$

Choosing $P_{cl} = \left[\begin{smallmatrix} S & N \\ N^* & Q \end{smallmatrix}\right]$, with $N = -Q = (P-S)$ then $P_{cl} \prec 0$ and partitioning $\Pi = \left[\begin{smallmatrix} \Pi_{11} & \Pi_{12} \\ \Pi_{12}^* & \Pi_{22} \end{smallmatrix}\right]$, we obtain from (71),

$$\begin{aligned}\Pi_{11} &= SA + A^*S + q_{11}A_0^*SA_0 + 2\gamma^2 C_2^*C_2 - C_1^*C_1 \\ &\quad -(SB_1 + q_{12}A_0^*SB_0 + \gamma^2 C_2^*D_{21})\Pi_\gamma(S)^{-1}(SB_1 + q_{12}A_0^*SB_0 + \gamma^2 C_2^*D_{21})^*, \\ \Pi_{12} &= SB_2B_2^*P + NA_K + A^*N - \gamma^2 C_2^*C_2 \\ &\quad -(SB_1 + q_{12}A_0^*SB_0 + \gamma^2 C_2^*D_{21})\Pi_\gamma(S)^{-1}(NB_1 - \gamma^2 C_2^*D_{21})^*, \\ \Pi_{22} &= NB_2B_2^*P + PB_2B_2^*N - NA_K - A_K^*N - PB_2B_2^*P \\ &\quad -(NB_1 - \gamma^2 C_2^*D_{21})\Pi_\gamma(S)^{-1}(NB_1 - \gamma^2 C_2^*D_{21})^*.\end{aligned}$$

Now $\Pi_{11} = \Pi_S$, and Π_{12} simplifies to

$$\Pi_{12} = SB_2B_2^*P + NA_K + A^*N - (SB_1 + q_{12}A_0^*SB_0)\Pi_\gamma(S)^{-1}B_1^*N.$$

Thus, choosing

$$A_K = -N^{-1}[SB_2B_2^*P + A^*N - (SB_1 + q_{12}A_0^*SB_0)\Pi_\gamma(S)^{-1}B_1^*N + \Pi_S], \tag{72}$$

we get $\Pi_{12} = -\Pi_S$. Finally, Π_{22} simplifies to

$$\Pi_{22} = NB_2B_2^*P + PB_2B_2^*N - NA_K - A_K^*N - PB_2B_2^*P - \gamma^2 C_2^*C_2 - NB_1\Pi_\gamma(S)^{-1}B_1^*N.$$

Substituting for A_K, we get $\Pi_{22} = \Pi_P + \Pi_S$. Hence $\Pi = \left[\begin{smallmatrix} \Pi_S & -\Pi_S \\ -\Pi_S & \Pi_P+\Pi_S \end{smallmatrix}\right]$, and since $\Pi_S \succ 0$, $\Pi_P \succ 0$, it follows that $\Pi \succ 0$, i.e., the above P_{cl} satisfies (71). We conclude from Theorem 2.8 that the closed loop system is stable and $\|\mathbb{L}_{cl}\| < \gamma$.

Remark 4.2. (i) Using (68) and (69) one can show that

$$A_K = A - B_K C_2 + B_2 C_K - B_1\Pi_\gamma(S)^{-1}(B_1^*P + q_{12}B_0^*SA_0) - N^{-1}\Pi_P.$$

The first three terms are familiar from pole-placement based deterministic dynamic output feedback stabilization. If $B_0 = 0$, the fourth term is $\gamma^{-2}B_1B_1^*P$ and this is familiar from deterministic H^∞ control. In this case, the last term ($N^{-1}\Pi_P$) is zero for the so-called "central controller."

(ii) We have shown in [16] that in a stochastic setting it is not possible, in general, to replace both inequalities (68) and (69) by equalities in Proposition 4.1.

5. Stability radii. In this section we turn to a *singular* control problem and discuss the application of our general results to stability radii. First we show how the results of section 2 can be used to derive a lower bound for stability radii of stochastic systems. Then we use the results of section 3 to show how to increase the radii via feedback. The corresponding H^∞-type control problem is singular because all three feedthrough matrices D_{11}, D_{12}, D_{21} are zero in this case. For the analysis problem, we adopt the notation of section 2 and, for the synthesis problem, the notation of section 3. Suppose that a stable linear stochastic model

$$\Sigma_0 : dx(t) = Ax(t)dt + A_0x(t)dw_1(t) \tag{73}$$

is perturbed to

$$\Sigma_\Delta : dx(t) = (A + B\Delta C)x(t)dt + A_0x(t)dw_1(t) + B_0\Delta Cx(t)dw_2(t), \tag{74}$$

where

$$(A, A_0, B_0, B, C) \in \mathbb{K}^{n\times n} \times \mathbb{K}^{n\times n} \times \mathbb{K}^{n\times \ell} \times \mathbb{K}^{n\times \ell} \times \mathbb{K}^{q\times n}.$$

The Wiener processes w_i, $i = 1, 2$ are as in section 2, and $\Delta \in \mathcal{D}(\mathbb{K}) = \mathbb{K}^{\ell\times q}$ represents an unknown disturbance matrix. We view the term $B\Delta C$ in (74) as a parameter perturbation of the nominal system matrix A and view $B_0\Delta Cx(t)dw_2(t)$ as a stochastic perturbation (multiplicative noise). If $w_1 = w_2 = w$, we can interpret $B_0\Delta C$ as a parameter perturbation of A_0 and write (74) in the following way:

$$\dot{x}(t) = (A + B\Delta C)x(t) + (A_0 + B_0\Delta C)x(t)dw(t). \tag{75}$$

The fact that the same Δ is used in both perturbations is not really a restriction since, if we set $B_0 = [B_0^0 \quad 0]$, $B = [0 \quad B^1]$, and $\Delta = \left[\begin{smallmatrix} \Delta_0 \\ \Delta_1 \end{smallmatrix}\right]$, we obtain

$$\dot{x}(t) = (A + B^1\Delta_1 C)x(t) + (A_0 + B_0^0\Delta_0 C)x(t)dw(t).$$

We will take this up again in Example 5.8.

The size of each $\Delta \in \mathcal{D}(\mathbb{K})$ is measured by its operator norm (with respect to the Euclidean norms on $\mathbb{K}^q, \mathbb{K}^\ell$). Our aim is to determine which bounds $\rho > 0$ on

the size of the perturbations ensure the stability of the perturbed system (74). The maximum ρ for which all the perturbed systems (74) with $\|\Delta\| < \rho$ are stable is called the stability radius of (73).

DEFINITION 5.1. *The* stability radius *of the stochastic system* (73), *with respect to perturbations as in* (74), *is*

$$r_{\mathbb{K}}^w = r_{\mathbb{K}}^w(A, A_0; B, B_0, C) = \inf\{\|\Delta\|; \Delta \in \mathcal{D}(\mathbb{K}), (74) \text{ is not stable}\}. \tag{76}$$

In particular, $r_{\mathbb{K}}^w = \infty$ *if there does not exist* $\Delta \in \mathcal{D}(\mathbb{K})$ *such that* (74) *is not stable.*

The stability radius is a quantitative index of robust stability of the system Σ_0 (73) under perturbations of the form $\Sigma_0 \rightsquigarrow \Sigma_\Delta$ (74). Since robust stability is a basic requirement for every control system with uncertain parameters, it is of considerable interest to have computable formulae or good estimates for the stability radii of a given system.

To connect the stability radius problem with the analysis in section 2, observe that the perturbed system (74) is identical with the closed loop system obtained from

$$\begin{aligned} dx(t) &= Ax(t)dt + A_0x(t)dw_1(t) + B_0v(t)dw_2(t) + Bv(t)dt \\ z(t) &= Cx(t), \end{aligned} \tag{77}$$

by setting $v(t) = \Delta z(t)$. The open loop gain of this closed loop system is given by $\|\mathbb{L}\Delta\|$, where $\mathbb{L} : v(\cdot) \mapsto Cx(\cdot, v, 0)$ is the perturbation operator associated with (77) (see Definition 2.3). It is therefore reasonable to expect that the norm of the perturbation operator plays a crucial role in the determination of the stability radius.

Remark 5.2. (i) If the data A, A_0, B, B_0, C are real, two stability radii are obtained depending on whether one chooses $\mathbb{K} = \mathbb{C}$ (complex perturbations) or $\mathbb{K} = \mathbb{R}$ (real perturbations) in (76). In a deterministic framework, the real and the complex stability radii are, in general, distinct; see [14]. The complex stability radius is equal to $\|\mathbb{L}\|^{-1}$ [12], whereas the real stability radius is characterized via second order singular values [24].

(ii) A stability radius with respect to *time-varying* and/or *nonlinear* perturbations can be defined via (76) by extending the perturbation class $\mathcal{D}(\mathbb{K})$ appropriately. For example, let $\mathcal{D}_{tn}(\mathbb{K})$ denote the set of all Lebesgue measurable $\Delta : \mathbb{R}_+ \times \mathbb{K}^q \mapsto \mathbb{K}^\ell$ which are *Lipschitz bounded* and *linearly bounded* in y; that is, for all $T > 0$ there exists $L = L(T)$ such that

$$\|\Delta(t, y) - \Delta(t, \hat{y})\| \le L\|y - \hat{y}\| \quad \text{for all } y, \hat{y} \in \mathbb{K}^q, \qquad t \in [0, T],$$

and there exists $K > 0$ such that

$$\|\Delta(t, y)\| \le K\|y\| \quad \text{for all } t \in \mathbb{R}_+, \qquad y \in \mathbb{K}^q. \tag{78}$$

The size of $\Delta \in \mathcal{D}_{tn}(\mathbb{K})$ is measured by the smallest K for which (78) holds. The stability radius of (73) with respect to time-varying nonlinear perturbations of the form

$$dx(t) = (Ax(t) + B\Delta(t, Cx(t)))dt + A_0x(t)dw_1(t) + B_0\Delta(t, Cx(t))dw_2(t) \tag{79}$$

is then defined by (76) with (74) replaced by (79), and $\mathcal{D}(\mathbb{K})$ replaced by $\mathcal{D}_{tn}(\mathbb{K})$. Here the nonlinear system (79) is said to be *stable* (recall Definition 2.1) if the solutions $x_\Delta(\cdot, x^0)$ of (79) satisfy

$$\int_0^\infty \mathcal{E}\|x_\Delta(t, x^0)\|^2 dt \le c\|x^0\|^2, \qquad x^0 \in \mathbb{K}^n,$$

for some suitable constant c. In the deterministic context ($A_0 = 0$, $B_0 = 0$), it is known [14] that the complex stability radius is not changed by such an extension of the perturbation class, whereas the real stability radius is. In the special case where the nominal model (73) is deterministic and the perturbations are purely stochastic, i.e., $A_0 = 0$, $B = 0$, it has been shown in [2] that the real and the complex stability radii coincide and are equal to the inverse of the norm of the perturbation operator ($\|\mathbb{L}\|^{-1}$) if *nonlinear* disturbances are considered. In this case, it is also possible to analyze the effect of *blockdiagonal perturbations*, where the single stochastic perturbation term $B_0\Delta Cx(t)dw_2(t)$ is replaced by a sum of the form $\sum_{i=1}^N B_0^i\Delta^i C^i x(t)dw_2^i(t)$. In the deterministic context, the analysis of blockdiagonal perturbations is the object of μ-analysis. In [16] it was shown that, in the case of purely stochastic perturbations of a deterministic system, the real and complex radii coincide and, although they are not equal to $\|\mathbb{L}\|^{-1}$, they are equal to the inverse of the norm of a suitably scaled perturbation operator. Analogous results are *not* available for deterministic blockdiagonal perturbations.

PROPOSITION 5.3. *Suppose that* (73) *is stable and* $\Delta \in \mathcal{D}_{tn}(\mathbb{K})$ *is a time-varying nonlinearity satisfying* $\|\Delta\| = \sup\{\|\Delta(t,y)\|/\|y\|;\ t \geq 0,\ y \in \mathbb{K}^q,\ y \neq 0\} < \|\mathbb{L}\|^{-1}$, *where* $\mathbb{L}$ *is the perturbation operator associated with data* $(A, A_0, B_0, B, C, 0)$ (*see Definition* 2.3). *Then the perturbed system* (79) *is stable. In particular,*

$$r_{\mathbb{K}}^w(A, A_0; B, B_0, C) \geq \|\mathbb{L}\|^{-1}. \tag{80}$$

Proof. Since Δ is Lipschitz bounded and linearly bounded, for every $x^0 \in \mathbb{K}^n$, $T > 0$, there exists a unique solution $x_\Delta(\cdot) = x_\Delta(\cdot, x^0) \in L_w^2([0,T]; L^2(\Omega, \mathbb{K}^n))$ of (79) satisfying $x_\Delta(0) = x^0$ with bounded second moments [19]. $x_\Delta(\cdot)$ is a continuous nonanticipative stochastic process on $\mathbb{R}_+$ satisfying the Ito integral equation

$$\begin{aligned} x_\Delta(t) = x^0 &+ \int_0^t (Ax_\Delta(s) + B\Delta(s, Cx_\Delta(s)))ds \\ &+ \int_0^t [A_0 x_\Delta(s) \quad B_0\Delta(s, Cx_\Delta(s))]d\begin{bmatrix} w_1(s) \\ w_2(s) \end{bmatrix}, \qquad t \geq 0. \end{aligned}$$

So $x_\Delta(\cdot)$ satisfies (7) with $v(\cdot) = v_\Delta(\cdot) = \Delta(\cdot, Cx_\Delta(\cdot)) \in L_w^2([0,T]; L^2(\Omega, \mathbb{K}^\ell))$ for every $T > 0$. Since $\|\Delta\| < \|\mathbb{L}\|^{-1}$, there exists $\gamma > \|\mathbb{L}\|$ such that $\gamma\|\Delta\| < 1$. Applying Theorem 2.8 to (74), there are $\delta > 0$ and $P = P^* \prec 0$ satisfying $M(P) \succeq \delta^2 I$. By Lemma 2.4 we obtain, for every $x^0 \in \mathbb{K}^n$ and $T > 0$,

$$\begin{aligned} J_T^{\gamma^2}(x^0, v_\Delta) = \langle x^0, Px^0\rangle &- \mathcal{E}\langle x_\Delta(T), Px_\Delta(T)\rangle \\ &+ \int_0^T \mathcal{E}\left(\left\langle \begin{bmatrix} x_\Delta(t) \\ v_\Delta(t) \end{bmatrix}, M(P)\begin{bmatrix} x_\Delta(t) \\ v_\Delta(t) \end{bmatrix}\right\rangle\right) dt. \end{aligned}$$

Substituting $\Delta(\cdot, Cs_\Delta(\cdot))$ for $v_\Delta(\cdot)$ and making use of definition (12) and inequality $M(P) \succeq \delta^2 I$, we obtain

$$\begin{aligned} \langle x^0, Px^0\rangle - \mathcal{E}\langle x_\Delta(T), Px_\Delta(T)\rangle \leq \int_0^T &[\gamma^2\mathcal{E}\|\Delta(t, Cx_\Delta(t))\|^2 \\ &- \mathcal{E}\|Cx_\Delta(t)\|^2 - \delta^2\mathcal{E}\|x_\Delta(t)\|^2]dt. \end{aligned}$$

Now, $\gamma^2\mathcal{E}\|\Delta(t,Cx_\Delta(t))\|^2 \le \gamma^2\|\Delta\|^2\mathcal{E}\|Cx_\Delta(t)\|^2 \le \mathcal{E}\|Cx_\Delta(t)\|^2$ and $-P \ge \eta I$ for some $\eta > 0$. Hence,

$$\eta\mathcal{E}\|x_\Delta(T)\|^2 \le -\mathcal{E}\langle x_\Delta(T), Px_\Delta(T)\rangle \le \|P\|\,\|x^0\|^2 - \int_0^T \delta^2\mathcal{E}\|x_\Delta(t)\|^2 dt, \qquad T > 0,$$

and it follows that

$$\int_0^\infty \mathcal{E}\|x_\Delta(t)\|^2 dt \le \|P\|\,\|x^0\|^2/\delta^2,$$

i.e., (79) is stable. □

We illustrate the above result by considering the same scalar stochastic system as in Example 2.15. In this simple example, we will see that the estimate (80) is tight.

Example 5.4. Consider

$$dx(t) = -x(t)dt + x(t)dw_1(t) + v(t)dw_2(t) + v(t)dt, \qquad z(t) = x(t), \tag{81}$$

and assume first that $q_{11} = 1$, $q_{12} = q_{22} = 0$ so that the stochastic perturbation term $v(t)dw_2(t)$ is absent from (81). We have shown in Example 2.15 that $\|\mathbb{L}\| = 2$ in this case. The corresponding perturbed equation (74) takes the form

$$dx(t) = -(1-\Delta)x(t)dt + x(t)dw_1(t).$$

By (8), this stochastic equation is stable if and only if there exists $p < 0$ such that

$$-(2-\Delta-\Delta^*)p + p > 0, \quad \text{i.e., } -(2-\Delta-\Delta^*) + 1 < 0.$$

Hence, $\Delta = 1/2$ is a destabilizing *real* disturbance, and by Proposition 5.3 there is no smaller disturbance $\Delta \in \mathbb{C}$ which destabilizes. So $r^w_{\mathbb{R}} = r^w_{\mathbb{C}} = \|\mathbb{L}\|^{-1} = 1/2$.

Now suppose $w_1 = w_2 = w$ and $q_{11} = q_{12} = q_{22} = 1$. We have shown in Example 2.15 that $\|\mathbb{L}\|^2 = 9 + \sqrt{80}$. The perturbed model takes the form

$$dx(t) = -(1-\Delta)x(t)dt + (1+\Delta)x(t)dw(t).$$

By (8), this stochastic equation is stable if and only if there exists $p < 0$ such that

$$-(2-\Delta-\Delta^*)p + |1+\Delta|^2 p > 0, \quad \text{i.e., } -(2-\Delta-\Delta^*) + |1+\Delta|^2 < 0.$$

A short calculation shows that $\Delta = \sqrt{5}-2$ is the smallest disturbance $\Delta \in \mathbb{C}$ violating this condition. Hence $r^w_{\mathbb{R}} = r^w_{\mathbb{C}} = \sqrt{5}-2$, but $\|\mathbb{L}\|^{-1} = 1/\sqrt{9+\sqrt{80}} = \sqrt{9-\sqrt{80}} = \sqrt{5}-2$. Therefore, in this case we again have $r^w_{\mathbb{R}} = r^w_{\mathbb{C}} = \|\mathbb{L}\|^{-1}$.

As was to be expected, the presence of the stochastic disturbance term $\Delta x(t)dw(t)$ effectively decreases the stability radius of the system. This is not necessarily so if there is more than one disturbance parameter, i.e., $\max\{\ell, q\} > 1$.

We now turn to the synthesis problem. The perturbed closed loop equation obtained by setting $v = \Delta z$ in (44) is

$$d\bar{x}(t) = (A_{cl} + B_{cl}\Delta C_{cl})\bar{x}(t)dt + (A^0_{cl}dw_1(t) + B^0_{cl}\Delta C_{cl}dw_2(t))\bar{x}(t). \tag{82}$$

As an immediate corollary of Proposition 5.3 and Theorem 3.3 we have the following.

COROLLARY 5.5. *Let γ_{opt} be defined by* (55)*. Then for any $\gamma > \gamma_{\text{opt}}$, there exists a stabilizing compensator* (43) *such that the corresponding closed loop system has a stability radius $r^w_{\mathbb{K}}(A_{cl}, A^0_{cl}; B_{cl}, B^0_{cl}, C_{cl}) > \gamma^{-1}$.*

In the following examples, we indicate how the synthesis problem may be solved under simplifying assumptions. We first consider two system classes (4) for which the estimate (80) is tight.

Example 5.6. $A_0 = 0, B_0 = 0$. For this deterministic case, we have shown [12] that $r^w_{\mathbb{C}} = \|\mathbb{L}_{cl}\|^{-1}$, but in general $r^w_{\mathbb{R}} > r^w_{\mathbb{C}}$ [14]. Equations (60) and (61) are equivalent to

$$\Pi_R = AR + RA^* - RC_1^*C_1R - B_1B_1^*/\gamma^2 + \alpha^2 B_2B_2^* \succ 0. \tag{83}$$

$$\Pi_S = SA + A^*S - C_1^*C_1 - SB_1B_1^*S/\gamma^2 + \beta^2 C_2^*C_2 \succ 0. \tag{84}$$

Let

$$r_{\text{opt}} = \sup\{r^w_{\mathbb{C}}(A_{cl}, 0; B_{cl}, 0, C_{cl}); \exists \text{ compensator } M_K \text{ s.t. } A_{cl} \text{ is stable}\}.$$

Then we have $r_{\text{opt}} = \gamma^{-1}_{\text{opt}}$. For any $\gamma > 0$, $\gamma^{-1} < r_{\text{opt}}$, using the same procedure as that in section 4, it is easy to verify that, provided there exist $R, S \in \mathcal{H}_n(\mathbb{K})$, $\alpha, \beta > 0$ satisfying $S \prec R^{-1} \prec 0$ and (83), (84), the following compensator of order n achieves $r^w_{\mathbb{C}} > \gamma^{-1}$:

$$\begin{aligned} B_K &= \beta^2(R^{-1} - S)^{-1}C_2^*, \quad C_K = \alpha^2\beta_2^* R^{-1}, \quad D_K = 0, \\ A_K &= A - B_KC_2 + B_2C_K - B_1B_1^*R^{-1}/\gamma^2 - (I - RS)^{-1}\Pi_R R^{-1}, \end{aligned}$$

where Π_R is defined by (83).

Example 5.7. $A_0 = 0, B_1 = 0$. For this case, we have shown that if nonlinear perturbations Δ are allowed, then $r^w_{\mathbb{R}} = r^w_{\mathbb{C}} = \|\mathbb{L}_{cl}\|^{-1}$ [16]. Equations, (53) and (54) are equivalent to

$$AR + RA^* - RC_1^*C_1R \succ 0 \quad \text{on ker } B_2^* \tag{85}$$

$$SA + A^*S - C_1^*C_1 \succ 0 \quad \text{on ker } C_2, \qquad \Pi_\gamma(S) = \gamma^2 I + q_{22}B_0^*SB_0 \succ 0. \tag{86}$$

Let

$$r_{\text{opt}} = \sup\{r^w_{\mathbb{C}}(A_{cl}, 0; 0, B^0_{cl}, C_{cl}), \exists \text{ a compensator } M_K \text{ s.t. } A_{cl} \text{ is stable}\}.$$

Then again we have $r_{\text{opt}} = \gamma^{-1}_{\text{opt}}$, and for any $\gamma > 0$, $\gamma^{-1} < r_{\text{opt}}$ we can use (85) and (86) together with (52) to obtain a compensator which achieves $r^w_{\mathbb{C}} > \gamma^{-1}$. In fact, in [16] we have shown that (by scaling) it is possible to explicitly construct such compensators for more general perturbation structures where $B_0\Delta C_1 x(t)dw_2(t)$ is replaced by a sum of the form $\sum_{i=1}^N B_0^i\Delta^i C_1^i x(t)dw_2^i(t)$, and w_2^i are independent Wiener processes.

Finally we consider an example where we do not know whether or not (80) is tight.

Example 5.8: $A_0 = 0, B_0 = [B_0^0 \quad 0], B_1 = [0 \quad B_1^1]$, where $B_0^0 \in \mathbb{K}^{n\times \ell_1}$. For $v = \left[\begin{smallmatrix} v_0 \\ v_1 \end{smallmatrix}\right]$, (42) has the form

$$\begin{aligned} dx(t) &= Ax(t)dt + B_0^0 v_0(t)dw_2(t) + B_1^1 v_1(t)dt + B_2u(t)dt, \\ z(t) &= C_1x(t), \\ y(t) &= C_2x(t). \end{aligned}$$

Moreover, if

$$\begin{bmatrix} v_0 \\ v_1 \end{bmatrix} = \Delta z = \begin{bmatrix} \Delta_0 \\ \Delta_1 \end{bmatrix} C_1x,$$

then the perturbed equation is

$$dx(t) = (A + B_1^1 \Delta_1 C_1)x(t)dt + B_0^0 \Delta_0 C_1 x(t) dw_2(t) \; + \; B_2 u(t) dt.$$

Because of the presence of both stochastic and deterministic perturbations, we do not know whether the stability radius is equal to $\|\mathbb{L}_{cl}\|^{-1}$ or whether this is just a lower bound.

Since $B_1 B_0^* = 0$, we have $B_1(\gamma^2 I + q_{22} B_0^* S B_0)^{-1} B_1^* = B_1 B_1^*/\gamma^2$, and hence (60) and (61) are equivalent to

$$\Pi_R = AR + RA^* - RC_1^* C_1 R - B_1 B_1^*/\gamma^2 + \alpha^2 B_2 B_2^* \succ 0, \tag{87}$$

$$\Pi_S = SA + A^* S - C_1^* C_1 - S B_1 B_1^* S/\gamma^2 + \beta^2 C_2^* C_2 \succ 0. \tag{88}$$

For $\gamma > 0$, provided there exist R, $S \in \mathcal{H}_n(\mathbb{K})$, $\alpha, \beta > 0$ satisfying $S \prec R^{-1} \prec 0$, $\gamma^2 I + q_{22} B_0^* S B_0 \succ 0$ and (87), (88), the same compensator as that given in Example 5.6 achieves $r_{\mathbb{C}}^w > \gamma^{-1}$.

6. Concluding remarks. We have posed and solved an H^∞-type problem where both stochastic and deterministic perturbations are present. In opening up this field, which appears to be fruitful, we think that it would be interesting to pursue research into the following problems.

- Since our theory includes both cases where w_1, w_2 are independent and $w_1 = w_2$, we think we have laid the foundation for considering the stochastic multiperturbation H^∞ problem

$$\begin{aligned} dx(t) &= Ax(t)dt + \sum_{i=1}^N A_0^i x(t) dw^i(t) + \sum_{i=1}^N B_0^i v^i(t) dw^i(t) \\ &\quad + \sum_{i=1}^N B_1^i v^i(t) dt + B_2 u(t) dt, \\ z(t) &= C_1 x(t) + \sum_{i=1}^N D_{11}^i v^i(t) + D_{12} u(t), \\ y(t) &= C_2 x(t) + \sum_{i=1}^N D_{21}^i v^i(t), \end{aligned} \tag{89}$$

  where w^i are independent Wiener processes.
- In Proposition 5.3, we obtained the estimate $r_{\mathbb{K}}^w(A, A_0; B, B_0, C) \geq \|\mathbb{L}\|^{-1}$ for the stochastic stability radii. It would be interesting to know under what conditions equality holds. To do this, it is necessary to construct a destabilizing perturbation with norm as close as we like to $\|\mathbb{L}\|^{-1}$.
- A stability radius can be associated with the above multiperturbation problem (89) in a number of different ways. For example, if all the D's are zero and $v_i = \Delta_i z = \Delta_i C_1 x$, we get the so-called *full block* case, whereas if $v_i = \Delta_i z_i = \Delta_i C_1^i x$ we get the *blockdiagonal* case. In both cases, $\|\mathbb{L}_{cl}\|^{-1}$ will be a lower bound for the radii and, for full bock perturbations, it may well be tight. But we cannot expect this for blockdiagonal perturbations since in a deterministic setting this is a μ problem. The estimate can be improved by scaling $B_0^i \mapsto \alpha_i B_0^i$, $B_1^i \mapsto \alpha_i B_1^i$, $C_1^i \mapsto \alpha_i^{-1} C_1^i$, $\alpha_i > 0$ which does not

change the radius but does change the corresponding $\|\mathbb{L}_{cl}^{\alpha}\|$, and we have shown in [16] that for suitable α_i this estimate is tight for purely stochastic multiperturbations of a deterministic system. It would be interesting to know under what conditions this is true when deterministic perturbations are also present.

SOLVING SCHEDULING PROBLEMS BY SIMULATED ANNEALING*

OLIVIER CATONI†

Abstract. We define a general methodology to deal with a large family of scheduling problems. We consider the case where some of the constraints are expressed through the minimization of a loss function. We study in detail a benchmark example consisting of some jigsaw puzzle problem with additional constraints. We discuss some algorithmic issues typical of scheduling problems, such as the apparition of small unused gaps or the representation of proportionality constraints. We also carry on an experimental comparison between the Metropolis algorithm, simulated annealing, and the iterated energy transformation method to see whether asymptotical theoretical results are a good guide towards practically efficient algorithms.

Key words. scheduling problems, Metropolis algorithm, simulated annealing, IET algorithm

Introduction. The aim of this paper is to describe a general strategy to deal with scheduling problems and to illustrate its use on the resolution of jigsaw puzzles. We will assume that we can put our scheduling problem in the form of a task assignment problem, and we will turn it into the minimization of a cost function defined on a suitable search space. This cost function will be minimized by a Monte Carlo algorithm of the Metropolis kind: either simulated annealing or our recently introduced iterated energy transformation (IET) method. We have already studied some of the theoretical aspects of these two methods in previous papers (see [6], [7]).

We have chosen to experiment on a jigsaw puzzle problem with rectangular pieces because this is a typical instance of the kind of difficulties encountered when building time tables, and because it is in itself a difficult problem (it is NP-complete) which deserves special attention. In the course of this experimentation, we will compare four algorithms: a randomized descent algorithm (the Metropolis dynamic at temperature zero), the Metropolis algorithm, simulated annealing, and the iterated energy transformation algorithm.

1. An abstract task assignment framework. Let B be a finite set of tasks. Let E be a set of resources needed to perform these tasks. The set E may be any kind of set, a finite set, a domain in $\mathbb{R}^n$, etc. In applications it can represent various things, such as a set of people who are to perform the tasks, in which case it is natural to see it as a finite set, or it can also represent space and time needed for the tasks, in which case it is sometimes natural to see it as a domain in $\mathbb{R}^n$. More often it is a product space of both kinds. Anyhow, we will only consider a finite collection of subsets of E; therefore it will always be possible to consider that E is a finite set from the theoretical point of view. This is reasonable, because a computer can only handle a finite number of possible ways to allocate resources and also because, in many problems of the time-table type, continuous quantities, such as time, are discretized (for instance when one tries to schedule lectures, they are usually constrained to start at full hours). Anyhow, the reader should think of E as a large set and our methods,

inherited from statistical mechanics, are precisely meant to cope with a large state space.

The abstract scheduling problem we will consider is to allocate to each task in B a set of resources in a way which satisfies a set of constraints.

At this level of generality, we will not represent the constraints by equations or logical relations; we will merely view them as a subset $\mathcal{S}$ of $\mathcal{P}(B \times E)$ (where $\mathcal{P}(A)$ is the set of subsets of the set A). We will call $\mathcal{S}$ the "solution space." A solution x in $\mathcal{S}$ is a subset of the product space $B \times E$. We will use the notations π_B and π_E for projections on B and E. The fact that $(b, e) \in x$ means that the task b uses the resource e. The set of resources used by b is $\pi_E(\pi_B^{-1}(b) \cap x)$, for which we will use the functional notation $x(b)$.

We will assume that each solution $x \in \mathcal{S}$ is a complete assignment, in the sense that all the tasks are scheduled:

$$\pi_B(x) = B \quad \text{for any } x \in \mathcal{S}.$$

Our scheduling problem is to construct a solution x belonging to the solution space $\mathcal{S}$.

The idea of considering scheduling problems as putting objects in boxes in a multi-dimensional space is not new and can be found, for instance, in Abramson [1], where a specialized simulated annealing hardware is described for handling some generic types of cost functions.

2. The jigsaw puzzle example. This example is meant to be a benchmark, where the main algorithmic issues of scheduling problems are present.

The set of resources E will be a discretized rectangular frame

$$E = \{0, \dots, M-1\} \times \{0, \dots, N-1\} \subset \mathbb{Z}^2.$$

The set of tasks B will be the set of pieces of the jigsaw puzzle. Each piece r has a rectangular shape defined by its width $w_r \in \mathbb{N}^*$ and by its height $h_r \in \mathbb{N}^*$. The constraint is that pieces should not overlap. Thus the solution space is

$$\mathcal{S} = \{x \subset B \times E \ : \ x(r) = [a_r, a_r + w_r[\times[b_r, b_r + h_r[, \quad (a_r, b_r) \in E, \quad r \in B, \\ \text{and } x(r) \cap x(r') = \emptyset, \quad r \neq r' \in B\}.$$

The problem is to build the jigsaw puzzle; that is, to construct $x \in \mathcal{S}$. Although the shape of pieces is very simple, this problem can be seen to be very complex. In fact, it is easy to see that it is NP complete, because it contains the partition problem among its instances (see [14]). Indeed, the partition of given integers $\{c_1, \dots, c_N\}$ into two sets I and J such that

$$\sum_{i \in I} c_i = \sum_{j \in J} c_j$$

can be viewed as a jigsaw puzzle with N pieces, respectively, of width c_i and height 1, and a frame of width $(1/2) \sum_{i=1}^N c_i$ and height 2 (see Fig. 2.1).

3. A method of resolution based on the Metropolis dynamic. In this section we will sketch a methodology to solve the abstract problem of section 1. The general idea is to perform a random search for a solution in a state space larger than the solution space. This search space should be easy to describe and easy to search

FIG. 2.1.

by a Markov chain performing a succession of elementary moves. Of course, we will not use a Markov chain which uniformly samples the search space because, usually, the search space we will be able to build will be very large when compared to the solution space, and drawing points at random in the search space would seldom lead to discovering a solution.

Instead we will use a Markov chain with rare transitions, whose invariant measure is concentrated in a neighborhood of the solution space. This optimization technique is well known, but its improvement is still a subject of active research. The prototype algorithm we will start from is the Metropolis dynamic at low temperature. The Metropolis dynamic has been designed to simulate statistical mechanics systems, and not for optimization purposes. In order to improve its performance as an optimization algorithm, some speed-up techniques have been proposed. The most famous one is simulated annealing [15], [18]. We have also proposed recently another technique, which we called *the iterated energy transformation method* (IET) [7]. We will describe and use both of these.

3.1. Choice of a search space. The first step of the method is to choose a search space $\tilde{\mathcal{S}}$ containing the solution space $\mathcal{S}$. The most popular way to construct $\tilde{\mathcal{S}}$ is to relax some constraints about the solution and to measure, instead, how much the constraints have been violated by a score function one has afterwards to minimize. For instance, in circuits placement applications (one of the earliest applications of simulated annealing) the constraint that circuits should not overlap is often relaxed, and the overlapping of circuits is instead merely discouraged by some score function of the surface of the overlap. Our strategy will be somewhat of the same kind, with the difference that we will not relax a constraint which is specific to the problem. Instead, we will allow partial solutions, where only some proportion of the tasks have been scheduled. Defining partial solutions is usually very easy and very natural. Most of the time, this is how the problem is posed from the beginning. Indeed the constraints come usually from incompatibilities between tasks, such as sharing the same resource or needing to be performed in a given order, and can be expressed without assuming that all the tasks are already scheduled.

From the technical point of view, we will assume that the search space (the space of partial solutions) satisfies the following properties:

- The empty solution is in the search space: $\emptyset \in \tilde{\mathcal{S}}$.
- There is a path from the empty solution leading to any partial solution $x \in \tilde{\mathcal{S}}$ along which tasks are scheduled one after the other. This can be expressed in the following way:

  For any $x \in \tilde{\mathcal{S}}, x \neq \emptyset$, there is $b \in \pi_B(x)$ such that $x \setminus \pi_B^{-1}(b) \in \tilde{\mathcal{S}}$.
- All complete solutions in the search space satisfy the constraints. In other words, the solution space is exactly made of the complete solutions of the

search space. This is expressed by the following equation:

$$\mathcal{S} = \{x \in \tilde{\mathcal{S}} \ : \ \pi_B(x) = B\}.$$

Let us notice that the "best" choice for $\tilde{S}$ would be $\{x \cap \pi_B^{-1}(C) \ : \ x \in \mathcal{S}, C \subset B\}$, the set of all partial solutions contained in global solutions. Anyhow, this set is, in practical situations, never defined by simple relations, because when you have scheduled some of the tasks, it is never possible (except for trivial problems) to foretell whether there will remain suitable resources to schedule the remaining ones. Therefore the search space $\tilde{S}$ is, most of the time, much broader than $\mathcal{S}$ and contains many dead ends.

3.2. Building the dynamic: Constructions and destructions. The next idea is to define on $\tilde{S}$ two kinds of dynamics, a *constructive dynamic* and a *destructive dynamic*. These two random dynamics are characterized by two Markov matrices q_C and q_D,

$$\begin{aligned} q_C &: \tilde{\mathcal{S}} \times \tilde{\mathcal{S}} \longrightarrow [0,1], \\ q_D &: \tilde{\mathcal{S}} \times \tilde{\mathcal{S}} \longrightarrow [0,1]. \end{aligned}$$

We will assume that the transitions allowed by q_C consist of either keeping the current partial solution or scheduling one more task. In a similar way the transitions allowed by q_D consist of unscheduling a given number of tasks. We allow unscheduling of more than one task at a time, because it is in some situations more sensible to do so. For instance, if many tasks have to share the same resource, it may sometimes speed up the allocation process to unschedule all of them at the same time (think of students sharing the same teacher).

This conception of constructions and destructions can be expressed by the following equations, where $|A|$ is the number of elements in the finite set A:

$$\left\{ \begin{array}{l} \bullet \ \{(x,y) \ : \ q_C(x,y) > 0, x \neq y\} \\ \qquad = \{(x,y) \ : \ y \cap \pi_B^{-1}(\pi_B(x)) = x, |\pi_B(y)| = |\pi_B(x)| + 1\}, \\ \bullet \ \{(x,y) \ : \ q_C(y,x) > 0, x \neq y\} \\ \qquad\qquad \subset \{(x,y) \ : \ q_D(x,y) > 0\} \\ \qquad\qquad\qquad \subset \bigcup_{n=1}^{+\infty} \{(x,y) \ : \ q_C^n(y,x) > 0\}. \end{array} \right. \tag{1}$$

Let us remark that, usually, constructions will decompose into two steps, one being to choose an unscheduled task $b \in B \setminus \pi_B(x)$ and the second one being to try to allocate a set of resources to it. This second step is sometimes unsuccessful (either because it is impossible or the proper allocation has not been discovered); therefore as a rule, we have $q_C(x,x) > 0$ for a substantial number of partial solutions. On the contrary, destructions are simple moves, where you have only to choose a scheduled task b in $\pi_B(x)$ and to remove it. Therefore as a rule, we will have $q_D(x,x) = 0$, except when $x = \emptyset$, for which $q_D(\emptyset, \emptyset) = 1$.

When the two above assumptions are satisfied, the whole search space $\tilde{\mathcal{S}}$ can be constructed by q_C starting from the empty solution $\emptyset$, and reversely, any solution can

be shrunk to the empty solution by successive applications of q_D. More precisely, the following proposition holds.

PROPOSITION 3.1.

$$\begin{aligned}\tilde{\mathcal{S}} &= \bigcup_{n=0}^{+\infty} \{y \ : \ q_C^n(\emptyset, y) > 0\} \\ &= \bigcup_{n=0}^{+\infty} \{x \ : \ q_D^n(x, \emptyset) > 0\}.\end{aligned}$$

3.3. Building the cost function. Now we will build a cost, or energy, function defined on the search space, which penalizes partial solutions: we will call it $U \ : \ \tilde{\mathcal{S}} \longrightarrow \mathbb{R}$. Namely, we will require the following properties to hold:

(2)
$$\begin{cases} \bullet \ \arg\min_{x \in \tilde{\mathcal{S}}} U(x) = \mathcal{S}. \\ \bullet \ \text{There is a positive constant } \gamma \text{ such that } U(y) \geq U(x) + \gamma \text{ when } x \neq y \text{ and } q_D(x, y) > 0. \end{cases}$$

A typical example for U is

$$U(x) = \mu(B \setminus \pi_B(x)),$$

where μ is a positive measure on B. In this case the assumptions on U are satisfied and the largest choice of γ is

$$\gamma = \min_{b \in B} \mu(b).$$

3.4. Building a Metropolis dynamic. From Proposition 3.1, we see that any Markov matrix of the form $\lambda q_C + (1 - \lambda) q_D$ with $\lambda \in]0, 1[$ is irreducible. Therefore a straightforward way to build a Metropolis dynamic would be to consider the Markov matrix

$$p_T(x, y) = \begin{cases} (\lambda \, q_C(x, y) + (1 - \lambda) \, q_D(x, y)) e^{-(U(y) - U(x))^+ / T}, & x \neq y \\ 1 - \sum_{z \neq x} p_T(x, z), & x = y. \end{cases}$$

In fact, we can do better because we know in advance that, during a construction, the energy will decrease, and that during a destruction, the energy will increase by a quantity at least equal to γ. This avoids applying uselessly the kernel q_D at low temperatures in situations where we know that it will, most of the time, generate a move to be rejected.

More precisely, we will use the following Markov matrix:

(3)
$$\begin{aligned} p_T(x, y) &= \lambda \ e^{-\gamma / T} q_D(x, y) e^{-(U(y) - U(x) - \gamma)^+ / T} \\ &\quad + q_C(x, y) \left(1 - \lambda \ \sum_{z \in \tilde{\mathcal{S}}} q_D(x, z) e^{-(U(z) - U(x) - \gamma)^+ / T - \gamma / T} \right), \end{aligned}$$

where λ is again a positive parameter in the interval $0 < \lambda \leq 1$. A choice of $\lambda < 1$ avoids that destructions should always be chosen at high temperatures. Usually we will take $\lambda = 1/2$ or $\lambda = 1$. The positive part in $(U(y) - U(x) - \gamma)^+$ is needed only to cover the case where $x = y$.

The computer implementation of this Metropolis dynamic is the following: starting from the state x,

- first flip a coin with odds $\lambda e^{-\gamma/T}$ and $1 - \lambda e^{-\gamma/T}$ to decide whether or not to try a destruction.
- in case a destruction is tried,
  - choose a transition (x, y), drawing y according to the probability distribution $q_D(x, y)$.
  - then flip a second coin with odds $\exp -((U(y) - U(x) - \gamma)^+/T)$ and $1 - \exp -((U(y) - U(x) - \gamma)^+/T)$ to decide whether or not to apply this move.
- if the answer to one of the two previous tosses was *no*, then choose a transition (x, y), where y is chosen according to the distribution $q_C(x, y)$, and apply it.

The hypotheses we made about q_C, q_D, and U are what are needed to prove the following proposition.

PROPOSITION 3.2. *For any temperature $T > 0$, the matrix p_T is an irreducible Markov matrix.*

Considering the rate function $V : \tilde{\mathbb{S}} \times \tilde{\mathbb{S}} \to \mathbb{R}_+ \cup \{+\infty\}$ defined by

$$V(x, y) = \begin{cases} (U(y) - U(x))^+ & \text{if } q_D(x, y) + q_C(x, y) > 0 \text{ and } x \neq y, \\ +\infty & \text{otherwise,} \end{cases}$$

we see that there is a positive constant κ such that, whenever $x, y \in \tilde{\mathbb{S}}$, $x \neq y$,

$$\kappa\, e^{-V(x,y)/T} \leq p_T(x, y) \leq \frac{1}{\kappa}\, e^{-V(x,y)/T}.$$

Moreover V satisfies the weak reversibility condition of Hajek–Trouvé with respect to U. More precisely, if $\Gamma_{x,y}$ is the set of paths from x to y, we put for any $\gamma = (\gamma_1 = x, \ldots, \gamma_r = y) \in \Gamma_{x,y}$

$$H(\gamma) = \max_{i=1,\ldots,r-1} U(\gamma_i) + V(\gamma_i, \gamma_{i+1})$$

and

$$H(x, y) = \min_{\gamma \in \Gamma_{x,y}} H(\gamma).$$

The weak reversibility condition of Hajek–Trouvé states that for any $x, y \in \tilde{\mathbb{S}}$

$$H(x, y) = H(y, x).$$

Due to this reversibility property, U is a quasi-potential for p_T. We mean by this statement that the (unique) invariant probability measure μ_T of p_T satisfies for some positive constant α (independent of T) and for any $x \in \tilde{\mathbb{S}}$

$$\alpha \leq \mu_T(x) e^{(U(x) - \min U)/T} \leq 1/\alpha.$$

COROLLARY 3.1. *We can build optimization algorithms based on p_T following the results of Catoni* [7] *and Trouvé* [22]. *More precisely, for any fixed value of the temperature T, the homogeneous Markov chain with transition matrix p_T is a generalized Metropolis algorithm with quasi-potential function U. In the same way, for any decreasing sequence of temperatures $(T_n)_{n\in\mathbb{N}}$, the nonhomogeneous Markov chain $(X_n)_{n\in\mathbb{N}}$ on $\tilde{\mathcal{S}}$ with transitions*

$$P(X_n = y \ : \ X_{n-1} = x) = p_{T_n}(x, y)$$

is a generalized simulated annealing algorithm. Its behavior has been studied in [22] *and* [24] *and is very similar to the behavior of classical simulated annealing as studied in* [6].

We can also apply the iterated energy transformation method to p_T, which will be described in a further section of this paper and is studied in [7].

Proof. The only nonstraightforward point to check is the Hajek–Trouvé weak reversibility condition. Let us consider $x, y \in \tilde{\mathcal{S}}$, and $\gamma \in \Gamma_{x,y}$. We build a path from y to x in the following way. Replace any edge $(z,t) \in \gamma$ by the edge (t,z) if $q_C(z,t) > 0$ or $p_T(z,t) = 0$. If neither of the above two conditions is true, this means that $q_D(z,t) > 0$; then there is a path $\varphi \in \Gamma_{t,z}$ such that $q_C(u,v) > 0$ for any edge $(u,v) \in \varphi$, and we replace (z,t) by φ. The path φ is such that $H(\varphi) = U(z) + V(z,t) = U(t)$ because for any $(u,v) \in \varphi$, $U(v) < U(u)$ and $V(u,v) = 0$. Therefore by concatenating all these reversed edges and paths in reverse order we get a path $\psi \in \Gamma_{y,x}$ such that $H(\psi) = H(\varphi)$. Therefore $H(y,x) = H(x,y)$. □

Remarks.

- In the search space we consider, there is a natural starting point for optimization algorithms, which is the empty schedule $\emptyset$.
- In many scheduling problems, it is not known in advance whether a complete solution exists or whether one can possibly be found within the available computer time. Our method has the advantage of finding at least a partial solution, where some proportion of the tasks are scheduled in a coherent way. This is not the case if other constraints are relaxed, as is usually done. For instance, if the aim is to schedule the lectures at a university, a solution where some lectures share the same room at the same time has no practical interest, whereas a solution where some proportion of the lectures are scheduled in a coherent way can be applied.
- A slight variant of the present setup is the case where the search space satisfies condition (1), but one does not know whether it is possible to schedule all the tasks, and wants instead to schedule as many tasks as possible. In this situation the energy can weigh (through a positive measure) the relative importance of tasks.

In the three following sections, we are going to recall briefly some theoretical results about the speed of convergence of three optimization algorithms.

3.5. Rate of convergence of the Metropolis algorithm. In this section we consider the canonical process $(X_n)_{n\in\mathbb{N}}$ on the canonical space $(\tilde{\mathcal{S}}^{\mathbb{N}}, \mathcal{B})$, where $\mathcal{B}$ is the sigma field generated by the events depending on a finite number of coordinates.

For any temperature $T \in \mathbb{R}_+$, P_T will be the probability distribution on $(\tilde{\mathcal{S}}^{\mathbb{N}}, \mathcal{B})$ of a Markov chain with transition matrix p_T (where p_T is as in Proposition 3.2). Under this distribution, $(X_n)_{n\in\mathbb{N}}$ is a Metropolis algorithm and has the following convergence speed.

PROPOSITION 3.3. *There exists a positive constant d, depending only on the choice of the search space $\tilde{\mathcal{S}}$, of the constructive and destructive dynamics q_C and q_D and of the parameter λ, $0 < \lambda < 1$, such that for any energy function U satisfying the hypothesis* (2) *of section* 3.3, *for any positive constant η,*

$$\max_{x\in\tilde{\mathcal{S}}} P_T(U(X_N) \geq U_{\min} + \eta \,|\, X_0 = x) \leq d\left(\exp - \left(\frac{N}{d} e^{-H_1/T}\right) + e^{-\eta/T}\right),$$

where $H_1(V)$ is the first critical depth of the rate function V defined in Proposition 3.2. *The exponent $H_1(V)/T$ is optimal when η is small and when T tends to* 0 *and N tends to $+\infty$. With the notations of Proposition* 3.2,

$$H_1(V) = \max_{x\notin\mathcal{S}} \min_{y\in\mathcal{S}} H(x,y) - U(x).$$

As a consequence, considering $1/T = (1/H_1)\log(N\, H_1/d\,\eta\, \log N)$, we see that there is a constant d (independent of U and η), such that

$$\inf_{T\in\mathbb{R}_+} \max_{x\in\tilde{\mathcal{S}}} P_T(U(X_N) \geq U_{\min} + \eta \,|\, X_0 = x) \leq d\left(\frac{d\,\eta}{H_1(V)}\,\frac{\log N}{N}\right)^{\eta/H_1(V)}.$$

Moreover the exponent $\eta/H_1(V)$ is optimal for small enough values of $\eta \in (U(E) - U_{\min})$.

For a proof see, for instance, Cot and Catoni [9].

This proposition does not give a quantitative upper bound for the probability of failure for N iterations, since it does not give an estimate for constant d; nevertheless, the fact that this constant is independent of U allows us to compare the probability of failure for different energy functions U for a large *finite* number of iterations N and not only when N tends to infinity. More precisely, it shows that the convergence speed of the Metropolis algorithm is slow when there are states with energies close to $U_{\min}$. Indeed if one wants to study the convergence to $\mathcal{S}$, one has to choose

$$\eta = \min\{U(x) - U_{\min}\,,\, x \in \tilde{\mathcal{S}} \setminus \mathcal{S}\}.$$

If η is small, then it will reflect on the exponent $\eta/H_1(V)$.

This is a theoretical justification for the introduction of simulated annealing, which will not suffer from this drawback, when proper robust cooling schedules are used.

3.6. Rate of convergence of simulated annealing. We consider now a non-increasing triangular sequence $T_1^N \geq T_2^N \geq \cdots \geq T_N^N$ of temperatures and the measure $P_{(T_1^N,\ldots,T_N^N)}$ on $\tilde{\mathcal{S}}^N$ of the nonhomogeneous Markov chain with transitions

$$P_{(T_1^N,\cdots,T_N^N)}(X_n = y \,|\, X_{n-1} = x) = p_{T_n^N}(x,y).$$

The rate of convergence of such an algorithm has been studied in [6], [8], and [22] (see also [24] in English, translated from [22]). We give here a simple result; for more precise estimates, we refer to the original papers.

PROPOSITION 3.4 ([6], [22], [24]). *There is a positive constant K such that*

$$K^{-1}N^{-D^{-1}} \leq \inf_{T_1^N \geq \cdots \geq T_N^N} \max_{x \in \tilde{\mathcal{S}}} P_{(T_1^N,\ldots,T_N^N)}(U(X_N) > U_{\min} \mid X_0 = x) \leq KN^{-D^{-1}},$$

where the constant $D = D(V)$ is the difficulty of the rate function V. With the notations of Proposition 3.2, *the definition of $D(V)$ is*

$$D(V) = \max_{x \in \tilde{\mathcal{S}} \setminus \mathcal{S}} \min_{y \in \mathcal{S}} \frac{H(x,y) - U(x)}{U(x) - \min U}.$$

For any $A > 0$, there is a positive constant K such that the triangular exponential schedule

$$T_n^N = \frac{1}{A}\left(\frac{A}{(\log N)^2}\right)^{n/N}$$

gives a convergence speed of

$$\max_{x \in \tilde{\mathcal{S}}} P_{T^N}(U(X_N) > U_{\min} \mid X_0 = x) \leq K\left(\frac{\log N \, \log\log N}{N}\right)^{D(V)^{-1}},$$

for N large enough.

In the case of simulated annealing, we have a probability of failure for N iterations of order $\epsilon \asymp_{\log} (1/N)^{1/D}$ (meaning that the logarithms on both sides of this equation are equivalent when N tends to infinity). The important feature of this theoretical result is that the exponent $1/D$ is independent of the precision with which we want to reach $U_{\min}$ but depends, on the contrary, only on the structure of the local minima of U.

One other interesting point is that the exponential triangular cooling schedule $T_n^N = A^{-1}(A/(\log N)^2)^{n/N}$ is robust: it gives a convergence rate with the optimal exponent $1/D(V)$ for any energy function U.

3.7. Rate of convergence of the energy transformation method. We introduced in [7] the iterated energy transformation method as another mean to discourage uphill moves from low energy states more than from high energy states. In simulated annealing this effect is produced by an exogenous control of the temperature parameter: in "typical" successful runs of simulated annealing, the energy of the current state is moving downwards on the average, and at the same time uphill moves are more and more discouraged. In the iterated energy transformation method, a temporary hypothesis is made about the value of $U_{\min}$, and a concave transformation is applied to U on the basis of this hypothesis. Then the algorithm is run at constant temperature using the transformed energy. This produces the desired effect of discouraging more uphill moves from low energy states. Of course, in the beginning, the hypothesis about $U_{\min}$ is necessarily grossly underestimated, so that the energy transform is not very efficient, but after some iterations, it can be improved (this will work with a probability close to one) depending on the values of the energies of the explored states.

The convergence of the lower bound estimate for $U_{\min}$ towards the true value of $U_{\min}$ is exponentially fast (with a probability close to one), and therefore the energy transformation is quickly tuned to an efficient value.

The iterated energy transformation method applied to our problem is described as follows. For any strictly concave, strictly increasing energy transformation $F : \mathbb{R} \longrightarrow \mathbb{R} \cup \{-\infty\}$, we consider the Markov matrix

$$p_F(x,y) = \mathbf{1}_{(F(x)>-\infty)} \Bigg\{ \lambda e^{(F(U(x))-F(U(x)+\gamma))} q_D(x,y) e^{(F(U(x)+\gamma)-F(U(y)))^-} + q_C(x,y) \left(1 - \lambda \sum_z q_D(x,z) e^{F(U(x))-F(U(x)+\gamma)+(F(U(x)+\gamma)-F(U(z)))^-} \right) \Bigg\} + \mathbf{1}_{(F(x)=-\infty)} \mathbf{1}_{(x=y)}.$$

Consider for any positive constant α, any real shift τ, and any positive temperature T, the transformation

$$F_{\alpha,T,\tau}(U) = \begin{cases} \alpha\, U + \dfrac{1}{T} \log(U+\tau) & \text{if } U+\tau > 0, \\ -\infty & \text{otherwise .} \end{cases}$$

Let us introduce the simplified notation $\overline{p}_{\alpha,T,\tau} = p_{F_{\alpha,T,\tau}}$.

Given parameters $M \in \mathbb{N}$ (number of iterations performed with each energy transform), two real numbers $\rho > 0$ and $\eta_0 \geq 0$ (two parameters for the update of the shift τ), and an initial lower bound $\delta < U_{\min}$, we consider the canonical process $(X_n)_{n\in\mathbb{N}}$ on $\tilde{\mathcal{S}}^{\mathbb{N}}$ with probability distribution $P_{\alpha,T,M,\rho,\eta_0}$ defined by the following conditional distributions:

$$\begin{aligned} P_{\alpha,T,M,\rho,\eta_0}(X_n = y \,|\, (X_0,\dots,X_{n-1}) = (x_0,\dots,x_{n-1})) \\ = \overline{p}_{\alpha,T,\tau_n(x_0,\dots,x_{n-1})}(x_{n-1}, y), \end{aligned}$$

with

$$\begin{cases} \tau_r &= \eta_0 - \delta, \quad 0 < r \leq M, \\ \tau_{kM+r} &= \tau_{k\,M} - \dfrac{1}{1+\rho} \left(\min\limits_{n, n\leq k\,M} U(X_n) + \tau_{k\,M} \right) + \eta_0, \quad 0 < k, 0 < r \leq M. \end{cases}$$

We have proved in [7] the following theorem.

THEOREM 3.1 (Catoni). *For any fixed $\alpha > 0$, the family of processes described above satisfies for some positive constants B and K, for any choice of $r \in \mathbb{N}$, $\eta_0 \geq 0$, $\rho > 0$,*

$$\max_{x\in\tilde{\mathcal{S}}} P_\theta(U(X_{r\,M}) \geq \eta \,|\, X_0 = x) \leq \epsilon$$

where $\theta = (\alpha, T, M, \rho, \eta_0)$,

$$\begin{aligned} T &= \frac{\log(1+\rho)}{\log(Kr/\epsilon)} \\ M &= B \left(\frac{\epsilon}{K\,r} \right)^{-\log(1+\tilde{D}_{\eta_0})/\log(1+\rho)} \log \frac{K\,r}{\epsilon}, \\ &= \frac{B}{T} \log(1+\rho) \left(1 + \tilde{D}_{\eta_0} \right)^{1/T}, \\ \eta &= U_{\min} + \rho \left(\frac{\rho}{1+\rho} \right)^{r-1} (U_{\min} - \delta + \eta_0) + \eta_0 \rho (1+\rho), \end{aligned}$$

and where the constant $\tilde{D}_{\eta_0}(V)$ *is given by*

$$\tilde{D}_{\eta_0}(V) = \max_{x \in \tilde{\mathcal{S}} \setminus \mathcal{S}} \min_{y \in \mathcal{S}} \frac{H(x,y) - U(x)}{U(x) - U_{\min} + \eta_0} < D(V).$$

COROLLARY 3.2.

$$\limsup_{N \to +\infty} (\log N)^{-2} \log \inf_{T,M,\eta_0,\rho} P(U(X_N) > U_{\min} \mid X_0 = x) \leq -\frac{1}{4\ \log(1+D)}.$$

The interest of this theorem lies mainly in its corollary, which shows that a proper tuning of the parameters leads to a faster scale of convergence speed than the one achieved by simulated annealing (see [7]). This remark of course deals with the comparison of two long runs of both algorithms. For repeated trials of bounded length, which we will consider in section 6.3, the question of knowing which algorithm is faster is open.

We will discuss practical means of choosing the parameters in connection with the jigsaw puzzle benchmark.

4. Solving jigsaw puzzles. We will illustrate on jigsaw puzzles the different steps of the general method of resolution.

First of all, we have to choose a search space. This will be the set of partial solutions where only some of the pieces are put in the frame.

$$\tilde{\mathcal{S}} = \{x \subset B \times E : x(r) = [a_r, a_r + w_r[\times[b_r, b_r + h_r[\,, \\ r \in \pi_B(x), x(r) \cap x(r') = \emptyset, r \neq r' \in \pi_B(x)\}.$$

Let us define now $q_C(x,.)$, the constructive dynamic starting from state x:

- First choose $r \in B \setminus \pi_B(x)$ according to the uniform distribution on this set.
- Then choose $(z,t) \in E \setminus \pi_E(x)$ according to the uniform distribution.
- Then try to expend this germ to a rectangle $[a_r, a_r + w_r[\times[b_r, b_r + h_r[$ of the desired size by adding alternatively a column to the left (or else to the right) and a line to the top (or else to the bottom). If it is not possible to grow the germ to its final size, just abandon the construction.
- Then draw a number k at random in the interval $[0, \text{max\_drift}[$ and move the location of $[a_r, b_r[$ k steps along the direction $(-1,-1)$ (that is, to the upper left corner, according to usual image indexing) if there is enough room to do so, or else move it as far as possible in this direction (until it bumps into other pieces).

The last two actions are better described by the following self-explanatory pseudo-C code, where $[a, c\,[\times[b, d\,[$ is the current germ:

```
int expend() {
  a=z; c=z+1; b=t; d=t+1;
  while((test1=(c-a<w))||(test2=(d-b<h))) {
  if (test1&&grow_left()&&grow_right()) return 1;
  if (test2&&grow_up()&&grow_down()) return 1;
  }
  for (k=rand(0,max_drift);k;k--) {
  if (move_left()&move_up()) break;
  } return 0;
}
```

where the functions `expend()`, `grow_left()`, `grow_right()`, `grow_up()`, `grow_down()`, `move_left()`, and `move_up()` return 0 on success and 1 on failure.

The destructive dynamic q_D is simpler:

- Draw $r \in \pi_B(x)$ at random,
- Form $y = x \cap \pi_B^{-1}(B \setminus \{r\})$, the partial solution where the piece labeled "r" has been removed from the frame.

The mechanism that was chosen for the constructions is meant to discourage the formation of small gaps between pieces. If nothing were done, when the discretization step of the grid is fine, small gaps would be left between the pieces with a large probability, and a complete solution to the puzzle, where pieces necessarily stick together, would never be discovered.

We have now to choose an energy function. Here again we will discourage the formation of gaps between pieces by introducing a term proportional to the contact length. By contact length we mean the sum of the contact lengths between pieces and between pieces and the edge of the frame.

Let μ be the counting measure on E. We take

$$U(x) = -\mu(\pi_E(x)) - \alpha \times \text{contact-length}.$$

For this choice of U, we can take the constant γ in equation (2) to be equal to the size of the smallest piece:

$$\gamma = \min_{r \in B} w_r \, h_r.$$

5. Minimizing a loss function.

5.1. Statement of the problem. We will discuss in the next two sections the case where some loss function $V : \mathcal{S} \longrightarrow \mathbb{R}$ has to be minimized on the state space $\mathcal{S}$ of global solutions of a task assignment problem. We consider the same framework as in the first section, with the difference that the problem is now to find a solution x belonging to $\arg\min_{y \in \mathcal{S}} V(y)$.

5.2. A general method of resolution. We will extend the method of section 3 to deal with a loss function.

The two first steps, building the search space and the constructive and destructive dynamics, will be the same as in section 3.

The change comes from the choice of the energy function. First we need to extend the loss function V to the search space $\tilde{\mathcal{S}}$ of partial solutions. Ideally, we would like to use the extension $\overline{V} : \tilde{\mathcal{S}} \longrightarrow \mathbb{R}$ defined by

$$\overline{V}(x) = \min\{V(y) \,:\, y \in \mathcal{S}, x \subset y\}.$$

Usually this is not an easily computable function, but in many situations there is a natural way to define a loss function for partial solutions. A simple way to do so, if there is nothing else at hand, is to set $V(y) = c$ for $y \in \tilde{\mathcal{S}} \setminus \mathcal{S}$, where c is a constant and $c \geq \max_{x \in \mathcal{S}} V(x)$. Then we build a compound energy function

$$W(x) = \alpha \, U(x) + V(x), \qquad x \in \tilde{\mathcal{S}},$$

where the real positive coefficient α is chosen such that, for some positive constant γ,

$$\begin{cases} \arg\min\limits_{x \in \tilde{\mathcal{S}}} W(x) \subset \mathcal{S}, \\ W(y) - W(x) \leq -\gamma < 0, \quad x \subset y, \ x \neq y \in \tilde{\mathcal{S}}. \end{cases}$$

These conditions are always satisfied for α large enough. However, the difficulty D of the energy landscape, related to the performance of simulated annealing, tends to $+\infty$ when α tends to $+\infty$. Therefore it is better to keep α as small as possible. In the next section, we will give an example for which we can take α arbitrarily small, and even $\alpha = 0$ if we are satisfied with $\gamma = 0$.

Equipped with this new energy function, we can proceed just as in the simpler case of section 3.

5.3. Some example of useful loss function. Often in task assignment problems, we would like some resources to be distributed according to some prescribed distribution. For instance, in a time-table problem we may want to schedule an equal number of hours in each week of the year.

This can be formalized in the following way. We consider first some function $\Phi : B \times E \longrightarrow F$, where F is a finite set (which may be the discretization of a domain in $\mathbb{R}^n$). Typically, Φ will be the projection on the time axis in a time-table problem. Then we consider a target distribution ρ defined on F. Let us consider some reference measure μ on $B \times E$ (such as the counting measure). To each partial solution $x \subset B \times E$, we may associate the restriction μ_x of μ to x, defined by

$$\mu_x(A) = \mu(x \cap A).$$

This induces a measure $\mu_x \circ \Phi^{-1}$ on F. The constraint we would like to represent by a loss function is that $\mu_x \circ \Phi^{-1}$ is approximately proportional to the reference measure ρ. This can be reflected in a loss function of the type

$$V(x) = \int h\left(\frac{\mu_x \circ \Phi^{-1}}{\rho}\right) d\rho,$$

where $h(x) = (1-x)^2$ or $h(x) = 1-x+x\log x$. The function h is in both cases strictly convex, satisfies $h(1) = h'(1) = 0$, and h' is strictly increasing; therefore $\mu_x \circ \Phi^{-1} = \rho$ if and only if $V(x) = 0$ and the minimum of $V(x)$ on the set $\mu_x(B \times E) = \textit{constant}$ is attained when $\mu_x \circ \Phi^{-1}$ is proportional to ρ, when this is feasible.

The following proposition holds.

PROPOSITION 5.1. *Assume that the total weight $\mu_x(B \times E)$ of any solution is a function of the tasks to be scheduled only. This means that there is a measure $\tilde{\mu}$ on B such that*

$$\mu_x(B \times E) = \mu(x) = \tilde{\mu}(\pi_B(x)), \quad x \in \tilde{\mathcal{S}}.$$

Then for all global solutions $x \in \mathcal{S}$, $\mu_x(B \times E) = \mu(x) = \tilde{\mu}(B)$ is a constant.

Assume moreover that the measure ρ defining the constraint is such that $\rho(F) \geq \tilde{\mu}(B)$, and assume also that

$$\left\{ x \in \mathcal{S} \,:\, \frac{\mu_x \circ \Phi^{-1}}{\rho} \equiv \textit{constant} \right\} \neq \emptyset.$$

Then

$$\arg\min_{s \in \tilde{\mathcal{S}}} V(x) = \left\{ s \in \mathcal{S} \,:\, \frac{\mu_x \circ \Phi^{-1}}{\rho} \equiv \textit{constant} \right\},$$

meaning that the partial solutions minimizing V are exactly the global solutions x for which $\mu_x \circ \Phi^{-1}$ is proportional to the constraint ρ.

The assumptions of the proposition will be satisfied when $\mu_x(B\times E)$ measures the amount of assigned resources, and the amount of resources to be allocated to a task depends only on the task and not on the way it is scheduled. Typically, for instance, the number of hours of a course of teaching will be prescribed in advance and will not depend on the choice of a schedule for the lectures.

Now let us make the supplementary assumption that $(\mu_x \circ \Phi^{-1}/\rho) \leq 1$ for any $x \in \tilde{\mathcal{S}}$. We can always make this assumption true by increasing ρ by a suitable multiplicative factor (at least when ρ is strictly positive on F). In some cases we may, on the contrary, want to restrict $\tilde{\mathcal{S}}$ by adding the new constraint $(\mu_x \circ \Phi^{-1}/\rho) \leq 1$. This will be done when the constraint has a practical meaning for the problem. For instance, if $\mu_x \circ \Phi^{-1}$ measures the number of lectures taking place in each hour of time in the week, we may want to fix ρ to a constant equal to the total number of available lecture rooms, add the constraint $(\mu_x \circ \Phi^{-1}/\rho) \leq 1$ to indicate that there is to be enough rooms to schedule all the lectures, and use the loss function $\int h(\mu_x \circ \Phi^{-1}/\rho)d\rho$ to indicate that we would like the rooms to be evenly occupied during the week (in a weekly time-table problem).

If the assumption $(\mu_x \circ \Phi^{-1}/\rho) \leq 1$, $x \in \tilde{\mathcal{S}}$ holds, then only the decreasing part of h is used, and the loss function V is always increasing during a destruction and decreasing during a construction. Therefore if γ is the constant corresponding to U in Eq. (2), we will have

$$W(y) \geq W(x) + \alpha\,\gamma, \quad x, y \in \tilde{\mathcal{S}}, \quad x \neq y, q_D(x,y) > 0.$$

6. The practical issue of the choice of parameters. In practical situations, the critical constants of the energy landscape are usually unknown. Therefore it is not possible to rely on the theoretical results we recalled in preceding sections to choose the parameters of algorithms. In the following subsections, we explain how we set the parameters in the experiments about jigsaw puzzles.

6.1. Simulated annealing. The cooling schedule can be written as

$$\frac{1}{T_n^N} = \beta_{\min}\left(\frac{\beta_{\max}}{\beta_{\min}}\right)^{n/N}.$$

We choose $\beta_{\min}$ and $\beta_{\max}$ by looking at the repartition function of the energies of the explored states in simulations at constant temperatures. We keep a value of $\beta_{\min}$ for which the slope of the repartition function stays large up to the largest values of the energies, meaning that states with high energies have a significant probability to be explored. For $\beta_{\max}$ we require, on the contrary, a repartition function concentrated on the lowest energy values.

The theory tells us that we can safely underestimate $\beta_{\min}$ and overestimate $\beta_{\max}$, which makes their choice possible from a qualitative inspection of repartition functions.

Figures 6.1 and 6.2 are two examples of repartition functions, corresponding to values of $\beta_{\min}$ and $\beta_{\max}$ which have been retained during the experiments.

6.2. The iterated energy transformation method. In this case, the choice of parameters is perhaps less straightforward. The analogy with simulated annealing can serve as a guideline: the high temperature regime corresponds to the case $\tau = \tau_1$ (i.e., to the first energy transform used). The low temperature regime corresponds to

$$\tau = (1+\rho)\eta_0 - U_{\min}.$$

FIG. 6.2.

In order to test the behavior of the algorithm in these two configurations, we make a short test using a small value of ρ ($\rho << 1$). The law of evolution of τ_k shows that, for a small value of ρ, the algorithm will quickly switch from the high temperature regime during the first step to a low temperature regime during the following steps. In fact the value $\rho = 0$ may sometimes even be used. However, when this is done the algorithm sometimes encounters a state with a nondefined energy transform too quickly, and there are not enough iterations to compute a reliable repartition function for the low temperature regime. This problem, when encountered, can be circumvented by using a low but nonzero value of ρ.

We compute the repartition function of energies during the first step of the test run and during the last. The first function describes the equivalent of the "high temperature regime" and is tuned by the choice of the constant α and of the temperature parameter T; the second function corresponds to the "low temperature regime" and is tuned by a proper choice of $\tilde{\eta_0} = \eta_0(1+\rho)$.

Once these two choices are made, there remains a free parameter, namely, ρ.

The theory [7] indicates an optimal choice of ρ of order $\sqrt{N}$ and an optimal choice of $r = N/M$ of order $\sqrt{N}\log(N)$. On the other hand, as soon as $\log(1+\rho) > 1$, the convergence rate will be better than for simulated annealing. This indicates that a large value of ρ may safely be chosen and that r can then be set to make

$$(U_{\min} - \gamma + \eta_0)\rho\left(\frac{\rho}{1+\rho}\right)^{(r-1)}$$

small. This will ensure a small dependence of the final value of the shift τ_N with respect to its initial value $\tau_1 = \delta - \eta_0$.

6.3. Repeated optimizations. In this section, we will consider that N iterations are to be divided into N/M trials of length M, and that we will keep the best solution found out of these N/M trials. In this context, the probability of failure in the worst case with respect to the starting point of each trial is $\epsilon_1(M)^{N/M}$, where

$$\epsilon_1(M) = \max_{x\in\tilde{S}} P\left(U(X_N) > U_{\min} \mid X_0 = x\right).$$

The first remark to be made (see Azencott [2], [3]) is that for all the algorithms we have considered, $\lim_{M\to+\infty}(1/M)\log\epsilon_1(M) = 0$. Therefore when N is large enough, the optimal value for M is independent of N.

We will discuss here the choice of the length M of each run of the algorithm. For simulated annealing, we can, on the basis of the theoretical bound on the probability of failure, namely, $(A/M^\alpha)^{N/M}$ for N iterations divided into N/M runs of length M, conjecture that an overestimation of M will be relatively harmless, whereas an underestimation would be more penalizing. This can be seen on the derivative

$$\frac{\partial}{\partial M}\left(\frac{A}{M^\alpha}\right)^{N/M} = \left(\frac{A}{M^\alpha}\right)^{N/M}\frac{N\left(\alpha(\log M - 1) - \log A\right)}{M^2},$$

but is may be more vividly illustrated by a small numerical application. If we take, for example, $A = e^4$, $\alpha = 1$, and $N = 1000$, and if we put $\epsilon(M) = (A/M^\alpha)^{N/M}$, we see that

$$\min_M \epsilon(M) = \epsilon(148) \simeq 0.0012,$$

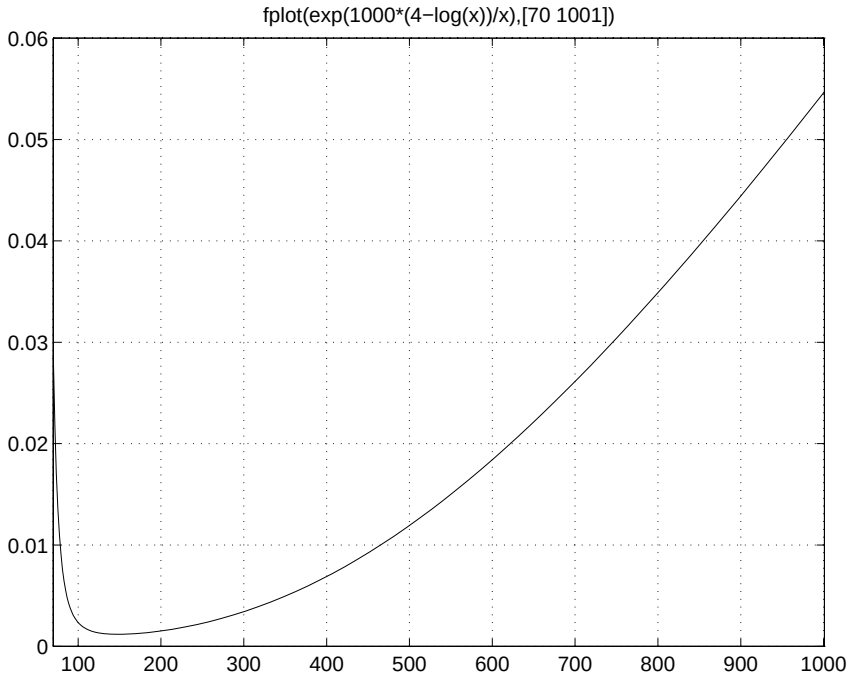

FIG. 6.3.

and that for this optimal value the probability of failure in each run is $\simeq 0.37$.

Here are some values taken by $\epsilon(M)$

M	74	100	148	300	500	1000
$\epsilon(M)$	0.016	0.0024	0.0012	0.0034	0.012	0.055

and a graphic of this function is shown in Fig. 6.3.

These figures show that, as far as this rough theoretical bound is a good guideline, there is a clear benefit in performing multiple runs instead of one long run, but that an overestimation of a factor two of the length of each run is relatively harmless. We remark also that a quite low confidence level for each run is favorable in this example where the difficulty is one.

The same kind of reasoning would also hold for the theoretical bound of order $\epsilon(M) = (A/M^{\alpha \log M})^{N/M}$ obtained for the iterated energy transformation method. In this case the derivative of the confidence level $\epsilon(M)$ is

$$\frac{\partial}{\partial M}\epsilon(M) = \epsilon(M)\frac{N\left(\alpha((\log M)^2 - 2\log M) - \log A\right)}{M^2}.$$

Figure 6.4 shows a plot of this function for some choice of the parameters α, N, and A: the tolerance with respect to an overestimation of M is even better than for simulated annealing.

For a comparison between repeated searches and interacting parallel searches, we refer to Graffigne [16] and Azencott and Graffigne [4].

6.4. A partial freezing method. In [7] we saw that the simulated annealing algorithm is not efficient to deal with a state space made of a large number of independent components. By "independent components," we mean the case when the energy

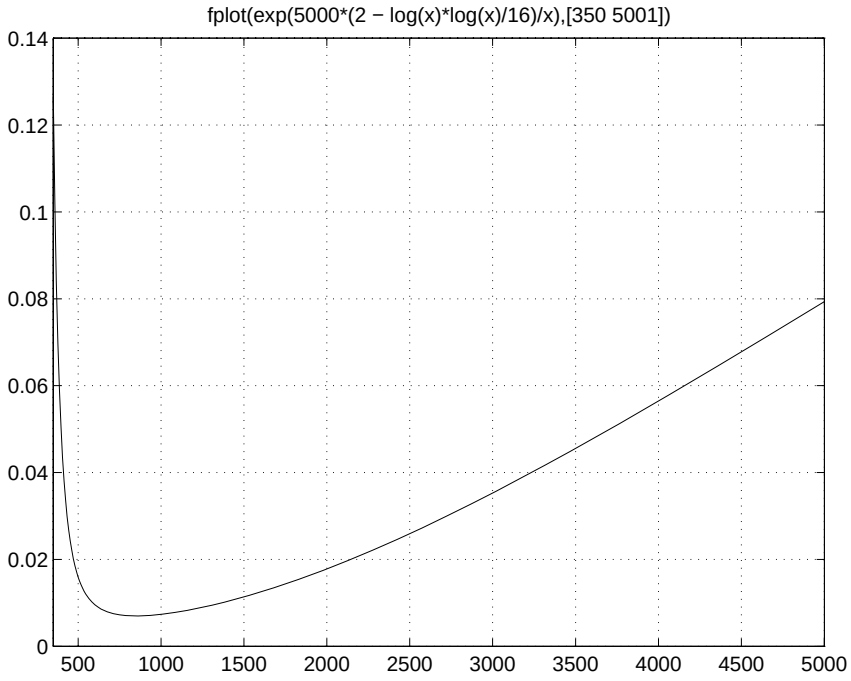

FIG. 6.4.

function is a sum of terms depending on distinct coordinates. Here the different tasks to be scheduled interact through the constraints and through the contact length term in the energy; therefore we cannot describe their assignment by independent coordinates. Nevertheless, in the end of the optimization process, we would like to be able to perform some last small local improvements on the current solution depending on distinct small subsets of tasks, with the assignment of the other tasks remaining untouched. We can write (formally) the energy function in a suitable neighborhood of the current solution as a sum of such possible local improvements. In the end of the optimization, we will be working at low temperature; therefore the current solution will, most of the time, be a local minimum and we will typically not try more than one local improvement at a time. Therefore (this is only a heuristic reasoning) we can expect the optimization process to behave approximately the same as in the independent component case when it draws to the end (that is, at low temperatures). It is easy to show (see [7]) that an efficient way to deal with independent components is to perform a series of local optimizations, resetting after each step the current solution to the best solution found. This will do much better than the global algorithms we described so far when the number of components is large. The reason is that a global algorithm cannot efficiently move one task around without disturbing the others. These considerations suggest adding a postprocessing to global optimization, made up of a series of local optimizations. When we put these things and the use of repeated optimizations together, we end up with a partial freezing method, which can be symbolically described by the following nested loops:

```
repeat
  reset the current solution to the empty assignment
  for (n taking increasing values from 0 to max)
    repeat
      choose at random a set of n ‘‘frozen’’ tasks among
      the scheduled tasks
      repeat
        run a stochastic optimization algorithm during
        which the frozen tasks stay untouched
      endrepeat
      reset the current solution to the best solution
      encountered in the previous loop
    endrepeat
  endfor
endrepeat
return the best solution encountered in the outer loop.
```

The stochastic algorithm used in the inner loop may be one of the three algorithms we studied here. It is applied to the subset of the state space defined by the current assignment of the frozen tasks. When the number of currently scheduled tasks is less than n, we freeze all the scheduled tasks. In the experimental section we will show results obtained with this partial freezing method applied to the iterated energy transformation algorithm. One advantage of the partial freezing method is that it is less demanding on the global optimization step and is therefore tolerant of a looser choice of the parameters of the algorithm.

7. Experimental results. We tried to solve two kinds of puzzles: a small "tight" puzzle with nine pieces and no loss function, and a big "loose" 60-piece puzzle with a loss function. By "tight" we mean that there is just enough room in the frame to put all the pieces, and by "loose" we mean, on the contrary, that there is some extra room left in the frame, the difficulty being then to minimize the loss function.

7.1. Small "tight" jigsaw puzzle. Our small jigsaw puzzle is a nine-piece problem. The algorithm we used to solve it corresponds to the description given in section 4. The frame is a 40×50 grid. The size of the pieces are $(14, 27)$, $(8, 36)$, $(8, 9)$, $(6, 14)$, $(34, 5)$, $(18, 9)$, $(22, 9)$, $(18, 21)$, $(18, 15)$. The problem has several solutions, due to symmetry properties. Figure 7.1 shows one solution: the parameters of the algorithms were set using the heuristics described in section 6.

We performed 40 runs of the simulated annealing algorithm and the same number of runs of the IET algorithm. For each algorithm, we computed the repartition function of the energy of the best solution encountered during each run and computed the repartition function of the energy of the final state of the algorithm. Of course, the former repartition function is always above the latter; therefore we can unambiguously plot them on the same diagram. In order to perform a "fair" comparison, we allowed the same number of iterations in both cases, namely, $N = 5000$ iterations per run.

The results (Figs. 7.2 and 7.3) are of the same order, with some advantage in favor of the IET method. This is especially true when the energy of the final state is considered. An interpretation of this fact is that the IET algorithm is more efficient in preventing the process from leaving the global minimum once it has reached it.

We were also able to check the influence of the drift towards the upper left corner.

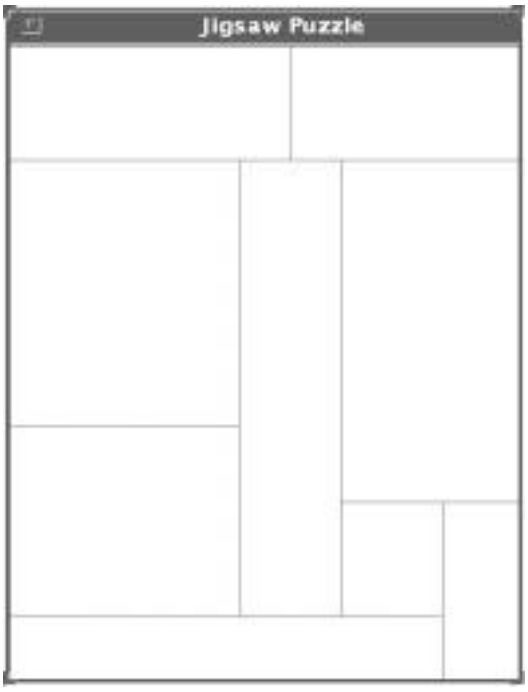

FIG. 7.1.

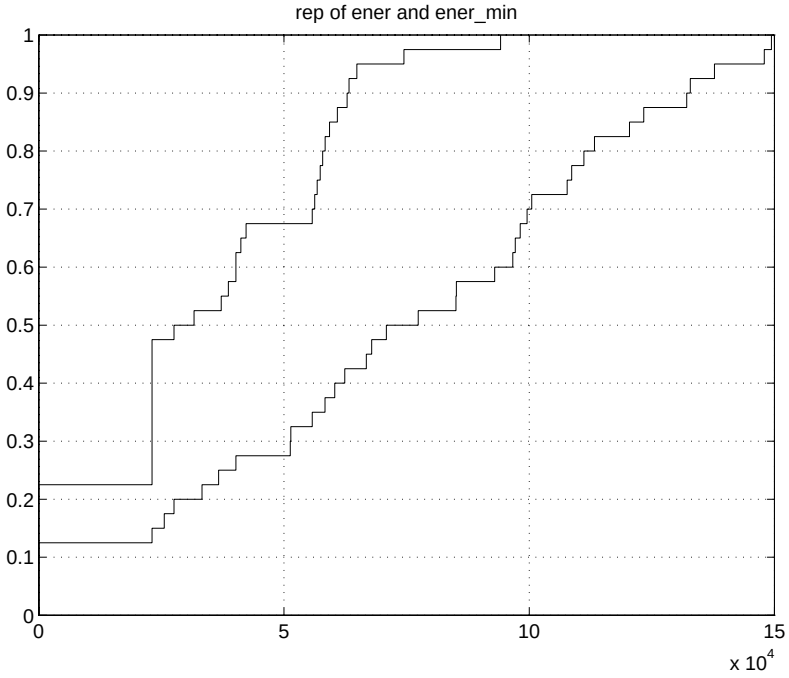

FIG. 7.2. *Performance of simulated annealing.*

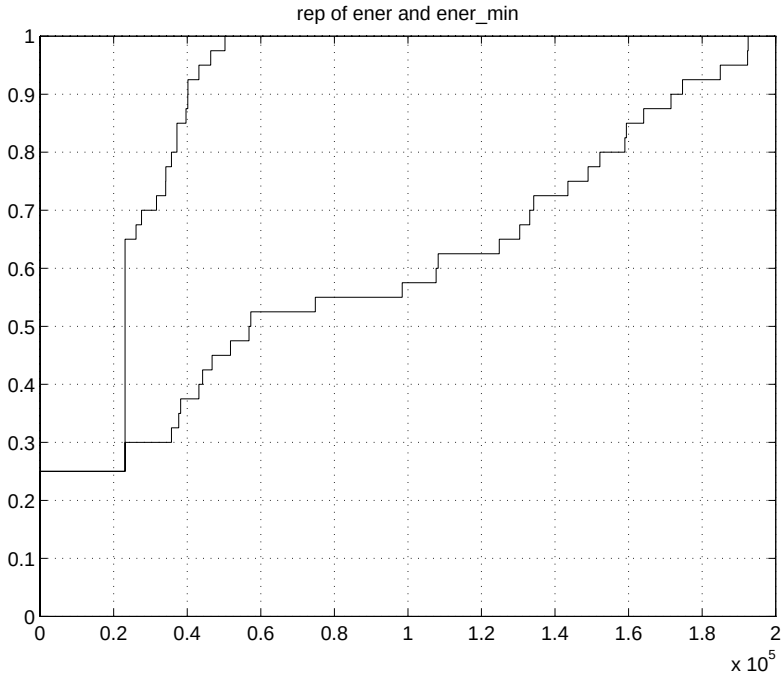

FIG. 7.3. *Performance of the iterated energy transformation method.*

In the two previous experiments, the maximum number of steps of the drift (the constant `max_drift` in the pseudocode of section 4) is 10. We have also tried a maximum number of steps of 50, for simulated annealing. We obtained on 40 runs the improvement in the performance shown in Fig. 7.4.

7.2. A big "loose" jigsaw puzzle. Our big jigsaw puzzle has 60 pieces, covering an area of 230 unit squares. The frame is a grid of size 30×10. The sizes of the pieces are the following:

number of pieces	width	height
15	3	2
15	2	1
5	5	2
5	2	4
20	1	1

The loss function is of the type described in the previous section. The function Φ here is the projection on the second axis, $\Phi((r, a, b)) = b$, $(r, a, b) \in B \times E$, so that the constraint indicates how much of each line the pieces should fill. On the following diagram, we have plotted the constraint function ρ (see Fig. 7.5).

With this choice of ρ, the constraint is tight, meaning that $\rho(F)$ is equal to the area of the pieces. When we use tight constraints, we build problems of the partition type, which are therefore NP complete. We chose the size of the pieces such that the set of global solutions is not empty. However, for a 60-piece problem, it is very difficult to find a (complete) solution.

We have chosen a coarse discretization step to keep the difficulty of the problem

to a reasonable level, since we had to switch off the vertical drift. Indeed keeping a vertical drift would have decreased the stability of minimizing configurations in an unfavorable way.

We tried two kinds of energies. In order to have a point of comparison, we tried to use the simple energy $U(x) = -\mu(x) + \max_{y \in \tilde{\mathrm{S}}} \mu(y)$, where μ is the counting measure.

Then we tried a compound energy $W(x) = U(x) + \alpha V(x)$ for a large value of α and for $V(x) = \int (1 - (\mu_x \circ \Phi/\rho)^2 d\rho$.

Eventually, we tried to relax the constraint, changing ρ to $\tilde{\rho} = 6/5 \times \rho$.

7.2.1. Experiments with a simple energy function. In order to have a point of comparison, we recorded first the performance of repeated relaxations. The relaxation algorithm we used corresponds to a choice of $\lambda = 0$, or equivalently to a choice of $\beta = +\infty$ in the Metropolis algorithm.

Then we considered the Metropolis algorithm for different values of λ and of β. We tried $\lambda = 1$ and $\lambda = 0.5$, two "natural" choices for λ. The former let us inhibit destructions only according to the energy increment, whereas the latter let constructions and destructions have equal frequencies at infinite temperature.

The first conclusion we reached was that a significant improvement over the relaxation scheme could be obtained using the Metropolis algorithm with a moderate number of steps. We compared relaxation with 300 steps (for which convergence was always reached) with Metropolis with $\lambda = 1$, $\beta = 1$, and $N = 4000$. In order to compare methods using the same number of iterations, we repeated Metropolis 20 times and the relaxation algorithm $\lfloor (4000 \times 20)/300 \rfloor = 266$ times. On the following diagram (Fig. 7.6) we plotted the repartition functions of the best solution found for each of the 20 runs of Metropolis (dashed lines), along with the best 20 results out of the 266 runs of the relaxation algorithm (solid lines).

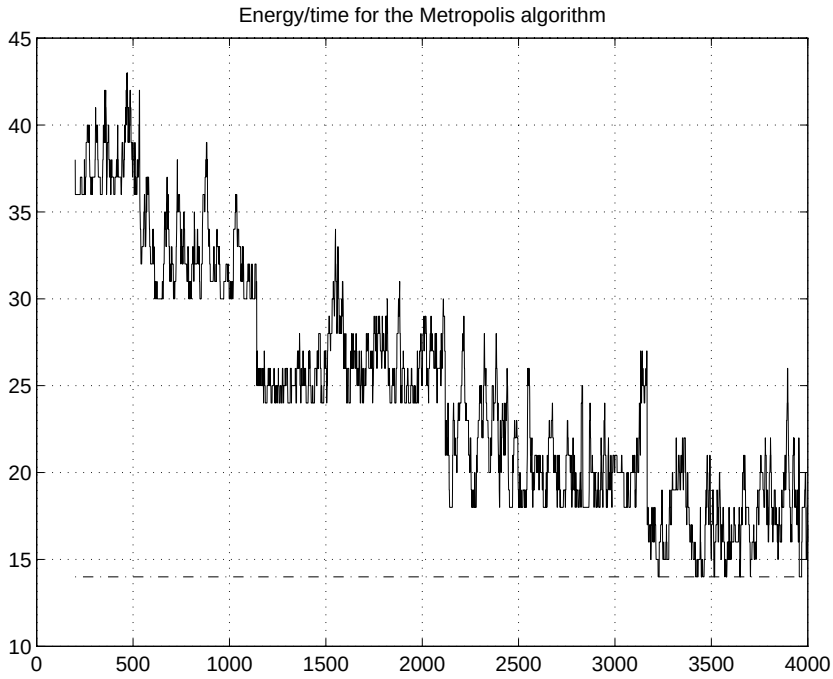

FIG. 7.7.

We obtained very suggestive evolutions for the Metropolis algorithm, such as the following (Fig. 7.7).

On this plot of $u_n = U(X_n)$ for $n = 300, \dots, 4000$, we see the "staircase" shape of the trajectories of the Metropolis algorithm. The algorithm "falls" into deeper and deeper maximal cycles [13] of the domain $\tilde{\mathcal{S}} \setminus \mathcal{S}$. We refer to [5] for a theoretical study of the exit path of the Metropolis algorithm from a domain at low temperature. For a study of the trajectories of simulated annealing algorithms, we refer to [6] and [22], which rely on more complex but also more general induction proofs which cover the time inhomogeneous case. For a semigroup approach of the same question in the continuous time case, we refer to [10], [11], [12], [17], [19], [20], and [21].

The energy evolution can be decomposed into a decreasing part $\underline{u}_n = \min_{k \le n} u_k$ and a "wandering" part $\overline{u}_n = u_n - \underline{u}_n$, as in the following diagram (Fig. 7.8).

The repartition function of the wandering part gives information about the depth of secondary attractors from which the algorithm is able to escape within the time of the simulation. It is a useful tool to choose the inverse temperature parameter β. Following is the repartition function corresponding to the preceding plot (Fig. 7.9).

The best results for the Metropolis algorithm of time length $N = 4000$ were obtained for $\beta = 1$ and $\lambda = 1$ or for $\beta = 0.8$ and $\lambda = 0.5$. This shows that in this case, the choice of λ is not crucial. In the following, we will use $\lambda = 1$, because we can hope to take better advantage of the discrimination made by the energy function between small and big pieces when we use this value of λ.

Then we used the Metropolis algorithm and simulated annealing on long time intervals. Namely, we took $N = 20000$, $\beta_{\min} = 0.7$, $\beta_{\max} = 1.1$ for simulated annealing and $\beta = 1$ for the Metropolis algorithm. On 10 runs of each algorithm, we could notice a clear gain in performance in favor of simulated annealing.

FIG. 7.9.

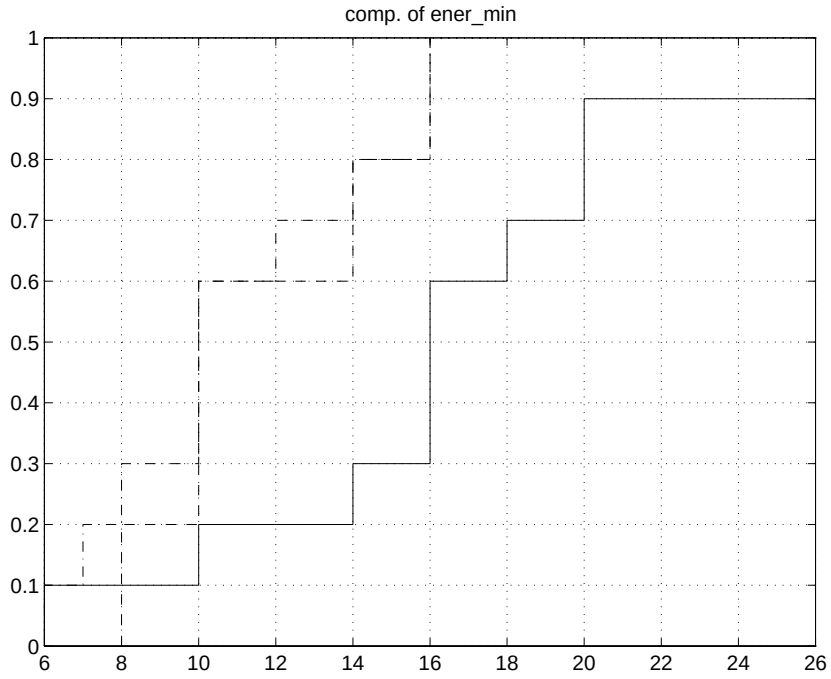

FIG. 7.10.

We tried eventually to get a better improvement using the IET algorithm. Since the state space is already rather large, we followed the idea introduced in [7] to use transformations $F_{\alpha,T,\tau}$ with a nonzero value of α.

We took $\alpha = 0.3$, $\beta = 1/T = 30$, $\frac{1}{1+\rho} = 0.5$, $r = 4$, and $\eta_0 = 15$. We obtained the following comparative results for the best energy found in each of 10 runs of each algorithm. The mean values are 16.2 for the Metropolis algorithm (solid lines), 11.6 for simulated annealing (dashed lines), and 10.9 for the IET algorithm (dash-dot lines). The repartition functions are plotted on the next diagram (Fig. 7.10).

7.2.2. Experiments with a compound energy function. We used the energy

$$W(x) = U(x) + \alpha V(x),$$

with a huge value of $\alpha = 10000$.

The range of this energy is very large, when compared with the previous one, since $W_{\max} = 2300230$, whereas $W_{\min} = 0$ and removing a piece of size 1×1 from a complete solution in a line of weight $\rho(y) = 30$ costs $\Delta W \simeq 334.33$. Therefore we may expect more spectacular improvements from the speed-up techniques.

We tried different temperatures for the Metropolis algorithm with $N = 20000$. The best results were obtained when $\beta = 8 \times 10^{-4}$. On 10 runs, the average best value was 15853.

Using simulated annealing with $\beta_{\min} = 10^{-4}$, $\beta_{\max} = 10^{-3}$, we improved the performance on the average, as shown in the next diagram. On 10 runs, the average best energy value was 8765.

We obtained some more improvement using the IET algorithm (with $\gamma = 5 \times 10^{-5}$, $\beta = 10$, and $\eta_0 = 2000$). On 10 runs the average best energy value was 6280.

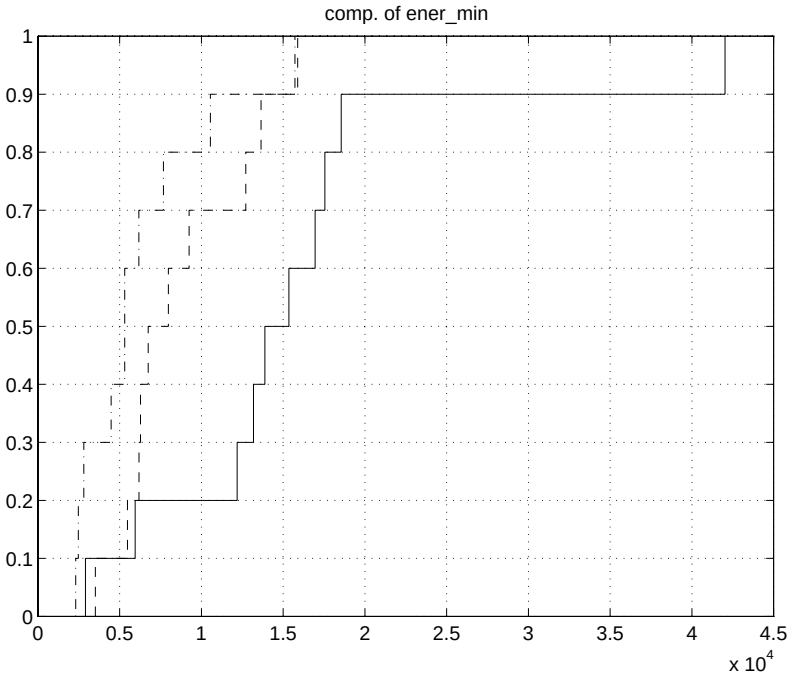

FIG. 7.11.

Figure 7.11 shows a diagram of the repartition functions of the best energy value for ten runs of the Metropolis algorithm (solid lines), simulated annealing (dashed lines), and the IET algorithm (dash-dot lines).

7.2.3. Experiments with a relaxed constraint. We explored also an alternative in the optimization design, which consists of replacing ρ by $\tilde{\rho} = \frac{6}{5}\rho$. We considered accordingly a larger search space $\tilde{\mathcal{S}}$ where the constraint $\frac{\mu_x \circ \Phi^{-1}}{\rho} \leq 1$ is relaxed to $\frac{\mu_x \circ \Phi^{-1}}{\tilde{\rho}} \leq 1$. We took again a compound energy of the type $W(x) = U(x) + \alpha\, V(x)$, with $\alpha = 10000$. The range of W is between $W_{\min} = 76666.66$ and $W_{\max} = 2760230$.

In this example, we can perform the same kind of comparison as in the case of tight constraints. We made 10 runs of length $N = 20000$ of each algorithm. The average of the best energy value found in each run is 8731 for the Metropolis algorithm, 8685 for simulated annealing, and 8567 for the IET algorithm. Figure 7.12 shows a diagram of the corresponding repartition functions (solid lines for the Metropolis algorithm, dashed lines for simulated annealing, and dash-dot lines for the IET algorithm).

The best solution was found by the IET algorithm. It has an energy of $W(x) = 78750$ and is shown in Fig. 7.13.

In this solution, all the pieces are set in the frame. We can judge the quality of the solution with respect to the proportionality constraint on the following diagram (Fig. 7.14), where we have plotted $\tilde{\rho}$ (dashed lines), the measure expressing the constraint, and $\mu_x \circ \Phi^{-1}$ (solid lines), giving the number of unit squares actually filled on each line by the solution. The optimum would be $\mu_x \circ \Phi^{-1} = \rho = 5/6 \times \tilde{\rho}$. We are not too far from that: the two entries $\mu_x \circ \Phi^{-1}(2)$ and $\mu_x \circ \Phi^{-1}(4)$ are one unit too large, and $\mu_x \circ \Phi^{-1}(9)$ is two units short from the optimum. This is the best approximation to an optimal solution we were able to compute on this example. This seems to show that

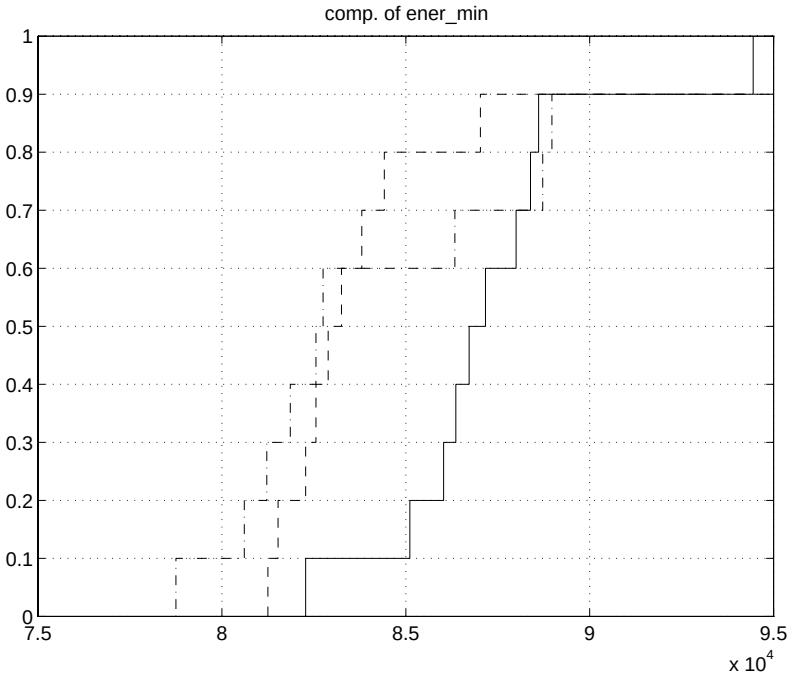

FIG. 7.12.

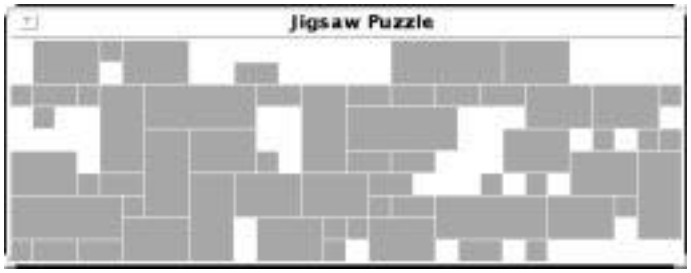

FIG. 7.13.

relaxing the constraint slightly and introducing the loss function $V(x)$ in the energy eases the optimization process.

This should be compared with the best solution found without relaxing the constraint (Fig. 7.15) and its constraint diagram (Fig. 7.16).

For this solution, $U(x) = 6$. Solutions of energy $U(x) = 6$ were also found using the simple energy U to guide the search. Therefore the advantage of introducing the V component in the energy function is not obvious when the constraint is really tight.

It is also interesting to consider typical energy evolutions of those three algorithms. On the following diagrams (Figs. 7.17–7.19), we have plotted the sequence

$$u_n = U(X_n).$$

As we have already mentioned, these sequences of energy values can be decomposed

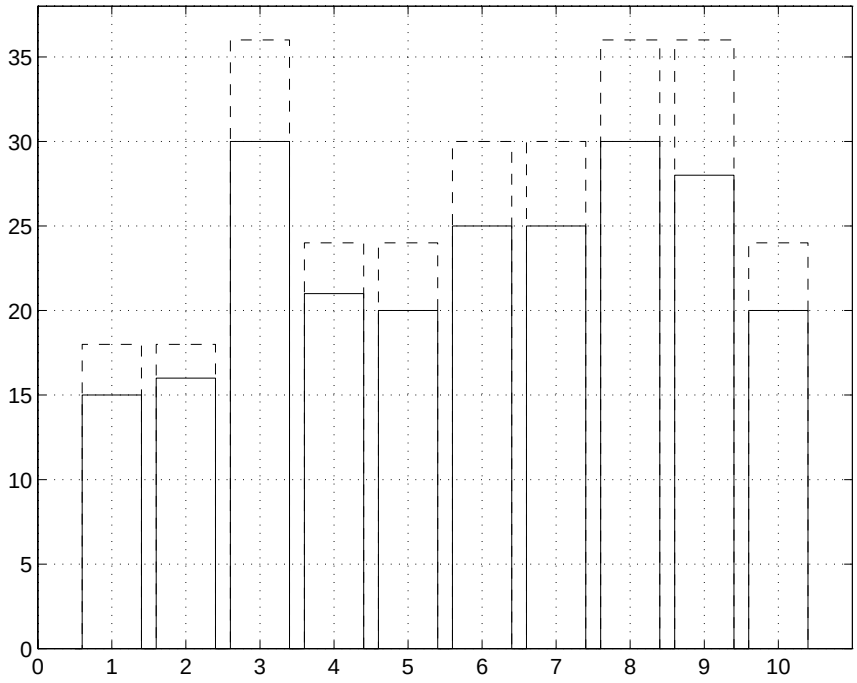

FIG. 7.14.

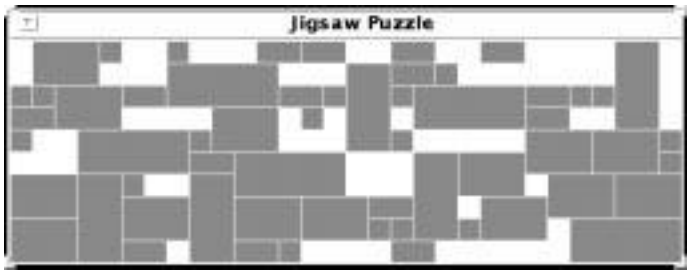

FIG. 7.15.

into a decreasing component

$$\underline{u}_n = \min\{u_k \,:\, k \leq n\},$$

and a wandering component

$$\overline{u}_n = u_n - \underline{u}_n.$$

The repartition functions of $(\overline{u}_n, n = 1, \ldots, N)$ can help to properly set the parameters. It indicates the depth of the attractors from which the algorithm is able to escape.

It is interesting to compare the energy evolutions of the three algorithms. The comparison between the Metropolis algorithm and simulated annealing shows clearly that the temperature used in Metropolis is too low during the first 4000 iterations and too high during the last 8000 iterations. As for the IET algorithm, we can see

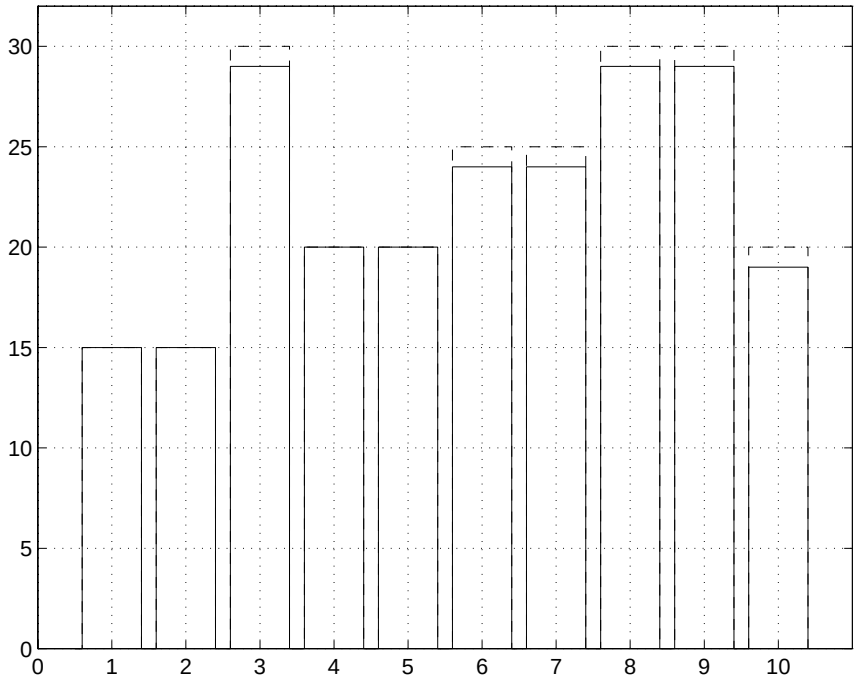

FIG. 7.16.

that the fluctuations of the wandering part are decreasing with time, as in the case of simulated annealing, but that the evolution of the energy is more unstable: it can go up and down faster (in other words, its peaks are sharper). This explains why it is able to sample more efficiently a state space containing many local minima.

7.2.4. Experiment with the partial freezing method. In this experiment, we took the IET algorithm, which had proved to be the best when used globally, and we added a postprocessing stage where we froze all but three of the tasks. At the same time we decreased the global optimization step from 20000 iterations to 3000 iterations and kept 50 times 300 iterations for postprocessing (we drew 50 different frozen configurations and made 300 iterations for each; in each frozen configuration, only three pieces were left unfrozen). Thus we decreased slightly the total number of iterations from 20000 to 18000 (in answer to a suggestion of one of our referees that a more complex algorithm should be allowed less iterations). At the same time, we got an improvement on 10 trials for both the mean value of the energy and its minimum value over the 10 trials (Fig. 7.20). We also found that it was much easier to tune the parameters of the IET algorithm.

Figure 7.21 shows an energy evolution typical of the partial freezing method, where the lower plot shows the evolution of $\eta_0 - \tau_n$: we see that the partial freezing allows us to go faster up and down the energy landscape (in other words, it allows us to work at a higher temperature).

7.2.5. Is the number of iterations a fair measure of complexity? In the case of the three algorithms in this paper, the inner loop is the same except for the computation of the rejection probabilities. When one goes from the Metropolis algorithm to simulated annealing, one has to add the cost of updating the temperature,

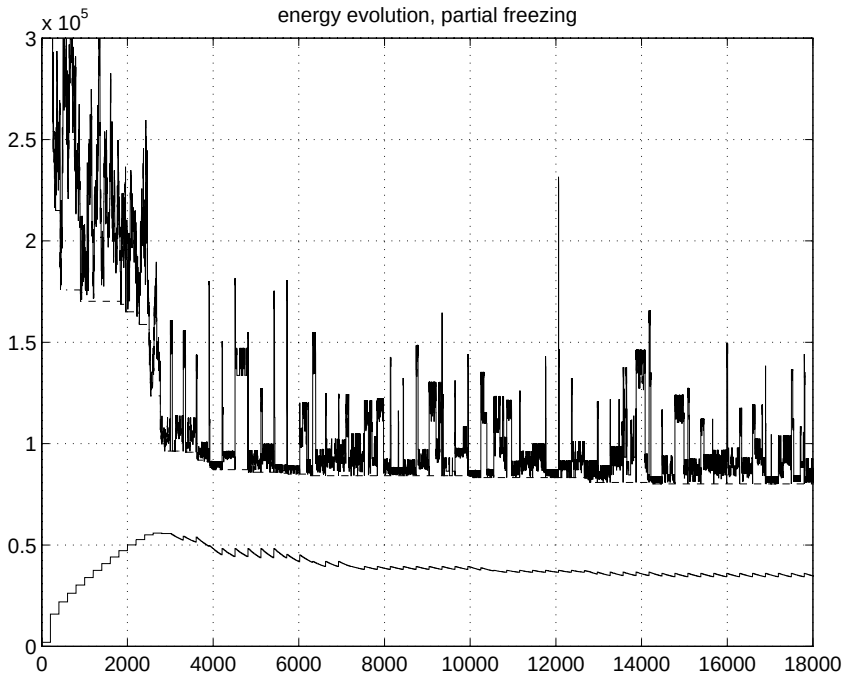

FIG. 7.17.

that is, the cost of one multiplication (in fact, it is even possible to use piecewise constant temperature schedules with the same theoretical properties; see [9], for which the update of the temperature is not in the inner loop and therefore has little influence on the computer time). When one goes from the Metropolis algorithm to the IET algorithm, one has to compute the energy transformation, that is, $\log \frac{U+\Delta U}{U}$, this means one addition, one multiplication, and a logarithm. The fact that one uses the value of U and not only the value of ΔU, the energy increment, does not really make a difference in practice since one will, anyhow, want to record the value of the energy U in order to keep the best solution encountered and not systematically keep the last current solution. Anyhow, computing U from the accumulated energy increments requires only one addition per iteration.

In fact, in our experiments, these differences in the computing time of the rejection probability does not seem to be the leading factor in the variations of the cpu time. The unix function "time" gave us the following figures: 66.3 seconds of user cpu time for 20000 iterations of the simulated annealing algorithm, 61.1 seconds for 20000 iterations of the IET algorithm, and 35.2 seconds for 18000 iterations of the IET algorithm combined with the partial freezing method. These figures are somewhat unexpected. Our interpretation is that all the moves do not have the same complexity. This is particularly true with the partial freezing method, where during most of the time (15000 iterations) the state space is restricted; therefore the choice of a task to schedule or to destroy and the choice of the resources to allocate are made from smaller sets and therefore are faster. To a minor degree the same happens with the IET algorithm and Simulated Annealing: the IET algorithm spends more time at low energy levels where more tasks are scheduled and where scheduling a new task is done from a smaller set of available tasks and resources.

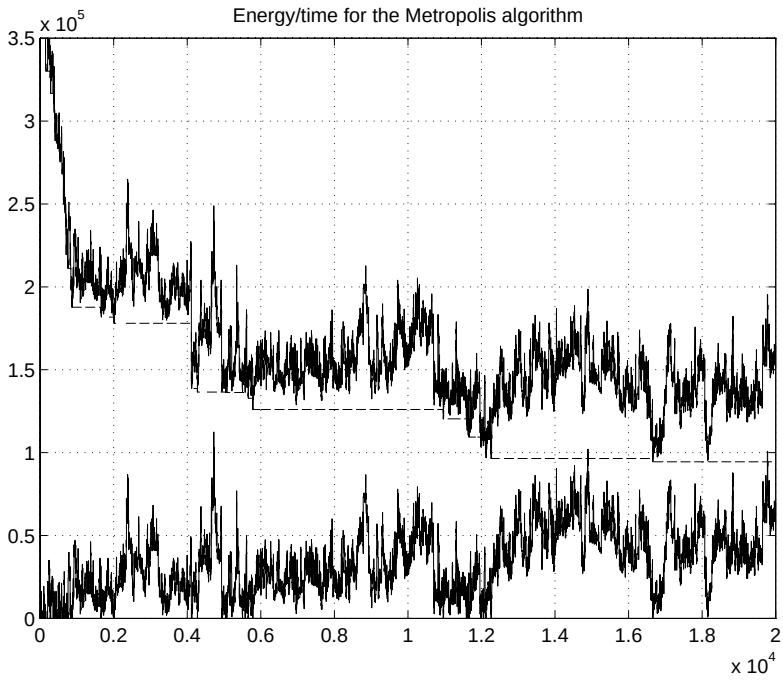

FIG. 7.18.

In conclusion, the number of iterations is not a perfect measure of complexity but has the advantage of being machine independent. To get a real cpu time complexity study, one would need to analyze dynamically the complexity of moves, which depends on the current configuration, and to gather statistics from profile files, which we have not done in the framework of this study.

8. Comparison with other energy landscapes. The most common way to enlarge the space of solutions to create a search space is to allow overlaps. In the task assignment formulation, this means that the same resource is allowed to be used by more than one task at the same time. In the jigsaw puzzle formulation, this means that we allow pieces to sit on top of each other. We will maintain the jigsaw puzzle terminology in the following discussion.

Let us discuss first the case where the aim is simply to find a complete admissible solution. We will discuss afterwards the case where a cost function has to be optimized on the set of complete solutions.

So for the moment, the energy in the overlap case will be made up of the total area of the overlaps and, in the partial solution case, will be made up of the total area of unused pieces.

We can expect the overlap approach to generate the same kind of energy barriers as ours. Indeed if the problem is "tight," meaning that there is just enough room to put all the pieces in the frame, it will be necessary, in order to move a task from one location to another distant location in the frame, to put it in an already occupied location, creating an overlap of the order of the area of the piece to be moved. In the partial solution approach, one has to remove two pieces from the frame. This means that the energy barrier will be from one to two times the energy barrier of the overlap

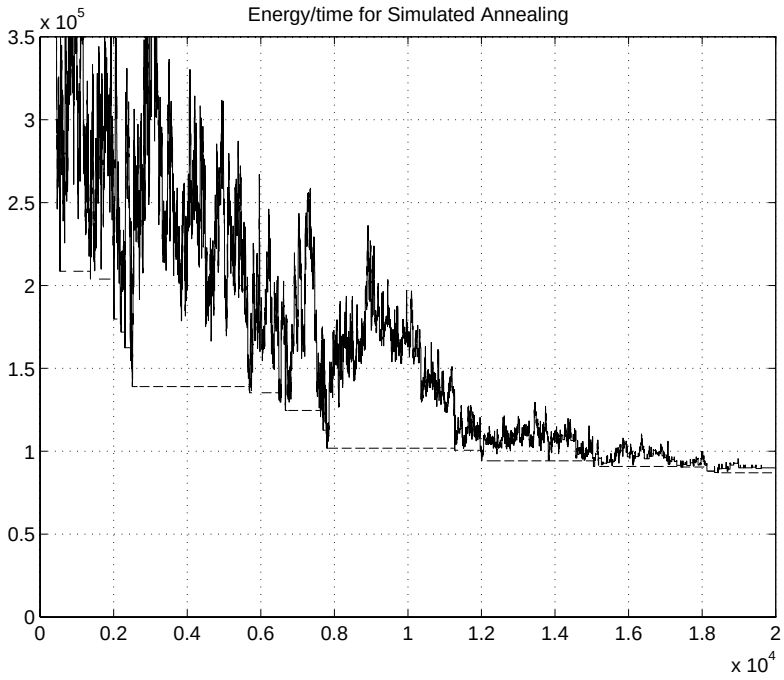

FIG. 7.19.

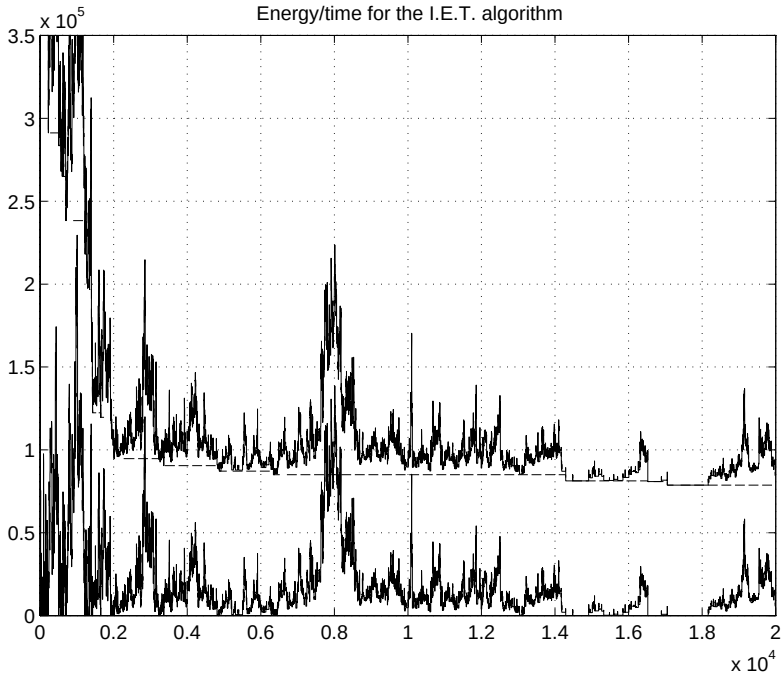

FIG. 7.20.

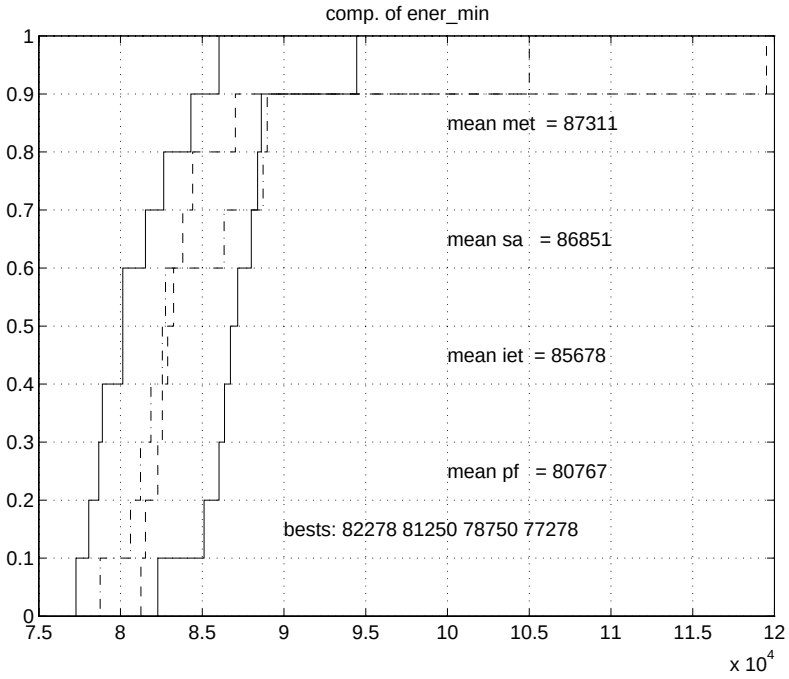

FIG. 7.21.

approach, depending on whether or not the pieces to be moved around are of equal bulk. If one has to exchange a large piece with a number of small pieces, the energy barrier will be the area of the large piece plus the largest area of the small pieces, because once the large piece is removed, the small ones can be transferred one at a time. This is what we can say about the "H" term in the difficulty. Now we have to compare it with the "U" term. For the U term, our approach is better since the energy is quantized: a local minimum solution has at least one piece out; therefore the "U" term is larger than the area of the smallest piece. On the contrary, if space is not discretized, or is finely discretized, the overlap in an imperfect solution of the overlap approach may be arbitrarily small, leading to an arbitrarily large difficulty. Thus the overlap energy cannot safely be used alone. Usually, what is done is to allow pieces to overlap not only between themselves, but also with the outside of the frame—this last kind of overlap being given a specific weight (increasing with time). This is very much like allowing partial solutions, leads to a more complicated algorithm where the balance between two energy terms has to evolve with time, and does not solve completely the problem posed by almost perfect solutions with small scattered overlaps which cannot be improved by local moves.

Let us discuss now the case where some other cost function has to be optimized on the state space of complete solutions. In the partial solution approach, it is usually quite easy to build a cost function which decreases with the number of scheduled tasks and therefore can be used alone. It will be the case, for instance, when the cost function is a sum of negative terms depending on (small) clusters of scheduled tasks. When a task is removed, some of the scheduled clusters are suppressed, the others being unchanged, and so the cost function is increased. It is not so easy and natural to build cost functions which are decreasing with the area of the overlap. Therefore

in the overlap approach an "artificial" overlap term with a big enough weight has to be added to the cost function in the definition of the energy function, creating new energy barriers and increasing the difficulty of the energy landscape.

For all these (qualitative) reasons, we think that the partial solution approach we propose here has some merits, at least in the case of "tight" problems, when it is compared with the traditional overlap approach. This would of course require confirmation by quantitative experimental comparisons.

Conclusion. We touched in this paper on three related topics with various degrees of generality. Our first aim was to bring experimental evidences comforting theoretical results about the behavior of algorithms. We wanted to show that the theory was not concerned with a "never-reached" asymptotic and led to the same qualitative ranking of performances to which an experimental benchmark would lead. Our second aim was to describe a general purpose methodology to deal with scheduling tasks. We insisted on two problems that are likely to be encountered in many situations: the creation of small gaps in the allocation of resources and the way to handle "proportionality constraints."

The third aspect of the paper was to account for experiments on a benchmark of the "jigsaw puzzle" type. Here we were confronted with the practical problem of the choice of parameters and of optimization design options (such as relaxing some of the constraints). Our conclusion on this third point is that we have acquired some know-how about the choice of parameters, which we tried to reflect in section 6, but that we have presently no systematic rule to choose them. We worked very much in a trial and error way, looking at the repartition functions we mentioned, to guide our intuition. A trial and error procedure is somehow justified by the theoretical result that many trials of moderate length are preferable to a long one. This gives us the opportunity to tune the parameters trial after trial.

Anyhow, we have to admit that the choice of parameters requires some skill, especially for the simulated annealing and IET algorithms, where there are more than one parameter to tune. What we did not find too hard to do was, starting from a given Metropolis algorithm at inverse temperature β_{Met}, to find $\beta_{\min} < \beta_{\mathrm{Met}} < \beta_{\max}$ for which simulated annealing performs better than Metropolis. Then we could get some more improvement using the IET algorithm, where again we chose the parameters in relation with those used for simulated annealing. We are not sure at all that this is the best way to tune simulated annealing or the IET algorithm, but it shows at least that the theoretical gains of one algorithm upon the previous one could be obtained in practice. Finally, in the partial freezing method the choice of parameters is easier because the algorithm runs, most of the time, on a restricted state space for which the tuning of parameters is less crucial.

Another positive result of these experiments is that it is possible to get good, if not optimal, solutions even in the case where very nonmonotonous evolutions of the energy are needed, as it is the case here, since the only way to move a piece of the puzzle is to remove it and put it somewhere else afterwards, a succession of two moves the first of which implies an energy increase.

Of course we have touched in this paper on only a limited number of questions. For instance, we leave open the practical question of the best choice of parameters for simulated annealing and for the IET algorithm, since we used only a robust "all purpose" set of parameters, namely, exponential temperature sequences in the case of simulated annealing and logarithmic energy transforms for the IET algorithm. Another question we left purposely in the dark is the choice of elementary moves.

Although it is clear that a benefit can be obtained from the use of more complex compound moves, we felt such an investigation would have been too dependent on the precise examples we chose to study. Rather we tried to lay the stress on general ideas and tools, with the hope that they could be useful in a variety of situations.

Acknowledgments. I wish to thank Professor Robert Azencott for many helpful discussions about this paper. I wish also to thank him for having involved me in the development of an algorithm for an industrial scheduling problem a few years ago. I am also pleased to acknowledge the useful comments of the referees which helped me to improve a first draft of this paper.

BOUNDARY CONTROLLABILITY OF A HYBRID SYSTEM CONSISTING IN TWO FLEXIBLE BEAMS CONNECTED BY A POINT MASS*

CARLOS CASTRO† AND ENRIQUE ZUAZUA†

Abstract. We consider a hybrid system consisting of two flexible beams connected by a point mass. The constant of rotational inertia is assumed to be nonzero. In a previous paper we have proved that, in the presence of the point mass, the system is well posed in asymmetric spaces in which solutions have one more degree of regularity to one side of the mass.

We are interested in the problem of controllability when the control acts on the free extreme of one of the beams. We prove that when the control time is large enough the system is exactly controllable in an asymmetric space. This result is sharp. The proofs combine classical techniques from asymptotic analysis and the theory of nonharmonic Fourier series.

Key words. flexible beams, point mass, asymmetric spaces, Fourier series, controllability

1. Introduction.

In this paper we study the boundary controllability of a linear system modelling the vibrations of two flexible beams connected by a point mass.

We assume that the beams occupy the intervals $(-1,0)$ and $(0,1)$ and that the point mass is located at $x=0$. By means of the scalar function $u=u(x,t)$ defined for $x\in(-1,1)$ and $t>0$, we describe the vertical displacements of the beams and the point mass. The linear equations describing the small vibrations of this system can be written as follows:

$$
\begin{cases}
\gamma\partial^2 u_{tt} - u_{tt} - \partial^4 u = 0, & \text{for } x\in(-1,0), t>0,\\
\gamma\partial^2 u_{tt} - u_{tt} - \partial^4 u = 0, & \text{for } x\in(0,1), t>0,\\
[u](0,t) = [\partial u](0,t) = 0, & \text{for } t>0,\\
M u_{tt}(0,t) + [\partial^3 u](0,t) = 0, & \text{for } t>0,\\
M\gamma_0 \partial u_{tt}(0,t) - [\partial^2 u](0,t) = 0 & \text{for } t>0,
\end{cases}
\tag{1}
$$

where ∂ denotes partial derivation with respect to x and the index t derivation with respect to time. $[u](0)=u(0^+)-u(0^-)$ denotes the jump of the function u at the point $x=0$ where the mass is located. Assuming that the beams are hinged at their extremes, system (1) has to be completed with the following boundary conditions:

$$
u(\pm 1,t) = \partial^2 u(\pm 1,t) = 0, \quad \text{for } t>0. \tag{2}
$$

In (1) the dynamic of the beams is described by the Rayleigh beam equation, where $\gamma\geq 0$ represents the constant of rotational inertia. The third equation guarantees

that u and ∂u are continuous across $x = 0$ while the last two equations describe the vibrations of the point mass at $x = 0$. M is the total mass concentrated in $x = 0$ and γ_0 is the rotational inertia at this point.

To simplify the exposition we assume $M = 1$ and $\gamma = \gamma_0$, although the analysis is valid for other values of the parameters.

It is worth noting that, in the particular case in which the constant γ of rotational inertia vanishes ($\gamma = 0$), $\partial^2 u$ is continuous across $x = 0$, also. This implies that the effect of the mass point is weaker on the behavior of the system when $\gamma = 0$ than when $\gamma > 0$. Thus the properties of system (1.1)–(1.2), when $\gamma = 0$, are much closer to the case in which the point mass is not present. We refer to [5] and [9] for precise statements and the details of the proofs.

Throughout this paper we assume that $\gamma > 0$.

System (1)–(2) has to be completed with suitable initial conditions for $u(x,t)$, $u(0,t)$, and $\partial u(0,t)$. The last two quantities will be denoted by y and z, resp., i.e.,

$$u(0,t) = y(t); \qquad \partial u(0,t) = z(t). \tag{3}$$

The initial conditions are then

$$\begin{cases} u(x,0) = u^0(x) & \text{in } (-1,0)\cup(0,1)\,; y(0) = y^0, \quad z(0) = z^0, \\ \\ u_t(x,0) = u^1(x) & \text{in } (-1,0)\cup(0,1);\ y_t(0) = y^1, \quad z_t(0) = z^1. \end{cases} \tag{4}$$

System (1)–(2) has been studied in [4] where it was proven that, with appropriate regularity and compatibility conditions, on the initial data it admits a unique solution in a suitable class. On the other hand, its energy

$$E(t) = \int_{-1}^{1} \left[\left|\partial^2 u(x,t)\right|^2 + \gamma \left|\partial u_t(x,t)\right|^2 + \left|u_t(x,t)\right|^2 \right] dx + \left|u_t(0,t)\right|^2 + \gamma \left|\partial u_t(0,t)\right|^2 \tag{5}$$

is constant along trajectories.

In this paper we assume that a control function $q = q(t)$ acts on the system through the extreme $x = 1$ on the quantity $\partial^2 u(1,t)$. Then the boundary conditions in (2) have to be replaced by

$$u(\pm 1,t) = \partial^2 u(-1,t) = 0; \quad \partial^2 u(1,t) = q(t) \quad \text{for } t > 0. \tag{6}$$

The problem of exact controllability can be formulated as follows: *Given $T > 0$, find the class H of initial conditions for which there exists a control q, say, in $L^2(0,T)$ such that the solution of* (1), (3) *with boundary conditions* (6) *is at rest at time $t = T$, i.e., it satisfies*

$$\begin{cases} u(x,T) = 0 & \textit{for } x \in (-1,0)\cup(0,1), \quad y(T) = 0, \quad z(T) = 0, \\ \\ u_t(x,T) = 0 & \textit{for } x \in (-1,0)\cup(0,1), \quad y_t(T) = 0, \quad z_t(T) = 0. \end{cases} \tag{7}$$

In this formulation of the control problem we have chosen the control to belong to $L^2(0,T)$. This is not, of course, the unique choice, but it is the one that comes more naturally when studying the problem of controllability by means of J.-L. Lions' HUM method (see [8]).

It turns out that the space H of controllable initial data cannot be found among the family of energy spaces in which system (1)–(2) is well posed. Indeed, all the energy

spaces have in common the fact that solutions in those classes have the same regularity on both sides of the point mass. For instance, the energy E in (5) corresponds to solutions u in H^2 to both sides of $x = 0$ and such that u_t belongs to $H^1(-1,1)$. However, the space of controllable data turns out to be asymmetric in the sense that its elements have one more degree of regularity to the left of $x = 0$.

The same phenomena was observed in [6] in the case of two flexible strings connected by a point mass. In [6] this was proved by using the explicit formula for solutions of the one-dimensional wave equation in terms of its initial data, and it was seen that this is a consequence of the fact that solutions gain one derivative when crossing the mass. In [6] it was also observed that the spectral gap of the wave equation vanishes in the presence of a point mass, and it was conjectured these two facts (i.e., the asymmetry of the controllable space and the lack of the spectral gap) to be closely related. Later on, in [3] it was proved that these two properties are equivalent (see also [1]).

For the fourth order system that we are considering here it has been observed that, in the presence of the point mass, the spectral gap vanishes, also (see [4]). Using Fourier developments of solutions, it is also proved in [4] that system (1)–(2) is well posed in asymmetric spaces in which the solutions have one more degree of regularity to one side of $x = 0$. This result applies only when $\gamma > 0$ since, as we said above, when $\gamma = 0$ the presence of the mass has a much weaker effect on the behavior of the system. In this case ($\gamma = 0$), system (1)–(2) is not well posed in asymmetric spaces of this kind.

Thanks to the existence of the asymmetric spaces in which system (1)–(2) is well posed and by means of the theory of nonharmonic Fourier series, and more precisely, of some results by D. Ulrich [10], we prove sharp observability results. These results establish the equivalence between a suitable asymmetric norm of the initial data and the quantity $\int_0^T |\partial u(1,t)|^2\, dt$ which measures the amount of energy concentrated at $x = 1$ during the time interval $t \in (0,T)$. This result requires the time T to be sufficiently large and, more precisely, $T \geq 4\sqrt{\gamma}$. This is due to the finite speed of propagation underlying in system (1) when $\gamma > 0$, and therefore it is a natural restriction to the observability to hold.

By means of HUM and as a direct consequence of this observability result, we prove the exact controllability of the system. We show, roughly, that when $\gamma > 0$ the space of controllable data coincides with the subspace of $H^2(-1,1) \times H^1(-1,1)$ of those elements that, restricted to $(-1,0)$, have one more degree of regularity, i.e., belong to $H^3(-1,0) \times H^2(-1,0)$.

It is worth mentioning that, in the absence of mass, the space of controllable data coincides with $H^2(-1,1) \times H^1(-1,1)$ (see [7]). Thus, as in the context of flexible strings with a point mass (see [6]), the presence of the point mass reduces the space of controllable data by one derivative on the opposite side of the mass with respect to the extreme in which the control is located.

The rest of the paper is organized as follows. In section 2 we recall without proofs some basic analytical results of the uncontrolled system (1)–(2) given in [4]. In particular we state the well posedness of the system in asymmetric spaces using Fourier series. In section 3 we prove suitable observability properties. In section 4 we solve system (1) with nonhomogeneous boundary conditions to give sense to the solutions of the controlled problem, where we have to consider the boundary condition (6). Finally, in section 5 we obtain the main controllability results.

2. Preliminary results. In this section, we set some analytical properties of the solutions of system (1) which will be used along this work. The proofs of the results can be seen in [4].

2.1. Spectral analysis. When decomposing solutions of (1)–(2) in Fourier series, one is led to consider solutions in separated variables $u = e^{i\lambda t}\varphi(x)$. In this class of solutions, system (1.1)–(1.2) becomes

$$\begin{cases} \partial^4\varphi = \lambda^2\varphi - \gamma\lambda^2\partial^2\varphi\,, & \text{for } x \in (-1,0),\\ \partial^4\varphi = \lambda^2\varphi - \gamma\lambda^2\partial^2\varphi\,, & \text{for } x \in (0,1),\\ [\varphi](0) = [\partial\varphi](0) = 0,\\ [\partial^2\varphi](0) = -\gamma\lambda^2\partial\varphi(0),\\ [\partial^3\varphi](0) = \lambda^2\varphi(0),\\ \varphi(\pm1) = \partial^2\varphi(\pm1) = 0. \end{cases} \tag{8}$$

We introduce the operator $(I-\gamma\partial^2)^{-1} : L^2(-1,1) \to H^2 \cap H_0^1(-1,1)$ such that $u = (I-\gamma\partial^2)^{-1}F$ if and only if $u \in H^2 \cap H_0^1(-1,1)$ and satisfies $u - \gamma\partial^2 u = F$.

If we define the vector valued eigenfunction $\phi = (\varphi, \varphi(0), \partial\varphi(0))$, system (8) can be written as

$$\begin{cases} K\phi = \lambda^2\phi,\\ \partial^2\varphi(\pm1) = 0, \end{cases} \tag{9}$$

where K is the linear operator given by

$$K = \begin{pmatrix} (I-\gamma\partial^2)^{-1}\partial^4_{(-1,1)/\{0\}} & 0 & 0\\ \partial^3_+ - \partial^3_- & 0 & 0\\ -\frac{1}{\gamma}\left(\partial^2_+ - \partial^2_-\right) & 0 & 0 \end{pmatrix}.$$

Here $\partial^4_{(-1,1)/\{0\}}$ represents the operator which assigns to each function, not necessarily continuous in $x = 0$, the fourth order derivative to both sides of $x = 0$, and $\partial^k_\pm$ represents the distribution which assigns to a function u the value $\partial^k u(0^\pm)$.

The following result is proved in [4].

PROPOSITION 2.1. *The eigenvalues $\{\lambda_k\}_{k\in\mathbb{N}}$ of system (9) are simple and constitute a sequence of positive real numbers:*

$$0 < \lambda_1 < \lambda_2 < \cdots < \lambda_k < \cdots \to \infty.$$

Moreover, the corresponding eigenfunctions $\{\phi_k\}_{k\in}\,\mathbb{N}$ may be normalized to form an orthonormal basis of the space

$$H = \left\{\phi = (\varphi, \varphi(0), \partial\varphi(0)) \in H^2 \cap H_0^1(-1,1) \times \mathbb{R} \times \mathbb{R}\right\}$$

with the norm

$$\|\phi\|_H = \left[\int_{-1}^{1} |\partial^2\varphi|^2 dx\right]^{1/2}.$$

REMARK 1. *All the results of the above proposition except the simplicity of the eigenvalues can be proved using classical theory on compact self-adjoint operators. The simplicity of the eigenvalues requires a detailed analysis of the system under consideration.*

From Proposition 2.1, the space H can also be written as follows:

$$H = \left\{ u : u = \sum_{k\in\mathbb{N}} a_k \phi_k, \| u \|_H^2 = \sum_{k\in\mathbb{N}} | a_k |^2 < \infty \right\}. \tag{10}$$

We can also define the following fractional Hilbert spaces $(H_\alpha, \| \cdot \|_\alpha)_{\alpha\in\mathbb{R}}$:

$$H_\alpha = \left\{ u = \sum_{k\in\mathbb{N}} a_k \phi_k : \| u \|_\alpha^2 = \sum_{k\in\mathbb{N}} | a_k |^2 \lambda_k^{4\alpha} < \infty \right\}. \tag{11}$$

We will denote by $< \cdot, \cdot >_\alpha$ the scalar product in H_α.

Clearly $H_0 = H$ and $\| \cdot \|_H = \| \cdot \|_0$.

Observe that, if $u = \sum_{k\in\mathbb{N}} a_k \phi_k$, then $Ku = \sum_{k\in\mathbb{N}} \frac{a_k}{\lambda_k^2} \phi_k$. Clearly K is an isomorphism from H_α into $H_{\alpha+1}$. We can also write explicitly K^{-1}:

$$K^{-1} u = \sum_{k\in\mathbb{N}} \lambda_k^2 a_k \phi_k$$

which is continuous from $H_{\alpha+1}$ into H_α.

We need to identify the spaces H_α for some values of the parameter $\alpha \in \mathbb{R}$. To do that, we denote by $H^s((-1,1)\setminus\{0\}) \cap H^2 \cap H_0^1(-1,1)$ the subspace of $H^2 \cap H_0^1(-1,1)$ constituted by the elements such that its restrictions to $(-1,0)$ and $(0,1)$ belong to H^s.

We have the following characterizations of the fractional spaces H_α.

PROPOSITION 2.2. (a) $H_{1/2}$ *coincides algebraically and topologically with the subspace of*

$$H^3((-1,1)\setminus\{0\}) \cap H^2 \cap H_0^1(-1,1) \times \mathbb{R} \times \mathbb{R}$$

constituted by the elements (u, y, z) *such that*

$$\partial^2 u(\pm 1) = 0, \quad u(0) = y, \quad \partial u(0) = z. \tag{12}$$

(b) $H_{-1/2}$ *coincides with the subspace of* $H_0^1(-1,1) \times \mathbb{R} \times \mathbb{R}$ *constituted by the elements* (u, y, z) *such that* $u(0) = y$.

Moreover,

$$\| (u, y, z) \|_{-1/2}^2 = \int_{-1}^{1} \left[\gamma | \partial u |^2 + | u |^2 \right] dx + | y |^2 + \gamma | z |^2. \tag{13}$$

(c) H_{-1} *coincides algebraically and topologically with the quotient space of* $L^2(-1,1) \times \mathbb{R} \times \mathbb{R}$ *constituted by the classes* (u, y, z) *characterized in the following way: Two elements* (u^1, y^1, z^1) *and* (u^2, y^2, z^2) *belong to the same class if and only if*

$$(u^1 - u^2, y^1 - y^2, z^1 - z^2) = \alpha(m, -1, 0) + \beta(n, 0, \gamma^{-1}),$$

where $\alpha, \beta \in \mathbb{R}$, *and* m *and* n *are the functions*

$$m(x) = \begin{cases} \frac{\sinh(\frac{1+x}{\sqrt{\gamma}})}{2\sqrt{\gamma}\cosh(\frac{1}{\sqrt{\gamma}})} & \text{if } x \in [-1,0], \\ \frac{\sinh(\frac{1-x}{\sqrt{\gamma}})}{2\sqrt{\gamma}\cosh(\frac{1}{\sqrt{\gamma}})} & \text{if } x \in [0,1], \end{cases} \qquad n(x) = \begin{cases} \frac{\sinh(\frac{1+x}{\sqrt{\gamma}})}{2\gamma\sinh(\frac{1}{\sqrt{\gamma}})} & \text{if } x \in [-1,0], \\ \frac{-\sinh(\frac{1-x}{\sqrt{\gamma}})}{2\gamma\sinh(\frac{1}{\sqrt{\gamma}})} & \text{if } x \in [0,1]. \end{cases}$$

(14)

(d) $H_{-3/2}$ *coincides with the quotient space of* $H^{-1}(-1,1) \times \mathbb{R} \times \mathbb{R}$ *constituted by the classes* (u,y,z) *characterized in the following way: Two elements* (u^1,y^1,z^1) *and* (u^2,y^2,z^2) *belong to the same class if and only if*

$$(u^1-u^2, y^1-y^2, z^1-z^2) = \alpha(m,-1,0) + \beta(n,0,\gamma^{-1}),$$

where $\alpha, \beta \in \mathbb{R}$, *and* m *and* n *are the functions given in* (14).

Let us recall now how solutions of (1)–(2) can be developed in Fourier series.

Consider the energy space $\mathcal{H} = H_0 \times H_{-1/2}$ and define $\bar{\phi}_k = (\phi_k, i\lambda_k\phi_k)$ where $\lambda_{-k} = -\lambda_k$ and $\phi_{-k} = \phi_k$. The set $(\bar{\phi}_k)_{k\in\mathbb{Z}}$ constitutes an orthonormal basis in $\mathcal{H}$. Then, for any initial data $((u^0,y^0,z^0),(u^1,y^1,z^1)) \in \mathcal{H}$ we can find a sequence of coefficients (a_k) such that

$$((u^0,y^0,z^0),(u^1,y^1,z^1)) = \sum_{k\in\mathbb{Z}} a_k\bar{\phi}_k,$$

and the vector valued solution $U = ((u,y,z),(u_t,y_t,z_t))$ of (1), (2), (3), and (4) is given by

$$U(t) = \sum_{k\in\mathbb{Z}} a_k e^{i\lambda_k t}\bar{\phi}_k. \tag{15}$$

The conservation of the energy E in (5) is equivalent to the fact that system (1)–(2) generates a group of isometries in $\mathcal{H}$. More precisely,

$$E(t) = \| U(t) \|^2_{\mathcal{H}} = \sum_{k\in\mathbb{Z}} \left| a_k e^{i\lambda_k t}\bar{\phi}_k \right|^2 = \sum_{k\in\mathbb{Z}} | a_k |^2 = \| U(0) \|^2_{\mathcal{H}} = E(0). \tag{16}$$

Obviously, one can also obtain developments in Fourier series of the form (15) for solutions of (1)–(2) in other classes $\mathcal{H}_\alpha = H_\alpha \times H_{\alpha-1/2}$.

2.2. Asymptotics of the spectrum. In this section we recall the main results concerning the asymptotic behavior of the eigenvalues and eigenfunctions of (9) that we will need later to prove the observability inequalities.

PROPOSITION 2.3. *We have*

$$\lambda_{2k-1} = \frac{k\pi - \pi/2}{\sqrt{\gamma}} - \frac{c_1(\gamma)}{\sqrt{\gamma}\,(k\pi-\pi/2)} + O(k^{-2}), \ \text{as } k \to \infty, \tag{17}$$

$$\lambda_{2k} = \frac{k\pi - \pi/2}{\sqrt{\gamma}} - \frac{c_2(\gamma)}{\sqrt{\gamma}\,(k\pi-\pi/2)} + O(k^{-2}), \ \text{as } k \to \infty, \tag{18}$$

where $c_1(\gamma) = \left(2\gamma + \sqrt{\gamma}\tanh\left(\gamma^{-1/2}\right)\right)^{-1} + (2\gamma)^{-1}$ *and* $c_2(\gamma) = \gamma^{-1/2}\coth\gamma^{-1/2} - 2 + (2\gamma)^{-1}$.

Moreover,

$$\lambda_{2k} - \lambda_{2k-1} = \frac{C(\gamma)}{(k\pi-\pi/2)\,\gamma^{1/2}} + O(k^{-2}), \ \text{as } k \to \infty, \tag{19}$$

where $C(\gamma) = c_1(\gamma) - c_2(\gamma) > 0$, *for all* $\gamma > 0$.

REMARK 2. *In the absence of mass the asymptotic behavior of eigenvalues is as follows:*

$$\lambda_k = \frac{k\pi}{2\sqrt{\gamma}} + O(k^{-2}), \text{ as } k \to \infty.$$

This shows that the first term of the asymptotic expansion of λ_{2k} *is affected by the presence of the mass but not the first term of the asymptotic expansion of* λ_{2k-1}.

In view of (19) *the asymptotic gap* $\lambda_{2k} - \lambda_{2k-1}$ *decays like* $1/k$ *as* $k \to \infty$ *in the presence of the mass. Note, however, that in the absence of the mass the eigenvalues are uniformly separated and the gap is of the order of* $\pi/(2\sqrt{\gamma})$ *for all* k.

Concerning the eigenfunctions we have the following.

PROPOSITION 2.4. *The eigenfunctions of* (9) *normalized in* $H^2 \cap H_0^1(-1,1)$ *are*

$$\varphi_{2k-1}(x) = \frac{\rho_{2k-1}}{(\mu^+_{2k-1})^2}\left[\sin\left(\mu^+_{2k-1}(1-|x|)\right) - \frac{\mu^+_{2k-1}\cos\mu^+_{2k-1}}{\mu^-_{2k-1}\cosh\mu^-_{2k-1}}\sinh\left(\mu^-_{2k-1}(1-|x|)\right)\right], \tag{20}$$

$$\varphi_{2k}(x) = -\frac{\rho_{2k}}{(\mu^+_{2k})^2}\left[\sin\left(\mu^+_{2k}\left(\frac{x}{|x|}-x\right)\right) - \frac{\sin\mu^+_{2k}}{\sinh\mu^-_{2k}}\sinh\left(\mu^-_{2k}\left(\frac{x}{|x|}-x\right)\right)\right], \tag{21}$$

where $\rho_k = 1 + \mathcal{O}(k^{-1})$ *and*

$$\mu^+_k = \lambda_k\sqrt{\gamma}\sqrt{\frac{1}{2}+\frac{1}{2}\sqrt{1+\frac{4}{\gamma^2\lambda_k^2}}}, \quad \mu^-_k = \frac{1}{\sqrt{\gamma}\sqrt{\frac{1}{2}+\frac{1}{2}\sqrt{1+\frac{4}{\gamma^2\lambda_k^2}}}}. \tag{22}$$

Moreover, $\partial\varphi_k(1) \neq 0$.

REMARK 3. *We observe that the eigenfunctions* φ_{2k-1} *are even while* φ_{2k} *are odd. This fact is due to the symmetry of the problem with respect to* $x = 0$. *On the other hand, as the mass only affects the first term in the asymptotic expansion of the eigenvalues corresponding to odd eigenfunctions, these are the only eigenfunctions which are affected in a significant way by the point mass.*

2.3. Asymmetric spaces. In this section we are going to introduce and characterize some asymmetric spaces. It is easy to see that these spaces are stable under the flow generated by system (1)–(2), and they are natural spaces to solve the boundary control problem.

With the notations of section 2.1 we set

$$Y_\alpha = \left\{ U = \sum_{k\in\mathbb{Z}\setminus\{0\}} a_k\bar{\phi}_k \in H \ : \right.$$

$$\left. \| U \|^2_{Y_\alpha} = \sum_{k\in\mathbb{Z}\setminus\{0\}} \left(\frac{|\, a_{2k-\sigma_k}\,|^2}{\delta_k^{4\alpha}} + \frac{|\, a_{2k} - a_{2k-\sigma_k}\,|^2}{\delta_k^{4\alpha+2}} \right) < \infty \right\}, \tag{23}$$

where $\delta_k = \lambda_{2k} - \lambda_{2k-\sigma_k}$, $\sigma_k = \operatorname{sgn} k$, i.e., $\sigma_k = 1$ if $k > 0$ and $\sigma_k = -1$ if $k < 0$.

Clearly Y_α endowed with the norm $\|\cdot\|_{Y_\alpha}$ is a Hilbert space. On the other hand, it is clear that if all the δ_k were uniformly positive and bounded above, then Y_α would coincide algebraically and topologically with one of the energy spaces $\mathcal{H}_\alpha$.

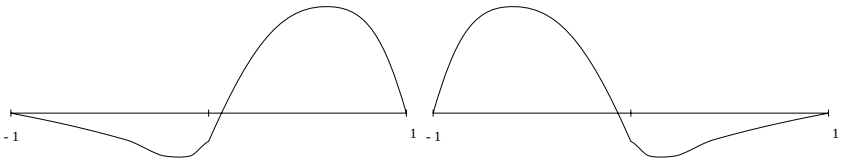

FIG. 1. $(\varphi_1 - \varphi_2)/2$ *and* $(\varphi_1 + \varphi_2)/2$.

Since, in view of Proposition 2.3, $\delta_k = \mathcal{O}(k^{-1}) = \mathcal{O}(\lambda_k^{-1}) \to 0$ as $k \to \infty$, we deduce that Y_α is a strict subspace of $\mathcal{H}_\alpha$.

We have the following result.

PROPOSITION 2.5. *Let* $U^0 = \big((u^0, y^0, z^0), (u^1, y^1, z^1)\big)$ *be an element of* Y_α. *Then, the solution* $U(t) = ((u(t), y(t), z(t)), (u_t(t), y_t(t), z_t(t)))$ *of* (1)–(2) *with initial data* U^0 *belongs to* Y_α *for every* $t > 0$ *and* $\alpha \in \mathbb{R}$. *Furthermore, for any* $T > 0$ *there exists a constant* $C(T) > 0$ *such that*

$$\| U(t) \|_{Y_\alpha} \leq C(T) \| U^0 \|_{Y_\alpha}, \quad \forall\ 0 \leq t \leq T, \quad \forall\ U^0 \in Y_\alpha. \tag{24}$$

The following theorem provides a precise characterization of the spaces Y_0 and Y_{-1}.

THEOREM 2.6. (a) Y_0 *is the subspace of elements* $U^0 = \big((u^0, y^0, z^0), (u^1, y^1, z^1)\big)$ *of* $\mathcal{H}$ *such that the restriction of* (u^0, u^1) *to* $(0,1)$ *belongs to* $H^3(0,1) \times H^2(0,1)$ *and, in addition to the compatibility conditions of* $\mathcal{H}$ $\big(u^0(0) = y^0, \partial u^0(0) = z^0, u^1(0) = y^1\big)$, *the following hold:*

$$\partial u^1(0^+) = z^1, \qquad \partial^2 u^0(1) = 0. \tag{25}$$

Furthermore, the norm $\| \cdot \|_{Y_0}$ *is equivalent to*

$$\Big[\| U \|_{\mathcal{H}}^2 + \big\| \big(u^0 \mid_{(0,1)}, u^1 \mid_{(0,1)}\big) \big\|_{H^3 \times H^2(0,1)}^2 \Big]^{1/2}.$$

(b) Y_{-1} *is the subspace of elements* $U^0 = \big((u^0, y^0, z^0), (u^1, y^1, z^1)\big)$ *of* $\mathcal{H}_{-1}$ *such that the restriction of* (u^0, u^1) *to* $(0,1)$ *belongs to* $H^1(0,1) \times L^2(0,1)$ *and verify*

$$u^0(0^+) = y^1, \qquad u^0(1) = 0. \tag{26}$$

REMARK 4. *The spaces* Y_α *are asymmetric in the sense that their elements have one more degree of regularity to the left of* $x = 0$.

The characterization of Y_α *as asymmetric spaces can be explained as follows: The vectors* $p_k = \delta_k^{2\alpha}(\bar{\phi}_{2k-1} + \bar{\phi}_{2k})/2$, $q_k = \delta_k^{2\alpha+1}(\bar{\phi}_{2k-1} - \bar{\phi}_{2k})/2$ *constitute a Riesz basis of* Y_α. *We observe that* p_k *and* q_k *are constituted by the functions* $(\varphi_{2k-1} + \varphi_{2k})/2$, $(\varphi_{2k-1} - \varphi_{2k})/2$ *weighted differently. As it can be seen in Figure* 1 *for* $k = 1$, *due to the presence of the mass, the profiles of* $(\varphi_{2k-1} + \varphi_{2k})/2$ *and* $(\varphi_{2k-1} - \varphi_{2k})/2$ *are essentially one reflection of the other with respect to* $x = 0$.

This explains the asymmetric structure of Y_α.

3. Observability. As we mentioned in the introduction, using HUM [8], the controllability of system (1) with controls of the form (6) can be reduced to the obtention of suitable observability estimates for the system in the absence of control:

$$
\left\{
\begin{array}{ll}
\gamma\partial^2 u_{tt} - u_{tt} - \partial^4 u = 0, & \text{for } x \in (-1,0),\ 0<t<T \\
\gamma\partial^2 u_{tt} - u_{tt} - \partial^4 u = 0, & \text{for } x \in (0,1),\ 0<t<T \\
[u](0,t) = [\partial u](0,t) = 0, & \text{for } 0<t<T \\
u_{tt}(0,t) + \left[\partial^3 u\right](0,t) = 0, & \text{for } 0<t<T \\
\gamma\partial u_{tt}(0,t) - \left[\partial^2 u\right](0,t) = 0, & \text{for } 0<t<T \\
u(\pm 1,t) = \partial^2 u(\pm 1,t) = 0, & \text{for } 0<t<T \\
(u(x,0), u(0,0), \partial u(0,0)) = (u^0, y^0, z^0), & \\
(u_t(x,0), u_t(0,0), \partial u_t(0,0)) = (u^1, y^1, z^1). &
\end{array}
\right. \tag{27}
$$

As in previous sections, we identify the solution u of (1) with the vector valued unknown U. The following holds.

LEMMA 3.1. *For any $T>0$, there exists $C(T)>0$ such that*

$$
\int_0^T |\partial u(1,t)|^2\, dt \le C \parallel U^0 \parallel^2_{Y_{-1}},\ \forall\ U^0 \in Y_{-1}. \tag{28}
$$

Moreover, if $T \ge 4\sqrt{\gamma}$, there exists $C(T)>0$ such that

$$
\parallel U^0 \parallel^2_{Y_{-1}} \le C \int_0^T |\partial u(1,t)|^2\, dt,\ \forall\ U^0 \in Y_{-1}. \tag{29}
$$

REMARK 5. *The first estimate* (28) *of this lemma establishes a hidden regularity result since, in view of Proposition* 2.5 *and Theorem* 2.6, *the fact that $U^0 \in Y_{-1}$ implies $u\big|_{(0,1)} \in C\big([0,T]; H^1(0,1)\big) \cap C^1\big([0,T]; L^2(0,1)\big)$, but this is not sufficient to guarantee that $\partial u(1,t) \in L^2(0,T)$.*

The second estimate (29) *of the lemma guarantees that the norm of the initial data in Y_{-1} can be observed continuously in terms of the $L^2(0,T)$-norm of $\partial u(1,t)$. In view of Proposition* 2.5 *this implies that the norm of the solution U in $C([0,T], Y_{-1})$ can be observed, also. Due to the finite speed of propagation of the system, the time required for the uniform observability* (29) *has to be large enough. The lower bound $4\sqrt{\gamma}$ is sharp.*

In order to prove Lemma 3.1, we need the following result on nonharmonic Fourier series due to Ulrich [10].

THEOREM 3.2. *Let $(\sigma_n)_{n\in\mathbb{Z}}$ and $(\tau_n)_{n\in\mathbb{Z}}$ be two sequences of distinct complex numbers such that $\sigma_n \ne \tau_n$ for all $n \in \mathbb{Z}$ and*

$$
\lim_{|n|\to\infty} |\sigma_n - n| = \lim_{|n|\to\infty} |\tau_n - n| = 0. \tag{30}
$$

Then $\left\{e^{i\sigma_n t}\right\}_{n\in\mathbb{Z}}$ forms a Riesz basis of $L^2(0,2\pi)$ and moreover,

$$
\left\{e^{i\sigma_n t}\right\}_{n\in\mathbb{Z}} \cup \left\{\frac{e^{i\sigma_n t} - e^{i\tau_n t}}{\sigma_n - \tau_n}\right\}_{n\in\mathbb{Z}} \tag{31}
$$

forms a Riesz basis of $L^2(0,4\pi)$.

REMARK 6. *We refer to* [3] *and* [1] *for a generalization of this result.*

As an immediate consequence of this result the following holds.

COROLLARY 3.3. *Let $\gamma > 0$. Then, if $\{\lambda_k^2\}_{k\in\mathbb{Z}}$ denote the eigenvalues of system* (27)*,*

$$\{e^{i\lambda_{2k}t}\}_{k\in\mathbb{Z}} \cup \left\{\frac{e^{i\lambda_{2k}t} - e^{i\lambda_{2k-\sigma_k}t}}{\lambda_{2k} - \lambda_{2k-\sigma_k}}\right\}_{k\in\mathbb{Z}} \tag{32}$$

form a Riesz basis of $L^2\left(0, 4\sqrt{\gamma}\right)$.

Proof. We introduce the change of variables $s = t\pi/\sqrt{\gamma}$ that transforms the functions in (32) into

$$e^{-is/2}\left\{e^{i\left(\lambda_{2k}\sqrt{\gamma}/\pi+1/2\right)s}\right\}_{k\in\mathbb{Z}} \cup e^{-is/2}\left\{\frac{e^{i\left(\lambda_{2k}\sqrt{\gamma}/\pi+1/2\right)s} - e^{i\left(\lambda_{2k-\sigma_k}\sqrt{\gamma}/\pi+1/2\right)s}}{\delta_k}\right\}_{k\in\mathbb{Z}},$$

and the interval $t \in \left(0, 4\sqrt{\gamma}\right)$ into $s \in (0, 4\pi)$. Obviously the common multiplicative factor $e^{-is/2}$ does not affect whether or not these functions constitute a Riesz basis of $L^2(0, 4\pi)$.

By setting

$$\tau_k = \lambda_{2k}\frac{\sqrt{\gamma}}{\pi} + \frac{1}{2}, \qquad \sigma_k = \lambda_{2k-\sigma_k}\frac{\sqrt{\gamma}}{\pi} + \frac{1}{2},$$

we are in the conditions of Theorem 3.2 in view of the asymptotic form of the eigenvalues proved in Propositions 2.3.

Undoing the change of variables, we deduce that Corollary 3.3 holds. □

The following characterization of Riesz basis (which can be seen in Young [11]) will also be used.

THEOREM 3.4. *Let H be a separable Hilbert space. The following two properties are equivalent:*

(a) *$\{e_n\}_{n\in\mathbb{Z}}$ forms a Riesz basis of H;*

(b) *$\{e_n\}_{n\in\mathbb{Z}}$ is a complete sequence in H and there exists two positive constants $A, B > 0$ such that*

$$A\sum_{i=1}^{n} |\, c_i \,|^2 \leq \left\|\sum_{i=1}^{n} c_i e_i\right\|_H^2 \leq B\sum_{i=1}^{n} |\, c_i \,|^2$$

for any $n \in \mathbb{N}$ and $c_i, i = 1, \cdots, n$.

We are now ready to prove Lemma 3.1.

Proof of Lemma 3.1. Recall that the solution u of (27) can be written as

$$(u, u(0), \partial u(0)) = \sum_{k\in\mathbb{Z}\setminus\{0\}} a_k e^{i\lambda_k t}\phi_k(x),$$

where $\phi_k = (\varphi_k, \varphi_k(0), \partial\varphi_k(0))$ are the eigenfunctions of the eigenvalue problem (8) with φ_k normalized in $H^2 \cap H_0^1(-1, 1)$ such that $(-1)^k\partial\varphi_k(1) > 0$.

The eigenfunctions are of the form

$$\varphi_{2k-\sigma_k}(x) = \frac{\rho_{2k-\sigma_k}}{\left(\mu^+_{2k-\sigma_k}\right)^2}\left[\sin\left(\mu^+_{2k-\sigma_k}(1-x)\right) - \frac{\mu^+_{2k-\sigma_k}\cos\mu^+_{2k-\sigma_k}}{\mu^-_{2k-\sigma_k}\cosh\mu^-_{2k-\sigma_k}}\sinh\left(\mu^-_{2k-\sigma_k}(1-x)\right)\right],$$

$$\varphi_{2k}(x) = -\frac{\rho_{2k}}{\left(\mu^+_{2k}\right)^2}\left[\sin\left(\mu^+_{2k}(1-x)\right) - \frac{\sin\left(\mu^+_{2k}\right)}{\sinh\left(\mu^-_{2k}\right)}\sinh\left(\mu^-_{2k}(1-x)\right)\right]$$

in the interval $(0, 1)$.

We introduce the following change in the Fourier coefficients of the solutions: $\widetilde{a}_k = a_k \lambda_k \, |\partial\varphi_k(1)|$. Then,

$$u(x,t) = \sum_{k\in\mathbb{Z}\setminus\{0\}} \frac{\widetilde{a}_k}{\lambda_k \mid \partial\varphi_k(1) \mid} e^{i\lambda_k t}\varphi_k(x).$$

Observe that $\{a_k\} \in \ell^2$ if and only if $\{\widetilde{a}_k\} \in \ell^2$. For that it is sufficient to see that there exist positive constants $A, B > 0$ such that $A \leq \mid \lambda_k \mid\mid \partial\varphi_k(1) \mid \leq B$ for all k. To do that, we observe that

$$|\lambda_{2k-\sigma_k}\partial\varphi_{2k-\sigma_k}(1)| = \frac{\lambda_{2k-\sigma_k}\rho_{2k-\sigma_k}}{\left(\mu^+_{2k-\sigma_k}\right)^2}\left(\mu^+_{2k-\sigma_k} - \mu^+_{2k-\sigma_k}\frac{\cos\mu^+_{2k-\sigma_k}}{\cosh\mu^-_{2k-\sigma_k}}\right)$$

$$= \frac{1}{\sqrt{\gamma}} + O(k^{-1}), \tag{33}$$

$$|\lambda_{2k}\partial\varphi_{2k}(1)| = \frac{\lambda_{2k}\rho_{2k}}{\left(\mu^+_{2k}\right)^2}\left(\mu^+_{2k} - \frac{\sin\left(\mu^+_{2k}\right)\mu^-_{2k}}{\sinh\left(\mu^-_{2k}\right)}\right) = \frac{1}{\sqrt{\gamma}} + O(k^{-1}) \tag{34}$$

in view of (22) and the asymptotic results of section 2.2. Thus $\mid \lambda_k\partial\varphi_k(1) \mid \to 1/\sqrt{\gamma}$ as $\mid k \mid \to \infty$ and, on the other hand, $\mid \lambda_k\partial\varphi_k(1) \mid \neq 0$ for all $k \neq 0$. Therefore constants $A, B > 0$ exist.

Consequently

$$A \sum_{k\in\mathbb{Z}\setminus\{0\}} \mid a_k \mid^2 \leq \sum_{k\in\mathbb{Z}\setminus\{0\}} \mid \widetilde{a}_k \mid^2 \leq B \sum_{k\in\mathbb{Z}\setminus\{0\}} \mid a_k \mid^2. \tag{35}$$

On the other hand, the norm in the asymmetric space Y_{-1} can also be written in an equivalent form in terms of the coefficients $\widetilde{a}_k$. Indeed,

$$\begin{aligned} &A^2\left(\sum_{k\in\mathbb{Z}\setminus\{0\}} \delta_k^4 \, |a_{2k-\sigma_k}|^2 + \sum_{k\in\mathbb{Z}\setminus\{0\}} \delta_k^2 \mid a_{2k} - a_{2k-\sigma_k} \mid^2\right) \\ &\quad\leq \sum_{k\in\mathbb{Z}\setminus\{0\}} \delta_k^4 \, |\widetilde{a}_{2k-\sigma_k}|^2 + \sum_{k\in\mathbb{Z}\setminus\{0\}} \delta_k^2 \mid \widetilde{a}_{2k} - \widetilde{a}_{2k-\sigma_k} \mid^2 \\ &\quad\leq B^2\left(\sum_{k\in\mathbb{Z}\setminus\{0\}} \delta_k^4 \mid a_{2k-\sigma_k} \mid^2 + \sum_{k\in\mathbb{Z}\setminus\{0\}} \delta_k^2 \mid a_{2k} - a_{2k-\sigma_k} \mid^2\right). \end{aligned} \tag{36}$$

We start with the second inequality:

$$\begin{aligned} &\sum_{k\in\mathbb{Z}\setminus\{0\}} \delta_k^2 \mid \widetilde{a}_{2k} - \widetilde{a}_{2k-\sigma_k} \mid^2 \\ &\quad= \sum_{k\in\mathbb{Z}\setminus\{0\}} \delta_k^2 \mid a_{2k}\lambda_{2k} \mid \partial\varphi_{2k}(1) \mid - a_{2k-\sigma_k}\lambda_{2k-\sigma_k} \mid \partial\varphi_{2k-\sigma_k}(1) \mid\mid^2 \\ &\quad\leq 4 \sum_{k\in\mathbb{Z}\setminus\{0\}} \left[\mid a_{2k} \mid^2 \delta_k^4 \left|\frac{\lambda_{2k} \mid \partial\varphi_{2k}(1) \mid -1/\sqrt{\gamma}}{\delta_k}\right|^2\right. \\ &\quad\left. + \mid a_{2k-\sigma_k} \mid^2 \delta_k^4 \left|\frac{\lambda_{2k-\sigma_k} \mid \partial\phi_{2k-\sigma_k}(1) \mid -1/\sqrt{\gamma}}{\delta_k}\right|^2\right] \end{aligned}$$

$$
\begin{aligned}
&+\frac{2}{\gamma}\sum_{k\in\mathbb{Z}\setminus\{0\}}\delta_k^2|\ a_{2k}-a_{2k-\sigma_k}\ |^2\\
&\le C\left\{\sum_{k\in\mathbb{Z}}\delta_k^4\,|a_{2k-\sigma_k}|^2+\sum_{k\in\mathbb{Z}\setminus\{0\}}\delta_k^4\mid a_{2k}\mid^2\right\}\\
&+\frac{2}{\gamma}\sum_{k\in\mathbb{Z}\setminus\{0\}}\delta_k^2|\ a_{2k}-a_{2k-\sigma_k}\ |^2 \qquad (37)
\end{aligned}
$$

since, in view of (33)–(34), $\mid \lambda_{2k}\mid \partial\varphi_{2k}(1)\mid -1/\sqrt{\gamma}\mid$, $\mid \lambda_{2k-\sigma_k}\mid \partial\varphi_{2k-\sigma_k}(1)\mid -1/\sqrt{\gamma}\mid$, and δ_k are of the order of $1/k$.

Clearly the last term in (37) can be bounded in terms of

$$\sum_{k\in\mathbb{Z}\setminus\{0\}}\delta_k^4\mid a_{2k-\sigma_k}\mid^2+\sum_{k\in\mathbb{Z}\setminus\{0\}}\delta_k^2\mid a_{2k}-a_{2k-\sigma_k}\mid^2.$$

The first inequality in (36) can be proved in a similar way.

Now, taking into account that $\partial u(1,t)=\sum_{k\in\mathbb{Z}\setminus\{0\}}a_k\partial\varphi_k(1)e^{i\lambda_k t}$ we deduce that

$$
\begin{aligned}
&\int_0^T|\partial u(1,t)|^2\,dt=\int_0^T\left|\sum_{k\in\mathbb{Z}\setminus\{0\}}a_k\partial\varphi_k(1)e^{i\lambda_k t}\right|^2dt=\int_0^T\left|\sum_{k\in\mathbb{Z}\setminus\{0\}}(-1)^k\frac{\widetilde{a}_k}{\lambda_k}e^{i\lambda_k t}\right|^2dt\\
&=\int_0^T\left|\sum_{k\in\mathbb{Z}\setminus\{0\}}\left[\left(\frac{\widetilde{a}_{2k}}{\lambda_{2k}}-\frac{\widetilde{a}_{2k-\sigma_k}}{\lambda_{2k-\sigma_k}}\right)e^{i\lambda_{2k}t}+\delta_k\left(\frac{\widetilde{a}_{2k-\sigma_k}}{\lambda_{2k-\sigma_k}}\right)\frac{e^{i\lambda_{2k}t}-e^{i\lambda_{2k-\sigma_k}t}}{\delta_k}\right]\right|^2dt\\
&\le C\sum_{k\in\mathbb{Z}\setminus\{0\}}\left(\left|\frac{\widetilde{a}_{2k}}{\lambda_{2k}}-\frac{\widetilde{a}_{2k-\sigma_k}}{\lambda_{2k-\sigma_k}}\right|^2+\delta_k^2\left|\frac{\widetilde{a}_{2k-\sigma_k}}{\lambda_{2k-\sigma_k}}\right|^2\right)\\
&\le C\sum_{k\in\mathbb{Z}\setminus\{0\}}\left(\frac{|\widetilde{a}_{2k}-\widetilde{a}_{2k-\sigma_k}|^2}{\lambda_{2k}^2}+|\widetilde{a}_{2k-\sigma_k}|^2\left|\frac{1}{\lambda_{2k}}-\frac{1}{\lambda_{2k-\sigma_k}}\right|^2+\frac{\delta_k^2}{\lambda_{2k-\sigma_k}}\,|\widetilde{a}_{2k-\sigma_k}|^2\right)\\
&\le C\sum_{k\in\mathbb{Z}\setminus\{0\}}\left(\delta_k^2\,|\widetilde{a}_{2k}-\widetilde{a}_{2k-\sigma_k}|^2+\delta_k^4\,|\widetilde{a}_{2k-\sigma_k}|^2\right)\le C\parallel U^0\parallel_Y^2
\end{aligned}
$$

in view of Corollary 3.3, inequalities (36), and the fact that $\lambda_{2k}\sim 1/\delta_k$ and $\lambda_{2k-\sigma_k}\sim 1/\delta_k$.

A similar computation shows that (29) holds, also.

Inequalities (36) imply the statement of Lemma 3.1 in view of Theorem 3.4. □

4. On the solvability of the system with nonhomogeneous data. In this section we analyze the existence, uniqueness, and regularity of nonhomogeneous boundary value problems that appear when addressing the control problem.

In order to state the main results of this section it is convenient to introduce the following asymmetric spaces:

$$V_0^+=\left\{(\varphi,\eta,\xi)\in H_{-3/2}\ :\ \varphi|_{(0,1)}\in L^2(0,1)\right\}; \qquad (38)$$

$$V_1^+=\left\{(\varphi,\eta,\xi)\in H_{-1}\ :\ \varphi|_{(0,1)}\in H^1(0,1),\ \varphi(0^+)=\eta,\ \varphi(1)=0\right\}. \qquad (39)$$

In these notations the superscripts + indicate that the elements of these spaces are more regular to the right of $x = 0$, while the subscripts 0 (resp., 1) indicates that the maximal regularity is L^2 (resp., H^1).

REMARK 7. *In view of the characterization of* Y_{-1} *given in Theorem* 2.6, *we observe that* $Y_{-1} = V_1^+ \times V_0^+$.

This section is divided in two parts. In the first one we analyze systems with nonzero right-hand side terms. In the second one we address nonhomogeneous boundary value problems by transposition.

4.1. Systems with nonzero right-hand side. Let us consider the nonhomogeneous system:

$$
\left\{
\begin{array}{l}
\gamma\partial^2 u_{tt} - u_{tt} - \partial^4 u = f,\ x \in (-1,0), 0 < t < T,\\
\gamma\partial^2 u_{tt} - u_{tt} - \partial^4 u = f,\ x \in (0,1), 0 < t < T,\\
[u](0,t) = [\partial u](0,t) = 0,\ 0 < t < T,\\
u_{tt}(0,t) + \left[\partial^3 u\right](0,t) = g,\ 0 < t < T,\\
\gamma\partial u_{tt}(0,t) - \left[\partial^2 u\right](0,t) = h,\ 0 < t < T,\\
u(\pm 1,t) = \partial^2 u(\pm 1,t) = 0,\ 0 < t < T,\\
(u(x,0), u(0,0), \partial u(0,0)) = \left(u^0, y^0, z^0\right),\\
(u_t(x,0), u_t(0,0), \partial u_t(0,0)) = (u^1, y^1, z^1).
\end{array}
\right. \tag{40}
$$

Observe that the boundary conditions at $x = \pm 1$ vanish.

We have the following result.

THEOREM 4.1. *Assume that* $U^0 = \left((u^0, y^0, z^0), (u^1, y^1, z^1)\right) \in H_{-1/2} \times H_{-1}$ *and*

$$
((1 - \gamma\partial^2)^{-1} f, g, h) \in L^2\left(0, T; H_{-1}\right). \tag{41}
$$

Then, there exists a unique solution $U \in C\left([0,T]; H_{-1/2} \times H_{-1}\right)$ *of* (40).

Moreover, there exists $C(T) > 0$ *such that*

$$
\begin{aligned}
&\int_0^T |\partial u(1,t)|^2\, dt\\
&\qquad \le C\left(\| ((1 - \gamma\partial^2)^{-1} f, g, h) \|^2_{L^1(0,T;H_0(-1,1))} + \| U^0 \|^2_{H_{-1/2}\times H_{-1}}\right)
\end{aligned} \tag{42}
$$

for all U^0 *and* (f, g, h) *as above.*

REMARK 8. *The first result of this theorem is classical and provides the existence of solutions with values in* $H_{-1/2} \times H_{-1}$, *which is a natural symmetric energy space for solving* (40).

Inequality (42) *extends the "hidden regularity" result of Lemma* 3.1 *to the solutions of the nonhomogeneous system. However,* (42) *is not sharp since it requires the same degree of regularity at both sides of* $x = 0$, *while in Lemma* 3.1 *this degree of regularity is only required on* $(0,1)$. *The next theorem provides a sharp result.*

THEOREM 4.2. *Assume that* $U^0 \in Y_{-1}$ *and* $((1 - \gamma\partial^2)^{-1} f, g, h) \in L^1(0,T; V_0^+)$. *Then, there exists a unique solution* $U \in C\left([0,T]; Y_{-1}\right)$ *of* (40).

Moreover, there exists $C(T) > 0$ *such that*

$$
\int_0^T |\partial u(1,t)|^2\, dt \le C\left[\, \| ((1 - \gamma\partial^2)^{-1} f, g, h) \|^2_{L^1(0,T;V_0^+)} + \| U^0 \|^2_{Y_{-1}} \,\right], \tag{43}
$$

for every U^0 *and* (f, g, h) *as above.*

The proof of both theorems is rather similar. For simplicity we only prove Theorem 4.2.

Proof of Theorem 4.2. Taking into account that the system is linear, and in view of Lemma 3.1, it is sufficient to prove it when $U^0 \equiv 0$.

To simplify the notation we identify $(I-\gamma\partial^2)^{-1}f$ and the vector valued function $\big((I-\gamma\partial^2)^{-1}f, g, h\big)$.

We observe that $(I-\gamma\partial^2)^{-1}f \in L^1(0,T;V_0^+)$ and then, in view of Remark 7, we have $\big(0,(I-\gamma\partial^2)^{-1}f\big) \in L^1(0,T;Y_{-1})$.

On the other hand, composing system (27) with the operator $(I-\gamma\partial^2)^{-1}$ and identifying the unknown vector $(u,u(0),\partial u(0))$ with u, it can be written as

$$u_{tt}+Au=(I-\gamma\partial^2)^{-1}f,$$

where $A=K^{-1}$ is the underlying elliptic operator.

Since $U^0\equiv 0$, by the variation of constants formula $u(t)=\int_0^t v(t-s;s)ds$, where $v(\cdot,\cdot;s)$ satisfies

$$\left\{\begin{array}{l} v_{tt}+Av=0,\\ v(0;s)=0, \quad v_t(0;s)=(I-\gamma\partial^2)^{-1}f(s).\end{array}\right. \tag{44}$$

In view of Proposition 2.5 it is easy to see that u or, more precisely, its corresponding vector valued solution U, belongs to $C([0,T];Y_{-1})$.

On the other hand, in view of Lemma 3.1, we have

$$\begin{aligned}\int_0^T |\partial v(1,t;s)|^2\,dt &\le C\left\|\left(0,\left[(I-\gamma\partial^2)^{-1}f\right](s)\right)\right\|^2_{Y_{-1}}\\ &= C\parallel\left[(I-\gamma\partial^2)^{-1}f\right](s)\parallel^2_{V_0^+},\quad \forall\, s\in[0,T].\end{aligned}$$

By Minkowski's inequality we deduce that

$$\begin{aligned}\parallel\partial u(1,t)\parallel_{L^2(0,T)} &= \left\|\int_0^t \partial v(1,t-s;s)ds\right\|_{L^2(0,T)}\\ &\le C\left\|(I-\gamma\partial^2)^{-1}f\right\|_{L^1(0,T;V_0^+)}.\end{aligned}$$

□

The following result is also needed.

THEOREM 4.3. *Assume that* $U^0\equiv 0$ *and* $(f,g,h)=\partial_t(F,G,H)$ *satisfying* $((I-\gamma\partial^2)^{-1}F,G,H)\in L^1\left(0,T;V_1^+\right)$. *Then the solution of* (40) *verifies* $U\in C([0,T];Y_{-1})$. *Moreover, there exists* $C(T)>0$ *such that*

$$\int_0^T |\partial u(1,t)|^2\,dt \le C\parallel((I-\gamma\partial^2)^{-1}F,G,H)\parallel^2_{L^1(0,T;V_1^+)} \tag{45}$$

for every (F,G,H) *as above.*

Proof of Theorem 4.3. As in Theorem 4.2 above, we identify $(I-\gamma\partial^2)^{-1}F$ (resp., $(I-\gamma\partial^2)^{-1}F_t$) with $((I-\gamma\partial^2)^1F,G,H)$ (resp., $(I-\gamma\partial^2)^{-1}F_t,G_t,H_t)$) to simplify the notation.

On the other hand, $u=v_t$ where v, which is also identified with the unknown vector $(v,v(0),\partial v(0))$, is the solution of

$$\left\{\begin{array}{l} v_{tt}+Av=(I-\gamma\partial^2)^{-1}F,\\ v(0)=v_t(0)=0.\end{array}\right. \tag{46}$$

Observe that we have taken null initial data for v. This is due to the fact that in this proof we may assume $((1-\gamma\partial^2)^{-1}F, G, H)$ to be of compact support in time. Indeed, if Theorem 4.3 is proved for those $((1-\gamma\partial^2)^{-1}F, G, H)$, it can then be extended by density to all $((1-\gamma\partial^2)^{-1}F, G, H) \in L^1(0,T;V_1^+)$.

With this in mind we see that the appropriate initial conditions for v are as follows:

$$v(0) = u_t(0) = 0;\ v_t(0) = u_{tt}(0) = (I-\gamma\partial^2)^{-1}F(0) - Au(0) = 0.$$

To complete the proof of Theorem 4.3 it is sufficient to prove that the following lemma holds.

LEMMA 4.4. *Assume that* $U^0 = 0$ *and* $((1-\gamma\partial^2)^{-1}f, g, h) \in L^1(0,T;V_1^+)$. *Then, there exists* $C > 0$ *such that the solution of* (40) *satisfies*

$$\int_0^T |\partial u_t(1,t)|^2\, dt \le C \parallel ((1-\gamma\partial^2)^{-1}f, g, h) \parallel^2_{L^1(0,T;V_1^+)} \tag{47}$$

for all (f, g, h) *as above.*

Proof of Lemma 4.4. First of all we observe that, in view of the characterization of the asymmetric space Y_{-1} given in Theorem 2.6, it is easy to see that $((I-\gamma\partial^2)^{-1}f, 0) \in L^1(0,T;Y_{-1})$. Note that we identify $(I-\gamma\partial^2)^{-1}f$ with the vector $((I-\gamma\partial^2)^{-1}f, g, h)$ to simplify the notation.

As in Theorem 4.2 above, $u = \int_0^t v(x, t-s; s)ds$ where v solves (44). Then $\omega = v_t$ verifies

$$\begin{cases} \omega_{tt} + A\omega = 0, \\ \omega(0;s) = (I-\gamma\partial^2)^{-1}f(s), \quad \omega_t(0;s) = 0. \end{cases} \tag{48}$$

In view of Lemma 3.2, we have

$$\int_0^T |\partial\omega(1,t)|^2\, dt \le C \parallel ((I-\gamma\partial^2)^{-1}f, 0) \parallel^2_{Y_{-1}} = C \parallel (I-\gamma\partial^2)^{-1}f \parallel^2_{V_1^+}. \tag{49}$$

On the other hand,

$$\partial u_t = \int_0^t \partial v_t(t-s;s)ds = \int_0^t \partial\omega(t-s;s)ds,$$

and therefore,

$$\int_0^T |\partial u_t(1,t)|^2\, dt = \left\| \int_0^t \partial\omega(1, t-s; s)ds \right\|^2_{L^2_t(0,T)}. \tag{50}$$

Now, by Minkowski's inequality and (49) we deduce that

$$\left\| \int_0^t \partial\omega(1, t-s; s)ds \right\|_{L^2_t(0,T)} \le C \parallel (I-\gamma\partial^2)^{-1}f \parallel_{L^1(0,T;V_1^+)}. \tag{51}$$

Combining (50)–(51) we deduce that (47) holds.

This concludes the proof of Lemma 4.4 and Theorem 4.3. ∎

4.2. Nonhomogeneous boundary conditions. Let us consider now the system

$$
\left\{
\begin{array}{l}
\gamma\partial^2 u_{tt} - u_{tt} - \partial^4 u = 0,\ x \in (-1,0),\ 0 < t < T,\\
\gamma\partial^2 u_{tt} - u_{tt} - \partial^4 u = 0,\ x \in (0,1),\ 0 < t < T,\\
[u](0,t) = [\partial u](0,t) = 0,\ 0 < t < T,\\
u_{tt}(0,t) + \left[\partial^3 u\right](0,t) = 0,\ 0 < t < T,\\
\partial u_{tt}(0,t) - \left[\partial^2 u\right](0,t) = 0,\ 0 < t < T,\\
u(\pm 1,t) = \partial^2 u(-1,t) = 0,\ \partial^2 u(1,t) = q(t),\ 0 < t < T,\\
(u(x,0), u(0,0), \partial u(0,0)) = \left(u^0, y^0, z^0\right),\\
(u_t(x,0), u_t(0,0), \partial u_t(0,0)) = \left(u^1, y^1, z^1\right).
\end{array}
\right. \tag{52}
$$

Observe that the boundary conditions in (52) are nonhomogeneous since the boundary condition $\partial^2 u(1,t)$ takes the value q.

We assume that

$$
q \in L^2(0,T) \tag{53}
$$

and

$$
\begin{aligned}
U^0 \in Y^- = \big\{ U^0 \in H_0 \times H_{-1/2}\ :\ & u^0|_{(-1,0)} \in H^3(-1,0),\ \partial^2 u^0(-1) = 0,\\
& u^1|_{(-1,0)} \in H^2(-1,0),\ \partial u^1(0^-) = z^1 \big\}.
\end{aligned} \tag{54}
$$

Observe that Y^- is the reflection of the space Y_0 (characterized in Theorem 2.6) with respect to $x = 0$. In other words, $U^0 \in Y^-$ if and only if $V^0(x) = U^0(-x) \in Y_0$.

In view of Proposition 2.5, and taking into account that system (52) is symmetric with respect to $x = 0$ when $q = 0$, the following holds.

LEMMA 4.5. *When $q \equiv 0$ and $U^0 \in Y^-$, system (6.16) admits a unique solution $U \in C([0,T]; Y^-)$. Moreover, there exists $C(T) > 0$ such that*

$$
\| U \|_{L^\infty(0,T;Y^-)} \leq C(T) \| U^0 \|_{Y^-},\ \forall\ U^0 \in Y^-. \tag{55}
$$

As a consequence of this lemma, and since system (52) is linear, it is sufficient to analyze solutions of (52) when $U^0 \equiv 0$ and q is as in (53). Therefore in the following we assume that $U^0 \equiv 0$.

Solutions of (52) can be understood in the sense of transposition. To make this notion precise we consider the adjoint system

$$
\left\{
\begin{array}{l}
\gamma\partial^2 \varphi_{tt} - \varphi_{tt} - \partial^4 \varphi = f,\ x \in (-1,0),\ 0 < t < T,\\
\gamma\partial^2 \varphi_{tt} - \varphi_{tt} - \partial^4 \varphi = f,\ x \in (0,1),\ 0 < t < T,\\
[\varphi](0,t) = [\partial\varphi](0,t) = 0,\ 0 < t < T,\\
\varphi_{tt}(0,t) + \left[\partial^3 \varphi\right](0,t) = g(t),\ 0 < t < T,\\
\gamma\partial\varphi_{tt}(0,t) - \left[\partial^2 \varphi\right](0,t) = h(t),\ 0 < t < T,\\
\varphi(\pm 1,t) = \partial^2 \varphi(\pm 1,t) = 0,\ 0 < t < T,\\
(\varphi(x,T), \varphi(0,T), \partial\varphi(0,T)) = (\varphi_t(x,T), \varphi_t(0,T), \partial\varphi_t(0,T)) \equiv 0.
\end{array}
\right. \tag{56}
$$

Given $((I - \gamma\partial^2)^{-1} f, g, h) \in L^1(0,T; V_0^+)$, and taking into account that system (56) is time reversible, in view of Theorem 4.2 we deduce that (56) admits a unique solution $\Phi \in C([0,T]; Y_{-1})$ (by Φ we denote the vector valued unknown associated with φ).

On the other hand, $\partial\varphi_t(1,t) \in L^2(0,T)$.

Multiplying in (52) by φ and integrating by parts we get, at least formally, the following identity:

$$\int_0^T < (I-\gamma\partial^2)u, (I-\gamma\partial^2)^{-1}f >_{H_0^1,H^{-1}} dt + \int_0^T y(t)g(t)dt + \int_0^T z(t)h(t)dt$$

$$= \int_0^T \partial\varphi(1,t)q(t)dt, \tag{57}$$

where $y(t) = u(0,t)$, $z(t) = \partial u(0,t)$, and $<,>_{H_0^1,H^{-1}}$ represents the duality product between $H_0^1(-1,1)$ and H^{-1}.

Note that we have used the self-adjointness of $(I-\gamma\partial^2)^{-1}$ in the identity

$$\int_{-1}^1 uf = \int_{-1}^1 (I-\gamma\partial^2)u(I-\gamma\partial^2)^{-1}f =< (I-\gamma\partial^2)u, (I-\gamma\partial^2)^{-1}f >_{H_0^1,H^{-1}}.$$

We adopt (57) as a definition of solution of (52) when $U^0 \equiv 0$.

DEFINITION 4.6. *We say that $U \in C(0,T;Y^-)$ is a solution of* (52) *with $U^0 \equiv 0$ in the sense of transposition if* (57) *holds for any $((I-\gamma\partial^2)^{-1}f, g, h) \in L^1(0,T;V_0^+)$.*

REMARK 9. *As we will see below, solutions in the sense of transposition are more regular on the left-hand side of $x = 0$. They satisfy*

$$u|_{(-1,0)} \in C\left([0,T];H^3(-1,0)\right) \cap C^1\left([0,T];H^2(-1,0)\right) \tag{58}$$

and the compatibility conditions

$$\partial u_t(0^-,t) = z_t(t), \quad \partial^2 u(-1) = 0. \tag{59}$$

Observe that the initial condition $U^0 \equiv 0$ is implicit in (57).

THEOREM 4.7. *When $U^0 \equiv 0$ and q is as in* (53)*, system* (52) *admits a unique solution in the sense of transposition.*

Moreover, there exists $C(T) > 0$ such that

$$\| U \|_{C([0,T];Y^-)} \leq C(T) \| q \|_{L^2(0,T)}, \tag{60}$$

for every q as above.

Proof of Theorem 4.7. In view of Theorem 4.2, the right-hand side of (57) defines a linear continuous operator in $L^1(0,T;V_0^+)$. Therefore, by duality we deduce that there exists a unique $(u,y,z) \in L^\infty\left(0,T;(V_0^+)'\right)$ solution of (57) where $\left(V_0^+\right)'$ denotes the dual of V_0^+. Moreover, there exists $C > 0$ such that

$$\| ((I-\gamma\partial^2)u, y, z) \|_{L^\infty\left(0,T;(V_0^+)'\right)} \leq C \| q \|_{L^2(0,T)}. \tag{61}$$

Furthermore, as a consequence of Theorem 4.2 we deduce that $(u_t, y_t, z_t) \in L^\infty(0,T;(V_1^+)')$, and the estimate

$$\left\| \left((I-\gamma\partial^2)u_t, y_t, z_t\right) \right\|_{L^\infty\left(0,T;\left(V_1^+\right)'\right)} \leq C \| q \|_{L^2(0,T)} \tag{62}$$

holds for every q as in (53).

Observe now that the duals of V_0^+, $\left(V_0^+\right)'$, and V_1^+ coincide, resp., with the spaces

$$V_1^- = \left\{(v,y,z) \in L^2(-1,1) \times \mathbb{R} \times \mathbb{R} \ : v|_{(-1,0)} \in H^1(-1,0),\ v(-1) = 0,\right.$$
$$\left.[(I-\gamma\partial^2)^{-1}v](0) = y,\ [\partial(I-\gamma\partial^2)^{-1}v](0) = z\right\},$$
$$V_0^- = \left\{(v,y,z) \in H^{-1}(-1,1) \times \mathbb{R} \times \mathbb{R} \ :\ v|_{(-1,0)} \in L^2(-1,0),\right.$$
$$\left.[(1-\gamma\partial^2)^{-1}v](0) = y,\ [\partial(1-\gamma\partial^2)^{-1}v](0^-) = z\right\}.$$

On the other hand, $V_1^- \times V_0^-$ is the image of the space Y^- by the operator $\mathcal{L}$ defined as

$$\mathcal{L}((u^0,y^0,z^0),(u^1,y^1,z^1)) = (((I-\gamma\partial^2)u^0,y^0,z^0),((I-\gamma\partial^2)u^1,y^1,z^1)). \tag{63}$$

We observe that $\mathcal{L}$ is in fact an isomorphism from Y^- to $V_1^- \times V_0^-$.

With the above considerations and (61)–(62), we deduce

$$\| U \|_{L^\infty(0,T;Y^-)} \leq C(T) \| q \|_{L^2(0,T)} .$$

Now by density it follows that (60) holds. To see this, it is sufficient to observe that when q is smooth enough and of compact support, solutions of (52) belong to $C\left([0,T];H_{1/2}\times H_0\right)$. □

5. Controllability. In this section we prove the main controllability result for the system

$$\begin{cases} \gamma\partial^2 u_{tt} - u_{tt} - \partial^4 u = 0,\ x\in(-1,0),\ 0<t<T, \\ \gamma\partial^2 u_{tt} - u_{tt} - \partial^4 u = 0,\ x\in(0,1),\ 0<t<T, \\ [u](0,t) = [\partial u](0,t) = 0,\ 0<t<T, \\ u_{tt}(0,t) + \left[\partial^3 u\right](0,t) = 0,\ 0<t<T, \\ \gamma\partial u_{tt}(0,t) - \left[\partial^2 u\right](0,t) = 0,\ 0<t<T, \\ u(\pm1,t) = \partial^2 u(-1,t) = 0,\ \partial^2 u(1,t) = q(t),\ 0<t<T, \\ (u(x,0),u(0,0),\partial u(0,0)) = \left(u^0,y^0,z^0\right), \\ (u_t(x,0),u_t(0,0),\partial u_t(0,0)) = \left(u^1,y^1,z^1\right). \end{cases} \tag{64}$$

The following holds.

THEOREM 5.1. *Assume that $T \geq 4\sqrt{\gamma}$. Then for every $((u^0,y^0,z^0),(u^1,y^1,z^1)) \in Y^-$ there exists a control $q \in L^2(0,T)$ such that the solution of* (64) *in the sense of transposition satisfies*

$$((u(x,T),u(0,T),\partial u(0,T)),(u_t(x,T),u_t(0,T),\partial u_t(0,T))) \equiv 0. \tag{65}$$

Moreover, there exists $C>0$ such that

$$\| q \|_{L^2(0,T)} \leq C \| U^0 \|_{Y^-},\ \forall\ U^0 \in Y^-. \tag{66}$$

REMARK 10. *Theorem* 5.1 *states the exact controllability of* (64) *in the space Y^- with controls in $L^2(0,T)$, provided $T \geq 4\sqrt{\gamma}$.*

The functional frame we have chosen for the control problem ($U^0 \in Y^-$ and $q \in L^2(0,T)$) is not unique. A similar result holds for U^0 in Y_{-1}^-, where

$$\begin{aligned} Y_{-1}^- = \big\{ U^0 \in H_{-1}\times H_{-3/2}\ :\ & u^0|_{(-1,0)} \in H^1(-1,0), \\ & u^1|_{(-1,0)} \in L^2(-1,0), u^0(0^-) = y^0,\ u^0(-1) = 0 \big\}, \end{aligned}$$

with controls $q \in H^{-2}(0,T)$. In this case exact controllability holds at time $T > 4\sqrt{\gamma}$, because it is convenient to take controls q of compact support in order to avoid further singularities in the solutions at $t=0$ and $t=T$.

Proof of Theorem 5.1. In view of the observability results of Lemma 3.1, it is a direct application of HUM (see [8]).

Given $T \geq 4\sqrt{\gamma}$, for any $\Phi^0 = \big((\varphi^0, \psi^0, \xi^0), (\varphi^1, \psi^0, \xi^1)\big) \in Y_{-1}$ we solve the adjoint system

$$
\left\{
\begin{array}{l}
\gamma\partial^2\varphi_{tt} - \varphi_{tt} - \partial^4\varphi = 0,\ -1 < x < 0,\ 0 < t < T,\\
\gamma\partial^2\varphi_{tt} - \varphi_{tt} - \partial^4\varphi = 0,\ 0 < x < 1,\ 0 < t < T,\\
[\varphi](0,t) = [\partial\varphi](0,t) = 0,\ 0 < t < T,\\
\varphi_{tt}(0,t) + \left[\partial^3\varphi\right](0,t) = 0,\ 0 < t < T,\\
\gamma\partial\varphi_{tt}(0,T) - \left[\partial^2\varphi\right](0,t) = 0,\ 0 < t < T,\\
\varphi(\pm 1,t) = \partial^2\varphi(\pm 1,t) = 0,\ 0 < t < T,\\
\Phi(0) \equiv \big((\varphi(x,0), \varphi(0,0), \partial\varphi(0,0)\big), \big(\varphi_t(x,0), \varphi_t(0,0), \partial\varphi_t(0,0))\big)\\
\quad = \big((\varphi^0, \psi^0, \xi^0), (\varphi^1, \psi^0, \xi^1)\big) = \Phi^0.
\end{array}
\right. \tag{67}
$$

In view of Proposition 2.5, system (67) admits a unique solution $\Phi \in C([0,T; Y_{-1})$. Moreover, thanks to Lemma 3.1, $\partial\varphi(1,t) \in L^2(0,T)$.

We then solve

$$
\left\{
\begin{array}{l}
\gamma\partial^2 u_{tt} - u_{tt} - \partial^4 u = 0,\ -1 < x < 0,\ 0 < t < T,\\
\gamma\partial^2 u_{tt} - u_{tt} - \partial^4 u = 0,\ 0 < x < 1,\ 0 < t < T,\\
[u](0,t) = [\partial u](0,t) = 0,\ 0 < t < T,\\
u_{tt}(0,t) + \left[\partial^3 u\right](0,t) = 0,\ 0 < t < T,\\
\gamma\partial u_{tt}(0,T) - \left[\partial^2 u\right](0,t) = 0,\ 0 < t < T,\\
u(\pm 1,t) = 0, \partial^2 u(-1,t) = 0, \partial^2 u(1,t) = \partial\varphi(1,t),\\
(u(x,T), u(0,T), \partial u(0,T)) \equiv (u_t(x,T), u_t(0,T), \partial u_t(0,T)) \equiv 0.
\end{array}
\right. \tag{68}
$$

In view of Theorem 4.7 and the time reversibility of system (68), we deduce that it has a unique solution defined by transposition.

We define the linear map

$$\Lambda\Phi^0 = \left((u(x,0), u(0,0), \partial u(0,0)\right), \left(u_t(x,0), u_t(0,0), \partial u_t(0,0)\right)).$$

Multiplying in (68) by φ and integrating by parts (this is a formal computation that may be done rigorously by the definition of the solution in the sense of transposition), it follows that

$$\langle L\Lambda\Phi^0, \Phi^0\rangle = \int_0^T |\partial\varphi(1,t)|^2\, dt,\ \forall\ \Phi^0 \in Y_{-1}, \tag{69}$$

where

$$L\Phi^0 = \big(\big((I - \gamma\partial^2)\varphi^1(x), \psi^1, \xi^1\big), -\big((I - \gamma\partial^2)\varphi^0(x), \psi^0, \xi^0)\big)\big).$$

In view of identity (69), it follows that $L\Lambda$ is an isomorphism from Y_{-1} into its dual Y'_{-1}, and therefore Λ is an isomorphism from Y_{-1} into $L^{-1}Y'_{-1}$.

Now we observe that, as was pointed out in Remark 7, $Y_{-1} = V_1^+ \times V_0^+$ and then $Y'_{-1} = V_0^- \times V_1^-$, where V_0^- and V_1^-, are the spaces introduced in the proof of Theorem 4.7.

It is easy to see that $L^{-1}(V_0^- \times V_1^-) \equiv Y^-$ algebraically and topologically.

This implies that $\Lambda : Y_{-1} \to Y^-$ is an isomorphism. Therefore, for any $U^0 \in Y^-$ there exists a unique $\Phi^0 \in Y_{-1}$ such that $\Lambda\Phi^0 = U^0$. This means that the solution U of (68) with control $q = \partial\varphi(1,t)$, where φ is the solution of (67) with initial data $\Phi^0 = \Lambda^{-1}U^0$, is such that $U(0) \equiv U^0$. Therefore, q is the control we were looking for.

We also have by construction, and in view of identity (69) and the observability inequalities of Lemma 3.1, that

$$\int_0^T |\partial\varphi(1,t)|^2\,dt = \left|\langle L\Lambda\Phi^0, \Phi^0\rangle\right| = \left|\langle LU^0, \Phi^0\rangle\right|$$
$$\leq C \parallel \Phi^0 \parallel_{Y_{-1}} \parallel U^0 \parallel_{Y^-} \leq C \left(\int_0^T |\partial\varphi(1,t)|^2\,dt\right)^{1/2} \parallel U^0 \parallel_{Y^-} .$$

Therefore,

$$\int_0^T |\partial\varphi(1,t)|^2\,dt \leq C \parallel U^0 \parallel_{Y^-}^2$$

and consequently (66) holds. □

THE MAXIMUM PRINCIPLE FOR PARTIALLY OBSERVED OPTIMAL CONTROL OF STOCHASTIC DIFFERENTIAL EQUATIONS*

SHANJIAN TANG†

Abstract. This paper concerns partially observed optimal control of possibly degenerate stochastic differential equations, with correlated noises between the system and the observation. The control is allowed to enter into all the coefficients. A general maximum principle is proved for the partially observed optimal control, and the relations among the adjoint processes are established. Adjoint vector fields, which are adapted to the past and present observations, are introduced as the solutions to some backward stochastic partial differential equations (BSPDEs), and their relations are established. Under suitable conditions, the adjoint processes are characterized in terms of the adjoint vector fields, their differentials and Hessians, along the optimal state process. Some other formulations of the partially observed stochastic maximum principle are then derived.

Key words. partially observed optimal control, adjoint processes, adjoint vector fields, maximum principle, backward stochastic partial differential equations

1. Formulation of the problem and some historical comments.

Throughout this paper, we use the Einstein convention for summation over repeated indices. For a matrix, we use superscripts to indicate (when necessary) the number of its columns or its rows or the position of its components, and the precise meaning can be specified from the context; the range of the superscripts will not be explicitly stated unless there is a danger of confusion. $\langle , \rangle$ denotes the product of two vectors in an Euclidean space, and $|\cdot|$ denotes the square root of the sum of all the squares of components of the underlying matrix. $*$ appearing in the superscripts denotes the transpose of a matrix, and $\mathbb{R}^n$ the n-dimensional Euclidean space. For a $\mathbb{R}^m$-valued vector function f on $\mathbb{R}^n$, we use the notation

$$f_x := \begin{pmatrix} \frac{\partial f^1}{\partial x^1} & \frac{\partial f^1}{\partial x^2} & \cdots & \frac{\partial f^1}{\partial x^n} \\ \frac{\partial f^2}{\partial x^1} & \frac{\partial f^2}{\partial x^2} & \cdots & \frac{\partial f^2}{\partial x^n} \\ \vdots & \vdots & \ddots & \vdots \\ \frac{\partial f^m}{\partial x^1} & \frac{\partial f^m}{\partial x^2} & \cdots & \frac{\partial f^m}{\partial x^n} \end{pmatrix}, \quad f^i_{xx} := \begin{pmatrix} \frac{\partial^2 f^i}{\partial (x^1)^2} & \frac{\partial^2 f^i}{\partial x^1 \partial x^2} & \cdots & \frac{\partial^2 f^i}{\partial x^1 \partial x^n} \\ \frac{\partial^2 f^i}{\partial x^2 \partial x^1} & \frac{\partial^2 f^i}{\partial (x^2)^2} & \cdots & \frac{\partial^2 f^i}{\partial x^2 \partial x^n} \\ \vdots & \vdots & \ddots & \vdots \\ \frac{\partial^2 f^i}{\partial x^n \partial x^1} & \frac{\partial^2 f^i}{\partial x^n \partial x^2} & \cdots & \frac{\partial^2 f^i}{\partial (x^n)^2} \end{pmatrix}.$$

Let $(\Omega, \mathcal{F}, P)$ be a probability space on which are defined two independent standard Brownian motions $w(\cdot)$ and $Y(\cdot)$ valued in $\mathbb{R}^m$ and $\mathbb{R}^d$, respectively. Let x_0 be a random variable with the law P_0 and independent of $(w(\cdot), Y(\cdot))$. Let $\{\mathcal{F}^w_t\}$ and $\{\mathcal{F}^Y_t\}$ be the P-completed natural filtrations generated by $w(\cdot)$ and $Y(\cdot)$, respectively,

†Department of Mathematics, Fudan University, Shanghai 200433, People's Republic of China (sjtang@fudan.edu.cn).

and $\sigma(x_0)$ the σ-algebra generated by x_0. Set

$$\mathcal{F}_t := \sigma(x_0) \vee \mathcal{F}_t^w \vee \mathcal{F}_t^Y, \quad \mathcal{F} := \mathcal{F}_1.$$

Let U be a nonempty Borel subset of some Euclidean space. An admissible control is defined as a stochastic process $u : [0,1] \times \Omega \to U$ which is $\mathcal{F}_t^Y$-adapted and satisfies

$$\sup_{0 \le t \le 1} E|u(t,\cdot)|^i < \infty, \quad i = 1, 2, \ldots$$

For simplification of notation, we write $u(t)$ for $u(t,\cdot)$ in the following. A set U_{ad} of admissible controls is called an admissible class of controls if U_{ad} has the following property: $\forall\, v_1(\cdot), v_2(\cdot) \in U_{\mathrm{ad}}$, and a Borel subset K of $[0,1]$, define

$$v(t) = v_1(t)\chi_K(t) + v_2(t)\chi_{[0,1]\setminus K}(t), \quad t \in [0,1];$$

then $v(\cdot) \in U_{\mathrm{ad}}$.

In the literature, a partially observed optimal control problem has been studied at least for the following two admissible classes of controls: one is based on the present observation and defined as

$$\begin{aligned}\widetilde{U}_{\mathrm{ad}} := \{&v : v \text{ is a } U\text{-valued stochastic process such that } v(t) \text{ is } \sigma(Y(t))\text{-measurable}\\ &\text{for } \textit{almost every } t \in [0,1] \text{ and } \sup_{0\le t\le 1} E|v(t)|^i < \infty,\ i = 1, 2, \ldots\};\end{aligned}$$

the other one is based on the past and present observations and defined as

$$\begin{aligned}\overline{U}_{\mathrm{ad}} := \{&v : v \text{ is a } U\text{-valued } \mathcal{F}_t^Y\text{-adapted stochastic process}\\ &\text{and satisfies } \sup_{0\le t\le 1} E|v(t)|^i < \infty,\ i = 1, 2, \ldots\}.\end{aligned}$$

A control is said to be partially observed if the control is a nonanticipative functional of the observation $Y(\cdot)$. A set of controls is said to be partially observed if its every element is partially observed. Obviously, a set of admissible controls is partially observed.

We make the following hypothesis.

($\mathcal{A}1$) *Let U_{ad} be a given admissible class of controls. The functions $f : [0,1]\times\mathbb{R}^n \times U \to \mathbb{R}^n, g : [0,1]\times\mathbb{R}^n\times U \to \mathbb{R}^{n\times m}, \widetilde{g} : [0,1]\times\mathbb{R}^n\times U \to \mathbb{R}^{n\times d}, h : [0,1]\times\mathbb{R}^n\times U \to \mathbb{R}^d, l : [0,1]\times\mathbb{R}^n\times U \to \mathbb{R}$, and $m : \mathbb{R}^n \to \mathbb{R}$ are Borel measurable, continuous in v, and twice continuously differentiable in x, and for some constant C,*

$$\begin{aligned}&(1+|x|+|v|)^{-1}|f(t,x,v)| + |f_x(t,x,v)| + |f_{xx}^{i_1}(t,x,v)| \le C,\\ &(1+|x|+|v|)^{-1}|g^i(t,x,v)| + |g_x^i(t,x,v)| + |g_{xx}^{i_1 i}(t,x,v)| \le C,\\ &|\widetilde{g}^j(t,x,v)| + |\widetilde{g}_x^j(t,x,v)| + |\widetilde{g}_{xx}^{i_1 j}(t,x,v)| \le C,\\ &|h(t,x,v)| + |h_x(t,x,v)| + |h_{xx}^j(t,x,v)| \le C,\\ &(1+|x|^2+|v|^2)^{-1}|l(t,x,v)| + (1+|x|+|u|)^{-1}|l_x(t,x,v)| + |l_{xx}(t,x,v)| \le C,\\ &(1+|x|^2)^{-1}|m(x)| + (1+|x|)^{-1}|m_x(x)| + |m_{xx}(x)| \le C.\end{aligned}$$

x_0 has finite moments of arbitrary order.

Our general partially observed optimal control problem is stated as follows.

Consider the system

$$\begin{cases} dx(t) = f(t,x(t),v(t))\,dt + g^i(t,x(t),v(t))\,dw^i(t)\\ \qquad\qquad + \widetilde{g}^j(t,x(t),v(t))\,d\widetilde{w}^j(t), \quad t \in (0,1],\\ x(0) = x_0 \end{cases} \tag{1.1}$$

and the observation

$$\begin{cases} dY(t) = h(t, x(t), v(t))\,dt + d\widetilde{w}(t), \quad t \in (0,1], \\ Y(0) = 0. \end{cases} \tag{1.2}$$

Putting (1.2) into (1.1), we have

$$\begin{cases} dx(t) = (f - \widetilde{g}h)(t, x(t), v(t))\,dt + g^i(t, x(t), v(t))\,dw^i(t) \\ \qquad\quad + \widetilde{g}^j(t, x(t), v(t))\,dY^j(t), \qquad t \in (0,1], \\ x(0) = x_0. \end{cases} \tag{1.3}$$

For each $v(\cdot) \in U_{\mathrm{ad}}$, (1.3) has a unique strong solution, which will be denoted by $x^v(\cdot)$. From Girsanov's theorem, it follows that if

$$\rho^v(t) := \exp\biggl\{\int_0^t h^*(s, x^v(s), v(s))\,dY(s) - \frac{1}{2}\int_0^t |h(s, x^v(s), v(s))|^2\,ds\biggr\}, \tag{1.4}$$

$$\widetilde{w}(t) := Y(t) - \int_0^t h(s, x^v(s), v(s))\,ds, \tag{1.5}$$

and if $dP^v := \rho^v(1)\,dP$, then $(P^v, x^v, Y, w, \widetilde{w})$ is a weak solution on $(\Omega, \mathcal{F}, \mathcal{F}_t)$ of (1.1) and (1.2).

The cost functional is

$$J(v(\cdot)) = E^v\biggl[\int_0^1 l(t, x^v(t), v(t))\,dt + m(x^v(1))\biggr]. \tag{1.6}$$

Here, E^v denotes the expectation with respect to the probability space $(\Omega, \mathcal{F}, P^v)$. Our partially observed optimal control problem is to minimize the cost functional (1.6) over $v(\cdot) \in U_{\mathrm{ad}}$, i.e.,

$$\min_{v \in U_{\mathrm{ad}}} J(v). \tag{1.7}$$

Here, the words "partially observed" indicates that the admissible class U_{ad} in the underlying optimal control problem is partially observed. Our aim is to seek the necessary conditions for the partially observed optimal control $\widehat{u}(\cdot)$.

Such a subject has been discussed by many authors, such as Fleming [4]; Kwakernaak [7] (with an explorative style); Bensoussan [2]; Haussmann [5]; Baras, Elliott, and Kohlmann [1]; Zhou [13]; and Li and Tang [8]. Usually, they made at least one of the following five assumptions: 1) The diffusion term σ is nondegenerate (see Fleming [4], Kwakernaak [7], Bensoussan [2], and Zhou [13]). 2) The coefficients $f, g, h,$ and l are differentiable in control variable u, and the set U, in which the control takes values, is convex (see Fleming [4] and Bensoussan [2]). 3) The control does not appear in the diffusion term g and the observation h (see Bensoussan [2]; Haussmann [5]; and Baras, Elliott, and Kohlmann [1]). 4) $\widetilde{g} = 0$ (see Bensoussan [2]; Haussmann [5]; Baras, Elliott, and Kohlmann [1]; and Li and Tang [8]). 5) The initial state x_0 has a regular density function (see Bensoussan [2] and Zhou [13]).

In this paper, we consider the general case of the partially observed optimal control problem (1.1), (1.2), (1.6), (1.7), where the control is allowed to enter into all the coefficients, the diffusion term g is allowed to be degenerate, the correlation

coefficient $\widetilde{g}$ is present, the set U is not necessarily convex, and the initial state does not necessarily have a regular density function. A general maximum principle is proved for the partially observed optimal control, and the relations among the adjoint processes are established. Adjoint vector fields are introduced as the solutions to some BSPDEs, and their relations are established. Under suitable conditions, the adjoint processes are characterized in terms of the adjoint vector fields, their differentials and Hessians, along the optimal state process. Some other formulations of the partially observed stochastic maximum principle are then obtained, and our results are compared with those existing in the literature. Our approach does not involve the Zakai equation, and thus we can get around a lot of complicated stochastic calculus in infinite-dimensional spaces, in contrast with Bensoussan [2], Haussmann [5], and Zhou [13].

The rest of this paper is organized as follows. In section 2, we derive a general maximum principle for partially observed optimal controls from the general maximum principle for optimal controls with full information. In section 3, the relations are established among the adjoint processes, which are introduced in the general partially observed maximum principle and which are characterized as the unique $\mathcal{F}_t$-adapted square-integrable solutions of backward stochastic differential equations (BSDEs). In section 4, adjoint vector fields are introduced as the solutions to some BSPDEs, and their relations are established; under suitable conditions, the adjoint processes are characterized in terms of the adjoint vector fields, their differentials and Hessians, along the optimal state process. Finally in section 5, some other formulations of the partially observed stochastic maximum principle are derived, and our results are compared with the existing ones.

2. A general partially observed maximum principle. Let $\widehat{u}(\cdot)$ be an optimal control and $(\widehat{x}(\cdot), Y(\cdot), w(\cdot), \widehat{\widetilde{w}(\cdot)}, \widehat{P})$ be the corresponding weak solution of (1.1) – (1.2). We introduce the notation: $\widehat{E} = E^{\hat{u}}$, $\Delta f(t;v) := \Delta f(t, \widehat{x}(t), \widehat{u}(t); v) := f(t, \widehat{x}(t), v) - f(t, \widehat{x}(t), \widehat{u}(t))$, and similar notation will be made for other functions $g, \widetilde{g}, l, h,$ and $\mathcal{H}$ (see (2.10) below). For each $v(\cdot) \in U_{\text{ad}}$, the stochastic process $\rho^v(\cdot)$ can be characterized as the solution of the following stochastic differential equation (SDE):

$$\begin{cases} d\rho^v(t) = \rho^v(t) h^*(t, x^v(t), v(t))\ dY(t), \quad t \in (0,1], \\ \rho^v(0) = 1. \end{cases} \tag{2.1}$$

The cost functional (1.6) can be rewritten as

$$J(v(\cdot)) = E\bigg[\int_0^1 \rho^v(t) l(t, x^v(t), v(t))\ dt + \rho^v(1) m(x^v(1))\bigg]. \tag{2.2}$$

Set

$$\begin{aligned} &X := \begin{pmatrix} \rho \\ x \end{pmatrix}, \quad \widehat{X} := \begin{pmatrix} \widehat{\rho} \\ \widehat{x} \end{pmatrix} := \begin{pmatrix} \rho^{\hat{u}} \\ x^{\hat{u}} \end{pmatrix}, \quad X_0 := \begin{pmatrix} 1 \\ x_0 \end{pmatrix}, \\ &F(t, X, v) := \begin{pmatrix} 0 \\ f(t,x,v) - \widetilde{g}(t,x,v) h(t,x,v) \end{pmatrix}, \\ &G(t, X, v) := \begin{pmatrix} 0 \\ g(t,x,v) \end{pmatrix}, \quad \widetilde{G}(t, X, v) := \begin{pmatrix} \rho h^*(t,x,v) \\ \widetilde{g}(t,x,v) \end{pmatrix}, \\ &L(t, X, v) := \rho l(t,x,v), \qquad M(X) := \rho m(x). \end{aligned} \tag{2.3}$$

Equations (1.1), (1.2), and (2.1) can be compressed into the following form:

$$\begin{cases} dX(t) = F(t, X(t), v(t))\,dt + G^i(t, X(t), v(t))\,dw^i(t) \\ \qquad\quad + \widetilde{G}^j(t, X(t), v(t))\,dY^j(t), \quad t \in (0, 1], \\ X(0) = X_0. \end{cases} \tag{2.4}$$

The cost functional (2.2) is rewritten as

$$J(v(\cdot)) = E\bigg[\int_0^1 L(t, X(t), v(t))\,dt + M(X(1))\bigg]. \tag{2.5}$$

Our partially observed optimal control problem becomes the following minimization problem: to minimize $J(v(\cdot))$ over $v(\cdot) \in U_{\rm ad}$ subject to (2.4). The present formulation of the partially observed optimal control problem is quite similar to a completely observed optimal control problem; the only difference lies in the admissible class $U_{\rm ad}$ of controls. We can follow the same arguments to the case of full information to derive the following maximum principle. See Peng [11] and Tang and Li [12] for details.

Define the Hamiltonian $H : [0, 1] \times \mathbb{R}^{n+1} \times U \times \mathbb{R}^{n+1} \times \mathbb{R}^{(n+1)\times m} \times \mathbb{R}^{(n+1)\times d} \to \mathbb{R}$ as follows:

$$\begin{aligned} H(t, X, v, a, b, \widetilde{b}) := \langle a, F(t, X, v)\rangle + \langle b^i, G^i(t, X, v)\rangle \\ + \langle \widetilde{b}^j, \widetilde{G}^j(t, X, v)\rangle + L(t, X, v) \end{aligned} \tag{2.6}$$

$\forall\, t \in [0, 1], X \in \mathbb{R}^{n+1}, v \in U, a \in \mathbb{R}^{n+1}, b \in \mathbb{R}^{(n+1)\times m}, \widetilde{b} \in \mathbb{R}^{(n+1)\times d}$.

Let $(a(\cdot), b(\cdot), \widetilde{b}(\cdot))$ be the unique $\mathcal{F}_t$-adapted square integrable solution of the first-order adjoint equation

$$\begin{cases} da(t) = -\,H^*_X(t, \widehat{X}(t), \widehat{u}(t), a(t), b(t), \widetilde{b}(t))\,dt \\ \qquad\quad + b(t)\,dw(t) + \widetilde{b}(t)\,dY(t), \quad t \in [0, 1), \\ a(1) = M^*_X(\widehat{X}(1)) \end{cases} \tag{2.7}$$

and $(A(\cdot), B(\cdot), \widetilde{B}(\cdot))$ be the unique $\mathcal{F}_t$-adapted square integrable solution of the second-order adjoint equation

$$\begin{cases} dA(t) = -\,\{F^*_X(t, \widehat{X}(t), \widehat{u}(t))A(t) + A(t)F_X(t, \widehat{X}(t), \widehat{u}(t)) \\ \qquad\quad + G^{i*}_X(t, \widehat{X}(t), \widehat{u}(t))A(t)G^i_x(t, \widehat{X}(t), \widehat{u}(t)) \\ \qquad\quad + \widetilde{G}^{i*}_X(t, \widehat{X}(t), \widehat{u}(t))A(t)\widetilde{G}^i_X(t, \widehat{X}(t), \widehat{u}(t)) \\ \qquad\quad + G^{i*}_X(t, \widehat{X}(t), \widehat{u}(t))B^i(t) + B^i(t)G^i_X(t, \widehat{X}(t), \widehat{u}(t)) \\ \qquad\quad + \widetilde{G}^{j*}_X(t, \widehat{X}(t), \widehat{u}(t))\widetilde{B}^j(t) + \widetilde{B}^j(t)\widetilde{G}^j_X(t, \widehat{X}(t), \widehat{u}(t)) \\ \qquad\quad + H_{XX}(t, \widehat{X}(t), \widehat{u}(t), a(t), b(t), \widetilde{b}(t))\}\,dt \\ \qquad\quad + B^i(t)\ dw^i(t) + \widetilde{B}^j(t)\,dY^j(t), \quad t \in [0, 1), \\ A(1) = M_{XX}(\widehat{X}(1)). \end{cases} \tag{2.8}$$

Then the following maximum condition holds:

$$
\begin{aligned}
&E\int_0^1 \{H(t,\widehat{X}(t),v(t),a(t),b(t),\widetilde{b}(t)) - H(t,\widehat{X}(t),\widehat{u}(t),a(t),b(t),\widetilde{b}(t))\}\,dt \\
&+\frac{1}{2}E\int_0^1 \operatorname{tr}[A(t)(\Delta G(t;v(t))\Delta G^*(t;v(t)) + \Delta\widetilde{G}(t;v(t))\Delta\widetilde{G}^*(t;v(t)))]\,dt \\
&\geq 0 \qquad \forall\, v(\cdot)\in U_{\mathrm{ad}}.
\end{aligned} \tag{2.9}
$$

The reader will see later that since the state variable ρ appears in the optimal control problem in a linear way, some adjoint processes are superfluous in the above maximum principle. Now we begin to dispense with these adjoint processes and reformulate the above maximum principle.

We introduce a new Hamiltonian $\mathcal{H}: [0,1]\times\mathbb{R}^n\times U\times\mathbb{R}^n\times\mathbb{R}^{n\times m}\times\mathbb{R}^d\times\mathbb{R}^{n\times d}\to\mathbb{R}$ as follows:

$$
\begin{aligned}
\mathcal{H}(t,x,v,q,k,\widetilde{R},\widetilde{k}) :=\ & \langle q, f(t,x,v)\rangle + \langle k^i, g^i(t,x,v)\rangle \\
&+ \widetilde{R}^j h^j(t,x,v) + \langle \widetilde{k}^j, \widetilde{g}^j(t,x,v)\rangle + l(t,x,v)
\end{aligned} \tag{2.10}
$$

$\forall\, t\in[0,1], x\in\mathbb{R}^n, v\in U, q\in\mathbb{R}^n, k\in\mathbb{R}^{n\times m}, \widetilde{R}\in\mathbb{R}^d, \widetilde{k}\in\mathbb{R}^{n\times d}$.

Decompose the matrices $a(t); b(t); \widetilde{b}(t); A(t);\ B^i(t), i=1,\dots,m;$ and $\widetilde{B}^j(t), j=1,\dots,d,$ into blocks in the following manner:

$$
\begin{aligned}
a(t) &= \begin{pmatrix} a_1(t)\\ a_2(t)\end{pmatrix}\begin{matrix}\}1\\ \}n\end{matrix}, \quad b(t) = \begin{pmatrix} b_1(t)\\ b_2(t)\end{pmatrix}\begin{matrix}\}1\\ \}n\end{matrix}, \quad \widetilde{b}(t) = \begin{pmatrix} \widetilde{b}_1(t)\\ \widetilde{b}_2(t)\end{pmatrix}\begin{matrix}\}1\\ \}n\end{matrix}, \\
A(t) &= \begin{matrix} \\ 1\{\\ n\{\end{matrix}\begin{pmatrix} \overbrace{A_{11}(t)}^{1} & \overbrace{A_{12}(t)}^{n} \\ A_{21}(t) & A_{22}(t)\end{pmatrix}, \\
B^i(t) &= \begin{matrix} \\ 1\{\\ n\{\end{matrix}\begin{pmatrix} \overbrace{B^i_{11}(t)}^{1} & \overbrace{B^i_{12}(t)}^{n} \\ B^i_{21}(t) & B^i_{22}(t)\end{pmatrix}, \quad i=1,\dots,m, \\
\widetilde{B}^j(t) &= \begin{matrix} \\ 1\{\\ n\{\end{matrix}\begin{pmatrix} \overbrace{\widetilde{B}^j_{11}(t)}^{1} & \overbrace{\widetilde{B}^j_{12}(t)}^{n} \\ \widetilde{B}^j_{21}(t) & \widetilde{B}^j_{22}(t)\end{pmatrix}, \quad j=1,\dots,d.
\end{aligned} \tag{2.11}
$$

Then, we can check the following

$$
\begin{aligned}
F_X(t,X,v) &:= (F_\rho(t,X,v), F_x(t,X,v)) \\
&= \begin{pmatrix} 0 & 0 \\ 0 & f_x(t,x,v) - \widetilde{g}^j_x(t,x,v)h^j(t,x,v) - \widetilde{g}(t,x,v)h_x(t,x,v) \end{pmatrix}, \\
G^i_X(t,X,v) &:= (G^i_\rho(t,X,v), G^i_x(t,X,v)) = \begin{pmatrix} 0 & 0 \\ 0 & g^i_x(t,x,v) \end{pmatrix}, \\
\widetilde{G}^j_X(t,X,v) &:= (\widetilde{G}^j_\rho(t,X,v), \widetilde{G}^j_x(t,X,v)) = \begin{pmatrix} h^j(t,x,v) & \rho h^j_x(t,x,v) \\ 0 & \widetilde{g}^j_x(t,x,v) \end{pmatrix}, \\
L_X(t,X,v) &:= (L_\rho(t,X,v), L_x(t,X,v)) = (l(t,x,v), \rho l_x(t,x,v)), \\
M_X(X) &:= (M_\rho(X), M_x(X)) = (m(x), \rho m_x(x)),
\end{aligned} \tag{2.12}
$$

$$
\begin{aligned}
&H(t,X,v,a,b,\widetilde{b}) \\
&= \langle a_2, f(t,x,v) - \widetilde{g}h(t,x,v)\rangle + \langle b^i_2, g^i(t,x,v)\rangle \\
&\quad + \langle \widetilde{b}^j_2, \widetilde{g}^j(t,x,v)\rangle + \langle \widetilde{b}^*_1, \rho h(t,x,v)\rangle + \rho l(t,x,v), \\
&H_X(t,X,v,a,b,\widetilde{b}) := \Big(H_\rho(t,X,v,a,b,\widetilde{b}), H_x(t,X,v,a,b,\widetilde{b})\Big) \\
&= \Big(l(t,x,v) + \langle \widetilde{b}^*_1, h(t,x,v)\rangle, H_x(t,X,v,a,b,\widetilde{b})\Big), \\
&H_{XX}(t,X,v,a,b,\widetilde{b}) := \begin{pmatrix} H_{\rho\rho}(t,X,v,a,b,\widetilde{b}) & H_{x\rho}(t,X,v,a,b,\widetilde{b}) \\ H_{\rho x}(t,X,v,a,b,\widetilde{b}) & H_{xx}(t,X,v,a,b,\widetilde{b}) \end{pmatrix} \\
&= \begin{pmatrix} 0 & l_x(t,x,v) + \widetilde{b}_1 h_x(t,x,v) \\ l^*_x(t,x,v) + h^*_x(t,x,v)\widetilde{b}^*_1 & H_{xx}(t,X,v,a,b,\widetilde{b}) \end{pmatrix}, \\
&H_x(t,X,v,a,b,\widetilde{b}) \\
&= \rho \mathcal{H}_x(t,x,v,\rho^{-1}a_2, \rho^{-1}b_2, \widetilde{b}_1 - \rho^{-1}a^*_2\widetilde{g}(t,x,v), \rho^{-1}[\widetilde{b}_2 - a_2 h^*(t,x,v)]), \\
&H_{xx}(t,X,v,a,b,\widetilde{b}) \\
&= \rho \mathcal{H}_{xx}(t,x,v,\rho^{-1}a_2, \rho^{-1}b_2, \widetilde{b}_1 - \rho^{-1}a^*_2\widetilde{g}(t,x,v), \rho^{-1}[\widetilde{b}_2 - a_2 h^*(t,x,v)]) \\
&\quad - \widetilde{g}^{j*}_x(t,x,v)a_2 h^j_x(t,x,v) - h^{j*}_x(t,x,v)a^*_2\widetilde{g}^j_x(t,x,v).
\end{aligned} \tag{2.13}
$$

In view of the above calculations, equation (2.7) is decomposed into the following two equations:

$$
\begin{cases}
da_1(t) = -\left[l(t,\widehat{x}(t),\widehat{u}(t)) + \langle \widetilde{b}^*_1(t), h(t,\widehat{x}(t),\widehat{u}(t))\rangle\right] dt \\
\qquad\qquad + b_1(t)\, dw(t) + \widetilde{b}_1(t)\, dY(t), \quad t \in [0,1), \\
a_1(1) = m(\widehat{x}(1))
\end{cases} \tag{2.14}
$$

and

$$
\begin{cases}
da_2(t) = -H^*_x(t,\widehat{X}(t),\widehat{u}(t),a(t),b(t),\widetilde{b}(t))\, dt \\
\qquad\qquad + b_2(t)\, dw(t) + \widetilde{b}_2(t)\, dY(t), \quad t \in [0,1), \\
a_2(1) = \widehat{\rho}(1) m^*_x(\widehat{x}(1)),
\end{cases} \tag{2.15}
$$

while equation (2.8) is decomposed into the following four equations:

$$\begin{cases} dA_{11}(t) = -\{h^*h(t,\widehat{x}(t),\widehat{u}(t))A_{11}(t) + 2\widetilde{B}^j_{11}(t)h^j(t,\widehat{x}(t),\widehat{u}(t))\}\,dt \\ \qquad\qquad + B^i_{11}(t)\,dw^i(t) + \widetilde{B}^j_{11}(t)\,dY^j(t), \quad t\in[0,1), \\ A_{11}(1) = 0, \end{cases} \tag{2.16}$$

(2.17)

$$\begin{cases} dA_{21}(t) = -[\mathcal{H}^*_x(t,\widehat{x}(t),\widehat{u}(t);A_{21}(t),B_{21}(t),\widetilde{b}_1(t) - A^*_{21}(t)\widetilde{g}(t,\widehat{x}(t),\widehat{u}(t)),\widetilde{B}_{21}(t)) \\ \qquad\qquad + \widehat{\rho}(t)h^*_x(t,\widehat{x}(t),\widehat{u}(t))h(t,\widehat{x}(t),\widehat{u}(t))A_{11}(t) + \widehat{\rho}(t)h^{j*}_x(t,\widehat{x}(t),\widehat{u}(t))\widetilde{B}^j_{11}(t) \\ \qquad\qquad + \widetilde{B}^j_{21}(t)h^j(t,\widehat{x}(t),\widehat{u}(t))]\,dt \\ \qquad\qquad + B^i_{21}(t)\,dw^i(t) + \widetilde{B}^j_{21}(t)\,dY^j(t), \quad t\in[0,1), \\ A_{21}(1) = m^*_x(\widehat{x}(1)), \end{cases}$$

$$A_{12}(t) = A^*_{21}(t), \quad t\in[0,1], \tag{2.18}$$

and

$$\begin{cases} dA_{22}(t) = -\{f^*_x(t,\widehat{x}(t),\widehat{u}(t))A_{22}(t) + A_{22}(t)f_x(t,\widehat{x}(t),\widehat{u}(t)) \\ \qquad\qquad + g^{i*}_x(t,\widehat{x}(t),\widehat{u}(t))A_{22}(t)g^i_x(t,\widehat{x}(t),\widehat{u}(t)) \\ \qquad\qquad + \widehat{\rho}^2(t)h^{i*}_x(t,\widehat{x}(t),\widehat{u}(t))A_{11}(t)h^i_x(t,\widehat{x}(t),\widehat{u}(t)) \\ \qquad\qquad + \widehat{\rho}(t)\widetilde{g}^{j*}_x(t,\widehat{x}(t),\widehat{u}(t))A_{21}(t)h^j_x(t,\widehat{x}(t),\widehat{u}(t)) \\ \qquad\qquad + \widehat{\rho}(t)h^{j*}_x(t,\widehat{x}(t),\widehat{u}(t))A_{12}(t)\widetilde{g}^j_x(t,\widehat{x}(t),\widehat{u}(t)) \\ \qquad\qquad + \widetilde{g}^{j*}_x(t,\widehat{x}(t),\widehat{u}(t))A_{22}(t)\widetilde{g}^j_x(t,\widehat{x}(t),\widehat{u}(t)) \\ \qquad\qquad + B^i_{22}(t)g^i_x(t,\widehat{x}(t),\widehat{u}(t)) + g^{i*}_x(t,\widehat{x}(t),\widehat{u}(t))B^i_{22}(t) \\ \qquad\qquad + (\widehat{\rho}(t)\widetilde{B}_{21}(t) - A_{22}(t)\widetilde{g}(t,\widehat{x}(t),\widehat{u}(t)))h_x(t,\widehat{x}(t),\widehat{u}(t)) \\ \qquad\qquad + (\widetilde{B}^j_{22}(t) - A_{22}(t)h^j(t,\widehat{x}(t),\widehat{u}(t)))\widetilde{g}^j_x(t,\widehat{x}(t),\widehat{u}(t)) \\ \qquad\qquad + h^*_x(t,\widehat{x}(t),\widehat{u}(t))(\widehat{\rho}(t)\widetilde{B}_{12}(t) - \widetilde{g}^*(t,\widehat{x}(t),\widehat{u}(t))A_{22}(t)) \\ \qquad\qquad + \widetilde{g}^{j*}_x(t,\widehat{x}(t),\widehat{u}(t))(\widetilde{B}^j_{22}(t) - h^j(t,\widehat{x}(t),\widehat{u}(t))A_{22}(t)) \\ \qquad\qquad + H_{xx}(t,\widehat{X}(t),\widehat{u}(t),a(t),b(t),\widetilde{b}(t))\}\,dt \\ \qquad\qquad + B^i_{22}(t)\,dw^i(t) + \widetilde{B}^j_{22}(t)\,dY^j(t), \quad t\in[0,1), \\ A_{22}(1) = \widehat{\rho}(1)m_{xx}(\widehat{x}(1)). \end{cases} \tag{2.19}$$

We can obtain, from the uniqueness of the $\mathcal{F}_t$-adapted square integrable solution of the BSDE (2.16) (see Pardoux and Peng [9]),

$$A_{11} = 0, \quad B_{11} := (B^1_{11},\dots,B^m_{11}) = 0, \quad \widetilde{B}_{11} := (\widetilde{B}^1_{11},\dots,\widetilde{B}^d_{11}) = 0, \tag{2.20}$$

and then establish from (2.15), (2.17), via Itô's formula, the following relations:

$$\begin{aligned} &A_{21}(t) = \widehat{\rho}^{-1}(t)a_2(t), \quad B^i_{21}(t) = \widehat{\rho}^{-1}(t)b^i_2(t), \\ &\widetilde{B}^j_{21}(t) = \widehat{\rho}^{-1}(t)\widetilde{b}^j_2(t) - \widehat{\rho}^{-1}(t)a_2(t)h^j(t,\widehat{x}(t),\widehat{u}(t)). \end{aligned} \tag{2.21}$$

Moreover, if we set

$$
\begin{aligned}
&r(t) := a_1(t), \quad R(t) := b_1(t), \quad \widetilde{R}(t) := \widetilde{b}_1(t),\\
&q(t) := \widehat{\rho}^{-1}(t)a_2(t), \quad k(t) := \widehat{\rho}^{-1}(t)b_2(t),\\
&\widetilde{k}(t) := \widehat{\rho}^{-1}(t)\widetilde{b}_2(t) - \widehat{\rho}^{-1}(t)a_2(t)h^*(t,\widehat{x}(t),\widehat{u}(t)),\\
&Q(t) := \widehat{\rho}^{-1}(t)A_{22}(t), \quad K^i(t) := \widehat{\rho}^{-1}(t)B^i_{22}(t),\\
&\widetilde{K}^j(t) := \widehat{\rho}^{-1}(t)\widetilde{B}^j_{22}(t) - \widehat{\rho}^{-1}(t)A_{22}(t)h^j(t,\widehat{x}(t),\widehat{u}(t)),
\end{aligned}
\tag{2.22}
$$

then $(r, R^i,\, i = 1,\dots,m;\, \widetilde{R}^j,\, j = 1,\dots,d)$ is characterized as the unique $\mathcal{F}_t$-adapted solution of the following BSDE:

$$
\begin{cases}
dr(t) = -\{l(t,\widehat{x}(t),\widehat{u}(t)) + \widetilde{R}^j(t)h^j(t,\widehat{x}(t),\widehat{u}(t))\}\,dt\\
\qquad\quad + R^i(t)\,dw^i(t) + \widetilde{R}^j(t)\,dY^j(t), \quad t \in [0,1),\\
r(1) = m(\widehat{x}(1));
\end{cases}
\tag{2.23}
$$

$(q, k^i, i = 1,\dots,m; \widetilde{k}^j, j = 1,\dots,d)$ solves

(2.24)

$$
\begin{cases}
dq(t) = -\{\mathcal{H}^*_x(t,\widehat{x}(t),\widehat{u}(t);q(t),k(t),\widetilde{R}(t) - q^*(t)\widetilde{g}(t,\widehat{x}(t),\widehat{u}(t)),\widetilde{k}(t))\\
\qquad\quad + \widetilde{k}^j(t)h^j(t,\widehat{x}(t),\widehat{u}(t))\}\,dt + k^i(t)\,dw^i(t) + \widetilde{k}^j(t)\,dY^j(t), \quad t \in [0,1),\\
q(1) = m^*_x(\widehat{x}(1));
\end{cases}
$$

and $(Q, K^i, i = 1,\dots,m; \widetilde{K}^j, j = 1,\dots,d)$ solves

$$
\begin{cases}
\begin{aligned}
dQ(t) = -\{&f^*_x(t,\widehat{x}(t),\widehat{u}(t))Q(t) + Q(t)f_x(t,\widehat{x}(t),\widehat{u}(t))\\
&+ g^{i*}_x(t,\widehat{x}(t),\widehat{u}(t))Q(t)g^i_x(t,\widehat{x}(t),\widehat{u}(t))\\
&+ \widetilde{g}^{j*}_x(t,\widehat{x}(t),\widehat{u}(t))Q(t)\widetilde{g}^j_x(t,\widehat{x}(t),\widehat{u}(t))\\
&+ g^{i*}_x(t,\widehat{x}(t),\widehat{u}(t))K^i(t) + K^i(t)g^i_x(t,\widehat{x}(t),\widehat{u}(t))\\
&+ \widetilde{g}^{j*}_x(t,\widehat{x}(t),\widehat{u}(t))\widetilde{K}^j(t) + \widetilde{K}^j(t)\widetilde{g}^j_x(t,\widehat{x}(t),\widehat{u}(t))\\
&+ \mathcal{H}_{xx}(t,\widehat{x}(t),\widehat{u}(t),q(t),k(t),\widetilde{R}(t) - q^*(t)\widetilde{g}(t,\widehat{x}(t),\widehat{u}(t)),\widetilde{k}(t))\\
&+ \widetilde{K}^j(t)h^j(t,\widehat{x}(t),\widehat{u}(t))\\
&+ (\widetilde{k}(t) - Q(t)\widetilde{g}(t,\widehat{x}(t),\widehat{u}(t)))h_x(t,\widehat{x}(t),\widehat{u}(t))\\
&+ h^*_x(t,\widehat{x}(t),\widehat{u}(t))(\widetilde{k}^*(t) - \widetilde{g}^*(t,\widehat{x}(t),\widehat{u}(t))Q(t))\}\,dt\\
&+ K^i(t)\,dw^i(t) + \widetilde{K}^j(t)\,dY^j(t), \quad t \in [0,1),
\end{aligned}\\
Q(1) = m_{xx}(\widehat{x}(1)).
\end{cases}
\tag{2.25}
$$

The rest of this section is to rewrite the maximum condition (2.9). We can verify the following:

$$
\begin{aligned}
&\widehat{\rho}^{-1}(t)\{H(t,\widehat{X}(t),v(t),a(t),b(t),\widetilde{b}(t)) - H(t,\widehat{X}(t),\widehat{u}(t),a(t),b(t),\widetilde{b}(t))\}\\
&= \Delta\mathcal{H}(t,\widehat{x}(t),\widehat{u}(t),q(t),k(t),\widetilde{R}(t) - q^*(t)\widetilde{g}(t,\widehat{x}(t),\widehat{u}(t)),\widetilde{k}(t);v(t))\\
&\quad - \langle q(t), \Delta\widetilde{g}(t;v(t))\Delta h(t;v(t))\rangle,
\end{aligned}
\tag{2.26}
$$

(2.27)
$$
\begin{aligned}
A(t) &= \begin{pmatrix} 0 & q^*(t) \\ q(t) & \widehat{\rho}(t)Q(t) \end{pmatrix}, \\
\Delta G(t;v(t)) &= \begin{pmatrix} 0 \\ \Delta g(t;v(t)) \end{pmatrix}, \\
\Delta \widetilde{G}(t;v(t)) &= \begin{pmatrix} \widehat{\rho}(t)\Delta h^*(t;v(t)) \\ \Delta \widetilde{g}(t;v(t)) \end{pmatrix}, \\
\Delta G(t;v(t))\Delta G^*(t;v(t)) &= \begin{pmatrix} 0 & 0 \\ 0 & \Delta g(t;v(t))\Delta g^*(t;v(t)) \end{pmatrix}, \\
&\Delta \widetilde{G}(t;v(t))\Delta \widetilde{G}^*(t;v(t)) \\
&= \begin{pmatrix} \widehat{\rho}^{\,2}(t)\Delta h^*(t;v(t))\Delta h(t;v(t)) & \widehat{\rho}(t)\Delta h^*(t;v(t))\Delta \widetilde{g}^*(t;v(t)) \\ \widehat{\rho}(t)\Delta \widetilde{g}(t;v(t))\Delta h(t;v(t)) & \Delta \widetilde{g}(t;v(t))\Delta \widetilde{g}^*(t;v(t)) \end{pmatrix},
\end{aligned}
$$

$$
\begin{aligned}
&\operatorname{tr}[A(t)(\Delta G(t;v(t))\Delta G^*(t;v(t)) + \Delta \widetilde{G}(t;v(t))\Delta \widetilde{G}^*(t;v(t)))] \\
&= 2q^*(t)\Delta \widetilde{g}(t;v(t))\Delta h(t;v(t))\widehat{\rho}(t) \qquad (2.28) \\
&\quad + \widehat{\rho}(t)\operatorname{tr}[Q(t)(\Delta g(t;v(t))\Delta g^*(t;v(t)) + \Delta \widetilde{g}(t;v(t))\Delta \widetilde{g}^*(t;v(t)))].
\end{aligned}
$$

Then the maximum condition (2.9) can be rewritten as

$$
\begin{aligned}
&\widehat{E}\int_0^1 \Delta \mathcal{H}(t,\widehat{x}(t),\widehat{u}(t),q(t),k(t),\widetilde{R}(t) - q^*(t)\widetilde{g}(t,\widehat{x}(t),\widehat{u}(t)),\widetilde{k}(t);v(t))\,dt \\
&+ \frac{1}{2}\widehat{E}\int_0^1 \operatorname{tr}\left[Q(t)\left(\Delta g(t;v(t))\Delta g^*(t;v(t)) + \Delta \widetilde{g}(t;v(t))\Delta \widetilde{g}^*(t;v(t))\right)\right]\,dt \qquad (2.29) \\
&\geq 0 \qquad \forall\, v(\cdot) \in U_{\mathrm{ad}}.
\end{aligned}
$$

THEOREM 2.1. *Assume that the hypothesis* $(\mathcal{A}1)$ *holds. Let* $\widehat{u}(\cdot)$ *be an optimal control and* $(r, R^i, i = 1,\dots,m; \widetilde{R}^j, j = 1,\dots,d), (q, k^i, i = 1,\dots,m; \widetilde{k}^j, j = 1,\dots,d)$, *and* $(Q, K^i, i = 1,\dots,m; \widetilde{K}^j, j = 1,\dots,d)$ *be the corresponding* $\mathcal{F}_t$*-adapted square-integrable solutions of BSDEs* (2.23), (2.24), (2.25)*, respectively. Then the maximum condition* (2.29) *holds.*

Note that Theorem 2.1 applies to an arbitrary admissible class U_{ad} of controls. In particular, it contains the following two special cases.

REMARK 2.1. *When* $U_{\mathrm{ad}} = \overline{U}_{\mathrm{ad}}$*, the maximum condition* (2.29) *implies the following inequality of expectations conditioned on the past and present observations* $\{Y(s) : 0 \leq s \leq t\}$:

$$
\begin{aligned}
&\widehat{E}[\Delta \mathcal{H}(t,\widehat{x}(t),\widehat{u}(t),q(t),k(t),\widetilde{R}(t) - q^*(t)\widetilde{g}(t,\widehat{x}(t),\widehat{u}(t)),\tilde{k}(t);v)|\mathcal{F}_t^Y] \\
&+ \frac{1}{2}\widehat{E}[\operatorname{tr}[Q(t)(\Delta g(t;v)\Delta g^*(t;v) + \Delta \widetilde{g}(t;v)\Delta \widetilde{g}^*(t;v))]|\mathcal{F}_t^Y] \qquad (2.30) \\
&\geq 0 \qquad \forall\, v \in U,\ a.s.a.e.\ (\textit{almost surely, almost everywhere}).
\end{aligned}
$$

REMARK 2.2. *When* $U_{\mathrm{ad}} = \widetilde{U}_{\mathrm{ad}}$*, the maximum condition* (2.29) *implies the following inequality of expectations conditioned on the present observation* $Y(t)$:

$$
\begin{aligned}
&\widehat{E}[\Delta \mathcal{H}(t,\widehat{x}(t),\widehat{u}(t),q(t),k(t),\widetilde{R}(t) - q^*(t)\widetilde{g}(t,\widehat{x}(t),\widehat{u}(t)),\widetilde{k}(t);v)|\,Y(t)] \\
&+ \frac{1}{2}\widehat{E}[\operatorname{tr}[Q(t)(\Delta g(t;v)\Delta g^*(t;v) + \Delta \widetilde{g}(t;v)\Delta \widetilde{g}^*(t;v))]|\,Y(t)] \qquad (2.31) \\
&\geq 0 \qquad \forall\, v \in U,\ a.s.a.e.
\end{aligned}
$$

We have derived a partially observed maximum principle, without involving at all the well-known Zakai equation, which is a stochastic PDE driven by the observation $Y(\cdot)$. However, our formulation of the maximum principle seems to be unsatisfactory since the adjoint equations (2.23)–(2.25) seem not to tell us what kind of functionals the adjoint processes (as their solutions) are of the initial state x_0 and the system noise $\dot{w}$, which is not available in practice. In the next two sections, we shall show that the adjoint equations do imply how the adjoint processes depend on the initial state x_0 and the system noise $\dot{w}$ in a special way, which is crucial in the computation of the conditional expectation appearing in the maximum condition (see (2.30) and (2.31), for example).

3. Relations among the adjoint processes. Let $\phi^{t,x}$ be the solution of the SDE

$$\begin{cases} d\phi^{t,x}(s) = (f-\widetilde{g}h)(s,\phi^{t,x}(s),\widehat{u}(s))\,ds + g^i(s,\phi^{t,x}(s),\widehat{u}(s))\,dw^i(s) \\ \qquad\qquad + \widetilde{g}^j(s,\phi^{t,x}(s),\widehat{u}(s))\,dY^j(s), \quad s\in(t,1], \\ \phi^{t,x}(t) = x, \end{cases} \tag{3.1}$$

$(r^{t,x}, R^{i,t,x}, i=1,\dots,m; \widetilde{R}^{j,t,x}, j=1,\dots,d)$ be the solution of the BSDE

$$\begin{cases} dr^{t,x}(s) = -\left[l(s,\phi^{t,x}(s),\widehat{u}(s)) + \widetilde{R}^{j,t,x}(s)h^j(s,\phi^{t,x}(s),\widehat{u}(s))\right]ds \\ \qquad\qquad + R^{i,t,x}(s)\,dw^i(s) + \widetilde{R}^{j,t,x}(s)\,dY^j(s), \quad s\in[t,1), \\ r^{t,x}(1) = m(\phi^{t,x}(1)), \end{cases} \tag{3.2}$$

$(q^{t,x}, k^{i,t,x}, i=1,\dots,m; \widetilde{k}^{j,t,x}, j=1,\dots,d)$ be the solution of the vector-valued BSDE

$$\begin{cases} dq^{t,x}(s) \\ = -\left[\mathcal{H}_x^*(s,\phi^{t,x}(s),\widehat{u}(s);q^{t,x}(s),k^{t,x}(s),\widetilde{R}^{t,x}(s) - q^{t,x,*}(s)\widetilde{g}(s,\phi^{t,x}(s),\widehat{u}(s)),\widetilde{k}^{t,x}(s)) \right. \\ \quad \left. + \widetilde{k}^{j,t,x}(s)h^j(s,\phi^{t,x}(s),\widehat{u}(s))\right]ds + k^{i,t,x}(s)\,dw^i(s) + \widetilde{k}^{j,t,x}(s)\,dY^j(s), \quad s\in[t,1), \\ q^{t,x}(1) = m_x^*(\phi^{t,x}(1)), \end{cases} \tag{3.3}$$

and $(Q^{t,x}, K^{i,t,x}, i=1,\dots,m; \widetilde{K}^{j,t,x}, j=1,\dots,d)$ be the solution of the matrix-valued BSDE

(3.4)
$$\begin{cases} dQ^{t,x}(s) \\ = -\{f_x^*(s,\phi^{t,x}(s),\widehat{u}(s))Q^{t,x}(s) + Q^{t,x}(s)f_x(s,\phi^{t,x}(s),\widehat{u}(s)) \\ \quad + g_x^{i*}(s,\phi^{t,x}(s),\widehat{u}(s))Q^{t,x}(s)g_x^i(s,\phi^{t,x}(s),\widehat{u}(s)) \\ \quad + \widetilde{g}_x^{j*}(s,\phi^{t,x}(s),\widehat{u}(s))Q^{t,x}(s)\widetilde{g}_x^j(s,\phi^{t,x}(s),\widehat{u}(s)) \\ \quad + g_x^{i*}(s,\phi^{t,x}(s),\widehat{u}(s))K^{i,t,x}(s) + K^{i,t,x}(s)g_x^i(s,\phi^{t,x}(s),\widehat{u}(s)) \\ \quad + \widetilde{g}_x^{j*}(s,\phi^{t,x}(s),\widehat{u}(s))\widetilde{K}^{j,t,x}(s) + \widetilde{K}^{j,t,x}(s)\widetilde{g}_x^j(s,\phi^{t,x}(s),\widehat{u}(s)) \\ \quad + \mathcal{H}_{xx}(s,\phi^{t,x}(s),\widehat{u}(s),q^{t,x}(s),k^{t,x}(s),\widetilde{R}^{t,x}(s) - q^{t,x,*}(s)\widetilde{g}(s,\phi^{t,x}(s),\widehat{u}(s)),\widetilde{k}^{t,x}(s)) \\ \quad + \widetilde{K}^{j,t,x}(s)h^j(s,\phi^{t,x}(s),\widehat{u}(s)) \\ \quad + (\widetilde{k}^{t,x}(s) - Q^{t,x}(s)\widetilde{g}(s,\phi^{t,x}(s),\widehat{u}(s)))h_x(s,\phi^{t,x}(s),\widehat{u}(s)) \\ \quad + h_x^*(s,\phi^{t,x}(s),\widehat{u}(s))(\widetilde{k}^{t,x,*}(s) - \widetilde{g}^*(s,\phi^{t,x}(s),\widehat{u}(s))Q^{t,x}(s))\}\,ds \\ \quad + K^{i,t,x}(s)\,dw^i(s) + \widetilde{K}^{j,t,x}(s)\,dY^j(s), \quad s\in[t,1), \\ Q^{t,x}(1) = m_{xx}(\phi^{t,x}(1)). \end{cases}$$

Obviously,

$$\begin{aligned} \phi^{0,x_0} &= \widehat{x}, \\ (r^{0,x_0}, R^{0,x_0}, \widetilde{R}^{0,x_0}) &= (r, R, \widetilde{R}), \\ (q^{0,x_0}, k^{i,0,x_0}, \widetilde{k}^{j,0,x_0}) &= (q, k^i, \widetilde{k}^j), \\ (Q^{0,x_0}, K^{i,0,x_0}, \widetilde{K}^{j,0,x_0}) &= (Q, K^i, \widetilde{K}^j). \end{aligned} \tag{3.5}$$

Under the hypothesis $(\mathcal{A}1)$, the stochastic flows $\phi^{t,x}$, $(r^{t,x}, R^{t,x}, \widetilde{R}^{t,x})$, and $(q^{t,x}, k^{i,t,x}, i=1,\dots,m; \widetilde{k}^{j,t,x}, j=1,\dots,d)$ are continuously differentiable with respect to x in suitable spaces (see Pardoux and Peng [10]). Their differentials $\phi_x^{t,x}$, $(\nabla r^{t,x}, \nabla R^{i,t,x}, i=1,\dots,m; \nabla\widetilde{R}^{j,t,x}, j=1,\dots,d)$, and $(q_x^{t,x}, k_x^{i,t,x}, i=1,\dots,m; \widetilde{k}_x^{j,t,x}, j=1,\dots,d)$ satisfy, respectively, the following SDE and BSDEs (see Pardoux and Peng [10]):

$$\begin{cases} d\phi_x^{t,x}(s) = (f - \widetilde{g}h)_x(s,\phi^{t,x}(s),\widehat{u}(s))\phi_x^{t,x}(s)\,ds \\ \qquad\qquad + g_x^i(s,\phi^{t,x}(s),\widehat{u}(s))\phi_x^{t,x}(s)\,dw^i(s) \\ \qquad\qquad + \widetilde{g}_x^j(s,\phi^{t,x}(s),\widehat{u}(s))\phi_x^{t,x}(s)\,dY^j(s), \quad s\in(t,1], \\ \phi_x^{t,x}(t) = I_{n\times n} : \text{identity matrix of order } n\times n, \end{cases} \tag{3.6}$$

$$\begin{cases} d\nabla r^{t,x}(s) = -\{\phi_x^{t,x,*}(s)l_x^*(s,\phi^{t,x}(s),\widehat{u}(s)) \\ \qquad\qquad + \phi_x^{t,x,*}(s)h_x^{j*}(s,\phi^{t,x}(s),\widehat{u}(s))\widetilde{R}^{j,t,x}(s) \\ \qquad\qquad + \nabla\widetilde{R}^{j,t,x}(s)h^j(s,\phi^{t,x}(s),\widehat{u}(s))\}\,ds \\ \qquad\qquad + \nabla R^{i,t,x}(s)\,dw^i(s) + \nabla\widetilde{R}^{j,t,x}(s)\,dY^j(s), \quad s\in[t,1), \\ \nabla r^{t,x}(1) = \phi_x^{t,x,*}(1)m_x^*(\phi^{t,x}(1)), \end{cases} \tag{3.7}$$

and

(3.8)
$$\begin{cases} dq_x^{t,x}(s) \\ = -\{\mathcal{H}_{xx}(s,\phi^{t,x}(s),\widehat{u}(s);q^{t,x}(s),k^{t,x}(s),\widetilde{R}^{t,x}(s)-q^{t,x,*}(s)\widetilde{g}(s,\phi^{t,x}(s),\widehat{u}(s)),\widetilde{k}^{t,x}(s)) \\ \quad\times\phi_x^{t,x}(s)+f_x^*(s,\phi^{t,x}(s),\widehat{u}(s))q_x^{t,x}(s)+g_x^{i*}(s,\phi^{t,x}(s),\widehat{u}(s))k_x^{i,t,x}(s) \\ \quad+h_x^{j*}(s,\phi^{t,x}(s),\widehat{u}(s))[\widetilde{R}_x^{j,t,x}(s)-q^{t,x,*}(s)\widetilde{g}_x^j(s,\phi^{t,x}(s),\widehat{u}(s)) \\ \quad-\widetilde{g}^{j*}(s,\phi^{t,x}(s),\widehat{u}(s))q_x^{t,x}(s)] \\ \quad+\widetilde{g}_x^{j*}(s,\phi^{t,x}(s),\widehat{u}(s))\widetilde{k}_x^{j,t,x}(s)+\widetilde{k}^{j,t,x}(s)h_x^j(s,\phi^{t,x}(s),\widehat{u}(s))\phi_x^{t,x}(s) \\ \quad+\widetilde{k}_x^{j,t,x}(s)h^j(s,\phi^{t,x}(s),\widehat{u}(s))\}\,ds+k_x^{i,t,x}(s)\,dw^i(s)+\widetilde{k}_x^{j,t,x}(s)\,dY^j(s), \quad s\in[t,1), \\ q_x^{t,x}(1)=m_{xx}(\phi^{t,x}(1))\phi_x^{t,x}(1). \end{cases}$$

Here and in the following, $\nabla r^{t,x} := (r_x^{t,x})^*$ and similar notations are made for $R^{i,t,x}$, $\widetilde{R}^{j,t,x}$ and other functions W, Z, V.

Using Itô's formula, we obtain the equation for the stochastic process $\{[\phi_x^{t,x}(s)]^{-1}; t \le s \le 1\}$:

$$\begin{cases} d[\phi_x^{t,x}(s)]^{-1} = -[\phi_x^{t,x}(s)]^{-1}\{(f-\widetilde{g}h)_x(s,\phi^{t,x}(s),\widehat{u}(s)) \\ \qquad\qquad -g_x^i(s,\phi^{t,x}(s),\widehat{u}(s))^2-\widetilde{g}_x^j(s,\phi^{t,x}(s),\widehat{u}(s))^2\}\,ds \\ \qquad\qquad -[\phi_x^{t,x}(s)]^{-1}g_x^i(s,\phi^{t,x}(s),\widehat{u}(s))\,dw^i(s) \\ \qquad\qquad -[\phi_x^{t,x}(s)]^{-1}\widetilde{g}_x^j(s,\phi^{t,x}(s),\widehat{u}(s))\,dY^j(s), \quad s\in(t,1], \\ [\phi_x^{t,x}(t)]^{-1} = I_{n\times n}. \end{cases} \tag{3.9}$$

From the uniqueness of the solutions of (3.3) and (3.4), we can check, using Itô's formula, the following theorem.

THEOREM 3.1. *Let the hypothesis* $(\mathcal{A}1)$ *be satisfied. Then, for* $s\in[t,1]$,

$$\begin{aligned} q^{t,x}(s) &= [\phi_x^{t,x,*}(s)]^{-1}\nabla r^{t,x}(s), \\ k^{i,t,x}(s) &= [\phi_x^{t,x,*}(s)]^{-1}\nabla R^{i,t,x}(s)-g_x^{i*}(s,\phi^{t,x}(s),\widehat{u}(s))q^{t,x}(s), \\ \widetilde{k}^{j,t,x}(s) &= [\phi_x^{t,x,*}(s)]^{-1}\nabla \widetilde{R}^{j,t,x}(s)-\widetilde{g}_x^{j*}(s,\phi^{t,x}(s),\widehat{u}(s))q^{t,x}(s); \\ Q^{t,x}(s) &= q_x^{t,x}(s)[\phi_x^{t,x}(s)]^{-1}, \\ K^{i,t,x}(s) &= k_x^{i,t,x}(s)[\phi_x^{t,x}(s)]^{-1}-Q^{t,x}(s)g_x^i(s,\phi^{t,x}(s),\widehat{u}(s)), \\ \widetilde{K}^{j,t,x}(s) &= \widetilde{k}_x^{j,t,x}(s)[\phi_x^{t,x}(s)]^{-1}-Q^{t,x}(s)\widetilde{g}_x^j(s,\phi^{t,x}(s),\widehat{u}(s)). \end{aligned} \tag{3.10}$$

Note that the uncertainty of the solution to a BSDE is introduced by the uncertainty of the drift and the terminal value, rather than by the terms of stochastic integrals. There are two different sources of uncertainty in the drifts and the terminal conditions of BSDEs (3.2)–(3.4): one comes from the initial state x_0 and the system noise $\dot{w}(\cdot)$, and the other comes from the observation noise $\dot{Y}(\cdot)$. The former enter into the drifts and the terminal conditions via $\phi^{t,x}(\cdot)$. Thus, we have reason to expect that the corresponding solutions depend on x_0 and $\dot{w}(\cdot)$ in the same manner. In fact, it is true at least under some reasonable conditions. The following theorem reveals such an assertion. We use D_x to denote the differential operator along the direction x, namely, $D_x := x^*\nabla$.

THEOREM 3.2. *Let the hypothesis* $(\mathcal{A}1)$ *be satisfied. Then*

$$\begin{aligned} &r^{t,x}(s) = W(s,\phi^{t,x}(s)), \qquad R^{i,t,x}(s) = D_{g^i(s,\phi^{t,x}(s),\widehat{u}(s))}W(s,\phi^{t,x}(s));\\ &q^{t,x}(s) = \nabla W(s,\phi^{t,x}(s)), \quad k^{i,t,x}(s) = D_{g^i(s,\phi^{t,x}(s),\widehat{u}(s))}\nabla W(s,\phi^{t,x}(s));\\ &Q^{t,x}(s) = \nabla^2 W(s,\phi^{t,x}(s)) := W_{xx}(s,\phi^{t,x}(s)). \end{aligned} \tag{3.11}$$

Here, $W(t,x) := r^{t,x}(t)$ *is a stochastic flow which is adapted to the history (including the present) of the observation* $Y(\cdot)$*. Let* $\mu^{t,x}$ *be the solution of the SDE*

$$\begin{cases} d\mu^{t,x}(s) = \mu^{t,x}(s)h^*(s,\phi^{t,x}(s),\widehat{u}(s))\,dY(s), \quad s\in(t,1],\\ \mu^{t,x}(t) = 1. \end{cases} \tag{3.12}$$

Then, $W(\cdot,\cdot)$ *has the following probabilistic interpretation:*

$$W(t,x) = E\bigg[\int_t^1 \mu^{t,x}(s)l(s,\phi^{t,x}(s),\widehat{u}(s))\,ds + \mu^{t,x}(1)m(\phi^{t,x}(1)) \,\bigg|\, \mathcal{F}_t^Y\bigg]. \tag{3.13}$$

Proof of Theorem 3.2. From the uniqueness of the solutions of (3.1) and (3.2), we derive

$$\phi^{t,x}(\tau) = \phi^{s,\phi^{t,x}(s)}(\tau), \quad r^{t,x}(\tau) = r^{s,\phi^{t,x}(s)}(\tau), \quad t\le s\le\tau\le 1. \tag{3.14}$$

The first relation of (3.11) then follows.

It can be verified, via Malliavin's calculus for the BSDE (3.2), as in Pardoux and Peng [10], that

$$R^{i,t,x}(s) = g^{i*}(s,\phi^{t,x}(s),\widehat{u}(s))[\phi_x^{t,x,*}(s)]^{-1}\nabla r^{t,x}(s). \tag{3.15}$$

In view of the first relation of (3.11), we get the second relation of (3.11).

The third relation of (3.11) comes from the second relation of (3.14) and the first relation of (3.10), while the fourth relation of (3.11) comes from the second relation of (3.10), and the fifth relation of (3.11) comes from the fourth relation of (3.10).

The probabilistic interpretation (3.13) of W can be obtained from computing the quantity $r^{t,x}(s)\mu^{t,x}(s)$ with Itô's formula. □

It is worth noting that, if $\widehat{u}(t) = \beta(t,Y(t))\ \forall\, t\in[0,1]$, for some U-valued Borel function β on $[0,1]\times\mathbb{R}^d$, then $W(t,x) = \overline{W}(t,x,Y(t))$ with

$$\begin{aligned} \overline{W}(t,x,y) := {}& E\int_t^1 \zeta^{t,x,y}(s)l(s,\Phi^{t,x,y}(s),\beta(s,y+Y(s)-Y(t)))\,ds\\ &+ E[\zeta^{t,x,y}(1)m(\Phi^{t,x,y}(1))] \quad \forall\, t\in[0,1],\ x\in\mathbb{R}^n,\ y\in\mathbb{R}^d. \end{aligned} \tag{3.16}$$

Here, $\Phi^{t,x,y}$ and $\zeta^{t,x,y}$ are the solutions of the SDEs

$$\begin{cases} d\Phi^{t,x,y}(s) = (f-\widetilde{g}h)(s,\Phi^{t,x,y}(s),\beta(s,y+Y(s)-Y(t)))\,ds\\ \qquad\qquad + g^i(s,\Phi^{t,x,y}(s),\beta(s,y+Y(s)-Y(t)))\,dw^i(s)\\ \qquad\qquad + \widetilde{g}^j(s,\Phi^{t,x,y}(s),\beta(s,y+Y(s)-Y(t)))\,dY^j(s), \quad s\in(t,1],\\ \Phi^{t,x,y}(t) = x \end{cases} \tag{3.17}$$

and

$$\begin{cases} d\zeta^{t,x,y}(s) = \zeta^{t,x,y}(s)h^*(s,\Phi^{t,x,y}(s),\beta(s,y+Y(s)-Y(t)))\,dY(s), \quad s\in(t,1],\\ \zeta^{t,x,y}(t)=1, \end{cases} \tag{3.18}$$

respectively. It can be checked that $\overline{W}$ is the unique viscosity solution of the following Hamilton–Jacobi equation of second order:

$$\begin{cases} \dfrac{1}{2}\mathrm{tr}[(gg^*+\widetilde{g}\,\widetilde{g}^*)(t,x,\beta(t,y))\overline{W}_{xx}]\\ +\mathrm{tr}[\widetilde{g}(t,x,\beta(t,y))\overline{W}_{xy}]+\dfrac{1}{2}\mathrm{tr}(\overline{W}_{yy})\\ +\langle f(t,x,\beta(t,y)),\overline{W}_x^*\rangle+\langle h(t,x,\beta(t,y)),\overline{W}_y^*\rangle+l(t,x,\beta(t,y))\\ =0, \quad t\in[0,1),\ x\in\mathbb{R}^n,\ y\in\mathbb{R}^d,\\ \overline{W}(1,x,y)=m(x), \quad x\in\mathbb{R}^n,\ y\in\mathbb{R}^d, \end{cases} \tag{3.19}$$

at least when the function β is bounded and continuous and when the coefficients $f,g,\widetilde{g},h,$ and l are jointly continuous with respect to all their arguments.

4. BSPDEs of adjoint vector fields. In this section, adjoint vector fields are introduced as the solutions of BSPDEs, and their relations are established. The adjoint processes are then characterized in terms of the adjoint vector fields, their differentials and Hessians, along the optimal state process $\widehat{x}(\cdot)$.

For all $v\in U$, define the following operators:

$$\begin{aligned} \mathcal{L}^v(t,x)Z &:= \frac{1}{2}\mathrm{tr}[(gg^*+\widetilde{g}\,\widetilde{g}^*)(t,x,v)\nabla^2 Z]+\langle f(t,x,v),\nabla Z\rangle,\\ \mathcal{L}(t,x)Z &:= \mathcal{L}^{\hat{u}(t)}(t,x)Z \quad \forall\, Z\in C^2(\mathbb{R}^n,\mathbb{R});\\ \mathcal{M}^{j,v}(t,x)V &:= \langle\widetilde{g}^j(t,x,v),\nabla V\rangle+h^j(t,x,v)V,\\ \mathcal{M}^j(t,x)V &:= \mathcal{M}^{j,\hat{u}(t)}(t,x)V \quad \forall\, V\in C^1(\mathbb{R}^n,\mathbb{R}). \end{aligned} \tag{4.1}$$

For a matrix-valued smooth function of $x\in\mathbb{R}^n$, say $\mathcal{U}:=(\mathcal{U}^{ij})\in C^2(\mathbb{R}^n,\mathbb{R}^{n_1\times n_2})$, set $\mathcal{L}(t,x)\mathcal{U}:=(\mathcal{L}(t,x)\mathcal{U}^{ij})$ and $\mathcal{M}^{j_1}(t,x)\mathcal{U}:=(\mathcal{M}^{j_1}(t,x)\mathcal{U}^{ij})$.

Consider the following BSPDEs:

$$\begin{cases} dZ(t,x) = -\,[\mathcal{L}(t,x)Z(t,x)+l(t,x,\widehat{u}(t))+\mathcal{M}^j(t,x)V^j(t,x)]\,dt\\ \qquad\qquad +V^j(t,x)\,dY^j(t), \quad t\in(0,1],\ x\in\mathbb{R}^n,\\ Z(1,x)=m(x), \quad x\in\mathbb{R}^n, \end{cases} \tag{4.2}$$

$$\begin{cases} d\lambda(t,x)\\ =-\{\mathcal{L}(t,x)\lambda(t,x)+\mathcal{M}^j(t,x)\theta^j(t,x)\\ \quad +\mathcal{H}_x^*(t,x,\widehat{u}(t),\lambda(t,x),\lambda_x(t,x)g(t,x,\widehat{u}(t)),V(t,x),\theta(t,x)+\lambda_x(t,x)\widetilde{g}(t,x,\widehat{u}(t)))\}\,dt\\ \quad +\theta^j(t,x)\,dY^j(t), \quad t\in(0,1],\ x\in\mathbb{R}^n,\\ \lambda(1,x)=m_x^*(x), \quad x\in\mathbb{R}^n, \end{cases} \tag{4.3}$$

and

(4.4)
$$
\begin{cases}
d\Lambda(t,x) \\
\quad = -\,[\mathcal{L}(t,x)\Lambda(t,x) + \mathcal{M}^j(t,x)\Theta^j(t,x) \\
\qquad + \mathcal{H}_{xx}(t,x,\widehat{u}(t),\lambda(t,x),\lambda_x(t,x)g(t,x,\widehat{u}(t)),V(t,x),\theta(t,x)+\lambda_x(t,x)\widetilde{g}(t,x,\widehat{u}(t))) \\
\qquad + f_x^*(t,x,\widehat{u}(t))\Lambda(t,x) + \Lambda(t,x)f_x(t,x,\widehat{u}(t)) \\
\qquad + g_x^{i*}(t,x,\widehat{u}(t))\Lambda(t,x)g_x^i(t,x,\widehat{u}(t)) + \widetilde{g}_x^{j*}(t,x,\widehat{u}(t))\Lambda(t,x)\widetilde{g}_x^j(t,x,\widehat{u}(t)) \\
\qquad + g_x^{i*}(t,x,\widehat{u}(t))D_{g^i(t,x,\hat{u}(t))}\Lambda(t,x) + D_{g^i(t,x,\hat{u}(t))}\Lambda(t,x)g_x^i(t,x,\widehat{u}(t)) \\
\qquad + \widetilde{g}_x^{i*}(t,x,\widehat{u}(t))D_{\tilde{g}^i(t,x,\hat{u}(t))}\Lambda(t,x) + D_{\tilde{g}^i(t,x,\hat{u}(t))}\Lambda(t,x)\widetilde{g}_x^i(t,x,\widehat{u}(t)) \\
\qquad + \widetilde{g}_x^{j*}(t,x,\widehat{u}(t))(t,x,\widehat{u}(t))\Theta^j(t,x) + \Theta^j(t,x)\widetilde{g}_x^j(t,x,\widehat{u}(t)) \\
\qquad + \theta^j(t,x)h_x^j(t,x,\widehat{u}(t)) + h_x^{j*}(t,x,\widehat{u}(t))\theta^{j*}(t,x)]\,dt \\
\qquad + \Theta^j(t,x)\,dY^j(t), \quad t\in(0,1],\ x\in\mathbb{R}^n, \\
\quad \Lambda(1,x) = m_{xx}(x), \quad x\in\mathbb{R}^n.
\end{cases}
$$

There is a close relation between the solutions of (3.2)–(3.4) and the solutions of (4.2)–(4.4), which is stated in the following theorem:

THEOREM 4.1. *Assume that the SPDEs* (4.2)–(4.4) *have unique* $\mathcal{F}_t^Y$*-adapted smooth solutions* (Z,V), $(\lambda,\theta^j, j=1,\dots,d)$, *and* $(\Lambda,\Theta^j, j=1,\dots,d)$, *respectively, and their partial derivatives of arbitrary order with respect to* x *are uniformly bounded. Then we have the following relations:*

$$
\begin{aligned}
r^{t,x}(s) &= Z(s,\phi^{t,x}(s)), \\
R^{i,t,x}(s) &= D_{g^i(s,\phi^{t,x}(s),\hat{u}(s))}Z(s,\phi^{t,x}(s)), \quad i=1,\dots,m, \\
\widetilde{R}^{j,t,x}(s) &= V^j(s,\phi^{t,x}(s)) + D_{\tilde{g}^j(s,\phi^{t,x}(s),\hat{u}(s))}Z(s,\phi^{t,x}(s)), \quad j=1,\dots,d; \\
q^{t,x}(s) &= \lambda(s,\phi^{t,x}(s)), \\
k^{i,t,x}(s) &= D_{g^i(s,\phi^{t,x}(s),\hat{u}(s))}\lambda(s,\phi^{t,x}(s)), \quad i=1,\dots,m, \\
\widetilde{k}^{j,t,x}(s) &= \theta^j(s,\phi^{t,x}(s)) + D_{\tilde{g}^j(s,\phi^{t,x}(s),\hat{u}(s))}\lambda(s,\phi^{t,x}(s)), \quad j=1,\dots,d; \\
Q^{t,x}(s) &= \Lambda(s,\phi^{t,x}(s)), \\
K^{i,t,x}(s) &= D_{g^i(s,\phi^{t,x}(s),\hat{u}(s))}\Lambda(s,\phi^{t,x}(s)), \quad i=1,\dots,m, \\
\widetilde{K}^{j,t,x}(s) &= \Theta^j(s,\phi^{t,x}(s)) + D_{\tilde{g}^j(s,\phi^{t,x}(s),\hat{u}(s))}\Lambda(s,\phi^{t,x}(s)), \quad j=1,\dots,d.
\end{aligned}
\tag{4.5}
$$

Proof of Theorem 4.1. We use the generalized Itô–Kunita formula (see Kunita [6] for details) to compute the quantities $Z(s,\phi^{t,x}(s)), \lambda(s,\phi^{t,x}(s)), \Lambda(s,\phi^{t,x}(s))$, and we observe that the right hand sides of the equalities in (4.5) solve the BSDEs (3.2)–(3.4), respectively. According to the uniqueness of the solutions of (3.2)–(3.4) (see Pardoux and Peng [9]), we get the desired results. □

Note that if (Z,V) is a smooth solution of the BSPDE (4.2), then $Z=W$. Hence, W can be viewed as a probabilistic interpretation of Z. In a heuristic way, $V^j(t,x)$ should be interpreted as $\widetilde{R}^{j,t,x}(t) - D_{\tilde{g}^j(t,x,\hat{u}(t))}Z(t,x)$.

From (3.5) and Theorem 4.1, we see that the solutions of BSPDEs (4.2)–(4.4) are closely related with the adjoint processes: the former, if they exist, help to show how the latter depend on the initial state x_0 and the system noise $\dot{w}(\cdot)$ in a special way. For this reason, we call the former the adjoint vector fields. The relations among the adjoint vector fields are stated in the following theorem.

THEOREM 4.2. *Assume that* 1) *the coefficients* $f, g, \widetilde{g}, h, l$, *and* m *are smooth in the variable* x, *and they are bounded, together with their partial derivatives with respect to* x; 2) $gg^*(t,x,\widehat{u}(t)) \geq \delta I_{n\times n}$ *for some real number* $\delta > 0$. *Then the SPDEs* (4.2)–(4.4) *have unique smooth solutions* (Z,V), $(\lambda,\theta^j, j=1,\dots,d)$, *and* $(\Lambda,\Theta^j, j=1,\dots,d)$. *Moreover, the solutions have the following relations:*

$$\begin{aligned} &\lambda = \nabla Z, \quad \theta^j = \nabla V^j;\\ &\Lambda = \lambda_x = \nabla^2 Z, \quad \Theta^j = \theta^j_x = \nabla^2 V^j, \quad j=1,\dots,d. \end{aligned} \tag{4.6}$$

Proof of Theorem 4.2. The uniqueness is obtained from Theorem 4.1 and the uniqueness of the solutions of the BSDEs (3.2)–(3.4).

The existence of a smooth solution of the BSPDE (4.2), under the conditions of Theorem 4.2, is proved by Zhou [14, Remark 4.1, p. 290].

Let (Z,V) be a smooth solution of (4.2). Take differentials on both sides of (4.2), and we see that the differential $(\nabla Z, \nabla V^j,\ j=1,\dots,d)$ satisfies the BSPDE (4.3). Thus, $(\nabla Z, \nabla V^j,\ j=1,\dots,d)$ is a smooth solution of (4.3).

Since

(4.7)
$$\begin{aligned} &\{\mathcal{L}(t,x)\lambda(t,x)\}_x\\ &= \mathcal{L}(t,x)\lambda_x(t,x) + \lambda_x(t,x)f_x(t,x,\widehat{u}(t))\\ &\quad + D_{g^i(t,x,\hat{u}(t))}\lambda_x(t,x)g^i_x(t,x,\widehat{u}(t)) + D_{\tilde{g}^j(t,x,\hat{u}(t))}\lambda_x(t,x)\widetilde{g}^j_x(t,x,\widehat{u}(t)),\\ &\quad \{\mathcal{M}^j(t,x)\theta^j(t,x)\}_x\\ &= \mathcal{M}^j(t,x)\theta^j_x(t,x) + \theta^j_x(t,x)\widetilde{g}^j_x(t,x,\widehat{u}(t)) + \theta^j(t,x)h^j_x(t,x,\widehat{u}(t)),\\ &\quad \{\mathcal{H}^*_x(t,x,\widehat{u}(t),\lambda(t,x),\lambda_x(t,x)g(t,x,\widehat{u}(t)),V(t,x),\theta(t,x)+\lambda_x(t,x)\widetilde{g}(t,x,\widehat{u}(t)))\}_x\\ &= \mathcal{H}_{xx}(t,x,\widehat{u}(t),\lambda(t,x),\lambda_x(t,x)g(t,x,\widehat{u}(t)),V(t,x),\theta(t,x)+\lambda_x(t,x)\widetilde{g}(t,x,\widehat{u}(t)))\\ &\quad + f^*_x(t,x,\widehat{u}(t))\lambda_x(t,x) + g^{i*}_x(t,x,\widehat{u}(t))D_{g^i(t,x,\hat{u}(t))}\lambda_x(t,x)\\ &\quad + h^{j*}_x(t,x,\widehat{u}(t))V^j_x(t,x) + \widetilde{g}^{j*}_x(t,x,\widehat{u}(t))[D_{\tilde{g}^j(t,x,\hat{u}(t))}\lambda_x(t,x)+\theta^j_x(t,x)]\\ &\quad + g^*_x(t,x,\widehat{u}(t))\lambda_x(t,x)g_x(t,x,\widehat{u}(t)), \end{aligned}$$

we have that $(Q := \lambda_x, K^j := \theta^j_x, j=1,\dots,d)$ satisfies the BSPDE (4.4). Hence, it is a smooth solution of (4.4). The relation (4.6) is then obtained. □

Combining Theorems 4.1 and 4.2, we have the following theorem.

THEOREM 4.3. *Let the hypotheses of Theorem* 4.2 *be satisfied, and* $(Z, V^j, j=1,\dots,d)$ *be the unique solution of the BSPDE* (4.2). *Then*

$$\begin{aligned} r^{t,x}(s) &= Z(s,\phi^{t,x}(s)),\\ R^{i,t,x}(s) &= D_{g^i(s,\phi^{t,x}(s),\hat{u}(s))}Z(s,\phi^{t,x}(s)), \quad i=1,\dots,m,\\ \widetilde{R}^{j,t,x}(s) &= V^j(s,\phi^{t,x}(s)) + D_{\tilde{g}^j(s,\phi^{t,x}(s),\hat{u}(s))}Z(s,\phi^{t,x}(s)), \quad j=1,\dots,d;\\ q^{t,x}(s) &= \nabla Z(s,\phi^{t,x}(s)),\\ k^{i,t,x}(s) &= D_{g^i(s,\phi^{t,x}(s),\hat{u}(s))}\nabla Z(s,\phi^{t,x}(s)), \quad i=1,\dots,m,\\ \widetilde{k}^{j,t,x}(s) &= \nabla V^j(s,\phi^{t,x}(s)) + D_{\tilde{g}^j(s,\phi^{t,x}(s),\hat{u}(s))}\nabla Z(s,\phi^{t,x}(s)), \quad j=1,\dots,d;\\ Q^{t,x}(s) &= \nabla^2 Z(s,\phi^{t,x}(s)),\\ K^{i,t,x}(s) &= D_{g^i(s,\phi^{t,x}(s),\hat{u}(s))}\nabla^2 Z(s,\phi^{t,x}(s)), \quad i=1,\dots,m,\\ \widetilde{K}^{j,t,x}(s) &= \nabla^2 V^j(s,\phi^{t,x}(s)) + D_{\tilde{g}^j(s,\phi^{t,x}(s),\hat{u}(s))}\nabla^2 Z(s,\phi^{t,x}(s)), \quad j=1,\dots,d. \end{aligned} \tag{4.8}$$

Before closing this section, we remark that, if the coefficients $f, g, \widetilde{g}, h, l$, and m are smooth with respect to all their arguments, they are bounded together with their partial derivatives, and $\widehat{u}(t) = \beta(t, Y(t))\, \forall\, t \in [0,1]$, for some smooth function $\beta : [0,1] \times \mathbb{R}^d \to U$ with bounded derivatives of arbitrary order, then the Hamilton–Jacobi equation (3.19) has a unique bounded smooth solution $\overline{W}$ and the BSPDE (4.2) has the following unique bounded smooth solution: $Z(t,x) = \overline{W}(t,x,Y(t))$, $V^j(t,x) = \overline{W}_{y^j}(t,x,Y(t))$, $j = 1, \dots, d$.

5. Versions of Theorem 2.1 and comparison with the existing results. Combining Theorems 2.1 and 3.2, we have the following theorem.

THEOREM 5.1. *Let the hypothesis* $(\mathcal{A}1)$ *be satisfied, and* $h := h(t,x)$, $\widetilde{g} := \widetilde{g}(t,x)$. *Assume that* $\widehat{u}(\cdot)$ *is an optimal control. Let* $\mu^{t,x}(\cdot)$ *be the solution of* (3.12), *and set*

$$W(t,x) := E\bigg[\int_t^1 \mu^{t,x}(s) l(s, \phi^{t,x}(s), \widehat{u}(s))\, ds + \mu^{t,x}(1) m(\phi^{t,x}(1)) \,\bigg|\, \mathcal{F}_t^Y\bigg] \tag{5.1}$$

and

$$\overline{\mathcal{L}}^{\,v}(t,x) W(t,x) := \frac{1}{2}\mathrm{tr}[(gg^*)(t,x,v)\nabla^2 W(t,x)] + \langle f(t,x,v), \nabla W(t,x)\rangle. \tag{5.2}$$

Then, the following maximum condition holds:

$$\begin{aligned} \widehat{E}\int_0^1 \big\{ &\overline{\mathcal{L}}^{\,v(t)}(t, \widehat{x}(t)) W(t, \widehat{x}(t)) + l(t, \widehat{x}(t), v(t)) \\ &- \overline{\mathcal{L}}^{\,\widehat{u}(t)}(t, \widehat{x}(t)) W(t, \widehat{x}(t)) - l(t, \widehat{x}(t), \widehat{u}(t)) \big\}\, dt \\ &\geq 0 \qquad \forall v(\cdot) \in U_{\mathrm{ad}}. \end{aligned} \tag{5.3}$$

Proof of Theorem 5.1. Since the observation term h and the correlation term $\widetilde{g}$ do not depend on the control variable, we derive from Theorem 3.2 that

$$\begin{aligned} &\Delta\mathcal{H}(t, \widehat{x}(t), \widehat{u}(t), q(t), k(t), \widetilde{R}(t) - q^*(t)\widetilde{g}(t, \widehat{x}(t), \widehat{u}(t)), \widetilde{k}(t); v(t)) \\ &= \langle q(t), \Delta f(t; v(t))\rangle + \langle k^i(t), \Delta g^i(t; v(t))\rangle + \Delta l(t; v(t)) \\ &= \langle \nabla W(t, \widehat{x}(t)), \Delta f(t; v(t))\rangle + \Delta l(t; v(t)) \\ &\quad + \mathrm{tr}[\nabla^2 W(t, \widehat{x}(t))(g(t, \widehat{x}(t), \widehat{u}(t)) \Delta g^*(t; v(t)))], \\ &\quad \mathrm{tr}[Q(t)(\Delta g(t; v(t)) \Delta g^*(t; v(t)) + \Delta\widetilde{g}(t; v(t)) \Delta\widetilde{g}^*(t; v(t)))] \\ &= \mathrm{tr}[Q(t)(\Delta g(t; v(t)) \Delta g^*(t; v(t)))] \\ &= \mathrm{tr}[\nabla^2 W(t, \widehat{x}(t))(\Delta g(t; v(t)) \Delta g^*(t; v(t)))]. \end{aligned} \tag{5.4}$$

The maximum condition (5.3) then follows from Theorem 2.1. □

COROLLARY 5.1. *Assume that* 1) *the hypothesis* $(\mathcal{A}1)$ *holds;* 2) $\widetilde{g} := \widetilde{g}(t,x), h := h(t,x)$*;* 3) $U_{\mathrm{ad}} = \widetilde{U}_{\mathrm{ad}}$. *Let* $\widehat{u}(\cdot)$ *be an optimal control. Then the following maximum condition holds:*

$$\begin{aligned} \widehat{E}\Big[&\overline{\mathcal{L}}^{\,v}(t, \widehat{x}(t)) \overline{W}(t, \widehat{x}(t), Y(t)) + l(t, \widehat{x}(t), v) \\ &- \overline{\mathcal{L}}^{\,\widehat{u}(t)}(t, \widehat{x}(t)) \overline{W}(t, \widehat{x}(t), Y(t)) - l(t, \widehat{x}(t), \widehat{u}(t)) \,|\, Y(t) \Big] \\ &\geq 0 \qquad \forall\, v \in U, \text{ a.s.a.e.}, \end{aligned} \tag{5.5}$$

with $\overline{W}$ *being defined by* (3.16)–(3.18).

The partially observed optimal control with the admissible class $\widetilde{U}_{\rm ad}$ of controls has been studied by Fleming [4]. His observation model is of the following form:

$$\begin{cases} dY(t) = h(t,x(t),Y(t),v(t))\,dt + \sigma^i(t,x(t),Y(t),v(t))\,dw^i(t) \\ \qquad\qquad + \widetilde{\sigma}^j(t,x(t),v(t))\,d\widetilde{w}^j(t), \quad t\in(0,1], \\ Y(0) = y_0, \end{cases} \tag{5.6}$$

and it is more general than (1.2). His terminal time T is the least time of the system state going beyond a bounded domain, while ours is the fixed time $T=1$. He made the following nondegenerate hypothesis:

$$\begin{pmatrix} g & \widetilde{g} \\ \sigma & \widetilde{\sigma} \end{pmatrix} \begin{pmatrix} g^* & \sigma^* \\ \widetilde{g}^* & \widetilde{\sigma}^* \end{pmatrix} \geq \delta I_{(n+d)\times(n+d)} \quad \text{for some } \delta>0, \tag{5.7}$$

which implies, in our situation (i.e., $\sigma=0, \widetilde{\sigma}=I_{d\times d}$), the following condition: $gg^*\geq \delta I_{n\times n}$ for some $\delta>0$. Corollary 5.1 allows gg^* to be degenerate and is new.

COROLLARY 5.2. *Assume that* 1) *the hypothesis* $(\mathcal{A}1)$ *holds;* 2) $\widetilde{g}:=\widetilde{g}(t,x), h:=h(t,x)$*;* 3) $U_{\rm ad}=\overline{U}_{\rm ad}$*. Let* $\widehat{u}(\cdot)$ *be an optimal control. Then the following maximum condition holds:*

$$\begin{aligned} &\widehat{E}\Big[\overline{\mathcal{L}}^{\,v}(t,\widehat{x}(t))W(t,\widehat{x}(t)) + l(t,\widehat{x}(t),v) \\ &\quad - \overline{\mathcal{L}}^{\,\hat{u}(t)}(t,\widehat{x}(t))W(t,\widehat{x}(t)) - l(t,\widehat{x}(t),\hat{u}(t))\,|\,\mathcal{F}_t^Y\Big] \\ &\quad \geq 0 \qquad \forall\, v\in U,\ a.s.a.e. \end{aligned} \tag{5.8}$$

Combining Theorems 2.1 and 4.3, we have the following theorem.

THEOREM 5.2. *Let the hypotheses of Theorem* 4.2 *be satisfied. Let* $\widehat{u}(\cdot)$ *be an optimal control, and* (Z,V) *be the unique solution of the BSPDE*

$$\begin{cases} dZ(t,x) = -\left[\mathcal{L}(t,x)Z(t,x) + l(t,x,\widehat{u}(t)) + \mathcal{M}^j(t,x)V^j(t,x)\right]dt \\ \qquad\qquad + V^j(t,x)\,dY^j(t), \quad t\in(0,1],\ x\in\mathbb{R}^n, \\ Z(1,x) = m(x), \quad x\in\mathbb{R}^n. \end{cases} \tag{5.9}$$

Then the following maximum condition holds:

$$\begin{aligned} \widehat{E}\int_0^1 &\{\mathcal{L}^{v(t)}(t,\widehat{x}(t))Z(t,\widehat{x}(t)) + l(t,\widehat{x}(t),v(t)) + \mathcal{M}^{j,v(t)}(t,\widehat{x}(t))V^j(t,\widehat{x}(t)) \\ &- \mathcal{L}^{\hat{u}(t)}(t,\widehat{x}(t))Z(t,\widehat{x}(t)) - l(t,\widehat{x}(t),\widehat{u}(t)) - \mathcal{M}^{j,\hat{u}(t)}(t,\widehat{x}(t))V^j(t,\widehat{x}(t))\}\,dt \\ &\geq 0 \qquad \forall\, v(\cdot)\in U_{\rm ad}. \end{aligned} \tag{5.10}$$

Proof of Theorem 5.2. From Theorem 4.3, we derive

$$\begin{aligned} &\Delta\mathcal{H}(t,\widehat{x}(t),\widehat{u}(t),q(t),k(t),\widetilde{R}(t) - q^*(t)\widetilde{g}(t,\widehat{x}(t),\widehat{u}(t)),\widetilde{k}(t);v(t)) \\ =&\langle\nabla Z(t,\widehat{x}(t)),\Delta f(t;v(t))\rangle + \langle\nabla V^j(t,\widehat{x}(t)),\Delta g^j(t;v(t))\rangle \\ &+ V^j(t,\widehat{x}(t))\Delta h^j(t;v(t)) + \Delta l(t;v(t)) \\ &+ \mathrm{tr}[\nabla^2 Z(t,\widehat{x}(t))(g(t,\widehat{x}(t),\widehat{u}(t))\Delta g^*(t;v(t)) + \widetilde{g}(t,\widehat{x}(t),\widehat{u}(t))\Delta\widetilde{g}^*(t;v(t)))], \\ &\mathrm{tr}[Q(t)(\Delta g(t;v(t))\Delta g^*(t;v(t)) + \Delta\widetilde{g}(t;v(t))\Delta\widetilde{g}^*(t;v(t)))] \\ =&\mathrm{tr}[\nabla^2 Z(t,\widehat{x}(t))(\Delta g(t;v(t))\Delta g^*(t;v(t)) + \Delta\widetilde{g}(t;v(t))\Delta\widetilde{g}^*(t;v(t)))]. \end{aligned} \tag{5.11}$$

The maximum condition (5.10) then follows from Theorem 2.1. □

COROLLARY 5.3. *Let the hypotheses of Theorem* 4.2 *be satisfied and* $U_{\rm ad} = \overline{U}_{\rm ad}$. *Let* $\widehat{u}(\cdot)$ *be an optimal control and* (Z, V) *be the unique solution of the BSPDE* (5.9). *Then the following maximum condition holds:*

(5.12)
$$\begin{aligned}

The partially observed optimal control with the admissible control class $\overline{U}_{\rm ad}$, has been studied by Kwakernaak [7]; Bensoussan [2]; Haussmann [5]; Baras, Elliott, and Kohlmann [1]; Zhou [13]; and Li and Tang [8]. Corollary 5.2 essentially covers the partially observed maximum principles of Bensoussan [2]; Haussmann [5]; and Baras, Elliott, and Kohlmann [1]; and it generalizes them at least in two of the following respects: 1) gg^* may be degenerate; 2) the control may appear in the diffusion coefficient g; 3) correlated noises may be present between the system and the observation (i.e., the correlation coefficient $\widetilde{g}$ is not necessarily zero); 4) the initial state x_0 does not necessarily have a regular density function. Note that Bensoussan [2] considered the case of $\widetilde{g} = 0$, and characterized his adjoint processes via the BSPDE (5.9) but in the sense of strong solution; in a heuristic way, the formula (5.1) should be the probabilistic interpretation of his adjoint processes.

Zhou [13], like Kwakernaak [7] and Bensoussan [2], treated a partially observed optimal control problem as an optimal control problem with full information, but for the Zakai equation, which is a stochastic PDE driven by the observation. His result excludes both the case when the initial state has no regular density function and the case when gg^* is degenerate while $\widetilde{g} \neq 0$. Corollaries 5.2 and 5.3 consider both cases and therefore are new. They partially answer Fleming's question (see Fleming [4, p. 209]).

It is worth pointing out that our derivation of Corollary 5.2 does not involve the Zakai equation at all and avoids the complicated stochastic analysis in infinite-dimensional spaces of Bensoussan [2], Haussmann [5], and Zhou [13].

Combining Theorem 2.1 and Remark 2.1 with Theorem 3.1, we obtain the following theorem.

THEOREM 5.3. *Let the hypothesis* $(\mathcal{A}1)$ *be satisfied,* $U_{\rm ad} = \overline{U}_{\rm ad}$, *and* $\widehat{u}(\cdot)$ *be an optimal control. Let* $\phi^{t,x}(\cdot)$ *solve the SDE* (3.1) *and* $(r^{t,x}(\cdot), R^{t,x}(\cdot), \widetilde{R}^{t,x}(\cdot))$ *solve the BSDE* (3.2). *Then the maximum condition* (2.30) *holds with*

(5.13)
$$\begin{aligned}
q(s) &= [\phi_x^{0,x_0,*}(s)]^{-1}\nabla r^{0,x_0}(s),\\
k^i(s) &= [\phi_x^{0,x_0,*}(s)]^{-1}\nabla R^{i,0,x_0}(s) - g_x^{i*}(s,\phi^{0,x_0}(s),\widehat{u}(s))q(s),\\
\widetilde{k}^j(s) &= [\phi_x^{0,x_0,*}(s)]^{-1}\nabla \widetilde{R}^{j,0,x_0}(s) - \widetilde{g}_x^{j*}(s,\phi^{0,x_0}(s),\widehat{u}(s))q(s),\\
Q(s) &= q_x^{0,x_0}(s)[\phi_x^{0,x_0}(s)]^{-1}\\
&= [\phi_x^{0,x_0,*}(s)]^{-1}\nabla^2 r^{0,x_0}(s)[\phi_x^{0,x_0}(s)]^{-1}\\
&\quad - [\phi_x^{0,x_0,*}(s)]^{-1}\phi_{xx}^{i,0,x_0}(s)[\phi_x^{0,x_0,*}(s)]^{-1,i}\nabla r^{0,x_0}(s)[\phi_x^{0,x_0}(s)]^{-1}.
\end{aligned}$$

Note that $\phi^{i,t,x}(s)$ *is the* i*th component of the column vector* $\phi^{t,x}(s)$ *and* $[\phi_x^{t,x,*}(s)]^{-1,i}$ *is the* i*th row vector of the matrix* $[\phi_x^{t,x,*}(s)]^{-1}$.

Elliott and Kohlmann [3] considered an optimal stochastic control problem with full information, which is the special case of our partially observable optimal stochastic control problem with

$$g \equiv 0, \quad h \equiv 0, \quad l \equiv 0, \quad U_{\rm ad} = \overline{U}_{\rm ad}. \tag{5.14}$$

In this case, the BSDEs (3.2) and (3.7) reduce to

$$\begin{cases} dr^{t,x}(s) = R^{i,t,x}(s)\,dw^i(s) + \widetilde{R}^{j,t,x}(s)\,dY^j(s), \quad s \in [t,1), \\ r^{t,x}(1) = m(\phi^{t,x}(1)) \end{cases} \tag{5.15}$$

and

$$\begin{cases} d\nabla r^{t,x}(s) = \nabla R^{i,t,x}(s)\,dw^i(s) + \nabla \widetilde{R}^{j,t,x}(s)\,dY^j(s), \quad s \in [t,1), \\ \nabla r^{t,x}(1) = \phi_x^{t,x,*}(1) m_x^*(\phi^{t,x}(1)) \end{cases} \tag{5.16}$$

respectively. Hence, for $s \in [t,1]$,

$$\begin{aligned} r^{t,x}(s) &= E[m(\phi^{t,x}(1)|\,\mathcal{F}_s^Y], \\ \nabla r^{t,x}(s) &= E[\phi_x^{t,x,*}(1) m_x^*(\phi^{t,x}(1))|\,\mathcal{F}_s^Y] \\ &= E[\phi_x^{t,x,*}(1) m_x^*(\phi^{t,x}(1))] + \int_t^s \nabla \widetilde{R}^{j,t,x}(\tau)\,dY^j(\tau), \\ R^{i,t,x}(s) &\equiv 0, \qquad \nabla R^{i,t,x}(s) \equiv 0, \\ \nabla^2 r^{t,x}(s) &= E[\phi_x^{t,x,*}(1) \nabla^2 m(\phi^{t,x}(1))|\,\mathcal{F}_s^Y] \\ &\quad + E[\phi_{xx}^{i,t,x}(1) m_{x^i}(\phi^{t,x}(1))|\,\mathcal{F}_s^Y]. \end{aligned} \tag{5.17}$$

Putting the relations (5.17) and (5.13) into the maximum condition (2.30), we arrive at Theorem 4.2 of Elliott and Kohlmann [3, p. 36]. Thus, our Theorem 5.3 contains Theorem 4.2 of Elliott and Kohlmann [3] as a special case.

Finally, we remark that a version of Theorem 2.1 for the case of $\widetilde{g} = 0$ has been obtained by Li and Tang [8], but the relations among the adjoint processes in Theorem 2.1 were not discussed there at all.

Acknowledgments. The author would like to thank the referees for their helpful comments on the original version of this paper. The author is also grateful to Prof. Jiongmin Yong for his help in improving the original version. In addition, the author would like to thank Professor Etienne Pardoux for his kind invitation.

ROBUSTNESS OF NONLINEAR FILTERS OVER THE INFINITE TIME INTERVAL*

AMARJIT BUDHIRAJA† AND HAROLD J. KUSHNER†

Abstract. Nonlinear filtering is one of the classical areas of stochastic control. From the point of view of practical usefulness, it is important that the filter not be too sensitive to the assumptions made on the initial distribution, the transition function of the underlying signal process and the model for the observation. This is particularly acute if the filter is of interest over a very long or potentially infinite time interval. Then the effects of small errors in the model which is used to construct the filter might accumulate to make the output useless for large time. The problem of asymptotic sensitivity to the initial condition has been treated in several papers. We are concerned with this as well as with the sensitivity to the signal model, uniformly over the infinite time interval. It is conceivable that the effects of even small errors in the model will accumulate so that the filter will eventually be useless. The robustness is shown for three classes of problems. For the first two cases, the signal model is Markov and the observations are taken in discrete time, and the observation is the usual function of the signal plus noise. The last class treated is a continuous time Markov process, with a point process observation.

Key words. nonlinear filtering, model robustness, asymptotic stability, Hilbert metric, Birkhoff's contraction coefficient

1. Introduction.

Nonlinear filtering is one of the classical areas of stochastic control, and a great deal of work has been done on it. Typically, in either discrete or continuous time, it is assumed that the signal process is Markov and that the observations are corrupted by white noise, assumptions that we retain. A fundamental question from the point of view of practical usefulness is the sensitivity of the filter to the assumptions made on the initial distribution, the transition function of the underlying signal process and the model for the observation. This is particularly acute if the filter is of interest over a very long or potentially infinite time interval. Then the effects of small errors in the model used to construct the filter might accumulate to make the output useless for large time. Suppose that the assumed transition function for the signal process is not correct. Direct methods of comparing the difference between the true optimal filter and the one actually constructed generally use crude bounds which might be useful over a bounded time interval but get at best exponentially growing error estimates as time goes to infinity. Clearly a more subtle analysis is called for. With the classical Kalman–Bucy filter, under observability and controllability, the effects of the initial condition disappear as time goes to infinity. But, regrettably, there is no workable analog of global observability for the nonlinear problem.

