ESTIMATES OF CONVERGENCE OF FULLY DISCRETE SCHEMES FOR THE ISAACS EQUATION OF PURSUIT-EVASION DIFFERENTIAL GAMES VIA MAXIMUM PRINCIPLE*

PIERPAOLO SORAVIA†

Abstract. We consider the Dirichlet problem for the Isaacs equation of pursuit-evasion differential games and prove estimates of convergence for a numerical scheme associated with it. The function that we approximate is the Hölder continuous viscosity solution of the problem, and the direct proof that we propose relies on some ideas related to the maximum principle for viscosity solutions.

Key words. pursuit-evasion games, Isaacs equations, numerical schemes, estimates of convergence, viscosity solutions

Introduction. In this paper we study the numerical approximation of the Dirichlet problem

$$\begin{cases} \mu v(x) + \min_{b\in B} \max_{a\in A}\{-f(x,a,b)\cdot Dv(x)\} - 1 = 0, & \mathbb{R}^N\backslash\mathcal{T}, \\ v(x) = 0, & \mathcal{T}, \end{cases} \tag{0.1}$$

where $\mu > 0$ and $\mathcal{T}$ is a nonempty closed set. It is known (see in various generalities Bardi and the author [6], [7], and [22]) that if the vector field f satisfies local-controllability-type assumptions on $\partial\mathcal{T}$, there is a unique Hölder continuous, bounded viscosity solution of the problem (0.1). Such a solution is nonnegative and the Kruzkov transform $v = (1 - \exp(-\mu T))/\mu$ of the capture time function T, the (lower) value of the pursuit-evasion differential game with dynamics

$$\dot{y} = f(x,a,b), \quad y(0) = x, \tag{0.2}$$

and target $\mathcal{T}$ (we refer to the mentioned papers for the actual definition of T). Therefore the pair (v,μ) can be thought of as a tool for the real problem we are interested in, which is the computation of T. From the numerical point of view, it is not convenient in general to study directly the equation for T since such function is not necessarily bounded and, as a matter of fact, may not be even finite at all points of the space. This gives us a reason for the change of variables.

As usual, for dynamic programming equations of control problems (in which case A or B is a singleton) or differential games (see, e.g., Falcone [15] for control problems, Bardi, Falcone, and the author [4], [5] for games), to recover an approximation scheme for the differential equation in (0.1) we proceed in two steps. First we approximate the directional derivative $f(x,a,b)\cdot Dv(x)$ as $\mu\tau/(1-\tau)\,(v(x+hf(x,a,b)) - v(x))$, where $\tau = \exp(-\mu h)$ and h is a time step for the underlying dynamical system (0.2)

This paper was written while the author was visiting the University of California at Santa Barbara. This research was partially supported by Consiglio Nazionale delle Ricerche of Italy.

of the differential game. This approximation looks natural when thinking that our main goal is to compute the value function T. As a result we obtain the equation

$$(0.3)\quad \begin{cases} v(x) + \tau \min_{b\in B} \max_{a\in A}\{-v(x+hf(x,a,b))\} - (1-\tau)/\mu = 0, & \mathbb{R}^N\backslash\mathcal{T}, \\ v = 0, & \mathcal{T}. \end{cases}$$

This is what we call the discrete-time approximation of (0.1) since the unique bounded solution of (0.3) is the Kruzkov transform of the value function of the discrete-time pursuit-evasion differential game in which in the dynamics (0.2) we substitute its Euler approximation with step h. The convergence of the solutions of (0.3) to the viscosity solution of (0.1) has been proved by Bardi and Falcone [3] for control problems and by Bardi and the author [8] for games.

Next we discretize the space as a countable union of simplices whose maximum diameter is k, the space step, and approximate equation (0.3) by computing it only at the vertices of the simplices. If $\mathcal{G} := \{x_i\}_{i\in\mathbb{N}}$ indicates the countable family of the vertices, we are led to consider

$$(0.4)\quad \begin{cases} v(x_i) + \tau \min_{b\in B} \max_{a\in A}\{-\sum_j \lambda_{ij}(a,b)v(x_j)\} - (1-\tau)/\mu = 0, & \mathcal{G}\backslash\mathcal{T}, \\ v(x_i) = 0, & \mathcal{T}, \end{cases}$$

where the coefficients λ_{ij} allow us to rewrite the point $\overline{x}_i = x_i + hf(x_i,a,b) = \sum_j \lambda_{ij}x_j$ in a unique way as a convex combination of the vertices of the simplex it belongs to. This is what we call the fully discrete approximation of (0.1). Equation (0.4) has a unique bounded solution which can be computed by finding the fixed point of a contraction functional, as we recall in the next section. For more details about the algorithm to actually compute the solution of (0.4), for control problems we refer to [15] and Capuzzo Dolcetta and Falcone [10], and for games we refer to [4] and the forthcoming review paper [5] for some numerical computations. In [10] the reader can also find details about an acceleration technique that can be applied to speed up the computation of the fixed point which would otherwise be rather time consuming. As one of the referees pointed out to us, another way to increase the speed of the algorithm could be to allow control and state dependent time steps. This extension would also be interesting by itself, but in order to keep technicalities at a minimum and present a rather concise proof, we preferred not to deal with such a generality in this presentation.

In this paper we show that under controllability assumptions on the vector field on $\mathcal{T}$, as long as the ratio of the steps k/h remains bounded, the solutions of (0.4) converge uniformly to the viscosity solution of (0.1). Moreover we compute explicitly the rate of convergence. When, for example, (0.1) has a Lipschitz continuous solution, as it happens under reasonable assumptions on the data (see (1.3) below), the rate is $\sqrt{h}$. In more general cases it is h^ρ, where $\rho = \min\{\beta, \alpha/2, \gamma/2\}$, γ is the Hölder exponent of the solution of (0.1), and α, β are parameters of a discrete estimate of the solutions of (0.4) at the boundary; see, however, the precise statement of the Theorem in section 1 and Remark 2. The Hölder exponent of the solution can be deduced from the controllability conditions we require. A proof of convergence of the algorithm in very general assumptions, also showing that the computations can be restricted to a bounded region, was already given in [4]. The main new contribution here concerns the estimates of convergence, remarking, however, that the different argument we give in our assumptions is easier than the one in [4] and our presentation is self-contained. Our results are new even for the minimum time problem in control theory.

Estimates of convergence of the same type were previously obtained in [15] for infinite horizon control problems, i.e., for equations in the whole space. In [15] the proof proceeds in two steps establishing first the rate of the convergence of the discrete-time approximations of (0.1) and next combining it with the rate of convergence of the fully discrete approximations to the solution of (0.3). In the case of a Dirichlet problem, the solution of (0.3) is discontinuous even if the solution of (0.1) is smooth and this makes this method difficult to implement. Instead, we directly compare the fully discrete approximations and the viscosity solution of (0.1) by means of a maximum-principle-type argument which follows the idea proposed for discrete-time approximations of infinite horizon control problems by Capuzzo Dolcetta and Ishii [11], adapted, of course, to deal with the boundary condition and the fully discrete scheme.

We finally want to mention that the approximation of Hamilton–Jacobi equations in the context of viscosity solutions was also studied by Crandall and Lions [13] and [14], Souganidis [24], Gonzalez and Rofman [16], Alziary de Roquefort [1], Barles and Souganidis [9], Pourtallier and Tidball [20], and Kocan [17]. Some results concerning the numerical approximation of discontinuous solutions of (0.1) can be found in [4]; Bardi, Bottacin, and Falcone [2]; and the paper by the author [23]. For general results concerning approximations of solutions of Hamilton–Jacobi equations with different methods, we refer to Kushner [18], Kushner and Dupuis [19], and the references therein.

1. Preliminaries and main result. We start this section with the precise assumptions we need. The function $f : \mathbb{R}^N \times A \times B \to \mathbb{R}^N$, where A, B are compact sets, is supposed to be continuous and to satisfy

$$\begin{cases} |f(x,a,b) - f(z,a,b)| \le L|x-z|, \\ |f(x,a,b)| \le L \quad \text{for all } x,z,a,b. \end{cases} \tag{1.1}$$

We are also given the closed set $\mathcal{T} \subset \mathbb{R}^N$, which is the target of the pursuit-evasion differential game with dynamics (0.2). The target may be nonsmooth and unbounded. We assume that the Dirichlet problem (0.1) has a unique continuous, bounded, nonnegative viscosity solution v. With this we mean that v satisfies the boundary condition, and for all test functions $\varphi \in C^1(\mathbb{R}^N)$ such that $v - \varphi$ attains a local maximum (resp., minimum) point at $x_0 \in \mathbb{R}^N \backslash \mathcal{T}$ we have

$$\mu v(x_0) + \min_{b\in B} \max_{a\in A} \{-f(x_0,a,b) \cdot D\varphi(x_0)\} - 1 \le 0 \text{ (resp., } \ge 0).$$

Continuous viscosity solutions exist if and only if the so-called small time local controllability of the pursuit-evasion game to $\mathcal{T}$ is satisfied. In this case, they are moreover Hölder continuous. Small time local controllability can be obtained by means of suitable assumptions on the direction of the vector field f and of its Lie brackets at the boundary of the target $\mathcal{T}$ (see, e.g., [6], [7], the paper by the author [22], and the references therein); see also (1.3) and the following discussion. More informations about the theory of viscosity solution as well as lots of references on the subject can be found in Crandall, Ishii, and Lions [12].

We now consider a discretization of the space with space step k, meaning a family of simplices $\{S_j\}_{j=1,2,\dots}$ such that $\mathbb{R}^N = \cup_j S_j$, $\text{int}(S_i) \cap \text{int}(S_j) = \emptyset$ for $i \ne j$, $\max_j\{diam(S_j)\} = k$. We denote by $\mathcal{G} = \{x_j\}_{j=1,2,\dots}$ the family of the vertices of the triangulation, we suppose that it has no accumulation points, and we remark that any

point $x \in S_i$ can be expressed, in a unique way, as a convex combination of the vertices of S_i; that is, $x = \sum_j \lambda_j x_j$, $\sum_j \lambda_j = 1$, $\lambda_j \in [0,1]$, $\lambda_j = 0$ if $x_j \notin S_i$. Given the time step h, for all a, b we indicate $\overline{x}_i = \overline{x}_i(a,b) = x_i + hf(x_i,a,b)$ and define the parameters $\lambda_{ij} = \lambda_{ij}(a,b)$ considering the unique convex representation $\overline{x}_i = \sum_j \lambda_{ij}(a,b)x_j$ with the properties above. For convenience we choose $h, k \in (0,1]$. Then we define the map $F : \mathbb{R}^{\mathbb{N}} \to \mathbb{R}^{\mathbb{N}}$ by setting

$$F_i(V) = \begin{cases} \tau \max_{b\in B} \min_{a\in A} P_i(a,b,V) + (1-\tau)/\mu & \text{if } x_i \in \mathcal{G}\backslash\mathcal{T}, \\ 0 \quad \text{if } x_i \in \mathcal{T}, \end{cases}$$

where $P_i(a,b,V) = \sum_j \lambda_{ij} V_j$. It is clear by construction that a fixed point of F is a solution of (0.4). The following result outlines the idea of the algorithm. Its easy proof is left to the reader; the detailed argument, however, can be found in the papers by Falcone [15] and Bardi, Falcone, and the author [4] and [5].

LEMMA 1. *Assume* (1.1). *The above map F is monotone with respect to the partial order $U \geq V$ if $U_i \geq V_i$ for all $i \in \mathbb{N}$ and has a restriction $F : [0, 1/\mu]^{\mathbb{N}} \to [0, 1/\mu]^{\mathbb{N}}$ which is a strict contraction.*

As we mentioned, the previous result applies to proving that the fixed point of the map F is a bounded, nonnegative solution of (0.4). Such function is defined only at grid points, so we extend it to the whole space by linear interpolation. The resulting function, which we denote by $w^{h,k}$, is our continuous approximation of the solution of (0.1). By construction $w^{h,k}$ satisfies

$$w^{h,k}(x_i) + \tau \min_{b\in B} \max_{a\in A} \{-w^{h,k}(\overline{x}_i(a,b))\} - (1-\tau)/\mu = 0, \quad x_i \in \mathcal{G}\backslash\mathcal{T},$$

and vanishes at the points of the grid in $\mathcal{T}$.

In the following we indicate with $d(x) = dist(x, \mathcal{T})$ the distance function from the target. In order to get the estimates of convergence, we need some additional conditions at the boundary. To this end we assume that there is a closed uniform neighborhood of $\mathcal{T}$, $\mathcal{T}_\delta = \{x : d(x) \leq \delta\}$ and positive constants $\alpha, \beta, \gamma \in (0,1]$ and K such that

$$\begin{cases} v(x) \leq K d^\gamma(x), \quad x \in \mathcal{T}_\delta, \\ w^{h,k}(x_i) \leq K(d^\alpha(x_i) + h^\beta(1 + (k/h)^2)), \quad x_i \in \mathcal{T}_\delta \cap \mathcal{G}. \end{cases} \tag{1.2}$$

As we assume δ independent of h, k, it is then clear that for small values of the parameters, $\mathcal{T}_\delta \cap \mathcal{G}$ is nonempty; therefore, the second inequality in (1.2) is meaningful. We can always add grid points on $\mathcal{T}$; however, the result will not depend on this fact but only on (1.2).

Remark 1. It is well known, and as a matter of fact easy to prove, that the first inequality in (1.2) is equivalent to the local γ-Hölder continuity of the capture-time function T; see, e.g., [21]. As a consequence of (1.1), when $\mu \geq L$ it is also equivalent to saying that the bounded solution v of (0.1) is γ-Hölder continuous in $\mathbb{R}^N$, as we proved in [6]. Therefore for any practical purposes, since our main goal is to compute T and we can then choose μ as we please, we will henceforth assume we are in this case. In control theory (when B is a singleton), the first inequality in (1.2) is well studied in the literature (see [7], [21], and the references therein) and sufficient conditions for it are well known. These are the so-called controllability conditions of order $[1/\gamma] - 1$ involving the vector field f and its Lie brackets up to order $[1/\gamma] - 1$ at the points of the boundary of the target $\mathcal{T}$. Sufficient conditions in the case of differential games

involving only the vector field f in a neighborhood of $\partial\mathcal{T}$ can be found in [22]. We propose the second inequality as the natural discrete version of the first, since, as we show below, it holds under the same kind of conditions. Finally note that since v, $w^{h,k}$ are bounded from above (by $1/\mu$ in fact), the properties (1.2) become global estimates by just changing the constant K.

To justify the second inequality in the assumption (1.2), we want to give an example where it is fulfilled. We show that even the second estimate in (1.2) is naturally related to the local controllability properties of the vector field f on $\partial\mathcal{T}$. It is known (see, e.g., [6] and [22] also for the extension to the nonsmooth and unbounded case) that if $\mathcal{T}$ is the closure of an open set whose boundary $\partial\mathcal{T}$ is C^2 and bounded, then the following condition on the vector field

$$\max_{b\in B}\min_{a\in A}\{f(x,a,b)\cdot n(x)\}<0,\quad x\in\partial\mathcal{T}, \tag{1.3}$$

where $n(x)$ indicates the interior unit normal vector of $\mathbb{R}^N\backslash\mathcal{T}$ at x, is sufficient for the first inequality in (1.2) to hold with $\gamma=1$ (and this is in turn equivalent to Lipschitz continuity of the solution of (0.1) if $\mu\geq L$). The next proposition shows that it is also sufficient for the second.

PROPOSITION. *Assume* (1.1) *and* (1.3). *Then there is* $C>0$ *such that for all* h,k

$$w^{h,k}(x_i)\leq C(d(x_i)+h(1+(k/h)^2))\quad \textit{for } x_i\in\mathcal{G};$$

hence the second inequality in (1.2) *is satisfied with* $\alpha=\beta=1$.

Proof. As a first step we prove the following lemma, which is a sort of discrete comparison principle for equation (0.4). □

LEMMA 2. *Assume that the sequence* $(V_i)_{i\in\mathbb{N}}$ *is such that* $V_i\in[0,1/\mu]$ *for all* i *and satisfies* $V\geq F(V)$. *Then we have* $V_i\geq w^{h,k}(x_i)$ *for all* i.

Proof of the lemma. The result follows immediately from Lemma 1 since for any fixed i, $F^n(V)_i$ is a nonincreasing sequence and $F^n(V)_i\to w^{h,k}(x_i)$, as $n\to+\infty$. Therefore $w^{h,k}(x_i)\leq F(V)_i\leq V_i$ and we can conclude. □

In the proceeding of the proof and only in this proof d is modified in $\mathcal{T}$ as the signed distance from $\partial\mathcal{T}$; i.e., $d(x)=-dist(x,\partial\mathcal{T})$ if $x\in\mathcal{T}$. We recall that if $\partial\mathcal{T}$ is of class C^2, then d is of class C^2 in a neighborhood of $\partial\mathcal{T}$. By (1.1) and (1.3) we can find $\rho,\sigma>0$, $\sigma\leq\rho^2\wedge1$, such that

$$\max_{b\in B}\min_{a\in A}\{f(x,a,b)\cdot Dd(x)\}\leq-\sigma,\quad x\in\{x:|d(x)|\leq\rho\}.$$

Let $||D^2d||_\infty=\sup_{|d(x)|\leq2\rho}|D^2d(x)|$, where the right-hand side makes sense if ρ is sufficiently small.

1. If the steps h,k are so that $\sigma/(||D^2d||_\infty+1)\leq h(L+k/h)^2$, then by choosing $C=(||D^2d||_\infty+1)/(\sigma\mu)$ we get directly that for any index i

$$w^{h,k}(x_i)\leq1/\mu\leq Ch(L+k/h)^2=Ch(L^2+2L(k/h)+(k/h)^2),$$

and immediately we obtain the conclusion since $k/h\leq1+(k/h)^2$.

2. Otherwise we can assume that the steps h,k satisfy

$$h(L+k/h)^2\leq\sigma/(||D^2d||_\infty+1). \tag{1.4}$$

Observe that a nonnegative sequence $V\in[0,1/\mu]^{\mathbb{N}}$ satisfies

$$V_i\geq F(V)_i=\tau\max_{b\in B}\min_{a\in A}\sum_j\lambda_{ij}(a,b)V_j\ +(1-\tau)/\mu, \tag{1.5}$$

for any index i such that $x_i \in \mathcal{G}\backslash\mathcal{T}$, if we can show that

$$0 \geq \max_{b\in B}\min_{a\in A}\sum_j \lambda_{ij}(V_j - V_i) \ + h\exp(\mu). \tag{1.6}$$

In fact, since it is not restrictive to assume $h \leq 1$, this follows from $\exp(x) - 1 \leq x\exp(x)$ for all $x \geq 0$, and $\tau = \exp(-\mu h)$. We want to check (1.5) for the sequence defined by the position

$$V_i = C(d(x_i) + h(L + k/h)) \wedge (1/\mu), \quad x_i \in \mathcal{G},$$

where we choose C sufficiently large so that $C\rho \geq 1/\mu$ and $C\sigma/2 \geq \exp(\mu)$. Then applying Lemma 2 we get

$$w^{h,k}(x_i) \leq C(d(x_i) + h(L + k/h)), \quad x_i \in \mathcal{G}, \tag{1.7}$$

and the conclusion. To this end, we only need to deal with indices x_i such that $0 < V_i < 1/\mu$, since (1.5) is obvious for the ith component if either $x_i \in \mathcal{T}$ or $V_i = 1/\mu$. For such indices, we will then prove (1.6). Let therefore x_i be such that $V_i \in (0, 1/\mu)$, and observe that then $x_i \in \mathcal{T}_\rho\backslash\mathcal{T}$ by the choice of C. By definition of V we have

$$V_j - V_i \leq C(d(x_j) - d(x_i)) \quad \text{for all } x_j \in \mathcal{G}. \tag{1.8}$$

We now use the regularity of the boundary $\partial\mathcal{T}$; note that by (1.1) and (1.4)

$$|x_j - x_i| \leq k + Lh (\leq \sqrt{\sigma} \leq \rho),$$

if $\lambda_{ij} \neq 0$ for some a, b, and compute

$$d(x_j) - d(x_i) \leq ||D^2 d||_\infty |x_j - x_i|^2/2 + Dd(x_i)\cdot(x_j - x_i), \quad \lambda_{ij} \neq 0. \tag{1.9}$$

By (1.8) and (1.9), the definition of $\lambda_{ij}(a, b)$, (1.3), and the assumption, we then conclude

$$\begin{aligned}\max_{b\in B}\min_{a\in A}\sum_j \lambda_{ij}(V_j - V_i) &\leq C\max_{b\in B}\min_{a\in A}\sum_j \lambda_{ij}(d(x_j) - d(x_i))\\ &\leq C(||D^2 d||_\infty (k + Lh)^2/2 + \max_{b\in B}\min_{a\in A}\sum_j \lambda_{ij}(x_j - x_i)\cdot Dd(x_i))\\ &\leq C(h\sigma/2 + h\max_{b\in B}\min_{a\in A} Dd(x_i)\cdot f(x_i, a, b)) \leq -h\exp(\mu),\end{aligned}$$

so (1.6) and, consequently, (1.5) hold for the fixed index i. □

Our main result is the following.

THEOREM. *Assume* (1.1) *and* (1.2)*, and let* $\mu \geq L$*. Then there is a constant* $C = C(K, L, \mu)$ *such that for all* h, k *we have*

$$||w^{h,k} - v||_\infty \leq Ch^\rho(1 + (k/h)^2), \tag{1.10}$$

where $\rho = \min\{\beta, \alpha/2, \gamma/2\}$ *and the parameters* α, β, γ *are defined in* (1.2)*.*

Remark 2. The constant C that appears in the estimate (1.10) can be explicitly computed in terms of K, L, and μ as can be seen from the proof of the result in the next section.

The theorem and the proposition prove that if the solution v of (0.1) is Lipschitz continuous, the target is smooth, and k/h remains bounded, then the rate of convergence is $\sqrt{h}$. If v is only Hölder continuous, we do not know the rate exactly unless we compute the parameters α, β in (1.2). In the proposition, we proved the discrete estimate in (1.2) by using (1.3) and showing that the right-hand side is a supersolution of the fully discrete equation (0.4). Then we applied a discrete comparison principle. This draws a parallel with a possible proof of the first estimate in (1.2), see, e.g., [22] and the references therein, and leads to conjecture that sufficient conditions on the vector field f and its Lie brackets to prove the first inequality in (1.2) with a certain γ also guarantee the discrete estimate with $\beta = \alpha = \gamma$. This would then give the rate of convergence for the scheme $h^{\gamma/2}$, as in infinite horizon problems without targets. However we did not attempt to prove this conjecture in more general situations than the statement of the proposition, as dealing with Lie brackets and discrete-time systems is a serious matter by itself. □

2. Proof of the theorem. In the following we indicate by $\varepsilon = h^{(2-\gamma)/2}$ and drop for convenience of notation the superscripts of $w^{h,k}$.

1. We start proving that

$$\sup_{\mathbb{R}^N}(w - v) \le Ch^\rho(1 + (k/h)^2).$$

We proceed by contradiction assuming that for any fixed constant $C > 0$, we can find h, k as small as we please and $\sigma(h, k) \in (0, 1]$ such that for any $0 < \sigma \le \sigma(h, k)$ we have

$$\sup_{\mathbb{R}^N}(w - v) \ge Ch^\rho(1 + (k/h)^2) + 2\sigma. \tag{2.1}$$

We introduce the function

$$\varphi(x, y) = w(x) - v(y) - |x - y|^2/\varepsilon, \quad (x, y) \in \mathbb{R}^{2N}.$$

By (2.1) it follows that

$$+\infty > \sup_{\mathbb{R}^{2N}} \varphi \ge Ch^\rho(1 + (k/h)^2) + 2\sigma.$$

We now choose a point (x_1, y_1) such that $\varphi(x_1, y_1) > \sup_{\mathbb{R}^{2N}} \varphi - \sigma$ and select a function $\xi \in C_c^1(\mathbb{R}^{2N})$ satisfying $0 \le \xi \le 1$, $\xi(x_1, y_1) = 1$, $|D\xi| \le 1$. If we denote $\psi = \varphi + \sigma\xi$, by construction the maximum point of ψ is attained at a point (x^o, y^o) in the support of ξ.

2. Observe that $w(x^o) > 0$. This immediately follows from

$$w(x^o) - v(y^o) + \sigma \ge \psi(x^o, y^o) \ge \psi(x_1, y_1) > \sup_{\mathbb{R}^{2N}} \varphi \ge Ch^\rho(1 + (k/h)^2) + 2\sigma. \tag{2.2}$$

We indicate the point x^o as the unique convex combination of the vertices of the simplex to which it belongs, i.e., $x^o = \sum \lambda_j x_j$, where $\sum \lambda_j = 1$, $\lambda_j \in [0, 1]$, $|x^o - x_j| \le k$ if $\lambda_j \ne 0$. Then it follows that for at least an index j such that $\lambda_j \ne 0$ we have $w(x_j) > 0$; therefore $x_j \notin \mathcal{T}$. We will need more, and as a matter of fact we prove that if $k \le \delta$, δ as in the assumption (1.2), none of such points x_j with $\lambda_j \ne 0$ can be

on $\mathcal{T}$. In fact if there is $x_i \in \mathcal{T}$, by (1.2) we obtain the following estimate

$$w(x^o) = \sum_j \lambda_j w(x_j) \le K\left(\sum_j \lambda_j d^\alpha(x_j) + h^\beta(1+(k/h)^2)\right)$$
$$\le K\left(\sum_j \lambda_j |x_j - x_i|^\alpha + h^\beta(1+(k/h)^2)\right) \le K(k^\alpha + h^\beta(1+(k/h)^2)),$$

which gives a contradiction with (2.1) when C is chosen sufficiently large, since we have $k^\alpha = (k/h)^\alpha h^\alpha \le (1+(k/h)^2)h^\alpha$, and v is nonnegative.

3. We now show that $y^o \notin \mathcal{T}$. We use the inequality $\psi(x^o, y^o) \ge \psi(x^o, x^o)$ and get

$$v(x^o) - v(y^o) + \sigma(\xi(x^o, y^o) - \xi(x^o, x^o)) \ge |x^o - y^o|^2/\varepsilon,$$

and therefore by the γ-Hölder continuity of v, see Remark 1, if we indicate with $M = M(L, \mu)$, the best γ-Hölder constant of v, we have

$$|x^o - y^o|^2/\varepsilon \le \sigma|x^o - y^o| + M|x^o - y^o|^\gamma,$$

which implies first that $|x^o - y^o| \le M_1$, where M_1 is independent of all small ε and σ. Consequently, choosing σ sufficiently small,

$$|x^o - y^o| \le (1+M)^{1/(2-\gamma)}\varepsilon^{1/(2-\gamma)}. \tag{2.3}$$

We can now conclude that $y^o \notin \mathcal{T}$; otherwise, from (1.2) and (2.3) for h, k sufficiently small so that

$$k + (1+M)^{1/(2-\gamma)}\varepsilon^{1/(2-\gamma)} \le \delta,$$

we obtain as in the final estimate in part 2 that

$$w(x^o) \le K\left(\sum_j \lambda_j d^\alpha(x_j) + h^\beta(1+(k/h)^2)\right) \le K\left(\sum_j \lambda_j |x_j - y^o|^\alpha + h^\beta(1+(k/h)^2\right)$$
$$\le K((k+|x^o - y^o|)^\alpha + h^\beta(1+(k/h)^2)) \le K(k^\alpha + (1+M)^{\alpha/(2-\gamma)}\varepsilon^{\alpha/(2-\gamma)}$$
$$+ h^\beta(1+(k/h)^2)) \le 2Kh^\rho(1+(1+M)^{\alpha/(2-\gamma)} + (k/h)^2),$$

which again gives a contradiction with (2.1) when C is sufficiently large. The last inequality follows by the definition of ε at the beginning of this section.

4. We can now use the equations for v at y^o and for w at all vertices x_j of the simplex containing x^o. By the definition of viscosity solution, equations (0.1) and (0.4), the maximality of (x^o, y^o), and the fact that w is defined in $\mathbb{R}^N$ by linear interpolation, we then obtain

$$\mu v(y^o) + \min_{b\in B}\max_{a\in A}\{-f(y^o, a, b)\cdot \sigma D_y\xi(x^o, y^o) + 2/\varepsilon\ f(y^o, a, b)\cdot(y^o - x^o)\} - 1 \ge 0,$$

$$w(x_j) + \min_{b\in B}\max_{a\in A}\{-\tau w(x_j + hf(x_j, a, b))\} - (1-\tau)/\mu = 0,$$

where we recall that $\tau = \exp(-\mu h)$. Choosing conveniently first $b_j \in B$ in the second equation and then $a_j \in A$ in the first, we then get

$$\mu v(y^o) - f(y^o, a_j, b_j) \cdot \sigma D_y \xi(x^o, y^o) + 2/\varepsilon \; f(y^o, a_j, b_j) \cdot (y^o - x^o) - 1 \geq 0, \tag{2.4}$$

$$w(x_j) - \tau w(x_j + h f(x_j, a_j, b_j)) - (1-\tau)/\mu \leq 0. \tag{2.5}$$

In the following we denote $\overline{x}_j = x_j + h f(x_j, a_j, b_j)$. By the optimality of (x^o, y^o), and therefore the fact that $\psi(x^o, y^o) \geq \psi(\overline{x}_j, y^o)$, we deduce

$$\begin{aligned} &w(\overline{x}_j) \leq w(x^o) + |\overline{x}_j - x^o|^2/\varepsilon + 2/\varepsilon \; (\overline{x}_j - x^o, x^o - y^o) + \sigma |x^o - \overline{x}_j| \\ &= w(x^o) + |\overline{x}_j - x^o|^2/\varepsilon + 2/\varepsilon \; (x_j - x^o, x^o - y^o) - 2h/\varepsilon \; f(x_j, a_j, b_j) \cdot (y^o - x^o) + \sigma |x^o - \overline{x}_j|. \end{aligned}$$

The last inequality and (2.5) then give

$$\begin{aligned} w(x_j) \leq \tau \{ & w(x^o) + |\overline{x}_j - x^o|^2/\varepsilon + 2/\varepsilon \; (x_j - x^o, x^o - y^o) \\ & - 2h/\varepsilon \; f(x_j, a_j, b_j) \cdot (y^o - x^o) + \sigma |x^o - \overline{x}_j| \} + (1-\tau)/\mu. \end{aligned}$$

We multiply by λ_j as defined in part 2 of the proof, sum on the index j, and get

$$\begin{aligned} \mu w(x^o) &\leq \mu\tau/(1-\tau) \; \sum_j \lambda_j \{ |\overline{x}_j - x^o|^2/\varepsilon + 2/\varepsilon \; (x_j - x^o, x^o - y^o) \\ &\qquad - 2h/\varepsilon \; f(x_j, a_j, b_j) \cdot (y^o - x^o) + \sigma |x^o - \overline{x}_j| \} + 1 \\ &= \mu\tau/(1-\tau) \; \sum_j \lambda_j \{ |\overline{x}_j - x^o|^2/\varepsilon - 2h/\varepsilon \; f(x_j, a_j, b_j) \\ &\qquad \cdot (y^o - x^o) + \sigma |x^o - \overline{x}_j| \} + 1, \end{aligned} \tag{2.6}$$

where the equality follows from the fact that $\sum_j \lambda_j x_j = x^o$ by definition.

We now multiply (2.4) by λ_j and sum on the index j, then add the result to (2.6) and obtain, also by the definition of τ,

$$\begin{aligned} &\mu(w(x^o) - v(y^o)) \leq \mu\tau/(1-\tau) \sum_j \lambda_j [|\overline{x}_j - x^o|^2/\varepsilon + \sigma |x^o - \overline{x}_j|] \\ &+ \sum_j \lambda_j [-(2/\varepsilon) \; \mu h \tau/(1-\tau) \; f(x_j, a_j, b_j) \cdot (y^o - x^o) - f(y^o, a_j, b_j) \cdot \sigma D_y \xi(x^o, y^o) \\ &\qquad + 2/\varepsilon \; f(y^o, a_j, b_j) \cdot (y^o - x^o)] \leq h^{-1} \sum_j \lambda_j [|\overline{x}_j - x^o|^2/\varepsilon + \sigma |x^o - \overline{x}_j|] \\ &\qquad\qquad + 2L/\varepsilon \; \sum_j \lambda_j [|x_j - y^o| |x^o - y^o| + \mu h |x^o - y^o|] + \sigma L, \end{aligned}$$

where to obtain the second inequality we added and subtracted in each bracket of the second sum the terms $(2/\varepsilon) \; f(x_j, a_j, b_j) \cdot (y^o - x^o)$ and used (1.1) and the fact that $0 \leq 1 - \mu h\tau/(1-\tau) \leq \mu h$. We now proceed with the estimate using (2.3), the fact that $|\overline{x}_j - x^o| \leq k + Lh$ if $\lambda_j \neq 0$, and the definition of ε. We then get, if we indicate $P = (1+M)^{1/(2-\gamma)}$ (and for $h \leq 1$),

$$\begin{aligned} &\mu(w(x^o) - v(y^o)) \leq (\varepsilon h)^{-1} (k + Lh)^2 + \sigma(2L + k/h) + 2LP(\mu h + k + P\varepsilon^{1/(2-\gamma)}) \\ &\varepsilon^{(\gamma-1)/(2-\gamma)} \leq h^{\gamma/2} (L + k/h)^2 + \sigma(2L + k/h) + 2LP(\mu + k/h) h^{(\gamma+1)/2} + 2LP^2 h^{\gamma/2} \\ &\qquad \leq h^{\gamma/2} [(k/h)^2 + 2L(1+P)(k/h) + L^2 + 2\mu LP + 2LP^2] + \sigma(2L + k/h). \end{aligned}$$

We finally use (2.2) and the fact that σ can be chosen arbitrarily small to get

$$Ch^\rho(1+(k/h)^2) \le \mu^{-1}h^{\gamma/2}[(k/h)^2 + 2L(1+P)(k/h) + L^2 + 2\mu LP + 2LP^2].$$

This gives a contradiction if the constant C was chosen sufficiently large, again since $k/h \le 1+(k/h)^2$.

5. To prove the other estimate we need

$$\sup_{\mathbb{R}^N}(v-w) \le Ch^\rho(1+(k/h)^2),$$

we proceed similarly, and we argue again by contradiction. We assume that for any fixed $C>0$ there are h,k as small as we want and $\sigma(h,k)\in(0,1]$ such that for all $0<\sigma\le\sigma(h,k)$ we have

$$\sup_{\mathbb{R}^N}(v-w) \ge Ch^\rho(1+(k/h)^2) + 2\sigma. \tag{2.7}$$

We follow along the lines above choosing the function $\varphi(x,y) = v(x)-w(y)-|x-y|^2/\varepsilon$ and constructing a maximum point (x^o,y^o) for ψ. As at the beginning of point 2, we prove that $v(x^o)>0$, so $x^o\notin\mathcal{T}$. Arguing as in point 3, using this time the inequality $\psi(x^o,y^o)\ge\psi(y^o,y^o)$, we show that $|x^o-y^o|\le(1+M)^{1/(2-\gamma)}\varepsilon^{1/(2-\gamma)}$. Moreover if we indicate $y^o=\sum_j\lambda_j y_j$ as the unique convex combination of the vertices of the simplex it belongs to, we can prove that none of the points y_j, $\lambda_j\neq0$, is in $\mathcal{T}$ as follows. Assume by contradiction that $y_i\in\mathcal{T}$; then we can estimate, by the first inequality in (1.2) and for h,k sufficiently small so that $k+(1+M)^{1/(2-\gamma)}\varepsilon^{1/(2-\gamma)}\le\delta$,

$$\begin{aligned} &v(x^o) \le Kd^\gamma(x^o) \le K|x^o-y_i|^\gamma \le K(|x^o-y^o|+k)^\gamma \\ &\le K((M+1)^{\gamma/(2-\gamma)}\varepsilon^{\gamma/(2-\gamma)}+k^\gamma) \le K((1+M)^{1/(2-\gamma)}h^{\gamma/2}+h^\gamma(1+(k/h)^2)), \end{aligned}$$

which provides a contradiction with (2.7) if C is sufficiently large.

We then apply part 4 of the proof with obvious modifications and the final result then follows. □

A GENERIC CLASSIFICATION OF TIME-OPTIMAL PLANAR STABILIZING FEEDBACKS*

A. BRESSAN† AND B. PICCOLI†

Abstract. Consider the problem of stabilization at the origin in minimum time for a planar control system affine with respect to the control. For a family of generic vector fields, a topological equivalence relation on the corresponding time-optimal feedback synthesis was introduced in a previous paper [*Dynamics of Continuous, Discrete and Impulsive Systems*, 3 (1997), pp. 335–371]. The set of equivalence classes can be put in a one-to-one correspondence with a discrete family of graphs. This provides a classification of the global structure of generic time-optimal stabilizing feedbacks in the plane, analogous to the classification of smooth dynamical systems developed by Peixoto.

Key words. time-optimal control, two-dimensional system, regular synthesis

1. Introduction.

Let F, G be smooth vector fields on the plane, with $F(0) = 0$, and consider the problem of reaching the origin in minimum time for the control system

$$\dot{x} = F(x) + G(x)u, \qquad |u(t)| \leq 1. \tag{1.1}$$

Under generic assumptions on F, G, it is known that the optimal control admits a regular feedback synthesis [2], [10]. Namely, for any given $\tau > 0$, on the set A_τ of points which can be steered to the origin within time τ, one can define a feedback control $u = \varphi(x)$ with the following properties:

(i) The set A_τ can be partitioned into finitely many submanifolds V_i such that the restriction of φ to each V_i is smooth.

(ii) Every trajectory of the feedback equation

$$\dot{x} = F(x) + G(x)\varphi(x) \tag{1.2}$$

starting inside A_τ reaches the origin in minimum time.

The set of manifolds V_i form a stratification of the set A_τ analogous to the analytic case; see [12], [15], [16].

For generic $F, G \in \mathcal{C}^3$, the optimal feedback $\varphi = \varphi_{F,G}$ is essentially unique. We thus regard (1.2) as a differential equation with discontinuous right-hand side, uniquely determined by the vector fields F, G. The aim of this paper is to provide a global classification of the flow generated by (1.2) in the generic case. This program can be outlined as follows:

1. Introduce an equivalence relation between couples of vector fields: $(F, G) \sim (F', G')$ determined by the topological equivalence of the corresponding flows (1.2). Roughly speaking, if $\varphi_{F,G}(x)$ and $\varphi_{F',G'}(x)$ are the corresponding time-optimal stabilizing feedbacks, the above equivalence should imply the existence of a homeomorphism, defined on a suitable subset of the plane, which maps oriented arcs of

trajectories of

$$\dot{x} = F(x) + G(x)\varphi_{F,G}(x) \tag{1.3}$$

onto oriented arcs of trajectories of

$$\dot{x} = F'(x) + G'(x)\varphi_{F',G'}(x). \tag{1.4}$$

2. With each equivalence class associate a discrete graph in such a way that two systems are equivalent if and only if they correspond to the same graph.

3. Show that, generically, the time-optimal feedbacks are structurally stable. In other words, given a couple of generic smooth vector fields F, G, prove that $(F', G') \sim (F, G)$ whenever F' is sufficiently close to F and G' is sufficiently close to G in the $\mathcal{C}^3$ norm. A small perturbation of the fields F, G will not change the global structure of the optimal feedback flow.

4. Characterize the family of all graphs which arise in connection with an optimal feedback for some system of the form (1.1). In practice, given a suitable graph $\mathcal{G}$, this requires the construction of vector fields F, G such that the corresponding optimal feedback flow (1.2) has precisely the topological structure specified by $\mathcal{G}$.

In [2] we completed the first part of this program introducing the equivalence relation, giving a detailed description of the structure of optimal syntheses, and proving the structural stability for systems in a generic set. For general theory of syntheses and further references we refer to [17]. The definition of graph and the second part of the program are developed in this paper.

For convenience, throughout this paper we consider the entirely equivalent problem of reaching points $x \in \mathbb{R}^2$ in minimum time, starting from the origin. It is also not restrictive to assume $\tau = 1$ and to study the global feedback synthesis on the set $R = R(1)$ of points reachable from the origin within unit time.

Section 2 reviews the basic definitions and some related results from [2], [10], [11], [14]. For general theory we refer to [13]. We also recall the definition of topological equivalence between optimal feedback flows, which plays a key role.

In section 3 we give the definition of graph and describe a standard procedure to associate a graph to a stable system, i.e., to a system for which the algorithm for constructing an optimal synthesis, described in [2], succeeds. In the following section admissibility conditions are given in order to single out graphs that correspond to some system.

In section 5 we prove that two stable systems are equivalent if and only if the corresponding graphs are equivalent. Moreover, we complete the classification program exhibiting, for every admissible graph $\mathcal{G}$, a structurally stable system that is in correspondence with $\mathcal{G}$.

Finally, in the last section we outline how to generalize all results to the case of a general two-dimensional manifold.

In [11] we computed a local classification of the syntheses near frame curves and points (i.e., the singularities of the optimal feedback); see section 2 for definitions. The countable family of equivalence classes of graphs which we obtain can be regarded as a *dictionary* of all possible structures of global optimal feedbacks in connection with generic vector fields F, G. For the flows generated by these discontinuous feedbacks, the present classification is analogous to the classical work of Peixoto [8], [9] for smooth dynamical systems.

2. Basic definitions. We first review some basic notations also used in [2], [10], and [14].

The topological frontier, the closure, and the interior of a set $D \subset \mathbb{R}^2$ are denoted by $Fr(D)$, $Cl(D)$, and $Int(D)$, respectively. If D is a manifold, then ∂D denotes its relative boundary. Given a map $\gamma : [a,b] \mapsto \mathbb{R}^2$ we denote by $Dom(\gamma) \doteq [a,b]$ its domain. The restriction of γ to a subinterval $J \subset [a,b]$ is written $\gamma \restriction J$.

In connection with the control system (1.1), consider the Banach space Ξ of pairs of vector fields $\Sigma = (F,G)$, with $F, G \in \mathcal{C}^3$, $F(0) = 0$, endowed with the $\mathcal{C}^3$ norm.

We recall that the *Lie bracket* of two vector fields F, G is the vector field

$$[F,G] \doteq \nabla G \cdot F - \nabla F \cdot G.$$

For convenience, we also define the vector fields

$$X = F - G, \qquad Y = F + G. \tag{2.1}$$

For $\Sigma = (F,G)$, we write $Traj(\Sigma)$ for the set of (Carathéodory) trajectories of (1.1). A trajectory $\gamma \in Traj(\Sigma)$ is called an X-trajectory [Y-trajectory] if it corresponds to the constant control $u \equiv -1$ [$u \equiv 1$, respectively].

For a fixed $\tau \geq 0$, the *reachable set* within time τ is

$$R(\tau) = \{x : \exists \gamma \in Traj(\Sigma) \quad \text{such that} \quad \gamma(0) = 0 \in \mathbb{R}^2, \quad \gamma(t) = x \quad \text{for some } t \leq \tau\}.$$

The *minimum time function*, $T : \mathbb{R}^2 \mapsto [0, +\infty]$ is defined by

$$T(x) \doteq \inf\{\tau : x \in R(\tau)\}.$$

A *synthesis* for the control system Σ on the set $R(\tau)$ is a family of trajectories $\Gamma = \{\gamma_x : [0, b_x] \mapsto \mathbb{R}^2, \quad x \in R(\tau)\}$ satisfying the following conditions:

(a) for each $x \in R(\tau)$ one has $\gamma_x(0) = 0$, $\gamma_x(b_x) = x$;

(b) if $y = \gamma_x(t)$ for some $t \in [0, b_x]$, then $\gamma_y = \gamma_x \restriction [0,t]$.

We say that the above synthesis is *time optimal* if $b_x = T(x)$ for each x, i.e., if each trajectory γ_x steers the system from the origin to the point x in the minimum time $T(x)$.

When a trajectory γ, corresponding to a control u, satisfies the Pontryagin maximum principle (PMP) with covector field λ, then λ is called an *adjoint covector field along* (u, γ) or simply an *adjoint variable*, and we say that (γ, λ) satisfies the PMP or that γ is an *extremal trajectory*.

Consider a trajectory γ corresponding to the control u, $t_0 \in Dom(\gamma)$ and $v_0 \in \mathbb{R}^2$. We write $v(v_0, t_0; t)$ to denote the value at time t of the variational vector field along (u, γ) (see (2.4) in [2]) with the boundary condition $v(t_0) = v_0$. If $t_0, t_1 \in Dom(\gamma)$, we say that t_0 and t_1 are *conjugate* along γ if the vectors $v(G(\gamma(t_1)), t_1; t_0)$ and $G(\gamma(t_0))$ are linearly dependent.

For each $x \in \mathbb{R}^2$, one can form the 2×2 matrices whose columns are the vectors F, G, or $[F,G]$. As in [14], we consider the following scalar functions on $\mathbb{R}^2$:

$$\Delta_A(x) \doteq \det(F(x), G(x)) = F(x) \wedge G(x), \tag{2.2}$$

$$\Delta_B(x) \doteq \det(G(x), [F,G](x)) = G(x) \wedge [F,G](x), \tag{2.3}$$

where det stands for determinant and $\wedge$ denotes an exterior product. A point $x \in \mathbb{R}^2$ is called an *ordinary point* if

$$\Delta_A(x) \cdot \Delta_B(x) \neq 0. \tag{2.4}$$

On the set of ordinary points we define the scalar functions f, g as the coefficients of the linear combination

$$[F, G](x) = f(x)F(x) + g(x)G(x). \tag{2.5}$$

In [14, p. 447] it was proved that

$$f(x) = -\frac{\Delta_B(x)}{\Delta_A(x)}. \tag{2.6}$$

For a generic system (see [14]) the only time-optimal trajectories γ that are not bang–bang must verify $\Delta_B(\gamma(t)) = 0$. A $\mathcal{C}^2$ embedded one-dimensional submanifold with boundary $S \in \mathbb{R}^2$ is a regular turnpike if $\Delta_B(x) = 0$ for every $x \in S$, and it verifies some technical conditions listed in [2], [14]. For every turnpike S we can define a control φ_S such that the corresponding trajectory runs S. Such a trajectory is called a Z-trajectory or a singular trajectory.

It may happen that a same point $x \in R = R(1)$ can be reached in minimum time using different controls. An *overlap curve* is a $\mathcal{C}^2$ one-dimensional connected embedded submanifold K of $\mathbb{R}^2$, with the property that for each point of K there exist two distinct time optimal trajectories $\gamma_1, \gamma_2 : [0, T(x)] \mapsto \mathbb{R}^2$, both steering the system from the origin to x in minimum time, with the following property: for some $\varepsilon > 0$, the restrictions of γ_1, γ_2 to $[T(x) - \varepsilon,\ T(x)]$ are an X- and a Y-trajectory, respectively.

For every system $\Sigma = (F, G)$ in a suitable open dense subset $\Xi^* \subset \Xi$, the algorithm $\mathcal{A}$ described in [2] constructs a structurally stable optimal synthesis. In the first step, the algorithm constructs the two trajectories $\gamma^{\pm}$, $\gamma^{\pm}(0) = 0$, corresponding to constant control ± 1, and marks some special points along these curves from which additional special curves bifurcate. At step N, the algorithm constructs precisely those trajectories which are concatenations of N bang or singular arcs and satisfy the PMP. We say that the algorithm succeeds for Σ if it stops in a finite number of steps and some stability conditions are fulfilled; see [2]. The set $R \doteq R(1)$ of points reachable from the origin within unit time can be partitioned in a natural way into a finite number of open regions, covered by Y- or X-trajectories, separated by curves called *frame curves*. The intersections of these frame curves are called *frame points*. In connection with the above partition, there exists a piecewise smooth feedback control $u = \varphi(x)$ with the property that the (Carathéodory) solutions of

$$\dot{x} = F(x) + G(x)\varphi(x), \qquad x(0) = 0 \tag{2.7}$$

are precisely the time-optimal trajectories. Each optimal trajectory is a finite concatenation of X-, Y-, and Z-trajectories.

All frame curves and frame points were classified in [11]. In particular, only five types of frame curves can generically occur:

(F1) the trajectories γ^- and γ^+ originating from 0 and corresponding to the constant controls $u^- \equiv -1$ and $u^+ \equiv 1$, respectively;

(F2) the topological frontier of the reachable set: $Fr(R)$;

(F3) curves of points conjugate to points of other frame curves, also called *switching curves*;

(F4) regular turnpikes,

(F5) overlap curves.

To denote the frame curves we use the symbols X, Y, F, C, S, and K, respectively. Moreover we use the same notation of [11] for frame points. For example, a point

that is the intersection of a switching curve and an overlap curve is called the (C, K) frame point. See [11] for a complete description of notations.

We now recall, from [2], the equivalence relation between systems expressing the fact that their time-optimal feedback flows have similar structures. Consider two systems $\Sigma_1, \Sigma_2 \in \Xi^*$. For $i = 1, 2$ let R_i be the reachable set for Σ_i at time $t = 1$. Define

$$\mathcal{K}_i = \{x \mid x \in K \setminus \partial K,\ K \text{ is an overlap curve of } \Gamma_{\mathcal{A}}(\Sigma_i)\},$$

and set $R_i' = R_i \setminus \mathcal{K}_i,\ \ i = 1, 2$. In the following, for each $x \in R_i$, we denote by $t \mapsto \gamma_x^i(t)$ a trajectory of Σ_i which reaches x from the origin in minimum time.

DEFINITION 1 (equivalence of feedback flows). *We say that the time-optimal feedback flows for Σ_1 on R_1 and Σ_2 on R_2 are equivalent, or simply that $\Sigma_1 \sim \Sigma_2$, if there exists a homeomorphism $\Psi : R_1' \mapsto R_2'$ such that the following hold:*

(E1) *Ψ maps arcs of optimal trajectories for Σ_1 onto arcs of optimal trajectories for Σ_2. More precisely, for every $x \in R_1'$ one has $\{\Psi(\gamma_x^1(t)) : t \in Dom(\gamma_x^1)\} = \{\gamma^2_{\Psi(x)}(t) : t \in Dom(\gamma^2_{\Psi(x)})\}$.*

(E2) *Ψ induces a bijection on frame curves that are not overlap curves; i.e., for each frame curve D_1, which occurs in the construction of the optimal feedback for Σ_1 and is not a K-curve, we have that $\varphi(D_1)$ is a frame curve of the same type corresponding to Σ_2 and vice versa.*

(E3) *If A is an open region of R_1' enclosed by frame curves and entirely covered by Y- or X-trajectories, then $\Psi(A)$ is enclosed by the corresponding frame curves and is covered by Y- or X-trajectories, respectively.*

3. Graphs. In this section we introduce the definition of graph and describe a procedure to associate a graph with every system for which the algorithm $\mathcal{A}$ succeeds. The points and edges of this topological graph correspond to frame points and curves of the system. Moreover, some additional *lines* must be included in the definition of graph to describe the *history* of all trajectories that form the optimal synthesis. In Remark 4.1 we give some examples to motivate the definition of graph.

From now on, we consider only the systems of Ξ for which the algorithm $\mathcal{A}$ succeeds.

DEFINITION 2 (graph). *A graph $\mathcal{G}$ is a finite set of points of $\mathbb{R}^2$ and smooth connected one-dimensional boundary manifolds connecting the points, called edges. Moreover, inside each region enclosed by edges there are possibly some other smooth manifolds, called lines, connecting points and edges. We assume that edges and lines do not cross one another.*

Every edge can be of one of the following type: X, Y, F, S, C, K, corresponding to the types of frame curves. An edge of type X, Y, or S has an orientation and hence an initial and a terminal point. The edges of type C have a positive side, corresponding to the fact that constructed trajectories cross a frame curve of type C passing from one side to another.

Every region enclosed by edges that are not all of F type has a sign $+$ or $-$. This corresponds to the fact that a region of the reachable set in unit time R that contains no frame curve is covered by X- or by Y-trajectories. On each region we can have some curves connecting points and edges. These correspond to constructed trajectories that pass through frame points. See Remark 3.1 below.

We say that two edges E_1, E_2 are related and we write $E_1 \sim E_2$ if they have in common a point of the graph.

We now describe a canonical way of associating a graph with a system. Given a system Σ (for which $\mathcal{A}$ succeeds) we associate a graph $\mathcal{G}$ with Σ in the following way. For every frame point we construct a point of $\mathcal{G}$ having the same coordinate in $\mathbb{R}^2$. For every frame curve D, with no frame point in $D \setminus \partial D$, $\partial D = \{x_1, x_2\}$, we construct an edge E of $\mathcal{G}$ of the same type connecting the points of $\mathcal{G}$ corresponding to x_1, x_2. If D is an X, Y, or S-curve, then D has the orientation of increasing time and we endow E with the corresponding orientation. If D is of type C, then some constructed trajectories enter one side of D. We define the corresponding side of E to be positive. For every region $A \subset R$ enclosed by frame curves there is a region A' in the plane of the graph enclosed by the corresponding edges. If A is covered by Y-trajectories, we assign to A' the positive sign, otherwise we assign to A' the negative sign.

Now we pass to the construction of lines. These lines are necessary to describe the behavior of every optimal trajectory of the synthesis; see Remark 3.1. Consider a frame point x of $Cl(A)$, which is not of (K, K) type (recall the terminology of [11]), and the constructed trajectory γ_x verifying $\gamma_x(t_x) = x$ for some t_x. Assume that $\gamma_x(I) \subset A$ for some $I = [a, b] \subset Dom(\gamma)$, $t_x \in I$. Notice that it can happen $a \neq t_x \neq b$, e.g., if x is of type $(X, K)_3$. If $t_x \neq a$ and $\gamma_x(a) \in D$ frame curve, then we construct a line in A' going from a point y of the edge E, corresponding to D, to the point x' of $\mathcal{G}$ corresponding to x. If $\gamma_x(a)$ is a frame point, then we choose y to be the corresponding point of E, otherwise we choose y in $E \setminus \partial E$. If D is of C type, and $\gamma_x(a) \in D \setminus \partial D$, then we consider the last switching point z of γ_x before $\gamma_x(a)$. If D is of S type then there exists a constructed trajectory γ_1 that switches at $\gamma_x(a)$ and enters the region on the opposite side, with respect to D, of the region entered by γ_x. Indeed, a Y and an X constructed trajectory originate from every point of a turnpike. In this case, we let z be the first switching point of γ_1 after $\gamma_x(a)$. If z belongs to a frame curve D_1 then we construct a line going from a point z' of the edge E_1, corresponding to D_1, to the point y. Again if z is a frame point we let z' be the corresponding point of $\mathcal{G}$. If D_1 is a C or S frame curve then we proceed in the same way. We continue until we reach a frame curve not of C or S type. We do the same if $t_x \neq b$.

We can construct these lines in such a way that they do not cross one another. If $\mathcal{G}$ is associated to Σ in this way then we say that $\mathcal{G}$ is *canonically associated* with Σ.

Remark 3.1. Consider the system

$$\begin{cases} \dot{x}_1 = 3x_1 + u, \\ \dot{x}_2 = x_1^2 + x_1. \end{cases}$$

For every time $\tau > \ln(4)/3$ the reachable set in time τ contains two switching curves starting from γ^-. There are two frame points of type (X, C) that are not topologically equivalent. See Example 3 of [11] for an accurate description of this system Σ_3 and for the classification of (X, C) frame points. Portrayed are the reachable set of Σ_3 in Fig. 1 and its associated graph $\mathcal{G}_3$ in Fig. 2. If we do not specify a sign for every region of $\mathcal{G}_3$ then the two (X, C) frame points are not distinguishable. Hence, for some system Σ with a frame point of type $(X, C)_1$ or $(X, C)_2$, we can construct a system with the same graph, except the signs of the regions, but not equivalent to Σ. This shows the necessity of specifying a sign for every region.

Consider the system Σ_4 of Example 4 of [11]. There is a region A that is a connected component of the complement of the reachable set and is bounded. In the corresponding graph, we cannot give a sign to the region corresponding to A.

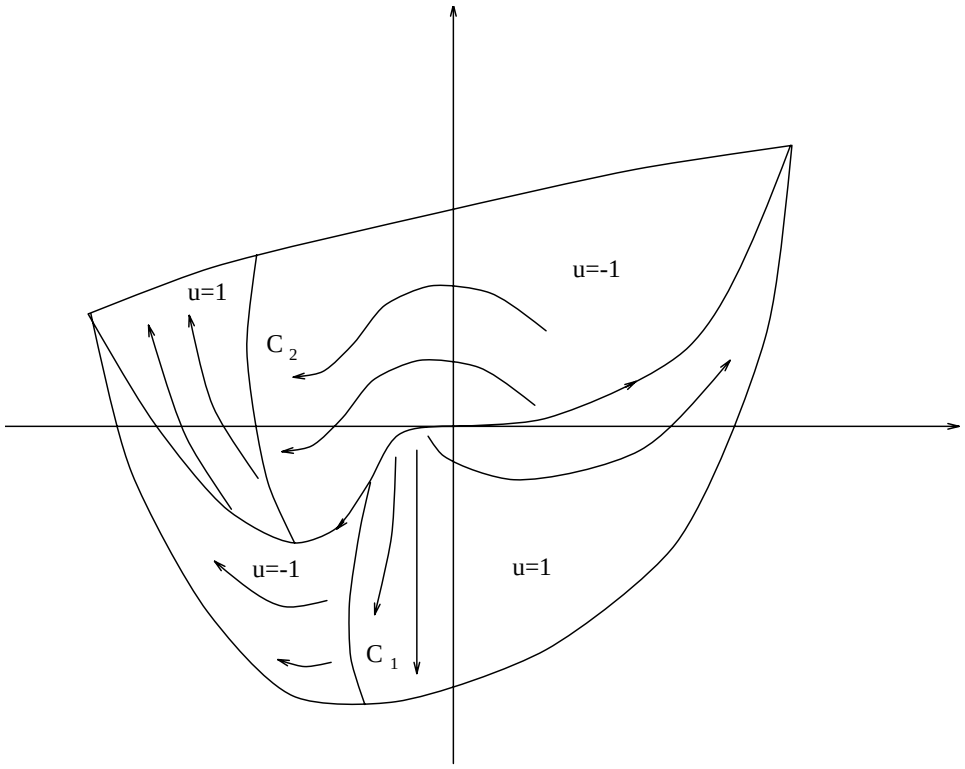

FIG. 1.

Otherwise, we would have equivalent systems corresponding to different graphs. The regions enclosed by edges all of F type correspond exactly to the *holes* of the reachable set.

Consider now the frame point x of $(C,S)_2$ type of Example 8 of [11]. If we do not specify, in the corresponding graph, a positive side for the edge corresponding to the switching curve then we do not know, from the graph, if the Y or the X trajectories enter the switching curve. Again there would exist two not equivalent systems corresponding to the same graph.

The lines divide the graphs into subregions in such a way that the trajectories, contained in the same subregion, have the same *history*, i.e., cross the same frame curves in the same order and are composed of the same sequence of elementary arcs. For example, $XYSX...$, where X, Y, and S denote, respectively, X,Y arcs and trajectories running a turnpike. If the lines are not constructed, then in some cases we cannot decide the story of every trajectory and then we cannot recognize equivalent systems. To appreciate this point, consider the following examples. First, let the syntheses of Figs. 3 and 4 correspond to some system. The associated graphs contain the same points and edges. However, the syntheses are not equivalent. Indeed, the homeomorphism Ψ should map the trajectory through the (X,S) point onto the corresponding one to satisfy (E1), but obviously in this case (E2) cannot be satisfied. To have an explicit example, consider now the system Σ_4 of the fourth example of [11]. Let γ be the constructed trajectory that passes through the (Y,S) point and then goes on as X trajectory. If we do not consider the lines, from the graph associated to

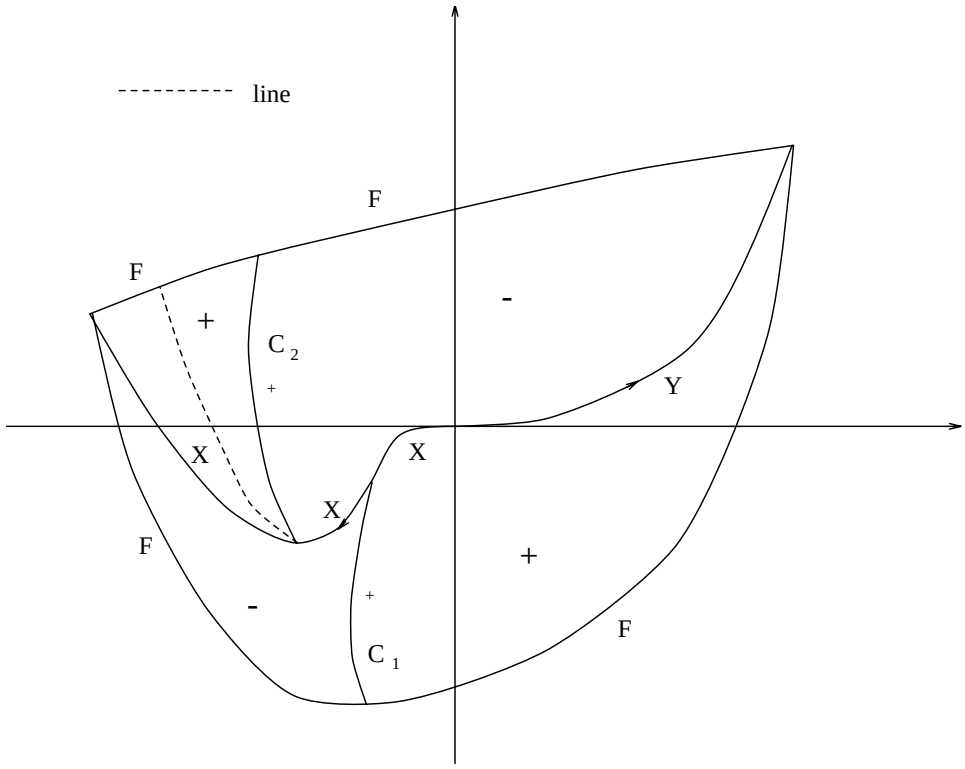

FIG. 2.

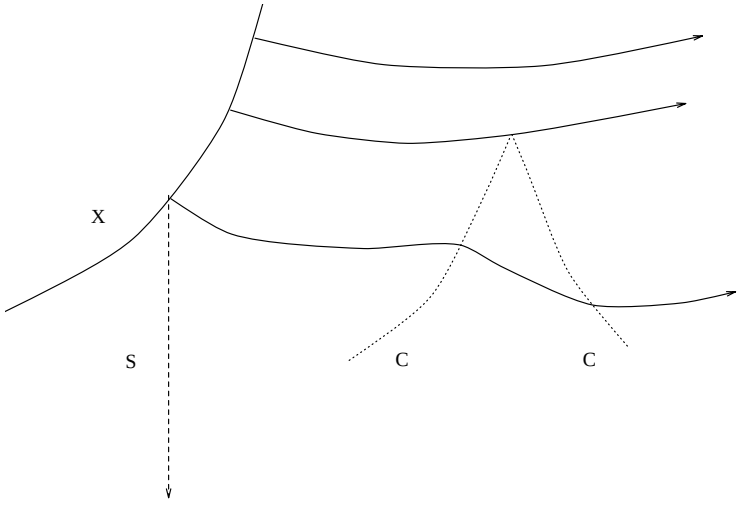

FIG. 3.

Σ_4 we cannot know if γ reaches the overlap curve or the frontier of the reachable set. Hence we cannot uniquely determine the synthesis from the graph.

4. Admissible graphs. We now give some admissibility conditions that characterize a class of graphs. This class will be proved to be the class of graphs that correspond to systems canonically.

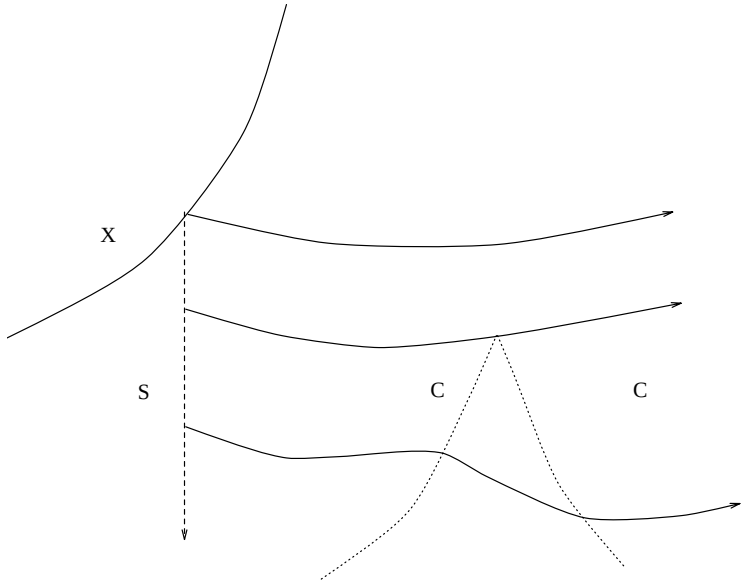

FIG. 4.

With every system of the examples of [11] we can associate a topological graph in the canonical way. We consider these examples restricted to a neighborhood of a frame point; then we obtain a set of graphs $\mathcal{E}$ whose elements are defined locally, and each one corresponds to a type of frame point. A point x' of a graph $\mathcal{G}$ is said to be *admissible* if there exists a graph $\mathcal{G}' \in \mathcal{E}$ such that $\mathcal{G}$ contains a copy of $\mathcal{G}'$ to which x' belongs. We use the same terminology for the points of $\mathcal{G}$, e.g., (X, Y) point. The first condition is

($\mathcal{G}1$) all points of $\mathcal{G}$ are admissible.

We consider graphs that contain exactly one point of the type (X, Y) and we call this point the *origin* of the graph. Assume that ($\mathcal{G}1$) holds. Let E be a Y-edge and let x be the initial point of E. If x is not the origin then there exists a Y-edge E_1 for which x is the terminal point. We consider the initial point x_1 of E_1 and do the same considerations. Since $\mathcal{G}$ is finite, proceeding by induction, we find a finite collection $E_1, \dots, E_n$ of Y-edges such that $E_i \sim E_{i+1}$, $i = 1, \dots, n-1$, and the initial point of E_n is the origin. Then, since there is only one origin, the Y-edges form a set $\{E_1, \dots, E_m\}$ such that the initial point of E_1 is the origin and for each $i = 1, \dots, m-1$ the terminal point of E_i is the initial point of E_{i+1}. We call η^+ the union of these edges. Analogously we define η^- for the X-edges. In the first step of $\mathcal{A}$ we have described all the possibilities for the sequence of frame points on a curve γ^+ of a system Σ. We say that η^+ is *admissible* if there exists a system Σ such that the curve γ^+ corresponds to η^+ canonically. That is, there is a correspondence defined for points, edges of η^+, for lines intersecting η^+, and for the regions to which η^+ belongs, that follows the rules of canonical correspondence. This happens exactly when η^+ and γ^+ have an ordered sequence of corresponding points. The second condition is

($\mathcal{G}2$) $\mathcal{G}$ has exactly one (X, Y) point, called the origin. The collections of edges $\eta^\pm$ are admissible.

Let E be a C-edge, x_1', x_2' be the endpoints of E, and A' be a region on one side of E. There exist two frame points x_1, x_2 corresponding to x_1', x_2'. Consider the correspondence between x_1' and x_1. Let D be the frame curve that corresponds to E

and $\tilde{A}_1$ the region corresponding to A'. We define A_1 to be the connected component of $\tilde{A}_1 \setminus \{x : \Delta_A(x)\Delta_B(x) = 0\}$ that contains D. Similarly we define the region A_2. We say that E is *admissible* if there exist x_1, x_2 such that the functions Δ_A, Δ_B has the same sign on A_1 and A_2.

Remark 4.1. If, for example, E connects two points of (C, S) type then A_1, A_2 are both covered by Y-trajectories or both are covered by X-trajectories. In this case, since the two vector fields must point to opposite sides of turnpikes, it follows that Δ_A has a different sign on the two regions A_1, A_2. From Theorem 3.9 of [14] we have that along C the function f (see (2.5), (2.6)) does not change sign. Hence there exists at least one curve, intersecting C, on which $\Delta_A = 0, \Delta_B = 0$. This is clearly not a generic situation and is not compatible with the condition (P_3) of section 4 of [10].

Another admissibility condition is

($\mathcal{G}3$) every C-edge is admissible.

The relation $\sim$ divides the set of F-edges into a finite number of equivalence classes. If ($\mathcal{G}1$) holds, then the union of the elements of an equivalence class forms a closed curve.

($\mathcal{G}4$) Only one closed curve that is union of the elements of an equivalence class of F-edges, encloses a region in which there are points and edges. Moreover, there are no frame curves and points outside this region.

Notice that we can have situations with more than one equivalence class of F-edges, e.g., the system in Example 4 of [11] where $R(\tau)$ has one hole.

DEFINITION 3 (entrance, exit, side). *Consider a region A' enclosed by edges of $\mathcal{G}$. If one edge E is of X type if A' is positive, of Y type if A' is negative, of C type with the negative side on A', or of S type, then we say that E is an entrance. If E is of K, F, or C type with positive side on A' then we say that E is an exit. Otherwise, we say that E is a side, i.e., if it is of Y type and A' is positive or of X type and A' is negative. The definitions are motivated by the fact that if D is a frame curve corresponding to E canonically, then through each point of D there pass a constructed trajectory that enters, resp., exits from the region corresponding to A' if and only if E is an entrance, resp., exit.*

We say that the set of lines of $\mathcal{G}$ is admissible if the following holds. Every line connects an entrance to an exit. If a point x' belongs to two entrances, resp., exits, then there is a line connecting x' with an exit, resp., entrance. Let x' be a point of one of the types $(X, C)_3, (X, K)_3, (C, C)_1, (C, S)_2, (C, K)_1, (S, K)$, and let A', B' be the two regions such that $x' \in Cl(A'), Cl(B')$. There are two lines l_1, l_2, both contained in A' or both in B', passing through x'; l_1 connects x' to an entrance and l_2 connects x' to an exit.

If x' is of type $(C, C)_2$ then there are two lines arriving at x' from different regions and at least one of them reaches another point. These are the only lines that connect two points.

If $x' \in E \setminus \partial E$, E is of C or S type and there is a line l arriving at x' from a region A' then there is a line arriving at x' from the other region B' such that $x' \in Cl(B')$.

There are no other lines. If all these conditions are satisfied then we say that the set of lines of $\mathcal{G}$ is admissible.

Remark 4.2. The conditions given for the set of lines follow directly from the canonical way of associating a graph with a system and from the description of frame points given in [11]. If we do not assume that the set of lines is admissible, then we cannot expect that there exists a system corresponding to $\mathcal{G}$.

Consider the closed curve $\tilde{F}$, union of F-edges, described in ($\mathcal{G}4$). Let U be the connected component of the complement of the union of F-edges, that is, enclosed by

$\tilde{F}$ and verifies $\tilde{F} \subset Cl(U)$. If A' is a region contained in U we define $L(A')$ to be the set of lines contained in A'. The last condition is

($\mathcal{G}5$) the set of lines of $\mathcal{G}$ is admissible. If $A' \subset U$ and A'_1 is a connected component of $A' \setminus L(A')$, then $Cl(A'_1)$ contains exactly one entrance and one exit.

We have given the conditions in ($\mathcal{G}_5$) only for regions $A' \subset U$, because if the opposite happens, then A' corresponds to an hole of R, $L(A) = \emptyset$ and $Cl(A')$ contains only exits.

If a graph $\mathcal{G}$ satisfies the conditions $(\mathcal{G}1), \dots, (\mathcal{G}5)$, then we say that $\mathcal{G}$ is *admissible*. It is easy to check that if $\mathcal{G}$ corresponds to a system Σ, then $\mathcal{G}$ is admissible. In the following we will prove the converse.

5. Classification. To ensure that the canonical way of associating a graph with a system is well defined we have to prove that two systems are equivalent if and only if the associated graphs are equivalent.

Since we have defined the equivalence between systems in *weak* form, excluding overlap curves, we have that equivalent systems may correspond to graphs having a different number of K edges. Hence we have to define an equivalence relation between graphs excluding K edges. We give below the exact definition.

Given two admissible graphs $\mathcal{G}_1, \mathcal{G}_2$, we say that they are equivalent and we write $\mathcal{G}_1 \sim \mathcal{G}_2$ if there is a correspondence ψ between edges and lines such that the following hold. We let ψ be multivalued and not injective on the set of K-edges, but it has to be a bijective function restricted to the edges not of K type. Moreover, ψ is a bijective function restricted to the set of lines. Finally the following holds:

(H1) For every edge E, not of K type, $\psi(E)$ is an edge of the same type; $E_1 \sim E_2$ if and only if $\psi(E_1) \sim \psi(E_2)$, when E_1, E_2 are not both K-edges; ψ preserves orientations and positive sides

(H2) If l is a line that connects E_1 with E_2, then $\psi(l)$ connects $\psi(E_1)$ with $\psi(E_2)$. The same holds for line connecting points. If l_1, l_2 arrive at the same point, then the same happens for $\psi(l_1), \psi(l_2)$.

(H3) If A' is a region enclosed by edges $E_1, \dots, E_n$, then the region enclosed by $\psi(E_1), \dots, \psi(E_n)$ has the same sign.

(H4) If $\mathcal{K}_1, \mathcal{K}_2$ is the set of equivalence classes of K-edges (for the relation $\sim$) of $\mathcal{G}_1, \mathcal{G}_2$, then ψ induces a bijective correspondence between $\mathcal{K}_1, \mathcal{K}_2$.

We have the following theorem.

THEOREM 5.1. *If Σ_1, Σ_2 are two systems and $\mathcal{G}_1, \mathcal{G}_2$ the corresponding graphs, then $\Sigma_1 \sim \Sigma_2$ if and only if $\mathcal{G}_1 \sim \mathcal{G}_2$.*

Proof. Assume first that $\Sigma_1 \sim \Sigma_2$ and let Ψ be as in the definition of equivalence. For simplicity we will use the symbols Γ_1, Γ_2 for $\Gamma_{\mathcal{A}}(\Sigma_1), \Gamma_{\mathcal{A}}(\Sigma_2)$, respectively.

Given a frame curve D of Γ_1 that is not a K-curve, let E_1, E_2 be the edges corresponding, respectively, to D and $\Psi(D)$. We define $\psi(E_1) = E_2$. We can proceed in the same way to define ψ on the set of lines. From (E1), (E2) it follows that (H1) and (H2) hold, and from (E3) it follows that (H3) holds.

Now, if K_1, K_2 are two K frame curves (of K type) of Γ_1, or of Γ_2, then we set $K_1 \sim K_2$ if they have a point in common. The union of the elements of an equivalence class of Γ_1 is a connected curve K. If we extend Ψ by continuity, then $\Psi(K)$ is the union of elements of an equivalence class of Γ_2. Therefore we can define ψ on K-edges in such a way that (H4) holds.

Assume now that $\mathcal{G}_1 \sim \mathcal{G}_2$. Let E_1 be an X, Y or S-edge of $\mathcal{G}_1$, let $E_2 = \psi(E_1)$, and let D_1, D_2 be the frame curves corresponding to E_1, E_2, respectively. From (H1) we have that D_1, D_2 are of the same type. Assume that $x_1, \dots, x_n$ are the points of

$D_1 \setminus \partial D_1$, ordered for increasing time, that are in relation with a frame point, not of (K, K) type, for the definition given in [2]. There are exactly n lines if D_1 is of X or Y type and $2n$ lines if D_1 is of S type, starting at x_i. From (H2) it follows that there exist $y_1, \dots, y_n \in D_2 \setminus \partial D_2$, ordered for increasing time, from which some lines of $\mathcal{G}_2$ start. Observe that, if l is a line passing through x_i and $\psi(l)$ passes through y_j, then $i = j$. Indeed, if $i \neq j$, there must be a crossing between lines, but this is not allowed by the definition of a graph. We define Ψ on D_1 in such a way that Ψ is a homeomorphism, $\Psi(D_1) = D_2$ and $\Psi(x_i) = y_i$, $i = 1, \dots, n$.

For every $y \in D_1$ consider the constructed trajectories $\gamma_y \in \Gamma_1$ for which $y = \gamma_y(b_y)$ is a switching point. If D_1 is of X or Y type, there is at most one such trajectory; if D_1 is of S type, then there are two such trajectories. If D_1 is of type X or Y and there exists γ_y, then from (H3) there exists a trajectory $\gamma_{\Psi(y)} \in \Gamma_2$ having the same property. Let $c_y > b_y$ be the first time in which γ_y reaches another frame curve and define $b_{\Psi(y)}, c_{\Psi(y)}$ similarly. We define

$$\Psi(\gamma_y(t)) \doteq \gamma_{\Psi(y)} \left(b_{\Psi(y)} + \frac{c_{\Psi(y)} - b_{\Psi(y)}}{c_y - b_y}(t - b_y) \right) \quad \forall t \in [b_y, c_y].$$

In this way we have defined Ψ also on the frame curves that are reached by the trajectories γ_y. We proceed in the same way, defining Ψ on the images of the constructed trajectories that switch at the point of these new frame curves. After a finite number of steps we define Ψ on the whole reachable set R_1 of the system Σ_1. Notice that we can have two different definitions of Ψ on the K frame curves, but Ψ restricted to R_1' (see the definition of equivalence) is well defined. Condition (E1) follows by construction. Conditions (H1), (H2) ensure that corresponding trajectories have the same history, i.e., they cross the same type of frame curves in the same order and are composed of the same elementary arcs. Finally from conditions (H1)–(H4) we have that Ψ satisfies (E1)–(E3). □

Assume now that $\mathcal{G}$ is an admissible graph. We want to find a system Σ such that $\mathcal{G}$ is associated with Σ in the canonical way. This and Theorem 5.1 show that the correspondence $\Sigma \leftrightarrow \mathcal{G}$ is a bijection between the set of equivalence classes of systems for which $\mathcal{A}$ succeeds and the set of equivalence classes of admissible graphs.

THEOREM 5.2. *If $\mathcal{G}$ is an admissible graph, then there exists a system Σ to which $\mathcal{G}$ is canonically associated.*

Proof. We construct $\Sigma = (F, G)$ defining it on a finite collection of open sets that cover $\mathcal{G}$ and then gluing together along the intersections. We proceed defining Σ and a synthesis Γ for Σ at the same time. Moreover, every trajectory $\gamma \in \Gamma$ will be endowed with an adjoint covector. At the end of the construction, we will have $\Gamma \equiv \Gamma_{\mathcal{A}}(\Sigma)$. It can happen that we will determine Σ defining two of the fields $F, G, X = F - G, Y = F + G$.

Let $\tilde{F}$ be the union of the elements of the equivalence class of F-edges described in $(\mathcal{G}4)$. Consider the connected components of the complement, in $\mathbb{R}^2$, of the union of F-edges of $\mathcal{G}$. There is only one such component R that is contained in the region enclosed by $\tilde{F}$ and such that $\tilde{F} \subset Cl(R)$. We have to construct Σ only on R.

From $(\mathcal{G}2)$, we have that there is one origin O and O will be also the origin for Σ. It is clear that, possibly translating $\mathcal{G}$, we can assume that O is the origin of $\mathbb{R}^2$. Consider a differentiable change of coordinates such that η^+ corresponds, in the new coordinates, to the line $\{(x_1, x_2) : x_2 = 0, 0 \leq x_1 \leq a\}$ for some $a > 0$. We define the field $Y = F + G$ to be the constant field $(1, 0)$ on a neighborhood N^+ of η^+ that contains only the points of $\mathcal{G}$ that are in η^+. Since η^+ is admissible there

exists a function $\tilde\theta$ such that the points $\{t_i, t_i', s_i, s_i'\}$ of (3.3), (3.4) of [2] determine the same sequence of frame points of η^+. We can define a vector field $G(x_1)$ on N^+ such that the function θ of (3.1) of [2] verifies $\theta(t) = \tilde\theta(t)$. This is easy because from the definition of Y we have that

$$\theta(t) = \theta(x_1) = \arg(G(0), G(x_1)).$$

Since the synthesis is determined by the sequence of maxima and minima of θ and not by the values at these points, we can assume that $|\theta| < \pi/2$ at every point of (3.3), (3.4) of [2]. Therefore, if $G(x_1) = (\alpha(x_1), \beta(x_1))$, then $\alpha > 0$ and

$$\nabla\Delta_B \cdot X = (1 - 2\alpha)\, \nabla\Delta_B \cdot Y.$$

Indeed, we have

$$\nabla\Delta_B = \begin{pmatrix} \alpha \frac{\partial^2 \beta}{\partial x_1^2} - \beta \frac{\partial^2 \alpha}{\partial x_1^2} \\ 0 \end{pmatrix}, \qquad X = \begin{pmatrix} 1 - 2\alpha \\ -2\beta \end{pmatrix}.$$

The choice of θ uniquely determines the direction of the vector G but not its norm. Hence, we can choose α in such a way that $\nabla\Delta_B \cdot Y$, $\nabla\Delta_B \cdot X$ have the same (resp., the opposite) sign at the points $p_i = \gamma^+(t_i), p_i' = \gamma^+(t_i')$ if at the corresponding points of η^+ there is a C-edge (resp., an S-edge). From (III) of Proposition 3.1 of [2] it follows that there is a canonical correspondence at the points p_i, p_i'.

We can again modify θ, G in such a way that $\dot\Gamma_i(0)$, $i > 1$ (see (3.23,24), (SA7) of [2]) lies in the cone determined by $Y(q_i), G(q_i)$, $q_i = \gamma^+(s_i)$. We proceed in the following way. For every y sufficiently small there exists an extremal trajectory γ_y, with second coordinate constantly equal to y after the last switching, that switches along Γ_i. Let λ_y be its associated covector. Now Y is constant; then λ_y is also constant after the last switching time of γ_y, and there exists $\zeta_1(y)$ such that $\lambda_y \cdot G(\zeta_1(y)) = 0$. Since θ is increasing near s_1, we have that $\lambda_y \cdot G(x_1)$ is a monotone function of x_1 in $[s_1 - \varepsilon, s_1 + \varepsilon]$ for some $\varepsilon > 0$ and then $\zeta_1(y)$ exists uniquely for y small. Assume we want to modify G in such a way that Γ_i is described by the points $(\zeta_2(y), y)$. Let $\xi(y, x_1)$ be a smooth function, monotone in x_1 for every y, verifying

$$\xi(y, s_i \pm \varepsilon) = s_i \pm \varepsilon, \qquad \xi(y, \zeta_2(y)) = \zeta_1(y).$$

We redefine G in such a way that if $\tilde\theta(x_1, x_2) = \arg(G(0), G(x_1, x_2))$ then $\tilde\theta(x_1, x_2) = \theta(\xi(x_2, x_1))$. From the definition of ξ and its monotonicity we have that γ_y switches at $(\zeta_2(y), y)$.

Now, choosing the module of $G(q_i)$ in a suitable way, we can assume that X, Y point to the same side, resp., to opposite side, of Γ_i if at the corresponding points of η^+ there is a C-edge, resp., a K-edge. We can repeat the same construction for $q_i' = \gamma^+(s_i')$.

Finally, possibly changing θ, G, we can assume that $\delta > 0$, resp., < 0 (see (SA8) of [2] for the definition of δ) if at the point of η^+ corresponding to q_1 there is a C-edge, resp., a K-edge. We repeat the same arguments for q_1'. Therefore from Propositions 3.1, 3.2, and 3.3 of [2] we have that η^+ corresponds to γ^+ in the canonical way. Since we have defined Y and G the system Σ is determined.

Now consider η^- and a change of coordinate as for η^+. Possibly restricting N^+, we can define X and G on a neighborhood N^- of η^- in such a way that they coincide on N^+ with the previous definitions and such that γ^- corresponds to η^- in the canonical

way. In this way we have defined Σ on $N^+ \cup N^-$, that is, a neighborhood of $\eta^+ \cup \eta^-$. We define $\Gamma = \Gamma_{\mathcal{A}}(\Sigma)$ on $N^+ \cup N^-$ and with every $\gamma \in \Gamma$ we associate the covector field constructed by $\mathcal{A}$.

Now, let x' be a point of $\mathcal{G}$ that is not in $N^+ \cup N^-$. From ($\mathcal{G}1$) there exists a frame point x, corresponding to x', that is of one of the types classified in [11]. We have shown, in [11], an example for every classified point; hence there exists a system $\Sigma(x')$, a synthesis $\Gamma(x')$ both defined on an open set $U(x')$ and a frame point $x \in \Gamma(x')$ that corresponds to x' in the canonical way. Consider an open neighborhood U' of x' that does not contain any other frame point and define a diffeomorphism $\Psi : U(x') \to U'$ in such a way that Ψ maps frame points and curves to corresponding points and edges. Moreover, Ψ maps some constructed trajectories to the corresponding lines. Using Ψ, we define Σ and Γ on U' and we associate a covector field to every $\gamma \in \Gamma$.

From ($\mathcal{G}3$) it follows that every C-edge E is admissible. However, it may happen that if x', y' are the points belonging to E, the functions Δ_A, Δ_B do not have the required signs on $U'(x'), U'(y')$. If $\Sigma(x') = (F, G)$ is one of the system of the examples of [11], we can consider the systems

$$\Sigma_1 = (F, -G), \qquad \Sigma_2 = (-F, G), \qquad \Sigma_3 = (-F, -G).$$

Let Δ_A^i, Δ_B^i be the functions Δ_A, Δ_B for Σ_i. We have that

$$\Delta_A^1, \Delta_A^2 = -\Delta_A; \qquad \Delta_A^3 = \Delta_A; \qquad \Delta_B^1 = \Delta_B; \qquad \Delta_B^2, \Delta_B^3 = -\Delta_B.$$

The systems Σ_i have the same type of synthesis of Σ (choosing the dual vectors in a suitable way). Therefore we can define $\Sigma(x'), \Sigma(y')$ in such a way that the functions Δ_A, Δ_B have the correct signs.

Next, we define Σ on neighborhoods of frame curves. Let E be a frame curve, not of X or Y type, connecting the points x', y'. We choose a differentiable change of coordinates Ψ in such a way that E corresponds to the line $\{(x_1, x_2) : x_2 = 0, 0 \leq x_1 \leq a\}$ for some $a > 0$. If E is of C, S, or K type then we define Ψ in such a way that the vector field Y (defined on $U'(x') \cup U'(y')$) corresponds to the vector field $(0, 1)$. If E is of F type and the region on one side of F is positive then again we let Y correspond to $(0, 1)$, otherwise we let X correspond to $(0, 1)$. For each type of curve we have shown an example in [11]. We choose the system $\Sigma(E)$ that gives an example of frame curve D of the same type of E and is defined on an open set $U(E)$. If E is of C type, we can choose $\Sigma(E)$ in such a way that Δ_A, Δ_B have the right sign, i.e., compatible with the systems $\Sigma(x'), \Sigma(y')$. We define a diffeomorphism $\Psi' : U(E) \to U'(E)$, where $U'(E)$ is a neighborhood of E, in such a way that Ψ' establishes a canonical correspondence between D and E, and its differential $d\Psi'$ sends either the vector field Y or X onto the vector field $(0, 1)$, following the same rules used for Ψ.

We now glue together the systems defined near points and edges. Let V_1, V_2 be two open neighborhoods of x' verifying

$$Cl(V_1) \subset V_2 \subset Cl(V_2) \subset U'(x')$$

and consider a smooth function $h_{x'}$ defined on

$$U = U'(x') \cup U'(y') \cup U'(E)$$

such that

$$h_{x'} \restriction V_1 \equiv 1, \qquad h_{x'} \restriction U \setminus V_2 \equiv 0.$$

We define $h_{y'}$ in the same way for y'. Let $(F', G'), (F'', G'')$ be the vector fields already defined on $U'(x') \cup U'(y'), U'(E)$, respectively, and define them to be zero elsewhere in U. We set

$$\tilde{F} \doteq (h_{x'} + h_{y'})F' + (1 - h_{x'} - h_{y'})F'', \qquad \tilde{G} \doteq (h_{x'} + h_{y'})G' + (1 - h_{x'} - h_{y'})G''.$$

In this way we have defined a system $\tilde{\Sigma} = (\tilde{F}, \tilde{G})$ on U. Since the syntheses corresponding to $\Sigma(x'), \Sigma(y')$, and $\Sigma(E)$ coincide on the set of intersections, Γ is well defined on U. However, if E is of C or of S type, it may happen that in the set where $h_{x'}, h_{y'} \neq 0, 1$, the functions $\tilde{\Delta}_A, \tilde{\Delta}_B$, do not have the required properties.