The earliest work on the subject of robustness over a long tome interval was that of Kushner and Huang [8]. They worked in continuous time and assumed only wide

bandwidth observation and system driving noise. The model for the filter was the natural one based on the weak convergence limit as the bandwidth went to infinity, and they were concerned with the average (mean square or other) errors per unit time for large time. Long term errors for numerical and other approximations to the signal process were also of interest. They reduced the problem to one concerning uniqueness of the invariant measure of the joint (signal, filter) process. If the signal is a Markov process in some locally compact space and one has the standard additive white noise model for the observations then the work of Kunita [7] and Stettner [12] showed that the ergodicity of the signal leads to a unique invariant measure for the filter, but nothing was said about the joint (signal, filter) process. See Stettner [13] for the existence and uniqueness of the invariant measure for the case where the signal is a finite state Markov chain.

We will use the term asymptotic stability to mean that the output of the filter is asymptotically insensitive to the initial condition, assuming that the signal model is fixed. Ocone and Pardoux [11] used the results and ergodicity assumptions of [12] to obtain the convergence, in an appropriate sense, of the output of the incorrectly initialized filter to that of the exact filter as time approaches infinity. In two fundamental papers, Delyon and Zeitouni [6] and Atar and Zeitouni [2, 1], studied a variety of signal–observation pairs with ergodicity hypothesis on the signal where they prove exponentially fast convergence of the output of an incorrectly initialized filter to that of the correct one. Another recent work on exponential asymptotic stability is Le Gland and Mevel [9] who study finite state Markov chains and under appropriate conditions prove geometric ergodicity of an extended chain, which includes as its states the filter and its gradient. The approach of [2, 1] is based on Hilbert's projective metric and Birkhoff's contraction inequality and provides some remarkable results on pathwise convergence. It requires a rather strong ergodicity condition on the signal, and in most situations it restricts the analysis to signals taking values in a compact state space. One can obtain asymptotic stability of the filter in the absence of the ergodicity of the signal. The classical example is the Kalman filter and some related problems, cf.[11]. Budhiraja and Ocone [5] derive exponential asymptotic stability of the filter for signals which are given as solutions to one dimensional stochastic difference equations. The observation noise is taken to be bounded; however, no assumption is made on the boundedness of the signal. However, in general the question of asymptotic stability in the absence of ergodicity of the signal process is a challenging problem and remains open.

All of the works cited (excluding [9]) in the last paragraph assumed that the correct transition function for the signal process was used in the construction of the filter. The only variable was the initial condition. In practice, one would rarely know the correct signal transition function, and it is important to know that small errors in the signal model do not have serious effects on the filter output, over an arbitrarily large time interval. Simultaneously, one still would like asymptotic insensitivity to the initial condition of the filter. This paper is devoted to this double robustness problem.

We consider three models, and compare the output of the optimal filter to that for a filter built with an incorrect signal model and initial condition (but with the same observation sequence). The first class, which we treat in section 3.1, is that of a discrete time Markov process observed via a nonlinear functional with additive white noise. The transition function of this Markov chain is assumed to satisfy the one step mixing condition of [2] (see (7)). The exponential stability for this class had been

derived in [2]. In the present work we show that for the general robustness problem the total variation distance between the filter for the misspecified model and the exact filter converges to zero, uniformly in time, as the misspecifications converge to zero. The uniformity in time is the key outcome.

The second result, derived in section 3.2, is for the class of nonbounded signals studied in [5]. Exponential asymptotic stability for this class is known from [5]. For the general robustness problem we show that the infinite time limit of the expected total variation distance between the exact filter and the filter for the misspecified model converges to zero as the misspecifications in the transition kernel and in the distribution of the observation noise go to zero. The result is not pathwise. The main difficulty is that we do not have a contraction in the distance between the filters at every observation update, and when there is a contraction it is random. It turns out (cf. [5]) that this is sufficient to yield a pathwise asymptotic stability result; however, for the problem of robustness, with respect to the signal model, we need to do an analysis of the contractions in the mean.

The final section of the paper is devoted to a continuous time Markov signal model, but with point process observations. The results are new even if the only misspecification is in the initial condition. The signal is assumed to satisfy a mixing type condition analogous to that used for the first case (see 30). Theorem 4.1 proves the asymptotic stability, and the general robustness problem is treated in Theorem 4.2. The main additional difficulties are due to the facts that the observations can occur at any time and the liklihood ratio is discontinuous at the times of the observations.

The central tools in all the arguments in this work are that of Hilbert's projective metric and Birkhoff's contraction inequality; cf. [3]. These were introduced to the study of asymptotic stability of filters in [1]. For the convenience of the reader we have included, in section 2, a brief overview of the central ideas concerning Hilbert metric which are important in filter analysis.

2. Hilbert's projective metric. In this section we present some preliminary definitions and results concerning Hilbert's projective metric which will be used in later sections. Let S be a Polish space and let $\mathcal{M}(S)$ (respectively, $\mathcal{M}^+(S)$) denote the space of finite signed measures (finite nonnegative measures, respectively) on S. For μ, $\nu \in \mathcal{M}^+(S)$ the Hilbert projective distance between them is defined as

$$h(\mu,\nu) := \ln\left[\sup_{A,A'\in\mathcal{S}} \frac{\mu(A)}{\nu(A)}\frac{\nu(A')}{\mu(A')}\right], \tag{1}$$

where $\mathcal{S}$ is the Borel $\sigma-$field on S and we employ the convention that $\alpha/0 = \infty$ for $\alpha \neq 0$ and $0/0 = 1$.

Observe that a necessary condition for $h(\mu,\nu)$ to be finite is that μ, ν are mutually absolutely continuous. In fact it can be shown (cf. [10]) that a necessary and sufficient condition for $h(\mu,\nu)$ to be finite for when μ and ν are positive measures is that there exist positive $c_i, i = 1, 2$, such that

$$c_1\nu \leq \mu \leq c_2\nu. \tag{2}$$

Then $h(\mu,\nu) = \inf \ln(c_2/c_1)$, where the infimum is taken over all pairs c_1, c_2 for which the above inequalities hold.

One of the important properties of the Hilbert metric from the point of view of nonlinear filtering problems is that of scale invariance; i.e., for μ, $\nu \in \mathcal{M}^+(S)$ and α and β positive numbers, $h(\mu,\nu) = h(\alpha\mu, \beta\nu)$. Thus, if μ and ν are conditional

distributions arising in a filtering problem, in computing the distance in the Hilbert projective metric it makes no difference whether they are normalized or unnormalized, and we will use this fact where convenient without further comment. The following inequality connects the Hilbert metric with the total variation norm. For μ, ν probability measures on $(S, \mathcal{S})$

$$||\mu - \nu||_{TV} \leq \frac{2}{\ln 3} h(\mu, \nu), \tag{3}$$

where $||.||_{TV}$ denotes the total variation norm on $\mathcal{M}(S)$. We refer the reader to [2] for a proof.

Another important property of Hilbert metric which makes it a very useful tool in stability analysis is the following contraction relation due to Birkhoff [3]. Let S_1, S_2 be Polish spaces and let $\mathcal{S}_1, \mathcal{S}_2$ be the respective Borel $\sigma-$ fields. Denote the Hilbert metric on $\mathcal{M}^+(S_1)$ and $\mathcal{M}^+(S_2)$ by the same symbol: namely, h. Let, $K : \mathcal{M}(S_1) \to \mathcal{M}(S_2)$ be a linear nonnegative operator. Then for μ, $\nu \in \mathcal{M}^+(S_1)$

$$h(K\mu, K\nu) \leq \tanh(C(K)/4) h(\mu, \nu), \tag{4}$$

where

$$\begin{aligned} C(K) &:= \sup\{h(K\mu, K\nu) : \mu, \nu \in \mathcal{M}^+(S_1)\} \\ &= \sup_{\mu,\nu \in \mathcal{M}^+(S_1)} \ln \left[\sup_{A,A' \in \mathcal{S}_2} \frac{K\mu(A)}{K\nu(A)} \frac{K\nu(A')}{K\mu(A')} \right]. \end{aligned} \tag{5}$$

We record one final observation for future use. Suppose that K is defined by

$$(K\mu)(A) = \int_A \int_{S_1} \mathcal{K}(x, y) \mu(dy) \lambda(dx), \ A \in \mathcal{S}_2,$$

where λ is a positive $\sigma-$ finite measure on $(S_2, \mathcal{S}_2)$ and $\mathcal{K} : S_2 \times S_1 \to [0, \infty)$ is a measurable map. Then

$$C(K) = \ln \left[\sup_{y,y' \in S_1} \operatorname{ess\,sup}_{x,x' \in S_2} \left(\frac{\mathcal{K}(x, y) \mathcal{K}(x', y')}{\mathcal{K}(x, y') \mathcal{K}(x', y)} \right) \right], \tag{6}$$

where same convention as before is employed for $\alpha/0; \alpha \neq 0$ and $0/0$. The essential supremum in (6) is with respect to the measure λ.

3. Discrete time signals. In this section we will consider the asymptotic errors when the observations are taken in discrete time. We will study the asymptotic sensitivity with respect to the incorrect initial condition, incorrect transition function, and incorrect observation noise distribution function. It will be seen that, under appropriate mixing-type conditions on the signal process, the effects of errors in the initial condition eventually disappear, and small errors in the transition or distribution functions cause only small errors in the filter output, uniformly over all time. We will work with two specific signal–observation pairs for which the Hilbert projective metric techniques can be applied. In our first result we consider signals whose transition kernels satisfy the boundedness condition (7), which was used in [2], which also proved the stability with respect to the initial condition. The second theorem is for a family of real valued signals observed in bounded noise, but which is not necessarily bounded. The stability of the filter for this class with respect to the misspecification of the initial condition alone had been studied in [5]. The second class of examples, although quite special, is interesting in that it shows that the boundedness conditions in [2] are not necessary.

3.1. The signal satisfies a one step mixing condition. Let (Ω, F, P) be a probability space. Let X_n be a Markov chain with a stationary transition probability distribution and a Polish state space S. Let $\mathcal{S}$ denote the Borel $\sigma-$ field on S. Assume that the signal admits a transition probability density $G(\cdot,\cdot)$, with respect to some $\sigma-$ finite measure λ on $(S,\mathcal{S})$.

Following the approach taken in [2], we assume that there exists a probability measure ρ on $(S,\mathcal{S})$ and finite positive constants, c_1, c_2, such that for all $A \in \mathcal{S}$:

$$c_1\rho(A) \leq \int_A G(x,y)\lambda(dy) \leq c_2\rho(A). \tag{7}$$

Since the left- and right-hand sides do not depend on the initial state x, the above key condition implies that the signal process has a stong one step mixing property. It would hold, for example, if the signal were a sampled nondegenerate diffusion on a compact state space. Let

$$Y_n = H(X_n) + \nu_n \tag{8}$$

be the observation sequence, where $H : S \to R^m$ is a measurable function and ν_n are R^m valued mutually independent and identically distributed random variables with a bounded density which we denote by g. (The condition that the distributions be independent of n can be weakened, but the assumption simplifies the notation.)

For fixed $y \in R^m$, define the following nonnegative operator $K(G,y)$ on $\mathcal{M}(S)$:

$$(K(G,y)\mu)(A) := \int_A \int_S g(y - H(z))G(x,z)\mu(dx)\lambda(dz). \tag{9}$$

Here, $\mu \in \mathcal{M}(S)$ and $A \in \mathcal{S}$.

If $K(G,y)\mu \neq 0$ (i.e., it is not the zero measure), then define the normalized measure $\tilde{K}(G,y) := K(G,y)\mu/[K(G,y)\mu](S)$. Otherwise set it equal to 0. Denote by Π_n the conditional distribution of X_n given $Y_1, \ldots, Y_n$. Then it is a simple verification (for a proof see Lemma 3.1 of [5]) that Π_n equals

$$\Pi_n = \tilde{K}(G,Y_n)o\tilde{K}(G,Y_{n-1})o\cdots o\tilde{K}(G,Y_1)p_0,$$

where p_0 is the distribution of X_0.

Let $\{G_k\}$ be a sequence of transition probability densities and $\{p_k\}$ a sequence of probability measures on S. Let us write

$$\Pi_n^{(k)} = \tilde{K}(G_k,Y_n)o\tilde{K}(G_k,Y_{n-1})o\cdots o\tilde{K}(G_k,Y_1)p_k.$$

The following theorem contains the main result of this subsection. It says essentially that if the filter is designed with an incorrect initial condition and incorrect signal transition function, then the pathwise difference between the true optimal filter and the incorrect one over an arbitrarily large or infinite time interval is bounded uniformly in the difference (in a suitable scale) between the correct and erroneous transition function, and initial condition.

THEOREM 3.1. *Suppose that,* $\forall x \in S$ *and* $\forall k \geq 1$, $G_k(x,\cdot)$ *and* $G(x,\cdot)$ *are positive and zero on the same sets. Let* $\ln G_k$ *converge to* $\ln G$ *uniformly on the* $(x,y)-$*set, where* $G(x,y) > 0$. *Then*

(a) $\lim_{k\to\infty} \limsup_{n\to\infty} h(\Pi_n^{(k)}, \Pi_n) = 0.$

(b) *If in addition, p_k converges to p_o in total variation norm as $k \to \infty$, then*

$$\lim_{k\to\infty} \sup_n ||\Pi_n^{(k)} - \Pi_n||_{TV} = 0.$$

Proof. For $q \in \mathcal{M}^+(S)$, define

$$\Pi_n^{[q]} := \tilde{K}(G, Y_n) o \tilde{K}(G, Y_{n-1}) o \cdots o \tilde{K}(G, Y_1) q.$$

We begin by noting that

$$h(\Pi_n^{(k)}, \Pi_n) \le h(\Pi_n^{(k)}, \Pi_n^{[p_k]}) + h(\Pi_n^{[p_k]}, \Pi_n). \tag{10}$$

Let us initially consider the second term on the right side of (10). Using the scale invariance property of Hilbert's projective metric, we have

$$\begin{aligned} h(\Pi_n^{[p_k]}, \Pi_n) &= h(K(G, Y_n)\Pi_{n-1}^{[p_k]}, K(G, Y_n)\Pi_{n-1}) \\ &\le \tanh\left(\frac{C(K(G, Y_n))}{4}\right) h(\Pi_{n-1}^{[p_k]}, \Pi_{n-1}). \end{aligned}$$

It is clear from (5) and (7) that $C(K(G, Y_n)) \le 2\ln(c_2/c_1)$. Using this observation in the above equality, we get

$$h(\Pi_n^{[p_k]}, \Pi_n) \le \delta h(\Pi_{n-1}^{[p_k]}, \Pi_{n-1}),$$

where $\delta := \tanh(\ln(c_2/c_1)/2)$.

Iterating the above inequality and observing from (7) and (1) that $h(\Pi_1^{[p_k]}, \Pi_1) \le 2\ln(c_2/c_1)$, we have

$$h(\Pi_n^{[p_k]}, \Pi_n) \le 2\delta^{n-1} \ln(c_2/c_1). \tag{11}$$

Consider now the first term on the right side of (10), namely,

$$\begin{aligned} h(\Pi_n^{(k)}, \Pi_n^{[p_k]}) &= h(K(G_k, Y_n)\Pi_{n-1}^{(k)}, K(G, Y_n)\Pi_{n-1}^{[p_k]}) \\ &\le h(K(G_k, Y_n)\Pi_{n-1}^{(k)}, K(G, Y_n)\Pi_{n-1}^{(k)}) \\ &\quad + h(K(G, Y_n)\Pi_{n-1}^{(k)}, K(G, Y_n)\Pi_{n-1}^{[p_k]}) \\ &\le h(K(G_k, Y_n)\Pi_{n-1}^{(k)}, K(G, Y_n)\Pi_{n-1}^{(k)}) + \delta h(\Pi_{n-1}^{(k)}, \Pi_{n-1}^{[p_k]}). \end{aligned} \tag{12}$$

The first term on the right side of (12) can be bounded as follows. Define ϵ_k by

$$\epsilon_k = \sup_{(x,y)\in B} |\ln G_k(x, y) - \ln G(x, y)|,$$

where $B := \{(x, y) : G(x, y) \ne 0\}$. By hypothesis, $\epsilon_k \to 0$ as $k \to \infty$. Also the following inequality holds $\forall (x, y) \in B$.

$$e^{-\epsilon_k} G(x, y) \le G_k(x, y) \le e^{\epsilon_k} G(x, y).$$

Using the above inequality and (1) it is easy to see that

$$h(K(G_k, Y_n)\Pi_{n-1}^{(k)}, K(G, Y_n)\Pi_{n-1}^{(k)}) \le 2\epsilon_k. \tag{13}$$

Combining (12) and (13) yields

$$h(\Pi_n^{(k)}, \Pi_n^{[p_k]}) \leq 2\epsilon_k + \delta h(\Pi_{n-1}^{(k)}, \Pi_{n-1}^{[p_k]}).$$

Iterating the above inequality and using the observation that $h(\Pi_1^{(k)}, \Pi_1^{[p_k]})$ is bounded by $2\epsilon_k$, we have that

$$h(\Pi_n^{(k)}, \Pi_n^{[p_k]}) \leq 2\epsilon_k/(1-\delta).$$

Combining the above inequality with (10) yields that

$$h(\Pi_n^{(k)}, \Pi_n) \leq \frac{2\epsilon_k}{1-\delta} + \delta^{n-1} h(\Pi_1^{(k)}, \Pi_1^{[p_k]}). \tag{14}$$

This proves (a).

To prove (b) it suffices to show that $||p_k - p||_{TV} \to 0$ implies that $h(\Pi_1^{(k)}, \Pi_1^{[p_k]})$ converges to zero. A straightforward inequality shows that

$$\frac{1}{1 + \frac{c_2}{c_1}||p_k - p_0||_{TV}} \leq \frac{\int G(x,y) p_0(dx)}{\int G(x,y) p_k(dx)} \leq 1 + \frac{c_2}{c_1}||p_k - p_0||_{TV},$$

a.e. y. This implies that

$$h(\Pi_1^{(k)}, \Pi_1^{[p_k]}) \leq 2\ln(1 + \frac{c_2}{c_1}||p_k - p_0||_{TV}).$$

The result now follows on combining this observation with (14). □

Remark 1. Theorem 3.1(a) can be shown to hold if G satisfies, instead of (7), the weaker condition

$$c_1 \rho(A) \leq \int_A G^k(x,y) \lambda(dy) \leq c_2 \rho(A), \tag{15}$$

for some $k \geq 1$, where G^k is the k-step transition kernel and c_1, c_2, A, ρ are as before. The proof is more involved mainly because the contraction coefficient(analogus to δ in the proof of Theorem 3.1) is now a random quantity. However (15) implies that the signal is ergodic and has a unique invariant measure. Also the observation noise sequence is ergodic. From this one can show that the contraction coefficients obtained for successive k-step updates of the filter form an ergodic sequence. One can then apply Birkhoff's ergodic theorem to complete the proof.

3.2. A difference equation model. The result in section 3.1 relies heavily on the mixing and boundedness properties of the signal and the observations played no role in the analysis. However, observations are a critical ingredient in the problem of nonlinear filtering, and should play a central role in any asymptotic analysis. Each time the filter is updated the observations recenter the distribution in an interval of the observed value and hence, intuitively, if the observations are "good" they should help the convergence of the output of an incorrectly initialized filter to that of the correct filter, and aid in stabilizing the effects of model error as well. One such model was studied in [5], and it was shown that the filter is asymptotically independent of its initial condition. In this subsection we revisit that example from the perspective of a more general robustness in the infinite time limit. Although the model is one dimensional, it is nonlinear and the observations play a crucial role.

Let $(\Omega, \mathcal{F}, P)$ be a probability space on which are defined two sequences, $\{\xi_n\}_{n=1}^{\infty}$ and $\{\nu_n\}_{n=1}^{\infty}$, which are mutually independent, and each has independent and identically distributed components. We assume that both ξ_1 and ν_1 have bounded densities with respect to Lebesgue measure, denoted by f and g, respectively. Furthermore, following the approach in [5] we assume that there is an $M < \infty$ such that

(A.1) $$\text{supp } g \subseteq [-M, M].$$

Let X_0 be another real-valued random variable on the above probability space, independent of both $\{\xi_i\}$ and $\{\nu_i\}$, with law p_0. The signal $\{X_n\}_{n=0}^{\infty}$ is defined as

$$X_{n+1} = m(X_n) + \sigma(X_n)\xi_{n+1}, \qquad n \geq 0. \tag{16}$$

We use the assumptions of [5], where m and σ are real-valued and Borel measurable and are assumed to satisfy

(A.2) $$0 < \underline{\sigma} := \inf_{x \in R} \sigma(x) \leq \sup_{x \in R} \sigma(x) =: \overline{\sigma} < \infty.$$

(A.3) $$C := \sup_{|z-z'| \leq 2M} |m(z) - m(z')| < \infty.$$

The observations on the signal are given by

$$Y_n = X_n + \nu_n, \qquad n \geq 1. \tag{17}$$

Next, in order to get the filter update formula we introduce the following linear operator. For $u, v \in R$, define the operator K by

$$K \equiv K(u, v, f, g, m) : \mathcal{M}[u - M, u + M] \to \mathcal{M}[v - M, v + M]$$

by

$$K\mu(A) = \int_A \int_{[u-M,u+M]} g(v - x) f\left(\frac{x - m(z)}{\sigma(z)}\right) \sigma^{-1}(z)\mu(dz)dx, \tag{18}$$

$A \in \mathcal{B}[v - M, v + M]$. As before, define the nonlinear operator $\tilde{K}$ to be the normalization of K. Define $\tilde{K}\mu = 0$ if $K\mu = 0$. For $n \geq 2$, let K_n denote the operator $K(Y_{n-1}, Y_n, f, g, m)$, and let $\tilde{K}_n$ denote its normalized form. Finally, for $P(R)$ denoting the family of probability measures on R, define

$$K_1 : P(R) \to \mathcal{M}[Y_1 - M, Y_1 + M]$$

by

$$K_1\mu(A) = \int_A \int_R g(v - x) f(\frac{x - m(z)}{\sigma(z)})\sigma^{-1}(z)\mu(dz)dx,$$

and let $\tilde{K}_1$ denote the normalized form. Let Π_n denote the conditional distribution of X_n given $Y_1, \ldots, Y_n$. Then it can be shown that, with probability one,

$$\Pi_n = \tilde{K}_n o \tilde{K}_{n-1} o \cdots o \tilde{K}_1 p_0.$$

Now let $\{g_k\}, \{f_k\}, \{m_k\}$ be sequences of maps from $R \to R$, where for every k, f_k is a probability density, and g_k is a probability density with support $[-M, M]$. Let $K_n^{(k)}$ denote the operator defined by $K(Y_{n-1}, Y_n, f_k, g_k, m)$ and let $K_n^{(k)\prime}$ denote the operator $K(Y_{n-1}, Y_n, f_k, g_k, m_k)$. Let $\tilde{K}_n^{(k)}, \tilde{K}_n^{(k)\prime}$ denote the respective normalizations. Let $\{p_k\}$ be a sequence of probability measures on R and define

$$\Pi_n^{(k)} = \tilde{K}_n^{(k)} o \tilde{K}_{n-1}^{(k)} o \cdots o \tilde{K}_1^{(k)} p_k$$

and

$$\Pi_n^{(k)\prime} = \tilde{K}_n^{(k)\prime} o \tilde{K}_{n-1}^{(k)\prime} o \cdots o \tilde{K}_1^{(k)\prime} p_k.$$

Define

$$\Pi_n^{[p_k]} := \tilde{K}_n o \tilde{K}_{n-1} o \cdots o \tilde{K}_1 p_k,$$

and set $S := \inf\{n : \Pi_n^{[p_k]} = 0 \text{ for some } k\}$.

Define $a(x) := [2M + C]/\underline{\sigma} + [\overline{\sigma}/\underline{\sigma}]|x| \equiv c_0 + c_1|x|$.

Then we have the following result. It will be seen that the conditions are not too restrictive.

THEOREM 3.2. *Assume that $S = \infty$ with probability one. Suppose that there is $\epsilon_0 > 0$ such that $\underline{f} := \inf\{f(u) : |u| \le c_0 + \epsilon_0\} > 0$, and*

$$\lim_{k\to\infty} \sup_{x\in[-M,M]} |\ln g_k(x) - \ln g(x)| = 0,$$

where $|\ln(0) - \ln(0)| = 0$. For all $k \in [0,\infty)$, define $\rho_k(\cdot)$ by

$$\sup_{x\in[-l,l]} |\ln f_k(x) - \ln f(x)| =: \rho_k(l), \tag{19}$$

and suppose that $E\rho_k(a + b|\xi_1|) \to 0$ as $k \to \infty$ for all positive a, b. Then

(i) $\lim_{k\to\infty} \limsup_{n\to\infty} E||\Pi_n - \Pi_n^{(k)}||_{TV} = 0$.

(ii) *Define $\rho^*(\cdot)$ by*

$$\sup_{x,y\in[-l,l];x\neq y} \frac{|\ln f(x) - \ln f(y)|}{|x-y|} =: \rho^*(l).$$

Suppose that for all positive a, b, $E\rho^*(a+b|\xi_1|) < \infty$. Finally assume that m_k converges to m uniformly on R. Then

$$\lim_{k\to\infty} \limsup_{n\to\infty} E||\Pi_n - \Pi_n^{(k)\prime}||_{TV} = 0.$$

Remark 2. We note that the condition $S = \infty$ with probability one is satisfied, for example, if p_k is mutually absolutely continuous with respect to p for every k. The above stated conditions on f, f_k are satisfied, if for example, $f \sim N(\mu,\sigma)$, $f_k \sim N(\mu_k,\sigma_k)$ and μ_k, σ_k converge to μ, σ, respectively, as $k \to \infty$. More generally, if we have the common forms $g_k(x) = e^{-\phi_k(x)}$ and $g(x) = e^{-\phi(x)}$ (and analogously for $f(\cdot)$ and $f_k(\cdot)$), then the conditions on the convergence of the logs of the densities become conditions on the convergence of the $\phi_k(\cdot)$, and we can see that they are not too stringent.

Proof of Theorem 3.2. By (3) and the triangle inequality for the total variation norm, we have

$$||\Pi_n^{(k)} - \Pi_n||_{TV} \le [2/\ln(3)]h(\Pi_n^{(k)}, \Pi_n^{[p_k]}) + ||\Pi_n^{[p_k]} - \Pi_n||_{TV}.$$

From Corollary 3.3 of [5] we know that for all k, $h(\Pi_n^{[p_k]}, \Pi_n)$ converges to zero with probability one as $n \to \infty$. This immediately yields L^1 convergence, of the second term in the above inequality, for each fixed k. Therefore it suffices to consider the first term in the above inequality.

Observe now that (as in Theorem 3.1)

$$h(\Pi_n^{(k)}, \Pi_n^{[p_k]}) \le h(K_n^{(k)}\Pi_{n-1}^{(k)}, K_n\Pi_{n-1}^{(k)}) + h(K_n\Pi_{n-1}^{(k)}, K_n\Pi_{n-1}^{[p_k]}). \tag{20}$$

We will now consider the second term above. From Birkhoff's contraction inequality, we know that it can be at most,

$$\tanh\left(\frac{C(K_n)}{4}\right) h(\Pi_{n-1}^{(k)}, \Pi_{n-1}^{[p_k]}).$$

Also, using the definition of $C(\cdot)$ and (18),

$$C(K_n) = \ln\left[\sup_{y,y'} \operatorname{ess\,sup}_{x,x'} \left(\frac{f(\frac{x-m(y)}{\sigma(y)})f(\frac{x'-m(y')}{\sigma(y')})}{f(\frac{x-m(y')}{\sigma(y')})f(\frac{x'-m(y)}{\sigma(y)})}\right)\right], \tag{21}$$

where the first supremum is taken over $x, x' \in [Y_{n-1} - M, Y_{n-1} + M]$ and the essential supremum is with respect to the Lebesgue measure on $[Y_n - M, Y_n + M]^2$. A straightforward computation using (A.2) and (A.3) shows that for $x \in [Y_n - M, Y_n + m]$ and $y \in [Y_{n-1} - M, Y_{n-1} + M]$, we have $\frac{x-m(y)}{\sigma(y)} < c_0 + c_1|\xi_n|$. Hence for $|\xi_n| < \epsilon_0/c_1$ and x, y as above, $f(\frac{x-m(y)}{\sigma(y)}) \ge \underline{f}$. In view of (21) it then follows that

$$C(K_n) I_{|\xi_n|<\epsilon_0/c_1} \le \ln\left(\frac{\overline{f}^2}{\underline{f}^2}\right) I_{|\xi_n|<\epsilon_0/c_1}.$$

This implies that

$$\tanh\left(\frac{C(K_n)}{4}\right) \le 1 - \left(1 - \tanh\left(\frac{1}{4}\ln\left(\frac{\overline{f}^2}{\underline{f}^2}\right)\right)\right) I_{|\xi_n|<\epsilon_0/c_1} := \delta(\xi_n).$$

Using the above inequality for the second term on the right side of (20) we have that

$$h(K_n\Pi_{n-1}^{(k)}, K_n\Pi_{n-1}^{[p_k]}) \le \delta(\xi_n) h(\Pi_{n-1}^{(k)}, \Pi_{n-1}^{[p_k]}) \tag{22}$$

Now we consider the first term on the right side of (20). For an arbitrary positive finite measure ν on $[Y_{n-1} - M, Y_{n-1} + M]$, and a Borel set A in $B[Y_n - M, Y_n + M]$, the term $K_n^{(k)}\nu(A)$ is equal to

$$\int_A \int g_k(Y_n - x) f_k\left(\frac{x - m(y)}{\sigma(z)}\right) \sigma^{-1}(y)\nu(dy)dx. \tag{23}$$

Now define

$$\overline{\rho}_k := \sup_{|x|<M} |\ln g_k(x) - \ln g(x)|.$$

Then clearly, for $x \in [Y_n - M, Y_n + M]$,

$$e^{-\overline{\rho}_k} g(Y_n - x) \le g_k(Y_n - x) \le e^{\overline{\rho}_k} g(Y_n - x). \tag{24}$$

Next note that in view of the convergence assumption on $\ln f_k$ (see (19)) and recalling that for $x \in [Y_n - M, Y_n + M]$and $y \in [Y_{n-1} - M, Y_{n-1} + M]$, we have $\frac{x-m(y)}{\sigma(y)} \le a(\xi_n)$, it follows that for such x, y,

$$e^{-\rho_k(a(\xi_n))} f\left(\frac{x - m(y)}{\sigma(y)}\right) \le f_k\left(\frac{x - m(y)}{\sigma(y)}\right) \le e^{\rho_k(a(\xi_n))} f\left(\frac{x - m(y)}{\sigma(y)}\right). \tag{25}$$

Using the inequalities, (24) and (25) in the representation for $K_n^{(k)}\nu(A)$ (see (23)), we have that

$$e^{-\rho_k(a(\xi_n))-\overline{\rho}_k}K_n\nu(A) \leq K_n^{(k)}\nu(A) \leq e^{\rho_k(a(\xi_n))+\overline{\rho}_k}K_n\nu(A).$$

The above inequality yields that

$$h(K_n^{(k)}\Pi_{n-1}^{(k)}, K_n\Pi_{n-1}^{(k)}) \leq 2\rho_k(a(\xi_n)) + 2\overline{\rho}_k. \tag{26}$$

This observation in conjunction with (22) when used on the right side of (20) gives

$$h(\Pi_n^{(k)}, \Pi_n^{[p_k]}) \leq 2\rho_k(a(\xi_n)) + 2\overline{\rho}_k + \delta(\xi_n)h(\Pi_{n-1}^{(k)}, \Pi_{n-1}^{[p_k]}).$$

Iterating the above inequality, we obtain

$$h(\Pi_n^{(k)}, \Pi_n^{[p_k]}) \leq \sum_{j=1}^{n}(2\rho_k(a(\xi_j)) + 2\overline{\rho}_k)\delta(\xi_{j+1})\cdots\delta(\xi_n).$$

Taking expectations we get

$$E[h(\Pi_n^{(k)}, \Pi_n^{[p_k]})] \leq 2(E\rho_k(a(\xi_1)) + \overline{\rho}_k)/(1-\delta),$$

where $\delta := E\delta(\xi_1)$ is strictly less than one, since in view of the assumption on the support of f, $P(|\xi_1| < \epsilon_0/c_1) > \underline{f}\epsilon_0/c_1 > 0$. (Note $c_1 \geq 1$.) This proves (i).

We now prove (ii). As in the proof of (i), we have the inequality:

$$||\Pi_n^{(k)\prime} - \Pi_n||_{TV} \leq [2/\ln(3)]h(\Pi_n^{(k)\prime}, \Pi_n^{[p_k]}) + ||\Pi_n^{[p_k]} - \Pi_n||_{TV}.$$

The second term converges in L^1 as $n \to \infty$ for each fixed k. Hence, it suffices to consider the first term. Again, an application of the triangle inequality as in (i) yields

$$h(\Pi_n^{(k)\prime}, \Pi_n^{[p_k]}) \leq h(K_n^{(k)\prime}\Pi_{n-1}^{(k)\prime}, K_n\Pi_{n-1}^{(k)\prime}) + \delta(\xi_n)h(\Pi_{n-1}^{(k)\prime}, \Pi_{n-1}^{[p_k]}). \tag{27}$$

Finally, consider the first term in the above inequality. By definition, $K_n^{(k)\prime}\Pi_{n-1}^{(k)\prime}$ equals

$$\int_{\cdot}\int g_k(Y_n - x)f_k\left(\frac{x - m_k(y)}{\sigma(z)}\right)\sigma^{-1}(y)\nu(dy)dx. \tag{28}$$

Let $\delta_k := \sup_{x\in R}|m_k(x) - m(x)|$. By hypothesis $\delta_k \to 0$ as $k \to \infty$. Now let $M_o > 0$ be such that, $\forall k \geq M, \delta_k < \underline{\sigma}$. Then $\forall k > M_o$, $x \in [Y_n - M, Y_n + M]$, $z \in [Y_{n-1} - M, Y_{n-1} + M]$,

$$|\frac{x - m_k(z)}{\sigma(z)}| \leq |\frac{x - m(z)}{\sigma(z)}| + |\frac{m(z) - m_k(z)}{\sigma(z)}| \leq a(\xi_n) + 1. \tag{29}$$

We have by a straightforward application of a triangle inequality that for all $k > M_o$, $|\ln f_k(\frac{x-m_k(z)}{\sigma(z)}) - \ln f(\frac{x-m(z)}{\sigma(z)})|$ is bounded above by the sum of

$$\left|\ln f_k\left(\frac{x - m_k(z)}{\sigma(z)}\right) - \ln f\left(\frac{x - m_k(z)}{\sigma(z)}\right)\right|$$

and

$$\left|\ln f\left(\frac{x-m_k(z)}{\sigma(z)}\right)-\ln f\left(\frac{x-m(z)}{\sigma(z)}\right)\right|.$$

In view of the definition (19), the first of these terms is bounded by $\rho_k(a(\xi_n)+1)$. In view of the Lipschitz condition on f, the second term is bounded by $\rho^*(a(\xi_n)+1)\delta_k/\underline{\sigma}$.

Using this observation in the representation of $K_n^{(k)\prime}\Pi_{n-1}^{(k)\prime}$(i.e., the expression (28) along with (24), we have that $\forall k > M_o$

$$e^{-\rho_k(a(\xi_n)+1)-\rho^*(a(\xi_n)+1)\delta_k/\underline{\sigma}-\overline{\rho}_k}K_n \le K_n^{(k)\prime} \le e^{\rho_k(a(\xi_n)+1)+\rho^*(a(\xi_n)+1)\delta_k/\underline{\sigma}+\overline{\rho}_k}K_n.$$

Therefore

$$h(K_n^{(k)\prime}\Pi_{n-1}^{(k)\prime}, K_n\Pi_{n-1}^{(k)\prime}) \le 2\left(\rho_k(a(\xi_n)+1)+\rho^*(a(\xi_n)+1)\delta_k/\underline{\sigma}+\overline{\rho}_k\right).$$

Using the above inequality in (27) we have that $\forall k > M_o$

$$h(\Pi_n^{(k)\prime}, \Pi_n^{[p_k]}) \le 2\left(\rho_k(a(\xi_n)+1)+\rho^*(a(\xi_n)+1)\delta_k/\underline{\sigma}+\overline{\rho}_k\right)+\delta(\xi_n)h(\Pi_{n-1}^{(k)\prime}, \Pi_{n-1}^{[p_k]}).$$

Iterating the above inequality and taking expectations, we get

$$E[h(\Pi_n^{(k)\prime}, \Pi_n^{[p_k]})] \le 2\left(E\left[\rho_k(a(\xi_1)+1)+\rho^*(a(\xi_1)+1)\delta_k/\underline{\sigma}+\overline{\rho}_k\right]\right)/(1-\delta),$$

The proof now follows on observing that

$$E\left[\rho_k(a(\xi_1)+1)+\rho^*(a(\xi_1)+1)\delta_k/\underline{\sigma}+\overline{\rho}_k\right] \to 0$$

as $k \to \infty$. □

4. Continuous time signals with point process observations. In this section we will examine the filter robustness properties for a continuous time signal where the observations are a point process. The signal satisfies one step mixing type properties similar to those used in Theorem 3.1. The first result on asymptotic stability (Theorem 4.1) shows that asymptotically the filter output does not depend on the initial condition. It is the point process analog of the results in [1], and is new. The proof uses the Hilbert projective metric and Birkhoff's contraction coefficient. The basic convergence result is pathwise. The main difficulty is that the contraction in the total variation distance between the filters is given from the time of one observation to the next, but the contraction is not uniform since the observations times are not equally spaced; the observations can occur at any time. Because of this the initial analysis is in the mean. Nevertheless, one can recover the almost sure convergence on noting that the distance in the Hilbert projective metric is nonincreasing. In the second theorem of this section we consider the general robustness problem. The analysis is more involved since one needs to keep track of the errors caused by the incorrect transition function, continuously in time, since the observations can occur at any time.

The precise model is the following. Let $(\Omega, \mathcal{F}, P)$ be a probability space and let $\{X_t, t \ge 0\}$ be a cadlag Markov process on this space taking values in a Polish space S. Let $\mathcal{S}$ be the Borel σ-field on S. We assume that $\{X_t, t \ge 0\}$ has a stationary transition density, denoted by $G_t(x,y), t \ge 0$, with respect to some σ-finite measure m on $(S, \mathcal{S})$. The distribution of X_0 is denoted by p_0. We assume that there exist maps f_1, f_2 from $(0,\infty)$ to $[0,\infty)$ and $a, b \in (0,\infty), a < b$ such that

(H) $$\sup_{t\in[a,b]} \frac{f_2(t)}{f_1(t)} < \infty,$$

and $\forall t \in (0,\infty)$ and for $x, y \in S$

$$f_1(t) \le G_t(x,y) \le f_2(t), \tag{30}$$

where $0/0 = 0$.

Condition (H) is not very restrictive since a, b are arbitrary. The observation process $\{Y_t, t \ge 0\}$ is assumed to be a real-valued (right continuous) Poisson process with intensity $\lambda(X_t, Y_t)$, where $\lambda(\cdot)$ is assumed to be bounded from both above and below, i.e., for all $x \in S$:

$$0 < \lambda_1 \le \lambda(x,y) \le \lambda_2 < \infty.$$

We note that the vector-valued observation case is treated in the same way, and with the same result, but we wish to keep the notation simple. To obtain a representation for the filter, we use the usual measure transformation method and introduce another probability space $(\Omega_1, \mathcal{F}_1, P_1)$ on which we define a copy of the process X_t, denoted by $X_t^{(0)}$. Let $(\overline{\Omega}, \overline{\mathcal{F}}, \overline{Q})$ be the product space: $(\Omega, \mathcal{F}, P) \otimes (\Omega_1, \mathcal{F}_1, P_1)$. We define processes $\{X_t, Y_t, t \ge 0\}$ and $\{X_t^{(0)}, t \ge 0\}$ on the extended space in the usual manner. By construction, the process $\{X_t^{(0)}, t \ge 0\}$ is independent of the processes $\{X_t, Y_t, t \ge 0\}$.

Let $\Pi_t^{(p_0)}$ denote the conditional distribution of X_t given $\sigma\{Y_s, 0 \le s \le t\}$. Let q be a real-valued, measurable, and bounded function on S. It is well known (cf. [4]) that $\Pi_t^{(p_0)}$ can be written as

$$\Pi_t^{(p_0)} q := \frac{\tilde{\Pi}_t^{(p_0)} q}{\tilde{\Pi}_t^{(p_0)} 1},$$

where

$$\tilde{\Pi}_t^{(p_0)} q := E_{\overline{Q}} \left[L_t q(X_t^{(0)}) | Y_s : s \le t \right],$$

where

$$L_t := \left(\prod_{0 \le s \le t} \lambda(X_s^{(0)}, Y_{s^-}) \Delta Y_s \right) \exp\left(- \int_0^t \lambda(X_s^{(0)}, Y_s) ds \right),$$

where $\Delta Y_s = Y_s - Y_{s-}$. The empty product is defined to be unity.

Now let p_1 be an arbitrary probability measure on $(S, \mathcal{S})$ and introduce a Markov process on $(\Omega_1, \mathcal{F}_1, P_1)$, denoted by $\{X_t^{(1)}, t \ge 0\}$, with initial distribution p_1 and the same transition function as $\{X_t^{(0)}, t \ge 0\}$. By the construction of the product space, under $\bar{Q}$ the process $\{X_t^{(1)}, t \ge 0\}$ is independent of $\{X_t, Y_t, t \ge 0\}$. Define

$$\Pi_t^{(p_1)} q := \frac{\tilde{\Pi}_t^{(p_1)} q}{\tilde{\Pi}_t^{(p_1)} 1},$$

where

$$\tilde{\Pi}_t^{(p_1)} q := E_{\overline{Q}} \left[\tilde{L}_t q(X_t^{(1)}) | Y_s : s \le t \right],$$

and

$$\tilde{L}_t := \left(\prod_{0 \le s \le t} \lambda(X_s^{(1)}, Y_{s^-}) \Delta Y_s \right) \exp\left(- \int_0^t \lambda(X_s^{(1)}, Y_s) ds \right).$$

The following result states that the effects of the initial condition disappear as time goes to infinity.

THEOREM 4.1. (a) $h(\Pi_t^{(p_1)}, \Pi_t^{(p_0)})$ *converges to* 0 *with probability one as* $t \to \infty$.
(b) *If* $h(p_0, p_1) < \infty$ *then the above convergence is in* L^p *for every* $0 < p < \infty$.

Proof. We begin by noting that $\Pi_t^{(p_i)}, i = 0, 1$, can be recursively obtained as follows: Let $T_1, T_2, \ldots$ be the jump times of the Poisson process $\{Y_t, t \ge 0\}$, and define $T_0 = 0$. For $j \ge 1$, define $\tau_j = T_j - T_{j-1}$. Let q be a bounded real-valued measurable function. For $s, t \in [T_j, T_{j+1}), s < t, j \ge 0, i = 0, 1$, we have the following equality:

$$\Pi_t^{(p_i)} q = c \int_S E_{\overline{Q}} \left[q(X_{t-s}^{(i)}) \exp\left\{ - \int_0^{t-s} \lambda(X_u^{(i)}, Y_{T_j}) du \right\} \Big| X_0^{(i)} = x, Y_{T_j}, T_j \right] \Pi_s^{(p_i)}(dx),$$

where c is some normalizing constant. For $s \in [T_j, T_{j+1}), t = T_{j+1}$ we have

$$\Pi_{T_{j+1}}^{(p_i)} q = c \int_S E_{\overline{Q}} \Bigg[q(X_{T_{j+1}-s}^{(i)}) \lambda(X_{T_{j+1}-s}^{(i)}, Y_{T_j}) \times \exp\left\{ - \int_0^{T_{j+1}-s} \lambda(X_u^{(i)}, Y_{T_j}) du \right\} \Big| X_0^{(i)} = x, Y_{T_j}, T_j, T_{j+1} \Bigg] \Pi_s^{(p_i)}(dx).$$

The first equation yields that for any positive-valued and measurable function q and $s, t \in [T_j, T_{j+1}), s < t$ and $j \ge 0$,

$$\begin{aligned} &\exp(-\lambda_1(t-s)) \int_S G_{t-s}(x, y) q(y) m(dy) \\ &\ge E_{\overline{Q}} \left[q(X_{t-s}^{(i)}) \exp\left\{ - \int_0^{t-s} \lambda(X_u^{(i)}, Y_{T_j}) du \right\} \Big| X_0^{(i)} = x, Y_{T_j}, T_j \right] \\ &\ge \exp(-\lambda_2(t-s)) \int_S G_{t-s}(x, y) q(y) m(dy). \end{aligned} \tag{31}$$

By (4), (6), and (31) we have the inequality

$$h(\Pi_t^{(p_1)}, \Pi_t^{(p_0)}) \le \tanh \left[\frac{\ln \frac{f_2(t-s)}{f_1(t-s)} + (\lambda_2 - \lambda_1)(t-s)}{2} \right] h(\Pi_s^{(p_1)}, \Pi_s^{(p_0)}).$$

Similar considerations show that for $s \in [T_j, T_{j+1})$ and $t = T_{j+1}$,

$$h(\Pi_{T_{j+1}}^{(p_1)}, \Pi_{T_{j+1}}^{(p_0)}) \le \tanh \left[\frac{\ln \frac{f_2(T_{j+1}-s)}{f_1(T_{j+1}-s)} + (\lambda_2 - \lambda_1)(T_{j+1}-s) + \ln \frac{\lambda_2}{\lambda_1}}{2} \right] h(\Pi_s^{(p_1)}, \Pi_s^{(p_0)}). \tag{32}$$

The above inequalities show in particular that $h(\Pi_t^{(p_1)}, \Pi_t^{(p_0)})$ is nonincreasing in t. This observation and assertion (a) yields assertion (b) via the monotone convergence theorem.

Now letting δ_i denote

$$\tanh\left[\frac{\ln\frac{f_2(\tau_i)}{f_1(\tau_i)}+(\lambda_2-\lambda_1)\tau_i+\ln\frac{\lambda_2}{\lambda_1}}{2}\right],$$

we obtain

$$h(\Pi_{T_n}^{(p_1)},\Pi_{T_n}^{(p_0)})\le\delta_n h(\Pi_{T_{n-1}}^{(p_1)},\Pi_{T_{n-1}}^{(p_0)}). \tag{33}$$

Denoting $\sigma\{X_t,t\ge 0\}$ by $\mathcal{F}_X$, we have for every $m>1$,

$$P\{\exists n:\tau_n>a,n\le m\}=1-E\left\{E\left[\prod_{i=1}^{m}I_{(\tau_j\le a)}\big|\mathcal{F}_X\right]\right\}.$$

Since $E[I_{(\tau_j\le a)}|\mathcal{F}_X,T_1,\ldots,T_{j-1}]$ is at most $1-e^{-a\lambda_1}$, we must have that

$$P\{\exists n:\tau_n>a\}=1.$$

Next observe that $\tau_n(\omega)>a$ implies that $h(\Pi_{T_n}^{(p_1)},\Pi_{T_n}^{(p_0)})$ is finite, since from (30) and the proved monotonicity of the Hilbert distance it can be at most $2[\ln f_2(a)/f_1(a)+(\lambda_2-\lambda_1)a]$, which is finite by hypothesis. Hence, it follows that

$$P\left\{\exists n:h(\Pi_{T_n}^{(p_1)},\Pi_{T_n}^{(p_0)})<\infty\right\}=1.$$

Now let $m=\inf\{n:h(\Pi_{T_n}^{(p_1)},\Pi_{T_n}^{(p_0)})<\infty\}$, then $P\{m<\infty\}=1$. We show now that $E[h(\Pi_{T_n}^{(p_1)},\Pi_{T_n}^{(p_0)})|\mathcal{F}_0]$ converges to zero with probability one as $n\to\infty$, where $\mathcal{F}_0:=\mathcal{F}_X\vee\sigma\{m,T_1,\ldots,T_m\}$. This will imply that $h(\Pi_{T_n}^{(p_1)},\Pi_{T_n}^{(p_0)})$ converges in probability to 0. Then the proved monotonicity property of $h(\Pi_{T_n}^{(p_1)},\Pi_{T_n}^{(p_0)})$ implies that $h(\Pi_t^{(p_1)},\Pi_t^{(p_0)})$ converges with probability one as $t\to\infty$.

We begin by observing that for $n>m(\omega)$,

$$E\left[h(\Pi_{T_n}^{(p_1)},\Pi_{T_n}^{(p_0)})|\mathcal{F}_0\right]\le E\left(\left(\prod_{i=m+1}^{n}\delta_i\right)|\mathcal{F}_0\right)h(\Pi_{T_m}^{(p_1)},\Pi_{T_m}^{(p_0)}). \tag{34}$$

Observe that

$$\delta_i=1-2\left[\frac{\frac{f_1(\tau_i)\lambda_1}{f_2(\tau_i)\lambda_2}e^{-(\lambda_2-\lambda_1)\tau_i}}{1+\frac{f_1(\tau_i)\lambda_1}{f_2(\tau_i)\lambda_2}e^{-(\lambda_2-\lambda_1)\tau_i}}\right].$$

Therefore, for $\tau_i\in[a,b]$,

$$\delta_i\le 1-2\frac{e^{-(\lambda_2-\lambda_1)b}/C}{1+e^{-(\lambda_2-\lambda_1)b}/C},$$

where

$$C:=\frac{\lambda_2}{\lambda_1}\sup_{t\in[a,b]}f_2(t)/f_1(t),$$

which is finite by hypothesis.

Defining $\gamma = 1 - 2\frac{e^{-(\lambda_2-\lambda_1)b}/C}{1+e^{-(\lambda_2-\lambda_1)b}/C}$, we can write

$$P\left\{\delta_i \le \gamma \middle| \mathcal{F}_0, T_{m+1}, \ldots, T_{i-1}\right\} \ge P\left\{\tau_i \in [a,b] \middle| \mathcal{F}_0, T_{m+1}, \ldots, T_{i-1}\right\}.$$

Finally, observe that for every $i > m(\omega)$

$$P\left\{\tau_i \in [a,b] \middle| \mathcal{F}_0, T_{m+1}, \ldots, T_{i-1}\right\} \ge e^{-a\lambda_2}\left(1 - e^{-\lambda_1(b-a)}\right) > 0.$$

This implies that there exists a constant $\overline{\gamma} < 1$ such that

$$E[\delta_{m+j} | \mathcal{F}_0, T_{m+1}, \ldots, T_{m+j-1}] \le \overline{\gamma}$$

for all $j \ge 0$. This and (34) imply that $E[h(\Pi_{T_n}^{(p_1)}, \Pi_{T_n}^{(p_0)}) | \mathcal{F}_0] \to 0$ a.s., which completes the proof. □

Remark 3. The hypothesis (H) is satisfied if $\{X_t, t \ge 0\}$ is a diffusion on a compact Riemannian manifold with smooth drift and diffusion coefficients and a strictly elliptic generator, as shown in [2].

In the final part of this section we consider the above filtering problem, where in addition to an incorrect initial condition, there is a misspecification in the transition kernel. Let G_t be as before and replace (H) with the following stronger condition (H1).

(H1) There exist maps f_1, f_2 from $(0,\infty)$ to $[0,\infty)$ such that
$\forall \quad a, b \in (0,\infty)\,, \quad \sup_{t\in[a,b]} \frac{f_2(t)}{f_1(t)} < \infty,$
and $\forall t \in (0,\infty)$ and for $x, y \in S$

$$f_1(t) \le G_t(x,y) \le f_2(t), \tag{35}$$

where $0/0 = 0$.

Let $G_t^{(k)}, k \ge 1$, be a sequence of transition probability kernels, and let $p_k, k \ge 1$, be a sequence of probability measures on $(S, \mathcal{S})$. Let $(\Omega_1, \mathcal{F}_1, P_1)$ and $(\overline{\Omega}, \overline{\mathcal{F}}, \overline{Q})$ be as before.

For $k \ge 1$, define the Markov processes $\{X_t^{(k)}, t \ge 0\}$, on $(\Omega_1, \mathcal{F}_1, P_1)$ with initial distribution p_k and transition probability kernel $G_t^{(k)}$. Under $\overline{Q}$, they are independent of $\{X_t, Y_t, t \ge 0\}$. Define

$$L_t^{(k)} := \left(\prod_{0\le s\le t} \lambda(X_s^{(k)}, Y_{s-})\Delta Y_s\right) \exp\left\{-\int_0^t \lambda(X_s^{(k)}, Y_s) ds\right\}, \tag{36}$$

and define the probability measure $\Pi_t^{(k)}$ as follows: For $A \in \mathcal{S}$,

$$\Pi_t^{(k)}(A) := \frac{E_{\overline{Q}}[L_t^{(k)} I_A(X_t^{(k)}) | Y_s : s \le t]}{E_{\overline{Q}}[L_t^{(k)} | Y_s : s \le t]}. \tag{37}$$

Finally, for later notational convenience, on $(\Omega_1, \mathcal{F}_1, P_1)$ we define Markov processes $\{X_t^{[k]}, t \ge 0\}$ with initial distribution p_k and transition probability kernel G_t. They are also independent of $\{X_t, Y_t, t \ge 0\}$, under $\overline{Q}$. Define $L_t^{[k]}$ and $\Pi_t^{[k]}$ as in (36) and (37) by replacing (k) with $[k]$. We will assume the following condition on the kernels $G_t^{(k)}$:

(H2) $\limsup_{k\to\infty} \sup_{0\le t\le\delta_0} \sup_{(x,y)\in S\times S} |\ln G_t^{(k)}(x,y) - \ln G_t(x,y)| = 0$,
for some $\delta_0 > 0$, where $|\ln(0) - \ln(0)| = 0$.

Condition (H2) says that the distance (in a log scale) between $G_t(\cdot)$ and $G_t^{(k)}(\cdot)$ is small for large k uniformly for t in some interval containing the origin. The theorem says that the outputs of filters (with the same observation process) but built under different assumptions on the transition kernel for the signal process, will eventually be close with a high probability if the two kernels are close in the given metric, irrespective of the (different) initial conditions.

THEOREM 4.2. *Assume that* (H1) *and* (H2) *hold, then* $\forall\delta$, $0 < \delta < \delta_0$, *there exists a sequence of stopping times,* t_n, *with respect to the filtration* $\sigma\{Y_s : s \le t\}$, *increasing to* ∞ *and satisfying* $|t_{n+1} - t_n| < \delta$, *with probability one and such that*

$$\lim_{k\to\infty} \limsup_{n\to\infty} P\left\{h(\Pi_{t_n}, \Pi_{t_n}^{(k)}) > \epsilon\right\} = 0$$

for every $\epsilon > 0$. *In fact, given* t_n, t_{n+1} *equals the time of the next observation if this occurs no later than* δ *units of time later; otherwise it is* $t_n + \delta$.

Proof. For notational simplicity we present the proof for the case where $\lambda(x,y) \equiv \lambda(x)$. Let $\{T_n\}$ continue to denote the jump times of Y. Define t_n as in the theorem statement. More formally, set $t_1 := T_1 \wedge \delta$ and for $n > 1$, define $t_n := t_{n-1} + (T_n^* - t_{n-1}) \wedge \delta$, where $T_n^* := \inf\{T_j : T_j > t_{n-1}\}$. Observe that $t_n - t_{n-1} \le \delta$ and t_n increases to infinity with probability one. We begin by observing that the triangle inequality implies that

$$h(\Pi_{t_n}, \Pi_{t_n}^{(k)}) \le h(\Pi_{t_n}, \Pi_{t_n}^{[k]}) + h(\Pi_{t_n}^{[k]}, \Pi_{t_n}^{(k)}). \tag{38}$$

By Theorem 4.1, for each fixed k the first term converges to zero with probability one as $n \to \infty$. Therefore it suffices to consider the second term. For the second term we will show that

$$\lim_{k\to\infty} \sup_n E\left[h(\Pi_{t_n}^{(k)}, \Pi_{t_n}^{[k]})\right] = 0. \tag{39}$$

Clearly, this will give the desired result. Let $\tau_n^* := t_n - t_{n-1}$. Define a sequence of nonnegative operators, $\{K_n\}_{n\ge1}$, on $\mathcal{M}(S)$ as follows. For a measurable function $q : S \to [0,\infty)$ and $\mu \in \mathcal{M}(S)$, $t_n \in \{T_j; j \ge 1\}$, set

$$\begin{aligned} K_n(\mu)q := \int_S E_{\overline{Q}}\Big[& q(X_{\tau_n^*}^{(0)})\lambda(X_{\tau_n^*}^{(0)}) \\ & \exp\left\{-\int_0^{\tau_n^*} \lambda(X_u^{(0)})du\right\} \big| X_0^{(0)} = x, T_j, j \ge 1\Big]\mu(dx). \end{aligned} \tag{40}$$

Otherwise, for $t_n \notin \{T_j; j \ge 1\}$, set

$$K_n(\mu)q := \int_S E_{\overline{Q}}\left[q(X_{\tau_n^*}^{(0)}) \exp\left\{-\int_0^{\tau_n^*} \lambda(X_u^{(0)})du\right\} \big| X_0^{(0)} = x, T_j, j \ge 1\right] \mu(dx). \tag{41}$$

Define the operators $K_n^{(k)}$ in a similar fashion by replacing $X^{(0)}$ by $X^{(k)}$. Then clearly, $\Pi_{t_n}^{(k)} = K_n^{(k)}\Pi_{t_{n-1}}^{(k)}$ and $\Pi_{t_n}^{[k]} = K_n\Pi_{t_{n-1}}^{[k]}$. By applying the triangle inequality to the first term on the right side of (38), we have

$$h(\Pi_{t_n}^{(k)}, \Pi_{t_n}^{[k]}) \le h(K_n^{(k)}\Pi_{t_{n-1}}^{(k)}, K_n\Pi_{t_{n-1}}^{(k)}) + h(K_n\Pi_{t_{n-1}}^{(k)}, K_n\Pi_{t_{n-1}}^{[k]}). \tag{42}$$

Now we will obtain an upper bound for the first term on the right side of the above inequality. Assume initially that $t_n \in \{T_j; j \geq 1\}$. Then for $x \in S$ and q as before, and letting δ_x denote the Dirac measure at x, $K_n^{(k)}(\delta_x)q$ can be written as

$$e^{-\lambda_2 \tau_n^*} E_{\overline{Q}} \left[q(X_{\tau_n^*}^{(k)}) \lambda(X_{\tau_n^*}^{(k)}) \exp\left\{ \int_0^{\tau_n^*} (\lambda_2 - \lambda(X_u^{(k)}))du \right\} \big| X_0^{(k)} = x, T_j, j \geq 1 \right].$$

For $y \in S$, define $\lambda^*(y) = \lambda_2 - \lambda(y)$. Then we can write

$$\exp\left\{ \int_0^{\tau_n^*} (\lambda_2 - \lambda(X_u^{(k)}))du \right\} = 1 + \sum_{j=1}^{\infty} \int_0^{\tau_n^*} \int_0^{s_{j-1}} \cdots \int_0^{s_1} \lambda^*(X_{s_{j-1}}^{(k)}) \cdots \lambda^*(X_{s_0}^{(k)})\, ds_0 \cdots ds_{j-1}.$$

The above representation yields that $K_n^{(k)}(\delta_x)q$ equals

$$e^{-\lambda_2 \tau_n^*} \Bigg[E_{\overline{Q}}[q(X_{\tau_n^*}^{(k)}) \lambda(X_{\tau_n^*}^{(k)}] + \sum_{j=1}^{\infty} \int_0^{\tau_n^*} \int_0^{s_{j-1}} \int_0^{s_1} E_{\overline{Q}}[q(X_{\tau_n^*}^{(k)}) \lambda(X_{\tau_n^*}^{(k)}) \lambda^*(X_{s_{j-1}}^{(k)}) \cdots \lambda^*(X_{s_0}^{(k)})] ds_0 \cdots ds_{j-1} \Bigg], \tag{43}$$

where the expectation is over everything but τ_n^*.

Next observe that the expectation inside the multiple integral above can be written as

$$\int_{S^{j+1}} \lambda(x_{j+1}) q(x_{j+1}) \lambda^*(x_j) \cdots \lambda^*(x_1) G_{\tau_n^* - s_j}^{(k)}(x_j, x_{j+1}) \cdots G_{s_0}^{(k)}(x, x_1) dm(x_1) \cdots dm(x_{j+1}) \tag{44}$$

Define

$$\rho_k := \sup_{0 \leq t \leq \delta_0} \sup_{(x,y) \in S \times S} |\ln G_t^{(k)}(x,y) - \ln G_t(x,y)|.$$

By hypothesis $\rho_k \to 0$ as $k \to \infty$. Moreover, $\forall u \in [0, \delta_0]$ and $(x,y) \in S \times S$,

$$e^{-\rho_k} G_u(x,y) \leq G_u^{(k)}(x,y) \leq e^{\rho_k} G_u(x,y).$$

Using this observation in (44) we obtain that $K_n^{(k)}(\delta_x)q$ is bounded above by

$$\exp\{\rho_k + \lambda_2 \tau_n^* (e^{\rho_k} - 1)\} E_{\overline{Q}} \Bigg[q(X_{\tau_n^*}^{(0)}) \lambda(X_{\tau_n^*}^{(0)}) \times \exp\left\{ -e^{\rho_k} \int_0^{\tau_n^*} \lambda(X_u^{(0)}) du \right\} \big| X_0^{(0)} = x, T_j, j \geq 1 \Bigg].$$

and below by

$$\exp\{-\rho_k + \lambda_2 \tau_n^* (e^{-\rho_k} - 1)\} E_{\overline{Q}} \left[q(X_{\tau_n^*}^{(0)}) \lambda(X_{\tau_n^*}^{(0)}) \times \exp\left\{ -e^{-\rho_k} \int_0^{\tau_n^*} \lambda(X_u^{(0)}) du \right\} \big| X_0^{(0)} = x, T_j, j \geq 1 \right].$$

Furthermore, the upper bound is bounded above by

$$\exp\left\{\rho_k + \lambda_2 \tau_n^* (e^{\rho_k} - 1)\right\} K_n(\delta_x) q,$$

and the lower bound is bounded below by

$$\exp\left\{-\rho_k + \lambda_2 \tau_n^* (e^{-\rho_k} - 1)\right\} K_n(\delta_x) q.$$

On recalling the definition of the Hilbert projective distance, using (2), and noting that $\tau_n^* \leq \delta$, these bounds yield

$$h(K_n^{(k)} \Pi_{t_{n-1}}^{(k)}, K_n \Pi_{t_{n-1}}^{(k)}) \leq \lambda_2 \delta [e^{\rho_k} - e^{-\rho_k}] + 2\rho_k.$$

Recall that we have proved the above inequality for $t_n \in \{T_j : j \geq 1\}$. However, it is easy to see that the inequality continues to hold for $t_n \notin \{T_j : j \geq 1\}$. (Compare (40) and (41).) Define $\epsilon_k = \lambda_2 \delta [e^{\rho_k} - e^{-\rho_k}] + 2\rho_k$. Then $\epsilon_k \to 0$ as $k \to \infty$ and

$$h(K_n^{(k)} \Pi_{t_{n-1}}^{(k)}, K_n \Pi_{t_{n-1}}^{(k)}) \leq \epsilon_k \, \forall n \geq 1. \tag{45}$$

Now consider the second term on the right side of (42). Using Birkhoff's contraction inequality, we have

$$h(K_n \Pi_{t_{n-1}}^{(k)}, K_n \Pi_{t_{n-1}}^{[k]}) \leq \tanh(C(K_n)/4) h(\Pi_{t_{n-1}}^{(k)}, \Pi_{t_{n-1}}^{[k]}). \tag{46}$$

Moreover, the arguments in the proof of Theorem 4.1 show that

$$C(K_n) \leq 2 \left(\ln \frac{f_2(\tau_n^*)}{f_1(\tau_n^*)} + \lambda_2 \tau_n^* + \ln \lambda_2/\lambda_1 \right). \tag{47}$$

It follows now from (42), (45), (46), (47) that

$$h(\Pi_{t_n}^{(k)}, \Pi_{t_n}^{[k]}) \leq \epsilon_k \sum_{j=1}^{n} \delta_j \cdots \delta_n, \tag{48}$$

where

$$\delta_n := \tanh \left[\frac{\ln \frac{f_2(\tau_n^*)}{f_1(\tau_n^*)} + \lambda_2 \tau_n^* + \ln \lambda_2/\lambda_1}{2} \right].$$

Next note that

$$E_{\overline{Q}} [\delta_j \cdots \delta_n] \leq E_{\overline{Q}} \left\{ \delta_j \cdots \delta_{n-1} E_{\overline{Q}} \left[\delta_n \middle| \mathcal{F}_X, t_1, \cdots, t_{n-1} \right] \right\}.$$

Also, as in Theorem 4.1 (see the arguments following inequality (34)),

$$E_{\overline{Q}} \left[\delta_n \middle| \mathcal{F}_X, t_1, \ldots, t_{n-1} \right] \leq 1 - \gamma^* P \left\{ \tau_n^* \in [\delta/2, \delta] \middle| \mathcal{F}_X, t_1, \ldots, t_{n-1} \right\},$$

where

$$\gamma^* := 2 \left[\frac{e^{-\lambda_2 \delta / C}}{1 + e^{-\lambda_2 \delta / C}} \right],$$

and

$$C := [\lambda_1/\lambda_2] \sup_{t\in[\delta/2,\delta]} f_2(t)/f_1(t).$$

Also

$$P\left\{\tau_n^* \in [\delta/2,\delta]\middle|\mathcal{F}_X, t_1,\dots,t_{n-1}\right\} > P\left\{Y_{t_{n-1}+\delta} - Y_{t_{n-1}} = 0\middle|\mathcal{F}_X, t_1,\dots,t_{n-1}\right\}.$$

The last term on the right is obviously greater than $e^{-\lambda_2\delta}$. Therefore,

$$E_{\overline{Q}}\left[\delta_n\middle|\ \mathcal{F}_X, t_1,\dots,t_{n-1}\right] \le 1-\gamma^* e^{-\lambda_2\delta} =: \kappa.$$

Using this observation in (48), we get

$$E[h(\Pi_{t_n}^{(k)}, \Pi_{t_n}^{[k]})] \le \epsilon_k/(1-\kappa).$$

This proves (39) and hence the theorem. □

Acknowledgments. We would like to thank a careful referee for pointing out an error in the proof of Theorem 3.1 and suggesting an alternate proof.

NONLINEAR FILTERING AND CONTROL OF A SWITCHING DIFFUSION WITH SMALL OBSERVATION NOISE*

Q. ZHANG†

Abstract. This paper is concerned with nonlinear filtering and control of a switching diffusion coupled by an unknown Markov chain. Two statistical estimation methods are used to track the unknown Markov chain. Computable approximate filters are obtained based on these methods. The filters are then used to construct controls for the partially observed system. These controls are shown to be asymptotically optimal as the observation noise tends to zero. Finally an example is considered and numerical experiments are reported.

Key words. nonlinear filtering, hybrid system, interacting multiple model, small observation noise, nearly optimal control

1. Introduction.

Let $(\alpha(t), x(t))$, $t \geq 0$, denote a pair of signal (or state) processes which is not directly observable. Consider the case that a function of $(\alpha(s), x(s))$, $s \leq t$, (linear in $x(\cdot)$) with an additive noise is observable given by $y(t)$. Let $u(t)$, $t \geq 0$, be a control process depending on the observation $y(\cdot)$ up to time t. Assume both $x(\cdot)$ and $y(\cdot)$ are $\mathbb{R}^p$-valued stochastic processes satisfying the equations

$$\begin{cases} dx(t) = b(t, \alpha(t), x(t), u(t))dt + \sigma(t, \alpha(t))dw(t), & x(0) = x_0, \\ dy(t) = h(t, \alpha(t), x(t))dt + \varepsilon dv(t), & y(0) = 0, \end{cases} \tag{1.1}$$

for $0 \leq t \leq T$, where T is a finite number, x_0 is a given random variable, $\alpha(\cdot)$ is an unknown Markov process, $(w(\cdot), v(\cdot))$ is a standard Brownian motion, and $\varepsilon > 0$ is a small parameter. Here we only consider those $u(\cdot)$ under which the equations in (1.1) have a (strong) solution.

Let $\mathcal{Y}_t$ denote the σ-algebra generated by the observation process $y(\cdot)$ up to time t, i.e., $\mathcal{Y}_t = \sigma\{y(s) : 0 \leq s \leq t\}$. The objective of the problem is to choose a $\mathcal{Y}_t$ progressively measurable control $u(\cdot)$ to minimize the cost functional

$$J(u(\cdot)) = E \int_0^T L(t, \alpha(t), x(t), u(t))dt. \tag{1.2}$$

First of all, let us consider the case when $\alpha(t)$ is a constant over time, say $\alpha(t) = \alpha_0$. If α_0 is known and $\varepsilon = 0$ in (1.1), then the system reduces to a completely observable system provided that h is one-to-one in x. So for ε small but different from zero, the problem under consideration is a singular perturbation of a "trivial" situation. In Haussmann and Zhang [11], such optimal control problems were studied with the aid of the extended Kalman filter (EKF) and the Picard filter (PF). Controls

based on the filtering outcomes were obtained, which are shown to be asymptotically optimal as $\varepsilon \to 0$.

When α_0 is not available to the controller of the system, the situation becomes more complicated. One of the major difficulties lies in the nonlinearility of system (1.1). If (1.1) is a linear system, the optimal control problem was solved by Hijab [14] and Caines and Chen [3] assuming an a priori distribution of the unknown parameter. However, in some practical situations, such a priori knowledge of α_0 is not available. To deal with the problem in this case, Haussmann and Zhang [12] used two statistical hypothesis tests, the quadratic variation test (QVT) and the likelihood ratio (least-squares) test (LRT), to estimate the value of α_0 and to choose among competing filters on successive time intervals. Then a control policy is obtained by using the filtering outcomes which is shown to be asymptotically optimal. The QVT and the LRT schemes were introduced by Fleming and Pardoux [7] to identify the sign of the state variable $x(t)$ in a partially observed system; see also Fleming and Zhang [9, 10] and Fleming et al. [6] for the corresponding discrete-time models and related numerical results along this line.

In this paper we consider the case when $\alpha(\cdot)$ is an unobservable Markov chain. Typically, to solve the underlying control problem, one needs to solve the associated filtering problem first, i.e., to find a conditional expectation $(\hat{\alpha}(t), \hat{x}(t)) = E[(\alpha(t), x(t))|\mathcal{Y}_t]$. However, owing to the nonlinearity of the system, especially the presence of $\alpha(\cdot)$, obtaining $(\hat{\alpha}(t), \hat{x}(t))$ requires solving the associated Zakai equation (or the nonlinear filtering equation), which is inherently infinite dimensional. Much effort in the literature was devoted to finite dimensional approximations. In Blom and Bar-Shalom [2], a discrete-time version of the corresponding filtering problem was considered. They proposed a numerical algorithm to compute $(\hat{\alpha}(\cdot), \hat{x}(\cdot))$. The algorithm seems to perform well numerically. However, there is no theoretical justification for the optimality (or the near optimality) of these filters; see Li [18] for further discussions.

In this paper, in order to design an approximate filter, we use the QVT (or the LRT) to estimate the value of $(\alpha(t), x(t))$ over time. We show that the resulting filters are asymptotically optimal as the observation noise goes to 0. The random jumps of $\alpha(\cdot)$ create one of the major difficulties when verifying the near optimality of these filters.

When dealing with a switching diffusion coupled by an unknown Markov chain, most of the nonlinear filters in the literature require the generator of $\alpha(\cdot)$ to be given. In practice, it usually takes a certain period of time to estimate the generator matrix. This creates a major problem if the generator is time dependent. The advantage of the filtering methods used in this paper is that they do not require knowing the generator of $\alpha(\cdot)$. In fact, the methods used in this paper can be easily extended to deal with much more general models in which even the Markovian assumption of $\alpha(\cdot)$ is unnecessary! In this connection, we refer to Remark 3.4 for discussions.

This paper extends the results on filtering and control in [12] to incorporate the case when $\alpha(\cdot)$ is an unknown Markov chain. The Markovian property is only required when dealing with the feedback controls. We design approximate filters and feedback controls for the problem under consideration. The main contribution of the paper is the verification of the asymptotic optimality of these filters and controls.

This paper is concerned with nonlinear filtering and control of a partially observed system. There is substantial literature on many related models and problems. For classical results on nonlinear filtering, we refer the books by Kallianpur [15] and

Liptser and Shiryayev [19]. For recent developments and review of the literature on partially observed systems, we refer the reader to the books by Bensoussan [1], Elliott, Aggoun, and Moore [5], Kushner [17], and references therein.

The paper is organized as follows. In the next section we formulate the problem under consideration and make assumptions. In section 3, we study the nonlinear filtering problem by using the QVT and the LRT methods and prove the asymptotic optimality of these filters. Then in section 4, we consider control policies based on the filtering results together with the dynamic programming approach. We show that the constructed control policies are nearly optimal as $\varepsilon \to 0$. In these sections we use the idea of an EKF to design nonlinear filters. For small ε, an EKF can be further approximated by a PF. In section 5, we extend these results to a hybrid linear quadratic system. In section 6, we consider the PF and present further extensions of these results to the case when the EKF is replaced by the corresponding PF. In section 7, we give a simple example and a set of numerical simulations to demonstrate the performance of the schemes and to compare with an existing algorithm in filtering. Finally, we conclude the paper by making some remarks. Technical results used in the paper are given in the Appendix.

Before moving on to the next section, let us give a list of notation used in the paper:

A'	the transpose of a matrix A;
B^c	the complement of a set B;
I	the identity matrix;
I_D	the indicator function of a set D;
$O(x)$	a function of x such that $\sup_{x\neq 0} \lvert O(x)\rvert/\lvert x\rvert < \infty$;
$[a]$	the integer part of a number a;
$\mathrm{tr}(A)$	the trace of a matrix A;
$\nabla_x f$	the partial derivative $\partial f/\partial x$;
$\lvert\xi(\cdot)\rvert_T$	$:= E\int_0^T \lvert\xi(t)\rvert dt$ for a stochastic process $\xi(\cdot)$.

Also, K is used as a generic positive constant throughout. The values of the K may be different for each appearance, but it should be clear from the context.

2. Problem formulation. Let $(\Omega, \mathcal{F}, P)$ denote a probability space and let $(w(\cdot), v(\cdot))$ be a standard Brownian motion. Given a positive integer m, let $\mathcal{M} = \{1, 2, \ldots, m\}$ denote the state space of $\alpha(\cdot)$, i.e., $\alpha(t) \in \mathcal{M}$, $t \geq 0$. We assume that $\alpha(\cdot)$ is a finite state Markov chain generated by a Borel measurable and bounded matrix $Q(t) = (q_{ij}(t))$, $t \geq 0$, with $q_{ij}(t) \geq 0$ for $i \neq j$ and $q_{ii}(t) = -\sum_{j\neq i} q_{ij}(t)$. The construction of a Markov chain generated by $Q(t)$ can be given as in Davis [4]. A particular case of the generator is when $Q(t) = Q$, which is independent of t, and the resulting Markov chain $\alpha(\cdot)$ is stationary.

We make the following assumptions in this paper.

(A1) For each $i \in \mathcal{M}$, $b(t, i, x, u)$ is a Borel measurable function of (t, x, u). The gradients $\nabla_x b(t, i, x, u)$ and $\nabla_u b(t, i, x, u)$ exist and are bounded.

(A2) There exist a matrix $H(t, i)$ and a constant $c > 0$ such that $h(t, i, x) = H(t, i)x$ with $H'(t, i)H(t, i) \geq cI > 0$ for all $t \geq 0$ and $i \in \mathcal{M}$. Furthermore, for each $i \in \mathcal{M}$, $H(t, i)$ is bounded and continuously differentiable in t.

(A3) $\sigma(t, i) = F(t, i)H'(t, i)$ for symmetric matrices $F(t, i) \geq cI > 0$. Moreover, $F(t, i)$ is bounded and continuously differentiable in t.

(A4) The initial value x_0 is a Gaussian random variable and $E|x_0 - Ex_0|^4 = O(\varepsilon^2)$. Moreover, x_0, $\alpha(\cdot)$, $w(\cdot)$, and $v(\cdot)$ are independent.

Remark 2.1. For notational simplicity, we use the Gaussian initial conditions

in (A4). This requirement can be relaxed as in Haussmann and Zhang [11] to non-Gaussian initial cases. The form assumed for $\sigma(t,i)$ in (A3) is not as restrictive as it appears. In fact, in the one-dimensional case, it is equivalent to the condition that $\sigma(t,i) \neq 0$. For higher dimensional cases, we refer the papers Haussmann and Zhang [11, 12] for related discussions.

3. Nonlinear filtering. In this section we consider the nonlinear filtering of the problem under consideration. For simplicity in notation, we suppress the variable u in (1.1) and consider the system given as

$$\begin{cases} dx(t) = b(t,\alpha(t),x(t))dt + \sigma(t,\alpha(t))dw(t), & x(0) = x_0, \\ dy(t) = h(t,\alpha(t),x(t))dt + \varepsilon dv(t), & y(0) = 0. \end{cases} \tag{3.1}$$

Remark 3.1. In the context of target tracking and filtering, the model in (3.1) is rich enough to capture many practical scenarios. To illustrate, let us consider $x(t) = (x^1(t), x^2(t))$ with $x^1(t) \in \mathbb{R}^3$ representing the position of the target and $x^2(t) \in \mathbb{R}^3$ its velocity. If we take $\alpha(t)$ to be the driving force of the target, then $\alpha(t)$ is proportional to the acceleration rate of the target given by the derivative of $x^2(t)$. Viewing the problem in this way, it is reasonable to consider the observation function $h(t,\alpha,x)$ is dependent on α.

In practice the observation noise level mainly depends on the sensor measurement characteristics. The development of new technology (such as the use of infrared technology) makes it possible for having fairly small disturbances in observation. So it is not only reasonable but also practical to consider the models with small observation noise.

Let $D[0,T]$ denote the space of functions defined on $[0,T]$ that are right-continuous and have a left-hand limit. Let

$$\Theta = \{\theta(\cdot) \in D[0,T] : \text{ such that } \theta(t) \in \mathcal{M},\ 0 \le t \le T\}.$$

For notational convenience, we write $\theta = \theta(\cdot)$, for each $\theta(\cdot) \in \Theta$. Let $(\tilde{x}^\theta(t), R^\theta(t))$, $t \ge 0$, denote the output of the EKF under the condition that $\alpha(\cdot) = \theta$. Then

$$\begin{aligned} d\tilde{x}^\theta(t) =\ & b(t,\theta(t),\tilde{x}^\theta(t))dt \\ & + \frac{1}{\varepsilon^2} R^\theta(t) H'(t,\theta(t)) \left(dy(t) - h(t,\theta(t),\tilde{x}^\theta(t))dt\right), \\ \frac{dR^\theta(t)}{dt} =\ & \nabla_x b(t,\theta(t),\tilde{x}^\theta(t)) R^\theta(t) + R^\theta(t)(\nabla_x b(t,\theta(t),\tilde{x}^\theta(t)))' \\ & + F(t,\theta(t)) H'(t,\theta(t)) H(t,\theta(t)) F(t,\theta(t)) \\ & - \frac{1}{\varepsilon^2} R^\theta(t) H'(t,\theta(t)) H(t,\theta(t)) R^\theta(t), \end{aligned} \tag{3.2}$$

with $\tilde{x}^\theta(0) = Ex_0 \in \mathbb{R}^p$ and $R^\theta(0) = \mathrm{Cov}(x_0) \in \mathbb{R}^{p\times p}$.

Given a fixed number $0 < \sigma < 1$, let

$$\Theta_\sigma^\varepsilon = \left\{\theta(\cdot) \in \Theta : \text{ the number of jumps of } \theta(\cdot) \le [1/\varepsilon^\sigma]\right\}.$$

Then in view of Lemma A.6 in the Appendix, there exists a constant K such that

$$P(\alpha(\cdot) \notin \Theta_\sigma^\varepsilon) = P(\alpha(\cdot) \text{ jumps more than } [1/\varepsilon^\sigma] \text{ times}) \le K\varepsilon^2. \tag{3.3}$$

Thus, the set $\Theta_\sigma^\varepsilon$ can be regarded as an approximation to Ω because $P(\alpha(\cdot) \in \Theta_\sigma^\varepsilon)$ is close to 1 due to the fact that

$$P(\alpha(\cdot) \in \Theta_\sigma^\varepsilon) = 1 - P(\alpha(\cdot) \notin \Theta_\sigma^\varepsilon) \ge 1 - K\varepsilon^2.$$

Let $\gamma_0 > 0$ be a constant and define

$$\Theta^{\varepsilon}_{\sigma,\gamma_0} = \Big\{\theta = \theta(\cdot) \in \Theta^{\varepsilon}_{\sigma} : \text{ the duration between any two jumps of } \theta(\cdot) \geq \gamma_0\varepsilon\Big\}.$$

If we let $0 = t_0 < t_1 < \cdots < t_n < T$ denote the jump times of $\theta(\cdot)$, then $\theta(\cdot) \in \Theta^{\varepsilon}_{\sigma,\gamma_0}$ implies that $n \leq [1/\varepsilon^{\sigma}]$ and $t_{j+1} - t_j \geq \gamma_0\varepsilon$.

Let $0 = \tau_0 < \tau_1 < \cdots$ denote the sequence of the random jump times of $\alpha(\cdot)$. Then, for $j = 0, 1, \ldots$, the distribution of $\tau_{j+1} - \tau_j$ is exponential. Thus, for some constant K, $P(\tau_{j+1} - \tau_j < t) \leq Kt$ for $t \geq 0$. It follows that

$$\begin{aligned} P(\alpha(\cdot) \notin \Theta^{\varepsilon}_{\sigma,\gamma_0}) &\leq P\Big(\bigcup_{j=0}^{[1/\varepsilon^{\sigma}]} \{\tau_{j+1} - \tau_j < \gamma_0\varepsilon\}\Big) + P(\alpha(\cdot) \notin \Theta^{\varepsilon}_{\sigma}) \\ &\leq \sum_{j=0}^{[1/\varepsilon^{\sigma}]} P(\tau_{j+1} - \tau_j < \gamma_0\varepsilon) + O(\varepsilon^2) \leq \sum_{j=0}^{[1/\varepsilon^{\sigma}]} K\varepsilon + O(\varepsilon^2) = O(\varepsilon^{1-\sigma}). \end{aligned} \tag{3.4}$$

Therefore, $\Theta^{\varepsilon}_{\sigma,\gamma_0}$ can also be considered as an approximation to Ω.

The sets $\Theta^{\varepsilon}_{\sigma}$ and $\Theta^{\varepsilon}_{\sigma,\gamma_0}$ are defined so that their elements meet certain requirements on the number of jumps and the duration between consecutive jumps. These requirements are useful in the subsequent analysis.

Then as can be shown in Lemma A.3 that there exist $\gamma_0 > 0$ and K such that for each $0 < \sigma < 1$, $0 < \varepsilon < \varepsilon_0$, and for all $\theta = \theta(\cdot) \in \Theta^{\varepsilon}_{\sigma,\gamma_0}$,

$$E^{\theta} \int_0^T \left|\hat{x}^{\theta}(t) - \tilde{x}^{\theta}(t)\right|^2 dt \leq K\varepsilon^4,$$

where $\hat{x}^{\theta}(t) = E^{\theta}[x(t)|\mathcal{Y}_t]$ and E^{θ} is the conditional expectation given $\alpha(\cdot) = \theta$.

It is important to estimate the value of $\alpha(\cdot)$ in the filtering problem under consideration because if an estimate of $\alpha(\cdot)$ is given, one can use such estimate to choose the corresponding EKF as an estimate for $\hat{x}(\cdot)$ as in Lemma A.3. In this section we consider two statistical tests, the QVT and the LRT, to identify the value of the unknown parameter process $\alpha(\cdot)$ at a given time t.

In Haussmann and Zhang [12], they considered the case when $\alpha(t) = \alpha_0$, a constant parameter. So there are only a finite number of parameter values to examine. In this paper we need to carry out the parameter identification at each time instant t to incorporate random fluctuations of $\alpha(\cdot)$.

QVT. For $k = 0, 1, \ldots$, let

$$\zeta(k) = \frac{1}{\varepsilon}\left(y(\varepsilon(k+2)) - 2y(\varepsilon(k+1)) + y(\varepsilon k)\right).$$

We define a test statistic

$$\Lambda^{n_0,n} = \frac{1}{\varepsilon(n-n_0)} \sum_{k=n_0}^{n-1} |\zeta(k)|^2.$$

Let

$$\mu_i^{n_0,n} = \frac{1}{\varepsilon(n-n_0)} \int_{\varepsilon n_0}^{\varepsilon(n+1)} \rho^{n_0,n}(s)\mathrm{tr}(H(s,i)Q(s,i)H'(s,i))^2 ds + 2p,$$

where, for $n_0, n = 0, 1, \ldots,$

$$\rho^{n_0,n}(s) = \begin{cases} \phi^2(s)I_{[\varepsilon n_0, \varepsilon n]} + \phi^2(s-\varepsilon)I_{[\varepsilon(n_0+1),\varepsilon n]} & \text{if } (n-n_0) \text{ even} \\ \phi^2(s)I_{[\varepsilon n_0, \varepsilon(n+1)]} + \phi^2(s-\varepsilon)I_{[\varepsilon(n_0+1),\varepsilon(n+1)]} & \text{if } (n-n_0) \text{ odd,} \end{cases}$$

and $\phi(s)$ is a "sawtooth" function on $[0, T]$ such that for any $j = 0, 2, 4, \ldots$ even,

$$\phi(s) = \begin{cases} \dfrac{s - j\varepsilon}{\varepsilon} & \text{if } j\varepsilon \le s < (j+1)\varepsilon \\ \dfrac{(j+2)\varepsilon - s}{\varepsilon} & \text{if } (j+1)\varepsilon \le s < (j+2)\varepsilon. \end{cases}$$

(See Haussmann and Zhang [12] for interpretation of these functions.)

Given $\alpha(t) = i$, $\varepsilon n_0 \le t < \varepsilon n$, it can be shown as in [12] that for large $(n - n_0)$, $\Lambda^{n_0,n}/\mu_i^{n_0,n}$ is close to 1 by the law of large numbers. In order to distinguish the $\mu_i^{n_0,n}$'s, we impose a detectability condition as in Fleming and Pardoux [7].

(A5) There exists a constant $c > 0$ such that

$$\left| \operatorname{tr}\left(H(t,i)F(t,i)H'(t,i)\right)^2 - \operatorname{tr}\left(H(t,j)F(t,j)H'(t,j)\right)^2 \right| \ge c > 0$$

for $i \ne j$ and all $t \ge 0$.

In one-dimensional case, if $F(t,i) = 1$ and $H(t,i) = H(i)$, which is independent of t, then (A5) is equivalent to the condition $|H(i)| \ne |H(j)|$.

The QVT is given as follows: Let $\alpha^{n_0,n}$ denote a random variable such that $\alpha^{n_0,n} = i_0$ if

$$\left| \frac{\Lambda^{n_0,n}}{\mu_{i_0}^{n_0,n}} - 1 \right| = \min\left\{ \left| \frac{\Lambda^{n_0,n}}{\mu_j^{n_0,n}} - 1 \right|,\ j \in \mathcal{M} \right\}. \tag{3.5}$$

The next lemma gives the error probability of the QVT, which can be proved similarly as in [12, Lemma 3.1].

LEMMA 3.1. *Assume* (A1)–(A5). *Then for each* $j = 1, 2, \ldots,$ *there exist* $k_0 > 0,\ K > 0, \varepsilon_0 > 0$ *such that for* $0 < \varepsilon < \varepsilon_0,\ n - n_0 \ge l_0 := [k_0(\log \varepsilon)^2] + 1,$

$$P(\alpha^{n_0,n} \ne i_0 | \alpha(t) = i_0,\ t \in [\varepsilon n_0, \varepsilon n]) \le K\varepsilon^2. \tag{3.6}$$

It follows that

$$P(\{\alpha^{n_0,n} \ne i_0\} \cap \{\alpha(t) = i_0,\ t \in [\varepsilon n_0, \varepsilon n]\}) \le K\varepsilon^2. \tag{3.7}$$

Remark 3.2. As in Fleming and Pardoux [7], the error bounds in (3.6) and (3.7) can be improved to an order of ε^k for any given k by choosing ε_0 small enough and K sufficiently large. In this paper, we need only the estimate up to an order of ε^2.

In general, for $\varepsilon n \le t < \varepsilon(n+1)$, $n = 0, 1, \ldots$, we define

$$\tilde{\alpha}(t) = \begin{cases} 1 & \text{if } t \in [0, \varepsilon), \\ \alpha^{0,n} & \text{if } n \le l_0, \\ \alpha^{n-l_0,n} & \text{if } n \ge l_0. \end{cases} \tag{3.8}$$

We will show in Theorem 3.3 that $\tilde{\alpha}(\cdot)$ is indeed a good approximation to $\alpha(\cdot)$.

Next let us give another method for estimating the unknown process $\alpha(\cdot)$ using the outputs of several EKFs based on the principle of the well known least squares algorithm; see [12] for related discussions.

LRT. In the LRT, the detectability condition (A5) used for the QVT can be relaxed to the following condition:

(A6) $\text{tr}\Big(H(t,i)F(t,i)H'(t,i) - H(t,j)F(t,j)H'(t,j)\Big)^2 \geq c > 0$ for $i \neq j$.

Note that the condition

$$\text{tr}\Big(H(t,i)F(t,i)H'(t,i) - H(t,j)F(t,j)H'(t,j)\Big)^2 = 0$$

implies $H(t,i)F(t,i)H'(t,i) = H(t,j)F(t,j)H'(t,j)$. Clearly, (A5) implies (A6) because $F(t,i)$ is a symmetric matrix.

Given $0 < \sigma < 1$, let $l_1 = [1/\varepsilon^\sigma]$. For each $0 \leq t \leq T$, we consider the interval of a moving window $\mathcal{I}(t)$ defined as follows:

$$\mathcal{I}(t) = [\gamma_1(t), \gamma_2(t)) = \begin{cases} \left[0, \left[\frac{t}{\varepsilon}\right]\varepsilon\right) & \text{if } t \leq l_1, \\ \left[\left[\frac{t}{\varepsilon}\right]\varepsilon - l_1\varepsilon, \left[\frac{t}{\varepsilon}\right]\varepsilon\right) & \text{if } t > l_1. \end{cases}$$

On the interval $\mathcal{I}(t)$, we consider the output of the EKF under the condition that $\alpha(\cdot) = i$ on $\mathcal{I}(t)$, i.e., $\alpha(s) = i$ for $s \in \mathcal{I}(t)$. Then

$$\begin{aligned} d\tilde{x}^{(i)}(t) =& \ b(t,i,\tilde{x}^{(i)}(t))dt + \frac{1}{\varepsilon^2}R^{(i)}(t)H'(t,i)\left(dy(t) - h(t,i,\tilde{x}^{(i)}(t))dt\right), \\ \frac{dR^{(i)}(t)}{dt} =& \ \nabla_x b(t,i,\tilde{x}^{(i)}(t))R^{(i)}(t) + R^{(i)}(t)(\nabla_x b(t,i,\tilde{x}^{(i)}(t)))' \\ & + F(t,i)H'(t,i)H(t,i)F(t,i) - \frac{1}{\varepsilon^2}R^{(i)}(t)H'(t,i)H(t,i)R^{(i)}(t), \end{aligned}$$

with $\tilde{x}^i(\gamma_1(t)) = \tilde{x}(\gamma_1(t))$, $R^{(i)}(\gamma_1(t)) = \widetilde{R}(\gamma_1(t))$, and $\tilde{x}(\gamma_1(t))$ and $\widetilde{R}(\gamma_1(t))$ will be defined in what follows.

For each $i \in \mathcal{M}$, let $L^{(i)}(\mathcal{I}(t))$ denote a test statistics on $\mathcal{I}(t)$,

$$L^{(i)}(\mathcal{I}(t)) = \frac{1}{\varepsilon}\left(\int_{\gamma_1(t)}^{\gamma_2(t)} (H(t,i)\tilde{x}^{(i)}(t))'dy(t) - \frac{1}{2}\int_{\gamma_1(t)}^{\gamma_2(t)} |H(t,i)\tilde{x}^{(i)}(t)|^2 dt\right). \tag{3.9}$$

For each t, define

$$\tilde{\alpha}(t) = \begin{cases} 1 & \text{if } t \in [0,\varepsilon), \\ i & \text{if } t \geq \varepsilon \text{ and } L^{(i)}(\mathcal{I}(t)) = \max\{L^{(j)}(\mathcal{I}(t)) : \ j \in \mathcal{M}\}. \end{cases} \tag{3.10}$$

Using $\tilde{\alpha}(\cdot)$, we define the EKF based on the LRT as follows:

$$\begin{aligned} d\tilde{x}(t) =& \ b(t,\tilde{\alpha}(t),\tilde{x}(t))dt \\ & + \frac{1}{\varepsilon^2}\widetilde{R}(t)H'(t,\tilde{\alpha}(t))\left(dy(t) - h(t,\tilde{\alpha}(t),\tilde{x}(t))dt\right), \\ \frac{d\widetilde{R}(t)}{dt} =& \ \nabla_x b(t,\tilde{\alpha}(t),\tilde{x}(t))\widetilde{R}(t) + \widetilde{R}(t)(\nabla_x b(t,\tilde{\alpha}(t),\tilde{x}(t)))' \\ & + F(t,\tilde{\alpha}(t))H'(t,\tilde{\alpha}(t))H(t,\tilde{\alpha}(t))F(t,\tilde{\alpha}(t)) \\ & - \frac{1}{\varepsilon^2}\widetilde{R}(t)H'(t,\tilde{\alpha}(t))H(t,\tilde{\alpha}(t))\widetilde{R}(t), \end{aligned} \tag{3.11}$$

where $\tilde{x}(0) = Ex_0$ and $\widetilde{R}(0) = \text{Cov}(x_0)$.

Note that the processes $(\tilde{x}(\cdot), \widetilde{R}(\cdot))$, $(\tilde{x}^{(i)}(\cdot), \widetilde{R}^{(i)}(\cdot))$, and $\tilde{\alpha}(\cdot)$ are well defined. In fact, it is easy to see that the processes $\tilde{\alpha}(\cdot)$ and $(\tilde{x}^{(i)}(\cdot), \widetilde{R}^{(i)}(\cdot))$ are defined on $[0, (l_1+1)\varepsilon)$, so is $(\tilde{x}(\cdot), \widetilde{R}(\cdot))$ because the lower limit of $\mathcal{I}(t)$ equals $\gamma_1(t) = 0$ and $(\tilde{x}(0), \widetilde{R}(0)) = (Ex_0, \mathrm{Cov}(x_0))$, which is given. The EKF gives the value of $(\tilde{x}(\varepsilon), \widetilde{R}(\varepsilon))$. Then $(\tilde{x}^{(i)}(\varepsilon), \widetilde{R}^{(i)}(\varepsilon))$ is used for computing $(\tilde{x}^{(i)}(\cdot), \widetilde{R}^{(i)}(\cdot))$ on the next interval $\mathcal{I}(t)$ for $t \in [(l_1+1)\varepsilon, (l_1+2)\varepsilon)$ and that leads to $\tilde{\alpha}(\cdot)$ on this interval. Then using $\tilde{\alpha}(\cdot)$ on $[(l_1+1)\varepsilon, (l_1+2)\varepsilon)$, we can compute $(\tilde{x}(\cdot), \widetilde{R}(\cdot))$ on this interval. This procedure can be repeated on intervals $[j\varepsilon, (j+1)\varepsilon)$ for all j.

LEMMA 3.2. *Assume* (A1)–(A4) *and* (A6). *Then there exist positive constants* ε_0, K *such that for* $0 < \varepsilon < \varepsilon_0$

$$P\Big(\tilde{\alpha}(t) \neq i_0 | \alpha(\cdot) = i_0 \text{ on } \mathcal{I}(t)\Big) \leq K\varepsilon^2.$$

Proof. The proof can be given similarly as in [12, Lemma 3.3]. □

Remark 3.3. In this paper we use a moving window (fixed sample size) to estimate the value of $\alpha(\cdot)$. The length of the window is εl_0 for the QVT and εl_1 for the LRT. Typically the QVT requires less time than the LRT with a given error probability; see [6] and [13]. Moreover, a sequential test can be used to estimate the value of $\alpha(\cdot)$, which usually requires less time when compared with the fixed sample size test.

Approximate filters. Next we study asymptotic filters based on the QVT and the LRT and estimate the corresponding error bounds.

For any given stochastic process $\xi(t)$, $t \geq 0$, we define the norm of $\xi(\cdot)$ as follows:

$$|\xi(\cdot)|_T = E\int_0^T |\xi(t)|dt.$$

The next theorem is concerned with the asymptotic property of $\tilde{\alpha}(\cdot)$ and the associate error bound in terms of the $|\cdot|_T$ norm.

THEOREM 3.3. *Let* $\tilde{\alpha}(\cdot)$ *be a filter based on the QVT, defined in* (3.8), *and assume* (A1)–(A5) (*or based on the LRT, defined in* (3.10), *and assume* (A1)–(A4) *and* (A6)). *Then for each* $0 < \delta < 1$, *there exist positive constants* ε_0 *and* K *such that for* $0 < \varepsilon < \varepsilon_0$,

$$|\tilde{\alpha}(\cdot) - \alpha(\cdot)|_T \leq K\varepsilon^{1-\delta}.$$

Proof. Let $0 < \tau_1 < \tau_2 < \cdots$ denote the random jump times of $\alpha(\cdot)$. Then, for $j = 1, 2, \ldots$,

$$P\Big(\tau_{j+1} - \tau_j \leq k_0\varepsilon(\log\varepsilon)^2\Big) = O\left(\varepsilon(\log\varepsilon)^2\right). \tag{3.12}$$

For notational convenience, let $\xi(t) = |\tilde{\alpha}(t) - \alpha(t)|$. Then, for $0 < \sigma < \delta$,

$$E\int_0^T |\tilde{\alpha}(t) - \alpha(t)|dt = E\int_0^T \xi(t)dt = E\int_0^T \xi(t)dtI_{\{\alpha(\cdot)\in\Theta_\sigma^\varepsilon\}} + E\int_0^T \xi(t)dtI_{\{\alpha(\cdot)\notin\Theta_\sigma^\varepsilon\}}.$$

Recall the inequalities $P(\alpha(\cdot) \notin \Theta_\sigma^\varepsilon) \leq K\varepsilon^2$ given in (2.3) and $|\xi(t)| \leq m$. It follows that

$$E\int_0^T \xi(t)dtI_{\{\alpha(\cdot)\notin\Theta_\sigma^\varepsilon\}} \leq mTEI_{\{\alpha(\cdot)\notin\Theta_\sigma^\varepsilon\}} = mTP(\alpha(\cdot) \notin \Theta_\sigma^\varepsilon) \leq K\varepsilon^2.$$

Moreover, note that the process $\alpha(\cdot)$ jumps at most $[1/\varepsilon^\sigma]$ times if $\alpha(\cdot) \in \Theta_\sigma^\varepsilon$. Thus,

$$E\int_0^T \xi(t)dtI_{\{\alpha(\cdot)\in\Theta_\sigma^\varepsilon\}} \le \sum_{j=0}^{[1/\varepsilon^\sigma]} E\int_{\tau_j\wedge T}^{\tau_{j+1}\wedge T} \xi(t)dt.$$

If we show that, for each $j = 0, 1, \ldots, [1/\varepsilon^\sigma]$,

$$E\int_{\tau_j\wedge T}^{\tau_{j+1}\wedge T} \xi(t)dt = O(\varepsilon(\log\varepsilon)^2), \tag{3.13}$$

then

$$E\int_0^T \xi(t)dtI_{\{\alpha(\cdot)\in\Theta_\sigma^\varepsilon\}} \le \sum_{j=0}^{[1/\varepsilon^\sigma]} O(\varepsilon(\log\varepsilon)^2) = O(\varepsilon^{1-\sigma}|\log\varepsilon|^2) = O(\varepsilon^{1-\delta}),$$

because for $0 < \sigma < \delta$, $\varepsilon^{\delta-\sigma}(\log\varepsilon)^2 \to 0$ as $\varepsilon \to 0$. Hence, it suffices to show (3.13).

We start from $j = 0$. Note that, for $l_0 = [k_0(\log\varepsilon)^2] + 1$ as in Lemma 3.1,

$$E\int_0^{\tau_1\wedge T} \xi(t)dt = E\int_0^T \xi(t)I_{[0,\tau_1)}dt = E\left(\int_0^{l_0\varepsilon} + \int_{l_0\varepsilon}^T\right)\xi(t)I_{[0,\tau_1)}dt.$$

Moreover, the boundedness of $\xi(t)$ implies that

$$E\int_0^{l_0\varepsilon} \xi(t)I_{[0,\tau_1)}dt = O(l_0\varepsilon) = O(\varepsilon(\log\varepsilon)^2).$$

Write

$$E\int_{l_0\varepsilon}^T \xi(t)I_{[0,\tau_1)}dt = E\sum_{j=l_0}^{T_\varepsilon}\int_{j\varepsilon}^{(j+1)\varepsilon} \xi(t)I_{[0,\tau_1)}dt,$$

where $T_\varepsilon = [T/\varepsilon]$. For all $j \ge l_0$, we have

$$\begin{aligned} E\int_{j\varepsilon}^{(j+1)\varepsilon} \xi(t)I_{[0,\tau_1)}dt = {} & E\int_{j\varepsilon}^{(j+1)\varepsilon} \xi(t)I_{[0,\tau_1)}dtI_{\{\tau_1<j\varepsilon\}} \\ & + E\int_{j\varepsilon}^{(j+1)\varepsilon} \xi(t)I_{[0,\tau_1)}dtI_{\{j\varepsilon\le\tau_1<(j+1)\varepsilon\}} \\ & + E\int_{j\varepsilon}^{(j+1)\varepsilon} \xi(t)I_{[0,\tau_1)}dtI_{\{\tau_1\ge(j+1)\varepsilon\}}. \end{aligned} \tag{3.14}$$

The first term on the right side equals 0 because $[j\varepsilon, (j+1)\varepsilon] \cap [0, \tau_1) = \emptyset$. The second term in (3.14) is of order ε^2 due to the fact that

$$\begin{aligned} E\int_{j\varepsilon}^{(j+1)\varepsilon} & \xi(t)I_{[0,\tau_1)}dtI_{\{j\varepsilon\le\tau_1<(j+1)\varepsilon\}} \\ & \le m\int_{j\varepsilon}^{(j+1)\varepsilon} EI_{\{j\varepsilon\le\tau_1<(j+1)\varepsilon\}} \\ & = m\int_{j\varepsilon}^{(j+1)\varepsilon} P(j\varepsilon \le \tau_1 < (j+1)\varepsilon) = O(\varepsilon^2). \end{aligned}$$

To estimate the third term on the right side of (3.14), note that

(1) $[j\varepsilon,(j+1)\varepsilon]\subset[0,\tau_1]$, which implies $\alpha(t)=i_0$ (no jump) on $[0,\tau_1]$;
(2) For $j\le t<(j+1)\varepsilon$, $\tilde\alpha(t)$ is defined based on the information given on the interval $[(j-l_0+1)\varepsilon,j\varepsilon]$.

These imply the following inequality:

$$E\int_{j\varepsilon}^{(j+1)\varepsilon}\xi(t)I_{[0,\tau_1)}dtI_{\{\tau_1\ge(j+1)\varepsilon\}}\le m\sum_{i_0=1}^{m}\int_{j\varepsilon}^{(j+1)\varepsilon}P(\{\alpha(t)=i_0,\ t\in[(j-l_0+1)\varepsilon,j\varepsilon]\}\cap\tilde\alpha(t)\ne i_0)dt.$$

It follows that

$$E\int_0^{\tau_1\wedge T}\xi(t)dt=O(\varepsilon(\log\varepsilon)^2).$$

Next we estimate $E\int_{\tau_1\wedge T}^{\tau_2\wedge T}\xi(t)dt$, which can be written as $E\int_0^T\xi(t)I_{[\tau_1,\tau_2)}dt$. Note that $P(\tau_2-\tau_1\le l_0\varepsilon)=O(\varepsilon(\log\varepsilon)^2)$ and

$$E\int_0^T I_{[\tau_1,l_0\varepsilon+\tau_1]}dt=O(l_0\varepsilon)=O(\varepsilon(\log\varepsilon)^2).$$

It follows that

$$E\int_0^T\xi(t)I_{[\tau_1,\tau_2)}dt=E\int_0^T\xi(t)I_{[\tau_1,\tau_2)}I_{\{\tau_2-\tau_1\ge l_0\varepsilon\}}dt+O(\varepsilon(\log\varepsilon)^2).$$

Note also that if $\tau_1>\varepsilon T_\varepsilon$, then $E\int_0^T\xi(t)I_{[\tau_1,\tau_2)}dt=O(\varepsilon)$. Write

$$\begin{aligned}&E\int_0^T\xi(t)I_{[\tau_1+l_0\varepsilon,\tau_2)}I_{\{\tau_2-\tau_1\ge l_0\varepsilon\}}dt\\&=\sum_{i=0}^{T_\varepsilon}E\int_0^T\xi(t)I_{[\tau_1+l_0\varepsilon,\tau_2)}I_{\{\tau_2-\tau_1\ge l_0\varepsilon\}}dtI_{\{i\varepsilon\le\tau_1<(i+1)\varepsilon\}}\\&=\sum_{i=0}^{T_\varepsilon}E\int_{(i+l_0)\varepsilon}^T\xi(t)I_{[\tau_1+l_0\varepsilon,\tau_2)}I_{\{\tau_2-\tau_1\ge l_0\varepsilon\}}dtI_{\{i\varepsilon\le\tau_1<(i+1)\varepsilon\}},\end{aligned}$$

because $I_{[\tau_1+l_0\varepsilon,\tau_2)}=0$ for $t\le(i+l_0)\varepsilon$ given $\{i\varepsilon\le\tau_1<(i+1)\varepsilon\}$. Moreover,

$$\begin{aligned}&E\int_{(i+l_0)\varepsilon}^T\xi(t)I_{[\tau_1+l_0\varepsilon,\tau_2)}I_{\{\tau_2-\tau_1\ge l_0\varepsilon\}}dtI_{\{i\varepsilon\le\tau_1<(i+1)\varepsilon\}}\\&=\sum_{j=i+l_0}^{T_\varepsilon}E\int_{j\varepsilon}^{(j+1)\varepsilon}\xi(t)I_{[\tau_1+l_0\varepsilon,\tau_2)}I_{\{\tau_2-\tau_1\ge l_0\varepsilon\}}dtI_{\{i\varepsilon\le\tau_1<(i+1)\varepsilon\}}\\&=O(\varepsilon^2)+\sum_{j=i+l_0+1}^{T_\varepsilon}E\int_{j\varepsilon}^{(j+1)\varepsilon}\xi(t)I_{[\tau_1+l_0\varepsilon,\tau_2)}I_{\{\tau_2-\tau_1\ge l_0\varepsilon\}}dtI_{\{i\varepsilon\le\tau_1<(i+1)\varepsilon\}}.\end{aligned}$$

The last equality is due to the fact that $P(i\varepsilon\le\tau_1<(i+1)\varepsilon)=O(\varepsilon)$. Let

$$\zeta=E\int_{j\varepsilon}^{(j+1)\varepsilon}\xi(t)I_{[\tau_1+l_0\varepsilon,\tau_2)}I_{\{\tau_2-\tau_1\ge l_0\varepsilon\}}dtI_{\{i\varepsilon\le\tau_1<(i+1)\varepsilon\}}.$$

Then for $j\ge i+l_0+1$, we have

(1) If $\tau_2 < j\varepsilon$, then $\zeta = 0$;
(2) If $j\varepsilon \le \tau_2 < (j+1)\varepsilon$, then $\zeta = O(\varepsilon^2)$ because $P(j\varepsilon \le \tau_2 < (j+1)\varepsilon) = O(\varepsilon)$;
(3) If $\tau_2 \ge (j+1)\varepsilon$, then

$$\zeta \le m \sum_{i_0=1}^{m} \int_{j\varepsilon}^{(j+1)\varepsilon} P(\{\alpha(t) = i_0,\ t \in [(j-l_0+1)\varepsilon, j\varepsilon]\} \cap \{\tilde{\alpha}(t) \ne i_0\})dt = O(\varepsilon^3).$$

Continue this way, we can show (3.13), for all $j = 1, 2, \ldots, [1/\varepsilon^\sigma]$, and thus complete the proof. □

Similar to the proof of Theorem 3.3, one can show the following result.

COROLLARY 3.4. *For each* $j = 0, 1, \ldots,$

$$P(\tilde{\alpha}(t) \ne \alpha(t) : \quad \textit{for some } t \in [\tau_j + l_0\varepsilon, \tau_{j+1})) = O(\varepsilon).$$

Using $\tilde{\alpha}(\cdot)$, we define an approximate filter $\tilde{x}(\cdot)$ satisfying the following equations:

$$\begin{aligned} d\tilde{x}(t) =\ & b(t, \tilde{\alpha}(t), \tilde{x}(t))dt \\ & + \frac{1}{\varepsilon^2}\widetilde{R}(t)H'(t, \tilde{\alpha}(t))\left(dy(t) - h(t, \tilde{\alpha}(t), \tilde{x}(t))dt\right), \\ \frac{d\widetilde{R}(t)}{dt} =\ & \nabla_x b(t, \tilde{\alpha}(t), \tilde{x}(t))\widetilde{R}(t) + \widetilde{R}(t)(\nabla_x b(t, \tilde{\alpha}(t), \tilde{x}(t)))' \\ & + F(t, \tilde{\alpha}(t))H'(t, \tilde{\alpha}(t))H(t, \tilde{\alpha}(t))F(t, \tilde{\alpha}(t)) \\ & - \frac{1}{\varepsilon^2}\widetilde{R}(t)H'(t, \tilde{\alpha}(t))H(t, \tilde{\alpha}(t))\widetilde{R}(t), \end{aligned} \tag{3.15}$$

with $\tilde{x}(0) = Ex_0$ and $\widetilde{R}(0) = \mathrm{Cov}(x_0)$.

In order to verify the asymptotic optimality of $(\tilde{\alpha}(\cdot), \tilde{x}(\cdot)))$ and estimate the corresponding error bound, we need to consider an intermediate "filter" $(\check{x}(t), \check{R}(t))$, $t \ge 0$, assuming $\alpha(\cdot)$ is given, defined as follows:

$$\begin{aligned} d\check{x}(t) =\ & b(t, \alpha(t), \check{x}(t))dt \\ & + \frac{1}{\varepsilon^2}\check{R}(t)H'(t, \alpha(t))\left(dy(t) - h(t, \alpha(t), \check{x}(t))dt\right), \\ \frac{d\check{R}(t)}{dt} =\ & \nabla_x b(t, \alpha(t), \check{x}(t))\check{R}(t) + \check{R}(t)(\nabla_x b(t, \alpha(t), \check{x}(t)))' \\ & + F(t, \alpha(t))H'(t, \alpha(t))H(t, \alpha(t))F(t, \alpha(t)) \\ & - \frac{1}{\varepsilon^2}\check{R}(t)H'(t, \alpha(t))H(t, \alpha(t))\check{R}(t), \end{aligned} \tag{3.16}$$

with $\check{x}(0) = Ex_0$ and $\check{R}(0) = \mathrm{Cov}(x_0)$. Clearly, $(\check{x}(\cdot), \check{R}(\cdot))$ can be obtained by replacing $\alpha(\cdot)$ with $\tilde{\alpha}(\cdot)$ in (3.15).

THEOREM 3.5. *Assume the conditions in Theorem* 3.3. *Then for a given* $0 < \delta < 1$, *there exists* $\varepsilon_0 > 0$ *such that for* $0 < \varepsilon < \varepsilon_0$,

$$|\hat{\alpha}(\cdot) - \tilde{\alpha}(\cdot)|_T + |\hat{x}(\cdot) - \tilde{x}(\cdot)|_T = O(\varepsilon^{1-\delta}),$$

where $(\hat{\alpha}(t), \hat{x}(t))$ *denotes the conditional mean of* $(\alpha(t), x(t))$ *given* $\mathcal{Y}_t$.

Proof. First of all, note that $\tilde{\alpha}(t)$ is $\mathcal{Y}_t$ measurable. It follows from the Jensen's inequality that

$$|\hat{\alpha}(t) - \tilde{\alpha}(t)| = |E[\alpha(t) - \tilde{\alpha}(t)|\mathcal{Y}_t]| \le E[\ |\alpha(t) - \tilde{\alpha}(t)|\ \ |\mathcal{Y}_t].$$

Taking expectation on both sides of the above inequality yields

$$E|\hat{\alpha}(t) - \tilde{\alpha}(t)| \le E|\alpha(t) - \tilde{\alpha}(t)|,$$

which implies, in view of Theorem 3.3,

$$|\hat{\alpha}(\cdot) - \tilde{\alpha}(\cdot)|_T \le |\alpha(\cdot) - \tilde{\alpha}(\cdot)|_T = O(\varepsilon^{1-\delta}).$$

We next show that $|\hat{x}(\cdot) - \tilde{x}(\cdot)|_T = O(\varepsilon^{1-\delta})$. The basic idea of the proof is to show that $\hat{x}(\cdot)$ is close to $\check{x}(\cdot)$, which can be further approximated by $\tilde{x}(\cdot)$. Let $0 < \sigma < \delta$ and γ_0 be as given in Lemmas A.3 and A.4 in the Appendix. We divide the rest of the proof into several steps. We only consider the case when $\tilde{\alpha}(\cdot)$ is obtained via the QVT since the proof for the LRT case is similar.

Step 1. We show that

$$\left|(\hat{x}(\cdot) - \tilde{x}(\cdot))I_{\{\alpha(\cdot)\notin\Theta^{\varepsilon}_{\sigma,\gamma_0}\}}\right|_T = O(\varepsilon^{1-\sigma}).$$

In fact, note that for each $t \ge 0$,

$$E\left|(\hat{x}(t) - \tilde{x}(t))I_{\{\alpha(\cdot)\notin\Theta^{\varepsilon}_{\sigma,\gamma_0}\}}\right| = \int E(|\hat{x}(t) - \check{x}(t)\,|\,|\,\alpha(\cdot) = \theta)I_{\{\theta\notin\Theta^{\varepsilon}_{\sigma,\gamma_0}\}}P(\alpha(\cdot) \in d\theta).$$

It is easy to see that the conditional expectation $E[\,|\hat{x}(t) - \tilde{x}(t)|\,|\alpha(\cdot) = \theta]$ is uniformly bounded with respect to $\theta \in \Theta$ and $t \ge 0$. Thus, in view of (3.4),

$$E\left|(\hat{x}(t) - \tilde{x}(t))I_{\{\alpha(\cdot)\notin\Theta^{\varepsilon}_{\sigma,\gamma_0}\}}\right| \le KP(\alpha(\cdot) \notin \Theta^{\varepsilon}_{\sigma,\gamma_0}) = O(\varepsilon^{1-\sigma}).$$

Step 2. We next show that

$$\left|(\hat{x}(\cdot) - \check{x}(\cdot))I_{\{\alpha(\cdot)\in\Theta^{\varepsilon}_{\sigma,\gamma_0}\}}\right|_T = O(\varepsilon^2). \tag{3.17}$$

Note that

$$\left|(\hat{x}(\cdot) - \check{x}(\cdot))I_{\{\alpha(\cdot)\in\Theta^{\varepsilon}_{\sigma,\gamma_0}\}}\right|_T = \int E(|\hat{x}(t) - \check{x}(t)||\alpha(\cdot) = \theta)I_{\{\theta\in\Theta^{\varepsilon}_{\sigma,\gamma_0}\}}P(\alpha(\cdot) \in d\theta).$$

Moreover, under the condition $\alpha(\cdot) = \theta$, we have

$$\hat{x}(\cdot) = \hat{x}^{\theta}(\cdot) \text{ and } \check{x}(\cdot) = \tilde{x}^{\theta}(\cdot).$$

Thus using Lemma A.3, we obtain (3.17).

Step 3. We show that $dy(t) = H(t,\alpha(t))\check{x}(t)dt + \varepsilon d\hat{v}(t) + \eta(t)dt$, where $\hat{v}(\cdot)$ is an innovation process and $\eta(t) = E(H(t,\alpha(t))x(t)|\mathcal{Y}_t) - H(t,\alpha(t))\check{x}(t)$. We also show that

$$\int_0^T E\,|\eta(t)|\,I_{\{\alpha(\cdot)\in\Theta^{\varepsilon}_{\sigma,\gamma_0}\}}dt = O(\varepsilon^2). \tag{3.18}$$

To prove these, it suffices to verify (3.18). In fact, we have

$$\begin{aligned}
&\textstyle\int_0^T E\,|E(H(t,\alpha(t))x(t)|\mathcal{Y}_t) - H(t,\alpha(t)\check{x}(t)|\,I_{\{\alpha(\cdot)\in\Theta^{\varepsilon}_{\sigma,\gamma_0}\}}dt\\
&\quad= \int\!\!\int_0^T E[|E(H(t,\alpha(t))x(t)|\mathcal{Y}_t) - H(t,\alpha(t))\check{x}(t)|\,|\alpha(\cdot) = \theta]I_{\{\theta\in\Theta^{\varepsilon}_{\sigma,\gamma_0}\}}dt\\
&\qquad\qquad \times P(\alpha(\cdot) \in d\theta)\\
&\quad= \int\!\!\int_0^T E[\left|H(t,\theta(t))\hat{x}^{\theta}(t) - H(t,\theta(t))\tilde{x}^{\theta}(t)\right|\,|\alpha(\cdot) = \theta]I_{\{\theta\in\Theta^{\varepsilon}_{\sigma,\gamma_0}\}}dtP(\alpha(\cdot) \in d\theta)\\
&\quad\le K\int\!\!\int_0^T E^{\theta}\left|\hat{x}^{\theta}(t) - \tilde{x}^{\theta}(t)\right|dtI_{\{\theta\in\Theta^{\varepsilon}_{\sigma,\gamma_0}\}}P(\alpha(\cdot) \in d\theta)\\
&\quad= O(\varepsilon^2).
\end{aligned}$$

Step 4. Given $\theta = \theta(\cdot) \in \Theta$ and a, b being the multiples of ε such that $0 \le a < b$, let

$$F^\theta_{a,b} = \{\alpha(\cdot) = \theta(\cdot) \text{ on } [a,b)\},\ (:= \{\alpha(t) = \theta(t) \text{ for all } t \in [a,b)\}),$$

and let $E^\theta_{a,b}$ denote the conditional expectation given $F^\theta_{a,b}$. We show that

$$E^\theta_{a,b}|\tilde{x}(t) - \check{x}(t)| = O\left(\varepsilon^{1-\sigma} + \exp\left(-\frac{\kappa(t-a-l_0\varepsilon)}{\varepsilon}\right)\right)$$

uniformly for $t \in [a + l_0\varepsilon, b]$; here $l_0 = [k_0(\log\varepsilon)^2] + 1$ as in Lemma 3.1. (l_0 needs to be replaced by l_1 as in Lemma 3.2 when the LRT is used to define $\tilde{\alpha}(\cdot)$).

First of all, by considering the differentials of $H(t,i_0)(\tilde{x}(t)-\check{x}(t))$ and $|H(t,i_0)(\tilde{x}(t)-\check{x}(t))|^2$, we obtain

$$\begin{aligned}
d(H(t,i_0)(\tilde{x}(t)-\check{x}(t))) &= \tfrac{\partial H(t,i_0)}{\partial t}(\tilde{x}(t)-\check{x}(t))dt \\
&\quad + H(t,i_0)\Big\{(b(t,\tilde{\alpha}(t),\tilde{x}(t)) - b(t,i_0,\check{x}(t)))dt \\
&\qquad -\frac{1}{\varepsilon^2}\widetilde{R}(t)H'(t,\tilde{\alpha}(t))(H(t,\tilde{\alpha}(t))\tilde{x}(t) - H(t,i_0)\check{x}(t))dt \\
&\qquad +\frac{1}{\varepsilon^2}\left(\widetilde{R}(t)H'(t,\tilde{\alpha}(t)) - \check{R}(t)H'(t,i_0)\right)\eta(t)dt \\
&\qquad +\frac{1}{\varepsilon}\left(\widetilde{R}(t)H'(t,\tilde{\alpha}(t)) - \check{R}(t)H'(t,i_0)\right)d\hat{v}(t)\Big\}
\end{aligned}$$

and

$$\begin{aligned}
d|H(t,i_0)(\tilde{x}(t)-\check{x}(t))|^2 &= 2(\tilde{x}(t)-\check{x}(t))'H'(t,i_0)d(H(t,i_0)(\tilde{x}(t)-\check{x}(t))) \\
&\quad +\frac{1}{\varepsilon^2}\mathrm{tr}\Big(\Big(\widetilde{R}(t)H'(t,\tilde{\alpha}(t)) - \check{R}(t)H'(t,i_0)\Big)\Big(\widetilde{R}(t)H'(t,\tilde{\alpha}(t)) - \check{R}(t)H'(t,i_0)\Big)'\Big) \\
&=: A(t)dt + B(t)d\hat{v}(t),
\end{aligned}$$

where

$$\begin{aligned}
A(t) &= 2(\tilde{x}(t)-\check{x}(t))'H'(t,i_0)\frac{\partial H(t,i_0)}{\partial t}(\tilde{x}(t)-\check{x}(t)) \\
&\quad +2(\tilde{x}(t)-\check{x}(t))'H'(t,i_0)H(t,i_0)\Big\{(b(t,\tilde{\alpha}(t),\tilde{x}(t)) - b(t,i_0,\check{x}(t))) \\
&\quad -\frac{1}{\varepsilon^2}\widetilde{R}(t)H'(t,\tilde{\alpha}(t))(H(t,\tilde{\alpha}(t))\tilde{x}(t) - H(t,i_0)\check{x}(t)) \\
&\quad +\frac{1}{\varepsilon^2}\left(\widetilde{R}(t)H'(t,\tilde{\alpha}(t)) - \check{R}(t)H'(t,i_0)\right)\eta(t)\Big\} \\
&\quad +\frac{1}{\varepsilon^2}\mathrm{tr}\Big(\Big(\widetilde{R}(t)H'(t,\tilde{\alpha}(t)) - \check{R}(t)H'(t,i_0)\Big)\Big(\widetilde{R}(t)H'(t,\tilde{\alpha}(t)) - \check{R}(t)H'(t,i_0)\Big)'\Big)
\end{aligned}$$

and

$$B(t) = \frac{2}{\varepsilon}(\tilde{x}(t)-\check{x}(t))'H'(t,i_0)\left(\widetilde{R}(t)H'(t,\tilde{\alpha}(t)) - \check{R}(t)H'(t,i_0)\right).$$

Let $\phi(t) = |H(t,i_0)(\tilde{x}(t)-\check{x}(t))|^2$. Then

$$\phi(t) = \phi(a+l_0\varepsilon) + \int_{a+l_0\varepsilon}^t A(s)ds + \int_{a+l_0\varepsilon}^t B(s)d\hat{v}(s).$$

Write

$$A(t) = A(t)I_{\{\tilde{\alpha}(\cdot)=i_0 \text{ on } [a+l_0\varepsilon,b]\}} + A(t)I_{\{\tilde{\alpha}(\cdot)=i_0 \text{ on } [a+l_0\varepsilon,b]\}^c}.$$

As in Lemma A.5, we can show that $(E^\theta_{a,b}|A(t)|^n)^{1/n} = O(1/\varepsilon)$, for $n = 1, 2, \ldots$. In view of Lemma 3.1, it follows that

$$\begin{aligned} &E^\theta_{a,b}\left|A(t)I_{\{\tilde{\alpha}(\cdot)=i_0 \text{ on } [a+l_0\varepsilon,b]\}^c}\right| \\ &\quad\le (E^\theta_{a,b}|A(t)|^n)^{\frac{1}{n}}(E^\theta_{a,b}I_{\{\tilde{\alpha}(\cdot)=i_0 \text{ on } [a+l_0\varepsilon,b]\}^c})^{\frac{n-1}{n}} \\ &\quad\le \frac{K}{\varepsilon}(P(\tilde{\alpha}(t)\ne i_0 \text{ for some } t\in[a+l_0\varepsilon,b]|F^\theta_{a,b}))^{\frac{n-1}{n}} \\ &\quad\le K\varepsilon^{(2(n-1)/n)-1} \le K\varepsilon^{1-\sigma} \text{ for } n \text{ large enough.} \end{aligned} \tag{3.19}$$

Given $\{\tilde{\alpha}(\cdot) = i_0 \text{ on } [a + l_0\varepsilon, b]\}$, we have

$$\begin{aligned} A(t) &= 2(\tilde{x}(t)-\check{x}(t))'H'(t,i_0)\frac{\partial H(t,i_0)}{\partial t}(\tilde{x}(t)-\check{x}(t)) \\ &\quad +2(\tilde{x}(t)-\check{x}(t))'H'(t,i_0)H(t,i_0)\Big\{(b(t,i_0,\tilde{x}(t))-b(t,i_0,\check{x}(t))) \\ &\quad -\frac{1}{\varepsilon^2}\widetilde{R}(t)H'(t,i_0)(H(t,i_0)(\tilde{x}(t)-\check{x}(t)) \\ &\quad +\frac{1}{\varepsilon^2}\left(\widetilde{R}(t)-\check{R}(t))H'(t,i_0)\right)\eta(t)\Big\} \\ &\quad +\frac{1}{\varepsilon^2}\mathrm{tr}\left((\widetilde{R}(t)-\check{R}(t))H'(t,i_0)H(t,i_0)(\widetilde{R}(t)-\check{R}(t))\right). \end{aligned}$$

Recall that $H(t, i_0)$ is invertible and both $\widetilde{R}(t)/\varepsilon$ and $\check{R}(t)/\varepsilon$ are uniformly bounded. Moreover, in view of Lemma A.4, we have

$$\frac{\widetilde{R}(t)-\check{R}(t)}{\varepsilon} = O\left(\varepsilon + \exp\left(-\frac{\kappa(t-a-l_0\varepsilon)}{\varepsilon}\right)\right).$$

Given $\{\tilde{\alpha}(\cdot) = i_0 \text{ on } [a + l_0\varepsilon, b]\}$, it follows that

$$A(t) \le K_0\phi(t) - \frac{\kappa_0}{\varepsilon}\phi(t) + K\left(\varepsilon + \frac{|\eta(t)|^2}{\varepsilon^2} + \exp\left(-\frac{\kappa(t-a-l_0\varepsilon)}{\varepsilon}\right)\right).$$

Hence,

$$\begin{aligned} E^\theta_{a,b}A(t) &\le \left(K_0 - \frac{\kappa}{\varepsilon}\right)E^\theta_{a,b}\phi(t) \\ &\quad +K\left(\varepsilon^{1-\sigma} + \frac{E^\theta_{a,b}|\eta(t)|^2}{\varepsilon^2} + \exp\left(-\frac{\kappa(t-a-l_0\varepsilon)}{\varepsilon}\right)\right). \end{aligned} \tag{3.20}$$

Next, we claim that

$$E^\theta_{a,b}\int_{a+l_0\varepsilon}^t B(s)d\hat{v}(s) = 0.$$

In fact, if we let $\mathcal{F}^\alpha_{a,b} = \sigma\{\alpha(r) : a \le r < b\}$ and $\zeta(t) = \int_{a+l_0\varepsilon}^t B(s)d\hat{v}(s)$, then for $0 \le t < b$, $E[\zeta(t)|\mathcal{F}^\alpha_{0,b}] = 0$ because $\hat{v}(\cdot)$ is a Brownian motion given $\alpha(\cdot)$. Note that $E[\zeta(t)|\mathcal{F}^\alpha_{a,b}] = E[E[\zeta(t)|\mathcal{F}^\alpha_{0,b}]|\mathcal{F}^\alpha_{a,b}]$. It follows that $E[\zeta(t)|\mathcal{F}^\alpha_{a,b}] = 0$, a.s. Thus,

$$E^\theta_{a,b}\int_{a+l_0\varepsilon}^t B(s)d\hat{v}(s) = 0, \text{ almost everywhere with respect to } \widehat{P}(d\theta) = P(\alpha(\cdot)\in d\theta).$$

By virtue of this claim, we have

$$E^\theta_{a,b}\phi(t) = E^\theta_{a,b}\phi(a+l_0\varepsilon) + E^\theta_{a,b}\int_{a+l_0\varepsilon}^t A(s)ds.$$

Thus, in view of (3.20),

$$\begin{aligned}\frac{dE^\theta_{a,b}\phi(t)}{dt} = E^\theta_{a,b}A(t) &\le \left(K_0 - \frac{\kappa}{\varepsilon}\right)E^\theta_{a,b}\phi(t)\\ &+K\left(\varepsilon^{1-\sigma} + \frac{E^\theta_{a,b}|\eta(t)|^2}{\varepsilon^2} + \exp\left(-\frac{\kappa(t-a-l_0\varepsilon)}{\varepsilon}\right)\right).\end{aligned}$$

Using Gronwall's inequality and the uniform boundedness of $E^\theta_{a,b}\phi(a+l_0\varepsilon)$, we obtain, by integration by parts,

$$E^\theta_{a,b}\phi(t) \le K\left(\varepsilon^{2-\sigma} + \exp\left(-\frac{\kappa(t-a-l_0\varepsilon)}{\varepsilon}\right)\right)$$

for some $\kappa > 0$. Therefore,

$$(E^\theta_{a,b}\phi(t))^{\frac{1}{2}} \le K\left(\varepsilon^{1-\sigma/2} + \exp\left(-\frac{\kappa(t-a-l_0\varepsilon)}{\varepsilon}\right)\right).$$

Step 5. We show that

$$\int_0^T E|\tilde{x}(t) - \check{x}(t)|I_{\{\alpha(\cdot)\in\Theta^\varepsilon_{\sigma,\gamma_0}\}}dt = O(\varepsilon^{1-\delta}). \tag{3.21}$$

Let $\xi(t) = |\tilde{x}(t) - \check{x}(t)|I_{\{\alpha(\cdot)\in\Theta^\varepsilon_{\sigma,\gamma_0}\}}$. Note that

$$E\int_0^T \xi(t)dt \le \sum_{j=0}^{[1/\varepsilon^\sigma]} E\int_0^T \xi(t)I_{[\tau_j,\tau_{j+1})}.$$

It suffices to show

$$E\int_0^T \xi(t)I_{[\tau_j,\tau_{j+1})} \le O(\varepsilon^{1-\sigma})$$

because

$$E\int_0^T \xi(t)dt \le \sum_{j=0}^{[1/\varepsilon^\sigma]} K\varepsilon^{1-\sigma} \le O(\varepsilon^{1-2\sigma}) = O(\varepsilon^{1-\delta})$$

when $2\sigma < \delta$.

For $j = 0$,

$$E\int_0^T \xi(t)I_{[0,\tau_1)}dt = \int_0^\infty E\left[\int_0^{s\wedge T}\xi(t)dt\Big|\tau_1 = s\right]p_1(s)ds,$$

where $p_1(s)$ is the density function of τ_1.

It is easy to see that

$$E\left[\int_0^{l_0\varepsilon}\xi(t)dt\Big|\tau_1=s\right]=O(l_0\varepsilon)=O(\varepsilon(\log\varepsilon)^2).$$

Moreover, using the result in Step 4, we have

$$E\left[\int_{l_0\varepsilon}^{s\wedge T}\xi(t)dt\Big|\tau_1=s\right]=O\left(\varepsilon^{1-\sigma}+\exp\left(-\frac{\kappa(s-l_0\varepsilon)}{\varepsilon}\right)\right).$$

Thus,

$$E\int_0^T\xi(t)I_{[0,\tau_1)}dt=O(\varepsilon^{1-\sigma}).$$

For $j\geq 1$, we have

$$\begin{aligned}E\int_0^T\xi(t)I_{[\tau_j,\tau_{j+1})}dt&=\int_0^\infty E\left[\int_r^T\xi(t)dt\Big|\tau_j=r\right]p_j(r)dr\\&=\int_0^\infty\int_r^T E\left[\xi(t)dtI_{[r,\tau_{j+1})}\Big|\tau_j=r\right]p_j(r)dr.\end{aligned}$$

Similarly, as in the case for $j=0$, we can show

$$\int_r^T E\left[\xi(t)dtI_{[r,\tau_{j+1})}\Big|\tau_j=r\right]=O(\varepsilon^{1-\sigma}).$$

It follows that

$$E\int_0^T\xi(t)I_{[\tau_j,\tau_{j+1})}dt=O(\varepsilon^{1-\sigma}).$$

Step 6. Combining Steps 3–5, we have

$$\begin{aligned}\left|(\hat{x}(\cdot)-\tilde{x}(\cdot))I_{\{\alpha(\cdot)\in\Theta^\varepsilon_{\sigma,\gamma_0}\}}\right|_T\leq{}&\left|(\hat{x}(\cdot)-\check{x}(\cdot))I_{\{\alpha(\cdot)\in\Theta^\varepsilon_{\sigma,\gamma_0}\}}\right|_T\\&+\left|(\check{x}(\cdot)-\tilde{x}(\cdot))I_{\{\alpha(\cdot)\in\Theta^\varepsilon_{\sigma,\gamma_0}\}}\right|_T\\={}&O(\varepsilon^2)+O(\varepsilon^{1-\delta})=O(\varepsilon^{1-\delta}).\end{aligned}$$

It follows from Step 1 that

$$|\hat{x}(\cdot)-\tilde{x}(\cdot)|_T=\left|(\hat{x}(\cdot)-\tilde{x}(\cdot))I_{\{\alpha(\cdot)\in\Theta^\varepsilon_{\sigma,\gamma_0}\}}\right|_T+\left|(\hat{x}(\cdot)-\tilde{x}(\cdot))I_{\{\alpha(\cdot)\notin\Theta^\varepsilon_{\sigma,\gamma_0}\}}\right|_T=O(\varepsilon^{1-\delta}).$$

This completes the proof. □

Remark 3.4. Note that the proofs of the filtering results in this section do not require the Markovian property of $\alpha(\cdot)$. In fact, the results hold for any general stochastic process $\alpha(\cdot)$ provided it satisfies the following conditions:

$$P(\alpha(\cdot)\notin\Theta^\varepsilon_\sigma)=O(\varepsilon^2)\text{ and }P(\tau_{j+1}-\tau_j\leq t)\leq Kt,\ t\geq 0,$$

where $\{\tau_j\}$ denotes the sequence of random jump times of $\alpha(\cdot)$.

4. Nearly optimal control. Now we turn to the optimal control problems. We assume the following additional conditions.

(A7) For each $i \in \mathcal{M}$, $L(t,i,x,u) \in C^{1,2,2}([0,T]\times\mathbb{R}^p\times\Gamma)$. There exists a constant K such that

$$|L(t,i,x,u)| + |\nabla_x L(t,i,x,u)| + |\nabla_x^2 L(t,i,x,u)| \le K.$$

For some constant c,

$$\frac{\partial^2 L(t,i,x,u)}{\partial u^2} \ge cI > 0.$$

Moreover, there exist $b_1(t,i,x)$, $b_2(t,i,x) \in C^{1,2}([0,T]\times R^p)$ such that

$$b(t,i,x,u) = b_1(t,i,x) + b_2(t,i,x)u.$$

Furthermore, the generator $Q(\cdot)$ is continuous on $[0,T]$ and the set of control points $\Gamma \in \mathbb{R}^{p_1}$ is compact and convex.

Remark 4.1. In order to prove the main results without undue technical complexities, we impose conditions in (A7). These conditions are somewhat conservative. The conditions on the drift term b are used to obtain the Lipschitz property of the optimal control policies as in Lemma 4.1. These conditions can be relaxed if we know a priori the optimal control is Lipschitz. The results to follow can also be extended to the case when L is independent of u as in Haussmann and Zhang [12]. Moreover, the terminal cost in the control problem was suppressed because essentially the terminal cost could be written as an integration of a running cost (e.g., [12]).

Let us temporarily consider the case when the state $(\alpha(t), x(t))$, $t \ge 0$, is completely observable. Let $\mathcal{U}_{\alpha,x}$ denote a set of controls $u(\cdot)$ which is progressively measurable with respect to $\sigma\{(\alpha(r), x(r)) : r \le t\}$ and $u(t) \in \Gamma$, $t \ge 0$.

Let $0 \le s \le T$, $\alpha(s) = i$, and $x(s) = x$, and define the corresponding value function

$$v(s,i,x) = \inf_{u(\cdot)\in\mathcal{U}_{\alpha,x}} E_{s,\alpha,x}\int_s^T L(t,\alpha(t),x(t),u(t))dt,$$

where $E_{s,\alpha,x}$ is the conditional expectation given $\alpha(s) = i$ and $x(s) = x$. Then the optimal control is determined by the value function $v(t,i,x)$, which satisfies the following Hamilton–Jacobi–Bellman (HJB) equation:

$$\text{(4.1)}\quad \begin{cases} 0 = \dfrac{\partial v(t,i,x)}{\partial t} + \min\limits_{u\in\Gamma}\{b(t,i,x,u)\nabla_x v(t,i,x) + L(t,i,x,u)\} \\ \qquad\quad + \dfrac{1}{2}\mathrm{tr}\left(F(t,i)H'(t,i)H(t,i)F(t,i)\nabla_x^2 v(t,i,x)\right) + Q(t)v(t,\cdot,x)(i), \\ v(T,i,x) = 0, \end{cases}$$

where $Q(t)v(t,\cdot,x)(i) = \sum_{j\ne i} q_{ij}(t)(v(t,j,x) - v(t,i,x))$.

Let $u^*(t,i,x)$ denote the feedback control policy minimizing the right-hand side of the HJB equation. The following results can be obtained similarly as in Fleming and Rishel [8] (or Krylov [16]).

LEMMA 4.1. *Assume* (A3) *and* (A7). *Then*

(a) *the value function* $v(t,i,x) \in C^{1,2}([0,T]\times R^p)$, $i \in \mathcal{M}$, *and is the unique solution to the HJB equation* (4.1).

(b) *there exist constants* $\kappa > 0$ *and* K *such that*

$$\left|\frac{\partial v(t,i,x)}{\partial t}\right| + |\nabla_x v(t,i,x)| + |\nabla_x^2 v(t,i,x)| \le K(1+|x|^\kappa).$$

(c) $u^*(t,i,x)$ *is an optimal feedback control and uniformly Lipschitz in* x.

We turn to consider the partially observed system. Let $\mathcal{U}_y$ denote a class of controls $u(\cdot)$ that are $\mathcal{Y}_t$ progressively measurable and $u(t) \in \Gamma$, $t \ge 0$. Given $u(\cdot) \in \mathcal{U}_y$, let $(\tilde{x}(\cdot), \widetilde{R}(\cdot))$ be the corresponding filter given by the equations

$$\begin{aligned} d\tilde{x}(t) =\ & b(t,\tilde{\alpha}(t),\tilde{x}(t),u(t))dt \\ & +\frac{1}{\varepsilon^2}\widetilde{R}(t)H'(t,\tilde{\alpha}(t))\left(dy(t)-h(t,\tilde{\alpha}(t),\tilde{x}(t))dt\right), \\ \frac{d\widetilde{R}(t)}{dt} =\ & \nabla_x b(t,\tilde{\alpha}(t),\tilde{x}(t),u(t))\widetilde{R}(t)+\widetilde{R}(t)(\nabla_x b(t,\tilde{\alpha}(t),\tilde{x}(t),u(t)))' \\ & +F(t,\tilde{\alpha}(t))H'(t,\tilde{\alpha}(t))H(t,\tilde{\alpha}(t))F(t,\tilde{\alpha}(t)) \\ & -\frac{1}{\varepsilon^2}\widetilde{R}(t)H'(t,\tilde{\alpha}(t))H(t,\tilde{\alpha}(t))\widetilde{R}(t), \end{aligned} \tag{4.2}$$

with $\tilde{x}(0) = Ex_0$ and $\widetilde{R}(0) = \mathrm{Cov}(x_0)$. Then the results in Theorems 3.3 and 3.5 hold uniformly with respect to $u(\cdot) \in \mathcal{U}_y$.

Regarding $(\tilde{\alpha}(\cdot), \tilde{x}(\cdot))$ as the "state" and using the feedback control $u^*(t,\alpha,x)$, we define $\tilde{u}(t) = u^*(t,\tilde{\alpha}(t),\tilde{x}(t))$.

Note that $\tilde{\alpha}(\cdot)$ changes values only at $t = j\varepsilon$, $j = 1,2,\ldots$, and for $t \in [j\varepsilon,(j+1)\varepsilon)$, $\tilde{\alpha}(t)$ is $\mathcal{Y}_{j\varepsilon}$ measurable. Therefore, a unique solution $(x(\cdot),y(\cdot),\tilde{x}(\cdot),\widetilde{R}(\cdot))$ to the equations (1.1) and (4.2) with $u(\cdot) = \tilde{u}(\cdot)$ can be obtained piecewisely over the intervals $[j\varepsilon,(j+1)\varepsilon)$, $j = 0,1,\ldots$. In view of these, $\tilde{u}(\cdot)$ is admissible, i.e., $\tilde{u}(\cdot) \in \mathcal{U}_y$. The next theorem concerns the performance of $\tilde{u}(\cdot)$.

THEOREM 4.2. *Assume the conditions of Theorem* 3.3 *and* (A7). *Then for each* $0 < \delta < 1$, *there exists* $\varepsilon_0 > 0$ *such that for* $0 < \varepsilon < \varepsilon_0$,

$$\begin{aligned} &\text{(a)}\ \inf_{u(\cdot)\in\mathcal{U}_y} J(u(\cdot)) = J(\tilde{u}(\cdot)) + O(\varepsilon^{1-\delta}); \\ &\text{(b)}\ \inf_{u(\cdot)\in\mathcal{U}_y} J(u(\cdot)) = Ev(0,\alpha(0),Ex_0) + O(\varepsilon^{1-\delta}). \end{aligned}$$

Proof. We first show part (a) and divide the proof into several steps.

Step 1. We show that

$$\inf_{u(\cdot)\in\mathcal{U}_y} J(u(\cdot)) = \inf_{u(\cdot)\in\mathcal{U}_y} E\int_0^T L(t,\tilde{\alpha}(t),\tilde{x}(t),u(t))dt + O(\varepsilon^{1-\delta}).$$

For each $u(\cdot) \in \mathcal{U}_y$, let $x(\cdot)$ and $\tilde{x}(\cdot)$ denote the the corresponding state and filter processes under $u(\cdot)$. Then, by noticing that $I_{\{\tilde{\alpha}(t)\neq\alpha(t)\}} \le |\tilde{\alpha}(t)-\alpha(t)|/m$ and recalling Theorem 3.3, we have

$$\begin{aligned} & E\int_0^T |L(t,\alpha(t),x(t),u(t)) - L(t,\tilde{\alpha}(t),x(t),u(t))|dt \\ & \le KE\int_0^T I_{\{\tilde{\alpha}(t)\neq\alpha(t)\}}dt \\ & \le \frac{K}{m}E\int_0^T |\tilde{\alpha}(t)-\alpha(t)|dt = O(\varepsilon^{1-\delta}). \end{aligned} \tag{4.3}$$

Moreover, in view of Taylor's expansion, we write

$$\begin{aligned} L(t,\tilde{\alpha}(t),x(t),u(t)) &= L(t,\tilde{\alpha}(t),\hat{x}(t),u(t)) \\ &\quad +\nabla_x L(t,\tilde{\alpha}(t),\hat{x}(t),u(t))(x(t)-\hat{x}(t)) + O(|x(t)-\hat{x}(t)|^2). \end{aligned} \tag{4.4}$$

Since $\tilde{\alpha}(t)$ and $u(t)$ are $\mathcal{Y}_t$ measurable, it follows that

$$\begin{aligned} &E\nabla_x L(t,\tilde{\alpha}(t),\hat{x}(t),u(t))(x(t)-\hat{x}(t)) \\ &\quad = E\left(E[\nabla_x L(t,\tilde{\alpha}(t),\hat{x}(t),u(t))(x(t)-\hat{x}(t))|\mathcal{Y}_t]\right) = 0. \end{aligned} \tag{4.5}$$

Combining (4.4) and (4.5) leads to

$$\begin{aligned} &EL(t,\tilde{\alpha}(t),x(t),u(t)) = EL(t,\tilde{\alpha}(t),\hat{x}(t),u(t)) + O(E|x(t)-\hat{x}(t)|^2) \\ &\quad \le EL(t,\tilde{\alpha}(t),\hat{x}(t),u(t)) + O(E|x(t)-\tilde{x}(t)|^2) + O(E|\tilde{x}(t)-\hat{x}(t)|^2). \end{aligned}$$

Hence, in view of Lemmas A.2 and A.3 and (3.4), for $0<\sigma<\delta$, we can show similarly as in (3.19) that

$$E\int_0^T L(t,\tilde{\alpha}(t),x(t),u(t))dt = E\int_0^T L(t,\tilde{\alpha}(t),\hat{x}(t),u(t))dt + O(\varepsilon^{1-\delta}). \tag{4.6}$$

Furthermore, note that

$$|L(t,\tilde{\alpha}(t),\hat{x}(t),u(t)) - L(t,\tilde{\alpha}(t),\tilde{x}(t),u(t))| \le K|\hat{x}(t)-\tilde{x}(t)|.$$

Thus, in view of Lemma A.3 and by conditioning on $\alpha(\cdot)\in\Theta^{\varepsilon}_{\sigma,\gamma_0}$, we have

$$E\int_0^T L(t,\tilde{\alpha}(t),\hat{x}(t),u(t))dt = E\int_0^T L(t,\tilde{\alpha}(t),\tilde{x}(t),u(t))dt + O(\varepsilon^{1-\delta}). \tag{4.7}$$

Combining (4.3), (4.6), and (4.7), we obtain

$$J(u(\cdot)) = E\int_0^T L(t,\tilde{\alpha}(t),\tilde{x}(t),u(t))dt + O(\varepsilon^{1-\delta})$$

uniformly with respect to $u(\cdot)\in\mathcal{U}_y$.

Step 2. In this step we show that

$$\begin{aligned} &\inf_{u(\cdot)\in\mathcal{U}_y} E\int_0^T L(t,\tilde{\alpha}(t),\tilde{x}(t),u(t))dt \\ &\qquad = \inf_{u(\cdot)\in\mathcal{U}_y} E\int_0^T L(t,\alpha(t),\check{x}(t),u(t))dt + O(\varepsilon^{1-\delta}). \end{aligned} \tag{4.8}$$

Note that (3.21) holds uniformly with respect to $u(\cdot)\in\mathcal{U}_y$ when $\check{x}(\cdot)$ is defined in (3.16) with $b=b(t,\alpha(t),\check{x}(t),u(t))$. In view of this, (4.8) follows from

$$E\int_0^T |L(t,\tilde{\alpha}(t),\tilde{x}(t),u(t))dt - L(t,\alpha(t),\tilde{x}(t),u(t))|dt = O(\varepsilon^{1-\delta})$$

and the Lipschitz property of L, which yields

$$\begin{aligned} &E\int_0^T |L(t,\alpha(t),\tilde{x}(t),u(t))dt - L(t,\alpha(t),\check{x}(t),u(t))|dt \\ &\qquad \le KE\int_0^T |\tilde{x}(t)-\check{x}(t)|dt = O(\varepsilon^{1-\delta}). \end{aligned}$$

Step 3. Let $\mathcal{U}_{y,\alpha} = \{u(\cdot) :\ u(t) \text{ is } \sigma\{y(s), \alpha(s) :\ 0 \le s \le t\}\text{- progressively measurable }\}$. Then, noticing the fact that $\mathcal{U}_y \subset \mathcal{U}_{y,\alpha}$, we obtain

$$\inf_{u(\cdot)\in\mathcal{U}_y} E\int_0^T L(t,\alpha(t),\check{x}(t),u(t))dt \ge \inf_{u(\cdot)\in\mathcal{U}_{y,\alpha}} E\int_0^T L(t,\alpha(t),\check{x}(t),u(t))dt,$$

Step 4. We prove the following estimate based on the dynamic programming approach:

$$\begin{aligned}
&\inf_{u(\cdot)\in\mathcal{U}_{y,\alpha}} E\int_0^T L(t,\alpha(t),\check{x}(t),u(t))dt\\
&\qquad = Ev(0,\alpha(0),\check{x}(0)) + O(\varepsilon^{1-\delta})\\
&\qquad = E\int_0^T L(t,\alpha(t),\check{x}(t),u^*(t,\alpha(t),\check{x}(t)))dt + O(\varepsilon^{1-\delta}).
\end{aligned}$$

For all $u(\cdot) \in \mathcal{U}_{y,\alpha}$, using Dynkin's formula and noticing that $v(T,i,x) = 0$, we have

$$\begin{aligned}
Ev(0,\alpha(0),\check{x}(0)) &= -E\int_0^T \Big\{ \frac{\partial v(t,\alpha(t),\check{x}(t))}{\partial t} + \nabla_x v(t,\alpha(t),\check{x}(t)) b(t,\alpha(t),\check{x}(t),u(t))\\
&+Q(t)v(t,\cdot,\check{x}(t))(\alpha(t)) + \frac{1}{2\varepsilon^2}\mathrm{tr}\left(\check{R}(t)H'(t,\alpha(t))H(t,\alpha(t))\check{R}(t)\nabla_x^2 v(t,\alpha(t),\check{x}(t))\right)\Big\}dt\\
&-E\int_0^T \nabla_x v(t,\alpha(t),\check{x}(t))\left(dy(t) - H(t,\alpha(t))\check{x}(t)dt\right).
\end{aligned}$$

Similarly as in Step 3 of the proof of Theorem 3.5, by conditioning on $\alpha(\cdot) = \theta$, we can show that

$$E\int_0^T \nabla_x v(t,\alpha(t),\check{x}(t))\left(E(H(t,\alpha(t))x(t)|\mathcal{Y}_t) - H(t,\alpha(t))\check{x}(t)\right)dt = O(\varepsilon^{1-\delta})$$

and

$$E\int_0^T \nabla_x v(t,\alpha(t),\check{x}(t))d\hat{v}(t) = 0.$$

Hence,

$$E\int_0^T \nabla_x v(t,\alpha(t),\check{x}(t))\left(dy(t) - H(t,\alpha(t))\check{x}(t)dt\right) = O(\varepsilon^{1-\delta}).$$

Moreover, in view of Lemma 4.1, for $0 < \sigma < \delta$, we have

$$\begin{aligned}
&E\int_0^T \mathrm{tr}\Big[\Big(\frac{\check{R}(t)H'(t,\alpha(t))H(t,\alpha(t))\check{R}(t)}{\varepsilon^2}\\
&\qquad -F(t,\alpha(t))H'(t,\alpha(t))H(t,\alpha(t))F(t,\alpha(t))\Big)\nabla_x^2 v(t,\alpha(t),\check{x}(t))\Big]dt\\
&\le KE\int_0^T \left|\frac{\check{R}(t)}{\varepsilon} - F(t,\alpha(t))\right|\cdot|\nabla_x^2 v(t,\alpha(t),\check{x}(t))|dt\\
&= KE\int_0^T \left|\frac{\check{R}(t)}{\varepsilon} - F(t,\alpha(t))\right|\cdot|\nabla_x^2 v(t,\alpha(t),\check{x}(t))|dtI_{\{\alpha(\cdot)\in\Theta^\varepsilon_{\sigma,\gamma_0}\}}\\
&\quad +KE\int_0^T \left|\frac{\check{R}(t)}{\varepsilon} - F(t,\alpha(t))\right|\cdot|\nabla_x^2 v(t,\alpha(t),\check{x}(t))|dtI_{\{\alpha(\cdot)\notin\Theta^\varepsilon_{\sigma,\gamma_0}\}}\\
&= KE\int_0^T \left|\frac{\check{R}(t)}{\varepsilon} - F(t,\alpha(t))\right|\cdot|\nabla_x^2 v(t,\alpha(t),\check{x}(t))|dtI_{\{\alpha(\cdot)\in\Theta^\varepsilon_{\sigma,\gamma_0}\}} + O(\varepsilon^{1-\sigma}).
\end{aligned}$$

For each $\theta \in \Theta^{\varepsilon}_{\sigma,\gamma_0}$, let $\{t_k\}$ denote the jump times of $\theta = \theta(\cdot)$. Then we obtain

$$\begin{aligned}
&\sum_{j=0}^{[1/\varepsilon^\sigma]} E^\theta \int_{t_j}^{t_{j+1}} \left| \frac{\check{R}(t)}{\varepsilon} - F(t,\alpha(t)) \right| \cdot |\nabla_x^2 v(t,\alpha(t),\check{x}(t))| dt \\
&\quad \le K \sum_{j=0}^{[1/\varepsilon^\sigma]} E^\theta \int_{t_j}^{t_{j+1}} \left(\varepsilon + \exp\left(-\frac{\kappa(t-t_j)}{\varepsilon} \right) \right) \cdot |\nabla_x^2 v(t,\alpha(t),\check{x}(t))| dt \\
&\quad = K \sum_{j=0}^{[1/\varepsilon^\sigma]} \int_{t_j}^{t_{j+1}} \left(\varepsilon + \exp\left(-\frac{\kappa(t-t_j)}{\varepsilon} \right) \right) E^\theta |\nabla_x^2 v(t,\alpha(t),\check{x}(t))| dt \\
&\quad \le K \sum_{j=0}^{[1/\varepsilon^\sigma]} K\varepsilon = O(\varepsilon^{1-\sigma}).
\end{aligned}$$

In view of these, we have

$$\begin{aligned}
Ev(0,\alpha(0),\check{x}(0)) &= -E\int_0^T \Big\{ \frac{\partial v(t,\alpha(t),\check{x}(t))}{\partial t} + b(t,\alpha(t),\check{x}(t),u(t)) \nabla_x v(t,\alpha(t),\check{x}(t)) \\
&\quad + Q(t) v(t,\cdot,\check{x}(t))(\alpha(t)) + L(t,\alpha(t),\check{x}(t),u(t)) \\
&\quad + \frac{1}{2} \mathrm{tr}\left(F(t,\alpha(t)) H'(t,\alpha(t)) H(t,\alpha(t)) F(t,\alpha(t)) \nabla_x^2 v(t,\alpha(t),\check{x}(t)) \right) \Big\} dt + O(\varepsilon^{1-\sigma}) \\
&\quad + E\int_0^T L(t,\alpha(t),\check{x}(t),u(t)) dt \\
&\le E\int_0^T L(t,\alpha(t),\check{x}(t),u(t)) dt + O(\varepsilon^{1-\sigma}),
\end{aligned}$$

where the last inequality is due to the HJB equation and the equality holds if $u(t) = u^*(t,\alpha(t),\check{x}(t))$.

Step 5. Finally, note that $\tilde{u}(\cdot) \in \mathcal{U}_y$. Thus,

$$J(\tilde{u}(\cdot)) \ge \inf_{u(\cdot)\in\mathcal{U}_y} J(u(\cdot)).$$

Moreover, using the Lipschitz property of $u^*(t,i,\cdot)$, we have

$$\begin{aligned}
&|L(t,\alpha(t),\check{x}(t),u^*(t,\alpha(t),\check{x}(t))) - L(t,\tilde{\alpha}(t),\tilde{x}(t),u^*(t,\tilde{\alpha}(t),\tilde{x}(t)))| \\
&\qquad \le K(|\tilde{\alpha}(t) - \alpha(t)| + |\check{x}(t) - \tilde{x}(t)|).
\end{aligned}$$

Thus, it follows that by using Theorem 3.3 and Step 5 in the proof of Theorem 3.5,

$$\begin{aligned}
&E\int_0^T L(t,\alpha(t),\check{x}(t),u^*(t,\alpha(t),\check{x}(t))) dt \\
&\qquad = E\int_0^T L(t,\tilde{\alpha}(t),\tilde{x}(t),u^*(t,\tilde{\alpha}(t),\tilde{x}(t))) dt + O(\varepsilon^{1-\sigma}).
\end{aligned}$$

To show (b), recall that $\check{x}(0) = Ex_0$. Following Steps 1–4, we have

$$\inf_{u(\cdot)\in\mathcal{U}_y} J(u(\cdot)) \ge Ev(0,\alpha(0),Ex_0) + O(\varepsilon^{1-\delta}).$$

Then Steps 4–5 yield

$$Ev(0,\alpha(0),Ex_0) \ge J(\tilde{u}(\cdot)) + O(\varepsilon^{1-\delta}) \ge \inf_{u(\cdot)\in\mathcal{U}_y} J(u(\cdot)) + O(\varepsilon^{1-\delta}).$$

Combine these two inequalities to obtain the result. The proof is now complete. □

5. Hybrid linear quadratic control. In this section we show that the compactness of Γ and boundedness of L in (A7) are not necessary and can be relaxed. We study a simple and useful case in which the system is linear in x and u with a quadratic running cost function. Consider the state $x(t) \in \mathbb{R}^p$, observation $y(t) \in \mathbb{R}^p$, and control $u(t) \in \mathbb{R}^{p_1}$ satisfying the differential equations

$$\left\{\begin{array}{ll} dx(t) = (B_1(t,\alpha(t))x(t) + B_2(t,\alpha(t))u(t))dt & \\ \qquad\qquad +\sigma(t,\alpha(t))dw(t), & x(0) = x_0 \\ dy(t) = H(t,\alpha(t))x(t)dt + \varepsilon dv(t), & y(0) = 0, \end{array}\right. \tag{5.1}$$

where $B_1(t,i)$, $B_1(t,i)$, $\sigma(t,i)$, and $H(t,i)$ are matrices of appropriate dimensions.

The cost function is given by

$$J(u(\cdot)) = E_{\alpha,x}\int_0^T \Big(x'(t)M_1(t,\alpha(t))x(t) + u'(t)M_2(t,\alpha(t))u(t)\Big)dt,$$

where $M_1(t,i)$ and $M_2(t,i)$ are positive definite matrices of appropriate dimensions and $E_{\alpha,x}$ is the conditional expectation given $\alpha(0) = \alpha$ and $x(0) = x$.

Assume all the conditions in the previous sections hold except the conditions on the running cost function L and the control set Γ. In this section we consider $\Gamma = \mathbb{R}^{p_1}$. First of all, consider the completely observable case. Let $\mathcal{U}_{\alpha,x}$ denote the set of admissible controls $u(\cdot)$, which is $\sigma\{(\alpha(r), x(r)) : r \le t\}$ progressively measurable, $E\int_0^T |u(t)|^k dt \le C_k$, $E|x(t)|^k \le C_k$, for each $k = 1, 2, \ldots$, and some constant C_k. In this case, the value function

$$\begin{aligned} v(s,i,x) &= \inf_{u(\cdot)\in\mathcal{U}_{\alpha,x}} E_{s,\alpha,x}\int_s^T \Big(x'(t)M_1(t,\alpha(t))x(t) + u'(t)M_2(t,\alpha(t))u(t)\Big)dt \\ &= x'\Phi(s,i)x + \phi(s,i), \end{aligned}$$

where $E_{s,\alpha,x}$ is the conditional expectation given $(\alpha(s), x(s)) = (\alpha, x)$ and the functions $\Phi(t,i)$ and $\phi(t,i)$ are determined by the following differential equations:

$$\left\{\begin{array}{l} \dfrac{d\Phi(t,i)}{dt} = -\Big\{\Phi(t,i)B_1(t,i) + B_1'(t,i)\Phi(t,i) \\ \quad -\Phi(t,i)B_2(t,i)M_2^{-1}(t,i)B_2'(t,i)\Phi(t,i) + M_1(t,i) + Q(t)\Phi(t,\cdot)(i)\Big\} \\ \Phi(T,i) = 0, \quad \text{for } i \in \mathcal{M} \end{array}\right. \tag{5.2}$$

and

$$\left\{\begin{array}{l} \dfrac{d\phi(t,i)}{dt} = -\Big\{\mathrm{tr}\Big(\sigma(t,i)\sigma'(t,i)\Phi(t,i)\Big) + Q(t)\phi(t,\cdot)(i)\Big\}, \\ \phi(T,i) = 0, \quad \text{for } i \in \mathcal{M}. \end{array}\right.$$

The optimal control for the completely observable case is given by (see Fleming and Rishel [8])

$$u^*(t,i,x) = -M_2^{-1}(t,i)B_2'(t,i)\Phi(t,i)x. \tag{5.3}$$

In the partially observable case, we consider the control

$$\tilde{u}(t) = u^*(t,\tilde{\alpha}(t),\tilde{x}(t)). \tag{5.4}$$

Let $\mathcal{U}_y$ denote the set of controls which are $\sigma\{y(r) : r \le t\}$ progressively measurable and for each $k = 1, 2, \ldots$, there exists C_k such that $E\int_s^T |u(t)|^k dt \le C_k$ and $E|x(t)|^k \le C_k$.

THEOREM 5.1. *For each $0 < \delta < 1$, there exists $\varepsilon_0 > 0$ such that for $0 < \varepsilon < \varepsilon_0$,*

$$\text{(a)} \inf_{u(\cdot)\in\mathcal{U}_y} J(u(\cdot)) = J(\tilde{u}(\cdot)) + O(\varepsilon^{1-\delta});$$
$$\text{(b)} \inf_{u(\cdot)\in\mathcal{U}_y} J(u(\cdot)) = Ev(0, \alpha(0), Ex_0) + O(\varepsilon^{1-\delta}).$$

Proof. The proof can be given following Steps 1-5 in the proof of Theorem 4.2 by using the Holder's inequality as in (3.19) and the quadratic property of the running function $L(t, i, x)$. □

6. Extensions to Picard filter. Note that in Lemma A.4, $R^\theta(t)/\varepsilon$ can be approximated by $F(t, \theta(t))$ for each $\theta \in \Theta$. If we replace $R^\theta(t)/\varepsilon$ by $F(t, \theta(t))$ in the EKF, then we obtain the PF; see Picard [20]. Let $\tilde{\alpha}(\cdot)$ be a filter of $\alpha(\cdot)$ obtained either by the QVT or by the LRT. Let $u(\cdot) \in \mathcal{U}_y$ and define the PF as follows:

$$\begin{aligned} dm(t) &= b(t, \tilde{\alpha}(t), m(t))dt \\ &\quad + \frac{1}{\varepsilon} F(t, \tilde{\alpha}(t)) H'(t, \tilde{\alpha}(t)) \left(dy(t) - h(t, \tilde{\alpha}(t), m(t))dt\right), \end{aligned} \tag{6.1}$$

with $m(0) = Ex_0$.

THEOREM 6.1. *Assume the condition of Theorem 4.2. Then for each $0 < \delta < 1$, there exists $\varepsilon_0 > 0$ such that for $0 < \varepsilon < \varepsilon_0$,*

$$\text{(a)} \ |\hat{x}(\cdot) - m(\cdot)|_T = O(\varepsilon^{\frac{1}{2}-\delta}), \ \textit{uniformly with respect to } u(\cdot) \in \mathcal{U}_y$$
$$\text{(b)} \inf_{u(\cdot)\in\mathcal{U}_y} J(u(\cdot)) = J(\bar{u}(\cdot)) + O(\varepsilon^{\frac{1}{2}-\delta}),$$

where $\bar{u}(t) = u^*(t, \tilde{\alpha}(t), m(t))$.

Proof. We define $\check{m}(t)$, $t \ge 0$, as in (6.1) with $\tilde{\alpha}(\cdot)$ replaced by $\alpha(\cdot)$. Let $0 < \sigma < \delta$. Then we can show as in [11, Theorem 2.6], Lemma A.2, and Step 1 in Theorem 3.5, that

$$E|\check{x}(t) - \check{m}(t)| I_{\{\alpha(\cdot)\in\Theta^\varepsilon_{\sigma,\gamma_0}\}} = O(\varepsilon^{\frac{3}{2}-\sigma}).$$

Then following the proof in Steps 3-5 of Theorem 3.5 we can show

$$E|\check{m}(t) - m(t)| I_{\{\alpha(\cdot)\in\Theta^\varepsilon_{\sigma,\gamma_0}\}} = O(\varepsilon^{\frac{1}{2}-\sigma}).$$

Thus in view of Step 5 in Theorem 3.5, we have

$$E|\tilde{x}(t) - \check{x}(t)| I_{\{\alpha(\cdot)\in\Theta^\varepsilon_{\sigma,\gamma_0}\}} = O(\varepsilon^{1-\sigma}). \tag{6.2}$$

Combining these estimates, we obtain part (a).

Part (b) follows from the fact that

$$\inf_{u(\cdot)\in\mathcal{U}_y} J(u(\cdot)) = E\int_0^T L(t, \alpha(t), \check{x}(t), u^*(t, \alpha(t), \check{x}(t)))dt + O(\varepsilon^{1-\delta}),$$

as in Step 4 of Theorem 4.2, the Lipschitz property of the function $L(t, \alpha, x, u^*(t, \alpha, x))$, part (a), and (6.2). □

As for the hybrid linear quadratic case, we can obtain similarly that

$$\inf_{u(\cdot)\in\mathcal{U}_y} J(u(\cdot)) = J(\bar{u}(\cdot)) + O(\varepsilon^{\frac{1}{2}-\delta}),$$

where $\bar{u}(t) = u^*(t, \tilde{\alpha}(t), m(t))$ with $u^*(t,\alpha,x)$ given by (5.3).

Remark 6.1. In general the EKF provides a better approximation than the PF. However, since the PF does not require computing $\widetilde{R}(\cdot)$, which reduces much of the computation effort, especially when the dimension of the system is large.

In the LRT, we used the EKF to define the test statistics $L^{(i)}(\mathcal{I}(t))$. An alternative way is to use the outcome of the PF to replace the EKF. The results in Lemma 3.2 follows in a similar way.

7. An example and numerical simulations. In this section we consider a simple example and report related computational experiments. We consider the following one-dimensional model:

$$\begin{cases} dx(t) = \Big(B_1(\alpha(t))x(t) + u(t)\Big)dt + \sigma(\alpha(t))dw(t), & x(0) = x_0 \\ dy(t) = H(\alpha(t))x(t)dt + \varepsilon dv(t), & y(0) = 0, \end{cases} \tag{7.1}$$

where $\alpha(t) \in \mathcal{M} = \{1,2\}$, $t \geq 0$, is a Markov chain generated by $Q = \left(\begin{smallmatrix} -\lambda & \lambda \\ \mu & -\mu \end{smallmatrix}\right)$ with $\lambda > 0$ and $\mu > 0$.

We discretize the equation in (7.1) with step size ε. The time horizons in the continuous-time model is $T = 10$ and in the corresponding discrete-time setting is $T_\varepsilon = 10/\varepsilon$. All of our results are based on computations with 100 sample paths.

We consider the model with the following specifications:

$$B_1(1) = -0.01, \quad B_1(2) = -0.02, \quad H(1) = 1, \quad H(2) = 2, \quad \sigma(1) = \sigma(2) = 1,$$

$$\lambda = \mu = 0.02, \quad x_0 = 0, \quad \alpha(0) = 2.$$

Note that the detectability condition in (A5) is satisfied because

$$|H^2(1) - H^2(2)| = 3 > 0.$$

We only consider the QVT because it performs better than the LRT; see Remark 3.3.

Filtering. We compare our results with the well-known interactive multiple models (IMM) algorithm given in Blom and Bar-Shalom [2]. Let $|\tilde{x} - x|_{\text{IMM}}$ denote the norm $\varepsilon \sum_{k=0}^{T_\varepsilon} E|\tilde{x}(k\varepsilon) - x(k\varepsilon)|$ with $\tilde{x}(k\varepsilon)$ obtained by using the IMM algorithm. Similarly, let $|\tilde{x} - x|_{\text{QVT}}$ and $|\tilde{\alpha} - \alpha|_{\text{QVT}}$ denote the corresponding norm when using the QVT algorithm. We take the control $u(t) = 0$. Our numerical results are illustrated by a sample path of $x(k\varepsilon)$, its estimates $\tilde{x}(k\varepsilon)$ using both the IMM and the QVT, and the corresponding errors with parameters $\varepsilon = 0.1$ and $T_\varepsilon = 100$. Their graphs are given in Fig. 7.1.

We also vary the value of ε and obtain upper bounds on estimates of $\tilde{x}(k\varepsilon)$ using the IMM and $(\tilde{\alpha}(k\varepsilon), \tilde{x}(k\varepsilon))$ using the QVT. These are given in Table 7.1.

Remark 7.1. The major advantages of the QVT algorithm is that it does not require the process $\alpha(\cdot)$ to be Markovian. So there is no need to require the generator matrix. Numerically, the QVT works better when ε is small and when the parameter process $\alpha(\cdot)$ does not jump too rapidly. On the other hand, the IMM algorithm works as "an average" device because it tends to average out the fluctuation of the signal

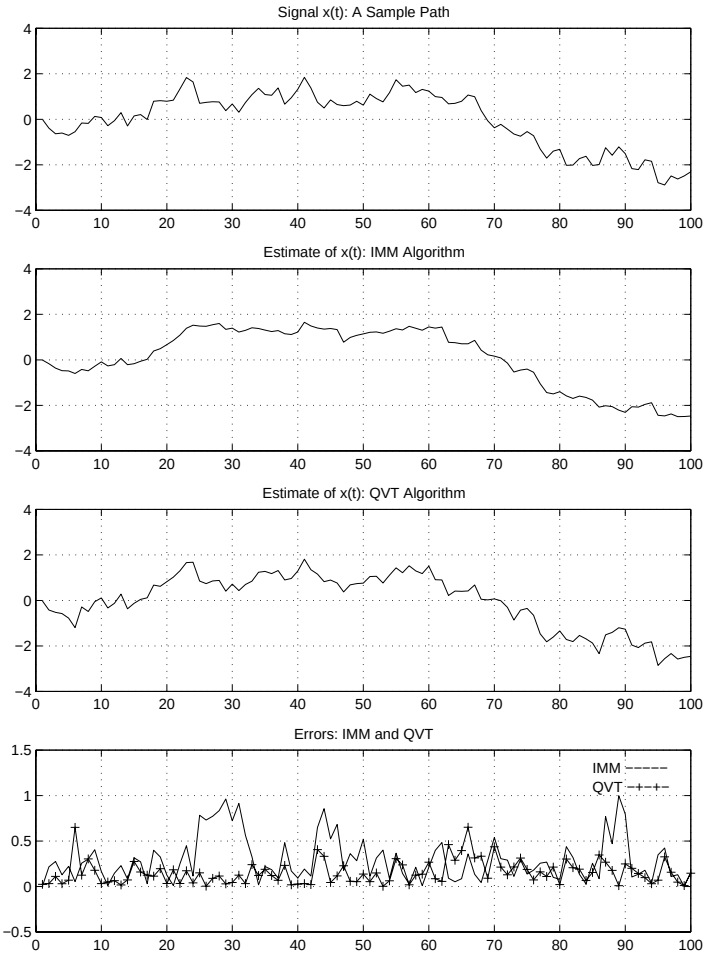

FIG. 7.1. *A sample path of $x(t)$, its estimates, and errors.*

TABLE 7.1
Upper error bounds: filtering.

ε	T_ε	$\lvert\tilde{x}-x\rvert_{\rm IMM}/\sqrt{\varepsilon}$	$\lvert\tilde{\alpha}-\alpha\rvert_{\rm QVT}/\sqrt{\varepsilon}$	$\lvert\tilde{x}-x\rvert_{\rm QVT}/\sqrt{\varepsilon}$
0.1	100	14.17	7.44	9.87
0.05	200	17.71	11.26	13.40
0.033	300	18.93	13.87	15.30
0.025	400	19.15	16.61	16.72
0.02	500	19.16	17.92	18.07

process. So it seems the IMM works better when $\alpha(\cdot)$ fluctuates more frequently. The QVT is a quite promising filtering device in target tracking. It complements the IMM in a number of ways. It could also be used in combination with the IMM algorithm to improve the performance.

Control. We consider the cost function

$$J(u(\cdot)) = E\int_0^T \Big(x^2(t) + u^2(t)\Big)dt.$$

TABLE 7.2
Upper error bounds: control.

ε	T_ε	$\widetilde{J}$	v	$\lvert\widetilde{J}/v-1\rvert/\sqrt{\varepsilon}$	$\lvert\widetilde{J}-v\rvert/\sqrt{\varepsilon}$
0.1	100	10.70	9.09	0.56	5.11
0.05	200	9.73	9.11	0.30	2.75
0.033	300	9.28	9.12	0.09	0.87
0.025	400	9.26	9.12	0.09	0.85
0.02	500	8.97	9.13	0.12	1.13

Then the associated Riccati equation is given by

$$\frac{d\Phi(t,1)}{dt} = -\Big\{2B_1(1)\Phi(t,1) - \Phi^2(t,1) + 1 + \lambda(\Phi(t,2) - \Phi(t,1))\Big\},$$
$$\frac{d\Phi(t,2)}{dt} = -\Big\{2B_1(2)\Phi(t,2) - \Phi^2(t,2) + 1 + \mu(\Phi(t,1) - \Phi(t,2))\Big\},$$

with $\Phi(T,1) = \Phi(T,2) = 0$. The control defined in (5.4) becomes

$$\tilde{u}(t) = -\Phi(t,\tilde{\alpha}(t))\tilde{x}(t).$$

Given $x(s) = x_0$ and $\alpha(s) = i$, the value function

$$v(s,i,x) = x_0^2\Phi(s,i) + \phi(s,i),$$

where $\phi(t,i)$ is determined by the equations

$$\frac{d\phi(t,1)}{dt} = -\Big\{\sigma^2(1)\Phi(t,1) + \lambda(\phi(t,2) - \phi(t,1))\Big\},$$
$$\frac{d\phi(t,2)}{dt} = -\Big\{\sigma^2(2)\phi(t,2) + \mu(\phi(t,1) - \phi(t,2))\Big\},$$

with $\phi(T,1) = \phi(T,2) = 0$.

Let

$$\widetilde{J} = J(\tilde{u}(\cdot)) = E\int_0^T (x^2(t) + \tilde{u}^2(t))dt$$

and $v = v(0,\alpha(0),x(0))$. Then for various ε we have the upper bounds given in Table 7.2.

It can be seen from the numerical simulations that our algorithm gives a quite good approximation to exact optimal solutions.

8. Conclusions. In this paper, we constructed asymptotic filters $(\tilde{x}(\cdot), \widetilde{R}(\cdot))$ and $m(\cdot)$. Using these filters, we constructed nearly optimal controls for the partially observed stochastic system. The information flow is illustrated in Fig. 8.1.

A key assumption in this paper is that the observation noise has to be small. To apply these results in a practical scenario, it is important to determine if the noise in a given problem is small enough to fit the requirement in the paper. In fact, as in general singular perturbation theory, the small parameter ε does not have to be very small in order to have decent numerical results. Typically, it works well when ε is less than 0.1 when all other elements in the coefficients of the system are of order 1.

This paper considers the case when the unknown $\alpha(\cdot)$ does not fluctuate too rapidly. Naturally, it would be interesting to consider the case when $\alpha(\cdot)$ jumps

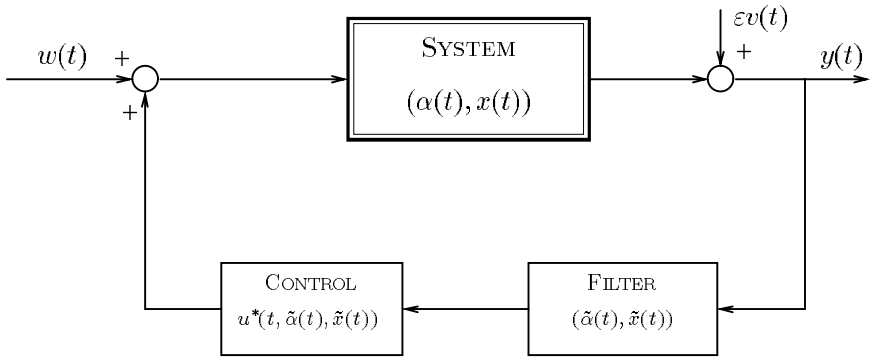

FIG. 8.1. *System diagram.*

rapidly from time to time. Quite often such situation can be formulated as a singular perturbed Markov chain with weak and strong interactions. In this connection, the asymptotic results in Yin and Zhang [21] appear to be useful for constructing filters and the ensuing optimality analysis.

Appendix. In this section we give six technical lemmas used in the paper.

LEMMA A.1. *Assume* (A1)–(A4). *Then there exist constants* ε_0 *and* K *such that for each* $0 < \varepsilon < \varepsilon_0$ *and* $\theta = \theta(\cdot) \in \Theta$,

$$E^\theta \int_0^T \left|\hat{x}^\theta(t) - \tilde{x}^\theta(t)\right|^2 dt \le K\varepsilon^2 E^\theta \int_0^T \left|x(t) - \tilde{x}^\theta(t)\right|^4 dt,$$

where $\hat{x}^\theta(t) = E^\theta[x(t)|\mathcal{Y}_t]$ *and* E^θ *is the conditional expectation given* $\alpha(\cdot) = \theta$.

Proof. The proof of this lemma can be the same as that given as in Haussmann and Zhang [11, Theorem 2.1]. □

LEMMA A.2. *Assume* (A1)–(A3). *Then there exist* γ_0 *and* K *such that for each* $0 < \sigma < 1$ *and for all* $\theta = \theta(\cdot) \in \Theta^\varepsilon_{\sigma,\gamma_0}$,

$$E^\theta \int_0^T \left|x(t) - \tilde{x}^\theta(t)\right|^4 dt \le K\varepsilon^2.$$

Proof. Let $\{t_j\}$ denote the set of jump times of θ. For each t_j, let

$$\begin{aligned} \phi_j &= E^\theta |x(t_j) - \tilde{x}^\theta(t_j)|^2, \\ \psi_j &= E^\theta |x(t_j) - \tilde{x}^\theta(t_j)|^4. \end{aligned}$$

Note that on interval $[t_j, t_{j+1})$, $\theta(\cdot)$ is a constant and therefore the function $H(t, \theta(t))$ is differentiable on this interval.

By considering the differential $d|H(t,\theta(t))x(t) - H(t,\theta(t))\tilde{x}^\theta(t)|^2$ on $[t_j, t_{j+1})$, we can show, by using Gronwall's inequality (as in [11, Lemma 2.3]), that

$$E^\theta |x(t) - \tilde{x}^\theta(t)|^2 \le K_1 \phi_j \exp\left(-\frac{\kappa(t - t_j)}{2\varepsilon}\right) + O(\varepsilon), \tag{A.1}$$

where $\kappa > 0$, $K_1 > 0$, and $O(\cdot)$ are independent of $\{t_j\}$ and σ.

Similarly, considering $d|H(t,\theta(t))x(t) - H(t,\theta(t))\tilde{x}^\theta(t)|^4$, we obtain

$$\begin{aligned} E^\theta|x(t)-\tilde{x}^\theta(t)|^4 \le\ & K_1\psi_j \exp\left(-\frac{\kappa(t-t_j)}{2\varepsilon}\right) \\ & + K_1\phi_j(t-t_j)\exp\left(-\frac{\kappa(t-t_j)}{2\varepsilon}\right) + O(\varepsilon^2). \end{aligned} \tag{A.2}$$

Setting $t = t_{j+1}$ in (9.1) and (9.2), respectively, we have

$$\begin{aligned} \phi_{j+1} \le\ & K_1\phi_j \exp\left(-\frac{\kappa(t_{j+1}-t_j)}{2\varepsilon}\right) + O(\varepsilon), \\ \psi_{j+1} \le\ & K_1\psi_j \exp\left(-\frac{\kappa(t_{j+1}-t_j)}{2\varepsilon}\right) \\ & + K_1\phi_j(t_{j+1}-t_j)\exp\left(-\frac{\kappa(t_{j+1}-t_j)}{2\varepsilon}\right) + O(\varepsilon^2), \end{aligned} \tag{A.3}$$

with $\phi_0 = O(\varepsilon)$ and $\psi_0 = O(\varepsilon^2)$.

Choose γ_0 large enough such that $K_1 e^{-\gamma_0/2} < 1/2$. Then for $\kappa(t_{j+1}-t_j) \ge \gamma_0\varepsilon$,

$$\begin{aligned} \phi_{j+1} &\le \frac{1}{2}\phi_j + O(\varepsilon), \\ \psi_{j+1} &\le \frac{1}{2}\psi_j + K_2\varepsilon\phi_j + O(\varepsilon^2). \end{aligned}$$

It follows by iteration that, for $j = 0, 1, \ldots,$

$$\begin{aligned} \phi_j &\le O(\varepsilon), \\ \psi_j &\le O(\varepsilon), \end{aligned}$$

with $O(\cdot)$ independent of $\{t_j\}$ and σ. In view of (9.3), we obtain

$$\begin{aligned} E^\theta|x(t)-\tilde{x}^\theta(t)|^2 &\le (K_1+1)O(\varepsilon) = O(\varepsilon), \\ E^\theta|x(t)-\tilde{x}^\theta(t)|^4 &\le (K_1+1)O(\varepsilon^2) = O(\varepsilon^2), \end{aligned}$$

with $O(\cdot)$ independent of $\{t_j\}$ and σ. □

Combining Lemmas A.1 and A.2, we have the following lemma.

LEMMA A.3. *Assume* (A1)–(A4). *Then there exist* ε_0, γ_0, *and* K *such that for each* $0 < \sigma < 1$, $0 < \varepsilon < \varepsilon_0$, *and for all* $\theta = \theta(\cdot) \in \Theta^\varepsilon_{\sigma,\gamma_0}$,

$$E^\theta \int_0^T \left|\hat{x}^\theta(t) - \tilde{x}^\theta(t)\right|^2 dt \le K\varepsilon^4.$$

The next lemma is concerned with the bounds and asymptotic estimate of $R^\theta(\cdot)$.

LEMMA A.4. *Assume* (A1)–(A4). *Then the following hold:*

(a) *There exist positive constants* c_1 *and* c_2, *independent of* $0 < \sigma < 1$, $\theta \in \Theta$, *and* $t \in [0,T]$, *such that*

$$c_1 I \le \frac{R^\theta(t)}{\varepsilon} \le c_2 I.$$

(b) *There exist* γ_0, K, *and* $\kappa > 0$ *such that, for each* $0 < \sigma < 1$ *and* $\theta \in \Theta^\varepsilon_{\sigma,\gamma_0}$, *we have*

$$\left|\frac{R^\theta(t)}{\varepsilon} - F(t,\theta(t))\right| \le K\left(\exp\left(-\frac{\kappa(t-t_j)}{\varepsilon}\right) + \varepsilon\right), \tag{A.4}$$

for $t \in [t_j, t_{j+1})$, *where* $\{t_j\}$ *is the set of jump times of* θ.

Proof. Part (a) can be shown as in [11, Lemma 2.5]. To show (b), note that on a given interval $[t_j, t_{j+1})$, $\theta(t)$ is a constant. Let

$$\eta(t) := \operatorname{tr}\left(\frac{R^\theta(t)}{\varepsilon} - F(t,\theta(t))\right)^2.$$

Recall that both $R^\theta(t)$ and $F(t,\theta(t))$ are symmetric matrices. To estimate (9.4), it suffices to obtain a similar upper bound for $\eta(\cdot)$.

Using the conditions in (A1) and (A3), the second equation in (3.2), and the inequality $a_1a_2 \le a_1^2/\varepsilon + \varepsilon a_2^2$ for any numbers a_1 and a_2, we obtain, by considering the derivative of $(R^\theta(t)/\varepsilon - F(t,\theta(t)))^2$,

$$\frac{d\eta(t)}{dt} \le -\frac{\kappa_1}{\varepsilon}\eta(t) + O(\varepsilon),$$

where $\kappa_1 > 0$ and $O(\cdot)$ are independent of the choice of $\{t_j\}$ and σ.

Using Gronwall's inequality, we obtain

$$\eta(t) \le \eta(t_j)\exp\left(-\frac{\kappa_1(t-t_j)}{\varepsilon}\right) + O(\varepsilon^2).$$

As in Lemma A.2, choose γ_0 large enough such that

$$\exp\left(-\frac{\kappa_1(t_{j+1}-t_j)}{\varepsilon}\right) \le \exp\left(-\kappa_1\gamma_0\right) \le \frac{1}{2}.$$

Then

$$\eta(t_{j+1}) \le \frac{\eta(t_j)}{2} + O(\varepsilon).$$

Note that $\eta(t_0) = \eta(0)$ is bounded. It follows that $\eta(t_j)$ is bounded for $j = 0, 1, \ldots$. Hence there exists a constant K_1 such that

$$\eta(t) \le K_1\exp\left(-\frac{\kappa_1(t-t_j)}{\varepsilon}\right) + O(\varepsilon^2).$$

Thus, taking square roots on both sides, we obtain (9.4) for some positive constants κ and K. □

LEMMA A.5. *Given $u(\cdot) \in \mathcal{U}_y$, let $x(t)$, $\tilde{x}(t)$, $\check{x}(t)$, and $\hat{x}(t)$, $t \ge 0$, denote the state, filter, intermediate filter, and conditional mean, respectively. Then, for each $n = 1, 2, \ldots$, there exists a constant K such that*

$$E\left(|x(t)|^n + |\tilde{x}(t)|^n + |\check{x}(t)|^n + |\hat{x}(t)|^n\right) \le K,$$

uniformly with respect to $u(\cdot) \in \mathcal{U}_y$.

Proof. The proof can be given similarly as in [12, Theorem 4.1]. □

LEMMA A.6. *Let $N(T)$ denote the number of jumps of $\alpha(\cdot)$ in $[0,T]$. Then, for each $\sigma > 0$ and $j = 1, 2, \ldots$, there exist positive constants ε_0 and K such that for $0 < \varepsilon < \varepsilon_0$,*

$$P\left(N(T) \ge \frac{1}{\varepsilon^\sigma}\right) \le K\varepsilon^j.$$

Proof. First of all, note that in view of the construction of Markov chains as in Davis [4], there exists a Poisson process $N_0(\cdot)$ with parameter a/ε for some $a > 0$ such that $N(t) \le N_0(t)$, $t \ge 0$. We may assume $a = 1$ for simplicity. Let n_ε denotes the integer part of $[1/\varepsilon^\sigma]$. By using the Poisson distribution of $N_0(\cdot)$, it follows

$$\begin{aligned} P\left(N(T) \ge \frac{1}{\varepsilon^\sigma}\right) &\le P\left(N_0(T) \ge \frac{1}{\varepsilon^\sigma}\right) \\ &\le e^{-T}\left(\frac{T^{n_\varepsilon}}{n_\varepsilon!} + \frac{T^{n_\varepsilon+1}}{(n_\varepsilon+1)!} + \cdots\right) \\ &\le e^{-T}\left(\frac{T^{n_\varepsilon}}{n_\varepsilon!}\right) e^T = \frac{T^{n_\varepsilon}}{n_\varepsilon!}. \end{aligned}$$

Using Stirling's formula, we have

$$\frac{T^{n_\varepsilon}}{n_\varepsilon!} \sim \frac{(Te)^{n_\varepsilon}}{n_\varepsilon^{n_\varepsilon}\sqrt{2\pi n_\varepsilon}} \le \left(\frac{Te}{n_e}\right)^{n_\varepsilon}.$$

Now choose ε_0 such that $Te/n_{\varepsilon_0} \le 1/2$. Then, for $0 < \varepsilon < \varepsilon_0$, we have

$$\left(\frac{Te}{n_\varepsilon}\right)^{n_\varepsilon} \le K\varepsilon^j.$$

The result follows. □

Acknowledgments. Comments and suggestions from the referees that lead to improvement of the paper are greatly appreciated.

FEEDBACK STABILIZATION OF BILINEAR CONTROL SYSTEMS*

HUALIN WANG†

Abstract. In this paper, we study the region in which a bilinear control system is feedback stabilizable. In particular, we find a necessary and sufficient condition for feedback stabilization in terms of the Lyapunov spectrum.

Key words. Lyapunov exponent, Lyapunov spectrum, Floquet spectrum, control set, feedback stabilization

1. Introduction.

In this paper, we consider the following bilinear control systems:

$$\dot{x}(t) = \left(A_0 + \sum_{i=1}^{m} u_i(t) A_i \right) x(t), \text{ in } \mathbb{R}^d$$

$u := (u_1, \ldots, u_m) \in \mathcal{U} := \{u : \mathbb{R} \to \mathbb{R}^m | u(\cdot)$ locally integrable, and $u(t) \in U$ almost everywhere (a.e.)$\}$. Here $A_0, A_1, \ldots, A_m$ are $d \times d$ matrices and $U \subset \mathbb{R}^m$ is compact and convex with $0 \in \text{int}(U)$, the interior of U.

These kinds of systems are obtained, for example, by linearizing nonlinear systems at a common fixed point with respect to the state x only. The purpose of this paper is to characterize the region in which the systems are asymptotically stabilizable using measurable or piecewise analytic feedback laws, which are defined in this paper. The methods used here are based on the Lyapunov spectrum of families of time varying matrices [CK6], in other words, on the collection of Lyapunov exponents of a class of linear differential equations, and on the construction of feedback rank controllers in [Li] which originates from [Su]. Under the accessibility rank condition in the projective space $\mathbb{P}^{d-1}$ (which is weaker than the accessibility rank condition in $\mathbb{R}^d$), the methods allow us not only to find a necessary and sufficient condition for asymptotic feedback stabilization, but also to characterize the region in which the systems are exponentially stabilizable. In particular, we prove the following result: For bilinear control systems with the control ranges satisfying the conditions stated above, exponential stabilization is equivalent to asymptotic stabilization using measurable feedbacks and also to (open loop) asymptotic null controllability.

Our paper is organized as follows: In section 2 we describe the general setup of this paper, in particular, we define the concepts used here, such as piecewise analytic feedback. We also mention some known results on projective systems of the bilinear control systems in $\mathbb{P}^{d-1}$, the projective space. In section 3 we state and prove our main results on the existence of stabilizing feedbacks for cones in the state space $\mathbb{R}^d$. In section 4 we give an example which exhibits the basic idea in this paper. The example can be understood without knowing the construction of the feedback in the proof of our main result. In the appendix, an outline of the proof of Lemma 2.8 is given.

A paper by Clarke et al. [CLSS] shows the equivalence of asymptotic controllability and feedback stabilization. This paper deals with nonlinear systems and their global stabilization. The feedback employed by them is discretized (in time) and their concept of stability is that of "practical stability," i.e., stabilization into arbitrarily small neighborhoods of the fixed point. In contrast, we deal with bilinear systems. Our feedback concept is the classical one (measurable functions on the state space that are not discretized) and stability is global asymptotic (or exponential) stability of the fixed point. Using spectral methods, Gruene constructs discretized controls for nonlinear systems that yield classical asymptotic stability. For semilinear control systems the result can be found in [Gr].

2. Setup and preliminaries. Let U, the control range, be compact, convex with $0 \in \text{int}U \subset \mathbb{R}^m$ and $\mathcal{U}$ be the space consisting of locally integrable open loop control functions taking values in U. Consider

$$\dot{x} = \left(A_0 + \sum_{i=1}^{m} u_i(t) A_i \right) x, \ x \in \mathbb{R}^d, \tag{B}$$

where $u(\cdot) := (u_1(\cdot), \dots, u_m(\cdot)) \in \mathcal{U}$ and A_i are $d \times d$ matrices for $i = 0, 1, \dots, m$. By $A(x, u)$ we denote the right-hand side of (B).

There are many papers devoted to feedback stabilization of (B) (cf., e.g., [AG] and the references listed therein). For two-dimensional systems, a Lyapunov function approach for systems with unconstrained control range is presented in [CSV], while the properties of the Lyapunov spectrum for $d = 2$ are exploited in [CK5] to yield characterizations of feedback stabilizability. Equation (B) can be studied via the associated (angular) system on the projective space $\mathbb{P}^{d-1}$ obtained by identifying opposite points on the sphere in $\mathbb{R}^d$ [CK2]:

$$\dot{s} = h_0(s) + \sum_{i=1}^{m} u_i(t) h_i(s), \ s \in \mathbb{P}^{d-1}, \tag{PB}$$

where $s = \frac{x}{|x|} \in \mathbb{P}^{d-1}$ and $h_i(s) = [A_i - s^T A_i s \cdot I]s, i = 0, 1, \dots m$. Here $|\cdot|$ is the 2-norm on $\mathbb{R}^d$, I is the $d \times d$ identity matrix, and ^{T} denotes transposition. By $h(s, u)$ we denote the right-hand side of (PB).

Assume the accessibility rank condition for (PB), i.e.,

$$\dim Lie\ [h(\cdot, u), u \in U](s) = d - 1 \tag{H}$$

for all $s \in \mathbb{P}^{d-1}$. (Here $\dim Lie\ (X)(s)$ denotes for a set X of vector fields, the dimension of the distribution generated by the Lie algebra $Lie\ (X)$ in the tangent space at the point s.) In order to study the system (PB) we introduce some notations and concepts.

For any point $p \in \mathbb{P}^{d-1}$ and $u \in \mathcal{U}$, let $s(t, p, u)$ denote the solution of (PB) with $s(0, p, u) = p$. For example,

$$\frac{d}{dt}(s(t, p, u)) = h_0(s(t, p, u)) + \sum_{i=1}^{m} u_i(t) h_i(s(t, p, u))$$

holds for all $t \in \mathbb{R}$ except on a set of Lebesque measure zero, where $u = (u_1(\cdot), \dots, u_m(\cdot)) \in \mathcal{U}$.

Define

$$\mathcal{O}^+(p) = \{q \in \mathbb{P}^{d-1} | s(t,p,u) = q \text{ for some } u \in \mathcal{U} \text{ and } t \geq 0\}$$

and

$$\mathcal{O}^-(p) = \{q \in \mathbb{P}^{d-1} | s(t,q,u) = p \text{ for some } u \in \mathcal{U} \text{ and } t \geq 0\}.$$

DEFINITION 2.1. *A set $D \subset \mathbb{P}^{d-1}$ is called a control set of the control system* (PB) *if*

1) *$D \subset c\ell\mathcal{O}^+(p)$ for every $p \in D$ where $c\ell\mathcal{O}^+(p)$ denotes the closure of $\mathcal{O}^+(p)$;*

2) *for every $p \in D$ there is $u \in \mathcal{U}$ such that the corresponding solution, $s(t,p,u)$, of* (PB) *satisfies $s(t,p,u) \in D$ for all $t \in \mathbb{R}$;*

3) *D is maximal (with respect to set inclusion) with the properties* 1) *and* 2).

A main control set is a control set with nonempty interior.

In [CK4] *it is proved that under assumption* (H) *the control system* (PB) *has $k (1 \leq k \leq d)$ main control sets which are linearly ordered, say, $D_1 \prec D_2 \prec \cdots \prec D_k$, where the order is defined by*

$$D_i \prec D_j \quad \text{if and only if there exist } p \in D_i, q \in D_j, \text{ and } u \in \mathcal{U} \text{ such that } s(t,p,u) = q \text{ for some } t \geq 0.$$

Our results will be closely related to various spectral concepts for the bilinear system (B). Here we include the following definition.

DEFINITION 2.2. *Let $u \in \mathcal{U}$, and let $\psi(t,x,u)$ solve* (B) *for all $t \geq 0$ except on a set of Lebesgue measure zero with $\psi(0,x,u) = x \neq 0$. Let*

$$\lambda(u,x) := \limsup_{t \to \infty} \frac{1}{t} \log |\psi(t,x,u)|.$$

Let D be a main control set of (PB), *and let $c\ell(D)$ denote the closure of D. The following set is called the Lyapunov spectrum over D:*

$$\Sigma_{LY}(D) := \left\{ \lambda(u,x) | (u,x) \in \mathcal{U} \times \mathbb{R}^d \text{ s.t. } \frac{\psi(t,x,u)}{|\psi(t,x,u)|} \in c\ell(D) \text{ for all } t \geq 0 \right\}.$$

The following set is called the Floquet spectrum over D:

$$\Sigma_{FL}(D) := \left\{ \lambda(u,x) | (u,x) \in \mathcal{U} \times \mathbb{R}^d, u \text{ piecewise constant periodic with period } T \text{ s.t. } s\left(t, \frac{x}{|x|}, u\right) := \frac{\psi(t,x,u)}{|\psi(t,x,u)|} \in \operatorname{int}(D) \text{ for all } t \geq 0 \text{ and } s\left(T, \frac{x}{|x|}, u\right) = \frac{x}{|x|} \right\}.$$

PROPOSITION 2.3 (see [CK6]). *Under assumption* (H) *we have the following:*

1) *$c\ell\left(\Sigma_{FL}(D_i)\right) =: I_i$ are bounded intervals for $i = 1, \ldots, k$.*

2) *If $D_i \prec D_j$, then $\inf I_i \leq \inf I_j$ and $\sup I_i \leq \sup I_j$.*

An outline of the proof is included here. (The detailed proof is given in [CK6], the proof of Theorem 4.4.)

Proof.

1) Abbreviate $D := D_i$ and let for $j = 1, 2$ $\lambda_j \in \Sigma_{FL}(D)$ with corresponding points $(u_j, p_j) \in \mathcal{U} \times \text{int}(D)$ and periods $T_j \geq 0$. Since $\{s(t, p_j, u_j) | t \geq 0\}$ are compact subsets of $\text{int}(D)$, there exist $T > 0$ and $v_j \in \mathcal{U}$, with $s(t_1, p_1, v_1) = p_2$ and $s(t_2, p_2, v_2) = p_1$ for some $t_1, t_2 \leq T$. For $m, n \in \mathbb{N}$ define a control $u^{m,n}$ via concatenation on the time interval $[0, t^{m,n})$ with $t^{m,n} = mT_1 + t_1 + nT_2 + t_2$ as

$$u^{m,n} = v_2 \cdot \underbrace{n \text{ -times}} \to u_2 \cdot \cdots \cdot u_2 \cdot v_1 \cdot \underbrace{m \text{ -times}} \to u_1 \cdot \cdots \cdot u_1,$$

and on $\mathbb{R}_+$ as the $t^{m,n}$-periodic continuation. By this construction and by virtue of assumption (H), it can be shown that Σ_{FL} is dense in the interval between λ_1 and λ_2.

2) The inequalities follow directly from the construction of the main control sets in the proof of Theorem 3.10 (ii) in [CK4]. □

Based on the following assumption we are going to investigate the region in which the system (B) is stabilizable with state feedback laws. There exists the index $i_0 \in \{1, \ldots, k\}$ such that

$$i_0 = \max\{i | \ \inf I_i < 0\}. \tag{A}$$

Only under some specific circumstances can the whole space or a whole neighborhood of the origin be stabilized. In other words, in general, only part of the space is feedback stabilizable with respect to a given equilibrium of a given control system. We introduce the following definition which allows us to study feedback stabilization in part of the space, specifically, in some directions from the equilibrium (the origin in our paper). So typically, the set of all directions in which (B) is feedback stabilizable is a cone.

DEFINITION 2.4. *For the control system* (B)*, we say that the system is feedback stabilizable in a cone K with the vertex at the origin, if there is a measurable function $u(x)$ defined on K such that*

1) *for any $x \in K$ there is a unique function $\varphi(t, x)(t \geq 0)$ such that*

$$\frac{d\varphi(t,x)}{dt} = A(\varphi(t,x), u(\varphi(t,x))) \text{ and } \varphi(0,x) = x$$

for all $t \geq 0$ except on a set of Lebesgue measure zero;

2) *all solutions starting at any point in K remain in K for all $t \geq 0$;*

3) *any solution starting at any point in K approaches 0 as $t \to \infty$;*

4) *for any cone $\widetilde{K} \subset K$ such that $\widetilde{K} \cap \mathbb{S}^{d-1}$ is compact, ($\mathbb{S}^{d-1}$ is the $d-1$ dimensional unit sphere in $\mathbb{R}^d$), and the following holds: For all $\varepsilon > 0$ $\exists \delta > 0$ s.t. all solutions stay in $K \cap B(\varepsilon)$ for all $t \geq 0$ whenever they start in $\widetilde{K} \cap B(\delta)$, where $B(r)$ denotes the open ball in $\mathbb{R}^d$ centered at the origin, with radius r.*

The system is said to be exponentially feedback stabilizable if 1), 2), 4)*, and the following condition are satisfied:*

3′) *There is $\gamma > 0$ s.t. any solution $\varphi(t, x)$ with $x \in K$ satisfies* $\lim_{t\to\infty} \varphi(t, x)e^{\gamma t} = 0$.

If K is maximal with respect to set inclusion, then we call K the asymptotically (exponentially, respectively) stabilizable region. In the first case we may simply say the stabilizable region. The reason for introducing the cone $\widetilde{K}$ in Definition 2.4.4 *is explained in section* 4.

Remark 2.5. Notice that if $\sup I_k < 0$, then $\lambda(u,x) < 0$ for all $(u,x) \in \mathcal{U} \times \mathbb{R}^d$ (cf. [CK2]); hence any constant u will stabilize (B) in $\mathbb{R}^d$. And if $\inf I_1 > 0$, then $\lambda(u,x) > 0$ for all $(u,x) \in \mathcal{U} \times \mathbb{R}^d$ (cf. [CK2]); hence, no (measurable) $u(x)$ defined on any subset of $\mathbb{R}^d$ will stabilize (B).

So we would like to know what happens if $i_0 \geq 1$ and $\sup I_k \geq 0$. For this we introduce the following definitions.

DEFINITION 2.6. *Let F be a subset of $\mathbb{P}^{d-1}$. The domain of attraction of F is defined as*

$$\mathcal{A}(F) := \{q \in \mathbb{P}^{d-1} | s(t,q,u) \in F \text{ for some } u(\cdot) \in \mathcal{U} \text{ and for some } t \geq 0\},$$

where $s(\cdot,q,u)$ denotes the solution of (PB) *with control $u(\cdot) \in \mathcal{U}$ and $s(0,q,u) = q$.*

In particular, if $F = \{p\}$ for $p \in \mathbb{P}^{d-1}$, we simply write $\mathcal{A}(F)$ as $\mathcal{A}(p)$, which is $\mathcal{O}^-(p)$. If $F = D$ a main control set contained in $\mathbb{P}^{d-1}$, then $\mathcal{A}(D) = \mathcal{A}(p)$ for any $p \in \operatorname{int}(D) : \mathcal{A}(p) \subset \mathcal{A}(D)$ is trivial. For the other direction, let $q \in \mathcal{A}(D)$. Then there exist $u_1 \in \mathcal{U}$ and $t \geq 0$ such that $z := s(t,q,u_1) \in D$. Since $p \in \operatorname{int}(D) \subset \mathcal{O}^+(z), p$ can be reached from z by some $u \in \mathcal{U}$ within finite time. Therefore, $\mathcal{A}(D) \subset \mathcal{A}(p)$. Briefly, we have $\mathcal{A}(D) = \mathcal{A}(p) = \mathcal{O}^-(p)$ for any $p \in \operatorname{int}(D)$.

DEFINITION 2.7 (see [Su]). *A piecewise analytic vectorfield on a real analytic manifold M is a quadruple $(\mathcal{L}, (\mathcal{L}_1, \mathcal{L}_2), \{V_S\}_{S \in \mathcal{L}_1}, E)$ where*

1) *$\mathcal{L}$ is an analytic stratification of M;*

2) *$(\mathcal{L}_1, \mathcal{L}_2)$ is a partition of $\mathcal{L}$ into two classes, i.e., $\mathcal{L} = \mathcal{L}_1 \cup \mathcal{L}_2, \mathcal{L}_1 \cap \mathcal{L}_2 = \emptyset$;*

3) *for each $S \in \mathcal{L}_1, V_S$ is an analytic vectorfield on S;*

4) *E is a map which assigns to each point p in a stratum $S \in \mathcal{L}_2$, a stratum $E(p) \in \mathcal{L}_1$;*

5) *for each $p \in S \in \mathcal{L}_1$, if we let γ denote the integral curve of V_S through p, then either $\gamma(t)$ is defined for all $t \geq 0$, or else, if γ is defined up to a time $T > 0$, and if $\gamma(t), 0 \leq t < T$, remains in a compact subset of M, then $\lim_{t \to T, t<T} \gamma(t)$ exists;*

6) *for each $p \in S \in \mathcal{L}_2$, there is a unique integral curve γ of $V_{E(p)}$ such that $\lim_{t \to 0, t>0} \gamma(t) = p$.*

In our situation we have $M = \mathbb{R}^d \setminus \{0\}$ or $M = \mathbb{P}^{d-1}$, and V is called (*piecewise analytic*) *feedback controller* if for every $p \in S \in \mathcal{L}_1$, there is $u \in U$ such that $V_S(x) = A(x,u), x \in \mathbb{R}^d$ for the system (B) or $V_S(p) = h(p,u), p \in \mathbb{P}^{d-1}$ for system (PB).

The basic idea of this definition is to partition M into two classes of connected real analytic submanifolds (called the strata). On each stratum in one class (i.e., in $\mathcal{L}_1$) an analytic vector field is well defined; hence, the integral curve of the vector field through each point in the stratum is uniquely defined, and in each point of a stratum in the other class an exit rule E is specified in such a way that there is a unique trajectory of $V_{E(p)}$ that starts at p.

The following lemma is one of the basic ingredients of our feedback construction. It extends the results of Sussmann [Su] on the existence of piecewise analytic feedback controllers to the case of systems that are not completely controllable. An outline of the proof is given in the Appendix.

LEMMA 2.8 (see [Li]). *Let $p \in \operatorname{int}(D_j)$, where D_j is a main control set. Then there exists a piecewise analytic feedback controller V_p for the system* (PB) *in $\mathbb{P}^{d-1}$ such that p can be reached from any point of $\mathcal{A}(p)$ in finite time.*

For any subset E of $\mathbb{P}^{d-1}$ let $\mathcal{E}$ be the largest subset of $\mathbb{S}^{d-1}$ whose identification in $\mathbb{P}^{d-1}$ is E, and let K_E be the corresponding cone in $\mathbb{R}^d$, i.e., $K_E = \{x \in \mathbb{R}^d | x = r \cdot e, r \in \mathbb{R} \setminus \{0\}, e \in \mathcal{E}\}$.

Before giving the next definition, let us recall what piecewise analytic feedback

controller means. Sussmann's definition of (piecewise analytic) feedback controller guarantees two things:

1) The vector field is almost surely (a.s.) analytic;

2) There is a unique trajectory of the vector field through any point.

In the next definition we maintain these two aspects with uniquely defined trajectories for all $t \geq 0$. Nevertheless, we relax the exit rule in the following sense: If a trajectory reaches a stratum $S \in \mathcal{L}_2$, it leaves immediately according to a rule (which will be clear from the construction), or it never gets back into any stratum $S \in \mathcal{L}_1$.

DEFINITION 2.9. *For the control system* (B)*, let K be a cone in $\mathbb{R}^d, u : K \to \mathbb{R}^m$ with $u(x) \in U$ for all $x \in K$. The function u is called a piecewise analytic feedback on K if*

1) *K has an analytic stratification $\mathcal{L}$ such that $\mathcal{L}$ is partitioned into two disjoint classes, say, $(\mathcal{L}_1, \mathcal{L}_2)$ with $\dim S = d$ for any $S \in \mathcal{L}_1$ and $\dim S < d$ for any $S \in \mathcal{L}_2$;*

2) *a $(x, u(x))$ is analytic on any $S \in \mathcal{L}_2$;*

3) *there is a rule so that, if a trajectory reaches a stratum $S \in \mathcal{L}_2$ in finite time, then it either leaves S immediately (i.e., for $p \in S$ we have the existence of an open time interval $(0, \tau)$ with $\varphi(t, p) \in S_1 \in \mathcal{L}_1$ for all $t \in (0, \tau)$ and some $S_1 \in \mathcal{L}_1$), or it stays in a lower dimensional submanifold such that for any $x_0 \in K$ the equation $\dot{x} = A(x, u(x))$ has a unique solution $\varphi(t, x_0)$ with $\varphi(0, x_0) = x_0$ and $\varphi(t, x_0) \in K$ for $t \geq 0$.*

Thus we may have different rules for different strata $S \in \mathcal{L}_2$, but for each point $p \in S \in \mathcal{L}_2$ we either assign a stratum $E(p) \in \mathcal{L}_1$ (see Definition 2.7), or $E(p) \in \mathcal{L}_2$ is the stratum S of which p is an element. In the latter case we require that $\varphi(t, p) \in S$ for all $t \geq 0$. Therefore, a piecewise analytic feedback u in the sense of Definition 2.9 guarantees global (in K) existence and uniqueness of solutions of $\dot{x} = A(x, u(x))$ for $t \geq 0$.

3. The existence of stabilizing feedbacks. In this section we prove the existence of stabilizing feedbacks under assumption (H), the accessibility condition on $\mathbb{P}^{d-1}$. Recall the definition of the index $i_0 = \max\{i | \inf \Sigma_{FL}(D_i) < 0\}$, and assume that $i_0 \in \{1, \ldots, k\}$.

THEOREM 3.1. *Under assumptions* (H) *and* (A) *there exists a piecewise analytic feedback $u(x)$ defined in $K_{A(D_{i_0})}$ such that*

$$\dot{x} = A(x, u(x)) \tag{FB}$$

is exponentially stable with respect to the origin in $K_{A(D_{i_0})}$.

Proof. Under assumption (A) we have $\inf \Sigma_{FL}(D_i) < 0$ for $1 \leq i \leq i_0$ and $\inf \Sigma_{FL}(D_i) \geq 0$ for $i_0 < i \leq k$. By the definition of $\Sigma_{FL}(D_{i_o})$, there exist a piecewise constant and periodic control $u_0 \in \mathcal{U}$ and $p \in \text{int}(D_{i_0})$ such that the solution of $\dot{s} = h(s, u_0)$, say, $s_p(t, p, u_0) \in \text{int}(D_{i_0})$ for all $t \geq 0$ and $\lambda(u_0, x_0) < 0$ where $\frac{x_0}{|x_0|} = p$ (or we can simply write $\lambda(u_0, p) < 0$ since $\lambda(u_0, x) = \lambda(u_0, y)$ if $x/|x| = y/|y|$). Let T be the period of both $u_0(\cdot)$ and $s_p(\cdot, p, u_0)$. So we have $s_p(0, p, u_0) = s_p(T, p, u_0) = p$. Let $\psi_0(t, x, u_0)$ be the solution of $\dot{x} = A(x, u_0)$ with $\psi_0(0, x_0, u_0) = x_0$. So $s_p(t, p, u_0)$ is the projection of $\psi_0(t, x_0, u_0)$ onto the projective space $\mathbb{P}^{d-1}$. Since $\lambda(u_0, x_0) < 0, \psi_0(t, x_0, u_0) \to 0$ exponentially as $t \to \infty$. From now on, p, x_0, s_p, and ψ_0 all are fixed throughout the proof.

By Lemma 2.8 there exists a piecewise analytic feedback controller V_p which is well defined on $\mathcal{A}(D_{i_o}) = \mathcal{A}(p)$. This implies the following:

1) There is an analytic stratification of $\mathcal{A}(p)$, say, $\mathcal{L}$;

2) $\mathcal{L}$ is partitioned into two disjoint classes of strata, say, $(\mathcal{L}_1, \mathcal{L}_2)$ with $\dim S = d-1$ for any $S \in \mathcal{L}_1$ and $\dim S < d-1$ for any $S \in \mathcal{L}_2$;

3) $V_p(q) = h(q, u_q)$ for some $u_q \in U$;

4) $V_p(\cdot)$ is analytic in $S \in \mathcal{L}_1$;

5) Instruction for motion for any point in $S \in \mathcal{L}_2$ is given so that p can be reached from any point of $\mathcal{A}(p)$ in finite time via a unique trajectory.

Now we can define $u(x)$ for any $x \in K_{\mathcal{A}(p)}$ (briefly written as K) as follows:

$$u(x) = \begin{cases} u_0(t), \ t = \min\left\{\tau | s_p(\tau, p, u_0) = \dfrac{x}{|x|}\right\}, \\ u_q, \quad \text{if } s_p(t, p, u_0) \neq \dfrac{x}{|x|} \text{ for all } t \geq 0, \end{cases}$$

where $q = \frac{x}{|x|}$ and $u_q \in U$ is specified by (3) above, i.e., by $V_p(q) = h(q, u_q)$. It is clear that $u(x)$ is well defined in the cone K. Note that $u_0(\cdot) \in \mathcal{U}$ is piecewise constant and for any constant c the vector field $h(s, c)$ is analytic in x; hence,

$$\mathcal{N} := \{s_p(t, p, u_0) | 0 \leq t \leq T\}$$

is a closed analytic subset. Therefore it is a subanalytic set. Let $\mathcal{L}$ be the (sub-) analytic stratification specified in 1) above. Let $\mathcal{B}$ the set of all strata belonging to $\mathcal{L}$, i.e.,

$$\mathcal{B} := \{S | S \in \mathcal{L}_1 \text{ or } S \in \mathcal{L}_2\}.$$

Now we are in the situation that $\mathcal{N}$ intersects some strata in $\mathcal{B}$, which may partition some strata in $\mathcal{B}$ into subanalytic sets. Specifically, if $S \in \mathcal{B}$ and $S \cap \mathcal{N} \neq \emptyset$, then $S \cap \mathcal{N}$ = the union of some subanalytic sets, say, $S \cap \mathcal{N} = \bigcup_{i=1}^{I_S} S_i$. Let $\mathcal{T}$ be the family of subanalytic subsets such that $\mathcal{T}$ contains $S \in \mathcal{B}$ if $S \cap \mathcal{N} = \emptyset$ and all $S_i (i = 1, \ldots, I_S)$ if $S \cap \mathcal{N} = \bigcup_{i=1}^{I_S} S_i \neq \emptyset$. Thus $\mathcal{T}$ is a locally finite family of subanalytic subsets of $\mathcal{A}(p)$. By Theorem 4.2 in [Ha] there exists a subanalytic stratification, say, $\mathcal{L}^*$ of $\mathcal{A}(p)$, compatible with $\mathcal{T}$, i.e., every $S \in \mathcal{T}$ is a union of strata of $\mathcal{L}^*$.

Let $\widetilde{\mathcal{A}}$ be the largest subset of $\mathbb{S}^{d-1}$ whose identification in $\mathbb{P}^{d-1}$ is $\mathcal{A}(p)$. Since $\{x = (x_1, \ldots, x_d) \in R^d | \ |x| = 1, x_d = 0\}$ is subanalytic in $\mathbb{S}^{d-1}$, $\mathcal{N}, \mathcal{B}, \mathcal{L}, \mathcal{T}$, and $\mathcal{L}^*$ in $\mathbb{P}^{d-1}$ all have their counterparts in $\mathbb{S}^{d-1}$. (Recall $\mathbb{P}^{d-1}$ is obtained by identifying the opposite points in $\mathbb{S}^{d-1}$). In particular, let $\overline{\mathcal{L}^*}$ be the subanalytic stratification of $\widetilde{\mathcal{A}}$. Notice K is the cone in $\mathbb{R}^d$ containing all x with $\frac{x}{|x|} \in \widetilde{\mathcal{A}}$. Hence, K has a subanalytic stratification whose strata are of the form: $\{r \cdot S | r > 0, S \in \overline{\mathcal{L}^*}\}$.

We need to prove that the feedback function $u(x)$ defined above does exponentially stabilize the system (B) in K (in the sense of Definitions 2.4 and 2.9).

Note that $u(x)$ is constant on each ray from the origin so it makes sense to consider the equation $\dot{s} = h(s, u(s))$ in $\mathcal{A}(p) \subset \mathbb{P}^{d-1}$. First, let us look at how trajectories evolve in $\mathcal{A}(p)$. For any $q \in \mathcal{A}(p)$ the trajectory of $h(s, u(s))$ from q first follows the vectorfield $V_p(s)$. In finite time it hits $\mathcal{N} = \{s_p(t, p, u_0) | 0 \leq t \leq T\}$, and then it follows the periodic solution $s_p(t, p, u_0)$ forever. Since $V_p(s)$ guarantees a unique trajectory from any point $q \in \mathcal{A}(p)$, there is a unique trajectory of $h(s, u(s))$ from q for positive time. Earlier we obtained the subanalytic stratification $\mathcal{L}^*$ of $\mathcal{A}(p)$. Let $\mathcal{L}^* = (\mathcal{L}_1^*, \mathcal{L}_2^*)$. If the trajectory from q reaches any stratum in $\mathcal{L}_2^*$ at r, then the exit rule is given in Lemma 2.8 if $r \notin \mathcal{N}$, or the trajectory follows $\mathcal{N}$ forever if $r \in \mathcal{N}$.

Since $V_p(s)$ steers all points in $\mathcal{A}(p)$ into p in finite time, any trajectory of $h(s,u(s))$ will reach $\mathcal{N}$ in finite time (since $p \in \mathcal{N}$). Since $u(r\cdot x) = u(x)$ for $r \in \mathbb{R}\setminus\{0\}$, (FB) can be projected into the projective space $\mathbb{P}^{d-1}$. The projection yields

$$\text{(FP)} \qquad \dot{s} = h(s,u(s)),\ u(s) = u\left(\frac{x}{|x|}\right),\ s = \frac{x}{|x|} \in \mathbb{P}^{d-1}$$

in $\mathcal{A}(p)$. Let $\varphi(t,x)(t \geq 0)$ be a solution of (FB) with $\varphi(0,x) = x$, i.e., $d\varphi/dt = A(\varphi, u(\varphi))$ a.e. For any $r \neq 0 \quad d(r\cdot\varphi)/dt = A(r\cdot\varphi, u(r\cdot\varphi))$ a.e. Hence, $r\cdot\varphi(t,x)$ is also a solution of (FB) with $r\cdot\varphi(0,x) = r\cdot x$. From this and the fact that (FP) has a unique solution for any initial point $q \in \mathcal{A}(p)$, it follows that (FB) has a unique solution for any initial point $x \in K$ for $t \geq 0$. Since $s_p(t,p,u_0)$ is the solution of $\dot{s} = h(s,u_0(t))$, the projection of $r\cdot\psi_0(t,x_0,u_0)$ for $r \in \mathbb{R}\setminus\{0\}$ is $s_p(t,p,u_0)$. Thus any solution in K will reach one of $r\cdot\psi_0(\cdot,x_0,u_0)$ for $r \in \mathbb{R}$ in finite time and then follow it. Since $r\cdot\psi_0(t,x_0,u_0) \to 0$ as $t \to \infty$ (with the same rate), conditions 1), 2), and 3) in Definition 2.4 are satisfied. To prove 4) let $\widetilde{K}$ be a subset of K considered in the definition. For $\alpha > 0$ all solutions starting at any points in $\widetilde{K} \cap B(\alpha)$ can be uniformly bounded by a constant $M(\alpha, \widetilde{K})$. This can be proved as follows: Consider $B_K := \widetilde{K} \cap \{x \in \mathbb{R}^d || x| = \alpha\}$, which is compact. B_K intersects only a finite number of strata of $\overline{\mathcal{L}^*}$. Let S be a stratum of the first kind and assume $S \cap B_K \neq \emptyset$. Since $A(x,u(x))$ is analytic in S, all solutions starting in $S\cap B_K$ leave S in times bounded by some constant $T(S)$, and the solutions are uniformly bounded by a constant $M(S)$. From the construction of the feedback controller in Theorem 9 [Su] or Lemma 2.8, any trajectory passes through only a finite number of strata before it hits $\{r\cdot\psi_0(t,x_0,u_0)|r \neq 0\}$. Hence all solutions starting in B_K are uniformly bounded by a constant, say, $M(\alpha,\widetilde{K})$, and they hit $\{r\cdot\psi_0|(t,x_0,u_0)|r \neq 0\}$ in times bounded by a constant. Since all solutions of $\dot{x} = A(x,u(x))$ satisfy $r\varphi(t,x) = \varphi(t,rx)$, all solutions starting in $\widetilde{K} \cap B(\alpha)$ are also uniformly bounded by $M(\alpha,\widetilde{K})$. Again in virtue of $r\varphi(t,x) = \varphi(t,rx)$ for $r \in \mathbb{R}$ and $x \in K, M(\alpha,\widetilde{K})$ can be chosen so that $M(r\alpha,\widetilde{K}) = rM(\alpha,\widetilde{K})$. This completes the proof of 4). □

In Theorem 3.1 we used assumption (A) which is related to the Floquet spectrum. An assumption related to the Lyapunov spectrum can be similarly stated as: There exists $i_0 \in \{1,\ldots,k\}$ s.t.

$$\text{(A}') \qquad i_0 = \max\{i|\ \inf \Sigma_{LY}(D_i) < 0\}.$$

There is a similar result using this assumption. Before we state the result, let us recall the following definition.

DEFINITION 3.2. *Let D be a main control set of* (PB). *Define the following subsets of the boundary ∂D:*

$$\begin{aligned}
\Gamma(D) = \{p \in \partial D|\ &\textit{there exist } q \in \operatorname{int}(D) \textit{ and } u \in \mathcal{U} \textit{ with} \\
&p = s(t,q,u) \textit{ for some } t > 0\}, \\
\Gamma^*(D) = \{p \in \partial D|\ &\textit{there exist } q \in \operatorname{int}(D) \textit{ and } u \in \mathcal{U} \textit{ with} \\
&q = s(t,p,u) \textit{ for some } t > 0\}, \\
\widetilde{\Gamma}(D) = \{p \in \partial D|&\mathcal{O}^+(p) \cap \operatorname{int}(D) = \emptyset \textit{ and } \mathcal{O}^-(p) \cap \operatorname{int}(D) = \emptyset\}.
\end{aligned}$$

$\Gamma(D), \Gamma^*(D)$, and $\widetilde{\Gamma}(D)$ are called exit, entrance, and tangential boundary, respectively.

In other words, the boundary of a main control set can be classified into three disjoint classes. From an exit boundary point at least one trajectory leaves $c\ell(D)$ *immediately; from an entrance boundary point at least one trajectory enters into* $\mathrm{int}(D)$ *immediately and the rest of the boundary is the tangential boundary.*

There is the following fact about these concepts.

PROPOSITION 3.3. 1) *The sets* $\Gamma(D)$ *and* $\Gamma^*(D)$ *are open in* ∂D *and* $\widetilde{\Gamma}(D)$ *is closed in* ∂D.

2) *Under* (H), $\widetilde{\Gamma}(D) \subset c\ell(\Gamma^*(D)) \cap c\ell(\Gamma(D))$, *in particular,* $\mathrm{int}_{\partial D}(\widetilde{\Gamma}(D)) = \emptyset$.

3) *For the main control set* D_1 *(the minimal one in the linear ordering), it holds that* $\partial D_1 = \Gamma(D_1)$, *and for the main control set* D_k *(the maximal one in the linear ordering), it holds that* $\partial D_k = \Gamma^*(D_k)$.

The proof is given in [CK4].

THEOREM 3.4. *Under assumptions* (H) *and* (A′), *there exists a measurable feedback law defined in a cone* K, *which exponentially stabilizes* (B) *in* K *if at least one negative Lyapunov exponent can be obtained from a point* $p \in \mathrm{int}(D_{i_o}) \cup \Gamma(D_{i_0})$, *in particular, if* $i_0 = 1$ *or* $\sup \Sigma_{LY}(D_{i_0}) < 0$. *In this case* $K = K_{\mathcal{A}(p)}$.

Proof. The proof is similar to that of Theorem 3.1 except that the periodic solution $s_p(t, p, u_0)$ is replaced by a solution, say, $s_p(t) \subset \mathrm{int}(D_{i_o}) \cup \Gamma(D_{i_0})$ whose corresponding solution of (B) exponentially approaches 0 as $t \to \infty$. This is because if there exists $\overline{p} \in \mathrm{int}(D_{i_o}) \cup \Gamma(D_{i_0})$ with $\lambda(\overline{u}_0, \overline{x}_0) < 0$ for some $\overline{u}_0 \in \mathcal{U}$ and $\frac{\overline{x}_0}{|\overline{x}_0|} = \overline{p}$, then the solution of $\dot{x} = A(x, \overline{u}_0)$, say, $\psi_{\overline{x}_0}(t) \to 0$ as $t \to \infty$. The projection of $\psi_{\overline{x}_0}(t)$, $s_{\overline{p}}(t)$, is a solution of $\dot{s} = h(s, \overline{u}_0)$. By the definition of $\lambda(\overline{u}_0, \overline{x}_0)$ we know $s_{\overline{p}}(t) \in c\ell(D_{i_0})$ for $t \geq 0$. Notice that $\Gamma(D_{i_0})$ is the exit boundary. Hence there exist $p \in \mathrm{int}(D_{i_0})$ and $\overline{u}_1 \in \mathcal{U}$ which steers p into $\overline{p}$ in finite time τ. Let u_0 be the concatenation of $\overline{u}_1(t)$ for $0 \leq t \leq \tau$ and $\overline{u}_0(t + \tau)$ for $t \geq 0$. Then the solution of $\dot{s} = h(s, u_0)$, say, $s_p(t) \in c\ell(D_{i_0})$ and $s_p(0) = p$. Let $\psi(t)$ be the solution of $\dot{x} = A(x, u_0)$, whose projection into $\mathbb{P}^{d-1}$ is $s_p(t)$. So $\psi(t) \to 0$ exponentially as $t \to \infty$ since $\lambda(u_0, x_0) = \lambda(\overline{u}_0, \overline{x}_0) < 0$, where $x_0/|x_0| = p$ and $\psi(0) = x_0$. Once we have these two solutions, $s_p(t)$ and $\psi(t)$, the rest of the proof follows the same lines in the proof of Theorem 3.1. Since $s_p(t)$ for $t \geq 0$ may not be piecewise analytic, the resulting vectorfield $A(x, u(x))$ may not be piecewise analytic. But $u(x)$ is measurable, so is $A(x, u(x))$. □

Remark 3.5. The assumptions (A) and (A′) agree if $c\ell\Sigma_{FL}(D_{i_0}) = \Sigma_{LY}(D_{i_0})$. Conditions for equality of the Floquet and the Lyapunov spectrum can be found in [CK6].

The following corollary leads to the main result (stated in Corollary 3.8). It gives a necessary and sufficient criterion for exponential feedback stabilization of bilinear control systems in $\mathbb{R}^d$.

COROLLARY 3.6. *Under assumption* (H), *there exists a measurable feedback law which exponentially stabilizes the system* (B) *in* $\mathbb{R}^d$ *if and only if at least one negative Lyapunov exponent can be obtained form* $\mathrm{int}(D_k)$, *here* D_k *is the maximal main control set.*

Proof. Let $p \in \mathrm{int}(D_k)$ and $\lambda(u, p) < 0$ for some $u \in \mathcal{U}$. Since D_k is the maximal main control set, $\mathcal{A}(D_k) = \mathcal{A}(p) = \mathbb{P}^{d-1}$. So $K = \mathbb{R}^d \setminus \{0\}$ in Theorem 3.3 and $u(x)$ is well defined in K. Thus $u(0) = 0$ completes the definition of $u(x)$ in $\mathbb{R}^d$.

Conversely, assume $\lambda(u, p) \geq 0$ for all $p \in \mathrm{int}(D_k)$ and $u \in \mathcal{U}$. By 3) of Proposition 3.3, $\partial(D_k) = \Gamma^*(D_k)$. That is to say that any trajectory starting in D_k never leaves D_k. Furthermore, any trajectory starting in $\mathrm{int}(D_k)$ never reaches $\partial(D_k)$ because, if u steered $p \in \mathrm{int}(D_k)$ into $q \in \partial(D_k)$, then u would steer a point near p into a point

not contained in D_k by continuous dependence of solution $\dot{s} = h(s,u)$ on the initial value. Hence $\text{int}(D_k)$ is positively invariant. From this together with $\lambda(u,p) \geq 0$ for any $u \in \mathcal{U}$ and $p \in \text{int}(D_k)$, we see that it is impossible to exponentially stabilize the system in any region containing $\text{int}(D_k)$. □

The next result explains why exponential feedback stability is appropriate stabilization concept for bilinear control systems with compact control ranges.

THEOREM 3.7. *Under* (H), (B) *is asymptotically feedback stabilizable in* $\mathbb{R}^d$ *if and only if it is exponentially feedback stabilizable in* $\mathbb{R}^d$ *(with measurable feedback laws).*

Proof. One direction is obvious. Now assume (B) is not exponentially feedback stabilizable. By Corollary 3.6 $\lambda(u,p) \geq 0$ for all $p \in \text{int}(D_k)$ and $u \in \mathcal{U}$. If (B) were asymptotically feedback stabilizable in $\mathbb{R}^d$ then there would exist a measurable $u : \mathbb{R}^d \to \mathbb{R}^m$ with $u(x) \in U$ for any $x \in \mathbb{R}^d$, such that $\dot{x} = A(x,u(x))$ is asymptotically stable with respect to the origin.

Choose any point $0 \neq x_0 \in \mathbb{R}^d$ with $\frac{x_0}{|x_0|} \in \text{int}(D_k)$ and look at the trajectory of $\dot{x} = A(x,u(x))$ from the point x_0. Since $\dot{x} = A(x,u(x))$ is asymptotically stable, we can choose $T > 0$ such that $|\varphi(T,x_0)| < |x_0|$, here $\varphi(t,x_0)$ is the solution of $\dot{x} = A(x,u(x))$ with $\varphi(0,x_0) = x_0$.

If $\varphi(T,x_0) = rx_0$ with $r \in (-1,1) \setminus \{0\}$, let $v(t) = u(\varphi(t,x_0))$ for $t \in [0,T]$, and extend $v(t)$ periodically with T for $t \in \mathbb{R}$. Consider $\dot{x} = A(x,v(t))$ in $\mathbb{R}^d$. Since $\varphi(t,x_0)$ satisfies $\dot{x} = A(x,u(x))$ for $t \in [0,T], \varphi(t,x_0)$ is a solution of $\dot{x} = A(x,v(t))$ with $\varphi(0,x_0) = x_0$ for $t \in [0,T]$. Notice that $A(x,v(t)) = [A_0 + \sum_{i=1}^m v_i(t)A_i]x$ and $\varphi(T,x_0) = rx_0 = r\varphi(0,x_0)$; hence $r\varphi(t-T,x_0)$ also satisfies $\dot{x} = A(x,v(t))$ with $r\varphi(2T-T,x_0) = r^2x_0$ for $t \in [T,2T]$ (since $v(t)$ is periodic). So, in general, $r^n\varphi(t-nT,x_0)$ for $t \in [nT,(n+1)T], n = 0,1,\ldots$ is a solution of $\dot{x} = A(x,v(t))$. Since for $t \in [0,T]$ $0 < m \leq |\varphi(t,x_0)| \leq M < \infty$ for some m and M, $\lim_{t\to\infty} \frac{1}{t} \log |r^n\varphi(t - nT,x_0)| = \frac{1}{T} \log |r| < 0$ is a Lyapunov exponent. But by assumption all Lyapunov exponents $\lambda(u,p)$ obtained from $\text{int}(D_k)$ are not less than 0.

Thus we have shown that if (B) is not exponentially feedback stabilizable and $\varphi(T,x_0) = rx_0$ for some $x_0 \in \text{int}(D_k)$ with $r \in (-1,1) \setminus \{0\}$, then (B) is not asymptotically feedback stabilizable.

Now pick any point $p_0 \in \text{int}(D_k)$ in $\mathbb{P}^{d-1}$. Let

$$T := \max_{p \in D_k} \min_{u \in \mathcal{U}} \{t | s(t,p,u) = p_0 \text{ and } u \in \mathcal{U}\},$$

where $s(\cdot,p,u)$ is a solution of (PB) with $s(0,p,u) = p$. Since D_k is a closed subset of the compact space $\mathbb{P}^{d-1}, D_k$ is compact. Hence, T is finite [CK1].

For any $\delta > 0$, define

$$L(\delta) := \max\{|\psi(t,x,u)| \mid 0 \leq t \leq T, x \in c\ell(B(\delta)) \text{ and } u \in \mathcal{U}\},$$

where $B(\delta)$ is the open ball in $\mathbb{R}^d$ with radius δ, and $\psi(t,x,u)$ is the solution of $\dot{x} = A(x,u)$ with $\psi(0,x,u) = x$.

Consider the set $\mathcal{U}$, consisting of the open loop control functions. In [CK3] it is proved that $\mathcal{U}$ is compact and metrizable in the week*-topology of $L^\infty(\mathbb{R},\mathbb{R}^m) = (L^1(\mathbb{R},\mathbb{R}^m))^*$. The metric for u and $v \in \mathcal{U}$ is given by

$$d(u,v) = \sum_{n=1}^{\infty} \frac{1}{2^n} \frac{\left| \int_{\mathbb{R}} < u(t) - v(t), x_n(t) > dt \right|}{1 + \left| \int_{\mathbb{R}} < u(t) - v(t), x_n(t) > dt \right|},$$

where $\{x_n | n \in \mathbb{N}\}$ is a countable dense subset of $L^1(\mathbb{R}, \mathbb{R}^m)$, and $\langle \cdot, \cdot \rangle$ denotes an inner product in $\mathbb{R}^m$.

Since $\{x \in \mathbb{R}^d |\ |x| = \delta\}$ and $(\mathcal{U}, d)$ are compact,

$$N(\delta) := \max\{|\psi(t, x, u)| \mid 0 \le t \le T, |x| = \delta \text{ and } u \in \mathcal{U}\}$$

is finite. Since $A(x, u(t)) = (A_0 + \sum_{i=1}^m u_i(t)A_i)x, N(r\delta) = rN(\delta)$ for any $r > 0$. Hence, $L(r\delta) = rL(\delta)$ and $\lim_{\delta \to 0} L(\delta) = 0$. Fix $\delta_0 > 0$ so that $L(\delta_0) < 1$.

Pick $x_0 \in \mathbb{R}^d$ with $|x_0| = 1$ and $\frac{x_0}{|x_0|} = x_0 \in \text{int}(D_k)$. Let $\varphi(\cdot, x_0)$ be the solution of $\dot{x} = A(x, u(x))$ with $\varphi(0, x_0) = x_0$. By assumption $\varphi(t, x_0) \to 0$ as $t \to \infty$ and $\varphi(t, x_0)/|\varphi(t, x_0)| \in \text{int}(D_k)$ for $t \ge 0$ since $\text{int}(D_k)$ is positively invariant.

Let $T_0 > 0$ such that $|\varphi(T_0, x_0)| < \delta_0$. Since (PB) is completely controllable in $\text{int}(D_k)$, there is $u_1 \in \mathcal{U}$ such that

$$s\left(\tau, \frac{\varphi(T_0, x_0)}{|\varphi(T_0, x_0)|}, u_1\right) = \frac{x_0}{|x_0|} \tag{1}$$

for some $\tau \in [0, T]$ (by the definition of T). Let ψ be the corresponding solution of $\dot{x} = A(x, u_1)$ with $\psi(0, \varphi(T_0, x_0), u_1) = \varphi(T_0, x_0)$ for $t \in [0, \tau]$. So $|\psi(\tau, \varphi(T_0, x_0), u_1)| \le L(\delta_0) < 1$. Define

$$v(t) = \begin{cases} u(\varphi(t, x_0)), & 0 \le t \le T_0, \\ u_1(t - T_0), & T_0 < t \le T_0 + \tau. \end{cases}$$

Let $\widetilde{T} = T_0 + \tau$. Then

$$\widetilde{\psi}(t, x_0, v(t)) := \begin{cases} \varphi(t, x_0), & 0 \le t \le T_0, \\ \psi(t - T_0, \varphi(T_0, x_0), v), & T_0 < t \le \widetilde{T} \end{cases}$$

is a solution of $\dot{x} = A(x, v)$ with $\widetilde{\psi}(\widetilde{T}, x_0, v) = rx_0$ for some $r \in (-1, 1) \setminus \{0\}$ (since $0 < |\psi(\tau, \varphi(T_0, x_0), u_1)| < 1$ and (1) holds). Thus we have constructed a solution $\widetilde{\psi}$ in $\mathbb{R}^d$ which satisfies $\widetilde{\psi}(\widetilde{T}, x_0, v) = rx_0$. This is the case we discussed before. So, if (B) is not exponentially feedback stabilizable in $\mathbb{R}^d$ using measurable feedback laws, then (B) is not asymptotically feedback stabilizable in $\mathbb{R}^d$ using measurable feedback laws. □

Combining Corollary 3.6 and Theorem 3.7 we get the following.

COROLLARY 3.8. *Under assumption* (H)*, the following are equivalent:*

1) (B) *is asymptotically feedback stabilizable in* $\mathbb{R}^d$*;*
2) (B) *is exponentially feedback stabilizable in* $\mathbb{R}^d$*;*
3) $\lambda(u, x) < 0$ *for some* $u \in \mathcal{U}$ *and* $x \in \mathbb{R}^d$ *with* $\frac{x}{|x|} \in \text{int}(D_k)$. □

Remark 3.9. Statement 3) of Corollary 3.8 can also be expressed in the following equivalent ways, involving the open loop system (B):

4) For all $x \in \mathbb{R}^d \setminus \{0\}$ there exists $u \in \mathcal{U}$ with $\lambda(u, x) < 0$;
5) The system (B) is asymptotically null-controllable for all $x \in \mathbb{R}^d \setminus \{0\}$;
6) The system (B) is exponentially null-controllable for all $x \in \mathbb{R}^d \setminus \{0\}$.

The proof of 3) $\Leftrightarrow$ 4) follows directly from the construction of the main control sets, for 4) $\Leftrightarrow$ 6) see [CK5], and 5) $\Leftrightarrow$ 6) follows along the same lines as the proof of Theorem 3.7.

4. Example. Consider the controlled linear oscillator $\ddot{y} + 2b\dot{y} + (1+u)y = 0$. With $x = (x_1, x_2)^T = (y, \dot{y})^T$, the equation becomes

$$\dot{x}(t) = \begin{pmatrix} 0 & 1 \\ -1 & -2b \end{pmatrix} x(t) + u(t) \begin{pmatrix} 0 & 0 \\ -1 & 0 \end{pmatrix} x(t) =: A(u)x, \tag{E1}$$

where $u(t) \in U = [A, B]$. This equation is studied in [CK2].

Projection of the equation onto the projective space $\mathbb{P}^1$ yields with $p = (\cos\theta, \sin\theta), \theta \in [0, \pi)$

$$\theta = -\sin^2\theta(t) - (1+u(t))\cos^2\theta(t) - b\sin(2\theta(t)). \tag{E2}$$

Now we consider the case: $b = -2, U = [-2, 2]$. Since the state space of (E2) is one-dimensional, the control sets of (E2) can be calculated simply by checking the monotonicity of $f(\cdot, u)$ where u is constant. The control sets are

$$D_1 = \pi_{\mathbb{P}^1}\left\{\begin{pmatrix} x_1 \\ x_2 \end{pmatrix} \in \mathbb{R}^2 \setminus \{0\} | x_2 = \alpha x_1, \alpha \in (2-\sqrt{5}, 1)\right\} \text{ and}$$
$$D_2 = \pi_{p^1}\left\{\begin{pmatrix} x_1 \\ x_2 \end{pmatrix} \in \mathbb{R}^2 \setminus \{0\} | x_2 = \beta x_1, \beta \in [3, 2+\sqrt{5}]\right\},$$

where $\pi_{\mathbb{P}^1}$ denotes the projection onto $\mathbb{P}^1$. If $\mathbb{P}^1 = [0, \pi)$, then D_1 and D_2 can also be written as

$$D_1 = \left[0, \frac{\pi}{4}\right) \cup \left(\pi + \arctan(2-\sqrt{5}),\ \pi\right) \text{ and}$$
$$D_2 = [\arctan 3,\ \arctan(2+\sqrt{5})],$$

where D_1 is open and D_2 is closed in $\mathbb{P}^1$. By the method provided in [CK2], we can calculate the spectral intervals which are

$$c\ell\Sigma_{FL}(D_1) = [2-\sqrt{5},\ 1] \text{ and}$$
$$c\ell\Sigma_{FL}(D_2) = [3,\ 2+\sqrt{5}].$$

(For this specific case we just need to compute all eigenvalues of $A(u)$ for constant $u \in U$.) It is easy to see that $\mathcal{A}(D_1)$, the domain of attraction of D_1, is D_1 itself (notice that D_1 is the minimal main control set). Hence, the cone generated by $\mathcal{A}(D_1)$ is $K := K_{\mathcal{A}(D_1)}$, which is equal to

$$\left\{\begin{pmatrix} x_1 \\ x_2 \end{pmatrix} \in \mathbb{R}^2 \setminus \{0\} | x_2 = \alpha x_1,\ \alpha \in (2-\sqrt{5}, 1)\right\}.$$

Now we want to find a piecewise analytic feedback law $u(x)$ defined in K to stabilize (E1) in K. First of all we define $u(\theta)$ in $\mathcal{A}(D_1) = D_1$ such that $u(\theta)$ steers any point in D_1 into a specific point p in finite time. Choose $p = \pi + \arctan(-0.05) \in [0, \pi) = \mathbb{P}^1$. Now $u(\theta)$ can be defined as

$$u(\theta) = \begin{cases} 2, & \theta \in \left[0, \frac{\pi}{4}\right) \cup (\pi + \arctan(-0.05),\ \pi), \\ -1.2025, & \theta = \arctan(-0.05), \\ -2, & \theta \in \left(\pi + \arctan(-0.05),\ \pi + \arctan(2-\sqrt{5})\right). \end{cases}$$

By checking the monotonicity of $f(\theta, u(\theta))$, we see that all trajectories starting in $\mathcal{A}(D_1) = D_1$ reach p in finite time. Now we can define $u(x)$ in K as

$$u(x) = \begin{cases} 2, & x \in \left\{ \begin{pmatrix} x_1 \\ x_2 \end{pmatrix} \in \mathbb{R}^2 \setminus \{0\} |\ x_2 = \alpha x_1, \alpha \in (-0.05,\ 1) \right\}, \\ -1.2025, & x_2 = -0.05 x_1, \\ -2, & x \in \left\{ \begin{pmatrix} x_1 \\ x_2 \end{pmatrix} \in \mathbb{R}^2 \setminus \{0\} |\ x_2 = \beta x, \beta \in (2-\sqrt{5},\ -0.05) \right\}. \end{cases}$$

The proof of stability of $\dot{x} = A(u(x))x$ is easy if we notice the following facts. When $u = -1.2025, A(u) = A(-1.2025)$ has one eigenvector $(x_1, -0.05x_1)^T$ associated with the eigenvalue $\lambda_1 = -0.05$. Let $L := \{(x_1, -0.05x_1)^T \in \mathbb{R}^2 | x_1 \in \mathbb{R}\}$. If $u = 2, A(2)$ has eigenvalues $\lambda_1 = 1$ and $\lambda_2 = 3$ whose corresponding eigenvectors are $(x_1, x_1)^T$ and $(x_1, 3x_1)^T$, respectively. So any trajectory starting in $\{(x_1, x_2)^T \in \mathbb{R}^2 \setminus \{0\} | x_2 = \alpha x_1, \alpha \in (-0.05, 1)\}$ will reach the line L in finite time. If $u = -2, A(-2)$ has eigenvalues $\lambda_1 = 2 - \sqrt{5}$ and $\lambda_2 = 2 + \sqrt{5}$, whose corresponding eigenvectors are $(x_1, (2-\sqrt{5})x_1)^T$ and $(x_1, (2+\sqrt{5})x_1)^T$, respectively. The line $x_2 = (2-\sqrt{5})x_1$ is in the boundary of K, and the line $x_2 = (2+\sqrt{5})x_1$ is outside of $c\ell(K)$. Hence, any trajectory starting in $\{(x_1, x_2)^T \in \mathbb{R}^2 \setminus \{0\} | x_2 = \beta x_1, \beta \in (2-\sqrt{5}, -0.05)\}$ will reach the line L in finite time. So with this feedback law, all trajectories of $\dot{x} = A(u(x))x$ will reach the line L in finite time, and then follow it and exponentially approach to zero. The exponential rate for this feedback is 0.05. (It is easy to see that we can construct feedbacks so that the rates belong to $(2-\sqrt{5}, 0)$.)

This example also shows the following two facts. One is that the set

$$\{t_x | t_x \text{ is the time that the trajectory of } \dot{x} = A(u(x))x \text{ first reaches } L \text{ from } x \in K\}$$

is unbounded on K, but it is bounded on any closed $\widetilde{K} \subset K$. This is the reason why we formulated Definition 2.4.4) using subcones $\widetilde{K} \subset K$ such that $\widetilde{K} \cap \mathbb{S}^{d-1}$ is compact. The other observation is that K may not be maximal. For this example, (E1) is exponentially stabilizable in $K \cup \{(x_1, x_2)^T \in \mathbb{R}^2 \setminus \{0\} | x_2 = (2-\sqrt{5})x_1\}$ (i.e., the union of K and part of its boundary).

Since $\mathbb{P}^1$ is one dimensional and the system (E2) has two control sets on $\mathbb{P}^1$, the periodic solution $s_p(t, p, u_0)$ constructed in the proof of Theorem 3.1 is a single point in this example, i.e., the point $p = \pi + \arctan(-0.05)$. If $d > 2$, or if the projected system has only one control set for $d = 2$, then the periodic solution $s_p(t, p, u_0)$ may not be a constant on $\mathbb{P}^{d-1}$.

Appendix. With the consent of Shan Lin, the author extracts part of the results from his Ph.D. dissertation [Li], from which Lemma 2.8 follows. Most of the notations follow [Su] and results extend those of [Su] to the not completely controllable case.

Consider an affine control system

$$\dot{x} = X_0(x) + \sum_{i=1}^{m} u_i X_i(x) \tag{C}$$

on a paracompact, connected, and real analytic manifold M of dimension n. The vector fields X_0 and X_i, $i = 1, \ldots, m$ are assumed to be real analytic. All admissible controls $u := (u_1, \ldots, u_m)$ are in $\mathcal{U} = \{u : \mathbb{R} \to U \text{ locally integrable}\}$, where $U \subset \mathbb{R}^m$ is compact. Let $\mathcal{U}_0 = \{\text{all piecewise constant controls in } \mathcal{U}\}$, $\mathcal{F} = \{X_0 + \sum_{i=1}^m u_i X_i(x) | u = (u_1, \ldots, u_m) \text{ constant in } U\}$.

We assume that the control system (C) satisfies the Lie algebra rank condition

$$\text{(H)} \qquad \dim Lie\left[X_0 + \sum_{i=1}^{m} u_i X_i,\ u := (u_1, \dots, u_m) \in U\right](x) = n$$

for all $x \in M$.

If X is a smooth vector field on M, Φ^X denotes the flow of X. Let $\xi = (Y_1, \dots, Y_k)$ be a finite sequence of smooth vector fields, and let $\tau = (t_1, \dots, t_k) \in \mathbb{R}^k$, where k is a positive integer. Set $|\xi| = k$ and $\|\tau\| = t_1 + \cdots + t_k$. Denote

$$\Phi_\tau^\xi := \Phi_{t_1}^{Y_1} \Phi_{t_2}^{Y_2} \dots \Phi_{t_k}^{Y_K},$$

where $\Phi_t^X(\cdot) = \Phi^X(t, \cdot)$. Also write $\Phi^\xi(\tau, x) = \Phi_\tau^\xi(x)$ for $\tau \in \mathbb{R}^{|\xi|}$. Define

$$\mathbb{R}_+^{k,T} := \{\tau \in \mathbb{R}_t^k \,|\, \|\tau\| \le T\} \text{ and}$$

for a given $\tau \in \mathbb{R}^k$ $C_\varepsilon^{|\xi|}(\tau) := \{(t_1', \dots, t_k') \in \mathbb{R}^k |\ |t_i' - t_i| \le \varepsilon \text{ for } i = 1, \dots, k\}$.

For $\tau = (t_1, \dots, t_k) \in \mathbb{R}^k$, define a map $\eta_\tau : [0, \|\tau\|] \to \mathbb{R}^k$ by

$$\begin{aligned}
\eta_\tau(t) &= (0, 0, \dots, 0, t), && \text{for } 0 \le t \le t_k \\
&= (0, 0, \dots, t - t_k, t), && \text{for } t_k \le t \le t_k + t_{k-1} \\
&\ \ \vdots && \ \ \vdots \\
&= (t - t_2 - \cdots - t_k, t_2, \dots, t_k), && \text{for } t_2 + t_3 + \cdots + t_k \le t \le \|\tau\|.
\end{aligned}$$

LEMMA A.1. *Assume* (H)*, the accessibility condition for the control system* (C)*, and let $x \in M$ and $y \in \operatorname{int}(D)$ where D is a main control set of control system* (C)*. If there is a $u \in \mathcal{U}$ such that $y = \psi(t, x, u)$ for some $t \in \mathbb{R}_+$, then there is $v \in \mathcal{U}_0$ such that $y = \psi(t', x, v)$ for some $t' \in \mathbb{R}_+$, where $\psi(t, x, u)$ is the trajectory of* (C) *with control u and $\psi(0, x, u) = x$.*

With this lemma, together with a similar argument as in [Su], we can prove the following.

LEMMA A.2. *Let $p \in \operatorname{int}(D)$ and $q \in \mathcal{A}(p)$, where $\mathcal{A}(p)$ is the domain of attraction of p. Then there exist* (1) *a finite subset $\mathcal{F}_p$ of $-\mathcal{F}$,* (2) *a finite sequence ξ of elements of $\mathcal{F}_p$,* (3) *a $\tau \in R_+^{|\xi|}$, and* (4) *an $\varepsilon > 0$ such that*

$$\begin{aligned}
&1)\ \Phi^\xi(\tau, p) = q; && 2)\ C_\varepsilon^{|\xi|}(\tau) \subset \mathbb{R}_+^{|\xi|}; \\
&3)\ \Phi^\xi(\cdot, p)(C_\varepsilon^{|\xi|}(\tau)) \text{ is a neighborhood of } q.
\end{aligned}$$

THEOREM A.3. *Assume* (H) *and let $p \in \operatorname{int}(D)$. Then there exists a piecewise analytic feedback controller V for system* (C) *such that p can be reached from any point of $\mathcal{A}(p)$ in finite time for the system $\dot{x} = X_0(x) + \sum_{i=1}^m u_i(x) X_i(x)$.*

Proof. For each $q \in \mathcal{A}(p)$, pick ξ_q, τ_q and ε_q so that they satisfy all the three properties in Lemma A.2. Let us use F_q to denote the map $\Phi^{\xi_q}(\cdot, p)$. Let A_q be the set of all points of $\mathbb{R}_+^{|\xi_q|}$ that are of the form $\eta_\tau(t)$ for some $\tau \in C_{\xi_q}^{|\xi_1|}(\tau_q)$ and some $t \in [0, \|\tau\|]$. For $i = 1, \dots, |\xi_q|$, put $a_q^i = \tau_{q,i} - \varepsilon_q$ and $b_q^i = \tau_{q,i} + \varepsilon_q$, where $\tau_q = (\tau_{q,1} \dots, \tau_{q,|\xi_q|})$.

Let A_q^i be the set of all points $(t_1, \ldots, t_{|\xi_q|})$ that satisfy (i) $t_j = 0$ for $j \leq |\xi_q| - i$; (ii) $0 \leq t_j \leq b_q^j$ for $j = |\xi_q| + 1 - i$; and (iii) $a_q^j \leq t_j \leq b_q^j$ for $j > |\xi_q| + 1 - i$. Then $A_q = A_q' \cup \cdots \cup A_q^{|\xi_q|}$ and $A_q^i \cap A_q^j = \emptyset$ if $i \neq j$.

Put $B_q = F_q(A_q), B_q^i = F_q(A_q^i)$ for $i = 1, \ldots, |\xi_q|$. Because A_q and A_q^i are compact semianalytic sets, and the map F_q is analytic, it follows that B_q are B_q^i are compact subanalytic subsets of M. Moreover, since $F_q(C_{\varepsilon_q}^{|\xi_q|}) \subset B_q$, the set B_q contains a neighborhood of q.

Let $\{K_j | j \in \mathbb{N}\}$ be a sequence of compact sets such that $K_j \subset \mathrm{int}(K_{j+1})$ and that $\mathcal{A}(p) = \bigcup_{j=1}^{\infty} K_j$. For each j, pick a finite set Q_j of points in $\mathcal{A}(p)$ in such a way that

$$K_j \setminus \mathrm{int}(K_{j-1}) \subset \bigcup_{q \in Q_j} B_q.$$

Let $q_1, q_2, q_3, \ldots$ be a sequence consisting of the points of Q_1, followed by the points of Q_2, followed by the points of Q_3, etc. Form a sequence of sets $D_j = B_{q_k}^i$, where $j \in \mathbb{N}$ and i, k are the unique numbers such that $|\xi_{q_1}| + \cdots + |\xi_{q_{k-1}}| + i = j, 1 \leq i \leq |\xi_{q_k}|$. Let $D_0 = \{p\}$. For $j \geq 0$, put $E_j = D_0 \cup \cdots \cup D_j$. Then the E_j's form an increasing sequence of compact subanalytic sets. Moreover, for every i there is j such that $K_i \subset E_j$. Hence, if we let $H_j = E_j \setminus E_{j-1}$, we find that the H_j's constitute a locally finite partition of $\mathcal{A}(p)$ into relatively compact subanalytic sets. Let $\mathcal{T}$ be the family of sets consisting of H_j for $j \in \mathbb{N}$.

For each set H_j, we have by construction that $j = |\xi_{q_1}| + \cdots + |\xi_{q_{k-1}}| + i$, with $1 \leq i \leq |\xi_{q_k}|$. Let $l = |\xi_{q_k}|, \xi_{q_k} = (Y_1, \ldots, Y_l)$. Then define an analytic vector field Z_j on H_j as $Z_j = -Y_{l+1-i}$. From Theorem 3 and Corollary 7 in [Su] (by letting $F(H_j) = \{Z_j\}$ in the notation of [Su]), we conclude that there is a subanalytic stratification $\mathcal{L}$ compatible with $\mathcal{T}$ such that every $S \in \mathcal{L}$ is a subset of some H_j, and that, if $S \in \mathcal{L}, S \subset H_j$, then either$Z_j$ is everywhere tangent to S, or it is nowhere tangent to S.

Now we can define a piecewise analytic vector field

$$V = (\mathcal{L}, (\mathcal{L}_1, \mathcal{L}_2), \{V_S\}_{S \in \mathcal{L}_1}, E)$$

as follows. We take the stratification to be $\mathcal{L}$. A stratum $S \in \mathcal{L}$ is in $\mathcal{L}_1$ if $S \subset H_j$ and Z_j is tangent to S for some j. Otherwise, S is in $\mathcal{L}_2$. If $S \in \mathcal{L}_1$ and $S \subset H_j$, then define $V_S = Z_j$.

If $S \in \mathcal{L}_2$ and $q \in S$, there is a unique j such that $S \subset H_j$. It is shown in Theorem 9 in [Su] that there is a unique $E(q) \in \mathcal{L}_1$ such that the integral curve γ of Z_j through q satisfies $\gamma(s) \in E(q)$ for small positive s.

Finally, it remains to prove that any point $q \in \mathcal{A}(q)$ can be steered into p in finite time by the feedback controller V defined above. Let $q \in H_j$. The integral curve γ_1 of Z_j through q is such that $\gamma_1(s) \in H_j$ for $0 \leq s < T_1$ and $\gamma_1(T_1) \in H_i$ for some $i < j$. Let γ_2 be the integral curve of Z_i through $\gamma_1(T_1)$. Then $\gamma_2(s) \in H_i$ for $0 \leq s < T_2$ and $\gamma_2(T_2) \in H_k$ for some $k < i$. Define γ_3 to be the integral curve of Z_k through $\gamma(T_2)$, etc. Then the curve γ obtained by following γ_1, then γ_2, then γ_3, and so on, reaches p in time $T \leq \sum_{i=1}^{j_q} T_i$ for some integer $j_q \leq j$, which means at most $j < \infty$ integral curves are needed. So T is finite because each of the T_i's is finite from the construction of Z_i and H_i. □

STOCHASTIC LINEAR QUADRATIC REGULATORS WITH INDEFINITE CONTROL WEIGHT COSTS*

SHUPING CHEN†, XUNJING LI‡, AND XUN YU ZHOU§

Abstract. This paper considers optimal (minimizing) control of stochastic linear quadratic regulators (LQRs). The assumption that the control weight costs must be positive definite, inherited from the deterministic case, has been taken for granted in the literature. It is, however, shown in this paper that some stochastic LQR problems with indefinite (in particular, negative) control weight costs may still be sensible and well-posed due to the deep nature of stochastic systems. New stochastic Riccati equations, which are backward stochastic differential equations involving complicated nonlinear terms, are presented and their solvability is proved to be sufficient for the well-posedness and the solutions of the optimal LQR problems. Existence and uniqueness of solutions to the Riccati equation for a special case are obtained. Finally, it is argued that, quite contrary to the deterministic systems, the stochastic maximum principle cannot fully characterize the optimality of the stochastic LQR problems.

Key words. stochastic linear quadratic regulator, well-posedness, stochastic Riccati equation, backward stochastic differential equation, maximum principle

1. Introduction.

Consider the following stochastic linear quadratic regulator (LQR) problem:

$$\text{Minimize} \quad J = E\{\int_0^T \tfrac{1}{2}[x'(t)Q(t)x(t) + u'(t)R(t)u(t)]dt + \tfrac{1}{2}x'(T)Hx(T)\}$$

$$\text{Subject to} \quad \begin{cases} dx(t) = [A(t)x(t) + B(t)u(t)]dt + [C(t)x(t) + D(t)u(t)]dW(t), \\ x(0) = y. \end{cases}$$

Here $W(t)$ is a Brownian motion and the control variable $u(t)$ takes value in some Euclidean space. In the deterministic case (i.e., $C = D = 0$), it is well known that the matrix $R(t)$, the so-called control weight, must be positive definite (for almost all t); otherwise the optimization problem would not be well-posed (or would become trivial) [8, 1]. To be precise, if $R(t)$ is negative (which means a benefit rather than a cost), then the optimal control u can be shown to be such that $|u(t)| = +\infty$, namely, "the larger the better." Stochastic LQR problems have been first studied by Wonham [13] and by many researchers later (cf., e.g., [2, 5]), but the assumption that $R(t) > 0$ has been taken for granted in all of these works. Recently, we observed that some stochastic LQR problems with $D \neq 0$ are nontrivial even when $R(t) < 0$, i.e., the

"the-larger-the-better" policy no longer applies. Let us look at a very simple example in one dimension. The following deterministic LQR problem

$$\begin{array}{ll} \text{Minimize} & J = \int_0^1 \frac{1}{2}[x^2(t) + r(t)u^2(t)]dt + \frac{1}{2}x^2(1) \\ \text{Subject to} & \begin{cases} dx(t) = 0, \\ x(0) = 0, \end{cases} \end{array} \tag{1.1}$$

where $r(t) < 0$, is not well-posed. In fact, $J = \int_0^1 \frac{1}{2} r(t)u^2(t)dt \to -\infty$ as $|u(t)| \to +\infty$. Now, consider a stochastic version of (1.1):

$$\begin{array}{ll} \text{Minimize} & J = E\Big\{ \int_0^1 \frac{1}{2}[x^2(t) + r(t)u^2(t)]dt + \frac{1}{2}x^2(1) \Big\} \\ \text{Subject to} & \begin{cases} dx(t) = u(t)dW(t), \\ x(0) = 0. \end{cases} \end{array} \tag{1.2}$$

Substituting $x(t) = \int_0^t u(s)dW(s)$ into the cost function, we obtain, via a simple calculation

$$J = \frac{1}{2} E \int_0^1 [r(t) + (2 - t)]u^2(t)dt. \tag{1.3}$$

Hence, when $r(t)$ is a deterministic function with $r(t) > t-2$, the optimization problem is sensible (with the optimal control $u^*(t) = 0$). In this case, the control weight cost, $r(t)$, could be *negative* as long as, say, $r(t) > -1$. Certainly, $r(t)$ cannot be *too* negative. For example, the problem would obviously become ill-posed if $r(t) < -2$.

The above seemingly surprising observation indeed makes perfect sense when we think a little deeper: the gain due to a larger control size may *not* outweigh the loss due to a greater uncertainty (because $D \neq 0$). It is emphasized that $D \neq 0$, which means that the controller can control the uncertainty or the decision made is going to affect the scale of the uncertainty in the system, plays a key role here. This kind of situation happens in real-world systems. In a stock market, for example, the trading made by the so-called "large investors" is going to influence the fluctuations of the stock prices. If $D = 0$, which is assumed in most of the previous work (see [5] and the references therein), then the control weight R must be positive definite for the well-posedness and the stochastic LQR problem can be treated almost completely parallel to the deterministic case. However, if $D \neq 0$, then R, even being negative, could be compensated by a quadratic term (which is related to D) by taking advantage of the underlying uncertainty. This observation reveals a fundamental difference between deterministic and stochastic systems.

Let us take a more concrete example to illustrate the above idea. Suppose an oil company is investing in an oil prospecting project. This project will cause a certain degree of pollution and suppose the pollution level $x(t)$ during a period of time $[0, T]$ is described by

$$\begin{cases} dx(t) = (\alpha x(t) + \beta u(t))dt + \delta u(t)dW(t), \\ x(0) = x_0, \end{cases} \tag{1.4}$$

where $u(t)$ represents the investment level of the company at time t, x_0 is the initial pollution level, and α, β, and δ are given constants. Suppose that the investment is expected to be very profitable and the return in the time period $[t, t+\Delta t]$ is $r|u(t)|^2\Delta t$

with a constant $r > 0$, and the company has sufficient funds to make the investment so that $u(t) \in (0, +\infty)$. On the other hand, the environmental impact of the project is supervised and monitored by the government so that the pollution level $x(t)$ cannot deviate too much from an allowable level $\bar{x}(t)$ at any time. The objective of the company is on one hand to maximize the total expected return, $E\int_0^T r|u(t)|^2dt$, and on the other hand to minimize the expected negative environmental impact, which in this case is measured by $E\int_0^T |x(t) - \bar{x}(t)|^2dt$. This is a multi-objective optimization problem and it may be converted into a single-objective problem by putting weights on the different objectives. Thus the following function is to be minimized:

$$J = E\int_0^T (\lambda_1|x(t) - \bar{x}(t)|^2 - \lambda_2 r|u(t)|^2)dt, \tag{1.5}$$

where $\lambda_1, \lambda_2 \in (0, 1)$ with $\lambda_1 + \lambda_2 = 1$ represent the weights. Note that this is a stochastic minimizing LQR problem with a negative control cost. If the problem were deterministic (i.e., there was no risk), where a positive return is guaranteed, then by the deterministic LQR theory that the control cost $-\lambda_2 r|u(t)|^2$ would be overwhelming in the overall cost, when λ_1 is small enough. In this case, the optimal policy would be $u(t) = +\infty$ (i.e., the larger the investment size the better) and the problem would become trivial. However, the problem is actually stochastic where the diffusion coefficient depends on the control (i.e., the risk of pollution increases as the investment level increases); then there is a trade-off (no matter how small λ_1 is) between the return (or the investment size) and the risk which makes the optimization problem sensible.

More generally, such a phenomenon can happen in the following situation. Suppose, in a deterministic (minimizing) optimization problem, that the cost *decreases* as the level of activity the decision maker carries out *increases* (a typical example of such situations is an investment that would be "guaranteed" to be profitable if the risk were to be excluded from consideration). Then it is not really an optimization problem because there is no *trade-off* in it, and the optimal decision is simply to take the maximum possible activity level. So the problem is trivial or ill-posed. However, in a stochastic environment, suppose that the uncertainty *increases* with *increasing* magnitude of the activity level and that the uncertainty results in certain additional cost (called *risk adjustment* in the terminology of economics); then there is a trade-off between the activity level and the uncertainty, and the decision maker has to carefully balance the two to achieve an optimal solution. The problem therefore becomes meaningful. Needless to say, such phenomena may occur in a much wider class of optimization problems that can go beyond linear systems and optimal control problems.

For LQR problems, it is natural to study an associated Riccati equation. The Riccati equation presented in this paper for the stochastic LQR problem with an indefinite control weight cost is a backward stochastic differential equation of the Pardoux and Peng type [11] and involves a term $(R + D'PD)^{-1}$ (P is the unknown of the Riccati equation). In the present paper, we show that the stochastic LQR problem is well-posed if there are solutions to the Riccati equation, and an optimal feedback control can then be obtained. However, the existence and uniqueness of the solutions to the Riccati equation, in general, seem to be very difficult problems due to the presence of the complicated nonlinear term. In this paper, we shall solve the existence and uniqueness for a special case where $C = 0$ and all of the matrices A, B, D, Q, R, H are deterministic functions.

For the deterministic LQR problems (with $R > 0$), the Pontryagin maximum prin-

ciple can completely characterize the optimality [1]. More precisely, the solvability of the so-called Hamiltonian system, which consists of the original state equation, the adjoint equation, and the maximum condition, is equivalent to the well-posedness of the LQR problem, and the solution to the Hamiltonian systems gives rise to an optimal feedback control. The stochastic maximum principle has been investigated since the 1960s [6, 9, 2, 7]. However, almost all of the results assume that the diffusion term does not depend on the control variable. Under this assumption, the statements of maximum principle (i.e., an optimal control should maximize pointwisely the usual Hamiltonian, which is *linear* in the drift term and *independent* of the diffusion term) and their proofs are very similar to those of the deterministic case. One does not see much difference between stochastic and deterministic systems from those results. The stochastic maximum principle for systems with control-dependent diffusion coefficients had long been an outstanding open problem until 1988 when Peng [12] first solved it (the proof of Peng was simplified by Zhou [15]). It is observed in [12, 15] that, in addition to the usual (first-order) adjoint equation, one has to introduce an *additional* adjoint equation—called the *second-order adjoint equation*—to represent the *risk factor* due to the underlying uncertainty. The maximum principle is to maximize an extended Hamiltonian, which includes an additional term that is *quadratic* in the diffusion coefficient, to reflect the risk-averse or risk-seeking attitudes of the decision makers. Moreover, it is shown by Zhou [16] that Peng's maximum principle is sufficient under certain convex conditions. However, while Peng's maximum principle has been widely recognized as a significant new result as well as the best result so far, it *cannot*, as will be shown via an example in this paper, lead to an optimal solution for some stochastic LQR problems that are well-posed but with $R < 0$. This is quite different to the deterministic case, which suggests that Peng's maximum principle could be further improved to give *tighter* necessary conditions of optimality which in particular would be sufficient for the stochastic LQR model.

The rest of the paper is organized as follows. In section 2 the optimal control problem of stochastic LQR models with indefinite control weight costs is formulated. In section 3 the corresponding stochastic Riccati equation is introduced and the existence of its solutions is shown to be sufficient for the LQR problem to be well-posed. Section 4 is devoted to the study of the Riccati equation for a special case. In section 5, the gap between Peng's maximum principle and the stochastic LQR problems is demonstrated. Finally, section 6 gives some concluding remarks.

2. Problem formulation and preliminaries. We consider in this paper a stochastic optimal control problem. The system is governed by the following linear Ito's stochastic differential equation (SDE)

$$\begin{cases} dx(t) = [A(t)x(t) + B(t)u(t)]dt + [C(t)x(t) + D(t)u(t)]dW(t), \\ x(s) = y, \end{cases} \tag{2.1}$$

where $(s, y) \in [0, T) \times R^n$ are the initial time and initial state, respectively, $W(t)$ is a given one-dimensional Brownian motion on $[0, T]$, and $u(\cdot)$, the control, is a U-valued $\mathcal{F}_t$-adapted measurable process with

$$\mathcal{F}_t = \sigma\{W(r) : 0 \le r \le t\}. \tag{2.2}$$

Here $U = R^m$. The set of all such admissible controls is denoted by U_{ad}. Note that we assumed the Brownian motion to be one-dimensional just for simplicity. There is no essential difficulty in the analysis below for the multidimensional case.

For each (s, y) and $u(\cdot) \in U_{ad}$, the associated cost is

$$J(s,y;u(\cdot)) = E^s\Big\{\int_s^T \frac{1}{2}[x'(t)Q(t)x(t) + u'(t)R(t)u(t)]dt + \frac{1}{2}x'(T)Hx(T)\Big\}, \tag{2.3}$$

where $E^s \equiv E(\cdot|\mathcal{F}_s)$. The solution $x(\cdot)$ of the SDE (2.1) is called the response of the control $u(\cdot) \in U_{ad}$, and $(x(\cdot), u(\cdot))$ is called an *admissible pair*. The objective of the optimal control problem is to minimize the cost function $J(s, y; u(\cdot))$, for a given $(s, y) \in [0, T) \times R^n$, over all $u(\cdot) \in U_{ad}$. We denote the above problem by $C_{s,y}$ to recall the dependence on the initial time s and the initial state y. The value function is defined as

$$V(s,y) = \inf_{u(\cdot)\in U_{ad}} J(s,y;u(\cdot)). \tag{2.4}$$

Note that V is an $\mathcal{F}_s$-adapted process for each fixed y. An admissible pair $(x^*(\cdot), u^*(\cdot))$ is called *optimal* for $C_{s,y}$ if $u^*(\cdot)$ achieves the infimum of $J(s, y; u(\cdot))$. The optimization problem (2.1)–(2.3) is called *well-posed* if $V(s, y) > -\infty$, $P - a.s.$, for *all* $(s, y) \in [0, T) \times R^n$.

Notation. We make use of the following notation in this paper:

M'	:	the transpose of any vector or matrix M;
M^j	:	the jth entry of any vector M;
$\|M\|$	:	$= \sqrt{\sum_{i,j} m_{ij}^2}$ for any matrix or vector $M = (m_{ij})$;
S^n	:	the space of all $n \times n$ symmetric matrices;
S_+^n	:	the subspace of all nonnegative definite matrices of S^n;
$\hat{S}_+^n$	:	the subspace of all positive definite matrices of S^n;
$C(0, T; X)$	:	the Banach space of X-valued continuous functions on $[0, T]$ endowed with the maximum norm $\|\cdot\|$ for a given Hilbert space X;
ρ_x	:	the gradient or Jacobian of a function ρ with respect to the variable x;
ρ_{xx}	:	the Hessian of a scalar function ρ with respect to the variable x .

Given a probability space $(\Omega, \mathcal{F}, P)$ with a filtration $\{\mathcal{F}_t : a \le t \le b\}$ $(-\infty \le a < b \le +\infty)$, a Hilbert space X with the norm $\|\cdot\|_X$, and p $(1 \le p \le +\infty)$, define the Banach space

$$L^p_{\mathcal{F}}(a,b;X) = \Big\{\phi(\cdot) = \{\phi(t,\omega) : a \le t \le b\}|\ \phi(\cdot) \text{ is an } \mathcal{F}_t - \text{adapted, } X\text{-valued measurable process on } [a,b], \text{ and } E\textstyle\int_a^b \|\phi(t,\omega)\|_X^p\, dt < +\infty\Big\},$$

with the norm

$$\|\phi(\cdot)\|_{\mathcal{F},p} = \left(E\int_a^b \|\phi(t,\omega)\|_X^p\, dt\right)^{\frac{1}{p}}.$$

In the rest of this paper, we shall employ the usual convention of suppressing the ω-dependence of all random functions. Sometimes we even write A for a (deterministic or stochastic) process $A(t)$, omitting the variable t, whenever no confusion arises. Under this convention, when $A \in C(0, T; S^n)$, $A \ge (>)0$ means $A(t) \ge (>)0$, $\forall t \in [0, T]$.

The following basic assumption will be in force throughout this paper:

(A) The data appearing in the LQR problem satisfy

$$\begin{aligned}
&A, C \in L^{\infty}_{\mathcal{F}}(0,T;R^{n\times n}) \cap L^2(\Omega; C(0,T;R^{n\times n})),\\
&B, D \in L^{\infty}_{\mathcal{F}}(0,T;R^{n\times m}) \cap L^2(\Omega; C(0,T;R^{n\times m})),\\
&Q \in L^2_{\mathcal{F}}(0,T;S^n_+) \cap L^2(\Omega; C(0,T;S^n_+)),\\
&R \in L^2_{\mathcal{F}}(0,T;S^m) \cap L^2(\Omega; C(0,T;S^m)),\\
&H \in L^2(\Omega, \mathcal{F}_T; S^n_+).
\end{aligned}$$

3. Stochastic Riccati equation. We introduce the following stochastic Riccati equation:

(3.1)

$$\begin{cases}
dP(t) = \Big\{ -\Big(P(t)A(t) + A'(t)P(t) + C'(t)P(t)C(t) + \Lambda(t)C(t) + C'(t)\Lambda(t) + Q(t)\Big)\\
\qquad +\Big(P(t)B(t) + C'(t)P(t)D(t) + \Lambda(t)D(t)\Big)\Big(R(t) + D'(t)P(t)D(t)\Big)^{-1}\Big(B'(t)P(t)\\
\qquad +D'(t)P(t)C(t) + D'(t)\Lambda(t)\Big)\Big\}dt + \Lambda(t)dW(t),\\
P(T) = H,\\
K(t) \equiv R(t) + D'(t)P(t)D(t) > 0, \quad P-a.s., \ \forall t \in [0,T].
\end{cases}$$

An $\mathcal{F}_t$-adapted *pair* $(P,\Lambda) \in [L^2_{\mathcal{F}}(0,T;S^n) \cap L^2(\Omega; C(0,T;S^n))] \times L^2_{\mathcal{F}}(0,T;S^n)$ is called a solution of the Riccati equation (3.1) if it satisfies all the constraints in (3.1). Note that it is a *backward stochastic differential equation* (BSDE). This type of equation was originally proposed by Bismut [3, 4] for the linear case, then extended to the nonlinear case by Pardoux and Peng [11], and has been further developed extensively in recent years. A distinctive feature of this type of equations is that their solutions are pairs (P,Λ), and the presence of Λ, which is derived by the martingale representation theorem, is necessary to reflect the uncertainty during the period between now and the given terminal time. Note that Λ itself may not satisfy any SDE. For details see [3, 4, 2, 12, 15, 11]. The Riccati equation (3.1) is nonlinear, and the nonlinearity does not satisfy the Lipschitz condition usually imposed in the literature due to the presence of the term $(R + D'PD)^{-1}$.

THEOREM 3.1. *If the stochastic Riccati equation* (3.1) *admits a solution, then the stochastic LQR problem* (2.1)–(2.3) *is well-posed.*

Proof. Let $P \in L^2_{\mathcal{F}}(0,T;S^n) \cap L^2(\Omega; C(0,T;S^n))$ be any semimartingale with the following decomposition:

$$dP(t) = \Gamma(t)dt + \Lambda(t)dW(t), \quad t \in [0,T], \tag{3.2}$$

and let $(x(\cdot), u(\cdot))$ be any admissible pair. Applying Ito's formula, we obtain

$$\begin{aligned}
d(x'Px) = \ & \Big\{x'(\Gamma + PA + A'P + C'PC + \Lambda C + C'\Lambda)x\\
& +2u'(B'P + D'PC + D'\Lambda)x + u'D'PDu\Big\}dt\\
& +\{...\}dW(t).
\end{aligned} \tag{3.3}$$

Integrating from s to T, taking expectations E^s on both sides, and dividing by 2, one gets

$$\begin{aligned}
&\tfrac{1}{2}E^s[x'(T)P(T)x(T)] - \tfrac{1}{2}y'P(s)y\\
&= \tfrac{1}{2}E^s\int_s^T \Big\{x'(\Gamma + PA + A'P + C'PC + \Lambda C + C'\Lambda)x\\
&\quad +2u'(B'P + D'PC + D'\Lambda)x + u'D'PDu\Big\}dt.
\end{aligned}$$

Adding this to (2.3) and, provided $K \equiv R + D'PD > 0$, using the square completion technique, we have

$$\begin{aligned}
&J(s,y;u(\cdot))\\
&= \tfrac{1}{2}E^s\int_s^T \Big\{x'(\Gamma + PA + A'P + C'PC + \Lambda C + C'\Lambda + Q)x\\
&\quad + 2u'(B'P + D'PC + D'\Lambda)x\\
&\quad + u'(R + D'PD)u\Big\}dt + \tfrac{1}{2}E^s[x'(T)(H - P(T))x(T)] + \tfrac{1}{2}y'P(s)y\\
&= \tfrac{1}{2}E^s\int_s^T \Big\{x'(\Gamma + PA + A'P + C'PC + \Lambda C + C'\Lambda + Q - L'K^{-1}L)x\\
&\quad + (u + K^{-1}Lx)'K(u + K^{-1}Lx)\Big\}dt\\
&\quad + \tfrac{1}{2}E^s[x'(T)(H - P(T))x(T)] + \tfrac{1}{2}y'P(s)y,
\end{aligned} \tag{3.4}$$

where $L = B'P + D'PC + D'\Lambda$. Now, if (P,Λ) satisfies the Riccati equation (see (3.2)), i.e.,

$$\Gamma = -(PA + A'P + C'PC + \Lambda C + C'\Lambda + Q - L'K^{-1}L), \tag{3.5}$$

with $K = R + D'PD > 0$ and $P(T) = H$, then

$$\begin{aligned}
&J(s,y;u(\cdot))\\
&= \tfrac{1}{2}E^s\int_s^T (u + K^{-1}Lx)'K(u + K^{-1}Lx)dt + \tfrac{1}{2}y'P(s)y\\
&\geq \tfrac{1}{2}y'P(s)y > -\infty,\ P-a.s.
\end{aligned} \tag{3.6}$$

Therefore, the stochastic LQR problem is well-posed. □

Remark 3.1. We see from the above proof that if the Riccati equation (3.1) admits a solution (P,Λ), then the optimal feedback control would be

$$\begin{aligned}
u(t) &= -K^{-1}(t)L(t)x(t)\\
&= -\Big(R(t) + D'(t)P(t)D(t)\Big)^{-1}\Big(B'(t)P(t) + D'(t)P(t)C(t) + D'(t)\Lambda(t)\Big)x(t)
\end{aligned} \tag{3.7}$$

if the corresponding solutions to the system equation exist. In this case, the value function is $V(t,x) = \frac{1}{2}x'P(t)x$. Note that under (3.7), the system (2.1) reduces to

$$\begin{cases} dx(t) = [A(t) - B(t)K^{-1}(t)L(t)]x(t)dt + [C(t) - D(t)K^{-1}(t)L(t)]x(t)dW(t),\\ x(s) = y. \end{cases} \tag{3.8}$$

This is a linear stochastic differential equation. The existence and uniqueness of its solutions depend on some moment estimates of the coefficients $A - BK^{-1}L$ and $C - DK^{-1}L$ and, in particular, K^{-1}. While existence and uniqueness results are hard to obtain in general, they are indeed available in some special cases; see Theorem 3.2 below.

We see that the solutions to the Riccati equation are pairs (P,Λ). As mentioned, the presence of Λ is necessary when the coefficients A, B, C, D, Q, R, H of the equation are random so as to get an $\mathcal{F}_t$-adapted solution. However, if all the coefficients are deterministic, then we may have a *deterministic* Riccati equation as follows:

$$\begin{cases} \dot{P} + PA + A'P + C'PC - (PB + C'PD)(R + D'PD)^{-1}(B'P + D'PC) + Q = 0,\\ P(T) = H,\\ K = R + D'PD > 0. \end{cases} \tag{3.9}$$

THEOREM 3.2. *Assume that all the coefficients A, B, C, D, Q, R, H are deterministic. Then the statement of Theorem* 3.1 *remains valid with the Riccati equation* (3.1) *replaced by* (3.9). *Moreover, the following feedback control*

$$u(t) = -\Big(R(t) + D'(t)P(t)D(t)\Big)^{-1}\Big(B'(t)P(t) + D'(t)P(t)C(t)\Big)x(t), \tag{3.10}$$

which results in a unique solution of the state equation (3.8), *is optimal.*

Proof. The first assertion comes directly from Theorem 3.1 since, if there exists a solution to (3.9), then there exists a solution to (3.1) with $\Lambda = 0$. As for the second assertion, note that by the conventional Riccati equation theory we have $P \in C(0,T;S^n_+)$. Moreover, $K^{-1} \in C(0,T;S^n_+)$. Hence, all the coefficients in (3.8) are uniformly bounded, which implies the existence and uniqueness of its solutions. This completes the proof. □

By virtue of the newly introduced Riccati equation (3.1) or (3.9), one may now understand why the control weight cost R may be allowed to be indefinite. Indeed, even when $R < 0$, the presence of the term $D'PD$ may offer compensation if it is positive enough so that $R + D'PD > 0$. This is possible, as we will see from the examples below. Note that $D \neq 0$ (namely, the diffusion term depends on the control) is vital for such phenomena to occur, which intuitively means that the controller must be able to control the variance of the uncertainty in dynamics. If $D = 0$, then R must be positive definite in order for the problem to be sensible.

Example 3.1. Consider the example (1.2) presented in the introduction. The corresponding Riccati equation (3.9) is

$$\dot{P}(t) = -1, \qquad P(1) = 1.$$

Hence, $P(t) = 2 - t$. The problem is then well-posed if and only if $r(t) + 2 - t > 0$, which is consistent with the conclusion obtained from the direct computation.

Example 3.2. Consider the following:

$$\begin{array}{ll} \text{Minimize} & J = E^s\Big\{\int_0^1 \frac{1}{2}ru^2(t)dt + \frac{1}{2}x^2(1)\Big\} \\ \text{Subject to} & \begin{cases} dx(t) = u(t)dt + u(t)dW(t), \\ x(s) = y. \end{cases} \end{array} \tag{3.11}$$

Here r is a given (deterministic) constant. We are going to show that the problem is well-posed if

$$-1 \le r < 0, \qquad \ln(-r) + 2 + r < 0 \text{ (or } -0.1586 < r < 0 \text{ approximately)}. \tag{3.12}$$

To this end, we first see that the corresponding Riccati equation (3.9) reads

$$\begin{cases} \dot{P}(t) = \frac{P^2(t)}{r+P(t)}, \\ P(1) = 1, \\ r + P(t) > 0. \end{cases} \tag{3.13}$$

It should be noted that if $r < -1$, then the above equation is not solvable. Indeed, in this case, $P(t) > -r > 1$, so the terminal condition of (3.13) is violated.

The equation (3.13) is equivalent to

$$\begin{cases} \ln P(t) - \frac{r}{P(t)} = t - 1 - r, \\ r + P(t) > 0. \end{cases} \tag{3.14}$$

Define $f^t(p) = \ln p - \frac{r}{p} - t + 1 + r$, $p \in (0, +\infty)$. Since

$$\begin{aligned} &f^t(-r) = \ln(-r) + 2 - t + r < 0, \\ &f^t(1) = 1 - t > 0, \quad \forall t \in [0,1), \end{aligned} \tag{3.15}$$

we conclude that there is $P(t) \in (-r, 1)$ (i.e., $r + P(t) > 0$) such that $f^t(P(t)) = 0$ for $t \in [0,1)$. Moreover,

$$\dot{f}^t(p) = \frac{p+r}{p^2} \begin{cases} < 0, & \text{if } p < -r, \\ > 0, & \text{if } p > -r, \\ = 0, & \text{if } p = -r. \end{cases} \tag{3.16}$$

Thus the $P(t)$ satisfying $f^t(P(t)) = 0$ and $r + P(t) > 0$ is unique. Finally, $f^1(1) = 0$ implies $P(1) = 1$. Hence, (3.14) or (3.13) does admit a solution. In this case, the optimal feedback control is (noting (3.7))

$$u(t) = -\frac{P(t)}{r + P(t)} x(t).$$

4. Existence and uniqueness: A special case. We conclude from the previous section that the study of the stochastic LQR problem may be reduced to that of the Riccati equation (3.1). However, (3.1) is so complicated that we are not able to prove the existence and uniqueness of its solutions at this moment. We can only prove the existence and uniqueness for a special case, where $C(t) \equiv 0$ and all the other coefficients A, B, D, Q, R, H are deterministic functions, which is the objective of this section.

First of all, when $C(t) \equiv 0$ and all the other coefficients are deterministic, the Riccati equation (3.9) is further reduced to

$$\begin{cases} \dot{P} + PA + A'P - PB(R + D'PD)^{-1}B'P + Q = 0, \\ P(T) = H, \\ K = R + D'PD > 0. \end{cases} \tag{4.1}$$

THEOREM 4.1. *If P is a solution to the Riccati equation* (4.1), *then $P \in C(0,T;S_+^n)$ and it is the only solution.*

Proof. That $P \in C(0,T;S_+^n)$ is clear from the conventional Riccati equation theory. Now suppose $\tilde{P}$ is another solution of (4.1). Set $\hat{P} = P - \tilde{P}$. Then $\hat{P}$ satisfies

$$\begin{cases} \dot{\hat{P}} + \hat{P}A + A'\hat{P} - \hat{P}B\tilde{K}^{-1}B'\tilde{P} + PBK^{-1}D'\hat{P}D\tilde{K}^{-1}B'\tilde{P} - PBK^{-1}B'\hat{P} = 0, \\ \hat{P}(T) = 0, \end{cases}$$

where $K = R + D'PD > 0$ and $\tilde{K} = R + D'\tilde{P}D > 0$. Since $|K^{-1}(t)|$ and $|\tilde{K}^{-1}(t)|$ are uniformly bounded due to their continuity, we can apply Gronwall's inequality to get $\hat{P}(t) \equiv 0$. This proves the uniqueness. □

Now let us turn to the existence. We consider the conventional Riccati equation

$$\begin{cases} \dot{P} + PA + A'P - PBK^{-1}B'P + Q = 0, \\ P(T) = H. \end{cases} \tag{4.2}$$

Denote $\mathcal{K} = \{K \in L^\infty(0,T;\hat{S}^m_+) \mid K^{-1} \in L^\infty(0,T;\hat{S}^m_+)\}$. It can be checked that $C(0,T;\hat{S}^m_+) \subset \mathcal{K}$. Fix $Q \in C(0,T;S^n_+)$. For each $K \in \mathcal{K}$, we know from the classical Riccati theory that (4.2) admits a unique solution $P \in C(0,T;S^n_+)$. Thus we can define a mapping $\Psi : \mathcal{K} \to C(0,T;S^n)$ as $P = \Psi(K)$.

LEMMA 4.2. *The operator Ψ is monotonely increasing and continuous.*

Proof. Let $K, \tilde{K} \in \mathcal{K}, P = \Psi(K)$ and $\tilde{P} = \Psi(\tilde{K})$. Denote $\hat{P} = P - \tilde{P}$. Then $\hat{P}$ satisfies

$$\begin{cases} \dot{\hat{P}} + \hat{P}\hat{A} + \hat{A}'\hat{P} - \hat{P}B\tilde{K}^{-1}B'\hat{P} + \hat{Q} = 0, \\ \hat{P}(T) = 0, \end{cases} \tag{4.3}$$

with $\hat{A} = A - B\tilde{K}^{-1}B'\tilde{P}$ and $\hat{Q} = PB(\tilde{K}^{-1} - K^{-1})B'P$. Now if $K \geq \tilde{K} (> 0)$, then $\tilde{K}^{-1} \geq K^{-1} > 0$ which results in $\hat{Q} \geq 0$. Hence, the solution of the conventional Riccati equation (4.3) is nonnegative definite, namely, $\hat{P} \geq 0$. This proves the monotonicity. On the other hand, if $\tilde{K} \to K$, then by (4.3) and Gronwall's inequality it is easily seen that $P - \tilde{P} = \hat{P} \to 0$. This yields the desired continuity, and the proof is complete. ∎

LEMMA 4.3. *The Riccati equation* (4.1) *admits a solution if and only if there is a $K \in C(0,T;\hat{S}^m_+)$ such that*

$$R = K - D'\Psi(K)D. \tag{4.4}$$

Proof. The proof is obvious. ∎

LEMMA 4.4. *The Riccati equation* (4.1) *admits a solution if and only if there exist $K^+, K^- \in C(0,T;\hat{S}^m_+)$ such that*

$$K^+ \geq R + D'\Psi(K^+)D \geq R + D'\Psi(K^-)D \geq K^-. \tag{4.5}$$

Proof. Necessity. If (4.1) admits a solution P, then (4.5) trivially holds by letting $K^+ = K^- = R + D'PD$.

Sufficiency. Let K^+, K^- be given with (4.5) satisfied. Define sequences $\{K^+_i\}^\infty_0$, $\{K^-_i\}^\infty_0$, $\{P^+_i\}^\infty_0$, and $\{P^-_i\}^\infty_0$ iteratively as follows:

$$\begin{cases} K^+_0 = K^+,\ K^-_0 = K^-,\ P^+_0 = \Psi(K^+_0),\ P^-_0 = \Psi(K^-_0); \\ K^+_{i+1} = R + D'P^+_iD,\ K^-_{i+1} = R + D'P^-_iD, \\ P^+_{i+1} = \Psi(K^+_{i+1}),\ P^-_{i+1} = \Psi(K^-_{i+1}),\ \ i = 0,1,2,\cdots \end{cases} \tag{4.6}$$

By (4.5), we have

$$K^+_0 \geq K^+_1 \geq K^-_1 \geq K^-_0 > 0.$$

Since Ψ is increasing (Lemma 4.2), we also have

$$P^+_0 \geq P^+_1 \geq P^-_1 \geq P^-_0 \geq 0.$$

By induction, we obtain

$$\begin{cases} P^+_0 \geq P^+_i \geq P^+_{i+1} \geq P^-_{i+1} \geq P^-_i \geq P^-_0 \geq 0, \\ K^+_0 \geq K^+_i \geq K^+_{i+1} \geq K^-_{i+1} \geq K^-_i \geq K^-_0 > 0, \end{cases} \tag{4.7}$$

for $i = 1,2,\cdots$.

From (4.10), we see that $K_i^+ \in \mathcal{K}$ and there exist $K^+ \in \mathcal{K}$ and P^+ such that

$$\lim_{i\to\infty} K_i^+ = K^+, \quad \lim_{i\to\infty} P_i^+ = P^+. \tag{4.8}$$

By Lemma 4.2, we have

$$P^+ = \lim_{i\to\infty} P_i^+ = \lim_{i\to\infty} \Psi(K_i^+) = \Psi(\lim_{i\to\infty} K_i^+) = \Psi(K^+). \tag{4.9}$$

From (4.9) we see $P^+ \in C(0,T;S^n)$, since it is a solution of Riccati equation (4.2) corresponding to $K = K^+$. This in turn yields $K^+ = R + D'P^+D \in C(0,T;\hat{S}_+^m)$. By Lemma 4.3, we conclude that P^+ is a solution to (4.1). □

Remark 4.1. By the same argument, the following limits exist

$$P^- = \lim_{i\to\infty} P_i^-, \qquad K^- = \lim_{i\to\infty} K_i^-$$

and P^- is also a solution of (4.1). In view of the uniqueness of the solutions, $P^- = P^+$.

Remark 4.2. If (4.5) holds, then we have the following algorithms to compute the solution of the stochastic Riccati equation:

$$K_0 = K^+, \quad P_i = \Psi(K_i), \quad K_{i+1} = R + D'P_iD, \quad i = 0,1,2,\cdots, \tag{4.10}$$

or

$$K_0 = K^-, \quad P_i = \Psi(K_i), \quad K_{i+1} = R + D'P_iD, \quad i = 0,1,2,\cdots. \tag{4.11}$$

The following proposition gives an estimate for the convergence speed of the algorithms (4.10) and (4.11).

PROPOSITION 4.5. *Suppose* (4.5) *holds. Let the sequence* $\{P_i\} \subset C(0,T;S^n)$ *be constructed by either algorithm* (4.10) *or* (4.11) *and let* P *be the solution to the Riccati equation* (4.1). *Then*

$$|P_i(t) - P(t)| \le C\sum_{j=i}^{\infty} \frac{c^{j-2}}{(j-2)!}(T-t)^{j-2}, \qquad i = 2,3,\cdots, \tag{4.12}$$

where C *is a constant that depends only on the coefficients of* (4.1).

Proof. We only prove the estimate (4.12) for the algorithm (4.10). The other one is the same. By definition,

$$P_i(t) = H - \int_t^T [P_iA + A'P_i - P_iBK_i^{-1}B'P_i + Q](s)ds.$$

Set $\hat{P}_i = P_{i+1} - P_i$. Then

$$\begin{aligned}\hat{P}_i(t) = &-\int_t^T [\hat{P}_i(A - BK_{i+1}^{-1}B'P_{i+1}) + (A - BK_i^{-1}B'P_i)'\hat{P}_i \\ &+P_iBK_{i+1}^{-1}D'\hat{P}_{i-1}DK_i^{-1}B'P_{i+1}](s)ds.\end{aligned} \tag{4.13}$$

In view of (4.7), the sequences $\{|P_i|\}, \{|K_i|\}$, and $\{|K_i^{-1}|\}$ are bounded. Hence,

$$|\hat{P}_i(t)| \le C\int_t^T [|\hat{P}_{i-1}(s)| + |\hat{P}_i(s)|]ds. \tag{4.14}$$

Denote $v_i(t) = \int_t^T |\hat{P}_i(s)|ds$. Then (4.14) reads

$$\dot{v}_i(t) + Cv_i(t) + Cv_{i-1}(t) \geq 0,$$

which implies

$$v_i(t) \leq Ce^{CT} \int_t^T v_{i-1}(s)ds \equiv c \int_t^T v_{i-1}(s)ds.$$

By induction, we deduce that

$$v_{i+1}(t) \leq \frac{c^i}{i!}(T-t)^i v_1(0).$$

It then follows from (4.14) that

$$|\hat{P}_i(t)| \leq C\Big\{\frac{c^{i-1}}{(i-1)!}(T-t)^{i-1} + \frac{c^{i-2}}{(i-2)!}(T-t)^{i-2}\Big\}v_1(0). \tag{4.15}$$

This easily yields (4.12). □

Let us examine the condition (4.5) again. Indeed, the existence of K^+ is guaranteed. To see this, put $K^+ = zI$ with $z > 0$. Since $\Psi(K)$ is bounded uniformly for all $K \in C(0,T;\hat{S}_+^m)$, we see that

$$K^+ \geq R + D'\Psi(K^+)D$$

for z sufficiently large. Hence, we have the following result.

THEOREM 4.6. *The Riccati equation* (4.1) *admits a solution if and only if there exist* $K \in C(0,T;\hat{S}_+^m)$ *such that*

$$R + D'\Psi(K)D \geq K. \tag{4.16}$$

This theorem says that while R can be indefinite (or negative definite) for the Riccati equation to have solutions, it cannot be *too* negative. Indeed, in any case, R cannot be smaller than $\inf_{K\in C(0,T;\hat{S}_+^m)} \big[K - D'\Psi(K)D\big]$!

In particular, the condition (4.16) is satisfied automatically if R is positive definite, i.e., $R \in C(0,T;\hat{S}_+^m)$, so we have the following corollary.

COROLLARY 4.7. *If* $R \in C(0,T;\hat{S}_+^m)$, *then the stochastic Riccati equation admits a unique solution* $P \in C(0,T;S_+^n)$.

Theorem 4.6 is very useful in estimating intervals where the Riccati equation (4.1) is solvable without directly dealing with (4.1) itself. Let us use an example to demonstrate.

Example 4.1. Consider the stochastic LQR problem in Example 3.2, where $-1 < r < 0$. By Theorem 4.6, the Riccati equation (3.13) admits a solution on some interval $[\tau,1]$ $(0 \leq \tau \leq 1)$ if and only if there is a positive continuous function $K(\cdot)$ such that

$$r + \Psi(K)(t) \geq K(t), \quad \forall t \in [\tau,1], \tag{4.17}$$

where $\Psi(K)$ is the solution of the conventional Riccati equation

$$\dot{x}(t) = \frac{x^2(t)}{K(t)}, \qquad x(1) = 1.$$

So $\Psi(K)(t) = (1 + \int_t^1 \frac{1}{K(s)} ds)^{-1}$. Setting $f(t) = \frac{1}{K(1-t)}$, one can rewrite (4.17) as

$$1 + \int_0^{1-t} f(s)ds \leq \frac{f(1-t)}{1 - rf(1-t)}, \ \ \forall t \in [\tau, 1],$$

or

$$\int_0^t f(s)ds \leq \frac{(1+r)f(t) - 1}{1 - rf(t)}, \ \ \forall t \in [0, 1-\tau]. \tag{4.18}$$

Since $f(t) > 0$, it is then necessary that $f(t) > \frac{1}{1+r}$ for $t \in [0, 1-\tau]$. Putting

$$f(t) = \frac{1}{1+r} + f_1(t) \ \text{ with } f_1(t) > 0, \ \forall t \in [0, 1-\tau],$$

and substituting into (4.18), we obtain

$$\int_0^t f_1(s)ds \leq \frac{(1+r)^2 f_1(t)}{1 - r(1+r)f_1(t)} - \frac{t}{1+r}, \ \ \forall t \in [0, 1-\tau]. \tag{4.19}$$

Hence, f_1 must satisfy

$$(1+r)[(1+r)^2 + rt]f_1(t) > t, \ \ \forall t \in [0, 1-\tau]. \tag{4.20}$$

It follows that

$$(1+r)^2 + rt > 0, \ \ \forall t \in [0, 1-\tau]. \tag{4.21}$$

The above inequality gives an estimate on the interval where the Riccati equation (3.13) admits a solution, namely,

$$1 - \tau < \left(\frac{1}{\sqrt{-r}} - \sqrt{-r} \right)^2.$$

In particular, in order for (3.13) to be solvable on the whole interval [0,1], it must hold that

$$1 < \left(\frac{1}{\sqrt{-r}} - \sqrt{-r} \right)^2, \ \text{or } r > \frac{\sqrt{5} - 3}{2}.$$

Therefore, while r is allowed to be negative, it cannot be *too* negative.

5. The gap between stochastic maximum principle and LQR problem. This section is going to reveal a gap between Peng's stochastic maximum principle [12, 15], which is regarded as the best result so far in terms of necessary conditions for stochastic optimality, and the solvability of the stochastic LQR problem.

For the reader's convenience, let us state here Peng's maximum principle for general nonlinear systems, and then specialize to the LQR model.

Given $(s, y) \in [0, T) \times R^n$, we are to

$$\text{Minimize } J(s, y; u(\cdot)) = E\left[\int_s^T l(t, x(t), u(t))dt + h(x(1)) \right], \tag{5.1}$$

$$\text{Subject to } \begin{cases} dx(t) = f(t, x(t), u(t))dt + \sigma(t, x(t), u(t))dW(t), \\ x(s) = y. \end{cases} \tag{5.2}$$

The set of admissible controls U_{ad} is defined similarly with U being a given closed set in R^m. Peng's maximum principle asserts that if $(x^*(\cdot), u^*(\cdot))$ is optimal, then it must satisfy

$$\begin{aligned} &\tfrac{1}{2}\mathrm{tr}\Big\{[\sigma(t, x^*(t), u) - \sigma(t, x^*(t), u^*(t))]' P_0(t)[\sigma(t, x^*(t), u) - \sigma(t, x^*(t), u^*(t))]\Big\} \\ &+p'(t)[f(t, x^*(t), u) - f(t, x^*(t), u^*(t))] + q'(t)[\sigma(t, x^*(t), u) - \sigma(t, x^*(t), u^*(t))] \\ &+l(t, x^*(t), u) - l(t, x^*(t), u^*(t)) \geq 0, \ \forall u \in U, \ P-a.s., \ a.e.\ t \in [s, T], \end{aligned} \tag{5.3}$$

where $(p(\cdot), q(\cdot))$ is the $\mathcal{F}_t$-adapted solution to the *first-order* adjoint equation

$$\begin{cases} dp(t) = -[f_x^*(t)' p(t) + \sigma_x^*(t)' q(t) + l_x^*(t)]dt + q(t)dB(t), \\ p(T) = h_x(x^*(T)), \end{cases} \tag{5.4}$$

and $(P_0(t), \Lambda_0(t))$ is the $\mathcal{F}_t$-adapted solution to the *second-order* adjoint equation

$$\begin{cases} dP_0(t) = -[f_x^*(t)' P_0(t) + P_0(t) f_x^*(t) + \sigma_x^*(t)' P_0(t) \sigma_x^*(t) \\ \qquad\quad +\sigma_x^*(t)' \Lambda_0(t) + \Lambda_0(t)\sigma_x^*(t) + \Phi(t)]dt + \Lambda_0(t)dW(t), \\ P_0(T) = h_{xx}(x^*(T)), \end{cases} \tag{5.5}$$

with $\Phi(t) = l_{xx}^*(t) + \sum_{i=1}^n \{p^i(t) f_{xx}^{i*}(t) + q^i(t)\sigma_{xx}^{i*}(t)\}$. In the above, we used the notation $f^*(t) = f(t, x^*(t), u^*(t))$, etc. for simplicity.