Consider first the case in which E is an S-edge. From E there originate Y-trajectories that enter the half plane $\{(x_1, x_2) : x_2 > 0\}$. In this case,

$$\tilde{X}_2 < 0, \qquad \tilde{X}_1 > 0, \qquad \tilde{G}_1 < 0, \qquad \tilde{\Delta}_A > 0.$$

We define a new system Σ by setting

$$Y \doteq \tilde{Y} + (0, \alpha), \qquad X \doteq \tilde{X},$$

where $|\alpha| < 1$. We have $\Delta_A = (1/2)(1 + \alpha)\tilde{X}_1 > 0$. If $\alpha(x_1, 0) \equiv 0$ then, after straightforward calculations, we obtain

$$\Delta_B(x_1, 0) = \frac{1}{2}\left(2\tilde{\Delta}_B + \frac{\partial \alpha}{\partial x_2}\tilde{G}_1\tilde{X}_2\right), \tag{5.1}$$

and then we can choose $(\partial\alpha/\partial x_2)(x_1, 0)$ in such a way that $\Delta_B(x_1, 0) \equiv 0$. Moreover,

$$\nabla\Delta_B(x_1, 0) = \nabla\tilde{\Delta}_B(x_1, 0) + \Theta_1 + \Theta_2, \qquad \Theta_1 = \begin{pmatrix} 0 \\ \frac{\partial^2 \alpha}{\partial x_2^2}\tilde{G}_1\tilde{X}_2 \end{pmatrix},$$

$$\Theta_2 = \frac{\partial \alpha}{\partial x_2}\left[\nabla(\tilde{G}_1\tilde{X}_2) + \begin{pmatrix} 0 \\ \tilde{G}_2\frac{\partial \tilde{X}_1}{x_2} - \tilde{G}_1\frac{\partial \tilde{X}_2}{x_2} - \frac{1}{2}[\tilde{X}, \tilde{Y}]_1 \end{pmatrix}\right] + \begin{pmatrix} \frac{\partial^2 \alpha}{\partial x_1 \partial x_2}\tilde{G}_1\tilde{X}_2 \\ \frac{\partial^2 \alpha}{\partial x_2 \partial x_1}\tilde{G}_1\tilde{X}_1 \end{pmatrix};$$

hence Θ_2 is determined by the previous choices but we can define α choosing

$$\frac{\partial^2 \alpha}{\partial x_2^2}(x_1, 0)$$

in such a way that $\nabla\Delta_B(x_1, 0) \neq 0$. From the compactness of E, it follows that there exists a neighborhood U' of E such that $\{x \in U' : \Delta_B(x) = 0\} = \{(x_1, x_2) : x_2 = 0\}$. Then we consider Σ restricted to U'.

Consider now the case in which E is a C-edge. Assume that from E start Y-trajectories that enter the half plane $\{(x_1, x_2) : x_2 > 0\}$ and that $\tilde{X}_1 > 0$ ($\tilde{X}_2 > 0$ follows from $\tilde{Y}_2 > 0$). Again we define $Y = \tilde{Y} + (0, \alpha), X = \tilde{X}$. If we set $\alpha(x_1, 0) = 0$, then (5.1) holds and we can choose $(\partial\alpha/\partial x_2)$ in such a way that $\Delta_B(x_1, 0) \neq 0$. Again by the compactness of E, there exists a neighborhood U' of E in which Δ_B does not vanish. We consider Σ restricted to U'.

Finally, we want to associate with every trajectory γ of Γ a covector field. If γ is contained in $V_1(x')$ or $V_1(y')$ or in $U'(E) \setminus (V_2(x') \cup V_2(y'))$ (see the definitions above), we can associate a dual variable with γ using Ψ or Ψ', because γ corresponds to a trajectory of the synthesis of $\Sigma(x')$ or $\Sigma(y')$ or $\Sigma(E)$. Otherwise assume that γ

verifies $\gamma(t_x) = x \in E \setminus \partial E$. If E is either an F- or K-edge and γ is a Y-trajectory, resp., X-trajectory, then we choose λ_γ such that $\lambda_\gamma \cdot G(x) > 0$, resp., < 0. If E is either an S- or a C-edge and γ is a Y-trajectory, resp., X-trajectory, after t_x, then we choose λ_γ in such a way that $\lambda_\gamma \cdot G(x) = 0$ and, if E is a C edge, $\lambda_\gamma \cdot [F, G](x) > 0$, resp., < 0. We associate to γ the adjoint variable that verifies $\lambda(t_x) = \lambda_\gamma$. It is clear that if $\gamma(I)$ is not a turnpike for every $I \subset Dom(\gamma)$, then (γ, λ) satisfies the PMP on some neighborhood of t_x. Assume now that $\gamma(I)$ is a turnpike, $I = [a, b]$. Let φ_S be the control defined in (2.16) of [2], and consider the system

$$\begin{cases} \dot{x} = F(x) + \varphi_S(x)G(x), \\ \dot{\lambda} = -\lambda \cdot (\nabla F(x) + \varphi_S(x)\nabla G(x)), \end{cases} \tag{5.2}$$

and the following submanifold of $\mathbb{R}^4$:

$$Z = \{(x, \lambda) : \lambda \cdot G(x) = 0\}.$$

From the definition of λ, we have $\lambda(b) \cdot G(\gamma(b)) = 0$. Since $\Delta_B(\gamma(t)) = 0$ for $t \in [a, b]$, from

$$\frac{d}{dt}(\lambda \cdot G) = \lambda \cdot [F, G],$$

we have

$$\lambda(t) \cdot G(\gamma(t)) = 0 \quad \Rightarrow \quad \frac{d}{ds}(\lambda(s) \cdot G(\gamma(s)))\Big|_{s=t} = 0.$$

By the standard theory of ODEs on closed set, we obtain the existence of a solution (x, μ) that verifies $x(b) = \gamma(b), \mu(b) = \lambda(b)$, and $(x(t), \mu(t)) \in Z$ for every $t \in [a, b]$. Since the right-hand side of (5.2) is Lipschitz continuous, there is a unique solution for every initial data. Hence $\lambda(t) \cdot G(\gamma(t)) = 0$ for every $t \in [a, b]$. We conclude that (γ, λ) satisfies the PMP.

From the compactness of E there exists a neighborhood U'' of E such that every $\gamma \in \Gamma$ restricted to U'' is extremal. We consider Σ restricted to U''.

In this way we have defined Σ, Γ on an open set that contains all frame points and curves. Now we complete the definition of Σ, Γ considering the regions enclosed by edges.

For every region $A \subset R$ let $B_i(A)$, $i = 1, \ldots, n(A)$, be the connected components of $A \setminus L(A)$, where $L(A)$ is the union of lines in A. Let $\mathcal{B}$ be the set of all $B_i(A)$, $i = 1, \ldots, n(A)$, as A ranges over the set of regions contained in R. We will define Σ on every B by induction. From $(\mathcal{G}5)$ we have that every $Cl(B)$, $B \in \mathcal{B}$, contains exactly one entrance $E(B)$. The induction hypotheses is that for every $x \in E(B)$ there exists $\gamma_x : [0, t_x] \to \mathbb{R}^2$, $\gamma_x \in \Gamma$, such that $\gamma_x(t_x) = x$; i.e., the system Σ is constructed along γ_x backward in time. We start defining Σ on the regions B for which $E(B)$ is of X or Y type. Then we consider the regions B such that on the region B', that lies on the other side of $E(B)$, the system Σ is already defined. If $E(B)$ is of S type and x is the initial point of $E(B)$, then we consider B if there is a trajectory γ_x that verifies the induction hypothesis. In a finite number of steps we define Σ on every $B \in \mathcal{B}$.

Now fix a region $B \in \mathcal{B}$ and assumes that the induction hypothesis holds. From $(\mathcal{G}5)$ we have that $Cl(B)$ contains exactly one entrance E_1 and one exit E_2. If $E_1 \sim E_2$ then B is enclosed by E_1, E_2, and either a line l or a side E_3. Otherwise, B is enclosed

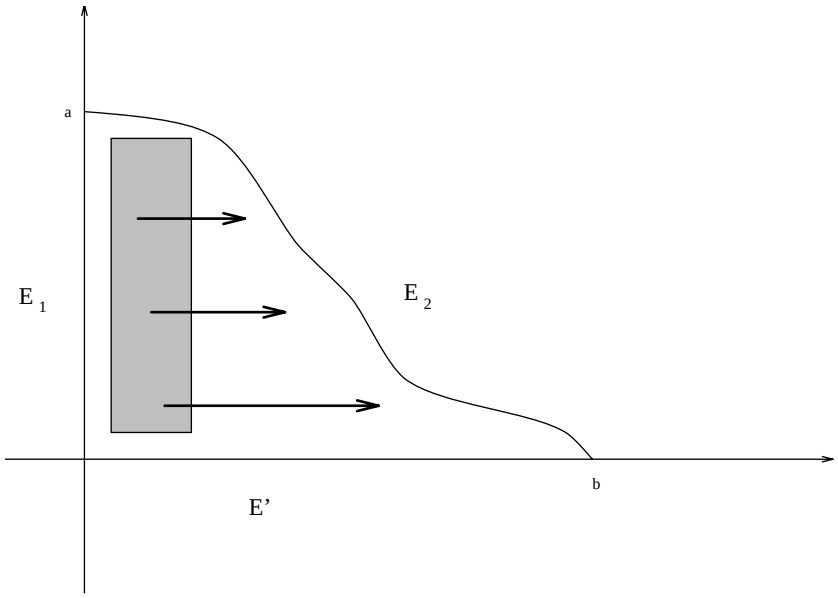

FIG. 5.

by E_1, E_2, a line l_1, and either another line l_2 or a side E_3. We define Σ on B defining Y or X, and G. Indeed, we define Σ also on a neighborhood of the lines in B if the system is not already defined near these lines. Consider the case $E_1 \sim E_2$ and assume that B is positive, being similar to the other case. Possibly using a change of coordinates, we can assume that

$$E_1 = \{(x_1, x_2) : x_1 = 0, 0 \le x_2 \le a\}, \qquad E' = \{(x_1, x_2) : x_2 = 0, 0 \le x_1 \le b\},$$

where either $E' = l$ or $E' = E_3$, and that Y is the constant vector field $(1, 0)$. We could define $Y \equiv (1, 0)$ on B and let Γ be formed by Y-trajectories, but we have to make some modifications to ensure that every $\gamma \in \Gamma$ is extremal.

Consider $\gamma_y \in \Gamma$ that verifies $\gamma_y(t_1) = (0, y)$, $\gamma_y(t_2) \in E_2$. By the induction hypothesis such a trajectory γ_y exists defined on $[0, t_2]$ for every $y \in [0, a]$. Since we have already defined Σ on a neighborhood of $E_1 \cup E_2$, there is a covector field λ_y associated with γ_y that is defined on

$$I = [t_1, t_1 + \mu_1] \cup [t_2 - \mu_2, t_2]$$

for some positive μ_1, μ_2. It can happen that $t_1 + \mu_1 = t_2 - \mu_2$, e.g., if we are near the point $E_1 \cap E_2$. We want to define Y in such a way that we can associate with γ_y a covector field, defined on $Dom(\gamma_y)$, that coincides with λ_y on I. This will ensure, choosing G in a suitable way, that every γ_y is extremal.

Consider a region

$$\Omega = [\delta_1, \delta_2] \times [\varepsilon, a - \delta_3], \qquad \delta_3 > 0, \qquad 0 < \delta_1 < \delta_2,$$

such that the following holds: $\Omega \subset A$, where A is the region containing B, and $\Omega \cap (E_1 \cup E_2) = \emptyset$. See Fig. 5 where Ω is the darkened region.

Let B' be the region on the other side of E'. If Σ is already defined on B', then $\varepsilon > 0$; otherwise $\varepsilon < 0$. Notice that if E' is a side (see the definition in section 3)

then it is of X or of Y type and the former case holds. We choose ε, δ_3 in such a way that Σ is already defined on $B \cap \{(x_1, x_2) : a - 2\delta_3 \leq x_2 \leq a\}$, and if $\varepsilon > 0$, then Σ is already defined on $B \cap \{(x_1, x_2) : 0 \leq x_2 \leq 2\varepsilon\}$. For every $y \in [\varepsilon, a - \delta_3]$, let $\gamma_y^1 \in \Gamma$ be the trajectory that verifies $\gamma_y^1(t_1(y)) = (0, y)$ and let λ_y^1 be the covector field associated with γ_y^1. We have that γ_y^1, λ_y^1 are defined on a neighborhood of $t_1(y)$. Consider the Mayer problem with final target E_2 and the cost function

$$\psi(T, x(T)) = -T + \psi_0(x(T)) \tag{5.3}$$

depending on terminal point and time, where we want to maximize ψ. For every $y \in [\varepsilon, a - \delta_3]$ let $\bar{x}(y)$ be such that $(\bar{x}(y), y) \in E_2$. There exists trajectories $\gamma_y^2 \in \Gamma$ that reach $(\bar{x}(y), y)$ with an associated covector field λ_y^2. Let $t_2(y)$ be such that $\gamma_y^2(t_2(y)) = (\bar{x}(y), y)$. Observe that γ_y^2, λ_y^2 are defined on a neighborhood of $t_2(y)$. We can define ψ in such a way that $(\gamma_y^2, \lambda_y^2)$ satisfies the PMP and the final transversality condition for the Mayer problem; see [6]. Indeed the PMP is satisfied because γ_y^2 is extremal for the time optimal problem. To satisfy the transversality condition, in view of (5.3) we need to find λ_0, λ_1 solution to

$$\lambda_0 = \max_{|\omega| \leq 1} \lambda_y^2(t_2(y)) \cdot (F + \omega G)(\bar{x}(y), y), \tag{5.4}$$

$$\lambda_y^2(t_2(y)) = \lambda_0 \nabla \psi_0(\bar{x}(y), y) + \lambda_1 n_2(\bar{x}(y), y), \tag{5.5}$$

where n_2 is a unit normal vector to E_2. Hence, (5.4) determines λ_0 and (5.5) gives a condition for λ_1, ψ_0.

Choose ν_1, ν_2, T_1, T_2 such that $\delta_1 < \nu_1 < \nu_2 < \delta_2$ and

$$T_1 > \sup\{t_1(y) : y \in [\varepsilon, a - \delta_3]\}, \qquad T_2 < \inf\{\psi_0((\bar{x}(y), y)) : y \in [\varepsilon, a - \delta_3]\}.$$

We define $Y = (\alpha, 0)$ on Ω, α continuous and positive, $\alpha \equiv 1$ on $\partial\Omega \cup [\nu_1, \nu_2] \times [\varepsilon, a - \delta_3]$, and we let $Y = (1, 0)$ outside Ω. We choose α in such a way that the following holds. For every y we have $\gamma_y^1(T_1) = (\nu_1, y)$. If $T_2(y) < t_2(y)$ is the time at which γ_y^2 reaches, backward in time, the point (ν_2, y), then

$$\psi(t_2(y) - T_2(y), (\bar{x}(y), y)) = T_2.$$

With this definition of Y we prolong $\gamma_y^{1,2}, \lambda_y^{1,2}$ defining them on the whole set B. Consider the reachable set $R(T_1)$; we have that

$$\{(\nu_1, y) : \varepsilon \leq y \leq a - \delta_3\} \subset \partial R(T_1).$$

Since $\lambda_y^1(T_1)$ has to be perpendicular to $\partial R(T_1)$, it follows that $\lambda_y^1(T_1)$ has the second component equal to zero. From Theorem 8.2 of Chapter IV of [4] we have that λ_y^2 has to be perpendicular to the level set of the function

$$\psi'(x, y) = \psi(t_2(y) - t(x, y), (\bar{x}(y), y)),$$

where $t(x, y)$ is defined by $\gamma_y^2(t(x, y)) = (x, y)$. Hence also the second component of $\lambda_y^2(T_2(y))$ has to be zero. By the PMP, since the Hamiltonian is positive (see (PMP2) of section 2 of [2]), the first components of $\lambda_y^1(T_1), \lambda_y^2(T_2(y))$ have the same sign. Since $\alpha = 1$ on $[\nu_1, \nu_2] \times [\varepsilon, a - \delta_3]$, we obtain that λ_y^1, λ_y^2 coincide up to a scalar multiple. We can now associate with every γ_y^1 the covector field λ_y^1 and define G in such a way that G is of class $\mathcal{C}^3$ and every γ_y^1 is extremal.

It may happen, however, that α is not smooth and hence Σ is not smooth. Since α is continuous there exists a sequence α_n of smooth functions converging uniformly to α. Let Σ_n, Γ_n be the system and synthesis associated with α_n. If E_2 is of K or F type, then for n large every $\gamma \in \Gamma_n$ is extremal and we are done. Indeed in this case no trajectory of Γ switches on E_2, and by compactness the same holds, if n is sufficiently large, for Γ_n. If E_2 is of C type then Σ_n has a switching curve C_n near to E_2. Since Σ has not already been defined on the region B' that lies on the other side of E_2, we can define $\Sigma = \Sigma_n$ for n sufficiently large. The only change is that we construct the system on a graph equivalent to $\mathcal{G}$, not exactly on $\mathcal{G}$.

The other case, that is, when B is enclosed by E_1, E_2 and either two lines or one line and one side, can be treated in an entirely similar manner. This concludes the construction on the regions $B \in \mathcal{B}$, and then we have defined Σ and Γ on the whole R.

We can again modify Σ on the regions $B \in \mathcal{B}$, using the same techniques described above in such a way that the following holds. If $\gamma \in \Gamma$ reaches $Fr(R)$, then it reaches $Fr(R)$ at time 1. If x belongs to an overlap curve, $\gamma_1, \gamma_2 \in \Gamma$, $\gamma_1(t_1) = x = \gamma_2(t_2)$, then $t_1 = t_2 \leq 1$, with equality holding only if $x \in Fr(R)$.

We can conclude that every $\gamma \in \Gamma$ is optimal and then $R = R(1)$, the reachable set in time 1 for Σ. It is possible to apply Theorem 3.1 of [17] or to use a dynamic programming argument. Indeed the time along the set of trajectories Γ satisfies the Hamilton–Jacobi–Bellman equation for the value function inside R and is constant on its frontier; see [1], [3]. It can happen that some points are reached by more than one trajectory of Γ. However, we can construct a synthesis from Γ, that we call again Γ, following the procedure described in section 5 of [10]. We obtain $\Gamma = \Gamma_{\mathcal{A}}(\Sigma)$. From the construction it is clear that $\mathcal{G}$ corresponds to Σ in the canonical way. □

6. Systems on two-dimensional manifolds. Since all the geometric techniques used in [2], [10], [11], [14] are local it is possible to establish analogous results for a control system defined on a general smooth two-dimensional manifold. In this case, the classification program is completed giving a new definition of graph. Indeed we have to allow reachable sets that are not diffeomorphic to a subset of the plane. By definition, a graph is a stratification (see [12]) of a connected two-dimensional manifold with the following properties.

DEFINITION 4 (graph 2). *A graph $\mathcal{G}$ is a finite collection of disjoint connected manifolds M_i such that the following holds. Each manifold M_i is two, one, or zero dimensional. For each i, $Fr(M_i)$ is the union of manifolds of $\mathcal{G}$ having strictly lower dimension. The two- (respectively, one-, zero-) dimensional manifolds correspond to regions (respectively, frame curves, frame points) of the reachable set of the system. The one-dimensional manifolds are of six types X, Y, C, S, K, or F and satisfy the same conditions of edges. The two-dimensional manifolds are not enclosed by F edges and have a sign. On each two-dimensional manifold there are possibly some marked one-dimensional submanifolds with boundary, which correspond to lines and follow the same rules. The union of the manifolds M_i is a two-dimensional connected manifold with boundary denoted by $\mathcal{T}_{\mathcal{G}}$.*

In this case, we define the relation between one-dimensional manifolds of a graph as for edges, i.e., $M_i \sim M_j$ if and only if $Fr(M_i) \cap Fr(M_j) \neq \emptyset$.

The admissibility conditions are defined in the same way as before. Given an admissible graph $\mathcal{G}$ our aim is to construct a corresponding system on a suitable manifold. For doing this, it is necessary to single out a manifold M that contains a subset diffeomorphic to $\mathcal{T}_{\mathcal{G}}$. In particular we are interested in conditions to ensure that $\mathcal{G}$ corresponds to a planar system.

The partition of $\mathcal{T}_\mathcal{G}$, naturally defined by $\mathcal{G}$, establishes a kind of triangulation, and proceeding as follows it is possible to determine its Euler–Poincaré characteristic $\chi(\mathcal{T}_\mathcal{G})$.

Recall that a finite collection T_i of boundary manifolds homeomorphic to a triangle is a triangulation provided that for every i, j, $T_i \cap T_j$ is empty, a *vertex*, or an *edge* (where by definition *vertices*, respectively, *edges*, are the images of the vertices, respectively, edges, of the corresponding triangle). If we denote by $\#T$, $\#E$, and $\#V$ the number of T_i's, edges, and vertices, respectively, then

$$\chi(\mathcal{T}_\mathcal{G}) = \#T - \#E + \#V. \tag{6.1}$$

Observe that the stratification of $\mathcal{T}_\mathcal{G}$ is not a triangulation. For every two-dimensional manifold M_i fix an internal point y and consider the frame points $x_1, \dots, x_n$ of ∂M_i. There exist n one-dimensional manifolds γ_j, $j = 1, \dots, n$, that connect x_j with y and that do not intersect each other. In this way we divide $\mathcal{T}_\mathcal{G}$ in *triangles*. It can happen that two *triangles* have two vertices in common on the boundary of $\mathcal{T}_\mathcal{G}$. However, it is easy to see that we can add an edge obtaining an admissible triangulation without changing the right-hand side of (6.1).

Now, the number of vertices is equal to the number $\#FP$ of frame points plus the number of regions $\#R$. Every frame point x produces two new edges if it either lies on the frontier of $\mathcal{T}_\mathcal{G}$ or is of type $(X,C)_3, (X,K)_3, (C,C)_1, (C,S)_2, (C,K)_1$, or (S,K) (see [11] for notations). In this case we say that x is a 2-frame point. If the frame point is of one of the remaining cases then it produces three new edges and we say that x is a 3-frame point. Let $\#FC$, $\#2FP$, and $\#3FP$ denote, respectively, the number of frame curves, 2-frame points, and 3-frame points. Then, the total number of edges is $\#FC + 2 \cdot \#2FP + 3 \cdot \#3FP$. Every region is divided in as many parts as the number of frame points on its boundary. Hence the number of triangles is $2 \cdot \#2FP + 3 \cdot \#3FP$. Finally, we obtain

$$\chi(\mathcal{T}_\mathcal{G}) = \#R - \#FC + \#FP.$$

Let $\#\mathcal{F}$ denote the number of equivalence classes of frame curves of type F. From the classification of compact two-dimensional boundary manifolds (see [5], [7]) it follows that the orientability, the Euler–Poincaré characteristic, and the number of connected components of the boundary determine one equivalence class of diffeomorphic manifolds. In particular, every reachable set of a planar system is diffeomorphic to a manifold H_k obtained from the unit closed ball B removing the interior of k distinct balls $B_1, \dots, B_k \subset Int(B)$. Moreover, $\chi(H_k) = 1 - k$ and ∂H_k has $k + 1$ connected components. Thus, we obtain the following theorem.

THEOREM 6.1. *An admissible graph $\mathcal{G}$ corresponds to a planar system if and only if $\mathcal{T}_\mathcal{G}$ is orientable and there exists $k \geq 0$ such that $\#R - \#FC + \#FP = 1 - k$ and $\#\mathcal{F} = k + 1$.*

MODEL REFERENCE ADAPTIVE CONTROL OF DISTRIBUTED PARAMETER SYSTEMS*

MICHAEL BÖHM†, M. A. DEMETRIOU‡, SIMEON REICH§, AND I. G. ROSEN¶

Abstract. A model reference adaptive control law is defined for nonlinear distributed parameter systems. The reference model is assumed to be governed by a strongly coercive linear operator defined with respect to a Gelfand triple of reflexive Banach and Hilbert spaces. The resulting nonlinear closed-loop system is shown to be well posed. The tracking error is shown to converge to zero, and regularity results for the control input and the output are established. With an additional richness, or persistence of excitation assumption, the parameter error is shown to converge to zero as well. A finite-dimensional approximation theory is developed. Examples involving both first- and second-order, parabolic and hyperbolic, and linear and nonlinear systems are discussed, and numerical simulation results are presented.

Key words. model reference adaptive control, parameter convergence, persistence of excitation, distributed parameter systems, infinite-dimensional systems, finite-dimensional approximation

1. Introduction.

In this paper we develop a model reference adaptive control (MRAC) scheme for rather broad classes of, in general, nonlinear distributed parameter systems. By a distributed parameter system we mean one in which the state space is infinite dimensional such as occurs in the case of partial differential equations. In the context of finite-dimensional systems, MRAC is one of the standard approaches taken in designing a control law for a plant with unknown parameters. A complete description and analysis of a variety of approaches to MRAC can be found in any one of a number of standard texts on adaptive control (see, for example, [2], [14], [30], and [35]). The objective of an MRAC scheme is to determine a feedback control law which forces the state of the plant to asymptotically *track* the state of a given *reference model*. At the same time, the unknown parameters in the plant model are estimated and used to update the control law. Typically, the resulting closed loop system consisting of the plant, the reference model, and the estimator, will be nonlinear. This is true even if the underlying plant and reference models, and the estimator, are linear. The nonlinearity arises in the coupling. Consequently, the scheme requires a careful stability analysis to ensure that all signals (both input and output) remain, in some sense, bounded. It is also desirable, although not necessarily essential, that some sort of *parameter convergence* be achieved.

The focus of the effort we describe here is the extension to infinite-dimensional systems of one approach to finite-dimensional MRAC. We consider nonlinear plants with the rather standard restriction that their dependence on the unknown parameters be affine. The operator describing the dynamics of the reference model is assumed to be linear and strongly V-coercive (in a Gelfand triple setting). The parameter space can be either finite or infinite dimensional, and the estimator dynamics for the unknown parameters are chosen in a fashion which renders the closed-loop error equations skew-self-adjoint. This is analogous to what is done in finite dimensions and has the effect of facilitating both tracking error and parameter convergence by forcing the time derivative of a certain energy functional to be negative semidefinite. We establish the global well-posedness of the closed-loop system via two different approaches. First we argue existence of a local solution and then its continuation by treating the closed-loop system as semilinear (i.e., a nonlinear perturbation of a linear system) with the linear component of the dynamics being the infinitesimal generator of an analytic semigroup. The second approach involves the application of an abstract version of the implicit function theorem to obtain a global solution when the initial tracking and parameter error are sufficiently small. Using an analogue of Barbălat's lemma, we establish that the tracking error approaches zero asymptotically. We also establish regularity results for both the input and output signals. In particular, we establish a boundedness result for the control signal. With the additional assumption of *persistence of excitation*, a richness condition on the plant, reference model, and input reference signal, we establish parameter convergence. The definition of persistence of excitation for infinite-dimensional systems given in section 3 below is the natural extension of the analogous definition for finite-dimensional systems as found in, for example, [29], [30], and [31]. Since the reference model and estimator are, in general, infinite dimensional, implementation requires some form of finite-dimensional approximation. Consequently, we develop an abstract finite-dimensional approximation and convergence theory. Finally, we illustrate the application of our general theory on a number of examples involving a variety of linear and nonlinear distributed parameter systems.

One drawback of our approach is that it requires (as do the analogous finite-dimensional schemes, see, for example, [30]) measurement of the full state and distributed input. Eliminating either of these restrictions represents a formidable challenge. For example, if only a partial state measurement is available, a coupled adaptive observer would be required. The corresponding analysis would be significantly more complicated than the already rather technical arguments we present here. We are currently looking at the extension of our treatment here to include partial measurements and finite-dimensional input.

Our effort here is related to our earlier treatment of adaptive identification for distributed parameter systems in [7], [8], and [9]. In fact, we employ the same estimator here to identify the unknown parameters in the plant, and the arguments used below (infinite-dimensional analogues of the finite-dimensional theory presented in [29] and [31]) to demonstrate the asymptotic convergence of the tracking and parameter error to zero, are similar to the ones employed to establish state and parameter convergence for the identification schemes. However, in the case of the identification schemes, the resulting estimator equations are linear. In the case of MRAC, the resulting closed-loop system is nonlinear. Consequently, certain aspects of the analysis, in particular, those dealing with the well-posedness of the closed-loop system and the convergence of the finite-dimensional approximation, are more delicate. Other related treatments

of on-line or adaptive identification for distributed parameter systems can be found in [1], [6], [16], [17], [18], and [37].

Recently there has been some attention given to the adaptive control of distributed parameter systems. First, with respect to approaches other than model reference, indirect adaptive control algorithms for a class of infinite-dimensional stochastic evolution equations have been developed by Duncan, Pasik-Duncan, and their coworkers in a recent series of papers [12], [13], [11], and [32]. Their approach involves the use of a least squares based estimator together with a linear quadratic control design. Parameter convergence together with a continuous dependence result (with respect to the unknown parameters) for the solutions to the operator algebraic Riccati equations yield convergence of the adaptive control law to the nonadaptive optimal LQ controller. Also, Kobayashi in [21], [22], [23], [24], and [25] has proposed a number of direct schemes based upon an input/output formulation. His approach is primarily directed toward the case of unknown input and/or output operators (i.e., the B and C operators) and places a number of restrictions on the A operator (for example, that it be self-adjoint, its eigenvalues be known, that only a finite number of modes be unstable, etc.).

In [40] and [41] a finite-dimensional approach to MRAC based upon the so-called command generator tracker is extended to infinite dimensions. The command generator tracker theory deals with the problem of a mismatch in the dimensionality of the plant and the reference model by assuming that there is an infinite-dimensional system that is input/output equivalent to the reference model. The authors establish closed-loop stability (and robustness properties) via a Lyapunov argument (which in infinite dimensions must be done with care) under a number of rather technical assumptions.

In a recent effort by Hong and Bentsman [19] the authors consider the MRAC of linear parabolic partial differential equations. The results in [19] apply only to plants and reference models which are linear parabolic partial differential equations with Dirichlet boundary conditions under the assumption that the reference signal and the plant and reference model parameters are analytic. In the present treatment, the structure of the plant and reference model are essentially independent and must satisfy only a few relatively mild abstract assumptions. In particular, we consider general nonlinear plants and require only that the reference model (but not the control system) dynamics be strongly V-coercive (in a Gelfand triple sense).

An outline of the remainder of the paper is as follows. In section 2 we define the plant, reference model, and estimator, we derive the closed-loop system, and we establish well-posedness. In section 3 we establish the convergence of the tracking error to zero, we define persistence of excitation, and we demonstrate parameter convergence. The finite-dimensional approximation and convergence theory is discussed in section 4, and examples and the results of our numerical studies are presented in section 5.

2. The MRAC Problem. Let $\{H, \langle\cdot,\cdot\rangle, |\cdot|\}$ be a Hilbert space over $\mathbf{R}$, and let $\{V, \|\cdot\|\}$ be a reflexive Banach space over $\mathbf{R}$ which is densely and continuously embedded in H. Then (see, for example, [27], [38], or [39])

$$V \hookrightarrow H \hookrightarrow V^*, \tag{2.1}$$

with the embeddings dense and continuous where V^* denotes the continuous dual of V. The notation $\langle\cdot,\cdot\rangle$ will also be used to denote the duality pairing between V^* and

V induced by the continuous and dense embeddings given in (2.1). That is, for $\varphi \in V^*$ and $\psi \in V$, $\langle \varphi, \psi \rangle$ denotes the action of the bounded linear functional φ on the vector ψ. Note that when φ is in fact an element in H (or, more precisely, can be identified with an element in H), the embeddings (2.1) imply that the value of φ *acting* on ψ is equal to the H inner product of φ and ψ. Moreover, since $\overline{H} \cong V^*$, for $\varphi \in V^*$ and $\{\varphi_n\}_{n=1}^{\infty} \subset H$ with $\lim_{n\to\infty} \varphi_n = \varphi$ in V^* we have $\lim_{n\to\infty} \langle \varphi_n, \psi \rangle = \langle \varphi, \psi \rangle$, $\psi \in V$. Consequently this minor abuse of notation is entirely justified. Let $\| \cdot \|_*$ denote the usual norm on V^*, and let $K > 0$ be such that

$$|\varphi| \leq K\|\varphi\|, \qquad \varphi \in V. \tag{2.2}$$

Let $\hat{V}^*$ be a subspace of V^*, and let $\{Q, \langle \cdot, \cdot \rangle_Q, |\cdot|_Q\}$ be a real Hilbert space.

For each $q \in Q$, let $A_1(q) : V \to V^*$ be an, in general, nonlinear operator, and for $q \in Q$, let $Dom(A_1(q)) = \{\varphi \in V : A_1(q)\varphi \in H\}$. Also, we let $A_2 : V \to V^*$ be an, in general, nonlinear operator, and we make the following standing assumptions.

(A1) (V-V^*-boundedness). There exist $\alpha_1, \alpha_2 > 0$ such that

$$|\langle A_1(q)\varphi, \psi \rangle| \leq \alpha_1 |q|_Q \|\varphi\| \|\psi\|, \ \varphi, \psi \in V, \ q \in Q, \text{ and}$$

$$|\langle A_2\varphi, \psi \rangle| \leq \alpha_2 \|\varphi\| \|\psi\|, \ \varphi, \psi \in V.$$

(A2) (Q-linearity). For each $\varphi \in V$, the map $q \to A_1(q)\varphi$ from Q into V^* is linear. For each $q \in Q$, let $A(q) : V \to V^*$ be given by

$$A(q)\varphi = A_1(q)\varphi + A_2\varphi, \qquad \varphi \in V. \tag{2.3}$$

We are interested in adaptively controlling the nonlinear plant given by

$$D_t u(t) + A(\overline{q})u(t) = f(t), \qquad \text{a.e. } t > 0, \tag{2.4}$$

$$u(0) = u_0, \tag{2.5}$$

where $\overline{q} \in Q$ is unknown, $u_0 \in H$, the operator $A(\overline{q})$ is given by (2.3) with $q = \overline{q}$, and the control input f is assumed to satisfy $f \in L_2(0, T; V^*)$ for all $T > 0$ with $f(t) \in \hat{V}^*$, a.e. $t > 0$. We assume minimally that the system (2.4), (2.5) is well-posed in at least some sense. That is, we assume that for sufficiently regular initial data, u_0, and input, f, there exists a *weak* solution. More precisely, we assume that for each $T > 0$, each $u_0 \in U_0$, U_0 a subset of H, and each $f \in L_2(0, T; V^*)$ sufficiently regular, there exists a unique V-valued function u which is V^*-absolutely continuous on $(0, T)$, $u \in C(0, T; H) \cap L_2(0, T; V)$, $D_t u \in L_2(0, T; V^*)$, and which satisfies

$$\langle D_t u(t), \varphi \rangle + \langle A(\overline{q})u(t), \varphi \rangle = \langle f(t), \varphi \rangle, \qquad \varphi \in V, \text{ a.e. } t > 0, \tag{2.6}$$

$$u(0) = u_0. \tag{2.7}$$

Theorem III.2.6 in [5] provides sufficient conditions for the existence of such a solution. Indeed, if the operator $A(\overline{q})$ is hemicontinuous (i.e., $\lim_{\lambda\to 0} \langle A(\overline{q})\{\varphi + \lambda\psi\} - A(\overline{q})\varphi, \chi \rangle = 0$, $\chi \in V$ for any $\varphi, \psi \in V$), monotone (i.e., $\langle A(\overline{q})\varphi - A(\overline{q})\psi, \varphi - \psi \rangle \geq 0$ for all $\varphi, \psi \in V$), bounded (i.e., there exists $\alpha > 0$ for which $\|A(\overline{q})\varphi\|_* \leq \alpha\{1 + \|\varphi\|\}$ for all $\varphi \in V$), and coercive (i.e., there exist $\rho > 0$ and $\sigma \in \mathbf{R}$ for which $\langle A(\overline{q})\varphi, \varphi \rangle \geq \rho\|\varphi\|^2 + \sigma$ for all $\varphi \in V$), then just such a *weak* solution exists for *all* $u_0 \in H$ and *all* $f \in L_2(0, T; V^*)$.

We are interested in designing a *model reference* adaptive controller for the plant, or system, (2.4), (2.5). That is, we wish to find a control input f in feedback form which forces the state of the unknown plant, u, to track the state of a given linear reference model,

$$\langle D_t v(t), \varphi\rangle + \langle A_0 v(t), \varphi\rangle = \langle g(t), \varphi\rangle, \qquad \varphi \in V, \text{ a.e. } t > 0, \tag{2.8}$$

$$v(0) = v_0, \tag{2.9}$$

where $v_0 \in H$, the input reference signal g is assumed to satisfy $g \in L_2(0,T;V^*)$, for all $T > 0$, with $g(t) \in \hat{V}^*$, a.e. $t > 0$, and the operator $A_0 \in \mathcal{L}(V, V^*)$ is assumed to satisfy the following conditions.

(A3) (V-V^*-boundedness). There exists $\alpha_0 > 0$ such that $|\langle A_0\varphi, \psi\rangle| \le \alpha_0\|\varphi\|\|\psi\|$, $\varphi, \psi \in V$.

(A4) (V-coercivity). There exists $\rho_0 > 0$ for which $\langle A_0\varphi, \varphi\rangle \ge \rho_0\|\varphi\|^2$, $\varphi \in V$.

(A5) ($\hat{V}^*$-range). For all $q \in Q$ we have $\mathcal{R}(A(q) - A_0) \subset \hat{V}^*$.

It is well known (see, for example, [27], [38], or [39]) that assumptions (A3) and (A4) are sufficient to conclude that the system (2.8), (2.9) admits a unique solution v satisfying $v \in C(0,T;H) \cap L_2(0,T;V)$ with $D_t v \in L_2(0,T;V^*)$ for all $T > 0$. Let $D_0 = Dom(A_0) = \{\varphi \in V : A_0\varphi \in H\}$. Then assumptions (A3) and (A4) also imply (see, for example, [33], [39], or [38]) that the operator $-A_0$ *restricted* to the subspace D_0 is the infinitesimal generator of an analytic semigroup, $\{T_0(t) : t \ge 0\}$, of bounded linear operators on H. It can also be shown (see [39]) that the operator $-A_0$ is the infinitesimal generator of an analytic semigroup on V^* and that appropriately restricted $-A_0$ generates an analytic semigroup on V (see [3]). Recalling (2.2), it follows that

$$|T_0(t)\varphi| \le e^{-\rho_0 K^{-2} t}|\varphi|, \qquad \varphi \in H, \tag{2.10}$$

and

$$\|T_0(t)\varphi\| \le M e^{-\rho_0 K^{-2} t}\|\varphi\|, \qquad \varphi \in V, \tag{2.11}$$

for some $M > 0$. The solution to the initial value problem (2.8), (2.9) is given by

$$v(t) = T_0(t)v_0 + \int_0^t T_0(t-s)g(s)ds, \qquad t \ge 0. \tag{2.12}$$

The primary motivation for the inclusion of assumption (A5) is to allow us to apply our abstract framework to second-order systems (i.e., abstract wave equations and the like). The relevance of assumption (A5) in this regard will become clearer when we discuss an example involving the control of a one-dimensional damped wave equation in section 5 below.

REMARK 2.1. *Many of the estimates contained in the arguments used to verify several of the results in this and the following section assume the existence of solutions belonging to particular regularity classes (i.e., the domains of certain operators, etc.). Thus our proofs deliver only a posteriori estimates with respect to those assumptions. A more precise argument in all of these cases would proceed as follows. The dynamical system, or initial value problem, would be approximated by a Galerkin system using smooth basis functions chosen as eigenfunctions of the relevant operator (in most cases A_0). A posteriori estimates for the approximating solutions with bounds independent*

of the number of basis functions are established using the same arguments we employ below. These estimates now serve as a priori estimates for the solutions. Weak, weak, and strong compactness properties (Aubin's lemma) of bounded subsets of time dependent functions are then used to obtain corresponding convergent subsequences and the corresponding regular solutions. Note that at the level of Galerkin solutions, with bases formed from eigenfunctions, it is immediately clear that the resulting approximate solutions are sufficiently regular to permit the estimates we make below. In particular, the Galerkin basis functions satisfy appropriate boundary conditions.*

We have the following regularity result for the reference model (2.8), (2.9).

THEOREM 2.2. *For the reference model given by* (2.8), (2.9)*, we have the following results.*

(i) *If* $g \in L_\infty(0,\infty;H)$*, then* $v \in L_\infty(0,\infty;H)$*.*
(ii) *If* $g \in L_\infty(0,\infty;V)$ *and* $v_0 \in V$*, then* $v \in L_\infty(0,\infty;V)$*.*
(iii) *If* $g \in L_2(0,\infty;V^*)$*, then* $v \in L_\infty(0,\infty;H) \cap L_2(0,\infty;V)$*.*
(iv) *If* $g \in L_2(0,\infty;H)$ *is Hölder continuous, i.e.,*

$$|g(t) - g(s)| \le C|t-s|^\rho, \qquad 0 \le t, s, < \infty, \tag{2.13}$$

for some $C > 0$ *and* $\rho \in (0,1]$*, and* $v_0 \in V$*, and if the operator* A_0 *is symmetric in the sense that*

$$\langle A_0\varphi, \psi\rangle = \langle A_0\psi, \varphi\rangle, \qquad \varphi, \psi \in V, \tag{2.14}$$

then $v \in L_\infty(0,\infty;V)$*,* $v(t) \in D_0$*, a.e.* $t > 0$*, and* $A_0 v \in L_2(0,\infty;H)$*.*

Proof. We note that (i)–(iv) are standard results for linear initial value problems. However, in order to establish some estimates for later reference, we include the following proof. Statements (i) and (ii) follow immediately from (2.10), (2.11), and (2.12). To verify (iii), for almost every $t > 0$ we have that

$$\begin{aligned} \frac{1}{2}D_t|v(t)|^2 &= \langle -A_0 v(t) + g(t), v(t)\rangle \\ &\le -\rho_0\|v(t)\|^2 + \|g(t)\|_*\|v(t)\| \\ &\le -\frac{\rho_0}{2}\,\|v(t)\|^2 + \frac{1}{2\rho_0}\,\|g(t)\|_*^2. \end{aligned} \tag{2.15}$$

Integrating both sides of the estimate (2.15) from 0 to t, it follows that

$$|v(t)|^2 + \rho_0\int_0^t \|v(s)\|^2 ds \le |v_0|^2 + \frac{1}{\rho_0}\|g\|^2_{L_2(0,\infty;V^*)}, \qquad t > 0,$$

from which the result is immediately obtained.

To verify (iv), first note that assumption (A4) and (2.14) imply that $A_0 : D_0 \subset H \to H$ is positive definite and self-adjoint. It follows that the square root of A_0, $A_0^{\frac{1}{2}}$, can be defined with $Dom(A_0^{\frac{1}{2}}) = V$ (see, for example, [39]). Moreover, for $\varphi \in V$, $\|\varphi\|_0 = |A_0^{\frac{1}{2}}\varphi|$ defines a norm on V and, by assumptions (A3) and (A4), we have that

$$\rho_0\|\varphi\|^2 \le \langle A_0\varphi, \varphi\rangle = \langle A_0^{\frac{1}{2}}\varphi, A_0^{\frac{1}{2}}\varphi\rangle = \|\varphi\|_0^2 = \langle A_0\varphi, \varphi\rangle \le \alpha_0\|\varphi\|^2 \tag{2.16}$$

for all $\varphi \in V$. The estimate (2.16) yields that the two norms $\|\cdot\|$ and $\|\cdot\|_0$ on V are equivalent.

The assumption of Hölder continuity on g, (2.13), and the fact that $\{T_0(t) : t \ge 0\}$, the semigroup of bounded linear operators on H generated by the operator $-A_0$, is

analytic, are sufficient to conclude that $A_0 v(t) \in H$ for almost all $t > 0$. It follows that $v(t) \in D_0$, a.e. $t > 0$, and recalling Remark 2.1, from (2.8), we obtain that $\langle D_t v(t), A_0 v(t)\rangle + |A_0 v(t)|^2 = \langle g(t), A_0 v(t)\rangle$, a.e. $t > 0$, and therefore that

$$\frac{1}{2} D_t \|v(t)\|_0^2 + |A_0 v(t)|^2 \le |g(t)||A_0 v(t)| \le \frac{1}{2}|g(t)|^2 + \frac{1}{2}|A_0 v(t)|^2, \quad \text{a.e. } t > 0.$$

Integrating the above estimate from 0 to t, and recalling (2.9), we find that

$$\|v(t)\|_0^2 + \int_0^t |A_0 v(s)|^2 ds \le \|v_0\|_0^2 + \int_0^t |g(s)|^2 ds \le \|v_0\|_0^2 + \|g\|^2_{L_2(0,\infty;H)}, \qquad t \ge 0,$$

from which the desired conclusion follows. □

For each $t > 0$, let $e(t) = u(t) - v(t)$. We would like to find a control input, f, such that

$$\lim_{t\to\infty} |e(t)| = 0, \tag{2.17}$$

with f remaining, in some sense, *bounded* (for example, bounded energy; $f \in L_2(0,\infty; V^*)$). If the plant (i.e., $\overline{q}$) were known, the convergence in (2.17) could be achieved by setting

$$f(t) = A(\overline{q})u(t) - A_0 u(t) + g(t), \qquad \text{a.e. } t > 0. \tag{2.18}$$

For then e would satisfy

$$\langle D_t e(t), \varphi\rangle + \langle A_0 e(t), \varphi\rangle = 0, \qquad \varphi \in V, \text{ a.e. } t > 0,$$

$$e(0) = e_0,$$

where $e_0 = u_0 - v_0 \in H$. It follows from assumption (A4) and (2.2) that $|e(t)| \le e^{-\rho_0 K^{-2} t}|e_0|$, $t \ge 0$ and, consequently, that (2.17) is satisfied. The closed-loop system is given by

$$\langle D_t u(t), \varphi\rangle + \langle A_0 u(t), \varphi\rangle = \langle g(t), \varphi\rangle, \qquad \varphi \in V, \text{ a.e. } t > 0, \tag{2.19}$$

$$u(0) = u_0. \tag{2.20}$$

THEOREM 2.3. *For the nonadaptive closed-loop system given by* (2.6), (2.7), (2.18), *or, equivalently,* (2.18)–(2.20), *we have* $f(t) \in \hat{V}^*$ *for a.e.* $t > 0$ *and the following results.*

(i) *If* $g \in L_2(0,\infty; V^*)$, *then* $u \in L_\infty(0,\infty; H) \cap L_2(0,\infty; V)$ *and, moreover,* $f \in L_2(0,\infty; V^*)$.

(ii) *If* $g \in L_\infty(0,\infty; V)$ *and* $u_0 \in V$, *then* $u \in L_\infty(0,\infty; V)$ *and* $f \in L_\infty(0,\infty; V^*)$.

(iii) *If the operator* A_0 *is symmetric in the sense of* (2.14), $u_0 \in V$, *and* $g \in L_2(0,\infty; H)$ *and satisfies* (2.13), *then* $u(t) \in D_0$, *a.e.* $t > 0$, $u \in L_\infty(0,\infty; V)$ *and* $A_0 u \in L_2(0,\infty; H)$. *If, in addition,*

(a) $g \in L_\infty(0,\infty; V^*)$, *then* $f \in L_\infty(0,\infty; V^*)$,

or

(b) *for* $\varphi \in D_0$, $A(\overline{q})\varphi \in H$, *and* $|A(\overline{q})\varphi| \le \gamma |A_0 \varphi|$, $\varphi \in D_0$, *for some* $\gamma > 0$, *then* $f \in L_2(0,\infty; H)$.

Proof. The fact that $f(t) \in \hat{V}^*$, a.e. $t > 0$, follows immediately from assumption (A5) and the assumption that $g(t) \in \hat{V}^*$, a.e. $t > 0$.

Using the same argument used in the proof of Theorem 2.2, we obtain $u \in L_\infty(0,\infty;H) \cap L_2(0,\infty;V)$. Assumptions (A1) and (A3) and the definition of the control input f given in (2.18) yield

$$\|f(t)\|_* \leq \{\alpha_1|\overline{q}|_Q + \alpha_2 + \alpha_0\}\|u(t)\| + \|g(t)\|_*, \qquad \text{a.e. } t > 0, \tag{2.21}$$

from which it follows that $f \in L_2(0,\infty;V^*)$.

The result given in (ii) follows immediately from (2.11); (2.19) and (2.20) imply that

$$u(t) = T_0(t)u_0 + \int_0^t T_0(t-s)g(s)ds, \qquad t \geq 0,$$

and (2.21).

An argument analogous to the one used in the proof of Theorem 2.2(iv) yields $u(t) \in D_0$, a.e. $t > 0$, $u \in L_\infty(0,\infty;V)$ and $A_0u \in L_2(0,\infty;H)$. The result given in (iii)(a) then follows immediately from (2.21), while the estimate $|f(t)| \leq \{\gamma + 1\}|A_0u(t)| + |g(t)|$, a.e. $t > 0$, yields the result given in (iii)(b). □

The importance of Theorem 2.3 lies in the fact that it serves as an upper bound for the results we can hope to obtain for a corresponding adaptive scheme wherein the plant $\overline{q}$ is unknown and is estimated in real time.

Since $\overline{q}$ is in fact unknown, we set

$$f(t) = A(q(t))u(t) - A_0u(t) + g(t), \qquad \text{a.e. } t > 0, \tag{2.22}$$

or

$$\langle f(t),\varphi\rangle = \langle A(q(t))u(t),\varphi\rangle - \langle A_0u(t),\varphi\rangle + \langle g(t),\varphi\rangle, \ \ \varphi \in V, \text{ a.e. } t > 0, \tag{2.23}$$

where for each $t > 0$, $q(t) \in Q$ denotes an adaptively updated *estimate* for $\overline{q}$. Once again, $f(t) \in \hat{V}^*$, a.e. $t > 0$ follows from assumption (A5) and the fact that $g(t) \in \hat{V}^*$, a.e. $t > 0$. By analogy to the finite-dimensional case, and for the purpose of forcing an appropriate energy functional which will be defined in the next section when we consider convergence, we let the adaptation law for q be given by

$$\langle D_tq(t),p\rangle_Q + \langle A_1(p)u(t),e(t)\rangle = 0, \qquad p \in Q, \text{ a.e. } t > 0, \tag{2.24}$$

$$q(0) = q_0, \tag{2.25}$$

where $q_0 \in Q$, and $e(t) = u(t) - v(t)$, $t > 0$. The closed-loop system is then given by

$$\langle D_tu(t),\varphi\rangle + \langle A_0u(t),\varphi\rangle + \langle A_1(\overline{q} - q(t))u(t),\varphi\rangle = \langle g(t),\varphi\rangle, \ \varphi \in V, \text{ a.e. } t > 0, \tag{2.26}$$

$$\langle D_tv(t),\varphi\rangle + \langle A_0v(t),\varphi\rangle = \langle g(t),\varphi\rangle, \qquad \varphi \in V, \ a.e. \ t > 0, \tag{2.27}$$

$$\langle D_tq(t),p\rangle_Q + \langle A_1(p)u(t),u(t)-v(t)\rangle = 0, \qquad p \in Q, \text{ a.e. } t > 0, \tag{2.28}$$

$$u(0) = u_0, \qquad v(0) = v_0, \qquad q(0) = q_0. \tag{2.29}$$

We are interested in showing that the nonlinear system (2.26)–(2.29) is, at least in some sense and under some set of minimally realizable assumptions, well-posed. Recalling that $u(t) = e(t) + v(t)$, and defining the parameter error r to be

$$r(t) = q(t) - \overline{q}, \qquad t > 0, \tag{2.30}$$

we consider instead the equivalent problem of establishing a well-posedness result for the nonlinear system

$$\langle D_t e(t),\varphi\rangle + \langle A_0 e(t),\varphi\rangle - \langle A_1(r(t))\{e(t)+v(t)\},\varphi\rangle = 0,\ \varphi\in V,\quad \text{a.e. } t>0, \tag{2.31}$$

$$\langle D_t v(t),\varphi\rangle + \langle A_0 v(t),\varphi\rangle = \langle g(t),\varphi\rangle,\qquad \varphi\in V,\ \text{a.e. } t>0, \tag{2.32}$$

$$\langle D_t r(t),p\rangle_Q + \langle A_1(p)\{e(t)+v(t)\},e(t)\rangle = 0,\qquad p\in Q,\ \text{a.e. } t>0, \tag{2.33}$$

$$e(0)=e_0,\qquad v(0)=v_0,\qquad r(0)=r_0, \tag{2.34}$$

where $r_0 = q_0 - \overline{q} \in Q$. In the discussion to follow, we present two approaches to demonstrating the well-posedness of the closed-loop system (2.31)–(2.34). We will first demonstrate the existence of a unique strong solution using the theory of semilinear equations with analytic semigroups. The second approach is based upon an application of an implicit function theorem. Necessarily, each of the two approaches will require its own set of additional hypotheses which must be satisfied in order for there to exist a unique solution. The nonlinear system (2.31)–(2.34) is the one we will be using to establish the tracking error and parameter convergence in the next section. It is worth noting that the *skew-self-adjoint*-like structure of the system (2.31)–(2.34) plays an essential role in the analysis to follow in sections 2.1 and 2.2. We also note that the equation for v, (2.32), could be decoupled from the rest of the system and v could be treated as an exogenous input signal. In fact, in our discussion of our convergence and approximation results in sections 3 and 4 to follow, and the implicit function theorem approach to well-posedness, it is convenient, and in some sense essential (for the arguments as given), to do just that. However, we have found that for our analytic semigroup approach to well-posedness, the arguments are most elegantly presented in the context of the complete dynamical system (2.31)–(2.34).

2.1. An analytic semigroup approach to closed-loop well-posedness. Let $X = H\times H\times Q$ be endowed with the inner product

$$\langle(\varphi_1,\psi_1,q_1),(\varphi_2,\psi_2,q_2)\rangle_X = \langle\varphi_1,\varphi_2\rangle + \langle\psi_1,\psi_2\rangle + \langle q_1,q_2\rangle_Q,\ \ (\varphi_i,\psi_i,q_i)\in X,\ i=1,2,$$

and let $|\cdot|_X$ denote the corresponding induced norm. Thus $\{X,\langle\cdot,\cdot\rangle_X,|\cdot|_X\}$ is a Hilbert space. Let $Y = V\times V\times Q$ be endowed with the norm $\|(\varphi,\psi,q)\|_Y = (\|\varphi\|^2+\|\psi\|^2+|q|_Q^2)^{\frac{1}{2}}$, $(\varphi,\psi,q)\in Y$. Then $\{Y,\|\cdot\|_Y\}$ is a reflexive Banach space which is densely and continuously embedded in X. It follows that

$$Y\hookrightarrow X\hookrightarrow Y^*, \tag{2.35}$$

with the embeddings dense and continuous. For $\lambda>0$, define the linear operator $\mathcal{A}_\lambda : Y\to Y^*$ by $\langle\mathcal{A}_\lambda(e,v,r),(\varphi,\psi,q)\rangle_{Y^*,Y} = \langle A_0 e,\varphi\rangle + \langle A_0 v,\psi\rangle + \langle\lambda r,q\rangle_Q$ for $(e,v,r),(\varphi,\psi,q)\in Y$. In the above definition, $\langle\cdot,\cdot\rangle_{Y^*,Y}$ denotes the duality pairing between Y^* and Y induced by the X inner product via the dense and continuous embeddings given in (2.35). Recalling that $D_0 = Dom(A_0) = \{\varphi\in V : A_0\varphi\in H\}$, for $\lambda>0$, define the operator $A_\lambda : Dom(A_\lambda)\subset X\to X$ by $Dom(A_\lambda) = \{(\varphi,\psi,q)\in Y : \mathcal{A}_\lambda(\varphi,\psi,q)\in X\} = D_0\times D_0\times Q$, $A_\lambda(\varphi,\psi,q) = \mathcal{A}_\lambda(\varphi,\psi,q)$, $(\varphi,\psi,q)\in Dom(A_\lambda)$. Note that $Dom(A_\lambda) = Dom(A)$ is independent of $\lambda>0$, that for $\lambda>0$, $-A_\lambda$ is the infinitesimal generator of a uniformly exponentially stable analytic semigroup, $\{T_\lambda(t) : t\geq 0\}$, on X, Y, and Y^*, and that $0\in\rho(-A_\lambda)$, the resolvent set of $-A_\lambda$.

For $\varphi \in V$, define the operator $B(\varphi) : Q \to V^*$ by

$$\langle B(\varphi)q, \psi\rangle = \langle A_1(q)\varphi, \psi\rangle, \qquad q \in Q, \ \ \psi \in V. \tag{2.36}$$

Assumptions (A1) and (A2) imply that for $\varphi \in V$, $B(\varphi) \in \mathcal{L}(Q, V^*)$ with $\|B(\varphi)\| \leq \alpha_1\|\varphi\|$. Recalling that V was assumed to be reflexive, and that Q is a Hilbert space, for $\varphi \in V$, let $B(\varphi)' \in \mathcal{L}(V, Q)$ denote the Banach space adjoint of $B(\varphi)$. That is, for $\varphi \in V$ we have

$$\langle B(\varphi)'\psi, q\rangle_Q = \langle B(\varphi)q, \psi\rangle = \langle A_1(q)\varphi, \psi\rangle, \qquad \psi \in V, \ \ q \in Q. \tag{2.37}$$

For $\lambda > 0$, define $G_\lambda : \mathbf{R}^+ \times Y \to Y^*$ by

$$\langle G_\lambda(t, \Phi), \Psi\rangle_{Y^*,Y} = \langle B(e + v)r, \varphi\rangle + \langle g(t), \psi\rangle + \langle \lambda r - B(e + v)'e, q\rangle_Q,$$

where $t \geq 0$, $\Phi = (e, v, r) \in Y$ and $\Psi = (\varphi, \psi, q) \in Y$.

We consider the system (2.31)–(2.34) written as

$$\langle D_t x(t), \Phi\rangle_{Y^*,Y} + \langle \mathcal{A}_\lambda x(t), \Phi\rangle_{Y^*,Y} = \langle G_\lambda(t, x(t)), \Phi\rangle_{Y^*,Y}, \ \Phi \in Y, \text{ a.e. } t > 0, \tag{2.38}$$

$$x(0) = x_0, \tag{2.39}$$

where $\lambda > 0$, and for each $t \geq 0$, $x(t) = (e(t), v(t), r(t))$. Under appropriate additional assumptions on the input reference signal g, the initial data e_0, v_0, and r_0, and the plant (i.e., the operator $A_1(q)$ for $q \in Q$), we establish the existence of a unique solution to the system (2.38), (2.39) by first establishing the existence of a unique local strong solution to the initial value problem in X given by

$$D_t x(t) + A_\lambda x(t) = G_\lambda(t, x(t)), \qquad \text{a.e. } t > 0, \tag{2.40}$$

$$x(0) = x_0, \tag{2.41}$$

and then showing that it is possible to continue this solution for all $t > 0$. By a strong (or classical) solution on the interval $[0, T)$ to the initial value problem (2.40), (2.41) we mean a function $x : [0, T) \to X$ which is continuous on $[0, T)$, continuously differentiable on $(0, T)$, $x(t) \in Dom(A) = Dom(A_\lambda)$ for $t \in (0, T)$, (2.40) is satisfied for $t \in (0, T)$, and (2.41) is satisfied.

To establish that the initial value problem (2.40), (2.41) is well-posed, we require the following *additional* assumptions.

(A6) (q-independent domain). The subset of V, $D_1 = Dom(A_1(q))$ is independent of $q \in Q$ and for some $\alpha \in (0, 1)$, $Dom(A_0^\alpha) \subset D_1$.

(A7) (A_0^α-boundedness). There exist $\beta_1 > 0$ such that for α as in assumption (A6), we have

$$|A_1(q)\varphi| \leq \beta_1|q|_Q|A_0^\alpha\varphi|, \qquad q \in Q, \ \ \varphi \in Dom(A_0^\alpha), \tag{2.42}$$

(A8) (A_0^α-Lipschitz). There exist $\gamma_1 > 0$ such that for α as in assumption (A6) we have

$$|A_1(q)\varphi - A_1(q)\psi| \leq \gamma_1|q|_Q|A_0^\alpha\varphi - A_0^\alpha\psi|, \quad q \in Q, \ \varphi, \psi \in Dom(A_0^\alpha), \tag{2.43}$$

(A9) (Hölder continuity). For $t \geq 0$, $g(t) \in H$, and there exist $\nu \in (0, 1]$ and $\delta > 0$ such that

$$|g(t) - g(s)| \leq \delta|t - s|^\nu, \qquad t, s \geq 0. \tag{2.44}$$

Note that assumptions (A3) and (A4) are sufficient for fractional powers of the operator A_0 to be well defined (see, for example, [33]).

THEOREM 2.4. *Suppose that assumptions* (A1)–(A9) *hold and that* $e_0, v_0 \in Dom(A_0^\alpha)$, *where* $\alpha \in (0,1)$ *is as in assumption* (A6). *Then there exists a* $T = T(x_0) > 0$ *such that the initial value problem* (2.40), (2.41) *has a unique local solution* $x \in C([0,T);X) \cap C^1((0,T);X)$.

Proof. For $\alpha \in (0,1)$, the linear operator A_0^α is closed and invertible with domain, $Dom(A_0^\alpha)$, dense in H. For the α in assumption (A6), let H_α denote the space $Dom(A_0^\alpha)$ endowed with the graph norm $\|\cdot\|_\alpha$ corresponding to A_0^α. That is, for $\varphi \in Dom(A_0^\alpha)$, $\|\varphi\|_\alpha = |\varphi| + |A_0^\alpha \varphi|$. Note that since A_0^α is closed, H_α is a Banach space, and since A_0^α is invertible, the norm $\|\cdot\|_\alpha$ is equivalent to the norm $|\cdot|_\alpha$ on $Dom(A_0^\alpha)$ given by $|\varphi|_\alpha = |A_0^\alpha \varphi|$ for $\varphi \in Dom(A_0^\alpha)$. Define the Banach space $\{X_\alpha, |\cdot|_{X_\alpha}\}$ by $X_\alpha = H_\alpha \times H_\alpha \times Q$ with $|\Phi|_{X_\alpha} = |\varphi_1|_\alpha + |\varphi_2|_\alpha + |\varphi_3|_Q$ for $\Phi = (\varphi_1, \varphi_2, \varphi_3) \in X_\alpha$.

The theorem will follow at once from Theorem 6.3.1 in [33] once we have established that for some $\lambda > 0$ and any neighborhood, $U \subset X_\alpha$, of x_0, $U = \{x \in X_\alpha : |x - x_0|_{X_\alpha} < \varepsilon\}$, there exists a constant $L = L(U,\lambda) = L(\varepsilon, x_0, \lambda) > 0$, such that

$$\begin{aligned} &|G_\lambda(t,\Phi) - G_\lambda(s,\Psi)|_X \\ &\qquad \le L\{|t-s|^\nu + |A_0^\alpha\varphi_1 - A_0^\alpha\psi_1| + |A_0^\alpha\varphi_2 - A_0^\alpha\psi_2| + |\varphi_3 - \psi_3|_Q\} \\ &\qquad = L\{|t-s|^\nu + |\varphi_1 - \psi_1|_\alpha + |\varphi_2 - \psi_2|_\alpha + |\varphi_3 - \psi_3|_Q\}, \qquad t,s > 0, \end{aligned} \tag{2.45}$$

for all $\Phi = (\varphi_1, \varphi_2, \varphi_3), \Psi = (\psi_1, \psi_2, \psi_3) \in U$. Let $\lambda > 0$ and $\Phi = (\varphi_1, \varphi_2, \varphi_3), \Psi = (\psi_1, \psi_2, \psi_3) \in U$, and consider for $t, s > 0$,

$$\begin{aligned} &|G_\lambda(t,\Phi) - G_\lambda(s,\Psi)|_X^2 \\ &\qquad = |B(\varphi_1+\varphi_2)\varphi_3 - B(\psi_1+\psi_2)\psi_3|^2 + |g(t) - g(s)|^2 \\ &\qquad + |\lambda\{\varphi_3 - \psi_3\} - \{B(\varphi_1+\varphi_2)'\varphi_1 - B(\psi_1+\psi_2)'\psi_1\}|_Q^2. \end{aligned} \tag{2.46}$$

Now, assumptions (A7) and (A8) imply that

$$\begin{aligned} |B(\varphi_1+\varphi_2)\varphi_3 - B(\psi_1+\psi_2)\psi_3| &\le |B(\varphi_1+\varphi_2)\varphi_3 - B(\varphi_1+\varphi_2)\psi_3| \\ &+ |B(\varphi_1+\varphi_2)\psi_3 - B(\psi_1+\psi_2)\psi_3| \\ &\le \beta_1|\varphi_3 - \psi_3|_Q\{|A_0^\alpha\varphi_1| + |A_0^\alpha\varphi_2|\} \\ &+ \gamma_1|\psi_3|_Q\{|A_0^\alpha\varphi_1 - A_0^\alpha\psi_1| + |A_0^\alpha\varphi_2 - A_0^\alpha\psi_2|\} \\ &= \beta_1|\varphi_3 - \psi_3|_Q\{|\varphi_1|_\alpha + |\varphi_2|_\alpha\} \\ &+ \gamma_1|\psi_3|_Q\{|\varphi_1 - \psi_1|_\alpha + |\varphi_2 - \psi_2|_\alpha\}. \end{aligned} \tag{2.47}$$

Finally, using assumptions (A7) and (A8), we obtain

$$\begin{aligned} &|\lambda\{\varphi_3 - \psi_3\} - \{B(\varphi_1+\varphi_2)'\varphi_1 - B(\psi_1+\psi_2)'\psi_1\}|_Q \\ &\le \lambda|\varphi_3 - \psi_3|_Q + \sup_{|q|_Q \le 1} |\langle\{B(\varphi_1+\varphi_2)'\varphi_1 - B(\psi_1+\psi_2)'\psi_1\}, q\rangle_Q| \\ &= \lambda|\varphi_3 - \psi_3|_Q + \sup_{|q|_Q \le 1} |\langle A_1(q)\{\varphi_1+\varphi_2\}, \varphi_1\rangle - \langle A_1(q)\{\psi_1+\psi_2\}, \psi_1\rangle| \\ &\le \lambda|\varphi_3 - \psi_3|_Q + \sup_{|q|_Q \le 1} |\langle A_1(q)\{\varphi_1+\varphi_2\} - A_1(q)\{\psi_1+\psi_2\}, \varphi_1\rangle| \\ &\qquad + \sup_{|q|_Q \le 1} |\langle A_1(q)\{\psi_1+\psi_2\}, \varphi_1 - \psi_1\rangle| \end{aligned} \tag{2.48}$$

$$
\begin{aligned}
&\leq \lambda|\varphi_3-\psi_3|_Q + \sup_{|q|_Q\leq 1}|A_1(q)\{\varphi_1+\varphi_2\}-A_1(q)\{\psi_1+\psi_2\}||\varphi_1| \\
&\qquad + \sup_{|q|_Q\leq 1}|A_1(q)\{\psi_1+\psi_2\}||\varphi_1-\psi_1| \\
&\leq \lambda|\varphi_3-\psi_3|_Q + \gamma_1|\varphi_1|\{|A_0^\alpha\varphi_1 - A_0^\alpha\psi_1| + |A_0^\alpha\varphi_2 - A_0^\alpha\psi_2|\} \\
&\qquad +\beta_1\{|A_0^\alpha\psi_1| + |A_0^\alpha\psi_2|\}|\varphi_1-\psi_1| \\
&\leq \lambda|\varphi_3-\psi_3|_Q + \gamma_1\kappa_\alpha|\varphi_1|_\alpha\{|\varphi_1-\psi_1|_\alpha + |\varphi_2-\psi_2|_\alpha\} \\
&\qquad +\beta_1\kappa_\alpha\{|\psi_1|_\alpha + |\psi_2|_\alpha\}|\varphi_1-\psi_1|_\alpha,
\end{aligned}
$$

where κ_α is such that $|\varphi| \leq \|\varphi\|_\alpha \leq \kappa_\alpha|\varphi|_\alpha$ for $\varphi \in H_\alpha$. Combining (2.46)–(2.48) and assumption (A9), we obtain (2.45), and the theorem is proved. □

In order to extend the local solution guaranteed to exist in Theorem 2.4 we require the estimate given in the following lemma.

LEMMA 2.5. *Let $x = (e, v, r)$ be the unique solution to the initial value problem* (2.40), (2.41) *guaranteed to exist on the interval $[0, T)$ by Theorem* 2.4. *It then follows that*

$$
|x(t)|_X^2 + \rho_0\int_0^t \left\{\|e(s)\|^2 + \|v(s)\|^2\right\} ds \leq |x_0|_X^2 + \frac{1}{\rho_0}\int_0^t \|g(s)\|_*^2 ds,\ 0 \leq t < T. \tag{2.49}
$$

Proof. For $s \in [0, T)$, using (2.40), we obtain

$$
\begin{aligned}
\frac{1}{2}D_t|x(s)|_X^2 &= \langle D_t x(s), x(s)\rangle_X \\
&= -\langle A_\lambda x(s), x(s)\rangle_X + \langle G_\lambda(s, x(s)), x(s)\rangle_X \\
&= -\langle A_0 e(s), e(s)\rangle - \langle A_0 v(s), v(s)\rangle + \langle g(s), v(s)\rangle \qquad (2.50) \\
&\leq -\rho_0\|e(s)\|^2 - \rho_0\|v(s)\|^2 + \|g(s)\|_*\|v(s)\| \\
&\leq -\frac{\rho_0}{2}\left\{\|e(s)\|^2 + \|v(s)\|^2\right\} + \frac{1}{2\rho_0}\|g(s)\|_*^2.
\end{aligned}
$$

Integrating both sides of (2.50) from 0 to t, and using (2.41), we obtain (2.49), and the lemma is proved. □

Note that the proof of Lemma 2.5 given above does not *explicitly* require that the additional assumptions (A6)–(A9) be satisfied.

THEOREM 2.6. *Suppose that assumptions* (A1)–(A9) *hold and that $e_0, v_0 \in Dom(A_0^\alpha)$, where $\alpha \in (0, 1)$ is as in assumption* (A6). *Then the initial value problem* (2.40), (2.41) *has a unique solution, $x = (e, v, r)$, which exists for all $t \geq 0$.*

Proof. The local solution x to the initial value problem (2.40), (2.41) guaranteed to exist by Theorem 2.4 can be continued so long as $|x(t)|_{X_\alpha}$ remains bounded. We show that this is in fact the case by using Lemma 2.5 to argue that $|x(t)|_{X_\alpha}$ remains bounded as $t \uparrow T$.

For $t \in [0, T)$ we have that

$$
x(t) = T_\lambda(t)x_0 + \int_0^t T_\lambda(t-s)G_\lambda(s, x(s))ds
$$

and therefore that

$$
A_\lambda^\alpha x(t) = A_\lambda^\alpha T_\lambda(t)x_0 + \int_0^t A_\lambda^\alpha T_\lambda(t-s)G_\lambda(s, x(s))ds.
$$

Equivalently, we have

$$A_0^\alpha e(t) = A_0^\alpha T_0(t)e_0 + \int_0^t A_0^\alpha T_0(t-s)B(e(s)+v(s))r(s)ds,$$
$$A_0^\alpha v(t) = A_0^\alpha T_0(t)v_0 + \int_0^t A_0^\alpha T_0(t-s)g(s)ds,$$

and

$$\lambda^\alpha r(t) = \lambda^\alpha e^{-\lambda t}r_0 + \int_0^t \lambda^\alpha e^{-\lambda(t-s)}\{\lambda r(s) - B(e(s)+v(s))'e(s)\}ds.$$

It follows from assumptions (A7) and (A9), (2.10), and Theorem 2.6.13 in [33] that

$$\begin{aligned}
|e(t)|_\alpha &\le e^{-\rho_0 K^{-2}t}|e_0|_\alpha + \textstyle\int_0^t M_\alpha(t-s)^{-\alpha}e^{-\rho_0 K^{-2}(t-s)}\beta_1|r(s)|_Q|e(s)|_\alpha ds \\
&\quad + \int_0^t M_\alpha(t-s)^{-\alpha}e^{-\rho_0 K^{-2}(t-s)}\beta_1|r(s)|_Q|v(s)|_\alpha ds \qquad (2.51)\\
&\le |e_0|_\alpha + M_\alpha\beta_1\int_0^t (t-s)^{-\alpha}|r(s)|_Q|x(s)|_{X_\alpha}ds, \\
|v(t)|_\alpha &\le e^{-\rho_0 K^{-2}t}|v_0|_\alpha + \int_0^t M_\alpha(t-s)^{-\alpha}e^{-\rho_0 K^{-2}(t-s)}|g(s)|ds \\
&\le e^{-\rho_0 K^{-2}t}|v_0|_\alpha + \int_0^t M_\alpha(t-s)^{-\alpha}e^{-\rho_0 K^{-2}(t-s)}|g(0)|ds \\
&\quad + \int_0^t M_\alpha(t-s)^{-\alpha}e^{-\rho_0 K^{-2}(t-s)}\left\{|g(s)-g(0)|\right\}ds \qquad (2.52)\\
&\le |v_0|_\alpha + M_\alpha\int_0^t (t-s)^{-\alpha}\{|g(0)| + \delta s^\nu\}ds \\
&\le |v_0|_\alpha + M_\alpha\left\{|g(0)| + \delta T^\nu\right\}\frac{T^{1-\alpha}}{1-\alpha},
\end{aligned}$$

and

$$\begin{aligned}
|r(t)|_Q &\le |r_0|_Q + \int_0^t e^{-\lambda(t-s)}\{\lambda|r(s)|_Q + |B(e(s)+v(s))'e(s)|_Q\}ds \\
&\le |r_0|_Q + \int_0^t \{\lambda|r(s)|_Q + \sup_{|q|_Q\le 1}|\langle A_1(q)\{e(s)+v(s)\}, e(s)\rangle|\}ds \\
&\le |r_0|_Q + \int_0^t \{\lambda|r(s)|_Q + \beta_1|e(s)|\{|A_0^\alpha e(s)| + |A_0^\alpha v(s)|\}\}ds \qquad (2.53)\\
&\le |r_0|_Q + \int_0^t \{\lambda|r(s)|_Q + \beta_1|e(s)|\{|e(s)|_\alpha + |v(s)|_\alpha\}\}ds \\
&\le |r_0|_Q + T^\alpha\int_0^t \max\{\lambda, \beta_1|e(s)|\}(t-s)^{-\alpha}|x(s)|_{X_\alpha}ds,
\end{aligned}$$

where M_α is a positive constant. Now Lemma 2.5 implies that for $s \in [0,T)$, $|x(s)|_X$ is bounded. It follows that $s \in [0,T)$, $|e(s)|$ and $|r(s)|_Q$ are bounded. Combining (2.51), (2.52), and (2.53), we obtain

$$|x(t)|_{X_\alpha} \le |x_0|_{X_\alpha} + M_\alpha\left\{|g(0)| + \delta T^\nu\right\}\frac{T^{1-\alpha}}{1-\alpha} + C\int_0^t (t-s)^{-\alpha}|x(s)|_{X_\alpha}ds, \qquad (2.54)$$

where $C > 0$. It follows from Theorem 5.6.7 in [33] that $|x(t)|_{X_\alpha} \leq C_1$ on $[0,T)$ for some $C_1 > 0$, and the theorem is proved. ∎

Theorem 2.6 yields the following regularity result for the controller f. We state it as a corollary.

COROLLARY 2.7. *Suppose that assumptions* (A1)–(A9) *hold, and that* $e_0, v_0 \in Dom(A_0^\alpha)$, *where* $\alpha \in (0,1)$ *is as in assumption* (A6). *If the operator* A_2 *is such that* $D_2 = Dom(A_2) = \{\varphi \in V : A_2\varphi \in H\} \supset Dom(A_0^\alpha)$, *where* $\alpha \in (0,1)$ *is as in assumption* (A6), *and satisfies a Lipschitz condition of the form*

$$|A_2\varphi - A_2\psi| \leq \gamma_2|\varphi - \psi|_\alpha, \qquad \varphi, \psi \in Dom(A_0^\alpha), \tag{2.55}$$

then the control law given in (2.22) *or* (2.23) *satisfies* $f(t) \in H$, $t > 0$, *and* $f \in C((0,\infty); H)$.

Proof. For $t > 0$, the controller f satisfies

$$f(t) = A(q(t))u(t) - A_0u(t) + g(t) = D_tu(t) + A(\overline{q})u(t). \tag{2.56}$$

Theorem 2.6 implies that $u(t) \in Dom(A_0)$, $t > 0$. It follows, therefore, that $u(t) \in Dom(A_0^\alpha)$, $t > 0$, and therefore that $u(t) \in D_j$, $j = 1, 2$, $t > 0$. Consequently, $A(\overline{q})u(t) \in H$, $t > 0$, and, hence, $f(t) \in H$, $t > 0$. Theorem 2.6 also implies that $D_tu \in C((0,\infty); H)$, and for $s, t > 0$, assumption (A8) together with (2.55) imply that

$$\begin{aligned} |A(\overline{q})u(t) - A(\overline{q})u(s)| &\leq |A_1(\overline{q})u(t) - A_1(\overline{q})u(s)| + |A_2u(t) - A_2u(s)| \\ &\leq \{\gamma_1|\overline{q}|_Q + \gamma_2\}|u(t) - u(s)|_\alpha. \end{aligned} \tag{2.57}$$

Inspection of the proof of Theorem 6.3.1 in [33] immediately reveals that u is continuous in H_α. It follows from (2.56) and (2.57) that $f \in C((0,\infty); H)$, which establishes the corollary. ∎

Example 2.8. We provide a simple example which satisfies assumptions (A1)–(A9). Let $H = L_2(0,1)$, and let it be endowed with the standard inner product $\langle \cdot, \cdot \rangle$ and corresponding induced norm $|\cdot|$. Let $V = H_L^1(0,1) = \{\varphi \in H^1(0,1) : \varphi(0) = 0\}$, and let it be endowed with the norm $\|\cdot\|$ given by $\|\varphi\| = \{\int_0^1 |D\varphi(x)|^2 dx\}^{\frac{1}{2}}$, $\varphi \in H_L^1(0,1)$. Then $\{V, \|\cdot\|\}$ is a reflexive Banach space and, in fact, a Hilbert space, which is densely and continuously embedded in H. We have $|\varphi| \leq \|\varphi\|$, $\varphi \in H_L^1(0,1)$. Let $\hat{V}^* = V^*$, and let $Q = \mathbf{R}^1$ with $|q|_Q = |q|$ for $q \in \mathbf{R}$. We are interested in controlling the first-order plant given by

$$\frac{\partial u}{\partial t}(t,x) + \overline{q}\frac{\partial u}{\partial x}(t,x) = f(t,x), \qquad 0 < x < 1,\ t > 0, \tag{2.58}$$

together with the boundary condition

$$u(t,0) = 0, \qquad t > 0, \tag{2.59}$$

and initial condition

$$u(0,x) = u_0(x), \qquad 0 \leq x \leq 1, \tag{2.60}$$

where $\overline{q} > 0$, $u_0 \in L_2(0,1)$, and $t \to f(t,\cdot) \in L_2(0,T;H)$ for each $T > 0$.

For each $q \in \mathbf{R}^1$, let the operator $A_1(q) : Dom(A_1(q)) \subset H \to H$ be given by $A_1(q)\varphi = qD\varphi$, $\varphi \in D_1$, where $D_1 = Dom(A_1(q)) = V$. For each $q \in Q$, let $A(q) = A_1(q)$. It follows that A_2 is the zero operator, that D_1 is independent of $q \in Q$, and that $A_1(q) : V \to V^*$. Moreover, for $q \in Q$ and $\varphi, \psi \in V$ we have that

$$|\langle A_1(q)\varphi, \psi\rangle| = |q|_Q \left| \int_0^1 D\varphi(x)\psi(x)dx \right| \leq |q|_Q|D\varphi||\psi| = |q|_Q\|\varphi\|\|\psi\| \leq |q|_Q\|\varphi\|\|\psi\|.$$

Consequently assumption (A1) is satisfied with $\alpha_1 = 1$. Assumption (A2) is trivially satisfied.

It is not difficult to show that the Hilbert space adjoint of the operator $A_1(\overline{q})$ is given by $A_1(\overline{q})^*\varphi = -\overline{q}D\varphi$, $\varphi \in D_1^*$, where $D_1^* = Dom(A_1(\overline{q})^*) = H_R^1(0,1) = \{\varphi \in H^1(0,1) : \varphi(1) = 0\}$. For $\varphi \in H_L^1(0,1)$, we have that

$$\langle A_1(\overline{q})\varphi, \varphi\rangle = \overline{q}\int_0^1 D\varphi(x)\varphi(x)dx = \frac{\overline{q}}{2}\int_0^1 D\varphi(x)^2dx = \frac{\overline{q}}{2}\varphi(1)^2 \geq 0 \tag{2.61}$$

and for $\varphi \in H_R^1(0,1)$ that

$$\langle A_1(\overline{q})^*\varphi, \varphi\rangle = -\overline{q}\int_0^1 D\varphi(x)\varphi(x)dx = -\frac{\overline{q}}{2}\int_0^1 D\varphi(x)^2dx = \frac{\overline{q}}{2}\varphi(0)^2 \geq 0. \tag{2.62}$$

It follows from (2.61) and (2.62) that (see, for example, [26, Theorem I.4.5]) the operator $-A_1(\overline{q})$ is *maximal dissipative* and therefore that it is the infinitesimal generator of a $\mathcal{C}_0$-semigroup of bounded linear operators (in fact, contractions), $\{S(t,\overline{q}) : t \geq 0\}$, on $H = L_2(0,1)$. For each $t \geq 0$, the unique mild solution, $u(t) = u(t,\cdot)$ to the system (2.58)–(2.60) is given by

$$u(t) = S(t;\overline{q})u_0 + \int_0^t S(t-s;\overline{q})f(s)ds, \tag{2.63}$$

where for each $t \geq 0$, $f(t) = f(t,\cdot) \in L_2(0,1)$. When $u_0 \in H_L^1(0,1)$, and f is strongly continuously differentiable for $t \geq 0$, the function u given by (2.63) is a strong solution (see, for example, [39, Theorem 3.2.2]). Such a solution certainly satisfies our minimal well-posedness requirement on the plant. Indeed, in addition to satisfying the differential equation and initial data, (2.4) and (2.5), we have (see, for example, [39, p. 64]) $u \in C^1([0,T];H)$, $u(t) \in Dom(A_1(\overline{q})) = V$, $t \in [0,T]$, and $A_1(\overline{q})u \in C([0,T];H)$ for all $T > 0$. It immediately follows that $u \in C(0,T;H) \cap L_2(0,T;V)$ and $D_t u \in L_2(0,T;V^*)$.

For the reference model, we consider the one-dimensional heat equation given by

$$\frac{\partial v}{\partial t}(t,x) - a_0\frac{\partial^2 v}{\partial x^2}(t,x) = g(t,x), \qquad 0 < x < 1,\ t > 0,$$

together with the boundary conditions $v(t,0) = 0$ and $\frac{\partial v}{\partial x}(t,1) = 0$, $t > 0$, and the initial conditions $v(0,x) = v_0(x)$, $0 \leq x \leq 1$, where $a_0 > 0$, $v_0 \in L_2(0,1)$, and $[t \to g(t,\cdot)] \in L_2(0,T;V^*)$ for each $T > 0$. In this case we have $A_0 \in \mathcal{L}(V,V^*)$ given by

$$\langle A_0\varphi, \psi\rangle = a_0\int_0^1 D\varphi(x)D\psi(x)dx, \qquad \varphi, \psi \in H_L^1(0,1).$$

It is immediately clear that assumptions (A3) and (A4) are satisfied with $\alpha_0 = \rho_0 = a_0$. Moreover, we have that $D_0 = Dom(A_0) = \{\varphi \in H_L^1(0,1) : \varphi \in H^2(0,1), D\varphi(1) = 0\}$ and that A_0 as an operator from V into V^* is symmetric or as an operator on H is self-adjoint. Assumption $(A5)$ is trivially satisfied with the choice of $\hat{V}^* = V^*$.

Since A_0 is symmetric, $V = Dom(A_0^{\frac{1}{2}})$ (see [39]). Consequently, we have

$$Dom(A_0^{\frac{1}{2}}) = V = Dom(A_1(q)) = D_1.$$

It follows that assumption (A6) is satisfied with $\alpha = \frac{1}{2}$. Moreover, for $\varphi \in H_L^1(0,1) = V$, we have that

$$\begin{aligned}|A_1(q)\varphi|^2 &= |qD\varphi|^2 = |q|_Q^2|D\varphi|^2 = |q|_Q^2\|\varphi\|^2 \\ &= |q|_Q^2\frac{1}{a_0}\langle A_0\varphi,\varphi\rangle = \frac{1}{a_0}|q|_Q^2\langle A_0^{\frac{1}{2}}\varphi, A_0^{\frac{1}{2}}\varphi\rangle = \frac{1}{a_0}|q|_Q^2|A_0^{\frac{1}{2}}\varphi|^2.\end{aligned}$$

It follows that assumptions (A7) and (A8) are satisfied with β_1 and γ_1 in (2.42) and (2.43), respectively, given by $\beta_1 = \gamma_1 = \frac{1}{\sqrt{a_0}}$. Thus, if $u_0, v_0 \in H_L^1(0,1)$, and g is sufficiently regular (i.e., assumption (A9) and (2.44) being satisfied for some $\delta > 0$ and $\nu \in (0,1]$), then the resulting closed-loop system will be well-posed.

2.2. Closed-loop well-posedness via an implicit function theorem. Assumptions (A6)–(A9) can be rather restrictive and may preclude the consideration of certain classes of problems of interest. In particular, assumption (A7) does not include the class of problems in which the plant and reference model dynamics are of the same *order* (i.e., $\alpha \in (0,1)$). Thus, for example, the above theory does not allow for both a plant and reference model described by a diffusion (or heat) equation. To remedy this, we propose a somewhat different approach to demonstrating the well-posedness of the closed-loop system (2.26)–(2.28). Our argument is based upon an application of the implicit function theorem (see, for example, [10]). Of course this approach requires additional assumptions as well. Indeed, in this case we can guarantee well-posedness only for initial data which is sufficiently small in norm. That is, the plant must initially be *close* to the reference model, and we require a reasonably good initial guess for the unknown parameters. Also, to simplify the presentation we make the following assumption on the linearity of the plant.

(A10) (linearity of the plant). For each $q \in Q$, $A_1(q) : V \to V^*$ is linear.

Note that assumptions (A1) and (A10) together imply that $A_1(q) \in \mathcal{L}(V, V^*)$ for each $q \in Q$. We note that assumption (A10) can be weakened quite a bit to allow for certain classes of nonlinear plants such as certain Lipschitz continuous or differentiable operators. However, the required technical assumptions would only complicate the exposition without significantly affecting its substance. Consequently, we opt for clarity and leave the generalization to the reader.

We also require the following regularity assumption on the state v of the reference model (2.8), (2.9).

(A11) (regularity of the reference model). The solution v to the system (2.8), (2.9) satisfies $v \in L_2(0,T;V)$ for all $T > 0$.

Theorem 2.2 (ii) provides sufficient conditions for assumption (A11) to be satisfied.

We consider v to be an *exogenous* signal and consider the initial value problem given by

$$\langle D_t e(t),\varphi\rangle + \langle A_0 e(t),\varphi\rangle - \langle A_1(r(t))\{e(t)+v(t)\},\varphi\rangle = 0,\ \varphi \in V,\ \text{a.e. } t > 0, \tag{2.64}$$

$$\langle D_t r(t), p\rangle_Q + \langle A_1(p)\{e(t)+v(t)\}, e(t)\rangle = 0, \qquad p \in Q,\ \text{a.e. } t > 0, \tag{2.65}$$

$$e(0) = e_0, \qquad r(0) = r_0, \tag{2.66}$$

THEOREM 2.9. *Suppose that assumptions* (A1)–(A5) *and assumptions* (A10) *and* (A11) *hold. Suppose further that* $e_0 \in V$. *Then there exists a constant* $C > 0$ *such that if*

$$\|e_0\| + |r_0|_Q < C, \tag{2.67}$$

then the initial value problem (2.64)–(2.66) *has a unique solution* (e, r) *with* $e \in L_2(0,T;V) \cap H^1(0,T;V^*)$ *and* $r \in L_\infty(0,T;Q) \cap W^{1,1}(0,T;Q)$ *for all* $T > 0$.

Proof. The proof follows from an application of the implicit function theorem (see, for example, [10]). We let $T > 0$, and we begin with the definition of the following Banach spaces. Let $X = X_1 \times X_2$ where $X_1 = V$ and $X_2 = Q$ with norm

$$\|(\varphi, q)\|_X = \|\varphi\|_{X_1} + \|q\|_{X_2} = \|\varphi\| + |q|_Q, \qquad \varphi \in V,\ q \in Q. \tag{2.68}$$

Let $Y = Y_1 \times Y_2$ where $Y_1 = L_2(0,T;V) \cap H^1_L(0,T;V^*)$ and $Y_2 = L_\infty(0,T;Q) \cap W^{1,1}_L(0,T;Q)$ with norm

$$\begin{aligned} \|(\varphi, q)\|_Y &= \|\varphi\|_{Y_1} + \|q\|_{Y_2} \\ &= \left\{\int_0^T \|\varphi(t)\|^2 dt\right\}^{\frac{1}{2}} + \left\{\int_0^T \|D_t\varphi(t)\|_*^2 dt\right\}^{\frac{1}{2}} \\ &\quad + \operatorname{ess\,sup}_{t\in[0,T]} |q(t)|_Q + \int_0^T |D_t q(t)|_Q dt, \end{aligned} \tag{2.69}$$

for $\varphi \in L_2(0,T;V) \cap H^1_L(0,T;V^*)$ and $q \in L_\infty(0,T;Q) \cap W^{1,1}_L(0,T;Q)$, and let $Z = Z_1 \times Z_2$, where $Z_1 = L_2(0,T;V^*)$ and $Z_2 = L_1(0,T;Q)$, with norm

$$\|(\varphi, q)\|_Z = \|\varphi\|_{Z_1} + \|q\|_{Z_2} = \left\{\int_0^T \|\varphi(t)\|_*^2 dt\right\}^{\frac{1}{2}} + \int_0^T |q(t)|_Q dt, \tag{2.70}$$

for $\varphi \in L_2(0,T;V^*)$ and $q \in L_1(0,T;Q)$. The subscript L in the above spaces denotes homogeneous boundary conditions at the left endpoint of the interval.

Define the function $\mathcal{F} : X \times Y \to Z$ by $\mathcal{F}(x,y) = (\mathcal{F}_1(x,y), \mathcal{F}_2(x,y))$, $x = (x_1, x_2) \in X$, $y = (y_1, y_2) \in Y$, where $\mathcal{F}_1 : X \times Y \to Z_1 = L_2(0,T;V^*)$ is given by $\mathcal{F}_1(x,y) = D_t y_1 + A_0\{y_1 + x_1\} - B(y_1 + x_1 + v)\{y_2 + x_2\}$, $x = (x_1, x_2) \in X$, $y = (y_1, y_2) \in Y$, and $\mathcal{F}_2 : X \times Y \to Z_2 = L_1(0,T;Q)$ is given by $\mathcal{F}_2(x,y) = D_t y_2 + B(y_1 + x_1 + v)'\{y_1 + x_1\}$, $x = (x_1, x_2) \in X$, $y = (y_1, y_2) \in Y$, where for $\varphi \in V$, the operator $B(\varphi) \in \mathcal{L}(Q, V^*)$ and its Banach space adjoint, $B(\varphi)' \in \mathcal{L}(V, Q)$ are given in (2.36) and (2.37), respectively.

The hypotheses of the theorem clearly imply that $\mathcal{F}(0,0) = 0$ and that $\mathcal{F} \in C(X \times Y, Z)$; that is, $\mathcal{F}$ is a continuous mapping from $X \times Y$ into Z. It is not difficult to show that $\mathcal{F}$ is continuously differentiable from $X \times Y$ into Z. Indeed, we need only to argue that (see [10, Theorem 8.9.1]) the maps $(x,y) \mapsto D_{x_i}\mathcal{F}_j$ from $X \times Y$ into $\mathcal{L}(X_i, Z_j)$, $i,j = 1,2$ and $(x,y) \mapsto D_{y_i}\mathcal{F}_j$ from $X \times Y$ into $\mathcal{L}(Y_i, Z_j)$, $i,j = 1,2$ are continuous. A straightforward calculation reveals that at $(x,y) \in X \times Y$ with $x = (x_1, x_2) \in X = X_1 \times X_2$ and $y = (y_1, y_2) \in Y = Y_1 \times Y_2$,

$$\begin{aligned}
&D_{x_1}\mathcal{F}_1\delta x_1 = A_0\delta x_1 - B(\delta x_1)\{y_2 + x_2\} \in Z_1, \qquad \delta x_1 \in X_1, \\
&D_{x_2}\mathcal{F}_1\delta x_2 = B(y_1 + x_1 + v)\delta x_2 \in Z_1, \qquad \delta x_2 \in X_2, \\
&D_{x_1}\mathcal{F}_2\delta x_1 = B(\delta x_1)'\{y_1 + x_1\} + B(y_1 + x_1 + v)'\delta x_1 \in Z_2, \qquad \delta x_1 \in X_1, \\
&D_{x_2}\mathcal{F}_2\delta x_2 = 0 \in Z_2, \qquad \delta x_2 \in X_2, \\
&D_{y_1}\mathcal{F}_1\delta y_1 = D_t\delta y_1 + A_0\delta y_1 - B(\delta y_1)\{y_2 + x_2\} \in Z_1, \qquad \delta y_1 \in Y_1, \\
&D_{y_2}\mathcal{F}_1\delta y_2 = B(y_1 + x_1 + v)\delta y_2 \in Z_1, \qquad \delta y_2 \in Y_2, \\
&D_{y_1}\mathcal{F}_2\delta y_1 = B(\delta y_1)'\{y_1 + x_1\} + B(y_1 + x_1 + v)'\delta y_1 \in Z_2, \qquad \delta y_1 \in Y_1, \\
&D_{y_2}\mathcal{F}_2\delta y_2 = D_t\delta y_2 \in Z_2, \qquad \delta y_2 \in Y_2,
\end{aligned}$$

and that the requisite continuity holds.

We show next that $D_y\mathcal{F}(0,0) = (D_y\mathcal{F}_1(0,0), D_y\mathcal{F}_2(0,0))$ is a linear homeomorphism of Y *onto* Z. We do this by demonstrating that for each $z = (z_1, z_2) \in Z$, $z_1 \in L_2(0,T;V^*)$, and $z_2 \in L_1(0,T;Q)$ there exists a unique $y = (y_1, y_2) \in Y$, $y_1 \in L_2(0,T;V) \cap H_L^1(0,T;V^*)$, and $y_2 \in L_\infty(0,T;Q) \cap W_L^{1,1}(0,T;Q)$ satisfying the linear initial value problem

$$D_t y_1 + A_0 y_1 - B(v) y_2 = z_1, \qquad t > 0, \tag{2.71}$$

$$D_t y_2 + B(v)' y_1 = z_2, \qquad t > 0, \tag{2.72}$$

$$y_1(0) = 0 \qquad \text{and} \qquad y_2(0) = 0, \tag{2.73}$$

and by providing estimates which establish the continuous dependence of y on z. If we assume that V is separable, then the argument establishing the existence of a unique solution to the system (2.71)–(2.73) is the same as the one used to prove Theorem III.1.2 in [27]. Galerkin approximation is used to define a sequence of finite-dimensional initial value problems which *approximate* the system (2.71)–(2.73). Of course each of the finite-dimensional systems admits a unique solution $y^n = (y_1^n, y_2^n)$. One then argues that these approximating solutions lie in a bounded subset of Y, that $y^n \to y$, weakly in Y, and that y is the unique solution to the initial value problem (2.71)–(2.73) (see also Remark 2.1). The key step in the proof depends upon the estimate for $\|y\|_Y$ in terms of $\|z\|_Z$ which we now derive. This estimate, which is given as an a posteriori estimate in (2.78) below, establishes the continuous dependence of y on z as well.

Taking the inner product of (2.71) with y_1 and (2.72) with y_2 and then adding, we obtain

$$\frac{1}{2}\left\{D_t|y_1|^2 + |y_2|_Q^2\right\} + \langle A_0 y_1, y_1\rangle = \langle z_1, y_1\rangle + \langle z_2, y_2\rangle_Q.$$

For any $\varepsilon > 0$, assumption (A4) implies that

$$\begin{aligned}\frac{1}{2}\left\{D_t|y_1|^2 + |y_2|_Q^2\right\} + \rho_0\|y_1\|^2 &\leq \|z_1\|_*\|y_1\| + |z_2|_Q|y_2|_Q \\ &\leq \frac{1}{2\varepsilon}\|z_1\|_*^2 + \frac{\varepsilon}{2}\|y_1\|^2 + \frac{1}{2}|z_2|_Q\left\{1 + |y_2|_Q^2\right\}.\end{aligned} \tag{2.74}$$

Choosing $\varepsilon < 2\rho_0$, setting $c_0 = 2\rho_0 - \varepsilon > 0$ and $c_1 = 1/\varepsilon$, integrating (2.74) from 0 to t, and recalling (2.73), we obtain

$$\begin{aligned}&|y_1(t)|^2 + |y_2(t)|_Q^2 + c_0\int_0^t \|y_1(s)\|^2 ds \\ &\qquad \leq c_1\int_0^t \|z_1(s)\|_*^2 ds + \int_0^t |z_2(s)|_Q ds + \int_0^t |z_2(s)|_Q|y_2(s)|_Q^2 ds \\ &\qquad \leq c_1\|z\|_Z^2 + \|z\|_Z + \int_0^t |z_2(s)|_Q|y_2(s)|_Q^2 ds.\end{aligned}$$

An application of the generalized Gronwall inequality (see [15]) yields

$$\begin{aligned}&|y_1(t)|^2 + |y_2(t)|_Q^2 + c_0\int_0^t \|y_1(s)\|^2 ds \\ &\qquad \leq \left\{c_1\|z\|_Z^2 + \|z\|_Z\right\}\left\{1 + \int_0^t |z_2(s)|_Q e^{\int_s^t |z_2(\tau)|_Q d\tau} ds\right\} \\ &\qquad \leq \left\{c_1\|z\|_Z^2 + \|z\|_Z\right\}\left\{1 + \|z\|_Z e^{\|z\|_Z}\right\}, \quad t \geq 0.\end{aligned} \tag{2.75}$$

Equation (2.71) and assumptions (A1), (A3), and (A11) yield the estimate $\|D_t y_1(t)\|_* \leq \|z_1(t)\|_* + \alpha_0\|y_1(t)\| + \alpha_1\|v(t)\||y_2(t)|_Q$, a.e. $t > 0$. Consequently there exists a constant $c_2 = c_2(\|v\|_{L_2(0,T;V)}) > 0$ such that

$$\|y_1\|^2_{H^1_L(0,T;V^*)} \leq c_2 \left\{ \|z_1\|^2_{L_2(0,T;V^*)} + \|y_1\|^2_{L_2(0,T;V)} + |y_2|^2_{L_\infty(0,T;Q)} \right\}. \tag{2.76}$$

Similarly, (2.72) yields $|D_t y_2(t)|_Q \leq |z_2(t)|_Q + \alpha_1\|v(t)\|\|y_1(t)\|$, a.e. $t > 0$, and therefore that

$$\|D_t y_2\|_{L_1(0,T;Q)} \leq \|z_2\|_{L_1(0,T;Q)} + \alpha_1\|v\|_{L_2(0,T;V)}\|y_1\|_{L_2(0,T;V)}. \tag{2.77}$$

Combining (2.75), (2.76), and (2.77), we obtain that

$$\|y\|_Y \leq h(\|z\|_Z), \tag{2.78}$$

where $h : \mathbf{R}^+ \to \mathbf{R}^+$ is continuous and monotone increasing.

The following estimates for the dependence on z on y can also be obtained. Once again, (2.71) and assumptions (A1), (A3), and (A11) imply that $\|z_1(t)\|_* \leq \|D_t y_1(t)\|_* + \alpha_0\|y_1(t)\| + \alpha_1\|v(t)\||y_2(t)|_Q$, a.e. $t > 0$, and, therefore, that

$$\|z_1\|^2_{L_2(0,T;V^*)} \leq c_2 \left\{ \|y_1\|^2_{H^1_L(0,T;V^*)} + \|y_1\|^2_{L_2(0,T;V)} + |y_2|^2_{L_\infty(0,T;Q)} \right\}. \tag{2.79}$$

Also (2.72) yields $|z_2(t)|_Q \leq |D_t y_2(t)|_Q + \alpha_1\|v(t)\|\|y_1(t)\|$, a.e. $t > 0$, and, therefore, that

$$\|z_2\|_{L_1(0,T;Q)} \leq \|D_t y_2\|_{L_1(0,T;Q)} + \alpha_1\|v\|_{L_2(0,T;V)}\|y_1\|_{L_2(0,T;V)}. \tag{2.80}$$

Combining (2.79) and (2.80), we obtain that $\|z\|_Z \leq h_0\|y\|_Y$, where $h_0 > 0$.

It follows from the implicit function theorem that there exists a $C > 0$ such that if $x_0 = (e_0, r_0) \in X$ satisfies (2.67), then there exists a unique $y = y(x_0) = (y_1(x_0), y_2(x_0)) \in Y$, which is continuously differentiable in x_0 and which satisfies $\mathcal{F}(x_0, y) = (\mathcal{F}_1(x_0, y), \mathcal{F}_2(x_0, y)) = 0$. Setting $e = y_1 + e_0$ and $r = y_2 + r_0$, we obtain the desired result. □

Under additional hypotheses a similar approach can be used to obtain a somewhat stronger result providing L_∞ estimates.

THEOREM 2.10. *Suppose that assumptions* (A1)–(A5) *and assumption* (A10) *are satisfied. Suppose further that*

(i) $D_1 = Dom(A_1(q))$ *is independent of* $q \in Q$, $D_1 \subseteq D_0$, *and there exists* $\gamma_0 > 0$ *for which* $|A_1(q)\varphi| \leq \gamma_0|q|_Q|A_0\varphi|$, $q \in Q$, *and* $\varphi \in D_1$;
(ii) A_0 *is symmetric* ($A_0 : D_0 \subset H \to H$ *is self-adjoint);*
(iii) $v \in L_\infty(0,T;V)$, $v(t) \in D_0$, *a.e.* $t > 0$, $A_0 v \in L_2(0,T;H)$; *and*
(iv) $e_0 \in D_0$.

Then there exists a constant $C > 0$ *such that if* $|A_0 e_0| + |r_0|_Q < C$, *then the initial value problem* (2.64)–(2.66) *has a unique solution* (e, r) *with* $e \in L_\infty(0,T;V) \cap H^1(0,T;H)$ *and* $r \in L_\infty(0,T;Q) \cap W^{1,1}(0,T;Q)$. *Moreover,* $e(t) \in D_0$, *a.e.* $t > 0$, *and* $A_0 e \in L_2(0,T;H)$.

Proof. Let D_0 be endowed with the graph norm. Then the proof is completely analogous to the one given above for Theorem 2.9 based upon the implicit function theorem. However, in this case we take the Banach spaces X, Y, and Z to be $X = D_0 \times Q$, $Y = \{L_2(0,T;D_0) \cap H^1_L(0,T;H)\} \times \{L_\infty(0,T;Q) \cap W^{1,1}_L(0,T;Q)\}$, and $Z = L_2(0,T;H) \times L_1(0,T;Q)$, respectively. The norms on these spaces are chosen analogously to (2.68), (2.69), and (2.70). □

It is worth noting that conditions sufficient to guarantee that hypothesis (iii) in the statement of Theorem 2.10 above holds are given in Theorem 2.2(iv).

Example 2.11. As an example of the kinds of systems to which the theory in this section applies, let $\Omega \subset \mathbf{R}^n$ be a bounded domain with Lipschitz boundary. Let $H = L_2(\Omega)$, $V = H_0^1(\Omega)$, and let Q be a closed subspace of $H^s(\Omega)^{n^2} \times H^s(\Omega)^n \times H^s(\Omega)$ with $s > n/2$. Let $V^* = V^* = H^{-1}(\Omega)$. Let $A_0 \in \mathcal{L}(V, V^*)$ be given by

$$A_0\varphi = -\sum_{i,j=1}^{n} D_j \{a_{i,j} D_i \varphi\} + \sum_{i=1}^{n} b_i D_i \varphi + c\varphi, \qquad \varphi \in V,$$

where $a_{i,j} \in L_\infty(\Omega)$, $a_{i,j}(x) = a_{j,i}(x)$, a.e. $x \in \Omega$, $i, j = 1, 2, \ldots, n$,

$$\rho_0 |\xi|^2 \le \sum_{i,j=1}^{n} a_{i,j}(x)\xi_i\xi_j \le \rho_1 |\xi|^2, \qquad \xi \in \mathbf{R}^n, \text{ a.e. } x \in \Omega,$$

for some constants $\rho_0, \rho_1 > 0$, $b_i \in W^{1,\frac{n}{2}}(\Omega)$, $i = 1, 2, \ldots, n$ with $\sum_{i=1}^n D_i b_i(x) \le 0$, a.e. $x \in \Omega$, and $c \in L^{\frac{n}{2}}(\Omega)$ with $c(x) \ge 0$, a.e. $x \in \Omega$.

For $q = (\{q_{i,j}\}, \{q_i\}, q_0) \in Q$, let $A_1(q) \in \mathcal{L}(V, V^*)$ be given by

$$A_1(q)\varphi = -\sum_{i,j=1}^{n} D_j \{q_{i,j} D_i \varphi\} + \sum_{i=1}^{n} q_i D_i \varphi + q_0 \varphi, \qquad \varphi \in V.$$

Note that these are not the most general conditions possible to guarantee that assumptions (A1)–(A5) hold for the general class of second-order elliptic plants and reference models.

3. Tracking and parameter error convergence. In this section we argue that the control objective is achieved (i.e., that the tracking error $e(t)$ converges to zero as $t \to \infty$ and that the feedback control f is, in some sense, bounded), and that under an additional richness condition on the reference model, parameter convergence is obtained (i.e., that $q(t) \to \overline{q}$ as $t \to \infty$). We require that our standing assumptions (A1)–(A5) continue to hold, and that the error equations (2.31)–(2.34) admit a unique solution (e, v, r), with $e, v \in L_2(0, T; V) \cap H^1(0, T; V^*)$ $(\subset C([0, T]; H)!)$ and $r \in H^1(0, T; Q)$ $(\subset C([0, T]; Q)!)$ for all $T > 0$.

Define $E : [0, \infty) \to \mathbf{R}^+$ by

$$E(t) = \frac{1}{2}\{|e(t)|^2 + |r(t)|_Q^2\}, \qquad t \ge 0. \tag{3.1}$$

LEMMA 3.1. *For (e, v, r) the solution to the initial value problem* (2.31)–(2.34)*, the function $E : [0, \infty) \to \mathbf{R}^+$ given by* (3.1) *is nonincreasing, and we have that*

$$E(t) + \rho_0 \int_0^t \|e(s)\|^2 ds \le \xi_0, \qquad t \ge 0, \tag{3.2}$$

where $\xi_0 = E(0) = \frac{1}{2}\{|e_0|^2 + |r_0|_Q^2\}$.

Proof. Using (2.31), (2.33), and assumption (A4), we obtain

$$\begin{aligned} D_t E(t) &= \langle D_t e(t), e(t)\rangle + \langle D_t r(t), r(t)\rangle_Q \\ &= -\langle A_0 e(t), e(t)\rangle \\ &\le -\rho_0 \|e(t)\|^2, \qquad \text{a.e. } t > 0. \end{aligned} \tag{3.3}$$

The estimate in (3.3) implies that E is nonincreasing. Integrating this expression from 0 to t, $t > 0$, we obtain the result given in (3.2). ∎

The above lemma yields the following immediate corollary.

COROLLARY 3.2. *For (e, v, r) the solution to the initial value problem* (2.31)–(2.34)*, we have $e \in L_\infty(0,\infty;H) \cap L_2(0,\infty;V)$ and $r \in L_\infty(0,\infty;Q)$. Consequently, $e \in BC([0,\infty);H)$ and $r \in BC([0,\infty);Q)$.*

LEMMA 3.3. *Let (e, v, r) be the solution to the initial value problem* (2.31)–(2.34)*. Then, if $g \in L_\infty(0,\infty;H)$, it follows that $\int_{t_1}^{t_2} \|v(t)\|^2 dt \le c_1 + c_2(t_2 - t_1)$ for all $t_2 \ge t_1 \ge 0$, where c_1 and c_2 are positive constants which do not depend on t_1 and t_2.*

Proof. It follows from (2.10) and (2.12) that if $g \in L_\infty(0,\infty;H)$ then $v \in L_\infty(0,\infty;H)$. Then, integrating (2.15) from t_1 to t_2, we obtain

$$|v(t_2)|^2 + \rho_0 \int_{t_1}^{t_2} \|v(t)\|^2 dt \le |v(t_1)|^2 + \int_{t_1}^{t_2} \|g(t)\|_*^2 dt. \tag{3.4}$$

Recalling (2.2), it follows from (3.4) that

$$\int_{t_1}^{t_2} \|v(t)\|^2 dt \le \frac{1}{\rho_0} |v|^2_{L_\infty(0,\infty;H)} + \frac{K^2}{\rho_0} |g|^2_{L_\infty(0,\infty;H)} (t_2 - t_1). \qquad \square$$

In the theorem that follows, we establish that the desired control objective is achieved. The proof we provide is in the spirit of the argument used to verify Barbălat's lemma in [34].

THEOREM 3.4. *For (e, v, r) the solution to the initial value problem* (2.31)–(2.34) *and f the adaptive feedback control law given by* (2.22) *or* (2.23)*, we have the following results.*

(i) *If $g \in L_2(0,\infty;V^*) \cup L_\infty(0,\infty;H)$, then $\lim_{t\to\infty} |e(t)| = 0$.*
(ii) *If $g \in L_2(0,\infty;V^*)$, then $u \in L_\infty(0,\infty;H) \cap L_2(0,\infty;V)$ and $f \in L_2(0,\infty;V^*)$.*
(iii) *If the operator A_0 is symmetric in the sense of* (2.14)*, $u_0, v_0 \in V$, $g \in L_2(0,\infty;H)$ and satisfies* (2.13)*, and for $\varphi \in D_0$ and $q \in Q$, we have $A(q)\varphi \in H$ and $|A_1(q)\varphi| \le \gamma_1 |q|_Q |A_0\varphi|$, for some $\gamma_1 > 0$ for which $\gamma_1 |r|_{L_\infty(0,\infty;Q)} < 1$, then $u(t) \in D_0$, a.e. $t > 0$, $u \in L_\infty(0,\infty;V)$, $A_0 u \in L_2(0,\infty;H)$. If, in addition,*
  (a) *$g \in L_\infty(0,\infty;V^*)$, then $f \in L_\infty(0,\infty;V^*)$,*

  or if, in addition,
  (b) *for $\varphi \in D_0$ we have $A_2\varphi \in H$ and $|A_2\varphi| \le \gamma_2 |A_0\varphi|$, for some $\gamma_2 > 0$, then $f \in L_2(0,\infty;H)$.*

Proof. Let $t_2 \ge t_1 \ge 0$ and note that assumptions (A1) and (A4), (2.31), and Lemma 3.1 imply that

$$\begin{aligned}
|e(t_2)|^2 - |e(t_1)|^2 &= \int_{t_1}^{t_2} \frac{d}{dt} |e(t)|^2 dt = 2 \int_{t_1}^{t_2} \langle D_t e(t), e(t) \rangle dt \\
&= -2 \int_{t_1}^{t_2} \langle A_0 e(t), e(t) \rangle dt \\
&\quad -2 \int_{t_1}^{t_2} \langle A_1(r(t))\{e(t) + v(t)\}, e(t) \rangle dt \qquad (3.5) \\
&\le -2\rho_0 \int_{t_1}^{t_2} \|e(t)\|^2 dt \\
&\quad +2\alpha_1 \int_{t_1}^{t_2} |r(t)|_Q \{\|e(t)\| + \|v(t)\|\} \|e(t)\| dt
\end{aligned}$$

$$\begin{aligned}
&\leq 2\alpha_1 \int_{t_1}^{t_2} |r(t)|_Q \{\|e(t)\| + \|v(t)\|\}\|e(t)\| dt \\
&= 2\alpha_1 \int_{t_1}^{t_2} |r(t)|_Q \|e(t)\|^2 dt + 2\alpha_1 \int_{t_1}^{t_2} |r(t)|_Q \|v(t)\|\|e(t)\| dt \\
&\leq 2\alpha_1 \sqrt{2} \xi_0^{\frac{1}{2}} \int_{t_1}^{t_2} \|e(t)\|^2 dt \\
&\quad + 2\alpha_1 \sqrt{2} \xi_0^{\frac{1}{2}} \left(\int_{t_1}^{t_2} \|v(t)\|^2 dt \right)^{\frac{1}{2}} \left(\int_{t_1}^{t_2} \|e(t)\|^2 dt \right)^{\frac{1}{2}}.
\end{aligned}$$

If $g \in L_2(0,\infty;V^*)$, then Theorem 2.2 implies that $\int_{t_1}^{t_2} \|v(t)\|^2 dt \leq \zeta_0$, for some $\zeta_0 > 0$, for all $t_2 \geq t_1 \geq 0$. It then follows from (3.5) that

$$|e(t_2)|^2 - |e(t_1)|^2 \leq \kappa_0 \int_{t_1}^{t_2} \|e(t)\|^2 dt + \kappa_1 \left(\int_{t_1}^{t_2} \|e(t)\|^2 dt \right)^{\frac{1}{2}}, \tag{3.6}$$

where $\kappa_0 = 2\sqrt{2}\alpha_1 \xi_0^{\frac{1}{2}}$ and $\kappa_1 = 2\sqrt{2}\alpha_1 \xi_0^{\frac{1}{2}} \zeta_0^{\frac{1}{2}}$. On the other hand, if $g \in L_\infty(0,\infty;H)$, then Lemma 3.3 and (3.5) imply that

$$|e(t_2)|^2 - |e(t_1)|^2 \leq \kappa_0 \int_{t_1}^{t_2} \|e(t)\|^2 dt + \kappa_0 \left(c_1 + c_2(t_2 - t_1)\right)^{\frac{1}{2}} \left(\int_{t_1}^{t_2} \|e(t)\|^2 dt \right)^{\frac{1}{2}}. \tag{3.7}$$

Now suppose that $\lim_{t\to\infty} |e(t)| \neq 0$. Then there exist $\varepsilon > 0$ and a sequence $\{t_i\}_{i=1}^{\infty}$ with $\lim_{i\to\infty} t_i = \infty$ for which

$$|e(t_i)|^2 > \varepsilon, \qquad i = 1, 2, \ldots. \tag{3.8}$$

If $g \in L_2(0,\infty;V^*)$, then (3.6) and (3.8) imply that for $\delta > 0$ and $i = 1, 2, \ldots$, we have

$$\begin{aligned}
\int_{t_i-\delta}^{t_i} |e(t)|^2 dt &= \int_{t_i-\delta}^{t_i} |e(t_i)|^2 dt - \int_{t_i-\delta}^{t_i} \{|e(t_i)|^2 - |e(t)|^2\} dt \\
&> \varepsilon\delta - \kappa_0 \int_{t_i-\delta}^{t_i} \int_t^{t_i} \|e(s)\|^2 ds dt - \kappa_1 \int_{t_i-\delta}^{t_i} \left(\int_t^{t_i} \|e(s)\|^2 ds \right)^{\frac{1}{2}} dt \\
&\geq \varepsilon\delta - \kappa_0\delta \int_{t_i-\delta}^{t_i} \|e(t)\|^2 dt - \kappa_1\delta \left(\int_{t_i-\delta}^{t_i} \|e(t)\|^2 dt \right)^{\frac{1}{2}}.
\end{aligned}$$

Recalling (2.2), it then follows that

$$\begin{aligned}
K^2 \int_{t_i-\delta}^{t_i} \|e(t)\|^2 dt &\geq \int_{t_i-\delta}^{t_i} |e(t)|^2 dt \\
&> \varepsilon\delta - \kappa_0\delta \int_{t_i-\delta}^{t_i} \|e(t)\|^2 dt - \frac{1}{2}\kappa_1^2\delta^2 - \frac{1}{2} \int_{t_i-\delta}^{t_i} \|e(t)\|^2 dt,
\end{aligned}$$

and therefore that $\left(K^2 + \kappa_0\delta + \frac{1}{2}\right) \int_{t_i-\delta}^{t_i} \|e(t)\|^2 dt > \varepsilon\delta - \frac{1}{2}\kappa_1^2\delta^2$. Choosing $\delta = \frac{\varepsilon}{\kappa_1^2}$ and replacing the sequence $\{t_i\}_{i=1}^{\infty}$ by a subsequence $\{t_{i_j}\}_{j=1}^{\infty}$ for which $t_{i_{j+1}} - t_{i_j} > \delta$, $j = 1, 2, \ldots$, we obtain

$$\int_{t_{i_j}-\delta}^{t_{i_j}} \|e(t)\|^2 dt \geq \frac{\varepsilon\delta}{2\left(K^2 + \kappa_0\delta + \frac{1}{2}\right)}, \qquad j = 1, 2, \ldots. \tag{3.9}$$

Similarly, if $g \in L_\infty(0,\infty;H)$, then (3.7) and (3.8) imply that for $\delta > 0$ and $i = 1, 2, \ldots$, we have

$$\begin{aligned}
\int_{t_i-\delta}^{t_i} |e(t)|^2 dt &= \int_{t_i-\delta}^{t_i} |e(t_i)|^2 dt - \int_{t_i-\delta}^{t_i} \{|e(t_i)|^2 - |e(t)|^2\} dt \\
&> \varepsilon\delta - \kappa_0 \int_{t_i-\delta}^{t_i} \int_t^{t_i} \|e(s)\|^2 ds dt \\
&\quad -\kappa_0 \int_{t_i-\delta}^{t_i} (c_1 + c_2(t_i - t))^{\frac{1}{2}} \left(\int_t^{t_i} \|e(s)\|^2 ds \right)^{\frac{1}{2}} dt \\
&\geq \varepsilon\delta - \kappa_0\delta \int_{t_i-\delta}^{t_i} \|e(t)\|^2 dt - \kappa_0\delta \left(c_1 + c_2\delta\right)^{\frac{1}{2}} \left(\int_{t_i-\delta}^{t_i} \|e(t)\|^2 dt \right)^{\frac{1}{2}}.
\end{aligned}$$

It follows that $\left(K^2 + \kappa_0\delta + \frac{1}{2}\right) \int_{t_i-\delta}^{t_i} \|e(t)\|^2 dt > \varepsilon\delta - \frac{1}{2}\kappa_0^2 \left(c_1 + c_2\delta\right)\delta^2$. Then, if we choose $\delta = \frac{\sqrt{c_1^2\kappa_0^2 + 4c_2\varepsilon} - c_1\kappa_0}{2c_2\kappa_0} > 0$, we again obtain (3.9). But (3.9) contradicts the fact that Lemma 3.1 implies that $\int_0^\infty \|e(t)\|^2 dt \leq \frac{\xi_0}{\rho_0} < \infty$. Consequently, $\lim_{t\to\infty} |e(t)|^2 = 0$, and therefore, $\lim_{t\to\infty} |e(t)| = 0$, which establishes (i).

Corollary 3.2 above implies that $e \in L_\infty(0,\infty;H) \cap L_2(0,\infty;V)$, and if $g \in L_2(0,\infty;V^*)$, then Theorem 2.2 implies that $v \in L_\infty(0,\infty;H) \cap L_2(0,\infty;V)$ as well. Consequently, it follows that $u = e + v \in L_\infty(0,\infty;H) \cap L_2(0,\infty;V)$. To establish that $f \in L_2(0,T;V^*)$, we note that (2.23), assumptions (A1) and (A3), and (2.30) imply that for a.e. $t > 0$

$$\begin{aligned}
\|f(t)\|_* &= \sup_{\|\varphi\|\leq 1} |\langle f(t), \varphi\rangle| \\
&= \sup_{\|\varphi\|\leq 1} |\langle A(q(t))u(t) - A_0u(t) + g(t), \varphi\rangle| \\
&= \sup_{\|\varphi\|\leq 1} |\langle A_1(q(t))u(t) + A_2u(t) - A_0u(t) + g(t), \varphi\rangle| \\
&\leq \{\alpha_1|q(t)|_Q + \alpha_2 + \alpha_0\}\|u(t)\| + \|g(t)\|_* \\
&\leq \{\alpha_1\{|r(t)|_Q + |\overline{q}|_Q\} + \alpha_2 + \alpha_0\}\|u(t)\| + \|g(t)\|_* \\
&\leq \sigma\|u(t)\| + \|g(t)\|_*,
\end{aligned}$$

where $\sigma = \alpha_1\{\sqrt{\xi_0} + |\overline{q}|_Q\} + \alpha_2 + \alpha_0$. It follows that

$$\|f(t)\|_*^2 \leq 2\sigma^2\|u(t)\|^2 + 2\|g(t)\|_*^2 \qquad \text{a.e. } t > 0. \tag{3.10}$$

The estimate (3.10) together with the fact that $g \in L_2(0,\infty;V^*)$ and $u \in L_2(0,\infty;V)$ immediately yields (ii).

To establish (iii), we first note that under the present assumptions, Theorem 2.2 implies that $v \in L_\infty(0,\infty;V)$, $v(t) \in D_0$, a.e. $t > 0$, and $A_0v \in L_2(0,\infty;H)$. Also, Corollary 3.2 implies that $r \in L_\infty(0,\infty;Q)$. Now, recalling the definition of the norm $\|\cdot\|_0$ on V from section 2, (2.31) with $\varphi = A_0e(t)$ (recall Remark 2.1) implies that

$$\langle D_te(t), A_0e(t)\rangle + |A_0e(t)|^2 = \langle A_1(r(t))\{e(t) + v(t)\}, A_0e(t)\rangle, \qquad \text{a.e. } t > 0,$$

and therefore, for any $\varepsilon > 0$, that

$$
\begin{aligned}
\tfrac{1}{2} D_t \|e(t)\|_0^2 + |A_0 e(t)|^2 &\leq |A_1(r(t))\{e(t) + v(t)\}||A_0 e(t)| \\
&\leq \gamma_1 |r(t)|_Q |A_0 e(t) + A_0 v(t)||A_0 e(t)| \\
&\leq \gamma_1 |r|_{L_\infty(0,\infty;Q)} |A_0 e(t)|^2 + \gamma_1 |r|_{L_\infty(0,\infty;Q)} \frac{\varepsilon}{2} |A_0 e(t)|^2 \\
&\quad + \gamma_1 |r|_{L_\infty(0,\infty;Q)} \frac{1}{2\varepsilon} |A_0 v(t)|^2 \qquad \text{a.e. } t > 0.
\end{aligned} \tag{3.11}
$$

Integrating (3.11) from 0 to t, recalling (2.34), (2.16), and our assumption that $\gamma_1 |r|_{L_\infty(0,\infty;Q)} < 1$, and choosing $\varepsilon > 0$ sufficiently small, we find that

$$
\begin{aligned}
&\rho_0 \|e(t)\|^2 + \sigma_0 \int_0^t |A_0 e(s)|^2 ds \\
&\qquad \leq \alpha_0 \|e_0\|^2 + \gamma_1 |r|_{L_\infty(0,\infty;Q)} \frac{1}{2\varepsilon} \int_0^t |A_0 v(s)|^2 ds, \quad t \geq 0
\end{aligned} \tag{3.12}
$$

for some $\sigma_0 > 0$. It follows from (3.12) that $e \in L_\infty(0,\infty;V)$, $e(t) \in D_0$, a.e. $t > 0$, and $A_0 e \in L_2(0,\infty;H)$. Consequently, $u = e + v \in L_\infty(0,\infty;V)$, $u(t) \in D_0$, a.e. $t > 0$, and $A_0 u \in L_2(0,\infty;H)$. This, together with (3.10) establishes the claim in (a). To establish the claim in (b), we have the estimate

$$
\begin{aligned}
|f(t)| &= \sup_{|\varphi| \leq 1} |\langle f(t), \varphi \rangle| \\
&= \sup_{|\varphi| \leq 1} |\langle A(q(t))u(t) - A_0 u(t) + g(t), \varphi \rangle| \\
&= \sup_{|\varphi| \leq 1} |\langle A_1(q(t))u(t) + A_2 u(t) - A_0 u(t) + g(t), \varphi \rangle| \\
&\leq \{\gamma_1 |q(t)|_Q + \gamma_2 + 1\} |A_0 u(t)| + |g(t)| \\
&\leq \{\gamma_1 \{|r|_{L_\infty(0,\infty;Q)} + |\overline{q}|_Q\} + \gamma_2 + 1\} |A_0 u(t)| + |g(t)|, \qquad \text{a.e. } t > 0,
\end{aligned}
$$

from which the desired result immediately follows. □

We note that the condition that $\gamma_1 |r|_{L_\infty(0,\infty;Q)} < 1$ can be satisfied with an appropriate choice of the reference model dynamics A_0, the initial estimate of the unknown parameters q_0 (i.e., that it be sufficiently close to the *true* parameters $\overline{q}$), and the initial state of the reference model v_0 (i.e., that it be sufficiently close to the initial state of the plant u_0). The last two sufficient conditions are a consequence of Lemma 3.1.

In addition to meeting the designated control objective, it is also desirable to have an adaptive control scheme provide parameter convergence as well. In order to establish that the scheme we consider here yields convergence of the parameters $q(t)$ to the *true* parameters $\overline{q}$ as $t \to \infty$, we require the following additional *richness* condition on the reference model.

DEFINITION 3.5. *The reference model* (2.8), (2.9) *or the triple* $\{A_0, g, v_0\}$ *consisting of the reference model dynamics operator* A_0*, the input reference signal,* g*, and the initial state of the reference model* v_0*, will be said to be persistently exciting, or, sufficiently rich, if there exist positive constants* τ_0*,* δ_0*, and* ε_0*, such that for each* $p \in Q$ *with* $|p|_Q = 1$ *and* $t \geq 0$ *sufficiently large, there exists* $\tilde{t} \in [t, t + \tau_0]$ *for which*

$$
\left\| \int_{\tilde{t}}^{\tilde{t}+\delta_0} A_1(p) u(\tau) d\tau \right\|_* \geq \varepsilon_0,
$$

where u *is the closed loop state of the plant as given by the system* (2.26)–(2.29).

THEOREM 3.6. *If either* $g \in L_2(0,\infty;V^*)$ *or* $g \in L_\infty(0,\infty;V)$ *and* $v_0 \in V$, *and if the reference model,* (2.8), (2.9), *is persistently exciting, then* $\lim_{t\to\infty}|r(t)|_Q = 0$.

Proof. If $g \in L_2(0,\infty;V^*)$, then Theorem 3.4 implies that $u \in L_2(0,\infty;V)$. Corollary 3.2 implies that $r \in BC([0,\infty);Q)$, and Lemma 3.1 together with Theorem 3.4 imply that $\lim_{t\to\infty}|r(t)|_Q$ exists. If we assume that $\lim_{t\to\infty}|r(t)|_Q \neq 0$, then there exists $\{t_k\}_{k=1}^{\infty}$, an increasing sequence of positive numbers for which $\lim_{k\to\infty} t_k = \infty$ and

$$|r(t_k)|_Q \geq \delta, \qquad k = 1,2,\ldots, \tag{3.13}$$

for some $\delta > 0$. If the reference model (2.8), (2.9) is persistently exciting, it then follows from assumption (A1) that for each $k = 1,2,\ldots$ and some $\tilde{t}_k \in [t_k, t_k+\tau_0]$, we have

$$\begin{aligned} 0 < \delta\varepsilon_0 &\leq |r(t_k)|_Q \left\| \int_{\tilde{t}_k}^{\tilde{t}_k+\delta_0} A_1\left(\frac{r(t_k)}{|r(t_k)|_Q}\right)u(t)dt \right\|_* \\ &= \left\| \int_{\tilde{t}_k}^{\tilde{t}_k+\delta_0} A_1(r(t_k))u(t)dt \right\|_* \\ &\leq \alpha_1 |r|_{L_\infty(0,\infty;Q)} \sqrt{\delta_0} \left\{ \int_{\tilde{t}_k}^{\tilde{t}_k+\delta_0} \|u(t)\|^2 dt \right\}^{\frac{1}{2}}. \end{aligned} \tag{3.14}$$

Letting $k \to \infty$ in (3.14), and using the fact that $u \in L_2(0,\infty;V)$ implies that

$$\lim_{k\to\infty} \int_{\tilde{t}_k}^{\tilde{t}_k+\delta_0} \|u(t)\|^2 dt = 0,$$

we obtain a contradiction.

Now suppose that $g \in L_\infty(0,\infty;V)$ and $v_0 \in V$. We first recall that Theorem 2.2 implies that $v \in L_\infty(0,\infty;V)$. Now, for $t_2 > t_1$, (2.31), assumption (A3), and (2.2) imply that

$$\begin{aligned} \left\| \int_{t_1}^{t_2} A_1(r(t))u(t)dt \right\|_* &= \left\| \int_{t_1}^{t_2} A_1(r(t))\{e(t)+v(t)\}dt \right\|_* \\ &\leq \|e(t_2)\|_* + \|e(t_1)\|_* + \int_{t_1}^{t_2} \|A_0 e(t)\|_* dt \\ &\leq K|e(t_2)| + K|e(t_1)| \\ &\quad + \alpha_0 (t_2-t_1)^{\frac{1}{2}} \left\{ \int_{t_1}^{t_2} \|e(t)\|^2 dt \right\}^{\frac{1}{2}}. \end{aligned} \tag{3.15}$$

Also, from (2.33), assumption (A1), and Lemma 3.1 it follows that

$$\begin{aligned} |r(t_2)-r(t_1)|_Q &= \sup_{|p|_Q\leq 1} |\langle r(t_2)-r(t_1), p\rangle_Q| \\ &= \sup_{|p|_Q\leq 1} \left| \left\langle \int_{t_1}^{t_2} D_t r(t)dt, p \right\rangle_Q \right| \\ &\leq \int_{t_1}^{t_2} \sup_{|p|_Q\leq 1} |\langle A_1(p)\{e(t)+v(t)\}, e(t)\rangle| \, dt \end{aligned} \tag{3.16}$$

$$
\begin{aligned}
&\leq \alpha_1 \int_{t_1}^{t_2} \{\|e(t)\| + \|v(t)\|\} \|e(t)\| dt \\
&\leq \alpha_1 \int_{t_1}^{t_2} \|e(t)\|^2 dt + \alpha_1 \|v\|_{L_\infty(0,\infty;V)} \int_{t_1}^{t_2} \|e(t)\| dt \\
&\leq \alpha_1 \int_{t_1}^{t_2} \|e(t)\|^2 dt \\
&\quad + \alpha_1 \|v\|_{L_\infty(0,\infty;V)} (t_2 - t_1)^{\frac{1}{2}} \left\{ \int_{t_1}^{t_2} \|e(t)\|^2 dt \right\}^{\frac{1}{2}}.
\end{aligned}
$$

Once again assume that $\lim_{t\to\infty} |r(t)|_Q \neq 0$, and let $\{t_k\}_{k=1}^{\infty}$ be an increasing sequence of positive numbers for which $\lim_{k\to\infty} t_k = \infty$ and for which (3.13) holds for some $\delta > 0$. Assume further that the reference model (2.8), (2.9) is persistently exciting, and for each $k = 1, 2, \ldots$, let $\tilde{t}_k \in [t_k, t_k + \tau_0]$ be such that

$$
\left\| \int_{\tilde{t}_k}^{\tilde{t}_k + \delta_0} A_1 \left(\frac{r(t_k)}{|r(t_k)|_Q} \right) u(t) dt \right\|_* \geq \varepsilon_0. \tag{3.17}
$$

Then, using (3.13), (3.15), (3.16), (3.17), and assumptions (A1) and (A2), we obtain the estimate

$$
\begin{aligned}
0 < \delta\varepsilon_0 &\leq |r(t_k)|_Q \left\| \int_{\tilde{t}_k}^{\tilde{t}_k + \delta_0} A_1 \left(\frac{r(t_k)}{|r(t_k)|_Q} \right) u(t) dt \right\|_* \\
&= \left\| \int_{\tilde{t}_k}^{\tilde{t}_k + \delta_0} A_1(r(t_k)) u(t) dt \right\|_* \\
&\leq \left\| \int_{\tilde{t}_k}^{\tilde{t}_k + \delta_0} A_1(r(t)) u(t) dt \right\|_* + \left\| \int_{\tilde{t}_k}^{\tilde{t}_k + \delta_0} A_1(r(t_k) - r(t)) \{e(t) + v(t)\} dt \right\|_* \\
&\leq K|e(\tilde{t}_k + \delta_0)| + K|e(\tilde{t}_k)| + \alpha_0 \sqrt{\delta_0 \int_{\tilde{t}_k}^{\tilde{t}_k + \delta_0} \|e(t)\|^2 dt} \\
&\quad + \alpha_1 \int_{\tilde{t}_k}^{\tilde{t}_k + \delta_0} |r(t) - r(t_k)|_Q \{\|e(t)\| + \|v(t)\|\} dt \qquad (3.18) \\
&\leq K|e(\tilde{t}_k + \delta_0)| + K|e(\tilde{t}_k)| + \alpha_0 \sqrt{\delta_0 \int_{\tilde{t}_k}^{\tilde{t}_k + \delta_0} \|e(t)\|^2 dt} \\
&\quad + \alpha_1^2 \left(\int_{\tilde{t}_k}^{\tilde{t}_k + \tau_0 + \delta_0} \|e(t)\|^2 dt + \|v\|_{L_\infty(0,\infty;V)} \sqrt{(\tau_0 + \delta_0) \int_{\tilde{t}_k}^{\tilde{t}_k + \tau_0 + \delta_0} \|e(t)\|^2 dt} \right) \\
&\quad \times \int_{\tilde{t}_k}^{\tilde{t}_k + \delta_0} \{\|e(t)\| + \|v(t)\|\} dt \\
&\leq K|e(\tilde{t}_k + \delta_0)| + K|e(\tilde{t}_k)| + \alpha_0 \sqrt{\delta_0 \int_{\tilde{t}_k}^{\tilde{t}_k + \delta_0} \|e(t)\|^2 dt}
\end{aligned}
$$

$$+\alpha_1^2\left(\int_{\tilde{t}_k}^{\tilde{t}_k+\tau_0+\delta_0}\|e(t)\|^2dt+\|v\|_{L_\infty(0,\infty;V)}\sqrt{(\tau_0+\delta_0)\int_{\tilde{t}_k}^{\tilde{t}_k+\tau_0+\delta_0}\|e(t)\|^2dt}\right)$$
$$\times\left(\sqrt{\delta_0\int_{\tilde{t}_k}^{\tilde{t}_k+\delta_0}\|e(t)\|^2dt}+\delta_0\|v(t)\|_{L_\infty(0,\infty;V)}\right).$$

Now Lemma 3.1 implies that for any $L>0$ $\lim_{t\to\infty}\int_t^{t+L}\|e(s)\|^2ds=0$. Therefore, letting $k\to\infty$ in (3.18), Lemma 3.1 and Theorem 3.4 imply that

$$\begin{aligned}
0 &< \delta\varepsilon_0\\
&\le K\lim_{k\to\infty}|e(\tilde{t}_k+\delta_0)|+K\lim_{k\to\infty}|e(\tilde{t}_k)|+\alpha_0\sqrt{\delta_0}\lim_{k\to\infty}\sqrt{\int_{t_k}^{t_k+\tau_0+\delta_0}\|e(t)\|^2dt}\\
&\quad+\alpha_1^2\left(\lim_{k\to\infty}\int_{\tilde{t}_k}^{\tilde{t}_k+\tau_0+\delta_0}\|e(t)\|^2dt\right.\\
&\qquad\left.+\|v\|_{L_\infty(0,\infty;V)}\sqrt{(\tau_0+\delta_0)\lim_{k\to\infty}\int_{\tilde{t}_k}^{\tilde{t}_k+\tau_0+\delta_0}\|e(t)\|^2dt}\right)\\
&\quad\times\left(\sqrt{\delta_0\lim_{k\to\infty}\int_{\tilde{t}_k}^{\tilde{t}_k+\delta_0}\|e(t)\|^2dt}+\delta_0\|v(t)\|_{L_\infty(0,\infty;V)}\right)\\
&= 0,
\end{aligned}$$

which is a contradiction, and the theorem is proved. □

We note that the persistence of excitation condition defined in Definition 3.5 is, in practice, difficult, if not impossible, to verify. However, this condition is analogous to a similar condition used to establish parameter convergence in an on-line identification scheme developed in [7]. In [9] a careful study and analysis of the persistence of excitation condition was carried out yielding valuable insight into how to recognize (based upon its performance) whether an adaptive scheme such as the one we treat here is either *overdamped* (i.e., the operator $-A_0$ is too stable) or *underdamped* (i.e., the persistence of excitation is insufficient). This information can then be used to tune the scheme (i.e., tune the reference model and reference input signal g) so as to achieve a balance between the tracking error convergence (i.e., $\lim_{t\to\infty}|e(t)|=0$) and parameter convergence (i.e., $\lim_{t\to\infty}|q(t)-\overline{q}|_Q=\lim_{t\to\infty}|r(t)|_Q=0$). We note also that it is possible to establish a weaker parameter convergence result in either the absence of persistence of excitation or the presence of *partial* persistence of excitation. The result and its proof are analogous to the corresponding notions in the case of a strict identification scheme (see [7] and [9]).

4. Finite-dimensional approximation. The reference model (2.8), (2.9) and the estimator, or adaptation law for q, (2.24), (2.25), reside in the memory of a computer. Moreover, they are both, in general, infinite-dimensional evolution equations. Consequently their real-time, or on-line, integration requires some form of finite-dimensional approximation. This results in an *approximating* closed-loop system. In this section we consider the finite-dimensional approximation of the reference model and the adaptation law and establish well-posedness and convergence results for the resulting approximating closed-loop systems.

For each $n = 1, 2, \ldots$, let H^n be a finite-dimensional subspace of H with $H^n \subset V$, and let Q^n be a finite-dimensional subspace of Q. Let $P^n : H \to H^n$ denote the orthogonal (with respect to the standard inner product on H) projection of H onto H^n. We then use a Galerkin approach to approximate (2.8), (2.9) and (2.24), (2.25). For each $n = 1, 2, \ldots$, we consider the approximating reference model

$$\langle D_t v^n(t), \varphi^n\rangle + \langle A_0 v^n(t), \varphi^n\rangle = \langle g(t), \varphi^n\rangle, \qquad \varphi^n \in H^n, \text{ a.e. } t > 0, \tag{4.1}$$

$$v^n(0) = v_0^n, \tag{4.2}$$

where $v^n(t), v_0^n \in H^n$, and the approximating adaptation law

$$\langle D_t q^n(t), p^n\rangle_Q + \langle A_1(p^n)u(t), u(t) - v^n(t)\rangle = 0, \qquad p^n \in Q^n, \text{ a.e. } t > 0, \tag{4.3}$$

$$q^n(0) = q_0^n, \tag{4.4}$$

where $q^n(t), q_0^n \in Q^n$. Recalling the definition of the adaptive control law given in (2.22) or (2.23), for each $n = 1, 2, \ldots$, we define an approximating adaptive feedback control law f^n by

$$f^n(t) = A(q^n(t))u(t) - A_0 u(t) + g(t), \quad \text{a.e. } t > 0, \tag{4.5}$$

or

$$\langle f^n(t), \varphi\rangle = \langle A(q^n(t))u(t), \varphi\rangle - \langle A_0 u(t), \varphi\rangle + \langle g(t), \varphi\rangle, \ \ \varphi \in V, \text{a.e. } t > 0, \tag{4.6}$$

where q^n is determined by the system (4.1)–(4.4). Combining (4.1)–(4.4) and either (4.5) or (4.6) together with the plant, (2.4), (2.5), or (2.6), (2.7), we obtain what we will refer to as the approximating closed-loop system

$$\begin{aligned}\langle D_t u^n(t), \varphi\rangle + \langle A_0 u^n(t), \varphi\rangle + \langle A_1(\overline{q} - q^n(t))u^n(t), \varphi\rangle \\ = \langle g(t), \varphi\rangle, \ \varphi \in V, \text{a.e. } t > 0,\end{aligned} \tag{4.7}$$

$$\langle D_t v^n(t), \varphi^n\rangle + \langle A_0 v^n(t), \varphi^n\rangle = \langle g(t), \varphi^n\rangle, \ \ \varphi^n \in H^n, \text{ a.e. } t > 0, \tag{4.8}$$

$$\langle D_t q^n(t), p^n\rangle_Q + \langle A_1(p^n)u^n(t), u^n(t) - v^n(t)\rangle = 0, \ \ p^n \in Q^n, \text{ a.e. } t > 0, \tag{4.9}$$

$$u^n(0) = u_0, \quad v^n(0) = v_0^n, \quad q^n(0) = q_0^n. \tag{4.10}$$

We begin by establishing a well-posedness result for the system (4.7)–(4.10). Our approach is similar to the one taken earlier in section 2 when we considered the well-posedness of the closed-loop system (2.26)–(2.29). We assume that assumptions (A1)–(A9) are satisfied, and we first note that the equation for the reference model (4.8) can be solved independently of equations (4.7) and (4.9). The solution $v^n \in C([0, \infty); H) \cap C^1((0, \infty); H)$ is given by (see, for example, [20])

$$v^n(t) = T_0^n(t)v_0^n + \int_0^t T_0^n(t - s)P^n g(s)ds, \qquad t \geq 0, \tag{4.11}$$

$\{T_0^n(t) : t \geq 0\}$ is the uniformly exponentially stable analytic semigroup of bounded linear operators on H^n generated by the Galerkin approximation, $-A_0^n \in \mathcal{L}(H^n, H^n)$, to the operator $-A_0$. That is, for each $n = 1, 2, \ldots$, $A_0^n \in \mathcal{L}(H^n, H^n)$ is the operator

defined by $A_0^n\varphi^n = \psi^n$, for $\varphi^n \in H^n$, where $\psi^n \in H^n$ is the unique element in H^n satisfying $\langle A_0\varphi^n, \chi^n\rangle = \langle \psi^n, \chi^n\rangle$, $\chi^n \in H^n$, guaranteed to exist by the Riesz representation theorem. Since H^n was assumed to be finite dimensional, we have that $T_0^n(t) = \exp(-A_0^n t) = e^{-A_0^n t}$, $t \geq 0$.

Let $\hat{X} = H \times Q$ be endowed with the inner product $\langle (\varphi, q), (\psi, p)\rangle_{\hat{X}} = \langle \varphi, \psi\rangle + \langle q, p\rangle_Q$, $(\varphi, q), (\psi, p) \in \hat{X}$, and let $|\cdot|_{\hat{X}}$ denote the corresponding induced norm. It follows that $\{\hat{X}, \langle\cdot,\cdot\rangle_{\hat{X}}, |\cdot|_{\hat{X}}\}$ is a Hilbert space. Moreover, as was done in the proof of Theorem 2.4, for the $\alpha \in (0,1)$ in assumption (A6), define the Banach space $\{\hat{X}_\alpha, |\cdot|_{\hat{X}_\alpha}\}$ by $\hat{X}_\alpha = H_\alpha \times Q$ with $|(\varphi, q)|_{\hat{X}_\alpha} = |\varphi|_\alpha + |q|_Q$ for $(\varphi, q) \in \hat{X}_\alpha$.

For $\lambda > 0$ and $\psi \in C([0,\infty); H)$ define the mapping $\hat{G}_\lambda(\cdot,\cdot;\psi) : [0,\infty) \times \hat{X}_\alpha \to \hat{X}$ by

$$\hat{G}_\lambda(t, (\varphi, q); \psi) = (g(t) - B(\varphi)\{\overline{q} - q\}, \lambda q - B(\varphi)'\{\varphi - \psi(t)\}), \tag{4.12}$$

for $t \geq 0$, $(\varphi, q) \in \hat{X}_\alpha$, where for $\varphi \in V$ the operators $B(\varphi) \in \mathcal{L}(Q, V^*)$ and its Banach space adjoint $B(\varphi)' \in \mathcal{L}(V, Q)$ are defined in (2.36) and (2.37), respectively. We note that in the above definition, since $\varphi \in H_\alpha$, assumption (A6) implies that the operator $B(\varphi)$ in fact has range in H and that the operator $B(\varphi)'$ is well defined on H. Consequently the mapping $\hat{G}_\lambda(\cdot,\cdot;\psi)$ given by (4.12) above is well defined on $[0,\infty) \times \hat{X}_\alpha$ with range in $\hat{X}$.

For $\lambda > 0$, define the operator $\hat{A}_\lambda : Dom(\hat{A}_\lambda) \subset \hat{X} \to \hat{X}$ by

$$Dom(\hat{A}_\lambda) = D_0 \times Q, \tag{4.13}$$

$$\hat{A}_\lambda(\varphi, q) = (A_0\varphi, \lambda q), \qquad (\varphi, q) \in Dom(\hat{A}_\lambda). \tag{4.14}$$

The operator $-\hat{A}_\lambda$ is the infinitesimal generator of a uniformly exponentially stable analytic semigroup, $\{\hat{T}_\lambda(t) : t \geq 0\}$, on $\hat{X}$, and $0 \in \rho(-\hat{A}_\lambda)$. For $n = 1, 2, \ldots$, let $\hat{X}^n = H \times Q^n$, and let $P_Q^n : Q \to Q^n$ denote the orthogonal (with respect to the standard inner product on Q, $\langle\cdot,\cdot\rangle_Q$) projection of Q onto Q^n. For $n = 1, 2, \ldots$, $\lambda > 0$ and $\psi \in C([0,\infty); H)$ define the mapping $\hat{G}_\lambda^n(\cdot,\cdot;\psi) : [0,\infty) \times \hat{X}_\alpha \to \hat{X}^n$ by

$$\hat{G}_\lambda^n(t, (\varphi, q); \psi) = (g(t) - B(\varphi)\{\overline{q} - q\}, \lambda P_Q^n q - P_Q^n B(\varphi)'\{\varphi - \psi(t)\}), \tag{4.15}$$

for $t \geq 0$, $(\varphi, q) \in \hat{X}_\alpha$. For $n = 1, 2, \ldots$ and $t \geq 0$, let $\hat{x}^n(t) = (u^n(t), q^n(t))$ and consider the system (4.7), (4.9), and (4.10) written in the form of an initial value problem in $\hat{X}^n$ as

$$D_t\hat{x}^n(t) + \hat{A}_\lambda\hat{x}^n(t) = \hat{G}_\lambda^n(t, \hat{x}^n(t); v^n), \qquad \text{a.e. } t > 0, \tag{4.16}$$

$$\hat{x}^n(0) = \hat{x}_0^n, \tag{4.17}$$

where $\lambda > 0$, $\hat{G}_\lambda^n$ is given by (4.15), $\hat{A}_\lambda$ is given by (4.13) and (4.14), v^n is given by (4.11), and $\hat{x}_0^n = (u_0, q_0^n) \in \hat{X}^n$.

In Theorem 4.1 to follow, we establish that the initial value problem (4.16), (4.17) has a unique local strong solution.

THEOREM 4.1. *If $u_0 \in Dom(A_0^\alpha)$, then for each $n = 1, 2, \ldots$, there exists a $T > 0$ and a unique function $\hat{x}^n \in C([0,T); \hat{X}) \cap C^1((0,T); \hat{X})$ satisfying* (4.16) *and* (4.17). *Moreover, $\hat{x}^n$ satisfies the integral equation*

$$\hat{x}^n(t) = \hat{T}_\lambda(t)\hat{x}_0^n + \int_0^t \hat{T}_\lambda(t-s)\hat{G}_\lambda^n(s, \hat{x}^n(s); v^n)ds, \qquad 0 \leq t < T. \tag{4.18}$$

Proof. For each $n = 1, 2, \ldots$, let $\hat{X}^n_\alpha = Dom(A^\alpha_0) \times Q^n$ be considered as a subspace of $\hat{X}_\alpha$, and let $\hat{U}^n \subset \hat{X}^n_\alpha$ be the neighborhood of $\hat{x}^n_0$ given by $\hat{U}^n = \{\hat{x}^n \in \hat{X}^n_\alpha : |\hat{x}^n - \hat{x}^n_0|_{\hat{X}_\alpha} < \varepsilon\}$. Let $\overline{T} > 0$ and $\lambda > 0$ be fixed. We show that there exists a constant $\hat{L}^n = \hat{L}^n(\varepsilon, \hat{x}^n_0, \lambda, \overline{T}) > 0$, such that

$$|\hat{G}^n_\lambda(t, \hat{\Phi}^n; v^n) - \hat{G}^n_\lambda(s, \hat{\Psi}^n; v^n)|_{\hat{X}} \le \hat{L}^n\{|t-s|^\nu + |\varphi - \psi|_\alpha + |q^n - p^n|_Q\}, \tag{4.19}$$

for $0 \le t, s \le \overline{T}$, and $\hat{\Phi}^n = (\varphi, q^n), \hat{\Psi}^n = (\psi, p^n) \in \hat{U}^n$. The desired result will then follow as in the proof of Theorem 6.3.1 in [33].

Let $0 \le t, s \le \overline{T}$, and let $\hat{\Phi}^n = (\varphi, q^n), \hat{\Psi}^n = (\psi, p^n) \in \hat{U}^n$. Then

$$\begin{aligned} &|\hat{G}^n_\lambda(t, \hat{\Phi}^n; v^n) - \hat{G}^n_\lambda(s, \hat{\Psi}^n; v^n)|^2_{\hat{X}} \\ &\qquad \le 2|g(t) - g(s)|^2 + 2|B(\varphi)\{\overline{q} - q^n\} - B(\psi)\{\overline{q} - p^n\}|^2 \\ &\qquad\quad + 2\lambda^2|q^n - p^n|^2_Q + 2|B(\varphi)'\{\varphi - v^n(t)\} - B(\psi)'\{\psi - v^n(s)\}|^2_Q. \end{aligned} \tag{4.20}$$

Assumptions (A7) and (A8) imply that

$$\begin{aligned} &|B(\varphi)\{\overline{q} - q^n\} - B(\psi)\{\overline{q} - p^n\}| \\ &\qquad \le |B(\varphi)\overline{q} - B(\psi)\overline{q}| + |B(\varphi)q^n - B(\varphi)p^n| + |B(\varphi)p^n - B(\psi)p^n| \\ &\qquad \le \gamma_1|\overline{q}|_Q|\varphi - \psi|_\alpha + \beta_1|\varphi|_\alpha|q^n - p^n|_Q + \gamma_1|p^n|_Q|\varphi - \psi|_\alpha. \end{aligned} \tag{4.21}$$

Now

$$\begin{aligned} &|B(\varphi)'\{\varphi - v^n(t)\} - B(\psi)'\{\psi - v^n(s)\}|_Q \\ &\qquad \le \sup_{|q|_Q \le 1} |\langle B(\varphi)'\varphi - B(\psi)'\psi, q\rangle_Q| \\ &\qquad\quad + \sup_{|q|_Q \le 1} |\langle B(\varphi)'v^n(t) - B(\psi)'v^n(s), q\rangle_Q|. \end{aligned} \tag{4.22}$$

Assumptions (A7) and (A8) imply that

$$\begin{aligned} &|\langle B(\varphi)'\varphi - B(\psi)'\psi, q\rangle_Q| \\ &\qquad \le |\langle B(\varphi)'\varphi - B(\varphi)'\psi, q\rangle_Q| + |\langle B(\varphi)'\psi - B(\psi)'\psi, q\rangle_Q| \\ &\qquad \le \kappa_\alpha\{\beta_1|\varphi|_\alpha + \gamma_1|\psi|_\alpha\}|\varphi - \psi|_\alpha|q|_Q, \end{aligned} \tag{4.23}$$

where, recalling that the space $\{H_\alpha, |\cdot|_\alpha\}$ is densely and continuously embedded in H, κ_α is such that $|\xi| \le \kappa_\alpha|\xi|_\alpha$, for $\xi \in H_\alpha$. Assumptions (A7) and (A8) also imply that

$$\begin{aligned} &|\langle B(\varphi)'v^n(t) - B(\psi)'v^n(s), q\rangle_Q| \\ &\qquad \le |\langle B(\varphi)'v^n(t) - B(\varphi)'v^n(s), q\rangle_Q| + |\langle B(\varphi)'v^n(s) - B(\psi)'v^n(s), q\rangle_Q| \\ &\qquad \le \beta_1|\varphi|_\alpha|v^n(t) - v^n(s)||q|_Q + \gamma_1|v^n(s)||\varphi - \psi|_\alpha|q|_Q \\ &\qquad \le \kappa_1|\varphi|_\alpha|t-s|^\nu|q|_Q + \kappa_2|\varphi - \psi|_\alpha|q|_Q, \end{aligned} \tag{4.24}$$

for some positive constants κ_1 and κ_2, where in the final estimate in (4.24) above, we have applied a regularity result for mild solutions to systems governed by analytic semigroups given in Theorem 4.3.1 in [33] and the fact that $v^n \in C([0, \overline{T}]; H)$ and is therefore H-bounded uniformly on $[0, \overline{T}]$.

Combining (4.20)–(4.24) and assumption (A9), we obtain (4.19), and the theorem is proved. □

It is also possible to establish a *global* existence result for the solution to the system (4.16), (4.17). However, to do this we require the following additional assumption.

(A12) The operator $A_1(\overline{q}) : V \to V^*$ is *monotone* in the sense that $\langle A_1(\overline{q})\varphi - A_1(\overline{q})\psi, \varphi - \psi\rangle \geq 0$, $\varphi, \psi \in V$.

We note that assumption (A12) is not excessively restrictive in that monotonicity can be demonstrated for relatively large classes of nonlinear operators. It corresponds physically to some form of energy dissipation in the plant. In particular, we note that the operator $A_1(\overline{q})$ appearing in the example presented in section 2.1 satisfies assumption (A12) (see (2.61)).

THEOREM 4.2. *Suppose that assumptions* (A1)–(A9) *and* (A12) *hold and that* $u_0 \in Dom(A_0^\alpha)$. *Then for each* $n = 1, 2, \ldots$, *the initial value problem* (4.16), (4.17) *has a unique solution* $\hat{x}^n = (u^n, q^n)$ *which exists for all* $t \geq 0$.

Proof. As in the proof of Theorem 2.6, we show that for each $n = 1, 2, \ldots$, the local solution $\hat{x}^n$ to the initial value problem (4.16), (4.17) shown to exist in Theorem 4.1 can be continued by arguing that $|\hat{x}^n(t)|_{\hat{X}_\alpha}$ remains bounded as $t \uparrow T$. For $t \in [0, T)$ we have $|\hat{x}^n(t)|_{\hat{X}_\alpha} = |u^n(t)|_\alpha + |q^n(t)|_Q$.

We begin by determining a bound for $|q^n(t)|_Q$ as $t \uparrow T$. From (4.7) and (4.9) and assumptions (A1), (A2), (A4), and (A12), for $t \in (0, T)$, and θ the *zero* vector in V, we obtain the estimate

$$
\begin{aligned}
\frac{1}{2}\left\{D_t|u^n(t)|^2 + D_t|q^n(t)|_Q^2\right\} &= \langle D_t u^n(t), u^n(t)\rangle + \langle D_t q^n(t), q^n(t)\rangle_Q \\
&= -\langle A_0 u^n(t), u^n(t)\rangle - \langle A_1(\overline{q})u^n(t), u^n(t)\rangle \\
&\quad +\langle g(t), u^n(t)\rangle + \langle A_1(q^n(t))u^n(t), v^n(t)\rangle \\
&= -\langle A_0 u^n(t), u^n(t)\rangle - \langle A_1(\overline{q})u^n(t) \\
&\quad -A_1(\overline{q})\theta, u^n(t)\rangle - \langle A_1(\overline{q})\theta, u^n(t)\rangle \\
&\quad +\langle g(t), u^n(t)\rangle + \langle A_1(q^n(t))u^n(t), v^n(t)\rangle \\
&\leq -\langle A_0 u^n(t), u^n(t)\rangle + |\langle A_1(\overline{q})\theta, u^n(t)\rangle| \\
&\quad +\langle g(t), u^n(t)\rangle + \langle A_1(q^n(t))u^n(t), v^n(t)\rangle \\
&\leq -\rho_0\|u^n(t)\|^2 + \|g(t)\|_*\|u^n(t)\| \\
&\quad +\alpha_1|q^n(t)|_Q\|u^n(t)\|\|v^n(t)\|.
\end{aligned} \tag{4.25}
$$

Now $v^n \in C([0, T]; H)$. But $v^n(t) \in H^n$, $t \in [0, T]$, and $H^n \subset V$ finite dimensional imply that $v^n \in C([0, T]; V)$ and, therefore, that $\|v^n(t)\|$ is bounded for $t \in [0, T]$. Consequently, for $\varepsilon > 0$, (4.25) yields

$$
\begin{aligned}
\frac{1}{2}\left\{D_t|u^n(t)|^2 + D_t|q^n(t)|_Q^2\right\} &\leq -\rho_0\|u^n(t)\|^2 + \frac{1}{2\varepsilon}\|g(t)\|_*^2 \\
&\quad +\frac{\varepsilon}{2}\|u^n(t)\|^2 + \frac{\kappa^n}{2\varepsilon}|q^n(t)|_Q^2 + \frac{\kappa^n\varepsilon}{2}\|u^n(t)\|^2
\end{aligned}
$$

or

$$
\frac{1}{2}\{D_t|u^n(t)|^2 + D_t|q^n(t)|_Q^2\} + \left\{\rho_0 - (1+\kappa^n)\frac{\varepsilon}{2}\right\}\|u^n(t)\|^2 \leq \frac{1}{2\varepsilon}\|g(t)\|_*^2 + \frac{\kappa^n}{2\varepsilon}|q^n(t)|_Q^2
$$

for some $\kappa^n > 0$. Choosing $\varepsilon = \varepsilon^n = 2\rho_0/(1+\kappa^n)$, we obtain

$$D_t|u^n(t)|^2 + D_t|q^n(t)|_Q^2 \leq \mu_1\|g(t)\|_*^2 + \mu_2^n|q^n(t)|_Q^2, \qquad 0 \leq t < T, \tag{4.26}$$

for some $\mu_1, \mu_2^n > 0$. Integrating both sides of the estimate in (4.26) from 0 to t, we find that for $0 \leq t < T$,

$$|u^n(t)|^2 + |q^n(t)|_Q^2 \leq |u_0|^2 + |q_0^n|_Q^2 + \mu_1\int_0^t \|g(s)\|_*^2 ds + \mu_2^n\int_0^t |q^n(s)|_Q^2 ds. \tag{4.27}$$

Applying the generalized Gronwall inequality (see, for example, [15]) to (4.27) above, we obtain

$$\begin{aligned} |u^n(t)|^2 + |q^n(t)|_Q^2 &\leq \zeta^n(t) + \mu_2^n\textstyle\int_0^t e^{\mu_2^n(t-s)}\zeta^n(s)ds \\ &\leq (1+\mu_2^n T e^{\mu_2^n T})\zeta^n(T) \\ &= \kappa_T^n, \qquad 0 \leq t < T, \end{aligned} \tag{4.28}$$

where for each $n = 1, 2, \ldots$, ζ^n is the monotone increasing function on $[0,T]$ given by

$$\zeta^n(t) = |u_0|^2 + |q_0^n|_Q^2 + \mu_1\int_0^t \|g(s)\|_*^2 ds, \qquad 0 \leq t \leq T.$$

Now for $t \in [0,T)$, from (4.18) we obtain

$$A_0^\alpha u^n(t) = A_0^\alpha T_0(t)u_0 + \int_0^t A_0^\alpha T_0(t-s)\{g(s) - B(u^n(s))\{\overline{q} - q^n(s)\}\}ds. \tag{4.29}$$

It follows from (4.29) and assumptions (A4) and (A7) that for $t \in [0,T)$ we have

$$\begin{aligned} |u^n(t)|_\alpha \leq\ & e^{-\rho_0 K^{-2}t}|u_0|_\alpha + \int_0^t M_\alpha(t-s)^{-\alpha}e^{-\rho_0 K^{-2}(t-s)}|g(s)|ds \\ & + \int_0^t M_\alpha(t-s)^{-\alpha}e^{-\rho_0 K^{-2}(t-s)}\beta_1\left\{|\overline{q}|_Q + |q^n(s)|_Q\right\}|u^n(s)|_\alpha ds \end{aligned}$$

for some positive constant M_α (see [33]). Assumption (A9) and (4.28) then imply that

$$\begin{aligned} |u^n(t)|_\alpha \leq\ & |u_0|_\alpha + M_\alpha\|g\|_{C([0,T];H)}\frac{T^{1-\alpha}}{1-\alpha} \\ & + M_\alpha\beta_1\{|\overline{q}|_Q + \sqrt{\kappa_T^n}\}\int_0^t (t-s)^{-\alpha}|u^n(s)|_\alpha ds \end{aligned} \tag{4.30}$$

for $0 \leq t < T$. An application of Lemma 5.6.7 in [33] to the estimate given in (4.30) above then yields the existence of a constant $\lambda_T^n > 0$ for which

$$|u^n(t)|_\alpha \leq \lambda_T^n, \qquad 0 \leq t < T. \tag{4.31}$$

Combining estimates (4.28) and (4.31), we obtain the desired result, and the theorem is proved. □

Before we present our convergence result, we discuss some computational considerations and, in particular, the matrix representations for the finite-dimensional

approximating reference model (4.1), (4.2) and adaptation law (4.3), (4.4). For each $n = 1, 2, \ldots$ let $\{\varphi_j^n\}_{j=1}^{k^n}$ be a basis for H^n and let $\{p_j^n\}_{j=1}^{\ell^n}$ be a basis for Q^n. Let

$$v^n(t) = \sum_{j=1}^{k^n} \tilde{v}_j^n(t)\varphi_j^n \qquad \text{and} \qquad q^n(t) = \sum_{j=1}^{\ell^n} \tilde{q}_j^n(t)p_j^n, \qquad t \geq 0. \tag{4.32}$$

That is, for each $t \geq 0$, let $\tilde{v}^n(t) \in \mathbf{R}^{k^n}$ and $\tilde{q}^n(t) \in \mathbf{R}^{\ell^n}$ be, respectively, the vector representations for $v^n(t) \in H^n$ and $q^n \in Q^n$ with respect to the bases $\{\varphi_j^n\}_{j=1}^{k^n}$ and $\{p_j^n\}_{j=1}^{\ell^n}$. We choose $v_0^n = P^n v_0 \in H^n$ and $q_0^n = P_Q^n q_0 \in Q^n$.

The matrix form of the approximating reference model (4.1), (4.2) then becomes

$$M^n D_t \tilde{v}^n(t) + K^n \tilde{v}^n(t) = g^n(t), \qquad t > 0, \tag{4.33}$$

$$M^n \tilde{v}^n(0) = \tilde{v}_0^n, \tag{4.34}$$

where the $k^n \times k^n$ matrices M^n and K^n are given by $[M^n]_{i,j} = \langle \varphi_j^n, \varphi_i^n \rangle$ and $[K^n]_{i,j} = \langle A_0 \varphi_j^n, \varphi_i^n \rangle$, $i, j = 1, 2, \ldots, k^n$, respectively, and $[\tilde{v}_0^n]_i = \langle v_0, \varphi_i^n \rangle$ and $[g^n(t)]_i = \langle g(t), \varphi_i^n \rangle$, $i = 1, 2, \ldots, k^n$, $t \geq 0$. Note that since $\{\varphi_j^n\}_{j=1}^{k^n}$ is a basis for H^n, the matrix M^n is nonsingular.

For $u(t) \in V$, the output of the plant, (2.4), (2.5), or (2.6), (2.7), at time $t \geq 0$, the matrix form of the approximating adaptation law (4.3), (4.4) is given by

$$M_Q^n D_t \tilde{q}^n(t) - L^n(u(t))\tilde{v}^n(t) = -h^n(u(t)), \qquad t > 0, \tag{4.35}$$

$$M_Q^n \tilde{q}^n(0) = \tilde{q}_0^n, \tag{4.36}$$

where the $\ell^n \times \ell^n$ matrix M_Q^n is given by $[M_Q^n]_{i,j} = \langle p_j^n, p_i^n \rangle_Q$, $i, j = 1, 2, \ldots, \ell^n$, for $\varphi \in V$, the $\ell^n \times k^n$ matrix $L^n(\varphi)$ and the ℓ^n-vector $h^n(\varphi)$ are given by $[L^n(\varphi)]_{i,j} = \langle A_1(p_i^n)\varphi, \varphi_j^n \rangle$ and $[h^n(\varphi)]_i = \langle A_1(p_i^n)\varphi, \varphi \rangle$, $i = 1, 2, \ldots, \ell^n$, $j = 1, 2, \ldots, k^n$, respectively, and the ℓ^n-vector $\tilde{q}_0^n$ is given by $[\tilde{q}_0^n]_i = \langle q_0, p_i^n \rangle_Q$, $i = 1, 2, \ldots, \ell^n$. Once again, since $\{p_j^n\}_{j=1}^{\ell^n}$ is a basis for Q^n, the matrix M_Q^n is nonsingular.

Combining (4.33), (4.34) and (4.35), (4.36), for $u(t) \in V$, the output of the plant, (2.4), (2.5), or (2.6), (2.7), at time $t \geq 0$, the $k^n + \ell^n$-dimensional *linear* system

$$\begin{bmatrix} D_t \tilde{v}^n(t) \\ D_t \tilde{q}^n(t) \end{bmatrix} + \begin{bmatrix} (M^n)^{-1} K^n & 0 \\ -(M_Q^n)^{-1} L^n(u(t)) & 0 \end{bmatrix} \begin{bmatrix} \tilde{v}^n(t) \\ \tilde{q}^n(t) \end{bmatrix} = \begin{bmatrix} (M^n)^{-1} g^n(t) \\ -(M_Q^n)^{-1} h^n(u(t)) \end{bmatrix}, \ t > 0,$$

$$\begin{bmatrix} \tilde{v}^n(0) \\ \tilde{q}^n(0) \end{bmatrix} = \begin{bmatrix} (M^n)^{-1} \tilde{v}_0^n \\ (M_Q^n)^{-1} \tilde{q}_0^n \end{bmatrix}$$

must be integrated to determine the state of the approximating reference model, $v^n(t)$, and the approximating parameter estimator, $q^n(t)$, at time $t > 0$. The estimate for the parameters is given by (4.32), and the control input is given by

$$f^n(t) = A\left(\sum_{j=1}^{\ell^n} \tilde{q}_j^n(t) p_j^n\right) u(t) - A_0 u(t) + g(t), \qquad t \geq 0.$$

We are now ready to turn to our convergence result. We require the following rather standard assumptions on the approximation properties of the finite-dimensional subspaces H^n and Q^n.

(A13) The subspace H^n is such that for each $n = 1, 2, \ldots$ there exists a mapping $\pi^n \in \mathcal{L}(V, V)$ for which $\pi^n \varphi \in H^n$, $\varphi \in V$, and $\lim_{n\to\infty} \|\pi^n \varphi - \varphi\| = 0$, $\varphi \in V$.

(A14) The subspace Q^n is such that $\lim_{n\to\infty} |P_Q^n q - q|_Q = 0$, $q \in Q$.

We note that assumption (A13) together with the dense and continuous embedding of V in H is sufficient to conclude that $\lim_{n\to\infty} |P^n \varphi - \varphi| = 0$, $\varphi \in H$. We note further that in many cases it is possible to choose $\pi_n = P^n$. Indeed, this is in fact the case for polynomial spline-based subspaces. Assumption (A13) can then be verified using the estimates found in, for example, [36].

The following theorem concerning the convergence of the approximating semigroups $\{T_0^n(t) : t \geq 0\}$ to the semigroup $\{T_0(t) : t \geq 0\}$ is established in [3] using the well-known Trotter–Kato theorem (see, for example, [20] and [33]).

THEOREM 4.3. *Under assumptions* (A3), (A4), *and* (A13), *for each* $T > 0$ *we have the following results.*

(i) *There exists a constant* $M_0 > 0$, *independent of* n, *for which* $\|T_0^n(t)\varphi^n\| \leq M_0\|\varphi^n\|$, $\varphi^n \in H^n$.

(ii) *For* $\varphi \in H$ *and* $t \in [0, T]$, $\lim_{n\to\infty} |T_0^n(t)P^n\varphi - T_0(t)\varphi| = 0$, *uniformly in* t *for* t *in compact subintervals of* $[0, T]$.

(iii) *For* $\varphi \in V$ *and* $t \in [0, T]$, $\lim_{n\to\infty} \|T_0^n(t)\pi^n\varphi - T_0(t)\varphi\| = 0$, *uniformly in* t *for* t *in compact subintervals of* $[0, T]$.

(iv) *For* $\varphi \in H$ *and* $t \in (0, T]$, $\lim_{n\to\infty} \|T_0^n(t)P^n\varphi - T_0(t)\varphi\| = 0$, *uniformly in* t *for* t *in compact subintervals of* $(0, T]$.

Once (i) has been established, the essence of the proof of (ii)–(iv) is demonstrating resolvent convergence in V. Let $\lambda > 0$ and $\varphi \in V$, and set $\psi = (\lambda I + A_0)^{-1}\varphi$ and $\psi^n = (\lambda I + A_0^n)^{-1}\pi^n\varphi$, $n = 1, 2, \ldots$. The triangle inequality yields

$$\|\psi - \psi^n\| \leq \|\psi - \pi^n\psi\| + \|\pi^n\psi - \psi^n\|. \tag{4.37}$$

Assumption (A13) implies that the first term on the right-hand side of the estimate in (4.37) tends to zero as $n \to \infty$. With regard to the second term, using assumptions (A3) and (A4) we obtain, for any $\varepsilon > 0$,

$$\begin{aligned}
\rho_0\|\psi^n - \pi^n\psi\|^2 &\leq \langle A_0\{\psi^n - \pi^n\psi\}, \psi^n - \pi^n\psi\rangle \\
&= \langle(\lambda I + A_0^n)\psi^n - (\lambda I + A_0)\psi, \psi^n - \pi^n\psi\rangle + \lambda\langle\psi - \pi^n\psi, \psi^n - \pi^n\psi\rangle \\
&\quad -\lambda\langle\psi^n - \pi^n\psi, \psi^n - \pi^n\psi\rangle + \langle A_0\{\psi - \pi^n\psi\}, \psi^n - \pi^n\psi\rangle \\
&\leq K\|\varphi - \pi^n\varphi\|\|\psi^n - \pi^n\psi\| + \lambda\|\psi - \pi^n\psi\|\|\psi^n - \pi^n\psi\| - \lambda|\pi^n\psi - \psi^n|^2 \\
&\quad +\alpha_0\|\psi - \pi^n\psi\|\|\psi^n - \pi^n\psi\| \\
&\leq \frac{K}{2\varepsilon}\|\varphi - \pi^n\varphi\|^2 + \frac{\lambda + \alpha_0}{2\varepsilon}\|\psi - \pi^n\psi\|^2 + \frac{1}{2}\{K + \lambda + \alpha_0\}\varepsilon\|\psi^n - \pi^n\psi\|^2.
\end{aligned}$$

Choosing $\varepsilon > 0$ sufficiently small, we find that

$$\|\psi^n - \pi^n\psi\|^2 \leq \nu_1\|\varphi - \pi^n\varphi\|^2 + \nu_2\|\psi - \pi^n\psi\|^2$$

for some constants $\nu_1, \nu_2 > 0$. Invoking assumption (A13) and recalling (4.37), we obtain

$$\lim_{n\to\infty} \|(\lambda I + A_0^n)^{-1}\pi^n\varphi - (\lambda I + A_0)^{-1}\varphi\| = 0, \qquad \varphi \in V.$$

We will require the following corollary to Theorem 4.3 above.

COROLLARY 4.4. *If $v_0 \in V$ and $v_0^n = \pi^n v_0$, then under assumptions* (A3), (A4), (A9), *and* (A13), *for each $T > 0$ we have the following results.*

(i) *For each $t \in [0,T]$, $\lim_{n\to\infty} \|v^n(t) - v(t)\| = 0$.*

(ii) *There exists a constant $\kappa_{v^n} = \kappa_{v^n}(T) > 0$, for which $\|v^n(t)\| \le \kappa_{v^n}$, $0 \le t \le T$, with $\kappa = \sup_n \kappa_{v^n} < \infty$.*

Proof. From (2.12) and (4.11) for $t \in [0,T]$, we obtain

$$\begin{aligned}\|v^n(t) - v(t)\| &\le \|T_0^n(t)\pi^n v_0 - T_0(t)v_0\| \\ &\quad + \int_0^t \|T_0^n(t-s)P^n g(s) - T_0(t-s)g(s)\|ds.\end{aligned}$$

Statement (iii) of Theorem 4.3 implies that the first term on the right-hand side of the above expression tends to zero as $n \to \infty$. Statement (iv) of Theorem 4.3 implies that the term under the integral sign tends to zero for almost every $s \in [0,T]$. Moreover, Lemma 3.6.2 in [39] implies that

$$\|T_0^n(t-s)P^n g(s) - T_0(t-s)g(s)\| \le \frac{C}{(t-s)^{\frac{1}{2}}}|g(s)|, \qquad 0 \le s < t,$$

where the constant $C > 0$ is independent of n. That the constant C is independent of n follows from the fact that the operators A_0^n are defined via Galerkin approximation and, consequently, the estimates given in Lemma 3.6.1 in [39] for the resolvent of $-A_0$ continue to hold for the resolvent of $-A_0^n$ with all constants independent of n (see also [4]). An application of the Lebesgue dominated convergence theorem then yields (i).

Statement (ii) is established analogously. Indeed, for $t \in [0,T]$, (4.11) yields

$$\begin{aligned}\|v^n(t)\| &\le \|T_0^n(t)\pi^n v_0\| + \int_0^t \|T_0^n(t-s)P^n g(s)\|ds \\ &\le M_0\kappa_\pi\|v_0\| + \int_0^t \frac{C}{(t-s)^{\frac{1}{2}}}|g(s)|ds \\ &\le M_0\kappa_\pi\|v_0\| + 2C\|g\|_{C([0,T];H)}\sqrt{T} = \kappa_{v^n}(T),\end{aligned}$$

where $\kappa_\pi > 0$ is the uniform bound on the operators $\pi^n \in \mathcal{L}(V,V)$, $n = 1,2,\ldots$, guaranteed to exist by assumption (A13) and the uniform boundedness principle. This proves the theorem. □

Using Corollary 4.4, the next corollary follows immediately by inspection.

COROLLARY 4.5. *Suppose that the assumptions* (A1)–(A9) *and* (A12)–(A14) *are satisfied, and that $u_0 \in Dom(A_0^\alpha)$. Suppose further that $v_0 \in V$, $v_0^n = \pi^n v_0$, and that $q_0^n = P_Q^n q_0$. Then the constants κ_T^n and λ_T^n defined in the proof of* Theorem 4.2 *above are in fact independent of n.*

The implication of Corollary 4.5 is that for $T > 0$ fixed, $|u^n(t)|_\alpha$ and $|q^n(t)|_Q$ are bounded uniformly in n and t for $t \in [0,T]$, where for each $n = 1,2,\ldots$ u^n and q^n satisfy (4.7)–(4.10). That is there exist constants $\kappa_T > 0$ and $\lambda_T > 0$, independent of n for which

$$|\hat{x}^n(t)|_{\hat{X}_\alpha} = |u^n(t)|_\alpha + |q^n(t)|_Q \le \lambda_T + \sqrt{\kappa_T}, \qquad 0 \le t \le T, \tag{4.38}$$

where for each $n = 1,2,\ldots$ $\hat{x}^n$, is the solution to the initial value problem (4.16), (4.17).

Our convergence result is given in Theorem 4.7 below. Its proof requires the following lemma.

LEMMA 4.6. *If $Dom(A_0^\alpha) \subset V$ for some $\alpha \in (0,1)$, then the Banach space $\{H_\alpha, |\cdot|_\alpha\}$ defined by $H_\alpha = Dom(A_0^\alpha)$ and $|\varphi|_\alpha = |A_0^\alpha \varphi|$, $\varphi \in Dom(A_0^\alpha)$ is continuously embedded in V. That is, there exists a constant $K_V > 0$ for which $\|\varphi\| \leq K_V |\varphi|_\alpha$, $\varphi \in Dom(A_0^\alpha)$.*

Proof. It can be shown (see [28, page 11]) that there exists a linear, self-adjoint, and positive operator $\Lambda : Dom(\Lambda) \subset H \to H$ for which $Dom(\Lambda) = V$ and for which the norm $\|\cdot\|_\Lambda$ on V given by $\|\varphi\|_\Lambda = \left\{|\varphi|^2 + |\Lambda\varphi|^2\right\}^{\frac{1}{2}}$, $\varphi \in V$, is equivalent to the standard norm, $\|\cdot\|$, on V. Then, for $\varphi \in Dom(A_0^\alpha)$, Corollary 2.6.11 in [33] implies that

$$\|\varphi\|^2 \leq K_1 \left\{|\varphi|^2 + |\Lambda\varphi|^2\right\} \leq K_2 \left\{|\varphi|^2 + |A_0^\alpha \varphi|^2\right\} \leq K_2 \|\varphi\|_\alpha^2 \leq K_V^2 |\varphi|_\alpha^2$$

for some constants $K_1, K_2, K_V > 0$, where the norm $\|\cdot\|_\alpha$ on H_α was defined and discussed in the proof of Theorem 2.4. □

THEOREM 4.7. *Suppose that assumptions* (A1)–(A9) *and assumptions* (A12)–(A14) *hold, that $u_0 \in Dom(A_0^\alpha)$, $\alpha \in (0,1)$ as in assumption* (A6)*, and that $v_0^n = \pi^n v_0$ and $q_0^n = P_Q^n q_0$. Then*

$$\lim_{n\to\infty} |u^n(t) - u(t)|_\alpha = \lim_{n\to\infty} |A_0^\alpha u^n(t) - A_0^\alpha u(t)| = 0 \tag{4.39}$$

and

$$\lim_{n\to\infty} |q^n(t) - q(t)|_Q = 0, \tag{4.40}$$

uniformly in t, for $t \in [0,T]$, where u^n, q^n satisfy (4.7)–(4.10)*, and u and q satisfy* (2.26)–(2.29)*. Moreover, if, in addition, the operator A_2 satisfies a Lipschitz condition of the form*

$$\|A_2\varphi - A_2\psi\|_* \leq \gamma_2 |\varphi - \psi|_\alpha, \qquad \varphi, \psi \in Dom(A_0^\alpha), \tag{4.41}$$

for some $\gamma_2 > 0$, where $\alpha \in (0,1)$ is as in assumption (A6)*, then we have*

$$\lim_{n\to\infty} f^n(t) = f(t) \tag{4.42}$$

in V^* uniformly in t, for $t \in [0,T]$, and therefore $\lim_{n\to\infty} f^n = f$ in $L_2(0,T;V^*)$, for each $T > 0$, where for each $n = 1, 2, \ldots$, f^n is given by (4.5) *or* (4.6)*, and f is given by* (2.22) *or* (2.23). Before we prove Theorem 4.7, we note that (4.39) implies that

$$\lim_{n\to\infty} |u^n(t) - u(t)| \leq \lim_{n\to\infty} \|u^n(t) - u(t)\|_\alpha \leq \kappa_\alpha \lim_{n\to\infty} |u^n(t) - u(t)|_\alpha = 0,$$

uniformly in t for $t \in [0,T]$. Moreover, (4.39) together with Lemma 4.6 also imply that

$$\lim_{n\to\infty} \|u^n(t) - u(t)\| \leq K_V \lim_{n\to\infty} |u^n(t) - u(t)|_\alpha = 0, \tag{4.43}$$

uniformly in t for $t \in [0,T]$.