Define the generalized Hamiltonian

$$G(t, x, u, p, S) = -\frac{1}{2}\mathrm{tr}\Big(\sigma(t, x, u)' S \sigma(t, x, u)\Big) - p' f(t, x, u) - l(t, x, u), \tag{5.6}$$

for $(t, x, u, p, S) \in [0, T] \times R^n \times R^m \times R^n \times S^n$, and an $\mathcal{H}$-function *corresponding to* the optimal pair $(x^*(\cdot), u^*(\cdot))$ as follows:

$$\mathcal{H}(t, x, u) = G(t, x, u, p(t), P_0(t)) - \sigma(t, x, u)'[q(t) - P_0(t)\sigma(t, x^*(t), u^*(t))], \tag{5.7}$$

for $(t, x, u) \in [s, T] \times R^n \times R^m$, where $p(t), q(t)$, and $P_0(t)$ are determined by adjoint equations (5.4) and (5.5). Then (5.3) is equivalent to the following maximum condition:

$$\mathcal{H}(t, x^*(t), u^*(t)) = \max_{u \in U} \mathcal{H}(t, x^*(t), u), \ \ P-a.s.; \ \ a.e.\ t \in [s, T]. \tag{5.8}$$

In stochastic optimal control theory, the system consisting of the state equation (5.2), adjoint equations (5.4), (5.5), and the maximum condition (5.8) is called a *Hamiltonian system* [14].

Applying the above maximum principle to the LQR model (2.1)–(2.3), we obtain the following result.

THEOREM 5.1. *Let $(x^*(\cdot), u^*(\cdot))$ be an optimal pair for $C_{s,y}$. Then there exist $\mathcal{F}_t$-adapted (p, q) and (P_0, Λ_0) satisfying*

$$\begin{cases} dp(t) = -(A'(t)p(t) + Q(t)x^*(t) + C'(t)q(t))dt + q(t)dW(t), \\ p(T) = Hx^*(T) \end{cases} \tag{5.9}$$

and

(5.10)
$$\begin{cases} dP_0(t) = -(A'(t)P_0(t) + P_0(t)A(t) + C'(t)P_0(t)C(t) + \Lambda_0(t)C(t) + C'(t)\Lambda_0(t) + Q(t))dt \\ \qquad\quad +\Lambda_0(t)dW(t), \\ P_0(T) = H \end{cases}$$

such that

$$R(t)u^*(t) + B'(t)p(t) + D'(t)q(t) = 0, \tag{5.11}$$

$$R(t) + D'(t)P_0(t)D(t) \geq 0, \quad P-a.s., \quad a.e.\ t \in [s,T]. \tag{5.12}$$

Proof. First of all, it is clear that the first- and second-order adjoint equations in the present LQR case are (5.9) and (5.10), respectively. Moreover, $\mathcal{H}(t, x^*(t), u)$ is a quadratic function in u, which attains its maximum at $u^*(t)$ by the maximum condition (5.8). Therefore, it is easily verified that (5.11) and (5.12) are nothing but the first- and second-order conditions, respectively, of the maximum point $u^*(t)$ for the quadratic function $\mathcal{H}(t, x^*(t), \cdot)$. □

We note that the second-order adjoint equation (together with (5.12)) is similar in form to the stochastic Riccati equation (3.1), except that the latter has an additional nonlinear term in its drift coefficient. The relationship between $P_0(t)$ and $P(t)$ is stated in the following proposition.

PROPOSITION 5.2. *If the LQR problem* (2.1)–(2.3) *is well-posed, then*

$$P_0(t) \geq P(t), \ P-a.s., \ \forall t \in [0,T]. \tag{5.13}$$

Proof. Let $(x^*(\cdot), u^*(\cdot))$ be an optimal pair for the problem $C_{0,y}$. Then by [15, Theorem 3.1],

$$P_0(t) \geq V_{xx}(t, x^*(t)), \ P-a.s., \ \forall t \in [0,T], \tag{5.14}$$

provided $V \in C^{1,2}([0,T] \times R^n)$. Now that the LQR problem is well-posed, $V(s,y) = \frac{1}{2}x'P(t)x$, which is smooth enough with $V_{xx}(t, x^*(t)) = P(t)$. The desired result follows. □

The inequality in (5.14) (and, therefore, (5.13) for the LQR problem) could be strict. An example is given in [15, p. 159], where the terminal cost is nonlinear. Another example is the LQR problem studied in Example 3.2. For that problem, it has been shown that $P(t) < 1$ for $t \in [0,1)$. However, The solution to (5.10) is $P_0(t) \equiv 1$.

For deterministic LQR problems, it is well known that the Hamiltonian system completely characterizes the optimal control, namely, a solution of the Hamiltonian system is an optimal pair of the LQR problem and vice versa. In this sense, the maximum principle and the well-posedness of the LQR problem are actually equivalent to each other. It is then natural to expect that in the stochastic case, the solvability of the Hamiltonian system (5.9)–(5.12) would yield the well-posedness of the LQR problem. Unfortunately, it is not true. Indeed, due to Proposition 5.2 and the fact that the inequality therein could be strict, the condition (5.12) is weaker than the inequality involved in the Riccati equation (3.1). Now let us look at an example to make it precise.

Example 5.1. Consider the following

$$\begin{array}{ll} \text{Minimize} & J = E^s\Big\{\int_s^1 -\frac{1}{2}u^2(t)dt + \frac{1}{2}x^2(1)\Big\} \\ \text{Subject to} & \begin{cases} dx(t) = (C(t)x(t) + D(t)u(t))dW(t), \\ x(s) = y, \end{cases} \end{array} \tag{5.15}$$

where C and D are bounded deterministic functions satisfying

$$\exp\left[-\int_0^1 C^2(r)dr\right] < 1, \qquad D(t) = \exp\left[-\frac{1}{2}\int_t^1 C^2(r)dr\right]. \tag{5.16}$$

The system (5.2), (5.9)–(5.12) in this case is

$$\begin{cases} dx^*(t) = (C(t)x^*(t) + D(t)u^*(t))dW(t), & x(s) = y, \\ dp(t) = -C(t)q(t)dt + q(t)dW(t), & p(1) = x^*(1), \\ dP_0(t) = -C^2(t)P_0(t)dt, & P_0(1) = 1, \\ -u^*(t) + D(t)q(t) = 0, \\ -1 + D^2(t)P_0(t) \geq 0. \end{cases} \tag{5.17}$$

Since $P_0(t) = \exp[\int_t^1 C^2(r)dr]$, the last inequality in the above system is satisfied by virtue of (5.16). Hence (5.17) reduces to

$$\begin{cases} dx^*(t) = (C(t)x^*(t) + D^2(t)q(t))dW(t), & x^*(s) = y, \\ dp(t) = -C(t)q(t)dt + q(t)dW(t), & p(1) = x^*(1). \end{cases} \tag{5.18}$$

This is a forward-backward stochastic differential equation, and it can be shown by using a standard contraction mapping theorem that it admits a unique solution $(x^*(\cdot), p(\cdot), q(\cdot))$ if $1 - s > 0$ is small enough (cf. Ma and Yong [10, Theorem 1.5.1]). Now we are going to show that the original LQR problem is *not* well-posed. Fix s and $y \neq 0$. Using the Ito formula, we have

$$dx^2(t) = 2x(t)(C(t)x(t) + D(t)u(t))dW(t) + (C(t)x(t) + D(t)u(t))^2dt. \tag{5.19}$$

Thus

$$J(s, y; u(\cdot)) = \frac{1}{2}E^s\int_s^1 [-u^2(t) + (C(t)x(t) + D(t)u(t))^2]dt + \frac{1}{2}y^2. \tag{5.20}$$

By (5.16), for a sufficiently small $\varepsilon_0 > 0$, one can find a $\delta_0 > 0$ such that

$$1 - D^2(t) \geq \varepsilon_0, \ \ \forall t \in [s, 1 - \delta_0]. \tag{5.21}$$

For an integer $k > 0$, define a feedback control

$$u_k(t) = \begin{cases} kC(t)x(t), & s \leq t < 1 - \delta_0, \\ -D^{-1}(t)C(t)x(t), & 1 - \delta_0 \leq t \leq 1. \end{cases} \tag{5.22}$$

It follows from (5.20) that

$$\begin{aligned} J(s, y; u_k(\cdot)) &= \frac{1}{2}E^s\int_s^{1-\delta_0} [-k^2 + (1 + kD(t))^2]|C(t)x(t)|^2dt - \frac{1}{2}E^s\int_{1-\delta_0}^1 u_k^2dt + \frac{1}{2}y^2 \\ &= -\frac{1}{2}E^s\int_s^{1-\delta_0} \left[(1 - D^2(t))(k - \frac{D(t)}{1 - D^2(t)})^2 - \frac{1}{1 - D^2(t)}\right]|C(t)x(t)|^2dt \\ &\quad -\frac{1}{2}E^s\int_{1-\delta_0}^1 u_k^2(t)dt + \frac{1}{2}y^2. \end{aligned}$$

Noting that

$$E^s x^2(t) = \exp \int_s^t (1 + D(t)k)^2 C^2(t) dt \cdot y^2 > 0,$$

we conclude

$$J(s, y; u_k(\cdot)) \to -\infty$$

as $k \to +\infty$. So the LQR problem is not well-posed.

6. Concluding remarks. In this paper, we have studied a general class of stochastic linear quadratic regulators with the diffusion coefficients dependent on the control variables. It is observed that the optimal control problem may be well-posed even when the control weight costs are indefinite by virtue of the uncertainty involved. A new stochastic Riccati equation is introduced, and the existence of solutions to it is shown to be sufficient for the well-posedness of the LQR problem. It is also found that the stochastic maximum principle cannot fully characterize the optimality. These distinctive features reveal some fundamental differences between the deterministic and stochastic situations.

Many interesting and challenging problems remain open. The first problem is the existence and uniqueness of solutions to the stochastic Riccati equation in a general situation. The resolution of this problem might have to involve some delicate analysis on the nonlinear backward SDEs. Second, how do we numerically solve the stochastic Riccati equation? For the special case (4.1), this paper gives an algorithm (Remark 4.2) along with its convergence speed (Proposition 4.5). Note that the algorithm involves computing the operator Ψ (i.e., the solution to the conventional Riccati equation), and numerical schemes have been widely available for solving Ψ. However, numerical solutions to the general Riccati equation (3.1) remain an interesting but perhaps difficult problem; to the best of our knowledge there has been few works on numerically solving nonlinear backward stochastic differential equations. Last but not least, what is a "better" stochastic maximum principle that can fully solve the LQR problem as in the deterministic case? These topics will be studied in forthcoming papers.

Acknowledgments. The authors wish to thank S. Peng and J. Yong for inspiring discussions. Thanks are also due to the referees for their constructive comments that led to an improved version of the paper.

ON QUADRATIC DIFFERENTIAL FORMS*

J. C. WILLEMS† AND H. L. TRENTELMAN†

Abstract. This paper develops a theory around the notion of quadratic differential forms in the context of linear differential systems. In many applications, we need to not only understand the behavior of the system variables but also the behavior of certain functionals of these variables. The obvious cases where such functionals are important are in Lyapunov theory and in LQ and H_∞ optimal control. With some exceptions, these theories have almost invariably concentrated on first order models and state representations. In this paper, we develop a theory for linear time-invariant differential systems and quadratic functionals. We argue that in the context of systems described by *one-variable* polynomial matrices, the appropriate tool to express quadratic functionals of the system variables are *two-variable* polynomial matrices. The main achievement of this paper is a description of the interaction of one- and two-variable polynomial matrices for the analysis of functionals and for the application of higher order Lyapunov functionals.

Key words. quadratic differential forms, linear systems, polynomial matrices, two-variable polynomial matrices, Lyapunov theory, positivity, spectral factorization, dissipativeness, storage functions

1. Introduction.

In the theory of models for dynamical systems, it has been customary to consider both external input/output as well as state space models. Also, there is a well developed theory for passing from one type of model to another. Thus, there are efficient algorithms for passing from a convolution, to a transfer function, to a state model, and back. Even for stochastic and nonlinear systems, there are methods for associating a first order state representation to a high order model.

However, in addition to understanding the interaction between system variables, we need in many applications to understand also the behavior of certain functionals of these variables. The obvious cases where such functionals are crucial are in Lyapunov theory, in the theory of dissipative systems, and in optimal control. In these contexts it is remarkable to observe that the theory of dynamics has almost invariably concentrated on first order models and state representations. Thus, in studying system stability using Lyapunov methods, we are constrained to consider state representations, and optimal control problems invariably assume that the cost is an integral of a function of the state and the input. The question thus occurs of whether it is possible to develop an external theory—for example, Lyapunov theory—for systems and functionals so that analysis of stability and passivity, for instance, could proceed on the basis of a *first principles* model instead of first having to find a state representation. In this paper, we consider models that are not in state form (even though some proofs use state representations). Our models are externally specified yet they are not completely general *first principles* models in that we concentrate on models in kernel or in image representation.

It is the purpose of this paper to develop such a theory. We do not, however, set our aims too high and start with a very well-understood class of systems and functionals: linear time-invariant differential systems and quadratic functionals in the

system variables and their derivatives. We shall see that *one-variable* polynomials are the appropriate tool in which to parametrize the model (see also, among others, [16], [17]) and *two-variable* polynomials are the appropriate tool for parametrizing the functionals. Thus, the paper presents an interesting interplay between one- and two-variable polynomial matrices. Two-variable polynomials turn out to be a very effective tool for analyzing linear systems with quadratic functionals.

This paper consists of a series of general concepts and questions, combined with some specific results concerned with Lyapunov stability and with dissipativity, i.e., with positivity of (integrals of) quadratic differential forms. As such, the paper aims at making a contribution to the development of the very useful and subtle notions of dissipative and lossless (conservative) systems.

In companion papers, these ideas will be applied to LQ and H_∞ problems. The main achievement of this paper—the interaction of one- and two-variable polynomial matrices for the analysis of functionals and application in higher order Lyapunov functions—appears to be new. However, seeds of this have appeared previously in the literature. We mention especially Brockett's early work on *path integrals* [7], [8] in addition to classical work on Routh–Hurwitz-type conditions (see, for example, [6]), and early work by Kalman [13], [14].

2. Review. In order to make this paper reasonably self-contained, we first introduce some notation and some basic facts from the behavioral approach to linear dynamical systems. References in which more details can be found include [31], [32], and [33].

We will deal exclusively with continuous-time real linear time-invariant differential dynamical systems. Thus, the time axis is $\mathbb{R}$, the signal space is $\mathbb{R}^q$ (the number of variables q, of course, depends on the case at hand), and the behavior $\mathfrak{B}$ is the solution set of a system of linear constant coefficient differential equations

$$R\left(\frac{d}{dt}\right)w = 0 \tag{2.1}$$

in the real variables $w_1, w_2, \cdots, w_q$, arranged as the column vector w; R is a real polynomial matrix with, of course, q columns. The number of rows of R depends, as do its coefficients, on the particular dynamical system described by (2.1). Hence we denote this as $R \in \mathbb{R}^{\bullet\times q}[\xi]$, where ξ denotes the indeterminate. Thus, if $R(\xi) = R_0 + R_1\xi + \cdots + R_N\xi^N$, then (2.1) denotes the system of differential equations

$$R_0 w + R_1\frac{dw}{dt} + \cdots + R_N\frac{d^N w}{dt^N} = 0. \tag{2.2}$$

For the behavior, i.e., for the solution set of (2.1) or (2.2), it is usually advisable to consider locally integrable w's as candidate solutions and to interpret the differential equation in the sense of distributions. However, it is our explicit intention to avoid mathematical technicalities as much as possible in this paper. In keeping with this, we assume that the solution set consists of infinitely differentiable functions, even though many of the results are valid without this assumption. Hence the behavior of (2.1) is defined as

$$\mathfrak{B} = \left\{ w \in \mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^q) \mid R\left(\frac{d}{dt}\right)w = 0 \right\}. \tag{2.3}$$

We denote the family of dynamical systems obtained this way by $\mathfrak{L}^q$. Hence elements of $\mathfrak{L}^q$ are dynamical systems $\Sigma = (\mathbb{R}, \mathbb{R}^q, \mathfrak{B})$ with time axis $\mathbb{R}$, signal space $\mathbb{R}^q$, and

behavior $\mathfrak{B}$ described through some $R \in \mathbb{R}^{\bullet\times q}[\xi]$ by (2.3). Note that instead of writing $\Sigma \in \mathfrak{L}^q$ we may as well write $\mathfrak{B} \in \mathfrak{L}^q$, and we prefer to use this notation in this paper.

As explained in the previous paragraphs, each $R \in \mathbb{R}^{\bullet\times q}[\xi]$ unambiguously defines a system $\mathfrak{B} \in \mathfrak{L}^q$. However, there are always many R's defining the same $\mathfrak{B} \in \mathfrak{L}^q$. For example, if U is any unimodular polynomial matrix such that the product UR makes sense, then R and UR induce the same element of $\mathfrak{L}^q$. Also, there are many other ways of specifying a given $\mathfrak{B} \in \mathfrak{L}^q$. Note that (2.1) describes $\mathfrak{B}$ as $\mathfrak{B} = \ker(R(\frac{d}{dt}))$ with $R(\frac{d}{dt})$ viewed as a map from $\mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^q)$ into $\mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^{\mathrm{rowdim}(R)})$. For obvious reasons we hence refer to (2.1) as *a kernel representation* of $\mathfrak{B} \in \mathfrak{L}^q$. We will meet other representations, in particular image, latent variable, input/output, state, and input/state/output representations. These are now briefly introduced.

A system $\mathfrak{B} \in \mathfrak{L}^q$ is said to be *controllable* if for each $w_1, w_2 \in \mathfrak{B}$ there exists a $w \in \mathfrak{B}$ and a $t' \geq 0$ such that $w(t) = w_1(t)$ for $t < 0$ and $w(t) = w_2(t - t')$ for $t \geq t'$. It can be shown that $\mathfrak{B}$ is controllable iff its kernel representation satisfies $\mathrm{rank}(R(\lambda)) = \mathrm{rank}(R)$ for all $\lambda \in \mathbb{C}$. Here, $\mathrm{rank}(R)$ is defined as the rank of R considered as a matrix with elements in the field $\mathbb{R}(\xi)$ of real rational functions. On the other hand, for a given $\lambda \in \mathbb{C}$, $R(\lambda)$ is a matrix with elements in $\mathbb{C}$. Accordingly, $\mathrm{rank}(R(\lambda))$ denotes the rank of the complex matrix $R(\lambda)$. It is easy to see that $\mathrm{rank}(R) = \max_{\lambda\in\mathbb{C}} \mathrm{rank}(R(\lambda))$.

Controllable systems are exactly those that admit image representations. More concretely, $\mathfrak{B} \in \mathfrak{L}^q$ is controllable iff there exists an $M \in \mathbb{R}^{q\times\bullet}[\xi]$ such that $\mathfrak{B} = \mathrm{im}(M(\frac{d}{dt}))$, with $M(\frac{d}{dt})$ viewed as a mapping from $\mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^{\mathrm{coldim}(M)})$ into $\mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^q)$. The resulting representation

$$w = M\left(\frac{d}{dt}\right)\ell \tag{2.4}$$

is called an *image representation* of $\mathfrak{B}$.

An image representation is a special case of what we call a latent variable representation of $\mathfrak{B}$. The system of differential equations

$$R\left(\frac{d}{dt}\right)w = M\left(\frac{d}{dt}\right)\ell \tag{2.5}$$

is said to be a *latent variable representation* of $\mathfrak{B} \in \mathfrak{L}^q$ if

$$\mathfrak{B} = \{w \in \mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^q) \mid \exists\, \ell \in \mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^\bullet) \text{ such that (2.5) holds}\}.$$

A latent variable representation is said to be *observable* if $(R(\frac{d}{dt})w = M(\frac{d}{dt})\ell_1$ and $R(\frac{d}{dt})w = M(\frac{d}{dt})\ell_2)$ implies $(\ell_1 = \ell_2)$. Observability is equivalent to the condition that $M(\lambda)$ is of full column rank for all $\lambda \in \mathbb{C}$. A controllable system, it turns out, always allows an observable image representation.

Of special interest in section 4 will be the observability of the system

$$A\left(\frac{d}{dt}\right)\ell = 0,\ w = C\left(\frac{d}{dt}\right)\ell. \tag{2.6}$$

Of course, the definition of observability applies to (2.6). If this is the case, then we call the pair of polynomial matrices (A, C) with the same number of columns an *observable pair*. Hence (A, C) is an observable pair iff

$$\begin{bmatrix} A(\lambda) \\ C(\lambda) \end{bmatrix} \tag{2.7}$$

is of full column rank for all $\lambda \in \mathbb{C}$.

Systems in $\mathfrak{L}^q$ admit many other useful representations. We already encountered kernel and image representations. Next, we introduce state and input/output representations.

In [22] the notion of state models and their construction has been discussed in detail. Here we limit ourselves to the bare essentials. Let $\mathfrak{B} \in \mathfrak{L}^q$. A latent variable representation (with the latent variable denoted by x this time) of the form (2.5) is said to be a *state model* if, whenever (w_1, x_1) and (w_2, x_2) are $\mathfrak{C}^\infty$-solutions of (2.5) with $x_1(0) = x_2(0)$, then the concatenation $(w_1, x_1) \wedge (w_2, x_2)$ also satisfies (2.5). Since this concatenation need not be in $\mathfrak{C}^\infty$, it need only be a weak solution of (2.5), that is, a solution in the sense of distributions. State models are governed by equations of the form (2.5) with special structure. In fact, (2.5) is a state model iff there exist matrices E, F, and G such that

$$Gw + Fx + E\frac{dx}{dt} = 0 \tag{2.8}$$

is equivalent to (2.5) in the case of state models. Thus (2.8) is called a *state representation* of the behavior $\mathfrak{B}$ if

$$\mathfrak{B} = \{w \in \mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^q) \mid \exists\, x \in \mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^n) \text{ such that (2.8) is satisfied}\}.$$

Here n denotes the dimension of the vector x. The important feature of (2.8) is that it is an (implicit) differential equation containing derivatives of order at most one in x and zero in w. We call a state representation *state minimal* if among all state representations of $\mathfrak{B}$, n is as small as possible. It is possible to prove that (2.8) is state minimal iff it is *state trim* (meaning that for all $a \in \mathbb{R}^n$ there exists $(w, x) \in \mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^{q+n})$ such that $x(0) = a$) and observable. The dimension of the state space of a state minimal representation of $\mathfrak{B} \in \mathfrak{L}^q$ is called the *McMillan degree* of $\mathfrak{B}$. The notion of McMillan degree usually refers to properties of polynomial matrices. Actually, for the case at hand this correspondence holds in terms of full row rank kernel representation matrices R or observable image representation matrices M, but we do not need this correspondence in this paper.

Every system $\mathfrak{B} \in \mathfrak{L}^q$ also admits an input/output representation. By reordering the components of the vector w, if need be, we can decompose w into

$$w = \begin{bmatrix} u \\ y \end{bmatrix} \tag{2.9}$$

with, in terms of R, $\operatorname{rank}(R)$ components for y and $q - \operatorname{rank}(R)$ components for u, such that $\mathfrak{B} \in \mathfrak{L}^q$ admits the special kernel representation

$$P\left(\frac{d}{dt}\right) y = Q\left(\frac{d}{dt}\right) u, \tag{2.10}$$

with P square, $\det P \neq 0$, and $P^{-1}Q$ a matrix of proper rational functions. Thus, in (2.10) u has the usual properties of input and y those of output. Therefore (2.10) is called an *input/output representation*.

Actually, for controllable systems, we can also recover the input/output structure in terms of the image representation. Thus the image representation

$$\begin{bmatrix} u \\ y \end{bmatrix} = \begin{bmatrix} U(\frac{d}{dt}) \\ Y(\frac{d}{dt}) \end{bmatrix} \ell \tag{2.11}$$

is an input/output representation if U is square, $\det U \neq 0$, and YU^{-1} is a matrix of proper rational functions. The number of input components of a system in image representation (2.4) equals $\operatorname{rank}(M)$.

It is possible to combine the above, leading to the familiar input/state/output representation

$$\frac{dx}{dt} = Ax + Bu, \quad y = Cx + Du. \tag{2.12}$$

This representation is state minimal iff it is observable, i.e., iff (A, C) is an observable pair of matrices (not to be confused with an observable pair of polynomial matrices).

Summarizing, given any $w \in \mathfrak{B}$, we may partition the components of w into inputs and outputs. Also, there exists an $X \in \mathbb{R}^{\bullet \times q}[\xi]$ such that

$$x = X\left(\frac{d}{dt}\right) w \tag{2.13}$$

is a (minimal) state map for $\mathfrak{B}$. For a system in image representation (2.4) this leads to a state representation of the form

$$x = X'\left(\frac{d}{dt}\right) \ell. \tag{2.14}$$

The resulting relation between u and y is as in (2.10); that between w and x is as in (2.8); and that between u, y, and x is as in (2.12).

We need a few more details about the state construction for systems in image representation (2.4). Assume that M is of full column rank. Then after permutation of the components of w (i.e., of the rows of M), if need be, M is of the form

$$M = \begin{bmatrix} U \\ Y \end{bmatrix},$$

with U square, $\det(U) \neq 0$, and YU^{-1} a matrix of proper rational functions. The resulting system

$$\begin{bmatrix} u \\ y \end{bmatrix} = \begin{bmatrix} U(\frac{d}{dt}) \\ Y(\frac{d}{dt}) \end{bmatrix} \ell$$

is then an input/output representation. Consider all polynomial row vectors $F \in \mathbb{R}^{1 \times \bullet}[\xi]$ such that FU^{-1} is strictly proper. It can be shown (see [22]) that this set is a vector space. Now

$$x = X\left(\frac{d}{dt}\right) \ell \tag{2.15}$$

is a state map for (2.4) iff the rows of X span this vector space. It is a minimal state map iff the rows of X form a basis for this vector space.

Next, consider associated with (2.4) the variable v governed by

$$v = L\left(\frac{d}{dt}\right) \ell.$$

Then it follows from the above that there exist matrices P and Q such that

$$v = Px + Qu$$

iff LU^{-1} is proper. Moreover, Q is zero iff LU^{-1} is strictly proper, and Q is invertible iff LU^{-1} is biproper.

3. Quadratic differential forms. Differential equations and one-variable polynomial matrices play an essential role in describing the dynamics of systems, as we have seen in section 2 and the references given therein. When studying functions of the dynamical variables, as in Lyapunov theory, studying dissipation and passivity, or specifying performance criteria in optimal control, we invariably encounter quadratic expressions in the variables and their derivatives. As we shall see, two-variable polynomial matrices are the proper mathematical tool to express these quadratic functionals. We aim to illustrate throughout this paper that linear dynamical equations expressed through one-variable polynomial matrices, and quadratic functionals expressed through two-variable polynomial matrices fit as a glove fits a hand.

Let $\mathbb{R}^{q_1\times q_2}[\zeta,\eta]$ denote the set of real polynomial matrices in the (commuting) indeterminates ζ and η. Explicitly, an element $\Phi\in\mathbb{R}^{q_1\times q_2}[\zeta,\eta]$ is thus given by

$$\Phi(\zeta,\eta)=\sum_{k,\ell}\Phi_{k\ell}\zeta^k\eta^\ell. \tag{3.1}$$

The sum in (3.1) ranges over the nonnegative integers and is assumed to be finite, and $\Phi_{k\ell}\in\mathbb{R}^{q_1\times q_2}$. Such a Φ induces a *bilinear differential form* (BLDF), that is, the map

$$L_\Phi:\mathfrak{C}^\infty(\mathbb{R},\mathbb{R}^{q_1})\times\mathfrak{C}^\infty(\mathbb{R},\mathbb{R}^{q_2})\to\mathfrak{C}^\infty(\mathbb{R},\mathbb{R}) \tag{3.2}$$

defined by

$$(L_\Phi(v,w))(t):=\sum_{k,\ell}\left(\frac{d^kv}{dt^k}(t)\right)^T\Phi_{k\ell}\left(\frac{d^\ell w}{dt^\ell}(t)\right). \tag{3.3}$$

If $q_1=q_2$ $(=:q)$, then Φ induces a *quadratic differential form* (QDF)

$$Q_\Phi:\mathfrak{C}^\infty(\mathbb{R},\mathbb{R}^q)\to\mathfrak{C}^\infty(\mathbb{R},\mathbb{R}) \tag{3.4}$$

defined by

$$Q_\Phi(w):=L_\Phi(w,w). \tag{3.5}$$

Define the asterisk operator * by

$$^*:\mathbb{R}^{q_1\times q_2}[\zeta,\eta]\to\mathbb{R}^{q_2\times q_1}[\zeta,\eta];\quad \Phi^*(\zeta,\eta):=\Phi^T(\eta,\zeta), \tag{3.6}$$

where ^{T} denotes transposition. Obviously $L_\Phi(v,w)=L_{\Phi^*}(w,v)$. If $\Phi\in\mathbb{R}^{q\times q}[\zeta,\eta]$ satisfies $\Phi=\Phi^*$, then Φ is called *symmetric*. The symmetric elements of $\mathbb{R}^{q\times q}[\zeta,\eta]$ are denoted by $\mathbb{R}^{q\times q}_s[\zeta,\eta]$. Clearly

$$Q_\Phi=Q_{\Phi^*}=Q_{\frac{1}{2}(\Phi+\Phi^*)} \tag{3.7}$$

This shows that when considering quadratic differential forms, we can hence in principle restrict our attention to Φ's in $\mathbb{R}^{q\times q}_s[\zeta,\eta]$. However, both bilinear and quadratic forms are of interest to us.

Associated with $\Phi\in\mathbb{R}^{q_1\times q_2}[\zeta,\eta]$, we can form the matrix

$$\tilde\Phi=\begin{bmatrix}\Phi_{00}&\Phi_{01}&\cdots&\cdot&\cdots\\ \Phi_{10}&\Phi_{11}&\cdots&\cdot&\cdots\\ \vdots&\vdots&&\vdots&\\ \cdot&\cdot&\cdots&\Phi_{k\ell}&\cdots\\ \vdots&\vdots&&\vdots&\end{bmatrix}. \tag{3.8}$$

Note that, although $\tilde{\Phi}$ is an infinite matrix, all but a finite number of its elements are zero. We can factor $\tilde{\Phi}$ as $\tilde{\Phi} = \tilde{N}^T \tilde{M}$, with $\tilde{N}$ and $\tilde{M}$ infinite matrices having a finite number of rows and all but a finite number of elements equal to zero. This decomposition leads, after premultiplication by $[I_{q_1} \;\; I_{q_1}\zeta \;\; I_{q_1}\zeta^2 \cdots]$ and postmultiplication by $\mathrm{col}[I_{q_2} \;\; I_{q_2}\eta \;\; I_{q_2}\eta^2 \cdots]$, to the following factorization of Φ:

$$\Phi(\zeta, \eta) = N^T(\zeta) M(\eta). \tag{3.9}$$

This decomposition is not unique, but if we take $\tilde{N}$ and $\tilde{M}$ surjective, then their number of rows is equal to the rank of $\tilde{\Phi}$. The factorization (3.9) is then called a *canonical factorization* of Φ. Associated with (3.9), we obtain the following expression for the BLDF L_Φ:

$$L_\Phi(w_1, w_2) = \left(N\left(\frac{d}{dt}\right) w_1 \right)^T M\left(\frac{d}{dt}\right) w_2. \tag{3.10}$$

Next we discuss the case that Φ is symmetric. Clearly $\Phi = \Phi^*$ iff $\tilde{\Phi}$ is symmetric. In that case, it can be factored as $\tilde{\Phi} = \tilde{M}^T \Sigma_M \tilde{M}$ with $\tilde{M}$ an infinite matrix having a finite number of rows and all but a finite number of elements equal to zero, and Σ_M a signature matrix, i.e., a matrix of the form

$$\begin{bmatrix} I_{r_+} & 0 \\ 0 & -I_{r_-} \end{bmatrix}.$$

This decomposition leads to the following decomposition of Φ:

$$\Phi(\zeta, \eta) = M^T(\zeta) \Sigma_M M(\eta). \tag{3.11}$$

Also, this decomposition is not unique but if we take $\tilde{M}$ surjective, then Σ_M is unique. We denote this Σ_M as Σ_Φ and the resulting pair (r_-, r_+) by (ϕ_-, ϕ_+). This pair is called the *inertia* of Φ. The resulting factorization

$$\Phi(\zeta, \eta) = M^T(\zeta) \Sigma_\Phi M(\eta) \tag{3.12}$$

is called a *symmetric canonical factorization* of Φ. Of course, a symmetric canonical factorization is not unique. However, they can all be obtained from one by replacing $M(\xi)$ by $UM(\xi)$ with $U \in \mathbb{R}^{\mathrm{rank}(\tilde{\Phi}) \times \mathrm{rank}(\tilde{\Phi})}$ such that $U^T \Sigma_\Phi U = \Sigma_\Phi$.

Associated with (3.11), we obtain the following decomposition of Q_Φ into a sum of positive and negative squares:

$$Q_\Phi(w) = \left\| P\left(\frac{d}{dt}\right) w \right\|^2 - \left\| N\left(\frac{d}{dt}\right) w \right\|^2, \tag{3.13}$$

where $N, P \in \mathbb{R}^{\bullet \times q}[\xi]$ are obtained by partitioning $\tilde{M}$ conform Σ_M as:

$$\tilde{M} = \begin{bmatrix} \tilde{P} \\ \tilde{N} \end{bmatrix}. \tag{3.14}$$

For a given symmetric $\Phi(\zeta, \eta)$ we are also interested in the symmetric two-variable polynomial matrix $|\Phi|(\zeta, \eta)$, the *absolute value* of Φ, which we define as follows. For a given real symmetric matrix $A \in \mathbb{R}^{n \times n}$ define its absolute value, $|A| \in \mathbb{R}^{n \times n}$, as the unique symmetric nonnegative definite matrix $X \in \mathbb{R}^{n \times n}$ such that $X^2 = A^2$. This

matrix $|A|$ can be computed as follows. Factor $A = \tilde{U}^T \Lambda \tilde{U}$, where Λ is the diagonal matrix with, on its diagonal, the nonzero eigenvalues of A in decreasing order, and where $\tilde{U}\tilde{U}^T = I$, and define $|A| := \tilde{U}^T |\Lambda| \tilde{U}$ with $|\Lambda|$ defined in the obvious way. Let $\tilde{\Phi}$ be the symmetric matrix associated with $\Phi(\zeta, \eta)$. Let $|\tilde{\Phi}|$ be the absolute value of $\tilde{\Phi}$. Next, define $|\Phi|(\zeta, \eta)$ as the symmetric two-variable polynomial matrix associated with $|\tilde{\Phi}|$:

$$|\Phi|(\zeta, \eta) := \begin{bmatrix} I \\ \zeta I \\ \zeta^2 I \\ \vdots \end{bmatrix}^T |\tilde{\Phi}| \begin{bmatrix} I \\ \eta I \\ \eta^2 I \\ \vdots \end{bmatrix}.$$

Note that a factorization $\tilde{\Phi} = \tilde{U}^T \Lambda \tilde{U}$ immediately yields a symmetric canonical factorization of $\Phi(\zeta, \eta)$. Indeed, define $\tilde{M}_c := \sqrt{|\Lambda|}\tilde{U}$. We then have

$$\tilde{\Phi} = \tilde{U}^T \sqrt{|\Lambda|} \Sigma_\Phi \sqrt{|\Lambda|} \tilde{U} = \tilde{M}_c^T \Sigma_\Phi \tilde{M}_c, \tag{3.15}$$

with $\tilde{M}_c$ surjective. The corresponding $M_c(\xi) := \tilde{M}_c \operatorname{col}[I \quad \xi I \quad \xi^2 I \quad \ldots]$ then yields a canonical factorization $\Phi(\zeta, \eta) = M_c^T(\zeta) \Sigma_\Phi M_c(\eta)$. This particular canonical factorization has the property that

$$|\Phi|(\zeta, \eta) = M_c^T(\zeta) M_c(\eta). \tag{3.16}$$

In general, if $M(\xi)$ is any canonical factor of Φ, then we have $UM(\xi) = M_c(\xi)$ with U satisfying $U^T \Sigma_\Phi U = \Sigma_\Phi$, and hence $|\Phi|(\zeta, \eta) = M^T(\zeta) U^T U M(\eta)$.

One of the conveniences of identifying BLDFs and QDFs with two-variable polynomial matrices is that they allow a very convenient calculus. One instance of this is differentiation. Obviously if L_Φ is a BLDF, so is $\frac{d}{dt} L_\Phi$, and if Q_Φ is a QDF, so is $\frac{d}{dt} Q_\Phi$. The result of differentiation is easily expressed in terms of the two-variable polynomial matrices and leads to the dot operator $\bullet$ defined as

$$\bullet : \mathbb{R}^{q_1 \times q_2}[\zeta, \eta] \to \mathbb{R}^{q_1 \times q_2}[\zeta, \eta]; \quad \overset{\bullet}{\Phi}(\zeta, \eta) := (\zeta + \eta)\Phi(\zeta, \eta). \tag{3.17}$$

It is easily calculated that

$$\frac{d}{dt} L_\Phi = L_{\overset{\bullet}{\Phi}} \text{ and } \frac{d}{dt} Q_\Phi = Q_{\overset{\bullet}{\Phi}} \tag{3.18}$$

In the following, an important role is played by certain one-variable polynomial matrices obtained from two-variable polynomial matrices by means of the delta operator ∂, defined as

$$\partial : \mathbb{R}^{q_1 \times q_2}[\zeta, \eta] \to \mathbb{R}^{q_1 \times q_2}[\xi]; \quad \partial\Phi(\xi) := \Phi(-\xi, \xi).$$

Note that, among other things, this allows one to associate a differential operator $\Phi(-\frac{d}{dt}, \frac{d}{dt})$ with a QDF—this is one of the key ingredients in LQ—and variational problems.

Introduce the star operator * acting on matrix polynomials by

$$^\star : \mathbb{R}^{q_1 \times q_2}[\xi] \to \mathbb{R}^{q_2 \times q_1}[\xi]; \quad R^\star(\xi) := R^T(-\xi).$$

The importance of this operation stems from the fact that $M(\frac{d}{dt})$ and $M^\star(\frac{d}{dt})$ are formal adjoints as differential operators. A polynomial matrix $M \in \mathbb{R}^{q \times q}[\xi]$ is called

para-Hermitian if $M = M^\star$. Note that $(\partial\Phi)^\star = \partial(\Phi^*)$. Hence if $\Phi \in \mathbb{R}_s^{q\times q}[\zeta,\eta]$, then $\partial\Phi$ is para-Hermitian.

In addition to studying BLDFs and QDFs as maps to $\mathfrak{C}^\infty(\mathbb{R},\mathbb{R})$, we are interested in their integrals. In order to make sure that those integrals exist, we assume in this case that the arguments have compact support. As is common, we denote by $\mathfrak{D}(\mathbb{R},\mathbb{R}^q) := \{w \in \mathfrak{C}^\infty(\mathbb{R},\mathbb{R}^q) \mid w \text{ has compact support}\}$. Let $\Phi \in \mathbb{R}^{q_1\times q_2}[\zeta,\eta]$. Then obviously $L_\Phi : \mathfrak{D}(\mathbb{R},\mathbb{R}^{q_1}) \times \mathfrak{D}(\mathbb{R},\mathbb{R}^{q_2}) \to \mathfrak{D}(\mathbb{R},\mathbb{R})$. Consider the integral

$$\int L_\Phi : \mathfrak{D}(\mathbb{R},\mathbb{R}^{q_1}) \times \mathfrak{D}(\mathbb{R},\mathbb{R}^{q_2}) \to \mathbb{R} \tag{3.19}$$

defined as

$$\int L_\Phi(v,w) := \int_{-\infty}^{+\infty} L_\Phi(v,w)dt. \tag{3.20}$$

The notation $\int Q_\Phi$ follows readily from this. Furthermore, consider the same integral over a finite interval $[t_1,t_2]$

$$\int_{t_1}^{t_2} L_\Phi(v,w)dt \tag{3.21}$$

denoted as $\int_{t_1}^{t_2} L_\Phi$. We call this integral *independent of path* if for any t_1 and t_2 the result of the integral (3.21) depends only on the values of v and w and (a finite number of) their derivatives at $t = t_1$ and $t = t_2$ but not on the intermediate path used to connect these endpoints, assuming, of course that $v \in \mathfrak{C}^\infty(\mathbb{R},\mathbb{R}^{q_1})$ and $w \in \mathfrak{C}^\infty(\mathbb{R},\mathbb{R}^{q_2})$.

The questions of when the map $\int L_\Phi$ is zero and when path independence holds are studied next.

THEOREM 3.1. *Let $\Phi \in \mathbb{R}^{q_1\times q_2}[\zeta,\eta]$. Then the following statements are equivalent:*

1. *$\int L_\Phi = 0$, equivalently $\int_{t_1}^{t_2} L_\Phi$ is independent of path.*
2. *There exists a $\Psi \in \mathbb{R}^{q_1\times q_2}[\zeta,\eta]$ such that $\Phi = \dot{\Psi}$, equivalently, such that $L_\Phi = \frac{d}{dt}L_\Psi$. Obviously Ψ is given by*

$$\Psi(\zeta,\eta) = \frac{\Phi(\zeta,\eta)}{\zeta+\eta}. \tag{3.22}$$

3. *$\partial\Phi = 0$, i.e., $\Phi(-\xi,\xi) = 0$.*

The same equivalence holds for QDFs. Simply assume $\Phi \in \mathbb{R}_s^{q\times q}[\zeta,\eta]$ and replace the L's by Q's in 1 *and* 2.

Proof. For the proof, see the appendix.

The importance of this theorem is that condition (3) gives a very convenient way of checking (1) or (2). Path integrals and path independence featured prominently in Brockett's work in the sixties (see [7], [8]), and indeed some of our results can be viewed as streamlined versions of this work. Another potentially interesting connection of the above theorem and our paper with the existing literature is [3] where, in our notation, $\Phi(\zeta,\eta) = R(\zeta)M(-\eta)$ is studied, with R and M associated with a kernel representation (2.1) and an image representation (2.4) of a controllable system. This Φ defines an intriguing path independent BLDF that can be associated with any controllable $\mathfrak{B}$.

In this paper we also study the behavior of QDFs evaluated along a differential behavior $\mathfrak{B} \in \mathfrak{L}^q$. In order to do so, it is convenient to introduce an equivalence relation on both the one- and two-variable polynomial matrices modulo a given $\mathfrak{B} \in \mathfrak{L}^q$.

Let $D_1, D_2 \in \mathbb{R}^{\bullet \times q}[\xi]$. Define $(D_1 \overset{\mathfrak{B}}{=} D_2) :\Leftrightarrow (D_1(\frac{d}{dt}) - D_2(\frac{d}{dt}))\mathfrak{B} = 0$. Let $\Phi_1, \Phi_2 \in \mathbb{R}_s^{q \times q}[\zeta, \eta]$. Define $(\Phi_1 \overset{\mathfrak{B}}{=} \Phi_2) :\Leftrightarrow (Q_{\Phi_1}(w) = Q_{\Phi_2}(w)$ for all $w \in \mathfrak{B})$. These equivalencies are easily expressed in terms of a kernel or an image representation of $\mathfrak{B}$.

PROPOSITION 3.2. *Let $R \in \mathbb{R}^{\bullet \times q}[\xi]$ define a kernel representation of $\mathfrak{B} \in \mathfrak{L}^q$. Then $D_1 \overset{\mathfrak{B}}{=} D_2$ iff*

$$D_1 - D_2 = FR \tag{3.23}$$

for some $F \in \mathbb{R}^{\bullet \times \bullet}[\xi]$ and $\Phi_1 \overset{\mathfrak{B}}{=} \Phi_2$ iff

$$\Phi_2(\zeta, \eta) = \Phi_1(\zeta, \eta) + R^T(\zeta)F(\zeta, \eta) + F^*(\zeta, \eta)R(\eta) \tag{3.24}$$

for some $F \in \mathbb{R}^{\bullet \times q}[\zeta, \eta]$. Let $M \in \mathbb{R}^{q \times \bullet}[\zeta, \eta]$ define an image representation of $\mathfrak{B} \in \mathfrak{L}^q$. Then $D_1 \overset{\mathfrak{B}}{=} D_2$ iff

$$D_1 M = D_2 M$$

and $\Phi_1 \overset{\mathfrak{B}}{=} \Phi_2$ iff

$$M^T(\zeta)\Phi_1(\zeta, \eta)M(\eta) = M^T(\zeta)\Phi_2(\zeta, \eta)M(\eta)$$

Proof. For the proof, see the appendix.

The first equivalence in the above proposition was already proven in [23], with an account of the history of the result, which goes back to 1895. We will return to the second equivalence at the end of section 4.

We now briefly discuss positivity of QDFs. This will be a major issue in the following; here we restrict our attention to the basic definitions.

DEFINITION 3.3. *Let $\Phi \in \mathbb{R}_s^{q \times q}[\zeta, \eta]$. We call the QDF Q_Φ* nonnegative, *denoted $\Phi \geq 0$, if $Q_\Phi(w) \geq 0$ for all $w \in \mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^q)$, and* positive, *denoted $\Phi > 0$, if $\Phi \geq 0$ and if the only $w \in \mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^q)$ for which $Q_\Phi(w) = 0$ is $w = 0$.*

Using the matrix representation of Φ, it is easy to see that $\Phi \geq 0$ iff there exists $D \in \mathbb{R}^{\bullet \times q}[\xi]$ such that $\Phi(\zeta, \eta) = D^T(\zeta)D(\eta)$. Simply factor $\tilde{\Phi}$ as $\tilde{\Phi} = \tilde{D}^T\tilde{D}$ and take $D(\xi) = \tilde{D}$ col $[I_q \;\; I_q\xi \;\; I_q\xi^2 \cdots]$. Moreover $\Phi > 0$ iff this D has the property that $D(\lambda)$ is of rank q for all $\lambda \in \mathbb{C}$; in other words, iff the image representation $w = D(\frac{d}{dt})\ell$ defined by D is observable. Note that, for $\Phi \in \mathbb{R}_s^{q \times q}[\zeta, \eta]$, we always have $|\Phi| \geq 0$.

We are also interested in QDFs which are zero or positive along a behavior $\mathfrak{B} \in \mathfrak{L}^q$.

DEFINITION 3.4. *We call* Φ zero along $\mathfrak{B}$, *denoted $\Phi \overset{\mathfrak{B}}{=} 0$, if $Q_\Phi(w) = 0$ for all $w \in \mathfrak{B}$. The notions of* nonnegative $(\overset{\mathfrak{B}}{\geq})$ *and* positive $(\overset{\mathfrak{B}}{>})$ along $\mathfrak{B}$ *follow readily.*

Note that it immediately follows from Proposition 3.2 that, if $R(\frac{d}{dt})w = 0$ is a kernel representation of $\mathfrak{B}$, then $\Phi \overset{\mathfrak{B}}{=} 0$ iff it can be written as $\Phi(\zeta, \eta) = F^*(\zeta, \eta)R(\eta) + R^T(\zeta)F(\zeta, \eta)$. A similar result holds for positivity as follows.

PROPOSITION 3.5. *Let $\Phi \in \mathbb{R}_s^{q \times q}[\zeta, \eta]$, $\mathfrak{B} \in \mathfrak{L}^q$, and $R \in \mathbb{R}^{\bullet \times q}[\xi]$ induce a kernel representation of $\mathfrak{B}$. Then*

(i) $\Phi \overset{\mathfrak{B}}{\geq} 0$ *iff there exists $\Phi' \in \mathbb{R}_s^{q \times q}[\zeta, \eta]$ with $\Phi \overset{\mathfrak{B}}{=} \Phi'$ and $\Phi' \geq 0$;*

(ii) $\Phi \overset{\mathfrak{B}}{>} 0$ *iff there exists* $\Phi' \in \mathbb{R}^{q\times q}_s[\zeta,\eta]$ *with* $\Phi \overset{\mathfrak{B}}{=} \Phi'$ *and* $\Phi'(\zeta,\eta) = D^T(\zeta)D(\eta)$, *with* (R, D) *an observable pair.*

Proof. For the proof, see the appendix.

4. Lyapunov theory. Lyapunov theory is a firmly established and very useful technique for establishing stability. It pertains to systems described by explicit first order differential equations. However, as argued in [33], models obtained from first principles are seldomly in first order form, will contain latent variables, and may contain high order derivatives. Writing them in explicit first order form without introducing spurious solutions may not be an easy matter. Moreover, stability considerations do not require systems to be in first order form. In fact, historically the very first stability questions and results, as Maxwell's statement of the stability problem and the Routh–Hurwitz conditions, pertain to high order differential equations. Oddly enough, to our knowledge, no attempts seem to have been made to establish Lyapunov theory for high order differential equations. This is the purpose of this section. We limit our attention, however, to linear differential systems and to Lyapunov functions that are quadratic differential forms, but we recognize the urgency of generalizing this work to nonlinear systems. We should remark that in this section for stability, we only consider systems in which the latent variables have been eliminated, although latent variables do not cause essential difficulties in the context of stability.

First, we introduce the notion of stability. We say that a system $\mathfrak{B} \in \mathfrak{L}^q$ is *asymptotically stable* if $(w \in \mathfrak{B}) \Rightarrow (w(t) \underset{t\to\infty}{\longrightarrow} 0)$ and *stable* if $(w \in \mathfrak{B}) \Rightarrow (w$ is bounded on the half-line $[0,\infty))$. For a system $\mathfrak{B} \in \mathfrak{L}^q$ to be (asymptotically) stable it has to be autonomous. A system $\mathfrak{B} \in \mathfrak{L}^q$ is said to be *autonomous* if $(w_1, w_2 \in \mathfrak{B})$ and $(w_1(t) = w_2(t)$ for $t < 0)$ imply $(w_1 = w_2)$. It is easy to see that the system with kernel representation $R(\frac{d}{dt})w = 0$ is autonomous iff $\operatorname{rank}(R) = q$; in particular, if R is square and $\det(R) \neq 0$.

DEFINITION 4.1. *Let* $R \in \mathbb{R}^{\bullet\times q}[\xi]$. *The complex number* $\lambda \in \mathbb{C}$ *is said to be a* singularity *of* R *if* $\operatorname{rank}(R(\lambda)) < \operatorname{rank}(R)$; R *is said to be* Hurwitz *if* $\operatorname{rank}(R) = q$ *and if* R *has all its singularities in the open left half of the complex plane.*

Thus a square $R \in \mathbb{R}^{q\times q}[\xi]$ is Hurwitz iff $\det(R)$ is a *Hurwitz polynomial*, i.e., a nonzero polynomial with its roots in the open left half-plane. We record the following classical result for easy reference.

PROPOSITION 4.2. *The system with kernel representation* (2.1) *is asymptotically stable iff* R *is Hurwitz.*

Our most basic Lyapunov theorem regarding high order systems is the following.

THEOREM 4.3. *Let* $\mathfrak{B} \in \mathfrak{L}^q$. *Then* $\mathfrak{B}$ *is asymptotically stable iff there exists* $\Psi \in \mathbb{R}^{q\times q}_s[\zeta,\eta]$ *such that* $\Psi \overset{\mathfrak{B}}{\geq} 0$ *and* $\overset{\bullet}{\Psi} \overset{\mathfrak{B}}{<} 0$.

Proof. For the proof, see the appendix.

Example 4.4. Consider the scalar system described by $w + \frac{dw}{dt} + \frac{d^2w}{dt^2} = 0$. Consider the QDF $w^2 + (\frac{dw}{dt})^2$. Its derivative QDF is $2(w + \frac{d^2w}{dt^2})\frac{dw}{dt}$. Since $w \in \mathfrak{B}$ iff $w + \frac{d^2w}{dt^2} = -\frac{dw}{dt}$, we see that this QDF is $\mathfrak{B}$-equivalent to the QDF $-2(\frac{dw}{dt})^2$. Finally observe that $(1 + \xi + \xi^2, \sqrt{2}\xi)$ is an observable pair. Hence $-2(\frac{dw}{dt})^2$ is negative on $\mathfrak{B}$. Theorem 4.3 establishes asymptotic stability (a rather trivial matter for the case at hand). Our aim was to show the use of Lyapunov theory without getting involved with state representations (admittedly also a trivial matter).

Example 4.5. Consider the multivariable system

$$Kw + D\frac{dw}{dt} + M\frac{d^2w}{dt^2} = 0, \tag{4.1}$$

with $K, D, M \in \mathbb{R}^{q\times q}$, $K = K^T \geq 0$, $D + D^T \geq 0$, and $M = M^T \geq 0$. Such second order equations occur frequently as models of (visco-)elastic mechanical systems. Take $\Psi(\zeta,\eta) = K + M\zeta\eta$. Then $\overset{\bullet}{\Psi}(\zeta,\eta) = K(\zeta+\eta) + M(\zeta^2\eta + \zeta\eta^2)$ which is obviously $\mathfrak{B}$-equivalent to $-(D+D^T)\zeta\eta$. Thus, asymptotic stability follows if

$$\left(K + D\xi + M\xi^2, \sqrt{(D+D^T)}\xi\right) \tag{4.2}$$

is an observable pair. This is the case, for example, if $\{0\} = \ker(K) \subset \ker(D+D^T) \subset \ker(M)$. Indeed, under this condition

$$\begin{bmatrix} K + D\lambda + M\lambda^2 \\ \sqrt{(D+D^T)}\lambda \end{bmatrix}$$

has full column rank for all $\lambda \in \mathbb{C}$.

State representations of autonomous systems take a very special form. Indeed, it is easy to see that $\mathfrak{B} \in \mathfrak{L}^q$ is autonomous iff it admits a state representation of the form $\frac{dx}{dt} = Ax$, $w = Cx$. Such state representations are automatically state trim. If (A, C) is observable, then they are state minimal. It also follows that for *every* $D \in \mathbb{R}^{\bullet\times q}[\xi]$ there exists a matrix $H \in \mathbb{R}^{\bullet\times n}$ such that $D(\frac{d}{dt})w \overset{\mathfrak{B}}{=} Hx$, i.e., every linear differential operator acting on an autonomous $\mathfrak{B} \in \mathfrak{L}^q$ is $\mathfrak{B}$-equivalent to an instantaneous function of the state. An analogous statement holds, of course, for QDFs.

Viewed from this perspective, one can regard Theorem 4.3 as being about state systems and in this sense not very different from classical Lyapunov theorems. The point of Theorem 4.3 is twofold:

1. It avoids the state construction which algorithmically (and conceptually) is not always easy in the multivariable case; and
2. It has the usual Lyapunov theory as a special case by applying it to systems in first order form and using memoryless QDFs. For the sake of completeness, we record this as a corollary.

COROLLARY 4.6. *Let $\mathfrak{B}$ be the behavior of $\frac{dw}{dt} = Aw$. Let $\Psi(\zeta,\eta) = \Psi_0$ with $\Psi_0 \in \mathbb{R}^{q\times q}$, $\Psi_0 = \Psi_0^T \geq 0$. Then $\overset{\bullet}{\Psi}(\zeta,\eta) \overset{\mathfrak{B}}{=} A\Psi_0 + \Psi_0 A^T =: \Delta_0$. Whence, if $\Delta_0 = \Delta_0^T \leq 0$ and if (A, Δ_0) is an observable pair of matrices, $\mathfrak{B}$ is asymptotically stable.*

Proof. For the proof, see the appendix.

In section 3, we discussed $\mathfrak{B}$-positive QDFs. When $\mathfrak{B}$ is autonomous, it is useful to consider also a stronger concept. Let $\mathfrak{B} \in \mathfrak{L}^q$ and $\Phi \in \mathbb{R}_s^{q\times q}[\zeta,\eta]$; we call Φ *strongly $\mathfrak{B}$-positive* (denoted $\Phi \overset{\mathfrak{B}}{\gg} 0$) if $\Phi \overset{\mathfrak{B}}{\geq} 0$ and if ($w \in \mathfrak{B}$ and $Q_\Phi(w)(0) = 0$) imply ($w = 0$). It is easy to see that $\Phi \overset{\mathfrak{B}}{\gg} 0$ implies $\Phi \overset{\mathfrak{B}}{>} 0$ and that in order for $\Phi \overset{\mathfrak{B}}{\gg} 0$, $\mathfrak{B}$ must be autonomous. In fact, $((Q_\phi(w)(0) = 0) \Rightarrow (w = 0))$ by itself already implies ($\Phi \overset{\mathfrak{B}}{\gg} 0$ or $\Phi \overset{\mathfrak{B}}{\ll} 0$). Using this notion we arrive at the following refinement of theorem 4.3.

PROPOSITION 4.7. *If $\Psi \overset{\mathfrak{B}}{\geq} 0$ and $\overset{\bullet}{\Psi} \overset{\mathfrak{B}}{<} 0$, then $\mathfrak{B}$ is asymptotically stable and $\Psi \overset{\mathfrak{B}}{\gg} 0$.*

Proof. For the proof, see the appendix.

We now formulate a stronger version of the "only if" part of Theorem 4.3.

THEOREM 4.8. *Assume that $\mathfrak{B} \in \mathfrak{L}^q$ is asymptotically stable. Then for any $\Phi \in \mathbb{R}^{q\times q}_s[\zeta,\eta]$ there exists a $\Psi \in \mathbb{R}^{q\times q}_s[\zeta,\eta]$ such that $\overset{\bullet}{\Psi} \overset{\mathfrak{B}}{=} \Phi$; Ψ is unique up to $\mathfrak{B}$-equivalence in the sense that, if $\overset{\bullet}{\Psi}_1 \overset{\mathfrak{B}}{=} \Phi$ and $\overset{\bullet}{\Psi}_2 \overset{\mathfrak{B}}{=} \Phi$, then $\Psi_1 \overset{\mathfrak{B}}{=} \Psi_2$. If $\Phi \overset{\mathfrak{B}}{\leq} 0$, then $\Psi \overset{\mathfrak{B}}{\geq} 0$, and if $\Phi \overset{\mathfrak{B}}{<} 0$, then $\Psi \overset{\mathfrak{B}}{\gg} 0$.*

In order to compute Ψ from Φ, the following algorithm may be used. Let $R \in \mathbb{R}^{\bullet\times q}[\xi]$ induce a kernel representation of $\mathfrak{B}$. Consider the polynomial matrix equation

$$X^T(-\xi)R(\xi) + R^T(-\xi)X(\xi) = \Phi(-\xi,\xi) \tag{4.3}$$

in the unknown $X \in \mathbb{R}^{\bullet\times q}[\xi]$. Then (4.3) has a solution. Let X_0 be a solution. If R is square, then all its solutions can be obtained from this one as

$$X(\xi) = X_0(\xi) + F(\xi)R(\xi), \tag{4.4}$$

where F ranges over all polynomial matrices of appropriate size satisfying

$$F^T(-\xi) = -F(\xi). \tag{4.5}$$

Consider any $Y \in \mathbb{R}^{\bullet\times q}[\zeta,\eta]$ such that

$$Y(-\xi,\xi) = X(\xi) \tag{4.6}$$

and compute

$$\Psi(\zeta,\eta) = \frac{\Phi(\zeta,\eta) - Y^*(\zeta,\eta)R(\eta) - R^T(\zeta)Y(\zeta,\eta)}{\zeta+\eta}. \tag{4.7}$$

Then $\overset{\bullet}{\Psi} \overset{\mathfrak{B}}{=} \Phi$. Since any two Ψ_1, Ψ_2 such that $\overset{\bullet}{\Psi}_1 \overset{\mathfrak{B}}{=} \Phi$ and $\overset{\bullet}{\Psi}_2 \overset{\mathfrak{B}}{=} \Phi$ satisfy $\Psi_1 \overset{\mathfrak{B}}{=} \Psi_2$, any other solutions of (4.3) and/or (4.6) yield Ψ's in (4.7) that are $\mathfrak{B}$-equivalent.

Proof. For the proof, see the appendix.

Theorem 4.8 is more than a mouthful and so we illustrate it for ordinary state space systems $\frac{dw}{dt} = Aw$. Let $\Phi = \Phi^T \in \mathbb{R}^{n\times n}$. Then (4.3) becomes

$$X^T(-\xi)(A - I\xi) + (A^T + I\xi)X(\xi) = \Phi. \tag{4.8}$$

This equation has a constant solution which must be symmetric, $X_0 = X_0^T$, the solution of the ordinary Lyapunov equation

$$X_0 A + A_0^T X = \Phi. \tag{4.9}$$

Choose $Y = X_0$ and verify that (4.7) reduces to $\Psi = X_0$, whence the Lyapunov function is $Q_\Psi(w) = w^T X_0 w$ and for $w \in \mathfrak{B}$ its derivative is $Q_\Phi(w) = w^T \Phi w$. Because of this analogy, we refer to (4.3) as the polynomial matrix *Lyapunov equation*.

The above shows that it seems to suffice to consider Lyapunov functions Ψ and their derivatives Φ that are of lower degree than that of R. That is, in fact, a general feature of the equations in Theorem 4.8. However, in order to formalize this, we return first to the notion of $\mathfrak{B}$-equivalence of differential operators in the case that $\mathfrak{B} \in \mathfrak{L}^q$ is autonomous.

Let $\mathfrak{B} \in \mathfrak{L}^q$ be autonomous. Then there always exists a square kernel representation for it. Let $R \in \mathbb{R}^{q\times q}[\xi]$ be such that $\mathfrak{B} = \ker(R(\frac{d}{dt}))$. We assume in the remainder of this section that R is square.

Let $D \in \mathbb{R}^{\bullet\times q}[\xi]$. We call D *R-canonical* if DR^{-1} is a matrix of strictly proper rational functions. Let $\Phi \in \mathbb{R}_s^{q\times q}[\zeta,\eta]$. We call Φ *R-canonical* if $(R^T(\zeta))^{-1}\Phi(\zeta,\eta)$ $(R(\eta))^{-1}$ is a matrix of strictly proper two-variable rational functions. (Note that there is no ambiguity about what "strictly proper" means for these two-variable rational functions.) Since for autonomous systems all differential operators can be seen as instantaneous functions of the state, it is clear that for any D there exists a canonical D' that is R-equivalent to D'. The aim of the next result is to derive this also for QDFs.

PROPOSITION 4.9. *Let $D \in \mathbb{R}^{\bullet\times q}[\xi]$. Among all differential operators $\mathfrak{B}$-equivalent to D, there is exactly one, D', which is R-canonical. This D' can be computed as follows. Compute $DR^{-1} \in \mathbb{R}^{\bullet\times q}(\xi)$ and write it as $DR^{-1} = P + S$, with P the polynomial part and S the strictly proper rational part of DR^{-1} . Then $D' = D - PR$. Let $\Phi \in \mathbb{R}_s^{q\times q}[\zeta,\eta]$. Among all QDFs $\mathfrak{B}$-equivalent to Φ there is exactly one, Φ', which is R-canonical. This Φ' can be computed as follows. Write Φ as $\Phi(\zeta,\eta) = M^T(\zeta)N(\eta)$. Compute the R-canonical representatives M' of M and N' of N. Then $\Phi'(\zeta,\eta) = M'^T(\zeta)N'(\eta)$.*

Proof. For the proof, see the appendix.

The following proposition shows that $\mathfrak{B}$-positivity reduces to positivity of the $\mathfrak{B}$-canonical representative.

PROPOSITION 4.10. *If Ψ is R-canonical, then we have*

(i) $(\Psi \overset{\mathfrak{B}}{=} 0) \Leftrightarrow (\Psi = 0)$,

(ii) $(\Psi \overset{\mathfrak{B}}{\geq} 0) \Leftrightarrow (\Psi \geq 0) \Leftrightarrow (\Psi(\zeta,\eta) = D^T(\zeta)D(\eta)$ *with D R-canonical*$)$,

(iii) $(\Psi \overset{\mathfrak{B}}{>} 0) \Leftrightarrow (\Psi > 0$ *and* $\Psi(\zeta,\eta) = D^T(\zeta)D(\eta)$ *with* (R,D) *observable*$) \Leftrightarrow$ $(\Psi(\zeta,\eta) = D^T(\zeta)D(\eta)$ *with* (R,D) *observable and D R-canonical*$)$.

Proof. For the proof, see the appendix.

We immediately obtain the following consequence of Theorem 4.3.

COROLLARY 4.11. *$\mathfrak{B} \in \mathfrak{L}^q$ is asymptotically stable iff there exists a $\Psi \in \mathbb{R}_s^{q\times q}[\zeta,\eta]$, $\Psi \geq 0$, such that the R-canonical representative of $(\zeta+\eta)\Psi(\zeta,\eta)$, computed as in Proposition* 4.9, *is ≤ 0 and factors as $-D^T(\zeta)D(\eta)$ with (R,D) observable.*

Our next result is perhaps the most useful of all. It shows how to walk through the algorithm of Theorem 4.8 and preserve canonicity.

THEOREM 4.12. *Assume that $\mathfrak{B} \in \mathfrak{L}^q$ is asymptotically stable and has kernel representation* (2.1) *with R square. Assume that Φ is R-canonical. Then the polynomial matrix Lyapunov equation* (4.3) *has a unique R-canonical solution. Denote it by X'. Then*

$$\Psi(\zeta,\eta) = \frac{\Phi(\zeta,\eta) - X'^T(\zeta)R(\eta) - R^T(\zeta)X'(\eta)}{\zeta+\eta} \tag{4.10}$$

is the unique R-canonical Ψ such that $\overset{\bullet}{\Psi} \overset{\mathfrak{B}}{=} \Phi$. Hence if $\Phi \leq 0$, then $\Psi \geq 0$, and if, in addition, $\Phi(\zeta,\eta) = -D^T(\zeta)D(\eta)$ with (R,D) observable, then $\Psi \overset{\mathfrak{B}}{\gg} 0$.

Proof. For the proof, see the appendix.

We make a short comment relating these results to state representations. The state maps (2.13) associating a minimal state to $\mathfrak{B}$ are uniquely defined up to $\mathfrak{B}$-equivalence. There is, consequently, a minimal state map (unique up to premultiplication by a nonsingular matrix that is R-canonical, say, $x = X(\frac{d}{dt})w$). An R-canonical

$\Phi \in \mathbb{R}^{q\times q}_s[\zeta,\eta]$ is of the form $Q_\Phi(w) = x^T\Gamma x$, i.e., $\Phi(\zeta,\eta) = X^T(\zeta)\Gamma X(\eta)$, with $\Gamma = \Gamma^T$ an $(n\times n)$ matrix. Of course for this Φ there holds $(\Phi \overset{\mathfrak{B}}{\geq} 0) \Leftrightarrow (\Phi \geq 0) \Leftrightarrow (\Gamma \geq 0)$; furthermore, $(\Phi \overset{\mathfrak{B}}{>} 0) \Leftrightarrow (\Gamma \geq 0$ and observability of the pair of matrices (A,Γ) (with A associated with the state x)), and finally $(\Phi \overset{\mathfrak{B}}{\gg} 0) \Leftrightarrow (\Gamma > 0)$.

The above results allow generalizations to unstable systems. Let us briefly mention a few. We have seen that ($\mathfrak{B}$ asymptotically stable) $\Leftrightarrow$ ($\exists\Psi(\zeta,\eta)$ such that ($\Psi \overset{\mathfrak{B}}{\geq} 0$ and $\overset{\bullet}{\Psi} \overset{\mathfrak{B}}{<} 0$)). There also holds ($\mathfrak{B}$ stable) $\Leftrightarrow$ ($\exists\Psi(\zeta,\eta)$ such that ($\Psi \overset{\mathfrak{B}}{>} 0$ and $\overset{\bullet}{\Psi} \overset{\mathfrak{B}}{\leq} 0$)) and (an autonomous $\mathfrak{B}$ is not stable) $\Leftrightarrow$ ($\exists\Psi(\zeta,\eta)$ such that ($\Psi \overset{\mathfrak{B}}{\not\geq} 0$ and $\overset{\bullet}{\Psi} \overset{\mathfrak{B}}{<} 0$)). Furthermore, the result that a Lyapunov function Ψ can be constructed so that it has a given derivative Φ (Theorem 4.8) can be generalized to autonomous systems, as long as they have the property that if λ is a singularity of R then $-\lambda$ will not be a singularity of R. As such this theorem extends in this sense to a large class of unstable systems.

We close this section with two extensive examples.

Example 4.13. In this first example we use Theorem 4.8 in order to give a Lyapunov proof of the Routh–Hurwitz test for stability of scalar systems. Let $R \in \mathbb{R}[\xi]$ be a Hurwitz polynomial. Hence $R(\frac{d}{dt})w = 0$ defines an asymptotically stable scalar system. Take, for the derivative of the Lyapunov function,

$$\Phi(\zeta,\eta) = -\frac{1}{2}R(-\zeta)R(-\eta) = -\frac{1}{2}R^\star(\zeta)R^\star(\eta). \tag{4.11}$$

Then obviously, since R has no imaginary axis roots, $(R,R^\star)$ is an observable (i.e., a coprime) pair. The polynomial matrix Lyapunov equation (4.3) yields $X(\xi) = -\frac{1}{4}R(\xi)$ as a solution. Take $Y(\zeta,\eta) = X(\eta)$. Then (4.7) yields

$$B(\zeta,\eta) = \frac{1}{2}\frac{R(\zeta)R(\eta) - R(-\zeta)R(-\eta)}{\zeta+\eta} \tag{4.12}$$

as a Lyapunov function. Note that this Lyapunov function can be written directly from the system parameters, without having to solve linear equations! This fact is actually well known, even though it is not presented in the vein of providing a higher order Lyapunov function ([6], [13], [14]).

The two-variable polynomial B defined by (4.12) is called the *Bezoutian* of R. Note that $\overset{\bullet}{B}(\zeta,\eta) \overset{\mathfrak{B}}{=} -\frac{1}{2}R(-\zeta)R(-\eta)$; B is R-canonical, but $\overset{\bullet}{B}$ is not. However, $\overset{\bullet}{B}$ is $\mathfrak{B}$-equivalent to $-\frac{1}{2}R(-\zeta)R(-\eta) + \frac{1}{2}R(\zeta)R(\eta)$, which is. If we take this for the Φ in Theorem 4.8, then the Lyapunov equation yields $X = 0$. Taking $Y = 0$ then also yields the Bezoutian (4.12) as the corresponding (hence R-canonical) Lyapunov function B.

A close examination of the arguments involved yields the equivalence of the following three conditions on a polynomial R of degree n and the corresponding $B \in \mathbb{R}[\zeta,\eta]$ given by (4.12):

1. R is Hurwitz,
2. $B \geq 0$ and $(R,R^\star)$ is coprime,
3. $\tilde{B}$ (the constant matrix associated with B) has rank n and is ≥ 0.

The Lyapunov function (4.12), the Bezoutian, is a very useful one for deriving various stability tests. It is a classical concept in stability (see [11] for a recent reference). Let us illustrate its usefulness by deriving the Routh stability test from it.

Let $R \in \mathbb{R}[\xi]$ be a polynomial of degree n. Decompose R in its even and odd parts as

$$R(\xi) = E_0(\xi^2) + \xi E_1(\xi^2).$$

Form the *Routh table* by computing the polynomials $E_2, E_3, \ldots, E_n$ as

$$E_k(\xi) = \xi^{-1}(E_{k-1}(0)E_{k-2}(\xi) - E_{k-2}(0)E_{k-1}(\xi)).$$

Assume for simplicity that $R(0) = E_0(0) \geq 0$. Routh's stability criterion states that R is Hurwitz iff all elements of the *Routh array* $E_0(0), E_1(0), \ldots, E_n(0)$ are positive. Define $R_k(\xi) = E_{k-1}(\xi^2) + \xi E_k(\xi^2)$ for $k = 1, \ldots, n$, and let B_k be the Bezoutian associated with R_k. Examining expression (4.12) yields, after a simple calculation

$$E_k(0)B_k(\zeta, \eta) = \zeta\eta B_{k+1}(\zeta, \eta) + E_{k-1}(0)E_k(\zeta^2)E_k(\eta^2) \tag{4.13}$$

for $k = 1, \ldots, n$ (define $B_{n+1} = 0$). Assume that $E_0(0), E_1(0), \ldots, E_n(0)$ are all positive. Then we obtain (note that $B = B_1$)

$$B(\zeta, \eta) = \sum_{k=1}^{n} \alpha_k \zeta^{k-1}\eta^{k-1}E_k(\zeta^2)E_k(\eta^2),$$

where $\alpha_k = E_{k-1}(0)/E_1(0)E_2(0)\ldots E_k(0)$. Obviously $\tilde{B} \geq 0$ and has rank n. Therefore R is Hurwitz. To show the converse, assume that R is Hurwitz. Then $E_0(0) > 0$. Also, $\tilde{B} \geq 0$ and has rank n. Therefore, by (4.13), $\tilde{B}_2 \geq 0$ and has rank $n-1$. Hence R_2 is Hurwitz, and $E_1(0) > 0$. Now proceed by induction.

The key point thus is that

$$\sum_{k=1}^{n} \alpha_k \left(E_k\left(\frac{d^2}{dt^2}\right) \frac{d^{k-1}}{dt^{k-1}} w \right)^2$$

is a QDF which is well defined and nonnegative definite when the Routh conditions are satisfied. It has derivative

$$\frac{1}{2}\left(\left(R\left(-\frac{d}{dt}\right) w \right)^2 - \left(R\left(\frac{d}{dt}\right) w \right)^2 \right),$$

which is obviously nonnegative definite along solutions of $R(\frac{d}{dt})w = 0$.

Example 4.14. Let $E_1, E_2, \ldots, E_N$ and $O_1, O_2, \ldots, O_{N'}$ be two sets of real polynomials, and assume that $R_{k,\ell}(\xi) := E_k(\xi^2) + \xi O_\ell(\xi^2)$ is Hurwitz for all $k = 1, 2, \ldots, N$ and $\ell = 1, 2, \ldots, N'$. Then any combination

$$R(\xi) = \sum_{k=1}^{N} \alpha_k E_k(\xi^2) + \sum_{\ell=1}^{N'} \beta_\ell \xi O_\ell(\xi^2)$$

is also Hurwitz whenever all the α_k's and β_ℓ's are positive. In order to see this, simply observe that, in the obvious notation, (4.12) yields

$$B(\zeta, \eta) = \sum_{k=1}^{N} \sum_{\ell=1}^{N'} \alpha_k \beta_\ell B_{k,\ell}(\zeta, \eta)$$

and the conclusion follows.

This may be applied to interval polynomials. Assume that $R \in R[\xi]$ is given by $R(\xi) = R_0 + R_1\xi + \cdots + R_n\xi^n$, with $R_k \in [a_k, A_k]$. The question arises under what conditions all these polynomials are Hurwitz. The *weak Kharitonov* test states that this is the case iff the 2^n extreme polynomials, that is, those obtained by replacing each R_k by a_k or A_k, are all Hurwitz. This result is an immediate consequence of the above. With a little bit of extra work, we can also obtain the *strong Kharitonov* test [15] which states that the interval polynomials are Hurwitz iff the four *Kharitonov* polynomials obtained by taking the initial sequences $a_0, a_1, A_2, \ldots$, or $a_0, A_1, A_2, \ldots$, or $A_0, A_1, a_2, \ldots$, or $A_0, a_1, a_2, \ldots$, and continuing by alternating between two consecutive maxima and minima, are all Hurwitz. Indeed (see [20]), observe that for all $\omega, R(i\omega)$ lies in the rectangle in the complex plane spanned by the four points obtained by taking for R the Kharitonov polynomials. This rectangle does not contain the origin since, by the above, the convex hull of the Kharitonov polynomials contains only Hurwitz polynomials if the Kharitonov polynomials are themselves Hurwitz.

5. Average positivity. Up to now, we have considered positivity of QDFs and its use in establishing stability through Lyapunov functions. However, in many applications, especially in control theory, we are interested in an average type of positivity. In section 3, we already discussed when $\int Q_\Phi$ is zero. We now study when it is positive. With an eye towards applications in LQ and H_∞ control we have to distinguish several (unfortunately not less than three) types of average positivity. All of them have quite logical definitions.

DEFINITION 5.1. *Let $\Phi \in \mathbb{R}^{q\times q}_s[\zeta, \eta]$. The QDF Q_Φ (or simply Φ) is said to be*

1. average nonnegative*, denoted $\int Q_\Phi \geq 0$, if $\int_{-\infty}^{+\infty} Q_\Phi(w)dt \geq 0$ for all $w \in \mathfrak{D}(\mathbb{R}, \mathbb{R}^q)$,*
2. average positive*, denoted by $\int Q_\Phi > 0$, if $\int Q_\Phi \geq 0$ and if $\int_{-\infty}^{+\infty} Q_\Phi(w)dt = 0$ implies $w = 0$,*
3. strongly average positive*, denoted $\int Q_\Phi \overset{\text{per}}{>} 0$, if for all nonzero periodic $w \in \mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^q)$ there holds $\frac{1}{T}\int_0^T Q_\Phi(w)dt > 0$, where T denotes the period of w.*

Note that (3) looks somewhat different from the other definitions in this paper since, for the first time, periodic functions are involved. Actually, wherever in the paper definitions refer to compact support functions, they could have been written just as well in terms of periodic functions. However, strong average positivity is the only instance where the converse is not true.

PROPOSITION 5.2. *Let $\Phi \in \mathbb{R}^{q\times q}_s[\zeta, \eta]$. Then*

(i) $(\int Q_\Phi \geq 0) \Longleftrightarrow (\partial\Phi(i\omega) \geq 0 \ \ \forall\omega \in \mathbb{R})$.

(ii) $(\int Q_\Phi > 0) \Longleftrightarrow (\partial\Phi(i\omega) \geq 0 \ \ \forall\omega \in \mathbb{R}$ *and* $\det(\partial\Phi) \neq 0)$.

(iii) $(\int Q_\Phi \overset{\text{per}}{>} 0) \Longleftrightarrow (\partial\Phi(i\omega) > 0 \ \ \forall\omega \in \mathbb{R})$.

Proof. For the proof, see the appendix.

Concerning the equivalence (ii), note that $\partial\Phi(i\omega) \geq 0 \ \forall\omega \in \mathbb{R}$ and $\det(\partial\Phi) \neq 0$ is equivalent to: $\partial\Phi(i\omega) > 0$ for all but finitely many $\omega \in \mathbb{R}$.

Intuitively, we think of $Q_\Phi(w)$ as the power going into a physical system. In many applications, the power is indeed a quadratic differential form of some system variables. For example, in mechanical systems, it is $\sum_k F_k \frac{dq_k}{dt}$ with F_k the external force acting on the system, and q_k the position of the kth pointmass; in electrical circuits it is $\sum_k V_k I_k$, with V_k the potential and I_k the current going into the circuit at the kth terminal. Note that in these examples the variables are themselves also related. When this relation is expressed as an image representation, then we obtain a general QDF in terms of latent variables for the power delivered to a system.

Average nonnegativity states that the net flow of energy going into the system is nonnegative: the system dissipates energy. Of course, sometimes energy flows into the system, while at other times it flows out of it. This outflow is due to the fact that energy is stored. However, because of dissipation, the rate of increase of storage cannot exceed the supply. This interaction between supply, storage, and dissipation is now formalized.

DEFINITION 5.3. *Let $\Phi \in \mathbb{R}^{q\times q}_s[\zeta,\eta]$ induce the QDF Q_Φ. The QDF Q_Ψ induced by $\Psi \in \mathbb{R}^{q\times q}_s[\zeta,\eta]$ is said to be a* storage function *for Φ if*

$$\frac{d}{dt}Q_\Psi \leq Q_\Phi. \tag{5.1}$$

A QDF Q_Δ induced by $\Delta \in \mathbb{R}^{q\times q}_s[\zeta,\eta]$ is said to be a dissipation function *for Φ if*

$$\Delta \geq 0 \text{ and } \int Q_\Phi = \int Q_\Delta. \tag{5.2}$$

The next proposition shows that one can always interpret average positivity by an instantaneous positivity condition involving the difference between the rate of change of storage function and the supply rate.

PROPOSITION 5.4. *The following conditions are equivalent:*

1. $\int Q_\Phi \geq 0$,
2. Φ *admits a storage function,*
3. Φ *admits a dissipation function.*

Moreover, there is a one-one relation between storage and dissipation functions, Ψ and Δ, respectively, defined by

$$\frac{d}{dt}Q_\Psi(w) = Q_\Phi(w) - Q_\Delta(w)$$

equivalently, $\overset{\bullet}{\Psi} = \Phi - \Delta$, i.e.,

$$\Psi(\zeta,\eta) = \frac{\Phi(\zeta,\eta) - \Delta(\zeta,\eta)}{\zeta+\eta}. \tag{5.3}$$

Proof. For the proof, see the appendix.

Of course, we should expect that a storage function is related to memory, to state. The question, however, is: *the state of which system*? After all, we are considering a QDF, not a dynamical system. However, the factorization of Φ as

$$\Phi(\zeta,\eta) = M^T(\zeta)\Sigma_M M(\eta) \tag{5.4}$$

discussed earlier in section 3 allows us to introduce a state for the QDF Q_Φ. Indeed, (5.4) induces the dynamical system in image representation

$$v = M\left(\frac{d}{dt}\right)w. \tag{5.5}$$

Note that in (5.5) we are considering w as the latent variable and v as the manifest one. This is in keeping with the idea that $v^T\Sigma_M v$, the supply rate, is the variable of interest and that w is a latent variable that explains it. We are hence considering the behavior of the possible trajectories v. Assume that M has r rows, i.e., that

$M \in \mathbb{R}^{r\times q}[\xi]$. Thus, (5.5) defines a system $\mathfrak{B} \in \mathfrak{L}^r$ with $\mathfrak{B} = \mathrm{im}(M(\frac{d}{dt}))$ and $M(\frac{d}{dt})$ viewed as a map from $\mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^q)$ to $\mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^r)$. Hence this system has a state representation. Assume that

$$x = X\left(\frac{d}{dt}\right) w \tag{5.6}$$

induces such a state representation. Thus $X \in \mathbb{R}^{\bullet\times q}[\xi]$ is a polynomial matrix defining a state map for $\mathfrak{B} = \mathrm{im}(M(\frac{d}{dt}))$. Let $\Psi \in \mathbb{R}^{q\times q}_s[\zeta, \eta]$. Then the QDF Q_Ψ is said to be a *state function* (relative to the state of Φ) if there exists a real (symmetric) matrix P such that

$$Q_\Psi(w) = \|X\left(\frac{d}{dt}\right) w\|^2_P. \tag{5.7}$$

It is said to be a *state/supply function* if there exists a real (symmetric) matrix E such that

$$Q_\Psi(w) = \| \begin{bmatrix} M(\frac{d}{dt}) \\ X(\frac{d}{dt}) \end{bmatrix} w\|^2_E \tag{5.8}$$

where, as always, $\|a\|^2_A$ denotes $a^T Aa$. Note that the factorization (5.4) is not unique. However, any such factorization is related in a simple way to a canonical one, say, to

$$\Phi(\zeta, \eta) = \hat{M}^T(\zeta)\Sigma_\Phi \hat{M}(\eta) \tag{5.9}$$

by the existence of a matrix $F \in \mathbb{R}^{\bullet\times\bullet}$ such that $\hat{M}(\xi) = FM(\xi)$. This relation has as a consequence that any (possibly nonminimal) state map X for the system in image representation (5.5) is related in a static way to a minimal state map $\hat{X}$ associated with the system in image representation

$$\hat{v} = \hat{M}\left(\frac{d}{dt}\right) w \tag{5.10}$$

based on a canonical factorization. Indeed, there exists a matrix $L \in \mathbb{R}^{\bullet\times\bullet}$ such that

$$\hat{X}(\xi) = LX(\xi). \tag{5.11}$$

Thus, considering arbitrary (i.e., not necessarily canonical) factorizations and arbitrary (i.e., not necessarily minimal) state representations yields *a* (rather than *the*) state of Q_Φ. Thus, the situation with the state is similar to the situation with the state of a system $\mathfrak{B} \in \mathfrak{L}^q$.

We have the following important result.

THEOREM 5.5. *Let $\int Q_\Phi \geq 0$, and let $\Psi \in \mathbb{R}^{q\times q}_s[\zeta, \eta]$ be a storage function for Φ, i.e., $\overset{\bullet}{\Psi} \leq \Phi$. Then Ψ is a state function. Let $\Delta \in \mathbb{R}^{q\times q}_s[\zeta, \eta]$ be a dissipation function for Φ. Then Δ is a state/supply function. In fact, if $X \in \mathbb{R}^{\bullet\times q}[\xi]$ is a state map for Φ, then there exist real symmetric matrices P and E such that*

$$\Psi(\zeta, \eta) = X^T(\zeta)PX(\eta), \tag{5.12}$$

$$\Delta(\zeta, \eta) = \begin{bmatrix} M(\zeta) \\ X(\zeta) \end{bmatrix}^T E \begin{bmatrix} M(\eta) \\ X(\eta) \end{bmatrix}. \tag{5.13}$$

Equivalently

$$L_\Psi(w_1, w_2) = \left(X\left(\frac{d}{dt}\right) w_1\right)^T PX\left(\frac{d}{dt}\right) w_2,$$

$$L_\Delta(w_1, w_2) = \begin{bmatrix} M(\frac{d}{dt})w_1 \\ X(\frac{d}{dt})w_1 \end{bmatrix}^T E \begin{bmatrix} M(\frac{d}{dt})w_2 \\ X(\frac{d}{dt})w_2 \end{bmatrix}$$

for all $w_1, w_2 \in \mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^q)$.

Proof. For the proof, see the appendix.

Let $\Gamma \in \mathbb{R}^{q\times q}[\xi]$ be para-Hermitian: $\Gamma^\star = \Gamma$. An $F \in \mathbb{R}^{q\times q}[\xi]$ is said to induce a *symmetric factorization* of Γ if $\Gamma(\xi) = F^T(-\xi)F(\xi)$. It is said to be a *symmetric Hurwitz factorization* if F is square and Hurwitz and a *symmetric anti-Hurwitz factorization* if $F^\star$ is square and Hurwitz. It is easy to see that for a symmetric factorization to exist we need to have $\Gamma(i\omega) \geq 0\ \forall \omega \in \mathbb{R}$ and for an (anti-)Hurwitz one to exist we must have $\Gamma(i\omega) > 0\ \forall \omega \in \mathbb{R}$. The converses are also true but not at all trivial in the matrix case. This result is well known (see, e.g., [9], [10], [18], [21]), and we state it for easy reference.

PROPOSITION 5.6. *Let* $\Gamma \in \mathbb{R}^{q\times q}[\xi]$ *be para-Hermitian. Then*

(i) Γ *allows a symmetric factorization iff* $\Gamma(i\omega) \geq 0$ *for all* $\omega \in \mathbb{R}$.

(ii) Γ *allows a symmetric Hurwitz factorization iff* $\Gamma(i\omega) > 0$ *for all* $\omega \in \mathbb{R}$. *Such a factorization* $\Gamma(\xi) = F^T(-\xi)F(\xi)$ *is unique up to premultiplication of* $F(\xi)$ *by an orthogonal matrix.*

(iii) Γ *allows a symmetric anti-Hurwitz factorization iff* $\Gamma(i\omega) > 0$ *for all* $\omega \in \mathbb{R}$. *Such a factorization* $\Gamma(\xi) = F^T(-\xi)F(\xi)$ *is unique up to premultiplication of* $F(\xi)$ *by an orthogonal matrix.*

An important issue of concern is the uniqueness of the storage function, and therefore of the dissipation function, because of the one-to-one relation between the two. When $\int Q_\Phi = 0$, then the associated storage function is unique ($\Psi(\zeta, \eta) = \frac{\Phi(\zeta,\eta)}{\zeta+\eta}$) and the dissipation function is zero. However, in general there are many possibilities.

THEOREM 5.7. *Let* $\int Q_\Phi \geq 0$. *Then there exist storage functions* Ψ_- *and* Ψ_+ *for* Φ *such that any other storage function* Ψ *for* Φ *satisfies*

$$\Psi_- \leq \Psi \leq \Psi_+. \tag{5.14}$$

If $\int Q_\Phi \overset{per}{>} 0$ *then* Ψ^- *and* Ψ^+ *may be constructed as follows. Let* $\partial\Phi(\xi) = H^T(-\xi)H(\xi)$ *and* $\partial\Phi(\xi) = A^T(-\xi)A(\xi)$ *be, respectively, Hurwitz and anti-Hurwitz factorizations of* $\partial\Phi$. *Then*

$$\Psi_+(\zeta, \eta) = \frac{\Phi(\zeta, \eta) - A^T(\zeta)A(\eta)}{\zeta + \eta} \tag{5.15}$$

and

$$\Psi_-(\zeta, \eta) = \frac{\Phi(\zeta, \eta) - H^T(\zeta)H(\eta)}{\zeta + \eta}. \tag{5.16}$$

Proof. For the proof, see the appendix.

We close this section with a few remarks.

Remark 5.8. In this section we have studied average positivity with, in $Q_\Phi(w)$, $w \in \mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^q)$ or $\mathfrak{D}(\mathbb{R}, \mathbb{R}^q)$, but otherwise free. It is of interest to generalize these

concepts to the case that $w \in \mathfrak{B}$ with $\mathfrak{B}$ a given element of $\mathfrak{L}^q$. Of course, in section 4 we have considered precisely such situations for $\mathfrak{B}$'s that are *autonomous*. Actually, it turns out that the theory of section 5 is immediately applicable to systems $\mathfrak{B} \in \mathfrak{L}^q$ that are *controllable*. Indeed, let $\mathfrak{B} \in \mathfrak{L}^q$ be controllable and assume that we want to study when

$$\int_{-\infty}^{+\infty} Q_\Phi(w)dt \geq 0 \quad \text{or} \quad \int_{-\infty}^{+\infty} Q_\Phi(w)dt = 0 \tag{5.17}$$

holds for all $w \in \mathfrak{B} \cap \mathfrak{D}(\mathbb{R}, \mathbb{R}^q)$. Simply construct an image representation for $\mathfrak{B}$, say,

$$w = M\left(\frac{d}{dt}\right)\ell. \tag{5.18}$$

Upon substituting (5.18) in (5.17), we see that the issue then becomes one of studying when

$$\int_{-\infty}^{+\infty} Q_\Phi\left(M\left(\frac{d}{dt}\right)\ell\right)dt \geq 0 \quad \text{or} \quad \int_{-\infty}^{+\infty} Q_\Phi\left(M\left(\frac{d}{dt}\right)\ell\right)dt = 0$$

for all $\ell \in \mathfrak{D}(\mathbb{R}, \mathbb{R}^\bullet)$. Since obviously $Q_\Phi(M(\frac{d}{dt})\ell) = Q_{\Phi'}(\ell)$ with

$$\Phi'(\zeta, \eta) := M^T(\zeta)\Phi(\zeta, \eta)M(\eta),$$

the problem reduces to studying Φ'. For example, the existence of a storage function is established as follows. Without loss of generality, take (5.18) to be an observable image representation. Then M has a polynomial left inverse $M^\dagger$. By Proposition 5.4, there exists Ψ' such that $\frac{d}{dt}Q_{\Psi'}(\ell) \leq Q_{\Phi'}(\ell)$ for all $\ell \in \mathfrak{D}(\mathbb{R}, \mathbb{R}^\bullet)$. Now define $\Psi(\zeta, \eta) := M^{\dagger T}(\zeta)\Psi'(\zeta, \eta)M^\dagger(\eta)$. Then for $w = M(\frac{d}{dt})\ell$ we have $Q_\Psi(w) = Q_{\Psi'}(M^\dagger(\frac{d}{dt})w) = Q_{\Psi'}(\ell)$ and $Q_\Phi(w) = Q_{\Phi'}(\ell)$, so we obtain $\frac{d}{dt}Q_\Psi(w) \leq Q_\Phi(w)$.

The case that $\mathfrak{B} \in \mathfrak{L}^q$ is neither controllable nor autonomous will be studied in a later publication. The next comment is relevant to the question of what the appropriate definition of dissipativity is in that case.

Remark 5.9. Finding an appropriate definition of a dissipative system is an issue that has attracted considerable attention (see [29], [12], [24], [27]). Of course, this is at the root of the issues discussed in the present article. Let $\mathfrak{B} \in \mathfrak{L}^q$. There are many examples where the instantaneous rate of supply (say, of energy) into the system is given, not by a static function of the external variables, but by a QDF, $Q_\Phi(w)$. The study of supply rates that are themselves dynamic is one of the novel aspects of the present paper. When would one want to call $\mathfrak{B}$ dissipative with respect to $Q_\Phi(w)$? Lossless? Conservative? When would one want to say that $\mathfrak{B}$ absorbs some of the supply? The definitions of average nonnegativity for dissipativeness, and $\int Q_\Phi = 0$ for losslessness (= conservativeness), are fully adequate *provided* that $\mathfrak{B}$ *is controllable* (see Remark 5.8). However, Proposition 5.4 points to another definition which does not need controllability and which, in the controllable case, reduces to it. Thus, we arrive at the following definition as the most general: $\mathfrak{B} \in \mathfrak{L}^q$ is said to be *dissipative* with respect to the supply rate Q_Φ if there exists a Q_Ψ such that $\frac{d}{dt}Q_\Psi(w) \leq Q_\Phi(w)$ for all $w \in \mathfrak{B}$, and *lossless, or conservative,* if this holds with equality. The unfortunate aspect of this definition is its *existential* nature — it shares this notorious feature with the first and second law of thermodynamics. It does not seem an easy matter in the noncontrollable case to reduce this to a statement involving only Q_Φ, and without

invoking a to-be-constructed Q_Ψ. In Theorem 5.5 we have unraveled this existence question a bit by proving that this Q_Ψ will be a state function.

Note that the proposed definition of dissipativity and losslessness is an interesting generalization of the notion of a Lyapunov function since, for autonomous systems, it is natural to take the external supply $\Phi = 0$. Also note that this definition holds for any $\mathfrak{B}$ and Φ and does not require the introduction of the notion of state. In other words, dynamical systems with free variables that allow interaction with the environment relate to flows on manifolds, just as dissipative systems relate to Lyapunov functions.

Remark 5.10. Let $\mathfrak{B}$ be controllable and assume that it is dissipative with respect to the supply rate $Q_\Phi(w)$ (see Remark 5.9). Also in this general case every storage function is a state function, and every dissipation function is a state/supply function. However, this time, not simply the state of Φ is involved, but the state of a system obtained by combining the dynamics of Φ and $\mathfrak{B}$. This is elaborated in [26].

Remark 5.11. Let $\Phi(\zeta, \eta) = M^T(\zeta)\Sigma_M M(\eta)$. Consider the system in image representation (5.5). Then it can be shown that for Φ to be average nonnegative, there must be an input/output partition for this system so that all the input components correspond to +1's in Σ_Φ. In other words, the supply rate $v^T\Sigma_M v$ is always of the form $\|u\|^2 + \|y_1\|^2 - \|y_2\|^2$, with u an input, and y_1, y_2 outputs.

Remark 5.12. It follows from Theorem 5.5 that a factorization of the polynomial matrix $\Phi(-\xi, \xi) = M^T(-\xi)\Sigma_M M(\xi)$ into $F^T(-\xi)F(\xi)$ always leads to a situation in which the McMillan degree of M is equal to that of $\mathrm{col}(M, F)$. This means that the factorization is a *regular* factorization (as this property is called). In the H_∞-problem factorization, questions are encountered in which the existence of a regular factorization poses a serious problem.

Remark 5.13. It is easy to see that the set of storage functions corresponding to a given supply rate is convex. Moreover, in the case of average positivity, $\Psi_- \neq \Psi_+$ and hence, in this case, there are an infinite number of possible storage functions. Actually, in this respect it is worth mentioning the following refinement of Theorem 5.7, which follows immediately from our proof of this theorem. If $\Phi(-\xi, \xi)$ satisfies $\Phi(-i\omega, i\omega) \geq 0$ (but not $\Phi(-i\omega, i\omega) > 0$) for all $\omega \in \mathbb{R}$, then a symmetric Hurwitz factorization does not exist. In this case, there are two possibilities: either $\det(\partial\Phi) \neq 0$ or $\det(\partial\Phi) = 0$. In the former case, $\Phi(-\xi, \xi)$ allows a factorization $\Phi(-\xi, \xi) = H^T(-\xi)H(\xi)$ with H "almost Hurwitz" (i.e., H has all its singularities in $\Re e(\lambda) \leq 0$). In the latter case, there exists a unimodular matrix U such that

$$\Phi(\zeta, \eta) = U^T(\zeta)\Phi'(\zeta, \eta)U(\eta),$$

with Φ' of the form

$$\Phi' = \begin{bmatrix} \Phi_1 & \Phi_2 \\ \Phi_2^* & \Phi_3 \end{bmatrix},$$

with $\det(\partial\Phi_1) \neq 0$ and $\partial\Phi_2 = 0$, $\partial\Phi_3 = 0$. Factor $\Phi_1(-\xi, \xi)$ as before as $H_1^T(-\xi)H_1(\xi)$. Then

$$H = \begin{bmatrix} H_1 & 0 \\ 0 & 0 \end{bmatrix} U_1$$

yields an almost Hurwitz-like factorization of $\partial\Phi$. Similarly, we can define an almost anti-Hurwitz-like factorization $\partial\Phi = A^\star A$ of any Φ satisfying $\Phi(-i\omega, i\omega) \geq 0$ for all $\omega \in \mathbb{R}$. The computation of Ψ_+ and Ψ_- given in Theorem 5.7 holds unaltered with

this A and H. Note that in the lossless case ($\partial\Phi = 0$) this yields $\Psi_+ = \Psi_-$, whence the uniqueness of Ψ.

Remark 5.14. It is easy to deduce from the proof of Theorem 5.7 that Ψ_- and Ψ_+ have the following interpretations. Let $x = X(\frac{d}{dt})w$ be the state (see 5.6). Let $a \in \mathbb{R}^n$. Consider all $w \in \mathfrak{D}(\mathbb{R}, \mathbb{R}^q)$ such that $(X(\frac{d}{dt})w)(0) = a$. Denote this set by $\mathfrak{B}_a$. By Theorem 5.5 we know that Q_{Ψ_-} is a state function, say, $Q_{\Psi_-}(w) = \|X(\frac{d}{dt})w\|_{K_-}$, for some symmetric matrix $K_- \in \mathbb{R}^{n\times n}$. Hence for $w \in \mathfrak{B}_a$ we have $Q_{\Psi_-}(w)(0) = a^T K_- a$. Similarly $Q_{\Psi_+}(w)(0) = a^T K_+ a$ for some symmetric matrix K_+. Then it can be shown that

$$a^T K_- a = \sup_{w\in\mathfrak{B}_a} \left(-\int_0^{+\infty} Q_\Phi(w)dt \right) \tag{5.19}$$

and

$$a^T K_+ a = \inf_{w\in\mathfrak{B}_a} \left(\int_{-\infty}^{0} Q_\Phi(w)dt \right). \tag{5.20}$$

For this reason, $Q_{\Psi_-}(w)(0)$ is called the *available storage* and $Q_{\Psi_+}(w)(0)$ the *required supply* at $t = 0$ due to w. In this inf and sup, one keeps the past, respectively, the future of w fixed.

6. Half-line positivity. In section 5, we studied QDFs for which $\int_{-\infty}^{+\infty} Q_\Phi(w)dt \geq 0$. The intuitive idea was that this expresses that the net supply (of "energy") is directed into the system: energy is being absorbed and dissipated in the system. There are, however, situations where at any moment in time the system has absorbed energy, i.e., $\int_{-\infty}^{t} Q_\Phi(w)(\tau)d\tau \geq 0$ for all $t \in \mathbb{R}$. For example, electrical circuits and mechanical devices at rest are in a state of minimum energy, and therefore the energy delivered *up to any time* is nonnegative. This type of positivity is studied in this section. It plays a crucial role in H_∞ problems.

DEFINITION 6.1. *Let $\Phi \in \mathbb{R}^{q\times q}_s[\zeta, \eta]$. The QDF Q_Φ (or simply Φ) is said to be* half-line nonnegative*, denoted by $\int^t Q_\Phi \geq 0$, if $\int_{-\infty}^0 Q_\Phi(w)dt \geq 0$ for all $w \in \mathfrak{D}(\mathbb{R}, \mathbb{R}^q)$, and* half-line positive*, denoted $\int^t Q_\Phi > 0$, if in addition $\int_{-\infty}^0 Q_\Phi(w)dt = 0$ implies $w(t) = 0$ for $t \leq 0$.*

Note that half-line nonnegativity implies average nonnegativity, and that half-line positivity implies average positivity.

Write $\Phi(\zeta, \eta) = M^T(\zeta)\Sigma_M M(\eta)$ and partition M conform Σ_M as

$$M = \begin{bmatrix} P \\ N \end{bmatrix} \tag{6.1}$$

so that $\Phi(\zeta, \eta) = P^T(\zeta)P(\eta) - N^T(\zeta)N(\eta)$ and hence $Q_\Phi(w) = \|P(\frac{d}{dt})w\|^2 - \|N(\frac{d}{dt})w\|^2$. In the following, for $\lambda \in \mathbb{C}$, let $\bar{\lambda}$ denote its complex conjugate.

PROPOSITION 6.2. *Let $\Phi \in \mathbb{R}^{q\times q}_s[\zeta, \eta]$. Then*

(i) $(\int^t Q_\Phi \geq 0) \Rightarrow (\Phi(\bar{\lambda}, \lambda) \geq 0 \ \forall \lambda \in \mathbb{C}, \Re e(\lambda) \geq 0)$

(ii) $(\int^t Q_\Phi > 0) \Rightarrow (\Phi(\bar{\lambda}, \lambda) \geq 0 \ \forall \lambda \in \mathbb{C}, \Re e(\lambda) \geq 0$ *and* $\det(\partial\Phi) \neq 0)$.

Proof. For the proof, see the appendix.

As noted before, it immediately follows from the definitions that half-line nonnegativity implies average nonnegativity, etc. Thus, Proposition 5.4 implies the existence of a storage function. It is the nonnegativity of the storage function that allows us to conclude the *half-line* positivity.

THEOREM 6.3. *Let $\Phi \in \mathbb{R}^{q\times q}_s[\zeta, \eta]$. Then the following statements are equivalent.*

1. $\int^t Q_\Phi \geq 0$,
2. *there exists a storage function* $\Psi \geq 0$ *for* Φ,
3. Φ *admits a storage function, and the storage function* Ψ_+ *defined in Theorem* 5.7 *satisfies* $\Psi_+ \geq 0$.

Proof. For the proof, see the appendix.

In order to check half-line nonnegativity, one could thus in principle proceed as follows. Verify that $\Phi(-i\omega, i\omega) \geq 0$ for all $\omega \in \mathbb{R}$, compute Ψ_+, and check whether $\Psi_+ \geq 0$. In some situations, it is actually possible to verify this condition in a more immediate fashion; for example, when $\Phi(\zeta, \eta) = \Phi_0$, a constant matrix, with $\Phi_0 \geq 0$ (trivial, but that is the case that occurs in standard LQ theory!), or when in (6.1) P is square and $\det(P) \neq 0$. Then, under the assumption that a storage function exists (equivalently: $N^T(-i\omega)N(i\omega) \leq P^T(-i\omega)P(i\omega)$ for all $\omega \in \mathbb{R}$), all storage functions are actually nonnegative if one of them is nonnegative. In fact, in this case the following theorem holds.

THEOREM 6.4. *Let* $\Phi \in \mathbb{R}^{q\times q}_s[\zeta, \eta]$. *Assume it is factored as* $\Phi(\zeta, \eta) = P^T(\zeta)P(\eta) - N^T(\zeta)N(\eta)$ *with* P *square and* $\det(P) \neq 0$. *Let* $X \in \mathbb{R}^{\bullet\times q}[\xi]$ *be a minimal state map for the* $\mathfrak{B}$ *given in image representation by* (6.1). *The following statements are equivalent:*

1. $\int^t Q_\Phi \geq 0$,
2. $\Phi(\bar{\lambda}, \lambda) \geq 0$ *for all* $\lambda \in \mathbb{C}$, $\Re e(\lambda) \geq 0$,
3. NP^{-1} *has no poles in* $\Re e(\lambda) \geq 0$ *and* $\Phi(-i\omega, i\omega) \geq 0$ *for all* $\omega \in \mathbb{R}$,
4. *there exists a storage function* $\Psi \geq 0$ *for* Φ,
5. *there exists a storage function for* Φ *and every storage function* Ψ *for* Φ *satisfies* $\Psi \geq 0$,
6. *there exists a real symmetric matrix* $K > 0$ *such that* $Q_K(w) := \|X(\frac{d}{dt})w\|^2_K$ *is a storage function for* Φ,
7. *there exists a storage function for* Φ *and every real symmetric matrix* K *such that* $Q_K(w) := \|X(\frac{d}{dt})w\|^2_K$ *is a storage function for* Φ *satisfies* $K > 0$.

Furthermore, if $\left[\begin{smallmatrix} P \\ N \end{smallmatrix}\right]$ *is observable, then any of the above statements is equivalent with*

3′. P *is Hurwitz and* $\Phi(-i\omega, i\omega) \geq 0$ *for all* $\omega \in \mathbb{R}$.

Proof. For the proof, see the appendix.

7. Observability. One of the noticeable features of QDFs is that a number of interesting systems theory concepts generalize very nicely to QDFs. We have already seen that the state of a symmetric canonical factorization of Φ functions as the state of the QDF Q_Φ. In this section we introduce observability of a QDF. In a later section we will discuss duality of QDFs.

For $\Phi \in \mathbb{R}^{q_1\times q_2}[\zeta, \eta]$ and $w_1 \in \mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^{q_1})$ fixed, the linear map $w_2 \mapsto L_\Phi(w_1, w_2)$ is denoted by $L_\Phi(w_1, \bullet)$. For $w_2 \in \mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^{q_2})$ fixed, the linear map $w_1 \mapsto L_\Phi(w_1, w_2)$ is denoted by $L_\Phi(\bullet, w_2)$. The BLDF Φ is called observable if $L_\Phi(w_1, \bullet)$ and $L_\Phi(\bullet, w_2)$ determine w_1 and w_2 uniquely. Equivalently we have the following.

DEFINITION 7.1. *Let* $\Phi \in \mathbb{R}^{q_1\times q_2}[\zeta, \eta]$. *We call* Φ observable *if, for all* $w_1 \in \mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^{q_1})$ *and for all* $w_2 \in \mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^{q_2})$, *we have*

$$L_\Phi(w_1, \bullet) = 0 \;\Leftrightarrow\; w_1 = 0$$

and

$$L_\Phi(\bullet, w_2) = 0 \;\Leftrightarrow\; w_2 = 0.$$

The following theorem gives necessary and sufficient conditions for observability purely in terms of the two-variable polynomial matrix Φ and in terms of the (one-

variable) polynomial matrices N and M occurring in any canonical factorization of Φ.

THEOREM 7.2. *Let $\Phi(\zeta,\eta) = N^T(\zeta)M(\eta)$ be a canonical factorization. The following statements are equivalent:*

1. *Φ is observable,*
2. *for every $\lambda \in \mathbb{C}$, the rows of $\Phi(\lambda,\xi) \in \mathbb{R}^{q_1\times q_2}[\xi]$, and the columns of $\Phi(\xi,\lambda) \in \mathbb{R}^{q_1\times q_2}[\xi]$ are linearly independent over $\mathbb{C}$,*
3. *$N(\lambda)$ and $M(\lambda)$ have full column rank for all $\lambda \in \mathbb{C}$; equivalently, the image representations $v_1 = N(\frac{d}{dt})w_1$ and $v_2 = M(\frac{d}{dt})w_2$ are observable,*

Proof. For the proof, see the appendix.

If Φ is symmetric, then we have $\Phi^T(\lambda,\xi) = \Phi(\xi,\lambda)$, so condition (ii) above can be replaced by a single statement on the independence of the rows of $\Phi(\lambda,\xi)$. Also, in this case the maps $L_\Phi(w,\bullet)$ and $L_\Phi(\bullet,w)$ coincide. Furthermore, for the particular symmetric canonical factorization $\Phi(\zeta,\eta) = M_c^T(\zeta)\Sigma_\Phi M_c(\eta)$ obtained from (3.15), we have $|\Phi|(\zeta,\eta) = M_c^T(\zeta)M_c(\eta)$. Hence observability of Φ is also equivalent with $|\Phi| > 0$ and with the condition $|\Phi|(\bar\lambda,\lambda) > 0$ for all $\lambda \in \mathbb{C}$. This immediately yields the following.

COROLLARY 7.3. *Let $\Phi \in \mathbb{R}_s^{q\times q}[\zeta,\eta]$ and let $\Phi(\zeta,\eta) = M^T(\zeta)\Sigma_\Phi M(\eta)$ be a symmetric canonical factorization. Then the following statements are equivalent:*

1. *Φ is observable,*
2. *$L_\Phi(w,\bullet) = 0 \;\Leftrightarrow\; w = 0$,*
3. *for every $\lambda \in \mathbb{C}$, the rows of $\Phi(\lambda,\xi) \in \mathbb{R}^{q_1\times q_2}[\xi]$ are linearly independent over $\mathbb{C}$,*
4. *$M(\lambda)$ has full column rank for all $\lambda \in \mathbb{C}$, equivalently, the image representation $v = M(\frac{d}{dt})w$ is observable,*
5. *$|\Phi| > 0$,*
6. *$|\Phi|(\bar\lambda,\lambda) > 0$ for all $\lambda \in \mathbb{C}$.*

8. Strict positivity. Throughout this section we assume that $\Phi \in \mathbb{R}_s^{q\times q}[\zeta,\eta]$ is observable. We now introduce and develop the notion of strict positivity. The concept of strict half-line positivity given here is very analogous to that used by Meinsma [19].

DEFINITION 8.1. *Let $\Phi \in \mathbb{R}_s^{q\times q}[\zeta,\eta]$ be observable. We call the QDF Q_Φ* strictly positive*, denoted $\Phi \gg 0$, if there exists $\epsilon > 0$ such that $\Phi - \epsilon|\Phi| \geq 0$. We call it* strictly average positive*, denoted by $\int Q_\Phi \gg 0$, if there exists $\epsilon > 0$ such that*

$$\int_{-\infty}^{+\infty} Q_\Phi(w)dt \geq \epsilon \int_{-\infty}^{+\infty} Q_{|\Phi|}(w)dt \tag{8.1}$$

for all $w \in \mathfrak{D}(\mathbb{R},\mathbb{R}^q)$. We call it strictly half-line positive*, denoted $\int^t Q_\Phi \gg 0$, if there exists an $\epsilon > 0$ such that*

$$\int_{-\infty}^{0} Q_\Phi(w)dt \geq \epsilon \int_{-\infty}^{0} Q_{|\Phi|}(w)dt \tag{8.2}$$

for all $w \in \mathfrak{D}(\mathbb{R},\mathbb{R}^q)$. Note that (because of observability) strict positivity implies positivity, and similarly for the other cases.

These notions of strict positivity involve $|\Phi|$ which may be difficult to evaluate. However, it is possible to relate it to any canonical factorization of Φ. This is stated in the next proposition. For simplicity we state only the case of strict average positivity. However, completely analogous statements hold for simple strict positivity or for strict half-line positivity.

PROPOSITION 8.2. *Let* $\Phi \in \mathbb{R}^{q\times q}_s[\zeta,\eta]$ *be observable and let* $\Phi(\zeta,\eta)=P^T(\zeta)P(\eta)-N^T(\zeta)N(\eta)$ *be a symmetric canonical factorization of* Φ (*see* (3.12)). *Denote* $M=\left[\begin{smallmatrix}P\\N\end{smallmatrix}\right]$ *The following are equivalent:*

1. Φ *is strictly average positive.*
2. *There exists an* $\epsilon>0$ *such that*

$$\int_{-\infty}^{+\infty} \|M\left(\frac{d}{dt}\right)w\|^2_{\Sigma_\Phi}dt \geq \epsilon \int_{-\infty}^{+\infty} \|M\left(\frac{d}{dt}\right)w\|^2 dt \tag{8.3}$$

for all $w\in\mathfrak{D}(\mathbb{R},\mathbb{R}^q)$. *Here* $\|a\|^2_{\Sigma_\Phi}$ *denotes* $a^T\Sigma_\Phi a$.

3. *There exists an* $\alpha<1$ *such that*

$$\int_{-\infty}^{+\infty} \|N\left(\frac{d}{dt}\right)w\|^2 dt \leq \alpha \int_{-\infty}^{+\infty} \|P\left(\frac{d}{dt}\right)w\| dt \tag{8.4}$$

for all $w\in\mathfrak{D}(\mathbb{R},\mathbb{R}^q)$.

Moreover, also for a noncanonical factorization (3.11), (2) *and* (3) *(with* Σ_Φ *replaced by* Σ_M) *are equivalent and imply* (1).

Proof. For the proof, see the appendix.

9. A Pick matrix condition for half-line positivity. It is surprisingly difficult to establish some type of analogue of Proposition 5.2 for half-line positivity, and earlier attempts [28], [30], [1]) turned out to be flawed. In Proposition 6.4 such an analogue of Proposition 5.2 was given but only in the special case where $\Phi(\zeta,\eta)=P^T(\zeta)P(\eta)-N^T(\zeta)N(\eta)$ with $\det(P)\neq 0$. In this section we give a necessary and sufficient condition for strict half-line positivity in terms of Φ.

As is well known, the Pick matrix plays an important role in system and circuit theory, in particular in connection with passivity properties of linear dynamical systems; see [34], [4], [5]. We derive a Pick-matrix-type test for nonnegativity of Ψ_+. This test is perhaps the most original specific result of this paper. For simplicity we consider only the case of strict half-line positivity. First, however, we need to define the Pick-type matrix which may be computed effectively from a $\Phi\in\mathbb{R}^{q\times q}_s[\zeta,\eta]$. Let $F\in\mathbb{R}^{q\times q}[\xi]$, and assume that $\det(F)\neq 0$. We call F *semisimple* if for all $\lambda\in\mathbb{C}$ the dimension of the kernel of $F(\lambda)$ is equal to the multiplicity of λ as a root of $\det(F)$. Note that F is certainly semisimple if $\det(F)$ has distinct roots. We now define the matrix T_Φ. Since the expression is much simpler in the semisimple case, we explain that case first.

DEFINITION 9.1 (semisimple case). *Let* $\Phi\in\mathbb{R}^{q\times q}_s[\zeta,\eta]$ *be observable, and assume that* $\det(\partial\Phi)$ *has no roots on the imaginary axis. Let* $\lambda_1,\lambda_2,\dots,\lambda_n\in\mathbb{C}$ *be the roots of* $\det(\partial\Phi)$ *with positive real part and let* $a_1,a_2,\dots,a_n\in\mathbb{C}^q$ *be such that* $\partial\Phi(\lambda_i)a_i=0$, *and such that the* a_k*'s associated with the same* λ_i *form a basis of* $\ker(\partial\Phi(\lambda_i))$. *Then the* Pick matrix *of* Φ *is defined as*

$$T_\Phi := \left[\frac{\bar a_i^T\Phi(\bar\lambda_i,\lambda_j)a_j}{\bar\lambda_i+\lambda_j}\right]_{i,j=1,\dots,n}. \tag{9.1}$$

In order to define the matrix T_Φ in the general case, we need to take into account the algebraic multiplicities of the roots λ_i.

DEFINITION 9.2 (general case). *Let* $\Phi\in\mathbb{R}^{q\times q}_s[\zeta,\eta]$ *be observable,* $\det(\partial\Phi)\neq 0$, *and assume that* $\det(\partial\Phi)$ *has no roots on the imaginary axis. Let* $\lambda_1,\lambda_2,\dots,\lambda_k\in\mathbb{C}$ *be the* distinct *roots of* $\det(\partial\Phi)$ *with positive real part, and denote by* n_i *the multiplicity*

of λ_i as a root of $\det(\partial\Phi)$. *For $i = 1, 2, \ldots, k$, there are n_i linearly independent vectors $a_{i,0}, a_{i,1}, \ldots, a_{i,n_i-1}$ determined by the (n_i) linear equations*

$$\sum_{j=\ell}^{n_i-1} \begin{pmatrix} j \\ \ell \end{pmatrix} (\partial\Phi)^{(j-\ell)}(\lambda_i) a_{i,j} = 0, \quad (\ell = 0, 1, \ldots, n_i - 1).$$

Here, $(\partial\Phi)^{(k)}(\xi)$ denotes the kth derivative of the polynomial matrix $\partial\Phi$.

For $i = 1, 2, \ldots, k$, define

$$A_i := \begin{bmatrix} a_{i,0} & 0 & \cdots & 0 \\ a_{i,0} & a_{i,1} & \ddots & \vdots \\ \vdots & \vdots & \ddots & 0 \\ a_{i,0} & a_{i,1} & \ldots & a_{i,n_i-1} \end{bmatrix} \in \mathbb{C}^{n_i q \times n_i}$$

Also, define $\Phi_{i,j} \in \mathbb{C}^{n_i q \times n_j q}$ by defining its (r,s)th block to be the $q \times q$ matrix

$$(\Phi_{i,j})_{r,s} := \Phi^{(r,s)}(\bar{\lambda}_i, \lambda_j), \quad r = 1, 2, \ldots, n_i \; ; \; s = 1, 2, \ldots, n_j,$$

where $\Phi^{(k,\ell)}$ means taking the kth partial derivative with respect to ζ and the ℓth with respect to η.

Then we define the Pick matrix *of Φ as the matrix T_Φ whose (i,j)th block is given by $T_{i,j} \in \mathbb{C}^{n_i \times n_j}$, with*

$$T_{i,j} := \frac{1}{\bar{\lambda}_i + \lambda_j} \bar{A}_i^T \Phi_{i,j} A_j.$$

Note that the sum $\sum_{i=1}^{k} n_i$ of the multiplicities is equal to $n := \frac{1}{2} \deg \det(\partial\Phi)$, and that T_Φ is a complex Hermitian matrix of size $n \times n$.

The next theorem is the most refined result of this paper. It shows, on the one hand, the relation between strict half-line positivity and positivity of a storage function, and, on the other hand, the relation with the positivity of the Pick matrix T_Φ.

We have seen in Theorem 5.5 that a storage function is a quadratic state function, i.e., $Q_\Phi(w)$ is of the form $x^T K x$, $K = K^T$, with $x = X(\frac{d}{dt})w$ a minimal state map for Φ. We call this state function *positive definite* if $K > 0$.

THEOREM 9.3. *Let $\Phi \in \mathbb{R}_s^{q \times q}[\zeta, \eta]$ be observable. The following are equivalent:*

1. $\int^t Q_\Phi \gg 0$,
2. (a) $\int Q_\Phi \gg 0$,
   (b) *there exists a storage function that is a positive definite state function,*
3. (a) $\exists \epsilon > 0$ *such that* $\Phi(-i\omega, i\omega) \geq \epsilon |\Phi|(-i\omega, i\omega)$ *for all* $\omega \in \mathbb{R}$,
   (b) $T_\Phi > 0$.

Proof. For the proof, see the appendix.

Remark 9.4. It follows from the proof of Theorem 9.3 that half-line nonnegativity implies that the Pick-type matrix T_Φ (see (9.1)) is ≥ 0 whenever any set of λ_i's in the right half of the complex plane and any set of a_i's are chosen. It is possible to prove that if T_Φ is nonnegative definite for any such choice for the λ_i's and a_i's, then we have half-line nonnegativity. The remarkable thing about Theorem 9.3 is that it suffices to evaluate T_Φ at the set of special λ_i's and a_i's obtained from the singularities of $\partial\Phi$.

Remark 9.5. It is well known that solvability of a certain Nevanlinna–Pick interpolation problem is equivalent to positive definiteness of a given Pick matrix. In fact, in [34] the necessity of the positive definite Pick matrix is shown using a half-line positivity argument. Theorem 9.3 states that positive definiteness of a given Pick matrix is also *sufficient* for half-line positivity.

Remark 9.6. It can be shown that if Φ is observable, then $\int Q_\Phi \gg 0$ implies that $\Psi_+ - \Psi_-$ is a positive definite state function, with Ψ_+ and Ψ_- as defined in Theorem 5.7.

Remark 9.7. It is possible to generalize the T_Φ-test of Theorem 9.3 to half-line positive (instead of strictly half-line positive QDFs) by including "infinite zeros" of $\det(\partial\Phi)$. However, the notation gets very involved, and therefore we will not do this here.

10. Duality. In the present section we discuss some remarkable relations between positivity of QDFs and their duals. These relations are of interest in their own right and will be of crucial importance in our treatment of the H_∞-problem [25].

Let $\mathfrak{B}_1$ and $\mathfrak{B}_2 \in \mathfrak{L}^q$. We call $\mathfrak{B}_1$ and $\mathfrak{B}_2$ *complementary* if $\mathfrak{B}_1 \oplus \mathfrak{B}_2 = \mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^q)$. It is easy to see that this implies that both $\mathfrak{B}_1$ and $\mathfrak{B}_2$ must be controllable: uncontrollable $\mathfrak{B}$'s in $\mathfrak{L}^q$ have no complement in $\mathfrak{L}^q$. We call them *dual* if they are complementary and if $\langle w_1, w_2\rangle = 0$ for all $w_1 \in \mathfrak{B}_1 \cap \mathfrak{D}(\mathbb{R}, \mathbb{R}^q)$ and $w_2 \in \mathfrak{B}_2 \cap \mathfrak{D}(\mathbb{R}, \mathbb{R}^q)$, where $\langle w_1, w_2\rangle$ denotes the usual inner product $\int_{-\infty}^{+\infty} w_1^T w_2 dt$. If this is the case, then we denote $\mathfrak{B}_2$ as $\mathfrak{B}_1^\perp$, since $\mathfrak{B}_1$ defines $\mathfrak{B}_1^\perp$ uniquely. Obviously we also have $(\mathfrak{B}_1^\perp)^\perp = \mathfrak{B}_1$.

It is easy to see that $R(\frac{d}{dt})w = 0$ is a minimal kernel representation of the controllable $\mathfrak{B}$ iff $v = R^T(-\frac{d}{dt})\ell$ is an observable image representation of $\mathfrak{B}^\perp$ (a kernel representation $R(\frac{d}{dt})w = 0$ of $\mathfrak{B}$ is called *minimal* if R has full row rank). Consequently, $w = M(\frac{d}{dt})\ell$ is an observable image representation of $\mathfrak{B}$ iff $M^T(-\frac{d}{dt})v = 0$ is a minimal kernel representation of $\mathfrak{B}^\perp$. This duality can also be extended to state representations, in the following sense. If

$$E\frac{dx}{dt} + Fx + Gw = 0, \tag{10.1}$$

is an n-dimensional minimal state representation of $\mathfrak{B}$, then $\mathfrak{B}^\perp$ admits an also n-dimensional minimal state representation (thus the dimensions of the minimal state representations are the same), say,

$$E'\frac{dz}{dt} + F'z + G'v = 0, \tag{10.2}$$

having the property that for all $(w, x) \in \mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^{q+n})$ satisfying (10.1), and for all $(v, z) \in \mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^{q+n})$ satisfying (10.2) there holds the following kind of duality involving the state

$$\frac{d}{dt}z^T x = v^T w. \tag{10.3}$$

In fact, this is an immediate consequence of the following.

PROPOSITION 10.1. *Let $R(\frac{d}{dt})w = 0$ and $w = M(\frac{d}{dt})\ell$ be a minimal kernel representation and an observable image representation, respectively, of the controllable system $\mathfrak{B} \in \mathfrak{L}^q$. Assume that $X \in \mathbb{R}^{n\times\bullet}[\xi]$ defines a minimal state map for $\mathfrak{B}$, i.e.,*

$x = X(\frac{d}{dt})\ell$ defines a minimal state of $\mathfrak{B}$. Then there exists a $Z \in \mathbb{R}^{n\times\bullet}[\xi]$ defining a minimal state map $Z(\frac{d}{dt})$ for $\mathfrak{B}^\perp$, such that for all $\ell, \ell' \in \mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^\bullet)$, we have

$$\frac{d}{dt}\left(Z\left(\frac{d}{dt}\right)\ell'\right)^T X\left(\frac{d}{dt}\right)\ell = \left(R^T\left(-\frac{d}{dt}\right)\ell'\right)^T M\left(\frac{d}{dt}\right)\ell. \tag{10.4}$$

If we define $\Psi(\zeta,\eta) := Z^T(\zeta)X(\eta)$ and $\Phi(\zeta,\eta) := R(-\zeta)M(\eta)$, then (10.4) is equivalent to $\overset{\bullet}{\Psi} = \Phi$.

Proof. For the proof, see the appendix.

If a pair of minimal state maps (X, Z) of $\mathfrak{B}$ and $\mathfrak{B}^\perp$ satisfies (10.4), then we call it a *matched pair* of state maps.

We now associate with a QDF a dual one and relate their average nonnegativity and average positivity. Let $\Phi \in \mathbb{R}^{q\times q}_s[\zeta,\eta]$ and let $\Phi(\zeta,\eta) = M^T(\zeta)\Sigma_\Phi M(\eta)$ be a symmetric canonical factorization, with

$$\Sigma_\Phi = \begin{bmatrix} I_{r_+} & 0 \\ 0 & -I_{r_-} \end{bmatrix}.$$

Let us assume that $M \in \mathbb{R}^{r\times q}[\xi]$. Partition M conformably to Σ_Φ as

$$M = \begin{bmatrix} P \\ N \end{bmatrix}$$

so that Φ is written as

$$\Phi(\zeta,\eta) = P^T(\zeta)P(\eta) - N^T(\zeta)N(\eta). \tag{10.5}$$

Consider the dynamical system $\mathfrak{B} \in \mathfrak{L}^r$ with image representation

$$w = M\left(\frac{d}{dt}\right)\ell. \tag{10.6}$$

There are a number of integers associated with M that are of interest to us:

$$r_+ = \operatorname{rowdim}(P), \tag{10.7}$$

$$r_- = \operatorname{rowdim}(N), \tag{10.8}$$

$$m = \operatorname{rank}(M)\ . \tag{10.9}$$

The number r_+ corresponds to the number of positive squares in Q_Φ, r_- to the number of negative squares, while m equals the number of inputs in any input/output or input/state/output representation of $\mathfrak{B}$. Since it is defined by an image representation, $\mathfrak{B}$ is a controllable system and, as such, it admits a dual, $\mathfrak{B}^\perp \in \mathfrak{L}^r$. Let $R(\frac{d}{dt})w = 0$ be a minimal kernel representation of $\mathfrak{B}$. Then

$$v = R^T\left(-\frac{d}{dt}\right)\ell' \tag{10.10}$$

is an observable image representation for $\mathfrak{B}^\perp$. Let $\Phi'(\zeta,\eta) := R(-\zeta)\Sigma_\Phi R^T(-\eta)$. Note that the QDFs $Q_\Phi(\ell) = (M(\frac{d}{dt})\ell)^T\Sigma_\Phi M(\frac{d}{dt})\ell$ and

$$Q_{\Phi'}(\ell') = \left(R^T\left(-\frac{d}{dt}\right)\ell'\right)^T \Sigma_\Phi R^T\left(-\frac{d}{dt}\right)\ell'$$

are in a sense also dual. Their positivity properties are very much related, as shown in the following theorem.

THEOREM 10.2. *Assume that $r_+ = m$. Then*

(i) $\int Q_\Phi \geq 0 \Leftrightarrow \int Q_{\Phi'} \leq 0$,
(ii) $\int Q_\Phi > 0 \Leftrightarrow \int Q_{\Phi'} < 0$,
(iii) (*assume* Φ *is observable*) $\int Q_\Phi \gg 0 \Leftrightarrow \int Q_{\Phi'} \ll 0$,
(iv) *Let* (X, Z) *be a matched pair of minimal state maps for* $\mathfrak{B}$ *and* $\mathfrak{B}^\perp$. *Assume that* $\int Q_\Phi \geq 0$, *and let* Ψ *define a storage function for* Φ. *By Theorem* 5.5, Ψ *is a state function, i.e., there exists a real symmetric matrix* K *such that*

$$Q_\Psi(\ell) = \left(X\left(\frac{d}{dt}\right)\ell\right)^T KX\left(\frac{d}{dt}\right)\ell. \tag{10.11}$$

Assume that K *is nonsingular. Then*

$$Q_{\Psi'}(\ell') = -\left(Z\left(\frac{d}{dt}\right)\ell'\right)^T K^{-1}Z\left(\frac{d}{dt}\right)\ell' \tag{10.12}$$

is a storage function for $-Q_{\Phi'}$.
(v) (assume Φ *is observable*) $\int_t Q_\Phi \gg 0 \Leftrightarrow \int_t Q_{\Phi'} \ll 0$. *Here* $\int_t Q_{\Phi'} \ll 0$ *is defined as the property that there exists* $\epsilon > 0$ *such that* $\int_0^\infty Q_{\Phi'}(w)dt \leq -\epsilon \int_0^\infty Q_{\Phi'|}(w)dt$ *for all* $w \in \mathfrak{D}(\mathbb{R}, \mathbb{R}^q)$ *(i.e., half-line positivity over the* positive *half-line).*

Proof. For the proof, see the appendix.

We close this section by pointing out that it is of interest to generalize the notion of duality by using, instead of the usual inner product, an inner product that is itself induced by a QDF. These ramifications are a matter of future research.

11. Conclusions. In this paper we studied two-variable polynomial matrices and their role in a number of problems in linear system theory. The basic premise set forward is the following. Dynamic models lead naturally to the study of one-variable polynomial matrices. By substituting the time derivative for the indeterminate, and by letting the resulting differential operator act on a variable, one arrives at a dynamical system, which may then be in kernel or in image representation. The study of quadratic functionals in a variable and its derivative, on the other hand, leads to two-variable polynomial matrices. Important instances where dynamical systems occur in conjunction with functionals are, for example, Lyapunov theory, the theory of dissipative systems, and LQ and H_∞ control. We developed the former two applications in the present paper. The latter two will be discussed elsewhere.

Appendix.

Proof of Theorem 3.1. We prove the equivalence of the two statements in (1) at the end of the proof and proceed with the first statement by running the circle (1) $\Rightarrow$ (3) $\Rightarrow$ (2) $\Rightarrow$ (1). Assume that $\int L_\Phi = 0$. Then obviously $\int_{-\infty}^\infty L_\Phi(v, w)dt = 0$ for all $v \in \mathfrak{D}(\mathbb{R}, \mathbb{C}^{q_1})$ and $w \in \mathfrak{D}(\mathbb{R}, \mathbb{C}^{q_2})$, with $L_\Phi(v, w)$ in this case (for complex functions) defined by $\sum_{k,\ell}(\frac{d^k\bar{v}}{dt^k})^T\Phi_{k,\ell}(\frac{d^\ell w}{dt^\ell})$. Then

$$\int_{-\infty}^\infty \hat{v}^T(-i\omega)\Phi(-i\omega, i\omega)\hat{w}(i\omega)d\omega = 0$$

for all $\hat{v} \in L_2(\mathbb{C}, \mathbb{C}^{q_1})$, $\hat{w} \in L_2(\mathbb{C}, \mathbb{C}^{q_2})$ that are Fourier transforms of $v \in \mathfrak{D}(\mathbb{R}, \mathbb{C}^{q_1})$, and $w \in \mathfrak{D}(\mathbb{R}, \mathbb{C}^{q_2})$. This implies that $\partial\Phi = 0$. Assume to the contrary that there exist $\omega_0 \in \mathbb{R}$, $a \in \mathbb{C}^{q_1}$, $b \in \mathbb{C}^{q_2}$ such that $\bar{a}^T\Phi(-i\omega_0, i\omega_0)b \neq 0$. Define $v_N \in \mathfrak{D}(\mathbb{R}, \mathbb{C}^{q_1})$

for $N = 1, 2, \ldots$, by

$$v_N(t) = \begin{cases} e^{i\omega_0 t}a & |t| \leq \frac{2\pi N}{\omega_0}, \\ \tilde{v}(t + \frac{2\pi N}{\omega_0}) & t < -\frac{2\pi N}{\omega_0}, \\ \tilde{v}(t - \frac{2\pi N}{\omega_0}) & t > \frac{2\pi N}{\omega_0}. \end{cases} \tag{A.1}$$

Define $w_N \in \mathfrak{D}(\mathbb{R}, \mathbb{C}^{q_2})$ analogously by replacing a by b. Note that $\tilde{v}$ and $\tilde{w}$ can be chosen independent of N, and obtain smoothness for all N: indeed, if v_1 is smooth, then by the periodic nature of v_N for $|t| \leq \frac{2\pi N}{\omega_0}$, v_N will also be smooth.

Next evaluate $\int_{-\infty}^{\infty} L_\Phi(v_N, w_N)dt$ and observe that this integral equals

$$\frac{4\pi N}{\omega_0}\bar{a}^T\Phi(-i\omega_0, i\omega_0)b + E$$

with E independent of N. It follows that $\int_{-\infty}^{\infty} L_\Phi(v_N, w_N)dt \neq 0$ for N sufficiently large. In order to obtain this for real-valued functions, consider the real and imaginary parts of v_N, w_N and the integrals. This establishes the contradiction. Hence (1) implies (3).

To prove (3) $\Rightarrow$ (2), view $\Phi(\zeta, \eta)$ as a one-variable polynomial in ζ and carry out the division by $\zeta + \eta$. This yields $\Phi(\zeta, \eta) = (\zeta + \eta)d(\zeta, \eta) + r(\zeta, \eta)$. Hence $\partial\Phi = 0$ implies $r = 0$. This yields (2).

To show that (2) $\Rightarrow$ (1), observe that $\int_{-\infty}^{\infty} L_\Phi(v, w)dt = \int_{-\infty}^{\infty} \frac{d}{dt}L_\Psi(v, w)dt$. The last term obviously vanishes since v and w have compact support.

To show the equivalence of the two statements in (1), observe that it follows trivially that $\int L_\Phi = 0$ implies path independence. Conversely, if $\partial\Phi = 0$ then, according to (3), there exists $\Psi \in \mathbb{R}^{q_1 \times q_2}[\zeta, \eta]$ such that $L_\Phi = \frac{d}{dt}L_\Psi$. Thus, for any pair of functions $v \in \mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^{q_1})$ and $w \in \mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^{q_2})$, and for any t_1 and t_2, we have

$$\int_{t_1}^{t_2} L_\Phi(v, w)dt = \int_{t_1}^{t_2} \frac{d}{dt}L_\Psi(v, w)dt = L_\Psi(v, w)(t_2) - L_\Psi(v, w)(t_1).$$

Hence the integral depends only on the values taken on by v and w and their derivatives at the endpoints t_1 and t_2. □

Proof of Proposition 3.2. This proposition is proven following the standard proofs used in behavioral theory: reduce the problem to the scalar case using the Smith form. Let $R = U\Delta V$ with U, V unimodular and Δ diagonal. Define $\mathfrak{B}' = V(\frac{d}{dt})\mathfrak{B}$. Then $\mathfrak{B}'$ has $\Delta(\frac{d}{dt})w = 0$ as kernel representation. To prove the proposition, note that the "if" parts are immediate.

To show the first "only if" part, we show that $D(\frac{d}{dt})\mathfrak{B} = 0$ implies that there exists F such that $D = FR$ or equivalently, with $D = D'V$, that $D'(\frac{d}{dt})\mathfrak{B}' = 0$ implies that there exists F' such that $D' = F'\Delta$. Let $\Delta = \mathrm{diag}(d, \Delta')$, let d' be the first column of D', and let w_1 be a solution of $d(\frac{d}{dt})w_1 = 0$. Since $\mathrm{col}[w_1, 0, \ldots, 0] \in \mathfrak{B}'$ and $D'(\frac{d}{dt})\mathfrak{B}' = 0$, it follows that $d'(\frac{d}{dt})w_1 = 0$. It is easily seen that $d(\frac{d}{dt})w_1 = 0$ implies $d'(\frac{d}{dt})w_1 = 0$ iff each element of the polynomial vector d' is a factor of d. Proceeding this way column by column yields $D' = F'\Delta$.

To show the second "only if" part, we prove first the analogous result for BLDFs. This states that with $\Phi \in \mathbb{R}^{q_1 \times q_2}[\zeta, \eta]$, the BLDF $L_\Phi(w_1, w_2) = 0$ for all $w_1 \in \mathfrak{B}_1$ and $w_2 \in \mathfrak{B}_2$ iff there exists F_1, F_2 such that

$$\Phi(\zeta, \eta) = R_1^T(\zeta)F_2(\zeta, \eta) + F_1(\zeta, \eta)R_2(\eta), \tag{A.2}$$

where R_1 and R_2 induce kernel representations of $\mathfrak{B}_1$ and $\mathfrak{B}_2$. The "if" part is once again obvious. To prove the "only if" part, consider first the following lemma, which proves the scalar case $q_1 = q_2 = 1$.

LEMMA A.1. *Let $r_1, r_2 \in \mathbb{R}[\xi]$ and $\Phi \in \mathbb{R}[\zeta, \eta]$. Let $\mathfrak{B}_m \in \mathfrak{L}^1$, $m = 1, 2$ be given in kernel representation by $r_m(\frac{d}{dt})w_m = 0$. Then $Q_\Phi(w_1, w_2) = 0$ for all $w_m \in \mathfrak{B}_m$ iff there exists $f_m \in \mathbb{R}[\zeta, \eta]$ such that*

$$\Phi(\zeta, \eta) = r_1(\zeta) f_2(\zeta, \eta) + f_1(\zeta, \eta) r_2(\eta). \tag{A.3}$$

Proof. The "if" part is obvious. To show the "only if" part, let r_1 have degree n_1 and r_2 have degree n_2, and assume that they are monic. Consider the term $\Phi_{k,\ell}\zeta^k\eta^\ell$ of $\Phi(\zeta, \eta)$. In the quadratic form $Q_\Phi(w_1, w_2)$ this term contributes $\Phi_{k,\ell}\frac{d^k w_1}{dt^k}\frac{d^\ell w_2}{dt^\ell}$. If w_1 satisfies $r_1(\frac{d}{dt})w_1 = 0$, and if $k \geq n_1$, then the contribution in $Q_\Phi(w_1, w_2)$ of $\Phi_{k,\ell}\zeta^k\eta^\ell$ is equivalent to that of $\Phi_{k,\ell}(\zeta^k - \zeta^{k-n_1}r_1(\zeta))\eta^\ell$. Proceeding analogously with the ℓ's and the other terms shows that there exists $\Phi'(\zeta, \eta) = \sum_{k,\ell}\Phi'_{k,\ell}\zeta^k\eta^\ell$ with $\Phi'_{k,\ell} = 0$ for $k \geq n_1$ or $\ell \geq n_2$ such that

$$\Phi(\zeta, \eta) = r_1(\zeta) f_2(\zeta, \eta) + f_1(\zeta, \eta) r_2(\eta) + \Phi'(\zeta, \eta). \tag{A.4}$$

Obviously $Q_{\Phi'}(w_1, w_2) = Q_\Phi(w_1, w_2)$ for $w_m \in \mathfrak{B}_m$. Therefore $Q_{\Phi'}(w_1, w_2) = 0$ for $w_m \in \mathfrak{B}_m$. Consider $Q_{\Phi'}(w_1, w_2)(0)$ and observe that this is a quadratic form in $w_1(0), \frac{dw_1}{dt}(0), \ldots, \frac{d^{n_1-1}w_1}{dt^{n_1-1}}(0)$ and $w_2(0), \frac{dw_2}{dt}(0), \ldots, \frac{d^{n_2-1}w_2}{dt^{n_2-1}}(0)$. These initial conditions can be chosen arbitrarily in the sense that for any values of $w_m(0), \frac{dw_m}{dt}(0), \ldots, \frac{d^{n_m-1}w_m}{dt^{n_m-1}}(0)$ there exist $w_m \in \mathfrak{B}_m$ having these initial values. It follows that $\Phi' = 0$. ∎

Now return to the proof of the case for general q_1, q_2. Bring R_1 and R_2 in Smith form, showing that it suffices to prove (A.2) for $R = \Delta_1$ and $R_2 = \Delta_2$ with Δ_1 and Δ_2 in Smith form. Let d_1 be the (k_1, k_1)th element of Δ_1 and d_2 the (k_2, k_2)th element of Δ_2. Examine (A.2) and observe that we need to show that the (k_1, k_2)th element of Φ, $\Phi_{k_1k_2}$, can be written as

$$\Phi_{k_1,k_2}(\zeta, \eta) = d_1(\zeta) f_2(\zeta, \eta) + f_1(\zeta, \eta) d_2(\eta) \tag{A.5}$$

whenever it holds that $d_1(\frac{d}{dt})v_1 = 0$ and $d_2(\frac{d}{dt})v_2 = 0$ implies that $L_{\Phi_{k_1k_2}}(v_1, v_2) = 0$. Now use the previous lemma.

In order to prove Proposition 3.2 for $\Phi \in \mathbb{R}_s^{n_1 \times n_2}[\zeta, \eta]$, use the *-operator on (A.2), and add.

The image representation part of Proposition 3.2 is proven analogously. ∎

Proof of Proposition 3.5. The proof follows exactly along the same lines as the proof of Proposition 3.2, and we can therefore be very brief. The Smith form once again implies that it suffices to prove the case $q_1 = q_2 = 1$. Denote a kernel representation of $\mathfrak{B}$ by $r(\frac{d}{dt})w = 0$. Using (A.4) with $r_1 = r_2 = r$ shows that $Q_\Phi \geq 0$ on $\mathfrak{B}$ iff $Q_{\Phi'} \geq 0$ on $\mathfrak{B}$. However, again by the arbitrariness of the initial conditions, ($Q_\Phi \geq 0$ on $\mathfrak{B}$) iff the matrix $\tilde{\Phi}'$ associated with Φ' is nonnegative definite. Part (i) of the proposition follows.

To show part (ii), factor Φ' (using $\tilde{\Phi}'$) as $\Phi'(\zeta, \eta) = D^T(\zeta)D(\eta)$ with $D \in \mathbb{R}^{\bullet \times 1}[\xi]$ having elements whose degree is less than that of r. It thus suffices to find conditions for $r(\frac{d}{dt})w = 0$ and $D(\frac{d}{dt})w = 0$ to imply $w = 0$. That, however, is exactly equivalent to the observability of the pair (r, D). ∎

Proof of Theorem 4.3. The "if" part is shown as follows. By Proposition 3.5 we know that $\overset{\bullet}{\Psi} \overset{\mathfrak{B}}{<} 0$ implies that $\overset{\bullet}{\Psi}(\zeta,\eta) \overset{\mathfrak{B}}{=} -D^T(\zeta)D(\eta)$ with $D \in \mathbb{R}^{\bullet\times q}[\xi]$ such that (R,D) is observable, with $R \in \mathbb{R}^{\bullet\times q}[\xi]$ a kernel representation of $\mathfrak{B}$. It also holds that

$$\frac{d}{dt}Q_\Psi(w) = Q_{\overset{\bullet}{\Psi}}(w). \tag{A.6}$$

Integrate this from 0 to T along a $w \in \mathfrak{B}$ and obtain

$$Q_\Psi(w)(T) - Q_\Psi(w)(0) = \int_0^T Q_{\overset{\bullet}{\Psi}}(w)dt = -\int_0^T \|D\left(\frac{d}{dt}\right)(w)\|^2 dt. \tag{A.7}$$

Using $\Psi \overset{\mathfrak{B}}{\geq} 0$, this yields

$$\int_0^T \|D\left(\frac{d}{dt}\right)(w)\|^2 dt \leq Q_\Psi(w)(0). \tag{A.8}$$

Therefore

$$\int_0^\infty \|D\left(\frac{d}{dt}\right)(w)\|^2 dt < \infty. \tag{A.9}$$

This implies the asymptotic stability of $\mathfrak{B}$. Assume that $ae^{\lambda t} \in \mathfrak{B}$, $a \neq 0$. Then $R(\lambda)a = 0$ and by (A.8) there must hold that either $D(\lambda)a = 0$ or $\Re e(\lambda) < 0$. (Note that we silently use the obvious fact that (A.8) also holds for the complexification of $\mathfrak{B}$.) However, by observability of (R,D), $R(\lambda)a = 0$ and $D(\lambda)a = 0$ imply $a = 0$. Hence all exponential solutions $ae^{\lambda t}$ of $R(\frac{d}{dt})w = 0$ must have $\Re e(\lambda) < 0$. It is well known from the theory of differential equations that this implies that all solutions approach zero as $t \to \infty$. The "only if" follows from the stronger Theorem 4.8 and will be proven then. □

Proof of Corollary 4.6. $\overset{\bullet}{\Psi}(\zeta,\eta) = (\zeta+\eta)\Psi_0$. In the case at hand, $R(\xi) = A - \xi I$. Using Proposition 3.2, $(\zeta+\eta)\Psi \overset{\mathfrak{B}}{=} A\Psi_0 + \Psi_0 A^T$. Finally, observe that observability of $(A-\xi I, \sqrt{\Delta_0})$ (as a pair of polynomial matrices) is equivalent to that of $(A, \sqrt{\Delta_0})$ (as a pair of matrices) which is equivalent to that of (A, Δ_0). □

Proof of Proposition 4.7. Examine formula (A.8) in the proof of Theorem 4.3. It implies $Q_\Psi(w)(0) \geq \int_0^\infty \|D(\frac{d}{dt})w\|^2 dt$. Therefore $Q_\Psi(w)(0) = 0$ implies $D(\frac{d}{dt})w = 0$. However, by observability of D, $D(\frac{d}{dt})w = 0$ in turn implies $w = 0$. □

Proof of Theorem 4.8. The proof is organized as follows. First, we prove that (4.3) is solvable; second, that if R is square (4.4), (4.5) gives all Sits solutions; third, that (4.7) yields $\overset{\bullet}{\Psi} \overset{\mathfrak{B}}{=} \Phi$; fourth, that $\overset{\bullet}{\Psi}_1 \overset{\mathfrak{B}}{=} \overset{\bullet}{\Psi}_2$ implies $\Psi_1 \overset{\mathfrak{B}}{=} \Psi_2$; fifth, that $\Phi \overset{\mathfrak{B}}{\leq} 0$ yields $\Psi \overset{\mathfrak{B}}{\geq} 0$; and sixth, that $\Phi \overset{\mathfrak{B}}{<} 0$ yields $\Psi \overset{\mathfrak{B}}{\gg} 0$.

(i) First put R in Smith form: let

$$R = U \begin{bmatrix} D \\ 0 \end{bmatrix} V,$$

with D diagonal and U, V unimodular. Observe that it suffices to prove (4.3) with $R = D$. The (k,ℓ)th component of the matrix equation (4.3) in the obvious notation takes the form

$$x_{\ell k}(-\xi)d_\ell(\xi) + d_k(-\xi)x_{k\ell}(\xi) = \Phi_{k\ell}(-\xi,\xi). \tag{A.10}$$

Since d_k and d_ℓ are Hurwitz, $d_\ell(\xi)$ and $d_k(-\xi)$ are coprime and hence, by Bezout, (A.10) has a solution. This then yields a solution of the matrix version.

(ii) Again use the Smith form. Obtain that the difference of two solutions must satisfy

$$x_{\ell k}(-\xi)d_\ell(\xi) + d_k(-\xi)x_{k\ell}(\xi) = 0. \tag{A.11}$$

Hence again using coprimeness of $d_\ell(\xi)$ and $d_k(-\xi)$, there exists a polynomial $f_{k\ell}$ such that $x_{k\ell}(\xi) = f_{k\ell}(\xi)d_\ell(\xi)$. This yields (4.4). To show (4.5), obtain

$$R^T(-\xi)(F(\xi) + F^T(-\xi))R(\xi) = 0. \tag{A.12}$$

If R is square and $\det(R) \neq 0$, (4.5) follows by pre- and postmultiplying by $(R^T(-\xi))^{-1}$ and $(R(\xi))^{-1}$.

(iii) This proof is obvious.

(iv) Let $w \in \mathfrak{B}$ and assume that $\overset{\bullet}{\Psi}_1 \overset{\mathfrak{B}}{=} \overset{\bullet}{\Psi}_2$, i.e., $\overset{\bullet}{\Delta} \overset{\mathfrak{B}}{=} 0$, where $\Delta = \Psi_1 - \Psi_2$. Then

$$\int_0^t Q_{\overset{\bullet}{\Delta}}(w)dt = \int_0^t \frac{d}{dt}Q_\Delta(w)dt = Q_\Delta(w)(t) - Q_\Delta(w)(0). \tag{A.13}$$

Since $Q_{\overset{\bullet}{\Delta}}(w) = 0$, asymptotic stability of $\mathfrak{B}$ implies $Q_\Delta(w)(t) \to 0$ as $t \to \infty$ and hence that $Q_\Delta(w)(0) = 0$. Therefore $\Delta \overset{\mathfrak{B}}{=} 0$.

(v) This follows immediately from (A.7), and Proposition 4.7 yields (vi). □

Proof of Proposition 4.9. Existence of both D' and Ψ' follows from the algorithm given in the statement of the proposition. To show uniqueness of D' observe that $D' \overset{\mathfrak{B}}{=} D''$, i.e., $D'' - D' = FR$, and $D'R^{-1}, D''R^{-1}$ strictly proper, implies $F = 0$, i.e., $D' = D''$. In the two-variable case assume $\Psi' \overset{\mathfrak{B}}{=} \Psi''$, i.e.,

$$\Psi'(\zeta,\eta) = \Psi''(\zeta,\eta) + F^T(\eta,\zeta)R(\eta) + R^T(\zeta)F(\zeta,\eta).$$

Thus,

$$(R^T(-\zeta))^{-1}(\Psi' - \Psi'')(\zeta,\eta)(R(\eta))^{-1} = (R^T(\zeta))^{-1}F^T(\eta,\zeta) + F(\zeta,\eta)(R(\eta))^{-1}$$

Strict properness again implies $F = 0$. □

Proof of Proposition 4.10. Let $\Psi \overset{\mathfrak{B}}{=} 0$. Then $\Psi(\zeta,\eta) = F^T(\eta,\zeta)R(\eta) + R^T(\zeta)F(\zeta,\eta)$. Pre- and postmultiply by $(R^T(\zeta))^{-1}$ and $(R(\eta))^{-1}$, respectively, and conclude that $F = 0$. The result follows. If $\Psi \overset{\mathfrak{B}}{\geq} 0$, use the same reasoning and Proposition 3.5 on $\Psi(\zeta,\eta) \overset{\mathfrak{B}}{=} D^T(\zeta)D(\eta)$ with D R-canonical. The case $\Psi \overset{\mathfrak{B}}{>} 0$ is similar. □

Proof of Theorem 4.12. We first show that (4.4) has an R-canonical solution. Let X be any solution. Factor XR^{-1} as $XR^{-1} = P + S$ with P polynomial and S strictly proper. First observe that it follows from (4.3) that $P(\xi) + P^T(-\xi) = 0$. Next, show that $X - PR$ is a canonical solution. Uniqueness of this R-canonical solution follows from (4.4).

Next, we show that (4.10) yields an R-canonical Ψ. Simply pre- and postmultiply by $(R^T(\zeta))^{-1}$ and $R^{-1}(\eta)$ and observe properness. Uniqueness follows from ($\overset{\bullet}{\Psi}_1 \overset{\mathfrak{B}}{=} \Phi$ and $\overset{\bullet}{\Psi}_2 \overset{\mathfrak{B}}{=} \Phi$) $\Longrightarrow$ ($\overset{\bullet}{\Psi}_1 \overset{\mathfrak{B}}{=} \overset{\bullet}{\Psi}_2$). Now apply Proposition 4.9.

The remaining statements follow from Proposition 4.10. □

Proof of Proposition 5.2. The proof of all three statements is analogous. Therefore we only give the proof of (i). To prove ($\Leftarrow$), let $w \in \mathfrak{D}(\mathbb{R}, \mathbb{R}^q)$ and let $\hat{w}$ be its Fourier transform. Observe, using Parseval's Theorem, that

$$\int_{-\infty}^{+\infty} Q_\Phi(w)dt = \frac{1}{2\pi}\int_{-\infty}^{+\infty} \hat{w}(-i\omega)^T\Phi(-i\omega, i\omega)\hat{w}(i\omega)d\omega, \tag{A.14}$$

whence ($\Leftarrow$). To show the converse, as in the proof of Theorem 3.1, we silently switch from $\mathbb{R}^q$ as signal space to $\mathbb{C}^q$. Assume that there exists $a \in \mathbb{C}^q$ and $\omega_0 \in \mathbb{R}$ such that $\bar{a}^T\Phi(-i\omega_0, i\omega_0)a < 0$. Consider the function $w_N \in \mathfrak{D}(\mathbb{R}, \mathbb{C}^q)$ for $N = 1, 2, \ldots$, defined exactly as v_N was in the proof of Theorem 3.1. Next evaluate $\int_{-\infty}^{+\infty} Q_\Phi(w_N)dt$ and observe (using the idea in the proof of Theorem 3.1) that this integral can be made negative by taking N sufficiently large. □

Proof of Proposition 5.4. We will run the circle (3) $\Rightarrow$ (2) $\Rightarrow$ (1) $\Rightarrow$ (3). To see that (3) $\Rightarrow$ (2), assume that Δ is a dissipation function. Then $\Phi(-\xi, \xi) = \Delta(-\xi, \xi)$, by Theorem 3.1. Define

$$\Psi(\zeta, \eta) = \frac{\Phi(\zeta, \eta) - \Delta(\zeta, \eta)}{\zeta + \eta}. \tag{A.15}$$

Hence $\overset{\bullet}{\Psi} = \Phi - \Delta$. Use $\Delta \geq 0$ to conclude that Ψ is a storage function. To see that (2) $\Rightarrow$ (1), use $\overset{\bullet}{\Psi} \leq \Phi$ and Theorem 3.1 to conclude (1). To see that (1) $\Rightarrow$ (3), use Propositions 5.2 and 5.6 to construct a D such that $\Phi(-\xi, \xi) = D^T(-\xi)D(\xi)$. Observe that $\Delta(\zeta, \eta) := D^T(\zeta)D(\eta)$ defines a dissipation function. The one-one relation between Ψ and Δ is given by (A.15). □

Proof of Theorem 5.5. By (5.11) it suffices to consider minimal state representations obtained from a canonical factorization of Φ. Let

$$v = M = \left(\frac{d}{dt}\right) w$$

be obtained from such a factorization, and let $x = X(\frac{d}{dt})w$ be a minimal state. There exists a permutation matrix P such that

$$PM = \begin{bmatrix} U \\ Y \end{bmatrix},$$

with $\det(U) \neq 0$ and such that YU^{-1} is a matrix of proper rational functions. Denote $u = U(\frac{d}{dt})w$. Consider $f = F(\frac{d}{dt})w$, where F is an arbitrary polynomial matrix. Then (see section 2) f is a state function, (i.e., there exists a matrix K such that $f = Kx$) iff FU^{-1} is strictly proper and a state/input function (i.e., there exists matrices L, J such that $f = Kx + Ju$) iff FU^{-1} is proper.

We first prove the second part of the theorem, i.e., that every dissipation function is a state/supply function. Let $\Delta(\zeta, \eta) = D^T(\zeta)D(\eta)$ be a dissipation function. Then

$$M^T(-\xi)\Sigma_\Phi M(\xi) = D^T(-\xi)D(\xi). \tag{A.16}$$

Pre- and postmultiply by U^{-1}, to obtain

$$(M(-\xi)U^{-1}(-\xi))^T\Sigma_\Phi M(\xi)U^{-1}(\xi) = (D(-\xi)U^{-1}(-\xi))^T D(\xi)U^{-1}(\xi). \tag{A.17}$$

Since the left-hand side is proper, so is the right-hand side. This obviously implies that $D(\xi)U^{-1}(\xi)$ is proper. Hence $D(\frac{d}{dt})w$ is a state/input function and equivalently,

$D(\xi) = KX(\xi) + JU(\xi)$ for suitable constant matrices K, J. From this it is readily seen that there exists a matrix E such that (5.13) holds.

We now prove the first part of the theorem, i.e., that every storage function is a state function. Let $\Psi(\zeta, \eta)$ define a storage function for Φ. Let $D(\xi)$ be such that

$$(\zeta + \eta)\Psi(\zeta, \eta) = M^T(\zeta)\Sigma_\Phi M(\eta) - D^T(\zeta)D(\eta).$$

By redefining

$$\tilde{M}^T(\zeta)\tilde{\Sigma}_\Phi \tilde{M}(\eta) = \begin{bmatrix} M(\zeta) \\ D(\zeta) \end{bmatrix}^T \begin{bmatrix} \Sigma_\Phi & 0 \\ 0 & -I \end{bmatrix} \begin{bmatrix} M(\eta) \\ D(\eta) \end{bmatrix},$$

and observing that a minimal state for the system with image representation $v = M(\frac{d}{dt})w$ is also a minimal state for the system with image representation

$$v = \begin{bmatrix} M(\frac{d}{dt}) \\ D(\frac{d}{dt}) \end{bmatrix} w,$$

it suffices to prove the claim in the lossless case, i.e., when $\overset{\bullet}{\Psi} = \Phi$.

Assume that $\Phi(\zeta, \eta) = M^T(\zeta)\Sigma_\Phi M(\eta)$ is a symmetric canonical factorization of Φ and that $\Psi(\zeta, \eta) = N^T(\zeta)\Sigma_\Psi N(\eta)$ is a symmetric canonical factorization of Ψ. Postmultiply the identity $\overset{\bullet}{\Psi} = \Phi$ by $U^{-1}(\eta)$ to obtain

$$(\zeta + \eta)N^T(\zeta)\Sigma_\Psi N(\eta)U^{-1}(\eta) = M^T(\zeta)\Sigma_\Phi M(\eta)U^{-1}(\eta). \tag{A.18}$$

Assume that $L_k\eta^k$ is the term of degree k in the polynomial part of the matrix of rational functions $N(\eta)U^{-1}(\eta)$. Using that the right-hand side of (A.18) is proper in η, by equating powers of η yields $N^T(\zeta)\Sigma_\Psi L_k = 0$. Express $N(\zeta)$ as

$$N(\zeta) = \begin{bmatrix} N_0 & N_1 & \dots & N_L \end{bmatrix} \begin{bmatrix} I \\ I\zeta \\ \vdots \\ I\zeta^L \end{bmatrix}$$

and use (A.18) to obtain $\begin{bmatrix} N_0 & N_1 & \dots & N_L \end{bmatrix}^T \Sigma_\Psi L_k = 0$. Since the factorization $\Psi(\zeta, \eta) = N^T(\zeta)\Sigma_\Psi N(\eta)$ is canonical, $\begin{bmatrix} N_0 & N_1 & \dots & N_L \end{bmatrix}$ is surjective. Hence (A.18) yields $L_k = 0$. This shows that $N(\xi)U^{-1}(\xi)$ is strictly proper and hence that $N(\frac{d}{dt})w$ is a state function as desired. Thus there exists a constant matrix K such that $N(\xi) = KX(\xi)$. This shows that there exists a matrix P such that (5.12) holds. This completes the proof of the theorem. □

Proof of Theorem 5.7. We first prove the second part, the part regarding strong average positivity. In this case it follows from Proposition 5.3 that $\Phi(-i\omega, i\omega) > 0$ for all ω. Hence by Proposition 5.6, $\Phi(-\xi, \xi)$ has a Hurwitz and an anti-Hurwitz factorization. The associated storage functions, Ψ_+ and Ψ_-, satisfy

$$\frac{d}{dt}(Q_{\Psi_+}(w) - Q_{\Psi_-}(w)) = \|H\left(\frac{d}{dt}\right)w\|^2 - \|A\left(\frac{d}{dt}\right)w\|^2. \tag{A.19}$$

Let $x = X(\frac{d}{dt})w$ be a minimal state associated with a canonical factorization of Φ. By Theorem 5.5, there exist real symmetric matrices, say K_+ and K_-, such that for

all $w \in \mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^q)$, we have

$$Q_{\Psi_+}(w) = X\left(\frac{d}{dt}w\right)^T K_+ X\left(\frac{d}{dt}\right) w,$$
$$Q_{\Psi_-}(w) = X\left(\frac{d}{dt}w\right)^T K_- X\left(\frac{d}{dt}\right) w.$$

Then if for all a there exists a solution w of $A(\frac{d}{dt})w = 0$ such that $(X(\frac{d}{dt})w)(0) = a$, we obtain, by integrating along this solution,

$$a^T K_+ a - a^T K_- a = Q_{\Psi_+}(w)(0) - Q_{\Psi_-}(w)(0) = \int_{-\infty}^{0} \|H\left(\frac{d}{dt}\right) w\|^2 dt, \tag{A.20}$$

whence $K_+ \geq K_-$, so $\Psi_+ \geq \Psi_-$.

The problem is that there may not be a solution of $A(\frac{d}{dt})w = 0$ for all a such that $(X(\frac{d}{dt})w)(0) = a$. In order to circumvent this difficulty we first prove the statements of the second part under the additional assumption that $\Phi \geq \epsilon|\Phi|$ for some $\epsilon > 0$, in addition to the assumption that $\Phi(-i\omega, i\omega) > 0$ for all ω. Next, we modify Φ to Φ_ϵ such that these conditions hold for $\epsilon > 0$, and, finally, take the limit for $\epsilon \downarrow 0$.

Assume that $\Phi(-i\omega, i\omega) > 0$ for all $\omega \in \mathbb{R}$ and $\Phi \geq \epsilon|\Phi|$ for some $\epsilon > 0$. The system (5.5) allows an I/O representation, in the sense that there exists a permutation matrix P such that

$$Pv = \begin{bmatrix} U(\frac{d}{dt}) \\ Y(\frac{d}{dt}) \end{bmatrix} w, \tag{A.21}$$

with $\det(U) \neq 0$ and $G := YU^{-1}$ proper. Let $u = U(\frac{d}{dt})w$, $y = Y(\frac{d}{dt})w$. There exist constant matrices A, B, C, and D such that u, x, and y are related by $\frac{dx}{dt} = Ax + Bu, y = Cx + Du$. Since AU^{-1} is biproper, $A(\frac{d}{dt})w$ is of the form $Fx + Lu$ with L nonsingular. Using $u = -L^{-1}Fx$ and $x(0) = a$ in these equations then results in a solution of $A(\frac{d}{dt})w = 0$. To show that AU^{-1} is indeed biproper, use Proposition 5.2 to obtain

$$\begin{bmatrix} U(-i\omega) \\ Y(-i\omega) \end{bmatrix}^T P\Sigma_\Phi P^T \begin{bmatrix} U(i\omega) \\ Y(i\omega) \end{bmatrix} =$$
$$A^T(-i\omega)A(i\omega) \geq \epsilon \begin{bmatrix} U(-i\omega) \\ Y(-i\omega) \end{bmatrix}^T \begin{bmatrix} U(i\omega) \\ Y(i\omega) \end{bmatrix}.$$

After pre- and postmultiplying by $(U^{-1}(-i\omega))^T$ and $U^{-1}(i\omega)$, respectively, we obtain that

$$\begin{bmatrix} I \\ G(-i\omega) \end{bmatrix}^T P\Sigma_\Phi P^T \begin{bmatrix} I \\ G(i\omega) \end{bmatrix} = ((AU^{-1})(-i\omega))^T (AU^{-1})(i\omega) \geq \epsilon I. \tag{A.22}$$

Since G is proper, AU^{-1} is proper, by the equality on the left. The inequality on the right gives biproperness.

Consider a general Φ and define Φ_ϵ by $\Phi_\epsilon = \Phi + \epsilon|\Phi| + \epsilon I$. Then Φ_ϵ satisfies the above conditions and hence there exists (in the obvious notation) Ψ_ϵ^- and Ψ_ϵ^+ such that $\Psi_\epsilon^- \leq \Psi_\epsilon \leq \Psi_\epsilon^+$. Observe that for $0 < \epsilon_1 \leq \epsilon_2$ there holds $\Phi_{\epsilon_1} \leq \Phi_{\epsilon_2}$ and deduce

from $\overset{\bullet}{\Psi}{}^+_{\epsilon_1} \leq \Phi_{\epsilon_1} \leq \Phi_{\epsilon_2}$ that $\Psi^+_{\epsilon_2} \geq \Psi^+_{\epsilon_1}$. Similarly, $\Psi^-_{\epsilon_2} \leq \Psi^-_{\epsilon_1}$. Consequently $\Psi^-_{\epsilon_2} \leq \Psi^-_{\epsilon_1} \leq \Psi^+_{\epsilon_1} \leq \Psi^+_{\epsilon_2}$. Prove (using for example the associated matrix representations) that this monotonicity implies the existence of $\lim_{\epsilon \downarrow 0} \Psi^-_\epsilon =: \Psi^-_0$ and $\lim_{\epsilon \downarrow 0} \Psi^+_\epsilon =: \Psi^+_0$.

We now prove that Ψ^-_0 and Ψ^+_0 satisfy $\overset{\bullet}{\Psi}{}^-_0 \leq \Phi$ and $\overset{\bullet}{\Psi}{}^+_0 \leq \Phi$, and subsequently that any storage function Ψ of Φ satisfies $\Psi^-_0 \leq \Psi \leq \Psi^+_0$. To prove the first part, observe that $\overset{\bullet}{\Psi}{}^-_\epsilon \leq \Phi_\epsilon$ and $\overset{\bullet}{\Psi}{}^+_\epsilon \leq \Phi_\epsilon$ for $\epsilon > 0$ and take the limit for $\epsilon \downarrow 0$. To prove the second part, assume that $\overset{\bullet}{\Psi} \leq \Phi$. Then $\overset{\bullet}{\Psi} \leq \Phi \leq \Phi_\epsilon$. Therefore $\Psi^-_\epsilon \leq \Psi \leq \Psi^+_\epsilon$. Now take the limit for $\epsilon \downarrow 0$.

We still have to prove the formulas (5.15) and (5.16) for the computation of Ψ_- and Ψ^+ for the case that we only have $\Phi(i\omega, -i\omega) > 0$ for all $\omega \in \mathbb{R}$ and not necessarily $\Phi \geq \epsilon|\Phi|$ for some $\epsilon > 0$. Let H_ϵ be a symmetric Hurwitz factor of $\Phi_\epsilon(-\xi, \xi)$: $\Phi_\epsilon(-\xi, \xi) = H^T_\epsilon(-\xi)H_\epsilon(\xi)$, as discussed in Proposition 5.6. In order to make it unique, normalize H_ϵ to $\sqrt{\Phi_\epsilon(0)}$. It holds that

$$H^T_\epsilon(\zeta)H_\epsilon(\eta) = \Phi_\epsilon(\zeta, \eta) - (\zeta + \eta)\Psi^-_\epsilon(\zeta, \eta).$$

Since $\Phi_\epsilon \to \Phi$ as $\epsilon \downarrow 0$ and $\Psi^-_\epsilon \to \Psi^-_0$ as $\epsilon \downarrow 0$, we also have that H_ϵ converges. Clearly the limit H_0 satisfies $\Phi(-\xi, \xi) = H^T_0(-\xi)H_0(\xi)$ and must be Hurwitz. The formula for Ψ^-_0 $(= \Psi^-)$ follows. The situation for Ψ^+ is treated analogously. □

Proof of Proposition 6.2: (i) Compute $\int^0_{-\infty} Q_\Phi(w)$ for $w(t) = e^{\lambda t}a$ with $\Re e(\lambda) > 0$ and $a \in \mathbb{C}^m$. This integral equals $\frac{\bar{a}^T \Phi(\bar{\lambda}, \lambda)a}{\bar{\lambda} + \lambda}$. This w is not of compact support, but an approximation argument can be used to complete the proof of (i). For $\Re e(\lambda) = 0$ the result follows from Proposition 5.2. (ii) is proven similarly. □

Proof of Theorem 6.3 : We prove that (3) ⇒ (2) ⇒ (1) ⇒ (3). That (3) ⇒ (2) is trivial. In order to see that (2) ⇒ (1), integrate $\frac{d}{dt}Q_\Psi(w) \leq Q_\Phi(w)$ from $-\infty$ to 0. We now prove that (1) ⇒ (3). Assume first that Φ satisfies the assumptions $\Phi(-i\omega, i\omega) > 0$ for all ω and $\Phi \geq \epsilon|\Phi|$ for some $\epsilon > 0$. By Theorem 5.7 we then have

$$\Psi_+(\zeta, \eta) = \frac{\Phi(\zeta, \eta) - A^T(\zeta)A(\eta)}{\zeta + \eta}. \tag{A.23}$$

This yields $\frac{d}{dt}Q_{\Psi_+}(w) = Q_\Phi(w) - \|A(\frac{d}{dt})w\|^2$ for all w. Let $x = X(\frac{d}{dt})w$ be a minimal state map of Φ. By Theorem 5.5, $Q_{\Psi_+}(w) = \|X(\frac{d}{dt})w\|^2_{K_+}$ for some real symmetric matrix K_+. Using this expression in (A.23) and integrating from $-\infty$ to 0 yields that, for all a such that $X(\frac{d}{dt})w(0) = a$ and $A(\frac{d}{dt})w = 0$, we have $a^T K_+ a = \int^0_{-\infty} Q_\Phi(w)dt$. This integral is ≥ 0, so we must have $a^T K_+ a \geq 0$ (actually, such w does not have compact support but, by an approximation argument, the integral cannot be < 0). As in the proof of Theorem 5.7, it can be shown that for any initial condition a such w exists. This proves that $\Psi_+ \geq 0$. Take a general Φ. As in the proof of Theorem 5.7, first replace Φ by Φ_ϵ. By applying the previous to Φ_ϵ, we can conclude that (in the obvious notation) $\Psi^\epsilon_+ \geq 0$. Then take the limit for $\epsilon \downarrow 0$. □

Proof of Theorem 6.4. We will first run the circle (1) ⇒ (2) ⇒ (3) ⇒ (7) ⇒ (4) ⇒ (1).

(1) ⇒(2). This was proven in Proposition 6.2.

(2) ⇒(3). We have $P^T(\bar{\lambda})P(\lambda) \geq N^T(\bar{\lambda})N(\lambda)$ for $\lambda \in \mathbb{C}$, $\Re e(\lambda) \geq 0$. Assume that NP^{-1} has a pole λ such that $\Re e(\lambda) \geq 0$. Then there exists a vector $v \neq 0$ such that $P(\lambda)v = 0$ while $N(\lambda)v \neq 0$. This, however, contradicts the above inequality.

(3) $\Rightarrow$(7). Let $Q_K(w) = \|X(\frac{d}{dt})w\|_K^2$ be a storage function. We want to show that $K > 0$. First we show that NP^{-1} is a proper rational matrix. We have $P^T(-i\omega)P(i\omega) - N^T(-i\omega)N(i\omega) \geq 0$. Define $G := NP^{-1}$. Then for all ω such that $P(i\omega)$ is nonsingular, we have $G^T(-i\omega)G(i\omega) \leq I$, which shows that G is proper.

There exist matrices A, B, C, and D such that all smooth x, w_1 and w_2 satisfying $\dot{x} = Ax + Bw_2$, $w_1 = Cx + Dw_2$ can be written as $x = X(\frac{d}{dt})w$, $w_1 = N(\frac{d}{dt})w$, and $w_2 = P(\frac{d}{dt})w$ for some $w \in \mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^\bullet)$. Since NP^{-1} has no poles in $\Re e(\lambda) \geq 0$, the matrix A can be chosen such that its eigenvalues are in the open left half of the complex plane. Moreover, we may assume that the pair (C, A) is observable. Let $a \in \mathbb{R}^n$. Choose $w_2 = 0$, let x satisfy $\frac{d}{dt}x = Ax$, $x(0) = a$, and let $w_1 = Cx$. This shows that there exists $w \in \mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^\bullet)$ such that $(X(\frac{d}{dt})w)(0) = a$ and $w_2 = P(\frac{d}{dt})w = 0$. Also, $X(\frac{d}{dt})w \in L_2[0, \infty)$ since A is a Hurwitz matrix. Since $w_1 = N(\frac{d}{dt})w = CX(\frac{d}{dt})w$, we also have that $N(\frac{d}{dt})w \in L_2[0, \infty)$. Thus we can integrate the dissipation inequality from 0 to ∞ to obtain

$$-\left\|\left(X\left(\frac{d}{dt}\right)w\right)(0)\right\|_K^2 \leq -\int_0^\infty \|N(\frac{d}{dt})w\|^2 dt. \tag{A.24}$$

This shows that $a^T K a \geq 0$. Assume that $a^T K a = 0$. Then we must have $w_1 = N(\frac{d}{dt})w = 0$. By observability of the pair (C, A) this implies that $a = 0$.

(7) $\Rightarrow$(4). Let Q_Ψ be any storage function. Since X is a state map, by Theorem 5.5 there exists a real symmetric matrix K such that $Q_\Psi(w) = \|X(\frac{d}{dt})w\|_K^2$ for all w. By assumption, K is positive definite.

(4) $\Rightarrow$(1). This was proven in Theorem 6.3.

The implications (7) $\Rightarrow$(5), (5) $\Rightarrow$(4), (7) $\Rightarrow$(6), and (6) $\Rightarrow$(4) are obvious.

Finally, if we assume observability, then the poles of NP^{-1} coincide with the singularities of the polynomial matrix P. This shows that, under this assumption, (3) and (3′) are equivalent. This completes the proof. □

Proof of Theorem 7.2. Consider the representation (3.10) of L_Φ. From the fact that the factorization is canonical, it is easily seen that the mappings $w_1 \mapsto (N(\frac{d}{dt})w_1)(0)$ and $w_2 \mapsto (M(\frac{d}{dt})w_2)(0)$ are surjective. Thus we have

$$L_\Phi(w_1, \bullet) = 0 \Leftrightarrow \left(N\left(\frac{d}{dt}\right)w_1\right)^T M\left(\frac{d}{dt}\right)w_2 = 0 \text{ for all } w_2 \Leftrightarrow N\left(\frac{d}{dt}\right)w_1 = 0.$$

Similarly, $L_\Phi(\bullet, w_2) = 0$ iff $M(\frac{d}{dt})w_2 = 0$. From this, the equivalence of (1) and (3) is immediate.

To prove (1) $\Rightarrow$ (2), assume that, for some $\lambda \in \mathbb{C}$, $a^T\Phi(\lambda, \xi) = 0$, where a is a complex vector. Define $w_1(t) := e^{\bar{\lambda}t}\bar{a}$. For any w_2 and for all t, we then have

$$L_\Phi(w_1, w_2)(t) = e^{\lambda t}\left(a^T\Phi\left(\lambda, \frac{d}{dt}\right)w_2\right)(t) = 0.$$

This implies $w_1 = 0$, so $a = 0$, which proves that the rows of $\Phi(\lambda, \xi)$ are linearly independent over $\mathbb{C}$. Similarly, we can prove that the columns of $\Phi(\xi, \lambda)$ are linearly independent.

Finally, we prove that (2) implies (3). Let $\lambda \in \mathbb{C}$ and put $M(\lambda)a = 0$ for some complex vector a. We want to prove that $a = 0$. We clearly get $N^T(\xi)M(\lambda)a = 0$ so $\Phi(\xi, \lambda)a = 0$. Since the columns of $\Phi(\xi, \lambda)$ are linearly independent over $\mathbb{C}$, this yields $a = 0$. Likewise we can prove that $N(\lambda)$ has full column rank for all λ. □

Proof of Proposition 8.2. Write (8.3) as

$$(1+\epsilon)\int_{-\infty}^{+\infty}\|N\left(\frac{d}{dt}\right)w\|^2dt \leq (1-\epsilon)\int_{-\infty}^{+\infty}\|P\left(\frac{d}{dt}\right)w\|^2dt. \tag{A.25}$$

Put $\alpha = \frac{1-\epsilon}{1+\epsilon}$ and conclude that (2) and (3) are equivalent (also in the noncanonical case). To show that (1) $\Longleftrightarrow$ (2), observe that $|\Phi|(\zeta,\eta) = M_c^T(\zeta)M_c(\eta)$ for the special symmetric canonical factorization of $\Phi(\zeta,\eta)$ corresponding to (3.15). Hence statement (1) of the theorem is actually statement (2) for this special canonical factorization of Φ. It thus suffices to prove that if (2) holds for one canonical factorization, then it holds for any. From matrix theory, it follows that two canonical factorizations

$$M_1^T(\zeta)\Sigma_\Phi M_1(\eta) = M_2^T(\zeta)\Sigma_\Phi M_2(\eta) \tag{A.26}$$

are related by $M_1(\xi) = SM_2(\xi)$, with S a nonsingular matrix. Hence (2) for M_2 implies

$$\begin{aligned}\int_{-\infty}^{+\infty}\|M_1\left(\frac{d}{dt}\right)w\|^2_{\Sigma_\Phi}dt &= \int_{-\infty}^{+\infty}\|M_2\left(\frac{d}{dt}\right)w\|^2_{\Sigma_\Phi}dt\\ &\geq \epsilon_2\int_{-\infty}^{+\infty}\|M_2\left(\frac{d}{dt}\right)w\|^2dt\\ &\geq \frac{\epsilon_2}{\|S\|^2}\int_{-\infty}^{+\infty}\|M_1\left(\frac{d}{dt}\right)w\|^2dt\end{aligned}$$

and (2) for M_1 follows. Obviously this proof can be reversed with M_1 playing the role of M_2. If M_2 comes from a noncanonical factorization, then S may not be nonsingular and the proof goes through (but cannot be reversed). □

Proof of Theorem 9.3. The proof is structured as follows. We first prove that (1) $\Leftrightarrow$ (2). Subsequently, we show that (1) $\Rightarrow$(3) and finally that (3) $\Rightarrow$(1).

(1) $\Rightarrow$(2). That $\int^t Q_\Phi \gg 0$ implies (2a) is obvious. In order to prove (2b) we need the following lemma. Recall that a quadratic state function Q_Ψ (or simply Ψ), $Q_\Psi(w) = \|X(\frac{d}{dt})w\|^2_K$, is called *positive definite* if $K > 0$.

LEMMA A.2. *Let $M \in \mathbb{R}^{\bullet\times q}[\xi]$ be observable. Then there exists a positive definite state function Ψ such that*

$$\frac{d}{dt}Q_\Psi(w) \leq \|M\left(\frac{d}{dt}\right)w\|^2. \tag{A.27}$$

Proof. We show that Ψ_+, the supremal storage function associated with $M^T(\zeta)M(\eta)$, fits the bill. By Theorem 5.5, Ψ_+ is a state function, say, $Q_{\Psi_+} = \|X(\frac{d}{dt})w\|^2_{K_+}$. Here we take X to be any minimal state map of M. Obviously $\Psi_+ \geq 0$, since $\Psi = 0$ satisfies (A.27) and $\Psi_+ \geq \Psi = 0$. In order to show that $K_+ > 0$, let $a \neq 0$ be arbitrary. We show that $a^TK_+a > 0$. Factor $M^T(-\xi)M(\xi) = A^T(-\xi)A(\xi)$, with $A(\xi)$ anti-Hurwitz. Then

$$\frac{d}{dt}Q_{\Psi_+}(w) = \|M\left(\frac{d}{dt}\right)w\|^2 - \|A\left(\frac{d}{dt}\right)w\|^2 \tag{A.28}$$

for all $w \in \mathfrak{C}^\infty(\mathbb{R},\mathbb{R}^q)$. As in the proof of Theorem 5.7, it is easily seen that there exists $w \neq 0$ such that $A(\frac{d}{dt})w = 0$ and $X(\frac{d}{dt})w(0) = a$ (show that AU^{-1} is biproper,

with $M = \mathrm{col}(U, Y)$ an I/O partitioning). For this w in (A.28) we obtain $a^T K_+ a = \int_{-\infty}^0 \|M(\frac{d}{dt})w\|^2 dt > 0$, where the strict inequality follows from the observability of M. □

We now return to the proof of (1) ⇒(2b) of Theorem 9.3. Let $\Phi(\zeta,\eta) = M^T(\zeta)\Sigma_\Phi M(\eta)$ be the symmetric canonical factorization such that $|\Phi|(\zeta,\eta) = M^T(\zeta)M(\eta)$ (i.e., the one obtained by factoring $\tilde{\Phi} = \tilde{U}^T\Lambda\tilde{U}$, with Λ the diagonal matrix consisting of the nonzero eigenvalues of $\tilde{\Phi}$, and putting $\tilde{M} := \sqrt{|\Lambda|}\tilde{U}$). By the above lemma there exists a positive definite state function $\tilde{\Psi}$ such that $\frac{d}{dt}Q_{\tilde{\Psi}}(w) \leq \|M(\frac{d}{dt})w\|^2$. Now, $\int^t Q_\Psi \gg 0$ implies that there exists $\epsilon > 0$ such that $\int^t Q_{\Phi_\epsilon} \geq 0$, where $\Phi_\epsilon := \Phi - \epsilon|\Phi|$. Let Ψ_+^ϵ be the supremal storage function associated with Φ_ϵ. Clearly $\dot{\Psi}_+^\epsilon \leq \Phi_\epsilon \leq \Phi$, so Ψ_+^ϵ is also a storage function for Φ. This immediately yields $\Psi_+^\epsilon \leq \Psi_+$. Consider the two-variable polynomial matrix $\Psi_+^\epsilon + \epsilon\tilde{\Psi}$. Clearly this defines a storage function for Φ as well, so $\Psi_+^\epsilon \leq \Psi_+^\epsilon + \epsilon\tilde{\Psi} \leq \Psi_+$. According to Theorem 6.3, $\Psi_+^\epsilon \geq 0$. Since $\tilde{\Psi}$ is a positive definite state function, this implies that Ψ_+ is a positive definite state function.

We show that (2) ⇒(1). Let $X \in \mathbb{R}^{n\times q}[\xi]$ define a minimal state map for the system $v = M(\frac{d}{dt})w$. By (2b) Ψ_+ is a positive definite state function. Hence there exists $K_+ = K_+^T > 0$ such that $Q_{\Psi_+}(w) = \|X(\frac{d}{dt})w\|^2_{K_+}$. Factor $M^T(-\xi)\Sigma_M M(\xi) = A^T(-\xi)A(\xi)$ with A anti-Hurwitz. Then we have

$$\int_{-\infty}^0 \|M\left(\frac{d}{dt}\right)\|^2_{\Sigma_\Phi} dt = \|X\left(\frac{d}{dt}\right)w(0)\|^2_{K_+} + \int_{-\infty}^0 \|A\left(\frac{d}{dt}\right)w\|^2 dt \tag{A.29}$$

for all $w \in \mathfrak{D}(\mathbb{R},\mathbb{R}^q)$. There exists a permutation matrix P such that $PM = \mathrm{col}(U, Y)$, with $\det(U) \neq 0$ and YU^{-1} proper. Write $u = U(\frac{d}{dt})w$, $y = Y(\frac{d}{dt})w$, and $x = X(\frac{d}{dt})w$, with w ranging over $\mathfrak{C}^\infty(\mathbb{R},\mathbb{R}^q)$. Write the associated input/state/output representation. Hence there are constant matrices A_1, B_1, C_1, and D_1 such that these u, y, and x are exactly those that are related by the equations

$$\dot{x} = A_1x + B_1u, \quad y = C_1x + D_1u. \tag{A.30}$$

As in the proof of Theorem 5.7, by strict positivity we have that AU^{-1} is biproper. Thus there exist constant matrices F and L, $\det(L) \neq 0$ such that $A(\frac{d}{dt})w = Fx + Lu$. Solving this equation for u and substituting the result in (A.30) yields that the relation between $a := A(\frac{d}{dt})w$, $v = P\mathrm{col}(u, y)$, and $x = X(\frac{d}{dt})w$ is given by linear equations of the form

$$\dot{x} = A_2x + B_2a \quad v = C_2x + D_2a \tag{A.31}$$

with (C_2, A_2) observable and where the eigenvalues of A_2 coincide with the singularities of the spectral factor $A(\xi)$. This shows that for given $a \in L_2((-\infty,0],\mathbb{R}^\bullet)$ and final condition $x(0) = x_0$, the corresponding v is in $L_2((-\infty,0],\mathbb{R}^\bullet)$. In other words (A.31) defines a bounded operator from $L_2((-\infty,0],\mathbb{R}^\bullet) \times \mathbb{R}^n$ to $L_2((-\infty,0],\mathbb{R}^\bullet)$, mapping (a, x_0) to v. Hence there exists a constants C_1 and C_2 such that

$$\int_{-\infty}^0 \|v\|^2 dt \leq C_1 \int_{-\infty}^0 \|a\|^2 dt + C_2\|x_0\|^2.$$

Since $K_+ > 0$, there exists $\epsilon > 0$ such that $\frac{1}{\epsilon}K_+ > C_2I$ and $\frac{1}{\epsilon} > C_1$. For this ϵ we have

$$\int_{-\infty}^0 \|v\|^2 dt \leq \frac{1}{\epsilon}\left(\int_{-\infty}^0 \|a\|^2 dt + x_0^T K_+ x_0\right)$$

which, by (A.29), is equivalent to

$$\int_{-\infty}^{0} \|M\left(\frac{d}{dt}\right)\|^2 dt \leq \frac{1}{\epsilon}\int_{-\infty}^{0} \|M\left(\frac{d}{dt}\right)\|^2_{\Sigma_\Phi} dt.$$

This shows that Φ is strictly half-line positive. Whence, (2) $\Rightarrow$(1).

Next we show that (1) $\Rightarrow$(3). We will only consider the semisimple case. That (1) $\Rightarrow$ (3a) follows from Proposition 5.2. To prove (3b), calculate $\int_{-\infty}^{0} Q_\Phi(a)dt$ for

$$a(t) = \sum_{k=1}^{n} \alpha_k e^{\lambda_k t} a_k$$

and obtain the result

$$\int_{-\infty}^{0} Q_\Phi(a)dt = \begin{bmatrix} \bar{\alpha}_1 \\ \bar{\alpha}_2 \\ \vdots \\ \bar{\alpha}_n \end{bmatrix}^T T_\Phi \begin{bmatrix} \alpha_1 \\ \alpha_2 \\ \vdots \\ \alpha_n \end{bmatrix}. \tag{A.32}$$

We know that, for some $\epsilon > 0$, $\int_{-\infty}^{0} Q_\Phi(w)dt \geq \epsilon \int_{-\infty}^{0} Q_{|\Phi|}(w)dt$ for all w of compact support. An approximation argument yields that this implies $\int_{-\infty}^{0} Q_\Phi(a)dt > 0$ for $a \neq 0$, equivalently for col $(\alpha_1, \alpha_2, \ldots, \alpha_n) \neq 0$. Hence, $T_\Phi > 0$.

Finally, we turn to (3) $\Rightarrow$(2). The implication (3) $\Rightarrow$(2a) follows from Proposition 5.2. To show that (3) $\Rightarrow$(2b), we show that $T_\Phi > 0$ implies that the supremal storage function Ψ_+ defines a positive definite state function. Let $\partial\Phi(\xi) = A^T(-\xi)A(\xi)$ be an anti-Hurwitz factorization. We claim that $\lambda_1, \lambda_2, \ldots, \lambda_n$ are exactly the singularities of $A(\xi)$, with associated vectors $a_1, a_2, \ldots, a_n$ in the kernel of $A(\lambda_k)$, $k = 1, 2, \ldots, n$. Indeed, if λ has $\Re e(\lambda) > 0$, then $A^T(-\lambda)$ is nonsingular. Hence $\Phi(-\lambda_k, \lambda_k)a_k = 0$ and $\Re e(\lambda_k) > 0$ implies $A(\lambda_k)a_k = 0$.

According to Theorem 5.7, it holds that

$$\frac{d}{dt}Q_{\Psi_+}(w) = Q_\Phi(w) - \|A\left(\frac{d}{dt}\right)w\|^2. \tag{A.33}$$

For any solution $w = \sum_{k=1}^{r} \alpha_k e^{\lambda_k t} a_k$ of $A(\frac{d}{dt})w = 0$, we thus have

$$Q_{\Psi_+}(w)(0) = \int_{-\infty}^{0} Q_\Phi(w)dt = \begin{bmatrix} \bar{\alpha}_1 \\ \bar{\alpha}_2 \\ \vdots \\ \bar{\alpha}_n \end{bmatrix}^T T_\Phi \begin{bmatrix} \alpha_1 \\ \alpha_2 \\ \vdots \\ \alpha_n \end{bmatrix}. \tag{A.34}$$

Also, there exists a real symmetric matrix K_+ such that

$$Q_{\Psi_+}(w) = \|X\left(\frac{d}{dt}\right)w\|^2_{K_+},$$

where $X(\frac{d}{dt})$ is a minimal state map. Since $T_\Phi > 0$, (A.34) implies that $K_+ > 0$. Indeed, let $a \neq 0$ be arbitrary. Let $w \in \mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^q)$ be such that $A(\frac{d}{dt})w = 0$, say,

$w = \sum_{k=1}^{r} a_k e^{\lambda_k t}\alpha_k$, and $X(\frac{d}{dt})w(0) = a$. Such w exists by strict positivity (see the proof of Theorem 5.7). Thus we have

$$a^T K_+ a = \left\| X\left(\frac{d}{dt}\right) w(0) \right\|^2_{K_+} = \begin{bmatrix} \bar{\alpha}_1 \\ \bar{\alpha}_2 \\ \vdots \\ \bar{\alpha}_n \end{bmatrix}^T T_\Phi \begin{bmatrix} \alpha_1 \\ \alpha_2 \\ \vdots \\ \alpha_n \end{bmatrix} > 0.$$

This completes the proof of Theorem 9.3. ∎

Proof of Proposition 10.1. Let $R(\frac{d}{dt})w = 0$ and $w = M(\frac{d}{dt})\ell$ be, respectively, a kernel and an observable image representation of $\mathfrak{B}$. Then we have $R(\xi)M(\xi) = 0$. Furthermore, $v = R^T(-\frac{d}{dt})\ell'$is an image representation of $\mathfrak{B}^\perp$. Consider the BLDF $(R^T(-\frac{d}{dt})\ell')^T M(\frac{d}{dt})\ell$. Note that this is the BLDF associated with the two-variable polynomial matrix $R(-\zeta)M(\eta)$. By Theorem 3.1, there exists $\Psi(\zeta,\eta)$ such that $\frac{d}{dt}Q_\Psi(\ell',\ell) = (R^T(-\frac{d}{dt})\ell')^T M(\frac{d}{dt})\ell$, and by Theorem 5.5 $Q_\Psi(\ell',\ell)$ is a state function; in other words, if $X(\frac{d}{dt})$ and $\tilde{Z}(\frac{d}{dt})$ are minimal state maps of $\mathfrak{B}$ and $\mathfrak{B}^\perp$, then $Q_\Psi(\ell,\ell') = (\tilde{Z}(\frac{d}{dt})\ell')^T K X(\frac{d}{dt})\ell$ for some matrix K. The proposition follows by taking $Z := K^T\tilde{Z}$ if we can show that K is nonsingular. To show this, assume to the contrary that $Ka = 0$. Let $\tilde{w} \in \mathfrak{B} \cap \mathfrak{D}(\mathbb{R},\mathbb{R}^q)$ be a trajectory emanating at $t = 0$ from $x(0) = a$. It follows that

$$\int_0^\infty v^T \tilde{w} dt = 0$$

for all $v \in \mathfrak{B}^\perp \cap \mathfrak{D}(\mathbb{R},\mathbb{R}^q)$. Consider the function $\hat{w} : \mathbb{R} \to \mathbb{R}^q$ such that $w(0) = 0$ for $t \le 0$ and $\hat{w}(t) = \tilde{w}(t)$ for $t \ge 0$. Obviously it holds that

$$\int_{-\infty}^{+\infty} v^T \hat{w} dt = 0$$

for all $v \in \mathfrak{B}^\perp \cap \mathfrak{D}(\mathbb{R},\mathbb{R}^q)$. Therefore $\hat{w}$ belongs to the $L_2(\mathbb{R},\mathbb{R}^q)$ closure of $\mathfrak{B}$ (this is the one point in this paper where $\mathfrak{C}^\infty$ solutions are inadequate). Since $\hat{w}(t) = 0$ for $t \le 0$, it must hold that $x(0) = 0$. Hence $Ka = 0$ implies $a = 0$, yielding the result. ∎

In order to prove Theorem 10.2 we use the following lemma. Recall that the inertia of an $n \times n$ complex Hermitian matrix H is the triple (π_-, π_0, π_+), with π_- the number of negative eigenvalues, π_+ the number of positive eigenvalues, and $\pi_0 (= n - \pi_- - \pi_+)$ the multiplicity of the zero eigenvalue.

LEMMA A.3. *Let $\mathcal{L}$ be a linear subspace of $\mathbb{R}^n$. Consider the quadratic form $x^T Q x$ on $\mathbb{R}^n$ with $Q = Q^T$ nonsingular. Let the inertia of Q be $(\pi_-, 0, \pi_+)$ and assume that $\pi_+ = \dim(\mathcal{L})$. Then $a^T Q a > 0$ for all $0 \ne a \in \mathcal{L}$ iff $a^T Q^{-1} a < 0$ for $0 \ne a \in \mathcal{L}^\perp$, and $a^T Q a \ge 0$ for all $a \in \mathcal{L}$ iff $a^T Q^{-1} a \le 0$ for $a \in \mathcal{L}^\perp$.*

Proof. Let $\mathcal{L} = \ker(R) = \mathrm{im}(M)$ with R surjective and M injective. Then $\mathcal{L}^\perp = \mathrm{im}(R^T) = \ker(M^T)$. Furthermore, $a^T Q a > 0$ for $0 \ne a \in \mathcal{L}$ means $M^T Q M > 0$. Consider the relations

$$\begin{bmatrix} M^T \\ RQ^{-1} \end{bmatrix} Q \begin{bmatrix} M & Q^{-1}R^T \end{bmatrix} = \begin{bmatrix} M^T Q M & 0 \\ 0 & RQ^{-1}R^T \end{bmatrix},$$

$$\begin{bmatrix} M^T \\ R \end{bmatrix} Q \begin{bmatrix} M & Q^{-1}R^T \end{bmatrix} = \begin{bmatrix} M^T Q M & 0 \\ RQM & RR^T \end{bmatrix}.$$

The second relation shows that $[M \;\; Q^{-1}R^T]$ is nonsingular. The first shows that

$$\text{in}(M^TQM) + \text{in}(RQ^{-1}R^T) = \text{in}(Q).$$

Hence $M^TQM > 0$ implies $RQ^{-1}R^T < 0$. To get the $\geq$ case, replace Q by $Q + \epsilon I$ and let $\epsilon \downarrow 0$. □

Proof of Theorem 10.2. To prove (i) and (ii), combine Proposition 5.2 and Lemma A.3 in the following way. For $\omega \in \mathbb{R}$ fixed, define $\mathcal{L} := \text{im}(M(i\omega)) = \ker(R(i\omega))$. Define $Q := \Sigma_\Phi$. Note that $Q^{-1} = \Sigma_\Phi$ as well. Using that $M(i\omega)$ and $R^T(-i\omega)$ are injective, we get the equivalence

$$M^T(i\omega)\Sigma_\Phi M(i\omega) > 0 \;\; \Leftrightarrow \;\; R(i\omega)\Sigma_\Phi R^T(-i\omega) < 0$$

which yields statement (ii). Statement (i) follows from the second assertion of Lemma A.3, which yields the same equivalence with nonstrict inequalities.

We now prove (iii). Again this can be proven using Lemma A.3, this time with $Q = \Sigma_\Phi - \epsilon I$. We then get

$$M^T(i\omega)(\Sigma_\Phi - \epsilon I)M(i\omega) \geq 0 \;\; \Leftrightarrow \;\; R(i\omega)(\Sigma_\Phi - \epsilon I)^{-1}R^T(-i\omega) \leq 0.$$

Using the formula $\Sigma_\Phi + \epsilon I = (1 - \epsilon^2)(\Sigma_\Phi - \epsilon I)^{-1}$, the latter is equivalent with

$$R(i\omega)\Sigma_\Phi R^T(-i\omega) \leq -\epsilon R(i\omega)R^T(-i\omega).$$

This shows (iii).

In order to prove (iv), we need the following lemma.

LEMMA A.4. *Let (X, Z) be a matched pair of minimal state maps for $\mathfrak{B}$ and $\mathfrak{B}^\perp$. Define subspaces $\mathcal{L} \subset \mathbb{R}^{r+2n}$, $\mathcal{M} \subset \mathbb{R}^{r+2n}$ by*

$$\text{(A.35)}\; \mathcal{L} := \left\{ \begin{bmatrix} w \\ x \\ a \end{bmatrix} \in \mathbb{R}^{r+2n} \mid \exists \ell \in \mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^\bullet) \;\; \begin{bmatrix} w \\ x \\ a \end{bmatrix} = \begin{bmatrix} M(\frac{d}{dt})\ell \\ X(\frac{d}{dt})\ell \\ \frac{d}{dt}X(\frac{d}{dt})\ell \end{bmatrix} (0) \right\},$$

$$\text{(A.36)}\; \mathcal{M} := \left\{ \begin{bmatrix} v \\ b \\ z \end{bmatrix} \in \mathbb{R}^{r+2n} \mid \exists \ell' \in \mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^\bullet) \;\; \begin{bmatrix} v \\ b \\ z \end{bmatrix} = \begin{bmatrix} R^T(-\frac{d}{dt})\ell' \\ -\frac{d}{dt}Z(\frac{d}{dt})\ell' \\ -Z(\frac{d}{dt})\ell' \end{bmatrix} (0) \right\}.$$

Then $\dim(\mathcal{L}) = n + m$ *and* $\mathcal{L}^\perp = \mathcal{M}$.

Proof. There exists a permutation matrix P such that

$$PM = \begin{bmatrix} U \\ Y \end{bmatrix}$$

with $U \in \mathbb{R}^{m\times m}[\xi]$ and YU^{-1} a proper rational matrix. If we define $u = U(\frac{d}{dt})\ell$ and $y = Y(\frac{d}{dt})\ell$, then u has the usual properties of input and y has the usual properties of output of $\mathfrak{B}$. There exist matrices $A \in \mathbb{R}^{n\times n}$, $B \in \mathbb{R}^{n\times m}$, $C \in \mathbb{R}^{p\times n}$, and $D \in \mathbb{R}^{p\times m}$ (with $p = r - m$, the number of outputs) such that $x = X(\frac{d}{dt})\ell$, $u = U(\frac{d}{dt})\ell$, and $y = Y(\frac{d}{dt})\ell$ are exactly related by $\frac{dx}{dt} = Ax + Bu$, $y = Cx + Du$. Thus for all $\ell \in \mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^\bullet)$ we have:

$$\begin{bmatrix} P & 0 & 0 \\ 0 & I & 0 \\ 0 & 0 & I \end{bmatrix} \begin{bmatrix} M(\frac{d}{dt})\ell \\ X(\frac{d}{dt})\ell \\ \frac{d}{dt}X(\frac{d}{dt})\ell \end{bmatrix} (0) = \begin{bmatrix} 0 & I_m \\ C & D \\ I_n & 0 \\ A & B \end{bmatrix} \cdot \begin{bmatrix} X(\frac{d}{dt})\ell \\ U(\frac{d}{dt})\ell \end{bmatrix} (0).$$

This implies

$$\begin{bmatrix} P & 0 & 0 \\ 0 & I & 0 \\ 0 & 0 & I \end{bmatrix} \mathcal{L} \subset \operatorname{im} \begin{bmatrix} 0 & I_m \\ C & D \\ I_n & 0 \\ A & B \end{bmatrix}.$$

Here, in fact, equality holds. Indeed, given col (x_0, u_0), take any $x \in \mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^n)$ and $u \in \mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^m)$ such that $x(0) = x_0$ and $u(0) = u_0$, and such that $\frac{dx}{dt} = Ax + Bu$, $y = Cx + Du$. There exists $\ell \in \mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^\bullet)$ such that $x = X(\frac{d}{dt})\ell$, $u = U(\frac{d}{dt})\ell$. This shows that equality holds and that $\dim(\mathcal{L}) = n + m$.

We now prove that $\mathcal{L}^\perp = \mathcal{M}$. For all $\ell \in \mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^\bullet)$ and $\ell' \in \mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^\bullet)$ we have that (10.4) holds. By evaluating this for $t = 0$, we immediately obtain that $\mathcal{L} \perp \mathcal{M}$. Thus it suffices to show that $\dim \mathcal{L} = n + (r - m)$. This is, however, an immediate consequence of the fact that the number of inputs of $\mathfrak{B}^\perp$, $m(\mathfrak{B}^\perp)$ is equal to $r - m$. ∎

We now return to the proof of (iv) of Theorem 10.2. Assume that $\int Q_\Phi \geq 0$ and let $\Psi(\zeta, \eta) = X^T(\zeta) K X(\eta)$, with $K = K^T$ a storage function for Φ, i.e., $\overset{\bullet}{\Psi} \leq \Phi$. In terms of $w = M(\frac{d}{dt})\ell$, $x = X(\frac{d}{dt})\ell$, $\frac{dx}{dt} = \frac{d}{dt}X(\frac{d}{dt})\ell$ this inequality yields, in particular,

$$\begin{bmatrix} w(0) \\ x(0) \\ \frac{dx}{dt}(0) \end{bmatrix}^T \begin{bmatrix} \Sigma_\Phi & 0 & 0 \\ 0 & 0 & -K \\ 0 & -K & 0 \end{bmatrix} \begin{bmatrix} w(0) \\ x(0) \\ \frac{dx}{dt}(0) \end{bmatrix} \geq 0. \tag{A.37}$$

Denote the symmetric matrix in (3.16) by Q. Note that (A.37) says that $a^T Q a \geq 0$ for all $a \in \mathcal{L}$, with $\mathcal{L}$ defined by (A.35). Since $\dim(\mathcal{L}) = n + m = n + r_+$, which is exactly the number of positive eigenvalues of Q, it follows from Lemma A.3 that $a^T Q^{-1} a \leq 0$ for all $a \in \mathcal{L}^\perp = \mathcal{M}$. More explicitly,

$$a^T \begin{bmatrix} \Sigma_\Phi & 0 & 0 \\ 0 & 0 & -K^{-1} \\ 0 & -K^{-1} & 0 \end{bmatrix} a \leq 0 \tag{A.38}$$

for $a \in \mathcal{L}^\perp$. A typical element of $\mathcal{M}$ has the form

$$a = \begin{bmatrix} R^T(-\frac{d}{dt})\ell' \\ -\frac{d}{dt}Z(\frac{d}{dt})\ell' \\ -Z(\frac{d}{dt})\ell' \end{bmatrix}(t),$$

where $\ell' \in \mathfrak{C}^\infty(\mathbb{R}, \mathbb{R}^\bullet)$. By letting $t \in \mathbb{R}$ be arbitrary, the inequality (A.38) yields exactly the dissipation inequality

$$\frac{d}{dt}\|Z\left(\frac{d}{dt}\right)\ell'\|^2_{-K^{-1}} \leq \|R^T\left(-\frac{d}{dt}\right)\ell'\|^2_{-\Sigma_\Phi}$$

which is the content of (4). To show (v), use (iv) and Theorem 9.3. ∎

TRUST-REGION INTERIOR-POINT SQP ALGORITHMS FOR A CLASS OF NONLINEAR PROGRAMMING PROBLEMS*

J. E. DENNIS†, MATTHIAS HEINKENSCHLOSS†, AND LUÍS N. VICENTE‡

Abstract. In this paper, a family of trust-region interior-point sequential quadratic programming (SQP) algorithms for the solution of a class of minimization problems with nonlinear equality constraints and simple bounds on some of the variables is described and analyzed. Such nonlinear programs arise, e.g., from the discretization of optimal control problems. The algorithms treat states and controls as independent variables. They are designed to take advantage of the structure of the problem. In particular they do not rely on matrix factorizations of the linearized constraints but use solutions of the linearized state equation and the adjoint equation. They are well suited for large scale problems arising from optimal control problems governed by partial differential equations.

The algorithms keep strict feasibility with respect to the bound constraints by using an affine scaling method proposed, for a different class of problems, by Coleman and Li [*SIAM J. Optim.,* 6 (1996), pp. 418–445] and they exploit trust-region techniques for equality-constrained optimization. Thus, they allow the computation of the steps using a variety of methods, including many iterative techniques.

Global convergence of these algorithms to a first-order Karush–Kuhn–Tucker (KKT) limit point is proved under very mild conditions on the trial steps. Under reasonable, but more stringent, conditions on the quadratic model and on the trial steps, the sequence of iterates generated by the algorithms is shown to have a limit point satisfying the second-order necessary KKT conditions. The local rate of convergence to a nondegenerate strict local minimizer is q-quadratic. The results given here include, as special cases, current results for only equality constraints and for only simple bounds.

Numerical results for the solution of an optimal control problem governed by a nonlinear heat equation are reported.

1. Introduction.

In this paper we introduce and analyze a family of algorithms for the solution of an important class of minimization problems which often arise from the discretization of optimal control problems. These problems are specially structured nonlinear programming problems of the following form:

$$\begin{aligned} &\text{minimize } f(y,u) \\ &\text{subject to } C(y,u)=0, \\ &\qquad u\in\mathcal{B}=\{u:\ a\le u\le b\}, \end{aligned} \tag{1}$$

where $y \in \mathbb{R}^m$, $u \in \mathbb{R}^{n-m}$, $a \in (\mathbb{R} \cup \{-\infty\})^{n-m}$, and $b \in (\mathbb{R} \cup \{+\infty\})^{n-m}$. The functions $f : \mathbb{R}^n \longrightarrow \mathbb{R}$ and $C : \mathbb{R}^n \longrightarrow \mathbb{R}^m$, $m < n$, are assumed to be at least continuously differentiable. As indicated above, minimization problems of the form (1) often arise from the discretization of optimal control problems. In this case y is the vector of state variables, u is the vector of control variables, and $C(y, u) = 0$ is the discretized state equation. Other applications, which might be viewed as special optimal control problems, include optimal design and parameter identification problems. Minimization problems (1) originating from optimal control problems governed by large systems of ordinary differential equations (ODEs) or partial differential equations (PDEs) are the targets of the algorithms in this paper.

Although there are algorithms available for the solution of nonlinear programming problems that are more general than (1), the family of algorithms presented in this paper is unique in the consequent use of structure inherent in many optimal control problems, the use of optimization techniques successfully applied in other contexts of nonlinear programming, and the rigorous theoretical justification.

Our algorithms are based on sequential quadratic programming (SQP) methods and use trust-region interior-point techniques to guarantee global convergence and to handle the bound constraints on the controls. SQP methods find a solution of the nonlinear programming problem (1) by solving a sequence of quadratic programming problems. It is known, see, e.g., [37], [38], that the structure of optimal control problems can be used to implement and analyze SQP methods. In particular, to implement SQP methods, it is sufficient to compute quantities of the form $C_y(y, u)v_y$, $C_y(y, u)^T v_y$, $C_u(y, u)v_u$, $C_u(y, u)^T v_y$ and to compute solutions of the linearized state equation $C_y(y, u)v_y = r$ and of the "adjoint equation" $C_y(y, u)^T v_y = r$. Here C_y and C_u denote the derivatives of C with respect to y and u. This is an important observation, because these are tasks that arise naturally in the context of optimal control problems. All of the early SQP algorithms, and many of the recent ones, rely on matrix factorizations, such as sparse LU decompositions, of the Jacobian $J(x)$ of $C(x)$. For the applications we have in mind this is not feasible. Often, the involved matrices are too large to perform such computations and very often these matrices are not even available in explicit form. On the other hand, matrix-vector multiplications $C_y(x)v_y$, $C_y(x)^T v_y$, $C_u(x)v_u$, $C_u(x)^T v_y$ can be performed, and efficient solvers for the linearized state equation $C_y(x)v_y = r$, and the adjoint equation $C_y(x)^T v_y = r$, are often available. For example, the partial Jacobian $C_y(x)$ in the application treated in section 11 has a block bidiagonal structure with diagonal matrices being tridiagonal. Thus, while the Jacobian is large, the solution of the linearized state equation or the adjoint equation can be done by block forward substitution or block backward substitution, respectively. In each substitution step, only a relatively small system with a tridiagonal system has to be solved. This is typical for many applications, in particular those in dynamical systems. Many SQP-based codes for optimal control problems governed by ODEs or DAEs (differential algebraic equations) exploit this structure efficiently in their numerical linear algebra. See, e.g., [1], [2], [42], [58], [62], and the references therein. For many applications, in particular those governed by PDEs, such factorizations of the Jacobian $J(x)$ of $C(x)$ are not feasible from a practical point of view, but solution techniques for $C_y(y, u)v_y = r$ and $C_y(y, u)^T v_y = r$ are available. This has motivated us to require only this information and to design a practicable algorithm that disjoins the particular equation solver from the optimization algorithm. In the presence of bound constraints, this task goes well beyond the mere replacement of matrix factorizations by black-box solvers. The implementation

of our algorithm is given in [16].

A purely local analysis for the case with no bound constraints has been given in [34], [36], [37], and [39]. However, we consider here the much more difficult issue of incorporating this entire structure into an algorithm that converges globally and handles bound constraints on the control variables u.

The global convergence of our algorithms is guaranteed by a trust-region strategy. In our framework the trust region serves a dual purpose. Besides ensuring global convergence, trust regions also introduce a regularization of the subproblems which is related to the Tikhonov regularization. For the solution of optimal control problems, the partitioning of the variables into states y and controls u motivates a partial decoupling of step components that leads to interesting alternatives for the choice of the trust region. In Sections 5.2.1 and 5.2.2 we will introduce a decoupled and a coupled trust-region approach. As indicated by the names, in the decoupled approach the trust region will act on step components separately. This allows a more efficient implementation of algorithms for the computation of these steps. However, for problems with ill-conditioned state equations, this decoupling does not give an accurate estimate of the size of the steps and might lead to poor performance. In this situation the coupled approach is better, and so we include both.

For the treatment of the bound constraints on u we use an affine scaling interior-point method introduced by Coleman and Li [13] for problems with simple bounds. Interior-point approaches are attractive for many optimization problems with a large number of bounds, including the structured problem (1). In our context, the affine scaling interior-point method is also of interest, because it does not interfere with the structure of the problem (1). To apply this method, no information in addition to that needed for the case without bound constraints is required from the user. This or similar interior-point approaches have recently also been used, e.g., in [6], [14], [43], [44], and [50]. The advantage of the approach in [13] is that the scaling matrix is determined by the distance of the iterates to the bounds and by the direction of the gradient. This dependence on the direction of the gradient is important for global convergence and its good effect can be seen in numerical examples; see, e.g., Figures 1 and 2.

Another important issue that is addressed in the implementations of the algorithms presented in this paper is the problem scaling inherent in optimal control problems. As we have pointed out, the problems we are primarily interested in are discretizations of optimal control problems governed by partial differential equations. The infinite-dimensional problem structure greatly influences the finite-dimensional problem. In our implementation, we take this into account by choosing scalar products for the states y, the controls u, and the duality pairing needed to represent $\lambda^T C(y, u)$, products that are discretizations of proper infinite-dimensional ones. It is beyond the scope of this paper to give a comprehensive theoretical study of these issues, but it is important to notice that the formulation of the algorithms discussed here fully supports the use of such scalar products without any changes. This is a great advantage. In some of our numerical experiments [11], [30] this improved the performance of our algorithms significantly, avoided artificial ill conditioning, and enhanced the quality of the solution computed for a given stopping tolerance. Moreover, our numerical experiments also indicate the mesh-independent behavior of our algorithms when this type of scaling is used.

We believe that the features and strong theoretical properties of these algorithms make them very attractive and powerful tools for the solution of optimal control

problems. They have been successfully applied to a boundary control problem (see section 11), a distributed nonlinear elliptic control problem [31], and optimal control problems arising in fluid flow [11], [30]. The software that produced these results is currently being beta-tested with the intent of electronic distribution [16].

Before we give an outline of this paper, it is worth discussing the relationship between the constrained minimization problem (1) and an equivalent reduced problem. Under the assumptions of the implicit function theorem it is possible to solve $C(y,u) = 0$ for y. This defines a smooth function $y(u)$ and allows us to reduce the minimization problem (1). The reduced problem is given by

$$\begin{aligned} &\text{minimize} && \hat{f}(u) \equiv f(y(u),u) \\ &\text{subject to} && u \in \mathcal{B} = \{u :\ a \le u \le b\}. \end{aligned} \tag{2}$$

This leads to the so-called *black-box* approach in which the nonlinear constraint $C(y,u) = 0$ is not visible to the optimizer. Its solution is part of the evaluation of the objective function $\hat{f}(u)$. The reduced problem can be solved by a gradient or a Newton-like method. For optimal control problems, many algorithms follow this approach. Often, projection techniques are used to handle the box constraints; see, e.g., [28], [51].

Recently, so-called *all-at-once* approaches that treat both y and u as independent variables have been proposed to solve optimal control problems; see, e.g., [1], [2], [4], [29], [32], [33], [34], [35], [36], [37], [39], [41], [42], [57], [58], [62].

Since *all-at-once approaches* move towards optimality and feasibility at the same time, they offer significant advantages. SQP methods are of particular interest. They do not require the possibly very expensive solution of the nonlinear state equation in every step, but as indicated above allow use of the structure of optimal control problems. In addition, SQP methods have proven to be very successful for the solution of other nonlinear programming problems. See, e.g., [5], [9], [23], [24], [40], [47], [48], [50], [56].

As outlined before, we use SQP-based methods for the solution of (1), i.e., the all-at-once approach. However, the reduced problem (2) is important to us for two reasons. Firstly, the relation between the full problem (1) and the reduced problem (2) gives important insight into the structure of (1) and allows us to extend techniques successfully applied to problems of the form (2). Secondly, black-box approaches are used very often to solve the problems we have in mind. We want to use this expertise in designing more efficient codes. Specifically, our consequent use of the structure of the optimal control problems leads to our family of trust-region interior-point SQP algorithms. These algorithms only require information that the user has to provide if a black-box approach is used with a Newton-like method for the solution of the nonlinear state equation and adjoint equation techniques for the computation of gradients. Thus, we combine the possible implementational advantages of a black-box approach with the generally more efficient all-at-once approach. It will be seen that in our algorithms the step s is decomposed into two components: $s = s^{\mathsf{n}} + s^{\mathsf{t}}$, where s^{n} is called the quasi-normal component and s^{t} is called the tangential component. The role of quasi-normal component s^{n} is to move towards feasibility. It is of the form $s^{\mathsf{n}} = ((s_y^{\mathsf{n}})^T\ 0^T)^T$, where s_y^{n} is essentially a Newton step for the solution of the nonlinear state equation $C(y,u) = 0$ for given u. For most problems of interest here, the computation of a "true" normal component is not practical. The tangential component s^{t} moves towards optimality. This component is in the null space of the linearized constraints and it is of the form $s^{\mathsf{t}} = ((-C_y(y,u)^{-1}C_u(y,u)s_u)^T\ s_u^T)^T$,

where s_u is essentially a Newton-like step for the reduced problem (2).

This paper is organized as follows: In section 2 we discuss the structure of the problem and motivate our SQP approach. We study the relationship between the all-at-once approach based on (1) and the black-box approach for (2) and the relationship between SQP methods for (1) and Newton methods for (2). For problems without box constraints, these connections are known, but for problems with box constraints, this will reveal useful new information. The first- and second-order Karush–Kuhn–Tucker (KKT) conditions for (1) are stated in section 3. We will state them in a nonstandard form that will lead to the scaling matrix used in the affine scaling interior-point approach. In section 4 we will discuss the application of Newton's method to the system of nonlinear equations arising from the first-order KKT conditions. This will be important for the derivation of our SQP method. In section 5 we describe our trust-region interior-point SQP algorithms. Sections 5.1 and 5.2 contain descriptions of the quasi-normal component and the tangential component. Using the derivations in sections 2 and 4, the connections between the quasi-normal component s^{n} and the Newton step for the solution of the nonlinear state equation $C(y,u) = 0$ for given u, and the relations between the tangential component s^{t} and Newton-like steps for the reduced problem (2), will be made precise. As noticed previously, the partial decoupling of the step components motivated by the partitioning of the variables into states y and controls u, and the roles of the decoupled and coupled trust-region approaches, will be exposed in sections 5.2.1 and 5.2.2. A complete statement of the trust-region interior-point SQP algorithms is given in section 5.4.

The convergence theory for these algorithms is given in sections 6, 7, 8, and 9. Section 6 contains some technical results. In section 7 we establish the existence of an accumulation point of the iterates which satisfies the first-order KKT conditions (Corollary 7.6). This result is established under very mild assumptions on the steps and on the Lagrange multipliers. It simultaneously extends the results presented recently by Coleman and Li [13] for simple bounds and those by Dennis, El-Alem, and Maciel [15] for equality constraints. Under additional conditions on the steps and the quadratic model, we show that the accumulation point satisfying the first-order necessary KKT conditions also solves the second-order necessary KKT conditions (Theorem 8.2). This latter result simultaneously extends those by Coleman and Li [13] for simple bounds and those by Dennis and Vicente [19] for equality constraints (see also [65]). Finally, we prove that if the sequence converges to a nondegenerate point satisfying the sufficient second-order KKT conditions, then the rate of convergence is q-quadratic (Corollary 9.4). Our analysis allows the application of a variety of methods for the computation of the step components s^{n} and s^{t}. In section 10 we discuss practical algorithms for the computation of trial steps and the multiplier estimates that are currently used in our implementation. Numerical results obtained with our implementation of these algorithms, called TRICE (trust-region interior-point SQP algorithms for optimal control and engineering design problems) [16], are reported in section 11. Section 12 contains conclusions and a discussion of future work.

We review the notation used in this paper. The vector x is given by

$$x = \begin{pmatrix} y \\ u \end{pmatrix}.$$

The Jacobian matrix of $C(x)$ is denoted by $J(x)$. We use subscripted indices to represent the evaluation of a function at a particular point of the sequences $\{x_k\}$ and

$\{\lambda_k\}$. For instance, f_k represents $f(x_k)$, and ℓ_k is the same as $\ell(x_k, \lambda_k)$. The vector and matrix norms used are the ℓ_2 norms, and I_l represents the identity matrix of order l. Also, $(z)_y$ and $(z)_u$ represent the subvectors of $z \in \mathbb{R}^n$ corresponding to the y and u components, respectively.

2. The structure of the minimization problem. The purpose of this section is to discuss some of the basic relationships between the problem (1) and its reduction (2). This will introduce fundamental quantities that are subsequently needed, and it will support our claim that the basic quantities needed to implement our SQP approach are already available if one uses a gradient or Newton-like method for the solution of the reduced problem (2).

The Lagrange function $\ell : \mathbb{R}^{n+m} \longrightarrow \mathbb{R}^n$ associated with the objective function $f(x)$ and the equality constraint $C(x) = (c_1(x), \ldots, c_m(x))^T = 0$ is given by

$$\ell(x, \lambda) = f(x) + \lambda^T C(x),$$

where $\lambda \in \mathbb{R}^m$ are the Lagrange multipliers.

The linearized constraints are given by $J(x)s = -C(x)$ or, equivalently, by

$$\begin{pmatrix} C_y(x) & C_u(x) \end{pmatrix} \begin{pmatrix} s_y \\ s_u \end{pmatrix} = -C(x). \tag{3}$$

We say that

$$s = \begin{pmatrix} s_y \\ s_u \end{pmatrix}, \quad s_y \in \mathbb{R}^m,\ s_u \in \mathbb{R}^{n-m}$$

satisfies the linearized state equation if it is a solution to (3). If $C_y(x)$ is invertible, the solutions of the linearized state equation are of the form

$$s = s^{\mathsf{n}} + W(x)s_u, \tag{4}$$

where

$$s^{\mathsf{n}} = \begin{pmatrix} -C_y(x)^{-1}C(x) \\ 0 \end{pmatrix} \tag{5}$$

is a particular solution and

$$W(x) = \begin{pmatrix} -C_y(x)^{-1}C_u(x) \\ I_{n-m} \end{pmatrix}$$

is a matrix whose columns form a basis for the null space $\mathcal{N}(J(x))$ of $J(x)$. One can see that matrix-vector multiplications of the form $W(x)^T s$ and $W(x)s_u$ involve only the solution of linear systems with the matrices $C_y(x)$ and $C_y(x)^T$. Moreover, the y component of the particular solution s^{n} is just the step that one would compute if one would apply Newton's method for the solution of the nonlinear equation $C(y, u) = 0$ for given u.

The point we want to convey in this section has nothing to do with the presence or absence of the bound constraints $a \leq u \leq b$. Therefore, for the remainder of this section, we consider the simpler case where there are no bound constraints, i.e., where $\mathcal{B} = \mathbb{R}^{n-m}$. If we solve (1) with $\mathcal{B} = \mathbb{R}^{n-m}$ by an SQP method, then the quadratic programming subproblem we have to solve at every iteration is of the form

$$\begin{aligned} \text{minimize} \quad & \nabla f(x)^T s + \tfrac{1}{2} s^T \nabla^2_{xx} \ell(x, \lambda)\ s \\ \text{subject to} \quad & C_y(x)s_y + C_u(x)s_u + C(x) = 0. \end{aligned} \tag{6}$$

If the reduced Hessian $W(x)^T\nabla^2_{xx}\ell(x,\lambda)W(x)$ is nonsingular, the solution of (6) is given by (4) with

$$s_u = -\Big(W(x)^T\nabla^2_{xx}\ell(x,\lambda)\,W(x)\Big)^{-1}W(x)^T\Big(\nabla f(x) + \nabla^2_{xx}\ell(x,\lambda)s^{\mathsf{n}}\Big). \tag{7}$$

In practice the Hessian $\nabla^2_{xx}\ell(x,\lambda)$ or the reduced Hessian $W(x)^T\nabla^2_{xx}\ell(x,\lambda)\,W(x)$ are often approximated using quasi-Newton updates. In the latter case, when an approximation to $\nabla^2_{xx}\ell(x,\lambda)$ is not available, then the "cross term" $W(x)^T\nabla^2_{xx}\ell(x,\lambda)s^{\mathsf{n}}$ has also to be approximated. This term can be approximated by zero, by finite differences, or by other quasi-Newton approximations; see, e.g., [3]. In the case where this cross term is approximated by zero, the right-hand side of the linear system (7) defining s_u can be written as

$$W(x)^T\nabla f(x) = -C_u(x)^TC_y(x)^{-T}\nabla_y f(x) + \nabla_u f(x).$$

Thus, if the Lagrange multiplier is computed by the adjoint formula

$$\lambda = -C_y(x)^{-T}\nabla_y f(x), \tag{8}$$

then

$$W(x)^T\nabla f(x) = C_u(x)^T\lambda + \nabla_u f(x) = \nabla_u\ell(x,\lambda).$$

Now we turn to the reduced problem with $\mathcal{B} = \mathbb{R}^{n-m}$. Suppose there exists an open set $\mathcal{U}$ such that for all $u \in \mathcal{U}$ there exists a solution y of $C(y,u) = 0$ and such that the matrix $C_y(x)$ is invertible for all $x = (y,u)$ with $u \in \mathcal{U}$ and $C(y,u) = 0$. Then the implicit function theorem guarantees the existence of a differentiable function

$$y : \mathcal{U} \to \mathbb{R}^m$$

defined by

$$C(y(u),u) = 0,$$

and the problem (1) can be reduced to (2). Since $y(\cdot)$ is differentiable, the function $\hat{f}$ is differentiable and its gradient is given by

$$\nabla\hat{f}(u) = W(y(u),u)^T\nabla f(y(u),u),$$

cf. [29]. Moreover, it can be shown that the Hessian of $\hat{f}$ is equal to the reduced Hessian

$$\nabla^2\hat{f}(u) = W(y(u),u)^T\nabla^2_{xx}\ell(y(u),u,\lambda)\;W(y(u),u),$$

provided that the Lagrange multiplier is computed from (8).

One can see that the gradient and the Hessian information in the SQP method for (1) and in the Newton method for (2) are the same if (y, u) solves $C(y, u) = 0$. Thus, if Newton-like methods are applied for the solution of (2), then one has all the available ingredients necessary to implement an SQP method for the solution of (1). The important difference, of course, is that in the SQP method we do not have to solve the nonlinear constraints $C(y, u) = 0$ at every iteration.

In these considerations we neglected the bound constraints $a \le u \le b$. These will be analyzed in the following sections. We already point out that these relationships between (1) and (2) are basically the same with or without the bound constraints.

3. Optimality conditions. A point x_* satisfies the first-order KKT conditions if there exist $\lambda_* \in \mathbb{R}^m$ and $\mu_*^a, \mu_*^b \in \mathbb{R}^{n-m}$ such that

$$
\begin{aligned}
&C(x_*) = 0,\\
&a \le u_* \le b,\\
&\begin{pmatrix} \nabla_y f(x_*) \\ \nabla_u f(x_*) \end{pmatrix} + \begin{pmatrix} C_y(x_*)^T \lambda_* \\ C_u(x_*)^T \lambda_* \end{pmatrix} - \begin{pmatrix} 0 \\ \mu_*^a \end{pmatrix} + \begin{pmatrix} 0 \\ \mu_*^b \end{pmatrix} = 0,\\
&((u_*)_i - a_i)\,(\mu_*^a)_i = (b_i - (u_*)_i)\,(\mu_*^b)_i = 0, \quad i = 1, \ldots, n-m, \quad \text{and}\\
&\mu_*^a \ge 0,\ \mu_*^b \ge 0.
\end{aligned}
$$

These KKT conditions are necessary conditions for x_* to be a local solution of (1). Note that the constraint qualifications are satisfied, since the invertibility of $C_y(x_*)$ and the form of the bound constraints imply the linear independence of the active constraints. Under the assumption of the invertibility of $C_y(x_*)$, we can rewrite the first-order KKT conditions:

$$
\begin{aligned}
&C(x_*) = 0,\\
&a \le u_* \le b,\\
&\lambda_* = -C_y(x_*)^{-T} \nabla_y f(x_*),\\
&a_i < (u_*)_i < b_i \implies (\nabla_u \ell(x_*, \lambda_*))_i = 0,\\
&(u_*)_i = a_i \implies (\nabla_u \ell(x_*, \lambda_*))_i \ge 0, \quad \text{and}\\
&(u_*)_i = b_i \implies (\nabla_u \ell(x_*, \lambda_*))_i \le 0.
\end{aligned}
$$

One can obtain a useful form of the first-order KKT conditions by noting that

$$
\begin{aligned}
\nabla_u \ell(x_*, \lambda_*) &= \nabla_u f(x_*) + C_u(x_*)^T \lambda_*\\
&= \nabla_u f(x_*) - C_u(x_*)^T C_y(x_*)^{-T} \nabla_y f(x_*)\\
&= W(x_*)^T \nabla f(x_*).
\end{aligned}
$$

In other words, $\nabla_u \ell(x_*, \lambda_*)$ is just the reduced gradient corresponding to the u variables. Hence x_* is a first-order KKT point if

$$
\begin{aligned}
&C(x_*) = 0,\\
&a \le u_* \le b,\\
&a_i < (u_*)_i < b_i \implies \big(W(x_*)^T \nabla f(x_*)\big)_i = 0,\\
&(u_*)_i = a_i \implies \big(W(x_*)^T \nabla f(x_*)\big)_i \ge 0, \quad \text{and}\\
&(u_*)_i = b_i \implies \big(W(x_*)^T \nabla f(x_*)\big)_i \le 0.
\end{aligned}
$$

Furthermore, x_* satisfies the second-order necessary KKT conditions if it satisfies the first-order KKT conditions and if the principal submatrix of the reduced Hessian

$$W(x_*)^T \nabla^2_{xx} \ell(x_*, \lambda_*) W(x_*)$$

corresponding to indices i such that $a_i < (u_*)_i < b_i$ is positive semidefinite, where the multipliers λ_* are given by $\lambda_* = -C_y(x_*)^{-T} \nabla_y f(x_*)$.

Now we adapt the idea of Coleman and Li [12] to this context and define $D(x) \in \mathbb{R}^{(n-m)\times(n-m)}$ to be the diagonal matrix with diagonal elements given by

$$\Big(D(x)\Big)_{ii} = \begin{cases} (b-u)_i^{\frac{1}{2}} & \text{if} \quad \big(W(x)^T \nabla f(x)\big)_i < 0 \text{ and } b_i < +\infty, \\ 1 & \text{if} \quad \big(W(x)^T \nabla f(x)\big)_i < 0 \text{ and } b_i = +\infty, \\ (u-a)_i^{\frac{1}{2}} & \text{if} \quad \big(W(x)^T \nabla f(x)\big)_i \geq 0 \text{ and } a_i > -\infty, \\ 1 & \text{if} \quad \big(W(x)^T \nabla f(x)\big)_i \geq 0 \text{ and } a_i = -\infty, \end{cases} \tag{9}$$

for $i = 1, \ldots, n-m$. In the following proposition we give the form of the first- and second-order necessary KKT conditions that we use in this paper. To us, they indicate the suitability of (9) as a scaling for (1). See also [13], [18], [64], and the remark below for further discussions on the choice of D as a scaling matrix.

PROPOSITION 3.1. *The point x_* satisfies the first-order KKT conditions if and only if*

$$\begin{aligned} &C(x_*) = 0, \quad a \leq u_* \leq b, \quad \textit{and} \\ &D(x_*) W(x_*)^T \nabla f(x_*) = 0. \end{aligned}$$

The point x_* satisfies the second-order necessary KKT conditions if and only if it satisfies the first-order KKT conditions and

$$D(x_*) W(x_*)^T \nabla^2_{xx} \ell(x_*, \lambda_*) W(x_*) D(x_*)$$

is positive semidefinite. The corresponding multiplier is given by

$$\lambda_* = -C_y(x_*)^{-T} \nabla_y f(x_*).$$

Remark 3.1. Proposition 3.1 remains valid for a larger class of diagonal matrices $D(x)$. The scalar 1 in the definition (9) of D can be replaced by any other positive scalar, and Proposition 3.1 also remains valid with $D(x)$ replaced by $D(x)^p$, $p > 0$. Most of our convergence results still hold true if $D(x)$ is replaced by $D(x)^p$, $p \geq 1$. See also Remark 8.1 and, for the case of simple bound constraints, see [18], [64]. However, the square roots in the definition of $D(x)$ will be necessary for the proof of local q-quadratic convergence of our algorithms.

The form of the sufficient optimality conditions used in this paper requires the definition of nondegeneracy or strict complementarity.

DEFINITION 3.2. *A point x in $\mathcal{B}$ is said to be nondegenerate if $(W(x)^T \nabla f(x))_i = 0$ implies $a_i < u_i < b_i$ for all $i \in \{1, \ldots, n-m\}$.*

We now define a diagonal $(n-m)\times(n-m)$ matrix $E(x)$ with diagonal elements given by

$$\Big(E(x)\Big)_{ii} = \begin{cases} \big|\big(W(x)^T\nabla f(x)\big)_i\big| & \text{if } \big(W(x)^T\nabla f(x)\big)_i < 0 \text{ and } b_i < +\infty, \text{ or} \\ & \text{if } \big(W(x)^T\nabla f(x)\big)_i > 0 \text{ and } a_i > -\infty, \\ 0 & \text{in all other cases,} \end{cases}$$

for $i = 1,\ldots,n-m$. The significance of this matrix will become clear in the next section when we apply Newton's method to the system of nonlinear equations arising from the first-order KKT conditions. From the definitions of $D(x)$ and $E(x)$ we have the following property.

PROPOSITION 3.3. *A nondegenerate point x_* satisfies the second-order sufficient KKT conditions if and only if it is a first-order KKT point and*

$$D(x_*)W(x_*)^T\nabla^2_{xx}\ell(x_*,\lambda_*)W(x_*)D(x_*) + E(x_*)$$

is positive definite, where $\lambda_* = -C_y(x_*)^{-T}\nabla_y f(x_*)$.

4. Newton's method. One way to motivate the algorithms described in this paper is to apply Newton's method to the system of nonlinear equations

$$\begin{aligned} &C(x) = 0, \\ &D(x)^2W(x)^T\nabla f(x) = 0, \end{aligned} \tag{10}$$

where x is strictly feasible with respect to the bounds on the variables u, i.e., $a < u < b$. This is related to Goodman's approach [27] for an orthogonal null-space basis and equality constraints. Although $D(x)^2$ is usually discontinuous at points where $(W(x)^T\nabla f(x))_i = 0$, the function $D(x)^2W(x)^T\nabla f(x)$ is continuous (but not differentiable) at such points. The application of Newton's method to this type of nonlinear systems has first been suggested by Coleman and Li [12] in the context of nonlinear minimization problems with simple bounds. They have shown that this type of nondifferentiability still allows the Newton process to achieve local q-quadratic convergence. In order to apply Newton's method we first need to compute some derivatives.

To calculate the Jacobian of the reduced gradient $W(x)^T\nabla f(x)$, we write

$$W(x)^T\nabla f(x) = \nabla_u f(x) + C_u(x)^T\lambda,$$

where λ is given by $C_y(x)^T\lambda = -\nabla_y f(x)$ and has derivatives

$$\begin{aligned} \tfrac{\partial\lambda}{\partial y} &= -C_y(x)^{-T}\left(\textstyle\sum_{i=1}^m \nabla^2_{yy}c_i(x)\lambda_i + \nabla^2_{yy}f(x)\right) \\ &= -C_y(x)^{-T}\nabla^2_{yy}\ell(x,\lambda), \\ \tfrac{\partial\lambda}{\partial u} &= -C_y(x)^{-T}\left(\textstyle\sum_{i=1}^m \nabla^2_{yu}c_i(x)\lambda_i + \nabla^2_{yu}f(x)\right) \\ &= -C_y(x)^{-T}\nabla^2_{yu}\ell(x,\lambda). \end{aligned}$$

This implies the equalities

$$\begin{aligned}\frac{\partial}{\partial y}\left(W(x)^T\nabla f(x)\right) &= C_u(x)^T\frac{\partial\lambda}{\partial y}+\nabla^2_{uy}f(x)+\textstyle\sum_{i=1}^m\nabla^2_{uy}c_i(x)\lambda_i\\ &= W(x)^T\begin{pmatrix}\nabla^2_{yy}\ell(x,\lambda)\\ \nabla^2_{uy}\ell(x,\lambda)\end{pmatrix},\\ \frac{\partial}{\partial u}\left(W(x)^T\nabla f(x)\right) &= C_u(x)^T\frac{\partial\lambda}{\partial u}+\nabla^2_{uu}f(x)+\textstyle\sum_{i=1}^m\nabla^2_{uu}c_i(x)\lambda_i\\ &= W(x)^T\begin{pmatrix}\nabla^2_{yu}\ell(x,\lambda)\\ \nabla^2_{uu}\ell(x,\lambda)\end{pmatrix},\end{aligned}$$

and we can conclude that

$$\frac{\partial}{\partial x}\left(W(x)^T\nabla f(x)\right)=W(x)^T\nabla^2_{xx}\ell(x,\lambda),$$

where $\lambda=-C_y(x)^{-T}\nabla_y f(x)$.

A linearization of (10) gives

$$C_y(x)s_y+C_u(x)s_u=-C(x), \tag{11}$$

$$\left(D(x)^2W(x)^T\nabla^2_{xx}\ell(x,\lambda)+\left[0\mid E(x)\right]\right)\begin{pmatrix}s_y\\ s_u\end{pmatrix}=-D(x)^2W(x)^T\nabla f(x), \tag{12}$$

where 0 denotes the $(n-m)\times m$ matrix with zero entries. Equation (11) is the linearized state equation. The diagonal elements of $E(x)$ are the product of the derivative of the diagonal elements of $D(x)^2$ and the components of the reduced gradient $W(x)^T\nabla f(x)$. The derivative of $(D(x)^2)_{ii}$ does not exist if $(W(x)^T\nabla f(x))_i=0$. In this case we set the corresponding quantities in the Jacobian to zero (see references [12], [13]). This gives the equation (12).

By using (4) we can rewrite the linear system (11)–(12) as

$$\begin{aligned}&s=s^{\mathsf{n}}+W(x)s_u,\\ &\quad\left(D(x)^2W(x)^T\nabla^2_{xx}\ell(x,\lambda)W(x)+E(x)\right)s_u\\ &=-D(x)^2W(x)^T\Big(\nabla^2_{xx}\ell(x,\lambda)s^{\mathsf{n}}+\nabla f(x)\Big).\end{aligned} \tag{13}$$

We define our Newton-like step as the solution of

$$\begin{aligned}&s=s^{\mathsf{n}}+W(x)s_u,\\ &\quad\left(\bar D(x)^2W(x)^T\nabla^2_{xx}\ell(x,\lambda)W(x)+E(x)\right)s_u\end{aligned} \tag{14}$$

$$=-\bar D(x)^2W(x)^T\Big(\nabla^2_{xx}\ell(x,\lambda)s^{\mathsf{n}}+\nabla f(x)\Big), \tag{15}$$

where $\bar D(x)\in\mathbb{R}^{(n-m)\times(n-m)}$ is the diagonal matrix defined by

(16)

$$\left(\bar D(x)\right)_{ii}=\begin{cases}(b-u)_i^{\frac12} & \text{if } \left(W(x)^T\left(\nabla^2_{xx}\ell(x,\lambda)s^{\mathsf{n}}+\nabla f(x)\right)\right)_i<0 \text{ and } b_i<+\infty,\\ 1 & \text{if } \left(W(x)^T\left(\nabla^2_{xx}\ell(x,\lambda)s^{\mathsf{n}}+\nabla f(x)\right)\right)_i<0 \text{ and } b_i=+\infty,\\ (u-a)_i^{\frac12} & \text{if } \left(W(x)^T\left(\nabla^2_{xx}\ell(x,\lambda)s^{\mathsf{n}}+\nabla f(x)\right)\right)_i\geq 0 \text{ and } a_i>-\infty,\\ 1 & \text{if } \left(W(x)^T\left(\nabla^2_{xx}\ell(x,\lambda)s^{\mathsf{n}}+\nabla f(x)\right)\right)_i\geq 0 \text{ and } a_i=-\infty,\end{cases}$$

for $i = 1, \ldots, n-m$. This change of the diagonal scaling matrix is based on the form of the right-hand side of (14). Unlike D, the scaling matrix $\bar{D}$ includes information from the cross term $\nabla^2_{xx}\ell(x,\lambda)s^{\mathsf{n}}$ and is therefore used as the scaling matrix for the computation of s_u in our algorithm, cf. (23). In the subsequent sections we will allow the replacement of the Hessian $\nabla^2_{xx}\ell(x,\lambda)$ to be a suitable matrix H.

If x is close to a nondegenerate point x_* satisfying the second-order sufficient KKT conditions, and if $W(x)^T\nabla^2_{xx}\ell(x,\lambda)s^{\mathsf{n}}$ is sufficiently small, a step s defined in this way is a Newton step on the following system of nonlinear equations:

$$\begin{aligned} &C(x) = 0, \\ &D(x)_u^2 W(x)^T \nabla f(x) = 0, \end{aligned} \tag{17}$$

where $D(x)_u$ depends on x_* as follows:

$$(D(x)_u)_{ii} = \begin{cases} 1 \text{ or } (b-u)_i^{\frac{1}{2}} \text{ or } (u-a)_i^{\frac{1}{2}} & \text{if } \left(W(x_*)^T\nabla f(x_*)\right)_i = 0, \\ (b-u)_i^{\frac{1}{2}} & \text{if } \left(W(x_*)^T\nabla f(x_*)\right)_i < 0, \\ (u-a)_i^{\frac{1}{2}} & \text{if } \left(W(x_*)^T\nabla f(x_*)\right)_i > 0, \end{cases}$$

for $i = 1, \ldots, n-m$. If $(W(x_*)^T\nabla f(x_*))_i = 0$, the ith diagonal element of $D(x)_u$ has to be chosen so that $\bar{D}(x)$ and $D(x)_u$ are the same matrix. Of course, this depends on the sign of $(W(x)^T(\nabla^2_{xx}\ell(x,\lambda)s^{\mathsf{n}} + \nabla f(x)))_i$. As Coleman and Li [12] pointed out, $D(x)_u$ is just for theoretical use since x_* is unknown. One can see that $D(x)_u^2 W(x)^T\nabla f(x)$ is continuously differentiable with Lipschitz continuous derivatives in an open neighborhood of x_*, that $D(x_*)_u^2 W(x_*)^T\nabla f(x_*) = 0$, and that the Jacobian of $D(x)_u^2 W(x)^T\nabla f(x)$ at x_* is nonsingular, for all choices of $D(x)_u$. These conditions are those typically required to get q-quadratic convergence for the Newton iteration (see [17, Thm. 5.2.1]). Thus the sequence of iterates generated by the Newton step (14)–(15) will converge q-quadratically to a nondegenerate point that satisfies the sufficient KKT conditions. The interior-point process damps the Newton step so that it stays strictly feasible, but this does not affect the rate of convergence. The details are provided in Corollary 9.4.

5. Trust-region interior-point SQP algorithms. The algorithms that we propose generate a sequence of iterates $\{x_k\}$ where

$$x_k = \begin{pmatrix} y_k \\ u_k \end{pmatrix}$$

and u_k is strictly feasible with respect to the bounds, i.e., $a < u_k < b$. At iteration k we are given x_k, and we need to compute a trial step s_k. If s_k is accepted, we set $x_{k+1} = x_k + s_k$. Otherwise we set x_{k+1} to x_k, reduce the trust-region radius, and compute a new trial step.

Following the application of Newton's method (14), each trial step s_k is decomposed as

$$s_k = s_k^{\mathsf{n}} + s_k^{\mathsf{t}} = s_k^{\mathsf{n}} + W_k(s_k)_u,$$

where s_k^{n} is called the quasi-normal component and s_k^{t} is the tangential component.

The role of s_k^{n} is to move towards feasibility. It will be seen that s_k^{n} is related to the Newton step for the solution of $C(y, u_k) = 0$ for fixed u_k. The role of s_k^{t} is to move towards optimality. The u component of s_k^{t} is related to the Newton step for the reduced problem (2). However, as made clear previously, we do not require feasibility with respect to the nonlinear equality constraints.

The global convergence is guaranteed by imposing an appropriate trust region on the step and monitoring the progress by a suitable merit function. The definition of the quasi-normal component, the tangential component, and the merit function, as well as the complete formulation of our algorithms, is the content of this section.

5.1. The quasi-normal component. Let δ_k be the trust radius at iteration k. The quasi-normal component s_k^{n} is related to the trust-region subproblem for the linearized constraints

$$\begin{aligned} &\text{minimize } \frac{1}{2}\|J_k s^{\mathsf{n}} + C_k\|^2 \\ &\text{subject to } \|s^{\mathsf{n}}\| \le \delta_k, \end{aligned}$$

and it is required to have the form

$$s_k^{\mathsf{n}} = \begin{pmatrix} (s_k^{\mathsf{n}})_y \\ 0 \end{pmatrix}. \tag{18}$$

Thus, the displacement along s_k^{n} is made only in the y variables, and as a consequence, x_k and $x_k + s_k^{\mathsf{n}}$ have the same u components. Since $(s_k^{\mathsf{n}})_u = 0$, the trust-region subproblem introduced above can be rewritten as

$$\text{minimize } \frac{1}{2}\|C_y(x_k)(s^{\mathsf{n}})_y + C_k\|^2 \tag{19}$$

$$\text{subject to } \|(s^{\mathsf{n}})_y\| \le \delta_k. \tag{20}$$

Thus, the quasi-normal component s_k^{n} is a trust-region globalization of the component s^{n} given in (5) of the Newton step (14). We do not have to solve (19)–(20) exactly; we only have to assume that the quasi-normal component satisfies the conditions

$$\|s_k^{\mathsf{n}}\| \le \kappa_1 \|C_k\| \tag{21}$$

and

$$\|C_k\|^2 - \|C_y(x_k)(s_k^{\mathsf{n}})_y + C_k\|^2 \ge \kappa_2 \|C_k\| \min\{\kappa_3 \|C_k\|, \delta_k\}, \tag{22}$$

where κ_1, κ_2, and κ_3 are positive constants independent of k. In section 10.1, we describe several ways of computing a quasi-normal component that satisfies the requirements (18), (21), and (22). Condition (21) tell us that the quasi-normal component is small close to feasible points. Condition (22) is just a weaker form of Cauchy decrease or simple decrease for the trust-region subproblem (19), (20).

5.2. The tangential component. The computation of the tangential component $(s_k)_u$ follows a trust-region globalization of the Newton step (15). Following Coleman and Li [13] we symmetrize (15) and get

$$\left(\bar{D}_k W_k^T H_k W_k \bar{D}_k + E_k\right) \bar{D}_k^{-1} s_u = -\bar{D}_k W_k^T \Big(H_k s_k^{\mathsf{n}} + \nabla f_k\Big),$$

where $E_k = E(x_k)$ and H_k denotes a symmetric approximation to the Hessian matrix $\nabla^2_{xx}\ell_k$. The scaling matrix $\bar{D}_k$ is equal to $\bar{D}(x_k)$ defined by (16) with $\nabla^2_{xx}\ell_k$ replaced by H_k. This suggests the change of variables $\hat{s}_u = \bar{D}_k^{-1} s_u$ and the consideration in the scaled space $\hat{s}_u$ of the trust-region subproblem

$$\begin{aligned} &\text{minimize } \left(\bar{D}_k W_k^T \left(H_k s_k^{\mathsf{n}} + \nabla f_k\right)\right)^T \hat{s}_u + \frac{1}{2}\hat{s}_u^T \left(\bar{D}_k W_k^T H_k W_k \bar{D}_k + E_k\right) \hat{s}_u \\ &\text{subject to } \|\hat{s}_u\| \le \delta_k. \end{aligned}$$

Now we can rewrite the previous subproblem in the unscaled space s_u as

$$\begin{aligned} &\text{minimize} \quad \left(W_k^T \left(H_k s_k^{\mathsf{n}} + \nabla f_k\right)\right)^T s_u + \tfrac{1}{2} s_u^T \left(W_k^T H_k W_k + E_k \bar{D}_k^{-2}\right) s_u \\ &\text{subject to} \quad \|\bar{D}_k^{-1} s_u\| \le \delta_k. \end{aligned} \tag{23}$$

Of course, we also have to require that the new iterate is in the interior of the box constraints. To ensure that $u_k + s_k$ is strictly feasible with respect to the box constraints, we choose $\sigma_k \in [\sigma, 1)$, $\sigma \in (0, 1)$ and compute s_u with $\sigma_k(a - u_k) \le s_u \le \sigma_k(b - u_k)$. However, one of the strengths of this trust-region approach is that we can allow for approximate solutions of this subproblem. In particular, it is not necessary to solve the full trust-region subproblem including the box constraints. For example, one can compute the solution of the trust-region subproblem without the box constraints and then scale the computed solution back so that the resulting damped s_u obeys $\sigma_k(a - u_k) \le s_u \le \sigma_k(b - u_k)$; see, e.g., section 5.2.4. We will show that under suitable assumptions this strategy guarantees global convergence and local q-quadratic convergence. Another way to compute an approximate u component of the step is to use a modified conjugate-gradient algorithm applied to the trust-region subproblem, without the box constraints, that is truncated if one of the bounds $\sigma_k(a - u_k) \le s_u \le \sigma_k(b - u_k)$ is violated. See section 10.2. More ways to compute the tangential component are possible. The conditions on the tangential component necessary to guarantee global convergence are stated in section 5.2.3.

We now introduce a quadratic model

$$q_k(s) = \ell_k + \nabla_x \ell_k{}^T s + \frac{1}{2} s^T H_k s$$

of $\ell(x_k + s, \lambda_k)$ about (x_k, λ_k). A trivial manipulation shows that

$$q_k(s_k^{\mathsf{n}} + W_k s_u) = q_k(s_k^{\mathsf{n}}) + \bar{g}_k^T s_u + \frac{1}{2} s_u{}^T W_k^T H_k W_k s_u, \tag{24}$$

with

$$\bar{g}_k = W_k^T \nabla q_k(s_k^{\mathsf{n}}) = W_k^T \Big(H_k s_k^{\mathsf{n}} + \nabla f_k\Big).$$

For convenience we define

$$\Psi_k(s_u) = q_k(s_k^{\mathsf{n}} + W_k s_u) + \frac{1}{2} s_u^T \left(E_k \bar{D}_k^{-2}\right) s_u. \tag{25}$$

5.2.1. The decoupled trust-region approach. We can restate the trust-region subproblem (23) as

$$\text{minimize } \Psi_k(s_u) \tag{26}$$

$$\text{subject to } \|\bar{D}_k^{-1} s_u\| \le \delta_k. \tag{27}$$

We refer to the approach based on this subproblem as the decoupled approach. In this decoupled approach, the trust-region constraint is of the form $\|\bar{D}_k^{-1}s_u\| \le \delta_k$ corresponding to the constraint $\|\hat{s}_u\| \le \delta_k$ in the scaled space. One can see from (20) and (27) that we are imposing the trust region separately on the y part of the quasi-normal component and on the u part of the tangential component. Moreover, if the cross term $W_k^T H_k s_k^{\mathsf{n}}$ is set to zero, then the trust-region subproblems for the quasi-normal component and for the tangential component are completely separated.

5.2.2. The coupled trust-region approach. The approach we present now forces the y and u parts of the tangential component $s_k^{\mathsf{t}} = W_k(s_k)_u$ to lie inside the trust region of radius δ_k. The reference trust-region subproblem is given by

$$\text{minimize } \Psi_k(s_u) \tag{28}$$

$$\text{subject to } \left\| \begin{pmatrix} -C_y(x_k)^{-1}C_u(x_k)s_u \\ \bar{D}_k^{-1}s_u \end{pmatrix} \right\| \le \delta_k. \tag{29}$$

In the case where there are no bounds on u, this trust-region constraint is of the form

$$\left\| \begin{pmatrix} -C_y(x_k)^{-1}C_u(x_k)s_u \\ s_u \end{pmatrix} \right\| = \|W_k s_u\| \le \delta_k.$$

As opposed to the decoupled case, one can see that the term $C_y(x_k)^{-1}C_u(x_k)s_u$ is present in the trust-region constraint (29). If W_k^+ denotes the Moore–Penrose pseudoinverse of W_k (see [25, sec. 5.5.4]), then

$$\frac{1}{\|W_k^+\|}\|s_u\| \le \|W_k s_u\| \le \|W_k\|\|s_u\|.$$

Thus, if the condition number $\kappa(W_k) = \|W_k^+\|\,\|W_k\|$ is small, then the decoupled and the coupled approach will generate similar iterates. In this case, the decoupled approach will be more efficient since it uses fewer linear system solvers with the system matrix $C_y(x_k)$. See section 10.2. However, if $\kappa(W_k)$ is large, e.g., if $C_y(x_k)$ is ill conditioned, then the coupled approach will use the true size of the tangential component, whereas the decoupled approach may vastly underestimate the size of this step component. This can lead to poor performance of the decoupled approach when steps are rejected and the trust-region radius is reduced based on the incorrect estimate $\|s_u\|$ of the norm of $s^{\mathsf{t}} = W_k s_u$. This indicates that when $C_y(x)$ is ill conditioned the coupled approach offers a better regularization of the step.

5.2.3. Cauchy decrease for the tangential component. To assure global convergence to a first-order KKT point, we consider analogues for the subproblems (26)–(27) and (28)–(29) of the fraction of Cauchy decrease or simple decrease conditions for the unconstrained minimization problem.

First we consider the decoupled trust-region subproblem (26)–(27). The Cauchy step c_k^{d} is defined for this case as the solution of

$$\begin{aligned} &\text{minimize } \Psi_k(s_u) \\ &\text{subject to } \|\bar{D}_k^{-1}s_u\| \le \delta_k, \quad s_u \in span\{-\bar{D}_k^2\bar{g}_k\}, \\ &\qquad \sigma_k(a - u_k) \le s_u \le \sigma_k(b - u_k), \end{aligned}$$

where $-\bar{D}_k^2\bar{g}_k$ is the steepest-descent direction for $\Psi_k(s_u)$ at $s_u = 0$ in the norm $\|\bar{D}_k^{-1}\cdot\|$. Here $\sigma_k \in [\sigma, 1)$ ensures that the Cauchy step c_k^{d} remains strictly feasible

with respect to the box constraints. The parameter $\sigma \in (0,1)$ is fixed for all k. As in many trust-region algorithms, we require the tangential component $(s_k)_u$ with $\sigma_k(a-u_k) \le (s_k)_u \le \sigma_k(b-u_k)$ to give a decrease on $\Psi_k(s_u)$ smaller than a uniform fraction of the decrease given by c_k^{d} for the same function $\Psi_k(s_u)$. This condition is often called fraction of Cauchy decrease, and in this case is

$$\Psi_k(0) - \Psi_k((s_k)_u) \ge \beta_1^{\mathsf{d}} \left(\Psi_k(0) - \Psi_k(c_k^{\mathsf{d}})\right), \tag{30}$$

where β_1^{d} is positive and fixed across all iterations. It is not difficult to see that dogleg or conjugate-gradient algorithms can conveniently compute components $(s_k)_u$ that satisfy condition (30) with $\beta_1^{\mathsf{d}} = 1$. We leave these issues to section 10.2.

In a similar way, the component $(s_k)_u$ with $\sigma_k(a-u_k) \le (s_k)_u \le \sigma_k(b-u_k)$ satisfies a fraction of Cauchy decrease for the coupled trust-region subproblem (28)–(29) if

$$\Psi_k(0) - \Psi_k((s_k)_u) \ge \beta_1^{\mathsf{c}} \Big(\Psi_k(0) - \Psi_k(c_k^{\mathsf{c}})\Big), \tag{31}$$

for some β_1^{c} independent of k, where the Cauchy step c_k^{c} is the solution of

$$\begin{aligned} &\text{minimize } \Psi_k(s_u) \\ &\text{subject to } \left\| \begin{pmatrix} -C_y(x_k)^{-1} C_u(x_k) s_u \\ \bar{D}_k^{-1} s_u \end{pmatrix} \right\| \le \delta_k, \quad s_u \in span\{-\bar{D}_k^2 \bar{g}_k\}, \\ &\sigma_k(a-u_k) \le s_u \le \sigma_k(b-u_k). \end{aligned}$$

In section 10.2 we show how to use conjugate gradients to compute components $(s_k)_u$ satisfying the condition (31).

One final comment is in order. In the coupled approach, the Cauchy step c_k^{c} was defined along the direction $-\bar{D}_k^2 \bar{g}_k$. To simplify this discussion, suppose that there are no bounds on u. In this case the trust-region constraint is of the form $\|W_k s_u\| \le \delta_k$. The presence of W_k gives the trust region an ellipsoidal shape. The steepest-descent direction for the quadratic (25) in the norm $\|W_k \cdot\|$ at $s_u = 0$ is given by $-(W_k^T W_k)^{-1} \bar{g}_k$. Our analysis still holds for this case since $\{\|(W_k^T W_k)^{-1}\|\}$ is a bounded sequence. The reason why we avoid the term $(W_k^T W_k)^{-1}$ is that in many applications there is no reasonable way to solve systems with $W_k^T W_k$. We will show in section 10.2 how this affects the use of conjugate gradients (see Remark 10.2). Finally, we point out that this problem does not arise if the decoupled approach is used.

5.2.4. Optimal decrease for the tangential component. The conditions in the previous subsection are sufficient to guarantee global convergence to a point satisfying first-order necessary KKT conditions, but they are too weak to guarantee global convergence to a point satisfying second-order necessary KKT conditions. To accomplish this, just as in the unconstrained case [46], [59], in the box-constrained case [13] and the equality-constrained case [19], we need to make sure that s_u satisfies an appropriate fraction of optimal decrease condition.

First we consider the decoupled approach and let o_k^{d} be an optimal solution of the trust-region subproblem (26)–(27). It follows from the KKT conditions for this trust-region subproblem that there exists $\gamma_k \ge 0$ such that

$$W_k^T H_k W_k + E_k \bar{D}_k^{-2} + \gamma_k \bar{D}_k^{-2} \quad \text{is positive semidefinite,} \tag{32}$$

$$\Big(W_k^T H_k W_k + E_k \bar{D}_k^{-2} + \gamma_k \bar{D}_k^{-2}\Big) o_k^{\mathsf{d}} = -\bar{g}_k, \text{ and} \tag{33}$$

$$\gamma_k(\delta_k - \|\bar{D}_k^{-1} o_k^{\mathsf{d}}\|) = 0.$$

(For practical algorithms to compute o_k^{d} see references [46], [53], [55], and [60]. These conditions are also sufficient for o_k^{d} to be an optimal solution [22], [59].) Since $u_k + o_k^{\mathsf{d}}$ might not be strictly feasible, we consider $\tau_k o_k^{\mathsf{d}}$, where τ_k is given by

$$\tau_k = \sigma_k \min_{i=1,\ldots,n-m} \left\{ 1,\ \max \left\{ \frac{b_i - (u_k)_i}{(o_k^{\mathsf{d}})_i},\ \frac{a_i - (u_k)_i}{(o_k^{\mathsf{d}})_i} \right\} \right\}. \tag{34}$$

The tangential component $(s_k)_u$ is then required to satisfy the following fraction of optimal decrease condition

$$\begin{aligned} &\Psi_k(0) - \Psi_k((s_k)_u) \geq \beta_2^{\mathsf{d}} \left(\Psi_k(0) - \Psi_k(\tau_k o_k^{\mathsf{d}}) \right) \quad \text{and} \\ &\|\bar{D}_k^{-1}(s_k)_u\| \leq \beta_3^{\mathsf{d}} \delta_k, \end{aligned} \tag{35}$$

where $\beta_2^{\mathsf{d}}, \beta_3^{\mathsf{d}}$ are positive parameters.

From conditions (32), (33), and (35), and $\tau_k < 1$, we can write

$$\begin{aligned} \Psi_k(0) - \Psi_k((s_k)_u) &\geq \beta_2^{\mathsf{d}} \left(-\tau_k \bar{g}_k^T o_k^{\mathsf{d}} - \frac{1}{2}\tau_k^2 (o_k^{\mathsf{d}})^T \left(W_k^T H_k W_k + E_k \bar{D}_k^{-2} \right) (o_k^{\mathsf{d}}) \right) \\ &\geq \beta_2^{\mathsf{d}} \tau_k \left(-\bar{g}_k^T o_k^{\mathsf{d}} - \frac{1}{2} (o_k^{\mathsf{d}})^T \left(W_k^T H_k W_k + E_k \bar{D}_k^{-2} + \gamma_k \bar{D}_k^{-2} \right) (o_k^{\mathsf{d}}) \right) \\ &\qquad + \frac{1}{2} \beta_2^{\mathsf{d}} \tau_k^2 \gamma_k (o_k^{\mathsf{d}})^T \bar{D}_k^{-2} (o_k^{\mathsf{d}}) \\ &\geq \frac{1}{2} \beta_2^{\mathsf{d}} \tau_k \|R_k o_k^{\mathsf{d}}\|^2 + \frac{1}{2} \beta_2^{\mathsf{d}} \tau_k^2 \gamma_k \delta_k^2 \\ &\geq \frac{1}{2} \beta_2^{\mathsf{d}} \tau_k^2 \gamma_k \delta_k^2, \end{aligned} \tag{36}$$

where $W_k^T H_k W_k + E_k \bar{D}_k^{-2} + \gamma_k \bar{D}_k^{-2} = R_k^T R_k$.

Now let us focus on the coupled approach and let o_k^{c} be the optimal solution of the trust-region subproblem (28)–(29). It follows from the KKT conditions for this trust-region subproblem, and the equality

$$\left(C_y(x_k)^{-1} C_u(x_k) \right)^T C_y(x_k)^{-1} C_u(x_k) \ = \ W_k^T W_k - I_{n-m},$$

that there exists $\gamma_k \geq 0$ such that

$$W_k^T H_k W_k + E_k \bar{D}_k^{-2} + \gamma_k \left(\bar{D}_k^{-2} + W_k^T W_k - I_{n-m} \right) \text{ is positive semidefinite,} \tag{37}$$

$$\begin{aligned} &\left(W_k^T H_k W_k + E_k \bar{D}_k^{-2} + \gamma_k \left(\bar{D}_k^{-2} + W_k^T W_k - I_{n-m} \right) \right) o_k^{\mathsf{c}} = -\bar{g}_k, \text{ and} \\ &\gamma_k \left(\delta_k - \left\| \begin{pmatrix} -C_y(x_k)^{-1} C_u(x_k) o_k^{\mathsf{c}} \\ \bar{D}_k^{-1} o_k^{\mathsf{c}} \end{pmatrix} \right\| \right) = 0. \end{aligned} \tag{38}$$

Now we damp o_k^{c} with τ_k given as in (34) but with o_k^{d} replaced by o_k^{c}. Thus, the resulting step $u_k + \tau_k o_k^{\mathsf{c}}$ is strictly feasible. We impose the following fraction of optimal decrease condition on the tangential component $(s_k)_u$:

$$\begin{aligned} &\Psi_k(0) - \Psi_k((s_k)_u) \geq \beta_2^{\mathsf{c}} \Big(\Psi_k(0) - \Psi_k(\tau_k o_k^{\mathsf{c}}) \Big) \quad \text{and} \\ &\left\| \begin{pmatrix} -C_y(x_k)^{-1} C_u(x_k)(s_k)_u \\ \bar{D}_k^{-1}(s_k)_u \end{pmatrix} \right\| \leq \beta_3^{\mathsf{c}} \delta_k. \end{aligned} \tag{39}$$

In this case it can be shown in a way similar to (36) that

$$\Psi_k(0) - \Psi((s_k)_u) \geq \frac{1}{2}\beta_2^{\mathfrak{c}}\tau_k^2\gamma_k\delta_k^2. \tag{40}$$

5.3. Reduced and full Hessians. In the previous section we considered an approximation H_k to the full Hessian. The algorithms and theory presented in this paper are also valid if we use an approximation $\widehat{H}_k$ to the reduced Hessian $W_k^T\nabla_{xx}^2\ell_k W_k$. In this case we set

$$H_k = \begin{pmatrix} 0 & 0 \\ 0 & \widehat{H}_k \end{pmatrix}. \tag{41}$$

Due to the form of W_k, we have

$$W_k^T H_k W_k = \widehat{H}_k.$$

This allows us to obtain the expansion (24) in the context of a reduced Hessian approximation.

For the algorithms with reduced Hessian approximation, the following observations are useful:

$$\begin{aligned} H_k d &= \begin{pmatrix} 0 \\ \widehat{H}_k d_u \end{pmatrix}, \\ d^T H_k d &= d_u^T \widehat{H}_k d_u, \\ W_k^T H_k d &= \widehat{H}_k d_u. \end{aligned} \tag{42}$$

5.4. Outline of the algorithms. We need to introduce a merit function and the corresponding actual and predicted reductions. The merit function used is the augmented Lagrangian

$$L(x, \lambda; \rho) = f(x) + \lambda^T C(x) + \rho C(x)^T C(x).$$

We follow [15] and define the actual decrease at iteration k as

$$ared(s_k; \rho_k) = L(x_k, \lambda_k; \rho_k) - L(x_k + s_k, \lambda_{k+1}; \rho_k),$$

and the predicted decrease as

$$pred(s_k; \rho_k) = L(x_k, \lambda_k; \rho_k) - \left(q_k(s_k) + \Delta\lambda_k^T(J_k s_k + C_k) + \rho_k\|J_k s_k + C_k\|^2\right),$$

with $\Delta\lambda_k = \lambda_{k+1} - \lambda_k$.

Remark 5.1. A possible redefining of the actual and predicted decreases is obtained by subtracting the term $\frac{1}{2}(s_k)_u^T\left(E_k\bar{D}_k^{-2}\right)(s_k)_u$ from both $ared(s_k; \rho_k)$ and $pred(s_k; \rho_k)$. This type of modification has been suggested in [13] for minimization with simple bounds, and it does not affect the global and local results given in this paper.

To decide whether to accept or reject a trial step s_k, we evaluate the ratio

$$\frac{ared(s_k; \rho_k)}{pred(s_k; \rho_k)}.$$

To update the penalty parameter ρ_k we use the scheme proposed by El-Alem [20]. Other schemes to update the penalty parameter have been suggested in [21] and [40].

We can now outline the main procedures of the trust-region interior-point SQP algorithms and leave the practical computation of $s_k^{\mathfrak{n}}$, $(s_k)_u$, and λ_k to section 10.

ALGORITHMS 5.1 (trust-region interior-point SQP algorithms).

1. Choose x_0 such that $a < u_0 < b$, pick $\delta_0 > 0$, and calculate λ_0. Choose α_1, η_1, σ, $\delta_{\min}$, $\delta_{\max}$, $\bar{\rho}$, and ρ_{-1} such that $0 < \alpha_1, \eta_1, \sigma < 1$, $0 < \delta_{\min} \le \delta_{\max}$, $\bar{\rho} > 0$, and $\rho_{-1} \ge 1$.
2. For $k = 0, 1, 2, \ldots$ do
   2.1. Compute s_k^{n} such that $\|s_k^{\mathsf{n}}\| \le \delta_k$.
   Compute $(s_k)_u$ based on the subproblem (26)–(27) (or (28)–(29) for the coupled approach) satisfying
   $$\sigma_k(a - u_k) \le (s_k)_u \le \sigma_k(b - u_k),$$
   with $\sigma_k \in [\sigma, 1)$. Set $s_k = s_k^{\mathsf{n}} + s_k^{\mathsf{t}} = s_k^{\mathsf{n}} + W_k(s_k)_u$.
   2.2. Compute λ_{k+1} and set $\Delta\lambda_k = \lambda_{k+1} - \lambda_k$.
   2.3. Compute $pred(s_k; \rho_{k-1})$:
   $$\begin{aligned} pred(s_k; \rho_{k-1}) = {} & q_k(0) - q_k(s_k) - \Delta\lambda_k^T(J_k s_k + C_k) \\ & + \rho_{k-1}\left(\|C_k\|^2 - \|J_k s_k + C_k\|^2\right). \end{aligned}$$
   If $pred(s_k; \rho_{k-1}) \ge \frac{\rho_{k-1}}{2}\Big(\|C_k\|^2 - \|J_k s_k + C_k\|^2\Big)$, then set $\rho_k = \rho_{k-1}$. Otherwise set
   $$\rho_k = \frac{2\left(q_k(s_k) - q_k(0) + \Delta\lambda_k^T(J_k s_k + C_k)\right)}{\|C_k\|^2 - \|J_k s_k + C_k\|^2} + \bar{\rho}.$$
   2.4. If $\frac{ared(s_k;\rho_k)}{pred(s_k;\rho_k)} < \eta_1$, set
   $$\delta_{k+1} = \alpha_1 \max\left\{\|s_k^{\mathsf{n}}\|, \|\bar{D}_k^{-1}(s_k)_u\|\right\} \text{ in the decoupled case or}$$
   $$\delta_{k+1} = \alpha_1 \max\left\{\|s_k^{\mathsf{n}}\|, \left\|\begin{pmatrix} -C_y(x_k)^{-1}C_u(x_k)(s_k)_u \\ \bar{D}_k^{-1}(s_k)_u \end{pmatrix}\right\|\right\} \text{ in the}$$
   coupled case, and reject s_k.
   Otherwise accept s_k and choose δ_{k+1} such that
   $$\max\{\delta_{\min}, \delta_k\} \le \delta_{k+1} \le \delta_{\max}.$$
   2.5. If s_k was rejected set $x_{k+1} = x_k$ and $\lambda_{k+1} = \lambda_k$. Otherwise set $x_{k+1} = x_k + s_k$ and $\lambda_{k+1} = \lambda_k + \Delta\lambda_k$.

Of course the rules to update the trust radius in the previous algorithm can be much more involved, but the above suffices to prove convergence results and to understand the trust-region mechanism.

5.5. Assumptions. In order to establish local and global convergence results we need some general assumptions. We list these assumptions below. Let Ω be an open subset of $\mathbb{R}^n$ such that for all iterations k, x_k and $x_k + s_k$ are in Ω.

A.1. The functions $f(x)$, $c_i(x)$, $i = 1, \ldots, m$, are twice continuously differentiable in Ω.
A.2. The partial Jacobian $C_y(x)$ is nonsingular for all $x \in \Omega$.
A.3. The functions $f(x)$, $\nabla f(x)$, $\nabla^2 f(x)$, $C(x)$, $J(x)$, $\nabla^2 c_i(x)$, $i = 1, \ldots, m$ are bounded in Ω.
A.4. The sequences $\{W_k\}$, $\{H_k\}$, and $\{\lambda_k\}$ are bounded.
A.5. The matrix $C_y^{-1}(x)$ is uniformly bounded in Ω.
A.6. The sequence $\{u_k\}$ is bounded.

It is equivalent to Assumptions A.3–A.6 that there exist positive constants $\nu_0, \ldots, \nu_9$ independent of k such that

$$|f(x)| \le \nu_0, \quad \|\nabla f(x)\| \le \nu_1, \quad \|\nabla^2 f(x)\| \le \nu_2, \quad \|C(x)\| \le \nu_3, \quad \|J(x)\| \le \nu_4,$$
$$\|\nabla^2 c_i(x)\| \le \nu_5, \quad i = 1, \ldots, m, \quad \text{and} \quad \|C_y(x)^{-1}\| \le \nu_6$$

for all $x \in \Omega$, and

$$\|W_k\| \le \nu_6, \quad \|H_k\| \le \nu_7, \quad \|\lambda_k\| \le \nu_8, \quad \text{and} \quad \|\bar{D}_k\| \le \nu_9$$

for all k.

For the rest of this paper we suppose that Assumptions A.1–A.6 are always satisfied.

As we have pointed out earlier, our approach is related to the Newton method presented in section 4. The u component $(s_k^{\mathsf{N}})_u$ of the Newton step $s_k^{\mathsf{N}} = s_k^{\mathsf{n}} + W_k(s_k^{\mathsf{N}})_u$, whenever it is defined, is given by

$$\begin{aligned}(s_k^{\mathsf{N}})_u &= -\left(\bar{D}_k^2 W_k^T H_k W_k + E_k\right)^{-1} \bar{D}_k^2 \bar{g}_k \\ &= -\bar{D}_k \left(\bar{D}_k W_k^T H_k W_k \bar{D}_k + E_k\right)^{-1} \bar{D}_k \bar{g}_k,\end{aligned} \tag{43}$$

where

$$s_k^{\mathsf{n}} = \begin{pmatrix} -C_y(x_k)^{-1} C_k \\ 0 \end{pmatrix}, \tag{44}$$

and $\bar{g}_k = W_k^T(H_k s_k^{\mathsf{n}} + \nabla f_k)$. From (43) we see that the Newton step is well defined in a neighborhood of a nondegenerate point that satisfies the second-order sufficient KKT conditions and for which $W_k^T H_k s_k^{\mathsf{n}}$ is sufficiently small. To guarantee strict feasibility of this step we consider a damped Newton step given by

$$s_k^{\mathsf{n}} + W_k \tau_k^{\mathsf{N}} (s_k^{\mathsf{N}})_u, \tag{45}$$

where $(s_k^{\mathsf{N}})_u$ and s_k^{n} are given by (43) and (44), and

$$\tau_k^{\mathsf{N}} = \sigma_k \min_{i=1,\ldots,n-m} \left\{ 1, \max\left\{ \frac{b_i - (u_k)_i}{((s_k^{\mathsf{N}})_u)_i}, \frac{a_i - (u_k)_i}{((s_k^{\mathsf{N}})_u)_i} \right\} \right\}. \tag{46}$$

If Algorithms 5.1 are particularized to satisfy the following conditions on the steps, on the quadratic model, and on the Lagrange multipliers, then we can prove global and local convergence.

C.1. The quasi-normal component s_k^{n} satisfies conditions (18), (21), and (22).
The tangential component $(s_k)_u$ satisfies the fraction of Cauchy decrease condition (30) ((31) for the coupled approach).
The parameter σ_k is chosen in $[\sigma, 1)$, where $\sigma \in (0, 1)$ is fixed for all k.

C.2. The tangential component $(s_k)_u$ satisfies the fraction of optimal decrease condition (35) ((39) for the coupled approach).

C.3. The second derivatives of f and c_i, $i = 1, \ldots, m$ are Lipschitz continuous in Ω.
The approximation to the Hessian matrix is exact, i.e., $H_k = \nabla^2_{xx}\ell(x_k, \lambda_k)$ with Lagrange multiplier $\lambda_k = -C_y(x_k)^{-T}\nabla_y f(x_k)$.

C.4. The step s_k is given by (45) provided $(s_k^{\mathsf{N}})_u$ exists, $(s_k^{\mathsf{n}})_y$ lies inside the trust region (20), and $\tau_k^{\mathsf{N}}(s_k^{\mathsf{N}})_u$ lies inside the trust region (27) ((29) for the coupled approach).

The parameter σ_k is chosen such that $\sigma_k \geq \sigma$ and $|\sigma_k - 1|$ is $\mathcal{O}(\|\bar{D}_k \bar{g}_k\|)$.

Condition C.1 assures global convergence to a first-order KKT point. Global convergence to a point that satisfies the second-order necessary KKT conditions requires Conditions C.1–C.3. To prove local q-quadratic convergence, we need Conditions C.1, C.3, and C.4. It should be pointed out that the satisfaction of C.2 or C.4 does not necessarily imply the satisfaction of C.1.

6. Intermediate results. We start by pointing out that (22), together with the fact that the tangential component lies in the null space of J_k, imply

$$\|C_k\|^2 - \|J_k s_k + C_k\|^2 \geq \kappa_2 \|C_k\| \min\{\kappa_3 \|C_k\|, \delta_k\}. \tag{47}$$

We calculated the first derivatives of $\lambda(x) = -C_y(x)^{-T} \nabla_y f(x)$ in section 4. It is clear that under Assumptions A.3 and A.5 these derivatives are bounded in Ω. Thus, if λ_k is computed as stated in Condition C.3, then there exists a positive constant ν_{10} independent of k such that

$$\|\Delta \lambda_k\| \leq \nu_{10} \|s_k\|. \tag{48}$$

From $\|s_k^{\mathsf{q}}\| \leq \delta_{\max}$ and Assumptions A.3–A.4 we also have

$$\|\bar{g}_k\| = \left\| W_k^T \left(H_k s_k^{\mathsf{q}} + \nabla f_k \right) \right\| \leq \nu_{11}, \tag{49}$$

where $\nu_{11} = \nu_6(\nu_7 \delta_{\max} + \nu_1)$.

The following lemma is required for the convergence theory.

LEMMA 6.1. *Every trial step satisfies*

$$\|s_k\| \leq \kappa_4 \delta_k \tag{50}$$

and, if s_k is rejected in step 2.4 *of Algorithms* 5.1, *then*

$$\delta_{k+1} \geq \kappa_5 \|s_k\|, \tag{51}$$

where κ_4 and κ_5 are positive constants independent of k.

Proof. In the coupled trust-region approach we bound s_k^{t} as follows:

$$\begin{aligned} \left\| \begin{pmatrix} -C_y(x_k)^{-1} C_u(x_k) s_u \\ s_u \end{pmatrix} \right\| &\leq \left\| \begin{pmatrix} I_m & 0 \\ 0 & \bar{D}_k \end{pmatrix} \right\| \left\| \begin{pmatrix} -C_y(x_k)^{-1} C_u(x_k) s_u \\ \bar{D}_k^{-1} s_u \end{pmatrix} \right\| \\ &\leq (1 + \nu_9)\, \delta_k\,, \end{aligned}$$

where ν_9 is a uniform bound for $\|\bar{D}_k\|$, see Assumption A.6. Since $\|s_k^{\mathsf{n}}\| \leq \delta_k$, we obtain $\|s_k\| \leq (2 + \nu_9)\, \delta_k$. It is not difficult to see now that in step 2.4 we have $\delta_{k+1} \geq \frac{\alpha_1}{2} \min\{1, \frac{1}{1+\nu_9}\} \|s_k\|$.

In the decoupled approach, $\|s_k\| = \|s_k^{\mathsf{n}} + W_k (s_k)_u\| \leq (1 + \nu_6 \nu_9) \delta_k$ and similarly $\delta_{k+1} \geq \frac{\alpha_1}{2} \min\{1, \frac{1}{\nu_6 \nu_9}\} \|s_k\|$, where ν_6 is a uniform bound for $\|W_k\|$; see Assumption A.4.

We can combine these bounds to obtain

$$\begin{aligned} \|s_k\| &\leq \max\{2 + \nu_9, 1 + \nu_6 \nu_9\}\, \delta_k, \\ \delta_{k+1} &\geq \tfrac{\alpha_1}{2} \min\left\{1, \tfrac{1}{1+\nu_9}, \tfrac{1}{\nu_6 \nu_9}\right\} \|s_k\|. \end{aligned}$$

In the case where fraction of optimal decrease (35) or (39) is imposed on $(s_k)_u$, the constants κ_4 and κ_5 depend also on β_3^{d} and β_3^{c}. ∎

In the following lemma we rewrite the fraction of Cauchy decrease conditions (30) and (31) in a more useful form for the analysis.

LEMMA 6.2. *If $(s_k)_u$ satisfies Condition C.1, then*

$$q_k(s_k^{\mathsf{n}}) - q_k(s_k^{\mathsf{n}} + W_k(s_k)_u) \geq \kappa_6 \|\bar{D}_k \bar{g}_k\| \min\left\{\kappa_7 \|\bar{D}_k \bar{g}_k\|, \kappa_8 \delta_k\right\}, \tag{52}$$

where κ_6, κ_7, and κ_8 are positive constants independent of the iteration k.

Proof. From the definition (25) of Ψ_k we find

$$\begin{aligned} q_k(s_k^{\mathsf{n}}) - q_k(s_k^{\mathsf{n}} + W_k(s_k)_u) &\geq q_k(s_k^{\mathsf{n}}) - q_k(s_k^{\mathsf{n}} + W_k(s_k)_u) - \frac{1}{2}(s_k)_u^T \left(E_k \bar{D}_k^{-2}\right)(s_k)_u \\ &= \Psi_k(0) - \Psi_k((s_k)_u). \end{aligned} \tag{53}$$

Let $\tilde{\delta}_k$ be the maximum $\|\bar{D}_k^{-1} \ \cdot\|$ norm of a step, say $(\tilde{s}_k)_u$, along $-\bar{D}_k \frac{\tilde{g}_k}{\|\tilde{g}_k\|}$ allowed inside the trust region. Here $\tilde{g}_k = \bar{D}_k \bar{g}_k$.

If the trust region is given by (27), then

$$\delta_k = \tilde{\delta}_k. \tag{54}$$

If the trust region is given by (29), then we can use Assumptions A.4–A.6 to deduce the inequality

$$\begin{aligned} \delta_k^2 &= \left\| \begin{pmatrix} -C_y(x_k)^{-1} C_u(x_k)(\tilde{s}_k)_u \\ \bar{D}_k^{-1}(\tilde{s}_k)_u \end{pmatrix} \right\|^2 \\ &= \| - C_y(x_k)^{-1} C_u(x_k) \bar{D}_k \bar{D}_k^{-1}(\tilde{s}_k)_u\|^2 + \|\bar{D}_k^{-1}(\tilde{s}_k)_u\|^2 \\ &\leq (\nu_6^2 \nu_9^2 + 1) \|\bar{D}_k^{-1}(\tilde{s}_k)_u\|^2 \\ &= (\nu_6^2 \nu_9^2 + 1)\, \tilde{\delta}_k^2 \end{aligned}$$

or, equivalently,

$$\tilde{\delta}_k \geq \frac{1}{\sqrt{\nu_6^2 \nu_9^2 + 1}}\, \delta_k. \tag{55}$$

Define $\psi : \mathbb{R}^+ \longrightarrow \mathbb{R}$ as $\psi(t) = \Psi_k(-t \bar{D}_k \frac{\tilde{g}_k}{\|\tilde{g}_k\|}) - \Psi_k(0)$. Then $\psi(t) = -\|\tilde{g}_k\| t + \frac{r_k}{2} t^2$, where $r_k = \frac{\tilde{g}_k^T \tilde{H}_k \tilde{g}_k}{\|\tilde{g}_k\|^2}$ and $\tilde{H}_k = \bar{D}_k (W_k^T H_k W_k + E_k \bar{D}_k^{-2}) \bar{D}_k$. Now we need to minimize ψ in $[0, T_k]$, where T_k is given by

$$T_k = \min\left\{\tilde{\delta}_k,\ \sigma_k \min\left\{\frac{\|\bar{D}_k \bar{g}_k\|}{(\bar{g}_k)_i} : (\bar{g}_k)_i > 0\right\},\ \sigma_k \min\left\{-\frac{\|\bar{D}_k \bar{g}_k\|}{(\bar{g}_k)_i} : (\bar{g}_k)_i < 0\right\}\right\}.$$

Let t_k^* be the minimizer of ψ in $[0, T_k]$. If $t_k^* \in (0, T_k)$, then

$$\psi(t_k^*) = -\frac{1}{2} \frac{\|\tilde{g}_k\|^2}{r_k} \leq -\frac{1}{2} \frac{\|\tilde{g}_k\|^2}{\|\tilde{H}_k\|}. \tag{56}$$

If $t_k^* = T_k$, then either $r_k > 0$, in which case $\frac{\|\tilde{g}_k\|}{r_k} \geq T_k$, or $r_k \leq 0$, in which case $r_k T_k \leq \|\tilde{g}_k\|$. In either event,

$$\psi(t_k^*) = \psi(T_k) = -T_k\|\tilde{g}_k\| + \frac{r_k}{2}T_k^2 \leq -\frac{T_k}{2}\|\tilde{g}_k\|. \tag{57}$$

We can combine (53), (56), and (57) with

$$\Psi_k(0) - \Psi_k((s_k)_u) \geq \beta_1^{\mathsf{d}}\left(\Psi_k(0) - \Psi_k(c_k^{\mathsf{d}})\right) = -\beta_1^{\mathsf{d}}\psi(t_k^*)$$

to get

$$q_k(s_k^{\mathsf{n}}) - q_k(s_k^{\mathsf{n}} + W_k(s_k)_u) \geq \frac{1}{2}\beta_1^{\mathsf{d}}\|\tilde{g}_k\| \min\left\{\frac{\|\tilde{g}_k\|}{\|\tilde{H}_k\|}, T_k\right\}.$$

The facts that $\sigma_k \geq \sigma$ and $\|\bar{g}_k\| \leq \nu_{11}$ (see (49)) imply that

$$\begin{aligned}&\Psi_k(0) - \Psi_k((s_k)_u)\\ &\geq \frac{1}{2}\beta_1^{\mathsf{d}}\|\bar{D}_k\bar{g}_k\| \min\left\{\frac{\|\bar{D}_k\bar{g}_k\|}{\|\bar{D}_k^T\left(W_k^T H_k W_k + E_k\bar{D}_k^{-2}\right)\bar{D}_k\|}, \min\left\{\tilde{\delta}_k, \frac{\sigma}{\nu_{11}}\|\bar{D}_k\bar{g}_k\|\right\}\right\}.\end{aligned}$$

To complete the proof, we use (54), (55), the Assumptions A.1–A.6, and the fact that $\delta_k \leq \delta_{\max}$ to establish (52) with $\kappa_6 = \frac{1}{2}\min\{\beta_1^{\mathsf{d}}, \beta_1^{\mathsf{c}}\}$, $\kappa_7 = \min\{\frac{1}{\nu_7\nu_6^2\nu_9^2+\nu_1\nu_6}, \frac{\sigma}{\nu_{11}}\}$, and $\kappa_8 = \min\{1, \frac{1}{\sqrt{\nu_6^2\nu_9^2+1}}\}$. ∎

Now we state the convenient form of the fraction of optimal decrease conditions (35) and (39).

LEMMA 6.3. *If $(s_k)_u$ satisfies Condition C.2, then*

$$q_k(s_k^{\mathsf{n}}) - q_k(s_k^{\mathsf{n}} + W_k(s_k)_u) \geq \kappa_9\tau_k^2\gamma_k\delta_k^2, \tag{58}$$

where κ_9 is a positive constant independent of the iteration k.

Proof. The proof follows immediately from observation (53) and conditions (36) and (40). ∎

We also need the following two inequalities.

LEMMA 6.4. *Under Condition C.1 there exists a positive constant κ_{10} such that*

$$q_k(0) - q_k(s_k^{\mathsf{n}}) - \Delta\lambda_k^T(J_k s_k + C_k) \geq -\kappa_{10}\|C_k\|. \tag{59}$$

Moreover, if we assume Condition C.3, then

$$q_k(0) - q_k(s_k^{\mathsf{n}}) - \Delta\lambda_k^T(J_k s_k + C_k) \geq -\kappa_{11}\|C_k\|\left(\|s_k^{\mathsf{n}}\| + \|s_k\|\right). \tag{60}$$

Proof. The term $q_k(0) - q_k(s_k^{\mathsf{n}})$ can be bounded using (21) and $\|s_k^{\mathsf{n}}\| \leq \delta_k$ in the following way:

$$\begin{aligned}q_k(0) - q_k(s_k^{\mathsf{n}}) &= -\nabla_x\ell_k^T s_k^{\mathsf{n}} - \tfrac{1}{2}(s_k^{\mathsf{n}})^T H_k(s_k^{\mathsf{n}})\\ &\geq -\kappa_1\left(\|\nabla_x\ell_k\| + \tfrac{1}{2}\delta_k\|H_k\|\right)\|C_k\|.\end{aligned}$$

On the other hand, it follows from $\|J_k s_k + C_k\| \leq \|C_k\|$ that

$$-\Delta\lambda_k^T(J_k s_k + C_k) \geq -\|\Delta\lambda_k\|\,\|C_k\|. \tag{61}$$

Combining these two bounds with Assumptions A.3 and A.4 we get (59).

To prove (60) we first observe that, due to the definition of λ_k in Condition C.3 and to the form (18) of the quasi-normal component s_k^{n},

$$\nabla_x \ell_k^T s_k^{\mathsf{n}} = \begin{pmatrix} 0 \\ \nabla_u f_k + C_u(x_k)^T \lambda_k \end{pmatrix}^T \begin{pmatrix} (s_k^{\mathsf{n}})_y \\ 0 \end{pmatrix} = 0. \tag{62}$$

Thus,

$$q_k(0) - q_k(s_k^{\mathsf{n}}) \geq -\frac{1}{2}\kappa_1 \|H_k\| \, \|C_k\| \, \|s_k^{\mathsf{n}}\| \geq -\frac{1}{2}\kappa_1 \nu_7 \, \|C_k\| \, \|s_k^{\mathsf{n}}\|. \tag{63}$$

Also, by appealing to (48) and (61),

$$-\Delta\lambda_k^T (J_k s_k + C_k) \geq -\nu_{10} \|s_k\| \, \|C_k\|. \tag{64}$$

The proof of (60) is complete by combining (63) and (64). ∎

The convergence theory for trust regions traditionally requires consistency of actual and predicted decreases. This is given in the following lemma.

LEMMA 6.5. *Under Condition C.1 there exists a positive constant* κ_{12} *such that*

$$|ared(s_k;\rho_k) - pred(s_k;\rho_k)| \leq \kappa_{12} \left(\|s_k\|^2 + \rho_k \left(\|s_k\|^3 + \|C_k\| \, \|s_k\|^2 \right) \right). \tag{65}$$

Moreover, if Condition C.3 is also valid, then

$$|ared(s_k;\rho_k) - pred(s_k;\rho_k)| \leq \kappa_{13} \rho_k \left(\|s_k\|^3 + \|C_k\| \, \|s_k\|^2 \right). \tag{66}$$

Proof. Adding and subtracting $\ell(x_{k+1}, \lambda_k)$ to $ared(s_k;\rho_k) - pred(s_k;\rho_k)$, and using Taylor expansion, we obtain

$$\begin{aligned} ared(s_k;\rho_k) - pred(s_k;\rho_k) \quad = \quad & \tfrac{1}{2} s_k^T \left(H_k - \nabla^2_{xx} \ell(x_k + t_k^1 s_k, \lambda_k) \right) s_k \\ & - \tfrac{1}{2} \textstyle\sum_{i=1}^m (\Delta\lambda_k)_i s_k^T \nabla^2 c_i(x_k + t_k^2 s_k) s_k \\ & - \rho_k \left(\textstyle\sum_{i=1}^m c_i(x_k + t_k^3 s_k)(s_k)^T \nabla^2 c_i(x_k + t_k^3 s_k)(s_k) \right. \\ & \qquad + (s_k)^T J(x_k + t_k^3 s_k)^T J(x_k + t_k^3 s_k)(s_k) \\ & \qquad \left. - (s_k)^T J(x_k)^T J(x_k)(s_k) \right), \end{aligned}$$

where t_k^1, t_k^2, and t_k^3 are in $(0,1)$. By expanding $c_i(x_k + t_k^3 s_k)$ around $c_i(x_k)$ and using Assumptions A.3 and A.4 we get (65).

The estimate (66) follows from (48), $\rho_k \geq 1$, and the Lipschitz continuity of the second derivatives. ∎

The last result in this section is a direct consequence of the scheme that updates ρ_k in step 2.3 of Algorithms 5.1.

LEMMA 6.6. *The sequence* $\{\rho_k\}$ *satisfies*

$$\begin{aligned} & \rho_k \geq \rho_{k-1} \geq 1 \quad \textit{and} \\ & pred(s_k;\rho_k) \geq \frac{\rho_k}{2} \Big(\|C_k\|^2 - \|J_k s_k + C_k\|^2 \Big). \end{aligned} \tag{67}$$

7. Global convergence to a first-order KKT point. The proof of the global convergence to a first-order KKT point (Theorem 7.5) established in this section follows the structure of the convergence theory presented in [15] for the equality-constrained optimization problem. This proof is by contradiction and is based on Condition C.1. We show that the supposition

$$\|\bar{D}_k \bar{g}_k\| + \|C_k\| > \epsilon_{tol},$$

for all k, leads to a contradiction.

The following three lemmas are necessary to bound the predicted decrease.

LEMMA 7.1. *Under Condition C.1, the predicted decrease in the merit function satisfies*

$$\begin{aligned} pred(s_k;\rho) \quad \geq \quad & \kappa_6 \|\bar{D}_k \bar{g}_k\| \min\left\{\kappa_7 \|\bar{D}_k \bar{g}_k\|, \kappa_8 \delta_k\right\} \\ & -\kappa_{10}\|C_k\| + \rho\Big(\|C_k\|^2 - \|J_k s_k + C_k\|^2\Big) \end{aligned} \tag{68}$$

for every $\rho > 0$.

Proof. The inequality (68) follows from a direct application of (59) and from the lower bound (52). ∎

LEMMA 7.2. *Assume that Condition C.1 and $\|\bar{D}_k \bar{g}_k\| + \|C_k\| > \epsilon_{tol}$ are satisfied. If $\|C_k\| \leq \alpha \delta_k$, where α is a positive constant satisfying*

$$\alpha \leq \min\left\{\frac{\epsilon_{tol}}{3\delta_{\max}}, \frac{\kappa_6 \epsilon_{tol}}{3\kappa_{10}} \min\left\{\frac{2\kappa_7 \epsilon_{tol}}{3\delta_{\max}}, \kappa_8\right\}\right\}, \tag{69}$$

then

$$pred(s_k;\rho) \geq \frac{\kappa_6}{2}\|\bar{D}_k \bar{g}_k\| \min\left\{\kappa_7 \|\bar{D}_k \bar{g}_k\|, \kappa_8 \delta_k\right\} + \rho\left(\|C_k\|^2 - \|J_k s_k + C_k\|^2\right), \tag{70}$$

for every $\rho > 0$.

Proof. From $\|\bar{D}_k \bar{g}_k\| + \|C_k\| > \epsilon_{tol}$ and the first bound on α given by (69), we get

$$\|\bar{D}_k \bar{g}_k\| > \frac{2}{3}\epsilon_{tol}. \tag{71}$$

If we use this, (68), and the second bound on α given by (69), we obtain

$$\begin{aligned} pred(s_k;\rho) \geq & \ \tfrac{\kappa_6}{2}\|\bar{D}_k \bar{g}_k\| \min\left\{\kappa_7 \|\bar{D}_k \bar{g}_k\|, \kappa_8 \delta_k\right\} + \tfrac{\kappa_6 \epsilon_{tol}}{3} \min\left\{\tfrac{2\kappa_7 \epsilon_{tol}}{3}, \kappa_8 \delta_k\right\} \\ & - \kappa_{10}\|C_k\| + \rho\Big(\|C_k\|^2 - \|J_k s_k + C_k\|^2\Big) \\ \geq & \ \tfrac{\kappa_6}{2}\|\bar{D}_k \bar{g}_k\| \min\left\{\kappa_7 \|\bar{D}_k \bar{g}_k\|, \kappa_8 \delta_k\right\} + \rho\Big(\|C_k\|^2 - \|J_k s_k + C_k\|^2\Big). \end{aligned}$$ ∎

We can use Lemma 7.2 with $\rho = \rho_{k-1}$ and conclude that if $\|\bar{D}_k \bar{g}_k\| + \|C_k\| > \epsilon_{tol}$ and $\|C_k\| \leq \alpha \delta_k$, then the penalty parameter at the current iteration does not need to be increased. See step 2.3 of Algorithms 5.1. This is equivalent to Lemma 7.7 in [15]. The next lemma states the same result as Lemma 7.8 in [15] but with a different choice of α.

LEMMA 7.3. *Assume Condition C.1 and* $\|\bar{D}_k\bar{g}_k\| + \|C_k\| > \epsilon_{tol}$. *If* $\|C_k\| \leq \alpha\delta_k$, *where* α *satisfies* (69), *then there exists a positive constant* $\kappa_{14} > 0$ *such that*

$$pred(s_k;\rho_k) \geq \kappa_{14}\delta_k. \tag{72}$$

Proof. From (70), with $\rho = \rho_k$ and $\|\bar{D}_k\bar{g}_k\| \geq \frac{2}{3}\epsilon_{tol}$, cf. (71), we obtain

$$\begin{aligned} pred(s_k;\rho_k) &\geq \tfrac{\kappa_6\epsilon_{tol}}{3}\min\{\tfrac{2\kappa_7\epsilon_{tol}}{3}, \kappa_8\delta_k\} \\ &\geq \tfrac{\kappa_6\epsilon_{tol}}{3}\min\{\tfrac{2\kappa_7\epsilon_{tol}}{3\delta_{\max}}, \kappa_8\}\delta_k. \end{aligned}$$

Hence (72) holds with

$$\kappa_{14} = \frac{\kappa_6\epsilon_{tol}}{3}\min\left\{\frac{2\kappa_7\epsilon_{tol}}{3\delta_{\max}}, \kappa_8\right\}. \qquad \square$$

The following lemma is also required.

LEMMA 7.4. *Under Condition C.1, if* $\|\bar{D}_k\bar{g}_k\| + \|C_k\| > \epsilon_{tol}$ *for all* k, *then the sequences* $\{\rho_k\}$ *and* $\{L_k\}$ *are bounded and* δ_k *is uniformly bounded away from zero.*

Proof. See Lemmas 7.9–7.13 and 8.2 in [15]. $\square$

Our first global convergence result follows.

THEOREM 7.5. *Under Condition C.1, the sequences of iterates generated by the trust-region interior-point SQP Algorithms* 5.1 *satisfy*

$$\liminf_k \left(\|D_k W_k^T \nabla f_k\| + \|C_k\|\right) = 0. \tag{73}$$

Proof. The proof is by contradiction. Suppose that for all k,

$$\|\bar{D}_k\bar{g}_k\| + \|C_k\| > \epsilon_{tol}. \tag{74}$$

At each iteration k, either $\|C_k\| \leq \alpha\delta_k$ or $\|C_k\| > \alpha\delta_k$, where α satisfies (69). In the first case we appeal to Lemmas 7.3 and 7.4 and obtain

$$pred(s_k;\rho_k) \geq \kappa_{14}\delta_*,$$

where δ_* is the lower bound on δ_k given by Lemma 7.4. If $\|C_k\| > \alpha\delta_k$, we have from $\rho_k \geq 1$, (47), (67), and Lemma 7.4, that

$$pred(s_k;\rho_k) \geq \frac{\kappa_2}{2}\alpha\min\{\kappa_3\alpha, 1\}\delta_*.$$

Hence $pred(s_k;\rho_k) \geq \kappa_{15}$ for all k, where the positive constant κ_{15} does not depend on k. From this and (65) we establish

$$\left|\frac{ared(s_k;\rho_k) - pred(s_k;\rho_k)}{pred(s_k;\rho_k)}\right| \leq \frac{\kappa_{12}}{\kappa_{15}}\left(\|s_k\|^2 + \rho_*\left(\|s_k\|^3 + \|C_k\|\,\|s_k\|^2\right)\right) \leq \kappa_{16}\delta_k^2,$$

where ρ_* is the upper bound on ρ_k guaranteed by Lemma 7.4. From the rules that update δ_k in step 2.4 of Algorithms 5.1, this inequality tells us that an acceptable step is always found after a finite number of unsuccessful iterations. Using this fact, we can ignore the rejected steps and work only with successful iterates. So, without loss of generality, we have

$$L_k - L_{k+1} = ared(s_k;\rho_k) \geq \eta_1 pred(s_k;\rho_k) \geq \eta_1\kappa_{15}.$$

Now, if we let k go to infinity, this contradicts the boundedness of $\{L_k\}$ guaranteed by Lemma 7.4. Hence the supposition (74) is false, and we must have that

$$\liminf_k \left(\|\bar{D}_k \bar{g}_k\| + \|C_k\| \right) = 0. \tag{75}$$

Let $\{k_j\}$ be a subsequence with $\lim_j (\|\bar{D}_{k_j} \bar{g}_{k_j}\| + \|C_{k_j}\|) = 0$. Together with (21) and the boundedness of $\{H_k\}$, this implies $\lim_j (\|\bar{D}_{k_j} W_{k_j}^T \nabla f_{k_j}\| + \|C_{k_j}\|) = 0$. To establish (73), it remains to show that $\bar{D}_{k_j}$, which is the scaling matrix defined with the reduced gradient $W_{k_j}^T (H_{k_j} s_{k_j}^{\mathsf{n}} + \nabla f_{k_j})$, can be replaced by D_{k_j}. This can be shown by standard arguments. Let $i \in \{1, \ldots, n-m\}$ be arbitrary. Assume there exists $\epsilon_1 > 0$ and a subsequence of $\{k_j\}$, for simplicity again denoted by $\{k_j\}$, such that

$$\left| \left((\bar{D}_{k_j} - D_{k_j}) W_{k_j}^T \nabla f_{k_j} \right)_i \right| > \epsilon_1. \tag{76}$$

If $(W_{k_j}^T \nabla f_{k_j})_i \to 0$, then the boundedness of $\bar{D}_{k_j}$ and D_{k_j} yields a contradiction to (76). Thus, there must exist $\epsilon_2 > 0$ and a subsequence of $\{k_j\}$, again denoted by $\{k_j\}$, such that $|(W_{k_j}^T \nabla f_{k_j})_i| > \epsilon_2$. Since $\lim_j H_{k_j} s_{k_j}^{\mathsf{n}} = 0$, the definitions of $\bar{D}$ and D imply that $|(\bar{D}_{k_j} - D_{k_j})_i| \to 0$, which again leads to a contradiction of (76). Consequently, the previous assumption cannot be satisfied and (73) is proven. ∎

Using the continuity of $C(x)$, $D(x)W(x)^T \nabla f(x)$, and Theorem 7.5, we can deduce the following result.

COROLLARY 7.6. *Let the conditions of Theorem* 7.5 *be valid. If $\{x_k\}$ is a bounded sequence, then $\{x_k\}$ has a limit point satisfying the first-order KKT conditions.*

8. Global convergence to a second-order KKT point. In this section we establish global convergence to a point that satisfies the second-order necessary KKT conditions.

THEOREM 8.1. *Under Conditions C.1–C.3, the sequences of iterates generated by the trust-region interior-point SQP Algorithms* 5.1 *satisfy*

$$\liminf_k \left(\|\bar{D}_k \bar{g}_k\| + \|C_k\| + \tau_k^2 \gamma_k \right) = 0, \tag{77}$$

where γ_k is the Lagrange multiplier corresponding to the trust-region constraint; see (32), (37)*, and τ_k is the damping parameter defined in* (34).

Proof. The proof is again by contradiction. Suppose that for all k,

$$\|\bar{D}_k \bar{g}_k\| + \|C_k\| + \tau_k^2 \gamma_k > \frac{5}{3} \epsilon_{tol}. \tag{78}$$

(i) Suppose that $\|C_k\| \le \alpha' \delta_k$, where

$$\alpha' = \min \left\{ \alpha, \frac{\kappa_9 \epsilon_{tol}}{3\kappa_{11}(1+\kappa_4)} \right\} \tag{79}$$

and α satisfies (69). From the first bound on α in (69), we get

$$\|\bar{D}_k \bar{g}_k\| + \tau_k^2 \gamma_k > \frac{4}{3} \epsilon_{tol}.$$

Thus, either $\|\bar{D}_k \bar{g}_k\| > \frac{2}{3}\epsilon_{tol}$ or $\tau_k^2 \gamma_k > \frac{2}{3}\epsilon_{tol}$. In the first case we proceed exactly as in Lemmas 7.2, 7.3 and obtain

$$\begin{aligned} pred(s_k; \rho) &\ge \frac{\kappa_6}{2} \|\bar{D}_k \bar{g}_k\| \min \left\{ \kappa_7 \|\bar{D}_k \bar{g}_k\|, \kappa_8 \delta_k \right\} + \rho \left(\|C_k\|^2 - \|J_k s_k + C_k\|^2 \right) \\ &\ge \frac{\kappa_{14}}{\delta_{\max}} \delta_k^2 \end{aligned} \tag{80}$$

for every $\rho > 0$. If $\tau_k^2 \gamma_k > \frac{2}{3}\epsilon_{tol}$, then from (50), (58), (60), $\|s_k^{\mathsf{n}}\| \leq \delta_k$, and the second bound on α' given in (79), we can write

$$\begin{aligned} pred(s_k;\rho) &= q_k(s_k^{\mathsf{n}}) - q_k(s_k^{\mathsf{n}} + W_k(s_k)_u) + q_k(0) - q_k(s_k^{\mathsf{n}}) - \Delta\lambda_k^T(J_k s_k + C_k) \\ &\quad + \rho\left(\|C_k\|^2 - \|J_k s_k + C_k\|^2\right) \\ &\geq \frac{1}{2}\kappa_9 \tau_k^2 \gamma_k \delta_k^2 + \left(\frac{1}{3}\kappa_9 \epsilon_{tol}\delta_k - \kappa_{11}\|C_k\|(1+\kappa_4)\right)\delta_k \\ &\quad + \rho\left(\|C_k\|^2 - \|J_k s_k + C_k\|^2\right) \qquad (81) \\ &\geq \frac{1}{2}\kappa_9 \tau_k^2 \gamma_k \delta_k^2 + \rho\left(\|C_k\|^2 - \|J_k s_k + C_k\|^2\right) \\ &\geq \frac{\kappa_9 \epsilon_{tol}}{3}\delta_k^2 \end{aligned}$$

for every $\rho > 0$. From the two bounds (80), (81), we conclude that if $\|C_k\| \leq \alpha'\delta_k$ then the penalty parameter does not increase. See step 2.3 of Algorithms 5.1. Moreover, these two bounds on $pred(s_k;\rho_k)$ show the existence of a positive constant κ_{17} independent of k such that

$$pred(s_k;\rho_k) \geq \kappa_{17}\delta_k^2, \qquad (82)$$

provided $\|C_k\| \leq \alpha'\delta_k$.

(ii) Now we prove that $\{\rho_k\}$ is bounded. If ρ_k is increased at iteration k, then it is updated according to the rule

$$\rho_k = 2\left(\frac{q_k(s_k) - q_k(0) + \Delta\lambda_k^T(J_k s_k + C_k)}{\|C_k\|^2 - \|J_k s_k + C_k\|^2}\right) + \bar{\rho}.$$

We can write

$$\begin{aligned} \tfrac{\rho_k}{2}\left(\|C_k\|^2 - \|J_k s_k + C_k\|^2\right) &= q_k(s_k) - q_k(s_k^{\mathsf{n}}) \\ &\quad -\left(q_k(0) - q_k(s_k^{\mathsf{n}})\right) + \Delta\lambda_k^T(J_k s_k + C_k) \\ &\quad +\tfrac{\bar{\rho}}{2}\left(\|C_k\|^2 - \|J_k s_k + C_k\|^2\right). \end{aligned}$$

By applying (47) to the left-hand side and applying (50), (58), (60), and $\|s_k^{\mathsf{n}}\| \leq \delta_k$ to the right-hand side, we obtain

$$\begin{aligned} \frac{\rho_k}{2}\kappa_2\|C_k\|\min\{\kappa_3\|C_k\|,\delta_k\} &\leq \kappa_{11}(1+\kappa_4)\delta_k\|C_k\| + \frac{\bar{\rho}}{2}\left(-2(J_k^T C_k)^T s_k - \|J_k s_k\|^2\right) \\ &\leq (\kappa_{11}(1+\kappa_4) + \bar{\rho}\nu_4\kappa_4)\delta_k\|C_k\|. \qquad (83) \end{aligned}$$

If ρ_k is increased at iteration k, then, because of part (i), $\|C_k\| > \alpha'\delta_k$. Now we use this fact to establish that

$$\left(\frac{\kappa_2}{2}\min\{\kappa_3\alpha', 1\}\right)\rho_k \leq \kappa_{11}(1+\kappa_4) + \bar{\rho}\nu_4\kappa_4.$$

This proves that $\{\rho_k\}$ and $\{L_k\}$ are bounded sequences.

(iii) The next step is to prove that δ_k is bounded away from zero.

If s_{k-1} was an acceptable step, then $\delta_k \geq \delta_{\min}$; see step 2.4 in Algorithms 5.1.

If s_{k-1} was rejected, then $\delta_k \geq \kappa_5 \|s_{k-1}\|$; see (51). We consider two cases. In both cases we will use the fact that

$$1 - \eta_1 \leq \left| \frac{ared(s_{k-1}; \rho_{k-1})}{pred(s_{k-1}; \rho_{k-1})} - 1 \right|.$$

In the first case we will assume that $\|C_{k-1}\| \leq \alpha' \delta_{k-1}$. From (82) we have $pred(s_{k-1}; \rho_{k-1}) \geq \kappa_{17} \delta_{k-1}^2$. Thus, we can use $\|s_{k-1}\| \leq \kappa_4 \delta_{k-1}$ (see (50)) and (66) with k replaced by $k-1$ to obtain

$$\left| \frac{ared(s_{k-1}; \rho_{k-1})}{pred(s_{k-1}; \rho_{k-1})} - 1 \right| \leq \frac{\kappa_{13} \rho_* \left(\kappa_4^2 \delta_{k-1}^2 + \kappa_4 \alpha' \delta_{k-1}^2 \right)}{\kappa_{17} \delta_{k-1}^2} \|s_{k-1}\|.$$

This gives $\delta_k \geq \kappa_5 \|s_{k-1}\| \geq \frac{\kappa_5 (1-\eta_1) \kappa_{17}}{\kappa_{13} \rho_* (\kappa_4^2 + \alpha' \kappa_4)} \equiv \kappa_{18}$.

The other case is $\|C_{k-1}\| > \alpha' \delta_{k-1}$. In this case we get, from (47) and (67) with k replaced by $k-1$, that

$$\begin{aligned} pred(s_{k-1}; \rho_{k-1}) &\geq \tfrac{\rho_{k-1}}{2} \kappa_2 \|C_{k-1}\| \min\{\kappa_3 \|C_{k-1}\|, \delta_{k-1}\} \\ &\geq \rho_{k-1} \kappa_{19} \delta_{k-1} \|C_{k-1}\| \\ &\geq \rho_{k-1} \alpha' \kappa_{19} \delta_{k-1}^2, \end{aligned}$$

where $\kappa_{19} = \frac{\kappa_2}{2} \min\{\kappa_3 \alpha', 1\}$. Again we use $\rho_{k-1} \geq 1$ and (66) with k replaced by $k-1$, this time with the last two lower bounds on $pred(s_{k-1}; \rho_{k-1})$, and we write

$$\begin{aligned} \left| \frac{ared(s_{k-1}; \rho_{k-1})}{pred(s_{k-1}; \rho_{k-1})} - 1 \right| &\leq \frac{\kappa_{13} \rho_{k-1} \|s_{k-1}\|^3}{|pred(s_{k-1}; \rho_{k-1})|} + \frac{\kappa_{13} \rho_{k-1} \|C_{k-1}\| \, \|s_{k-1}\|^2}{|pred(s_{k-1}; \rho_{k-1})|} \\ &\leq \left(\frac{\kappa_{13} \rho_{k-1} \kappa_4^2 \delta_{k-1}^2}{\rho_{k-1} \alpha' \kappa_{19} \delta_{k-1}^2} + \frac{\kappa_{13} \rho_{k-1} \kappa_4 \delta_{k-1} \|C_{k-1}\|}{\rho_{k-1} \kappa_{19} \delta_{k-1} \|C_{k-1}\|} \right) \|s_{k-1}\|. \end{aligned}$$

Hence $\delta_k \geq \kappa_5 \|s_{k-1}\| \geq \frac{\kappa_5 (1-\eta_1) \alpha' \kappa_{19}}{\kappa_{13} (\kappa_4^2 + \alpha' \kappa_4)} \equiv \kappa_{20}$.

Combining the two cases yields

$$\delta_k \geq \delta_* = \min\{\delta_{\min}, \kappa_{18}, \kappa_{20}\}$$

for all k.

(iv) The rest of the proof consists of proving that an acceptable trial step is always found after a finite number of iterations and then concluding from this that the supposition (78) is false. The proof of these facts is exactly the proof of Theorem 7.5, where α is now α' and $\kappa_{14} \delta_*$ is replaced by $\kappa_{17} \delta_*^2$. ∎

The following result finally establishes global convergence to a point satisfying the second-order necessary KKT conditions. The proof uses ideas applied in [13, Lem. 3.8]. However, we show that convergence to a limit point satisfies the second-order necessary conditions even in the degenerate case.

THEOREM 8.2. *Let $\{x_k\}$ be a bounded sequence of iterates generated by the trust-region interior-point SQP Algorithms* 5.1 *under Conditions C.1–C.3. Then $\{x_k\}$ has a limit point x_* satisfying the first-order KKT conditions. Furthermore, x_* satisfies the second-order necessary KKT conditions.*

Proof. Consider the subsequence of $\{x_k\}$ for which the limit in (77) is zero. Since this subsequence is bounded, we can use the same arguments as in the proof of Theorem 7.5 to show that it has a convergent subsequence indexed by $\{k_j\}$ such that

$$\lim_j \left(\|\bar{D}_{k_j} \bar{g}_{k_j}\| + \|C_{k_j}\| \right) = \lim_j \left(\|D_{k_j} W_{k_j}^T \nabla f_{k_j}\| + \|C_{k_j}\| \right) = 0. \tag{84}$$

Moreover,

$$\lim_j \tau_{k_j}^2 \gamma_{k_j} = 0, \tag{85}$$

where τ_{k_j} is given by (34). Let x_* denote the limit of $\{x_{k_j}\}$. It follows from (84) and the continuity of $C(x)$ and $D(x)W(x)^T\nabla f(x)$ that x_* satisfies the first-order KKT conditions.

Next, we will prove that $\lim_j \gamma_{k_j} = 0$. First we consider the decoupled approach. Define the vector-valued function h as follows:

$$h(x)_i = \begin{cases} 1 & \text{if } \left(W(x)^T\nabla f(x)\right)_i = 0 \text{ and } \left(D(x)_{ii}\right) = 0, \\ \left(W(x)^T\nabla f(x)\right)_i & \text{otherwise,} \end{cases}$$

for all $i = 1, \ldots, n-m$. The function h is used to identify the active indices. By definition of h and since x_* satisfies the first-order KKT conditions, the implications

$$D(x_*)_{ii} = 0 \iff h(x_*)_i \neq 0, \quad i = 1, \ldots, n-m \tag{86}$$

are valid. (If x_* is nondegenerate, then $h(x_*) = W(x_*)^T\nabla f(x_*)$.) Moreover,

$$\lim_{x \to x_*} D(x)h(x) = 0. \tag{87}$$

Since $\lim_j x_{k_j} = x_*$, (86) implies the existence of $\epsilon_0 \in (0,1)$ such that

$$\min\left\{ (u_{k_j})_i - a_i,\, b_i - (u_{k_j})_i \right\} + \left|\left(h_{k_j}\right)_i\right| > 2\epsilon_0, \qquad i = 1, \ldots, n-m \tag{88}$$

for large enough j, and

$$2\epsilon_0 < \min\{b_i - a_i,\ i = 1, \ldots, n-m\}.$$

Without loss of generality, we will only consider the cases where $\tau_{k_j} \leq \sigma_{k_j} < 1$. In the following the index i will be the index defining τ_{k_j} in (34). (The index i is really i_j but we drop the j from i_j to alleviate the notation.) We also assume that j is large enough such that

$$\left|\left(\bar{D}_{k_j}^2 h_{k_j}\right)_i\right| < \epsilon_0^2; \tag{89}$$

cf. (87).

Multiplying both sides of (33) by $\bar{D}_{k_j}^2$ gives

$$\left(E_{k_j} + \gamma_{k_j} I_{n-m}\right) o_{k_j}^{\mathsf{d}} = \bar{D}_{k_j}^2 \left(-\bar{g}_{k_j} - W_{k_j}^T H_{k_j} W_{k_j} o_{k_j}^{\mathsf{d}} \right),$$

which in turn implies

$$\gamma_{k_j} |(o_{k_j}^{\mathsf{d}})_i| \leq (\bar{D}_{k_j}^2)_{ii} \left| \left(-\bar{g}_{k_j} - W_{k_j}^T H_{k_j} W_{k_j} o_{k_j}^{\mathsf{d}} \right)_i \right|. \tag{90}$$

Also, Assumption A.6 implies $\|o_{k_j}^{\mathsf{d}}\| \leq \nu_9 \delta_{k_j} \leq \nu_9 \delta_{\max}$. From this, (49), and Assumptions A.3–A.4, we can write

$$\frac{1}{(o_{k_j}^{\mathsf{d}})_i} \geq \frac{\gamma_{k_j}}{\kappa_{21}(\bar{D}_{k_j})_{ii}^2} \tag{91}$$

for some κ_{21} independent of k. Now we distinguish between two cases.

In the first case we consider $|(h_{k_j})_i| \leq \epsilon_0$ and appeal to (88) to get $\min\{(u_{k_j})_i - a_i,\, b_i - (u_{k_j})_i\} > \epsilon_0$. Thus, from (91) and the definition (34) of τ_{k_j} we obtain

$$\tau_{k_j} \geq \frac{\sigma_{k_j}\gamma_{k_j}\epsilon_0}{\kappa_{21}(\bar{D}_{k_j})_{ii}^2}. \tag{92}$$

Now we analyze the case $|(h_{k_j})_i| > \epsilon_0$. Two possibilities can occur.

(i) The first possibility is that the value of the numerator defining τ_{k_j} is equal to $(\bar{D}_{k_j})_{ii}^2$. In this situation, (91) immediately implies

$$\tau_{k_j} \geq \frac{\sigma_{k_j}\gamma_{k_j}}{\kappa_{21}}. \tag{93}$$

(ii) The other possibility is that the value of the numerator defining τ_{k_j} is not equal to $(\bar{D}_{k_j})_{ii}^2$. In this case we have from (89) that $(\bar{D}_{k_j})_{ii}^2 < \epsilon_0$ and, since $b_i - a_i > 2\epsilon_0$, the numerator in the definition (34) of τ_{k_j} is bigger than ϵ_0. Thus,

$$\tau_{k_j} \geq \frac{\sigma_{k_j}\gamma_{k_j}\epsilon_0}{\kappa_{21}(\bar{D}_{k_j})_{ii}^2}. \tag{94}$$

Using (85), (92), (93), (94), $\sigma_{k_j} \geq \sigma$, and the boundedness of $\bar{D}_{k_j}$ this proves that

$$\lim_j \gamma_{k_j} = 0.$$

By (32) we know that

$$\bar{D}_{k_j} W_{k_j}^T H_{k_j} W_{k_j} \bar{D}_{k_j} + E_{k_j} + \gamma_{k_j} I_{n-m}$$

is positive semidefinite. Hence condition (84), the continuity of $W(x)^T \nabla_{xx}^2 \ell(x,\lambda) W(x)$, and the limits $\lim_j \|W_{k_j}^T H_{k_j} s_{k_j}^{\mathsf{n}}\| = 0$ and $\lim_j \gamma_{k_j} = 0$ imply that the limit of the principal submatrix of $W_{k_j}^T H_{k_j} W_{k_j}$ corresponding to indices l such that $a_l < (u_*)_l < b_l$ is positive semidefinite. Hence the second-order necessary KKT conditions are satisfied at x_*. This completes the proof for the decoupled approach.

The proof for the coupled trust-region approach differs only from the proof for the decoupled approach in the use of equations (37) and (38) and in the use of $\|W_{k_j} o_{k_j}^{\mathsf{c}}\| \leq (1+\nu_9)\delta_{\max}$ to bound the right-hand side of inequality (90). ∎

Remark 8.1. The global convergence results of sections 7 and 8 hold true if the quadratic $\Psi_k(s_u)$ is redefined as $\Psi_k(s_u) = q_k(s_k^{\mathsf{n}} + W_k s_u)$ (see (24) and (25)) without the Newton augmentation term $\frac{1}{2} s_u^T (E_k \bar{D}_k^{-2}) s_u$. They are valid also if the matrices D_k and $\bar{D}_k$ are redefined, respectively, as D_k^p and $\bar{D}_k^p$ with $p \geq 1$.

9. Local rate of convergence. We will now analyze the local behavior of Algorithms 5.1 under Conditions C.1, C.3, and C.4. We start by looking at the behavior of the trust radius close to a nondegenerate point that satisfies the second-order sufficient KKT conditions. For this purpose we require the following lemma.

LEMMA 9.1. *Under Condition C.1, the quasi-normal component satisfies*

$$\|s_k^{\mathsf{n}}\| \leq \kappa_{22}\|s_k\|, \tag{95}$$

where κ_{22} is positive and independent of the iteration counter k.

Proof. From $s_k = s_k^{\mathsf{n}} + W_k(s_k)_u$, we obtain

$$\|s_k^{\mathsf{n}}\| \leq \|s_k\| + \|W_k\|\,\|(s_k)_u\|.$$

But since $\|s_k\|^2 = \|(s_k)_y\|^2 + \|(s_k)_u\|^2$, we use Assumption A.4 to obtain

$$\|s_k^{\mathsf{n}}\| \leq (1+\nu_6)\,\|s_k\|,$$

and (95) holds with $\kappa_{22} = 1+\nu_6$. ∎

THEOREM 9.2. *Let $\{x_k\}$ be a sequence of iterates generated by the trust-region interior-point SQP Algorithms 5.1 under Conditions C.1 and C.3. If x_k converges to a nondegenerate point x_* satisfying the second-order sufficient KKT conditions, then δ_k is uniformly bounded away from zero and eventually all the iterations will be successful.*

Proof. It follows from $\lim_k x_k = x_*$ and $C(x_*) = 0$ that $\lim_k \|C_k\| = 0$. This fact, condition (21), and Assumptions A.3–A.4, together imply

$$\lim_k \|W_k^T H_k s_k^{\mathsf{n}}\| = 0.$$

Since x_k converges to a nondegenerate point that satisfies the second-order sufficient KKT conditions and $\lim_k \|W_k^T H_k s_k^{\mathsf{n}}\| = 0$, there exists a $\bar\gamma > 0$ such that the smallest eigenvalue of $\bar D_k W_k^T H_k W_k \bar D_k + E_k$ is greater than $\bar\gamma$ for k sufficiently large.

First we will proof that $\{\rho_k\}$ is a bounded sequence. Since $\Psi_k(0) - \Psi_k((s_k)_u) \geq 0$, we obtain

$$\begin{aligned}\tfrac{1}{2}(\bar D_k^{-1}(s_k)_u)^T\left(\bar D_k W_k^T H_k W_k \bar D_k + E_k\right)(\bar D_k^{-1}(s_k)_u) &\leq -(\bar D_k^{-1}(s_k)_u)^T(\bar D_k \bar g_k)\\ &\leq \|\bar D_k^{-1}(s_k)_u\|\,\|\bar D_k \bar g_k\|,\end{aligned}$$

which, by using the upper bounds on W_k and $\bar D_k$ given by Assumptions A.4 and A.6, implies

$$\|s_k^{\mathsf{t}}\| = \|W_k(s_k)_u\| \leq \frac{2\nu_6\nu_9}{\bar\gamma}\|\bar D_k \bar g_k\|. \tag{96}$$

Using (52) and (96), we find that

$$\begin{aligned} q_k(s_k^{\mathsf{n}}) - q_k(s_k^{\mathsf{n}} + W_k(s_k)_u) &\geq \kappa_6\|\bar D_k\bar g_k\|\min\{\kappa_7\|\bar D_k\bar g_k\|, \kappa_8\delta_k\}\\ &\geq \kappa_{23}\|s_k^{\mathsf{t}}\|^2, \end{aligned} \tag{97}$$

where $\kappa_{23} = \frac{\kappa_6\bar\gamma}{2\nu_6\nu_9}\min\{\frac{\kappa_7\bar\gamma}{2\nu_6\nu_9}, \frac{\kappa_8}{\nu_6\nu_9}, \frac{\kappa_8}{1+\nu_9}\}$ accounts for the decoupled and coupled cases.

Next, we prove that if $\|C_k\| \leq \alpha''\|s_k\|$, where α'' will be defined later, then the penalty parameter does not need to be increased. From (21) and $\|C_k\| \leq \alpha''\|s_k\|$, we get

$$\begin{aligned}\|s_k\|^2 \leq \left(\|s_k^{\mathsf{n}}\| + \|s_k^{\mathsf{t}}\|\right)^2 &\leq 2\|s_k^{\mathsf{n}}\|^2 + 2\|s_k^{\mathsf{t}}\|^2\\ &\leq 2\alpha''\kappa_1^2\|C_k\|\,\|s_k\| + 2\|s_k^{\mathsf{t}}\|^2.\end{aligned}$$

This estimate, (21), (60), (97), and $\|C_k\| \le \alpha''\|s_k\|$ yield

$$\begin{aligned} pred(s_k;\rho) &= q_k(s_k^{\mathsf{n}}) - q_k(s_k^{\mathsf{n}} + W_k(s_k)_u) + q_k(0) - q_k(s_k^{\mathsf{n}}) - \Delta\lambda_k^T(J_k s_k + C_k) \\ &\quad + \rho\left(\|C_k\|^2 - \|J_k s_k + C_k\|^2\right) \\ &\ge \frac{1}{4}\kappa_{23}\|s_k\|^2 + \left(\frac{1}{4}\kappa_{23}\|s_k\| - (\alpha''\kappa_1^2\kappa_{23} + \kappa_{11}(\alpha''\kappa_1 + 1))\|C_k\|\right)\|s_k\| \\ &\quad + \rho\left(\|C_k\|^2 - \|J_k s_k + C_k\|^2\right), \end{aligned} \tag{98}$$

for every $\rho > 0$. If $\|C_k\| \le \alpha''\|s_k\|$, where α'' satisfies

$$(4\kappa_{11})\ \alpha'' + \left(4\kappa_1^2\kappa_{23} + 4\kappa_1\kappa_{11}\right)\ (\alpha'')^2 \le \kappa_{23}\,, \tag{99}$$

then we set $\rho = \rho_{k-1}$ in (98) and deduce that the penalty parameter does not need to be increased. See step 2.3 of Algorithms 5.1. Hence if ρ_k is increased, then the inequality $\|C_k\| > \alpha''\|s_k\|$ must hold, and we can proceed as in Theorem 8.1, equation (83), and write

$$\frac{\rho_k}{2}\kappa_2\|C_k\| \min\left\{\kappa_3\|C_k\|, \frac{1}{\kappa_4}\|s_k\|\right\} \le (\kappa_{11}(\kappa_{22}+1) + \bar\rho\nu_4)\|s_k\|\,\|C_k\|$$

(here we used inequality (95)), which in turn implies

$$\left(\frac{\kappa_2}{2}\min\left\{\kappa_3\alpha'', \frac{1}{\kappa_4}\right\}\right)\rho_k \le \kappa_{11}(\kappa_{22}+1) + \bar\rho\nu_4.$$

This gives the uniform boundedness of the penalty parameter

$$\rho_k \le \rho_*$$

for all k.

Given the boundedness of $\{\rho_k\}$ we can complete the proof of the theorem. If $\|C_k\| > \alpha''\|s_k\|$, where α'' satisfies (99), then from (47) and (67) we find that

$$pred(s_k;\rho_k) \ge \rho_k\frac{\kappa_2}{2}\|C_k\|\min\{\kappa_3\|C_k\|, \delta_k\} \ge \rho_k\kappa_{24}\|s_k\|^2, \tag{100}$$

where $\kappa_{24} = \frac{\kappa_2\alpha''}{2}\min\{\kappa_3\alpha'', \frac{1}{\kappa_4}\}$. In this case it follows from (66) and (100) that

$$\left|\frac{ared(s_k;\rho_k)}{pred(s_k;\rho_k)} - 1\right| \le \frac{\kappa_{13}}{\kappa_{24}}\left(\|s_k\| + \|C_k\|\right). \tag{101}$$

Now, suppose that $\|C_k\| \le \alpha''\|s_k\|$. From (98) with $\rho = \rho_k$ we obtain $pred(s_k;\rho_k) \ge \frac{\kappa_{23}}{4}\|s_k\|^2$. Now we use (66) and $\rho_k \le \rho_*$ to get

$$\left|\frac{ared(s_k;\rho_k)}{pred(s_k;\rho_k)} - 1\right| \le \frac{4\kappa_{13}\rho_*}{\kappa_{23}}\left(\|s_k\| + \|C_k\|\right). \tag{102}$$

Finally from (101), (102), $\lim_k x_k = x_*$, and $\lim_k \|C_k\| = 0$, we get

$$\lim_k \frac{ared(s_k;\rho_k)}{pred(s_k;\rho_k)} = 1,$$

which by the rules for updating the trust radius given in step 2.4 of Algorithms 5.1, shows that δ_k is uniformly bounded away from zero. ∎

We use the following straightforward globalization of the quasi-normal component s_k^{n} of the Newton step given in (44). The new quasi-normal component is given by

$$s_k^{\mathsf{n}} = \begin{pmatrix} -\xi_k C_y(x_k)^{-1} C_k \\ 0 \end{pmatrix}, \tag{103}$$

where

$$\xi_k = \begin{cases} 1 & \text{if } \|C_y(x_k)^{-1} C_k\| \le \delta_k, \\ \frac{\delta_k}{\|C_y(x_k)^{-1} C_k\|} & \text{otherwise.} \end{cases} \tag{104}$$

Before we state the q-quadratic rate of convergence, we prove the following important result.

LEMMA 9.3. *The quasi–normal component* (103) *satisfies conditions* (18), (21), *and* (22) *for some positive* κ_1, κ_2, *and* κ_3 *independent of* k.

Proof. It is obvious that (18) holds. Condition (21) is a direct consequence of the condition (22). In fact, using $\|C_y(x_k)(s_k^{\mathsf{n}})_y + C_k\| \le \|C_k\|$ and the boundedness of $\{C_y(x_k)^{-1}\}$, we find that

$$\begin{aligned} \|s_k^{\mathsf{n}}\| &= \|s_k^{\mathsf{n}} + C_y(x_k)^{-1} C_k - C_y(x_k)^{-1} C_k\| \\ &\le \|C_y(x_k)^{-1}\| \Big(\|C_y(x_k)(s_k^{\mathsf{n}})_y + C_k\| + \|C_k\| \Big) \quad \le \quad 2\nu_6 \|C_k\|. \end{aligned} \tag{105}$$

So, let us prove (22). A simple manipulation shows that

$$\begin{aligned} \|C_k\|^2 - \|C_y(x_k)(s_k^{\mathsf{n}})_y + C_k\|^2 &= \|C_k\|^2 - \| - \xi_k C_y(x_k) C_y(x_k)^{-1} C_k + C_k\|^2 \\ &= \|C_k\|^2 - \Big((1-\xi_k)\|C_k\| \Big)^2 \\ &= \xi_k (2 - \xi_k) \|C_k\|^2 \ \ge \ \xi_k \|C_k\|^2. \end{aligned}$$

We need to consider two cases. If $\xi_k = 1$, then

$$\|C_k\|^2 - \|C_y(x_k)(s_k^{\mathsf{n}})_y + C_k\|^2 \ge \|C_k\| \min\{\|C_k\|, \delta_k\}.$$

Otherwise $\xi_k = \frac{\delta_k}{\|C_y(x_k)^{-1} C_k\|}$. In this case we get

$$\|C_k\|^2 - \|C_y(x_k)(s_k^{\mathsf{n}})_y + C_k\|^2 \ge \frac{1}{\nu_6} \|C_k\| \, \delta_k \ge \frac{1}{\nu_6} \|C_k\| \min\{\|C_k\|, \delta_k\}.$$

Thus, the result holds with $\kappa_2 = \min\{1, \frac{1}{\nu_6}\}$ and $\kappa_3 = 1$. ∎

COROLLARY 9.4. *Let* $\{x_k\}$ *be a sequence of iterates generated by the trust-region interior-point SQP Algorithms* 5.1 *under Conditions C.1, C.3, and C.4. If* x_k *converges to a nondegenerate point* x_* *satisfying the second-order sufficient KKT conditions, then* x_k *converges q-quadratically.*

Proof. We start by showing that $|\tau_k^{\mathsf{N}} - 1|$ is $\mathcal{O}(\|x_k - x_*\|)$, where τ_k^{N} is given by (46). Since $\lim_k \|W_k^T H_k s_k^{\mathsf{n}}\| = 0$, we have that $|\frac{\tau_k^{\mathsf{N}}}{\sigma_k} - 1|$ is $\mathcal{O}(\|(s_k^{\mathsf{N}})_u\|)$ (see [12, Eq. (6.4) and Lem. 12]). Also since by Condition C.4 $|\sigma_k - 1|$ is $\mathcal{O}(\|\bar{D}_k \bar{g}_k\|)$ and $\bar{D}_k \bar{g}_k$ is $\mathcal{O}(\|(s_k^{\mathsf{N}})_u\|)$ (see (43)), we can see that $|\sigma_k - 1|$ is also $\mathcal{O}(\|(s_k^{\mathsf{N}})_u\|)$. Furthermore,

$$|\tau_k^{\mathsf{N}} - 1| \le \sigma_k \left| \frac{\tau_k^{\mathsf{N}}}{\sigma_k} - 1 \right| + |\sigma_k - 1|.$$

Hence $|\tau_k^{\mathsf{N}}-1|$ is $\mathcal{O}(\|(s_k^{\mathsf{N}})_u\|)$. But $(s_k^{\mathsf{N}})_u$ is $\mathcal{O}(\|x_k+s_k^{\mathsf{n}}-x_*\|)$ and s_k^{n} is $\mathcal{O}(\|x_k-x_*\|)$ and this shows that $|\tau_k^{\mathsf{N}}-1|$ is $\mathcal{O}(\|x_k-x_*\|)$.

We need to prove that Condition C.4 does not conflict with Condition C.1 so that Theorem 9.2 can be applied. In other words, we need to show that the decrease conditions given in Condition C.1 hold for the Newton damped step (45) whenever it is taken. In Lemma 9.3 we showed that the quasi-normal component s_k^{n} given in (103) satisfies (18), (21), and (22). From Condition C.4, s_k^{n} given by (44) is used when it coincides with the s_k^{n} given by (103). Thus s_k^{n} given by (44) satisfies also (18), (21), and (22). It remains to prove that $\tau_k^{\mathsf{N}}(s_k^{\mathsf{N}})_u$ satisfies the Cauchy decrease condition (30) ((31) for the coupled approach). This is indeed the case, since

$$\begin{aligned}
&\Psi_k(0)-\Psi_k(\tau_k^{\mathsf{N}}(s_k^{\mathsf{N}})_u)\\
&\quad\geq -\tau_k^{\mathsf{N}}\bar{g}_k^T(s_k^{\mathsf{N}})_u-\frac{1}{2}(\tau_k^{\mathsf{N}})^2((s_k^{\mathsf{N}})_u)^T\left(W_k^TH_kW_k+E_k\bar{D}_k^{-2}\right)((s_k^{\mathsf{N}})_u)\\
&\quad\geq \tau_k^{\mathsf{N}}\left(-\bar{g}_k^T(s_k^{\mathsf{N}})_u-\frac{1}{2}((s_k^{\mathsf{N}})_u)^T\left(W_k^TH_kW_k+E_k\bar{D}_k^{-2}\right)((s_k^{\mathsf{N}})_u)\right)\\
&\quad\geq \tau_k^{\mathsf{N}}\left(\Psi_k(0)-\Psi_k(c_k^{\mathsf{d}})\right),
\end{aligned}$$

and $|\tau_k^{\mathsf{N}}-1|$ is $\mathcal{O}(\|x_k-x_*\|)$.

Now we need to show that eventually s_k is given by (45). Since $\{x_k\}$ converges to a nondegenerate point satisfying the second-order sufficient KKT conditions, $(s_k^{\mathsf{N}})_u$ exists for k sufficiently large. Furthermore, $(s_k^{\mathsf{n}})_y=-C_y(x_k)^{-1}C_k$ for k large enough because $\lim_k\|C_y(x_k)^{-1}C_k\|=0$, and from Theorem 9.2, δ_k is eventually bounded away from zero. Using a similar argument we see that $\tau_k^{\mathsf{N}}(s_k^{\mathsf{N}})_u$ is inside the trust region (27) for the decoupled approach or (29) for the coupled approach. So, from Condition C.4 we conclude that there exists a positive integer $\bar{k}$ such that s_k is given by (45) for $k\geq\bar{k}$.

Using the fact that $(s_k^{\mathsf{N}})_u$ is $\mathcal{O}(\|x_k-x_*\|)$, we conclude that $\tau_k^{\mathsf{N}}(s_k^{\mathsf{N}})_u-(s_k^{\mathsf{N}})_u$ is $\mathcal{O}(\|x_k-x_*\|^2)$. Thus,

$$s_k-s_k^{\mathsf{N}}=\begin{pmatrix} s_k^{\mathsf{n}}-C_y(x_k)^{-1}C_u(x_k)\tau_k^{\mathsf{N}}(s_k^{\mathsf{N}})_u\\ \tau_k^{\mathsf{N}}(s_k^{\mathsf{N}})_u\end{pmatrix}-\begin{pmatrix} s_k^{\mathsf{n}}-C_y(x_k)^{-1}C_u(x_k)(s_k^{\mathsf{N}})_u\\ (s_k^{\mathsf{N}})_u\end{pmatrix}$$

is $\mathcal{O}(\|x_k-x_*\|^2)$. This completes the proof since s_k^{N} can be seen as a Newton step on a given vector function of the type (17). This function vanishes at x_* and is continuously differentiable with Lipschitz continuous derivatives and a nonsingular Jacobian matrix in an open neighborhood of x_*. See the discussion at the end of section 4. Thus, the q-quadratic rate of convergence follows from [17, Thm. 5.2.1] and from the fact that $s_k-s_k^{\mathsf{N}}$ is $\mathcal{O}(\|x_k-x_*\|^2)$. ∎

10. Trial steps and multiplier estimates. When we described the trust-region interior-point SQP algorithms, we deferred the practical computation of the quasi-normal and tangential components and of the multiplier estimates. In the following sections we address these issues.

10.1. Computation of the quasi-normal component. The quasi-normal component s_k^{n} is an approximate solution of the trust-region subproblem

$$\begin{aligned}&\text{minimize } \frac{1}{2}\|C_y(x_k)(s^{\mathsf{n}})_y+C_k\|^2\\ &\text{subject to } \|(s^{\mathsf{n}})_y\|\leq\delta_k,\end{aligned}\tag{106}$$

and it is required for global convergence to a point that satisfies the necessary KKT conditions to satisfy conditions (18), (21), and (22). As we saw in equation (105) of the proof of Lemma 9.3, property (21) is a consequence of (22). Whether property (22) holds depends on the way in which the quasi-normal component is computed. We will show below that (22) is satisfied by many reasonable ways to compute s_k^{n}.

There are various ways to compute the quasi-normal component s_k^{n} for large scale problems. For example, one can use the conjugate-gradient method as suggested in [61] and [63], or one can use the Lanczos bidiagonalization as described in [26]. Both methods compute an approximate minimizer to the least squares functional in (106) from a subspace which contains its negative gradient $-C_y(x_k)^T C_k$. Thus, the components s_k^{n} generated by these methods satisfy $||s_k^{\mathsf{n}}|| \leq \delta_k$ and

$$\frac{1}{2}\|C_y(x_k)(s_k^{\mathsf{n}})_y + C_k\|^2 \leq \min\left\{\frac{1}{2}\|C_y(x_k)s + C_k\|^2 : s \in span\{-C_y(x_k)^T C_k\}, \|s\| \leq \delta_k\right\}.$$

We can appeal to a classical result due to Powell (see [52, Thm. 4], [45, Lem. 4.8]) to show that

$$\|C_k\|^2 - \|C_y(x_k)(s_k^{\mathsf{n}})_y + C_k\|^2 \geq \frac{1}{2}\|C_y(x_k)^T C_k\| \min\left\{\frac{\|C_y(x_k)^T C_k\|}{\|C_y(x_k)^T C_y(x_k)\|}, \delta_k\right\}.$$

Now one can use the fact that $\{C_y(x_k)\}$ and $\{C_y(x_k)^{-T}\}$ are bounded and can write

$$\|C_k\|^2 - \|C_y(x_k)(s_k^{\mathsf{n}})_y + C_k\|^2 \geq \kappa_2\|C_k\| \min\{\kappa_3\|C_k\|, \delta_k\},$$

where κ_2 and κ_3 are positive and do not depend on k.

An alternative to the previous procedures is to compute the solution of $C_y(x_k)s = -C(x_k)$ and to scale this solution back into the trust region (see (103)). In Lemma 9.3, we proved that (103) satisfies conditions (18), (21), and (22).

10.2. Computation of the tangential component. In this section we show how to derive conjugate-gradient algorithms to compute $(s_k)_u$. Other practical algorithms to compute trial steps for box-constrained minimization trust-region subproblems are introduced in [7] using three-dimensional subspace approximations and conjugate gradients.

Let us consider first the decoupled trust-region approach given in section 5.2.1. If we ignore the bound constraints for the moment, we can apply the conjugate-gradient algorithm proposed by Steihaug [61] and Toint [63] to solve the problem

$$\begin{aligned} &\text{minimize } \Psi_k(s_u) \\ &\text{subject to } \|\bar{D}_k^{-1} s_u\| \leq \delta_k. \end{aligned}$$

However, we also need to incorporate the constraints

$$\sigma_k(a - u_k) \leq s_u \leq \sigma_k(b - u_k).$$

This leads to the following algorithm:

ALGORITHM 10.1 (computation of $s_k = s_k^{\mathsf{n}} + W_k(s_k)_u$ (decoupled approach)).

1. Set $s_u^0 = 0$, $r_0 = -\bar{g}_k = -W_k^T \nabla q_k(s_k^{\mathsf{n}})$, $q_0 = \bar{D}_k^2 r_0$, $d_0 = q_0$, and $\epsilon > 0$.
2. For $i = 0, 1, 2, \ldots$ do
   2.1. Compute $\gamma_i = \frac{r_i^T q_i}{d_i^T (W_k^T H_k W_k + E_k \bar{D}_k^{-2}) d_i}$.

2.2. Compute
$$\tau_i = \max\{\tau > 0 \quad : \quad \|\bar{D}_k^{-1}(s_u^i + \tau d_i)\| \le \delta_k, \\ \sigma_k(a - u_k) \le s_u^i + \tau d_i \le \sigma_k(b - u_k)\}.$$
2.3. If $\gamma_i \le 0$, or if $\gamma_i > \tau_i$, then set $(s_k)_u = s_u^i + \tau_i d_i$, where τ_i is given as in 2.2 and go to 3; otherwise set $s_u^{i+1} = s_u^i + \gamma_i d_i$.
2.4. Update the residuals: $r_{i+1} = r_i - \gamma_i(W_k^T H_k W_k + E_k \bar{D}_k^{-2})d_i$ and $q_{i+1} = \bar{D}_k^2 r_{i+1}$.
2.5. Check truncation criteria: if $\sqrt{\frac{r_{i+1}^T q_{i+1}}{r_0^T q_0}} \le \epsilon$, set $(s_k)_u = s_u^{i+1}$ and go to 3.
2.6. Compute $\alpha_i = \frac{r_{i+1}^T q_{i+1}}{r_i^T q_i}$ and set $d_{i+1} = q_{i+1} + \alpha_i d_i$.
3. Compute $s_k = s_k^{\mathsf{n}} + W_k(s_k)_u$ and stop.

Step 2 iterates entirely in the vector space of the u variables. After the u component of the step s_k has been computed, step 3 finds its y component. The decoupled approach allows an efficient use of an approximation $\widehat{H}_k$ to the reduced Hessian $W_k^T \nabla_{xx}^2 \ell_k W_k$. In this case, only two linear systems are required, one with $C_y(x_k)^T$ in step 1 to compute $\bar{g}_k$ and the other with $C_y(x_k)$ in step 3 to compute $W_k(s_k)_u$. If the Hessian $\nabla_{xx}^2 \ell_k$ is being approximated, then the total number of linear systems is $2I(k) + 2$, where $I(k)$ is the number of conjugate-gradient iterations.

One can transform this algorithm to work in the whole space rather than in the reduced space by considering the coupled trust-region approach given in section 5.2.2. This alternative is presented below.

ALGORITHM 10.2 (computation of $s_k = s_k^{\mathsf{n}} + W_k(s_k)_u$ (coupled approach)).
1. Set $s^0 = 0$, $r_0 = -\bar{g}_k = -W_k^T \nabla q_k(s_k^{\mathsf{n}})$, $q_0 = \bar{D}_k^2 r_0$, $d_0 = W_k q_0$, and $\epsilon > 0$.
2. For $i = 0, 1, 2, \ldots$ do
2.1. Compute $\gamma_i = \frac{r_i^T q_i}{d_i^T H_k d_i + (d_i)_u^T E_k \bar{D}_k^{-2}(d_i)_u}$.
2.2. Compute
$$\tau_i = \max\left\{\tau > 0 \quad : \quad \left\| \begin{pmatrix} -C_y(x_k)^{-1} C_u(x_k)\tau(d_i)_u \\ \bar{D}_k^{-1}\tau(d_i)_u \end{pmatrix} \right\| \le \delta_k, \right. \\ \left. \sigma_k(a - u_k) \le s_u^i + \tau(d_i)_u \le \sigma_k(b - u_k) \right\}.$$
2.3. If $\gamma_i \le 0$, or if $\gamma_i > \tau_i$, then $s_k^{\mathsf{t}} = s^i + \tau_i d_i$, where τ_i is given as in 2.2, and go to 3; otherwise set $s^{i+1} = s^i + \gamma_i d_i$.
2.4. Update the residuals: $r_{i+1} = r_i - \gamma_i \left(W_k^T H_k d_i + E_k \bar{D}_k^{-2}(d_i)_u\right)$ and $q_{i+1} = \bar{D}_k^2 r_{i+1}$.
2.5. Check truncation criteria: if $\sqrt{\frac{r_{i+1}^T q_{i+1}}{r_0^T q_0}} \le \epsilon$, set $s_k^{\mathsf{t}} = s^{i+1}$ and go to 3.
2.6. Compute $\alpha_i = \frac{r_{i+1}^T q_{i+1}}{r_i^T q_i}$ and set $d_{i+1} = W_k(q_{i+1} + \alpha_i d_i)$.
3. Compute $s_k = s_k^{\mathsf{n}} + s_k^{\mathsf{t}}$ and stop.

Note that in step 2 both the y and the u components of the tangential component are being computed. The coupled approach is suitable particularly when an approximation H_k to the full Hessian $\nabla_{xx}^2 \ell_k$ is used. The coupled approach can be used also with an approximation $\widehat{H}_k$ to the reduced Hessian $W_k^T \nabla_{xx}^2 \ell_k W_k$. In this case, we consider H_k that is given by (41) and use the equalities (42) to compute the terms involving H_k in Algorithm 10.2. If the Hessian $\nabla_{xx}^2 \ell_k$ is approximated, the total number of linear systems is $2I(k) + 2$, where $I(k)$ is the number of conjugate-

gradient iterations. If the reduced Hessian $W_k^T \nabla_{xx}^2 \ell_k W_k$ is approximated, this number is $I(k) + 2$.

Two final important remarks are in order.

Remark 10.1. If $W_k^T W_k$ was included as a preconditioner in Algorithm 10.2, then the conjugate-gradient iterates would monotonically increase in the norm $\|W_k \cdot\|$. Dropping this preconditioner means that the conjugate-gradient iterates do not necessarily increase in this norm (see [61]). As a result, if the quasi-Newton step is inside the trust region, Algorithm 10.2 can terminate prematurely by stopping at the boundary of the trust region.

Remark 10.2. Since the conjugate-gradient Algorithms 10.1 and 10.2 start by minimizing the quadratic function $\Psi_k(s_u)$ along the direction $-\bar{D}_k^2 \bar{g}_k$, it is quite clear that they produce reduced tangential components $(s_k)_u$ that satisfy (30) and (31), respectively, with $\beta_1^{\mathsf{d}} = \beta_1^{\mathsf{c}} = 1$.

10.3. Multiplier estimates. A convenient estimate for the Lagrange multipliers is the adjoint update

$$\lambda_k = -C_y(x_k)^{-T} \nabla_y f_k, \tag{107}$$

which we use after each successful step. However, we also consider the following update:

$$\lambda_{k+1} = -C_y(x_k)^{-T} \nabla_y q_k(s_k^{\mathsf{n}}) = -C_y(x_k)^{-T} \left((H_k s_k^{\mathsf{n}})_y + \nabla_y f_k \right). \tag{108}$$

Here the use of (108) instead of

$$\lambda_{k+1} = -C_y(x_k + s_k)^{-T} \nabla_y f(x_k + s_k), \tag{109}$$

might be justified, since we obtain (108) without any further cost from the first iteration of any of the conjugate-gradient algorithms described above. The updates (107), (108), and (109) satisfy the requirement given by A.4 needed to prove global convergence to a first-order KKT point.

11. Numerical example. A typical application that has the structure described in this paper is the control of a heating process. In this section we introduce a simplified model discussed in [8] for the heating of a probe in a kiln. The temperature $y(x,t)$ inside the probe is governed by a nonlinear partial differential equation. The spatial domain is given by $(0,1)$. The boundary $x = 1$ is the inside of the probe and $x = 0$ is the boundary of the probe.

The goal is to control the heating process in such a way that the temperature inside the probe follows a certain desired temperature profile $y_d(t)$. The control $u(t)$ acts on the boundary $x = 0$. The problem can be formulated as follows.

$$\text{minimize } \frac{1}{2} \int_0^T [(y(1,t) - y_d(t))^2 + \gamma u^2(t)] dt \tag{110}$$

subject to

$$\begin{aligned}
\tau(y(x,t)) \tfrac{\partial y}{\partial t}(x,t) - \partial_x(\kappa(y(x,t)) \partial_x y(x,t)) &= q(x,t), \quad (x,t) \in (0,1) \times (0,T), \\
\kappa(y(0,t)) \partial_x y(0,t) &= g[y(0,t) - u(t)], \quad t \in (0,T), \\
\kappa(y(1,t)) \partial_x y(1,t) &= 0, \quad t \in (0,T), \\
y(x,0) &= y_0(x), \quad x \in (0,1), \\
u_{low} \leq \quad u \quad &\leq u_{upp},
\end{aligned}$$

where $y \in L^2(0,T;H^1(0,1))$ and $u \in L^2(0,T)$. The functions $\tau : \mathbb{R} \to \mathbb{R}$ and $\kappa : \mathbb{R} \to \mathbb{R}$ denote the specific heat capacity and the heat conduction, respectively, y_0 is the initial temperature distribution, q is the source term, g is a given scalar, and γ is a regularization parameter. Here $u_{low}, u_{upp} \in L^\infty(0,T)$ are given functions.

If the partial differential equation and the integral are discretized, we obtain an optimization problem of the form (1). The discretization uses finite elements and was introduced in [8] (see also [29] and [39]). The spatial domain $(0,1)$ is divided into N_x subintervals of equidistant length, and the spatial discretization is done using piecewise linear finite elements. The time discretization is performed by partitioning the interval $[0,T]$ into N_t equidistant subintervals. Then the backward Euler method is used to approximate the state space in time, and piecewise constant functions are used to approximate the control space. This leads to a discretized problem with dimension $n = N_t(N_x + 1) + N_t$ and $m = N_t(N_x + 1)$. Under the assumptions on the coefficient functions κ and τ stated in [8] and [39] which guarantee the well posedness of the infinite-dimensional problem, it is shown in [39] that the constraints $C(y,u)$ of the discretized problem satisfy the assumptions A.3 and A.5, provided the discretization parameters N_x and N_t are chosen appropriately. For more details we refer to the comprehensive treatments in [8] and [39].

The algorithms studied in this paper have been implemented in `FORTRAN 77`. The resulting software package TRICE (trust-region interior-point SQP algorithms for optimal control and engineering design problems) is available via the internet [16].

We use the formula (103) to compute the quasi-normal component, and use Algorithms 10.1 and 10.2 to calculate the tangential component. The numerical test computations were done on a Sun Sparcstation 10 in double precision. These results demonstrate the effectiveness of the algorithms.

With this discretization scheme, $C_y(x)$ is a block bidiagonal matrix with tridiagonal blocks. Hence linear systems with $C_y(x)$ and $C_y(x)^T$ can be solved efficiently by block forward substitution or block backward substitution, respectively. In each substitution step, only a small system with tridiagonal system has to be solved. In the implementation we use the LINPACK subroutine DGTSL to solve the tridiagonal systems. Notice that direct factorizations are only applied to the small $(N_x+1)\times(N_x+1)$ tridiagonal subblocks of $C_y(x)$ but not to the entire Jacobian matrix $(C_y(x)\ C_u(x))$. See also [39].

As we pointed out in section 1, the inner products and norms used in the trust-region interior-point SQP algorithms are not necessarily the Euclidean ones. In our implementation [16], we call subroutines to calculate the inner products $\langle y^1, y^2\rangle$ and $\langle u^1, u^2\rangle$ with $y^1, y^2 \in \mathbb{R}^m$ and $u^1, u^2 \in \mathbb{R}^{n-m}$. The user may supply these subroutines to incorporate a specific scaling. If the inner product $\langle x^1, x^2\rangle$ is required, then it is calculated as $\langle y^1, y^2\rangle + \langle u^1, u^2\rangle$. In this example, we used discretizations of the $L^2(0,T)$ and $L^2(0,T;H^1(0,1))$ norms for the control and the state spaces, respectively. This is important for the correct computation of the adjoint and the appropriate scaling of the problem.

In our numerical example we use the functions

$$\tau(y) = q_1 + q_2 y, \quad y \in \mathbb{R}, \quad \kappa(y) = r_1 + r_2 y, \quad y \in \mathbb{R},$$

with parameters $r_1 = q_1 = 4$, $r_2 = -1$, and $q_2 = 1$. The desired and initial tempera-

tures, and the right-hand side, are given by

$$\begin{aligned} y_d(t) &= 2 - e^{\eta t}, \\ y_0(x) &= 2 + \cos \pi x, \quad \text{and} \\ q(x,t) &= [\eta(q_1 + 2q_2) + \pi^2(r_1 + 2r_2)]e^{\eta t} \cos \pi x \\ &\quad -r_2\pi^2 e^{2\eta t} + (2r_2\pi^2 + \eta q_2)e^{2\eta t} \cos^2 \pi x, \end{aligned}$$

with $\eta = -1$. The final temperature is chosen to be $T = 0.5$ and the scalar $g = 1$ is used in the boundary condition. The functions in this example are those used in [39, Ex. 4.1]. The size of the problem tested is $n = 2200$, $m = 2100$ corresponding to the values $N_t = 100$, $N_x = 20$.

The scheme used to update the trust radius is the following fairly standard one:

- If $\text{ratio}(s_k; \rho_k) < 10^{-4}$, reject s_k and set $\delta_{k+1} = 0.5 \text{ norm}(s_k)$;
- if $10^{-4} \leq \text{ratio}(s_k; \rho_k) < 0.1$, reject s_k and set $\delta_{k+1} = 0.5 \text{ norm}(s_k)$;
- if $0.1 \leq \text{ratio}(s_k; \rho_k) < 0.75$, accept s_k and set $\delta_{k+1} = \delta_k$;
- if $\text{ratio}(s_k; \rho_k) \geq 0.75$, accept s_k and set $\delta_{k+1} = \min\{2\delta_k, 10^{10}\}$;

where $\text{ratio}(s_k; \rho_k) = \frac{ared(s_k;\rho_k)}{pred(s_k;\rho_k)}$,

$$\text{norm}(s_k) = \max\{\|s_k^{\mathfrak{n}}\|, \|\bar{D}_k^{-1}(s_k)_u\|\}$$

in the decoupled approach, and

$$\text{norm}(s_k) = \max\left\{\|s_k^{\mathfrak{n}}\|, \left\|\begin{pmatrix} -C_y(x_k)^{-1}C_u(x_k)(s_k)_u \\ \bar{D}_k^{-1}(s_k)_u \end{pmatrix}\right\|\right\}$$

in the coupled approach. The algorithms are stopped if the trust radius gets below 10^{-8}.

We have used $\sigma_k = \sigma = 0.99995$ for all k; $\delta_0 = 1$ as initial trust radius; $\rho_{-1} = 1$ and $\bar{\rho} = 10^{-2}$ in the penalty scheme. The tolerance used in the conjugate-gradient iteration was $\epsilon = 10^{-4}$. The upper and lower bounds were $b_i = 10^{-2}$, $a_i = -1000$, $i = 1, \ldots, n - m$. The starting vector was $x_0 = 0$.

For both the decoupled and the coupled approaches, we did tests using approximations to reduced and to full Hessians. We approximate these matrices with the limited memory BFGS representations given in [10] with a memory size of five pairs of vectors. For the reduced Hessian we use a null-space secant update (see [49], [67]). The initial approximation chosen was γI_{n-m} for the reduced Hessian and γI_n for the full Hessian, where γ is the user specified regularization parameter in the objective function (110).

In our implementation we use the following form of the diagonal matrix $\bar{D}_k$:

$$\left(\bar{D}_k\right)_{ii} = \begin{cases} \min\{1, (b - u_k)_i\} & \text{if} \quad (\bar{g}_k)_i < 0, \\ \min\{1, (u_k - a)_i\} & \text{if} \quad (\bar{g}_k)_i \geq 0, \end{cases} \tag{111}$$

for $i = 1, \ldots, n - m$. This form of $\bar{D}_k$ gives a better transition between the infinite and finite bound and is less sensitive to the introduction of meaningless bounds. See also Remark 3.1.

The algorithms were stopped when

$$\|D_k W_k^T \nabla f_k\| + \|C_k\| < 10^{-8}.$$

The results are shown in Tables 1 and 2 corresponding to the values $\gamma = 10^{-2}$ and $\gamma = 10^{-3}$, respectively. There were no rejected steps. The different alternatives tested performed quite similarly. The decoupled approach with reduced Hessian approximation seems to be the best for this example. Note that in this case the computation of each trial step costs only three linear system solvers with $C_y(x_k)$ and $C_y(x_k)^T$—one to compute the quasi-normal component and two for the computation of the tangential component.

We performed an experiment to compare the use of the Coleman–Li affine scaling with the Dikin–Karmarkar affine scaling. When applied to our class of problems, the Coleman–Li affine scaling is given by the matrices D_k and $\bar{D}_k$. A study of the Dikin–Karmarkar affine scaling for steepest descent is given in [54]. For our class of problems, this scaling is given by

$$\Big(K_k\Big)_{ii} = \min\{1,\, (u_k - a)_i,\, (b - u_k)_i\},\ i = 1, \ldots, n-m, \tag{112}$$

and has no dual information built in. We ran the trust-region interior-point SQP algorithm with the decoupled and reduced Hessian approximation and with (111) replaced by (112). The algorithm took only 11 iterations to reduce $\|K_k W_k^T \nabla f_k\| + \|C_k\|$ to 10^{-8}. However, as we can see from the plots of the controls in Figures 1 and 2, the algorithm did not find the correct solution when it used the Dikin–Karmarkar affine scaling (112). Some of the variables are at the wrong bound corresponding to negative multipliers.

12. Conclusions. In this paper we have introduced and analyzed some trust-region interior-point SQP algorithms for an important class of nonlinear programming problems that appear in many engineering applications. These algorithms use the structure of the problem, and they combine trust-region techniques for equality-constrained optimization with an affine scaling interior-point approach for simple bounds. We have proved global and local convergence results for these algorithms

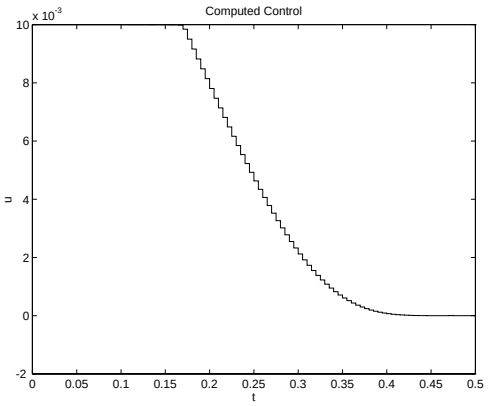

FIG. 1. *Coleman–Li affine scaling.*

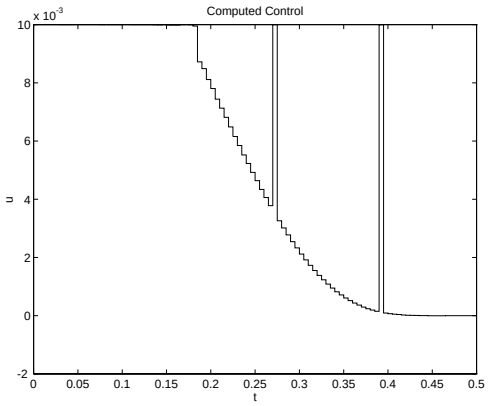

FIG. 2. *Dikin–Karmarkar affine scaling.*

that includes as special cases both the results established for equality constraints [15], [19] and those for simple bounds [13].

We have implemented the trust-region interior-point SQP algorithms covering several trial step computations and second-order approximations. In this paper we have reported numerical results for the solution of a specific optimal control problem governed by a nonlinear heat equation. In [11], [30], and [31], these algorithms have been applied to other optimal control problems. The numerical results have been quite satisfactory.

We are investigating extensions of these algorithms to handle bounds on the state variables y. See [66]. We are also developing an inexact analysis to deal with trial step computations that allow for inexact linear system solvers and inexact directional derivatives [31]. The formulation and analysis of these methods in an infinite-dimensional framework is also part of our current studies.

Acknowledgments. This research collaboration on the tailoring of current optimization algorithm design to exploit the structure of problems in computational design and control was begun as the result of conversations held during the April 1994 Workshop on Optimal Design and Control held at Virginia Polytechnic Institute and State University, Blacksburg. This workshop was organized by the Interdisciplinary Center for Applied Mathematics at Virginia Tech and sponsored by the AFOSR.

We would like to thank two referees for their patient and careful reading and their helpful comments on an earlier draft of this paper.

A PENALIZED NEUMANN CONTROL APPROACH FOR SOLVING AN OPTIMAL DIRICHLET CONTROL PROBLEM FOR THE NAVIER–STOKES EQUATIONS*

L. S. HOU† AND S. S. RAVINDRAN‡

Abstract. We introduce a penalized Neumann boundary control approach for solving an optimal Dirichlet boundary control problem associated with the two- or three-dimensional steady-state Navier–Stokes equations. We prove the convergence of the solutions of the penalized Neumann control problem, the suboptimality of the limit, and the optimality of the limit under further restrictions on the data. We describe the numerical algorithm for solving the penalized Neumann control problem and report some numerical results.

Key words. optimal control, Neumann control, Dirichlet control, Navier–Stokes equations, finite element method

1. Introduction.

Optimal control for the Navier–Stokes equations has been the subject of extensive study in recent years and much progress has been made both mathematically and computationally; see, e.g., [AT], [FS1], [FS2], [FS3], [Fu1], [Fu2], [Fu3], [Gun], [GHS1], [GHS2], [GHS3], [HS], [HY1], [HY2], [HYR], [Li], [S1], and [S2]. In this work we confine ourselves to optimal Dirichlet control problems for the steady-state Navier–Stokes equations. Dirichlet controls, i.e., boundary velocity controls or boundary mass flux controls, are common in applications. For instance, one often attempts, through the suction and injection of fluid through orifices on the boundary to reduce the drag on a body moving through a fluid. Optimal Dirichlet control problems for time-dependent Navier–Stokes equations were studied in [FGH] for general Dirichlet controls and in [FS1], [FS2], [FS3] and [S1], [S2] for Dirichlet controls in a special case, namely, when the control is of the separation-of-variable type. Optimal Dirichlet control problems for steady-state Navier–Stokes equations were studied in [GHS2], [GHS3], and [HS]. In [GHS3], optimal Dirichlet controls of finite dimensions were analyzed and some numerical results presented. In [GHS2], the existence and regularity of optimal solutions for optimal Dirichlet control problems were proved; an optimality system of equations was derived; and finite element approximations were defined and optimal error estimates established. In [HS], optimal control problems with smooth Dirichlet controls were studied; in particular, an optimality system of equations was derived. The optimality systems in [GHS2] and [HS] involve a boundary Laplacian or a boundary biharmonic equation that complicates the numerical resolution of the optimality systems. In finite element approximations of (uncontrolled)

boundary value problems for partial differential equations, Neumann boundary conditions are generally easier to handle than the Dirichlet ones; and the same is true of optimal boundary control problems. Inspired by the penalty method for solving Dirichlet problems for (uncontrolled) elliptic partial differential equations (see [Ba]), we propose in this article a penalty method for solving the optimal Dirichlet control problem. The proposed penalty approach avoids the boundary Laplacian or boundary biharmonic equations that appeared in [GHS2] and [HS]. The advantages (as well as disadvantages) of the penalty method in solving uncontrolled Dirichlet boundary value problems essentially hold true in solving optimal Dirichlet boundary control problems.

The optimal Dirichlet control problem we consider is to minimize the vorticity of viscous, incompressible flow by choosing an appropriate boundary velocity. Precisely, we will study the following optimal control problem: find a triplet $(\mathbf{u}, p, \mathbf{g})$ such that the functional

$$\mathcal{J}(\mathbf{u}, \mathbf{g}) = \frac{\alpha}{2}\int_{\Omega} |\operatorname{curl} \mathbf{u}|^2 \, d\mathbf{x} + \frac{\beta}{2}\int_{\Gamma} |\mathbf{g}|^2 \, ds \tag{1.1}$$

is minimized subject to the steady-state Navier–Stokes equations

$$-\nu \Delta \mathbf{u} + (\mathbf{u} \cdot \nabla)\mathbf{u} + \nabla p = \mathbf{f} \qquad \text{in } \Omega\,, \tag{1.2}$$

$$\operatorname{div} \mathbf{u} = 0 \qquad \text{in } \Omega, \tag{1.3}$$

and

$$\mathbf{u} = \mathbf{g} \qquad \text{on } \Gamma\,. \tag{1.4}$$

Here, Ω is a two- or three-dimensional bounded and simply connected flow domain (Ω is assumed to be of class $C^{1,1}$ or convex in $\mathbb{R}^2$ and of class $C^{1,1}$ in $\mathbb{R}^3$); Γ denotes the boundary of Ω; $\nu > 0$ denotes the constant viscosity; $\mathbf{u}$ and p denote the velocity field and the pressure field, respectively; $\mathbf{f}$ is a prescribed forcing term; and $\mathbf{g}$ is the boundary velocity—the control field. Because of the divergence-free condition on $\mathbf{u}$, $\mathbf{g}$ must necessarily satisfy $\int_{\Gamma} \mathbf{g} \cdot \mathbf{n}\, ds = 0$. The constants α and β appearing in the functional (1.1) are two positive parameters that adjust the relative weights of the two terms in the functional. Note that we use the same notation curl to denote the curl operators in two dimensions and three dimensions, although they are defined differently. The choice of the functional is motivated by the fact that irrotational flows have no local flow recirculations. We hope that minimizing the L^2-norm of the vorticity will lead to reduction in flow recirculations.

The plan of the paper is as follows. In section 2, we review mathematical background materials related to the steady-state Navier–Stokes equations and give a precise description of the optimal control problem we consider. In section 3, we introduce the penalized Neumann control approach and prove the existence of an optimal solution for the penalized Neumann control problem. In section 4, we demonstrate the convergence of the penalized optimal boundary control solutions and show that the limit is suboptimal. In section 5, we show that the limit found in section 4 is indeed an optimal solution for the optimal Dirichlet control problem. Finally in section 6, we describe the formal procedures for computing an approximate optimal solution and present some numerical results.

2. Preliminaries. Throughout, C or C_i (where i is any subscript) denotes a constant depending only on the domain Ω. We denote by $L^2(\Omega)$ the collection of Lebesgue square-integrable functions defined on Ω. Let $H^1(\Omega) = \{v \in L^2(\Omega) : \frac{\partial v}{\partial x_i} \in L^2(\Omega) \text{ for } i = 1, \ldots, d\}$, where $d = 2$ or 3; $H_0^1(\Omega) = \{v \in H^1(\Omega) : v|_\Gamma = 0\}$; $L_0^2(\Omega) = \{q \in L^2(\Omega) : \int_\Omega q \, d\mathbf{x} = 0\}$; and $H^m(\Omega) = \{v \in L^2(\Omega) : \frac{\partial^{|\alpha|} v}{\partial x_1^{\alpha_1} \cdots \partial x_d^{\alpha_d}} \in L^2(\Omega) \text{ for all } \alpha = (\alpha_1, \ldots, \alpha_d) \text{ with } |\alpha| \le m\}$, where $d = 2$ or 3. Here $m > 0$ is an integer. For the definition of fractional ordered Sobolev spaces $H^s(\Omega)$ (s noninteger), see [Ad]. Negative ordered Sobolev spaces $H^{-s}(\Omega)$ ($s > 0$) are defined as the dual space, i.e., $H^{-s}(\Omega) = \{H_0^s(\Omega)\}^*$. Vector-valued counterparts of these spaces are denoted by boldface symbols, e.g., $\mathbf{H}^1(\Omega) = [H^1(\Omega)]^d$, where $d = 2$ or 3. The trace spaces $H^r(\Gamma)$ are the restriction to the boundary of $H^{r+1/2}(\Omega)$. We denote the norms and inner products for $H^s(\Omega)$ or $\mathbf{H}^s(\Omega)$ by $\|\cdot\|_s$ and $(\cdot,\cdot)_s$, respectively. The $L^2(\Omega)$ or $\mathbf{L}^2(\Omega)$ inner product is denoted by $(\cdot,\cdot)$. We denote the norms and inner products for $H^r(\Gamma)$ or $\mathbf{H}^r(\Gamma)$ by $\|\cdot\|_{r,\Gamma}$ and $(\cdot,\cdot)_{r,\Gamma}$, respectively. The $L^2(\Gamma)$ or $\mathbf{L}^2(\Gamma)$ inner product is denoted by $(\cdot,\cdot)_\Gamma$. The duality pairing between a Sobolev space $H^s(\Omega)$ ($s > 0$) and its dual space is denoted by $\langle\cdot,\cdot\rangle$. The duality pairing between a trace space $H^r(\Gamma)$ ($r > 0$) and its dual space is denoted by $\langle\cdot,\cdot\rangle_\Gamma$.

We define the following standard bilinear, trilinear forms associated with the Navier–Stokes equations

$$a(\mathbf{u}, \mathbf{v}) = \int_\Omega (\nabla \mathbf{u}) : (\nabla \mathbf{v}) \, d\mathbf{x} \qquad \forall\, \mathbf{u}, \mathbf{v} \in \mathbf{H}^1(\Omega)\,,$$

$$b(\mathbf{u}, q) = -\int_\Omega q \operatorname{div} \mathbf{u} \, d\mathbf{x} \qquad \forall\, \mathbf{u} \in \mathbf{H}^1(\Omega), \forall\, q \in L^2(\Omega),$$

and

$$c(\mathbf{u}, \mathbf{v}, \mathbf{w}) = \int_\Omega (\mathbf{u} \cdot \nabla)\mathbf{v} \cdot \mathbf{w} \, d\mathbf{x} \qquad \forall\, \mathbf{u}, \mathbf{v}, \mathbf{w} \in \mathbf{H}^1(\Omega)\,.$$

We now summarize some properties of these linear forms. We have the coercivity relations associated with $a(\cdot,\cdot)$:

$$a(\mathbf{u}, \mathbf{u}) = \|\nabla \mathbf{u}\|_0^2 \ge C_0 \|\mathbf{u}\|_1^2 \qquad \forall\, \mathbf{u} \in \mathbf{H}_0^1(\Omega) \tag{2.1}$$

(which is a direct consequence of Poincaré inequality) and

$$\int_\Gamma |\mathbf{v}|^2 \, ds + \int_\Omega \left|\nabla \mathbf{v}\right|^2 d\mathbf{x} \ge C_1 \|\mathbf{v}\|_1^2 \qquad \forall\, \mathbf{v} \in \mathbf{H}^1(\Omega) \tag{2.2}$$

(whose proof can be found in [Ne]). The forms $a(\cdot,\cdot)$, $b(\cdot,\cdot)$, and $c(\cdot,\cdot,\cdot)$ are all continuous; in particular, we have

$$\left|c(\mathbf{u}, \mathbf{v}, \mathbf{w})\right| \le C_2 \|\mathbf{u}\|_1 \|\mathbf{v}\|_1 \|\mathbf{w}\|_1\,. \tag{2.3}$$

The bilinear form $b(\cdot,\cdot)$ satisfies the following inf-sup conditions:

$$\inf_{q \in L^2(\Omega)} \sup_{\mathbf{v} \in \mathbf{H}^1(\Omega)} \frac{\int_\Omega q \operatorname{div} \mathbf{v} \, d\mathbf{x}}{\|q\|_0 \|\mathbf{v}\|_1} \ge C_3 \tag{2.4}$$

and

$$\inf_{q\in L_0^2(\Omega)} \sup_{\mathbf{v}\in \mathbf{H}_0^1(\Omega)} \frac{\int_\Omega q \operatorname{div} \mathbf{v}\, d\mathbf{x}}{\|q\|_0 \, \|\mathbf{v}\|_1} \geq C_3 \,. \tag{2.5}$$

The proof of (2.5) can be found in [GR], and that of (2.4) in [Ma]. Using integration-by-parts techniques we may deduce

$$\int_\Omega (\mathbf{v}\cdot\nabla)\mathbf{v}\cdot\mathbf{v}\, d\mathbf{x} = \frac{1}{2}\int_\Gamma (\mathbf{v}\cdot\mathbf{n})|\mathbf{v}|^2\, ds \qquad \forall\, \mathbf{v}\in \mathbf{H}^1(\Omega) \text{ with } \operatorname{div}\mathbf{v} = 0\,. \tag{2.6}$$

We now give the definition of a solution for the Navier–Stokes equations with a Dirichlet boundary condition. Throughout, we assume $\mathbf{f}\in \mathbf{L}^2(\Omega)$.

DEFINITION 2.1. *Let* $\mathbf{g}\in \mathbf{H}^{1/2}(\Gamma)$. *A pair* $(\mathbf{u},p)\in \mathbf{H}^1(\Omega)\times L_0^2(\Omega)$ *is said to be a solution of the Navier–Stokes equations* (1.2)–(1.4) *iff*

$$\nu\, a(\mathbf{u},\mathbf{v}) + c(\mathbf{u},\mathbf{u},\mathbf{v}) + b(\mathbf{v},p) = \int_\Omega \mathbf{f}\cdot\mathbf{v}\, d\mathbf{x} \qquad \forall\, \mathbf{v}\in \mathbf{H}_0^1(\Omega)\,, \tag{2.7}$$

$$b(\mathbf{u},q) = 0 \qquad \forall\, q\in L_0^2(\Omega), \tag{2.8}$$

and

$$\mathbf{u}\big|_\Gamma = \mathbf{g}\,. \tag{2.9}$$

A proof of the existence of a solution in the sense of Definition 2.1 can be found in [GR] and [Te].

The optimal Dirichlet control problem we consider can be stated as:

(P) seek a $(\mathbf{u},p,\mathbf{g})\in \mathbf{H}^1(\Omega)\times L_0^2(\Omega)\times \mathbf{L}^2(\Gamma)$ such that (1.1) is minimized subject to (2.7)–(2.9).

We define the admissible set $\mathcal{U}_{ad}$ for (P) by

$$\mathcal{U}_{ad} = \big\{(\mathbf{u},p,\mathbf{g})\in \mathbf{H}^1(\Omega)\times L_0^2(\Omega)\times \mathbf{L}^2(\Gamma) : (\mathbf{u},p,\mathbf{g}) \text{ satisfies (2.7)–(2.9)}\big\}\,.$$

3. Penalized optimal Neumann control problems. For each $\epsilon\in(0,1/\nu)$, we consider the following Neumann control problem: find a $(\mathbf{u}_\epsilon,p_\epsilon,\mathbf{g}_\epsilon)\in \mathbf{H}^1(\Omega)\times L^2(\Omega)\times \mathbf{L}^2(\Gamma)$ such that the functional

$$\mathcal{J}(\mathbf{u},\mathbf{g}) = \frac{\alpha}{2}\int_\Omega |\operatorname{curl}\mathbf{u}|^2\, d\mathbf{x} + \frac{\beta}{2}\int_\Gamma |\mathbf{g}|^2\, ds \tag{3.1}$$

is minimized subject to the steady-state Navier–Stokes equations (1.2)–(1.3) with the nonlinear Neumann (or Robin)-type boundary condition

$$-p\mathbf{n} + \nu\frac{\partial\mathbf{u}}{\partial\mathbf{n}} - \frac{1}{2}(\mathbf{u}\cdot\mathbf{n})\mathbf{u} + \frac{1}{\epsilon}\,\mathbf{u} = \frac{1}{\epsilon}\,\mathbf{g} \qquad \text{on } \Gamma\,. \tag{3.2}$$

Formally, we see that as $\epsilon\to 0$, the Neumann boundary condition (3.2) reduces to the Dirichlet boundary condition (1.4), and therefore we expect that optimal solutions for the Neumann boundary control problems approach an optimal solution for the

Dirichlet boundary control problem. Here, ϵ acts as a penalty constant. By formally multiplying (1.2) by a test function $\mathbf{v}$ and integrating by parts, we obtain

$$\nu\int_\Omega(\nabla\mathbf{u}):(\nabla\mathbf{v})\,d\mathbf{x}-\nu\int_\Gamma\frac{\partial\mathbf{u}}{\partial\mathbf{n}}\cdot\mathbf{v}\,ds+\int_\Omega(\mathbf{u}\cdot\nabla)\mathbf{u}\cdot\mathbf{v}\,d\mathbf{x}$$
$$-\int_\Omega p\,\mathrm{div}\,\mathbf{v}\,d\mathbf{x}+\int_\Gamma p\mathbf{n}\cdot\mathbf{v}\,ds=\int_\Omega\mathbf{f}\cdot\mathbf{v}\,d\mathbf{x}\qquad\forall\,\mathbf{v}\in\mathbf{H}^1(\Omega)\,.$$

Eliminating $-p\mathbf{n}+\nu\frac{\partial\mathbf{u}}{\partial\mathbf{n}}$ in the boundary integrals using (3.2), we are led to the following definition of a (weak) solution for the Navier–Stokes equations with the Neumann boundary condition (3.2).

DEFINITION 3.1. *Let $\mathbf{g}\in\mathbf{L}^2(\Gamma)$. A pair $(\mathbf{u},p)\in\mathbf{H}^1(\Omega)\times L^2(\Omega)$ is said to be a solution of* (1.2)–(1.3) *with the Neumann condition* (3.2) *iff $(\mathbf{u},p)$ satisfies*

$$\begin{aligned}&\nu\int_\Omega(\nabla\mathbf{u}):(\nabla\mathbf{v})\,d\mathbf{x}+\frac{1}{\epsilon}\int_\Gamma\mathbf{u}\cdot\mathbf{v}\,ds-\frac{1}{2}\int_\Gamma(\mathbf{u}\cdot\mathbf{n})\mathbf{u}\cdot\mathbf{v}\,ds+\int_\Omega(\mathbf{u}\cdot\nabla)\mathbf{u}\cdot\mathbf{v}\,d\mathbf{x}\\&\quad-\int_\Omega p\,\mathrm{div}\,\mathbf{v}\,d\mathbf{x}=\int_\Omega\mathbf{f}\cdot\mathbf{v}\,d\mathbf{x}+\frac{1}{\epsilon}\int_\Gamma\mathbf{g}\cdot\mathbf{v}\,ds\qquad\forall\,\mathbf{v}\in\mathbf{H}^1(\Omega)\end{aligned}\tag{3.3}$$

and

$$-\int_\Omega q\,\mathrm{div}\,\mathbf{u}\,d\mathbf{x}=0\qquad\forall\,q\in L^2(\Omega)\,.\tag{3.4}$$

For each $\epsilon>0$, the penalized optimal Neumann control problems we consider can be stated as follows:

$$\begin{aligned}&\text{seek a }(\mathbf{u}_\epsilon,p_\epsilon,\mathbf{g}_\epsilon)\in\mathbf{H}^1(\Omega)\times L^2(\Omega)\times\mathbf{L}^2(\Gamma)\text{ such}\\&\text{that (3.1) is minimized subject to (3.3)–(3.4)}\,.\end{aligned}\tag{P}_\epsilon$$

In this section we will derive an estimate for solutions of the constraint equations (3.3)–(3.4) and then prove the existence of a solution for the optimal control problem $(\mathrm{P})_\epsilon$.

LEMMA 3.2. *Assume $\epsilon\in(0,1/\nu)$ and $\mathbf{g}\in\mathbf{L}^2(\Gamma)$. Then there exists a $(\mathbf{u},p)\in\mathbf{H}^1(\Omega)\times L^2(\Omega)$ satisfying* (3.3)–(3.4)*; furthermore,*

$$\frac{\nu}{2}\int_\Omega|\nabla\mathbf{u}|^2\,d\mathbf{x}+\frac{1}{4\epsilon}\int_\Gamma|\mathbf{u}|^2\,ds\le\frac{1}{2\nu C_1}\int_\Omega|\mathbf{f}|^2\,d\mathbf{x}+\frac{1}{\epsilon}\int_\Gamma|\mathbf{g}|^2\,ds\tag{3.5}$$

and

$$\|\overline{p}\|_0\le\frac{1}{C_3}\big(\nu\,\|\mathbf{u}\|_1+C_2\|\mathbf{u}\|_1^2+\|\mathbf{f}\|_0\big)\,,\tag{3.6}$$

where $\overline{p}=p-\big(1/|\Omega|\big)\int_\Omega p\,d\mathbf{x}$.

Proof. Since $\epsilon\in(0,1/\nu)$, we may use (2.2) to obtain

$$\nu\int_\Omega|\nabla\mathbf{v}|\,d\mathbf{x}+\frac{1}{\epsilon}\int_\Gamma|\mathbf{v}|^2\,ds\ge\nu\Big(\int_\Omega|\nabla\mathbf{v}|\,d\mathbf{x}+\int_\Gamma|\mathbf{v}|^2\,ds\Big)\ge\nu C_1\|\mathbf{v}\|_1^2\tag{3.7}$$

for every $\mathbf{v}\in\mathbf{H}^1(\Omega)$. This coercivity relation together with the inf-sup condition (2.4) allow us to prove the existence of a solution for (3.3)–(3.4) by using standard techniques for proving the existence of a solution for the Navier–Stokes equations with

homogeneous Dirichlet conditions (see [Te] or [GR]). Here we also used the fact that $\mathbf{H}^1(\Omega)\big|_\Gamma = \mathbf{H}^{1/2}(\Gamma)$ and $\mathbf{H}^{1/2}(\Gamma)$ is continuously embedded into $\mathbf{L}^3(\Gamma)$ so that we have the continuity of the trilinear term $\int_\Gamma (\mathbf{u}\cdot\mathbf{n})\mathbf{w}\cdot\mathbf{v}\,ds$ on $\mathbf{H}^1(\Omega)\times\mathbf{H}^1(\Omega)\times\mathbf{H}^1(\Omega)$. It remains to show that estimates (3.5)–(3.6) hold. Setting $\mathbf{v}=\mathbf{u}$ in (3.3) and using (3.4) we obtain

$$\nu\int_\Omega |\nabla\mathbf{u}|^2\,d\mathbf{x} + \frac{1}{\epsilon}\int_\Gamma |\mathbf{u}|^2\,ds \le \frac{1}{2\nu C_1}\int_\Omega |\mathbf{f}|^2\,d\mathbf{x} + \frac{\nu C_1}{2}\int_\Omega |\mathbf{u}|^2\,d\mathbf{x} + \frac{1}{\epsilon}\int_\Gamma |\mathbf{g}|^2\,ds + \frac{1}{4\epsilon}\int_\Gamma |\mathbf{u}|^2\,ds,$$

so that using (3.7) we are led to

$$\frac{\nu}{2}\int_\Omega |\nabla\mathbf{u}|^2\,d\mathbf{x} + \frac{1}{4\epsilon}\int_\Gamma |\mathbf{u}|^2\,ds \le \frac{1}{2\nu C_1}\int_\Omega |\mathbf{f}|^2\,d\mathbf{x} + \frac{1}{\epsilon}\int_\Gamma |\mathbf{g}|^2\,ds\,;$$

i.e., (3.5) is proved. For test functions $\mathbf{v}\in\mathbf{H}_0^1(\Omega)$, equation (3.3) reduces to

$$\nu\, a(\mathbf{u},\mathbf{v}) + c(\mathbf{u},\mathbf{u},\mathbf{v}) + b(\mathbf{v},p) = (\mathbf{f},\mathbf{v}) \qquad \forall\,\mathbf{v}\in\mathbf{H}_0^1(\Omega)\,.$$

Note that $\overline{p}\in L_0^2(\Omega)$, where $\overline{p} = p - \big(1/|\Omega|\big)\int_\Omega p\,d\mathbf{x}$, and

$$\begin{aligned} b(\mathbf{v},\overline{p}) &= -\int_\Omega \Big(p - \frac{1}{|\Omega|}\int_\Omega p\,d\mathbf{x}\Big)\operatorname{div}\mathbf{v}\,d\mathbf{x} = -\int_\Omega p\operatorname{div}\mathbf{v}\,d\mathbf{x} + \frac{1}{|\Omega|}\int_\Omega p\,d\mathbf{x}\int_\Omega \operatorname{div}\mathbf{v}\,d\mathbf{x} \\ &= b(\mathbf{v},p) + \frac{1}{|\Omega|}\int_\Omega p\,d\mathbf{x}\int_\Gamma \mathbf{v}\cdot\mathbf{n}\,ds = b(\mathbf{v},p) \qquad \forall\,\mathbf{v}\in\mathbf{H}_0^1(\Omega)\,. \end{aligned}$$

Using the last two relations and the second inf-sup condition (2.5) we easily obtain the estimate for $\overline{p}$:

$$\|\overline{p}\|_0 \le \frac{1}{C_3}\big(\nu\,\|\mathbf{u}\|_1 + C_2\|\mathbf{u}\|_1^2 + \|\mathbf{f}\|_0\big)\,. \qquad \square$$

We will make use of the following two lemmas to prove the existence of a solution for $(\mathrm{P})_\epsilon$.

LEMMA 3.3. *There exists a positive constant C_4 such that*

$$\|\mathbf{w}\|_1^2 \le C_4\Big(\int_\Omega |\operatorname{div}\mathbf{w}|^2\,d\mathbf{x} + \int_\Omega |\operatorname{curl}\mathbf{w}|^2\,d\mathbf{x} + \int_\Gamma |\mathbf{w}|^2\,ds\Big) \qquad \forall\,\mathbf{w}\in\mathbf{H}^1(\Omega)\,.$$

Proof. The proof follows standard techniques dealing with norm equivalence on Sobolev spaces (see, e.g., [Ne]). It proceeds as follows. Assume Lemma 3.3 is false. Then we may choose a sequence $\{\mathbf{w}^{(n)}\}_{n=1}^\infty \subset \mathbf{H}^1(\Omega)$ such that $\|\mathbf{w}^{(n)}\|_1 = 1$ for all n and

$$\int_\Omega |\operatorname{curl}\mathbf{w}^{(n)}|^2\,d\mathbf{x} + \int_\Omega |\operatorname{div}\mathbf{w}^{(n)}|^2\,d\mathbf{x} + \int_\Gamma |\mathbf{w}^{(n)}|^2\,ds < \frac{1}{n}\,. \tag{3.8}$$

The boundedness of $\{\mathbf{w}^{(n)}\}$ in $\mathbf{H}^1(\Omega)$ implies that there exists a $\mathbf{w}\in\mathbf{H}^1(\Omega)$ and a subsequence of $\{\mathbf{w}^{(n)}\}$, still denoted by $\{\mathbf{w}^{(n)}\}$, such that as $n\to\infty$,

$$\mathbf{w}^{(n)} \rightharpoonup \mathbf{w} \quad \text{in } \mathbf{H}^1(\Omega)\,, \qquad \mathbf{w}^{(n)} \to \mathbf{w} \quad \text{in } \mathbf{L}^2(\Omega)\,,$$

$$\operatorname{curl}\mathbf{w}^{(n)} \rightharpoonup \operatorname{curl}\mathbf{w} \quad \text{in } L^2(\Omega) \qquad \text{and} \qquad \operatorname{div}\mathbf{w}^{(n)} \rightharpoonup \operatorname{div}\mathbf{w}^{(n)} \quad \text{in } L^2(\Omega)\,.$$

Also, since the trace of $\mathbf{H}^1(\Omega)$ equals $\mathbf{H}^{1/2}(\Gamma)$ and the space $\mathbf{H}^{1/2}(\Gamma)$ is continuously imbedded into $\mathbf{L}^2(\Gamma)$, we have that

$$\mathbf{w}^{(n)} \rightharpoonup \mathbf{w} \quad \text{in } \mathbf{L}^2(\Gamma)\,.$$

From (3.8) we deduce that

$$\operatorname{curl}\mathbf{w}^{(n)} \to 0 \quad \text{in } L^2(\Omega)\,, \qquad \operatorname{div}\mathbf{w}^{(n)} \to 0 \quad \text{in } L^2(\Omega)\,,$$

and

$$\mathbf{w}^{(n)}|_\Gamma \to \mathbf{0} \quad \text{in } \mathbf{L}^2(\Gamma)\,.$$

By uniqueness of weak limits we have that

$$\operatorname{curl}\mathbf{w} = 0\,, \qquad \operatorname{div}\mathbf{w} = 0, \qquad \text{and} \qquad \mathbf{w}\big|_\Gamma = \mathbf{0}\,.$$

Since the boundary value problem $\operatorname{curl}\mathbf{w} = 0$, $\operatorname{div}\mathbf{w} = 0$, and $(\mathbf{w}\cdot\mathbf{n})|_\Gamma = 0$ admits a unique trivial solution (see [GR, Theorem I.3.6, p. 48]), we conclude $\mathbf{w} = \mathbf{0}$. This, of course, contradicts $\|\mathbf{w}\|_1 \geq \liminf_{n\to\infty}\|\mathbf{w}^{(n)}\|_1 = 1$. Thus the lemma is proved. □

LEMMA 3.4. *Assume* $\mathbf{u} \in \mathbf{V} \equiv \{\mathbf{v} \in \mathbf{H}^1(\Omega) : \operatorname{div}\mathbf{v} = 0\}$ *is a solution of*

$$\begin{aligned}\nu\int_\Omega (\nabla\mathbf{u}) : (\nabla\mathbf{v})\,d\mathbf{x} + \frac{1}{\epsilon}\int_\Gamma \mathbf{u}\cdot\mathbf{v}\,ds - \frac{1}{2}\int_\Gamma (\mathbf{u}\cdot\mathbf{n})\mathbf{u}\cdot\mathbf{v}\,ds + \int_\Omega (\mathbf{u}\cdot\nabla)\mathbf{u}\cdot\mathbf{v}\,d\mathbf{x}\\ = \int_\Omega \mathbf{f}\cdot\mathbf{v}\,d\mathbf{x} + \frac{1}{\epsilon}\int_\Gamma \mathbf{g}\cdot\mathbf{v}\,ds \qquad \forall\,\mathbf{v}\in\mathbf{V}.\end{aligned}$$

Then, there exists a $p \in L^2(\Omega)$ *such that* (3.3)–(3.4) *hold.*

Proof. The result follows directly from the first inf-sup condition (2.4) and [GR, Theorem IV.1.4, p. 283]. □

We are now in a position to prove the existence of a solution to $(\mathrm{P})_\epsilon$.

THEOREM 3.5. *Assume* $\epsilon \in (0, 1/\nu)$. *Then there exists a solution* $(\mathbf{u}_\epsilon, p_\epsilon, \mathbf{g}_\epsilon) \in \mathbf{H}^1(\Omega)\times L^2(\Omega)\times\mathbf{L}^2(\Gamma)$ *for the optimal control problem* $(\mathrm{P})_\epsilon$.

Proof. From Lemma 3.2 it is obvious that there exists a $(\mathbf{u}, p, \mathbf{g}) \in \mathbf{H}^1(\Omega)\times L^2(\Omega)\times\mathbf{L}^2(\Gamma)$ such that (3.3)–(3.4) holds. Hence we may choose a minimizing sequence $\{(\mathbf{u}_m, p_m, \mathbf{g}_m)\} \subset \mathbf{H}^1(\Omega)\times L^2(\Omega)\times\mathbf{L}^2(\Gamma)$ such that

$$\begin{aligned}\nu\int_\Omega \nabla\mathbf{u}_m : \nabla\mathbf{v}\,d\mathbf{x} + \frac{1}{\epsilon}\int_\Gamma \mathbf{u}_m\cdot\mathbf{v}\,ds - \frac{1}{2}\int_\Gamma (\mathbf{u}_m\cdot\mathbf{n})\mathbf{u}_m\cdot\mathbf{v}\,ds - \int_\Omega p_m \operatorname{div}\mathbf{v}\,d\mathbf{x}\\ + \int_\Omega (\mathbf{u}_m\cdot\nabla)\mathbf{u}_m\cdot\mathbf{v}\,d\mathbf{x} = \int_\Omega \mathbf{f}\cdot\mathbf{v}\,d\mathbf{x} + \frac{1}{\epsilon}\int_\Gamma \mathbf{g}_m\cdot\mathbf{v}\,ds \qquad \forall\,\mathbf{v}\in\mathbf{H}^1(\Omega)\,,\end{aligned} \tag{3.9}$$

$$-\int_\Omega q\operatorname{div}\mathbf{u}_m\,d\mathbf{x} = 0 \qquad \forall\,q\in L^2(\Omega)\,, \tag{3.10}$$

and

$$\lim_{m\to\infty}\mathcal{J}(\mathbf{u}_m,\mathbf{g}_m) = \inf\big\{\mathcal{J}(\mathbf{u},\mathbf{g}) : (\mathbf{u},p,\mathbf{g})\in\mathbf{H}^1(\Omega)\times L^2(\Omega)\times\mathbf{L}^2(\Gamma) \text{ and } (\mathbf{u},p,\mathbf{g}) \text{ satisfies (3.3)–(3.4)}\big\}\,.$$

The boundedness of $\{\mathcal{J}(\mathbf{u}_m, \mathbf{g}_m)\}$ implies the boundedness of $\{\|\mathbf{g}_m\|_{0,\Gamma}\}$. Then using (3.5) we see that the set $\{\|\mathbf{u}_m\|_1\}$ is also bounded independent of m (although the bound depends on ϵ, which is fixed). Hence we may extract subsequences (still denoted by $\mathbf{u}_m$ and $\mathbf{g}_m$, respectively) such that

$$\mathbf{u}_m \rightharpoonup \mathbf{u}_\epsilon \quad \text{in } \mathbf{H}^1(\Omega)\,, \qquad \text{and} \qquad \mathbf{g}_m \rightharpoonup \mathbf{g}_\epsilon \quad \text{in } \mathbf{L}^2(\Gamma)$$

for some $(\mathbf{u}_\epsilon, \mathbf{g}_\epsilon) \in \mathbf{H}^1(\Omega) \times \mathbf{L}^2(\Gamma)$, as $m \to \infty$. Compact imbedding results imply the strong convergence $\mathbf{u}_m \to \mathbf{u}_\epsilon$ in $\mathbf{L}^4(\Omega)$ as $m \to \infty$. Using standard techniques in proving the existence of a solution to the steady-state Navier–Stokes equations, we may pass to the limit in (3.9)–(3.10) as $m \to \infty$ to conclude that $\mathbf{u}_\epsilon \in \mathbf{V}$ and $(\mathbf{u}_\epsilon, \mathbf{g}_\epsilon)$ satisfies

$$\begin{aligned}\nu \int_\Omega (\nabla \mathbf{u}_\epsilon) : (\nabla \mathbf{v})\, d\mathbf{x} + \frac{1}{\epsilon}\int_\Gamma \mathbf{u}_\epsilon \cdot \mathbf{v}\, ds - \frac{1}{2}\int_\Gamma (\mathbf{u}_\epsilon \cdot \mathbf{n})\mathbf{u}_\epsilon \cdot \mathbf{v}\, ds \\ + \int_\Omega (\mathbf{u}_\epsilon \cdot \nabla)\mathbf{u}_\epsilon \cdot \mathbf{v}\, d\mathbf{x} = \int_\Omega \mathbf{f} \cdot \mathbf{v}\, d\mathbf{x} + \frac{1}{\epsilon}\int_\Gamma \mathbf{g}_\epsilon \cdot \mathbf{v}\, ds \qquad \forall\, \mathbf{v} \in \mathbf{V}\,.\end{aligned}$$

The last equations and Lemma 3.4 imply that there exists a $p_\epsilon \in L^2(\Omega)$ such that

$$\begin{aligned}\nu \int_\Omega (\nabla \mathbf{u}_\epsilon) : (\nabla \mathbf{v})\, d\mathbf{x} + \frac{1}{\epsilon}\int_\Gamma \mathbf{u}_\epsilon \cdot \mathbf{v}\, ds - \frac{1}{2}\int_\Gamma (\mathbf{u}_\epsilon \cdot \mathbf{n})\mathbf{u}_\epsilon \cdot \mathbf{v}\, ds - \int_\Omega p_\epsilon \operatorname{div} \mathbf{v}\, d\mathbf{x} \\ + \int_\Omega (\mathbf{u}_\epsilon \cdot \nabla)\mathbf{u}_\epsilon \cdot \mathbf{v}\, d\mathbf{x} = \int_\Omega \mathbf{f} \cdot \mathbf{v}\, d\mathbf{x} + \frac{1}{\epsilon}\int_\Gamma \mathbf{g}_\epsilon \cdot \mathbf{v}\, ds \qquad \forall\, \mathbf{v} \in \mathbf{H}^1(\Omega)\end{aligned} \tag{3.11}$$

and

$$\int_\Omega q \operatorname{div} \mathbf{u}_\epsilon\, d\mathbf{x} = 0 \qquad \forall\, q \in L^2(\Omega)\,; \tag{3.12}$$

i.e., $(\mathbf{u}_\epsilon, p_\epsilon, \mathbf{g}_\epsilon) \in \mathbf{H}^1(\Omega) \times L^2(\Omega) \times \mathbf{L}^2(\Gamma)$ satisfies the constraint equations (3.3)–(3.4). Finally, using the sequential weak lower semicontinuity of the functional $\mathcal{J}(\cdot,\cdot)$ we obtain

$$\begin{aligned}\mathcal{J}(\mathbf{u}_\epsilon, \mathbf{g}_\epsilon) &\le \liminf_{m\to\infty} \mathcal{J}(\mathbf{u}_m, \mathbf{g}_m) \\ &= \inf\big\{\mathcal{J}(\mathbf{u}, \mathbf{g}) : (\mathbf{u}, p, \mathbf{g}) \in \mathbf{H}^1(\Omega) \times L^2(\Omega) \times \mathbf{L}^2(\Gamma) \\ &\qquad \text{and } (\mathbf{u}, p, \mathbf{g}) \text{ satisfies (3.3)–(3.4)}\big\}\,.\end{aligned}$$

Hence, we have shown that $(\mathbf{u}_\epsilon, p_\epsilon, \mathbf{g}_\epsilon)$ is a solution for problem $(\mathrm{P})_\epsilon$. □

4. Convergence of solutions of Neumann control problems and suboptimality of the limit. Having shown the existence of a solution for $(\mathrm{P})_\epsilon$ for each ϵ, we now examine the convergence of $(\mathbf{u}_\epsilon, p_\epsilon, \mathbf{g}_\epsilon)$ as $\epsilon \to 0$.

THEOREM 4.1. *For each $\epsilon \in (0, 1/\nu)$, let $(\mathbf{u}_\epsilon, p_\epsilon, \mathbf{g}_\epsilon) \in \mathbf{H}^1(\Omega) \times L^2(\Omega) \times \mathbf{L}^2(\Gamma)$ be a solution of the optimal Neumann control problem $(\mathrm{P})_\epsilon$. Then there exists a $(\widehat{\mathbf{u}}, \widehat{p}, \widehat{\mathbf{g}}) \in \mathcal{U}_{ad}$ and a subsequence $\{\epsilon_k\}_{k=1}^\infty$ such that as $k \to \infty$,*

$$\mathbf{u}_{\epsilon_k} \rightharpoonup \widehat{\mathbf{u}} \quad \textit{in } \mathbf{H}^1(\Omega)\,, \qquad \overline{p_{\epsilon_k}} \rightharpoonup \widehat{p} \quad \textit{in } L^2_0(\Omega) \qquad \textit{and} \qquad \mathbf{g}_{\epsilon_k} \rightharpoonup \widehat{\mathbf{g}} \quad \textit{in } \mathbf{L}^2(\Gamma)\,,$$

where $\overline{p_{\epsilon_k}} = p_{\epsilon_k} - (1/|\Omega|)\int_\Omega p_{\epsilon_k}\, d\mathbf{x}$. Moreover,

$$\mathbf{u}_{\epsilon_k} \to \widehat{\mathbf{u}} \quad \textit{in } \mathbf{L}^2(\Omega)\,.$$

Proof. We first prove that the sets $\{\|\mathbf{u}_\epsilon\|_1\}$, $\{\|\overline{p_\epsilon}\|_0\}$, and $\{\|\mathbf{g}_\epsilon\|_{0,\Gamma}\}$ are all bounded independent of ϵ. Let $(\widetilde{\mathbf{u}}_\epsilon, \widetilde{p}_\epsilon)$ be the solution of (3.3)–(3.4) with $\mathbf{g} = \mathbf{0}$, i.e.,

$$\nu\int_\Omega (\nabla\widetilde{\mathbf{u}}_\epsilon) : (\nabla\mathbf{v})\,d\mathbf{x} + \frac{1}{\epsilon}\int_\Gamma \widetilde{\mathbf{u}}_\epsilon\cdot\mathbf{v}\,ds - \frac{1}{2}\int_\Gamma (\widetilde{\mathbf{u}}_\epsilon\cdot\mathbf{n})\widetilde{\mathbf{u}}_\epsilon\cdot\mathbf{v}\,ds + \int_\Omega (\widetilde{\mathbf{u}}_\epsilon\cdot\nabla)\widetilde{\mathbf{u}}_\epsilon\cdot\mathbf{v}\,d\mathbf{x} - \int_\Omega \widetilde{p}_\epsilon \operatorname{div}\mathbf{v}\,d\mathbf{x} = \int_\Omega \mathbf{f}\cdot\mathbf{v}\,d\mathbf{x} \qquad \forall\,\mathbf{v}\in\mathbf{H}^1(\Omega)$$

and

$$-\int_\Omega q\operatorname{div}\widetilde{\mathbf{u}}_\epsilon\,d\mathbf{x} = 0 \qquad \forall\, q\in L^2(\Omega)\,.$$

Lemma 3.2 gives us the estimate

$$\frac{\nu}{2}\int_\Omega |\nabla\widetilde{\mathbf{u}}_\epsilon|^2\,d\mathbf{x} + \frac{1}{4\epsilon}\int_\Gamma |\widetilde{\mathbf{u}}_\epsilon|^2\,ds \le \frac{1}{2\nu C_1}\int_\Omega |\mathbf{f}|^2\,d\mathbf{x}\,.$$

Since $(\widetilde{\mathbf{u}}_\epsilon, \widetilde{p}_\epsilon, \mathbf{0})$ is an admissible element for $(\mathrm{P})_\epsilon$, we have that

$$\mathcal{J}(\mathbf{u}_\epsilon, \mathbf{g}_\epsilon) \le \mathcal{J}(\widetilde{\mathbf{u}}_\epsilon, \mathbf{0})\,,$$

so that

$$\begin{aligned}\frac{\alpha}{2}\int_\Omega |\operatorname{curl}\mathbf{u}_\epsilon|^2\,d\mathbf{x} + \frac{\beta}{2}\int_\Gamma |\mathbf{g}_\epsilon|^2\,ds &\le \frac{\alpha}{2}\int_\Omega |\operatorname{curl}\widetilde{\mathbf{u}}_\epsilon|^2\,d\mathbf{x}\\ &\le \frac{\alpha}{2}\int_\Omega |\nabla\widetilde{\mathbf{u}}_\epsilon|^2\,d\mathbf{x} \le \frac{\alpha}{2\nu^2 C_1}\int_\Omega |\mathbf{f}|^2\,d\mathbf{x}\,,\end{aligned}$$

which implies

$$\int_\Omega |\operatorname{curl}\mathbf{u}_\epsilon|^2\,d\mathbf{x} \le \frac{1}{\nu^2 C_1}\int_\Omega |\mathbf{f}|^2\,d\mathbf{x}$$

and

$$\int_\Gamma |\mathbf{g}_\epsilon|^2\,ds \le \frac{\alpha}{\beta\nu^2 C_1}\int_\Omega |\mathbf{f}|^2\,d\mathbf{x}\,.$$

Since $(\mathbf{u}_\epsilon, p_\epsilon, \mathbf{g}_\epsilon)$ satisfies (3.3)–(3.4), we have the estimate (from Lemma 3.2)

$$\frac{\nu}{2}\int_\Omega |\nabla\mathbf{u}_\epsilon|^2\,d\mathbf{x} + \frac{1}{4\epsilon}\int_\Gamma |\mathbf{u}_\epsilon|^2\,ds \le \frac{1}{2\nu C_1}\int_\Omega |\mathbf{f}|^2\,d\mathbf{x} + \frac{1}{\epsilon}\int_\Gamma |\mathbf{g}_\epsilon|^2\,ds$$

so that

$$\int_\Gamma |\mathbf{u}_\epsilon|^2\,ds \le \frac{2\epsilon}{\nu C_1}\int_\Omega |\mathbf{f}|^2\,d\mathbf{x} + 4\int_\Gamma |\mathbf{g}_\epsilon|^2\,ds \le \frac{2+4\alpha/\beta}{\nu^2 C_1}\int_\Omega |\mathbf{f}|^2\,d\mathbf{x}\,.$$

Using Lemma 3.3 and the divergence-free condition of $\mathbf{u}_\epsilon$ we easily deduce that

$$\|\mathbf{u}_\epsilon\|_1^2 \le C_4\Big(\int_\Omega |\operatorname{curl}\mathbf{u}_\epsilon|^2\,d\mathbf{x} + \int_\Gamma |\mathbf{u}_\epsilon|^2\,ds\Big) \le \frac{C_4\big(3+4\alpha/\beta\big)}{\nu^2 C_1}\int_\Omega |\mathbf{f}|^2\,d\mathbf{x}\,.$$

Combining this last estimate with (3.6) we easily see that

$$\|\overline{p_\epsilon}\|_0 \le C_3\left(\sqrt{\frac{C_4(3+4\alpha/\beta)}{\nu C_1}}\|\mathbf{f}\|_0 + \frac{C_2C_4(3+4\alpha/\beta)}{\nu^2C_1}\|\mathbf{f}\|_0^2 + \|\mathbf{f}\|_0\right),$$

where $\overline{p_\epsilon} = p_\epsilon - (1/|\Omega|)\int_\Omega p_\epsilon\, d\mathbf{x}$. Thus we may extract a subsequence $\{\mathbf{u}_{\epsilon_k}\}$, $\{\overline{p_{\epsilon_k}}\}$, and $\{\mathbf{g}_{\epsilon_k}\}$ such that as $k \to \infty$,

$$\epsilon_k \to 0\,, \quad \mathbf{u}_{\epsilon_k} \rightharpoonup \widehat{\mathbf{u}} \quad \text{in } \mathbf{H}^1(\Omega)\,, \quad \overline{p_{\epsilon_k}} \rightharpoonup \widehat{p} \quad \text{in } L^2_0(\Omega)\,, \quad \text{and } \mathbf{g}_{\epsilon_k} \rightharpoonup \widehat{\mathbf{g}} \quad \text{in } \mathbf{L}^2(\Gamma)$$

for some $(\widehat{\mathbf{u}}, \widehat{p}, \widehat{\mathbf{g}}) \in \mathbf{H}^1(\Omega) \times L^2_0(\Omega) \times \mathbf{L}^2(\Gamma)$. Compact imbedding implies $\mathbf{u}_{\epsilon_k} \to \widehat{\mathbf{u}}$ in $\mathbf{L}^4(\Omega)$. We recall that $(\mathbf{u}_\epsilon, p_\epsilon, \mathbf{g}_\epsilon)$ satisfies equations (3.11)–(3.12). For each $\mathbf{v} \in \mathbf{H}^1_0(\Omega)$ and when $\epsilon = \epsilon_k$, equation (3.11) reduces to

$$\nu\int_\Omega \nabla\mathbf{u}_{\epsilon_k} : \nabla\mathbf{v}\, d\mathbf{x} + \int_\Omega (\mathbf{u}_{\epsilon_k}\cdot\nabla)\mathbf{u}_{\epsilon_k}\cdot\mathbf{v}\, d\mathbf{x} - \int_\Omega p_{\epsilon_k}\operatorname{div}\mathbf{v}\, d\mathbf{x} = \int_\Omega \mathbf{f}\cdot\mathbf{v}\, d\mathbf{x}\,.$$

Letting $k \to \infty$ yields

$$\nu\int_\Omega \nabla\widehat{\mathbf{u}} : \nabla\mathbf{v}\, d\mathbf{x} + \int_\Omega (\widehat{\mathbf{u}}\cdot\nabla)\widehat{\mathbf{u}}\cdot\mathbf{v}\, d\mathbf{x} - \int_\Omega \widehat{p}\operatorname{div}\mathbf{v}\, d\mathbf{x} = \int_\Omega \mathbf{f}\cdot\mathbf{v}\, d\mathbf{x} \qquad \forall\,\mathbf{v} \in \mathbf{H}^1_0(\Omega)\,.$$

Letting $k \to \infty$ in (3.12) yields

$$-\int_\Omega q\operatorname{div}\widehat{\mathbf{u}}\, d\mathbf{x} = 0 \qquad \forall\, q \in L^2_0(\Omega)\,.$$

Multiplying (3.11) (where we set $\epsilon = \epsilon_k$) by ϵ_k and letting $k \to \infty$ we obtain

$$\int_\Gamma \widehat{\mathbf{u}}\cdot\mathbf{v}\, ds = \int_\Gamma \widehat{\mathbf{g}}\cdot\mathbf{v}\, ds \qquad \forall\,\mathbf{v} \in \mathbf{H}^1(\Omega)\,,$$

which implies $\widehat{\mathbf{u}}\big|_\Gamma = \widehat{\mathbf{g}}$. This last relation and trace theorems imply $\widehat{\mathbf{g}} \in \mathbf{H}^{1/2}(\Gamma)$. Hence we have shown that $(\widehat{\mathbf{u}}, \widehat{p}, \widehat{\mathbf{g}})$ satisfies (2.7)–(2.9), i.e., that $(\widehat{\mathbf{u}}, \widehat{p}, \widehat{\mathbf{g}})$ is an admissible element for the optimal control problem (P). The strong convergence $\mathbf{u}_{\epsilon_k} \to \widehat{\mathbf{u}}$ in $\mathbf{L}^2(\Omega)$ follows from the compact imbedding $\mathbf{H}^1(\Omega) \hookrightarrow\hookrightarrow \mathbf{L}^2(\Omega)$. ∎

REMARK. *In the Neumann control problem* $(\mathrm{P})_\epsilon$ *we do not require* $\int_\Gamma \mathbf{g}_\epsilon\cdot\mathbf{n}\, ds = 0$. *However, the limit* $\widehat{\mathbf{g}}$ *automatically satisfies* $\int_\Gamma \widehat{\mathbf{g}}\cdot\mathbf{n}\, ds = 0$ *from the fact that* $\operatorname{div}\widehat{\mathbf{u}} = 0$ *and* $\widehat{\mathbf{u}}\big|_\Gamma = \widehat{\mathbf{g}}$. *The fact that* $\widehat{\mathbf{u}}\big|_\Gamma = \widehat{\mathbf{g}}$ *also implies* $\mathbf{g} \in \mathbf{H}^{1/2}(\Gamma)$, *although each* $\mathbf{g}_\epsilon$ *is merely in* $\mathbf{L}^2(\Gamma)$. ∎

We wish to show that the limit $(\widehat{\mathbf{u}}, \widehat{p}, \widehat{\mathbf{g}})$ is indeed a solution of the optimal Dirichlet control problem (P); namely, we will verify that

$$\mathcal{J}(\widehat{\mathbf{u}}, \widehat{\mathbf{g}}) \le \mathcal{J}(\mathbf{w}, \mathbf{z}) \qquad \forall\,(\mathbf{w}, r, \mathbf{z}) \in \mathcal{U}_{ad}. \tag{4.1}$$

In the remainder of this section we will prove that $(\widehat{\mathbf{u}}, \widehat{p}, \widehat{\mathbf{g}})$ is suboptimal in the sense that (4.1) is satisfied if $(\mathbf{w}, r)$ satisfies the additional condition

$$-r\mathbf{n} + \nu\frac{\partial\mathbf{w}}{\partial\mathbf{n}} \in \mathbf{L}^2(\Gamma)\,. \tag{4.2}$$

The optimality of $(\widehat{\mathbf{u}}, \widehat{p}, \widehat{\mathbf{g}})$ will be studied in the next section.

We will need the following lemma on integration by parts for functions in the space $H(\mathrm{div}\,,\Omega) \equiv \{\mathbf{v} \in \mathbf{L}^2(\Omega) : \mathrm{div}\,\mathbf{v} \in L^2(\Omega)\}$.

LEMMA 4.2. *Let* $\mathbf{w} \in H(\mathrm{div}\,,\Omega)$. *Then* $(\mathbf{w}\cdot\mathbf{n})\big|_\Gamma \in H^{-1/2}(\Gamma)$ *and*

$$\langle \mathbf{w}\cdot\mathbf{n}, v\rangle_\Gamma = \int_\Omega v\,\mathrm{div}\,\mathbf{w}\,d\mathbf{x} + \int_\Omega \mathbf{w}\cdot\nabla v\,d\mathbf{x} \qquad \forall\, v \in H^1(\Omega)\,,$$

where $\langle\cdot,\cdot\rangle_\Gamma$ *is the duality pairing between* $H^{-1/2}(\Gamma)$ *and* $H^{1/2}(\Gamma)$.

Proof. See [GR, equation (I.2.17), p. 28]. ∎

THEOREM 4.3. *Assume that* $(\widehat{\mathbf{u}},\widehat{p},\widehat{\mathbf{g}}) \in \mathcal{U}_{ad}$ *is the limit defined in Theorem* 4.1. *Then*

$$\mathcal{J}(\widehat{\mathbf{u}},\widehat{\mathbf{g}}) \le \mathcal{J}(\mathbf{w},\mathbf{z}) \qquad \forall\,(\mathbf{w},r,\mathbf{z}) \in \mathcal{U}_{ad} \text{ satisfying } (4.2).$$

Proof. Let $(\mathbf{w},r,\mathbf{z})$ be an arbitrary element in $\mathcal{U}_{ad}$ satisfying (4.2). By the definition of $\mathcal{U}_{ad}$, $(\mathbf{w},r,\mathbf{z})$ is a solution of

$$-\nu\Delta\mathbf{w} + (\mathbf{w}\cdot\nabla)\mathbf{w} + \nabla r = \mathbf{f} \qquad \text{in } \Omega\,, \tag{4.3}$$

$$\mathrm{div}\,\mathbf{w} = 0 \qquad \text{in } \Omega, \tag{4.4}$$

and

$$\mathbf{w}\big|_\Gamma = \mathbf{z}\,. \tag{4.5}$$

From (4.2) and the regularity results for the Navier–Stokes equations we obtain $(\mathbf{w},r) \in \mathbf{H}^{3/2}(\Omega)\times H^{1/2}(\Omega)$ and $-r\mathbf{n} + \nu\frac{\partial\mathbf{w}}{\partial\mathbf{n}} \in \mathbf{L}^2(\Gamma)$. Using (4.3) and the imbedding results for Sobolev spaces we obtain

$$\mathrm{div}\,\big(-rI + \nu\nabla\mathbf{w}\big) = \nu\Delta\mathbf{w} - \nabla r = -\mathbf{f} + (\mathbf{w}\cdot\nabla)\mathbf{w} \in \mathbf{L}^2(\Omega)\,.$$

By the integration-by-parts formula (Lemma 4.2) we have

$$\begin{aligned}\int_\Gamma [(-rI+\nu\nabla\mathbf{w})\cdot\mathbf{n}]\cdot\mathbf{v}\,ds &= \int_\Omega [-\nabla r + \nu\Delta\mathbf{w}]\cdot\mathbf{v}\,d\mathbf{x} + \int_\Omega [-rI+\nu\nabla\mathbf{w}] : \nabla\mathbf{v}\,d\mathbf{x}\\ &= \int_\Omega [-\mathbf{f} + (\mathbf{w}\cdot\nabla)\mathbf{w}]\cdot\mathbf{v}\,d\mathbf{x} - \int_\Omega r\,\mathrm{div}\,\mathbf{v}\,d\mathbf{x} + \nu\int_\Omega \nabla\mathbf{w} : \nabla\mathbf{v}\,d\mathbf{x},\end{aligned}$$

so that using (4.5) and adding/subtracting terms, we are led to

$$\begin{aligned}\nu\int_\Omega \nabla\mathbf{w} : \nabla\mathbf{v}\,d\mathbf{x} + \frac{1}{\epsilon}\int_\Gamma \mathbf{w}\cdot\mathbf{v}\,ds - \frac{1}{2}\int_\Gamma (\mathbf{w}\cdot\mathbf{n})\mathbf{w}\cdot\mathbf{v}\,ds + \int_\Omega (\mathbf{w}\cdot\nabla)\mathbf{w}\cdot\mathbf{v}\,d\mathbf{x}\\ - \int_\Omega r\,\mathrm{div}\,\mathbf{v}\,d\mathbf{x} = \int_\Omega \mathbf{f}\cdot\mathbf{v}\,d\mathbf{x} + \frac{1}{\epsilon}\int_\Gamma \mathbf{z}_\epsilon\cdot\mathbf{v}\,ds \qquad \forall\,\mathbf{v}\in\mathbf{H}^1(\Omega)\end{aligned}$$

where

$$\mathbf{z}_\epsilon \equiv \mathbf{z} + \epsilon\Big(-r\mathbf{n} + \nu\frac{\partial\mathbf{w}}{\partial\mathbf{n}}\Big) - \frac{\epsilon}{2}(\mathbf{w}\cdot\mathbf{n})\mathbf{w} \in \mathbf{L}^2(\Gamma)\,.$$

Thus, $(\mathbf{w},r,\mathbf{z}_\epsilon)$ is an admissible element for $(\mathrm{P})_\epsilon$, so that

$$\mathcal{J}(\mathbf{w},\mathbf{z}_\epsilon) \ge \mathcal{J}(\mathbf{u}_\epsilon,\mathbf{g}_\epsilon)\,.$$

Combining the last inequality with

$$\begin{aligned}\mathcal{J}(\mathbf{w},\mathbf{z}_\epsilon) &\equiv \frac{\alpha}{2}\int_\Omega |\operatorname{curl}\mathbf{w}|^2\,d\mathbf{x} + \frac{\beta}{2}\int_\Gamma \Big|\mathbf{z} - \epsilon r\mathbf{n} + \epsilon\nu\frac{\partial\mathbf{w}}{\partial\mathbf{n}} - \frac{\epsilon}{2}(\mathbf{w}\cdot\mathbf{n})\mathbf{w}\Big|^2\,ds \\ &= \mathcal{J}(\mathbf{w},\mathbf{z}) + \frac{\epsilon^2\beta}{2}\int_\Gamma \Big|-r\mathbf{n} + \nu\frac{\partial\mathbf{w}}{\partial\mathbf{n}} - \frac{1}{2}(\mathbf{w}\cdot\mathbf{n})\mathbf{w}\Big|^2\,ds \\ &\quad + \epsilon\beta\int_\Gamma \mathbf{z}\cdot\Big(-r\mathbf{n} + \nu\frac{\partial\mathbf{w}}{\partial\mathbf{n}} - \frac{1}{2}(\mathbf{w}\cdot\mathbf{n})\mathbf{w}\Big)\,ds,\end{aligned}$$

we obtain

$$\begin{aligned}\mathcal{J}(\mathbf{w},\mathbf{z}) \geq \mathcal{J}(\mathbf{u}_\epsilon,\mathbf{g}_\epsilon) &- \frac{\epsilon^2\beta}{2}\int_\Gamma \Big|-r\mathbf{n} + \nu\frac{\partial\mathbf{w}}{\partial\mathbf{n}} - \frac{1}{2}(\mathbf{w}\cdot\mathbf{n})\mathbf{w}\Big|^2\,ds \\ &- \epsilon\beta\int_\Gamma \mathbf{z}\cdot\Big(-r\mathbf{n} + \nu\frac{\partial\mathbf{v}}{\partial\mathbf{n}} - \frac{1}{2}(\mathbf{w}\cdot\mathbf{n})\mathbf{w}\Big)\,ds\,.\end{aligned}$$

Setting $\epsilon = \epsilon_k$ in the above relation (where ϵ_k is as defined in Theorem 4.1) and letting $k \to \infty$ we obtain

$$\mathcal{J}(\mathbf{w},\mathbf{z}) \geq \liminf_{k\to\infty} \mathcal{J}(\mathbf{u}_{\epsilon_k},\mathbf{g}_{\epsilon_k}) \geq \mathcal{J}(\widehat{\mathbf{u}},\widehat{\mathbf{g}})\,. \qquad \square$$

5. Optimality of the limit. In this section we will show that under certain restrictions on the data ν, $\mathbf{f}$, etc., the limit $(\widehat{\mathbf{u}},\widehat{p},\widehat{\mathbf{g}})$ defined in Theorem 4.1 is indeed a solution of the optimal Dirichlet control problem (P).

LEMMA 5.1. *Assume that* $(\widehat{\mathbf{u}},\widehat{p},\widehat{\mathbf{g}})$ *is the limit defined in Theorem* 4.1. *Then*

$$\mathcal{J}(\widehat{\mathbf{u}},\widehat{\mathbf{g}}) \leq \frac{\alpha}{2\nu^2 C_1}\int_\Omega |\mathbf{f}|^2\,d\mathbf{x}$$

Proof. Let $(\mathbf{u}_0,p_0) \in \mathbf{H}^1(\Omega)\times L^2(\Omega)$ be the solution of the Navier–Stokes equations (2.7)–(2.9) with the zero Dirichlet condition. Then $(\mathbf{u}_0,p_0,\mathbf{0}) \in \mathcal{U}_{ad}$. Lemma 3.2 gives us the estimate

$$\frac{\nu}{2}\int_\Omega |\nabla\mathbf{u}_0|^2\,d\mathbf{x} \leq \frac{1}{2\nu C_1}\int_\Omega |\mathbf{f}|^2\,d\mathbf{x}\,.$$

The regularity theory for the Navier–Stokes equations implies $(\mathbf{u}_0,p_0) \in \mathbf{H}^2(\Omega)\times H^1(\Omega)$ so that $-p_0\mathbf{n} + \nu\frac{\partial\mathbf{u}_0}{\partial\mathbf{n}} \in \mathbf{L}^2(\Gamma)$. Hence by Theorem 4.3,

$$\mathcal{J}(\widehat{\mathbf{u}},\widehat{\mathbf{g}}) \leq \mathcal{J}(\mathbf{u}_0,\mathbf{0}) = \frac{\alpha}{2}\int_\Omega |\operatorname{curl}\mathbf{u}_0|^2\,d\mathbf{x} \leq \frac{\alpha}{2}\int_\Omega |\nabla\mathbf{u}_0|^2\,d\mathbf{x} \leq \frac{\alpha}{2\nu^2 C_1}\int_\Omega |\mathbf{f}|^2\,d\mathbf{x}\,. \qquad \square$$

LEMMA 5.2. *Define* $\mathbf{H}_n^{1/2}(\Gamma) \equiv \big\{\mathbf{z}\in\mathbf{H}^{1/2}(\Gamma) : \int_\Gamma \mathbf{z}\cdot\mathbf{n}\,ds = 0\big\}$. *Then there exist a constant* $C_5 > 0$ *(depending on* Ω *only) and an extension operator* $E : \mathbf{H}_n^{1/2}(\Gamma) \to \mathbf{V}$ *such that* $\|E\mathbf{z}\|_1 \leq C_5\|\mathbf{z}\|_{1/2,\Gamma}$ *for every* $\mathbf{z}\in\mathbf{H}_n^{1/2}(\Gamma)$.

Proof. For each $\mathbf{z}\in\mathbf{H}_n^{1/2}(\Gamma)$ we define $\mathbf{w} = E\mathbf{z} \in \mathbf{V}$ as the unique solution of the Stokes problem

$$-\Delta\mathbf{w} + \nabla r = \mathbf{0} \qquad \text{in } \Omega\,,$$

$$\operatorname{div}\mathbf{w} = 0 \qquad \text{in } \Omega,$$

and

$$\mathbf{w}\big|_{\Gamma} = \mathbf{z}\,.$$

Clearly E maps $\mathbf{H}_n^{1/2}(\Gamma)$ into $\mathbf{V}$ linearly. The estimate $\|E\mathbf{z}\|_1 = \|\mathbf{w}\|_1 \le C_5\|\mathbf{z}\|_{1/2,\Gamma}$ follows from the estimates for Dirichlet boundary value problems for the steady-state Stokes equations (see [Te]). ∎

LEMMA 5.3. *Assume that* $(\mathbf{w}, r, \mathbf{z}) \in \mathbf{H}^1(\Omega) \times L_0^2(\Omega) \times \mathbf{H}_n^{1/2}(\Gamma)$ *and* $(\widetilde{\mathbf{w}}, \widetilde{r}, \widetilde{\mathbf{z}}) \in \mathbf{H}^1(\Omega) \times L_0^2(\Omega) \times \mathbf{H}_n^{1/2}(\Gamma)$ *satisfy, respectively,*

$$\begin{cases} -\nu\Delta\mathbf{w} + (\mathbf{w}\cdot\nabla)\mathbf{w} + \nabla r = \mathbf{f} & \text{in } \Omega\,, \\ \operatorname{div}\mathbf{w} = 0 & \text{in } \Omega, \\ \mathbf{w} = \mathbf{z} & \text{on } \Gamma, \end{cases}$$

and

$$\begin{cases} -\nu\Delta\widetilde{\mathbf{w}} + (\widetilde{\mathbf{w}}\cdot\nabla)\widetilde{\mathbf{w}} + \nabla\widetilde{r} = \mathbf{f} & \text{in } \Omega \\ \operatorname{div}\widetilde{\mathbf{w}} = 0 & \text{in } \Omega, \\ \widetilde{\mathbf{w}} = \widetilde{\mathbf{z}} & \text{on } \Gamma\,. \end{cases}$$

Assume further that $\|\mathbf{w}\|_1 < \frac{\nu C_0}{4C_2}$ *and* $\|\mathbf{z} - \widetilde{\mathbf{z}}\|_{1/2,\Gamma} \le \frac{\nu C_0}{4C_2C_5}$. *Then*

$$\|\widetilde{\mathbf{w}} - \mathbf{w}\|_1 \le \Big(\frac{4C_5}{C_0} + \sqrt{2}C_5 + C_5\Big)\|\widetilde{\mathbf{z}} - \mathbf{z}\|_{1/2,\Gamma} + \frac{4C_2C_5^2}{\nu C_0}\|\widetilde{\mathbf{z}} - \mathbf{z}\|_{1/2,\Gamma}^2\,.$$

Proof. Set $\boldsymbol{\xi} = \widetilde{\mathbf{w}} - \mathbf{w}$ and $\sigma = \widetilde{r} - r$. Then, by subtracting the relevant equations for $(\widetilde{\mathbf{w}}, \widetilde{r})$ and $(\mathbf{w}, r)$, we see that $(\boldsymbol{\xi}, \sigma) \in \mathbf{H}^1(\Omega) \times L_0^2(\Omega)$ satisfies

$$-\nu\Delta\boldsymbol{\xi} + (\boldsymbol{\xi}\cdot\nabla)\mathbf{w} + (\mathbf{w}\cdot\nabla)\boldsymbol{\xi} + (\boldsymbol{\xi}\cdot\nabla)\boldsymbol{\xi} + \nabla\sigma = \mathbf{0} \qquad \text{in } \Omega\,,$$

$$\operatorname{div}\boldsymbol{\xi} = 0 \qquad \text{in } \Omega,$$

and

$$\boldsymbol{\xi} = \widetilde{\mathbf{z}} - \mathbf{z} \qquad \text{on } \Gamma\,.$$

Put $\boldsymbol{\eta} = E(\widetilde{\mathbf{z}} - \mathbf{z})$, where E is the extension operator defined in Lemma 5.2. Then $\boldsymbol{\eta} \in \mathbf{H}^1(\Omega)$, $\boldsymbol{\eta}\big|_{\Gamma} = \widetilde{\mathbf{z}} - \mathbf{z}$, and $\|\boldsymbol{\eta}\|_1 \le C_5\|\widetilde{\mathbf{z}} - \mathbf{z}\|_{1/2,\Gamma}$. Setting $\boldsymbol{\zeta} = \boldsymbol{\xi} - \boldsymbol{\eta}$ we see that

$$\begin{aligned} -\nu\Delta\boldsymbol{\zeta} + (\boldsymbol{\zeta}\cdot\nabla)\mathbf{w} + (\boldsymbol{\eta}\cdot\nabla)\mathbf{w} + (\mathbf{w}\cdot\nabla)\boldsymbol{\zeta} + (\mathbf{w}\cdot\nabla)\boldsymbol{\eta} + (\boldsymbol{\eta}\cdot\nabla)\boldsymbol{\zeta} \\ + (\boldsymbol{\zeta}\cdot\nabla)\boldsymbol{\eta} + (\boldsymbol{\eta}\cdot\nabla)\boldsymbol{\eta} + (\boldsymbol{\zeta}\cdot\nabla)\boldsymbol{\zeta} + \nabla\sigma = \nu\Delta\boldsymbol{\eta} \qquad \text{in } \Omega\,, \end{aligned}$$

$$\operatorname{div}\boldsymbol{\zeta} = 0 \qquad \text{in } \Omega,$$

and

$$\boldsymbol{\zeta} = \mathbf{0} \qquad \text{on } \Gamma\,.$$

Using the weak form of these equations (see Definition 2.1) and the fact that $c(\mathbf{u}, \mathbf{v}, \mathbf{v}) = 0$ for all $\mathbf{v} \in \mathbf{H}_0^1(\Omega)$ and all $\mathbf{u} \in \mathbf{V}$, we obtain

$$\nu\|\nabla\boldsymbol{\zeta}\|_0^2 + c(\boldsymbol{\zeta}, \mathbf{w}, \boldsymbol{\zeta}) + c(\boldsymbol{\eta}, \mathbf{w}, \boldsymbol{\zeta}) + c(\mathbf{w}, \boldsymbol{\eta}, \boldsymbol{\zeta}) + c(\boldsymbol{\zeta}, \boldsymbol{\eta}, \boldsymbol{\zeta}) + c(\boldsymbol{\eta}, \boldsymbol{\eta}, \boldsymbol{\zeta}) = -\nu\int_{\Omega} (\nabla\boldsymbol{\eta}) : (\nabla\boldsymbol{\zeta})\, d\mathbf{x}$$

so that using inequalities (2.1), (2.3), and $rs \le \delta r^2 + \frac{1}{4\delta}s^2$, we are led to (for any $\delta > 0$)

$$\big(\nu C_0 - C_2\|\mathbf{w}\|_1 - C_2\|\boldsymbol{\eta}\|_1 - 3\delta\big)\|\boldsymbol{\zeta}\|_1^2 - \frac{C_2^2}{4\delta}\big(2\|\boldsymbol{\eta}\|_1^2\,\|\mathbf{w}\|_1^2 + \|\boldsymbol{\eta}\|_1^4\big) \le \frac{\nu^2}{4\delta}\|\nabla\boldsymbol{\eta}\|_0^2 + \delta\|\boldsymbol{\zeta}\|_1^2\,.$$

Choosing $\delta = \frac{\nu C_0}{16}$ and noting that $C_2\|\boldsymbol{\eta}\|_1 \le C_2C_5\|\widetilde{\mathbf{z}} - \mathbf{z}\|_{1/2,\Gamma} \le \frac{\nu C_0}{4}$, we obtain

$$\frac{\nu C_0}{4}\|\boldsymbol{\zeta}\|_1^2 \le \frac{\nu^2C_5^2}{4\delta}\|\widetilde{\mathbf{z}} - \mathbf{z}\|_{1/2,\Gamma}^2 + \frac{2C_2^2C_5^2}{4\delta}\Big(\frac{\nu C_0}{4C_2}\Big)^2\|\widetilde{\mathbf{z}} - \mathbf{z}\|_{1/2,\Gamma}^2 + \frac{C_2^2C_5^4}{4\delta}\|\widetilde{\mathbf{z}} - \mathbf{z}\|_{1/2,\Gamma}^4\,,$$

so that

$$\|\boldsymbol{\zeta}\|_1^2 \le \Big(\frac{16C_5^2}{C_0^2} + 2C_5^2\Big)\|\widetilde{\mathbf{z}} - \mathbf{z}\|_{1/2,\Gamma}^2 + \frac{16C_2^2C_5^4}{\nu^2C_0^2}\|\widetilde{\mathbf{z}} - \mathbf{z}\|_{1/2,\Gamma}^4\,.$$

Hence, using the inequality $(r^2 + s^2) \le (r + s)^2$ we are led to

$$\|\boldsymbol{\zeta}\|_1 \le \Big(\frac{4C_5}{C_0} + \sqrt{2}C_5\Big)\|\widetilde{\mathbf{z}} - \mathbf{z}\|_{1/2,\Gamma} + \frac{4C_2C_5^2}{\nu C_0}\|\widetilde{\mathbf{z}} - \mathbf{z}\|_{1/2,\Gamma}^2\,.$$

Finally, we use the triangle inequality to derive the estimate for $\boldsymbol{\xi}$:

$$\|\boldsymbol{\xi}\|_1 \le \|\boldsymbol{\eta}\|_1 + \|\boldsymbol{\zeta}\|_1 \le \Big(\frac{4C_5}{C_0} + \sqrt{2}C_5 + C_5\Big)\|\widetilde{\mathbf{z}} - \mathbf{z}\|_{1/2,\Gamma} + \frac{4C_2C_5^2}{\nu C_0}\|\widetilde{\mathbf{z}} - \mathbf{z}\|_{1/2,\Gamma}^2\,. \qquad \square$$

THEOREM 5.4. *Assume that*

$$\frac{\|\mathbf{f}\|_0}{\nu^2}\sqrt{\frac{\alpha}{\min\{\alpha,\beta\}}} < \frac{1}{4}\,\frac{C_0}{C_2}\sqrt{\frac{C_1}{C_4}} \tag{5.1}$$

and let $(\widehat{\mathbf{u}}, \widehat{p}, \widehat{\mathbf{g}})$ *be the limit defined in Theorem* 4.1. *Then* $(\widehat{\mathbf{u}}, \widehat{p}, \widehat{\mathbf{g}})$ *is a solution of the optimal Dirichlet control problem* (P).

Proof. Let $(\mathbf{w}, r, \mathbf{z}) \in \mathcal{U}_{ad}$ be given. We need to prove that $\mathcal{J}(\widehat{\mathbf{u}}, \widehat{\mathbf{g}}) \le \mathcal{J}(\mathbf{w}, \mathbf{z})$. Using Lemma 3.3 and the facts that $\operatorname{div}\mathbf{w} = 0$ and $\mathbf{w}\big|_\Gamma = \mathbf{z}$, we obtain

$$\mathcal{J}(\mathbf{w}, \mathbf{z}) \ge \frac{1}{2C_4}\min\{\alpha,\beta\}\|\mathbf{w}\|_1^2\,.$$

Hence, if $\frac{1}{2C_4}\min\{\alpha,\beta\}\|\mathbf{w}\|_1^2 > \mathcal{J}(\widehat{\mathbf{u}}, \widehat{\mathbf{g}})$, then $\mathcal{J}(\mathbf{w}, \mathbf{z}) > \mathcal{J}(\widehat{\mathbf{u}}, \widehat{\mathbf{g}})$. So we only need to consider the case where

$$\frac{1}{2C_4}\min\{\alpha,\beta\}\|\mathbf{w}\|_1^2 \le \mathcal{J}(\widehat{\mathbf{u}}, \widehat{\mathbf{g}})\,. \tag{5.2}$$

We assume (5.2) holds. Then using (5.1)–(5.2) and Lemma 5.1 we obtain

$$\begin{aligned}\|\mathbf{w}\|_1 \le \Big\{\frac{2C_4}{\min\{\alpha,\beta\}}\mathcal{J}(\widehat{\mathbf{u}}, \widehat{\mathbf{g}})\Big\}^{1/2} &\le \Big\{\frac{2C_4}{\min\{\alpha,\beta\}}\,\frac{\alpha}{2\nu^2C_1}\int_\Omega |\mathbf{f}|^2\,d\mathbf{x}\Big\}^{1/2}\\ &\le \Big\{\frac{2\alpha C_4}{\nu^2C_1\min\{\alpha,\beta\}}\Big\}^{1/2}\|\mathbf{f}\|_0 \le \frac{\nu C_0}{4C_2}\,.\end{aligned}$$

Using the denseness of $\mathbf{C}^\infty(\Gamma)\cap\mathbf{H}_n^{1/2}(\Gamma)$ in $\mathbf{H}_n^{1/2}(\Gamma)$ we may choose a sequence $\{\mathbf{z}_m\} \subset \mathbf{C}^\infty(\Gamma) \cap \mathbf{H}_n^{1/2}(\Gamma)$ such that $\|\mathbf{z}_m - \mathbf{z}\|_{1/2,\Gamma} \to 0$ as $m \to \infty$. For sufficiently large m, we have

$$\|\mathbf{z}_m - \mathbf{z}\|_{1/2,\Gamma} < \frac{\nu C_0}{4C_2C_5}\,.$$

Let $(\mathbf{w}_m, r_m) \in \mathbf{H}^1(\Omega) \times L_0^2(\Omega)$ be the solution of (2.7)–(2.8) with the Dirichlet condition $\mathbf{w}_m\big|_\Gamma = \mathbf{z}_m$. Using Lemma 5.3 we obtain $\|\mathbf{w}_m - \mathbf{w}\|_1 \to 0$ as $m \to \infty$. The regularity theories for the Navier–Stokes equations imply $(\mathbf{w}_m, r_m) \in \mathbf{H}^{3/2}(\Omega) \times H^{1/2}(\Omega)$ and $-r_m\mathbf{n} + \nu\frac{\partial \mathbf{w}_m}{\partial \mathbf{n}} \in \mathbf{L}^2(\Gamma)$. From Theorem 4.3 we obtain $\mathcal{J}(\mathbf{w}_m, \mathbf{z}_m) \geq \mathcal{J}(\widehat{\mathbf{u}}, \widehat{\mathbf{g}})$. Upon letting $m \to \infty$ we conclude that

$$\mathcal{J}(\mathbf{w}, \mathbf{z}) = \lim_{m\to\infty} \mathcal{J}(\mathbf{w}_m, \mathbf{z}_m) \geq \mathcal{J}(\widehat{\mathbf{u}}, \widehat{\mathbf{g}})\,. \qquad \square$$

REMARK. *Combining Theorems* 4.1 *and* 5.4 *we see that if the solution for* (P) *is unique, then we have the convergence as* $\epsilon \to 0$ *(instead of merely a subsequence convergence):*

$$\mathbf{u}_\epsilon \rightharpoonup \widehat{\mathbf{u}}\,, \quad \overline{p_\epsilon} \rightharpoonup \widehat{p}\,, \quad \textit{and } \mathbf{g}_\epsilon \rightharpoonup \widehat{\mathbf{g}}\,. \qquad \square$$

REMARK. *The small data requirement* (5.1) *is due to the small data requirements in Lemma* 5.3. *On the other hand, the small data requirements in Lemma* 5.3 *are those that are needed in order to show the continuous dependence of solutions on Dirichlet data for the Navier–Stokes equations. It is well known that the Navier–Stokes equations do not always have a unique solution; thus it seems hopeless to prove, without the small data requirement, the continuous dependence on Dirichlet data of solutions of the Navier–Stokes equations. This in turn suggests that it seems hopeless to prove Theorem* 5.4 *for arbitrary data. But for most practical purposes, one should be content with the suboptimal result of Theorem* 4.3 (*which does not require the smallness of data*). $\square$

6. Finite element approximations and numerical results. We have shown that the optimal solutions of Neumann control problems $(\mathrm{P})_\epsilon$ converge to an optimal solution of the Dirichlet control problem (P). Thus, we may choose a sufficiently small ϵ and solve $(\mathrm{P})_\epsilon$ to obtain an approximate solution for (P). In this section we briefly describe the solution procedures for $(\mathrm{P})_\epsilon$ with a fixed ϵ and present some numerical results. The purpose of this section is merely to confirm numerically the convergence of the optimal Neumann boundary control solutions which we have proven rigorously. Thus the presentation of this section is mostly formal.

The solution procedures for $(\mathrm{P})_\epsilon$ are as follows. First, by introducing the Lagrangian for $(\mathrm{P})_\epsilon$,

$$\begin{aligned}\mathcal{L}(\mathbf{u}, p, \mathbf{g}, \boldsymbol{\mu}, \rho) = \mathcal{J}(\mathbf{u}, \mathbf{g}) - \Big(\nu\, a(\mathbf{u}, \boldsymbol{\mu}) + \frac{1}{\epsilon}\int_\Gamma \mathbf{u}\cdot\boldsymbol{\mu}\, ds - \frac{1}{2}\int_\Gamma (\mathbf{u}\cdot\mathbf{n})\mathbf{u}\cdot\boldsymbol{\mu}\, ds \\ + c(\mathbf{u}, \mathbf{u}, \boldsymbol{\mu}) + b(\boldsymbol{\mu}, p) + b(\mathbf{u}, \rho) - \int_\Omega \mathbf{f}\cdot\boldsymbol{\mu}\, d\mathbf{x} - \frac{1}{\epsilon}\int_\Gamma \mathbf{g}\cdot\boldsymbol{\mu}\, ds\Big),\end{aligned}$$

and differentiating the Lagrangian with respect to each of its arguments we obtain the following optimality system of equations that the optimal solution for $(\mathrm{P})_\epsilon$ must satisfy:

$$\begin{aligned}\nu\int_\Omega (\nabla\mathbf{u}) : (\nabla\mathbf{v})\, d\mathbf{x} + \frac{1}{\epsilon}\int_\Gamma \mathbf{u}\cdot\mathbf{v}\, ds - \frac{1}{2}\int_\Gamma (\mathbf{u}\cdot\mathbf{n})\mathbf{u}\cdot\mathbf{v}\, ds + \int_\Omega (\mathbf{u}\cdot\nabla)\mathbf{u}\cdot\mathbf{v}\, d\mathbf{x} \\ -\int_\Omega p\,\mathrm{div}\,\mathbf{v}\, d\mathbf{x} = \int_\Omega \mathbf{f}\cdot\mathbf{v}\, d\mathbf{x} + \frac{1}{\epsilon}\int_\Gamma \mathbf{g}\cdot\mathbf{v}\, ds \qquad \forall\, \mathbf{v} \in \mathbf{H}^1(\Omega)\,,\end{aligned} \tag{6.1}$$

$$-\int_\Omega q\,\mathrm{div}\,\mathbf{u}\, d\mathbf{x} = 0 \qquad \forall\, q \in L^2(\Omega)\,, \tag{6.2}$$

$$\begin{aligned}
&\nu\int_\Omega(\nabla\boldsymbol{\mu}):(\nabla\mathbf{w})\,d\mathbf{x}+\frac{1}{\epsilon}\int_\Gamma\boldsymbol{\mu}\cdot\mathbf{w}\,ds-\frac{1}{2}\int_\Gamma(\mathbf{w}\cdot\mathbf{n})\mathbf{u}\cdot\boldsymbol{\mu}\,ds\\
&\quad-\frac{1}{2}\int_\Gamma(\mathbf{u}\cdot\mathbf{n})\mathbf{w}\cdot\boldsymbol{\mu}\,ds+\int_\Omega(\mathbf{u}\cdot\nabla)\mathbf{w}\cdot\boldsymbol{\mu}\,d\mathbf{x}+\int_\Omega(\mathbf{w}\cdot\nabla)\mathbf{u}\cdot\boldsymbol{\mu}\,d\mathbf{x}\\
&\quad-\int_\Omega\rho\,\mathrm{div}\,\mathbf{w}\,d\mathbf{x}=\int_\Omega(\mathrm{curl}\,\mathbf{u})\cdot(\mathrm{curl}\,\mathbf{w})\,d\mathbf{x}\qquad\forall\,\mathbf{w}\in\mathbf{H}^1(\Omega)\,,
\end{aligned}\tag{6.3}$$

$$-\int_\Omega r\,\mathrm{div}\,\boldsymbol{\mu}\,d\mathbf{x}=0\qquad\forall\,r\in L^2(\Omega),\tag{6.4}$$

and

$$\int_\Gamma\Big(\beta\mathbf{g}+\frac{1}{\epsilon}\boldsymbol{\mu}\Big)\cdot\mathbf{z}\,ds=0\qquad\forall\,\mathbf{z}\in\mathbf{L}^2(\Gamma)\,.$$

Note that we may use the last relation to eliminate $\mathbf{g}$ in (6.1) to obtain

$$\begin{aligned}
&\nu\int_\Omega\nabla\mathbf{u}:\nabla\mathbf{v}\,d\mathbf{x}+\frac{1}{\epsilon}\int_\Gamma\mathbf{u}\cdot\mathbf{v}\,ds-\frac{1}{2}\int_\Gamma(\mathbf{u}\cdot\mathbf{n})\mathbf{u}\cdot\mathbf{v}\,ds+\int_\Omega(\mathbf{u}\cdot\nabla)\mathbf{u}\cdot\mathbf{v}\,d\mathbf{x}\\
&\quad-\int_\Omega p\,\mathrm{div}\,\mathbf{v}\,d\mathbf{x}=\int_\Omega\mathbf{f}\cdot\mathbf{v}\,d\mathbf{x}-\frac{1}{\epsilon^2\beta}\int_\Gamma\boldsymbol{\mu}\cdot\mathbf{v}\,ds\qquad\forall\,\mathbf{v}\in\mathbf{H}^1(\Omega).
\end{aligned}\tag{6.5}$$

The system formed by (6.2)–(6.5) will be called *an optimality system of equations.*

Next we choose finite element subspaces and define finite element approximations of the optimality system. The finite element spaces $\mathbf{X}_h\subset\mathbf{H}^1(\Omega)$ and $S_h\subset L^2(\Omega)$ are chosen such that

$$\inf_{\mathbf{v}_h\in\mathbf{X}_h}\|\mathbf{v}_h-\mathbf{v}\|_1\le Ch^m\|\mathbf{v}\|_{m+1}\qquad\forall\,\mathbf{v}\in\mathbf{H}^{m+1}(\Omega)\,,$$

$$\inf_{q_h\in S_h}\|q_h-q\|_1\le Ch^m\|q\|_m\qquad\forall\,q\in H^m(\Omega)\,,$$

and

$$\inf_{q_h\in S_h}\sup_{\mathbf{v}_h\in\mathbf{X}_h}\frac{b(\mathbf{v}_h,q_h)}{\|\mathbf{v}_h\|_1\|q_h\|_0}\ge C_6\,.$$

The last discrete inf-sup condition is needed in finite element approximations of the Navier–Stokes equations (see, e.g., [GR]) and naturally is also needed in the approximations of the optimality system of equations. We define finite element approximations of the optimality system (6.2)–(6.5) as follows:

$$\begin{aligned}
&\nu\int_\Omega\nabla\mathbf{u}_h:\nabla\mathbf{v}_h\,d\mathbf{x}+\frac{1}{\epsilon}\int_\Gamma\mathbf{u}_h\cdot\mathbf{v}_h\,ds-\frac{1}{2}\int_\Gamma(\mathbf{u}_h\cdot\mathbf{n})\mathbf{u}_h\cdot\mathbf{v}_h\,ds-\int_\Omega p_h\,\mathrm{div}\,\mathbf{v}_h\,d\mathbf{x}\\
&\quad+\int_\Omega(\mathbf{u}_h\cdot\nabla)\mathbf{u}_h\cdot\mathbf{v}_h\,d\mathbf{x}=\int_\Omega\mathbf{f}\cdot\mathbf{v}_h\,d\mathbf{x}-\frac{1}{\epsilon^2\beta}\int_\Gamma\boldsymbol{\mu}_h\cdot\mathbf{v}_h\,ds\qquad\forall\,\mathbf{v}_h\in\mathbf{X}_h\,,
\end{aligned}\tag{6.6}$$

$$-\int_\Omega q_h\,\mathrm{div}\,\mathbf{u}_h\,d\mathbf{x}=0\qquad\forall\,q_h\in S_h\,,\tag{6.7}$$

$$\begin{aligned}
&\nu\int_\Omega(\nabla\boldsymbol{\mu}_h):(\nabla\mathbf{w}_h)\,d\mathbf{x}+\frac{1}{\epsilon}\int_\Gamma\boldsymbol{\mu}_h\cdot\mathbf{w}_h\,ds-\frac{1}{2}\int_\Gamma(\mathbf{w}_h\cdot\mathbf{n})\mathbf{u}_h\cdot\boldsymbol{\mu}_h\,ds\\
&\quad-\frac{1}{2}\int_\Gamma(\mathbf{u}_h\cdot\mathbf{n})\mathbf{w}_h\cdot\boldsymbol{\mu}_h\,ds+\int_\Omega(\mathbf{u}_h\cdot\nabla)\mathbf{w}_h\cdot\boldsymbol{\mu}_h\,d\mathbf{x}-\int_\Omega\rho_h\,\mathrm{div}\,\mathbf{w}_h\,d\mathbf{x}\\
&\quad+\int_\Omega(\mathbf{w}_h\cdot\nabla)\mathbf{u}_h\cdot\boldsymbol{\mu}_h\,d\mathbf{x}=\int_\Omega(\mathrm{curl}\,\mathbf{u}_h)\cdot(\mathrm{curl}\,\mathbf{w}_h)\,d\mathbf{x}\qquad\forall\,\mathbf{w}_h\in\mathbf{X}_h,
\end{aligned}\tag{6.8}$$

TABLE 1
$\mathbf{L}^2(\Omega)$ *errors of each two consecutive optimal solutions.*

i	1	2	3	4	5	6	7	8
ϵ_i	10	1	10^{-1}	10^{-2}	10^{-3}	10^{-4}	10^{-5}	10^{-6}
$\left\|\mathbf{u}_i - \mathbf{u}_{i+1}\right\|_2^2$	.3553	.04725	.01763	.002506	.0002618	.00002627	.000009	

and

$$-\int_\Omega r_h \operatorname{div} \boldsymbol{\mu}_h \, d\mathbf{x} = 0 \qquad \forall\, r_h \in S_h\,. \tag{6.9}$$

We solve the discrete, nonlinear system of equations (6.6)–(6.9) by Newton's method with the initial guess obtained from solving the corresponding linear system of equations (simply dropping all nonlinear terms in the optimality system).

It is possible to use the techniques of [GHS1] to mathematically justify these solution procedures, e.g., to prove the existence of a solution $(\mathbf{u}, p, \boldsymbol{\mu}, \rho)$ for (6.2)–(6.5) such that $(\mathbf{u}, p, -\boldsymbol{\mu}/(\beta\epsilon))$ gives a solution of $(\mathrm{P})_\epsilon$; to prove that for each solution of (6.2)–(6.5) and for each sufficiently small h, there exists a solution $(\mathbf{u}_h, p_h, \boldsymbol{\mu}_h, \rho_h)$ such that as $h \to 0$,

$$\mathbf{u}_h \to \mathbf{u}, \quad p_h \to p, \quad \boldsymbol{\mu}_h \to \boldsymbol{\mu}, \quad \text{and} \quad \rho_h \to \rho\,;$$

and to prove that if $(\mathbf{u}_h, p_h, \boldsymbol{\mu}_h, \rho_h) \in \mathbf{H}^{m+1}(\Omega) \times \mathbf{H}^m(\Omega) \times \mathbf{H}^{m+1}(\Omega) \times \mathbf{H}^m(\Omega)$, then

$$\begin{aligned}\|\mathbf{u}_h - \mathbf{u}\|_1 + \|p_h - p\|_0 + \|\boldsymbol{\mu}_h - \boldsymbol{\mu}\|_1 + \|\rho_h - \rho\|_0 \\ \le Ch^m\big(\|\mathbf{u}\|_{m+1} + \|p\|_m + \|\boldsymbol{\mu}\|_{m+1} + \|\rho\|_m\big)\,.\end{aligned}$$

However, the detailed justification of these results are beyond the scope of this paper.

We conclude this paper by presenting some numerical results for two test problems. These results confirm numerically the convergence results we established, i.e., Theorem 4.1. Further computational studies of the proposed method will be reported elsewhere.

In the first example we consider a Dirichlet optimal control problem for the Navier–Stokes equations (1.2)–(1.4) with the following data: Ω is the unit square; $\nu = 0.1$; and the prescribed body force $\mathbf{f} = (f_1, f_2)^T$, where $f_1 = 0.8\pi^2 \sin(2\pi x)\cos(2\pi y) + 2\pi \sin(2\pi x)\cos(2\pi x)$ and $f_2 = -0.8\pi^2 \cos(2\pi x)\sin(2\pi y) + 2\pi \sin(2\pi y)\cos(2\pi y)$. The functional is given by (1.1), wherein we choose $\alpha = \beta = 1$. For each sufficiently small ϵ, we can compute an optimal solution for $(\mathrm{P})_\epsilon$ by solving the discrete optimality system (6.6)–(6.9). We used a uniform mesh in Ω with 162 triangles and chose the finite element spaces to be continuous piecewise quadratics for the velocity/adjoint velocity and continuous piecewise linear functions for the pressure/adjoint pressure. We computed the optimal solutions for a sequence of ϵ values: $\epsilon_1 = 10$, $\epsilon_2 = 1$, $\epsilon_3 = 10^{-1}$, $\epsilon_4 = 10^{-2}$, $\epsilon_5 = 10^{-3}$, $\epsilon_6 = 10^{-4}$, $\epsilon_7 = 10^{-5}$, and $\epsilon_8 = 10^{-6}$. We also computed the $\mathbf{L}^2(\Omega)$ norms of $\widehat{\mathbf{u}}_{\epsilon_{i+1}} - \widehat{\mathbf{u}}_{\epsilon_i}$, and these are summarized in Table 1.

The computational results in Table 1 are consistent with the convergence results of Theorem 4.1. The solution $(\mathbf{u}_0, p_0)$ of the equations with $\mathbf{g} = \mathbf{0}$ is given by $\mathbf{u}_0 = \big(\sin(2\pi x)\cos(2\pi y), -\cos(2\pi x)\sin(2\pi y)\big)^T$ and $p_0 = 0$, and $\int_\Omega |\operatorname{curl} \mathbf{u}_0|^2 \, d\mathbf{x} = 38.8605$. The values of $\int_\Omega |\operatorname{curl} \mathbf{u}_\epsilon|^2 \, d\mathbf{x}$ for $\epsilon \le 10^{-5}$ are around 18.

In the second example we consider a Dirichlet optimal control problem for the Navier–Stokes equations (1.2)–(1.4) with the following data: Ω is the unit square;

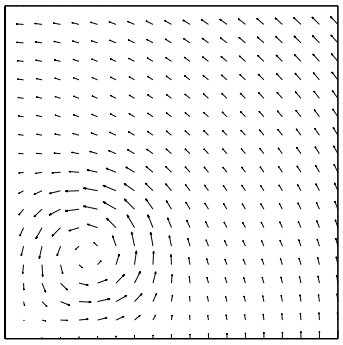

FIG. 1. *Uncontrolled velocity field.*

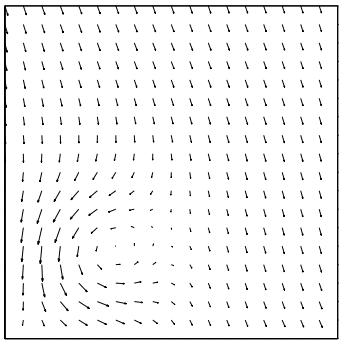

FIG. 2. *Optimal velocity field* ($\epsilon = 1$).

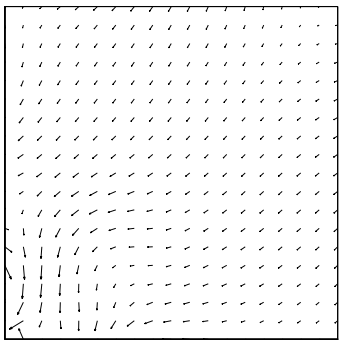

FIG. 6. *Optimal velocity field* ($\epsilon = 10^{-7}$).

TABLE 2
The $\mathbf{L}^2(\Omega)$-norm of the vorticity of optimal solutions.

ϵ_i	1	10^{-1}	10^{-2}	10^{-3}	10^{-4}	10^{-5}	10^{-6}	10^{-7}
$\left\|\left\|\operatorname{curl}\mathbf{u}_\epsilon\right\|\right\|_2^2$	12.20	11.81	11.64	11.63	11.62	11.62	11.62	11.62

$\nu = 0.1$; and the prescribed body force $\mathbf{f} = (f_1, f_2)^T$, where

$$\mathbf{f} = \begin{pmatrix} -50\nu\pi\,\cos((x-0.25)\pi/0.4)\,\sin((y-0.25)\pi/0.4) - \frac{20}{\pi}\,\sin((x-0.25)\pi/0.2) \\ 50\nu\pi\,\sin((x-0.25)\pi/0.4)\,\cos((y-0.25)\pi/0.4) - \frac{20}{\pi}\,\sin((y-0.25)\pi/0.2) \end{pmatrix}$$

in the region $\{(x,y) : |x-0.25| \le 0.2, |y-0.25| \le 0.2\}$ and $\mathbf{f} = (-0.25x, -0.25y)^T$ elsewhere on the unit square. The functional is given by (1.1), wherein we choose $\alpha = 100$ and $\beta = 1$. We used the same mesh as in the first example. We computed the optimal solutions for a sequence of ϵ values by solving the discrete optimality system (6.6)–(6.9): $\epsilon_1 = 1$, $\epsilon_2 = 10^{-1}$, $\epsilon_3 = 10^{-2}$, $\epsilon_4 = 10^{-3}$, $\epsilon_5 = 10^{-4}$, $\epsilon_6 = 10^{-5}$, $\epsilon_7 = 10^{-6}$, and $\epsilon_8 = 10^{-7}$. We also computed the $\mathbf{L}^2(\Omega)$-norms of $\operatorname{curl}\widehat{\mathbf{u}}_{\epsilon_i}$ as shown in Table 2. The $\mathbf{L}^2(\Omega)$-norm of the the vorticity of the uncontrolled velocity field is 39.77.

Figure 1 shows the uncontrolled flow field. Figures 2–6 depict the optimal velocity fields for various ϵ values we tested. We could easily visualize from these figures the convergence of the optimal solutions as $\epsilon \to 0$. Also, by comparing the uncontrolled flow field with the optimal flow fields (for small ϵ), we clearly see the reduction in recirculation in the optimal control solutions.

APPROXIMATE JACOBIAN MATRICES FOR NONSMOOTH CONTINUOUS MAPS AND C^1-OPTIMIZATION*

V. JEYAKUMAR† AND D. T. LUC‡

Abstract. The notion of approximate Jacobian matrices is introduced for a continuous vector-valued map. It is shown, for instance, that the Clarke generalized Jacobian is an approximate Jacobian for a locally Lipschitz map. The approach is based on the idea of convexificators of real-valued functions. Mean value conditions for continuous vector-valued maps and Taylor's expansions for continuously Gâteaux differentiable functions (i.e., C^1-functions) are presented in terms of approximate Jacobians and approximate Hessians, respectively. Second-order necessary and sufficient conditions for optimality and convexity of C^1-functions are also given.

Key words. generalized Jacobians, nonsmooth analysis, mean value conditions, optimality conditions

1. Introduction.

Over the past two decades, a great deal of research has focused on the study of first- and second-order analysis of real-valued nonsmooth functions [2, 3, 4, 5, 11, 12, 14, 15, 21, 23, 24, 20, 25, 27, 28, 29, 30, 34, 35]. The results of nonsmooth analysis of real-valued functions now provide basic tools of modern analysis in many branches of mathematics, such as mathematical programming, control, and mechanics. Indeed, the range of applications of nonsmooth calculus demonstrates its basic nature of nonsmooth phenomena in the mathematical and engineering sciences.

On the other hand, research in the area of nonsmooth analysis of vector-valued maps has been of substantial interest in recent years [2, 6, 7, 8, 9, 10, 18, 21, 22, 23, 24, 29, 31]. In particular, it is known that the development and analysis of generalized Jacobian matrices for nonsmooth vector-valued maps are crucial from the viewpoint of control problems and numerical methods of optimization. For instance, the Clarke generalized Jacobian matrices [2] of a locally Lipschitz map play an important role in the Newton-based numerical methods for solving nonsmooth equations and optimization problems (see [26] and other references therein, and see also [17, 18, 19] for other applications). Warga [32, 33] examined derivative (unbounded derivative) containers in the context of local and global inverse function theorems as set-valued derivatives for locally Lipschitz (continuous) vector-valued maps. Mordukhovich [21, 22] developed generalized differential calculus for general nonsmooth vector-valued maps using the set-valued derivatives, called coderivatives [9, 21].

Our aim in this paper is to introduce a new concept of approximate Jacobian matrices for continuous vector-valued maps that are not necessarily locally Lipschitz, develop certain calculus rules for approximate Jacobians, and apply the concept to optimization problems involving continuously Gâteaux differentiable functions. This

concept is a generalization of the idea of convexificators of real-valued functions, studied recently in [4, 5, 13], to vector-valued maps. Convexificators provide two-sided convex approximations [30] for real-valued functions. Unlike the set-valued generalized derivatives [9, 21, 22, 32, 33], mentioned above for vector-valued maps, the approximate Jacobian is defined as a closed subset of the space of $(n \times m)$ matrices for a vector-valued map from $\mathbb{R}^n$ into $\mathbb{R}^m$.

Approximate Jacobians not only extend the nonsmooth analysis of locally Lipschitz maps to continuous maps but also unify and strengthen various results of nonsmooth analysis. They also enjoy useful calculus, such as the generalized mean value property and chain rules. Moreover, approximate Jacobians allow us to present second-order optimality conditions in easily verifiable forms in terms of approximate Hessian matrices for C^1-optimization problems, extending the corresponding results for $C^{1,1}$-problems [7].

The outline of the paper is as follows. In section 2, approximate Jacobian matrices are introduced, and it is shown that for a locally Lipschitz map the Clarke generalized Jacobian is an approximate Jacobian. Various examples of approximate Jacobians are also given. Section 3 establishes mean value conditions for continuous vector-valued maps and provides necessary and sufficient conditions in terms of approximate Jacobians for a continuous map to be locally Lipschitz. Various calculus rules for approximate Jacobians are given in section 4. Approximate Hessian matrices are introduced in section 5, and their connections to $C^{1,1}$-functions are discussed. Section 6 presents generalizations of Taylor's expansions for C^1-functions. In section 7, second-order necessary and sufficient conditions for optimality and convexity of C^1-functions are given.

2. Approximate Jacobians for continuous maps. This section contains notation, definitions, and preliminaries that will be used throughout the paper. Let $F : \mathbb{R}^n \to \mathbb{R}^m$ be a continuous function which has components $(f_1, \ldots, f_m)$. For each $v \in \mathbb{R}^m$, the composite function, $(vF) : \mathbb{R}^n \to \mathbb{R}$, is defined by

$$(vF)(x) = \langle v,\ F(x)\rangle = \sum_{i=1}^{m} v_i f_i(x).$$

The lower Dini directional derivative and the upper Dini directional derivative of vF at x in the direction $u \in \mathbb{R}^n$ are defined by

$$(vF)^-(x,u) := \liminf_{t\downarrow 0} \frac{(vF)(x+tu) - (vF)(x)}{t},$$

$$(vF)^+(x,u) := \limsup_{t\downarrow 0} \frac{(vF)(x+tu) - (vF)(x)}{t}.$$

We denote by $L(\mathbb{R}^n, \mathbb{R}^m)$ the space of all $(n \times m)$ matrices. The *convex hull* and the *closed convex hull* of a set A in a topological vector space are denoted by $co(A)$ and $\overline{co}(A)$, respectively.

DEFINITION 2.1. *The map $F : \mathbb{R}^n \to \mathbb{R}^m$ admits an* approximate Jacobian *$\partial^* F(x)$ at $x \in R^n$ if $\partial^* F(x) \subseteq L(\mathbb{R}^n, \mathbb{R}^m)$ is closed, and for each $v \in R^m$,*

$$(vF)^-(x,u) \le \sup_{M \in \partial^* F(x)} \langle Mv, u\rangle \ \ \forall u \in \mathbb{R}^n. \tag{2.1}$$

A matrix M of $\partial^* F(x)$ is called an approximate Jacobian matrix of F at x. Note that condition (2.1) is equivalent to the condition

$$(vF)^+(x,u) \geq \inf_{M\in\partial^* F(x)} \langle Mv, u\rangle \ \ \forall u \in \mathbb{R}^n. \tag{2.2}$$

It is worth noting that the inequality (2.1) means that the set $\partial^* F(x)v$ is an upper convexificator [13, 16] of the function vF at x. Similarly, the inequality (2.2) states that $\partial^* F(x)v$ is a lower convexificator of vF at x. In the case $m = 1$, the inequality (2.1) (or (2.2)) is equivalent to the condition

$$F^-(x,u) \leq \sup_{x^*\in\partial^* F(x)} \langle x^*, u\rangle \ \text{ and } \ F^+(x,u) \geq \inf_{x^*\in\partial^* F(x)} \langle x^*, u\rangle; \tag{2.3}$$

thus, the set $\partial^* F(x)$ is a convexificator of F at x. Also note that in the case $m = 1$, condition (2.3) is also equivalent to the condition that for each $\alpha \in \mathbb{R}$,

$$(\alpha F)^-(x,u) \leq \sup_{x^*\in\partial^* F(x)} \langle \alpha x^*, u\rangle \ \ \forall u \in \mathbb{R}^n. \tag{2.4}$$

Similarly, the condition (2.3) is also equivalent to the condition that for each $\alpha \in \mathbb{R}$,

$$(\alpha F)^+(x,u) \geq \inf_{x^*\in\partial^* F(x)} \langle \alpha x^*, u\rangle \ \ \forall u \in \mathbb{R}^n. \tag{2.5}$$

For applications of convexificators, see [5, 13, 16]. To clarify the definition, let us consider some examples.

Example 2.2. If $F : \mathbb{R}^n \to \mathbb{R}^m$ is continuously differentiable at x, then any closed subset $\Phi(x)$ of $L(\mathbb{R}^n, \mathbb{R}^m)$ containing the Jacobian $\nabla F(x)$ is an approximate Jacobian of F at x. In this case, for each $v \in \mathbb{R}^m$,

$$(vF)^-(x,u) = \langle \nabla F(x)v, u\rangle \leq \sup_{M\in\Phi(x)} \langle Mv, u\rangle \quad \forall u \in \mathbb{R}^n.$$

Observe from the definition of the approximate Jacobian that for any map $F : \mathbb{R}^n \to \mathbb{R}^m$, the whole space $L(\mathbb{R}^n, \mathbb{R}^m)$ serves as a trivial approximate Jacobian for F at any point in $\mathbb{R}^n$. Let us now examine approximate Jacobians for locally Lipschitz maps.

Example 2.3. Suppose that $F : \mathbb{R}^n \to \mathbb{R}^m$ is locally Lipschitz at x. Then the Clarke generalized Jacobian $\partial_C F(x)$ is an approximate Jacobian of F at x. Indeed, for each $v \in \mathbb{R}^m$,

$$\partial^\circ(vF)(x) = \partial_C F(x)v. \tag{2.6}$$

Consequently, for each $u \in \mathbb{R}^n$,

$$(vF)^\circ(x,u) = \max_{\xi\in\partial^\circ(vF)(x)} \langle \xi, u\rangle = \max_{M\in\partial_C F(x)} \langle Mv, u\rangle,$$

where

$$\partial_C F(x) = co\{\lim_{n\to\infty} \nabla F(x_n)^T : x_n \in \Omega,\ x_n \to x\},$$

Ω is the set of points in $\mathbb{R}^n$ where F is differentiable, and the Clarke directional derivative of vF is given by

$$(vF)^\circ(x,u) = \limsup_{\substack{x'\to x\\ t\downarrow 0}} \frac{\langle v, F(x'+tu) - F(x')\rangle}{t}.$$

Since for each $u \in \mathbb{R}^n$,

$$(vF)^-(x,u) \le (vF)^\circ(x,u) \ \ \forall u \in R^n,$$

the set $\partial_C F(x)$ is an approximate Jacobian of F at x.

For the locally Lipschitz map $F : \mathbb{R}^n \to \mathbb{R}^m$, the set

$$\partial_B F(x) := \{ \lim_{n\to\infty} \nabla F(x_n)^T : x_n \in \Omega,\ x_n \to x\}$$

is also an approximate Jacobian of F at x. The set $\partial_B F(x)$ is known as the B-subdifferential of F at x, which plays a significant role in the development of nonsmooth Newton methods (see [26]). In passing, note that for each $v \in \mathbb{R}^m$,

$$\partial^\circ(vF)(x) = co(\partial_M(vF)(x)) = co(D^*F(x)(v)),$$

where the set-valued mapping $D^*F(x)$ from $\mathbb{R}^m$ into $\mathbb{R}^n$ is the coderivative of F at x and $\partial_M(vF)(x)$ is the first-order subdifferential of vF at x in the sense of Mordukhovich [22]. However, for locally Lipschitz maps, the coderivative does not appear to have a representation of the form (2.6), which allowed us above to compare approximate Jacobians with the Clarke generalized Jacobian. The reader is referred to [9, 21, 22, 29] for a more general definition and associated properties of coderivatives. A second-order analogue of the coderivative for vector-valued maps is given recently in [10].

Let us look at a numerical example of a locally Lipschitz map where the Clarke generalized Jacobian strictly contains an approximate Jacobian.

Example 2.4. Consider the function $F : \mathbb{R}^2 \to \mathbb{R}^2$

$$F(x,y) = (|x|, |y|).$$

Then

$$\partial^* F(0) = \left\{ \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \begin{pmatrix} -1 & 0 \\ 0 & 1 \end{pmatrix}, \begin{pmatrix} -1 & 0 \\ 0 & -1 \end{pmatrix} \right\}$$

is an approximate Jacobian of F at 0. On the other hand, the Clarke generalized Jacobian

$$\partial_C F(0) = \left\{ \begin{pmatrix} \alpha & 0 \\ 0 & \beta \end{pmatrix} \ :\ \alpha, \beta \in [-1,\ 1] \right\},$$

which is also an approximate Jacobian of F at 0 and contains $\partial^* F(0)$.

Observe in this example that $\partial_C F(0)$ is the convex hull of $\partial^* F(0)$. However, this is not always the case. The following example illustrates that even for the case where $m = 1$, the convex hull of an approximate Jacobian of a locally Lipschitz map may be strictly contained in the Clarke generalized Jacobian.

Example 2.5. Define $F : \mathbb{R}^2 \to \mathbb{R}$ by

$$F(x,y) = |x| - |y|.$$

Then it can easily be verified that

$$\partial_1^* F(0) = \{(1,1), (-1,-1)\} \ \text{ and } \ \partial_2^* F(0) = \{(1,-1), (-1,1)\}$$

are approximate Jacobians of F at 0, whereas

$$\partial_B F(0) = \{(1,1), (-1,1), (1,-1), (-1,-1)\}$$

and

$$\partial_C F(0) = co(\{(1,1), (-1,1), (1,-1), (-1,-1)\}).$$

It is also worth noting that

$$co(\partial_1^* F(0)) \subset co(\partial_M F(0)) = \partial_C F(0).$$

Clearly, this example shows that certain results, such as mean value conditions and necessary optimality conditions that are expressed in terms of $\partial^* F(x)$, may provide sharp conditions even for locally Lipschitz maps (see section 3).

Let us now present an example of a continuous map where the Clarke generalized Jacobian does not exist, whereas approximate Jacobians are quite easy to calculate.

Example 2.6. Define $F : \mathbb{R}^2 \to \mathbb{R}^2$ by

$$F(x,y) = (\sqrt{|x|}\,\operatorname{sgn}(x) + |y|, \quad \sqrt{|y|}\,\operatorname{sgn}(y) + |y|),$$

where $\operatorname{sgn}(x) = 1$ for $x > 0$, 0 for $x = 0$, and -1 for $x < 0$. Then F is not locally Lipschitz at $(0,0)$, and so the Clarke generalized Jacobian does not exist. However, for each $c \in \mathbb{R}$, the set

$$\partial^* F(0,0) = \left\{ \begin{pmatrix} \alpha & 1 \\ 0 & \beta \end{pmatrix}, \begin{pmatrix} \alpha & -1 \\ 0 & \beta \end{pmatrix} \,:\, \alpha, \beta \geq c \right\}$$

is an approximate Jacobian of F at $(0,0)$.

3. Generalized mean value theorems. In this section we derive mean value theorems for continuous maps in terms of approximate Jacobians and show how locally Lipschitz vector-valued maps can be characterized using approximate Jacobians.

THEOREM 3.1. *Let $a, b \in R^n$ and $F : \mathbb{R}^n \to \mathbb{R}^m$ be continuous. Assume that for each $x \in [a,b]$, $\partial^* F(x)$ is an approximate Jacobian of F at x. Then*

$$F(b) - F(a) \in \overline{co}(\partial^* F([a,b])(b-a)).$$

Proof. Let us first note that the right-hand side above is the closed convex hull of all points of the form $M(b-a)$, where $M \in \partial^* F(\zeta)$ for some $\zeta \in [a,b]$. Let $v \in \mathbb{R}^m$ be arbitrary and fixed. Consider the real-valued function $g : [0,1] \to \mathbb{R}$

$$g(t) = \langle v, F(a + t(b-a)) - F(a) + t(F(a) - F(b))\rangle.$$

Then g is continuous on $[0,1]$ with $g(0) = g(1)$. So g attains a minimum or a maximum at some $t_0 \in (0,1)$. Suppose that t_0 is a minimum point. Then, for each $\alpha \in \mathbb{R}$, $g^-(t_0, \alpha) \geq 0$. It now follows from direct calculations that

$$g^-(t_0, \alpha) = (vF)^-(a + t_0(b-a), \alpha(b-a)) + \alpha\langle v, F(a) - F(b)\rangle.$$

Hence, for each $\alpha \in \mathbb{R}$,

$$(vF)^-(a + t_0(b-a), \alpha(b-a)) \geq \alpha\langle v, F(b) - F(a)\rangle.$$

Now, by taking $\alpha = 1$ and $\alpha = -1$, we obtain that

$$-(vF)^-(a + t_0(b-a), a-b) \le \langle v, F(b) - F(a)\rangle \le (vF)^-(a + t_0(b-a), b-a)\rangle.$$

By (2.1), we get

$$\inf_{M\in\partial^* F(a+t_0(b-a))} \langle Mv, b-a\rangle \le \langle v, F(b) - F(a)\rangle \le \sup_{M\in\partial^* F(a+t_0(b-a))} \langle Mv, b-a\rangle.$$

Consequently,

$$\langle v, F(b) - F(a)\rangle \in \overline{co}(\partial^* F(a + t_0(b-a))v)(b-a),$$

and so

$$\langle v, F(b) - F(a)\rangle \in \overline{co}(\partial^* F([a,b])v)(b-a). \tag{3.1}$$

Since this inclusion holds for each $v \in \mathbb{R}^m$, we claim that

$$F(b) - F(a) \in \overline{co}(\partial^* F([a,b])(b-a)).$$

If this is not so, then it follows from the separation theorem

$$\langle p, F(b) - F(a)\rangle - \epsilon > \sup_{u\in\overline{co}(\partial^* F([a,b])(b-a))} \langle p, u\rangle$$

for some $p \in \mathbb{R}^m$ since $\overline{co}(\partial^* F([a,b])(b-a))$ is a closed convex subset of $\mathbb{R}^m$. This implies

$$\langle p, F(b) - F(a)\rangle > \sup\{\alpha : \alpha \in \overline{co}(\partial^* F([a,b])p)(b-a)\},$$

which contradicts (3.1).

Similarly, if t_0 is a maximum point, then $g^+(t_0, \alpha) \le 0$ for each $\alpha \in \mathbb{R}$. Using the same line of arguments as above, we arrive at the same conclusion, and so the proof is complete. □

COROLLARY 3.2. *Let $a, b \in \mathbb{R}^n$ and $F : \mathbb{R}^n \to \mathbb{R}^m$ be continuous. Assume that $\partial^* F(x)$ is a bounded approximate Jacobian of F at x for each $x \in [a,b]$. Then*

$$F(b) - F(a) \in co(\partial^* F([a,b])(b-a)). \tag{3.2}$$

Proof. Since for each $x \in [a,b]$, $\partial^* F(x)$ is compact, the set

$$co(\partial^* F([a,b])(b-a) = co\{\partial^* F([a,b])(b-a)\}$$

is closed, and so the conclusion follows from Theorem 3.1. □

In the following corollary we deduce the mean value theorem for locally Lipschitz maps (see [1, 6]) as a special case of Theorem 3.1.

COROLLARY 3.3. *Let $a, b \in R^n$ and $F : \mathbb{R}^n \to \mathbb{R}^m$ be locally Lipschitz on $\mathbb{R}^n$. Then*

$$F(b) - F(a) \in co(\partial_C F([a,b])(b-a)). \tag{3.3}$$

Proof. In this case the Clarke generalized Jacobian $\partial_C F(x)$ is a convex and compact approximate Jacobian of F at x. Hence, the conclusion follows from Corollary 3.2. □

Note that even for the case where F is locally Lipschitz, Corollary 3.2 provides a stronger mean value condition than condition (3.3) of Corollary 3.3. To see this, let $n = 2,\ m = 1,\ F(x, y) = |x| - |y|$, $a = (-1, -1)$, and $b = (1, 1)$. Then condition (3.2) of Corollary 3.2 is verified by

$$\partial^* F(0) = \{(1, -1), (-1, 1)\}.$$

However, condition (3.3) holds for $\partial_C F(0)$, where

$$\partial_C F(0) = co(\{(1, 1), (-1, -1), (1, -1), (-1, 1)\}) \supset \partial^* F(0).$$

As a special case of the above theorem, we see that if F is real-valued, then an asymptotic mean value equality is obtained. This was shown in [13].

COROLLARY 3.4. *Let $a, b \in X$ and $F : \mathbb{R}^n \to \mathbb{R}$ be continuous. Assume that, for each $x \in [a, b]$, $\partial^* F(x)$ is a convexificator of F. Then there exist $c \in (a, b)$ and a sequence $\{x_k^*\} \subset co(\partial^* F(c))$ such that*

$$F(b) - F(a) = \lim_{k\to\infty} \langle x_k^*,\ b - a\rangle.$$

Proof. The conclusion follows from the proof of Theorem 3.1 by noting that a convexificator $\partial^* F(x)$ is an approximate Jacobian of F at x. □

We now see how locally Lipschitz functions can be characterized using the above mean value theorem. We say that a set-valued mapping $G : \mathbb{R}^n \to L(\mathbb{R}^n, \mathbb{R}^m)$ is *locally bounded* at x if there exist a neighborhood U of x and a positive α such that $||A|| \le \alpha$ for each $A \in G(U)$. Recall that the map G is said to be *upper semicontinuous* at x if for each open set V containing $G(x)$ there is a neighborhood U of x such that $G(U) \subset V$. Clearly, if G is upper semicontinuous at x and if $G(x)$ is *bounded*, then G is locally bounded at x.

THEOREM 3.5. *Let $F : \mathbb{R}^n \to \mathbb{R}^m$ be continuous. Then F has a locally bounded approximate Jacobian map $\partial^* F$ at x if and only if F is locally Lipschitz at x.*

Proof. Assume that $\partial^* F(y)$ is the approximate Jacobian of F for each y in a neighborhood U of x and that $\partial^* F$ is locally bounded on U. Without loss of generality, we may assume that U is convex. Then there exists $\alpha > 0$ such that $||A|| \le \alpha$ for each $A \in \partial^* F(U)$. Let $x, y \in U$. Then $[x, y] \subset U$, and by the mean value theorem,

$$F(x) - F(y) \in \overline{co}(\partial^* F([x, y])(x - y)) \subset \overline{co}(\partial^* F(U)(x - y)).$$

Hence,

$$\|F(x) - F(y)\| \le \|x - y\| \max\{\|A\| : A \in \partial^* F(U)\}.$$

This gives us that

$$\|F(x) - F(y)\| \le \alpha\|x - y\|,$$

and so F is locally Lipschitz at x.

Conversely, if F is locally Lipschitz at x, then the Clarke generalized Jacobian can be chosen as an approximate Jacobian for F, which is locally bounded at x. □

4. Calculus rules for approximate Jacobians. In this section, we present some basic calculus rules for approximate Jacobians. We begin by introducing the notion of regular approximate Jacobians which are useful in some applications.

DEFINITION 4.1. *The map $F : \mathbb{R}^n \to \mathbb{R}^m$ admits a regular approximate Jacobian, $\partial^* F(x)$ at $x \in R^n$ if $\partial^* F(x) \subseteq L(\mathbb{R}^n, \mathbb{R}^m)$ is closed, and for each $v \in R^m$,*

$$(vF)^+(x,u) = \sup_{M \in \partial^* F(x)} \langle Mv, u\rangle \ \ \forall u \in \mathbb{R}^n, \tag{4.1}$$

or equivalently,

$$(vF)^-(x,u) = \inf_{M \in \partial^* F(x)} \langle Mv, u\rangle \ \ \forall u \in \mathbb{R}^n. \tag{4.2}$$

Note that in the case $m = 1$, this definition collapses to the notion of the regular convexificator studied in [13]. Thus, a closed set $\partial^* h(x) \subset \mathbb{R}^n$ is a regular convexificator of the real-valued function h at x if for each $u \in \mathbb{R}^n$,

$$h^-(x,u) = \inf_{\xi \in \partial^* h(x)} \langle \xi, u\rangle \ \text{ and } \ h^+(x,u) = \sup_{\xi \in \partial^* h(x)} \langle \xi, u\rangle.$$

It is evident that these equalities follow from (4.1) by taking $F = h$ and $v = -1$ and $v = 1$, respectively.

It is immediate from the definition that if F is differentiable at x, then $\{\nabla f(x)\}$ is a regular approximate Jacobian of F at x. However, if F is locally Lipschitz at x, then the Clarke generalized Jacobian $\partial_C F(x)$ is not necessarily a regular approximate Jacobian of F at x. It is also worth noting that if $\partial_1^* F(x)$ and $\partial_2^* F(x)$ are two regular approximate Jacobians of F at x, then $\overline{co}(\partial_1^* F(x)) = \overline{co}(\partial_2^* F(x))$.

In passing, we note that if F is locally Lipschitz on a neighborhood U of x, then there exists a dense set $K \subset U$ such that F admits a regular approximate Jacobian at each point of K. By Rademacher's theorem, the dense subset can be chosen as the set where F is differentiable.

THEOREM 4.2 (Rule 1). *Let F and H be continuous maps from R^n to R^m. Assume that $\partial^* F(x)$ is an approximate Jacobian of F at x and $\partial^* H(x)$ is a regular approximate Jacobian of H at x. Then the set $\partial^* F(x) + \partial^* H(x)$ is an approximate Jacobian of $F + H$ at x.*

Proof. Let $v \in R^m,\ u \in R^n$ be arbitrary. By definition,

$$\langle v, F + H\rangle^-(x,u) = \liminf_{t \downarrow 0} \frac{\langle v, F(x+tu) - F(x) + H(x+tu) - H(x)\rangle}{t}.$$

Let $\{t_n\}$ be a sequence of positive numbers converging to 0 such that

$$\langle v, F + H\rangle^-(x,u) = \lim_{n \to \infty} \frac{\langle v, F(x+t_n u) - F(x) + H(x+t_n u) - H(x)\rangle}{t_n}.$$

Further, let $\{s_n\}$ be another sequence of positive numbers converging to 0 such that

$$\langle v, F\rangle^-(x,u) = \liminf_{t \downarrow 0} \frac{\langle v, F(x+tu) - F(x)\rangle}{t} = \lim_{n \to \infty} \frac{\langle v, F(x+s_n u) - F(x)\rangle}{s_n}.$$

Then we have

$$\lim_{n \to \infty} \frac{\langle v, F(x+s_n u) - F(x)\rangle}{s_n} \le \sup_{M \in \partial^* F(x)} \langle Mv,\ u\rangle$$

and

$$\limsup_{n\to\infty} \frac{\langle v, H(x+s_nu)-H(x)\rangle}{s_n} \le \langle v, H\rangle^+(x,u) = \sup_{M\in\partial^* H(x)} \langle Mv, u\rangle.$$

Consequently,

$$\begin{aligned}\langle v, F+H\rangle^-(x,u) &\le \lim_{n\to\infty} \frac{\langle v, F(x+s_nu)-F(x)\rangle}{s_n} + \frac{\langle v, H(x+s_nu)-H(x)\rangle}{s_n}\\ &\le \sup_{M\in\partial^* F(x)} \langle Mv, u\rangle + \sup_{N\in\partial^* H(x)} \langle Nv, u\rangle\\ &= \sup_{P\in\partial^* F(x)+\partial^* H(x)} \langle Pv, u\rangle.\end{aligned}$$

Since u and v are arbitrary, we conclude that $\partial^* F(x) + \partial^* H(x)$ is an approximate Jacobian of $F+H$ at x. □

Note that as in the case of convexificators of real-valued functions [18], the set $\partial^* F(x) + \partial^* H(x)$ is not necessarily regular at x.

THEOREM 4.3 (Rule 2). *Let $F : \mathbb{R}^n \to \mathbb{R}^m$ and $H : \mathbb{R}^m \to \mathbb{R}^l$ be continuous maps. Assume that $\partial^* F(x)$ is a bounded approximate Jacobian of F at x and $\partial^* H(x)$ is a bounded approximate Jacobian of H at $F(x)$. If the maps $\partial^* F$ and $\partial^* H$ are upper semicontinuous at x and $F(x)$, respectively, then $\partial^* H(F(x))\partial^* F(x)$ is an approximate Jacobian of $H \circ F$ at x.*

Proof. Let $w \in \mathbb{R}^l$ and $u \in \mathbb{R}^m$ be arbitrary. Consider the lower Dini directional derivative of $\langle w,\ H \circ F\rangle$ at x:

$$\langle w,\ H\circ F\rangle^-(x,u) = \liminf_{t\downarrow 0} \frac{\langle w,\ H(F(x+tu)) - H(F(x))\rangle}{t}.$$

By applying the mean value theorem (see Theorem 3.1) to H and F, we obtain

$$\begin{aligned} F(x+tu) - F(x) &\in t\overline{co}(\partial^* F([x, x+tu])u),\\ H(F(x+tu)) - H(F(x)) &\in \overline{co}(\partial^* H([F(x,),\ F(x+tu)])(F(x+tu)-F(x)))\end{aligned}$$

It now follows from the upper semicontinuity of $\partial^* F$ and $\partial^* H$ that for an arbitrary small positive ϵ we can find $t_0 > 0$ such that for $t \in (0, t_0)$ we have

$$\begin{aligned}\partial^* F([x, x+tu]) &\subseteq \partial^* F(x) + \epsilon B_1,\\ \partial^* H([F(x),\ F(x+tu)]) &\subseteq \partial^* H(F(x)) + \epsilon B_2,\end{aligned}$$

where B_1 and B_2 are the unit balls in $L(\mathbb{R}^n, \mathbb{R}^m)$ and $L(\mathbb{R}^m, \mathbb{R}^l)$, respectively. Using these inclusions, we obtain

$$\frac{\langle w,\ H(F(x+tu)) - H(F(x))\rangle}{t} \in \langle w, A\rangle,$$

where

$$A := \overline{co}((\partial^* H(F(x))\partial^* F(x) + \epsilon(\partial^* H(F(x))B_1 + B_2\partial^* F(x)) + \epsilon^2 B_2 B_1)u).$$

Since $\partial^* H(F(x))$ and $\partial^* F(x)$ are bounded, we can find $\alpha > 0$ such that $\|M\| \le \alpha$ for all $M \in \partial^* H(F(x))$ or $M \in \partial^* F(x)$. Consequently,

$$\langle w, H\circ F\rangle^-(x,u) \le \sup_{M\in\partial^* H(F(x))\partial^* F(x)} \langle Mw, u\rangle + 2\epsilon\|u\| + \epsilon^2\|u|.$$

As ϵ is arbitrary, we conclude that $\partial^* H(F(x))\partial^* F(x)$ is an approximate Jacobian of $H \circ F$ at x. □

5. Approximate Hessian matrices. In this section, unless stated otherwise, we assume that $f : \mathbb{R}^n \to \mathbb{R}$ is a C^1- function, that is, a continuously Gâteaux differentiable function, and introduce the notion of approximate Hessian for such functions. Note that the derivative of f, which is denoted by ∇f, is a map from $\mathbb{R}^n$ to $\mathbb{R}^n$.

DEFINITION 5.1. *The function f admits an* approximate Hessian $\partial^2_* f(x)$ *at x if this set is an approximate Jacobian to ∇f at x.*

Note that $\partial^2_* f(x) = \partial^* \nabla f(x)$ and the matrix $M \in \partial^2_* f(x)$ is an approximate Hessian matrix of F at x. Clearly, if f is twice differentiable at x, then $\nabla^2 f(x)$ is a symmetric approximate Hessian matrix of f at x.

Let us now examine the relationships between the approximate Hessians and the generalized Hessians, studied for $C^{1,1}$-functions, that is, Gâteaux differentiable functions with locally Lipschitz derivatives. Recall that if $f : \mathbb{R}^n \to \mathbb{R}$ is $C^{1,1}$, then the generalized Hessian in the sense of Hiriart-Urruty, Strodiot, and Hien Nguyen [7] is given by

$$\partial^2_H f(x) = co\{M \ : \ M = \lim_{n\to\infty} \nabla^2 f(x_n),\ x_n \in \Delta,\ x_n \to x\},$$

where Δ is the set of points in $\mathbb{R}^n$ where f is twice differentiable. Clearly, $\partial^2_H f(x)$ is a nonempty convex compact set of symmetric matrices. The second-order directional derivative of f at x in the directions $(u, v) \in \mathbb{R}^n \times \mathbb{R}^n$ is defined by

$$f^{\circ\circ}(x; u, v) = \limsup_{\substack{y\to x \\ s\to 0}} \frac{\langle \nabla f(y + su), v\rangle - \langle \nabla f(y), v\rangle}{s}.$$

Since $(v\nabla f)^-(x, u) \le f^{\circ\circ}(x; u, v)$, for each $(u, v) \in \mathbb{R}^n$ and

$$f^{\circ\circ}(x; u, v) = \max_{M\in\partial^2_H f(x)} \langle Mu, v\rangle = \max_{M\in\partial^2_H f(x)} \langle Mv, u\rangle,$$

$\partial^2_H f(x)$ is an approximate Hessian of f at x.

The generalized Hessian of f at x as a set-valued map, $\partial^{\circ\circ} f(x) : \mathbb{R}^n \to \mathbb{R}^n$, which was given in Cominetti and Correa [3], is defined by

$$\partial^{\circ\circ} f(x)(u) = \{x^* \in \mathbb{R}^n : f^{\circ\circ}(x; u, v) \ge \langle x^*, v\rangle \forall v \in \mathbb{R}^n\}.$$

It is known that the mapping $(u, v) \longrightarrow f^{\circ\circ}(x; u, v)$ is finite and sublinear and that $\partial^{\circ\circ} f(x)(u)$ is a nonempty, convex, and compact subset of $\mathbb{R}^n$, and for each $x, u, v \in \mathbb{R}^n$,

$$f^{\circ\circ}(x; u, v) = \max\{\langle x^*, v\rangle : x^* \in \partial^{\circ\circ} f(x)(u)\}.$$

Moreover, for each $u \in \mathbb{R}^n$,

$$\partial^{\circ\circ} f(x)(u) = \partial^2_H f(x)u.$$

If f is twice continuously differentiable at x, then the generalized Hessian $\partial^{\circ\circ} f(x)(u)$ is a singleton for every $u \in \mathbb{R}^n$.

In [34, 35], another generalized second-order directional derivative and a generalized Hessian set-valued map for a $C^{1,1}$ function f at x were given as follows:

$$f^{\diamond\diamond}(x; u, v) = \sup_{z\in\mathbb{R}^n} \limsup_{s\downarrow 0} \frac{\langle \nabla f(x + sz + su), v\rangle - \langle \nabla f(x + sz), v\rangle}{s},$$

$$\partial^{\diamond\diamond} f(x)(u) = \{x^* \in X^* : f^{\diamond\diamond}(x; u, v) \geq \langle x^*, v\rangle \, \forall v \in X\}.$$

It was shown that the mapping $(u, v) \longrightarrow f^{\diamond\diamond}(x; u, v)$ is finite and sublinear; $\partial^{\diamond\diamond} f(x)(u)$ is a nonempty, convex, and compact subset of $\mathbb{R}^n$; and $\partial^{\diamond\diamond} f(x)(u)$ is singled-valued for each $u \in \mathbb{R}^n$ if and only if f is twice Gâteaux differentiable at x. Further, for each $u \in \mathbb{R}^n$, $\partial^{\diamond\diamond} f(x)(u) \subset \partial^{\circ\circ} f(x)(u) = \partial^2_H f(x)u$. If for each $(u, v) \in \mathbb{R}^n$ the function $y \longrightarrow f^{\diamond\diamond}(y; u, v)$ is upper semicontinuous at x, then

$$\partial^{\diamond\diamond} f(x)(u) = \partial^2_H f(x)u.$$

The following proposition gives us necessary and sufficient conditions in terms of approximate Hessians for a C^1-function to be $C^{1,1}$.

PROPOSITION 5.2. *Let $f : \mathbb{R}^n \to \mathbb{R}$ be a C^1-function. Then f has a locally bounded approximate Hessian map $\partial^2_* f$ at x if and only if f is $C^{1,1}$ at x.*

Proof. This follows from Theorem 3.5 by taking F as ∇f. □

We complete this section with an example showing that for a $C^{1,1}$ function the approximate Hessian may be a singleton which is contained in the generalized Hessian of Hiriart-Urruty, Strodiot, and Hien Nguyen [7].

Example 5.3. Let g be an odd, linear piecewise continuous function on $\mathbb{R}$ as follows. $g(x) = x$ for $x \geq 1$ and $g(0) = 0$; $g(x) = 2x - 1$ for $x \in [\frac{1}{2}, 1]$; $g(x) = -\frac{1}{2}x + \frac{1}{4}$ for $x \in [\frac{1}{6}, \frac{1}{2}]$; $g(x) = 2x - \frac{1}{6}$ for $x \in [\frac{1}{12}, \frac{1}{6}]$; $g(x) = -\frac{1}{4}x + \frac{1}{48}$ for $x \in [\frac{1}{60}, \frac{1}{12}]$, etc. Let

$$G(x) = \int_0^{|x|} g(t)dt, \quad x \in \mathbb{R}.$$

Define

$$f(x, y) = G(x) + \frac{y^2}{2}.$$

Then the function f is a $C^{1,1}$ function, and the generalized Hessian of f at $(0, 0)$ is

$$\partial^2_H f(0) = \left\{ \begin{pmatrix} \alpha & 0 \\ 0 & 1 \end{pmatrix} \, : \, \alpha \in [0,\ 2] \right\}.$$

However, the approximate Hessian of f at $(0, 0)$ is the singleton

$$\partial^2_* f(0) = \left\{ \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix} \right\}.$$

6. Generalized Taylor's expansions for C^1-functions. In this section, we see how Taylor's expansions can be obtained for C^1- functions using approximate Hessians.

THEOREM 6.1. *Let $f : \mathbb{R}^n \to \mathbb{R}$ be continuously Gâteaux differentiable on $\mathbb{R}^n$; let $x, y \in \mathbb{R}^n$. Suppose that for each $z \in [x, y]$, $\partial^2_* f(z)$ is an approximate Hessian of f at z. Then there exists $\zeta \in (x, y)$ such that*

$$f(y) \in f(x) + \langle \nabla f(x), y - x\rangle + \frac{1}{2}\overline{co}\langle \partial^2_* f(\zeta)(y - x), (y - x)\rangle.$$

Proof. Let $h(t) = f(y + t(x - y)) + t\langle \nabla f(y + t(x - y)), y - x\rangle + \frac{1}{2}at^2 - f(y)$, where $a = -2(f(x) - f(y) + \langle \nabla f(x), y - x\rangle)$. Then $h(0) = 0, h(1) = f(x) - f(y) +$

$\langle \nabla f(x), y-x\rangle + \frac{1}{2}a = 0$, and h is continuous. So h attains its extremum at some $\gamma \in (0,1)$. Suppose that γ is a minimum point of h. Now, by necessary conditions, we have for all $v \in \mathbb{R}$

$$h^-(\gamma; v) \geq 0.$$

Then

$$\begin{aligned}
0 &\leq h^-(\gamma; v)\\
&= \liminf_{\lambda\to 0^+} \frac{h(\gamma+\lambda v) - h(\gamma)}{\lambda}\\
&= \lim_{\lambda\to 0^+} \frac{f(y+(\gamma+\lambda v)(x-y)) - f(y+\gamma(x-y))}{\lambda}\\
&\quad + \frac{1}{2}\lim_{\lambda\to 0^+} \frac{a(\gamma+\lambda v)^2 - a\gamma^2}{\lambda}\\
&\quad + \liminf_{\lambda\to 0^+} \frac{(\gamma+\lambda v)\langle \nabla f(y+(\gamma+\lambda v)(x-y)), y-x\rangle - \gamma\langle \nabla f(y+\gamma(x-y)), y-x\rangle}{\lambda}\\
&= v\langle \nabla f(y+\gamma(x-y)), x-y\rangle + a\gamma v + v\langle \nabla f(y+\gamma(x-y)), y-x\rangle\\
&\quad + \gamma \liminf_{\lambda\to 0^+} \frac{\langle \nabla f(y+(\gamma+\lambda v)(x-y)), y-x\rangle - \langle \nabla f(y+\gamma(x-y)), y-x\rangle}{\lambda}\\
&= a\gamma v + \gamma \liminf_{\lambda\to 0^+} \frac{\langle \nabla f(y+(\gamma+\lambda v)(x-y)), y-x\rangle - \langle \nabla f(y+\gamma(x-y)), y-x\rangle}{\lambda}.
\end{aligned}$$

Let $\zeta = y+\gamma(x-y)$. Then $\zeta \in (x,y)$, and for $v=1$ we get

$$\begin{aligned}
0 &\leq a\gamma + \gamma \liminf_{\lambda\to 0^+} \frac{\langle \nabla f(y+\gamma(x-y)+\lambda(x-y)), y-x\rangle - \langle \nabla f(y+\gamma(x-y)), y-x\rangle}{\lambda}\\
&\leq a + \sup_{M\in\partial_*^2 f(\zeta)} \langle M(y-x), x-y\rangle.
\end{aligned}$$

This gives us that

$$a \geq \inf_{M\in\partial_*^2 f(\zeta)} \langle M(y-x), y-x\rangle.$$

Similarly, for $v=-1$, we obtain

$$\begin{aligned}
0 &\leq -a\gamma + \gamma \liminf_{\lambda\to 0^+} \frac{\langle \nabla f(y+\gamma(x-y)+\lambda(y-x)), y-x\rangle - \langle \nabla f(y+\gamma(x-y)), y-x\rangle}{\lambda}\\
&\leq -a + \sup_{M\in\partial_*^2 f(\zeta)} \langle M(y-x), y-x\rangle;
\end{aligned}$$

thus,

$$a \leq \sup_{M\in\partial_*^2 f(\zeta)} \langle M(y-x), y-x\rangle.$$

Hence, it follows that

$$\inf_{M\in\partial_*^2 f(\zeta)} \langle M(y-x), y-x\rangle \leq a \leq \sup_{M\in\partial_*^2 f(\zeta)} \langle M(y-x), y-x\rangle,$$

and so

$$a \in \overline{co}\langle \partial_*^2 f(\zeta)(y-x), (y-x)\rangle;$$

thus,

$$f(y) - f(x) - \langle \nabla f(x), y - x\rangle = \frac{a}{2} \in \frac{1}{2}\overline{co}\langle \partial_*^2 f(\zeta)(y-x), (y-x)\rangle. \tag{6.1}$$

The case where γ is a maximum point of h also yields the same condition (6.1). The details are left to the reader. □

COROLLARY 6.2. *Let $f : \mathbb{R}^n \to \mathbb{R}$ be continuously Gâteaux differentiable on $\mathbb{R}^n$ and $x, y \in \mathbb{R}^n$. Suppose that for each $z \in [x, y]$, $\partial_*^2 f(z)$ is a convex and compact approximate Hessian of f at z. Then there exist $\zeta \in (x, y)$ and $M_\zeta \in \partial_*^2 f(\zeta)$ such that*

$$f(y) = f(x) + \langle \nabla f(x), y - x\rangle + \frac{1}{2}\langle M_\zeta(y-x), y-x\rangle.$$

Proof. It follows from the hypothesis that for each $z \in [x, y]$, $\partial_*^2 f(z)$ is convex and compact, and so the $\overline{co}$ in the conclusion of the previous theorem is superfluous. Thus, the inequalities

$$\inf_{M \in \partial_*^2 f(\zeta)} \langle M(y-x), y-x\rangle \le a \le \sup_{M \in \partial_*^2 f(\zeta)} \langle M(y-x), y-x\rangle$$

give us that

$$a \in \langle \partial_*^2 f(\zeta)(y-x), (y-x)\rangle. \qquad \square$$

COROLLARY 6.3 (see [7]). *Let $f : \mathbb{R}^n \to \mathbb{R}$ be $C^{1,1}$ and $x, y \in \mathbb{R}^n$. Then there exist $\zeta \in (x, y)$ and $M_\zeta \in \partial_H^2 f(\zeta)$ such that*

$$f(y) = f(x) + \langle \nabla f(x), y - x\rangle + \frac{1}{2}\langle M_\zeta(y-x), y-x\rangle.$$

Proof. In this case, the conclusion follows from the above corollary by choosing the generalized Hessian $\partial_H^2 f(x)$ as an approximate Hessian of f for each x. □

7. Second-order conditions for optimality and convexity of C^1-functions. In this section, we present second-order necessary and sufficient conditions for optimality and convexity of C^1-functions using approximate Hessian matrices. Consider the optimization problem

$$\begin{aligned} (\mathrm{P}) \quad & \text{minimize } f(x) \\ & \text{subject to } x \in \mathbb{R}^n, \end{aligned}$$

where $f : \mathbb{R}^n \longrightarrow \mathbb{R}$ is a continuously Gâteaux differentiable function on $\mathbb{R}^n$. We say that a map $F : \mathbb{R}^n \to \mathbb{R}^m$ admits a *semiregular approximate Jacobian* $\partial^* F(x)$ at $x \in R^n$ if $\partial^* F(x) \subseteq L(\mathbb{R}^n, \mathbb{R}^m)$ is closed, and for each $v \in R^m$,

$$(vF)^+(x, u) \le \sup_{M \in \partial^* F(x)} \langle Mv, u\rangle \ \ \forall u \in \mathbb{R}^n.$$

Similarly, the C^1-function $f : \mathbb{R}^n \to \mathbb{R}$ admits a *semiregular approximate Hessian* $\partial_*^2 f(x)$ at x if this set is a semiregular approximate Jacobian to ∇f at x.

Of course, every semiregular approximate Hessian to f at x is an approximate Hessian at x. For a $C^{1,1}$ function $f : \mathbb{R}^n \to \mathbb{R}$, the generalized Hessian, $\partial^2_H f(x)$, of f at x is a bounded semiregular approximate Hessian of f at x since

$$(v\nabla f)^+(x,u) \le f^{\circ\circ}(x;u,v) = \max_{M\in\partial^2_H f(x)} \langle Mu, v\rangle = \max_{M\in\partial^2_H f(x)} \langle Mv, u\rangle.$$

THEOREM 7.1. *For the problem* (P)*, let* $\bar{x} \in \mathbb{R}^n$*. Assume that* $\partial^2_* f(\bar{x})$ *is a semiregular approximate Hessian of* f *at* $\bar{x}$*.*

(i) *If* $\bar{x}$ *is a local minimum of* (P)*, then* $\nabla f(\bar{x}) = 0$*, and for each* $u \in \mathbb{R}^n$*,*

$$\sup_{M\in\partial^2_* f(\bar{x})} \langle Mu, u\rangle \ge 0.$$

(ii) *If* $\bar{x}$ *is a local maximum of* (P)*, then* $\nabla f(\bar{x}) = 0$*, and for each* $u \in \mathbb{R}^n$*,*

$$\inf_{M\in\partial^2_* f(\bar{x})} \langle Mu, u\rangle \le 0.$$

Proof. Let $u \in \mathbb{R}^n$. Since $\bar{x}$ is a local minimum of (P), there exists $\delta > 0$ such that for each $s \in [0, \delta]$,

$$f(\bar{x} + su) \ge f(\bar{x}).$$

Then, by the mean value theorem, for each $s \in (0, \delta]$, there exists $0 < t < s$ such that

$$\langle \nabla f(\bar{x} + tu), u\rangle \ge 0.$$

So, there exists a positive sequence $\{t_n\} \downarrow 0$ such that $\langle \nabla f(\bar{x} + t_n u), u\rangle \ge 0$. Now, as $\nabla f(\bar{x}) = 0$, it follows that

$$\begin{aligned}(u\nabla f)^+(\bar{x};u) &= \limsup_{s\downarrow 0} \frac{\langle \nabla f(\bar{x}+su), u\rangle - \langle \nabla f(\bar{x}), u\rangle}{s}\\ &\ge 0.\end{aligned}$$

Since $\partial^2_* f(x)$ is a semiregular approximate Hessian of f at x, we have

$$(u\nabla f)^+(\bar{x};u) \le \sup_{M\in\partial^2_* f(\bar{x})} \langle Mu, u\rangle,$$

and hence,

$$\sup_{M\in\partial^2_* f(\bar{x})} \langle Mu, u\rangle \ge 0.$$

On the other hand, if f attains a local maximum at $\bar{x}$, then it follows by the similar arguments as above that for each $u \in \mathbb{R}^n$,

$$\inf_{M\in\partial^2_* f(\bar{x})} \langle Mu, u\rangle \le 0.$$

Note in this case that it is convenient to use the inequality

$$(u\nabla f)^-(\bar{x},u) \ge \inf_{M\in\partial^2_* f(\bar{x})} \langle Mu, u\rangle. \qquad \square$$

Let us look at a numerical example to illustrate the significance of the optimality conditions obtained in the previous theorem.

Example 7.2. Define $f : \mathbb{R}^2 \to \mathbb{R}$ by

$$f(x,y) = \frac{2}{3}|x|^{\frac{3}{2}} + \frac{1}{2}y^2.$$

Then f is C^1 but is not $C^{1,1}$ since the gradient

$$\nabla f(x,y) = \left(\sqrt{|x|}\,\operatorname{sgn}(x), y\right)$$

is not locally Lipschitz at $(0,0)$. Evidently, $(0,0)$ is a minimum point of f, $\nabla f(0,0) = (0,0)$, and

$$\partial_*^2 f(0) = \left\{ \begin{pmatrix} \alpha & 0 \\ 0 & 1 \end{pmatrix} \;:\; \alpha \geq 0 \right\}$$

is a semiregular approximate Hessian of f at $(0,0)$. And for each $u = (u_1, u_2) \in \mathbb{R}^2$,

$$\sup_{M \in \partial_*^2 f(0)} \langle Mu, u\rangle = \sup\{\alpha u_1^2 + u_2^2 \;:\; \alpha \geq 0\} \geq 0.$$

Hence, the statement (i) of Theorem 7.1 is verified. However, the generalized Hessians [7] do not apply to this function.

COROLLARY 7.3. *For the problem* (P)*, let* $\bar{x} \in \mathbb{R}^n$*. Suppose that* $\partial_*^2 f(\bar{x})$ *is a bounded semiregular approximate Hessian of* f *at* $\bar{x}$*.*

(i) *If* $\bar{x}$ *is a local minimum of* (P)*, then* $\nabla f(\bar{x}) = 0$*, and for each* $u \in \mathbb{R}^n$ *there exists a matrix* $M \in \partial_*^2 f(\bar{x})$ *such that* $\langle Mu, u\rangle \geq 0$*.*

(ii) *If* $\bar{x}$ *is a local maximum of* (P)*, then* $\nabla f(\bar{x}) = 0$*, and for each* $u \in \mathbb{R}^n$ *there exists a matrix* $M \in \partial_*^2 f(\bar{x})$ *such that* $\langle Mu, u\rangle \leq 0$*.*

Proof. Since $\partial_*^2 f(\bar{x})$ is closed and bounded, it follows from Theorem 7.1 that $\nabla f(\bar{x}) = 0$, and for each $u \in \mathbb{R}^n$,

$$\max_{M \in \partial_*^2 f(\bar{x})} \langle Mu, u\rangle \geq 0,$$

and so the first conclusion holds. The second conclusion similarly follows from Theorem 7.1. □

We now see how optimality conditions for the problem (P) where f is $C^{1,1}$ follows from Corollary 7.3 (cf. [7]).

COROLLARY 7.4. *For the problem* (P)*, assume that the function* f *is* $C^{1,1}$ *and* $\bar{x} \in \mathbb{R}^n$*.*

(i) *If* $\bar{x}$ *is a local minimum of* (P)*, then* $\nabla f(\bar{x}) = 0$*, and for each* $u \in \mathbb{R}^n$ *there exists a matrix* $M \in \partial_H^2 f(\bar{x})$ *such that* $\langle Mu, u\rangle \geq 0$*.*

(ii) *If* $\bar{x}$ *is a local maximum of* (P)*, then* $\nabla f(\bar{x}) = 0$*, and for each* $u \in \mathbb{R}^n$ *there exists a matrix* $M \in \partial_H^2 f(\bar{x})$ *such that* $\langle Mu, u\rangle \leq 0$*.*

Proof. The conclusion follows from Corollary 7.3 by choosing $\partial_H^2 f(\bar{x})$ as the semiregular bounded approximate Hessian $\partial_*^2 f(\bar{x})$ of f at $\bar{x}$. □

Clearly, the conditions of Theorem 7.1 are not sufficient for a local minimum, even for a C^2-function f. The generalized Taylor's expansion is now applied to obtain a version of second-order sufficient condition for a local minimum. For related results, see [34, 16].

THEOREM 7.5. *For the problem* (P), *let* $\bar{x} \in \mathbb{R}^n$. *Assume that for each* x *in a neighborhood of* $\bar{x}$, $\partial_*^2 f(x)$ *is a bounded approximate Hessian of* f *at* x. *If* $\nabla f(\bar{x}) = 0$ *and for* $0 < \alpha < 1$, *each* $u \in \mathbb{R}^n$ *satisfies* $u \neq 0$; *then the following holds:*

$$(\forall M \in \overline{co}(\partial_*^2 f(\bar{x} + \alpha u))), \quad \langle Mu, u\rangle \geq 0. \tag{7.1}$$

Then $\bar{x}$ *is a local minimum of* (P).

Proof. Suppose that $\bar{x}$ is not a local minimum of (P). Then there exists a sequence $\{x_n\}$ such that $x_n \neq \bar{x}$, $x_n \longrightarrow \bar{x}$ as $n \longrightarrow +\infty$, and $f(x_n) < f(\bar{x})$ for each n. Let $x_n = \bar{x} + u_n$, where $u_n \neq 0$. From the generalized Taylor expansion, Theorem 6.1, there exists $0 < \alpha_n < 1$ such that

$$f(x_n) \in f(\bar{x}) + \langle \nabla f(\bar{x}), x_n - \bar{x}\rangle + \frac{1}{2}\overline{co}\langle \partial_*^2 f(\bar{x} + \alpha_n u_n)(u_n), u_n\rangle.$$

Thus, there exists $M_n \in \overline{co}(\partial_*^2 f(\bar{x} + \alpha_n u_n))$ such that $f(x_n) = f(\bar{x}) + \langle M_n u_n, u_n\rangle$, and so $\langle M_n u_n, u_n\rangle < 0$. This contradicts (7.1). Hence, $\bar{x}$ is a local minimum of (P). □

The following theorem gives us second-order sufficient optimality conditions for a strict local minimum.

THEOREM 7.6. *For the problem* (P), *let* $\bar{x} \in \mathbb{R}^n$. *Assume that, for each* x *in a neighborhood of* $\bar{x}$, $\partial_*^2 f(x)$ *is a bounded approximate Hessian of* f *at* x. *If* $\nabla f(\bar{x}) = 0$ *and for* $0 < \alpha < 1$, *each* $u \in \mathbb{R}^n$ *satisfies* $u \neq 0$, *then the following holds:*

$$(\forall M \in \overline{co}(\partial_*^2 f(\bar{x} + \alpha u))), \quad \langle Mu, u\rangle > 0. \tag{7.2}$$

Then $\bar{x}$ *is a strict local minimum of* (P).

Proof. The method of proof is similar to the one given above for Theorem 7.5 and so it is omitted. □

We now see how the mean value theorem of section 3 and approximate Hessians can be used to characterize convexity of C^1- functions.

THEOREM 7.7. *Let* $f : \mathbb{R}^n \to R$ *be a continuously Gâteaux differentiable function. Assume that* $\partial_*^2 f(x)$ *is an approximate Hessian of* f *for each point* $x \in \mathbb{R}^n$. *If the matrices* $M \in \partial_*^2 f(x)$ *are positive semidefinite for each* $x \in \mathbb{R}^n$, *then* f *is convex.*

Proof. Let $x, u \in \mathbb{R}^n$. Then, by the mean value theorem,

$$\nabla f(x + u) - \nabla f(x) \in \overline{co}(\partial_*^2 f([x, x + u])u),$$

and so,

$$\langle \nabla f(x + u) - \nabla f(x),\ u\rangle \in \langle \overline{co}(\partial_*^2 f([x, x + u])u), u\rangle.$$

Thus, there exist $z \in [x, x + u]$ and $M \in \overline{co}(\partial_*^2 f(z))$ such that

$$\langle \nabla f(x + u) - \nabla f(x),\ u\rangle = \langle Mu, u\rangle.$$

It follows by the assumption that

$$\langle \nabla f(x + u) - \nabla f(x),\ u\rangle \geq 0.$$

Since $x, u \in \mathbb{R}^n$ are arbitrary, we get that ∇f is monotone in the sense that for each $x, u \in \mathbb{R}^n$,

$$\langle \nabla f(x + u) - \nabla f(x),\ u\rangle \geq 0.$$

The conclusion now follows from the standard result of convex analysis that f is convex if and only if ∇f is monotone. □

COROLLARY 7.8. *Let $f : \mathbb{R}^n \to \mathbb{R}$ be $C^{1,1}$. Then f is convex if and only if for each $x \in \mathbb{R}^n$, the matrices $M \in \partial_H^2 f(x)$ are positive semidefinite.*

Proof. Since f is $C^{1,1}$ for each $x \in \mathbb{R}^n$, $\partial_H^2 f(x)$ is an approximate Hessian of f at x. Hence, it follows from Theorem 7.7 that f is convex.

Conversely, assume that f is convex. Let Δ be a set of points in $\mathbb{R}^n$ on which f is twice differentiable. Then, each matrix M of

$$\{ \lim_{n\to\infty} \nabla^2 f(x_n) \ : \ \{x_n\} \subset \Delta,\ x_n \to x\}$$

is positive semidefinite as it is a limit of a sequence of positive semidefinite matrices. Hence, each matrix M of

$$\partial_H^2 f(x) = co\{ \lim_{n\to\infty} \nabla^2 f(x_n) \ : \ \{x_n\} \subset \Delta,\ x_n \to x\}$$

is also positive semidefinite. □

Acknowledgments. The authors are grateful to the referees for their detailed comments and valuable suggestions which have contributed to the final preparation of the paper. The first author is grateful to Professor Jonathan Borwein for his helpful comments on the earlier version of the paper and for certain useful references. The second author wishes to thank the first author for his kind invitation and hospitality.

$\mathbb{L}^2$ SUFFICIENT CONDITIONS FOR END-CONSTRAINED OPTIMAL CONTROL PROBLEMS WITH INPUTS IN A POLYHEDRON*

J. C. DUNN†

Abstract. An $\mathbb{L}^2$-local optimality sufficiency theorem is proved for a class of structured infinite-dimensional nonconvex programs with constraints of the form $u \in \Omega$ and $h(u) = 0$, where Ω is a set of Lebesgue measurable essentially bounded vector-valued functions $u(\cdot) : [0,1] \to \mathbb{R}^m$ with range in a polyhedron U, and h is a smooth map of the space of essentially bounded functions $u(\cdot)$ into R^k. The sufficiency theorem is based on formal counterparts of the finite-dimensional Karush–Kuhn–Tucker sufficient conditions in a Cartesian product of polyhedra, a strengthened variant of Pontryagin's necessary condition, and structure and continuity conditions on the first and second differentials of the objective function and equality constraint functions. The new sufficient conditions are directly applicable to nonconvex continuous-time Bolza optimal control problems with control-quadratic Hamiltonians, unqualified affine inequality constraints on vector-valued control inputs, and equality constraints on the terminal state vector or equivalent isoperimetric constraints on integrals of functions depending on the state and control variables.

Key words. infinite-dimensional programs, affine inequality constraints, nonconvex equality constraints, nonconvex objectives, $\mathbb{L}^2$-local optimality, second-order sufficient conditions, optimal control, constrained inputs, terminal state constraints

1. Introduction.

In finite-dimensional spaces, all norms are equivalent and local optimality is a norm-invariant property. On the other hand, in infinite-dimensional spaces, norm-equivalence is lost and local optimality in one norm need not imply local optimality in another. This fact has computational and theoretical implications for refined finite-dimensional approximations to constrained minimization problems in infinite-dimensional function spaces [13], [15].

The distinction between strong and weak minimizing curves in the calculus of variations provides a classic illustration of norm-dependent local optimality in function spaces. For variational problems, strict versions of the necessary conditions of Legendre and Jacobi are sufficient for weak local optimality but not strong local optimality; however, strong local optimality can be deduced when a strict version of the Weierstrass necessary condition is added to the weak local optimality sufficient conditions. This classical development has a natural extension to Bolza optimal control problems for ordinary differential equations [3], [4], [21], [22], [23], [24], [28], [29], [30]. In the optimal control setting, some strict form of the Pontryagin necessary condition replaces the Weierstrass condition since pointwise constraints on control or state variables are generally present. Variants of the Pontryagin minimum principle are also invoked in the global optimality sufficient conditions of [5], [6], [7], and [8] for time-optimal control of state-constrained ordinary differential inclusions.

Alternative local optimality sufficient conditions for optimal control problems have been established with modifications of a basic proof strategy for finite-dimensional

nonlinear programs. As one might expect, these sufficient conditions are closely related to the strict complementarity and coercivity hypotheses in the Karush–Kuhn–Tucker (KKT) theory. Initially, the KKT approach produced sufficient conditions for weak local optimality in the control context, i.e., local optimality in the $\mathbb{L}^\infty$ norm on control functions [9], [20], [21]; however, recent investigations have deduced both weak ($\mathbb{L}^\infty$) and strong ($\mathbb{L}^2$) local optimality from strict complementarity and coercivity hypotheses, and an additional condition of the Pontryagin type for specially structured infinite-dimensional nonlinear programs and related optimal control problems [11], [14], [15], [27].

The strong $\mathbb{L}^2$-local optimality sufficient conditions established in [14], [15], [27] apply to infinite-dimensional nonlinear programs,

$$\min J(u), \tag{1.1a}$$

subject to

$$u \in \Omega = \{u \in \mathbb{L}^\infty_m[0,1] : u(t) \overset{a.e.}{\in} U\}, \tag{1.1b}$$

where $\mathbb{L}^\infty_m[0,1]$ is the vector space of Lebesgue measurable essentially bounded functions $u(\cdot) : [0,1] \to \mathbb{R}^m$, U is a polyhedral convex set in $\mathbb{R}^m$, and the first and second Gâteaux differentials of J satisfy certain structure conditions and $\mathbb{L}^2$ continuity conditions described in section 2. The latter conditions have been shown to hold for Bolza optimal control problems with control-quadratic Hamiltonians and, more specifically, for nonconvex nonquadratic regulator optimal control problems [27]. In the present article, the $\mathbb{L}^2$-local optimality sufficiency proof strategy in [15] is extended to a larger class of smooth structured nonconvex constrained minimization problems,

$$\min J(u), \tag{1.2a}$$

subject to

$$u \in \Omega_h = \{u \in \Omega : h(u) = 0\}, \tag{1.2b}$$

where Ω is defined in (1.1b), h maps $\mathbb{L}^\infty_m[0,1]$ to $\mathbb{R}^k$, and J and $h_1, \ldots, h_k$ satisfy the structure and continuity conditions in section 2. The results obtained for (1.2) are immediately applicable to an important class of Bolza optimal control problems with nonconvex objective functions and end-constraint functions defined by

$$J(u) = P\left(x(u)(1)\right) + \int_0^1 f^0\left(t, x(u)(t), u(t)\right) dt, \tag{1.3a}$$

and

$$h_i(u) = \pi_i\left(x(u)(1)\right) + \int_0^1 \phi^0_i\left(t, x(u)(t), u(t)\right) dt, \quad i = 1, \ldots, k, \tag{1.3b}$$

where $x(u) : [0,1] \to \mathbb{R}^n$ is the unique (absolutely continuous) solution of an initial value problem

$$\frac{dx}{dt}(t) \overset{a.e.}{=} f\left(t, x(t), u(t)\right), \tag{1.3c}$$

$$x(0) = x^0. \tag{1.3d}$$

As in [27], the structure and continuity conditions of section 2 will hold for these problems when the Hamiltonians,

$$H(t,\psi,x,u) = f^0(t,x,u) + \langle \psi, f(t,x,u)\rangle, \tag{1.4}$$

and

$$H(t,\psi,x,u) = \phi_i^0(t,x,u) + \langle \psi, f(t,x,u)\rangle, \tag{1.5}$$

are quadratic in the control input vector $u \in \mathbb{R}^m$ and when P, π_i, f^0, ϕ_i^0, and f satisfy suitable smoothness and growth conditions. Note that (1.3b) admits both terminal state constraints ($\phi_i^0 = 0$) and isoperimetric constraints ($\pi_i = 0$).

In finite-dimensional nonconvex programming, second-order sufficient conditions are natural starting points in the development of sensitivity analyses and local convergence theories for gradient-related methods, multiplier methods, sequential quadratic programming methods, and other iterative computational schemes. Analogous theories rest on function space local optimality sufficient conditions and related growth estimates for J in the feasible set near an optimal u_* [3], [9], [15], [17], [18], [19], [26], [27]. In particular, a strengthened corollary of the $\mathbb{L}^2$-local optimality sufficient conditions in [11], [14], and [15] supports well-developed local convergence and active constraint identification theorems for gradient projection methods in the setting of problem (1.1) [15], [26], [27]. It seems likely that an analogous corollary of the $\mathbb{L}^2$-local optimality sufficient conditions established in section 4 will find similar uses in local convergence theories for augmented gradient projection methods and sequential quadratic programming methods applicable to problem (1.2).

2. Structure and continuity conditions. As in [15], problem (1.2) is set in the pre-Hilbert space $\{\mathbb{L}_m^\infty[0,1], \langle\cdot,\cdot\rangle_2\}$, with the standard $\mathbb{L}^2$ inner product,

$$\langle u, v\rangle_2 = \int_0^1 \langle u(t), v(t)\rangle dt,$$

associated norm,

$$\|u\|_2 = \sqrt{\langle u, u\rangle_2} = \left(\int_0^1 \|u(t)\|^2 dt\right)^{\frac{1}{2}},$$

and open balls,

$$B_2(u,\delta) = \{v \in \mathbb{L}_m^\infty[0,1] : \|v-u\|_2 < \delta\},$$

where $\langle\cdot,\cdot\rangle$ and $\|\cdot\|$ are the Euclidean inner product and norm on $\mathbb{R}^m$. The analysis in section 4 requires that the structure conditions and $\mathbb{L}^2$ continuity conditions imposed on J in [15] hold here for J *and* the constraint components h_i, $i = 1,\dots,k$. For a generic real functional F, these conditions specify that for all u in $\mathbb{L}_m^\infty[0,1]$, there exist $\nabla F(u) \in \mathbb{L}_m^\infty[0,1]$, $S_F(u) \in \mathbb{L}_{m\times m}^\infty[0,1]$, and $K_F(u) \in \mathbb{L}_{m\times m}^2([0,1]\times[0,1])$ such that

$$d^1F(u\,;\,v) = \langle \nabla F(u), v\rangle_2 = \int_0^1 \langle \nabla F(u)(t), v(t)\rangle dt, \tag{2.6}$$

$$d^2F(u\,;\,v,w) = \langle v, \nabla^2 F(u)w\rangle_2 = \int_0^1 \langle v(t), (\nabla^2 F(u)w)(t)\rangle dt, \tag{2.7a}$$

$$(\nabla^2 F(u)w)(t) = S_F(u)(t)w(t) + \int_0^1 K_F(u)(t,s)w(s)ds \tag{2.7b}$$

for all v and w in $\mathbb{L}_m^\infty[0,1]$ and almost all t in $[0,1]$ and (s,t) in $[0,1]\times[0,1]$, with

$$\lim_{\|v-u\|_2\to 0} \|S_F(v) - S_F(u)\|_\infty = 0, \tag{2.8a}$$

$$\lim_{\|v-u\|_2\to 0} \|K_F(v) - K_F(u)\|_2 = 0, \tag{2.8b}$$

where

$$\|S_F(v) - S_F(u)\|_\infty \stackrel{def}{=} ess \sup_{t\in[0,1]} \|S_F(v)(t) - S_F(u)(t)\|$$

and

$$\|K_F(v) - K_F(u)\|_2 \stackrel{def}{=} \left(\int_0^1 \int_0^1 \|K_F(v)(t,s) - K_F(u)(t,s)\|^2 dtds\right)^{\frac{1}{2}}.$$

It is also assumed that the $m\times m$ matrices $S_F(u)(t)$ and $K_F(u)(t,s)$ are symmetric, with $K_F(u)(t,s) = K_F(u)(s,t)$, and that the vector and matrix norms on $\mathbb{R}^m$ and $\mathbb{R}^{m\times m}$ in (2.6)–(2.8) are induced by the standard Euclidean inner product on $\mathbb{R}^m$. These conditions imply that F is twice continuously Fréchet differentiable on the pre-Hilbert space $\{\mathbb{L}_m^\infty[0,1], \|\cdot\|_2\}$, and therefore establish the Taylor formula,

$$\begin{aligned} F(u) - F(u_*) &= \langle \nabla F(u_*), u-u_*\rangle_2 \\ &\quad + \frac{1}{2}\langle u-u_*, \nabla^2 F(u_*)(u-u_*)\rangle_2 + r_F(u_*\,;\, u-u_*), \end{aligned} \tag{2.9a}$$

with

$$\lim_{\|u-u_*\|_2\to 0} \frac{r_F(u_*\,;\, u-u_*)}{\|u-u_*\|_2^2} = 0. \tag{2.9b}$$

Note 2.1. In the Bolza optimal control formulation (1.3), the vectors $\nabla J(u)(t)$ and matrices $S_J(u)(t)$ are formally derived from the u-gradient and u-Hessian of the Hamiltonian (1.4) evaluated on the state and co-state trajectories $x(u)(\cdot)$ and $\psi(u)(\cdot)$ corresponding to $u(\cdot)$. More precisely,

$$\nabla J(u)(t) = \nabla_u H(t, \psi(u)(t), x(u)(t), u(t))$$

and

$$S_J(u)(t) = \nabla_{uu}^2 H(t, \psi(u)(t), x(u)(t), u(t)),$$

where $x(u)(\cdot)$ solves the initial value problem, (1.3c) and (1.3d), and $\psi(u)(\cdot)$ solves the *adjoint* backward initial value problem,

$$\frac{d\psi}{dt}(t) \stackrel{a.e.}{=} -\nabla_x H(t, \psi, x(u)(t), u(t)),$$

$$\psi(1) = \nabla P(x(u)(1)).$$

In the same way, $\nabla h_i(u)(t)$ and $S_{h_i}(u)(t)$ are formally obtained by an analogous construction, with H defined by (1.5) instead of (1.4) and P replaced by π_i. If conditions (2.6)–(2.8) are to hold for J and h_i, then the corresponding Hamiltonians must be u-quadratic, and the functions P, π_i, f^0, ϕ_i^0, and f must satisfy additional differentiability and growth hypotheses to ensure existence, uniqueness, and smooth dependence on u in the $\mathbb{L}^2$ norm for the state and costate trajectories $x(u)(\cdot)$ and $\psi(u)(\cdot)$. The global hypotheses in [15] and [27] admit nontrivial nonconvex optimal control problems, including certain nonquadratic regulator problems with u-quadratic integrands f^0 and ϕ_i^0, and nonlinear state equations with u-linear right sides f.

3. Preliminary results. By definition [25], the cone of exterior normals at a point u in the convex set Ω is

$$\mathcal{N}_\Omega(u) = \{w \in \mathbb{L}_m^\infty[0,1] : \forall v \in \Omega \quad \langle w, v-u\rangle_2 \le 0\}. \tag{3.10}$$

This cone, the associated complementary orthogonal closed subspaces,

$$\mathbb{N}_\Omega(u) = \text{cl } span\mathcal{N}_\Omega(u), \tag{3.11a}$$

$$\mathbb{T}_\Omega(u) = \mathbb{N}_\Omega(u)^\perp, \tag{3.11b}$$

the constraint derivative null space,

$$\mathbb{T}_h(u_*) = \ker h'(u_*) = \{w \in \mathbb{L}_m^\infty[0,1] : \langle \nabla h_i(u_*), w\rangle_2 = 0, \quad i = 1,\dots,k\}, \tag{3.12}$$

and the subspace,

$$\mathbb{T}(u) = \mathbb{T}_\Omega(u) \cap \mathbb{T}_h(u), \tag{3.13}$$

are fundamental objects in the sufficiency theorem and proof of section 4. Basic properties of the orthogonal projection maps $P_{\mathbb{N}_\Omega(u)}$ and $P_{\mathbb{T}_\Omega(u)}$ established in [14] and [15] are reviewed in this section, and an elementary right inverse lemma is proved for the restriction of the linear map $h'(u)$ to the subspace $\mathbb{T}_\Omega(u)$. Note that the existence portion of the Hilbert space projection theorem and the standard Banach space right inverse lemma [1, pp. 79–80], [16, p. 155] can't be invoked here since the inner product space $\{\mathbb{L}_m^\infty[0,1], \langle\cdot,\cdot\rangle_2\}$ is incomplete. Our arguments rely instead on the orthogonality characterization of projector maps and the finite codimensionality of $\mathbb{T}_h(u)$. This approach is straightforward enough and works equally well for the counterpart of problem (1.2) in the Hilbert space $\{\mathbb{L}_m^2[0,1], \langle\cdot,\cdot\rangle_2\}$ (However, see Note 4.5).

References [14] and [15] supply the following key representations for the cone and subspaces in (3.10) and (3.11) and related projection decomposition formulas:

$$\mathcal{N}_\Omega(u) = \{w \in \mathbb{L}_m^\infty[0,1] : w(t) \overset{a.e}{\in} \mathcal{N}_U(u(t))\} \tag{3.14}$$

and

$$\mathbb{N}_\Omega(u) = \{w \in \mathbb{L}_m^\infty[0,1] : w(t) \overset{a.e}{\in} \mathbb{N}_U(u(t))\}, \tag{3.15a}$$

$$\mathbb{T}_\Omega(u) = \{w \in \mathbb{L}_m^\infty[0,1] : w(t) \overset{a.e}{\in} \mathbb{T}_U(u(t))\}, \tag{3.15b}$$

where

$$\mathcal{N}_U(\xi) = \{\zeta \in \mathbb{R}^m : \forall \eta \in U \quad \langle \zeta, \eta - \xi \rangle \leq 0\},$$

$$\mathbb{N}_U(\xi) = span\, \mathcal{N}_U(\xi),$$

and

$$\mathbb{T}_U(\xi) = \mathbb{N}_U(\xi)^{\perp}$$

for ξ in U. Note that the polyhedron U is the union of the relative interiors of its polyhedral faces $\{\mathcal{F}_1, \ldots, \mathcal{F}_d\}$, with $ri\ \mathcal{F}_i \cap ri\ \mathcal{F}_j = \emptyset$ for $i \neq j$, and $\mathcal{N}_U(\cdot)$ *constant* on each set $ri\ \mathcal{F}_i$. Hence, the set-valued functions $\mathcal{N}_U(u(\cdot))$, $\mathbb{N}_U(u(\cdot))$, and $\mathbb{T}_U(u(\cdot))$ are constant on the sets

$$\alpha_i(u) = u^{-1}\,[ri\ \mathcal{F}_i], \quad i = 1, \ldots, d, \tag{3.16a}$$

with

$$\alpha_i(u) \cap \alpha_j(u) = \emptyset \text{ for } i \neq j \tag{3.16b}$$

and

$$\mu\left([0,1] \setminus \cup_{i=1}^{d}\, \alpha_i(u)\right) = 0, \tag{3.16c}$$

where μ denotes Lebesgue measure. From this it follows easily that for each measurable essentially bounded z, the pointwise projection decomposition formulas,

$$\left(P_{\mathbb{N}_\Omega(u)} z\right)\ (t) = P_{\mathbb{N}_U(u(t))}\ z(t), \tag{3.17a}$$

$$\left(P_{\mathbb{T}_\Omega(u)} z\right)\ (t) = P_{\mathbb{T}_U(u(t))}\ z(t), \tag{3.17b}$$

produce measurable essentially bounded functions $P_{\mathbb{N}_\Omega(u)} z$ in $\mathbb{N}_\Omega(u)$ and $P_{\mathbb{T}_\Omega(u)} z$ in $\mathbb{T}_\Omega(u)$ such that $z - P_{\mathbb{N}_\Omega(u)} z$ and $z - P_{\mathbb{T}_\Omega(u)} z$ are orthogonal to $\mathbb{N}_\Omega(u)$ and $\mathbb{T}_\Omega(u)$, respectively. Thus, (3.17) defines *orthogonal projection maps*, $P_{\mathbb{N}_\Omega(u)}$ and $P_{\mathbb{T}_\Omega(u)}$, from $\mathbb{L}^\infty_m[0,1]$ into the complementary orthogonal closed subspaces $\mathbb{N}_\Omega(u)$ and $\mathbb{T}_\Omega(u)$. In fact, $\mathbb{N}_\Omega(u)$ and $\mathbb{T}_\Omega(u)$ are actually *pointwise orthogonal* in the sense that

$$\forall v \in \mathbb{N}_\Omega(u),\ \forall w \in \mathbb{T}_\Omega(u), \quad \langle v(t), w(t) \rangle \overset{a.e.}{=} 0. \tag{3.18}$$

A pre-Hilbert space variant of the Banach space right inverse lemma in [1, pp. 79–80] and [16, p. 155] is also needed in the sufficiency proof of section 4. The following simple lemmas lead directly to the required result in Corollary 3.3.

LEMMA 3.1. *Let* $\{a_1, \ldots, a_l\}$ *be a linearly independent set in a real inner product space* $\{\mathbb{U}, \langle \cdot, \cdot \rangle_{\mathbb{U}}\}$, *let* $\mathbb{V} = \{a_1, \ldots, a_l\}^{\perp}$, *and let* $\mathbb{U}/\mathbb{V}$ *denote the corresponding quotient space of cosets* $[u] = u + \mathbb{V}$ *with* u *in* $\mathbb{U}$. *Then* $\{[a_1], \ldots, [a_l]\}$ *is a basis for* $\mathbb{U}/\mathbb{V}$, *and consequently* $\dim \mathbb{U}/\mathbb{V} = l$.

Proof. Fix u in $\mathbb{U}$. Since $\{a_1, \ldots, a_l\}$ is linearly independent, the corresponding Gramian matrix is invertible and there is a unique $\alpha \in \mathbb{R}^l$ such that

$$\left\langle a_i, u - \sum_{j=1}^{l} \alpha_j a_j \right\rangle_{\mathbb{U}} = 0, \quad i = 1, \ldots, l,$$

or equivalently

$$u - \sum_{j=1}^{l} \alpha_j a_j \in \mathbb{V}.$$

It follows that for each $[u]$ in $\mathbb{U}/\mathbb{V}$, there is a unique $\alpha \in \mathbb{R}^l$ such that

$$[u] = \left[\sum_{j=1}^{l} \alpha_j a_j\right] = \sum_{j=1}^{l} \alpha_j [a_j]$$

with $\alpha = 0$ iff $[u] = 0$. □

LEMMA 3.2. *Let $\{a_1, \ldots, a_k\}$ be a finite set in a real inner product space $\{\mathbb{U}, \langle\cdot,\cdot\rangle_{\mathbb{U}}\}$, and define $A : \mathbb{U} \to \mathbb{R}^k$ by the rule*

$$\forall w \in \mathbb{U},\ \forall i = 1, \ldots, k, \quad (Aw)_i = \langle a_i, w\rangle_{\mathbb{U}}.$$

Then there is a real number $b > 0$ and a map $B : A(\mathbb{U}) \to \mathbb{U}$ such that

$$\forall \xi \in A(\mathbb{U}), \quad AB(\xi) = \xi, \text{ and } \|B(\xi)\|_{\mathbb{U}} \le b\|\xi\|. \tag{3.19}$$

Proof. If $a_i = 0$ for $i = 1, \ldots, k$, then $A(\mathbb{U}) = \{0\}$ and condition (3.19) holds trivially with $B(0) = 0$ and any $b \ge 0$. Suppose that $a_i \ne 0$ for some i, and relabel the a_i's if necessary so that $\{a_1, \ldots, a_l\}$ is a basis for $span\{a_1, \ldots, a_k\}$. By construction, the null space of A is $\mathbb{V} = \{a_1, \ldots, a_l\}^{\perp}$. By Lemma 3.1, $\dim\mathbb{U}/\mathbb{V} = l$. Hence the rule

$$\forall [u] \in \mathbb{U}/\mathbb{V}, \quad \hat{A}[u] = Au$$

defines a one-to-one linear map from the finite-dimensional space $\mathbb{U}/\mathbb{V}$ onto the finite-dimensional space $A(\mathbb{U}) \subset \mathbb{R}^k$, and the corresponding inverse map $\hat{A}^{-1} : A(\mathbb{U}) \to \mathbb{U}/\mathbb{V}$ is therefore automatically *bounded*, i.e.,

$$\exists \hat{b}\ \forall \xi \in A(\mathbb{U}), \quad \|\hat{A}^{-1}\xi\|_{\mathbb{U}/\mathbb{V}} \le \hat{b}\|\xi\|,$$

where

$$\|\hat{A}^{-1}\xi\|_{\mathbb{U}/\mathbb{V}} \stackrel{def}{=} \inf_{u \in \hat{A}^{-1}\xi} \|u\|_{\mathbb{U}}.$$

Put $b = \hat{b} + 1$. Then for each $\xi \in A(\mathbb{U})$, there is a $B(\xi) \in \hat{A}^{-1}\xi \subset \mathbb{U}$ such that

$$AB(\xi) = \hat{A}[B(\xi)] = \hat{A}\hat{A}^{-1}\xi = \xi$$

and

$$\|B(\xi)\|_{\mathbb{U}} \le \inf_{u \in \hat{A}^{-1}\xi} \|u\|_{\mathbb{U}} + \|\xi\|. \qquad \square$$

COROLLARY 3.3. *Let h be Gâteaux differentiable at a point u_* in Ω, with*

$$(h'(u_*)w)_i = d^1 h_i(u_*\ ;\ w) = \langle \nabla h_i(u_*), w\rangle_2, \quad i = 1, \ldots, k,$$

for some $\nabla h_i(u_*) \in \mathbb{L}^\infty_m[0,1]$ *and all* $w \in \mathbb{L}^\infty_m[0,1]$. *Then there is a real number* $b_* \geq 0$ *and a map* $B_* : h'(u_*)(\mathbb{T}_\Omega(u_*)) \to \mathbb{T}_\Omega(u_*)$ *such that for all* $w \in \mathbb{T}_\Omega(u_*)$,

$$h'(u_*)B_*(h'(u_*)w) = h'(u_*)w$$

and

$$\|B_*(h'(u_*)w)\|_2 \leq b_*\|h'(u_*)w\|.$$

Proof. Apply the lemma with $\mathbb{U} = \mathbb{T}_\Omega(u_*)$, $\langle\cdot,\cdot\rangle_\mathbb{U} = \langle\cdot,\cdot\rangle_2$, and $a_i = P_{\mathbb{T}_\Omega(u_*)}\nabla h_i(u_*)$ for $i = 1,\ldots,k$. ∎

4. $\mathbb{L}^2$-local optimality sufficient conditions. $\mathbb{L}^2$-local optimality sufficiency theorems are proved in [11], [14], and [15] for problem (1.1), where U is a polyhedral convex set in $\mathbb{R}^m$ and J satisfies the structure and continuity conditions of section 2. The developments in [14] and [15] are guided by an analogy between (1.1) and its finite-dimensional counterpart in Cartesian products $\Omega^k = U \times \cdots \times U \subset \mathbb{R}^{k\times m}$. This analogy suggests that sufficiency theorems for (1.1) may rest on the following pointwise strict complementarity condition and $\mathbb{L}^2$ coercivity condition at a point $u_* \in \Omega$:

$$-\nabla J(u_*)(t) \overset{a.e.}{\in} ri\, \mathcal{N}_U(u_*(t)), \tag{4.20a}$$

$$\forall w \in \mathbb{T}_\Omega(u_*), \qquad \langle w, \nabla^2 J(u_*)w\rangle_2 \geq c_T\, \|w\|_2^2, \tag{4.20b}$$

where $\mathcal{N}_U(\xi)$ is the cone of outer normals to the polyhedron U at $\xi \in U$, $T_\Omega(u_*)$ is the orthogonal complement of the normal cone $\mathcal{N}_\Omega(u_*)$ in the inner product space $\{\mathbb{L}^\infty_m[0,1], \langle\cdot,\cdot\rangle_2\}$ (section 3), and c_T is a positive real number. These conditions are indeed central hypotheses in the sufficiency theorems of [11], [14], and [15]; however, (4.20a) is so much weaker than its finite-dimensional componentwise counterpart in the sets Ω^k that (4.20a) and (4.20b) alone are *not* sufficient for local optimality, even in the $\mathbb{L}^\infty$ norm. More precisely, since (4.20a) does not imply that the gradient values $-\nabla J(u_*)(t)$ are essentially bounded away from the *relative boundary* $rb\, \mathcal{N}_U(u_*(t))$ for $t \in [0,1]$, and since the essential sup norm $\|u - u_*\|_\infty$ can increase without bound as $\|u - u_*\|_2$ approaches zero, it follows that (4.20a) does not ensure adequate growth of the first-order term $\langle\nabla J(u_*), u - u_*\rangle_2$ for $u \in \Omega$, $\|u - u_*\|_2$ small, and $u - u_*$ bounded away from $T_\Omega(u_*)$ *in direction* [14]. Additional hypotheses and modified proof techniques are therefore required to compensate for the deficiency in (4.20a) in the infinite-dimensional setting of (1.1). For the $\mathbb{L}^\infty$-local optimality sufficiency theorems in [11], [14], and [15], the hypotheses take the form of restrictions on the behavior of the operators $S_J(u_*)(t)$ in section 2 and the subspaces *span* $\mathcal{N}_U(u_*(t))$ near frontier points of the sets $\alpha_i \subset [0,1]$ in (3.16a), where $u_*(t)$ passes from the relative interior of one polyhedral face in U to another. On the other hand, in the $\mathbb{L}^2$-local optimality theorems of [11], [14], and [15], conditions (4.20a) and (4.20b) are supplemented by a strengthened variant of an $\mathbb{L}^2$-local optimality necessary condition akin to Pontryagin's minimum principle, namely,

$$\forall \xi \in U, \quad \mathcal{H}_J(u_*\,;\,\xi,t) - \mathcal{H}_J(u_*\,;\,u_*(t),t) \geq \frac{1}{2}\, c_P\|\xi - u_*(t)\|^2 \tag{4.20c}$$

a.e. in $[0,1]$, where c_P is a positive number and

$$\mathcal{H}_J(u_* \,;\, \xi, t) = \langle \nabla J(u_*)(t), \xi - u_*(t)\rangle + \frac{1}{2}\langle \xi - u_*(t), S_J(u_*)(t)\,(\xi - u_*(t))\rangle.$$

Conditions (4.20) appear once again in the present analysis for problem (1.2) with J replaced everywhere by a Lagrangian function,

$$L(\lambda_*, \cdot) = J(\cdot) + \langle \lambda_*, h(\cdot)\rangle,$$

and $\mathbb{T}_\Omega(u_*)$ replaced by the subspace $\mathbb{T}(u_*) = \mathbb{T}_\Omega(u_*) \cap \mathbb{T}_h(u_*)$ in (3.13). An $\mathbb{L}^2$-local optimality sufficiency theorem based on these conditions will now be proved with suitable modifications of the proof strategy developed in [15], and the following technical lemma.

LEMMA 4.1. *Suppose that h satisfies the hypotheses of Corollary* 3.3 *at some point u_* in Ω and that b_* is the nonnegative real number in Corollary* 3.3. *Assume that β is a Lebesgue measurable set in $[0,1]$ and $u \in \mathbb{L}^\infty_m[0,1]$, and put*

$$w = (1 - \chi_\beta)(u - u_*)$$

and

$$w_{\mathbb{T}_\Omega} = P_{\mathbb{T}_\Omega(u_*)} w,$$

where χ_β is the characteristic function of β. Then for some $\hat{w}$ in the subspace $\mathbb{T}(u_*)$,

$$\|w - \hat{w}\|_2 \le (1 + b_*\|h'(u_*)\|)\|w - w_{\mathbb{T}_\Omega}\|_2 \tag{4.21}$$

$$+ b_* \left(\int_\beta \sum_{i=1}^k \|\nabla h_i(u_*)(t)\|^2 dt \right)^{\frac{1}{2}} \|u - u_*\|_2 \tag{4.22}$$

$$+ b_* \|h'(u_*)(u - u_*)\|.$$

Proof. Let $B_* : h'(u_*)(\mathbb{T}_\Omega(u_*)) \to \mathbb{T}_\Omega(u_*)$ be the right inverse map in Corollary 3.3. For u in $\mathbb{L}^\infty_m[0,1]$, put

$$\hat{w} = w_{\mathbb{T}_\Omega} - B_*(h'(u_*) w_{\mathbb{T}_\Omega}).$$

By construction, $\hat{w} \in \mathbb{T}_\Omega(u_*)$ and $h'(u_*)\hat{w} = 0$, and therefore $\hat{w} \in \mathbb{T}(u_*)$. By the triangle inequality and Corollary 3.3,

$$\begin{aligned}
\|w - \hat{w}\|_2 &\le \|w - w_{\mathbb{T}_\Omega}\|_2 + \|w_{\mathbb{T}_\Omega} - \hat{w}\|_2 \\
&\le \|w - w_{\mathbb{T}_\Omega}\|_2 + b_*\|h'(u_*) w_{\mathbb{T}_\Omega}\|_2 \\
&\le (1 + b_*\|h'(u_*)\|)\|w - w_{\mathbb{T}_\Omega}\|_2 \\
&\quad + b_*(\|h'(u_*)(u - u_* - w)\| + \|h'(u_*)(u - u_*)\|)
\end{aligned}$$

with

$$\begin{aligned}
\|h'(u_*)(u - u_* - w)\| &= \left(\sum_{i=1}^k \langle \nabla h_i(u_*), \chi_\beta(u - u_*)\rangle_2^2 \right)^{\frac{1}{2}} \\
&\le \left(\int_\beta \sum_{i=1}^k \|\nabla h_i(u_*)(t)\|^2 dt \right)^{\frac{1}{2}} \|u - u_*\|_2. \qquad \square
\end{aligned}$$

THEOREM 4.2. *Suppose that the structure and continuity conditions* (2.6)–(2.8b) *are met by the objective function* J*, the constraint functions,* $h_1, \ldots, h_k$*, and hence the Lagrangians* $L(\lambda, \cdot)$ *for problem* (1.2)*. Let* $S(\lambda, u)$ *denote the corresponding matrix-valued function* $S_{L(\lambda,\cdot)}(u)$ *in conditions* (2.6)–(2.8) *for* $L(\lambda, \cdot)$*. Let* $u_* \in \Omega_h$ *and assume that for some* $\lambda_* \in \mathbb{R}^k$*,* $c_T > 0$*, and* $c_P > 0$*, the following conditions hold at* u_**:*

$$-\nabla L(\lambda_*, u_*)(t) \overset{a.e.}{\in} ri\, \mathcal{N}_U(u_*(t)), \tag{4.23a}$$

$$\forall w \in \mathbb{T}(u_*), \qquad \langle w, \nabla^2 L(\lambda_*, u_*) w\rangle_2 \geq c_T \, \|w\|_2^2, \tag{4.23b}$$

and

$$\forall \xi \in U, \quad \mathcal{H}(\lambda_*, u_* \,;\, \xi, t) - \mathcal{H}(\lambda_*, u_* \,;\, u_*(t), t) \geq \frac{1}{2}\, c_P \|\xi - u_*(t)\|^2 \tag{4.23c}$$

a.e. in $[0,1]$*, with* $\mathcal{H}(\lambda_*, u_* \,;\, \xi, t) = \mathcal{H}_{L(\lambda_*,\cdot)}(u_* \,; \xi, t)$*, i.e.,*

$$\mathcal{H}(\lambda_*, u_* \,;\, \xi, t) = \langle \nabla L(\lambda_*, u_*)(t), \xi - u_*(t)\rangle + \frac{1}{2}\langle \xi - u_*(t), S(\lambda_*, u_*)(t)\,(\xi - u_*(t))\rangle.$$

Then u_* *is an* $\mathbb{L}^2$*-local minimizer for problem* (1.2)*; more specifically, for each* c_2 *in the interval* $0 < c_2 < \min\{c_T, c_P\}$*, there is a corresponding* $\delta_2 > 0$ *such that*

$$J(u) - J(u_*) \geq \frac{1}{2} c_2 \|u - u_*\|_2^2 \tag{4.24}$$

for all $u \in \Omega_h \cap B_2(u_*, \delta_2)$*.*

Proof. Conditions (2.6)–(2.8) are satisfied by J and $h_1, \ldots, h_k$, and hence by the Lagrangian $L(\lambda_*, \cdot)$. Thus, Taylor's formula (2.9) is valid for $L(\lambda_*, \cdot)$ and the components of h, and it follows that for all u in Ω_h,

$$\begin{aligned} J(u) - J(u_*) &= \langle \nabla L(\lambda_*, u_*), u - u_*\rangle_2 \\ &\quad + \frac{1}{2}\langle u - u_*, \nabla^2 L(\lambda_*, u_*)(u - u_*)\rangle_2 + r_L(\lambda_*, u_* \,;\, u - u_*), \end{aligned} \tag{4.25a}$$

$$r_L(\lambda_*, u_* \,;\, u - u_*) = o(\|u - u_*\|_2^2), \tag{4.25b}$$

and

$$\|h'(u_*)(u - u_*)\| = \left(\sum_{i=1}^{k} \langle \nabla h_i(u_*), u - u_*\rangle_2^2\right)^{\frac{1}{2}} = o(\|u - u_*\|_2). \tag{4.26}$$

The desired estimate (4.24) will now be obtained from (4.23), (4.25), (4.26), and the decomposition,

$$u - u_* = (1 - \chi_{\varphi(u)})(u - u_*) + \chi_{\varphi(u)}(u - u_*), \tag{4.27}$$

where $\varphi(u)$ is a suitably constructed measurable set in $[0,1]$ corresponding to u.

Let $K(\lambda_*, u_*)$ denote the matrix-valued function $K_{L(\lambda_*,\cdot)}(u_*)$ in conditions (2.6)–(2.8) for $L(\lambda_*, \cdot)$. Then (2.6)–(2.8), (4.23c), (4.25), and (4.27) immediately produce

$$\begin{aligned} J(u) - J(u_*) \geq\ & \langle \nabla L(\lambda_*, u_*), w(u)\rangle_2 \\ & + \frac{1}{2}\langle w(u), \nabla^2 L(\lambda_*, u_*) w(u)\rangle_2 + \frac{1}{2} c_P \|\chi_{\varphi(u)}(u - u_*)\|_2^2 \\ & - \frac{1}{2}\left(\int\int_{(\varphi(u)^c \times \varphi(u)^c)^c} \|K(\lambda_*, u_*)(t,s)\|^2 \, dtds \right)^{\frac{1}{2}} \|u - u_*\|_2^2 \\ & + r_L(\lambda_*, u_* \,;\, u - u_*), \end{aligned}$$

with

$$w(u) = (1 - \chi_{\varphi(u)})(u - u_*),$$

where $\varphi^c = [0,1] \setminus \varphi$ and $(\varphi^c \times \varphi^c)^c = ([0,1] \times [0,1]) \setminus (\varphi^c \times \varphi^c)$. Hence (4.24) follows at once if the sets $\varphi(u)$ are constructed so that

$$\begin{aligned} -\frac{1}{2}\left(\int\int_{(\varphi(u)^c \times \varphi(u)^c)^c} \|K(\lambda_*, u_*)(t,s)\|^2 \, dtds \right)^{\frac{1}{2}} \|u - u_*\|_2^2 \\ + r_L(\lambda_*, u_* \,;\, u - u_*) \geq -\frac{1}{4}(\min\{c_T, c_P\} - c_2)\|u - u_*\|_2^2 \end{aligned} \tag{4.28}$$

and

$$\begin{aligned} \langle \nabla L(\lambda_*, u_*), w(u)\rangle_2 + \frac{1}{2}\langle w(u), \nabla^2 L(\lambda_*, u_*) w(u)\rangle_2 \\ \geq\ \frac{1}{2} c_T \|w(u)\|_2^2 - \frac{1}{4}(\min\{c_T, c_P\} - c_2)\|u - u_*\|_2^2 \end{aligned} \tag{4.29}$$

for all $u \in \Omega_h \cap B_2(u_*, \delta_2)$ with δ_2 sufficiently small. Condition (4.28) holds if δ_2 and the Lebesgue measure $\mu(\varphi(u))$ are merely sufficiently small; however, (4.29) also requires that $\sup_{t \in \varphi(u)^c} \|u(t) - u_*(t)\|$ is sufficiently small, and that $-\nabla L(\lambda_*, u_*)(t)$ is bounded away from the relative boundary of $\mathcal{N}_U(u_*(t))$ in $\mathbb{N}_U(u_*(t))$ for t in $\varphi(u)^c$. Suitable sets $\varphi(u)$ are described fully below, along with the estimates that establish (4.28) and (4.29). As in [14] and [15], the cone

$$C_\epsilon(u_*) = \{u \in \mathbb{L}_m^\infty[0,1] : \|w(u) - w(u)_{\mathbb{T}_\Omega}\|_2 \leq \epsilon \|w(u)\|_2\}$$

is at the center of this development. More specifically, (4.29) is proved by first applying (4.23a), (4.23b), and Lemma 4.1 for $w(u)$ in $C_\epsilon(u_*)$ with ϵ sufficiently small, and then invoking (4.23a) and the above-mentioned properties of $\varphi(u)$ for $w(u)$ in $C_\epsilon(u_*)^c$.

Fix c_2 in the interval $0 < c_2 < \min\{c_T, c_P\}$, and let b_* be the nonnegative real number in Lemma 4.1. Put

$$M = 1 + 3b_* \|h'(u_*)\|, \tag{4.30a}$$

and choose $\epsilon > 0$ so that

$$(2 + 3M\epsilon)(c_T + \|\nabla^2 L(\lambda_*, u_*)\|)M\epsilon \leq \frac{1}{2}(\min\{c_T, c_P\} - c_2). \tag{4.30b}$$

Note that $\mu((\varphi^c \times \varphi^c)^c) \leq 2\mu(\varphi)$, and that Lebesgue integrals are absolutely continuous functions of their domain sets. Hence, there is a $\nu \in (0,1]$ such that

$$\left(\int\int_{(\varphi^c \times \varphi^c)^c} \|K(\lambda_*, u_*)(t,s)\|^2 \, dtds \right)^{\frac{1}{2}} \leq \frac{1}{4}(\min\{c_T, c_P\} - c_2) \tag{4.31}$$

and

$$\left(\int_{\varphi} \sum_{i=1}^{k} \|\nabla h_i(u_*)(t)\|^2 dt \right)^{\frac{1}{2}} \leq \epsilon \|h'(u_*)\| \tag{4.32}$$

for all measurable sets $\varphi \subset [0,1]$ with $\mu(\varphi) \leq \nu$. Furthermore, by (4.25) and (4.26), there is a $\delta' > 0$ such that

$$|r_L(\lambda_*, u_* \,;\, u - u_*)| \leq \frac{1}{8}(\min\{c_T, c_P\} - c_2)\|u - u_*\|_2^2 \tag{4.33}$$

and

$$\|h'(u_*)(u - u_*)\| \leq \epsilon \|h'(u_*)\| \|u - u_*\|_2 \tag{4.34}$$

for all u in $\Omega_h \cap B_2(u_*, \delta')$. Recall that the set-valued map $\mathcal{N}_U(\cdot)$ is constant on each of the sets $\alpha_i(u_*)$ in (3.16a), and that for each nonempty set $\mathcal{S}$ in $\mathbb{R}^m$, the real function, $dist(\cdot, \mathcal{S}) : \mathbb{R}^m \to \mathbb{R}^1$, is continuous. Hence, if S is the relative boundary of $\mathcal{N}_U(u_*(t))$, then the formula,

$$\Delta(u_*)(t) = dist[-\nabla L(\lambda_*, u_*)(t), rb\mathcal{N}_U(u_*(t))],$$

defines a measurable extended real-valued function on $[0,1]$[1]; moreover, $\Delta(u_*)(t) > 0$ almost everywhere, in view of (4.23a). It follows that for some measurable set β in $[0,1]$,

$$\mu(\beta^c) \leq \frac{1}{2}\nu \tag{4.35a}$$

and

$$c_\beta \stackrel{def}{=} \inf_{t \in \beta} \Delta(u_*)(t) > 0. \tag{4.35b}$$

Now choose $\delta \in (0, \delta']$ so that

$$\frac{\epsilon^2 c_\beta}{\delta} - \frac{1}{2}\|\nabla^2 L(\lambda_*, u_*)\| \geq \frac{1}{2}c_T, \tag{4.36a}$$

and let

$$\delta_2 = \sqrt{\frac{\nu}{2}}\delta. \tag{4.36b}$$

Finally, for u in Ω_h, put

$$\varphi(u) = (\beta \cap \theta(u))^c = \beta^c \cup \theta(u)^c, \tag{4.37a}$$

[1] With $\Delta(u_*)(t) = +\infty$ when the relative boundary $rb\mathcal{N}_U(u_*(t))$ is empty.

with

$$\theta(u) = \{t \in [0,1] : \|u(t) - u_*(t)\| \leq \delta\}. \tag{4.37b}$$

By construction, $\delta_2 \leq \delta'$ and

$$\mu(\varphi(u)) \leq \mu(\beta^c) + \mu(\theta(u)^c) \leq \frac{\nu}{2} + \frac{\nu}{2}$$

for all u in $\Omega_h \cap B_2(u_*, \delta_2)$. Hence, (4.31) and (4.33) immediately yield (4.28) for all u in $\Omega_h \cap B_2(u_*, \delta_2)$. To see that (4.29) also holds, suppose that $u \in \Omega_h \cap B_2(u_*, \delta_2)$ and $w(u) \in C_\epsilon(u_*)$. Note that $w(u) = v(u) - u_*$, with $v(u) = (1 - \chi_{\varphi(u)})u + \chi_{\varphi(u)}u_* \in \Omega$. Hence, (4.23a) implies that

$$\langle \nabla L(\lambda_*, u_*), w(u)\rangle_2 \geq 0. \tag{4.38}$$

Furthermore, by Lemma 4.1 and the estimates (4.32) and (4.34), there is a $\hat{w}(u)$ in the subspace $\mathbb{T}(u_*)$ such that

$$\|w(u) - \hat{w}(u)\|_2 \leq M\epsilon\|u - u_*\|_2$$

and therefore

$$\|\hat{w}(u)\|_2 \leq (1 + M\epsilon)\|u - u_*\|_2$$

and

$$\begin{aligned}\|\hat{w}(u)\|_2^2 &= \|w(u)\|_2^2 - \langle w(u) + \hat{w}(u), w(u) - \hat{w}(u)\rangle_2 \\ &\geq \|w(u)\|_2^2 - (\|w(u)\|_2 + \|\hat{w}(u)\|_2)\|w(u) - \hat{w}(u)\|_2 \\ &\geq \|w(u)\|_2^2 - (2 + M\epsilon)M\epsilon\|u - u_*\|_2^2.\end{aligned}$$

Conditions (4.23b) and (4.30) now yield

$$\begin{aligned}\langle w(u), \nabla^2 L(\lambda_*, u_*)w(u)\rangle_2 &\geq c_T\|\hat{w}(u)\|_2^2 \\ &\quad - \|\nabla^2 L(\lambda_*, u_*)\|(2\|\hat{w}(u)\|_2\|w(u) - \hat{w}(u)\|_2 \\ &\qquad + \|w(u) - \hat{w}(u)\|_2^2) \\ &\geq c_T\|\hat{w}(u)\|_2^2 - \frac{1}{2}(\min\{c_T, c_P\} - c_2)\|u - u_*\|_2^2.\end{aligned}$$

This estimate and (4.38) establish (4.29) for $u \in \Omega_h \cap B_2(u_*, \delta_2)$ and $w(u) \in C_\epsilon(u_*)$. On the other hand, suppose that $u \in \Omega_h \cap B_2(u*, \delta_2)$ and $w(u) \in C_\epsilon(u_*)^c = \mathbb{L}_m^\infty[0,1] \setminus C_\epsilon(u_*)$. As in [15], put $z = c_\beta\delta^{-1}(w(u) - w(u)_{\mathbb{T}_\Omega})$ and note that $z(t) \overset{a.e.}{\in} \mathbb{N}_U(u_*(t))$ and $ess\sup_{t\in[0,1]} \|z(t)\| \leq c_\beta$, in view of (3.17) and (4.37). Conditions (4.35) and (4.37) then yield

$$-\nabla L(\lambda_*, u_*)(t) + z(t) \overset{a.e.}{\in} \mathcal{N}_U(u_*(t)),$$

in which case

$$\langle \nabla L(\lambda_*, u_*)(t), w(u)(t)\rangle \overset{a.e.}{\geq} \frac{c_\beta}{\delta}\|w(u)(t) - w(u)_{\mathbb{T}_\Omega}(t)\|^2,$$

and therefore

$$\langle \nabla L(\lambda_*, u_*), w(u)\rangle_2 \geq \frac{c_\beta}{\delta}\|w(u) - w(u)_{\mathbb{T}_\Omega}\|_2^2 \geq \frac{\epsilon^2 c_\beta}{\delta}\|w(u)\|_2^2.$$

This estimate and (4.36) establish (4.29) for $u \in \Omega_h \cap B_2(u*, \delta_2)$ and $w(u) \in C_\epsilon(u_*)^c$. □

COROLLARY 4.3. *Assume that the hypotheses of Theorem* 4.2 *hold, with the Pontryagin condition* (4.23c) *replaced by a stronger coercivity condition of the Legendre–Clebsch type, i.e., for some* $c_P > 0$,

$$\forall \xi \in \mathbb{R}^m, \quad \langle \xi, S(\lambda_*, u_*)(t)\xi \rangle \geq c_P \|\xi\|^2 \tag{4.39}$$

a.e. in $[0,1]$. *Then* u_* *is an* $\mathbb{L}^2$*-local minimizer of* J *in* Ω_h, *and the growth condition* (4.24) *holds in* $B_2(u_*, \delta_2)$ *for some* $\delta_2 > 0$.

The sufficient conditions in Theorem 4.2 imply the $\mathbb{L}^2$-quadratic growth property (4.24), which is clearly stronger than $\mathbb{L}^2$-local optimality, per se. Condition (4.24) and similar uniform local growth properties are needed in Liapunov-like local asymptotic stability analyses for iterative constrained minimization algorithms in infinite-dimensional spaces, where local minimizers (or even strict local minimizers) need not be stable local attractors for the standard iterative maps [10], [12], [13], [15], [26], [27], [9]. Examples 1 and 2 in [13] demonstrate the gap between (4.24) and $\mathbb{L}^2$-local optimality for (1.1); each of these problems has a convex objective function J and a unique global minimizer u_* that does not have property (4.24). The following simple examples accomplish the same purpose for (1.2).

Example 4.1. Let $J(u) = \int_0^1 u\ dt$, $U = [0, \infty)$, and $h(u) = \int_0^1 (1-2t)u\ dt$ in (1.2). Then $u_* = 0$ is the unique global (and hence $\mathbb{L}^2$-local) minimizer for the linear functional J in Ω_h. To see that (4.24) does not hold at u_*, let $\epsilon \in (0, 1/2)$, $u_\epsilon = \epsilon^{-\frac{1}{3}} \chi_{[\frac{1}{2}-\epsilon, \frac{1}{2}+\epsilon]}$, and note that $u_\epsilon \in \Omega_h$ and

$$J(u_\epsilon) - J(u_*) = \int_{\frac{1}{2}-\epsilon}^{\frac{1}{2}+\epsilon} \epsilon^{-\frac{1}{3}}\ dt = 2\epsilon^{\frac{2}{3}} = \frac{1}{2}\|u_\epsilon\|^4,$$

with

$$\lim_{\epsilon \to 0^+} \|u_\epsilon - u_*\|_2 = 0.$$

Now let $L(\lambda, u) = \int_0^1 u\ dt + \lambda \int_0^1 (1-2t)u\ dt$, and consider that $ri\ \mathcal{N}_U(u_*(t)) = (-\infty, 0)$, $\mathbb{T}_U(u_*(t)) = \{0\}$, and $\nabla L(\lambda, u)(t) = 1 + \lambda(1-2t)$ for $t \in [0,1]$. Moreover, (2.6)–(2.8) hold trivially with $S(\lambda, u) = 0$ and $K(\lambda, u) = 0$. Thus, (4.23a) holds at u_* for any $\lambda_* \in [-1, 1]$, and (4.23b) is satisfied trivially since $\mathbb{T}(u_*) = \{0\}$. In addition, the Pontryagin condition,

$$\forall \xi \in [0, \infty), \quad (1 + \lambda_*(1-2t))\xi \geq 0,$$

is satisfied almost everywhere in $[0,1]$ for any $\lambda_* \in [-1, 1]$. On the other hand, the strengthened Pontryagin condition (4.23c) requires that

$$\forall \xi \in [0, \infty), \quad (1 + \lambda_*(1-2t))\xi \geq \frac{1}{2} c_P \xi^2$$

almost everywhere in $[0,1]$, and this is impossible for $c_P > 0$ and $\lambda_* \in [-1, 1]$.

Example 4.2. Let $J(u) = \int_0^1 u^2\ dt - (\int_0^1 u\ dt)^2$, $U = [0,1]$, and $h(u) = \int_0^1 (1-2t)u\ dt$ in (1.2). By Cauchy's inequality, J has a global (and hence $\mathbb{L}^2$-local)

minimizer in Ω_h at $u_* = 0$. To see that (4.24) does not hold at u_*, let $\epsilon \in [0,1]$, $u_\epsilon(t) = \epsilon$ for $t \in [0,1]$, and note that $u_\epsilon \in \Omega_h$ and

$$J(u_\epsilon) - J(u_*) = \int_0^1 \epsilon^2 \, dt - \left(\int_0^1 \epsilon \, dt \right)^2 = 0,$$

with

$$\lim_{\epsilon \to 0^+} \|u_\epsilon - u_*\|_2 = 0.$$

Now let $L(\lambda, u) = \int_0^1 u^2 \, dt - (\int_0^1 u \, dt)^2 + \lambda \int_0^1 (1-2t)u \, dt$, and observe that $\mathcal{N}_U(u_*(t)) = (-\infty, 0]$, $ri\ \mathcal{N}_U(u_*(t)) = (-\infty, 0)$, $\mathbb{T}_U(u_*(t)) = \{0\}$, $\nabla L(\lambda, u)(t) = 2u(t) - 2\int_0^1 u \, dt + \lambda(1-2t)$, and $(\nabla^2 L(\lambda, u)w)(t) = (\nabla^2 J(u)w)(t) = 2w(t) - 2\int_0^1 w \, dt$. By Cauchy's inequality, $\nabla^2 J(u)$ is positive semidefinite and hence J and $L(\lambda, \cdot)$ are convex. Furthermore (2.6)–(2.8) hold for L with $S(\lambda, u)(t) = 2$ and $K(\lambda, u)(t, s) = -2$. Since $1 - 2t$ changes sign at $t = 1/2$, it is clear that (4.23a) can't hold at u_* for any λ_*. On the other hand, the weaker first-order necessary condition,

$$-\nabla L(\lambda_*, u_*)(t) \overset{a.e.}{\in} \mathcal{N}_U(u_*(t)), \tag{4.40}$$

is satisfied iff $\lambda_* = 0$, and condition (4.23b) holds trivially since $\mathbb{T}(u_*) = \{0\}$. Finally, if $\lambda_* = 0$, then $\nabla L(\lambda_*, u_*) = 0$ and the strengthened Pontryagin condition (4.23c) is satisfied, since $S(\lambda_*, u_*)(t) = 2 > 0$. □

The simple convex programs in Examples 4.1 and 4.2 show that the $\mathbb{L}^2$-quadratic growth property (4.24) may be lost if either of the conditions (4.23a) or (4.23c) is weakened appreciably. For nonconvex programs, similar relaxations in the hypotheses of Theorem 4.2 may admit functions u_* that not only fail to have property (4.24) but also are not locally optimal even in the weak $\mathbb{L}^\infty$ sense (cf. Example 1 in [11]). On the other hand, the sufficient conditions in Theorem 4.2 are certainly not *necessary* for the $\mathbb{L}^2$-quadratic growth property (4.24). In particular, suppose that h is affine and continuous in the $\mathbb{L}^2$ norm and that J is twice continuously Fréchet differentiable in the $\mathbb{L}^2$ norm and strongly convex with coercive Hessians, i.e.,

$$\forall u \exists c_u \forall w, \quad \langle w, \nabla^2 J(u) w \rangle_2 \geq c_u \|w\|_2^2.$$

Then for all $\lambda \in \mathbb{R}^k$, the Lagrangian $L(\lambda, \cdot)$ is also twice continuously Fréchet differentiable in the $\mathbb{L}^2$ norm and strongly convex, with $\nabla^2 L(\lambda, u) = \nabla^2 J(u)$ and therefore

$$J(u) - J(u_*) \geq \langle \nabla L(\lambda_*, u_*), u - u_* \rangle_2 + \frac{1}{2} c_{u_*} \|u - u_*\|_2^2 + o(\|u - u_*\|_2^2)$$

for all $u, u_* \in \Omega_h$ and $\lambda_* \in \mathbb{R}^k$. The growth property (4.24) now follows at once if the first-order necessary condition (4.40) holds for some $\lambda_* \in \mathbb{R}^k$. Thus, when h is affine, the strong coercivity condition on $\nabla^2 J$ yields (4.24) directly, *without* (2.6)–(2.8), (4.23a), and (4.23c). However, if (2.6)–(2.8) happen to hold, then the $\mathbb{L}^2$ coercivity condition on J implies that the operators $S(\lambda_*, u_*)(t)$ are essentially uniformly coercive (cf. the proof of Theorem 6.4 in [14]), and this immediately yields (4.23c).

Hypotheses (2.6)–(2.8), (4.23a), (4.23c) are also superfluous in Theorem 4.2 when $u_*(t) \overset{a.e.}{\in} \text{int } U$ (or more generally, when $u_*(t) \overset{a.e.}{\in} ri\ U$). In this exceptional case, it is possible to establish (4.24) with a variant of the classic sufficiency proof for

equality-constrained problems with feasible sets $h^{-1}(0)$ (cf. [1]). More specifically, if $u_*(t) \overset{a.e.}{\in} int\ U$, then $ri\ \mathcal{N}_U(u_*(t)) \overset{a.e}{=} \mathcal{N}_U(u_*(t)) \overset{a.e}{=} \{0\}$, $rb\ \mathcal{N}_U(u_*(t)) \overset{a.e}{=} \emptyset$, $dist\ (-\nabla L(\lambda_*, u_*)(t), rb\ \mathcal{N}_U(u_*(t))) \overset{a.e}{=} +\infty$, $\mathbb{T}_U(u_*(t) \overset{a.e.}{=} \mathbb{R}^m$, $\mathbb{T}_\Omega(u_*) = \mathbb{L}^\infty_m[0,1]$, and therefore $\mathbb{T}(u_*) = \mathbb{T}_h(u_*) = ker\ h'(u_*)$. If J and h are twice continuously Fréchet differentiable and the first-order necessary condition (4.40) holds at u_*, then Taylor's formula (2.9) reduces to

$$J(u) - J(u_*) = \frac{1}{2}\langle u - u_*, \nabla^2 L(\lambda_*, u_*)(u - u_*)\rangle_2 + o(\|u - u_*\|_2^2)$$

for $u \in \Omega_h = h^{-1}(0)$. An application of Lemma 4.1 with $\beta = \emptyset$ now produces the $\mathbb{L}^2$-quadratic growth estimate (4.24) directly from the coercivity condition (4.23b). Note that the hypothesis $u_*(t) \overset{a.e.}{\in} \text{int}\, U$ does *not* imply that $u_* \in \text{int}\, \Omega$ in either the $\mathbb{L}^2$ or the $\mathbb{L}^\infty$ sense; in fact, the $\mathbb{L}^2$ interior of Ω is *empty* whenever U is a proper subset of $\mathbb{R}^m$. Note also that if the structure and continuity conditions (2.6)–(2.8) are satisfied, then (4.40) and (4.23b) once again imply (4.23c).

Finally, if (2.6)–(2.8) hold with $K(\lambda_*, u_*) = 0$, then the proof of Theorem 4.2 can be drastically simplified. In this rare and essentially trivial case, Taylor's formula (2.9) reduces to

$$J(u) - J(u_*) = \int_0^1 [\langle \nabla L(\lambda_*, u_*)(t), u(t) - u_*(t)\rangle + \langle u(t) - u_*(t), S(\lambda_*, u_*)(t)(u(t) - u_*(t))\rangle]\, dt + o(\|u - u_*\|_2^2),$$

for $u \in \Omega_h$. The $\mathbb{L}^2$-quadratic growth condition (4.24) now follows at once from (4.23c), and the remaining hypotheses (4.23a) and (4.23b) in Theorem 4.2 are superfluous. However, it can be shown that (4.23c) implies (4.23b) in the present special circumstances.

Note 4.3. For the Bolza optimal control scheme (1.3), our earlier observations in Note 2.1 establish that $\nabla L(\lambda, u)(t)$ and $S(\lambda, u)(t)$ are formally obtained from

$$\nabla L(\lambda, u)(t) = \nabla_u H(\lambda, t, \psi(\lambda, u)(t), x(u)(t), u(t))$$

and

$$S(\lambda, u)(t) = \nabla^2_{uu} H(\lambda, t, \psi(\lambda, u)(t), x(u)(t), u(t)),$$

where $x(u)(\cdot)$ solves the initial value problem, (1.3c) and (1.3d), and $\psi(\lambda, u)(\cdot)$ solves the *adjoint* backward initial value problem,

$$\frac{d\psi}{dt}(t) \overset{a.e.}{=} -\nabla_x H(\lambda, t, \psi, x(u)(t), u(t)),$$

$$\psi(1) = \nabla P(x(u)(1)) + \sum_{i=1}^k \lambda_i \nabla \pi_i(x(u)(1)),$$

with

$$H(\lambda, t, \psi, x, u) = f^0(t, x, u) + \sum_{i=1}^k \lambda_i \phi_i^0(t, x, u) + \langle \psi, f(t, x, u)\rangle.$$

When $H(\lambda, t, \psi, x, u)$ is quadratic in u, it can now be seen that $\mathcal{H}(\lambda_*, u_* \,;\, \xi, t)$ coincides with the increment,

$$H(\lambda_*, t, \psi(\lambda_*, u_*)(t), x(u_*)(t), \xi) - H(\lambda_*, t, \psi(\lambda_*, u_*)(t), x(u_*)(t), u_*(t)).$$

Hence, condition (4.23c) amounts to a strengthening of the Pontryagin Minimum Principle for problem (1.3), i.e.,

$$H(\lambda_*, t, \psi(\lambda_*, u_*)(t), x(u_*)(t), u_*(t)) = \min_{\xi \in U} H(\lambda_*, t, \psi(\lambda_*, u_*)(t), x(u_*)(t), \xi) \tag{4.41}$$

a.e. in $[0, 1]$. Under minimal smoothness requirements on P, π_i, f^0, ϕ_i^0, and f in the Bolza formulation, condition (4.41) will hold at *normal* $\mathbb{L}^2$-local minimizers that satisfy additional end-constraint regularity and controllability conditions. Similarly, the pointwise strict complementarity condition (4.23a) is a strengthening of the Lagrange stationarity condition,

$$-\nabla L(\lambda_*, u_*)(t) \overset{a.e.}{\in} \mathcal{N}_U(u_*(t)),$$

which also follows as a corollary of the stronger Pontryagin condition (4.41) in the convex set U. Finally, the analysis in [15] for problem (1.1) suggests that the $\mathbb{L}^2$ coercivity condition (4.23b) may be viewed as a stronger version of a second-order necessary condition,

$$\forall w \in \mathbb{T}(u_*), \qquad \langle w, \nabla^2 L(\lambda_*, u_*) w \rangle_2 \geq 0; \tag{4.42}$$

however, while the necessity of (4.42) is certainly plausible, it remains to be proved in the context of problem (1.2), since the set Ω is not a polyhedron, and standard second-order necessary conditions in nonpolyhedral feasible sets require representation-dependent constraint qualifications for Ω that are not invoked in the present geometric development.

Note 4.4. For Bolza optimal control problems, $\mathbb{L}^2$ coercivity conditions like (4.23b) are implied by second-order necessary conditions, Legendre–Clebsch conditions, and disconjugacy conditions of the Jacobi type [21], [28], [29]. The Legendre–Clebsch condition (4.39) and Corollary 4.3 are also important in $\mathbb{L}^2$-local convergence theories for gradient projection methods [15], [27] and other familiar constrained minimization schemes whose iteration maps have fixed points at $\mathbb{L}^\infty$-local minimizers [13], [15]. Condition (4.39) is a natural requirement for nonconvex nonquadratic regulator Bolza problems with u-linear state equations, and integrands f^0 and ϕ_i^0 of the form $q(t, x) + \langle r(t, x), u \rangle + \langle u, s(t, x) u \rangle$, with uniformly positive-definite $m \times m$ matrices $s(t, x)$.

Note 4.5. As noted earlier, the proof techniques and results in this section are equally valid in the Hilbert space $\{\mathbb{L}^2_m[0, 1], \| \cdot \|_2\}$; however, in this complete inner product space, it is possible to treat equality constraint functions h with range in an infinite-dimensional Banach space $\mathbb{Y}$ by invoking the Banach space right inverse lemma in place of Lemma 3.2. In this setting, the Lagrangian is defined by $L(\lambda_*, \cdot) = J(u) + \lambda_*(h(\cdot))$ with λ_* a bounded linear functional on $\mathbb{Y}$, the structure and continuity hypotheses (2.6)–(2.8) are imposed directly on $L(\lambda, \cdot)$, h is assumed to be twice continuously Fréchet differentiable, the range of $h'(u_*)$ is assumed to be closed in $\mathbb{Y}$, and $h'(u_*)$ is required to satisfy the absolute continuity condition,

$$\lim_{\mu(\beta) \to 0} \sup_{\|w\|_2 = 1} \|h'(u_*) \chi_\beta w\| = 0.$$

Under these circumstances, counterparts of Lemma 4.1 and Theorem 4.2 can be proved exactly as before.

Acknowledgments. The author gratefully acknowledges several valuable exposition-related comments offered by one of the referees. These observations are incorporated in Examples 4.1 and 4.2 and the accompanying discussion between Corollary 4.3 and Note 4.3.

PONTRYAGIN'S PRINCIPLE FOR STATE-CONSTRAINED CONTROL PROBLEMS GOVERNED BY PARABOLIC EQUATIONS WITH UNBOUNDED CONTROLS*

J. P. RAYMOND† AND H. ZIDANI†

Abstract. This paper deals with optimal control problems governed by semilinear parabolic equations with pointwise state constraints and unbounded controls. Under some strong stability assumption, we obtain necessary optimality conditions in the form of a Pontryagin's minimum principle in qualified form. A Pontryagin's principle in nonqualified form is also proved without any stability condition.

Key words. optimal control, nonlinear boundary controls, semilinear parabolic equations, state constraints, Pontryagin's minimum principle, unbounded controls

1. Introduction.

This article concerns optimal control problems for the following parabolic system:

$$\frac{\partial y}{\partial t} + Ay + f(x,t,y) = 0 \text{ in } Q, \quad \frac{\partial y}{\partial n_A} + g(s,t,y,v) = 0 \text{ on } \Sigma, \quad y(0) = w \text{ in } \Omega, \tag{1.1}$$

where $\Omega \subset \mathbb{R}^N$, $Q = \Omega \times]0,T[$, $\Sigma = \Gamma \times]0,T[$, Γ is the boundary of Ω, $T > 0$, v is a boundary control, w is a control of the initial condition, and A is a second order elliptic operator. Constraints of the form

$$v \in V_{ad} \subset L^{\sigma}(\Sigma), \qquad w \in W_{ad} \subset C(\overline{\Omega}),$$

$$\phi(y) \in \mathcal{C} \tag{1.2}$$

are imposed on the control variables v, w, and the state variable y (here ϕ is a continuous mapping from $C(\overline{Q})$ into $C(\overline{D})$, $\mathcal{C} \subset C(\overline{D})$ is a closed convex subset with nonempty interior in $C(\overline{D})$, and $\overline{D}$ is a nonempty compact subset of $\overline{Q}$). The control problem is

$$(P) \quad \inf \left\{ J(y,v,w) \mid (y,v,w) \in C(\overline{Q}) \times V_{ad} \times W_{ad},\ (y,v,w) \text{ satisfies (1.1), (1.2)} \right\},$$

where the cost functional is defined by

$$J(y,v,w) = \int_Q F(x,t,y)\,dx\,dt + \int_\Sigma G(s,t,y,v)\,ds\,dt + \int_\Omega L(x,y(T),w)dx. \tag{1.3}$$

We are mainly interested in optimality conditions for such problems, in the form of Pontryagin's principles. The existence of optimal solutions for (P) is a priori assumed.

In recent years there has been growing interest in optimality conditions for state-constrained control problems governed by partial differential equations (or variational

†Universityé Paul Saltier, Laboratory MAP, URN CARS 9974, 31062 Toulouse cede 4, France (raymond@mip.ups-Tyler., zidani@mip.ups-Tyler).

inequalities). This is reflected by an important number of papers on this subject. For convex control problems we refer to [1], [4], [5], [7], and [33]. In the case of nonconvex control problems, the method of Lagrange multipliers provides optimality conditions for both bounded and unbounded controls [3], [11], [39], [34], [35]. When no qualification condition is assumed, optimality conditions are obtained in nonqualified form (optimality conditions of Fritz John type). To get optimality conditions in qualified form with a Lagrange multiplier theorem, a qualification condition such as the Zowe–Kurcyusz regularity condition is needed. (In many problems, this regularity condition corresponds to a Slater type qualification condition; see [39] and [34].)

Another method proceeds by penalizing the state constraints and then characterizing optimal solutions of the original problem as ε-solutions of the penalized problems. The characterization of ε-solutions is carried out thanks to the Ekeland variational principle. By this method optimality conditions are obtained in the form of Pontryagin principles, which are in general more precise than optimality conditions deduced from Lagrange multiplier theorems. Moreover, assumptions on the data of the problems (differentiability assumptions, convexity requirement, etc.) are less restrictive than those necessary for Lagrange multiplier theorems. To the best of our knowledge, except in [25], this method has so far been used only for problems with bounded controls (bounded in time [30], [31], [32] or in space and time [12], [23], [24], [26]).

There is a fundamental reason for this limitation. When we apply Ekeland's principle to obtain Pontryagin's principle, we need a complete metric space, let us say (V_{ad}, d_E) (the space of controls V_{ad}, endowed with the so-called Ekeland's metric d_E, in order to recover a Pontryagin principle), and a penalized functional $F_\varepsilon(v) = J_\varepsilon(y_v, v)$ (v is the control variable, y_v is the solution of the state equation corresponding to v) which must be lower semicontinuous on (V_{ad}, d_E). To prove this lower semicontinuity property we need some assumptions on J_ε and we have to prove that the mapping $\mathcal{T} : v \longmapsto y_v$ is continuous from (V_{ad}, d_E) into a Banach space Z (which depends on the considered problem). The continuity of $\mathcal{T}$ depends on regularity results for the state equation. In the problems studied in the articles mentioned above, V_{ad} is a subset of some Lebesgue space L^σ with $1 \leq \sigma \leq \infty$, and (thanks to regularity results for partial differential equations) it can be proved that the mapping $\mathcal{T}$ is continuous from L^σ into Z for every $\sigma > \bar{\sigma}$, where $\bar{\sigma}$ depends on the state equation.

If V_{ad} is bounded in L^∞ and if a sequence of controls converges for the Ekeland metric, it can easily be proved that this sequence still converges for the topology of L^σ for any $\sigma > \bar{\sigma}$. Therefore in this case, the mapping $\mathcal{T}$ is continuous and Ekeland's principle can be applied.

If V_{ad} is not bounded in L^∞, convergence in the Ekeland metric does not imply convergence in the Lebesgue space norm; moreover, (V_{ad}, d_E) is not necessarily complete. This is the reason why, up to now, in the presence of pointwise state constraints, Pontryagin's principles have only been proved for bounded controls (at least for nonconvex problems; indeed for convex problems the optimality conditions deduced from Lagrange multiplier theorems correspond to Pontryagin principles).

Let us stress that the growth conditions on the integrands and the nonlinear terms in the state equations, postulated in ([32, Chapter 4, Hypothesis 2, p. 130]) correspond to bounded controls. The same remark is valid for [12].

In [25], Fattorini and Sritharan prove a Pontryagin principle in nonqualified form for control problems of Navier–Stokes equations in which the controls are not necessarily bounded. Their idea is to work with bounded perturbations (see [25, p. 227]).

Here we consider a control set of the form

$$V_{ad} = \{v \in L^\sigma(\Sigma) \mid v(s,t) \in K_V(s,t) \text{ a.e. in, } \Sigma\},$$

where K_V is a measurable multimapping with nonempty and closed values in $\mathcal{P}(\mathbb{R})$ (see section 2). We do not think that the method developed in [25] can be applied to such a control set. Moreover, the method developed in [25] deals with Pontryagin principles in nonqualified form and requires some convexity condition on the cost functional (see Hypothesis 2.9 in [25]).

The purpose of this paper is to extend the method based on Ekeland's principle to problems with unbounded controls. In order to explain the main ideas of this extension let us recall the starting point of the method described above. If $\bar{v}$ is an ε^2-solution of the problem

$$(P_\varepsilon) \qquad \inf\{F_\varepsilon(v) \mid v \in V_{ad}\},$$

where F_ε and (V_{ad}, d_E) satisfy the assumptions of Ekeland's principle, then there exists another ε^2-solution v_ε such that

$$d_E(v_\varepsilon, \bar{v}) \le \varepsilon \quad \text{and} \quad F_\varepsilon(v_\varepsilon) - F_\varepsilon(v) \le \varepsilon d(v, v_\varepsilon) \quad \text{for every } v \in V_{ad}.$$

In order to exploit this optimality condition, v is replaced by some perturbation of v_ε. The methods developed in [8], [12], [21], [24], [26], [31], and [32] differ both in their choices of F_ε and in their choices of the perturbations. Pontryagin principles in qualified form are only obtained in [8] and [12] by choosing for F_ε a regularization of an exact penalized functional. A Pontryagin principle is then obtained under a strong stability condition. Pontryagin principles in nonqualified form are obtained in [8] under a weak stability condition by a method of spike perturbations. With another choice for the penalized functional and other kinds of perturbations, Pontryagin principles in nonqualified form are obtained in [24], [26], [31], and [32]. In [24] Fattorini and Murphy use a method of multispike perturbations. The type of perturbations used in [31], [40], [26], [12], [13], and [32] can be viewed as a generalization of multispike perturbations, which we call diffuse perturbations.

In contrast to spike or multispike perturbations, which are precisely localized, a diffuse perturbation is not localized around some points but is implicitly defined by some relations (see [12], [31], [40], [42], and [26]). The existence of diffuse perturbations satisfying relations a priori defined is proved in [29], [30], [26], and in [12] in a constructive manner. To our knowledge this kind of perturbation has been introduced for the first time by Yao [40] and Li [28]. We prove here that all the relations needed to define a diffuse perturbation can be obtained as a consequence of the Lyapunov convexity theorem. Connections with Lyapunov's convexity theorem or with Uhl's theorem are clarified in [42, p. 1315], and [30]. (See also [22] for another process.)

Preliminary results related to this topic were announced in [36]. The metric space used in [36] is different from the one defined in section 3.2. This is the reason why a convexity condition (assumption (A7)) is needed in [36] to ensure some semicontinuity property. Thus, the methods of the present paper improve upon those of [36].

The paper is organized as follows. In the next section we formulate the control problem governed by a semilinear parabolic equation and state the main results: the weak and strong Pontryagin's principles. In section 3 we give some regularity results for solutions of the state and adjoint equations. In section 4, we derive some technical results used in section 5 to prove the main result stated in section 2.

2. Assumptions and main results. Throughout the paper Ω is a bounded open subset of $\mathbb{R}^N$ ($N \geq 2$) of class $C^{2,\beta}$ for some $0 < \beta \leq 1$ (that is, the boundary Γ of Ω is an $(N-1)$-dimensional manifold of class $C^{2,\beta}$ such that Ω lies locally on one side of Γ. A function is of class $C^{2,\beta}$ if it is of class C^2 and if its second order derivatives are Hölder continuous of exponent β). We denote by q, σ positive numbers satisfying

$$q > N/2 + 1, \quad \sigma > N + 1 \quad \text{and} \quad q\sigma + q > qN + 2\sigma.$$

The differential operator A in equation (1.1) is defined by

$$Ay(x) = -\sum_{i,j=1}^{N} D_i(a_{ij}(x)D_j y(x)),$$

with coefficients a_{ij} belonging to $C^{1,\beta}(\overline{\Omega})$ and satisfying the conditions

$$(2.1)\quad a_{ij}(x) = a_{ji}(x) \qquad \text{for every } i,j \in \{1,...,N\}, \qquad m_0|\xi|^2 \leq \sum_{i,j=1}^{N} a_{ij}(x)\xi_j\xi_i$$

for all $x \in \overline{\Omega}$ and all $\xi \in \mathbb{R}^N$, with $0 < m_0$ (D_i denotes the partial derivative with respect to x_i). In (1.1), $\frac{\partial y}{\partial n_A}$ is the conormal derivative of y with respect to A, that is,

$$\frac{\partial y}{\partial n_A}(s,t) = \sum_{i,j} a_{ij}(s)D_j y(s,t)n_i(s),$$

where $n = (n_1, \ldots, n_N)$ is the unit normal to Γ outward Ω.

For all $1 \leq \tau \leq \infty$, the norms in the spaces $L^\tau(\Omega)$, $L^\tau(\Gamma)$, $L^\tau(Q)$, $L^\tau(\Sigma)$ will be denoted by $\|\cdot\|_{\tau,\Omega}$, $\|\cdot\|_{\tau,\Gamma}$, $\|\cdot\|_{\tau,Q}$, $\|\cdot\|_{\tau,\Sigma}$. The Hilbert space $W(0,T;H^1(\Omega),(H^1(\Omega))') = \{y \in L^2(0,T;H^1(\Omega)) \mid \frac{dy}{dt} \in L^2(0,T;(H^1(\Omega))')\}$, endowed with its usual norm, will be denoted by $W(0,T)$. Also set $\overline{\Omega}_0 = \overline{\Omega} \times \{0\}$ and $\overline{\Omega}_T = \overline{\Omega} \times \{T\}$.

2.1. Assumptions.

(A1) For every $y \in \mathbb{R}$, $f(\cdot,y)$ is measurable on Q. For almost every $(x,t) \in Q$, $f(x,t,\cdot)$ is of class C^1 on $\mathbb{R}$. The following estimates hold:

$$|f(x,t,0)| \leq M_1(x,t), \qquad C_0 \leq f'_y(x,t,y) \leq M_1(x,t)\eta(|y|),$$

where M_1 belongs to $L^q(Q)$, η is a nondecreasing function from $\mathbb{R}^+$ to $\mathbb{R}^+$, and $C_0 \in \mathbb{R}$. (We have denoted by f'_y the partial derivative of f with respect to y, and in the following we adopt the same kind of notation for other functions.)

(A2) For every $(y,v) \in \mathbb{R}^2$, $g(\cdot,y,v)$ is measurable on Σ. For almost every $(s,t) \in \Sigma$ and every $v \in \mathbb{R}$, $g(s,t,\cdot,v)$ is of class C^1 on $\mathbb{R}$. For almost every $(s,t) \in \Sigma$, $g(s,t,\cdot)$ and $g'_y(s,t,\cdot)$ are continuous on $\mathbb{R} \times \mathbb{R}$. The following estimates hold:

$$|g(s,t,0,v)| \leq M_2(s,t) + m_1|v|, \qquad C_0 \leq g'_y(s,t,y,v) \leq (M_2(s,t) + m_1|v|)\eta(|y|),$$

where M_2 belongs to $L^\sigma(\Sigma)$, $m_1 > 0$, and C_0 and η are as in (A1).

(A3) For every $(y,w) \in \mathbb{R}^2$, $L(\cdot,y,w)$ is measurable on Ω. For almost every $x \in \Omega$, $L(x,\cdot)$ is of class C^1 on $\mathbb{R} \times \mathbb{R}$. The following estimate holds:

$$|L(x,y,w)| + |L'_w(x,y,w)| + |L'_y(x,y,w)| \leq M_3(x)\eta(|w|)\eta(|y|),$$

where $M_3 \in L^1(\Omega)$, and η is as in (A1).

(A4) For every $y \in \mathbb{R}$, $F(\cdot, y)$ is measurable on Q. For almost every $(x,t) \in Q$, $F(x,t,\cdot)$ is of class C^1 on $\mathbb{R}$. The following estimate holds:

$$|F(x,t,y)| + |F'_y(x,t,y)| \le M_4(x,t)\eta(|y|),$$

where $M_4 \in L^1(Q)$, and η is as in (A1).

(A5) For every $(y,v) \in \mathbb{R}^2$, $G(\cdot,y,v)$ is measurable on Σ. For almost every $(s,t) \in \Sigma$ and every $v \in \mathbb{R}$, $G(s,t,\cdot,v)$ is of class C^1 on $\mathbb{R}$. For almost every $(s,t) \in \Sigma$, $G(s,t,\cdot)$ and $G'_y(s,t,\cdot)$ are continuous on $\mathbb{R} \times \mathbb{R}$. The following estimate holds:

$$|G(s,t,y,v)| + |G'_y(s,t,y,v)| \le (M_5(s,t) + m_1|v|^\sigma)\eta(|y|),$$

where $M_5 \in L^1(\Sigma)$, and m_1 and η are as in (A2).

(A6) The set of constraints on v is defined by

$$V_{ad} = \{v \in L^\sigma(\Sigma) \mid v(s,t) \in K_V(s,t) \text{ for a.e. } (s,t) \in \Sigma\},$$

where K_V is a measurable multimapping with nonempty and closed values in $\mathcal{P}(\mathbb{R})$ (that is, the set of all subsets of $\mathbb{R}$). The constraint on the initial condition is $w \in W_{ad}$, where W_{ad} is a closed convex subset of $C(\overline{\Omega})$.

(A7) In the state constraint (1.2), ϕ is a mapping of class C^1 from $C(\overline{Q})$ into $C(\overline{D})$, $\overline{D}$ is a nonempty compact subset of $\overline{Q}$, and $\mathcal{C} \subset C(\overline{D})$ is a closed convex subset with nonempty interior in $C(\overline{D})$.

The assumption "$\mathcal{C}$ has a nonempty interior in $C(\overline{D})$" is used, in nonqualified form of the Pontryagin's principle, to prove that the pair of multipliers is nonzero (see section 5.3). In section 3.1 we recall an existence and uniqueness result in $W(0,T) \cap C(\overline{Q})$ for (1.1), already proved in [37]. Therefore, the state constraint (1.2) makes sense because the weak solution of (1.1) is continuous on $\overline{Q}$. Let us give some examples of state constraints described by (1.2).

Example 2.1. If we choose $\overline{D} = \overline{\Omega} \times \{T\}$, we have a problem with a terminal state constraint. We may consider $\phi(y) = y|_{\overline{D}}$ ($y|_{\overline{D}}$ is the restriction of y to $\overline{D}$) and $\mathcal{C} = \{z \in C(\overline{D}) \mid ||z - y_T||_{C(\overline{D})} \le \epsilon\}$, where $\epsilon > 0$ and $y_T \in C(\overline{D})$ are given.

Example 2.2. We consider $\phi(y) = \psi(\cdot, y(\cdot))|_{\overline{D}}$, where $\psi \in C(\overline{Q} \times \mathbb{R})$ is such that ψ'_y (the partial derivative of ψ with respect to y) belongs to $C(\overline{Q} \times \mathbb{R})$, $\mathcal{C} = \{z \in C(\overline{D}) \mid z \le 0\}$, and $\overline{D}$ is any nonempty compact subset of $\overline{Q}$.

2.2. Strong stability assumption. For $\gamma \ge 0$, set

$$\mathcal{C}_\gamma = \left\{ \varphi \in C(\overline{D}) \mid \inf_{z \in \mathcal{C}} \|\varphi - z\|_{C(\overline{D})} \le \gamma \right\},$$

and consider the perturbed state constraint

$$\phi(y) \in \mathcal{C}_\gamma. \tag{2.2}$$

We denote by (P_γ) the problem

$$(P_\gamma) \quad \inf \left\{ J(y,v,w) \mid (y,v,w) \in C(\overline{Q}) \times V_{ad} \times W_{ad},\ (y,v,w) \text{ satisfies (1.1), (2.2)} \right\}.$$

Observe that (P) is identical to (P_0). Following [8], [12], and [13], we say that (P_γ) is strongly stable on the right if there exist $\tilde{\varepsilon} > 0$ and $\tilde{r} > 0$ such that, for every $\gamma' \in [\gamma, \gamma + \tilde{\varepsilon}]$, we have

$$\inf(P_\gamma) - \inf(P_{\gamma'}) \le \tilde{r}(\gamma - \gamma').$$

With the additional assumption (A8), a Pontryagin principle for (P) may be obtained in qualified form. Some remarks on (A8) are made after Theorem 2.1.

(A8) (P) is strongly stable on the right.

2.3. Statement of the main result. We define the boundary Hamiltonian function by

$$H_\Sigma(s,t,y,v,p,\nu) = \nu G(s,t,y,v) - pg(s,t,y,v)$$

for every $(s,t,y,v,p,\nu) \in \Gamma \times [0,T] \times \mathbb{R}^4$. The main result of this paper is the Pontryagin principle for (P), stated in the following theorem.

THEOREM 2.1. *If* (A1)–(A7) *are fulfilled and if* $(\bar y, \bar v, \bar w)$ *is a solution of* (P)*, then there exist* $\bar p \in L^1(0,T;W^{1,1}(\Omega))$*,* $\bar\nu \in \mathbb{R}$*,* $\bar\mu \in \mathcal{M}(\overline{D})$ *(the space of Radon measures on* $\overline{D}$*) and a measurable subset* $\widetilde{\Sigma} \subset \Sigma$ *such that*

$$(\bar\nu,\bar\mu) \neq 0, \quad \bar\nu \geq 0, \quad \langle \bar\mu, z - \phi(\bar y)\rangle_{\mathcal{M}(\overline{D})\times C(\overline{D})} \leq 0 \qquad \text{for all } z \in \mathcal{C}, \tag{2.3}$$

$$\begin{cases} -\dfrac{\partial \bar p}{\partial t} + A\bar p + f'_y(x,t,\bar y)\bar p = \bar\nu F'_y(x,t,\bar y) + [\phi'(\bar y)^*\bar\mu]|_Q & \text{in } Q, \\ \dfrac{\partial \bar p}{\partial n_A} + g'_y(s,t,\bar y,\bar v)\bar p = \bar\nu G'_y(s,t,\bar y,\bar v) + [\phi'(\bar y)^*\bar\mu]|_\Sigma & \text{on } \Sigma, \\ \bar p(T) = \bar\nu L'_y(x,\bar y(T),\bar w) + [\phi'(\bar y)^*\bar\mu]|_{\overline{\Omega}_T} & \text{in } \Omega, \end{cases} \tag{2.4}$$

$$H_\Sigma(s,t,\bar y(s,t),\bar v(s,t),\bar p(s,t),\bar\nu) = \min_{v\in K_V(s,t)} H_\Sigma(s,t,\bar y(s,t),v,\bar p(s,t),\bar\nu) \tag{2.5}$$

for all $(s,t) \in \widetilde{\Sigma}$*, with* $\mathcal{L}^N(\widetilde{\Sigma}) = \mathcal{L}^N(\Sigma)$,

$$\int_\Omega \bar\nu L'_w(x,\bar y(T),\bar w)(\bar w - w)\,dx + \langle \bar p(0) + [\phi'(\bar y)^*\bar\mu]|_{\overline{\Omega}_0}, \bar w - w\rangle_{\mathcal{M}(\overline{\Omega})\times C(\overline{\Omega})} \leq 0 \tag{2.6}$$

for all $w \in W_{ad}$*, where* $[\phi'(\bar y)^*\bar\mu]|_Q$ *is the restriction of* $[\phi'(\bar y)^*\bar\mu]$ *to* Q*,* $[\phi'(\bar y)^*\bar\mu]|_\Sigma$ *is the restriction of* $[\phi'(\bar y)^*\bar\mu]$ *to* Σ*,* $[\phi'(\bar y)^*\bar\mu]|_{\overline{\Omega}_T}$ *is the restriction of* $[\phi'(\bar y)^*\bar\mu]$ *to* $\overline{\Omega}_T$*, and* $[\phi'(\bar y)^*\bar\mu]|_{\overline{\Omega}_0}$ *is the restriction of* $[\phi'(\bar y)^*\bar\mu]$ *to* $\overline{\Omega}_0$*,* ($[\phi'(\bar y)^*\bar\mu]$ *is the Radon measure on* $\overline{Q}$ *defined by* $z \longmapsto \langle \bar\mu, \phi'(\bar y)z\rangle_{\mathcal{M}(\overline{D})\times C(\overline{D})}$ *for* $z \in C(\overline{Q})$ *and* $\mathcal{L}^N$ *denotes the* N*-dimensional Lebesgue measure*)*. Moreover, if* (A8) *is satisfied, we can take* $\bar\nu = 1$ *in* (2.4)*,* (2.5)*, and* (2.6)*.*

The meaning of weak solutions for (2.4), regularity results for $\bar p$, and the definition of $\bar p(0)$ are given in section 3.