Proof of Theorem 4.7. For each $t \geq 0$, let $\hat{x}(t) = (u(t), q(t))$, where u and q satisfy (2.26)–(2.29). Then for each $\lambda > 0$, $\hat{x}$ satisfies

$$\hat{x}(t) = \hat{T}_\lambda(t)\hat{x}_0 + \int_0^t \hat{T}_\lambda(t-s)\hat{G}_\lambda(s, \hat{x}(s); v)ds, \qquad t \geq 0, \tag{4.44}$$

where $\hat{G}_\lambda$ is given by (4.12), $\{\hat{T}_\lambda(t) : t \geq 0\}$ is the uniformly exponentially stable semigroup of bounded linear operators on $\hat{X}$ generated by the operator $-\hat{A}_\lambda$ defined in (4.13) and (4.14), and v satisfies (2.8), (2.9) and is given by (2.12). Subtracting (4.44) from (4.18) and taking norms in $\hat{X}_\alpha$, for each $t \geq 0$, we find that

$$
\begin{aligned}
|\hat{x}^n(t) - \hat{x}(t)|_{\hat{X}_\alpha} &\leq e^{-\lambda t}|P_Q^n q_0 - q_0|_Q \\
&\quad + \int_0^t |A_0^\alpha T_0(t-s)\{B(u^n(s))\{q^n(s) - q(s)\} \\
&\quad + B(u(s))\{\overline{q} - q(s)\}\}| \\
&\quad + e^{-\lambda(t-s)}|\lambda\{q^n(s) - q(s)\} + B(u(s))'\{u(s) - v(s)\} \\
&\quad - P_Q^n B(u^n(s))'\{u^n(s) - v^n(s)\}|_Q ds \\
&\leq |P_Q^n q_0 - q_0|_Q + \int_0^t M_\alpha (t-s)^{-\alpha} \left\{\gamma_1 |\overline{q}_Q| u^n(s) - u(s)|_\alpha \right. \\
&\quad + \gamma_1 |q^n(s)|_Q |u^n(s) - u(s)|_\alpha \\
&\quad \left. + \beta_1 |q^n(s) - q(s)|_Q |u(s)|_\alpha\right\} + \lambda |q^n(s) - q(s)|_Q \\
&\quad + \gamma_1 |u^n(s) - u(s)|_\alpha |u^n(s)| + \gamma_1 |u^n(s) - u(s)||u(s)|_\alpha \\
&\quad + \gamma_1 |u^n(s) - u(s)|_\alpha |v^n(s)| + \gamma_1 |u(s)|_\alpha |v^n(s) - v(s)| \\
&\quad + |\{I - P_Q^n\} B(u(s))'\{u(s) - v(s)\}|_Q ds,
\end{aligned} \tag{4.45}
$$

where in the above estimate we have invoked assumptions (A7) and (A8). Assumption (A14), Corollary 4.4, (2.54), and (4.38) then imply that

$$
|\hat{x}^n(t) - \hat{x}(t)|_{\hat{X}_\alpha} \leq \varepsilon^n + \kappa \int_0^t (t-s)^{-\alpha} |\hat{x}^n(s) - \hat{x}(s)|_{\hat{X}_\alpha} ds, \tag{4.46}
$$

where $\kappa > 0$ and $\lim_{n\to\infty} \varepsilon^n = 0$. The estimate given in (4.46) together with a careful inspection of the proof of Lemma 5.6.7 in [33] then yield that $|\hat{x}^n(t) - \hat{x}(t)|_{\hat{X}_\alpha} \leq \varepsilon^n K_T$, $0 \leq t \leq T$, where $K_T = \frac{T^{1-\alpha}}{1-\alpha} > 0$. This establishes (4.39) and (4.40).

We now turn our attention to establishing (4.42). For $t \in [0, T]$ and $\varphi \in V$, Assumptions (A2), (A3), (A6), (A7), and (A8), (2.2), (4.41), and Lemma 4.6 (or, equivalently, (4.43)) imply that

$$
\begin{aligned}
|\langle f^n(t) - f(t), \varphi\rangle| &= |\langle A(q^n(t))u^n(t) - A_0 u^n(t) - A(q(t))u(t) + A_0 u(t), \varphi\rangle| \\
&\leq |\langle A_1(q^n(t))u^n(t) - A_1(q(t))u^n(t), \varphi\rangle| \\
&\quad + |\langle A_1(q(t))u^n(t) - A_1(q(t))u(t), \varphi\rangle| \\
&\quad + |\langle A_2 u^n(t) - A_2 u(t), \varphi\rangle| + |\langle A_0 u^n(t) - A_0 u(t), \varphi\rangle| \\
&\leq K\beta_1 |q^n(t) - q(t)|_Q |u^n(t)|_\alpha \|\varphi\| \\
&\quad + K\gamma_1 |q(t)|_Q |u^n(t) - u(t)|_\alpha \|\varphi\| \\
&\quad + \|A_2 u^n(t) - A_2 u(t)\|_* \|\varphi\| + \alpha_0 \|u^n(t) - u(t)\| \|\varphi\| \\
&\leq K\beta_1 |q^n(t) - q(t)|_Q |u^n(t)|_\alpha \|\varphi\| \\
&\quad + K\gamma_1 |q(t)|_Q |u^n(t) - u(t)|_\alpha \|\varphi\| \\
&\quad + \gamma_2 |u^n(t) - u(t)|_\alpha \|\varphi\| + \alpha_0 K_V |u^n(t) - u(t)|_\alpha \|\varphi\|.
\end{aligned}
$$

Recalling (2.54), (4.38), (4.39), and (4.40), we obtain $\lim_{n\to\infty} \|f^n(t) - f(t)\|_* = 0$, uniformly in t for $t \in [0, T]$, and the theorem is proved. □

5. Examples and numerical results. In this section we describe and discuss four different examples which illustrate the application of the general theory developed in the previous sections. We consider the example involving a first-order hyperbolic plant and a diffusion equation reference model discussed in section 2.1, an example involving the identification of a spatially varying thermal conductivity in a heat equation plant, an example involving the identification of a damped wave equation (a parabolic regularized hyperbolic system; see [27]), and an example in which we identify the nonlinearity in a quasi-linear heat equation. All of the computations to be described below were carried out via codes written in Fortran and run on either a Sun SPARCstation 10 in the Department of Mathematics at the University of Southern California or an IBM RISCSystem 6000 at the Center for Research in Scientific Computation at North Carolina State University. The closed-loop system (2.26)–(2.29) was discretized using a spline-based Galerkin scheme. The resulting finite-dimensional system of nonlinear ordinary differential equations was integrated using either the stiff ordinary differential equation solver from the NAG Library, routine D02NBF (at USC), or a fourth-order Runge–Kutta scheme (at NCSU). All required integrals were computed numerically via a composite two-point Gauss–Legendre quadrature rule.

We note that the plants and reference models in *all* of the examples to follow satisfy our basic assumptions (A1)–(A5). In Example 5.1, assumptions (A6)–(A9), which are required by the analytic semigroup approach to well-posedness presented in section 2.1, are satisfied as well. In Examples 5.2 and 5.3, assumptions (A10) and (A11), which are required by the implicit function theorem based well-posedness theory in section 2.2, are also satisfied. As we pointed out earlier, the theory in section 2.2 can probably be extended so as to be applicable to the nonlinear plant treated in Example 5.4 as well. The basic assumptions required for the finite-dimensional approximation and convergence theory discussed in section 4, assumptions (A12)–(A14), are satisfied in all four of the examples below.

Regarding the regularity assumptions on the input reference signal g (e.g., $g \in L_2(0, \infty; V^*)$, etc.), the symmetry of the reference model operator A_0, and the persistence of excitation condition, all of which form the core of the hypotheses for our stability and convergence results in sections 2 and 3, we do not explicitly address these hypotheses in the context of the particular examples presented below. There are a number of reasons for this. First, our computational results are necessarily on a finite time interval, while our stability and convergence results are asymptotic results as $t \to \infty$. Consequently, the reconciling of our theoretical and numerical results is, in some sense, ill posed. More precisely, if $g \in L_2(0, T; V^*)$ for some $T \in (0, \infty)$, then g can be extended to a function in $L_2(0, \infty; V^*)$ by simply defining it to be identically zero on (T, ∞). Second, with regard to the persistence of excitation condition, for most systems this condition is difficult, if not impossible, to verify. However, indication of the presence or absence of persistence of excitation and the degree thereof is immediately evident from the parameter estimator trajectories (see [9]). These observations can then be used to tune the scheme, either manually or autonomously, to obtain parameter convergence and optimal performance. In fact, we did just that in carrying out the computations in the examples below. And, finally, and most significantly, we point out that as is the case with virtually all theoretical and analytical studies of the type we have presented here, the assumptions we make are the ones minimally required to allow us to establish our stability and convergence results. Whether or

not the examples we present satisfy these assumptions is essentially irrelevant. Indeed, the fact that in these cases the scheme performs satisfactorily illustrates that our results are *robust* and that our approach appears to be applicable to a far broader class of problems than those that satisfy the hypotheses of our theorems.

Example 5.1. We consider Example 2.8 discussed in section 2.1. In particular, we use this example to illustrate the approximation results obtained in section 4. Recall from section 2.1 that $H = L_2(0,1)$, $V = H_L^1(0,1) = \{\varphi \in H^1(0,1) : \varphi(0) = 0\}$, $\hat{V}^* = V^*$, and $Q = \mathbf{R}^1$. The inner product on Q was chosen to be $\langle q, p\rangle_Q = \omega\, q \cdot p$ for $q, p \in \mathbf{R}^1$. The weighting factor $\omega > 0$ serves as an *adaptive gain* which can be used to *tune* the estimator. The plant is given by

$$\frac{\partial u}{\partial t}(t,x) + \overline{q}\frac{\partial u}{\partial x}(t,x) = f(t,x), \qquad 0 < x < 1,\ t > 0,$$

$$u(t,0) = 0, \qquad t > 0,$$

$$u(0,x) = u_0(x), \qquad 0 \le x \le 1,$$

where $\overline{q} > 0$, $u_0 \in L_2(0,1)$, and $t \to f(t,\cdot) \in L_2(0,T;H)$ for each $T > 0$. The reference model is given by

$$\frac{\partial v}{\partial t}(t,x) - a_0\frac{\partial^2 v}{\partial x^2}(t,x) = g(t,x), \qquad 0 < x < 1,\ t > 0,$$

$$v(t,0) = 0, \qquad \text{and} \qquad \frac{\partial v}{\partial x}(t,1) = 0, \qquad t > 0,$$

$$v(0,x) = v_0(x), \qquad 0 \le x \le 1,$$

where $a_0 > 0$, $v_0 \in L_2(0,1)$, and $t \to g(t,\cdot) \in L_2(0,T;V^*)$ for each $T > 0$.

We approximate using linear B-splines. For $n = 1, 2, \ldots$, let $\{\varphi_j^n\}_{j=0}^n$ be the standard linear B-splines on the interval $[0,1]$ defined with respect to the uniform mesh $\{0, \frac{1}{n}, \frac{2}{n}, \ldots, 1\}$. That is, for $i = 0, 1, 2, \ldots, n$,

$$\varphi_i^n(x) = \begin{cases} 1 - |nx - i|, & x \in [\frac{i-1}{n}, \frac{i+1}{n}], \\ 0 & \text{elsewhere on } [0,1]. \end{cases} \tag{5.1}$$

Set $H^n = \operatorname{span}\{\varphi_j^n\}_{j=1}^n \subset V$. Since Q is finite dimensional, we simply set $Q^n = Q = \mathbf{R}^1$, $n = 1, 2, \ldots$. For each $n = 1, 2, \ldots$, let P^n denote the orthogonal projection of H onto H^n and setting $\pi_n = P^n$, standard approximation results for spline functions (see [36]) can be used to establish that assumption (A13) is satisfied. Thus the conclusions of Theorem 4.7 hold.

We set $\overline{q} = 1.0$, $a_0 = .1$, $\omega = .02$, and $q_0 = 0.0$. We also set $u_0(x) = 0.0$, $v_0(x) = \sin(\frac{\pi}{2}x)$, $0 \le x \le 1$, and $g(t,x) = 5\sin\left(\frac{\pi}{2}t\right)\chi_{[.215,.315]}(x)$, $0 < x < 1$, $t > 0$. We simulated the plant using a 64 linear spline based Galerkin scheme and approximated the reference model in H^n with $n = 8, 16$, and 32. In Figure 5.1a we have plotted the parameter estimator trajectories, $q^n(t)$, along with the trajectory of the *infinite-dimensional* estimator (i.e., $n = 64$), $q(t)$, for $0 \le t \le 100$. In Figure 5.1b we plot the L_2 norms of the corresponding state tracking errors, $|e^n(t)| = |u(t) - v^n(t)|$, for $0 \le t \le 100$. It is clear from the figures that the scheme performed well for n

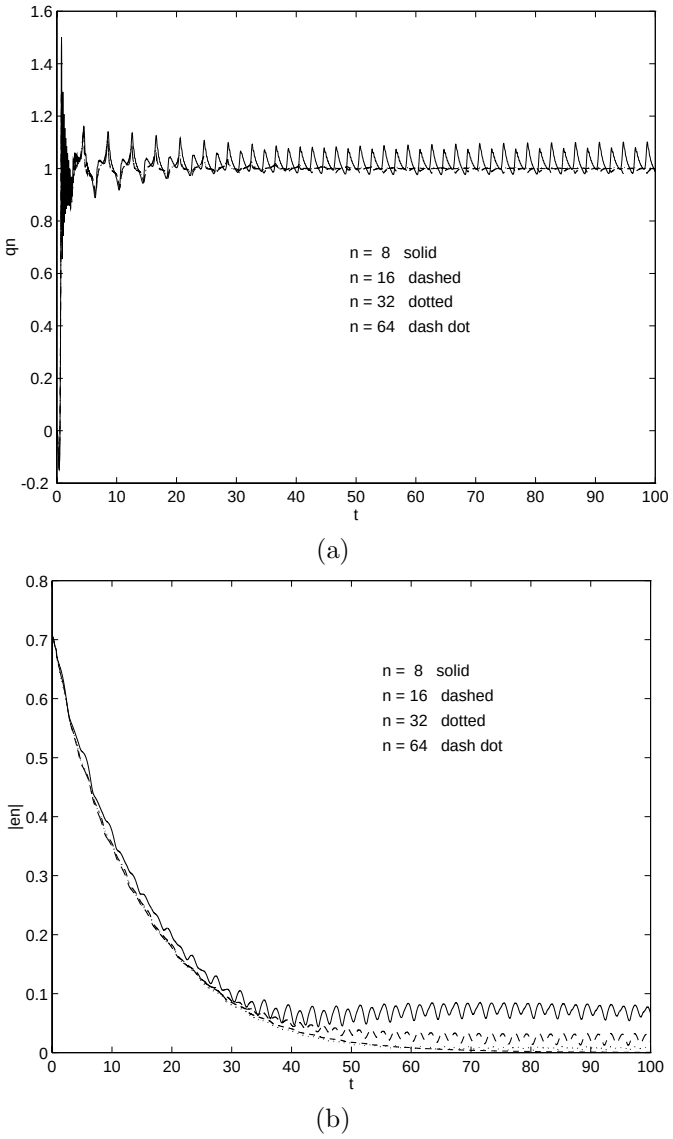

FIG. 5.1. *Results for Example* 5.1 *for various choices of* n*:* (a) *the parameter estimates versus time;* (b) *the tracking error versus time.*

as small as 8. We note that the scheme even performed reasonably well for $n = 4$, although we have not plotted these results here.

Example 5.2. In this example we consider the control of the one-dimensional heat or diffusion equation

$$\frac{\partial u}{\partial t}(t,x) = \frac{\partial}{\partial x}\left\{\overline{q}(x)\frac{\partial u}{\partial x}(t,x)\right\} + f(t,x), \quad t > 0, \quad 0 < x < 1,$$

together with the Dirichlet boundary conditions $u(t,0) = 0 = u(t,1)$, $t > 0$. We take

the reference model to be given by

$$\frac{\partial v}{\partial t}(t,x) - a_0 \frac{\partial^2 v}{\partial x^2}(t,x) = g(t,x) \qquad 0 < x < 1,\ t > 0, \tag{5.2}$$

$$v(t,0) = 0, \qquad \text{and} \qquad v(t,1) = 0, \qquad t > 0, \tag{5.3}$$

$$v(0,x) = v_0(x), \qquad 0 \le x \le 1, \tag{5.4}$$

where $a_0 > 0$, $v_0 \in L_2(0,1)$, and $t \to g(t,\cdot) \in L_2(0,T;V^*)$ for each $T > 0$.

In this case we have $H = L_2(0,1)$ and $V = H_0^1(0,1)$, each endowed with its usual inner product and corresponding induced norm. We set $\hat{V}^* = V^*$, and we let $Q = H^1(0,1)$ and take it to be endowed with the weighted inner product

$$\langle q,p\rangle_Q = \omega_1 \int_0^1 q(x)p(x)dx + \omega_2 \int_0^1 Dq(x)Dp(x)dx, \qquad p,q \in H^1(0,1),$$

where the weights ω_1 and ω_2, assumed to be positive, serve as adaptive gains or tuning parameters. For $q \in Q$, the operator $A(q) = A_1(q) \in \mathcal{L}(V,V^*)$ is given by

$$\langle A(q)\varphi,\psi\rangle = \langle A_1(q)\varphi,\psi\rangle = \int_0^1 q(x)D\varphi(x)D\psi(x)dx, \qquad \varphi,\psi \in H^1(0,1).$$

The operator $A_0 \in \mathcal{L}(V,V^*)$ is given by

$$\langle A_0\varphi,\psi\rangle = a_0 \int_0^1 D\varphi(x)D\psi(x)dx, \qquad \varphi,\psi \in H_0^1(0,1). \tag{5.5}$$

It is easily verified that assumptions (A1)–(A5) are satisfied and that the theory in section 2.2 applies.

To simulate the closed-loop system, we discretized equations (2.26)–(2.29) using a linear spline based Galerkin scheme. We approximated the plant and reference model state space H by $H^n = \text{span}\,\{\varphi_j^n\}_{j=1}^{n-1}$, where the linear B-splines φ_j^n are given by (5.1). We also used linear B-splines to discretize the parameter space Q. We set $Q^m = span\{\varphi_j^m\}_{j=0}^m$, where the linear spline basis $\{\varphi_j^m\}_{j=0}^m$ is again given by (5.1) with n replaced by m. Note that $\dim H^n = n-1$ and $\dim Q^m = m+1$. Consequently, the dimension of the approximating estimator is $n-1+m+1 = n+m$.

We set $a_0 = 0.1$, $\omega_1 = 0.1$, $\omega_2 = 0.0001$, $\overline{q}(x) = \frac{1}{10}\left\{1 - \frac{1}{2}\sin\left(2\pi\{x - \frac{1}{4}\}\right)\right\}$, $0 < x < 1$, $q_0(x) = 0.1$, $u_0(x) = 0.3(0.5 - |0.5 - x|)$, and $v_0(x) = -0.1\sin(\pi x)$ for $0 \le x \le 1$. We chose the input reference signal g to be given by

$$g(t,x) = .1\left\{\sin\left(\frac{\pi}{24}t\right) + \cos\left(\frac{\pi}{50}t\right) + \frac{1}{2}\cos\left(\frac{\pi}{30}t\right)\right\}\chi_{[.4,.6]}(x), \quad 0 < x < 1,\ t > 0.$$

The results of our numerical study with $n = 24$ and $m = 16$ are displayed in Figures 5.2a and 5.2b. In Figure 5.2a we have plotted q_0, $\overline{q}$, and the estimate for $\overline{q}$, $q(t)$, at $t = 25$. In Figure 5.2b we have plotted the L_2 norm of the state tracking error $|e(t)| = |u(t) - v(t)|$ for $0 \le t \le 50$. It is clear that the control objective has been met and that an excellent estimate for $\overline{q}$ has been obtained.

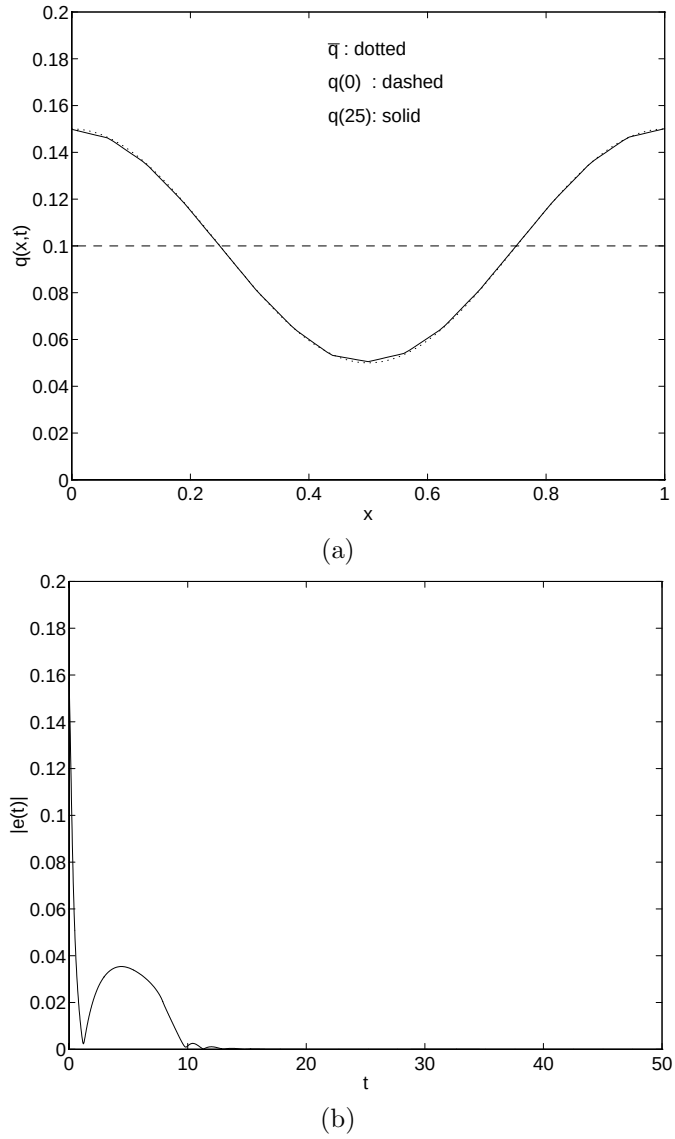

FIG. 5.2. *Results for Example* 5.2*:* (a) *the parameter estimate versus time;* (b) *the tracking error versus time.*

Example 5.3. In this example we consider the control of the one-dimensional wave equation with Kelvin–Voigt viscoelastic damping given by

$$\frac{\partial^2 u_1}{\partial t^2}(t,x) - \overline{q}_2 \frac{\partial^2}{\partial x^2}\frac{\partial u_1}{\partial t}(t,x) - \overline{q}_1 \frac{\partial^2 u_1}{\partial x^2} = f_1(t,x),\ 0 < x < 1,\ t > 0, \tag{5.6}$$

with the Dirichlet (fixed endpoint) boundary conditions

$$u_1(t,0) = 0 = u_1(t,1), \qquad t > 0, \tag{5.7}$$

and the initial conditions

$$u_1(0,x) = u_{01}(x), \qquad \text{and} \qquad \frac{\partial u_1}{\partial t}(0,x) = u_{02}(x), \qquad 0 \le x \le 1. \tag{5.8}$$

We take the reference model to be given by

$$\frac{\partial^2 v_1}{\partial t^2}(t,x) - b_0 \frac{\partial^2}{\partial x^2}\frac{\partial v_1}{\partial t}(t,x) - a_0 \frac{\partial^2 v_1}{\partial x^2} = g_1(t,x),\ 0 < x < 1,\ t > 0, \tag{5.9}$$

$$v_1(t,0) = 0 = v_1(t,1), \qquad t > 0, \tag{5.10}$$

$$v_1(0,x) = v_{01}(x), \qquad \text{and} \qquad \frac{\partial v_1}{\partial t}(0,x) = v_{02}(x), \qquad 0 \le x \le 1, \tag{5.11}$$

where $a_0, b_0 > 0$. To apply our theory in this case requires rewriting the plant and reference model as equivalent first-order systems. Let $H_1 = L_2(0,1)$ be endowed with the standard inner product and corresponding induced norm denoted by $\langle \cdot, \cdot \rangle_1$ and $|\cdot|_1$, respectively. Let $V_1 = H_0^1(0,1)$ be endowed with the inner product (and corresponding induced norm) given by $[\varphi, \psi]_1 = \langle D\varphi, D\psi \rangle_1$ for $\varphi, \psi \in V_1$. Let $H = V_1 \times H_1$ and $V = V_1 \times V_1$. We endow V with the usual product inner product, but we endow H with the inner product given by

$$\langle \varphi, \psi \rangle = \gamma \{a_0[\varphi_1, \psi_1]_1 + \langle \varphi_2, \psi_2 \rangle_1\} + \langle \varphi_1, \psi_2 \rangle_1 + \langle \varphi_2, \psi_1 \rangle_1 + b_0[\varphi_1, \psi_1]_1,$$

for $\varphi = (\varphi_1, \varphi_2), \psi = (\psi_1, \psi_2) \in H$, where $\gamma > 0$. It is not difficult to argue that if $\gamma > \max\{1, a_0^{-1}, b_0^{-1}\}$, then the norm induced by this inner product is equivalent to the standard norm on H. The inner product on H is chosen in this way so that assumption (A4) will be satisfied by the operator A_0 to be defined below. We note that this choice of an inner product affects the form of the estimator equation (2.24). Thus, in practice, γ serves as an additional tuning parameter or adaptive gain.

We let $Q = \mathbf{R}^2$ with the weighted inner product given by $\langle q, p \rangle = q^T \Omega p$, $q, p \in \mathbf{R}^2$, where Ω is the 2×2 matrix given by $\Omega = \operatorname{diag}(\omega_1, \omega_2)$, with $\omega_1, \omega_2 > 0$.

For $q = (q_1, q_2)^T \in Q$, we define the operator $A(q) \in \mathcal{L}(V, V)$ by $A(q) = A_1(q) + A_2$, where $\langle A_1(q)\varphi, \psi \rangle = q_2 \langle D\varphi_2, D\psi_2 \rangle + q_1 \langle D\varphi_1, D\psi_2 \rangle$, $\varphi = (\varphi_1, \varphi_2)$, $\psi = (\psi_1, \psi_2) \in V$, and $\langle A_2\varphi, \psi \rangle = -a_0 \langle D\varphi_2, D\psi_1 \rangle$, $\varphi = (\varphi_1, \varphi_2)$, $\psi = (\psi_1, \psi_2) \in V$. We take the operator $A_0 \in \mathcal{L}(V, V^*)$ to be given by $A_0 = A(q^*)$, where $q^* = (a_0, b_0) \in Q$. We set $f = (0, f_1)$, $g = (0, g_1)$, $u_0 = (u_{01}, u_{02})$, and $v = (v_{01}, v_{02})$. Thus we have rewritten the plant (5.6)–(5.8) in the form (2.6), (2.7) and the reference model (5.9)–(5.11) in the form (2.8), (2.9) with $u = (u_1, D_t u_1)$ and $v = (v_1, D_t v_1)$. It can be verified that assumptions (A1)–(A5) are satisfied with $\hat{V}^* = \{(0, \varphi) : \varphi \in H^{-1}(0,1)\} \subset V^* = H_0^1(0,1) \times H^{-1}(0,1)$.

To simulate the closed-loop system, we again approximate using the linear spline basis given in (5.1) and a Galerkin scheme. We set $H_1^n = \operatorname{span}\{\varphi_j^n\}_{j=1}^{n-1}$ and set $H^n = H_1^n \times H_1^n$. We took $\overline{q} = (0.0308, 0.01)$, $q^* = (a_0, b_0) = (0.0056, 0.0028)$, and $q_0 = (0.02, 0.005)$. We set $u_{01}(x) = 0.01 \sin(\pi x)$, $u_{02}(x) = 0.001 \sin(4\pi x)$, $0 \le x \le 1$, $v_{01}(x) = 0$, $v_{02}(x) = 0$, $0 \le x \le 1$, and

$$g_1(t,x) = \{4 \sin(4\pi t) + \cos(\pi t) + 2\}\, \chi_{[.215,.315]}(x),\ t > 0,\ 0 < x < 1.$$

We chose the adaptive gains to be $\omega_1 = \omega_2 = 1600/3$ and $\gamma = 100 + 1/b_0 = 457.15$. We then simulated the closed-loop system with $n = 16$. In Figure 5.3 we have plotted

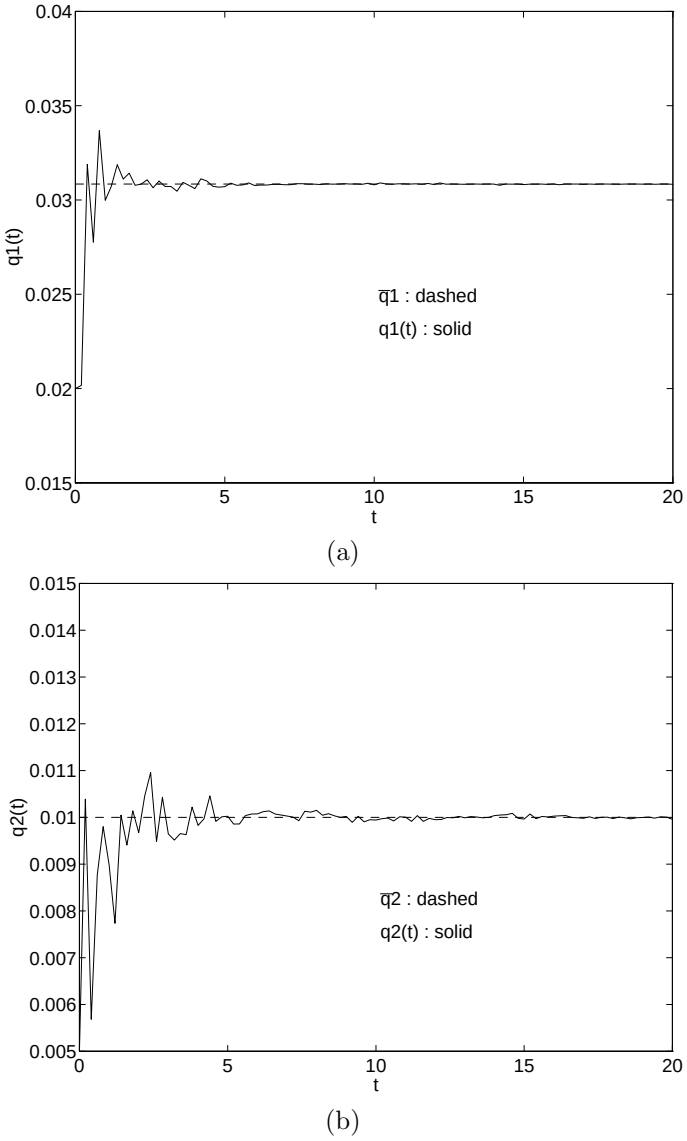

FIG. 5.3. *Results for Example* 5.3: (a) *the parameter estimate* $q_1(t)$ *versus time;* (b) *the parameter estimate* $q_2(t)$ *versus time.*

the estimate for $\overline{q}_1$ $q_1(t)$, and the estimate for $\overline{q}_2$, $q_2(t)$, for $t \in [0, 20]$. In Figure 5.4 we have plotted the V_1 norm of the displacement tracking error $\|e(t)\|_1 = \|u_1(t) - v_1(t)\|_1$ and the H_1 norm of the velocity tracking error $|D_t e(t)|_1 = |D_t u_1(t) - D_t v_1(t)|_1$ for $t \in [0, 100]$.

Example 5.4. In this example we consider the control of the one-dimensional nonlinear (strictly speaking, quasi-linear) heat equation

$$\frac{\partial u}{\partial t}(t,x) - \frac{\partial}{\partial x}\left\{\overline{q}\left(\min\left\{M, \left|\frac{\partial u}{\partial x}(t,x)\right|\right\}\right)\frac{\partial u}{\partial x}(t,x)\right\} = f(t,x), \tag{5.12}$$

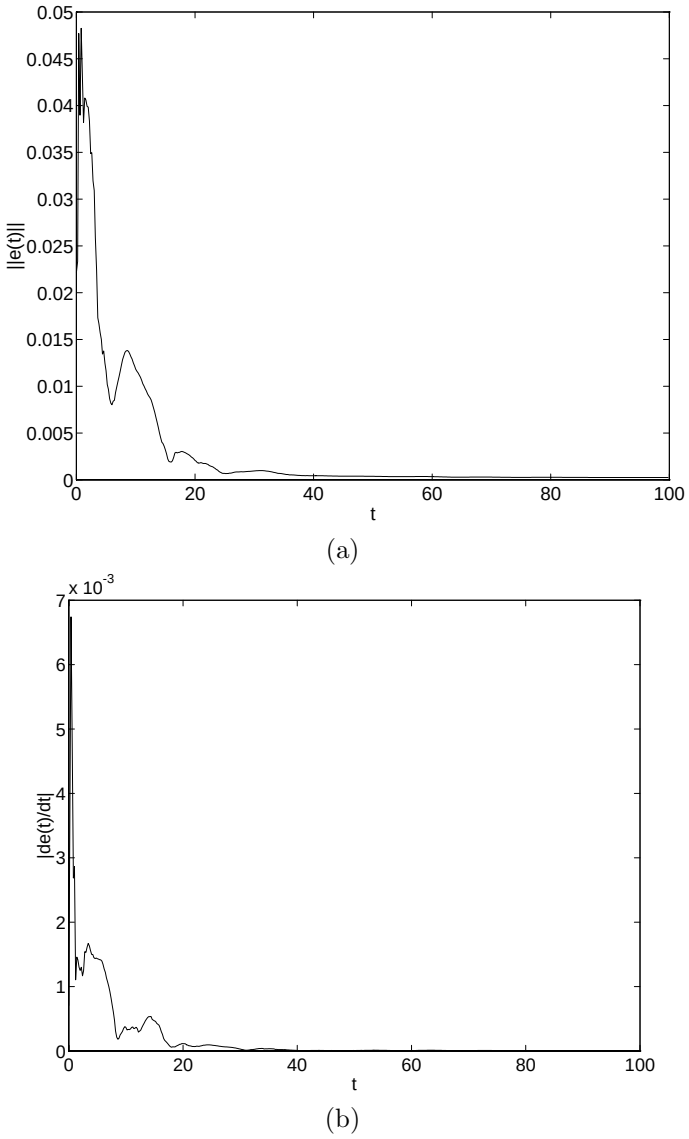

FIG. 5.4. *Results for Example* 5.3: (a) *the V_1-norm of the displacement tracking error;* (b) *the H_1-norm of the velocity tracking error.*

for $0 < x < 1$, $t > 0$, together with the Dirichlet boundary conditions

$$u(t,0) = 0 \qquad \text{and} \qquad u(t,1) = 0, \qquad t > 0, \tag{5.13}$$

and the initial conditions

$$u(0,x) = u_0(x), \qquad 0 \le x \le 1. \tag{5.14}$$

We assume that $M \in [0,\infty)$, $u_0 \in L_2(0,1)$, and $f(t,\cdot) \in L_2(0,1)$ for $t \ge 0$. We assume that the nonlinearity $\overline{q}$ is unknown and is to be identified as the system

(5.12)–(5.13) is being adaptively controlled. Once again, we take the reference model to be given by (5.2)–(5.4).

We let $H = L_2(0,1)$ be endowed with the standard inner product, we let $V = H_0^1(0,1)$ be endowed with the usual norm, and we define the Hilbert space Q as follows. Let $\hat{Q} = H^1(\mathbf{R}^+)$ and define the inner product, $\langle \cdot, \cdot \rangle_Q$, on $\hat{Q}$ by

$$\langle q, p \rangle_Q = \int_0^\infty \omega_0(\theta) q(\theta) p(\theta) d\theta + \int_0^\infty \omega_1(\theta) Dq(\theta) Dp(\theta) d\theta, \quad q, p \in \hat{Q}, \tag{5.15}$$

where $\omega_0, \omega_1 \in L_1(\mathbf{R}^+)$ are positive weighting functions. Let $|\cdot|_Q$ denote the norm induced by the inner product given in (5.15), and define the Hilbert space Q to be the completion of the inner product space $\{\hat{Q}, \langle \cdot, \cdot \rangle_Q, |\cdot|_Q\}$. For $q \in Q$, the operator $A(q) : V \to V^*$ is given by $A(q) = A_1(q)$, where $A_1(q) : V \to V^*$ is defined by

$$\langle A_1(q)\varphi, \psi \rangle = \int_0^1 q \left(\min \{M, |D\varphi(x)|\} \right) D\varphi(x) D\psi(x) dx, \qquad \varphi, \psi \in V.$$

The operator $A_0 \in \mathcal{L}(V, V^*)$ is once again given by (5.5). We set $\hat{V}^* = V^* = H^{-1}(0,1)$. It is not difficult to verify that assumptions (A1)–(A5) are satisfied.

To simulate the closed-loop system, we again approximate the plant and reference model state space H and the parameter space Q using linear B-spline functions. We approximate H by $H^n = span\{\varphi_j^n\}_{j=1}^{n-1}$, where for each $n = 2, 3, \ldots$ and $j = 1, 2, \ldots n-1$, φ_j^n is given by (5.1). For each $m = 1, 2, \ldots$ and each $r > 0$, let $\{\hat{\psi}_j^{m,r}\}_{j=0}^m$ be the standard linear B-splines on the interval $[0, r]$ defined with respect to the uniform mesh $\{0, \frac{r}{m}, \frac{2r}{m}, \ldots, r\}$. We approximate Q by $Q^{m,r} = span\{\psi_j^{m,r}\}_{j=0}^m$, where

$$\psi_j^{m,r} = \begin{cases} \hat{\psi}_j^{m,r}, & j = 0, 1, 2, \ldots, m-1, \\ \hat{\psi}_m^{m,r} + \chi_{[r,\infty)}, & j = m, \end{cases}$$

with χ_J denoting the characteristic function for the interval J. In the simulations to be described below, only q is discretized. The *true value* of $\overline{q}$, $\overline{q}(\theta) = 0.9(1 - \frac{1}{2}e^{-\frac{1}{2}\theta^2})$, $\theta \geq 0$, is used. We chose g to be given by

$$\begin{aligned} g(t,x) \quad = \quad & 1 \times 10^{-4} \{ \sin(100\pi t) + \sin(250\pi t) + \sin(450\pi t) + \sin(550\pi t) \\ & + \sin(650\pi t) + \sin(850\pi t) + \cos(150\pi t) + \cos(350\pi t) \\ & + \cos(500\pi t) + \cos(700\pi t) \} \, \chi_{[0.6, 0.8]}(x), \quad 0 < x < 1, \ t > 0, \end{aligned}$$

and set $u_0(x) = 5 \times 10^{-5}$ and $v_0(x) = -0.1 \, (0.5 - |0.5 - x|)$, $0 < x < 1$. We set $a_0 = .1$, $r = 3.5$, $M = 10.0$,

$$\omega_0(\theta) = \omega_1(\theta) = \begin{cases} 1, & 0 \leq \theta < r, \\ \frac{1}{2} e^{-20\theta}, & r < \theta < \infty, \end{cases}$$

and $q_0(\theta) = 1$, $0 < \theta < \infty$. We simulated the closed-loop system over the time interval $[0, 20]$ using $n = 32$ and $m = 24$. In Figure 5.5a we have plotted our final (i.e., at time $t = 20$) estimate for $\overline{q}$, and in Figure 5.5b we have plotted the H-norm of the tracking error, $|e(t)| = |u(t) - v(t)|$, for $t \in [0, 20]$. We note that convergence of the

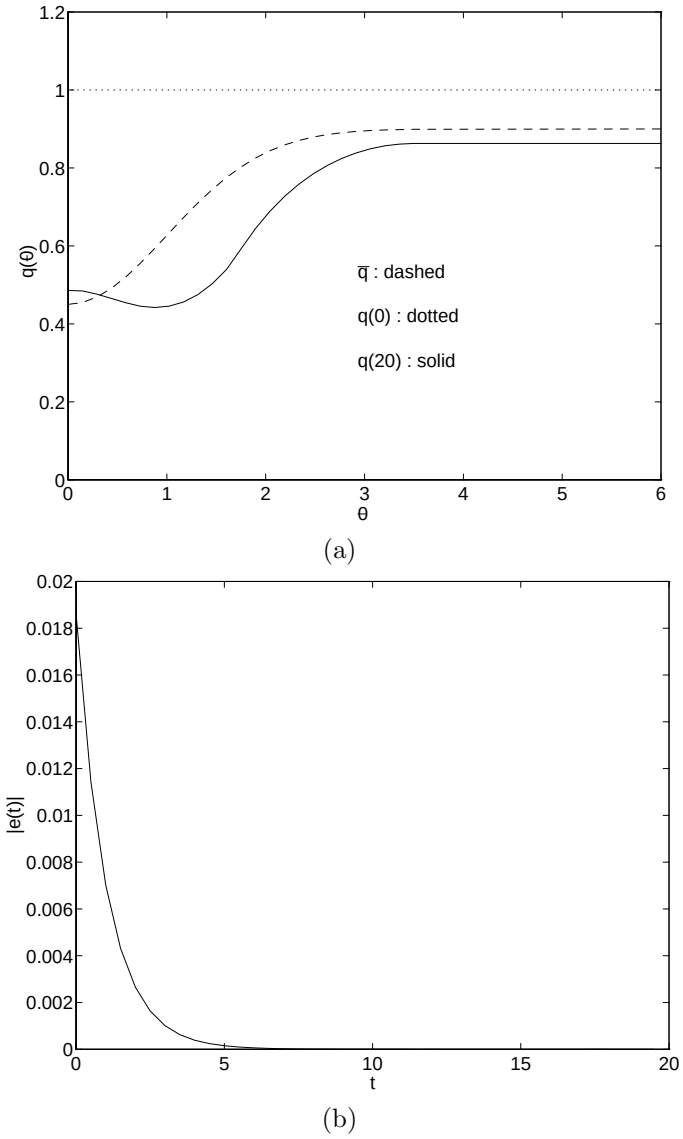

FIG. 5.5. *Results for Example* 5.4: (a) *the parameter estimate* $q(\theta)$ *versus* θ*;* (b) *the tracking error versus time.*

parameter estimates actually occurred at about $t = 5$. Our estimate for $\overline{q}$ in this example is not quite as good as the estimate obtained in Example 5.2. However, both the nonlinearity and the infinite domain of $\overline{q}$ (and therefore the need for an additional degree of approximation in the form of truncation) contribute to making this example a far more significant challenge for our scheme than the linear example discussed in Example 5.2.

Acknowledgments. The authors would like to gratefully acknowledge the referees for their careful reading of the manuscript and for their substantive comments and suggestions.

AN APPROXIMATION THEORY OF SOLUTIONS TO OPERATOR RICCATI EQUATIONS FOR H^∞ CONTROL*

KAZUFUMI ITO† AND K. A. MORRIS‡

Abstract. As in the finite-dimensional case, the appropriate state feedback for the infinite-dimensional H^∞ disturbance-attenuation problem may be calculated by solving a Riccati equation. This operator Riccati equation can rarely be solved exactly. We approximate the original infinite-dimensional system by a sequence of finite-dimensional systems and consider the corresponding finite-dimensional disturbance-attenuation problems. We make the same assumptions required in approximations for the classical linear quadratic regulator problem and show that the sequence of solutions to the corresponding finite-dimensional Riccati equations converge strongly to the solution to the infinite-dimensional Riccati equation. Furthermore, the corresponding finite-dimensional feedback operators yield performance arbitrarily close to that obtained with the infinite-dimensional solution.

1. Introduction.

In this paper we discuss H^∞ control problems for the linear system in a Hilbert space X:

$$\frac{d}{dt}x(t) = Ax(t) + Bu(t) + Dv(t), \quad x(0) = x \in X, \tag{1.1}$$

where the linear closed operator A generates the C_0-semigroup $S(t)$ on X. Let W, U, and Y be separable Hilbert spaces. The signal $v(t) \in L^2(0,\infty;W)$ is a W-valued disturbance and $u(t) \in L^2(0,\infty;U)$ is the control input. We assume that the disturbance operator D and the input operator B are bounded, i.e., $D \in \mathcal{L}(W,X)$ and $B \in \mathcal{L}(U,X)$. Let $C \in \mathcal{L}(X,Y)$ be the reference output operator. For control cost $\epsilon > 0$, define the output

$$z(t) = \operatorname{col}\left(Cx(t), \sqrt{\epsilon}\, u(t)\right) \tag{1.2}$$

and the performance index

$$\rho(u,v;x) = |z|^2_{L^2(0,\infty;Y)} = \int_0^\infty |Cx(t)|^2 + \epsilon|u(t)|^2\, dt.$$

Let

$$\mathcal{U} = L^2(0,\infty;U), \quad \mathcal{W} = L^2(0,\infty;W).$$

This paper is concerned with the problem of constructing a stabilizing feedback control law $u(t) = -Kx(t)$ such that for each disturbance $w \in \mathcal{W}$, the closed-loop solution of

*Received by the editors September 19, 1994; accepted for publication (in revised form) October 8, 1996.

(1.1) with $x(0) = 0$ satisfies

$$\rho(-Kx(t), v; 0) \leq (\gamma^2 - \delta)\, |v|^2_{L^2(0,\infty;W)} \tag{1.3}$$

for given attenuation bound $\gamma > 0$ and some $\delta > 0$. The problem described above is equivalent to so-called H^∞-disturbance attenuation: for given $\gamma > 0$ construct an exponentially stabilizing linear feedback $u(t) = -Kx(t)$ such that the attenuation bound

$$\sup_{\omega \in \mathbf{R}} \left| \begin{pmatrix} C \\ \sqrt{\epsilon} K \end{pmatrix} (i\omega I - (A - BK))^{-1} D \right| < \gamma \tag{1.4}$$

is satisfied. Such problems arise in a variety of contexts; robust stabilization is one of the most important.

DEFINITION 1.1. *If there is $\delta > 0$ such that for each $v \in \mathcal{W}$ there exists a control $u \in \mathcal{U}$ with*

$$\rho(u, v; 0) \leq (\gamma^2 - \delta)\, |v|^2_{\mathcal{W}},$$

the problem is said to be stabilizable with attenuation γ.

As in the finite-dimensional case, the H^∞ disturbance-attenuation problem is solvable if and only if the problem is stabilizable with attenuation γ (Theorem 2.2). Furthermore, in this case an appropriate state feedback may be calculated by solving an operator Riccati equation. Unfortunately, this Riccati equation can rarely be solved exactly. In this paper we approximate the original system (1.1)–(1.2) by a sequence of finite-dimensional systems and consider the corresponding finite-dimensional disturbance-attenuation problems.

The classical linear quadratic regulator (LQR) problem may be regarded as a limiting case of the H^∞ disturbance-attenuation problem, with the required disturbance attenuation $\gamma \to \infty$. The approximation theory for the linear quadratic case is fairly complete (e.g., see [GI, BK, IT1, IT2]). We make the same assumptions required in the linear quadratic case and show that a sequence of solutions to finite-dimensional Riccati equations converges strongly to the solution to the infinite-dimensional Riccati equation required to solve the H^∞ disturbance-attenuation problem. Furthermore, and more importantly, the corresponding finite-dimensional feedback control operators yield performance arbitrarily close to that obtained with the infinite-dimensional solution. A key step of the proof of these results is the game-theoretic representation ([KE, (2.10) in the proof of Theorem 2.2]) of the solution to the H^∞ Riccati equation in terms of the closed-loop solution to the standard LQR problem.

The notation that is used in this paper is standard as in [PA]. Background on linear semigroup theory may also be found in [PA]. An outline of the paper is as follows. In section 2 the solution to the H^∞ disturbance-attenuation problem in terms of the operator Riccati equation (2.1) is described, and an approximation theory of solutions to (2.1) is developed. Our theoretical results are demonstrated numerically in section 3 using a Euler–Bernoulli beam example.

2. Approximation theory. In this section we develop an approximation theory for the H^∞ disturbance-attenuation problem.

DEFINITION 2.1. (1) *The pair (A, B) is* stabilizable *if there exists a bounded linear operator $F : X \to U$ such that $A - BF$ generates an exponentially stable semigroup on X.*

(2) *The pair* (A, C) *is* detectable *if there exists a bounded linear operator* $G : Y \to X$ *such that* $A - GC$ *generates an exponentially stable semigroup on* X.

(3) *The state feedback* $K \in \mathcal{L}(X, U)$ *is* γ-admissible *if it is exponentially stabilizing and the linear feedback* $u(t) = -Kx(t)$ *is such that the attenuation bound* (1.3) *is achieved.*

A key result in the finite-dimensional and the infinite-dimensional theory is that if the problem is stabilizable with attenuation γ, then it is stabilizable by state feedback.

THEOREM 2.2 (see, e.g., [KE, Thm. 4.4]). *Assume that* (A, B) *is stabilizable and* (A, C) *is detectable. For* $\gamma > 0$ *the following are equivalent:*

- *there exists a* γ*-admissible state feedback;*
- *the system is stabilizable with disturbance attenuation* γ*;*
- *there exists a nonnegative, self-adjoint operator* Σ *on* X *satisfying the Riccati equation*

$$\left(A^*\Sigma + \Sigma A - \frac{1}{\epsilon}\Sigma BB^*\Sigma + \frac{1}{\gamma^2}\Sigma DD^*\Sigma + C^*C\right)x = 0 \tag{2.1}$$

for all $x \in dom(A)$*, and* $A - \frac{1}{\epsilon}BB^*\Sigma + \frac{1}{\gamma^2}DD^*\Sigma$ *generates an exponentially stable semigroup on* X.

Moreover, in this case a γ*-admissible state feedback is given by* $\hat{K} = \frac{1}{\epsilon}B^*\Sigma$.

An approximation theory for solutions to (2.1) which numerically approximate the feedback operator $\hat{K} = B^*\Sigma/\epsilon$ is developed below. Let X^N be a finite-dimensional subspace of X, and let P^N be the orthogonal projection of X onto X^N. The space X^N is equipped with the induced norm from X. Consider a sequence of operators $A^N \in \mathcal{L}(X^N, X^N)$, $B^N = P^N B \in \mathcal{L}(U, X^N)$, $D^N = P^N D$, and $C^N =$ the restriction of C onto X^N. The operator A^N can be extended to all of X by $A^N P^N x$.

Approximation Assumptions.

(A1) For each $x \in X$ we have

$$\text{(i)} \quad e^{A^N t}P^N x \to S(t)x,$$

$$\text{(ii)} \quad (e^{A^N t})^* P^N x \to S^*(t)x,$$

uniformly in t on bounded intervals.

(A2) (i) The family of pairs (A^N, B^N) is uniformly exponentially stabilizable; i.e., there exists a uniformly bounded sequence of operators $K^N \in \mathcal{L}(X^N, U)$ such that

$$\left|e^{(A^N - B^N K^N)t}P^N x\right|_X \le M_1\, e^{-\omega_1 t}\,|x|_X \tag{2.2}$$

for some positive constants $M_1 \ge 1$ and ω_1.

(ii) The family of pairs (A^N, C^N) is uniformly exponentially detectable; i.e., there exists a uniformly bounded sequence of operators $G^N \in \mathcal{L}(Y, X^N)$ such that

$$\left|e^{(A^N - G^N C^N)t}P^N x\right|_X \le M_2\, e^{-\omega_2 t}, \quad t \ge 0, \tag{2.3}$$

for some positive constants $M_2 \ge 1$ and ω_2.

(A3) The input operator B and disturbance operator D are compact.

Remarks. (1) Note that (A1) implies that $P^N x \to x$ for $x \in X$.

(2) Assumption (A1) and the uniform boundedess theorem imply the boundedness of $|e^{A^N t}P^N|_{\mathcal{L}(X,X)}$ uniformly in $t \in [0, 1]$ and N. Then the standard semigroup

theorem, e.g., [PA, Chapter 1, Theorem 2.2], implies that $|e^{A^N t}P^N x|_X \le M_0\, e^{\omega_0 t}|x|_X$ for some $M_0 \ge 1$ and $\omega_0 \in R$.

(3) For an important equivalent statement of (A1)(i) we note the Trotter–Kato theorem.

THEOREM 2.3 (Trotter–Kato Theorem; see, e.g., [PA, Chapter 3, Theorem 4.2]). *Assume the stability of approximation*

$$|e^{A^N t}P^N x|_X \le M_0\, e^{\omega_0 t}|x|_X \quad \textit{for some } M_0 \ge 1 \textit{ and } \omega_0 \in R.$$

Then the convergence (A1)(i)

$$e^{A^N t}P^N x \to S(t)x \quad \textit{for every } x \in X \textit{ and uniformly on bounded } t \textit{ intervals}$$

is equivalent to the consistency: for some $\lambda \in \rho(A)$

$$\left|(\lambda I - A^N)^{-1}P^N x - (\lambda I - A)^{-1}x\right|_X \to 0$$

as $N \to \infty$ *for all* $x \in X$.

(4) The convergence (A1)(ii) of the adjoint semigroup sequence $(e^{A^N t})^*$ is required for the strong convergence of the approximating feedback gain operators. A counterexample may be found in [BIP].

(5) In (A2)(i) if we let $K^N = KP^N$, then condition (2.2) becomes the preservation of exponential stability under approximation of the semigroup $T(t)$ generated by $A - BK$.

(6) Assumption (A3) is equivalent to

$$\lim |P^N D - D| = 0, \quad \lim |P^N B - B| = 0 \quad \text{as } N \to \infty$$

since X^N is finite dimensional.

Assumptions (A1)–(A2) are identical to those required to show that the solutions to the Riccati equations arising in the approximation theory for linear quadratic problem converge, e.g., [IT1]. Assumption (A3) is not required in the standard LQR problem for the existence of solutions to a family of approximating finite-dimensional Riccati equations. However, this assumption is required to ensure continuity of performance measure and to guarantee that the approximating controllers stabilize the infinite-dimensional system [IT2, MO1, MO2].

Before presenting the approximation result and its proof we state a technical lemma which plays an important role in the proof.

LEMMA 2.4 (Datko lemma; see, e.g., [SA, Theorem 6.2]). *Let* $S(t),\ t \ge 0$ *be a linear* C_0*-semigroup on a Banach space* X *satisfying the exponential bound*

$$|S(t)| \le Me^{\omega t}$$

for some constants $M \ge 1,\ \omega \ge 0$. *Moreover, let* $1 \le p < \infty$, *and suppose that there exists a constant* $c > 0$ *such that*

$$\int_0^\infty |S(t)x|_X^p\, dt \le c^p\, |x|_X^p, \quad x \in X.$$

Then, for every

$$\alpha > -\frac{1}{pc^p M^p},$$

there exists a $\gamma = \gamma(\alpha, \omega, M, c, p) \geq 1$ *such that*

$$|S(t)| \leq \gamma\, e^{\alpha t}, \quad t \geq 0.$$

Now we state our main approximation result.

THEOREM 2.5. *Assume that* (A, B) *is stabilizable,* (A, C) *is detectable, and* (A1)–(A3) *are satisfied. If the original problem is stabilizable with attenuation* γ*, then so are the approximating systems for sufficiently large* N*. For such* N*, the Riccati equation*

$$(A^N)^*\Sigma^N + \Sigma^N A^N - \frac{1}{\epsilon}\Sigma^N B^N (B^N)^*\Sigma^N + \frac{1}{\gamma^2}\Sigma^N D^N (D^N)^*\Sigma^N + (C^N)^* C^N = 0 \tag{2.4}$$

has a nonnegative, self-adjoint solution Σ^N *and* $\Sigma^N P^N x \to \Sigma\, x$ *strongly in* X *as* $N \to \infty$*. Moreover,* $\hat{K}^N = \frac{1}{\epsilon}(B^N)^*\Sigma^N$ *converges to* $\hat{K} = \frac{1}{\epsilon}B^*\Sigma$ *in norm. For* N *sufficiently large,* $\hat{K}^N$ *is* γ*-admissible for the infinite-dimensional problem.*

Proof. The proof is given in several steps. First, we give a brief description of the representation of Σ. This is used to show that for large N the approximating systems are stabilizable with attenuation γ and so for such N the finite-dimensional Riccati equation (2.4) has a solution Σ^N. We show that $\Sigma^N \to \Sigma$ and $\hat{K}^N \to \hat{K}$. Finally, we show that the approximating finite-dimensional feedback $\hat{K}^N$ is γ-admissible for the original system.

Step 1. First we briefly review the representation of Σ. Details may be found in [KE, Theorem 4.4] or [BB]. Since (A, B) is stabilizable and (A, C) is detectable, the (LQR) Riccati equation

$$\left(A^*\Pi + \Pi A - \frac{1}{\epsilon}\Pi B B^*\Pi + C^*C\right)x = 0 \quad \text{for all } x \in \mathrm{dom}(A) \tag{2.5}$$

has the unique nonnegative, self-adjoint solution Π. Let $S_c(t)$ be the exponentially stable semigroup generated by $A - \frac{1}{\epsilon}BB^*\Pi$.

Consider the quadratic differential game

$$\max_{v \in \mathcal{W}} \min_{u \in \mathcal{U}} \rho(u, v; x) - \gamma^2 |v|^2_{\mathcal{W}}$$

subject to (1.1).

Define $L \in \mathcal{L}(\mathcal{W}, L^2(0, \infty; X))$ by

$$(Lv)(t) = \int_t^\infty S_c^*(\tau - t)\Pi D v(\tau)\, d\tau. \tag{2.6}$$

For a disturbance v and $x \in X$

$$u^*(t) = -\frac{1}{\epsilon}B^*\left[\Pi x(t) + (Lv)(t)\right] \tag{2.7}$$

minimizes $\rho(u, v; x)$ over $u \in \mathcal{U}$ subject to (1.1).

For $x \in X$, $v \in \mathcal{W}$, write $r(t) = (Lv)(t)$ and define the quadratic form

$$\begin{aligned} J(v; x) &= \rho(u^*, v; x) - \gamma^2 |v|^2_{\mathcal{W}} \\ &= (x, \Pi x + 2\, r(0)) + \int_0^\infty 2\,(Dv(t), r(t)) - \frac{1}{\varepsilon}\,|B^* r(t)|^2 - \gamma^2\,|v(t)|^2\, dt. \end{aligned}$$

Defining the self-adjoint operator Q on $\mathcal{W}$ by

$$Q = \gamma^2\, I + \frac{1}{\epsilon}L^* B B^* L - D^* L - L^* D, \tag{2.8}$$

we have

$$J(v;x) = -(Qv,v)_{\mathcal{W}} + 2\,(D^*\Pi S_c(\cdot)x, v)_{\mathcal{W}} + (\Pi x, x).$$

If the system (1.1)−(1.2) is stabilizable with attenuation γ, then for some $\delta > 0$

$$J(v;0) = \rho(u^*, v; 0) - \gamma^2\,|v|^2_{\mathcal{W}} \le -\delta\,|v|^2_{\mathcal{W}}.$$

Thus $Q \ge \delta I$ and maximization of $J(v;x)$ over $v \in \mathcal{W}$ is well posed. The solution to this problem, the worst disturbance v^*, is the unique solution to

$$Qv^* - D^*\Pi S_c(\cdot)x = 0, \quad x \in X. \tag{2.9}$$

We define the self-adjoint operator Σ on X by

$$(\Sigma x, x) = \max\ J(v,x) = (D^*\Pi S_c(\cdot)x, v^*)_{\mathcal{W}} + (\Pi x, x)$$

for $x \in X$. This implies

$$\Sigma x = \Pi x + \int_0^\infty S_c^*(t)\Pi D v^*(t)\,dt. \tag{2.10}$$

It is shown in [KE, BB] that Σ satisfies the Riccati equation (2.1) and is unique within the class of nonnegative, self-adjoint solutions to (2.1) such that the closed-loop semigroup generated by $A - \frac{1}{\epsilon}BB^*\Sigma + \frac{1}{\gamma^2}DD^*\Sigma$ is exponentially stable on X.

Moreover, the optimal pair (u^*, v^*) to the differential game is of feedback form:

$$u^*(t) = -\frac{1}{\epsilon}\,B^*\Sigma x(t), \quad v^*(t) = \frac{1}{\gamma^2}\,D^*\Sigma x(t).$$

Step 2. Next, we show that the finite-dimensional Riccati equation (2.4) has a nonnegative solution by showing that the finite-dimensional system is stabilizable with attenuation γ.

Under assumptions (A1)−(A2) it is shown in [IT1] that the (LQR) Riccati equation on X^N

$$(A^N)^*\Pi + \Pi^N A^N - \frac{1}{\epsilon}\Pi^N B^N (B^N)^*\Pi^N + (C^N)^* C^N = 0 \tag{2.11}$$

has the unique nonnegative, self-adjoint solution Π^N and also that $\Pi^N P^N x \to \Pi\, x$ strongly in X as $N \to \infty$. Define $S_c^N(t) = e^{(A^N - \frac{1}{\epsilon}B^N B^{N*}\Pi^N)t}$. It is also shown in [IT1] that there exist constants $M_3 \ge 1$ and $\omega_3 > 0$ such that

$$|S_c^N(t)P^N x| \le M_3 e^{-\omega_3 t}\,|x|_X. \tag{2.12}$$

Let $\bar{K}^N = \frac{1}{\epsilon}B^{N*}\Pi^N$ and $\bar{K} = \frac{1}{\epsilon}B^*\Pi$. Then, since B is compact, $|\bar{K}^N P^N - \bar{K}| \to 0$ as $N \to \infty$. Assumption (A1) implies

$$\left|(\lambda I - (A^N - B^N\bar{K}^N))^{-1}P^N x - (\lambda I - (A - B\bar{K}))^{-1}x\right|_X \to 0$$

for all $x \in X$ and also the similar statement for the sequence of adjoint operators. It thus follows from the Trotter–Kato theorem that

$$S_c^N(t)P^N x \to S_c(t)x \quad \text{and} \quad (S_c^N)^*(t)P^N x \to S_c^*(t)x \tag{2.13}$$

for all $x \in X$, uniformly on bounded t-intervals.

Since D is compact,

$$|(S_c^N)^*(t)\Pi^N D^N - S_c^*(t)\Pi D| \to 0 \tag{2.14}$$

uniformly in any bounded t-interval. For $\tau > 0$ and $p \in [1, \infty)$,

$$\begin{aligned}\int_0^\infty |(S_c^N)^*(t)\Pi^N D^N - S_c^*(t)\Pi D|^p \, dt \\ \leq \int_0^\tau |(S_c^N)^*(t)\Pi^N D^N - S_c^*(t)\Pi D|^p \, dt \\ + \int_\tau^\infty (|S_c^N(t)|^p |\Pi^N|^p + |S_c^*(t)|^p |\Pi|^p)|D|^p \, dt.\end{aligned}$$

Since from (2.12) the second term of the right-hand side is bounded by $Me^{-\omega\tau}$ for some positive constants M and ω, it follows from (2.13) that

$$\int_0^\infty |(S_c^N)^*(t)\Pi^N D^N - S_c^*(t)\Pi D|^p \, dt \to 0 \tag{2.15}$$

as $N \to \infty$ for all $p \in [1, \infty)$.

Define the linear operators L^N and Q^N on $\mathcal{W}$ for the approximate problem that corresponds to L and Q defined in (2.6) and (2.8), respectively. It then follows from (2.15) that

$$|L^N - L| \quad \text{and} \quad |Q^N - Q| \to 0 \tag{2.16}$$

as $N \to \infty$.

Define

$$z^N(u, v; x) = \operatorname{col}(C^N x^N(t), \sqrt{\epsilon} u(t)),$$

where x^N is the state of the approximating system with control u, disturbance v, and initial condition x. Also define the finite-dimensional cost

$$\rho^N(u, v, x) = |z^N|^2_{L^2(0,\infty;Y)}.$$

As in (2.7) define the control

$$u^N(t) = -\frac{1}{\epsilon}(B^N)^*[\Pi^N x^N(t) + L^N v(t)]. \tag{2.17}$$

Then, with initial condition $x = 0$,

$$x^N(t) = \int_0^t S_c^N(t-s)\left(-\frac{1}{\epsilon} B^N (B^N)^* (L^N v)(s) + D^N v(s)\right) ds. \tag{2.18}$$

Define the linear operators $\tilde{L}^N$, $\tilde{L} \in \mathcal{L}(L^2(0,\infty;X), L^2(0,\infty,X))$ by

$$(\tilde{L}^N f)(t) = \int_0^t S_c^N(t-s)\left(\frac{1}{\epsilon} B^N (B^N)^* f(s)\right) ds$$

and

$$(\tilde{L}f)(t) = \int_0^t S_c(t-s)\left(\frac{1}{\epsilon}BB^*f(s)\right)\,ds$$

Using the same arguments as above we can show that $|\tilde{L}^N - \tilde{L}| \to 0$ as $N \to \infty$. Since from (2.7)

$$x^*(t) = \int_0^t S_c(t-s)\left(-\frac{1}{\epsilon}BB^*(Lv)(s) + Dv(s)\right)\,ds,$$

it follows from (2.16) and (2.18) that

$$|x^N - x^*|^2_{L^2(0,\infty;X)} \le \epsilon_1(N)\,|v|^2_{\mathcal{W}},$$

where $\epsilon_1(N) \to 0$ as $N \to \infty$. Since C^N is the restriction of C on X^N it follows that

$$|\rho^N(u^N, v; 0) - \rho(u^*, v; 0)| \le \epsilon(N)\,|v|^2_{\mathcal{W}},$$

where $\epsilon(N) \to 0$ as $N \to \infty$. Therefore, for sufficiently large N, the approximating problems are stabilizable with attenuation γ.

This implies that the finite-dimensional Riccati equation (2.4) has a self-adjoint solution Σ^N on X^N

$$\Sigma^N P^N x = \Pi^N P^N x + \int_0^\infty (S_c^N)^*(t)\Pi^N D^N v^N(t)\,dt, \tag{2.19}$$

where $v^N(t) \in \mathcal{W}$ is the unique solution of

$$Q^N v^N - (D^N)^*\Pi^N S_c^N(\cdot)P^N x = 0. \tag{2.20}$$

Furthermore, $A^N - \frac{1}{\epsilon}B^N(B^N)^*\Sigma^N + \frac{1}{\gamma^2}D^N(D^N)^*\Sigma^N$ generates an exponentially stable semigroup on X^N, and $\hat{K}^N = \frac{1}{\epsilon}(B^N)^*\Sigma^N$ is γ-admissible for the approximating problem.

Step 3. We now show that Σ^N converges strongly to Σ and $\hat{K}^N$ converges uniformly to $\hat{K}$.

The uniform convergence of Q^N to Q implies that Q^N is coercive with $Q^N \ge \frac{\delta}{2}$ for N sufficiently large. Also, (2.15) implies that

$$\int_0^\infty |(D^N)^*\Pi^N S_c^N(t)P^N - D^*\Pi S_c(t)|^2 dt \to 0$$

as $N \to \infty$. Therefore, the solution to (2.20) satisfies

$$|v^N|_{\mathcal{W}} \le M\,|x|_X \tag{2.21}$$

for some constant M. Note that

$$Q(v^N - v^*) = (Q - Q^N)v^N + (D^N)^*\Pi^N S_c^N(t)P^N x - D^*\Pi S_c(t)x.$$

Hence, from (2.16) and (2.21) v^N converges strongly to v^* in $\mathcal{W}$ as $N \to \infty$ for each $x \in X$.

It now follows from (2.10), (2.15), and (2.19) that

$$\Sigma^N P^N x \to \Sigma x \quad \text{for all } x \in X.$$

Since B is compact, we have that $|(B^N)^*\Sigma^N P^N - B^*\Sigma| \to 0$. That is, $\hat{K}^N$ converges uniformly to $\hat{K}$.

Step 4. To prove that for large N the approximating feedback operators $\hat{K}^N$ are γ-admissible for the system (1.1)–(1.2), first note that by the Trotter–Kato theorem the convergence of $\hat{K}^N$ to $\hat{K}$ in norm implies that the semigroup $S_{\hat{K}^N}$ generated by $A - B\hat{K}^N$ converges to the semigroup $S_{\hat{K}}$ generated by $A - B\hat{K}$, strongly in X, uniformly in bounded intervals of time. Also, there exists $\tilde{M} \geq 1$, $\tilde{\omega} > 0$ such that for sufficiently large N,

$$|S_{\hat{K}^N}(t)|_X \leq \tilde{M} e^{-\tilde{\omega} t}.$$

The output (1.2) with a disturbance v, feedback control $u(t) = -\hat{K}^N x(t)$, and initial condition $x(0) = 0$ is

$$\bar{z}^N(t) = \begin{bmatrix} C \\ -\sqrt{\epsilon}\hat{K}^N \end{bmatrix} \int_0^t S_{\hat{K}^N}(t-s) D v(s)\, ds.$$

The convergence of the semigroups and the compactness of D imply, as in equation (2.15), that for any $p \in [1, \infty)$,

$$\int_0^\infty |S_{\hat{K}^N}(t)D - S_{\hat{K}}(t)D|^p \, dt \to 0.$$

Let $\bar{z}$ indicate the output (1.2) obtained with the same disturbance v but with feedback control $-\hat{K}x(t)$. Then

$$\int_0^\infty |\bar{z}^N(t) - \bar{z}(t)|_Y^2 \, dt \leq \epsilon(N)\, |v|_{\mathcal{W}}^2,$$

where $\epsilon(N) \to 0$ as $N \to \infty$. This implies that for large N, $\hat{K}^N$ is γ-admissible for the original system. □

COROLLARY 2.6. *Under the same assumptions as in Theorem* 2.3, *we have*

$$|v^N(t) - v^*(t)|_{\mathcal{W}} = 0,$$

$$|u^N(t) - u^*(t)|_{\mathcal{U}} = 0,$$

and there exist positive constants M_4, ω_4, M_5, *and* ω_5 *such that*

$$|e^{(A^N - \frac{1}{\epsilon}B^N(B^N)^*\Sigma^N + \frac{1}{\gamma^2}D^N(D^N)^*\Sigma^N)t} P^N x| \leq M_4 e^{-\omega_4 t}\, |x|_X\,, \tag{2.22}$$

$$|e^{(A^N - B^N\hat{K}^N)t} P^N x| \leq M_5 e^{-\omega_5 t}\, |x|_X\,. \tag{2.23}$$

Proof. The convergence of the worst disturbance v^N follows from the proof of Theorem 2.3.

We show that for large N, $A^N - \frac{1}{\epsilon}B^N(B^N)^*\Sigma^N + \frac{1}{\gamma^2}D^N(D^N)^*\Sigma^N$ generates a uniformly stable semigroup $T^N(t)$. Note that

$$v^N(t) = \frac{1}{\gamma^2}(D^N)^*\Sigma^N x^N(t), \quad u^N(t) = -\frac{1}{\epsilon}(B^N)^*\Sigma^N x^N(t)$$

and

$$\int_0^\infty |C^N x^N(t)|^2 + \epsilon|u^N(t)|^2\,dt = (\Sigma^N P^N x, x) + \gamma^2|v^N(t)|^2_{\mathcal{W}}, \tag{2.24}$$

where

$$x^N(t) = T^N(t)x = e^{(A^N - \frac{1}{\epsilon}B^N(B^N)^*\Sigma^N + \frac{1}{\gamma^2}D^N(D^N)^*\Sigma^N)t}P^N x, \quad x \in X.$$

Let G^N be as in (A2)(ii) so that $e^{(A^N - G^N C^N)t}$ is uniformly exponentially stable. Then we have

$$\begin{aligned} x^N(t) &= e^{(A^N - G^N C^N)t}P^N x \\ &\quad + \int_0^t e^{(A^N - G^N C^N)(t-s)}(G^N C^N x^N(s) + B^N u^N(t) + D^N v^N(t))\,dt. \end{aligned}$$

Note that from Hölder's inequality and the Fubini theorem

$$\begin{aligned} \int_0^\infty \left|\int_0^t f(t-s)g(s)\,ds\right|^2 dt &\le \int_0^\infty \int_0^t |f(t-s)|\,ds \int_0^t |f(t-s)||g(s)|^2\,ds \\ &\le \int_0^\infty |f(\sigma)|\,d\sigma \int_0^\infty \left(\int_s^\infty |f(t-s)|\,dt\right)|g(s)|^2\,ds \\ &\le \left(\int_0^\infty |f(\sigma)|\,d\sigma\right)^2 \int_0^\infty |g(t)|^2\,dt \end{aligned}$$

for $f \in L^1(0,\infty)$ and $g \in L^2(0,\infty)$. It thus follows from (A2)(ii), (2.21), (2.24) that

$$\begin{aligned} \int_0^\infty |x^N(t)|^2\,dt &\le \frac{M_2^2}{\omega_2}|x|^2 \\ &\quad + \frac{2M_2}{\omega_2}\int_0^\infty (|G^N|^2|C^N x^N(t)|^2 + |B^N|^2|u^N|^2 + |D^N|^2|v^N(t)|^2)\,dt \\ &\le \beta|x|_X^2 \quad \text{for some } \beta > 0. \end{aligned}$$

Hence, (2.22) follows from the Datko lemma. The proof of (2.23) is identical.

Let $T(t)$ be the semigroup generated by $A - \frac{1}{\epsilon}BB^*\Sigma + \frac{1}{\gamma^2}DD^*\Sigma$ on X. The above implies that $x^N(t)$ converges in $L^2(0,\infty;X)$ to $T(t)x$ (see the proof of Theorem 2.3) and so $u^N(t) \to u^*(t)$ in $L^2(0,\infty;X)$. □

Conversely, we have the following theorem.

THEOREM 2.7. *Suppose the Riccati equation* (2.4) *has uniformly bounded nonnegative self-adjoint solutions* Σ^N *on* X^N *for* N *sufficiently large with*

$$|v^N(t)|_{\mathcal{W}} \le M|x|_X^2 \quad \textit{for some } M > 0, \tag{2.25}$$

where

$$v^N(t) = \frac{1}{\gamma^2}(D^N)^*\Sigma^N e^{(A^N - \frac{1}{\epsilon}B^N(B^N)^*\Sigma^N + \frac{1}{\gamma^2}D^N(D^N)^*\Sigma^N)t}P^N x.$$

Assume that (A1), (A2)(ii), *and* (A3) *hold. Then, the system* (1.1) *is stabilizable with attenuation* γ.

Proof. It follows from [GI] that there exist a nonnegative self-adjoint operator Σ on X and a subsequence of Σ^N such that $\Sigma^N P^N x$ converges weakly to Σx in X for $x \in X$. It follows from (A3) that $(B^N)^*\Sigma^N P^N x$ and $(D^N)^*\Sigma^N P^N x$ converge strongly to $B^*\Sigma x$ and $D^*\Sigma x$, respectively. Let

$$T^N(t) = e^{(A^N - \frac{1}{\epsilon}B^N(B^N)^*\Sigma^N + \frac{1}{\gamma^2}D^N(D^N)^*\Sigma^N)t}$$

and $T(t)$ be the semigroup generated by $A - \frac{1}{\epsilon}BB^*\Sigma + \frac{1}{\gamma^2}DD^*\Sigma$ on X. It then follows from (A1) and the Trotter–Kato theorem that

$$T^N(t)P^N x \to T(t)x \quad \text{for each } x \in X,$$

uniformly on bounded t-intervals.

Note that

$$\Sigma^N P^N x = e^{(A^N)^* t}\Sigma^N T^N(t)P^N x + \int_0^t e^{(A^N)^*(t-s)}(C^N)^* C^N T^N(t-s)P^N x\, ds,\ x \in X.$$

Taking the limit as $N \to \infty$, we obtain

$$\Sigma x = S^*(t)\Sigma T(t)x + \int_0^t S^*(t-s)C^*CT(t-s)x\, ds,$$

which implies that Σ is a solution to (2.4).

Moreover, it follows from (2.25) and the proof of Corollary 2.6 that

$$|T^N(t)P^N x| \le M_4 e^{-\omega_4 t}\,|x|_X$$

for some positive constants M_4, ω_4, provided that (A2)(ii) holds. Hence, the semigroup $T(t)$ is exponentially stable.

It follows from Theorem 2.2 that the system (1.1) is stabilizable with attenuation γ. □

The optimal disturbance attenuation problem for the infinite-dimensional system (1.1) is to find

$$\hat{\gamma} = \inf\ \gamma$$

over all γ such that (1.2) is stabilizable with attenuation γ. Let $\{\hat{\gamma}^N\}$ indicate the corresponding optimal disturbance attenuation for the approximating problems. Theorem 2.3 implies that

$$\limsup_{N\to\infty} \hat{\gamma}^N \le \hat{\gamma}. \tag{2.26}$$

However, we have a stronger result.

THEOREM 2.8. *Assume that* (A1)–(A3) *hold,* (A, B) *is stabilizable, and* (A, C) *is detectable. Then*

$$\lim_{N\to\infty} \hat{\gamma}^N = \hat{\gamma}.$$

Proof. Because of (2.26), it is sufficient to show that

$$\liminf_{N\to\infty} \hat{\gamma}^N \geq \hat{\gamma}.$$

Assume that this statement is false. Then there is an $\delta > 0$ such that for all N there is $M > N$ with $\hat{\gamma}^M < \hat{\gamma} - \delta$. In this way we can construct a subsequence $\{\hat{\gamma}^M\}$ of the sequence $\{\hat{\gamma}^N\}$ with

$$\hat{\gamma}^M < \hat{\gamma} - \delta.$$

Thus, the approximating system is stabilizable with attenuation $\hat{\gamma} - \delta/2$ and

$$\rho^M(u^M, v; 0) \leq (\hat{\gamma} - \delta/2)\,|v|^2_{\mathcal{W}},$$

where for any $v \in \mathcal{W}$, $u^M(t)$ is defined by (2.17). Moreover, we have

$$|\rho^M(u^M, v; 0) - \rho(u^*, v; 0)| \leq \epsilon(M)\,|v|^2_{\mathcal{W}},$$

where $\epsilon(M) \to 0$ as $M \to \infty$ and $u^*(t) \in \mathcal{U}$ is given by (2.7). Hence the original problem is stabilizable with attenuation $\hat{\gamma} - \delta/2$. This contradicts the optimality of $\hat{\gamma}$ and thus (2.26) holds. ∎

The above theorem implies that if a sequence of approximating problems that satisfy assumptions (A1)–(A3) are stabilizable with attenuation γ, then so is the infinite-dimensional problem. Thus, Theorem 2.7 can be regarded as a partial converse of Theorem 2.3. The difference between this theorem and Theorem 2.5 is that the assumption of uniform stabilizability (A2)(i) in Theorem 2.5 is replaced by uniform boundedness of Σ^N and v^N.

3. Example. Consider a Euler–Bernoulli beam clamped at one end and let $w(r,t)$ denote the deflection of the beam from its rigid body motion at time t and position r. The deflection can be controlled by applying a torque at the clamped end ($r = 0$). We assume that the hub inertia I_h is much larger than the beam inertia, so that, letting $\theta(t)$ indicate the rotation angle, $u(t) = I_h\ddot{\theta}(t)$ is a reasonable approximation to the applied torque. The disturbance $v(t)$ induces a uniformly distributed load $\rho d v(t)$. Use of the Kelvin–Voigt damping model leads to the following description of the beam vibrations:

$$\rho\frac{\partial^2 w}{\partial t^2} + C_v\frac{\partial w}{\partial t} + \frac{\partial^2}{\partial r^2}\left[EI\frac{\partial^2 w}{\partial r^2} + C_d I\frac{\partial^3 w}{\partial r^2 \partial t}\right] = \frac{\rho r}{I_h}u(t) + \rho\, d\, v(t), \qquad 0 < r < L.$$

The boundary conditions are

$$w(0,t) = 0, \qquad \frac{\partial w}{\partial r}(0,t) = 0,$$

$$\left[EI\frac{\partial^2 w}{\partial r^2} + C_d I\frac{\partial^3 w}{\partial r^2 \partial t}\right]_{r=L} = 0, \qquad \left[EI\frac{\partial^3 w}{\partial r^3} + C_d I\frac{\partial^4 w}{\partial r^3 \partial t}\right]_{r=L} = 0.$$

The values of the physical parameters in this example are listed in Table 1. Let $x(t) = (w(\cdot,t), \frac{\partial}{\partial t}w(\cdot,t))$, H be the closed linear subspace of $H^2(0,1)$ defined by

$$H = \left\{w \in H^2(0,1) : w(0) = \frac{dw}{dr}(0) = 0\right\},$$

and $X = H \times L^2(0,1)$. Here $H^2(0,1)$ is the Hilbert space defined by

$$H^2(0,1) = \left\{ \phi \in C^1(0,1) : \frac{d}{dr}\phi \text{ is absolutely continuous and } \frac{d^2}{dr^2}\phi \in L^2(0,1) \right\}.$$

If the tip deflection is measured, a state-space formulation of the above partial differential equation problem is

$$\frac{d}{dt}x(t) = Ax(t) + Bu(t) + Dv(t),$$

$$y(t) = Cx(t) = w(L,t),$$

where

$$A = \begin{bmatrix} 0 & I \\ -\dfrac{EI}{\rho}\dfrac{d^4}{dr^4} & -\dfrac{C_d I}{\rho}\dfrac{d^4}{dr^4} - \dfrac{C_v}{\rho} \end{bmatrix}, \qquad B = \begin{bmatrix} 0 \\ \dfrac{r}{I_h} \end{bmatrix}, \quad D = \begin{bmatrix} 0 \\ d \end{bmatrix}$$

with domain

$$\operatorname{dom}(A) = \Bigg\{ (\phi,\psi) \in X : \psi \in H \text{ and } M = EI\,\frac{d^2}{dr^2}\phi + C_d I \frac{d^2}{dr^2}\psi \in H^2(0,1) \text{ with } M(L) = \frac{d}{dr}M(L) = 0 \Bigg\}.$$

Define $V = H \times H$. Then A can be defined by

$$\langle Ax, z\rangle_{V^* \times V} = -a(x,z) \quad \text{for } x,\ z \in V,$$

where the sesquilinear form $a(\cdot,\cdot)$ on $V \times V$ is given by

$$a((\phi_1,\psi_1),(\phi_2,\psi_2)) = -\sigma(\psi_1,\phi_2) + \sigma\left(\phi_1 + \frac{C_d}{E}\,\psi_1,\ \psi_2\right) + \left(\frac{C_v}{\rho}\,\psi_1,\ \psi_2\right)_{L^2}$$

for $(\phi_i,\psi_i) \in V,\ i = 1,2$. Here,

$$\sigma(\phi,\psi) = \int_0^L \frac{EI}{\rho}\frac{d^2}{dr^2}\phi(r)\frac{d^2}{dr^2}\psi(r)\,dr\,.$$

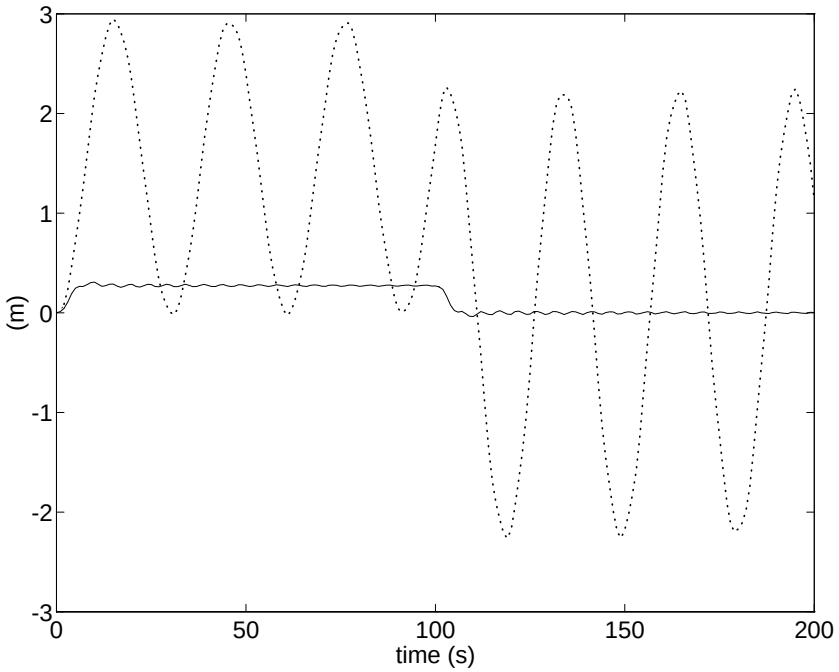

FIG. 1. *Response of open (..) and closed loop (–) to* $v(t) = 1, t \leq 100s$*: 10 elements.*

The sesquilinear form a is continuous on $V \times V$ and coercive; i.e.,

$$\operatorname{Re} a(z,z) \geq \omega \, |z|_V^2 - \beta \, |z|_X^2 \quad \text{for } z \in V$$

for appropriately chosen positive constants $\omega,\ \beta$. It thus follows that A generates an exponentially stable analytic semigroup on X [SH, section 4]. The operators B and D are clearly bounded operators from R to X. Sobolev's inequality implies that evaluation at a point is bounded on H, and so the output operator C is bounded from X to R.

Let $H^N \subset H$ be a sequence of finite-dimensional subspaces. The approximating generator A^N on $X^N = H^N \times H^N$ is defined by

$$\langle -A^N x^N, z^N \rangle = a(x^N, z^N) \quad \forall x^N,\ z^N \in X^N,$$

and $P^N,\ B^N,\ C^N$ are as defined at the beginning of section 2. This type of approximation is generally referred to as a *Galerkin* approximation. Suppose that the approximating subspaces H^N satisfy the H-approximation property: for all $\phi \in H$ there exists a sequence $\phi^N \in H^N$ with

$$\lim_{N \to \infty} |\phi^N - \phi|_H = 0. \tag{H1}$$

It is shown in [IT2, MO2] that as long as the approximating spaces satisfy the H-approximation property, assumptions (A1)–(A3) are satisfied. The standard finite-element cubic B-spline approximations [OP] do satisfy the H-approximation property, and so all the assumptions of Theorem 2.3 are satisfied by this problem.

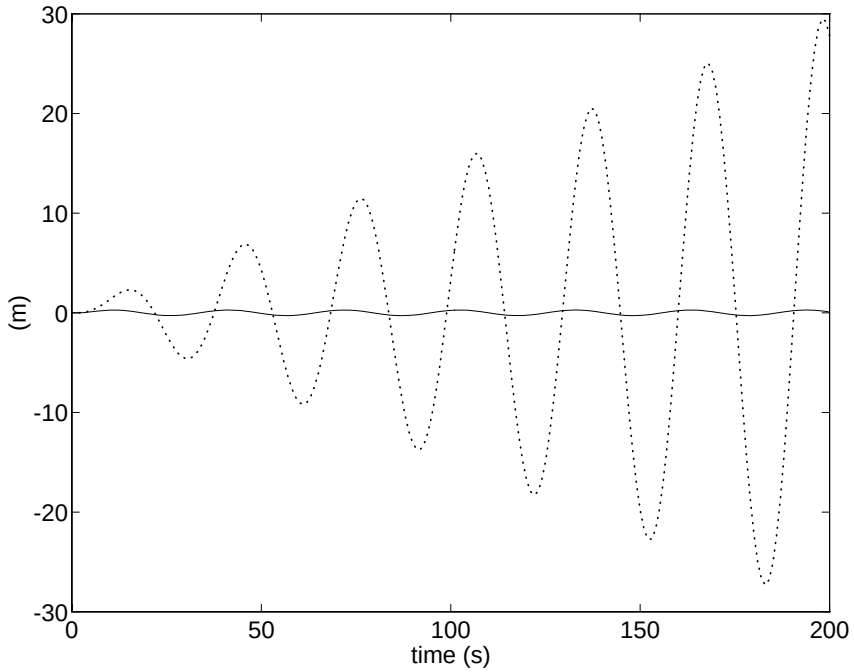

FIG. 2. *Response of open (..) and closed loop (–) to* $v(t) = \sin(\omega t)$ *:* 10 *elements.*

Our numerical calculations were carried out using a series of cubic B-spline approximations for H^N, and the corresponding series of finite-dimensional Riccati equations were solved with $\epsilon = .1$ and $\gamma = 2.3$. Figure 1 compares the open- and closed-loop responses $Cx(t) = w(L,t)$ with a temporary step disturbance for the approximation with 10 elements. The feedback controller leads to a closed loop which is able to almost entirely reject this disturbance. Figure 2 compares the open- and closed-loop responses to the periodic disturbance $\sin(\omega t)$ where ω is the first resonant frequency: $\omega = \min_i |\mathrm{Im}(\lambda_i(A^{10})|$. The resonance in the open loop is not present in the closed loop.