The notion of stability considered in (A8) is closely related to the notion of calmness introduced by Clarke [16]. In the above setting this notion is due to Burke [9]. It has been used in control problems by Bonnans and Casas [8]. We do not know sufficient conditions ensuring that a state-constrained control problem is strongly stable on the right. However, even if (P) is not strongly stable on the right, (P_γ) will be strongly stable for all $\gamma > 0$, except on a subset of $\mathbb{R}^+$ of zero Lebesgue measure [8], [12]. In some situations, Pontryagin's principles in qualified form may be derived from a nonqualified form. Consider the example described below.

Example 2.3. Suppose that Ω is connected and consider the state equation

$$\frac{\partial y}{\partial t} - \Delta y = 0 \text{ in } Q, \quad \frac{\partial y}{\partial n} + y^4 = v \text{ on } \Sigma, \quad y(0) = y_0 \text{ on } \Omega, \tag{2.7}$$

where y_0 is a given function in $C(\overline{\Omega})$. We set $V_{ad} = \{v \in L^\sigma(\Sigma) \mid v(s,t) \geq 0 \text{ a.e. on } \Sigma\}$. The state constraints are defined by

$$0 \leq y(x,t) \leq \gamma_d \quad \text{on } \overline{Q},$$

for some given $\gamma_d > 0$. (We suppose that $0 \leq y_0(x) < \gamma_d$ on $\overline{\Omega}$.) Since for $v \in V_{ad}$, the solution y of (2.7) is nonnegative, then we can restrict the state constraints to $y(x,t) \leq \gamma_d$. We denote by J a cost functional defined as in (1.3), with $w \equiv y_0$, for which assumptions (A3)–(A5) are satisfied. We suppose that the control problem

$$(P_{ex}) \qquad \inf\{J(y,v) \mid y \in C(\overline{Q}),\ v \in V_{ad},\ (y,v) \text{ satisfies (2.7)},\ y(x,t) \leq \gamma_d \text{ on } \overline{Q}\}$$

admits solutions. We wish to prove that every solution of (P_{ex}) satisfies the Pontryagin principle in qualified form. For this we suppose that $(\bar{y}, \bar{v})$ is a solution which satisfies the Pontryagin principle in nonqualified form. For (P_{ex}), the adjoint equation (2.4) corresponding to $(\bar{y}, \bar{v})$ and $\bar{\nu} = 0$ is

$$-\frac{\partial \bar{p}}{\partial t} - \Delta \bar{p} = \bar{\mu}_Q \text{ in } Q, \quad \frac{\partial \bar{p}}{\partial n} + 4\bar{y}^3 \bar{p} = \bar{\mu}_\Sigma \text{ on } \Sigma, \quad \bar{p}(T) = \bar{\mu}_{\overline{\Omega}_T} \text{ on } \overline{\Omega},$$

where the measure $\bar{\mu} = \bar{\mu}_Q + \bar{\mu}_\Sigma + \bar{\mu}_{\overline{\Omega}_T}$ satisfies

$$\bar{\mu} \geq 0, \quad \bar{\mu} \neq 0, \quad \langle \bar{\mu}, \bar{y} - \gamma_d \rangle_{\mathcal{M}(\overline{Q}) \times C(\overline{Q})} = 0. \tag{2.8}$$

(Observe that, for (P_{ex}), (2.8) corresponds to (2.3) with $\bar{\nu} = 0$.) The Pontryagin principle in nonqualified form is expressed as

$$\bar{p}(s,t)(v - \bar{v}(s,t)) \geq 0 \quad \text{for all } v \geq 0 \quad \text{and for almost all } (s,t) \in \Sigma. \tag{2.9}$$

We set $\bar{t} = \inf\{t \in [0,T] \mid \bar{\mu}(\overline{\Omega} \times]t,T]) = 0\}$. Following [34, Theorems 4.2, 4.3, and Remark 4.7], we can define $\bar{p}_{\overline{\Omega}}(t^+)$ as the function in $L^1(\Omega)$ which satisfies the Green formula

$$\int_{\Omega \times]t,T[} \bar{p} \left(\frac{\partial y}{\partial t} - \Delta y \right) dx\, dt + \int_{\Gamma \times]t,T[} \bar{p} \left(\frac{\partial y}{\partial n} + 4\bar{y}^3 y \right) ds\, dt$$

$$= \langle \bar{\mu}_{\Omega \times]t,T[}, y \rangle_{\mathcal{M}_b(\Omega \times]t,T[) \times C_b(\Omega \times]t,T[)} + \langle \bar{\mu}_{\Gamma \times]t,T[}, y \rangle_{\mathcal{M}_b(\Gamma \times]t,T[) \times C_b(\Gamma \times]t,T[)}$$

$$+ \langle p(T), y(T) \rangle_{\mathcal{M}(\overline{\Omega}) \times C(\overline{\Omega})} - \langle p_{\overline{\Omega}}(t^+), y(t) \rangle_{\mathcal{M}(\overline{\Omega}) \times C(\overline{\Omega})},$$

for all $y \in C^2(\overline{Q})$ (for $A \subset \overline{Q}$, $\bar{\mu}_A$ denotes the restriction of $\bar{\mu}$ to A). With such a definition for $\bar{p}_{\overline{\Omega}}(t^+)$, the restriction of $\bar{p}$ to $\overline{\Omega} \times]0,t[$ is the unique solution of

$$-\frac{\partial p}{\partial t} - \Delta p = \bar{\mu}_{\Omega \times]0,t[} \text{ in } \Omega \times]0,t[, \quad \frac{\partial p}{\partial n} + 4\bar{y}^3 p = \bar{\mu}_{\Gamma \times]0,t[} \text{ on } \Gamma \times]0,t[,$$
$$p(t) = \bar{p}_{\overline{\Omega}}(t^+) + \bar{\mu}_{\overline{\Omega} \times \{t\}} \text{ on } \overline{\Omega}.$$

We can easily prove that if $\bar{p}_{\overline{\Omega}}(t^+) = 0$, then $\bar{\mu}_{\overline{\Omega}\times]t,T]} = 0$. From the definition of $\bar{t}$ we see that, for every $\varepsilon > 0$, $\bar{p}_{\overline{\Omega}}((\bar{t}-\varepsilon)^+) \geq 0$ and $\bar{p}_{\overline{\Omega}}((\bar{t}-\varepsilon)^+) \neq 0$. Let $\hat{p}$ be the solution of

$$-\frac{\partial p}{\partial t} - \Delta p = 0 \text{ in } \Omega\times]0,\bar{t}-\varepsilon[, \quad \frac{\partial p}{\partial n} + kp = 0 \text{ on } \Gamma\times]0,\bar{t}-\varepsilon[, \quad p(t) = \bar{p}_{\overline{\Omega}}((\bar{t}-\varepsilon)^+) \text{ on } \overline{\Omega},$$

where $k = \max\{4\bar{y}^3(x,t) \mid (x,t) \in \overline{Q}\}$. By a comparison principle, we can verify that $\bar{p} \geq \hat{p}$ on $\overline{\Omega}\times]0,\bar{t}-\varepsilon[$ and in particular on $\Gamma\times]0,\bar{t}-\varepsilon[$. Moreover, $\hat{p}$ belongs to $C^2(\overline{Q}\times[0,\bar{t}-\varepsilon[)$, and the function $\hat{p}(\bar{t}-2\varepsilon)$ belongs to $C^2(\overline{\Omega})$, is nonnegative, and not identically zero. Therefore, from the maximum principle for classical solutions of parabolic equations, we deduce that $\hat{p} > 0$ on $\overline{\Omega}\times[0,\bar{t}-2\varepsilon[$. Thus, $\bar{p}(s,t) > 0$ a.e. on $\Gamma\times]0,\bar{t}[$. With (2.9), this implies $\bar{v} \equiv 0$ on $\Gamma\times]0,\bar{t}[$. Thus, $0 \leq \bar{y}(x,t) \leq \max_{\overline{\Omega}} y_0 < \gamma_d$ on $\overline{\Omega}\times[0,\bar{t}]$. From (2.8), it follows $\bar{\mu}_{\overline{\Omega}\times[0,\bar{t}]} = 0$. Thus, $\bar{\mu} \equiv 0$ and we get a contradiction.

In this simple example we see that the Pontryagin principle in qualified form follows from the Pontryagin principle in nonqualified form.

3. State equation and adjoint equation.

3.1. Existence, uniqueness and regularity of the state variable.

THEOREM 3.1. *Under assumptions* (A1) *and* (A2), *if* $v \in L^\sigma(\Sigma)$ *and* $w \in C(\overline{\Omega})$, *then* (1.1) *admits a unique weak solution* y_{vw} *in* $W(0,T)\cap C(\overline{Q})$. *This solution satisfies*

$$\|y_{vw}\|_{\infty,Q} \leq C_1(\|v\|_{\sigma,\Sigma} + \|w\|_{\infty,\Omega} + 1),$$

where $C_1 = C_1(T,\Omega,N,q,\sigma,C_0)$. *Moreover, the mapping* $(v,w) \longmapsto y_{vw}$ *is continuous from* $L^\sigma(\Sigma)\times C(\overline{\Omega})$ *into* $C(\overline{Q})$.

Proof. The existence of a unique weak solution y_{vw} in $W(0,T)\cap C(\overline{Q})$ for equation (1.1), is proved in ([37, Theorem 3.1]). The last part of the theorem can be proved as in ([37], Proposition 4.3). □

COROLLARY 3.2. *For every* $k > 0$ *and every* $\varepsilon > 0$, *there exist* $C_2 = C_2(T,\Omega,N,q,\sigma,C_0,k)$, $C_3 = C_3(T,\Omega,N,q,\sigma,C_0,k,\varepsilon)$, *and* $\alpha > 0$ *such that, for every* $(v,w) \in V_{ad}\times W_{ad}$ *satisfying* $\|v\|_{L^\sigma(\Sigma)} + \|w\|_{\infty,\Omega} \leq k$, *the weak solution* y_{vw} *of* (1.1) *corresponding to* (v,w) *is Hölder continuous on* $[\varepsilon,T]\times\overline{\Omega}$ *and obeys*

$$\|y_{vw}\|_{C(\overline{Q})} \leq C_2, \qquad \|y_{vw}\|_{C^{\alpha,\frac{\alpha}{2}}(\overline{\Omega}\times[\varepsilon,T])} \leq C_3.$$

Moreover, if w *is Hölder continuous on* $\overline{\Omega}$, *then* y_{vw} *is Hölder continuous on* $\overline{Q}$.

Proof. Since y_{vw} belongs to $C(\overline{Q})$, thanks to (A1)–(A2), we see that y_{vw} is also the unique weak solution of

$$\frac{\partial y}{\partial t} + Ay = \tilde{f} \text{ in } Q, \quad \frac{\partial y}{\partial n_A} = \tilde{g} \text{ on } \Sigma, \quad y(0) = w \text{ in } \Omega,$$

where

$$\tilde{f}(\cdot) = -f(\cdot, y_{vw}(\cdot)) \in L^q(Q), \qquad \tilde{g}(\cdot) = -g(\cdot, y_{vw}(\cdot), v(\cdot)) \in L^\sigma(\Sigma).$$

We denote by γ_0 the trace operator from $L^{\sigma'}(0,T;W^{1,\nu}(\Omega))$ into $L^{\sigma'}(0,T;W^{1-\frac{1}{\nu},\nu}(\Gamma))$ (with $\nu = N/(\sigma N - N + 1)$), and by i the embedding from $L^{\sigma'}(0,T;W^{1-\frac{1}{\nu},\nu}(\Gamma))$ into $L^{\sigma'}(0,T;L^{\sigma'}(\Gamma))$, we can write

$$\langle \tilde{g}, (i\circ\gamma_0)z\rangle_{L^\sigma(\Sigma)\times L^{\sigma'}(\Sigma)} = \langle (\gamma_0^t \circ i^t)\tilde{g}, z\rangle_{L^\sigma(0,T;(W^{1,\nu}(\Omega))')\times L^{\sigma'}(0,T;W^{1,\nu}(\Omega))}$$

for every $z \in L^{\sigma'}(0,T;W^{1,\nu}(\Omega))$. We can identify $(\gamma_0^t \circ i^t)\tilde{g}$ with $(f_0, f_1, \ldots, f_N) \in (L^\sigma(0,T;L^{\nu'}(\Omega)))^{N+1}$ $(\nu' = \frac{N\sigma}{N-1})$ in the following manner:

$$\langle (\gamma_0^t \circ i^t)\tilde{g}, z\rangle_{L^\sigma(0,T;(W^{1,\nu}(\Omega))')\times L^{\sigma'}(0,T;W^{1,\nu}(\Omega))} = \int_Q (f_0 z + \Sigma_i f_i D_i z)\, dxdt$$

for every $z \in L^{\sigma'}(0,T;W^{1,\nu}(\Omega))$. Therefore, y_{vw} is the weak solution (in the sense of [17]) of the initial boundary value problem

$$\frac{\partial y}{\partial t} - \operatorname{div}(a(x,t,\nabla y)) = \tilde{f} + f_0 \text{ in } Q, \quad a(x,t,\nabla y).n = 0 \text{ on } \Sigma, \quad y(0) = w \text{ in } \Omega, \tag{3.1}$$

where

$$a(x,t,\nabla y) = \left(\sum_{j=1}^N a_{ij} D_j y - f_i\right)_{i=1,..,N}.$$

Now we can easily verify that assumptions of ([17, Chapter 3, Theorem 1.3]) are satisfied by system (3.1), and the Hölder continuity results of corollary 3.2 follow from this theorem. □

3.2. Metric space of controls. To apply the Ekeland variational principle, we have to define a metric space of controls in order that the mapping $(v,w) \longmapsto y_{vw}$ be continuous from this metric space to $C(\overline{Q})$. Thanks to Theorem 3.1, this continuity condition will be realized if convergence in the metric space of controls implies convergence in $L^\sigma(\Sigma) \times C(\overline{\Omega})$. In the case where boundary controls are bounded, convergence in (V_{ad}, d_E) (where d_E is the so-called Ekeland distance) implies convergence in $L^\sigma(\Sigma)$. This condition is no longer true for unbounded controls (see [25, p. 227]). To overcome this difficulty, we define a new metric space in the following way.

Let $\tilde{v}$ be in V_{ad} (in section 5, $\tilde{v}$ will be an optimal boundary control that we want to characterize). For $0 < k < \infty$, we define the set

$$V_{ad}(\tilde{v},k) = \{v \in V_{ad} \mid |v(s,t) - \tilde{v}(s,t)| \le k \text{ for a.e. } (s,t) \in \Sigma\}.$$

We endow the set $V_{ad}(\tilde{v},k) \times W_{ad}$ with the following metric:

$$d((v_1,w_1),(v_2,w_2)) = \mathcal{L}^N(\{(s,t) \mid v_1(s,t) \neq v_2(s,t)\}) + \|w_1 - w_2\|_{\infty,\Omega}.$$

Remark 3.1. From [19], we know that the mapping

$$d_E : (v_1,v_2) \longmapsto \mathcal{L}^N(\{(s,t) \mid v_1(s,t) \neq v_2(s,t)\})$$

is a distance on $V_{ad}(\tilde{v},k)$. Moreover, if $(v_n)_n \subset V_{ad}(\tilde{v},k)$, if $v \in V_{ad}(\tilde{v},k)$, and if $\lim_n d_E(v_n,v) = 0$, then $(v_n)_n$ converges to v in $L^\sigma(\Sigma)$. This is no longer true for any sequence $(v_n)_n$ included in V_{ad}.

LEMMA 3.3. *$(V_{ad}(\tilde{v},k) \times W_{ad}, d)$ is a complete metric space, and the mapping which associates $(y_{vw}, J(y_{vw},v,w))$ with (v,w) is continuous from $(V_{ad}(\tilde{v},k) \times W_{ad}, d)$ into $C(\overline{Q}) \times \mathbb{R}$.*

Proof. (i) To prove that $(V_{ad}(\tilde{v},k) \times W_{ad}, d)$ is a complete metric space, it remains to prove that $(V_{ad}(\tilde{v},k), d_E)$ is complete. Let $(v_n)_n$ be a Cauchy sequence in $(V_{ad}(\tilde{v},k), d_E)$. Following [19], we can prove that $(v_n)_n$ converges for d_E to some

measurable function v such that $v(s,t) \in K_V(s,t)$ and $|v(s,t) - \tilde{v}(s,t)| \leq k$ for almost all $(s,t) \in \Sigma$. Therefore, $v \in L^\sigma(\Sigma)$ and $v \in V_{ad}(\tilde{v},k)$.

(ii) Now, we consider $(v_n, w_n)_{n\geq 1} \subset V_{ad}(\tilde{v},k) \times W_{ad}$ and $(v,w) \in V_{ad}(\tilde{v},k) \times W_{ad}$ such that $(v_n,w_n)_n$ converges to (v,w) for the metric d. We denote by y and y_n $(n \geq 1)$ the solution of (1.1) corresponding, respectively, to (v,w) and to (v_n,w_n). To prove the continuity result, it remains to prove that the sequence $(y_n, J(y_n,v_n,w_n))_n$ converges to $(y, J(y,v,w))$ in $C(\overline{Q}) \times \mathbb{R}$.

For this, we observe that $(w_n)_n$ converges to w in $C(\overline{\Omega})$ and $(v_n)_n$ converges to v in $L^\sigma(\Sigma)$. We complete the proof thanks to the continuity assumptions on F, G, L and to the continuity results stated in Theorem 3.1. □

3.3. Adjoint equation. Let (a,b) be in $L^q(Q) \times L^\sigma(\Sigma)$ with $a \geq C_0$ and $b \geq C_0$. We consider the following terminal boundary value problem:

$$-\frac{\partial p}{\partial t} + Ap + ap = \mu_Q \text{ in } Q, \quad \frac{\partial p}{\partial n_A} + bp = \mu_\Sigma \text{ on } \Sigma, \quad p(T) = \mu_{\overline{\Omega}_T} \text{ on } \overline{\Omega}, \tag{3.2}$$

where $\mu = \mu_Q + \mu_\Sigma + \mu_{\overline{\Omega}_T}$ is a bounded Radon measure on $\overline{Q} \setminus \overline{\Omega}_0$, μ_Q is the restriction of μ to Q, μ_Σ is the restriction of μ to Σ, and $\mu_{\overline{\Omega}_T}$ is the restriction of μ to $\overline{\Omega}_T$.

DEFINITION 3.4. *We shall say that p is a weak solution of* (3.2) *in* $L^1(0,T;W^{1,1}(\Omega))$ *if and only if the two following conditions are fulfilled:*

(i) $ap \in L^1(Q)$ *and* $bp \in L^1(\Sigma)$,

(ii) *For every* $\varphi \in C^1(\overline{Q})$ *satisfying* $\varphi(x,0) = 0$ *on* $\overline{\Omega}$, *we have*

$$\int_Q \left\{ p\frac{\partial \varphi}{\partial t} + \Sigma_{i,j} a_{ij} D_j \varphi D_i p + a\varphi p \right\} dxdt + \int_\Sigma b\varphi p \, dsdt = \langle \varphi, \mu \rangle_{C_b(\overline{Q}\setminus\overline{\Omega}_0) \times \mathcal{M}_b(\overline{Q}\setminus\overline{\Omega}_0)}.$$

($C_b(\overline{Q}\setminus\overline{\Omega}_0)$ *denotes the space of bounded continuous functions on* $\overline{Q}\setminus\overline{\Omega}_0$, *while* $\mathcal{M}_b(\overline{Q}\setminus\overline{\Omega}_0)$ *denotes the space of bounded Radon measures on* $\overline{Q} \setminus \overline{\Omega}_0$, *that is, the topological dual of* $C_0(\overline{Q} \setminus \overline{\Omega}_0)$.)

In the following, we shall say that a pair $(\delta, d) \in \mathbb{R}^2$ fulfills the condition $(C_{q\sigma})$ if and only if

$$(C_{q\sigma}) \quad \begin{cases} \frac{N\sigma}{\sigma-2} < d \leq \frac{N\sigma}{N-1} \quad \text{and} \quad \frac{2d}{d-N} < \delta \leq \sigma & \text{if } \sigma \leq q, \\ \frac{Nq}{q-2} < d \leq \frac{N\sigma}{N-1} \quad \text{and} \quad \frac{2d}{d-N} < \delta \leq q & \text{if } N \leq q < \sigma, \\ \frac{Nq}{q-2} < d \leq \inf(\frac{N\sigma}{N-1}, \frac{Nq}{N-q}) \quad \text{and} \quad \frac{2d}{d-N} < \delta \leq q & \text{if } q < N. \end{cases}$$

Since $q > \frac{N}{2} + 1$, $\sigma > N+1$, and $q\sigma + q > qN + 2\sigma$, we notice that the set of pairs (δ, d) satisfying $(C_{q\sigma})$ is nonempty. These conditions appear in a natural manner when we study equation (3.2) (see Remark 3.3). We now recall an existence theorem for parabolic equations with measures as data stated in [34].

THEOREM 3.5. *Let* (a,b) *be in* $L^q(Q) \times L^\sigma(\Sigma)$ *satisfying* $a \geq C_0$, $b \geq C_0$ *and let* μ *be in* $\mathcal{M}_b(\overline{Q}\setminus\overline{\Omega}_0)$. *Equation* (3.2) *admits a unique weak solution* $p \in L^1(0,T;W^{1,1}(\Omega))$. *For every* (δ,d) *satisfying* $(C_{q\sigma})$, p *belongs to* $L^{\delta'}(0,T;W^{1,d'}(\Omega))$ *and we have*

$$\|p\|_{L^{\delta'}(0,T;W^{1,d'}(\Omega))} \leq C_4 \|\mu\|_{\mathcal{M}_b(\overline{Q}\setminus\overline{\Omega}_0)},$$

where $C_4 = C_4(T,\Omega,N,\delta,d,C_0)$ *is independent of* a *and* b. *Moreover, there exists a Radon measure on* $\overline{\Omega}$, *denoted by* $p(0)$ *such that*

$$\int_Q p\left\{\frac{\partial y}{\partial t}+Ay+ay\right\}dxdt+\int_\Sigma p\left\{\frac{\partial y}{\partial n_A}+by\right\}dsdt$$

$$=\langle y,\mu\rangle_{C_b(\overline{Q}\setminus\overline{\Omega}_0)\times\mathcal{M}_b(\overline{Q}\setminus\overline{\Omega}_0)}-\langle y(0),p(0)\rangle_{C(\overline{\Omega})\times\mathcal{M}(\overline{\Omega})}$$

for every $y\in Y=\{y\in W(0,T)\cap C(\overline{Q})\mid \frac{\partial y}{\partial t}+Ay\in L^q(Q),\ \frac{\partial y}{\partial n_A}\in L^\sigma(\Sigma)\}$.

Remark 3.2. If $p\in L^{\delta'}(0,T;W^{1,d'}(\Omega))$ (where (δ,d) satisfies $(C_{q\sigma})$), and if

$$\mathrm{div}_{xt}\left((\Sigma_j a_{ij}D_jp)_{1\le i\le N},p\right)=\frac{\partial p}{\partial t}-Ap\quad\text{belongs to }\mathcal{M}_b(Q),$$

then we can define the normal trace of the vector field $((\sum_j a_{ij}D_jp)_{1\le i\le N},p)$ in the space $W^{\frac{-1}{m},m}(\partial Q)$ (for some $1<m<\frac{N+1}{N}$). If we denote by $\gamma_n((\sum_j a_{ij}D_jp)_{1\le i\le N},p)$ this normal trace, we can prove (see Theorem 4.2 in [34]) that this normal trace belongs to $\mathcal{M}(\partial Q)$ and the restriction of $\gamma_n((\sum_j a_{ij}D_jp)_{1\le i\le N},p)$ to $\overline{\Omega}_T$ is equal to $\mu_{\overline{\Omega}_T}$, the restriction of $\gamma_n((\sum_j a_{ij}D_jp)_{1\le i\le N},p)$ to Σ is equal to $\mu_\Sigma-bp$, and if $p(0)$ is the measure on $\overline{\Omega}$ which satisfies the Green formula of Theorem 3.4, then $-p(0)$ is the restriction of $\gamma_n((\sum_j a_{ij}D_jp)_{1\le i\le N},p)$ to $\overline{\Omega}_0$. In fact it can be proved that $p(0)$ belongs to $L^1(\Omega)$ (see Theorem 4.3 in [34]).

Remark 3.3. Let us explain the origin of the condition $(C_{q\sigma})$. In [34], the existence of a weak solution in $L^1(0,T;W^{1,1}(\Omega))$ for equation (3.2) is proved by duality arguments and an approximation process. The condition $\delta>2d/(d-N)$ appears to get C^0-regularity results for some adjoint equation associated with (3.2) (see ([34, Theorem 4.1])). Condition $\delta>2d/(d-N)$, together with conditions $p\in L^{\delta'}(0,T,W^{1,d'}(\Omega))$, $a\in L^q(Q)$, $b\in L^\sigma(\Sigma)$, $ap\in L^1(Q)$, and $bp\in L^1(\Sigma)$ are equivalent to the condition "(δ,d) satisfies $(C_{q\sigma})$." In the case where $a\in L^\infty(Q)$ and $b\in L^\infty(\Sigma)$, condition $(C_{q\sigma})$ can be replaced by the only condition $\delta>2d/(d-N)$.

4. Existence of diffuse perturbations. In section 5, we consider control problems in which the state constraints are penalized. The penalization is chosen in such a way that the solution of (P) that we want to characterize will be an ε-solution of the penalized problem. In order to exploit optimality conditions deduced from Ekeland's variational principle, we need to construct admissible perturbations of approximate optimal solutions. For this we use a kind of perturbation that we call "diffuse perturbation" and which goes back to Yao [40] and Li [28]. A diffuse perturbation of a control $\bar v\in V_{ad}$ is a function v_ρ defined by

$$v_\rho(s,t)=\begin{cases}\bar v(s,t) & \text{on }\Sigma\setminus E_\rho,\\ v(s,t) & \text{on }E_\rho,\end{cases}$$

where $v\in V_{ad}$ and E_ρ is some measurable subset of Σ. It is clear that $v_\rho\in V_{ad}$. Contrary to spike or multispike perturbations, where E_ρ is precisely defined, here E_ρ must satisfy some relations such as (4.9), (4.10), and (4.11). As explained in Lemma 4.2, the existence of E_ρ follows from the Lyapunov convexity theorem. To get optimality conditions, we need some differential calculus rules for this type of perturbation, stated in the following theorem.

THEOREM 4.1. *Let* ρ *be positive constant such that* $0<\rho<1$. *For every* $v_1,v_2\in V_{ad}$ *and for every* $w_1,w_2\in C(\overline{\Omega})$, *there exists a measurable subset* $E_\rho\subset\Sigma$ *such that*

$$\mathcal{L}^N(E_\rho)=\rho\mathcal{L}^N(\Sigma),\tag{4.1}$$

$$\int_{E_\rho} (G(\cdot, y_1, v_2) - G(\cdot, y_1, v_1))\, dsdt = \rho \int_\Sigma (G(\cdot, y_1, v_2) - G(\cdot, y_1, v_1))\, dsdt, \tag{4.2}$$

$$y_\rho = y_1 + \rho z + r_\rho, \qquad \textit{with} \quad \lim_{\rho \to 0} \frac{1}{\rho} \|r_\rho\|_{C(\overline{Q})} = 0, \tag{4.3}$$

$$J(y_\rho, v_\rho, w_\rho) = J(y_1, v_1, w_1) + \rho \Delta J + o(\rho), \tag{4.4}$$

where v_ρ, w_ρ are the controls defined by

$$v_\rho(s,t) = \begin{cases} v_1(s,t) & \text{on } \Sigma \setminus E_\rho, \\ v_2(s,t) & \text{on } E_\rho, \end{cases} \tag{4.5}$$

$$w_\rho = w_1 + \rho w_2, \tag{4.6}$$

y_ρ, y_1 are the solutions of (1.1) corresponding, respectively, to (v_ρ, w_ρ) and to (v_1, w_1), z is the weak solution of

$$\begin{cases} \dfrac{\partial z}{\partial t} + Az + f'_y(x,t,y_1)z = 0 & \text{in } Q, \\ \dfrac{\partial z}{\partial n_A} + g'_y(s,t,y_1,v_1)z = g(s,t,y_1,v_1) - g(s,t,y_1,v_2) & \text{on } \Sigma, \\ z(0) = w_2 & \text{in } \Omega, \end{cases} \tag{4.7}$$

and

$$\Delta J = J'_y(y_1, v_1, w_1)z + J(y_1, v_2, w_1) - J(y_1, v_1, w_1) + \int_\Omega L'_w(x, y_1(T), w_1) w_2\, dx. \tag{4.8}$$

The proof relies on the following lemma.

LEMMA 4.2. *Let v_1, v_2 be in V_{ad} and let y be in $C(\overline{Q})$. For every $\rho \in]0,1[$, there exists a sequence of measurable subsets $(E^n_\rho)_n$ in Σ such that*

$$\mathcal{L}^N(E^n_\rho) = \rho \mathcal{L}^N(\Sigma), \tag{4.9}$$

$$\int_{E^n_\rho} (G(s,t,y,v_1) - G(s,t,y,v_2))\, dsdt = \rho \int_\Sigma (G(s,t,y,v_1) - G(s,t,y,v_2))\, dsdt, \tag{4.10}$$

$$\frac{1}{\rho} \chi_{E^n_\rho} \rightharpoonup 1 \text{ weak star in } L^\infty(\Sigma), \text{ when } n \to \infty, \tag{4.11}$$

where $\chi_{E^n_\rho}$ is the characteristic of E^n_ρ.

Remark 4.1. A statement similar to (4.1), (4.3), (4.4) is given in [30], [31], [26], and [12] (conditions (4.9), (4.11) are also stated in [12]). In [30] the proof relies on an extension of Uhl's theorem. The proofs in [26] and [12] are constructive. Since the existence of E^n_ρ, satisfying together conditions (4.9), (4.10), (4.11), is not proved, neither in [12] nor in [30], we here give a short proof of Lemma 4.2 based on the Lyapunov convexity theorem (see, for example, [14, Theorem 16.1.ii]).

Proof of Lemma 4.2. We consider a family $(\varphi_n)_n$ dense in $L^1(\Sigma)$. For $n \geq 0$, we set

$$f^n = (1, G(\cdot, y, v_1) - G(\cdot, y, v_2), \varphi_0, \varphi_1, \ldots, \varphi_n) \in (L^1(\Sigma))^{n+3}.$$

Thanks to Lyapunov's convexity theorem, for every $n \geq 0$ and every $\rho \in]0,1[$, there exists a measurable subset $E_\rho^n \subset \Sigma$ satisfying

$$\int_{E_\rho^n} f^n \, dsdt = \rho \int_\Sigma f^n \, dsdt.$$

Thus, for every $n \geq 0$, E_ρ^n satisfies (4.9), (4.10) and

$$\int_{E_\rho^n} \varphi_m \, dsdt = \rho \int_\Sigma \varphi_m \, dsdt, \tag{4.12}$$

for every $m \in \{0, \ldots, n\}$. Now, for any fixed φ in $L^1(\Sigma)$, we have

$$\begin{aligned} |\int_\Sigma \left(\frac{1}{\rho}\chi_{E_\rho^n} - 1\right) \varphi \, dsdt| &\leq |\int_\Sigma \left(\frac{1}{\rho}\chi_{E_\rho^n} - 1\right) (\varphi - \varphi_m) \, dsdt| + |\int_\Sigma \left(\frac{1}{\rho}\chi_{E_\rho^n} - 1\right) \varphi_m \, dsdt| \\ &\leq \left(\frac{1}{\rho} + 1\right) \|\varphi - \varphi_m\|_{1,\Sigma} + |\int_\Sigma \left(\frac{1}{\rho}\chi_{E_\rho^n} - 1\right) \varphi_m \, dsdt|. \end{aligned}$$

Since $(\varphi_m)_m$ is dense in $L^1(\Sigma)$, for $\epsilon > 0$ there exists $\bar{m} > 0$ such that $\|\varphi - \varphi_{\bar{m}}\|_{1,\Sigma} \leq \frac{\epsilon}{\frac{1}{\rho}+1}$.

Thanks to (4.12), for every $n \geq \bar{m}$, we have $\int_\Sigma \left(\frac{1}{\rho}\chi_{E_\rho^n} - 1\right) \varphi_{\bar{m}} \, dsdt = 0$. Thus, it follows that

$$\lim_n |\int_\Sigma \left(\frac{1}{\rho}\chi_{E_\rho^n} - 1\right) \varphi \, dsdt| = 0,$$

and the proof is complete. ∎

Proof of Theorem 4.1. The existence of E_ρ satisfying (4.1), (4.2) is an easy consequence of Lemma 4.2. The only delicate point is the proof of (4.3). This kind of result is already given in ([12, Theorem 5.2]) and in ([26, Theorem 3.3]). Since we deal with unbounded controls and nonmonotone operators, our assumptions are different from those in [12] and [26]. However, the proof of (4.3) can be adapted from the proofs given in [12] and [26].

Let ρ be in $]0,1[$ and let $(E_\rho^n)_n$ be the sequence of measurable subsets defined in Lemma 4.2. We set

$$v_\rho^n(s,t) = \begin{cases} v_1(s,t) & \text{on } \Sigma \setminus E_\rho^n, \\ v_2(s,t) & \text{on } E_\rho^n, \end{cases} \qquad w_\rho = w_1 + \rho w_2.$$

Let y_ρ^n be the solution of (1.1) corresponding to (v_ρ^n, w_ρ) and let z be the weak solution of (4.7). It is clear that $\xi_\rho^n = (y_\rho^n - y_1)/\rho - z$ is the weak solution in $C(\overline{Q}) \cap W(0,T)$ of

$$\frac{\partial \xi}{\partial t} + A\xi + a_\rho^n \xi = f_\rho^n \text{ in } Q, \quad \frac{\partial \xi}{\partial n_A} + b_\rho^n \xi = g_\rho^n + h_\rho^n \text{ on } \Sigma, \quad \xi(0) = 0 \text{ in } \Omega,$$

where

$$a_\rho^n(x,t) = \int_0^1 f_y'(x,t,(y_1+\theta(y_\rho^n - y_1))(x,t))\,d\theta,$$
$$b_\rho^n(s,t) = \int_0^1 g_y'(s,t,(y_1+\theta(y_\rho^n - y_1))(s,t),v_\rho^n(s,t))\,d\theta,$$
$$f_\rho^n = (f_y'(x,t,y_1) - a_\rho^n)z,$$
$$g_\rho^n = (g_y'(s,t,y_1,v_1) - b_\rho^n)z,$$
$$h_\rho^n = \left(1 - \frac{1}{\rho}\chi_{E_\rho^n}\right)(g(s,t,y_1,v_2) - g(s,t,y_1,v_1)),$$

and $\chi_{E_\rho^n}$ is the characteristic function of E_ρ^n. We denote by $\xi_\rho^{n,1}$ the solution in $C(\overline{Q}) \cap W(0,T)$ of

$$\frac{\partial \xi}{\partial t} + A\xi + a_\rho^n \xi = f_\rho^n \text{ in } Q, \quad \frac{\partial \xi}{\partial n_A} + b_\rho^n \xi = g_\rho^n \text{ on } \Sigma, \quad \xi(\cdot,0) = 0 \text{ in } \Omega,$$

by $\xi_\rho^{n,2}$ the solution in $C(\overline{Q}) \cap W(0,T)$ of

$$\frac{\partial \xi}{\partial t} + A\xi + a_\rho^n \xi = 0 \text{ in } Q, \quad \frac{\partial \xi}{\partial n_A} + b_\rho^n \xi = h_\rho^n \text{ on } \Sigma, \quad \xi(\cdot,0) = 0 \text{ in } \Omega,$$

and by ζ_ρ^n the solution in $C(\overline{Q}) \cap W(0,T)$ of

$$\frac{\partial \zeta}{\partial t} + A\zeta + a\zeta = 0 \text{ in } Q, \quad \frac{\partial \zeta}{\partial n_A} + b\zeta = h_\rho^n \text{ on } \Sigma, \quad \zeta(\cdot,0) = 0 \text{ in } \Omega,$$

where $a(x,t) = f_y'(x,t,y_1(x,t))$, $b(s,t) = g_y'(s,t,y_1(s,t),v_1(s,t))$. We also have

$$\frac{\partial(\xi_\rho^{n,2} - \zeta_\rho^n)}{\partial t} + A(\xi_\rho^{n,2} - \zeta_\rho^n) + a_\rho^n(\xi_\rho^{n,2} - \zeta_\rho^n) = (a - a_\rho^n)\zeta_\rho^n \qquad \text{in } Q,$$
$$\frac{\partial(\xi_\rho^{n,2} - \zeta_\rho^n)}{\partial n_A} + b_\rho^n(\xi_\rho^{n,2} - \zeta_\rho^n) = (b - b_\rho^n)\zeta_\rho^n \qquad \text{on } \Sigma,$$
$$(\xi_\rho^{n,2} - \zeta_\rho^n)(\cdot,0) = 0 \qquad \text{in } \Omega.$$

Due to ([37, Proposition 3.3]), there exists $C = C(T,\Omega,N,q,\sigma,C_0) > 0$ (independent of n and ρ) such that

$$\|\xi_\rho^{n,2} - \zeta_\rho^n\|_{C(\overline{Q})} \le C(\|a - a_\rho^n\|_{q,Q} + \|b - b_\rho^n\|_{\sigma,\Sigma})\|\zeta_\rho^n\|_{C(\overline{Q})}, \tag{4.13}$$

$$\|\xi_\rho^{n,1}\|_{C(\overline{Q})} \le C(\|f_\rho^n\|_{q,Q} + \|g_\rho^n\|_{\sigma,\Sigma}). \tag{4.14}$$

The operator $\mathcal{T}$ which associates ζ, the solution in $C(\overline{Q}) \cap W(0,T)$ of

$$\frac{\partial \zeta}{\partial t} + A\zeta + a\zeta = \varphi \text{ in } Q, \quad \frac{\partial \zeta}{\partial n_A} + b\zeta = \psi \text{ on } \Sigma, \quad \zeta(0) = 0 \text{ in } \Omega,$$

with (φ,ψ), is continuous from $L^q(Q) \times L^\sigma(\Sigma)$ into $C^{\alpha,\frac{\alpha}{2}}(\overline{Q})$ for some $0 < \alpha < 1$ (as for Corollary 3.2, this continuity result can be deduced from Chapter 3, Theorem 1.3, in [17]). Since the embedding from $C^{\alpha,\frac{\alpha}{2}}(\overline{Q})$ into $C(\overline{Q})$ is compact, $\mathcal{T}$ may also be considered as a compact operator from $L^q(Q) \times L^\sigma(\Sigma)$ into $C(\overline{Q})$.

Because of (4.11), for every $0 < \rho < 1$ the sequence $(h_\rho^n)_n$ converges to zero for the weak topology of $L^\sigma(\Sigma)$. Therefore, since $\mathcal{T}$ is compact from $L^q(Q) \times L^\sigma(\Sigma)$ into

$C(\overline{Q})$, the sequence $(\zeta_\rho^n)_n$ converges to zero in $C(\overline{Q})$. There then exists an integer depending on ρ, denoted by $n(\rho)$, such that

$$\|\zeta_\rho^{n(\rho)}\|_{C(\overline{Q})} \leq \rho. \tag{4.15}$$

Notice that $(v_\rho^{n(\rho)})_\rho$ converges to v_1 in $L^\sigma(\Sigma)$ and $(w_\rho)_\rho$ converges to w in $C(\overline{\Omega})$ as ρ tends to zero. From Theorem 3.1 it follows that $(y_\rho^{n(\rho)})_\rho$ uniformly converges to y_1 on $\overline{Q}$ as ρ tends to zero. Therefore, due to (A1) and (A2), $f_\rho^{n(\rho)}$ and $(a - a_\rho^{n(\rho)})$ both converge to zero in $L^q(Q)$ when ρ tends to zero and $g_\rho^{n(\rho)}$, $(b - b_\rho^{n(\rho)})$ both converge to zero in $L^\sigma(\Sigma)$ when ρ tends to zero. Thus, thanks to (4.13)–(4.15), we obtain

$$\lim_{\rho\to 0} \|\xi_\rho^{n(\rho)}\|_{C(\overline{Q})} \leq \lim_{\rho\to 0} \|\xi_\rho^{n(\rho),1}\|_{C(\overline{Q})} + \lim_{\rho\to 0} \|\xi_\rho^{n(\rho),2} - \zeta_\rho^{n(\rho)}\|_{C(\overline{Q})} + \lim_{\rho\to 0} \|\zeta_\rho^{n(\rho)}\|_{C(\overline{Q})} = 0.$$

Now we set $E_\rho = E_\rho^{n(\rho)}$, $v_\rho = v_\rho^{n(\rho)}$, and $\frac{1}{\rho} r_\rho = \xi_\rho^{n(\rho)}$. Conditions (4.1) to (4.3) are clearly satisfied; moreover, taking (4.2), (4.3), and the definition of (v_ρ, w_ρ) into account, we easily verify (4.4). ∎

5. Proof of Pontryagin's principle.

5.1. Penalized problem. We first give the proof of optimality conditions in qualified form (the case $\bar{\nu} = 1$ in Theorem 2.1). The proof of the nonqualified form can be obtained with slight modifications that we give in section 5.3. For notational simplicity, throughout what follows we set

$$H_\Sigma(s, t, y, v, p, 1) = H_\Sigma(s, t, y, v, p)$$

for every $(s, t, y, v, p) \in \Gamma \times [0, T] \times \mathbb{R} \times \mathbb{R} \times \mathbb{R}$. Following [30] and [31], since $C(\overline{D})$ is separable, there exists a norm $|\cdot|_{C(\overline{D})}$, which is equivalent to the norm $\|\cdot\|_{C(\overline{D})}$ such that $(C(\overline{D}), |\cdot|_{C(\overline{D})})$ is strictly convex, and $\mathcal{M}(\overline{D})$, endowed with the dual norm of $|\cdot|_{C(\overline{D})}$ (denoted by $|\cdot|_{\mathcal{M}(\overline{D})}$), is also strictly convex (see [18, Corollary 2, p. 148 or Corollary 2, p. 167]). We define the distance function to $\mathcal{C}$ (for the new norm $|\cdot|_{C(\overline{D})}$) by

$$d_{\mathcal{C}}(\varphi) = \inf_{z\in\mathcal{C}} |\varphi - z|_{C(\overline{D})}.$$

Since $\mathcal{C}$ is convex, then $d_{\mathcal{C}}$ is convex and Lipschitz of rank 1, and we have

$$\limsup_{\substack{\rho\searrow 0,\\ \varphi'\to\varphi}} \frac{d_{\mathcal{C}}(\varphi' + \rho z) - d_{\mathcal{C}}(\varphi')}{\rho} = \max\{\langle \xi, z\rangle_{\mathcal{M}(\overline{D})\times C(\overline{D})} \mid \xi \in \partial d_{\mathcal{C}}(\varphi)\} \tag{5.1}$$

for every $\varphi, z \in C(\overline{D})$, where $\partial d_{\mathcal{C}}$ is the subdifferential in the sense of convex analysis (see [16]). Therefore, for a given $\varphi \in C(\overline{D})$ we have

$$\langle \xi, z - \varphi\rangle_{\mathcal{M}(\overline{D})\times C(\overline{D})} + d_{\mathcal{C}}(\varphi) \leq d_{\mathcal{C}}(z) \quad \text{for all } \xi \in \partial d_{\mathcal{C}}(\varphi) \text{ and all } z \in C(\overline{D}), \tag{5.2}$$

$$|\xi|_{\mathcal{M}(\overline{D})} \leq 1 \quad \text{for all } \xi \in \partial d_{\mathcal{C}}(\varphi).$$

Moreover, it is proved in ([31, Lemma 3.4]) that, since $\mathcal{C}$ is a closed convex subset of $C(\overline{D})$, for every $\varphi \notin \mathcal{C}$, and every $\xi \in \partial d_{\mathcal{C}}(\varphi)$, we have $|\xi|_{\mathcal{M}(\overline{D})} = 1$. Since $\partial d_{\mathcal{C}}(\varphi)$ is

convex in $\mathcal{M}(\overline{D})$ and $(\mathcal{M}(\overline{D}), |\cdot|_{\mathcal{M}(\overline{D})})$ is strictly convex, then if $\varphi \notin \mathcal{C}$, $\partial d_{\mathcal{C}}(\varphi)$ is a singleton and $d_{\mathcal{C}}$ is Gâteaux differentiable at φ.

Let $(\bar{y}, \bar{v}, \bar{w})$ be a solution of problem (P). Thanks to (A8), we prove in the proposition below that $(\bar{y}, \bar{v}, \bar{w})$ is also a local solution of some related penalized problems.

PROPOSITION 5.1. *For every $k > 0$, there exists $\lambda = \lambda(k)$ such that $(\bar{y}, \bar{v}, \bar{w})$ is a solution of the following problem:*

$$(P^{r,k}) \qquad \inf\{J_r(y,v,w) \mid y \in W(0,T) \cap C(\overline{Q}),\ (v,w) \in (V_{ad}(\bar{v},k) \times W_{ad}) \cap \mathcal{B}^d_{\lambda(k)}(\bar{v},\bar{w}) \text{ and } (y,v,w) \text{ satisfies (1.1)}\},$$

where $J_r(y,v,w) = J(y,v,w) + r d_{\mathcal{C}}(\phi(y))$, $\mathcal{B}^d_{\lambda(k)}(\bar{v},\bar{w}) \subset V_{ad} \times W_{ad}$ is the closed ball centered on $(\bar{v},\bar{w})$ and with radius $\lambda(k)$ (for the distance d), r only depends on the constant $\tilde{r}$ given in (A8) *and on $\overline{D}$.*

Proof. From (A8), there exist $\tilde{\varepsilon} > 0$ and $\tilde{r} > 0$ such that

$$\inf(P) = \inf\{J(y_{vw}, v, w) + \tilde{r}\gamma \mid (v,w) \in V_{ad} \times W_{ad},\ \phi(y_{vw}) \in \mathcal{C}_\gamma,\ \ \gamma \in [0,\tilde{\varepsilon}]\}.$$

Now by writing

$$\inf(P) = \inf\{\inf\{J(y_{vw}, v, w) + \tilde{r}\gamma \mid\ \phi(y_{vw}) \in \mathcal{C}_\gamma,\ \ \gamma \in [0,\tilde{\varepsilon}]\} \mid (v,w) \in V_{ad} \times W_{ad}\},$$

we have

$$\inf(P) = \inf\left\{J(y_{vw}, v, w) + \tilde{r} \inf_{z \in \mathcal{C}} \|\phi(y_{vw}) - z\|_{C(\overline{D})} \mid (v,w) \in V_{ad} \times W_{ad},\ \phi(y_{vw}) \in \mathcal{C}_{\tilde{\varepsilon}}\right\}.$$

Since the norms $|\cdot|_{C(\overline{D})}$ and $\|\cdot\|_{C(\overline{D})}$ are equivalent, there exist $r \geq \tilde{r}$ and $0 < \varepsilon \leq \tilde{\varepsilon}$ such that

$$\inf\left\{J(y_{vw}, v, w) + \tilde{r} \inf_{z \in \mathcal{C}} \|\phi(y_{vw}) - z\|_{C(\overline{D})} \mid (v,w) \in V_{ad} \times W_{ad},\ \phi(y_{vw}) \in \mathcal{C}_{\tilde{\varepsilon}}\right\}$$
$$\leq \inf\{J(y_{vw}, v, w) + r d_{\mathcal{C}}(\phi(y_{vw})) \mid (v,w) \in V_{ad} \times W_{ad},\ d_{\mathcal{C}}(\phi(y_{vw})) \leq \varepsilon\}.$$

Moreover, taking (A6) and Lemma 3.3 into account, there exists $\lambda(k) > 0$ such that

$$d_{\mathcal{C}}(\phi(y_{vw})) \leq \varepsilon \quad \text{for every} \quad (v,w) \in (V_{ad}(\bar{v},k) \times W_{ad}) \cap \mathcal{B}^d_{\lambda(k)}(\bar{v},\bar{w}).$$

Thus,

$$\inf(P) \leq \inf\left\{J(y_{vw}, v, w) + r d_{\mathcal{C}}(\phi(y_{vw})) \mid (v,w) \in (V_{ad}(\bar{v},k) \times W_{ad}) \cap \mathcal{B}^d_{\lambda(k)}(\bar{v},\bar{w})\right\}$$
$$= \inf(P^{r,k}) \leq J(\bar{y},\bar{v},\bar{w}) = \inf(P). \qquad \square$$

Now we set $J_{r,n}(y,v,w) = J(y,v,w) + r[(d_{\mathcal{C}}(\phi(y)))^2 + n^{-2}]^{\frac{1}{2}}$, and we denote by $(P^{r,k}_n)$ the problem

$$\inf\{J_{r,n}(y,v,w) \mid y \in W(0,T) \cap C(\overline{Q}),\ (v,w) \in (V_{ad}(\bar{v},k) \times W_{ad}) \cap \mathcal{B}^d_{\lambda(k)}(\bar{v},\bar{w}) \text{ and } (y,v,w) \text{ satisfies (1.1)}\}.$$

PROPOSITION 5.2. *For every $k > 0$,*

$$\inf(P^{r,k}) = \lim_{n\to\infty} \inf(P_n^{r,k}) \quad \textit{and} \quad \lim_{n\to\infty} J_{r,n}(y,v,w) = J_r(y,v,w)$$

for every $y \in C(\overline{Q})$ and every $(v,w) \in L^\sigma(\Sigma) \times C(\overline{\Omega})$. Moreover, $(\bar{y},\bar{v},\bar{w})$ is a ε^2-solution of $(P_n^{r,k})$ with $\varepsilon^2 = rn^{-1}$.

Proof. The first part of the proof is immediate if we observe that

$$J_r(y,v,w) \le J_{r,n}(y,v,w) \le J_r(y,v,w) + rn^{-1}$$

for every $(y,v,w) \in C(\overline{Q}) \times L^\sigma(\Sigma) \times C(\overline{\Omega})$. Moreover, since $(\bar{y},\bar{v},\bar{w})$ is solution of $(P^{r,k})$, with the previous inequalities, we obtain

$$\begin{aligned} J_{r,n}(\bar{y},\bar{v},\bar{w}) &\le J_r(\bar{y},\bar{v},\bar{w}) + rn^{-1} \\ &\le J_r(y,v,w) + rn^{-1} \le J_{r,n}(y,v,w) + rn^{-1}, \end{aligned}$$

for every $y \in C(\overline{Q})$ and every $(v,w) \in (V_{ad}(\bar{v},k) \times W_{ad}) \cap \mathcal{B}^d_{\lambda(k)}(\bar{v},\bar{w})$ such that (y,v,w) obeys (1.1). ∎

5.2. Proof of Theorem 2.1 (Pontryagin principle in qualified form). Let k be a positive constant. Thanks to Proposition 5.2, for every $n \ge 1$, $(\bar{y},\bar{v},\bar{w})$ is an ε_n^2-solution of $(P_n^{r,k})$, with $\varepsilon_n^2 = rn^{-1}$. For every $k > 0$, we choose $n(k)$ such that

$$\varepsilon_{n(k)} = \left(\frac{r}{n(k)}\right)^{\frac{1}{2}} \le \min\left(\frac{1}{k^{2\sigma}}, \frac{\lambda(k)}{2}\right).$$

The metric space $((V_{ad}(\bar{v},k) \times W_{ad}) \cap \mathcal{B}^d_{\lambda(k)}(\bar{v},\bar{w}), d)$ is complete and the functional $(v,w) \longmapsto J_{r,n(k)}(y_{vw},v,w)$ is continuous on this metric space. Thanks to Ekeland's variational principle, for every $k \ge 1$, there exists $(v_k,w_k) \in (V_{ad}(\bar{v},k) \times W_{ad}) \cap \mathcal{B}^d_{\lambda(k)}(\bar{v},\bar{w})$ such that

$$d((v_k,w_k),(\bar{v},\bar{w})) \le \varepsilon_{n(k)}, \tag{5.3}$$

$$J_{r,n(k)}(y_k,v_k,w_k) \le J_{r,n(k)}(y_{vw},v,w) + \varepsilon_{n(k)} d((v_k,w_k),(v,w)) \tag{5.4}$$

for every $(v,w) \in (V_{ad}(\bar{v},k) \times W_{ad}) \cap \mathcal{B}^d_{\lambda(k)}(\bar{v},\bar{w})$ (y_k and y_{vw} being the states corresponding, respectively, to (v_k,w_k) and to (v,w)).

The proof is split into five steps.

Step 1. *Approximate optimality conditions for the boundary control v_k satisfying* (5.3) *and* (5.4). For fixed v_0 in V_{ad}, we denote by v_{0k} ($k > 0$) the function in $V_{ad}(\bar{v},k)$ defined by

$$v_{0k}(s,t) = \begin{cases} v_0(s,t) & \text{if } |v_0(s,t) - \bar{v}(s,t)| \le k, \\ \bar{v}(s,t) & \text{if not.} \end{cases} \tag{5.5}$$

Applying Theorem 4.1, we deduce the existence of measurable sets E_ρ^k, such that $\mathcal{L}^N(E_\rho^k) = \rho \mathcal{L}^N(\Sigma)$,

$$y_{1,\rho}^k = y_k + \rho z_k^1 + r_\rho^k, \qquad \lim_{\rho\to 0} \frac{1}{\rho} \|r_\rho^k\|_{C(\overline{Q})} = 0, \tag{5.6}$$

$$J(y^k_{1,\rho}, v^k_{1,\rho}, w^k_{1,\rho}) = J(y_k, v_k, w_k) + \rho \Delta J^1_k + o(\rho), \tag{5.7}$$

where $v^k_{1,\rho}$ and $w^k_{1,\rho}$ are defined by

$$v^k_{1,\rho}(s,t) = \begin{cases} v_k(s,t) & \text{on } \Sigma \setminus E^k_\rho, \\ v_{0k}(s,t) & \text{on } E^k_\rho, \end{cases} \quad w^k_{1,\rho} = w_k, \tag{5.8}$$

$y^k_{1,\rho}$ is the state corresponding to $(v^k_{1,\rho}, w^k_{1,\rho})$, z^1_k is the weak solution of

$$\begin{aligned} &\frac{\partial z^1_k}{\partial t} + Az^1_k + f'_y(x,t,y_k)z^1_k = 0 && \text{in } Q, \\ &\frac{\partial z^1_k}{\partial n_A} + g'_y(s,t,y_k,v_k)z^1_k = g(s,t,y_k,v_k) - g(s,t,y_k,v_{0k}) && \text{on } \Sigma, \\ &z^1_k(\cdot,0) = 0 && \text{in } \Omega, \end{aligned}$$

and

$$\begin{aligned} \Delta J^1_k = &\int_Q F'_y(x,t,y_k(x,t))z^1_k(x,t)\,dxdt \int_\Sigma G'_y(s,t,y_k(s,t),v_k(s,t))z^1_k(s,t)\,dsdt \\ &+ \int_\Sigma [G(s,t,y_k(s,t),v_{0k}(s,t)) - G(s,t,y_k(s,t),v_k(s,t))]\,dsdt \\ &+ \int_\Omega L'_y(x,y_k(x,T),w_k(x))z^1_k(x)\,dx. \end{aligned}$$

On the other hand, we have

$$\begin{aligned} d((v^k_{1,\rho}, w^k_{1,\rho}), (\bar v, \bar w)) &\le d((v^k_{1,\rho}, w^k_{1,\rho}), (v_k, w_k)) + d((v_k, w_k), (\bar v, \bar w)) \\ &\le \mathcal{L}^N(E^k_\rho) + \varepsilon_{n(k)} \le \rho \mathcal{L}^N(\Sigma) + \varepsilon_{n(k)}. \end{aligned}$$

There then exists ρ_k such that, for every $0 < \rho < \rho_k$, we have

$$d((v^k_{1,\rho}, w^k_{1,\rho}), (\bar v, \bar w)) \le \rho \mathcal{L}^N(\Sigma) + \varepsilon_{n(k)} \le \lambda(k).$$

Therefore, for all $k > 0$ and all $0 < \rho < \rho_k$, $(v^k_{1,\rho}, w^k_{1,\rho})$ belongs to $(V_{ad}(\bar v, k) \times W_{ad}) \cap \mathcal{B}^d_{\lambda(k)}(\bar v, \bar w)$. If we set $(v,w) = (v^k_{1,\rho}, w^k_{1,\rho})$ in (5.4), it follows that

$$\limsup_{\rho \to 0} \frac{J_{r,n(k)}(y_k, v_k, w_k) - J_{r,n(k)}(y^k_{1,\rho}, v^k_{1,\rho}, w^k_{1,\rho})}{\rho} \le \varepsilon_{n(k)} \mathcal{L}^N(\Sigma). \tag{5.9}$$

Taking (5.2), (5.7), and the definition of $J_{r,n}$ into account, we get

$$-\Delta J^1_k - \langle \mu_k, \phi'(y_k) z^1_k \rangle_{\mathcal{M}(\overline{D}) \times C(\overline{D})} \le \varepsilon_{n(k)} \mathcal{L}^N(\Sigma), \tag{5.10}$$

where

$$\mu_k = \begin{cases} \dfrac{r d_{\mathcal{C}}(\phi(y_k)) \nabla d_{\mathcal{C}}(\phi(y_k))}{[d_{\mathcal{C}}(\phi(y_k))^2 + n(k)^{-2}]^{\frac{1}{2}}} & \text{if } d_{\mathcal{C}}(\phi(y_k)) > 0, \\ 0 & \text{if not.} \end{cases} \tag{5.11}$$

For every $k > 0$, we consider the weak solution p_k of

$$(5.12)\quad \begin{cases} -\dfrac{\partial p_k}{\partial t} + Ap_k + f'_y(x,t,y_k)p_k = F'_y(x,t,y_k) + [\phi'(y_k)^*\mu_k]|_Q & \text{in } Q, \\ \dfrac{\partial p_k}{\partial n_A} + g'_y(s,t,y_k,v_k)p_k = G'_y(s,t,y_k,v_k) + [\phi'(y_k)^*\mu_k]|_\Sigma & \text{on } \Sigma, \\ p_k(T) = L'_y(x,y_k(T),w_k) + [\phi'(y_k)^*\mu_k]|_{\overline{\Omega}_T} & \text{in } \Omega, \end{cases}$$

where $[\phi'(y_k)^*\mu_k]|_Q$ is the restriction of $[\phi'(y_k)^*\mu_k]$ to Q, $[\phi'(y_k)^*\mu_k]|_\Sigma$ is the restriction of $[\phi'(y_k)^*\mu_k]$ to Σ, and $[\phi'(y_k)^*\mu_k]|_{\overline{\Omega}_T}$ is the restriction of $[\phi'(y_k)^*\mu_k]$ to $\overline{\Omega}_T$. By using the Green formula of Theorem 3.4, we obtain

$$\int_Q F'_y(x,t,y_k)z_k^1\,dxdt + \int_\Sigma G'_y(s,t,y_k,v_k)z_k^1\,dsdt + \int_\Omega L'_y(x,y_k(T),w_k)z_k^1(T)\,dx$$

$$+\langle \mu_k, \phi'(y_k)z_k^1\rangle_{\mathcal{M}(\overline{D})\times C(\overline{D})}$$

$$= \int_Q p_k\left(\frac{\partial z_k^1}{\partial t} + Az_k^1 + f'_y(x,t,y_k)z_k^1\right)dxdt + \int_\Sigma p_k\left(\frac{\partial z_k^1}{\partial n_A} + g'_y(s,t,y_k,v_k)z_k^1\right)dsdt$$

$$= \int_\Sigma p_k\left[g(s,t,y_k,v_k) - g(s,t,y_k,v_{0k})\right]\,dsdt.$$

With this equality, with (5.10) and the definition of ΔJ_k^1, we get

$$(5.13)\quad \int_\Sigma [G(s,t,y_k,v_k) - p_k g(s,t,y_k,v_k)]\,dsdt$$

$$\le \int_\Sigma [G(s,t,y_k,v_{0k}) - p_k g(s,t,y_k,v_{0k})]\,dsdt + \varepsilon_{n(k)}\mathcal{L}^N(\Sigma)$$

$$\le \int_\Sigma [G(s,t,y_k,v_{0k}) - p_k g(s,t,y_k,v_{0k})]\,dsdt + \frac{1}{k^{2\sigma}}\mathcal{L}^N(\Sigma)$$

for every $k > 0$ and every $v_0 \in V_{ad}$ (where v_{0k} is defined according to v_0 in (5.5)).

Step 2. *Approximate optimality conditions for the initial control w_k satisfying* (5.3) and (5.4).

Let w_0 be in W_{ad}. We consider the sequence $(v_{2,\rho}^k, w_{2,\rho}^k)$ defined by

$$v_{2,\rho}^k = v_k, \qquad w_{2,\rho}^k = w_k + \rho(w_0 - w_k)$$

and we denote by $y_{2,\rho}^k$ the state corresponding to $(v_{2,\rho}^k, w_{2,\rho}^k)$. Since W_{ad} is convex, we see that $\{(v_{2,\rho}^k, w_{2,\rho}^k), k > 0\} \subset V_{ad}(\bar{v},k) \times W_{ad}$. Moreover, we have

$$d((v_{2,\rho}^k, w_{2,\rho}^k), (\bar{v},\bar{w})) \le \rho\|w_0 - w_k\|_{\infty,\Omega} + \varepsilon_{n(k)}$$

$$\leq \varepsilon_{n(k)} + \rho(\|w_0 - \bar{w}\|_{\infty,\Omega} + \|w_k - \bar{w}\|_{\infty,\Omega})$$

$$\leq \varepsilon_{n(k)} + \rho(\varepsilon_{n(k)} + \|w_0 - \bar{w}\|_{\infty,\Omega}).$$

As in Step 1, if ρ_k is small enough, for every $0 < \rho < \rho_k$, we have

$$d((v^k_{2,\rho}, w^k_{2,\rho}), (\bar{v}, \bar{w})) \leq \lambda(k).$$

Thus, $(v^k_{2,\rho}, w^k_{2,\rho})$ belongs to $(V_{ad}(\bar{v}, k) \times W_{ad}) \cap \mathcal{B}^d_{\lambda(k)}(\bar{v}, \bar{w})$, for every $k > 0$ and for every $0 < \rho < \rho_k$. Then Theorem 4.1 gives

$$y^k_{2,\rho} = y_k + \rho z^2_k + r^k_\rho, \qquad \lim_{\rho\to 0} \frac{1}{\rho}\|r^k_\rho\|_{C(\overline{Q})} = 0, \tag{5.14}$$

$$J(y^k_{2,\rho}, v^k_{2,\rho}, w^k_{2,\rho}) = J(y_k, v_k, w_k) + \rho\Delta J^2_k + o(\rho), \tag{5.15}$$

where z^2_k is the weak solution of

$$\begin{aligned}
&\frac{\partial z^2_k}{\partial t} + Az^2_k + f'_y(x,t,y_k)z^2_k = 0 && \text{in } Q,\\
&\frac{\partial z^2_k}{\partial n_A} + g'_y(s,t,y_k,v_k)z^2_k = 0 && \text{on } \Sigma,\\
&z^2_k(0) = w_0 - w_k && \text{in } \Omega,
\end{aligned}$$

and

$$\begin{aligned}
\Delta J^2_k = &\int_Q F'_y(x,t,y_k)z^2_k\,dxdt + \int_\Sigma G'_y(s,t,y_k,v_k)z^2_k\,dsdt\\
&+ \int_\Omega L'_y(x,y_k(T),w_k)z^2_k(T)\,dx + \int_\Omega L'_w(x,y_k(T),w_k)(w_0 - w_k)\,dx.
\end{aligned}$$

As in Step 1, from (5.4) and (5.15) we deduce that

$$\begin{aligned}
&-\Delta J^2_k - \langle \mu_k, \phi'(y_k)z^2_k\rangle_{\mathcal{M}(\overline{D})\times C(\overline{D})}\\
&\leq \limsup_{\rho\to 0} \frac{J_{r,n(k)}(y_k,v_k,w_k) - J_{r,n(k)}(y^k_{2,\rho}, v^k_{2,\rho}, w^k_{2,\rho})}{\rho}\\
&\leq \varepsilon_{n(k)}\|w_0 - w_k\|_{\infty,\Omega} \leq \varepsilon_{n(k)}(\varepsilon_{n(k)} + \|w_0 - \bar{w}\|_{\infty,\Omega}),
\end{aligned} \tag{5.16}$$

where μ_k is defined in (5.11).

If we consider the weak solution p_k of (5.12), still using the Green formula of Theorem 3.4, we obtain

$$\begin{aligned}
&\int_Q F'_y(x,t,y_k)z^2_k\,dxdt + \int_\Sigma G'_y(s,t,y_k,v_k)z^2_k\,dsdt + \int_\Omega L'_y(x,y_k(T),w_k)z^2_k(T)\,dx\\
&\qquad + \langle [\phi'(y_k)^*\mu_k]|_{\overline{Q}\setminus\overline{\Omega}_0}, z^2_k\rangle_{\mathcal{M}_b(\overline{Q}\setminus\overline{\Omega}_0)\times C_b(\overline{Q}\setminus\overline{\Omega}_0)}
\end{aligned}$$

$$= \int_Q p_k \left(\frac{\partial z_k^2}{\partial t} + A z_k^2 + f_y'(x,t,y_k) z_k^2 \right) dxdt + \int_\Sigma p_k \left(\frac{\partial z_k^2}{\partial n_A} + g_y'(s,t,y_k,v_k) z_k^2 \right) dsdt$$
$$+ \langle p_k(0), z_k^2(0) \rangle_{\mathcal{M}(\overline{\Omega})\times C(\overline{\Omega})} = \langle p_k(0), w_0 - w_k \rangle_{\mathcal{M}(\overline{\Omega})\times C(\overline{\Omega})}.$$

Taking (5.16) and the definition of ΔJ_k^2 into account, we get

$$(5.17) \quad -\int_\Omega L_w'(x, y_k(T), w_k)(w_0 - w_k)\, dx - \langle p_k(0), w_0 - w_k \rangle_{\mathcal{M}(\overline{\Omega})\times C(\overline{\Omega})}$$
$$-\langle [\phi_y'(y_k)^* \mu_k]|_{\overline{\Omega}_0}, w_0 - w_k \rangle_{\mathcal{M}(\overline{\Omega})\times C(\overline{\Omega})} \le \varepsilon_{n(k)} (\varepsilon_{n(k)} + \|w_0 - \bar{w}\|_{\infty,\Omega})$$

for every $w_0 \in W_{ad}$.

Step 3. *Convergence of sequences* $(\mu_k)_k$ *and* $(p_k)_k$. We observe that

$$|\mu_k|_{\mathcal{M}(\overline{D})} \le r d_{\mathcal{C}}(\phi(y_k)) \left[(d_{\mathcal{C}}(\phi(y_k)))^2 + n(k)^{-2} \right]^{-1/2} \le r.$$

The sequence $(\mu_k)_k$ is bounded in $\mathcal{M}(\overline{D})$, so there exist $\bar{\mu} \in \mathcal{M}(\overline{D})$ and a subsequence, still denoted by $(\mu_k)_k$, such that

$$(5.18) \qquad \mu_k \rightharpoonup \bar{\mu} \ \text{ weak}^* \text{ in } \mathcal{M}(\overline{D}).$$

Let (δ, d) be a pair fulfilling $(C_{q\sigma})$. From Theorem 3.4, we deduce

$$\|p_k\|_{L^{\delta'}(0,T;W^{1,d'}(\Omega))} \le C_4 \Big\{ \|F_y'(\cdot, y_k)\|_{1,Q} + \|G_y'(\cdot, y_k, v_k)\|_{1,\Sigma} + \|L_y'(\cdot, y_k(T), w_k)\|_{1,\Omega}$$
$$+ |\mu_k|_{\mathcal{M}(\overline{D})} \|\phi'(y_k)\|_{\mathcal{L}(C(\overline{Q});C(\overline{D}))} \Big\}.$$

(Here $\mathcal{L}(C(\overline{Q}); C(\overline{D}))$ denotes the space of linear continuous mappings from $C(\overline{Q})$ to $C(\overline{D})$.)

Since the sequences $(\mu_k)_k, (y_k)_k, (v_k)_k$, and $(w_k)_k$ are bounded, respectively, in $\mathcal{M}(\overline{D})$, $C(\overline{Q})$, $L^\sigma(\Sigma)$, and in $C(\overline{\Omega})$, the sequence $(p_k)_k$ is bounded in $L^{\delta'}(0,T;W^{1,d'}(\Omega))$. There then exist $\bar{p} \in L^{\delta'}(0,T;W^{1,d'}(\Omega))$ and a subsequence, still denoted by $(p_k)_k$, such that $(p_k)_k$ weakly converges to $\bar{p}$ in $L^{\delta'}(0,T;W^{1,d'}(\Omega))$.

Let us prove that $\bar{p}$ is the weak solution of (2.4). Let φ be in $C^1(\overline{Q})$ satisfying $\varphi(\cdot, 0) = 0$ in $\overline{\Omega}$. For every $k > 0$, we have

$$(5.19) \qquad \int_Q \left\{ p_k \frac{\partial \varphi}{\partial t} + \sum_{i,j=1}^N a_{ij} D_j p_k D_i \varphi + f_y'(\cdot, y_k) p_k \varphi \right\} dxdt$$
$$+ \int_\Sigma \left\{ p_k \frac{\partial \varphi}{\partial n_A} + g_y'(\cdot, y_k, v_k) p_k \varphi \right\} dsdt$$
$$= \int_Q F_y'(x,t,y_k)\varphi\, dxdt + \int_\Sigma G_y'(s,t,y_k,v_k)\varphi\, dsdt + \int_\Omega L_y'(x, y_k(T), w_k)\varphi(T)\, dx$$
$$+ \langle \mu_k, \phi'(y_k)\varphi \rangle_{\mathcal{M}(\overline{D})\times C(\overline{D})}.$$

Since (δ, d) satisfies $(C_{q\sigma})$, the following imbeddings are continuous:

$$L^{\delta'}(0,T;W^{1,d'}(\Omega)) \hookrightarrow L^{q'}(Q), \qquad L^{\delta'}(0,T;W^{1-\frac{1}{d'},d'}(\Gamma)) \hookrightarrow L^{\sigma'}(\Sigma).$$

Therefore, $(p_k)_k$ weakly converges to $\bar p$ in $L^{q'}(Q)$ and the sequence of traces $(p_k|_\Sigma)_k$ weakly converges to the trace $\bar p|_\Sigma$ in $L^{\sigma'}(\Sigma)$.

Moreover, since $(v_k)_k$ converges to $\bar v$ in $L^\sigma(\Sigma)$ (indeed, since $d_E(v_k,\bar v)\le \varepsilon_{n(k)}\le \frac{1}{k^{2\sigma}}$ and $|v_k-\bar v|\le k$ a.e. on Σ, we have $\int_\Sigma |v_k-\bar v|^\sigma\,dsdt\le \frac{1}{k^\sigma}$), since $(w_k)_k$ converges to $\bar w$ in $C(\overline{\Omega})$, and since $(y_k)_k$ converges to $\bar y$ in $C(\overline{Q})$, due to assumptions on f,g,F,G,L,ϕ, we have

$$\lim_k \|f'_y(\cdot,y_k)-f'_y(\cdot,\bar y)\|_{q,Q}=0,\qquad \lim_k \|F'_y(\cdot,y_k)-F'_y(\cdot,\bar y)\|_{1,Q}=0,$$

$$\lim_k \|g'_y(\cdot,y_k,v_k)-g'_y(\cdot,\bar y,\bar v)\|_{\sigma,\Sigma}=0,\qquad \lim_k \|G'_y(\cdot,y_k,v_k)-G'_y(\cdot,\bar y,\bar v)\|_{1,\Sigma}=0,$$

$$\lim_k \|L'_y(\cdot,y_k(T),w_k)-L'_y(\cdot,\bar y(T),\bar w)\|_{1,\Omega}=0,\qquad \lim_k \|\phi'(y_k)-\phi'(\bar y)\|_{\mathcal{L}(C(\overline{Q});C(\overline{D}))}=0.$$

Thus, by passing to the limit in (5.19), it follows that

$$\int_Q\left\{\bar p\frac{\partial\varphi}{\partial t}+\sum_{i,j=1}^N a_{ij}D_j\bar pD_i\varphi+f'_y(x,t,\bar y)\bar p\varphi\right\}dxdt+\int_\Sigma\left\{\bar p\frac{\partial\varphi}{\partial n_A}+g'_y(s,t,\bar y,\bar v)\bar p\varphi\right\}dsdt$$
$$=\int_Q F'_y(x,t,\bar y)\varphi\,dxdt+\int_\Sigma G'_y(s,t,\bar y,\bar v)\varphi\,dsdt+\int_\Omega L'_y(x,\bar y(T),\bar w)\varphi(T)\,dx$$
$$+\langle\bar\mu,\phi'(\bar y)\varphi\rangle_{\mathcal{M}(\overline{D})\times C(\overline{D})}$$

for every $\varphi\in C^1(\overline{Q})$ satisfying $\varphi(\cdot,0)=0$ in $\overline{\Omega}$. Therefore, $\bar p$ is the unique weak solution of (2.4). Since the weak solution of (2.4) is unique in the sense of Definition 3.1, we can deduce by classical arguments that $\bar p$ is independent of the pair (δ,d) (chosen after (5.18)) and that the original sequence $(p_k)_k$ converges weakly to $\bar p$ in $L^{\delta'}(0,T;W^{1,d'}(\Omega))$ for every (δ,d) satisfying $(C_{q\sigma})$. To pass to the limit in (5.17), we prove that

(5.20) $(p_k(0)+[\phi'_y(y_k)^*\mu_k]|_{\overline{\Omega}_0})_k \rightharpoonup \bar p(0)+[\phi'_y(\bar y)^*\bar\mu]|_{\overline{\Omega}_0}$ weakly star in $\mathcal{M}(\overline{\Omega})$.

For this, let φ be in $C(\overline{\Omega})$ and let y be the solution of

$$\frac{\partial y}{\partial t}+Ay=0\ \text{ in } Q,\quad \frac{\partial y}{\partial n_A}=0\ \text{ on }\Sigma,\quad y(0)=\varphi\ \text{ in }\Omega.$$

With the Green formula of Theorem 3.4, we have

$$\langle p_k(0)+[\phi'_y(y_k)^*\mu_k]|_{\overline{\Omega}_0},\varphi\rangle_{\mathcal{M}(\overline{\Omega})\times C(\overline{\Omega})}-\langle\bar p(0)+[\phi'_y(\bar y)^*\bar\mu]|_{\overline{\Omega}_0},\varphi\rangle_{\mathcal{M}(\overline{\Omega})\times C(\overline{\Omega})}$$

$$=\int_Q\left[\bar pf'_y(x,t,\bar y)y-p_kf'_y(x,t,y_k)y\right]dxdt+\int_\Sigma\left[\bar pg'_y(s,t,\bar y,\bar v)y-p_kg'_y(s,t,y_k,v_k)y\right]dsdt$$
$$+\langle\mu_k,\phi'_y(y_k)y\rangle_{\mathcal{M}(\overline{D})\times C(\overline{D})}-\langle\bar\mu,\phi'_y(\bar y)y\rangle_{\mathcal{M}(\overline{D})\times C(\overline{D})}.$$

Now (5.20) follows from the previous convergence results.

Step 4. *Integral Pontryagin's principle.* Notice that $(v_{0k})_k$ tends to v_0 in $L^\sigma(\Sigma)$ and $(v_k)_k$ tends to $\bar v$ in $L^\sigma(\Sigma)$. By passing to the limit when k tends to infinity in (5.13) and (5.17), and by using the convergence results stated in Step 3, we obtain

$$\int_\Sigma H_\Sigma(s,t,\bar y,\bar v,\bar p)\,dsdt\le\int_\Sigma H_\Sigma(s,t,\bar y,v_0,\bar p)\,dsdt \tag{5.21}$$

for every $v_0 \in V_{ad}$, and

$$\int_\Omega L'_w(x,\bar y(T),\bar w)(\bar w - w_0)\,dx + \langle \bar p(0) + [\phi'_y(\bar y)^*\bar\mu]|_{\overline{\Omega}_0}, \bar w - w_0\rangle_{\mathcal{M}(\overline{\Omega})\times C(\overline{\Omega})} \le 0 \tag{5.22}$$

for every $w_0 \in W_{ad}$. On the other hand, from the definition of μ_k and from (5.2), we deduce

$$\langle \mu_k, z - \phi(y_k)\rangle_{\mathcal{M}(\overline{D})\times C(\overline{D})} \le 0 \quad \text{for all } z \in \mathcal{C}.$$

By passing to the limit in this expression, we obtain (2.3).

Step 5. *Pointwise Pontryagin's principle.* The functions

$$(s,t) \longmapsto \bar v(s,t), \qquad (s,t) \longmapsto H_\Sigma(s,t,\bar y(s,t),\bar v(s,t),\bar p(s,t))$$

are measurable on Σ, and the function

$$(s,t,v) \longmapsto H_\Sigma(s,t,\bar y(s,t),v,\bar p(s,t))$$

is a Carathéodory function from $\Sigma\mathbb{R}$ into $\mathbb{R}$. Thanks to Lusin's theorem and Scorza–Dragoni's theorem, for every $\epsilon > 0$, there exist a compact subset $\Sigma_\epsilon \subset \Sigma$, continuous mappings $\varphi_0^\epsilon, \varphi_1^\epsilon$ from Σ_ϵ into $\mathbb{R}$, and a continuous mapping φ_2^ϵ from $\Sigma_\epsilon\mathbb{R}$ into $\mathbb{R}$ such that

$$\mathcal{L}^N(\Sigma \setminus \Sigma_\epsilon) \le \epsilon, \qquad \varphi_0^\epsilon(s,t) = \bar v(s,t) \ \text{ on } \Sigma_\epsilon,$$

$$\varphi_1^\epsilon(s,t) = H_\Sigma(s,t,\bar y(s,t),\bar v(s,t),\bar p(s,t)) \ \text{ on } \Sigma_\epsilon,$$

$$\varphi_2^\epsilon(s,t,v) = H_\Sigma(s,t,\bar y(s,t),v,\bar p(s,t)) \ \text{ on } \Sigma_\epsilon\mathbb{R}.$$

Since $\bar v$ is continuous on Σ_ϵ, $\bar v$ is bounded on Σ_ϵ and, for $M > \|\bar v\|_{\infty,\Sigma_\epsilon}$, the multimapping

$$(s,t) \longmapsto K_M(s,t) := K_V(s,t) \cap [-M,M]$$

has nonempty compact values for all $(s,t) \in \Sigma_\epsilon$. From a Lusin type theorem for measurable multimappings with compact values (see, for example, [2, Theorem 1.4.1]), for every integer $M > \|\bar v\|_{\infty,\Sigma_\epsilon}$, there exists a measurable subset $\Sigma_{\epsilon M} \subset \Sigma_\epsilon$ such that $\mathcal{L}^N(\Sigma_\epsilon \setminus \Sigma_{\epsilon M}) \le \frac{\epsilon}{2^M}$ and the restriction of K_M to $\Sigma_{\epsilon M}$ is continuous. Let us denote by $\widetilde{\Sigma}_{\epsilon M}$ the set of Lebesgue points in $\Sigma_{\epsilon M}$, of the characteristic function of $\Sigma_{\epsilon M}$. Now let (s_0,t_0) be in $\widetilde{\Sigma}_{\epsilon M}$ and let $v \in K_M(s_0,t_0)$. Since the multimapping K_M is continuous on $\Sigma_{\epsilon M}$ (in fact we only use the lower semicontinuity of K_M), for every integer $n > 0$, the multimapping K_M admits a measurable selection v_n and there exists an increasing function γ from $\mathbb{R}^+$ into $\mathbb{R}^+$ such that

$$|v_n(s,t) - v| \le \frac{1}{n} \ \text{ on } \ B\left((s_0,t_0),\gamma\left(\frac{1}{n}\right)\right) \cap \Sigma_{\epsilon M} \ \text{ and } \ \lim_{n\to\infty} \gamma\left(\frac{1}{n}\right) = 0,$$

where $B((s_0,t_0),\gamma(\frac{1}{n}))$ is the ball in $\mathbb{R}^N$ centered on (s_0,t_0) and of radius $\gamma(\frac{1}{n})$. We now set

$$S_{\epsilon,M,n} = \widetilde{\Sigma}_{\epsilon M} \cap B\left((s_0,t_0),\gamma\left(\frac{1}{n}\right)\right),$$

and we consider the variation

$$v_M(s,t) = \begin{cases} \bar{v}(s,t) & \text{on } \Sigma \setminus S_{\epsilon,M,1}, \\ v_n(s,t) & \text{on } S_{\epsilon,M,n} \setminus S_{\epsilon,M,n+1} \quad \text{for every } n > 0, \\ v & \text{if } (s,t) = (s_0,t_0). \end{cases}$$

It is clear that $v_M \in V_{ad}$ and that

$$\lim_{(s,t)\to(s_0,t_0)} v_M(s,t) = v.$$

If we take $v_0 = \chi_{S_{\epsilon,M,n}} v_M + (1-\chi_{S_{\epsilon,M,n}})\bar{v}$ in (5.21) (where $\chi_{S_{\epsilon,M,n}}$ is the characteristic function of $S_{\epsilon,M,n}$), it follows that

$$\frac{1}{\mathcal{L}^N(S_{\epsilon,M,n})} \int_{S_{\epsilon,M,n}} \varphi_1^\varepsilon(s,t)\, ds dt \le \frac{1}{\mathcal{L}^N(S_{\epsilon,M,n})} \int_{S_{\epsilon,M,n}} \varphi_2^\varepsilon(s,t,v_M(s,t))\, ds dt.$$

(Note that for every $n \ge 1$, $\mathcal{L}^N(S_{\epsilon,M,n}) \neq 0$ because $(s_0,t_0) \in \widetilde{\Sigma}_{\epsilon M}$.) By passing to the limit in the above inequality when n tends to infinity, and using the continuity of φ_1^ε and φ_2^ε, we obtain

$$\varphi_1^\varepsilon(s_0,t_0) = H_\Sigma(s_0,t_0,\bar{y}(s_0,t_0),\bar{v}(s_0,t_0),\bar{p}(s_0,t_0))$$

$$\le \varphi_2^\varepsilon(s_0,t_0,v) = H_\Sigma(s_0,t_0,\bar{y}(s_0,t_0),v,\bar{p}(s_0,t_0))$$

for every $(s_0,t_0) \in \widetilde{\Sigma}_{\epsilon M}$ and every $v \in K_V(s_0,t_0)$ such that $|v| \le M$.

We set

$$\widetilde{\Sigma}_\epsilon = \bigcap_{\substack{M \in N^* \\ M > \|\bar{v}\|_{\infty,\Sigma_\epsilon}}} \widetilde{\Sigma}_{\epsilon M}$$

and we observe that $\mathcal{L}^N(\Sigma \setminus \widetilde{\Sigma}_\epsilon) \le 2\epsilon$. For every $(s,t) \in \widetilde{\Sigma}_\epsilon$ and every $v \in K_V(s,t)$ we have

$$H_\Sigma(s,t,\bar{y}(s,t),\bar{v}(s,t),\bar{p}(s,t)) \le H_\Sigma(s,t,\bar{y}(s,t),v,\bar{p}(s,t)).$$

Upon setting $\widetilde{\Sigma} = \bigcup_{\epsilon>0} \widetilde{\Sigma}_\epsilon$, we have $\mathcal{L}^N(\widetilde{\Sigma}) = \mathcal{L}^N(\Sigma)$. The pointwise Pontryagin's principle is satisfied on $\widetilde{\Sigma}$ and the proof is complete. □

5.3. Proof of Pontryagin principle in nonqualified form. In this case, as in [21], [31], [42], [26], and [12], we can consider the penalized functional

$$J_n(y,v,w) = \left\{ \left[\left(J(y,v,w) - J(\bar{y},\bar{v},\bar{w}) + \frac{1}{n^2} \right)^+ \right]^2 + (d_{\mathcal{C}}(\phi(y)))^2 \right\}^{1/2}.$$

With such a choice, for every $k > 0$, $(\bar{y},\bar{v},\bar{w})$ is a $\frac{1}{n^2}$-solution of the penalized problem

$$(P_n^k) \qquad \inf\{J_n(y,v,w) \mid (y,v,w) \in C(\overline{Q}) \times V_{ad}(\bar{v},k) \times W_{ad},\ (y,v,w) \text{ satisfies (1.1)}\}.$$

As in section 5.2, for every $k > 0$, we choose $n(k)$ such that

$$\frac{1}{n(k)} \le \frac{1}{k^{2\sigma}}.$$

Due to Ekeland's principle, there exists $(v_k, w_k) \in V_{ad}(\bar{v}, k) \times W_{ad}$ such that

$$d((v_k, w_k), (\bar{v}, \bar{w})) \leq \frac{1}{n(k)},$$

$$J_{n(k)}(y_k, v_k, w_k) \leq J_{n(k)}(y_{vw}, v, w) + \frac{1}{n(k)} d((v_k, w_k), (v, w))$$

for every $(v, w) \in V_{ad}(\bar{v}, k) \times W_{ad}$ (y_k is the solution of (1.1) corresponding to (v_k, w_k)).

With calculations similar to those in [26], [42], and [12], by using diffuse perturbations, we get

$$\int_\Sigma H(s,t,y_k(s,t),v_k(s,t),p_k(s,t),\nu_k)\,dsdt$$

$$\leq \int_\Sigma H(s,t,y_k(s,t),v_{0k}(s,t),p_k(s,t),\nu_k) + \frac{1}{n(k)}\mathcal{L}^N(\Sigma)$$

for every $k > 0$ and every $v_0 \in V_{ad}$ (v_{0k} is defined in function of v_0 in (5.5)) and

$$-\int_\Omega^{\nu_k} L'_w(x, y_k(T), w_k)(w_0 - w_k)\,dx - \langle p_k(0) + [\phi'_y(y_k)^* \mu_k]|_{\overline{\Omega}_0}, w_0 - w_k \rangle_{\mathcal{M}(\overline{\Omega}) \times C(\overline{\Omega})}$$

$$\leq \frac{1}{n(k)} \left(\frac{1}{n(k)} + \|w_0 - \bar{w}\|_{\infty,\Omega} \right)$$

for every $w_0 \in W_{ad}$, where

$$\nu_k = \frac{\left(J(y_k, v_k, w_k) - J(\bar{y}, \bar{v}, \bar{w}) + \frac{1}{n(k)^2} \right)^+}{J_{n(k)}(y_k, v_k, w_k)},$$

$$\mu_k = \begin{cases} \dfrac{d_{\mathcal{C}}(\phi(y_k)) \nabla d_{\mathcal{C}}(\phi(y_k))}{J_{n(k)}(y_k, v_k, w_k)} & \text{if } \phi(y_k)) \notin \mathcal{C}, \\ 0 & \text{otherwise,} \end{cases}$$

and p_k is the weak solution of

$$\begin{aligned} &-\frac{\partial p_k}{\partial t} + Ap_k + f'_y(x,t,y_k)p_k = \nu_k F'_y(x,t,y_k) + [\phi'_y(y_k)^* \mu_k]|_Q && \text{in } Q, \\ &\frac{\partial p_k}{\partial n_A} + g'_y(s,t,y_k,v_k)p_k = \nu_k G'_y(s,t,y_k,v_k) + [\phi'_y(y_k)^* \mu_k]|_\Sigma && \text{on } \Sigma, \\ &p_k(T) = \nu_k L'_y(x, y_k(T), w_k) + [\phi'_y(y_k)^* \mu_k]|_{\overline{\Omega}_T} && \text{in } \Omega. \end{aligned}$$

By passing to the limit when k tends to infinity, as in section 5.2, we finally get the Pontryagin principle in nonqualified form with $\bar{\nu} = \lim_k \nu_k$ and $\bar{\mu}$ the weak-star limit of μ_k. To prove that $(\bar{\nu}, \bar{\mu})$ is nonzero, we remark that $\nu_k^2 + |\mu_k|^2_{\mathcal{M}(\overline{D})} = 1$. If $\bar{\nu} > 0$, the proof is complete. If $\bar{\nu} = 0$, we can prove that $|\bar{\mu}|_{\mathcal{M}(\overline{D})} > 0$ by using $\lim_k |\mu_k|_{\mathcal{M}(\overline{D})} = 1$ and $\text{int}_{C(\overline{D})} \mathcal{C} \neq \emptyset$. Indeed, if $\text{int}_{C(\overline{D})} \mathcal{C}$ is nonempty, there exists a ball $B(z; \rho) \subset \mathcal{C}$ with $\rho > 0$ (where $B(z; \rho)$ is the ball in $C(\overline{D})$, centered at z and with

radius ρ). We can choose $z_k \in B(0;\rho)$ such that $\langle \mu_k, z_k \rangle_{\mathcal{M}(\overline{D})\times C(\overline{D})} = \frac{1}{2}\rho|\mu_k|_{\mathcal{M}(\overline{D})}$. Since $z + z_k \in \mathcal{C}$, from the definition of μ_k and from (5.2), we have

$$\langle \mu_k, z + z_k - \phi(y_k) \rangle_{\mathcal{M}(\overline{D})\times C(\overline{D})} \leq 0.$$

By passing to the limit, we obtain

$$\frac{1}{2}\rho + \langle \bar{\mu}, z - \phi(\bar{y}) \rangle_{\mathcal{M}(\overline{D})\times C(\overline{D})} \leq 0;$$

thus $\bar{\mu} \neq 0$.

Acknowledgments. We thank the Associate Editor and the referees for several suggestions which improved the language of the paper.

RENDEZVOUS ON THE LINE WHEN THE PLAYERS' INITIAL DISTANCE IS GIVEN BY AN UNKNOWN PROBABILITY DISTRIBUTION*

VIC BASTON† AND SHMUEL GAL‡

Abstract. Two players A and B are randomly placed on a line. The distribution of the distance between them is unknown except that the expected initial distance of the (two) players does not exceed some constant μ. The players can move with maximal velocity 1 and would like to meet one another as soon as possible. Most of the paper deals with the asymmetric rendezvous in which each player can use a different trajectory. We find rendezvous trajectories which are efficient against all probability distributions in the above class. (It turns out that our trajectories do not depend on the value of μ.) We also obtain the minimax trajectory of player A if player B just waits for him. This trajectory oscillates with a geometrically increasing amplitude. It guarantees an expected meeting time not exceeding 6.8μ. We show that, if player B also moves, then the expected meeting time can be reduced to 5.7μ.

The expected meeting time can be further reduced if the players use mixed strategies. We show that if player B rests, then the optimal strategy of player A is a mixture of geometric trajectories. It guarantees an expected meeting time not exceeding 4.6μ. This value can be reduced even more (below 4.42μ) if player B also moves according to a (correlated) mixed strategy. We also obtain a bound for the expected meeting time of the corresponding symmetric rendezvous problem.

Key words. rendezvous, linear search

1. Introduction.

Rendezvous search is a form of cooperative optimal search in which two or more people wish to meet as quickly as possible. Although the topic was discussed by Schelling in a book published in 1960 [15], it was not until 1994 that rendezvous search was formulated into a rigorous mathematical manner in a seminal paper by Alpern [1]. Schelling's discussion concentrates on *focal points* to which the players would move, whereas Alpern places emphasis on the symmetries of the region X in which the people are situated and formalizes the problem by specifying a particular subgroup of the isomorphism group of X. (These symmetries reflect the knowledge of the players about their location and movement in the region.) The field is an attractive one because many of the problems are mathematically challenging even though they are simple to state and understandable to a nonmathematician. Anderson and Weber [4] investigated rendezvous search on a complete graph in 1990 but a solution of the problem for a complete graph with 4 or more vertices has still not been found. Many one-dimensional rendezvous search problems also remain unsolved, and our purpose in this paper is to present some results on problems on the line. The main problem that we will investigate is the linear rendezvous problem which was described by Alpern in [1] as follows.

> Two friends have agreed to meet at noon on a certain street but have neglected to specify a specific point on the street. Assuming they know the distribution of their arrival points on the street at noon, how should they move to meet in minimum expected time?

It can be formulated mathematically in the following way.

At time $t = 0$ two players are placed on a line at a distance d from each other, where d is chosen by means of a cumulative distribution function F with support in $[0, \infty)$. The players know F but not d and neither player knows the direction of the other (nor do they have a common notion of positive direction). They can move with a maximum speed of 1 and wish to meet up with each other in the shortest possible expected time (called the *rendezvous value*).

There are in fact several different rendezvous values depending on which search strategies are permitted. We shall be primarily concerned with *asymmetric* problems in which the players are distinguishable and so are able to adopt different strategies. A strategy α is any continuous trajectory with speed not exceeding 1. A player placed at point d will have the time paths $d \pm \alpha(t)$ equiprobably. We choose the coordinate system such that the first player, say A, starts at 0 and the other, say B, starts equiprobably at $\pm d$, where d is drawn from F. If player A uses trajectory α, and B trajectory β, then their expected meeting time is the average of the meeting time of player A following trajectory α with 4 agents (representing B) following the paths: $\pm d \pm \beta(t)$; we will adopt the convention that agents 1, 2, 3, and 4 follow the paths $+d - \beta(t)$, $+d + \beta(t)$, $-d + \beta(t)$, and $-d - \beta(t)$, respectively. The *asymmetric* rendezvous value is the minimal expected time achievable by the players.

Alpern and Gal [2] obtained a number of results when the support of F is bounded or discrete and found the asymmetric rendezvous value for the case when the support of F is a single point. They also pointed out that the asymmetric rendezvous problem is closely related to the linear search problem (searching for a stationary target on the line) which was introduced by Bellman [9] and extensively studied by Anatole Beck and others (the latest references are [6] and [7]). In particular they found inequalities connecting the two problems. Note that a rendezvous search problem on the line in which one of the players has to remain stationary is just a symmetric linear search problem. (A linear search problem in which the distribution of the target is symmetric around the origin.) This problem is equivalent to finding the expected meeting time of the *wait for mummy* strategy in which one player stays in his original location and the other looks for him in an optimal way.

In contrast to the work in [2], we shall deal with general distribution functions having support in $[0, \infty)$. We consider the case where the distribution F is unknown, with the only information being that $E(d) \leq \mu$. (Such an approach has been used by Beck and Newman [8] for the linear search problem.) Our results will provide upper bounds for rendezvous values in the form $K\mu$, where K is a universal constant and μ is the mean of F. However, it should be noted that our analysis does not require the value of μ to be known. The work has a natural interpretation as a "game against nature" and can also be viewed as a version of Alpern's "adversary-rendezvous game" [1] in which the initial placement of the players is made by an opponent who wishes to maximize their rendezvous time.

In section 2 we find the minimax solution for the symmetric linear search problem. Work on the linear search problem has concentrated primarily on the searcher adopting a *pure* search strategy; we conclude the section by demonstrating that, when this restriction is removed and we allow the use of mixed strategies, the optimal so-

lution yields an expected meeting time which is significantly lower. The next section presents a strategy pair which yields an upper bound of at most 5.73μ for the asymmetric rendezvous value; in this strategy pair the players have symmetric roles in which one player takes a turn moving while the other remains stationary. The concept of correlated strategies is well established in game theory and it has recently been introduced into rendezvous search by Lim [13]. In section 4 we prove that the asymmetric rendezvous value is at most 4.42μ when the players are permitted to use correlated strategies. Symmetric rendezvous problems (ones in which both players have to play the same strategy) appear to be more difficult to analyze than symmetric ones; the symmetric problem on the line when the support of F comprises a single point (see [3]) remains unsolved, whereas the corresponding asymmetric problem has a comparatively simple solution [2]. In section 5 we find an upper bound for the symmetric rendezvous value. Many attractive problems remain open and the paper concludes with two conjectures.

2. The symmetric linear search problem. When players can adopt different strategies in trying to meet up with each other, an obvious plan is for one of them to remain stationary while the other one tries to find him. In this case the rendezvous search problem reduces to a linear search problem in which the distribution function is symmetric. The following theorem gives a best possible result for this case.

THEOREM 2.1. *For the symmetric linear search problem, there is a trajectory such that the expected meeting time is at most* $(4+2\sqrt{2})\mu \approx 6.83\mu$, *where* μ *is the mean of* F.

Furthermore, this result is best possible in the sense that the constant cannot be lowered. Moreover, the minimax search trajectory is unique up to a multiplicative constant.

Proof. Adopting a coordinate system which has the searcher's starting point as origin, the proofs of Theorem 3.1 and Lemma 3.2 in [7] show that it is sufficient to consider a search strategy of the form $((-1)^i x_i)$, where $x_i \geq 0$ and $x_i < x_{i+1}$ whenever $x_i > 0$; this search strategy represents a path beginning at 0 and consisting of the intervals $\cdots, [-x_{2i-1}, x_{2i}]$ traversed in the positive direction followed by $[-x_{2i+1},\ x_{2i}]$ traversed in the negative direction, $\cdots$. Put $s_i = \sum_{j=-\infty}^{i} x_j$, then the expected meeting time $L(F)$ is given by

$$\begin{aligned} L(F) &= \sum_{i=-\infty}^{\infty} \frac{1}{2}\int_{x_i}^{x_{i+1}} (2s_{i+1}+t)\,dF(t) + \frac{1}{2}\int_{x_i}^{x_{i+1}} (2s_i+t)\,dF(t) \\ &= \mu + \sum_{i=-\infty}^{\infty} \int_{x_i}^{x_{i+1}} (s_i+s_{i+1})\,dF(t). \end{aligned}$$

Let

$$x_i = (1+\sqrt{2})^i, \tag{2.1}$$

then $s_i = (1+\sqrt{2})x_i/\sqrt{2}$ and

$$\begin{aligned} \sum_{i=-\infty}^{\infty} \int_{x_i}^{x_{i+1}} (s_i+s_{i+1})\,dF(t) &= \sum_{i=-\infty}^{\infty} \int_{x_i}^{x_{i+1}} x_i(1+\sqrt{2})(2+\sqrt{2})/\sqrt{2}\,dF(t) \\ &= (3+2\sqrt{2}) \sum_{i=-\infty}^{\infty} \int_{x_i}^{x_{i+1}} x_i\,dF(t) \leq (3+2\sqrt{2})\mu, \end{aligned}$$

and the first part of the result follows.

We now show it is best possible. Let $\lambda = \sup_{x_j \neq 0} x_{j+1}/x_j$; we will only consider the case where λ is finite because the case $\lambda = \infty$ follows in an analogous manner. For each $\epsilon > 0$, we can choose a k such that $x_{k+1}/x_k > \lambda - \epsilon$. Putting $r_j = x_j/x_{j+1}$ if $x_j \neq 0$ and $r_j = 0$ otherwise, we have

$$\begin{aligned}\frac{s_k + s_{k+1}}{x_k} &= r_k^{-1} + 2(1 + r_{k-1} + r_{k-1}r_{k-2} + r_{k-1}r_{k-2}r_{k-3} + \cdots) \\ &> \lambda - \epsilon + 2(1 + \lambda^{-1} + \lambda^{-2} + \lambda^{-3} + \cdots) = \lambda - \epsilon + 2\lambda/(\lambda - 1).\end{aligned}$$

It is routine to check that the right-hand side is minimized as a function of λ by $\lambda = 1 + \sqrt{2}$, so we have

$$s_k + s_{k+1} \geq (3 + 2\sqrt{2})x_k.$$

Let F_η be the distribution function given by 0 if $t < x_k + \eta$, and 1 otherwise; then, by taking $\eta > 0$ sufficiently small, $L(F_\eta)$ can be made as near as we please to $(4+2\sqrt{2})\mu$. Hence the asserted constant is the best possible and the second part of the theorem is established.

The above result can also be proved using a general theorem (Theorem 7 in Chapter 6.5 of [11]). Moreover, it also follows from the general theorem that any trajectory with $s_k + s_{k+1} \leq (3 + \sqrt{2})x_k$ is equal to (2.1) up to a multiplicative constant.

Note that the corresponding value for the (usual) linear search problem is 9μ (see [8]).

COROLLARY 2.2. *For all distribution functions with support in* $[0, \infty)$, *the asymmetric linear rendezvous value is at most* $(4 + 2\sqrt{2})\mu$, *where* μ *is the mean of* F.

Proof. From Theorem 2.1 such a value can be achieved by a "wait for mummy" strategy.

THEOREM 2.3. *When the searcher can use a mixed strategy, an upper bound for the expected meeting time in the symmetric linear search problem is*

$$\left(1 + \frac{g^* + 1}{\ln g^*}\right)\mu,$$

where μ *is the mean of* F *and* g^* *is the value of* g *which minimizes* $(g + 1)/\ln g$; *the upper bound is approximately* 4.6μ *and* g^* *approximately* 3.6.

This is a best possible result in the sense that the constant cannot be lowered.

Proof. Let S be the searcher strategy given by (x_i), where $x_i = (-1)^i g^{i+u}$ and u is a random variable uniformly distributed in [0,1). For a distance x and a fixed trajectory, let $D = D(x)$ be the first geometric term numerically greater than or equal to x; then the expected time of the searcher to find an object which is initially at distance x from the searcher's starting point is given by

$$\frac{1}{2}\left(\frac{2D}{g-1} + x\right) + \frac{1}{2}\left(\frac{2Dg}{g-1} + x\right) = x + \frac{D(g+1)}{g-1}.$$

Put $x = g^{i+v}$, where $0 \leq v < 1$. Then

$$D = \begin{cases} g^{i+u} & \text{if } v \leq u < 1, \\ g^{i+1+u} & \text{if } 0 \leq u < v. \end{cases}$$

Hence the expected time for strategy S to reach x is

$$x+\frac{g+1}{g-1}\left(\int_0^v g^{i+1+u}du+\int_v^1 g^{i+u}du\right)$$
$$=x+\frac{g+1}{(g-1)\ln g}\left(g^{i+1}(g^v-1)+g^i(g-g^v)\right)=x+\frac{(g+1)g^{i+v}}{\ln g}=x\left(1+\frac{g+1}{\ln g}\right).$$

Thus S yields an expected meeting time of at most

$$\mu\left(1+\frac{g+1}{\ln g}\right).$$

The minimum of $(g+1)/\ln g$ is attained when g is approximately 3.6 which gives an upper bound of at most 4.6μ.

Note that this is the same result as for the (usual) linear search problem (see [8]). This is not surprising because the worst (actually ϵ-worst) distribution for the linear search problem is symmetric. This distribution can keep the expected meeting time for both problems to at least $(1+(g^*+1)/\ln g^*)\mu$ which shows that this constant cannot be lowered and that the strategy described in the proof is optimal.

3. The asymmetric linear rendezvous problem. It is not easy to improve the bound in Corollary 2.2. If the other player, say B, is also moving, then any reduction in the meeting time of player A and agent 1 also increases the meeting time with agent 2. Similarly, meeting agent 3 earlier causes player A to meet agent 4 later and vice versa.

THEOREM 3.1. *The asymmetric linear rendezvous value is at most* 5.73μ*, where* μ *is the mean of* F.

Proof. We describe the trajectories of the players in time intervals $[\rho_{2i},\rho_{2i+2}]$, where $-\infty<i<\infty$ and $\rho_i=(g^2+1)g^{i-1}/(g-1)$. Note that $\rho_{i+1}=\rho_i+g^{i+1}+g^{i-1}$.

In the interval $[\rho_{2i},\rho_{2i+1}]$, player A remains stationary at a point g^{2i} from his starting point while player B moves at speed 1 from a point g^{2i-1} from his starting point to the point g^{2i+1} on the opposite side of his starting point.

In the interval $[\rho_{2i+1},\rho_{2i+2}]$, player B remains stationary at a point g^{2i+1} from his starting point while player A moves at speed 1 from a point g^{2i} from his starting point to the point g^{2i+2} on the opposite side of his starting point.

Suppose the players start at distance x apart, where $g^{i-1}<x\le g^i$ and $g\ge(1+\sqrt{5})/2$. At time $\rho_{i-1}+g^{i-2}$, one player, say A, is back at his starting point and the other, say B, is at a distance g^{i-1} from his starting point. Take a coordinate system with origin being the starting point of A and positive direction being the direction of A's motion in $[\rho_{i-1},\rho_i]$; then the agents 1, 2, 3, and 4 of player B are located at the points $x-g^{i-1}$, $x+g^{i-1}$, $-x+g^{i-1}$, and $-x-g^{i-1}$, respectively. Note that the agents of B remain stationary in $[\rho_{i-1}+g^{i-2},\rho_i]$.

Agent 1. Player A will meet agent 1 at time $\rho_{i-1}+g^{i-2}+x-g^{i-1}<\rho_i$ and so at time

$$x+\frac{2g^{i-1}}{g-1}.$$

Agent 2. Player A will meet agent 2 at time $\rho_{i-1}+g^{i-2}+x+g^{i-1}\le\rho_i$ if $x\le g^i-g^{i-1}$ and at time $\rho_i+x+g^{i-1}-g^i<\rho_{i+1}$ if $x>g^i-g^{i-1}$. Thus they meet

at time

$$x + \frac{2g^i}{g-1}.$$

Agent 3. Player A will meet agent 3 at time $\rho_{i-2} + g^{i-3} + x - g^{i-2} \le \rho_{i-1}$ if $x \le g^{i-1} + g^{i-2}$ and at time $\rho_{i+1} + x + g^i + g^{i+1} < \rho_{i+2}$ if $x > g^{i-1} + g^{i-2}$ and $x \le g^i(g^2 - g)$. The last inequality holds because $g \ge (1+\sqrt{5})/2$, and so they meet at time

$$x + \frac{2}{g-1}\begin{cases} g^{i-2} & \text{if } x \le g^{i-1} + g^{i-2}, \\ g^{i+2} & \text{if } x > g^{i-1} + g^{i+2}. \end{cases}$$

Agent 4. Player A will meet agent 4 at time $\rho_i + g^{i-1} + x + g^i \le \rho_{i+1}$ if $x \le g^{i+1} - g^i$ and at time $\rho_{i+1} + x + g^i - g^{i+1}$ if $x > g^{i+1} - g^i$. Thus they meet at time

$$x + \frac{2g^{i+1}}{g-1}.$$

Hence the expected meeting time for the players when they start at distance x apart is at most

$$x + \frac{(g+1)(g^2+1)}{2(g-1)}\begin{cases} g^{i-2} & \text{if } x \le g^{i-1} + g^{i-2} \\ g^{i-1} & \text{if } x > g^{i-1} + g^{i-2} \end{cases}$$

and so at most

$$x + \frac{g^2+1}{2(g-1)} \max\left\{ gx, \frac{(g+1)x}{g} \right\} = x\left\{ 1 + \frac{g(g^2+1)}{2(g-1)} \right\}$$

because $(1+\sqrt{5})/2 \le g$. The minimum occurs when $2g + 1 = 2/(g-1)^2$, and taking $g = 1.6775$ gives a bound slightly less than 5.73.

It is easy to see that, for a particular distribution function, the expected meeting time is not increased if player B continues moving after ρ_{2i+1}, provided he arranges to be stationary at the point g^{2i+1} from his starting point during the time interval $[\rho_{2i+1} + g^{2i+1} + g^{2i-1}, \rho_{2i+2}]$. A corresponding comment holds for player A in the time interval $[\rho_{2i}, \rho_{2i+1}]$. Although this modification does not result in an improvement in our bound, it does suggest that the bound might be lowered by using strategies in which players move simultaneously for at least some of the time. Note that, when the support of F is a single point, the minimum expected meeting time is achieved by strategies in which the players are always moving; furthermore, the trajectories of the players are not symmetrical.

How much can the bound be reduced? The problem seems difficult but we can get an idea by looking at the point distribution considered in [2]. There, the expected meeting time is 2μ for the wait for mummy strategy and $13\mu/8$ for the optimum, i.e., a reduction of nearly 19%. Such an extrapolation leads to about 5.55μ in our case. While this is in no way a precise argument it may hint that the value 5.73μ we obtained in Theorem 3.1 is not far from the optimum.

4. The correlated asymmetric linear rendezvous problem. Aumann [5] has pointed out that, in game theory, it is often important whether players can use the same randomizing device for their strategies; if they can, the resulting strategies

are called correlated strategies and lead to the concept of correlated equilibria. The idea has proved fruitful and is now covered in standard textbooks on game theory ([10], [14]). Lim [13] recently introduced the concept into rendezvous search, and our analysis will address the simple case in which both players observe the same random variable and know the realization value. Note that Theorem 2.3 provides us with an upper bound for the correlated asymmetric linear rendezvous value where the random variable is uniformly distributed in [0,1]. The next theorem shows that this bound can be improved.

THEOREM 4.1. *Correlated strategies can reduce the expected meeting time of the asymmetric linear rendezvous below* 4.42μ, *where* μ *is the mean of* F.

Proof. Let $g > 1$ be fixed and let u be the realization value (known to both players) of a random variable uniformly distributed in [0,1]. Put $D(i) = g^{i+u}$. We describe the trajectories of the players in the time interval $[\sigma_{i-1}, \sigma_i]$, where $\sigma_i = (g+1)D(i)/(g-1)$.

At time σ_{i-1}, player A is at distance $D(i-1)$ from his starting point and in the interval moves at speed 1 to the point $D(i)$ on the opposite side of his starting point.

Player B chooses a direction at random as forward at $t = 0$ and is at his starting point at time σ_{i-1}; at speed 1 he moves forward, then backward, then forward, then backward for times $D(i-1)$, $D(i-1)$, $(D(i) - D(i-1))/2$, $(D(i) - D(i-1))/2$, respectively.

Note that the movement in this time interval corresponds to an optimal trajectory under the assumption that the initial distance is $D(i)$.

Suppose the players start at distance x apart where $D(i-1) < x \le D(i)$. With the given trajectories, player A will meet two of player B's agents in $[\sigma_{i-1}, \sigma_i]$ at times

$$\sigma_{i-1}+2D(i-1)+\frac{x-D(i-1)}{2} \quad \text{and} \quad \sigma_{i-1}+2D(i-1)+\frac{D(i)-D(i-1)}{2}+\frac{x-D(i-1)}{2}$$

and the other two in $[\sigma_i, \sigma_{i+1}]$ at times

$$\sigma_i + (D(i)+x)/2 \quad \text{and} \quad \sigma_i + D(i) + (D(i)+x)/2;$$

since $\sigma_i = \sigma_{i-1} + D(i-1) + D(i)$, the expected time of meeting is therefore

$$\sigma_{i-1} + x/2 + 9(D(i-1) + D(i))/8 = x/2 + D(i-1)\left\{\frac{2}{g-1} + \frac{17}{8} + \frac{9g}{8}\right\}.$$

Hence if the players start at distance d apart, where $d = g^{i+a}$ and $0 \le a \le 1$, the expected meeting time is

$$\frac{d}{2}+\left\{\frac{2}{g-1}+\frac{17}{8}+\frac{9g}{8}\right\}\left\{\int_0^a g^{i+u}\,du+\int_a^1 g^{i-1+u}\,du\right\} = \frac{d}{2}+\left\{\frac{2}{g-1}+\frac{17}{8}+\frac{9g}{8}\right\}\frac{g-1}{g\ln g}d.$$

On minimizing with respect to g, the optimal g is approximately 3.5, giving a bound of less than $4.42d$, and the result follows.

5. Symmetric rendezvous on the line. We now turn to the case where the players have to use the same strategy. Let g and a be positive constants. Consider the situation in which the players adopt a (mixed) strategy which has the properties (i)–(iii) listed below in time intervals $[\tau_n, \tau_{n+1}]$, where $\tau_n = ag^n/(g-1)$ and $-\infty < n < \infty$. Assume that the players have not met up to and including time τ_n and that, at time τ_n, they are in the same relative position to each other as they were at the start.

(i) If the players do not meet in $[\tau_n, \tau_{n+1}]$ then, at time τ_{n+1}, they are also in the same relative position to each other as they were at the start.

(ii) If their distance apart at time τ_n is greater than g^n, the players do not meet in $[\tau_n, \tau_{n+1}]$.

(iii) If their distance apart at time τ_n is at most g^n, then there is a probability $\rho > 0$ (a pure constant) that the players will meet in $[\tau_n, \tau_{n+1}]$; if they meet in $[\tau_n, \tau_{n+1}]$, their expected meeting time is $\tau_n + x/2 + \nu g^n$, where ν is a pure constant.

Suppose the players start at distance x apart, where $x \in (g^{n-1}, g^n]$. By property (ii), the players do not meet in any of the time intervals $[\tau_r, \tau_{r+1}]$ for $r \le n-1$. By property (iii), for $r \ge n$, there is a probability $(1-\rho)^{r-n}\rho$ that the players will meet for the first time in $[\tau_r, \tau_{r+1}]$. Hence provided $(1-\rho)g < 1$, the expected meeting time is

$$\sum_{r=n}^{\infty}(1-\rho)^{r-n}\rho\left\{\frac{ag^r}{g-1}+\frac{x}{2}+\nu g^r\right\} = \frac{x}{2}+\frac{\rho(a/(g-1)+\nu)}{(1-\rho)^n}\sum_{r=n}^{\infty}(1-\rho)^r g^r$$
$$= \frac{x}{2}+\frac{\rho(a/(g-1)+\nu)g^n}{1-(1-\rho)g} \le \frac{x}{2}+\frac{\rho(a/(g-1)+\nu)}{1-(1-\rho)g}gx.$$

The last expression tends to infinity as $g \to 1$ from the right and as $g \to 1/(1-\rho)$ from the left, so it has a minimum g^* in $(1, (1-\rho)^{-1})$; note that $g^*(1-\rho) < 1$. The turning points are at

$$g = \frac{\nu \pm \sqrt{a^2+\nu a\rho - a^2\rho}}{\nu + a - a\rho} \quad \text{so} \quad g^* = \frac{\nu+\sqrt{a^2+\nu a\rho-a^2\rho}}{\nu+a-a\rho}.$$

We use this analysis to prove the following theorem.

THEOREM 5.1. *The symmetric linear rendezvous value is at most* $(7+2\sqrt{10})\mu$, *where* μ *is the mean of* F.

Proof. We describe the trajectories of the players in the time interval $[\tau_n, \tau_{n+1}]$, where $\tau_n = 2g^n/(g-1)$.

At time τ_n a player is at his starting point and chooses a direction at random as forward; he then moves at speed 1 forward, then backward, then forward for times $g^n/2,\ g^n,\ g^n/2$, respectively.

Clearly the players meet in $[\tau_n, \tau_{n+1}]$ if and only if they start at distance $x \le g^n$ apart and they choose opposite directions as forward. Thus for such x, they meet with probability $1/2$ and the expected meeting time is $\tau_n + x/2 + g^n/2$. Hence we have a special case of the above analysis with $a = 2,\ \rho = 1/2 = \nu$, so $g^* = (1+\sqrt{10})/3$ giving the asserted bound of $(7+2\sqrt{10})\mu$; the value of g is approximately 1.39 and the bound slightly less than 13.33μ.

THEOREM 5.2. *Correlated strategies can reduce the expected meeting time of the symmetric linear rendezvous below* 11.4μ, *where* μ *is the mean of* F.

Proof. Let $g > 1$ be fixed and let u be the realization value (known to both players) of a random variable uniformly distributed in [0,1]. Put $D(i) = g^{i+u}$. We describe the trajectories of the players in the time interval $[\eta_n, \eta_{n+1}]$, where $\eta_n = 2D(n)/(g-1)$.

At time η_n a player is at his starting point and chooses a direction at random as forward; he then moves at speed 1 forward, then backward, then forward for times $D(n)/2,\ D(n),\ D(n)/2$, respectively.

Suppose, at time $t = 0$, the players are at distance x apart, where $D(i-1) < x \le D(i)$, then, from our earlier analysis in this section, their expected meeting time is

$$\frac{x}{2}+\frac{1/(g-1)+(1/4)}{1-g/2}D(i) = \frac{x}{2}+\frac{g+3}{2(2-g)(g-1)}D(i).$$

Hence if the players start at distance d apart, where $d = g^{i+a}$ and $0 \le a \le 1$, the expected meeting time is

$$\frac{d}{2} + \frac{g+3}{2(2-g)(g-1)}\left\{\int_0^a g^{i+u+1}du + \int_a^1 g^{i+u}du\right\} = \frac{d}{2} + \frac{g+3}{2(2-g)\ln g}d.$$

The last expression is minimized in [1,2] at approximately 1.43, giving a value for the expression slightly less than 10.9μ. The theorem now follows.

6. Conclusions. Although our bounds are given in the form $K\mu$, where μ is the mean of the distribution function, we do not need to know the value of μ in the analysis of any of our cases. Apart from Theorems 2.1 and 2.3, it would be surprising if our results were best possible. Many attractive problems remain, especially finding the minimax trajectories and optimal correlated strategies for the linear rendezvous, and we now formulate two conjectures.

The *greedy strategy pair of length* D is given by the following:

• At time $t = 0$ player A chooses a direction as forward, then moves at speed 1 forward for a time D and then backward for a time $2D$;

• At time $t = 0$ player B chooses a direction as forward, then moves at speed 1 forward, then backward, then forward, then backward for times $D/2$, $D/2$, D, and D, respectively.

The motions of the players after time $3D$ can be defined arbitrarily.

The name "greedy" originates from the fact that, if the players start at distance D apart, then at time $t = 0$ player A and agent 1 move at maximum speed towards each other; after they meet then player A and agent 2 move at maximum speed towards each other and so on.

Note that the greedy strategy pair of length D is optimal for the asymmetric linear rendezvous search problem where the players know they start at distance D apart.

Note that in a time interval $(t, t + \delta t)$ the players gain by **both** moving if the distribution of their distance is increasing in $(0, \delta t)$. If it is decreasing, then it is better for one of them to remain stationary while the other player moves. This fact has been observed in [12] (which also showed that "wait for mummy" is never optimal). Thus the following conjectures seem reasonable.

CONJECTURE 6.1. *Let F be a distribution function with support in $[0, D]$ which has a density function that is nondecreasing in $[0, D]$; then the greedy strategy pair of length D is optimal for the asymmetric linear rendezvous search problem having distribution function F.*

CONJECTURE 6.2. *Let F be a distribution function with support in $[0, D]$ which has a density function that is strictly decreasing in $[0, D]$; then there is an optimal strategy pair for the asymmetric linear rendezvous search problem which takes the following form:*

• *player A oscillates with speed 1;*

• *player B is stationary while player A discovers new points and moves at speed 1 forward, then backward for times $t/2$ and $t/2$ during any period of length t in which player A does not discover new points.*

ADAPTIVE LINEAR QUADRATIC GAUSSIAN CONTROL: THE COST-BIASED APPROACH REVISITED*

M. C. CAMPI† AND P. R. KUMAR‡

Abstract. In adaptive control, a standard approach is to resort to the so-called certainty equivalence principle which consists of generating some standard parameter estimate and then using it in the control law as if it were the true parameter. As a consequence of this philosophy, the estimation problem is decoupled from the control problem and this substantially simplifies the corresponding adaptive control scheme. On the other hand, the complete absence of dual properties makes certainty equivalent controllers run into an identifiability problem which generally leads to a strictly suboptimal performance.

In this paper, we introduce a cost-biased parameter estimator to overcome this difficulty. This estimator is applied to a linear quadratic Gaussian controller. The corresponding adaptive scheme is proven to be stable and optimal when the unknown system parameter lies in an infinite, yet compact, parameter set.

Key words. adaptive control, linear quadratic Gaussian control, self-optimizing control, cost-biased approach, certainty equivalence

1. Introduction.

Consider a linear time-invariant system

$$x_{t+1} = A^\circ x_t + B^\circ u_t + w_{t+1}, \tag{1}$$

where $x_t \in \mathbf{R}^n$ is the state, $u_t \in \mathbf{R}^m$ the control variable, and w_t is a noise process of independent, Normal $N(0,1)$ random variables. The system matrices A° and B° are unknown.

Our control objective is to select the input u_t in such a way as to minimize the long-term average quadratic cost criterion

$$\limsup_{t\to\infty} \frac{1}{t} \sum_{s=1}^{t} \left[x_s^T Q x_s + u_s^T R u_s\right], \qquad Q = Q^T \geq 0, \quad R = R^T > 0. \tag{2}$$

To this purpose, we observe the state x_t and, based on this, we first generate an estimate of the system matrices A° and B° and then exploit these estimates in a certainty equivalence fashion.

A common way to generate an estimate of A° and B° is to resort to the least squares method which corresponds to minimizing the performance index

$$V_t(A,B) = \sum_{s=1}^{t} \|x_s - Ax_{s-1} - Bu_{s-1}\|^2. \tag{3}$$

It is well known, however, that the corresponding certainty equivalent adaptive control law can suffer from an identifiability problem and that this can result in a degradation of the control system performance; see [1, 2, 3, 4]. In particular, for the case where matrices A° and B° belong to a finite known set, it is shown in [2] that the least squares estimate can converge with positive probability to a false estimate, which then leads to a strictly suboptimal value of the long-term average cost criterion. For the case of controlled Markov chains, such a counterexample had earlier been exhibited in [1]. Parameter consistency is guaranteed under certain conditions which are satisfied only in specific adaptive control situations, as, e.g., studied in [5] and [6].

This inability to identify the open loop system from closed-loop measurements is one of the fundamental obstacles to self-optimizing adaptive control. To overcome this, one approach is to occasionally probe the system. This can be done by either adding dither to the control or by occasionally breaking the control loop. However, such perturbations should be of small enough magnitude or infrequent enough so that they do not in themselves add to the cost incurred. An account of this approach can be found in Chen and Guo [7, 8, 9, 10, 11, 12].

To overcome this general problem of identifiability in closed loop, a very different approach, which still preserves the certainty equivalent structure of the adaptive controller and holds out the promise of general self-optimizing controllers, was proposed in [13] for the class of controlled Markov chains. The novelty of this adaptive controller is the employment of a *cost-biased maximum likelihood* parameter estimator, rather than the usual maximum likelihood parameter estimator. This cost biasing modifies the log-likelihood criterion by incorporating an additional term which favors parameter estimates with smaller optimal costs. For controlled Markov chains with a finite parameter set, it was shown in [13] that such a cost biasing eliminates parameters with costs larger than the optimal cost from occurring as limit points of the estimator. As a consequence, the corresponding adaptive controller was proved to provide optimal performance. This result was extended in [14] to the case of general parameter sets, for controlled Markov chains with finite state spaces. Another extension to the case of a finite parameter set, but allowing for a general state space and nonlinear systems, was provided in [15]. In the reference most pertinent to this paper, [2], it was shown that the cost-biased maximum likelihood-based certainty equivalent controller yielded an optimal cost for linear systems with quadratic costs, as in (1) and (2), provided that the parameter set is finite.

The assumption that the parameter set is finite is crucial in the derivations of [2]. Indeed, it was shown in [2] that the log-likelihood ratio $V_t(A^\circ, B^\circ) - V_t(A,B)$ stays bounded for any *fixed* parameter (A,B), and, therefore, a wrong fixed parameter (A,B) can gain, at most, a finite advantage over the true parameter (A°, B°) in the standard least squares criterion. Thus, when the number of possible parameters is finite, the maximum of these finite advantages is still finite, and so a mild biasing is sufficient to prevent elements (A,B) with larger cost than the optimal cost from occurring as limit points of the parameter estimator. This mildness of the biasing is important in order not to destroy the ability of the least squares estimate to identify closed-loop dynamics. Unfortunately, this argument is no longer true when turning to

a more general setting allowing for infinitely possible true parameterizations. Indeed, in such a case, $inf_{(A,B)}[V_t(A^\circ, B^\circ) - V_t(A, B)]$ is no longer bounded and the above argument valid for the finite case fails to apply. As a consequence of this and other difficulties, the infinite parameter set case has remained so far unsolved.

It is the purpose of this paper to establish the optimality of a certainty equivalent controller based on the cost-biased maximum likelihood parameter estimator for linear quadratic Gaussian systems, in the case of compact parameter uncertainty set. The aforementioned difficulty that the log-likelihood ratio $V_t(A^\circ, B^\circ) - V_t(A, B)$ is unbounded is circumvented by resorting to a Bayesian embedding approach. In this setting, one can show that the least squares estimate converges along the directions of diverging information to the true parameter value. As a consequence, a sequence of parameters (A'_t, B'_t) can be determined with the property that it converges to the true parameter (A°, B°) and for which $inf_{(A,B)}[V_t(A'_t, B'_t) - V_t(A, B)]$ remains bounded. Loosely speaking, (A'_t, B'_t) can be used in the analysis in place of (A°, B°) and, by a careful use of continuity arguments, the optimality of the adaptive controller can be established.

The paper is organized as follows. Our adaptive control scheme is described in section 2. In section 3, the properties of the cost-biased maximum likelihood parameter estimator are worked out. Section 4 is devoted to the study of the self-tuning properties of the adaptive scheme, and its stability and optimality are established in section 5.

2. The adaptive control system. Throughout this paper, let $[A, B] \in \mathbf{R}^{n\times(n+m)}$ denote the matrix obtained by concatenating matrices $A \in \mathbf{R}^{n\times n}$ and $B \in \mathbf{R}^{n\times m}$.

In our adaptive control problem, matrices A° and B° of system (1) are unknown and belong to a known compact set Θ as precisely stated in the following assumptions.

(A.i) There is a known compact set $\Theta \subset R^{n\times(n+m)}$ such that

$$[A^\circ, B^\circ] \in \text{interior}(\Theta).$$

(A.ii) (A, B) is reachable and $(A, Q^{1/2})$ is observable, $\forall [A, B] \in \Theta$.

Given the system parameters $[A, B] \in \Theta$, the control law minimizing the cost (2) for the system $x_{t+1} = Ax_t + Bu_t + w_{t+1}$ is easily derived (see, e.g., Kumar and Varaiya [16] or Bertsekas [17] for a comprehensive presentation of linear quadratic control problems). First, one has to compute the positive semidefinite solution to the algebraic Riccati equation

$$P = A^T PA - A^T PB(B^T PB + R)^{-1}B^T PA + Q.$$

The existence and uniqueness of such a solution is a consequence of the reachability and observability assumption (A.ii). Denoting such a solution by $P(A, B)$, the control law is then given by

$$u_t = K(A, B)x_t, \tag{4}$$

where $K(A, B)$ is the linear quadratic Gaussian (LQG) optimal gain defined by

$$K(A, B) = -(B^T P(A, B)B + R)^{-1}B^T P(A, B)A. \tag{5}$$

The corresponding optimal cost is denoted by $J(A, B)$.

When one is facing an adaptive control problem, the system matrices (A°, B°) are not known and some estimates $\widehat{A}_t$ and $\widehat{B}_t$ of them are needed. Once these estimates have been generated, in the certainty equivalence approach they are simply used as if they were the true system matrices. Correspondingly, the adaptive control law is given by

$$u_t = K(\widehat{A}_t, \widehat{B}_t)x_t. \tag{6}$$

The heart of our adaptive control scheme lies in the cost-biased least squares estimator of the system matrices as described below.

Choose a deterministic sequence μ_t such that $\mu_t \to \infty$ and $\mu_t = o(\log t)$ as $t \to \infty$. The parameter estimate sequence $\{[\widehat{A}_t, \widehat{B}_t]\}$ is given by

$$[\widehat{A}_t, \widehat{B}_t] = \begin{cases} \arg\min_{[A,B]\in\Theta} \left\{ \sum_{s=1}^{t} \|x_s - Ax_{s-1} - Bu_{s-1}\|^2 + \mu_t J(A,B) \right\}, & \text{for } t \text{ even}, \\ \left[\widehat{A}_{t-1}, \widehat{B}_{t-1}\right], & \text{for } t \text{ odd} \end{cases} \tag{7}$$

(when there is more than one minimizer, any of them can be chosen).

The distinguishing feature of the criterion (7) is the term $\mu_t J(A, B)$, which introduces a mild bias in favor of parameters (A, B) with lower optimal costs. The biasing is "mild" because $\mu_t = o(\log t)$. On the other hand, it is nonnegligible because $\mu_t \to \infty$. Without this term one would simply have the usual least squares parameter estimator, with its attendant difficulty in identifying the system in closed loop.

The intuitive rationale for the cost biasing in the least squares criterion is as follows. Suppose that one simply employs a straightforward least squares parameter estimator. Then, generically, it can be shown that the least squares parameter estimates sequence $[\widehat{A}_t^{LS}, \widehat{B}_t^{LS}]$ converges to a limiting random variable $[\widehat{A}_\infty^{LS}, \widehat{B}_\infty^{LS}]$ (see [18]). Such a limiting estimate results in a limiting controller $u_t = K(\widehat{A}_\infty^{LS}, \widehat{B}_\infty^{LS})x_t$. It is natural to expect that the least squares estimator will asymptotically identify, at a minimum, the closed-loop behavior of the system. Thus, one expects that the behavior of the true system with the loop closed by $u_t = K(\widehat{A}_\infty^{LS}, \widehat{B}_\infty^{LS})x_t$ will be the same as the closed-loop estimated system, i.e., their closed-loop gains are equal:

$$A^\circ + B^\circ K(\widehat{A}_\infty^{LS}, \widehat{B}_\infty^{LS}) = \widehat{A}_\infty^{LS} + \widehat{B}_\infty^{LS} K(\widehat{A}_\infty^{LS}, \widehat{B}_\infty^{LS}).$$

This implies that the cost of running the true system (A°, B°) with the feedback gain $K(\widehat{A}_\infty^{LS}, \widehat{B}_\infty^{LS})$ is the same as the cost of running the estimated system $(\widehat{A}_\infty^{LS}, \widehat{B}_\infty^{LS})$ with the feedback $K(\widehat{A}_\infty^{LS}, \widehat{B}_\infty^{LS})$. The latter is, however, the optimal configuration for the system $x_{t+1} = \widehat{A}_\infty^{LS} x_t + \widehat{B}_\infty^{LS} u_t + w_{t+1}$, while the former is not necessarily an optimal configuration for the true system. Thus one has

$$J(\widehat{A}_\infty^{LS}, \widehat{B}_\infty^{LS}) \geq J(A^\circ, B^\circ).$$

This means that the least squares estimator has a natural tendency to return estimates with larger optimal cost than the optimal cost associated with the true system. This motivates the idea of somehow introducing a bias into the parameter estimator so that it favors parameters (A, B) with smaller values of $J(A, B)$.

Thus, one conceives of adding a term such as $\mu_t J(A, B)$ to the squared error in (7). However, one needs to choose μ_t with care. One does not want to destroy the

ability of the least squares estimator to identify the closed-loop dynamics. This is achieved by choosing μ_t small enough so that $\mu_t = o(logt)$. On the other hand, one definitely wants the $\mu_t J(A,B)$ term to assert itself, and this is achieved by choosing $\mu_t \to \infty$. Hence, we arrive at the cost-biased least squares parameter estimator (7).

Notation. For brevity, the following notation will be used throughout the paper: $P^\circ := P(A^\circ, B^\circ)$, $\widehat{P}_t := P(\widehat{A}_t, \widehat{B}_t)$, $K^\circ := K(A^\circ, B^\circ)$, $\widehat{K}_t := K(\widehat{A}_t, \widehat{B}_t)$, $J^\circ := J(A^\circ, B^\circ)$, and $\widehat{J}_t := J(\widehat{A}_t, \widehat{B}_t)$. □

3. The properties of the parameter estimates. In this section, we study the properties of the estimates $[\widehat{A}_t, \widehat{B}_t]$ returned by the estimator (7). Our main result is that the introduction of the cost-bias term $\mu_t J(A,B)$ in the identification criterion prevents parameters $[A,B]$ with cost $J(A,B)$ strictly larger than the optimal cost from occurring as limit points of $[\widehat{A}_t, \widehat{B}_t]$ (Theorem 2). In this way, our modification is proven successful in counteracting the natural tendency of least squares to return estimates with larger cost than the optimal one. In addition, we show that the estimator preserves the capability of the least squares method of identifying the control system closed-loop dynamics (Theorem 3).

We start by summarizing some known results on the least squares estimates relevant to the forthcoming developments.

Denote by $[\widehat{A}_t^{LS}, \widehat{B}_t^{LS}]$ the least squares estimate of $[A^\circ, B^\circ]$:

$$\left[\widehat{A}_t^{LS}, \widehat{B}_t^{LS}\right] := \arg\min_{[A,B]\in\mathbf{R}^{n\times(n+m)}} \sum_{s=1}^{t} \|x_s - Ax_{s-1} - Bu_{s-1}\|^2 .$$

The partial ability of the least squares estimates $(\widehat{A}_t^{LS}, \widehat{B}_t^{LS})$ to estimate a portion of the open-loop system can be stated precisely using the notion of the *excited subspace*, originally introduced in [19].

DEFINITION 1. *Defining* $v_s^T := [x_s^T \quad u_s^T]$, *the subspace*

$$\mathcal{E}^\perp := \left\{ z \in \mathbf{R}^{n+m} : \qquad z^T \sum_{s=1}^{\infty} v_s v_s^T z < \infty \right\}$$

is called the unexcited *subspace. Its orthogonal complement* $\mathcal{E}$ *is the* excited *subspace.*

Given $[A,B]$, let $[A,B]_{\mathcal{E}}$ and $[A,B]_{\mathcal{E}^\perp}$ denote the matrices in $\mathbf{R}^{n\times(n+m)}$ formed by projecting the rows of $[A,B]$ onto $\mathcal{E}$ and $\mathcal{E}^\perp$, respectively.

The main properties of the least squares estimate are stated in Theorem 1 below (the proof of point (i) can be derived as a slight modification to that of Theorem 1 in [18], whereas point (ii) follows from Theorem 2 in [20] and Theorem 2 in [21]).

THEOREM 1. *There exists a set* $N \in \mathbf{R}^{n+m}$ *with zero Lebesgue measure such that, if* $[A^\circ, B^\circ]$ *does not belong to* N, *then*

(i)

$$\lim_{t\to\infty} [\widehat{A}_t^{LS}, \widehat{B}_t^{LS}] = [\widehat{A}_\infty^{LS}, \widehat{B}_\infty^{LS}] \qquad a.s.,$$

where $[\widehat{A}_\infty^{LS}, \widehat{B}_\infty^{LS}]$ *is an almost surely (a.s.) bounded random variable.*

(ii)

$$[\widehat{A}_\infty^{LS}, \widehat{B}_\infty^{LS}]_{\mathcal{E}} = [A^\circ, B^\circ]_{\mathcal{E}} \qquad a.s.$$

In particular, point (ii) asserts that the asymptotic estimation error is confined to the unexcited subspace. This is not surprising since the uncertainty in the excited

directions is overcome by the information, which diverges with time. This turns out to be a crucial property in the derivation of several results concerning our adaptive scheme.

Throughout, we assume that $[A^\circ, B^\circ]$ does not belong to N.

Our first result on the cost-biased estimate $[\widehat{A}_t, \widehat{B}_t]$ proves that it abandons the region with costs larger than the optimal cost, for t large enough. A key role is played by the composite estimate

$$[A'_t, B'_t] := [\widehat{A}_t^{LS}, \widehat{B}_t^{LS}]_{\mathcal{E}} + [A^\circ, B^\circ]_{\mathcal{E}^\perp}.$$

THEOREM 2.

$$\limsup_{t\to\infty} \hat{J}_t \le J^\circ \qquad a.s.$$

Proof. Define

$$V_t(A,B) := \sum_{s=1}^{t} \|x_s - Ax_{s-1} - Bu_{s-1}\|^2,$$
$$D_t(A,B) := V_t(A,B) + \mu_t J(A,B).$$

Note for future use that

$$V_t(A,B) - V_t(\widehat{A}_t^{LS}, \widehat{B}_t^{LS}) = \sum_{s=1}^{t} \left\| \left\{ [A,B] - [\widehat{A}_t^{LS}, \widehat{B}_t^{LS}] \right\} v_{s-1} \right\|^2.$$

Indeed, recalling that the minimizer of $V_t(A,B)$ is given by $[\widehat{A}_t^{LS}, \widehat{B}_t^{LS}] = (\sum_{s=1}^t x_s v_{s-1}^T)(\sum_{s=1}^t v_{s-1} v_{s-1}^T)^{-1}$, one has

$$\begin{aligned}
V_t(A,B) - V_t(\widehat{A}_t^{LS}, \widehat{B}_t^{LS}) - \sum_{s=1}^{t} \left\| \left\{ [A,B] - [\widehat{A}_t^{LS}, \widehat{B}_t^{LS}] \right\} v_{s-1} \right\|^2 \\
= \sum_{s=1}^{t} \|x_s\|^2 + \sum_{s=1}^{t} v_{s-1}^T [A,B]^T [A,B] v_{s-1} - 2\sum_{s=1}^{t} v_{s-1}^T [A,B]^T x_s \\
- \sum_{s=1}^{t} \|x_s\|^2 - \sum_{s=1}^{t} v_{s-1}^T [\widehat{A}_t^{LS}, \widehat{B}_t^{LS}]^T [\widehat{A}_t^{LS}, \widehat{B}_t^{LS}] v_{s-1} + 2\sum_{s=1}^{t} v_{s-1}^T [\widehat{A}_t^{LS}, \widehat{B}_t^{LS}]^T x_s \\
- \sum_{s=1}^{t} v_{s-1}^T [A,B]^T [A,B] v_{s-1} - \sum_{s=1}^{t} v_{s-1}^T [\widehat{A}_t^{LS}, \widehat{B}_t^{LS}]^T [\widehat{A}_t^{LS}, \widehat{B}_t^{LS}] v_{s-1} \\
+ 2\sum_{s=1}^{t} v_{s-1}^T [A,B]^T [\widehat{A}_t^{LS}, \widehat{B}_t^{LS}] v_{s-1} \\
= -2\sum_{s=1}^{t} v_{s-1}^T [A,B]^T x_s - 2Trace\left\{ [\widehat{A}_t^{LS}, \widehat{B}_t^{LS}] \left(\sum_{s=1}^{t} v_{s-1} v_{s-1} \right) [\widehat{A}_t^{LS}, \widehat{B}_t^{LS}]^T \right\} \\
+ 2\sum_{s=1}^{t} v_{s-1}^T [\widehat{A}_t^{LS}, \widehat{B}_t^{LS}]^T x_s + 2Trace\left\{ [\widehat{A}_t^{LS}, \widehat{B}_t^{LS}] \left(\sum_{s=1}^{t} v_{s-1} v_{s-1} \right) [A,B]^T \right\}
\end{aligned}$$

$$
\begin{aligned}
&= -2\sum_{s=1}^{t} v_{s-1}^T [A,B]^T x_s - 2Trace\left\{\sum_{s=1}^{t} x_s v_{s-1}^T [\widehat{A}_t^{LS}, \widehat{B}_t^{LS}]^T\right\} \\
&+ 2\sum_{s=1}^{t} v_{s-1}^T [\widehat{A}_t^{LS}, \widehat{B}_t^{LS}]^T x_s + 2Trace\left\{\sum_{s=1}^{t} x_s v_{s-1}^T [A,B]^T\right\} \\
&= 0.
\end{aligned}
$$

For every $[A,B] \in S_\epsilon := \{[A,B] \in \Theta \ : \ J(A,B) \geq J^\circ + \epsilon\}, \epsilon > 0$, the following chain of inequalities holds true:

$$
\begin{aligned}
D_t(A,B) - D_t(A'_t,B'_t) &\geq V_t(\widehat{A}_t^{LS}, \widehat{B}_t^{LS}) + \mu_t J(A,B) \\
&\quad - V_t(A'_t,B'_t) - \mu_t J(A'_t,B'_t) \\
&\geq -\sum_{s=1}^{t} \left\| \left\{ [A'_t,B'_t] - [\widehat{A}_t^{LS}, \widehat{B}_t^{LS}] \right\} v_{s-1} \right\|^2 \\
&\quad + \mu_t \left\{ J^\circ + \epsilon - J(A'_t,B'_t) \right\}. \qquad (8)
\end{aligned}
$$

Recalling that $J(A,B) = TraceP(A,B)$ (see [16] or [17]), and that $P(\cdot,\cdot)$ is a continuous function of the entries of matrices A and B for any $[A,B] \in \Theta$ (see [22]), we can conclude that $J(\cdot,\cdot)$ is continuous in $[A^\circ, B^\circ]$. Since $[A'_t,B'_t] \to [A^\circ,B^\circ]$ (which follows from (ii) of Theorem 1), we therefore have

$$
J^\circ + \epsilon - J(A'_t,B'_t) \to \epsilon \qquad \text{a.s.}
$$

Thus, the second term on the right-hand side of (8) tends to infinity as $t \to \infty$. On the other hand, by the very definition of unexcited subspace and $[A'_t,B'_t]$, the first term stays bounded. Therefore, the right-hand side of (8) is diverging, uniformly in $[A,B] \in S_\epsilon$. That is, $D_t(A,B)$ is strictly larger than $D_t(A'_t,B'_t)$ for any $[A,B] \in S_\epsilon$ when t is large enough. Finally, by noting that $[A'_t,B'_t] \in \Theta$ for t large enough, the conclusion is drawn that $[\widehat{A}_t, \widehat{B}_t]$ leaves set S_ϵ in finite time. In view of the arbitrariness of $\epsilon > 0$, the proof is complete. □

We now introduce C_δ as the set of parameters $[A,B]$ such that the gain of the corresponding optimal closed-loop system differs from the gain of the true system with the loop closed by $K(A,B)$ by at least δ in norm, i.e.,

$$
C_\delta := \{[A,B] \in \Theta \ : \ \|[A^\circ + B^\circ K(A,B)] - [A + BK(A,B)]\| \geq \delta\}.
$$

We now prove that the estimate $[\widehat{A}_t, \widehat{B}_t]$ can visit C_δ only rarely, and so our cost-biased estimator (7) still possesses good closed-loop identification properties.

THEOREM 3.

$$
\sum_{s=1}^{t} 1([\widehat{A}_s, \widehat{B}_s] \in C_\delta) = O(\mu_t) \qquad a.s., \qquad \forall \delta > 0.
$$

Proof. We first prove that

$$
\sum_{s=1}^{t} \left\| \left\{ [A'_t,B'_t] - [\widehat{A}_t, \widehat{B}_t] \right\} v_{s-1} \right\|^2 = O(\mu_t), \qquad t \text{ even} \qquad \text{a.s.} \qquad (9)
$$

Indeed,

$$\sum_{s=1}^{t} \left\| \left\{ [A_t', B_t'] - [\widehat{A}_t, \widehat{B}_t] \right\} v_{s-1} \right\|^2$$

$$\leq 2 \sum_{s=1}^{t} \left\| \left\{ [A^\circ, B^\circ]_{\mathcal{E}^\perp} - [\widehat{A}_t^{LS}, \widehat{B}_t^{LS}]_{\mathcal{E}^\perp} \right\} v_{s-1} \right\|^2$$
$$+ 2 \sum_{s=1}^{t} \left\| \left\{ [\widehat{A}_t^{LS}, \widehat{B}_t^{LS}] - [\widehat{A}_t, \widehat{B}_t] \right\} v_{s-1} \right\|^2 .$$

The first term is bounded because of the definition of unexcited subspace. As for the second term, it can be handled as follows:

$$\sum_{s=1}^{t} \left\| \left\{ [\widehat{A}_t^{LS}, \widehat{B}_t^{LS}] - [\widehat{A}_t, \widehat{B}_t] \right\} v_{s-1} \right\|^2 = V_t(\widehat{A}_t, \widehat{B}_t) - V_t(\widehat{A}_t^{LS}, \widehat{B}_t^{LS})$$
$$= D_t(\widehat{A}_t, \widehat{B}_t) - D_t(A_t', B_t') + \mu_t \left\{ J(A_t', B_t') - \widehat{J}_t \right\}$$
$$+ \left\{ V_t(A_t', B_t') - V_t(\widehat{A}_t^{LS}, \widehat{B}_t^{LS}) \right\}.$$

The last term equals $\sum_{s=1}^{t} ||\{[A_t', B_t'] - [\widehat{A}_t^{LS}, \widehat{B}_t^{LS}]\} v_{s-1}||^2$ and is bounded, whereas, by noting that $[A_t', B_t'] \in \Theta$ for t large enough, the first term is less than or equal to zero in the limit. Result (9) then follows from the fact that $J(A_t', B_t') - \widehat{J}_t$ is bounded (remember that $J(\cdot, \cdot)$ is a continuous function on Θ and Θ is a compact set).

Note now that the matrix

$$[A^\circ + B^\circ K(A, B)] - [\bar{A} + \bar{B} K(A, B)]$$

is continuous as a function of $[A, B] \in \Theta$ and $[\overline{A}, \overline{B}] \in \Theta$ (this follows from the expression (5) of the gain $K(A, B)$ and the continuity of $P(A, B)$ in Θ (see [22])). Therefore, $\forall [\widetilde{A}, \widetilde{B}] \in C_\delta$, there exists a neighborhood $N(\widetilde{A}, \widetilde{B})$ of $[\widetilde{A}, \widetilde{B}]$ and a nonzero matrix H such that

$$\left([A^\circ + B^\circ K(A, B)] - [\overline{A} + \overline{B} K(A, B)] \right)^T \left([A^\circ + B^\circ K(A, B)] - [\overline{A} + \overline{B} K(A, B)] \right)$$
$$\geq H^T H, \qquad \forall [A, B], [\overline{A}, \overline{B}] \in N(\widetilde{A}, \widetilde{B}). \tag{10}$$

The set of all these neighborhoods constitutes a cover of C_δ, from which a finite subcover $\{N_j\}_{j=1}^{q}$ can be extracted. The thesis of the theorem can then be recast as

$$\sum_{s=1}^{t} 1([\widehat{A}_s, \widehat{B}_s] \in N_j) = O(\mu_t) \qquad \text{a.s.,} \qquad \forall j \in [1, q]. \tag{11}$$

Equation (11) will be proven by contradiction. To this purpose, set

$$\#_{j,t} := \sum_{\substack{s=1 \\ s \text{ even}}}^{t} 1([\widehat{A}_s, \widehat{B}_s] \in N_j)$$

and assume that there exist $\bar{j} \in [1, q]$ and a sequence of even time points $\{t_k\}$ such that $[\widehat{A}_{t_k}, \widehat{B}_{t_k}] \in N_{\bar{j}} \forall k$, and

$$\lim_{k\to\infty} \frac{1}{\mu_{t_k}} \#_{\bar{j},t_k} = \infty. \tag{12}$$

We prove that (12) implies

$$\liminf_{k\to\infty} \frac{1}{\#_{\bar{j},t_k}} \sum_{\substack{s=1 \\ s \text{ even}}}^{t_k} \alpha_{\bar{j},s+1} > 0, \tag{13}$$

where

$$\alpha_{\bar{j},s+1} := (\|Hx_{s+1}\|^2 \wedge 1) 1([\widehat{A}_s, \widehat{B}_s] \in N_{\bar{j}}) \tag{14}$$

(H is the matrix introduced in (10) associated with $N_{\bar{j}}$) and, in turn, this contradicts (9).

For the proof of (13), define $\mathcal{F}_s := \sigma(w_1, \dots, w_s)$ and note first that

$$\begin{aligned} E[\|Hx_{s+1}\|^2 \wedge 1 \mid \mathcal{F}_s] &= E[\|H(A^\circ x_s + B^\circ u_s) + Hw_{s+1}\|^2 \wedge 1 \mid \mathcal{F}_s] \\ &\geq \text{Prob}(\|H(A^\circ x_s + B^\circ u_s) + Hw_{s+1}\| \geq 1 \mid \mathcal{F}_s) \\ &\geq 1 - \text{Prob}\left(\|H(A^\circ x_s + B^\circ u_s)\| - 1 < \|Hw_{s+1}\| \right. \\ &\qquad \left. < \|H(A^\circ x_s + B^\circ u_s\| + 1 \mid \mathcal{F}_s)\right) \\ &\geq 1 - \sup_\alpha \text{Prob}(\alpha - 1 < \|Hw_{s+1}\| < \alpha + 1) \\ &\geq c, \end{aligned}$$

for a suitable constant $c > 0$, the last inequality following from the fact that $H \neq 0$. We therefore have

$$\frac{1}{\#_{\bar{j},t_k}} \sum_{\substack{s=1 \\ s \text{ even}}}^{t_k} E[\alpha_{\bar{j},s+1} \mid \mathcal{F}_s] \geq \frac{1}{\#_{\bar{j},t_k}} \sum_{\substack{s=1 \\ s \text{ even}}}^{t_k} 1([\widehat{A}_s, \widehat{B}_s] \in N_{\bar{j}}) \cdot c = c. \tag{15}$$

On the other hand,

$$\begin{aligned} &\sum_{\substack{s=1 \\ s \text{ even}}}^{t_k} \left\{\alpha_{\bar{j},s+1} - E[\alpha_{\bar{j},s+1} \mid \mathcal{F}_s]\right\} \\ &= \sum_{\substack{s=1 \\ s \text{ even}}}^{t_k} 1([\widehat{A}_s, \widehat{B}_s] \in N_{\bar{j}}) \left\{(\|Hx_{s+1}\|^2 \wedge 1) - E[\|Hx_{s+1}\|^2 \wedge 1 \mid \mathcal{F}_s]\right\} \\ &= o\left(\sum_{\substack{s=1 \\ s \text{ even}}}^{t_k} 1([\widehat{A}_s, \widehat{B}_s] \in N_{\bar{j}})\right), \end{aligned} \tag{16}$$

on the set where

$$\sum_{\substack{s=1 \\ s \text{ even}}}^{t_k} 1([\widehat{A}_s, \widehat{B}_s] \in N_{\bar{j}}) = \infty \tag{17}$$

(see [23]). Since (17) is satisfied if (12) holds, equations (15) and (16) prove that (13) follows from (12).

We now prove that (13) contradicts (9).

The convergence result $[A'_t, B'_t] \to [A^\circ, B^\circ]$ (see Theorem 1) implies that

$$\begin{aligned}\left([A'_t + B'_t K(A,B)] - [\overline{A} + \overline{B}K(A,B)]\right)^T \left([A'_t + B'_t K(A,B)] - [\overline{A} + \overline{B}K(A,B)]\right) \\ \geq \left(\frac{1}{2}H\right)^T \left(\frac{1}{2}H\right) \qquad \forall [A,B], [\overline{A},\overline{B}] \in N_{\overline{j}},\end{aligned}$$

for t sufficiently high (see (10)). In view of this, the following chain of inequalities can be derived when (12), and, consequently, inequality (13) hold true:

$$\begin{aligned}\infty &= \lim_{k\to\infty} \frac{1}{\mu_{t_k}} \#_{\overline{j},t_k} \cdot \liminf_{k\to\infty} \frac{1}{\#_{\overline{j},t_k}} \sum_{\substack{s=1 \\ s \text{ even}}}^{t_k} \alpha_{\overline{j},s+1} \\ &\leq \lim_{k\to\infty} \frac{1}{\mu_{t_k}} \sum_{\substack{s=1 \\ s \text{ even}}}^{t_k-2} \alpha_{\overline{j},s+1} \\ &\leq \lim_{k\to\infty} \frac{1}{\mu_{t_k}} \sum_{\substack{s=1 \\ s \text{ even}}}^{t_k-2} \|Hx_{s+1}\|^2 \cdot 1([\widehat{A}_s, \widehat{B}_s] \in N_{\overline{j}}) \\ &\leq \lim_{k\to\infty} \frac{1}{\mu_{t_k}} \sum_{\substack{s=1 \\ s \text{ even}}}^{t_k-2} 4\| \left\{[A'_{t_k} + B'_{t_k}\widehat{K}_s] - [\widehat{A}_{t_k} + \widehat{B}_{t_k}\widehat{K}_s]\right\} x_{s+1}\|^2 \cdot 1([\widehat{A}_s, \widehat{B}_s] \in N_{\overline{j}}) \\ &\leq \lim_{k\to\infty} \frac{1}{\mu_{t_k}} \sum_{\substack{s=1 \\ s \text{ even}}}^{t_k-2} 4\| \left([A'_{t_k}, B'_{t_k}] - [\widehat{A}_{t_k}, \widehat{B}_{t_k}]\right) v_{s+1}\|^2.\end{aligned}$$

This contradicts (9). Thus, (12) is false with probability 1, and so (11) is proven. □

4. The self-tuning property. A key issue in the analysis of any adaptive control method consists of determining whether it is able to generate, at least asymptotically, control laws close to the optimal control law for the true system. The objective of the present section is to prove that this is indeed the case for our adaptive scheme, except for very rare time instants. This result will play a crucial role in the next section where we address stability and optimality issues.

THEOREM 4.

$$\sum_{s=1}^{t} 1(\|\widehat{K}_s - K^\circ\| > \rho) = O(\mu_t) \qquad a.s., \qquad \forall \rho > 0.$$

Proof. Since Θ is compact,

$$\sup_{[A,B]\in\Theta} \lambda_{\max}[A + BK(A,B)] < 1.$$

This implies that $A^\circ + B^\circ K(A,B)$ is stable for $[A,B]$ belonging to the closed set $\overline{C_\delta^c}$ (where the overbar indicates closure and the superscript "c" indicates the complement of the set), for δ small enough.

Denote by $J(A, B; K)$ the cost for the system $x_{t+1} = Ax_t + Bx_t + w_{t+1}$ controlled by $u_t = Kx_t$, whenever the corresponding closed-loop system is stable. It is known that (see [16] or [17])

$$J(A, B; K) = TraceP(A, B; K), \tag{18}$$

where $P(A, B; K)$ is the unique positive semidefinite solution of the Lyapunov equation

$$P = K^T RK + [A + BK]^T P[A + BK] + Q. \tag{19}$$

From this, it is easy to verify that $J(A^\circ, B^\circ; K(A, B))$ is a continuous function of $[A, B] \in \overline{C_\delta^c}$. On the other hand, the optimal gain K° for the true system (1) is unique within the class of stabilizing gains:

$$J(A^\circ, B^\circ; K) > J^\circ, \qquad \forall K \neq K^\circ, \qquad K \text{ stabilizing.}$$

Therefore, there exists $\nu(\rho) > 0$ such that every gain $K = K(A, B)$, $[A, B] \in \overline{C_\delta^c}$, for which

$$J(A^\circ, B^\circ; K) \leq J^\circ + \nu(\rho)$$

also satisfies the bound

$$\|K - K^\circ\| \leq \rho. \tag{20}$$

Note now that since $A+BK(A, B)$ is close to $A^\circ+B^\circ K(A, B)$ when $[A, B] \in \overline{C_\delta^c}$, δ small, from (19), we have

$$\sup_{[A,B]\in C_\delta^c} \|P(A^\circ, B^\circ; K(A, B)) - P(A, B; K(A, B))\| \to 0, \qquad \delta \to 0,$$

and, in view of (18),

$$\sup_{[A,B]\in C_s^c} |J(A^\circ, B^\circ; K(A, B)) - J(A, B; K(A, B))| \to 0, \qquad \delta \to 0.$$

Fix $\delta(\rho)$ such that

$$\sup_{[A,B]\in C_{\delta(\rho)}^c} \|J(A^\circ, B^\circ; K(A, B)) - J(A, B; K(A, B))\| \leq \frac{1}{2}\nu(\rho). \tag{21}$$

Finally,

$$\begin{aligned}
&\limsup_{t\to\infty} \frac{1}{\mu_t} \sum_{s=1}^{t} 1(\|\widehat{K}_s - K^\circ\| > \rho) \\
&\qquad \leq \limsup_{t\to\infty} \frac{1}{\mu_t} \sum_{s=1}^{t} 1(J(A^\circ, B^\circ; \widehat{K}_s) - J^\circ > \nu(\rho)) \qquad \text{(using (20))} \\
&\qquad \leq \limsup_{t\to\infty} \frac{1}{\mu_t} \sum_{s=1}^{t} 1\left(|J(A^\circ, B^\circ; \widehat{K}_s) - \widehat{J}_s| > \frac{1}{2}\nu(\rho)\right) \\
&\qquad\qquad \text{(using Theorem 2)} \\
&\qquad \leq \limsup_{t\to\infty} \frac{1}{\mu_t} \sum_{s=1}^{t} 1\left([\widehat{A}_s, \widehat{B}_s] \in C_{\delta(\rho)}\right) \qquad \text{(using (21))} \\
&\qquad < \infty \qquad \text{(using Theorem 3).} \quad \square
\end{aligned}$$

5. Stability and optimality. According to Theorem 4, the adaptive gain $\widehat{K}_s$ is close to the optimal gain K° except at very rare time instants, the number of which grows at most as μ_t. At these exceptional time points, the closed-loop system may be unstable. However, due to their rare occurrence, we establish that they cannot endanger the stability of the adaptive closed-loop control system. The corresponding stability result is given in Theorem 5. The proof of Theorem 5 relies heavily on the results of [24] concerning stability of rarely destabilized time-varying systems. It is very similar to that of Theorem 12 in [2] and is provided here only for the sake of completeness.

THEOREM 5.

$$\limsup_{t\to\infty} \frac{1}{t}\sum_{s=1}^{t}[\|x_s\|^p + \|u_s\|^p] < \infty \qquad a.s., \qquad \forall p > 0.$$

Proof. We start by noting that, since $A^\circ + B^\circ K^\circ$ is a stable matrix, there exists a suitable norm on $\mathbf{R}^n$ such that, under the corresponding induced matrix norm, $\|A^\circ + B^\circ K^\circ\| < 1$ (see, e.g., [25]). Throughout this proof all the norm symbols refer to this particular norm.

It is easy to verify that the following inequality holds true for any integer n and real numbers a, b, and $\epsilon > 0$,

$$(a+b)^{2^n} \le (1+\epsilon^2)^{2^n-1}a^{2^n} + (1+\epsilon^{-2})^{2^n-1}b^{2^n}. \tag{22}$$

Taking into account the relation $x_{t+1} = A^\circ x_t + B^\circ \widehat{K}_t x_t + w_{t+1}$, from (22) we obtain

$$\|x_{t+1}\|^{2^n} \le (1+\epsilon^2)^{2^n-1}\|A^\circ + B^\circ \widehat{K}_t\|^{2^n}\|x_t\|^{2^n} + (1+\epsilon^{-2})^{2^n-1}\|w_{t+1}\|^{2^n},$$

for any integer n and positive real ϵ.

Now fix $\bar{n}$ such that $2^{\bar{n}} \ge p$ and choose $\bar{\epsilon} > 0$ such that $(1+\bar{\epsilon}^2)^{2^{\bar{n}}-1}\|A^\circ + B^\circ K^\circ\|^{2^{\bar{n}}} < 1$. Further, select ρ in such a way that

$$a := \sup_{K\,:\,\|K-K^\circ\|\le\rho} (1+\bar{\epsilon}^2)^{2^{\bar{n}}-1}\|A^\circ + B^\circ K\|^{2^{\bar{n}}} < 1$$

and also let

$$b := \sup_{[A,B]\in\Theta} (1+\bar{\epsilon}^2)^{2^{\bar{n}}-1}\|A^\circ + B^\circ K(A,B)\|^{2^{\bar{n}}}.$$

Then

$$\|x_{t+1}\|^{2^{\bar{n}}} \le \gamma_t\|x_t\|^{2^{\bar{n}}} + (1+\bar{\epsilon}^{-2})^{2^{\bar{n}}-1}\|w_{t+1}\|^{2^{\bar{n}}}, \tag{23}$$

where

$$\gamma_t = \begin{cases} a, & \text{if } \|\widehat{K}_t - K^\circ\| \le \rho, \\ b, & \text{otherwise.} \end{cases}$$

We now apply Theorem 2 in [24] to (23) (see also Remark 1 in the same paper). By noting that $\sum_{s=1}^{t} 1(\|\widehat{K}_s - K^\circ\| > \rho) = O(\mu_t)$ (Theorem 4) and that $\mu_t = o(\log t)$, from that theorem we can conclude that

$$\limsup_{t\to\infty} \frac{1}{t}\sum_{s=1}^{t}\|x_s\|^{2^{\bar{n}}} < \infty \qquad \text{a.s.}$$

This implies that (recall that $2^{\bar{n}} \geq p$)

$$\limsup_{t\to\infty} \frac{1}{t} \sum_{s=1}^{t} \|x_s\|^p < \infty \qquad \text{a.s.}$$

Since $\|u_s\| \leq \sup_{[A,B]\in\Theta} \|K(A,B)\| \|x_s\|$, we also have

$$\limsup_{t\to\infty} \frac{1}{t} \sum_{s=1}^{t} \|u_s\|^p < \infty \qquad \text{a.s.}$$

This proves the stability result. □

We are now in a position to prove the optimality of the adaptive scheme, namely, that the incurred cost equals the optimal cost that could be obtained if the true system parameter were known at the start.

THEOREM 6.

$$\limsup_{t\to\infty} \frac{1}{t} \sum_{s=1}^{t} \left[x_s^T Q x_s + u_s^T R u_s\right] = J^\circ \qquad \textit{a.s.}$$

Proof. The dynamic programming equation for model $x_{s+1} = \widehat{A}_s x_s + \widehat{B}_s u_s + w_{s+1}$ is (see [16])

$$\begin{aligned}
&\widehat{J}_s + x_s^T \widehat{P}_s x_s \\
&\quad = x_s^T Q x_s + u_s^T R u_s + E[(\widehat{A}_s x_s + \widehat{B}_s u_s + w_{s+1})^T \widehat{P}_s (\widehat{A}_s x_s + \widehat{B}_s u_s + w_{s+1}) \mid \mathcal{F}_s] \\
&\quad = x_s^T Q x_s + u_s^T R u_s + E[x_{s+1}^T \widehat{P}_s x_{s+1} \mid \mathcal{F}_s] \\
&\quad + \left\{(\widehat{A}_s x_s + \widehat{B}_s u_s)^T \widehat{P}_s (\widehat{A}_s x_s + \widehat{B}_s u_s) - (A^\circ x_s + B^\circ u_s)^T \widehat{P}_s (A^\circ x_s + B^\circ u_s)\right\}.
\end{aligned}$$

From this,

$$\begin{aligned}
&\underbrace{\frac{1}{t}\sum_{s=1}^{t} \widehat{J}_s}_{A} + \underbrace{\frac{1}{t}\sum_{s=1}^{t} \left\{x_s^T \widehat{P}_s x_s - E[x_{s+1}^T \widehat{P}_{s+1} x_{s+1} \mid \mathcal{F}_s]\right\}}_{B} \\
&\qquad = \frac{1}{t}\sum_{s=1}^{t} [x_s^T Q x_s + u_s^T R u_s] + \underbrace{\frac{1}{t}\sum_{s=1}^{t} E[x_{s+1}^T (\widehat{P}_s - \widehat{P}_{s+1}) x_{s+1} \mid \mathcal{F}_s]}_{C} \\
&\qquad + \underbrace{\frac{1}{t}\sum_{s=1}^{t} \left\{(\widehat{A}_s x_s + \widehat{B}_s u_s)^T \widehat{P}_s (\widehat{A}_s x_s + \widehat{B}_s u_s) - (A^\circ x_s + B^\circ u_s)^T \widehat{P}_s (A^\circ x_s + B^\circ u_s)\right\}}_{D}.
\end{aligned} \tag{24}$$

Let us study separately the different terms appearing in this expression.

(A) From Theorem 2 we have

$$\limsup_{t\to\infty} \frac{1}{t} \sum_{s=1}^{t} \widehat{J}_s \leq J^\circ.$$

(B)

$$\frac{1}{t}\sum_{s=1}^{t}\left\{x_s^T\widehat{P}_s x_s - E[x_{s+1}^T\widehat{P}_{s+1}x_{s+1}\mid\mathcal{F}_s]\right\}$$

$$= \frac{1}{t}x_1^T\widehat{P}_1x_1 - \frac{1}{t}x_{t+1}^T\widehat{P}_{t+1}x_{t+1} + \frac{1}{t}\sum_{s=1}^{t}\left\{x_{s+1}^T\widehat{P}_{s+1}x_{s+1} - E[x_{s+1}^T\widehat{P}_{s+1}x_{s+1}\mid\mathcal{F}_s]\right\}.$$

The first term obviously tends to zero. As for the second one, note that, $\widehat{P}_{t+1} \le \sup_{[A,B]\in\Theta} P(A,B)$ being bounded, it tends to zero provided that $\|x_t\|^2/t \to 0$. The fact that this is the case can be proven by contradiction. Suppose that there exists a time sequence $\{t_k\}$ and a real number $\alpha > 0$ such that $\|x_{t_k}\|^2 > \alpha t_k, \forall k$. Then $\limsup_{t\to\infty}\frac{1}{t}\sum_{s=1}^{t}\|x_s\|^4 \ge \limsup_{k\to\infty}\frac{1}{t_k}\|x_{t_k}\|^4 \ge \limsup_{k\to\infty}\frac{1}{t_k}\alpha^2 t_k^2 = \infty$. This contradicts Theorem 5. In the third term,

$$\{\alpha_{s+1}\} := \{x_{s+1}^T\widehat{P}_{s+1}x_{s+1} - E[x_{s+1}^T\widehat{P}_{s+1}x_{s+1}\mid\mathcal{F}_s]\}$$

is a martingale difference. Therefore, $\frac{1}{t}\sum_{s=1}^{t}\alpha_{s+1}\to 0$, provided that

$$\sum_{s=1}^{\infty} s^{-2}E[\alpha_{s+1}^2\mid\mathcal{F}_s] < \infty$$

(see [26]). Since $\widehat{P}_{s+1}$ is bounded, it is easily seen that this last condition is implied by $\sum_{s=1}^{\infty}s^{-2}[\|x_s\|^4+\|u_s\|^4] < \infty$. Again, this conclusion can be drawn by contradiction from Theorem 5. In fact, if this conclusion were false, sequence $s^{-1/2}[\|x_s\|^4+\|u_s\|^4]$ would be unbounded and, therefore, there would exist a sequence of times $\{t_k\}$ such that $[\|x_{t_k}\|^4+\|u_{t_k}\|^4] \ge t_k^{1/2}\forall k$. From this, $\limsup_{k\to\infty}\frac{1}{t}\sum_{s=1}^{t}[\|x_s\|^4+\|u_s\|^4]^4 \ge \limsup_{k\to\infty}\frac{1}{t_k}[\|x_{t_k}\|^4+\|u_{t_k}\|^4]^4 \ge \limsup_{k\to\infty}\frac{1}{t_k}t_k^2 = \infty$, and this is in contradiction with Theorem 5. In conclusion,

$$\lim_{t\to\infty}\frac{1}{t}\sum_{s=1}^{t}\left\{x_s^T\widehat{P}_s x_s - E[x_{s+1}^T\widehat{P}_{s+1}x_{s+1}\mid\mathcal{F}_s]\right\} = 0 \qquad \text{a.s.}$$

(C) We start by proving that

$$\lim_{t\to\infty}\frac{1}{t}\sum_{s=1}^{t}\|\widehat{P}_s - \widehat{P}_{s+1}\|^2 = 0 \qquad \text{a.s.} \tag{25}$$

Since P° satisfies the equation

$$P^\circ = K^{\circ T}RK^\circ + [A^\circ + B^\circ K^\circ]^T P^\circ[A^\circ + B^\circ K^\circ] + Q,$$

and $\widehat{P}_s$ satisfies the equation

$$\widehat{P}_s = \widehat{K}_s^T R\widehat{K}_s + [\widehat{A}_s + \widehat{B}_s\widehat{K}_s]^T\widehat{P}_s[\widehat{A}_s + \widehat{B}_s\widehat{K}_s] + Q,$$

P° is close to $\widehat{P}_s$ when K° is close to $\widehat{K}_s$ and $A^\circ + B^\circ K^\circ$ is close to $\widehat{A}_s + \widehat{B}_s\widehat{K}_s$. In view of Theorems 3 and 4, the total of the numbers of time points in which this does not happen is $O(\mu_t)$. Therefore,

$$\sum_{s=1}^{t} 1(\|\widehat{P}_s - P^\circ\| > \rho) = O(\mu_t) \qquad \text{a.s.}, \qquad \forall \rho > 0.$$

Equation (25) then easily follows from

$$\begin{aligned}\frac{1}{t}\sum_{s=1}^{t}\|\widehat{P}_s - \widehat{P}_{s+1}\|^2 &\le \frac{2}{t}\sum_{s=1}^{t}\left[\|\widehat{P}_s - P^\circ\|^2 + \|\widehat{P}_{s+1} - P^\circ\|^2\right] \\ &\le \frac{4}{t}\sum_{s=1}^{t+1}\|\widehat{P}_s - P^\circ\|^2 1(\|\widehat{P}_s - P^\circ\| > \rho) + \frac{4(t+1)}{t}\rho^2 \\ &\to 4\rho^2,\end{aligned}$$

since ρ is an arbitrary positive real number.

Notice now that, by the Schwarz inequality,

$$\frac{1}{t}\sum_{s=1}^{t}|x_{s+1}^T(\widehat{P}_s - \widehat{P}_{s+1})x_{s+1}| \le \left(\frac{1}{t}\sum_{s=1}^{t}\|\widehat{P}_s - \widehat{P}_{s+1}\|^2\right)^{1/2}\left(\frac{1}{t}\sum_{s=1}^{t}\|x_{s+1}\|^4\right)^{1/2}.$$

Therefore, $t^{-1}\sum_{s=1}^{t}\|x_{s+1}\|^4$ being bounded (Theorem 5), (25) implies

$$\lim_{t\to\infty}\frac{1}{t}\sum_{s=1}^{t}x_{s+1}^T(\widehat{P}_s - \widehat{P}_{s+1})x_{s+1} = 0 \qquad \text{a.s.} \tag{26}$$

Finally, the conclusion

$$\lim_{t\to\infty}\frac{1}{t}\sum_{s=1}^{t}E[x_{s+1}^T(\widehat{P}_s - \widehat{P}_{s+1})x_{s+1} \mid \mathcal{F}_s] = 0 \qquad \text{a.s.}$$

is drawn from (26) by observing that

$$\{\beta_{s+1}\} := \{x_{s+1}^T(\widehat{P}_s - \widehat{P}_{s+1})x_{s+1} - E[x_{s+1}^T(\widehat{P}_s - \widehat{P}_{s+1})x_{s+1} \mid \mathcal{F}_s]\}$$

is a martingale difference for which, by calculations resembling those developed in point (B), $\sum_{s=1}^{\infty} s^{-2}E[\beta_{s+1}^2 \mid \mathcal{F}_s] < \infty$.

(D) Since

$$\|P^TP - R^TR\| \le \|P - R\|(\|P\| + \|R\|), \qquad \forall P, R \in \mathbb{R}^{n\times n},$$

we have

$$\begin{aligned}&|(\widehat{A}_sx_s + \widehat{B}_su_s)^T\widehat{P}_s(\widehat{A}_sx_s + \widehat{B}_su_s) - (A^\circ x_s + B^\circ u_s)^T\widehat{P}_s(A^\circ x_s + B^\circ u_s)| \\ &\quad= |x_s^T(\widehat{A}_s + \widehat{B}_s\widehat{K}_s)^T\widehat{P}_s(\widehat{A}_s + \widehat{B}_s\widehat{K}_s)x_s - x_s^T(A^\circ + B^\circ\widehat{K}_s)^T\widehat{P}_s(A^\circ + B^\circ\widehat{K}_s)x_s| \\ &\quad\le \|x_s\|^2\|\widehat{P}_s\|\,\|(\widehat{A}_s + \widehat{B}_s\widehat{K}_s) - (A^\circ + B^\circ\widehat{K}_s)\|(\|\widehat{A}_s + \widehat{B}_s\widehat{K}_s\| + \|A^\circ + B^\circ\widehat{K}_s\|).\end{aligned}$$

Also, $\|\widehat{P}_s\|$ is uniformly bounded over time. The same holds for $(\|\widehat{A}_s+\widehat{B}_s\widehat{K}_s\|+\|A^\circ+B^\circ\widehat{K}_s\|)$. Furthermore, using the Schwarz inequality,

$$\frac{1}{t}\sum_{s=1}^{t}\|x_s\|^2\|(\widehat{A}_s+\widehat{B}_s\widehat{K}_s)-(A^\circ+B^\circ\widehat{K}_s)\|$$

$$\leq\left(\frac{1}{t}\sum_{s=1}^{t}\|x_s\|^4\right)^{1/2}\left(\frac{1}{t}\sum_{s=1}^{t}\|(\widehat{A}_s+\widehat{B}_s\widehat{K}_s)-(A^\circ+B^\circ\widehat{K}_s)\|^2\right)^{1/2}.$$

By Theorem 5 the first term is bounded. In light of Theorem 3, the second term can be handled analogously to the calculations for $t^{-1}\sum_{s=1}^{t}\|\widehat{P}_s-\widehat{P}_{s+1}\|^2$ in point (C), thus yielding

$$\lim_{t\to\infty}\frac{1}{t}\sum_{s=1}^{t}\|(\widehat{A}_s+\widehat{B}_s\widehat{K}_s)-(A^\circ+B^\circ\widehat{K}_s)\|^2=0\qquad\text{a.s.}$$

This suffices to prove that $D\to 0$, a.s.

By inserting all the partial results in (24) we finally obtain

$$\limsup_{t\to\infty}\frac{1}{t}\sum_{s=1}^{t}\left[x_s^TQx_s+u_s^TTu_s\right]\leq J^\circ\qquad\text{a.s.}$$

Since J° is the optimal cost for the true system, this proves the theorem. □

6. Concluding remarks. In an adaptive control context, the minimization of a given cost function is made difficult by the general identifiability problem stemming from the natural tendency of classical identification methods to return estimates with the corresponding optimal cost larger than the optimal cost for the true system. A way out of this problem is to employ a more fine-grained estimation scheme which exploits the properties of the set to which the estimates converge. Such a scheme has been presented and analyzed in this paper for the linear quadratic Gaussian control problem.

The results of this paper need to be extended in several directions to provide a fuller theory of optimal adaptation:

- *The presented scheme is nonrecursive.* However, one can conceive of somehow recursively minimizing our identification performance index so as to retain its asymptotic identification properties. This must be further investigated.
- *We assume full state observations.* This limitation needs to be removed.
- *Our adaptive scheme is, to some extent, tailored to linear quadratic Gaussian control.* In particular, a central role in the analysis is played by the uniqueness of the optimal gain in linear quadratic Gaussian control problems. It would be of interest to investigate how the biasing idea applies to other control strategies. An additional point is concerning the Gaussianity of the noise. This assumption is exploited in proving that the least squares estimate converges and that it tends to the true value in the excited subspace. In an attempt to remove the Gaussianity assumption one can use a weighted least squares algorithm, as suggested in [12], guaranteeing estimate convergence. In doing so, however, consistency in the excited subspace is lost and this may pose a difficulty in the derivation of many results.

• *Assumption $\mu_t = o(\log t)$ may be very conservative.* It is mainly motivated by the stability analysis and it is possible that our results still hold with μ_t growing at a faster rate. This and other choices made in the definition of our algorithm may be further investigated.

All the above problems suggest interesting research opportunities and a promise of self-optimizing adaptive control for nonlinear stochastic systems.

MINIMIZING AND STATIONARY SEQUENCES OF CONSTRAINED OPTIMIZATION PROBLEMS*

CHIN-CHENG CHOU†, KUNG-FU NG‡, AND JONG-SHI PANG§

Abstract. We study some fundamental asymptotic properties associated with the well-posedness of constrained optimization problems. Emphasis is placed on the relation between minimizing and stationary sequences and their characterizations in terms of a set of asymptotic Karush–Kuhn–Tucker (KKT) optimality conditions. Unlike the subdifferential approach used by Auslender, Cominetti, and Crouzeix, we use a residual function approach that is closely tied to the theory of error bounds; this approach handles constraints explicitly and allows the effective treatment of infeasible, stationary sequences. The asymptotic KKT conditions provide an asymptotic optimality certificate for inequality constrained programs. Specializations of the results to convex quadratically constrained convex quadratic spline minimization problems and convex programs with Hölderian minima are discussed. An application of the results to the convergence of a family of Newton-type iterative descent methods involving singular quasi-Newton matrices for solving a constrained minimization problem is also presented.

Key words. well-posed optimization problems, minimizing sequences, stationary sequences, approximate optimality conditions, convex analysis, residual functions, error bounds, weak sharp minima, quadratic splines, convergence of algorithms

1. Introduction.

This paper studies some fundamental asymptotic aspects of the finite-dimensional, constrained, differentiable optimization problem:

$$\begin{aligned} &\text{minimize} && \theta(x) \\ &\text{subject to} && x \in X, \end{aligned} \tag{1}$$

where $\theta : \Re^n \to \Re$ is a continuously differentiable function and X is a nonempty closed subset of $\Re^n$. We write

$$\theta_{\inf} \equiv \inf_{x \in X} \theta(x) \geq -\infty.$$

Throughout the paper we do not assume, unless explicitly stated, that $\theta_{\inf}$ is finite or a global minimizer of (1) exists. Thus the theory developed herein is applicable to problems (1) whose optimum objective values are not necessarily attained.

The asymptotic properties studied in this work are closely tied to the theory of well-posedness for constrained optimization problems [8, 21]. According to the introductory discussion in these two books, the well-posedness concept for minimization problems originates with A.N. Tykhonov [36]. Whereas the original Tykhonov well-posedness concept was concerned with an unconstrained optimization problem, the extension to the constrained case was introduced by Levitin and Polyak [17], who were interested in the convergence analysis of numerical methods for solving constrained optimization problems. Central to the Levitin–Polyak theory of well-posedness for the problem (1) is the concept of a minimizing sequence. Specifically, a sequence $\{x^k\} \subset \Re^n$ is said to be *Levitin–Polyak minimizing* (or in short, LP minimizing) for (1) if

(i) it is *asymptotically feasible*; i.e.,

$$\lim_{k\to\infty} \operatorname{dist}(x^k, X) = 0,$$

where $\operatorname{dist}(x, X)$ is the distance function from a vector $x \in \Re^n$ to the set X measured in the Euclidean norm; and

(ii) it is *asymptotically optimal*; i.e.,

$$\lim_{k\to\infty} \theta(x^k) = \theta_{\inf}.$$

Based on this fundamental definition, various well-posedness concepts can be defined for the problem (1); see [8, 21, 31]. Invariably, all of these concepts assume that the optimization problem in question has a global minimizer which may or may not be unique. In contrast, many results obtained in the present paper do not require that (1) attains its minimum. This is an important point of departure of our work from the classical well-posedness studies.

Independently of the classical Tykhonov–Levitin–Polyak theory of well-posedness, a closely related theory of well-behaved convex functions is developed in the papers by Auslender, Crouzeix, and Cominetti [3, 2, 1]. Cast in the framework of extended-valued convex functions [33], the latter theory studies the class of well-behaved convex functions and their role in the convergence theory of iterative minimization methods. Specifically, a proper closed convex function $f : \Re^n \to \Re \cup \{\infty\}$ is said to be well-behaved if for all sequences $\{x^k\}$ and $\{a^k\}$ such that $\lim_{k\to\infty} a^k = 0$ and $a^k \in \partial f(x^k)$ for all k, where ∂f denotes the subdifferential of f, we have $\lim_{k\to\infty} f(x^k) = \inf\{f(x) : x \in \Re^n\}$. Note that a well-behaved convex function is not required to attain its global minimum. Characterizations of well-behaved proper closed convex functions are obtained in [3]. A large subclass of these functions, denoted $\mathcal{R}$, is introduced in [2] which consists of those proper closed convex functions f such that the origin is an element of the relative interior of the domain of the subdifferential of the conjugate f^* of f. Some nice properties of functions in this subclass are obtained; among these, a function in the class $\mathcal{R}$ must have a nonempty set of global minimizers. In a later section, we will discuss how this subdifferential approach is related to the Levitin–Polyak approach, which handles constraints explicitly.

In an interesting paper [15], Lemaire refined the analysis in [3, 2, 1] and introduced several additional asymptotic concepts that tie together the theory of well-behaved convex functions in a Banach space with that of well-posed optimization problems. Since an important goal of Lemaire's study was to connect these two theories, he had assumed that his problems all attained their global minima. Further details of Lemaire's results are given in sections 4.1 and 4.3.

This paper has two major goals. One is to study the detailed connection between an LP minimizing sequence and a "stationary sequence"; the other is to investigate how these sequences can be characterized in terms of some asymptotic KKT-type optimality conditions. We use two classes of constrained optimization problems to illustrate our results: one class involves the minimization of a "convex quadratic spline function" subject to convex quadratic inequality constraints; the other class consists of convex programs with "Hölderian minima." An application of the derived results to the convergence of a family of Newton-type iterative descent methods involving singular quasi-Newton matrices for solving the problem (1) is also presented.

Unlike the subdifferential approach employed by Auslender and Crouzeix [3] and Lemaire [15], our definition of a stationary sequence (see the next section) is based on the concept of a residual function that is derived from the theory of error bounds. There are multiple reasons to introduce a residual-based concept of asymptotic stationarity. One is that this approach handles constraints more effectively (than the subdifferential approach) and allows the treatment of infeasible sequences. Another motivation is that residuals are computable quantities often used to define stopping rules in the practical implementation of iterative methods; thus it is reasonable to develop an asymptotic theory that is based on these residuals.

Apart from the difference in the employed approaches, an important topic included in our study that has not been treated by Auslender, Cominetti, Crouzeix and Lemaire is the converse question: Are LP minimizing sequences necessarily stationary? As we shall see, the answer to this question is in the negative in general; it turns out that the well-known ε-variational principle by Ekeland [9] has a key role to play in the analysis of this question. In addition to this question, we shall consider an alternate definition of a minimizing sequence in the case where the problem (1) actually has a global minimizer; we shall investigate when this alternate notion and the notion of an LP minimizing sequence are equivalent.

The dominant role of the (exact) KKT optimality conditions for the study of inequality constrained nonlinear programs is well known. Inspired by such a role, we will introduce a set of asymptotic KKT conditions as a characterization of an LP minimizing sequence for these programs. To the best of our knowledge, these asymptotic optimality conditions have never been formally considered in optimization theory.

Although the motivation of studying minimizing sequences stems from a computational consideration, one should be cautious in directly applying the results obtained herein to sequences generated by specific algorithms [35]. The principal reason for such caution is that, by the way they are generated, the latter sequences typically possess additional properties that are not taken into account in a general study of this type. In particular the convergence results in the papers [14, 38, 40] that pertain to specific descent methods should not be inferred as immediate consequences of the results in this work and the theory of well-posedness. Instead, the latter theory is developed in order to identify key properties of optimization problems that will render these problems to behave well when solved by numerical methods of a broad nature. In such an algorithmic context, there has been some initial success of the theory [3, 2]. The present paper will add to this success by demonstrating that a condition important for LP minimizing sequences is necessary and sufficient for the convergence of the (singular) Newton-type descent methods for solving the constrained minimization problem (1). This result provides a new piece of evidence showing that by focusing on the class of "well-behaved" constrained optimization problems, convergence of some

well-known algorithms can be established under assumptions that are less restrictive than those usually made in the literature.

The rest of this paper is divided into several sections. In the next section we introduce several asymptotic stationarity concepts and clarify their relationships. Sections 3 and 4 treat the main topic of this paper, namely, the connection between minimizing and stationary sequences. Section 5 discusses some approximate optimality systems and how they are related to LP minimizing sequences. Two results that summarize the various properties studied in the paper will be presented there. Finally, in section 6, we establish the convergence of the (singular) Newton-type methods for solving the problem (1), using the arguments established in the previous sections.

In addition to the results obtained herein, the accompanying paper [13] studies minimizing sequences of merit functions for nonlinear complementarity problems and variational inequalities; a distinguishing feature of these functions is that they are typically nonconvex but are nonnegative.

2. Stationary sequences. Associated with the constrained optimization problem (1), we have defined the concept of an LP minimizing sequence. Another central concept in the asymptotic analysis of this problem is that of a stationary sequence. For an unconstrained problem which has $X = \Re^n$ and a differentiable objective function θ, the concept of a stationary sequence can be defined easily. Namely, a sequence $\{x^k\}$ is stationary if $\{\nabla\theta(x^k)\}$ converges to zero. Nevertheless, for a problem with constraints which has X being a proper subset of $\Re^n$, there are several closely related definitions. In this section, we shall present the various definitions of asymptotic stationarity and clarify their interrelationships.

2.1. Residual-based asymptotic stationarity. In order to define the concept of a stationary sequence of (1), we introduce the residual function

$$R_N(x) \equiv x - \Pi_X(x - \nabla\theta(x)), \quad x \in \Re^n,$$

where Π_X is the Euclidean projector onto the set X. Clearly, when $X = \Re^n$, $R_N(x)$ reduces to $\nabla\theta(x)$. Moreover it follows from the well-known variational principle of nonlinear programming that if x is a local minimum of (1), then $R_N(x) = 0$; conversely, if θ is convex, then every zero of R_N is a global minimum of (1).

The residual function $R_N(x)$ plays an important role in the error bound theory for variational inequalities and complementarity problems; see [28, 29]. In [27], the term "natural residual" was coined for this function. Borrowing this terminology (which explains the subscript N in the function R_N), we say that a sequence $\{x^k\} \subset \Re^n$ is *naturally stationary* (or in short, N-stationary) for the constrained optimization problem (1) if $\lim_{k\to\infty} R_N(x^k) = 0$. This definition does not require the sequence $\{x^k\}$ to be feasible to (1). Nevertheless it is easy to see that

$$\lim_{k\to\infty} R_N(x^k) = 0 \implies \lim_{k\to\infty} \operatorname{dist}(x^k, X) = 0.$$

Thus if $\{x^k\}$ is N-stationary, then it must be asymptotically feasible. We note a fundamental property of the residual vector $R_N(x)$. Namely, for all vectors $x \in \Re^n$ and $y \in X$,

$$(y - x + R_N(x))^T(\nabla\theta(x) - R_N(x)) \geq 0; \tag{2}$$

this inequality is a consequence of the variational principle for the Euclidean projector.

An alternative definition of a stationary sequence is based on the normal map for the problem (1). Like the function R_N, the normal map is also fundamental for variational inequalities and complementarity problems [32]. Specifically, associated with the pair $(\nabla\theta, X)$, the normal map $R_{\mathcal{N}} : \Re^n \to \Re^n$ is defined as

$$R_{\mathcal{N}}(z) \equiv \nabla\theta \circ \Pi_X(z) + z - \Pi_X(z), \quad z \in \Re^n.$$

We say that a sequence $\{x^k\} \subset \Re^n$ is *normally stationary* (or in short, $\mathcal{N}$-stationary) for the constrained optimization problem (1) if

(i) $\{x^k\}$ is asymptotically feasible, and

(ii) there exists a sequence $\{z^k\} \subset \Re^n$ such that $\lim_{k\to\infty} R_{\mathcal{N}}(z^k) = 0$ and $\Pi_X(x^k) = \Pi_X(z^k)$ for each k.

Unlike the concept of N-stationarity, in which the asymptotic feasibility of the sequence $\{x^k\}$ is an easy consequence of the limit condition $\lim_{k\to\infty} R_N(x^k) = 0$, we give below an example which shows that it is possible for a sequence $\{x^k\}$ to satisfy condition (ii) in the definition of $\mathcal{N}$-stationarity and fail condition (i) in the same definition. Thus for such a sequence $\{x^k\}$, we cannot expect it to be LP minimizing because asymptotic feasibility is part of the requirement of the LP minimizing property.

Example 1. Let $\theta(x_1, x_2) \equiv \cos^2(x_1 x_2)$ and

$$X \equiv \{\, (x_1, x_2) \in \Re^2 \,:\, (x_1, x_2) \leq 0,\ x_1 x_2 \geq \pi/2 \,\}.$$

We have $\theta_{\inf} = 0$. Consider the sequence $\{x^k\}$ with $x^k \equiv (1, -k\pi/2)$ for all k. Clearly,

$$\theta(x^k) = \begin{cases} 0 & \text{if } k \text{ is odd,} \\ 1 & \text{if } k \text{ is even,} \end{cases}$$

and $\operatorname{dist}(x^k, X) \geq 1$ for all k. Thus $\{x^k\}$ is neither asymptotically feasible nor asymptotically minimizing. Yet the projected vector $\bar{x}^k = (\bar{x}^k_1, \bar{x}^k_2)$ must satisfy $\bar{x}^k_1 \bar{x}^k_2 = \pi/2$ and $\nabla\theta(\bar{x}^k_1, \bar{x}^k_2) = (0, 0)$. Thus with $z^k \equiv \bar{x}^k$, we have $R_{\mathcal{N}}(z^k) = 0$ for all k. Consequently condition (ii) in the definition of $\mathcal{N}$-stationarity holds for the sequence $\{x^k\}$, but condition (i) fails. Thus for this sequence $\{x^k\}$, the corresponding projected sequence $\{\bar{x}^k\}$ is LP minimizing, N-stationary, and $\mathcal{N}$-stationary; yet the sequence $\{x^k\}$ itself does not satisfy any of the asymptotic properties defined so far.

The above example illustrates an important feature of the natural residual function $R_N(x)$ which is not shared by the normal residual function $R_{\mathcal{N}}(z)$. Namely, the former residual function itself captures both the asymptotic feasibility and minimizing property of an infinite sequence, whereas the latter residual function alone is not sufficient to handle infeasible sequences.

Since residual functions are practical tools employed in termination rules of iterative methods, it would be useful for us to say a few words about the potential utility of the two residual functions $R_N(x)$ and $R_{\mathcal{N}}(z)$ in this regard. In an iterative algorithm for solving the constrained optimization problem (1), one generates an infinite sequence of iterates $\{x^k\}$ which is not always feasible to the problem; sometimes an auxiliary sequence $\{z^k\}$ is also obtained in the computational process. If this is the situation, then both residual functions $R_N(x^k)$ and $R_{\mathcal{N}}(z^k)$ can legitimately be used in tests for terminating the iterative process (although as we have seen from the above example, one needs to be somewhat cautious in using $R_{\mathcal{N}}(z^k)$ as the sole termination indicator). If no auxiliary sequence $\{z^k\}$ is readily available, then it may be

computationally difficult to employ the residual function $R_{\mathcal{N}}$ to verify the asymptotic stationarity of $\{x^k\}$; in this case, $R_N(x^k)$ is the natural choice.

For later purposes, it is useful to state a relation between the two maps $R_N(x)$ and $R_{\mathcal{N}}(z)$ as follows. For $\bar{x} \equiv \Pi_X(z)$, we have

$$R_N(\bar{x}) \;=\; \Pi_X(\bar{x} - \nabla\theta(\bar{x}) + R_{\mathcal{N}}(z)) - \Pi_X(\bar{x} - \nabla\theta(\bar{x})),$$

which implies, by the nonexpansiveness of the projection,

$$\| R_N(\bar{x}) \| \;\leq\; \| R_{\mathcal{N}}(z) \|.$$

Consequently, for any two sequences $\{\bar{x}^k\}$ and $\{z^k\}$ such that $\bar{x}^k \equiv \Pi_X(z^k)$, we have

$$\lim_{k\to\infty} R_{\mathcal{N}}(z^k) \;=\; 0 \;\Longrightarrow\; \lim_{k\to\infty} R_N(\bar{x}^k) \;=\; 0. \tag{3}$$

2.2. Subdifferential-based asymptotic stationarity. Since every constrained optimization problem can be equivalently stated as an unconstrained problem with the use of the indicator function of the feasible set, one can also define the concept of asymptotic stationarity using the subdifferential approach of Auslender and Crouzeix [3] (this concept was not formally defined in the reference). In order to introduce this definition, we recall such standard notation as $\partial\phi$ and $\mathrm{dom}(\partial\phi)$ for the subdifferential and its domain of an (extended-valued) convex function ϕ; we also use $\partial_\varepsilon\phi$ for the ε-subdifferential of ϕ [16]. If ϕ is the indicator function (denoted $\mathbf{I}_S$) of a closed convex set $S \subseteq \Re^n$ (that is, $\mathbf{I}_S(x)$ is equal to 0 if $x \in S$ and equal to ∞ if $x \notin S$), then $\partial_\varepsilon\phi(x)$ coincides with the set of ε-normals to the set S at the vector $x \in S$; that is,

$$\partial_\varepsilon \mathbf{I}_S(x) \;=\; \{\, v \in \Re^n \,:\, v^T(y - x) \;\leq\; \varepsilon \text{ for all } y \in S\}.$$

Consider the problem (1), where we assume that θ is convex. Let

$$\phi(x) \;\equiv\; \theta(x) + \mathbf{I}_X(x) \quad \forall\, x \in \Re^n. \tag{4}$$

We say that a sequence $\{x^k\} \subset \Re^n$ is *AC-stationary* (AC for Auslender and Crouzeix) if

(i) $\{x^k\}$ is asymptotically feasible, and
(ii) the projected sequence $\{\bar{x}^k\}$, where $\bar{x}^k \equiv \Pi_X(x^k)$ for all k, has the property that for each k there exists $a^k \in \partial\phi(\bar{x}^k)$ and the sequence of subgradients $\{a^k\}$ converges to zero.

(Note: Since $\mathrm{dom}(\partial\phi) \subseteq X$, we need to use the projected sequence in condition (ii) in order to allow for the possibility that the original sequence $\{x^k\}$ is not feasible.) We say that the sequence $\{x^k\} \subset \Re^n$ is AC_ε-stationary if

(i) $\{x^k\}$ is asymptotically feasible, and
(ii) the projected sequence $\{\bar{x}^k\}$ has the property that for some sequence of nonnegative scalars $\{\varepsilon_k\}$ converging to zero, there exists for each k a vector $a^k \in \partial_{\varepsilon_k}\phi(\bar{x}^k)$, and the sequence of ε-subgradients $\{a^k\}$ converges to zero, where $\partial_\varepsilon\phi$ denotes the ε-subdifferential of ϕ.

2.3. Connections. As mentioned in the Introduction, Auslender, Crouzeix, and Lemaire used the subdifferential approach to analyze the connection between an asymptotically stationary sequence and an LP minimizing sequence. Their analysis dealt principally with feasible sequences $\{\bar{x}^k\} \subset X$, satisfying requirement (ii) in the definition of an AC-stationary sequence; we broaden this treatment by permitting the sequence $\{x^k\}$ to be infeasible.

We say that a function $F : \Re^n \to \Re^m$ is *uniformly continuous* near a sequence $\{x^k\}$ if, for every $\varepsilon > 0$, there exists a $\delta > 0$ such that for all k and y,

$$\|y - x^k\| \leq \delta \;\Rightarrow\; \|F(y) - F(x^k)\| \leq \varepsilon.$$

Uniform continuity is known to have an important role to play in the asymptotic well-posedness theory of optimization problems; see [8]. There is no exception in our work.

In what follows, we present a result that clarifies the relationship between the asymptotic stationarity concepts defined so far. Specifically, this result states that AC-stationarity is equivalent to $\mathcal{N}$-stationarity, whereas these two concepts are not necessarily equivalent to N-stationarity without some restrictions.

PROPOSITION 2.1. *Let $\theta : \Re^n \to \Re$ be a convex, continuously differentiable function and X a closed convex subset of $\Re^n$. Let $\{x^k\}$ be an arbitrary sequence of vectors in $\Re^n$. The following statements are valid.*

(a) *The sequence $\{x^k\}$ is AC-stationary if and only if it is $\mathcal{N}$-stationary.*
(b) *If $\{x^k\}$ is AC-stationary and each $x^k \in X$, then $\{x^k\}$ is N-stationary.*
(c) *If $\{x^k\}$ is AC-stationary and $\nabla\theta$ is uniformly continuous near $\{x^k\}$, then $\{x^k\}$ is N-stationary.*
(d) *If $\{x^k\}$ is N-stationary, $\{\nabla\theta(x^k)\}$ is bounded, and $\nabla\theta$ is uniformly continuous near $\{x^k\}$, then $\{x^k\}$ is AC_ε-stationary.*

Proof. Write $\bar{x}^k \equiv \Pi_X(x^k)$. Let ϕ be defined by (4). Since θ is differentiable, it follows that

$$\partial\phi(x) \;=\; \nabla\theta(x) + \partial\mathbf{I}_X(x), \quad \text{for all } x \in \Re^n.$$

To prove (a), let $\{x^k\}$ be AC-stationary. Let $\{a^k\}$ be a sequence of vectors converging to zero such that $a^k \in \partial\phi(\bar{x}^k)$ for each k. For each k, let $b^k \in \partial\mathbf{I}_X(\bar{x}^k)$ be such that $a^k = \nabla\theta(\bar{x}^k) + b^k$. Define $z^k \equiv \bar{x}^k + b^k$. It is then easy to verify that $\Pi_X(z^k) = \bar{x}^k$ and $R_{\mathcal{N}}(z^k) = a^k$. This establishes the "only if" statement in (a). The converse can be proved easily be reversing the argument. The details are omitted. Thus (a) holds.

To prove (b) and (c), let $\{x^k\}$ be AC-stationary. Let $\{z^k\}$ be the auxiliary sequence as stated in condition (ii) of AC-stationarity. By (3), it follows that $\lim_{k\to\infty} R_N(\bar{x}^k) = 0$. If each x^k belongs to X, then $x^k = \bar{x}^k$ and (b) follows readily. Instead, if $\nabla\theta$ is uniformly continuous near $\{x^k\}$, then since $\lim_{k\to\infty} \|x^k - \bar{x}^k\| = 0$, it follows that $\lim_{k\to\infty} R_N(x^k) = 0$ also, establishing (c).

To prove (d), let $\{x^k\}$ be N-stationary. It has been noted this implies $\{x^k\}$ is asymptotically feasible. Moreover, the uniform continuity of $\nabla\theta$ near $\{x^k\}$ implies that $\lim_{k\to\infty} R_N(\bar{x}^k) = 0$ and $\{\nabla\theta(\bar{x}^k)\}$ is bounded. Hence by letting

$$\varepsilon_k \;\equiv\; |\, R_N(\bar{x}^k)^T \nabla\theta(\bar{x}^k)\,|,$$

the sequence $\{\varepsilon_k\}$ converges to zero. It remains to show that $R_N(\bar{x}^k) \in \partial_{\varepsilon_k}\phi(\bar{x}^k)$, or equivalently, for all $y \in X$,

$$(R_N(\bar{x}^k) - \nabla\theta(\bar{x}^k))^T(y - \bar{x}^k) \;\leq\; \varepsilon_k.$$

By (2), we have

$$(R_N(\bar{x}^k) - \nabla\theta(\bar{x}^k))^T(y - \bar{x}^k) \;\leq\; R_N(\bar{x}^k)^T(\nabla\theta(\bar{x}^k) - R_N(\bar{x}^k)) \;\leq\; \varepsilon_k,$$

as desired. ∎

3. Minimizing ⇒ stationary. We are now ready to investigate the detailed relationships between an LP minimizing sequence and an asymptotically stationary sequence for the constrained optimization problem (1). Throughout the analysis, we let $\{x^k\} \subset \Re^n$ be an arbitrary sequence satisfying $\theta(x^k) > \theta_{\inf}$ for all k. We do *not* assume that $\{x^k\}$ is bounded.

This section deals with the issue stated in its heading. Specifically, we wish to answer the question, If $\{x^k\}$ is an LP minimizing sequence, is it necessarily an N-stationary sequence? For this part of the analysis, we need $\theta_{\inf}$ to be finite but do not need the convexity of θ. Thus the assumption that $\theta_{\inf} > -\infty$ is made throughout this section. A remark about the assumption is made at the closing of the section.

We begin by giving an example to show that a minimizing sequence is not necessarily stationary. This example illustrates the difference between an unbounded minimizing sequence and a bounded minimizing sequence and provides the motivation for the remaining study. Since this example deals with an unconstrained optimization problem (with $X = \Re^2$), there is no distinction between $\mathcal{N}$-stationarity and N-stationarity; in this case, a sequence $\{x^k\}$ is stationary if $\lim_{k\to\infty} \nabla\theta(x^k) = 0$.

Example 2. Consider an unconstrained optimization problem with the objective function given by

$$\theta(x_1, x_2) \equiv e^{x_1^2 - x_2}, \quad (x_1, x_2) \in \Re^2.$$

The function θ is convex and differentiable with an infimum value of zero that is not attained. Consider the sequence $\{x^k\}$ defined by

$$x^k = (x_1^k, x_2^k) \equiv (k, k^2 + \tfrac{1}{2}\log k).$$

It is trivial to check that

$$\theta(x^k) = 1/\sqrt{k} \quad \text{and} \quad \nabla\theta(x^k) = \begin{pmatrix} 2\sqrt{k} \\ -1/\sqrt{k} \end{pmatrix}.$$

Thus $\{x^k\}$ is minimizing but not stationary. Alternatively, consider the perturbed sequence $\{y^k\}$ defined by

$$y^k = (y_1^k, y_2^k) \equiv (k - 1/\sqrt{k}, k^2 + \tfrac{1}{2}\log k).$$

It is easy to verify that $\{y^k\}$ is both minimizing and stationary; moreover, $\{x^k - y^k\} \to 0$.

The above example illustrates an interesting phenomenon; namely, although the sequence $\{x^k\}$ is not stationary, we have identified a nearby sequence $\{y^k\}$ that is both minimizing and stationary. This phenomenon is not incidental, it is actually a fact as stated in the proposition below. The proof of this proposition uses the well-known ε-variational principle due to Ekeland [9]. Our original proof of the result used a smooth variant of this principle obtained recently by Deville, Godefroy, and Zizler [7]. The present proof is inspired by a referee's comment.

PROPOSITION 3.1. *Let X be a nonempty closed convex subset of $\Re^n$, and let $\theta : \Re^n \to \Re$ be a continuously differentiable function with θ_{inf} finite. Let $\{x^k\} \subset \Re^n$ be an LP minimizing sequence of θ on X. If θ is uniformly continuous near $\{x^k\}$, then there exists a nearby feasible sequence $\{y^k\} \subset X$ satisfying*

$$\text{(i)} \lim_{k\to\infty}(x^k - y^k) = 0, \quad \text{(ii)} \lim_{k\to\infty} \theta(y^k) = \theta_{inf}, \quad \textit{and} \quad \text{(iii)} \lim_{k\to\infty} R_N(y^k) = 0.$$

Proof. For each k, let $\bar{x}^k \equiv \Pi_X(x^k)$; then $\lim_{k\to\infty} \|x^k - \bar{x}^k\| = 0$ because $\{x^k\}$ is asymptotically feasible. Since θ is uniformly continuous near $\{x^k\}$, it follows that $\{\bar{x}^k\}$ is a feasible LP minimizing sequence. Take an arbitrary sequence of positive scalars $\{\varepsilon_k\}$ such that

$$\lim_{k\to\infty} \varepsilon_k = 0 \quad \text{and} \quad \theta(\bar{x}^k) < \theta_{\inf} + \varepsilon_k \quad \forall\, k.$$

Let $\phi(x)$ be defined by (4). We clearly have

$$\phi_{\inf} \equiv \inf_{x\in\Re^n} \phi(x) = \theta_{\inf},$$

and for each k, $\phi(\bar{x}^k) < \phi_{\inf} + \varepsilon_k$. By Ekeland's variational principle, there exists a vector y^k such that with

$$g_k(y) \equiv \sqrt{\varepsilon_k}\, \| y - y^k \|, \quad y \in \Re^n,$$

(a) $\phi + g_k$ attains its global minimum at y^k, (b) $\phi(y^k) \le \phi(\bar{x}^k)$, and (c) $\|\bar{x}^k - y^k\| \le \sqrt{\varepsilon_k}$. Clearly, $\lim_{k\to\infty}(x^k - y^k) = 0$. Moreover, $y^k \in X$ because ϕ takes the value ∞ outside X. Indeed y^k is a global minimizer of the problem

$$\begin{aligned} \text{minimize} \quad & \theta(x) + g_k(x) \\ \text{subject to} \quad & x \in X. \end{aligned}$$

Thus $\lim_{k\to\infty} \theta(y^k) = \theta_{\inf}$. For any $y \in X$, the directional derivative of $\theta + g_k$ at y^k along $y - y^k$ must be nonnegative. So there exists $w^k \in \partial(\theta + g_k)(y^k)$ such that $(w^k)^T(y - y^k) \ge 0$. By [6, Propositions 2.3.3 and 2.1.1], w^k can be written as $\nabla\theta(y^k) + z^k$ with $\|z^k\| \le \sqrt{\varepsilon_k}$. Since $y^k = \Pi_X(y^k - w^k)$, the global nonexpansiveness of the Euclidean projector and the fact that $w^k - \nabla\theta(y^k) = z^k \to 0$ imply

$$\lim_{k\to\infty} \left[\, y^k - \Pi_X(y^k - \nabla\theta(y^k)) \,\right] = 0;$$

that is,

$$\lim_{k\to\infty} R_N(y^k) = 0$$

as desired. ∎

We remark that the only place in the above proof where the uniform continuity of θ is used is to establish that the projected sequence $\{\bar{x}^k\}$ is also LP minimizing. In particular, this assumption can be dropped if the given sequence $\{x^k\}$ is already feasible to (1). As the following example shows, in general, if $\{x^k\}$ is LP minimizing, the projected sequence $\{\bar{x}^k\}$ is not necessarily LP minimizing if θ is not uniformly continuous near $\{x^k\}$. (See also Example 1, which gives a sequence $\{x^k\}$ for which the projected sequence $\{\bar{x}^k\}$ is LP minimizing but $\{x^k\}$ itself is not.)

Example 3. Let $\theta(x_1, x_2) \equiv \sin(x_1 x_2)$ and

$$X \equiv \{(x_1, x_2) \in \Re^2 : (x_1, x_2) \le 0,\, x_1 x_2 \ge \pi/2\}.$$

We have $\theta_{\inf} = -1$. Consider the sequence $\{x^k\}$ with $x^k \equiv (1/k, -k\pi/2)$ for all k. Since the distance between x^k and the vector $y^k \equiv (-1/k, -k\pi/2) \in X$ approaches zero as $k \to \infty$, it follows that $\{x^k\}$ is asymptotically feasible; thus $\{x^k\}$ is an LP minimizing sequence for the constrained program (1). Since each projected vector

$\bar{x}^k = (\bar{x}_1^k, \bar{x}_2^k)$ must satisfy $\bar{x}_1^k \bar{x}_2^k = \pi/2$, it follows that the sequence $\{\bar{x}^k\}$ is not LP minimizing.

An immediate consequence of Proposition 3.1 is the following result, which does not require a proof.

THEOREM 3.2. *Let X be a nonempty closed convex subset of $\Re^n$, and let $\theta : \Re^n \to \Re$ be a continuously differentiable function with θ_{inf} finite. Let $\{x^k\} \subset \Re^n$ be an LP minimizing sequence of θ on X. If θ and $\nabla\theta$ are uniformly continuous near $\{x^k\}$, then $\{x^k\}$ is an N-stationary sequence.*

The finiteness assumption of $\theta_{\inf}$ is essential for Ekeland's variational principle to be applicable in the proof of Proposition 3.1. Indeed Theorem 3.2 fails to hold without this assumption. A trivial counterexample is the one-dimensional unconstrained problem with $\theta(x) \equiv x$, $x \in X \equiv \Re$. Clearly, $\theta_{\inf} = -\infty$. Since the derivative is equal to the constant 1, there is no stationary sequence; yet any sequence that tends to $-\infty$ is minimizing.

4. Stationary $\Rightarrow$ minimizing. We next turn to the converse of Theorem 3.2. Although this issue has been treated to a reasonable extent in the papers [3, 2, 1], our treatment offers a fresh perspective and additional insights for the results. Consistent with the residual approach, we stress the importance of error bounds for the level sets of (1) in our treatment. For this part of the analysis, we need the convexity of θ but do not need the finiteness of $\theta_{\inf}$.

4.1. The role of error bounds. As evidenced in the work of Auslender and Crouzeix, a key element in the treatment of the issue stated in this section's heading is the theory of error bounds for the level sets of the problem (1). In light of the recent advances in this theory as described in the survey [29], we find it useful to give a summary of the relevant error bound results that are useful for our purpose here.

First, we introduce a concept for the problem (1). Specifically, we say that this problem has *H-metrically regular level sets*, or in short, (1) is H-metrically regular (H for Hölderian) if for every scalar $\lambda > \theta_{\inf}$, there exist positive scalars c and γ (possibly depending on λ) with $\gamma < 1$ such that

$$\operatorname{dist}(x, L(\lambda)) \leq c\, r_\gamma(x) \quad \forall\, x \in X, \tag{5}$$

where $L(\lambda)$ is the λ-level set of (1); that is,

$$L(\lambda) \equiv \{\, x \in X : \theta(x) \leq \lambda \,\},$$

and $r_\gamma(x)$ is the following residual for $L(\lambda)$:

$$r_\gamma(x) \equiv \max\left([\, (\theta(x) - \lambda)_+ \,]^\gamma,\ (\theta(x) - \lambda)_+ \right).$$

The function $r_\gamma(x)$ is a computable measure of the violation of the constraints by vectors $x \in X$ that fail to be in the λ-level set. (A remark: $L(\lambda)$ is nonempty for all $\lambda > \theta_{\inf}$.) In a nutshell, the H-metric regularity of (1) stipulates that error bounds of a Hölderian type [29] hold for the λ-level sets of this problem for all $\lambda > \theta_{\inf}$. Note that we do not require the exponent γ to be the same for all λ. If error bounds of a Lipschitzian type hold for all of these level sets (i.e., (5) holds with $\gamma = 1$ for all $\lambda > \theta_{\inf}$), then we say that (1) is L(ipschitzian)-metrically regular.

The H- or L-metric regularity of (1) does not require this problem to attain a finite optimum objective value. If the set of optimal solutions

$$X_{\text{opt}} \equiv \{\, x \in X : \theta(x) \leq \theta_{\inf} \,\}$$

is nonempty, several additional concepts can be defined. Specifically, (1) is said to have *weak sharp minima* if $X_{\rm opt}$ is nonempty and a Lipschitzian error bound holds for $X_{\rm opt}$, i.e., there exists a constant $c > 0$ such that

$$\mathrm{dist}(x, X_{\rm opt}) \leq c\,(\,\theta(x) - \theta_{\rm inf}\,) \quad \forall\, x \in X.$$

This concept was introduced in Michael Ferris's Ph.D. dissertation [10], and its roles are investigated extensively in [5, 11]. An obvious generalization of this definition is the following. We say that (1) has *Hölderian minima* if $X_{\rm opt}$ is nonempty and an Hölderian error bound holds for $X_{\rm opt}$; that is, there exist positive constants c and γ such that (5) holds for $\lambda = \theta_{\rm opt}$.

The concept of ψ-sharp minima has played an important role in the Tykhonov–Levitin–Polyak well-posedness theory of optimization problems. A continuous function $\psi : [0,\infty) \to [0,\infty)$ is said to be a *forcing function* if for every sequence $\{t_k\} \subset [0,\infty)$,

$$\lim_{k\to\infty} \psi(t_k) = 0 \implies \lim_{k\to\infty} t_k = 0.$$

We say that the problem (1) has ψ-sharp minima if $X_{\rm opt}$ is nonempty and

$$\theta(x) \geq \theta_{\rm inf} + \psi(\mathrm{dist}(x, X_{\rm opt})) \quad \forall\, x \in X,$$

where ψ is a given forcing function. Adopting Lemaire's terminology [15] to our setting, we say that (1) has *well-conditioned minima* if $X_{\rm opt}$ is nonempty and there exists a forcing function ψ such that (1) has ψ-sharp minima. If the forcing function satisfies the stronger property that for every sequence $\{t_k\} \subset (0,\infty)$,

$$\lim_{k\to\infty} \frac{\psi(t_k)}{t_k} = 0 \implies \lim_{k\to\infty} t_k = 0,$$

we use the terminology "ψ-very-sharp minima" and "very-well-conditioned minima," respectively.

Clearly, weak sharp minima is a special case of well-conditioned minima with the forcing function being a positive multiple of the identity function; more generally, Hölderian minima can also be shown to imply well-conditioned minima with a forcing function ψ being the inverse of the strictly increasing function $s \in [0,\infty) \mapsto c\,(s+s^\gamma) \in [0,\infty)$, where c and γ are the constants in the Hölderian error bound for $X_{\rm opt}$.

Admittedly, the concept of ψ-sharp minima is significantly broader than that of Hölderian minima. Nevertheless, it is generally not easy to identify the forcing function ψ (thus to verify that (1) has well-conditioned sharp minima). The theory of error bounds as summarized in [29], with the postulate of a specific family of ψ functions as given above, offers a practical way of verifying this sharp property of $X_{\rm opt}$.

In what follows, we return to L- and H-metric regularity of the problem (1). In the remainder of this section, we do not assume the nonemptiness of $X_{\rm opt}$ unless otherwise stated.

Inspired by a "strong Slater" condition proposed recently by Mangasarian [26], we present a necessary and sufficient condition for the problem (1) to be L-metrically regular. In addition to [29], we refer the reader to [18] for a systematic treatment of error bounds for convex inequality systems.

LEMMA 4.1. *Let $\theta : \Re^n \to \Re$ be a convex function and X be a closed convex subset of $\Re^n$. For a scalar $c > 0$, the following two conditions are equivalent.*

(a) *For all* $x \in X$ *with* $\theta(x) > \theta_{inf}$, *there exists* $\hat{x} \in X$ *satisfying* $\theta(\hat{x}) < \theta(x)$ *and*

$$\| \hat{x} - x \| \leq c\,(\theta(x) - \theta(\hat{x})).$$

(b) *For all* $\lambda > \theta_{inf}$,

$$dist(x, L(\lambda)) \leq c\,(\theta(x) - \lambda)_+ \quad \forall\ x \in X.$$

In particular, if (1) *has weak sharp minima, then* (1) *is L-metrically regular.*

Proof. (a) $\Rightarrow$ (b). Let $\lambda > \theta_{\inf}$ and $x \in X$ be given. Without loss of generality, we may assume that $\theta(x) > \lambda$. Consider the problem of projecting x onto $L(\lambda)$:

$$\begin{array}{ll} \text{minimize} & \frac{1}{2}\,(z - x)^T(z - x) \\ \text{subject to} & z \in L(\lambda). \end{array}$$

Let $\bar{x} \equiv \Pi_{L(\lambda)}(x)$. We must have $\theta(\bar{x}) = \lambda$. Let $\hat{x} \in X$ be the vector such that $\theta(\hat{x}) < \theta(\bar{x})$ and

$$\| \hat{x} - \bar{x} \| \leq c\,(\theta(\bar{x}) - \theta(\hat{x})).$$

By results from convex analysis [33], there exist a nonnegative scalar η and a vector $a \in \partial\theta(\bar{x})$ such that for all $z \in X$,

$$(z - \bar{x})^T(\bar{x} - x + \eta\, a) \geq 0. \tag{6}$$

Letting $z = \hat{x}$, we deduce

$$\eta\, a^T(\hat{x} - \bar{x}) \geq -(\hat{x} - \bar{x})^T(\bar{x} - x).$$

By the definition of a, we have

$$\theta(\hat{x}) - \theta(\bar{x}) \geq a^T(\hat{x} - \bar{x}),$$

which implies

$$\eta\,(\theta(\hat{x}) - \theta(\bar{x})) \geq -(\hat{x} - \bar{x})^T(\bar{x} - x).$$

Consequently, it follows that

$$\eta \leq c\,\| \bar{x} - x \|.$$

Letting $z = x$ in (6), we deduce

$$\| \bar{x} - x \|^2 \leq \eta\, a^T(x - \bar{x}) \leq \eta\,(\theta(x) - \theta(\bar{x})).$$

Since $x \neq \bar{x}$ and $\theta(\bar{x}) = \lambda < \theta(x)$, we obtain

$$\| \bar{x} - x \| \leq c\,(\theta(x) - \lambda)_+.$$

Thus (b) holds.

(b) $\Rightarrow$ (a). Let $x \in X$ with $\theta(x) > \theta_{\inf}$ be given. Choose λ such that $\theta(x) > \lambda > \theta_{\inf}$. Let $\hat{x}$ be the Euclidean projection of x onto the level set $L(\lambda)$. Then $\hat{x} \in X$ and $\theta(\hat{x}) = \lambda < \theta(x)$. By (b), we have

$$\| \hat{x} - x \| = \operatorname{dist}(x, L(\lambda)) \leq c\,(\theta(x) - \lambda)_+ = c\,(\theta(x) - \theta(\hat{x})).$$

Thus (a) holds.

If (1) has weak sharp minima, then clearly (a) holds with $\hat{x} \in X_{\rm opt}$ satisfying $\| x - \hat{x} \| = {\rm dist}(x, X_{\rm opt})$. Thus (b) follows. □

We review some terminology of piecewise smooth functions; see Li [19]. We say that a function $\theta : \Re^n \to \Re$ is *piecewise quadratic* if θ is continuous and there exist finitely many convex polyhedra P_i, $i = 1, \ldots, p$ for some positive integer p, whose union is $\Re^n$ such that θ is a quadratic function on each P_i; the latter quadratic functions are called the *pieces* of θ. A vector function $F : \Re^n \to \Re^m$ is *piecewise linear* if F is continuous and there exist finitely many convex polyhedra S_i, $i = 1, \ldots, q$, for some positive integer q, whose union is $\Re^n$ such that F is an affine function on each S_i; these affine functions are called the *pieces* of F. It is well known [12] that a piecewise linear function on $\Re^n$ is globally Lipschitz continuous. Clearly, if θ is a differentiable piecewise quadratic real-valued function, then the gradient map $\nabla\theta$ is a piecewise linear vector-valued function. We say that a real-valued function θ defined on $\Re^n$ is *convex piecewise quadratic*, or CPQ in short, if θ is convex and piecewise quadratic (thus the pieces of θ must be convex quadratic functions). A *convex quadratic spline* is a differentiable CPQ function. A simple one-dimensional convex quadratic spline is the function $t \in \Re \mapsto (\max(0, t))^2 \in \Re_+$.

Lemma 4.2 below identifies two sufficient conditions for the problem (1) to be H-metrically regular. The first condition assumes that this problem has an analytic objective function and its feasible set is compact and defined by finitely many analytic inequalities; the conclusion follows easily from the error bound theory of analytic inequality systems [23]. This part of the result illustrates the fact that H-metric regularity holds trivially for the broad class of "analytic programs" with compact feasible regions; this conclusion will not be used later. In contrast, the second condition of Lemma 4.2 will serve two important objectives. One, it further illustrates that H-metric regularity is a condition that will be easily satisfied by another class of constrained optimization problems. As a result, we can readily establish that this class of problems is well behaved. Second, the proof of Lemma 4.2 under the second condition is based on an Hölderian error bound for a general convex quadratic inequality system established in [37]; it is a significant extension of the result of Luo and Luo [22] for a convex quadratic inequality system which requires a Slater condition.

LEMMA 4.2. *Suppose that the pair (θ, X) satisfies either one of the two conditions below:*

(a) *θ is an analytic function and X is a compact set defined by finitely many analytic inequalities;*

(b) *$\theta(x)$ is a CPQ function and*

$$X \equiv \{\, x \in \Re^n : g_i(x) \leq 0,\ i = 1, \ldots, m \,\},$$

where each g_i is a convex quadratic function and m is a given positive integer. Then the problem (1) *has H-metrically regular level sets. Furthermore if X_{opt} is nonempty, then an Hölderian error bound holds for X_{opt}.*

Proof. We prove the lemma under condition (b); the same proof given below can be applied when (a) holds by using the error bound results in [23]. Let $\{P_i : i = 1 \ldots, p\}$ be the family of convex polyhedra whose union is $\Re^n$ such that θ is equal to a quadratic function, which we denote q_i, on each P_i. Let $\lambda > \theta_{\rm inf}$ be given. Clearly,

$$L(\lambda) = \bigcup_{i=1}^{p} L_i(\lambda),$$

where each

$$L_i(\lambda) \equiv \{\, x \in X \cap P_i : q_i(x) \leq \lambda \,\}$$

is the solution set of a system of finitely many convex quadratic inequalities ($L_i(\lambda)$, if nonempty, need not have a nonempty interior). By the error bound in [37], for each i for which $L_i(\lambda)$ is nonempty, there exists positive constant c_i and γ_i with $\gamma_i < 1$ such that

$$\operatorname{dist}(x, L_i(\lambda)) \leq c_i \max\left([\, (q_i(x) - \lambda)_+ \,]^{\gamma_i},\ (q_i(x) - \lambda)_+ \right) \quad \forall\, x \in X \cap P_i.$$

Since

$$\operatorname{dist}(x, L_i(\lambda)) \geq \operatorname{dist}(x, L(\lambda))$$

and q_i coincides with θ on P_i, it follows that

$$\operatorname{dist}(x, L(\lambda)) \leq c_i \max\left([\, (\theta(x) - \lambda)_+ \,]^{\gamma_i},\ (\theta(x) - \lambda)_+ \right) \quad \forall\, x \in X \cap P_i.$$

Since the union of the P_i is $\Re^n$, it follows that by letting

$$c \equiv \max(\, c_i : i = 1, \ldots, p \,) \quad \text{and} \quad \gamma \equiv \min(\, \gamma_i : i = 1, \ldots, p \,),$$

we obtain

$$\operatorname{dist}(x, L(\lambda)) \leq c \max\left([\, (\theta(x) - \lambda)_+ \,]^{\gamma},\ (\theta(x) - \lambda)_+ \right) \quad \forall\, x \in X,$$

as desired. The above proof is clearly applicable to X_{opt} if this set is nonempty. ∎

By the main result, Theorem 3.1 in [37], one can show that if X is a convex polyhedron, the exponent γ in the error bounds for the level sets $L(\lambda)$ can be chosen to be equal to $1/2$ for all $\lambda \geq \theta_{\text{inf}}$. This conclusion extends a result of Li [19, Corollary 2.8] which pertains to $\lambda = \theta_{\text{inf}}$. An extension of this conclusion is presented in Proposition 4.10 in section 4.3, which was proved by Li recently [20].

4.2. The implication and special cases. We are now ready to state the principal result regarding the topic of this section. Although the main idea of proof is borrowed from [3], the result itself is a useful refinement of this work in several respects. First, our result gives a full treatment of infeasible sequences; second, it is based on residual functions which are closely tied to the practical implementation of iterative methods; third, the assumption of H-metric regularity offers an effortless demonstration that an important class of constrained optimization problems is well behaved; see Corollary 4.5 and Theorem 5.3.

THEOREM 4.3. *Let X be a nonempty closed convex subset of $\Re^n$, and let $\theta : \Re^n \to \Re$ be a continuously differentiable convex function. Let $\{x^k\} \subset \Re^n$ be an arbitrary sequence of vectors satisfying any one of the following three conditions:*

(i) *$\{\nabla\theta(x^k)\}$ is bounded, $\nabla\theta$ is uniformly continuous near $\{x^k\}$, and $\{x^k\}$ is N-stationary;*

(ii) *θ is uniformly continuous near $\{x^k\}$ and $\{x^k\}$ is $\mathcal{N}$-stationary;*

(iii) *each x^k is feasible to (1) and $\{x^k\}$ is $\mathcal{N}$-stationary.*

If (1) is H-metrically regular, then $\{x^k\}$ is an LP minimizing sequence of θ on X.

Proof. We first establish that the conclusion holds under (iii). In essence, if (1) is L-metrically regular, then the conclusion follows immediately from the work of Auslender and Crouzeix [3]. Our proof below is a slight extension of their argument

in the case where the level sets have Hölderian (instead of Lipschitzian) error bounds. For completeness, we give the detailed proof.

So we assume that each x^k is feasible to (1) and the sequence $\{x^k\}$ is $\mathcal{N}$-stationary. It suffices to show $\lim_{k\to\infty}\theta(x^k) = \theta_{\inf}$. Assume for the sake of contradiction that this is not true. Let the scalar λ be such that $\liminf_{k\to\infty}\theta(x^k) > \lambda > \theta_{\inf}$. Let c and γ be such that (5) holds. Since $L(\lambda)$ is a nonempty closed convex set, it follows that for each k, there exists $y^k \in L(\lambda)$ such that $\operatorname{dist}(x^k, L(\lambda)) = \|x^k - y^k\|$; moreover since the line segment joining x^k and y^k lies in X, we must have $\theta(y^k) = \lambda$. Since θ is convex, by the gradient inequality,

$$\lambda \;=\; \theta(y^k) \;\geq\; \theta(x^k) + \nabla\theta(x^k)^T(y^k - x^k).$$

Since $\{x^k\}$ is $\mathcal{N}$-stationary, there exists a sequence $\{z^k\}$ such that $x^k = \Pi_X(z^k)$ for all k and

$$\lim_{k\to\infty} R_{\mathcal{N}}(z^k) \;=\; 0.$$

By the definition of $R_{\mathcal{N}}(z^k)$, it follows that

$$(y^k - x^k)^T(\nabla\theta(x^k) - R_{\mathcal{N}}(z^k)) \;\geq\; 0, \tag{7}$$

which implies

$$\nabla\theta(x^k)^T(y^k - x^k) \;\geq\; R_{\mathcal{N}}(z^k)^T(y^k - x^k).$$

Thus

$$\theta(x^k) - \lambda \;\leq\; -R_{\mathcal{N}}(z^k)^T(y^k - x^k).$$

since $\theta(x^k) > \lambda$, by the Cauchy–Schwarz inequality and (5), we deduce

$$\theta(x^k) - \lambda \;\leq\; c\,\|\,R_{\mathcal{N}}(z^k)\,\|\,\max\left(\theta(x^k) - \lambda,\,(\theta(x^k) - \lambda)^{\gamma}\right).$$

Dividing by $\theta(x^k) - \lambda$, we obtain

$$1 \;\leq\; c\,\|R_{\mathcal{N}}(z^k)\|\,\max\left(1, (\theta(x^k) - \lambda)^{\gamma-1}\right).$$

Since $\{R_{\mathcal{N}}(z^k)\}$ converges to zero and $\liminf_{k\to\infty}\theta(x^k) > \lambda$, we obtain a contradiction from the above expression by passing to the limit $k \to \infty$.

To prove (ii), let $\bar{x}^k \equiv \Pi_X(x^k)$. Then $\{\bar{x}^k\}$ satisfies the conditions in (iii). By the above proof, we deduce

$$\lim_{k\to\infty} \theta(\bar{x}^k) \;=\; \theta_{\inf}. \tag{8}$$

Since θ is uniformly continuous near $\{x^k\}$, the same limit holds for the sequence $\{x^k\}$.

Finally, assume the conditions in (i). We have noted that $\{x^k\}$ must be asymptotically feasible to (1); let $\bar{x}^k \equiv \Pi_X(x^k)$. The sequence $\{\bar{x}^k\}$ is also N-stationary because $\nabla\theta$ is uniformly continuous near $\{x^k\}$.

At this point, there are two ways to finish the proof. Both require us to show that θ is uniformly continuous near $\{x^k\}$. So we show this first. By the mean-value theorem, for any vector $y \in \Re^n$, there exists a scalar $\tau_k \in [0,1]$ such that

$$\begin{aligned}\theta(y) - \theta(x^k) &= \nabla\theta(x^k + \tau_k(y - x^k))^T(y - x^k)\\ &= [\nabla\theta(x^k + \tau_k(y - x^k)) - \nabla\theta(x^k)]^T(y - x^k) + \nabla\theta(x^k)^T(y - x^k),\end{aligned}$$

which easily establishes the uniform continuity of θ near $\{x^k\}$ under the assumptions in (i).

To complete the proof, one way is to apply Proposition 2.1(c) to conclude that $\{x^k\}$ is AC_ε-stationary; hence so is $\{\bar{x}^k\}$. By following the argument in Proposition 2.1 in [3] (which uses the theorem of Bronstedt and Rockafellar [4] about ε-subgradients), we can deduce that (8) holds. Thus the uniform continuity of θ near $\{x^k\}$ completes the proof.

Alternatively, we can follow our proof above and use instead of (7) the inequality

$$(y^k - \bar{x}^k + R_N(\bar{x}^k))^T(\nabla\theta(\bar{x}^k) - R_N(\bar{x}^k)) \geq 0,$$

which follows from (2). Either way, the desired conclusion of the theorem holds under (i). □

The above proof reveals a general fact that is worth further discussion; namely, if θ is a continuously differentiable function with $\{\nabla\theta(x^k)\}$ being bounded and $\nabla\theta$ uniformly continuous near $\{x^k\}$, then θ is uniformly continuous near $\{x^k\}$. When θ is a quadratic function (not necessarily convex), then $\nabla\theta(x)$ is an affine function in x; thus $\nabla\theta$ is uniformly continuous near any sequence. In this case, θ is uniformly continuous near a sequence $\{x^k\}$ if and only if $\{\nabla\theta(x^k)\}$ is bounded. Indeed it suffices to prove the "only if" part. In turn, this proof is rather easy because, by means of an orthogonal transformation of variables, we may assume without loss of generality that θ is a separable quadratic function; under this assumption, the desired assertion is easily seen to be valid.

Combining the above discussion with the globally Lipschitz continuous property of a piecewise linear function, we state a useful property of a differentiable piecewise quadratic function. The following lemma requires no proof.

LEMMA 4.4. *Let $\theta : \Re^n \to \Re$ be a differentiable piecewise quadratic function. The following two statements hold:*

(a) *$\nabla\theta$ is globally Lipschitz continuous;*

(b) *if $\{\nabla\theta(x^k)\}$ is bounded, then θ is uniformly continuous near $\{x^k\}$.*

Based on Lemmas 4.4 and 4.2(b), we establish a corollary of Theorem 4.3 that pertains to the following convex quadratically constrained quadratic spline program (CQQSP):

$$\begin{aligned} &\text{minimize} && \theta(x) \\ &\text{subject to} && G_i(x) \equiv \tfrac{1}{2}x^T C_i x + a_i^T x + b_i \leq 0, \quad i = 1, \ldots, m, \end{aligned} \tag{9}$$

where θ is a convex quadratic spline, each C_i is an $n \times n$ symmetric positive semidefinite matrix, each a_i is an n-vector, and each b_i is a scalar. A special case of the CQQSP is the convex quadratically constrained quadratic program (CQQP) in which the objective function θ is a convex quadratic function. The corollary below illustrates an important benefit of weakening the Auslender–Crouzeix assumption of L-metric regularity to H-metric regularity.

COROLLARY 4.5. *Assume that the above CQQSP is feasible and that θ_{inf} is finite. Let $\{x^k\}$ be an arbitrary sequence of vectors such that $\{\nabla\theta(x^k)\}$ is bounded. Then $\{x^k\}$ is N-stationary for* (9) *if and only if it is LP minimizing.*

Proof. By the boundedness of $\{\nabla\theta(x^k)\}$, Lemma 4.4 implies that both θ and $\nabla\theta$ are uniformly continuous near $\{x^k\}$. Consequently, if $\{x^k\}$ is LP minimizing for (9), then Theorem 3.2 implies that $\{x^k\}$ is N-stationary.

Conversely assume that $\{x^k\}$ is N-stationary for the CQQSP. Condition (i) in

Theorem 4.3 is thus satisfied. Moreover by Lemma 4.2, the CQQSP is H-metrically regular. Theorem 4.3 completes the proof. □

Using Lemma 4.1, we can easily establish the following result which identifies another sufficient condition under which LP minimizing sequences and N-stationary sequences are equivalent. As with the other results in this subsection, the result below does not require $X_{\rm opt}$ to be nonempty.

PROPOSITION 4.6. *Let $\theta : \Re^n \to \Re$ be a convex, continuously differentiable function, and let X be a closed convex subset of $\Re^n$. Suppose $\theta_{inf} > -\infty$ and there exists a constant $c > 0$ such that for all $x \in X$ with $\theta(x) > \theta_{inf}$, there exists $\hat{x} \in X$ satisfying $\theta(\hat{x}) < \theta(x)$ and*

$$\| \hat{x} - x \| \leq c\,(\theta(x) - \theta(\hat{x})).$$

Let $\{x^k\}$ be an arbitrary sequence such that $\{\nabla\theta(x^k)\}$ is bounded and $\nabla\theta$ is uniformly continuous near $\{x^k\}$. Then $\{x^k\}$ is LP minimizing for (1) *if and only if it is N-stationary.*

Proof. This follows easily from Theorems 3.2 and 4.3 and Lemma 4.1. □

An immediate consequence of the above theorem is that if the program (1) has weak sharp minima, then for any sequence $\{x^k\}$ such that $\{\nabla\theta(x^k)\}$ is bounded and $\nabla\theta$ is uniformly continuous near $\{x^k\}$, the sequence $\{x^k\}$ is LP minimizing for (1) if and only if it is N-stationary. This conclusion will be generalized in the next subsection in which an expanded study is presented for the program (1) under the assumption that $X_{\rm opt}$ is nonempty.

4.3. When optimal solutions exist. The boundedness of the sequence of gradients $\{\nabla\theta(x^k)\}$ has played an important role in several results in the last subsection. In what follows, we derive some results that pertain to this boundedness issue. In particular, these results lend support to the presumption that this boundedness assumption is not too restrictive in order for the results in the last subsection to hold.

Consider the case where the problem (1) attains its global minimum; i.e., assume $X_{\rm opt} \neq \emptyset$. In this case, we say that a sequence $\{x^k\} \subset \Re^n$ is *near the optimal set* if $\lim_{k\to\infty} {\rm dist}(x^k, X_{\rm opt}) = 0$. This notion requires $X_{\rm opt}$ to be nonempty. The next result shows that if θ is uniformly continuous, then the property of "near the optimal set" implies that of LP minimizing. This implication does not require θ to be differentiable.

PROPOSITION 4.7. *Assume $X_{opt} \neq \emptyset$. If $\{x^k\} \subset \Re^n$ is a sequence near the optimal set of* (1) *and θ is uniformly continuous near $\{x^k\}$, then $\{x^k\}$ is LP minimizing for* (1).

Proof. Since $X_{\rm opt} \subseteq X$, it follows that

$${\rm dist}(x^k, X) \leq {\rm dist}(x^k, X_{\rm opt}) \quad \forall k.$$

Thus the sequence $\{x^k\}$ is asymptotically feasible. Moreover if $y^k \equiv \Pi_{X_{\rm opt}}(x^k)$, then

$$\lim_{k\to\infty} \theta(y^k) = \lim_{k\to\infty} \theta(x^k),$$

by the uniform continuity of θ near $\{x^k\}$. Hence $\{x^k\}$ is LP minimizing for (1), as desired. □

The following example shows that the uniform continuity assumption in the above proposition is essential for the result to hold.

Example 4. Let θ and X be as given in Example 3. Let

$$x^k \equiv -\begin{pmatrix} 1/k \\ k\pi/2 \end{pmatrix}, \quad y^k \equiv -\begin{pmatrix} 3/k \\ k\pi/2 \end{pmatrix} \quad \text{for } k = 0, 1, 2, \ldots.$$

Each $y^k \in X_{\text{opt}}$ and $\lim_{k\to\infty} \|x^k - y^k\| = 0$. Thus the sequence $\{x^k\}$ is near the optimal set. Yet it is clear that $\{x^k\}$ is not LP minimizing because $\theta(x^k) = 1$ for all k.

Next we show that under the condition of Hölderian minima, the converse of the above proposition holds.

PROPOSITION 4.8. *Assume that* (1) *has Hölderian minima. If* $\{x^k\} \subset \Re^n$ *is an LP minimizing sequence of* (1)*, and if* θ *is uniformly continuous near* $\{x^k\}$*, then* $\{x^k\}$ *is near the optimal set.*

Proof. Let $\bar{x}^k \equiv \Pi_X(x^k)$ for each k. Since θ is uniformly continuous near $\{x^k\}$, the projected sequence $\{\bar{x}^k\}$ is also LP minimizing. We have

$$\text{dist}(x^k, X_{\text{opt}}) \le \|x^k - \bar{x}^k\| + \text{dist}(\bar{x}^k, X_{\text{opt}});$$

the right-hand sum clearly approaches zero as $k \to \infty$ because $\{x^k\}$ is asymptotically feasible and the Hölderian error bound for X_{opt} implies that $\text{dist}(\bar{x}^k, X_{\text{opt}}) \to 0$ as k tends to ∞. Thus $\{x^k\}$ is near the optimal set. □

An immediate consequence of the above proposition is that if θ is uniformly continuous on $\Re^n$ and (1) has weak sharp minima, then an arbitrary sequence $\{x^k\} \subset \Re^n$ is LP minimizing if and only if it is near the optimal set. The CQQSP is another instance where these two sequential properties are equivalent; see Theorem 5.3.

It has been shown by Mangasarian [24] that for a differentiable convex program, i.e., for (1) where θ is a continuously differentiable convex function and X is a convex set, the gradient of θ is equal to a constant on X_{opt}. (Actually, this result was extended to a nondifferentiable function in the reference; nevertheless, consistent with the treatment of this paper, we restrict the discussion to differentiable functions.) Based on this fact, we establish a related property of a sequence near the optimal set; this property can be used to partially atone for the boundedness assumption of the gradient sequence $\{\nabla\theta(x^k)\}$ in Theorem 4.3. In particular, under the assumptions of Propositions 4.8 and 4.9, if these gradients are unbounded, then $\{x^k\}$ cannot be an LP minimizing sequence for (1).

PROPOSITION 4.9. *Let* X *be a nonempty closed convex subset of* $\Re^n$*, and let* $\theta : \Re^n \to \Re$ *be a continuously differentiable convex function such that* $X_{opt} \neq \emptyset$*. Let* $g \equiv \nabla\theta(\bar{x})$ *for any* $\bar{x} \in X_{opt}$*. If* $\{x^k\}$ *is a sequence near the optimal set of* (1) *and* $\nabla\theta$ *is uniformly continuous near* $\{x^k\}$*, then* $\lim_{k\to\infty} \nabla\theta(x^k)$ *exists and equals* g*.*

Proof. Let $y^k \equiv \Pi_{X_{\text{opt}}}(x^k)$. Since $\nabla\theta(y^k) = g\,\forall k$, the desired conclusion follows easily. □

Under the assumption $X_{\text{opt}} \neq \emptyset$, several of our results are closely related to the work of Lemaire [15], which is cast in the framework of an extended-valued convex function (such as the function ϕ in (4)) in a Banach space. Phrased in our terminology, Theorem 3.1 in this reference says that the following statements are equivalent.

(i) Every feasible, LP-minimizing sequence is near the optimal set.
(ii) The function ϕ defined in (4) has well-conditioned minima in the sense of Lemaire's Definition 2.1.
(iii) The function ϕ has very well-conditioned minima in the sense of Lemaire's Definition 2.2.
(iv) Every feasible AC-stationary sequence is near the optimal set.

There are two obvious differences between Lemaire's work and ours. The first difference lies in the treatment of infeasible sequences. In our case, the given sequence $\{x^k\}$ is not necessarily feasible; this is a broadening of Lemaire's treatment. The other difference is that Lemaire did not consider the question of whether a sequence that is near the optimal set is necessarily LP minimizing. As we see from Example 4 above, the answer to this question in general is in the negative. Although easy, the issue considered in Proposition 4.9 has not been dealt with before.

To end this section, we give a result for the program (1) under a convexity assumption and the existence of Hölderian minima for this convex program. This result, which is obtained by Li [20], is related in spirit to some results in [3], like Proposition 2.8 therein; cf. also Lemma 4.1 in section 4.1.

PROPOSITION 4.10. *Let $\theta : \Re^n \to \Re$ be a convex function, and let X be a closed convex subset of $\Re^n$. Suppose that, for some scalar $\lambda_0 \geq \theta_{inf}$, $L(\lambda_0)$ is nonempty and there exist constants $c > 0$ and $\gamma \in (0,1)$ such that*

$$\operatorname{dist}(x, L(\lambda_0)) \leq c \max\left([\,(\theta(x) - \lambda_0)_+\,]^\gamma,\ (\theta(x) - \lambda_0)_+ \right) \quad \forall\, x \in X.$$

Then for all $\lambda > \lambda_0$,

$$\operatorname{dist}(x, L(\lambda)) \leq c \max\left([\,(\theta(x) - \lambda)_+\,]^\gamma,\ (\theta(x) - \lambda)_+ \right) \quad \forall\, x \in X.$$

In particular, if (1) has Hölderian minima, then (1) has H-metrically regular level sets.

Proof. Let $x \in X$ and $\lambda > \lambda_0$ be given. Without loss of generality, we may assume that $\theta(x) > \lambda$. Let $\bar{x} \in \lambda_0$ be such that

$$\operatorname{dist}(x, L(\lambda_0)) = \| x - \bar{x} \|.$$

We must have $\theta(\bar{x}) = \lambda_0$. Let $\tau \in (0,1)$ be such that

$$\theta(x^\tau) = \lambda, \quad \text{where} \quad x^\tau \equiv \tau\, x + (1 - \tau)\, \bar{x}.$$

By the convexity of θ, it follows easily that

$$\lambda = \theta(x^\tau) \leq \tau\, \theta(x) + (1 - \tau)\, \theta(\bar{x}),$$

which yields

$$(1-\tau)\,(\theta(x)-\lambda_0)_+ \leq (\theta(x)-\lambda)_+ \quad \text{and} \quad [\,(1-\tau)\,(\theta(x)-\lambda_0)_+\,]^\gamma \leq [\,(\theta(x)-\lambda)_+\,]^\gamma.$$

Consequently, since $x^\tau \in L(\lambda)$, we have

$$\begin{aligned}
\operatorname{dist}(x, L(\lambda)) &\leq \| x - x^\tau \| \\
&= (1 - \tau)\, \| x - \bar{x} \| = (1 - \tau) \operatorname{dist}(x, L(\lambda_0)) \\
&\leq (1 - \tau)\, c \max\left([\,(\theta(x) - \lambda_0)_+\,]^\gamma,\ (\theta(x) - \lambda_0)_+ \right) \\
&\leq c \max\left([\,(1 - \tau)\,(\theta(x) - \lambda_0)_+\,]^\gamma,\ (\theta(x) - \lambda)_+ \right) \\
&\leq c \max\left([\,(\theta(x) - \lambda)_+\,]^\gamma,\ (\theta(x) - \lambda)_+ \right),
\end{aligned}$$

where the next-to-last inequality holds because $\tau \in (0,1)$ and $\gamma \in (0,1)$. Finally, with $\lambda_0 \equiv \theta_{\inf}$, the last assertion of the proposition is obvious. □

5. Asymptotic optimality systems. We return to the general situation where we do not assume the nonemptiness of $X_{\rm opt}$.

When the set X possesses additional structure, we can use some asymptotic optimality systems to characterize the LP minimizing property of a sequence. This section is divided into two subsections. In the first one we consider the case where X is a closed convex cone; in the second one we assume that X is defined by a finite differentiable inequality system. In both subsections we will focus only on feasible sequences. From Theorems 3.2 and 4.3 we see that by postulating some uniform continuity assumptions on θ or $\nabla\theta$ near a given (infeasible) sequence, results that are derived for the projected (feasible) sequence will easily yield corresponding results for the given (infeasible) sequence.

5.1. Approximate complementarity conditions. Consider the problem (1) where X is a closed convex cone. In this case it follows that if x is a local minimum of (1), then the following complementarity system holds:

$$X \ni x \perp \nabla\theta(x) \in X^*, \tag{10}$$

where $u \perp v$ means $u^T v = 0$ and

$$X^* \equiv \{y \in \Re^n : y^T v \geq 0 \text{ for all } v \in X\}$$

is the dual cone of X. Conversely, if θ is convex, then every vector x satisfying (10) is a global minimum of (1). The goal in this subsection is to study the case where instead of a single vector x, we are given a sequence $\{x^k\} \subset X$ (possibly unbounded), and we want to characterize the LP minimizing property of this sequence in terms of some approximate complementarity conditions. The following theorem is the main result in this regard.

THEOREM 5.1. *Let X be a nonempty closed convex cone in $\Re^n$, and let $\theta : \Re^n \to \Re$ be a continuously differentiable function. Let $\{x^k\} \subset X$ be an arbitrary feasible sequence.*

(a) *Assume $\theta_{inf} > -\infty$. If $\{x^k\}$ is LP minimizing for* (1) *and $\nabla\theta$ is uniformly continuous near this sequence, then there exists a sequence $\{w^k\} \subset X^*$ such that*

$$\lim_{k\to\infty} (\nabla\theta(x^k) - w^k) = 0 \quad \textit{and} \quad \lim_{k\to\infty} (x^k)^T w^k = 0. \tag{11}$$

(b) *Conversely, if θ is convex,* (1) *is H-metrically regular, and there exists a sequence $\{w^k\} \subset X^*$ satisfying* (11) *, then $\{x^k\}$ is LP minimizing for* (1).

Proof. We first prove (a). By the proof of Proposition 3.1, we deduce the existence of two sequences of vectors $\{y^k\} \subset X$ and $\{w^k\} \subset \Re^n$ such that for each k, $y^k = \Pi_X(y^k - w^k)$, and

$$\lim_{k\to\infty} (w^k - \nabla\theta(y^k)) = 0, \quad \lim_{k\to\infty} (y^k - x^k) = 0, \quad \text{and} \quad \lim_{k\to\infty} \theta(y^k) = \theta_{\rm inf}. \tag{12}$$

Since X is a convex cone, we have

$$X \ni y^k \perp w^k \in X^*.$$

We have

$$\nabla\theta(x^k) - w^k = (\nabla\theta(x^k) - \nabla\theta(y^k)) + (\nabla\theta(y^k) - w^k),$$

which clearly approaches zero as $k \to \infty$, by the uniform continuity of $\nabla\theta$ near $\{x^k\}$. It remains to show $\lim_{k\to\infty}(x^k)^T w^k = 0$. We have

$$\begin{aligned}(x^k)^T w^k &= (x^k - y^k)^T w^k + (y^k)^T w^k \\ &= (x^k - y^k)^T (w^k - \nabla\theta(y^k)) \\ &\quad + (x^k - y^k)^T \nabla\theta(x^k) + (x^k - y^k)^T (\nabla\theta(y^k) - \nabla\theta(x^k)).\end{aligned}$$

In view of (12) and by the uniform continuity of $\nabla\theta$ near $\{x^k\}$, it suffices to show

$$\lim_{k\to\infty} (x^k - y^k)^T \nabla\theta(x^k) = 0. \tag{13}$$

We have

$$\theta(y^k) - \theta(x^k) = (y^k - x^k)^T \nabla\theta(x^k) + o(\|y^k - x^k\|),$$

where $o(t)$ is a quantity which approaches zero as $t \downarrow 0$. Since $\{y^k\}$ is also LP minimizing for (1), the limit of the left-hand side is equal to zero as $k \to \infty$; thus (13) follows. This establishes (a).

To prove (b), we follow the proof of Theorem 4.3 and assume for the sake of contradiction that there is a scalar λ satisfying $\liminf_{k\to\infty} \theta(x^k) > \lambda > \theta_{\inf}$. Let c and γ be the scalars in the error bound for the level set $L(\lambda)$, and let $y^k \in X$ be such that $\theta(y^k) = \lambda$ and $\operatorname{dist}(x^k, L(\lambda)) = \|x^k - y^k\|$. As in previous arguments, we have

$$\theta(x^k) - \lambda \leq -\nabla\theta(x^k)^T (y^k - x^k).$$

The right-hand side is equal to

$$\begin{aligned}\nabla\theta(x^k)^T (x^k - y^k) &= (w^k)^T (x^k - y^k) + (\nabla\theta(x^k) - w^k)^T (x^k - y^k) \\ &\leq |(w^k)^T x^k| + \|\nabla\theta(x^k) - w^k\| \, \|y^k - x^k\|,\end{aligned}$$

where the inequality holds because $(w^k)^T y^k = 0$. Thus we deduce

$$1 \leq c \, \| \nabla\theta(x^k) - w^k \| \, \max\left(1, (\theta(x^k) - \lambda)^{\gamma - 1}\right) + \frac{|\,(w^k)^T x^k\,|}{\theta(x^k) - \lambda},$$

which again is a contradiction upon passing to the limit $k \to \infty$. □

It is natural to ask how the approximate complementarity system, (11) plus $\{w^k\} \subset X^*$, is related the limiting residual condition, $\lim_{k\to\infty} R_N(x^k) = 0$, used in the last sections; in particular, whether they are equivalent for an arbitrary feasible sequence $\{x^k\}$. Our preliminary analysis suggests a negative answer. Since this issue is not of primary importance in the remainder of the paper, we will not pursue it further.

The conditions $\{w^k\} \subset X^*$ and $\lim_{k\to\infty}(\nabla\theta(x^k) - w^k) = 0$ imply

$$\lim_{k\to\infty} \operatorname{dist}(\nabla\theta(x^k), X^*) = 0.$$

Nevertheless the vector w^k is not necessarily the closest point in X^* to the vector $\nabla\theta(x^k)$, as illustrated in the example below.

Example 5. Consider the convex program in 4 variables:

$$\begin{array}{ll} \text{minimize} & \theta(x) \equiv (x_{12}-1)^2 + (x_{21}-1)^2 + 1.5\,x_{22}^2 \\ \text{subject to} & x \equiv \begin{pmatrix} x_{11} & x_{12} \\ x_{21} & x_{22} \end{pmatrix} \text{ is symmetric positive semidefinite.} \end{array}$$

Thus the constraint set is the cone of 2×2 symmetric positive semidefinite matrices. It is easy to check that

$$x^\varepsilon \equiv \begin{pmatrix} 1/\varepsilon^2 & \varepsilon+1 \\ \varepsilon+1 & \varepsilon \end{pmatrix}, \quad \varepsilon \downarrow 0,$$

constitutes an LP minimizing sequence and $\theta_{\inf} = 0$; moreover this optimal objective value is not attained. We have

$$\nabla\theta(x^\varepsilon) \equiv \varepsilon \begin{pmatrix} 0 & 2 \\ 2 & 3 \end{pmatrix},$$

which is not positive semidefinite. With

$$w^\varepsilon \equiv \begin{pmatrix} \varepsilon^3 & 0 \\ 0 & 3\varepsilon \end{pmatrix},$$

we can easily verify that the sequence $\{w^\varepsilon\}$ satisfies the conditions in Theorem 5.1. However the Frobenius projection of the matrix $\nabla\theta(x^\varepsilon)$ onto the cone of 2×2 symmetric positive semidefinite matrices can be calculated to be

$$\frac{4\varepsilon}{5} \begin{pmatrix} 1 & 2 \\ 2 & 4 \end{pmatrix},$$

which is not equal to w^ε; moreover the above matrix is not asymptotically perpendicular to x^ε as $\varepsilon \downarrow 0$.

5.2. Approximate KKT conditions. Consider the nonlinear program

$$\begin{array}{ll} \text{minimize} & \theta(x) \\ \text{subject to} & G(x) \leq 0, \end{array} \tag{14}$$

where $\theta : \Re^n \to \Re$ and $G : \Re^n \to \Re^m$ are continuously differentiable functions. We assume that each G_i is convex and that a Slater point exists for the constraints, i.e., there exists a vector $\hat{x} \in \Re^n$ satisfying $G_i(\hat{x}) < 0$ for all i. In this setting it follows that if x is a local minimum of (14), then there exist multipliers μ_i, $i = 1, \ldots, m$, such that the following KKT conditions hold:

$$\begin{aligned} \mathcal{L}(x,\mu) \equiv \nabla\theta(x) + \sum_{i=1}^m \mu_i \nabla G_i(x) = 0, \\ 0 \geq G(x) \perp \mu \geq 0; \end{aligned}$$

conversely if θ is also convex and (x, μ) satisfies the latter KKT system, then x is a global minimum of (14). In what follows, we generalize these basic results in nonlinear

programming to the context of an LP minimizing sequence. For this purpose we recall an asymptotic constraint qualification (ACQ) stated in Luo and Luo [22] that is essentially due to Mangasarian [25]:
(ACQ) The scalar

$$\sup_{x,\mu,I}\left\{\|\mu_I\| \,:\, G(x) \le 0,\, \mu_I > 0,\, G_I(x) = 0,\, \left\|\sum_{i\in I}\mu_i\,\nabla G_i(x)\right\| = 1,\right.$$
$$\left.\nabla G_i(x) \text{ linearly independent},\, i \in I \subseteq \{1,\ldots,m\}\right\}$$

is finite.

THEOREM 5.2. *Let $\theta : \Re^n \to \Re$ and $G : \Re^n \to \Re^m$ be continuously differentiable functions. Assume that each G_i is convex and a Slater point exists. Let $\{x^k\}$ be an arbitrary sequence of feasible vectors to* (14).

(a) *Assume $\theta_{inf} > -\infty$ and ACQ holds. If $\{x^k\}$ is LP minimizing for* (14)*, $\nabla\theta$ and each ∇G_i are uniformly continuous near $\{x^k\}$, and $\{\nabla\theta(x^k)\}$ is bounded, then there exists a sequence of bounded vectors $\{\mu^k\} \subset \Re^m_+$ such that*

$$\lim_{k\to\infty} v^k = 0 \quad \textit{and} \quad \lim_{k\to\infty} (\mu^k)^T G(x^k) = 0, \tag{15}$$

where $v^k \equiv \mathcal{L}(x^k, \mu^k)$.

(b) *Conversely if θ is convex,* (1) *is H-metrically regular, and there exists a sequence of bounded vectors $\{\mu^k\} \subset \Re^m_+$ such that* (15) *holds, then $\{x^k\}$ is LP minimizing for* (14).

Proof. Let X denote the feasible set of (14). We first prove (a). Similar to the proof of Theorem 5.1, we deduce the existence of two sequences of vectors $\{y^k\} \subset X$ and $\{w^k\} \subset \Re^n$ such that for each k, $y^k = \Pi_X(y^k - w^k)$ and (12) holds. In particular, y^k is an optimal solution of the following minimization problem:

$$\begin{aligned} \text{minimize} \quad & \tfrac{1}{2}\,\|\, y - (\, y^k - w^k\,)\,\|^2 \\ \text{subject to} \quad & y \in X. \end{aligned}$$

Since a Slater point exists for X, it follows that for each k there exists multipliers $\{\mu^k\} \subset \Re^m$ such that

$$w^k + \sum_{i=1}^m \mu_i^k \nabla G_i(y^k) = 0,$$
$$0 \ge G(y^k) \perp \mu^k \ge 0.$$

By ACQ, it follows that for some constant $c > 0$, each multiplier μ^k can be chosen to satisfy

$$\|\mu^k\| \le c\,\|\, w^k\,\|.$$

Since $\{\nabla\theta(x^k)\}$ is bounded and $\{\nabla\theta(x^k) - w^k\}$ converges to zero (see the proof of Theorem 5.1), it follows that $\{w^k\}$ is bounded; thus so is $\{\mu^k\}$. We have

$$v^k = \nabla\theta(x^k) - w^k + \sum_{i=1}^m \mu_i^k\,(\nabla G_i(x^k) - \nabla G_i(y^k)),$$

which easily implies $\lim_{k\to\infty} v^k = 0$.

To complete the proof of (i), it remains to show $\lim_{k\to\infty}(\mu^k)^T G(x^k) = 0$. We have

$$0 \geq (\mu^k)^T G(x^k) \geq (\mu^k)^T G(y^k) + \sum_{i=1}^{m} \mu_i^k \nabla G_i(y^k)^T (x^k - y^k) = (w^k)^T (y^k - x^k).$$

Since the last term tends to zero as k tends to infinity, the proof of (a) is completed.

The proof of (b) is by contradiction. Since this is very similar to the proofs of Theorem 4.3 and part (b) of Theorem 5.1, we omit the details. □

We conclude this section by giving two results that combine all the essential concepts presented in the paper. The first result pertains to the CQQSP (9) where θ is a convex quadratic spline; the other result is for the convex program (14) with Hölderian sharp minima.

THEOREM 5.3. *Assume that the CQQSP* (9) *has a strictly feasible solution and that the objective function $\theta(x)$ is bounded below on the feasible set X. Then θ_{inf} is finite and attained. Moreover for an arbitrary feasible sequence $\{x^k\} \subset X$, the following statements are equivalent:*

(a) *$\{x^k\}$ is LP minimizing for the CQQSP* (9)*;*

(b) *there exists a sequence of bounded multipliers $\{\mu^k\} \subset \Re^m_+$ such that* (15) *holds, where $v^k \equiv \mathcal{L}(x^k, \mu^k)$;*

(c) *$\{x^k\}$ is near the optimal set of the CQQSP;*

(d) *$\{\nabla\theta(x^k)\}$ is bounded and $\{x^k\}$ is N-stationary for the CQQSP.*

Proof. Let $\{P_i : i = 1, \ldots, p\}$ be the family of convex polyhedra whose union is equal to $\Re^n$, and let $\{q_i(x) : i = 1, \ldots, p\}$ be the corresponding family of convex quadratic pieces of θ. By the theory of ℓ_p-programming [34], it follows that for each i for which $X \cap P_i$ is nonempty, the CQQP below attains its finite optimal objective value:

$$\begin{aligned} &\text{minimize} && q_i(x) \\ &\text{subject to} && x \in X \cap P_i. \end{aligned}$$

The smallest of these p optimal objective values is clearly equal to θ_{inf}; moreover X_{opt} is obviously nonempty. By Lemma 4.2, the CQQSP has Hölderian minima and H-metrically regular level sets.

(a) ⇒ (c). This follows easily because $\{x^k\}$ is assumed feasible and the CQQSP has Hölderian minima.

(c) ⇒ (a). Assume (c). By Proposition 4.9, the sequence $\{\nabla\theta(x^k)\}$ is bounded. Since $\nabla\theta$ is uniformly continuous near $\{x^k\}$, it follows that θ is uniformly continuous near $\{x^k\}$. Hence (a) follows by Proposition 4.7.

(a) ⇒ (b). Assume (a). By Lemma 3.5 in [22], (ACQ) holds for the feasible set X. By the equivalence of (a) and (c) and the above argument, the sequence $\{\nabla\theta(x^k)\}$ is bounded. Hence (b) follows from Theorem 5.2.

(b) ⇒ (a). This follows easily from Theorem 5.2.

(d) ⇔ (a). This is the content of Corollary 4.5. □

THEOREM 5.4. *Let $\theta : \Re^n \to \Re$ and $G : \Re^n \to \Re^m$ be continuously differentiable functions. Assume that θ and each G_i are convex, a Slater point exists for the feasible set*

$$X \equiv \{\, x \in \Re^n : G(x) \leq 0 \,\},$$

the ACQ holds for X, and the problem (14) *has Hölderian minima. Let $\{x^k\}$ be an arbitrary sequence of feasible vectors to* (14). *Suppose that $\nabla\theta$ and each ∇G_i are uniformly continuous near $\{x^k\}$. The following statements are equivalent:*

(a) *$\{x^k\}$ is LP minimizing for the program* (14);
(b) *there exists a sequence of bounded multipliers $\{\mu^k\} \subset \Re^m_+$ such that* (15) *holds, where $v^k \equiv \mathcal{L}(x^k, \mu^k)$;*
(c) *$\{x^k\}$ is near X_{opt};*
(d) *$\{\nabla\theta(x^k)\}$ is bounded and $\{x^k\}$ is N-stationary.*

Proof. This follows from the same argument as in the previous theorem, except that Proposition 4.10 is used in place of Lemma 4.2. □

Remark. When X is an arbitrary closed convex set, statements (a), (c), and (d) of Theorem 5.4 remain equivalent without the Slater assumption and the ACQ.

6. Convergence of an iterative algorithm. In this last section, we consider a family of iterative methods for solving the constrained minimization problem (1). Our goal is to show that the H-metric regularity assumption that has played such an important role in the study of LP minimizing sequences is key to the convergence of these methods.

Consider the minimization problem (1) where θ is continuously differentiable and X is closed and convex. We present below an iterative descent method for solving this problem. The method generates a sequence of feasible vectors $\{x^k\} \subset X$ with decreasing objective function values $\{\theta(x^k)\}$. The generation of each iterate x^{k+1} is by solving a convex subprogram with a quadratic objective function which yields a feasible descent direction d^k for (1) at x^k, followed by an Armijo line search on θ starting at x^k and moving along d^k. Since the convergence analysis does not require X to be a polyhedron, we do not make this polyhedral assumption on X; thus the direction subprogram is not necessarily a quadratic program. In practice, this algorithm is perhaps restricted to a linearly constrained nonlinear program in order for the subprograms to be solved effectively.

A descent algorithm.

Step 0 (initialization). Let $\rho, \sigma \in (0,1)$ be given scalars. Let $\delta > 0$ be an arbitrary constant. Let $x^0 \in X$ be a given vector, and let B_0 be a symmetric positive semidefinite matrix. Set $k = 0$.

Step 1 (direction generation). Solve the convex program in the variable $d \in \Re^n$:

$$\begin{array}{lll} & \text{minimize} & \nabla\theta(x^k)^T d + \frac{1}{2}\, d^T B_k d \\ (16) & \text{subject to} & x^k + d \in X \\ & \text{and} & \| d \| \leq \delta. \end{array}$$

Let d^k be an arbitrary globally optimal solution, which must exist and satisfy $\nabla\theta(x^k)^T d^k \leq 0$.

If $\nabla\theta(x^k)^T d^k = 0$, stop because x^k is a stationary point of (1); thus x^k is a globally optimal solution if θ is convex. If $\nabla\theta(x^k)^T d^k < 0$, continue.

Step 2 (Armijo line search). Let m_k be the smallest nonnegative integer m such that

$$\theta(x^k + \rho^m d^k) - \theta(x^k) \leq \sigma\, \rho^m\, \nabla\theta(x^k)^T d^k.$$

Let $\tau_k \equiv \rho^{m_k}$ and set $x^{k+1} \equiv x^k + \tau_k\, d^k$.

Step 3 (termination check). Test x^{k+1} to determine if it satisfies a prescribed stopping rule. If so, stop; x^{k+1} is a desired approximate solution of (1). Otherwise

choose a symmetric positive semidefinite matrix B_{k+1} and return to Step 1 with k replaced by $k+1$.

We make several remarks about the above algorithm. First, $d = 0$ is a feasible solution to the subprogram (16) because $x^k \in X$. Moreover a globally optimal solution to this subprogram must exist because it has a nonempty compact feasible region. Such an optimal solution is not necessarily unique because the matrix B_k is not assumed to be positive definite. In the algorithm the direction d^k can be any optimal solution of (16). The assertion about the iterate x^k in the case where $\nabla\theta(x^k)^T d^k = 0$ can easily be proved; see [30] for a proof, which we omit. The integer m_k is well defined; the justification is standard. Finally, each iterate x^{k+1} clearly belongs to X.

The following is the main convergence result for the above algorithm. In the theorem, the infimum value $\theta_{\inf}$ is not assumed to be finite; moreover the sequence $\{x^k\}$ is not assumed to be bounded.

THEOREM 6.1. *Let $\theta : \Re^n \to \Re$ be a continuously differentiable convex function, and let X be a closed convex subset of $\Re^n$. Let $\{B_k\}$ be a sequence of symmetric positive semidefinite matrices. Let $\{x^k\}$ be an infinite sequence of vectors generated by the iterative descent algorithm. Assume that*

(a) *$\{B_k\}$ is bounded;*

(b) *$\nabla\theta$ is uniformly continuous near $\{x^k\}$;*

(c) *for each $\lambda > \theta_{inf}$, there exist scalars $c > 0$ and $\gamma \in (0,1)$ such that for all k,*

$$dist(x^k, L(\lambda)) \;\le\; c \max\left((\theta(x^k) - \lambda)_+, [(\theta(x^k) - \lambda)_+]^\gamma \right).$$

Then $\lim_{k\to\infty} \theta(x^k) = \theta_{inf}$.

Before proving this theorem we make several remarks about the assumptions. The first remark concerns the sequence $\{B_k\}$. We assume that each matrix B_k is only semidefinite and not definite. This is a significant departure from many convergence results of this type which assume that there exist constants $\alpha > \beta > 0$ such that

$$\beta\, v^T v \;\le\; v^T B_k v \;\le\; \alpha\, v^T v \quad \forall k \text{ and } v;$$

see, e.g., the recent note [38]. Our assumption is equivalent to the existence of the positive upper bound α but allows the lower bound β to be zero. Wu and Wu [39], focusing on the case where each B_k is identically equal to zero, established the above theorem without conditions (b) and (c). In a private discussion, S. Wu told the authors that he was not able to generalize his result to nonzero matrices B_k. Condition (c) is of course the error bound assumption that is central to the issue of whether a stationary sequence is LP minimizing. (We remind the reader that this condition holds, for instance, in the case of the CQQSP and a convex program with Hölderian minima.) In the present context, this condition can easily be seen to be necessary for the conclusion of the theorem to hold. Thus, condition (c) is actually necessary for the claimed convergence of the sequence $\{\theta(x^k)\}$. We suspect that condition (b) is not essential to the theorem; however, the proof below makes use of this condition. Finally we note that simple examples can be constructed to show that the theorem is false without assumption (a).

Proof of Theorem 6.1. Clearly $\{\theta(x^k)\}$ is a decreasing sequence of real numbers. Thus the limit $\lim_{k\to\infty} \theta(x^k)$ exists and is not smaller than $\theta_{\inf}$. We may assume by way of contradiction that this limit is greater than $\theta_{\inf}$. Let λ be such that

$$\lim_{k\to\infty} \theta(x^k) \;>\; \lambda \;>\; \theta_{\inf}.$$

By assumption, it follows that, for all k, there exists a vector $\bar{x}^k \in L(\lambda)$ satisfying $\theta(\bar{x}^k) = \lambda$ and

$$\| x^k - \bar{x}^k \| \leq c \max\left((\theta(x^k) - \lambda), (\theta(x^k) - \lambda)^\gamma\right).$$

Thus the sequence $\{x^k - \bar{x}^k\}$ is bounded. Moreover, defining the scalar

$$\delta_k \equiv \begin{cases} 1 & \text{if } \| x^k - \bar{x}^k \| \leq 1, \\ \| x^k - \bar{x}^k \|^{-1} & \text{otherwise,} \end{cases}$$

we see that the vector $d \equiv \delta_k(\bar{x}^k - x^k)$ is feasible to the subprogram (16). Hence, by the variational principle for this problem, we obtain

$$[\, \delta_k\, (\bar{x}^k - x^k) - d^k\,]^T (\nabla\theta(x^k) + B_k d^k) \geq 0.$$

By the gradient inequality, we have, for each k,

$$\begin{aligned} \lambda - \theta(x^k) &= \theta(\bar{x}^k) - \theta(x^k) \geq (\bar{x}^k - x^k)^T \nabla\theta(x^k) \\ &\geq \delta_k^{-1}\, (d^k)^T (\nabla\theta(x^k) + B_k d^k) - (\bar{x}^k - x^k)^T B_k d^k. \end{aligned} \tag{17}$$

Since $\{x^k - \bar{x}^k\}$ is bounded, it follows that

$$0 < \inf_k \delta_k \leq \sup_k \delta_k \leq 1.$$

Thus $\{\delta_k^{-1}\}$ is bounded. For each k, we have

$$\nabla\theta(x^k)^T d^k + \frac{1}{2}(d^k)^T B_k d^k \leq 0 \tag{18}$$

and

$$\theta(x^{k+1}) - \theta(x^k) \leq \sigma\, \tau_k\, \nabla\theta(x^k)^T d^k \leq 0.$$

It follows that

$$\lim_{k\to\infty} \tau_k\, \nabla\theta(x^k)^T d^k = 0.$$

If $\inf_k \tau_k > 0$, then we deduce

$$\lim_{k\to\infty} \nabla\theta(x^k)^T d^k = 0. \tag{19}$$

Assume that $\inf_k \tau_k = 0$. Let $\{\tau_k : k \in \kappa\}$ be a subsequence of $\{\tau_k\}$ that converges to zero. Thus

$$\lim_{k(\in\kappa)\to\infty} m_k = \infty.$$

We claim that

$$\lim_{k(\in\kappa)\to\infty} \nabla\theta(x^k)^T d^k = 0. \tag{20}$$

Since $\{d^k\}$ is bounded and $\nabla\theta$ is uniformly continuous near $\{x^k\}$, it follows that

$$\lim_{k(\in\kappa)\to\infty} \frac{\theta(x^k + \rho^{m_k - 1} d^k) - \theta(x^k) - \rho^{m_k - 1}\, \nabla\theta(x^k)^T d^k}{\rho^{m_k - 1}} = 0.$$

By the definition of m_k, we have

$$\theta(x^k + \rho^{m_k-1} d^k) - \theta(x^k) > \sigma \rho^{m_k-1} \nabla\theta(x^k)^T d^k.$$

Using the fact that $\sigma \in (0,1)$, we easily deduce from the last two expressions that (20) must hold.

Consequently, we have shown that regardless of the infimum value of the sequence $\{\tau_k\}$, (20) must hold for an infinite set κ. Without loss of generality, we may assume that (19) holds. By (18), and the positive semidefiniteness of each B_k, it follows that the sequence of scalars $\{(d^k)^T B_k d^k\}$ converges to zero. Furthermore, since $\{B_k\}$ is bounded (which implies that the eigenvalues of B_k are bounded above), it can easily be shown, by diagonalizing each B_k, that the sequence of vectors $\{B_k d^k\}$ converges to the zero vector.

Since $\{x^k - \bar{x}^k\}$ and $\{\delta_k^{-1}\}$ are bounded, passing to the limit $k \to \infty$ in (17), we deduce that the left-hand side converges to a negative limit, whereas the right-hand side converges to zero. This is a contradiction. □

Acknowledgments. The authors are grateful to Dr. Asen Dontchev for pointing out the connection between the subject of this paper and the theory of well-posedness of constrained optimization problems and for bringing to their attention the references [8, 21]. We are also grateful to Professor Zhi-Quan Luo, who drew our attention to the reference [34]. We acknowledge some fruitful discussions with Dr. Shiquan Wu on the topic of section 6. Three referees of the paper have made many constructive and insightful comments on previous versions of the paper that have significantly contributed to the present revision. One of them supplied us the reference [15], which had prompted us to include the discussion relating Lemaire's work at our second revision. Finally the authors are indebted to Professor Wu Li at Old Dominion University for his contribution of Proposition 4.10, which has allowed us to establish Theorem 5.4 under the Hölderian minima assumption. (In a previous version of this paper, the theorem was established under the (more restrictive) assumption of weak sharp minima, and the proof used Lemma 4.1 instead.)

ON THE OPTIMALITY OF THE DISCRETE KARHUNEN–LOÈVE EXPANSION*

ARNE DÜR†

Abstract. A short proof of the optimality of the discrete Karhunen–Loève expansion as the best linear approximation in the quadratic mean is presented.

Key words. Karhunen–Loève expansion

AMS subject classifications. 93E24, 94A12

PII. S0363012997315750

Let $\mathbf{R}$ denote the field of real numbers, and view vectors in $\mathbf{R^n}$ as column vectors. For $x, y \in \mathbf{R^n}$, let $\langle x, y\rangle = \sum_{i=1}^{n} x_i y_i$ denote the scalar product, and let $\|x\| = \sqrt{\langle x, x\rangle}$ denote the Euclidean norm. Then the Karhunen–Loève expansion is defined as follows.

THEOREM 0.1. *Let $X = (X_1, \ldots, X_n)^T$ be a real-valued random-vector with finite second moments, and let m be a fixed natural number not greater than n.*

Let a and A denote the expectation vector or the covariance matrix of X, respectively, and let $\lambda_1 \geq \lambda_2 \geq \cdots \geq \lambda_n$ be the eigenvalues of A with corresponding orthonormal eigenvectors $w_1, \ldots, w_n$.

Then, for any vectors $v_0, v_1, \ldots, v_m$ and any linear functionals $\phi_1, \ldots, \phi_m : \mathbf{R^n} \to \mathbf{R}$, the expectation

$$E\left(\left\|X - \left(v_0 + \sum_{i=1}^{m} \phi_i(X-a)v_i\right)\right\|^2\right)$$

is minimal if $v_0 = a$, $v_i = w_i$, and $\phi_i(x) = \langle x, w_i\rangle$ for $i = 1, \ldots, m$. Hence,

$$Y := a + \sum_{i=1}^{m} \langle X - a, w_i\rangle w_i$$

is the best m-dimensional linear approximation to X in the quadratic mean and is called the Karhunen–Loève expansion of X of order m. The approximation error is

$$E(\|X - Y\|^2) = \lambda_{m+1} + \cdots + \lambda_n.$$

An application of the discrete Karhunen–Loève expansion to image processing can be found in [4, p. 382]. In this book this optimality property of the discrete Karhunen–Loève expansion is stated without proof. For the author, the proof given in [3] is unclear. In [1], the optimality of the Karhunen–Loève transform among all unitary transforms is proved by Lagrangian multipliers but neglecting the orthogonality constraints among the basis vectors. Therefore, the author suggests the following short proof. Another optimality property of the Karhunen–Loève expansion is discussed in [2].

Proof. For $i = 1, \ldots, m$, write $\phi_i(x) = F_i x$ with row vector F_i. Then $G := \sum_{i=1}^m v_i F_i$ is a quadratic matrix of rank $\leq m$. Let $H := I - G$, where I is the identity matrix, and let $Z := X - a$ be the centralized random vector. Then

$$X - \left(v_0 + \sum_{i=1}^m \phi_i(X-a) v_i \right) = \left(I - \sum_{i=1}^m v_i F_i \right) Z - (v_0 - a) = HZ - (v_0 - a)$$

and, since $E(Z) = 0$,

$$E\left(\left\| X - \left(v_0 + \sum_{i=1}^m \phi_i(X-a) v_i \right) \right\|^2 \right) = E(\|HZ\|^2) + \|v_0 - a\|^2.$$

As $E(\|HZ\|^2)$ does not depend on v_0, the optimal choice for v_0 is $v_0 = a$. Moreover

$$E(\|HZ\|^2) = \sum_{i,j=1}^n E(Z_i Z_j)(H^T H)_{ji} = tr(AH^T H).$$

If $v_i = w_i$ and $\phi_i(x) = \langle x, w_i \rangle = w_i^T x$ for $i = 1, \ldots, m$, then

$$H = I - \sum_{i=1}^m w_i w_i^T = \sum_{i=m+1}^n w_i w_i^T$$

is the orthogonal projection onto the subspace spanned by $w_{m+1}, \ldots, w_n$; thus $H^T H = H$ and

$$\mathrm{tr}(AH^T H) = \sum_{i=m+1}^n \mathrm{tr}(A w_i w_i^T) = \sum_{i=m+1}^n \lambda_i \mathrm{tr}(w_i w_i^T) = \sum_{i=m+1}^n \lambda_i.$$

For general v_i and ϕ_i, we invoke Theorem 1 of [6] or [5] to obtain

$$\mathrm{tr}(AH^T H) \geq \sum_{i=1}^n \lambda_i \mu_{n+1-i},$$

where $\mu_1 \geq \mu_2 \geq \cdots \geq \mu_n$ denote the eigenvalues of $H^T H$. We end the proof by showing that

$$\mu_1 \geq \cdots \geq \mu_{n-m} \geq 1,$$

which implies

$$\sum_{i=1}^n \lambda_i \mu_{n+1-i} \geq \sum_{i=m+1}^n \lambda_i.$$

Let U be the nullspace of the matrix G. As G has rank $k \leq m$, U has dimension $n - k \geq n - m$. But for all nonzero unit vectors $u \in U$ we have $Hu = (I - G)u = u$, and hence $\|Hu\|^2 = 1$. Now the Courant–Fischer minimax theorem [7, p. 100] implies that $\mu_{n-k} \geq 1$, and hence $\mu_{n-m} \geq 1$. □

INTEGRAL CONTROL OF INFINITE-DIMENSIONAL LINEAR SYSTEMS SUBJECT TO INPUT SATURATION*

H. LOGEMANN†, E. P. RYAN†, AND S. TOWNLEY‡

Abstract. Closing the loop around an exponentially stable single-input single-output regular linear system, subject to a globally Lipschitz and nondecreasing actuator nonlinearity and compensated by an integral controller, is shown to ensure asymptotic tracking of constant reference signals, provided that (a) the steady-state gain of the linear part of the plant is positive, (b) the positive integrator gain is sufficiently small, and (c) the reference value is feasible in a very natural sense. The class of actuator nonlinearities under consideration contains standard nonlinearities important in control engineering such as saturation and deadzone.

Key words. regular infinite-dimensional systems, integral control, actuator nonlinearities, input saturation, robust tracking, operator Riccati equations

1. Introduction.

The synthesis of low-gain integral (I) and proportional-plus-integral (PI) controllers for uncertain stable plants has received considerable attention in the last 20 years. The following principle is well known (see Davison [5], Lunze [20], and Morari [24]): closing the loop around a stable, finite-dimensional, continuous-time, single-input, single-output plant with transfer function $\mathbf{G}(s)$, compensated by a pure integral controller k/s (see Fig. 1.1), will result in a stable closed-loop system which achieves asymptotic tracking of arbitrary constant reference signals, provided that $|k|$ is sufficiently small and $k\mathbf{G}(0) > 0$. Therefore, if a plant is known to be stable and if the sign of $\mathbf{G}(0)$ is known (this information can be obtained from plant step response data), then the problem of tracking by low-gain integral control reduces to that of tuning the gain parameter k. Such a controller design approach ("tuning regulator theory" [5]) has been successfully applied in process control; see, for example, Coppus, Sha, and Wood [3] and Lunze [19].

An analogous result holds for finite-dimensional multivariable systems under suitable assumptions on $\mathbf{G}(0)$; see [5, 20] and [24]. Moreover, the result has been extended by Logemann, Bontsema, and Owens [13], Logemann and Owens [14], Logemann and Townley [17], Pohjolainen [27, 28], and Pohjolainen and Lätti [29] to various classes of (abstract) infinite-dimensional systems and by Jussila and Koivo [9] and Koivo and Pohjolainen [11] to differential delay systems. Furthermore, the problem of tuning the integrator gain adaptively has been addressed recently in a number of papers; see Cook [2] and Miller and Davison [22, 23] for the finite-dimensional case and Logemann and Townley [16, 17, 18] for the infinite-dimensional case.

In this paper we present results which show that the above principle remains true if the plant to be controlled is a single-input, single-output, infinite-dimensional, linear

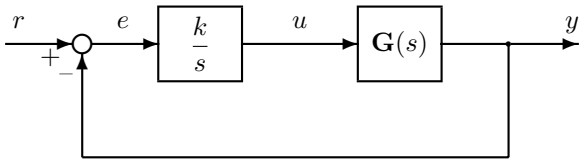

FIG. 1.1. *Low-gain control system.*

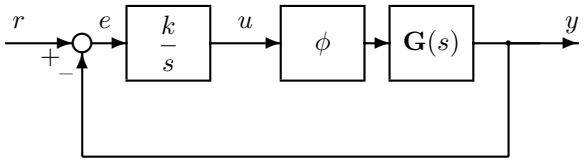

FIG. 1.2. *Low-gain control with input nonlinearity.*

system subject to an input nonlinearity (see Fig. 1.2). More precisely, we prove that, for an exponentially stable system with $\mathbf{G}(0) > 0$, there exists a number $K > 0$ such that, for all nondecreasing globally Lipschitz nonlinearities ϕ with Lipschitz constant λ and all $k \in (0, K/\lambda)$, the output $y(t)$ of the closed-loop system shown in Fig. 1.2 converges to r as $t \to \infty$, provided that $[\mathbf{G}(0)]^{-1} r \in \operatorname{clos}(\operatorname{im} \phi)$. The number K is the supremum of the set of all numbers $k > 0$ such that the function

$$1 + k\mathrm{Re}\,\frac{\mathbf{G}(s)}{s}$$

is positive real. The essence of our approach is to invoke a particular coordinate transformation and perform a Liapunov-type analysis on the transformed system. A parametrized operator Riccati equation plays a central role in the latter analysis, which further develops an idea presented in Townley and Kamstra [34].

The linear, infinite-dimensional part of the plant in Fig. 1.2 is assumed to be regular. The class of regular linear infinite-dimensional systems, introduced by Weiss [35, 36, 37, 38, 39], is rather general. It includes most distributed parameter systems and all time-delay systems (retarded and neutral) which are of interest in applications. Although there exist well-posed abstract infinite-dimensional systems which are not regular, the authors are of the opinion that any physically motivated, *well-posed*, linear, time-invariant control system is regular. We emphasize that our assumptions on the actuator nonlinearity allow for standard nonlinearities occurring in control engineering such as saturation and deadzone.

To our knowledge some of the results in this paper are new even for the finite-dimensional case. While Desoer and Lin [6] consider the low-gain tracking problem for a class of nonlinear finite-dimensional systems, their framework does not include input saturation.

The paper is organized as follows. Definitions and fundamental facts pertaining to regular systems are assembled in section 2. Section 3 contains the main result of the paper as outlined above. Examples and simulations illustrating our results are given in section 4. The proofs of three technical lemmas are given in the appendix.

Notation.

- For $\alpha \in \mathbb{R}$, set $\mathbb{C}_\alpha := \{s \in \mathbb{C} \,|\, \mathrm{Re}s > \alpha\}$.

- For $\alpha \in \mathbb{R}$ and H a Hilbert space, we define the exponentially weighted L^2-space $L^2_\alpha(\mathbb{R}_+, H) := \{f \in L^2_{loc}(\mathbb{R}_+, H) \,|\, f(\cdot)\exp(-\alpha\,\cdot) \in L^2(\mathbb{R}_+, H)\}$.
- If A is a linear operator, then the domain, spectrum, and resolvent set of A are denoted by $\mathrm{dom}\,(A)$, $\sigma(A)$, and $\varrho(A)$, respectively.
- The set of all linear bounded operators from H_1 to H_2 (where H_1, H_2 are Hilbert spaces) is denoted by $\mathcal{B}(H_1, H_2)$. We write $\mathcal{B}(H)$ for $\mathcal{B}(H, H)$.
- The Laplace transform is denoted by $\mathfrak{L}$.

2. Preliminaries on regular systems. In this section we give some background on well-posed linear systems; the reader is referred to Weiss [35, 36, 37, 38, 39] for full details.

First, we introduce some further notation. For any Hilbert space H and any $\tau \geq 0$, $\mathbf{R}_\tau$ denotes the right shift by τ on $L^2_{loc}(\mathbb{R}_+, H)$. The truncation operator $\mathbf{P}_\tau : L^2_{loc}(\mathbb{R}_+, H) \to L^2(\mathbb{R}_+, H)$ is given by

$$(\mathbf{P}_\tau u)(t) = \begin{cases} u(t) & \text{if} \quad t \in [0, \tau], \\ 0 & \text{if} \quad t > \tau. \end{cases}$$

For $u, v \in L^2_{loc}(\mathbb{R}_+, H)$ and $\tau \geq 0$, the *τ-concatenation* $u \overset{\tau}{\diamondsuit} v$ is defined by

$$u \overset{\tau}{\diamondsuit} v = \mathbf{P}_\tau u + \mathbf{R}_\tau v\,.$$

The fundamental concept of a well-posed linear system was introduced by Weiss [39]; an equivalent definition can be found in Salamon [33].

DEFINITION 2.1. *Let U, X, and Y be real Hilbert spaces. A* well-posed *linear system with* state-space X, input-space U, *and* output-space Y *is a quadruple* $\mathbf{\Sigma} = (\mathbf{T}, \mathbf{\Phi}, \mathbf{\Psi}, \mathbf{F})$, *where*

(1) $\mathbf{T} = (\mathbf{T}_t)_{t\geq 0}$ *is a C_0-semigroup of bounded linear operators on X,*

(2) $\mathbf{\Phi} = (\mathbf{\Phi}_t)_{t\geq 0}$ *is a family of bounded linear operators from $L^2(\mathbb{R}_+, U)$ to X such that*

$$\mathbf{\Phi}_{\tau+t}(u \overset{\tau}{\diamondsuit} v) = \mathbf{T}_t\mathbf{\Phi}_\tau u + \mathbf{\Phi}_t v$$

for all $u, v \in L^2(\mathbb{R}_+, U)$, and all $\tau, t \geq 0$,

(3) $\mathbf{\Psi} = (\mathbf{\Psi}_t)_{t\geq 0}$ *is a family of bounded linear operators from X to $L^2(\mathbb{R}_+, Y)$ such that*

$$\mathbf{\Psi}_{\tau+t}x_0 = \mathbf{\Psi}_\tau x_0 \overset{\tau}{\diamondsuit} \mathbf{\Psi}_t\mathbf{T}_\tau x_0$$

for all $x_0 \in X$ and all $\tau, t \geq 0$, and $\mathbf{\Psi}_0 = 0$,

(4) $\mathbf{F} = (\mathbf{F}_t)_{t\geq 0}$ *is a family of bounded linear operators from $L^2(\mathbb{R}_+, U)$ to $L^2(\mathbb{R}_+, Y)$ such that*

$$\mathbf{F}_{\tau+t}(u \overset{\tau}{\diamondsuit} v) = \mathbf{F}_\tau u \overset{\tau}{\diamondsuit} (\mathbf{\Psi}_t\mathbf{\Phi}_\tau u + \mathbf{F}_t v)\,,$$

$u, v \in L^2(\mathbb{R}_+, U)$ and all $\tau, t \geq 0$, and $\mathbf{F}_0 = 0$.

Let an input $u \in L^2_{loc}(\mathbb{R}_+, U)$ and an initial state $x_0 \in X$ be given. The state $x(t) = x(t; x_0, u)$ of $\mathbf{\Sigma}$ at time $t \geq 0$ and the output $y(\cdot) = y(\cdot\,; x_0, u)$ of $\mathbf{\Sigma}$ are defined by

$$x(t) = \mathbf{T}_t x_0 + \mathbf{\Phi}_t\mathbf{P}_t u\,, \tag{2.1}$$

$$\mathbf{P}_t y = \mathbf{\Psi}_t x_0 + \mathbf{F}_t\mathbf{P}_t u\,. \tag{2.2}$$

The state trajectory $x(\cdot)$ is a continuous function from $\mathbb{R}_+$ to X, and the output $y(\cdot)$ is in $L^2_{loc}(\mathbb{R}_+, Y)$.

We say that $\mathbf{\Sigma}$ is *exponentially stable* if the semigroup $\mathbf{T}$ is exponentially stable, i.e.,

$$\omega(\mathbf{T}) := \lim_{t\to\infty} \frac{1}{t} \log \|\mathbf{T}_t\| < 0\,.$$

If $\mathbf{\Sigma}$ is exponentially stable, then the operators $\mathbf{\Phi}_t$ and $\mathbf{\Psi}_t$ are uniformly bounded. It is clear that there exist unique operators $\mathbf{\Psi}_\infty : X \to L^2_{loc}(\mathbb{R}_+, Y)$ and $\mathbf{F}_\infty : L^2_{loc}(\mathbb{R}_+, U) \to L^2_{loc}(\mathbb{R}_+, Y)$ such that, for all $\tau \geq 0$,

$$\mathbf{\Psi}_\tau = \mathbf{P}_\tau \mathbf{\Psi}_\infty\,, \quad \mathbf{F}_\tau = \mathbf{P}_\tau \mathbf{F}_\infty\,.$$

It follows easily that $\mathbf{P}_\tau \mathbf{F}_\infty = \mathbf{P}_\tau \mathbf{F}_\infty \mathbf{P}_\tau$ for all $\tau \geq 0$, i.e., $\mathbf{F}_\infty$ is a *causal* operator. Moreover, if $\mathbf{\Sigma}$ is exponentially stable, then $\mathbf{\Psi}_\infty$ is a bounded operator from X into $L^2(\mathbb{R}_+, Y)$ and $\mathbf{F}_\infty$ maps $L^2(\mathbb{R}_+, U)$ boundedly into $L^2(\mathbb{R}_+, Y)$.

The generator of $\mathbf{T}$ is denoted by A. Let X_1 be the space $\mathrm{dom}\,(A)$ endowed with the graph norm. The norm on X is denoted by $\|\cdot\|$, while $\|\cdot\|_1$ denotes the graph norm. Let X_{-1} be the completion of X with respect to the norm $\|x\|_{-1} = \|(sI - A)^{-1}x\|$, where $s \in \varrho(A)$ is fixed. We have $X_1 \subset X \subset X_{-1}$, and the canonical injections are bounded and dense. The semigroup $\mathbf{T}$ can be restricted to a C_0-semigroup on X_1 and extended to a C_0-semigroup on X_{-1}. The exponential growth constant is the same on all three spaces. The generator on X_{-1} is an extension of A to X (which is bounded as an operator from X to X_{-1}). We shall use the same symbol $\mathbf{T}$ (respectively, A) for the original semigroup (respectively, its generator) and the associated restrictions and extensions. With this convention, we may write $A \in \mathcal{B}(X, X_{-1})$. Considered as a generator on X_{-1}, the domain of A is X.

By a representation theorem due to Salamon [33] (see also Weiss [37, 38]) there exist unique operators $B \in \mathcal{B}(U, X_{-1})$ and $C \in \mathcal{B}(X_1, Y)$ (the *control operator* and the *observation operator* of $\mathbf{\Sigma}$, respectively) such that, for all $t \geq 0$, $u \in L^2_{loc}(\mathbb{R}_+, U)$, and $x_0 \in X_1$,

$$\mathbf{\Phi}_t \mathbf{P}_t u = \int_0^t \mathbf{T}_{t-\tau} B u(\tau)\, d\tau \quad \text{and} \quad (\mathbf{\Psi}_\infty x_0)(t) = C\mathbf{T}_t x_0\ .$$

B is called *bounded* if $B \in \mathcal{B}(U, X)$ (and *unbounded* otherwise), whereas C is called *bounded* if it can be extended continuously to X (and *unbounded* otherwise). If $\mathbf{T}$ is exponentially stable, then there exist constants $\alpha, \beta > 0$ such that, for all $t \geq 0$, $u \in L^2(\mathbb{R}_+, U)$, and $x_0 \in X_1$,

$$\|\mathbf{\Phi}_t \mathbf{P}_t u\| = \left\| \int_0^t \mathbf{T}_{t-\tau} B u(\tau)\, d\tau \right\| \leq \alpha \|u\|_{L^2(0,t;\,U)}\,, \tag{2.3}$$

$$\|(\mathbf{\Psi}_\infty x_0)(\cdot)\|_{L^2(0,t;\,Y)} = \left(\int_0^t \|C\mathbf{T}_\tau x_0\|^2\, d\tau \right)^{1/2} \leq \beta \|x_0\|\,. \tag{2.4}$$

As in [38], the *Lebesgue extension* of C is defined by

$$C_L x_0 = \lim_{t\to 0} C \frac{1}{t} \int_0^t \mathbf{T}_\tau x_0\, d\tau\,,$$

where $\operatorname{dom}(C_L)$ is the set of all those $x_0 \in X$ for which the above limit exists. Clearly $X_1 \subset \operatorname{dom}(C_L) \subset X$ and, for any $x_0 \in X$, we have $\mathbf{T}_t x_0 \in \operatorname{dom}(C_L)$ for almost every (a.e.) $t \geq 0$. Furthermore,

$$(\mathbf{\Psi}_\infty x_0)(t) = C_L \mathbf{T}_t x_0 \quad \text{for a.e. } t \geq 0\,.$$

It can be shown (see Weiss [36, 38]) that, if $\alpha > \omega(\mathbf{T})$, $x_0 \in X$, and $u \in L^2_\alpha(\mathbb{R}_+, U)$, then $\mathbf{\Psi}_\infty x_0 \in L^2_\alpha(\mathbb{R}_+, Y)$, $\mathbf{F}_\infty u \in L^2_\alpha(\mathbb{R}_+, Y)$, and there exists a unique holomorphic $\mathbf{G} : \mathbb{C}_{\omega(\mathbf{T})} \to \mathcal{B}(U, Y)$ such that, for all $s \in \mathbb{C}_\alpha$,

$$\mathbf{G}(s)(\mathfrak{L}u)(s) = [\mathfrak{L}(\mathbf{F}_\infty u)](s)\,.$$

In particular, $\mathbf{G}$ is bounded on $\mathbb{C}_\alpha$ for all $\alpha > \omega(\mathbf{T})$. The function $\mathbf{G}$ is called the *transfer function* of $\mathbf{\Sigma}$.

$\mathbf{\Sigma}$ and its transfer function $\mathbf{G}$ are said to be *regular* if, for any $u \in U$, the limit

$$\lim_{s \to \infty,\, s \in \mathbb{R}} \mathbf{G}(s)u = Du$$

exists. It follows, from the principle of uniform boundedness, that $D \in \mathcal{B}(U, Y)$. The operator D is called the *feedthrough operator* of $\mathbf{\Sigma}$. If $\mathbf{\Sigma}$ is regular, then for any $x_0 \in X$ and $u \in L^2_{loc}(\mathbb{R}_+, U)$ the functions $x(\cdot)$ and $y(\cdot)$, defined by (2.1) and (2.2), satisfy the equations

$$\dot{x}(t) = Ax(t) + Bu(t)\,, \quad x(0) = x_0\,, \tag{2.5}$$

$$y(t) = C_L x(t) + Du(t) \tag{2.6}$$

for a.e. $t \geq 0$ (in particular $x(t) \in \operatorname{dom}(C_L)$ for a.e. $t \geq 0$). The derivative on the left-hand side of (2.5) has to be understood in X_{-1}. In other words, if we consider the initial value problem (2.5) in the space X_{-1}, then for any $x_0 \in X$ and $u \in L^2_{loc}(\mathbb{R}_+, U)$ the classical solution of (2.5) is given by the variation of parameters formula

$$x(t) = \mathbf{T}_t x_0 + \int_0^t \mathbf{T}_{t-\tau} B u(\tau)\, d\tau\,.$$

It has been demonstrated in [36] that if $\mathbf{\Sigma}$ is regular, then $(sI - A)^{-1}BU \subset \operatorname{dom}(C_L)$ for all $s \in \varrho(A)$ and the transfer function $\mathbf{G}$ can be expressed in the following way:

$$\mathbf{G}(s) = C_L(sI - A)^{-1}B + D \qquad \text{for all } s \in \mathbb{C}_{\omega(\mathbf{T})}\,,$$

which is familiar from finite-dimensional systems theory. The operators A, B, C, and D are called the *generating operators* of $\mathbf{\Sigma}$.

The following lemma will be needed in section 3. Certainly, it should be well known. However, since we could not find it in the literature, we include the proof.

LEMMA 2.1. *Suppose that $\mathbf{\Sigma} = (\mathbf{T}, \mathbf{\Phi}, \mathbf{\Psi}, \mathbf{F})$ is exponentially stable. Then the following statements hold:*

(1) *There exist $\alpha, \beta > 0$ such that, for any $x_0 \in X$ and any $u \in L^2(\mathbb{R}_+, U)$, the solution $x(\cdot)$ of the initial-value problem* (2.5) *satisfies*

$$\|x\|_{L^2(\mathbb{R}_+, X)} \leq \alpha \|u\|_{L^2(\mathbb{R}_+, U)} + \beta \|x_0\|.$$

(2) *If $u \in L^\infty(\mathbb{R}_+, U)$ and $\lim_{t \to \infty} u(t) = u_\infty$ exists, then for any $x_0 \in X$, $x(\cdot)$ defined by* (2.5) *satisfies*

$$\lim_{t \to \infty} \|x(t) + A^{-1}Bu_\infty\| = 0\,.$$

Proof. By the exponential stability we may assume, without loss of generality, that $x_0 = 0$. Consequently, we have $x(t) = \int_0^t \mathbf{T}_{t-\tau} B u(\tau)\, d\tau$ for all $t \geq 0$. Let $H^2(\mathbb{C}_0, X)$ denote the usual Hardy space of holomorphic functions defined on $\mathbb{C}_0$ with values in X. Appealing to the Paley–Wiener theorem, statement (1) will follow if we can show that there exists $\alpha > 0$ such that, for all $u \in L^2(\mathbb{R}_+, U)$,

$$\|\mathfrak{L}x\|_{H^2(\mathbb{C}_0,X)} \leq \alpha \|\mathfrak{L}u\|_{H^2(\mathbb{C}_0,U)}\,. \tag{2.7}$$

To this end, set $\omega_0 := \omega(\mathbf{T})$ and recall from [35] that for any $\omega > \omega_0$ there exists $M_\omega > 0$ such that, for all $s \in \mathbb{C}_\omega$,

$$\|(sI - A)^{-1} B\|_{\mathcal{B}(U,X)} \leq \frac{M_\omega}{\sqrt{\operatorname{Re}\, s - \omega}}\,. \tag{2.8}$$

It is clear that $s \mapsto (sI - A)^{-1}B$ is a holomorphic $\mathcal{B}(U, X_{-1})$-valued function: using the resolvent identity, it follows that it is also holomorphic as a $\mathcal{B}(U, X)$-valued function. The Laplace transform $\mathfrak{L}x$ of x satisfies

$$(\mathfrak{L}x)(s) = (sI - A)^{-1} B (\mathfrak{L}u)(s) \quad \text{for all } s \in \mathbb{C}_{\omega_0}\,. \tag{2.9}$$

By hypothesis, $\omega_0 < 0$ and $\mathfrak{L}u \in H^2(\mathbb{C}_0, X)$. Therefore, choosing $\omega_1 \in (\omega_0, 0)$ and combining (2.8) and (2.9) we see that (2.7) holds with, for example, $\alpha = M_{\omega_1}/\sqrt{|\omega_1|}$. This establishes statement (1).