Since the input space $U = R$, the feedback operator $\hat{K}^N$ is a bounded linear functional on X^N and hence can be uniquely identified with an element of X^N, usually called the gain. Figure 3 displays the convergence of the feedback gains predicted by Theorem 2.3. Since X^N is a product space, the first and second components of the gains are displayed separately as displacement and velocity gains, respectively.

The sequence of operators $A^N - B^N\hat{K}^N$ is uniformly exponentially stable, and so

$$\max_{1\le i\le N} \mathrm{Re}\,\lambda_i(A^N - B^N\hat{K}^N)$$

converges to a nonzero number as $N \to \infty$, which can be verified theoretically. This convergence is displayed in Figure 4 for several different values of ϵ and $\gamma = 2.3$. Notice that as ϵ is decreased, the convergence becomes slower. A robust stability theorem provides some insight into this behavior.

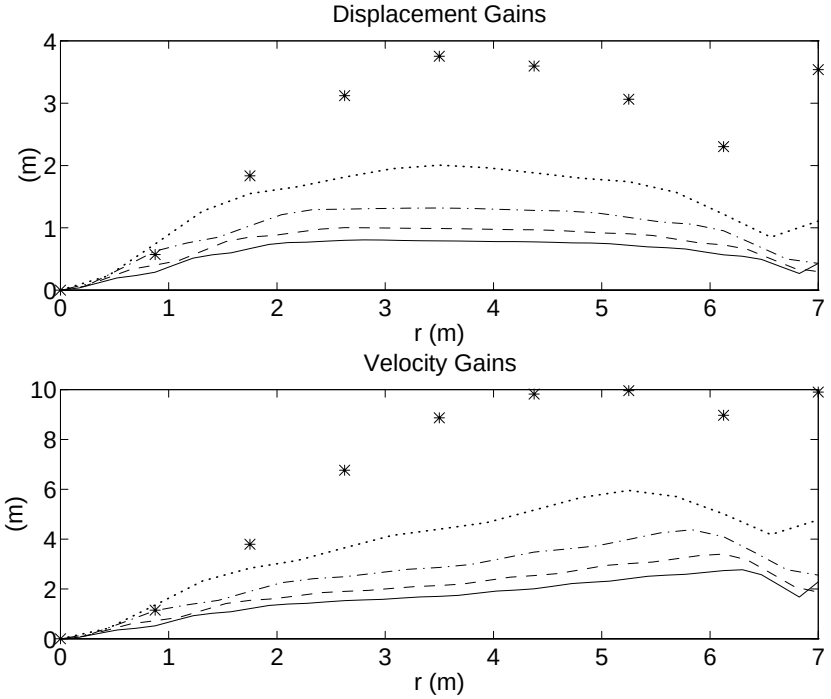

FIG. 3. *Convergence of the feedback gains:* 2 *elements* *, 4 *elements* ..., 6 *elements* _._., 8 *elements* _ _, 10 *elements,* __ .

Let the functions H, G_o, and G in the following theorem indicate transfer functions of systems with a finite number of inputs and outputs. For a given nominal plant G_o and weighting function $r \in H^\infty$, the class $\mathcal{A}(G_o, r)$ consists of all plants G that have the same number of right-hand-plane poles as G_o and that satisfy

$$|G(i\omega) - G_o(i\omega)| \; < \; |r(i\omega)|.$$

That is, $\mathcal{A}(G_o, r)$ contains the systems whose frequency response is within $r(i\omega)$ at each frequency ω of that of the nominal system G_o.

THEOREM 3.1 (see [CD]). *Suppose that a controller H stabilizes the system G_o. For any $r \in H^\infty$ the controller H stabilizes all $G \in \mathcal{A}(\, G_o, r)$ if and only if, for all ω,*

$$|H(1 + G_o H)^{-1}(i\omega)|\, |r(i\omega)| \; \leq 1. \tag{3.1}$$

For any approximation N, we have the nominal plant

$$G_o = (sI^N - A^N)^{-1}[B^N \; D^N]$$

and the controller

$$H = \begin{bmatrix} \hat{K}^N \\ 0 \end{bmatrix}.$$

Thus, we have

$$H(I + G_o H)^{-1} = \hat{K}^N (sI^N - A^N + B^N \hat{K}^N)^{-1}(sI^N - A^N)$$

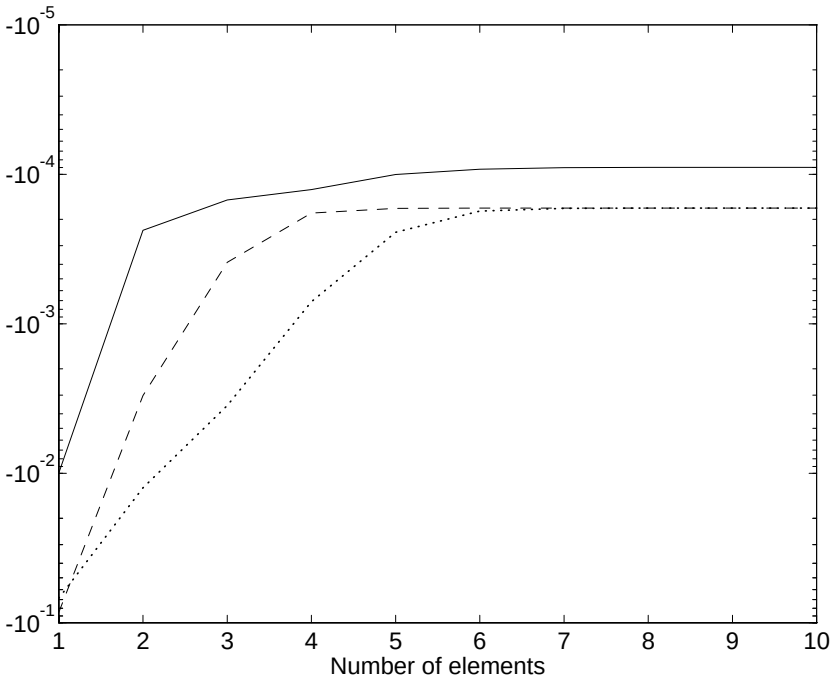

FIG. 4. *Convergence of* $\max_{1\le i\le N} \mathrm{Re}(\lambda_i)$*:* $\epsilon = .1$ *(—),* .001 *(- -),* .00001*.(...).*

and

$$H(I + G_o H)^{-1} G_o \begin{bmatrix} 0 \\ v \end{bmatrix} = \hat{K}^N (sI^N - A^N + B^N \hat{K}^N)^{-1} D^N v.$$

The second row in the attenuation bound (1.4) is commonly interpreted as a constraint on the control effort. However, it can also be interpreted as a robust stability constraint. If the inequality (1.4) is satisfied, then the robustness criterion (3.1) is satisfied with

$$r(i\omega) = \frac{\sqrt{\epsilon}}{\gamma} G_o(i\omega) \begin{bmatrix} 0 \\ I \end{bmatrix}.$$

This interpretation explains why convergence is slower for smaller ϵ. The stability margin for the approximation N is affected by the constraint that the higher-order approximations also be stabilized. Increasing ϵ while holding all other parameters such as γ constant means that the computed controller must stabilize a larger family of systems. Hence the stability margin is less sensitive to change in the approximation index N.

CONVERGENCE RATE OF STOCHASTIC APPROXIMATION ALGORITHMS IN THE DEGENERATE CASE*

HAN-FU CHEN†

Abstract. Let $f(\cdot)$ be an unknown function whose root x^0 is sought by stochastic approximation (SA). Convergence rate and asymptotic normality are usually established for the nondegenerate case $f'(x^0) \neq 0$. This paper demonstrates the convergence rate of SA algorithms for the degenerate case $f'(x^0) = 0$. In comparison with the previous work, in this paper no growth rate restriction is imposed on $f(\cdot)$, no statistical property is required for the measurement noise, the general step size is considered, and the result is obtained for the multidimensional case, which is not a straightforward extension of the one-dimensional result. Although the observation noise may be either deterministic or random, the analysis is purely deterministic and elementary.

Key words. stochastic approximation, convergence rate

AMS subject classification. 62L20

PII. S0363012995281730

1. Introduction.

The topic of SA is to search the roots or extremes of an unknown function $f(\cdot) : R^l \to R^l$ which can be observed with noise. Since its pioneer work by Robbins and Monro [1], SA has obtained much attention from researchers [2, 3] and is applied in various areas, such as parameter identification, adaptive control, optimization, pattern recognition, and others [4].

In many applications not only convergence but also convergence rate of the algorithm is of interest. Intuitively, the rate of convergence depends on the derivative $f'(x^0)$ of the function at its root x^0; the rate in the nondegenerate case ($f'(x^0) \neq 0$) should be faster than it is in the degenerate case ($f'(x^0) = 0$). To be precise, the Robbins–Monro algorithm is defined by

$$x_{n+1} = x_n + a_n y_{n+1}, \tag{1.1}$$

$$y_{n+1} = f(x_n) + \epsilon_{n+1}, \tag{1.2}$$

where y_{n+1} is the observation and ϵ_{n+1} is the noise. $\{a_n\}$ is the step size and is selected to have the following properties:

$$a_n > 0, \quad a_n \xrightarrow[n \to \infty]{} 0 \quad \text{and} \quad \sum_{i=1}^{\infty} a_i = \infty.$$

Under certain conditions [1–4, 7] imposed on $f(\cdot)$ and ϵ_n, x_n defined by (1.1), (1.2) converges to the root x^0 of $f(\cdot)$, i.e.,

$$x_n \xrightarrow[n \to \infty]{} x^0, \quad f(x^0) = 0.$$

Further, in the nondegenerate multidimensional case assume

$$f(x) = H(x - x^0) + \Delta(x), \quad H < 0, \tag{1.3}$$

†Laboratory of Systems and Control, Institute of Systems Science, Chinese Academy of Sciences, Beijing 100080, People's Republic of China (hfchen@iss03.iss.ac.cn).

$$\Delta(x) = O(\|x - x^0\|^2) \quad \text{as} \quad x \to x^0. \tag{1.4}$$

Then under some conditions on the observation noise

$$\|x_n - x^0\| = o(a_n^\delta) \quad \forall \delta \in \left(0, \frac{1}{2}\right), \tag{1.5}$$

provided $H + q\delta I$ is a stable matrix where α by assumption is defined by

$$a_{n+1}^{-1} - a_n^{-1} \xrightarrow[n \to \infty]{} q \geq 0.$$

The convergence rate in the case $f'(x^0) = 0$ was addressed in [5] for the special case where (i) $f(\cdot)$ is a scalar function, i.e., $l = 1$, and $f(x)$ grows not faster than linearly as $|x| \to \infty$; (ii) $(x - x^0)f(x) < 0 \; \forall x \neq x^0$; (iii) $f(x) = f_0|x - x^0|^{1+\gamma}\text{sign}(x - x^0)\cdot(1 + o(1))$ as $x \to x^0$, $\gamma > 0$; (iv) the conditional variance of ϵ_{n+1} given x_n is bounded, i.e., $\text{Var}(\epsilon_{n+1}|x_n) \leq \sigma^2$; (v) ϵ_{n+1} is conditionally independent of $x_0, \ldots, x_{n-1}$ given x_n; and (vi) the step size is special: $a_n = \frac{1}{n}$. In comparison with [5] this paper derives the convergence rate for the general case. To be precise, we do not impose any growth rate restriction on $f(\cdot)$; we do not require any statistical property of the noise, which is allowed to be stochastic or deterministic; we consider the general step size a_n and, finally, we give the convergence rate for both multidimensional and one-dimensional cases. The approach used here is completely different from that used in [5] and is purely deterministic. A purely deterministic approach in a discrete setting was used in [9, 10] as an alternative means for obtaining convergence results, and the approach used here is similar in flavor. We further show the power of an elementary deterministic analysis by obtaining convergence rates. It is worth noting that extension from the one-dimensional result to the multidimensional case is not straightforward. As will be seen in section 2, in the multidimensional case only the upper bound is obtained, while in the one-dimensional case it is shown that the upper bound is attainable.

2. Main results. Before describing the main results of the paper we present a convergence result, proved in [4, 6]. The algorithm considered in this paper is a modified version of (1.1), (1.2) and is defined as follows.

Let $\{M_k\}$ be a sequence of real numbers, $M_i > 0$, $M_i \uparrow \infty$ and let x^* be a fixed point in R^l. The estimate x_n is recursively given by

$$\widehat{x}_{k+1} = x_k + a_k y_{k+1}, \quad x_0 \text{ arbitrary}, \tag{2.1}$$

$$x_{k+1} = \widehat{x}_{k+1} I_{[\|\widehat{x}_{k+1}\| \leq M_{\sigma_k}]} + x^* I_{[\|\widehat{x}_{k+1}\| > M_{\sigma_k}]}, \tag{2.2}$$

$$\sigma_k = \sum_{i=0}^{k-1} I_{[\|\widehat{x}_{i+1}\| > M_{\sigma_i}]}, \tag{2.3}$$

$$y_{k+1} = f(x_k) + \epsilon_{k+1}. \tag{2.4}$$

Since M_i diverges, algorithm (2.1)–(2.4) coincides with the Robbins–Monro algorithm (1.1), (1.2) starting from some time, if we can prove that $\{x_k\}$ defined by (2.1)–(2.4) is bounded.

Let us list conditions which will be used later on.

A1. $f(\cdot)$ is an $R^l \to R^l$ measurable and locally bounded function, and $f(x) = 0$ $\forall x \in J$; i.e., J is the root set of $f(\cdot)$.

A2. $a_k > 0$, $a_k \xrightarrow[k\to\infty]{} 0$, $\sum_{i=1}^{\infty} a_i = \infty$.

A3. There is a differentiable function $v(\cdot) : R^l \to R$ such that

$$d(v(x), v(J)) > 0 \quad \text{if} \quad d(x, J) > 0$$

and

$$\sup_{\delta \le d(x,J) \le \Delta} f^{\tau}(x) v_x(x) < 0 \quad \forall \quad 0 < \delta < \Delta,$$

where $v_x(x)$ denotes the gradient of $v(x)$:

$$d(x, J) = \inf\{\|x - y\| : \forall y \in J\}, \text{ and } v(J) = \{v(x) : x \in J\}.$$

A4. As $x \to x^0$ the function $f(x)$ is expressed as

$$f(x) = H(x - x^0)\|x - x^0\|^{\gamma} + r(x), \qquad \gamma > 0, \tag{2.5}$$

where H is a stable matrix (i.e., all its eigenvalues have negative real parts) and

$$r(x) \in R^l, \quad r(x)/\|x - x^0\|^{1+\gamma} \to 0 \quad \text{as} \quad x \to x^0. \tag{2.6}$$

A5.

$$q_n \overset{\triangle}{=} a_{n+1}^{-1} - a_n^{-1}, 0 \le q_n, \limsup_{n\to\infty} q_n = q, 0 \le q < \infty, \tag{2.7}$$

$$\sum_{i=1}^{\infty} b_i = \infty, \quad \text{where} \quad b_i = \frac{a_i}{\log a_i^{-1}}. \tag{2.8}$$

PROPOSITION. *Assume* A1–A3 *hold. If there is a constant* c_0 *such that* $\|x^*\| < c_0$, $v(x^*) < \inf_{\|x\|} = c_0 v(x)$ *and if* $v(J)$ *is not dense in any interval, then* $\{x_k\}$ *defined by* (2.1)–(2.4) *converges to* J

$$\lim_{k\to\infty} d(x_k, J) = 0$$

whenever $\{\epsilon_i\}$ *satisfies the following condition:*

$$\lim_{T\to 0} \limsup_{k\to\infty} \frac{1}{T} \left\| \sum_{i=k}^{m(k,t)} a_i \epsilon_{i+1} \right\| = 0 \quad \forall t \in [0, T], \tag{2.9}$$

where

$$m(k, t) = \max\left\{ m : \sum_{i=k}^{m} a_i \le t \right\}.$$

Remark 1. An obvious condition which guarantees (2.9) is the convergence of the series

$$\sum_{i=1}^{\infty} a_i \epsilon_{i+1}.$$

Condition (2.9) is also necessary for convergence of x_n to the root of $f(x)$. This is discussed in the recent paper [8], which also shows that (2.9) is equivalent to the

standard Kushner–Clark condition [3]. However, when ϵ_k depends on $\{x_0, \ldots, x_{k-1}\}$, it is difficult to directly verify (2.9). In [4, 6] it is shown that it suffices to verify (2.9) not along the whole sequence $\{k\}$ but along the subsequence $\{n_k\}$ whenever $\{x_{n_k}\}$ converges. In [4, 6] it is also demonstrated that this verification can be done in many practically important problems.

Remark 2. If $\{x_k\}$ given by (1.1), (1.2) is a priori known to be bounded, then under conditions A1–A3 and (2.9)

$$\lim_{k\to\infty} d(x_n, J) = 0; \tag{2.10}$$

i.e., in this case the truncations introduced in (2.1)–(2.4) are not necessary.

In A4 the matrix H is stable. By the Lyapunov equality there is a positive definite matrix $P > 0$ such that

$$PH + H^\tau P = -I. \tag{2.11}$$

Denote by $\lambda_{\max}$ and $\lambda_{\min}$ the maximum and minimum eigenvalue of P, respectively, and by K the condition number $\lambda_{\max}/\lambda_{\min}$.

THEOREM. (i) *If conditions* A1–A5 *are satisfied and* x^0 *is the unique root of* $f(\cdot)$*, then for* $\{x_n\}$ *defined by* (2.1)–(2.4)

$$\limsup_{n\to\infty} (\log a_n^{-1})^{\frac{1}{\gamma}} \|x_n - x^0\| \le \sqrt{K} \left(\frac{2q\lambda_{\max}}{\gamma}\right)^{\frac{1}{\gamma}} \tag{2.12}$$

if $\{\epsilon_i\}$ *satisfies the following condition*:

$$\sum_{i=1}^{\infty} a_i (\log a_{i+1}^{-1})^{\frac{1}{\gamma}} \epsilon_{i+1} < \infty, \tag{2.13}$$

where γ *and* q *are given by* (2.5), (2.7), *respectively.*

(ii) *If, in addition,* H *is symmetric, then*

$$\limsup_{n\to\infty} (\log a_n^{-1})^{\frac{1}{\gamma}} \|x_n - x^0\| \le \left(\frac{q}{\lambda_l \gamma}\right)^{\frac{1}{\gamma}}, \tag{2.14}$$

where λ_l *is the smallest eigenvalue of* $-H$ *and* γ *and* q *are given by* (2.5), (2.7), *respectively.*

(iii) *Further, in the one-dimensional case, i.e.,* $l = 1$*, under the conditions stated in* (i) *except A3, the upper bound in* (2.14) *is attainable if* $q_n \to q > 0$.

The proof of the theorem is given in section 3.

Remark 3. From the theorem it is seen that the convergence rate of $(x_n - x^0)$ depends upon the decreasing rate of a_n. However, it is interesting to note that this dependence in the degenerate case is completely different from that in the nondegenerate case.

From (1.5) it is seen that for the nondegenerate case, if $a_n = \frac{1}{n^\alpha}$, $0 < \alpha \le 1$, then the convergence rate of $(x_n - x^0)$ is improving as α increases from 0 to 1. However, in the degenerate case the picture is different. By the theorem, $\lim_{n\to\infty} (\alpha \log n)^{\frac{1}{\gamma}} |x_n - x^0|$ equals 0 for all $\alpha \in (0, 1)$, while it may attain $(\frac{1}{|H|\gamma})^{\frac{1}{\gamma}}$ if $\alpha = 1$. This means that in contrast to the nondegenerate case, the convergence rate of $|x_n - x^0|$ for $\alpha \in (0, 1)$ is

better than that for $\alpha = 1$. This fact is verified by simulation of the following simple example:

$$f(x) = -x|x|, \quad x^0 = 0, \quad f'(x^0) = 0, \quad \gamma = 1, \quad H = -1,$$
$$\epsilon_i \equiv 0,$$
$$x_{n+1}^{(1)} = x_n^{(1)} - \frac{x_n^{(1)}|x_n^{(1)}|}{n}, \quad x_0^{(1)} = 0.5,$$
$$x_{n+1}^{(2)} = x_n^{(2)} - \frac{x_n^{(2)}|x_n^{(2)}|}{\sqrt{n}}, \quad x_0^{(2)} = 0.5.$$

The simulation shows that

$$x_n^{(1)} \log n \xrightarrow[n \to \infty]{} 1, \quad \text{while} \quad x_n^{(2)} \log n \xrightarrow[n \to \infty]{} 0,$$

which are reconciled with results stated in the theorem.

It is also worth noting that the right-hand sides of (2.14) depend upon the smallest eigenvalue λ_l of $-H$ when H is symmetric. As λ_l decreases the upper bound in (2.14) increases. In other words, the faster $f(x)$ leaves the abscissa, the faster x_n converges to x^0. This phenomenon is consistent with the convergence rate change from (1.5) for the nondegenerate case to (2.12) for the degenerate case. This is also verified by computation: if in the example considered above "$H = -1$" is replaced by "$H = -\frac{1}{2}$", i.e., if $f(x) = -\frac{1}{2}x|x|$, then the recursion with $a_n = \frac{1}{n}$ becomes $x_{n+1} = x_n - \frac{x_n|x_n|}{2n}$, $\quad x_0 = 0.5$. The computation shows

$$x_n \log n \xrightarrow[n \to \infty]{} 2,$$

which is larger than the limit of $x_n^{(1)} \log n$.

Remark 4. In the case $q > 0$, the convergence rate given in the theorem cannot be improved. However, when $q = 0$, i.e., when a slowly decreasing gain is applied, we have only established $\|x_n - x^0\| = o(\log a_n^{-1})^{-\frac{1}{r}}$. The estimate may be not sharp, but the computation shows that $x_n^{(2)} \log n$ in Remark 3 converges to zero very slowly. This means that we should not expect a much faster rate than (2.15).

3. Order of estimation error. In this section we establish the order of estimation error when the estimation algorithm (2.1)–(2.4) is applied. As a matter of fact, we intend to show that $\|z_n\| \stackrel{\triangle}{=} \|(\log a_n^{-1})^{\frac{1}{\gamma}}(x_n - x_0)\|$ is bounded. This is an intermediate step toward proving the theorem which gives either upper bound or an exact limit of $\|z_n\|$.

LEMMA 1. *If* A5 *holds, then* (2.13) *implies* (2.9).

Proof. Let (2.13) be held. Setting

$$s_n = \sum_{i=1}^{n} a_i (\log a_{i+1}^{-1})^{\frac{1}{\gamma}} \epsilon_{i+1}, \quad s_0 = 0,$$

we have

$$\begin{aligned} \sum_{i=m}^{n} a_i \epsilon_{i+1} =& \sum_{i=m}^{n} (s_i - s_{i-1})(\log a_{i+1}^{-1})^{-\frac{1}{\gamma}} \\ =& s_n (\log a_{n+1}^{-1})^{-\frac{1}{\gamma}} + \sum_{i=m}^{n-1} s_i [(\log a_{i+1}^{-1})^{-\frac{1}{\gamma}} - (\log a_{i+2}^{-1})^{-\frac{1}{\gamma}}]. \end{aligned} \tag{3.1}$$

Since s_n converges, the first term on the right-hand side of (3.1) tends to zero as $n \to \infty$, while the last term is dominated by

$$\sup_{m \le i \le n} |s_i| \sum_{i=m}^{n-1} |(\log a_{i+1}^{-1})^{-\frac{1}{\gamma}} - (\log a_{i+2}^{-1})^{-\frac{1}{\gamma}}| = \sup_{m \le i \le n} |s_i| [(\log a_{m+1}^{-1})^{-\frac{1}{\gamma}} - (\log a_{n+1}^{-1})^{-\frac{1}{\gamma}}],$$

which tends to zero as $n \to \infty$ and $m \to \infty$.

Hence, $\sum_{i=1}^{\infty} a_i \epsilon_{i+1}$ converges and (2.9) holds by Remark 1. □

LEMMA 2. *Under the conditions stated in* (i) *or in* (iii) *of the theorem,* x_k *defined by* (2.1)–(2.4) *converges to* x^0 *as* $k \to \infty$.

Proof. By Lemma 1 and the Proposition presented in section 2, under the conditions stated in (i) we see $x_k \xrightarrow[k \to \infty]{} x^0$. For the one-dimensional case stated in (i) we also have $x_k \xrightarrow[k \to \infty]{} x^0$ if we can verify A3.

Since x^0 is the unique root of $f(\cdot)$ by A1, we have by A4

$$(x - x^0) f(x) < 0 \quad \forall x \neq x^0.$$

Then the function $v(x) = (x - x^0)^2$ satisfies A3. □

Define

$$z_n = (\log a_n^{-1})^{\frac{1}{\gamma}} (x_n - x^0), \tag{3.2}$$

$$h(z) = Hz\|z\|^{\gamma} + \frac{q + \Delta}{\gamma} z, \quad z \in R^l, \quad \Delta > 0. \tag{3.3}$$

LEMMA 3 (key lemma). *Under the conditions stated in* (i) *of the theorem,* $\{z_n\}$ *is bounded if* (2.13) *holds.*

Proof. To prove boundedness of $\{z_n\}$ we first express z_n in the recursive form. For any $\Delta > 0$ and sufficiently large n by (2.7), we have $q_n \le q + \Delta$ and

$$\begin{aligned}
\left(\frac{\log a_{n+1}^{-1}}{\log a_n^{-1}} \right)^{\frac{1}{\gamma}} &= \left(\frac{\log a_n^{-1} + \log \dfrac{a_{n+1}^{-1}}{a_n^{-1}}}{\log a_n^{-1}} \right)^{\frac{1}{\gamma}} \\
&= \left(1 + \frac{\log(1 + a_n q_n)}{\log a_n^{-1}} \right)^{\frac{1}{\gamma}} \\
&= \left(1 + \frac{a_n q_n + O(a_n^2)}{\log a_n^{-1}} \right)^{\frac{1}{\gamma}} \\
&= 1 + \frac{a_n (q + \Delta + o(1))}{\gamma \log a_n^{-1}}. \qquad (3.4)
\end{aligned}$$

By Lemma 2 $\{x_n\}$ is bounded, and hence x_k is defined by the Robbins–Monro algorithm starting from some n_0. Consequently, by (3.4) for $n \ge n_0$ we derive the recursive formula for $\{z_n\}$:

$$
\begin{aligned}
z_{n+1} =& \left(1+\frac{a_n}{\gamma\log a_n^{-1}}(q+\Delta+o(1))z_n\right)\\
&+\frac{a_n}{\log a_n^{-1}}\left(1+\frac{a_n}{\gamma\log a_n^{-1}}(q+\Delta+o(1))\right)(\log a_n^{-1})^{1+\frac{1}{\gamma}}\\
&\cdot[H(x_n-x^0)\|x_n-x^0\|^\gamma+r(x_n)]+a_n(\log a_{n+1}^{-1})^{\frac{1}{\gamma}}\epsilon_{n+1}\\
=&\left(1+\frac{a_n}{\gamma\log a_n^{-1}}(q+\Delta+o(1))\right)z_n\\
&+\frac{a_n}{\log a_n^{-1}}\left(1+\frac{a_n}{\gamma\log a_n^{-1}}(q+\Delta+o(1))\right)\left[Hz_n\|z_n\|^\gamma+\frac{\|z_n\|^{1+\gamma}r(x_n)}{\|x_n-x^0\|^{1+\gamma}}\right]\\
&+a_n(\log a_{n+1}^{-1})^{\frac{1}{\gamma}}\epsilon_{n+1}
\end{aligned}
$$

$$
=z_n+b_nh_n(z_n)+a_n(\log a_{n+1}^{-1})^{\frac{1}{\gamma}}\epsilon_{n+1} \tag{3.5}
$$

$$
=z_n+b_nH_nz_n+a_n(\log a_{n+1}^{-1})^{\frac{1}{\gamma}}\epsilon_{n+1}, \tag{3.6}
$$

where

$$
\begin{aligned}
h_n(z) =&\left(Hz\|z\|^\gamma+\frac{\|z\|^{1+\gamma}r(x_n)}{\|x_n-x^0\|^{1+\gamma}}\right)\left(1+\frac{a_n}{\gamma\log a_n^{-1}}(q+\Delta+o(1))\right)\\
&+\frac{q+\Delta+o(1)}{\gamma}z=H_nz
\end{aligned} \tag{3.7}
$$

and

$$
H_n=\left[\left(H+\frac{r(x_n)}{\|x_n-x^0\|^{1+\gamma}}\cdot\frac{z_n^\tau}{\|z_n\|}\right)(1+o(1))+\frac{q+\Delta+o(1)}{\gamma\|z_n\|^\gamma}\cdot I\right]\|z_n\|^\gamma. \tag{3.8}
$$

Assume that the converse is true, i.e., assume $\{\|z_n\|\}$ is unbounded.

Let us fix a large enough constant $c>1$ such that

$$
\frac{q+\Delta}{\gamma c^\gamma}\lambda_{\max}<\frac{1}{5}. \tag{3.9}
$$

Denote by $\{z_{l_i}\}$, $i=1,2,\dots,n_c$, those of $\{z_n, n\ge n_0\}$ for which $\|z_{l_i}\|\le c$ and $\|z_i\|>c\ \forall i: i\notin\{1,\dots,n_c\}$ where n_c may be infinite. For both cases $n_c<\infty$ and $n_c=\infty$ from the unboundedness of $\{\|z_n\|\}$ we will obtain a contradiction. This implies the conclusion of the lemma.

Case 1. If $n_c<\infty$, then $\|z_i\|>c\ \forall i\ge n_c$.

We now show that by selection (3.9) for c the difference equation (3.5) in Case 1 is asymptotically stable and $z_n\xrightarrow[i\to\infty]{}0$. This implies impossibility of $\|z_i\|>c\ \forall i\ge n_c$.

Define

$$
\Phi_{n,j}=(I+b_nH_n)(I+b_{n-1}H_{n-1})\cdots(I+b_jH_j),\quad \Phi_{j,j+1}\stackrel{\triangle}{=}I, \tag{3.10}
$$

$$
\Phi_{n,j}^\tau P\Phi_{n,j}=\Phi_{n-1,j}^\tau(P+b_n(H_n^\tau P+PH_n)+b_n^2H_n^\tau PH_n)\Phi_{n-1,j}, \tag{3.11}
$$

where H_n is defined by (3.8).

From A4 and Lemma 2, notice that $r(x_n)/\|x_n - x^0\|^{1+\gamma} \xrightarrow[n\to\infty]{} 0$ and for $n \geq n_c$,

$$b_n\|H_n^\tau P H_n\| \leq c_1 b_n \|z_n\|^{2\gamma} = c_1 \frac{a_n}{\log a_n^{-1}} (\log a_n^{-1})^2 \|x_n - x^0\|^{2\gamma} \xrightarrow[n\to\infty]{} 0, \tag{3.12}$$

where c_1 is a constant. Then by (2.11), (3.9), (3.12) for sufficiently large n we have

$$(H_n^\tau P + P H_n) + b_n H_n^\tau P H_n < -\frac{1}{2}\|z_n\|^\gamma I. \tag{3.13}$$

Without loss of generality we may assume that n_0 is large enough so that (3.13) is valid for $n \geq n_0$. By (3.11), (3.13) for $j \geq n_c$ we see that

$$\Phi_{n,j}^\tau P \Phi_{n,j} \leq \Phi_{n-1,j}^\tau \left(P - \frac{1}{2} b_n \|z_n\|^\gamma I\right) \Phi_{n-1,j} \leq \left(1 - \frac{b_n\|z_n\|^\gamma}{2\lambda_{\max}}\right) \Phi_{n-1,j}^\tau P \Phi_{n-1,j},$$

where as defined in section 2 $\lambda_{\max}$ is the maximum eigenvalue of P.

This implies that

$$\begin{aligned}\Phi_{n,n_c}^\tau P \Phi_{n,n_c} \leq & (1 - \mu b_n \|z_n\|^\gamma) \Phi_{n-1,n_c}^\tau P \Phi_{n-1,n_c} \\ < & e^{-\mu b_n \|z_n\|^\gamma} \Phi_{n-1,n_c}^\tau P \Phi_{n-1,n_c} < \lambda_{\max} e^{-\mu \sum_{i=n_c}^n b_i \|z_i\|^\gamma} I,\end{aligned}$$

where $\mu = \frac{1}{2\lambda_{\max}}$.

Consequently, we have

$$\|\Phi_{n,n_c}\| < \sqrt{K} e^{-\frac{\mu}{2} \sum_{i=n_c}^n b_i \|z_i\|^\gamma}. \tag{3.14}$$

We remind the reader that $K = \lambda_{\max}/\lambda_{\min}$ and $\lambda_{\min}$ is the minimum eigenvalue of P.

From (3.6) it follows that

$$z_{n+1} = \Phi_{n,n_c} z_{n_c} + \sum_{j=n_c}^n \Phi_{n,j+1} a_j (\log a_{j+1}^{-1})^{\frac{1}{\gamma}} \epsilon_{j+1}. \tag{3.15}$$

Since $\|z_i\| > c \ \forall i \geq n_c$ and $\sum_{i=n_c}^\infty b_i = \infty$, by (3.14) the first term on the right-hand side of (3.15) tends to zero as $n \to \infty$. Let us now estimate the last term of (3.15).

Set

$$\xi_n = \sum_{j=n_c}^n a_j (\log a_{j+1}^{-1})^{\frac{1}{\gamma}} \epsilon_{j+1}.$$

By (2.13) it follows that $\xi_n \xrightarrow[n\to\infty]{} \xi < \infty$. We now have

$$\begin{aligned}&\sum_{j=n_c}^n \Phi_{n,j+1} a_j (\log a_{j+1}^{-1})^{\frac{1}{\gamma}} \epsilon_{j+1} \\ &= \sum_{j=n_c}^n \Phi_{n,j+1} (\xi_j - \xi_{j-1}) \\ &= \xi_n - \sum_{j=n_c+1}^n (\Phi_{n,j+1} - \Phi_{n,j}) \xi_{j-1} - \Phi_{n,n_c+1} \xi_{n_c-1}\end{aligned}$$

$$
\begin{aligned}
&= \xi_n - \sum_{j=n_c+1}^{n} (\Phi_{n,j+1} - \Phi_{n,j})\xi \\
&\quad - \sum_{j=n_c+1}^{n} (\Phi_{n,j+1} - \Phi_{n,j})(\xi_{j-1} - \xi) - \Phi_{n,n_{n_c+1}}\xi_{n_c-1} \\
&= (\xi_n - \xi) + \Phi_{n,n_c+1}\xi - \sum_{j=n_c+1}^{n_1} (\Phi_{n,j+1} - \Phi_{n,j})(\xi_{j-1} - \xi) \\
&\quad + \sum_{j=n_1+1}^{n} \Phi_{n,j+1} b_j H_j(\xi_{j-1} - \xi) - \Phi_{n,n_{n_c+1}}\xi_{n_c-1}. \qquad (3.16)
\end{aligned}
$$

By (3.14) it is clear that on the right-hand side of (3.16) all terms except the second-to-last one tend to zero as $n \to \infty$ for any fixed n_1. We now show that the second-to-last term of (3.16) can be made arbitrarily small by choosing n_1 sufficiently large. For any $\epsilon > 0$, take sufficiently large n_1 such that

$$
|\xi_j - \xi| < \epsilon \quad \text{and} \quad 1 \geq \frac{\mu b_j \|z_j\|^\gamma}{2} \quad \forall j \geq n_1,
$$

which is possible because

$$
b_j \|z_j\|^\gamma = \frac{a_j}{\log a_j^{-1}} \cdot [(\log a_j^{-1})^{\frac{1}{\gamma}} \|x_j - x^0\|]^\gamma = a_j \|x_j - x^0\|^\gamma \to 0. \qquad (3.17)
$$

Using (3.14), (3.17), and noticing that $\|H_n\| \leq c_2 \|z_n\|^\gamma \ \forall n \geq n_c$ for some constant $c_2 > 0$ we derive

$$
\begin{aligned}
\left\| \sum_{j=n_1+1}^{n} \Phi_{n,j+1} b_j H_j(\xi_{j-1} - \xi) \right\| &\leq \epsilon c_2 \sqrt{K} \sum_{j=n_1+1}^{n} e^{-\frac{\mu}{2}\sum_{i=j+1}^{n} b_i \|z_i\|^\gamma} b_j \|z_j\|^\gamma \\
&\leq \frac{4\epsilon c_2 \sqrt{K}}{\mu} \sum_{j=n_1+1}^{n} e^{-\frac{\mu}{2}\sum_{i=j+1}^{n} b_i \|z_i\|^\gamma} (1 - e^{-\frac{\mu}{2} b_i \|z_j\|^\gamma}) \leq \frac{4\epsilon c_2 K}{\mu},
\end{aligned}
$$

where we use the fact that $\frac{x}{2} \leq 1 - e^{-x}$ for $x \in [0, 1]$.

Consequently, the left-hand side of (3.16) tends to zero as $n \to \infty$, and hence $z_n \xrightarrow[n \to \infty]{} 0$. This contradicts $\|z_i\| > c$, $\forall i \geq n_c$. Therefore, n_c must be ∞.

Case 2. Assume $n_c = \infty$. In this case $\{z_i\}$ will come back to the ball $\{\|z\| \leq c\}$ infinitely many times and at the same time $\{z_i\}$ is unbounded. From this we can conclude that $\{\|z_i\|\}$ crosses a nonempty interval infinitely often. To be precise, let $z_{l_i}^\tau P z_{l_i} \leq \lambda_{\max} c^2$, $i = 1, \ldots, n_c$, where P is given in (2.11). Starting from any z_{l_i}, $i \in \{1, 2, \ldots, n_c\}$, there exists an $m_i > l_i$ such that $z_{m_i}^\tau P z_{m_i} > 4c^2 \lambda_{\max}^2 / \lambda_{\min}$ since $\{\|z_n\|\}$ is unbounded. Further, noticing $n_c = \infty$ we can find an integer n_{i+1} in the set $\{l_i, i = 1, 2, \ldots, n_c\}$ such that $n_{i+1} > m_i$. This procedure can be continued infinitely many times. Without loss of generality, we may assume

$$
\begin{gathered}
z_{n_i}^\tau P z_{n_i} \leq \lambda_{\max} c^2, \quad z_{m_i}^\tau P z_{m_i} \geq 4c^2 \lambda_{\max}^2 / \lambda_{\min}, \\
\lambda_{\max} c^2 < z_j^\tau P z_j < 4c^2 \lambda_{\max}^2 / \lambda_{\min}, \\
n_i < j < m_i, \quad i = 1, 2, \ldots. \qquad (3.18)
\end{gathered}
$$

This implies the crossing property of $\{\|z_i\|\}$:

$$\|z_{n_i}\| \le \sqrt{K}c, \quad \|z_{m_i}\| \ge 2c\sqrt{K}, \quad c < \|z_j\| < 2cK, \tag{3.19}$$

$$n_i < j < m_i, \quad i = 1, 2, \ldots.$$

We now show that $\sum_{j=n_i}^{m_i-1} b_j \ge T > 0$ and $\|z_s - z_{n_i}\| = O(T)$ as $T \to 0$ for all large i and s: $\sum_{j=n_i}^{s} b_j \le T$. This implies a contradiction to (3.19). We now prove this in detail.

Noticing that there are constants c_3 and c_4 such that

$$\begin{aligned} b_n\|H_n z_n\| &\le \frac{a_n}{\log a_n^{-1}}[c_3\|z_n\|^{1+\gamma} + c_4\|z_n\|] \\ &\le \frac{a_n}{\log a_n^{-1}}[c_3(\log a_n^{-1})^{\frac{\gamma+1}{\gamma}}\|x_n - x^0\|^{1+\gamma} \\ &\quad + c_4(\log a_n^{-1})^{\frac{1}{\gamma}}\|x_n - x^0\|] \xrightarrow[n\to\infty]{} 0, \end{aligned} \tag{3.20}$$

by (2.13) from (3.6) we see that

$$z_{n+1} - z_n \xrightarrow[n\to\infty]{} 0. \tag{3.21}$$

Summing up both sides of (3.6) from n_i to m_i we derive

$$z_{m_i} = z_{n_i} + \sum_{j=n_i}^{m_i-1} b_j H_j z_j + \sum_{j=n_i}^{m_i-1} a_j (\log a_{j+1}^{-1})^{\frac{1}{\gamma}} \epsilon_{j+1}. \tag{3.22}$$

From (3.22) using (3.18), (3.19), (3.20) we obtain

$$\begin{aligned} 2c\sqrt{K} &\le \sqrt{K}c + \sum_{j=n_i}^{m_i-1} b_j(c_3\|z_j\|^{1+\gamma} + c_4\|z_j\|) + \left\|\sum_{j=n_i}^{m_i-1} a_j(\log a_{j+1}^{-1})^{\frac{1}{\gamma}}\epsilon_{j+1}\right\| \\ &\le \sqrt{K}c + \sum_{j=n_i}^{m_i-1} b_j(c_3(2cK)^{1+\gamma} + c_4 2cK) + \left\|\sum_{j=n_i}^{m_i-1} a_j(\log a_{j+1}^{-1})^{\frac{1}{\gamma}}\epsilon_{j+1}\right\|. \end{aligned} \tag{3.23}$$

Since (2.13) the last term of (3.23) can be made arbitrarily small, say, less than $\epsilon\,(< \sqrt{K}c)$ if i is sufficiently large. Then from (3.23) it follows that

$$\sum_{j=n_i}^{m_i-1} b_j \ge \frac{\sqrt{K}c - \epsilon}{c_3(2cK)^{1+\gamma} + 2cc_4K} \triangleq T > 0$$

for all large enough i. This means that $l(n_i, T) \le m_i - 1$, where

$$l(n,t) = \max\left\{l : \sum_{i=n}^{l} b_i \le t\right\}, \quad b_i = \frac{a_i}{\log a_i^{-1}}. \tag{3.24}$$

Consequently, we have

$$\|z_j - z_{n_i}\| \le \left\| \sum_{s=n_i}^{j-1} b_s H_s z_s + \sum_{s=n_i}^{j-1} a_s (\log a_{s+1}^{-1})^{\frac{1}{\gamma}} \epsilon_{s+1} \right\|$$

$$\le (c_3(2cK)^{1+\gamma} + 2c_4 cK)T + o(1) \le \alpha T, \quad \alpha > 0, \tag{3.25}$$

$$\forall j \in [n_i, \dots, l(n_i, T)],$$

where α is a constant

Therefore, by Taylor's formula there exists $\widetilde{z} \in R^l$ such that

$$\|\widetilde{z} - z_{n_i}\| \le \alpha T \tag{3.26}$$

and

$$\begin{aligned} z_{l(n_i,T)}^\tau P z_{l(n_i,T)} - z_{n_i}^\tau P z_{n_i} =& \widetilde{z}^\tau P \left(\sum_{j=n_i}^{l(n_i,t)} b_j H_j z_j + \sum_{j=n_i}^{l(n_i,T)} a_j (\log a_{j+1}^{-1})^{\frac{1}{\gamma}} \epsilon_{j+1} \right) \\ =& \sum_{j=n_i}^{l(n_i,t)} b_j z_j^\tau P H_j z_j + \sum_{j=n_i}^{l(n_i,T)} b_j (\widetilde{z} - z_j)^\tau P H_j z_j \\ &+ \widetilde{z}^\tau P \sum_{j=n_i}^{l(n_i,T)} a_j (\log a_{j+1}^{-1})^{\frac{1}{\gamma}} \epsilon_{j+1}. \end{aligned} \tag{3.27}$$

Using (3.20), (3.25), and (3.26) we see that

$$\left\| \sum_{j=n_i}^{l(n_i,T)} b_j (\widetilde{z} - z_j)^\tau P H_j z_j \right\| \le 2\alpha T^2 \lambda_{\max}(c_3(2cK)^{1+\gamma} + c_4 2cK).$$

By (2.13), the last term of (3.27) can be made arbitrarily small. Hence, by (3.12), (3.13), (3.19), (3.21) we have

$$z_j^\tau P H_j z_j = \frac{1}{2} z_j^\tau (P H_j + H_j^\tau P) z_j < -\frac{1}{4} \|z_j\|^{2+\gamma} \le -\frac{1}{4} c^{2+\gamma} \quad \forall j = n_i, \dots, l(n_i, T).$$

From (3.27) we can conclude that

$$\begin{aligned} & z_{l(n_i,T)}^\tau P z_{l(n_i,T)} - z_{n_i}^\tau P z_{n_i} \\ \le & -\frac{1}{4} c^{2+\gamma} T + 2\alpha T^2 (c_3 (2cK)^{1+\gamma} + 2cc_4 K) + o(1) \le -\frac{1}{5} c^{2+\gamma} T, \end{aligned} \tag{3.28}$$

if i is large enough and T is sufficiently small. By (3.18) inequality (3.28) implies that

$$\lambda_{\max} c^2 < z_{l(n_i,T)}^\tau P z_{l(n_i,T)} \le z_{n_i}^\tau P z_{n_i} - \frac{1}{5} c^{2+\gamma} T \to \lambda_{\max} c^2 - \frac{c^{2+\gamma} T}{5},$$

which is impossible. The obtained contradiction shows that $\{z_n\}$ is bounded. □

4. Proof of the theorem. We are now in a position to prove our theorem.

Proof of the theorem. (i) For assertion (2.12) of the theorem it suffices to show

$$\limsup_{n\to\infty} z_n^\tau P z_n \le \lambda_{\max}\left(\frac{2(q+\Delta)\lambda_{\max}}{\gamma}\right)^{\frac{2}{\gamma}} \triangleq a \tag{4.1}$$

for arbitrarily small $\Delta > 0$. Let us fix $\Delta > 0$.

The idea of proof for (4.1) is that we show that $z_n^\tau P z_n$ crosses a nonempty interval infinitely often if (4.1) is not true and, at same time, $z_n^\tau P z_n$ is decreasing in a certain sense. This contains a contradiction.

By Lemma 3 $\{z_n\}$ is bounded; i.e.,

$$\|z_n\| \le \zeta < \infty \quad \forall n. \tag{4.2}$$

Hence, from (3.8) we see that

$$H_n = H\|z_n\|^\gamma + \frac{q+\Delta}{\gamma} I + o(1). \tag{4.3}$$

From (3.3), (3.6), and (4.3) it follows that

$$z_{n+1} = z_n + b_n h(z_n) + b_n o(1) + a_n(\log a_{n+1}^{-1})^{\frac{1}{\gamma}}\epsilon_{n+1}. \tag{4.4}$$

Fix any small $\epsilon > 0$ consider $z \in R^l$ for which

$$z^\tau P z \ge \lambda_{\max}\left(\frac{2(q+\Delta)\lambda_{\max}+\epsilon}{\gamma}\right)^{\frac{2}{\gamma}} \triangleq b. \tag{4.5}$$

This implies that

$$\|z\| \ge \left(\frac{2(q+\Delta)\lambda_{\max}+\epsilon}{\gamma}\right)^{\frac{1}{\gamma}}.$$

Then by (2.11) and (4.4) we have

$$\begin{aligned} & z^\tau\left((PH + H^\tau P)\|z\|^\gamma + \frac{2(q+\Delta)}{\gamma}P\right)z \\ & \le\ z^\tau\left(-\|z\|^\gamma I + \frac{2(q+\Delta)\lambda_{\max}}{\gamma} I\right) z \le -\frac{\epsilon}{\gamma}\|z\|^2. \end{aligned} \tag{4.6}$$

Assume (4.1) is not true. Then there is a small $\delta > 0$ such that

$$\limsup_{n\to\infty} z_n^\tau P z_n > a + \delta. \tag{4.7}$$

Therefore, there is a subsequence

$$z_{n_k}^\tau P z_{n_k} > a + \delta, \quad k = 1, 2, \ldots. \tag{4.8}$$

Let $\epsilon > 0$ be small enough so that

$$a + \delta > b, \tag{4.9}$$

where b is given by (4.5).

We now show that from any n_k, $k = 1, 2, \ldots$, $\{z_n\}$ will enter the ellipsoid $\{z : z^\tau P z \le b\}$. Assume the converse, i.e.,

$$\|z_i^\tau P z_i\| \ge b \quad \forall i \ge n_k \tag{4.10}$$

for some n_k.

By the boundedness of $\{z_n\}$ we have

$$\|z_j - z_n\| \le c_5 T, \quad j = n, \ldots, l(n,T) \quad \forall n, \tag{4.11}$$

and hence

$$|z_j^\tau P z_j - z_n^\tau P z_n| \le c_6 T, \quad j = n, \ldots, l(n,T) \quad \forall n, \tag{4.12}$$

where c_5 and c_6 are constants. Similar to (3.27), by (4.2), (4.11) we obtain

$$\begin{aligned} z_{l(n_k,T)}^\tau P z_{l(n_k,T)} - z_{n_k}^\tau P z_{n_k} &\le \sum_{j=n_k}^{l(n_k,T)} b_j z_j^\tau P H_j z_j + c_7 T^2 + o(1) \\ &= \sum_{j=n_k}^{l(n_k,T)} b_j z_j^\tau \left(PH \left(\|z_j\|^\gamma + \frac{q+\Delta}{\gamma} P \right) \right) z_j + c_7 T^2 + o(1). \end{aligned} \tag{4.13}$$

Using (2.11) leads to

$$z_{l(n_k,T)}^\tau P z_{l(n_k,T)} - z_{n_k}^\tau P z_{n_k} = \frac{1}{2} \sum_{j=n_k}^{l(n_k,T)} b_j z_j^\tau \left(-\|z_j\|^\gamma I + \frac{2(q+\Delta)}{\gamma} P \right) z_j + c_7 T^2 + o(1).$$

From this by (4.6), (4.10) we obtain

$$\begin{aligned} z_{l(n_k,T)}^\tau P z_{l(n_k,T)} - z_{n_k}^\tau P z_{n_k} &< -\frac{1}{2} \sum_{j=n_k}^{l(n_k,T)} b_j \frac{\epsilon}{2\gamma} \|z_j\|^2 + c_7 T^2 + o(1) \\ &< -\frac{\epsilon}{2\gamma} \left(\frac{2(q+\Delta)\lambda_{\max} + \epsilon}{\gamma} \right)^{\frac{2}{\gamma}} T + c_7 T^2 + o(1) \\ &\le -\frac{\epsilon}{3\gamma} \left(\frac{2(q+\Delta)\lambda_{\max} + \epsilon}{\gamma} \right)^{\frac{2}{\gamma}} T \end{aligned} \tag{4.14}$$

for sufficiently small T and large enough k. This means that after a finite number of steps (4.10) will not be satisfied; i.e., z_n will enter the ellipsoid $\{z : z^\tau P z \le b\}$. This together with (4.8) implies that $\{z_n^\tau P z_n\}$ will cross the interval $[b, a+\delta]$ infinitely often; i.e., there are two subsequences $\{z_{l_k}\}$ and $\{z_{m_k}\}$ such that

$$z_{l_k}^\tau P z_{l_k} \le b, \qquad z_{m_k}^\tau P z_{m_k} \ge a + \delta,$$

$$b < z_i^\tau P z_i < a + \delta \quad \forall i : l_k < i < m_k.$$

Take T sufficiently small such that $c_6 T < a + \delta - b$. Then by (4.12) we see $l(l_i, T) < m_i$ $\forall i$ and

$$z_{l(l_k,T)}^\tau P z_{l(l_k,T)} \in (b, a+\delta),$$

which combined with (4.14) leads to a contradiction:

$$0 < z_{l(l_k,T)}^{\tau} P z_{l(l_k,T)} - z_{l_k}^{\tau} P z_{l_k} \le -\frac{\epsilon}{3\gamma} \left(\frac{2(q+\Delta)\lambda_{\max} + \epsilon}{\gamma} \right)^{\frac{2}{\gamma}} T.$$

Therefore, (4.8) is impossible or (4.7) is impossible. Since δ may be arbitrarily small, the impossibility of (4.7) implies (4.1). Tending Δ to zero, from (4.1) we derive (2.12).

(ii) Now, let H be symmetric. We simply consider $\|z\|^2$ instead of $z^{\tau}Pz$ and set in (4.1) and (4.5)

$$a = \left(\frac{q+\Delta}{\lambda_l \gamma} \right)^{\frac{2}{\gamma}}, \quad b = \left(\frac{q+\Delta+\epsilon}{\lambda_l \gamma} \right)^{\frac{2}{\gamma}}.$$

The proof can be carried out along the lines of that given for the general case. For example, corresponding to (4.5), (4.6) we now have

$$\|z\|^2 \ge b, \text{ and } z^{\tau} \left(H\|z\|^{\gamma} + \frac{q+\Delta}{\gamma} I \right) z \le z^{\tau} \left(-\lambda_l \frac{q+\Delta+\epsilon}{\lambda_l \gamma} + \frac{q+\Delta}{\gamma} \right) z = -\frac{\epsilon}{\gamma} \|z\|^2,$$

respectively, while (4.13) becomes

$$\|z_{l(n_k,T)}\|^2 - \|z_{n_k}\|^2 \le -\sum_{j=n_k}^{l(n_k,T)} b_j z_j^{\tau} \left(H \left(\|z_j\|^{\gamma} + \frac{q+\Delta}{\gamma} I \right) z_j + c_7 T^2 + o(1) \right).$$

(iii) Since $q > 0$, we may set $\Delta = 0$ in (3.3) and in the proofs of Lemma 3 and part (i) of the theorem.

In the one-dimensional case H in (2.5) is a negative number, and λ_l in (2.14) equals $|H|$. The root set of $h(z)$ defined by (3.3) with $\Delta = 0$ is $J = \{0, \pm(\frac{q}{-H\gamma})^{\frac{1}{\gamma}}\}$.

It is easy to define a twice differentiable function $v(z)$ such that

$$v(z) = v(-z),\ 0 < v(z) < v(0) \quad \forall z : |z| \le \zeta,$$

$$v'(z)h(z) < 0 \quad \forall z \notin \left\{ 0, \pm \left(\frac{q}{-H\gamma} \right)^{\frac{1}{\gamma}} \right\},$$

where ζ is given in (4.2).

For $\forall t \le T$ we find that

$$\lim_{T\to 0} \limsup_{k\to\infty} \frac{1}{T} \left\| \sum_{i=k}^{l(k,t)} (b_i o(1) + a_i (\log a_{i+1}^{-1})^{\frac{1}{\gamma}} \epsilon_{i+1}) \right\|$$

$$\le \lim_{T\to 0} \limsup_{k\to\infty} \frac{1}{T} \{t \cdot o(1)\} + \lim_{T\to 0} \limsup_{k\to\infty} \frac{1}{T} \left\| \sum_{i=k}^{l(k,t)} a_i (\log a_{i+1}^{-1})^{\frac{1}{\gamma}} \epsilon_{i+1} \right\|$$

$$= 0. \tag{4.15}$$

Applying Remark 2 in section 2 to (4.4) leads to

$$\lim_{k\to\infty} d(z_k, J) = 0.$$

This is valid for any $\{\epsilon_i\}$ satisfying (4.15). In particular, if $\{\epsilon_i\}$ is such that $b_i o(1) + a_i(\log a_{i+1}^{-1})^{\frac{1}{\gamma}}\epsilon_{i+1} = 0\ \forall i \geq 1$, then (4.4) becomes the following recursion:

$$z_{n+1} = z_n + b_n h(z_n). \tag{4.16}$$

Note that $h'(0) = \frac{q}{\gamma} > 0$, and hence 0 is not stable for the equation

$$\dot{z}_t = h(z_t).$$

It is clear that 0 cannot be the limit point of (4.16).

Therefore, in this case z_n can converge either to $(\frac{q}{|H|\gamma})^{\frac{1}{\gamma}}$ or to $-(\frac{q}{|H|\gamma})^{\frac{1}{\gamma}}$. This verifies the attainability of the upper bound in (2.14). □

5. Concluding remarks. By using a deterministic analysis we have shown the pathwise convergence rate of SA when $f(x^0) = 0$ and $f'(x^0) = 0$. Some problems are still open and belong to further research. First, it might be possible to obtain more precise results. For example, as a conjecture, the limit of the left-hand side of (2.14) is one of $(\frac{q}{\lambda_i\gamma})^{\frac{1}{\gamma}}$, $i = 1, \ldots, l$, depending upon the initial value where λ_i, $i = 1, \ldots, l$ are the eigenvalues of H. Second, it is not clear what happens if $f(\cdot)$ has more complicated behavior as $x \to x^0$.

THE VALUE FUNCTION OF THE SINGULAR QUADRATIC REGULATOR PROBLEM WITH DISTRIBUTED CONTROL ACTION*

FRANCESCA BUCCI† AND LUCIANO PANDOLFI‡

Abstract. We study the regularity properties of the value function of a quadratic regulator problem for a linear distributed parameter system with distributed control action. No definiteness assumption on the cost functional is assumed. We study the regularity in time of the value function and also the space regularity in the case of a holomorphic semigroup system.

Key words. value function, quadratic regulator, distributed systems

1. Introduction. In this paper we are concerned with a general class of finite horizon linear-quadratic optimal control problems for evolution equations with distributed control and *nondefinite* cost. More precisely, we consider the following abstract differential equation over a finite interval $[\tau, T]$, $0 \le \tau < T < +\infty$:

$$\dot{x} = Ax + Bu, \qquad x(\tau) = x_0 \in X, \tag{1.1}$$

where A is the infinitesimal generator of a strongly continuous semigroup e^{At} on a Hilbert space X, B is a linear bounded operator from the control space U to X. With the dynamics (1.1), we associate the cost functional

$$J_\tau(x_0, u) = \int_\tau^T F(x(t), u(t))dt + \langle x(T), P_0\, x(T)\rangle, \tag{1.2}$$

where $x(\cdot) = x(\cdot, \tau, x_0, u)$ is the mild solution to equation (1.1) and F is the quadratic form

$$F(x, u) = \langle x, Qx\rangle + \langle x, Su\rangle + \langle Su, x\rangle + \langle u, Ru\rangle \tag{1.3}$$

(we denoted by $\langle\cdot,\cdot\rangle$ inner products in both the spaces X and U). All the operators Q, S, R, and P_0 contained in the functional (1.2) are linear bounded operators in the proper spaces, with $Q = Q^*$, $R = R^*$, $P_0 = P_0^*$. We define as usual the *value function* of the problem:

$$V(\tau, x_0) := \inf_{u \in L^2(\tau, T; U)} J_\tau(x_0, u).$$

The goal of this work is

- to characterize the property

$$V(\tau, x_0) > -\infty \quad \forall x_0 \in X, \quad \forall \tau \in [0, T]; \tag{1.4}$$

- to study the regularity properties of the map

$$\tau \to V(\tau, x_0)$$

on the interval $[0, T]$, when x_0 is fixed.

We shall consider also the map $x_0 \to V(\tau, x_0)$ in a special case; see section 6. It is well known that if the regulator problem is *standard*, i.e.,

$$Q \geq 0, \quad S = 0, \quad R \geq \alpha > 0, \quad P_0 \geq 0, \tag{1.5}$$

then the solution to the operator Riccati equation corresponding to problem (1.1)–(1.2) provides the synthesis of the unique optimal control. This problem is well understood, both in finite and in infinite dimensions, over a finite or infinite time horizon (compare [10], [2], [3]).

The purpose of this paper is to examine the case when (1.5) fails, with special interest in noncoercive R. We shall see that in this case the function $\tau \to V(\tau, x_0)$ has some mild regularity properties; see section 4. More regularity is obtained in the coercive case; see section 5.

The study of linear quadratic regulator (LQR) problems with nondefinite cost is related to a large variety of problems. Among them, we recall the study of *dissipative* systems (see [20]), the analysis of the stability of feedback systems [14], the analysis of second variations of nonlinear optimization problems (see [5], [15]). When game theory is studied for linear systems then the quadratic form (1.3) is nonpositive. In particular, the suboptimal H^∞-problem can be recast in this setting [1]. Finally, very recently, singular control theory has been used to obtain new results on *regular* control problems for some class of boundary control systems: systems with input delays first [16], and later systems described by wave- or plate-like equations with high internal damping [9].

We recall that the existing results for finite-dimensional systems over an infinite time interval ([19], [21]; see also [4]) were extended to distributed systems in [22], [23], [12], [13], [8]. If $T < +\infty$, the only work we know in an infinite-dimensional context, in which a nonpositive cost functional is studied, is [6]. This paper considers even time-varying systems but under the restriction $R = I$.

2. A simple example. The interest of the results presented in this paper is justified by the possible applications that we already quoted, for instance to H^∞-control theory over a finite time interval, or to the analysis of the second variation of general cost functionals. However, the following example may help the reader to understand our problem. The example is a bit artificial, since we want to present a very simple one. Nevertheless it is suggested by nontrivial problems in network theory.

A delay line in its simpler form is described by an input-output relation,

$$v(t, x) = v(t + x) = \int_{-1}^{0} u(t + s + x)\, d\eta(s), \tag{2.1}$$

where $t > 0$, $x \in (-1, 0)$ and the integral is a Stieltjes integral.

For simplicity we assume that the input $u(\cdot)$ is continuous, a condition that can be very much relaxed.

The simplest case described by (2.1) is

$$v(t, x) = u(t + x - 1) \tag{2.2}$$

and corresponds to a jump function η, with jump at -1. If the system is started at $t = 0$ then the input (2.1) is read only for $t > 0$, so that the output $v(\cdot)$ from (2.1) is given by

$$v(t,x) = \begin{cases} \phi(x+t), & -1 < x+t < 0, \\ \int_{-1}^{0} u(t+s+x)\, d\eta(s) & \text{otherwise.} \end{cases}$$

The function ϕ describes the "initial state" of the system (quite often it will be $\phi = 0$). In the case of equation (2.2) we have in particular

$$v(t,x) = \begin{cases} u(t+x-1), & t+x > 1, \\ \phi(t+x-1), & t+x < 1. \end{cases}$$

Notice that if $\phi(\cdot)$ and $u(\cdot)$ are regular then $v(t,x) = v(t+x)$ solves the first-order hyperbolic equation

$$v_t = v_x, \qquad v(0,x) = \phi(x), \quad v(t,0) = u(t-1).$$

The function v can be interpreted as a delayed potential at the output of the network produced by the potential $u(\cdot)$ at the input. If the delay line is connected to a resistive load, it produces a current $i(t) = \frac{1}{R} v(t-1)$, and the energy dissipated by the load in time T is given by

$$-\int_0^T i(t)v(t-1)\, dt = -\int_0^T \frac{1}{R}|v(t-1)|^2\, dt.$$

Since

$$v(t,-1) = \begin{cases} \phi(t-1), & 0 < t < 1, \\ u(t-1), & t > 1, \end{cases}$$

then

$$-\int_0^T i(t)v(t-1)\, dt = \begin{cases} -\int_0^T \frac{1}{R}|\phi(t-1)|^2\, dt & \text{if } T < 1, \\ -\int_0^1 \frac{1}{R}|\phi(t-1)|^2\, dt - \int_1^T \frac{1}{R}|u(t-1)|^2\, dt & \text{if } T > 1. \end{cases}$$

The energy that the load can dissipate is at most

$$\inf_{u(\cdot)} -\int_0^T i(t)v(t-1)\, dt.$$

We see from this that the load dissipates a finite amount of energy $V(\phi)$ if $T < 1$, described by the quadratic functional

$$V(\phi) = -\int_0^T \frac{1}{R}|\phi(t-1)|^2\, dt. \tag{2.3}$$

Otherwise, the load can dissipate as much energy as we want.

Hence it makes sense to study the energy function $E(T)$:

$$E(T) = \inf_{u \in L^2(0,T)} -\int_0^T i(t)v(t-1)\, dt.$$

In this example the function $E(T)$ is finite only if $T < 1$, and in this case $E(T)$ is the quadratic functional (2.3).

In this paper we consider an analogous problem in more generality: we study the dependence on the interval $[\tau, T]$ of the "energy" dissipated by a certain linear time invariant system.

3. Preliminary results. We recall that the solution to (1.1) is

$$x(t) = e^{A(t-\tau)}x_0 + (L_\tau u)(t), \tag{3.1}$$

with

$$(L_\tau u)(t) = \int_\tau^t e^{A(t-s)}Bu(s)\,ds,$$

$$: \text{ continuous } L^2(\tau,T;U) \to L^2(\tau,T;X). \tag{3.2}$$

Note that $t \to (L_\tau u)(t)$ is an X-valued continuous function.

The adjoint L_τ^* of L_τ: $\langle L_\tau u, f\rangle_{L^2(\tau,T;X)} = \langle u, L_\tau^* f\rangle_{L^2(\tau,T;U)}$ is given by

$$(L_\tau^* f)(t) = B^* \int_t^T e^{A^*(s-t)}\, f(s)\,ds,$$

$$: \text{ continuous } L^2(\tau,T;X) \to L^2(\tau,T;U).$$

Introduce also the bounded operator from U to X:

$$L_{\tau,T}u = \int_\tau^T e^{A(T-s)}Bu(s)\,ds$$

(which describes the map (3.1) from the input u to the solution of (1.1) at time $t = T$, with initial time τ and $x_0 = 0$). The adjoint of $L_{\tau,T}$ is the map given by

$$(L_{\tau,T}^* y)(t) = B^*\, e^{A^*(T-t)}y.$$

Using (3.1), one can easily show the following lemma.

LEMMA 3.1. *The cost functional* (1.2) *can be rewritten as*

$$J_\tau(x_0,u) = \langle \mathcal{M}_\tau x_0, x_0\rangle + 2\,Re\,\langle \mathcal{N}_\tau x_0, u\rangle + \langle \mathcal{R}_\tau u, u\rangle, \tag{3.3}$$

with $\mathcal{M}_\tau \in \mathcal{L}(X)$, $\mathcal{N}_\tau \in \mathcal{L}(X, L^2(\tau,T;U))$, *and* $\mathcal{R}_\tau \in \mathcal{L}(L^2(\tau,T;U))$, $\mathcal{M}_\tau$ *and* $\mathcal{R}_\tau$ *self-adjoint, defined as follows:*

$$\mathcal{M}_\tau x = e^{A^*(T-\tau)}\,P_0\,e^{A(T-\tau)}x + \int_\tau^T e^{A^*(t-\tau)}Q\,e^{A(t-\tau)}x\,dt, \tag{3.4}$$

$$(\mathcal{N}_\tau x)(t) = (L_\tau^* Q\, e^{A(\cdot-\tau)}x)(t) + S^* e^{A(t-\tau)}x + (L_{\tau,T}^* P_0\, e^{A(T-\tau)}x)(t), \tag{3.5}$$

$$(\mathcal{R}_\tau u)(t) = (L_\tau^* Q\,(L_\tau u))(t) + S^*(L_\tau u)(t) + (L_\tau^* S u)(t)$$

$$+ Ru(t) + (L_{\tau,T}^* P_0\, L_{\tau,T} u)(t). \tag{3.6}$$

We first state a lemma, which will be useful later.

LEMMA 3.2. *If there exists* τ_0 *and a constant* γ *such that*

$$\mathcal{R}_{\tau_0} \geq \gamma\, I, \tag{3.7}$$

then $\mathcal{R}_\tau \geq \gamma\, I$ *for any* $\tau > \tau_0$.

Proof. It is sufficient to notice that if $\tau > \tau_0$ we can write

$$\langle \mathcal{R}_\tau u, u\rangle_{L^2(\tau,T;U)} = \langle \mathcal{R}_{\tau_0} v, v\rangle_{L^2(\tau_0,T;U)},$$

where $v(\cdot)$ is given by $v(t) = 0$ if $\tau_0 \le t < \tau$ and $u(t)$ when $t \ge \tau$. Hence, from (3.7) it follows that $\mathcal{R}_\tau \ge \gamma\, I$ for any $\tau \in [\tau_0, T]$. □

We shall use the following general result pertaining to continuous quadratic forms in Hilbert spaces, whose proof is given for the sake of completeness.

LEMMA 3.3. *Let X and U be two Hilbert spaces, and consider*

$$f(x,u) = 2Re\langle \mathcal{N}x, u\rangle + \langle \mathcal{R}u, u\rangle$$

with $\mathcal{N} \in \mathcal{L}(X,U)$, $\mathcal{R} \in \mathcal{L}(U)$, $\mathcal{R} = \mathcal{R}^*$.

1. *If there exists $x \in X$ such that*

$$V(x) := \inf_{u\in U} f(x,u) > -\infty,$$

then $\mathcal{R} \ge 0$.

2. *The infimum of $f(x,\cdot)$ is attained if and only if the equation*

$$\mathcal{R}u = -\mathcal{N}x \tag{3.8}$$

is solvable, and in this case any solution u of (3.8) gives a minimum.

3. *If for each $x \in X$ there exists a* unique *u_x such that*

$$f(x,u_x) = \min_u f(x,u),$$

then $\mathcal{R}$ is invertible (the inverse $\mathcal{R}^{-1}$ may not be bounded) and $u_x = -\mathcal{R}^{-1}\mathcal{N}x$ so that the transformation $x \to u_x$ is linear and continuous from X to U.

4. *Let us assume that $V(x) > -\infty$ for each $x \in X$. Then there exists a linear bounded operator $P \in \mathcal{L}(X)$ such that*

$$V(x) = \langle x, Px\rangle \qquad \forall x \in X\,. \tag{3.9}$$

Proof. If there exists v such that $\langle \mathcal{R}v, v\rangle < 0$ then $f(x,\lambda v) \to -\infty$ as $\lambda \to +\infty$. This proves Lemma 3.3(1). The second item is well known [23, Lemma 2.3]. To prove the third item we use item 2: the minimum u_x is characterized by (3.8). This equation is uniquely solvable for every x by assumption. Hence, $\ker \mathcal{R} = \{0\}$ and $\operatorname{im} \mathcal{N} \subseteq \operatorname{im} \mathcal{R}$. Consequently, $u_x = -\mathcal{R}^{-1}\mathcal{N}x$ where $\mathcal{R}^{-1}$ acts from the closure of the image of $\mathcal{R}$. Hence, $\mathcal{R}^{-1}\mathcal{N}$ is bounded since $\mathcal{R}^{-1}$ is closed and $\mathcal{N}$ is bounded.

The proof of the fourth item follows an approach in [7]. If $\mathcal{R}$ is coercive, then it is boundedly invertible, so that $f(x,\cdot)$ admits a unique minimum, namely, $u^+ = -\mathcal{R}^{-1}\mathcal{N}x$, and

$$V(x) = f(x,u^+) = -\langle x, \mathcal{N}^*\mathcal{R}^{-1}\mathcal{N}x\rangle.$$

Hence, (3.9) holds true and we have obtained an explicit expression for P, i.e.,

$$P = -\mathcal{N}^*\mathcal{R}^{-1}\mathcal{N}.$$

If we simply have $\mathcal{R} \ge 0$, we consider the function

$$f_n(x,u) = f(x,u) + \frac{1}{n}|u|^2.$$

Now $\mathcal{R}_n = \mathcal{R} + \frac{1}{n} I$ is coercive; hence

$$V_n(x) = \min_u f_n(x,u) = \langle x, P_n x \rangle,$$

with $P_n \in \mathcal{L}(X)$. By construction

$$n \to \langle x, P_n x \rangle$$

is a decreasing numerical sequence for any $x \in X$, and

$$V(x) \le \langle x, P_n x \rangle \le \langle x, P_1 x \rangle; \tag{3.10}$$

hence there exists $P \in \mathcal{L}(X)$ such that

$$\langle x, Px \rangle = \lim_{n \to +\infty} \langle x, P_n x \rangle = \inf_n \langle x, P_n x \rangle \ge V(x) \quad \forall x \in X.$$

To conclude, it remains to show that $V(x)$ *coincides* with $\langle x, Px \rangle$ for any $x \in X$. Assume by contradiction that $V(x) < \langle x, Px \rangle$ for a given $x \in X$, and let $\alpha > 0$ such that

$$\langle x, Px \rangle = V(x) + \alpha\,.$$

Since $V(x) = \inf_u f(x,u)$ there exists $\overline{u} \in U$ such that

$$f(x, \overline{u}) < V(x) + \frac{\alpha}{2}. \tag{3.11}$$

Correspondingly, there exists an integer $n_0 \in \mathbb{N}$ such that

$$0 \le f_{n_0}(x, \overline{u}) - f(x, \overline{u}) = \frac{1}{n_0} |\overline{u}|^2 < \frac{\alpha}{2}. \tag{3.12}$$

From (3.11) and (3.12) it follows that

$$V(x) \le \langle x, P_{n_0} x \rangle \le f_{n_0}(x, \overline{u}) < V(x) + \alpha,$$

which is a contradiction; compare (3.10). □

The above lemma and (3.3) imply a first necessary condition for finiteness of the value function.

LEMMA 3.4. *If there exists x_0 such that $V(\tau, x_0) > -\infty$, then*

$$J_\tau(0,u) = \langle \mathcal{R}_\tau u, u \rangle \ge 0 \quad \forall u \in L^2(\tau, T; U). \tag{3.13}$$

This observation is now used to obtain a necessary condition of more practical interest, which is well known in the finite-dimensional case. The symbol I denotes the identity operator acting on a space which will be clear from the context.

PROPOSITION 3.5. *If there exists $\tau_0 \in [0, T)$ and a constant $\gamma \ge 0$ such that $\mathcal{R}_{\tau_0} \ge \gamma\, I$, then $R \ge \gamma I$.*

Consequently,

$$\text{if there exists } x_0 \text{ and } \tau_0 \text{ such that } V(\tau_0, x_0) > -\infty, \text{ then } R \ge 0. \tag{3.14}$$

Proof. We first consider the case $\gamma = 0$; hence by assumption $\mathcal{R}_{\tau_0} \ge 0$. By contradiction, suppose that there exists a control $u_0 \in U$ and a constant $\alpha > 0$ such that $\langle R u_0, u_0 \rangle = -\alpha$. Given a small $\epsilon > 0$, choose a control u as follows:

$$u(t) = \begin{cases} 0, & \tau_0 \le t < T - \epsilon, \\ u_0, & T - \epsilon \le t \le T, \end{cases}$$

and compute

$$\begin{aligned}\langle \mathcal{R}_{\tau_0} u, u\rangle &= \int_{T-\epsilon}^{T} \left\langle Q \int_{T-\epsilon}^{t} e^{A(t-s)} B u_0 \, ds, \int_{T-\epsilon}^{t} e^{A(t-s)} B u_0 \, ds \right\rangle dt \\ &+ \epsilon \langle R u_0, u_0\rangle + 2\, Re \int_{T-\epsilon}^{T} \left\langle \int_{T-\epsilon}^{t} e^{A(t-s)} B u_0 \, ds, S u_0 \right\rangle dt \\ &+ \int_{T-\epsilon}^{T} \left\langle P_0 \int_{T-\epsilon}^{T} e^{A(T-s)} B u_0 \, ds, \int_{T-\epsilon}^{T} e^{A(T-s)} B u_0 \, ds \right\rangle dt \\ &= -\epsilon\alpha + o(\epsilon) + o(\epsilon^2) \quad \text{as } \epsilon \text{ tends to zero.} \end{aligned} \tag{3.15}$$

Since ϵ can be taken arbitrarily small, (3.15) yields $\langle \mathcal{R}_{\tau_0} u, u\rangle < 0$, and this contradicts the assumption.

Assume instead $\mathcal{R}_{\tau_0} \geq \gamma I > 0$. By choosing $u(t) = 0$ for $t \in [\tau_0, T-\epsilon[$, $u(t) = u_0 \in U$ arbitrary when $t \in [T-\epsilon, T]$, a direct computation yields

$$\gamma\epsilon \|u_0\|^2 \leq \epsilon \langle R u_0, u_0\rangle + o(\epsilon)\|u_0\|^2,$$

which implies $\langle R u_0, u_0\rangle \geq \gamma \|u_0\|^2$ for any $u_0 \in U$.

Finally, if $V(\tau_0, x_0) > -\infty$ for some $\tau_0 \in [0, T)$ and $x_0 \in X$, then from Lemma 3.4 it follows that $\mathcal{R}_\tau$ is a nonnegative operator for $\tau \geq \tau_0$. Therefore, from the previous part of the proof, $R \geq 0$. ∎

We now show that the value function satisfies Bellman's optimality principle, which is known, in the context of linear-quadratic problems, as linear operator inequality (LOI) or dissipation inequality (DI).

We begin with the following lemma.

LEMMA 3.6. *If for some number τ and some $x_0 \in X$ we have $V(\tau, x_0) > -\infty$, then we have also $V(t, x(t)) > -\infty$ for each $t \in [\tau, T]$. Here, $x(t)$ denotes the value at time t of the function given by* (3.1) *for any fixed control $u(\cdot)$ on $[\tau, t]$.*

Proof. Let $t \in (\tau, T)$. Then

$$\begin{aligned} J_\tau(x_0, u) &= \int_\tau^t F(x(s), u(s))\, ds + \int_t^T F(x(s), u(s))\, ds \\ &+ \langle x(T), P_0 x(T)\rangle = \int_\tau^t F(x(s), u(s)) ds + J_t(x(t), u), \end{aligned}$$

where $x(\cdot) = x(\cdot, \tau, x_0, u)$ for any $u \in L^2(\tau, T; U)$. Now take a control $v \equiv 0$ on $[\tau, t)$; then

$$J_\tau(x_0, u+v) = \int_\tau^t F(x(s), u(s))\, ds + J_t(x(t), u+v)$$

and

$$\inf_v J_\tau(x_0, u+v) = \int_\tau^t F(x(s), u(s))\, ds + \inf_v J_t(x(t), u+v). \tag{3.16}$$

The conclusion immediately follows since in fact $\inf_v J_t(x(t), u+v) = V(t, x(t))$. ∎

THEOREM 3.7. *Let $\tau \in [0,T]$ and $x_0 \in X$ be given. Let V be the value function of problem* (1.1), (1.2) *and assume that $V(\tau, x_0) > -\infty$. Then*

$$\int_\tau^t F(x(s), u(s))\, ds \,+\, V(t, x(t)) - V(\tau, x_0) \geq 0 \tag{3.17}$$

for any $u(\cdot) \in L^2(\tau, T; U)$ and any $t \in (\tau, T)$, with $x(\cdot) = x(\cdot, \tau, x_0, u)$. Moreover, the equality holds true if and only if the control u in (3.17) *is optimal.*

Proof. We return to the conclusion of Lemma 3.6 and observe again that

$$\inf_v J_t(x(t), u+v) = \inf_u J_t(x(t), u) \,=\, V(t, x(t)), \tag{3.18}$$

while

$$\inf_v J_\tau(x_0, u+v) \geq V(\tau, x_0); \tag{3.19}$$

hence plugging (3.18) into (3.16) and taking into account (3.19), we get

$$V(\tau, x_0) \leq \int_\tau^t F(x(s), u(s)) ds \,+\, V(t, x(t)), \tag{3.20}$$

which is nothing but (3.17). Thus, if for a given initial datum x_0 there exists an optimal control $u^+(\cdot, \tau, x_0)$ minimizing $J_\tau(x_0, u)$, then we can rewrite (3.16) and (3.19) with $u = u^+(\cdot, \tau, x_0)$, and (3.19) is in fact an equality. Therefore, (3.20) becomes an equality as well. For these arguments compare also [11].

Vice versa, assume that (3.17) is satisfied for any control $u \in L^2(\tau, T; U)$ and it is an equality for a given u^*. Then, passing to the limit, as $t \to T^-$, in (3.17) with $u = u^*$ and $x = x^* = x(\cdot\,, \tau, x_0, u^*)$ and assuming for the moment that

$$\lim_{t \to T^-} V(t, x^*(t)) = \langle x^*(T), P_0 x^*(T) \rangle, \tag{3.21}$$

we readily get

$$V(\tau, x_0) = \int_\tau^T F(x^*(s), u^*(s))\, ds \,+ \langle x^*(T), P_0 x^*(T) \rangle;$$

that is,

$$V(\tau, x_0) = J_\tau(x_0, u^*);$$

hence by definition u^* is optimal.

To conclude, it remains to show that if (x^*, u^*) satisfies

$$\int_\tau^t F(x^*(s), u^*(s))\, ds \,+\, V(t, x^*(t)) - V(\tau, x_0) \,=\, 0, \tag{3.22}$$

then (3.21) holds true. From (3.22) it follows that there exists

$$\lim_{t \to T^-} V(t, x^*(t)) = V(\tau, x_0) - \int_\tau^T F(x^*(s), u^*(s))\, ds,$$

and by the very definition of the value function it follows that

$$\lim_{t \to T^-} V(t, x^*(t)) \leq \langle x^*(T), P_0 x^*(T) \rangle.$$

To see this rewrite the above limit as

$$\lim_{t\to T^-} V(t,x^*(t)) = V(\tau,x_0) - \int_\tau^T F(x^*(s),u^*(s))\,ds - \langle x^*(T),P_0x^*(T)\rangle + \langle x^*(T),P_0x^*(T)\rangle.$$

By contradiction, assume now that

$$\lim_{t\to T^-} V(t,x^*(t)) = \langle x^*(T),P_0x^*(T)\rangle - \gamma,$$

where γ is a suitable positive constant. Then there exists $\delta>0$ such that

$$V(t,x^*(t)) < \langle x^*(T),P_0x^*(T)\rangle - \frac{\gamma}{2} \tag{3.23}$$

for any $t\in(T-\delta,T)$. Recall now that

$$x^*(T) = x(T,\tau,x_0,u^*) = x(T,t,x^*(t),u^*{}_{|s\geq t});$$

hence we can rewrite

$$\langle x^*(T),P_0x^*(T)\rangle = \underbrace{\langle e^{A(T-t)}x^*(t),P_0\,e^{A(T-t)}x^*(t)\rangle}_{A_1} + \underbrace{2\,Re\int_t^T \langle u^*(s),B^*e^{A^*(T-s)}P_0\,e^{A(T-t)}x^*(t)\rangle\,ds}_{A_2} + \underbrace{\int_t^T \langle u^*(s),B^*e^{(T-s)A^*}P_0\,L_{t,T}u^*\rangle\,ds}_{A_3}.$$

Take a possibly smaller δ, in order to get

$$A_2 + A_3 < \frac{\gamma}{4}, \tag{3.24}$$

so that (3.23) yields

$$V(t,x^*(t)) < A_1 - \frac{\gamma}{4}. \tag{3.25}$$

Finally, let δ such that

$$\left|\int_t^T \langle Qe^{A(s-t)}x^*(t),e^{A(s-t)}x^*(t)\rangle ds\right| < \frac{\gamma}{8}. \tag{3.26}$$

Now fix $t\in(T-\delta,T)$ so that (3.24) and (3.26) hold true. From (3.25) it follows that there exists a control $v=v_t\in L^2(t,T;U)$ such that

$$J_t(x^*(t),v_t) < A_1 - \frac{\gamma}{4};$$

that is, by means of (3.3),

$$\langle \mathcal{M}_t x^*(t), x^*(t)\rangle + 2\,Re\,\langle \mathcal{N}_t x^*(t), v_t\rangle + \langle \mathcal{R}_t v_t, v_t\rangle \,<\, A_1 - \frac{\gamma}{4},$$

with $\mathcal{M}_t$, $\mathcal{N}_t$, $\mathcal{R}_t$ defined in (3.4), (3.5), and (3.6), respectively. We know that $\langle \mathcal{M}_t x^*(t), x^*(t)\rangle$ is $A_1 + \int_t^T \langle\, e^{A^*(s-t)} Q\, e^{A(s-t)} x^*(t), x^*(t)\rangle\, ds$. Thus we cancel the term A_1, we take into account (3.26), and we obtain

$$2\,Re\,\langle \mathcal{N}_t x^*(t), v_t\rangle + \langle \mathcal{R}_t v_t, v_t\rangle \,<\, -\frac{\gamma}{8}\,. \tag{3.27}$$

In particular this implies that $v_t \neq 0$. Notice now that

$$|\langle \mathcal{N}_t x^*(t), v_t\rangle| \le \epsilon\,(T-t)\cdot |v_t(\cdot)|_{L^2(t,T;U)}, \quad |\langle \mathcal{R}_{t,T} v_t, v_t\rangle| \le \text{const}\cdot |v_t(\cdot)|^2_{L^2(t,T;U)},$$

and therefore

$$\liminf_{t\to T^-} |v_t(\cdot)|_{L^2(t,T;U)} = \beta > 0 \qquad (\text{possibly } \beta = +\infty).$$

Hence there exists a sequence t_n such that

$$\frac{1}{|v_{t_n}(\cdot)|^2}\,\langle \mathcal{N}_{t_n} x^*(t), v_{t_n}\rangle \to 0,$$

so that we see from (3.27) for n large

$$\frac{1}{|v_{t_n}(\cdot)|^2}\,\langle \mathcal{R}_{t_n} v_{t_n}, v_{t_n}\rangle \,<\, 0.$$

In other words $J_{t_n}(0, v_{t_n}) < 0$ and this is a contradiction since by assumption $J_\tau(0,u)$ is nonnegative for any $u \in L^2(\tau, T; U)$. □

The next proposition is an immediate consequence of Lemmas 3.1 and 3.3. We omit the proof.

PROPOSITION 3.8. *Let $\tau \in [0,T]$. If*

$$V(\tau, x_0) \,>\, -\infty \quad \forall x_0 \in X, \tag{3.28}$$

there exists a self-adjoint operator $W(\cdot) \in \mathcal{L}(X)$ such that $W(T) = P_0$ and

$$V(\tau, x_0) = \langle x_0, W(\tau) x_0\rangle. \tag{3.29}$$

4. Time regularity of the value function: The noncoercive case. In this section we investigate the regularity properties of $V(\tau, x_0)$ with respect to the initial time τ.

We note that several regularity results are known for the value function even of nonlinear systems, and with more general cost but under special boundedness properties, which are not satisfied in the present case, compare [11, Chapter 6].

Our first result is Lemma 4.1.

LEMMA 4.1. *Let $\tau_0 \in [0,T]$ and x_0 be such that $V(\tau_0, x_0)$ is finite. Then $\tau \to V(\tau, x_0)$ is upper semicontinuous at τ_0.*

Proof. Fix $x_0 \in X$, and let $\tau_0 \in [0,T]$. In order to show that

$$\limsup_{\tau\to\tau_0} V(\tau, x_0) \le V(\tau_0, x_0),$$

we shall show that for any real number $\alpha > V(\tau_0, x_0)$ we have $\alpha > V(\tau, x_0)$ if $|\tau - \tau_0|$ is taken small enough. We first consider the case when $\tau > \tau_0$. Let u be an admissible control such that

$$J_{\tau_0}(x_0, u) < \alpha, \tag{4.1}$$

and define

$$x_\tau(t) = e^{A(t-\tau)}x_0 + \int_\tau^t e^{A(t-s)}Bu(s)\,ds.$$

It is readily verified that

1. $\lim_{\tau\to\tau_0} x_\tau(T) = x_{\tau_0}(T)$,
2. $\lim_{\tau\to\tau_0} \int_\tau^T F(x_\tau(s), u(s))\,ds = \int_{\tau_0}^T F(x_{\tau_0}(s), u(s))\,ds$

so that if $|\tau - \tau_0|$ is small enough,

$$V(\tau, x_0) \le J_\tau(x_0, u) < \alpha.$$

Finally, if $\tau < \tau_0$, choose once more $u \in L^2(\tau_0, T; U)$ in such a way that (4.1) holds true. It is now sufficient to repeat the same arguments used before, after replacing u with $\hat{u}$ defined as follows:

$$\hat{u}(t) := \begin{cases} 0, & t < \tau_0, \\ u(t), & t \ge \tau_0. \end{cases}$$

The proof is complete. □

As to lower semicontinuity, the following result holds true.