To prove statement (2), we proceed as follows. Choose $t^* > 0$ such that $\|\mathbf{T}_t\| \leq 1/2$ for all $t \geq t^*$, let (t_n) be a sequence of real numbers satisfying

$$t^* \leq t_{n+1} - t_n \leq 2t^*\,,$$

and set $\beta = \sup\{\|\mathbf{T}_t\| \,|\, 0 \leq t \leq 2t^*\}$. For $t \geq t_n$ we have

$$x(t) = \mathbf{T}_{t-t_n} x(t_n) + \int_{t_n}^t \mathbf{T}_{t-\tau} B u(\tau)\, d\tau\,,$$

and so, by exponential stability, (2.3), and statement (1) above, there exists $\alpha > 0$ such that, for all $n \in \mathbb{N}$,

$$\|x(t)\| \leq \beta \|x(t_n)\| + \alpha\sqrt{2t^*}\|u\|_{L^\infty(t_n,t_{n+1})} \qquad \text{if } t \in [t_n, t_{n+1}] \tag{2.10}$$

and

$$\|x(t_{n+1})\| \leq \frac{1}{2}\|x(t_n)\| + \alpha\sqrt{2t^*}\|u\|_{L^\infty(t_n,t_{n+1})}\,. \tag{2.11}$$

We first consider the case when $u_\infty = 0$. Then

$$\lim_{n\to\infty} \|u\|_{L^\infty(t_n,t_{n+1})} = 0 \tag{2.12}$$

and (2.11) implies that

$$\lim_{n\to\infty} \|x(t_n)\| = 0\,. \tag{2.13}$$

Combining (2.10), (2.12), and (2.13) shows that $\lim_{t\to\infty} \|x(t)\| = 0$. Finally, if $u_\infty \neq 0$, then, by writing $u(t) = (u(t) - u_\infty) + u_\infty$, it is clear that it suffices to show that

$$\lim_{t\to\infty} \left\| \int_0^t \mathbf{T}_\tau B u_\infty\, d\tau + A^{-1} B u_\infty \right\| = 0\,. \tag{2.14}$$

Setting $z(t) = \int_0^t \mathbf{T}_\tau B u_\infty \, d\tau$ we have that

$$\lim_{t\to\infty} \|\dot{z}(t)\|_{-1} = \lim_{t\to\infty} \|\mathbf{T}_t B u_\infty\|_{-1} = 0\,. \tag{2.15}$$

The function $z(\cdot)$ is the classical solution of the initial-value problem $\dot{z}(t) = Az(t) + Bu_\infty$, $z(0) = 0$, considered in X_{-1}, and so we may write

$$z(\cdot) + A^{-1}Bu_\infty = A^{-1}\dot{z}(\cdot)\,. \tag{2.16}$$

Since $A^{-1} \in \mathcal{B}(X_{-1}, X)$, (2.14) follows from (2.15) and (2.16). □

3. Integral control in the presence of nonlinearities. In the following, let (A, B, C, D) be the generating operators of a linear, single-input, single-output regular system with state space X and transfer function $\mathbf{G}$. Suppose that the system is subject to an input nonlinearity ϕ, where $\phi : \mathbb{R} \to \mathbb{R}$ is locally Lipschitz. Denoting the constant reference signal by r, an application of the integrator

$$u(t) = u_0 + k \int_0^t [r - C_L x(\tau) - D\phi(u(\tau))]\, d\tau\,,$$

where k is a real parameter (see Fig. 1.2), leads to the following nonlinear system of differential equations:

$$\dot{x} = Ax + B\phi(u)\,, \quad x(0) = x_0 \in X, \tag{3.1}$$

$$\dot{u} = k[r - C_L x - D\phi(u)]\,, \quad u(0) = u_0 \in \mathbb{R}\,. \tag{3.2}$$

For $a \in (0, \infty]$, a continuous function

$$[0, a) \to X \times \mathbb{R}\,, \quad t \mapsto (x(t), u(t))$$

is called a *solution* of (3.1)–(3.2) if $(x(\cdot), u(\cdot))$ is absolutely continuous as an $(X_{-1} \times \mathbb{R})$-valued function, $x(t) \in \operatorname{dom}(C_L)$ for a.e. $t \in [0, a)$, $(x(0), u(0)) = (x_0, u_0)$, and the differential equations (3.1) and (3.2) are satisfied a.e. on $[0, a)$. Of course, the derivative on the left-hand side on (3.1) has to be understood in X_{-1}.[1]

An application of a well-known result on abstract Cauchy problems (see Pazy [26, Thm. 2.4, p. 107]), shows that a continuous $(X \times \mathbb{R})$-valued function $(x(\cdot), u(\cdot))$ is a solution of (3.1)–(3.2) if and only if it satisfies the following integrated version of (3.1)–(3.2):

$$x(t) = \mathbf{T}_t x_0 + \int_0^t \mathbf{T}_{t-\tau} B\phi(u(\tau))\, d\tau\,, \tag{3.3}$$

$$u(t) = u_0 + k \int_0^t [r - C_L x(\tau) - D\phi(u(\tau))]\, d\tau\,. \tag{3.4}$$

The next result shows that (3.1)–(3.2) has a unique solution.

PROPOSITION 3.1. *For any pair $(x_0, u_0) \in X \times \mathbb{R}$ of initial conditions there exists a unique solution $(x(\cdot), u(\cdot))$ of (3.1)–(3.2) defined on a maximal interval $[0, a_{max})$. If $a_{max} < \infty$, then*

$$\limsup_{t\to a_{max}} \|(x(t), u(t))\| = \infty\,. \tag{3.5}$$

[1] Being a Hilbert space, $X_{-1} \times \mathbb{R}$ is reflexive. Hence any absolutely continuous $(X_{-1} \times \mathbb{R})$-valued function is a.e. differentiable and can be recovered from its derivative by integration; see [1, Thm. 3.1, p. 10].

If ϕ is globally Lipschitz, then $a_{max} = \infty$.

For the proof of the above result it will be useful to consider the following initial-value problem for u:

$$\dot{u} = k[r - \mathbf{\Psi}_\infty x_0 - \mathbf{F}_\infty \phi(u)], \quad u(0) = u_0. \tag{3.6}$$

Clearly, (3.6) [2] is obtained from (3.2) on noting that $C_L x(t) + D\phi(u(t)) = (\mathbf{\Psi}_\infty x_0)(t) + (\mathbf{F}_\infty \phi(u))(t)$. An absolutely continuous function $u : [0, a) \to \mathbb{R}$ is a *solution* of (3.6) if $u(0) = u_0$ and the differential equation in (3.6) is satisfied a.e. on $[0, a)$.

LEMMA 3.2. *Let $x_0 \in X$. For any initial condition $u_0 \in \mathbb{R}$ there exists a unique solution $u(\cdot)$ of (3.6) defined on a maximal interval $[0, a_{max})$. If $a_{max} < \infty$, then*

$$\limsup_{t \to a_{max}} |u(t)| = \infty. \tag{3.7}$$

If ϕ is globally Lipschitz, then $a_{max} = \infty$.

The proof of this lemma is relegated to the appendix.

Proof of Proposition 3.1. Let $u : [0, a_{max}) \to \mathbb{R}$ be the unique maximal solution of (3.6) (whose existence is guaranteed by Lemma 3.2), and *define* $x(\cdot)$ to be the unique solution of

$$\dot{x} = Ax + B\phi(u), \quad x(0) = x_0.$$

Then $(x(\cdot), u(\cdot))$ is the unique solution of equations (3.1)–(3.2), which satisfies equation (3.5) if $a_{max} < \infty$. Moreover, it follows trivially from Lemma 3.2 that $a_{max} = \infty$ if ϕ is globally Lipschitz. □

Henceforth, let $\mathcal{M}$ denote the set of all bounded measures on $[0, \infty)$. A measure $\mu \in \mathcal{M}$ can be written in the form

$$\mu(dt) = a(t)dt + \sum_{i=0}^{\infty} a_i \delta_{t_i}(dt) + \mu_s(dt),$$

where $a(\cdot) \in L^1(0, \infty)$, $\sum_{i=0}^{\infty} a_i \delta_{t_i}$, and μ_s, respectively, represent the absolutely continuous, the discrete, and the singular parts of μ. In particular, δ_{t_i} denotes the unit point mass at $t_i \geq 0$ and the a_i are real numbers such that $\sum_{i=0}^{\infty} |a_i| < \infty$.

Furthermore, for $\lambda > 0$, let $\mathcal{N}(\lambda)$ denote the set of all nondecreasing globally Lipschitz nonlinearities $\phi : \mathbb{R} \to \mathbb{R}$ with Lipschitz constant λ. Finally, if $\mathbf{G}$ is holomorphic and bounded on $\mathbb{C}_\alpha$ for some $\alpha < 0$ and $\mathbf{G}(0) > 0$, then it is easy to show that

$$1 + k\mathrm{Re}\,\frac{\mathbf{G}(s)}{s} \geq 0 \qquad \text{for all } s \in \mathbb{C}_0 \tag{3.8}$$

for all sufficiently small $k > 0$; see Lemma 3.10 in [17]. We define

$$K := \sup\{k > 0 \,|\, (3.8) \text{ holds}\}.$$

The main result of this section is the following theorem.

THEOREM 3.3. *Let $\lambda > 0$ and $\phi \in \mathcal{N}(\lambda)$. Assume that $\mathbf{T}_t$ is exponentially stable, $\mathbf{G}(0) > 0$, $k \in (0, K/\lambda)$, and $r \in \mathbb{R}$ is such that*

$$\phi_r := [\mathbf{G}(0)]^{-1} r \in \mathrm{clos}\,(\mathrm{im}\,\phi). \tag{3.9}$$

If C is bounded, then for all $(x_0, u_0) \in X \times \mathbb{R}$ the unique solution $(x(\cdot), u(\cdot))$ of (3.1)–(3.2) exists on $[0, \infty)$ and satisfies

[2] Strictly speaking, to make sense of (3.6) we have to give a meaning to $\mathbf{F}_\infty v$ when v is a continuous function defined on a *finite* interval $[0, a)$ (recall that $\mathbf{F}_\infty$ operates on the space of locally square-integrable functions defined on the *infinite* interval $[0, \infty)$). This can easily be done using the causality of $\mathbf{F}_\infty$. Moreover, by slight abuse of notation, the expression $\phi(u)$ on the right-hand side of (3.6) denotes the function $t \mapsto \phi(u(t))$.

(1) $\lim_{t\to\infty} \phi(u(t)) = \phi_r$,
(2) $\lim_{t\to\infty} \|x(t) + A^{-1}B\phi_r\| = 0$,
(3) $\lim_{t\to\infty}(r - y(t)) = 0$, *where* $y(t) = Cx(t) + D\phi(u(t))$,
(4) *if* $\phi_r \in \operatorname{im}\phi$, *then*

$$\lim_{t\to\infty} \operatorname{dist}(u(t), \phi^{-1}(\phi_r)) = 0\,, \tag{3.10}$$

(5) *if* $\phi_r \in \operatorname{int}(\operatorname{im}\phi)$, *then* $u(\cdot)$ *is bounded.*

If C *is unbounded, then the statements* (1), (2), (4), *and* (5) *remain true provided that* $\mathfrak{L}^{-1}(\mathbf{G}) \in \mathcal{M}$ *and statement* (3) *remains true provided that* $x_0 \in \operatorname{dom}(A)$ *and* $\mathfrak{L}^{-1}(\mathbf{G}) \in \mathcal{M}$.

In particular, statement (4) says that $u(t)$ converges as $t \to \infty$ if the set $\phi^{-1}(\phi_r)$ is a singleton, which, in turn, is true if ϕ_r is not a critical value of ϕ.

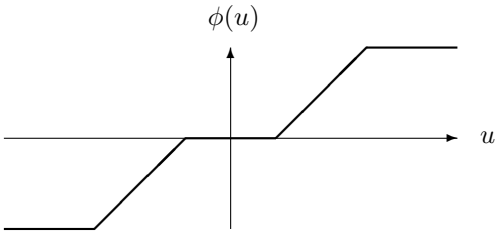

FIG. 3.1. *Nonlinearity with saturation and deadzone.*

The conditions imposed in Theorem 3.3 on ϕ are satisfied by saturation and deadzone nonlinearities and combinations of the two, as shown in Fig. 3.1. The assumption that $\mathfrak{L}^{-1}(\mathbf{G}) \in \mathcal{M}$ is not very restrictive and seems to be satisfied in all practical examples of systems with H^∞-transfer functions (in applications one usually has $\mu_s = 0$). If C is unbounded and $x_0 \notin \operatorname{dom}(A)$, then statement (3) does not hold in general. However, in that case, as an inspection of the proof of Theorem 3.3 will show, the error $e(\cdot) = r - y(\cdot)$ admits a decomposition $e = e_1 + e_2$, where $e_1 \in L^2_\alpha(\mathbb{R}_+, \mathbb{R})$ for some $\alpha < 0$ and e_2 is a continuous function satisfying $\lim_{t\to\infty} e_2(t) = 0$. Thus, while the error does not necessarily converge asymptotically to 0 as $t \to \infty$, it is small for large t in the sense that for all $\delta, \varepsilon > 0$ there exists $T > 0$ such that

$$\operatorname{meas}(\{t \geq T \,|\, |e(t)| \geq \delta\}) \leq \varepsilon\,,$$

where meas denotes the Lebesgue measure. In applying Theorem 3.3 it is important to know the constant K or at least a lower bound for K. In principle, K can be obtained from frequency-response experiments performed on the linear part of the plant; see [15] for details.

For the proof of Theorem 3.3 two lemmas are required, the proofs of which can be found in the appendix.

LEMMA 3.4. *Suppose that* $\mathbf{T}_t$ *is exponentially stable and* $\mathbf{G}(0) > 0$. *Define*

$$\mathbf{H}(s) = \frac{1}{s}(\mathbf{G}(s) - \mathbf{G}(0))\,.$$

If $0 < 2\kappa < K$, *then*

$$\|\mathbf{H}(1 + \kappa\mathbf{H})^{-1}\|_\infty < \frac{1}{\kappa} \tag{3.11}$$

and there exists $P \in \mathcal{B}(X)$, with $P = P^* \geq 0$ and such that the Riccati equation

$$\begin{aligned}\langle A_\kappa x_1, Px_2\rangle + \langle Px_1, A_\kappa x_2\rangle + \kappa^2\langle C_L x_1, C_L x_2\rangle \\ + \langle (A^{-1}B)^* Px_1, (A^{-1}B)^* Px_2\rangle = 0\end{aligned} \tag{3.12}$$

is satisfied for all $x_1, x_2 \in \mathrm{dom}(A_\kappa) = \mathrm{dom}(A)$, where $A_\kappa := A - \kappa A^{-1}BC_L$.

LEMMA 3.5. *Let $\phi : \mathbb{R} \to \mathbb{R}$ be locally Lipschitz and (ε_n) be any sequence with $\varepsilon_n > 0$ and $\lim_{n\to\infty} \varepsilon_n = 0$. Define the function $\phi^\diamond : \mathbb{R} \to \mathbb{R}$ by*

$$\phi^\diamond(\xi) = \limsup_{n\to\infty} \frac{\phi(\xi + \varepsilon_n) - \phi(\xi)}{\varepsilon_n}\,.$$

Then $\phi^\diamond \in L^\infty_{loc}(-\infty, \infty)$ ($\phi^\diamond \in L^\infty(-\infty, \infty)$ if ϕ is globally Lipschitz) and $\phi^\diamond \circ u$ is Lebesgue measurable for all Lebesgue measurable functions $u : [0, \infty) \to \mathbb{R}$. If u is absolutely continuous, so is $\phi \circ u$ and

$$\frac{d}{dt}(\phi \circ u)(t) = \phi^\diamond(u(t))\dot{u}(t) \quad \textit{for a.e. } t \in [0, \infty)\,.$$

Proof of Theorem 3.3. By Proposition 3.1, there exists a unique solution of (3.1)–(3.2) on $[0, \infty)$. We denote this solution by $(x(\cdot), u(\cdot))$ and introduce new variables by defining

$$z(t) := x(t) + A^{-1}B\phi(u(t))\,, \quad v(t) := \phi(u(t)) - \phi_r \quad \text{for all } t \geq 0.$$

By regularity it follows that $z(t) \in \mathrm{dom}\,(C_L)$ for a.e. $t \in [0, \infty)$. Moreover, by Lemma 3.5, $\dot{v}(t) = \phi^\diamond(u(t))\dot{u}(t)$ for a.e. $t \in [0, \infty)$. Therefore, an easy calculation yields

$$\dot{z} = Az - k\phi^\diamond(u)A^{-1}B(C_L z + \mathbf{G}(0)v)\,, \quad z(0) = z_0 := x_0 + A^{-1}B\phi(u_0), \tag{3.13}$$

$$\dot{v} = -k\phi^\diamond(u)(C_L z + \mathbf{G}(0)v)\,, \quad v(0) = v_0 := \phi(u_0) - \phi_r\,. \tag{3.14}$$

The derivative on the left-hand side of (3.13) and (3.14) has to be understood in X_{-1}. Notice that, since ϕ is nondecreasing, $\phi^\diamond(\xi) \geq 0$ for all $\xi \in \mathbb{R}$. We observe that, while in these new variables we still have an unbounded operator $A^{-1}BC_L$, the operator $A^{-1}B$ is in $\mathcal{B}(\mathbb{R}, X)$. We will investigate the stability properties of (3.13) and (3.14) using a Liapunov approach.

Since $0 < k\lambda < K$, it follows that there exists $\mu > \lambda/2$ such that $0 < 2\mu k < K$, and therefore, by Lemma 3.4,

$$\|\mathbf{H}(1 + \mu k\mathbf{H})^{-1}\|_\infty < \frac{1}{\mu k}\,.$$

By the same lemma, the Riccati equation (3.12) with $\kappa = \mu k$ has a solution $P \in \mathcal{B}(X)$ satisfying $P = P^* \geq 0$. Set

$$\tilde{P} = \begin{pmatrix} P & 0 \\ 0 & \mu k\mathbf{G}(0) \end{pmatrix},$$

and define

$$\tilde{A}_k = \begin{pmatrix} A - \mu kA^{-1}BC_L & -\mu kA^{-1}B\mathbf{G}(0) \\ -\mu kC_L & -\mu k\mathbf{G}(0) \end{pmatrix}, \quad \tilde{B} = \begin{pmatrix} A^{-1}B \\ 1 \end{pmatrix}, \quad \tilde{C} = (C_L \;\; \mathbf{G}(0))\,,$$

where $\mathrm{dom}(\tilde{A}_k) = \mathrm{dom}(A) \times \mathbb{R}$. The operator $\tilde{A}_k$ generates a C_0-semigroup. Using (3.12), it is easy to show that

$$\langle \tilde{A}_k \tilde{x}_1, \tilde{P}\tilde{x}_2\rangle + \langle \tilde{P}\tilde{x}_1, \tilde{A}_k\tilde{x}_2\rangle + \mu^2 k^2 \langle \tilde{C}\tilde{x}_1, \tilde{C}\tilde{x}_2\rangle + \langle \tilde{B}^*\tilde{P}\tilde{x}_1, \tilde{B}^*\tilde{P}\tilde{x}_2\rangle = 0 \tag{3.15}$$

is satisfied for all $\tilde{x}_1, \tilde{x}_2 \in \mathrm{dom}(\tilde{A}_k)$.

Setting $\tilde{z}(\cdot) = (z(\cdot), v(\cdot))$, (3.13) and (3.14) can be reformulated as

$$\dot{\tilde{z}} = \tilde{A}_k \tilde{z} + k(\mu - \phi^\diamond(u))\tilde{B}\tilde{C}\tilde{z}\,, \quad \tilde{z}(0) = \tilde{z}_0 := \begin{pmatrix} z_0 \\ v_0 \end{pmatrix}, \tag{3.16}$$

where the derivative on the left-hand side has to be understood in $X_{-1} \times \mathbb{R}$. For an intermediate step in the Liapunov analysis we need differentiability in $X \times \mathbb{R}$, and therefore, we will use an approximation argument. To this end let $T > 0$ be fixed but arbitrary, and choose $(w_n) \subset W^{1,2}(0,T;\mathbb{R})$ and $(\tilde{z}_0^n) \subset \mathrm{dom}(\tilde{A}_k)$ such that

$$\lim_{n\to\infty} \|k(\mu - \phi^\diamond(u))\tilde{C}\tilde{z} - w_n\|_{L^2(0,T)} = 0\,, \quad \lim_{n\to\infty} \|\tilde{z}_0 - \tilde{z}_0^n\|_{X\times\mathbb{R}} = 0\,. \tag{3.17}$$

Consider the system

$$\dot{\eta}(t) = \tilde{A}_k \eta(t) + \tilde{B} w_n(t)\,, \qquad \eta(0) = \tilde{z}_0^n\,. \tag{3.18}$$

$$\xi(t) = \tilde{C}\eta(t)\,. \tag{3.19}$$

The abstract initial-value problem (3.18) has a strong solution $\tilde{z}_n$ on $[0,T]$ in the sense that $\tilde{z}_n(0) = \tilde{z}_0^n$ and (3.18) is satisfied for a.e. $t \in [0,T]$ (see Pazy [26, Cor. 2.10, p. 109]). Using (3.17) we obtain

$$\lim_{n\to\infty} \|\tilde{z} - \tilde{z}_n\|_{L^2(0,T)} = 0\,; \qquad \lim_{n\to\infty} \|\tilde{z}(t) - \tilde{z}_n(t)\|_{X\times\mathbb{R}} = 0 \quad \text{for all } t \in [0,T]\,. \tag{3.20}$$

Setting $\xi_n(t) = \tilde{C}\tilde{z}_n(t)$, it follows from the regularity of (3.18) that

$$\lim_{n\to\infty} \|\tilde{C}\tilde{z} - \xi_n\|_{L^2(0,T)} = 0\,. \tag{3.21}$$

Differentiating the function

$$\tau \mapsto V_n(\tau) = \langle \tilde{z}_n(\tau), \tilde{P}\tilde{z}_n(\tau)\rangle$$

shows that, for a.e. $\tau \in [0,T]$,

$$\dot{V}_n(\tau) = \langle \tilde{z}_n(\tau), \tilde{P}\tilde{A}_k\tilde{z}_n(\tau)\rangle + \langle \tilde{A}_k\tilde{z}_n(\tau), \tilde{P}\tilde{z}_n(\tau)\rangle + 2\langle \tilde{B}w_n(\tau), \tilde{P}\tilde{z}_n(\tau)\rangle\,. \tag{3.22}$$

If $t \in [0,T]$, then integrating (3.22) from 0 to t, taking limits as $n \to \infty$, invoking (3.15), (3.17), (3.20), and (3.21), and setting

$$V(\tau) = \langle \tilde{z}(\tau), \tilde{P}\tilde{z}(\tau)\rangle$$

we obtain

$$V(t) - V(0) = -\int_0^t \mu^2 k^2 (\tilde{C}\tilde{z})^2 - \int_0^t (\tilde{B}^*\tilde{P}\tilde{z})^2 + 2\int_0^t \langle \tilde{B}k(\mu - \phi^\diamond(u))\tilde{C}\tilde{z}, \tilde{P}\tilde{z}\rangle\,.$$

Completing the square gives

$$V(t) - V(0) = -\int_0^t [\mu^2 k^2 - k^2(\phi^\diamond(u) - \mu)^2](\tilde{C}\tilde{z})^2 - \int_0^t [k(\phi^\diamond(u) - \mu)\tilde{C}\tilde{z} + \tilde{B}^*\tilde{P}\tilde{z}]^2\,,$$

and hence

$$V(t) - V(0) = -k^2 \int_0^t [2\mu\phi^\diamond(u) - (\phi^\diamond)^2(u)](\tilde{C}\tilde{z})^2 - \int_0^t [k(\phi^\diamond(u) - \mu)\tilde{C}\tilde{z} + \tilde{B}^*\tilde{P}\tilde{z}]^2 \,, \tag{3.23}$$

which holds for all $t \in [0, T]$. Since $T > 0$ was arbitrary, it follows that (3.23) holds for all $t \geq 0$. Therefore, using (3.23) and the definition of $\tilde{C}$,

$$k^2 \int_0^t (2\mu\phi^\diamond(u) - (\phi^\diamond)^2(u))(C_L z + \mathbf{G}(0)v)^2 \leq V(0) < \infty \quad \text{for all } t \geq 0 \,. \tag{3.24}$$

Now recall that $2\mu > \lambda$ and $\|\phi^\diamond(u)\|_{L^\infty(\mathbb{R}_+)} \leq \lambda$, so that

$$2\mu\phi^\diamond(u) - (\phi^\diamond)^2(u) > \varepsilon(\phi^\diamond)^2(u)$$

for some $\varepsilon > 0$. Therefore, (3.24) gives

$$\varepsilon k^2 \int_0^t (\phi^\diamond)^2(u)(C_L z + \mathbf{G}(0)v)^2 \leq V(0) < \infty \qquad \text{for all } t \geq 0 \,.$$

It follows that

$$\phi^\diamond(u)(C_L z + \mathbf{G}(0)v) \in L^2(\mathbb{R}_+) \,. \tag{3.25}$$

Using this in (3.13) and appealing to the fact that A, $A^{-1}B$, and C are the generating operators of a stable regular system we may conclude that

$$C_L z \in L^2(\mathbb{R}_+) \,. \tag{3.26}$$

Hence, by (3.25) and the boundedness of $\phi^\diamond(u)$,

$$\phi^\diamond(u)v \in L^2(\mathbb{R}_+), \tag{3.27}$$

and thus

$$(C_L z)\phi^\diamond(u)v \in L^1(\mathbb{R}_+) \,. \tag{3.28}$$

Using (3.24), (3.26)–(3.28), and the boundedness of $\phi^\diamond(u)$ it follows that

$$\phi^\diamond(u)v^2 \in L^1(\mathbb{R}_+) \,. \tag{3.29}$$

Multiplying (3.14) by $v(t)$, integrating, and then using (3.28) and (3.29) shows that

$$\lim_{t\to\infty} v^2(t) = v_0^2 + 2 \lim_{t\to\infty} \int_0^t v\dot{v} = \nu$$

for some $\nu \in [0, \infty)$. By continuity of $v(\cdot)$ it follows that

$$\lim_{t\to\infty} v(t) = \sqrt{\nu} \qquad \text{or} \qquad \lim_{t\to\infty} v(t) = -\sqrt{\nu} \,.$$

In the following we distinguish two cases: bounded and unbounded observation.

Let us first consider the case of bounded C. In order to prove statement (1), we have to show that $\nu = 0$. Seeking a contradiction, suppose that $\nu > 0$. Assuming

that $\lim_{t\to\infty} v(t) = \sqrt{\nu}$ (the case $\lim_{t\to\infty} v(t) = -\sqrt{\nu}$ can be dealt with in an entirely analogous fashion), we obtain that

$$\phi_\infty := \lim_{t\to\infty} \phi(u(t)) > \phi_r \,. \tag{3.30}$$

By Lemma 2.1, part (2), it follows that

$$\lim_{t\to\infty} \|x(t) + A^{-1}B\phi_\infty\| = 0 \,. \tag{3.31}$$

Using the boundedness of C it follows from (3.2), (3.30), and (3.31) that

$$\lim_{t\to\infty} \dot{u}(t) = k(r + CA^{-1}B\phi_\infty - D\phi_\infty) = k\mathbf{G}(0)(\phi_r - \phi_\infty) < 0 \,,$$

and so

$$\lim_{t\to\infty} u(t) = -\infty \,. \tag{3.32}$$

Since ϕ is nondecreasing we obtain

$$\phi_\infty = \lim_{t\to\infty} \phi(u(t)) = \inf(\operatorname{im}\phi) \le \phi_r \,,$$

contradicting (3.30). Therefore, $\nu = 0$, and consequently $\lim_{t\to\infty} \phi(u(t)) = \phi_r$, which is statement (1). Statement (2) follows now from Lemma 2.1, part (2), and statement (3) is a consequence of statements (1) and (2).

To prove statement (4), let $\phi_r \in \operatorname{im}\phi$. Seeking a contradiction, suppose that the claim is not true. Then there exists a sequence of positive numbers (t_n) with $\lim_{n\to\infty} t_n = \infty$ and $\varepsilon > 0$ such that

$$\operatorname{dist}(u(t_n), \phi^{-1}(\phi_r)) \ge \varepsilon \,. \tag{3.33}$$

If the sequence $(u(t_n))$ is bounded, we may assume, without loss of generality, that it converges to a finite limit u_∞. By continuity of ϕ and statement (1) we have that $\phi(u_\infty) = \phi_r$, and thus $u_\infty \in \phi^{-1}(\phi_r)$. This contradicts (3.33). So, suppose that $(u(t_n))$ is unbounded. Without loss of generality, we may then assume that $\lim_{n\to\infty} u(t_n) = \infty$. By monotonicity and statement (1) it follows that $\phi_r = \sup\phi$. Since $\phi_r \in \operatorname{im}\phi$ there exists ξ^* such that

$$\phi(\xi^*) = \phi_r = \sup\phi = \max\phi \,.$$

By monotonicity of ϕ we have

$$\phi(\xi) = \phi_r = \max\phi \qquad \text{for all } \xi \ge \xi^* \,.$$

In particular, we see that $u(t_n) \in \phi^{-1}(\phi_r)$ for all sufficiently large n, contradicting (3.33).

To prove statement (5) assume that $\phi_r \in \operatorname{int}(\operatorname{im}\phi)$. Again seeking a contradiction, suppose that the claim is not true. Then there exists a sequence of positive numbers (t_n) with $\lim_{n\to\infty} t_n = \infty$ and $\lim_{n\to\infty} |u(t_n)| = \infty$. Without loss of generality, we may assume that $\lim_{n\to\infty} u(t_n) = \infty$. By monotonicity it then follows that

$$\phi_r = \lim_{n\to\infty} \phi(u(t_n)) = \sup\phi \,,$$

contradicting the hypothesis $\phi_r \in \operatorname{int}(\operatorname{im}\phi)$.

Now let us consider the case of unbounded C with $\mathfrak{L}^{-1}(\mathbf{G}) \in \mathcal{M}$. We will again be seeking a contradiction, and hence assume that $\nu > 0$. It is clear that (3.30) and (3.31) still hold. It only remains to show that (3.32) is also true in this case. To this end, write (3.2) in the form

$$\dot{u} = k[r - C_L \mathbf{T}_t x_0 - \mathfrak{L}^{-1}(\mathbf{G}) \star \phi(u)]\,. \tag{3.34}$$

Since $\lim_{t\to\infty} \phi(u(t)) = \phi_\infty$ and $\mathfrak{L}^{-1}(\mathbf{G}) \in \mathcal{M}$ it follows that $\lim_{t\to\infty}(\mathfrak{L}^{-1}(\mathbf{G}) \star \phi(u))(t) = \mathbf{G}(0)\phi_\infty$ (see [8, Thm. 6.1, part (ii), p. 96]). Therefore, by (3.30) there exists $\delta > 0$ and $T > 0$ such that

$$\mathbf{G}(0)\phi_r - (\mathfrak{L}^{-1}(\mathbf{G}) \star \phi(u))(t) \le -\delta \qquad \text{for all } t \ge T\,. \tag{3.35}$$

Integrating (3.34) from T to t and using (3.35) gives

$$u(t) \le u(T) + k\left[\int_T^t |C_L \mathbf{T}_\tau x_0|\, d\tau - \delta(t - T)\right]\,. \tag{3.36}$$

By exponential stability of $\mathbf{T}_t$ we have that the map $t \mapsto C_L \mathbf{T}_t x_0$ is in $L^2_\alpha(\mathbb{R}_+, \mathbb{R})$ for some $\alpha < 0$, and hence in $L^1(\mathbb{R}_+, \mathbb{R})$. As a consequence, (3.36) yields

$$\lim_{t\to\infty} u(t) = -\infty\,,$$

which is (3.32). Statements (2), (4), and (5) then follow as in the case of bounded C. Finally, write $y(t)$ in the form

$$y(t) = C_L \mathbf{T}_t x_0 + (\mathfrak{L}^{-1}(\mathbf{G}) \star \phi(u))(t)\,.$$

Under the assumption that $x_0 \in \operatorname{dom}(A)$ and $\mathfrak{L}^{-1}(\mathbf{G}) \in \mathcal{M}$, we obtain

$$\lim_{t\to\infty} y(t) = \mathbf{G}(0) \lim_{t\to\infty} \phi(u(t))\,.$$

Combining this with statement (1) yields statement (3). □

One of the conditions imposed in Theorem 3.3 is that $[\mathbf{G}(0)]^{-1} r \in \operatorname{clos}(\operatorname{im}\phi)$. The following proposition shows that this condition is necessary for solvability of the tracking problem.

PROPOSITION 3.6. *Let $r \in \mathbb{R}$, and suppose that $\phi : \mathbb{R} \to \mathbb{R}$ is continuous, $\mathbf{T}_t$ is exponentially stable, and $\mathbf{G}(0) \neq 0$. If there exist an initial condition $x_0 \in X$ and a continuous function $u : [0, \infty) \to \mathbb{R}$ such that $\phi(u(\cdot))$ is bounded and*

$$\lim_{t\to\infty} [C_L x(t) + D\phi(u(t))] = r\,,$$

where $x(t) = \mathbf{T}_t x_0 + \int_0^t \mathbf{T}_{t-\tau} B\phi(u(\tau))\, d\tau$, then $\phi_r = [\mathbf{G}(0)]^{-1} r \in \operatorname{clos}(\operatorname{im}\phi)$.

The proof of the above proposition requires some preparation. Recall the concept of an ω-limit point (and ω-limit set $\Omega(\psi)$) of a continuous function $\psi : [0, \infty) \to \mathbb{R}$. A point ψ^* is an *ω-limit point* of ψ if there exists an increasing sequence $(t_n) \subset [0, \infty)$ such that $t_n \to \infty$ and $\psi(t_n) \to \psi^*$ as $n \to \infty$. The set $\Omega(\psi)$ of all ω-limit points is the *ω-limit set* of ψ.

The following lemma is probably standard; however, we were unable to locate it in the literature and so include a proof for completeness.

LEMMA 3.7. *Let $\psi : [0,\infty) \to \mathbb{R}$ be continuous and bounded. Then*

$$\lim_{s\to 0,\, s>0} [s(\mathfrak{L}\psi)(s)] = \omega \quad \Longrightarrow \quad \omega \in \Omega(\psi)\,.$$

Proof. It suffices to prove the result in the case $\omega = 0$ (if $\omega \neq 0$, then simply replace ψ by $\psi_\omega : t \mapsto \psi(t) - \omega$). It is well known that $\Omega(\psi)$ is compact and is approached by $\psi(t)$ as $t \to \infty$ (see, for example, [10, p. 113]). Seeking a contradiction, suppose $0 \notin \Omega(\psi)$. Then there exists $\varepsilon > 0$ and $T > 0$ such that for all $t \geq T$, $|\psi(t)| \geq \varepsilon$. Since ψ is continuous, we may restrict our attention, without loss of generality, to the case $\psi(t) \geq \varepsilon$ for all $t \geq T$. Then, for all $s \in (0,\infty)$, we have

$$(\mathfrak{L}\psi)(s) = \int_0^\infty e^{-st}\psi(t)\,dt \geq \int_0^T e^{-st}\psi(t)\,dt + \varepsilon \int_T^\infty e^{-st}\,dt \tag{3.37}$$

$$= \int_0^T e^{-st}\psi(t)\,dt + \frac{\varepsilon e^{-sT}}{s}\,, \tag{3.38}$$

whence the contradiction

$$0 = \lim_{s\to 0,\, s>0} s(\mathfrak{L}\psi)(s) \geq \varepsilon > 0\,.$$

□

Proof of Proposition 3.6. For $\delta \in (0, \pi/2)$ define the open sector $\mathcal{S}(\delta) \subset \mathbb{C}_0$ by

$$\mathcal{S}(\delta) := \{\rho e^{i\alpha} \mid \rho \in (0,\infty),\, \alpha \in (-\delta, \delta)\}\,.$$

Setting $\psi(t) = \phi(u(t))$ and $y(t) = C_L x(t) + D\psi(t)$ we obtain

$$(\mathfrak{L}y)(s) = \mathbf{G}(s)(\mathfrak{L}\psi)(s) + C(sI - A)^{-1}x_0\,,$$

and so by the final-value theorem (see [7, Satz 34.2] or [25, Thm. 14, p. 95])

$$r = \lim_{t\to\infty} y(t) = \lim_{s\to 0,\, s\in\mathcal{S}(\delta)} s(\mathfrak{L}y)(s) = \lim_{s\to 0,\, s\in\mathcal{S}(\delta)} s\mathbf{G}(s)(\mathfrak{L}\psi)(s)\,.$$

Since $\mathbf{G}(0) \neq 0$ it follows using Lemma 3.7 that

$$\phi_r = [\mathbf{G}(0)]^{-1} r = \lim_{s\to 0,\, s\in\mathcal{S}(\delta)} s(\mathfrak{L}\psi)(s) \in \Omega(\psi) \subset \operatorname{clos}(\operatorname{im}\phi)\,. \qquad \square$$

A result similar to Proposition 3.6 was stated without proof by Miller and Davison [22] in a finite-dimensional context. However, their approach (as outlined by Miller [21]) does not extend to infinite-dimensional regular systems.

4. Example: Controlled diffusion process with output delay. Consider a diffusion process (with diffusion coefficient $a > 0$ and with Dirichlet boundary conditions), on the one-dimensional spatial domain $[0,1]$, with scalar nonlinear pointwise control action (applied at point $x_b \in (0,1)$ via a nonlinearity ϕ with Lipschitz constant $\lambda > 0$) and delayed (delay $h \geq 0$) pointwise scalar observation (output at point $x_c \in (0,1)$, $x_c \geq x_b$.). We formally write this single-input, single-output system as

$$z_t(t,x) = az_{xx}(t,x) + \delta(x - x_b)\phi(u(t)), \quad y(t) = z(t-h, x_c),$$
$$z(t,0) = 0 = z(t,1) \qquad \text{for all } t > 0\,.$$

For simplicity, we assume zero initial conditions as follows:

$$z(t,x) = 0 \qquad \text{for all } (t,x) \in [-h,0] \times [0,1]\,.$$

With input $\phi(u(\cdot))$ and output $y(\cdot)$, this example qualifies as a regular linear system with transfer function given by

$$\mathbf{G}(s) = \frac{e^{-sh}\sinh\left(x_b\sqrt{(s/a)}\right)\sinh\left((1-x_c)\sqrt{(s/a)}\right)}{a\sqrt{(s/a)}\sinh\sqrt{(s/a)}}\,.$$

In this case, a detailed analysis (see [15] for related investigations) yields

$$\begin{aligned} K &:= \sup\{k > 0 \,|\, (3.8) \text{ holds}\} \\ &= \frac{1}{|\mathbf{G}'(0)|} = \frac{6a^2}{x_b(1-x_c)(6ha + 1 - x_b^2 - (1-x_c)^2)}. \end{aligned}$$

Therefore, by Theorem 3.3, for each $k \in (0, K/\lambda)$, the integral control

$$u(t) = k\int_0^t [r - y(t)]\,dt$$

guarantees asymptotic tracking of every constant reference signal r satisfying

$$\frac{r}{\mathbf{G}(0)} = \frac{ar}{x_b(1-x_c)} \in \operatorname{clos}(\operatorname{im}\phi)\,.$$

For purposes of illustration, we adopt the following values:

$$a = 0.1, \quad x_b = \frac{1}{3}, \quad x_c = \frac{2}{3}, \quad h = 1, \quad r = 1.$$

We consider a nonlinearity ϕ of saturation type, defined as follows:

$$u \mapsto \phi(u) := \begin{cases} 1, & u \geq 1, \\ u, & u \in (0,1), \\ 0, & u \leq 0 \end{cases}$$

in which case $\lambda = 1$ and

$$K = \frac{243}{620}\ (\approx 0.3919).$$

For $r = 1$, we have

$$\frac{r}{\mathbf{G}(0)} = \frac{a}{x_b(1-x_c)} = 0.9 \in [0,1] = \operatorname{clos}(\operatorname{im}\phi)\,.$$

In each of the following three cases of admissible controller gains

$$\text{(i) } k = 0.39, \quad \text{(ii) } k = 0.26, \quad \text{(iii) } k = 0.13,$$

Fig. 4.1 depicts the output behavior of the system under integral control, while Fig. 4.2 depicts the corresponding control input. These figures were generated using SIMULINK Simulation Software within MATLAB wherein a truncated eigenfunction expansion, of order 10, was adopted to model the diffusion process.

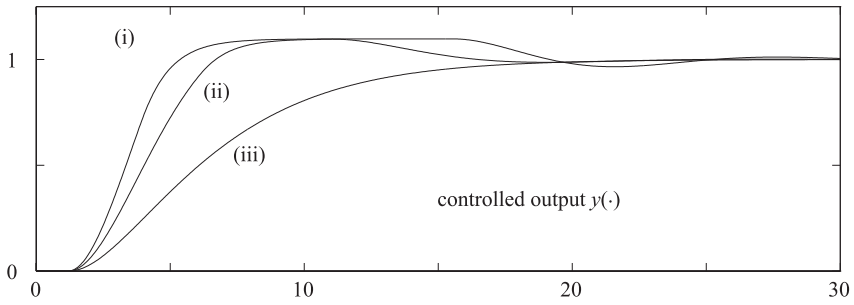

FIG. 4.1. *Controlled output.*

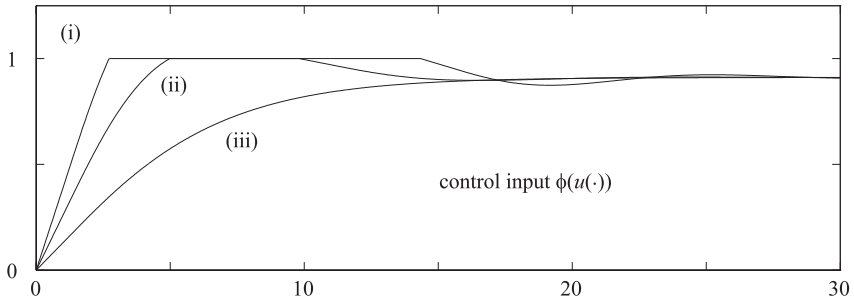

FIG. 4.2. *Control input.*

Appendix.

Proof of Lemma 3.2. In proving Lemma 3.2, we will study an initial-value problem which is slightly more general than (3.6). Let $\alpha \geq 0$, and let $w \in C([0,\alpha],\mathbb{R})$. Consider the initial-value problem

$$\dot{u}(t) = k[r - (\mathbf{\Psi}_\infty x_0)(t) - (\mathbf{F}_\infty \phi(u))(t)]\,, \quad t \geq \alpha\,, \tag{A.1}$$

$$u(t) = w(t)\,, \quad t \in [0,\alpha]\,. \tag{A.2}$$

LEMMA A.1. *Let $x_0 \in X$. For any initial function $w \in C([0,\alpha],\mathbb{R})$ there exists $\varepsilon > 0$ and a unique function $u \in C([0,\alpha+\varepsilon],\mathbb{R})$ with $u(t) = w(t)$ for all $t \in [0,\alpha]$ and such that u is absolutely continuous on $[\alpha,\alpha+\varepsilon]$ and* (A.1) *is satisfied for a.e. $t \in [\alpha,\alpha+\varepsilon]$.*

Proof. Without loss of generality, we may assume that $k = 1$. For $\delta > 0$ and $\eta > \|w\|_\infty$, define

$$\begin{aligned}\mathcal{C}_{\delta,\eta} = \{u \in C([0,\alpha+\delta],\mathbb{R}) \mid\ & |u(t) - w(t)| \leq \eta \quad \text{if } 0 \leq t \leq \alpha\,; \\ & |u(t) - w(\alpha)| \leq \eta \quad \text{if } \alpha \leq t \leq \alpha+\delta\}\,.\end{aligned}$$

Choosing $\eta > \|w\|_\infty$ guarantees that $\mathcal{C}_{\delta,\eta}$ contains the zero function. Using the causality of $\mathbf{F}_\infty$, the boundedness of the operators $\mathbf{P}_t\mathbf{F}_\infty$, and the Lipschitz continuity of ϕ, it is clear that, for given numbers $\delta > 0$ and $\eta > \|w\|_\infty$, there exists $\lambda > 0$ such that, for all $\varepsilon \in (0,\delta]$ and all $u, v \in \mathcal{C}_{\varepsilon,\eta}$,

$$\int_\alpha^{\alpha+\varepsilon} |\mathbf{F}_\infty\phi(u) - \mathbf{F}_\infty\phi(v)|^2 \leq \lambda^2 \int_0^{\alpha+\varepsilon} |u - v|^2\,.$$

Using Hölder's inequality we obtain the estimate

$$\int_\alpha^{\alpha+\varepsilon} |\mathbf{F}_\infty\phi(u) - \mathbf{F}_\infty\phi(v)| \le \lambda\sqrt{\varepsilon}\left(\int_0^{\alpha+\varepsilon} |u-v|^2\right)^{1/2}, \tag{A.3}$$

which holds for all $u, v \in \mathcal{C}_{\varepsilon,\eta}$, and all $\varepsilon \in (0,\delta]$. Moreover, if $v = 0$, then we may conclude that, for all $u \in \mathcal{C}_{\varepsilon,\eta}$ and all $\varepsilon \in (0,\delta]$,

$$\int_\alpha^{\alpha+\varepsilon} |\mathbf{F}_\infty\phi(u)| \le \int_\alpha^{\alpha+\varepsilon} |(\mathbf{F}_\infty\phi(0))(\tau)|\,d\tau + \lambda\sqrt{\varepsilon}\left(\int_0^{\alpha+\varepsilon} |u|^2\right)^{1/2}. \tag{A.4}$$

Set $f(t) = r - (\mathbf{\Psi}_\infty x_0)(t)$, and choose $\rho > 0$ such that

$$\int_\alpha^{\alpha+\rho} (|f(\tau)| + |(\mathbf{F}_\infty\phi(0))(\tau)|)\,d\tau \le \frac{\eta}{2}. \tag{A.5}$$

Now choose $\varepsilon > 0$ such that

$$\varepsilon \le \delta, \quad \varepsilon \le \rho, \quad \varepsilon < \frac{1}{\lambda}, \quad \varepsilon \le \frac{1}{4(\alpha+\rho)}\left(\frac{\eta}{\lambda\max\{\|w\|_\infty, |w(\alpha)|+\eta\}}\right)^2. \tag{A.6}$$

Define the operator Γ by

$$\begin{aligned}(\Gamma u)(t) &= w(t), \qquad 0 \le t \le \alpha,\\ (\Gamma u)(t) &= w(\alpha) + \int_\alpha^t f(\tau)\,d\tau - \int_\alpha^t (\mathbf{F}_\infty\phi(u))(\tau)\,d\tau, \qquad t \ge \alpha,\end{aligned}$$

and set

$$\tilde{\mathcal{C}}_{\varepsilon,\eta} := \{u \in \mathcal{C}_{\varepsilon,\eta} \mid u(t) = w(t) \quad \text{if } 0 \le t \le \alpha\}.$$

Clearly, $\tilde{\mathcal{C}}_{\varepsilon,\eta}$ is a complete metric space, and the lemma follows if we can show that Γ is a contraction on $\tilde{\mathcal{C}}_{\varepsilon,\eta}$.

We first show that $\Gamma(\tilde{\mathcal{C}}_{\varepsilon,\eta}) \subset \tilde{\mathcal{C}}_{\varepsilon,\eta}$. Using (A.4)–(A.6) we obtain, for all $u \in \mathcal{C}_{\varepsilon,\eta}$ and all $t \in [\alpha, \alpha+\varepsilon]$,

$$\begin{aligned}|(\Gamma u)(t) - w(\alpha)| &\le \lambda\sqrt{\varepsilon}\left(\int_0^{\alpha+\varepsilon} |u(\tau)|^2\,d\tau\right)^{1/2} + \frac{\eta}{2}\\ &\le \frac{\eta}{2} + \lambda\sqrt{\varepsilon(\alpha+\rho)}\max\{\|w\|_\infty, |w(\alpha)|+\eta\}\\ &\le \eta,\end{aligned}$$

which shows that $\Gamma(\tilde{\mathcal{C}}_{\varepsilon,\eta}) \subset \tilde{\mathcal{C}}_{\varepsilon,\eta}$. It remains to show that Γ is a contraction on $\tilde{\mathcal{C}}_{\varepsilon,\eta}$. To this end, let $u, v \in \tilde{\mathcal{C}}_{\varepsilon,\eta}$. Using (A.3) we obtain

$$\sup_{0\le\tau\le\alpha+\varepsilon} |(\Gamma u)(\tau) - (\Gamma v)(\tau)| \le \lambda\sqrt{\varepsilon}\left(\int_\alpha^{\alpha+\varepsilon} |u-v|^2\right)^{1/2} \le \varepsilon\lambda \sup_{0\le\tau\le\alpha+\varepsilon} |u(\tau) - v(\tau)|.$$

By (A.6) we have that $\varepsilon\lambda < 1$, showing that Γ is a contraction on $\tilde{\mathcal{C}}_{\varepsilon,\eta}$. ∎

Proof of Lemma 3.2. We proceed in several steps.

Step 1. Existence and uniqueness on a small interval.

An application of Lemma A.1 with $\alpha = 0$ shows that there exists an $\varepsilon > 0$ such that (3.6) has a unique solution on the interval $[0, \varepsilon)$.

Step 2. Extended uniqueness.

Let u_i be a solution of (3.6) on the interval $[0, a_i)$, $i = 1, 2$. We claim that $u_1(t) = u_2(t)$ for all $t \in [0, a)$, where $a = \min(a_1, a_2)$. Seeking a contradiction, assume that there exists $t \in (0, a)$ such that $u_1(t) \neq u_2(t)$. Defining

$$t^* = \inf\{t \in (0, a) \,|\, u_1(t) \neq u_2(t)\}\,,$$

it follows that $t^* > 0$ (by Step 1), $t^* < a$ (by assumption), and $u_1(t^*) = u_2(t^*)$ (by continuity of u_1 and u_2). Clearly, the initial-value problem

$$\begin{aligned} \dot{u}(t) &= k[r - (\mathbf{\Psi}_\infty x_0)(t) - (\mathbf{F}_\infty \phi(u))(t)]\,, \quad t \geq t^*\,, \\ u(t) &= u_1(t)\,, \quad t \in [0, t^*]\,, \end{aligned}$$

is solved by u_1 and u_2. This implies (by Lemma A.1) that there exists an $\varepsilon > 0$ such that $u_1(t) = u_2(t)$ for all $t \in [0, t^* + \varepsilon)$, which contradicts the definition of t^*.

Step 3. Continuation of solutions.

Let u be a solution of (3.6) on the interval $[0, a)$, $a < \infty$. In order to prove that u can be extended to a maximal solution (which satisfies (3.7) if $a_{max} < \infty$), it is sufficient to show that u can be continued to the right (beyond a) if u is bounded on $[0, a)$. Now $u(t) = (\Gamma u)(t)$ for all $t \in [0, a)$, where Γ is the operator defined in the proof of Lemma A.1 with $\alpha = 0$. It is clear that $\lim_{t \to a-} (\Gamma u)(t) = \gamma$ exists and is finite. Consequently, $\lim_{t \to a-} u(t) = \gamma$, and hence setting $u(a) = \gamma$ makes u into a continuous function on $[0, a]$. Finally, Lemma A.1 shows that the initial value problem

$$\begin{aligned} \dot{v} &= k[r - \mathbf{\Psi}_\infty x_0 - \mathbf{F}_\infty \phi(v)]\,, \quad t \geq a\,, \\ v(t) &= u(t)\,, \quad t \in [0, a]\,, \end{aligned}$$

has a unique solution u^* on $[0, a + \varepsilon)$ for some $\varepsilon > 0$. By the causality of the map $\mathbf{F}_\infty \phi$, the function u^* is a solution of (3.6) on $[0, a + \varepsilon)$, i.e., u^* is a continuation of u.

Step 4. Global existence if ϕ is globally Lipschitz.

Assume that ϕ is globally Lipschitz. Seeking a contradiction suppose that $a_{max} < \infty$. Let u be the solution of (3.6) defined on $[0, a_{max})$. Multiplying (3.6) by u and estimating we obtain that, for all $\tau \in [0, a_{max})$,

$$u(\tau)\dot{u}(\tau) \leq k[r^2 + (\mathbf{\Psi}_\infty x_0)^2(\tau) + u^2(\tau) + |(\mathbf{F}_\infty \phi(u))(\tau) u(\tau)|\,]\,. \tag{A.7}$$

Integrating (A.7) from 0 to t and combining the estimate

$$\int_0^t |(\mathbf{F}_\infty \phi(u))u| \,\leq \int_0^t |\mathbf{F}_\infty(\phi(u) - \phi(0))|\,|u| \,+ \frac{1}{2}\left(\int_0^t (\mathbf{F}_\infty \phi(0))^2 \,+ \int_0^t u^2\right),$$

the Cauchy–Schwarz inequality, and the global Lipschitz property of ϕ, it can be readily shown that there exists positive constants α and β such that, for all $t \in [0, a_{max})$,

$$u^2(t) \leq \alpha + \beta \int_0^t u^2(\tau)\, d\tau\,.$$

An application of Gronwall's lemma then shows that $u^2(t) \leq \alpha e^{\beta t}$ for all $t \in [0, a_{max})$. Hence u is bounded on $[0, a_{max})$, which by Step 3 is in contradiction to the maximality of a_{max}. ∎

Proof of Lemma 3.4. Since $0 < 2\kappa < K$, it follows that there exists $\varepsilon > 0$ such that

$$1 + 2\kappa \mathrm{Re}\, \frac{\mathbf{G}(s)}{s} \geq \varepsilon \qquad \text{for all } s \in \mathbb{C}_0 \,.$$

Hence

$$1 + 2\kappa \mathrm{Re}\, \frac{\mathbf{G}(i\omega)}{i\omega} \geq \varepsilon \qquad \text{for all } \omega \in \mathbb{R},\, \omega \neq 0 \,,$$

and thus

$$1 + 2\kappa \mathrm{Re}\mathbf{H}(i\omega) \geq \varepsilon \qquad \text{for all } \omega \in \mathbb{R} \,. \tag{A.8}$$

By considering

$$e^{-(1+2\kappa \mathrm{Re}\mathbf{H}(s))} = \left| e^{-(1+2\kappa \mathbf{H}(s))} \right| ,$$

applying the maximum modulus theorem, and using the fact that $\mathbf{H}(s) \to 0$ as $|s| \to \infty$ in $\mathbb{C}_0$, it follows from (A.8) that

$$1 + 2\kappa \mathrm{Re}\mathbf{H}(s) \geq \varepsilon \qquad \text{for all } s \in \mathbb{C}_0 \,.$$

Therefore, for all $s \in \mathbb{C}_0$,

$$\varepsilon + \kappa^2 \mathbf{H}(s)\bar{\mathbf{H}}(s) \leq (1 + \kappa \mathbf{H}(s))(1 + \kappa \bar{\mathbf{H}}(s)) \,.$$

Consequently, for all $s \in \mathbb{C}_0$,

$$\mathbf{H}(s)(1 + \kappa \mathbf{H}(s))^{-1} \bar{\mathbf{H}}(s)(1 + \kappa \bar{\mathbf{H}}(s))^{-1} < \frac{1}{\kappa^2} \,,$$

yielding (3.11).

By using the identity $s(sI - A)^{-1} = A(sI - A)^{-1} + I$, we easily obtain

$$\mathbf{H}(s) = \frac{1}{s} \left(\mathbf{G}(s) - \mathbf{G}(0) \right) = C_L (sI - A)^{-1} A^{-1} B \,.$$

Consider the state-space system given by the triple $(A, A^{-1}B, C_L)$. For any $T > 0$, the input-to-state map of this system maps $L^2(0,T)$ boundedly into X_1. Consequently, the triple $(A, A^{-1}B, C_L)$ defines a Pritchard–Salamon system with respect to the spaces X_1 and X; see Curtain et al. [4] or Pritchard and Townley [31]. Now, (3.11) means in particular that the closed-loop system obtained from $\mathbf{H}$ by negative output feedback with gain κ is input-output stable. By the equivalence of input-output and exponential stability (see [4] or [32]), we may conclude that the semigroup generated by A_κ, with $0 < 2\kappa < K$, is exponentially stable. Moreover, combining Theorem 2.4 in Pritchard and Townley [30] (or, alternatively, Theorem 1 in Logemann [12]) and (3.11), it follows that the structured complex stability radius of A_κ with respect to the weightings $A^{-1}B$ and C_L is greater than κ. Therefore, an application of Proposition 1.5 in [31] shows that the Riccati equation (3.12) has a self-adjoint positive-semidefinite solution $P \in \mathcal{B}(X)$ such that (3.12) holds for all $x_1, x_2 \in \mathrm{dom}(A_\kappa)$. □

Proof of Lemma 3.5. It is clear that $\phi^\diamond \in L^\infty_{loc}(-\infty, \infty)$ if ϕ is locally Lipschitz and that $\phi^\diamond \in L^\infty(-\infty, \infty)$ if ϕ is globally Lipschitz. Moreover, as the limsup of a

sequence of Borel functions, $\phi^\diamond$ is a Borel function. Consequently, $\phi^\diamond \circ u$ is Lebesgue measurable for all Lebesgue measurable functions u. Let u be absolutely continuous. Setting $v = \phi \circ u$, it follows from the Lipschitz continuity of ϕ and the absolute continuity of u that v is absolutely continuous. If $t \in \mathbb{R}$ is such that u is differentiable at t, then we have

$$v(t+h) - v(t) = \phi(u(t) + h\dot{u}(t)) - \phi(u(t)) + \phi(u(t+h)) - \phi(u(t) + h\dot{u}(t))\,. \tag{A.9}$$

Moreover, by Lipschitz continuity of ϕ, there exists a constant $L > 0$ such that, for all sufficiently small $|h|$,

$$\left|\frac{1}{h}\left[\phi(u(t+h)) - \phi(u(t) + h\dot{u}(t))\right]\right| \le L\left|\frac{1}{h}[u(t+h) - u(t)] - \dot{u}(t)\right|. \tag{A.10}$$

Let $\mathcal{D} \subset \mathbb{R}$ be the set of all points t such that both u and v are differentiable at t. Then $\mathcal{D}$ is of full measure, and combining (A.9) and (A.10) yields

$$\lim_{h\to 0}\frac{1}{h}[v(t+h) - v(t)] = \lim_{h\to 0}\frac{1}{h}[\phi(u(t) + h\dot{u}(t)) - \phi(u(t))] \quad \text{for all } t \in \mathcal{D}.$$

Therefore, for every $t \in \mathcal{D}$,

$$\dot{v}(t) = 0 \qquad \text{if } \dot{u}(t) = 0\,, \tag{A.11}$$

$$\dot{v}(t) = \lim_{h\to 0}\frac{\phi(u(t) + h\dot{u}(t)) - \phi(u(t))}{h\dot{u}(t)}\,\dot{u}(t)$$

$$= \phi'(u(t))\dot{u}(t) \qquad \text{if } \dot{u}(t) \neq 0\,. \tag{A.12}$$

In particular, if $t \in \mathcal{D}_0 := \{t \in \mathcal{D} \,|\, \dot{u}(t) \neq 0\}$, then ϕ is differentiable at $u(t)$. For $t \in \mathcal{D}_0$ we have, of course, $\phi^\diamond(u(t)) = \phi'(u(t))$, and thus it follows from (A.11) and (A.12) that

$$\dot{v}(t) = \phi^\diamond(u(t))\dot{u}(t) \qquad \text{for a.e. } t \in [0,\infty)\,. \qquad \square$$

ON THE STABILIZATION OF A FLEXIBLE BEAM WITH A TIP MASS*

FRANCIS CONRAD† AND ÖMER MORGÜL‡

Abstract. We study the stability of a flexible beam that is clamped at one end and free at the other; a mass is also attached to the free end of the beam. To stabilize this system we apply a boundary control force at the free end of the beam. We prove that the closed-loop system is well-posed and is exponentially stable. We then analyze the spectrum of the system for a special case and prove that the spectrum determines the exponential decay rate for the considered case.

1. Introduction. In this paper, we study the stability of a flexible beam that is clamped at one end and is free at the other end; a mass is also attached to the free end. The equations of motion for this system are given by

$$u_{tt} + u_{xxxx} = 0, \qquad 0 < x < 1, \qquad t \geq 0, \tag{1.1}$$

$$u(0,t) = u_x(0,t) = u_{xx}(1,t) = 0, \qquad t \geq 0, \tag{1.2}$$

$$-u_{xxx}(1,t) + mu_{tt}(1,t) = w(t), \qquad t \geq 0, \tag{1.3}$$

where $m > 0$ is the tip mass and $w(t)$ is the boundary control force applied at the free end of the beam; a subscript letter denotes the partial derivation with respect to that variable. For simplicity, and without loss of generality, the length of the beam, the mass per unit length, and the flexural rigidity of the beam are chosen to be unity. Our problem is to find a feedback control law for $w(t)$ so that the solutions of the resulting closed-loop system decay uniformly to zero. This can be achieved with a highly unbounded feedback law; see (2.1).

The model given by (1.1)–(1.3) is a variant of the SCOLE model in the sense that one has neglected the moment of inertia at $x = 1$, which has been studied in the past; see, e.g., [1], [9], [14], [15]. It is known that for such types of models the feedback law

$$w(t) = -\alpha u_t(1,t), \qquad \alpha > 0, \qquad t \geq 0, \tag{1.4}$$

is sufficient for strong (i.e., *asymptotic*) stability but not sufficient for uniform (i.e., *exponential*) stability; see [9], where arbitrarily slow decay is proven by using asymptotic estimates of the eigenvalues. In fact, as shown in [14], the control law given by

(1.4) may be considered as a compact perturbation of the uncontrolled system. It is well known that such compact perturbations are not sufficient to provide uniform stabilization; see [6], [17], [20]. Hence, to obtain uniform stability one has to choose "stronger" feedback terms, such as u_{xxxt} (see [13], [14]), where the lack of uniform stability for the SCOLE model with usual feedback laws (e.g., velocity feedback; see (1.4)) was proven by using the compactness argument, and uniform decay of the energy was obtained by means of higher-order feedback for rather smooth initial data. Also in [15], decay estimates for a flexible cable with a tip mass were given. Let us mention that these papers study the asymptotic or uniform decay for hybrid systems by using energy multipliers; thus the decay is qualitative, and one cannot conclude on the optimality of the decay rate. In [3] a flexible beam with rate control on the bending moment was considered, the uniform decay was proven by using the estimates of the resolvent operator on the imaginary axis, and a careful analysis of the eigenvalues and eigenfunctions was given (similar to the one given in [12] but for a harder problem). In [1] a three-dimensional model for the SCOLE system, including the moment of inertia at $x = 1$, is considered, and then a feedback law similar to (1.4) and another feedback law based on optimal control techniques are studied. As stated above, these results also show the asymptotical or uniform decay of energy for the system considered, but do not give the optimality of the decay rate.

In this paper we investigate the uniform stability of the system given by (1.1)–(1.3). The paper is organized as follows. In the next section we prove the well-posedness and the uniform stability of (1.1)–(1.3) with a proper choice for $w(t)$ for a norm weaker than the one used in [14] by introducing a specific change of variables. Then we study the spectrum of the system for a particular case and prove that for the considered case the spectrum determines the exponential decay rate for almost all $\alpha > 0$. We also show that in case $m = 0$ in (1.1)–(1.4) (i.e., the case of the cantilevered beam with a boundary force control), for almost all $\alpha > 0$, the spectrum determines the exponential growth rate (see Appendix). Finally we give some concluding remarks.

2. Stability results. For the system given by (1.1)–(1.3) we propose the following linear feedback control law for $w(t)$:

$$w(t) = -\alpha u_t(1,t) + \beta u_{xxxt}(1,t), \qquad t \geq 0, \tag{2.1}$$

where α and β are positive constants.

We define the auxiliary function η as

$$\eta(t) = -u_{xxx}(1,t) + \frac{m}{\beta} u_t(1,t), \qquad t \geq 0. \tag{2.2}$$

Upon substituting (2.1) and (2.2) into (1.3), the latter becomes

$$\beta\dot{\eta}(t) + \eta(t) + \left(\alpha - \frac{m}{\beta}\right) u_t(1,t) = 0, \qquad t \geq 0, \tag{2.3}$$

where a dot represents the time derivative. We note that a similar control law has been applied to the stabilization of a cable with a tip mass, see [10].

Let us introduce the following spaces:

$$\mathcal{V} = \{u : [0,1] \to \mathbf{R} | u \in H^2(0,1), \quad u(0) = u_x(0) = 0\}, \tag{2.4}$$

$$\mathcal{H} = \{(u\ v\ \eta)^T | u \in \mathcal{V},\ v \in L^2(0,1),\ \eta \in \mathbf{R}\}, \tag{2.5}$$

where the superscript T stands for the transpose; the spaces $L^2(0,1)$ and $H^k(0,1)$ are defined as

$$L^2(0,1) = \left\{ y : [0,1] \to \mathbf{R} | \int_0^1 y^2 dx < \infty \right\}, \tag{2.6}$$

$$H^k(0,1) = \{ y : [0,1] \to \mathbf{R} | y,\ y^{(1)}, \ldots, y^{(k)} \in L^2(0,1) \}. \tag{2.7}$$

In $\mathcal{H}$ we define the following inner-product:

$$< y, \tilde{y} >_{\mathcal{H}} = \int_0^1 (u_{xx}\tilde{u}_{xx} + v\tilde{v})dx + \ K\eta\tilde{\eta}, \tag{2.8}$$

where $y = (u\ v\ \eta)^T \in \mathcal{H}$, $\tilde{y} = (\tilde{u}\ \tilde{v}\ \tilde{\eta})^T \in \mathcal{H}$, $K > 0$ is chosen as

$$K = \frac{\beta^2}{m + \alpha\beta}. \tag{2.9}$$

The reason for this choice will become clear later. Next we define the unbounded operator $A : D(A) \subset \mathcal{H} \to \mathcal{H}$ as follows:

$$A \begin{pmatrix} u \\ v \\ \eta \end{pmatrix} = \begin{pmatrix} v \\ -u_{xxxx} \\ -\frac{1}{\beta}\eta - \frac{1}{\beta}(\alpha - \frac{m}{\beta})v(1) \end{pmatrix}, \tag{2.10}$$

where the domain $D(A)$ of the operator A is defined as

$$D(A) = \Big\{ (u\ v\ \eta\ )^T | u \in H^4(0,1) \cap \mathcal{V}, v \in \mathcal{V},\ \eta \in \mathbf{R}, \\ u_{xx}(1) = 0, \quad \eta = -u_{xxx}(1) + \frac{m}{\beta}v(1) \Big\}. \tag{2.11}$$

With the previous notation, (1.1)–(1.2) and (2.3) can be written formally as

$$\dot{y} = Ay, \qquad y(0) \in \mathcal{H}, \tag{2.12}$$

where $y = (u\ v\ \eta)^T$, η is defined by (2.2), and $v = u_t$.

THEOREM 2.1. *The operator A, defined by* (2.10) *and* (2.11)*, generates a C_0 semigroup of contractions on $\mathcal{H}$. (For the terminology on the semigroup theory, the reader is referred to* [11].)

Proof. We apply the Lumer–Phillips theorem; see, e.g., [11, p. 14]. First, for any $y = (u\ v\ \eta)^T \in D(A)$,

$$\begin{aligned} \langle Ay,\ y \rangle_{\mathcal{H}} &= \int_0^1 (u_{xx}v_{xx} - vu_{xxxx})dx - \frac{K}{\beta}\eta\left(\eta + \left(\alpha - \frac{m}{\beta}\right)v(1)\right) \\ &= -\frac{K}{\beta}u_{xxx}^2(1) - \frac{Km\alpha}{\beta^2}v^2(1), \end{aligned} \tag{2.13}$$

where to derive the last equation we integrated by parts twice and used (1.2), (2.2), and (2.9). Note that due to the particular choice of K given by (2.9), the term multiplying $v(1)u_{xxx}(1)$ in (2.13) vanishes. It follows from (2.13) that the operator A is dissipative.

Next we show that the range of the operator $\lambda I - A : D(A) \subset \mathcal{H} \to \mathcal{H}$ is onto for $\lambda > 0$; that is, for any given $z = (f\ g\ h)^T \in \mathcal{H}$, we have to find $y = (u\ v\ \eta)^T \in D(A)$ so that

$$(\lambda I - A)y = z, \tag{2.14}$$

which is equivalent to the following set of equations:

$$\lambda u - v = f, \tag{2.15}$$

$$\lambda v + u_{xxxx} = g, \tag{2.16}$$

$$\left(\lambda + \frac{1}{\beta}\right)\eta + \frac{1}{\beta}\left(\alpha - \frac{m}{\beta}\right)v(1) = h. \tag{2.17}$$

Upon substituting (2.15) into (2.16), the latter becomes

$$\lambda^2 u + u_{xxxx} = \lambda f + g. \tag{2.18}$$

By using (2.15) and (2.2) in (2.17), the latter becomes

$$-\left(\lambda + \frac{1}{\beta}\right)u_{xxx}(1) + \frac{\lambda(\alpha + m\lambda)}{\beta}u(1) = h + \frac{m\lambda + \alpha}{\beta}f(1)\ . \tag{2.19}$$

Therefore to prove that $\lambda I - A$ is onto, we have to prove the existence of a solution for the following set of equations:

$$\lambda^2 u + u_{xxxx} = f^*, \tag{2.20}$$

$$u(0) = u_x(0) = u_{xx}(1) = 0, \tag{2.21}$$

$$-u_{xxx}(1) + cu(1) = h^*, \tag{2.22}$$

where f^*, h^*, and c are given by

$$f^* = \lambda f + g \in L^2(0,1), \qquad h^* = \frac{\beta}{\lambda\beta + 1}h + \frac{m\lambda + \alpha}{\lambda\beta + 1}f(1) \in \mathbf{R}, \tag{2.23}$$
$$c = \frac{\lambda(m\lambda + \alpha)}{\lambda\beta + 1} > 0.$$

The existence, as well as the uniqueness and continuous dependence, of a solution of (2.20)–(2.23) with respect to (f^*, h^*) can be considered as standard. One way to prove it is to use the weak formulation of (2.20)–(2.23), which is

$$\int_0^1 u_{xx}\varphi_{xx}dx + \lambda^2\int_0^1 u\varphi dx + cu(1)\varphi(1) = \int_0^1 f^*\varphi dx + h^*\varphi(1), \qquad u \in \mathcal{V}, \forall\varphi \in \mathcal{V}. \tag{2.24}$$

Since $c > 0$, the left-hand side of (2.24) is a coercive bilinear form of φ and u. Then the existence and uniqueness of a $u \in \mathcal{V}$ satisfying (2.24) follow from the well-known

Lax–Milgram theorem; see e.g. [19, p. 26]. By standard regularity $u \in H^4(0,1)$ and by using particular φ, one recovers the boundary conditions in u. Then v given by (2.15) and η given by (2.17) are unique and $(u\ v\ \eta)^T \in D(A)$. This shows that the operator $\lambda I - A$ is onto for $\lambda > 0$, and the proof of the theorem now follows from the Lumer–Phillips theorem. □

Remark 1. It follows from Theorum 2.1 that for $(u_0\ v_0\ \eta_0)^T \in D(A)$, the problem (2.12) has a strong solution $(u(t)\ v(t)\ \eta(t))^T \in C^1(\mathbf{R}_+, \mathcal{V} \times L^2(0,1) \times \mathbf{R}) \cap C^0(\mathbf{R}_+, D(A))$. Thus $\eta(t) = -u_{xxx}(1,t) + \frac{m}{\beta} u_t(1,t)$ is differentiable, but $u_{xxx}(1,t)$ and $u_t(1,t)$ are not guaranteed to be separably differentiable. This will be the case if $(u_0\ v_0\ \eta_0)^T \in D(A^2)$.

Next we prove that the semigroup generated by the operator A decays exponentially to zero.

THEOREM 2.2. *Let $T(t)$ be the C_0 semigroup of contractions generated by the operator A on $\mathcal{H}$. Then there exist positive constants M and δ such that the following holds:*

$$\|T(t)\|_{\mathcal{L}(\mathcal{H})} \le M e^{-\delta t}, \qquad t \ge 0, \tag{2.25}$$

where the norm used is the norm induced by the inner-product given by (2.8).

Proof. We first define the following function:

$$V(t) = tE(t) + \int_0^1 x\ u_t(x,t)\ u_x(x,t)dx, \tag{2.26}$$

where the "energy" $E(t)$ is given by

$$E(t) = \frac{1}{2}\|z(t)\|^2_{\mathcal{H}} = \frac{1}{2}\int_0^1 (u_t^2(x,t) + u_{xx}^2(x,t))dx + \frac{K}{2}\eta^2(t), \tag{2.27}$$

$z(t) = (u(\cdot,t)\ u_t(\cdot,t)\ \eta(t))^T \in \mathcal{H}$ is the solution of (2.12), and K is given by (2.9). Assume that $z(0) \in D(A)$; then by semigroup property we have $z(t) = T(t)z(0) \in D(A)\ \forall t \ge 0$. Hence, in view of (2.13), we have

$$\dot{E}(t) = < Az(t),\ z(t) >_{\mathcal{H}} = -\frac{K}{\beta} u_{xxx}^2(1,t) - \frac{Km\alpha}{\beta^2} u_t^2(1,t)\ \le\ 0. \tag{2.28}$$

Next, by using Cauchy–Schwarz and Poincaré's inequalities, it can easily be shown that the following holds for a positive constant C:

$$(t - C)E(t) \le V(t) \le (t + C)E(t), \qquad t \ge 0. \tag{2.29}$$

(One can take $C = 1$ or even $C = 1/\sqrt{2}$.) By differentiating (2.26) with respect to time and by using (1.1), we obtain

$$\begin{aligned} \dot{V}(t) = E(t) + t\dot{E}(t) &+ \int_0^1 x\ u_{xt}(x,t)\ u_t(x,t)dx \\ &- \int_0^1 x\ u_x(x,t)\ u_{xxxx}(x,t)dx. \end{aligned} \tag{2.30}$$

Using integration by parts and (1.2), we obtain

$$\int_0^1 x\ u_x(x,t)\ u_{xxxx}(x,t)dx = u_x(1,t)\ u_{xxx}(1,t) + \frac{3}{2}\int_0^1 u_{xx}^2(x,t)dx, \tag{2.31}$$

$$\int_0^1 x\ u_{xt}(x,t)\ u_t(x,t)dx = \frac{1}{2}u_t^2(1,t) - \frac{1}{2}\int_0^1 u_t^2(x,t)\ dx. \tag{2.32}$$

By using (1.2), we obtain

$$u_x^2(1,t) \le \int_0^1 u_{xx}^2(x,t)dx. \tag{2.33}$$

We also have the following inequalities:

$$u_x(1,t)u_{xxx}(1,t) \le \delta_1 u_x^2(1,t) + \frac{1}{\delta_1}u_{xxx}^2(1,t), \tag{2.34}$$

$$\eta^2(t) \le 2u_{xxx}^2(1,t) + 2\frac{m^2}{\beta^2}u_t^2(1,t), \tag{2.35}$$

where $\delta_1 > 0$ is an arbitrary constant. By using (2.28) and (2.31)–(2.35) in (2.30), we obtain

$$\begin{aligned}\dot{V}(t)\ \le -(1-\delta_1)\int_0^1 u_{xx}^2(x,t)dx - \left[\frac{K}{\beta}t - K - \frac{1}{\delta_1}\right]u_{xxx}^2(1,t)\\ - \left[\frac{Km\alpha}{\beta^2}t - \frac{1}{2} - \frac{Km^2}{\beta^2}\right]u_t^2(1,t).\end{aligned} \tag{2.36}$$

By choosing $\delta_1 < 1$, the integral term in (2.36) is negative. Hence there exists a constant $T \ge 0$, which depends only on the constants $K,\ m,\ \alpha,\ \beta,$ and δ_1 such that the following holds:

$$\dot{V}(t) \le 0, \qquad t \ge T. \tag{2.37}$$

Now, from (2.29) and (2.37) we obtain the following:

$$E(t) \le \frac{T+C}{t-C}E(0), \qquad t > \max\{C,T\}. \tag{2.38}$$

Note that $E(t) = \frac{1}{2}\|z(t)\|_{\mathcal{H}}^2 = \frac{1}{2}\|T(t)z(0)\|_{\mathcal{H}}^2$; hence from (2.38) it follows that $\|T(t)\|_{\mathcal{L}(\mathcal{H})} < 1$ for $t > 0$ sufficiently large. Hence it follows from the semigroup property that the exponential decay, i.e., (2.25), holds. □

Remark 2. From (2.25) and (2.27) we conclude that both the "energy" associated with the flexible beam (i.e., the integral terms in (2.27)) and η defined by (2.2) decay exponentially to zero. However, we cannot conclude that the same holds separately for the tip mass velocity $u_t(1,t)$ and $u_{xxx}(1,t)$. If we assume that $z(0) \in D(A)$, then we also have for the graph norm

$$\|T(t)z(0)\|_{D(A)} \le Me^{-\delta t}\|z(0)\|_{D(A)}.$$

In this case, $T(t)z(0)$ decays exponentially to zero in $H^4(0,1) \times H^2(0,1) \times \mathbf{R}$. Since, similar to (2.33), we have

$$u_t^2(1,t) \le \int_0^1 u_{xt}^2(x,t)dx,$$

we obtain exponential decay of the tip mass velocity $u_t(1,t)$ and $u_{xxx}(1,t)$ uniformly for all smooth initial data $z(0) \in D(A)$ bounded in $D(A)$ for the graph norm.

3. Analysis of the spectrum. In this section we calculate the spectrum of the operator A for a special case and claim that the spectrum determines the optimal exponential decay rate given by (2.25) for the considered case. Our method is to prove that a system of eigenvectors of A forms a Riesz basis in $\mathcal{H}$. To obtain this result we compare the flexible beam with a tip mass to the flexible beam without a tip mass for the spectral properties. Here we have to work in the complexified Hilbert spaces $\mathcal{V}$, $L^2(0,1)$ and $\mathcal{H}$. For convenience we do not change the notation for these spaces.

Let $\lambda \in \mathbf{C}$ be an eigenvalue of A and let $y = (u\ v\ \eta)^T \in D(A)$ be a corresponding eigenvector. To find y we have to solve (2.14), and hence (2.15)–(2.17) for $z = (f\ g\ h)^T = 0$. Using (2.15) in (2.16), the latter, together with the boundary conditions, becomes

$$\lambda^2 u + u_{xxxx} = 0, \tag{3.1}$$

$$u(0) = u_x(0) = u_{xx}(1) = 0. \tag{3.2}$$

Similarly, by using (2.15) and (2.2) in (2.17), the latter becomes (cf. (2.19))

$$-\left(\lambda + \frac{1}{\beta}\right) u_{xxx}(1) + \frac{\lambda(\alpha + m\lambda)}{\beta} u(1) = 0. \tag{3.3}$$

By solving (3.1)–(3.3) one can find u. Then v and η can be found from (2.15) and (2.2), respectively.

The solutions of (3.1), together with the first two boundary conditions in (3.2), can be found as (for $0 \le x \le 1$)

$$u(x) = c_1(\cosh \tau x - \cos \tau x) + c_2(\sinh \tau x - \sin \tau x), \qquad \lambda = i\tau^2, \tag{3.4}$$

where c_1 and c_2 are constants to be determined by the remaining boundary conditions, cosh and sinh are the hyperbolic cosine and sine functions, respectively, and τ is one square root of λ/i. The choice of the sign is not important since by using $-\tau$ instead of τ nothing changes except the signs of the eigenvectors associated with λ.

By using (3.4) in (3.3) and the last boundary condition in (3.2), we obtain

$$\tau^2(\cosh \tau + \cos \tau)c_1 + \tau^2(\sinh \tau + \sin \tau)c_2 = 0, \tag{3.5}$$

$$\begin{aligned}[-q_1(\lambda)\tau^3(\sinh \tau - \sin \tau) + q_2(\lambda)(\cosh \tau - \cos \tau)]c_1 \\ +[-q_1(\lambda)\tau^3(\cosh \tau + \cos \tau) + q_2(\lambda)(\sinh \tau - \sin \tau)]c_2 = 0,\end{aligned} \tag{3.6}$$

where

$$q_1(\lambda) = \lambda + \frac{1}{\beta}, \qquad q_2(\lambda) = \frac{\lambda(m\lambda + \alpha)}{\beta}.$$

By writing (3.5)–(3.6) in matrix form and taking the determinant of the coefficient matrix, it can easily be shown that (3.5)–(3.6) admit nontrivial solutions for c_1 and c_2 if and only if λ (hence τ) satisfies the following equation with λ necessarily nonzero:

$$-\tau^3 q_1(\lambda)(1 + \cosh \tau \cos \tau) + q_2(\lambda)(\sinh \tau \cos \tau - \cosh \tau \sin \tau) = 0. \tag{3.7}$$

The solutions of (3.7) give the eigenvalues of A; the corresponding eigenvectors can be found from (3.4)–(3.6), (2.15), and (2.2).

In what follows we analyze the spectrum of A for the case $\alpha = \frac{m}{\beta}$. From (2.3) or (2.10) it is clear that this choice leads to simplifications in the system (1.1)–(1.3) or (2.12), especially for the asymptotic behavior since the system is then uncoupled, except for the initial conditions. Then (3.7) can be written in the following form:

$$\left(\lambda + \frac{1}{\beta}\right)[-\tau^3(1+\cosh\tau\cos\tau) + \alpha\lambda(\sinh\tau\cos\tau - \cosh\tau\sin\tau)] = 0. \tag{3.8}$$

From (3.8) it follows that $\lambda_* = -\frac{1}{\beta}$ is an eigenvalue of A. To find the remaining eigenvalues of A let us define the function $f(\cdot)$ given by

$$f(\tau) = -\tau^3(1+\cosh\tau\cos\tau) + \alpha\lambda(\sinh\tau\cos\tau - \cosh\tau\sin\tau), \tag{3.9}$$

which is just the remaining factor of (3.8) after the division by the term $(\lambda + \frac{1}{\beta})$. Hence the remaining eigenvalues of A are precisely the (nonzero) roots of this factor:

$$-\tau^3(1+\cosh\tau\cos\tau) + \alpha\lambda(\sinh\tau\cos\tau - \cosh\tau\sin\tau) = 0. \tag{3.10}$$

It is known that (3.10) is just the characteristic equation for the system given by (1.1)–(1.4) with $m = 0$, i.e., the clamped-free (cantilevered) beam with boundary force controller at the free end; see, e.g., [12]. Moreover the eigenvectors of A corresponding to the roots of (3.10) are also related to the eigenvectors of the cantilevered beam in a simple way. For these reasons we will briefly study the spectral properties of the cantilevered beam in the following subsection.

3.1. Spectral analysis of the cantilevered beam. We consider the Euler–Bernoulli beam with boundary force control:

$$u_{tt} + u_{xxxx} = 0, \qquad 0 < x < 1, \quad t \geq 0, \tag{3.11}$$

$$u(0,t) = u_x(0,t) = u_{xx}(1,t) = 0, \quad u_{xxx}(1,t) = \alpha u_t(1,t), \quad t \geq 0, \tag{3.12}$$

where $\alpha > 0$. Note that this system is the same as (1.1)–(1.4) with $m = 0$.

We define the following spaces:

$$V = \{v \in \mathbf{H}^2(0,1); \quad v(0) = v_x(0) = 0\}, \tag{3.13}$$

$$D(B) = \{(u\ v)^T | u \in \mathbf{H}^4(0,1) \cap V, v \in V, u_{xx}(1) = 0,\ u_{xxx}(1) = \alpha v(1)\}. \tag{3.14}$$

The operator B for the problem (3.11)–(3.12) is

$$B\begin{pmatrix} u \\ v \end{pmatrix} = \begin{pmatrix} v \\ -u_{xxxx} \end{pmatrix}, \qquad (u\ v)^T \in D(B). \tag{3.15}$$

The system given by (3.11), (3.12) can be written formally as

$$\dot{z}(t) = Bz(t), \quad z(0) \in V \times \mathbf{L}^2(0,1), \tag{3.16}$$

where $z = (u(\cdot,t)\ u_t(\cdot,t))^T$, and the domain of B is given by (3.14).

We first state the following well-known result.

LEMMA 3.1. *Consider the system given by* (3.16).

i : *B generates an exponentially stable C_0 semigroup of contractions in $V \times \mathbf{L}^2(0,1)$.*

ii : *B has compact resolvent for $\lambda > 0$.*

iii : *The eigenvalues of B are countable and isolated. Moreover each eigenvalue has finite algebraic multiplicity.*

Proof. For **i** and **ii**, see [3]. Then **iii** follows from **ii**; see, e.g., [8, p. 187], [5, p. 2292]. □

Writing $z = (u\ v)^T$ and $Bz = \lambda z$, we get the following well-known characteristic equation:

$$f(\tau) = -\tau^3(1 + \cosh\tau\cos\tau) + i\alpha\tau^2(\sinh\tau\cos\tau - \cosh\tau\sin\tau) = 0, \tag{3.17}$$

where $\lambda = i\tau^2$. Note that $\lambda = 0$ is not an eigenvalue of B. Hence the roots of (3.17) are precisely the eigenvalues of B, and by Lemma 3.1, (3.17) has only countably many roots; moreover each root is isolated and has finite algebraic multiplicity. Eigenvectors corresponding to $\lambda = i\tau^2$ can be taken as $(\varphi_1\ \lambda\varphi_1)^T$, where

$$\begin{aligned}\varphi_1(\tau,x) = {} & (\ \cosh\tau + \cos\tau)(\sinh\tau x - \sin\tau x) \\ & - (\sinh\tau + \sin\tau)(\cosh\tau x - \cos\tau x).\end{aligned} \tag{3.18}$$

All eigenvalues are geometrically simple. For the algebraic multiplicity we have the following result.

LEMMA 3.2. *Consider the operator B on $V \times \mathbf{L}^2(0,1)$ given by* (3.15)*, where $D(B)$ is given by* (3.14)*. Let λ be an eigenvalue of B and set $\lambda = i\tau^2$. Then the algebraic multiplicity of λ is* 1 *if and only if $f(\tau) = 0$ and $f'(\tau) \neq 0$ (i.e., if and only if τ is a simple root of* (3.17)).

Proof. The algebraic multiplicity of λ is greater than 1 if and only if $\mathrm{Ker(B - \lambda I)^2 \backslash Ker(B - \lambda I) \neq \emptyset}$, i.e., there exists $(\psi_1\ \psi_2)^T$ which satisfies

$$(B - \lambda I)\begin{pmatrix} \psi_1 \\ \psi_2 \end{pmatrix} = \begin{pmatrix} \varphi_1 \\ \lambda\varphi_1 \end{pmatrix}, \tag{3.19}$$

which is equivalent to the following set of equations:

$$\psi_2 - \lambda\psi_1 = \varphi_1, \tag{3.20}$$

$$-\psi_{1xxxx} - \lambda\psi_2 = \lambda\varphi_1, \tag{3.21}$$

$$\psi_1(0) = \psi_{1x}(0) = \psi_{1xx}(1) = 0, \quad \psi_{1xxx}(1) = \alpha\psi_2(1). \tag{3.22}$$

By eliminating ψ_2, we obtain the following set of equations:

$$-\psi_{1xxxx} - \lambda^2\psi_1 = 2\lambda\varphi_1, \tag{3.23}$$

$$\psi_1(0) = \psi_{1x}(0) = \psi_{1xx}(1) = 0, \quad \psi_{1xxx}(1) = \alpha\lambda\psi_1(1) + \alpha\varphi_1(1). \tag{3.24}$$

The general solution of (3.23) satisfying the first three conditions of (3.24) is given for all λ by $\psi_1 = \frac{d\varphi_1}{d\lambda} + z$, where $\frac{d\varphi_1}{d\lambda} = \frac{1}{2i\tau}\frac{d\varphi_1}{d\tau}$ and z satisfies

$$z_{xxxx} + \lambda^2 z = 0, \tag{3.25}$$

$$z(0) = z_x(0) = z_{xx}(1) = 0. \tag{3.26}$$

The last condition of (3.24) becomes

$$z_{xxx}(1) - \alpha\lambda z(1) = \alpha\varphi_1(1) + \alpha\lambda\frac{d\varphi_1}{d\lambda}(1) - \left(\frac{d\varphi_1}{d\lambda}\right)_{xxx}(1) = \mu. \tag{3.27}$$

By computing μ defined in (3.27) from φ_1 and $\frac{d\varphi_1}{d\lambda}$ we get

$$\mu = \frac{d}{d\lambda}[\alpha\lambda\varphi_1(1) - \varphi_{1xxx}(1)] = 2\frac{df(\tau)}{d\lambda} = \frac{1}{i\tau}f'(\tau). \tag{3.28}$$

We conclude that the algebraic multiplicity of λ is larger than 1 if and only if (3.25)–(3.27) admit a solution z. Multiplying (3.25) by φ_1, integrating by parts, and using the boundary conditions on z and φ_1, we obtain

$$z_{xxx}(1)\varphi_1(1) - z(1)\varphi_{1xxx}(1) = [z_{xxx}(1) - \alpha\lambda z(1)]\varphi_1(1) = 0. \tag{3.29}$$

Since φ_1 is an eigenfunction of B, it could easily be shown that $\varphi_1(1) \neq 0$ (otherwise one obtains a contradiction; see, e.g., [4, p. 429]). Hence (3.25)–(3.27) admit a solution if and only if $\mu = 0$, in which case we could choose $z = \varphi_1$. Hence λ is algebraically simple if and only if $f(\tau) = 0$ and $f'(\tau) \neq 0$, i.e., if and only if λ is a simple root of (3.17). □

By Lemma 3.1, B has at most countably many and isolated eigenvalues. Let $\lambda_n = i\tau_n^2$, $n \in \mathbf{Z}$, be the roots of (3.17). The corresponding eigenvectors of B can be given as

$$F_{nr} = \begin{pmatrix} \varphi_1(\tau_n, x) \\ \lambda_n\varphi_1(\tau_n, x) \end{pmatrix}, \tag{3.30}$$

where φ_1 is given by (3.18).

THEOREM 3.3. *Consider the operator B on $V \times \mathbf{L}^2(0,1)$ given by* (3.15), *where $D(B)$ is given by* (3.14).

i. *For any $\alpha > 0$, all eigenvalues of B with sufficiently large modulus are algebraically simple.*

ii. *For almost all $\alpha > 0$, the eigenvalues of B are algebraically simple.*

iii. *If all eigenvalues are algebraically simple, then the set of eigenvectors $\{F_{nr}, n \in \mathbf{Z}\}$ is a Riesz basis for $V \times \mathbf{L}^2(0,1)$, provided that the normalization of eigenvectors is suitable.*

Proof. The proof requires detailed and lengthy calculations and is given in the appendix. In this proof we compare the set of eigenfunctions of B for $\alpha = 0$, denoted by $\{G_{nr}, n \in \mathbf{Z}\}$ with $\{F_{nr}, n \in \mathbf{Z}\}$, and show that these two sets are quadratically close. Since the former set is a Riesz basis for $V \times \mathbf{L}^2(0,1)$, we then conclude that the same is true for the latter set. □

3.2. Spectral analysis of the operator A. We now consider the operator A given by (2.10) for the case $\alpha = m/\beta$. The eigenvalues of A are given by (3.8). From (3.8) it follows that $\lambda_* = -\frac{1}{\beta}$ is an eigenvalue of A. To find the corresponding eigenfunction, we again set $\lambda_* = i\tau_*^2$ and rewrite (3.5) as ($\tau_* \neq 0$):

$$(\cosh\tau_* + \cos\tau_*)c_1 + (\sinh\tau_* + \sin\tau_*)c_2 = 0. \tag{3.31}$$

Note that since τ_* is a solution of (3.8), (3.6) is linearly dependent on (3.5) and hence will not be used to determine c_1 and c_2.

In (3.31) the coefficients c_1 and c_2 cannot be zero simultaneously. This follows easily since τ_* is not a purely imaginary number (note that $\lambda_* = -\frac{1}{\beta} = i\tau_*^2$). So the natural choice for c_1 and c_2 given by (3.5)–(3.6) is:

$$c_1 = -(\sinh \tau_* + \sin \tau_*), \tag{3.32}$$

$$c_2 = (\cosh \tau_* + \cos \tau_*). \tag{3.33}$$

Therefore an eigenfunction F_* corresponding to λ_* is

$$F_* = \begin{pmatrix} u_* \\ v_* \\ \eta_* \end{pmatrix}, \tag{3.34}$$

where

$$\begin{aligned} u_*(x) = \varphi_1(\tau_*, x) = &(\cosh \tau_* + \cos \tau_*)(\sinh \tau_* x - \sin \tau_* x) \\ &-(\sinh \tau_* + \sin \tau_*)(\cosh \tau_* x - \cos \tau_* x), \end{aligned} \tag{3.35}$$

$$v_* = \lambda_* u_*(x), \tag{3.36}$$

$$\eta_* = 2f(\tau_*), \tag{3.37}$$

where $f(\cdot)$ and φ_1 are given by (3.17) and (3.18), respectively. The remaining eigenvalues of A are precisely the (nonzero) roots of (3.10). From the preceding section it follows that these eigenvalues are the roots of (3.17), and hence the eigenvalues of B, i.e., the eigenvalues of the cantilevered beam without a tip mass. By Lemma 3.1, (3.17) admits countably many distinct roots $\lambda_n = i\tau_n^2$, $n \in \mathbf{Z}$, $\mathcal{R}e\ \{\lambda_n\} < 0$. We set

$$\begin{aligned} u_n(x) = \varphi_1(\tau_n, x) = &(\cosh \tau_n + \cos \tau_n)(\sinh \tau_n x - \sin \tau_n x) \\ &-(\sinh \tau_n + \sin \tau_n)(\cosh \tau_n x - \cos \tau_n x), \end{aligned} \tag{3.38}$$

$$v_n = \lambda_n u_n(x), \tag{3.39}$$

$$\eta_n = 2f(\tau_n) = 0, \tag{3.40}$$

where φ_1 is given in (3.18). As before, since $\mathcal{R}e\{\lambda_n\} < 0$ implies that τ_n is not a purely imaginary number, the constant factors in (3.18) cannot vanish simultaneously. Then

$$F_n = \begin{pmatrix} u_n \\ v_n \\ 0 \end{pmatrix} \tag{3.41}$$

is an eigenvector for A associated with the eigenvalue λ_n. Note that $(u_n\ v_n)^T$ is an eigenvector of B (i.e., of the cantilevered beam) associated with the same eigenvalue.

Assume now that all the eigenvalues λ_n of the cantilevered beam are algebraically simple. By Lemma 3.2, this assumption can be written as

$$f(\tau_n) = 0, \qquad f'(\tau_n) \neq 0, \tag{3.42}$$

where $\lambda = i\tau^2$ and for $f(\tau) = 0$ we have

$$f'(\tau) = -\tau^2 \left(1 + \frac{\tau^2}{i\alpha}\right)(1 + \cosh\tau\cos\tau) - 2i\alpha\tau^2 \sinh\tau \sin\tau. \tag{3.43}$$

Under the assumption given by (3.42), we now compute the algebraic multiplicity of all the eigenvalues $(\lambda_*, \lambda_n, n \in \mathbf{Z})$ of A. We note that the algebraic simplicity of λ_n as an eigenvalue of B does not imply the algebraic simplicity of λ_n as an eigenvalue of A. We have to distinguish two cases: $\eta_* = 2f(\tau_*) \neq 0$, in which case $\lambda_* \neq \lambda_n \ \forall n \in \mathbf{Z}$, or $\eta_* = 0$, in which case $\lambda_* = \lambda_N$ for some $N \in \mathbf{Z}$.

An easy computation shows that $\eta_* = 0$ if and only if

$$\alpha = \frac{\beta_*(2 + \cosh 2\beta_* + \cos 2\beta_*)}{\sinh 2\beta_* - \sin 2\beta_*}, \tag{3.44}$$

where $\beta_* = 1/\sqrt{2\beta}$. Hence the case $\eta_* = 0$ is just an exceptional one in the sense that (α, β) have to belong to the curve defined by (3.44). For instance, if α is sufficiently small, η_* is always nonzero.

Let $\tilde{\lambda}$ be an eigenvalue of A, and let $(\tilde{u}\ \tilde{v}\ \tilde{\eta})^T$ be the corresponding eigenvector. Let us study when the algebraic multiplicity of $\tilde{\lambda}$ is equal to one or not.

Obviously $\mathrm{Ker}(\mathrm{A} - \tilde{\lambda}\mathrm{I})^2 \setminus \mathrm{Ker}(\mathrm{A} - \tilde{\lambda}\mathrm{I}) \neq \emptyset$ if and only if there exists $(u\ v\ \eta)^T \in D(A)$ such that

$$A \begin{pmatrix} u \\ v \\ \eta \end{pmatrix} - \tilde{\lambda} \begin{pmatrix} u \\ v \\ \eta \end{pmatrix} = \begin{pmatrix} \tilde{u} \\ \tilde{v} \\ \tilde{\eta} \end{pmatrix}, \tag{3.45}$$

which is equivalent to the following:

$$v = \tilde{\lambda}u + \tilde{u}, \tag{3.46}$$

$$-u_{xxxx} - \tilde{\lambda}v = \tilde{v} = \tilde{\lambda}\tilde{u}, \tag{3.47}$$

$$-\left(\tilde{\lambda} + \frac{1}{\beta}\right)\eta = \tilde{\eta}, \tag{3.48}$$

where $(u\ v\ \eta)^T \in D(A)$. Equations (3.46)–(3.48) have a solution if and only if the equations

$$-u_{xxxx} - \tilde{\lambda}^2 u = 2\tilde{\lambda}\tilde{u}, \tag{3.49}$$

$$-\left(\tilde{\lambda} + \frac{1}{\beta}\right)\eta = \tilde{\eta}, \tag{3.50}$$

$$u(0) = u_x(0) = u_{xx}(1) = 0, \tag{3.51}$$

$$\eta = -u_{xxx}(1) + \alpha\tilde{\lambda}u(1) + \alpha\tilde{u}(1) \tag{3.52}$$

admit a solution.

LEMMA 3.4. *Let $\alpha = m/\beta$ and consider the operator A given by* (2.10). *Let α be such that the eigenvalues of the operator B given by* (3.15) *are algebraically simple* (*note that this is true for almost all $\alpha > 0$ by Theorem* 3.3). *Let (λ_*, F_*) be the eigenvalue-eigenvector pair of A given by $\lambda_* = 1/\beta$ and* (3.34), *respectively, and let (λ_n, F_n), $n \in \mathbf{Z}$ be the remaining eigenvalue-eigenvector pairs of A, where λ_n is a root of* (3.10) *and F_n is given by* (3.41).

i. *If $\eta_* \neq 0$, then all eigenvalues of A are algebraically simple.*

ii. *If $\eta_* = 0$, then the algebraic multiplicity of λ_* is exactly* 2 *and all the eigenvalues $\lambda_n \neq \lambda_*$ are algebraically simple.*

Proof. **i.** Let $\eta_* \neq 0$, which implies $\lambda_* \neq \lambda_n,\ n \in \mathbf{Z}$. Then, for $\tilde{\lambda} = \lambda_*$, (3.50) implies $\eta_* = 0$, which is a contradiction. Thus λ_* is algebraically simple. Choose now $\tilde{\lambda} = \lambda_n$ for $n \in \mathbf{Z}$, and for simplicity, denote by $\lambda = i\tau^2$ the eigenvalue λ_n. Then $\tilde{\eta} = \eta_n = 0$, and since $(\tilde{\lambda} + \frac{1}{\beta}) \neq 0$, we get $\eta = 0$ so that (3.49)–(3.52) reduces to

$$-u_{xxxx} - \lambda^2 u = 2\lambda u_n, \tag{3.53}$$

$$u(0) = u_x(0) = u_{xx}(1) = 0, \tag{3.54}$$

$$u_{xxx}(1) = \alpha\lambda u(1) + \alpha u_n(1). \tag{3.55}$$

Then, proceeding exactly as in Lemma 3.2, we obtain that (3.53)–(3.55) has a solution if and only if $f'(\tau) = 0$ (cf. (3.23), (3.24)). By Lemma 3.2 this implies that λ_n is not algebraically simple as an eigenvalue of B, which is a contradiction. Hence by Lemma 3.2 we see that λ_n is also algebraically simple as an eigenvalue of A.

ii. For the case $\eta_* = 0$, by the argument given above, all the λ_n such that $\lambda_n \neq \lambda_*$ are also algebraically simple.

Let $\lambda_* = \lambda_N$ for some $N \in \mathbf{Z}$, which is denoted by λ for simplicity. Then (3.49)–(3.52) reduces to

$$-u_{xxxx} - \lambda^2 u = 2\lambda u_*, \tag{3.56}$$

$$u(0) = u_x(0) = u_{xx}(1) = 0, \tag{3.57}$$

$$-u_{xxx}(1) + \alpha\lambda u(1) + \alpha u_*(1) = \eta. \tag{3.58}$$

Now proceeding again as in Lemma 3.2, but replacing the right-hand side of (3.27) by $\mu - \eta$, we obtain that (3.56)–(3.58) has a solution if and only if

$$\eta = \frac{f'(\tau)}{i\tau}, \tag{3.59}$$

and hence is nonzero by Lemma 3.2 if λ is an algebraically simple eigenvalue of B. Consequently it is always possible to compute $\eta_{**} \neq 0$ in a unique way such that (3.59) is true for $\eta = \eta_{**}$, and then one has a (nonunique) solution $u = u_{**}$ of (3.56)–(3.58) with $v = v_{**} = \lambda_* u_{**} + u_*$ such that (3.46)–(3.48) is satisfied. Thus in case $\eta_* = 0$, λ_* has algebraic multiplicity at least two, $F_* = (u_*\ v_*\ 0)^T$ is an eigenvector

of A, and $F_{**} = (u_{**}\ v_{**}\ \eta_{**})^T$ with $\eta_{**} \neq 0$ is a generalized eigenvector (but not an eigenvector) of A. In fact, λ_* has algebraic multiplicity exactly two, since for $w = (u\ v\ \eta)^T \in D(A)$, $w \in \mathrm{Ker(A} - \lambda_*\mathrm{I)}^3 \setminus \mathrm{Ker(A} - \lambda_*\mathrm{I)}^2$ implies $(A - \lambda_* I)w \in \mathrm{Ker(A} - \lambda_*\mathrm{I)}^2 \setminus \mathrm{Ker(A} - \lambda_*\mathrm{I)}$; thus $(A - \lambda_* I)w = (u_{**}\ v_{**}\ \eta_{**})^T$. But this implies that $-(\lambda_* + 1/\beta)\eta = \eta_{**}$ (cf.(3.48)), hence $\eta_{**} = 0$, which is impossible. □

We have now the material to write down the Riesz basis property. Recall that $(u_n\ v_n)^T$ are not the functions given exactly by (3.38)–(3.39) but have been suitably normalized to posses the adequate Riesz basis property for the cantilevered beam, (see Theorem 3.3).

THEOREM 3.5. *Let $\alpha = m/\beta$, $\lambda_* = -1/\beta$, λ_n, $n \in \mathbf{Z}$, be the roots of* (3.10). *Assume* (3.42) *and $\eta_* = 2f(\tau_*) \neq 0$. Then $\{F_*,\ F_n,\ n \in \mathbf{Z}\}$ is a Riesz basis for $\mathcal{H}$. Moreover the estimate* (2.25) *is valid with $\delta > 0$ such that*

$$-\delta = \max\{-1/\beta,\ \mathcal{R}e\{\lambda_n\},\ n \in \mathbf{Z}\}, \tag{3.60}$$

which is the optimal rate of decay.

Proof. Let $z = (u\ v\ \eta)^T \in \mathcal{H}$ be given. Since $\eta_* \neq 0$, we can write

$$z = \begin{pmatrix} \tilde{u} \\ \tilde{v} \\ 0 \end{pmatrix} + c_* F_*, \tag{3.61}$$

where

$$c_* = \eta/\eta_*, \quad \tilde{u} = u - c_* u_* \in \mathcal{V}, \quad \tilde{v} = v - c_* v_* \in \mathbf{L}^2(0,1). \tag{3.62}$$

Since $(u_n\ v_n)^T,\ n \in \mathbf{Z}$, is a Riesz basis for $\mathcal{V} \times \mathbf{L}^2(0,1)$, we can write

$$\begin{pmatrix} \tilde{u} \\ \tilde{v} \end{pmatrix} = \sum_{n \in \mathbf{Z}} c_n \begin{pmatrix} u_n \\ v_n \end{pmatrix}, \tag{3.63}$$

where $c_n \in l^2(\mathbf{Z})$, and there exist positive constants C_1, C_2 such that

$$C_1 \sum_{n \in \mathbf{Z}} |c_n|^2 \leq \left\| \begin{pmatrix} \tilde{u} \\ \tilde{v} \end{pmatrix} \right\|^2_{\mathcal{V} \times L^2} \leq C_2 \sum_{n \in \mathbf{Z}} |c_n|^2. \tag{3.64}$$

Note that

$$\left\| \begin{pmatrix} \tilde{u} \\ \tilde{v} \end{pmatrix} \right\|^2_{\mathcal{V} \times L^2} = \int_0^1 (\tilde{u}_{xx}^2 + \tilde{v}^2) dx\ ,\ \|z\|^2_{\mathcal{H}} = \int_0^1 (u_{xx}^2 + v^2) dx + K\eta^2, \tag{3.65}$$

where K is given by (2.9). By using (3.62) we obtain

$$u_{xx}^2 = \tilde{u}_{xx}^2 + 2c_* \tilde{u}_{xx} u_{*xx} + c_*^2 u_{*xx}^2, \tag{3.66}$$

$$v^2 = \tilde{v}^2 + 2c_* \tilde{v} v_* + c_*^2 v_*^2. \tag{3.67}$$

It follows from Young's inequality that

$$\begin{aligned} \left| \int_0^1 2c_* \tilde{u}_{xx} u_{*xx} dx \right| &\leq \sigma \int_0^1 \tilde{u}_{xx}^2 dx + \frac{1}{\sigma} \int_0^1 |\ c_*\ |^2 u_{*xx}^2 dx \\ &\leq \sigma \int_0^1 \tilde{u}_{xx}^2 dx + \frac{M_1}{\sigma} \eta^2, \end{aligned} \tag{3.68}$$

where $\sigma > 0$ is an arbitrary constant and (using (3.62))

$$M_1 = \frac{\int_0^1 u_{*xx}^2}{\eta_*^2}.$$

Similarly we obtain

$$\left| \int_0^1 2c_* \tilde{v} v_* dx \right| \leq \sigma \int_0^1 \tilde{v}^2 dx + \frac{M_2}{\sigma} \eta^2, \tag{3.69}$$

where

$$M_2 = \frac{\int_0^1 v_*^2}{\eta_*^2}.$$

By using (3.66)–(3.69) in (3.65), we obtain

$$\|z\|_{\mathcal{H}}^2 \leq (1+\sigma) \left\| \begin{pmatrix} \tilde{u} \\ \tilde{v} \end{pmatrix} \right\|_{\mathcal{V} \times L^2}^2 + \left(K + M_1 + M_2 + \frac{M_1}{\sigma} + \frac{M_2}{\sigma} \right) \eta^2, \tag{3.70}$$

$$\|z\|_{\mathcal{H}}^2 \geq (1-\sigma) \left\| \begin{pmatrix} \tilde{u} \\ \tilde{v} \end{pmatrix} \right\|_{\mathcal{V} \times L^2}^2 + \left(K + M_1 + M_2 - \frac{M_1}{\sigma} - \frac{M_2}{\sigma} \right) \eta^2 \ . \tag{3.71}$$

From (3.61)–(3.63) it follows that

$$z = \sum_{n \in \mathbf{Z}} c_n F_n + c_* F_*. \tag{3.72}$$

Next we choose $\sigma > 0$ such that

$$\frac{M_1 + M_2}{K + M_1 + M_2} < \sigma < 1,$$

which implies that all coefficients in (3.71) are positive. Since η is proportional to c_* (see (3.62)), it follows from (3.64), (3.70)–(3.71) that there exist positive constants C_3 and C_4 such that the following holds:

$$C_3 \Big(\sum_{n \in \mathbf{Z}} |c_n|^2 + |c_*|^2 \Big) \leq \|z\|_{\mathcal{H}}^2 \leq C_4 \Big(\sum_{n \in \mathbf{Z}} |c_n|^2 + |c_*|^2 \Big). \tag{3.73}$$

It follows from (3.72)–(3.73) that the system $\{F_*, F_n, n \in \mathbf{Z}\}$ is a Riesz basis in $\mathcal{H}$.

Since $F_*,\ F_n,\ n \in \mathbf{Z}$ are all eigenvectors of A, we then have

$$T(t)z = T(t) \left[\sum_{n \in \mathbf{Z}} c_n F_n + c_* F_* \right] = \sum_{n \in \mathbf{Z}} e^{\lambda_n t} c_n F_n + e^{\lambda_* t} c_* F_*. \tag{3.74}$$

That (3.60) determines the optimal decay rate for the semigroup is now an immediate and general consequence of the Riesz basis property in $\mathcal{H}$. □

THEOREM 3.6. *Let $\alpha = m/\beta$, $\lambda_* = -1/\beta$, λ_n, $n \in \mathbf{Z}$, be the roots of* (3.10). *Assume* (3.42) *and $\eta_* = 2f(\tau_*) = 0$. Then $\{F_{**},\ F_n,\ n \in \mathbf{Z}\}$ is a Riesz basis for $\mathcal{H}$. Moreover, for any $\epsilon > 0$, the estimate* (2.25) *is valid for $\delta - \epsilon$, where $-\delta$ is given by* (3.60). *Hence $-\delta$ is again the optimal decay rate.*

Proof. We recall that here $F_* = F_N$ for some $N \in \mathbf{Z}$, F_n being suitably normalized eigenvectors of A. The Riesz basis property can be proven as in Theorem 3.5 by just replacing F_* by F_{**} and using the fact that $\eta_{**} \neq 0$, so that with $c_{**} = \eta/\eta_{**}$ we have

$$z = \begin{pmatrix} u \\ v \\ \eta \end{pmatrix} = \begin{pmatrix} \tilde{u} \\ \tilde{v} \\ 0 \end{pmatrix} + c_{**}F_{**}, \tag{3.75}$$

and for $(\tilde{u}\ \tilde{v})^T$ we use the Riesz basis property of F_n, $n \in \mathbf{Z}$. Then we get

$$z = \sum_{n\in\mathbf{Z}} c_n F_n + c_{**}F_{**}, \tag{3.76}$$

where F_n, $n \in \mathbf{Z}$, are the eigenvectors of A, with $F_N = F_*$, $\lambda_N = \lambda_*$, but $F_{**} \in \mathrm{Ker(A} - \lambda_{\mathrm{N}}\mathrm{I)}^2 \setminus \mathrm{Ker(A} - \lambda_{\mathrm{N}}\mathrm{I)}$. Since F_{**} satisfies $(A - \lambda_* I)F_{**} = F_*$, we get

$$\frac{d}{dt}\Big(e^{\lambda_* t}(tF_* + F_{**})\Big) = e^{\lambda_* t}A(tF_* + F_{**}). \tag{3.77}$$

From (3.76)–(3.77) we get

$$T(t)z = \sum_{n\neq N,\ n\in\mathbf{Z}} e^{\lambda_n t}c_n F_n + e^{\lambda_* t}\Big((c_N + tc_{**})F_* + c_{**}F_{**}\Big). \tag{3.78}$$

Now the fact that the estimate (2.25) holds for $\delta - \epsilon$, for any $\epsilon > 0$, is an immediate and general consequence of the Riesz basis property. Due to the fact that $-\delta$ given by (3.60) may be achieved by λ_*, $\epsilon > 0$ comes from the possible compensation of $e^{2Re\lambda_* t}t^2$ by $e^{(2Re\lambda_* + \epsilon)t}$. If $-\delta > \lambda_* = -1/\beta$, then ϵ is unnecessary. ∎

4. Conclusion. In this paper we studied the stability of a flexible beam with a tip mass. The flexible beam is assumed to be clamped at one end and is free at the other, where a mass is also attached. This model is a variant of the SCOLE model and has been studied before; see, e.g., [1], [9], [13]. To stabilize this hybrid system we apply a boundary control force at the free end of the beam. It is well known that for this model the standard velocity feedback for the control force (e.g., (1.4)), which is widely used in boundary control systems, yields only *asymptotic*, but not *exponential*, stability; see e.g., [9], [13]. In this paper we proposed a (new) control law (see (2.1)), which contains the term $u_{xxxt}(1,t)$ in addition to the standard feedback term $u_t(1,t)$. We then proved that the system is well-posed and that the energy associated with the system decays exponentially to zero if the initial data are in $\mathcal{H}$. We also showed that if the initial data are sufficiently smooth (i.e., in $D(A)$), then the tip mass velocity also decays exponentially to zero. Then we analyzed the spectrum of the system for the special case $m = \alpha\beta$ and proved that the spectrum determines the exponential decay rate for the considered case for almost all $\alpha > 0$.

Appendix A. On the Riesz basis property of eigenvectors of the cantilevered beam with boundary force control. Here our aim is to prove Theorem 3.3. We will consider the set of eigenvectors of the operator B given by (3.15) for the cases $\alpha = 0$ (i.e., uncontrolled cantilevered beam) and $\alpha > 0$ (i.e., controlled cantilevered beam) and show that these two sets are quadratically close. Since the former set of eigenvectors is known to be a Riesz basis in $V \times \mathbf{L}^2(0,1)$, we conclude that the latter set is also a Riesz basis in the same space.

Before we prove the Riesz basis property, first we will show that the number of eigenvalues of the uncontrolled and controlled cantilevered beam are the same, counting multiplicities, in sufficiently large disks. This result will enable us to enumerate the eigenvalues of both systems in a similar way. We recall that the eigenvalues of B for $\alpha \geq 0$ are precisely the roots of (3.10). Since $\lambda = 0$ is not an eigenvalue, equivalently the eigenvalues are the roots of the following function (for $\lambda = i\tau^2$)

$$h(\tau) = \frac{f(\tau)}{\tau^2} = \tau(1 + \cosh\tau\cos\tau) - i\alpha(\sinh\tau\cos\tau - \cosh\tau\sin\tau); \tag{A.1}$$

hence for the uncontrolled case (i.e., $\alpha = 0$), the eigenvalues are the roots of the following function

$$g(\tau) = \tau(1 + \cosh\tau\cos\tau). \tag{A.2}$$

Note that $\tau = 0$ is a simple root of both (A.1) and (A.2) but not an eigenvalue of B for $\alpha \geq 0$. Hence it follows that if $h(\cdot)$ and $g(\cdot)$ have the same number of roots in a large disk, then the same is true for the eigenvalues of the operator B for $\alpha = 0$ and $\alpha > 0$.

LEMMA A.1. *There exists a sequence $R_k \in \mathbf{R}$ such that $R_k \to \infty$ as $k \to \infty$ and the number of roots of* (A.1) *and* (A.2) *are the same, counting multiplicities, in $B(0, R_k)$ where $B(0, R)$ is defined as*

$$B(0, R) = \{\ \tau \in \mathbf{C}\ \ |\ \ |\ \tau\ | \leq R\ \ \}. \tag{A.3}$$

Proof. Let $R > 0$ be given and $\gamma = \{\ \tau \in \mathbf{C}\ \ |\ \ |\ \tau\ | = R\ \ \}$, i.e., a circle of radius R. Since both $h(\cdot)$ and $g(\cdot)$ are analytic in $B(0, R)$, by Rouché's theorem they have the same number of roots, counting multiplicities, if $|\ h(\tau) - g(\tau)\ | < |\ g(\tau)\ |$ for $\tau \in \gamma$. We will show that this is true for some sufficiently large R. For convenience let us define

$$s(\tau) = i\alpha(\sinh\tau\cos\tau - \cosh\tau\sin\tau); \tag{A.4}$$

hence equivalently we need to show the following:

$$\left|\frac{s(\tau)}{g(\tau)}\right| \quad < \quad 1, \qquad \tau \in \gamma. \tag{A.5}$$

Since both $g(\cdot)$ and $s(\cdot)$ are odd functions it is sufficient to consider the upper half plane, and since $\cosh i\tau = \cos\tau$, $\cos i\tau = \cosh\tau$, $\sinh i\tau = i\sin\tau$, $\sin i\tau = i\sinh\tau$, it is sufficient to consider only the first quadrant, i.e., $\tau = Re^{i\theta}$ for $0 \leq \theta \leq \pi/2$.

Let $\tau = Re^{i\theta}$. After straightforward calculations it could be shown that the following holds:

$$|\ s(\tau)\ | \leq \frac{\alpha}{2}(e^{RD} + e^{-RD} + e^{RS} + e^{-RS}), \tag{A.6}$$

$$4\cosh\tau\cos\tau = e^{RD}e^{iRS} + e^{RS}e^{-iRD} + e^{-RS}e^{iRD} + e^{-RD}e^{-iRS}, \tag{A.7}$$

where $D = \cos\theta - \sin\theta$, $S = \cos\theta + \sin\theta$.

For $0 \leq \theta \leq \pi/2$ we have $S \geq 1$ and $S \geq \mid D \mid$; hence $\mid s(\tau) \mid \leq 2\alpha e^{RS}$. For $0 < \theta < \pi/4$ we have $D > 0$; hence for sufficiently large R the following holds:

$$\frac{\mid s(\tau) \mid}{\mid \cosh\tau \cos\tau \mid} \leq \frac{2\alpha}{\mid e^{-RS} \cosh\tau \cos\tau \mid} \leq M \tag{A.8}$$

for some $M > 0$. For $\pi/4 < \theta < \pi/2$ we have $D < 0$, and from (A.6) and (A.7) it easily follows that an estimate similar to (A.8) holds. Hence for $0 < \theta < \pi/2$ and $\theta \neq \pi/4$ we have $\lim_{R\to\infty} \mid \frac{s(\tau)}{g(\tau)} \mid = 0$. For $\theta = 0$ or $\theta = \pi/2$ we have $D = 1$ or $D = -1$, respectively; $S = 1$ and $1 + \cosh\tau\cos\tau = 1 + \cosh R \cos R$ in both cases. Hence if we choose $R = 2n\pi$, we have $\lim_{n\to\infty} \mid \frac{s(\tau)}{g(\tau)} \mid = 0$. We note that this holds if $R \to \infty$ in such a way that $\mid \cos R \mid \geq \delta$ for any $\delta > 0$. For $\theta = \pi/4$ we have $D = 0$, $S > 1$, and $4\cosh\tau\cos\tau = 2\cos RS + 2\cosh RS$; hence $\lim_{R\to\infty} \mid \frac{s(\tau)}{g(\tau)} \mid = 0$. Therefore, for $\tau = Re^{i\theta}$, $R = 2n\pi$, and $0 \leq \theta \leq 2\pi$ we have $\lim_{n\to\infty} \mid \frac{s(\tau)}{g(\tau)} \mid = 0$. Hence there exists a sequence $R_k = 2k\pi$, $k \in \mathbf{N}$, and $k \to \infty$ such that $\lim_{k\to\infty} \mid \frac{s(\tau)}{g(\tau)} \mid < 1$ for $\mid \tau \mid = R_k$. Therefore, by Rouchée's theorem, the number of roots of $g(\cdot)$ and $h(\cdot)$, or equivalently the eigenvalues of the operator B for the cases $\alpha = 0$ and $\alpha > 0$, respectively, are the same in $B(0, R_k)$, counting multiplicities. □

The lemma given above lets us enumerate the eigenvalues of uncontrolled and controlled cantilevered beam in a similar way, at least if they are algebraically simple (see Remark 3 for an extension). In what follows we will give asymptotic formulas for these eigenvalues and then compare the corresponding eigenvectors.

Consider the system and the corresponding eigenvalue problem given by (3.11)–(3.18). From (3.17) it follows that the eigenvalues occur in complex conjugate pairs. Since there are countably many eigenvalues and each eigenvalue is isolated (see Lemma 3.1), the eigenvalues which have positive imaginary part can be numerated by considering the imaginary parts with increasing order. By using asymptotic analysis it can be shown that asymptotically the solutions of (3.17) can be given as ($\lambda = i\tau^2$):

$$\lambda_k = -2\alpha + \mathcal{O}(1/k^2) + i((m\pi)^2 + \alpha\mathcal{O}(1/k)), \tag{A.9}$$

for sufficiently large $k \in \mathbf{N}$, where $m = k + 1/2$; see [12, p. 76]. We note that this estimate can also be obtained by using the wave propagation method (see [2]) for similar estimates. Here the symbol $\mathcal{O}(f(k))$ denotes any function such that $\lim_{k\to\infty} \mathcal{O}(f(k))/f(k)$ exists and is finite.

By using $\lambda_k = i\tau_k^2$, the corresponding τ_k can easily be found as

$$\tau_k = \pm\left[(m\pi + \mathcal{O}(1/k^2)) + i\left(\frac{\alpha}{m\pi} + \mathcal{O}(1/k^3)\right)\right] \tag{A.10}$$

for sufficiently large k. In what follows we will consider (A.10) with + sign; the same conclusions hold with - sign as well (see below). By using (A.10), with + sign, we obtain the following estimates:

$$e^{\tau_k x} = e^{m\pi x}\left((1 + \mathcal{O}(1/k^2)f_1(x)) + i\left(\frac{\alpha x}{m\pi} + \mathcal{O}(1/k^3)f_2(x)\right)\right), \tag{A.11}$$

$$e^{-\tau_k x} = e^{-m\pi x}\left((1 + \mathcal{O}(1/k^2)f_3(x)) - i\left(\frac{\alpha x}{m\pi} + \mathcal{O}(1/k^3)f_4(x)\right)\right), \tag{A.12}$$

$$
\begin{aligned}
e^{i\tau_k x} &= e^{-\frac{\alpha x}{m\pi}}((\cos m\pi x + \cos m\pi x \;\; \mathcal{O}(1/k^3)f_5(x) \\
&\quad - \sin m\pi x \;\; \mathcal{O}(1/k^2)f_6(x)) + i(\sin m\pi x + \sin m\pi x \;\; \mathcal{O}(1/k^3)f_7(x) \\
&\quad + \cos m\pi x \;\; \mathcal{O}(1/k^2)f_8(x))),
\end{aligned} \tag{A.13}
$$

$$
\begin{aligned}
e^{-i\tau_k x} &= e^{\frac{\alpha x}{m\pi}}((\cos m\pi x + \cos m\pi x \;\; \mathcal{O}(1/k^3)f_9(x) \\
&\quad - \sin m\pi x \;\; \mathcal{O}(1/k^2)f_{10}(x)) - i(\sin m\pi x + \sin m\pi x \;\; \mathcal{O}(1/k^3)f_{11}(x) \\
&\quad + \cos m\pi x \;\; \mathcal{O}(1/k^2)f_{12}(x))),
\end{aligned} \tag{A.14}
$$

where the functions $f_i(\cdot)$, $i = 1, \ldots, 12$, are smooth and bounded functions with bounded derivatives. By using (A.11)–(A.14), we obtain the following estimates:

$$
\begin{aligned}
&(\cosh\tau_k + \cos\tau_k)(\sinh\tau_k x - \sin\tau_k x) = \frac{e^{\tau_k}e^{\tau_k x}}{4} + \bigg(- \frac{e^{m\pi}e^{-m\pi x}}{4} \\
&+e^{m\pi}\mathcal{O}(1/k^2)o_1(x) + e^{m\pi x}o_2(x) - \frac{e^{m\pi}}{2}\sin m\pi x + o_3(x)\bigg) \\
&+i(e^{m\pi}\mathcal{O}(1/k)o_4(x) + e^{m\pi x}\mathcal{O}(1/k)o_5(x) + o_6(x)),
\end{aligned} \tag{A.15}
$$

$$
\begin{aligned}
&(\sinh\tau_k + \sin\tau_k)(\cosh\tau_k x - \cos\tau_k x) = \frac{e^{\tau_k}e^{\tau_k x}}{4} + \bigg(\frac{e^{m\pi}e^{-m\pi x}}{4} \\
&+e^{m\pi}\mathcal{O}(1/k^2)o_7(x) + e^{m\pi x}o_8(x) - \frac{e^{m\pi}}{2}\cos m\pi x + o_9(x)\bigg) \\
&+i(e^{m\pi}\mathcal{O}(1/k)o_{10}(x) + e^{m\pi x}\mathcal{O}(1/k)o_{11}(x) + o_{12}(x)),
\end{aligned} \tag{A.16}
$$

where the functions $o_i(\cdot)$, $i = 1, \ldots, 12$, are smooth and bounded functions (as a function of k), and their derivatives are either bounded or satisfy the following:

$$
o_i^{(n)}(x) = (k\pi)^n \hat{o}_i(x), \qquad i = 1, \ldots, 12, \qquad n \in \mathbf{N}, \tag{A.17}
$$

where the functions $\hat{o}_i(\cdot)$ are also smooth and bounded functions. By using (A.15) and (A.16) in (3.18) we obtain

$$
\begin{aligned}
\varphi_1(\tau_k, x) &= \bigg[- \frac{e^{m\pi}e^{-m\pi x}}{2} + e^{m\pi}\mathcal{O}(1/k^2)o_{13}(x) + e^{m\pi x}o_{14}(x) \\
&\quad + \frac{e^{m\pi}}{2}\cos m\pi x - \frac{e^{m\pi}}{2}\sin m\pi x + o_{15}(x)\bigg] \\
&\quad + i[e^{m\pi}\mathcal{O}(1/k)o_{16}(x) + e^{m\pi x}\mathcal{O}(1/k)o_{17}(x) + o_{18}(x)],
\end{aligned} \tag{A.18}
$$

where the functions $o_i(\cdot)$ are of the same form as given in (A.15)–(A.16).

Let $\lambda \in \mathbf{C}$ be an eigenvalue of B (see (3.15)), and let $E \in H = V \times L^2(0,1)$ be the corresponding (unnormalized) eigenvector given by

$$
E = \begin{pmatrix} \varphi_1(\tau, x) \\ i\tau^2\varphi_1(\tau, x) \end{pmatrix}; \tag{A.19}
$$

see (3.18). The norm of E can be found as

$$
\|E\|_H^2 = (\mid \lambda \mid^2 - \lambda^2) \int_0^1 \varphi_1\bar{\varphi}_1 dx - \alpha\lambda \mid \varphi_1(1) \mid^2, \tag{A.20}
$$

where a bar denotes the complex conjugate. Let λ_k and E_k be an eigenvalue, (unnormalized) eigenvector pair. By using (A.18) it easily follows that

$$\int_0^1 (\mathrm{Im}\{\varphi_1\})^2 dx = \mathcal{O}(e^{2k\pi}/(k\pi)^2) \tag{A.21}$$

for k sufficiently large. By using the simple integrals

$$\int_0^1 \cos^2 m\pi x dx = \int_0^1 \sin^2 m\pi x dx = 1/2, \qquad \int_0^1 \sin m\pi x \cos m\pi x dx = \frac{1}{2m\pi}$$

(note that $m = k + 1/2$), it follows from (A.18) that

$$\int_0^1 (Re\{\varphi_1\})^2 dx = C_1 e^{2k\pi} + \mathcal{O}(e^{2k\pi}/(k\pi)) \tag{A.22}$$

for k sufficiently large, where $C_1 > 0$ is a constant. By using (A.9), (A.21), and (A.22) in (A.20) it follows that

$$\|E_k\|_H^2 = C_2 (k\pi)^4 e^{2k\pi} + \mathcal{O}(e^{2k\pi}(k\pi)^3) \tag{A.23}$$

for k sufficiently large, where $C_2 > 0$ is a constant. Hence we define the (approximately) normalized eigenvectors as

$$F_{kr} = \frac{1}{(k\pi)^2 e^{k\pi}} \begin{pmatrix} \varphi_1(\tau_k, x) \\ i\tau_k^2 \varphi_1(\tau_k, x) \end{pmatrix}, \tag{A.24}$$

where τ_k and φ_1 are given by (3.17) and (3.18), respectively.

Now consider the system (3.11)–(3.12) with $\alpha = 0$, i.e., uncontrolled system. By using μ instead of τ, the characteristic equation (3.17) becomes

$$1 + \cosh \mu \cos \mu = 0, \qquad \lambda = i\mu^2, \tag{A.25}$$

whose roots are asymptotically given by

$$\mu_k = m\pi + \mathcal{O}(e^{-m\pi}), \qquad m = k + 1/2 \tag{A.26}$$

for k sufficiently large. It follows that the corresponding function $\varphi_1(\mu_k, x)$ is real. By following the analysis given above, similar to (A.18), we obtain

$$\begin{aligned} \varphi_1(\mu_k, x) &= -\frac{e^{m\pi} e^{-m\pi x}}{2} + e^{m\pi} \mathcal{O}(e^{-m\pi}) o_{19}(x) + e^{m\pi x} o_{20}(x) \\ &\quad + \frac{e^{m\pi}}{2} \cos m\pi x - \frac{e^{m\pi}}{2} \sin m\pi x + o_{21}(x), \end{aligned} \tag{A.27}$$

where the functions $o_i(\cdot)$ are as given in (A.15)–(A.16). Hence, by following the analysis given above, we define the (approximately) normalized eigenvector corresponding to μ_k as

$$G_{kr} = \frac{1}{(k\pi)^2 e^{k\pi}} \begin{pmatrix} \varphi_1(\mu_k, x) \\ i\mu_k^2 \varphi_1(\mu_k, x) \end{pmatrix}. \tag{A.28}$$

THEOREM A.2. *Consider the (approximately) normalized eigenvectors F_k and G_k given by* (A.24) *and* (A.28), *respectively. Then the estimate*

$$\|F_{kr} - G_{kr}\|_H = \mathcal{O}(1/k) \tag{A.29}$$

holds for sufficiently large k.

Proof. From (A.18) and (A.27) it follows that

$$\begin{aligned}\varphi_1(\tau_k,x)-\varphi_1(\mu_k,x) &= e^{m\pi}\mathcal{O}(1/k^2)o_{22}(x)+e^{m\pi x}o_{23}(x)+o_{24}(x)\\ &\quad + i[e^{m\pi}\mathcal{O}(1/k)o_{25}(x)+e^{m\pi x}\mathcal{O}(1/k)o_{26}(x)+o_{27}(x)],\end{aligned} \tag{A.30}$$

where the functions $o_i(\cdot)$ are as given in (A.15). Also note that

$$\begin{aligned}i\tau_k^2\varphi_1(\tau_k,x)-i\mu_k^2\varphi_1(\mu_k,x) &= i\tau_k^2[\varphi_1(\tau_k,x)-\varphi_1(\mu_k,x)]\\ &\quad + i(\tau_k^2-\mu_k^2)\varphi_1(\mu_k,x).\end{aligned} \tag{A.31}$$

From (A.17), (A.30), and (A.31) it follows that

$$\int_0^1 \mid \varphi_{1xx}(\tau_k,x)-\varphi_{1xx}(\mu_k,x) \mid^2 dx = \mathcal{O}(e^{2k\pi}(k\pi)^2), \tag{A.32}$$

$$\int_0^1 \mid \tau_k^2\varphi_1(\tau_k,x)-\mu_k^2\varphi_1(\mu_k,x) \mid^2 dx = \mathcal{O}(e^{2k\pi}(k\pi)^2) \tag{A.33}$$

for k sufficiently large. Hence (A.29) easily follows from (A.32) and (A.33). ∎

Now we consider the algebraic simplicity of the eigenvalues of B for the case $\alpha > 0$ and prove the statement **i** of Theorem 3.3.

LEMMA A.3. *Consider the system given by* (3.11)–(3.12) *for* $\alpha > 0$. *All eigenvalues of B with sufficiently large modulus are algebraically simple.*

Proof. Since the operator B has compact resolvent (see Lemma 3.1), it follows that the spectrum of B consists entirely of isolated points, at most countable, and each eigenvalue has a finite algebraic multiplicity.

Let τ be a root of (3.17), and let $\lambda = i\tau^2$ be the corresponding eigenvalue. From Lemma 3.2 it follows that λ has algebraic multiplicity greater than 1 if and only if $f'(\tau) = 0$; see (3.43).

First note that by using (A.10), (A.13), (A.14), it follows that

$$\cos\tau_k = -(-1)^k\mathcal{O}(1/k^2) - i\left((-1)^k\frac{\alpha}{m\pi}+(-1)^k\mathcal{O}(1/k^3)\right), \tag{A.34}$$

$$\sin\tau_k = (-1)^k + (-1)^k\mathcal{O}(1/k^2) - i((-1)^k\mathcal{O}(1/k^3)). \tag{A.35}$$

By using (A.11), (A.12), (A.34), (A.35) in (3.43) we obtain

$$-i\frac{f'(\tau_k)}{\tau_k^2} = (e^{m\pi}o_1(k)+o_2(k)) + i(-m\pi e^{m\pi}/2 + e^{m\pi}o_3(k)+o_4(k)), \tag{A.36}$$

where $o_i(k)$, $i = 1,\dots,4$ are bounded functions of k. Hence it follows that, for sufficiently large k, we have $f'(\tau_k) \neq 0$, which implies that all eigenvalues with sufficiently large modulus are algebraically simple. ∎

Next we prove that, for almost all $\alpha > 0$, the eigenvalues of B are algebraically simple. Moreover the set of $\alpha > 0$, for which there exists at least one eigenvalue which is not algebraically simple, does not contain a limit point, i.e., any such $\alpha > 0$ is necessarily isolated.

Let $F(\tau)$ be defined as

$$F(\tau) = G(\tau) + i\alpha S(\tau), \tag{A.37}$$

where

$$G(\tau) = -\tau(1 + \cosh\tau\cos\tau), \qquad S(\tau) = \sinh\tau\cos\tau - \cosh\tau\sin\tau. \tag{A.38}$$

We know that for a given $\alpha > 0$, $\lambda = i\tau^2$ is an algebraically simple eigenvalue of B if and only if $F(\tau) = 0,\ F'(\tau) \neq 0$, (see Lemma 3.2). Note that we have

$$F'(\tau) = G'(\tau) + i\alpha S'(\tau). \tag{A.39}$$

Also note that if for some $\alpha > 0$ and $\tau \in \mathbf{C}$ we have $F(\tau) = F'(\tau) = 0$, then by eliminating α in (A.37) and (A.39) we obtain $R(\tau) = 0$, where $R(\tau)$ is given by

$$R(\tau) = G'(\tau)S(\tau) - G(\tau)S'(\tau). \tag{A.40}$$

Note that $G(\tau) = 0$ and $S(\tau) = 0$ cannot be satisfied simultaneously. To see that, assume that for some $\tau \in \mathbf{C}$ we have $G(\tau) = S(\tau) = 0$. Then, since $\tau = 0$ is not an eigenvalue, from (A.38) we obtain $\cos\tau = -1/\cosh\tau$, $\sin\tau = -\sinh\tau/\cosh^2\tau$. Then, by using $\sin^2\tau + \cos^2\tau = 1$, we obtain $\cosh\tau = \pm 1$, and then (A.38) implies $\cos\tau = \mp 1$. It can now easily be shown that such a $\tau \in \mathbf{C}$ does not exist. Hence if $F(\tau) = 0$, then both $G(\tau) \neq 0$ and $S(\tau) \neq 0$ must be true.

LEMMA A.4. *Let, for $a > 0$, the sets $\mathcal{C}_a$ and $\mathcal{C}_\infty$ be defined as*

$$\mathcal{C}_a = \{\alpha \in \mathbf{R},\ 0 < \alpha < a | \exists \tau \in \mathbf{C}, F(\tau) = F'(\tau) = 0\}, \tag{A.41}$$

$$\mathcal{C}_\infty = \{\alpha \in \mathbf{R},\ \alpha > 0 | \exists \tau \in \mathbf{C}, F(\tau) = F'(\tau) = 0\}. \tag{A.42}$$

Then

i. *The set $\mathcal{C}_\infty$, if not empty, is at most countable.*

ii. *The set $\mathcal{C}_a$, if not empty, contains finitely many points.*

Proof. **i.** For some $\alpha > 0$ and $\tau \in \mathbf{C}$ we have $F(\tau) = F'(\tau) = 0$. Then we assume $R(\tau) = 0$, where $R(\tau)$ is given by (A.40). Since $R(\tau)$ is a nonconstant analytic function, it follows that its zero set (i.e., the roots of $R(\tau) = 0$) is at most countable; see, e.g., [16, p. 209, Thm. 10.18]. This also shows that the eigenvalues $\lambda = i\tau^2$ which are not algebraically simple also satisfy $R(\tau) = 0$, and hence are independent of α. From (A.37) we obtain

$$\alpha = i\frac{G(\tau)}{S(\tau)}. \tag{A.43}$$

Since there are countably many $\tau \in \mathbf{C}$ for which the eigenvalues $\lambda = i\tau^2$ are not algebraically simple, and since for these τ (A.43) is satisfied, it follows that there are at most countable many values for $\alpha > 0$ such that there exists at least one eigenvalue with algebraic multiplicity greater that one. Hence the set $\mathcal{C}_\infty$ is countable.

ii. Let $a > 0$ be given and let $0 < \alpha < a$. From Lemma A.3 we know that all eigenvalues with sufficiently large modulus are algebraically simple. Hence there exists a $M > 0$ such that, for all $0 < \alpha < a$ and for all eigenvalues $\lambda = i\tau^2$ which are not algebraically simple, we have $\tau \in B(0, M)$, defined by (A.3). Moreover (A.36) implies that $f'(\tau_k) \neq 0$ for sufficiently large k, uniformly with respect to α, for $0 < \alpha \leq a$.

This fact implies that the constant M is independent of α, for $0 < \alpha \leq a$. However such τ must also satisfy $R(\tau) = 0$, where $R(\tau)$ is given by (A.40). Since $B(0, M)$ is a compact set, the number of roots of $R(\tau) = 0$ in $B(0, M)$ must be finite, for otherwise there will be a limit point of zeros of $R(\tau)$ in $B(0, M)$, which is a contradiction; see, e.g., [16, p. 209, Thm. 10.18]. Since in $B(0, M)$ there are at most finitely many candidates of τ for eigenvalues which are not algebraically simple, it follows from (A.43) that the set $\mathcal{C}_a$ also contains finitely many points. □

The next corollary now proves assertion **ii** of Theorem 3.3.

COROLLARY A.5. **i.** *For almost all $\alpha > 0$ the eigenvalues of the operator B given by* (3.15) *are algebraically simple.*

ii. *If for some $\alpha_0 > 0$ and $\tau_0 \in \mathbf{C}$, $\lambda_0 = i\tau_0^2$ is an eigenvalue which is not algebraically simple, then there exists an open set $U \subset \mathbf{R}$ such that $\alpha_0 \in U$, and for $\alpha \in U$, $\alpha \neq \alpha_0$, the eigenvalues of B are algebraically simple.*

Proof. **i.** This follows easily from Lemma A.4.

ii. Note that the right-hand side of (A.43) is an analytic function around any possible $\tau \in \mathbf{C}$ such that the eigenvalue $\lambda = i\tau^2$ is not algebraically simple. Then the result follows from, e.g., [16, p. 216, Thm. 10.32], and from the fact that all eigenvalues with sufficiently large modulus are algebraically simple. □

To prove that the generalized eigenfunctions of B form a Riesz basis in $\mathcal{H}$, we need the following simple fact.

LEMMA A.6. *Let B be a densely defined closed linear operator in a Hilbert space $\mathcal{H}$. Assume that the spectrum of B consists entirely of, at most countable, isolated points, each of which has a finite algebraic multiplicity. Moreover assume that the eigenvalues are distinct. Then the generalized eigenfunctions are ω-linearly independent (for the definition of ω-independence, see, e.g.,*[7, *p.* 316], *or* [18, *p.* 50]).

Proof. Proof of this fact is essentially the same as given in [7, p. 329] for bounded operators. For closed (unbounded) operators with compact resolvent (discrete in the notation of [5]), we may proceed by using [8, p. 178] or [5, pp. 2292–2293] as follows. Let λ_n and ν_n denote the eigenvalues and their algebraic multiplicity of B, respectively. Let ψ_{ij}, $i = 1, 2, \ldots, n, \ldots$, $j = 1, \ldots, \nu_i$, denote the set of generalized eigenfunctions. Since the spectrum of A does not contain an accumulation point, for each λ_i we can find a constant $r_i > 0$ such that the circle $C_i = \{\lambda \in \mathbf{C} | \mid \lambda - \lambda_i \mid = r_i\}$ does not encircle any eigenvalue other than λ_i. It is well known that the operator

$$P_i = \frac{1}{2\pi i} \int_{C_i} (\lambda I - A)^{-1} d\lambda, \tag{A.44}$$

is well defined and is the projection operator onto the generalized eigenspace corresponding to λ_i; see, e.g., [8, p. 178], [5, pp. 2292–2293]. Now consider the following equation:

$$\sum_{i=1}^{\infty} \sum_{j=1}^{\nu_i} c_{ij} \psi_{ij} = 0. \tag{A.45}$$

By using the projection operator P_i given by (A.44), we obtain

$$P_i \left(\sum_{i=1}^{\infty} \sum_{j=1}^{\nu_i} c_{ij} \psi_{ij} \right) = \sum_{j=1}^{\nu_i} c_{ij} \psi_{ij} = 0. \tag{A.46}$$

Since $\nu_i < \infty$ and the generalized eigenfunctions are linearly independent, it follows from (A.46) that $c_{ij} = 0$, $j = 1, \ldots, \nu_i$. Since this is true for each $i \in \mathbf{N}$, it follows that the generalized eigenfunctions are ω-linearly independent. □

THEOREM A.7. *Let $\alpha > 0$ be given and assume the eigenvalues of the operator B are all algebraically simple (note that this condition holds for almost all $\alpha > 0$; see* Corollary A.5). *Then the set of eigenvectors of B forms a Riesz basis for $\mathcal{H}$.*

Proof. Let F_{kr} and G_{kr} be given by (A.24) and (A.28), respectively. Note that F_{kr} and G_{kr} are the (appropriately) normalized eigenvectors of the operator B, corresponding to given $\alpha > 0$ and $\alpha = 0$, respectively. We note that by Lemma A.1, it is possible to enumerate these eigenvectors similarly, and because of algebraic simplicity we consider only the eigenvectors and not the generalized eigenvectors. This point is important in Theorum 3.5 and Theorum 3.6 in proving the spectrum-determined growth property, which is our main aim.

From Theorum A.2 it follows that for some N we have

$$\sum_{|k|>N} \|F_{kr} - G_{kr}\|_{\mathcal{H}}^2 < \infty; \tag{A.47}$$

see (A.29). Since $N < \infty$, it follows that

$$\sum_{k\in\mathbf{Z}} \|F_{kr} - G_{kr}\|_{\mathcal{H}}^2 < \infty. \tag{A.48}$$

Hence the set of vectors $\{F_{kr}\}$ is quadratically close to the set of vectors $\{G_{kr}\}$. It is well known that the latter set of vectors forms a Riesz basis for $\mathcal{H}$, since for $\alpha = 0$ the operator B becomes a skew adjoint operator. Also by Lemma A.6, the former set of vectors is ω-linearly independent. This implies that the set of vectors $\{F_{kr}\}$ also forms a Riesz basis in $\mathcal{H}$; see, e.g., [18, p. 347, Thm. 11.3]. □

Remark 3. The requirement that the eigenvalues of B for $\alpha > 0$ be algebraically simple is not essential and could be relaxed. Let $\alpha > 0$, and let $\lambda \in \mathbf{C}$ be a root of (A.1), i.e., an eigenvalue of B. It is not known a priori whether the multiplicity of λ as a root of (A.1) and the algebraic multiplicity of λ as an eigenvalue of B are the same. Let us assume that these two multiplicities are the same, and let the set of vectors $\{F_{kr}\}$ include all eigenvectors and the generalized eigenvectors of B. Then by using Lemma A.1, Lemma A.3, Theorem A.2, and Theorem A.7, we conclude that the sets $\{F_{kr}\}$ and $\{G_{kr}\}$ are quadratically close; i.e., (A.48) holds. Hence the set $\{F_{kr}\}$ also forms a Riesz basis in $\mathcal{H}$, and the spectrum-determined growth property stated in Theorum 3.5 and Theorum 3.6 holds. The assumption on the equality of the multiplicities stated above seems to be true; however, the proof of this statement could be rather tedious. If we assume algebraic simplicity, which is generic (i.e., holds for almost all $\alpha > 0$), then these two multiplicities are the same; see Lemma 3.2. This is the basic reason for the assumption on algebraic simplicity.

COROLLARY A.8. *There exists an $a > 0$ such that, for all $0 < \alpha < a$, the set of eigenfunctions of B forms a Riesz basis for $\mathcal{H}$.*

Proof. This fact was proven in [4]. Here we may obtain this result as a corollary by using Lemma A.4, part ii, and Theorem A.7. □

Appendix B. The authors thank the anonymous referees, who suggested many improvements of the paper, and also Bo Peng Rao, who made valuable comments.

ON THE VALIDITY OF THE MAXIMUM PRINCIPLE AND OF THE EULER–LAGRANGE EQUATION FOR A MINIMUM PROBLEM DEPENDING ON THE GRADIENT*

ARRIGO CELLINA† AND STEFANIA PERROTTA‡

Abstract. We consider the limiting case $\alpha = \infty$ of the problem of minimizing

$$\int_\Omega (\|\nabla u(x)\|^\alpha + g(u))dx \text{ on } u \in u_0 + W_0^{1,\alpha}(\Omega),$$

where g is differentiable and strictly monotone. If this infimum is finite, it is evidently attained; we show that any minimizing function u satisfies the appropriate form of the Euler–Lagrange equation, i.e., for some function p,

$$\operatorname{div} p(x) = g'(u(x)) \quad \text{for} \quad p(x) \in \partial j_B(\nabla u(x)),$$

where j_B is the indicator function of the closed unit ball in the Euclidean norm of $\mathbb{R}^N$ and ∂ is the subdifferential of the convex function j_B.

1. Introduction.

In this paper we consider the problem of minimizing

$$\int_\Omega g(u)dx$$

for $u \in u_0 + W_0^{1,\infty}(\Omega)$, subject to the Hamilton–Jacobi control equation

$$\nabla u(x) = v, \qquad v \in B,$$

where B is the Euclidean unit ball of $\mathbb{R}^N$, i.e., $\{y \in \mathbb{R}^N : \|y\| \le 1\}$. By the convexity and compactness of the control set B, the minimization problem above admits a solution whenever the set of functions u satisfying the control and boundary conditions is nonempty. Under some assumptions on g (that include the linear case), but essentially without assumptions on Ω and on the boundary datum u_0, we show that to a solution u we can associate a map $p \in (L^1(\Omega))^N$ such that, denoting by H the map

$$H(u, p, v) = -g(u) + < p, v >,$$

we have

$$\nabla u(x) = \nabla_p H(x); \quad \operatorname{div} p(x) = -\frac{\partial H}{\partial u},$$

and almost everywhere (a.e.) $H(u(x), p(x), v(x)) = \max_{w \in B}\{H(u(x), p(x), w)\}$, i.e., the solution satisfies the Pontryagin maximum principle [5].

Equivalently, the problem we consider can be seen as the problem of minimizing the functional

$$F(u) = \int_\Omega (j_B(\nabla u(x)) + g(u))dx$$

for $u \in u_0 + W_0^{1,\infty}(\Omega)$, where j_B is the indicator function of the closed unit ball B. The map $y \to j_B(y)$ is convex, lower semicontinuous, and extended valued. The coercivity requirement for the existence of solutions to the minimum problem is obviously satisfied; hence, when the functional F assumes a finite value for at least one function $u \in u_0 + W_0^{1,\infty}(\Omega)$, the minimization problem admits a solution. Even though the integrand is not differentiable, the convexity of the function $y \to j_B(\|y\|)$ leads one to expect the validity of a Euler–Lagrange inclusion in the form

$$\operatorname{div} p(x) = g'(u(x)) \quad \text{for} \quad p(x) \in \partial j_B(\nabla u(x)).$$

This inclusion can be reduced to the usual language of an equation noticing that

$$\partial j_B(y) = \begin{cases} \{0\}, & \text{if } \|y\| < 1, \\ \{\alpha y \,:\, \alpha \geq 0\}, & \text{if } \|y\| = 1, \\ \emptyset, & \text{if } \|y\| > 1. \end{cases}$$

Hence, establishing the validity of the above differential inclusion for an admissible function u amounts to providing a non-negative function $\alpha \in L^1(\Omega)$, with $\alpha(x) = 0$ when $\|\nabla u(x)\| < 1$, such that

$$\operatorname{div} \alpha(x)\, \nabla u(x) = g'(u(x)).$$

This is what we mean by the Euler–Lagrange equation for this problem; solutions to the above partial differential equation have to be understood in the standard distributional sense. We have that, for this problem, the two formulations of the necessary conditions, namely, the validity of the maximum principle or the validity of the Euler–Lagrange equations, are entirely equivalent. In fact, the following identities hold for $v \in B$:

$$\langle p, v\rangle = \max_{w \in B} \langle p, w\rangle \quad \Leftrightarrow \quad v \in \begin{cases} \{p/\,\|p\|\}, & \text{if } p \neq 0, \\ B, & \text{if } p = 0, \end{cases} \quad \Leftrightarrow \quad p \in \partial j_B(v).$$

It follows from our result, in particular, that whenever the functional F is finite along exactly one function (the boundary function u_0), then u_0 must be a solution to the Euler–Lagrange equation.

Although convex analysis is a guide to write the suitable form of the Euler–Lagrange equation, it is of no help in establishing its validity for this problem. In fact, the basic assumption needed for the applicability of the theory, namely the continuity of the map $\xi \in L^\beta(\Omega) \to \int_\Omega j_B(\|\xi(x)\|)dx$ ([2, Theorem 4.1, p. 59]), is violated in this case, no matter what β is.

In contrast with the usual approach, where regularity of the solution is obtained as a consequence of its being a solution to the Euler–Lagrange equation, in our case we must first prove some regularity of the solution in order to obtain from it the validity of the equation.

Finally, the minimization problem we consider can be seen as a limiting case for $\beta = \infty$ of the problem

$$\text{minimize } \int_\Omega (\|\nabla u(x)\|^\beta + g(u))dx \quad \text{ on } u \in u_0 + W_0^{1,\beta}(\Omega),\ 1 < \beta < \infty.$$

It is known (see [4]) that (under some suitable assumptions) solutions to these problems do exist and satisfy the Euler–Lagrange equation

$$\beta \operatorname{div}(\|\nabla u\|^{\beta-2}\nabla u) = g'(u).$$

Hence, our equation can be seen as a limiting case of the above equation.

Among several other results, a related problem, but with boundary condition identically zero, has been considered by Bhattacharya, Di Benedetto, and Manfredi [1].

2. Main results. We consider the functional

$$F(u) = \int_\Omega (j_B(\|\nabla u(x)\|) + g(u(x)))\, dx$$

and the problem (P) of minimizing $F(u)$ for $u \in u_0 + W_0^{1,\infty}(\Omega)$. We wish to prove the following result.

THEOREM 2.1. *Let Ω be an open bounded subset of $\mathbb{R}^N$, let $g : \mathbb{R} \to \mathbb{R}$ be differentiable and strictly monotonic. Let u_0 in $W^{1,\infty}(\Omega)$ be such that $F(u_0)$ is finite. Then the minimum in problem (P) is attained and any minimizing u is a distributional solution to the Euler–Lagrange inclusion*

$$\operatorname{div} p(x) = g'(u(x)) \quad \text{for} \quad p(x) \in \partial j_{[0,1]}(\|\nabla u(x)\|),$$

i.e., there exists a non-negative function $\alpha \in L^1(\Omega)$, with $\alpha(x) = 0$ when $\|\nabla u(x)\| < 1$ such that

$$\operatorname{div} \alpha(x)\, \nabla u(x) = g'(u(x))$$

in the sense of distributions.

The validity of the theorem is based in the monotonicity of g, needed to establish Lemma 2.3. To prove it we should consider separately the two cases, g increasing and g decreasing. We shall present the proof for the case g increasing. We shall use the notation: for $A \subset \mathbb{R}^N$, $\rho(x, A) = \inf_{y\in A}\{\|x - y\|\}$.

The following lemma is a first regularity result on the solution u.

LEMMA 2.2. *Under the same assumptions as in Theorem 2.1, let u be a solution to problem (P). Then for every x_0 and $r > 0$ such that $B_r(x_0)$ is contained in Ω, we have*

$$\sup\{u(x) - u(x_0) : \|x - x_0\| = r\} = r.$$

Proof. The map u must be, on $B_r(x_0)$, Lipschitzian of Lipschitz constant 1. Hence, the supremum above cannot be larger than r. Assume it is equal to ζr, with $\zeta < 1$. Let η be a Lipschitzian function such that

(i) $\eta(x_0) = -r$,

(ii) $\|\nabla\eta\| = 1$,

(iii) $\eta(x) = 0, x \in \Omega \setminus B_r(x_0)$.

Fix $\lambda \in (\zeta, 1)$ and consider the function

$$\eta_\lambda(x) = \lambda\eta(x) - (u(x) - u(x_0)) + \zeta r.$$

We have that: for $x \in \partial B_r(x_0)$, $\eta_\lambda(x) = \zeta r - (u(x) - u(x_0)) \geq 0$ while $\eta_\lambda(x_0) = -\lambda r + \zeta r < 0$. Call E the connected component of the set $\{\eta_\lambda \leq 0\}$ containing x_0 (the measure of E is positive). The map η_λ^- is then defined to be

$$\eta_\lambda^-(x) = \begin{cases} \eta_\lambda(x), & x \in E, \\ 0, & \text{elsewhere.} \end{cases}$$

We have that $\eta_\lambda^-(x) = 0$ for $x \in \partial B_r(x_0)$ and that $\eta_\lambda^-(x_0) < 0$; moreover,

$$\nabla\eta_\lambda^-(x) = \begin{cases} \lambda\nabla\eta(x) - \nabla u(x), & x \in E, \\ 0, & \text{elsewhere,} \end{cases}$$

so that $\|\nabla\eta_\lambda\| \leq 2$. It is our purpose to show that for parameters $t > 0$ sufficiently small, we have $\|\nabla u + t\nabla\eta_\lambda^-\| \leq 1$.

a) Consider first those $x \in E$ such that $\|\nabla u(x)\| > \frac{1+\lambda}{2}$. We have

$$\langle \nabla u, \nabla\eta_\lambda^- \rangle \leq \lambda\|\nabla u\|\|\nabla\eta\| - \|\nabla u\|^2 = \|\nabla u\|(\lambda - \|\nabla u\|) \leq \|\nabla u\|\frac{\lambda - 1}{2} < 0$$

and

$$|\langle \nabla u, \nabla\eta_\lambda^- \rangle| = -\langle \nabla u, \nabla\eta_\lambda^- \rangle \geq \|\nabla u\|\frac{1-\lambda}{2} \geq \frac{1-\lambda^2}{4}.$$

Hence, for $t \in (0, \frac{1-\lambda^2}{8})$ and a.e. $x \in E$, we have that $2|\langle \nabla u, \nabla\eta_\lambda^- \rangle| > 4t > t\|\nabla\eta_\lambda^-\|^2$. Since

$$\|\nabla u + t\nabla\eta_\lambda^-\|^2 = \|\nabla u\|^2 + t^2\|\nabla\eta_\lambda^-\|^2 + 2t\langle \nabla u, \nabla\eta_\lambda^- \rangle,$$

we obtain

$$\begin{aligned} \|\nabla u + t\nabla\eta_\lambda^-\|^2 &= \|\nabla u\|^2 + t(t\|\nabla\eta_\lambda^-\|^2 + 2\langle \nabla u, \nabla\eta_\lambda^- \rangle) \\ &\leq 1 + t(t\|\nabla\eta_\lambda^-\|^2 - 2|\langle \nabla u, \nabla\eta_\lambda^- \rangle|) < 1. \end{aligned}$$

b) Consider now those $x \in E$ such that $\|\nabla u(x)\| \leq \frac{1+\lambda}{2}$. Then, for t in $(0, \frac{1-\lambda^2}{8})$, we simply have

$$\|\nabla u + t\nabla\eta_\lambda^-\| \leq \|\nabla u(x)\| + t\|\nabla\eta_\lambda^-\| < \frac{1+\lambda}{2} + \frac{1-\lambda}{4}2 = 1.$$

Hence, from the above, the variation η_λ^- is admissible, in the sense that a.e. in Ω, for all t sufficiently small,

$$\|\nabla u + t\nabla\eta_\lambda^-\| \leq 1.$$

For one such t, since: $j_B(\|\nabla u + t\nabla\eta_\lambda^-\|) = 0$, a.e. in Ω; $u + t\eta_\lambda^- \leq u$, a.e. in Ω; $u + t\eta_\lambda^- < u$, a.e. in E, we have

$$F(u + t\eta_\lambda^-) = \int_\Omega g(u(x) + t\eta_\lambda^-(x))\,dx < \int_\Omega g(u(x))\,dx = F(u),$$

a contradiction. The strict monotonicity of g is essential in this step. □

As a simple consequence of the previous lemma, we have the following result.

LEMMA 2.3. *Under the same assumptions as in Lemma* 2.2*, for a.e.* $x \in \Omega$*, we have* $\|\nabla u(x)\| = 1$*; there exist at least one direction* d^x *and a related interval* $[0, b^x)$ *such that for* $\lambda \in [0, b^x), u(x + \lambda d^x) - u(x) = \lambda$ *and* $x + b^x\, d^x \in \partial\Omega$.

Proof. From Lemma 2.2, it follows that to any point $x \in \Omega$ we can associate at least one unit vector (a direction) d^x and (at least) one nonvanishing interval $[0, l)$ such that for $t \in [0, l)$, $u(x + td^x) - u(x) = t$. Given x and d^x, let b^x be such that $[0, b^x)$ is the largest such interval. Let y be on the closure of this segment. When y is in Ω, by the previous lemma we can associate to it at least one direction d^y with the property stated above. This direction d^y must coincide with d^x. Otherwise, choose $x_1 = x + \lambda d^x$ with $\lambda < b^x$ and sufficiently close to it, and choose $y_1 = y + \mu d^y$ with μ positive and sufficiently small, so that the segment from x_1 to y_1 is contained in Ω. Then u is defined on this segment and $u(y_1) - u(x_1) = (u(y_1) - u(y)) + (u(y) - u(x_1)) = \|y_1 - y\| + \|y - x_1\| > \|y_1 - x_1\|$, a contradiction to the fact that u, a solution to the minimum problem, is Lipschitzian with constant 1. In particular, $x + b^x d^x$ must be in $\partial\Omega$ otherwise we would contradict the maximality of b^x. □

Remarks. i) The set of the directions $\{d^x\}$ gives rise to a multivalued map $x \to D(x)$.

ii) From the proof of the above lemma, in particular, we infer that d^y is unique whenever there exist $x \in \Omega$, a direction d^x and t in the interval $(0, b^x)$ such that $y = x + t\, d^x$.

iii) For fixed x and d^x, call (a^x, b^x) the largest open interval such that $u(x + t_1 d^x) - u(x + t_2 d^x) = t_2 - t_1$ for $t_2 > t_1$ and t_1 and t_2 in (a^x, b^x). Whenever x belongs to $S(x) = \{x + td^x : t \in (a^x, b^x)\}$, i.e., when $a^x < 0$, we have that d^x is unique and that a^x and b^x depend only on x, i.e., we can consider the univalent maps $x \to d(x) = d^x, x \to a(x) = a^x$, and $x \to b(x) = b^x$. It will be convenient to set

$$\mathcal{S} = \cup_{\{x \in \Omega\}} S(x).$$

Proof of Theorem 2.1. Let u be a solution to the minimum problem. We have to define a function α with the properties stated in Theorem 2.1 such that for every ϕ in $C_0^\infty(\Omega)$ we have

$$\int_\Sigma \alpha(x) \langle \nabla u(x), \nabla \phi(x) \rangle\, dx + \int_\Sigma g'(u(x)) \phi(x)\, dx = 0.$$

Step a) For k in $\{1, \dots N\}$, let d_k denote the kth component of the vector d. About the properties of the map $x \to d(x)$, we have the following claim, a first regularity result on ∇u.

Claim 2.1. Fix $k \in \{1, \dots, N\}$ and $\varepsilon > 0$. On

$$E_\varepsilon^k = \{x \in \mathcal{S} : (x - \varepsilon d(x), x + \varepsilon d(x)) \subset S(x);\ d_k(x) \geq \frac{1}{\sqrt{N}};\ \rho(x, \partial\Omega) \geq 3\varepsilon\},$$

the map $x \to d(x)$ is Lipschitzian of constant $\frac{2\sqrt{N}}{8}$.

Proof of Claim 2.1. Consider two points P and P' in E_ε^k and set $d = d(P)$, $d' = d(P')$. In the case $\|P - P'\| \geq \frac{\varepsilon}{2\sqrt{n}} \|d - d'\|$, we have

$$\|d(P) - d(P')\| \leq \frac{2\sqrt{N}}{\varepsilon} \|P - P'\|.$$

Hence, we consider the case $\|P-P'\| < \frac{\varepsilon}{2\sqrt{N}}|d-d'|$. Set r to be $\{P+\lambda d : \lambda \in \mathbb{R}\}$ and r' to be $\{P'+\lambda d' : \lambda \in \mathbb{R}\}$. Let $O \in r$ and $O' \in r'$ be the two points of minimal distance for r and r'; then $\langle O'-O, d\rangle = \langle O'-O, d'\rangle = 0$. When $O \neq O'$ we shall refer to the unique three-dimensional space containing r and r' (the case $O = O'$ being similar and simpler). On the plane orthogonal to $O'-O$ and containing r, let r'' be the projection of the line r'. Also let P^* be the nearest point to P on r'', so that $\|P-P'\| \geq \|P-P^*\|$. The point P'' on r'' is defined to be the point having $\|P-O\| = \|P''-O\|$ and lying on the same side (with respect to 0) as P^*. By elementary geometry we have

$$\frac{\|P-P''\|}{\|P-O\|} = \frac{\|d-d'\|}{1}.$$

Consider the triangle O, P, P'' and let H be $\frac{1}{2}P + \frac{1}{2}P''$. We obtain

$$\frac{\|P-P^*\|}{\|P-P''\|} = \frac{\|H-O\|}{\|P''-O\|}.$$

Since, by the definition of E^k_ε, we have that $\frac{\|H-O\|}{\|P''-O\|} \geq \frac{1}{\sqrt{N}}$, we obtain

$$\|P-P''\| = \|P-P^*\|\frac{\|P''-O\|}{\|H-O\|} \leq \sqrt{N}\|P^*-P\|$$

so that

$$\|P-O\| = \frac{\|P-P''\|}{\|d-d'\|} \leq \sqrt{N}\frac{\|P-P^*\|}{\|d-d'\|} \leq \sqrt{N}\frac{\|P-P'\|}{\|d-d'\|} \leq \frac{\varepsilon}{2}.$$

For symmetry reasons, also $\|P'-O'\| \leq \frac{\varepsilon}{2}$. Hence, we have obtained that both O and O' are in Ω, and u is, therefore, defined at O and O'. At this point we are free to assume that $u(O) \geq u(O')$.

Let A and D be the extremes of a segment on $S(P)$ centered on O and of half-length $\frac{\varepsilon}{2}$ and B', C' be the same on $S(P')$ with respect to O'. We have $\|P-A\| \leq \varepsilon$, $\|P-D\| \leq \varepsilon$, and

$$\|P-B'\| \leq \|B'-O'\| + \|O'-P'\| + \|P'-P\| \leq \frac{\varepsilon}{2} + \frac{\varepsilon}{2} + \frac{\varepsilon}{\sqrt{N}} \leq 2\varepsilon, \quad \|P-C'\| \leq 2\varepsilon.$$

Therefore, all the points A, D, B', and C' lie in the ball $B_{2\varepsilon}(P) \subset \Omega$. On this set, the map u is Lipschitzian of Lipschitz constant 1. Let B and C be the projections of the points B' and C' on the plane orthogonal to $O'-O$ and containing O. We can assume that

$$u(D)-u(A) = \|D-A\| \quad \text{and} \quad u(C')-u(B') = \|C'-B'\| = \|C-B\|.$$

Hence, we have

$$\begin{aligned} \|B'-D\| &\geq u(D)-u(B') = u(D)-u(O)+u(O)-u(O')+u(O')-u(B') \\ &= \|D-O\| + u(O)-u(O') + \|B'-O'\| \geq \|D-O\| + \|B'-O'\|, \end{aligned} \tag{1}$$

while, on the other hand,

$$\begin{aligned} \|B'-D\|^2 &= \|B'-B\|^2 + \|B-D\|^2 \\ &= \|O'-O\|^2 + \|B-O\|^2 + \|O-D\|^2 + 2\langle O-D, B-O\rangle. \end{aligned} \tag{2}$$

By (1) and (2) we obtain

$$\|O'-O\|^2+\|B-O\|^2+\|O-D\|^2+2\langle O-D,B-O\rangle \\ \geq \|D-O\|^2+\|B'-O'\|^2+2\|D-O\|\|B'-O'\|;$$

hence,

$$\|O'-O\|^2 \geq 2\|D-O\|\,\|B-O\|\left(1-\left\langle\frac{O-D}{\|D-O\|},\frac{B-O}{\|B-O\|}\right\rangle\right) \\ =\|D-O\|\,\|B'-O'\|(2-2\langle d,d'\rangle)=\left(\frac{\varepsilon}{2}\right)^2\|d-d'\|^2.$$

It follows then that $\|d-d'\|\leq\frac{2}{\varepsilon}\|O-O'\|\leq\frac{2}{\varepsilon}\|P-P'\|$. Hence, we have

$$\|d(P)-d(P')\|\leq\frac{2\sqrt{N}}{\varepsilon}\|P-P'\|$$

for every P and P' in E^k_ε. This proves the claim. □

Step b) The purpose of this step is to define a countable partition of $\mathcal{S}$ consisting of measurable sets.

Consider the set $\mathcal{P}$ of pairs (p,q), where p and q are integers and q is positive, and let $\sigma:\mathbb{N}\to\mathcal{P}$ be a numbering of this set. Denote by (p_n,q_n) the image $\sigma(n)$. To $n\in\mathbb{N}$ and $k\in 1,\dots,N$, we associate the two disjoint sets

$$E_n^{+,k}=\left\{y\in S(x):x_k=\frac{p_n}{q_n};\ d_k(x)=\sup_{1\leq i\leq N}|d_i(x)|;\ \rho(x,\partial\Omega)\geq\frac{3}{q_n}\right. \\ \left.\text{and } x-\frac{1}{q_n}d(x),x+\frac{1}{q_n}d(x)\in S(x)\right\}$$

and

$$E_n^{-,k}=\left\{y\in S(x):x_k=\frac{p_n}{q_n};\ d_k(x)=-\sup_{1\leq i\leq N}|d_i(x)|;\ \rho(x,\partial\Omega)\geq\frac{3}{q_n}\right. \\ \left.\text{and } x-\frac{1}{q_n}d(x),x+\frac{1}{q_n}d(x)\in S(x)\right\}.$$

In order to obtain a partition of $\mathcal{S}$ we operate in the standard way. Set $\Sigma_1^{+,1}=E_1^{+,1}$ and, in general, $\Sigma_1^{+,k+1}=E_1^{+,k+1}\backslash\{\cup_{i=1,\dots,k}\Sigma_1^{+,i}\}$. Set

$$\sum_{n+1}^{+,1}=E_{n+1}^{+,1}\setminus\left\{\bigcup_{i=1,\dots,N;m=1,\dots,n}\sum_m^{+,i}\right\}$$

and

$$\sum_{n+1}^{+,k+1}=E_{n+1}^{+,k+1}\setminus\left\{\left(\bigcup_{i=1,\dots,N;m=1,\dots,n}\sum_m^{+,i}\right)\bigcup\left(\bigcup_{i=1,\dots,k}\sum_{n+1}^{+,i}\right)\right\}.$$

An analogous procedure is applied to the family $E_n^{-,k}$ to yield the disjoint family $\{\Sigma_n^{-,k}\}$. This second family is defined so as to be disjoint from $\{\Sigma_n^{+,k}\}$ as well.

We have defined a disjoint family. We wish to show that it covers $\mathcal{S}$.

Claim 2.2. $\mathcal{S} = \cup_{k=1,\dots,N;n\in\mathbb{N}}(\Sigma_n^{+,k} \cup \Sigma_n^{-,k})$.

Proof of Claim 2.2. We have only to show that

$$\bigcup_{k=1,\dots,N;n\in\mathbb{N}} \left(\sum_n^{+,k} \bigcup \sum_n^{-,k} \right) \supset \mathcal{S}.$$

Since

$$\bigcup_{k=1,\dots,N;n\in\mathbb{N}} \left(\sum_n^{+,k} \bigcup \sum_n^{-,k} \right) = \bigcup_{k=1,\dots,N;n\in\mathbb{N}} \left(E_n^{+,k} \bigcup E_n^{-,k} \right),$$

we have to show that, for every $x \in \Omega$, $S(x)$ is contained in the set at the right-hand side. Let $x \in S(x')$ for some $x' \in \Omega$. There exists a k such that either $d_k(x) = \sup_{i=1,\dots,N} |d_i(x)|$ or $d_k(x) = -\sup_{i=1,\dots,N} |d_i(x)|$. Let us consider the first case (the other being analogous). Call $\Delta = \rho(x, \partial\Omega)$. Since $S(x')$ is an open interval, there exists δ, $0 < \delta < \frac{\Delta}{2}$, such that

$$\{x + \lambda d(x) : -\delta \le \lambda \le \delta\} \subset S(x').$$

Let q be a positive integer such that $1/q < \delta/(2\sqrt{N})$; there exists p such that $|p/q - x_k| \le 1/2q$. The point $y = x + (\frac{p}{q} - x_k)/d_k(x)d(x)$ has the following properties: its kth component y_k equals p/q; recalling that $d_k(x) \ge 1/\sqrt{N}$, we have that $\|x - y\| = \left|(\frac{p}{q} - x_k)/d_k(x)\right| \le \sqrt{N}/2q < \delta/4$. As a consequence, an interval (on $S(x')$) centered at y and of half-length $1/q$ is contained in $S(y)$ $(= S(x'))$ and contains x. Moreover, $\rho(y, \partial\Omega) \ge \Delta - \delta/4 \ge 7/4\delta \ge 3/q$. Hence, setting $n = \sigma^{-1}(p, q)$, we have $x \in E_n^{+,k}$. This proves Claim 2.2. □

Claim 2.3. The measure of $\Omega\backslash\mathcal{S}$ equals zero.

Proof of Claim 2.3. Since the subset of Ω of those points where u is not differentiable is of measure zero, it is enough to show that the subset of $\Omega\backslash\mathcal{S}$ where u is differentiable is of measure zero. In particular, for x in such a set, we can assume that there exists a unique vector d^x, as defined in Step a); otherwise we would contradict the differentiability at x.

Since $\cup_{k,n}(E_n^{+,k} \cup E_n^{-,k}) = \mathcal{S}$, we shall prove that $m(\Omega\backslash \cup_{k,n} (E_n^{+,k} \cup E_n^{-,k})) = 0$. Assume, on the contrary, that this set is of positive measure and let x_0 be a point of density of it. As it easy to see, the map $x \to D(x)$ as defined in Step a) is upper semicontinuous. In fact, it has a closed graph and its range is contained in the compact set B. Then a well-known criterion for upper semicontinuity applies. It follows then that for every ε there exists δ such that $\|d^x - d(x_0)\| < \varepsilon$ for $\|x - x_0\| < \delta$ and $d^x \in D(x)$. By changing coordinates we shall assume $x_0 = 0$ and $d_N(x_0) = 1$.

Let us consider the (family of) sets $Q_\ell = \{x : 0 \le |x_i| \le \ell,\ i = 1, \dots, N\}$ and let us choose ℓ so small that, for every $x \in Q_\ell$, we have:

i) $\rho(x, \partial\Omega) \ge \ell$,

ii) $d_N(x) \ge \max\{\frac{1}{\sqrt{N}}, \frac{2}{\sqrt{5}}\}$.

Let us consider the subset of Q_ℓ defined by

$$I_\ell = \left\{ x : x_N = 0 \text{ and } |x_i| \le \frac{\ell}{2},\ i = 1, \dots, N-1 \right\}.$$

The $(N-1)$-dimensional measure of I_ℓ is ℓ^{N-1}, while the N-dimensional measure of Q_ℓ is $(2\ell)^N$. Fix t, $\frac{\ell}{3} \le t \le \frac{2}{3}\ell$ and consider, on the hyperplane $\{x_N = t\}$, the set

$$P_t = \left\{ x + t\frac{d(x)}{d_N(x)} : x \in I_\ell \text{ and } d \in D(x) \right\}.$$

Every point y in this set is interior to $S(y)$; $D(y) = d(y)$ so that it is possible to define the map $F_t : P_t \to I_\ell$ defined by

$$F_t(y) = y - t\frac{d(y)}{d_N(y)}.$$

Notice that P_t is contained in E^N_ε as defined in Claim 2.1, with $\varepsilon = \ell/3$; hence the restriction of d to P_t is Lipschitzian with constant $(6\sqrt{N})/\ell$. For y and y' in P_t, we have

$$\begin{aligned}\left\|\frac{d(y)}{d_N(y)} - \frac{d(y')}{d_N(y')}\right\| &\le \frac{\|d(y) - d(y')\|}{d_N(y)} + \frac{\|d(y')\|}{d_N(y)d_N(y')}|d_N(y) - d_N(y')| \\ &\le \sqrt{N}\frac{6\sqrt{N}}{\ell}\|y - y'\| + N\frac{6\sqrt{N}}{\ell}\|y - y'\| \le \frac{12N\sqrt{N}}{\ell}\|y - y'\|.\end{aligned}$$

Hence, the map F_t is Lipschitzian with constant $1 + t\frac{12N\sqrt{N}}{\ell} \le 1 + 8N\sqrt{N}$.

Considering the $(N-1)$-dimensional measure of a subset A of P_t, we have then $m(F_t(A)) \le (1 + 8N\sqrt{N})m(A)$. Hence,

$$m(P_t) \ge \frac{m(F_t(P_t))}{1 + 8N\sqrt{N}} = \frac{m(I_\ell)}{1 + 8N\sqrt{N}} = \frac{\ell^{N-1}}{1 + 8N\sqrt{N}}.$$

The set $\cup_{\ell/3 \le t \le 2\ell/3} P_t$ is contained in $\mathcal{S}$ and, by Fubini's theorem, its N-dimensional measure is at least $\ell^N/(3 + 24N\sqrt{N})$, a fixed fraction of the total measure of Q_ℓ. Hence, x_0 cannot be a point of density. This proves Claim 2.3. □

Claim 2.4. For every $k = 1, \dots, N$, for every n, the sets $\Sigma^{\pm,k}_n$ are measurable.

From now up to Step d) we shall fix a choice of either $+$ or $-$, of k and of n. Hence, for simplicity's sake, we will drop $\pm, n, k$ and simply denote $E^{\pm,k}_n$ by E and $\Sigma^{\pm,k}_n$ by Σ. We shall denote by $\hat{x}$ the $(N-1)$-dimensional vector $(x_1, \dots, x_{k-1}, x_{k+1}, \dots, x_N)$. It is convenient to set $\hat{E}$ to be the subset of $\mathbb{R}^{N-1}$ defined by $\hat{E} = \{\hat{x} : x \in E \cap \{x : x_k = p_n/q_n\}\}$, and analogously for $\hat{\Sigma}$. Consider $(\hat{x}, t)$, $\hat{x} \in \hat{E}, a(\hat{x}) < t < b(\hat{x})$ and define the map

$$\Xi(\hat{x}, t) = x + td(x).$$

This map is uniformly Lipschitz continuous.

Proof of Claim 2.4. As it is easy to see, both the maps $a(\hat{x})$ and $b(\hat{x})$ are lower semicontinuous on $\hat{E}$, and $\hat{E}$ can be described as the intersection of a closed set with the counterimages through a and b of the interval $[-1/q_n, 1/q_n]$; hence it is a measurable set. The subset of $\mathbb{R}^N$ described by $\{(\hat{x}, t) : \hat{x} \in \hat{E}; a(\hat{x}) < t < b(\hat{x})\}$ is measurable and so is E, its image through the Lipschitz continuous map Ξ. Similarly for E. It follows that Σ is measurable. This proves Claim 2.4. □

Step c) We wish to study the properties of the maps $\Xi(\hat{x}, t)$ defined above and of $J\Xi(\hat{x}, t)$.

For a.e. $(\hat{x}, t) \in (\Xi)^{-1}(\Sigma)$, we have that $\nabla\Xi$ exists and a computation shows that it can be obtained as follows. Consider the $N \times N$ matrix $\nabla d(x)$ and form the matrix $I + t\nabla d(x)$. Replace the kth column by the components of $d(x)$, and compute it by setting the kth component of x to be p_n/q_n and the other components to be the components of $\hat{x}$. This is the matrix $\nabla\Xi$. Hence, $J\Xi$ is uniformly bounded on Σ. It is also a.e. different from zero. In fact, differentiating the identity $\|d(x)\| = 1$, we obtain

$(\nabla d(x))\, d(x) = 0$, so that $(I + t\nabla d(x))\, d(x) = d(x)$. By Cramer's rule and the above computation of $\nabla \Xi$, we obtain

$$d_k(x) = \pm \frac{J\Xi(\hat{x}, t)}{det(I + t\nabla d(x))}.$$

Since (on Σ), $|d_k| > \frac{1}{\sqrt{N}}$, we finally have $J\Xi(\hat{x}, t) \neq 0$.

We wish to define a map α and prove it is in $L^1(\Sigma)$. Define first the map β on $(\Xi)^{-1}(\Sigma)$ setting,

$$\beta(\hat{x}, t) = \frac{1}{J\Xi(\hat{x}, t)} \int_{a(\hat{x})}^{t} g'(u(\Xi(\hat{x}, s)))\, J\Xi(\hat{x}, s)\, ds.$$

For $x \in \Sigma$ define α as

$$\alpha(x) = \beta((\Xi)^{-1}(x)).$$

Claim 2.5. $\alpha \in L^1(\Sigma)$.

Proof of Claim 2.5. We recall the change of variables formula ([3, Theorem 2, p. 99]) that states for a function $v \in L^1$ and an invertible and Lipschitzian transformation Ξ, we can write

$$\int v(\Xi(\hat{x}, t)\, J\Xi(\hat{x}, t)\, d(\hat{x}, t) = \int v(x)\, dx.$$

By this formula we obtain

$$\begin{aligned}\int_{\Sigma} g'(u(x))\, dx &= \int_{(\Xi)^{-1}(\Sigma)} g'(u(\Xi(\hat{x}, t)))J\Xi(\hat{x}, t)\, d(\hat{x}, t) \\ &= \int_{\hat{\Sigma}} \left(\int_{a(\hat{x})}^{b(\hat{x})} g'(u(\Xi(\hat{x}, t)))J\Xi(\hat{x}, t)\, dt \right) d\hat{x}.\end{aligned}$$

Similarly, by the change of variables formula and applying the definitions of α and β, we have

$$\begin{aligned}\int_{\Sigma} \alpha(x)\, dx &= \int_{(\Xi)^{-1}(\Sigma)} \beta(\hat{x}, t)J\Xi(\hat{x}, t)\, d(\hat{x}, t) = \int_{\hat{\Sigma}} \left(\int_{a(\hat{x})}^{b(\hat{x})} \beta(\hat{x}, t)J\Xi(\hat{x}, t)\, dt \right) d\hat{x} \\ &= \int_{\hat{\Sigma}} \left(\int_{a(\hat{x})}^{b(\hat{x})} \int_{a(\hat{x})}^{t} g'(u(\Xi(\hat{x}, s)))J\Xi(\hat{x}, s)\, ds\, dt \right) d\hat{x}.\end{aligned}$$

Integrating by parts we obtain that

$$\int_{a(\hat{x})}^{b(\hat{x})} \int_{a(\hat{x})}^{t} g'(u(\Xi(\hat{x}, s)))J\Xi(\hat{x}, s)\, ds\, dt = -\int_{a(\hat{x})}^{b(\hat{x})} (t - b(\hat{x}))g'(u(\Xi(\hat{x}, t)))J\Xi(\hat{x}, t)\, dt.$$

Hence,

$$\begin{aligned}\int_{\Sigma} \alpha(x)\, dx &\leq \int_{\hat{\Sigma}} \operatorname{diam}(\Omega) \left(\int_{a(\hat{x})}^{b(\hat{x})} g'(u(\Xi(\hat{x}, t)))J\Xi(\hat{x}, t)\, dt \right) d\hat{x} \\ &= \operatorname{diam}(\Omega) \int_{\Sigma} g'(u(x))\, dx. \qquad \square\end{aligned}$$

Step d) Since the sets $\Sigma_n^{\pm,k}$ are disjoint and (with the addition of a null set) form a partition of Ω, α is actually defined a.e. on Ω and by adding the previous inequalities over $+$ and $-$ and all k and n, we have that $\alpha \in L^1(\Omega)$.

Setting $p(x) = \alpha(x)\nabla u(x)/(\|\nabla u(x)\|)$, we want to show that the pair $(u(x), p(x))$ is a solution to the Euler–Lagrange equation for the minimization problem (P).

Fix arbitrarily ϕ in $C_0^\infty(\Omega)$ and consider

$$\int_\Omega \alpha(x)\langle \nabla u(x), \nabla\phi(x)\rangle \, dx.$$

Since $\|\langle \nabla u(x), \nabla\phi(x)\rangle\|$ is bounded, the integrand is in $L^1(\Omega)$ and the integral over Ω is the sum of the integrals over $\Sigma_n^{\pm,k}$. We fix one such $\Sigma_n^{\pm,k}$ that we denote by Σ and recall the corresponding notations introduced in Step b). Recall that, by the definition of Ξ and the properties of ∇u,

$$\frac{\partial}{\partial t}\Xi(\hat{x}, t) = \nabla u(\Xi(\hat{x}, t)),$$

independent of t. Hence,

$$\frac{\partial}{\partial t}\phi(\Xi(\hat{x}, t)) = \langle \nabla u(\Xi(\hat{x}, t)), \nabla\phi(\Xi(\hat{x}, t))\rangle.$$

By the change of variables formula and the definition of α, we have

$$\begin{aligned}\int_\Sigma \alpha(x)\langle \nabla u(x), \nabla\phi(x)\rangle \, dx &= \int_{\hat{\Sigma}} \left(\int_{a(\hat{x})}^{b(\hat{x})} \alpha(\Xi(\hat{x}, t)) \frac{\partial}{\partial t}\phi(\Xi(\hat{x}, t)) \, J\Xi(\hat{x}, t) dt \right) d\hat{x} \\ &= \int_{\hat{\Sigma}} \left(\int_{a(\hat{x})}^{b(\hat{x})} \frac{\partial}{\partial t}\phi(\Xi(\hat{x}, t)) \int_{a(\hat{x})}^{t} g'(u(\Xi(\hat{x}, s))) \, J\Xi(\hat{x}, s) \, ds \, dt \right) d\hat{x}.\end{aligned}$$

Integrating by parts we have

$$\begin{aligned}\int_\Sigma \alpha(x)\langle \nabla u(x), \nabla\phi(x)\rangle \, dx = \int_{\hat{\Sigma}} \Bigg(&\left[\phi(\Xi(\hat{x}, t)) \int_{a(\hat{x})}^{t} g'(u(\Xi(\hat{x}, s))) \, J\Xi(\hat{x}, s) \, ds \right]_{a(\hat{x})}^{b(\hat{x})} \\ &- \int_{a(\hat{x})}^{b(\hat{x})} g'(u(\Xi(\hat{x}, t)))\phi(\Xi(\hat{x}, t)) \, J\Xi(\hat{x}, t) \, dt \Bigg) d\hat{x}.\end{aligned}$$

The first term at the right-hand side is zero since $\Xi(\hat{x}, b(\hat{x}))$ belongs to $\partial\Omega$.

In the same way we compute $\int_\Sigma g'(u(x))\phi(x) \, dx$. We have

$$\int_\Sigma g'(u(x))\phi(x) \, dx = \int_{\hat{\Sigma}} \left(\int_{a(\hat{x})}^{b(\hat{x})} g'(u(\Xi(\hat{x}, t)))\phi(\Xi(\hat{x}, t)) \, J\Xi(\hat{x}, t) \, dt \right) d\hat{x}.$$

Hence,

$$\int_\Sigma \alpha(x)\langle \nabla u(x), \nabla\phi(x)\rangle \, dx + \int_\Sigma g'(u(x))\phi(x) \, dx = 0$$

for every $\Sigma_n^{\pm,k}$, hence the same is true on Ω. The pair $(p(x), u(x))$, where $p = \alpha\nabla u/(\|\nabla u\|)$, is a distributional solution to the differential inclusion

$$\operatorname{div} p(x) = g'(u(x)) \quad \text{for} \quad p(x) \in \partial j_{[0,1]}(\|\nabla u(x)\|). \qquad \square$$

A FEASIBLE DIRECTIONS ALGORITHM FOR OPTIMAL CONTROL PROBLEMS WITH STATE AND CONTROL CONSTRAINTS: CONVERGENCE ANALYSIS*

R. PYTLAK† AND R. B. VINTER†

Abstract. In this paper we describe an optimization algorithm for the computation of solutions to optimal control problems with control, state, and terminal constraints. Inequality and equality constraints are dealt with by means of feasible directions and exact penalty approaches, respectively. We establish a general convergence property of the algorithm which makes no reference to the existence of accumulation points; in this analysis the compactness of the space of relaxed controls is used only to guarantee boundedness of the sequence of penalty parameters. We also demonstrate that relaxed accumulation points of sequences generated by the algorithm satisfy standard first-order necessary conditions of optimality. The algorithm contains a number of computation saving features, including an ε-active strategy for dealing with the "infinite dimensional" inequality constraints. Our convergence analysis provides techniques for studying the convergence properties of related optimization algorithms in which direction-finding subproblems involve the approximation of directional derivatives of the Chebyshev functional associated with state constraints. A companion paper provides details of implementation and numerical examples.

1. Introduction.

This paper concerns a new first-order, feasible directions algorithm for the solution of the following optimal control problem with pathwise state inequality constraints, labeled **(P)**:

$$\begin{aligned} &\min_u \phi(x(1)) \\ &\text{s.t. } \dot{x}(t) = f(t, x(t), u(t)), \text{ a.e. on } [0,1],\ x(0) = x_0, \\ &u(t) \in \Omega \ \text{ a.e. on } [0,1], \\ &h_i^1(x(1)) = 0\ \forall i \in E, \\ &h_j^2(x(1)) \le 0\ \forall j \in I, \\ &q(t, x(t)) \le 0\ \forall t \in [0,1], \end{aligned} \tag{1.1}$$

expressed in terms of the data: finite sets of index values E, I, functions $f : [0,1] \times \mathcal{R}^n \times \mathcal{R}^m \to \mathcal{R}^n$, $\phi : \mathcal{R}^n \to \mathcal{R}$, $h_i^1 : \mathcal{R}^n \to \mathcal{R}$ for $i \in E$, $h_j^2 : \mathcal{R}^n \to \mathcal{R}$ for $j \in I$ and $q : [0,1] \times \mathcal{R}^n \to \mathcal{R}$, a vector $x_o \in \mathcal{R}^n$, and a set $\Omega \subset \mathcal{R}^m$ of the form

$$\Omega = \{u \in \mathcal{R}^m :\ b_-^i \le u_i \le b_+^i \text{ for } i = 1, 2, \ldots, m\}, \tag{1.2}$$

in which b_-^i, b_+^i, $i = 1, 2, \ldots, m$ are constants. Throughout, T denotes $[0,1]$.

Everything that follows can be adapted to allow for multiple pathwise inequality constraints and also for presence of an integral cost term; we limit ourselves to the above special case for notational simplicity.

A *control function* $u : T \to \mathcal{R}^m$ is a measurable function which satisfies $u(t) \in \Omega$ a.e. Given any control function, under the hypotheses we shall impose there is a unique absolutely continuous function $x : T \to \mathcal{R}^n$ satisfying $\dot{x}(t) = f(t, x(t), u(t))$ a.e. on T and $x(0) = x_0$. It is denoted by x^u and is referred to as the *state trajectory corresponding to* u.

The control problem **(P)** can be expressed as an optimization problem over the set of control functions

$$\mathcal{U} = \{u : T \to \mathcal{R}^m : \ u \text{ is measurable and } u(t) \in \Omega \text{ a.e. on } T\}$$

with the aid of the functions $\tilde{F}_0 : \mathcal{L}^2_m[T] \to \mathcal{R}$, $\tilde{h}^1_i : \mathcal{L}^2_m[T] \to \mathcal{R}$ for $i \in E$, $\tilde{h}^2_j : \mathcal{L}^2_m[T] \to \mathcal{R}$ for $j \in I$ and $\tilde{q} : \mathcal{L}^2_m[T] \to \mathcal{C}[T]$:

$$\begin{aligned}
\tilde{F}_0(u) &= \phi(x^u(1)),\\
\tilde{h}^1_i(u) &= h^1_i(x^u(1)) \ \forall i \in E,\\
\tilde{h}^2_j(u) &= h^2_j(x^u(1)) \ \forall j \in I,\\
\tilde{q}(u)(t) &= q(t, x^u(t)) \ \forall t \in T.
\end{aligned}$$

The reformulated problem is

$$\min_{u \in \mathcal{U}} \tilde{F}_0(u)$$

s.t.

$$\begin{gathered}
\tilde{h}^1_i(u) = 0 \ \forall i \in E, \ \tilde{h}^2_j(u) \le 0 \ \forall j \in I,\\
\tilde{q}(u)(t) \le 0 \ \forall t \in T.
\end{gathered}$$

The algorithm which we propose has the following features:

a) the algorithm aims to solve a related problem $(\mathbf{P_c})$ in which the equality constraints are replaced by an "exact penalty term" in the cost:

$$\begin{gathered}
\min_{u \in \mathcal{U}} \tilde{F}_c(u)\\
\text{s.t. } \tilde{h}_j(u) \le 0 \ \forall j \in I \text{ and } \tilde{q}(u)(t) \le 0 \ \forall t \in T
\end{gathered}$$

in which

$$\tilde{F}_c(u) = \tilde{F}_0(u)/c + \max_{i \in E} |\tilde{h}^1_i(u)|.$$

(The penalty parameter c is updated according to a simple test, along the lines of that earlier employed by Mayne and Polak [8].)

b) The algorithm generates a sequence of controls whose corresponding state trajectories satisfy the pathwise and endpoint inequality constraints. Search directions are generated by solving a convex control subproblem. The new control is found by conducting an Armijo line search along the direction point obtained from a direction finding subproblem.

Algorithms involving function space iterations for the solution of optimal control problems with pathwise state inequality constraints, with accompanying convergence analysis, have been proposed by Warga [20], Mayne and Polak [9], and Polak, Yang, and Mayne [11]. Both the Warga and Mayne–Polak algorithms involve proximity-type subalgorithms to generate search directions, and their effective implementation is

hampered by the poor performance of proximity-type algorithms applied to the convex sets in infinite dimensional spaces which arise in this context. The algorithm of Warga generates a sequence of relaxed controls, accumulation points of which are shown to satisfy a strong version of the relaxed maximum principle. None of these algorithms involves an ε-active strategy for state constraints, a feature of our algorithm which greatly enhances its efficiency. In the later Polak–Yang–Mayne algorithm, barrier functions are used to eliminate pathwise state constraints from the direction-finding problems. Computation experience of this algorithm is limited, though preliminary findings are promising [11]. The algorithm applies only to problems with no equality constraints.

Machielsen [10] and Alt and Malanowski [1] investigate "function space" second-order methods for solving optimal control problems with state constraints; a local convergence analysis and numerical examples are to be found in [1] and [10], respectively. The fact that the direction-finding subproblems of [10] and [1] are, in general, nonconvex optimal control problems creates difficulties both regarding efficient implementation and global convergence analysis.

A companion paper provides a full discussion of implementational aspects of the algorithm and also numerical examples. The examples include an optimal control problem arising in flight mechanics, concerning optimal control strategies in the presence of windshear, extensively studied by Bulirsh, Montrone, and Pesch [4], [5]. The fact that our feasible directions algorithm provides a solution to the "windshear" problem without recourse to prior information about junction times or control structure (which are required in the method employed in [5]) is evidence of the effectiveness of our algorithm (and indirect, nonlinear programming methods in general) as a computational tool.

What special characteristics of the algorithm provided in this paper promote efficient implementation? One is that search directions generated by the algorithm drive state trajectories into the interior of the state constraint region. This means that satisfaction of the state constraint over the entire time interval T can still be guaranteed, even if we impose the state constraint at only relatively few points in T [16]. Consequently a coarser discretization can be applied to the state constraint than that associated with the parametrization of control functions. This is significant since it is precisely the "dimensionality" of the pathwise constraint which makes it difficult to compute optimal controls for (**P**). Techniques for the approximation of sets on which the state constraint is required to be satisfied were anticipated in an algorithm proposed by Fedorenko [6].

While techniques for deriving conditions on accumulation points generated in both feasible directions and also exact penalty methods in finite dimensional nonlinear programming are now available and well understood, developing a convergence analysis for the optimal control problem (**P**) poses additional difficulties, notably those associated with an inequality constraint function having infinite dimensional range and with the fact that the set $\mathcal{U}$ is not compact. Novel features of the convergence analysis are as follows. We propose the convergence analysis based on the "nonpositive descent function," which along the sequences generated by our algorithm is convergent. Its limit point, equal to zero, is the statement of necessary optimality conditions. A customary result in the literature would be that "relaxed" accumulation points of sequences generated by our algorithm satisfy necessary conditions of optimality in the form of a "relaxed" version of the maximum principle. Our convergence result is stronger in the sense that it is valid for the whole sequence generated by our algo-

rithm. The compactness of the space of relaxed controls is needed only to guarantee boundedness of penalty parameters. The algorithm allows for a computation-saving ε-active strategy in dealing with the "infinite dimensional" inequality constraint. A single, simply stated constraint qualification (hypothesis (**CQ**) below) is invoked both to ensure finite increase of the penalty parameter and to derive properties of accumulation points in place of a pair of constraint qualification–type hypotheses featured, for example, in [8], [9]. We clarify the relationship between standard necessary conditions of optimality and the "nonpositive descent function"–type conditions.

It is to be expected that analytical techniques developed here will also be of benefit in studying the convergence properties of related algorithms for solving optimal control problems, involving Chebyshev-type functional constraints where, owing to the use of a variable stepsize in integration or high order integration procedures, it is either not possible or inconvenient to base the analysis on an a priori discretization of the dynamic equations (see [13]). The algorithm (and its convergence analysis) presented in the paper can easily be adapted to control problems with state constraints whose control functions are defined by piecewise constant (or piecewise polynomial) functions. One such method, a second-order method which exploits the convergence analysis presented here, is described in [13]. It favorably compares with efficient implementations of sequential quadratic programming (SQP) algorithms [7], [22] applied to nonlinear programming problems which are generated by collocation schemes [18].

2. Representation of functional directional derivatives. At each iteration of the feasible directions algorithm, search directions are generated by solving a simplified version of the exact penalty function problem in which the dynamics and cost functional and constraint functionals are replaced by their first-order approximations around the current control function u.

For $d \in \mathcal{U} - u$ we need to consider the first-order approximation $x^u + y^{u,d}$ to x^{u+d} in which the perturbation $y^{u,d}$ to the nominal state trajectory x^u is the unique solution to the linearized equations

$$\begin{aligned} &\dot{y}(t) = f_x(t, x^u(t), u(t))y(t) + f_u(t, x^u(t), u(t))d(t), \\ &y(0) = 0. \end{aligned} \tag{2.1}$$

First-order approximations to the functionals $\tilde{F}_0(u+d) - \tilde{F}_0(u)$, $\tilde{h}^1_i(u+d) - \tilde{h}^1_i(u)$ $(i \in E)$, $\tilde{h}^2_j(u+d) - \tilde{h}^2_j(u)$ $(j \in I)$, and $\tilde{q}(u+d)(t) - \tilde{q}(u)(t)$ $(t \in [0,1])$ can now be defined via $y^{u,d}$ as follows:

$$\begin{aligned} \langle \nabla \tilde{F}_0(u), d\rangle &:= \phi_x(x^u(1))y^{u,d}(1), \\ \langle \nabla \tilde{h}^1_i(u), d\rangle &:= (h^1_i)_x(x^u(1))y^{u,d}(1) \text{ for } i \in E, \\ \langle \nabla \tilde{h}^2_j(u), d\rangle &:= (h^2_j)_x(x^u(1))y^{u,d}(1) \text{ for } j \in I, \\ \langle \nabla \tilde{q}(u)(t), d\rangle &:= q_x(t, x^u(t))y^{u,d}(t) \ \forall\ t \in T. \end{aligned}$$

The notation $\langle \nabla \tilde{F}_0(u), d\rangle$ is intended to convey the suggestion that $\langle \nabla \tilde{F}_0(u), \cdot\rangle$ is a directional derivative associated with some kind of "derivative" $\nabla \tilde{F}_0$ of the functional $\tilde{F}_0$ at u. It is, however, unnecessary to pursue this interpretation (this would require us to specify function spaces and the precise notation of the derivative $\nabla \tilde{F}_0$). As far as describing the feasible directions algorithm and analyzing its convergence properties are concerned, the simplest course is to take the above formulas for $\langle \nabla \tilde{F}_0(u), d\rangle$, etc., as *definitions* of constructs featured in the algorithm whose properties can be

analyzed directly with the help of the results on the relationship between nonlinear control systems and their linear approximations.

The propositions stated below are useful in the analysis of the convergence properties of optimal control algorithms (and our algorithm in particular). Reference will be made in this and the subsequent sections to the following hypotheses.

(H1) $f(t,\cdot,\cdot)$ is continuously differentiable for fixed t, and f, f_x, and f_u are continuous functions. There exists $K<\infty$ such that

$$\|f_x(t,x,u)\| \le K \text{ for all } (t,x,u)\in T\times\mathcal{R}^n\times\Omega. \tag{2.2}$$

(H2) ϕ, h_i^1, $i\in E$, h_j^2, $j\in I$, are continuously differentiable functions. $q(t,\cdot)$ is differentiable for each t, and q, q_x are continuous functions.

Conditions **(H1)** and **(H2)** are regularity hypotheses on the data. Condition (2.2) could be substituted by any condition ensuring the uniform boundedness of state trajectories, for then we can always arrange that (2.2) is satisfied by redefining f for large values of the x variable, values which will never be encountered.

Proofs of the propositions, which are not provided here for the lack of space, are to be found in [15].

PROPOSITION 2.1. *Assume* **(H1)**. *For each* $u\in\mathcal{U}$ *and* $d\in\mathcal{L}_m^2[T]$, (1.1) *and* (2.1) *have unique solutions* (*in the class of absolutely continuous vector valued functions on* $[0,1]$) x^u *and* $y^{u,d}$, *respectively. Furthermore there exist finite constants* c_1, c_2, *and* c_3 *such that*

$$\begin{aligned}\|x^u\|_{\mathcal{L}^\infty} &\le c_1,\\ \|x^u-x^v\|_{\mathcal{L}^\infty} &\le c_2\|u-v\|_{\mathcal{L}^2},\\ \|y^{u,d}\|_{\mathcal{L}^\infty} &\le c_3\|d\|_{\mathcal{L}^2}\end{aligned}$$

$\forall u,\ v\in\mathcal{U},\ d\in\mathcal{L}_m^2[T]$. *In particular,*

$$\|y^{u,d}\|_{\mathcal{L}^\infty} \le c_3\|d\|_{\mathcal{L}^\infty}$$

if $u\in\mathcal{U},\ d\in\mathcal{L}_m^\infty[T]$.

PROPOSITION 2.2. *Assume* **(H1)**. *Then there exists a function* $o_1(\cdot):(0,\infty)\to(0,\infty)$ *such that* $s^{-1}o_1(s)\to 0$ *as* $s\downarrow 0$ *and*

$$\|x^{u+d}-(x^u+y^{u,d})\|_{\mathcal{L}^\infty} \le o_1(\|\,d\|_{\mathcal{L}^\infty})$$

$\forall u\in\mathcal{U}$ *and* $d\in\mathcal{L}_m^\infty[T]$.

PROPOSITION 2.3. *Assume* **(H1)**. *Take a function* $q:T\times\mathcal{R}^n\to\mathcal{R}$ *such that* $q(t,\cdot)$ *is differentiable and* q, q_x *are continuous. Then for any* $\varepsilon>0$ *there exists* $o_2^\varepsilon(\cdot):(0,\infty)\to(0,\infty)$ *such that* $s^{-1}o_2^\varepsilon(s)\to 0$ *as* $s\downarrow 0$ *and*

$$|\max_{t\in R_{\varepsilon,u}}[q(t,x^u(t))+q_x(t,x^u(t))y^{u,d}(t)]-\max_{t\in T}q(t,x^{u+d}(t))| \le o_2^\varepsilon(\|d\|_{\mathcal{L}^\infty}) \tag{2.3}$$

$\forall u\in\mathcal{U}$ *and* $d\in\mathcal{L}_m^\infty[T]$. $R_{\varepsilon,u}$, *the set of times at which the state constraint is* ε*-active, is defined in* (4.1).

PROPOSITION 2.4. *Assume* **(H1)**. *Take a continuously differentiable function* $h:\mathcal{R}^n\to\mathcal{R}$. *Then there exists* $o_3(\cdot):(0,\infty)\to(0,\infty)$ *such that* $s^{-1}o_3(s)\to 0$ *as* $s\downarrow 0$ *and*

$$|h(x^{u+d}(1))-[h(x^u(1))+h_x(x^u(1))y^{u,d}(1)]| \le o_3(\|d\|_{\mathcal{L}^\infty})$$

for all $u \in \mathcal{U}$ *and* $d \in \mathcal{L}^\infty_m[T]$.

PROPOSITION 2.5. *Assume* **(H1)**. *Take continuously differentiable functions* $h_i : \mathcal{R}^n \to \mathcal{R}$, $i \in E$. *Then there exists* $o_4(\cdot) : (0,\infty) \to (0,\infty)$ *such that* $s^{-1}o_4(s) \to 0$ *as* $s \downarrow 0$ *and*

$$|\max_{i\in E}|h_i(x^u(1)) + (h_i)_x(x^u(1))y^{u,d}(1)| - \max_{i\in E}|h_i(x^{u+d}(1))|| \le o_4(\|d\|_{\mathcal{L}^\infty})$$

for all $u \in \mathcal{U}$, $d \in \mathcal{L}^\infty_m[T]$.

3. Relaxed controls. The convergence analysis to follow involves relaxed controls. In this section we briefly review their properties and introduce some notation.

We recall that a *Radon probability measure* ς on the Borel sets of Ω is a regular positive measure such that $\varsigma(\Omega) = 1$. The set of all Radon probability measures is denoted by $rpm(\Omega)$. A *relaxed control*, μ, is a measurable function $\mu : T \to rpm(\Omega)$, where "measurability" is as defined in [19]. The set of relaxed controls is denoted by $\bar{\mathcal{U}}$.

Let $\mathcal{L}^1(T, \mathcal{C}(\Omega))$ denote the space of absolutely integrable functions from T to $\mathcal{C}(\Omega)$. Then the topology imposed on $\bar{\mathcal{U}}$ is the weakest topology such that the mapping

$$\mu \to \int_T \int_\Omega \psi(t,u)\mu(t)(du)dt$$

is continuous for all $\psi \in \mathcal{L}^1(T, \mathcal{C}(\Omega))$.

We recall [19, p. 287] that $\bar{\mathcal{U}}$ is a compact and convex subset of a normed vector space (namely, the dual space of $\mathcal{L}^1(T, \mathcal{C}(\Omega))$ with a "weak" norm whose topology restricted to $\bar{\mathcal{U}}$ coincides with the weak star topology).

Relaxed controls give rise to the relaxed dynamics:

$$\dot{x}(t) = f_r(t, x(t), \mu(t)) := \int_\Omega f(t, x(t), u)\mu(t)(du),\ x(0) = x_0,$$

whose solution we denote by x^μ_r. Extensions to relaxed controls of functions in problem (**P**) are denoted as follows: $\hat{F}_0(\mu) = \phi(x^\mu_r(1))$, $\hat{h}^1_i(\mu) = h^1_i(x^\mu_r(1))$, $\hat{h}^2_j(\mu) = h^2_j(x^\mu_r(1))$, $\hat{q}(\mu)(t) = q(t, x^\mu_r(t))$. We can define then the relaxed problem ($\mathbf{P^r}$) as the problem (**P**) in which functions $\tilde{F}_0$, etc., are substituted by $\hat{F}_0$, etc., ordinary controls u by relaxed controls μ and $\mathcal{U}$ by $\bar{\mathcal{U}}$.

With each ordinary control $u \in \mathcal{U}$ we associate a relaxed control $\mu \in \bar{\mathcal{U}}$ defined by the property $\mu(t)(S) = \delta_{u(t)}(S)$ for all Borel sets $S \subset \Omega$, where $\delta_u(S) = 1$ if $u \in S$ and $\delta_u(S) = 0$ otherwise. We write this control $\mathbf{u}$. Naturally, u and $\mathbf{u}$ give rise to the same state trajectory.

A useful concept, introduced in [3], for studying approximations to relaxed state trajectories is the set of *search directions*:

$$\mathcal{D} := \{d(\cdot,\cdot) : T \times \Omega \to \mathcal{R}^m :\ d(\cdot,u) \text{ is measurable},\ d(t,\cdot) \text{ is continuous},\\ \text{and } u + d(t,u) \in \Omega\ \forall u \in \Omega \text{ a.e. on } T\}.$$

Take $\mu \in \bar{\mathcal{U}}$ and $d \in \mathcal{D}$. $y^{\mu,d}_r$ is the solution to

$$\dot{y}(t) = (f_x)_r(t, x^\mu_r(t), \mu(t))y(t) + \int_\Omega f_u(t, x^\mu_r(t), u)d(t,u)\mu(t)(du),$$
$$y(0) = 0.$$

Notice that if $\mu(t) = \delta_{u(t)}$ and $d(t,u) = v(t) - u$ for some $v \in \mathcal{U}$, then $y_r^{\mu,d} = y^{u,v-u}$.

For $\mu \in \bar{\mathcal{U}}$ and $d \in \mathcal{D}$ we denote

$$\begin{aligned}
\langle \nabla \hat{F}_0(\mu), d\rangle_r &:= \phi_x(x_r^\mu(1)) y_r^{\mu,d}(1),\\
\langle \nabla \hat{h}_i^1(\mu), d\rangle_r &:= (h_i^1)_x(x_r^\mu(1)) y_r^{\mu,d}(1) \text{ for } i \in E,\\
\langle \nabla \hat{h}_j^2(\mu), d\rangle_r &:= (h_j^2)_x(x_r^\mu(1)) y_r^{\mu,d}(1) \text{ for } j \in I,\\
\langle \nabla \hat{q}(\mu)(t), d\rangle_r &:= q_x(t, x_r^\mu(t)) y_r^{\mu,d}(t) \text{ for all } t \in T.
\end{aligned}$$

Under the hypotheses **(H1)** and **(H2)** we deduce from standard properties of relaxed controls [19]. For fixed $d \in \mathcal{D}$, the following mappings are continuous:

$$\begin{gathered}
\mu \to x_r^\mu, \quad \mu \to \langle \nabla \hat{F}_0(\mu), d\rangle_r, \quad \mu \to \langle \nabla \hat{h}_i^1(\mu), d\rangle_r, \ i \in E,\\
\mu \to \langle \nabla \hat{h}_j^2(\mu), d\rangle_r, \ j \in I, \quad \mu \to \langle \nabla \hat{q}(\mu)(\cdot), d\rangle_r,
\end{gathered}$$

where the domain in each case is $\bar{\mathcal{U}}$ and the range spaces $\mathcal{C}(T, \mathcal{R}^n)$, $\mathcal{R}^{|E|}$, $\mathcal{R}^{|I|}$, and $\mathcal{C}(T, \mathcal{R}^n)$, respectively.

4. The algorithm. We begin by describing the direction-finding subproblem and some functions associated with it. First we define an approximation to the active region of the pathwise inequality constraint with reference to the control function

$$R_{\varepsilon,u} := \{t \in T : \ \tilde{q}(u)(t) \geq \max_{\tilde{t} \in T} \tilde{q}(u)(\tilde{t}) - \varepsilon\}. \tag{4.1}$$

Here $\varepsilon > 0$ is a parameter which governs the tightness of the approximation.

For fixed c and u the direction-finding subproblem $\mathbf{P_c}(\mathbf{u})$ for problem $(\mathbf{P_c})$ is

$$\min_{d \in \mathcal{U}-u, \beta \in \mathcal{R}} \beta + 1/(2c)\|d\|^2_{\mathcal{L}^2}$$

s.t.

$$\begin{aligned}
\langle \nabla \tilde{F}_0(u), d\rangle/c + \max_{i \in E} |\tilde{h}_i^1(u) + \langle \nabla \tilde{h}_i^1(u), d\rangle| - \max_{i \in E} |\tilde{h}_i^1(u)| &\leq \beta,\\
\tilde{h}_j^2(u) + \langle \nabla \tilde{h}_j^2(u), d\rangle &\leq \beta \ \forall j \in I,\\
\tilde{q}(u)(t) + \langle \nabla \tilde{q}(u)(t), d\rangle &\leq \beta \ \forall t \in R_{\varepsilon,u}.
\end{aligned}$$

The subproblem can be reformulated as an optimization problem over the space $\mathcal{L}^2_m[T]$ whose objective function is strictly convex and has quadratic growth. It therefore has a unique solution $(\bar{d}, \bar{\beta})$. Since this solution depends on c and u, we may define the *descent function* $\sigma_c(u)$ and the *penalty test function* $t_c(u)$, which will be used to test optimality of a control u and to adjust c, respectively, as

$$\sigma_c(u) = \bar{\beta}$$

and

$$t_c(u) = \bar{\beta} + \max_{i \in E} |\tilde{h}_i^1(u)|/c$$

for given $c > 0$ and $u \in \mathcal{U}$.

A starting point is required which is feasible with respect to the inequality constraints. This point is computed by applying a few iterations of an algorithm which

is a simple variant of the algorithm below (see, e.g., [14]). (Other approaches are possible, such as that described in [12].)

The algorithm is as follows.

ALGORITHM 1. Fix parameters $\varepsilon > 0,\ \gamma,\ \eta \in (0,1),\ c^0 > 0,\ \kappa > 1$.

1. Choose the initial control $u_0 \in \mathcal{U}$ which satisfies $\tilde{h}_j^2(u_0) \leq 0\ \forall j \in I$ and $\tilde{q}(u_0)(t) \leq 0\ \forall t \in T$. Set $k = 0$, $c_{-1} = c^0$.

2. Let c_k be the smallest number chosen from $\{c_{k-1}, \kappa c_{k-1}, \kappa^2 c_{k-1}, \ldots\}$ such that the solution (d_k, β_k) to the direction-finding subproblem $\mathbf{P_{c_k}(u_k)}$ satisfies

$$t_{c_k}(u_k) \leq 0.$$

If $\sigma_{c_k}(u_k) = 0$, then STOP.

3. Let α_k be the largest number chosen from the set $\{1, \eta, \eta^2, \ldots, \}$ such that $u_{k+1} = u_k + \alpha_k d_k$ satisfies the relations

$$\begin{aligned} \tilde{F}_{c_k}(u_{k+1}) - \tilde{F}_{c_k}(u_k) &\leq \gamma \alpha_k \sigma_{c_k}(u_k), \\ \tilde{h}_j^2(u_{k+1}) &\leq 0\ \forall j \in I, \\ \tilde{q}(u_{k+1})(t) &\leq 0\ \forall t \in T. \end{aligned}$$

Increase k by 1. Go to Step 2.

The descent function $\sigma_{c_k}(u_k)$ is nonpositive valued at each iteration. Suppose that subsequences $\{u_k\}_{k\in K},\ \{c_k\}_{k\in K}$ of the sequences of control functions and penalty parameters generated by the algorithm have limit points (in some sense) $\bar{u}$ and $\bar{c}$. We would then expect that $\sigma_{c_k}(u_k) \to \sigma_{\bar{c}}(\bar{u})$ (along the subsequence) and $\sigma_{\bar{c}}(\bar{u}) \geq 0$, a condition which asserts that the direction-finding subproblem for $c_k = \bar{c}$ and $u_k = \bar{u}$ has the solution $(d = 0, \beta = 0)$ and which (together with the feasibility of $\bar{u}$) can be interpreted as a first-order optimality condition satisfied by $\bar{u}$. If $\{c_k\}$ is nondecreasing and bounded (thus convergent), then $\sigma_{c_k}(u_k) \to_{k\to\infty} 0$ would be a stronger result because the existence of a convergent subsequence of $\{u_k\}$ is not requested. Justifying these arguments (under precisely specified hypotheses) is the essence of the convergence analysis to follow.

If u is not a stationary point for the problem $(\mathbf{P})$, then $d \neq 0$ and $\beta < 0$, which implies that

$$\tilde{q}(u)(t) + \langle \nabla \tilde{q}(u)(t), d \rangle < 0\ \forall t \in R_{\varepsilon,u}. \tag{4.2}$$

We can show, under the continuity assumption imposed on $q_x(\cdot,\cdot)$, that $\tilde{q}(u)(t) + \langle \nabla \tilde{q}(u)(t), d \rangle$ is a Lipschitz function with respect to t [16]; therefore there is a finite set of points $A \subset R_{\varepsilon,u}$ such that if

$$\tilde{q}(u)(t) + \langle \nabla \tilde{q}(u)(t), d \rangle < 0\ \forall t \in A,$$

then (4.2) is also satisfied. This property is exploited in the implementable version of the algorithm discussed in [16].

Notice that the only requirement in the directional minimization related to the state constraint is the feasibility of u_{k+1}. Other exact penalty function methods such as that in [9] do not combine the strict descent property (4.2) with the unrestrictive direction minimization procedure regarding the state constraint.

The role of the penalty parameter test function t_c is to ensure that the penalty parameter is large enough in the limit (but finite) to force satisfaction of the equality endpoint constraint. The algorithm ensures that, at the kth iteration,

$$t_{c_k}(u_k) = \sigma_{c_k}(u_k) + \max_{i\in E} |\tilde{h}_i^1(u_k)|/c_k \leq 0.$$

Since under favorable circumstances $\sigma_{c_k}(u_k) \to 0$ and $\{c_k\}$ is bounded, as we will show, we conclude from this inequality that $\max_{i\in E} |\tilde{h}_i^1(\bar{u})| = 0$; i.e., the limiting control satisfies the endpoint equality constraint.

Before concluding this section we need to clarify two points about the algorithm. They are to guarantee that Step 2 and 3 of Algorithm 1 can always be carried out (under the hypotheses of section 2). These gaps are filled by the following proposition in which we invoke a constraint qualification.

(CQ) For each $\mu \in \bar{\mathcal{U}}$ which is feasible w.r.t. the inequality constraints of the problem $(\mathbf{P^r})$ we have $\mathcal{F}(\mu) \neq \emptyset$ and, in the case $E \neq \emptyset$,

$$0 \in \text{interior}[\mathcal{E}(\mu)],$$

where

$$\mathcal{E}(\mu) := \{\{\langle \nabla \hat{h}_i^1(\mu), d\rangle_r\}_{i\in E} \in \mathcal{R}^{|E|} : \ d \in \mathcal{F}(\mu)\}$$

and

$$\begin{aligned}\mathcal{F}(\mu) := \{d \in \mathcal{D} : &\max_{j\in I}[\hat{h}_j^2(\mu) + \langle \nabla \hat{h}_j^2(\mu), d\rangle_r] < 0,\\ &\max_{t\in T}[\hat{q}(\mu)(t) + \langle \nabla \hat{q}(\mu)(t), d\rangle_r] < 0\}.\end{aligned}$$

In the case $I = \emptyset$ (no terminal inequality constraints) we interpret $\max_{j\in I}[\tilde{h}_j^2(\mu) + \cdots] = -\infty$.

(CQ) is related to hypotheses earlier invoked by Mayne and Polak [8]. It is a local controllability condition on values of the (linearized) equality constraint functions with respect to control functions which are strictly feasible w.r.t. the linearized inequality constraints. The role of **(CQ)** is to ensure uniform boundedness of penalty parameter values and that a convergence analysis can be carried out in terms of "normal" extremality conditions (conditions in which the cost multiplier is nonzero) as stated in the next section.

PROPOSITION 4.1.

(i) *Assume that hypotheses* **(H1)**, **(H2)**, *and* **(CQ)** *are satisfied. Then for any* $u \in \mathcal{U}$ *satisfying the endpoint and pathwise inequality constraints of* **(P)** *there exists* $\bar{c} > 0$ *such that for all* $c > \bar{c}$

$$t_c(u) \leq 0.$$

(ii) *Assume that hypotheses* **(H1)** *and* **(H2)** *are satisfied. Then for any* $u \in \mathcal{U}$ *satisfying the endpoint and pathwise inequality constraints and* $c > 0$ *such that* $\sigma_c(u) < 0$, *there exists* $\bar{\alpha} > 0$ *such that if* $\alpha \in [0, \bar{\alpha})$, *then*

$$\begin{aligned}\tilde{F}_c(\tilde{u}) - \tilde{F}_c(u) &\leq \gamma\alpha\sigma_c(u),\\ \tilde{h}_j^1(\tilde{u}) &\leq 0 \ \forall j \in I,\\ \tilde{q}(\tilde{u})(t) &\leq 0 \ \forall t \in T,\end{aligned}$$

where $\tilde{u} = u + \alpha d$ *and* $(d, \beta = \sigma_c(u))$ *is the solution to the direction-finding subproblem corresponding to* c *and* u.

A proof of this proposition is given in section 6.

5. Convergence properties of the algorithm. In this section we show that the descent function $\sigma_c(u)$ converges to zero along the sequences $\{c_k\}$, $\{u_k\}$ generated by Algorithm 1. Furthermore we show that $\{c_k\}$ is bounded and that $\{u_k\}$, regarded as sequences in $\bar{\mathcal{U}}$, satisfy necessary optimality conditions.

Results are given in relation to the necessary conditions (**NC**) in normal form for a control function $\bar{\mu}$, which is feasible for the relaxed problem ($\mathbf{P^r}$), to be a minimizer.

(NC) There exist nonnegative numbers α_j^2, $j \in I$, numbers α_i^1, $i \in E$, an absolutely continuous function $p : [0,1] \to \mathcal{R}^n$ and a nonnegative regular measure ν on the Borel subsets of $[0,1](= T)$ such that

$$
\begin{aligned}
-\dot{p}_r(t) &= (f_x)_r(t, x_r^{\bar{\mu}}(t), \bar{\mu}(t))^T (p_r(t) + \int_{[0,t)} q_x(s, x_r^{\bar{\mu}}(s))\nu(ds)),\\
-(p_r(1) + \int_{[0,1]} q_x(s, x_r^{\bar{\mu}}(s))\nu(ds)) &= \phi_x(x_r^{\bar{\mu}}(1))\\
&\quad + \sum_{i\in E} \alpha_i^1 (h_i^1)_x(x_r^{\bar{\mu}}(1)) + \sum_{j\in I} \alpha_j^2 (h_j^2)_x(x_r^{\bar{\mu}}(1)),\\
\left(p_r(t) + \int_{[0,t)} q_x(s, x_r^{\bar{\mu}}(s))\nu(ds)\right)^T &\int_\Omega f_u(t, x_r^{\bar{\mu}}(t), u) d(t,u) \bar{\mu}(t)(du) \le 0\\
&\qquad \forall d \in \mathcal{D} \text{ a.e. on } [0,1],\\
\operatorname{supp}\{\nu\} &\subset \{t \in T :\ q(t, x_r^{\bar{\mu}}(t)) = 0\} \text{ and } \alpha_j^2 = 0 \text{ if } h_j^2(x_r^{\bar{\mu}}(1)) < 0.
\end{aligned}
\tag{5.1}
$$

Here $\operatorname{supp}\{\nu\}$ denotes the support of the measure ν.

Conditions (**NC**) are standard necessary optimality conditions for a relaxed minimizer (derivable, for example, from [19, Theorem VI.2.3]) valid under hypotheses (**H1**), (**H2**), and (**CQ**) with the exception that (5.1) replaces the customary

$$
\operatorname{supp}\{\bar{\mu}(t)\} \subset \arg\min_{u\in\Omega} r(t)^T f(t, x_r^{\bar{\mu}}(t), u) \text{ a.e. on } T,
\tag{5.2}
$$

where $r(t) = p(t) + \int_{[0,t)} q_x(s, x_r^{\bar{\mu}}(s))\nu(ds)$.

However, (5.2) implies that for all $d \in \mathcal{D}$ and $\varepsilon > 0$

$$
\varepsilon^{-1} \int_\Omega r(t)^T (f(t, x_r^{\bar{\mu}}(t), u + \varepsilon d(t,u)) - f(t, x_r^{\bar{\mu}}(t), u)) \bar{\mu}(t)(du) \le 0 \text{ a.e. on } T.
$$

Passing to the limit as $\varepsilon \downarrow 0$ with the help of the dominated convergence theorem gives (5.1). It follows that (**NC**) are necessary conditions as claimed.

THEOREM 5.1. *Assume that the data for* **(P)** *satisfies hypotheses* **(H1)**, **(H2)**, *and* **(CQ)**. *Let* $\{u_k\}$ *be a sequence of control functions generated by Algorithm* 1, *and let* $\{c_k\}$ *be the corresponding sequence of penalty parameters. Then*

(i) $\{c_k\}$ *is a bounded sequence;*

(ii)

$$
\lim_{k\to\infty} \sigma_{c_k}(u_k) = 0, \quad \lim_{k\to\infty} \max_{i\in E} |\tilde{h}_i^1(u_k)| = 0;
$$

(iii) *if* $\bar{\mu}$ *is any accumulation point of* $\{\mathbf{u}_k\}$ *in* $\bar{\mathcal{U}}$ *(and such an accumulation point always exists), then* $\bar{\mu}$ *is feasible for the relaxed problem* ($\mathbf{P^r}$) *and satisfies necessary conditions* (**NC**).

Notice that if $\{u_k\}$ is a sequence in $\mathcal{U}$ such that $u_k \to \bar{u}$ for some $\bar{u} \in \mathcal{L}^2_m[T]$ with respect to the $\mathcal{L}^2$ norm, then $\mathbf{u}_k \to \bar{\mathbf{u}}$ converges in $\bar{\mathcal{U}}$ ([21]; see also [17]). Part (iii) of Theorem 5.1 may therefore be substituted by the following weaker assertion:

(iii) *if $\bar{u} \in \mathcal{U}$ is any $\mathcal{L}^2$ accumulation point of $\{u_k\}$, then $\bar{u}$ is feasible for* (**P**) *and satisfies* (**NC**).

Notice that the conditions (**NC**), when applied at an ordinary control, reduce to simpler "nonrelaxed" necessary conditions of optimality. We see then that the "relaxed" analysis subsumes the $\mathcal{L}^2$ analysis and improves on it by giving information about asymptotic behavior of the algorithm even when $\mathcal{L}^2$ accumulation points do not exist.

Part (iii) of the theorem implies that if $u \in \mathcal{U}$ is feasible and $\sigma_c(u) = 0$ for some $c > 0$, then u satisfies necessary conditions (**NC**) of optimality. Fix $\varepsilon_{\text{STOP}} > 0$. Part (ii) of the theorem implies that the stopping condition

$$\sigma_{c_k}(u_k) \geq -\varepsilon_{\text{STOP}},\ \max_{i\in E} |\tilde{h}^1_i(u_k)| \leq \varepsilon_{\text{STOP}},\ \max_{j\in I} \tilde{h}^2_j(u_k) \leq 0,\ \max_{t\in T} \tilde{q}(u_k)(t) \leq 0$$

is satisfied after a finite number of iterations. Termination of the algorithm still occurs after a finite number of iterations if the above stopping criterion is supplemented by

$$|\tilde{F}_0(u_{k+1}) - \tilde{F}_0(u_k)| \leq \varepsilon_{\text{STOP}},\quad \|u_{k+1} - u_k\|_{\mathcal{L}^2} \leq \|d_k\|_{\mathcal{L}^2} \leq \varepsilon_{\text{STOP}}.$$

The first inequality follows from (i), (ii), and the first inequality of Proposition 4.1(ii). The second inequality is a consequence of the fact that the optimal value of the subproblem $\mathbf{P_c}(\mathbf{u})$ is nonpositive whence

$$\|d_k\|_{\mathcal{L}^2} \leq -2c_k\sigma_{c_k}(u_k) \ \text{ and (ii)} \ \Rightarrow \lim_{k\to\infty} \|d_k\|_{\mathcal{L}^2} = 0.$$

Notice that (i) and (ii) correspond to the following general convergence result in nonlinear programming related to minimizing a bounded (from below), continuously differentiable function f: $\lim_{k\to\infty} \nabla f(x_k) = 0$. (The condition does not require the existence of accumulation points of $\{x_k\}$ and is relevant, for example, in situations when we seek to minimize $f(x) = e^x$.) We are not aware of convergence results, of this general nature, elsewhere in the constrained nonlinear programming literature.

6. Proof of the convergence theorem, etc. We precede the proof of Proposition 4.1 with a lemma which describes important implications of the (**CQ**).

LEMMA 6.1. *Assume* (**H1**), (**H2**), *and* (**CQ**). *For any relaxed control μ satisfying the inequality constraints for the relaxed problem there exist a neighborhood $\mathcal{O}(\mu)$ of μ, in the relaxed topology, $K_1 > 0$ and $K_2 > 0$ with the following properties: given any $u \in \mathcal{U}$ satisfying the inequality constraints and such that $\mathbf{u} \in \mathcal{O}(\mu)$, there exists $v \in \mathcal{U}$ such that*

$$\max_{i\in E} |\tilde{h}^1_i(u) + \langle \nabla \tilde{h}^1_i(u), v - u\rangle| - \max_{i\in E} |\tilde{h}^1_i(u)| \leq -K_1 \max_{i\in E} |\tilde{h}^1_i(u)|, \tag{6.1}$$

$$\max_{j\in I} [\tilde{h}^2_j(u) + \langle \nabla \tilde{h}^2_j(u), v - u\rangle] \leq -K_1 \max_{i\in E} |\tilde{h}^1_i(u)|, \tag{6.2}$$

$$\max_{t\in T} [\tilde{q}(u)(t) + \langle \nabla \tilde{q}(u)(t), v - u\rangle] \leq -K_1 \max_{i\in E} |\tilde{h}^1_i(u)|, \tag{6.3}$$

$$\text{and} \quad \|v - u\|_{\mathcal{L}^2} \leq \quad K_2 \max_{i\in E} |\tilde{h}^1_i(u)|. \tag{6.4}$$

The lemma is proved in the appendix.

Proof of Proposition 4.1. (i) Fix $u \in \mathcal{U}$ satisfying the inequality constraints. We must find $\hat{c} > 0$ such that if $c > \hat{c}$, then $t_c(u) \leq 0$. If $M(u) := \max_{i \in E} |\tilde{h}_i^1(u)| = 0$, then of course $t_c(u) \leq 0$ for any $c > 0$. If $M(u) > 0$, then according to Lemma 6.1 there exists $\hat{d} \in \mathcal{U} - u$ such that if we set $\varepsilon = K_1 M(u) > 0$ with K_1 as in Lemma 6.1, then

$$\theta(u) < -\varepsilon.$$

Here

$$\begin{aligned}\theta(u) := \max[&\max_{i \in E} |\tilde{h}_i^1(u) + \langle \nabla \tilde{h}_i^1(u), \hat{d}\rangle| - \max_{i \in E} |\tilde{h}_i^1(u)|,\\ &\max_{j \in I}[\tilde{h}_j^2(u) + \langle \nabla \tilde{h}_j^2(u), \hat{d}\rangle],\\ &\max_{t \in T}[\tilde{q}(u)(t) + \langle \nabla \tilde{q}(u)(t), \hat{d}\rangle]].\end{aligned}$$

Because $\sigma_c(u) \leq \langle \nabla \tilde{F}_0(u), \hat{d}\rangle/c + \theta(u)$, from the definition of t_c and Proposition 2.1, we get

$$t_c(u) \leq [W + \max_{i \in E} |\tilde{h}_i^1(u)|]/c + \theta(u),$$

where $W := \max[0, \langle \nabla \tilde{F}_0(u), \hat{d}\rangle]$. It follows that $t_c(u) \leq 0$ for any $c > \hat{c}$ where

$$\hat{c} := \frac{W + M(u)}{-\theta(u)}.$$

(ii) Take $u \in \mathcal{U}$ satisfying the inequality constraints and $c > 0$ such that $\sigma_c(u) < 0$. Let (d, β) be the solution to $\mathbf{P_c(u)}$. Since $\sigma_c(u) \neq 0$, it follows that $d \neq 0$.

We deduce from the differentiability properties of ϕ, h_i^1, h_j^2, and q and Proposition 2.2 that there exists $o : [0, \infty) \to [0, \infty)$ such that $s^{-1} o(s) \to 0$ as $s \downarrow 0$, and the following three inequalities are valid for any $\alpha \in [0, 1]$:

$$\begin{aligned}\tilde{F}_c(u + \alpha d) - \tilde{F}_c(u) \leq\ &\alpha \langle \nabla \tilde{F}_0(u), d\rangle/c + \max_{i \in E} |\tilde{h}_i^1(u) + \alpha \langle \nabla \tilde{h}_i^1(u), d\rangle|\\ &- \max_{i \in E} |\tilde{h}_i^1(u)| + o(\alpha),\end{aligned} \tag{6.5}$$

$$\tilde{h}_j^2(u + \alpha d) \leq \tilde{h}_j^2(u) + \alpha \langle \nabla \tilde{h}_j^2(u), d\rangle + o(\alpha)\ \forall j \in I, \tag{6.6}$$

$$\tilde{q}(u + \alpha d)(t) \leq \tilde{q}(u)(t) + \langle \nabla \tilde{q}(u)(t), d\rangle + o(\alpha)\ \forall t \in T. \tag{6.7}$$

By the convexity of the function $e \to \max_{i \in E} |\tilde{h}_i^1(u) + \langle \nabla \tilde{h}_i^1(u), e\rangle|$,

$$\begin{aligned}&\max_{i \in E} |\tilde{h}_i^1(u) + \alpha \langle \nabla \tilde{h}_i^1(u), d\rangle| - \max_{i \in E} |\tilde{h}_i^1(u)|\\ &\leq \alpha(\max_{i \in E} |\tilde{h}_i^1(u) + \langle \nabla \tilde{h}_i^1(u), d\rangle| - \max_{i \in E} |\tilde{h}_i^1(u)|).\end{aligned}$$

From inequality (6.5), then

$$\begin{aligned}\tilde{F}_c(u + \alpha d) - \tilde{F}_c(u) &\leq \alpha[\langle \nabla \tilde{F}_0(u), d\rangle/c + \max_{i \in E} |\tilde{h}_i^1(u) + \langle \nabla \tilde{h}_i^1(u), d\rangle|\\ &\quad - \max_{i \in E} |\tilde{h}_i^1(u)|] + o(\alpha)\\ &\leq \alpha \sigma_c(u) + o(\alpha).\end{aligned}$$

It follows that

$$\tilde{F}_c(u+\alpha d) - \tilde{F}_c(u) \le \alpha\gamma\sigma_c(u) \ \forall \alpha \in [0,\alpha_1], \tag{6.8}$$

where $\alpha_1 > 0$ is such that $o(\beta) \le \beta(\gamma-1)\sigma_c(u)$ for all $\beta \in [0,\alpha_1]$.

It remains to show that $u+\alpha d$ is feasible w.r.t. the inequality constraints for sufficiently small α. Since $\tilde{h}_j^2(u) \le 0$ and $\alpha \in [0,1]$, (6.6) implies

$$\begin{aligned}\tilde{h}_j^2(u+\alpha d) &\le \alpha[\tilde{h}_j^2(u) + \langle \nabla \tilde{h}_j^2(u), d\rangle] + o(\alpha)\\ &\le \alpha\sigma_c(u) + o(\alpha) \le \alpha\gamma\sigma_c(u) < 0\end{aligned}$$

for all $\alpha \in [0,\alpha_1]$, as required.

We deduce from the differentiability properties of q (Proposition 2.3) that

$$\begin{aligned}\max_{t\in T} \tilde{q}(u+\alpha d)(t) &\le \max_{t\in R_{\varepsilon,u}} [\tilde{q}(u)(t) + \alpha\langle \nabla\tilde{q}(u)(t), d\rangle] + o(\alpha)\\ &\le \alpha\sigma_c(u) + o(\alpha)\\ &\le \alpha\gamma\sigma_c(u) < 0\end{aligned}$$

for $\alpha \in [0,\alpha_1]$, as required. □

Proof of Theorem 5.1. (i) Let $\{u_k\}$ be the sequence generated by Algorithm 1, and let $\{c_k\}$ be the corresponding penalty parameters. Let $\{k_l\}$ be the sequence of index values at which the penalty parameter increases. By extracting a further subsequence (we do not relabel) we can arrange that the sequence $\{\mathbf{u}_{k_l}\}$ has a limit point $\bar{\mu} \in \bar{\mathcal{U}}$ because $\bar{\mathcal{U}}$ is compact. For simplicity of presentation we denote this subsequence by $\{\mathbf{u}_{k_l}\}$. We shall find a number $\hat{c} < \infty$ such that for sufficiently large k_l, $c_{k_l} > \hat{c}$ implies $\sigma_{c_{k_l}}(u_{k_l}) \le -\max_{i\in E} |\tilde{h}_i^1(u_{k_l})|/c_{k_l}$. This contradicts our assumption that the penalty parameter increases along the subsequence. So we may conclude that $\{c_k\}$ is bounded.

Fix k_l such that $\mathbf{u}_{k_l} \in \mathcal{O}(\bar{\mu})$, where $\mathcal{O}(\bar{\mu})$ is in the neighborhood of $\bar{\mu}$ as specified in Lemma 6.1. From the minimizing property of $\sigma_{c_{k_l}}(u_{k_l})$ we deduce

$$\begin{aligned}\sigma_{c_{k_l}}(u_{k_l}) \le{}& 1/(2c_{k_l})\|v_{k_l} - u_{k_l}\|_{\mathcal{L}^2}^2 + \langle \nabla\tilde{F}_0(u_{k_l}), v_{k_l} - u_{k_l}\rangle/c_{k_l}\\ &+ \max\{\max_{i\in E} |\tilde{h}_i^1(u_{k_l}) + \langle \nabla\tilde{h}_i^1(u_{k_l}), v_{k_l} - u_{k_l}\rangle| - \max_{i\in E} |\tilde{h}_i^2(u_{k_l})|,\\ &\quad \max_{j\in I}[\tilde{h}_j^2(u_{k_l}) + \langle \nabla\tilde{h}_j^2(u_{k_l}), v_{k_l} - u_{k_l}\rangle],\\ &\quad \max_{t\in T}[\tilde{q}(u_{k_l})(t) + \langle \nabla\tilde{q}(u_{k_l})(t), v_{k_l} - u_{k_l}\rangle]\}\end{aligned} \tag{6.9}$$

for a control function v_{k_l} satisfying conditions (6.1)–(6.4) of Lemma 6.1 in which v_{k_l}, u_{k_l} replace v, u, respectively. (Notice that Lemma 6.1 may be invoked since $\tilde{h}_j^2(u_{k_l}) \le 0 \ \forall j \in I$ and $\tilde{q}(u_{k_l})(t) \le 0 \ \forall t \in T$.) It follows

$$\begin{aligned}\sigma_{c_{k_l}}(u_{k_l}) \le{}& 1/(2c_{k_l}) \int_0^1 \|v_{k_l}(t) - u_{k_l}(t)\|^2 dt + |\langle \nabla\tilde{F}_0(u_{k_l}), v_{k_l} - u_{k_l}\rangle|/c_{k_l}\\ &- K_1 \max_{i\in E} |\tilde{h}_i^1(u_{k_l})|.\end{aligned}$$

Since the control constraint Ω is bounded and in view of Proposition 2.1, there exists $r > 0$ (independent of k_l) such that

$$\begin{aligned}1/(2c_{k_l}) \int_0^1 \|v_{k_l}(t) - u_{k_l}(t)\|^2 dt + |\langle \nabla\tilde{F}_0(u_{k_l}), v_{k_l} - u_{k_l}\rangle|/c_{k_l}\\ \le (r/c_{k_l})\|v_{k_l} - u_{k_l}\|_{\mathcal{L}^2}.\end{aligned}$$

Hence

$$\sigma_{c_{k_l}}(u_{k_l}) \leq -(K_1 - rK_2/c_{k_l}) \max_{i\in E} |\tilde{h}_i^1(u_{k_l})|.$$

We conclude that

$$\sigma_{c_{k_l}}(u_{k_l}) \leq -\max_{i\in E} |\tilde{h}_i^1(u_{k_l})|/c_{k_l}$$

if $c_{k_l} \geq \hat{c}$, where $\hat{c} = K_1^{-1}(rK_2 + 1)$.

(ii) and (iii) Let $\{u_k\}$ be an infinite sequence generated by the algorithm. We must show that $\lim_{k\to\infty} \sigma_{c_k}(u_k) = 0$ and, if a convergent subsequence of $\{\mathbf{u}_k\}$ has a limit point $\bar{\mu} \in \bar{\mathcal{U}}$, that conditions (**NC**) are satisfied at $\bar{\mu}$.

Stage 1 (convergence analysis). Since the c_k's are bounded and can increase only by multiples of c^0, we must have $c_k = c$ for all $k \geq k_0$, for some k_0 and $c > 0$. In view of the manner in which u_k's are constructed, we have

$$\tilde{F}_c(u_{k+1}) - \tilde{F}_c(u_k) \leq \gamma\alpha_k\sigma_c(u_k)$$

$\forall k \geq k_0$. This means that, $\forall j \geq 1$, $k \geq k_0$

$$\tilde{F}_c(u_{k+j}) - \tilde{F}_c(u_k) \leq \gamma \sum_{i=0}^{j-1} \alpha_{k+i}\sigma_c(u_{k+i}). \tag{6.10}$$

Since $\{\tilde{F}_c(u_k)\}$ is a bounded sequence and $\alpha_k\sigma_c(u_k)$ is nonpositive, we conclude

$$\alpha_k\sigma_c(u_k) \to 0 \quad \text{as } k \to \infty. \tag{6.11}$$

Since $\sigma_c(\mu)$ is bounded as μ ranges over $\bar{\mathcal{U}}$, we can arrange by a subsequence extraction (we do not relabel) that

$$\sigma_c(u_k) \to \beta \text{ for some } \beta \leq 0.$$

We claim that $\beta = 0$. To show this, suppose to the contrary that $\beta < 0$. Then by (6.11) $\alpha_k \to 0$.

We must have

$$\begin{aligned} &\tilde{F}_c(u_k + \eta^{-1}\alpha_k d_k) - \tilde{F}_c(u_k) > \gamma\eta^{-1}\alpha_k\sigma_c(u_k) \\ \text{or} \quad &\max_{j\in I} \tilde{h}_j^2(u_k + \eta^{-1}\alpha_k d_k) > 0 \\ \text{or} \quad &\max_{t\in T} \tilde{q}(u_k + \eta^{-1}\alpha_k d_k)(t) > 0 \end{aligned}$$

for all k sufficiently large.

However, $\|\alpha_k d_k\|_{\mathcal{L}^\infty} \to 0$ as $k \to \infty$. We deduce then from Proposition 2.3 and the continuity of q that

$$\max_{t\in R_{\varepsilon,u_k}} \tilde{q}(u_k + \eta^{-1}\alpha_k d_k)(t) \ = \max_{t\in T} \tilde{q}(u_k + \eta^{-1}\alpha_k d_k)(t)$$

for all k sufficiently large. Since $\sigma_c(u_k) \leq 0$, we conclude that

$$\begin{aligned} \max\{\tilde{F}_c(u_k + \eta^{-1}\alpha_k d_k) - \tilde{F}_c(u_k), &\max_{j\in I} \tilde{h}_j^2(u_k + \eta^{-1}\alpha_k d_k), \\ &\max_{t\in R_{\varepsilon,u_k}} \tilde{q}(u_k + \eta^{-1}\alpha_k d_k)(t)\} \geq \gamma\eta^{-1}\alpha_k\sigma_c(u_k). \end{aligned} \tag{6.12}$$

It follows now from Propositions 2.4–2.5 that there exists a function $o : [0,\infty) \to [0,\infty)$ such that $s^{-1}o(s) \to 0$ as $s \downarrow 0$ and

$$\begin{aligned} \max_{j\in I} \tilde{h}_j^2(u_k + \eta^{-1}\alpha_k d_k) &\le \max_{j\in I} [\tilde{h}_j^2(u_k) + \langle \nabla \tilde{h}_j^2(u_k), \eta^{-1}\alpha_k d_k\rangle] \\ &\quad + o(\eta^{-1}\alpha_k \|d_k\|_{\mathcal{L}^\infty}), \end{aligned} \tag{6.13}$$

$$\begin{aligned} \max_{t\in R_{\varepsilon,u_k}} \tilde{q}(u_k + \eta^{-1}\alpha_k d_k)(t) &\le \max_{t\in R_{\varepsilon,u_k}} [\tilde{q}(u_k)(t) + \langle \nabla \tilde{q}(u_k), \eta^{-1}\alpha_k d_k\rangle] \\ &\quad + o(\eta^{-1}\alpha_k \|d_k\|_{\mathcal{L}^\infty}) \end{aligned} \tag{6.14}$$

and

$$\begin{aligned} \tilde{F}_c(u_k + \eta^{-1}\alpha_k d_k) - \tilde{F}_c(u_k) &\le \langle \nabla \tilde{F}_0(u_k), \eta^{-1}\alpha_k d_k\rangle / c \\ &\quad + \max_{i\in E} |\tilde{h}_i^1(u_k) + \langle \nabla \tilde{h}_i^1(u_k), \eta^{-1}\alpha_k d_k\rangle| \\ &\quad - \max_{i\in E} |\tilde{h}_i^1(u_k)| + o(\eta^{-1}\alpha_k \|d_k\|_{\mathcal{L}^\infty}). \end{aligned} \tag{6.15}$$

Since u_k is feasible w.r.t. the inequality constraints, we have

$$\begin{aligned} \max_{j\in I} [\tilde{h}_j^2(u_k) + \langle \nabla \tilde{h}_j^2(u_k), \eta^{-1}\alpha_k d_k\rangle] &\le \eta^{-1}\alpha_k \max_{j\in I} [\tilde{h}_j^2(u_k) \\ &\quad + \langle \nabla \tilde{h}_j^2(u_k), d_k\rangle] \end{aligned} \tag{6.16}$$

and

$$\begin{aligned} \max_{t\in R_{\varepsilon,u_k}} [\tilde{q}(u_k)(t) + \langle \nabla \tilde{q}(u_k)(t), \eta^{-1}\alpha_k d_k\rangle] &\le \eta^{-1}\alpha_k \max_{t\in R_{\varepsilon,u_k}} [\tilde{q}(u_k)(t) \\ &\quad + \langle \nabla \tilde{q}(u_k)(t), d_k\rangle] \end{aligned} \tag{6.17}$$

for k sufficiently large. Also, by the convexity of $e \to \max_{i\in E} |\tilde{h}_i^1(u_k) + \langle \nabla \tilde{h}_i^1(u_k), e\rangle|$,

$$\begin{aligned} &\max_{i\in E} |\tilde{h}_i^1(u_k) + \langle \nabla \tilde{h}_i^1(u_k), \eta^{-1}\alpha_k d_k\rangle| - \max_{i\in E} |\tilde{h}_i^1(u_k)| \\ &\le \eta^{-1}\alpha_k (\max_{i\in E} |\tilde{h}_i^1(u_k) + \langle \nabla \tilde{h}_i^1(u_k), d_k\rangle| - \max_{i\in E} |\tilde{h}_i^1(u_k)|). \end{aligned} \tag{6.18}$$

Combining inequalities (6.12)–(6.18), noting the definition of $\sigma_c(u_k)$ and the fact that (d_k, β_k) solves $\mathbf{P_c}(\mathbf{u_k})$, and dividing across the resulting inequality by α_k we arrive at

$$\eta^{-1}\sigma_c(u_k) + \alpha_k^{-1} o(\eta^{-1}\alpha_k \|d_k\|_{\mathcal{L}^\infty}) \ge \eta^{-1}\gamma\sigma_c(u_k).$$

We get $\eta^{-1}\beta \ge \eta^{-1}\gamma\beta$ in the limit. But this implies $\gamma \ge 1$, since $\beta < 0$ by assumption. From this contradiction we conclude the validity of $\beta = 0$. Assertion (ii) of the theorem follows from the definition of t_c and part (i).

Let $\{\mathbf{u}_k\}$ be a convergent subsequence with the limit point $\bar{\mu} \in \bar{\mathcal{U}}$. We must show that conditions (**NC**) are satisfied at $\bar{\mu}$. First we establish that $\bar{\mu}$ is feasible for $(\mathbf{P^r})$ and, for some $c > 0$,

$$\begin{aligned} 0 \le \{&\langle \nabla \hat{F}_0(\bar{\mu}), d\rangle_r / c + \max_{i\in E} |\langle \nabla \hat{h}_i^1(\bar{\mu}), d\rangle_r|, \\ &\max_{j\in I} \langle \nabla \hat{h}_j^2(\bar{\mu}), d\rangle_r, \max_{t\in R_{0,\bar{\mu}}} \langle \nabla \hat{q}(\bar{\mu})(t), d\rangle_r\} \end{aligned}$$

for all $d \in \mathcal{D}$.

Since $\mathbf{u}_k \to \bar{\mu}$ we know that $x_r^{\mathbf{u}_k} \to x_r^{\bar{\mu}}$ uniformly. Because u_k is feasible w.r.t. the inequality constraints and the penalty parameter is not updated for k sufficiently large, we have

$$\sigma_c(u_k) \leq -\max_{i\in E} |\tilde{h}_i^1(u_k)|/c,\ \max_{j\in I} \tilde{h}_j^2(u_k) \leq 0,\ \max_{t\in T} \tilde{q}(u_k)(t) \leq 0.$$

But we have shown that $\sigma_c(u_k) \to 0$ as $k \to \infty$. It follows now from the fact that $\mathbf{u}_k \to \bar{\mu} \in \bar{\mathcal{U}}$ that in the limit

$$\max_{i\in E} |\hat{h}_i^1(\bar{\mu})| = 0,\ \max_{j\in I} \hat{h}_j^2(\bar{\mu}) \leq 0,\ \max_{t\in T} \hat{q}(\bar{\mu})(t) \leq 0. \tag{6.19}$$

We have established that $\bar{\mu}$ is feasible for $(\mathbf{P^r})$.

Now choose any sequence $\rho_k \downarrow 0$, $\rho_k \leq 1\ \forall k$ such that

$$\rho_k^{-1}\sigma_c(u_k) \to 0 \ \text{ as } k \to \infty. \tag{6.20}$$

Choose any $d \in \mathcal{D}$. By the convexity of $\mathcal{U}$, $\rho_k d(\cdot, u_k) \in \mathcal{U} - u_k$ for each k.

By definition of σ_c, then

$$\begin{aligned}\sigma_c(u_k) \leq\ & 1/2\rho_k^2 \|d(\cdot,u_k)\|_{\mathcal{L}^2}/c + \max\{\phi_x(x^{u_k}(1))y^{u_k,\rho_k d(\cdot,u_k)}(1)/c \\ & + \max_{i\in E} |h_i^1(x^{u_k}(1)) + (h_i^1)_x(x^{u_k}(1))y^{u_k,\rho_k d(\cdot,u_k)}(1)| - \max_{i\in E} |h_i^1(x^{u_k}(1))|, \\ & \max_{j\in I} [h_j^2(x^{u_k}(1)) + (h_j^2)_x(x^{u_k}(1))y^{u_k,\rho_k d(\cdot,u_k)}(1)], \\ & \max_{t\in T} [q(t,x^{u_k}(t)) + q_x(t,x^{u_k}(t))y^{u_k,\rho_k d(\cdot,u_k)}(t)]\}.\end{aligned} \tag{6.21}$$

Fix $\hat{\varepsilon} > 0$. Since $\rho_k \downarrow 0$ (and consequently $y^{u_k,\rho_k d(\cdot,u_k)} \to 0$ uniformly), and also u_k is feasible w.r.t. the inequality constraints for each k, we have:

$$\max_{j\in I} [h_j^2(x^{u_k}(1)) + (h_j^2)_x(x^{u_k}(1))y^{u_k,\rho_k d(\cdot,u_k)}(1)] \leq \max_{I_{\hat{\varepsilon},\bar{\mu}}} (h_j^2)_x(x^{u_k}(1))y^{u_k,\rho_k d(\cdot,u_k)}(1),$$

$$\max_{t\in T} [q(t,x^{u_k}(t)) + q_x(t,x^{u_k}(t))y^{u_k,\rho_k d(\cdot,u_k)}(t)] \leq \max_{t\in R_{\hat{\varepsilon},\bar{\mu}}} q_x(t,x^{u_k}(t))y^{u_k,\rho_k d(\cdot,u_k)}(t)$$

$\forall k$ sufficiently large. Inserting these inequalities into (6.21), noting that $y^{u_k,\rho_k d(\cdot,u_k)} = \rho_k y^{u_k,d(\cdot,u_k)}$, dividing across by ρ_k, and passing to the limit with the help of (6.20) and continuity of $\hat{F}_0(\cdot)$, $\mu \to \langle \nabla \hat{F}_0(\mu), d\rangle_r$, etc., we obtain

$$\begin{aligned}0 \leq\ & \max\{\phi_x(x_r^{\bar{\mu}}(1))y_r^{\bar{\mu},d}(1)/c + \max_{i\in E} |(h_i^1)_x(x_r^{\bar{\mu}}(1))y_r^{\bar{\mu},d}(1)|, \\ & \max_{j\in I_{\hat{\varepsilon},\bar{\mu}}} (h_j^2)_x(x_r^{\bar{\mu}}(1))y_r^{\bar{\mu},d}(1),\ \max_{t\in R_{\hat{\varepsilon},\bar{\mu}}} q_x(t,x_r^{\bar{\mu}}(t))y_r^{\bar{\mu},d}(t)\}.\end{aligned} \tag{6.22}$$

This inequality is valid for each $\hat{\varepsilon} > 0$ and $d \in \mathcal{D}$.

Again choose arbitrary $d \in \mathcal{D}$ and take $\varepsilon_k \downarrow 0$. For each k let $(h_j^2)_x(x_r^{\bar{\mu}}(1))y_r^{\bar{\mu},d}(1)$ achieve its maximum over $I_{\varepsilon_k,\bar{\mu}}$ at $j = j_k$, and let $q_x(t,x_r^{\bar{\mu}}(t))y_r^{\bar{\mu},d}(t)$ achieve its maximum over $t \in R_{\varepsilon_k,\bar{\mu}}$ at $t = t_k$. Then

$$\begin{aligned}0 \leq\ & \max\{\phi_x(x_r^{\bar{\mu}}(1))y_r^{\bar{\mu},d}(1)/c + \max_{i\in E} |(h_i^1)_x(x_r^{\bar{\mu}}(1))y_r^{\bar{\mu},d}(1)|, \\ & (h_{j_k}^2)_x(x_r^{\bar{\mu}}(1))y_r^{\bar{\mu},d}(1),\ q_x(t_k,x_r^{\bar{\mu}}(t_k))y_r^{\bar{\mu},d}(t_k)\}.\end{aligned} \tag{6.23}$$

Extract a subsequence (we do not relabel) such that $j_k = \bar{j}$ for all k and $t_k \to \bar{t}$ for some index value $\bar{j}$ and some $\bar{t}$. By continuity of the functions involved, $\bar{j} \in I_{0,\bar{\mu}}$, $\bar{t} \in R_{0,\bar{\mu}}$, and (6.23) is valid with $\bar{j}$ and $\bar{t}$ replacing j_k and t_k, respectively.

We have arrived at

$$0 \leq \max\{\phi_x(x_r^{\bar{\mu}}(1))y_r^{\bar{\mu},d}(1)/c + \max_{i\in E} |(h_i^1)_x(x_r^{\bar{\mu}}(1))y_r^{\bar{\mu},d}(1)|,$$
$$\max_{j\in I_{0,\bar{\mu}}} (h_j^2)_x(x_r^{\bar{\mu}}(1))y_r^{\bar{\mu},d}(1), \max_{t\in R_{0,\bar{\mu}}} q_x(t, x_r^{\bar{\mu}}(t))y_r^{\bar{\mu},d}(t)\}.$$

This inequality, which holds for all $d \in \mathcal{D}$, in particular for $(d \equiv 0) \in \mathcal{D}$, is what we set out to prove.

Finally we must attend to the case when Algorithm 1 generates a finite sequence which terminates at a control $\mathbf{u}_{\bar{k}} = \bar{\mu}$, satisfying the stopping criterion. This case is dealt with by applying the preceding arguments to the infinite sequence of controls obtained by "filling in" with repetitions of the following control u_k.

Stage 2 (dualization). The conclusions of Stage 1 can be expressed as

$$\min_{d\in\mathcal{D}} \max_{\gamma\in\mathcal{K}} \Phi(d,\gamma) = 0,$$

where

$$\mathcal{K} := \Big\{\gamma = (\alpha_0, \{\alpha_i^1\}_{i\in E}, \{\alpha_j^2\}_{j\in I}, \nu) \in \mathcal{R}^{1+|E|+|I|} \times \mathcal{C}^\star(T) :$$
$$\alpha_0 \geq 0,\ \alpha_j^2 \geq 0,\ j \in I,\ \sum_{i\in E} |\alpha_i^1| \leq \alpha_0,\ \alpha_0 + \sum_{j\in I} \alpha_j^2 + \int_T \nu(dt) = 1,$$
$$\alpha_j^2 = 0 \ \text{ if } j \notin I_{0,\bar{\mu}},\ \nu \geq 0,\ \operatorname{supp}\{\nu\} \subset R_{0,\bar{\mu}}\Big\}$$

and

$$\Phi(d,\gamma) := \alpha_0\langle\nabla\hat{F}_0(\bar{\mu}), d\rangle_r/c + \sum_{i\in E} \alpha_i^1\langle\nabla\hat{h}_i^1(\bar{\mu}), d\rangle_r$$
$$+ \sum_{j\in I_{0,\bar{\mu}}} \alpha_j^2\langle\nabla\hat{h}_j^2(\bar{\mu}), d\rangle_r + \int_T \langle\nabla\hat{q}(\bar{\mu})(t), d\rangle_r \nu(dt).$$

$\Phi(\cdot,\gamma)$ is a linear function on $\mathcal{L}^1(T, \mathcal{C}(\Omega))$, of which $\mathcal{D}$ is a convex subset. $\Phi(d,\cdot)$ is a bounded linear map and $\mathcal{K}$ is a compact convex set with respect to the product topology of $\mathcal{R}^{1+|E|+|I|} \times \mathcal{C}^\star(T)$, in which the weak star topology is imposed on the last component. It follows from the minimax theorem [2] that there exists some nonzero $\bar{\gamma} \in \mathcal{K}$ such that

$$\min_{d\in\mathcal{D}} \max_{\gamma\in\mathcal{K}} \Phi(d,\gamma) = \min_{d\in\mathcal{D}} \Phi(d,\bar{\gamma}) = 0, \tag{6.24}$$

with $\bar{\gamma} = (\bar{\alpha}_0, \{\bar{\alpha}_i^1\}_{i\in E}, \{\bar{\alpha}_j^2\}_{j\in I}, \bar{\nu})$.

We readily deduce from (**CQ**) that $\bar{\alpha}_0 \neq 0$. By scaling the multipliers we may arrange that $\bar{\alpha}_0/c = 1$.

Now define p to be the solution to the differential equation

$$-\dot{p}_r(t) = (f_x)_r(t, x_r^{\bar{\mu}}(t), \bar{\mu}(t))^T \left(p_r(t) + \int_{[0,t)} q_x(s, x_r^{\bar{\mu}}(s))\bar{\nu}(ds)\right)$$

and

$$-p_r(1) = \int_{[0,1]} q_x(s, x_r^{\bar\mu}(s))\bar\nu(ds) + \phi_x(x_r^{\bar\mu}(1)) + \sum_{i\in E} \bar\alpha_i^1 (h_i^1)_x(x_r^{\bar\mu}(1)) + \sum_{j\in I} \bar\alpha_j^2 (h_j^2)_x(x_r^{\bar\mu}(1)).$$

We have, for any $d \in \mathcal{D}$,

$$\Phi(d,\bar\gamma) + \int_{[0,1]} \left(p_r(t) + \int_{[0,t)} q_x(s, x_r^{\bar\mu}(s))\bar\nu(ds) \right)^T (\dot y_r^{\bar\mu,d}(t) - (f_x)_r(t, x_r^{\bar\mu}(t), \bar\mu(t))^T y_r^{\bar\mu,d}(t) - \int_\Omega f_u(t, x_r^{\bar\mu}(t), u) d(t,u)\bar\mu(t)(du))dt \geq 0.$$

This inequality reduces, via an integration by parts, to

$$\int_{[0,1]} (p_r(t) + \int_{[0,t)} q_x(s, x_r^{\bar\mu}(s))\bar\nu(ds))^T \int_\Omega f_u(t, x_r^{\bar\mu}(t), u) d(t,u)\bar\mu(t)(du)dt \geq 0.$$

These relationships imply that $(x_r^{\bar\mu}, \bar\mu)$ satisfies the stated necessary conditions. ∎

7. Appendix.

Proof of Lemma 6.1. Take any arbitrary $\tilde\mu \in \bar{\mathcal{U}}$ which is feasible w.r.t. the inequality constraints. Let $r > 0$ be a number such that

$$\max_{i\in E} |\hat h_i^1(\mu)| < r$$

$\forall \mu \in \bar{\mathcal{U}}$. We deduce from (**CQ**) that there is a simplex in $\mathcal{E}(\tilde\mu) \subset \mathcal{R}^{n_E}$ ($n_E = |E|$) with vertices $\{e_j\}_{j=0}^{n_E}$ which contains 0 as an interior point. By definition of $\mathcal{E}(\tilde\mu)$, there exist $d_0, \ldots, d_{n_E} \in \mathcal{D}$ and $\delta > 0$ such that for $j = 0, \ldots, n_E$

$$\begin{aligned} \{\langle \nabla \hat h_i^1(\tilde\mu), d_j\rangle_r\}_{i\in E} &= e_j, \\ \max_{i\in I} [\hat h_i^2(\tilde\mu) + \langle \nabla \hat h_i^2(\tilde\mu), d_j\rangle_r] &\leq -\delta, \\ \max_{t\in T} [\hat q(\tilde\mu)(t) + \langle \nabla \hat q(\tilde\mu)(t), d_j\rangle_r] &\leq -\delta. \end{aligned}$$

Let $(\lambda_0, \lambda_1, \ldots, \lambda_{n_E})$ be the barycentric coordinates of 0 w.r.t. the vertices e_j of the simplex; i.e.,

$$0 \left(= \sum_{j=0}^{n_E} \lambda_j e_j \right) = \nabla \hat h^1(\tilde\mu) \circ \sum_{j=0}^{n_E} \lambda_j d_j.$$

Here

$$\nabla \hat h^1(\mu) \circ d := \{\langle \nabla \hat h_i^1(\mu), d\rangle_r\}_{i\in E}.$$

We shall also write

$$\hat h^1(\mu) := \{\hat h_i^1(\mu)\}_{i\in E}.$$

$\nabla \tilde h^1(u) \circ d$ and $\tilde h^1(u)$ are defined analogously.

Since the vertices are in general position and 0 is an interior point, the λ_i's are all positive, and we may find $\delta_1 > 0$ such that

$$\left\{ \lambda_0 - \sum_{j=1}^{n_E} \alpha_j, \lambda_1 + \alpha_1, \ldots, \lambda_{n_E} + \alpha_{n_E} \right\} \in \left\{ \gamma \in \mathcal{R}^{n_E+1} : \ \gamma_j \geq 0 \ \forall j, \ \sum_{j=0}^{n_E} \gamma_j = 1 \right\}$$

whenever $\alpha \in \mathcal{B}(0, \delta_1) \subset \mathcal{R}^{n_E}$. ($\mathcal{B}(0, \delta_1)$ is a ball of radius δ_1.) Furthermore the $n_E \times n_E$ matrix $M(\mu)$ defined by

$$M(\mu)\alpha := \sum_{j=1}^{n_E} \nabla \hat{h}^1(\mu) \circ \alpha_j (d_j - d_0) \tag{7.1}$$

is invertible for $\mu = \tilde{\mu}$ from the definition of $d_j, \ j = 1, \ldots, n_E$.

In consequence of hypothesis (**CQ**) and in view of the continuity properties of the mapping $\mu \to y_r^{\mu,d}$ for fixed d, we may choose a neighborhood $\mathcal{O}(\tilde{\mu})$ of $\tilde{\mu}$ in $\bar{\mathcal{U}}$ and numbers $r > 0$ and $\delta_2 \in (0, r^{-1}]$ such that for any $u \in \mathcal{U}$ satisfying $\mathbf{u} \in \mathcal{O}(\tilde{\mu})$

(i) $$\max_{i \in I} [\tilde{h}_i^2(u) + \langle \nabla \tilde{h}_i^2(u), v_j - u \rangle] \leq -\delta/2 \ \ \forall j,$$

(ii) $$\max_{t \in T} [\tilde{q}(u)(t) + \langle \nabla \tilde{q}(u)(t), v_j - u \rangle] \leq -\delta/2 \ \ \forall j,$$

(iii) $M(u)$ is invertible,

(iv) $$\left\| M(u)^{-1} \nabla \tilde{h}^1(u) \circ \left(\left(\sum_{j=0}^{n_E} \lambda_j v_j \right) - u \right) \right\| \leq \delta_1/2,$$

(v) $$\delta_2 \| M(u)^{-1} \| n_E^{1/2} \leq \delta_1/2.$$

(In (v) the norm is the Euclidean norm and $M(u)$ is defined analogously to $M(\mu)$.)

Here the controls $v_j \in \mathcal{U}$, $j = 0, \ldots, n_E$, are defined to be

$$v_j(t) := u(t) + d_j(t, u(t)).$$

Now suppose that the control u is feasible w.r.t. the inequality constraints and $\tilde{h}^1(u) \neq 0$. Set

$$\alpha = M(u)^{-1} \left[-\nabla \tilde{h}^1(u) \circ \left(\left(\sum_{j=0}^{n_E} \lambda_j v_j \right) - u \right) - \delta_2 \| \tilde{h}^1(u) \|_\infty^{-1} \tilde{h}^1(u) \right], \tag{7.2}$$

in which $\| \tilde{h}^1(u) \|_\infty := \max_{i \in E} |\tilde{h}_i^1(u)|$. Notice that, by properties (iv) and (v), $\|\alpha\| \leq \delta_1$. Also set

$$\hat{v} = v_0 + \sum_{j=1}^{n_E} (\lambda_j + \alpha_j)(v_j - v_0).$$

Because $\|\alpha\| \leq \delta_1$ we have that $\hat{v} \in \mathcal{U}$. Finally we define v to be

$$v = u + (\| \tilde{h}^1(u) \|_\infty / r)(\hat{v} - u).$$

Since $\| \tilde{h}^1(u) \|_\infty / r \leq 1$, it follows that $v \in \mathcal{U}$. We now verify that this control function has the required properties.

Notice first that

$$\|v-u\|_{\mathcal{L}^2} \leq (2d/r)\ \|\ \tilde{h}^1_i(u)\|_\infty, \tag{7.3}$$

where d is a bound on the $\mathcal{L}^2_m[T]$ norms of elements in $\mathcal{U}$.

We have from (7.1) and (7.2) that

$$\begin{aligned} M(u)\alpha &= \nabla\tilde{h}^1(u)\circ\sum_{j=1}^{n_E}\alpha_j(v_j-v_0) \\ &= -\nabla\tilde{h}^1(u)\circ\left(\sum_{j=1}^{n_E}\lambda_j(v_j-v_0)+v_0-u\right)-\delta_2\|\tilde{h}^1(u)\|_\infty^{-1}\tilde{h}^1(u). \end{aligned}$$

By definition of $\hat{v}$,

$$\nabla\tilde{h}^1(u)\circ(\hat{v}-u) = -\delta_2\|\tilde{h}^1(u)\|_\infty^{-1}\tilde{h}^1(u).$$

But then

$$\nabla\tilde{h}^1(u)(v-u) = -(\delta_2/r)\tilde{h}^1(u).$$

Since $\delta_2/r \leq 1$, it follows that

$$\begin{aligned} &\max_{i\in E}|\tilde{h}^1_i(u)+\langle\nabla\tilde{h}^1_i(u),v-u\rangle| - \max_{i\in E}|\tilde{h}^1_i(u)| \\ &\qquad\leq -(\delta_2/r)\|\tilde{h}^1(u)\|_\infty. \end{aligned} \tag{7.4}$$

We deduce from property (i) that

$$\left\langle\nabla\tilde{h}^2_j(u), v_0+\sum_{i=1}^{n_E}(\lambda_i+\alpha_i)(v_i-v_0)-u\right\rangle \leq -\tilde{h}^2_j(u)-\delta/2\ \forall j\in I.$$

It follows that

$$\langle\nabla\tilde{h}^2_j(u),v-u\rangle \leq (\|\tilde{h}^1(u)\|_\infty/r)(-\tilde{h}^2_j(u)-\delta/2)\ \forall j\in I.$$

Since $\|\tilde{h}^1(u)\|_\infty/r \leq 1$ and $\tilde{h}^2_j(u)\leq 0$ for all $j\in I$, we deduce that

$$\tilde{h}^2_j(u)+\langle\nabla\tilde{h}^2_j(u),v-u\rangle \leq -(\delta/(2r))\|\tilde{h}^1(u)\|_\infty\ \forall j\in I. \tag{7.5}$$

Likewise we deduce from property (ii) that

$$\tilde{q}(u)(t)+\langle\nabla\tilde{q}(u)(t),v-u\rangle \leq -(\delta/(2r))\|\tilde{h}^1(u)\|_\infty\ \forall t\in T. \tag{7.6}$$

Surveying inequalities (7.3)–(7.6), we see that v satisfies all relevant conditions for completion of the proof when we set $K_1=\min\{\delta_2,\delta/(2r)\}$ and $K_2=2d/r$, numbers whose magnitudes do not depend on our choice of u. ∎

NEWTON'S LAW AND INTEGRABILITY OF NONHOLONOMIC SYSTEMS*

A. M. BLOCH† AND P. E. CROUCH‡

Abstract. In this paper we consider nonholonomic control systems on Riemannian manifolds. Such systems evolve on subbundles of tangent bundles, defined by the nonholonomic constraints. This paper promotes the view of such systems as the restriction to the nonholonomic subbundle of "Newton law"-type problems on the entire tangent bundle, defined by, in general, non-Riemannian connections. These connections should be related to specific geometric properties of the nonholonomic system. We introduce a particular class of connections and demonstrate the richness of the class through four examples—the rolling ball, the constrained particle, the rolling penny, and the generalized rolling ball. This class of connections is strongly related to questions of integrability of the original nonholonomic system. This, in turn, provides additional insight into the relation between nonholonomic control systems formulated as kinematic equations and those that are formulated as the full dynamic equations.

Key words. Newton's law, nonholonomic, integrability, connections

1. Introduction.

In this paper we consider nonholonomic control systems on Riemannian manifolds, as a general framework in which to consider control problems associated with classical nonholonomic mechanical systems. There has been much work on nonholonomic mechanics and associated control systems, including work by the authors [1], [2], [3], and others including Vershik and Gershkovich [4], Vershik and Fadeev [5], and Bloch, Krishnaprasad, Marsden, and Murray [9]. An abstract notion of mechanics may be cast in terms of second-order equations on manifolds through the extra structure of a connection and from which a notion of "Newton law" systems may be formed. Systems with constraints limited to only the configuration variables, denoted holonomic systems, can be identified with Lagrangian systems. Constraints on such systems which include the phase variables, not simply the configuration variables, yield nonholonomic systems through application of d'Alembert's principle. These systems are not naturally identified as Lagrangian systems. If one treats the constraints as in a constrained variational problem, rather than invoking d'Alembert's principle, one obtains a class of systems called vakonomic systems [4]–[5]. Nonholonomic and vakonomic systems are contrasted in Vershik and Fadeev [5] (see also Bloch and Crouch [2]).

Since nonholonomic systems are not naturally Lagrangian, one can ask about other natural structures identified with nonholonomic systems. Vershik and Gershkovich [4] identify a new connection on a reduced phase space on which nonholonomic systems are given as a "Newton law" system. Other approaches include Bates and

Sniatycki [6], Bloch, Krishnaprasad, Marsden, and Murray [9]. In this regard it is interesting to note the fundamental contributions by Cartan [7] and Vershik and Fadeev [5] (see also Arnold [10]).

In this work we expand upon the previous note [8] by the authors and take a different point of view from the work described above. The fundamental perspective is that nonholonomic systems may be viewed as "Newton law" systems defined by connections on the entire phase space which are related to the system geometry.

Although there are many choices for these connections, we concentrate on one particular class which has a very appealing structure. This sheds some light on the ability to generate nonholonomic systems from "Newton law" systems defined by metric connections. The structure also sheds light on the kinematic and dynamic formulations on nonholonomic systems and the associated integrability problems.

To be more specific, we suppose that $M^n, \langle \cdot, \cdot \rangle$ is a Riemannian manifold with symmetric Riemannian connection ∇ and covariant derivative $D/\partial t$. We sometimes denote the metric by G. We may describe a class of nonholonomic control systems on M, driven by external forces, by following the works of Bloch and Crouch [1], [2], [3]. These are generally defined by systems of equations:

$$\frac{D^2 q}{\partial t^2} = \sum_{i=1}^{m} \lambda_i W_i + F; \quad q \in M, \quad \omega_i(\dot{q}) \equiv 0, \quad 1 \leq i \leq m, \tag{1}$$

where ω_i, $1 \leq i \leq m$, are m independent constraint forms on M satisfying

$$\omega_i(X) = \langle W_i, X \rangle; \qquad X \in \Gamma(TM),$$

where $\Gamma(V)$ denotes the space of sections of a vector bundle V, $W_i \in \Gamma(TM)$, $1 \leq i \leq m$, and $F \in \Gamma(TM)$ is an arbitrary external force field.

System (1) is nonholonomic precisely when the distribution $N \subset TM$ defined by

$$N_p = \{X_p : X \in \Gamma(TM), \omega_i(X) \equiv 0, 1 \leq i \leq m\}, \quad p \in M, \tag{2}$$

is not integrable. Let $a_{ij} = \omega_i(W_j)$, $1 \leq i, j \leq m$. The independence of the forms ω_i implies that the matrix $[a_{ij}]_{1 \leq i,j \leq m}$ is invertible on the whole of M. By differentiating the constraints we obtain from (1)

$$\frac{D\omega_i}{\partial t}(\dot{q}) + \omega_i\left(\sum_j \lambda_j W_j + F \right) \equiv 0, \quad 1 \leq i \leq m,$$

and so we may solve for the multipliers λ_i as

$$\lambda_k = -\sum_j a_{kj}^{-1} \left(\frac{D\omega_j}{\partial t}(\dot{q}) + \omega_j(F) \right), \quad 1 \leq k \leq m.$$

We may, therefore, obtain an equivalent formulation of the system described by (1) in the form

$$\frac{D^2 q}{\partial t^2} + \sum_{k,j} W_k a_{kj}^{-1} \frac{D\omega_j}{\partial t}(\dot{q}) = F - \sum_{k,j} W_k a_{k,j}^{-1} \omega_j(F), \tag{3}$$

$$\omega_i(\dot{q}) = 0, \quad 1 \leq i \leq m.$$

Much effort has gone into understanding or rationalizing this system of equations. We briefly review the approach of Vershik and Gershkovich [4] and Fadeev and Vershik [5].

For any $X \in \Gamma(TM)$ we set

$$\pi_N(X) = X - \sum_{ki} W_k a_{ki}^{-1} \omega_i(X).$$

It is evident that $\pi_N(X) \in \Gamma(N)$ and $\pi_N(\pi_N(X)) = \pi_N(X)$. Thus π_N is the projection onto the subbundle $N \subset TM$. By differentiating the constraints we find that

$$\begin{aligned}\pi_N\left(\frac{D^2q}{\partial t^2}\right) &= \frac{D^2q}{\partial t^2} - \sum_{i,k} W_k a_{ki}^{-1} \omega_i\left(\frac{D^2q}{\partial t^2}\right) \\ &= \frac{D^2q}{\partial t^2} + \sum_{i,k} W_k a_{ki}^{-1} \frac{D\omega_i}{\partial t}(\dot{q}).\end{aligned}$$

We may, therefore, write (3) in the form

$$\pi_N\left(\frac{D^2q}{\partial t^2}\right) = \pi_N(F), \quad \dot{q} \in N. \tag{4}$$

Definition 1.1. *In general, if $\bar{\nabla}$ is any connection on M, with corresponding covariant derivative $\bar{D}/\partial t$, then we define the following second-order system*

$$\frac{\bar{D}^2q}{\partial t^2} = \bar{F}, \quad q \in M \tag{5}$$

to be a "Newton law" system on M, with external forces modeled by the vector field $\bar{F}$ on M.

Thus, the nonholonomic system (1) may be viewed as simply the projection (4) of the Newton law system, $D^2q/\partial t^2 = F$, onto the subbundle N. However, even more is true. We may define a new connection ∇' on M by setting

$$\nabla'_X Y = \nabla_X Y + \sum_{k,i=1}^{m} W_i a_{ik}^{-1} (\nabla_X \omega_k)(Y); \quad X, Y \in \Gamma(TM), \tag{6}$$

which, in turn, defines a covariant derivative $D'/\partial t$. Moreover, from (6), the connection ∇' has the property

$$\omega_i(\nabla'_X Y) = \omega_i(\nabla_X Y) + (\nabla_X \omega_i)(Y) = X(\omega_i(Y)).$$

Thus, if $X, Y \in \Gamma(N)$, $\nabla'_X Y \in \Gamma(N)$, and so $\nabla'|_N$ defines a connection on the subbundle N. Thus, we may write the nonholonomic system (1) in the form

$$\frac{D'^2q}{\partial t^2} = \pi_N(F); \dot{q} \in N, \tag{7}$$

and view the system as a Newton law system on the bundle N. These observations were made by Fadeev and Vershik [5]. We take a different perspective in this paper and begin by noting that system (7) defines a perfectly good Newton law system on all of TM:

$$\frac{D'^2q}{\partial t^2} = \pi_N(F), \quad q \in M. \tag{8}$$

DEFINITION 1.2. *Consider a Newton law system on M, defined by a connection $\bar{\nabla}$ and external force $\bar{F}$ of the form*

$$\frac{\bar{D}^2 q}{\partial t^2} = \bar{F}, \quad q \in M.$$

We say that the system has the restriction property if it restricts to the subbundle N, and on N it coincides with the nonholonomic system (1).

It follows that system (8) has the restriction property. However, the choice of connection ∇' seems to be an arbitrary choice, and motivated by conversations with Vershik, we ask if there are not more natural choices, related to the geometry of the nonholonomic system? To begin an analysis of this question in this paper, we consider another n dimensional bundle over M, denoted V, with connection ∇^V, and a vector bundle isomorphism $A : TM \to V$, and introduce a class of connections on TM, parameterized by A, and a symmetric two tensor $S : TM \otimes TM \to \mathbb{R}$ on M, denoted $\nabla^{(A,S)}$. Corresponding to $\nabla^{(A,S)}$, we may construct a covariant derivative $D^{(A,S)}/\partial t$, and pose a similar question. When does the system

$$\frac{D^{(A,S)^2} q}{\partial t} = \pi_N(F), \quad q \in M \tag{9}$$

have the restriction property? We answer this question by making various assumptions on the nonholonomic system and choices for V, ∇^V, and A. The defining property of the connection $\nabla^{(A,S)}$ is that when the system (9) is restricted to N it may be rewritten as

$$\frac{D^V v}{\partial t} = A_q(\pi_N(F)); \quad \dot{q} = A_q^{-1}(v) \in N.$$

The particular choices of V, ∇^V, and A of course impact the form and properties of these transformed equations. We investigate the results for the particular choices made in answering the question above, especially the question of integrability.

We may also ask another question. Is there another metric g on M, (which is different from G), generating a Riemannian connection ∇^g on M, such that the Newton law system

$$\frac{D^{g^2} q}{\partial t^2} = \pi_N(F), \quad q \in M$$

has the restriction property? We provide a partial answer to this question by providing sets of conditions on g, A, and S, so that $\nabla^g = \nabla^{(A,S)}$. Examples we have examined thus far do not seem to arise from such a Riemannian connection.

We now outline the specific agenda for the paper. In section 2 we define the general class of connections $\nabla^{(A,S)}$ on M and prove some properties of these connections and the associated Newton law systems. In section 3 we further develop our understanding of the general class of connections by introducing a specific subclass of nonholonomic systems (in which M must be parallelizable and including a large class of systems of interest) and examining the proposed class of connections for the specific class of nonholonomic systems. In section 4 we study the question of existence of Newton law systems generated by Riemannian connections which have the restriction property. In section 5 we discuss the relationship between the class of connections $\nabla^{(A,S)}$ and integrability of the corresponding Newton law, or nonholonomic systems. Finally,

in section 6 we give four examples within the subclass identified in section 3 and demonstrate the results of the paper in each case. These examples illustrate that the connections introduced in section 2 are of real interest to the understanding of nonholonomic systems in general.

2. Connections defined by bundle maps. We introduce another vector bundle V over M; isomorphic to TM, $\pi : V \to M$, with $V_q = \pi^{-1}(q)$ and $\dim(V_q) = n$ for $q \in M$. We assume that V comes equipped with a connection ∇^V, which defines a covariant derivative $D^V/\partial t$ on V. We let $A : TM \to V$ be a vector bundle isomorphism so that

$$A_q : T_qM \to V_q$$

is a nonsingular vector space isomorphism for each $q \in M$, and hence $A^{-1} : V \to TM$ is well defined. Assume also that we are given a Newton law system on M,

$$\frac{\bar{D}^2 q}{\partial t^2} = \bar{F}$$

defined by a connection $\bar{\nabla}$ on M. We are interested in how this system behaves under the bundle map

$$v = A_q(\dot{q}). \tag{10}$$

To differentiate this expression we must introduce a connection on the bundle $L(TM; V)$ over M, of all bundle maps from TM to V. The connections $\bar{\nabla}$ and ∇^V allow us to define the induced connection $\bar{\nabla}$ on $L(TM, V)$ by setting

$$(\bar{\nabla}_X A)(Y) \stackrel{\Delta}{\to} = \nabla^V_X(AY) - A(\bar{\nabla}_X Y), A \in \Gamma(L(TM; V)), X, Y \in \Gamma(TM). \tag{11}$$

The implication for the notation is that the connection ∇^V is fixed, whereas the connection $\bar{\nabla}$ on M is allowed to vary. We may now differentiate equation (10) to obtain

$$\frac{D^V v}{\partial t} = \frac{\bar{D} A_q}{\partial t}(\dot{q}) + A_q\left(\frac{\bar{D}^2 q}{\partial t^2}\right). \tag{12}$$

Substituting our Newton law system (5), we obtain the following system on V:

$$\begin{aligned} \frac{D^V v}{\partial t} &= \frac{\bar{D} A_q}{\partial t}(A_q^{-1} v) + A_q(\bar{F}), \\ \dot{q} &= A_q^{-1}(v). \end{aligned} \tag{13}$$

Thus, by "changing coordinates" as in (10), we have complicated our Newton law system (5) by the introduction of the term

$$\frac{\bar{D} A_q}{\partial t}(A_q^{-1} v) = \frac{\bar{D} A_q}{\partial t}(\dot{q}). \tag{14}$$

We can, therefore, ask the natural question "Can we choose the connection $\bar{\nabla}$ so that the term (14) vanishes identically?" We may recast this question by introducing another definition.

DEFINITION 2.1. *$A \in \Gamma(L(TM;V))$ is Killing with respect to $\bar{\nabla}$ if*

$$(\bar{\nabla}_X A)(Y) + (\bar{\nabla}_Y A)(X) \equiv 0, \quad X, Y \in \Gamma(TM), \tag{15}$$

or

$$(\bar{\nabla}_X A)(X) \equiv 0, \quad X \in \Gamma(TM).$$

Clearly, the last question may now be rephrased as "Is it possible to choose $\bar{\nabla}$ on M so that A is Killing?" Our choice of terminology is clearly reminiscent of the definition in the case of vector fields $X \in \Gamma(TM)$.

Recall that the Riemannian connection ∇, defined by the metric G, is uniquely determined by the properties

(i) $X\langle Y, Z\rangle = \langle \nabla_X Y, Z\rangle + \langle Y, \nabla_X Z\rangle$, (i.e., $\nabla G \equiv 0$);

(ii) $T(X,Y) \overset{\Delta}{=} \nabla_X Y - \nabla_Y X - [X,Y] = 0$.

T is known as the torsion tensor corresponding to ∇. In general, we say any connection $\bar{\nabla}$ on M is symmetric if the torsion tensor corresponding to $\bar{\nabla}$ is identically zero.

THEOREM 2.2. *The unique symmetric connection ∇^A on M, so that $A \in \Gamma(L(TM;V))$ is Killing with respect to ∇^A is given by*

$$\nabla^A_X Y = \nabla_X Y + \frac{1}{2} A^{-1}((\nabla_X A)(Y) + (\nabla_Y A)(X)); \quad X, Y \in \Gamma(TM). \tag{16}$$

Proof. We first show that A is indeed Killing with respect to ∇^A defined by (16). From the definition (11), we find that

$$\begin{aligned}(\nabla^A_X A)(Y) &= \nabla^V_X(AY) - A(\nabla^A_X Y) \\ &= \nabla^V_X(AY) - A(\nabla_X Y) - \frac{1}{2}((\nabla_X A)(Y) + (\nabla_Y A)(X)).\end{aligned}$$

Thus

$$\begin{aligned}(\nabla^A_X A)(Y) + (\nabla^A_Y A)(X) &= \nabla^V_X(AY) + \nabla^V_Y(AX) - A(\nabla_X Y + \nabla_Y X) \\ &\quad -((\nabla_X A)(Y) + (\nabla_Y A)(X)) \\ &= 0.\end{aligned}$$

Since ∇^A is a symmetric connection, if $\bar{\nabla}$ is any other symmetric connection, we may write

$$\bar{\nabla}_X Y = \nabla^A_X Y + S(X,Y),$$

where S is a symmetric two tensor. Thus

$$\begin{aligned}(\bar{\nabla}_X A)(X) &= \nabla^V_X(AX) - A(\bar{\nabla}_X X) = \nabla^V_X(AX) - A(\nabla^A_X X) - AS(X,X) \\ &= (\nabla^A_X A)(X) - AS(X,X).\end{aligned}$$

But A is Killing with respect to ∇^A, so

$$(\bar{\nabla}_X A)(X) = -AS(X,X).$$

Since A is full rank, if A is to be Killing with respect to $\bar{\nabla}$, we must have $S \equiv 0$. Hence, $\bar{\nabla} = \nabla^A$ and ∇^A is unique. ∎

Since we are interested primarily in nonholonomic systems (1), it is interesting to study this result in the context of Newton law systems (5) which have the restriction property. In this case we can weaken the requirement in (13) that the term $\bar{D}A/\partial t(\dot{q})$ vanish identically, and simply require that the term vanish for $\dot{q} \in N$. In this case the transformation (10) maps the nonholonomic system (1) into a system of the form

$$\frac{D^V v}{\partial t} = A_q(\pi_N(F)), \quad \dot{q} = A_q^{-1}(v), \quad \dot{q} \in N. \tag{17}$$

DEFINITION 2.3. *$A \in \Gamma(L(TM;V))$ is Killing on N with respect to $\bar{\nabla}$ if*

$$(\bar{\nabla}_X A)(Y) + (\bar{\nabla}_Y A)(X) = 0 \qquad X, Y \in \Gamma(N), \tag{18}$$

or

$$(\bar{\nabla}_X A)(X) = 0 \qquad X \in \Gamma(N).$$

THEOREM 2.4. *Let $\nabla^{(A,S)}$ be a symmetric connection on M for which $A \in \Gamma(L(TM;V))$ is Killing on N, with respect to $\nabla^{(A,S)}$. Then*

$$\nabla_X^{(A,S)} Y = \nabla_X Y + \frac{1}{2} A^{-1}((\nabla_X A)(Y) + (\nabla_Y A)(X)) + S(X,Y), \quad X, Y \in \Gamma(TM), \tag{19}$$

for some symmetric two tensor S such that $S|_N \equiv 0$.

Proof. Since $S(X,Y) = 0$, for $X, Y \in \Gamma(N)$, the proof of the previous theorem demonstrates that A is indeed Killing on N with respect to $\nabla^{(A,S)}$, as defined in (19). The same proof demonstrates that the additional term S, such that $S|_N \equiv 0$, is the only flexibility in the definition of such a connection. □

Corresponding to the connection $\nabla^{(A,S)}$ on M, defined by (19), there exists a covariant differentiation $D^{(A,S)}/\partial t$. From (19) we have

$$\frac{D^{(A,S)^2} q}{\partial t^2} = \frac{D^2 q}{\partial t^2} + A^{-1}\left(\frac{DA}{\partial t}\right)(\dot{q}) + S(\dot{q}, \dot{q}). \tag{20}$$

We may now ask another question. When does the Newton law system

$$\frac{D^{(A,S)^2} q}{\partial t^2} = \pi_N(F), \quad q \in M$$

have the restriction property? Since $S|_N \equiv 0$, by comparing equations (3) and (20), we obtain the necessary and sufficient condition

$$A^{-1}\frac{DA}{\partial t}(\dot{q}) - \sum_{k,j} W_k a_{kj}^{-1} \frac{D\omega_j}{\partial t}(\dot{q})\Big|_N \equiv 0. \tag{21}$$

Now we set $A(W_k) \stackrel{\Delta}{\to} = \hat{W}_k$, $1 \le k \le m$, and

$$B \stackrel{\Delta}{\to} = A - \sum_{j,k=1}^{m} \hat{W}_k a_{kj}^{-1} \omega_j = A \circ \pi_N. \tag{22}$$

It follows that $B|_{N^\perp} = 0$ and

$$(\nabla_X B)(Y) = (\nabla_X A)(Y) - \sum_{j,k=1}^{m} \nabla_X(\hat{W}_k a_{kj}^{-1})\omega_j(Y) - \sum_{j,k=1}^{m} \hat{W}_k a_{kj}^{-1}(\nabla_X \omega_j)(Y),$$

so

$$A^{-1}(\nabla_X B)(X) = A^{-1}(\nabla_X A)(X) - \sum_{j,k=1}^{m} W_k a_{kj}^{-1}(\nabla_X \omega_j)(X); X \in \Gamma(N).$$

Since A is full rank, condition (21) is, therefore, equivalent to the fact that B is Killing on N with respect to ∇.

THEOREM 2.5. *Given a vector bundle V, connection ∇^V, symmetric tensor S, $S|_N = 0$, then a necessary and sufficient condition for the Newton law system on M*

$$\frac{D^{(A,S)^2} q}{\partial t} = \pi_N(F), \quad q \in M$$

to have the restriction property is that $A \circ \pi_N$ is Killing on N with respect to ∇.

3. A special class of nonholonomic systems. Given a vector bundle V, connection ∇^V, we wish to find examples of bundle maps $A : TM \to V$ so that $A \circ \pi_N$ is Killing on N with respect to ∇. To work toward this goal we restrict our attention to a special subclass of nonholonomic systems which we describe here.

DEFINITION 3.1. *A one form ν on M is said to be a Killing form with respect to a connection $\bar{\nabla}$ on M if*

$$(\bar{\nabla}_X \nu)(X) \equiv 0, \qquad X \in \Gamma(TM). \tag{23}$$

A one form ν on M is said to be a Killing form on N with respect to a connection $\bar{\nabla}$ on M if

$$(\bar{\nabla}_X \nu)(X) \equiv 0, \qquad X \in \Gamma(N). \tag{24}$$

We note that if $\nu(X) = \langle V, X\rangle$, $X \in \Gamma(TM)$, then

$$\begin{aligned} X(\nu(Y)) &= \langle \nabla_X V, Y\rangle + \langle V, \nabla_X Y\rangle \\ &= (\nabla_X \nu)(Y) + \nu(\nabla_X Y). \end{aligned}$$

Thus $(\nabla_X \nu)(Y) = \langle \nabla_X V, Y\rangle$, and, in particular, $(\nabla_X \nu)(X) = \langle \nabla_X V, X\rangle$. Hence, ν is Killing with respect to ∇ if and only if V is Killing in the classical sense. We now describe the importance of Killing forms for Newton law and nonholonomic systems.

LEMMA 3.2. *If ν is a Killing form with respect to $\bar{\nabla}$, then $\nu(\dot{q})$ is a constant of motion for the Newton law system $\bar{D}^2 q/\partial t^2 = 0$.*

Proof.

$$\frac{d}{dt}\nu(\dot{q}) = \left(\frac{\bar{D}\nu}{\partial t}\right)(\dot{q}) + \nu\left(\frac{\bar{D}^2 q}{\partial t^2}\right) = 0. \qquad \square$$

LEMMA 3.3 (Arnold [10]). *If ν is a Killing form on N with respect to ∇ such that $\nu(N^\perp) = 0$, then $\nu(\dot{q})$ is a constant of motion for the nonholonomic system* (3) *with $F \equiv 0$.*

Proof.

$$\frac{d}{dt}\nu(\dot{q}) = \frac{D\nu}{\partial t}(\dot{q}) + \nu\left(\frac{D^2q}{\partial t^2}\right)$$
$$= \frac{D\nu}{\partial t}(\dot{q}) + \sum_{k,j} \nu(W_k)a_{kj}^{-1}\frac{D\omega_j}{\partial t}(\dot{q}) = 0,$$

since for $\dot{q} \in N$, $\frac{D\nu}{\partial t}(\dot{q}) = 0$, and $W_k \in N^{\perp}$. □

Clearly, the existence of Killing one forms as in Lemmas 3.2 and 3.3 is linked to the integrability of the systems. We discuss this further in section 5.

Assumption 3.1.

(i) M is parallelizable;

(ii) In the nonholonomic system (1) we may complete the set $\{\omega_1, \dots, \omega_m\}$ to a basis of $\Gamma(T^*M)$ by the set $\{\nu_1, \dots, \nu_{n-m}\}$ of one forms ν_k that are Killing on N with respect to ∇ and $\nu_k(N^{\perp}) = 0$, $1 \le k \le n-m$.

Let V_k, $1 \le k \le n-m$ be the vector fields defined by $\nu_k(X) = \langle V_k, X\rangle$, $X \in \Gamma(TM)$, and set $A(V_k) = \hat{V}_k$, $1 \le k \le n-m$, $b_{kj} = \nu_k(V_j)$, $1 \le k, j \le n-m$. Assumption 3.1 ensures that the matrix $[b_{kj}]_{1\le k,j\le n-m}$ is invertible on all of M. It follows that

$$B = A \circ \pi_N = \sum_{j,k=1}^{n-m} \hat{V}_j b_{jk}^{-1}\nu_k,$$

and so

$$A = \sum_{j,k=1}^{m} \hat{W}_j a_{jk}^{-1}\omega_k + \sum_{j,k=1}^{n-m} \hat{V}_j b_{jk}^{-1}\nu_k. \tag{25}$$

LEMMA 3.4. *$B = A\circ\pi_N$ is Killing on N with respect to ∇, under Assumption* 3.1*, if and only if*

$$\nabla_X^V\left(\sum_{j=1}^{n-m} \hat{V}_j b_{jk}^{-1}\right) \equiv 0, \qquad 1 \le k \le n-m, \quad X \in \Gamma(N). \tag{26}$$

Proof.

$$(\nabla_X B)(X) = \sum_k \nabla_X^V\left(\sum_j \hat{V}_j b_{jk}^{-1}\right)\nu_k(X) + \sum_{jk} \hat{V}_j b_{jk}^{-1}(\nabla_X\nu_k)(X).$$

Since ν_k is Killing on N with respect to ∇, $(\nabla_X B)(X) \equiv 0$, for $X \in \Gamma(N)$ if and only if condition (26) is satisfied. □

The condition expressed by (26) is not particularly attractive. We, therefore, make some choices for V, ∇^V, and A, namely, the following assumption.

Assumption 3.2. Under Assumption 3.1 set $V = TM$, $\hat{V}_k = \sum_m V_m b_{mk}$, $\hat{W}_k = \sum_m W_m a_{mk}$ so that

$$A = \sum_m V_m\nu_m + \sum_m W_m\omega_m \tag{27}$$

and

$$\nabla^V V_k = 0, \quad 1 \le k \le n-m, \quad \nabla^V W_k = 0, \quad 1 \le k \le m.$$

COROLLARY 3.5. *Under Assumptions* 3.1 *and* 3.2, $B = A \circ \pi_N$ *is always Killing on* N *with respect to* ∇.

COROLLARY 3.6. *Under Assumptions* 3.1 *and* 3.2, *then for any symmetric tensor* S, $S|_N = 0$, *the Newton law system on* M

$$\frac{D^{(A,S)^2} q}{\partial t^2} = \pi_N(F), \quad q \in M$$

has the restriction property. The corresponding nonholonomic system may be rewritten in the form

$$\frac{D^V v}{\partial t} = \sum_{i=1}^{n-m} V_i \nu_i(F), \quad \dot{q} = A_q^{-1}(v), \quad v, \dot{q} \in N. \tag{28}$$

Clearly, there may be other means of satisfying the property that $A \circ \pi_N$ be Killing on N with respect to ∇ in addition to assumptions 3.1 and 3.2. In particular, Theorem 2.5 does not preclude cases in which M is not parallelizable and more interesting choices of V and ∇^V are appropriate.

4. Riemannian connections compatible with bundle maps. In this section we consider the question, "Does there exist a metric g on M such that $\nabla^g = \nabla^{(A,S)}$ for some bundle map $A : TM \to V$ and symmetric tensor S." We first examine this question in general, and then under Assumptions 3.1 and 3.2, making a natural choice for g. We begin by giving a useful characterization of ∇^g.

LEMMA 4.1. *The unique Riemannian connection* ∇^g *on* M *corresponding to the metric* g *on* M *is given by*

$$\begin{aligned} g(Z, \nabla^g_X Y) = g(Z, \nabla_X Y) + \frac{1}{2}\{&(\nabla_Y g)(X,Z) \\ &+ (\nabla_X g)(Y,Z) - (\nabla_Z g)(X,Y)\}, \quad X, Y, Z \in \Gamma(TM). \end{aligned} \tag{29}$$

Proof. Note that ∇ is, of course, the unique Riemannian connection corresponding to the metric G. Clearly ∇^g, defined by (29), is a symmetric connection. Hence, if ∇^g, defined by (29), also satisifes $\nabla^g g \equiv 0$, it must be the unique Riemannian connection corresponding to the metric g. It is, therefore, sufficient to prove that $\nabla^g g \equiv 0$, or

$$Zg(X,Y) = g(\nabla^g_Z X, Y) + g(X, \nabla^g_Z Y)$$

or

$$(\nabla_Z g)(X,Y) + g(\nabla_Z X, Y) + g(X, \nabla_Z Y) = g(\nabla^g_Z X, Y) + g(X, \nabla^g_Z Y). \tag{30}$$

Now, from (29) we have

$$\begin{aligned} g(\nabla^g_Z X, Y) + g(X, \nabla^g_Z Y) = g(\nabla_Z X, Y) + g(X, \nabla_Z Y) \\ + \frac{1}{2}[(\nabla_Z g)(X,Y) + (\nabla_X g)(Z,Y) \\ - (\nabla_Y g)(Z,X) + (\nabla_Z g)(Y,X) \\ + (\nabla_Y g)(Z,X) - (\nabla_X g)(Z,Y)]. \end{aligned}$$

But this is just the left-hand side of (30). □

We may now compare ∇^g, given by (29), and ∇^A, defined by (16). In particular, we see that

$$g(Z, \nabla^A_X Y) = g(Z, \nabla_X Y) + \frac{1}{2} g(Z, A^{-1}((\nabla_X A)(Y) + (\nabla_Y A)(X))).$$

Comparing this expression with that of ∇^g we see that $\nabla^g = \nabla^A$ if and only if

$$g(Z, A^{-1}((\nabla_X A)(Y) + (\nabla_Y A)(X))) = (\nabla_Y g)(X, Z) + (\nabla_X g)(Y, Z) - (\nabla_Z g)(X, Y).$$

Since this expression is symmetric in X and Y, we may simplify this condition, as in the following lemma.

LEMMA 4.2. *$\nabla^g = \nabla^A$ if and only if*

$$g(Z, A^{-1}(\nabla_X A)(X)) = (\nabla_X g)(X, Z) - \frac{1}{2}(\nabla_Z g)(X, X), \quad X, Z \in \Gamma(TM). \tag{31}$$

Ascertaining solutions A and g of (31) is a hard problem in general, but there is an obvious candidate for g, namely,

$$g(X, Y) = h(AX, AY), \quad X, Y \in \Gamma(TM), \tag{32}$$

where h is a metric on V with $\nabla^V h \equiv 0$. We may substitute this special case into the condition (31) to obtain a condition on the map A alone. Since $(\nabla_Z g)(X, Y) = Z(g(X, Y)) - g(\nabla_Z X, Y) - g(X, \nabla_Z Y)$ for the special case of (32) we have

$$\begin{aligned}(\nabla_Z g)(X, Y) &= (\nabla^V_Z h)(AX, AY) + h(\nabla^V_Z (AX), AY) + h(AX, \nabla^V_Z (AY)) \\ &\quad - h(A\nabla_Z X, Y) - h(AX, A\nabla_z Y) \\ &= h((\nabla_Z A)(X), AY) + h(AX, (\nabla_Z A)(Y)).\end{aligned}$$

Thus from (29) and (16) we have

$$\begin{aligned}h(AZ, A\nabla^g_X Y) = h(AZ, A\nabla^A_X Y) &+ \frac{1}{2} h(AX, (\nabla_Y A)(Z) - (\nabla_Z A)(Y)) \\ &+ \frac{1}{2} h(AY, \nabla_X A)(Z) - (\nabla_Z A)(X)).\end{aligned}$$

We may summarize these observations in the following result.

THEOREM 4.3. *For the metric $g(X, Y) = h(AX, AY)$, $\nabla^V h \equiv 0$, we have*

$$\nabla^g = \nabla^{(A,S)},$$

where S is the symmetric tensor defined by

$$\begin{aligned}h(AZ, AS(X, Y)) = \frac{1}{2} h(AX, (\nabla_Y A)(Z) - (\nabla_Z A)(Y)) \\ + \frac{1}{2} h(AY, (\nabla_X A)(Z) - (\nabla_Z A)(X)).\end{aligned} \tag{33}$$

We may apply this result in the situation of Theorem 2.5 to obtain the following corollary.

COROLLARY 4.4. *The Newton law system on M, with g given by* (32),

$$\frac{D^{g^2}q}{\partial t^2} = \frac{D^{(A,S)^2}q}{\partial t^2} = \pi_N(F), \quad q \in M$$

has the restriction property if and only if

(34) (i) $A \circ \pi_N$ is Killing on N with respect to ∇;
(ii) $S|_N \equiv 0$, S defined in (33).

We now examine condition (34) (ii) in the case where Assumptions 3.1 and 3.2 hold. We set

(35) $$\hat{\omega}_k(W_m) = \delta_{k,m}, \qquad \hat{\omega}_k(V_m) \equiv 0,$$
$$\hat{\nu}_k(V_m) = \delta_{k,m}, \qquad \hat{\nu}_k(W_m) \equiv 0,$$

so that $\{\hat{\omega}_1, \dots, \hat{\omega}_m, \hat{\nu}_1, \dots, \hat{\nu}_{n-m}\}$ is a dual frame for $\{W_1, \dots, W_m, V_1, \dots, V_{n-m}\}$ and choose the metric h to be

(36) $$h = \frac{1}{2}\sum_{k=1}^{m} \hat{\omega}_k \otimes \hat{\omega}_k + \frac{1}{2}\sum_{k=1}^{n-m} \hat{\nu}_k \otimes \hat{\nu}_k.$$

We must now check that indeed $\nabla^V h \equiv 0$, where $V = TM$ and ∇^V is defined in Assumption 3.2. Since

$$\nabla^V_Z X = \sum_{k=1}^{m} Z(\hat{\omega}_k(X))W_k + \sum_{k=1}^{n-m} Z(\hat{\nu}_k(X))V_k,$$

it is clear that

$$(\nabla^V_Z h)(X,Y) = Z(h(X,Y)) - h(\nabla^V_Z X, Y) - h(X, \nabla^V_Z Y) \equiv 0.$$

Now we may simplify the definition of S in (33), using the expression (36) for h and (27) for A. We see that

$$(\nabla_X A)(Y) = \sum_m \nabla^V_X V_m \nu_m(Y) + \sum_m \nabla^V_X W_m \omega_m(Y)$$
$$+ \sum_m V_m(\nabla_X \nu_m)(Y) + \sum_m W_m(\nabla_X \omega_m)(Y).$$

Now we have the identity

$$d\nu(X,Y) = (\nabla_X \nu)(Y) - (\nabla_Y \nu)(X), \quad X, Y \in \Gamma(TM), \quad \nu \in \Gamma(T^*M).$$

Thus, from the definition of ∇^V, we see that

$$(\nabla_X A)(Y) - (\nabla_Y A)(X) = \sum_m V_m d\nu_m(X,Y) + \sum_m W_m d\omega_m(X,Y),$$

and hence we have from (33)

$$\sum_m \nu_m(Z)\nu_m(S(X,Y)) + \sum_m \omega_m(Z)\omega_m(S(X,Y))$$
$$= \frac{1}{2}\sum_m (\nu_m(X)\, d\nu_m(Y,Z) + \omega_m(X)\, d\omega_m(Y,Z))$$
$$+ \frac{1}{2}\sum_m (\nu_m(Y)\, d\nu_m(X,Z) + \omega_m(Y)\, d\omega_m(X,Z)).$$

We deduce the following result.