LEMMA 4.2. *Let x_0 be such that $\tau \to V(\tau, x_0)$ is finite on $[0, T]$. Then*

- *the map $\tau \to V(\tau, x_0)$ is lower semicontinuous at τ_0 provided that for each element τ_n of a sequence $\{\tau_n\}$ which tends monotonically to τ_0 there exists a control $u_{\tau_n} \in L^2(\tau_n, T; U)$ such that*

$$\begin{aligned} &\text{(i)} \quad V(\tau_n, x_0) \le J_{\tau_n}(x_0, u_{\tau_n}) \le V(\tau_n, x_0) + \tfrac{1}{n}\,; \\ &\text{(ii)} \quad \text{there exists } \gamma_0 > 0 \text{ for which } |u_{\tau_n}(\cdot)|_{L^2(\tau_n, T; U)} \le \gamma_0. \end{aligned} \tag{4.2}$$

Proof. Let $\tau_0 \in [0, T]$ be given, and consider a sequence $\{\tau_n\}_{n\in\mathbb{N}}$ such that $\tau_n \downarrow \tau_0$. Introduce the inputs

$$\hat{u}_{\tau_n}(t) := \begin{cases} 0, & \tau_0 < t < \tau_n, \\ u_{\tau_n}(t), & t \ge \tau_n, \end{cases}$$

and define

$$x_{\tau_n}(t) := x(t; \tau_n, x_0, u_{\tau_n}), \quad \hat{x}_{\tau_n}(t) := x(t; \tau_0, x_0, \hat{u}_{\tau_n}).$$

Notice that $x_{\tau_n}(t) - \hat{x}_{\tau_n}(t) \to 0$, as $n \to \infty$, for any t, and that its norm is uniformly bounded in $L^2(\tau_0, T; U)$; hence

$$\lim_{n\to\infty} [J_{\tau_0}(x_0, \hat{u}_{\tau_n}) - J_{\tau_n}(x_0, u_{\tau_n})] = 0.$$

Therefore,

$$\liminf_{n\to\infty} J_{\tau_0}(x_0, \hat{u}_{\tau_n}) = \liminf_{n\to\infty} J_{\tau_n}(x_0, u_{\tau_n}) = \liminf_{n\to\infty} V(\tau_n, x_0),$$

where the last equality is due to (i). On the other hand (ii) implies the existence of an admissible control $v \in L^2(\tau_0, T; U)$ such that

$$\hat{u}_{\tau_n} \rightharpoonup v$$

as $n \to \infty$. Now the map

$$u(\cdot) \to J_{\tau_0}(x_0, u)$$

is convex continuous, hence weakly lower semicontinuous, so that

$$V(\tau_0, x_0) \le J_{\tau_0}(x_0, v) \le \liminf_{n\to\infty} J_{\tau_0}(x_0, \hat{u}_{\tau_n}) = \liminf_{n\to\infty} V(\tau_n, x_0). \tag{4.3}$$

To conclude the proof, we need to consider a sequence $\{r_n\}_{n\in\mathbb{N}}$ such that $r_n \uparrow \tau_0$. In this case, we introduce

$$\tilde{u}_{r_n}(t) := \begin{cases} u_{r_n}(t), & t \ge \tau_0, \\ 0 & \text{otherwise.} \end{cases}$$

Again from (ii) it follows that there exists an input $v \in L^2(\tau_0, T; U)$ such that $\tilde{u}_{r_n} \rightharpoonup v$ in $L^2(\tau_0, T; U)$. A similar argument gives

$$V(\tau_0, x_0) \le \liminf_{n\to\infty} V(r_n, x_0),$$

which finally yields

$$V(\tau_0, x_0) \le \liminf_{\tau\to\tau_0^-} V(\tau, x_0). \qquad \square$$

Consequently, we can deduce Theorem 4.3.

THEOREM 4.3. *Under the same assumptions as Lemma* 4.2*, the map* $\tau \to V(\tau, x_0)$ *is continuous for any* $\tau \in [0, T]$.

In the case that an optimal control exists for each τ near τ_0, Lemma 4.2 takes a simpler form. We state this form under the assumption that an optimal control exists for each τ.

COROLLARY 4.4. *Let* $x_0 \in X$ *be fixed. Assume that*

(i) *for any* $\tau \in [0, T]$ *there exists an optimal control* $u_\tau^+ \in L^2(\tau, T; U)$*;*

(ii) *there exists a constant* $\gamma > 0$*, independent of* τ*, such that*

$$|u_\tau^+|_{L^2(\tau,T:U)} \le \gamma \quad \forall \tau \in [0, T]. \tag{4.4}$$

Under these conditions, the map $\tau \to V(\tau, x_0)$ *is continuous.*

We note explicitly that if there exists an optimal control u^* for $J_\tau(x_0, v)$ then for each $\tau' > \tau$ there exists an optimal control for $J_{\tau'}(x(\tau'; \tau, x_0, u^*), v)$.

It has some interest to see that if the operator A generates a strongly continuous *group* then we can prove more in Theorem 4.5.

THEOREM 4.5. *Let us assume that for each* $\tau \in [0, T)$ *and each* $x_0 \in X$ *there exists a unique optimal control* $u^+(\cdot, \tau, x_0)$ *which minimizes* $J_\tau(x_0, u)$*. If* e^{At} *is a strongly continuous* group *then the value function is continuous from the right.*

Proof. We prove continuity from the right at a fixed $\tau_0 \in [0,T)$. We know from Lemma 3.3(2) that $x_0 \to u_\tau^+(\cdot,x_0)$ is linear and continuous from X to $L^2(\tau,T;U)$ for each $\tau \in [0,T)$.

Now we consider points $\tau > \tau_0$. We show that for each fixed $\tau > \tau_0$ there exists $x_1 = x_1(x_0)$ such that

$$u^+(\cdot,\tau_0,x_1(x_0))_{|[\tau,T]} = u^+(\cdot,\tau,x_0)\,. \tag{4.5}$$

It is sufficient to see for this that there exists a solution x_1 of

$$x^+(\tau,\tau_0,x_1) = e^{A(\tau-\tau_0)}x_1 + \int_{\tau_0}^{\tau} e^{A(\tau-s)}Bu^+(s,\tau_0,x_1)\,ds = x_0\,. \tag{4.6}$$

If this is true, unicity of the optimal control shows that (4.5) holds.

We noted above that $\|u^+(\cdot,\tau_0,x_1)\|_{L^2(\tau_0,T)} \le M\|x_1\|$ so that the norm of the operator

$$\mathcal{T}x_1 = \int_{\tau_0}^{\tau} e^{A(\tau-s)}Bu^+(s,\tau_0,x_1)\,ds$$

can be estimated as follows: $\|\mathcal{T}x_1\| \le (\tau-\tau_0)Mk\|x_1\|$.

We write (4.6) in the form

$$x_1 + e^{-A(\tau-\tau_0)}\mathcal{T}x_1 = e^{-A(\tau-\tau_0)}x_0\,. \tag{4.7}$$

If $\tau-\tau_0$ is sufficiently small, $\|e^{-A(\tau-\tau_0)}\mathcal{T}\|$ is less then 1; hence (4.7) can be continuously solved for x_1 and gives a linear continuous transformation $x_1 = x_1(x_0)$, which, of course, depends upon τ. The element x_1,

$$x_1 = x_1(x_0) = [I + e^{-A(\tau-\tau_0)}\mathcal{T}]^{-1}e^{-A(\tau-\tau_0)}x_0$$

is continuous with respect to x_0 and also with respect to τ if τ is close to τ_0. In particular, $\tau \to x_1(x_0)$ is bounded in a neighborhood of τ_0. Therefore,

$$\begin{aligned}\|u_\tau^+(\cdot,x_0)\| &= \|u_{\tau_0}^+(\cdot,x_1)_{|_{[\tau,T]}}\|_{L^2(\tau,T)}\\ &\le \|u_{\tau_0}^+(\cdot,x_1)\|_{L^2(\tau_0,T)} \le c\cdot\|x_1(x_0)\| \le \gamma\|x_0\|\,.\end{aligned}$$

Right continuity follows from Lemma 4.2. □

The previous theorem presents a case in which the quite involved condition of Lemma 4.2 is satisfied. The next example shows that the condition in that lemma cannot be avoided if we are to obtain continuity of the value function.

We note first that the value function is not continuous in general, even for finite-dimensional systems: if the cost is $|x(T)|^2$ and the system is controllable then the value function has a jump at T. The following example shows that the value function may be discontinuous even at points $\tau < T$.

Example 4.6. Consider the *delay system* given by

$$\begin{cases} \dot{x} = y(t-1), \\ \dot{y} = u(t), \end{cases} \tag{4.8}$$

with initial datum $\phi_0 = \mathrm{col}[x_0, y_0(\cdot)] \in \mathbb{R}\times L^2(-1,0)$. The quadratic functional is

$$J_\tau(\phi_0,u) = \int_\tau^2 |x(t)|^2\,dt + 3|x(2)|^2\,.$$

Take $\phi_0 = \text{col}(1,0)$. When $\tau \in [1,2]$, then $y(t-1) = 0$; hence $x(t) = 1$ on $[\tau, 2]$. Consequently,

$$J_\tau(\phi_0, u) = (2-\tau) + 3 \quad \forall u\,, \forall \tau \in [1,2]\,.$$

In particular $J_1(\phi_0, u) = 4$ and

$$V(1, \phi_0) = 4.$$

On the other hand, if $\tau \in [0,1[$, then $y(t-1) \neq 0$ when $t > \tau + 1$, and it can be arbitrarily fixed, by means of suitable choices of the control u, within the class of $W^{1,2}$ functions which are zero at $t = \tau + 1$. This set is dense in $L^2(1+\tau, 2)$; hence suitable functions y can be found in order to drive $x(t)$ to zero in time $\epsilon > 0$, namely, from $1+\tau$ to $1+\tau+\epsilon$, while remaining uniformly bounded. Therefore, we have that $x(t) = 1$ in $(\tau, 1+\tau)$, and

$$\int_{1+\tau}^{1+\tau+\epsilon} x^2(t)dt \to 0$$

as $\epsilon \to 0$. In conclusion, if $\tau < 1$, $V(\tau, \phi_0) = 1$ and the value function is *not* continuous at $\tau = 1$.

REMARK 4.7. The previous example shows that in the statement of Lemma 4.2—which concerns lower semicontinuity of $V(\tau, x_0)$—assumption (ii) *cannot* be dispensed with. In fact that assumption holds in the previous example for $\tau \to 1^+$ but not for $\tau \to 1^-$.

5. Time regularity of the value function: The coercive case. Let $\hat\tau \in [0,T]$ be given, and consider the operator $\mathcal{R}_{\hat\tau}$ as defined in (3.6). Throughout this section we shall assume that $\mathcal{R}_{\hat\tau}$ is *coercive*, i.e.,

$$\exists\, \gamma > 0 : \quad \mathcal{R}_{\hat\tau} \geq \gamma. \tag{5.1}$$

Our current goal is to show that under assumption (5.1) the value function $V(\tau, x_0)$ displays better regularity properties with respect to τ. We start by showing that the map

$$\tau \to V(\tau, x_0)$$

is *continuous* for any $\tau \in [\hat\tau, T]$, with $x_0 \in X$ fixed.

We recall that from (5.1), by virtue of Lemma 3.2, it follows that $\mathcal{R}_\tau \geq \gamma$ for any $\tau \in [\hat\tau, T]$, and by continuity also on an interval $(\tau', T] \supset [\hat\tau, T]$. Hence there exists a constant γ' such that

$$\|\mathcal{R}_\tau^{-1}\| \leq \frac{1}{\gamma'} \qquad \forall \tau \in (\tau', T] \supseteq [\hat\tau, T]. \tag{5.2}$$

Moreover (5.1) implies that for any initial time $\tau \in [\hat\tau, T]$ there exists a unique optimal control $u_\tau^+(t) = u^+(\cdot\,; \tau, x_0)$ ($u_\tau^+(\cdot)$ for short), explicitly given in terms of the initial state by

$$u^+(t; \tau, x_0) = -\left(\mathcal{R}_\tau^{-1}(\mathcal{N}_\tau x_0)(\cdot)\right)(t) \tag{5.3}$$

(compare item 3 of Lemma 3.3); and from (5.2) it follows

$$|u_\tau^+(\cdot)|_{L^2(\tau,T;U)} \leq k_{\hat\tau}|x_0|, \quad \text{with } k_{\hat\tau} \text{ independent of } \tau. \tag{5.4}$$

The following theorem provides a simple explicit expression of the value function in terms of the optimal pair which will be useful in the next section.

THEOREM 5.1. *Let $\mathcal{R}_\tau$ be coercive, and let $(x^+(\cdot,\tau,x_0),u^+(\cdot,\tau,x_0))$ the optimal pair for problem* (1.1)–(1.2). *Then*

$$W(\tau)x_0 = e^{A^*(T-\tau)}P_0x^+(T,\tau,x_0) + \int_\tau^T e^{A^*(t-\tau)}\left(Qx^+(t,\tau,x_0)+Su^+(t,\tau,x_0)\right)dt. \tag{5.5}$$

Proof. Since the infimum of the cost is attained at $u^+(\cdot,\tau,x_0)$ (u_τ^+ for short), plugging (5.3) into (3.3) we easily obtain

$$W(\tau)x_0 = \mathcal{M}_\tau x_0 + \mathcal{N}_\tau^* u_\tau^+. \tag{5.6}$$

The adjoint operator $\mathcal{N}_\tau^* : L^2(\tau,T;U)\to X$ maps any $L^2(\tau,T)$-function v in

$$\mathcal{N}_\tau^* v = e^{A^*(T-\tau)}P_0L_{\tau,T}v + \int_\tau^T e^{A^*(t-\tau)}\left((Q\,L_\tau+S)v\right)(t)\,dt;$$

hence (5.5) follows from (5.6) by a direct computation. □

As a consequence of Corollary 4.4, we first have Theorem 5.2.

THEOREM 5.2. *Let $x\in X$ be given. Assume that* (5.1) *is satisfied. Then $\tau\to V(\tau,x)$ is continuous on $[\hat\tau,T]$.*

Actually we are able to show that the value function satisfies a further regularity property. Before we state a preliminary result, see Lemma 5.3.

LEMMA 5.3. *Assume that $\mathcal{R}_{\hat\tau}$ is coercive. If $w(\cdot)$ is a continuous function, then the function*

$$s\to\phi(s) := (\mathcal{R}_\tau^{-1}w)(s) \tag{5.7}$$

is continuous for any $\tau\ge\hat\tau$.

In particular, if $\mathcal{R}_\tau$ is coercive then the optimal control is continuous.

Proof. Since $\mathcal{R}_{\hat\tau}$ is coercive, R is coercive, so that we can assume that $R=I$. Moreover, for any $\tau>\hat\tau$, $\mathcal{R}_\tau$ is coercive, hence invertible.

Let $\phi(t) := (\mathcal{R}_\tau^{-1}w)(t)$, with $w(\cdot)$ continuous: we know that $\phi(\cdot)$ is at least a U-valued L^2 function. But

$$\begin{aligned}\phi(t) = w(t) &- B^*\int_t^T e^{A^*(s-t)}Q\int_\tau^s e^{A(s-r)}\,B\phi(r)\,dr\,ds\\ &- S^*\int_\tau^t e^{A(t-s)}\,B\phi(s)\,ds - B^*\int_t^T e^{A^*(s-t)}S\phi(s)\,ds\\ &- B^*\,e^{A^*(T-t)}\,P_0\int_\tau^T e^{A(T-s)}B\phi(s)\,ds,\end{aligned}$$

and the right-hand side is apparently a U-valued *continuous* function.

The second statement follows from (5.3) since $(\mathcal{N}_\tau x_0)(\cdot)$ is a continuous function; compare (3.5). □

THEOREM 5.4. *Let $x\in D(A)$ be given. Assume that* (5.1) *is satisfied. Then the map $\tau\to V(\tau,x)$ is differentiable in $[\hat\tau,T]$.*

Proof. Let $x_0 \in D(A)$ and let $u_\tau^+ = u^+(\cdot, \tau, x_0)$ the unique optimal control of problem (1.1)–(1.2), $\tau \geq \hat{\tau}$. As in (5.6)

$$V(\tau, x_0) = \langle x_0, W(\tau)x_0 \rangle = \langle \mathcal{M}_\tau x_0, x_0 \rangle + \langle \mathcal{N}_\tau x_0, u_\tau^+ \rangle \,, \tag{5.8}$$

with $\mathcal{M}_\tau$ and $\mathcal{N}_\tau$ given by (3.4), (3.5), respectively.

From the very definition of $\mathcal{M}_\tau$ it readily follows that the derivative $\frac{\partial}{\partial \tau}\langle \mathcal{M}_\tau x_0, x_0 \rangle$ exists for any $x_0 \in D(A)$. In order to show that the second summand in (5.8), namely,

$$\int_\tau^T (\mathcal{N}_\tau x_0)(t) \cdot \overline{u_\tau^+(t)}\, dt, \tag{5.9}$$

is differentiable with respect to τ, we first observe that the factor $(\mathcal{N}_\tau x_0)(\cdot)$ is differentiable, with

$$\frac{\partial}{\partial \tau}(\mathcal{N}_\tau x_0)(t) = -(\mathcal{N}_\tau(Ax_0))(t). \tag{5.10}$$

Moreover, again from (3.5) it follows that (5.10) is a continuous function.

We next want to show that for each $t > \tau$ the U-valued function $\tau \to u_\tau^+(t)$ admits the first derivative with respect to τ and that this is continuous. Fix τ_0 and first consider the case $\tau > \tau_0$. Introduce the operator $\hat{\mathcal{N}}_\tau \in \mathcal{L}(X, L^2(\tau_0, T; U))$ defined as follows:

$$(\hat{\mathcal{N}}_\tau x_0)(t) = \begin{cases} (\mathcal{N}_\tau x_0)(t), & t \in [\tau, T], \\ (\mathcal{N}_{\tau_0} x_0)(t), & t \in [\tau_0, \tau[. \end{cases}$$

By construction

$$\hat{\mathcal{N}}_\tau x_0\big|_{t \geq \tau} \equiv \mathcal{N}_\tau x_0,$$

and for instance

$$\mathcal{R}_\tau^{-1}(\mathcal{N}_\tau x_0) = \mathcal{R}_\tau^{-1}(\hat{\mathcal{N}}_\tau x_0).$$

Moreover, we take into account (5.10) and we see that

$$\lim_{\tau \to \tau_0^+} \frac{(\hat{\mathcal{N}}_\tau x_0)(t) - (\mathcal{N}_{\tau_0} x_0)(t)}{\tau - \tau_0} = -\mathcal{N}_{\tau_0} A x_0 \quad \forall x_0 \in D(A). \tag{5.11}$$

In fact it is sufficient to observe that

$$(\hat{\mathcal{N}}_\tau x_0)(t) - (\mathcal{N}_{\tau_0} x_0)(t) = \begin{cases} 0, & t \in [\tau_0, \tau\,[, \\ (\mathcal{N}_\tau x_0)(t) - (\mathcal{N}_{\tau_0} x_0)(t), & t \in [\tau, T]. \end{cases}$$

Now we compute, via (5.3),

$$\frac{1}{\tau - \tau_0}(u_\tau^+ - u_{\tau_0}^+)(t)$$

$$= \frac{1}{\tau - \tau_0}\left[\left(\mathcal{R}_{\tau_0}^{-1}(\mathcal{N}_{\tau_0} x_0)(\cdot)\right)(t) - \left(\mathcal{R}_\tau^{-1}(\mathcal{N}_\tau x_0)(\cdot)\right)(t)\right]$$

$$= -\mathcal{R}_{\tau_0}^{-1}\left[\frac{(\hat{\mathcal{N}}_\tau x_0 - \mathcal{N}_{\tau_0} x_0)(\cdot)}{\tau - \tau_0}\right](t) + \mathcal{R}_\tau^{-1}\frac{[\mathcal{R}_{\tau_0} - \mathcal{R}_\tau]}{\tau - \tau_0}\mathcal{R}_{\tau_0}^{-1}(\hat{\mathcal{N}}_\tau x_0)(t). \tag{5.12}$$

The first summand in (5.12) tends to

$$(5.13)\quad -\left[\mathcal{R}_{\tau_0}^{-1}\left(\frac{\partial}{\partial\tau_0}(\mathcal{N}_{\tau_0}x_0)(\cdot)\right)\right](t)=\left(\mathcal{R}_{\tau_0}^{-1}(\mathcal{N}_{\tau_0}Ax_0)(\cdot)\right)(t)=-u_{\tau_0}^{+}(t,Ax_0),$$

when $\tau\to\tau_0^+$, due to (5.11).

As for the second summand, it can be rewritten in the following way:

$$\begin{aligned}
&\mathcal{R}_\tau^{-1}\frac{[\mathcal{R}_{\tau_0}-\mathcal{R}_\tau]}{\tau-\tau_0}\mathcal{R}_{\tau_0}^{-1}(\hat{\mathcal{N}}_\tau x_0)(t)\\
&=\mathcal{R}_\tau^{-1}B^*\int_t^T e^{A^*(s-t)}Q\underbrace{\frac{1}{\tau-\tau_0}\left[\int_{\tau_0}^{\tau}e^{A(s-r)}B(\mathcal{R}_{\tau_0}^{-1}\hat{\mathcal{N}}_\tau x_0)(r)dr\right]}_{a(\tau,s)}ds\\
&+\mathcal{R}_\tau^{-1}S^*\frac{1}{\tau-\tau_0}\int_{\tau_0}^{\tau}e^{A(t-s)}B(\mathcal{R}_{\tau_0}^{-1}\hat{\mathcal{N}}_\tau x_0)(s)ds\\
&+\mathcal{R}_\tau^{-1}B^*\,e^{A^*(T-t)}P_0\frac{1}{\tau-\tau_0}\int_{\tau_0}^{\tau}e^{A(T-s)}B(\mathcal{R}_{\tau_0}^{-1}\hat{\mathcal{N}}_\tau x_0)(s)ds\\
&=\boxed{1}+\boxed{2}+\boxed{3}.
\end{aligned}$$

We rewrite, in turn,

$$\begin{aligned}
a(\tau,s)=&\underbrace{\frac{1}{\tau-\tau_0}\int_{\tau_0}^{\tau}e^{A(s-r)}B(\mathcal{R}_{\tau_0}^{-1}\mathcal{N}_{\tau_0}x_0)(r)dr}_{b(\tau,s)}\\
&+\underbrace{\int_{\tau_0}^{\tau}e^{A(s-r)}B\left(\mathcal{R}_{\tau_0}^{-1}\left(\frac{\hat{\mathcal{N}}_\tau x_0-\mathcal{N}_{\tau_0}x_0}{\tau-\tau_0}\right)\right)(r)dr}_{c(\tau,s)}.
\end{aligned}$$

Observe now that as a consequence of Lemma 5.3 we have

$$\lim_{\tau\to\tau_0^+}b(\tau,s)=e^{A(s-\tau_0)}B(\mathcal{R}_{\tau_0}^{-1}\mathcal{N}_{\tau_0}x_0)(\tau_0)=-e^{A(s-\tau_0)}Bu_{\tau_0}^{+}(\tau_0,x_0),$$

while $\lim_{\tau\to\tau_0^+}c(\tau,s)=0$; hence

$$a(s):=\lim_{\tau\to\tau_0^+}a(\tau,s)=-e^{A(s-\tau_0)}Bu_{\tau_0}^{+}(\tau_0,x_0).$$

Finally, since $(\tau,s)\to a(\tau,s)$ is bounded, we can conclude that $\boxed{1}$ converges to

$$-\mathcal{R}_{\tau_0}^{-1}B^*\int_t^T e^{A^*(s-t)}Qe^{A(s-\tau_0)}B\,u_{\tau_0}^{+}(\tau_0,x_0)ds$$

as τ tends to τ_0^+. The convergence of the terms $\boxed{2}$ and $\boxed{3}$ can be proved even more easily.

If $\tau < \tau_0$ we define instead

$$(\hat{\mathcal{N}}_{\tau_0} x_0)(t) = \begin{cases} (\mathcal{N}_{\tau_0} x_0)(t), & t \in [\tau_0, T], \\ (\mathcal{N}_\tau x_0)(t), & t \in [\tau, \tau_0[, \end{cases}$$

and rewrite the term $\mathcal{R}_\tau^{-1}\mathcal{N}_\tau - \mathcal{R}_{\tau_0}^{-1}\mathcal{N}_{\tau_0}$ as

$$\mathcal{R}_\tau^{-1}(\mathcal{N}_\tau - \hat{\mathcal{N}}_{\tau_0}) + (\mathcal{R}_\tau^{-1} - \mathcal{R}_{\tau_0}^{-1})\hat{\mathcal{N}}_{\tau_0}$$

$$= \mathcal{R}_\tau^{-1}(\mathcal{N}_\tau - \hat{\mathcal{N}}_{\tau_0}) + \mathcal{R}_{\tau_0}^{-1}(\mathcal{R}_{\tau_0} - \mathcal{R}_\tau)\mathcal{R}_\tau^{-1}\hat{\mathcal{N}}_{\tau_0}.$$

The rest of the proof is completely similar.

Therefore we have proved that for each τ there exists $\frac{\partial}{\partial\tau} u_\tau^+(t)$ and that

$$\frac{\partial}{\partial\tau} u_\tau^+(t) = u_\tau^+(t, Ax_0) - \mathcal{R}_\tau^{-1} B^* \int_t^T e^{A^*(s-t)} Q e^{A(s-\tau)} B u_\tau^+(\tau, x_0)\, ds$$

$$-\mathcal{R}_\tau^{-1} S^* e^{A(t-\tau)} B u_\tau^+(\tau, x_0) - \mathcal{R}_\tau^{-1} B^* e^{A^*(T-t)} P_0 e^{A(T-\tau)} B u_\tau^+(\tau, x_0).$$

In conclusion we saw that the function $(\mathcal{N}_\tau x_0)(t)\,\overline{u_\tau^+(t)}$ is differentiable with respect to τ, and moreover its derivative is a continuous function in $[\hat{\tau}, T] \times [\hat{\tau}, T]$. Therefore, (5.9) is differentiable, and

$$\frac{\partial}{\partial\tau} \int_\tau^T (\mathcal{N}_\tau x_0)(t) \cdot \overline{u_\tau^+(t)}\, dt$$

$$= -(\mathcal{N}_\tau x_0)(\tau)\overline{u_\tau^+(\tau)} - \int_\tau^T (\mathcal{N}_\tau A x_0)(t)\overline{u_\tau^+(t)}\, dt + \int_\tau^T (\mathcal{N}_\tau x_0)(t)\overline{\frac{\partial}{\partial\tau} u_\tau^+(t)}\, dt. \qquad \square$$

We are now able to deduce a *differential form* of the DI.

PROPOSITION 5.5. *Assume that* (5.1) *holds true. Then there exists a self-adjoint operator* $W(\cdot) \in \mathcal{L}(X)$ *such that*

(i) $W(T) = P_0$*;*

(ii) $W(\cdot)$ *satisfies*

$$\frac{d}{d\tau}\langle a, W(\tau)\, a\rangle + 2Re\langle Aa + Bv, W(\tau)a\rangle + F(a, v) \geq 0 \tag{5.14}$$

for any $(a, v) \in D(A) \times U$ *for any* $\tau \in [\hat{\tau}, T]$.

Proof. We fix $a \in D(A)$, $v \in U$, and take a control $u(\cdot) \in C^1([\tau, T]; U)$ such that $u(\tau) = v$. We define $x(t) = x(t, \tau, a, u)$. It is well known (see, for instance, [2]) that in this case x is a *strict* solution to (1.1); that is, $x \in C^1([\tau, T]; X) \cap C([\tau, T]; D(A))$ and it satisfies (1.1) on $[\tau, T]$.

We write the DI (3.17) for $(x(t), u(t))$, $t \in [\tau, T]$; namely,

$$\int_\tau^t F(x(s), u(s))ds \,+\, \langle x(t), W(t)x(t)\rangle - \langle x(\tau), W(\tau)x(\tau)\rangle \geq 0. \tag{5.15}$$

If we divide in (5.15) by $t - \tau$ and let $t \to \tau$, we have

$$\frac{d}{ds}\langle x(\tau), W(s)x(\tau)\rangle_{|s=\tau} + 2\mathrm{Re}\langle Ax(\tau) + Bu(\tau), W(\tau)x(\tau)\rangle + F(x(\tau), u(\tau)) \geq 0.$$

To conclude, substitute $x(\tau) = a$ and $u(\tau) = v$. $\square$

We proved that if we replace an optimal pair in the left-hand side of the DI in integral form, then we get an equality. Hence we get an equality also in the differential form (5.14). In particular, we fix $a \in \operatorname{dom} A$ and we see that $u^+(\tau,\tau,a)$ is a minimum of the left-hand side of inequality (5.14). Hence we find that $u = u^+(\tau,\tau,a)$ satisfies

$$Ru + S^*a + B^*W(\tau)a = 0\,.$$

Since $\mathcal{R}$ is coercive then R is coercive too and we see that the optimal control has the well-known feedback form

$$u = u^+(\tau,\tau,a) = -R^{-1}[S^* + B^*W(\tau)]\,a$$

(if $a \in D(A)$ and, by continuity, for each $a \in X$, see item 3 of Lemma 3.3). Moreover, as $u^+(t,\tau,a) = u^+(t,t,x^+(t,\tau,a))$, the previous equality gives the feedback form of the optimal control on the interval $[0,T]$. We replace this expression for the unique optimal control in the left-hand side of (5.14) and find a quadratic differential equation for $W(\tau)$ which is the usual Riccati equation.

Of course, the Riccati equation can be written provided that R^{-1} is a bounded operator. But, an example in [6] shows that if $\mathcal{R}$ is not coercive then the minimum of the cost may exist and be unique, in spite of the fact that the corresponding Riccati equation is not solvable on $[\tau,T]$.

6. Space regularity of the value function. This section is devoted to the study of some space regularity properties of the value function in the case that the optimal control problem is driven by an abstract equation of *parabolic* type. See [17] for analogous arguments. More precisely, we shall make the following assumption.

*H*1. A is the generator of an analytic semigroup e^{tA} on X.

It is well known (see for instance [18]) that in this case there exists an $\omega \in \mathbb{R}$ such that the fractional powers $(\omega I - A)^\alpha$ are well defined for any $\alpha \in (0,1)$, and moreover there exist constants M_α, β such that the following estimates hold true

$$\|t^\alpha(\omega I - A)^\alpha\, e^{At}\|_{\mathcal{L}(X)} \le M_\alpha e^{\beta t}, \quad t > 0. \tag{6.1}$$

For the sake of simplicity we assume that the semigroup is exponentially stable, i.e., that we can choose $\omega = 0$.

We associate the following output to system (1.1):

$$y = Cx + Du,$$

where y belongs to a third Hilbert space Y and $C \in L(X,Y)$, $D \in L(U,Y)$. We assume that the cost penalizes the output y, i.e., that the quadratic functional F in (1.3) is given by

$$F(x,u) = \|y\|_Y^2 + \langle u, R_1 u\rangle$$

so that $Q = C^*C$, $S = C^*D$, $R = R_1 + D^*D$. (A special and important case is $D = 0$.) We make the following assumption.

*H*2. $R_1 \ge 0, \quad P_0 \ge 0$.

We now use similar arguments as in Lemma 3.3. Introduce a regularized optimal control problem with cost given by

$$J_{\tau,n}(x_0,u) = J_\tau(x_0,u) + \frac{1}{n}\,\|u\|^2_{L^2(\tau,T;U)}, \quad n \in \mathbb{N} \tag{6.2}$$

and observe that since the operator $\mathcal{R}_n = \mathcal{R} + \frac{1}{n}I$ is coercive for each n, then there exists a unique optimal control u_n^+ and

$$V_n(\tau, x_0) := \inf_u J_{\tau,n}(x_0, u) = J_{\tau,n}(x_0, u_n^+) = \langle x_0, W_n(\tau)x_0\rangle.$$

Arguing as in the proof of statement 4 in Lemma 3.3 we know that

$$W_n(\tau)x_0 \to W(\tau)x_0 \qquad \forall x_0 \in X.$$

Let $x_n^+(\cdot) = x_n(\cdot, \tau, x_0, u_n^+)$ and $y_n^+(\cdot) = Cx_n^+(\cdot) + Du_n^+(\cdot)$. Then we have the following lemma.

LEMMA 6.1. *Let $\gamma_0 \geq 0$ such that $(-A^*)^{\gamma_0}C^* \in \mathcal{L}(X)$, and assume that there exists a number $\gamma \in (0, \gamma_0 + \frac{1}{2})$ such that*

$$(-A^*)^{\gamma} P_0^{1/2} \in \mathcal{L}(X). \tag{6.3}$$

Then there exists a constant c such that

$$\|y_n^+(\cdot)\|^2_{L^2(\tau,T)} + \|P_0^{1/2}x_n^+(T)\|_X^2 \leq c\,\|(-A)^{-\gamma}x_0\|^2 \quad \forall n \in \mathbb{N}. \tag{6.4}$$

Proof. The estimate is easily obtained as follows (note that $0 \in \rho(A)$ since we assumed $\omega = 0$):

$$\int_\tau^T \|y_n^+(t)\|^2\,dt + \|P_0^{1/2}x_n^+(T)\|^2 \leq J_{\tau,n}(x_0, u_n^+) \leq J_1(x_0, u_1^+)$$

$$\leq J_1(x_0, 0) = \int_\tau^T \|Ce^{A(t-\tau)}x_0\|^2\,dt + \|P_0^{1/2}e^{A(T-\tau)}x_0\|^2$$

$$\leq \|C(-A)^{\gamma_0}\|^2 \cdot M^2\,\frac{T^{1-2(\gamma-\gamma_0)}}{1-2(\gamma-\gamma_0)}\,\|(-A)^{-\gamma}x_0\|^2$$

$$+ \|P_0^{1/2}(-A)^{\gamma}\|^2\,\|(-A)^{-\gamma}x_0\|^2. \qquad \square$$

REMARK 6.2. We stress that since

$$c = \max\left(\|C(-A)^{\gamma_0}\|^2 \cdot M^2\,\frac{T^{1-2(\gamma-\gamma_0)}}{1-2(\gamma-\gamma_0)}, \|P_0^{1/2}(-A)^{\gamma}\|^2\right),$$

the estimate (6.4) is uniform with respect to n and τ.

LEMMA 6.3. *Under the same assumptions of Lemma* 6.1 *there exists a constant k such that*

$$\|(-A^*)^{\gamma}W_n(\tau)(-A)^{\gamma}\| \leq k \quad \forall n \in \mathbb{N}. \tag{6.5}$$

Proof. Let $\xi_0 \in X$. We recall that since by construction the operator $\mathcal{R}_{\tau,n}$ relative to $J_n(\xi_0, u)$ is coercive for each fixed n, then the regularized control problem admits a unique optimal pair $(x_n^+(\cdot, \xi_0), u_n^+(\cdot, \xi_0))$, and Theorem 5.1 yields

$$W_n(\tau)\xi_0 = e^{A^*(T-\tau)}P_0x_n^+(T, \xi_0) + \int_\tau^T e^{A^*(t-\tau)}C^*y_n^+(t, \xi_0)\,dt.$$

The regularity assumptions on C and P_0 imply that $W_n(\tau)\xi_0 \in D((-A^*)^\gamma)$ and

$$(-A^*)^\gamma W_n(\tau)\xi_0 = e^{A^*(T-\tau)}[(-A^*)^\gamma P_0^{1/2}][P_0^{1/2}x_n^+(T,\xi_0)]$$
$$+(-A^*)^{\gamma-\gamma_0}\int_\tau^T e^{A^*(s-\tau)}[(-A^*)^{\gamma_0}C^*][y_n^+(s,\xi_0)]\,ds.$$

Now, as a consequence of (6.4) there exists k such that

$$\|(-A^*)^\gamma W_n(\tau)\xi_0\| \le k\,\|(-A)^{-\gamma}\xi_0\|$$

uniformly in n. The conclusion follows immediately by choosing $\xi_0 = (-A)^\gamma x_0$ with $x_0 \in D((-A)^\gamma)$. □

Consequently we have the following theorem.

THEOREM 6.4. *Under the same assumptions of Lemma* 6.1 *the operator*

$$(-A^*)^\gamma W(\tau)(-A)^\gamma$$

admits a bounded extension to X *for any* $\gamma < \gamma_0 + \frac{1}{2}$.

MINIMAL (MAX,+) REALIZATION OF CONVEX SEQUENCES*

STÉPHANE GAUBERT†, PETER BUTKOVIČ‡, AND RAYMOND CUNINGHAME-GREEN‡

Abstract. We show that the minimal dimension of a linear realization over the (max,+) semiring of a convex sequence is equal to the minimal size of a decomposition of the sequence as a supremum of discrete affine maps. The minimal-dimensional realization of any convex realizable sequence can thus be found in linear time. The result is based on a bound in terms of minors of the Hankel matrix.

Key words. max plus algebra, minimal realization, rational sequences, discrete-event systems

AMS subject classifications. 93B20, 15A15

1. Introduction.

A classical problem consists in studying infinite sequences $h_0, h_1, \dots$ with values in a semiring $(\mathcal{S}, \oplus, \otimes)$, generated by a finite device. The simplest and most studied class is probably that of *realizable* or *recognizable* sequences, obtained as the scalar output of finite-dimensional recurrent $\mathcal{S}$-linear systems:

$$x_0 = b, \quad x_{k+1} = Ax_k, \quad h_k = cx_k, \quad k = 0, 1, \dots, \tag{1.1}$$

where $A \in \mathcal{S}^{n\times n}, b, x_0, x_1, \dots \in \mathcal{S}^{n\times 1}, c \in \mathcal{S}^{1\times n}$ for some positive integer n, and where concatenation denotes the matrix product as usual.[1] Equivalently,

$$h_k = cA^k b, \quad k = 0, 1, \dots. \tag{1.2}$$

The triple (A, b, c) is called a linear *realization* or *representation* of the sequence h, and n is called the dimension of the realization (A, b, c). By the Kleene–Schützenberger theorem [3], realizable sequences coincide with *rational sequences* (sequences of coefficients of rational series). The theory of these sequences is much developed in the case of fields (particularly $\mathcal{S} = \mathbb{R}$ or $\mathbb{C}$). The case of realizable sequences over the semiring of nonnegative reals $(\mathbb{R}^+, +, \times)$ is also much studied in connection with probability measures and Markov chains [13, 22]. Here, we are concerned with realizable sequences over the "(max,+)" semiring $\mathbb{R}_{\max} \stackrel{\text{def}}{=} (\mathbb{R} \cup \{-\infty\}, \oplus, \otimes)$, with max as addition ($a \oplus b \stackrel{\text{def}}{=} \max(a, b)$) and + as product ($a \otimes b \stackrel{\text{def}}{=} a + b$). The interest in realizable sequences over $\mathbb{R}_{\max}$ arises from at least two fields.

a) In discrete-event systems theory, it is known that an important subclass of man-made systems with synchronization features (manufacturing systems, transportations networks, etc.) can be modeled by input-output variants of the dynamics (1.1), namely,

$$x_{k+1} = Ax_k \oplus bu_{k+1}, \quad y_k = cx_k, \qquad k \in \mathbb{Z}, \tag{1.3}$$

where $u_k, y_k \in \mathbb{R} \cup \{-\infty\}$. In the case of manufacturing systems, typically, the input u_k represents the availability date of the kth unit of raw material, and y_k represents

[1] E.g., $(Ax_k)_i = \oplus_{j=1}^n A_{ij} \otimes (x_k)_j$, $cx_k = \oplus_{j=1}^n c_j \otimes (x_k)_j$, etc.

the availability date of the kth finished part, while the vector x_k represents the dates of completion of internal events. It is not difficult to see that the *minimal* output y of (1.3) corresponding to the *earliest* behavior of the system is given by the sup-convolution

$$y_k = \bigoplus_{p\in\mathbb{N}} h_p \otimes u_{k-p} = \sup_{p\in\mathbb{N}}[h_p + u_{k-p}], \tag{1.4}$$

so that the realizable sequence h determines the input-output relation of (1.3). As in the case of conventional linear systems, the sequence $h_0, h_1, \ldots$ is called the *impulse response* of the system, for it coincides with the output y associated with the *impulse* input u: $u_k = 0$ if $k = 0$, $u_k = -\infty$ otherwise. See [1] for a complete presentation.

b) In dynamic programming, the simplest stationary deterministic Markovian decision problem with finite state space $Q = \{1, \ldots, n\}$, transition reward $A : Q\times Q \to \mathbb{R} \cup \{-\infty\}$, initial reward $c : Q \to \mathbb{R} \cup \{-\infty\}$, final reward $b : Q \to \mathbb{R} \cup \{-\infty\}$, and horizon k, writes

$$\max_{q_0,\ldots,q_k} \left[c(q_0) + \sum_{i=1}^{k} A(q_{i-1}, q_i) + b(q_k) \right]. \tag{1.5}$$

Identifying A, b, c with matrices of appropriate sizes, it is immediately seen that the optimal reward in horizon k, given by (1.5), coincides with $h_k = cA^k b$.

In this paper, we are concerned with the *minimal realization problem*, which, given a sequence h, consists in finding a (linear) realization (A, b, c) with minimal dimension. For instance, in the Markov decision context, the minimal realization problem asks whether or not there exists another decision problem (A', b', c') of type (1.5), with state space Q' of strictly smaller cardinality but the same reward history $h_0, h_1, \ldots$ as (A, b, c). In the context of discrete-event systems, this is a natural problem, which consists in finding a minimal internal realization of the system (1.4), known only by its input-output relation $u \to y$. This has often interesting practical interpretations: loosely speaking, the nonminimality of the triple (A, b, c) arises from the existence of nontrivial temporal relations between the different physical events in the system. Particularly, nonminimalities occur when some component of the system (a particular machine or process) which plays a physical role in the production process is invisible from the performance evaluation point of view, i.e., when the normal functioning of this process will never delay the output dates due to the existence of margins. This striking phenomenon is illustrated on the cover page of the book [1], to which the reader is referred for more motivation.

Unlike in the field's case, the minimal realization problem over $\mathbb{R}_{\max}$ is not solved by rank arguments. It is indeed very much analogous to that of the nonnegative realization (over the usual algebra) [14] for which only partial solutions are known. We refer the reader to Olsder [29, 28], Cuninghame-Green [6], Qi and Chen [31], Gaubert [15, Chap. VI], De Schutter and De Moor [10, 11, 12, 9] for existing results (realization procedures, bounds, heuristics, reduction of the partial realization problem to an extended linear complementarity problem). See also [1, sections 1.3 and 9.2.3]. In the present paper, we characterize the minimal dimension of a realization for the subclass of *convex* realizable sequences, extending a result given by Cuninghame-Green and Butkovič [7] for the strictly convex case. The proof requires the minor bound given by Gaubert in [15, Chapter VI; 16], together with a classical *majorization* result [26].

It is worth noting that the convexity assumption, although restrictive, is natural with respect to a subclass of discrete-event systems. Input-output systems (1.4) with

affine realizable impulse response, $h_k = \alpha + \beta \times k$, can be interpreted as (delayed) *flow limiters* [1, section 6.2.2], i.e., as periodic systems, with minimal interevent delay β and transfer delay α. When building complex discrete-event systems from simple ones, one uses in particular the synchronization (or parallel composition) operation [1], which corresponds to the pointwise max of the impulse responses. Since a convex map is the upper envelope of its tangent lines, it is not difficult to see that realizable convex responses correspond exactly to parallel composition of finitely many delayed flow limiters.

Finally, we refer the reader interested in an overview of the theory and applications of the (max,+) semiring to [5, 19, 1, 27, 21]. General results on semirings can be found in [18].

2. Statement of the result. A sequence $h_0, h_1, \ldots \in \mathbb{R}$ is *convex* if

$$k \geq 1 \Rightarrow h_{k+1} - h_k \geq h_k - h_{k-1}.$$

It follows from the well-known periodicity property of (max,+) realizable sequences (see [5], [1, Theorem 3.112], [17, Theorem 7]) that a realizable convex sequence is eventually periodic of period one; that is, there exists $N \in \mathbb{N}$ and $\lambda \in \mathbb{R}$ such that

$$k \geq N \Rightarrow \qquad h_{k+1} = \lambda + h_k. \tag{2.1}$$

In what follows, N will always stand for the least natural number satisfying (2.1) and will be called the *length of the transient* of the sequence. A *max-polynomial* [8] is the function

$$p(x) = \max_{1 \leq i \leq r} (\alpha_i + \beta_i x), \tag{2.2}$$

with $\alpha_i \in \mathbb{R}, \beta_i \in \mathbb{R}$. The name "polynomial" refers to the notation of the semiring $\mathbb{R}_{\max}$: $a \oplus b = \max(a, b)$, $a \otimes b = a + b$, and, for $n \in \mathbb{N}$, $a^n = \underbrace{a \otimes \cdots \otimes a}_{n \text{ times}}$ $(= n \times a)$.

Then, (2.2) becomes

$$p(x) = \bigoplus_{i=1}^{r} \alpha_i \otimes x^{\beta_i}. \tag{2.3}$$

Note that we extend the exponent notation and use x^{β_i} for $x \times \beta_i$, even when $\beta_i \notin \mathbb{N}$: unlike in the conventional case, maxpolynomials may have real (nonintegral) exponents. We say that p is a *polynomial realization* of h if for all nonnegative integers k, $p(k) = h_k$. We denote by $\mathsf{mpr}(h)$ the minimal number of monomials of a polynomial realization of h (i.e., the minimal value of r). By convention, $\mathsf{mpr}(h) = +\infty$ when h does not admit a polynomial realization. Denote by $\mathsf{mlr}(h)$ the minimal dimension of a linear realization (with $\mathsf{mlr}(h) = +\infty$ if h is not realizable). The main result of this paper is the following characterization which solves the minimal realization problem for convex sequences.

THEOREM 2.1. *For every convex sequence h there holds*

$$\mathsf{mpr}(h) = \mathsf{mlr}(h). \tag{2.4}$$

Note that the theorem states in particular that the existence of a polynomial realization is equivalent to that of a linear one, for convex sequences.

Efficient computation of $\mathsf{mpr}(h)$ is not difficult: given a convex sequence h with the length of the transient N, the algorithm given in the Appendix provides a minimal polynomial realization in time $O(N)$.

The inequality $\mathsf{mlr}(h) \leq \mathsf{mpr}(h)$ is immediate: if p is a polynomial realization of h of type (2.3), then $h_k = c\,\mathrm{diag}(\beta)^k\, b$, where b denotes the $r \times 1$ matrix with entries $0, c$ the $1 \times r$ matrix with entries $\alpha_1, \ldots, \alpha_r$, and $\mathrm{diag}(\beta)$ the $r \times r$ matrix with diagonal entries $\beta_1, \ldots, \beta_r$ and off-diagonal elements equal to $-\infty$. The proof of the reverse inequality will use a bound in terms of determinants and Hankel matrices, which we introduce next.

3. Minor bound for the minimal dimension of realization. Recall that the *Hankel matrix* [13, 3] associated with the sequence $h_0, h_1, \ldots$ is the $\mathbb{N} \times \mathbb{N}$-matrix

$$\mathcal{H} = (\mathcal{H}_{ij}), \mathcal{H}_{ij} = h_{i+j} \text{ for all } i, j = 0, 1, \ldots .$$

A classical result for the minimal realization problem over fields states that the minimal dimension of any realization of a sequence h is equal to the *rank* of its Hankel matrix, which can be defined equivalently as the cardinality of a basis of the vector space generated by the rows (or columns) of $\mathcal{H}$ or as the maximal size of a square submatrix of $\mathcal{H}$ with nonzero determinant.

Over a general (commutative) semiring $\mathcal{S}$, several nonequivalent rank notions exist,[2] which do not characterize the minimal dimension of realization but only provide bounds. Here, we will need the rank notion originating from determinants and bideterminants over semirings.

Given a positive integer n, let $\mathfrak{S}_n^+$, $\mathfrak{S}_n^-$, respectively, denote the sets of even and odd permutations on $\{1, \ldots, n\}$ (we use the concepts of even and odd permutations in the conventional sense [4]). The *positive* and *negative* determinants of an $n \times n$ matrix A with entries from a (commutative) semiring $\mathcal{S}$ are defined as follows:

$$\det{}^+ A = \bigoplus_{\sigma \in \mathfrak{S}_n^+} \bigotimes_{i=1}^{n} A_{i\sigma(i)},$$

$$\det{}^- A = \bigoplus_{\sigma \in \mathfrak{S}_n^-} \bigotimes_{i=1}^{n} A_{i\sigma(i)}.$$

The *bideterminant* [20] or, equivalently, the determinant in the *symmetrized* semiring $\mathcal{S}^2$ [30, 15] of a square matrix A is the ordered pair

$$\det A \stackrel{\text{def}}{=} (\det{}^+ A, \det{}^- A).$$

We say that the determinant is *balanced* if $\det^+ A = \det^- A$, otherwise it is *unbalanced*. Let $I, J \subseteq \mathbb{N}$ denote (possibly infinite) sets of row and column indices. Given an $I \times J$ matrix A and two subsets $I' = \{i_1, \ldots, i_r\} \subseteq I, J' = \{j_1, \ldots, j_s\} \subseteq J$, with $i_1 < \cdots < i_r$, $j_1 < \cdots < j_s$, we denote by $A[I'|J']$ or $A[i_1, \ldots, i_r | j_1, \ldots, j_s]$ the $r \times s$ submatrix $(A_{i_m j_t})_{1 \leq m \leq r, 1 \leq t \leq s}$. Let $\| X \|$ denote the cardinality of a set X. The *minor rank* $\mathrm{rk}_m A$ of a matrix A is the supremum of the order of the finite square submatrices of A with unbalanced determinant

$$\mathrm{rk}_m A = \sup \left\{ r > 0 \,;\; \begin{array}{c} \exists I' \subseteq I,\ \exists J' \subseteq J,\ \| I' \| = \| J' \| = r \\ \text{and } \det^+ A[I'|J'] \neq \det^- A[I'|J'] \end{array} \right\},$$

[2] Row rank, column rank, Schein rank are distinct standard notions for Boolean matrices [24], which can also be defined in general semirings. Moreover, in the $\mathbb{R}_{\max}$ case, other rank notions have been used in relation to the uniqueness of solutions of linear systems [5], [15, Chapter 3, section 10].

and $\mathrm{rk}_m A = 0$ if no submatrix of A with unbalanced determinant exists. The following result taken from [15, 16] is a semiring weak version of a well-known result over fields [13, 3].

THEOREM 3.1 (minor bound). *The dimension of a linear realization of a sequence h is not less than the minor rank of its Hankel matrix.*

Hence,

$$\mathrm{rk}_m \mathcal{H} \leq \mathsf{mlr}(h). \tag{3.1}$$

This result holds in an arbitrary commutative semiring $\mathcal{S}$ (and not only in $\mathbb{R}_{\max}$). It is purely combinatorial in nature. We will prove it as a consequence of the following semiring version [15, 16] of the classical Binet–Cauchy identity [25, section 2.4.14].

LEMMA 3.2 (Binet–Cauchy formula). *Let $\mathcal{S}$ be an arbitrary commutative semiring. Let $A \in \mathcal{S}^{n\times r}$, $B \in \mathcal{S}^{r\times p}$. For all subsets $I \subseteq \{1,\dots,n\}$, $J \subseteq \{1,\dots,p\}$ of k elements, we have*

$$\begin{aligned}\det{}^+(AB)[I|J] \oplus \bigoplus_{K'} \big(\det{}^+ A[I|K'] \det{}^- B[K'|J] \oplus \det{}^- A[I|K'] \det{}^+ B[K'|J]\big) \\ = \det{}^-(AB)[I|J] \oplus \bigoplus_{K} \big(\det{}^+ A[I|K] \det{}^+ B[K|J] \oplus \det{}^- A[I|K] \det{}^- B[K|J]\big);\end{aligned} \tag{3.2}$$

where the sums are taken over all the k-element subsets $K, K' \subseteq \{1,\dots,r\}$. By convention, these two sums are equal to the zero element of $\mathcal{S}$ if $k > r$.

More generally, a folklore "transfer principle" [15, Chapter 1] asserts that usual ring identities admit semiring analogues whenever written without minus sign. Such semiring analogues can be obtained by direct combinatorial means (Zeilberger [33] proves the case $n = p = r$ of (3.2); the general case can be proved along the same lines). They can also be deduced formally from their classical ring versions, following an algebraic argument due to Reutenauer and Straubing [32], which we reproduce here for the sake of completeness. Note also that a different Binet–Cauchy identity in the (max,+) semiring (valid for permanents) has been given by Bapat [2].

Proof of Lemma 3.2. Let $X = \{a'_{ij}, b'_{kl}; 1 \leq i \leq n; 1 \leq j,k \leq r; 1 \leq l \leq p\}$ denote a family of distinct commuting indeterminates, and consider the semiring of (formal) commutative polynomials with coefficients in $\mathbb{N}$ and indeterminates $x \in X$: $\mathcal{S}' = \mathbb{N}[X] \subseteq \mathbb{Z}[X]$. Introduce the two matrices $A' = (a'_{ij}), B' = (b'_{kl})$ with entries in $\mathcal{S}'$. We first note that the identity (3.2) holds for A' and B'. Indeed, using the invertibility of the addition of $\mathbb{Z}[X]$, the identity (3.2) for A' and B' is equivalent to the conventional Binet–Cauchy identity which is known to be valid in the *ring* $\mathbb{Z}[X]$:

$$\det A'B'[I|J] = \sum_K \det A'[I|K] \det B'[K|J]. \tag{3.3}$$

Now, there is a unique morphism of semirings $\varphi : \mathcal{S}' \to \mathcal{S}$, such that $\forall i,j,k,l,\ \varphi(a'_{ij}) = a_{ij}, \varphi(b'_{kl}) = b_{kl}$. This morphism transforms the identity (3.2), applied to the matrices A', B' with entries in $\mathcal{S}'$, to the required identity for the matrices A, B with entries in $\mathcal{S}$. □

Proof of Theorem 3.1. Consider a linear realization (A, b, c) of h of dimension r. Let $\mathcal{O} = [c, cA, cA^2, \dots]^T$ and $\mathcal{C} = [b, Ab, A^2b, \dots]$, and consider two finite subsets $I, J \subseteq \mathbb{N}$. Applying the Binet–Cauchy identity to the finite size factorization $\mathcal{H}[I|J] = \mathcal{O}[I|1\dots r]\mathcal{C}[1\dots r|J]$ following from $\mathcal{H} = \mathcal{O}\mathcal{C}$, we get $\det^+(\mathcal{H}[I|J]) = \det^-(\mathcal{H}[I|J])$ if $|I| = |J| > r$. Hence, $\mathrm{rk}_m \mathcal{H} \leq r$. □

4. Preliminary majorization results. The proof of Theorem 2.1 will use standard convexity results that we recall here. The following famous result, due to Hardy, Littlewood, and Pólya, states the equivalence of two possible definitions of the relation of *majorization*.

THEOREM 4.1 (see [23, section 2.20], [26]). *Let $\alpha_1 \leq \alpha_2 \leq \cdots \leq \alpha_k$ and $\alpha'_1 \leq \alpha'_2 \leq \cdots \leq \alpha'_k$ be real nonnegative numbers. The following two statements are equivalent:*

1. *$\alpha_1 + \cdots + \alpha_k = \alpha'_1 + \cdots + \alpha'_k$ and*
   $\alpha_\nu + \cdots + \alpha_k \geq \alpha'_\nu + \cdots + \alpha'_k$ for all ν, $2 \leq \nu \leq k$.
2. *There exists a doubly stochastic[3] matrix P such that $\alpha' = P\alpha$ where $\alpha = (\alpha_1, \ldots, \alpha_k)^T$, $\alpha' = (\alpha'_1, \ldots, \alpha'_k)^T$.*

We write $\alpha' \prec \alpha$ and say that α' is majorized *by α when these two equivalent statements hold.*

The following majorization inequality is standard [23, 26]. We single out the strict-inequality case for further use.

THEOREM 4.2. *Let g be a convex function $\mathbb{R} \to \mathbb{R}$.*

1. *If $\alpha' \prec \alpha$, then*

$$\sum_i g(\alpha'_i) \leq \sum_i g(\alpha_i). \tag{4.1}$$

2. *Take $P = (P_{jm})$ such that $\alpha' = P\alpha$ as in Theorem 4.1. If for some j the restriction of g to the set $\{\alpha_m \mid P_{jm} \neq 0\}$ does not coincide with an affine function, then the strict inequality holds in (4.1).*

Proof. Classically, (4.1) is obtained by summing up the convexity inequalities

$$\forall j, \;\; g(\alpha'_j) \leq \sum_m P_{jm} g(\alpha_m). \tag{4.2}$$

The strict inequality in (4.1) follows from the strict inequality in (4.2), as soon as j satisfies condition 4.2 of the theorem. ∎

5. Proof of Theorem 2.1. Suppose that the sequence $h_0, h_1, \ldots$ is convex. To prove Theorem 2.1, it remains to show that $\mathsf{mlr}(h) \geq \mathsf{mpr}(h)$. We will assume that $\mathsf{mlr}(h) < \infty$ (otherwise, there is nothing to prove). Then, the existence of a polynomial realization follows readily from the convexity of h together with (2.1). Let p be such a polynomial realization satisfying

$$\forall x \in \mathbb{R}, \;\; p(x) = \max_{1 \leq i \leq r} \ell_i(x) = \max_{1 \leq i \leq r} (\alpha_i + \beta_i x), \tag{5.1}$$

with

$$\beta_1 < \beta_2 < \cdots < \beta_r \quad \text{and} \quad r = \mathsf{mpr}(h). \tag{5.2}$$

We set

$$\begin{array}{lll} I_0 = [x_0, z_0] & \stackrel{\text{def}}{=} & \{x \in \mathbb{N} \mid \; p(x) = \ell_1(x)\} \qquad\qquad \text{and} \\ I_i = [x_i, z_i] & \stackrel{\text{def}}{=} & \{x \in \mathbb{N} \mid \; p(x) = \ell_{i+1}(x) > \ell_i(x)\} \quad \text{for} \;\; i = 1, \ldots, r-1, \end{array} \tag{5.3}$$

[3] "Doubly stochastic" refers, as usual, to a matrix with nonnegative entries in which both the row and column sums are equal to 1.

with $x_i, z_i \in \mathbb{N}$, except the last value $z_{r-1} = \infty$. (The fact that I_i is nonempty follows from the minimality of r. The fact that it is an interval is immediate due to the convexity of $\max_i \ell_i$.) Note that $\alpha_1 > \alpha_i$ for $i = 2, \dots, r$ (otherwise, using (5.2), we get $\ell_1(k) \le \ell_i(k) \forall k \ge 0$, which contradicts the minimality or r). Hence, $p(0) = \alpha_1 = \ell_1(0)$, and thus $x_0 = 0$. To summarize,

$$0 = x_0 \le z_0 < x_1 \le z_1 \cdots \le z_{r-2} < x_{r-1}. \tag{5.4}$$

The following elementary lemma states the existence of a minimal polynomial realization in which each line passes through at least two consecutive points.

LEMMA 5.1. *There exists a minimal polynomial realization* (5.1) *such that*

$$x_{i+1} \ge x_i + 2 \quad \text{for } i = 0, \dots, r-2. \tag{5.5}$$

The proof of the lemmas is at the end of this part.

COROLLARY 5.2. *If p is the polynomial realization in Lemma* 5.1*, then p does not coincide with an affine function on $[x_i, x_{i+1}]$ for $i = 0, \dots, r-2$.* □

Without loss of generality, we suppose that the polynomial realization p satisfies the conditions of Lemma 5.1 and Corollary 5.2. We set

$$u_i \stackrel{\text{def}}{=} x_i - i \qquad \text{for } i = 0, \dots, r-1. \tag{5.6}$$

We get from (5.5) that

$$u_0 < u_1 < \cdots < u_{r-1}.$$

LEMMA 5.3. *Let $M = \mathcal{H}[0, 1, \dots, r-1 | u_0, u_1, \dots, u_{r-1}]$. We have*

$$\det{}^+ M = \bigotimes_{i=0}^{r-1} p(x_i) > \det{}^- M. \tag{5.7}$$

Thus, $\mathcal{H}$ contains an $r \times r$ submatrix with unbalanced minor, i.e., $\mathrm{rk}_m \mathcal{H} \ge r$, which together with the minor bound gives $\mathsf{mlr}(h) \ge \mathrm{rk}_m \mathcal{H} \ge r = \mathsf{mpr}(h)$, and Theorem 2.1 follows.

Proof of Lemma 5.1. We show that there exists a minimal polynomial realization of the form (5.1) with

$$z_i \ge x_i + 1 \quad \text{for } i = 0, \dots, r-1. \tag{5.8}$$

We start from an arbitrary minimal realization (5.1). Let $i_0 = \min\{i \mid x_i = z_i\}$. By replacing ℓ_{i_0+1} with the affine map ℓ passing through the two points $(x_{i_0}, h_{x_{i_0}}), (x_{i_0} + 1, h_{x_{i_0}+1})$, we obtain a new decomposition of the form (5.1) with $i_0 < i_0' = \min\{j \mid x_j' = z_j'\}$, where x_j', z_j' are points defined by (5.3) for the new polynomial realization. Indeed, $x_i' = x_i, z_i' = z_i$ for all $i < i_0$ and $x_{i_0}' = x_{i_0}, z_{i_0}' \ge x_{i_0} + 1 > x_{i_0} = x_{i_0}'$. Note that $\ell \ne \ell_{i_0+2}$; otherwise ℓ_{i_0+1} could be removed from p and the arising function would still be a polynomial realization of h which contradicts the minimality of p. After a finite number of such replacements, we get $z_i > x_i$ for all i, so that (5.5) becomes satisfied. □

Proof of Lemma 5.3. From the definition of M we have

$$M = (h_{i+u_j}) = (p(i + u_j))_{i,j=0,\dots,r-1}.$$

We prove that for all permutations σ of $0,\dots,r-1$ such that $\sigma \neq \mathrm{Id}$,

$$\bigotimes_{i=0}^{r-1} p(i+u_i) > \bigotimes_{i=0}^{r-1} p(i+u_{\sigma(i)}). \tag{5.9}$$

Clearly, it is sufficient to show that for all elementary cycles $c=(i_1,\dots,i_k)$ $(k\geq 2)$,

$$\begin{aligned} &p(i_1+u_{i_1})\otimes p(i_2+u_{i_2})\otimes\cdots\otimes p(i_k+u_{i_k}) \\ &> \ p(i_1+u_{i_2})\otimes p(i_2+u_{i_3})\otimes\cdots\otimes p(i_k+u_{i_1}) \end{aligned} \tag{5.10}$$

or with the conventional notation

$$\begin{aligned} &p(i_1+u_{i_1})+p(i_2+u_{i_2})+\cdots+p(i_k+u_{i_k}) \\ &> \ p(i_1+u_{i_2})+p(i_2+u_{i_3})+\cdots+p(i_k+u_{i_1}). \end{aligned} \tag{5.11}$$

Let $\alpha_1,\dots,\alpha_k$, with $\alpha_1<\cdots<\alpha_k$, denote the sequence obtained by reordering the $x_l=i_l+u_{i_l}$ (since $x_t<x_s \Leftrightarrow t<s \Leftrightarrow u_t<u_s$, i_l and u_{i_l} are ordered in the same way), and let $\alpha'_1,\dots,\alpha'_k$ with $\alpha'_1\leq\cdots\leq\alpha'_k$ denote the sequence obtained by reordering the $i_l+u_{i_{l+1}}$.

We claim that $\alpha'\prec\alpha$. Indeed, condition 1 of Theorem 4.1 is satisfied, because $\alpha_\nu+\cdots+\alpha_k$ is equal to the sum of the $k-\nu+1$ highest possible values of i_l and u_{i_l}; hence, it is greater than $\alpha'_\nu+\cdots+\alpha'_k$ which is also the sum of $k-\nu+1$ values of i_l and u_{i_l}.

Moreover, take P such that $\alpha'=P\alpha$ as in Theorem 4.1. Since P is doubly stochastic, there is at least one $j\in\{1,2,\dots,k\}$ such that $P_{jk}\neq 0$. Since $\alpha'_j\leq\alpha'_k<\alpha_k$, we have $P_{jk}\neq 1$; thus there is at least one $m\in\{1,2,\dots,k-1\}$ such that $P_{jm}\neq 0$. It remains to apply Corollary 5.2 together with the strict inequality case in Theorem 4.2 to get (5.11). □

Example 1. The function $p(x)=\max(0,-3+x,-8+2x,-22+4x)$ is a polynomial realization of the sequence $h=0,0,0,0,1,2,4,6,10,14,\dots$. From (5.3) we have

$$x_0=0,\quad x_1=4,\quad x_2=6,\quad x_3=8,$$

$$u_0=0,\quad u_1=3,\quad u_2=4,\quad u_3=5,$$

$$\det\mathcal{H}[0,1,2,3|0,3,4,5]=\det\begin{bmatrix}0&0&1&2\\0&1&2&4\\0&2&4&6\\0&4&6&10\end{bmatrix}=(15,14),$$

which is unbalanced. Hence, $\mathsf{mlr}(h)=4$ and a minimal linear realization of h is (A,b,c), where $A=\mathrm{diag}(0,1,2,4)$, $c=(0,-3,-8,-22)$, $b=(0,0,0,0)^T$. Note that this minimal realization is not unique.

6. Appendix. Now we develop a method for finding a polynomial realization of the minimal dimension.

Suppose that $h_0,h_1,\dots$ is a convex sequence satisfying (2.1). Consider the points $P_j=[j,h_j], j=0,1,\dots,M$, in the plane with Cartesian coordinate system. If $M=N+1$, then p is a polynomial realization of h iff $p(j)=h_j$ for $j=0,\dots,M$,

so that we may restrict our investigation to a method for finding a polynomial realization of the finite sequence $P_0, \ldots, P_M$. It is evident that to every polynomial realization (which in general may contain redundant monomials) we can assign another polynomial realization of no greater dimension in which every line (monomial) passes through at least two points of the set $\{P_0, \ldots, P_M\}$. Indeed, in what follows we consider only polynomial realizations which possess this property.

A subset T of the set

$$S = \{[j, h_j] \mid \ j = 0, 1, \ldots, M\}$$

is called *aligned* if $\| T \| \geq 3$ and there exists a line q such that

1. $T \subseteq q$,
2. $(S - T) \cap q = \emptyset$.

Note that an aligned subset of S may not exist and that two different aligned subsets are either disjoint or have exactly one common point.

Let T be a fixed aligned set of points lying on a line q. Since $\| T \| \geq 3$, $[j - 1, h_{j-1}], [j, h_j], [j + 1, h_{j+1}] \in q$ for some j.

Let $s(t)$ represent a line of an arbitrary polynomial realization which passes through $[j, h_j]$. Since

$$h_{j-1} \geq s(j - 1), \qquad h_{j+1} \geq s(j + 1),$$

and $[j - 1, h_{j-1}], [j, h_j], [j + 1, h_{j+1}]$ are collinear, we have that q coincides with s. Hence every polynomial realization contains each line passing through all points of an aligned subset, and thus in the construction of the minimal polynomial realization we must always include these lines. This concerns also the two special lines: one covering $[0, h_0], [1, h_1]$ and the other passing through $[M - 1, h_{M-1}], [M, h_M]$, which by trivial reasons must be involved too.

The point $[j, h_j]$ $(0 < j < M)$ is called a *breaking point* if $[j - 1, h_{j-1}], [j, h_j], [j + 1, h_{j+1}]$ are not collinear. Clearly, the first and last points of every aligned set are breaking points (except $[0, h_0], [M, h_M]$).

Consider a fixed set

$$B = \{[r, h_r], [r + 1, h_{r+1}], \ldots, [s, h_s]\}$$

of consecutive breaking points which is maximal; i.e., both $[r, h_r]$ belongs to an aligned set or $r = 1$ and $[s, h_s]$ belongs to an aligned set or $s = M - 1$. Hence both $[r, h_r]$ and $[s, h_s]$ can be assumed to belong already to a line of the realization. Clearly, a line cannot pass through more than two consecutive breaking points. If B consists of k points, then the minimal number of lines joining pairs of consecutive points which contain all the points in B (except for the extreme points $[r, h_r], [s, h_s]$) is

$$\left\lceil \frac{k}{2} \right\rceil - 1.$$

A self-evident strategy to achieve this lower bound is to take alternatively every other line consecutively joining the pairs of adjacent points starting by the line passing through

$$[r + 1, h_{r+1}], \quad [r + 2, h_{r+2}].$$

The foregoing discussion justifies the following algorithm, which starts from $[0, h_0]$. (Note that $\ell \equiv (P, Q)$ reads, "line ℓ determined by the points P and Q.")

Algorithm. MINIMAL POLYNOMIAL REALIZATION (MPR)

Input: Finite sequence $h_0, \ldots, h_M$ of real numbers, with $M \geq 3$.

Output: Polynomial realization of h of minimal dimension represented by the lines $\ell_1, \ell_2, \ldots$; "no" if h is not convex.

(1) $r := 1$, $s := 0$, $j := 0$, $P_i = [i, h_i]$, $(i = 0, 1, \ldots, M)$.
(2) Accept $\ell_r \equiv (P_j, P_{j+1})$.
(3) $r := r + 1$.
(4) Let j $(j > s)$ be the least index for which ℓ_{r-1} does not pass through P_j (if no such exists then stop).
(5) If P_j is below ℓ_{r-1} then stop ("no").
(6) If $j = M$ then go to (8).
(7) $s := j$ and go to (2).
(8) Accept $\ell_r \equiv (P_{j-1}, P_j)$, stop.

Example 2. Input: $h = 1, 0, -1, -1, 0, 2, 5, 8$. $(M = 7)$

$P_0 = (0, 1)$, $P_1 = (1, 0)$, $P_2 = (2, -1)$, $P_3 = (3, -1)$, $P_4 = (4, 0)$, $P_5 = (5, 2)$, $P_6 = (6, 5)$, $P_7 = (7, 8)$.

The algorithm MPR produces the following:

$r = 1, s = 0$		
accept $\ell_1 \equiv (P_0, P_1)$	accept $\ell_2 \equiv (P_3, P_4)$	accept $\ell_3 \equiv (P_5, P_6)$
$r = 2$	$r = 3$	$r = 4$
$j = 3$	$j = 5$	
$s = 3$	$s = 5$	
		stop

$p_1(t) = -t + 1$ (line ℓ_1)
$p_2(t) = t - 4$ (line ℓ_2)
$p_3(t) = 3t - 13$ (line ℓ_3)
$A = \mathrm{diag}(-1, 1, 3)$, $c = (1, -4, -13)$, $b = (0, 0, 0)^T$.

STABILIZATION OF ELASTIC PLATES WITH DYNAMICAL BOUNDARY CONTROL*

BOPENG RAO†

Abstract. We consider a hybrid system composed of a plate equation and two ordinary differential equations. We prove that the system is strongly but not uniformly stable. By a new approach, we show that the smooth solution has a rational decay rate. Finally we establish the uniform energy decay rate for a simplified hybrid system.

Key words. hybrid system, compact boundary feedback, lack of uniform stability, rational energy decay rate

1. Introduction.

The purpose of this work (the results of which were announced in Rao [18]) is to investigate the stabilization of a thin elastic plate, which is clamped on one part of the edge and rimmed along the other part with a flange that has mass and moment of inertia of the boundary. Let $\Omega \subset \mathbb{R}^2$ denote a bounded domain, with smooth boundary Γ consisting of two disjoint pieces: Γ_0, the clamped part, and Γ_1, the rimmed part. Following the linear elasticity theory (see Lagnese and Lions [6]), the vibration y of the plate is governed by the plate equation associated with two dynamical boundary conditions:

$$\begin{cases} y'' + \Delta^2 y = 0 & \text{in } \Omega\times]0,+\infty[, \\ y = \partial_\nu y = 0 & \text{on } \Gamma_0\times]0,+\infty[, \\ J\partial_\nu y'' + \Delta y + (1-\mu)B_1 y = m & \text{on } \Gamma_1\times]0,+\infty[, \\ \rho y'' - \partial_\nu \Delta y - (1-\mu)\partial_\tau B_2 y = f & \text{on } \Gamma_1\times]0,+\infty[, \end{cases} \tag{1.1}$$

where $\nu = (\nu_1, \nu_2)$ is the unit outer normal vector and $\tau = (-\nu_2, \nu_1)$ is the unit tangent vector. The inertial properties of the boundary are supported along the rimmed part Γ_1 whereon the boundary feedback controls m, f are applied. $0 < \mu < 1/2$ is the Poisson coefficient. $\rho > 0$ is the linear boundary density; $J > 0$ is the bending moment of inertia of the boundary. B_1, B_2 are the usual boundary operators associated with the plate equation:

$$B_1 y = 2\nu_1\nu_2 \frac{\partial^2 y}{\partial x_1 \partial x_2} - \nu_1^2 \frac{\partial^2 y}{\partial x_2^2} - \nu_2^2 \frac{\partial^2 y}{\partial x_1^2}, \tag{1.2}$$

$$B_2 y = (\nu_1^2 - \nu_2^2)\frac{\partial^2 y}{\partial x_1 \partial x_2} + \nu_1\nu_2\Big(\frac{\partial^2 y}{\partial x_1^2} - \frac{\partial^2 y}{\partial x_2^2}\Big). \tag{1.3}$$

In the present work, we use the following boundary feedback controls:

$$m = -L\partial_\nu y', \qquad f = -Ly', \tag{1.4}$$

where L is the canonical isomorphism from $H^{-s}(\Gamma_1)$ onto $H^s(\Gamma_1)$. If we consider the usual initial data, $y(0) \in H^2(\Omega), y_t(0) \in L^2(\Omega)$, then the regularity of the weak solution is insufficient for defining the dynamical terms $J\partial_\nu y''$ and $\rho y''$ on the boundary Γ_1. Following an idea of Slemrod [21], the dynamical boundary conditions have to be treated as ordinary differential equations in the time variable. Therefore, indeed we have a system made up of one partial differential equation and two ordinary differential equations, called a hybrid system.

For these kinds of problems, a classical method developed in Littman and Markus [11] is based on the spectrum theory. Roughly speaking, if the spectrum of the system approaches asymptotically the imaginary axis, then the system loses the uniform energy decay rate. Further, if the eigenvectors of the system form a Riesz basis, then the smooth solution has a rational decay rate. Because of the essential difficulty intervening in the determination of the spectrum of the system, this method is obviously limited to one-dimensional problems (Lee and You [8], Littman and Markus [11, 12]).

In [17], we considered the well-known SCOLE model (Euler–Bernoulli beam equation associated with dynamical boundary conditions). We introduced a new method, which is based on a result of compact perturbation due to Russell [20]. We established the uniform stability in the case of hinged beam with the usual boundary feedback controls, as well as in the case of a clamped beam with the boundary feedback controls of high order. In the case of a clamped beam with the usual boundary feedback controls, we proved that the system loses the uniform energy decay rate. Unlike the usual method, this method does not require any knowledge of the spectrum of the system. For other applications, we refer to Rao [19] for the Rayleigh beam equation and Komornik and Rao [4] for compactly coupled waves equations.

Now we outline briefly the content of this work. In section 2, we formulate the system (1.1)–(1.4) into an evolutionary equation,

$$u' + Au + Bu = 0, \tag{1.5}$$

where A is a maximal monotone operator and B is the canonical isomorphism from $H^{-s}(\Gamma_1) \times H^{-s}(\Gamma_1)$ onto $H^s(\Gamma_1) \times H^s(\Gamma_1)$. Therefore, we can give a semigroup approach of the system (1.1)–(1.4). In section 3, we prove the strong stability of the system (1.5) for all $s \geq 0$. Therefore, we improve a recent result of Markus and You [13], which asserts the strong stability of the system (1.5) in the case $s = 0$. Further, we show that the system (1.5) actually loses the uniform energy decay rate if $s > 0$. Notice that in this case the control operator B is compact. In section 4, we establish the rational energy decay rate for the smooth solution. To this end, we introduce a new multiplier method which is based on a nonlinear technique. Once again, this method does not require any knowledge of the spectrum of the system. In section 5, we consider a simplified plate model in which we have taken $J = 0$. We prove that the usual multiplier method can be applied for obtaining the uniform energy decay rate of the system.

2. Well-posedness. Throughout this paper, we assume that $\Omega \subset \mathbb{R}^2$ is a bounded domain with smooth boundary $\Gamma = \Gamma_0 \cup \Gamma_1$. We assume that Γ_0 and Γ_1 are of class C^2 and $\bar{\Gamma}_0 \cap \bar{\Gamma}_1 = \{\emptyset\}$.

Let us denote by L the canonical isomorphism from $H^{-s}(\Gamma_1)$ onto $H^s(\Gamma_1)$:

$$\langle L\eta, \zeta\rangle_{H^s(\Gamma_1)\times H^{-s}(\Gamma_1)} = \langle \eta, \zeta\rangle_{H^{-s}(\Gamma_1)}, \qquad s \geq 0. \tag{2.1}$$

If $s = 0$, then L is the identity of $L^2(\Gamma_1)$; we find again the usual boundary feedback controls used in Markus and You [13].

Now let y be a smooth solution of the closed-loop hybrid system

$$\begin{cases} y'' + \Delta^2 y = 0 & \text{in } \Omega\times]0,+\infty[, \\ y = \partial_\nu y = 0 & \text{on } \Gamma_0\times]0,+\infty[, \\ J\partial_\nu y'' + \Delta y + (1-\mu)B_1 y + L\partial_\nu y' = 0 & \text{on } \Gamma_1\times]0,+\infty[, \\ \rho y'' - \partial_\nu \Delta y - (1-\mu)\partial_\tau B_2 y + L y' = 0 & \text{on } \Gamma_1\times]0,+\infty[. \end{cases} \tag{2.2}$$

Setting

$$z = y', \qquad \xi = \partial_\nu y'|_{\Gamma_1}, \qquad \eta = y'|_{\Gamma_1}, \tag{2.3}$$

then we transform the hybrid system (2.2) into a system of first order

$$\begin{pmatrix} y \\ z \\ \xi \\ \eta \end{pmatrix}' + \begin{pmatrix} -z \\ \Delta^2 y \\ \frac{1}{J}\big(\Delta y + (1-\mu)B_1 y\big) \\ -\frac{1}{\rho}\big(\partial_\nu \Delta y + (1-\mu)\partial_\tau B_2 y\big) \end{pmatrix} + \begin{pmatrix} 0 \\ 0 \\ \frac{1}{J}L\xi \\ \frac{1}{\rho}L\eta \end{pmatrix} = 0. \tag{2.4}$$

Denoting the columns by u', Au, and Bu, we get an abstract evolutionary equation

$$u' + Au + Bu = 0, \qquad u(0) = u_0 \in H. \tag{2.5}$$

According to the formulation (2.4), we are led to introduce the following energy space:

$$H = H^2_{\Gamma_0}(\Omega) \times L^2(\Omega) \times L^2(\Gamma_1) \times L^2(\Gamma_1), \tag{2.6}$$

where we have put

$$H^2_{\Gamma_0}(\Omega) = \{y \in H^2(\Omega) \ : \quad y = \partial_\nu y = 0 \quad \text{on } \Gamma_0\}. \tag{2.7}$$

For $u = (y, z, \xi, \eta), \widetilde{u} = (\widetilde{y}, \widetilde{z}, \widetilde{\xi}, \widetilde{\eta}) \in H$, we define the inner product by

$$(u, \widetilde{u})_H = \int_\Omega \big(a(y,\widetilde{y}) + z\widetilde{z}\big)dx + J\int_{\Gamma_1} \xi\widetilde{\xi} d\Gamma + \rho\int_{\Gamma_1} \eta\widetilde{\eta} d\Gamma, \tag{2.8}$$

where the bilinear form $a(\cdot,\cdot)$ is defined by

$$\begin{aligned} a(y,z) \ :=& \frac{\partial^2 y}{\partial x_1^2}\frac{\partial^2 z}{\partial x_1^2} + \frac{\partial^2 y}{\partial x_2^2}\frac{\partial^2 z}{\partial x_2^2} \\ &+\mu\Big(\frac{\partial^2 y}{\partial x_1^2}\frac{\partial^2 z}{\partial x_2^2} + \frac{\partial^2 y}{\partial x_2^2}\frac{\partial^2 z}{\partial x_1^2}\Big) + 2(1-\mu)\frac{\partial^2 y}{\partial x_1 \partial x_2}\frac{\partial^2 z}{\partial x_1 \partial x_2} \ . \end{aligned} \tag{2.9}$$

We next introduce the linear bounded operator B and the linear unbounded operator A as follows:

$$Bu = \begin{pmatrix} 0 \\ 0 \\ \frac{1}{\rho}L\xi \\ \frac{1}{J}L\eta \end{pmatrix}, \qquad Au = \begin{pmatrix} -z \\ \Delta^2 y \\ \frac{1}{\rho}\big(\Delta y + (1-\mu)B_1 y\big) \\ -\frac{1}{J}\big(\partial_\nu \Delta y + (1-\mu)\partial_\tau B_2 y\big) \end{pmatrix}. \tag{2.10}$$

The domain $D(A)$ is defined by

$$D(A) = \begin{pmatrix} u = (y, z, \xi, \eta) \in W \times H^2_{\Gamma_0}(\Omega) \times L^2(\Gamma_1) \times L^2(\Gamma_1) \\ \text{such that} \quad \xi = \partial_\nu z|_{\Gamma_1} \quad \text{and} \quad \eta = z|_{\Gamma_1} \end{pmatrix}, \tag{2.11}$$

where the subspace W is defined as

$$W = \begin{pmatrix} y \in H^2_{\Gamma_0}(\Omega), \quad \Delta^2 y \in L^2(\Omega) \\ \Delta y + (1-\mu) B_1 y \in L^2(\Gamma_1) = v_1 \\ \partial_\nu \Delta y + (1-\mu)\partial_\tau B_2 y = v_2 \in L^2(\Gamma_1) \end{pmatrix}. \tag{2.12}$$

The trace functions in (2.12) are defined by means of the following Green formula:

$$\int_\Omega \Delta^2 y \phi dx = \int_\Omega a(y, \phi) dx + \int_{\Gamma_1} v_2 \phi d\Gamma - \int_{\Gamma_1} v_1 \phi d\Gamma \qquad \forall \phi \in H^2_{\Gamma_0}(\Omega). \tag{2.13}$$

LEMMA 2.1. *The operator B is self-adjoint nonnegative definite and compact if $s > 0$.*

Proof. Let $u = (y, z, \xi, \eta) \in H$. Then using (2.8) and (2.10) we have

$$(Bu, u)_H = (L\xi, \xi)_{L^2(\Gamma_1)} + (L\eta, \eta)_{L^2(\Gamma_1)}. \tag{2.14}$$

Since $\xi \in L^2(\Gamma_1), L\xi \in H^s(\Gamma_1)$, we have

$$(L\xi, \xi)_{L^2(\Gamma_1)} = \langle L\xi, \xi \rangle_{H^s(\Gamma_1) \times H^{-s}(\Gamma_1)} = \|\xi\|^2_{H^{-s}(\Gamma_1)}.$$

It follows from (2.14) that

$$(Bu, u)_H = \|\xi\|^2_{H^{-s}(\Gamma_1)} + \|\eta\|^2_{H^{-s}(\Gamma_1)} \geq 0. \tag{2.15}$$

Since L is self-adjoint and compact for $s > 0$, so is B. The proof is complete. □

LEMMA 2.2. *The operator A is maximal monotone and skew adjoint. Moreover the resolvent $(I + A)^{-1}$ is compact in H.*

Proof. Let $u = (y, z, \xi, \eta) \in D(A)$. Using (2.8) and (2.10) we have

$$(Au, u)_H = \int_\Omega a(-z, y) dx + \int_\Omega \Delta^2 yz dx$$

$$- \int_{\Gamma_1} (\partial_\nu \Delta y + (1-\mu)\partial_\tau B_2 y) z d\Gamma_1 + \int_{\Gamma_1} (\Delta y + (1-\mu) B_1 y) \partial_\nu z d\Gamma.$$

Since $y \in W$ and $z \in H^2_{\Gamma_0}(\Omega)$, it follows from (2.13) that

$$(Au, u)_H = 0 \qquad \forall u \in D(A). \tag{2.16}$$

Now given $u_0 \in H$, we solve the equation $u + Au = u_0$. This means that

$$\begin{cases} y - z = y_0, \\ z + \Delta^2 y = z_0, \\ J\partial_\nu z + \Delta y + (1-\mu) B_1 y = J\xi_0, \\ \rho z - \partial_\nu \Delta y - (1-\mu)\partial_\tau B_2 y = \rho \eta_0. \end{cases} \tag{2.17}$$

Then eliminating z and using $\xi = \partial_\nu z|_{\Gamma_1}, \eta = z|_{\Gamma_1}$, we find that y satisfies the system

$$\begin{cases} y + \Delta^2 y = y_0 + z_0 \in L^2(\Omega), \\ y = \partial_\nu y = 0 \qquad \text{on } \Gamma_0, \\ J\partial_\nu y + \Delta y + (1-\mu)B_1 y = J(\xi_0 + \partial_\nu y_0) \qquad \text{on } \Gamma_1, \\ \rho y - \partial_\nu \Delta y - (1-\mu)\partial_\tau B_2 y = \rho(\eta_0 + y_0) \qquad \text{on } \Gamma_1. \end{cases} \tag{2.18}$$

Using the Green formula (2.13), we prove that the system (2.18) is equivalent to the following variational equation:

$$\begin{aligned} &\int_\Omega \big(y\phi + a(y,\phi)\big)dx + \rho\int_{\Gamma_1} y\phi d\Gamma + J\int_{\Gamma_1} \partial_\nu y \partial_\nu \phi d\Gamma \\ &= \int_\Omega \big(y_0 + z_0\big)\phi dx + \rho\int_{\Gamma_1} (\eta_0 + y_0)\phi + J\int_{\Gamma_1} (\xi_0 + \partial_\nu y_0)\partial_\nu \phi d\Gamma \end{aligned} \tag{2.19}$$

for all $\phi \in H^2_{\Gamma_0}(\Omega)$. Thanks to the Lax–Milgram theorem, equation (2.19) admits a unique solution $y \in H^2_{\Gamma_0}(\Omega)$. Then defining

$$z = y - y_0 \in H^2_{\Gamma_0}(\Omega), \quad \xi = \partial_\nu z|_{\Gamma_1}, \quad \eta = z|_{\Gamma_1},$$

we see that $u = (y, z, \xi, \eta) \in D(A)$ and solves the equation $u + Au = u_0$. Therefore, we conclude that A is maximal monotone in the energy space H.

On the other hand, thanks to the elliptic theory (Lions and Magenes [9]), we see that $y \in H^{5/2}(\Omega)$. It follows that

$$\|(y, z, \eta, \xi)\|_{H^{5/2}(\Omega)\times H^2_{\Gamma_0}(\Omega)\times H^{3/2}(\Gamma_1)\times H^{1/2}(\Gamma_1)} \le C\|u_0\|_H. \tag{2.20}$$

In particular, we obtain the compactness of the resolvent $(I + A)^{-1}$.

Finally, since A is antisymmetric and maximal monotone with compact resolvent, A is therefore skew adjoint in H (see Brezis [1]). The proof is thus complete. □

THEOREM 2.3. *Assume that $s \ge 0$. Then*

(i) *for any $u_0 \in D(A)$, equation (2.5) admits a unique strong solution $u(t) = \big(y(t), z(t), \xi(t), \eta(t)\big)$ such that*

$$y(t) \in C^0\big(\mathbb{R}^+; H^{5/2}(\Omega)\big) \cap C^1\big(\mathbb{R}^+; H^2_{\Gamma_0}(\Omega)\big) \cap C^2\big(\mathbb{R}^+; L^2(\Omega)\big), \tag{2.21}$$

$$y|_{\Gamma_1} \in C^2\big(\mathbb{R}^+; L^2(\Gamma_1)\big), \qquad \partial_\nu y|_{\Gamma_1} \in C^2\big(\mathbb{R}^+; L^2(\Gamma_1)\big). \tag{2.22}$$

(ii) *for any $u_0 \in H$, equation (2.5) admits a unique weak solution $u(t) = \big(y(t), z(t), \eta(t), \xi(t)\big)$ such that*

$$y(t) \in C^0\big(\mathbb{R}^+; H^2_{\Gamma_0}(\Omega)\big) \cap C^1\big(\mathbb{R}^+; L^2(\Omega)\big), \tag{2.23}$$

$$y|_{\Gamma_1} \in C^1\big(\mathbb{R}^+; L^2(\Gamma_1)\big), \qquad \partial_\nu y|_{\Gamma_1} \in C^1\big(\mathbb{R}^+; L^2(\Gamma_1)\big). \tag{2.24}$$

Proof. Since A is maximal monotone and B is nonnegative definite, the operator $A + B$ with the domain $D(A + B) = D(A)$ is maximal monotone. Applying the Hille–Yosida theorem (see Brezis [1] and Pazy [14]), we know that for any $u_0 \in D(A)$ equation (2.5) admits a unique strong solution:

$$u(t) = \big(y(t), z(t), \xi(t), \eta(t)\big) \in C^0\big(\mathbb{R}^+; D(A)\big) \cap C^1\big(\mathbb{R}^+; H\big). \tag{2.25}$$

On the other hand, thanks to (2.20), we have $D(A) \subset H^{5/2}(\Omega) \times H^2_{\Gamma_0}(\Omega) \times H^{3/2}(\Gamma_1) \times H^{1/2}(\Gamma_1)$. It follows that

$$\begin{cases} y(t) \in C^0\big(\mathbb{R}^+; H^{5/2}(\Omega)\big) \cap C^1\big(\mathbb{R}^+; H^2_{\Gamma_0}(\Omega)\big), \\ y_t(t) \in C^0\big(\mathbb{R}^+; H^2_{\Gamma_0}(\Omega)\big) \cap C^1\big(\mathbb{R}^+; L^2(\Omega)\big), \\ y(t)|_{\Gamma_1} \in C^0\big(\mathbb{R}^+; H^{3/2}(\Gamma_1)\big) \cap C^1\big(\mathbb{R}^+; L^2(\Gamma_1)\big), \\ \partial_\nu y(t)|_{\Gamma_1} \in C^0\big(\mathbb{R}^+; H^{1/2}(\Gamma_1)\big) \cap C^1\big(\mathbb{R}^+; L^2(\Gamma_1)\big). \end{cases} \tag{2.26}$$

This gives (2.21)–(2.22).

Now let $u_0 \in H$; then equation (2.5) admits a unique weak solution given by $u(t) = S_{A+B}(t)u_0$, where $S_{A+B}(t)$ is the semigroup of contractions generated by the operator $-(A+B)$ on the energy space H. Moreover we have

$$u(t) = \big(y(t), z(t), \xi(t), \eta(t)\big) \in C^0\big(\mathbb{R}^+; H\big). \tag{2.27}$$

Interpreting (2.27) gives (2.23)–(2.24). The proof is complete. □

Notice that for a general function y possessing only the smoothness property (2.21), the trace functions $y''|_{\Gamma_1}$ and $\partial_\nu y''|_{\Gamma_1}$ don't make sense. Here they are defined by means of the equations

$$\begin{cases} y'' = \frac{1}{\rho}\big(\partial_\nu \Delta y + (1-\mu)\partial_\tau B_2 y\big) & \text{on } \Gamma_1, \\ \partial_\nu y'' = -\frac{1}{J}\big(\Delta y + (1-\mu) B_1 y\big) & \text{on } \Gamma_1. \end{cases} \tag{2.28}$$

From (2.21), we see that the right-hand sides of these equations are continuous functions.

3. Strong stability and lack of uniform energy decay rate. Let $u = (y, z, \xi, \eta)$ be a solution of equation (2.5). We define the associated energy by

$$E(t) = \frac{1}{2}\Big\{ \int_\Omega \big(|y'|^2 + a(y,y)\big)dx + \int_{\Gamma_1} \big(\rho|y'|^2 + J|\partial_\nu y'|^2\big)d\Gamma \Big\}. \tag{3.1}$$

Then using (2.15)–(2.16) we have

$$\frac{d}{dt}E(t) = -\|y'\|^2_{H^{-s}(\Gamma_1)} - \|\partial_\nu y'\|^2_{H^{-s}(\Gamma_1)} \le 0. \tag{3.2}$$

Therefore, $E(t)$ is a nonincreasing function. Moreover, we have the following strong stability result.

THEOREM 3.1. *For any initial data $u_0 \in H$, the energy $E(t)$ of system (2.5) satisfies*

$$\lim_{t\to+\infty} E(t) = 0. \tag{3.3}$$

Proof. Since B is self-adjoint and nonnegative definite, there exists a linear operator $\widetilde{B}$ such that $B = \widetilde{B}\widetilde{B}^*$. Then indeed we have

$$(Bu, u)_H = (\widetilde{B}^* u, \widetilde{B}^* u)_H, \tag{3.4}$$

which, together with (2.15), implies that

$$Bu = 0 \Leftrightarrow \widetilde{B}^* u = 0. \tag{3.5}$$

Applying LaSalle's invariance principle (see Slemrod [21]), it is sufficient to prove that the equation $\widetilde{B}^* S_A(t)u_0 = 0$ has only trivial solution $u_0 = 0$, where $S_A(t)$ denotes the semigroup generated by the operator A on the space H. Thanks to (3.5), this is equivalent to proving that the equation $BS_A(t)u_0 = 0$ has only trivial solution $u_0 = 0$. Assume that $u_0 \in D(A)$. Then indeed writing $S_A(t)u_0 = \big(y(t), z(t), \eta(t), \xi(t)\big)$, we see that y satisfies the system

$$\begin{cases} y'' + \Delta^2 y = 0 & \text{in } \Omega\times]0,+\infty[, \\ J\partial_\nu y'' + \Delta y + (1-\mu)B_1 y = 0 & \text{on } \Gamma_1\times]0,+\infty[, \\ \rho y'' - \partial_\nu \Delta y - (1-\mu)\partial_\tau B_2 y = 0 & \text{on } \Gamma_1\times]0,+\infty[, \end{cases} \tag{3.6}$$

with the supplementary conditions

$$y' = \partial_\nu y' = 0 \qquad \text{on } \Gamma_1\times]0,+\infty[. \tag{3.7}$$

A straightforward computation shows that z satisfies the following conditions (see Lasiecka [7]):

$$\begin{cases} z'' + \Delta^2 z = 0 & \text{in } \Omega\times]0,+\infty[, \\ z = \partial_\nu z = \Delta z = \partial_\nu \Delta z = 0 & \text{on } \Gamma_1\times]0,+\infty[. \end{cases} \tag{3.8}$$

Applying the Holmgren theorem (see Lions [10]), it follows that $z = 0$. This, together with (3.6)–(3.7), implies that y satisfies the following conditions:

$$\begin{cases} \Delta^2 y = 0 & \text{in } \Omega\times]0,+\infty[, \\ y = \partial_\nu y = 0 & \text{on } \Gamma_0\times]0,+\infty[, \\ \Delta y + (1-\mu)B_1 y = 0 & \text{on } \Gamma_1\times]0,+\infty[, \\ \partial_\nu \Delta y + (1-\mu)\partial_\tau B_2 y = 0 & \text{on } \Gamma_1\times]0,+\infty[. \end{cases} \tag{3.9}$$

Multiplying the first equation by y and using the Green formula (2.13), we obtain

$$\int_\Omega a(y,y)dx = 0 \Rightarrow y = 0.$$

This yields that $u_0 = 0$. We complete the case $u_0 \in H$ by a standard argument of density of $D(A)$ in H and the continuity of the semigroup $S_A(t)$. The proof is thus complete. □

LEMMA 3.2. *Let $A = -A^*$ be the infinitesimal generator of a C_0 group, and let B be a compact operator in the Hilbert space H. Then the group $S_{A+B}(t)$, generated by the operator $-(A+B)$, has no uniform energy decay rate for $t > 0$.*

Proof. We first notice that $S_{A-B^*}(t)$ is also a group in H. Since $(A+B)^* = -(A-B^*)$, we have

$$\|S_{A+B}(t)\| = \|S_{-(A-B^*)}(t)\| = \|S_{A-B^*}(-t)\| \qquad \forall t \in \mathbb{R}. \tag{3.10}$$

Since B and B^* are compact, thanks to a result of compact perturbation due to Russell [20], we know that for any $t > 0$ the following two conditions can't be simultaneously held

$$\|S_{A+B}(t)\| < 1 \quad \text{and} \quad \|S_{A-B^*}(-t)\| < 1. \tag{3.11}$$

It follows from (3.10) and (3.11) that $\|S_{A+B}(t)\| \geq 1$ for any $t > 0$. The proof is complete. □

Remark. Lemma 3.2 has been formulated in another form in Gibson [2]. But the present version seems to adapt well to the first-order evolutionary equations.

THEOREM 3.3. *Assume that $s > 0$. Then the energy $E(t)$ of system (2.5) has no uniform decay rate.*

Proof. Since A is maximal monotone and skew adjoint (Lemma 2.2), and since B is compact (Lemma 2.1), then applying Lemma 3.2 we conclude that the group $S_{A+B}(t)$ has no uniform decay rate for $t > 0$. □

Remark. If $s = 0$, then L becomes the identity of $L^2(\Gamma_1)$, and the control operator B is not compact. Therefore Lemma 3.2 does not apply directly to the system (2.5). Let us consider an example where Ω is the unit disc and Γ_1 is the whole circle. Considering the radial solutions of the system (2.5), then the control space $L^2(\Gamma_1) \times L^2(\Gamma_1)$ will be reduced into $\mathbb{R}^2$ and the control operator B becomes again compact. Consequently, system (2.5) actually loses the uniform energy decay rate, even in this geometrically favorable case (see Lagnese [5]). Of course, the uniform stability of system (2.5) remains an open problem in the general case.

4. Rational energy decay rate. In this section, we will establish the rational energy decay rate for the smooth solution of system (2.5). We first recall the following classical result (Komornik [3] and Lagnese [5]).

LEMMA 4.1. *Let $E : \mathbb{R}^+ \to \mathbb{R}^+$ be a nonincreasing function. Assume that there exists a positive constant M such that*

$$\int_T^\infty E^2(t)dt \leq ME(0)E(T) \qquad \forall T > 0. \tag{4.1}$$

Then we have

$$E(t) \leq E(0)\frac{2M}{M+t} \qquad \forall t \geq 0. \tag{4.2}$$

In sections 4 and 5, we assume that there exists a point $x_0 \in \mathbb{R}^2$ such that, setting $m = x - x_0$, we have

$$\Gamma_0 = \{x \in \Gamma \ : \quad (m \cdot \nu) \leq 0\}, \qquad \Gamma_1 = \{x \in \Gamma \ : \quad (m \cdot \nu) > 0\}. \tag{4.3}$$

LEMMA 4.2. *Let y satisfy the following conditions:*

$$\begin{cases} y \in H^2_{\Gamma_0}(\Omega), \qquad \Delta^2 y \in L^2(\Omega), \\ \Delta y + (1-\mu)B_1 y = v_1 \in L^2(\Gamma_1), \\ \partial_\nu \Delta y + (1-\mu)\partial_\tau B_2 y = v_2 \in L^2(\Gamma_1). \end{cases} \tag{4.4}$$

Then we have

$$-\int_\Omega m \cdot \nabla y \Delta^2 y dx \leq -\frac{1}{2}\int_\Omega a(y,y)dx + C_0 \int_{\Gamma_1} (|v_1|^2 + |v_2|^2)d\Gamma, \tag{4.5}$$

where C_0 is a positive constant depending only on the domain Ω.

Proof. We start with $v_1 \in H^{3/2}(\Gamma_1)$ and $v_2 \in H^{1/2}(\Gamma_1)$. In that case, since $y \in H^4(\Omega)$ we have the following Green formula (see Lagnese [5]):

$$\int_\Omega \Delta^2 y\ (m\cdot\nabla y)dx \tag{4.6}$$

$$= \int_\Omega a(y,y)dx + \int_\Gamma v_2(m\cdot\nabla y)d\Gamma - \int_\Gamma v_1\partial_\nu(m\cdot\nabla y)d\Gamma$$

$$+\frac{1}{2}\int_\Gamma (m\cdot\nu)\Big\{\Big(\frac{\partial^2 y}{\partial x_1^2}\Big)^2 + \Big(\frac{\partial^2 y}{\partial x_2^2}\Big)^2 + 2\mu\frac{\partial^2 y}{\partial x_1^2}\frac{\partial^2 y}{\partial x_2^2} + 2(1-\mu)\Big(\frac{\partial^2 y}{\partial x_1\partial x_2}\Big)^2\Big\}d\Gamma.$$

Since $y = \partial_\nu y = 0$ on Γ_0, it follows that

$$\nabla y = 0, \qquad B_1 y = 0, \qquad \partial_\nu(m\cdot\nabla y) = (m\cdot\nu)\Delta y, \tag{4.7}$$

$$\Big(\frac{\partial^2 y}{\partial x_1^2}\Big)^2 + \Big(\frac{\partial^2 y}{\partial x_2^2}\Big)^2 + 2\mu\frac{\partial^2 y}{\partial x_1^2}\frac{\partial^2 y}{\partial x_2^2} + 2(1-\mu)\Big(\frac{\partial^2 y}{\partial x_1\partial x_2}\Big)^2 = (\Delta y)^2. \tag{4.8}$$

On the other hand, we have

$$\Big(\frac{\partial^2 y}{\partial x_1^2}\Big)^2 + \Big(\frac{\partial^2 y}{\partial x_2^2}\Big)^2 + 2\mu\frac{\partial^2 y}{\partial x_1^2}\frac{\partial^2 y}{\partial x_2^2} + 2(1-\mu)\Big(\frac{\partial^2 y}{\partial x_1\partial x_2}\Big)^2$$

$$\geq (1-\mu)\left\{\Big(\frac{\partial^2 y}{\partial x_1^2}\Big)^2 + \Big(\frac{\partial^2 y}{\partial x_2^2}\Big)^2 + 2\Big(\frac{\partial^2 y}{\partial x_1\partial x_2}\Big)^2\right\}. \tag{4.9}$$

Inserting (4.7)–(4.9) into (4.6) gives

$$\int_\Omega \Delta^2 y(m\cdot\nabla y)dx \tag{4.10}$$

$$\geq \int_\Omega a(y,y)dx + \int_{\Gamma_1} v_2(m\cdot\nabla y)d\Gamma - \int_{\Gamma_1} v_1\partial_\nu(m\cdot\nabla y)d\Gamma$$

$$+\frac{\delta}{2}(1-\mu)\int_{\Gamma_1}\Big\{\Big(\frac{\partial^2 y}{\partial x_1^2}\Big)^2 + \Big(\frac{\partial^2 y}{\partial x_2^2}\Big)^2 + 2\Big(\frac{\partial^2 y}{\partial x_1\partial x_2}\Big)^2\Big\}d\Gamma,$$

where δ is positive constant such that $(m\cdot\nu)\geq\delta$ for all $x\in\Gamma_1$.

Now a direct computation gives

$$2\big|\partial_\nu(m\cdot\nabla y)\big|^2 \leq |\partial_\nu y|^2 + R^2\left\{\Big(\frac{\partial^2 y}{\partial x_1^2}\Big)^2 + \Big(\frac{\partial^2 y}{\partial x_2^2}\Big)^2 + 2\Big(\frac{\partial^2 y}{\partial x_1\partial x_2}\Big)^2\right\}, \tag{4.11}$$

where $R = \|m\|_{L^\infty(\Gamma_1)}$ is the diameter of Ω. For any $\lambda>0$, it follows that

$$\int_{\Gamma_1} v_1\partial_\nu(m\cdot\nabla y)d\Gamma \geq -\lambda\int_{\Gamma_1}|v_1|^2 d\Gamma - \frac{1}{8\lambda}\int_{\Gamma_1}|\partial_\nu y|^2 d\Gamma \tag{4.12}$$

$$-\frac{R^2}{8\lambda}\int_{\Gamma_1}\left\{\Big(\frac{\partial^2 y}{\partial x_1^2}\Big)^2 + \Big(\frac{\partial^2 y}{\partial x_2^2}\Big)^2 + 2\Big(\frac{\partial^2 y}{\partial x_1\partial x_2}\Big)^2\right\}d\Gamma,$$

$$\int_{\Gamma_1} v_2(m\cdot\nabla y)d\Gamma \geq -\lambda\int_{\Gamma_1}|v_2|^2 d\Gamma - \frac{R^2}{4\lambda}\int_{\Gamma_1}|\nabla y|^2 d\Gamma. \tag{4.13}$$

Inserting (4.12)–(4.13) into (4.10), we obtain

$$\int_\Omega \Delta^2 y(m\cdot\nabla y)dx \geq \int_\Omega a(y,y)dx \tag{4.14}$$
$$-\lambda\int_{\Gamma_1}(|v_1|^2+|v_2|^2)d\Gamma - \frac{1}{4\lambda}\int_{\Gamma_1}\big(|\partial_\nu y|^2 + R^2|\nabla y|^2\big)d\Gamma$$

provided

$$\lambda \geq \frac{R^2}{4\delta(1-\mu)}. \tag{4.15}$$

We obtain (4.3) by taking $\lambda > 0$ sufficiently large in (4.14):

$$\int_{\Gamma_1}\big(|\partial_\nu y|^2 + R^2|\nabla y|^2\big)d\Gamma \leq \lambda\int_\Omega a(y,y)dx \qquad \forall y\in H^2_{\Gamma_0}(\Omega). \tag{4.16}$$

The case $v_1, v_2 \in L^2(\Gamma_1)$ can be easily completed by a standard argument of density (see Lemma 3.1 in Rao [16]). The proof is complete. □

THEOREM 4.3. *Assume that $s = 0$. Then given any $u_0 \in D(A)$, there exists a constant $M > 0$ depending only on u_0 such that the following rational energy decay rate holds:*

$$E(t) \leq E(0)\frac{2M}{M+t} \qquad \forall t > 0 \tag{4.17}$$

for all smooth solution u of system (2.5).

Proof. Let $0 \leq T < S < +\infty$, we multiply the plate equation by $E(t)(m\cdot\nabla y)$ and integrate over $\Omega\times[T,S]$:

$$\int_T^S\int_\Omega E(t)(m\cdot\nabla y)y''dxdt = -\int_T^S\int_\Omega E(t)(m\cdot\nabla y)\Delta^2 y dxdt. \tag{4.18}$$

In the left-hand side of (4.18), one integration by parts gives

$$\int_T^S\int_\Omega E(t)(m\cdot\nabla y)y''dxdt \tag{4.19}$$
$$= \int_\Omega\Big[E(t)(m\cdot\nabla y)y'dx\Big]_T^S - \int_T^S\int_\Omega E'(t)(m\cdot\nabla y)y'dxdt$$
$$+\int_T^S\int_\Omega E(t)|y'|^2dxdt - \frac{1}{2}\int_T^S\int_{\Gamma_1}E(t)(m\cdot\nu)|y'|^2d\Gamma dt.$$

Next using the Cauchy–Schwarz inequality we have

$$\Big|\int_\Omega (m\cdot\nabla y)y'dx\Big| \leq C_1E(t). \tag{4.20}$$

Then it follows that

$$\int_\Omega\Big[E(t)(m\cdot\nabla y)y'dx\Big]_T^S - \int_T^S\int_\Omega E'(t)(m\cdot\nabla y)y'dxdt \tag{4.21}$$
$$\geq -C_1(E^2(T)+E^2(S)) + C_1\int_T^S E'(t)E(t)dt \geq -2C_1E^2(T).$$

Inserting (4.21) into (4.19) gives

$$\int_T^S \int_\Omega E(t)(m\cdot\nabla y)y''dxdt \tag{4.22}$$

$$\geq \int_T^S \int_\Omega E(t)|y'|^2dxdt - \frac{R}{2}\int_T^S \int_{\Gamma_1} E(t)|y'|^2d\Gamma dt - 2C_1E^2(T).$$

Because of (2.21)–(2.22), y satisfies conditions (4.4). Then applying Lemma 4.2 in the right-hand side of (4.18) gives

$$-\int_T^S \int_\Omega E(t)(m\cdot\nabla y)dxdt \leq -\frac{1}{2}\int_T^S \int_\Omega E(t)a(y,y)\Delta^2 ydxdt \tag{4.23}$$

$$+C_0\int_T^S \int_{\Gamma_1} E(t)\big(|\rho y''+y'|^2+|J\partial_\nu y''+\partial_\nu y'|^2\big)d\Gamma dt.$$

Inserting (4.22)–(4.23) into (4.18) gives that

$$\int_T^S E^2(t)dt \leq 2C_1E^2(T) \tag{4.24}$$

$$+C_2\int_T^S \int_{\Gamma_1} E(t)\big(|y'|^2+|\partial_\nu y'|^2+|y''|^2+|\partial_\nu y''|^2\big)d\Gamma dt,$$

where we have put

$$C_2 = 2C_0(1+\rho^2+J^2)+\frac{R}{2}. \tag{4.25}$$

Since the energy $E(t)$ is nonincreasing, it follows that

$$\int_T^S E^2(t)dt \leq 2C_1E^2(T) \tag{4.26}$$

$$+C_2E(T)\int_T^S \int_{\Gamma_1} \big(|y'|^2+|\partial_\nu y'|^2+|y''|^2+|\partial_\nu y''|^2\big)d\Gamma dt.$$

On the other hand, from (3.2) we deduce that

$$\int_T^S \int_{\Gamma_1} \big(|y'|^2+|\partial_\nu y'|^2\big)d\Gamma dt \leq E(T). \tag{4.27}$$

Differentiating the system (2.5) with respect to the variable t gives

$$\int_T^S \int_{\Gamma_1} \big(|y''|^2+|\partial_\nu y''|^2\big)d\Gamma dt \leq E_1(T), \tag{4.28}$$

where the energy of high-order $E_1(t)$ is defined by

$$E_1(t) = \frac{1}{2}\|u'(t)\|^2 = \frac{1}{2}\|(A+B)u(t)\|^2. \tag{4.29}$$

Use of (4.27)–(4.28) in (4.26) gives

$$\int_T^S E^2(t)dt \le ME(T)E(0), \tag{4.30}$$

where we have put

$$M = 2C_1 + C_2 + C_2\frac{\|(A+B)u_0\|^2}{\|u_0\|^2}. \tag{4.31}$$

Finally, thanks to Lemma 4.1 we deduce the rational energy decay rate (4.17) from (4.30). The proof is thus complete. □

Remark. For most linear problems we use the classical multiplier $m \cdot \nabla y$. The idea of the proof of Theorem 4.3 consists in taking the multiplier $E(t)m \cdot \nabla y$ which is usually used in nonlinear problems. This method is very simple and can be easily applied to other problems.

There is another natural approach based on the spectral theory (Littman and Markus [11]). Roughly speaking, let $\lambda_n = \alpha_n + i\beta_n$ be the eigenvalues of the operator $A + B$. Assume that (i) $\alpha_n \ge 1/n^p$ $(p > 0)$ and (ii) the associated eigenvectors ϕ_n form a Riesz basis; then the trajectory $S_{A+B}(t)u_0$ has a rational decay rate for smooth initial data u_0. This method was applied to one-dimensional problems such as the Euler–Bernoulli beam model (Littman and Markus [11]) and string/mass model (Lee and You [8]) with very careful calculation of the eigenvalues. It seems to be impossible to justify conditions (i) and (ii) for the plate model of general shape.

5. Uniform stability of a simplified model. In this section we consider a simplified model in which the bending moment of inertia of the boundary J is neglected. Therefore, we obtain the following hybrid system:

$$\begin{cases} y'' + \Delta^2 y = 0 & \text{in } \Omega\times]0,+\infty[, \\ y = \partial_\nu y = 0 & \text{on } \Gamma_0\times]0,+\infty[, \\ \Delta y + (1-\mu)B_1 y = -\partial_\nu y' & \text{on } \Gamma_1\times]0,+\infty[, \\ \rho y'' - \partial_\nu \Delta y - (1-\mu)\partial_\tau B_2 y = -y' & \text{on } \Gamma_1\times]0,+\infty[. \end{cases} \tag{5.1}$$

Let us first introduce the energy space H,

$$H = H^2_{\Gamma_0}(\Omega) \times L^2(\Omega) \times L^2(\Gamma_1), \tag{5.2}$$

and the linear unbounded operator A,

$$Au = \begin{pmatrix} -z \\ \Delta^2 y \\ -\frac{1}{\rho}\big(\partial_\nu \Delta y + (1-\mu)\partial_\tau B_2 y - z\big) \end{pmatrix}. \tag{5.3}$$

The domain of the operator A is defined as

$$D(A) = \begin{pmatrix} u = (y,z,\eta) \in W \times H^2_{\Gamma_0}(\Omega) \times L^2(\Gamma_1) \\ \eta = z|_{\Gamma_1}, \quad \Delta y + (1-\mu)B_1 y + \partial_\nu z = 0 \quad \text{on } \Gamma_1 \end{pmatrix}, \tag{5.4}$$

where we have put

$$W = \begin{pmatrix} y \in H^2_{\Gamma_0}(\Omega), \quad \Delta^2 y \in L^2(\Omega) \\ \Delta y + (1-\mu)B_1 y \in H^{1/2}(\Gamma_1) \\ \partial_\nu \Delta y + (1-\mu)\partial_\tau B_2 y \in L^2(\Gamma_1) \end{pmatrix} . \tag{5.5}$$

Now let y be a smooth solution of the hybrid system (5.1). Setting

$$z = y', \qquad \eta = y'|_{\Gamma_1},$$

we transform the hybrid system (5.1) into an abstract evolutionary equation:

$$u' + Au = 0, \qquad u(0) = u_0 \in H. \tag{5.6}$$

Given $u_0 \in D(A)$, using the definition (5.3)–(5.5) and the Green formula (2.13), a straightforward computation gives

$$(Au, u)_H = \int_{\Gamma_1} \big(|z|^2 + |\partial_\nu z|^2\big) d\Gamma \geq 0 \ . \tag{5.7}$$

Moreover by an argument analogous to that of Lemma 2.2, we can easily verify the rank condition $R(I+A) = H$. This implies that the operator A is maximal monotone. Therefore, equation (5.6) is well posed in the sense of a semigroup of contractions. Similarly we have the following result.

THEOREM 5.1. (i) *For any $u_0 \in D(A)$, equation* (5.6) *admits a unique strong solution $u(t) = \big(y(t), z(t), \eta(t)\big) \in D(A)$ such that*

$$y(t) \in C^0\big(\mathbb{R}^+; H^{7/2}(\Omega)\big) \cap C^1\big(\mathbb{R}^+; H^2_{\Gamma_0}(\Omega)\big) \cap C^2\big(\mathbb{R}^+; L^2(\Omega)\big), \tag{5.8}$$

$$y|_{\Gamma_1} \in C^2\big(\mathbb{R}^+; L^2(\Gamma_1)\big). \tag{5.9}$$

(ii) *For any $u_0 \in H$, equation* (5.6) *admits a unique weak solution $u(t) = S_A(t)u_0 = \big(y(t), z(t), \eta(t)\big) \in H$ such that*

$$y(t) \in C^0\big(\mathbb{R}^+; H^2_{\Gamma_0}(\Omega)\big) \cap C^1\big(\mathbb{R}^+; L^2(\Omega)\big), \tag{5.10}$$

$$y|_{\Gamma_1} \in C^1\big(\mathbb{R}^+; L^2(\Gamma_1)\big), \tag{5.11}$$

where $S_A(t)$ is the semigroup of contractions generated by $-A$. □

Now let $u(t) = (y(t), z(t), \eta(t))$ be a solution of equation (5.6); we define the associated energy by setting

$$E(t) = \frac{1}{2}\Big\{ \int_\Omega \big(|y'|^2 + a(y,y)\big) dx + \rho \int_{\Gamma_1} |y'|^2 d\Gamma \Big\}. \tag{5.12}$$

Then using (5.7) we have

$$\frac{d}{dt} E(t) = -\int_{\Gamma_1} \big(|y'|^2 + |\partial_\nu y'|^2\big) d\Gamma \leq 0.$$

Hence for any $T > 0$ we have

$$\int_0^T \int_{\Gamma_1} \big(|y'|^2 + |\partial_\nu y'|^2\big) d\Gamma dt \leq E(0). \tag{5.13}$$

By a slight modification, we can easily establish the following analogue of Lemma 4.2.

LEMMA 5.2. *Let y satisfy the following conditions:*

$$\begin{cases} y \in H^2_{\Gamma_0}(\Omega), \qquad \Delta^2 y \in L^2(\Omega), \\ \Delta y + (1-\mu)B_1 y = v_1, \\ \partial_\nu \Delta y + (1-\mu)\partial_\tau B_2 y = v_2 + \widehat{v}_2 \end{cases} \tag{5.14}$$

with $v_1, v_2, \widehat{v}_2 \in L^2(\Gamma_1)$. Then the following estimate holds:

$$-\int_\Omega m \cdot \nabla y \Delta^2 y dx \tag{5.15}$$

$$\leq -\frac{1}{2}\int_\Omega a(y,y)dx - \int_{\Gamma_1} \widehat{v}_2 (m \cdot \nabla y) d\Gamma + C_0 \int_{\Gamma_1} (|v_1|^2 + |v_2|^2) d\Gamma,$$

where C_0 is a positive constant depending only on Ω. □

THEOREM 5.3. *There exist two positive constants M and ω such that*

$$E(t) \leq M E(0) e^{-\omega t} \qquad \forall t > 0 \tag{5.16}$$

for any solution u of equation (5.6).

Proof. Because of the density of $D(A)$ into H and the continuity of the energy $E(t)$ with respect to the initial data u_0, it is sufficient to consider the smooth initial data $u_0 \in D(A)$. Then indeed, multiplying the plate equation (5.1) by $(m \cdot \nabla y)$ and integrating over $\Omega \times [0,T]$, we obtain

$$\int_0^T \int_\Omega (m \cdot \nabla y) y'' dx dt = -\int_0^T \int_\Omega (m \cdot \nabla y) \Delta^2 y dx dt. \tag{5.17}$$

In the left-hand side, one integration by parts gives

$$\int_0^T \int_\Omega (m \cdot \nabla y) y'' dx dt = \int_\Omega \left[(m \cdot \nabla y) y' dx \right]_0^T \tag{5.18}$$

$$+ \int_0^T \int_\Omega |y'|^2 dx dt - \frac{1}{2}\int_0^T \int_{\Gamma_1} (m \cdot \nu) |y'|^2 d\Gamma dt.$$

Next using the Cauchy–Schwarz inequality we have

$$\int_\Omega \left[(m \cdot \nabla y) y' dx \right]_0^T \geq -C_1 E(0), \tag{5.19}$$

where $C_1 > 0$ is a constant depending only on Ω. Inserting (5.19) into (5.18) and taking (5.13) into account gives

$$\int_0^T \int_\Omega (m \cdot \nabla y) y'' dx dt \geq \int_0^T \int_\Omega |y'|^2 dx dt - C_1 E(0). \tag{5.20}$$

Using (5.8)–(5.9), we verify easily that $y, v_1 = -\partial_\nu y', v_2 = y'$, and $\widehat{v}_2 = \rho y''$ satisfy conditions (5.14). Applying Lemma 5.2 in the right-hand side of (5.17), we

obtain that

$$-\int_0^T\int_\Omega (m\cdot\nabla y)\Delta^2 y dxdt \le -\frac{1}{2}\int_0^T\int_\Omega a(y,y)dxdt \tag{5.21}$$
$$-\rho\int_0^T\int_{\Gamma_1}(m\cdot\nabla y)y''d\Gamma dt + C_0\int_0^T\int_{\Gamma_1}\big(|y'|^2+|\partial_\nu y'|^2\big)d\Gamma dt.$$

One integration by parts gives

$$-\int_0^T\int_{\Gamma_1}(m\cdot\nabla y)y''d\Gamma dt \tag{5.22}$$
$$=-\int_{\Gamma_1}\big[(m\cdot\nabla y)y'd\Gamma\big]_0^T+\int_0^T\int_{\Gamma_1}(m\cdot\nabla y')y'd\Gamma dt.$$

Using the Cauchy–Schwarz inequality we have

$$-\int_{\Gamma_1}\big[(m\cdot\nabla y)y'\big]_0^T d\Gamma \le CE(0). \tag{5.23}$$

On the other hand, a straightforward computation gives

$$\int_{\Gamma_1}(m\cdot\nabla y')y'd\Gamma \tag{5.24}$$
$$=\int_{\Gamma_1}\Big((m\cdot\nu)y'\partial_\nu y'-\frac{1}{2}\partial_\tau(m\cdot\tau)|y'|^2\Big)d\Gamma$$
$$\le (R+K)\int_{\Gamma_1}(|y'|^2+|\partial_\nu y'|^2)d\Gamma,$$

where we have put

$$R=\|m\|_{L^\infty(\Gamma)},\qquad K=\|\partial_\tau(m\cdot\tau)\|_{L^\infty(\Gamma)}. \tag{5.25}$$

Inserting (5.22)–(5.24) into (5.21) and taking (5.13) into account, we get

$$\int_0^T\int_\Omega(m\cdot\nabla y)\Delta^2 y dxdt \le -\frac{1}{2}\int_0^T\int_\Omega a(y,y)dxdt+CE(0), \tag{5.26}$$

where $C>0$ is a constant depending only on Ω.

Finally inserting (5.20) and (5.26) into (5.17), we obtain the integral inequality

$$\int_0^T E(t)dt \le CE(0)\qquad \forall T>0. \tag{5.27}$$

Thanks to the well-known result of Datko (Pazy [14]), this implies the uniform energy decay rate (5.16). The proof is thus complete. □

Remark. We have shown that the hybrid system (5.1) can be uniformly stabilized by means of the usual boundary feedback controls. But if we take $\rho=0$ and $J>0$, then contrary to the previous case the uniform stability of the corresponding hybrid system remains an *open* problem. See also [15] for other uniformly stable hybrid systems.

CONFIGURATION FLATNESS OF LAGRANGIAN SYSTEMS UNDERACTUATED BY ONE CONTROL*

MURUHAN RATHINAM† AND RICHARD M. MURRAY‡

Abstract. Lagrangian control systems that are differentially flat with flat outputs that depend only on configuration variables are said to be configuration flat. We provide a complete characterization of configuration flatness for systems with n degrees of freedom and $n-1$ controls whose range of control forces only depends on configuration and whose Lagrangian has the form of kinetic energy minus potential. The method presented allows us to determine if such a system is configuration flat and, if so, provides a constructive method for finding all possible configuration flat outputs. Our characterization relates configuration flatness to Riemannian geometry. We illustrate the method with two examples.

Key words. differential flatness, nonlinear control, Lagrangian mechanics

1. Introduction.

Roughly speaking, an underdetermined system of ODEs

$$F^k(t, x^1, \ldots, x^N, \dot{x}^1, \ldots, \dot{x}^N) = 0, \qquad k = 1, \ldots, n < N,$$

is differentially flat if there is a smooth locally one-to-one correspondence between solutions $x(t)$ of the system and arbitrary functions $y(t)$ of the form

$$x(t) = g(t, y(t), \ldots, y^{(l)}(t)),$$
$$y(t) = h(t, x(t), \ldots, x^{(q)}(t)),$$

where $(y^1, \ldots, y^p) \in \mathbb{R}^p$ and $p = N - n$. Here g, h are smooth maps, $y^{(k)}$ is the kth derivative of y, and l, q are integers. The variables y^j are referred to as flat outputs. The special class of systems given by

$$\dot{x}^i = f^i(t, x^1, \ldots, x^n, u^1, \ldots, u^p), \quad i = 1, \ldots, n,$$

is more familiar to control theorists and the flat outputs depend on states, inputs, and derivatives of inputs

$$y^j = h^j(t, x, u, u^{(1)}, \ldots, u^{(q)}), \quad j = 1, \ldots, p.$$

For a detailed discussion of differential flatness see Fliess et al. [3, 4], Martin [9], Pomet [12], van Nieuwstadt, Rathinam, and Murray [21], and Rathinam and Sluis [13].

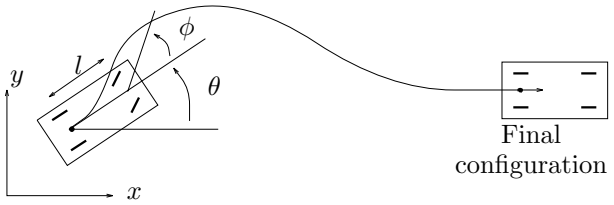

FIG. 1.1. *Path planning for kinematic car.*

The importance of flatness to control applications lies in the fact that it provides a systematic and relatively simple way to generate solution trajectories between two given states. One uses the maps g and h to transform between original system space (states as well as inputs) and the smaller-dimensional flat output space. See van Nieuwstadt and Murray [20] and Murray, Rathinam, and Sluis [11] for more details.

For example consider the "kinematic car" shown in Figure 1.1. Ignoring dynamics we assume the velocity of the midpoint between the rear wheels and the steering velocity are directly controlled. Then the system is differentially flat with the coordinates of the midpoint between rear wheels providing the two flat outputs (see Rouchon et al. [14] and Tilbury, Murray, and Sastry [19]). Given any trajectory for this point one can determine the entire motion of the car: the tangent to the trajectory determines the orientation of the car and the curvature (second derivative) determines the orientation of the front wheels. Hence all feasible paths of the vehicle can be parametrized in terms of the trajectories of the flat output point. A given set of initial and final configurations of the car then determine two end points and first- and second-order derivatives at these end points for feasible trajectories of the flat output point. One could choose any trajectory for the flat output point that satisfies these end conditions and obtain a feasible trajectory for the car that passes through the given initial and final conditions. In this example, flat outputs are rather obvious. This is not the case with many other examples, and one needs a theoretical tool to provide a systematic way of finding them if they exist.

In the case of single input systems a complete characterization of differential flatness is available; see, e.g., Shadwick [16]. In that case, flatness is the same as static feedback linearizability. See also [2]. In the framework of exterior differential systems, checking for flatness of a single input system reduces to calculating "derived systems" and checking certain rank and integrability conditions. See van Nieuwstadt, Rathinam, and Murray [21], Sluis [17], and Sluis and Tilbury [18]. For multi-input systems no complete theory exists.

Many interesting examples of mechanical systems are differentially flat, and in most known examples flat outputs have been found that depend only on the configuration variables but not on their derivatives. We refer to such flat outputs as "configuration flat outputs" and systems possessing such outputs as "configuration flat." For instance, the above example of the kinematic car is configuration flat. All Lagrangian systems that are fully actuated (number of controls equals number of degrees of freedom) are configuration flat with all the configuration variables as flat outputs. See [11] for a catalogue of other examples. The reasons for studying configuration flatness are as follows. First, it is a simpler case than the general case of differential flatness and is possibly the first thing to study if one were to be able to relate the mechanical structure with differential flatness. For instance, configuration controllability of mechanical systems has already been studied and related to the

mechanical structure (see Lewis and Murray [8]). Second, the smaller the number of derivatives of configuration variables the flat outputs depend upon the simpler the numerical implementation of the transformations involved in trajectory generation. In this paper we completely characterize configuration flatness for a special class of mechanical systems. The class under consideration involves systems whose dynamics are described by Lagrangian mechanics with a Lagrangian function of the form "kinetic energy minus potential." Also, the number of independent controls is assumed to be one less than the number of degrees of freedom (the simplest case next to fully actuated systems) and the possible range of control forces only depends on the configuration and not on the velocity. We describe an algorithm for deciding if such a system is configuration flat and if it is so, we describe a procedure for finding all possible configuration flat outputs. We do not consider systems with nonholonomic constraints. The kinematic car example hence does not fall into the class of systems under our consideration.

The paper is organized as follows. Section 2 introduces some concepts from Lagrangian control systems theory and also provides a definition of configuration flatness. Section 3 introduces some concepts from Riemannian geometry that are necessary for our theory and also states and proves the main proposition and outlines an algorithm for coordinate calculations to check configuration flatness. Section 4 explores how system symmetries relate to symmetries of the flat outputs. Finally, section 5 gives two examples to illustrate the theory.

2. Lagrangian control systems and configuration flatness. Consider a Lagrangian system with configuration manifold Q of dimension n and a Lagrangian $L : TQ \to \mathbb{R}$. When no external (generalized) forces are applied, the motion of this system satisfies the Euler–Lagrange equations, written in coordinates $(q^1, \dots, q^n)$ as

$$\frac{d}{dt}\left(\frac{\partial L}{\partial \dot{q}^i}\right) - \frac{\partial L}{\partial q^i} = 0, \quad i = 1, \dots, n. \tag{2.1}$$

In a control situation external control forces are applied and it is natural to think of forces as covectors on the manifold Q. In other words, for a configuration $q \in Q$ the total external force acting on the system can be represented by an element of T_q^*Q. This is because forces naturally pair with velocities, which can be thought of as elements of T_qQ, to give instantaneous power. The possible range of control forces lies in a subspace of T_q^*Q which may depend on position q as well as velocity v_q. In other words the control forces can be described by a horizontal-valued codistribution $\bar{P} \subset T^*(TQ)$, and $p = \dim \bar{P}$ is the number of independent controls. For an interesting and wide class of systems this subspace depends only on configuration q and hence can be described by a codistribution $P \subset T^*Q$ of dimension p. For the rest of the discussion we shall consider only this case. All feasible paths (solutions) of such a system are characterized by the following underdetermined system of ODEs in coordinates $(q^1, \dots, q^n)$:

$$a_k^i \left(\frac{d}{dt}\left(\frac{\partial L}{\partial \dot{q}^i}\right) - \frac{\partial L}{\partial q^i}\right) = 0, \quad k = 1, \dots, n-p, \tag{2.2}$$

where $a_k^i \frac{\partial}{\partial q^i}$ for $k = 1, \dots, n-p$ span the annihilator of P, denoted $\operatorname{ann} P$.

It is useful to think in terms of the associated submanifold $\mathrm{E} \subset J^2(\mathbb{R}, Q)$ of the second-order jet space (see [15]), which geometrically describes such a second-order system of equations. E has codimension $n-p$ and in local coordinates $(t, q, \dot{q}, \ddot{q})$ is

cut out by the common zeros of the functions

$$a_k^i \left(\frac{\partial^2 L}{\partial \dot{q}^i \partial \dot{q}^j} \ddot{q}^j + \frac{\partial^2 L}{\partial \dot{q}^i \partial q^j} \dot{q}^j - \frac{\partial L}{\partial q^i} \right), \quad k = 1, \dots, n-p.$$

Let $q \in Q$ be a point and let $y : U \subset Q \to \mathbb{R}^p$ be a submersion locally defined around q. Let $y = (y^1, \dots, y^p)$. We say $y^1, \dots, y^p$ are *differentially independent* around q if $y^1, \dots, y^p$ do not have to satisfy an ODE along solutions local to q. More precisely, when restricted to E , $dy^1, \dots, dy^p, d\dot{y}^1, \dots, d\dot{y}^p, d\ddot{y}^1, \dots, d\ddot{y}^p$ are linearly independent for generic points on $\pi_2^{-1}(V) \cap \mathrm{E}$ where $V \subset U$ is an open neighborhood of q and $\pi_2 : J^2(\mathbb{R}, Q) \to Q$ is the standard projection. If $dy^1, \dots, dy^p, d\dot{y}^1, \dots, d\dot{y}^p, d\ddot{y}^1, \dots, d\ddot{y}^p$ are linearly dependent when restricted to E , for points on $\pi_2^{-1}(V) \cap \mathrm{E}$ where $V \subset U$ is an open neighborhood of q, then $y^1, \dots, y^p$ are *differentially dependent* around q.

Suppose $y^1, \dots, y^p$ are differentially independent around q. If there are functions f^i and a neighborhood W of q such that along a generic solution $c : \mathbb{R} \to W \subset Q$,

$$(z^i \circ c)(t) = f^i \left((y \circ c)(t), \dots, \frac{d^r}{dt^r}(y \circ c)(t) \right), \quad i = 1, \dots, n-p, \tag{2.3}$$

where $z^1, \dots, z^{n-p}$ are any complementary coordinates to $y^1, \dots, y^p$, then $y^1, \dots, y^p$ are said to be *configuration flat outputs* around q and the system is *configuration flat* around q. In other words, given $y^1(t), \dots, y^p(t)$ we can determine a (locally) unique trajectory for the Lagrangian system (2.2).

We present the following lemma which will be of use later.

LEMMA 2.1. *Let $q \in Q$, U be an open neighborhood of q, and $y : U \to \mathbb{R}^p$ be a configuration flat output. Then generically the set of solutions $c : \mathbb{R} \to U$ that project down to the same curve $y \circ c$ are all isolated.*

Proof. By definition of flatness, along generic solutions, given $y(t)$ the complementary coordinates $z(t)$ are locally uniquely determined by equations (2.3). ∎

3. Mechanical systems with n degrees of freedom and $n-1$ controls. Consider the mechanical system whose Lagrangian is given by

$$L(v) = \frac{1}{2} g(v, v) - V \circ \tau_Q(v), \tag{3.1}$$

where g is the Riemannian metric (assumed to be nondegenerate) corresponding to kinetic energy and V is the potential energy function on Q and $\tau_Q : TQ \to Q$ is the tangent bundle projection. Suppose the number of controls $p = n-1$, in other words $\dim P = n-1$. In this section we shall present a method for determining if this system is configuration flat. If the system is configuration flat our approach provides us with a constructive method for finding all possible (configuration) flat outputs.

Before proceeding further we present some concepts from Riemannian geometry. Given a metric g we have a notion of differentiation of objects on the manifold such as functions, vector fields, differential forms, and tensors along a given vector field Z. This is the covariant derivative ∇ given by the Levi–Cività connection (see [1]). ∇_Z denotes covariant derivative along a vector field Z and is related to parallel (with respect to metric) transport of objects along the integral curves of Z. The covariant derivative of a function f along Z denoted $\nabla_Z f$ is just the familiar directional derivative $Z(f)$ or the Lie derivative. But the covariant derivative of a vector field X along Z denoted $\nabla_Z X$ is not the same as the Lie derivative $[Z, X]$. Some properties of ∇

are

$$\nabla_Z(X_1 + X_2) = \nabla_Z X_1 + \nabla_Z X_2, \tag{3.2}$$

$$\nabla_Z(fX) = \nabla_Z X + Z(f)X, \tag{3.3}$$

$$\nabla_{fZ} X = f\nabla_Z X, \tag{3.4}$$

$$\nabla_Z X - \nabla_X Z = [Z, X], \tag{3.5}$$

where X, X_1, X_2, Z are arbitrary vector fields and f is an arbitrary function on the manifold. In a coordinate system $(q^1, \ldots, q^n)$ on manifold Q the covariant derivatives are calculated with the aid of Christoffel symbols Γ^i_{jk}, where $i, j, k = 1, \ldots, n$ and Christoffel symbols are defined by

$$\nabla_{\frac{\partial}{\partial q^j}} \frac{\partial}{\partial q^k} = \Gamma^i_{jk} \frac{\partial}{\partial q^i}. \tag{3.6}$$

From the properties (3.5) of ∇ it follows that $\Gamma^i_{jk} = \Gamma^i_{kj}$. The symbols Γ^i_{jk} can be computed from metric g by the formula

$$\Gamma^m_{jk} = \frac{1}{2}\left(\frac{\partial g_{ik}}{\partial q^j} + \frac{\partial g_{ij}}{\partial q^k} - \frac{\partial g_{jk}}{\partial q^i}\right) g^{im}, \quad j, m = 1, \ldots, n, \tag{3.7}$$

where $g^{ik} g_{kj} = \delta^i_j$ (g^{ik} are components of the inverse of matrix g_{ik}). Then the covariant derivative of vector field $X = X^k \frac{\partial}{\partial q^k}$ along $Z = Z^j \frac{\partial}{\partial q^j}$ is given by

$$\nabla_Z X = Z^j X^k \Gamma^i_{jk} \frac{\partial}{\partial q^i} + Z^j \frac{\partial X^k}{\partial q^j} \frac{\partial}{\partial q^k}. \tag{3.8}$$

For the mechanical system under consideration let us define an associated distribution D by

$$D = \operatorname{span}\{\xi, \nabla_Z \xi \ : \ Z \in \mathfrak{X}(Q)\}, \tag{3.9}$$

where ξ is any vector field such that $\operatorname{ann} P = \operatorname{span}\{\xi\}$ and $\mathfrak{X}(Q)$ is the set of all smooth vector fields on Q.

It is easy to check that D doesn't depend on the choice of $\xi \in \operatorname{ann} P$. By the linearity of covariant derivative it follows that

$$D = \operatorname{span}\{\xi, \nabla_{\frac{\partial}{\partial q^i}} \xi \ : \ i = 1, \ldots, n\}, \tag{3.10}$$

where $(q^1, \ldots, q^n)$ are any set of coordinates. Hence D is easily calculated using equations (3.7), (3.8), and (3.10). The following proposition characterizes configuration flat outputs $y^1, \ldots, y^p$ by conditions on $\ker Ty$, which in coordinates is the null space of the Jacobian of the map y.

PROPOSITION 3.1. *Let q be a point on Q and U be an open neighborhood of q, and suppose $y : U \subset Q \to \mathbb{R}^p$ is a submersion. If $y^1, \ldots, y^p$ are configuration flat outputs, then*

$$g(\ker Ty, D) = 0. \tag{3.11}$$

Conversely if $g(\ker Ty, D) = 0$ and if a certain regularity condition holds at q, then $y^1, \ldots, y^p$ are configuration flat outputs around q.

The regularity condition is that the ratios of functions in the following set should not all be the same at q:

$$\{\nabla_\eta(g(\xi,Z)) : g(\xi,Z), \nabla_\eta(g(\nabla_{Z_1}Z_2,\xi)) : g(\nabla_{Z_1}Z_2,\xi), \nabla_\eta(\xi(V)) : \xi(V)\}, \tag{3.12}$$

where Z, Z_1, Z_2 are arbitrary vector fields around q that are y-related to some vector field on $\mathbb{R}^p$ and ξ, η are fixed nonvanishing vector fields such that $\operatorname{ann} P = \mathit{span}\{\xi\}$ *and* $\ker Ty = \mathit{span}\{\eta\}$.

REMARK 3.2. *Proposition* 3.1 *states the conditions for configuration flatness in intrinsic geometric terms. In coordinates the algorithm for deciding if the system is configuration flat is as follows. Calculate D using equation* (3.10). *If $D = TQ$, then system is not configuration flat, since for any y, one can find some vector field $Z \in D = TQ$, such that $g(\ker Ty, Z) \neq 0$. Suppose* $\dim D \leq n-1$. *Then choose a one-dimensional distribution, say spanned by a vector field η, that is orthogonal to D. Since a one-dimensional distribution is integrable locally, one can find independent functions $y^1, \dots, y^p$ ($p = n-1$) around q that "cut out" the leaves of the corresponding foliation. These will be flat outputs provided the regularity conditions are met.*

The regularity conditions can be checked in coordinates as follows. Choose a function z that completes $y^1, \dots, y^p$ to a coordinate system. Then $y^1, \dots, y^p$ will be flat outputs if the following ratios of functions are not all identically equal in a local neighborhood:

$$\begin{aligned}
&\frac{\partial}{\partial z}\left(g\left(\xi, \frac{\partial}{\partial y^j}\right)\right) : g\left(\xi, \frac{\partial}{\partial y^j}\right), && j = 1, \dots, p,\\
&\frac{\partial}{\partial z}\left(g\left(\nabla_{\frac{\partial}{\partial y^k}}\frac{\partial}{\partial y^j}, \xi\right)\right) : g\left(\nabla_{\frac{\partial}{\partial y^k}}\frac{\partial}{\partial y^j}, \xi\right), && j,k = 1, \dots, p,\\
&\frac{\partial}{\partial z}(\xi(V)) : \xi(V).
\end{aligned} \tag{3.13}$$

If these are all identically equal that means $y^1, \dots, y^p$ are differentially dependent and another one-dimensional distribution must be tried.

REMARK 3.3. *It is readily seen that configuration flatness is determined primarily by the kinetic energy metric g since the role of potential function V only enters via the regularity conditions. This explains why in many known examples* (see [11]) *the presence or absence of gravity does not alter the configuration flat outputs but only the solution curves where singularities occur. However, we present an example in the next section where the potential function plays a crucial role via the regularity conditions.*

Proof of Proposition 3.1. Given a submersion $y : Q \to \mathbb{R}^p$, one can choose a local coordinate chart on Q such that y is the canonical submersion of $\mathbb{R}^n$ onto $\mathbb{R}^p$. Let the corresponding coordinates on Q be $(q^1, \dots, q^n)$. Then, $y^j(q) = q^j$ for $j = 1, \dots, p = n-1$. Let $\xi = a^i \frac{\partial}{\partial q^i}$ span ann P. Then all solutions of the system satisfy the single ODE

$$a^i\left(\frac{d}{dt}\left(\frac{\partial L}{\partial \dot{q}^i}\right) - \frac{\partial L}{\partial q^i}\right) = 0. \tag{3.14}$$

Suppose in these coordinates g is given by g_{ij}. Then we can rewrite equation (3.14) as

$$a^i\left(g_{ij}\ddot{q}^j + \frac{\partial g_{ik}}{\partial q^j}\dot{q}^j\dot{q}^k - \frac{1}{2}\frac{\partial g_{jk}}{\partial q^i}\dot{q}^j\dot{q}^k + \frac{\partial V}{\partial q^i}\right) = 0. \tag{3.15}$$

Using the formula (3.7) for the Christoffel symbols and using $q^j = y^j$ for $j = 1, \dots, p$ to separate the terms involving $\dot{q}^n$ and $\ddot{q}^n$, we rewrite equation (3.15) as

$$a^i \left(g_{ij}\ddot{y}^j + \Gamma^m_{jk} g_{mi} \dot{y}^j \dot{y}^k + \frac{\partial V}{\partial q^i} + g_{in}\ddot{q}^n + \Gamma^m_{nn} g_{mi} (\dot{q}^n)^2 + \Gamma^m_{jn} g_{mi} \dot{y}^j \dot{q}^n \right) = 0, \tag{3.16}$$

where the range of summation of various indices is clear.

Necessity. Suppose that y are flat outputs. Then it follows that the coefficient of $\ddot{q}^n$ in the above ODE must to be zero. Otherwise we can rewrite the equation as

$$\frac{d\dot{q}^n}{dt} = f(y, \dot{y}, \ddot{y}, q^n, \dot{q}^n)$$

for some smooth function f, and by the existence theorem of solutions to ODEs, given any curve $y(t)$ we get a 2-parameter family of solutions $q(t)$ (parametrized by initial conditions $q^n(t_0), \dot{q}^n(t_0)$) that project to $y(t)$, and they are not isolated from each other and hence by Lemma 2.1 y cannot be flat, contradicting our assumption. So $a^i g_{in} = 0$ and this leaves us with an ODE of the form

$$A(y)(\dot{q}^n)^2 + B(y, \dot{y})\dot{q}^n + C(y, \dot{y}, \ddot{y}, q^n) = 0.$$

A similar reasoning tells us that the term $\dot{q}^n$ should be absent; in other words, $A(y) = 0$ and $B(y, \dot{y}) = 0$. Here A and B are given by

$$A = a^i \Gamma^m_{nn} g_{mi}, \quad B = a^i \Gamma^m_{jn}\, g_{mi} \dot{y}^j.$$

Observe that B is linear in terms $\dot{y}$ with coefficients that are functions only of (y, q^n). Hence the condition $B = 0$ can be written as $n - 1$ equations that set the coefficients of $\dot{y}^j$ to be zero. The equation $A = 0$ has the same form as these, and we get the following n equations:

$$a^i \Gamma^m_{jn} g_{im} = 0, \quad j = 1, \dots, n.$$

So, all together, flatness of y implies the following equations:

$$\begin{aligned} a^i g_{in} &= 0, \\ a^i \Gamma^m_{jn} g_{im} &= 0, \quad j = 1, \dots, n. \end{aligned} \tag{3.17}$$

If $\ker Ty = \operatorname{span}\{\eta\}$, then in our choice of coordinates $\eta = \lambda \frac{\partial}{\partial q^n}$ where λ is some nonvanishing function on Q. Hence, $g(\xi, \eta) = a^i g_{in} = 0$ by the first condition, where $\xi = a^i \frac{\partial}{\partial q^i}$ spans $\operatorname{ann} P$. Also since

$$\nabla_{\frac{\partial}{\partial q^j}} \eta = \lambda \Gamma^m_{jn} \frac{\partial}{\partial q^m} + \frac{\partial \lambda}{\partial q^j} \frac{\partial}{\partial q^n},$$

it follows that

$$g(\nabla_{\frac{\partial}{\partial q^j}} \eta, \xi) = \lambda a^i \Gamma^m_{jn} g_{im} + \frac{\partial \lambda}{\partial q^j} a^i g_{in} = 0.$$

But, by the derivation property,

$$\nabla_Z (g(\xi, \eta)) = (\nabla_Z g)(\xi, \eta) + g(\nabla_Z \xi, \eta) + g(\xi, \nabla_Z \eta)$$

and since $\nabla_Z g = 0$ for any $Z \in \mathfrak{X}(Q)$ (by the property of Levi–Cività connection) and since $g(\eta, \xi) = 0$ it follows that

$$g(\nabla_{\frac{\partial}{\partial q^j}} \xi, \eta) = 0, \quad j = 1, \dots, n.$$

By linearity of ∇ it follows that

$$g(\nabla_Z \xi, \eta) = 0 \quad \forall Z \in \mathfrak{X}(Q).$$

Hence, $\ker Ty$ is orthogonal to D.

Sufficiency. Conversely, if $\ker Ty$ is orthogonal to D, previous reasoning shows that in the same coordinate system equations (3.17) hold. As seen before these imply that the solution curves of the system are given by the ODE

$$E(q^n, y, \dot{y}, \ddot{y}) = 0,$$

where

$$E = a^i g_{ij} \ddot{y}^j + a^i g_{im} \Gamma^m_{jk} \dot{y}^j \dot{y}^k + a^i \frac{\partial V}{\partial q^i}.$$

This is not sufficient for flatness of $y^1, \dots, y^p$ since it is possible that $y^1, \dots, y^p$ are differentially dependent and this happens when E does not depend on q^n. More precisely $y^1, \dots, y^p$ are differentially dependent around q when there exists a neighborhood V of q such that $\frac{\partial E}{\partial q^n}$ is identically zero on $(\pi_2^{-1}(V) \cap \{E = 0\}) \subset J^2(\mathbb{R}, Q)$ where $\pi_2 : J^2(\mathbb{R}, Q) \to Q$ is the standard projection. The functions E and $\frac{\partial E}{\partial q^n}$ are both affine in $\ddot{y}$ and quadratic in $\dot{y}$ with the coefficients functions only of (y, q^n), and E depends on $\ddot{y}$ nontrivially since metric g is nondegenerate. Hence either $\frac{\partial E}{\partial q^n}$ is identically zero on $\pi_2^{-1}(q) \cap \{E = 0\}$ or it is non zero for generic points on $\pi_2^{-1}(q) \cap \{E = 0\}$. Furthermore, $\frac{\partial E}{\partial q^n}$ is identically zero on $\pi_2^{-1}(q) \cap \{E = 0\}$ if and only if it is a multiple of E as a polynomial in $\dot{y}$ and $\ddot{y}$ for points on $\pi_2^{-1}(q)$. Hence the regularity condition we impose is that $\frac{\partial E}{\partial q^n}$ is a not a multiple of E as a polynomial in $\ddot{y}$ and $\dot{y}$ for points on $\pi_2^{-1}(q)$. Then it would follow from continuity and the implicit function theorem that for generic points on $\pi_2^{-1}(V) \cap \{E = 0\}$ where V is some neighborhood of q, q^n can be locally solved for in terms of $y, \dot{y}, \ddot{y}$, implying flatness around q.

The rest of the proof is concerned with showing that this condition translates to the regularity condition stated in the proposition. It is sufficient to show that $\frac{\partial E}{\partial q^n}$ is a multiple of E as a polynomial in $\dot{y}, \ddot{y}$ with the ratio being a smooth function on Q in a neighborhood of q if and only if the set of ratios of functions (3.12) are all identically equal in a neighborhood of q.

Let η span $\ker Ty$. Then $\eta = \lambda \frac{\partial}{\partial q^n}$ for some nonvanishing function λ. Also let $\xi = a^i \frac{\partial}{\partial q^i}$ span $\operatorname{ann} P$. Suppose $\frac{\partial E}{\partial q^n} = fE$ for some function f defined in a neighborhood of q on Q. Considering coefficients of $\ddot{y}^j$ terms we get

$$\frac{\partial}{\partial q^n}(a^i g_{ij}) = f a^i g_{ij}, \quad j = 1, \dots, p. \tag{3.18}$$

Also observe that any vector field Z on Q is y-related if and only if it has the form $Z^j(y) \frac{\partial}{\partial y^j} + Z^n(y, q^n) \frac{\partial}{\partial q^n}$. Hence

$$\nabla_\eta(g(\xi, Z)) = \lambda \frac{\partial}{\partial q^n}(Z^j a^i g_{ij})$$

$$= \lambda Z^j \frac{\partial}{\partial q^n}(a^i g_{ij}) = \lambda f Z^j a^i g_{ij},$$

where we have used $a^i g_{in} = 0$ and equation (3.18). Hence equation (3.18) is equivalent to

$$\nabla_\eta(g(\xi, Z)) = \lambda f g(\xi, Z), \tag{3.19}$$

where Z is any arbitrary y-related vector field.

Considering coefficients of $\dot{y}^j \dot{y}^k$ we get

$$\frac{\partial}{\partial q^n}(a^i g_{im} \Gamma^m_{jk}) = f a^i g_{im} \Gamma^m_{jk}, \quad j, k = 1, \ldots, p. \tag{3.20}$$

Assuming equation (3.18), this is equivalent to

$$\nabla_\eta(g(\nabla_{Z_1} Z_2, \xi)) = f\lambda g(\nabla_{Z_1} Z_2, \xi), \tag{3.21}$$

where Z_1, Z_2 are arbitrary y-related vector fields. This is because substituting $Z_l = Z_l^j(y)\frac{\partial}{\partial y^j} + Z_l^n(y, q^n)\frac{\partial}{\partial q^n}$ for $l = 1, 2$ we get

$$g(\nabla_{Z_1} Z_2, \xi) = Z_1^j Z_2^k g\left(\Gamma^m_{jk}\frac{\partial}{\partial y^m}, \xi\right) + Z_1^j \frac{\partial Z_2^k}{\partial y^j} g\left(\frac{\partial}{\partial y^k}, \xi\right),$$

where we have used $a^i g_{in} = 0$, $a^i \Gamma^m kng_{im} = 0$ (since $\ker Ty$ is orthogonal to D) and $\frac{\partial Z_2^k}{\partial q^n} = 0$ for $k = 1, \ldots, p$. Hence

$$\begin{aligned}
&\nabla_\eta(g(\nabla_{Z_1} Z_2, \xi)) \\
&= \lambda Z_1^j Z_2^k \frac{\partial}{\partial q^n}(a^i g_{im} \Gamma^m_{jk}) + \lambda Z_1^j \frac{\partial Z_2^k}{\partial y^j}\frac{\partial}{\partial q^n}(a^i g_{ik}) \\
&= \lambda f Z_1^j Z_2^k a^i g_{im} \Gamma^m_{jk} + \lambda f Z_1^j \frac{\partial Z_2^k}{\partial y^j} a^i g_{ik},
\end{aligned}$$

where we have used equations (3.18) and (3.20). This simplifies to

$$\nabla_\eta(g(\nabla_{Z_1} Z_2, \xi)) = \lambda f g(\nabla_{Z_1} Z_2, \xi). \tag{3.22}$$

Finally considering the coefficients of the terms independent of $\dot{y}$ and $\ddot{y}$ we get

$$\frac{\partial}{\partial q^n}\left(a^i \frac{\partial V}{\partial q^i}\right) = f a^i \frac{\partial V}{\partial q^i}.$$

Clearly this is equivalent to

$$\nabla_\eta(\xi(V)) = \lambda f \xi(V), \tag{3.23}$$

completing the proof. □

4. Systems with n degrees of freedom, $n-1$ controls, and symmetry. In this section we shall consider systems of the type considered in the previous section that also exhibit symmetries. We shall suppose that a Lie group G acts on our configuration space Q with action Φ_h corresponding to $h \in G$ and that

$$\Phi_h^* g = g, \qquad \Phi_h^* P = P \quad \forall h \in G. \tag{4.1}$$

In other words the kinetic energy of the system as well as the range of control forces both are invariant under the group action. However, we do not assume that V is

invariant under the group action. Many mechanical systems fall under this category. Rigid body systems moving in Euclidean space actuated by body fixed forces are typical examples where the group is $G = SE(3)$, even though the equations of motion often do not have $SE(3)$ as a symmetry group since potential forces due to gravity break the symmetry. But since V plays a very limited role in configuration flatness we may expect that when the system is configuration flat that it would be possible to find flat outputs that reflect this symmetry. We believe this to be true and shall prove it for the case $\dim D = n-1$. The general case $\dim D < n-1$ has not yet been resolved completely (see Remark 4.4).

LEMMA 4.1. *Consider a system satisfying* (4.1). *Let* D *be defined as in* (3.9). *Then* $\Phi_{h_*} D = D$.

Proof. Let ξ span $\operatorname{ann} P$. Clearly $\Phi_{h_*}(\operatorname{ann} P) = \operatorname{ann} P$. Hence $\Phi_{h_*}\xi = \lambda_h \xi \in D$ where λ_h is some smooth function. Since Φ_h is an isometry by (4.1), it follows that $\Phi_{h_*}(\nabla_Z \xi) = \nabla_{\Phi_{h_*} Z}(\Phi_{h_*}\xi)$ by properties of ∇ (see, for example, [5, p. 161]). Hence

$$\begin{aligned} \Phi_{h_*}\nabla_Z \xi &= \nabla_{\Phi_{h_*} Z}(\lambda_h \xi) \\ &= \lambda_h \nabla_{\Phi_{h_*} Z}\xi + (\nabla_{\Phi_{h_*} Z}\lambda_h)\xi \in D. \end{aligned} \tag{4.2}$$

So we have $\Phi_{h_*} D \subset D$. Since Φ_h is a diffeomorphism, the result follows by dimension count. ∎

Let $y : Q \to \mathbb{R}^p$ be a map defined locally around $q \in Q$. We shall say $y^1, \ldots, y^p$ are *G-equivariant* if

$$\Phi_{h_*} \ker Ty = \ker Ty.$$

This means level sets of y are mapped to level sets by the group action.

PROPOSITION 4.2. *Consider a system satisfying* (4.1). *Suppose* $\dim D = n-1$ *and that the system is configuration flat. Then the flat outputs are G-equivariant.*

Proof. The proof follows from the fact that $\ker Ty$ is the orthogonal complement to D and Lemma 4.1. ∎

REMARK 4.3. *The case* $\dim D = n-1$ *is not as restrictive as it may seem. Typically* $\dim D = n$, *implying that the system is not configuration flat. When the system is configuration flat* ($\dim D \leq n-1$), *most likely* $\dim D = n-1$. *In fact, many examples of systems that are configuration flat fall into this category including the first example in next section as well as the "ducted fan with stand" in* [20] *and the "planar coupled rigid bodies" example in* [13].

REMARK 4.4. *In the case when* $\dim D < n-1$, *given the system is flat with flat outputs* $y : Q \to \mathbb{R}^p$ *around* $q \in Q$, *it is possible to construct outputs* $\tilde{y} : Q \to \mathbb{R}^p$ *around* q *that are G-equivariant and satisfy* $g(\ker T\tilde{y}, D) = 0$. *But it hasn't been resolved whether it is possible to construct* $\tilde{y}$ *in such a way that it also satisfies the regularity conditions* (3.12). *The authors are currently trying to resolve this technical issue but suspect that at least in typical cases this construction should work. The second example in the next section falls into the case* $\dim D = n-2$, *and we see that it possesses G-equivariant flat outputs.*

5. Examples. In this section we shall consider some examples to illustrate the theory developed in the previous section.

5.1. Underwater vehicle. We shall study a simple model of an underwater vehicle (see Figure 5.1) that is controlled by a force applied through a fixed point P on the body whose magnitude and direction can be independently controlled.

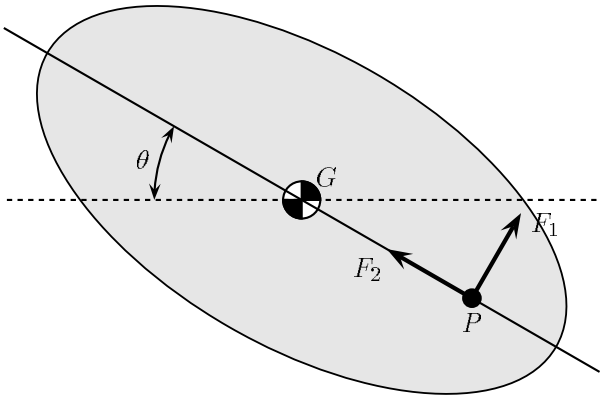

FIG. 5.1. *Underwater vehicle in* $\mathbb{R}^2$.

Only the motion in the vertical plane is considered and hence our configuration space is $SE(2) = \mathbb{R}^2 \times S^1$. This is reasonable when the vehicle has symmetries about three orthogonal planes. In addition if we assume that the center of buoyancy is coincident with the center of mass, the kinetic energy is given by

$$\frac{1}{2}(m+\delta m)(\dot{x}_1\cos\theta - \dot{x}_2\sin\theta)^2 + \frac{1}{2}(m-\delta m)(\dot{x}_1\sin\theta + \dot{x}_2\cos\theta)^2 + \frac{1}{2}I(\dot{\theta})^2, \tag{5.1}$$

where (x_1, x_2) are horizontal and vertical coordinates of the center of mass G, θ is the orientation (measured clockwise) of line PG with respect to horizontal axis, $m = M + (m_1 + m_2)/2$ and $\delta m = (m_1 - m_2)/2$, where M is the mass of the vehicle and m_1 and m_2 are added mass terms that take into account inertia of the fluid, and I is the effective moment of inertia taking into account the fluid. This model assumes an incompressible, irrotational flow and neglects viscosity effects. It is assumed that the motion of the fluid is entirely due to that of the solid. The body and the fluid together are considered to form a dynamical system, and the kinetic energy is the combined energy of body and fluid. See [7] and [6] for details. The analysis in [7] assumes a neutrally buoyant model, but we need not make this assumption since this only alters the form of the potential function but does not affect the kinetic energy. In fact for the first part of the analysis we shall not assume any specific form for potential V. If the vehicle is in air (strictly speaking vacuum) $m_1 = m_2 = 0$, so $m = M$ and $\delta m = 0$ and the kinetic energy takes the familiar form

$$\frac{1}{2}(m(\dot{x}_1)^2 + m(\dot{x}_2)^2 + I(\dot{\theta})^2),$$

where I is the usual moment of inertia and the model is the same as that of VTOL (see [10]).

The metric g in coordinates x_1, x_2, θ is given by the matrix

$$\begin{bmatrix} m+\delta m\cos 2\theta & -\delta m\sin 2\theta & 0 \\ -\delta m\sin 2\theta & m-\delta m\cos 2\theta & 0 \\ 0 & 0 & I \end{bmatrix}.$$

The control forces lie in the codistribution

$$\begin{aligned} P &= \operatorname{span}\{d(x_1 + R\cos\theta), d(x_2 - R\sin\theta)\} \\ &= \operatorname{span}\{dx_1 - R\sin\theta d\theta, dx_2 - R\cos\theta\ d\theta\} \end{aligned}$$

and $\xi = \frac{\partial}{\partial\theta} + R\sin\theta\frac{\partial}{\partial x_1} + R\cos\theta\frac{\partial}{\partial x_2}$ spans $\operatorname{ann} P$, where R is the length of PG.

The Christoffel symbols Γ^i_{jk} can be computed from g using equation (3.7). Then using formula (3.8) we see that

$$\begin{aligned}
\nabla_{\frac{\partial}{\partial x_1}}\xi &= -\frac{m\delta m}{m^2-(\delta m)^2}\sin 2\theta\frac{\partial}{\partial x_1} - \frac{\delta m}{m^2-(\delta m)^2}(\delta m + m\cos 2\theta)\frac{\partial}{\partial x_2} \\
&\quad + \frac{R\delta m\cos\theta}{I}\frac{\partial}{\partial\theta}, \\
\nabla_{\frac{\partial}{\partial x_2}}\xi &= -\frac{\delta m}{m^2-(\delta m)^2}(-\delta m + m\cos 2\theta)\frac{\partial}{\partial x_1} + \frac{m\delta m}{m^2-(\delta m)^2}\sin 2\theta\frac{\partial}{\partial x_2} \\
&\quad - \frac{R\delta m\sin\theta}{I}\frac{\partial}{\partial\theta}, \\
\nabla_{\frac{\partial}{\partial\theta}}\xi &= \frac{mR\cos\theta}{m+\delta m}\frac{\partial}{\partial x_1} - \frac{mR\sin\theta}{m+\delta m}\frac{\partial}{\partial x_2}. \qquad (5.2)
\end{aligned}$$

It can be seen by computation that the above vector fields together with ξ span the full tangent space for generic points and generic parameter values $m, \delta m, I, R$. Since by equation (3.10)

$$D = \operatorname{span}\{\nabla_{\frac{\partial}{\partial x_1}}\xi, \nabla_{\frac{\partial}{\partial x_2}}\xi, \nabla_{\frac{\partial}{\partial\theta}}\xi, \xi\},$$

it follows that $D = TQ$ for generic points on Q and for generic parameter values and hence the system is not configuration flat for generic parameter values regardless of the potential energy function.

However, for the case $\delta m = 0$ we see that

$$D = \operatorname{span}\left\{R\cos\theta\frac{\partial}{\partial x_1} - R\sin\theta\frac{\partial}{\partial x_2}, R\sin\theta\frac{\partial}{\partial x_1} + R\cos\theta\frac{\partial}{\partial x_2} + \frac{\partial}{\partial\theta}\right\}.$$

Hence $\dim D = 2$ and $\eta = \frac{\partial}{\partial\theta} - \frac{I}{mR}\sin\theta\frac{\partial}{\partial x_1} - \frac{I}{mR}\cos\theta\frac{\partial}{\partial x_2}$ spans the orthogonal complement to D. Since D has codimension 1, up to a diffeomorphism there is at most 1 set of flat outputs. One set of functions that "cut out" the foliation due to η is

$$y_1 = x_1 - \frac{I}{mR}\cos\theta, \quad y_2 = x_2 + \frac{I}{mR}\sin\theta.$$

To ensure that y_1, y_2 are indeed flat outputs we must check the regularity conditions (3.13). Let us choose $z = \theta$ as a complementary coordinate to y_1, y_2. Then,

$$\begin{aligned}
\frac{\partial}{\partial y_1} &= \frac{\partial}{\partial x_1}, \quad \frac{\partial}{\partial y_2} = \frac{\partial}{\partial x_2}, \\
\frac{\partial}{\partial z} &= -\frac{I}{mR}\sin\theta\frac{\partial}{\partial x_1} - \frac{I}{mR}\sin\theta\frac{\partial}{\partial x_1} + \frac{\partial}{\partial\theta}.
\end{aligned}$$

Hence

$$\begin{aligned}
\frac{\partial}{\partial z}\left(g\left(\xi, \frac{\partial}{\partial y_1}\right)\right) : g\left(\xi, \frac{\partial}{\partial y_1}\right) &= -\sin z : \cos z, \\
\frac{\partial}{\partial z}\left(g\left(\xi, \frac{\partial}{\partial y_2}\right)\right) : g\left(\xi, \frac{\partial}{\partial y_2}\right) &= \cos z : \sin z. \qquad (5.3)
\end{aligned}$$

So at any point $q = (y_1, y_2, z)$ these two ratios are unequal. This ensures that y_1, y_2 are indeed flat outputs everywhere.

When the vehicle is in air (strictly speaking vacuum) $\delta m = 0$, and in this case it is already known to be flat (see [10, 11]). We have just shown that up to a diffeomorphism these are the only configuration flat outputs. Also we have covered the case of an underwater vehicle of spherical shape (since then $m_1 = m_2$), and this result is independent of any assumptions we make on the potential function V.

Now let us suppose that the system is moving under gravity in air and the potential energy is given by $V = mgx_2$, where $g \approx 9.8$ m/s^2 is the acceleration due to gravity. Then the solutions of the system in coordinates y_1, y_2, z satisfy the ODE

$$\ddot{y}_1 \sin z + \ddot{y}_2 \cos z + g \cos z = 0.$$

So along generic solution curves we get

$$z(t) = \tan^{-1} \frac{\ddot{y}_2 + g}{\ddot{y}_1}$$

or

$$z(t) = \tan^{-1} \frac{\ddot{y}_2 + g}{\ddot{y}_1} + \pi.$$

The exception being the singularity at $\ddot{y}_1 = 0, \ddot{y}_2 + g = 0$. Note that this singularity is not a point on Q but corresponds to a submanifold in the jet space $J^2(\mathbb{R}, Q)$, the space with coordinates $(t, q, \dot{q}, \ddot{q})$, and such singularities are very common in practical examples. We still want to regard such systems as flat, and this is the reason why our definition of flatness refers to generic curves as opposed to all curves. Also note that although potential V does not affect the flat outputs of the system it influences where the singularities occur.

We also see that the general system (no assumptions on δm) possesses an $SE(2)$ symmetry when the potential function is ignored. If we consider translating and rotating our spatial frame of reference the expression for kinetic energy as well as the expression for P are invariant. We may state this more precisely as follows. Consider the following action of $SE(2)$ on $Q = SE(2)$. Given $h = (\alpha_1, \alpha_2, \phi) \in SE(2)$ the action Φ_h corresponds to first rotating the spatial frame counterclockwise by ϕ about its origin and then with respect to this frame translating the frame without rotation by $(-\alpha_1, -\alpha_2)$. Hence if $q = (x_1, x_2, \theta) \in Q$ then

$$\Phi_h(q) = (x_1 \cos\phi + x_2 \sin\phi + \alpha_1, -x_1 \sin\phi + x_2 \sin\phi + \alpha_2, \theta + \phi).$$

The corresponding tangent map $T\Phi_h$ is given by

$$\begin{aligned} \frac{\partial}{\partial x_1} &\to \cos\phi \frac{\partial}{\partial x_1} + \sin\phi \frac{\partial}{\partial x_2}, \\ \frac{\partial}{\partial x_2} &\to -\sin\phi \frac{\partial}{\partial x_1} + \cos\phi \frac{\partial}{\partial x_2}, \\ \frac{\partial}{\partial \theta} &\to \frac{\partial}{\partial \theta}. \end{aligned} \tag{5.4}$$

It is easy to verify this preserves g. Recalling that $\xi = \frac{\partial}{\partial\theta} + R\sin\theta\frac{\partial}{\partial x_1} + R\cos\theta\frac{\partial}{\partial x_2}$ spans $\operatorname{ann} P$, we see that $\Phi_{h_*}\xi = \xi$, implying $\Phi_h^* P = P$. In particular these statements are true for the $\delta m = 0$ case as well. Hence by Proposition 4.2 the flat outputs are G-equivariant. This is indeed true since $\eta = \frac{\partial}{\partial\theta} - \frac{I}{mR}\sin\theta\frac{\partial}{\partial x_1} - \frac{I}{mR}\cos\theta\frac{\partial}{\partial x_2}$ spans $\ker Ty$ and $\Phi_{h_*}\eta = \eta$.

5.2. Particle in the force field. This example does not necessarily correspond to an engineering example but illustrates the regularity conditions. We consider a particle of unit mass moving in three-dimensional Euclidean space in the presence of a potential field $V = x_2x_3$. Hence the kinetic energy metric is given by the 3×3 identity matrix in orthogonal coordinates x_1, x_2, x_3. Suppose that we control independently the forces along x_1 and x_3 directions. Hence $P = \operatorname{span}\{dx_1, dx_3\}$ and $\xi = \frac{\partial}{\partial x_2}$ spans $\operatorname{ann} P$. We see that Christoffel symbols are all zero by (3.7) (which is a feature of Euclidean space), and using (3.8) and (3.10) we obtain $D = \operatorname{span}\{\frac{\partial}{\partial x_2}\}$; hence the orthogonal complement to D is $\operatorname{span}\{\frac{\partial}{\partial x_1}, \frac{\partial}{\partial x_3}\}$, which is two dimensional. Hence we have infinitely many "candidates" for flat outputs that are not equivalent via a diffeomorphism. But these "candidates" may not satisfy the regularity conditions (3.13). Following the method outlined in Remark 3.2 we pick some η, say $\eta = \frac{\partial}{\partial x_3}$, which is orthogonal to D. Then $y_1 = x_1, y_2 = x_2$ are possible choices of corresponding "candidates" for flat outputs (since they cut out the one-dimensional foliation by η). We may choose $z = x_3$ to complete the coordinate system, and then we see that the ratio of functions $\frac{\partial}{\partial z}(\xi(V)) : \xi(V)$ in the set (3.13) is $1 : x_3$, whereas the ratio of $\frac{\partial}{\partial z}(g(\xi, \frac{\partial}{\partial y^2})) : g(\xi, \frac{\partial}{\partial y^2})$ is $0 : 1$. Hence x_1, x_2 are configuration flat outputs (globally). But alternatively another choice could have been $\eta = \frac{\partial}{\partial x_1}$ with corresponding candidates $y_1 = x_2, y_2 = x_3$. Choosing $z = x_1$ we see that all the ratios in (3.13) are zero and hence equal. Hence x_2, x_3 are not flat outputs as they are differentially dependent. This example is simple enough that the above conclusions can be reached by inspecting the equations of motion for the system

$$\ddot{x}_1 - \frac{\partial V}{\partial x_1} = F_1, \tag{5.5}$$

$$\ddot{x}_2 - \frac{\partial V}{\partial x_2} = 0, \tag{5.6}$$

$$\ddot{x}_3 - \frac{\partial V}{\partial x_3} = F_3, \tag{5.7}$$

where F_1, F_3 are the forces along x_1, x_3 directions. Equation (5.6) alone characterizes all solution trajectories of system and substituting $V = x_2x_3$ we obtain

$$\ddot{x}_2 - x_3 = 0. \tag{5.8}$$

It is clear from the equation that x_2, x_3 are differentially dependent and hence are not flat outputs. However, it is also clear from the equations that x_1, x_2 are flat outputs since along solution curves

$$x_3(t) = \frac{d^2x_2(t)}{dt^2}$$

and x_1, x_2 do not satisfy an ODE.

Also note that the system is globally controllable since it is globally flat. However if $V = 0$ then the system is not configuration flat and not even locally accessible.

It is easy to see that translations by the group $\mathbb{R}^3$ leave g and P invariant. But Proposition 4.2 does not apply since $\dim D = n - 2$. However, as mentioned in Remark 4.4 we see that G-equivariant flat outputs exist. In fact $y = (x_1, x_2)$ are G-equivariant, although not all (configuration) flat outputs are G-equivariant, since $\tilde{y} = (f(x_1, x_3), x_2)$, where f is an arbitrary smooth function with $\frac{\partial f}{\partial x_1} \neq 0$, are not G-equivariant for a typical f but are configuration flat outputs.

6. Conclusions and future work. We have presented a method for determining configuration flatness of Lagrangian control systems with n degrees of freedom and $n-1$ controls. Our method is constructive and provides a way for finding configuration flat outputs if they exist. We assumed a Lagrangian of the form "kinetic energy minus potential." We also assumed that the range of control forces depends only on configuration. These assumptions are not unreasonable since a wide class of systems falls into this category. However $n-1$ controls is a special case and is the simplest case next to fully actuated (n controls) systems which are always flat. In that sense we regard this as a first step toward a general theory of configuration flatness of Lagrangian systems. The authors are currently working on generalizing this result to an arbitrary number of controls.

Acknowledgment. It is a pleasure to thank Jerrold Marsden for valuable comments and Naomi Leonard for important corrections on the underwater vehicle example. The authors would also like to thank the reviewers for the useful comments and corrections.

PARTIAL DISTURBANCE REJECTION WITH INTERNAL STABILITY AND H_∞ NORM BOUND*

VASFI ELDEM†, HITAY ÖZBAY‡, HASAN SELBUZ†, AND KADRI ÖZÇALDIRAN†§

Abstract. Complete disturbance rejection problems are equivalent to zeroing (cancelling) all the Markov parameters of the closed loop system between the disturbance and the controlled output. When this is not possible, one might consider partial disturbance rejection which can be defined as zeroing the first, say k, Markov parameters. In this article, our objective is to present general solvability conditions for the partial disturbance rejection problem by dynamic output feedback under the constraint of internal stability. With this solution we also obtain a suitable parametrization for the set of all solutions of the problem which is then used to obtain an H_∞ norm bound on the closed loop system. In the first part of the paper, a natural framework for the partial disturbance rejection problem is introduced. This framework consists of the ring of stable and proper rational functions and its quotient rings. Thus, the solvability conditions and the set of all solutions to the problem are easily obtained. The parametrization of the set of all solutions provides an opportunity to pursue further design goals. Along this line, H_∞ minimization has been incorporated into the problem. The upper and lower bounds on the H_∞ norm of the closed loop transfer function is obtained and compared with direct H_∞ disturbance attenuation. The results are illustrated with a simple example.

Key words. disturbance rejection, Markov parameters, internal stability, H_∞ norm

1. Introduction.

In this work, linear, time-invariant systems described as

$$\begin{bmatrix} y \\ z \end{bmatrix} = \begin{bmatrix} Z_1 & Z_2 \\ Z_3 & Z_4 \end{bmatrix} \begin{bmatrix} u \\ d \end{bmatrix} \tag{1.1}$$

are considered. Here, y, z, u, and d take values from p-, q-, m-, and r-dimensional linear spaces. Z_1, Z_2, Z_3, and Z_4 are proper transfer matrices of appropriate dimensions. The literature contains a rich variety of control problems related to the system given above. The essential motivation in these problems is to design the closed loop transfer function T_{zd} between the disturbance d and the controlled output z. The early attempts along this line were devoted to cancelling (zeroing) the effect of the disturbance on the controlled output ($T_{zd} = 0$). This problem is usually referred to as the disturbance rejection (or disturbance decoupling) problem and is abbreviated to DRP. The solvability conditions for DRP can be expressed as matching of the zeros of certain subsystems. The reader may refer to Willems and Commault (1981), Özgüler and Eldem (1985), and Eldem and Özgüler (1988) for the details of the "zero-matching" conditions. Although DRP has been very useful from a purely algebraic point of view, it did not have much to offer for a practical design, because

the rigid algebraic solvability conditions for DRP are hardly met in practical cases. This is probably one of the basic reasons why an alternative design procedure which minimizes the H_∞ norm of T_{zd} has been very popular during the last decade. The H_∞ design techniques offer a breakaway from the rigid algebraic structure of DRP and at the same time guarantee a certain disturbance attenuation level at all frequencies.

In this work, we consider yet another alternative design to DRP, which has not attracted much attention in the literature, namely, partial disturbance rejection (PDR). PDR can be defined as zeroing the first, say k, Markov parameters of T_{zd}. More specifically, in PDR problems (PDRPs) a feedback control which makes the least infinite zero order of T_{zd} greater then k is being sought. This problem was initially introduced by Emre and Silverman (1980) as a dynamic cover problem. Later it has been considered by Malabre and Martinez Garcia (1993) and Martinez, Malabre, and Kucera (1995). In the latter, dynamic state feedback together with disturbance feedthrough was used to achieve PDR with internal stability. Thus, the controller has "full information" structure which is equivalent to the so-called "one-sided model matching" problem. Here, we consider the case with dynamic measurement feedback, which is equivalent to "two-sided model matching." It turns out that the solvability conditions of these problems are quite similar and can also be expressed as zero-matching conditions. The first and an incomplete version of the results in this paper is given in Eldem (1994).

An interesting feature of PDR is that it can be interpreted as optimization at infinity. In fact, increasing the infinite zero order of T_{zd} results in increased attenuation levels at high frequencies. In H_∞ design, on the other hand, all frequencies are taken into account. This implies that PDR and H_∞ can be used together. More specifically, after obtaining a certain attenuation level at high frequencies via PDR, the remaining flexibility can be used to minimize the response at low frequencies. This has been first pointed out and illustrated by an example in Martinez, Malabre, and Kucera (1995). Here, after characterizing the set of all solutions to PDR, we also emphasize the incorporation of H_∞ point of view to PDR and show that an upper bound on $\| T_{zd} \|_\infty$ can be obtained in terms of the problem data. The results are illustrated by simple examples.

It is true that attenuation at high frequencies (or high frequency rolloff as usually called) can also be achieved by employing suitable weights on the disturbance in standard H_∞ optimization problems. Here, we exploit the algebraic structure of the system to achieve the same goal. The assessment of the superiority of one method over the other naturally calls for further study, and perhaps it depends on the particular system being considered. If, for instance, the algebraic structure of the system allows a partial disturbance rejecting design, then our method might at least give more intuition and flexibility to pursue further design goals.

2. Notation and problem formulation. As usual $\mathbf{R}$ denotes the field of real numbers. The ring of polynomials in the indeterminant s, with coefficients from $\mathbf{R}$, is denoted as $\mathbf{R}[s]$. The field of fractions of $\mathbf{R}[s]$, i.e., the field of rational functions, is represented by $\mathbf{R}(s)$. We will use $\mathbf{R}^{p\times m}(s)$ to denote $p \times m$ matrices with entries from $\mathbf{R}(s)$. The Laurent series expansion of $N(s)$ in $\mathbf{R}^{p\times m}(s)$ is given as

$$N(s) = \sum_{i=-k}^{\infty} N_i s^{-i}, \tag{2.1}$$

where N_i's are $p\times m$ matrices over $\mathbf{R}$. $N(s)$ is called proper if $N_{-k} = N_{-(k-1)} = \cdots = N_{-1} = 0$. It is called strictly proper, if it is proper and $N_0 = 0$. If N_0 is square and

nonsingular, it is called biproper. Strictly polynomial, strictly proper, polynomial, and proper parts of N are denoted as N^+, N^-, N_+, and N_-, respectively. More specifically,

$$N^+ := \sum_{i=-k}^{-1} N_i s^{-i}, \quad N_+ := \sum_{i=-k}^{0} N_i s^{-i}, \tag{2.2}$$

$$N^- := \sum_{i=1}^{\infty} N_i s^{-i}, \quad N_- := \sum_{i=0}^{\infty} N_i s^{-i}. \tag{2.3}$$

$\mathbf{R}_p(s)$ and $\mathbf{R}_{ps}(s)$ will be used to denote the ring of proper rational functions and the ring of proper and stable rational functions, respectively. If we let $\partial(.)$ denote the usual degree function for the polynomial ring, then $\mathbf{R}_p(s)$ and $\mathbf{R}_{ps}(s)$ become Euclidean domains with the following degree functions:

$$\partial_p(p/q) := \partial(q) - \partial(p), \tag{2.4}$$

$$\partial_{ps}(p/q) := \partial(q) - \partial(p) + \text{number of unstable zeros of } p. \tag{2.5}$$

$\partial(.)_p$ is sometimes called "the relative degree." Recall that $\mathbf{R}_p^{m\times m}(s)$ and $\mathbf{R}_{ps}^{m\times m}(s)$ are rings with the usual definition of matrix addition and multiplication. An element in a ring is called a unit if it has an inverse in the ring. The units in $\mathbf{R}_p^{m\times m}(s)$ are called biproper matrices. A similar terminology will be used for the units in $\mathbf{R}_{ps}^{m\times m}(s)$, and they will be called *biproper* and *bistable*. Let us now go back to the PDRP. The objective in this problem, given the system (1.1), is to find a proper Z_c such that under the control law

$$u = -Z_c y \tag{2.6}$$

the closed loop transfer matrix between z and d, T_{zd} has first k Markov parameters equal to zero. Note that T_{zd} can be written as

$$T_{zd} = Z_4 - Z_3 Z_c (I + Z_1 Z_c)^{-1} Z_2. \tag{2.7}$$

Thus, if we assume that Z_1 is strictly proper, $(1 + Z_1 Z_c)^{-1}$ exists and it is proper. In view of this, the partial disturbance rejection problem via measurement feedback (PDRPM) can be defined as follows in Definition 2.1.