LEMMA 4.5. *If Assumptions* 3.1 *and* 3.2 *hold, and if* S *is the tensor defined in* (33)*, then* $S|_N \equiv 0$ *if and only if*

$$d\nu_k(X,\cdot) \equiv 0, \quad 1 \le k \le n-m, \quad X \in \Gamma(N). \tag{37}$$

It turns out that in all of the examples in section 6, this condition is never satisfied. This negative result does not, of course, exclude the possibility that we can find solutions to the equations

$$\nabla^g = \nabla^{(A,S)}$$

for some metric g on M, and pairs (A,S) satisfying condition (34), which yields a Newton law system with the restriction property, as in Corollary 4.4.

5. Integrability of nonholonomic systems. In this section we consider the implications for the preceding analysis for the integrability of nonholonomic systems. We recall that if we are given a differential equation on $\mathbb{R}^N$,

$$\dot{x} = f(x,t), \quad x \in \mathbb{R}^N,$$

then the system is said to be integrable, if through coordinate transforms, it may be reduced to a system of algebraic relations and quadratures. Of course, this property may also be a local one, defined only in a particular open domain of $\mathbb{R}^N$. In the case of differential equations defined on a Riemannian manifold, the situation is complicated by the geometry in the case of a global property, but locally the properties are identical. Our analysis and assumptions in this paper are particularly concerned with the global integrability properties of a nonholonomic system defined on a Riemannian manifold, even though our examples are such that the manifold is parallelizable, if not Euclidean.

First we consider the situation studied in section 2, where we are given V, ∇^V, the map A, and corresponding Newton law system on M,

$$\frac{D^{A^2}q}{\partial t^2} = \bar{F}, \quad q \in M. \tag{38}$$

Since ∇^A is the unique connection so that A is Killing with respect to ∇^A, we have that if $v = A_q\dot{q}$ we may rewrite this system in the form

$$\frac{D^V v}{\partial t} = A_q(\bar{F}), \quad \dot{q} = A_q^{-1}(v), \quad (q,v) \in V. \tag{39}$$

In general, this global transformation of coordinates does nothing to simplify the integration of the system of equations. This depends upon the choice of vector bundle V and connection ∇^V. In particular, if V is parallelizable, with frame $\{Z_1,\dots,Z_n\}$, and dual frame $\{z_1,\dots,z_n\}$ with $\nabla^V Z_k \equiv 0$, $1 \le k \le n$, then independent of the original connection ∇ on M we are able to simplify system (39) as follows. Setting $v_i = z_i(v)$, $1 \le i \le n$, we have $v = \sum_{i=1}^n v_i z_i(q)$, so now equations (39) become

$$\begin{aligned} \dot{v}_i &= z_i(\bar{F}), \quad 1 \le i \le n, \\ \dot{q} &= \sum_{i=1}^n A_q^{-1}(Z_i)v_i, \quad q \in M. \end{aligned} \tag{40}$$

Thus the "dynamics" of (38), i.e., the first equation in (39), has been reduced to quadratures, and one is essentially left with the "kinematics," i.e., the second equation in (39). In the case of classical dynamical systems, (with $\bar{F} \equiv 0$), the v_i are indeed constants and we would say that they are n integrals of the motion, through which we can reduce the dynamics to a system evolving on a phase space of dimension n only and not $2n$.

In the case of a nonholonomic system (1), Theorem (2.5) provides a means of reviewing it as a restriction to N of the Newton law system

$$\frac{D^{(A,S)^2}q}{\partial t^2} = \pi_N(F), \quad q \in M,$$

assuming, of course, that $S|_N \equiv 0$ and $A \circ \pi_N$ is Killing with respect to ∇. We may apply the same analysis as above to the restriction to N and transform the nonholonomic system to the form (39). If we now also insist that Assumptions 3.1 and 3.2 hold, then we may set

$$\{Z_1, \dots, Z_n\} = \{W_1, \dots, W_m, V_1, \dots, V_{n-m}\},$$
$$\{z_1, \dots, z_n\} = \{\hat{\omega}_1, \dots, \hat{\omega}_m, \hat{\nu}_1, \dots, \hat{\nu}_{n-m}\},$$

$$v = \sum_{i=1}^{n-m} v_i V_i(q) + \sum_{i=1}^{m} w_i W_i(q),$$
$$A = \sum_{m} V_m \nu_m + \sum_{m} W_m \omega_m,$$
$$A^{-1} = \sum_{j,k} V_m b_{jk}^{-1} \hat{\nu}_k + \sum_{j,k} W_m a_{jk}^{-1} \hat{\omega}_k.$$

The nonholonomic system (1) is then reduced to system (40), which in this case takes the form

$$\dot{v}_i = \nu_i(F), \quad 1 \le i \le n-m, \quad \dot{w}_i = 0, \quad 1 \le i \le m,$$
$$\dot{q} = \sum_{k,j=1}^{n-m} V_j b_{jk}^{-1} v_k.$$

Indeed, under Assumptions 3.1 and 3.2 we may now make precise the relationship between nonholonomic control systems formulated as kinematic or dynamic systems. If we set $u_i = v_i(F)$, $1 \le i \le n-m$, then the nonholonomic control system modelled with dynamics is

$$\dot{v}_i = u_i, \quad \dot{w}_i = 0, \quad \dot{q} = \sum_{j,k=1}^{m} V_j b_{jk}^{-1} v_k,$$

while the control system modeled on kinematics alone is simply

$$\dot{q} = \sum_{j,k=1}^{m} V_j b_{jk}^{-1} u_k.$$

The reader should compare this discussion with the less succinct discussion in Bloch and Crouch [2]. Note that the process of reducing the full nonholonomic dynamics to the kinematics is a different reduction to the procedures detailed in Bloch and Crouch [1], and Bloch, Krishnaprasad, Marsden, and Murray [9].

In the special case illustrated above, where we are able to reduce the system to quadratures and the kinematics, the issue of complete integrability remains. In general we cannot expect a nonholonomic system to satisfy Assumption 3.1, even though the four examples we give in section 6 do satisfy this assumption. For example, the chain of trailers, analyzed in Crouch and Jakubczyk [11], does not satisfy Assumption 3.1. In some sense Assumption 3.1 provides $n-m$ integrals, while the nonholonomic constraints provide another m integrals, and these integrals are all linear in the velocities. Indeed, Lemmas 3.2 and 3.3 demonstrate this fact for the classical Newton law system and unforced nonholonomic motion. In general, however, we cannot expect linearity in the velocities, even if we are able to find integrals. For material on the integrability of nonholonomic systems, see Zenkov [12], Hermans [13], and Arnold [10]. Arnold does demonstrate that the rolling ball is indeed integrable, although he makes use of an abstract result, applicable to all systems admitting an invariant measure. We make some further comments about this example, which is also one of the examples we treat in the next section.

6. Examples. In these examples we refer the reader to the cited references for details of the notation employed.

Example 6.1 (rolling penny, Bloch, and Crouch [2]).

$$\begin{pmatrix} \ddot{x} \\ \ddot{y} \\ \ddot{\theta} \\ \ddot{\phi} \end{pmatrix} = \lambda_1 \begin{pmatrix} 1 \\ 0 \\ -\cos\phi \\ 0 \end{pmatrix} + \lambda_2 \begin{pmatrix} 0 \\ 1 \\ -\sin\phi \\ 0 \end{pmatrix} + u_1 \begin{pmatrix} 0 \\ 0 \\ 1 \\ 0 \end{pmatrix} + u_2 \begin{pmatrix} 0 \\ 0 \\ 0 \\ 1 \end{pmatrix} \tag{41}$$

with the nonholonomic constraints: $\dot{x} = \cos\phi\dot{\theta}$, $\dot{y} = \sin\phi\dot{\theta}$, and Euclidean metric structure.

We make the definitions

$$\begin{aligned} \omega_1 &= dx - \cos\phi\, d\theta, \qquad \omega_2 = dy - \sin\phi\, d\theta, \\ W_1 &= \frac{\partial}{\partial x} - \cos\phi\frac{\partial}{\partial\theta}, \qquad W_2 = \frac{\partial}{\partial y} - \sin\phi\frac{\partial}{\partial\theta}, \\ \nu_2 &= d\phi, \qquad \nu_1 = d\theta + \cos\phi\, dx + \sin\phi\, dy, \\ V_2 &= \frac{\partial}{\partial\phi}, \qquad V_1 = \frac{\partial}{\partial\theta} + \cos\phi\frac{\partial}{\partial x} + \sin\phi\frac{\partial}{\partial y}. \end{aligned}$$

Although W_1, W_2, V_1, and V_2 are not mutually orthogonal, W_1 and W_2 are orthogonal to V_1 and V_2. Clearly, ν_2 is Killing. We calculate $(D\nu_1/\partial t)(\dot{q})$.

$$\begin{aligned} \frac{D\nu_1}{\partial t}(\dot{q}) &= -\sin\phi\dot{\phi}\dot{x} + \cos\phi\dot{\phi}\dot{y} = \dot{\phi}(\dot{y}\cos\phi - \dot{x}\sin\phi) \\ &= \cos\phi\nu_2(\dot{q})\omega_2(\dot{q}) - \sin\phi\nu_2(\dot{q})\omega_1(\dot{q}). \end{aligned}$$

Thus ν_1 is not Killing, but it is Killing when restricted to N. Thus, this example does satisfy Assumption 3.1, and we may impose Assumption 3.2, in which case we may view system (41) as the restriction of a Newton law system defined by a connection $\nabla^{(A,S)}$ described in Corollary 3.6.

We note that if $\eta_1 = \sin\phi\, d\phi$, $\eta_2 = \cos\phi\, d\phi$, then

$$(\nabla_X\nu_1)(Y) = \eta_2(X)\omega_2(Y) - \eta_1(X)\omega_1(Y)$$

and

$$d\nu_1(X,Y) = (\nabla_X \nu_1)(Y) - (\nabla_Y \nu_1)(X) = (\eta_2 \wedge \omega_2 - \eta_1 \wedge \omega_1)(X,Y).$$

In particular, even though $d\nu_1|_N \equiv 0$, condition (37) is not satisfied and we are unable to cast $\nabla^{(A,S)}$ as a metric connection.

Example 6.2 (Bates–Sniatycki example of a constrained particle [6]).

$$\begin{pmatrix} \ddot{x} \\ \ddot{y} \\ \ddot{z} \end{pmatrix} = \lambda \begin{pmatrix} -y \\ 0 \\ 1 \end{pmatrix} + \frac{u_1}{\sqrt{1+y^2}} \begin{pmatrix} 1 \\ 0 \\ y \end{pmatrix} + u_2 \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix} \tag{42}$$

with the nonholonomic constraint $\dot{z} = y\dot{x}$ and Euclidean metric structure.

We make the following definitions:

$$\begin{aligned} &\omega = dz - ydx, \qquad W = \frac{\partial}{\partial z} - y\frac{\partial}{\partial x}, \\ &\nu_1 = \frac{1}{\sqrt{1+y^2}}(dx + ydz), \qquad V_1 = \frac{1}{\sqrt{1+y^2}}\left(\frac{\partial}{\partial x} + y\frac{\partial}{\partial z}\right), \\ &\nu_2 = dy, \qquad V_2 = \frac{\partial}{\partial y}. \end{aligned}$$

Thus, W, V_1, and V_2 form an orthogonal set. Clearly, ν_2 is Killing. We calculate $(D\nu_1/\partial t)(\dot{q})$.

$$\begin{aligned} \frac{D\nu_1}{\partial t}(\dot{q}) &= \frac{d}{dt}\left(\frac{1}{\sqrt{1+y^2}}\right)\dot{x} + \frac{d}{dt}\left(\frac{y}{\sqrt{1+y^2}}\right)\dot{z} \\ &= \frac{\nu_2(\dot{q})\omega(\dot{q})}{(1+y^2)^{3/2}}. \end{aligned}$$

Thus ν_1 is not Killing, but it is Killing when restricted to N. Hence, the example does satisfy Assumption 3.1, and we may impose Assumption 3.2, in which case we may view system (42) as the restriction of a Newton law system defined by a connection $\nabla^{(A,S)}$ as described in Corollary 3.6.

We note that if we set $\eta = (dy/(1+y^2)^{3/2})$, then

$$(\nabla_X \nu_1)(Y) = \eta(X)\omega(Y)$$

and

$$d\nu_1(X,Y) = (\eta \wedge \omega)(X,Y).$$

In particular, even though $d\nu_1|_N \equiv 0$, condition (37) is not satisfied, and we are unable to cast $\nabla^{(A,S)}$ as a metric connection.

Example 6.3 (rolling ball, Bloch, and Crouch [2]).

$$\begin{aligned} J\dot{\nu} &= S(\nu)J\nu + \lambda_1 Pe_1 + \lambda_2 Pe_2, \qquad \nu \in \mathbb{R}^3, \\ \dot{P} &= S(\nu)P, \qquad P \in SO(3), \\ m\ddot{x} &= \lambda_2 + u_1, \qquad x, y \in \mathbb{R}, \\ m\ddot{y} &= -\lambda_1 + u_2, \end{aligned} \tag{43}$$

with the nonholonomic constraints

$$e_2^T P^T \nu + \dot{x} = 0, \qquad e_1^T P^T \nu - \dot{y} = 0,$$

and metric structure

$$\langle (\nu_A, \dot{x}_A, \dot{y}_A), (\nu_B, \dot{x}_B, \dot{y}_B) \rangle = \frac{1}{2} \nu_A^T J \nu_B + \frac{1}{2} m (\dot{x}_A \dot{x}_B + \dot{y}_A \dot{y}_B).$$

Here ν is the angular velocity, measured in axes fixed in the rotating ball; P is the angular position, represented by a special orthogonal matrix; x and y are the coordinates of the center, and center of mass of the ball relative to inertial axes. J is the inertia tensor of the ball and $S(a)$ is the skew-symmetric matrix representation of the three vector a, which is uniquely defined by the identity

$$S(a)b = b \times a, \quad a, b \in \mathbb{R}^3,$$

where "$\times$" is the vector cross product in $\mathbb{R}^3$.

This system is 10-dimensional, evolving on $T(\mathbb{R}^2 \times SO(3))$. For simplicity we denote by $a^T \partial/\partial\nu$ ($a^T\, d\nu$) the right invariant vector field (one form) on $SO(3)$ with generator a. We may obtain

$$\begin{aligned}
W_1 &= (J^{-1} P e_1)^T \frac{\partial}{\partial \nu} - \frac{1}{m} \frac{\partial}{\partial y}, & \omega_1 &= (P e_1)^T\, d\nu - dy, \\
W_2 &= (J^{-1} P e_2)^T \frac{\partial}{\partial \nu} + \frac{1}{m} \frac{\partial}{\partial x}, & \omega_2 &= (P e_2)^T\, d\nu + dx, \\
V_1 &= (P e_1)^T \frac{\partial}{\partial \nu} + \frac{\partial}{\partial y}, & \nu_1 &= (JP e_1)^T\, d\nu + m\, dy, \\
V_2 &= (P e_2)^T \frac{\partial}{\partial \nu} - \frac{\partial}{\partial x}, & \nu_2 &= (JP e_2)^T\, d\nu - m\, dx, \\
V_3 &= (P e_3)^T \frac{\partial}{\partial \nu}, & \nu_3 &= (JP e_3)^T\, d\nu.
\end{aligned}$$

V_3 corresponds to the fact that along the motion $e_3^T P^T J \nu$ is a constant. In general, we could insert another torque, u, exerted about Pe_3, by adding a term uPe_3 to the first equation. Although W_1, W_2, V_1, V_2, V_3 is not an orthogonal set relative to the metric, $\{W_1, W_2\}$ is orthogonal to $\{V_1, V_2, V_3\}$, from which it is easy to see that they form a spanning set for the tangent spaces $T_q(\mathbb{R}^2 \times SO(3))$.

It was demonstrated in Bloch and Crouch [1], that $(Pe_k)^T(\partial/\partial\nu)$ are Killing vector fields, relative to the metric structure so V_1, V_2, V_3 are indeed Killing, even without restricting to N. It is also interesting to integrate the system equations using the easily verified identities

$$\begin{aligned}
&\frac{d}{dt} \nu_1(\dot{q}) = u_2, \qquad \frac{d}{dt} \nu_2(\dot{q}) = -u_1, \\
&\frac{d}{dt} \nu_3(\dot{q}) = \omega_2(\dot{q}) = \omega_1(\dot{q}) \equiv 0.
\end{aligned}$$

Setting $\mathbb{J} = J + m(Pe_1 e_1^T P^T + Pe_2 e_2^T P^T)$ and $e_3^T P^T J \nu = d (= \text{const})$, we obtain equations (40) in the form

$$\begin{aligned}
\dot{P} &= S(\mathbb{J}^{-1} P(e_1 a_2 + e_2(-a_1) + e_3 d)) P, \\
\dot{x} &= -e_2^T P^T \mathbb{J}^{-1} P(e_1 a_2 + e_2(-a_1) + e_3 d), \\
\dot{y} &= e_1^T P^T \mathbb{J}^{-1} P(e_1 a_2 + e_1(-a_1) + e_3 d), \\
\dot{a}_1 &= u_1, \qquad \dot{a}_2 = u_2.
\end{aligned} \tag{44}$$

It is useful to rewrite equations (43) in terms of $M = \mathbb{J}\nu$. Note that

$$Pe_1e_1^TP + Pe_2e_2^TP = I - Pe_3e_3^TP = -S(Pe_3)S(Pe_3),$$

so $M = \mathbb{J}\nu = J\nu + mS(Pe_3)S(\nu)Pe_3$. From (44) we see that

$$\nu = \mathbb{J}^{-1}P(e_1a_2 + e_2(-a_1) + e_3d),$$

so

$$\dot{M} = \frac{d}{dt}\mathbb{J}\nu = S(\nu)M + P(e_1u_2 - e_2u_1).$$

Thus these equations, together with the kinematics (44) are equivalent to the original system equations (43). It turns out that the rolling ball system (with $u_1 \equiv u_2 \equiv 0$) is completely integrable, as demonstrated by Arnold [10]. This is not obvious from the reduced order kinematic equations (44), and indeed Arnold demonstrates integrability in another way—by applying an abstract result to the subsystem in M and P:

$$\dot{M} = S(\nu)M, \quad \dot{P} = S(\nu)P, \quad \nu = \mathbb{J}^{-1}M. \tag{45}$$

As is clear from (44), once these equations are integrated, the remaining states may be obtained by quadratures. The main ingredient in the proof of Arnold's result is noting that system (45) admits an invariant measure,

$$(m - (Pe_3)^T(J + mI)^{-1}Pe_3)^{1/2}$$

and four integrals, M^TM, M^TPe_3, $(Pe_3)^TPe_3$, and $M^T\nu$. It is clear that the first three expressions are integrals from the structure of equations (45). To establish that $M^T\nu$ is an integral we proceed as follows. Since, for the rolling ball system (43), the total kinetic energy of the system is conserved for $u_1 \equiv u_2 \equiv 0$ (see [2]), we have that

$$r = \nu^TJ\nu + m\dot{x}^2 + m\dot{y}^2$$

is an integral of the motion (43). Using the nonholonomic constraints we see that

$$r = \nu^TJ\nu + m[(\nu^TPe_2)^2 + (\nu^TPe_1)^2].$$

But $(\nu^TPe_2)^2 + (\nu^TPe_1)^2 = ||Pe_3 \times \nu||^2 = ||S(\nu)Pe_3||^2$. Thus, $M^T\nu = \nu^TJ\nu + m||S(\nu)Pe_3||^2$ is indeed an integral for motion (43) and reduced motion (45).

The "angular" momentum M is, in fact, the nonholonomic momentum map discussed in Bloch, Krishnaprasad, Marsden, and Murray [9]. As a final remark, it is very interesting to contrast the work described here with that of Cartan [7]. Indeed, many of the constructions in Cartan [7] for the rolling ball example use exactly the frame discussed in our Example 6.3. Clearly there is much further structure underlying many of the observations made in this paper.

Example 6.4 (generalized rolling ball, Bloch, and Crouch [1], [2]). We assume that G is a compact, semisimple Lie group of dimension L, with Lie algebra $\mathfrak{d}$. We assume that $\langle\cdot,\cdot\rangle_G$ is a right invariant metric on G, with

$$\langle \dot{g}_A, \dot{g}_B\rangle_G = \mathcal{K}(\dot{g}_A, J_g\dot{g}_B),$$

where $\mathcal{K}$ is a bi-invariant metric on G and $J_g : T_gG \to T_gG$ is a positive definite operator for each $g \in G$. The generalized rolling ball system described in Bloch and Crouch [1], [2], is defined by the system of equations

$$\begin{aligned} \frac{D^2 g}{\partial t^2} &= \sum_{k=1}^{N} \lambda_k J_g^{-1} X_k^l, \quad g \in G, \quad L > N, \\ m\ddot{x}_k &= -\lambda_k + u_k, \quad 1 \le k \le N, \\ \dot{x}_k &= \langle \dot{g}, J_g^{-1} X_k^l \rangle_G, \quad 1 \le k \le N \quad \text{(nonholonomic constraints)}, \end{aligned} \tag{46}$$

where $D/\partial t$ is the covariant derivative corresponding to the metric connection determined by $\langle \cdot, \cdot \rangle$, and X^l is the left invariant vector field corresponding to an element $X \in \mathfrak{d}$. We assume that $X_1, \ldots, X_N, X_{N+1}, \ldots, X_L$ is a basis for $\mathfrak{d}$. There is a natural metric on the configuration space $M = G \times \mathbb{R}^N$ determined by

$$\langle (\dot{g}_A, \dot{x}_A), (\dot{g}_B, \dot{X}_B) \rangle_M = \frac{1}{2} \langle \dot{g}_A, \dot{g}_B \rangle_G + \frac{m}{2} \dot{x}_A^T \dot{x}_B. \tag{47}$$

It was proved in Bloch and Crouch [1] that X^l is a Killing vector field for $X \in \mathfrak{d}$. We define one forms on $G \times \mathbb{R}^N$ by

$$\begin{aligned} \omega_k(\dot{g}, \dot{x}) &= \langle \dot{g}, J_g^{-1} X_k^l \rangle_G - \dot{x}_k, \quad 1 \le k \le N, \\ \nu_k(\dot{g}, \dot{x}) &= \langle \dot{g}, X_k^l \rangle_G + \dot{x}_k m, \quad 1 \le k \le N, \\ \nu_k(\dot{g}, \dot{x}) &= \langle \dot{g}, X_k^l \rangle_G, \quad N+1 \le k \le L. \end{aligned}$$

The corresponding vector fields are

$$\begin{aligned} W_k &= J_g^{-1} X_k^l - \frac{1}{m} \partial/\partial x_k, \quad 1 \le k \le N, \\ V_k &= X_k^l + \partial/\partial x_k, \quad 1 \le k \le N, \\ V_k &= X_k^l, \quad N+1 \le k \le L. \end{aligned} \tag{48}$$

Clearly, V_k and ν_k are Killing with respect to the metric connection determined by metric (47). We also compute, for $0 \le k, j \le N$,

$$\begin{aligned} \langle W_k, V_j \rangle_M &= \frac{1}{2} \langle J_g^{-1} X_k^l, X_j^l \rangle_G + \frac{m}{2} \left(- \frac{1}{m} \right) \left\langle \frac{\partial}{\partial x_k}, \frac{\partial}{\partial x_j} \right\rangle_{\mathbb{R}^n} \\ &= \frac{1}{2} \mathcal{K}(X_k^l, X_j^l) - \frac{1}{2} \delta_{kj}. \end{aligned}$$

Thus if we assume that $X_1, \ldots, X_L$ is an orthonormal basis of $\mathfrak{d}$ with respect to $\mathcal{K}$, we see that $\{W_1, \ldots, W_N\}$ is orthogonal to $\{V_1, \ldots, V_L\}$. It follows that the system (46) and choice of vector fields (48) satisfy our Assumption (3.1). Hence, system (46) may be viewed as the restriction of a Newton law system defined by a connection described in Corollary 3.6. Note that in this example, just as in Example 6.3, we do not have to restrict to the subbundle nonholonomic constraints.

Setting

$$\begin{aligned} v_k &= \nu_k(\dot{g}, \dot{x}), \quad 1 \le k \le N, \\ d_k &= \nu_k(\dot{g}, \dot{x}), \quad N+1 \le k \le L, \end{aligned}$$

we can show (using analysis in [1], [2]) that $\dot{d}_k = 0$, $\dot{v}_k = u_k$. By the independence of the vector fields W_k, V_k, we may solve the $L + N$ equations

$$0 = \omega_k(\dot{g}, \dot{x}), 1 \leq k \leq N, \quad v_k = \nu_k(\dot{g}, \dot{x}), 1 \leq k \leq N, \quad d_k = \nu_k(\dot{g}, \dot{x}), \quad N{+}1 \leq k \leq L,$$

for $(\dot{g}, \dot{x})$ in terms of v_k and d_k. Hence, as in section (5), we may integrate the $2(L + N)$-dimensional system (46), to obtain the corresponding $(L + N)$-dimensional kinematic system.

SINGULAR PERTURBATION OF A FINITE HORIZON PROBLEM WITH STATE-SPACE CONSTRAINTS*

FABIO BAGAGIOLO† AND MARTINO BARDI‡

Abstract. We study the singular perturbation of optimal control problems for nonlinear systems with constraints on the fast state variables and a cost functional either of Bolza type or involving the exit time of the system from a given domain. Under a controllability assumption on the fast variables, we show that these variables become controls in the limit problem. Our method consists of passing to the limit in the associated Hamilton–Jacobi–Bellman (HJB) equations by means of some tools in the theory of viscosity solutions.

Key words. singular perturbations, optimal control, nonlinear systems, viscosity solutions, Hamilton–Jacobi equations, Bolza problem, exit time problems, state constraints

PII. S0363012996314476

Introduction. In this paper we study a class of singular perturbation problems for nonlinear systems of the form

$$\begin{cases} y'(t) = f(y(t), z(t), \alpha(t)), & \alpha(t) \in A, \qquad t > 0, \\ z'(t) = \dfrac{1}{\varepsilon} g(y(t), z(t), \beta(t)), & \beta(t) \in B, \qquad t > 0, \\ (y(0), z(0)) = (x, \zeta), \end{cases} \tag{0.1}$$

where $\varepsilon > 0$, A and B are compact, f and g are Lipschitzean in the state variables and continuous, with Bolza cost functional

$$J_\varepsilon(x, \zeta, t, \alpha, \beta) := \int_0^t e^{-\lambda s} l(y(s), z(s), \alpha(s)) ds + e^{-\lambda t} h(y(t), z(t)), \tag{0.2}$$

where l and h are bounded and continuous, $\lambda \geq 0$, and the fast state variables $z(\cdot)$ satisfy the constraint

$$z(t) \in \overline{\Omega} \qquad \forall t > 0, \tag{0.3}$$

where Ω is an open connected subset of $\mathbb{R}^M$ with Lipschitz boundary.

Problems of this kind have been extensively studied by many authors; see, e.g., the survey paper by Kokotović [19], the books by Kokotović, Khalil, and O'Reilly [20] and Bensoussan [9], and a recent article [23]. However, we will make here rather different assumptions and use different methods. Typically, in fact, one assumes some solvability with respect to ζ of the algebraic equation

$$g(x, \zeta, b) = 0, \tag{0.4}$$

and expects that the limit optimal control problem involve the system

$$\begin{cases} y'(t) = f(y(t), z(t), \alpha(t)), & \alpha(t) \in A, \quad t > 0, \\ 0 = g(y(t), z(t), \beta(t)), & \beta(t) \in B, \quad t > 0, \\ y(0) = x, \end{cases} \tag{0.5}$$

which is obtained by setting $\varepsilon = 0$ in (0.1).

In this paper, instead of the solvability of (0.4), we will assume a controllability condition on the fast variables $z(\cdot)$ of the following type:

$$\overline{\text{co}}\, g(y, z, B) \supseteq \overline{B}_{\mathbb{R}^M}(0, 1) \quad \forall\ y \in \mathbb{R}^N,\ z \in \overline{\Omega}, \tag{0.6}$$

where $\overline{\text{co}}$ denotes the closed convex hull and the set on the right-hand side is the closed unit ball centered at 0 in $\mathbb{R}^M$ (see section 4 for more general assumptions). The optimal control problem we obtain in the limit as $\varepsilon \to 0$ is the minimization of the functional

$$J(x, t, z, \alpha) := \int_0^t e^{-\lambda s} l(y(s), z(s), \alpha(s)) ds + e^{-\lambda t} \inf_{\zeta \in \overline{\Omega}} h(y(t), \zeta) \tag{0.7}$$

for the system

$$\begin{cases} y'(t) = f(y(t), z(t), \alpha(t)), & z(t) \in \overline{\Omega}, \quad t > 0, \\ y(0) = x, \end{cases} \tag{0.8}$$

instead of (0.5). Our main result states that the value function $V(x, t)$ of this problem is the limit (uniform on compact sets), as $\varepsilon \to 0$, of the value functions $V_\varepsilon(x, \zeta, t)$ of the problems corresponding to $\varepsilon > 0$.

The heuristic explanation of this result is the following. The controllability condition (0.6) allows the system to reach any point $\xi \in \overline{\Omega}$ from any starting point ζ in a lap of time of order $\varepsilon|\zeta - \xi|$. Therefore, the value function V_ε is less and less sensitive to ζ as $\varepsilon \to 0$. Moreover, since the control β does not appear in the equations for the slow variables $y(\cdot)$, nor in the cost functional J_ε, its role reduces to driving optimally the z variable within $\overline{\Omega}$. Since this can be done arbitrarily fast as $\varepsilon \to 0$, β disappears in the limit problem, and z takes the role of a control varying in $\overline{\Omega}$.

Our method is also quite different from usual. In fact we consider the viscosity solution of the problem

$$\begin{cases} u_t + \lambda u + H\left(y, z, \nabla_y u, \dfrac{1}{\varepsilon} \nabla_z u\right) = 0, & \text{in } \mathbb{R}^N \times \overline{\Omega} \times]0, +\infty[, \\ u(x, \zeta, 0) = h(x, \zeta), & \text{in } \mathbb{R}^N \times \overline{\Omega}, \end{cases} \tag{0.9}$$

and prove that it converges to the viscosity solution of

$$\begin{cases} u_t + \lambda u + \sup_{z \in \overline{\Omega}} H(y, z, \nabla_y u, 0) = 0, & \text{in } \mathbb{R}^N \times]0, +\infty[, \\ u(x, 0) = \inf_{z \in \overline{\Omega}} h(x, z), & \text{in } \mathbb{R}^N. \end{cases} \tag{0.10}$$

Then we get the desired result because the value functions V_ε and V are, respectively, the viscosity solution of (0.9) and (0.10) with Bellman's Hamiltonian

$$\begin{aligned} H(x, \zeta, p, q) := & \sup_{a \in A} \Big\{ - f(x, \zeta, a) \cdot p - l((x, \zeta, a) \Big\} \\ & + \sup_{b \in B} \Big\{ - g(x, \zeta, b) \cdot q \Big\}, \quad \forall (x, \zeta) \in \mathbb{R}^N \times \overline{\Omega},\ \forall (p, q) \in \mathbb{R}^N \times \mathbb{R}^M. \end{aligned} \tag{0.11}$$

Note that the Hamilton–Jacobi equation in (0.9) has to be solved in a set which is not open, thus solutions must be interpreted in the sense of constrained viscosity solutions introduced by Soner [24]; see also Capuzzo Dolcetta and Lions [10].

Our convergence result for the solutions of the Cauchy problem (0.9) is more general than we need for the specific application, because it holds for any Hamiltonian satisfying a comparison principle and the conditions

$$\begin{aligned} &\lim_{|q|\to+\infty} H(y,z,p,q) = +\infty, \qquad \text{uniformly for bounded } y,z,p; \\ &\varepsilon_1 \le \varepsilon_2 \Rightarrow H\left(y,z,p,\frac{q}{\varepsilon_1}\right) \ge H\left(y,z,p,\frac{q}{\varepsilon_2}\right), \end{aligned} \tag{0.12}$$

but not necessarily convex in the variables p and q as is Bellman's Hamiltonian defined by (0.11). In [21] Lions outlined a proof of a similar result for the case $\Omega = \mathbb{R}^M$, $\lambda = 0$, and under hypotheses of uniform continuity of the solutions and of the initial data h, but with a weaker assumption on the Hamiltonian, namely, $H(y,z,p,q) \ge H(y,z,p,0)$ for all (y,z,p,q), instead of the second of (0.12). His proof is based on approximating (0.9) with the addition of a small viscosity term, obtaining uniform gradient bounds, independent of ε, for the solutions of these parabolic approximations, and using the Ascoli–Arzelà theorem to extract a convergent sequence of V_ε. The hard estimates involved in this procedure are based on earlier work of Jensen and Lions [18] on partial differential equations (PDE) methods for singular perturbation problems in the optimal control of diffusion processes. Here, instead, we use the method of weak limits in viscosity sense, or "relaxed half-limits," introduced by Barles and Perthame [6], [7], and a comparison theorem for merely semicontinuous sub- and supersolutions of the limit HJB equation, which allow us to pass to the limit in the equations with only L^∞-estimates on V_ε.

To show the flexibility of our method we also apply it to optimal control problems where the cost functional is computed until the exit time of the system from a given domain, either open or closed. In this case the value functions satisfy a Dirichlet boundary value problem for a stationary HJB equation, and in the limit procedure described previously we use the notion of boundary condition in viscosity sense and a comparison theorem due to Ishii [16] (see also [7], [5], and [4]).

A simple application of the main result is given in section 3. We consider control problems for the system (0.8) with controls $z(\cdot)$ restricted to Lipschitzean functions with Lipschitz constant less than $1/\varepsilon$ and initial point $\zeta \in \overline{\Omega}$. This corresponds to the system (0.1) with $g(x,\zeta,b) = b \in \overline{B}_{\mathbb{R}^M}(0,1)$. From the main result we obtain that, as $\varepsilon \to 0$, these value functions converge (uniformly on compact sets) to the value function of the limit problem with measurable controls $z(\cdot)$. This problem is studied in Chapter V, Section 6, of the book [9] in the special case $\Omega = \mathbb{R}^M$ by different methods. The issue of Lipschitz controls was also studied by Barron, Evans, and Jensen [8] in the more general framework of differential games (see also the references therein) in the case that the set $\overline{\Omega}$ where the controls are constrained is the unit cube and the dynamics and the running cost are 1-periodic in the corresponding variables. They use the theory of viscosity solutions and gradient estimates on approximating parabolic equations.

We believe that our method is general enough to apply to several other singular perturbation problems, in particular for differential games. A similar analysis has been done for the infinite horizon problem (which is simpler with our PDE approach) in [2], [3], [4], and recently extended in [1] to the case when the slow state variables

$y(\cdot)$ are constrained by means of a comparison theorem of Ishii and Koike [17]. We mention also that similar problems have been studied recently by Subbotina [27] within Subbotin's theory of minimax solutions [26], and that Soner studied singular perturbations for some stochastic control problems by viscosity solutions methods in [25] .

We refer to the books [20], [9] and the references therein for the motivations and applications of singular perturbation problems in optimal control. We recall that the pioneering work on the theory of viscosity solutions is due to Crandall and Lions [13], Crandall, Evans, and Lions [12], and Lions [22]. For a comprehensive account of the theory of viscosity solutions and its applications to optimal control, with special attention to discontinuous solutions and the weak limit technique employed here, we refer to the books by Barles [5], and Bardi and Capuzzo Dolcetta [4] for first-order equations, and by Fleming and Soner [15] for second-order equations.

The paper is organized as follows. In section 1 we list the precise assumptions and give some preliminary results. In section 2 we prove the main theorem, and in section 3 we apply it to the problem of Lipschitz controls. In section 4 we relax the controllability assumption (0.6) and illustrate the convergence result for singular perturbations of exit time problems. An Appendix contains the proof of the continuity of the value function for problems with state constraints.

1. Statement of the problem and basic results. Let Ω be an open connected subset of $\mathbb{R}^M$, A, B be two compact sets and $f : \mathbb{R}^N \times \mathbb{R}^M \times A \to \mathbb{R}^N$, $g : \mathbb{R}^N \times \mathbb{R}^M \times B \to \mathbb{R}^M$ be two continuous functions. For every $(x, \zeta) \in \mathbb{R}^N \times \overline{\Omega}$ and for every $\varepsilon > 0$, let us consider the controlled dynamical system (0.1), where the controls $\alpha(\cdot)$ and $\beta(\cdot)$ are measurable functions defined on $[0, +\infty[$ and taking values in A and B, respectively. The dynamics f and g are supposed to be Lipschitz functions on $(y, z) \in \mathbb{R}^N \times \mathbb{R}^M$ uniformly on $a \in A$ and $b \in B$, respectively; moreover, we suppose that f has linear growth with respect to $y \in \mathbb{R}^N$, i.e., there exists $K > 0$ such that

$$|f(y, z, a)| \le K(1 + |y|) \qquad \forall\ (y, z, a) \in \mathbb{R}^N \times \overline{\Omega} \times A.$$

Under these assumptions on the dynamics, the system (0.1) has a unique continuous solution (trajectory), which continuously depends on the initial datum (x, ζ). When no ambiguity arises about the dependence on ε, on (x, ζ), and on the choice of the controls α and β, we shall denote this trajectory by $(y(t), z(t))$.

We want the trajectories of the system (0.1) to respect the *state-space constraint* (0.3). Hence, we consider the possibly empty set of admissible controls for the system (0.1), which depends on ε and on the starting point (x, ζ):

$$(\mathcal{A} \times \mathcal{B})^{\varepsilon}_{(x,\zeta)} := \big\{(\alpha, \beta) : [0, +\infty[\to A \times B \text{ measurable} \mid z(t) \in \overline{\Omega} \quad \forall\ t \ge 0\big\}. \tag{1.1}$$

Now we consider a finite horizon optimal control problem. Let $l : \mathbb{R}^N \times \mathbb{R}^M \times A \to \mathbb{R}$ be a bounded continuous function, uniformly continuous with respect to $(y, z) \in \mathbb{R}^N \times \mathbb{R}^M$ uniformly in $a \in A$; let $h : \mathbb{R}^N \times \mathbb{R}^M \to \mathbb{R}$ be a bounded continuous function, which is uniformly continuous in the bounded sets of $\mathbb{R}^N$ uniformly in $z \in \overline{\Omega}$, i.e., for every $R > 0$ there exists a continuous increasing function $\omega_R : [0, +\infty[\to \mathbb{R}$ such that $\omega_R(0) = 0$ and

$$|h(y_1, z) - h(y_2, z)| \le \omega_R(|y_1 - y_2|) \qquad \forall z \in \overline{\Omega},\ \forall y_1, y_2 \in \mathbb{R}^N,\ |y_1|, |y_2| \le R. \tag{1.2}$$

Let us consider the *cost functional* J_ε defined in (0.2), where $(\alpha, \beta) \in (\mathcal{A} \times \mathcal{B})^{\varepsilon}_{(x,\zeta)}$, $t \in [0, +\infty[$, $(x, \zeta) \in \mathbb{R}^N \times \overline{\Omega}$ and the subscript ε means that the trajectories are

relative to system (0.1) with (x,ζ) as initial point and the admissible controls α and β. The optimal control problem is to minimize the cost J_ε over the set of admissible controls, therefore respecting the state-space constraint $z(t) \in \overline{\Omega}$. Hence, we define the *value function*:

$$V_\varepsilon(x,\zeta,t) := \inf_{(\alpha,\beta)\in(\mathcal{A}\times\mathcal{B})^\varepsilon_{(x,\zeta)}} J_\varepsilon(x,\zeta,t,\alpha,\beta). \tag{1.3}$$

If the set of admissible controls is not empty for every initial point, then, by the hypotheses on l and h, V_ε is a real-valued function.

Now we define another control problem, which will turn out to be the limit problem as ε goes to zero. Let us consider the controlled dynamical system (0.8), where $x \in \mathbb{R}^N$, $\alpha \in \mathcal{A} := \{\alpha : [0,+\infty[\to A \text{ measurable}\}$ and $z \in \mathcal{Z} := \{z : [0,+\infty[\to \overline{\Omega} \text{ measurable}\}$.

The trajectories of system (0.8) will be denoted by $y(\cdot)$. Then we define the following *final cost*:

$$\tilde{h}(y) := \inf_{z\in\overline{\Omega}} h(y,z), \tag{1.4}$$

which is bounded and continuous, and consider the cost functional J defined in (0.7). We have the following value function:

$$V(x,t) := \inf_{(z,\alpha)\in\mathcal{Z}\times\mathcal{A}} J(x,t,z,\alpha), \tag{1.5}$$

which is a real-valued function. Hence, we have a control problem without state-space constraint and with α and z as controls.

Before stating our main result, we need some other hypotheses. The first is a regularity assumption on the domain Ω, whose boundary should be piecewise of class $C^{1,1}$ and should have a uniform *interior cone property*, i.e., there exist two positive constants h, r, a bounded uniformly continuous function $\eta : \overline{\Omega} \to \mathbb{R}^M$, and functions $g_i \in C^{1,1}(\mathbb{R}^M)$, $i = 1,\dots,q$, $q \in \mathbb{N}$, such that

$$\begin{aligned} &\big\{\xi \in \mathbb{R}^M \big| |\xi - (z + t\eta(z))| \le rt\big\} \subseteq \Omega \qquad \forall z \in \overline{\Omega}, \forall t \in [0,h], \\ &\overline{\Omega} = \big\{z \in \mathbb{R}^M : g_i(z) \le 0 \quad \forall i = 1,\dots,q\big\}, \\ &\big|\nabla g_i(z)\big| > 0 \qquad \forall z \text{ such that } g_i(z) = 0. \end{aligned} \tag{1.6}$$

The next hypothesis states the controllability in the z-variables, i.e.,

$$\overline{\text{co}}\, g(y,z,B) \supseteq \big\{\xi \in \mathbb{R}^M \big| |\xi| \le 1\big\} \quad \forall\, y \in \mathbb{R}^N,\ z \in \overline{\Omega}, \tag{1.7}$$

where $\overline{\text{co}}$ means the closed convex hull of the set. Observe that (1.7) implies the existence of an "inward field" on the boundary of Ω, i.e.,

$$\forall z \in \partial\Omega\ \forall y \in \mathbb{R}^N\ \exists b \in B \text{ such that } g_i(z) = 0 \Rightarrow g(y,z,b)\cdot\nabla g_i(z) < 0. \tag{1.8}$$

THEOREM 1.1. *Under all the hypotheses stated before, the sequence of the value functions defined in* (1.3) *uniformly converges to the value function defined in* (1.5)*, over the compact sets of* $\mathbb{R}^N \times \overline{\Omega} \times]0,+\infty[$ *as* $\varepsilon \to 0$*. Moreover, if the final cost* h *does not depend on the variable* $z \in \overline{\Omega}$*, then the uniform convergence is over the compact sets of* $\mathbb{R}^N \times \overline{\Omega} \times [0,+\infty[$.

Next, we give some basic results about optimal control and viscosity solutions of Hamilton–Jacobi–Bellman equations. Let us consider the optimal control problem with state-space constraint given by system (0.1), the constraint (0.3), the cost functional (0.2), and the value function (1.3). Under all the hypotheses stated before, the following proposition holds.

PROPOSITION 1.2. *For every $\varepsilon > 0$, for every $(x,\zeta) \in \mathbb{R}^N \times \overline{\Omega}$, the set of admissible controls is not empty. Moreover, the value function V_ε is continuous and bounded over the sets $\mathbb{R}^N \times \overline{\Omega} \times [0,T]$, for every $T \in]0,+\infty[$.*

This proposition is a special case of Theorem A.1 in the Appendix.

Now we consider an open subset $\mathcal{O} \subseteq \mathbb{R}^m$, and a continuous real-valued function H defined on $\overline{\mathcal{O}} \times \mathbb{R}^m$. Consider the Cauchy problem

$$(P)\begin{cases} u_t(x,t) + \lambda u(x,t) + H(x, \nabla u(x,t)) = 0, & \text{in } \overline{\mathcal{O}} \times]0,T[, \\ u(x,0) = h(x), & \text{in } \overline{\mathcal{O}}, \end{cases} \tag{1.9}$$

where ∇ means the gradient with respect to the spatial variables and u_t the time derivative.

DEFINITION 1.3. *We say that a bounded and continuous function $u : \overline{\mathcal{O}} \times [0,T[\to \mathbb{R}$ is a constrained viscosity solution of (P) if u satisfies the initial condition and for every test function $\varphi \in C^1(\overline{\mathcal{O}} \times]0,T[)$, the following holds:*

(1.10)
if $(x_0,t_0) \in \mathcal{O} \times]0,T[$ is a local maximum point for $u - \varphi$ in $\mathcal{O} \times]0,T[$, then
$$\varphi_t(x_0,t_0) + \lambda u(x_0,t_0) + H(x_0, \nabla\varphi(x_0,t_0)) \le 0;$$

(1.11)
if $(x_0,t_0) \in \overline{\mathcal{O}} \times]0,T[$ is a local minimum point for $u - \varphi$ in $\overline{\mathcal{O}} \times]0,T[$, then
$$\varphi_t(x_0,t_0) + \lambda u(x_0,t_0) + H(x_0, \nabla\varphi(x_0,t_0)) \ge 0.$$

If u satisfies (1.10) *only, then we say that u is a viscosity subsolution in $\mathcal{O} \times]0,T[$ of* (1.9)*; if u satisfies* (1.11) *only, then we say that u is a viscosity supersolution in $\overline{\mathcal{O}} \times]0,T[$ of* (1.9).

Next, let us consider the following Cauchy problem, in $\mathbb{R}^N \times \overline{\Omega} \times [0,T[$ for every $T > 0$:

$$(P_\varepsilon)\begin{cases} (V_\varepsilon)_t(x,\zeta,t) + \lambda V_\varepsilon(x,\zeta,t) + H\left(x,\zeta,\nabla_y V_\varepsilon(x,\zeta,t), \dfrac{1}{\varepsilon}\nabla_z V_\varepsilon(x,\zeta,t)\right) = 0 \\ V_\varepsilon(x,\zeta,0) = h(x,\zeta), \end{cases} \tag{1.12}$$

where ∇_y and ∇_z, respectively, mean the gradient with respect to the variable $y \in \mathbb{R}^N$ and $z \in \overline{\Omega} \subset \mathbb{R}^M$ and the Hamiltonian H is defined in (0.11). Note that (P_ε) is a particular case of (P).

THEOREM 1.4. *The value function V_ε defined in* (1.3) *is the unique constrained viscosity solution of* (P_ε)*, among the bounded and continuous functions in $\mathbb{R}^N \times \overline{\Omega} \times [0,T]$.*

Proof. Using standard techniques, the proof of the fact that V_ε is a constrained viscosity solution is easy (see, for instance, [24] or [4]). The uniqueness follows from a comparison result, which we state next. □

THEOREM 1.5. *Let $u, v : \mathbb{R}^N \times \overline{\Omega} \times [0,T] \to \mathbb{R}$ be two bounded and continuous functions, such that u is a subsolution in $\mathbb{R}^N \times \Omega \times]0,T[$ of* (1.12)*, v is a supersolution in $\mathbb{R}^N \times \overline{\Omega} \times]0,T[$ of* (1.12)*, and $u(x,\zeta,0) \le v(x,\zeta,0)$ for every $(x,\zeta) \in \mathbb{R}^N \times \overline{\Omega}$. Then $u \le v$ in $\mathbb{R}^N \times \overline{\Omega} \times [0,T]$.*

Proof. This result is obtained using standard techniques. In particular, we use test functions with penalization terms as in [24] (see also [10], [4]). The detailed proof can be found in [2]. □

Finally, let us consider the following Cauchy problem in $\mathbb{R}^N \times [0,T[$ without state-space constraint:

$$(\mathrm{P}_0)\begin{cases} V_t(x,t) + \lambda V(x,t) + \sup_{z\in\overline{\Omega}} H(x,z,\nabla V(x,t),0) = 0, \\ V(x,0) = \tilde{h}(x), \end{cases} \tag{1.13}$$

where ∇ means the gradient with respect to the variable $y \in \mathbb{R}^N$ and the initial datum $\tilde{h}$ is defined in (1.4). Note that (P_0) is a particular case of (P).

THEOREM 1.6. *The value function V defined in* (1.5) *is continuous and bounded in $\mathbb{R}^N \times [0,T]$ and it is the only viscosity solution of* (P_0) *in $\mathbb{R}^N \times]0,T[$ among the continuous and bounded functions.*

For the proof, see, for instance, [4]. In particular, the uniqueness follows from a comparison result.

THEOREM 1.7. *Let $u, v : \mathbb{R}^N \times [0,T] \to \mathbb{R}$ be bounded. If u is an upper semicontinuous subsolution and v is a lower semicontinuous supersolution in $\mathbb{R}^N \times]0,T[$ of* (1.13) *and $u(x,0) \le v(x,0)$, for every $x \in \mathbb{R}^N$, then $u \le v$ in $\mathbb{R}^N \times [0,T]$.*

2. The singular perturbation problem. This section is devoted to the proof of Theorem 1.1. Hence, we put ourselves in the framework of section 1. Since we need some technical results, we shall break the proof into several lemmas.

The value functions V_ε are equibounded in $\mathbb{R}^N \times \overline{\Omega} \times [0,T]$ for every $T > 0$. Hence, for every $(x,\zeta,t) \in \mathbb{R}^N \times \overline{\Omega} \times [0,+\infty[$, we can define the following real-valued *weak limits*:

$$\begin{aligned} \underline{V}(x,\zeta,t) &:= \liminf_{(y,z,\tau,\varepsilon)\to(x,\zeta,t,0)} V_\varepsilon(y,z,\tau), \\ \overline{V}(x,\zeta,t) &:= \limsup_{(y,z,\tau,\varepsilon)\to(x,\zeta,t,0)} V_\varepsilon(y,z,\tau), \end{aligned} \tag{2.1}$$

where the limits are taken in $(y,z,\tau,\varepsilon) \in \mathbb{R}^N \times \overline{\Omega} \times [0,+\infty[\times]0,+\infty[$. Note that $\underline{V}$ is lower semicontinuous and $\overline{V}$ is upper semicontinuous.

LEMMA 2.1. *For every $(x,\zeta,t) \in \mathbb{R}^N \times \overline{\Omega} \times [0,+\infty[$, the following inequality holds:*

$$V(x,t) \le \underline{V}(x,\zeta,t).$$

Proof. Let us define the following function:

$$\tilde{V}(x,\zeta,t) := V(x,t) \qquad \forall (x,\zeta,t) \in \mathbb{R}^N \times \overline{\Omega} \times [0,+\infty[. \tag{2.2}$$

It is easy to check that $\tilde{V}$ is a subsolution of (1.12) for all $\varepsilon > 0$.

On the other hand, we have, for every $\varepsilon > 0$,

$$\tilde{V}(x,\zeta,0) = V(x,0) = \tilde{h}(x) \le h(x,\zeta) = V_\varepsilon(x,\zeta,0).$$

Hence, by Theorem 1.5, we get for every $\varepsilon > 0$ and for every $(x,\zeta,t) \in \mathbb{R}^N \times \overline{\Omega} \times [0,+\infty[$: $V(x,t) = \tilde{V}(x,\zeta,t) \le V_\varepsilon(x,\zeta,t)$. By (2.1) and the continuity of V, we obtain

$$V(x,t) = \liminf_{(y,\tau)\to(x,t)} V(y,\tau) \le \liminf_{(y,z,\tau,\varepsilon)\to(x,\zeta,t,0)} V_\varepsilon(y,z,\tau) = \underline{V}(x,\zeta,t). \qquad \square$$

LEMMA 2.2. *For every* $(x,\zeta)\in\mathbb{R}^N\times\overline{\Omega}$,

$$\overline{V}(x,\zeta,0)=h(x,\zeta). \tag{2.3}$$

Proof. Let us note that the Hamiltonian in (0.9) can be written as

$$H\left(x,\zeta,p,\frac{1}{\varepsilon}q\right)=\sup_{a\in A}\Big\{-f(x,\zeta,a)\cdot p-l(x,\zeta,a)\Big\}-\frac{1}{\varepsilon}\inf_{b\in B}\Big\{g(x,\zeta,b)\cdot q\Big\}.$$

By (1.7), the last term of the right-hand side is nonnegative. Hence, if $\varepsilon_1\le\varepsilon_2$, then V_{ε_2} is a supersolution of (1.12) with $\varepsilon=\varepsilon_1$. So, by Theorem 1.5

$$0<\varepsilon_1\le\varepsilon_2\Rightarrow V_{\varepsilon_1}\le V_{\varepsilon_2}\qquad\text{in }\mathbb{R}^N\times\overline{\Omega}\times[0,+\infty[. \tag{2.4}$$

Using (2.4), the definition of $\overline{V}$ (2.1) and the fact that the V_ε are continuous and $V_\varepsilon(x,\zeta,0)=h(x,\zeta)$, it is not hard to get (2.3). ∎

LEMMA 2.3. *Let* $\mathcal{O}\subseteq\mathbb{R}^m$ *be open and connected and* $u:\mathcal{O}\to\mathbb{R}$ *be a bounded upper semicontinuous function solving in the viscosity sense*

$$|\nabla u|\le 0\quad \textit{in } \mathcal{O}.$$

Then u *is constant.*

Proof. We shall prove that u is locally Lipschitz. Hence, u solves the equation almost everywhere and we get the conclusion.

Let M be a lower bound for u in $\mathcal{O}$. Let us take $x_0\in\mathcal{O}$ and consider $r_0>0$ such that the open ball B with radius r_0 and centre x_0 is contained in $\mathcal{O}$. Denoting by B' the open ball with radius $r_0/2$ and centre x_0, let us take $x'\in B'$ and consider the function

$$\phi(y)=u(y)-C|x'-y|^2\quad\forall y\in\mathcal{O},$$

where the constant $C>0$ will be fixed later. The function ϕ is upper semicontinuous and, hence, it reaches its maximum in the closure of B. Let y' be a point of maximum. We claim that y' belongs to B'. In fact, $\phi(x')=u(x')\ge M$ and, for a suitable choice of the constant C, $\phi(y)\le M$ for all $y\in B\setminus B'$. Hence, by definition of subsolution,

$$2C|x'-y'|\le 0,$$

which implies $y'=x'$ and, hence, we get

$$u(y)-u(x')\le C|y-x'|\quad\forall y\in B.$$

By the arbitrariness of $x'\in B'$, u is Lipschitz in B'. ∎

LEMMA 2.4. *The upper weak limit* $\overline{V}$ *is constant with respect to the variable* $\zeta\in\Omega$, *for every* $(x,t)\in\mathbb{R}^N\times]0,+\infty[$.

Proof. First, we prove that $\overline{V}$ solves

$$|\nabla_z\overline{V}|\le 0\qquad\text{in }\mathbb{R}^N\times\Omega\times]0,+\infty[, \tag{2.5}$$

where ∇_z denotes the gradient of $\overline{V}$ with respect to ζ. Let us take a test function φ and a strict local maximum point (x_0,ζ_0,t_0) for $\overline{V}-\varphi$ in $\mathbb{R}^N\times\Omega\times]0,+\infty[$. Hence, there exists a sequence $(x_\varepsilon,\zeta_\varepsilon,t_\varepsilon)$ of local maxima in $\mathbb{R}^N\times\Omega\times]0,+\infty[$ for $V_\varepsilon-\varphi$, such

that, for $\varepsilon \to 0$, the sequence converges to (x_0, ζ_0, y_0) and $V_\varepsilon(x_\varepsilon, \zeta_\varepsilon, t_\varepsilon)$ converges to $\overline{V}(x_0, \zeta_0, t_0)$. Consequently, at $(x_\varepsilon, \zeta_\varepsilon, t_\varepsilon)$, we have

$$\varphi_t + \lambda V_\varepsilon + \sup_A \big\{ - f \cdot \nabla_y \varphi - l \big\} \le \frac{1}{\varepsilon} \inf_B \big\{ g \cdot \nabla_z \varphi \big\}. \tag{2.6}$$

Using the controllability condition (1.7), we have the following inequality:

$$\frac{1}{\varepsilon} \inf_{b \in B} \big\{ g(x_\varepsilon, \zeta_\varepsilon, b) \cdot \nabla_z \varphi(x_\varepsilon, \zeta_\varepsilon, t_\varepsilon) \big\} \le -\frac{1}{\varepsilon} \big| \nabla_z \varphi(x_\varepsilon, \zeta_\varepsilon, t_\varepsilon) \big|.$$

Since in a neighborhood of (x_0, ζ_0, t_0) the left-hand side of (2.6) is bounded; we then get $\nabla_z \varphi(x_0, \zeta_0, t_0) = 0$ and hence (2.5).

Next, applying Lemma 2.3, we get the conclusion. □

Now, our purpose is to compare the function $\overline{V}$ with the function V, in particular, we want $\overline{V}(x, \zeta, t) \le V(x, t)$. This will be done using the comparison result for the limit problem (P_0), Theorem 1.7. Unfortunately, if h is not constant with respect to $\zeta \in \overline{\Omega}$, then the inequality $\overline{V}(x, \zeta, 0) \le V(x, 0)$ does not hold. Note that, by Lemma 2.4, the function

$$\mathcal{V}(x, t) := \inf_{\zeta \in \Omega} \overline{V}(x, \zeta, t) \qquad \forall (x, t) \in \mathbb{R}^N \times [0, +\infty[.$$

satisfies

$$\mathcal{V}(x, t) = \overline{V}(x, \zeta, t) \qquad \forall (x, \zeta, t) \in \mathbb{R}^N \times \Omega \times]0, +\infty[. \tag{2.7}$$

LEMMA 2.5. *For every* $(x, t) \in \mathbb{R}^N \times [0, +\infty[$

$$\mathcal{V}(x, t) \le V(x, t). \tag{2.8}$$

Proof. First, we prove that $\mathcal{V}$ is a subsolution in $\mathbb{R}^N \times]0, +\infty[$ of (1.13). Let us consider a test function $\varphi \in C^1(\mathbb{R}^N \times]0, +\infty[)$ and a point (x_0, t_0) of strict local maximum for $\mathcal{V} - \varphi$ in $\mathbb{R}^N \times]0, +\infty[$. Let us take an arbitrary point $\zeta_0 \in \Omega$ and consider the function $\phi(x, \zeta, t) := \varphi(x, t) + |\zeta - \zeta_0|^2$. Using Lemma 2.4 and (2.7), we can say that (x_0, ζ_0, t_0) is a strict local maximum point for $\overline{V} - \phi$. Hence, there exists a sequence $(x_\varepsilon, \zeta_\varepsilon, t_\varepsilon)$ of maximum point for $V_\varepsilon - \phi$, converging to (x_0, ζ_0, t_0) and, moreover, $V_\varepsilon(x_\varepsilon, \zeta_\varepsilon, t_\varepsilon)$ converges to $\overline{V}(x_0, \zeta_0, t_0)$. Then, by (1.12), we get

$$\begin{aligned} &\varphi_t(x_\varepsilon, t_\varepsilon) + \lambda V_\varepsilon(x_\varepsilon, \zeta_\varepsilon, t_\varepsilon) \\ &+ \sup_{a \in A} \big\{ - f(x_\varepsilon, \zeta_\varepsilon, a) \cdot \nabla_y \varphi(x_\varepsilon, t_\varepsilon) - l(x_\varepsilon, \zeta_\varepsilon, a) \big\} \\ &\le \frac{1}{\varepsilon} \inf_{b \in B} \big\{ g(x_\varepsilon, \zeta_\varepsilon, b) \cdot 2(\zeta_\varepsilon - \zeta_0) \big\} \le 0, \end{aligned}$$

where the last inequality holds by virtue of the controllability condition (1.7). Hence, passing to the limit for $\varepsilon \to 0$, recalling (2.7), using the arbitrariness of $\zeta_0 \in \Omega$ and the continuity of f and l, we obtain

$$\varphi_t + \lambda \mathcal{V} + \sup_{\overline{\Omega} \times A} \big\{ - f \cdot \nabla \varphi - l \big\} \le 0 \qquad \text{at } (x_0, t_0).$$

On the other hand, by Lemma 2.2, the limit problem (P_0) and the definition of $\tilde{h}$, it turns out that $\mathcal{V}(x, 0) = V(x, 0)$, for every $x \in \mathbb{R}^N$. Hence, since V is a supersolution of (1.13), Theorem 1.7 gives the conclusion. □

PROPOSITION 2.6. *The sequence of value functions V_ε uniformly converges to V, over the compact sets of $\mathbb{R}^N \times \Omega\times]0,+\infty[$.*

Proof. Using (2.7), Lemma 2.1, Lemma 2.5, and the definitions of the weak limits (2.1), we obtain

$$V(x,t) \le \underline{V}(x,\zeta,t) \le \overline{V}(x,\zeta,t) \le V(x,t) \qquad \forall (x,\zeta,t) \in \mathbb{R}^N \times \Omega\times]0,+\infty[,$$

and the conclusion easily follows. ∎

Proposition 2.6 is close to the first statement of Theorem 1.1. The only difference is that we have not yet proved the convergence up to the boundary of Ω. To complete the proof, we consider a stronger controllability condition than (1.7), i.e.,

$$g(y,z,B) \supseteq \left\{\xi \in \mathbb{R}^M \middle| |\xi| \le 1\right\} \qquad \forall (y,z) \in \mathbb{R}^N \times \overline{\Omega}, \tag{2.9}$$

which, however, is not restrictive. Indeed, the next lemma shows that, for g and B satisfying (1.7), there exist $\tilde{g}$ and $\tilde{B}$ satisfying (2.9), such that the corresponding Cauchy problems (P_ε) are the same. Hence, the corresponding value functions V_ε and $\tilde{V}_\varepsilon$ coincide by the uniqueness statement of Theorem 1.4.

LEMMA 2.7. *There exist a compact set $\tilde{B}$ and a function $\tilde{g} : \mathbb{R}^N \times \mathbb{R}^M \times \tilde{B} \to \mathbb{R}^M$ with the same regularity properties as g, satisfying in addition* (2.9)*, such that equations* (1.12) *are the same.*

Proof. Let us consider the set

$$\Lambda := \left\{ (\lambda_1,\dots,\lambda_{M+1}) \in \mathbb{R}^{M+1} \middle| \lambda_i \ge 0 \ \forall i = 1,\dots,M+1, \ \sum_{i=1}^{M+1} \lambda_i = 1 \right\}$$

and define $\tilde{B} := B^{M+1} \times \Lambda$. We denote the elements $(b_1,\dots,b_{M+1},\lambda_1,\dots,\lambda_{M+1})$ of $\tilde{B}$ by $\tilde{b}$ and we define

$$\tilde{g}(y,z,\tilde{b}) := \sum_{i=1}^{M+1} \lambda_i g(y,z,b_i) \qquad \forall (y,z,\tilde{b}) \in \mathbb{R}^N \times \mathbb{R}^M \times \tilde{B}.$$

It is easy to prove that $\tilde{B}$ is compact and that $\tilde{g}$ has the same regularity properties as g. Moreover, by Carathéodory's theorem (see, for instance, [11])

$$\operatorname{cog}(y,z,B) = \tilde{g}(y,z,\tilde{B}) \qquad \forall (y,z) \in \mathbb{R}^N \times \mathbb{R}^M. \tag{2.10}$$

Since $\tilde{g}(y,z,\tilde{B})$ is closed, from (1.7) we see that $\tilde{g}$ has the property (2.9).

Now, let us note that the last term of the Hamiltonian is equal to

$$-\frac{1}{\varepsilon} \inf_{\xi \in \operatorname{cog}(x,\zeta,B)} \left\{ \xi \cdot \nabla_z V_\varepsilon(x,\zeta,t) \right\}.$$

Hence, by (2.10), the corresponding equations (1.12) are the same. ∎

In the sequel, we shall suppose that (2.9) holds for g and B.

LEMMA 2.8. *For every $(x,\zeta,t) \in \mathbb{R}^N \times \partial\Omega\times]0,+\infty[$, there exist $0 < \bar{t} < t$, a continuous path $\gamma : [0,\bar{t}] \to \mathbb{R}^N \times \overline{\Omega}$, $\gamma(\tau) = (y_\tau, z_\tau)$, and a constant $C > 0$, such that*

$$\begin{cases} (y_0,z_0) = (x,\zeta), & \\ (y_\tau,z_\tau) \in \mathbb{R}^N \times \Omega & \forall \tau \in]0,\bar{t}], \\ V_\varepsilon(x,\zeta,t) - V_\varepsilon(y_\tau,z_\tau,t-\tau) \le C\tau & \forall \tau \in [0,\bar{t}], \forall \varepsilon \in]0,1]. \end{cases} \tag{2.11}$$

Proof. Let $(x,\zeta,t) \in \mathbb{R}^N \times \partial\Omega \times]0,+\infty[$ be fixed and $\eta \in \mathbb{R}^M$, $0 < \bar{t} < t$ be such that

$$\tau \in]0,\bar{t}] \Rightarrow \zeta + \tau\eta \in \Omega.$$

Such a η exists by virtue of (1.6). It is not restrictive to suppose $|\eta| \leq 1$. We take an arbitrary control $\alpha \in \mathcal{A}$ and consider the continuous trajectory in $\mathbb{R}^N$, starting from x and defined by

$$\overline{y}(\tau) = x + \int_0^\tau f(\overline{y}(s), \zeta + s\eta, \alpha(s))ds.$$

Next, for every $0 < \varepsilon \leq 1$, let us consider the set

$$D(\varepsilon) := \big\{(\tau,b) \in [0,\bar{t}] \times B \big| g(\overline{y}(\tau), \zeta + \tau\eta, b) = \varepsilon\eta\big\}.$$

The set $D(\varepsilon)$ is compact and, by virtue of (2.9), it is not empty. Hence, by a selection lemma, see, for instance, [14], for every such ε, there exists a measurable function $\beta^\varepsilon : [0,\bar{t}] \to B$ such that

$$g(\overline{y}(\tau), \zeta + \tau\eta, \beta^\varepsilon(\tau)) = \varepsilon\eta, \qquad \text{a.e. } \tau \in [0,\bar{t}].$$

Then, for every $0 < \varepsilon \leq 1$, the following dynamical system

$$\begin{cases} y'(\tau) = f(y(\tau), z(\tau), \alpha(\tau)), & \tau \in]0,\bar{t}[, \\ z'(\tau) = \dfrac{1}{\varepsilon} g(y(\tau), z(\tau), \beta^\varepsilon(\tau)), & \tau \in]0,\bar{t}], \\ (y(0), z(0)) = (x,\zeta) \end{cases}$$

has the unique solution: $\tau \to (\overline{y}(\tau), \zeta + \tau\eta) \in \mathbb{R}^N \times \Omega$. If we define $\gamma(\tau) = (y_\tau, z_\tau) := (\overline{y}(\tau), \zeta + \tau\eta)$, then γ has the first two properties listed (2.11). Next, we prove the third one. Take any $\tau \in]0,\bar{t}]$, $\mu > 0$ and $0 < \varepsilon \leq 1$. Consider a control $(\alpha',\beta') \in \mathcal{A}^\varepsilon_{(y_\tau,z_\tau)}$ such that

$$V_\varepsilon(y_\tau, z_\tau, t-\tau) + \mu \geq J_\varepsilon(x,\zeta,t-\tau,\alpha',\beta'). \tag{2.12}$$

Then we define the control

$$(\alpha''(s),\beta''(s)) = \begin{cases} (\alpha(s), \beta^\varepsilon(s)), & \text{if } 0 \leq s < \tau, \\ (\alpha'(s-\tau), \beta'(s-\tau)), & \text{if } s \geq \tau, \end{cases}$$

which is admissible for (x,ζ). Hence, using (2.12) and the controls (α',β') and (α'',β''), we obtain the following estimate:

$$\begin{aligned} &V_\varepsilon(x,\zeta,t) - V_\varepsilon(y_\tau, z_\tau, t-\tau) \\ &\qquad \leq J_\varepsilon(x,\zeta,t,\alpha'',\beta'') - J_\varepsilon(y_\tau, z_\tau, t-\tau, \alpha',\beta') + \mu. \end{aligned} \tag{2.13}$$

From this, it is easy to deduce the last inequality in (2.11). □

LEMMA 2.9. *The sequence of value functions V_ε converges pointwise to the function V in the set $\mathbb{R}^N \times \overline{\Omega} \times]0,+\infty[$.*

Proof. The pointwise convergence in $\mathbb{R}^N \times \Omega \times]0,+\infty[$ immediately follows from Proposition 2.6. Hence, let us consider $(x,\zeta,t) \in \mathbb{R}^N \times \partial\Omega \times]0,+\infty[$. Using the notations of Lemma 2.8, let us fix $\delta > 0$ and take $\tau \in]0,\bar{t}[$ and $0 < \bar{\varepsilon} \leq 1$ such that

$$\begin{aligned} & C\tau \leq \frac{\delta}{3}, \\ & \left|V_\varepsilon(y_\tau, z_\tau, t-\tau) - V(y_\tau, t-\tau)\right| \leq \frac{\delta}{3} \qquad \forall 0 < \varepsilon \leq \bar{\varepsilon}, \\ & \left|V(y_\tau, t-\tau) - V(x,t)\right| \leq \frac{\delta}{3}, \end{aligned} \tag{2.14}$$

where the second inequality comes from Lemma 2.8 and Proposition 2.6 and the third one by the continuity of V. Hence, using Lemma 2.8 again, we obtain

$$V_\varepsilon(x,\zeta,t) - V(x,t) \leq \delta$$

and we get the conclusion because $V_\varepsilon \geq V$ (see Lemma 2.1). ∎

Proof of Theorem 1.1. Recalling (2.4), we know that the sequence of value functions V_ε is monotone in $\mathbb{R}^N \times \overline{\Omega} \times [0,+\infty[$. By Lemma 2.9, in the set $\mathbb{R}^N \times \overline{\Omega} \times]0,+\infty[$, the V_ε are continuous and pointwise converge to the continuous function V. Hence, the sequence uniformly converges to V, over any compact sets. Moreover, if the final cost h does not depend on $z \in \overline{\Omega}$, then by (1.4) both V_ε and V satisfy the same initial condition. Hence, by (2.3) and Lemma 2.4, we can conclude that $\overline{V}$ is constant in the variable $\zeta \in \Omega$, for every $(x,t) \in \mathbb{R}^N \times [0,+\infty[$. From this, proceeding as before, we obtain the uniform convergence over any compact set of $\mathbb{R}^N \times \overline{\Omega} \times [0,+\infty[$. ∎

3. The case of Lipschitz controls. In this section we give a simple application of Theorem 1.1. We consider $\Omega \subseteq \mathbb{R}^M$, $\zeta \in \overline{\Omega}$, $\varepsilon > 0$, $\lambda \geq 0$, $f : \mathbb{R}^N \times \mathbb{R}^M \to \mathbb{R}^N$, and $l, h : \mathbb{R}^N \times \mathbb{R}^M \to \mathbb{R}$. All the regularity hypotheses on Ω, f, l, and h for applying the results of the previous sections, are supposed to hold. Let us consider the following controlled dynamical system in $\mathbb{R}^N$:

$$\begin{cases} y'(t) = f(y(t), z(t)), & t > 0, \\ y(0) = x, \end{cases} \tag{3.1}$$

where the controls z belong to the set

$$\mathcal{L}^\varepsilon_\zeta := \left\{ z : [0,+\infty[\to \overline{\Omega} \;\middle|\; |z(t_1) - z(t_2)| \leq \frac{1}{\varepsilon}|t_1 - t_2|,\ z(0) = \zeta \right\}.$$

Note that $\mathcal{L}^\varepsilon_\zeta$ is the set of Lipschitz functions with Lipschitz constant less than $1/\varepsilon$ and with initial point ζ.

We want to minimize the cost functional

$$J(x,t,z) := \int_0^t e^{-\lambda s} l(y_x(s;z), z(s)) ds + e^{-\lambda t} h(y_x(t;z), z(t)). \tag{3.2}$$

Hence, we define the value function

$$V_\varepsilon(x,t,\zeta) := \inf_{z \in \mathcal{L}^\varepsilon_\zeta} J(x,t,z),$$

which depends also on the initial point ζ for the control z.

Next, we consider the optimal control problem defined by system (3.1), measurable controls $z \in \mathcal{Z}$ taking value in $\overline{\Omega}$ and value function

$$V(x,t) := \inf_{z\in\mathcal{Z}} \left(\int_0^t e^{-\lambda s} l(y_x(s;z), z(s))ds + e^{-\lambda t} \inf_{\zeta\in\overline{\Omega}} h(y_x(t;z),\zeta) \right).$$

PROPOSITION 3.1. *The value functions V_ε uniformly converge to the value function V, over any compact set of $\mathbb{R}^N \times \overline{\Omega} \times]0,+\infty[$. Moreover, if h does not depend on $\zeta \in \overline{\Omega}$, then the convergence is uniform over any compact set of $\mathbb{R}^N \times \overline{\Omega} \times [0,+\infty[$.*

Proof. We set $\mathcal{B} := \{\beta : [0,+\infty[\to \{\xi \in \mathbb{R}^M, |\xi| \le 1\} \text{ measurable}\}$ and consider the system

$$\begin{cases} y'(t) = f(y(t), z(t)), & t > 0, \\ z'(t) = \dfrac{1}{\varepsilon}\beta(t), & t > 0, \\ (y(0), z(0)) = (x, \zeta). \end{cases} \tag{3.3}$$

This is a special case of system (0.1) (where A is a singleton) and the hypotheses of Theorem 1.1 are satisfied. Then, we consider the set $\mathcal{B}^\varepsilon_{(x,\zeta)}$ of admissible controls with respect to the state-space constraint: $z(t) \in \overline{\Omega}$. By Theorem 1.1, if we take J defined in (3.2) and the value function

$$V^\varepsilon(x,\zeta,t) := \inf_{\beta\in\mathcal{B}^\varepsilon_{(x,\zeta)}} J(x,t,z),$$

they uniformly converge to V over the compact sets, as desired. On the other hand, a function z is Lipschitz, with Lipschitz constant less than $1/\varepsilon$, if and only if it satisfies the equation $z' = (1/\varepsilon)\beta$ almost everywhere, with $\beta \in \mathcal{B}$. Therefore, it is easy to see that $V_\varepsilon = V^\varepsilon$ and the proof is complete. □

Now, we consider the set $\mathcal{L}$ of Lipschitz controls $z : [0,+\infty[\to \overline{\Omega}$, with arbitrary Lipschitz constant and without fixed initial point. Again, we consider the corresponding value function

$$V_{\mathcal{L}}(x,t) := \inf_{z\in\mathcal{L}} J(x,t,z).$$

Since piecing together two elements of $\mathcal{L}$ does not necessary give an element of $\mathcal{L}$, the dynamic programming principle (DPP) does not obviously hold. Hence, the standard proof that the function $V_{\mathcal{L}}$ satisfies the Hamilton–Jacobi equation does not work. However, $V_{\mathcal{L}}$ turns out to coincide with V by Proposition 3.1 because

$$V(x,t) \le V_{\mathcal{L}}(x,t) \le V_\varepsilon(x,t,\zeta) \qquad \forall \varepsilon > 0,\ \forall (x,\zeta,t) \in \mathbb{R}^N \times \overline{\Omega} \times [0,+\infty[.$$

4. Remarks and extensions. In this section, we give some ideas about possible extensions and applications of our method to other control problems.

First of all, we consider the controllability hypothesis (0.6). If we replace (0.6) with the following assumption:

$$\forall (y,z) \in \mathbb{R}^N \times \overline{\Omega}\ \exists r > 0 \text{ such that } \overline{\text{co}}\, g(y,z,B) \supseteq \overline{B}(0,r), \tag{4.1}$$

then our method still works. The difference between (0.6) and (4.1) is that in (4.1) the radius of the ball depends on the point (y,z). Actually, we can further enlarge

the class of perturbation problems as follows. We replace the equation for the fast variables z in (0.1) with

$$z'(t) = g_1(y(t), z(t), \beta(t)) + \frac{1}{\varepsilon} g(y(t), z(t), \beta(t)), \tag{4.2}$$

with g and g_1 satisfying the standard uniform Lipschitz continuity assumption and g verifying (4.1). We note that the function $\varepsilon g_1 + g$ does not necessarily satisfy (0.6); however, since g_1 is locally bounded, for every (y, z) we can take suitably small ε, such that the function $\varepsilon g_1 + g$ satisfies condition (4.1) in a neighborhood of (y, z). For instance, a linear system

$$z' = M_1 y + M_2 z + \frac{1}{\varepsilon} M_3 b,$$

where M_1, M_2 and M_3 are matrices, satisfies (4.1) if $M_3 B \supseteq \overline{B}(0, r)$ for some r, but the vector field $\varepsilon(M_1 y + M_2 z) + M_3 b$ satisfies (0.6) only if M_1 and M_2 are both null.

THEOREM 4.1. *For every $\varepsilon > 0$, let V_ε be the value function of the control problem where the fast variables are driven by (4.2). Then, the sequence $(V_\varepsilon)_{\varepsilon>0}$ uniformly converges in any compact set of $\mathbb{R}^N \times \overline{\Omega} \times]0, +\infty[$, as $\varepsilon \to 0$, to the value function V of the same limit problem as in section 2.*

Sketch of the proof. Using the Lipschitz continuity of g and g_1 in (y, z) uniformly with respect to b, it is not hard to prove that the function

$$r(y, z, \varepsilon) := \max \left\{ r > 0 \Big| \overline{\text{co}} \Big[g_1(y, z, B) + \frac{1}{\varepsilon} g(y, z, B) \Big] \supseteq \overline{B}(0, r) \right\}$$

is well defined and continuous in $(y, z, \varepsilon) \in \mathbb{R}^N \times \overline{\Omega} \times]0, +\infty[$. Moreover, for every (y, z), $r(y, z, \varepsilon) > 0$ for suitable small ε, by (4.1); hence for every compact set of $\mathbb{R}^N \times \overline{\Omega}$ and small ε, r has a strictly positive minimum. Thus, modifying appropriately the proofs of Lemmas 2.2, 2.4, 2.5, and 2.8 to the new system (4.2), (4.1), Theorem 4.1 can be easily proved. □

Remark 4.1. We can consider the system (0.1) with the second equation

$$z'(t) = \frac{1}{\varepsilon} \left(g_1(y(t), z(t), \beta(t)) + g(y(t), z(t), \beta(t)) \right), \tag{4.3}$$

and make the proofs of Lemmas 2.2, 2.4, and 2.5 work again, provided that, for every $\varepsilon > 0$, the value function V_ε is a subsolution of

$$\nabla_z V_\varepsilon \cdot g_1 \leq 0. \tag{4.4}$$

In this case, the sign of the uncontrollable terms in the proofs of the lemmas is the correct one. Hence, we get the usual convergence result, at least in any compact set of $\mathbb{R}^N \times \Omega \times]0, +\infty[$. □

Next we explain how our method applies to exit time problems. With the notions and hypotheses of the Introduction and section 1, we take an open bounded set $\mathcal{O} \subset \mathbb{R}^N$ with smooth boundary, in particular with the interior cone property (i.e., the obvious analogue of the first property in (1.6)). For every trajectory $(y(\cdot), z(\cdot))$ of the system (0.1) we define the exit time from $\mathcal{O}$, which depends on the starting point (x, ζ), on the admissible control (α, β), and on $\varepsilon > 0$:

$$\tau^\varepsilon = \tau(x, \zeta, \alpha, \beta, \varepsilon) := \min \left\{ t \geq 0 \big| y(t) \in \partial\mathcal{O} \right\}. \tag{4.5}$$

In the same way, we define the exit time from $\mathcal{O}$ for the limit system (0.8), which depends on the starting point x and on the measurable controls z and α:

$$\tau = \tau(x, z, \alpha) := \min\left\{t \geq 0 \middle| y(t) \in \partial\mathcal{O}\right\}. \tag{4.6}$$

We consider the following cost functionals:

$$J_\varepsilon(x, \zeta, \alpha, \beta) := \int_0^{\tau^\varepsilon} e^{-\lambda s} l(y(s), z(s), \alpha(s)) ds + e^{-\lambda \tau^\varepsilon} h(y(\tau^\varepsilon)), \tag{4.7}$$

$$J(x, z, \alpha) := \int_0^{\tau} e^{-\lambda s} l(y(s), z(s), \alpha(s)) ds + e^{-\lambda \tau} h(y(\tau)), \tag{4.8}$$

where $\lambda > 0$ and the terminal cost h is a continuous function in a neighborhood $B(\partial\mathcal{O}, \delta)$ of $\partial\mathcal{O}$. Next we define the value functions for the perturbed problems and for the limit problem as, respectively,

$$V_\varepsilon(x, \zeta) := \inf_{(\alpha,\beta)\in(\mathcal{A}\times\mathcal{B})^\varepsilon_{(x,\zeta)}} J_\varepsilon(x, \zeta, \alpha, \beta) \tag{4.9}$$

and

$$V(x) := \inf_{(z,\alpha)\in\mathcal{Z}\times\mathcal{A}} J(x, z, \alpha). \tag{4.10}$$

Let us now suppose that the terminal cost h satisfies the compatibility condition

$$h(x) \leq J(x, z, \alpha) \qquad \forall x \in B(\partial\mathcal{O}, \delta),\ \forall (z, \alpha) \in \mathcal{Z} \times \mathcal{A}, \tag{4.11}$$

and the limit system has the controllability property

$$\sup_{(\zeta,a)\in\overline{\Omega}\times A} f(x, \zeta, a) \cdot \nu(x) > 0 \quad \forall x \in \partial\mathcal{O}, \tag{4.12}$$

where $\nu(x)$ is the exterior normal to $\mathcal{O}$. These assumptions ensure the continuity of the value function V by the results in Chapter 4 of [4] (see also [22] for similar results; note that (4.11) implies $h(x) \leq V(x)$ in $B(\partial\mathcal{O}, \delta)$; thus V is lower semicontinuous at all $x \in \partial\mathcal{O}$, whereas (4.12) implies the upper semicontinuity of V at boundary points). The value functions V_ε, however, may be discontinuous.

Under the previous assumptions, the following theorem holds.

THEOREM 4.2. *When ε tends to 0, the sequence of value functions V_ε converges to the value function V uniformly over the compact sets of $\mathcal{O} \times \Omega$.*

Sketch of the proof. By the assumptions (4.11) and (4.12), $V \in BUC(\overline{\mathcal{O}})$ and it is the solution of the boundary value problem

$$\begin{cases} \lambda V + \sup_{z\in\overline{\Omega}} H(y, z, \nabla V, 0) = 0 & \text{in } \mathcal{O}, \\ V = h & \text{on } \partial\mathcal{O}, \end{cases} \tag{4.13}$$

where the Hamiltonian H is defined in (0.11).

Now, for every $\varepsilon > 0$, we denote by V_ε^* the upper semicontinuous envelope of V_ε. By the results of Ishii [16], V_ε^* is subsolution of

$$\begin{cases} \lambda V_\varepsilon^* + H(y, z, \nabla_y V_\varepsilon^*, \frac{1}{\varepsilon}\nabla_z V_\varepsilon^*) \leq 0 & \text{in } \mathcal{O} \times \Omega, \\ V_\varepsilon^* \leq h \text{ or } \lambda V_\varepsilon^* + H(y, z, \nabla_y V_\varepsilon^*, \frac{1}{\varepsilon}\nabla_z V_\varepsilon^*) \leq 0 & \text{on } \partial\mathcal{O} \times \Omega, \end{cases} \tag{4.14}$$

where the boundary condition is also interpreted in the viscosity sense.

Then, as in (2.1), we define the lower weak limit $\underline{V}$ and the upper weak limit $\overline{V}$. Also in this case, for every strict local maximum point (x_0, ζ_0) for $\overline{V} - \varphi$ there exists a sequence $(x_\varepsilon, \zeta_\varepsilon) \in \overline{\mathcal{O}} \times \Omega$ of maximum points for $V_\varepsilon^* - \varphi$ converging to (x_0, ζ_0), such that $V_\varepsilon^*(x_\varepsilon, \zeta_\varepsilon)$ converges to $\overline{V}(x_0, \zeta_0)$. Hence, as in Lemma 2.4, we can say that $\overline{V}$ is constant with respect $\zeta \in \Omega$ in $\mathcal{O} \times \Omega$. Then, if we define the function

$$\mathcal{V}(x) := \inf_{\zeta \in \Omega} \overline{V}(x, \zeta) \qquad \forall x \in \overline{\mathcal{O}}, \tag{4.15}$$

we obtain that $\mathcal{V} = \overline{V}$ in $\mathcal{O}$. As in Lemma 2.5, we can prove that $\mathcal{V}$ is an upper semicontinuous subsolution of

$$\begin{cases} \lambda \mathcal{V} + \sup_{z \in \overline{\Omega}} H(y, z, \nabla \mathcal{V}, 0) = 0 & \text{in } \mathcal{O}, \\ \mathcal{V} = h \text{ or } \lambda \mathcal{V} + \sup_{z \in \overline{\Omega}} H(y, z, \nabla \mathcal{V}, 0) = 0 & \text{on } \partial \mathcal{O}. \end{cases} \tag{4.16}$$

The only difference is the boundary condition, and we observe that if $\mathcal{V}(x_0) > h(x_0)$ for some $x_0 \in \partial \mathcal{O}$, then, along the above sequence $(x_\varepsilon, \zeta_\varepsilon)$ converging to (x_0, ζ_0) with arbitrary $\zeta_0 \in \Omega$, we have $V_\varepsilon^*(x_\varepsilon, \zeta_\varepsilon) > h(x_\varepsilon)$, at least for small ε. Therefore, the Hamilton–Jacobi equation holds at such points by (4.14), and by letting $\varepsilon \to 0$ we obtain that $\mathcal{V}$ satisfies the Hamilton–Jacobi equation at the boundary point x_0.

Now we apply the comparison result in Ishii [16] (see also [4]) and get

$$\overline{V}(x, \zeta) \le V(x) \qquad \forall (x, \zeta) \in \mathcal{O} \times \Omega.$$

Since the inequality $V \le \underline{V}$ follows from the definitions of V, V_ε, and $\underline{V}$, we easily get the conclusion. □

Remark 4.2. The same convergence result as in Theorem 4.2 holds if we consider the control problem with exit time from the closure of $\mathcal{O}$. In this case we define

$$\hat{\tau}^\varepsilon = \hat{\tau}(x, \zeta, \alpha, \beta, \varepsilon) := \inf \left\{ t \ge 0 \middle| y(t) \notin \overline{\mathcal{O}} \right\}, \tag{4.17}$$

$$\hat{\tau} = \hat{\tau}(x, z, \alpha) := \inf \left\{ t \ge 0 \middle| y(t) \notin \overline{\mathcal{O}} \right\}. \tag{4.18}$$

Let $\hat{V}_\varepsilon$ and $\hat{V}$ be the value functions defined as in (4.9) and (4.10) with cost functionals J_ε and J as in (4.7) and (4.8) with τ^ε and τ replaced by $\hat{\tau}^\varepsilon$ and $\hat{\tau}$, respectively.

Then, under the hypotheses (4.11) and (4.12), $\hat{V}_\varepsilon \to \hat{V} = V$ when $\varepsilon \to 0$, where V is the value function defined in (4.10). In fact, $\hat{V} = V$ because the upper semicontinuous and lower semicontinuous envelopes $\hat{V}^*$ and $\hat{V}_*$ are, respectively, sub- and supersolution of (4.16), hence, by a comparison theorem, $\hat{V}^* \le V \le \hat{V}_*$ (see [16], [4]). On the other hand, the functions $\hat{V}_\varepsilon$ do not necessarily coincide with V_ε defined in (4.9), but $\hat{V}_\varepsilon^*$ satisfies (4.14) for every ε. Thus the upper weak limit of $\hat{V}_\varepsilon$ is a subsolution of (4.16) and the conclusion follows as in the previous proof. □

Appendix: Continuity of the value function. In this Appendix we shall use the notation $B(x, r)$ for the open ball with radius r and centre x.

We consider a general controlled dynamical system in $\mathbb{R}^m$:

$$\begin{cases} y'(t) = f(y(t), \alpha(t)), & t > 0, \\ y(0) = x, \end{cases} \tag{A.1}$$

with the constraint on the trajectories

$$y(t) := y_x(t; \alpha) \in \overline{\Omega} \qquad \forall t > 0. \tag{A.2}$$

We have the measurable controls $\alpha \in \mathcal{A}$, which takes values in a compact set A. Hence, we consider the cost functional

$$J(x,t,\alpha) := \int_0^t e^{-\lambda s} l(y(s),\alpha(s))ds + e^{-\lambda t} h(y(t)) \tag{A.3}$$

and the value function

$$V(x,t) := \inf_{\alpha\in\mathcal{A}_x} J(x,t,\alpha), \tag{A.4}$$

where $\mathcal{A}_x$ is the set of admissible controls. The hypotheses are the following:

$$\begin{aligned}
&\Omega \subseteq \mathbb{R}^m \text{ is open and connected and satisfies (1.6), with } M \text{ replaced by } m;\\
&f : \mathbb{R}^m \times A \to \mathbb{R}^m \text{ is continuous;}\\
&|f(x,a) - f(y,a)| \le L|x-y| \qquad \forall x,y \in \mathbb{R}^m, \forall a \in A;\\
&|f(x,a)| \le K(1+|x|) \qquad \forall x,y \in \mathbb{R}^m, \forall a \in A;\\
&l : \mathbb{R}^m \times A \to \mathbb{R} \text{ is continuous;}\\
&|l(x,a) - l(y,a)| \le \omega(|x-y|),\ |l(x,a)| \le K \qquad \forall x,y \in \mathbb{R}^m, \forall a \in A;\\
&h : \mathbb{R}^m \to \mathbb{R} \text{ is continuous and bounded,}
\end{aligned} \tag{A.5}$$

where $\omega(0) = 0$ and ω is continuous and increasing. Note, that the fourth inequality in (A.5), follows from the continuity of f and the compactness of A. Moreover, we will use the following controllability assumption at points of $\partial\Omega$:

$$\forall z \in \partial\Omega\ \exists a \in A \text{ such that } g_i(z) = 0 \Rightarrow f(z,a)\cdot\nabla g_i(z) < 0. \tag{A.6}$$

It is easy to see that, for every $\varepsilon > 0$, the problem described in the previous section by (0.1), (0.2), (0.3), and (1.3) is a particular case of the last one, with $m = N + M$.

THEOREM A.1. *Under the assumptions above, $\mathcal{A}_x$ is not empty and V is bounded and continuous in $\overline{\Omega}\times[0,T]$, for every $T > 0$.*

We need a lemma. First, let us define

$$\begin{aligned}
I_t(x,\alpha) &:= \int_0^t e^{-\lambda s} l(y_x(s;\alpha),\alpha(s))ds \qquad \forall x \in \overline{\Omega},\ \forall \alpha \in \mathcal{A},\ \forall t > 0,\\
G_i &:= \{x \in \mathbb{R}^N : g_i(x) \le 0\}, \qquad i = 1,\dots,q.
\end{aligned} \tag{A.7}$$

LEMMA A.2. *For every $x_0 \in \overline{\Omega}$ there exist constants $r_0 > 0$, $t^* > 0$, $C > 0$ such that, for every $x \in B(x_0,r_0)\cap\overline{\Omega}$ and for every $\alpha \in \mathcal{A}$, there exists $\overline{\alpha} \in \mathcal{A}$ such that*

$$y_x(t;\overline{\alpha}) \in \overline{\Omega} \qquad \forall t \in [0,t^*], \tag{A.8}$$

$$\left|I_{t^*}(x,\overline{\alpha}) - I_{t^*}(x,\alpha)\right| \le C \max\left\{\operatorname{dist}(y_x(t,\alpha),G_i) : t \in [0,t^*], i = 1,\dots,q\right\}. \tag{A.9}$$

Proof. This proof is a modification of the Soner's one [24]. If $x_0 \in \Omega$, then we are done, since, by the third and the fourth of (A.5) and Gronwall's lemma, we get

$$\begin{cases} |y_x(t;\alpha) - y_z(t;\alpha)| \le e^{Lt}|x-z| & \forall x,z \in \mathbb{R}^m,\ \forall \alpha \in \mathcal{A},\ \forall t \ge 0;\\ |y_x(t;\alpha) - x| \le Kt(1+|x|)e^{Kt} & \forall x \in \mathbb{R}^m,\ \forall \alpha \in \mathcal{A},\ \forall t \ge 0, \end{cases} \tag{A.10}$$

and so, for a suitable small time interval independent on the control, all the trajectories starting from the same point do not go out of a fixed compact set. Hence, let us suppose $x_0 \in \partial\Omega$. By (A.5) and (A.6), there exist a nonempty set $I \subseteq \{1,\dots,q\}$, a constant control $\overline{a} \in A$, and two positive numbers δ_0, ξ_0, such that

$$(A.11)\qquad \begin{cases} g_i(x_0) = 0 & \forall i \in I,\ g_j(x_0) < 0,\ \forall j \notin I, \\ B(x_0,\delta_0) \subseteq \overset{\circ}{G}_j & \forall j \notin \mathrm{I}, \\ f(x,\overline{a})\cdot\nabla g_i(x) < -\xi_0 < 0 & \forall x \in B(x_0,\delta_0)\cap\overline{\Omega},\ \forall i \in I. \end{cases}$$

Now, let us take $r_0 < \delta_0$, a point $x \in B(x_0,r_0)\cap\overline{\Omega}$ and fix $t' > 0$ sufficiently small such that

$$(A.12)\qquad \begin{cases} y_x(t;\alpha) \in B(x_0,\delta_0) & \forall t \in [0,t'],\ \forall \alpha \in \mathcal{A}, \\ f(y_x(t;\alpha),\overline{a})\cdot\nabla g_i(y_x(t,\alpha)) \le -\xi_0 < 0 & \forall t \in [0,t'],\ \forall i \in I, \end{cases}$$

which is possible by (A.11). So we have

$$(A.13)\qquad y_z(t;\alpha) \in G_j \qquad \forall t \in [0,t'],\ \forall z \in B(x_0,r_0)\cap\overline{\Omega},\ \forall \alpha \in \mathcal{A},\ \forall j \notin I.$$

Then, let us take a measurable control $\alpha \in \mathcal{A}$ and define

$$(A.14)\qquad \begin{aligned} &t_0 := \inf\big\{t \in]0,t'] : y_x(t;\alpha) \in \partial\Omega\big\}, \qquad t_0 := t' \text{ if } y_x(t;\alpha) \notin \partial\Omega\ \forall t \in [0,t'], \\ &\mu := \max\big\{\mathrm{dist}(y_x(t;\alpha),G_s) : t \in [0,t'],\ s = 1,\dots,q\big\}, \\ &\overline{\alpha}(t) := \alpha(t)\chi_{[0,t_0[}(t) + \overline{a}\chi_{[t_0,t_0+h\mu]}(t) + \alpha(t-h\mu)\chi_{]t_0+h\mu,+\infty[}(t), \end{aligned}$$

where $h > 0$ will be fixed later and χ_S denotes the characteristic function of the set S.

By (A.12), for proving (A.8), we have only to prove that $y_x(t;\overline{\alpha}) \in G_i$, that is $g_i(y_x(t;\overline{\alpha})) \le 0$, for every fixed $t \in [0,t']$ and every $i \in I$ (note that only for the moment t' is our main candidate as t^*).

If $0 \le t \le t_0$ then, by virtue of definition (A.14), there is nothing to prove. If $t_0 < t \le t_0 + h\mu$ and $t \le t'$, then using (A.12), (A.13), and the fact that $y_x(t;\overline{\alpha})$ is a solution of (A.1), we get for every $i \in I$:

$$g_i(y_x(t;\overline{\alpha})) = g_i(y_x(t_0;\overline{\alpha})) + \int_{t_0}^{t} \nabla g_i(y_x(s;\overline{\alpha}))\cdot f(y_x(s;\overline{\alpha}),\overline{\alpha}(s))ds \le -\xi_0(t-t_0) < 0,$$

and, hence, we get $y_x(t;\overline{\alpha}) \in \overline{\Omega}$ for every $t \le t'$,$t \in [t_0,t_0+h\mu]$. If $t \le t'$ and $t > t_0 + h\mu$, then for a suitable $\tau > t_0$ it is $t = \tau + h\mu$. Then, using the definition of $\overline{\alpha}$, we have

$$(A.15)\qquad \begin{aligned} &g_i(y_x(\tau+h\mu;\overline{\alpha})) = g_i(y_x(t_0;\overline{\alpha})) + \int_{t_0}^{t_0+h\mu} \nabla g_i(y_x(s;\overline{\alpha}))\cdot f(y_x(s,\overline{\alpha}),\overline{a})ds \\ &+ \int_{t_0+h\mu}^{\tau+h\mu} \nabla g_i(y_x(s;\overline{\alpha}))\cdot f(y_x(s;\overline{\alpha}),\alpha(s-h\mu))ds \\ &\le g_i(y_x(t_0;\overline{\alpha})) - \xi_0 h\mu + \int_{t_0}^{\tau} \nabla g_i(y_x(s+h\mu;\overline{\alpha}))\cdot f(y_x(s+h\mu;\overline{\alpha}),\alpha(s))ds. \end{aligned}$$

Now, using (A.5) and the fact that g_i is $C^{1,1}$ and, hence, bounded and Lipschitz, with its first derivatives over compact sets and using (A.10), we obtain, after adding and subtracting suitable terms

$$(A.16)\qquad g_i(y_x(\tau+h\mu;\overline{\alpha})) \le -\xi_0 h\mu + Ch\mu\int_{t_0}^{\tau}\Big[e^{L(s-t_0)}ds + (g_i\circ y_x(\cdot,\alpha))'(s)\Big]ds,$$

where the constant $C > 0$ depends on x_0 only. Next, we suppose that the radius r_0 is small enough, such that, in the ball $B(x_0, r_0)$, the following inequality holds: $g_i(z) \leq \mathrm{dist}(z, G_i)$ for every $z \in B(x_0, r_0)$. The last is not restrictive; it is sufficient to divide the function g_i by its Lipschitz constant in the ball $B(x_0, 2\delta_0)$ and to note that the set G_i remains unchanged after this operation. Hence, if we take $0 < t^* \leq t'$ such that

$$t^* \leq \frac{1}{L} \log\left(1 + \frac{L\xi_0}{2C}\right),$$

then we get

$$g_i(y_x(\tau + h\mu; \overline{\alpha})) \leq \mu\left(1 - \frac{\xi_0}{2}h\right).$$

Hence, if we take $h = 2/\xi_0$, (A.8) is proved.

Now, let us note that it is not restrictive to suppose the running cost l to be a Lipschitz function on $x \in \mathbb{R}^M$ uniformly in $a \in A$. In fact, we are interested in the continuity of the value function and hence, if the value function with Lipschitz running cost is continuous, then, taking a uniformly approximating sequence of Lipschitz running cost, we have a uniformly approximating sequence of continuous value functions. So, for Lipschitz l, using the construction of $\overline{\alpha}$ and standard estimates, it is easy to prove that (A.9) holds. □

Remark A.1. It is easy to convince oneself that, for x in a compact subset of $\overline{\Omega}$, the constants r_0, t^* and C of Lemma A.2, and also the quantity h, can be uniformly chosen. □

Proof of Theorem A.1. Let us prove that $\mathcal{A}_x \neq \emptyset$ for every $x \in \overline{\Omega}$. Let us take $x_0 \in \overline{\Omega}$ and let t_0^* be the supremum of the values for t^*. If $t_0^* = +\infty$, then we are done. If it is not the case, let us take $\alpha_0 \in \mathcal{A}$ such that $y_{x_0}(t; \alpha_0) \in \overline{\Omega}$ for every $0 \leq t \leq t_0^*$. In a similar way, we define t_1^* with respect to $x_1 := y_{x_0}(t_0^*; \alpha_0)$. If $t_1^* = +\infty$, we are done. If it is not the case, let us take $\alpha_1 \in \mathcal{A}$ such that $y_{x_1}(t; \alpha_1) \in \overline{\Omega}$ for every $0 \leq t \leq t_1^*$ and take t_2^* with respect to $x_2 := y_{x_1}(t; \alpha_1)$. Then we consider the measurable control $\overline{\alpha}$, constructed by gluing the controls α_n; it belongs to $\mathcal{A}_{x_0}$ if and only if $\sum_{n=0}^{+\infty} t_n^* = +\infty$. But if this is not true, then, by (A.10), the trajectory $y_{x_0}(\cdot; \overline{\alpha})$ does not exit from a compact subset of $\overline{\Omega}$. Hence, by Remark A.1, the values t_n^* are bounded away from zero, which is a contradiction to $\sum_{n=0}^{+\infty} t_n^* < +\infty$.

The boundedness of the value function is obvious; then we prove the continuity in every set $\overline{\Omega} \times [0, T]$ with $T > 0$. Let us take $T > 0$, $x_0 \in \overline{\Omega}$ and consider a ball B with x_0 as centre. We shall show that, for a suitable ball B' inside B and centered in x_0, the value function is uniformly continuous in $B' \cap \overline{\Omega} \times [0, T]$. Hence, the continuity in $\overline{\Omega} \times [0, T]$ will be proved. By Remark A.3, we can take the constants t^*, r_0, and C uniformly in B. Using (A.10), we take B' such that, $y_x(t; \alpha) \in B$ for every $t \in [0, T]$, for every $\alpha \in \mathcal{A}$ and for every $x \in B'$. Hence, using Lemma A.2 and proceeding as in Soner [24], we get the following estimates, which hold for every $x, z \in B' \cap \overline{\Omega}$, for every α, for every $\overline{\alpha}$ as in Lemma A.2 with respect to x and α, and for every $t \in [0, t^*]$:

$$\begin{aligned} &\big|y_x(t; \overline{\alpha}) - y_z(t; \alpha)\big| \leq C\big|x - z\big|, \\ &\big|I_t(x, \overline{\alpha}) - I_t(z, \alpha)\big| \leq C\big|x - z\big|, \end{aligned} \tag{A.17}$$

where $C > 0$ and I_t is defined as in (A.6). Moreover, starting from two points $x, z \in B'$, the same estimates hold even for every $t \in [0, T]$, if $T > t^*$. In fact, if

$T \le t^*$, during the time-interval $[0,T]$, for every fixed $\alpha \in \mathcal{A}$, the trajectories starting from a point of B' do not exit from B. Hence, we can repeat the same argument, used for getting the estimate, with respect to the starting points $y_x(t^*;\overline{\alpha})$, $y_z(t^*;\alpha)$ and to the same value t^*. Let us iterate this argument. At every nth step, we construct, as in Lemma A.2, a control $\overline{\alpha}_n$ depending on the starting point $y_x(nt^*;\overline{\alpha}_{n-1})$ and on the control α. Hence, for every $x \in B' \cap \overline{\Omega}$ and for every $\alpha \in \mathcal{A}$ there exists a control $\overline{\alpha}$ such that $y_x(t;\overline{\alpha}) \in \overline{\Omega}$ and all the previous estimates hold for every $t \in [0,T]$.

Next, let us fix $\delta > 0$. Then, by definition of V (A.4), for a suitable $\alpha \in \mathcal{A}_z$ we have

$$
\begin{aligned}
&V(x,t) - V(z,s) \\
&\qquad \le I_t(x,\overline{\alpha}) - I_s(z,\alpha) + e^{-\lambda t} h(y_x(t;\overline{\alpha})) - e^{-\lambda s} h(y_z(s;\alpha)) + \delta.
\end{aligned} \tag{A.18}
$$

Hence, using the estimates (A.17), the definition of I_t, denoting by ω_h a modulus of continuity of h in B, and adding and subtracting suitable terms, we get

$$
V(x,t) - V(z,s) \le C_1 \big|t-s\big| + C\big|x-z\big| + \omega_h\big(C\big|x-z\big|\big) + \delta,
$$

for a suitable positive constant C_1 and for C as in (A.17). Hence, we reach the conclusion by the arbitrariness of $\delta > 0$. □

DISSIPATIVITY AND THE LUR'E PROBLEM FOR PARABOLIC BOUNDARY CONTROL SYSTEMS*

L. PANDOLFI†

Abstract. Dissipativity is studied for a class of boundary control systems whose free evolution is described by a holomorphic semigroup. It is proved that the system is dissipative if and only if there exists a (bounded selfadjoint) solution of the corresponding linear operator inequality. In addition, the Lur'e problem is solved under particular assumptions.

Key words. singular regulator, distributed control, Popov function, holomorphic semigroups, Lur'e problem

AMS subject classifications. 43N10, 93C20

PII. S0363012997315439

1. Introduction.

The quadratic regulator problem with stability is a complex body of results; see [24]. Extensions to distributed systems were given in [25] for uniformly continuous semigroup systems and in [14] for C_0-semigroup systems. A partial extension to a class of boundary control systems is in [13].

In this paper we present a further extension to a class of boundary control problems, a result on the spectral factorization of the related Popov function, and a proof of existence of solutions to the corresponding Lur'e problem.

Now we describe the problems that we are going to study. We denote X and U to be complex Hilbert spaces, and we consider a continuous quadratic form (QF) on $X \times U$,

$$F(x,u) = \langle x, Qx\rangle + \langle x, Su\rangle + \langle Su, x\rangle + \langle u, Ru\rangle, \tag{1}$$

where "$\langle\cdot,\cdot\rangle$" denotes both the inner product in the Hilbert space X and that in the Hilbert space U. We assume that Q, S, R are linear bounded operators in the proper spaces and that $Q = Q^*$ and $R = R^*$, but we are not assuming either that $Q \geq 0$ or that $R \geq 0$ (this last condition will be a consequence of Property P1 described below).

We consider the boundary control system (S),

$$\dot{x} = A(x - Du), \qquad x(0) = x_0 \tag{2}$$

($x \in X$, $u \in U$). Systems of the form (2) have been studied in many papers in order to describe boundary control systems.

The pair of the quadratic functional (QF) and of the system (S) is called a *Popov pair* ((S),(QF)).

We must give a meaning to the solutions of the equation that describes system (S). Formally, it is given by

$$x(t) = x(t; x_0, u) = e^{At}x_0 - A\int_0^t e^{A(t-s)}Du(s)\,\mathrm{d}\,s\,. \tag{3}$$

Of course, this equation does not make any sense in X unless we introduce some restrictions. Two main classes under which this expression defines an element of the space X are singled out in [9]. In this paper we study systems of the first class: holomorphic semigroup systems. More precisely, we assume the following.

(i) Let α be any number larger than the exponential order $\omega(A)$ of the semigroup. We define $X_\gamma = \mathrm{dom}(\alpha I - A)^\gamma$, a space which is independent of α as long as $\alpha > \omega(A)$. Analogously, $X_\gamma^{(*)} = \mathrm{dom}(\alpha I - A^*)^\gamma$. We assume that there exists a number $\tilde{\gamma} \in (0,1)$ such that $\mathrm{Im}D \subseteq X_{1-\tilde{\gamma}}$. Hence $B = -AD = (\alpha I - A)^{\tilde{\gamma}}(\alpha I - A)^{1-\tilde{\gamma}}D - \alpha D$ belongs to $\mathcal{L}(U, (X_\gamma^{(*)})')$.

We note that here and in the following we use the same symbol A in order to denote the original operator A and its extension $A^{*'} \in \mathcal{L}(X, (\mathrm{dom}A^*)')$.

(ii) The pair (A, D) is stabilizable by a bounded feedback operator. This means that there exists an operator $K \in \mathcal{L}(X, U)$ with the following property: we consider the operator A_K defined by

$$A_K x = A(I - DK)x, \qquad \mathrm{dom}A_K = \{x \in X, (I - DK)x \in \mathrm{dom}A\}\,.$$

We require that the operator A_K generate an exponentially stable semigroup (which turns out to be a holomorphic semigroup; see [10, part 2, section 4].

Under these assumptions, it is known that the function $x(\cdot)$ is almost everywhere (a.e.) X-valued and locally square integrable on $(0, +\infty)$, but in general it is not continuous; see [10] and references therein.

In this paper we call "trajectory" of the control system (S) a pair $(x(\cdot), u(\cdot))$, which satisfies (3) for a given $x_0 \in X$. The function $x(\cdot)$ given in (3) will be called the "state function," which corresponds to the "initial datum" x_0 and to the "input" or "control function" $u(\cdot)$.

We consider the following quadratic functional computed along the trajectories of the control systems (S):

$$J(x_0; u) = \int_0^{+\infty} F(x(t), u(t))\, \mathrm{d}\, t\,, \tag{4}$$

where $x(t) = x(t; x_0, u)$.

The first problem that we consider is the "regulator problem with stability." This means that we want to give equivalent conditions for the following property.

Property P1. There exists a number $\eta \in \mathbb{R}$ such that for each $x_0 \in X$ we have

$$\inf\{J(x_0; u)\,,\ u(\cdot) \in L^2(0, +\infty; U) \text{ such that } x(\cdot) \in L^2(0, +\infty; X)\} \geq \eta \|x_0\|^2\,.$$

Here $x(\cdot) = x(\cdot; x_0, u)$.

We stress that we are not assuming simply integrability of $F(x(\cdot), u(\cdot))$, but we require that possible trajectories which are not square integrable be discarded from consideration. Hence we consider only the controls $u(\cdot)$ which belong to the set

$$\mathcal{M}_{x_0} = \{u(\cdot) \in L^2(0, +\infty; U) \text{ such that } x(\cdot) \in L^2(0, +\infty; X)\}\,.$$

The stabilizability assumption guarantees that for each x_0 the set $\mathcal{M}_{x_0}$ is nonempty but, in general, $\mathcal{M}_{x_0}$ will depend upon x_0. If it happens that the semigroup e^{At} is exponentially stable, then $\mathcal{M}_{x_0} = L^2(0, +\infty; U)$.

When Property P1 is satisfied, the pair of system (S) and of the quadratic functional (QF) is called *dissipative* (or, in special applications, *passive* or *positive.*)

We already noted that the previous problem was studied and solved in [14] in the case in which $\mathrm{Im}D \subseteq \mathrm{dom}A$ (distributed control action). The extensions of the results in [14] to boundary control systems may follow two routes, the first one being a direct extension of the chain of lemmas in [14] to our system. Instead, following an idea which we introduced already in the previous papers [15, 16], we prefer a different route. We associate an "augmented system" to system (2). This is a distributed control system. Then we can directly apply the results in [14] to the augmented system in order to obtain the corresponding results for the boundary control system.

The methods used for the analysis of Property P1 were already used in the papers [11, 12, 17, 18].

A second problem that we are going to study is the Lur'e problem. A precise description, with assumptions and references, will be given in section 2, after the description of the main results which concern Property P1. Roughly speaking, the Lur'e problem is the following problem: we consider the case that the semigroup is exponentially stable. A necessary condition which is satisfied when Property P1 holds is that a certain operator valued function defined on the imaginary axis is nonnegative; see the last statement of Theorem 1. This function is called the Popov function of the system. This condition is necessary *but not sufficient* for Property P1, and it is required that we find *additional conditions* under which Property P1 holds. This problem is known as the Lur'e problem. It is an important and classical problem in control theory which has not yet been completely clarified even for finite dimensional systems. See [2, 5] for recent finite dimensional results.

The plan of the paper is as follows: in the next section we present our main results; the augmented system is derived in section 3 and it is studied in section 3.1, where Theorem 1 is proved under the further assumption that the semigroup e^{At} is exponentially stable. The stability assumption is removed in section 4.

If the system is stable, the Popov function (defined in the next section) has an analytic extension (with singularities) to the right half plane, and it makes sense to study the factorization properties of this function; see section 5 where the Lur'e problem is solved.

2. Main results and description of the Lur'e problem. If P_1 and P_2 are continuous selfadjoint operators on X, we write $P_1 \geq P_2$ if $P_1 - P_2 \geq 0$.

The first result that we are going to prove is the following one.

THEOREM 1. *We have that Property P*1 *holds if and only if there exists a linear bounded operator P on X, $P = P^*$, such that the following holds for each $x \in \mathrm{dom}A$, $u \in U$:*

$$\langle Ax, P(x + Du)\rangle + \langle P(x + Du), Ax\rangle + F(x + Du, u) \geq 0. \tag{5}$$

In this case, $\inf_{u \in \mathcal{M}_{x_0}} J(x_0; u) = \langle x_0, \hat{P}x_0\rangle$, *where the operator $\hat{P}$ is the maximal solution to the inequality* (5).

*If Property P*1 *holds, then*

$$\begin{cases} F(x + Du, u) \geq 0 \text{ for each } \ x \in \mathrm{dom}A\,, u \in U \text{ such that} \\ \\ \text{there exists a real } \omega \text{ for which } i\omega(x + Du) = Ax\,, \end{cases} \tag{6}$$

and $R \geq 0$.

Inequality (5) is known as the *dissipation inequality* or *linear operator inequality* (LOI).

We note that if it happens that $i\omega$ belongs to the resolvent set of the operator A, then the last condition can be written in the form

$$\Pi(i\omega) = F(-i\omega(i\omega I - A)^{-1}Du + Du, u) = F((i\omega I - A)^{-1}Bu, u) \geq 0\,. \tag{7}$$

The function $\omega \to F((i\omega I - A)^{-1}Bu, u)$ is called the *Popov function* of system (S).

A case in which the Popov function is defined for each real ω is the case that the semigroup e^{At} is exponentially stable. In this case $(i\omega I - A)^{-1}Bu = (i\omega I - A)^{-1}A^{\tilde{\gamma}}A^{1-\tilde{\gamma}}Du \to 0$ for $\omega \to \infty$ (we use the fact that the semigroup is holomorphic here). Hence, if Property P1 holds and if the semigroup is exponentially stable, then

$$0 \leq \lim_{\omega\to\infty} F((i\omega I - A)^{-1}Bu, u) = \langle u, Ru\rangle;$$

i.e., R is positive semidefinite.

We shall prove that the condition $R \geq 0$ is implied by Property P1 even if the semigroup is not exponentially stable.

Remark 1. The assumption that the semigroup is *holomorphic* has a crucial role in the proof of the positivity of R. In particular, for hyperbolic control systems, the condition $\Pi(i\omega) \geq 0$ for every real ω *does not imply* $R \geq 0$. See [20] for a counterexample.

Now we can describe the Lur'e problem and the results that we are going to prove concerning this problem.

The Lur'e problem is an important and difficult problem, which can be described as follows: we assume that the semigroup is *exponentially stable* so that the Popov function is defined on the imaginary axis. Let us assume that the Popov function $\Pi(i\omega)$ is nonnegative, $\langle u, \Pi(i\omega)u\rangle \geq 0$ for each u. The problem is to find additional conditions under which there exists a solution P to (LOI). The oldest finite dimensional results are due to [8, 23]. In those papers the additional condition was *complete controllability.* Recent papers show that a much weaker condition than controllability is sufficient; see [2, 5]. See [4, 19] for recent proofs which hold for distributed systems under the assumption that e^{At} is a C_0-*group,* still under a controllability assumption. These proofs essentially reproduce the proof given in [25], which was based on the assumption that e^{At} is a *uniformly continuous group.* Instead, the arguments in the present paper are closer to the paper [1], where the Lur'e problem is studied for *semigroup* systems with *distributed* control under quite demanding regularity assumptions on the input and output operators. In fact, we study a problem analogous to the one studied in [1] under the additional condition that the semigroup is holomorphic but with *control acting through the boundary* and less stringent assumptions on the output operator.

The Lur'e problem is difficult even for finite dimensional systems, and we are able to attack it only under particular conditions.

We describe the assumptions under which we study the Lur'e problem.

1. We assume that the input u is *scalar* so that $S \in X$ and $D \in X$ and the Popov function is a scalar function.
2. We assume that the semigroup is holomorphic and *exponentially stable*, and moreover, we assume $\sigma(A) = \sigma_p(A) = \{z_n\}$; each z_n is a simple eigenvalue and the sequence $\{v_n\}$ of the normalized eigenvectors is a Riesz basis of X. The eigenvalues of A are denoted $z_n = -x_n + iy_n$ (it will be assumed that $x_n > 0$ in section 5).

3. There exists a number μ such that

$$\left|\frac{y_k}{x_k}\right| < \mu\,.$$

4. There exists an exponent $\delta < 1$ and a *positive* number H such that, for $|\omega|$ large enough,

$$|\omega|^{\delta}|\Pi(i\omega)| > H\,. \tag{8}$$

Now we state our result and then we discuss briefly the previous assumptions.

The result that we prove is the following.

THEOREM 2. *Let assumptions* 1–4 *hold. If* $\Pi(i\omega) \geq 0$ *for every real* ω*, then there exists a solution* $P = P^* \in \mathcal{L}(X)$ *of the (LOI)* (5).

The proof of this result rests on the same ideas as [1]; see section 5.

Now we discuss the assumptions. The assumption that the spectrum of the generator is point spectrum with simple eigenvalues and that the eigenvectors are a Riesz basis is satisfied in many cases of practical interest.

As to condition 3, we note that the spectrum of an analytic semigroup is contained in a sector. In principle it could be a sector of amplitude π. We are assuming that the amplitude is less then π. This assumption is not too restrictive. In particular, in the very important case that the operator A is selfadjoint, the eigenvalues are real (and in this case the proof of Theorem 2 can be simplified).

If we compare the previous assumptions with the existing finite dimensional theory, we see that the weakest condition under which the (finite dimensional) Lur'e problem was solved is that there exists at least one point ω_0 such that $P(i\omega_0) \neq 0$ (if the control is scalar). We expect that this condition *is not* sufficient in the case of distributed systems since for finite dimensional systems it implies that there are only finitely many zeros of $P(i\omega)$ and a polynomial rate of decrease at ∞. Both these conditions are not true for distributed systems.

This observation explains assumption 4, which is the most demanding (also from the point of view of practical verification). We note that this assumption is extremely strong for systems with *distributed control action:* the simple Popov function is $\Re e\, 1/[1+i\omega] = \mathrm{O}(1/\omega^2)$ for $\omega \to +\infty$. In fact, assumption 4 can be relaxed if the operator S is more regular. We note also that assumption 4 is not used if the system has only finitely many eigenvalues. Hence, our proof *can* be applied to finite dimensional systems, even if assumption 4 does not hold when $R = 0$.

Finally, we show an example of a system which satisfies assumptions 1–4. We consider the heat equation in one space dimension with scalar control and observation

$$x_t = x_{ss}, \quad t > 0\,, \quad 0 < s < 1\,; \qquad x(t,0) = u(t)\,, \quad x_s(t,1) = 0\,.$$

It is well known that assumptions 2 and 3 are satisfied.

Let $Q = 0$, $R = 0$, and

$$S^*(x(\cdot)) = \int_0^1 x(s)\,\mathrm{d}\,s,$$

and let us consider assumption 4. A simple calculation shows that the transfer function is

$$S^*A(i\omega I - A)^{-1}D = -\frac{1}{\sigma}\frac{\sinh\sigma}{\cosh\sigma}, \quad \sigma = e^{i\pi/4}\sqrt{\omega}$$

(when $\omega > 0$; otherwise $\sigma = e^{-i\pi/4}\sqrt{\omega}$). It is a long but elementary computation to see that there exist numbers $0 < m < M$ such that

$$\frac{m}{\sqrt{\omega}} \leq \Pi(i\omega) \leq \frac{M}{\sqrt{\omega}}\,.$$

Hence, assumption 4 is satisfied, too.

3. Preliminaries: Stable semigroup systems. In this section we assume that the operator A generates an exponentially stable semigroup, and we show that it is possible to introduce an *augmented* Popov pair, whose analysis directly provides the proof of Theorem 1. The special feature of this new Popov pair is that it is described by a *distributed* (i.e., not boundary) control system.

A preliminary observation is the following one:

$$\inf_{u\in L^2(0,+\infty;U)} J(x_0;u) \leq J(x_0,0) \leq M\|x_0\|^2$$

for some number M. We note that $\inf_u J(x_0;u)$ is computed with respect to any $u \in L^2(0,+\infty;U)$ since we are assuming that system (S) is exponentially stable.

The state function of an exponentially stable system depends continuously, in the $L^2(0,+\infty;X)$ norm, on the input function $u(\cdot) \in L^2(0,+\infty;U)$ and also on the initial datum $x_0 \in X$ (see [10]). This observation is used in the following proof.

LEMMA 3. *Let e^{At} be an exponentially stable semigroup. We have the following.*

1. *Let H be a dense subspace of X and let us assume that*

$$\inf_{u\in L^2(0,+\infty;U)} J(x_0;u) \geq \eta\|x_0\|^2 \tag{9}$$

for each initial condition $x_0 \in H$. Then inequality (9) *holds for each initial condition $x_0 \in X$.*

2. *Let $\mathcal{H}$ be a dense subspace of $L^2(0,+\infty;U)$, and let us define the two numbers*

$$\alpha(x_0) = \inf_{u\in L^2(0,+\infty;U)} J(x_0;u), \tag{10}$$

$$\beta(x_0) = \inf_{u\in\mathcal{H}} J(x_0;u)\,. \tag{11}$$

Then $\alpha(x_0) = \beta(x_0)$.

Proof. First, we prove item 1. By contradiction, let us assume that we can find $\tilde{x} \in X$ and a control $\tilde{u}(\cdot) \in L^2(0,+\infty;U)$ such that $J(\tilde{x},\tilde{u}) < (\eta-\epsilon)\|\tilde{x}\|^2$ for some $\epsilon > 0$.

Let us choose a sequence $\{x_n\}$ $x_n \to \tilde{x}$, $x_n \in H$. Then, $x(\cdot;x_n,\tilde{u}) \to x(\cdot;\tilde{x},\tilde{u})$ in $L^2(0,+\infty;X)$ so that we have $J(x_n;\tilde{u}) < (\eta-\epsilon)\|\tilde{x}\|^2$ if n is large enough. As $(\eta-\epsilon)\|x_n\|^2 \to (\eta-\epsilon)\|\tilde{x}\|^2$ we see that $(\eta-\epsilon)\|\tilde{x}\|^2 < (\eta-\epsilon/2)\|x_n\|^2$ for large n. This contradicts condition (9), which is assumed on H.

Next, we prove item 2. It is clear that $\alpha(x_0) \leq \beta(x_0)$. By contradiction, let us assume that $\alpha(x_0) < \beta(x_0) - \epsilon$ so that we can find $u_0 \in L^2(0,+\infty;U)$ such that $\alpha(x_0) < J(x_0;u_0) < \beta(x_0) - \epsilon$. We choose a sequence $\{u_n\}$ in $\mathcal{H}$ which converges to u_0 in the norm of $L^2(0,+\infty;U)$. Stability of e^{At} implies that $J(x_0;u_n) \to J(x_0;u)$ so that, for large n, $J(x_0;u_n) < \beta(x_0) - \epsilon$. This is a contradiction. □

This lemma shows that we can confine ourselves to study the boundedness from below of the quadratic functional $J(x_0;u)$ by using regular controls, in particular by using C^1 controls.

If the control $u(\cdot)$ is of class C^1, then we have

$$x(t) = x(t; x_0, u) = e^{At}\{x_0 - Du(0)\} + Du(t) - \int_0^t e^{A(t-s)} D\dot{u}(s)\, \mathrm{d}\, s,$$

i.e.,

$$x(t) = e^{At}\{x_0 - Du(0)\} + Du(t) - \int_0^t e^{A(t-s)} Dv(s)\, \mathrm{d}\, s, \tag{12}$$

$$u(t) = u(0) + \int_0^t v(s)\, \mathrm{d}\, s\,. \tag{13}$$

This observation is the essence of the method that we shall use: the functions $\xi(\cdot)$, $u(\cdot)$, $v(\cdot)$ in (12), (13) represent the trajectories of the *augmented system* (AS),

$$\left\{ \begin{array}{lcllcl} \dot{\xi} & = & A\xi - Dv, & \xi(0) & = & x_0 - Du_0, \\ \dot{u} & = & v, & u(0) & = & u_0\,. \end{array} \right. \tag{14}$$

We shall see that it is possible to study a suitable quadratic functional along the trajectories of the augmented system in order to get informations on the original problem.

We note that the block operators which describe the augmented system are the operators $\mathcal{A}_0$, $\mathcal{D}$:

$$\mathcal{A}_0 = \left[\begin{array}{cc} A & 0 \\ 0 & 0 \end{array} \right], \qquad \mathcal{D} = \left[\begin{array}{c} -D \\ I \end{array} \right].$$

Remark 2. Also, the subspace $\{u(\cdot) \in L^2(0, +\infty; U) \cap C^1(0, +\infty; U)\,,\ u(0) = 0\}$ is dense in $L^2(0, +\infty; U)$ so that we could even consider $u_0 = 0$ from the beginning. It seems more interesting to show that the vector $u(0) = u_0$ has no influence on the results, even if it is nonzero (see the next section). Moreover, the applications of the results in [14] are more direct if we do not assume $u(0) = 0$.

3.1. The quadratic regulator problem with stability. The previous arguments suggest the following considerations. We define the quadratic functional (QFS)

$$\Phi(\xi, u, v) = F(\xi + Du, u)\,. \tag{15}$$

We note that this functional does not depend on v. We introduce the quadratic cost

$$J(\xi_0, u_0; v) = \int_0^{+\infty} \Phi(\xi(t), u(t), v(t))\, \mathrm{d}\, t$$

computed along the trajectories of the augmented system (AS) described by (12), (13). This cost *does not involve the input v explicitly.* If $u(\cdot)$ is a C^1 input function, then

$$J(x_0 - Du(0), u(0); v)_{|_{v=\dot{u}}} = J(x_0; u)\,.$$

Hence, Lemma 3 shows that Property P1 holds if and only if for every x_0, for every $u_0 \in U$, and for every $v(\cdot) \in L^2(0, +\infty; U)$ we have

$$J(x_0 - Du_0, u_0; v) \geq \eta \|x_0\|^2 = \eta \|(x_0 - Du_0) + Du_0\|^2\,,$$

provided that the corresponding *trajectory* $(\xi(\cdot), u(\cdot), v(\cdot))$ of the augmented system (AS) is square integrable. Hence, we shall denote by $\mathcal{M}_{\xi_0,u_0}$ the set

$$\mathcal{M}_{\xi_0,u_0} = \{v(\cdot) \in L^2(0,+\infty;U) \text{ which produces a square integrable trajectory of system (AS) whose initial datum is } (\xi_0,u_0)\},$$

and we consider the following property.

Property P2. There exists a real number η such that

$$\inf_{v\in\mathcal{M}_{\xi_0,u_0}} J(\xi_0,u_0;v) > \eta\|\xi_0 + Du_0\|^2 .$$

The previous considerations show that Property P1 and Property P2 are equivalent.

Now we observe that the augmented system (AS) *is not exponentially stable but is stabilizable.* In fact, $v=-u$ is a stabilizing feedback, because e^{At} is exponentially stable.

A result from [14] shows that for stabilizable systems with distributed controls we can study, instead of Property P2, the following apparently weaker condition.

Property P3. For each (ξ_0,u_0) we have $\inf_{v\in\mathcal{M}_{\xi_0,u_0}} J(\xi_0,u_0;v) > -\infty$.

Property P3 is characterized in Theorem 3 in [14] as follows. Property P3 is equivalent to the existence of an operator $W = W^* \in \mathcal{L}(X\times U)$ such that

$$\begin{aligned} &\langle \mathcal{A}_0\mathcal{X} + \mathcal{D}v, W\mathcal{X}\rangle + \langle W\mathcal{X}, \mathcal{A}_0\mathcal{X} + \mathcal{D}v\rangle + \Phi(\xi,u,v) \geq 0 \\ &\forall \mathcal{X} = \operatorname{col}[\xi,u] \in \operatorname{dom}\mathcal{A}_0,\ \forall v \in U . \end{aligned} \tag{16}$$

The operators $\mathcal{A}_0$, $\mathcal{D}$ are the operators of the augmented system (AS).

Inequality (16) is the inequality (LOI) written for the augmented system. We stress that Property P3 and (16) are equivalent conditions provided that the pair $(\mathcal{A},\mathcal{D})$ is stabilizable, as in our case.

From [14], Property P3 implies that

$$\inf_{v\in\mathcal{M}_{\xi_0,u_0}} J(\xi_0,u_0;v) = \left\langle \begin{bmatrix} \xi_0 \\ u_0 \end{bmatrix} \hat{W}, \begin{bmatrix} \xi_0 \\ u_0 \end{bmatrix} \right\rangle,$$

where $\hat{W}$ is the *maximal* solution to (LOI). Hence there exists $M \leq \inf\sigma(\hat{W})$ such that

$$\inf_{v\in\mathcal{M}_{\xi_0,u_0}} J(\xi_0,u_0;v) > M\left\| \begin{bmatrix} \xi_0 \\ u_0 \end{bmatrix} \right\|^2 .$$

This proves the equivalence of Property P2 and Property P3. Furthermore, if Property P3 holds, then for every $(\omega,\xi,u,v) \in \mathbb{R}\times X\times U\times U$ such that $(i\omega I - \mathcal{A})\mathcal{X} = \mathcal{D}v$ ($\mathcal{X}$ =col$[\xi,u]$) we have that $\Phi(\xi,u,v)\geq 0$ (the frequency domain inequality).

These results are proved in [14, Theorem 3]. Now we shall elaborate on these properties in order to obtain conditions for Property P1. A crucial observation is that the left-hand side of (16) does not contain a quadratic term of v. Consequently inequality (16) implies that the coefficient of v is zero, i.e., that $W\mathcal{D}=0$. In other terms, this shows that the operator W solves the Lur'e problem for the augmented system, with the functional $\Phi(\xi,u,v)$ (constant with respect to v).

From $W\mathcal{D}=0$ we see that any operator W which satisfies (16) has the following block form:

$$W = \begin{bmatrix} P & PD \\ D^*P & D^*PD \end{bmatrix}, \qquad P = P^* \in \mathcal{L}(X). \tag{17}$$

We shall write $\hat{P}$ for the $(1,1)$ block of the maximal solution $\hat{W}$. In fact, if $W_{i\,j}$, $1 \le i,\, j \le 2$, are the blocks of W, then the equation $W\mathcal{D} = 0$ shows that $-W_{1\,1}D + W_{1\,2} = 0$, $-W_{2\,1}D + W_{2\,2} = 0$, and $W_{2\,1} = W_{1\,2}^*$, since W is selfadjoint.

Now we prove the following lemma.

LEMMA 4. *Let us define*

$$\alpha = \inf_{u \in L^2(0,+\infty;U)} J(x_0;u) \qquad \gamma = \inf_{u_0} \inf_{v \in \mathcal{M}_{x_0+Du_0,u_0}} J(x_0 + Du_0, u_0; v)\,.$$

Then $\alpha = \gamma$.

Proof. The inequality $\alpha \le \gamma$ is clear. We assume that $\alpha + \epsilon < \gamma - \epsilon$ $(\epsilon > 0)$ and we show a contradiction.

We know that

$$\gamma - \epsilon < \gamma \le J(x_0 + Du_0, u_0; v) \tag{18}$$

for each $u_0 \in U$ and $v(\cdot) \in \mathcal{M}_{x_0+Du_0,u_0}$.

We know that (AS) is stabilizable. Let $\mathcal{K}$ be a stabilizing feedback and denote by $(AS)_{\mathcal{K}}$ the closed loop. Let $J_{\mathcal{K}}(\xi,u;v)$ be the cost obtained from the quadratic functional $\Phi_{\mathcal{K}}(\xi,u,w) = \Phi(\xi,u,\mathcal{K}X + w) = \Phi(\xi,u)$ (since $v = \mathcal{K}X + w$ does not appear explicitly in the quadratic functional Φ), $X = \operatorname{col}[\xi,u]$, i.e., the original cost computed along the trajectories of system $(AS)_{\mathcal{K}}$. Then,

$$\gamma = \inf_{u_0} \inf_{w(\cdot) \in L^2(0,+\infty;U)} J_{\mathcal{K}}(x_0 + Du_0, u_0; w),$$

i.e.,

$$\gamma - \epsilon < \gamma \le J_{\mathcal{K}}(x_0 + Du_0, u_0; w),$$

for each $u_0 \in U$ and $w(\cdot) \in L^2(0,+\infty;U)$ since we noted that

$$\{J(x_0 + Du_0; u_0; v)\ v \in \mathcal{M}_{x_0+Du_0,u_0}\} = \{J_{\mathcal{K}}(x_0 + Du_0; u_0; w)\ w \in L^2(0,+\infty;U)\}\,.$$

Stability of $(AS)_{\mathcal{K}}$ implies that the transformation

$$(x_0,u_0,w) \to J_{\mathcal{K}}(x_0 + Du_0, u_0; w), \qquad X \times U \times L^2(0,+\infty;U) \to \mathbb{R}$$

is continuous. Hence we can find $\sigma > 0$ such that

$$\gamma - \epsilon < J_{\mathcal{K}}(\tilde{x} + D\tilde{u}, \tilde{u}; \tilde{w}) \tag{19}$$

provided that $\|\tilde{x} - x_0\|_X < \sigma$ and also $\|\tilde{u} - u_0\|_U < \sigma$, $\|\tilde{w}(\cdot) - w(\cdot)\|_{L^2} < \sigma$. The elements u_0 and $w(\cdot)$ are arbitrary in U and in $L^2(0,+\infty;U)$. Hence, (19) holds provided that $\|\tilde{x} - x_0\|_X < \sigma$ and each $\tilde{u} \in U$, $\tilde{w}(\cdot) \in L^2(0,+\infty;U)$.

Now let $\hat{u}$ be such that

$$\alpha \le J(x_0;\hat{u}) < \alpha + \epsilon\,.$$

We can assume that $\hat{u}$ belongs to $C^1(0,+\infty;U) \cap L^2(0,+\infty;U)$, and we can also assume that $\|u(0) - u_0\|_U \le \sigma$, since $w = \dot{u}$ does not appear explicitly in $J_K(\xi_0,u_0;w)$. Hence,

$$\alpha \le J(x_0 + D\hat{u}(0), \hat{u}(0); \hat{u}'(\cdot)) < \alpha + \epsilon < \gamma - \epsilon\,.$$

This contradicts (19). ∎

The previous result implies that

$$\inf_{u\in\mathcal{M}_{x_0}} J(x_0;u) = \inf_{u_0} \left\langle \begin{bmatrix} x_0 - Du_0 \\ u_0 \end{bmatrix}, \begin{bmatrix} \hat{P} & \hat{P}D \\ D^*\hat{P} & D^*\hat{P}D \end{bmatrix} \begin{bmatrix} x_0 - Du_0 \\ u_0 \end{bmatrix} \right\rangle = \langle x_0, \hat{P}x_0\rangle,$$

and we have the following.

THEOREM 5. *A necessary and sufficient condition for Property P*1 *is the existence of an operator* $\hat{P} = \hat{P}^* \in \mathcal{L}(X)$ *such that*

$$\inf_{u(\cdot)\in L^2(0,+\infty;U)} J(x_0;u) = \langle x_0, \hat{P}x_0\rangle\,.$$

We show that $\hat{P}$ solves a suitable dissipation inequality.

Let W of the form (17) be a solution of (16). Its $(1,1)$ block P solves

$$\langle A\xi, P(\xi + Du)\rangle + \langle P(\xi + Du), A\xi\rangle + F(\xi + Du, u) \geq 0 \tag{20}$$

for every $\xi \in \mathrm{dom}A$, $u \in U$, as wanted.

The previous observation applies in particular to the maximal solution $\hat{W}$, hence to $\hat{P}$. Now we show that, if a solution P to (20) exists, this implies Property P1. This is easy since, if P satisfies (20), then we construct a solution W to (16) (see (17)), and this implies Property P3 from [14]. Hence, Property P1 holds.

This proves the first part of Theorem 1 under the further assumption that the semigroup e^{At} is exponentially stable. Now we consider the frequency domain condition. We note that the equality $(i\omega I - \mathcal{A})\mathcal{X} = \mathcal{D}v$ can be written as

$$(i\omega I - A)\xi = -Dv, \qquad i\omega u = v \tag{21}$$

so that, if $i\omega(\xi + Du) = A\xi$, then we have the required inequality

$$F(\xi + Du, u) \geq 0\,. \tag{22}$$

Equivalently, we proved that $F(x,u) \geq 0$ when $x - Du \in \mathrm{dom}A$ (i.e., x satisfies the prescribed boundary conditions) and $i\omega x = A(x - Du)$ for some real ω.

Remark 3. The crucial assumption in this section is that e^{At} is an exponentially stable semigroup. The assumption that the semigroup is holomorphic *is not used* in the previous arguments. It is used, instead, in the proof that $R \geq 0$; see section 2. In fact, Property P1 does not imply $R \geq 0$ in general; see [20] for a counterexample.

In the next section we examine the case that system (S) is stabilizable, while in section 5, we return to stable systems in order to study the Lur'e problem. For this reason we consider now some additional material for stable systems, which will be used in section 5.

We noted already that if system (S) is stable, then the augmented system can be stabilized by using the simple feedback $v = -u$. We apply this special feedback and we get a special stabilized augmented system (SAS). The operators of system (SAS) are

$$\mathcal{A}_S = \begin{bmatrix} A & D \\ 0 & -I \end{bmatrix}, \qquad \mathcal{D} = \begin{bmatrix} -D \\ I \end{bmatrix}.$$

In fact, the input matrix is not affected by the feedbacks. Also, the quadratic functional is not affected since it does not depend upon v.

We compare the Popov function $\Pi(i\omega)$ of the original Popov pair ((S),(QF)) with the Popov function $P(i\omega)$ of the Popov pair of the stabilized augmented system ((SAS),(QFS)).

The Popov function of ((S),(QF)) is the function $\omega \to \Pi(\omega)$ in (7).

We note that

$$\begin{aligned}\Phi(\xi,u,v) &= \langle \xi + Du, Q[\xi + Du]\rangle + \langle \xi + Du, Su\rangle + \langle Su, \xi + Du\rangle + \langle u, Ru\rangle \\ &= \left\langle \begin{bmatrix} \xi \\ u \end{bmatrix}, \begin{bmatrix} Q & S+QD \\ D^*Q + S^* & R + D^*QD \end{bmatrix} \begin{bmatrix} \xi \\ u \end{bmatrix} \right\rangle = \left\langle \begin{bmatrix} \xi \\ u \end{bmatrix}, \mathcal{Q} \begin{bmatrix} \xi \\ u \end{bmatrix} \right\rangle\end{aligned}$$

and

$$\begin{aligned}&\langle w, P(i\omega)w\rangle = \langle (i\omega I - \mathcal{A}_{\mathcal{S}})^{-1}\mathcal{D}w, \mathcal{Q}(i\omega I - \mathcal{A}_{\mathcal{S}})^{-1}\mathcal{D}w\rangle \\ &= -\langle \mathcal{D}^*(i\omega I + {\mathcal{A}_{\mathcal{S}}}^*)^{-1}\mathcal{Q}(i\omega I - \mathcal{A}_{\mathcal{S}})^{-1}\mathcal{D}w, w\rangle \\ &= \frac{1}{1+\omega^2} F(Dw - i\omega(i\omega I - A)^{-1}Dw, w) = \frac{1}{1+\omega^2}\langle w, \Pi(i\omega)w\rangle\end{aligned}$$

admits the holomorphic extension

$$\langle w, P(z)w\rangle = -\langle \mathcal{D}^*(zI + {\mathcal{A}_{\mathcal{S}}}^*)^{-1}\mathcal{Q}(zI - \mathcal{A}_{\mathcal{S}})^{-1}\mathcal{D}w, w\rangle. \tag{23}$$

This extension is bounded in a strip $|\Re e\, z| < \epsilon$, since $\mathcal{A}_{\mathcal{S}}$ generates an exponentially stable semigroup.

4. Stabilizable systems. In this section we show that the results in section 3 can be extended to stabilizable systems.

We stabilize system (S) first by applying a stabilizing feedback $u = Kx + v$. We get a new system, the *stabilized system,* described by

$$\dot{x} = (A + BK)x + Bv(t), \tag{24}$$

where $A_K = A + BK$ generates a stable holomorphic semigroup; see [10, section 4]. Moreover,

$$(zI - A_K)^{-1} = [I + (zI - A)^{-1}ADK]^{-1}(zI - A)^{-1}$$

for every z in a sector contained in $\rho(A) \cap \rho(A_K)$, $|z|$ large enough (see [10, section 4]). Hence,

$$\begin{aligned}&\|(zI - A_K)^{-1}B\| \\ &= \|[I + (zI - A)^{-1}ADK]^{-1}(zI - A)^{-1}[(\alpha I - A)^{\tilde{\gamma}}(\alpha I - A)^{1-\tilde{\gamma}}D - \alpha D]\|\end{aligned}$$

is of the order of $1/|z|^{1-\tilde{\gamma}}$. In particular, it is a bounded operator and the first resolvent equation shows that $D_K = A_K^{-1}AD \in X$. This shows that system (24) can be written as

$$\dot{x} = A_K[x - D_K v], \tag{25}$$

and we can apply the results of the previous section to this stabilized system.

We denote by (SS) the system described by (25) (the *stabilized system*).

The cost that we should associate with system (SS) is

$$J_K(x_0; v) = \int_0^{+\infty} F(x(t), u(t))\, \mathrm{d}\, t = \int_0^{+\infty} F(x(t), v(t) + Kx(t))\, \mathrm{d}\, t$$

and, of course,

$$\inf_{v\in L^2(0,+\infty;U)} J_K(x_0;v) = \inf_{u\in\mathcal{M}_{x_0}} J(x_0;u)$$

(we used already an argument like this in the proof of Lemma 4). Consequently we can check Property P1 with respect to system (SS), and system (SS) produces a *stabilizable* augmented system, the pair (A,D) being replaced by the pair (A_K,D_K). For maximum clarity let us call (ASS) the augmented system which is obtained starting from system (SS). Hence system (ASS) is the following system, where $\xi = x - D_K v$:

$$\dot\xi = A_K\xi - D_K w, \qquad \dot v = w\,.$$

We associate the following cost with system (ASS):

$$J_K(\xi_0,v_0;w) = \int_0^{+\infty} F_K(\xi,v,w)\,\mathrm{d}\,t\,, \quad F_K(\xi,v,w) = F(\xi + D_K v, v + K(\xi + D_K v))\,.$$

Moreover, the set $\mathcal{M}_K(\xi_0,v_0)$ is defined as $\mathcal{M}(\xi_0,u_0)$ but with respect to (ASS).

The same arguments as those used in the proofs of Lemmas 3 and 4 show the following.

LEMMA 6. *We have that*

$$\inf_{u\in\mathcal{M}_{x_0}} J(x_0,u) = \inf_{v\in L^2(0,+\infty;U)} J_K(x_0,v) > -\infty \qquad \forall x_0\in X$$

if and only if

$$\inf_{w\in\mathcal{M}_K(\xi_0,v_0)} J_K(\xi_0,v_0;w) > -\infty \qquad \forall(\xi_0,u_0)\in X\times U\,.$$

Lemma 6, Theorem 4, and following considerations show that Property P1 holds if and only if the dissipation inequality written with respect to system (ASS) and to the functional $J_K(\xi_0,v_0;w)$ admits a solution, i.e., from the arguments of the previous section, if and only if there exists $P = P^* \in \mathcal{L}(X)$ such that the quadratic form

$$\langle A_K\xi, P(\xi + D_K v)\rangle + \langle P(\xi + D_K v), A_K\xi\rangle + F(\xi + D_K v, v + K(\xi + D_K v)) \tag{26}$$

is nonnegative for each $\xi \in \mathrm{dom}A_K$ and for each $v\in U$.

We make a formal computation now, which is justified below.

Let the vectors ξ and v in (26) be fixed. We introduce the vectors ζ, u, x defined by

$$\xi = \zeta - D_K v, \qquad u = v + K\zeta, \qquad x = \zeta - Du\,. \tag{27}$$

In terms of ζ, v we have

$$\begin{aligned}&\langle A(I-DK)[\zeta - D_K v], P\zeta\rangle = \langle A_K\zeta - ADv, P\zeta\rangle,\\ &F(\xi + D_K v, v + K(\xi + D_K v)) = F(\zeta, v + K\zeta)\,.\end{aligned}$$

If we introduce the vectors x, u we get

$$\begin{aligned}&\langle A_K\xi, P\zeta\rangle = \langle Ax, P(x + Du)\rangle,\\ &F(\zeta, v + K\zeta) = F(x + Du, u),\end{aligned} \tag{28}$$

and this shows that the dissipation inequality (20) is equivalent to the dissipation inequality for the augmented system, i.e., that Theorem 1 holds.

The following lemma justifies the previous assertions.

LEMMA 7. *Let $\xi \in \mathrm{dom}A_K$, v be given, and x be defined as in* (27). *We have that $x \in \mathrm{dom}A$ and $A_K\xi = Ax$ so that equality* (28) *holds.*

Proof. We introduce the operator $A^{*'} \in \mathcal{L}(X, (\mathrm{dom}A^*)')$. We know that $A^{*'}$ is an extension to X of the operator A in the following sense: let i be the (continuous and dense) injection of $\mathrm{dom}A^*$ into X so that its adjoint $i' \in \mathcal{L}(X, (\mathrm{dom}A^*)')$ is the continuous and dense injection of X in $(\mathrm{dom}A^*)'$ (the operator i' is the restriction to $\mathrm{dom}A^*$ of linear continuous functionals on X; see [22, section 5.1]). Then, $x \in \mathrm{dom}A$ if and only if $A^{*'}x = i'\tilde{x} \in i'X$ and in this case $Ax = \tilde{x}$. So we prove the lemma as follows: we show that $A^{*'}x = i'A_K\xi$. This means that we show that the two functionals $A^{*'}x$ and $i'A_K\xi$ act in the same way on $\mathrm{dom}A^*$.

Let $\langle\langle\cdot,\cdot\rangle\rangle$ be the pairing of $\mathrm{dom}A^*$ and its dual. We prove that for each $y \in \mathrm{dom}A^* \subseteq \mathrm{dom}A_K^*$ we have

$$\langle\langle i'A_K\xi, y\rangle\rangle = \langle\langle A^{*'}x, y\rangle\rangle.$$

We have

$$\langle\langle i'A_K\xi, y\rangle\rangle = \langle A_K\xi, y\rangle = \langle \xi, A_K^*y\rangle, \qquad \langle\langle A^{*'}x, y\rangle\rangle = \langle x, A^*y\rangle\,.$$

We shall prove that

$$\langle D_Kv, A_K^*y\rangle = \langle A_K^{-1}ADv, A_K^*y\rangle = \langle Dv, A^*y\rangle\,. \tag{29}$$

This equality being granted, we have

$$\begin{aligned}\langle \xi, A_K^*y\rangle &= \langle \zeta - D_Kv, A_K^*y\rangle = \langle \zeta, A_K^*y\rangle - \langle D_Kv, A_K^*y\rangle\\ &= \langle (I-DK)\zeta, A^*y\rangle - \langle Dv, A^*y\rangle = \langle \zeta - D[K\zeta + v], A^*y\rangle\\ &= \langle \zeta - Du, A^*y\rangle = \langle x, A^*y\rangle\end{aligned}$$

as wanted. It remains to be proven that (29) holds if $y \in \mathrm{dom}A^*$.

We noted that the vector $A_K^{-1}ADv = (A_K^{*'})^{-1}A^{*'}Dv$ belongs to X. This means that the operator $A^{*'}Dv$, which is an element of $(\mathrm{dom}A^*)'$, is extensible to $(\mathrm{dom}A_K^*)$ and $\langle A_K^{-1}ADv, A_K^*y\rangle$ is the action of $ADv = A^{*'}Dv$ as an element of $(\mathrm{dom}A_K^*)'$ on $y \in \mathrm{dom}A^* \subseteq \mathrm{dom}A_K^*$. The value taken by $A^{*'}Dv$ on y is equal to $\langle Dv, A^*y\rangle$ as wanted. This completes the proof. ∎

The proved equality justifies (28).

Now we consider the frequency domain inequality (FDC) for (ASS), i.e.,

$$F(\xi + D_Kv, v + K(\xi + D_Kv)) \geq 0 \quad \text{if } i\omega(\xi + D_Kv) = A_K\xi\,. \tag{30}$$

More explicitly, with ζ, x, u defined in (27),

$$F(\xi + D_Kv, v + K(\xi + D_Kv)) = F(\zeta, v + K\zeta) = F(x + Du, u) \geq 0$$

if $Ax = A_K\xi = i\omega(\xi + D_Kv) = i\omega(x + Du)$.

An important consequence of the (FDC) is easily seen from (30). We fix v and we read (30) with

$$\xi = \xi(\omega) = -(i\omega I - A_K)^{-1}i\omega D_Kv\,.$$

Hence, $\lim_{|\omega|\to+\infty}\xi(\omega) = -D_K v$ so that

$$F(\xi(\omega) + D_K v,\, v + K[\xi(\omega) + D_K v]) \to F(0, v) = \langle v, Rv\rangle,$$

and we get the following theorem.

THEOREM 8. *The condition $R \geq 0$ is implied by Property P*1.

5. Scalar systems: Spectral factorization and the Lur'e problem. In this section we solve the Lur'e problem. Hence, we assume that the conditions in Theorem 2 are satisfied. The proof makes use of the same ideas as in [1] so that the first step is the construction of the spectral factorization of the positive Popov function. This part of the proof follows ideas which are completely different from those in [1]. The demanding assumption 4 is not used in this part of the proof. But, the assumption that the semigroup is holomorphic is explicitly used.

5.1. Spectral factorization of $P(i\omega)$. In this section we put ourselves in the following case, which is in particular the case of the augmented system (SAS) when the control is scalar.

(i) The control u enters as a distributed control and takes scalar values.
(ii) The semigroup generated by A is holomorphic and stable.
(iii) The Popov function is not identically zero.

We prove the following fact.

THEOREM 9. *Under the previous assumptions, and if $P(i\omega) \geq 0$ for each real ω, there exists a function $M_0(i\omega)$ which is holomorphic and bounded in $\Re e\, z > 0$ and such that*

$$P(i\omega) = M_0^*(i\omega) M_0(i\omega)\,.$$

We use a penalization method for the proof. We consider the sequence of Popov functions

$$P_n(z) = P(z) + \frac{1}{n}$$

which correspond to the "penalized" cost obtained by the addition of $\frac{1}{n}\|u\|^2$ to (QFS). We said already that the extension $P(z)$ is holomorphic (and bounded) in a strip $|\Re e\, z| < \epsilon$. In this strip $|P_n(z)|$ is bounded by $\max|P(z)| + 1$. In particular, it is uniformly bounded with respect to n.

We can exhibit explicitly a spectral factorization of the function $P_n(z)$. This function satisfies the conditions in Theorem 2 of [14] so that there exists a stabilizing solution W_n of the corresponding dissipation inequality. We use this solution in order to construct the factor

$$M_n(z) = \frac{1}{\sqrt{n}} + \sqrt{n}\mathcal{D}^* W_n [zI - \mathcal{A}_{\mathcal{S}}]^{-1}\mathcal{D}\,.$$

The function $M_n(z)$ is holomorphic and bounded in $\Re e\, z > 0$. It is easily seen, as for finite dimensional systems, that

$$P_n(i\omega) = |M_n(i\omega)|^2\,. \tag{31}$$

In fact, it happens that W_n solves the Riccati equation

$$\langle \mathcal{A}_{\mathcal{S}} X, W_n Y\rangle + \langle W_n X, \mathcal{A}_{\mathcal{S}} Y\rangle + \langle X, \mathcal{Q} Y\rangle = \langle X, W_n \mathcal{D}^* n \mathcal{D} W_n Y\rangle \qquad \forall X, Y \in \mathrm{dom}\mathcal{A}_{\mathcal{S}}$$

so that we have also

$$(i\omega I + \mathcal{A}_{\mathcal{S}}{}^*)^{-1} W_n \mathcal{D}^* n \mathcal{D} W_n (i\omega I - \mathcal{A}_{\mathcal{S}})^{-1}$$
$$= W_n (i\omega I - \mathcal{A}_{\mathcal{S}})^{-1} - (i\omega I + \mathcal{A}_{\mathcal{S}}{}^*)^{-1} W_n + (i\omega I + \mathcal{A}_{\mathcal{S}}{}^*)^{-1} \mathcal{Q} (i\omega I - \mathcal{A}_{\mathcal{S}})^{-1}.$$

Once this formula is known, a direct computation shows (31). Furthermore, $M_n^{-1}(z)$ is holomorphic and bounded in the right half plane:

$$M_n^{-1}(z) = \sqrt{n} - n^{3/2} \mathcal{D}^* W_n (zI - \mathcal{A}_{\mathcal{S}} - \sqrt{n} \mathcal{D} \mathcal{D}^* W_n)^{-1} \mathcal{D}.$$

The proof that the previous function is the inverse of $M_n(z)$ is based on the second resolvent identity, [7, p. 197, Theorem 5.103].

The boundedness of $M_n^{-1}(z)$ shows that the function $M_n(z)$ is an *outer* function.

The fact that $M_n(z)$ is holomorphic and bounded in $\Re e\, z > 0$ shows that for each z we have

$$\sup_{\Re e\, z>0} \|M_n(z)\|^2 = \sup_{\omega \in \mathbb{R}} |M_n(i\omega)|^2 = \sup_{\omega} \|P(i\omega) + 1/n\| \leq 1 + \|P(\cdot)\|_\infty . \tag{32}$$

Montel's theorem [3, p. 153] shows that $M_n(z)$ has a subsequence, still denoted $\{M_n(z)\}$, which converges to an H^∞ function $M_0(z)$ *uniformly on compact sets of* $\Re e\, z > 0$. We noted that boundedness holds in a strip around the imaginary axis, too, so that $\{M_n(z)\}$ converges to $M_0(z)$ for $\Re e\, z > -\epsilon$, $\epsilon > 0$, uniformly on compact sets.

It follows that $M_0(i\omega)$ is *continuous on the imaginary axis* and $|P(i\omega)| = |M_0(i\omega)|^2$.

We noted that the functions $M_n(z)$ are *outer* functions. We prove that $M_0(z)$ is an outer function, too.

We invoke a characterization of outer functions from [6, Theorem 4.6]. A function $L(z)$ is outer if and only if there exists a particular $z = x + iy$ with $x > 0$ such that the following equality holds:

$$\log |L(z)| = \frac{1}{\pi} \int_{-\infty}^{+\infty} \log |L(it)| \frac{x}{x^2 + (y-t)^2} \, \mathrm{d}\, t \,. \tag{33}$$

In fact, if the previous equality holds for one z it holds for every z such that $\Re e\, z > 0$.

The function $M_0(z)$ is not zero since we are assuming that the Popov function is not identically zero. Hence there exists a point x_0 of the real axis in which $M_0(x_0) \neq 0$. Also, the functions $M_n(\cdot)$ are not zero in this point since an outer function is never zero in the right half plane. Moreover, (33) holds for every $M_n(\cdot)$ and $M_n(x_0) \to M(x_0)$, so that $\log |M_n(it)| \to \log |M_0(it)|$ for each t. We prove that

$$\int_{-\infty}^{+\infty} \log |M_n(it)| \frac{x_0}{x_0^2 + t^2} \, \mathrm{d}\, t \longrightarrow \int_{-\infty}^{+\infty} \log |M_0(it)| \frac{x_0}{x_0^2 + t^2} \, \mathrm{d}\, t \,.$$

For this, we introduce the functions $\log^+ a = \max\{0, \log a\}$ and $\log^- a = \min\{0, \log a\}$. We note that $\log^+ |M_n(it)|$ is nonnegative and bounded above, since $\{M_n(it)\}$ is bounded. The *dominated convergence theorem* shows that

$$\int_{-\infty}^{+\infty} \log^+ |M_n(it)| \frac{x_0}{x_0^2 + t^2} \, \mathrm{d}\, t \to \int_{-\infty}^{+\infty} \log^+ |M_0(it)| \frac{x_0}{x_0^2 + t^2} \, \mathrm{d}\, t \,.$$

In order to show the corresponding convergence for the integrals with $\log^-$ we invoke the *monotone convergence theorem.*

By assumption, $P(it) \geq 0$ so that

$$|M_n(it)| = \left[P(it) + \frac{1}{n}\right]^{1/2} \geq \left[P(it) + \frac{1}{n+1}\right]^{1/2} = |M_{n+1}(it)|\,.$$

Hence, $\{|M_n(it)|\}$ is a *decreasing* sequence of functions. Consequently, $\{\log^- |M_n(it)|\}$ is a *decreasing sequence* of *negative* functions. Convergence of the integrals follows from monotone convergence theorem.

Consequently we proved the following.

THEOREM 10. *The function $M_0(i\omega)$ is an outer factor of $P(i\omega)$ and $P(i\omega) = |M_0(i\omega)|^2$.*

COROLLARY 11. *The factor $M_0(z)$ does not have zeros in $\Re e\, z > 0$. Moreover, the function $M_0(z)$ belongs to H^2 of the right half plane.*

Proof. The first statement follows since an outer function does not have unstable zeros. The second statement follows since when $R = 0$ we have from (23) that

$$|M_0(i\omega)|^2 = |P(i\omega)| \leq \frac{K}{|\omega|^2}$$

and $M_0(i\omega)$ is continuous; in particular it is continuous for $\omega = 0$.

This shows that $M_0(z)$ is H^∞ and square integrable on the imaginary axis; hence it is H^2. □

COROLLARY 12. *The function $M_0(z)$ is the Laplace–Fourier transformation of a function $\check{M}_0(t)$ whose support is in $t \geq 0$ and which is square integrable.*

Of course, we are not asserting that the factor $M(z)$ has an inverse in H^∞.

5.2. The Lur'e problem. In this section we prove Theorem 2. As we said, we use the same method as in [1]; hence we make use of the factorization of $\Pi(i\omega)$ found in the previous section, with the properties in Corollaries 11 and 12. Moreover, we prefer again to work with the stabilized augmented system so that we show that there exists an operator W which solves the Lur'e equation (LuE),

$$2\Re e\, \langle \mathcal{A}_{\mathcal{S}}\Xi, W\Xi\rangle + \langle \Xi, \mathcal{Q}\Xi\rangle \geq 0 \quad \forall \Xi \in \mathrm{dom}\mathcal{A}_{\mathcal{S}}\,, \qquad W\mathcal{D} = 0\,. \tag{LuE}$$

Here $\mathcal{Q}$ is the operator matrix of the functional (QFS) (see (23)) and $\mathcal{D}$ is the input operator which is now a vector in $X \times \mathbb{C}$ since we are considering scalar controls.

We prove the following lemmas first.

LEMMA 13. *Let the assumptions of Theorem 2 hold. Then there exist a number $c > 0$ and a number $\gamma < 1/2$ such that $|\bar{z}_k|^{1+\gamma}|M_0(-\bar{z}_k)| > c$.*

Proof. We assume first that $\Pi(i\omega)$ does not have $i\omega$-axis zeros. Later we remove this assumption.

We recall the assumptions that

$$\left|\frac{y_k}{x_k}\right| < \mu, \qquad \Pi(i\omega) > \frac{\mathrm{const}}{\omega^\beta}\,,\ \beta < 1\,.$$

Moreover, we recall that $P(i\omega) = \Pi(i\omega)/(1+\omega^2)$ so that there exists $s < 3$ such that

$$P(i\omega)|\omega|^s > k > 0. \tag{34}$$

We can assume that the previous estimate holds for each ω since we consider the case in which the Popov function does not have zeros on the imaginary axis.

Let us recall that $-\bar{z}_k = x_k + iy_k$, $x_k > 0$.

We know that $M_0(z)$ is an outer function so that from [6] we know that

$$\log|M_0(-\bar{z}_k)| = \frac{1}{\pi}\int_{-\infty}^{+\infty} \log P(it)^{1/2} \frac{x_k}{x_k^2 + (y_k - t)^2}\, \mathrm{d}\, t,$$

and also

$$\log\{|\bar{z}_k|^{1+\gamma}|M_0(-\bar{z}_k)|\} = \frac{1}{\pi}\int_{-\infty}^{+\infty} \log|\bar{z}_k|^{1+\gamma} P(it)^{1/2} \frac{x_k}{x_k^2 + (y_k - t)^2}\, \mathrm{d}\, t$$

$$= \frac{1}{\pi}\int_{-\infty}^{+\infty} \log|\bar{z}_k|^{\gamma+1} P(i[y_k - tx_k])^{1/2} \frac{1}{1+t^2}\, \mathrm{d}\, t$$

$$= \frac{1}{2\pi}\int_{-\infty}^{+\infty} \log \frac{[x_k^2 + y_k^2]^{\gamma+1}}{|y_k - tx_k|^s} \left[|y_k - tx_k|^s P(i[y_k - tx_k])\right] \frac{1}{1+t^2}\, \mathrm{d}\, t \tag{35}$$

$$= \frac{1}{2\pi}\int_{-\infty}^{+\infty} \log \frac{[x_k^2 + y_k^2]^{\gamma+1}}{|y_k - tx_k|^s} \frac{1}{1+t^2}\, \mathrm{d}\, t \tag{36}$$

$$+\frac{1}{2\pi}\int_{-\infty}^{+\infty} \log \left[|y_k - tx_k|^s P(i[y_k - tx_k])\right] \frac{1}{1+t^2}\, \mathrm{d}\, t. \tag{37}$$

The integral in (37) is bounded from below by $(\log k)/2$; see (34).

We write the integral in (36) as follows:

$$\int_{-\infty}^{+\infty} \log \frac{[x_k^2 + y_k^2]^{\gamma+1}}{|y_k - tx_k|^s} \frac{1}{1+t^2}\, \mathrm{d}\, t$$

$$= \pi \log x_k^{2(\gamma+1)-s} + \pi \log \left[1 + \left(\frac{y_k}{x_k}\right)^2\right]^{\gamma+1} - s\int_{-\infty}^{+\infty} \log\left|\frac{y_k}{x_k} - t\right| \frac{1}{1+t^2}\, \mathrm{d}\, t\,.$$

It is now sufficient to notice that the last integral is bounded from above (so that minus the integral is bounded from below). This is clear since

$$\log\left|\frac{y_k}{x_k} - t\right| \le \log(\mu + t)\,.$$

The second addendum is nonnegative and $\log x_k^{2(\gamma+1)-s}$ is bounded from below if $2(\gamma+1) - s \ge 0$. We know that $s = 3 - \epsilon$ so that γ must satisfy $\gamma > \frac{1}{2} - \epsilon/2$. In particular there exists $\gamma < 1/2$ with this property.

Now we remove the assumption that $\Pi(i\omega)$ does not have imaginary axis zeros. By assumption, the zeros on the imaginary axis must be finite in number since we assumed inequality (34) for large $|\omega|$. Hence, it is sufficient to show how one of them, say it_0, can be handled. Moreover, we can confine ourselves to consider only those z_k with $|z_k|$ large. Hence we consider z_k such that $|t_0/z_k| < 1/2$.

A zero t_0 of $P(i\omega)$ must have even multiplicity $2n$. We remove the zero by multiplying and dividing the term $P(i\omega)$ by the factor

$$\left[\frac{1 + i(t - t_0)}{t - t_0}\right]^{2n}.$$

It is still true that

$$|t|^s \left[\frac{|1 + i(t - t_0)|}{|t - t_0|}\right]^{2n} P(it) > m > 0\,.$$

We replace the integrand in (35) with

$$\log\left\{\frac{[x_k^2+y_k^2]^{\gamma+1}}{|y_k-tx_k|^s}\frac{|y_k-tx_k-t_0|^{2n}}{|1+i(y_k-tx_k-t_0)|^{2n}}\right.$$
$$\left.\cdot\frac{|1+i(y_k-tx_k-t_0)|^{2n}}{|y_k-tx_k-t_0|^{2n}}|y_k-tx_k|^s P(i[y_k-tx_k])\right\}.$$

This operation replaces the integral (37) with

$$\int_{-\infty}^{+\infty}\log|y_k-tx_k|^s\left\{\frac{|1+i[y_k-tx_k]-it_0|}{|y_k-tx_k-t_0|}\right\}^{2n}P(i[y_k-tx_k])\frac{1}{1+t^2}\,\mathrm{d}\,t,$$

which is larger than $\frac{1}{2}\log m$; this operation produces a new addendum,

$$\frac{1}{2\pi}\int_{-\infty}^{+\infty}\log\left|\frac{y_k-tx_k-t_0}{1+i[y_k-tx_k]-it_0}\right|^{2n}\frac{1}{1+t^2}\,\mathrm{d}\,t$$
$$=\frac{n}{\pi}\int_{-\infty}^{+\infty}\log\left|\frac{i(t-t_0)}{1+i(t-t_0)}\right|\frac{x_k}{x_k+(t-y_k)^2}\,\mathrm{d}\,t=\log\left|\frac{z_k-it_0}{1+z_k-it_0}\right|,$$

since the function $\frac{z-it_0}{1+z-it_0}$ is H^∞ and outer. Boundedness from below follows since

$$\left|\frac{z_k-it_0}{z_k+1-it_0}\right|\geq\frac{1}{2}\frac{1}{1+|1-it_0|/|\tilde{z}|},$$

where $\tilde{z}$ is one of the points $-\bar{z}_k$ with minimal norm among those for which $|\frac{t_0}{z_k}|<1/2$.

This completes the proof. □

Now we prove the following.

LEMMA 14. *There exists a vector $q\in(\mathrm{dom}(-\mathcal{A}_{\mathcal{S}})^\alpha)'$, $0\leq\alpha<1/2$, which satisfies*

$$\int_0^{+\infty}e^{\mathcal{A}_{\mathcal{S}}{}^*t}q\check{M}_0(t)\;dt=\int_0^{+\infty}e^{\mathcal{A}_{\mathcal{S}}{}^*t}\mathcal{Q}e^{\mathcal{A}_{\mathcal{S}}t}\mathcal{D}\;dt\,. \tag{38}$$

This vector q also satisfies

$$\check{M}_0(t)=\begin{cases}\langle\mathcal{D},e^{\mathcal{A}_{\mathcal{S}}{}^*t}q\rangle & \text{if}\quad t>0,\\ 0 & \text{if}\quad t<0\,.\end{cases}$$

Proof. We note that the integral on the left of (38) makes sense for every $q\in(\mathrm{dom}(-\mathcal{A}_{\mathcal{S}}{}^*)^\alpha)'$ if $\alpha<1/2$, since we know that $\check{M}_0(t)$ is square integrable. In fact, it is known that

$$\|(-\mathcal{A}_{\mathcal{S}}{}^*)^\alpha e^{\mathcal{A}_{\mathcal{S}}{}^*t}\|\leq\frac{\mathrm{const}}{t^\alpha}e^{-\sigma t}$$

for a positive number σ; see [21]. For this same reason the integral on the right side defines a vector in $\mathrm{dom}(-\mathcal{A}_{\mathcal{S}}{}^*)^{1-\epsilon}$ for each $\epsilon>0$; see [10, part 1, Theorem 2.8]. Consequently, we must solve an equation of the form

$$\int_0^{+\infty}e^{\mathcal{A}_{\mathcal{S}}{}^*t}q\check{M}_0(t)\,\mathrm{d}\,t=(-\mathcal{A}_{\mathcal{S}}{}^*)^{-(1-\epsilon)}l \tag{39}$$

for a given vector $l\in X$.

We introduce the basis v_k of the eigenvectors of $\mathcal{A}_\mathcal{S}$. We multiply scalarly both sides of (39) by v_k. We put $l_k = \langle v_k, l\rangle$ and $q_k = \langle v_k, (-\mathcal{A}_\mathcal{S}^*)^{-\alpha} q\rangle = \langle v_k, \tilde{q}\rangle$, $\tilde{q} \in X$. We see that q is a solution if and only if

$$\frac{1}{(-z_k)^{1-\epsilon}} l_k = \int_0^{+\infty} \langle (-\mathcal{A}_\mathcal{S})^\alpha e^{\mathcal{A}_\mathcal{S} t} v_k, \tilde{q}\rangle \overline{\check{M}_0(t)}\, \mathrm{d}\, t \tag{40}$$

$$= (-z_k)^\alpha \overline{M}_0(-z_k) q_k\,. \tag{41}$$

This shows that q_k is well defined:

$$q_k = \frac{1}{(-z_k)^{\alpha+1-\epsilon}\overline{M_0(-\bar{z}_k)}} l_k\,.$$

In fact, $M_0(z)$ does not have zeros in the right half plane, since it is an outer function. In order to prove the existence of q we must ascertain that the sequence $\{q_k\}$ belongs to l^2, i.e., that the sequence $\{M_0(-\bar{z}_k)(-z_k)^{\alpha+1-\epsilon}\}$ is bounded away from zero, since we know that $\{l_k\}$ belongs to l^2. This follows from the previous lemma with $\alpha = \gamma + \epsilon$. We know that it is possible to choose $\gamma < \frac{1}{2}$ so that α can be chosen less then $\frac{1}{2}$ too, since the positive number ϵ is arbitrary.

Now we prove the formula for $\check{M}_0(t)$. We introduce the functions

$$K(t) = \begin{cases} e^{\mathcal{A}_\mathcal{S} t}\mathcal{D} & \text{if} \quad t > 0, \\ 0 & \text{if} \quad t < 0\,, \end{cases} \qquad H(t) = \begin{cases} \mathcal{Q} e^{\mathcal{A}_\mathcal{S} t}\mathcal{D} & \text{if} \quad t > 0, \\ 0 & \text{if} \quad t < 0\,, \end{cases}$$

and we consider the Fourier transformation of

$$t \to \int_0^{+\infty} \langle K(s), H(t+s)\rangle\, \mathrm{d}\, s, \tag{42}$$

which is $P(-i\omega)$, i.e., $M^*(-i\omega)M(-i\omega)$. This is also the Fourier transformation of

$$\int_0^{+\infty} \check{M}_0(s)\overline{\check{M}_0(t+s)}\, \mathrm{d}\, s\,. \tag{43}$$

We replace $K(\cdot)$ and $H(\cdot)$ with their expressions and we use (38). We see that the difference of the integrals in (42) and (43) is

$$\int_0^{+\infty} \{\check{M}_0(t+s) - \langle \mathcal{D}, e^{\mathcal{A}_\mathcal{S}^*(t+s)} q\rangle\} \overline{\check{M}_0(s)}\, \mathrm{d}\, s$$

for each t, and it is identically zero since both integrals are equal to $P(-i\omega)$.

The function $M_0(z)$ has a set of zeros of null measure, since it is a nonzero H^∞ function, and this implies that the brace is zero a.e., as wanted. □

Now we define W:

$$\langle \Xi', W\Xi\rangle = \int_0^{+\infty} \langle \Xi', e^{\mathcal{A}_\mathcal{S}^* t}\mathcal{Q} e^{\mathcal{A}_\mathcal{S} t}\Xi\rangle\, \mathrm{d}\, t - \int_0^{+\infty} \langle \Xi', e^{\mathcal{A}_\mathcal{S}^* t} q\rangle \cdot \overline{\langle \Xi, e^{\mathcal{A}_\mathcal{S}^* t} q\rangle}\, \mathrm{d}\, t\,.$$

The last integral makes sense since each factor is square integrable.

For each $\Xi \in \mathrm{dom}\mathcal{A}_\mathcal{S}$, we have

$$2\Re e\, \langle \mathcal{A}_\mathcal{S}\Xi, W\Xi\rangle = -\langle \Xi, \mathcal{Q}\Xi +\rangle + |\langle\langle \Xi, q\rangle\rangle|^2 \geq -\langle \Xi, \mathcal{Q}\Xi\rangle$$

and

$$\langle \Xi, W\mathcal{D}\rangle = \int_0^{+\infty} \langle e^{\mathcal{A}_S t}\Xi, \mathcal{Q}e^{\mathcal{A}_S t}\mathcal{D}\rangle \,\mathrm{d}\,t - \int_0^{+\infty} \langle \Xi, e^{\mathcal{A}_S{}^* t}q\rangle\overline{\langle e^{\mathcal{A}_S{}^* t}q, \mathcal{D}\rangle} \,\mathrm{d}\,t$$
$$= \int_0^{+\infty} \langle e^{\mathcal{A}_S t}\Xi, \mathcal{Q}e^{\mathcal{A}_S t}\mathcal{D}\rangle \,\mathrm{d}\,t - \int_0^{+\infty} \langle \Xi, e^{\mathcal{A}_S{}^* t}q\rangle\overline{\check{M}_0(t)} \,\mathrm{d}\,t = 0\,,$$

as wanted. This ends the proof of the existence of solutions to the Lur'e problem (LuE).

Acknowledgment. The author thanks the referee for useful comments, which improved the style of the paper.

VALUATION OF INVESTMENTS IN REAL ASSETS WITH IMPLICATIONS FOR THE STOCK PRICES*

THOMAS S. KNUDSEN†, BERNHARD MEISTER‡, AND MIHAIL ZERVOS§

Abstract. A general model for the valuation of natural resource investments is formulated and analyzed within a stochastic control theoretic framework. Using dynamic programming, the value of such an investment with a general payoff function is determined under the assumption that the commodity price process is given by a stochastic differential equation. The analysis results in closed form analytic solutions which can easily be computed and exhibits qualitatively different optimal behaviors, depending on parameter values. Implications for stocks and options are also considered.

Key words. stochastic control, optimal stopping, real assets, options

1. Introduction.

The area of *real options* has recently attracted considerable interest (see Dixit and Pindyck [12] for a review). This approach to contractual claims on real assets concentrates on their optionlike characteristics and uses option theory to evaluate them. Techniques which are similar to the ones developed in finance, especially to the seminal results of Black and Scholes, offer a new perspective and turn out to be very useful in the valuation of investment decisions in industry. To some extent, the same is true for the dynamic programming approach. Unlike the traditional but, in some ways, still orthodox net present value approach, the real options approach, as well as the dynamic programming approach can incorporate some of the uncertainty, irreversibility, and timing on which investment decisions depend.

In this paper, dynamic programming is used to study investments in industry and, in particular, in the natural resource industry. More specifically, we consider the problem of evaluating an investment in industry under the assumptions that it produces a single commodity and its value depends on the commodity price as well as on the way in which production is scheduled. Our model generalizes the one studied in section 6.3 of Dixit and Pindyck [12], notably in the directions of adding an abandonment option and of considering a much more general running payoff function. With reference to the natural resource industry, our model is closely related to the model studied by Brennan and Schwartz [7] using the contingent claim approach and which was further analyzed by Paddock, Siegel, and Smith [20]. Also, other related models have been studied by McDonald and Siegel [19], Pindyck [21], Dixit [11], Cortazar and Schwartz [9], Brekke and Øksendal [6], and Shirakawa [23]. At this point, it is important to emphasize that despite adopting the dynamic programming

approach, we have implicitly solved the problem for the contingent claim approach as well, provided the convenience yield of the commodity is constant. Further information regarding this point can be found in Paddock, Siegel, and Smith [20] and the references therein, as well as in Dixit and Pindyck [12]; following either of the two approaches, the value of the project/firm is shown to satisfy equivalent nonlinear differential equations which are connected by a simple change of variables which involves only trivial algebra.

Apart from giving a price for an investment, our analysis also addresses the question of how production should be optimally scheduled. Our model is formulated as a stochastic control problem in which one has to decide on the production rate (i.e., the production per time unit) and the project's abandonment time. With regard to the production rate level, we make the assumption that this can be changed instantly and without cost to any value within a given set of admissible values. Also, with reference to the natural resource industry, we assume that the investment/firm under consideration has access to an infinite amount of the resource. Undoubtedly, this assumption is unrealistic from the perspective of a specific investment. However, it provides a certain approximation of reality which is further supported by the fact that we obtain easily computable results in a closed analytic form (see also the discussion at the end of section 2).

The first step of our analysis is to establish the dynamic programming equation, which is a variational inequality of the form encountered in the theory of optimal stopping. Optimal stopping problems have been addressed by many authors in numerous papers. Notable contributions to the solution of the general problem with a probabilistic approach include Fakeev [14], Bismut and Skalli [5], El Karoui [13] and a number of references therein. In a Markovian setting, Bensoussan and Lions [3] and Krylov [18] have studied optimal stopping problems and have proved under very general conditions that the corresponding value functions satisfy appropriate variational inequalities. In this paper, we will adopt an approach which is classical in the theory of stochastic optimal control (see, for example, Fleming and Soner [15, section IV.3] and which consists of finding a solution of the dynamic programming differential equation which satisfies the assumptions of a "verification theorem" which identifies this solution with the control problem's value function. In particular, we prove an appropriate "verification theorem," we explicitly solve the dynamic programming differential equation, and we derive an optimal strategy. An important feature of our results is that the optimal strategy can take qualitatively different forms, depending on parameter values. It is worth mentioning that similar analyses of related problems have been made by Brekke and Øksendal [6], who study a very general model of optimal switching related to investment decisions, and Davis and Zervos [10], who study a problem of combined singular stochastic control and optimal stopping.

Our analysis has a further implication. By deriving a value which is dependent solely on the commodity price, a connection between asset valuation and equity prices is established. In order to fix ideas, consider a company which produces a single commodity and whose total asset value uncertainty depends only on the uncertainty linked with the commodity price (e.g., the firm does not have debt). By assigning an asset value $v(x)$ to such a company, given that the commodity price is x, we obtain an expression for the company's stock price in terms of the commodity price. Furthermore, under the assumption that the commodity price follows a geometric Brownian motion, we show that the company's asset value, and therefore its stock price, is *not* a geometric Brownian motion (note that in Bensoussan, Crouhy, and Galai [1], [2], a similar observation is made for the stock price of a firm for which the total asset value is debt and equity, and the total asset value follows a geometric

Brownian motion). However, we show that, for the simplest case considered here, the Black & Scholes formula can be used to calculate an upper bound for the value of a European option on the stock of the company, as well as an approximate value for such options which is valid for short times to maturity and high commodity prices. At this point, it is worth noting that the idea of establishing a connection between a firm's total asset value and the firm's stock price under various conditions is not novel. For example, in [1], [2] an extensive analysis in this direction is carried out. However, a central drawback of these analyses is the simplifying assumption that the company's asset value always follows a geometric Brownian motion.

The paper is organized as follows. In section 2, a stochastic control problem which models the decisions on how to optimally schedule production and on which the foundations of our analysis are laid is formulated and discussed. Section 3 is concerned with establishing the Hamilton–Jacobi–Bellman (HJB) equation, which takes the form of a variational inequality, and proving a general existence result, whereas in section 4, an associated ODE is studied. The HJB equation is explicitly solved and the optimal strategy is derived in section 5 under certain additional hypotheses, whereas in section 6, the solution is further developed for a special case which arises in the comparison of our model to the model developed by Brennan and Schwartz [7] and which has special significance for the natural resource industry. In section 7, a European option written on the firm's stock is analyzed. Finally, section 8 contains a summary of our results as well as a description of certain possible extensions of our research.

2. Formulation of the control problem. Let $(\Omega, \mathcal{F}, P)$ be a probability space equipped with a filtration $(\mathcal{F}_t)$ satisfying the usual conditions of right continuity and augmentation by P-negligible sets and carrying a standard one-dimensional $(\mathcal{F}_t)$-Brownian motion W. We will denote by $\mathcal{T}$ the set of all $(\mathcal{F}_t)$-stopping times and by $\mathcal{C}$ the set of all progressively measurable processes U with values in a compact subset of the real line $\mathcal{U}$.

We model the *commodity price* by the solution of the SDE

$$dX_t = b(X_t)dt + \sigma(X_t)dW_t \ , \qquad X_0 = x > 0 \ , \tag{2.1}$$

where the following assumption holds.

Assumption A1. $b, \sigma : \mathbb{R}_+ \to \mathbb{R}_+$ are given functions such that (2.1) has a unique strong solution with values in $]0, \infty[$, P-almost surely (a.s.).

Specific assumptions under which (2.1) has a unique solution can be found in any book treating the subject of SDEs (e.g., see Corollary 5.5.16 and Proposition 5.5.17 in Karatzas and Shreve [16], or Theorem IX.3.5 in Revuz and Yor [22]), whereas Feller's Test for Explosions (see [16, Theorem 5.5.29]) yields necessary and sufficient conditions for the solution of (2.1) to have values in $]0, \infty[$, P-a.s.

A *production rate process* will be any process $U \in \mathcal{C}$, whereas an *abandonment time* will be any stopping time $\tau \in \mathcal{T}$. The set of *admissible strategies* Π will be the family of all pairs (U, τ) such that $U \in \mathcal{C}$ and $\tau \in \mathcal{T}$.

With any admissible strategy $(U, \tau) \in \Pi$, we associate the payoff

$$J_x(U, \tau) = E\left\{ \int_0^\tau e^{-rt} \overline{h}(X_t, U_t)dt + \mathrm{I}_{\{\tau < \infty\}} e^{-r\tau} g(X_\tau) \right\} \ , \tag{2.2}$$

where $\overline{h} :]0, \infty[\times \mathcal{U} \to \mathbb{R}$ and $g :]0, \infty[\to \mathbb{R}$ are given functions; given $(x, u) \in]0, \infty[\times \mathcal{U}$, $\overline{h}(x, u)$ represents the *running payoff* resulting if the commodity price is x and the production rate is u, whereas $-g(x)$ represents the project's *abandonment*

cost. Note that, from a financial point of view, the abandonment cost should not depend on the commodity price, and so, as far as modeling is concerned, g should be a constant. However, for the part of our analysis that we shall consider nonconstant g, such a generality adds no extra cost. The objective of the control problem is to maximize $J_x(U,\tau)$ over Π. Accordingly, we define the value function v by

$$v(x) = \sup_{(U,\tau)\in\Pi} J_x(U,\tau) \ . \tag{2.3}$$

The following assumptions on $\overline{h}$ and g will ensure that the optimization problem is well posed in the sense that there are no policies with infinite payoff. (Obviously, any project in the real world complies with such a restriction.)

Assumption A2. The running payoff function $\overline{h}$ is upper semicontinuous and if $h :]0,\infty[\to\mathbb{R}$ is the function defined by

$$h(x) := \max_{u\in\mathcal{U}} \overline{h}(x,u) \ , \tag{2.4}$$

then

$$E\int_0^\infty e^{-rt}|h(X_t)|dt < \infty \tag{2.5}$$

for every initial condition $x > 0$. Also, given any $x > 0$, the abandonment payoff g satisfies

$$E \operatorname*{ess\,sup}_{\tau\in\mathcal{T}} \left\{ \mathrm{I}_{\{\tau<\infty\}} e^{-r\tau} |g(X_\tau)| \right\} < \infty \ . \tag{2.6}$$

Note that since $\overline{h}$ is upper semicontinuous, h is upper semicontinuous as well (see Bertsekas and Shreve [4, Proposition 7.32]). Moreover (see [4, Proposition 7.33]), there exists a Borel measurable $u :]0,\infty[\to\mathcal{U}$ such that

$$h(x) = \overline{h}(x,u(x)) \ . \tag{2.7}$$

The very general Assumptions A1 and A2 will be used to prove part of the results of section 3. In the same section, we will obtain a general existence result under the following additional assumption.

Assumption A3. The functions b, σ, h are twice continuously differentiable,

$$\sigma(x) > 0 \qquad \forall x \in]0,\infty[\ ,$$

and there exist constants C, k such that $\forall x, y \in]0,\infty[$

$$|b(x) - b(y)| + |\sigma(x) - \sigma(y)| \le C|x - y| \ ,$$

$$|b'(x)| + |b''(x)| + |\sigma'(x)| + |\sigma''(x)| \le C(1 + x^k) \ ,$$

$$|h(x)| + |h'(x)| + |h''(x)| + |g(x)| + g'(x)| + |g''(x)| \le C(1 + x^k) \ .$$

The analysis of sections 4–7 will assume that the commodity price follows a geometric Brownian motion, that g is constant, and that $\overline{h}$ satisfies some different conditions. More specifically, we will impose the following assumptions.

Assumption A4.a. The functions b, σ are given by $b(x) = bx$, $\sigma(x) = \sqrt{2}\sigma x$, for some constants b, σ.

Assumption A4.b. The function $\overline{h}$ is upper semicontinuous, and if h is defined by (2.4), then h is increasing and satisfies (2.5) as well as $\lim_{x\to\infty} h(x) = \infty$. Also, $g \equiv K$ for some constant $K \in \mathbb{R}$.

The additional hypotheses on $\overline{h}$ are satisfied in all economically sensible cases since the running payoff function should be an increasing function of the commodity price and should tend to infinity when the price explodes.

With reference to the natural resource industry, the assumption that an investment/firm has access to an infinite amount of the resource can intuitively be viewed as reasonable as long as either production in the distant future has little effect on the present value due to large discounting or a replacement cost for produced resource has been incorporated into the model through appropriate choice of $\overline{h}$. In the latter case, every unit produced is replaced by a new one which is "added" to the reserves at a given cost (such a cost can account for the exploration and development of new reserves); in effect, the firm would then have an unlimited supply.

3. Existence of an optimal strategy. Consider the control problem described in the previous section. With reference to Assumption A2, since $h(x)$ is the best rate of return given that the commodity price is x, it is intuitively clear that the optimal production process should be indistinguishable from $u \circ X$. In this way, the problem reduces to optimally choosing the abandonment time τ, i.e., to an optimal stopping problem. As a consequence, with reference to standard results of the theory of optimal stopping, we should expect that the value function satisfies the following variational inequality

$$\max\left\{\frac{1}{2}\sigma^2 w'' + bw' - rw + h\ ,\ g - w\right\} = 0\ . \tag{3.1}$$

In general, (3.1) does not admit a unique solution even within the space of infinitely differentiable functions.

Example 3.1. For $\sigma(x) = \sqrt{2}x$, $b(x) = x$, $r = 4$, $h(x) = x$, $g(x) = 0$, it is straightforward to verify that each of the functions defined by

$$w(x) = Ax^2 + Bx^{-2} + \frac{1}{3}x\ ,$$

where $A, B \geq 0$, satisfies (3.1). □

On the other hand, with reference to the theory of optimal stopping, and as we will see in subsequent sections, we should expect that the value function is *not* twice continuously differentiable. For this reason, we consider solutions of the HJB equation (3.1) which belong to a Sobolev space $W^{2,p}_{loc}(]0,\infty[)$, $1 \leq p \leq \infty$. Recall (see, for example, Brezis [8, Chapter VIII]) that a function $w \in W^{2,p}_{loc}(]0,\infty[)$, $1 \leq p \leq \infty$ admits a representative which is continuous with continuous classical first derivative; moreover, it has a second derivative in the sense of distributions which is a function $w'' \in L^p_{loc}(]0,\infty[)$. Therefore, whenever we write $w \in W^{2,p}_{loc}(]0,\infty[)$ we will refer to this continuous representative and we will denote by w' its continuous classical first derivative and by w'' any function which identifies with its distributional second derivative. Also, when we say that $w \in W^{2,p}_{loc}(]0,\infty[)$ satisfies the HJB equation (3.1), we mean that equality holds in (3.1) for Lebesgue almost all x. Of course, since we consider the solvability of (3.1) in $W^{2,p}_{loc}(]0,\infty[)$, we have to *assume* that $g \in W^{2,p}_{loc}(]0,\infty[)$, as long as abandonment can ever be optimal.

Note that identifying the value function of the control problem with a solution of (3.1) in $W^{2,p}_{loc}(]0,\infty[)$ incorporates the so-called smooth pasting condition of optimal stopping which, in the context of the problem studied here, requires that $v'(x) = g'(x)\ \forall x \in \mathcal{S} := \{x \in]0,\infty[:\ v(x) = g(x)\}$ and, in particular, on the boundary of this set. The "smooth pasting condition" is a necessary condition for a wide class of optimal stopping problems; related results can be found in Shiryayev [24, section 3.8] and Krylov [18, Corollary 4.7.9].

We now prove a "verification theorem" that we will use in subsequent sections and which relates the value function of the control problem with a solution of the HJB equation (3.1).

THEOREM 3.2. *Consider the control problem described in section* 2*, and assume that* A1 *and* A2 *hold. Suppose that the HJB equation* (3.1) *has a solution* $w \in W^{2,p}_{loc}(]0,\infty[)$ *for some* $p \in [1,\infty]$ *such that if* M *is the process defined by*

$$M_t = \int_0^t e^{-rs}\sigma(X_s)w'(X_s)dW_s\ , \qquad t \geq 0\ , \tag{3.2}$$

then, for every constant $T > 0$*, the stopped process* M^T *is a martingale. Given any initial condition* $x > 0$*,*

a) $v(x) \leq w(x)$*, and*

b) *if*

$$\liminf_{t\to\infty} e^{-rt}E|w(X_t)| = 0\ , \tag{3.3}$$

then $v(x) = w(x)$ *and the optimal strategy is given by*

$$\tilde{U}_t = u(X_t)\ , \qquad \tilde{\tau} = \inf\{t \geq 0:\ X_t \in \mathcal{S}\}\ , \tag{3.4}$$

where u *satisfies* (2.7) *and* $\mathcal{S} := \{x \in]0,\infty[:\ w(x) = g(x)\}$.

Proof. a) Fix an arbitrary admissible strategy $(U,\tau) \in \Pi$. An application of Itô–Tanaka's formula (see Theorem IV.1.5, Corollary IV.1.6, and the remarks thereafter in Revuz and Yor [22]) yields

$$\begin{aligned} e^{-rt}w(X_t) = w(x) &+ \int_0^t e^{-rs}\left[\frac{1}{2}\sigma^2(X_s)w''(X_s) + b(X_s)w'(X_s) - rw(X_s)\right]ds \\ &+ \int_0^t e^{-rs}\sigma(X_s)w'(X_s)dW_s\ . \end{aligned}$$

This implies that

$$\begin{aligned} &\int_0^{\tau\wedge t} e^{-rs}h(X_s)ds + e^{-r(\tau\wedge t)}g(X_{\tau\wedge t}) \\ &\quad = w(x) + e^{-r(\tau\wedge t)}\left[g(X_{\tau\wedge t}) - w(X_{\tau\wedge t})\right] + \int_0^{\tau\wedge t} e^{-rs}\sigma(X_s)w'(X_s)dW_s \\ &\qquad + \int_0^{\tau\wedge t} e^{-rs}\left[\frac{1}{2}\sigma^2(X_s)w''(X_s) + b(X_s)w'(X_s) - rw(X_s) + h(X_s)\right]ds\ . \end{aligned} \tag{3.5}$$

Since w satisfies (3.1), we obtain

$$\int_0^{\tau\wedge t} e^{-rs}h(X_s)ds + e^{-r(\tau\wedge t)}g(X_{\tau\wedge t}) \leq w(x) + \int_0^{\tau\wedge t} e^{-rs}\sigma(X_s)w'(X_s)dW_s\ .$$

Taking expectations, we find that

$$E\left\{\int_0^{\tau\wedge t} e^{-rs}h(X_s)ds + e^{-r(\tau\wedge t)}g(X_{\tau\wedge t})\right\} \leq w(x)\ .$$

Letting $t \to \infty$, we obtain (by (2.5), (2.6), and the dominated convergence theorem)

$$E\left\{\int_0^{\tau} e^{-rt}h(X_t)dt + \mathrm{I}_{\{\tau<\infty\}}e^{-r\tau}g(X_\tau)\right\} \leq w(x)\ .$$

However, this and the fact that (because of (2.2), (2.7), and (2.4))

$$J_x(U,\tau) \leq E\left\{\int_0^{\tau} e^{-rt}h(X_t)dt + \mathrm{I}_{\{\tau<\infty\}}e^{-r\tau}g(X_\tau)\right\} \tag{3.6}$$

imply that $v(x) \leq w(x)$.

b) If $\tilde{U}$ and $\tilde{\tau}$ are as in (3.4), then (3.5) and (3.1) imply that

$$\begin{aligned}\int_0^{\tilde{\tau}\wedge t} e^{-rs}\overline{h}(X_s,\tilde{U}_s)ds + \mathrm{I}_{\{\tilde{\tau}\leq t\}}e^{-r\tilde{\tau}}g(X_{\tilde{\tau}}) &\\ = \int_0^{\tilde{\tau}\wedge t} e^{-rs}h(X_s)ds + \mathrm{I}_{\{\tilde{\tau}\leq t\}}e^{-r\tilde{\tau}}g(X_{\tilde{\tau}}) &\\ = w(x) - \mathrm{I}_{\{\tilde{\tau}>t\}}e^{-rt}w(X_t) + \int_0^{\tilde{\tau}\wedge t} e^{-rs}\sigma(X_s)w'(X_s)dW_s\ .&\end{aligned}$$

Taking expectations, we obtain

$$E\left\{\int_0^{\tilde{\tau}\wedge t} e^{-rs}\overline{h}(X_s,\tilde{U}_s)ds + \mathrm{I}_{\{\tilde{\tau}\leq t\}}e^{-r\tilde{\tau}}g(X_{\tilde{\tau}})\right\} = w(x) - e^{-rt}E\left\{\mathrm{I}_{\{\tilde{\tau}>t\}}w(X_t)\right\}\ .$$

In view of (3.3), we can pass to the limit $t \to \infty$ through an appropriate sequence to obtain $J_x(\tilde{U},\tilde{\tau}) = w(x)$, which, combined with part a) of the theorem, implies that $v(x) = w(x)$. □

Note that, among other things, the preceding theorem asserts that if the value function of the control problem satisfies the HJB equation (3.1), then it is "minimal" in the set of all solutions of (3.1), which may be uncountably many.

We now have the following existence result.

THEOREM 3.3. *Consider the control problem described in section* 2 *and assume that* A1–A3 *hold. The value function* v *belongs to* $W^{2,\infty}_{loc}(]0,\infty[)$ *and satisfies* (3.1)*, whereas the optimal strategy is given by* (3.4)*.*

Proof. Consider the optimal stopping problem defined by

$$\hat{v}(x) = \sup_{\tau\in\mathcal{T}} E\left\{\int_0^{\tau} e^{-rt}h(X_t)dt + \mathrm{I}_{\{\tau<\infty\}}e^{-r\tau}g(X_\tau)\right\}\ .$$

The value function $\hat{v}$ belongs to $W^{2,\infty}_{loc}(]0,\infty[)$, satisfies (3.1), and the stopping time $\tilde{\tau}$ defined by (3.4) is optimal (see Krylov [18, Theorem 6.4.14]). Now, in view of (3.6) and the fact that (3.6) holds with equality for $U = \tilde{U}$, it is clear that $v = \hat{v}$, and the proof is complete. □

It is well known that if $|w'|$ is bounded by a polynomial, then the process M defined by (3.2) is a square integrable martingale if stopped at any constant time. The following lemma provides a similar condition which will be of use in section 5.

LEMMA 3.4. *Consider the SDE* (2.1)*, assume that* b*,* σ *satisfy* A4.a*, and let* M *be the process defined by* (3.2)*. If there exist constants* C*,* k *such that*

$$|w'(x)| \leq C(x^{-k} + x^k) \quad \forall x > 0 \ ,$$

then, for every $T > 0$*, the stopped process* M^T *is a square integrable martingale.*

Proof. In the case that we consider here, the unique strong solution of the SDE (2.1) is given by (see Karatzas and Shreve [16, section 5.6.C])

$$X_t = x \exp\left\{(b - \sigma^2)t + \sqrt{2}\sigma W_t\right\} \ , \quad t \geq 0 \ . \tag{3.7}$$

Therefore, given any reals κ, λ, and any $t \geq 0$,

$$\begin{aligned} e^{\kappa t} E X_t^\lambda &= x^\lambda \exp\left\{\left[\sigma^2\lambda^2 + (b - \sigma^2)\lambda + \kappa\right] t\right\} \, E \exp\left\{-\sigma^2\lambda^2 t + \sqrt{2}\sigma\lambda W_t\right\} \\ &= x^\lambda \exp\left\{\left[\sigma^2\lambda^2 + (b - \sigma^2)\lambda + \kappa\right] t\right\} \ , \end{aligned} \tag{3.8}$$

and so,

$$E \int_0^T e^{\kappa t} X_t^\lambda dt = \int_0^T e^{\kappa t} E[X_t^\lambda] dt < \infty \quad \forall T > 0 \ .$$

As a consequence, given any $T > 0$,

$$\begin{aligned} E M_T^2 &= 2\sigma^2 E \int_0^T e^{-2rt} X_t^2 |w'(X_t)|^2 dt \\ &\leq 2\sigma^2 C^2 E \int_0^T e^{-2rt} \left(X_t^{-2k+2} + 2X_t^2 + X_t^{2k+2}\right) dt \\ &< \infty \ , \end{aligned}$$

which implies that the stopped local martingale M^T has integrable quadratic variation and therefore is a square integrable martingale (see Revuz and Yor [22, Proposition IV.1.23]. □

4. Study of a fundamental ODE. In the following section, we will explicitly solve the control problem which arises when the drift and dispersion of the SDE (2.1) satisfy Assumption A4.a by finding a solution of the HJB equation which satisfies the requirements of the Verification Theorem 3.2. In this case, the HJB equation takes the form

$$\max\left\{\sigma^2 x^2 w''(x) + bxw'(x) - rw(x) + h(x) \ , \ g(x) - w(x)\right\} = 0 \ . \tag{4.1}$$

It is well known that the general solution of the ODE

$$\sigma^2 x^2 w''(x) + bxw'(x) - rw(x) + h(x) = 0 \tag{4.2}$$

which is associated with (4.1) is given by

$$w_g(x) = Ax^m + Bx^n \ , \tag{4.3}$$

where $A, B \in \mathbb{R}$ and m, n are given by

$$m = \frac{1}{2\sigma^2}\left[\sigma^2 - b - \sqrt{(\sigma^2 - b)^2 + 4\sigma^2 r}\right] \tag{4.4}$$

and

$$n = \frac{1}{2\sigma^2}\left[\sigma^2 - b + \sqrt{(\sigma^2 - b)^2 + 4\sigma^2 r}\right]. \tag{4.5}$$

The following proposition is concerned with the construction and certain properties of a special solution of (4.2). Note that part of these results are similar to results presented in section 2 of Kobila [17]; in particular, conclusions b) and c) are the same as Propositions 2.2 and 2.4 in this reference, respectively.

PROPOSITION 4.1. *Consider a measurable function* $h :]0,\infty[\to \mathbb{R}$*, and let* X *be the solution of the SDE* (2.1) *under* A4.a. *The following statements are equivalent:*

i) $E\int_0^\infty e^{-rt}|h(X_t)|dt < \infty$ *for every initial condition* $x > 0$.

ii) *There exists an initial condition* $x > 0$ *such that* $E\int_0^\infty e^{-rt}|h(X_t)|dt < \infty$.

iii) $x \to x^{-m-1}h(x) \in L^1(]0, y[)$ *and* $x \to x^{-n-1}h(x) \in L^1(]y,\infty[)$ $\forall y > 0$.

iv) *There exists a* $y > 0$ *such that* $x \to x^{-m-1}h(x) \in L^1(]0, y[)$ *and* $x \to x^{-n-1}h(x) \in L^1(]y,\infty[)$.

If i)–iv) *are true, then*

a) $\liminf_{x\to\infty} x^{-n}|h(x)| = \liminf_{x\downarrow 0} x^{-m}|h(x)| = 0$

and

$$w_p(x) := \frac{1}{\sigma^2(n-m)}\left[x^m\int_0^x s^{-m-1}h(s)ds + x^n\int_x^\infty s^{-n-1}h(s)ds\right], \quad x \in]0,\infty[\tag{4.6}$$

defines a real valued function such that

b) w_p *is twice differentiable in the classical sense and is a special solution of the ODE* (4.2),

c) *there exists a constant* C *such that*

$$|w_p'(x)| \le C(x^{m-1} + x^{n-1}) \quad \forall x > 0\ ,$$

d) w_p *satisfies*

$$w_p(x) = E\int_0^\infty e^{-rt}h(X_t)dt \quad \forall x > 0\ , \tag{4.7}$$

and

e) $\lim_{t\to\infty} e^{-rt}E|w_p(X_t)| = 0$.

Proof. iii) $\Leftrightarrow$ iv): Assume that there exists a $y \in]0,\infty[$ such that

$$C_1 := \int_0^y s^{-m-1}|h(s)|ds < \infty \quad \text{and} \quad C_2 := \int_y^\infty s^{-n-1}|h(s)|ds < \infty\ .$$

Given any $x \in]0, y[$, it is clear that

$$\int_0^x s^{-m-1}|h(s)|ds \le C_1\ . \tag{4.8}$$

On the other hand, since $m - n < 0$,

$$\begin{aligned}\int_x^\infty s^{-n-1}|h(s)|ds &= \int_x^y s^{m-n}\cdot s^{-m-1}|h(s)|ds + C_2\\ &\le x^{m-n}\int_x^y s^{-m-1}|h(s)|ds + C_2\\ &\le C_1 x^{m-n} + C_2\ .\end{aligned} \tag{4.9}$$

Similarly, given any $x \in]y, \infty[$,

$$\int_0^x s^{-m-1}|h(s)|ds \leq C_1 + C_2 x^{n-m} \tag{4.10}$$

and

$$\int_x^\infty s^{-n-1}|h(s)|ds \leq C_2 \ . \tag{4.11}$$

However, these bounds prove that iv) $\Rightarrow$ iii). The reverse implication is obvious.

Proof of b). If iii) is satisfied, then w_p is well defined, in which case it is trivial to verify b).

Proof of c). The bounds (4.8)–(4.11) imply that

$$x^m \int_0^x s^{-m-1}|h(s)|ds, \quad x^n \int_x^\infty s^{-n-1}|h(s)|ds \quad \leq \quad C_1 x^m + C_2 x^n \ . \tag{4.12}$$

Using these, we calculate

$$\begin{aligned} |w_p'(x)| &= \frac{1}{\sigma^2(n-m)} \left| m x^{m-1} \int_0^x s^{-m-1} h(s) ds + n x^{n-1} \int_x^\infty s^{-n-1} h(s) ds \right| \\ &\leq \frac{1}{\sigma^2(n-m)} \left(|m| x^{m-1} \int_0^x s^{-m-1} |h(s)| ds + n x^{n-1} \int_x^\infty s^{-n-1} |h(s)| ds \right) \\ &\leq \frac{1}{\sigma^2} \big(C_1 x^{m-1} + C_2 x^{n-1} \big), \end{aligned}$$

which proves c).

i) $\Leftrightarrow$ iii) and ii) $\Leftrightarrow$ iv): Assume first that h is positive and bounded. In this case, it is clear that all of the statements i)–iv) are true. Also, it is easy to check that both w_p and $x \to x w_p'(x)$ are bounded. Applying Itô–Tanaka's formula and the occupation times formula, and using the fact that w_p satisfies (4.2) (because iii), and therefore b), is true), we obtain

$$\int_0^t e^{-rs} h(X_s) ds = w_p(x) - e^{-rt} w_p(X_t) + \sqrt{2}\sigma \int_0^t e^{-rs} X_s w_p'(X_s) dW_s \ . \tag{4.13}$$

Taking expectations and passing to the limit $t \to \infty$, we obtain (4.7).

Now assume that h is an arbitrary positive function, and consider the sequences of functions (h_k) and $(w_{p,k})$, where $h_k(x) = h(x) \wedge k$ and $w_{p,k}$ is defined by (4.6) with h_k in place of h. Since (h_k) converges pointwise to h and (4.7) holds with $w_{p,k}$, h_k in place of w_p, h, respectively, for every k, the monotone convergence theorem implies (4.7), where both sides may be equal to ∞.

In particular, we have just proved that for every measurable h,

$$E \int_0^\infty e^{-rt} |h(X_t)| dt = \frac{1}{\sigma^2(n-m)} \left[x^m \int_0^x s^{-m-1} |h(s)| ds + x^n \int_x^\infty s^{-n-1} |h(s)| ds \right] \tag{4.14}$$

$\forall x \in]0, \infty[$. However, this establishes the equivalences i) $\Leftrightarrow$ iii) and ii) $\Leftrightarrow$ iv).

Proof of d). We have proved the result for positive h. For an arbitrary h satisfying i)–iv), the result follows by considering its positive and negative parts h^+ and h^-, respectively.

Proof of e). Define $\bar{w}_p$ by

$$\bar{w}_p(x) := \frac{1}{\sigma^2(n-m)}\left[x^m \int_0^x s^{-m-1}|h(s)|ds + x^n \int_x^\infty s^{-n-1}|h(s)|ds\right],$$

and note that if h satisfies iii), then the same is true for $|h|$. Now, since $\bar{w}_p$ satisfies the ODE (4.2) with h replaced by $|h|$ (because of b)),

$$\int_0^t e^{-rs}|h(X_s)|ds = \bar{w}_p(x) - e^{-rt}\bar{w}_p(X_t) + \sqrt{2}\sigma \int_0^t e^{-rs} X_s \bar{w}_p'(X_s) dW_s \ .$$

Taking expectations and noting that the stochastic integral has expectation zero because of c) and Lemma 3.4, we obtain

$$e^{-rt} E\bar{w}_p(X_t) = \bar{w}_p(x) - E\int_0^t e^{-rs}|h(X_s)|ds \ .$$

However, (4.14) and the monotone convergence theorem imply that the right-hand side of this equation converges to zero as $t \to \infty$, and so, $\lim_{t\to\infty} e^{-rt} E\bar{w}_p(X_t) = 0$. Now, e) follows from the fact that $|w_p| \le \bar{w}_p$.

Proof of a). Suppose that $\liminf_{x\to\infty} x^{-n}|h(x)| > 0$, and let $\epsilon > 0$ and y be such that $x^{-n}|h(x)| \ge \epsilon \ \forall x \ge y$. Then,

$$\int_y^\infty x^{-n-1}|h(x)|dx \ge \epsilon \int_y^\infty x^{-1}dx = \infty \ ,$$

and so, (iii) does not hold. Similarly, we prove that $\liminf_{x\downarrow 0} x^{-m}|h(x)| = 0$. □

Note that, at this generality, the necessary conditions a) of the preceding proposition cannot be strengthened.

Example 4.2. Assume that the function h is defined by

$$h(x) = \begin{cases} x^{n+1} & \text{if } x \in [k, k+k^{-2}] \ , \ k \in \mathbb{N}, \\ 0 & \text{otherwise.} \end{cases}$$

We can calculate

$$w_p(1) = \frac{1}{\sigma^2(n-m)} \sum_{k=1}^\infty \frac{1}{k^2} = \frac{\pi^2}{6\sigma^2(n-m)} < \infty \ ,$$

and so, w_p satisfies statement iv) of the preceding proposition. However,

$$\limsup_{x\to\infty} x^{-n} h(x) = \infty. \qquad \square$$

Remark 4.3. Using (3.8) we find that, given any constant λ,

$$\begin{aligned} E\int_0^\infty e^{-rt} X_t^\lambda dt &= \int_0^\infty e^{-rt} E[X_t^\lambda] dt \\ &= x^\lambda \int_0^\infty \exp\left\{\left[\sigma^2\lambda^2 + (b-\sigma^2)\lambda - r\right] t\right\} dt, \end{aligned}$$

which implies that

$$E\int_0^\infty e^{-rt} X_t^\lambda dt < \infty \quad \Leftrightarrow \quad \lambda \in \,]m, n[\ .$$

As a consequence, if there exist constants k, l, and C such that $m < k < l < n$ and

$$|h(x)| \leq C(x^k + x^l) \qquad \forall x \in]0, \infty[\ ,$$

then statements i)–iv) of Proposition 4.1 are satisfied. □

Remark 4.4. At this point, note that since

$$w_p''(x) = \frac{1}{\sigma^2(n-m)} \left(m(m-1)x^{m-2} \int_0^x s^{-m-1} h(s) ds \right.$$
$$\left. + n(n-1)x^{n-2} \int_x^\infty s^{-n-1} h(s) ds \right) - \frac{1}{\sigma^2} x^{-2} h(x) \ ,$$

the bounds given by (4.12) imply that if $h \in L^p_{loc}(]0, \infty[)$, then $w_p \in W^{2,p}_{loc}(]0, \infty[)$. In particular, if h is a monotone function, then it is bounded on compact subsets of $]0, \infty[$ and therefore $w_p \in W^{2,\infty}_{loc}(]0, \infty[)$, whereas if h is continuous, then $w_p \in C^2(]0, \infty[)$. □

We will also need the following lemma.

LEMMA 4.5. *Consider any function h satisfying the requirements of Assumption* A4.b. *If w_p is the function defined by* (4.6)*, then w_p is increasing and* $\lim_{x\to\infty} w_p(x) = \infty$. *Moreover,*

$$n \int_x^\infty s^{-n-1} h(s) ds = x^{-n} h(x) + \int_x^\infty s^{-n} dh(s) \ . \tag{4.15}$$

Proof. Let any $x < y$, and denote by X^x and X^y the solutions of (2.1) with initial conditions $X_0 = x$ and $X_0 = y$, respectively. In view of (3.7), $X^x_t < X^y_t$ $\forall t$, P-a.s., and therefore (4.7) and the fact that h is increasing imply that $w_p(x) < w_p(y)$, which proves that w_p is increasing.

Now, let any y such that $h(y) > 0$; such a y exists because we have assumed that $\lim_{x\to\infty} h(x) = \infty$. For $x > y$,

$$w_p(x) \geq \frac{1}{\sigma^2(n-m)} \left[x^m \int_0^y s^{-m-1} h(s) ds + x^n \int_x^\infty s^{-n-1} h(s) ds \right]$$
$$\geq \frac{1}{\sigma^2(n-m)} \left[x^m \int_0^y s^{-m-1} h(s) ds + \frac{1}{n} h(x) \right] \ .$$

Since $m < 0 < n$ and $\lim_{x\to\infty} h(x) = \infty$, the last term in this expression tends to ∞ as $x \to \infty$, and therefore $\lim_{x\to\infty} w_p(x) = \infty$.

Finally, with reference to Proposition 4.1a), let (a_k) be any sequence converging to ∞ such that $\lim_{k\to\infty} a_k^{-n} h(a_k) = 0$. Using the dominated and the monotone convergence theorems and the integration by parts formula (see, for example, Revuz and Yor [22, Proposition 0.4.5]), we calculate

$$\int_x^\infty s^{-n-1} h(s) ds = \lim_{k\to\infty} \int_x^{a_k} s^{-n-1} h(s) ds$$
$$= \lim_{k\to\infty} \left(-\frac{1}{n} \int_x^{a_k} h(s) ds^{-n} \right)$$
$$= \lim_{k\to\infty} \left(\frac{1}{n} x^{-n} h(x) - \frac{1}{n} a_k^{-n} h(a_k) + \frac{1}{n} \int_x^{a_k} s^{-n} dh(s) \right)$$
$$= \frac{1}{n} x^{-n} h(x) + \frac{1}{n} \int_x^\infty s^{-n} dh(s) \ ,$$

which proves (4.15). □

Remark 4.6. Note that the calculations used to establish (4.15) remain true if h satisfies conditions i)–iv) of Proposition 4.1 and is decreasing instead of increasing. Also, using similar arguments we can show that if h is a monotone function satisfying i)–iv) of Proposition 4.1, then

$$m\int_0^x s^{-m-1}h(s)ds = -x^{-m}h(x) + \int_0^x s^{-m}dh(s) \ .$$

Moreover, we can use this identity, (4.15), and a simple limiting argument to show that

$$\lim_{x\to\infty} x^{-n}h(x) = \lim_{x\downarrow 0} x^{-m}h(x) = 0 \ ,$$

which is stronger than Proposition 4.1a). □

5. The solution of the control problem. Consider the control problem described in section 2 and assume A4. One possibility is that abandonment is never optimal. Given an initial condition $x > 0$, never abandoning yields a payoff equal to $w_p(x)$ (see Proposition 4.1d), whereas abandoning straightaway yields a payoff equal to K. As a consequence, we should expect that abandonment is never optimal if $w_p(x) \geq K \ \forall x > 0$, in which case the value function is equal to w_p. If abandonment is ever optimal, it should occur whenever the commodity price is sufficiently small. In this case, we should expect that the optimal policy consists of producing optimally as long as the commodity price is larger than a certain value y and abandoning as soon as the commodity price falls below y. If this policy is optimal, we should find a solution w of the HJB equation (4.1) such that $w(x) = K \ \forall x \in]0, y[$ and, in view of (4.3) and Proposition 4.1b),

$$w(x) = Ax^m + Bx^n + w_p(x) \qquad \forall x \in]y, \infty[\ ,$$

where w_p is given by (4.6) and A, B are parameters to be specified. Note that, given any $A, B \in \mathbb{R}$, this candidate solution of (4.1) can be expressed as

$$w(x) = g(x) + Bx^n + w_p(x)\mathrm{I}_{\{x\geq y\}} \qquad \forall x \in]0, \infty[\ ,$$

where g is a bounded function. Therefore, in view of (3.8) and Proposition 4.1e), we must have $B = 0$ because otherwise (3.3) cannot hold. The remaining two parameters A and y should be specified by the requirement that w is C^1 at y (the "smooth pasting condition" of optimal stopping). The next lemma is concerned with this issue.

LEMMA 5.1. *The system of equations*

$$Ay^m + w_p(y) = K \ , \tag{5.1}$$

$$mAy^{m-1} + w_p'(y) = 0 \tag{5.2}$$

for the parameters A and y has a solution with $y > 0$ if and only if

$$\inf_{x\in]0,\infty[} w_p(x) < K \ , \tag{5.3}$$

or equivalently, if and only if

$$\inf_{x\in]0,\infty[} h(x) < rK \ . \tag{5.4}$$

In this case, $y > 0$ is the unique solution of

$$\int_y^\infty s^{-n-1}[h(s) - rK]ds = 0 \tag{5.5}$$

whereas

$$A = -\frac{1}{m} y^{-m+1} w_p'(y) \ . \tag{5.6}$$

Proof. The proof is organized as follows. We first show that the system of equations (5.1), (5.2) is equivalent to (5.5), (5.6). We then show that if (5.5) has a solution $y > 0$, then (5.3) is true. Next, we prove that (5.3) implies (5.4), and finally, we prove that if (5.4) is true, then (5.5) has a unique solution $y > 0$.

It is straightforward to verify that the system of equations (5.1) and (5.2) is equivalent to the system of equations consisting of (5.6) and

$$f(y) := mK - mw_p(y) + yw_p'(y) = 0 \ . \tag{5.7}$$

Using the fact that $\sigma^2 mn = -r$, we can see that

$$f(y) = \frac{1}{\sigma^2} y^n \int_y^\infty s^{-n-1}[h(s) - rK]ds \ , \tag{5.8}$$

which proves that the system (5.1), (5.2) is equivalent to (5.5), (5.6).

Since $yw_p'(y) > 0 \ \forall y > 0$ and w_p increases to ∞ as $y \to \infty$ (see Lemma 4.5), it is clear that (5.7) can have a solution only if (5.3) is true. Therefore existence of solution of (5.5) implies (5.3).

Now, assume that (5.3) is true, and let any $z > 0$ such that

$$w_p(z) - K < 0 \ .$$

Using the identity $\sigma^2 mn = -r$, we can calculate that this is equivalent to

$$z^m \int_0^z s^{-m-1}[h(s) - rK]ds + z^n \int_z^\infty s^{-n-1}[h(s) - rK]ds < 0 \ ,$$

which implies (5.4), because otherwise, both integrands would be nonnegative functions and the inequality would not hold.

Finally, suppose that (5.4) is true, and let any $z > 0$ such that $h(z) < rK$. Since h is increasing, given $y < z$,

$$\begin{aligned} f(y) &\leq \frac{1}{\sigma^2} y^n \left[\int_y^z s^{-n-1}[h(z) - rK]ds + \int_z^\infty s^{-n-1}[h(s) - rK]ds \right] \\ &= \frac{h(z) - rK}{\sigma^2 n} + y^n \left[-\frac{[h(z) - rK]z^{-n}}{\sigma^2 n} + \frac{1}{\sigma^2} \int_z^\infty s^{-n-1}[h(s) - rK]ds \right] \\ &\underset{y \downarrow 0}{\longrightarrow} \frac{h(z) - rK}{\sigma^2 n} < 0 \ , \end{aligned}$$

which proves that $f(y)$ is negative for sufficiently small y. On the other hand, f increases to ∞ as $y \to \infty$ (see Lemma 4.5). As a consequence, (5.5) has at least one solution. However, this solution is unique because f is strictly increasing as follows:

$$
\begin{aligned}
f'(y) &= -\frac{1}{\sigma^2}y^{-1}[h(y)-rK] + \frac{n}{\sigma^2}y^{n-1}\int_y^\infty s^{-n-1}[h(s)-rK]ds \\
&= \frac{1}{\sigma^2}y^{n-1}\left[-y^{-n}[h(y)-rK] + n\int_y^\infty s^{-n-1}[h(s)-rK]ds\right] \\
&= \frac{1}{\sigma^2}y^{n-1}\int_y^\infty s^{-n}dh(s) \;>\; 0\ ,
\end{aligned}
$$

where we have used (4.15) with $h(\cdot)-rK$ in place of h. □

We can now prove the main result of this section.

THEOREM 5.2. *Consider the control problem described in section* 2*, and assume that* A4 *holds. We have the following two cases:*

a) *If* $\inf_{x\in]0,\infty[} h(x) \geq rK$*, then the value function* v *is equal to the function* w_p *defined by* (4.6)*.*

b) *If* $\inf_{x\in]0,\infty[} h(x) < rK$*, then the value function* v *is given by*

$$
v(x) = \begin{cases} K & \text{if} \quad x \in [0,y], \\ Ax^m + w_p(x) & \text{if} \quad x \in [y,\infty[, \end{cases} \tag{5.9}
$$

where w_p *is given by* (4.6)*,* y *is the unique solution of* (5.5)*, and the parameter* A *is given by* (5.6)*.*

In both cases, the optimal production process $\tilde{U}$ *is given by* (3.4)*. In the first case, the optimal abandonment time is* $\tilde{\tau} = \infty$*, whereas in the second case, the optimal abandonment time is given by* $\tilde{\tau} = \inf\{t \geq 0 :\ X_t \in [0,y]\}$*.*

Proof. First, note that, in both cases, the candidate value functions belong to $W^{2,\infty}_{loc}(]0,\infty[)$ (see Remark 4.4; also note that, in case b, the function v defined by (5.9) is C^1 at y, by construction).

We now prove that, in both cases, the candidate value functions are nondecreasing functions. In the first case, this has been proved in Lemma 4.5. In the second case, it follows from the fact that, for $x > y$,

$$
v'(x) = x^{m-1}\left[x^{-m+1}w_p'(x) - y^{-m+1}w_p'(y)\right] > 0
$$

because

$$
\begin{aligned}
\frac{d}{dx}\left(x^{-m+1}w_p'(x)\right) &= \frac{1}{\sigma^2}x^{n-m-1}\left[-x^{-n}h(x) + n\int_x^\infty s^{-n-1}h(s)ds\right] \\
&\overset{(4.15)}{=} \frac{1}{\sigma^2}x^{n-m-1}\int_x^\infty s^{-n}dh(s) \;>\; 0\ ,
\end{aligned}
$$

which proves that the function $x \to x^{-m+1}w_p'(x)$ is increasing.

If (5.3) is not true, then it is clear that w_p satisfies the HJB equation (4.1), that it satisfies (3.3) (because of Proposition 4.1e), and that the process M defined as in (3.2) is a square integrable martingale if stopped at any constant time (because of Lemma 3.4 and Proposition 4.1c). Therefore it satisfies the assumptions of the Verification Theorem 3.2, and hence the statements concerning part a) of the theorem follow.

If (5.3) is true, then the function v defined by (5.9) will satisfy the HJB equation (4.1) if

$$
-rK + h(x) \leq 0 \qquad \forall x \in [0,y[\tag{5.10}
$$

and

$$K \leq v(x) \qquad \forall x \in]y, \infty[\ . \tag{5.11}$$

(5.11) follows trivially from the fact that v is nondecreasing. On the other hand, in view of (5.5), if $z := \inf\{s > 0 : \ h(s) > rK\}$, then $y < z$. However, this proves (5.10) because h is increasing. We conclude that w satisfies the HJB equation (4.1) as well as (3.3) (because of Proposition 4.1e) and that the process M defined as in (3.2) is a square integrable martingale if stopped at any constant time (because of Lemma 3.4 and Proposition 4.1c); i.e., it satisfies the requirements of Theorem 3.2, and the proof is complete. □

6. Closed form solution for a specific payoff function. In this section we study the special case of the problem solved in section 5, which arises when the control set is $\mathcal{U} = [0, c]$ for some constant $c > 0$, and the running payoff function $\overline{h}$ is given by

$$\overline{h}(x, u) = [\alpha x - \beta]u - \gamma \ . \tag{6.1}$$

Here, α, β, γ are some given positive constants. With reference to the natural resource industry, β is the extraction cost per unit of the resource, $1 - \alpha$ is proportional to the "royalties," and γ represents the running cost; for further information concerning the choice of these parameters, the reader may consult Brennan and Schwartz [7]. A standing assumption in this section is that

$$r > b \ . \tag{6.2}$$

In the absence of (6.2), it is easy to show that the policy consisting of producing at any constant positive capacity has infinite payoff, and so, Assumptions A2 and A4.b do not hold.

The functions h, u defined by (2.4), (2.7) are now given by

$$h(x) = [\alpha x - \beta]^+ c - \gamma \ , \qquad u(x) = c \, \mathrm{I}_{\{x \geq \beta/\alpha\}} \ ,$$

respectively, and $\overline{h}$ clearly satisfies A4.b. Noting that (6.2) implies that $n > 1$ and using the fact that $mn = -r/\sigma^2$ as well as the identities

$$\sigma^2 n(n-1) = r - bn \ , \qquad \sigma^2 m(m-1) = r - bm \ , \tag{6.3}$$

it is a matter of simple calculations to verify that, in the case that we consider here, the function w_p defined by (4.6) is given by

$$w_p(x) = \frac{\beta c}{(n-m)(r-bn)} \left(\frac{\alpha}{\beta}\right)^n x^n - \frac{\gamma}{r} \ , \tag{6.4}$$

if $x \leq \beta/\alpha$, and by

$$w_p(x) = \frac{\beta c}{(n-m)(r-bm)} \left(\frac{\alpha}{\beta}\right)^m x^m + \frac{\alpha c}{r-b} x - \frac{\beta c + \gamma}{r} \ , \tag{6.5}$$

if $x \geq \beta/\alpha$. Also, the function g which identifies with the left-hand side of (5.8), the solution of which determines the "stopping barrier" y, is given by

$$f(x) = \frac{\beta c}{n(n-1)} x^{-n} \left[\left(\frac{\alpha x}{\beta}\right)^n - \frac{(\gamma + rK)(n-1)}{\beta c} \right] \ ,$$

if $x \leq \beta/\alpha$, and by

$$f(x) = \frac{\alpha c}{n-1} x^{-n} \left[x - \frac{(\beta c + \gamma + rK)(n-1)}{\alpha c n} \right] ,$$

if $x \geq \beta/\alpha$.

With reference to Theorem 5.2, depending on whether abandonment is part of the optimal policy and, if yes, on whether the unique solution y of $f(y) = 0$ is larger than or less than β/α, the optimal policy can take three qualitatively different forms, depending on parameter values. In the first case (the *PW-case*), it is optimal either to produce at full capacity or not to produce at all (i.e., wait); abandonment is never optimal. In the second case (the *PS-case*), at each time instant, it is optimal either to produce at full capacity or to abandon. In the third case (the *PWS-case*), the scenario of optimal actions consists of producing at full capacity, not producing at all, and abandoning. In view of Theorem 5.2 and the preceding calculations, we can now analyze the three cases.

The PW-case. The strategy defined by

$$\tilde{U}_t = c \, \mathrm{I}_{\{X_t \geq \beta/\alpha\}} \quad \forall t \geq 0 \quad \text{and} \quad \tilde{\tau} = \infty$$

is optimal if and only if

$$\inf_{x \in]0,\infty[} h(x) \equiv -\gamma \geq rK \ . \tag{6.6}$$

The value function v coincides with the function w_p defined piecewisely by (6.4) and (6.5).

The PS-case. The strategy defined by

$$\tilde{U}_t = c \ \ \forall t \geq 0 \quad \text{and} \quad \tilde{\tau} = \inf\{t \geq 0 : \ X_t \in]0, y]\} \ ,$$

where

$$y = \frac{(\beta c + \gamma + rK)(n-1)}{\alpha c n} \ ,$$

is optimal if and only if (6.6) is not true and $y \geq \beta/\alpha$, which is equivalent to

$$(\gamma + rK)(n-1) \geq \beta c \ . \tag{6.7}$$

The value function is given by $v(x) = K$ if $x \leq y$ and by

$$v(x) = -\frac{\alpha c}{m(r-b)} y^{-m+1} x^m + \frac{\alpha c}{r-b} x - \frac{\beta c + \gamma}{r}$$

if $x \geq y$.

The PWS-case. The strategy defined by

$$\tilde{U}_t = c \, \mathrm{I}_{\{X_t \geq \beta/\alpha\}} \quad \forall t \geq 0 \quad \text{and} \quad \tilde{\tau} = \inf\{t \geq 0 : \ X_t \in]0, y]\},$$

where

$$y = \frac{\beta}{\alpha} \left[\frac{(\gamma + rK)(n-1)}{\beta c} \right]^{1/n} \ , \tag{6.8}$$

is optimal if and only if (6.6) is not true and $y \leq \beta/\alpha$, or equivalently, if and only if (6.6) and (6.7) do not hold. In this case, the value function v is given by $v(x) = K$ if $x \leq y$, by

$$v(x) = \frac{\beta c}{(n-m)(r-bn)} \left(\frac{\alpha}{\beta}\right)^n \left[x^n - \frac{n}{m} y^{n-m} x^m\right] - \frac{\gamma}{r} \tag{6.9}$$

if $x \in [y, \beta/\alpha]$, and by

$$v(x) = \frac{\beta c}{n-m} \left[\frac{1}{r-bm} \left(\frac{\alpha}{\beta}\right)^m - \frac{n}{m(r-bn)} \left(\frac{\alpha}{\beta}\right)^n y^{n-m}\right] x^m + \frac{\alpha c}{r-b} x - \frac{\beta c + \gamma}{r} \tag{6.10}$$

if $x \in [\beta/\alpha, \infty[$. It is worth noting that if we use (6.8) and the identities

$$\frac{1}{r-bn} = -\frac{m}{r(n-1)}\ , \qquad \frac{1}{r-bm} = -\frac{n}{r(m-1)}\ ,$$

which follow directly from (6.3) and the fact that $mn = -r/\sigma^2$, we can show that (6.9) is equivalent to

$$v(x) = \frac{\gamma + rK}{r(n-m)} \left[n \left(\frac{x}{y}\right)^m - m \left(\frac{x}{y}\right)^n\right] - \frac{\gamma}{r}\ ,$$

whereas (6.10) is equivalent to

$$v(x) = \frac{\beta c n}{r(n-m)} \left[\frac{1}{n-1} \left(\frac{\alpha y}{\beta}\right)^n - \frac{1}{m-1} \left(\frac{\alpha y}{\beta}\right)^m\right] \left(\frac{x}{y}\right)^m + \frac{\alpha c}{r-b} x - \frac{\beta c + \gamma}{r}\ .$$

7. Options on stocks in the natural resource industry. In this section, we consider a company whose total asset value conforms to the model analyzed in sections 5 and 6. We assume that the commodity price is modeled by the geometric Brownian motion defined by (2.1) and A4.a and the running payoff function is given by (6.1) in the preceding section. Moreover, we make the assumption that $K < 0$, which conforms to the idea that $-K$ is the investment's abandonment cost, and we suppose that, at abandonment, the investment is scrapped and therefore becomes totally worthless.

Now, given a function $f \in W^{2,p}_{loc}$, we can show using the Itô–Tanaka formula that $f \circ X$ is a geometric Brownian motion if and only if $f(x) = Cx^k$ for some $C, k \in \mathbb{R}$. Therefore, in view of Theorem 5.2, the total asset value of the company, and therefore its stock price, is not in general a geometric Brownian motion. Plainly, this means that one cannot value options on these stocks using the Black & Scholes formula. However, in the special case that we consider here, the Black & Scholes formula can be used to calculate an approximate value for a European option when the commodity price is high, as well as an upper bound for the value of such an option.

If the commodity price is high relative to the boundary of the "production region," the value function of the company can be approximated by

$$v(x) \approx \frac{\alpha c}{r-b} x - \frac{\beta c + \gamma}{r}\ , \qquad x \gg y \vee (\beta/\alpha)\ , \tag{7.1}$$

because $m < 0$. (Note that this approximation holds for any of the PW, PS, PWS cases.) Also, in the PS or PWS case, the probability that the company is abandoned

within a short time interval can be reasonably neglected. Therefore a European call option on the stock of the company with a *short* time to maturity consisting of payout $(v(X_T)\mathrm{I}_{\{T<\tilde{\tau}\}} - p)^+$ at maturity T is almost like a European call option giving the right to buy $\alpha c/(r-b)$ units of commodity at time T for the price $p + (\beta c + \gamma)/r$. Similarly, a European put option on the investment with strike price p is almost equivalent to a European put option with strike price $p + (\beta c + \gamma)/r$ on $\alpha c/(r-b)$ units of commodity. The price of such options is given by the Black & Scholes formula, so for very large commodity prices, the valuation of European options on stocks in the investment has no problems.

Now, in view of the assumption that $r > b$, the facts that $m < 0$, $1 < n$, and the identities (6.3), we can easily check that, in any of the PW, PS, PWS cases, the second derivative of the value function v is nonnegative, which implies that v is convex. Combining this with the asymptotic expression (7.1), and taking into account that $v(0) = -\gamma/r$ or $K < 0$, depending on whether the PW or the PS, PWS is the case, we can conclude that

$$v(x) \leq \frac{\alpha c}{r-b} x \qquad \forall x \geq 0 \ ,$$

which implies that

$$\big(v(X_T)\mathrm{I}_{\{T<\tilde{\tau}\}} - p\big)^+ \leq \left(\frac{\alpha c}{r-b} X_T - p\right)^+ \qquad \forall T \geq 0 \ , \qquad P\text{-a.s.}$$

As a consequence, the value of a European option on the stock of the company is bounded from above by the value of a European option on the stock of a fictitious company whose stock price is given by $\alpha c/(r-b)X$, which can be calculated by the Black & Scholes formula.

8. Conclusion. An improved model for evaluating natural resources projects and stocks in the natural resource industry has been formulated and studied. This will be useful for both investors who are interested in finding out discrepancies between quoted prices and underlying values of companies, as well as for company executives who are looking for tools to evaluate investment decisions. Here, we have adopted the viewpoint that one can identify asset value with total stock value for a company without debt or outstanding warrants. Our analysis can most easily be applied to companies who (almost) exclusively have producing fields with firmly established reserves with relatively little uncertainty attached. As Paddock, Siegel, and Smith [20] mention, there are a number of publicly quoted companies which more or less fit this profile. Also, the mathematical analysis presented analyzes a much larger class of payoffs than previously possible. With reference to the natural resource industry, it is worth repeating that our model relies on the assumption that the investment/firm under consideration has access to an infinite amount of the resource. Although such an assumption does not hold in the real world, it can be defended as a good approximation of reality by using a number of arguments. Its relaxation is the subject of current research.

We are hereby able to move beyond the natural resource industry to other sectors. One example concerns investments into microchip production facilities. The investment decisions for companies producing microchips fall squarely into the context of our model. In this problem, the X process would be the price of one particular type of microchip; the choice of a geometric Brownian motion with negative drift reflects the fact that microchips of a particular variety are on average declining in price as

their availability increases, the production processes become more widespread, and new microchip generations are introduced. The controlled process U would be the amount of microchips produced per unit of time and the payoff function could be chosen appropriately. In this model, it is plain that the assumption discussed at the end of the previous paragraph presents no difficulties at all because there is no upper limit for the amount of chips producible over an infinite time horizon.

Finally, there is a natural need for comparing our theoretical results with market data. As mentioned in [20], there is enough data available in a variety of forms to be able to conduct some reasonable analysis.

Acknowledgments. We would like to express our gratitude to Mark Davis for numerous helpful discussions during the first stages of this research. We also wish to thank Martin Clark, Lane Hughston, Vassilios Katsouros, Ralph Korn, and Nilay Shah for useful conversations and suggestions.

MATRIX RATIONAL H_2 APPROXIMATION: A GRADIENT ALGORITHM BASED ON SCHUR ANALYSIS*

PASCALE FULCHERI† AND MARTINE OLIVI†

Abstract. This paper deals with the rational approximation of specified order n to transfer functions which are assumed to be matrix-valued functions in the Hardy space for the complement of the closed unit disk endowed with the L_2-norm. An approach is developed leading to a new algorithm, the first one to our knowledge which concerns matrix-transfer functions in L_2-norm. This approach generalizes the ideas presented in [L. Baratchart, M. Cardelli, and M. Olivi, *Automatica*, 27(1991), pp. 413–418] in the scalar case but involves substantial new difficulties.

Using the Douglas–Shapiro–Shields factorization of transfer functions, the criterion for the rational approximation problem above is expressed in terms of inner matrix functions of McMillan degree n. These functions, which possess a manifold structure, are represented by means of local coordinate maps obtained in [D. Alpay, L. Baratchart, and A. Gombani, *Oper. Theory Adv. Appl.*, 73(1994), pp. 30–66] from a tangential Schur algorithm and for which the coordinates range over n copies of the unit ball. A gradient algorithm is then employed to solve the approximation problem using the coordinate maps to describe the manifold locally and changing from one coordinate map to another when required. However, while processing the gradient algorithm a boundary point can be reached. It is proved that such a point can be considered as an initial point for searching for a local minimum of lower degree while a local minimum of McMillan degree $k < n$ provides a starting point for searching for a local minimum at degree $k + 1$. The minimization process then pursues through different degrees. The convergence of this algorithm to a local minimum of appropriate degree is proved and demonstrated on a simple example.

1. Introduction.

The identification of linear time-invariant systems can be formalized as a rational approximation problem in which some criterion function is optimized over a set of systems. This approach has led to a wide variety in model structure, performance criteria, and actual methods of estimation (see [38] and the bibliography therein). Our interest is focused mainly on the particular class of discrete time, linear, time-invariant, and strictly causal systems and their strictly proper transfer functions. The *order* of such a system is defined to be its McMillan degree, that is, the dimension of the state space in its minimal realizations. The criterion which is chosen here is the L_2-norm, and our approximation problem states in the Hardy space $\bar{H}_2^{p\times m}$ of the complement of the unit disk: *given a transfer function* $F \in \bar{H}_2^{p\times m}$*, we are concerned in minimizing*

$$\|F - H\|_2^2 = \frac{1}{2\pi}\mathrm{Tr}\int_0^{2\pi} [F-H](e^{it})[F-H](e^{it})^* dt\,, \tag{1}$$

as H ranges over the set of rational stable (i.e., analytic for $|z| > 1$) functions of order at most n. Here, the symbol Tr stands for the trace and the superscript $*$ denotes transpose-conjugate. It should be noticed that in a stochastic framework, (1) is equal

to the mean square error between the output of a given system and the output of a model of fixed order when both systems have the same white noise input (see [32]).

The above problem has received attention in [41], [40], [4], and more recently [37] and [30], either in the discrete-time form studied here or in the continuous-time equivalent. Many qualitative results have been proved in [6], such as the existence of a best approximant and the property usually called normality: if F is not itself rational of degree at most n, then a best local approximant H has degree exactly n. In [8], an algorithm to find local minima in the L_2 rational approximation problem is described for scalar systems. It is the purpose of this paper to present an algorithm which enables the results of this previous paper to be extended to the multivariable case.

Let us recall the main line of our approach in the scalar case (see [8] and [13]). In this case, the minimum in (1) must be performed over the set of irreducible fractions p/q, where q is a polynomial of degree n whose roots belong to the unit disk $\mathbb{U}$. Our optimization problem being linear with respect to the parameters of the numerator p, we are led to minimize a cost function Ψ^n defined on the set $\mathcal{P}_n^1$ of monic polynomials q of degree n whose roots belong to $\mathbb{U}$. This set can be described by the coefficients of q and is open and bounded in $\mathbb{R}^n$; the function Ψ^n is smooth, so that we can use a gradient algorithm, producing a sequence of improving estimates, which either converges to a local minimum or meets the boundary of the domain at some point having some roots of modulus one. However, roots on the unit circle cancel and the cost function Ψ^n extends to a neighborhood of the closure of $\mathcal{P}_n^1$. At the boundary the extension of Ψ^n can be interpreted as the cost function of a lower-order approximation problem. Thus the search for a local minimum can continue through different orders, until such a minimum (of order $k \leq n$) is actually reached. Conversely, multiplying by $z-1$ or $z+1$ a minimum of order k provides an initial point for the optimization problem at order $k+1$: at such a point, the opposite of the gradient points inside the domain. Finally, the procedure can continue until a local minimum of order n is actually found.

Transition to the multivariable case involves substantial new difficulties, mainly due to the fact that the domain of the cost function is no longer an open subset of a Euclidean space but it does possess a manifold structure. A manifold has a covering by countably many open coordinate neighborhoods, each of these coordinate neighborhoods corresponding to an open subset of some $\mathbb{R}^d$ by a local coordinate homeomorphism (d is then the dimension of the manifold). The methods developed for the Euclidean case then apply to each of the coordinate neighborhoods separately. Over a manifold, an optimization problem can be tackled by using a search algorithm through the manifold as a whole, using the coordinate maps to describe the manifold locally and changing from one coordinate map to another when required. Such a representation of the elements of the domain has the advantage to get rid of redundancy and ensure identifiability [22]. Using state space representations, it was first established by Hazewinkel and Kalman [26] that the set of stable transfer functions of fixed degree possesses a manifold structure. Several atlases of local coordinate maps (called sets of overlapping canonical forms in system theory) have been derived from this approach ([33], [25]). However, this manifold is never compact, and convergence of a gradient algorithm to points outside can occur. To avoid this problem, a transfer function will be represented by means of the inner-unstable or Douglas–Shapiro–Shields factorization (see [15]). The elimination of the parameters in which the system is linear (namely, those of the unstable factor) allows us to perform the search for an optimum on the manifold of *inner matrix functions* of degree n. We are

then in a position to proceed to the generalization to the multivariable case of the above-mentioned procedure.

The paper is organized as follows: Section 2 states the problem within the framework of the Hardy spaces and introduces the cost function by means of the inner-unstable factorization. In section 3, we first recall some results of [1], in which the theory of reproducing kernel Hilbert spaces is used to construct local coordinates of the manifold of inner matrix functions of fixed McMillan degree: such functions are obtained by iterating a linear fractional transformation which changes an inner function into another one, the McMillan degree being increased by one. Then, a fractional representation of this transformation is given in which the numerator (a polynomial matrix) and the denominator (a polynomial) are polynomial functions in the local coordinates. This representation allows us, in section 4, to study the cost function on the boundary of the domain and to elaborate an algorithm which converges generically to a local minimum. The numerical aspects have been examined in section 5.

2. Minimizing over the set of inner matrices. The Hardy spaces H_2 and H_∞ of the unit disk are the closed subspaces of $L_2(\mathbb{T})$ and $L_\infty(\mathbb{T})$, respectively, consisting of functions whose Fourier coefficients (a_n) satisfy $a_n = 0$ when $n < 0$; while the Hardy space $\bar{H}_{2,0}$ consists of functions for which $a_n = 0$ when $n \geq 0$. Note the orthogonal decomposition

$$L_2(\mathbb{T}) = H_2 \oplus \bar{H}_{2,0}.$$

It is well known (see, e.g., [27]) that members of H_2 are the nontangential limits on $\mathbb{T}$ of analytic functions f in the unit disk for which the functions $f_r(t) = f(re^{it}),\ r < 1$, are bounded in L_2-norm as $r \to 1$. Members of H_∞ correspond to bounded holomorphic functions in this process. Similarly, members of $\bar{H}_{2,0}$ correspond to analytic functions f in the complement of the unit disk vanishing at infinity and satisfying an analogous growth condition for $r > 1$. Thus, f belongs to H_2 (resp., to $\bar{H}_{2,0}$) if and only if it can be written as

$$f(z) = \sum_{k\geq 0} a_k\ z^k \qquad \left(\text{resp.,}\quad f(z) = \sum_{k>0} a_k\ z^{-k} \right), \qquad \sum |a_k|^2\ <\ \infty. \tag{2}$$

Note that (2) is the Taylor expansion at 0 (resp., at ∞) and at the same time the Fourier expansion if we substitute $z = e^{i\theta}$.

The space $L_2^{p\times m}(\mathbb{T})$ of $(p \times m)$-matrices whose entries belong to $L_2(\mathbb{T})$ becomes a Hilbert space when endowed with the scalar product

$$\langle F, G\rangle = \frac{1}{2\pi}\mathrm{Tr}\int_0^{2\pi} F(e^{it})G(e^{it})^*\, dt. \tag{3}$$

The corresponding norm will also be given, for $F = (f_{ij})$, by $\|F\|_2^2 = \sum_{i,j} \|f_{ij}\|_2^2$, and the orthogonal decomposition

$$L_2^{p\times m}(\mathbb{T}) = H_2^{p\times m} \oplus \bar{H}_{2,0}^{p\times m} \tag{4}$$

is still valid. Taking into account the fact that $\bar{z} = z^{-1}$ on $\mathbb{T}$, and using the notation

$$G^\sharp(z) = G(1/\bar{z})^*,$$

(3) may be converted into the line integral

$$\langle F, G\rangle = \frac{1}{2i\pi}\mathrm{Tr}\int_{\mathbb{T}} G^\sharp(z)F(z)\frac{dz}{z}.$$

The Banach space $L_\infty^{p\times m}(\mathbb{T})$ is endowed with the norm

$$\|F\|_\infty = \sup_\theta ||F(e^{i\theta})||,$$

where $||\ .\ ||$ denotes the operator norm $\mathbb{C}^m \to \mathbb{C}^p$. The prefix $\mathcal{R}$ in front of the name of some set ($\mathcal{R}\bar{H}_{2,0}^{p\times m}$, $\mathcal{R}H_2^{p\times m}$, etc.) will indicate that we consider the *real* subspace of functions whose Fourier coefficients are real. Such functions are relevant in most applications. However, the natural framework for our study is the complex case which plainly includes the real case by restriction. When necessary, the results will be stated for real transfer functions.

The normality result mentioned in the introduction allows us to state the rational approximation problem in degree n as follows: *Given $F \in \bar{H}_{2,0}^{p\times m}$, minimize* (1) *over the set $\Sigma_{p,m}^-(n)$ of rational stable functions of McMillan degree exactly n.* It is well known that $\Sigma_{p,m}^-(n)$ possesses the structure of a real analytic manifold of dimension $2n(m+p)$ (see, e.g., [24]). We shall now give a description of this set which suits our purpose by using the inner-unstable or Douglas–Shapiro–Shields factorization (see [15] and [11]).

Recall that a $\mathbb{C}^{p\times p}$-valued analytic function Q in the unit disk is called *inner* if it is analytic in $\mathbb{U}$ and takes unitary values on the unit circle $\mathbb{T}$:

$$Q(e^{it})\ Q(e^{it})^* \ = \ Q(e^{it})^*\ Q(e^{it}) \ = \ I_p, \tag{5}$$

where I_p is the identity matrix of size p. This equality implies that the inverse of a rational inner functions agrees with $Q^\sharp$ and thus is analytic outside the unit disk. Naturally associated with Q is the space $QH_2^p \subset H_2^p$ which is invariant by the shift operator (i.e., multiplication by z), and its orthogonal complement $\mathcal{H}(Q)$. Note that $\mathcal{H}(Q)$ consists of vectors $v \in H_2^p$ of the form Qu for some u in $\bar{H}_{2,0}^p$. These spaces and the inner-unstable factorization are closely related to the shift realization (see [19]). Observe that the McMillan degree of a rational matrix may be defined even if this matrix fails to be analytic at infinity, using, for instance, Smith–McMillan forms (see [28]). Furthermore, the McMillan degrees of Q and Q^{-1} agree.

Proposition 1 (inner-unstable factorization). *Any rational function H in $\bar{H}_{2,0}^{p\times m}$ can be written*

$$H \ = \ Q^{-1}\ C, \tag{6}$$

where Q is a $(p\times p)$-rational inner function and C a $(p\times m)$-rational matrix whose columns belong to $\mathcal{H}(Q)$. The matrices Q and C may be chosen left co-prime. With this condition, the factorization is unique up to a common left unitary factor and Q and H have same McMillan degree.

The matrix Q is called the *left inner factor* of H and the matrix Q^{-1} is usually named in system theory an *all-pass stable transfer function.* To ensure uniqueness in the inner-unstable factorization, we shall require that Q satisfies the condition

$$Q(1) = I_p. \tag{7}$$

The set of $\mathbb{C}^{p\times p}$-valued rational inner functions of degree n will be denoted by $\mathcal{I}_n^p$, and by $\mathcal{I}_n^p(1)$ we denote the subset of functions satisfying the extra condition (7). As

previously mentioned, $\mathcal{RI}_n^p$ and $\mathcal{RI}_n^p(1)$ will denote the corresponding sets of *real* inner functions. It is proved in [1] that $\mathcal{I}_n^p$ and $\mathcal{I}_n^p(1)$ are smooth manifolds of dimension $2np + p^2$ and $2np$, respectively (embedded in $H_\infty^{p\times p}$), while $\mathcal{RI}_n^p$ and $\mathcal{RI}_n^p(1)$ have dimension $np + p(p-1)/2$ and np, respectively. Moreover, the set $\Sigma_{p,m}^-(n)$ is a vector bundle whose base space is $\mathcal{I}_n^p(1)$ and whose fiber above Q is the vector space $\mathcal{F}_Q$ of matrices C whose columns belong to $\mathcal{H}(Q)$ (see [12]).

Now, we can write our approximation problem as

$$\min_{Q,C} \|F - Q^{-1}C\|_2^2,$$

where $Q \in \mathcal{I}_n^p(1)$ and $C \in \mathcal{F}_Q$. Observe that for fixed Q, the minimum is obtained when C is the projection of QF onto $\mathcal{F}_Q$. Since $F \in \bar{H}_{2,0}^{p\times m}$, C is also the projection of QF onto $H_2^{p\times m}$ that we shall denote by $L(Q)$. Therefore, minimizing (1) is equivalent to minimizing the function

$$\begin{array}{rccl} \Psi^n : & \mathcal{I}_n^p(1) & \to & \mathbb{R}, \\ & Q & \to & \|F - Q^{-1}L(Q)\|_2^2, \end{array} \tag{8}$$

which is going to be the main purpose of the remainder of this paper. The first step consists of studying the domain of this function and will be the content of the next section.

First of all, we give a fractional representation of an inner matrix which will be useful in the sequel. If q is a polynomial of degree n, we define its *reciprocal polynomial* as being

$$\widetilde{q}(z) = z^n\ q^\sharp(z), \tag{9}$$

and if D is a polynomial matrix whose degree does not exceed n, we also put

$$\widetilde{D}(z)\ =\ z^n\ D^\sharp(z). \tag{10}$$

Recall that the degree of a polynomial matrix is defined to be the degree of its highest degree entry. While both this degree and the McMillan degree are used in this work, there should be no confusion from the context which is used.

PROPOSITION 2. *An inner matrix $Q \in \mathcal{I}_n^p$ has a representation of the form $Q = D/\widetilde{q}$ by means of a polynomial matrix D whose degree does not exceed n and a polynomial q of exact degree n whose roots belong to the open unit disk, satisfying $D\widetilde{D} = q\widetilde{q}I_p$ and $\det D = \epsilon q\widetilde{q}^{p-1}$, ϵ being a complex number of modulus one. Conversely, these conditions are sufficient for the rational matrix $D/\widetilde{q}$ to belong to $\mathcal{I}_n^p$.*

Proof. Since Q^{-1} is analytic outside the unit disk, it has a representation of the form $\widetilde{D}/q$, where q is, up to a constant factor, its *polynomial of poles* (see [28]). Condition (5) yields an analogous representation for Q, i.e., $Q = D/\widetilde{q}$, so that $D\widetilde{D} = q\widetilde{q}I_p$. It also implies that $\det Q$ is an inner scalar rational function, that is to say a Blaschke product, and the number of zeros of $\det Q$ within $\mathbb{U}$ determines the McMillan degree of Q, by the Potapov decomposition [35]. ∎

3. Parametrization of inner matrices. We describe here a parametrization of the set of inner functions obtained in [1] from a matrix version of the classical Schur algorithm that we now explain; in a fundamental paper [36], Schur proved that every function $f \in \mathcal{I}_n^1$ can be uniquely parameterized by a sequence y_j, $j = n, \ldots, 1$, of

complex numbers with $|y_j| < 1$. Moreover, Schur gave an algorithm for computing these parameters:

$$y_j = f_j(0),$$

where $f_n = f$ and

$$f_{j-1}(z) = \frac{f_j(z) - f_j(0)}{(1 - \overline{f_j(0)} f_j(z))\, z}, \quad j = n, \dots, 1. \tag{11}$$

Since f_j is an inner function it follows from the maximum modulus principle that $|y_j| < 1$, and f_j has degree j, since a zero is eliminated at each step. Since f has degree n, f_0 is equal to a constant of modulus one. Other sequences of inner functions of decreasing degree may be constructed from f in a similar way. The most general recursion formula is the following (see [21]):

$$\frac{f_{j-1}(z) + \mu_j}{1 + \bar{\mu}_j f_{j-1}(z)} = \frac{f_j(z) - y_j}{1 - \overline{y_j} f_j(z)} \frac{1 - \bar{w}_j z}{z - w_j}, \quad j = n, \dots, 1,$$

where the w_j's are the interpolation points, $y_j = f_j(w_j)$ and the μ_j's belong to $\mathbb{U}$. The w_j's and the μ_j's being given, the sequence of numbers y_j completely characterizes the function f, which can recover inductively by the linear fractional transformations:

$$f_j(z) = \frac{[(z - w_j) + \bar{\mu}_j y_j (1 - \bar{w}_j z)]\, f_{j-1}(z) + [\mu_j (z - w_j) + y_j (1 - \bar{w}_j z)]}{[\bar{y}_j (z - w_j) + \bar{\mu}_j (1 - \bar{w}_j z)]\, f_{j-1}(z) + [\mu_j \bar{y}_j (z - w_j) + (1 - \bar{w}_j z)]}. \tag{12}$$

The map $(y_1, \dots, y_n, f_0) \to f$ is a diffeomorphism from the product of n copies of the open unit disk and of a copy of the unit circle onto $\mathcal{I}_n^1$.

This Schur algorithm is related to the classical interpolation problems of Nevanlinna–Pick and Carathéodory–Fejér (see [39]), which have a remarkable diversity of applications in systems engineering (see [5], [29]). Several approaches allow the extension of these problems to matrix-valued analytic functions (see [42] and the bibliography therein); however, the operator-theoretic one, involving reproducing kernel Hilbert spaces, clarifies the connections between interpolation and realization theory and gives a unified presentation of these problems (see, e.g., [17], [16], [3]). Another fundamental treatment can be found in [18], which emphasizes the relevance of the commutant lifting theorem in these interpolations issues and also presents several applications to engineering problems.

3.1. Reproducing kernel Hilbert spaces. For the convenience of the reader, we shall recall some basic facts about reproducing kernel Hilbert spaces which may be found in [16]. A complex Hilbert space $\mathcal{H}$ of $\mathbb{C}^p$-valued functions defined on some Ω open in $\mathbb{C}$ is called a *reproducing kernel Hilbert space* (RKHS) if there exists a $\mathbb{C}^{p\times p}$-valued function $K(z, w)$ defined on $\Omega \times \Omega$ such that for every choice of $w \in \Omega$, $c \in \mathbb{C}^p$ and $f \in \mathcal{H}$:

(i) $K(., w)c \in \mathcal{H}$,

(ii) $\langle f, K(., w)c\rangle_{\mathcal{H}} = c^* f(w)$.

The function K is called the *reproducing kernel,* and the main facts are that it is unique and it is a *positive function* in the following sense:

$$\sum_{i,j=1}^{r} c_j^* K(w_j, w_i) c_i \geq 0 \tag{13}$$

for every choice of points $w_1, w_2, \ldots, w_r \in \Omega$, and vectors $c_1, c_2, \ldots, c_r \in \mathbb{C}^p$.

The Hardy space H_2^p is clearly a reproducing kernel Hilbert space whose kernel is

$$\frac{I_p}{1-\bar{w}z}, \quad w \in \mathbb{U}, \quad z \in \mathbb{U},$$

and property (ii) is just the Cauchy formula. Finite dimensional Hilbert spaces of $\mathbb{C}^p$-valued functions are also reproducing kernel Hilbert spaces. Let $(f_1, f_2, \ldots, f_N)$ be some base of a finite dimensional Hilbert space. Then its reproducing kernel is easily computed to be

$$K(z,w) = (f_1(z), f_2(z), \ldots, f_N(z))P^{-1}(f_1(w), f_2(w), \ldots, f_N(w))^*,$$

where $P = (P_{ij})$ is the Gram matrix with entries $P_{ij} = \langle f_j, f_i \rangle$. The space $\mathcal{H}(Q)$ introduced in the previous section as being the orthogonal complement of QH_2^p in H_2^p is a reproducing kernel Hilbert space with reproducing kernel

$$K_Q(z,w) = \frac{I_p - Q(z)Q(w)^*}{1-\bar{w}z}, \tag{14}$$

which is the projection onto $\mathcal{H}(Q)^p$ of the reproducing kernel of H_2^p. This is readily seen with the help of the evaluation

$$\pi^+\left(Q(z)^{-1}\frac{I_p c}{1-\bar{w}z}\right) = \frac{Q(w)^* c}{1-\bar{w}z}, \tag{15}$$

where π^+ denotes the orthogonal projection onto H_2^p.

More generally, a RKHS is attached to every J-inner function. The study of these spaces, which play a central role in the theory of realization and interpolation, originates with de Branges and Rovnyak (see [14]). Put

$$J = \begin{pmatrix} I_p & 0 \\ 0 & -I_p \end{pmatrix}.$$

A $\mathbb{C}^{2p\times 2p}$-valued rational function Θ is called J-inner if at every point of analyticity of Θ in $\mathbb{U}$, $J - \Theta(z)J\Theta(z)^*$ is positive semidefinite:

$$\Theta(z)J\Theta(z)^* \leq J, \tag{16}$$

and equality holds for z point of analyticity on $\mathbb{T}$. Consider the space H_2^{2p} endowed with the sesquilinear Hermitian form, $\langle f, g \rangle_J = \langle f, Jg \rangle$. This form is not positive definite but it is nondegenerate. Hence, the space ΘH_2^{2p} has an orthogonal complement in H_2^{2p}, which we call $\mathcal{H}(\Theta)$. Restricted to $\mathcal{H}(\Theta)$, the form $\langle ., . \rangle_J$ is positive definite, so that $\mathcal{H}(\Theta)$ is a Hilbert space. Moreover, it is a reproducing kernel Hilbert space with reproducing kernel

$$K_\Theta(z,w) = \frac{J - \Theta(z)J\Theta(w)^*}{1-\bar{w}z} \tag{17}$$

and the dimension of $\mathcal{H}(\Theta)$ agrees with the McMillan degree of Θ. In the next section, we shall make an intensive use of one-dimensional $\mathcal{H}(\Theta)$ spaces; let f be the function defined by

$$f(z) = \frac{\begin{pmatrix} u \\ v \end{pmatrix}}{1-\bar{w}z},$$

where $w \in \mathbb{U}$, $u \in \mathbb{C}^p$ with $\|u\| = 1$, and $v \in \mathbb{C}^p$; let $\mathcal{M}$ be the linear span of f endowed with the form $\langle\ ,\ \rangle_J$. If $\|v\| \leq 1$, then the Gram matrix $P = \langle f, f\rangle_J$ is positive and $\mathcal{M}$ is of the form $\mathcal{H}(\Theta)$, where Θ is unique up to a J-unitary constant multiplier on the right. It can be specified by the formula

$$\Theta(z) \ = \ I_{2p} - (1 - \bar{\xi}z) f(z) P^{-1} f(\xi)^* J$$

for any point $\xi \in \mathbb{T}$. In the sequel, we shall work with the J-inner function associated with $\mathcal{M}$ which satisfies the condition $\Theta(1) = I_{2p}$. It is given by

$$\Theta(w,u,v)(z) \ = \ I_{2p} - (1-z)\frac{1-|w|^2}{1-\|v\|^2}\frac{\begin{pmatrix} u \\ v \end{pmatrix}}{1-\bar{w}z}\frac{\begin{pmatrix} u^* & v^* \end{pmatrix}}{1-w} J. \tag{18}$$

3.2. The linear fractional transformation associated with a *J*-inner function. In this section we introduce the linear fractional transformation T_Θ, which generalizes (12) to the matrix case (for a precise comparison see the remark after Theorem 7). The statements and the proofs of this section and the following are adapted from [1].

LEMMA 3. *Let*

$$\Theta \ = \ \begin{pmatrix} \Theta_{11} & \Theta_{12} \\ \Theta_{21} & \Theta_{22} \end{pmatrix} \tag{19}$$

be a $(2p \times 2p)$-rational J-inner function analytic in $\mathbb{U}$ and let A be a $(p \times p)$-rational inner function. Then $(\Theta_{21}A + \Theta_{22})$ is invertible in $\mathbb{U}$ and

$$T_\Theta(A) \ = \ (\Theta_{11}A + \Theta_{12})\ (\Theta_{21}A + \Theta_{22})^{-1} \tag{20}$$

is inner. Note that if $\Theta(1) = I_{2p}$ and $A(1) = I_p$, then $[T_\Theta(A)](1) = I_p$, and if A and Θ have real coefficients, then $T_\Theta(A)$ also has real coefficients.

Proof. First, let us show that $(\Theta_{21}A + \Theta_{22})$ is invertible at every point of $\mathbb{U}$. Indeed, condition (16) implies

$$\Theta_{22}\Theta_{22}^* \ \geq \ I_p + \Theta_{21}\Theta_{21}^* \quad \text{in } \mathbb{U},$$

so that $\Theta_{22}\Theta_{22}^*$ is positive definite, and Θ_{22} is invertible at any point of $\mathbb{U}$. Now, we have

$$I_p \ \geq \ \Theta_{22}^{-1}(\Theta_{22}^{-1})^* + (\Theta_{22}^{-1}\Theta_{21})(\Theta_{22}^{-1}\Theta_{21})^* \quad \text{in } \mathbb{U},$$

and thus $\|\Theta_{22}(z)^{-1}\Theta_{21}(z)\| \ < \ 1,\ \forall z \in \mathbb{U}$. The matrix A, being inner, is contractive in $\mathbb{U}$: $\|A(z)\| \ \leq \ 1,\ \forall z \in \mathbb{U}$, so that $\|\Theta_{22}(z)^{-1}\Theta_{21}(z)A(z)\| \ < \ 1,\ \forall z \in \mathbb{U}$. Finally, $(\Theta_{21}A + \Theta_{22}) \ = \ \Theta_{22}\ (I_p + \Theta_{22}^{-1}\Theta_{21}A)$ is invertible at any point of $\mathbb{U}$, and thus $B = T_\Theta(A)$ is analytic in $\mathbb{U}$. Then, condition (5) for B can be written

$$B^*B - I_p \ = \ \begin{pmatrix} B^* & I_p \end{pmatrix} J \begin{pmatrix} B \\ I_p \end{pmatrix} \ = \ 0 \quad \text{on } \mathbb{T}.$$

Using the relation

$$\begin{pmatrix} B \\ I_p \end{pmatrix} \ = \ \Theta \begin{pmatrix} A \\ I_p \end{pmatrix} (\Theta_{21}A + \Theta_{22})^{-1}, \tag{21}$$

we obtain

$$B^*B - I_p \ = \ ((\Theta_{21}A + \Theta_{22})^{-1})^* \ \begin{pmatrix} A^* & I_p \end{pmatrix} \ \Theta^* J \Theta \ \begin{pmatrix} A \\ I_p \end{pmatrix} (\Theta_{21}A + \Theta_{22})^{-1},$$

and since condition (5) is satisfied for A, it will be satisfied for B as well. ∎

LEMMA 4. *The matrix* $B = T_{\Theta(w,u,v)}(A)$, *where* $\Theta(w,u,v)$ *is given by* (18), *satisfies the interpolation condition*

$$B(w)^* u = v. \tag{22}$$

Proof. Indeed, it can be verified that $\Theta(w,u,v)$ satisfies the equation

$$\begin{pmatrix} u^* & -v^* \end{pmatrix} \Theta(w) = 0.$$

Thus

$$\begin{pmatrix} u^* & -v^* \end{pmatrix} \Theta(w) \begin{pmatrix} A(w) \\ I_p \end{pmatrix} = 0,$$

and together with (21) this implies our interpolation condition. ∎

Now, the question is the converse: let B be some rational inner matrix, and Θ J-inner analytic in $\mathbb{U}$. Can we write B in the form $B = T_\Theta(A)$ for some inner matrix A? First, note that if $B = T_\Theta(A)$, then A is the rational function given by

$$A = (\Theta_{11} - B\Theta_{21})^{-1}(B\Theta_{22} - \Theta_{12}), \tag{23}$$

unless $\det(\Theta_{11} - B\Theta_{21})$ vanishes identically. This may not happen since condition (16) for Θ implies $\Theta_{11}^*\Theta_{11} - \Theta_{21}^*\Theta_{21} = I_p$ on $\mathbb{T}$. So, $\Theta_{11} - B\Theta_{21}$ is invertible at any point of $\mathbb{T}$. However, it may fail to be invertible at some point of $\mathbb{U}$, so that A may not be analytic in $\mathbb{U}$. To ensure analyticity, we must make an additional assumption.

THEOREM 5. *Let* B *be a rational inner function, and let* $\Theta(w,u,v)$ *be the* J*-inner function* (18). *There exists an inner function* A *such that* $B = T_\Theta(A)$ *if and only if the interpolation condition* $B(w)^* u = v$ *is satisfied. We then have* $\deg B = \deg A + 1$.

Proof. This is a special case of a more general result proved in [1, Thm. 3.3] which is based on the links between $\mathcal{H}(\Theta)$ and $\mathcal{H}(Q)$ spaces. For more details on these problems we refer the reader to [2]. The content of the result of [1] is the following: let $B \in \mathcal{I}_n^p$ and Θ be a J-inner $(2p \times 2p)$-rational function; consider the map

$$\begin{array}{rccl} \tau : & \mathcal{H}(\Theta) & \to & H_2^p, \\ & \begin{pmatrix} f_1 \\ f_2 \end{pmatrix} & \to & f_1 - Bf_2. \end{array}$$

Then there exists an inner function A such that $B = T_\Theta(A)$ if and only if τ is an isometry from $\mathcal{H}(\Theta)$ to $\mathcal{H}(B)$. Moreover, $\deg B = \deg\Theta + \deg A$. We shall admit this result.

If $\Theta(w,u,v)$ is given by (18), the conditions:

(i) τ is an isometry from $\mathcal{H}(\Theta)$ to $\mathcal{H}(B)$,

(ii) $B(w)^* u = v$

are equivalent. Indeed, τ sends the generator of $\mathcal{H}(\Theta)$ as follows:

$$\tau : \frac{\begin{pmatrix} u \\ v \end{pmatrix}}{1 - \bar{w}z} \to \frac{u - B(z)\, v}{1 - \bar{w}z}.$$

With the help of the evaluation (15), it is readily proved that $\frac{u - B(z)\, v}{1 - \bar{w}z} \in \mathcal{H}(B)$ if and only if condition (ii) holds. In this case,

$$\left\langle \begin{pmatrix} f_1 \\ f_2 \end{pmatrix}, \begin{pmatrix} f_1 \\ f_2 \end{pmatrix} \right\rangle_J = \|f_1\|_2^2 - \|f_2\|_2^2 = \|f_1\|_2^2 - \|Bf_2\|_2^2 = \|f_1 - Bf_2\|_2^2,$$

and τ is an isometry from $\mathcal{H}(\Theta)$ (endowed with the scalar product $\langle\ ,\ \rangle_J$) to $\mathcal{H}(B)$. This proves the theorem. ∎

3.3. Description of the charts. If Θ is of the form (18), then $T_\Theta(A)$ and A have the same value at $z = 1$. We can construct from the identity matrix I_p, using n linear fractional transformations of this type, an inner matrix of degree n which belongs to $\mathcal{I}_n^p(1)$. Conversely, any matrix of $\mathcal{I}_n^p(1)$ can be obtained in this way. This is the content of the tangential Schur algorithm for which we need the following lemma.

LEMMA 6. *Let B be an inner function and $w \in \mathbb{U}$. Then, there exists $u \in \mathbb{C}^p$, $\|u\| = 1$, such that*

$$\|B(w)^* u\| < 1.$$

Proof. Suppose that for all unit vector $u \in \mathbb{C}^p$, $\|B(w)^* u\| = 1$. Then, since

$$\|K_B(.,w)u\|_2^2 \;=\; u^* K_B(w,w)u \;=\; \frac{1 - \|B(w)^* u\|}{1 - \bar{w}w},$$

for all $u \in \mathbb{C}^p$, $K_B(.,w)u \;=\; 0$. So, $K_B(.,w)$ is identically 0 and the matrix B must be constant. But this contradicts the fact that B has McMillan degree n. ∎

THEOREM 7 (tangential Schur algorithm). *Let $Q \in \mathcal{I}_n^p(1)$, and $w_k \in \mathbb{U}$, $k = n, \ldots, 1$. Then, for $k = n, \ldots, 1$ there exist unit vectors $u_k \in \mathbb{C}^p$ such that the vectors $y_k \in \mathbb{C}^p$ given by*

$$y_k = Q^{(k)}(w_k)^* u_k \tag{24}$$

satisfy $\|y_k\| < 1$, where $Q^{(n)} = Q$,

$$Q^{(k)} \;=\; T_{\Theta_k}(Q^{(k-1)}), \tag{25}$$

and $\Theta_k = \Theta(w_k, u_k, y_k)$ is the J-inner matrix given by (18). *Then*

$$Q \;=\; T_{\Theta_n}(T_{\Theta_{n-1}} \ldots T_{\Theta_1}(I_p)) \ldots \;=\; T_{\Theta_n \ldots \Theta_1}(I_p).$$

Proof. This is an obvious consequence of Theorem 5 and Lemma 6. ∎

Let $\mathbf{w} = (w_1, w_2, \ldots, w_n)$ and $\mathbf{u} = (u_1, u_2, \ldots, u_n)$. Define the subset $\mathcal{V}_{(\mathbf{w},\mathbf{u})}$ of $\mathcal{I}_n^p(1)$ by

$$\mathcal{V}_{(\mathbf{w},\mathbf{u})} \;=\; \{Q \in \mathcal{I}_n^p(1) \;/\; \|Q^{(k)}(w_k)^* u_k\| < 1\},$$

and the function $\varphi_{(\mathbf{w},\mathbf{u})}$ by

$$\begin{array}{rccl} \varphi_{(\mathbf{w},\mathbf{u})} \;:\; & \mathcal{V}_{(\mathbf{w},\mathbf{u})} & \to & \mathcal{B}_p^n, \\ & Q & \to & (y_1, y_2, \ldots, y_n), \end{array}$$

where the $Q^{(k)}$'s and the *Schur parameters* y_k's are defined recursively by (24) and (25), and $\mathcal{B}_p^n$ denotes the product of n copies of the unit ball of $\mathbb{C}^p$.

Remark. Note that in the scalar case and for $w_j = 0$, the transformation $Q^{(j)} = T_{\Theta_j}(Q^{(j-1)})$ is given by

$$Q^{(j)}(z) = \frac{(z - |y_j|^2)\, Q^{(j-1)}(z) + (1 - z)u_j \bar{y}_j}{(z-1)\bar{u}_j y_j\, Q^{(j-1)}(z) + (1 - |y_j|^2 z)}.$$

This formula is exactly (12) in which y_j has been replaced by $u_j\bar{y}_j$, since the interpolation condition is now $Q^{(j)}(0) = u_j\bar{y}_j$, and μ_j is chosen to be $-u_j\bar{y}_j$. The general formula with an arbitrary μ_j can also be obtained by a T_Θ transformation where Θ is of the form (18) multiplied by an adequate constant J-inner function. In this case the normalization (7) is not conserved.

THEOREM 8. *The family $(\mathcal{V}, \varphi)$ defines a C^∞ atlas on $\mathcal{I}_n^p(1)$, which is compatible with its natural structure of embedded submanifold of $H_2^{p\times p}$.*

Proof. It follows from Lemma 6 that the collection of sets $\mathcal{V}_{(\mathbf{w},\mathbf{u})}$ covers $\mathcal{I}_n^p(1)$. It remains to prove that the map $\varphi_{(\mathbf{w},\mathbf{u})}$ is an homeomorphism and that the change of chart $\varphi_{(\mathbf{w},\mathbf{u})} \circ \varphi_{(\mathbf{w}',\mathbf{u}')}$ is smooth. The map $\varphi_{(\mathbf{w},\mathbf{u})}$ is one-to-one and onto by construction. The coefficients of $Q^{(k)}$ depend continuously on that of $Q^{(k-1)}$ and on $y_k, \dots, y_1$, so that the coefficients of Q depend continuously on the Schur parameters. Since the matrix Q is inner and thus bounded in the unit disk, $\|Q(z)\| \le 1$, $\forall z \in \mathbb{U}$, Lebesgue's theorem finally implies that $\varphi^{-1}_{(\mathbf{w},\mathbf{u})}$ is continuous. Conversely, note that the evaluation map $Q \to Q(w_n)^* u_n$ is continuous, so that $Q \to y_n$ is continuous. The coefficients of $Q^{(n-1)}$ depend continuously on that of Q and on y_n, and, if two normalized rational functions of bounded degree are closed in $H_2^{p\times p}$, then their coefficients must also be closed; then, the map $Q \to Q^{(n-1)}$ from $\mathcal{I}_n^p$ to $\mathcal{I}_{n-1}^p$, both endowed with the H_2-topology, is continuous. We thus prove inductively that $\varphi_{(\mathbf{w},\mathbf{u})}$ is continuous and consequently is an homeomorphism. Furthermore, the map $\varphi_{(\mathbf{w},\mathbf{u})} \circ \varphi_{(\mathbf{w}',\mathbf{u}')} : \mathcal{B}_p^n \to \mathcal{B}_p^n$ is C^∞, as a bounded rational function. ∎

In any chart of this atlas, *the local coordinates are the $2np$ real and imaginary parts of the components of the Schur parameters.* Note that an atlas for $\mathcal{RI}_n^p(1)$ can be obtained in a similar way, for which the w_i's lie in $(-1, 1)$, the u_i's and the y_i's have real components; indeed, in Lemma 6 u can be chosen real, and if A and Θ have real coefficients, $T_\Theta(A)$ also has real coefficients. The range of the charts is thus the product of n copies of the unit ball of $\mathbb{R}^p$.

3.4. Fractional representation in the local coordinates. In this section, we give a fractional representation of the form $D^{(k)}/\widetilde{q}^{(k)}$ for the matrix $Q^{(k)}$ (see Proposition 2). We introduce the map $\mathcal{S}_{(w,u)} : (A, y) \to T_{\Theta(w,u,y)}(A)$, so that the inner matrix $Q = \varphi^{-1}_{(\mathbf{w},\mathbf{u})}(y)$ is computed by the iterative process:

$$I_p \to Q^{(1)} \to \cdots \to Q^{(k)} = \mathcal{S}_{(w_k,u_k)}(Q^{(k-1)}, y_k) \to \cdots \to Q^{(n)} = Q.$$

LEMMA 9. *For any $A \in \mathcal{I}_k^p$, $w \in \mathbb{U}$, $u \in \mathbb{C}^p$, $\|u\| = 1$, and $v \in \mathbb{C}^p$, $\|v\| < 1$, we have*

$$S_{(w,u)}(A, y) = A + \frac{1-\beta_w}{1 - u^*Ay - \beta_w(y^*y - u^*Ay)}(u - Ay)(y^* - u^*A), \tag{26}$$

with $\beta_w = b_w/\widetilde{b}_w$, where $b_w(z) = (z - w)(1 - \bar{w})$.

Proof. Using (18) yields

$$T_{\Theta(w,u,y)}(A) = \left(A + (1-\beta_w)\frac{u(y^* - u^*A)}{1 - y^*y}\right)\left(I_p + (1-\beta_w)\frac{y(y^* - u^*A)}{1 - y^*y}\right)^{-1}.$$

A classical formula (see [28, Appendix A.20]) allows us to compute the inverse as follows

$$\left(I_p + (1-\beta_w)\frac{y(y^* - u^*A)}{1 - y^*y}\right)^{-1} = I_p - (1-\beta_w)\frac{y(y^* - u^*A)}{1 - u^*Ay - \beta_w(y^*y - u^*Ay)},$$

from which we deduce (26) by expanding the product. ∎

PROPOSITION 10. *A fractional representation $D^{(k)}/\widetilde{q}^{(k)}$ of the inner matrix $Q^{(k)} = T_{\Theta_k \dots \Theta_1}(I_p)$ can be computed by the recursion formulas: $D^{(0)} = I_p$, $\widetilde{q}^{(0)} = 1$, and for $k = 1, \dots, n$,*

$$
\begin{aligned}
D^{(k)} = {} & (\widetilde{b}_{w_k} - y_k^* y_k \, b_{w_k}) D^{(k-1)} - (\widetilde{b}_{w_k} - \ b_{w_k}) \Big\{ u_k u_k^* D^{(k-1)} + D^{(k-1)} y_k y_k^* \\
& - \widetilde{q}^{(k-1)} \ u_k y_k^* + \frac{u_k^* D^{(k-1)} y_k \ D^{(k-1)} - D^{(k-1)} y_k u_k^* D^{(k-1)}}{\widetilde{q}^{(k-1)}} \Big\},
\end{aligned} \tag{27}
$$

$$
\widetilde{q}^{(k)} = (\widetilde{b}_{w_k} - y_k^* y_k \, b_{w_k}) \, \widetilde{q}^{(k-1)} - (\widetilde{b}_{w_k} - b_{w_k}) \, u_k^* D^{(k-1)} y_k, \tag{28}
$$

where $b_{w_k} = (1 - \bar{w}_k)(z - w_k)$. The stable polynomial $q^{(k)}$ has degree k, and the coefficients of the polynomials $\widetilde{q}^{(k)}$ and $d_{ij}^{(k)}$ (the entries of $D^{(k)}$) are polynomial functions in the local coordinates.

Proof. Assume that such a fractional representation has been obtained for $Q^{(k-1)}$. Replacing $Q^{(k-1)}$ by $D^{(k-1)}/\widetilde{q}^{(k-1)}$ in $S_{(w_k,u_k)}(Q^{(k-1)}, y_k)$ given by (26) yields a fractional representation for $Q^{(k)}$. Note that (27) actually defines a polynomial matrix, since $\widetilde{q}^{(k-1)}$ does indeed divide $u_k^* D^{(k-1)} y_k \ D^{(k-1)} - D^{(k-1)} y_k \ u_k^* D^{(k-1)}$. In order to prove this, put $u_k^* = (\bar{u}_1^k, \dots, \bar{u}_p^k)$, $y_k^* = (\bar{y}_1^k, \dots, \bar{y}_p^k)$, and $D^{(k-1)} = (d_{ij}^{(k-1)})$. A straightforward computation shows that

$$
\begin{aligned}
& \left(u_k^* D^{(k-1)} y_k \, D^{(k-1)} - D^{(k-1)} y_k \, u_k^* D^{(k-1)} \right)_{ij} \\
& \qquad = \sum_{l,m} \left(d_{lm}^{(k-1)} d_{ij}^{(k-1)} - d_{im}^{(k-1)} d_{lj}^{(k-1)} \right) \bar{u}_l^k y_m^k,
\end{aligned}
$$

where $d_{lm}^{(k-1)} d_{ij}^{(k-1)} - d_{im}^{(k-1)} d_{lj}^{(k-1)}$ is a minor of order 2 of $D^{(k-1)}$. But in the fractional representation $\widetilde{q}^{(k-1)}$ is, up to a constant factor, the polynomial of poles of $Q^{(k-1)}$, which is the least common denominator of all the minors of $Q^{(k-1)}$ (see [28]). Thus, it must divide all the minors of order 2 of $D^{(k-1)}$.

Now, let us prove by induction that, for $k = 1, \dots, n$, the coefficients of $d_{ij}^{(k)}$ and $\widetilde{q}^{(k)}$ are polynomial functions in the local coordinates. This is true for $d_{ij}^{(1)}$ and $\widetilde{q}^{(1)}$ and we shall assume that this is also true for $d_{ij}^{(k-1)}$ and $\widetilde{q}^{(k-1)}$: for $l = 1, \dots, n$, put

$$
y_j^l = \xi_j^l + i \, \eta_j^l,
$$

where y_j^l is the jth component of y_l; then the coefficients of $d_{ij}^{(k-1)}$ and $\widetilde{q}^{(k-1)}$ belong to the ring $\mathcal{P}_{k-1}$ of complex polynomials in the $2(k-1)p$ variables ξ_j^l and η_j^l, $l = 1, \dots, k-1$, $j = 1, \dots, p$. In order to prove our assumption at order k, we must verify that $\widetilde{q}^{(k-1)}$ divides all the minors of order 2 of $D^{(k-1)}$ in the ring $\mathcal{P}_{k-1}[z]$. Let

$$
D^{(k-1)} \begin{pmatrix} i_1 & \cdots & i_l \\ j_1 & \cdots & j_l \end{pmatrix}
$$

be the minor of $D^{(k-1)}$ computed from the lines $i_1, \dots, i_l$ and the columns $j_1, \dots, j_l$. Since the matrix $D/\widetilde{q}$ is the inverse of $\widetilde{D}/q$, the minors of order 2 of $D^{(k-1)}$ are related

to those of order $p-2$ of $\widetilde{D}^{(k-1)}$ by the formula (see [20]):

$$\begin{aligned}&\{q^{(k-1)}\}^{p-3}\, D^{(k-1)}\begin{pmatrix} i_1 & i_2 \\ j_1 & j_2 \end{pmatrix}\\ &\qquad = (-1)^{\{i_1+i_2+j_1+j_2\}}\, \widetilde{D}^{(k-1)}\begin{pmatrix} i'_1 & \cdots & i'_{p-2} \\ j'_1 & \cdots & j'_{p-2} \end{pmatrix} \widetilde{q}^{(k-1)},\end{aligned} \tag{29}$$

where $\{i_1, i_2, i'_1, \ldots, i'_{p-2}\}$ and $\{j_1, j_2, j'_1, \ldots, j'_{p-2}\}$ form complete sets of rows and columns. If $\widetilde{q}^{(k-1)}$ is irreducible we are done. We shall prove this still by induction. First, $\widetilde{q}^{(0)}$ is irreducible. Then, assume that $\widetilde{q}^{(l-1)}$ is irreducible while $\widetilde{q}^{(l)}$ can be factored as

$$\widetilde{q}^{(l)} = \alpha\beta, \quad \alpha \in \mathcal{P}_l[z], \quad \beta \in \mathcal{P}_l[z].$$

The polynomial $\widetilde{q}^{(l)}$ can be viewed as a polynomial in the $2p$ coordinates $\xi_1^l, \ldots, \xi_p^l$, $\eta_1^l, \ldots, \eta_p^l$, with coefficients in $\mathcal{P}_{l-1}[z]$:

$$\widetilde{q}^{(l)} = \left(\widetilde{b}_{w_l} - b_{w_l}\left\{\sum_{j=1}^{p}(\xi_j^l)^2 + (\eta_j^l)^2\right\}\right)\widetilde{q}^{(l-1)} - (\widetilde{b}_{w_l} - b_{w_l})\sum_{j=1}^{p}\left\{\sum_{i=1}^{p}\bar{u}_i^l d_{ij}^{(l-1)}\right\}(\xi_j^l + i\eta_j^l).$$

If α does not depend on ξ_1^l, for example, then α must divide $-b_{w_l}\widetilde{q}^{(l-1)}$ and since b_{w_l} does not divide $\widetilde{q}^{(l)}$, we must have $\alpha = \widetilde{q}^{(l-1)}$. Therefore, $\widetilde{q}^{(l-1)}$ must divide each component of $u_l^* D^{(l-1)}$ in $\mathcal{P}_{l-1}[z]$. But this is clearly impossible; indeed, since $Q^{(l-1)}(1) = I_p$ we should have $u_l^* D^{(l-1)} = \widetilde{q}^{(l-1)} u_l$ for every choice of local coordinates. Thus both α and β have degree one in each ξ_j^l and η_j^l. But then, writing $\alpha = \alpha_1\xi_1^l + \cdots + \alpha_p\xi_1^p + \alpha'_1\eta_1^l + \cdots + \alpha'_p\eta_1^p + \alpha_0$ and $\beta = \beta_1\xi_1^l + \cdots + \beta_p\xi_1^p + \beta'_1\eta_1^l + \cdots + \beta'_p\eta_1^p + \beta_0$, we can see that such a factorization is impossible, so that $\widetilde{q}^{(l)}$ is actually irreducible. ∎

Though the quotient in formula (27) is exact, we fail in searching for an explicit formula for it, and we do not know if such a formula exists.

4. A generic algorithm to find a local minimum. The closure of $\mathcal{I}_n^p(1)$ in $H_2^{p\times p}$ is a compact set, so that we can think of using a gradient algorithm to find a local minimum of the function Ψ^n defined by (8) in section 2. The elements of $\mathcal{I}_n^p(1)$ will be parameterized as explained in the previous section, the local coordinates being the real and imaginary parts of the components of the vectors $y_1, \ldots, y_n$. We shall work with the local representations of Ψ^n and denote by $\Psi^n_{(\mathbf{w},\mathbf{u})}$ the local representation associated with the chart defined by $(\mathbf{w}, \mathbf{u})$:

$$\begin{array}{rlcl}\Psi^n_{(\mathbf{w},\mathbf{u})}: & \mathcal{B}_p^n & \to & \mathbb{R}, \\ & \mathbf{y} = (y_1, \ldots y_n) & \to & \Psi^n \circ \varphi^{-1}_{(\mathbf{w},\mathbf{u})}(\mathbf{y}).\end{array}$$

4.1. Limit points in the charts. The object of this section is to study what happens when, running a gradient algorithm, the norm of some Schur parameter tends to 1. In the scalar case, the structure of $\mathcal{I}_n^1(1)$ is particularly simple, since only one coordinate map is needed; as some $|y_k|$ tends to 1, the boundary of $\mathcal{I}_n^1(1)$ is reached. This boundary has been completely studied in the case of real functions; it has been proved in [7] that the set $\mathcal{RI}_n^1(1)$ can be identified with the set $\mathcal{P}_n^1$ of monic stable polynomials of degree n and established in [10] that its closure is a

topological manifold with boundary, this boundary having corners. The smooth part of the boundary, which plays an important role in the algorithm, consists of those polynomials having exactly one irreducible factor over $\mathbb{R}$ whose roots are of modulus one. In the matrix case, as some $\|y_k\|$ tends to 1, either the chart is no more available and another one must be used, or some point of the boundary of $\mathcal{I}_n^p(1)$ is reached. Moreover, as we shall see later, the closure of $\mathcal{I}_n^p(1)$ is no more a topological manifold with boundary, and possesses some *singular* boundary points (see Proposition 13).

Proposition 11 below, describes *regular* boundary points. Observe that if $\|y\| = 1$, the J-inner function $\Theta(w, u, y)$ is no more defined; however, if u^*Ay is not identically equal to 1, the transformation $S_{(w,u)}$ keeps a sense and is given by

$$S_{(w,u)}(A, y) = A + \frac{(u - Ay)(y^*A - u^*)}{(1 - u^*Ay)}.$$

PROPOSITION 11. *Let $\mathbf{y} \in \partial\mathcal{B}_p^n$, the boundary of $\mathcal{B}_p^n$, $\mathbf{w} \in \mathbb{U}^n$, and $\mathbf{u} \in \partial\mathcal{B}_p^n$, and let $(D^{(k)}, \widetilde{q}^{(k)})$ be the sequence associated with $\mathbf{w}, \mathbf{u}, \mathbf{y}$ by the recursion formulas* (27) *and* (28). *A sequence*

$$I_p \to Q^{(1)} \to \cdots \to Q^{(k)} = \mathcal{S}_{(w_k,u_k)}(Q^{(k-1)}, y_k) \to \cdots \to Q^{(n)}$$

of inner matrices can be computed, provided that $u_k^*Q^{(k-1)}(w_k)y_k$ is not identically equal to 1 as $\|y_k\| = 1$, or equivalently, $\widetilde{q}^{(k)}$ does not vanish identically. In this case, $\mathbf{y}$ will be called a regular limit point in the chart defined by $(\mathbf{w}, \mathbf{u})$. Then $Q^{(k)} = D^{(k)}/\widetilde{q}^{(k)}$, and

(a) *$q^{(k)}$ still has degree k,*

(b) *if $\|y_k\| = 1$, then $\widetilde{q}^{(k)}$ and $D^{(k)}$ have common roots on $\mathbb{T}$ and $Q^{(k)}$ has degree less than k.*

Moreover, there exists a neighborhood $\mathcal{W}$ of $\mathbf{y}$, such that $\varphi^{-1}_{(\mathbf{w},\mathbf{u})}$ extends smoothly to $\mathcal{W}$.

Proof. Assume that these assertions have been proved until order $k-1$, and let us prove that they still hold at order k. If $\|y_k\| < 1$, there is nothing to prove. If $\|y_k\| = 1$, then

$$\widetilde{q}^{(k)} = (1 - |w_k|^2)(1 - z)(\widetilde{q}^{(k-1)} - u_k^*D^{(k-1)}y_k),$$

and since $Q^{(k-1)}$ is inner, by the maximum modulus principle, either $u_k^*Q^{(k-1)}y_k$ is identically equal to 1, and $\widetilde{q}^{(k)}$ vanishes identically, or

$$\widetilde{q}^{(k)}(0) = (1 - |w_k|^2)\widetilde{q}^{(k-1)}(0)(1 - u_k^*Q^{(k-1)}(0)y_k)$$

does not vanish and thus $q^{(k)}$ has degree k. In this case, $Q^{(k)} = \mathcal{S}_{(w_k,u_k)}(Q^{(k-1)}, y_k) = D^{(k)}/\widetilde{q}^{(k)}$ is well defined and still inner; 1, which is a root of $\widetilde{q}^{(k)}$, must also be a root of $D^{(k)}$, and the degree of $Q^{(k)}$ cannot exceed that of $Q^{(k-1)}$. More precisely,

$$\deg Q^{(k)} = \deg Q^{(k-1)} - \sharp\{\xi \in \mathbb{T}, y_k = Q^{(k-1)}(\xi)^* u_k\}.$$

By induction, the first part of the proposition is proved. Now, $\varphi^{-1}_{(\mathbf{w},\mathbf{u})}(\mathbf{y}) = D^{(n)}/\widetilde{q}^{(n)}$ and since, by Proposition 10, the coefficients of the polynomials $\widetilde{q}^{(n)}$ and $d_{ij}^{(n)}$ are polynomial functions in the local coordinates, there exists a neighborhood $\mathcal{W}$ of $\mathbf{y}$, such that $\varphi^{-1}_{(\mathbf{w},\mathbf{u})}$ extends smoothly to $\mathcal{W}$. ∎

In the next lemma, we shall prove that any inner matrix of degree strictly less than n can be viewed, up to a unitary matrix, as a boundary point of $\mathcal{I}_n^p(1)$ of this type.

LEMMA 12. *For each $Q \in \mathcal{I}_d^p(1)$ of degree d strictly less than n, there exist $\mathbf{w}' \in \mathbb{U}^n$, $\mathbf{u}' \in \partial\mathcal{B}_p^n$, $\mathbf{y}' \in \partial\mathcal{B}_p^n$, and a unitary matrix $\mathcal{U}$, such that $\mathbf{y}'$ is a regular limit point in the chart defined by $(\mathbf{w}', \mathbf{u}')$ and $\mathcal{U}Q = \varphi^{-1}_{(\mathbf{w}',\mathbf{u}')}(\mathbf{y}')$.*

Proof. Let $\mathbf{y} = (y_1, \ldots, y_d)$, $\mathbf{w} = (w_1, \ldots, w_d)$, and $\mathbf{u} = (u_1, \ldots, u_d)$ be such that $Q = \varphi^{-1}_{(\mathbf{w},\mathbf{u})}(\mathbf{y})$:

$$I_p \to Q^{(1)} = \mathcal{S}_{(w_1,u_1)}(I_p, y_1) \to Q^{(2)} \cdots \to Q = \mathcal{S}_{(w_d,u_d)}(Q^{(n-1)}, y_d).$$

The Schur transform $S_{(w,u)}$ applied to some unitary matrix $\mathcal{X}$ and some unit vector y such that $y \neq \mathcal{X}^* u$ will give another unitary matrix. Thus, we can construct a unitary matrix $\mathcal{U}$ in the following way:

$$\mathcal{U}_0 = I_p \to \mathcal{U}_1 = \mathcal{S}_{(w_1',u_1')}(I_p, y_1') \to \mathcal{U}_2 \cdots \to \mathcal{U} = \mathcal{S}_{(w_{n-d}',u_{n-d}')}(\mathcal{U}_{n-d-1}, y_{n-d}'),$$

where $w_1', \ldots, w_{n-d}'$, are chosen arbitrarily and $u_1', \ldots, u_{n-d}', y_1', \ldots, y_{n-d}'$, are unit vectors in $\mathbb{C}^p$, satisfying for $k = 1, \ldots, n-d$, ${u_k'}^* \mathcal{U}_{k-1} y_k' \neq 1$. Since we have

$$S_{(w,\,\mathcal{X}u)}(\mathcal{X}A, y) \;=\; \mathcal{X} S_{(w,\,u)}(A, y)$$

for any unitary matrix $\mathcal{X}$, $\mathcal{U}Q$ can be computed by the following iterative process:

$$I_p \to \mathcal{U}_1 = \mathcal{S}_{(w_1',u_1')}(I_p, y_1') \to \mathcal{U}_2 \cdots \to \mathcal{U} = \mathcal{S}_{(w_{n-d}',u_{n-d}')}(\mathcal{U}_{n-d-1}, y_{n-d}')$$

$$\to \mathcal{U}Q^{(1)} = \mathcal{S}_{(w_1,\mathcal{U}u_1)}(\mathcal{U}, y_1) \to \mathcal{U}Q^{(2)} \cdots \to \mathcal{U}Q = \mathcal{S}_{(w_d,\mathcal{U}u_d)}(\mathcal{U}Q^{(n-1)}, y_d).$$

Put

$$\begin{aligned}
\mathbf{w}' &= (w_1', \ldots, w_{n-d}', w_1, \ldots, w_d),\\
\mathbf{u}' &= (u_1', \ldots, u_{n-d}', \mathcal{U}u_1, \ldots, \mathcal{U}u_d),\\
\mathbf{y}' &= (y_1', \ldots, y_{n-d}', y_1, \ldots, y_d),
\end{aligned}$$

then $\mathbf{y}'$ is a regular limit point in the chart defined by $(\mathbf{w}', \mathbf{u}')$ and $\mathcal{U}Q = \varphi^{-1}_{(\mathbf{w}',\mathbf{u}')}(\mathbf{y}')$ as required. ∎

The next proposition is concerned with *singular* boundary points.

PROPOSITION 13. *Let $\eta(t) : [0,1] \to \overline{\mathcal{B}_p^n}$ be a smooth path whose terminal point $\mathbf{y} = \eta(1)$ belongs to $\partial\mathcal{B}_p^n$ and let $D(t)/\widetilde{q}(t)$ be the fractional representation of $Q(t) = \varphi^{-1}_{(\mathbf{w},\mathbf{u})}(\eta(t))$ obtained by the recursion formulas (27) and (28). Assume that $\widetilde{q}(t)$ vanishes identically as $t \to 1$. Then, $Q(t)$ converges to some inner function Q_η, depending in general on the path and whose degree may be less than or equal to n; it is given by the number of roots of $q(t)$ which converges within the unit disk.*

Proof. Since $D(t)$ and $\widetilde{q}(t)$ are polynomial functions in the local coordinates, they do converge, respectively, to a polynomial matrix D and a polynomial $\widetilde{q}$. We deal with the case where $\widetilde{q}$ is the zero polynomial. However, the quotient $D(t)/\widetilde{q}(t)$ must converge to some inner function Q_η. Let $q(t)(z) = q_n(t)z^n + \cdots + q_1(t)z + q_0(t)$. As $t \to 1$, each coefficient tends to 0 while the quotients $q_k(t)/q_n(t)$ being the well-known elementary symmetric polynomials in the roots (of modulus at most 1) are bounded by

the binomial coefficients $\binom{n}{k}$ and thus converges. The polynomial $q(t)/q_n(t)$ converges to some monic polynomial, which may have roots of modulus one, while the number of its roots within the unit circle gives the degree of Q_η.

Now, we are going to show that the limit Q_η actually depends on the path and may have degree as well less than or equal to n. Let us study the case where $n = 1$ ($\eta(t) = y_1(t)$). Formulas (27) and (28) yield

$$\widetilde{q}^{(1)}(t) = \widetilde{b}_{w_1} u_1^*(u_1 - y_1(t)) + b_{w_1}(u_1 - y_1(t))^* u_1 - b_{w_1}(u_1 - y_1(t))^*(u_1 - y_1(t)),$$

and

$$D^{(1)}(t) = \widetilde{q}^{(1)}(t) I_p - (\widetilde{b}_{w_1} - b_{w_1})(u_1 - y_1(t))(u_1 - y_1(t))^*,$$

so that

$$Q^{(1)}(t) = I_p - \frac{\widetilde{b}_{w_1} - b_{w_1}}{\widetilde{q}^{(1)}(t)}\ (u_1 - y_1(t))(u_1 - y_1(t))^*.$$

Now, as $t \to 1$, $\widetilde{q}^{(1)}(t)$ vanishes identically by assumption, and thus $y_1(t)$ must converge to u_1. Let

$$y_1(t) = u_1 - \sum_{k \geq l} (1-t)^k \xi_k, \quad \xi_l \neq 0, \quad \xi_k \in \mathbb{C}^p$$

be its expansion. Consequently, $\widetilde{q}^{(1)}(t) \sim (\widetilde{b}_{w_1} u_1^* \xi_l + b_{w_1} \xi_l^* u_1)(1-t)^l$ and $Q^{(1)}(t)$ converges to I_p, unless $u_1^* \xi_l = 0$. In this case, let s be the smallest index satisfying $s > l$ and $u_1^* \xi_s \neq 0$. Then, if $s < 2l$, $Q(t)$ still converges to I_p, while if $s \geq 2l$,

$$\widetilde{q}^{(1)}(t) \sim (\widetilde{b}_{w_1} u^* \xi_{2l} + b_{w_1} \xi_{2l}^* u_1 - \widetilde{b}_{w_1} \xi_l^* \xi_l)(1-t)^{2l},$$

and

$$Q^{(1)}(t) \to I_p - \frac{\widetilde{b}_{w_1} - b_{w_1}}{\widetilde{b}_{w_1} u_1^* \xi_{2l} + b_{w_1} \xi_{2l}^* u_1 - \widetilde{b}_{w_1} \xi_l^* \xi_l}\ \xi_l \xi_l^*,$$

which is an inner function of degree 1. In conclusion, as $y_1(t)$ converges to u_1, $Q^{(1)}(t)$ converges either to I_p or to some inner matrix of degree 1, in which case, we leave the domain of the chart while staying inside the manifold. The same situation arises at each order, though it may be more complicated if the norms of several Schur parameters go to 1. □

As an illustration, the closure of $\mathcal{RI}_1^2(1)$ can be viewed as a cone. The summit represents the identity matrix and is a singular boundary point while the base represents the circle of orthogonal matrices of determinant -1 and forms a regular boundary. Two charts are needed to describe this manifold. For example, the chart given by $w = 0$ and $u = (1, 0)^*$ parametrizes all the inner functions except for those of the form (a line of the cone) $\left(\begin{smallmatrix} 1 & 0 \\ 0 & \frac{z-a}{1-az} \end{smallmatrix}\right)$, $a \in (-1, 1)$, while the chart given by $w = 0$ and $u = (0, 1)^*$ parametrizes all the inner functions except for those of the form $\left(\begin{smallmatrix} \frac{z-a}{1-az} & 0 \\ 0 & 1 \end{smallmatrix}\right)$.

4.2. Properties of the local representations of the criterion. The object of this section is to study the behavior of the local representations of the criterion at the neighborhood of a boundary point of $\mathcal{I}_n^p(1)$. We have distinguished in the last

section two kinds of limit points, the regular and the singular ones. In both cases, if $\eta(t)$ is a path whose terminal point $\mathbf{y}$ corresponds to a boundary point of degree $d < n$, say Q_η, then it is easily proved that

$$\lim_{t\to 1} \Psi^n_{(\mathbf{w},\mathbf{u})}(\eta(t)) = \Psi^d(Q_\eta).$$

However, regular limit points play a central role in our algorithm, mainly due to the fact that the local representations of the criterion extends smoothly at the neighborhood of such points. To prove this result, we shall need the following expression for Ψ^n.

PROPOSITION 14. *Let $G(z) = F^\sharp(z)/z$ and $Q = D/\widetilde{q}$ as in Proposition 2. Let R be the remainder in the Weierstrass division in $H_2^{p\times m}$ of $G\widetilde{D}$ by q:*

$$G\widetilde{D} \;=\; V\; q \;+\; R. \tag{30}$$

Then q divides RD and if P is the matrix quotient, of degree at most $n-1$, we have that

$$\Psi^n(Q) \;=\; \|F\|_2^2 - \left\langle F, \frac{\widetilde{P}}{q} \right\rangle. \tag{31}$$

Proof. Since $Q^{-1}L(Q)$ and $F - Q^{-1}L(Q)$ are orthogonal, the cost function can be rewritten:

$$\Psi^n(Q) = \|F\|_2^2 - \langle F, Q^{-1}L(Q)\rangle.$$

The orthogonal projection $L(Q)$ of QF onto $H_2^{p\times m}$ is easily computed from the division (30) as being given by $L(Q) \;=\; \widetilde{R}/\widetilde{q}$, where $\widetilde{R} \;=\; z^{n-1}\; R^\sharp(z)$. Now, multiplying (30) by D on the right shows that q divides RD, and $Q^{-1}L(Q) = \widetilde{D}/q\;\widetilde{R}/\widetilde{q} = \widetilde{P}/q$. ∎

PROPOSITION 15. *Assume that $G(z) = F^\sharp(z)/z$ is analytic in $D_r = \{z,\ \|z\| \le r\}$ for some $r > 1$. Let $\mathbf{y} \in \partial\mathcal{B}_p^n$ be a regular limit point in some chart defined by $(\mathbf{w},\mathbf{u})$ (see Proposition 11) and let $Q = \varphi^{-1}_{(\mathbf{w},\mathbf{u})}(\mathbf{y})$ belong to $\mathcal{I}_d^p$ for some $d < n$. Then, $\Psi^n_{(\mathbf{w},\mathbf{u})}$ extends in some open neighborhood of $\mathbf{y}$ to a smooth function still denoted by $\Psi^n_{(\mathbf{w},\mathbf{u})}$. Moreover, we have*

$$\Psi^n_{(\mathbf{w},\mathbf{u})}(\mathbf{y}) \;=\; \Psi^d\left(Q(1)^{-1}Q\right).$$

Proof. Let $\mathcal{W}$ be a neighborhood of $\mathbf{y}$ on which, by Proposition 11, $\varphi^{-1}_{(\mathbf{w},\mathbf{u})}$ extends smoothly. We may assume that in $\mathcal{W}$, $|\widetilde{q}(0)| \ge \mu$, for some $\mu > 0$. In order to proceed to our extension, we shall use the expression (31) of Ψ^n, in which the polynomial matrices D, R, and P, and the polynomial q, depend on the local coordinates. A well-known integral representation for the remainder R (cf. [39]) is

$$R(z) \;=\; \frac{1}{2i\pi}\int_{\mathbb{T}} \frac{G\widetilde{D}}{q}\frac{q(\xi)-q(z)}{\xi - z}d\xi.$$

We may also restrict $\mathcal{W}$ so that the roots of q lie in a disk $D_s = \{z, |z| < s\}$ for some s, $1 < s < r$. Then, we can extend R in $\mathcal{W}$ by putting

$$R(z) \;=\; \frac{1}{2i\pi}\int_{\Gamma} \frac{G\widetilde{D}}{q}\frac{q(\xi)-q(z)}{\xi - z}d\xi, \tag{32}$$

where Γ is any contour lying in the open annulus between D_s and D_r. Indeed, the coefficient of order k of R is given by

$$R_k \;=\; \frac{1}{2i\pi}\int_\Gamma \frac{G\widetilde{D}}{q}(\xi^{n-k-1}q_n + \cdots + q_{k+1})d\xi$$

and since $|q(\xi)| > \mu\ d(\Gamma, D_s)^n$, the integrand is bounded, and its derivatives are also bounded. Finally, Lebesgue's theorem says that the integral representation (32) defines a smooth function. The extension of R is still the remainder of the division (30). In $\mathcal{W}$, q keeps on dividing RD and the quotient extends smoothly P. As for R, $\Psi^n_{(\mathbf{w},\mathbf{u})}$ extends smoothly by the integral representation

$$\Psi^n_{(\mathbf{w},\mathbf{u})}(\mathbf{y}) \;=\; \|F\|_2^2 - \frac{1}{2i\pi}\overline{\mathrm{Tr}\int_\Gamma G(z)\frac{\widetilde{P}}{q}(z)dz}. \qquad \square$$

Let us give two important consequences of Proposition 15.

LEMMA 16. *Let $Q \in \mathcal{I}_k^p(1)$ for some $k < n$ and let $\mathbf{y} = (y_1, \ldots, y_k)$ be its Schur parameters in some chart defined by $\mathbf{w} = (w_1, \ldots, w_k)$ and $\mathbf{u} = (u_1, \ldots, u_k)$. Let $w_0 \in \mathbb{U}$, u_0 and y_0 be two distinct unit vectors and put*

$$\mathcal{U} = I_p - \frac{(u_0 - y_0)(u_0 - y_0)^*}{1 - u_0^* y_0},$$

$\mathbf{w}' = (w_0, w_1, \ldots, w_k)$, $\mathbf{u}' = (u_0, \mathcal{U}u_1, \ldots, \mathcal{U}u_k)$, and $\mathbf{y}' = (y_0, y_1, \ldots, y_k)$. Then $\mathbf{y}'$ is a regular limit point in the chart defined by $(\mathbf{w}', \mathbf{u}')$ and $Q' = \mathcal{U}Q$ is given by $Q' = \varphi^{-1}_{(\mathbf{w}',\mathbf{u}')}(y')$. Moreover,

$$\psi^{k+1}_{(\mathbf{w}',\mathbf{u}')}(\mathbf{y}') = \psi^k_{(\mathbf{w},\mathbf{u})}(\mathbf{y}). \tag{33}$$

COROLLARY 17. *Suppose that $\mathbf{y}$ is a local minimum of $\psi^k_{(\mathbf{w},\mathbf{u})}(\mathbf{y})$. Then, the gradient of $\psi^{k+1}_{(\mathbf{w}',\mathbf{u}')}$ at $\mathbf{y}'$ is orthogonal to the surface $\mathcal{S} = \{(y_0, \ldots, y_n),\ \|y_0\| = 1,\ \|y_j\| < 1,\ j = 1, \ldots n\}$ and points outwards.*

Proof. From Proposition 15 we see that the projection of the gradient of $\psi^{k+1}_{(\mathbf{w}',\mathbf{u}')}$ at $\mathbf{y}'$ on $\mathcal{S}$ is just the gradient of $\psi^k_{(\mathbf{w},\mathbf{u})}$ at $\mathbf{y}$, whence orthogonality holds. Moreover, it cannot point inwards because this would imply that Q' which is rational of order k is a local minimum at order $k+1$, and this is impossible except if F itself has degree $k+1$ (cf. [6]). $\square$

4.3. The algorithm. The algorithm searching for a local minimum at order n splits into four main operations.

A. *Choosing an initial point.* This choice involves the choice of $(\mathbf{w}, \mathbf{u})$ indexing a chart. The initial point $Q_i = \varphi^{-1}_{(\mathbf{w},\mathbf{u})}(\mathbf{y}_i)$ may have degree less than or equal to the target order n.

B. *Minimizing at fixed order k.* A software is used which integrates the vector field $-\mathrm{grad}\,\Psi^k_{(\mathbf{w},\mathbf{u})}$ from an initial point $\mathbf{y}_i \in \mathcal{B}_p^k$. The cost function is computed by (31) where $q = q^{(k)}$ and $\widetilde{D} = \widetilde{D}^{(k)}$ are given by the following recursion formulas, immediately deduced from (27) and (28),

$$\widetilde{D}^{(l)} = (b_{w_l} - y_l^* y_l \widetilde{b}_{w_l})\widetilde{D}^{(l-1)} - (b_{w_l} - \widetilde{b}_{w_l}) \left\{ \widetilde{D}^{(l-1)} u_l u_l^* + y_l y_l^* \widetilde{D}^{(l-1)} \right.$$

$$\left. -q^{(l-1)}\ y_l u_l^* + \frac{y_l^* \widetilde{D}^{(l-1)} u_l\ \widetilde{D}^{(l-1)} - \widetilde{D}^{(l-1)} u_l y_l^* \widetilde{D}^{(l-1)}}{q^{(l-1)}} \right\}, \tag{34}$$

$$q^{(l)} = (b_{w_l} - y_l^* y_l \widetilde{b}_{w_l})\, q^{(l-1)} - (b_{w_l} - \widetilde{b}_{w_l})\, y_l^* \widetilde{D}^{(l-1)} u_l, \tag{35}$$

and initialized by $q^{(0)} = 1$ and $\widetilde{D}^{(0)} = 1$. Then, one of the following possibilities occurs:

(i) *a local minimum is reached.* If $k = n$, we are done, while if $k < n$, this local minimum provides an initial point for searching for a minimum of order $k + 1$, as described in point D.

(ii) *the norm of some Schur parameter tends to* 1. This situation has been studied in section 4.1; either a change of chart is necessary, or a boundary point of the manifold is reached. More precisely, if the polynomial $\widetilde{q}^{(k)}$ nearly vanishes while its roots stay far from the unit circle, then the limit point belongs to $\mathcal{I}_k^p(1)$, and the first eventuality is true. In any other case, a boundary point is reached.

C. *Meeting a boundary point.* Such a boundary point, up to an unitary matrix, is an element Q_b of $\mathcal{I}_d^p(1)$ for some $d < k$, and the criterion at order k converges to $\Psi^d(Q_b)$. Then, a minimization process at order d can restart from Q_b. If only the first Schur parameter has norm 1, we can directly deduce from Lemma 16 some chart and Schur parameters for Q_b. Otherwise, the matrix Q_b must be computed from the recursion formulas (27) and (28), eliminating the roots of modulus one. Then, an adequate chart has to be provided.

D. *Choosing an adequate coordinate chart.* Given a normalized inner matrix Q, of order k, we must find a couple $(\mathbf{w}, \mathbf{u})$ such that Q belongs to the local neighborhood $\mathcal{V}_{(\mathbf{w},\mathbf{u})}$ defined in section 3.3, or equivalently such that a sequence $Q^{(k)} = Q, Q^{(k-1)}, \ldots, Q^{(1)} = I_p$ of inner functions of decreasing degree can be constructed by the Schur algorithm. The fractional representation of $Q^{(l-1)}$ is computed from that of $Q^{(l)}$ by the recursion formulas

$$b_{w_l}\, \tilde{b}_{w_l}\, \tilde{D}^{(l-1)} = (\tilde{b}_{w_l} - y_l^* y_l\, b_{w_l})\tilde{D}^{(l)} - (\tilde{b}_{w_l} - b_{w_l}) \left(\tilde{D}^{(l)} u_l u_l^* + y_l y_l^* \tilde{D}^{(l)} - q^{(l)}\ y_l u_l^* + \frac{y_l^* \tilde{D}^{(l)} u_l\ \tilde{D}^{(l)} - \tilde{D}^{(l)} u_l y_l^* \tilde{D}^{(l)}}{q^{(l)}} \right),$$

$$b_{w_l}\, \tilde{b}_{w_l}\, q^{(l-1)} = (\tilde{b}_{w_l} - y_l^* y_l\, b_{w_l})\, q^{(l)} - (\tilde{b}_{w_l} - b_{w_l})\, y_l^* \tilde{D}^{(l)} u_l.$$

The polynomial $b_{w_l}\, \tilde{b}_{w_l}$ divides the right-hand sides, so that $\tilde{D}^{(l-1)}$ and $q^{(l-1)}$ actually are polynomial, and $Q^{(l-1)}$ has degree $l - 1$ as required.

E. *Increasing the degree.* When the minimization procedure leads to a local minimum of order $k < n$, say Q_m, then Lemma 16, for any choice of w_0, u_0, and $y_0 \neq u_0$, provides a boundary point Q'_m of $\mathcal{I}_{k+1}^p(1)$ together with a local parametrization $Q'_m = \varphi^{-1}_{(\mathbf{w}',\mathbf{u}')}(\mathbf{y}'_m)$, deduced from a local parametrization $\varphi^{-1}_{(\mathbf{w},\mathbf{u})}(\mathbf{y}_m)$ of Q_m, satisfying (33). Since by Corollary 17, $-\operatorname{grad} \Psi^{k+1}_{(\mathbf{w}',\mathbf{u}')}$ points inwards at $\mathbf{y}'$, this point can be used as an initial point for a minimization process at order $k + 1$.

The point is that the value of the criterion, where the criterion must be understood as being Ψ^k when working at order k, decreases continuously, being conserved while the order changes, so that the minimization process pursues through different orders.

To ensure the good behavior of the algorithm, we shall make two extra assumptions. First, we shall assume that grad Ψ^k *does not vanish on the boundary of* $\mathcal{I}_k^p(1)$*, for* $1 \leq k \leq n$. Second, we shall require *all the critical points of* Ψ^k *in* $\mathcal{I}_k^p(1)$ *to be nondegenerate,* i.e., to have a second derivative which is a nondegenerate quadratic form. These two properties hold generically, that is for almost every F in some sense, and we refer the reader to [8] for the first one, and [6] for the second one. They ensure in particular that critical points in $\mathcal{I}_k^p(1)$ are finite in number. Since the criterion decreases continuously, we never meet twice the same local minimum and *this ensures that the procedure eventually comes to an end.* Note that if the minimization process stops at a critical point which is not a minimum, since this point is nondegenerate, it will be unstable under small perturbations, thereby allowing us to continue the procedure.

The choice of an initial point is crucial for our purpose (see the example in the next section). In many problems, we hope that some more information or engineering judgment could help us to select an initial point which ensures rapid convergence of the procedure to the global minimum. However, it is well known that the L_2 approximation problem possesses many local minima. Since our final goal is to find the global minimum, we may think of initializing the algorithm at enough points to reach all local minima and compare between them. But we do not know what "enough" means and we do not have a bound for the number of initializing points. Consequently, more efficient strategies should be investigated. For instance, we can find all the local minima at order 1 and then, initialize our procedure at order 2, by replacing them on the boundary of $\mathcal{I}_2^p(1)$ as described in point D, choosing w_0, u_0, and y_0 in several ways, and so on, step by step, until the target order. This strategy gives rather good results.

The choice of a local chart at the neighborhood of a given point is an important and difficult task. The main purpose of using coordinates is to be able to perform calculations on a computer and as such it is desirable that the numerical conditioning of the chart is good. A criterion must be chosen to decide upon the quality of local coordinates around a point on a manifold. Moreover, a distortion occurs when mapping part of a manifold to Euclidean space, so that the sequence of improving estimates produced by an optimization algorithm is dependent on the choice of the chart, and it would be interesting to select the charts with the view to improve the convergence of the algorithm. But in this case, the selection strategy will depend upon the problem at hand and bring along a lot of "overhead costs." The present version of our algorithm uses a basic selection strategy, which minimizes the norm of the Schur parameters at each step of the Schur algorithm over a finite atlas. This point must be improved and is presently under study.

4.4. A numerical example. The sole purpose of the following example is to demonstrate the procedure of computing local minima. For more real-data simulations, we refer to the scalar case paper [8] or [9]. This example has been first considered in [31] to demonstrate the procedure of computing the minimal degree approximation in a Hankel-norm model reduction problem and refers to a fourth-order system:

$$F(z) = \begin{pmatrix} \dfrac{1+z}{z^2-z+1/4} & \dfrac{1}{z-1/2} \\ \dfrac{-z^2+z+1}{z^3+1/2z^2-1/4z-1/8} & \dfrac{z-1/4}{z^2+z+1/4} \end{pmatrix},$$

or equivalently $F = N/d$, where

$$d(z) = z^4 - 1/2z^2 + 1/16$$

and

$$N(z) = \begin{pmatrix} z^3 + 2z^2 + 5/4z + 1/4 & z^3 + 1/2z^2 - 1/4z - 1/8 \\ -z^3 + 3/2z^2 + 1/2z - 1/2 & z^3 - 5/4z^2 + 1/2z - 1/16 \end{pmatrix}.$$

The system has four poles located at $1/2$, $1/2$, $-1/2$, $-1/2$. According to the theory, if we look for a minimum of (1) with $n = 4$, we must recover the function F itself, since from consistency, the criterion has no other critical points [12]. We shall use this fact to test the procedure.

The function to be approximated is represented in the program by a great number of Fourier coefficients (computed from frequency data in practice). Thus in this example, the input of the program is not actually the function F but the 200 first Fourier coefficients of its rational entries. The software package Scilab is used for the implementation. We have run a great number of tests changing the starting point and the initial chart. We present here a case in which every step of the algorithm must be visited before, according to the theory, we finally recover the function F.

Step 1. *We integrate at order* 4 *and reach the boundary.* The initial point has parameters $\mathbf{y} = ((0.5, 0.5)^*, ((0.5, 0.5)^*, (-0.5, -0.5)^*, (0.5, 0.5)^*)$ in the chart indexed by $\mathbf{w} = (0, 0, 0, 0)$ and $\mathbf{u} = ((1, 0)^*, (1, 0)^*, (0, 1)^*, (1, 0)^*)$, and corresponds to the inner matrix $Q_i = D_i/\widetilde{q}_i$, where

$$\widetilde{D}_i(z) = \begin{pmatrix} -0.3 + 0.4z + 0.4z^2 - 0.8z^3 + 0.5z^4 & -0.5 + 0.8z - 0.4z^2 + 0.4z^3 - 0.3z^4 \\ 0.3 - 0.4z + 0.4z^2 - 0.8z^3 + 0.5z^4 & 0.5 - 0.8z + 0.4z^2 + 0.4z^3 - 0.3z^4 \end{pmatrix}, \tag{36}$$

$$q_i(z) = z^2(z^2 - 1.2z + 0.4). \tag{37}$$

Note that q_i is not exactly the stable polynomial $q^{(4)}$ computed from the recursion formulas (34) and (35) which has a leading coefficient equal to 0.3125. As we integrate the opposite of the gradient using the Scilab function "ode," the norm of the first parameter tends to 1, while $\widetilde{q}^{(1)}(0) = 0.49$ stays far from 0. Thus we have reached a *regular* boundary point Q_b of parameters

$$\mathbf{y}_b = ((0.509, 0.86)^*, (0.357, 0.55)^*, (-0.659, -0.405)^*, (0.556, 0.264)^*).$$

The criterion is equal to 3.786.

Step 2. *We integrate at order* 3 *and get a local minimum.* We put $u_0 = (1, 0)^*$ and $y_0 = (0.509, 0.86)^*$ and we compute the unitary matrix

$$\mathcal{U} = I_p - \frac{(u_0 - y_0)(u_0 - y_0)^*}{1 - u_0^* y_0}.$$

Lemma 16 implies that $Q_b = \mathcal{U}Q$, where Q is the normalized inner matrix of degree 3 of parameters $\mathbf{y} = ((0.357, 0.55)^*, (-0.66, -0.405)^*, (0.556, 0.265)^*))$ in the chart indexed by $\mathbf{w} = (0, 0, 0)$ and $\mathbf{u} = ((0.509, 0.86)^*, (0.86, -0.509)^*, (0.509, 0.86))$. According to the theory, the criterion at Q is still equal to 3.786. We restart the minimization procedure from this point and find a third degree minimum for

$$\mathbf{y}_m = ((-0.574, 0.652)^*, (0.0214, -0.433)^*, (0.205, 0.428)^*),$$

where the criterion is equal to 0.997 and the relative error to 0.05.

Step 3. *We increase the degree and get out of the domain of the chart.* This third order local minimum provides starting points for fourth order minimizations. For instance, applying Lemma 16 with $w_0 = 0$, $u_0 = (1,0)^*$, and $y_0 = (0,1)^*$, which are distinct unit vectors, yields to the initial point of parameters

$$\mathbf{y} = ((0,1)^*, (-0.574, 0.652)^*, (0.021, -0.433)^*, (0.205, 0.428)^*)$$

in the chart indexed by $\mathbf{w} = (0,0,0,0)$ and

$$\mathbf{u} = ((1,0)^*, (0.86, 0.509)^*, (-0.509, 0.86)^*, (0.86, 0.509)^*).$$

The minimization process leads us to leave the domain of the chart. Indeed, it produces a sequence of inner functions whose denominators computed by formulas (27) and (28), have leading coefficients which tends to 0 but roots which stay far from the unit circle. We stop at

$$\mathbf{y} = ((0.88, 0.096)^*, (-0.688, 0.102)^*, (0.169, 0.232)^*, (0.264, -0.027)^*)$$

at which the value of $\widetilde{q}(0)$ is about 0.125 which can produce important errors in the computation.

Step 4. *We change the chart and recover the function* F. We choose to work with a finite subset of the atlas described in section 3.3; the family $(\mathcal{V}_{(\mathbf{w},\mathbf{u})}, \varphi_{(\mathbf{w},\mathbf{u})})$ where $\mathbf{w} = (0,0,0,0)$, and $\mathbf{u}$ is composed of unit vectors either equal to $e_1 = (1,0)^*$ or to $e_2 = (0,1)^*$. This family is a covering of the manifold $\mathcal{I}_n^p(1)$. At each step of the Schur algorithm, we choose $u_k = e_j$, where e_j is the vector for which the norm of the Schur parameter $y_k = Q^{(k)}(0)^*(e_j)$ is the smallest. It may happen that this process provides Schur parameters of norm almost equal to 1. In this case we can try each chart of our finite atlas to find a better one. In our case this process gives a new chart indexed by $\mathbf{w} = (0,0,0,0)$ and $\mathbf{u} = ((1,0)^*, (1,0)^*, (0,1)^*, (1,0)^*)$. The parameters of the point are given in this chart by $\mathbf{y} = ((0.632, -.278)^*, (-0.578, -.337)^*, (0.262, 0.192)^*, (0.157, -.142)^*)$. The minimization can continue and the minimum is reached for

$$\mathbf{y}_m = ((0.495, -0.32)^*, (-0.57, -0.328)^*, (0.266, 0.202)^*, (0.146, -0.129)^*).$$

The approximant computed from these parameters agrees with F with four significant digits.

If we start in the same initial chart $\mathbf{w} = (0,0,0,0)$, and

$$\mathbf{u} = ((1,0)^*, (1,0)^*, (0,1)^*, (1,0)^*),$$

from the point

$$\mathbf{y} = ((0.5, -0.5)^*, (-0.5, -0.5)^*, (0.5, 0.5)^*, (0.5, -0.5)^*),$$

we immediately reach the minimum with a very good accuracy. This emphasizes the importance of the choice of the initial point. On the other hand, if we start from the same initial point Q_i given by (36) and (37), but in the chart indexed by $\mathbf{w} = (0,0,0,0)$ and $\mathbf{u} = ((0,1)^*, (1,0)^*, (0,1)^*, (0,1)^*)$ (the Schur parameters are given by $\mathbf{y} = ((-.338, -.444)^*, (.0476, .506)^*, (.515, .515)^*, (-.3, -.3)^*)$), then we do not meet the boundary and we again reach the minimum with a very good accuracy. This illustrates the dependence on the chart of the iterative path produced by the gradient algorithm.

5. Conclusion. A rational approximation problem in L_2-norm has been studied. A new parametrization of stable all-pass transfer functions has been used, based on Schur analysis [1]. Such an overlapping parametrization (in differential geometry an atlas of charts) has allowed us to use classical optimization procedures within a local neighborhood, changing the neighborhood when necessary, in order to solve our minimization problem. Using the state space approach, other parametrizations of stable all-pass transfer functions are available as the one obtained in [25] in continuous-time, based on the work of Ober on balanced canonical forms [33]. A link between the two approaches is probable and a better understanding of the situation seems desirable. In this connection, a state space formulation of the Schur algorithm has been described in continuous-time in [23]. A balanced canonical form for discrete time stable all-pass systems has been obtained in the SISO case [34] by requiring the realization to be balanced and such that the reachability matrix is upper triangular with positive diagonal entries. This canonical form can be parametrized by the Schur parameters obtained in the classical algorithm (11). The generalization of these results to the multivariable case is under study.

Using this parametrization, a minimization algorithm has been described and its convergence to local minima has been proved. We have implemented this algorithm using the matrix-based scientific software Scilab and demonstrated the procedure of computing a local minimum in many simple examples. Later, using this work, a software package named Hyperion has been implemented by J. Grimm to solve a problem provided by the French CNES: identify from frequency data a 2×2 hyperfrequency filter of order 8. Very good results have been obtained on this problem [9]. However, the selection strategy algorithm used in this package is still basic and must be improved. This is going to be the object of forthcoming research.

Acknowledgments. The authors would like to thank D. Alpay who introduced them to Schur analysis and L. Baratchart for providing them with several helpful suggestions during this research. We would also like to thank E. Saff, A. Gombani, and N. Duddley Ward for their very careful reading of this paper and useful criticisms.

APPROXIMATE CONTROLLABILITY OF A SEMILINEAR HEAT EQUATION IN $\mathbb{R}^{N*}$

LUZ DE TERESA†

Abstract. We prove the approximate controllability of the semilinear heat equation in $\mathbb{R}^N$. We introduce the weighted Sobolev spaces of Escobedo and Kavian and in that functional setting we adapt the technique introduced by Fabre, Puel, and Zuazua for the problem in bounded domains. That is, we first prove the approximate controllability of the linear equation and by a fixed-point method obtain the main result.

Key words. approximate controllability, unbounded domains, weighted Sobolev spaces

1. Introduction. This paper is concerned with the approximate controllability of the semilinear heat equation in unbounded domains Ω when the control acts on the interior of Ω.

The general statement of the problem is as follows: Let ω be an open and nonempty subset of Ω. We consider the following semilinear heat equation:

$$\begin{cases} y_t - \Delta y + f(y) = h\chi_\omega \ \text{ in } \ Q = \Omega \times (0,T), \\ y = 0 \ \text{ on } \ \Sigma = \partial\Omega \times (0,T), \\ y(x,0) = y^0(x) \ \text{ in } \ \Omega, \end{cases} \tag{1.1}$$

where $h = h(x,t) \in L^2(\omega \times (0,T))$, χ_ω is the characteristic function of ω, and $y^0 \in L^2(\Omega)$. We shall assume that f is a real and globally Lipschitz function such that $f(0) = 0$. Let M be its Lipschitz constant, i.e.,

$$|f(s) - f(\sigma)| \le M|s - \sigma|, \qquad \forall s, \forall \sigma \in \mathbb{R}. \tag{1.2}$$

We say that the system (1.1) is approximately controllable in $L^2(\Omega)$ at time $T > 0$ if the following holds: "For every $y^0 \in L^2(\Omega)$, the set of reachable states at time $T > 0$,

$$E(T) = \{y(x,T),\ y \ \text{ solution of (1.1) with } \ h \in L^2(Q)\}$$

is dense in $L^2(\Omega)$."

When Ω is a bounded set, Fabre, Puel, and Zuazua [6] proved the approximate controllability of (1.1) in $L^p(\Omega), 1 \le p < \infty$. Their proof is divided in two parts: a) approximate controllability of the linearized system; b) fixed-point technique.

This technique cannot be applied when Ω is an unbounded set since the compactness of Sobolev's embeddings is one of the main ingredients used in b). In [14], we proved the approximate controllability of the semilinear heat equation in unbounded domains by an approximation method (used also in [13] for an insensitizing control problem). We considered the control problem in bounded domains of the form $\Omega_r = \Omega \cap B_r$, where B_r denotes the ball centered in zero of radius r. We showed

*Received by the editors May 28, 1997; accepted for publication September 26, 1997; published electronically August 31, 1998.

†Instituto de Matemáticas, Universidad Nacional Autonoma de México, Circuito Exterior, C.U. 04510, D.F. México (deteresa@matem.unam.mx).

that the controls proposed in [6], for the problem restricted to Ω_r, converge weakly in $L^p(\omega \times (0,T))$ as $r \to \infty$ to an approximate control for our problem in the whole domain Ω. Nevertheless, this proof is indirect and rather technical and it does not provide a method to effectively compute numerically the control.

The aim of this paper is to adapt the techniques introduced in [6] to unbounded domains by introducing the weighted Sobolev spaces of Escobedo and Kavian [4] that guarantee the compactness of the Sobolev's embeddings. The use of these spaces is interesting since it allows us to prove our approximate controllability result in a "direct" way. It could also be interesting for numerical purposes.

Even if it is a known technique in the study of the asymptotic behavior of some systems, it has not been used for controllability problems, as far as we know.

Nevertheless, this proof is valid only when $\Omega = \mathbb{R}^N$ or a cone-like domain, since it is necessary to make a change of variables. For simplicity we limit ourselves to the case $\Omega = \mathbb{R}^N$ and $p = 2$.

Under these conditions, the semilinear heat equation given in (1.1) reads as follows:

$$\begin{cases} u_t - \Delta u + f(u) = h\chi_\omega \quad \text{in} \quad \mathbb{R}^N \times (0,T), \\ u(x,0) = u^0(x) \quad \text{in} \quad \mathbb{R}^N. \end{cases} \tag{1.3}$$

The main result of the paper follows.

PROPOSITION 1.1. *If f is globally Lipschitz and $f(0) = 0$, system (1.3) is approximately controllable in $L^2(\mathbb{R}^N)$ at any time $T > 0$. Furthermore, we can reach a dense set of final states by using controls of the form*

$$h(x,t) = (t+1)^{-N/2-1} K^{-1}\left(\frac{x}{\sqrt{1+t}}\right) \|\phi\|_{L^1(q')} \tilde{\lambda}\chi_\omega,$$

where $\tilde{\lambda} \in sgn\tilde{\phi}$ and $\tilde{\phi}(x,t) = \phi(\frac{x}{\sqrt{1+t}}, \log(1+\mathrm{t}))$ with ϕ solution of a suitable heat equation, $q' = \{(y,s), s \in (0, \log(T+1)), y = e^{-s/2}x, x \in \omega\}$ and K a weight.

In order to implement the fixed point argument introduced by Fabre, Puel, and Zuazua in [6], we must first study the approximate controllability problem associated with the linear system with potential:

$$\begin{cases} u_t - \Delta u + a(x,t)u = h\chi_\omega \quad \text{in} \quad \mathbb{R}^N \times (0,T), \\ u(x,0) = u^0(x) \quad \text{in} \quad \mathbb{R}^N \end{cases} \tag{1.4}$$

with $a(x,t) \in L^\infty((0,T) \times \mathbb{R}^N)$.

To avoid the problems related to the noncompactness of the Sobolev's embeddings in $\mathbb{R}^N$, we consider the operator

$$Lf = -\Delta f - \frac{y \cdot \nabla f}{2} = -\frac{1}{K}\mathrm{div}(K\nabla f),$$

$$K(y) = \exp\left(\frac{|y|^2}{4}\right),$$

$$D(L) \subset L^2(K) = \left\{ f : \int_{\mathbb{R}}^N K(y)|f(y)|^2 dy < \infty \right\}$$

and the evolution equation

$$\begin{cases} v_s + Lv + A(s,y)v = \dfrac{N}{2}v + H(y,s)\chi_{\omega'(s)} \quad \text{in} \quad \mathbb{R}^N \times (0,S), \\ v(y,0) = v^0(y) \quad \text{in} \quad \mathbb{R}^N \end{cases} \tag{1.5}$$

with $v^0(y) \in L^2(K)$, ω' a suitable set in $\mathbb{R}^N \times (0,S)$, and $S = \log(\mathrm{T}+1)$. A change of variables transforms (1.4) in (1.5). In fact, if we define for $s \geq 0,\ y \in \mathbb{R}^N$

$$\begin{aligned} v(y,s) &= e^{\frac{sN}{2}} u(e^{s/2}y, e^s - 1), \\ A(y,s) &= e^s a(e^{s/2}y, e^s - 1), \\ H(y,s) &= e^{\frac{s(N+2)}{2}} h(e^{s/2}y, e^s - 1); \end{aligned} \tag{1.6}$$

then, for $u^0 \in L^2(K)$ and u solution of (1.4), v verifies (1.5) with $v^0 = u^0$, $S = \log(T+1)$, and $\omega'(s) = e^{-s/2}\omega$.

Reciprocally, if we know a solution v of (1.5), and we define for $t \geq 0$, $x \in \mathbb{R}^N$

$$u(x,t) = (1+t)^{-N/2} v\left(\frac{x}{\sqrt{1+t}}, \log(1+t)\right), \tag{1.7}$$

it is not difficult to see that u satisfies (1.4) with $u^0 = v^0$, $T = e^S - 1$, and

$$\begin{aligned} a(x,t) &= (1+t)^{-1} A\left(\frac{x}{\sqrt{1+t}}, \log(1+t)\right), \\ h(x,t) &= (1+t)^{-N/2-1} H\left(\frac{x}{\sqrt{1+t}}, \log(1+t)\right). \end{aligned}$$

That change of variables is interesting because the operator L defined above has compact inverse in $L^2(K)$ and then the equation (1.5) can be studied in the same manner as the heat equation in a bounded region Ω of $\mathbb{R}^N$.

The paper is organized as follows. In section 2 we introduce the weighted Sobolev spaces of Escobedo and Kavian and give some a priori estimates of the norm of the solution in these spaces. In section 3 we state some preliminary results concerning the existence and properties of the minima of a functional arising in the approximate controllability of the linear case. Section 4 is devoted to proving the approximate controllability of the linear case. We conclude with section 5 by proving Proposition 1.1 by a fixed-point method. Finally, in section 6 we discuss some extensions of the methods used in this paper.

2. Weighted Sobolev spaces. In this section we introduce the weighted Sobolev spaces of Escobedo and Kavian. We are going to see that system (1.5) is well posed in these spaces. We give some a priori estimates on the norm of the solution.

DEFINITION 2.1. *Let $K(y) = \exp(|y|^2/4)$. We define*

$$L^2(K) = \left\{ f; \int_{\mathbb{R}^N} K(y)|f(y)|^2 dy < \infty \right\},$$

$$H^s(K) = \{ f \in L^2(K); D^\alpha f \in (L^2(K))^N, \forall \alpha : |\alpha| \leq s \}.$$

We endow this space with the inner products $(f,g)_{L^2(K)} = \int_{\mathbb{R}^N} Kfg dy$, $(f,g)_{H^1(K)} = (f,g)_{L^2(K)} + (\nabla f, \nabla g)_{(L^2(K))^N}$, $(f,g)_{H^2(K)} = (f,g)_{H^1(K)} + (\Delta f, \Delta g)_{L^2(K)}$ with, respectively, the associated norm $\| \ \|_{L^2(K)}$, $\| \ \|_{H^1(K)}$, $\| \ \|_{H^2(K)}$.

We recall the following result due to Escobedo and Kavian (see [4], [7]).

LEMMA 2.2.

i) *There exists* $C > 0$ *such that for every* $v \in H^1(K)$

$$\int_{\mathbb{R}^N} K(y)|v(y)|^2|y|^2dy \le C\int_{\mathbb{R}^N} K(y)|\nabla v(y)|^2dy.$$

ii) *The imbedding* $H^1(K) \hookrightarrow L^2(K)$ *is compact.*

iii) $\forall v \in H^1(K)$, $\frac{N}{2}\int_{\mathbb{R}^N} K(y)|v|^2dy \le \int_{\mathbb{R}^N} K(y)|\nabla v|^2dy$.

iv) $v \in H^1(K) \iff K^{1/2}v \in H^1(\mathbb{R}^N)$.

v) $\forall f \in L^2(K)$ *there exists a unique* $u \in H^2(K)$ *such that* $Lu = f$, *i.e.,* $D(L) = H^2(K)$.

vi) $\varphi_1 = \exp(-|y|^2/4)$ *is an eigenfunction of* L *corresponding to* $\lambda_1 = N/2$, *the minimum eigenvalue of* L, *i.e.,* $L\varphi_1 = N/2\varphi_1$.

vii) L *is a positive operator, self-adjoint in* $L^2(K)$ *with compact inverse.*

viii)

$$\begin{array}{l} \textit{If} \quad N = 1,\ v \in H^1(K), \quad \textit{then} \quad K^{1/2}v \in L^\infty(\mathbb{R}). \\ \textit{If} \quad N = 2,\ H^1(K) \subset L^q(K) \quad \forall q \ge 2, \quad \textit{and} \quad q < \infty. \\ \textit{If} \quad N \ge 3,\ H^1(K) \subset L^{2^*}(K) \ \textit{with}\ 2^* = \frac{2N}{N-2}. \end{array}$$

Remark 1. Moreover, we have $L^2(K) \subset L^1(\mathbb{R}^N)$ with continuous embedding. If $v \in L^2(K)$, then

$$\int_{\mathbb{R}^N} |v| = \int_{\mathbb{R}^N} \frac{1}{K^{1/2}} K^{1/2}|v| \le \left(\int_{\mathbb{R}^N} K|v|^2\right)^{1/2} \left(\int_{\mathbb{R}^N} \frac{1}{K}\right)^{1/2} < \infty.$$

The results of Lemma 2.2 allow us to prove (see, e.g., [9, Theorem 4.1, p. 257]), that if $H \in L^\infty(0, S; L^2(K))$, $A(s, y) \in L^\infty(\mathbb{R}^N \times (0, S))$, and $u_0 \in L^2(K)$, then (1.5) has a unique solution:

$$\begin{array}{l} v \in C([0, S]; L^2(K)) \cap C((0, S]; H^2(K)), \\ v_s \in L^\infty((0, S]; L^2(K)). \end{array} \tag{2.1}$$

Moreover, v is given by the variation of constants formula. That is,

$$v(s) = S_*(s)v^0 + \int_0^s S_*(s-\sigma)(A(\sigma)v(\sigma) + H(\sigma))d\sigma, \tag{2.2}$$

where S_* is the analytic semigroup generated by $L-(N/2)I$ in $L^2(K)$. This semigroup is given in the following way (cf. Kavian [7], Escobedo–Zuazua [5]): For every $g \in L^2(K)$, for every $s > 0$, and for every $y \in \mathbb{R}^N$

$$(S_*(s)g)(y) = e^{sN/2}(G(e^s - 1) * g)(e^{s/2}y),$$

where G is the heat kernel, i.e., $G(x, t) = (4\pi t)^{-N/2}\exp(\frac{-|x|^2}{4t})$.

PROPOSITION 2.3. *Let* v *be the solution of* (1.5) *given in* (2.1). *Then, there exists a constant* $C = C(A, S) > 0$ *depending only on* A, S *such that*

i)

$$\|v\|_{\infty,K} \le C(\|v^0\|_{L^2(K)} + \|H\|_{\infty,K}), \tag{2.3}$$

ii)

$$\|v(s)\|_{H^1(K)} \le C(1 + s^{-1/2})(\|v^0\|_{L^2(K)} + \|H\|_{\infty,K}) \ \forall s > 0, \tag{2.4}$$

iii)

$$\|v_s(s)\|_{(H^1(K))'} \leq C(1+s^{-1/2})\left(\|v^0\|_{L^2(K)} + \|H\|_{\infty,K}\right) \ \forall s>0, \tag{2.5}$$

where $\|\ \|_{\infty,K}$ *denotes the norm in* $L^\infty((0,S);L^2(K))$ *and* $(H^1(K))'$ *is the dual space of* $H^1(K)$.

Proof. The proofs of i) and ii) are classical. We give a sketch of the proof. For proving i) it is enough to multiply (1.5) by v (in $L^2(K)$) and then to apply Hölder's, Schwarz's, and Gronwall's inequalities.

For proving ii) we express v by the variation of constants formula (2.2) and take $H^1(K)$ norms (see, e.g., [3] or [12]). To prove iii) we observe that (1.5) is satisfied in $(H^1(K))'$, that is,

$$v_s = -Lv + A(s,y)v + \frac{N}{2}v + H(y,s)\chi_{\omega'(s)} \ \text{ in } \ (H^1(K))'.$$

Let $\varphi \in H^1(K)$; then

$$\begin{aligned}\langle v_s(s),\varphi\rangle_1 = \ & -\int_{\mathbb{R}^N} K(Lv(s))\varphi - \int_{\mathbb{R}^N} KA(s)v(s)\varphi + \int_{\mathbb{R}^N}\frac{N}{2}Kv(s)\varphi \\ & + \int_{\mathbb{R}^N} KH(s)\varphi,\end{aligned}$$

where $\langle\ ,\ \rangle_1$ denotes the duality pairing $((H^1(K))', H^1(K))$. We then have that

$$\|v_s(s)\|_{(H^1(K))'} \leq C\{\|v(s)\|_{H^1(K)} + \|H(s)\|_{L^2(K)}\},$$

and by ii) we conclude

$$\|v_s(s)\|_{(H^1(K))'} \leq C(1+s^{-1/2})\left(\|v^0\|_{L^2(K)} + \|H(s)\|_{\infty,K}\right) \ \forall s>0,$$

where the constant C may vary from line to line. ∎

3. Study of a functional arising in the controllability of linear systems. In this section we study the existence and properties of the minima of a functional arising in the linear control problem. Let $\phi^0 \in L^2(K)$, $v^1 \in L^2(K)$, $A(y,s) \in L^\infty(\mathbb{R}^N \times (0,S))$, and $\alpha > 0$. We introduce the functional

$$J(\phi^0; A, v^1) = \frac{1}{2}\left(\int_{q'} |\phi(x,s)|dsdx\right)^2 + \alpha\|\phi^0\|_{L^2(K)} - \int_{\mathbb{R}^N} Kv^1\phi^0, \tag{3.1}$$

where $q' = \{(y,s); s \in (0,T), y = e^{-s/2}x, x \in \omega\}$ and ϕ denotes the solution of the transposed problem:

$$\begin{cases} -\phi_s + L\phi + A(y,s)\phi = \dfrac{N}{2}\phi \text{ in } \ \mathbb{R}^N \times (0,S), \\ \phi(S) = \phi^0 \ \text{ in } \ \mathbb{R}^N. \end{cases} \tag{3.2}$$

The main result of this section is the following.

PROPOSITION 3.1. *For every* $\alpha > 0, v^1 \in L^2(K)$ *and* $A \in L^\infty(\mathbb{R}^N \times (0,S))$, $J(.;A,v^1)$ *is a real strictly convex continuous function in* $L^2(K)$ *and satisfies*

$$\liminf_{\|\phi^0\|_{L^2(K)}\to\infty} \frac{J(\phi^0;A,v^1)}{\|\phi^0\|_{L^2(K)}} \geq \alpha. \tag{3.3}$$

The functional $J(.;A,v^1)$ *achieves its minimum at a unique point* $\hat{\phi}^0 \in L^2(K)$. *Furthermore,*

$$\hat{\phi}^0 = 0 \Longleftrightarrow \alpha \geq \|v^1\|_{L^2(K)}.$$

The proof of Proposition 3.1 is based on the following two results. The first one is a unique continuation property that is a direct consequence of a result due to Saut and Scheurer [10, Th. 1.1]. The second one is a classical compactness result (see, e.g., [11, Th. 5, p. 84]). We state it for completeness.

PROPOSITION 3.2. *Let* ω *be an open an nonempty set,* $\omega'(s) = e^{-s/2}\omega$ *and* $q' = \{(y,s), s \in (0,T), y \in \omega'(s)\}$. *Assume that* $A(y,s) \in L^\infty(\mathbb{R}^N \times (0,S))$. *Let* $\phi \in L^2((0,S);H^2(K))$ *be such that*

$$\begin{cases} -\phi_s + L\phi + A(y,s)\phi = \dfrac{N}{2}\phi \text{ in } \mathbb{R}^N \times (0,S), \\ \phi = 0 \text{ in } q'. \end{cases} \tag{3.4}$$

Then $\phi \equiv 0$.

THEOREM 3.3. *Let* X, B, Y *be Banach spaces such that* $X \subset B \subset Y$ *with continuous embeddings, the embedding* $X \subset B$ *being compact. Let* $1 \leq p \leq \infty$. *If* $\mathcal{F}$ *is a bounded subset of* $L^p(0,T;X)$ *and*

$$\|\tau_h f - f\|_{L^p(0,T-h;Y)} \to 0 \text{ as } h \to 0 \text{ uniformly for } f \in \mathcal{F},$$

where $\tau_h f(t) = f(t+h)$, *then* $\mathcal{F}$ *is relatively compact in* $L^p(0,T;B)$ *(in* $C([0,T];B)$ *if* $p = \infty$*).*

Proof of Proposition 3.1. The continuity and strict convexity are immediate. In order to prove (3.3) we proceed by contradiction. That is, suppose that there exists a sequence $\{\phi_n^0\} \subset L^2(K)$ such that

$$\|\phi_n^0\|_{L^2(K)} \to \infty, \qquad n \to \infty, \tag{3.5}$$

$$\liminf_{n\to\infty} \frac{J(\phi_n^0;A,v^1)}{\|\phi_n^0\|_{L^2(K)}} < \alpha. \tag{3.6}$$

We put $\psi_n^0 = \frac{\phi_n^0}{\|\phi_n^0\|_{L^2(K)}}$. Then,

$$\frac{J(\phi_n^0;A,v^1)}{\|\phi_n^0\|_{L^2(K)}} = \frac{1}{2}\|\phi_n^0\|_{L^2(K)}\left(\int_{q'}|\psi_n|\right)^2 + \alpha - \int_{\mathbb{R}^N} Kv^1\psi_n^0, \tag{3.7}$$

where ψ_n denotes the solution of (3.2) with data $\psi_n(S) = \psi_n^0$.

Since $\|\psi_n^0\|_{L^2(K)} = 1$, we can extract a subsequence (still denoted ψ_n^0) such that $\psi_n^0 \rightharpoonup \psi^0$ weakly in $L^2(K)$. On the other hand, by Proposition 2.3, $\|\psi_n\|_{L^2((0,S);L^2(K))} \leq C$, and, therefore, we can extract a subsequence (of the previous one) such that

$$\psi_n \rightharpoonup \psi \quad \text{weakly in } L^2((0,S);L^2(K)). \tag{3.8}$$

But (2.4) and (2.5) in Proposition 2.3 and Theorem 3.3 imply that for every $T \geq \varepsilon > 0$

$$\psi_n \to \psi \quad \text{strongly in } C([0,S-\varepsilon];L^2(K)). \tag{3.9}$$

Multiplying the equation satisfied by ψ_n by suitable test functions, and passing to the limit along the sequence, we obtain that $\psi \in L^2(0,S;H^2(K))$ satisfies

$$-\psi_s + L\psi + A\psi = \frac{N}{2}\psi \quad \text{in} \quad \mathbb{R}^N \times (0,S), \qquad \psi(S) = \psi^0.$$

Let us see that (3.5) and (3.6) imply $\psi \equiv 0$. Observe that (3.8) and (3.9) imply that $\psi_n \chi_{\omega'(s)} \to \psi \chi_{\omega'(s)}$ in $L^1(\mathbb{R}^N \times (0,S))$. In fact,

$$\int_{q'} |\psi - \psi_n| \le \int_0^{S-\varepsilon} \int_{\mathbb{R}^N} |\psi - \psi_n| + \int_{S-\varepsilon}^{S} \int_{\mathbb{R}^N} |\psi - \psi_n|.$$

In view of (3.9), the first term in the right-hand side converges to zero as $n \to \infty$. The second term is, by (3.8), bounded by εC with C independent of n. Therefore,

$$\int_{q'} |\psi| = \lim_{n\to\infty} \int_{q'} |\psi_n|.$$

We observe that $\int_{q'} |\psi| = 0$. Otherwise, (3.5) and (3.7) contradict (3.6). This proves that $\psi \equiv 0$ in q'. Hence, by Proposition 3.2, $\psi \equiv 0$ in $\mathbb{R}^N \times (0,S)$ and $\psi^0 = 0$. But

$$J(\phi_n^0; A, v^1) \ge \|\phi_n^0\|_{L^2(K)} \left(\alpha - \int_{\mathbb{R}^N} K v^1 \psi_n^0 dy \right).$$

In view of (3.5) and the convergence $\psi_n^0 \rightharpoonup 0$, we obtain a contradiction with (3.6) and we prove (3.3).

Now, if $\alpha \ge \|v^1\|_{L^2(K)}$, we have $J(\phi^0; A, v^1) \ge 0$ for every ϕ^0 and, hence, $\hat{\phi}^0 = 0$. Suppose now $\hat{\phi}^0 = 0$; then $J(\phi^0; A, v^1) \ge 0$ for all $\phi^0 \in L^2(K)$. In particular,

$$\lim_{t\to 0^+} \frac{J(t\phi^0; A, v^1)}{t} \ge 0 \quad \forall \phi^0 \in L^2(K),$$

and, therefore,

$$\alpha \|\phi^0\|_{L^2(K)} \ge \int_{\mathbb{R}^N} K v^1 \phi^0 \quad \forall \phi^0 \in L^2(K).$$

In particular, for $\phi^0 = v^1 \in L^2(K)$ we get $\alpha \ge \|v^1\|_{L^2(K)}$. □

In order to study the nonlinear case, we need to make precise the dependence of the minima with respect to the potential. This is gathered in the following proposition.

PROPOSITION 3.4.

(i) *If we denote by M the mapping*

$$M : L^\infty(\mathbb{R}^N \times (0,S)) \times L^2(K) \to L^2(K); \; M(A, v^1) = \hat{\phi}^0,$$

and if W is a compact subset of $L^2(K)$ and B a bounded subset of $L^\infty(\mathbb{R}^N \times (0,S))$, then $M(B \times W)$ is a bounded subset of $L^2(K)$.

(ii) *Moreover, if $A_n \rightharpoonup A$ weakly* in $L^\infty((0,S) \times \mathbb{R}^N)$ and $v_n^1 \to v^1$ strongly in $L^2(K)$, then $\hat{\phi}_n^0$ converges strongly in $L^2(K)$ to $\hat{\phi}^0$.*

Proof. In order to get (i), we first prove that (3.3) is uniform for (A, v^1) in $B \times W$. We again argue by contradiction and follow the same argument used in the proof of (3.3): suppose that there exist sequences $\{A_n\} \subset B; \{v_n^1\} \subset W$ such that the

corresponding sequence of minimizers $\{\hat{\phi}_n^0\} \subset L^2(K)$ verify (3.5). Since B is bounded and W is compact, there exist $A \in L^\infty(\mathbb{R}^N \times (0,S))$, $v^1 \in L^2(K)$, and a subsequence (still denoted by n) such that

$$A_n \rightharpoonup A \quad \text{weakly* in} \quad L^\infty(\mathbb{R}^N \times (0,S)), \tag{3.10}$$

and

$$v_n^1 \to v^1 \quad \text{strongly in} \quad L^2(K). \tag{3.11}$$

Suppose that

$$\liminf_{n\to\infty} \frac{J(\hat{\phi}_n^0; A_n, v_n^1)}{\|\hat{\phi}_n^0\|_{L^2(K)}} < \alpha. \tag{3.12}$$

As above, we denote by $\psi_n^0 = \frac{\phi_n^0}{\|\phi_n^0\|_{L^2(K)}}$. Since $\|\psi_n^0\|_{L^2(K)} = 1$ and A_n is bounded in $L^\infty(\mathbb{R}^N \times (0,S))$, the solution ψ_n of (3.2) corresponding to A_n with data $\psi_n(S) = \psi_n^0$, is also bounded. We can repeat the arguments of the previous proof to obtain

$$\liminf_{n\to\infty} \frac{J(\hat{\phi}_n^0; A_n, v_n^1)}{\|\hat{\phi}_n^0\|_{L^2(K)}} \geq \alpha, \tag{3.13}$$

which contradicts (3.12). Now, if we suppose that the range of M is not bounded, we can construct a sequence $\{A_n, v_n^1, \hat{\phi}_n^0\} \subset B \times W \times L^2(K)$ satisfying (3.10), (3.11), and $\|\hat{\phi}_n^0\|_{L^2(K)} \to \infty$. But for every n,

$$J(\hat{\phi}_n^0; A_n, v_n^1) \leq J(0; A_n, v_n^1) = 0, \tag{3.14}$$

which contradicts (3.13) and proves (i).

We now prove (ii). From (i), we know that the minimizers $\hat{\phi}_n^0$ are bounded in $L^2(K)$. Hence, they weakly converge to an element $\tilde{\phi}^0 \in L^2(K)$ and $\hat{\phi}_n$ weakly converge in $L^2(0,S;L^2(K))$ to the solution $\tilde{\phi}$ of (3.2) corresponding to A and $\tilde{\phi}(S) = \tilde{\phi}^0$. We can argue, as in the proof of Proposition 3.1, to show that

$$\int_{q'} |\tilde{\phi}| = \lim_{n\to\infty} \int_{q'} |\hat{\phi}_n|,$$

and then

$$J(\tilde{\phi}^0; A, v^1) \leq \liminf_{n\to\infty} J(\hat{\phi}_n^0; A_n, v_n^1). \tag{3.15}$$

Let us prove that for every $\phi^0 \in L^2(K)$,

$$\lim_{n\to\infty} J(\phi^0; A_n, v_n^1) = J(\phi^0; A, v^1). \tag{3.16}$$

We denote by ϕ_n the solution of (3.2) with potential A_n and $\phi_n(S) = \phi^0$. Since $\{A_n\}$ is a uniformly bounded sequence, Proposition 2.3 and Theorem 3.3 give us the strong convergence of ϕ_n in $L^2(0,S;L^2(K))$ to the solution ϕ of (3.2) with potential A and $\phi(S) = \phi^0$. Passing to the limit in each term of the functional, we obtain (3.16).

Moreover, we have that

$$\forall \phi^0 \in L^2(K), \quad J(\hat{\phi}_n^0; A_n, v_n^1) \leq J(\phi^0; A_n, v_n^1). \tag{3.17}$$

Combining (3.15) and (3.17), we obtain

$$J(\tilde{\phi}^0; A, v^1) \leq \liminf_{n\to\infty} J(\hat{\phi}_n^0; A_n, v_n^1) \leq \limsup_{n\to\infty} J(\hat{\phi}_n^0; A_n, v_n^1)$$
$$\leq \lim_{n\to\infty} J(\phi^0; A_n, v_n^1) \quad \forall \phi^0 \in L^2(K); \tag{3.18}$$

hence, we obtain

$$\forall \phi^0 \in L^2(K), \quad J(\tilde{\phi}^0; A, v^1) \leq J(\phi^0; A, v^1). \tag{3.19}$$

The strict convexity of $J(.; A, v^1)$ and (3.19) imply that $\tilde{\phi}^0 = \hat{\phi}^0$. But, with this equality, (3.18) gives

$$J(\hat{\phi}^0; A, v^1) = \lim_{n\to\infty} J(\hat{\phi}_n^0; A_n, v_n^1). \tag{3.20}$$

On the other hand, we have

$$\lim_{n\to\infty} \int_{\mathbb{R}^N} K v_n^1 \hat{\phi}_n^0 dy = \int_{\mathbb{R}^N} K v^1 \hat{\phi}^0 dy,$$
$$\int_{q'} |\hat{\phi}| dy ds = \lim_{n\to\infty} \int_{q'} |\hat{\phi}_n| dy ds,$$
$$\|\hat{\phi}^0\|_{L^2(K)} \leq \liminf_{n\to\infty} \|\hat{\phi}_n^0\|_{L^2(K)}.$$

Equation (3.20) then implies that

$$\lim_{n\to\infty} \|\hat{\phi}_n^0\|_{L^2(K)} = \|\hat{\phi}^0\|_{L^2(K)}.$$

Since $\hat{\phi}_n^0$ converges weakly to $\hat{\phi}^0$ in $L^2(K)$ and $L^2(K)$ is uniformly convex, we deduce that the convergence is strong in $L^2(K)$, which ends the proof of Proposition 3.4. □

We are now going to interpret the results of Proposition 3.1: Since the functional $J(.; A, v^1)$ is convex continuous with real values, it possesses a subdifferential at every point of $L^2(K)$ (e.g., Aubin [1, p. 187]). At its minimum, we have $0 \in \partial J(\hat{\phi}^0; A, v^1)$.

Let us now prove the following proposition.

PROPOSITION 3.5. *For every $\phi^0 \in L^2(K)$, $\phi^0 \neq 0$, denoting by ϕ the solution of* (3.2) *with $\phi(S) = \phi^0$, we have*

$$\partial J(\phi^0; A, v^1) = \Big\{ \xi \in L^2(K); \exists \lambda \in sgn(\phi)\chi_{q'} \quad \textit{satisfying}$$
$$\int_{\mathbb{R}^N} K\xi(y)\theta^0(y)dy = \left(\int_{q'} |\phi| dy\ ds\right)\left(\int_{q'} \lambda\theta dy\ ds\right)$$
$$+\alpha \int_{\mathbb{R}^N} \frac{K\phi^0(y)}{\|\phi^0\|_{L^2(K)}}\theta^0(y)dy - \int_{\mathbb{R}^N} K v^1(y)\theta^0(y)dy \textit{ for every } \theta^0 \in L^2(K),$$
$$\textit{where } \theta \textit{ is the solution of } (3.2) \textit{ with } \theta(S) = \theta^0 \Big\}.$$

Proof. Since the functions A and v^1 are fixed, we write $J(\phi^0)$. We have $J(\phi^0) = \jmath_1(\phi^0) + \jmath_2(\phi^0)$, where

$$\jmath_1 = \frac{1}{2}\left(\int_{q'} |\phi|\right)^2; \quad \jmath_2 = \alpha\|\phi^0\|_{L^2(K)} - \int_{q'} K v^1 \phi^0.$$

Since $\jmath_2$ is Gateaux differentiable at every $\phi^0 \neq 0$ in $L^2(K)$, and $\jmath_1$ is subdifferentiable at every $\phi^0 \neq 0$ in $L^2(K)$, we have for every $\phi^0 \neq 0$ in $L^2(K)$: $\partial J(\phi^0) = \partial \jmath_1(\phi^0) + \partial \jmath_2(\phi^0)$.

We now determine the set $\partial \jmath_1(\phi^0)$. Let $\xi \in \partial \jmath_1(\phi^0)$. By definition, we have

$$\forall \theta^0 \in L^2(K) \quad (\xi, \theta^0)_{L^2(K)} \leq \lim_{t \to 0^+} \frac{\jmath_1(\phi^0 + t\theta^0) - \jmath_1(\phi^0)}{t}. \tag{3.21}$$

We can prove that

$$\lim_{t \to 0^+} \frac{\jmath_1(\phi^0 + t\theta^0) - \jmath_1(\phi^0)}{t} = \left(\int_{q'} |\phi| \right) \left(\int_{q'/\mathcal{A}} (sgn\phi)\theta + \int_{\mathcal{A}} |\theta| \right),$$

where $\mathcal{A} = \{(y,s) | \phi(y,s) = 0\} \cap q'$. In view of (3.21), that implies

$$(\xi, \theta^0)_{L^2(K)} \leq \left(\int_{q'} |\phi| \right) \left(\int_{q/\mathcal{A}} (sgn\phi)\theta + \int_{\mathcal{A}} |\theta| \right). \tag{3.22}$$

Let us call F the mapping from $L^2(K)$ to $L^1(q')$, $F(\theta^0) = \theta$, with θ the solution of (3.2) corresponding to θ^0. Then, the mapping $F(\theta^0) \to (\xi, \theta^0)_{L^2(K)}$ is a linear form on $F(L^2(K)) \subset L^1(q')$ and applying the Hahn–Banach theorem, there exists a linear form $\mathcal{V}$ on $L^1(q')$, such that $\forall \theta^0 \in L^2(K)$, $(\xi, \theta^0)_{L^2(K)} = \mathcal{V}(\theta)$, and for every $\vartheta \in L^1(q')$

$$\mathcal{V}(\vartheta) \leq \left(\int_{q'} |\phi| \right) \left(\int_{\mathcal{A}} |\vartheta| + \int_{q'/\mathcal{A}} (sgn\phi)\vartheta \right). \tag{3.23}$$

From (3.23), we deduce that $\mathcal{V}$ is linear and continuous on $L^1(q')$ and, hence, $\mathcal{V} \in L^\infty(q')$. Therefore, for every $\vartheta \in L^1(q')$, we have

$$\left| \int_{q'} \mathcal{V}(y,s)\vartheta(y,s)dyds - \left(\int_{q'} |\phi| \right) \left(\int_{q'/\mathcal{A}} (sgn\phi)\vartheta \right) \right| \leq \left(\int_{q'} |\phi| \right) \left(\int_{\mathcal{A}} |\vartheta| \right). \tag{3.24}$$

Take first $\vartheta \in L^1(q')$, whose support is contained in $q'/\mathcal{A}$ to obtain $\mathcal{V}(y,s) = (\int_{q'} |\phi|) \frac{\phi(y,s)}{|\phi(y,s)|}$ for almost every $(y,s) \in q'/\mathcal{A}$. Now take ϑ whose support is contained in $\mathcal{A}$. We obtain that $|\mathcal{V}(y,s)| \leq (\int_{q'} |\phi|)$ almost everywhere on $\mathcal{A}$. This proves that $\mathcal{V} = (\int_{q'} |\phi|)\lambda$ with $\lambda \in sgn\phi\chi_{q'}$.

Reciprocally, let $\mathcal{V} \in (\int_{q'} |\phi|) sgn\phi\chi_{q'}$. Then, if θ is the solution of (3.2) with $\theta(S) = \theta^0$, the mapping $\theta^0 \to \int_{q'} \mathcal{V}\theta dyds$ is linear and continuous on $L^2(K)$. Thus, there exists a unique $\xi \in L^2(K)$ such that

$$(\xi, \theta^0)_{L^2(K)} = \int_{q'} \mathcal{V}\theta(y,s)dyds. \tag{3.25}$$

One can easily prove that ξ satisfies (3.22) and, hence, $\xi \in \partial \jmath_1$ concluding the proof of Proposition 3.5. □

4. The linear case. In this section, we prove the approximate controllability in $L^2(\mathbb{R}^N)$ of the linear heat equation with potential. To this aim we need the following approximate controllability result in $L^2(K)$.

PROPOSITION 4.1. *Let $v^1 \in L^2(K)$ with $\|v^1\|_{L^2(K)} > \alpha$, and $\hat{\phi}$ the solution of (3.2) with $\hat{\phi}(S) = \hat{\phi}^0$ the minimizer of $J(.; A, v^1)$. Then, there exists $\lambda \in sgn(\hat{\phi})\chi_{q'}$ such that the solution v of*

$$\begin{cases} v_s + Lv + A(y,s)v = \dfrac{N}{2}v + \|\hat{\phi}\|_{L^1(q')}K^{-1}\lambda\chi_{\omega'(s)} \text{ in } \mathbb{R}^N \times (0,S), \\ v(0) = 0 \quad in \quad \mathbb{R}^N \end{cases} \tag{4.1}$$

satisfies

$$v(S) = v^1 - \alpha\frac{\hat{\phi}^0}{\|\hat{\phi}^0\|_{L^2(K)}}.$$

Therefore,

$$\|v(S) - v^1\|_{L^2(K)} = \alpha.$$

Remark 2. If $\|v^1\|_{L^2(K)} \leq \alpha$, we can take $v = 0$ to obtain $\|v(S) - v^1\|_{L^2(K)} \leq \alpha$ with control zero.

Proof of Proposition 4.1. Since $\|v^1\|_{L^2(K)} > \alpha, \hat{\phi}^0$ minimizes $J(.; A, v^1)$ and J is subdifferentiable in $\hat{\phi}^0 \neq 0$, we have that $0 \in \partial J(\hat{\phi}^0)$. In view of Proposition 3.5, there exists $\lambda \in sgn(\phi)\chi_q$ such that for every $\theta^0 \in L^2(K)$

$$0 = \left(\int_{q'} |\hat{\phi}|\right)\left(\int_{q'} \lambda\theta\right) + \alpha\int_{\mathbb{R}^N} K\frac{\hat{\phi}^0}{\|\hat{\phi}^0\|_{L^2(K)}}\theta^0 - \int_{\mathbb{R}^N} Kv^1\theta^0, \tag{4.2}$$

where θ is the solution of (3.2) with $\theta(S) = \theta^0$.

Now, if we multiply (4.1) by θ in $L^2(K)$, we obtain

$$\begin{aligned} &\int_0^S\int_{\mathbb{R}^N} Kv_s\theta - \int_0^S\int_{\mathbb{R}^N} \theta\mathrm{div}(K\nabla v) + \int_0^S\int_{\mathbb{R}^N} KA\theta v \\ &= \frac{N}{2}\int_0^S\int_{\mathbb{R}^N} K\theta v + \|\hat{\phi}\|_{L^1(q')}\int_0^S\int_{\mathbb{R}^N} \lambda\theta\chi_{\omega'}. \end{aligned} \tag{4.3}$$

Therefore,

$$\int_{\mathbb{R}^N} Kv(S)\theta^0 = \|\hat{\phi}\|_{L^1(q')}\int_{q'} \lambda\theta. \tag{4.4}$$

By (4.2), we see that (4.4) is equivalent to

$$(v(S), \theta^0)_{L^2(K)} = \left(-\alpha\frac{\hat{\phi}^0}{|\hat{\phi}^0|_{L^2(K)}} + v^1, \theta^0\right)_{L^2(K)},$$

which concludes the proof. □

We can now prove the main result in this section

PROPOSITION 4.2. *Let $u^0, u^1 \in L^2(\mathbb{R}^N)$, $\omega \subset \mathbb{R}^N$ an open and nonempty set. Then, for every $\alpha > 0$, there exists $h \in L^\infty(\mathbb{R}^N \times (0,T))$ such that the solution u of*

$$\begin{cases} u_t - \Delta u + a(x,t)u = h\chi_\omega & \text{in } \mathbb{R}^N \times (0,T), \\ u(x,0) = u_0(x) & \text{in } \mathbb{R}^N \end{cases} \tag{4.5}$$

satisfies

$$\|u(T) - u^1\|_{L^2(\mathbb{R}^N)} \leq \alpha.$$

Proof. We divide the proof into several steps.

Step 1. The case $u^0 = 0$ and $u^1 \in L^2(K)$.

We define A like in (1.6) and $v^1(y) = (T+1)^{N/2}u^1((T+1)^{1/2}y)$. We have that $v^1 \in L^2(K)$. If $\|v^1\|_{L^2(K)} > \alpha$ we construct H like in Proposition 4.1; otherwise $H \equiv 0$. Then v solution of (4.1) satisfies $\|v(S) - v^1\|_{L^2(K)} \leq \alpha$ with $S = \log(T+1)$.

Therefore, $u(x,t) = (1+t)^{-N/2}v(\frac{x}{\sqrt{1+t}}, \log(1+t))$ satisfies (4.5) with $h(x,t)\chi_\omega = (1+t)^{-N/2-1}e^{\frac{-x^2}{1+t}}\|\phi\|_{L^1(q')}\lambda$, $\lambda \in sgn\phi$, and

$$\begin{aligned} \|u(T) - u^1\|^2_{L^2(\mathbb{R}^N)} \leq & \int_{\mathbb{R}^N} e^{\frac{|x|^2}{4(1+T)}}(1+T)^{-N}|v\left(\frac{x}{\sqrt{1+T}}, S\right) - v^1\left(\frac{x}{\sqrt{1+T}}\right)|^2 dx \\ & \leq \int_{\mathbb{R}^N} K(1+T)^{-N/2}|v(S,y) - v^1(y)|^2 dy \\ & \leq (1+T)^{-N/2}\|v(S) - v^1\|^2_{L^2(K)} \leq \alpha^2. \end{aligned}$$

Step 2. The case $u^0 = 0$ and $u^1 \in L^2(\mathbb{R}^N)$.

Since $L^2(K) \subset L^2(\mathbb{R}^N)$ with dense inclusion, we know that there exists a sequence $u^1_n \subset L^2(K)$ and $\tilde{N} > 0$ such that $n > \tilde{N}$ implies

$$\|u^1_n - u^1\|_{L^2(\mathbb{R}^N)} < \frac{\alpha}{2}.$$

We just proved that there exists $h_n \in L^\infty((0,T); L^2(\mathbb{R}^N))$ such that the solution u of (4.5) satisfies

$$\|u(T) - u^1_n\|_{L^2(\mathbb{R}^N)} \leq \frac{\alpha}{2}.$$

Therefore, h_n with $n > \tilde{N}$ is an approximate control of our problem.

Step 3. The general case, i.e., u^0, $u^1 \in L^2(\mathbb{R}^N)$ arbitrary.

We write $u = y + Y$, where y is the solution of

$$\begin{cases} y_t - \Delta y + a(x,t)y = 0 & \text{in } \mathbb{R}^N \times (0,T), \\ y(x,0) = u_0(x) & \text{in } \mathbb{R}^N. \end{cases} \tag{4.6}$$

Then $y(T) \in L^2(\mathbb{R}^N)$. We construct $h(u^1 - y(T))$ such that the solution Y of

$$\begin{cases} Y_t - \Delta Y + a(x,t)Y = h\chi_\omega & \text{in } \mathbb{R}^N \times (0,T), \\ Y(x,0) = 0 & \text{in } \mathbb{R}^N \end{cases} \tag{4.7}$$

satisfies

$$\|Y(T) - (u^1 - y(T))\|_{L^2(\mathbb{R}^N)} \leq \alpha. \tag{4.8}$$

Therefore, in (4.5) it is enough to chose $h = h(u^1 - y(T))$, since the unique solution is $u = y + Y$ and in view of (4.8) we conclude the proof. ∎

5. The nonlinear case. We first analyze the case where f is of class C^1, $f(0) = 0$ and verifies (1.2). We define the continuous function

$$g(z) = \begin{cases} \dfrac{f(z)}{z} \text{ if } z \neq 0, \\ f'(0) \text{ if } z = 0. \end{cases}$$

For $\tilde{\nu} \in L^2(0, S; L^2(K))$, $u_0 \in L^2(K)$ we consider the solution u of

$$\begin{cases} u_t - \Delta u + g(\tilde{\nu})u = h\chi_\omega \text{ in } \mathbb{R}^N \times (0, T), \\ u(0) = u_0 \text{ in } \mathbb{R}^N. \end{cases} \tag{5.1}$$

Remark 3. The definition of g indicates that if $\tilde{\nu} = u$, then u is the solution of the semilinear equation (1.3).

We define v and H like in (1.6), $\nu(y, s) = e^{sN/2}\tilde{\nu}(e^{s/2}y, e^s - 1)$ and $G(\nu, s) = e^s g(e^{-sN/2}\nu)$, $\omega'(s) = e^{-s/2}\omega$. We see that if u is the solution of (5.1), then v satisfies

$$\begin{cases} v_s + Lv + G(s, \nu)v = \dfrac{N}{2}v + H\chi_{\omega'(s)} \quad \text{in} \quad \mathbb{R}^N \times (0, S), \\ v(0) = u^0 \quad \text{in} \quad \mathbb{R}^N \end{cases} \tag{5.2}$$

We are going to work on this equation to apply the fixed-point method introduced in [6] to obtain the approximate control of (1.3).

We write $v = w + V$, where w is the solution of

$$\begin{cases} w_s + Lw + G(s, \nu)w = \dfrac{N}{2}w \quad \text{in} \quad \mathbb{R}^N \times (0, S), \\ w(y, 0) = u^0(y) \quad \text{in} \quad \mathbb{R}^N. \end{cases} \tag{5.3}$$

For every $\nu \in L^2(K)$, $G(s, \nu) \in L^\infty((0, S) \times \mathbb{R}^N)$ and, therefore, $w \in C([0, S]; L^2(K))$. We can apply Theorem 3.3 to obtain that

$$\{v^1 - w(S), \quad \text{when} \quad \nu \in L^2(0, S; L^2(K))\} \tag{5.4}$$

is a compact subset of $L^2(K)$.

In view of Proposition 4.1 we know that there exists $\lambda(\nu, v^0, v^1) \in sgn(\hat{\phi}(\nu, v^0, v^1))\chi_{q'}$ with $\hat{\phi}$ minimizing $J(\phi^0; G(s, \nu), v^1 - w(S))$ and such that the solution V of

$$\begin{cases} V_s + LV + G(s, \nu)V = \dfrac{N}{2}V + \|\hat{\phi}\|_{L^1(q')}K^{-1}\lambda\chi_{\omega'} \quad \text{in} \quad \mathbb{R}^N \times (0, S), \\ V(y, 0) = 0 \quad \text{in} \quad \mathbb{R}^N \end{cases} \tag{5.5}$$

satisfies

$$\|V(S) - v^1 + w(S)\|_{L^2(K)} \leq \alpha.$$

We deduce that $v = w + V$ satisfies $\|v(S) - v^1\|_{L^2(K)} \leq \alpha$.

For $\lambda \in sgn(\hat{\phi}(\nu, v^0, v^1))\chi_{q'}$, we denote by $v(\lambda)$ the solution of

$$\begin{cases} v_s + Lv + G(s, \nu)v = \dfrac{N}{2}v + \|\hat{\phi}\|_{L^1(q')}K^{-1}\lambda\chi_{\omega'} \quad \text{in} \quad \mathbb{R}^N \times (0, S), \\ v(y, 0) = v^0 \quad \text{in} \quad \mathbb{R}^N, \end{cases} \tag{5.6}$$

and consider the following set valued mapping:

$\Lambda : L^2((0,S);L^2(K)) \to \mathcal{P}\left(L^2((0,S);L^2(K))\right)$ with

$$\Lambda(\nu) = \{v(\lambda), \lambda \in sgn(\hat{\phi}(\nu, v^0, v^1))\chi_{q'} \quad \text{and} \quad \|v(S) - v^1\|_{L^2(K)} \leq \alpha\}. \tag{5.7}$$

We just proved that $\Lambda(\nu)$ is always a nonempty subset of $L^2((0,S);L^2(K))$ and we have the following result.

PROPOSITION 5.1. *If f is of class C^1 in $\mathbb{R}$, $f(0) = 0$ and satisfies (1.2), then:*

(i) *There exists a compact subset X of $L^2(0,S;L^2(K))$ such that for every $\nu \in L^2(0,S;L^2(K))$, $\Lambda(\nu) \subset X$.*

(ii) *For all $\nu \in L^2(0,S;L^2(K))$, $\Lambda(\nu)$ is a nonempty, convex, and compact subset of $L^2(0,S;L^2(K))$.*

(iii) *Λ is upper hemicontinuous on $L^2(0,S;L^2(K))$.*

Proof. (i) Since $G \in L^\infty((0,S)\times\mathbb{R}^N)$ and from Proposition 3.4, the solutions of

$$\begin{cases} -\phi + L\phi + G(t,\nu)\phi = \dfrac{N}{2}\phi \quad \text{in} \quad \mathbb{R}^N \times (0,S), \\ \phi(S) = \hat{\phi}^0, \end{cases} \tag{5.8}$$

where $\hat{\phi}^0$ is the minimizer of $J(.;G(t,\nu),v^1)$, are bounded in $L^\infty(0,S;L^2(K))$. Therefore, there exists a bounded set X in $L^2(0,S;L^2(K))$ such that for every $\nu \in L^2(0,S;L^2(K))$, $\Lambda(\nu) \subset X$. Let us now prove that we can choose X being compact in $L^2(0,S;L^2(K))$. For this, it is sufficient to prove that the set $\mathcal{V} = \{v(\lambda), \lambda \in sgn(\hat{\phi}(\nu,v^0,v^1)), \nu \in L^2(0,S;L^2(K))\}$ is relatively compact in $L^2(0,S;L^2(K))$.

If $v = v(\lambda) \in \mathcal{V}$, then there exist $\nu \in L^2(0,S;L^2(K))$ and $\lambda \in sgn(\hat{\phi}(\nu,v^0,v^1))$ such that we can write $v = v^* + \hat{v} + V(\lambda)$, where $v^*, \hat{v}$, and $V = V(\lambda)$ are defined by the following equations:

$$\begin{cases} v^*_s + Lv^* = \dfrac{N}{2}v^* \quad \text{in} \quad \mathbb{R}^N \times (0,S), \\ v^*(0) = u^0 \quad \text{in} \quad \mathbb{R}^N, \end{cases}$$

$$\begin{cases} \hat{v}_s + L\hat{v} + G(s,\nu)(v^* + \hat{v}) = \dfrac{N}{2}\hat{v} \quad \text{in} \quad \mathbb{R}^N \times (0,S), \\ \hat{v}(0) = 0 \quad \text{in} \quad \mathbb{R}^N, \end{cases}$$

$$\begin{cases} V_s + LV + G(s,\nu)V = \dfrac{N}{2}V + \|\hat{\phi}(\nu,v^0,v^1)\|_{L^1(q')}K^{-1}\lambda\chi_\omega \quad \text{in} \quad (0,S)\times\mathbb{R}^N, \\ V(0) = 0 \quad \text{in} \quad \mathbb{R}^N. \end{cases}$$

The function v^* is fixed in $L^2(0,S;L^2(K))$. When varying ν in $L^2(0,S;L^2(K))$, $G(s,\nu)v^*$ describes a bounded set in $L^2(0,S;L^2(K))$. From (2.3), (2.4), (2.5), and applying again Theorem 3.3, we see that $\hat{v}$ describes (when varying ν) a relatively compact set $B_1 \subset L^2(0,S;L^2(K))$.

Since the functions $\hat{\phi}(\nu,v^0,v^1)$ are bounded in $L^2(0,S;L^2(K))$, we have

$$\|\hat{\phi}\|_{L^1(q')}\|K^{-1/2}\lambda\|_{L^\infty(\mathbb{R}^N\times(0,T))} \leq C$$

for some constant $C > 0$.

Therefore, using again (2.3), (2.4), (2.5), and Theorem 3.3, we see that $V(\lambda)$ describes a relatively compact set B_2 in $L^2(0,S;L^2(K))$. That proves that $\mathcal{V} \subset v^* + B_1 + B_2$ is relatively compact in $L^2(0,S;L^2(K))$. We choose for X the closure of $\mathcal{V}$ in $L^2(0,S;L^2(K))$ to obtain (i).

(ii) We have already seen that for all $\nu \in L^2(0,S;L^2(K))$, $\Lambda(\nu)$ is a nonempty set of $L^2(0,S;L^2(K))$. Since the sets $sgn(\hat{\phi})$ and $B(v^1,\alpha)$ are convex, it is easy to prove that $\Lambda(\nu)$ is convex so we are just going to prove that it is compact. As we already have $\Lambda(\nu) \subset X$ with X compact, we only have to prove that it is closed. Let $\{v_n\}_n$ be a sequence of elements of $\Lambda(\nu)$, which converges in $L^2(0,S;L^2(K))$ to an element $v \in X$. Let us prove that $v \in \Lambda(\nu)$.

There exist functions $\lambda_n \in sgn(\hat{\phi})$ such that

$$(5.9)\begin{cases} v_n' + Lv_n + G(s,\nu)v_n = \dfrac{N}{2}v_n + \|\hat{\phi}\|_{L^1(q')}K^{-1}\lambda_n\chi_{\omega'(s)} & \text{in } (0,S)\times\mathbb{R}^N, \\ v_n(0) = v^0 \quad \text{in } \mathbb{R}^N, \\ \|v_n(S) - v^1\|_{L^2(K)} \le \alpha. \end{cases}$$

Since $\|\lambda_n\|_\infty \le 1$, there exists a subsequence λ_n converging weakly* in $L^\infty(q')$ to an element $\lambda \in L^\infty(q')$. Furthermore, as $\lambda_n \in sgn(\hat{\phi})$ for every n, we have that $\|\lambda\|_\infty \le 1$ and $\lambda = sgn_0(\hat{\phi})$ in $\{\hat{\phi}(\nu,v^0,v^1) \neq 0\} \cap q'$. This proves that $\lambda \in sgn\hat{\phi}$.

Now, by Proposition 2.3 and passing to the limit in (5.9), we obtain

$$\begin{cases} v_s + Lv + G(s,\nu)v = \dfrac{N}{2}v + \|\hat{\phi}\|_{L^1(q')}K^{-1}\lambda\chi_{\omega'(s)} & \text{in } (0,S)\times\mathbb{R}^N, \\ v(0) = v^0 \quad \text{in } \mathbb{R}^N. \end{cases}$$

Due to the smoothing effects, $v_n(S)$ converges in $L^2(K)$ to $v(S)$ and, therefore, $\|v(S) - v^1\|_{L^2(K)} \le \alpha$. This proves that $v \in \Lambda(\nu)$ and concludes the proof of (ii).

(iii) We first recall that Λ is hemicontinuous at $\nu_0 \in L^2(0,S;L^2(K))$ if

$$\nu \to \sigma(\Lambda(\nu),\varphi) = \sup_{v\in\Lambda(\nu)} \int_0^S \int_{\mathbb{R}^N} K\varphi v dy ds$$

is upper semicontinuous at ν_0 for every $\varphi \in L^2(0,S;L^2(K))$.

We then have to show that

$$\forall \nu_0 \in L^2(0,S;L^2(K)), \quad \limsup_{\nu_n\to\nu_0} \sigma(\Lambda(\nu_n),\varphi) \le \sigma(\Lambda(\nu_0),\varphi).$$

We denote by $\langle u,v\rangle$ the integral $\int_0^S\int_{\mathbb{R}^N} Kuv\,dyds$. From (ii), we know that $\Lambda(\nu)$ is compact in $L^2(0,S;L^2(K))$. Then, for every $n \in \mathbb{N}$, there exists $v_n \in \Lambda(\nu_n)$ such that

$$\sigma(\Lambda(\nu_n),\varphi) = \langle v_n,\varphi\rangle.$$

From (i), $(v_n)_n \subset X$ and, therefore, $v_n \to v$ in $L^2(0,S;L^2(K))$. Let us prove that $v \in \Lambda(\nu_0)$. We write $\phi_n = \hat{\phi}(\nu_n,v^0,v^1)$. There exists $\lambda_n \in sgn(\phi_n)$ such that v_n satisfies

$$\begin{cases} v_{n,s} + Lv_n + G(s,\nu_n)v_n = \dfrac{N}{2}v_n + \|\phi_n\|_{L^1(q')}K^{-1}\lambda_n\chi_\omega & \text{in } \mathbb{R}^N\times(0,S), \\ v(y,0) = v^0 \quad \text{in } \mathbb{R}^N, \\ \|v_n(S) - v^1\|_{L^2(K)} \le \alpha. \end{cases}$$

We will need the following lemma.

LEMMA 5.2. *If $\nu_n \to \nu_0$ strongly in $L^2(0,S;L^2(K))$, then $\hat{\phi}(\nu_n, v^0, v^1) \to \hat{\phi}(\nu_0, v^0, v^1)$ strongly in $L^2(K)$.*

Proof of Lemma 5.2. The functions $G(s,\nu_n)$ are bounded in $L^\infty((0,S)\times\mathbb{R}^N)$. Hence, for a subsequence, it converges in the weak* topology to an element $\tilde{G}$ in $L^\infty((0,S)\times\mathbb{R}^N)$. But G is continuous and that means that $\tilde{G} = G(s,\nu_0)$. Moreover, from (5.4) we know the existence of a subsequence $w_n(S)$ (where w_n is the solution of (5.3) corresponding to $G(s,\nu_n)$) such that $w_n(S) \to w(S)$ strongly in $L^2(K)$, where w is the solution of (5.3) corresponding to $G(s,\nu_0)$. In view of Proposition 3.4 (ii), we have that

$$\hat{\phi}_n^0 \to \hat{\phi}^0 \quad \text{strongly in } L^2(K),$$

where $\hat{\phi}^0$ is the minimizer of $J(.; G(s,\nu_0), v^1 - w(S))$. □

From Lemma 5.2 and Proposition 2.3, $\hat{\phi}_n$ converges strongly to $\hat{\phi}(\nu_0, v^0, v^1)$ in $L^2(0,S;L^2(K))$. Hence, $\|\hat{\phi}_n\|_{L^1(q')} \to \|\hat{\phi}\|_{L^1(q')}$ and

$$\hat{\phi}_n(s,y) \to \hat{\phi}(s,y) \quad \text{almost everywhere in } q'.$$

Since $\lambda_n \in sgn(\hat{\phi}_n)$, we can extract a subsequence converging weakly* in $L^\infty(q')$ to $\lambda \in sgn(\hat{\phi})\chi_{\omega'(s)}$. We then deduce that v is the solution of

$$\begin{cases} v_s + Lv + G(s,\nu_0)v = \dfrac{N}{2}v + \|\hat{\phi}\|_{L^1(q')}K^{-1}\lambda\chi_{\omega'(s)} & \text{in } \mathbb{R}^N\times(0,S), \\ v(y,0) = v^0 & \text{in } \mathbb{R}^N. \end{cases}$$

Moreover, due to the smoothing effects we keep the condition $v(S) \in B(v^1,\alpha)$; thus $v \in \Lambda(\nu_0)$.

Now, we have $\langle w, v_n\rangle \to \langle w, v\rangle$ with $v \in \Lambda(\nu_0)$, which proves that Λ is upper hemicontinuous in ν_0. □

PROPOSITION 5.3. *If f is of class C^1, $f(0) = 0$, and satisfies* (1.2)*, then there exists $v \in L^2(0,S;L^2(K))$ such that $v \in \Lambda(v)$.*

Proof The restriction of Λ to the convex hull of $X, conv(X)$ (that is compact in $L^2(0,S;L^2(K))$) satisfies the hypothesis of Kakutani's theorem, (see, e.g., Aubin [1, p. 344]). We deduce that Λ has a fixed point v. We then have the existence of $\phi^0 \in L^2(K)$ and $\lambda \in sgn(\phi)\chi_{q'}$ such that

$$(5.10)\quad \begin{cases} -\phi_s + L\phi + G(s,v)\phi = \dfrac{N}{2}\phi & \text{in } \mathbb{R}^N\times(0,S), \\ \phi(S) = \phi^0 \text{ in } \mathbb{R}^N, \\ v_s + Lv + G(s,v)v = \dfrac{N}{2}v + \|\phi\|_{L^1(q')}K^{-1}\lambda\chi_{\omega'(s)} & \text{in } \mathbb{R}^N\times(0,S), \\ v(y,0) = v^0(y) & \text{in } \mathbb{R}^N, \\ \|v(S) - v^1\|_{L^2(K)} \le \alpha. \end{cases}$$ □

As a direct consequence of Proposition 5.3, the general case for globally Lipschitz nonlinearities is easy to obtain.

PROPOSITION 5.4. *Let f be a globally Lipschitz function with $f(0) = 0$. There exists $A > 0$ and $\{f_n\} \in C^1(\mathbb{R}^N)$, $f_n(0) = 0$ and such that*

$$(5.11)\qquad \forall n \in \mathbb{N}, \qquad \forall \sigma \in \mathbb{R}, \qquad \left|\frac{f_n(\sigma)}{\sigma}\right| \le A,$$

$$\lim_{n\to\infty} f_n = f \quad \textit{locally uniformly.}$$

For each $n \in \mathbb{N}$, if we denote by $\varphi_n, \lambda_n \in sgn(\varphi_n)$ and v_n the solution of (5.10) *associated to f_n, there exists $\tilde{G} \in L^\infty(\mathbb{R}^N \times (0,T))$ such that φ_n^0 converges strongly in $L^2(K)$ to the minimum φ^0 of $J(\cdot;\tilde{G}, v^1 - w(S))$ and (φ_n, v_n) converge strongly in $L^2(0,T;L^2(K)) \times L^2(0,T;L^2(K))$ to the solution of*

$$(5.12)\quad \begin{cases} -\phi_s + L\phi + \tilde{G}\phi = \dfrac{N}{2}\phi, \\ \phi(S) = \phi^0, \\ v_s + Lv + G(v,s)v = \dfrac{N}{2}v + \|\phi\|_{L^1(q')}K^{-1}\lambda\chi_{\omega'(s)} \quad \textit{in} \ \ \mathbb{R}^N \times (0,S), \\ v(y,0) = v^0(y) \quad \textit{in} \quad \mathbb{R}^N, \\ \|v(S) - v^1\|_{L^2(K)} \le \alpha, \end{cases}$$

where $\lambda \in sgn(\varphi)\chi_{q'}$. Furthermore, $\tilde{G}(y,s) = G(v(y,s),s)$ on the set $v(y,s) \neq 0$.

Since the proof of this proposition is a straightforward adaptation of Proposition 3.4 in [6], we refer to it to avoid technical details. We only mention that, in fact, once the sequence satisfying (5.11) is obtained, we can obtain (5.12) as a direct consequence of Propositions 5.3 and 3.4.

We conclude with the proof of Proposition 1.1.

Proof of Proposition 1.1. As in the proof of Proposition 4.2, we divide the proof into steps.

Step 1. u^0, u^1 in $L^2(K)$.

We make the change of variables $v^1(y) = (T+1)^{N/2}u^1((T+1)^{1/2}y)$ and $S = \log(1+\mathrm{T})$. From Proposition 5.4 we know the existence of $\phi \in L^2(0,S;L^2(K))$, $\lambda \in sgn(\phi)\chi_{q'}$, and v solution of

$$\begin{cases} v_s + Lv + G(v,s)v = \dfrac{N}{2}v + \|\phi\|_{L^1(q')}K^{-1}\lambda\chi_{\omega'(s)} \ \text{ in } \mathbb{R}^N \times (0,S), \\ v(y,0) = u^0(y) \quad \text{in} \quad \mathbb{R}^N, \\ \|v(S) - u^1\|_{L^2(K)} \le \alpha. \end{cases}$$

We define $u(x,t)$ as in (1.7). By construction of G, u is the solution of (1.3) with

$$h(x,t) = (t+1)^{-N/2-1}K^{-1}\left(\frac{x}{\sqrt{1+t}}\right)\|\phi\|_{L^1(q')}\tilde{\lambda}\chi_\omega,$$

where $\tilde{\lambda} \in sgn\tilde{\phi}$ and $\tilde{\phi}(x,t) = \phi(\frac{x}{\sqrt{1+t}}, \log(1+t))$. Moreover, we observe that $\tilde{\phi}$ is a solution of

$$\begin{cases} -\tilde{\phi}_s - \Delta\tilde{\phi} + g(u)\tilde{\phi} = 0 \text{ in } \mathbb{R}^N \times (0,T), \\ \tilde{\phi}(T) = (1+T)^{-N/2}\phi^0\left(\dfrac{x}{\sqrt{1+T}}, S\right) \text{ in } \mathbb{R}^N. \end{cases}$$

The end of the proof follows as in Step 1 in the proof of Proposition 4.2 obtaining

$$\|u(T) - u^1\|_{L^2(\mathbb{R}^N)} \le \alpha.$$

Step 2. $u^0 \in L^2(K)$, $u^1 \in L^2(\mathbb{R}^N)$.

Since $L^2(K) \subset L^2(\mathbb{R}^N)$ with dense inclusion, there exists a sequence $\{u_n^1\} \subset L^2(K)$ such that $u_n^1 \to u^1$ strongly in $L^2(\mathbb{R}^N)$. From the first step, we know the existence of controls h_n such that u_n, the solution of (1.3) with $h = h_n$, satisfies

$$\|u_n(T) - u_n^1\|_{L^2(\mathbb{R}^N)} \leq \frac{\alpha}{2}.$$

Let $\tilde{N}$ be such that for every $n > \tilde{N}$,

$$\|u^1 - u_n^1\|_{L^2(\mathbb{R}^N)} \leq \frac{\alpha}{2}.$$

Then u, the solution of (1.3) with $h = h_{\tilde{N}}$, satisfies $\|u(T) - u^1\|_{L^2(\mathbb{R}^N)} \leq \alpha$.

Step 3. $u_0 \in L^2(\mathbb{R}^N)$.

Then there exists a sequence u_n^0 such that $u_n^0 \to u^0$ strongly in $L^2(\mathbb{R}^N)$. Moreover, as we saw previously, there exists a sequence of controls h_n such that u_n, the solution of (1.3) corresponding to u_n^0 and h_n, satisfies

$$\|u_n(T) - u^1\|_{L^2(\mathbb{R}^N)} \leq \frac{\alpha}{2}.$$

Let $\tilde{N} > 0$ be such that

$$\|u_{\tilde{N}}^0 - u^0\|_{L^2(\mathbb{R}^N)} \leq e^{\frac{-MT}{2}} \frac{\alpha}{2},$$

where M is the constant given in (1.2).

Consider u the solution of (1.3) corresponding to u^0 and $h = h_{\tilde{N}}$. Let $z = u - u_{\tilde{N}}$. Then z satisfies

$$\begin{cases} z_t - \Delta z + f(u) - f(u_{\tilde{N}}) = 0 & \text{in } \mathbb{R}^N \times (0,T), \\ z(x,0) = u^0(x) - u_{\tilde{N}}^0(x) & \text{in } \mathbb{R}^N. \end{cases} \tag{5.13}$$

We multiply (5.13) by z and integrate over $\mathbb{R}^N$. Since f satisfies (1.2), we obtain

$$\|z(T)\|_{L^2(\mathbb{R}^N)} \leq e^{\frac{MT}{2}} \|z(0)\|_{L^2(\mathbb{R}^N)} \leq \frac{\alpha}{2},$$

and, therefore,

$$\|u(T) - u^1\|_{L^2(\mathbb{R}^N)} \leq \|z(T)\| + \|u_{\tilde{N}}(T) - u^1\| \leq \alpha. \qquad \square$$

6. Further results. In this section we mention some possible extensions of the results and techniques of this article.

6.1. Cone-like domains. All the results of this paper hold for the semilinear heat equation (1.1) when Ω is a cone-like domain. In fact, consider a domain Ω satisfying

$$0 \in \bar{\Omega}, \qquad \forall \lambda > 0, \qquad \forall x \in \Omega, \lambda x \in \Omega.$$

Then we can study the controllability of the linear equation

$$\begin{cases} u_t - \Delta u + a(x,t)u = h\chi_\omega & \text{in } \Omega \times (0,T), \\ u = 0 \quad \text{on } \partial\Omega \times (0,T), \\ u(x,0) = u^0 \quad \text{in } \Omega \end{cases} \tag{6.1}$$

in the same way as the case of the whole space $\mathbb{R}^N$.

Observe that defining v, H, A as in (1.6) we obtain that v satisfies

$$\begin{cases} v_t + Lv + A(y,t)v = \dfrac{N}{2}v + H\chi_{\omega'} & \text{in } \Omega \times (0,S), \\ v = 0 \qquad \text{on } \partial\Omega \times (0,S), \\ v(y,0) = u^0 \qquad \text{in } \Omega. \end{cases} \tag{6.2}$$

In this case the functional setting will be

$$H_0^1(K,\Omega) = \left\{ v; \int_\Omega (|v|^2 + |\nabla v|^2) K(y) dy < \infty,\ v|_{\partial\Omega} = 0 \right\}.$$

6.2. Other functional settings. In this article we have chosen to work in the $L^2(\mathbb{R}^N)$ functional setting. The same type of results can be proved in $L^p(\mathbb{R}^N)$ spaces for $1 \le p < \infty$. In this aim it is necessary to introduce the corresponding weighted Sobolev spaces, i.e., $L^p(K) = \{u : \mathbb{R}^N \to \mathbb{R} : \int_{\mathbb{R}^N} |u|^p K(y) dy < \infty\}$ and $W^{1,p}(K) = \{u \in L^p(K); \nabla u \in L^p(K)\}$.

The only essential change that has to be done in the proof is that we have to minimize a functional of the form (3.1) in the dual space to the one we have chosen to prove controllability. We refer to [6] in the case where the domain is bounded.

6.3. Insensitizing controls. Suppose that in (1.3) the initial data are partially known, i.e., $u^0 = \hat{u}^0 + \tau \bar{u}^0$, where $\bar{u}^0 \in L^2(\mathbb{R}^N)$ is unknown, $\|\bar{u}^0\|_{L^2(\mathbb{R}^N)} = 1$ and $\tau \in \mathbb{R}$ is unknown and small enough. The insensitizing problem consists of finding a control function such that some functional of the state is locally insensitive to the perturbations of these initial data. We say that the control h, ε-insensitizes $\Phi(u)$ if

$$\left| \frac{\partial \Phi(u(x,t;h,\tau))}{\partial \tau}|_{\tau=0} \right| \le \varepsilon. \tag{6.3}$$

Let $\theta \subset \mathbb{R}^N$ be an open "observation" subset. When

$$\Phi(u) = \frac{1}{2} \int_0^T \int_\Theta u^2(x,t) dx dt, \tag{6.4}$$

the condition of ε-insensitivity is equivalent to an approximate control problem. Let y and q be the solutions of the following cascade system:

$$\begin{cases} y_t - \Delta y + f(y) = h\chi_\omega \ \text{ in } \mathbb{R}^N \times (0,T), \\ y(.,0) = u^0 \ \text{ in } \ \mathbb{R}^N, \end{cases} \tag{6.5}$$

$$\begin{cases} -q_t - \Delta q + f'(y)q = y\chi_\Theta \ \text{ in } \ \mathbb{R}^N \times (0,T), \\ q(.,T) = 0 \ \text{ in } \ \mathbb{R}^N, \end{cases} \tag{6.6}$$

where χ_Θ is the characteristic function of the observation subset Θ.

Then the condition of ε-insensitivity is equivalent to

$$\|q(.,0)\|_{L^2(\mathbb{R}^N)} \le \varepsilon. \tag{6.7}$$

The techniques of this paper may be adapted to prove that when $\omega \cap \theta \neq \emptyset$, f is of class C^1 and globally Lipschitz, then there exists an ε-insensitizing control for the functional (6.4). For insensitizing controls in bounded domains we refer to [2]. The case of insensitizing controls in unbounded domains is treated in [13] by using the approximation technique mentioned in the introduction.

A STRUCTURE THEORY FOR LINEAR DYNAMIC ERRORS-IN-VARIABLES MODELS*

W. SCHERRER† AND M. DEISTLER†

Abstract. We deal with problems connected with the identification of linear dynamic systems in situations when inputs and outputs may be contaminated by noise. The case of uncorrelated noise components and the bounded noise case is considered. If also the inputs may be contaminated by noise, a number of additional complications in identification arise, in particular the underlying system is not uniquely determined from the population second moments of the observations. A description of classes of observationally equivalent systems is given, continuity properties of mappings relating classes of observationally equivalent systems to the spectral densities of the observations are derived and the classes of spectral densities corresponding to a given maximum number of outputs are studied.

Key words. errors-in-variables, factor analysis, system identification

1. Introduction.

In the "main stream approach" to linear systems identification (see Deistler [7]) one of the basic assumptions is that all noise is added to the outputs (or to the equations, which is the same for our purpose). The noise thereby is assumed to be orthogonal to the inputs. In econometrics this is called the *errors-in-equations* approach. Here we are concerned with a different and, in principle, more general approach to noise modeling, where all variables may be contaminated by noise. Models of this kind are called *errors-in-variables* (EV) or *latent variables models*, or in a different but equivalent formulation, *factor models*. For the case of static systems, such models have been analyzed and used for a long time in statistics, science (in particular, chemistry), psychometrics, and econometrics (see, e.g., Adcock [1], Spearman [26], Gini [14], Frisch [13]). In the last two decades there has been a resurging interest in such models (see, e.g., Aigner et al. [2], Anderson [5]). Recently—mainly triggered by Kalman's work [18, 19, 20]—EV models have also been analyzed in systems engineering. The dynamic case has been treated, e.g., in Anderson and Deistler [3] and Deistler and Anderson [9].

The traditional errors-in-equations approach is justified in a great number of applications dealing, for instance, with prediction. On the other hand, in a number of cases the asymmetry in errors-in-equations modeling cannot be justified and may lead to "prejudiced" results (Kalman [20]). For example, in sonar array processing, when an array of n sensors is assumed to receive noisy signals from $n - m$ sources (Haykin [16]), EV models arise in a natural way. More generally, we can distinguish the following three main areas for EV modeling:

1. If we are interested in the "true system" underlying the data (rather than, for instance, in prediction) and if we cannot be sure a priori that the inputs have been observed free of noise. This is the "classical" motivation for EV models, for example, in econometrics.

2. If we want to approximate a high dimensional data vector by a small number of factors. This is the "classical" motivation for factor analysis (e.g., in psychometrics, where an example would be determining the intelligence factors underlying the test scores). A related issue is that EV modeling may considerably reduce the dimension of parameter spaces in comparison with multivariate AR or ARMA models.

3. In a number of cases, no sufficient a priori information about the number of equations and/or about the classification of the variables into inputs and outputs is available. Then, one has to use a *symmetric system model* which in turn demands a *symmetric noise model*. This point has been emphasized in particular by Kalman [18].

The systems considered are of the form

$$w(\mathrm{z})\hat{x}_t = 0, \tag{1.1}$$

where $\hat{x}_t$ is an n-dimensional vector of *latent* (i.e., not necessarily observed) real valued random variables, z is used for the backward-shift on the integers $\mathbb{Z}$ (i.e., $\mathrm{z}\,(\hat{x}_t|t \in \mathbb{Z}) = (\hat{x}_{t-1}|t \in \mathbb{Z})$) as well as for a complex variable, and where

$$w(\mathrm{z}) = \sum_{j=-\infty}^{\infty} W_j \mathrm{z}^j; \qquad W_j \in \mathbb{R}^{m\times n} \text{ and } \sum_{j=-\infty}^{\infty} \|W_j\| < \infty. \tag{1.2}$$

We will call $w(\mathrm{z})$ the *relation function*; it represents an exact (i.e., deterministic) linear system of a very general form. Clearly, systems of the form (1.1) are symmetric in the sense that no a priori classification of the variables $\hat{x}_t$ as inputs and outputs and no a priori information about causality are needed. Here also the number of equations, m, in (1.1) is not assumed to be known a priori. Without restriction of generality, we will assume that $1 \le m \le n$ holds and that $w(\mathrm{z})$ contains no linearly dependent rows.

The observed variables x_t are of the form

$$x_t = \hat{x}_t + u_t, \tag{1.3}$$

where u_t is the n-dimensional noise vector.

Throughout the paper we will assume the following:

(a.1) The processes (x_t), $(\hat{x}_t)$, and (u_t) are (wide sense) stationary with absolutely summable autocovariance functions. Thus, in particular, the spectral densities Σ, $\hat{\Sigma}$, and $\tilde{\Sigma}$ of (x_t), $(\hat{x}_t)$, and (u_t), respectively, exist and are bounded continuous functions. (In addition, limits of random variables are understood in the sense of mean square convergence.)

(a.2) $\mathrm{E}\hat{x}_t = 0$ and $\mathrm{E}u_t = 0$.

(a.3) $\mathrm{E}\hat{x}_t u_s' = 0$.

(a.4) Unless the contrary is stated explicitly, we assume that $\Sigma > 0$ holds.

Assumptions (a.1)–(a.4) are not severe restrictions of generality. They are either natural or are imposed to avoid technical problems.

Due to (1.1), the spectral density $\hat{\Sigma}$ is singular and

$$w(e^{-i\lambda})\hat{\Sigma}(\lambda) = 0 \tag{1.4}$$

holds. Note that for a given process $(\hat{x}_t)$, a relation function w satisfies (1.1) iff w satisfies (1.4) for the spectral density $\hat{\Sigma}$ of $\hat{x}_t$; in other words, there is no loss of information concerning w in going from the process $(\hat{x}_t)$ to its spectral density.

Assume that the spectral density $\hat{\Sigma}$ of corank m is given and that the $m\times n$ matrix w satisfies $w\hat{\Sigma} = 0$, where w has rank m. Then we may select m independent columns

from w and regroup the columns of w such that these columns appear in the first m positions, which gives a partitioning of w as (w_1, w_2). By a conformal rearrangement of the components of $\hat{x}_t$ and a corresponding partitioning of $\hat{x}_t = ((\hat{x}_t^1)', (\hat{x}_t^2)')'$, we obtain from (1.1) that $w_1\hat{x}_t^1 + w_2\hat{x}_t^2 = 0$. Now assume that w_1^{-1} has an absolutely summable Laurent series expansion in an annulus containing the unit circle; then by premultiplying w with w_1^{-1} we obtain

$$\hat{x}_t^1 = \underbrace{-w_1^{-1}(\mathrm{z})w_2(\mathrm{z})}_{k(\mathrm{z})}\hat{x}_t^2$$

which describes the input-output behavior of the system (1.1). In general this choice of outputs $\hat{x}_t^1$ is not unique. Note that for a nonsingular $m \times m$ transfer function $t(\mathrm{z})$, which satisfies additional conditions (e.g., that both t and t^{-1} have an absolutely summable Laurent series expansion in an annulus containing the unit circle) the relation functions $w(\mathrm{z})$ and $t(\mathrm{z})w(\mathrm{z})$ are equivalent in the sense that, for a given choice of outputs, they represent the same input-output behavior $k(\mathrm{z})$.

Note that there is a close relation to the behavioral approach developed by Willems [29]; also see Heij, Scherrer, and Deistler [17]. The main differences of the behavioral approach to the setup of this paper are that here we impose stationarity and that we do not require the system to be finite dimensional.

Under rather general conditions, the restriction that $(\hat{x}_t)$ is contained in the kernel of $w(\mathrm{z})$ (see (1.1)) can be replaced by the restriction that $(\hat{x}_t)$ is contained in the image of a suitably chosen $n \times (n-m)$ transfer function $\Lambda(\mathrm{z})$, i.e.,

$$\hat{x}_t = \Lambda(\mathrm{z})\epsilon_t, \tag{1.5}$$

where, in particular, (1.5) can be chosen to be the Wold representation of the process $(\hat{x}_t)$. This gives rise to the linear dynamic factor model

$$x_t = \Lambda(\mathrm{z})\epsilon_t + u_t, \tag{1.6}$$

where (ϵ_t) is interpreted as the $(n-m)$ dimensional factor process, which by assumption is white noise. $\Lambda(\mathrm{z})$ is called the matrix of factor loadings.

We commence from the equation

$$\Sigma = \hat{\Sigma} + \tilde{\Sigma} \tag{1.7}$$

for the spectral densities. For given Σ, the matrix $\hat{\Sigma}$ is called *compatible* (with Σ) if (1.7) is satisfied, where $\hat{\Sigma}$ and $\tilde{\Sigma}$ are positive semidefinite and where, in addition, $\hat{\Sigma}$ is singular and typically, $\tilde{\Sigma}$ satisfies further assumptions such as (a.5) or (a.6) below. Instead of *compatible*, we also use the term *observationally equivalent*. A relation function $w(\mathrm{z})$ is called *compatible* (with Σ) if there exists a compatible $\hat{\Sigma}$, such that $w\hat{\Sigma} = 0$ holds.

Without imposing additional a priori assumptions such as (a.5) or (a.6) below, the problem considered is not sufficiently structured. In particular, without such assumptions, *every* relation function w would be compatible with a given $\Sigma > 0$. This is an easy consequence of the fact that, for every singular $n \times n$ spectral density $\hat{\Sigma}$, a constant $c > 0$ exists such that $\hat{\Sigma} = c\hat{\Sigma}$ is compatible with a given $\Sigma > 0$. Thus, some additional structure has to be imposed, which can be justified in a sufficiently large number of cases. In this paper, the two following alternative assumptions are considered:

(a.5) $\tilde{\Sigma}$ is diagonal.

This case will be called the Frisch case. The idea behind this assumption is to provide a decoupling of common and individual effects between the variables. The common effects are attributed to the system and the individual effects to the noise. Another motivation for this assumption relates to the case where all noise is measurement noise and the measurement devices for each channel are independent. Note that the Frisch case, in particular for the static case, has a long tradition in econometrics and psychometrics; see, e.g., Aigner et al. [2], Anderson [5], Anderson and Rubin [6], Gini [14], Ledermann [22], and Spearman [26].

An alternative assumption is that the noise level is bounded. This will be expressed as follows:

(a.6) $\lambda_n(\tilde{\Sigma}(\lambda)) \leq \epsilon$.

This case will be called the bounded noise case. Here λ_n denotes the maximum eigenvalue of $\tilde{\Sigma}(\lambda)$ and ϵ is an a priori given bound. This assumption is justified, for instance, if all noise is measurement noise and the magnitude of the error of the measurement devices (in terms of the noise spectrum) is known a priori. Additional information about the noise spectra may be taken into account by appropriate prefiltering of the data. This, in particular, relates to scale transformations and weightings of frequency bands.

Identification of errors-in-variables models is considerably more complicated than identification of errors-in-equations models. The purpose of this paper is twofold: first, to add a further step towards a theory of identification for this general case and second, to illustrate the additional complications arising with the departure from errors-in-equations models. We restrict ourselves to structure theory, i.e., we commence from population second moments rather than from real data. The main problem considered in this paper is obtaining the underlying systems from the population second moments of the observations (x_t) given by the spectral density Σ. One of the main complications of the errors-in-variables problem is that, in general, the underlying system is not uniquely determined from Σ. This is a major difference to the errors-in-equations approach, where the underlying transfer function is uniquely determined from the second moments of the observations under a so-called *persistent excitation* condition. This nonuniqueness in the EV case is caused by a lack of a priori knowledge concerning the noise structure. This is an uncertainty about the underlying system which has nothing to do with sampling variation; it remains even in the case of an "infinite" sample.

Here our basic philosophy is not to impose additional conditions which guarantee identifiability. Such conditions, in many cases, are not justified by a priori knowledge and thus may lead to prejudiced results. For this reason, the aim considered here is to obtain *classes* of observationally equivalent systems from the second moments of the observations rather than a *single* system. Since, in general, an exact description of such equivalence classes has not yet been obtained, we will give a qualitative description in terms of topological and geometrical properties. These results may be helpful for the development of numerical procedures to compute the equivalence classes. In addition, they give an illustration of the uncertainty about the underlying model due to the lack of knowledge about the error structure.

The structure theory presented in this paper, in our opinion, is of central importance for the more general problem of identification in a linear dynamic errors-in-variables setting, where we commence from data $(x_1, \ldots, x_T)$ rather than from the second order population moments. We will give a brief sketch of this more general identification problem in order to motivate the results obtained in this paper.

In linear system identification, in many cases in a first step the data are compressed in an estimate of the second moments of the observations, in our case in an estimate Σ_T of the spectrum Σ.

Let $\Sigma_T(\lambda)$ denote an estimate of $\Sigma(\lambda)$, where T denotes the sample size. Then the class of observationally equivalent systems corresponding to Σ_T is an estimate for the class corresponding to Σ. Therefore any (numerical) procedure which constructs the equivalence class to a given Σ gives an identification procedure. Such a procedure is not only reasonable, but it seems to be the obvious one.

Under general conditions, the spectral density $\Sigma(\lambda)$ of (x_t) can be consistently estimated. If the mapping attaching to Σ the corresponding class of observationally equivalent systems is continuous, then the above estimate is consistent. Therefore, in addition to describing equivalence classes for a given Σ, the continuity of the mapping described above will be considered in this paper. Since the statistical analysis of spectral estimates is well known for a number of decades, the two problems of structure theory addressed in this paper are a major and perhaps the most important module for a general theory of identification of EV models.

The main approaches to spectral estimation are as follows: on the one hand nonparametric spectral estimation, where the spectrum is estimated at a finite number of frequencies (here the number of frequencies may increase with the sample size T); on the other hand the spectrum may be estimated by fitting AR or ARMA models.

For the rest of this paper the spectral densities Σ, $\hat{\Sigma}$, and $\tilde{\Sigma}$ as well as the relation function $w(e^{-i\lambda})$ are considered for *arbitrary* but *fixed* frequency λ. If we commence from a nonparametric spectral estimate, and if no additional a priori assumptions on the order of the relation functions $w(z)$ are imposed, then our results, obtained for an arbitrary but fixed frequency, can be applied immediately.

However, our results can also be applied for varying frequencies by putting them together pointwise, e.g., a relation function w is compatible with Σ if and only if $w(e^{-i\lambda})$ is compatible with $\Sigma(\lambda)$ for every frequency λ. In particular for instance, we can check whether a given relation function w is compatible. However, we do not analyze, e.g., the additional restrictions on the equivalence classes coming from rational parametrization for $\Sigma, \hat{\Sigma}, \tilde{\Sigma}$, and w with bounded order. Such an approach seems to be very complicated; see Stemmer [27] and also some remarks in section 5.

Clearly, the results obtained for fixed frequency also apply to situations where only a narrow frequency band is considered.

No information from the observations, besides the second moments, Σ is used. This is a reasonable limitation; however, it should be mentioned that in the non-Gaussian case, higher order moments may provide important information to identify the system (see, e.g., Deistler [8], Tugnait [28]). In this respect, EV models are different from errors-in-equations models; however, we will not comment further on this issue here.

The paper is organized as follows. In section 2 we present the basic notations and definitions as well as a short description of the main results of the paper. The main results are contained in section 3 (for the Frisch case) and section 4 (for the bounded noise case). As an illustration, in section 5 the bivariate case is studied.

2. Problem statement. Remember that from now on we only consider the case of fixed frequency. For fixed frequency $\Sigma, \hat{\Sigma}$, and $\tilde{\Sigma}$ are constant positive semidefinite matrices with complex entries, rather than functions of the frequency λ. The relation (function) is a constant matrix $w \in \mathbb{C}^{m \times n}$ and we will assume that it is of full rank m. In order to be completely precise, we partly repeat definitions which have been given before now for the case of fixed frequency.

From equations (1.7) and (1.4) and our assumptions we have, for the case of fixed frequency,

$$\begin{gathered}\Sigma, \hat{\Sigma}, \tilde{\Sigma} \in \mathbb{C}^{n\times n},\\ \Sigma = \hat{\Sigma} + \tilde{\Sigma}; \qquad \hat{\Sigma} \geq 0, \tilde{\Sigma} \geq 0,\\ \hat{\Sigma} \text{ is singular.}\end{gathered} \tag{2.1}$$

For a given Σ, a matrix $\hat{\Sigma}$ is called *compatible* with Σ if $\hat{\Sigma}$ and $\tilde{\Sigma} = \Sigma - \hat{\Sigma}$ satisfy (2.1) and where, typically, $\tilde{\Sigma}$ satisfies further assumptions such as (a.5) or (a.6). Analogously then, $\tilde{\Sigma}$ and the decomposition (2.1) are called *compatible* with Σ. A relation w, i.e., a full rank matrix $w \in \mathbb{C}^{m\times n}$, is called *compatible* with Σ if there exists a compatible $\hat{\Sigma}$ such that $w\hat{\Sigma} = 0$.

The set of all compatible relations corresponding to Σ with m rows is called the *m-relation set* $\underline{\mathcal{R}}_m$ (of Σ). Sometimes we use the notation $\underline{\mathcal{R}}_m(\Sigma)$. For many purposes it is appropriate to describe the system in terms of the linear m-dimensional subspace of $\mathbb{C}^n$ generated by the rows of the relation w. By $\mathcal{R}_m(\Sigma)$ we denote the set of all such subspaces corresponding to $\underline{\mathcal{R}}_m(\Sigma)$. By system we mean either a relation w or the subspace generated by the rows of w. Thus $\underline{\mathcal{R}}_m(\Sigma)$ and $\mathcal{R}_m(\Sigma)$ in this sense are the sets of all systems with m outputs compatible with Σ.

An important integer is the maximum corank of $\hat{\Sigma}$, denoted by $\mathrm{mc}(\Sigma)$, among the set of all $\hat{\Sigma}$ which are compatible with a given Σ. At the same time, $\mathrm{mc}(\Sigma)$ is the maximum number of equations and $(n - \mathrm{mc}(\Sigma))$ is the minimum number of factors. The subclass $\mathcal{R}_m$ corresponding to $m = \mathrm{mc}(\Sigma)$ is of special interest, since in many cases we want to explain as much as possible by the system.

We define $\mathcal{S}$ as the set of all spectral densities Σ and $\mathcal{S}_m$ as the subset of $\mathcal{S}$ where $\mathrm{mc}(\Sigma) = m$ holds, i.e.,

$$\mathcal{S} = \{\Sigma | \Sigma > 0\}; \quad \mathcal{S}_m = \{\Sigma | \Sigma > 0, \mathrm{mc}(\Sigma) = m\}.$$

Note that the sets $\underline{\mathcal{R}}_m(\Sigma)$, $\mathcal{R}_m(\Sigma)$, and $\mathcal{S}_m$ depend on the particular assumption (a.i); i=5,6 imposed. We will not introduce distinct notation for each assumption since it will become clear from the context which assumption is considered.

For the Frisch case it is convenient to consider the set of all compatible noise spectral densities for given Σ, $\mathcal{E}(\Sigma)$ say, and the subsets $\mathcal{E}_m(\Sigma)$ of $\mathcal{E}(\Sigma)$ corresponding to a given corank m of $\hat{\Sigma} = \Sigma - \tilde{\Sigma}$. Of course $\mathcal{E}(\Sigma) = \mathcal{E}_1(\Sigma) \cup \cdots \cup \mathcal{E}_n(\Sigma)$, and $\mathcal{E}_m(\Sigma)$ is empty for all $m > \mathrm{mc}(\Sigma)$. Since $\tilde{\Sigma}$ is diagonal with real elements, the sets $\mathcal{E}(\Sigma)$ and $\mathcal{E}_m(\Sigma)$ can be considered as subsets of $\mathbb{R}^n$.

The following three structural problems are analyzed in detail in the paper:

1. As has been said already, our basic philosophy is not to obtain identifiability by imposing additional restrictions (which in many cases would be a prejudice). The ultimate aim is to estimate classes of observationally equivalent systems. Thus one important structural problem is to describe classes of observationally equivalent systems, i.e. sets of systems which are compatible with given Σ. The main results concerning the description of classes of compatible systems are as follows:

   For the Frisch case, section 3 contains a number of results concerning observationally equivalent systems in terms of the sets $\mathcal{E}$ and $\mathcal{E}_m$. An integer of central importance for the Frisch case is the so-called Ledermann bound $\mathrm{m_L} = \sqrt{n}$.

   The structure of the set $\mathcal{E}(\Sigma)$, as well as of the sets $\mathcal{E}_m(\Sigma)$, is analyzed in Propositions 3.1 and 3.3, respectively. A central result is contained in

Proposition 3.5, namely, that "typically" for $m \leq \mathrm{m_L}$ the sets $\mathcal{E}_m(\Sigma)$ are differentiable submanifolds of $\mathbb{R}^n$ with boundaries of dimension $n - m^2$. In addition by Proposition 3.6, for $m = \mathrm{mc}(\Sigma)$, the set of systems $\mathcal{R}_m(\Sigma)$ is a differentiable submanifold of the set of all m-dimensional subspaces of $\mathbb{C}^n$.

In the bounded noise case, things are different and in a certain sense easier. Note that in the Frisch case all off-diagonal elements of $\tilde{\Sigma}$ have to be zero, which means that we have $n(n-1)$ real equality constraints on $\tilde{\Sigma}$, whereas in the bounded noise case there is only one inequality constraint on $\tilde{\Sigma}$. This is an intuitive explanation of why, in the bounded noise case, the set of systems $\mathcal{R}_m(\Sigma)$ are typically "thick" for $m \leq \mathrm{mc}(\Sigma)$, in the sense that they contain a nonvoid open subset of the set of all m-dimensional subspaces of $\mathbb{C}^n$. See Proposition 4.3.

2. As has been stated already, from the point of view of identification the continuity of the mapping attaching classes of observationally equivalent systems to Σ is important. This relates to consistency of estimation of these equivalence classes, as explained above.

   For the Frisch case we show, in particular, that the mapping attaching $\mathcal{E}(\Sigma)$ to Σ is continuous (Proposition 3.7) and that on a generic subset of $\mathcal{S}$ the mapping attaching $\mathcal{R}_m(\Sigma)$ to Σ is continuous (Proposition 3.9). For the bounded noise case, by Proposition 4.5 the mapping attaching $\mathcal{R}_m(\Sigma)$ to Σ is continuous on a generic subset of $\mathcal{S}$.

3. Another important problem is estimation of $\mathrm{mc}(\Sigma)$. For this purpose some properties of the sets $\mathcal{S}_m$ of spectral densities Σ such that $\mathrm{mc}(\Sigma) = m$ holds are analyzed.

   In the Frisch case, for $m \leq \mathrm{m_L}$, all sets $\mathcal{S}_m$ of spectral densities with $\mathrm{mc}(\Sigma) = m$ are "thick" in the sense that they contain a nonvoid open subset of $\mathcal{S}$. On the other hand, for $m > \mathrm{m_L}$, the sets $\mathcal{S}_m$ are "thin" in the sense that they have Lebesgue measure zero. In this sense, spectral densities which allow for a system having more than $\mathrm{m_L}$ outputs are a priori unlikely.

   Let Σ_T denote an unrestricted and consistent estimate of Σ and let $\mathrm{mc}(\Sigma) \leq \mathrm{m_L}$; then by the results of Proposition 3.5, generically, $\mathrm{mc}(\Sigma_T)$ will be equal to $\mathrm{mc}(\Sigma)$ from a certain T onwards. On the other hand, for $\mathrm{mc}(\Sigma) > \mathrm{m_L}$, typically $\mathrm{mc}(\Sigma_T) \leq \mathrm{m_L}$ will hold. Thus in the first case $\mathrm{mc}(\Sigma)$ can be directly determined from $\mathrm{mc}(\Sigma_T)$, whereas in the second case the distance of Σ_T to the set $\mathcal{S}_m$ has to be taken into account in order to decide whether or not $\mathrm{mc}(\Sigma) = m$ holds. Such a decision can be based on a test or an information criterion.

   Again, for the bounded noise case things are simpler. By Proposition 4.4 all sets $\mathcal{S}_m$ are "thick."

Now let us introduce some notation. For a matrix A, say, we use the corresponding lowercase letter a_{ij} to denote its i,jth entry. The (left) kernel of a matrix A is denoted by $\ker(A)$; $\mathrm{rank}(A)$ and $\mathrm{corank}(A)$, respectively, denote the rank and corank, respectively, of A. If $A \in \mathbb{C}^{n\times n}$ is a Hermitian matrix, then $\lambda_1(A) \leq \lambda_2(A) \leq \cdots \leq \lambda_n(A)$ denote its eigenvalues. For a vector v, $\mathrm{diag}(v)$ denotes the (square) diagonal matrix whose diagonal elements are the corresponding entries of v. For a complex matrix $A \in \mathbb{C}^{m\times n}$, the matrix A^* is the complex conjugate transposed matrix. For a subset $\mathcal{A}$, say, of a topological space, $\mathcal{A}^o$ denotes the interior of $\mathcal{A}$ and $\overline{\mathcal{A}}$ denotes the closure of $\mathcal{A}$.

In the remaining part of this section we will describe topologies and geometrical structures used in this paper.

For many purposes, it is appropriate to describe the system in terms of the linear m-dimensional subspace (of $\mathbb{C}^n$) generated by the rows of the relation (function) w. Let $\mathcal{G}(m,n)$ denote the Grassmannian of all complex subspaces of dimension m of $\mathbb{C}^n$. Note that these subspaces can be identified with the equivalence classes $\{tw | t \in \mathbb{C}^{m\times m}, \det(t) \neq 0\}$, $w \in \mathbb{C}^{m\times n}$, $\operatorname{rank}(w) = m$. The topology of the Grassmannian is the quotient topology and $\mathcal{G}(m,n)$ is a differentiable manifold of real dimension $2m(n-m)$. Clearly $\mathcal{R}_m(\Sigma)$ is a subset of the corresponding Grassmannian $\mathcal{G}(m,n)$.

We always identify the set of all Hermitian $\mathbb{C}^{n\times n}$ matrices with $\mathbb{R}^{n^2}$ in an obvious way. (Note that a Hermitian $n\times n$ matrix is given by its n real diagonal elements and by its $n(n-1)/2$ complex upper diagonal elements.) The set of all strictly positive matrices $\Sigma > 0$ (of all positive semidefinite matrices $\Sigma \geq 0$) is denoted by $\mathcal{S}$ (and $\mathcal{M}$, respectively). Note that $\mathcal{S}$ is an open subset of $\mathbb{R}^{n^2}$ and $\mathcal{M}$ is the closure of $\mathcal{S}$ in $\mathbb{R}^{n^2}$, i.e., $\overline{\mathcal{S}} = \mathcal{M} \subseteq \mathbb{R}^{n^2}$.

By $\mathcal{M}_m \subset \mathcal{M}$ we denote the set of all nonnegative definite matrices of corank m. $\mathcal{M}_m$ is a differentiable submanifold of $\mathbb{R}^{n^2}$ of dimension $n^2 - m^2$. By rearranging the rows and corresponding columns, we may partition $\hat{\Sigma} \in \mathcal{M}_m$ as

$$\hat{\Sigma} = \begin{array}{c} \left(\begin{array}{cc} \hat{\Sigma}_{11} & \hat{\Sigma}_{12} \\ \hat{\Sigma}_{12}^* & \hat{\Sigma}_{22} \end{array} \right) \\ \underbrace{\phantom{\hat{\Sigma}_{11}}}_{m} \quad \underbrace{\phantom{\hat{\Sigma}_{22}}}_{n-m} \end{array} \begin{array}{l} \} \, m \\ \} \, n-m \end{array},$$

where $\hat{\Sigma}_{22} > 0$ holds. For $\hat{\Sigma}_{22} > 0$ the statements $\hat{\Sigma} \geq 0$, $\operatorname{corank}(\hat{\Sigma}) = m$, and

$$\mathrm{g}_{n,m}(\hat{\Sigma}) = (\hat{\Sigma}_{11} - \hat{\Sigma}_{12}\hat{\Sigma}_{22}^{-1}\hat{\Sigma}_{12}^*) = 0$$

are equivalent. Since $\mathrm{g}_{n,m}(\hat{\Sigma})$ is a Hermitian $m\times m$ matrix, we can interpret $\mathrm{g}_{n,m}$ as a function defined on an open subset of $\mathbb{R}^{n^2}$ mapping to $\mathbb{R}^{m^2}$. As $\mathrm{g}_{n,m}$ is infinitely often differentiable and has full rank m^2 everywhere, $\mathrm{g}_{n,m}(\hat{\Sigma}) = 0$ is a local equation system for $\mathcal{M}_m$ and

$$\left(\begin{array}{cc} \hat{\Sigma}_{11} & \hat{\Sigma}_{12} \\ \hat{\Sigma}_{12}^* & \hat{\Sigma}_{22} \end{array} \right) \longmapsto (\hat{\Sigma}_{12}, \hat{\Sigma}_{22})$$

is a local coordinate system for $\mathcal{M}_m$.

In the following, we will often use partitionings analogous to the partitioning above, without further explaining the notation used.

Let us define the set of all diagonal covariance matrices

$$\mathcal{D} = \{\tilde{\Sigma} \geq 0 \,|\, \tilde{\Sigma} \text{ is diagonal } \} \subseteq \mathbb{R}^n,$$

and for an index set $\mathcal{I} \subseteq \{1,\ldots,n\}$ we define

$$\mathcal{D}_{\mathcal{I}} = \{\tilde{\Sigma} \in \mathcal{D} \,|\, \tilde{\sigma}_{ii} > 0 \text{ for } i \in \mathcal{I} \text{ and } \tilde{\sigma}_{ii} = 0 \text{ otherwise}\}.$$

$|\mathcal{I}|$ denotes the number of elements of the index set $\mathcal{I}$.

Let $\mathcal{A}$ be a metric space endowed with the metric $\mathrm{d}(x,y)$. Then for two compact subsets $\mathcal{U}, \mathcal{V} \subseteq \mathcal{A}$, the Haussdorff distance $\mathrm{d_H}(\mathcal{U},\mathcal{V})$ is defined by

$$\mathrm{d_H}(\mathcal{U},\mathcal{V}) = \min(\rho(\mathcal{U},\mathcal{V}), \rho(\mathcal{V},\mathcal{U})),$$

where

$$\rho(\mathcal{U},\mathcal{V}) = \sup_{x\in\mathcal{U}} \inf_{y\in\mathcal{V}} \mathrm{d}(x,y).$$

If $\mathcal{C}(\mathcal{A})$ denotes the set of all compact subsets of $\mathcal{A}$, then $\mathrm{d_H}$ is a metric defined on $\mathcal{C}(\mathcal{A})$. We will consider the following three cases:

1. $\mathcal{A} = \mathbb{R}^n$ and $\mathrm{d}(x,y) = \|x-y\|$ is the usual Euclidean distance. The Haussdorff distance is then defined on $\mathcal{C}(\mathbb{R}^n)$, the set of all compact subsets of $\mathbb{R}^n$.

2. Using the Haussdorff distance we can define a metric on the Grassmannian $\mathcal{G}(m,n)$: let $\mathfrak{x},\mathfrak{y} \in \mathcal{G}(m,n)$; then we define

$$\mathrm{d}_{\mathcal{G}}(\mathfrak{x},\mathfrak{y}) = \mathrm{d_H}(\{x\in\mathfrak{x}, \|x\|\le 1\}, \{y\in\mathfrak{y}, \|y\|\le 1\}).$$

In other words, the distance of two m-dimensional subspaces of $\mathbb{C}^n$ is defined as the Haussdorff distance of the intersections of these subspaces with the unit ball. This distance has a close connection to the canonical correlations of the spaces $\mathfrak{x}$ and $\mathfrak{y}$.

3. $\mathcal{A} = \mathcal{G}(m,n)$ and $\mathrm{d}(\mathfrak{x},\mathfrak{y}) = \mathrm{d}_{\mathcal{G}}(\mathfrak{x},\mathfrak{y})$. The Haussdorff distance is then defined on $\mathcal{C}(\mathcal{G}(m,n))$, the set of all compact subsets of $\mathcal{G}(m,n)$.

3. The Frisch case. Here condition (a.5), i.e., that $\tilde{\Sigma}$ is diagonal, is imposed throughout. For given Σ then, a decomposition (2.1) is called a Frisch decomposition.

3.1. The set of all observationally equivalent systems. This subsection is concerned with the description of sets of observationally equivalent (i.e., compatible) spectra $\hat{\Sigma}$ of the latent variables $(\hat{x}_t)$ and of observationally equivalent systems. For convenience, in this section we will consider sets of observationally equivalent noise spectral densities $\tilde{\Sigma}$. Since for given Σ the matrices $\hat{\Sigma}$ and $\tilde{\Sigma}$ are in an obvious one-to-one relation, this also gives a description of the set of all observationally equivalent $\hat{\Sigma}$. Replacing $\hat{\Sigma}$ by $\tilde{\Sigma}$ is only done since sets of $\tilde{\Sigma}$'s can be embedded in $\mathbb{R}^n$. Whether or not sets of observationally equivalent $\hat{\Sigma}$'s or of observationally equivalent systems are of primary interest depends on the particular application.

The main results obtained in this subsection are as follows: In Proposition 3.1 we give a topological description of the set $\mathcal{E}(\Sigma)$ of all compatible noise spectra: $\mathcal{E}(\Sigma)$ is shown to be topologically equivalent to the intersection of the unit sphere with the first orthant in $\mathbb{R}^n$. This result is important for illustrating the nonuniqueness inherent in the Frisch case. In Proposition 3.3 we consider subsets of $\mathcal{E}$ corresponding to different numbers of outputs. In particular we see that the set $\mathcal{E}_1$ corresponding to the single output case is generic and that the closures of these sets are nested in the sense that $\overline{\mathcal{E}_1} \supseteq \cdots \supseteq \overline{\mathcal{E}_n}$ holds.

Proposition 3.5 contains one of the most important results of the paper. It is shown that, for a generic set of spectra Σ, the sets $\mathcal{E}_m(\Sigma)$ are either empty (for $m > \mathrm{mc}(\Sigma)$) or differentiable manifolds of dimension $n-m^2$ with boundaries. In particular this generic set contains only spectra with a Frisch corank $\mathrm{mc}(\Sigma) \le \sqrt{n}$. As has been mentioned already, the case $m = \mathrm{mc}(\Sigma)$ is of particular interest. In many cases only systems with the maximum number of outputs are considered. In Proposition 3.6 we show that in this case, the set of observationally equivalent $\tilde{\Sigma}$ is homeomorphic to the set of all observationally equivalent systems $\mathcal{R}_m(\Sigma)$. In addition, in this case the set of observationally equivalent systems is generically a differentiable manifold of dimension $n-m^2$ with boundaries.

We start with the following description of the set $\mathcal{E} \subseteq \mathbb{R}^n$ of all observationally equivalent $\tilde{\Sigma}$. For the next Proposition see Deistler and Scherrer [11].

PROPOSITION 3.1. *$\mathcal{E}$ is homeomorphic to $\mathcal{K}^+ = \{d \in \mathbb{R}^n \mid d_i \geq 0, \|d\| = 1\}$. Thus $\mathcal{E}$ is compact and is a topological manifold with boundaries of real dimension $n-1$.*

Proof. For each $d \in \mathcal{K}^+$, the matrix $(\Sigma - \lambda \operatorname{diag}(d))$ is positive semidefinite and singular (and thus compatible with Σ) iff λ is the smallest real number, λ_0 say, for which $(\Sigma - \lambda \operatorname{diag}(d))$ is singular. Clearly then, $1/\lambda_0$ is the largest eigenvalue of $\Sigma^{-1/2} \operatorname{diag}(d) \Sigma^{-*/2}$. Now we define a function on $\mathcal{K}^+$ by $d \mapsto \lambda_0 \operatorname{diag}(d)$. This function is continuous, because the largest eigenvalue is a continuous function of the matrix elements. (See, e.g., Golub and van Loan [15].) Since Σ is nonsingular, the inverse mapping defined by $\tilde{\Sigma} \mapsto (\tilde{\sigma}_{11}, \ldots, \tilde{\sigma}_{nn})/\|(\tilde{\sigma}_{11}, \ldots, \tilde{\sigma}_{nn})\|$ is well defined and continuous, too.

The second statement of the proposition is an immediate consequence of the first. □

It is a trivial consequence of the proposition above that the Frisch decompositions always exist and that $\tilde{\Sigma}$ is never unique without imposing further restrictions. The intersection of $\mathcal{E}(\Sigma)$ with a coordinate axis corresponds to the regression of one component of x_t on all other components, i.e., to the case where only one component of x_t is corrupted by noise. It has been shown in Schachermayer and Deistler [24] that $\mathcal{E}$ is smooth exactly at the points where $\operatorname{corank}(\Sigma - \tilde{\Sigma}) = 1$ holds.

In the next step we analyze the partitioning of the set $\mathcal{E}$ as $\mathcal{E} = \mathcal{E}_1 \cup \cdots \cup \mathcal{E}_n$, i.e., according to different numbers of outputs. The first problem in this context is to determine $\operatorname{mc}(\Sigma)$. We have the following result (compare Deistler and Anderson [10]).

PROPOSITION 3.2. *$m = \operatorname{mc}(\Sigma)$ if and only if $\underline{\mathcal{R}}_m(\Sigma) \neq \emptyset$ and $\underline{\mathcal{R}}_m(\Sigma)$ contains no w with a column equal to zero.*

Proof. As can be easily seen, $m > \operatorname{mc}(\Sigma)$ if and only if $\underline{\mathcal{R}}_m(\Sigma) = \emptyset$. Let $w \in \underline{\mathcal{R}}_{\operatorname{mc}(\Sigma)}(\Sigma)$. Clearly, by the appropriate choice of a nonsingular transformation t, a column of w can be made equal to the first unit vector. By omitting the first $m - \operatorname{mc}(\Sigma)$ rows from w, we obtain an element of $\underline{\mathcal{R}}_m(\Sigma)$ with a zero column.

Conversely, suppose that $w \in \underline{\mathcal{R}}_m(\Sigma)$ contains a zero column, e.g., the first one. We can interpret $(\Sigma - \tilde{\Sigma})$ as a variance-covariance matrix of a certain vector of complex valued random variables. The regression of the first component of this random vector on the remaining components gives a relation. By adding this relation as a row to w, we get a compatible relation for Σ with rank $m+1$. □

Note that Proposition 3.2 does not provide us with a criterion of great practical use. Practically useful criteria are available for the case $\operatorname{mc}(\Sigma) \geq m_u = (n+1)/2$ and for the static case $\operatorname{mc}(\Sigma) = 1$. See Anderson and Rubin [6], Anderson and Deistler [4], and Deistler and Scherrer [11] for the first case and see Frisch [13], Kalman [18], and Klepper and Leamer [21] for the static case.

PROPOSITION 3.3. *For every $1 \leq m \leq n$, the set $\mathcal{E}_m$ is open and dense in $\mathcal{E}_m \cup \cdots \cup \mathcal{E}_n$.*

Proof. Let $\tilde{\Sigma}^k \in \mathcal{E}_{m+1} \cup \cdots \cup \mathcal{E}_n$ be a convergent sequence with $\tilde{\Sigma}^k \to \tilde{\Sigma}^0$. Since $\mathcal{E}$ is compact, $\tilde{\Sigma}^0 \in \mathcal{E}$ holds. Note that the corank is an upper semicontinuous function of the matrix elements, since the determinant is a continuous function. Therefore $\operatorname{corank}(\Sigma - \tilde{\Sigma}^0) \geq m+1$ holds and thus $\mathcal{E}_{m+1} \cup \cdots \cup \mathcal{E}_n$ is closed.

We now show that $\mathcal{E}_m$ is dense in $\mathcal{E}_m \cup \cdots \cup \mathcal{E}_n$ by showing that every neighborhood of a $\tilde{\Sigma}^0 \in \mathcal{E}_{k+1}$ contains a $\tilde{\Sigma}$ in $\mathcal{E}_k$. Let w be a basis of $\ker(\Sigma - \tilde{\Sigma}^0)$. From $w\Sigma = w\tilde{\Sigma}^0 \neq 0$, we see that at least one column of w and the corresponding diagonal element of $\tilde{\Sigma}^0$ are unequal to zero. Then, after rearrangement of variables in x_t and by a suitable transformation t, we may write $w = (I, w_2)$ and $\tilde{\sigma}^0_{11} > 0$ holds. Now $\tilde{\Sigma} = \tilde{\Sigma}^0 - \epsilon \operatorname{diag}(1, 0, \ldots, 0)$ for $0 < \epsilon < \tilde{\sigma}^0_{11}$ is still compatible and the corank of $\Sigma - \tilde{\Sigma} = \Sigma - \tilde{\Sigma}^0 + \epsilon \operatorname{diag}(1, 0, \ldots, 0)$ has been decreased by one. Thus $\tilde{\Sigma} \in \mathcal{E}_k$. □

It is an immediate consequence of the above proposition that $\overline{\mathcal{E}_m(\Sigma)} = \mathcal{E}_m(\Sigma) \cup \cdots \cup \mathcal{E}_n(\Sigma) = \mathcal{E}_m(\Sigma) \cup \cdots \cup \mathcal{E}_{\mathrm{mc}(\Sigma)}(\Sigma)$, and in addition by the inequality $\tilde{\Sigma} \leq \Sigma$, it follows that $\overline{\mathcal{E}_m(\Sigma)}$ and in particular $\mathcal{E}_{\mathrm{mc}(\Sigma)}(\Sigma)$ are compact subsets of $\mathbb{R}^n$.

The next proposition gives some basic results for the sets $\mathcal{R}_m(\Sigma)$ and $\underline{\mathcal{R}}_m(\Sigma)$, respectively. Note that for any compatible m-relation there exists a compatible $\tilde{\Sigma} \in \overline{\mathcal{E}_m(\Sigma)} = \mathcal{E}_m(\Sigma) \cup \cdots \cup \mathcal{E}_n(\Sigma)$. Thus the sets $\underline{\mathcal{R}}_m(\Sigma)$ and $\mathcal{R}_m(\Sigma)$ are related to $\overline{\mathcal{E}_m(\Sigma)}$ rather than to $\mathcal{E}_m(\Sigma)$. Furthermore there is, in general, no one-to-one relation between $\tilde{\Sigma}$ and the system, since the mapping attaching to $\tilde{\Sigma}$ the kernel of $(\Sigma - \tilde{\Sigma})$ is not injective in general. This can be seen from $w\Sigma = w\tilde{\Sigma}$ by considering the case where w has a zero column.

PROPOSITION 3.4. *$\mathcal{R}_m(\Sigma)$ is a compact subset of $\mathcal{G}(m,n)$.*

Proof. This is an immediate consequence of the fact that $\mathcal{E}_m(\Sigma) \cup \cdots \cup \mathcal{E}_n(\Sigma)$ is compact. □

Now let us consider the mapping

$$\begin{array}{rccc} \mathrm{f}_m : & \mathcal{M}_m \times \mathcal{D} : & \longrightarrow & \mathcal{M} \subseteq \mathbb{R}^{n^2}, \\ & (\hat{\Sigma}, \tilde{\Sigma}) & \longmapsto & \Sigma = (\hat{\Sigma} + \tilde{\Sigma}), \end{array}$$

and the restrictions $\mathrm{f}_{m,\mathcal{I}}$ of f_m on $\mathcal{M}_m \times \mathcal{D}_{\mathcal{I}}$ attaching to every $\hat{\Sigma}$ with corank m and every $\tilde{\Sigma} \in \mathcal{D}_{\mathcal{I}}$ the corresponding Σ.

A heuristic motivation for the dimension of $\mathcal{E}_m$ can be given as follows. The dimension of the domain of definition of f_m is $n^2 - m^2 + n$; the dimension of $\mathcal{M}$ is n^2. Thus by comparing the dimensions, one may expect that for $m < \mathrm{m_L}$, where

$$\mathrm{m_L} = \sqrt{n}, \tag{3.1}$$

the set $\mathcal{E}_m$ is either empty or has dimension $n - m^2$. In the following we give a precise formulation of this statement. On the other hand, for $m \geq \mathrm{m_L}$ the set $\mathcal{E}_m$ can be expected to either be empty or to consist of a finite number of points. The number $\mathrm{m_L}$ is called the Ledermann bound. (Strictly speaking this term has been used only for the static case where the Ledermann bound is $\mathrm{m_L} = (-1 + \sqrt{1 + 8n})/2$. See, e.g., Ledermann [22].)

Let $\mathcal{S}^r \subseteq \mathcal{S}$ be the set of all Σ, which are regular points of all the mappings $\mathrm{f}_{m,\mathcal{I}}$, $1 \leq m \leq n$ and $\mathcal{I} \subseteq \{1, \ldots, n\}$. Note that $(\hat{\Sigma}, \tilde{\Sigma}) \in (\mathcal{M}_m \times \mathcal{D}_{\mathcal{I}})$ is called a regular point of $\mathrm{f}_{m,\mathcal{I}}$ if the derivative has full rank n^2 in $(\hat{\Sigma}, \tilde{\Sigma})$. A point $\Sigma \in \mathbb{R}^{n^2}$ is called a regular point of $\mathrm{f}_{m,\mathcal{I}}$ if all decompositions $(\hat{\Sigma}, \tilde{\Sigma}) \in \mathrm{f}_{m,\mathcal{I}}^{-1}(\Sigma)$ are regular points of $\mathrm{f}_{m,\mathcal{I}}$. (Note that, therefore, all points Σ for which $\mathrm{f}_{m,\mathcal{I}}^{-1}$ is empty are regular.) A point Σ is an "irregular" point of $\mathrm{f}_{m,\mathcal{I}}$ iff there exists a decomposition $\Sigma = \hat{\Sigma} + \tilde{\Sigma}$, $(\hat{\Sigma}, \tilde{\Sigma}) \in (\mathcal{M}_m \times \mathcal{D}_{\mathcal{I}})$, where the derivative of $\mathrm{f}_{m,\mathcal{I}}$ has rank less than n^2.

For this set $\mathcal{S}^r$ of *regular* points we have the following. (For parts of this proposition compare Dufour [12], Deistler and Scherrer [11], and Scherrer [25].)

PROPOSITION 3.5.

1. *The complement of $\mathcal{S}^r$, i.e., $\mathcal{S} \setminus \mathcal{S}^r$, is a set of Lebesgue measure zero (in this sense $\mathcal{S}^r$ is generic in $\mathcal{S}$).*
2. *$\mathcal{S}_m \cap \mathcal{S}^r = \emptyset$ for all $m > \mathrm{m_L}$.*
3. *$\mathcal{S}_m \cap \mathcal{S}^r$ is open and nonvoid in $\mathcal{S}$, and dense in $\mathcal{S}_m$, for all $m \leq \mathrm{m_L}$.*
4. *For $\Sigma \in \mathcal{S}^r$ and $m < \mathrm{m_L}$, the set $\mathcal{E}_m(\Sigma)$ is either empty or a differentiable submanifold of $\mathbb{R}^n$ with boundaries of dimension $n - m^2$. For $\Sigma \in \mathcal{S}^r$ and $m = \mathrm{m_L}$, the set $\mathcal{E}_m(\Sigma)$ contains only a finite number of points.*

Proof. 1. By the theorem of Sard (see Milnor [23]) we know that the set of "irregular" points of $\mathrm{f}_{m,\mathcal{I}}$ is a set of Lebesgue measure zero. Therefore $\mathcal{S} \setminus \mathcal{S}^r$ has Lebesgue measure zero, since it is a finite union of sets of measure zero.

2. The domain of definition of $\mathrm{f}_{m,\mathcal{I}}$ has dimension $n^2 - m^2 + |\mathcal{I}|$, which is strictly smaller than n^2 for $m > \mathrm{m_L}$.

3. We first prove that $\mathcal{S}^r$ is open in $\mathcal{S}$. Suppose that $\mathcal{S}^r$ is not open. Then there exists a sequence $\Sigma^k \in \mathcal{S} \setminus \mathcal{S}^r$ with $\Sigma^k \to \Sigma^0 \in \mathcal{S}^r$. For each Σ^k there exists a Frisch decomposition $(\hat{\Sigma}^k, \tilde{\Sigma}^k) \in (\mathcal{M}_{m(k)}, \mathcal{D}_{\mathcal{I}(k)})$, which is an "irregular" point of $\mathrm{f}_{m(k),\mathcal{I}(k)}$. There is only a finite number of possible combinations $(m(k), \mathcal{I}(k))$; thus at least one of them, $(s, \mathcal{J})$ say, must occur infinitely often. Since $(\hat{\Sigma}^k, \tilde{\Sigma}^k)$ are bounded, there exists a convergent subsequence. Putting this together we have $(\hat{\Sigma}^k, \tilde{\Sigma}^k) \in (\mathcal{M}_s, \mathcal{D}_{\mathcal{J}}) \to (\hat{\Sigma}^0, \tilde{\Sigma}^0)$. Clearly we have $\Sigma^0 = \hat{\Sigma}^0 + \tilde{\Sigma}^0$ and $\hat{\Sigma}^0 \in \mathcal{M}_m$, $m \geq s$, $\tilde{\Sigma}^0 \in \mathcal{D}_{\mathcal{I}}$, $\mathcal{I} \subseteq \mathcal{J}$. Since $(\hat{\Sigma}^0, \tilde{\Sigma}^0)$ is a regular point of $\mathrm{f}_{m,\mathcal{I}}$, we may construct a neighborhood $\mathcal{U}$ of $(\Sigma^0, \tilde{\Sigma}^0)$ as indicated in Lemma A.2. Now by assumption, $(\Sigma^k, \tilde{\Sigma}^k)$ must be an element of $\mathcal{U}$ for all k large enough; thus $(\hat{\Sigma}^k, \tilde{\Sigma}^k)$ is a regular point of $\mathrm{f}_{s,\mathcal{J}}$ for all such k, in contradiction to our assumptions.

In Proposition 3.12 we will show, that $\mathcal{S}_m$ is nonvoid and that $\mathcal{S}_m \cup \cdots \cup \mathcal{S}_1$ is open. Therefore, for $\Sigma^0 \in \mathcal{S}_m$, there exists an open neighborhood $\mathcal{U} \subseteq \mathcal{S}_m \cup \cdots \cup \mathcal{S}_1$. By Lemma A.3 and by the continuity of $\mathrm{f}_{m,\mathcal{I}}$, we may find a $\Sigma = \hat{\Sigma} + \tilde{\Sigma} \in \mathcal{U}$, where $(\hat{\Sigma}, \tilde{\Sigma})$ is a regular point of $\mathrm{f}_{m,\mathcal{I}}$. Since $\mathrm{f}_{m,\mathcal{I}}$ is locally surjective in $(\hat{\Sigma}, \tilde{\Sigma})$, we may find an open neighborhood $\mathcal{V} \subseteq \mathcal{S}_n \cup \cdots \cup \mathcal{S}_m$ of Σ. Thus $\mathcal{V} \cap \mathcal{U} \subseteq \mathcal{S}_m$ is a nonvoid open neighborhood of Σ. Since $\mathcal{S} \setminus \mathcal{S}^r$ has Lebesgue measure zero also $\mathcal{S}^r \cap \mathcal{V} \cap \mathcal{U} \subseteq \mathcal{S}^r \cap \mathcal{S}_m$ is open and nonvoid, which proves that $\mathcal{S}_m \cap \mathcal{S}^r$ is nonvoid. For each $\Sigma \in \mathcal{S}_m \cap \mathcal{S}^r$ we may construct neighborhoods $\mathcal{U}$, $\mathcal{V}$ as above. Then $\mathcal{U} \cap \mathcal{V} \cap \mathcal{S}^r \subseteq \mathcal{S}_m \cap \mathcal{S}^r$ is an open neighborhood of Σ.

Let $\Sigma^0 \in \mathcal{S}_m$. By the same arguments as above, we see that in any neighborhood of Σ^0 there exists an $\Sigma \in \mathcal{S}_m$, which has an open neighborhood $\mathcal{U} \subseteq \mathcal{S}_m$, i.e., $\Sigma \in \mathcal{S}_m^o$. Since $\mathcal{S} \setminus \mathcal{S}^r$ has Lebesgue measure zero, we can find in any neighborhood of Σ an element in $\mathcal{S}^r$ and thus in $\mathcal{S}^r \cap \mathcal{S}_m$.

4. Let $\Sigma^0 \in \mathcal{S}^r$, $\mathrm{mc}(\Sigma^0) \geq m$, and $\mathrm{m_L} > m$ hold. Thus there exists a decomposition $\Sigma^0 = \hat{\Sigma}^0 + \tilde{\Sigma}^0$, $\hat{\Sigma}^0 \in \mathcal{M}_m$, and $\tilde{\Sigma}^0 \in \mathcal{D}_{\mathcal{I}}$ for some index set $\mathcal{I}$. Since $\Sigma^0 > 0$, we may arrange the variables such that $\mathcal{I} = \{1, \ldots, l\}$ and that $\hat{\Sigma}^0_{22} > 0$ holds. Since $(\hat{\Sigma}^0, \tilde{\Sigma}^0)$ is a regular point of $\mathrm{f}_{m,\mathcal{I}}$, we may construct a neighborhood $\mathcal{U} \subseteq \mathbb{R}^n$ as in Lemma A.1.

Let $\mathcal{J} \subseteq \mathcal{I}$, $|\mathcal{J}| = m^2$ be such that the derivative of $\mathrm{g}_{n,m}(\Sigma^0 - \tilde{\Sigma})$ with respect to $d_{\mathcal{J}}(\tilde{\Sigma})$ has full rank m^2. If $\mathcal{K} = \{1, \ldots, n\} \setminus \mathcal{J}$, then the mapping

$$\begin{array}{rccc} \mathrm{h}: & \mathcal{U} & \to & \mathbb{R}^n, \\ & \tilde{\Sigma} & \mapsto & (\mathrm{g}_{n,m}(\Sigma^0 - \tilde{\Sigma}), d_{\mathcal{K}}(\tilde{\Sigma})) \end{array}$$

has full rank n in the point $\tilde{\Sigma}^0$. Thus we may further restrict $\mathcal{U}$ in a way such that $\mathrm{h}: \mathcal{U} \subseteq \mathbb{R}^n \to \mathcal{V} = \mathrm{h}(\mathcal{U}) \subseteq \mathbb{R}^n$ is a local diffeomorphism of $\mathbb{R}^n$. By this construction we have found a coordinate system h of $\mathbb{R}^n$, such that

$$\mathrm{h}(\mathcal{E}_m(\Sigma^0) \cap \mathcal{U}) = (\{0\} \times (\mathbb{R}^+)^{n-m^2}) \cap \mathcal{V}$$

holds.

Now we consider the case $m = \mathrm{m_L}$. Note that $\Sigma^0 \in \mathcal{S}^r$ implies that $\mathrm{mc}(\Sigma^0) \leq \mathrm{m_L}$ and thus $m = \mathrm{m_L} = \mathrm{mc}(\Sigma^0)$ or $\mathcal{E}_m(\Sigma^0)$ is empty. If $\mathcal{E}_m(\Sigma^0)$ contains infinitely many points, then $\mathcal{E}_m(\Sigma^0)$ must contain a limiting point, $\tilde{\Sigma}^0$ say, since $\mathcal{E}_{\mathrm{mc}}(\Sigma^0)$ is closed and bounded. On the other hand, since all points $\tilde{\Sigma} \in \mathcal{E}_m$ give regular points $(\Sigma^0 - \tilde{\Sigma}, \tilde{\Sigma})$ of $\mathrm{f}_{m,\mathcal{I}}$ (and in this case $\mathrm{f}_{m,\mathcal{I}}$ is locally injective) all points of $\mathcal{E}_m$ must be isolated. □

From the proposition above we see that $\mathcal{S}^r$ is a set of "well-behaved" spectral densities in the sense that, for every $\Sigma \in \mathcal{S}^r$, the sets $\mathcal{E}_m(\Sigma)$ are nice mathematical

objects, i.e., they are differentiable manifolds. In addition, $\mathrm{mc}(\Sigma)$ is a continuous function on $\mathcal{S}^r$, since $\mathcal{S} \setminus \mathcal{S}^r$ contains all points of discontinuity of $\mathrm{mc}(\Sigma)$.

Note that, in addition, $\mathcal{S}_1$ is fully contained in $\mathcal{S}^r$, since for all $\Sigma \in \mathcal{S}_1$ and $\tilde{\Sigma}^0 \in \mathcal{E}(\Sigma)$,

$$\mathrm{g}_{n,1}(\Sigma - \tilde{\Sigma}) = \sigma_{11} - \tilde{\sigma}_{11} - \Sigma_{12}(\Sigma_{22} - \tilde{\Sigma}_{22})^{-1}\Sigma_{12}^*$$

is defined in a neighborhood of $\tilde{\Sigma}^0$ and has full rank 1. Thus for all $\Sigma \in \mathcal{S}_1$, the set $\mathcal{E}(\Sigma)$ is differentiable submanifold of $\mathbb{R}^n$ with boundaries of dimension $n-1$.

The set $\mathcal{S} \setminus \mathcal{S}^r$ in particular contains all spectral densities with Frisch corank larger than the Ledermann bound. Thus the latter case is highly nongeneric.

For $\Sigma \in \mathcal{S} \setminus \mathcal{S}^r$ the following cases may occur (see Scherrer [25]):

1. $\mathcal{E}_m(\Sigma)$ is not a differentiable submanifold of $\mathbb{R}^n$.
2. $\mathcal{E}_m(\Sigma)$ is a differentiable submanifold of $\mathbb{R}^n$, but the dimension of $\mathcal{E}_m(\Sigma)$ is either larger or smaller than $n - m^2$.

As has been stated already, in many cases the class of observationally equivalent systems with a maximum number of equations is of particular interest. In this case we have the following.

PROPOSITION 3.6. *For $m = \mathrm{mc}(\Sigma)$, the sets $\mathcal{E}_m(\Sigma)$ and $\mathcal{R}_m(\Sigma)$ are homeomorphic. If, in addition, $\Sigma \in \mathcal{S}^r$ and $\mathrm{mc}(\Sigma) < \mathrm{m_L}$ hold, then $\mathcal{R}_m(\Sigma)$ is a differentiable submanifold of $\mathcal{G}(m,n)$ with boundaries of dimension $n - m^2$ and $\mathcal{E}_m(\Sigma)$ and $\mathcal{R}_m(\Sigma)$ are diffeomorphic.*

Proof. First we note that, for $m = \mathrm{mc}(\Sigma)$, the mapping

$$\begin{array}{rccc} \kappa_m : & \mathcal{E}_m(\Sigma) & \longrightarrow & \mathcal{R}_m(\Sigma), \\ & \tilde{\Sigma} & \longmapsto & \ker(\Sigma - \tilde{\Sigma}) \end{array}$$

is bijective by Proposition 3.2; this is true because we can compute $\tilde{\Sigma}$ from the equation $w\Sigma = w\tilde{\Sigma}$, since $w \in \underline{\mathcal{R}}_m(\Sigma)$ contains no zero column for $m = \mathrm{mc}(\Sigma)$. (Note that w and tw give the same $\tilde{\Sigma}$.)

Now let $\tilde{\Sigma}^0 \in \mathcal{E}_m(\Sigma)$, where w.l.o.g. we assume that $(\Sigma_{22} - \tilde{\Sigma}^0_{22}) > 0$ holds. Therefore the matrix $w = (I, -\Sigma_{12}(\Sigma_{22} - \tilde{\Sigma}_{22})^{-1})$ is a basis for $\ker(\Sigma - \tilde{\Sigma})$, and this is true in a neighborhood $\mathcal{U} \subseteq \mathcal{E}_m(\Sigma)$ of $\tilde{\Sigma}^0$. In addition, in a neighborhood $\mathcal{V} \subseteq \mathcal{G}(m,n)$ of $\ker(\Sigma - \tilde{\Sigma}^0)$, we can use the coordinate mapping

$$\begin{array}{rccc} \mathrm{k} : & \mathcal{G}(m,n) \supseteq \mathcal{V} & \longrightarrow & \mathcal{V}' \subseteq \mathbb{R}^{2m(n-m)}, \\ & \{t(w_1, w_2) | \det(t) \neq 0\} & \longmapsto & w_1^{-1} w_2 \end{array}$$

for $\mathcal{G}(m,n)$. Therefore $\kappa_m(\tilde{\Sigma}) = \mathrm{k}^{-1}(-\Sigma_{12}(\Sigma_{22} - \tilde{\Sigma}_{22})^{-1})$ for all $\tilde{\Sigma} \in \mathcal{U}$ and $\kappa_m(\cdot)$ is continuous, since k is a homeomorphism.

Next, define the mapping

$$\mathrm{h} : w \in \mathbb{C}^{m \times n} \longmapsto \mathrm{diag}((w_j^* w \Sigma_j)/(w_j^* w_j))_{j=1,\ldots,n},$$

where w_j denotes the jth column of w and Σ_j denotes the jth column of Σ. The mapping h is defined and continuous for all $w \in \mathbb{C}^{m \times n}$, which have no zero column. Then we have $\kappa_m^{-1}(\mathfrak{x}) = \mathrm{h}(I, \mathrm{k}(\mathfrak{x}))$ for all $\mathfrak{x} \in \mathcal{V} \cap \mathcal{R}_m(\Sigma)$, which proves that κ_m^{-1} is continuous.

Now we consider the case $\Sigma \in \mathcal{S}^r$ and $m = \mathrm{mc}(\Sigma) < \mathrm{m_L}$. As is shown in the proof of Proposition 3.5, we can use the mapping

$$\begin{array}{rccc} \mathrm{h} : & \mathcal{U} \subseteq \mathcal{E}_m(\Sigma) & \longrightarrow & \mathcal{U}' \cap (\mathbb{R}^+)^{n-m^2}, \\ & \tilde{\Sigma} & \longmapsto & x = d_{\mathcal{K}}(\tilde{\Sigma}) \end{array}$$

as a coordinate mapping for $\mathcal{E}_m(\Sigma)$, where $d_{\mathcal{K}}(\tilde{\Sigma})$ denotes a (suitable) selection of $n-m^2$ diagonal entries of $\tilde{\Sigma}$. (Note that $\mathcal{U}' \subseteq \mathbb{R}^{n-m^2}$ is open in $\mathbb{R}^{n-m^2}$.) Since $\mathcal{E}_m(\Sigma)$ and $\mathcal{R}_m(\Sigma)$ are homeomorphic by the above considerations, we can choose $\mathcal{U},\mathcal{U}'$ and $\mathcal{V},\mathcal{V}'$ in a way such that $\kappa_m(\mathcal{U}) = \mathcal{R}_m(\Sigma) \cap \mathcal{V}$ holds.

Next we consider the mapping

$$\mathrm{k} \circ \kappa_m \circ \mathrm{h}^{-1} : x \mapsto \tilde{\Sigma} \mapsto \ker(\Sigma - \tilde{\Sigma}) \mapsto -\Sigma_{12}(\Sigma_{22} - \tilde{\Sigma}_{22})^{-1}.$$

Note that (by choosing $\mathcal{U}'$ small enough) $\mathrm{k} \circ \kappa_m \circ \mathrm{h}^{-1}$ is defined and differentiable on $\mathcal{U}'$. (Thus we allow for the moment also small negative entries in $\tilde{\Sigma}$.) The derivative is given by

$$\delta x \mapsto \delta\tilde{\Sigma} \mapsto \delta\ker(\Sigma - \tilde{\Sigma}) \mapsto \underbrace{-\Sigma_{12}(\Sigma_{22} - \tilde{\Sigma}_{22})^{-1}}_{w_2} \delta\tilde{\Sigma}_{22}(\Sigma_{22} - \tilde{\Sigma}_{22})^{-1},$$

which is zero iff $\delta\tilde{\Sigma}_{22} = 0$, since w_2 contains no zero column. Since $\mathrm{g}_{n,m}(\Sigma - \tilde{\Sigma}) \equiv 0$, each direction $\delta\tilde{\Sigma}$ in the tangent space of $\mathcal{E}_m(\Sigma)$ must fulfill the equation

$$-\delta\tilde{\Sigma}_{11} - w_2\delta\tilde{\Sigma}_{22}w_2^* = 0.$$

Thus $\delta\tilde{\Sigma}_{22} = 0$ implies $\delta\tilde{\Sigma} = 0$, and $\mathrm{k} \circ \kappa_m \circ \mathrm{h}^{-1}$ has full rank $n-m^2$ in all points of $\mathcal{U}' \cap (\mathbb{R}^+)^{n-m^2}$. Therefore we can find a diffeomorphism $\mathrm{k}' : \mathcal{V}' \subseteq \mathbb{R}^{2m(n-m)} \to \mathcal{V}'' \subseteq \mathbb{R}^{2m(n-m)}$ such that $\mathrm{k}' \circ \mathrm{k} \circ \kappa_m \circ \mathrm{h}^{-1}$ takes the form

$$(x_1, \ldots, x_{n-m^2}) \mapsto (x_1, \ldots, x_{n-m^2}, 0, \ldots, 0).$$

(Again we have to shrink the neighborhoods $\mathcal{U},\mathcal{U}'$ and $\mathcal{V},\mathcal{V}',\mathcal{V}''$ suitably.) Putting this together we have found a coordinate mapping $\mathrm{k}'' = \mathrm{k}' \circ \mathrm{k} : \mathcal{V} \to \mathcal{V}''$ of $\mathcal{G}(m,n)$ such that

$$\mathrm{k}''(\mathcal{R}_m(\Sigma) \cap \mathcal{V}) = ((\mathbb{R}^+)^{n-m^2} \times \{0\}) \cap \mathcal{V}''$$

holds. □

3.2. Continuity results. If we commence from real data, Σ is not known a priori but has to be estimated. As is well known under general assumptions on (x_t), e.g., the usual nonparametric estimates Σ_T of the spectral density of Σ are consistent. Then, e.g., $\mathcal{R}_m(\Sigma_T)$ is an estimate for $\mathcal{R}_m(\Sigma)$. In this context the question arises whether the estimate $\mathcal{R}_m(\Sigma_T)$ is close to the "true" set of systems $\mathcal{R}_m(\Sigma)$, if Σ_T is close to Σ; in other words, whether the mapping $\Sigma \mapsto \mathcal{R}_m(\Sigma)$ is continuous. Then if $\Sigma_T \to \Sigma$, this implies $\mathcal{R}_m(\Sigma_T) \to \mathcal{R}_m(\Sigma)$, i.e., $\mathcal{R}_m(\Sigma_T)$ are consistent estimates.

First we consider the continuity of the mappings $\Sigma \mapsto \mathcal{E}(\Sigma)$ and $\Sigma \mapsto \mathcal{E}_m(\Sigma)$. Proposition 3.8 shows that the mapping $\Sigma \mapsto \overline{\mathcal{E}_m(\Sigma)}$ is continuous for $\Sigma \in \mathcal{S}^r$ and Proposition 3.7 shows that $\Sigma \mapsto \mathcal{E}(\Sigma)$ is globally continuous. Proposition 3.9 shows that the mapping $\Sigma \mapsto \mathcal{R}_m(\Sigma)$ is continuous for $\Sigma \in \mathcal{S}^r$.

PROPOSITION 3.7. *The mapping $\mathcal{S} \to \mathcal{C}(\mathbb{R}^n) : \Sigma \to \mathcal{E}(\Sigma)$ is continuous (with respect to the Haussdorff distance).*

Proof. We consider a sequence $(\Sigma^k \in \mathcal{S})$ which converges to $\Sigma^0 \in \mathcal{S}$, i.e., $\Sigma^k \to \Sigma^0$. In order to prove that $\mathrm{d_H}(\mathcal{E}(\Sigma^0), \mathcal{E}(\Sigma^k)) \to 0$ holds, by Lemmas A.4 and A.5, we have to construct, for every $\tilde{\Sigma}^0 \in \mathcal{E}(\Sigma^0)$, a sequence $(\tilde{\Sigma}^k \in \mathcal{E}(\Sigma^k))$ with $\tilde{\Sigma}^k \to \tilde{\Sigma}^0$. It is easy to see that $\tilde{\Sigma}^k = \lambda\tilde{\Sigma}^0$, where λ is the reciprocal of the largest eigenvalue of the matrix $(\Sigma^k)^{-1/2}\tilde{\Sigma}^0(\Sigma^k)^{-*/2}$, gives such a sequence, since $\lambda \to 1$. Note that the largest

eigenvalue of $(\Sigma^0)^{-1}\tilde{\Sigma}^0(\Sigma^0)^{-1}$ is equal to one. (Compare the proof of Proposition 3.1.) ∎

PROPOSITION 3.8. *The mapping* $\mathcal{S}^r \to \mathcal{C}(\mathbb{R}^n)$*:* $\Sigma \to \overline{\mathcal{E}_m(\Sigma)}$ *is continuous (with respect to the Haussdorff distance).*

Proof. We consider a point $\Sigma^0 \in \mathcal{S}^r$ and a sequence $\Sigma^k \in \mathcal{S}^r$ with $\Sigma^k \to \Sigma^0$. By Proposition 3.5, w.l.o.g. we can assume that $\mathrm{mc}(\Sigma^k) = \mathrm{mc}(\Sigma^0) = m_0 \leq \mathrm{m_L}$ holds. If $m > m_0$, then $\overline{\mathcal{E}_m(\Sigma^0)} = \emptyset = \overline{\mathcal{E}_m(\Sigma^k)}$. Thus we have only to consider the case $m \leq m_0$.

Let $\tilde{\Sigma}^0 \in \overline{\mathcal{E}_m(\Sigma^0)}$; then $(\hat{\Sigma}^0, \tilde{\Sigma}^0) \in (\mathcal{M}_s \times \mathcal{D}_\mathcal{I})$ is a regular point of $\mathrm{f}_{s,\mathcal{I}}$, where $\hat{\Sigma}^0 = \Sigma^0 - \tilde{\Sigma}^0$, $s \geq m$, and $\mathcal{I} \subseteq \{1, \ldots, n\}$. For each neighborhood $\mathcal{U} \subseteq (\mathcal{M}_s \times \mathcal{D}_\mathcal{I})$ of $(\hat{\Sigma}^0, \tilde{\Sigma}^0)$, the image $\mathrm{f}_{s,\mathcal{I}}(\mathcal{U}) \subseteq \mathbb{R}^{n^2}$ is a neighborhood of Σ^0 in $\mathbb{R}^{n^2}$, since $\mathrm{f}_{s,\mathcal{I}}$ is locally surjective. Since $\Sigma^k \to \Sigma^0$, we have $\Sigma^k \in \mathrm{f}_{s,\mathcal{I}}(\mathcal{U})$ for all k large enough and we can find a decomposition $\Sigma^k = \hat{\Sigma}^k + \tilde{\Sigma}^k$, $(\hat{\Sigma}^k, \tilde{\Sigma}^k) \in \mathcal{U}$ (and thus $\tilde{\Sigma}^k \in \overline{\mathcal{E}_m(\Sigma^k)}$) for all such k's. Now, by considering a sequence of "shrinking" neighborhoods of $(\hat{\Sigma}^0, \tilde{\Sigma}^0)$, we can construct a sequence $\tilde{\Sigma}^k \in \overline{\mathcal{E}_m(\Sigma^k)}$ with $\tilde{\Sigma}^k \to \tilde{\Sigma}^0$. By Lemmata A.4 and A.5 we therefore have $\mathrm{d_H}(\overline{\mathcal{E}_m(\Sigma^0)}, \overline{\mathcal{E}_m(\Sigma^k)}) \to 0$. ∎

In the following proposition we describe the continuity results for the relation sets $\mathcal{R}_m(\Sigma)$. Note that by Proposition 3.4, the relation sets $\mathcal{R}_m(\Sigma)$ are compact subsets of the Grassmannian $\mathcal{G}(m, n)$.

PROPOSITION 3.9. *The function* $\mathcal{S}^r \to \mathcal{C}(\mathcal{G}(m,n))$*:* $\Sigma \mapsto \mathcal{R}_m(\Sigma)$ *is continuous (with respect to the Haussdorff distance).*

Proof. This result immediately follows from Proposition 3.8 and Lemma A.7. ∎

Note that for $\mathrm{mc}(\Sigma) > \sqrt{n}$, typically the set $\mathcal{E}_m(\Sigma)$ for $m = \mathrm{mc}(\Sigma)$ will be a singleton, i.e., the system corresponding to the maximum number of outputs will be unique; see Scherrer [25]. If $m = \mathrm{mc}(\Sigma)$ is known, then estimates for Σ taking into this restriction may be used. For this case the following result holds.

PROPOSITION 3.10. *For a sequence* $\Sigma^k \in \mathcal{S}$*,* $\mathrm{mc}(\Sigma^k) \geq m$*,* $\Sigma^k \to \Sigma^0 \in \mathcal{S}$*,* $\mathcal{E}_m(\Sigma^0) = \{\tilde{\Sigma}^0\}$*, and* $\mathcal{R}_m(\Sigma^0) = \{\mathfrak{r}^0\}$*, we have*

$$\mathrm{d_H}(\mathcal{E}_m(\Sigma^k), \mathcal{E}_m(\Sigma^0)) \to 0 \quad \text{and} \quad \mathrm{d_H}(\mathcal{R}_m(\Sigma^k), \mathcal{R}_m(\Sigma^0)) \to 0.$$

Proof. Note that for $m < \mathrm{mc}(\Sigma^0)$, the set $\mathcal{E}_m(\Sigma^0)$ contains infinitely many elements. Thus the assumption $\mathcal{E}_m(\Sigma^0) = \{\tilde{\Sigma}^0\}$ implies $\mathrm{mc}(\Sigma^0) = m$. Since $\mathcal{S}_1 \cup \cdots \cup \mathcal{S}_m$ is open (see Proposition 3.12), our assumptions imply that $\mathrm{mc}(\Sigma^k) = m$ for all k large enough. Thus $\mathcal{E}_m(\Sigma^0)$ and $\mathcal{E}_m(\Sigma^k)$ are compact subsets of $\mathbb{R}^n$ for all such k's.

Now we define a sequence $(\tilde{\Sigma}^k \in \mathcal{E}_m(\Sigma^k))$ by

$$\|\tilde{\Sigma}^0 - \tilde{\Sigma}^k\| = \inf_{\tilde{\Sigma} \in \mathcal{E}_m(\Sigma^k)} \|\tilde{\Sigma}^0 - \tilde{\Sigma}\|.$$

Since the $(\tilde{\Sigma}^k)$'s are bounded, there exist a limiting point $\tilde{\Sigma}^l$, say. As in the proof of Lemma A.5, we can see that $\tilde{\Sigma}^l \in \mathcal{E}_m(\Sigma^0)$ and thus $\tilde{\Sigma}^l = \tilde{\Sigma}^0$. Therefore Lemmata A.4 and A.5 imply the convergence of the sets $\mathcal{E}_m(\Sigma^k) \to \mathcal{E}_m(\Sigma^0)$.

The convergence of the sets $\mathcal{R}_m(\Sigma^k) \to \mathcal{R}_m(\Sigma^0)$ follows from an analogous reasoning. ∎

In the next proposition, continuity results are considered when the true system is observed with small noise satisfying (a.5). Then the set of observationally equivalent systems is small and close to the true system.

PROPOSITION 3.11 (low noise). *Let* $\hat{\Sigma}^0 \in \mathcal{M}_m$ *and* $w \in \mathbb{C}^{m \times n}$ *be a basis for the left kernel of* $\hat{\Sigma}^0$ *such that* w *contains no zero column. If* $\Sigma^k \in \mathcal{S} \to \hat{\Sigma}^0$*, then* $\mathcal{E}(\Sigma^k) \to$

$\{0 \in \mathbb{C}^{n\times n}\}$ *holds. If we have, in addition,* $\mathrm{mc}(\Sigma^k) \geq m$, *then* $\mathcal{E}_m(\Sigma^k) \to \{0 \in \mathbb{C}^{n\times n}\}$ *and* $\mathcal{R}_m(\Sigma^k) \to \{\ker(\hat{\Sigma}^0)\}$ *hold.*

Proof. By assumption there is a vector $v \in \ker(\hat{\Sigma}^0)$ such that all components v_i of v are nonzero. Let us define $\epsilon^k = v(\Sigma^k - \hat{\Sigma}^0)v^*$. Then we have

$$0 \leq v(\Sigma^k - \tilde{\Sigma})v^* = \underbrace{v\hat{\Sigma}^0 v^*}_{=0} + \underbrace{v(\Sigma^k - \hat{\Sigma}^0)v^*}_{=\epsilon^k} - v\tilde{\Sigma}v^*,$$

and thus

$$\tilde{\sigma}_{ii} \leq \epsilon^k / v_i^2 \to 0$$

for all $\tilde{\Sigma} \in \mathcal{E}(\Sigma^k)$. The second statement can be proved analogously to the proof of Proposition 3.10. ∎

3.3. Some further properties of $\mathcal{S}_m$. In applications one might be interested in determining $\mathrm{mc}(\Sigma)$ from data. For this purpose one may use, for instance, a sequence of likelihood ratio tests. In order to derive the properties of such a procedure, the properties of the sets $\mathcal{S}_m$ have to be investigated. In addition to Proposition 3.5, we have the following properties of these sets: from Propositions 3.5 and 3.12 we see that $\mathcal{S}_1$ is a nonvoid open subset of $\mathcal{S}$, $\mathcal{S}_2, \ldots, \mathcal{S}_m$, $m \leq \mathrm{m_L}$ contain nonvoid open subsets, and $\mathcal{S}_m$, $m > \mathrm{m_L}$ are thin subsets of $\mathcal{S}$. The closures of the sets $\mathcal{S}_m$, $m \geq \mathrm{m_L}$ are nested. It should be noted, however, that for the derivation of the statistical properties of likelihood ratio test, in addition a manifold structure usually is required.

PROPOSITION 3.12.

1. $\mathcal{S}_m$ *is nonvoid for all* $1 \leq m \leq n$.
2. $\mathcal{S}_m \cup \cdots \cup \mathcal{S}_1$ *is open in* $\mathcal{S}$ *for all* $1 \leq m \leq n$.
3. $\overline{\mathcal{S}_m} = \overline{\mathcal{S}_m \cup \cdots \cup \mathcal{S}_n}$ *for* $m \geq \mathrm{m_L}$.

Proof. 1. Let $w = (1, \ldots, 1)$ and $O \in \mathbb{C}^{n\times(n-m)}$ with $wO = 0$ and $O^*O = I \in \mathbb{C}^{(n-m)\times(n-m)}$. We now prove that $\Sigma = OO^* + \epsilon I$ is an element of $\mathcal{S}_m$ for all $0 < \epsilon < 1/(n-1)$. Clearly $\mathrm{mc}(\Sigma) \geq m$. Suppose that $\Sigma = \hat{\Sigma} + \tilde{\Sigma}$ is a Frisch decomposition of Σ. Now $0 \leq w\hat{\Sigma}w^* = wOO^*w^* + \epsilon ww^* - w\tilde{\Sigma}w^*$ implies that $\tilde{\sigma}_{ii} \leq n\epsilon$ for all i. Thus we have for all $v = \lambda O^*$, $\lambda \in \mathbb{C}^{1\times n-m}$, $\lambda\lambda^* = 1 = vv^*$,

$$v\hat{\Sigma}v^* = vOO^*v^* + \epsilon vv^* - v\tilde{\Sigma}v^* = 1 + \epsilon - v\tilde{\Sigma}v^* \geq (1+\epsilon) - n\epsilon = 1 - (n-1)\epsilon > 0.$$

Therefore $O^*\hat{\Sigma}O > 0$, and thus $\mathrm{corank}(\hat{\Sigma}) \leq m$ must hold.

2. Consider a sequence $\Sigma^k \in \mathcal{S}_n \cup \cdots \cup \mathcal{S}_{m+1}$, $\Sigma^k \to \Sigma^0 \in \mathcal{S}$. For each k there exists a Frisch decomposition $\Sigma = \hat{\Sigma}^k + \tilde{\Sigma}^k$ with $\mathrm{corank}(\hat{\Sigma}^k) \geq m+1$. Since the $(\hat{\Sigma}^k, \tilde{\Sigma}^k)$ are bounded there exists a limiting point $(\hat{\Sigma}^0, \tilde{\Sigma}^0)$. For this point we have $\Sigma^0 = \hat{\Sigma}^0 + \tilde{\Sigma}^0$, $\hat{\Sigma}^0 \geq 0$, $\mathrm{corank}(\hat{\Sigma}^0) \geq m+1$, and $\tilde{\Sigma}^0 \geq 0$ which implies $\Sigma^0 \in \mathcal{S}_n \cup \cdots \cup \mathcal{S}_{m+1}$.

3. Let $\Sigma^0 \in \mathcal{S}_{m+1}$. We consider all matrices Σ of the form $\Sigma = \Sigma^0 + \Lambda\Lambda^*$, $\Lambda \in \mathbb{C}^{n\times n}$, where the largest eigenvalue of $\Lambda\Lambda^*$ is smaller than some $\epsilon > 0$. Clearly this set contains an open and nonvoid subset of $\mathcal{S}$. Since $\mathcal{S}^r$ is dense in $\mathcal{S}$, there exists a Λ such that $\Sigma^0 + \Lambda\Lambda^* \in \mathcal{S}^r$, and therefore $\mathrm{mc}(\Sigma^0 + \Lambda\Lambda^*) \leq \mathrm{m_L}$. We now define n matrices $\Sigma^i = \Sigma^0 + \sum_{j=1}^{i} \lambda_j\lambda_j^*$, where λ_j denotes the jth column of Λ. It is trivial to see that $\mathrm{mc}(\Sigma^i) \geq \mathrm{mc}(\Sigma^{i-1}) - 1$ holds. Thus we must have $\mathrm{mc}(\Sigma^i) = m$ for some index i. In this way we may find a matrix $\Sigma \in \mathcal{S}_m$ in any neighborhood of $\Sigma^0 \in \mathcal{S}_{m+1}$. ∎

4. The bounded noise case. In a number of applications, the assumption (a.5) that $\tilde{\Sigma}$ is diagonal, i.e., that the noise components are mutually uncorrelated, is not appropriate. Here we consider the alternative assumption that the noise level is bounded. This assumption is expressed as

(a.6) $\lambda_n(\tilde{\Sigma}(\lambda)) \leq \epsilon$.

The idea behind this assumption is that the order of magnitude of the noise is known a priori and nothing else. We will adhere to assumption (a.6) throughout this section. Clearly, terms such as *compatible* or *m-relation set* in this section relate to assumption (a.6) and not to (a.5).

If we replace assumption (a.6) by

$$\mathrm{tr}\tilde{\Sigma} \leq \epsilon,$$

most results can be shown analogously. Note that in the static case, $\mathrm{tr}(\tilde{\Sigma}) = \mathrm{E}u'u$ is the mean square error.

In Proposition 4.1, for a given relation w a corresponding minimal noise spectrum $\tilde{\Sigma}$ is derived. In Proposition 4.2, a characterization of compatible relations is given and it is shown that $\mathrm{mc}(\Sigma)$ can be easily determined from the eigenvalues of Σ. From Proposition 4.3, we see that for $\lambda_m(\Sigma) < \epsilon$ the sets $\mathcal{R}_m(\Sigma)$, in a certain sense, are of the same topological dimension as $\mathcal{G}(m,n)$, namely, $2m(n-m)$. For the Frisch case, on the other hand for the special case $m = \mathrm{mc}(\Sigma) < \mathrm{m_L}$, we see from Propositions 3.5 and 3.6 that $\mathcal{R}_m(\Sigma)$ has generically dimension $n-m^2$ which is smaller than $2m(n-m)$. This result is not implausible, since (a.5) imposes more restrictions than (a.6). Some topological properties of the sets $\mathcal{S}_m$ are considered in Proposition 4.4; it is shown that all sets $\mathcal{S}_m$ are "thick" in the sense that they contain an open nonvoid subset of $\mathcal{S}$. Finally, Proposition 4.5 shows that the mapping $\Sigma \mapsto \mathcal{R}_m(\Sigma)$ is continuous on a generic subset of $\mathcal{S}$.

For the next proposition see Kalman [20].

PROPOSITION 4.1. *Let Σ be given, let w be an arbitrary but fixed relation, and consider the set of all $\tilde{\Sigma}$ satisfying* (1.7) *and* (1.4), *and $\hat{\Sigma}, \tilde{\Sigma} \geq 0$. With respect to the semi-ordering given by semipositivity of matrices, this set has a unique minimal element*

$$\tilde{\Sigma}_w = \Sigma w^*(w\Sigma w^*)^{-1} w\Sigma. \tag{4.1}$$

Proof. Since w has full rank, there is "coordinate transformation" $x_t \to t(\mathrm{z})x_t$, such that $\bar{w} = wt^{-1} = (I, 0)$. If $\bar{\Sigma}$, $\hat{\bar{\Sigma}}$, and $\tilde{\bar{\Sigma}}$ denote the corresponding transformed spectral densities Σ, $\hat{\Sigma}$, and $\tilde{\Sigma}$, respectively, then in an obvious partitioning,

$$\begin{pmatrix} \bar{\Sigma}_{11} & \bar{\Sigma}_{12} \\ \bar{\Sigma}_{21} & \bar{\Sigma}_{22} \end{pmatrix} = \begin{pmatrix} 0 & 0 \\ 0 & \hat{\bar{\Sigma}}_{22} \end{pmatrix} + \begin{pmatrix} \tilde{\bar{\Sigma}}_{11} & \tilde{\bar{\Sigma}}_{12} \\ \tilde{\bar{\Sigma}}_{21} & \tilde{\bar{\Sigma}}_{22} \end{pmatrix}$$

holds. Since $\tilde{\bar{\Sigma}}$ must be positive semidefinite, the above equation implies $\tilde{\bar{\Sigma}}_{22} \geq \bar{\Sigma}_{21}\bar{\Sigma}_{11}^{-1}\bar{\Sigma}_{12}$. This inequality now gives

$$\tilde{\bar{\Sigma}} \geq \begin{pmatrix} \bar{\Sigma}_{11} & \bar{\Sigma}_{12} \\ \bar{\Sigma}_{21} & \bar{\Sigma}_{21}\bar{\Sigma}_{11}^{-1}\bar{\Sigma}_{12} \end{pmatrix} = \bar{\Sigma}\bar{w}^*(\bar{w}\bar{\Sigma}\bar{w}^*)^{-1}\bar{w}\bar{\Sigma},$$

and thus by backsubstituting, $\tilde{\Sigma} = t^{-1}\tilde{\bar{\Sigma}}t^{-*} \geq \Sigma w^*(w\Sigma w^*)^{-1}w\Sigma$. ∎

An (almost) immediate consequence of the above proposition is the following characterization of compatible relations, and of the maximum corank, for a given Σ.

PROPOSITION 4.2.

1. *$w \in \mathbb{C}^{m\times n}$, $\mathrm{rank}(w) = m$ is compatible with Σ iff $wSw^* \geq 0$ holds, where $S = \epsilon\Sigma - \Sigma\Sigma$.*

2. $\mathrm{mc}(\Sigma) = m$ *iff* $\lambda_1(\Sigma) \leq \lambda_2(\Sigma) \leq \cdots \leq \lambda_m(\Sigma) \leq \epsilon < \lambda_{m+1}(\Sigma) \leq \cdots \leq \lambda_n(\Sigma)$ *holds.*

Proof. By Proposition 4.1, we know that w is compatible iff

$$\tilde{\Sigma}_w = \Sigma w^*(w\Sigma w^*)^{-1} w\Sigma \leq \epsilon I$$

holds. As can be easily seen, this equivalent to

$$\begin{pmatrix} \epsilon I & \Sigma w^* \\ w\Sigma & w\Sigma w^* \end{pmatrix} \geq 0,$$

which in turn is equivalent to $w\Sigma w^* \geq \frac{1}{\epsilon} w\Sigma\Sigma w^*$.

Now $\underline{\mathcal{R}}_m(\Sigma)$ is not empty iff $S = \epsilon\Sigma - \Sigma\Sigma$ has at least m eigenvalues greater than or equal to zero. Thus item 2 follows immediately. □

Note that in this case, as opposed to the Frisch case, the characterization of $\mathrm{mc}(\Sigma)$ from Σ is easy. Note also that in the bounded noise case considered here, all m-relation sets may be empty (if ϵ is too small) and thus $\mathrm{mc}(\Sigma) = 0$ may hold.

In the next proposition, some topological and geometric properties of the m-relation set $\mathcal{R}_m(\Sigma)$ are given.

PROPOSITION 4.3.

1. $\mathcal{R}_m(\Sigma)$ *is a compact subset of* $\mathcal{G}(m,n)$.

2. *For* $\lambda_m(\Sigma) < \epsilon$, *the set* $\mathcal{R}_m(\Sigma)$ *contains an open (and nonvoid) subset of* $\mathcal{G}(m,n)$ *and* $\mathcal{R}_m(\Sigma) = \overline{\mathcal{R}_m(\Sigma)^o}$.

Proof. 1. Since $\mathcal{G}(m,n)$ is compact, it remains to prove that $\mathcal{R}_m(\Sigma)$ is closed. Let $\mathfrak{x}_k \in \mathcal{R}_m(\Sigma)$ be a sequence converging to $\mathfrak{x}_0 \in \mathcal{G}(m,n)$. Without loss of generality, let $w_0 = (I, w_2^0)$ be a basis for $\mathfrak{x}_0$ and let $w_k = (I, w_2^k)$ be the corresponding basis for $\mathfrak{x}_k$. Then clearly $w_k \to w_0$ and $\tilde{\Sigma}_{w_k} \to \tilde{\Sigma}_{w_0}$, where $\tilde{\Sigma}_w$ denotes the least squares error covariance defined by (4.1). Clearly $\tilde{\Sigma}_{w_0}$ satisfies (a.6) and thus $\mathfrak{x}_0 \in \mathcal{R}_m(\Sigma)$ holds.

2. By assumption, the matrix $S = \epsilon\Sigma - \Sigma\Sigma$ has at least m eigenvalues strictly larger than zero. If $w \in \mathbb{C}^{m\times n}$ spans the corresponding eigenspace of S, then $wSw^* > 0$ holds. Thus $\underline{\mathcal{R}}_m(\Sigma)$ and therefore, also, $\mathcal{R}_m(\Sigma)$ contains an open and nonvoid subset.

Clearly $\mathcal{R}_m^o \subseteq \mathcal{R}_m$ and thus $\overline{\mathcal{R}_m^o} \subseteq \overline{\mathcal{R}_m} = \mathcal{R}_m$.

Since unitary coordinate transformations do not change the topological structure of $\mathcal{R}_m(\Sigma)$, we may, w.l.o.g., assume that Σ is a diagonal matrix and that the diagonal elements of Σ are ordered increasing in size. Let $S = \epsilon\Sigma - \Sigma\Sigma$ be partitioned as

$$S = \begin{pmatrix} \Theta_{11} & 0 \\ 0 & \Theta_{22} \end{pmatrix},$$

where Θ_{11} is an $s \times s$, $s \geq m$ matrix and $\Theta_{11} \geq 0$ and $\Theta_{22} < 0$ hold. If $\mathfrak{x} \in \mathcal{R}_m(\Sigma)$ has a basis $w = (w_1, w_2)$, which is partitioned conformingly, then it is easy to see that w_1 must have full rank m. If $tw_1 = 0$ holds for some vector $t \in \mathbb{C}^{1\times m}$, then $0 \leq twSw^*t^* = tw_2\Theta_{22}w_2^*t^*$ implies $tw_2 = 0$, since $\Theta_{22} < 0$ holds. Since by assumption Θ_{11} has at least rank m, it follows that in any neighborhood of w_1 there exists a full rank matrix $\bar{w}_1$, such that $\bar{w}_1\Theta_{11}\bar{w}_1^* > w_1\Theta_{11}w_1^*$ holds. Let $\bar{w} = (\bar{w}_1, w_2)$; then clearly $\bar{w}S\bar{w}^* > 0$ holds, i.e., the corresponding subspace $\bar{\mathfrak{x}}$ is an element of $\mathcal{R}_m^o$. □

Item 2 of the above proposition shows that the boundary of $\mathcal{R}_m(\Sigma)$ has a simple structure. Next we consider some topological properties of the sets $\mathcal{S}_m$ of all spectral densities Σ with $\mathrm{mc}(\Sigma) = m$.

PROPOSITION 4.4. $\mathcal{S}_m$ *contains an open nonvoid subset and* $\mathcal{S}_n \cup \cdots \cup \mathcal{S}_m$ *is closed in* $\mathcal{S}$.

Proof. The result is a straightforward consequence of the fact that, for two Hermitian matrices A, E, the following relations for the eigenvalues holds:

$$\lambda_k(A) + \lambda_1(E) \leq \lambda_k(A+E) \leq \lambda_k(A) + \lambda_n(E).$$

(See, e.g., Golub and van Loan [15].) □

The above propositions state that all sets $\mathcal{S}_m$ are "thick subsets" of the set of all spectral densities. Note that in the Frisch scheme, on the contrary, the set of all spectral densities corresponding to a corank $m > \sqrt{n}$ are "thin subsets."

With the same motivation as in the Frisch case, we now consider the continuity of the mapping $\Sigma \mapsto \mathcal{R}_m(\Sigma)$.

PROPOSITION 4.5. *The mapping*

$$\begin{array}{rcl} \mathcal{S}(\epsilon) & \longrightarrow & \mathcal{C}, \\ \Sigma & \longmapsto & \mathcal{R}_m(\Sigma), \end{array}$$

is continuous for all $1 \leq m \leq n$. *Here* $\mathcal{C}$ *denotes the set of compact subspaces of* $\mathcal{G}(m,n)$ *endowed with the Haussdorff metric and* $\mathcal{S}(\epsilon) \subseteq \mathcal{S}$ *is the set of spectral densities, which have no eigenvalue equal to* ϵ.

Proof. This follows immediately from Lemma A.8. □

For the low noise case, a continuity result similar to Proposition 3.11 holds. However, in this case ϵ has to go to zero at a suitable rate.

5. The bivariate case. As an important special case and as a further explanation of some of the preceding results, we now discuss the case $n = 2$. This is done for the Frisch case and for the bounded noise case.

First we consider the Frisch case. In this case $\mathrm{mc}(\Sigma) = 2$ holds iff Σ is diagonal. This case is not really interesting since we may then choose $\hat{\Sigma} = 0$ and $\tilde{\Sigma} = \Sigma$ and thus every $w \in \mathbb{C}^{1\times 2}$ is compatible.

For $\mathrm{mc}(\Sigma) = 1$, by Proposition 3.2, w.l.o.g., we may choose a normalization $w = (1, -k)$ for the relation functions. Then k corresponds to the transfer function of the second component of $\hat{x}$ to the first component. Clearly $\hat{\Sigma}$ is compatible iff

$$\begin{array}{c} \hat{\sigma}_{11}\hat{\sigma}_{22} - |\sigma_{12}|^2 = 0, \\ 0 \leq \hat{\sigma}_{11} \leq \sigma_{11}, \\ 0 \leq \hat{\sigma}_{22} \leq \sigma_{22}, \end{array}$$

and thus k is compatible iff

$$k = \frac{\sigma_{12}}{\hat{\sigma}_{22}} \text{ where } \hat{\sigma}_{22} \in \left[\frac{|\sigma_{21}|^2}{\sigma_{11}}, \sigma_{22} \right].$$

(See Anderson and Deistler [3].) In particular here, the phase is uniquely determined and the gain is in an interval whose boundaries correspond to the Wiener filter formula, where all noise is added either to the second or first component.

Next we consider the bounded noise case. Again we introduce the normalization $w = (1, -k)$. This normalization excludes relation functions of the form $w = (0, k)$ which by Proposition 4.2 are compatible iff $s_{22} \geq 0$ holds. Using the normalization above, w is a compatible relation iff

$$wSw^* = ks_{22}k^* - ks_{21} - s_{12}k^* + s_{11} \geq 0.$$

For $s_{22} \neq 0$ this is equivalent to

$$\left(k - \frac{s_{12}}{s_{22}}\right) s_{22} \left(k - \frac{s_{12}}{s_{22}}\right)^* + \frac{\det(S)}{s_{22}} \geq 0,$$

TABLE 5.1

	s_{22}	$\det(S)/s_{22}$	compatible k	mc(Σ)
$0 \le \epsilon < \lambda_1$	< 0	< 0	none	0
$\lambda_1 \le \epsilon < \epsilon_0$	< 0	≥ 0	$\lvert k - s_{12}/s_{22}\rvert \le \sqrt{-\det(S)/s_{22}^2}$	1
$\epsilon = \epsilon_0$	0	∞	$2\Re(ks_{21}) \le s_{11}$	1
$\epsilon_0 < \epsilon < \lambda_2$	> 0	< 0	$\lvert k - s_{12}/s_{22}\rvert \ge \sqrt{-\det(S)/s_{22}^2}$	1
$\lambda_2 \le \epsilon$	> 0	≥ 0	all	2

and for $s_{22} = 0$ this is equivalent to

$$2\Re(ks_{21}) \le s_{11}.$$

In the next step we analyze the variation of the 1-relation set for a fixed spectral density Σ but with a varying noise bound ϵ. To simplify the analysis we assume that Σ is not diagonal and that $0 < \lambda_1 < \lambda_2$ holds for the eigenvalues of Σ. Clearly $\det(S) \le 0$ holds for $\lambda_1 \le \epsilon \le \lambda_2$ and $\det(S) > 0$ otherwise. Let ϵ_0 denote the value of ϵ for which s_{22} becomes zero. Since $s_{22} = e_2 S e_2^*$, where $e_2 = (0, 1)$, we see that $\lambda_1 \le \epsilon_0 \le \lambda_2$ must hold. Since Σ is not diagonal and thus e_2 is not an eigenvector of S, we have $\lambda_1 < \epsilon_0 < \lambda_2$. Putting this together gives cases shown in Table 5.1.

The three cases corresponding to mc = 1 are shown in Figure 5.1 for

$$\Sigma = \begin{pmatrix} 0.5 & 0.2 + 0.5i \\ 0.2 - 0.5i & 1.5 \end{pmatrix}. \tag{5.1}$$

Note that the set of compatible transfer functions k is unbounded for $\epsilon_0 \le \epsilon < \lambda_2$. This is a consequence of our normalization $w_1 = 1$. In these cases the relation function $w = (0, k)$ is compatible!

In Figure 5.2, we show in an exemplary way how our results, which have been obtained for a fixed frequency, can be applied for the case of varying frequencies. By putting together sets of compatible systems frequency by frequency, we obtain a "tube" containing all compatible transfer functions. To be more precise, the set of all compatible transfer functions is the set of all transfer functions contained in this tube. Note, however, that the tube may contain functions which are not transfer functions, e.g., if k is not continuous (compare (1.2)). The figures are given for the spectrum

$$A = \begin{pmatrix} 0.25 & 1 \\ 0.2 & 0.55 \end{pmatrix} \quad \Sigma(\lambda) = \left(I - Ae^{-i\lambda}\right)^{-1} \left(I - A'e^{i\lambda}\right)^{-1}. \tag{5.2}$$

Rationality of transfer functions, bounding of order, and causality impose additional restrictions on the set of compatible transfer functions; see, e.g., [9] for the Frisch case. An extreme example can be easily seen from Figure 5.2, where both equivalence classes do not contain a static system (i.e., a system of order 0).

6. Conclusion. In identification of errors-in-variables models—where also inputs may be contaminated by noise—often there is not sufficient a priori knowledge about the noise available in order to obtain unique models. Imposing additional assumptions, which are not justified by a priori knowledge, in order to get uniqueness may give prejudiced results. Therefore our basic philosophy is to attach to the data a set of observationally equivalent models, rather than a single model. Clearly such an approach faces additional complications. These complications, treated in an idealized

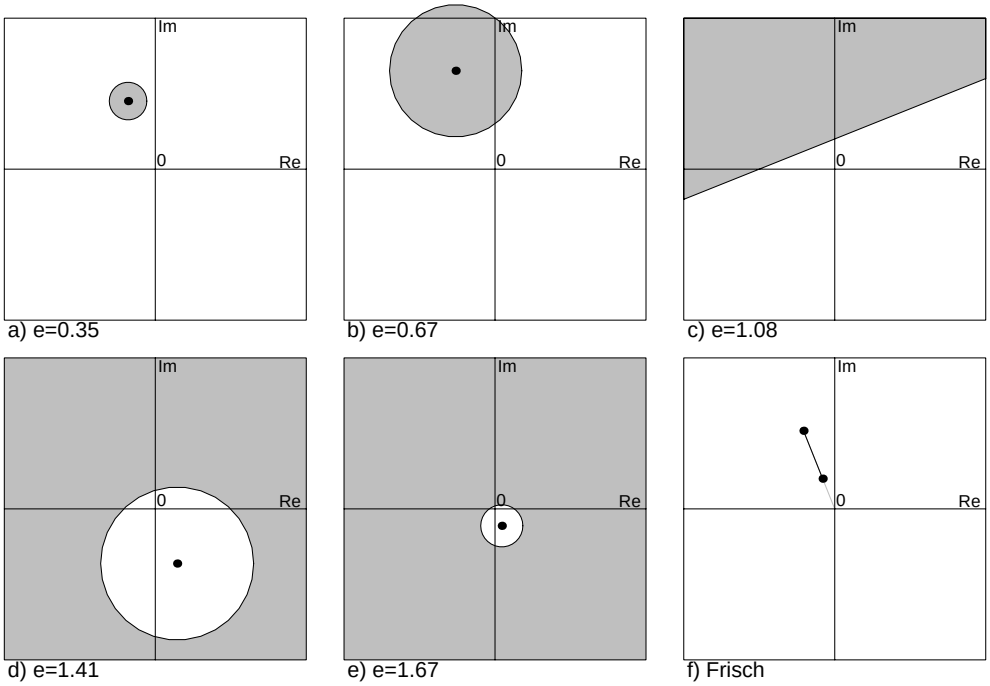

FIG. 5.1. *Here, for* Σ *given in* (5.1), *sets of compatible transfer functions* k, *evaluated at a fixed frequency, are represented in the complex plane marked by dark areas. Figures* (a)–(e) *show the bounded noise case for a growing noise bound* ϵ (*see also Table* 5.1). *Figure* (f) *shows the Frisch case. Note that the sets have dimension* 2 *in the bounded noise case and dimension* 1 *in the Frisch case.*

setting, where the relation between second moments of the observations (rather than data) and models is analyzed, are studied here.

In particular the following problems are addressed:

1. The description of the classes of observationally equivalent models. In many cases a simple analytic description is not available; for this reason we focus on topological and geometric properties of these classes.

2. For the well-posedness of the identification problem, the continuity of the mapping attaching equivalence classes to second moments of the observations is important.

3. The class of observationally equivalent models may contain systems with a different number of outputs. Here the maximum number of outputs is of special interest. For inference for this number (e.g., by likelihood ratio testing) some topological properties of sets of spectral densities corresponding to a given maximum number of outputs are analyzed.

These problems are investigated for two different assumptions on the noise, namely, for the Frisch case (mutually uncorrelated noise components) and for the case of bounded noise.

Appendix A. Some lemmata.

Lemmas A.1–A.7 deal with the Frisch case and Lemma A.8 deals with the bounded noise case.

LEMMA A.1. *Let* $\hat{\Sigma}^0 \in \mathcal{M}_m$, $\tilde{\Sigma}^0 \in \mathcal{D}_{\mathcal{I}}$, $\Sigma^0 = \hat{\Sigma}^0 + \tilde{\Sigma}^0 > 0$, *where* $\mathcal{I} = \{1, \ldots, l\}$

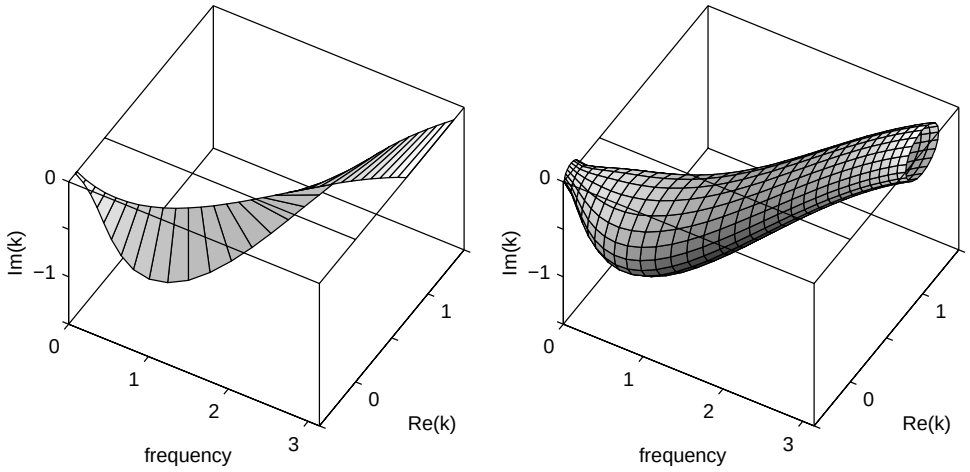

FIG. 5.2. *Here, for the spectrum* Σ *given in* (5.2), *the set of compatible transfer functions* k *is shown. The left-hand figure shows the Frisch case and the right-hand figure shows the bounded noise case. The above figures are obtained by putting together the sets shown in Figure* 5.1, *frequency by frequency. (Of course, here only one noise bound* ϵ *was used.) Note that the Frisch case gives a "band," whereas the bounded noise case gives a "tube" of compatible* k*'s.*

and $\hat{\Sigma}^0_{22} > 0$ *holds. Then the following statements hold:*

1. *We can find an open neighborhood* $\mathcal{U} \subseteq \mathbb{R}^n$ *of* $\tilde{\Sigma}^0$ *such that* $(\Sigma^0_{22} - \tilde{\Sigma}_{22}) > 0$ *and* $\tilde{\sigma}_{ii} > 0$ *for* $i \in \mathcal{I}$ *hold for all* $\tilde{\Sigma} \in \mathcal{U}$. *In this neighborhood the mapping* $\tilde{\Sigma} \mapsto \mathrm{g}_{n,m}(\Sigma^0 - \tilde{\Sigma})$ *is defined and differentiable, and* $\tilde{\Sigma} \in \mathcal{E}_m(\Sigma^0)$ *holds iff* $\mathrm{g}_{n,m}(\Sigma^0 - \tilde{\Sigma}) = 0$ *and* $\tilde{\Sigma} \geq 0$ *holds.*

2. *The mapping* $\mathrm{f}_{m,\mathcal{I}}$ *has full rank in* $(\hat{\Sigma}^0, \tilde{\Sigma}^0)$ *iff the derivative of* $\mathrm{g}_{n,m}(\Sigma^0 - \tilde{\Sigma})$, *with respect to* $d_{\mathcal{I}}(\tilde{\Sigma})$, *has full rank in* $\tilde{\Sigma}^0$. *Here* $d_{\mathcal{I}}(\tilde{\Sigma})$ *denotes the vector of the diagonal elements of* $\tilde{\Sigma}$ *corresponding to the index set* $\mathcal{I}$.

Proof. The first statement is evident. In order to prove the second statement note that the derivative of $\mathrm{f}_{m,\mathcal{I}}$ is given by

$$\begin{pmatrix} I & 0 & 0 & 0 & 0 & 0 \\ 0 & I & 0 & 0 & 0 & 0 \\ 0 & 0 & I & 0 & 0 & 0 \\ X & X & H_2 & H_1 & 0 & 0 \\ 0 & 0 & 0 & I & I & 0 \\ X & X & X & X & 0 & I \end{pmatrix} \begin{matrix} \} \partial v(\Sigma_{12}) \\ \} \partial o(\Sigma_{22}) \\ \} \partial d_2(\Sigma_{22}) \\ \} \partial o(\Sigma_{11}) \\ \} \partial d_1(\Sigma_{22}) \\ \} \partial d(\Sigma_{11}) \end{matrix} .$$

$$\underbrace{}_{\partial v(\hat{\Sigma}_{12})} \; \underbrace{}_{\partial o(\hat{\Sigma}_{22})} \; \underbrace{}_{\partial d_2(\hat{\Sigma}_{22})} \; \underbrace{}_{\partial d_1(\hat{\Sigma}_{22})} \; \underbrace{}_{\partial d_1(\tilde{\Sigma}_{22})} \; \underbrace{}_{\partial d(\tilde{\Sigma}_{11})}$$

Here block entries of this derivative, which do not play a role in our analysis, are simply marked with an X. Furthermore, the vector of diagonal elements of $\hat{\Sigma}_{22}$ and $\tilde{\Sigma}_{22}$ is split into two parts $d_1(\cdot)$ and $d_2(\cdot)$, such that $d_{\mathcal{I}}(\tilde{\Sigma}) = (d(\tilde{\Sigma}_{11})', d_1(\tilde{\Sigma}_{22})')'$.

On the other hand, the derivative of $\mathrm{g}_{n,m}(\Sigma^0 - \tilde{\Sigma})$ with respect to $d(\tilde{\Sigma})$ is given by

$$\begin{pmatrix} -I & X & X \\ 0 & H_1 & H_2 \end{pmatrix} \begin{matrix} \} \partial d(\mathrm{g}_{n,m}) \\ \} \partial o(\mathrm{g}_{n,m}) \end{matrix} .$$

$$\underbrace{}_{\partial d(\tilde{\Sigma}_{11})} \; \underbrace{}_{\partial d_1(\tilde{\Sigma}_{22})} \; \underbrace{}_{\partial d_2(\tilde{\Sigma}_{22})}$$

Since both matrices have full rank iff H_1 has full rank, statement 2 has been proven. ∎

LEMMA A.2. *Let $\Sigma^0 = \hat{\Sigma}^0 + \tilde{\Sigma}^0$, $(\hat{\Sigma}^0, \tilde{\Sigma}^0) \in \mathcal{M}_m \times \mathcal{D}_\mathcal{I}$ be a regular point of $\mathrm{f}_{m,\mathcal{I}}$. There exists an open neighborhood $\mathcal{U} \subseteq (\mathbb{R}^{n^2} \times \mathbb{R}^n)$, of $(\Sigma^0, \tilde{\Sigma}^0)$, such that for all $(\Sigma, \tilde{\Sigma}) \in \mathcal{U}$ we have that: if $\hat{\Sigma} = (\Sigma - \tilde{\Sigma}) \in \mathcal{M}_s$ and $\tilde{\Sigma} \geq 0$ hold, then*

1. *$s \leq m$,*
2. *$\tilde{\Sigma} \in \mathcal{D}_\mathcal{J}$, $\mathcal{J} \supseteq \mathcal{I}$, and*
3. *$(\hat{\Sigma}, \tilde{\Sigma})$ is a regular point of $\mathrm{f}_{s,\mathcal{J}}$.*

Proof. By a rearrangement of variables in x_t we may achieve that $\hat{\Sigma}^0_{22} > 0$ and $\mathcal{I} = \{1, \ldots, l\}$ hold. We then can choose $\mathcal{U}$ in such a way that $(\Sigma_{22} - \tilde{\Sigma}_{22}) > 0$ and $\tilde{\sigma}_{ii} > 0$ for all $i \in \mathcal{I}$ hold for all $(\Sigma, \tilde{\Sigma}) \in \mathcal{U}$. Thus we have shown 1 and 2.

By Lemma A.1 we know that the derivative of $\mathrm{g}_{n,m}(\Sigma - \tilde{\Sigma})$ with respect to $d_\mathcal{I}(\tilde{\Sigma})$ evaluated at $(\Sigma^0, \tilde{\Sigma}^0)$ has full rank m^2, since $(\hat{\Sigma}^0, \tilde{\Sigma}^0)$ is a regular point of $\mathrm{f}_{m,\mathcal{I}}$. Now let $\mathcal{U}$ be so small that this derivative has full rank m^2 for all points $(\Sigma, \tilde{\Sigma}) \in \mathcal{U}$. We consider a pair $(\Sigma, \tilde{\Sigma}) \in \mathcal{U}$, $\hat{\Sigma} = (\Sigma - \tilde{\Sigma}) \in \mathcal{M}_s$, $\tilde{\Sigma} \in \mathcal{D}_\mathcal{J}$. Again by rearrangement of the first m variables in x_t, we can achieve that the lower right $(n-s) \times (n-s)$ corner of $\hat{\Sigma}$ has full rank $n - s$. By the identity $\mathrm{g}_{n,s} = \mathrm{g}_{m,s} \circ \mathrm{g}_{n,m}$ and the chain rule, the derivative of $\mathrm{g}_{n,s}(\Sigma - \hat{\Sigma})$ with respect to $d_\mathcal{I}(\tilde{\Sigma})$ has full rank s^2, since the derivative of $\mathrm{g}_{m,s}$ has rank s^2 and since the derivative of $\mathrm{g}_{n,m}$ with respect to $d_\mathcal{I}(\tilde{\Sigma})$ has rank m^2. Therefore we again have by Lemma A.1 that $(\hat{\Sigma}, \tilde{\Sigma})$ is a regular point of $\mathrm{f}_{s,\mathcal{I}}$. ∎

LEMMA A.3. *The set of all pairs $(\hat{\Sigma}, \tilde{\Sigma}) \in (\mathcal{M}_m \times \mathcal{D}_\mathcal{I})$, where $\mathrm{f}_{m,\mathcal{I}}$ has full rank $\min(n^2, n^2 - m^2 + |\mathcal{I}|)$, is open and dense in $(\mathcal{M}_m \times \mathcal{D}_\mathcal{I})$.*

Proof. We first prove that the set of pairs $(\hat{\Sigma}, \tilde{\Sigma})$ with a full rank derivative is dense. Let us consider a pair $(\hat{\Sigma}^0, \tilde{\Sigma}^0)$, where, w.l.o.g., we may assume that $\hat{\Sigma}^0_{22} > 0$ and $\mathcal{I} = \{1, \ldots, l\}$ holds. By the results of Lemma A.1, it suffices to consider the derivative of $o(\hat{\Sigma}_{12}\hat{\Sigma}_{22}\hat{\Sigma}_{21})$ with respect to the first $s = l - m$ diagonal elements of $\hat{\Sigma}_{22}$. Let $A = \hat{\Sigma}_{12}\hat{\Sigma}_{22}^{-1}$; then this derivative is given by

$$\left(\begin{array}{ccccc}
\Re(a_{11}a_{21}^*) & \Re(a_{12}a_{22}^*) & \ldots & \ldots & \Re(a_{1s}a_{2s}^*) \\
\Im(a_{11}a_{21}^*) & \Im(a_{12}a_{22}^*) & \ldots & \ldots & \Im(a_{1s}a_{2s}^*) \\
\Re(a_{11}a_{31}^*) & \Re(a_{12}a_{32}^*) & \ldots & \ldots & \Re(a_{1s}a_{3s}^*) \\
\Im(a_{11}a_{31}^*) & \Im(a_{12}a_{32}^*) & \ldots & \ldots & \Im(a_{1s}a_{3s}^*) \\
\vdots & \vdots & & & \vdots \\
\Re(a_{11}a_{m1}^*) & \Re(a_{12}a_{m2}^*) & \ldots & \ldots & \Re(a_{1s}a_{ms}^*) \\
\Im(a_{11}a_{m1}^*) & \Im(a_{12}a_{m2}^*) & \ldots & \ldots & \Im(a_{1s}a_{ms}^*) \\
\Re(a_{21}a_{31}^*) & \Re(a_{22}a_{32}^*) & \ldots & \ldots & \Re(a_{2s}a_{3s}^*) \\
\Im(a_{21}a_{31}^*) & \Im(a_{22}a_{32}^*) & \ldots & \ldots & \Im(a_{2s}a_{3s}^*) \\
\vdots & \vdots & & & \vdots \\
\vdots & \vdots & & & \vdots \\
\Re(a_{m-1,1}a_{m1}^*) & \Re(a_{m-1,2}a_{m,2}^*) & \ldots & \ldots & \Re(a_{m-1,s}a_{m,s}^*) \\
\Im(a_{m-1,1}a_{m1}^*) & \Im(a_{m-1,2}a_{m,2}^*) & \ldots & \ldots & \Im(a_{m-1,s}a_{m,s}^*)
\end{array}\right)
\begin{array}{l}
\}\partial\Re((\cdot)_{12}) \\
\}\partial\Im((\cdot)_{12}) \\
\}\partial\Re((\cdot)_{13}) \\
\}\partial\Im((\cdot)_{13}) \\
\vdots \\
\}\partial\Re((\cdot)_{1s}) \\
\}\partial\Im((\cdot)_{1s}) \\
\}\partial\Re((\cdot)_{23}) \\
\}\partial\Im((\cdot)_{23}) \\
\vdots \\
\vdots \\
\}\partial\Re((\cdot)_{m-1,m}) \\
\}\partial\Im((\cdot)_{m-1,m})
\end{array}$$

In each neighborhood of $A^0 = \hat{\Sigma}^0_{12}(\hat{\Sigma}^0_{22})^{-1}$, we may find a matrix A such that all entries a_{ij} are nonzero and $\Re(a_{11}a_{21}^*) \neq 0$ holds. Now let us consider the left upper $(k+1) \times (k+1)$ block of the above matrix, which is partitioned as

$$\left(\begin{array}{cc} H_{11} & h_{12} \\ h_{21} & H_{22} \end{array}\right).$$

If H_{11} is regular, then the determinant of this block is equal to $\det(H_{11})(h_{22} - h_{21}H_{11}^{-1}h_{21})$. The element h_{22} is the real or imaginary part of a product of the form $a_{i,k+1}a_{j,k+1}^*$ for some $i \neq j$. It is easy to see that we can disturb these two entries $a_{i,k+1}$ and $a_{j,k+1}$ such that $(h_{22} - h_{21}H_{11}^{-1}h_{21})$ is nonzero. Then after a finite number of such steps, we end up with a full rank matrix H. Since $A = \hat{\Sigma}_{12}\hat{\Sigma}_{22}^{-1}$, these arbitrarily small changes in A may be achieved by arbitrarily small changes in $\hat{\Sigma}_{12}$. Thus we have proved that, in any neighborhood of $(\hat{\Sigma}^0, \tilde{\Sigma}^0)$, we may find a pair $(\hat{\Sigma}, \tilde{\Sigma})$ such that the derivative $\mathrm{f}_{m,\mathcal{I}}$ has full rank.

Since the determinant of the derivative is a continuous functions of the entries of $(\hat{\Sigma}, \tilde{\Sigma})$, it follows that the set of pairs $(\hat{\Sigma}, \tilde{\Sigma})$ with a full rank derivative is open. □

LEMMA A.4. *Let $\mathcal{A}$ be a metric space endowed with the metric $\mathrm{d}(x,y)$ and let $(\mathcal{U}_k \in \mathcal{C}(\mathcal{A}))$ be a sequence of compact subsets of $\mathcal{A}$ and $\mathcal{U}_0 \in \mathcal{C}(\mathcal{A})$. Then*

$$\rho(\mathcal{U}_0, \mathcal{U}_k) = \sup_{x \in \mathcal{U}_0} \inf_{y \in \mathcal{U}_k} \mathrm{d}(x,y) \longrightarrow 0$$

iff

$$i_k(x) = \inf_{y \in \mathcal{U}_k} \mathrm{d}(x,y) \longrightarrow 0 \quad \textit{for all } x \in \mathcal{U}_0,$$

i.e., iff for all $x \in \mathcal{U}_0$ there exists a sequence $y_k \in \mathcal{U}_k$, such that $y_k \to x$ holds.

Proof. Let us consider two points $x_1, x_2 \in \mathcal{U}_0$. Since $\mathcal{U}_k$ is compact, there are two points $y_1, y_2 \in \mathcal{U}_k$ such that $i_k(x_j) = \inf_{y \in \mathcal{U}_k} \mathrm{d}(x_j, y) = \mathrm{d}(x_j, y_j)$, $j = 1, 2$. From the triangle inequality, we get

$$\begin{aligned} i_k(x_1) &= \mathrm{d}(x_1, y_1) \leq \mathrm{d}(x_1, y_2) \leq \mathrm{d}(x_1, x_2) + \mathrm{d}(x_2, y_2) = \mathrm{d}(x_1, x_2) + i_k(x_2), \\ i_k(x_2) &= \mathrm{d}(x_2, y_2) \leq \mathrm{d}(x_2, y_1) \leq \mathrm{d}(x_2, x_1) + \mathrm{d}(x_1, y_1) = \mathrm{d}(x_1, x_2) + i_k(x_1), \end{aligned}$$

and thus

$$|i_k(x_1) - i_k(x_2)| \leq \mathrm{d}(x_1, x_2).$$

Now suppose that $i_k(x) \to 0$ holds for all $x \in \mathcal{U}_0$, but $\sup_{x \in \mathcal{U}_0} i_k(x)$ does not converge to zero. Then there exist an $\epsilon > 0$ and a sequence of points $x_k \in \mathcal{U}_0$, such that $i_k(x_k) \geq \epsilon$ for infinitely many k's. Since $\mathcal{U}_0$ is compact, there exists a limiting point $x_0 \in \mathcal{U}_0$ of these sequence of points x_k. By the above inequality, we further get

$$i_k(x_k) \leq \underbrace{|i_k(x_k) - i_k(x_0)|}_{\leq \mathrm{d}(x_k, x_0) \to 0} + \underbrace{i_k(x_0)}_{\to 0} \longrightarrow 0,$$

in contradiction to $i_k(x_k) \geq \epsilon$. Thus we have shown that $i_k(x) \to 0$, $\forall x \in \mathcal{U}_0$ implies that $\rho(\mathcal{U}_0, \mathcal{U}_k) \to 0$. The reverse statement is evident. Clearly $i_k(x) \to 0$ is equivalent to the existence of a sequence $y_k \in \mathcal{U}_k$, with $y_k \to x$. □

Now we consider the mapping $\Sigma \mapsto \overline{\mathcal{E}_m(\Sigma)}$. In the next proposition the semicontinuity of this mapping, in the sense that the limiting set of a sequence $\overline{\mathcal{E}_m(\Sigma^k)}$ is a subset of $\overline{\mathcal{E}_m(\lim \Sigma^k)}$, is stated.

LEMMA A.5. *For $\mathcal{S} \ni \Sigma^k \to \Sigma^0 \in \mathcal{S}$, we have*

$$\rho(\overline{\mathcal{E}_m(\Sigma^k)}, \overline{\mathcal{E}_m(\Sigma^0)}) = \sup_{\tilde{\Sigma}^k \in \overline{\mathcal{E}_m(\Sigma^k)}} \inf_{\tilde{\Sigma}^0 \in \overline{\mathcal{E}_m(\Sigma^0)}} \|\tilde{\Sigma}^k - \tilde{\Sigma}^0\| \to 0.$$

Proof. Note that $\overline{\mathcal{E}_m(\Sigma)}$ is closed and bounded by Propositions 3.1 and 3.3. Thus $\rho(\overline{\mathcal{E}_m(\Sigma^k)}, \overline{\mathcal{E}_m(\Sigma^0)})$ is well defined.

If $\mathrm{mc}(\Sigma^0) < m$ (and thus $\overline{\mathcal{E}_m(\Sigma^0)} = \emptyset$), then also $\mathrm{mc}(\Sigma^k) < m$ (and thus $\overline{\mathcal{E}_m(\Sigma^k)} = \emptyset$) must hold from some k onwards. (This follows from the fact that $\mathcal{S}_1 \cup \cdots \cup \mathcal{S}_{m-1}$ is open; see Proposition 3.12.) If we define $\rho(\emptyset, \emptyset) = 0$, then the proposition is proved in this case.

Suppose that there is an $\epsilon > 0$ such that $\rho(\overline{\mathcal{E}_m(\Sigma^k)}, \overline{\mathcal{E}_m(\Sigma^0)}) > \epsilon$ holds for infinitely many k's. Then for each such k there exists a $\tilde{\Sigma}^k \in \overline{\mathcal{E}_m(\Sigma^k)}$ such that $\inf_{\tilde{\Sigma} \in \overline{\mathcal{E}_m(\Sigma^0)}} \|\tilde{\Sigma}^k - \tilde{\Sigma}\| > \epsilon$ holds. Since the $\tilde{\Sigma}^k$'s are bounded, there is a limiting point $\tilde{\Sigma}^0$, say. Note that $\tilde{\Sigma}^0 \in \overline{\mathcal{E}_m(\Sigma^0)}$ holds, since $(\Sigma^k - \tilde{\Sigma}^k) \geq 0$, $\mathrm{corank}(\Sigma^k - \tilde{\Sigma}^k) \geq m$, and $\tilde{\Sigma}^k \geq 0$ hold.

Therefore we have

$$\inf_{\tilde{\Sigma} \in \overline{\mathcal{E}_m(\Sigma^0)}} \|\tilde{\Sigma}^k - \tilde{\Sigma}\| \leq \|\tilde{\Sigma}^k - \tilde{\Sigma}^0\| \to 0,$$

in contradiction to the construction of the $\tilde{\Sigma}^k$'s. ∎

LEMMA A.6. *For a convergent sequence* $(\Sigma^k \in \mathcal{S})$, $\Sigma^k \to \Sigma^0 \in \mathcal{S}$, *we have*

$$\rho(\mathcal{R}_m(\Sigma^k), \mathcal{R}_m(\Sigma^0)) \to 0.$$

Proof. In the case $\mathrm{mc}(\Sigma^0) < m$, we have $\mathrm{mc}(\Sigma^k) < m$ from some k_0 onwards. Thus $\mathcal{R}_m(\Sigma^0) = \emptyset = \mathcal{R}_m(\Sigma^k)$ for all $k \geq k_0$.

Now we consider the case where $\mathrm{mc}(\Sigma^0) \geq m$ holds. We suppose that there exist an $\epsilon > 0$ and a sequence $\mathfrak{x}^k \in \mathcal{R}_m(\Sigma^k)$, such that $\inf_{\mathfrak{y} \in \mathcal{R}_m(\Sigma^0)} \mathrm{d}_{\mathcal{G}}(\mathfrak{x}^k, \mathfrak{y}) \geq \epsilon$ holds for infinitely many k's. Since $\mathcal{G}(m,n)$ is compact, there exists a limiting point $\mathfrak{x}^0 \in \mathcal{G}(m,n)$ of these $\mathfrak{x}^k$'s.

To each $\mathfrak{x}^k$ there exists a corresponding $\tilde{\Sigma}^k \in \mathcal{E}(\Sigma^k)$, such that $\mathfrak{x}^k \subseteq \ker(\Sigma^k - \tilde{\Sigma}^k)$. Since the $\tilde{\Sigma}^k$'s are bounded, there exist a limiting point $\tilde{\Sigma}^0$, say. It is easy to see that $\tilde{\Sigma}^0 \in \mathcal{E}(\Sigma^0)$ and $\mathfrak{x}^0 \subseteq \ker(\Sigma^0 - \tilde{\Sigma}^0)$ hold. Thus $\mathfrak{x}^0 \in \mathcal{R}_m(\Sigma^0)$ holds and we have

$$\inf_{\mathfrak{y} \in \mathcal{R}_m(\Sigma^0)} \mathrm{d}_{\mathcal{G}}(\mathfrak{x}^k, \mathfrak{y}) \leq \mathrm{d}_{\mathcal{G}}(\mathfrak{x}^k, \mathfrak{x}^0) \to 0,$$

in contradiction to the construction of the sequence $\mathfrak{x}^k$. ∎

LEMMA A.7. *Consider a sequence* $\Sigma^k \in \mathcal{S}$, $\Sigma^k \to \Sigma^0 \in \mathcal{S}$, *where* $\mathrm{mc}(\Sigma^0) = m_0$, *and* $\overline{\mathcal{E}_s(\Sigma^k)} \to \overline{\mathcal{E}_s(\Sigma^0)}$ *for all* $m \leq s \leq m_0$ *holds. In this case,*

$$\mathrm{d_H}(\mathcal{R}_m(\Sigma^k), \mathcal{R}_m(\Sigma^0)) \to 0$$

holds.

Proof. For $\mathfrak{x}^0 \in \mathcal{R}_m(\Sigma^0)$ there is a $\tilde{\Sigma}^0 \in \overline{\mathcal{E}_m(\Sigma^0)}$ such that $\mathfrak{x}^0 \subseteq \ker(\Sigma^0 - \tilde{\Sigma}^0)$. In order to prove the proposition we consider the following two cases:

1. $\mathfrak{x}^0 = \ker(\Sigma^0 - \tilde{\Sigma}^0)$, i.e. $\tilde{\Sigma}^0 \in \mathcal{E}_m(\Sigma^0)$. Since $\overline{\mathcal{E}_m(\Sigma^k)} \to \overline{\mathcal{E}_m(\Sigma^0)}$, we can find a sequence $\tilde{\Sigma}^k \in \overline{\mathcal{E}_m(\Sigma^k)}$, such that $\tilde{\Sigma}^k \to \tilde{\Sigma}^0$ holds. There must be an index k_0 such that $\mathrm{corank}(\Sigma^k - \tilde{\Sigma}^k) = m$, and thus $\tilde{\Sigma}^k \in \mathcal{E}_m(\Sigma^k)$, holds for all $k \geq k_0$. Thus $\mathfrak{x}^k = \ker(\Sigma^k - \tilde{\Sigma}^k) \in \mathcal{R}_m(\Sigma^k)$ holds for all $k \geq k_0$. Since $\ker(\hat{\Sigma})$ continuously depends on $\hat{\Sigma}$, we have found a sequence $\mathfrak{x}^k \in \mathcal{R}_m(\Sigma^k) \to \mathfrak{x}^0$.

2. $\mathfrak{x}^0 \subset \ker(\Sigma^0 - \tilde{\Sigma}^0)$, i.e., $\tilde{\Sigma}^0 \in \mathcal{E}_s(\Sigma^0)$ for some $s > m$. We can construct a sequence $\mathfrak{y}^k \in \mathcal{R}_s(\Sigma^k) \to \mathfrak{y}^0 = \ker(\Sigma^0 - \tilde{\Sigma}^0)$ as described above. Without loss of generality, we assume that $w^0 = (I, w_2^0)$ is a basis for $\mathfrak{y}^0$. For all k large enough, $\mathfrak{y}^k$

has a basis $w^k = (I, w_2^k)$. Clearly $w^k \to w^0$ holds. Since $\mathfrak{x}^0 \subset \ker(\Sigma^0 - \tilde{\Sigma}^0) = \mathfrak{y}^0$, there exists a matrix $o \in \mathbb{C}^{m\times s}$ such that $ow^0 \in \mathbb{C}^{m\times n}$ is a basis for $\mathfrak{x}^0$. Then $ow^k \in \underline{\mathcal{R}}_m(\Sigma^k)$ holds and the corresponding subspace $\mathfrak{x}^k$ (spanned by the rows of ow^k) is an element of $\mathcal{R}_m(\Sigma^k)$. Thus we have found a sequence $\mathfrak{x}^k \in \mathcal{R}_m(\Sigma^k) \to \mathfrak{x}^0 \in \mathcal{R}_m(\Sigma^0)$.

Now, using Lemmata A.4 and A.6 gives us the desired result. ∎

LEMMA A.8. *Let $\Sigma^k \in \mathcal{S}$ be a convergent sequence of spectral densities with $\lim_{n\to\infty} \Sigma^k = \Sigma^0 \in \mathcal{S}$.*

1. $\rho(\mathcal{R}_m(\Sigma^k), \mathcal{R}_m(\Sigma^0)) = \sup_{\mathfrak{x}\in\mathcal{R}_m(\Sigma^k)} \inf_{\mathfrak{y}\in\mathcal{R}_m(\Sigma^0)} \mathrm{d}_{\mathcal{G}}(\mathfrak{x}, \mathfrak{y}) \longrightarrow 0$.
2. *If $\lambda_m(\Sigma^0) < \epsilon$, then* $\rho(\mathcal{R}_m(\Sigma^0), \mathcal{R}_m(\Sigma^k)) = \sup_{\mathfrak{x}\in\mathcal{R}_m(\Sigma^0)} \inf_{\mathfrak{y}\in\mathcal{R}_m(\Sigma^k)} \mathrm{d}_{\mathcal{G}}(\mathfrak{x}, \mathfrak{y}) \longrightarrow 0$

Proof. 1. First we note that, if $\mathrm{mc}(\Sigma^0) < m$ holds (and thus $\mathcal{R}_m(\Sigma^0)$ is void), then $\mathrm{mc}(\Sigma^k) < m$ (and thus $\mathcal{R}_m(\Sigma^k) = \emptyset$) must hold for all k large enough. If we define $\mathrm{d}_{\mathrm{H}}(\emptyset, \emptyset) = 0$, then the statement is true for this case.

Next we consider the case $\mathrm{mc}(\Sigma^0) \geq m$. If $\rho(\mathcal{R}_m(\Sigma^k), \mathcal{R}_m(\Sigma^0))$ does not converge to zero, then there exist a $\mu > 0$ and a sequence $\mathfrak{x}^k \in \mathcal{R}_m(\Sigma^k)$ such that $\inf_{\mathfrak{y}\in\mathcal{R}_m(\Sigma^0)} \mathrm{d}_{\mathcal{G}}(\mathfrak{x}^k, \mathfrak{y}) \geq \mu$ holds. Since $\mathcal{G}(m, n)$ is compact, the sequence $\mathfrak{x}^k$ has a convergent subsequence. To simplify the notation we use the same index k for this subsequence. We now have $\lim_k \mathfrak{x}^k = \mathfrak{x}^0$. If (after possibly reordering variables) $w^0 = (I, w_2^0)$ is a basis for the subspace $\mathfrak{x}^0$, then we can find $w^k = (I, w_2^k)$ which span the subspaces $\mathfrak{x}^k$. Since $\mathfrak{x}^k \to \mathfrak{x}^0$, we have $w^k \to w^0$ and $w^0(\epsilon\Sigma^0 - \Sigma^0\Sigma^0)(w^0)^* = \lim_k w^k(\epsilon\Sigma^k - \Sigma^k\Sigma^k)(w^k)^* \geq 0$. Thus $\mathfrak{x}^0 \in \mathcal{R}_m(\Sigma^0)$ and

$$\inf_{\mathfrak{y}\in\mathcal{R}_m(\Sigma^0)} \mathrm{d}_{\mathcal{G}}(\mathfrak{x}^k, \mathfrak{y}) \leq \mathrm{d}_{\mathcal{G}}(\mathfrak{x}^k, \mathfrak{x}^0) \to 0$$

holds, which gives the desired contradiction.

2. By Lemma A.4 it suffices to show that for each $w^0 \in \underline{\mathcal{R}}_m(\Sigma^0)$ a sequence $w^k \in \underline{\mathcal{R}}_m(\Sigma^k)$ with $w^k \to w^0$ can be constructed. Let $S^k = \epsilon\Sigma^k - \Sigma^k\Sigma^k$ and $S^0 = \epsilon\Sigma^0 - \Sigma^0\Sigma^0$. Since S^0 has at least m eigenvalues strictly larger than zero, we may find a sequence $v^l \to w^0$ such that $v^l\Sigma^0(v^l)^* > 0$ holds (see item 2 of Proposition 4.3.) Since $\Sigma^k \to \Sigma^0$, for each l there exists an integer $k(l)$ such that $v^l\Sigma^k(v^l)^* \geq 0$ holds for all $k \geq k(l)$. Now we define the sequence w^k by $w^k = v^l$ for $k(l) \leq k < k(l+1)$. ∎

Appendix B. Notation.

$\mathcal{S} \subseteq \mathbb{C}^{n\times n}$	set of all $n \times n$ complex positive definite matrices
$\mathcal{M} \subseteq \mathbb{C}^{n\times n}$	set of all $n \times n$ complex positive semidefinite matrices
$\mathcal{M}_m \subseteq \mathcal{M}$	set of all $n \times n$ complex positive semidefinite matrices of corank m
$\mathcal{S}_m \subseteq \mathcal{S}$	set of all Σ with $\mathrm{mc}(\Sigma) = m$
$\mathcal{G}(m, n)$	set of all m-dimensional subspaces of $\mathbb{C}^n$ (Grassmannian)
x_t	observations
$\hat{x}_t$	latent variables
u_t	noise
$\Sigma \in \mathcal{S}$	spectral density of (x_t) evaluated at a fixed frequency λ
$\Sigma_T \in \mathcal{S}$	an estimate of Σ based on a sample of length T
$\hat{\Sigma} \in \mathcal{M}_m$	spectral density of $(\hat{x}_t)$ evaluated at a fixed frequency λ
$\tilde{\Sigma} \in \mathcal{M}$	spectral density of (u_t) evaluated at a fixed frequency λ
$w \in \mathbb{C}^{m\times n}$	relation function evaluated at a fixed frequency λ

$\mathcal{E}(\Sigma)$	set of all compatible $\tilde{\Sigma}$
$\mathcal{E}_m(\Sigma) \subseteq \mathcal{E}(\Sigma)$	set of all compatible $\tilde{\Sigma}$, such that $\hat{\Sigma} = \Sigma - \tilde{\Sigma}$ has corank m
$\underline{\mathcal{R}}_m(\Sigma) \subseteq \mathbb{C}^{m \times n}$	set of all compatible w, m-relation set of Σ
$\mathcal{R}_m(\Sigma) \subseteq \mathcal{G}(m,n)$	set of all subspaces spanned by a compatible $w \in \underline{\mathcal{R}}_m(\Sigma)$
$\mathrm{mc}(\Sigma)$	maximum corank of all compatible $\hat{\Sigma} = \Sigma - \tilde{\Sigma}$
$\mathrm{m_L} = \sqrt{n}$	Ledermann bound
$\mathcal{D} \subseteq \mathbb{R}^n$	set of all positive semidefinite diagonal $n \times n$ matrices $\tilde{\Sigma}$
$\mathcal{D}_{\mathcal{I}} \subseteq \mathcal{D}$	set of all positive semidefinite diagonal $n \times n$ matrices $\tilde{\Sigma}$, where $\tilde{\sigma}_{ii} > 0$ for all $i \in \mathcal{I} \subseteq \{1, \ldots, n\}$ and $\tilde{\sigma}_{ii} = 0$ else
$\ker(A)$	kernel of a complex matrix A
$\mathrm{rank}(A), \mathrm{corank}(A)$	rank and corank of a complex matrix A
$\lambda_i(A)$	eigenvalues of a complex Hermitian matrix
$\mathcal{A}^o, \overline{\mathcal{A}}$	interior and closure of a set $\mathcal{A}$
$\mathrm{d_H}(\cdot,\cdot)$	Hausdorff distance
$\mathrm{d}_{\mathcal{G}}(\cdot,\cdot)$	gap metric, defined on $\mathcal{G}(m,n)$
$\Re(\mathrm{z}), \Im(\mathrm{z})$	real and imaginary part of a complex number z

COMPUTATIONAL COMPLEXITY OF LYAPUNOV STABILITY ANALYSIS PROBLEMS FOR A CLASS OF NONLINEAR SYSTEMS*

MARC W. MCCONLEY†, BRENT D. APPLEBY†, MUNTHER A. DAHLEH‡, AND ERIC FERON§

Abstract. Nonlinear control systems can be stabilized by constructing control Lyapunov functions and computing the regions of state space over which such functions decrease along trajectories of the closed-loop system under an appropriate control law. This paper analyzes the computational complexity of these procedures for two classes of control Lyapunov functions. The systems considered are those which are nonlinear in only a few state variables and which may be affected by control constraints and bounded disturbances. This paper extends previous work by the authors, which develops a procedure for stability analysis for these systems whose computational complexity is exponential only in the dimension of the "nonlinear" states and polynomial in the dimension of the remaining states. The main results are illustrated by a numerical example for the case of purely quadratic control Lyapunov functions.

Key words. Lyapunov methods, nonlinear control systems, computational methods, robustness, bounded control

1. Introduction.

Many dynamical systems can be represented by ordinary differential equations in the physical states of the system influenced by other parameters, such as disturbance and control inputs. The focus of state-feedback control theory is to design a *control law* (a function which maps measured states of the system to control inputs) which produces a desired performance for the system. Very different theories apply to this problem depending on whether the state derivatives are linear or nonlinear functions of the states in the differential equations defining the system. Many simple, straightforward techniques for robust optimal control of linear systems have been developed. Extensions of these methods to nonlinear systems are sometimes possible, but the analogous procedures which result from this exercise cannot typically be executed in a computationally tractable way. As a result, control of nonlinear systems has been a topic of intense research for some time.

Progress on the nonlinear control problem is difficult because of the inherent complexity of methods which are general enough to apply to arbitrary nonlinear systems. One method which has recently come into favor is to construct a stabilizing control law based on a known *control Lyapunov function* (CLF) for the system [2, 13, 27, 29]. A function is a CLF if a control law exists to render it a Lyapunov function for the closed-loop system. The computation of a stabilizing control law is straightforward

from any of a number of universal formulas [13, 17, 27] based on the CLF and the system dynamics, so the control synthesis problem is reduced to constructing a CLF for the system and computing the region of state space over which a control exists to stabilize the system based on the given CLF. Recently, the authors have developed a computationally efficient procedure for solving a version of the nonlinear control problem (Problem 1 below) based on a given CLF [18, 19]. In its general form, the procedure requires one to construct a CLF and to determine the region of state space over which that CLF guarantees stability of the closed-loop system. In this paper, we analyze the computational complexity of these two problems for two important classes of Lyapunov functions.

We consider the problem of designing a control law which stabilizes a nonlinear system in the sense prescribed by Definition 1.2 below. The formal stability definition is a version of the concept of uniform asymptotic stability used in [16]. That definition is repeated below.

DEFINITION 1.1 (see [16]). *Given a system $\dot{x} = f(x, w)$ with $w(t) \in \mathcal{W} \subseteq R^l$ for all $t \geq 0$ and a compact subset $\Omega \subset R^n$, define $\|x\|_\Omega \doteq \inf\{\|x - y\|, y \in \Omega\}$. Then the system is* robustly uniformly asymptotically stable with respect to Ω, *or RUAS-Ω, if the following conditions hold:*

1. *For every $x(0) \in R^n$ and $w(t) \in \mathcal{W}$, the solution $x(t)$ is defined for all $t \geq 0$.*
2. *Uniform stability: There exists a radially unbounded, continuous, strictly increasing function $\delta(\epsilon)$, with $\delta(0) = 0$, such that, for any $\epsilon > 0$, $\|x(0)\|_\Omega \leq \delta(\epsilon)$, $t \geq 0$, and $w(t) \in \mathcal{W}$, we have $\|x(t)\|_\Omega < \epsilon$.*
3. *Uniform attraction: For any $r, \epsilon > 0$, there exists $T > 0$, such that for every $w(t) \in \mathcal{W}$, $\|x(t)\|_\Omega < \epsilon$ whenever $\|x(0)\|_\Omega < r$ and $t \geq T$.*

DEFINITION 1.2. *Given a system $\dot{x} = f(x, w)$ with $w(t) \in \mathcal{W} \subseteq R^l$ for all $t \geq 0$, a positively invariant set $\mathcal{X} \subseteq R^n$, and a compact subset $\Omega \subset \mathcal{X}$, the system is* robustly uniformly asymptotically stable over $\mathcal{X}$ with respect to Ω, *or RUAS($\mathcal{X}$,Ω), if it is RUAS-Ω whenever $x(0) \in \mathcal{X}$. We call the set $\mathcal{X}$ a* region of stability *for the system.*

In particular, we consider the following control synthesis problem.

PROBLEM 1. *Consider a continuous time, time-invariant, nonlinear system influenced by a control $u(t)$ in a closed subset $\mathcal{U} \subseteq R^m$ and a disturbance $w(t) \in \mathcal{W} \subseteq R^l$. The state vector $x(t) \in R^n$ is partitioned into $x_N \in R^k$ and $x_L \in R^{n-k}$, and the system has the form*

$$\begin{aligned} \begin{bmatrix} \dot{x}_N \\ \dot{x}_L \end{bmatrix} &= \begin{bmatrix} f_N(x_N) \\ f_L(x_N) \end{bmatrix} + \begin{bmatrix} A_N(x_N) \\ A_L(x_N) \end{bmatrix} x_L \\ &\quad + \begin{bmatrix} g_w^N(x_N) \\ g_w^L(x_N) \end{bmatrix} w + \begin{bmatrix} g_u^N(x_N) \\ g_u^L(x_N) \end{bmatrix} u, \end{aligned} \tag{1.1}$$

where all functions of x_N are C^1. Construct sets $\Omega \subset \mathcal{X} \subseteq R^n$ containing an equilibrium point at $x = 0$ and a static state-feedback control law $\mu : \mathcal{X} \to \mathcal{U}$ such that the closed-loop system with $u = \mu(x)$ is RUAS($\mathcal{X}$,Ω).

Note that Problem 1 includes the problem of analyzing robust stability for an autonomous system without control, since this is just the case $\mathcal{U} = \{0\}$.

Obviously, we would like $\mathcal{X}$ to be as large as possible and Ω as small as possible. When $\mathcal{W} = \{0\}$ and the system is locally asymptotically stabilizable, local stabilization theory yields a set $\mathcal{X}$ such that the system is RUAS($\mathcal{X}$,$\{0\}$) [30, 13]. To compute the region of stability generally requires computation times which are exponential in the state dimension n; for the system (1.1), however, the computations required to find $\mathcal{X}$ are tractable.

In many applications, the engineer knows from the physics of the problem that only a few physical quantities affect the system dynamics in a nonlinear way, so that the system can be modeled in the form (1.1). Such systems are also considered in [3], where the *output-feedback* stabilization problem (with output x_N) is solved based on an output control Lyapunov function, assuming that the solution to the state-feedback stabilization problem is already available and the output CLF can be constructed.

We now define some relevant terms pertaining to a system of the general form given below, where $f \in C^1(R^n \to R^n)$ and $g_w(x)$ and $g_u(x)$ are continuous:

$$\dot{x} = f(x) + g_w(x)w + g_u(x)u. \tag{1.2}$$

DEFINITION 1.3. *A* level set *of a proper, positive-definite function $V : R^n \to R$ is defined by real numbers $c_2 > c_1 \geq 0$ via $V^{-1}[c_1, c_2] \doteq \{x \in R^n \mid c_1 \leq V(x) \leq c_2\}$.*

DEFINITION 1.4 (see [5]). *Given a locally Lipschitz function $V : R^n \to R$ and a continuous vector field f on R^n, the* Lie derivative of $V(x)$ along $f(x)$ *is defined by*

$$L_f V(x) \doteq \limsup_{t \to 0^+} \frac{V(x + tf(x)) - V(x)}{t}.$$

If $V(x)$ is differentiable at a point $x \in R^n$, then $L_f V(x) = \frac{\partial V}{\partial x}(x) f(x)$.

DEFINITION 1.5 (see [12, 27]). *Consider a subset $\mathcal{W} \subseteq R^l$, a closed subset $\mathcal{U} \subseteq R^m$, a positive-definite function $W(x)$, and real numbers $c_2 > c_1 \geq 0$. A proper, positive-definite C^1 function $V(x)$ is a* robust control Lyapunov function (RCLF) with stability margin $W(x)$ with controls in $\mathcal{U}$ over $V^{-1}[c_1, c_2]$ *for the system* (1.2) *if there exists a control law $\mu : R^n \to \mathcal{U}$ such that*

$$\sup_{x \in V^{-1}[c_1,c_2]} \sup_{w \in \mathcal{W}} L_f V(x) + L_{g_w} V(x) w + L_{g_u} V(x) \mu(x) + W(x) \leq 0.$$

Equivalently,

$$\sup_{x \in V^{-1}[c_1,c_2]} \inf_{u \in \mathcal{U}} \sup_{w \in \mathcal{W}} L_f V(x) + L_{g_w} V(x) w + L_{g_u} V(x) u + W(x) \leq 0.$$

REMARK 1. *If $\mathcal{U} = R^m$, the condition in Definition* 1.5 *is equivalent to*

$$\sup_{x \in V^{-1}[c_1,c_2] \cap \ker(L_{g_u} V)} \sup_{w \in \mathcal{W}} L_f V(x) + L_{g_w} V(x) w + W(x) \leq 0.$$

By Definition 1.5, if $V(x)$ is an RCLF, then a static state-feedback control law exists such that the closed-loop system is robustly stable in the sense defined by Definition 1.2. We now proceed to show how to determine whether a given function $V(x)$ is an RCLF over a given level set in section 2. In section 3, we investigate the problem of finding the RCLF $V(x)$ which maximizes the volume of the region over which stability can be guaranteed. We also analyze the computational complexity of these procedures in each of these sections. A numerical example is presented in section 4 to illustrate the findings of the paper. The main results are summarized in section 5.

2. Stability analysis using a given RCLF. Given an RCLF $V(x)$ and a stability margin $W(x)$, our objective is to determine whether $V(x)$ is an RCLF with stability margin $W(x)$ with controls in $\mathcal{U}$ over some level set given by $V^{-1}[c_1, c_2]$ for

the nonlinear system (1.1). By Definition 1.5, this stability condition holds if and only if

$$\sup_{x\in V^{-1}[c_1,c_2]} \inf_{u\in\mathcal{U}} \sup_{w\in\mathcal{W}} L_f V(x) + L_{g_w} V(x) w + L_{g_u} V(x) u + W(x) \le 0. \tag{2.1}$$

Since the term $\inf_{u\in\mathcal{U}} L_{g_u} V(x) u$ is a constant over sets of the form $\{x \in R^n \mid L_{g_u} V(x) = \psi^T\}$ for $\psi \in R^m$, it is useful to parameterize sets of this form when evaluating the condition (2.1).

Under certain assumptions which are made precise in sections 2.1–2.2, the set $\{x \in R^n \mid L_{g_u} V(x) = \psi^T\}$ can be parameterized by x_N and a parameter $\lambda \in R^{n-k-m}$. With this parameterization, we can express $V(x)$ restricted to $\{x \in R^n \mid L_{g_u} V(x) = \psi^T\}$ by a function $V(x_N, \psi, \lambda)$. This parameterization can be chosen so that $V(x_N, \psi, \lambda)$ is minimized at $\lambda = 0$ for each (x_N, ψ).

To analyze stability over the level set $V^{-1}[c_1, c_2]$, we first make the following definitions:

$$\begin{aligned}
\mathcal{Y}(c_2) &\doteq \{(x_N, \psi) \in R^k \times R^m \mid V(x_N, \psi, 0) \le c_2\},\\
\mathcal{Z}(c_1, c_2, x_N, \psi) &\doteq \{\lambda \in R^{n-k-m} \mid c_1 \le V(x_N, \psi, \lambda) \le c_2\},\\
\Gamma(x_N, \psi, \lambda) &\doteq \sup_{w\in\mathcal{W}} L_f V(x) + L_{g_w} V(x) w + \left[\inf_{u\in\mathcal{U}} \psi^T u\right] + W(x),\\
\Gamma(c_1, c_2, x_N, \psi) &\doteq \max_{\lambda\in\mathcal{Z}(c_1,c_2,x_N,\psi)} \Gamma(x_N, \psi, \lambda).
\end{aligned}$$

The set $\mathcal{Y}(c_2)$ is simply the allowable range of (x_N, ψ) in the given level set, and $\mathcal{Z}(c_1, c_2, x_N, \psi)$ maps the level set to the parameter space of the variable λ.

PROPOSITION 2.1. *$V(x)$ is an RCLF with stability margin $W(x)$ with controls in $\mathcal{U}$ over $V^{-1}[c_1, c_2]$ if and only if $\Gamma(c_1, c_2, x_N, \psi) \le 0$ for all $(x_N, \psi) \in \mathcal{Y}(c_2)$.*

The condition in Proposition 2.1 implies that $\Gamma(c_1, c_2, x_N, \psi) \le 0$ for all $(x_N, \psi) \in R^k \times R^m$. Since $\mathcal{Y}(c_2)$ is compact, we check the condition in Proposition 2.1 by gridding $\mathcal{Y}(c_2)$ and solving a feasibility problem to determine whether $\Gamma(c_1, c_2, x_N, \psi) \le 0$ for all (x_N, ψ) in the grid.

When $\mathcal{U} = R^m$, we see from Remark 1 that we need only to check whether $\Gamma(c_1, c_2, x_N, \psi) \le 0$ for $\psi = 0$. In this case, it is necessary only to grid over the permissible values of x_N, which is a compact region of dimension k rather than dimension $(k + m)$. Therefore, Proposition 2.1 holds with the following modified definition:

$$\mathcal{Y}(c_2) \doteq \{(x_N, \psi) \in R^k \times R^m \mid \psi = 0, V(x_N, 0, 0) \le c_2\}.$$

REMARK 2. *The procedure just described also applies in the analysis of closed-loop robust stability under a control law of the form $\mu(x) = \mu_N(x_N) + \mu_L(x_N) x_L$. In this case, the control is already fixed, so we do not need to parameterize sets of the form $\{x \in R^n \mid L_{g_u} V(x) = \psi^T\}$. In other words, we simply parameterize the level set $V^{-1}[c_1, c_2]$ by the variable x_N. The only additional step is to check that $\mu(x) \in \mathcal{U}$ over $V^{-1}[c_1, c_2]$, but this is straightforward for certain common classes of control constraint sets* [21].

In sections 2.1–2.2, we fill in the details of this stability analysis procedure for two specific Lyapunov function classes and evaluate the computational complexity of the procedure in each case.

2.1. Quadratic RCLF with constant P matrix. In this section, we fill in the details of the stability analysis procedure for the special case of a standard quadratic RCLF and stability margin of the form

$$V(x) = x^T P x = x_N^T P_{NN} x_N + x_N^T P_{NL} x_L + x_L^T P_{LN} x_N + x_L^T P_{LL} x_L, \tag{2.2}$$

$$W(x) = x^T Q x = x_N^T Q_{NN} x_N + x_N^T Q_{NL} x_L + x_L^T Q_{LN} x_N + x_L^T Q_{LL} x_L. \tag{2.3}$$

We begin by parameterizing sets of the form $\{x \in R^n \mid L_{g_u} V(x) = \psi^T\}$ for $\psi \in R^m$. For a system of the form (1.1) and a Lyapunov function (2.2), we have

$$\begin{aligned} L_{g_u} V(x) &= 2x_N^T [P_{NN} g_u^N(x_N) + P_{NL} g_u^L(x_N)] + 2x_L^T Y(x_N), \\ Y(x_N) &\doteq P_{LN} g_u^N(x_N) + P_{LL} g_u^L(x_N). \end{aligned}$$

To simplify the algebra, we make the following assumption.

ASSUMPTION 1. *For all $x_N \in R^k$, rank $Y(x_N) = m \leq n - k$.*

Assumption 1 can be relaxed, if necessary, with some modifications to the analysis which follows. Theorem 2.2 shows how the set $\{x \in R^n \mid L_{g_u} V(x) = \psi^T\}$ can be parameterized by x_N and a parameter $\lambda \in R^{n-k-m}$.

THEOREM 2.2. *Given a function $V(x)$ of the form (2.2) and a vector $\psi \in R^m$,*

$$\begin{aligned} &\{x \in R^n \mid L_{g_u} V(x) = \psi^T\} \\ &\quad = \left\{ \begin{bmatrix} x_N \\ G(x_N)\lambda - P_{LL}^{-1} P_{LN} x_N - \xi(x_N, \psi) \end{bmatrix}, x_N \in R^k, \lambda \in R^{n-k-m} \right\}, \\ &\xi(x_N, \psi) \doteq P_{LL}^{-1} Y(x_N) [Y(x_N)^T P_{LL}^{-1} Y(x_N)]^{-1} \left[g_u^N(x_N)^T R x_N - \frac{1}{2}\psi \right], \\ &\quad R \doteq P_{NN} - P_{NL} P_{LL}^{-1} P_{LN}, \end{aligned}$$

for any matrix $G(x_N) \in R^{(n-k)\times(n-k-m)}$ of full rank such that $Y(x_N)^T G(x_N) \equiv 0$.

Proof. Note that since $G(x_N)$ is full rank, $G(x_N)\lambda$ completely characterizes the null space of $Y(x_N)^T$. Therefore, if any element in the set described above is an element of $\{x \in R^n \mid L_{g_u} V(x) = \psi^T\}$, then that set is equal to $\{x \in R^n \mid L_{g_u} V(x) = \psi^T\}$. Hence, it is sufficient to check the value of $L_{g_u} V(x)$ when $\lambda = 0$:

$$\begin{aligned} L_{g_u} V(x) &= 2x_N^T [P_{NN} g_u^N(x_N) + P_{NL} g_u^L(x_N)] + 2x_L^T Y(x_N) \\ &= 2x_N^T [P_{NN} g_u^N(x_N) + P_{NL} g_u^L(x_N)] - 2[P_{LL}^{-1} P_{LN} x_N + \xi(x_N, \psi)]^T Y(x_N) \\ &= 2x_N^T R g_u^N(x_N) - 2\left[g_u^N(x_N) R x_N - \frac{1}{2}\psi \right]^T = \psi^T. \end{aligned}$$

With the parameterization of Theorem 2.2, we can express $V(x)$ restricted to $\{x \in R^n \mid L_{g_u} V(x) = \psi^T\}$ as follows:

$$V(x_N, \psi, \lambda) = x_N^T R x_N + \xi(x_N, \psi)^T P_{LL} \xi(x_N, \psi) + \lambda^T G(x_N)^T P_{LL} G(x_N) \lambda.$$

In order to grid $\mathcal{Y}(c_2)$, we need bounds on the values of x_N and ψ which can be achieved on this set. The permissible values of x_N are those satisfying $x_N^T R x_N \leq c_2$. Now, for fixed x_N, $L_{g_u} V(x)$ is affine in x_L for systems of the form (1.1). Hence, each element of $L_{g_u} V(x)$ can be represented as $[L_{g_u} V(x)]_p = a_p(x_N) + x_L^T b_p(x_N)$, where

$$\begin{aligned} \begin{bmatrix} a_1(x_N) & \cdots & a_m(x_N) \end{bmatrix} &= 2x_N^T [P_{NN} g_u^N(x_N) + P_{NL} g_u^L(x_N)], \\ \begin{bmatrix} b_1(x_N) & \cdots & b_m(x_N) \end{bmatrix} &= 2Y(x_N). \end{aligned}$$

The bounds on each element ψ_p are therefore given as follows:

$$\min_{V(x)\le c_2} a_p(x_N) + x_L^T b_p(x_N) \le \psi_p \le \max_{V(x)\le c_2} a_p(x_N) + x_L^T b_p(x_N).$$

By the method of Lagrange multipliers [28], we find this to be equivalent to

$$\alpha_p(x_N) - \beta_p(x_N) \le \psi_p \le \alpha_p(x_N) + \beta_p(x_N), \tag{2.4}$$

where, for $x_N^T R x_N \le c_2$,

$$\alpha_p(x_N) \doteq a_p(x_N) - b_p(x_N)^T P_{LL}^{-1} P_{LN} x_N,$$
$$\beta_p(x_N) \doteq \sqrt{[c_2 - x_N^T R x_N][b_p(x_N)^T P_{LL}^{-1} b_p(x_N)]}.$$

The bounds in (2.4) give us the set of values of $L_{g_u} V(x)$ over which we must grid in order to complete the stability analysis. If $\psi = 0$ is within the allowable range for a given x_N, we should use this as one of the grid points to ensure that at least the condition for stability from Remark 1 for the case of unlimited control ($\mathcal{U} = R^m$) is satisfied.

By Theorem 2.2, we can parameterize the stability condition as follows for each $(x_N, \psi) \in \mathcal{Y}(c_2)$:

$$\begin{aligned}\Gamma(x_N, \psi, \lambda) = \sup_{w\in\mathcal{W}} & a_0(x_N, \psi) + b_0(x_N, \psi)^T \lambda + \lambda^T C_0(x_N)\lambda \\ & + w^T[s(x_N, \psi) + T(x_N)\lambda].\end{aligned} \tag{2.5}$$

The coefficients can be found by straightforward algebra. We can check the condition $\Gamma(c_1, c_2, x_N, \psi) \le 0$ by solving a linear matrix inequality (LMI) feasibility problem using the $\mathcal{S}$-procedure as discussed in [6]. Let us first consider the case of no disturbances ($\mathcal{W} = \{0\}$), for which the parameterized stability condition (2.5) gives us

$$\Gamma(c_1, c_2, x_N, \psi) = \max_{c_1 \le V(x_N, \psi, \lambda) \le c_2} a_0(x_N, \psi) + b_0(x_N, \psi)^T \lambda + \lambda^T C_0(x_N)\lambda. \tag{2.6}$$

Checking whether $\Gamma(c_1, c_2, x_N, \psi) \le 0$ is therefore a quadratic feasibility problem with quadratic constraints, which can be solved using the $\mathcal{S}$-procedure in the manner discussed in [6]. With only one quadratic constraint, the $\mathcal{S}$-procedure is nonconservative [6], but a potential problem arises in our case because there are two constraints. Fortunately, the two constraints are never simultaneously active, as shown in the following theorem.

THEOREM 2.3. *Suppose $(x_N, \psi) \in \mathcal{Y}(c_2)$, and consider the maximization problem (2.6). If $C_0(x_N) \not\prec 0$, then $\Gamma(c_1, c_2, x_N, \psi) = \Gamma(0, c_2, x_N, \psi)$. If $C_0(x_N) < 0$, one of the following applies for $\lambda^* = -\frac{1}{2} C_0(x_N)^{-1} b_0(x_N, \psi)$:*

1. *If $V(x_N, \psi, \lambda^*) < c_1$, then $\Gamma(c_1, c_2, x_N, \psi) = \Gamma(c_1, \infty, x_N, \psi)$.*
2. *If $V(x_N, \psi, \lambda^*) > c_2$, then $\Gamma(c_1, c_2, x_N, \psi) = \Gamma(0, c_2, x_N, \psi)$.*
3. *Otherwise, $\Gamma(c_1, c_2, x_N, \psi) = a_0(x_N, \psi) - \frac{1}{4} b_0(x_N, \psi)^T C_0(x_N)^{-1} b_0(x_N, \psi)$.*

Proof. See Appendix A.

Consider next the case where $\mathcal{W}$ is polytopic; for example, $\mathcal{W} = \{w \mid \|w\|_\infty \le 1\}$ belongs to this category. Since the expression in (2.5) is affine in w, robust stability can be analyzed exactly using Theorem 2.3 with each of the extreme points of $\mathcal{W}$ substituted for w. This approach gives us the value of

$$\begin{aligned}\Gamma(c_1, c_2, x_N, \psi) = \max_{w\in\mathcal{V}} \max_{c_1 \le V(x_N, \psi, \lambda) \le c_2} & [a_0(x_N, \psi) + s(x_N, \psi)^T w] \\ & + [b_0(x_N, \psi) + T(x_N)^T w]^T \lambda + \lambda^T C_0(x_N)\lambda,\end{aligned}$$

TABLE 2.1
Computation times for stability analysis using a quadratic RCLF with a constant P matrix.

Operation	Time (unbounded control)	Time (bounded control)
Solve for $L_{g_u}V(x) = \psi^T$	$\mathcal{O}(N_c^k n^3)$	$\mathcal{O}(N_c^{k+m} n^3)$
Compute $V(x_N, \psi, \lambda)$	$\mathcal{O}(N_c^k n^4)$	$\mathcal{O}(N_c^{k+m} n^4)$
Check $\Gamma(c_1, c_2, x_N, \psi) \leq 0$	$\mathcal{O}(2^l N_c^k n^3)$	$\mathcal{O}(2^l N_c^{k+m} n^3)$

where $\mathcal{V}$ is the set of extreme points of $\mathcal{W}$. Other classes of disturbance constraints can be handled in the $\mathcal{S}$-procedure framework, but we do not enumerate them here.

We now analyze the computational complexity of the stability analysis procedure outlined in this section. To verify whether a desired stability margin is achieved over a given level set, we must parameterize the set $\{x \in R^n \mid L_{g_u}V(x) = \psi^T\}$ and the level set. We then evaluate robust stability over the resulting parameterized set at various grid point values of x_N (and ψ if there are control limitations). Approximate computation times determined numerically for a system influenced by disturbances contained in $\mathcal{W} = \{w \in R^l \mid \|w\|_\infty \leq 1\}$ are listed in Table 2.1. The quantity N_c is the number of grid points in $\mathcal{Y}(c_2)$ over each dimension, so that the total number of grid points is roughly N_c^k (or N_c^{k+m} if there are control limitations).

The complexity of this procedure should be compared with the complexity of evaluating Lyapunov derivatives over a level set to determine the region of stability for a general nonlinear system. This problem is discussed in [8, 9, 10, 14, 15, 20, 24, 26]. For an arbitrary nonlinear system, it is necessary to grid the level set over all dimensions, so the computation times required to solve this problem to some desired accuracy grow exponentially with the state dimension. In the procedure developed here for the system (1.1), on the other hand, we grid only $(x_N, \psi) \in \mathcal{Y}(c_2)$ and evaluate whether $\Gamma(c_1, c_2, x_N, \psi) \leq 0$ at each grid point. By Theorem 2.3, this reduces to an LMI feasibility problem, and there are standard methods for solving this problem to a desired level of accuracy with a computation time which is polynomial in the state dimension [6, 23]. For example, the author implemented an ellipsoid algorithm [6] and found the computation time to vary roughly as $(n-k-m)^3$. Due to gridding over $\mathcal{Y}(c_2)$, the computation time is still exponential in $\dim(x_N)$ or in $\dim(x_N) + \dim(u)$ when control constraints are active. In other words, the computational complexity is exponential only in the degree of nonlinearity in the problem.

2.2. Quadratic RCLF with state-dependent *P* matrix. In this section, we fill in the details of the stability analysis procedure for the special case of an RCLF and stability margin which are arbitrarily nonlinear in x_N but quadratic in x_L. In other words, $V(x)$ and $W(x)$ have the form

$$V(x) = x^T P(x_N) x, \tag{2.7}$$

$$W(x) = x^T Q(x_N) x, \tag{2.8}$$

where $P \in C^1(R^k \to R^{n \times n})$ and $Q \in C^0(R^k \to R^{n \times n})$. We assume that $V(x)$ and $W(x)$ are positive-definite and that the matrices $P(x_N)$ and $Q(x_N)$ are partitioned in the same manner as for the P and Q matrices in section 2.1.

We begin by parameterizing sets of the form $\{x \in R^n \mid L_{g_u}V(x) = \psi^T\}$ for $\psi \in R^m$. We can simplify the treatment considerably by making the following assumption on the system (1.1).

ASSUMPTION 2. *For all $x_N \in R^k$, $g_u^N(x_N) = 0$.*

For a system of the form (1.1) satisfying Assumption 2 and a Lyapunov function of the form (2.7), we have

$$L_{g_u}V(x) = 2x_N^T P_{NL}(x_N) g_u^L(x_N) + x_L^T Y(x_N),$$
$$Y(x_N) \doteq 2P_{LL}(x_N) g_u^L(x_N).$$

To simplify the algebra, we make the following assumption.

ASSUMPTION 3. *For all* $x_N \in R^k$, rank $g_u^L(x_N) = m \le n-k$.

Note that Assumption 3 is equivalent to the condition that rank $Y(x_N) = m$ for all $x_N \in R^k$. This assumption can be relaxed, if necessary, with some modifications to the analysis which follows. Theorem 2.4 shows how the set $\{x \in R^n \mid L_{g_u}V(x) = \psi^T\}$ can be parameterized by x_N and a parameter $\lambda \in R^{n-k-m}$.

THEOREM 2.4. *Given a function* $V(x)$ *of the form* (2.7) *and a vector* $\psi \in R^m$,

$$\{x \in R^n \mid L_{g_u}V(x) = \psi^T\} = \left\{ \begin{bmatrix} x_N \\ \sigma(x_N, \psi) \end{bmatrix}, x_N \in R^k, \lambda \in R^{n-k-m} \right\},$$
$$\sigma(x_N, \psi) \doteq G(x_N)\lambda - P_{LL}(x_N)^{-1}P_{LN}(x_N)x_N + P_{LL}(x_N)^{-1}Y(x_N)[Y(x_N)^T P_{LL}(x_N)^{-1}Y(x_N)]^{-1}\psi,$$

for any matrix $G(x_N) \in R^{(n-k)\times(n-k-m)}$ *of full rank such that* $Y(x_N)^T G(x_N) \equiv 0$.

Proof. The proof of Theorem 2.4 follows the same arguments as the proof of Theorem 2.2.

With the parameterization of Theorem 2.4, we can express $V(x)$ restricted to $\{x \in R^n \mid L_{g_u}V(x) = \psi^T\}$ as follows:

$$V(x_N, \psi, \lambda) = x_N^T R(x_N) x_N + \psi^T [Y(x_N)^T P_{LL}(x_N)^{-1} Y(x_N)]^{-1}\psi + \lambda^T G(x_N)^T P_{LL}(x_N) G(x_N)\lambda,$$
$$R(x_N) \doteq P_{NN}(x_N) - P_{NL}(x_N)P_{LL}(x_N)^{-1}P_{LN}(x_N).$$

In order to grid $\mathcal{Y}(c_2)$, we need bounds on the values of x_N and ψ which can be achieved on this set. The permissible values of x_N are those satisfying $x_N^T R(x_N) x_N \le c_2$. Similarly, the permissible values of $L_{g_u}V(x) = \psi^T$ corresponding to each such value of x_N are those contained in the ellipsoid described by

$$\psi^T [Y(x_N)^T P_{LL}(x_N)^{-1} Y(x_N)]^{-1}\psi \le c_2 - x_N^T R(x_N) x_N.$$

This is the set of values of $L_{g_u}V(x)$ over which we must grid in order to complete the stability analysis. We should always use $\psi = 0$ as one of the grid points to ensure that at least the condition for stability from Remark 1 for the case of unlimited control ($\mathcal{U} = R^m$) is satisfied.

By Theorem 2.4, we can parameterize the stability condition as follows for each $(x_N, \psi) \in \mathcal{Y}(c_2)$:

$$\Gamma(x_N, \psi, \lambda) = \sup_{w \in \mathcal{W}} a_0(x_N, \psi) + b_0(x_N, \psi)^T\lambda + \lambda^T C_0(x_N, \psi)\lambda + w^T[s(x_N, \psi) + T(x_N, \psi)\lambda] + \sum_{i=1}^{k} [\lambda^T D_i(x_N)\lambda][h_i(x_N)^T\lambda + v_i(x_N)^T w]. \tag{2.9}$$

The coefficients can be found by straightforward algebra. We can rearrange the expression for $\Gamma(c_1, c_2, x_N, \psi)$ when $(x_N, \psi) \in \mathcal{Y}(c_2)$ by introducing the following scaling matrix:

$$K(x_N, \psi) \doteq \sqrt{c_2 - V(x_N, \psi, 0)}\left[G(x_N)^T P_{LL}(x_N) G(x_N)\right]^{-1/2},$$

where $M^{-1/2}$ is the positive-definite square root of M^{-1} for $M = M^T > 0$. Then we can replace λ by $K(x_N, \psi)\lambda$ and set $b_0 \leftarrow Kb_0$, $C_0 \leftarrow KC_0K$, $T \leftarrow TK$, $D_i \leftarrow KD_iK$, and $h_i \leftarrow Kh_i$ to obtain

$$\begin{aligned}\Gamma(c_1, c_2, x_N, \psi) = \max_{\beta(x_N,\psi)\le\lambda^T\lambda\le 1} \sup_{w\in\mathcal{W}} & a_0(x_N,\psi) + b_0(x_N,\psi)^T\lambda + \lambda^T C_0(x_N,\psi)\lambda \\ & + w^T[s(x_N,\psi) + T(x_N,\psi)\lambda] \\ & + \sum_{i=1}^{k}[\lambda^T D_i(x_N,\psi)\lambda][h_i(x_N,\psi)^T\lambda + v_i(x_N)^T w],\end{aligned} \tag{2.10}$$

where $\beta(x_N, \psi) = [c_1 - V(x_N, \psi, 0)]/[c_2 - V(x_N, \psi, 0)] \le 1$. This alternative form simplifies the development of a method to evaluate the stability condition.

Checking the condition $\Gamma(c_1, c_2, x_N, \psi) \le 0$ is a nonconvex constrained feasibility problem, which is known to be NP-hard [7, 22]. However, in practice, good upper and lower bounds can be computed in polynomial time by transforming the problem to a real μ analysis problem of the type developed in [31]. Let us first consider the case of no disturbances ($\mathcal{W} = \{0\}$). We approximate the parameterized stability condition (2.10) by

$$\begin{aligned}\tilde{\Gamma}(0, c_2, x_N, \psi) &\doteq \max_{\|\lambda\|_\infty\le 1} \phi_0(\lambda), \\ \phi_0(\lambda) &\doteq a_0 + b_0^T\lambda + \lambda^T C_0\lambda + \sum_{i=1}^{k}\lambda^T h_i(\lambda^T D_i\lambda),\end{aligned} \tag{2.11}$$

where we have suppressed the dependence of the coefficients in (2.11) on (x_N, ψ). By assuming $\mathcal{W} = \{0\}$, we guarantee that $c_1 = 0$. This implies that $\beta(x_N, \psi) \le 0$; in other words, the constraint set in (2.10) is given by $\|\lambda\|_2 \le 1$. It is useful to the development of the procedure which follows that this set is convex. We also replace the condition $\|\lambda\|_2 \le 1$ by $\|\lambda\|_\infty \le 1$. Since $\|\lambda\|_\infty \le \|\lambda\|_2$, this approach is conservative because $\Gamma(0, c_2, x_N, \psi) \le \tilde{\Gamma}(0, c_2, x_N, \psi)$. Nevertheless, we obtain the following test for stability, which is adapted from Proposition 2.1.

PROPOSITION 2.5. *If $\mathcal{W} = \{0\}$, then $V(x)$ is an RCLF with stability margin $W(x)$ with controls in $\mathcal{U}$ over $V^{-1}[0, c_2]$ if $\tilde{\Gamma}(0, c_2, x_N, \psi) \le 0$ for all $(x_N, \psi) \in \mathcal{Y}(c_2)$.*

We now show how Proposition 2.5 can be converted to a real μ analysis problem. Recall that in the real μ analysis problem, we are given a matrix M and an uncertainty class $\mathbf{\Delta}$, and we seek to evaluate

$$\mu(M, \mathbf{\Delta}) \doteq \begin{cases} \left[\min_{\Delta\in\mathbf{\Delta}}\{\bar{\sigma}(\Delta) \mid \det(I + M\Delta) = 0\}\right]^{-1} & \exists\Delta \in \mathbf{\Delta} \mid \det(I + M\Delta) = 0, \\ 0 & \text{otherwise.}\end{cases}$$

In other words, $\mu(M, \mathbf{\Delta})$ is the maximum singular value of the smallest perturbation $\Delta \in \mathbf{\Delta}$ which destabilizes a linear fractional interconnection between M and Δ by the small gain theorem [31]. Our objective here is to transform Proposition 2.5 to a problem of computing $\mu(M, \mathbf{\Delta})$ for some relevant M and $\mathbf{\Delta}$.

The following theorem is a general result on how to convert the problem of maximizing any rational function of a constrained variable to a real μ analysis problem.

THEOREM 2.6 (see [7]). *For any $q \ge 0$ and any expression $\phi_0(\lambda)$ which can be expressed as a linear fractional transformation of λ and λ^T, there exists a matrix M*

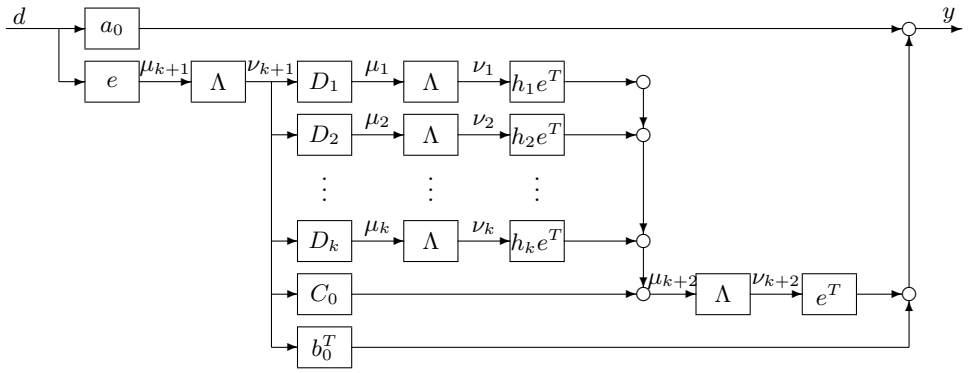

FIG. 2.1. *Block diagram representation of* $\phi_0(\lambda)$ *from* (2.11).

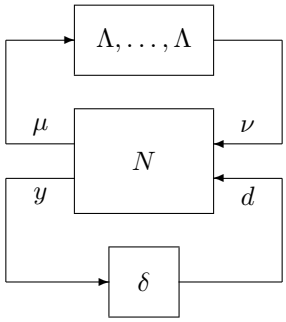

FIG. 2.2. *Block diagram from Figure* 2.1 *with uncertainty representation.*

and an uncertainty class $\mathbf{\Delta}$ *such that*

$$\max_{\|\lambda\|_\infty \le 1} |\phi_0(\lambda)| < q \Leftrightarrow \mu(M, \mathbf{\Delta}) < q. \tag{2.12}$$

A basic idea of how to compute M and $\mathbf{\Delta}$ is given in [7], where this is done (in slightly more generality) for a quadratic $\phi_0(\lambda)$. We seek to apply Theorem 2.6 when $\phi_0(\lambda)$ has the form (2.11), where $C_0 = C_0^T$ and $D_i = D_i^T$ for all $i = 1, \ldots, k$. Following [7], the first step is to generate a block diagram representation for $\phi_0(\lambda)$ from (2.11) such that $y = \phi_0(\lambda)d$ for $d, y \in R$. To this end, we define $e \doteq [1, \ldots, 1]^T$ with $\dim(e) = \dim(\lambda)$ and $\Lambda \doteq \mathrm{diag}(\lambda)$, so that $\lambda = \Lambda e$. Then $\phi_0(\lambda)$ is represented in block diagram form as in Figure 2.1.

Note that the Λ block is repeated $k+2$ times in Figure 2.1. It is useful to transform the block diagram to the alternative form shown in Figure 2.2, where

$$N = \left[\begin{array}{ccc|cc|c} 0 & \cdots & 0 & D_1 & 0 & 0 \\ \vdots & \ddots & \vdots & \vdots & \vdots & \vdots \\ 0 & \cdots & 0 & D_k & 0 & 0 \\ \hline 0 & \cdots & 0 & 0 & 0 & e \\ h_1e^T & \cdots & h_ke^T & C_0 & 0 & 0 \\ \hline 0 & \cdots & 0 & b_0^T & e^T & a_0 \end{array}\right], \quad \Delta = \left[\begin{array}{ccc|cc|c} \Lambda & & & & & \\ & \ddots & & & & \\ & & \Lambda & & & \\ \hline & & & \Lambda & & \\ & & & & \Lambda & \\ \hline & & & & & \delta \end{array}\right].$$

Note from (2.12) and the discussion in [7] that the condition $|\phi_0(\lambda)| < q$ is equivalent to $\mu(M, \mathbf{\Delta}) < q$ for any $q > 0$, where M is obtained by multiplying all but the last row of N by q.

At this stage we notice that $|\phi_0(\lambda)|$ is used in Theorem 2.6, but what we are really interested in is the maximum of $\phi_0(\lambda)$ itself over $\|\lambda\|_\infty \leq 1$. Fortunately, this distinction is not restrictive. Indeed, it is straightforward to find a crude lower bound L such that $\phi_0(\lambda) \geq L$ for all λ satisfying $\|\lambda\|_\infty \leq 1$. Given such a lower bound, we can define $\tilde{\phi}_0(\lambda) \doteq \phi_0(\lambda) - L$, and we have $|\tilde{\phi}_0(\lambda)| = \tilde{\phi}_0(\lambda)$ whenever $\|\lambda\|_\infty \leq 1$. By constructing $\tilde{M}$ based on $\tilde{\phi}_0(\lambda)$ rather than $\phi_0(\lambda)$, we obtain the following necessary and sufficient condition for a given bound on $\tilde{\Gamma}(0, c_2, x_N, \psi)$ to hold:

$$\mu(\tilde{M}, \mathbf{\Delta}) < q \Leftrightarrow \tilde{\Gamma}(0, c_2, x_N, \psi) < q + L.$$

In other words, the condition in Proposition 2.5 holds if $\mu(\tilde{M}, \mathbf{\Delta}) < -L$. Therefore, we can evaluate the stability condition using the standard real μ analysis procedure from [32].

Consider next the case where $\mathcal{W} = \{w \in R^l \mid \|w\|_\infty \leq 1\}$. Since the expression in (2.10) is affine in w, robust stability can be analyzed exactly by solving the nonconvex feasibility problem with each of the extreme points of $\mathcal{W}$ substituted for w. Alternatively, we could add a block $W \doteq \mathrm{diag}(w)$ to Figures 2.1 and 2.2 so that $y = \phi_0(\lambda)d$, where

$$\tilde{\Gamma}(0, c_2, x_N, \psi) \doteq \max_{\|\lambda\|_\infty \leq 1} \max_{\|w\|_\infty \leq 1} \phi_0(\lambda),$$

$$\phi_0(\lambda) \doteq a_0 + b_0^T\lambda + \lambda^T C_0 \lambda + w^T[s + T\lambda] + \sum_{i=1}^{k} (\lambda^T D_i \lambda)(h_i^T \lambda + v_i^T w).$$

Note, however, that we can only analyze stability in the special case $c_1 = 0$ using this procedure because the level set must be convex. In general, we expect the stability condition to be violated over the level set $V^{-1}[0, c_2]$ unless a matching condition on $g_w(x_N)$ and $g_u(x_N)$ holds.

We now analyze the computational complexity of the stability analysis procedure outlined in this section. The parameterizations of the set $\{x \in R^n \mid L_{g_u} V(x) = \psi^T\}$ and of the level set do not differ significantly from those used in section 2.1. Robust stability analysis can be accomplished either by general techniques for solving nonconvex constrained feasibility problems or by conversion to a real μ analysis problem. The nonconvex solution procedure is NP-hard [7, 22], but the solution (if it can be found) is exact. Alternatively, approximate bounds on $\tilde{\Gamma}(0, c_2, x_N, \psi)$ can be found using standard techniques for real μ analysis. The computational complexity of this approximation is analyzed in [32]. Approximate computation times for a system influenced by disturbances contained in $\mathcal{W} = \{w \in R^l \mid \|w\|_\infty \leq 1\}$ are listed in Table 2.2. The quantity N_c is the number of grid points in $\mathcal{Y}(c_2)$ over each dimension, so that the total number of grid points is roughly N_c^k (or N_c^{k+m} if there are control limitations). The quantity $N_\Delta \doteq (n - k - m)(k + 2) + l + 1$ is the dimension of the perturbation block Δ. The nonconvex solution procedure is at least as complex as gridding over the entire state space to evaluate the Lyapunov derivative.

3. Optimization over the RCLF. Now we turn our attention to the problem of constructing an RCLF such that the volume of the level set for guaranteed stability is maximized. This problem formulation is inspired by [10], in which a quadratic Lyapunov function is used to find the stability region of maximum volume for an

TABLE 2.2
Computation times for stability analysis using a quadratic RCLF with a state-dependent P matrix.

Operation	Time (unbounded control)	Time (bounded control)
Solve for $L_{g_u}V(x) = \psi^T$	$\mathcal{O}(N_c^k n^3)$	$\mathcal{O}(N_c^{k+m} n^3)$
Compute $V(x_N, \psi, \lambda)$	$\mathcal{O}(N_c^k n^4)$	$\mathcal{O}(N_c^{k+m} n^4)$
Nonconvex solution	$\mathcal{O}(2^l N_c^n)$	$\mathcal{O}(2^l N_c^n)$
μ upper bound	$\mathcal{O}(N_c^k N_\Delta^3)$	$\mathcal{O}(N_c^{k+m} N_\Delta^3)$

arbitrary nonlinear autonomous system of the form $\dot{x} = f(x)$. For this problem, we do not wish to impose a particular stability margin, so we consider the following modified definition for a function to be an RCLF.

DEFINITION 3.1. *Consider a subset $\mathcal{W} \subseteq R^l$, a closed subset $\mathcal{U} \subseteq R^m$, and real numbers $c_2 > c_1 > 0$. A proper, positive-definite C^1 function $V(x)$ is an RCLF with controls in $\mathcal{U}$ over $V^{-1}[c_1, c_2]$ for the system* (1.2) *if there exists a control law $\mu : R^n \to \mathcal{U}$ such that*

$$\sup_{x \in V^{-1}[c_1,c_2]} \sup_{w \in \mathcal{W}} L_f V(x) + L_{g_w} V(x) w + L_{g_u} V(x) \mu(x) < 0.$$

Equivalently,

$$\sup_{x \in V^{-1}[c_1,c_2]} \inf_{u \in \mathcal{U}} \sup_{w \in \mathcal{W}} L_f V(x) + L_{g_w} V(x) w + L_{g_u} V(x) u < 0.$$

REMARK 3. *If $\mathcal{U} = R^m$, the condition in Definition* 3.1 *is equivalent to*

$$\sup_{x \in V^{-1}[c_1,c_2] \cap \ker(L_{g_u} V)} \sup_{w \in \mathcal{W}} L_f V(x) + L_{g_w} V(x) w < 0.$$

Note that the analysis of stability over a level set in this scenario is slightly different from the procedure used in section 2 because we require the Lyapunov derivative to be strictly negative. In other words, if we define

$$\Gamma(x_N, \psi, \lambda) \doteq \sup_{w \in \mathcal{W}} L_f V(x) + L_{g_w} V(x) w + \left[\inf_{u \in \mathcal{U}} \psi^T u \right],$$
$$\Gamma(c_1, c_2, x_N, \psi) \doteq \max_{\lambda \in \mathcal{Z}(c_1,c_2,x_N,\psi)} \Gamma(x_N, \psi, \lambda),$$

then a condition for $V(x)$ to be an RCLF is given by Proposition 3.2.

PROPOSITION 3.2. *$V(x)$ is an RCLF with controls in $\mathcal{U}$ over $V^{-1}[c_1, c_2]$ if and only if $\Gamma(c_1, c_2, x_N, \psi) < 0$ for all $(x_N, \psi) \in \mathcal{Y}(c_2)$.*

Since we are optimizing over $V(x)$ at this point, we do not need to iterate over the level values to determine the largest region of stability. Therefore, we shall henceforth consider the problem of finding the function $V(x)$, which is an RCLF with controls in $\mathcal{U}$ over $V^{-1}[\gamma, 1]$ for some $\gamma > 0$ such that the volume of the set $V^{-1}[0, 1]$ is maximized. The appropriate value of γ depends on the RCLF. However, if we assume that there exists some nominal $V_0(x)$ which is an RCLF with controls in $\mathcal{U}$ over $V_0^{-1}[c_1, c_2]$, then we could fix γ to be the largest value satisfying $V^{-1}[0, \gamma] \subseteq V_0^{-1}[0, c_2]$. In this way, we can find a control law which renders the system RUAS($\mathcal{X}$,Ω) with $\mathcal{X} = V^{-1}[0, 1]$ and $\Omega = V_0^{-1}[0, c_1]$ by the method in [19]. In other words, the inner level set over which stability is guaranteed is independent of the particular RCLF used. Therefore,

a direct comparison of the volumes of sets of the form $V^{-1}[0,1]$ for different RCLFs is a meaningful comparison of the size of the stability region.

In sections 3.1–3.2, we describe the optimization procedures which might be applied to the two Lyapunov function classes of section 2 and evaluate the computational complexity of the procedure in each case.

3.1. Quadratic RCLF with constant P matrix. Our objective is to find a quadratic function $V(x)$ of the form (2.2) which is an RCLF with controls in $\mathcal{U}$ over $V^{-1}[\gamma,1]$ and which maximizes the volume of the level set $V^{-1}[0,1]$. Following [10], we can pose the following optimization problem.

PROBLEM 2. *Suppose that $V_0(x) \doteq x^T P_0 x$ is an RCLF with controls in $\mathcal{U}$ over $V_0^{-1}[c_1,c_2]$. Determine $P = P^T$ and γ from the following optimization problem:*

$$\begin{aligned} &\textit{minimize} && \det(P) \\ &\textit{subject to} && \gamma > 0, \\ &&& P/\gamma \geq P_0/c_2, \\ &&& \Gamma(\gamma, 1, x_N, \psi) < 0 \ \textit{ for all } (x_N,\psi) \in \mathcal{Y}(1). \end{aligned}$$

Problem 2 is a nonlinear, nonconvex optimization problem in the variables P and γ. From [6], we note that by casting the problem in terms of P^{-1} instead of P, we can rewrite the objective using the convex function $\log\det(P^{-1})$. However, the stability condition $\Gamma(\gamma,1,x_N,\psi) < 0$ is nonconvex in both P and P^{-1}, and there is no obvious way to reformulate Problem 2 to be convex. Consequently, Problem 2 is NP-hard. In particular, the computational complexity of this problem is comparable to the complexity of gridding over the set of symmetric positive-definite matrices P. Note that the largest value of γ which satisfies the constraint $P/\gamma \geq P_0/c_2$ can be computed exactly by $\gamma = c_2\lambda_{min}(PP_0^{-1})$.

An approximate solution to Problem 2 is developed in [11]. If the nonlinear terms in the dynamics of (1.1) are rational functions of x_N, then the system can be written in the following *linear fractional representation*:

$$\begin{aligned} \dot{x} &= Ax + B_w w + B_u u + B_p p, \\ q &= C_q x + D_{qw} w + D_{qu} u + D_{qp} p, \\ p &= \Delta(x) q, \\ \Delta(x_N) &= \operatorname{diag}(x_1 I_{r_1}, \ldots, x_k I_{r_k}). \end{aligned}$$

In other words, the nonlinear dynamics of the system are written as a linear fractional transformation (LFT) between a nominal linear time-invariant system and a perturbation block containing (possibly repeated) values of the "nonlinear" states x_N. Note that $\dim(q) = \dim(p) = \sum_{i=1}^{k} r_i$, which is the size of the perturbation block required to represent the nonlinear terms in the dynamics. This quantity could possibly be much larger than $\dim(x_N)$, depending on the types of nonlinearities present.

The control design method proposed in [11] could therefore be used to obtain an RCLF $V(x) = x^T P x$. Since the problem formulation in [11] is an LMI convex optimization problem, we can use this procedure to try to optimize any convex function of the matrix P subject to the constraint of stability over a level set. However, there are two important sources of conservatism in this procedure. The first is that a linear controller structure is assumed, and the solution to the optimization problem under this assumption may not yield the optimal Lyapunov function when nonlinear control laws are allowed. The conservatism due to this assumption could probably

TABLE 3.1
Computation times for optimization using a quadratic RCLF with a constant P matrix.

Operation	Time (unbounded control)	Time (bounded control)
Nonconvex solution	$\mathcal{O}(2^l N_c^n)$	$\mathcal{O}(2^l N_c^n)$
LFT solution	$\mathcal{O}(N_c^k[l+r]^3)$	$\mathcal{O}(N_c^{k+m}[l+r]^3)$

be reduced by assuming an LFT structure for the control as well as the plant in a manner analogous to the incorporation of time-varying parameters in the control for a linear parameter-varying (LPV) system in [25].

The second source of conservatism is probably more important. The stability constraint in [11] is derived from the small gain theorem from robust control and actually requires that the following system is stable:

$$\begin{aligned}\dot{x} &= Ax + B_w w + B_u u + B_p p,\\ q &= C_q x + D_{qw} w + D_{qu} u + D_{qp} p,\\ p &= \Delta(t) q.\end{aligned}$$

In this alternative system description, the perturbation block is allowed to be any matrix function $\Delta(t) \in \mathbf{\Delta}$ for some constraint set $\mathbf{\Delta}$ representing an upper bound on the allowable magnitude of the nonlinear states over the appropriate level set of $V(x)$. Treating nonlinearities as disturbances and applying robust control techniques is known to be an overly conservative approach to nonlinear control [1]. Consequently, there is no guarantee that the matrix P obtained using this procedure solves the original optimization problem. Nevertheless, this procedure is an alternative which may yield good results in some cases.

We now analyze the computational complexity of the optimization procedure described in this section. The optimization can be accomplished either by general nonconvex optimization techniques or by solving an equivalent real μ analysis problem applied to the LFT representation. The general nonconvex optimization problem is NP-hard [22], but the solution (if it can be found) is exact. The number of variables in this problem is equal to $n(n+1)/2$, the dimension of the set of symmetric matrices. Alternatively, approximate bounds on $\Gamma(\gamma, 1, x_N, \psi)$ can be found using standard techniques for real μ analysis [32]. Approximate computation times for a system influenced by disturbances contained in $\mathcal{W} = \{w \in R^l \mid \|w\|_\infty \leq 1\}$ are listed in Table 3.1. Note that the perturbation block in the robust stability problem with an LFT representation for the nonlinear terms has dimension $l + r$, where $r = \sum_{i=1}^k r_i$.

An alternative to the LFT representation would be to regard the system (1.1) as a quasi-LPV system and apply the procedure from [4] for LPV systems. In this procedure, an RCLF is computed by solving a family of LMI convex optimization problems parameterized over the "nonlinear" states x_N. Here again the computational complexity is exponential in k (exponential in $k+m$ in the bounded control case) and polynomial in the remaining state dimension. Note, however, that LPV systems are slightly different from the system (1.1): in (1.1) the dynamics of x_N are known and x_N is part of the state vector to be regulated to a desired equilibrium point.

3.2. Quadratic RCLF with state-dependent *P* matrix. The problem of optimizing over a function $V(x)$ of the form (2.7) is substantially more complicated than the problem in section 3.1. The optimization problem under consideration here is the following.

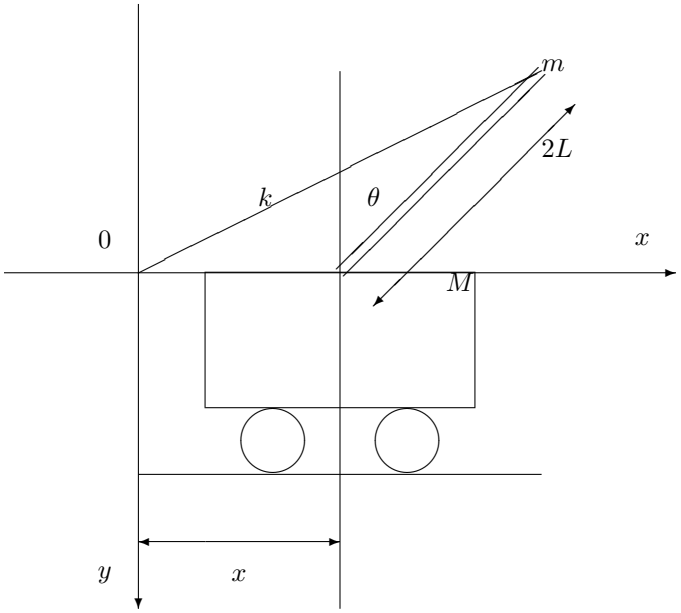

FIG. 3.1. *Cart with inverted pendulum and spring.*

PROBLEM 3. *Suppose that* $V_0(x) \doteq x^T P_0(x_N)x$ *is an RCLF with controls in* $\mathcal{U}$ *over* $V_0^{-1}[c_1, c_2]$. *Determine* $P(x_N) = P^T(x_N)$ *and* γ *from the following optimization problem:*

$$\begin{array}{ll} \textit{maximize} & \textit{vol}\, V^{-1}[0,1] \\ \textit{subject to} & \gamma > 0, \\ & V^{-1}[0,\gamma] \subseteq V_0^{-1}[0,c_1], \\ & \Gamma(\gamma, 1, x_N, \psi) < 0 \ \textit{for all}\ (x_N, \psi) \in \mathcal{Y}(1). \end{array}$$

To develop a tractable approximate solution to Problem 3, we would like to view the problem as an optimization over $P(x_N)$, which is analogous to Problem 2 but parameterized by the x_N states. We can write the objective and the second constraint in Problem 3 in terms of $P(x_N)$, although the formulas may be complicated. In the stability constraint, however, the *derivatives* of $P(x_N)$ with the x_N states appear in $\Gamma(\gamma, 1, x_N, \psi)$. Therefore, we cannot simply evaluate this constraint at a given value of x_N independent of the others; we really need to optimize over the whole function $P(x_N)$. Consequently, we cannot view Problem 3 as a parameterized collection of subproblems for fixed x_N as we would like. We do not currently have a procedure for solving Problem 3 even approximately which is not NP-hard.

4. Numerical example. In the system shown in Figure 3.1, a pole is hinged on a cart, and a spring joins the top of the pole to a fixed point on the wall behind the cart. The control is a force on the cart, which is limited by a saturation constraint. We want a control design to drive the system to the origin from an initial condition. A simplified model of the dynamics has the form

$$\begin{bmatrix} \dot{\theta} \\ \dot{x}_L \end{bmatrix} = f(\theta) + A(\theta)x_L + g_u(\theta)u,$$

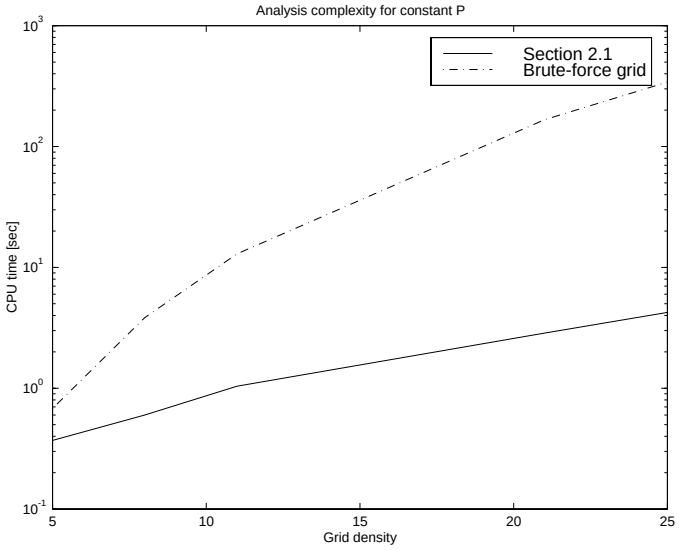

FIG. 4.1. *Computation time required for analysis with constant P using a Sparc* 20 *processor.*

where $x_N = \theta$ and $x_L = [\dot{\theta}; x; \dot{x}]$. After designing an RCLF $V(x)$ and stability margin $W(x)$, we analyze stability over $V^{-1}[0,1]$ under the saturation constraint using the method described in section 2.1. A comparison of the computational complexity of this procedure with that of a "brute-force" gridding procedure for different grid densities N_c is shown in Figure 4.1. This example shows the computational complexity increasing as a function of N_c with a higher exponent for the case of the brute-force grid than for the method of section 2.1. Specifically, for large N_c the complexity increases as N_c^4 for the brute-force grid and as N_c^2 for the method of section 2.1, as expected.

5. Conclusions. The most serious hindrance to progress on the nonlinear control problem is the inherent complexity of the class of arbitrary nonlinear systems. Therefore, it is important to identify a class of systems which is sufficiently restricted so that computations can be made tractable, yet which is general enough to apply to a wide variety of real control systems. We have shown some ways in which systems of the form (1.1) form such a class. When the dynamics are nonlinear in only a fixed number of variables x_N, the computation time required for stability analysis given a quadratic RCLF is exponential only in $\dim(x_N)$ and polynomial in the dimension of the remaining states. For an RCLF of the form $V(x) = x^T P(x_N) x$, the stability analysis problem is NP-hard. In practice, however, good bounds on the Lyapunov derivative can be found by converting the problem to a real μ analysis problem. This results in an approximate solution procedure with a computational complexity which is exponential in $\dim(x_N)$ and polynomial in the dimension of the remaining states.

Similarly, the problem of optimizing over RCLFs to get the largest possible stability region is NP-hard. We can get a computationally tractable, approximate solution procedure by finding an LFT representation for the system dynamics. The computational complexity of this problem is exponential only in $\dim(x_N)$. The computation time also depends polynomially on the dimension of the perturbation block needed to represent the nonlinear dynamics. Since this procedure relies on bounding the nonlinear terms in the dynamics and applying robust control techniques, we expect this

procedure to be overly conservative. We do not obtain a computationally tractable optimization procedure for RCLFs of the form $V(x) = x^T P(x_N)x$.

Appendix A. Proof of Theorem 2.3. Suppose that $C_0(x_N) \not< 0$. It is clear that $\Gamma(c_1, c_2, x_N, \psi) \leq \Gamma(0, c_2, x_N, \psi)$. Let $\lambda^* \in \mathcal{Z}(0, c_2, x_N, \psi)$ be such that $\Gamma(x_N, \psi, \lambda^*) = \Gamma(0, c_2, x_N, \psi)$. By the $\mathcal{S}$-procedure, this quantity is equal to the smallest r such that $\tau \geq 0$ exists to satisfy the following for *all* values of λ:

$$-\Gamma(x_N, \psi, \lambda) + r + \tau[V(x_N, \psi, \lambda) - c_2] \geq 0. \tag{A.1}$$

Therefore, $\tau[V(x_N, \psi, \lambda^*) - c_2] \geq 0$. On the other hand, the constraint and $\tau \geq 0$ combine to give $\tau[V(x_N, \psi, \lambda^*) - c_2] \leq 0$. Therefore, $\tau[V(x_N, \psi, \lambda^*) - c_2] = 0$. Since (A.1) must hold for all λ, we require $C_0(x_N) - \tau C_1(x_N) \leq 0$ for $C_1(x_N) = G(x_N)^T P_{LL} G(x_N) > 0$. Hence, if $C_0(x_N) \not\leq 0$, then we require $\tau > 0$, which implies $V(x_N, \psi, \lambda^*) = c_2$. If $C_0(x_N) \leq 0$ but $C_0(x_N) \not< 0$, then there exists $\mu \neq 0$ such that $C_0(x_N)\mu = 0$. We want to show that for any λ satisfying $V(x_N, \psi, \lambda) < c_2$, there exists $\beta \in R$ such that $\Gamma(x_N, \psi, \lambda + \beta\mu) \geq \Gamma(x_N, \psi, \lambda)$ but $V(x_N, \psi, \lambda + \beta\mu) = c_2$, and this will complete the proof. Now $V(x_N, \psi, \lambda + \beta\mu) = [\mu^T C_1(x_N)\mu]\beta^2 + [2\mu^T C_1(x_N)\lambda]\beta + V(x_N, \psi, \lambda)$. Therefore, the equation $V(x_N, \psi, \lambda + \beta\mu) = c_2$ is quadratic in β, and if $V(x_N, \psi, \lambda) < c_2$, there are two real roots: one positive and one negative. Since $\Gamma(x_N, \psi, \lambda + \beta\mu) = \Gamma(x_N, \psi, \lambda) + \beta b_0(x_N, \psi)^T \mu$, and at least one of the roots has the property $\beta b_0(x_N, \psi)^T \mu \geq 0$, we get $\Gamma(x_N, \psi, \lambda + \beta\mu) \geq \Gamma(x_N, \psi, \lambda)$ and $V(x_N, \psi, \lambda + \beta\mu) = c_2$. Therefore, there exists λ^* with the property $V(x_N, \psi, \lambda^*) = c_2$ and $\Gamma(x_N, \psi, \lambda^*) = \Gamma(0, c_2, x_N, \psi)$, and we conclude that $\Gamma(c_1, c_2, x_N, \psi) = \Gamma(0, c_2, x_N, \psi)$. Finally, suppose that $C_0(x_N) < 0$. Then $\Gamma(x_N, \psi, \lambda)$ is concave and is maximized for $\lambda^* = -\frac{1}{2} C_0(x_N)^{-1} b_0(x_N, \psi)$. If $\lambda^* \notin \mathcal{Z}(c_1, c_2, x_N, \psi)$, then $\Gamma(x_N, \psi, \lambda)$ is maximized on the boundary of $\mathcal{Z}(c_1, c_2, x_N, \psi)$ closest to λ^*. This proves the first two statements. Otherwise, $\Gamma(c_1, c_2, x_N, \psi) = \Gamma(x_N, \psi, \lambda^*) = a_0(x_N, \psi) - \frac{1}{4} b_0(x_N, \psi)^T C_0(x_N)^{-1} b_0(x_N, \psi)$, which proves the third statement.

CORRIGENDUM: FEEDBACK STABILIZATION OVER COMMUTATIVE RINGS: THE MATRIX CASE*

V. R. SULE†

PII. S0363012997319668

In a previous paper [1] certain arguments in the proofs of Proposition 1, Proposition 4, and subsection 4.4 are erroneous. These errors are highly regretted by this author and are corrected as follows. These corrections, however, do not affect the main results of the paper.

1. In Definition 1 (of a strictly causal matrix) the second sentence should be corrected as "*A causal matrix M is called strictly causal if all entries of M are in $\mathcal{J}$.*"

2. In the sufficiency part of the proof of Proposition 1, the two sentences starting in line 3 of the paragraph "Since $I_t(N) \subseteq \mathcal{J}$, using ... units of $R^{-1}\mathcal{A}$," should be replaced by the following:

"From $NY = (I - X)d$ and the assumption that all entries of P are in $\mathcal{J}$ (and hence that of N, since d is nonzerodivisor), it follows that all entries of $I - X$ are in $\mathcal{J}$. Hence $\det X = \det(I - (I - X))$ is of the form $1 + j$ where j is in $\mathcal{J}$. This implies that $\det X$ is a unit of $R^{-1}\mathcal{A}$ as $\mathcal{J}$ is the Jacobson's radical."

3. The proof of the necessity part of Proposition 4 is erroneous. Since this result is not needed further in the paper. We replace it with the following version stating only the sufficient condition.

PROPOSITION 4. *A strictly causal $P = Nd^{-1}$ in $(\mathcal{F})_n$ is stabilizable if*

$$a + b = \mathcal{A}.$$

The proof should be read from the third paragraph of the existing proof after deleting the line "Second, the proof is by sufficiency."

4. The arguments made in subsection 4.4 are erroneous. This subsection should be replaced by the following:

"**4.4. Relaxing strict causality.** We now show that for integral domains the strict causality of P can be replaced by a more concrete and weaker condition (than strict causality), which makes Proposition 1 stronger. (Recall that the strict causality of P is required in the necessity part of the proof of Proposition 1. This condition is as follows.)

Now let $\mathcal{A}$ be an integral domain and P satisfy the condition that the equation $\det(I - PY) = 0$ has no solution Y over $\mathcal{A}$.

Since the solutions of equation (1) are invariant with respect to the choice of fractions of P, choose a pair of fractions N and $d \neq 0$. Now, as $X = I - PY$ is equivalent to $NY = (I - X)d$, it follows from the above condition that if X is a solution of (1) then $\det X \neq 0$. Thus every solution of (1), satisfies this condition. Note further that this condition is not necessary for existence of solutions X with

nonzero determinants. For instance, P of example 2 does not satisfy this condition but is still stabilized by the controller $C = [0\ X_1^2+X_2^2+X_3^2]$, as can be easily checked."

Acknowledgment. The author is thankful to Kazuyoshi Mori for his query on item 2 above.