DEFINITION 2.1 (PDRPM). *Given proper Z_4, Z_3, and Z_2, find a proper X such that*

$$Z_4 - Z_3 X Z_2 = \frac{1}{s^{k+1}} P \tag{2.8}$$

for some proper P.

For the case with internal stability, a similar definition can be used. Before doing that, we shall assume without loss of generality, that Z_4, Z_3, and Z_2 are both proper and stable. (If not, Youla parametrization of internally stabilizing compensators could be used to get a similar equation as above with Z_4, Z_3, Z_2 stable and proper and with X as the free parameter matrix over $\mathbf{R}_{ps}(s)$. The reader is referred to Francis (1987) for the details.) In view of this observation, the partial disturbance rejection problem by measurement feedback with internal stability (PDRPMS) can be defined as follows in Definition 2.2.

DEFINITION 2.2 (PDRPMS). *Given proper, stable matrices Z_4, Z_3, and Z_2, find a proper, stable Q such that*

$$Z_4 - Z_3 Q Z_2 = \frac{1}{\pi(s)} P \tag{2.9}$$

for some stable, proper P and a stable polynomial $\pi(s)$ of degree $k+1$.

Observe that the solvability condition of PDRPMS is independent of the polynomial $\pi(s)$. More precisely, if Q is a solution for some polynomial $\pi_1(s)$ and a proper P_1, i.e., $Z_4 - Z_3 Q Z_2 = P_1(s)/\pi_1(s)$, then it is also a solution for an arbitrary stable polynomial $\pi_2(s)$ of degree $k+1$, i.e., $Z_4 - Z_3 Q Z_2 = P_2(s)/\pi_2, (P_2 := \pi_2 P_1/\pi_1)$. Therefore, we can fix $\pi(s)$ and define PDRPMS accordingly in Definition 2.3.

DEFINITION 2.3 (PDRPMS). *Given stable, proper matrices Z_4, Z_3, and Z_2 and a stable polynomial $\pi(s)$ of degree $k+1$, find a stable, proper Q such that*

$$Z_4 - Z_3 Q Z_2 = \frac{1}{\pi} P \tag{2.10}$$

for some proper and stable P.

Also observe that the above definition, where the polynomial is fixed as π, gives rise to a very natural algebraic setup for PDRPs. This consists of the ideal $(1/\pi)R_{ps}(s)$ and the quotient ring $\mathbf{R}_{ps}(s)/(1/\pi)R_{ps}(s)$ which is extensively investigated in the next section.

3. Preliminary results. In this section, a simple version of the problem is introduced in order to give an insight for the algebraic setup behind the partial model matching problems. More specifically, the problem to be considered can be defined in Definition 3.1.

DEFINITION 3.1 (Problem P1). *Given m and n in $\mathbf{R}_{ps}(s)$ and a stable polynomial π of degree $k+1$, find q in $\mathbf{R}_{ps}(s)$ such that*

$$n - mq = \frac{1}{\pi} p \tag{3.1}$$

for some p in $\mathbf{R}_{ps}(s)$.

Consider the ideal $(1/\pi)R_{ps}(s)$. Using this ideal, let us define an equivalence relation on $\mathbf{R}_{ps}(s)$ as follows: *n_1 and n_2 in $\mathbf{R}_{ps}(s)$ are said to be equivalent if $n_1 - n_2$ is in $(1/\pi)R_{ps}(s)$*. This relation gives the quotient ring $\mathbf{R}_{ps}(s)/(1/\pi)R_{ps}(s)$. We will denote this quotient ring by $\mathbf{R}_{ps}(\pi)$.

LEMMA 3.2. *$\mathbf{R}_{ps}(\pi)$ is a $(k+1)$-dimensional $\mathbf{R}$-linear space. A basis for $\mathbf{R}_{ps}(\pi)$ can be given as*

$$\frac{s^i}{\pi}, \quad i = 1, 2, ..., k+1. \tag{3.2}$$

Proof. The reader may refer to, for instance, Özgüler (1994). □

For a given n_1 in $\mathbf{R}_{ps}(s)$, n_1 mod $(1/\pi)\mathbf{R}_{ps}(s)$ can be calculated easily as follows:

$$n_1(\pi) := n_1 \bmod \frac{1}{\pi}\mathbf{R}_{ps}(s) = \frac{1}{\pi}(\pi n_1)^+. \tag{3.3}$$

It is clear from the above equation that $\{s^i/\pi, \ \ i = 1, ..., k+1\}$ is a basis for $\mathbf{R}_{ps}(\pi)$. Furthermore, for any n_1 in $\mathbf{R}_{ps}(s)$ we have

$$n_1 = \frac{1}{\pi}(\pi n_1)^+ \ + \ \frac{1}{\pi}(\pi n_1)_-. \tag{3.4}$$

LEMMA 3.3. *P*1 *is solvable for given* n, m, *and a stable polynomial* $\pi(s)$ *of degree* $k+1$ *iff it is solvable for* $n(\pi)$ *and* $m(\pi)$.

Proof. The proof directly follows from the definition of $n(\pi)$ and $m(\pi)$ and equation (3.4). ∎

For a given stable and proper m, let us now consider the set of equivalence classes generated by mq as q ranges over $\mathbf{R}_{ps}(s)$. It is clear that this set is equivalent to the quotient ring $mR_{ps}(s)/(1/\pi)R_{ps}(s)$ which we denote as $\mathbf{R}_{ps}(m\pi)$.

LEMMA 3.4. $\mathbf{R}_{ps}(m\pi)$ *is an R-linear subspace of* $\mathbf{R}_{ps}(\pi)$ *of dimension* $k+1-\partial_p(m)$.

Proof. Let q be in $\mathbf{R}_{ps}(s)$. Then $mq \bmod 1/\pi R_{ps}(s)$ can be calculated as

$$mq \bmod \left(\frac{1}{\pi}R_{ps}\right) = \frac{1}{\pi}(\pi mq)^+. \tag{3.5}$$

Note that since q and m are proper $\partial(\pi mq)^+ \le k+1-\partial_p(m)$ and the equality is achieved if q is biproper. Consequently, $\mathbf{R}_{ps}(m\pi)$ has dimension $k+1-\partial_p(m)$. Now we have to show that for any given polynomial δ with $\partial(\delta) \le k+1-\partial_p(m)$, there exists a q in $\mathbf{R}_{ps}$ such that

$$mq \bmod \left(\frac{1}{\pi}R_{ps}\right) = \frac{\delta}{\pi}. \tag{3.6}$$

To this end, let $m = m_1/m_2$ where m_1 *and* m_2 are in $\mathbf{R}[s]$. Also let $\hat{m}_1$ be a Hurwitz polynomial such that $\partial(\hat{m}_1) = \partial(m_1)$. Now we can choose q as $q := m_2\beta/\pi\hat{m}_1$ where $\beta := ((\hat{m}_1/m_1)\delta)^+$. Note that q is stable and furthermore, since $\partial(\beta) = \partial(\delta) \le k+1-\partial(m_2)+\partial(m_1)$, it follows that it is also proper. Then

$$(\pi mq)^+ = \left(\pi\frac{m_1}{m_2}\frac{m_2\beta}{\pi\hat{m}_1}\right)^+ = \left(\frac{m_1\beta}{\hat{m}_1}\right)^+ = \delta \tag{3.7}$$

$$\Rightarrow mq \bmod \frac{1}{\pi}R_{ps} = \frac{\delta}{\pi}. \tag{3.8}$$

Hence the proof is complete. ∎

LEMMA 3.5. *P*1 *is solvable iff* $n(\pi)$ *is in* $\mathbf{R}_{ps}(m\pi)$.

Proof. The proof directly follows from the definition of $n(\pi)$, $\mathbf{R}_{ps}(m\pi)$, and Lemma 3.3. ∎

Remark 3.6. *Note that if* $\partial_p(n) \ge k+1$, *then P*1 *is trivially solved by* $q=0$. *Therefore, assume that* $\partial_p(n) < k+1$. *Let* $n(\pi) = \psi/\pi$ *and* $m(\pi) = \phi/\pi$ *where* ψ *and* ϕ *are in* $\mathbf{R}[s]$. *The above lemma implies that the inequality* $\partial(\psi) \le k+1-\partial_p(m)$ $(=\partial(\phi))$ *is a necessary and sufficient condition for the solvability of P*1. *Thus, an equivalent condition for the solvability of P*1 *is* $\partial_p(n(\pi)) \ge \partial_p(m(\pi))$, *which, in turn, is equivalent to* $\partial_p(n) \ge \partial_p(m)$. *This condition can be interpreted as a matching condition for the infinite zero orders. Consequently, we have the following lemma.*

LEMMA 3.7. *P*1 *is solvable iff* $\partial_p(n) \ge \min\{\partial_p(m), k+1\}$.

4. The solution of PDRPMS. In this section, the solvability conditions for PDRPMS is presented. Since Z_4, Z_3, and Z_2 are matrices with entries from $\mathbf{R}_{ps}(s)$, there exist biproper and bistable matrices B_1, B_2, C_1, and C_2 such that

$$B_1Z_3B_2 := \begin{bmatrix} \Lambda & 0 \\ 0 & 0 \end{bmatrix}, \qquad C_1Z_2C_2 := \begin{bmatrix} \Gamma & 0 \\ 0 & 0 \end{bmatrix}, \tag{4.1}$$

where Λ and Γ are diagonal matrices defined as

$$\Lambda := \text{diag}\{\lambda_i\}, \qquad \Gamma := \text{diag}\{\gamma_i\}. \tag{4.2}$$

Clearly, λ_i and γ_i are in $\mathbf{R}_{ps}(s)$. Also partition $B_1 Z_4 C_2$ compatibly as

$$B_1 Z_4 C_2 := \begin{bmatrix} Z_{41} & Z_{42} \\ Z_{43} & Z_{44} \end{bmatrix}.$$

Let π be a maximum-degree stable polynomial such that

$$\pi \begin{bmatrix} 0 & Z_{42} \\ Z_{43} & Z_{44} \end{bmatrix} \tag{4.3}$$

is proper and denote the degree of π as $\partial(\pi) = k^* + 1$. Then Theorem 4.1 holds.

THEOREM 4.1. *PDRPMS is solvable for some integer k iff*

1. $k \le k^*$,
2. $\min\{\partial_p(\lambda_i) + \partial_p(\gamma_j), k+1\} \le \partial_p(Z_{41})_{ij}$,

where $(.)_{ij}$ *denotes the* ij*th entry.*

Proof. Suppose that the problem is solvable. Then, there exist stable and proper Q and P such that $Z_4 - Z_3 Q Z_2 = (1/\pi)P$. Using B_1, B_2, C_1, and C_2 defined by equation (4.1) and defining

$$B_2^{-1} Q C_1^{-1} := \begin{bmatrix} Q_1 & Q_2 \\ Q_3 & Q_4 \end{bmatrix}, \qquad B_1 P C_2 := \begin{bmatrix} P_1 & P_2 \\ P_3 & P_4 \end{bmatrix}, \tag{4.4}$$

we obtain the following equality:

$$\begin{bmatrix} Z_{41} & Z_{42} \\ Z_{43} & Z_{44} \end{bmatrix} - \begin{bmatrix} \Lambda & 0 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} Q_1 & Q_2 \\ Q_3 & Q_4 \end{bmatrix} \begin{bmatrix} \Gamma & 0 \\ 0 & 0 \end{bmatrix} = \frac{1}{\pi} \begin{bmatrix} P_1 & P_2 \\ P_3 & P_4 \end{bmatrix}. \tag{4.5}$$

Since

$$\begin{bmatrix} 0 & Z_{42} \\ Z_{43} & Z_{44} \end{bmatrix} = \frac{1}{\pi} \begin{bmatrix} 0 & P_2 \\ P_3 & P_4 \end{bmatrix}, \tag{4.6}$$

it is clear that $k \le k^*$. Furthermore, since

$$(Z_{41})_{ij} - \lambda_i \gamma_j (Q_1)_{ij} = \frac{1}{\pi}(P_1)_{ij} \tag{4.7}$$

Lemma 3.7 implies Theorem 4.1(2).

For sufficiency, note that if $\min\{\partial_p(\lambda_i) + \partial_p(\gamma_j), k+1\} = k+1$, then $(Q_1)_{ij}$ can be chosen as zero. Otherwise, Lemma 3.3 can be used to construct $(Q_1)_{ij}$. Finally, Q can be obtained from Q_1 via equation (4.1). ∎

In order to characterize the set of all solutions of PDRPMS, a different quotient ring is employed. To this end, let $\sigma(s)$ be a stable polynomial of degree equal to $\partial(\phi)(= k+1-\partial_p(m))$ and consider the quotient ring $\mathbf{R}_{ps}(\sigma)$. This quotient ring is also an R-linear space of dimension $k+1-\partial_p(m)$ with a basis $s^i/\sigma, i = 1, 2, ..., k+1-\partial_p(m)$.

LEMMA 4.2. *Let n and m be stable proper rationals and* π *be a stable polynomial of degree* $k+1$. *Suppose that* $\partial_p(n) \ge \partial_p(m)$ *(P*1 *is solvable for all k). Then, there exists a unique solution* q^* *of P*1 *in* $\mathbf{R}_{ps}(\sigma)$ *and furthermore every solution q can be represented as*

$$q = q^* + \frac{1}{\sigma} R_{ps}(s). \tag{4.8}$$

Proof. Note that any solution q can be uniquely decomposed as in (3.4)

$$q = q^* + \frac{1}{\sigma}\hat{q}, \tag{4.9}$$

where q^* is in $\mathbf{R}_{ps}(\sigma)$ and $\hat{q}$ is stable and proper. This implies that

$$\frac{1}{\pi}p = n - mq = n - mq^* - m\frac{1}{\sigma}\hat{q} \;\;\Rightarrow\;\; n - mq^* = \frac{1}{\pi}\left(p + \frac{m\pi}{\sigma}\hat{q}\right). \tag{4.10}$$

Since $m\pi/\sigma$ is biproper, it follows that q^* is a solution in $\mathbf{R}_{ps}(\sigma)$. q^* can be expressed as α^*/σ for some polynomial α^* of degree $\leq k + 1 - \partial_p(m)$. Note that

$$(\pi n)^+ = \left(\pi m\frac{\alpha^*}{\sigma}\right)^+ \;\;\Rightarrow\;\; \alpha^* = \left(\frac{\sigma n}{m}\right)^+; \tag{4.11}$$

i.e., α^* is unique. Consequently, the set of all solutions can be obtained as $q = q^* + (1/\sigma)\hat{q}$ as $\hat{q}$ ranges over $\mathbf{R}_{ps}$. ∎

Remark 4.3. *Note that by the above result the order of the compensator increases with k, the lower bound for the relative degree of the closed loop transfer function. This can be seen by observing that the unique part q^* of the solution q is expressed as $q^* = \alpha^*/\sigma$, where $\partial(\sigma) = k + 1 - \partial_p(m)$. This increase basically comes from the nature of the problem rather than the method being employed. In order to see this, let n and m be as in the above lemma with m biproper and bistable; i.e., PDRPMS is solvable for all k. Then it follows that $(1/\pi)p/m = n/m - q$. This implies that the first k Markov parameters of n/m are cancelled with the first k Markov parameters of q. This is only possible if q has order greater than k. The increase in the order of the compensator could be taken as a disadvantage of the approach presented here. However, it will be shown in Corollary* 5.11 *that if π is chosen to have real and negative zeros which tend to $-\infty$, then one can get arbitrarily close to the best achievable $\mathcal{H}_\infty$ performance. This fact holds true regardless of the degree $(k+1)$ of π (provided of course that the degree is high enough to yield a solution). Thus, one might not need to increase k too much to get a better performance.*

Using the above characterization and Theorem 4.1 we can also determine the set of all solutions in the general case. Note that by equation (4.1) we have

$$(Z_{41})_{ij} - \lambda_i\gamma_j(Q_1)_{ij} = \frac{1}{\pi}(P_1)_{ij}, \tag{4.12}$$

where $(Q_1)_{ij}$ can be expressed as

$$(Q_1)_{ij} = (Q_1^*)_{ij} + \frac{w_j}{\tau_i}(\hat{Q}_1)_{ij}, \tag{4.13}$$

where τ_i and w_j are stable polynomials with degrees $\partial(\tau_i) = k + 1 - \partial_p(\lambda_i)$, $\partial(w_j) = \partial_p(\gamma_j)$. Let us now define the solution Q as follows:

$$Q = B_2\begin{bmatrix} Q_1^* + \Omega_1\hat{Q}_1\Omega_2 & Q_2 \\ Q_3 & Q_4 \end{bmatrix}C_1, \tag{4.14}$$

where $\Omega_1 := \text{diag}\,\{1/\tau_i\}$, $\Omega_2 := \text{diag}\,\{w_j\}$, and B_2 and C_1 are stable, biproper matrices defined in equation (4.1). Then, we have

$$Z_4 - Z_3QZ_2 = Z_4 - B_1^{-1}\begin{bmatrix} \Lambda & 0 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} Q_1^* + \Omega_1\hat{Q}_1\Omega_2 & 0 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} \Gamma & 0 \\ 0 & 0 \end{bmatrix}C_2^{-1} \tag{4.15}$$

$$= \frac{1}{\pi}P_1^* - B_1^{-1}\begin{bmatrix} \Lambda\Omega_1\hat{Q}_1\Omega_2\Gamma & 0 \\ 0 & 0 \end{bmatrix}C_2^{-1}, \tag{4.16}$$

where

$$\frac{1}{\pi}P_1^* := Z_4 - B_1^{-1}\begin{bmatrix} \Lambda Q_1^*\Gamma & 0 \\ 0 & 0 \end{bmatrix} C_2^{-1}. \tag{4.17}$$

Let

$$\tilde{B}_1 := B_1^{-1}\begin{bmatrix} \Lambda\Omega_1 \\ 0 \end{bmatrix} \text{ and } \tilde{C}_2 = [\Omega_2\Gamma \;\; 0]C_2^{-1}. \tag{4.18}$$

Note that $\tilde{C}_2$ is left biproper and $\pi\tilde{B}_1$ is right biproper. Furthermore, the set of all closed loop transfers T_{zd} of PDRPMS can be generated by

$$T_{zd} = \frac{1}{\pi}(P_1^* - \pi\tilde{B}_1\hat{Q}_1\tilde{C}_2) \tag{4.19}$$

as $\hat{Q}_1$ ranges over $\mathbf{R}_{ps}$.

5. A comparison of PDRPMS with H_∞ disturbance attenuation. A very natural question which can be raised about the parametrization of all possible closed loop transfers T_{zd} given in the previous section is the infimum value of $\| T_{zd} \|_\infty$ that can be obtained via PDRPMS. In the following discussion, this infimum will be denoted by γ^*_{pdrs}. That is to say,

$$\gamma^*_{pdrs} := \inf_{\hat{Q}_1 \in R_{ps}} \left\| \frac{1}{\pi}(P_1^* - \pi\tilde{B}_1\hat{Q}_1\tilde{C}_2) \right\|_\infty . \tag{5.1}$$

We also define γ^*_π by

$$\gamma^*_\pi := \inf_{\hat{Q}_1 \in R_{ps}} \| P_1^* - \pi\tilde{B}_1\hat{Q}_1\tilde{C}_2 \|_\infty . \tag{5.2}$$

Clearly,

$$\gamma^*_{pdrs} \le \left\| \frac{1}{\pi} \right\|_\infty \gamma^*_\pi. \tag{5.3}$$

As PDRPMS is nothing but a restricted model matching problem, it follows that

$$\gamma^* \le \gamma^*_{pdrs}, \tag{5.4}$$

where γ^* denotes the $\mathcal{H}_\infty$ optimal model mismatch, i.e.,

$$\gamma^* := \inf_{Q \in R_{ps}} \| Z_4 - Z_3 Q Z_2 \|_\infty . \tag{5.5}$$

Thus, it follows from equations (5.3) and (5.4) that

$$\gamma^* \le \gamma^*_{pdrs} \le \left\| \frac{1}{\pi} \right\|_\infty \gamma^*_\pi. \tag{5.6}$$

In this section, we shall establish that, under a number of assumptions, γ^*_{pdrs} tends to γ^* as the roots of π tend to infinity. The assumptions that we adopt to this end are as follows.

A1. Z_3 has full row rank.

A2. Z_2 has full column rank.

A3. Z_2 and Z_3 do not have any finite imaginary axis zeros.

Remark 5.1. *Note that the assumptions above are adopted only for the comparison of PDRPMS with H_∞ disturbance attenuation and they have no relation to the solvability conditions of the PDRPMS presented in the previous sections. The first two of these assumptions are adopted to keep the comparison simple, because with these two assumptions we would be dealing with a* one-block *problem which is the simplest case in H_∞ disturbance attenuation. Without these assumptions, we would be considering* two-block or four-block *problems, which would make the comparison quite lengthy and complicated. We believe, however, that such a comparison is possible and would probably yield results similar to those we obtain for the* one-block *case.*

The third assumption above, on the other hand, is less restrictive than its counterpart in H_∞ disturbance attenuation. Assumption A3 *allows for zeros at infinity whereas in H_∞ disturbance attenuation zeros at infinity are not usually allowed as they give rise to improper compensators. This is then taken care of by employing high gain feedback. Therefore, PDRPMS can be viewed also as an alternative way (to high gain feedback) of dealing with zeros at infinity.*

Now, we let $Z_3 := Z_{3,i}Z_{3,0}$ and $Z_2 := Z_{2,co}Z_{2,ci}$ be inner-outer and co-inner-co-outer factorizations of Z_3 and Z_2, respectively. Under the assumptions introduced above, $Z_{3,i}^{-1}$ and $Z_{2,ci}^{-1}$ exist and are from $\mathcal{L}_\infty$.

We first recall the following result from Francis (1987).

LEMMA 5.2. $\gamma^* = \| Z_{3,i}^{-1} Z_4 Z_{2,ci}^{-1} \|_H$ *where* $\| (\cdot) \|_H$ *denotes the Hankel norm of* $(\cdot)$.

Similarly, we have Lemma 5.3.

LEMMA 5.3. $\gamma_\pi^* = \| \pi Z_{3,i}^{-1} Z_4 Z_{2,ci}^{-1} \|_H$.

Proof. Recall that $Z_3 = B_1^{-1}[\Lambda \ : \ 0]B_2^{-1}$. Thus,

$$Z_{3,i}^{-1} Z_3 = Z_{3,i}^{-1} B_1^{-1}[\Lambda \ : \ 0]B_2^{-1} \tag{5.7}$$

is outer. Since B_2 is bistable and biproper and Ω_1 is stable, it follows that

$$Z_{3,i}^{-1} B_1^{-1}[\Lambda\Omega_1] \tag{5.8}$$

is also outer. Also recall that $\Omega_1 = \mathrm{diag}\{1/\tau_i\}$, where τ_i's are Hurwitz polynomials of degree $k + 1 - \partial(\lambda_i)$. This implies that

$$\pi Z_{3,i}^{-1} \tilde{B}_1 := Z_{3,i}^{-1} B_1^{-1}[\Lambda\Omega_1] \tag{5.9}$$

is bistable and biproper. Using a similar argument, it is easy to see that $\tilde{C}_2 Z_{2,ci}^{-1}$ is also bistable and biproper. Then, it follows that γ_π^* is the solution of a Nehari problem. More specifically,

$$\gamma_\pi^* := \inf_{\hat{Q}_1 \in R_{ps}} \| P_1^* - \pi \tilde{B}_1 \hat{Q}_1 \tilde{C}_2 \|_\infty \tag{5.10}$$

$$= \inf_{\hat{Q}_1 \in R_{ps}} \| Z_{3,i}^{-1} P_1^* Z_{2,ci}^{-1} - \pi Z_{3,i}^{-1} \tilde{B}_1 \hat{Q}_1 \tilde{C}_2 Z_{2,ci}^{-1} \|_\infty \tag{5.11}$$

$$= \| Z_{3,i}^{-1} P_1^* Z_{2,ci}^{-1} \|_H = \| \pi Z_{3,i}^{-1} Z_4 Z_{2,ci}^{-1} \|_H \ . \tag{5.12}$$

Furthermore, because $\pi Z_{3,i}^{-1} \tilde{B}_1$ and $\tilde{C}_2 Z_{2,ci}^{-1}$ are bistable and biproper, we can solve for $\hat{Q}_1$. ∎

Remark 5.4. *In case Z_i, $i = 1, 2, 3, 4$, are SISO transfer functions with distinct unstable zeros, the Nevanlinna–Pick interpolation theory can be used to show that* (*see, e.g., Foias, Özbay, and Tannenbaum* (1996)) *the Hankel norm above can be computed as* $[\lambda_{max}(S^*V^*SV)]^{1/2}$ *where* $S_{ij} := 1/(a_i + \bar{a_j})$ *and* $V = \mathrm{diag}\{\alpha_i\}$ *where* α_i*'s and* a_i*'s come from the partial fraction expansion*

$$Z_{3,i}^{-1} Z_4 Z_{2,ci}^{-1} = \sum_{k=1}^{l} \frac{\alpha_k}{(a_k - s)}. \tag{5.13}$$

However, to bypass the difficulties associated with the interpolation problem for multivariable systems, in the sequel we shall adopt a slightly different approach to the problem.

Before computing γ_π^* explicitly, we recall the computation of γ^*. Let (C, A, B) be a minimal realization of $(Z_{3,i}^{-1} Z_4 Z_{2,ci}^{-1})_u$, the strictly proper and antistable part of $Z_{3,i}^{-1} Z_4 Z_{2,ci}^{-1}$. Let L_c and L_o denote the controllability and observability Gramians which are given as the unique solutions of

$$AL_c + L_c A^T = BB^T, \tag{5.14}$$

$$A^T L_o + L_o A = C^T C. \tag{5.15}$$

Then, we have (see Francis (1987))

$$\gamma^* = \| Z_{3,i}^{-1} Z_4 Z_{2,ci}^{-1} \|_H = [\lambda_{max}(L_c L_o)]^{\frac{1}{2}}. \tag{5.16}$$

To use this fact in computing γ_π^*, we first note the following fact.

LEMMA 5.5. *Let (C, A, B) be a minimal realization of $(Z_{3,i}^{-1} Z_4 Z_{2,ci}^{-1})_u$ with controllability and observability Gramians L_c and L_o.*

1. *$(C, A, \pi(A)B)$ is a minimal realization of $(\pi Z_{3,i}^{-1} Z_4 Z_{2,ci}^{-1})_u$.*
2. *Controllability and observability Gramians of $(C, A, \pi(A)B)$ are given by $\pi(A)L_c\pi(A^T)$ and L_o, respectively.*

Proof. Using the Laurent series expansion we have

$$(Z_{3,i}^{-1} Z_4 Z_{2,ci}^{-1})_u = \sum_{i=1}^{\infty} CA^{i-1} B s^{-i}, \tag{5.17}$$

$$(\pi Z_{3,i}^{-1} Z_4 Z_{2,ci}^{-1})_u = [\pi (Z_{3,i}^{-1} Z_4 Z_{2,ci}^{-1})_u]^- = \left[\pi(s) \sum_{i=1}^{\infty} CA^{i-1} B s^{-i} \right]^- \tag{5.18}$$

$$= \sum_{i=1}^{\infty} CA^{i-1} \pi(A) B s^{-i}. \tag{5.19}$$

Note that minimality of (C, A, B) implies minimality of $(C, A, \pi(A)B)$ iff the set of roots of π does not intersect the spectrum of A. In this case, A is antistable and π is Hurwitz. Thus, $(C, A, \pi(A)B)$ is minimal.

To prove Lemma 5.5(2), simply note that

$$A[\pi(A)]L_c\pi(A^T) + \pi(A)L_c\pi(A^T)A^T = \pi(A)BB^T\pi(A^T), \tag{5.20}$$

$$A^T L_o + L_o A = C^T C. \tag{5.21}$$

This completes the proof. □

Thus, we conclude from equation (5.16) and the lemma above that the following corollary holds.

COROLLARY 5.6. $\gamma_\pi^* = \| \pi Z_{3,i}^{-1} Z_4 Z_{2,ci}^{-1} \|_H = [\lambda_{max}(\pi(A)L_c\pi(A^T)L_o)]^{1/2}$.

COROLLARY 5.7. *Let (C, A, B) be a balanced realization of $(Z_{3,i}^{-1} Z_4 Z_{2,ci}^{-1})_u$ so that $L_c = L_o = D$, where D is a diagonal matrix. Then*

1. $\gamma^* = \lambda_{max}(D)$.
2. $\gamma_\pi^* = [\lambda_{max}(\pi(A)D\pi(A^T)D)]^{1/2}$.

In the sequel it will be assumed, without loss of generality, that (C, A, B) is a balanced realization. This assumption together with the corollary above immediately yield an upper bound for γ_π^* as shown in the following lemma.

LEMMA 5.8. $\lambda_{max}(\pi(A)D\pi(A^T)D) \le \lambda_{max}(D^2)\lambda_{max}(\pi(A)\pi(A^T))$.

Proof. The proof depends on two simple observations:

1. For square nonsingular matrices X and Y, the eigenvalues of XY and YX are the same.
2. If P is positive semidefinite then $\lambda_{max}(Q^TPQ) \le \lambda_{max}(P)\lambda_{max}(Q^TQ)$ (see Marcus and Minc (1992)).

Then, using the properties above successively, we get

$$\lambda_{max}(\pi(A)D\pi(A^T)D) = \lambda_{max}(D^{\frac{1}{2}}\pi(A)D\pi(A)D^{\frac{1}{2}}) \tag{5.22}$$

$$\le \lambda_{max}(D)\lambda_{max}(D^{\frac{1}{2}}\pi(A)\pi(A^T)D^{\frac{1}{2}}) \tag{5.23}$$

$$= \lambda_{max}(D)\lambda_{max}(\pi(A^T)D\pi(A)) \tag{5.24}$$

$$\le \lambda_{max}(D^2)\lambda_{max}(\pi(A^T)\pi(A)). \tag{5.25}$$

This completes the proof. □

Thus, it follows from Corollary 5.6, Lemma 5.5, and the fact $[\lambda_{max}(D^2)]^{1/2} = \lambda_{max}(D)$ that Corollary 5.9 holds.

COROLLARY 5.9. $\gamma_\pi^* \le \gamma^*[\lambda_{max}(\pi(A)\pi(A^T))]^{\frac{1}{2}}$.

Let us assume without loss of generality that $\pi(s)$ is a monic polynomial with real distinct roots. We can now present the main result of this section.

THEOREM 5.10. *Let δ_i denote the roots of π which are assumed to be distinct. Then*

$$\gamma^* \le \gamma_{pdrs}^* \le \gamma^* \left[\lambda_{max} \left\{ \prod_{i=1}^{k+1} \left(\frac{A^T}{\delta_i} + I \right)' \prod_{j=1}^{k+1} \left(\frac{A}{\delta_i} + I \right) \right\} \right]^{\frac{1}{2}}.$$

Proof. Note that $\| 1/\pi \|_\infty = (\prod_{i=1}^{k+1} \delta_i)^{-1}$. Then

$$\gamma_{pdrs}^* \le \left(\prod_{i=1}^{k+1} \delta_i \right)^{-1} \gamma^*[\lambda_{max}(\pi(A)\pi(A^T))]^{\frac{1}{2}} \tag{5.26}$$

$$= \left(\prod_{i=1}^{k+1} \delta_i \right)^{-1} \gamma^* \left[\lambda_{max} \left[\left(\prod_{i=1}^{k+1} (A + \delta_i I) \prod_{i=1}^{k+1} (A^T + \delta_i I) \right) \right] \right]^{\frac{1}{2}} \tag{5.27}$$

$$= \left(\prod_{i=1}^{k+1}\delta_i\right)^{-1}\gamma^*\left[\lambda_{max}\left[\left(\prod_{i=1}^{k+1}\delta_i\right)^2\prod_{i=1}^{k+1}\left(\frac{A}{\delta_i}+I\right)\prod_{i=1}^{k+1}\left(\frac{A^T}{\delta_i}+I\right)\right]\right]^{\frac{1}{2}} \tag{5.28}$$

$$= \left(\prod_{i=1}^{k+1}\delta_i\right)^{-1}\gamma^*\left[\left(\prod_{i=1}^{k+1}\delta_i\right)^2\lambda_{max}\left[\prod_{i=1}^{k+1}\left(\frac{A}{\delta_i}+I\right)\prod_{i=1}^{k+1}\left(\frac{A^T}{\delta_i}+I\right)\right]\right]^{\frac{1}{2}}. \tag{5.29}$$

Thus, we conclude that

$$\gamma^* \le \gamma^*_{pdrs} \le \gamma^*\left[\lambda_{max}\left[\prod_{i=1}^{k+1}\left(\frac{A}{\delta_i}+I\right)\prod_{i=1}^{k+1}\left(\frac{A^T}{\delta_i}+I\right)\right]\right]^{\frac{1}{2}} \tag{5.30}$$

and this completes the proof. □

Noting that the matrix on the right-hand side of the theorem above tends to identity as $\delta_i \to \infty$, we conclude that Corollary 5.11 holds.

COROLLARY 5.11. *As* $\delta_i \to \infty$, $i = 1, \ldots, k+1$, $\gamma^*_{pdrs} \to \gamma^*$.

The same fact is also emphasized in Martinez, Malabre, and Kucera (1995), without proof. We now illustrate this by the following example.

Example. Let $N := Z_4 = (s-2)/(s+1)^2$ and $M := Z_2Z_3 = (s-1)/(s+1)^2$. Fix $k = 1, \pi = (s+1)^2$. Then $Q_1^* = 1$, which yields $P_1^* = -1$. Now consider the problem defined by (5.40) with $\sigma = s + a$:

$$\gamma^*_\pi = \min\left\|P_1^* - \frac{\pi M}{\sigma}\hat{Q}_1\right\|_\infty = \min\left\|1 + \frac{s-1}{s+a}\hat{Q}_1\right\|_\infty = 1. \tag{5.31}$$

If we choose $\hat{Q}_1 = -1$, then we have the following parametric expression:

$$\left\|P_1^* - \frac{\pi M}{\sigma}\hat{Q}_1\right\|_\infty = \left\|\frac{a+1}{s+a}\right\|_\infty \;\Rightarrow\; \| T_{zd} \|_\infty \le \left\|\frac{1}{(s+1)^2}\right\|_\infty \left\|\frac{a+1}{s+a}\right\|_\infty. \tag{5.32}$$

Thus, the limit, as a goes to infinity, of the H_∞ norm of T_{zd} becomes 1 (note that the optimal value for the H_∞ norm of T_{zd} is 1/4). In this way, the parametrization of σ as $s + a$ yields a suboptimal solution for the problem defined by (5.39), where at high frequencies attenuation is provided by the term $1/(s+1)^2$ and for the lower frequencies the parameter a could be used to minimize the response.

Now let us parametrize π as $\pi = (s+a)^2$. Also let $\sigma = s + a$ and choose $\hat{Q}_1 = d(s+c)/(s+a)$, where c and d are free parameters. Note that with the above choice, $P_1^* = ((s+a)/(s+1))^2$ which is independent of σ. Then

$$P_1^* - \frac{\pi M}{\sigma}\hat{Q}_1 = \frac{(s+a)^2}{(s+1)^2} - \frac{d(s+c)(s-1)}{(s+1)^2}. \tag{5.33}$$

Now if we choose d and c as $d := (a^2+2a-3)/4$ and $c := (3a^2-2a-1)/(a^2+2a-3)$, we obtain

$$P_1^* - \frac{\pi M}{\sigma}\hat{Q}_1 = \frac{(a+1)^2}{4} \;\Rightarrow\; \| T_{zd} \|_\infty \le \left\|\frac{(a+1)^2}{4(s+a)^2}\right\|_\infty \tag{5.34}$$

$$\Rightarrow \lim_{a\to\infty} \| T_{zd} \|_\infty \le \lim_{a\to\infty}\left\|\frac{(a+1)^2}{4(s+a)^2}\right\|_\infty = \frac{1}{4}. \tag{5.35}$$

Therefore, optimal attenuation is obtained in the limit. Using this second parametrization, a trade-off value for the parameter a can be chosen. If a is small, then a good attenuation at high frequencies is obtained, but there is sacrifice at the lower frequencies. If a is large, then the low frequency attenuation level is close to the optimal attenuation, but the response at high frequencies increases in magnitude.

6. Conclusions. In this work, partial disturbance rejection problems are investigated in a natural framework which consists of the subrings of $\mathbf{R}_{ps}(s)$ of a given relative degree and their quotient rings. First, the solvability conditions and the characterization of the set of all solutions are obtained for the scalar case. It is shown that these solvability conditions immediately imply the solvability condition in the case when dynamic measurement feedback is used. Furthermore, it is demonstrated by an example that partial disturbance rejection can be used together with H_∞ design to get stronger attenuation at high frequencies while minimizing the response (as much as possible) at lower frequencies. At this point, an upper bound for the infinity norm of the closed loop transfer function is also calculated.

BIFURCATION AND NORMAL FORM OF NONLINEAR CONTROL SYSTEMS, PART I*

WEI KANG†

Abstract. The bifurcations of control systems with a single input are studied. Based on the normal forms of control systems, the equilibrium sets are classified. A set of quadratic invariants for control systems is found. Sufficient conditions for a system to be linearly controllable or stabilizable near a bifurcation point are given in terms of the quadratic invariants.

Key words. nonlinear systems, bifurcations, normal forms, invariants, linearly controllable, stabilizable

AMS subject classifications. 93C10, 93C15

1. Introduction.

Bifurcation theory studies the changes in qualitative structure of the flow of a dynamic system as parameters are varied. Local bifurcation theory focuses on the stability of the bifurcating solution [6], [15]. In this paper, some bifurcation problems for control systems are addressed. Given a control system with parameters and control inputs, the location of the equilibrium points depends on the values of the parameters and control inputs. The set of equilibrium points is not necessarily a smooth manifold in the state and parameter space. Furthermore, the fundamental properties such as stabilizability and controllability change as the equilibrium point is varied. Understanding the change of these properties is important in feedback design. For instance, a bifurcation occurs in the system of axial flow compressor (see [13]). On one branch of the equilibria, the system is linearly controllable. On the other branch, the system is not stabilizable on one side of the bifurcation point. In fact, feedback is found to achieve the desired stability pattern on the controllable branch [12], [11]. The information about controllability and stabilizability along a set of equilibrium points is also helpful when gain scheduling methods are applied to a nonlinear system. In this paper, local bifurcations of equilibrium sets are classified based on the normal forms of control systems. The controllability and stabilizability at points in the equilibrium set depend on the values of the quadratic invariants. Recent research shows that the bifurcation in the Moore and Greitzer model of the axial flow compressor is equivalent to the two branch bifurcation given in Theorems 3.2 and 4.2.

The behavior of any Hopf bifurcation can be reduced to a few different cases. This is possible because a nonlinear dynamic system can be transformed into a simplified normal form based on Poincaré's theory. Since the bifurcation phenomenon is invariant under change of coordinates, one can study the bifurcation of dynamic systems by focusing on their normal forms. This idea simplifies the problem. An affine control system consists of two vector fields (the drift vector and the control vector). To study the bifurcations of control systems, it is necessary to find normal forms in which both vectors are simplified. For linear systems, a normal form is the controller form. In

this paper, a set of nonlinear control system normal forms is found. All the results on equilibrium sets, controllability, and stabilizability are proved based on these normal forms and their invariants. The normal forms in this paper generalized the work in [8] to parameter-dependent systems which are not linearly controllable. Since the control system normal forms have the Brunovsky form in their linearization and the triangle structure in the quadratic parts, the study of their controllability and stabilizability is simple.

In general, a control system can have more than one equilibrium point even without parameters. This is because of the existence of control inputs. In the presence of parameters, the bifurcation of a control system has at least two-dimensional freedom. This paper is organized in the following way. In Part I, we focus on control systems without parameters. For single input systems, this is a one-dimensional bifurcation problem. In Part II [16], the problem is addressed for control systems with one parameter, which is a two-dimensional bifurcation problem. In both parts, we only consider systems with a single input, although the formulation of the problems are given for general multi-input systems.

In section 1 of Part I, the problem is formulated from bifurcation viewpoint and then an intuitive example is given. In section 2, the quadratic normal forms and invariants of control systems are introduced; these play a key role in the proofs of the main theorems. The problems formulated in section 1.1 are addressed in sections 3–5 for nonlinear systems without parameters. Sufficient conditions in terms of quadratic invariants for controllability of linearization and local stabilizability are proved. In [16], the problems formulated in this section will be addressed for systems with a single parameter.

Some interesting problems related to control system in the presence of bifurcation are addressed in [1], [2], and [5].

1.1. Problem formulation. Classic bifurcation theory studies the changes in qualitative properties such as stability of a dynamic system about bifurcating constant solutions as parameters are varied. More specifically, a system with parameters is defined by

$$\dot{x} = f_\mu(x) \tag{1.1}$$

where $x \in \mathbb{R}^n$ is the state variable and μ is the parameter. For different values of μ, the behavior of the dynamic flows can be qualitatively different. For instance, the equilibrium point x_0 defined by $f_\mu(x_0) = 0$ depends on the value of μ. Furthermore, the stability of the system around x_0 can be different if the value of μ is changed.

Consider a control system

$$\dot{x} = f(x, \mu) + g(x, \mu)u \tag{1.2}$$

where $x \in \mathbb{R}^n$ is the state variable, $u \in \mathbb{R}^m$ is the control input, and μ is the parameter. The performance of the system depends on the values of μ and u. For instance, the equilibrium point x_0 of the system defined by

$$f(x_0, \mu) + g(x_0, \mu)u = 0$$

changes if the values of μ and u are changed. Furthermore, more than one branch of equilibrium points can occur. The controllability of the system at these equilibrium points also changes. In this paper, we classify the bifurcations of equilibrium sets. The change of properties such as controllability and stabilizability is also studied.

Given a system (1.2), assume that

$$f(0,0)=0,$$

and we only consider local bifurcation around $(x,u,\mu)=(0,0,0)$. Assume the rank of the matrix $g(0,0)$ is m. In a local neighborhood of $(x,u,\mu)=(0,0,0)$, if

$$f(x_0,\mu_0)+g(x_0,\mu_0)u_0=0, \tag{1.3}$$

then u_0 is the unique value of u for which the vector field in (1.2) vanishes at (x_0,u,μ_0).

DEFINITION 1.1. *The set*

$$E=\{(x,\mu)|\exists u_0\in\mathbb{R}\ such\ that f(x,\mu)+g(x,\mu)u_0=0\} \tag{1.4}$$

is called the equilibrium set of (1.2).

In this definition of the equilibrium set, the parameter μ is treated as a variable satisfying $\dot{\mu}=0$. A point in E is called an *equilibrium point* of system (1.2). It is known that feedback of the form $u=u(x)$ can change the closed-loop system equilibria. The set E consists of all the possible closed-loop equilibria under state feedbacks. Understanding the topology of E is fundamental in the study of control of stationary bifurcations by state feedback. A special case of equilibrium set is given by systems without parameters. Consider a system

$$\dot{x}=f(x)+g(x)u \tag{1.5}$$

which is independent of the parameter μ. The equilibrium point $x=0$, $u=0$ is not unique even if the matrix

$$\frac{\partial f}{\partial x}(0)$$

has full rank. This is caused by the presence of input variable u.

DEFINITION 1.2. *The equilibrium set of* (1.5) *is defined by*

$$E=\{x|\exists u_0\in\mathbb{R}\ such\ that f(x)+g(x)u_0=0\}.$$

Dynamic bifurcation theory is always connected with the problem of stability, in particular, the stability of the bifurcating solution. For control systems, it makes more sense to study the controllability and stabilizability of control systems around the equilibrium points in E. The general concept of controllability of nonlinear systems is not addressed in this paper. We focus on the property of controllability of the linearization. Given a point $(x_0,\mu_0)\in E$. Suppose $u=u_0$ is the unique value of u satisfying (1.3). The *linearization* of (1.2) at (x_0,μ_0) is defined to be the pair $(A_{x_0\mu_0},B_{x_0\mu_0})$ in which

$$A_{x_0\mu_0}=\left.\frac{\partial f(x,\mu)+g(x,\mu)u_0}{\partial x}\right|_{\substack{x=x_0\\ \mu=\mu_0}},\ B_{x_0\mu_0}=g(x_0,\mu_0).$$

DEFINITION 1.3. *Given a point* (x_0,μ_0) *in* E*, the control system* (1.2) *is called linearly controllable at* (x_0,μ_0) *if its linearization* $(A_{x_0\mu_0},B_{x_0\mu_0})$ *defines a controllable linear system.*

In this paper, the term "controllability" is used for controllability of the linearization. In the following, the problems addressed in this paper are formulated from the bifurcation viewpoint.

Question 1. Find a classification of equilibrium sets. This is similar to the problem of finding all the "bifurcation diagrams" in the bifurcation theory of ODEs.

Question 2. Is the system linearly controllable at the equilibrium points in E?

Question 3. Is the system locally stabilizable by state feedback at the equilibrium points in E?

Remark. In this paper, Questions 1–3 are addressed only for systems which are not linearly controllable at the origin. In fact, if a system is linearly controllable at $(x_0, \mu_0) = (0, 0)$, then the system is always linearly controllable at all points in E near $(x_0, \mu_0) = (0, 0)$. So, the answers to Question 2 and 3 are trivial. For linearly controllable systems, the solution of Question 1 is simple. For instance, if a system has a single input and a single parameter, from the Brunovsky form of its linearization and the implicit function theorem it can be proved that the equilibrium set E is (locally) a smooth manifold of dimension two. Any small values of x_1 and μ uniquely determine a point in E. Therefore, all the equilibrium sets of such systems are diffeomorphic to each other.

Questions 2 and 3 are closely related in the sense that a linearly controllable system must be locally stabilizable by state feedback. As mentioned above, a control system usually has more than one equilibrium point. Questions 1–3 are applicable to a control system even if the system is independent of any parameter. In Part I, we address these problems for systems without parameters. In Part II, systems with a single parameter are considered.

1.2. An example of control system with bifurcation. In the following, an example is given for which the equilibrium set is found. The answer to Question 2 is given. The stabilizability at the origin is also proved. This example is a bifurcation discussed in section 3. In fact, this system is in normal form.

Example. Consider a two-dimensional control system without parameter

$$\begin{aligned} \dot{z} &= zx + z^2, \\ \dot{x} &= u. \end{aligned} \tag{1.6}$$

The origin $(z, x) = (0, 0)$ is an equilibrium point of the system; however, it is certainly not the only one. The system is not linearly controllable at the origin since the linearization (A, B) is

$$A = \begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix}, \qquad B = \begin{bmatrix} 0 \\ 1 \end{bmatrix}.$$

However, at the equilibrium points nearby, the system can be linearly controllable. First of all, where are the equilibrium points? They are determined by $zx + z^2 = 0$ and they have the following parametrization

$$E = \{(z, x) | x = \nu \text{ and either } z = -\nu \text{ or } z = 0\}.$$

The graph of E is shown in Figure 1.1. From Figure 1.1, it is obvious that a bifurcation occurs at the origin. The equilibrium set E has two branches, which intersect at $(z, x) = (0, 0)$. In the following, the notation E_- and E_+ are used to represent the subsets of E for $z = -\nu$ and $z = 0$, respectively.

To answer the second question, it is necessary to find the linearization and its controllability matrix at any point in E. In fact, the controllability matrix is

$$\begin{bmatrix} 0 & z \\ 1 & 0 \end{bmatrix}.$$

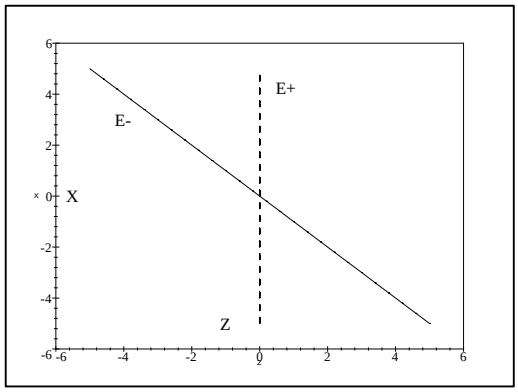

FIG. 1.1. *The equilibrium set in zx_1-plane. On the solid line, the system is linearly controllable. On the dotted line, the system is not linearly controllable.*

Therefore, the system is linearly controllable at points in the branch $E_- \backslash \{(0,0)\}$, and the system is not linearly controllable at points in E_+.

At points in E_-, the system can be stabilized locally by state feedback because it is linearly controllable. However, at a point in E_+, the stabilizability depends on the nonlinear part of the system. For instance, the system is stabilizable at the origin. One stabilizing feedback is

$$u = -x - z - z^2.$$

To show that the closed-loop system is asymptotically stable, one can check that the reduced dynamic system on the center manifold is

$$\dot{z} = -z^3 + O(z)^4.$$

This implies that the closed-loop system is asymptotically stable at $(z, x) = (0, 0)$.

2. Normal forms and invariants. The normal forms of control systems are introduced in this section. They are a tool in the proofs of the main theorems on bifurcation of control systems. Normal forms for linearly controllable systems have been introduced in [8] and [10]. In [9], normal forms for control systems which are not linearly controllable were introduced. The techniques and results in these papers generalized Poincaré's normal form of ODE to control systems. In this section, we also introduce a set of quadratic invariants. The advantage of introducing invariants is that the normal form of a given system can be found without finding the change of coordinates and feedback. Furthermore, these invariants provide information about the parametrization of equilibrium set E and the properties such as stabilizability or controllability of the system. In fact, most conditions in the main theorems of this paper are given in terms of the quadratic invariants.

2.1. Assumptions. In Part I of this paper we consider only control systems without a parameter. A control system is defined by

$$\dot{\xi} = f(\xi) + g(\xi)v, \tag{2.1}$$

where the variable $\xi \in \mathbb{R}^n$ is the state of the system. Assume that $f(0) = 0$ and $g(0) \neq 0$. Also assume that $v \in \mathbb{R}$; i.e., the system has a single input. All the vectors

and functions in this paper are assumed to be C^k for some sufficiently large k. As pointed out in the remark in section 1.1, we assume that the linearization of system (2.1) at $x = 0$, $u = 0$,

$$(A, B) = \left(\frac{\partial f}{\partial \xi}(0), g(0)\right)$$

is not controllable. Furthermore, the controllability index of (A, B) is assumed to be $n - 1$. Equivalently,

Assumption. We have that

$$\operatorname{rank}(\begin{bmatrix} B & AB & A^2B & \cdots & A^{n-1}B \end{bmatrix}) = n - 1. \tag{2.2}$$

The origin is in the equilibrium set. Near the origin, there is a unique value u_0 satisfying $f(\xi) + g(\xi)u_0 = 0$ for any $\xi \in E$ because $g(0) \neq 0$. So, given a point in E, the linearization of the system at this point is unique. The transformations used in this section are change of coordinates and feedback in the form

$$\begin{aligned} x &= \phi(\xi), \\ u &= \alpha(\xi) + \beta(\xi)v, \end{aligned} \tag{2.3}$$

in which $\phi(\xi)$ is a diffeomorphism near the origin $\xi = 0$ and $\beta(0) \neq 0$. Before we introduce the normal forms and invariants, it is necessary to make sure that Questions 1–3 are well proposed under the transformations of form (2.3). In fact, it is well known that changes of coordinates and state feedbacks do not change the controllability (of the linearization) and the local stabilizability of a control system [14]. So if one system is transformed into another by (2.3), the answers to Question 2 and 3 for these two systems are the same. If (2.3) is considered as a map from (ξ, v) to (x, u), it is a local diffeomorphism. Therefore, in a local neighborhood of $\xi = 0$, $\xi_0 \in E$ if and only if $x_0 = \phi(\xi_0)$ is an equilibrium point for the resulting system. Here, the equilibrium set is invariant under the transformations (2.3). So, if a class of nonlinear control systems can be simplified into a normal form, the bifurcation problems for this class of systems are equivalent to the same problems for a system in the normal form.

2.2. Normal forms. Given a system (2.1) satisfying assumption (2.2), it is well known (see, for instance, [7], [9]) that the system can be transformed into the following form by a linear change of coordinates and feedback:

$$\begin{aligned} \dot{z} &= \lambda z + f_1^{[2]}(z, x) + g_1^{[1]}(z, x)u + O(x, z, u)^3, \\ \dot{x} &= A_2 x + B_2 u + f_2^{[2]}(z, x) + g_2^{[1]}(z, x)u + O(x, z, u)^3, \end{aligned} \tag{2.4}$$

where $z \in \mathbb{R}$ and $x \in \mathbb{R}^{n-1}$. The pair (A_2, B_2) is in the following (Brunovsky) form:

$$A_2 = \begin{bmatrix} 0 & 1 & 0 & \cdots & 0 \\ 0 & 0 & 1 & \cdots & 0 \\ \vdots & \vdots & \vdots & & \vdots \\ 0 & 0 & 0 & \cdots & 1 \\ 0 & 0 & 0 & \cdots & 0 \end{bmatrix}_{(n-1)\times(n-1)}, \qquad B_2 = \begin{bmatrix} 0 \\ 0 \\ \vdots \\ 0 \\ 1 \end{bmatrix}_{(n-1)\times 1}. \tag{2.5}$$

The superscripts of $f_i^{[2]}$ and $g_i^{[1]}$, $i = 1$ or 2, denote that $f_i^{[2]}$ and $g_i^{[1]}$ are homogeneous polynomials of second and first degree, respectively. Similar superscripts will also be

applied to other vector fields and functions (e.g., $\alpha^{[2]}$ or $\beta^{[1]}$). The notation $O(z,x,u)^3$ represents nonlinear terms of third and higher degrees. In (2.4) the linearization is already in its normal form; the next step of finding normal form is to simplify the quadratic part of (2.4) while leaving its linear part invariant. Following the idea in [8] and [9], we use the quadratic transformation (or quadratic change of coordinates and feedback)

$$\begin{aligned} \begin{bmatrix} z \\ x \end{bmatrix} &= \begin{bmatrix} \bar{z} \\ \bar{x} \end{bmatrix} + \phi^{[2]}(\bar{z},\bar{x}), \\ u &= \bar{u} + \alpha^{[2]}(\bar{z},\bar{x}) + \beta^{[1]}(\bar{z},\bar{x})\bar{u} \end{aligned} \tag{2.6}$$

to simplify the quadratic part. In [9] it is proved that (2.4) can be transformed into the following normal form. The coefficients in its normal form are uniquely determined by the quadratic part of (2.4). For the reason of simplicity, we still use z, x, and u as state and control variables.

If $\lambda \neq 0$,

$$\begin{aligned} \dot{z} &= \lambda z + \sum_{i=1}^{n-1} \gamma_{x_i x_i} x_i^2 + \gamma_{z x_1} z x_1 + O(x,z,u)^3, \\ \dot{x} &= A_2 x + B_2 u + \tilde{f}_2^{[2]}(x) + O(x,z,u)^3; \end{aligned} \tag{2.7}$$

if $\lambda = 0$,

$$\begin{aligned} \dot{z} &= \sum_{i=1}^{n-1} \gamma_{x_i x_i} x_i^2 + \gamma_{z x_1} z x_1 + \gamma_{zz} z^2 + O(x,z,u)^3, \\ \dot{x} &= A_2 x + B_2 u + \tilde{f}_2^{[2]}(x) + O(x,z,u)^3. \end{aligned} \tag{2.8}$$

In (2.7) and (2.8), the vector $\tilde{f}_2^{[2]}(x)$ is in the extended quadratic controller form introduced in [8]

$$\begin{aligned} &\tilde{f}_2^{[2]}(x) = [\tilde{f}_{21}(x), \tilde{f}_{22}(x), \ldots, \tilde{f}_{2\,n-1}(x)]^T, \quad \tilde{f}_{2i}(x) = \sum_{j=i+2}^{n-1} a_{i\,n-j} x_j^2 \ \text{ for } \ 1 \le j \le n-3, \\ &\tilde{f}_{2\,n-2}(x) = \tilde{f}_{2\,n-1}(x) = 0. \end{aligned} \tag{2.9}$$

The symbols $\gamma_{x_i x_i}$, $\gamma_{z x_1}$ and γ_{zz} denote the constant coefficients of the quadratic terms. These normal forms will be used as a tool in the proofs of the theorems in sections 3, 4, and 5.

Given a system, formulas for finding the coefficients in its normal form are given in Definition 2.1. In fact, they are a complete set of invariants. A change of coordinates transforming a system to its normal form can be found by solving a set of linear algebraic equations, which are called homological equations [9].

2.3. Invariants. In the following, we introduce quadratic invariants. They are the "intrinsic parameters" of a system which completely determine the equivalent class of quadratic parts of a system under quadratic transformations of the form (2.6). Conditions in many theorems of this paper will be given in terms of these invariants.

Although the invariants are defined at an equilibrium point (we define them at $(z,x)=(0,0)$), they carry important information of controllability and stabilizability of a system at all the equilibrium points near the origin.

Denote by C_x, C_z, and X_z the following n-dimensional row or column vectors:

$$\begin{aligned} C_x &= [0 \quad 1 \quad 0 \quad \cdots \quad 0], \qquad C_z = [1 \quad 0 \quad 0 \quad \cdots \quad 0], \\ X_z &= [1 \quad 0 \quad 0 \quad \cdots \quad 0]^T. \end{aligned} \tag{2.10}$$

Given two vector fields $X(x)$ and $Y(x)$ defined in $\mathbb{R}^n$, the operator ad_X is defined by $ad_X(Y)=[X,Y]$, where the right-hand side is the Lie bracket of two vector fields which is defined by

$$\frac{\partial Y}{\partial x}X - \frac{\partial X}{\partial x}Y.$$

The Lie operator L_X is defined by

$$L_X(\phi(x)) = \frac{\partial \phi}{\partial x}X$$

for C^1 functions defined in $\mathbb{R}^n$. In Definition 2.1, we use the notation $f(z,x)+g(z,x)u$ to represent the right side of a system (2.4). The notation A represents the matrix in the linearization of $f(z,x)$, i.e.,

$$A = \left.\frac{\partial f}{\partial (z,x)}\right|_{\substack{z=0\\x=0}} = \begin{bmatrix} \lambda & 0 \\ 0 & A_2 \end{bmatrix}.$$

DEFINITION 2.1. *Given a system* (2.4)*, the* quadratic invariants *are defined by*

$$\begin{aligned} a_{tr} &= \frac{1}{2}C_x A^{t-1}[ad_f^r(g), ad_f^{r-1}(g)]\Big|_{z=0,x=0}, \qquad \begin{matrix} 1 \le r \le n-3, \\ 1 \le t \le n-r-2, \end{matrix} \\ \gamma_{x_{n-r}x_{n-r}} &= \frac{1}{2}C_z[ad_f^r(g), ad_f^{r-1}(g)]\Big|_{z=0,x=0}, \quad 1 \le r \le n-1, \\ \gamma_{zx_1} &= (-1)^{n-1}C_z[X_z, ad_f^{n-1}(g)]\Big|_{z=0,x=0}, \\ \gamma_{zz} &= \frac{1}{2}C_z ad_{X_z}^2(f)\Big|_{z=0,x=0}. \end{aligned} \tag{2.11}$$

THEOREM 2.2. *Given a control system satisfying assumption* (2.2)*, assume that its linearization is in the form of* (2.4)*.*

(i) *The quadratic transformation* (2.6) *does not change the values of the quadratic invariants.*

(ii) *The quadratic invariants* (2.11) *are equal to the coefficients of the quadratic terms of the normal form* (2.7), (2.8)*.*

(iii) *Given two systems in the form of* (2.4) *with the same linearization (i.e., they have the same* λ*), the quadratic part of one system can be transformed into that of another system by a suitable transformation* (2.6) *if and only if they have the same quadratic invariants.*

Proof. (i) The proof of (i) has two parts. In the first part, we only consider changes of coordinates without feedback, i.e., $u = \bar{u}$ in the quadratic transformation (2.6). In the second part, we prove that the invariants cannot be changed by any quadratic feedback. Suppose that system (2.4) is transformed into the following system by a quadratic change of coordinates:

$$\begin{aligned} \dot{\bar{z}} &= \lambda\bar{z} + \bar{f}_1^{[2]}(\bar{z},\bar{x}) + \bar{g}_1^{[1]}(\bar{z},\bar{x})\bar{u} + O(\bar{x},\bar{z},\bar{u})^3, \\ \dot{\bar{x}} &= A_2\bar{x} + B_2\bar{u} + \bar{f}_2^{[2]}(\bar{z},\bar{x}) + \bar{g}_2^{[1]}(\bar{z},\bar{x})\bar{u} + O(\bar{x},\bar{z},\bar{u})^3. \end{aligned} \tag{2.12}$$

Denote the invariants of (2.4) and (2.12) by a_{tr}, $\gamma_{x_ix_i}$, γ_{zx_1}, γ_{zz} and $\bar{a}_{tr}$, $\bar{\gamma}_{x_ix_i}$, $\bar{\gamma}_{zx_1}$, $\bar{\gamma}_{zz}$, respectively. Notice that if we treat X_z, $f(z,x)$ and $g(z,x)$ as vector fields in $\mathbb{R}^n$, then f and $\bar{f}$ represent the same vector field. Similarly, g and $\bar{g}$ represent the same vector field. Since Lie bracket and Lie operators are independent of the choice of coordinate systems, sometimes we use f and g to represent these two vector fields without mentioning the coordinate system (z,x or $\bar{z},\bar{x}$). The vectors X_z and $\overline{X}_z$ are defined based on coordinate systems (see (2.10)). The invariants can be expressed in the following way using Lie bracket and Lie operators:

$$\begin{aligned} a_{tr} &= \frac{1}{2}\, L_{[ad_f^r(g),ad_f^{r-1}(g)]}L_f^{t-1}(x_1)\Big|_{\substack{z=0\\x=0}}, \\ \gamma_{x_{n-r}x_{n-r}} &= \frac{1}{2}\, L_{[ad_f^r(g),ad_f^{r-1}(g)]}(z)\Big|_{\substack{z=0\\x=0}}, \\ \gamma_{zx_1} &= (-1)^{n-1}L_{[X_z,ad_f^{n-1}(g)]}(z). \end{aligned} \tag{2.13}$$

Under the new coordinates, we have

$$x_1 = \bar{x}_1 + O(\bar{z},\bar{x})^2, \quad z = \bar{z} + O(\bar{z},\bar{x})^2, \quad X_z = \overline{X}_z + O(\bar{z},\bar{x}). \tag{2.14}$$

From (2.13) and (2.14),

$$a_{tr} = \frac{1}{2}\, L_{[ad_f^r(g),ad_f^{r-1}(g)]}L_f^{t-1}(\bar{x}_1)\Big|_{\substack{z=0\\x=0}} + \frac{1}{2}\, L_{[ad_f^r(g),ad_f^{r-1}(g)]}L_f^{t-1}(O(\bar{z},\bar{x})^2)\Big|_{\substack{z=0\\x=0}}.$$

In this relation, the second term on the right side is zero. The first term on the right side is $\bar{a}_{tr}$. This proves that $a_{tr} = \bar{a}_{tr}$. Similarly, we can prove that $\gamma_{x_ix_i} = \bar{\gamma}_{x_ix_i}$.

Now, let's consider γ_{zx_1}. By (2.13) and (2.14), we have

$$\begin{aligned} \gamma_{zx_1} &= L_{[\overline{X}_z,ad_f^{n-1}(g)]}(\bar{z})\Big|_{\substack{\bar{z}=0\\\bar{x}=0}} + L_{[\overline{X}_z,ad_f^{n-1}(g)]}(O(\bar{z},\bar{x})^2)\Big|_{\substack{\bar{z}=0\\\bar{x}=0}} \\ &+ L_{[O(\bar{z},\bar{x}),ad_f^{n-1}(g)]}(\bar{z}+O(\bar{z},\bar{x})^2)\Big|_{\substack{\bar{z}=0\\\bar{x}=0}}. \end{aligned} \tag{2.15}$$

From (2.13), we know that

$$L_{[\overline{X}_z,ad_f^{n-1}(g)]}(\bar{z})\Big|_{\substack{\bar{z}=0\\\bar{x}=0}} = \bar{\gamma}_{zx_1}. \tag{2.16}$$

It is easy to check that

$$L_{[\overline{X}_z,ad_f^{n-1}(g)]}(O(\bar{z},\bar{x})^2)\Big|_{\substack{\bar{z}=0\\\bar{x}=0}} = 0 \tag{2.17}$$

and

$$ad_f^r(g) = (-1)^r \begin{bmatrix} \lambda^r & 0 \\ 0 & A_2^r \end{bmatrix} \begin{bmatrix} 0 \\ B_2 \end{bmatrix} + O(\bar{z}, \bar{x}).$$

Therefore,

$$ad_f^{n-1}(g) = O(\bar{z}, \bar{x}).$$

So

$$L_{[O(\bar{z},\bar{x}),ad_f^{n-1}(g)]}(\bar{z} + O(\bar{z}, \bar{x})^2)\Big|_{\substack{\bar{z}=0 \\ \bar{x}=0}} = 0. \tag{2.18}$$

Equations (2.16), (2.17), and (2.18) imply $\gamma_{zx_1} = \bar{\gamma}_{zx_1}$. If $\lambda = 0$, there is another invariant γ_{zz}. By the separation principle in [9, Lemma 4.2], it is enough to show that γ_{zz} is invariant under the change of coordinates $z = z + \phi^{[2]}(z)$. However, this is a well-known result in dynamic systems. In fact, z^2 is a resonant term in the dynamic system of z (the definition can be found in [3]). In Poincaré's theory of normal forms for dynamic systems, the coefficient of a quadratic resonant term cannot be changed by quadratic change of coordinates. This shows that γ_{zz} is invariant under a quadratic change of coordinates.

If feedback is applied to system (2.4), then the new vector fields in the resulting system are

$$\bar{f}(z, x) = f(z, x) + \alpha^{[2]}(z, x)g(z, x), \quad \bar{g}(z, x) = g(z, x) + \beta^{[1]}(z, x)g(z, x).$$

It is obvious that γ_{zz} will not be changed by the feedback. By mathematical induction, it can be proved that

$$ad_{\bar{f}}^r(\bar{g}) = ad_f^r(g) + \sum_{i=0}^{r} h_{ri}(z, x) ad_f^i(g) + O(z, x)^2, \quad h_{ri}(z, x) = O(z, x),$$

$$\left[ad_{\bar{f}}^r(\bar{g}), ad_{\bar{f}}^{r-1}(\bar{g})\right] = [ad_f^r(g), ad_f^{r-1}(g)] + \sum_{i=1}^{r} q_{ri}(z, x) ad_f^i(g) + O(z, x),$$

$$C_x A^{t-1} ad_f^i(g)|_{z=0,x=0} = 0 \quad \text{if } t + i \le n - 2,$$

$$C_z ad_f^i(g)|_{z=0,x=0} = 0 \qquad \text{if } 0 \le i \le n - 1.$$

Substituting these relations into the definition of invariants (2.11), it shows that $\bar{a}^{tr}$, $\bar{\gamma}_{x_i x_i}$, $\bar{\gamma}_{zx_1}$ are equal to a_{tr}, $\gamma_{x_i x_i}$, γ_{zx_1}.

(ii) The proof of the second part is based on calculation. By mathematical induction, it can be proved that, if $1 \le r < n - 2$,

$$ad_f^r(g) = (-1)^r \left(\left\{ \begin{bmatrix} 0 \\ \vdots \\ 0 \\ 1 \\ 0 \\ \vdots \\ 0 \end{bmatrix} \right\} = n - r \quad + \left\{ \begin{bmatrix} 2\gamma_{x_{n-r}x_{n-r}} x_{n-r} \\ 2a_{1\,r} x_{n-r} \\ \vdots \\ 2a_{n-r-2\,r} x_{n-r} \\ 0 \\ \vdots \\ 0 \end{bmatrix} \right\} = n - r - 1 \right)$$

$$+ h_r(x_{n-r+1}, x_{n-r+2}, \ldots, x_{n-1}) + O(x, z)^2. \tag{2.19}$$

Therefore,

$$[ad_f^r(g), ad_f^{r-1}(g)] = \begin{bmatrix} 2\gamma_{x_{n-r}x_{n-r}} & 2a_{1\,r} & \cdots & 2a_{n-r-2\,r} & 0 & \cdots & 0 \end{bmatrix}^T + O(z,x) \tag{2.20}$$

for $r < n-2$. Equations (2.20) and (2.11) imply

$$a_{tr} = \frac{1}{2}\, C_x A^{t-1} [ad_f^r(g), ad_f^{r-1}(g)]\Big|_{z=0,x=0},$$
$$\gamma_{x_{n-r}x_{n-r}} = \frac{1}{2}\, C_z [ad_f^r(g), ad_f^{r-1}(g)]\Big|_{z=0,x=0}$$

for $1 \le r \le n-3$ and $1 \le t \le n-r-2$. Similarly, we can show that

$$ad_f^{n-2}(g) = (-1)^{n-2} \left(\begin{bmatrix} 0 \\ 1 \\ 0 \\ \vdots \\ 0 \end{bmatrix} + \begin{bmatrix} 2\gamma_{x_2x_2}x_2 \\ 0 \\ 0 \\ \vdots \\ 0 \end{bmatrix} \right) + h_{n-2}(x_3, x_4, \ldots, x_{n-1}) + O(x,z)^2,$$

$$ad_f^{n-1}(g) = (-1)^{n-1} \begin{bmatrix} 2\gamma_{x_1x_1}x_1 + \gamma_{zx_1}z \\ 0 \\ \vdots \\ 0 \end{bmatrix} + h_{n-1}(x_2, x_3, \ldots, x_{n-1}) + O(x,z)^2.$$

So, it is easy to check that

$$\gamma_{x_2x_2} = \frac{1}{2} C_z [ad_f^{n-2}(g), ad_f^{n-3}(g)]\Big|_{\substack{z=0\\x=0}}, \quad \gamma_{x_1x_1} = \frac{1}{2} C_z [ad_f^{n-1}(g), ad_f^{n-2}(g)]\Big|_{\substack{z=0\\x=0}},$$

$$\gamma_{zx_1} = (-1)^{n-1} C_z [X_z, ad_f^{n-1}(g)]\Big|_{\substack{z=0\\x=0}}.$$

If $\lambda = 0$, then γ_{zz} is the coefficient of z^2 because of Definition 2.1.

(iii) From the result in [9], we know that a system (2.4) can be transformed into a normal form (2.7) or (2.8). Therefore, two systems can be transformed from one to the other if and only if they have the same normal form. From (ii), the coefficients in normal form and the invariants have one-to-one correspondence. So, the two systems have the same normal form if and only if they have the same invariants. This concludes the proof of the theorem. □

Theorem 2.2 implies that the coefficients of the normal form can be computed without finding the transformation. Furthermore, it will be shown in the next three sections that the properties such as controllability and stabilizability are closely related to these invariants.

3. Classification of equilibrium sets. In this section, Question 1 is addressed. Different systems have different equilibrium sets. However, the equilibrium sets of systems with the same normal form are diffeomorphic to one other. Based on the normal forms in section 2, the equilibrium sets of systems satisfying (2.2) are classified to three different classes. For each class of equilibrium sets, a parametrization of the equilibrium set is also found, which is a linear approximation of E.

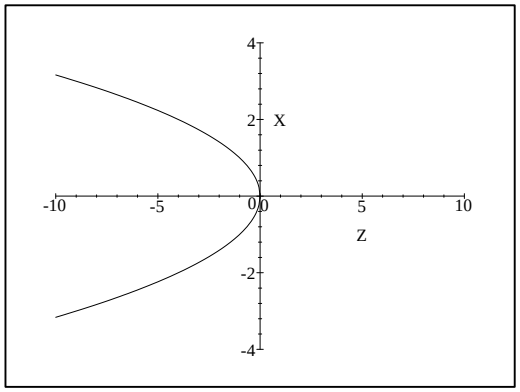

FIG. 3.1. *The equilibrium set in zx_1-plane.*

Given a nonlinear control system, if its linearization has controllability index $n-1$, then it can be transformed into a system in the form of (2.4). So, we only consider system (2.4) in sections 3, 4, and 5.

THEOREM 3.1. *Given a system of the form* (2.4)*, if $\lambda \neq 0$, then there exists an open neighborhood U of $(z, x) = (0, 0)$ such that the points in $E \cap U$ satisfy*

$$\begin{aligned} &x_1 = \nu, \\ &z = O(\nu)^2, \\ &x_i = O(\nu)^2 \ \text{ for } \ i = 2, 3, \ldots, n-1. \end{aligned} \tag{3.1}$$

Remark. This theorem shows that, in a neighborhood of the origin, there exists a unique equilibrium point of the system for a given value of x_1. The set E is a smooth curve tangent to the x_1-axis at the origin. Therefore, the equilibrium set does not show an obvious bifurcation. However, in Theorem 4.1 it is proved that the controllability of the system changes near the origin for different equilibrium points. A typical graph of the equilibrium set for the systems with $\lambda \neq 0$ is shown in Figure 3.1 for the following system in normal form:

$$\begin{aligned} &\dot{z} = z + x_1^2 + x_2^2, \\ &\dot{x}_1 = x_2, \\ &\dot{x}_2 = u. \end{aligned} \tag{3.2}$$

The equilibrium set E is $x_1 = \nu$, $x_2 = 0$, $z = -\nu^2$.

Proof of Theorem 3.1. For a point (z, x) to be an equilibrium point of system (2.4), it must satisfy

$$\begin{aligned} &\lambda z + f_1^{[2]} + g_1^{[1]} u + O(z, x, u)^3 = 0, \\ &A_2 x + B_2 u + f_2^{[2]} + g_2^{[1]} u + O(z, x, u)^3 = 0. \end{aligned} \tag{3.3}$$

Denote the left side of the equations by $G(z, x, u)$. This is a system of equations and

$$\left.\frac{\partial G}{\partial(z, x_2, ..., x_{n-1}, u)}\right|_{z=0, x=0, u=0} = \begin{bmatrix} \lambda & 0 \\ 0 & I \end{bmatrix}$$

where I is the $(n-1) \times (n-1)$ identity matrix. By the implicit function theorem, in a local neighborhood of the origin there exists a unique set of functions

$z(x_1), x_2(x_1), \ldots, x_{n-1}(x_1), u(x_1)$ satisfying equations (3.3). Since $\partial G/\partial x_1$ is the zero matrix at the origin, these functions do not contain linear terms in x_1. This proves the theorem. □

The topology of the equilibrium sets for systems with $\lambda = 0$ depends on the quadratic part of its normal form. The quadratic function of z, x_1 of the uncontrollable dynamics in the normal form has an associated symmetric matrix, which is

$$Q = \begin{bmatrix} \gamma_{zz} & \frac{1}{2}\gamma_{zx_1} \\ \frac{1}{2}\gamma_{zx_1} & \gamma_{x_1x_1} \end{bmatrix}.$$

Denote d_1 and d_2 the eigenvalues of this matrix. Then there is an orthonormal matrix T, the column vectors of which are unit eigenvectors of Q, such that

$$Q = T \begin{bmatrix} d_1 & 0 \\ 0 & d_2 \end{bmatrix} T^T. \tag{3.4}$$

THEOREM 3.2. *Given a system* (2.4) *with* $\lambda = 0$*, the following hold.*
(i) *If*

$$\det(Q) > 0, \tag{3.5}$$

then there is no equilibrium point other than $(z, x) = (0, 0)$ *near the origin.*
(ii) *If*

$$\det(Q) < 0, \tag{3.6}$$

then the equilibrium set has the following parametrization

$$x_i = O(\nu)^2, \qquad for \;\; i = 2, \ldots, n-1,$$

$$\begin{bmatrix} z \\ x \end{bmatrix} = T \begin{bmatrix} 1 \\ \pm\sqrt{-\dfrac{d_1}{d_2}} \end{bmatrix} \nu + O(\nu)^2 \tag{3.7}$$

in an open neighborhood of the origin.

Remark. The relation (3.7) implies that if (3.6) holds, the equilibrium set has two branches. At the origin, the two branches have tangent vectors

$$T \begin{bmatrix} 1 & \pm\sqrt{-\dfrac{d_1}{d_2}} \end{bmatrix}^T. \tag{3.8}$$

A typical example of such equilibrium set is given by the system (1.6) in section 1.2 which satisfies (3.6). The system is in normal form. The bifurcation diagram is shown in Figure 1.1.

Proof of Theorem 3.2. A system (2.4) can be simplified to (2.8). A transformation (2.6) does not change the linear part of the functions in (3.7). Therefore, it is sufficient to prove the theorem for the normal form (2.8). In this case, the equilibrium point (z, x) satisfies

$$x_2 + O(z, x, u)^2 = 0, \ldots, x_{n-1} + O(z, x, u)^2 = 0, \quad u + O(z, x, u)^2 = 0.$$

TABLE 3.1
The classification of equilibrium sets.

Condition	Equilibrium set	Example
$\lambda \neq 0$	Smooth 1-d manifold tangent to x_1-axis	Figure 3.1
$\lambda = 0$, $\det(Q) > 0$	Single point	
$\lambda = 0$, $\det(Q) < 0$	Two smooth curves tangent to vectors (3.8) at origin	Figure 1.1

This implies that $x_i = O(x_1, z)^2$, for $i = 2, \ldots, n-1$, and $u = O(x_1, z)^2$. Substituting this into the relation

$$\sum_{i=2}^{n-1} \gamma_{x_i x_i} x_i^2 + \gamma_{z x_1} z x_1 + \gamma_{zz} z^2 + O(z, x, u)^3 = 0$$

yields

$$\gamma_{x_1 x_1} x_1^2 + \gamma_{z x_1} z x_1 + \gamma_{zz} z^2 + O(x_1, z)^3 = 0. \tag{3.9}$$

If the left side of (3.9) is denoted by $F(z, x_1)$, then

$$F(z, x_1) = [z, x_1] Q \begin{bmatrix} z \\ x_1 \end{bmatrix} + O(z, x_1)^3.$$

The condition (3.5) is equivalent to the fact that the matrix Q in (3.4) is sign definite. Therefore, except for the point $(z, x_1) = (0, 0)$, the value of $F(z, x_1)$ is not zero near the origin. This implies that $(z, x) = (0, 0)$ is an isolated equilibrium point. The first part of the theorem is proved.

If (3.6) holds, then the matrix (3.4) is not sign definite and it has full rank. By the change of coordinates

$$\begin{bmatrix} w_1 & w_2 \end{bmatrix} = \begin{bmatrix} z & x_1 \end{bmatrix} T, \tag{3.10}$$

the equation $F(z, x) = 0$ becomes $d_1 w_1^2 + d_2 w_2^2 + O(w_1, w_2)^3 = 0$. Therefore,

$$w_2 = \pm \sqrt{-\frac{d_1}{d_2}} w_1 + O(w_1)^2.$$

Substituting this into (3.10) and denoting ν as variable w_1 yield equation (3.7). This completes the proof of the second part. □

We summarize the classification of equilibrium sets in Table 3.1. The uncontrollable eigenvalue λ (a linear invariant) and the quadratic invariants determine the class of the equilibrium set.

4. Controllability. In this section and the next section, we study problems related to Question 2 and 3. Suppose we choose an equilibrium point in E. If it is not the origin, then the controllability of its linearization depends on the quadratic part of the system. Sufficient conditions for a system to be linearly controllable at equilibrium points are given in this section.

THEOREM 4.1. *Given a system in the form of* (2.4) *with* $\lambda \neq 0$, *if* $\gamma_{x_1 x_1} \neq 0$, *then there is a neighborhood* U *of* $(z, x) = (0, 0)$ *such that the system is linearly controllable at all the equilibrium points in* U *except the origin.*

Remark. Given a system with $\lambda \neq 0$, if $\lambda > 0$, then the system cannot be stabilized at the origin by C^1 state feedback. However, an interesting corollary of Theorem 4.1 is that, if $\gamma_{x_1x_1} \neq 0$, there is a neighborhood U of the origin such that the system is locally stabilizable at all equilibrium points in U except $(z, x) = (0, 0)$.

Proof. Given a system (2.4). It can be transformed into its normal form (2.7). Since a change of coordinates and feedback does not change the controllability of the linearization, it is enough to prove the theorem for normal forms. Denote the linearization of the normal form at an equilibrium (3.1) by (A_ν, B_ν). Using (3.1) it is easy to check that, at an equilibrium point in E, we have

$$A_\nu = \begin{bmatrix} \lambda & 0 \\ 0 & A_2 \end{bmatrix} + \begin{bmatrix} \gamma_{zx_1}\nu & 2\gamma_{x_1x_1}\nu & 0 \\ 0 & 0 & 0 \end{bmatrix}_{n\times n} + O(\nu)^2,$$

$$B_\nu = \begin{bmatrix} 0 & 0 & \cdots & 0 & 1 \end{bmatrix}^T + O(\nu)^2.$$

Therefore,

$$\begin{aligned} A_\nu^k B_\nu &= [\overbrace{0 \quad 0 \quad \cdots \quad 1}^{n-k} \quad 0 \quad \cdots \quad 0]^T + O(\nu)^2, \quad 0 \le k \le n-2, \\ A_\nu^{n-1} B_\nu &= \begin{bmatrix} 2\gamma_{x_1x_1}\nu & 0 & \vdots & 0 \end{bmatrix}^T + O(\nu)^2. \end{aligned} \tag{4.1}$$

Equations in (4.1) imply that the controllability matrix $[B_\nu, A_\nu B_\nu, \ldots, A_\nu^{n-1} B_\nu]$ has full rank for small nonzero values of ν if $\gamma_{x_1x_1} \neq 0$. From the assumption in the theorem, the system is linearly controllable near the origin. □

System (3.2) satisfies the condition of Theorem 4.1. In fact, $\gamma_{x_1x_1} = 1$. Therefore, the system is linearly controllable at all points in E near $z = 0$, $x = 0$ except the origin. The condition in Theorem 4.1 is sufficient but not necessary. If $\gamma_{x_1x_1} = 0$, the controllability of the system depends on both the quadratic and higher degree terms.

If $\lambda = 0$, then the equilibrium set may have two branches. The following theorem studies the controllability of such systems.

THEOREM 4.2. *Consider a system in the form of* (2.4) *with* $\lambda = 0$. *Assume that inequality* (3.6) *holds. If* $\gamma_{x_1x_1} \neq 0$, *then the system is linearly controllable at all the equilibrium points in* $E \setminus \{(0, 0)\}$ *near the origin.*

Proof. It is simpler to consider a system in normal form (2.8). The linearization of (2.8) at an equilibrium point $(z, x) \in E$ is

$$\begin{aligned} A_\nu &= \begin{bmatrix} 0 & 0 \\ 0 & A_2 \end{bmatrix} + \begin{bmatrix} \gamma_{zx_1}x_1 + 2\gamma_{zz}z & 2\gamma_{x_1x_1}x_1 + \gamma_{zx_1}z & 0 \\ 0 & 0 & 0 \end{bmatrix}_{n\times n} + O(\nu)^2, \\ B_\nu &= \begin{bmatrix} 0 & 0 & \cdots & 0 & 1 \end{bmatrix}^T + O(\nu)^2. \end{aligned} \tag{4.2}$$

By calculation, it is easy to check that

$$\begin{aligned} A_\nu^r B_\nu &= [\overbrace{0 \quad \cdots \quad 0 \quad 1}^{n-r} \quad 0 \quad \cdots \quad 0]^T + O(\nu)^2, \quad 1 \le r \le n-2, \\ A_\nu^{n-1} B_\nu &= \begin{bmatrix} 2\gamma_{x_1x_1}x_1 + \gamma_{zx_1}z & 0 & \cdots & 0 \end{bmatrix}^T + O(\nu)^2. \end{aligned}$$

From (ii) of Theorem 3.2, the controllability matrix at the equilibrium point is in the

following form:

$$[B_\nu, A_\nu B_\nu, \ldots, A_\nu^{n-1} B_\nu] = \begin{bmatrix} 0 & 0 & \cdots & 0 & p\nu \\ 0 & 0 & \cdots & 1 & 0 \\ \vdots & \vdots & & \vdots & \vdots \\ 1 & 0 & \cdots & 0 & 0 \end{bmatrix} + O(\nu)^2, \tag{4.3}$$

where

$$p = \begin{bmatrix} \gamma_{zx_1} & 2\gamma_{x_1x_1} \end{bmatrix} T \begin{bmatrix} 1 \\ \pm\sqrt{-\dfrac{d_1}{d_2}} \end{bmatrix}.$$

The result in the theorem follows the following claim.

Claim. If $\gamma_{x_1x_1} \neq 0$, then $p \neq 0$.

Proof of the claim. Assume that $p = 0$. Then

$$\begin{bmatrix} 0 & 1 \end{bmatrix} QT \begin{bmatrix} 1 & \pm\sqrt{-\dfrac{d_1}{d_2}} \end{bmatrix}^T = 0.$$

By (3.4), this equation is equivalent to

$$\begin{bmatrix} 0 & 1 \end{bmatrix} T \begin{bmatrix} d_1 & 0 \\ 0 & d_2 \end{bmatrix} \begin{bmatrix} 1 & \pm\sqrt{-\dfrac{d_1}{d_2}} \end{bmatrix}^T = 0.$$

Without loss of generality we assume $d_1 < 0$; then

$$\begin{aligned} \begin{bmatrix} 0 & 1 \end{bmatrix} T \begin{bmatrix} d_1 & 0 \\ 0 & d_2 \end{bmatrix} &= s \begin{bmatrix} -\sqrt{-d_1} & \pm\sqrt{d_2} \end{bmatrix}, \\ \begin{bmatrix} 0 & 1 \end{bmatrix} T &= s \begin{bmatrix} \frac{1}{\sqrt{-d_1}} & \frac{\pm 1}{\sqrt{d_2}} \end{bmatrix} \end{aligned} \tag{4.4}$$

for some $s \in \mathbb{R}$. From (3.4) and (4.4),

$$\gamma_{x_1x_1} = \begin{bmatrix} 0 & 1 \end{bmatrix} T \begin{bmatrix} d_1 & 0 \\ 0 & d_2 \end{bmatrix} T^T \begin{bmatrix} 0 \\ 1 \end{bmatrix} = s^2 \begin{bmatrix} -\sqrt{-d_1} & \pm\sqrt{d_2} \end{bmatrix} \begin{bmatrix} \frac{1}{\sqrt{-d_1}} \\ \frac{\pm 1}{\sqrt{d_2}} \end{bmatrix} = 0.$$

It is a contradiction. Therefore, $p \neq 0$. The claim is proved. □

Remark. In the case of $\lambda = 0$ and $\det(Q) < 0$, if $\gamma_{x_1x_1} = 0$, one branch of the equilibrium set E is tangent to $z = 0$. The controllability of the linearization at points in this branch depends on the cubic and higher degree terms of the system. If the system is not linearly controllable on this branch, it is proved in Part II that the stabilizability of the system changes as the equilibrium point passing through the origin along this curve. On the other branch of E, the system is linearly controllable if this branch is not tangent to $x_1 = 0$ (i.e., $\gamma_{zz} \neq 0$). This result can be proved by finding the controllability matrix of the normal form. If $\gamma_{zz} = 0$, then the controllability of the linearization at points in this branch depends on cubic and higher degree terms.

Example. Consider system (1.6) in the example of section 1.2. The invariants of the system are $\gamma_{x_1x_1} = 0$, $\gamma_{zx_1} = 1$, and $\gamma_{zz} = 1$. The matrix Q is

$$Q = \begin{bmatrix} 1 & \dfrac{1}{2} \\ \dfrac{1}{2} & 0 \end{bmatrix}. \tag{4.5}$$

Since E_- is not tangent to $x = 0$ (see Figure 1.1), the system is linearly controllable in E_- except the origin. The branch E_+ is tangent to $z = 0$; the controllability in E_+ depends on higher degree terms. The system (1.6) is not linearly controllable at points in E_+ because there is no cubic term in the nonlinear system.

5. Stabilizability of control systems. In this section, we prove a sufficient condition in terms of quadratic invariants for stabilizability of control systems. Consider a system of form (2.4). The system is stabilizable when $\lambda < 0$, and it is not stabilizable by C^1 state feedback if $\lambda > 0$. So we consider only the case in which λ is zero. If the system is nonlinear, its center manifold can have different shapes under different feedback. In the following we prove that if the quadratic invariants satisfy certain conditions, then there exists feedback so that the reduced dynamics on the center manifold are asymptotically stable. The center manifold theory can be found in [4]. Therefore, the feedback renders the closed-loop system locally asymptotically stable. The following theorem is a partial answer to Question 3 in the sense that the sufficient condition for stabilizability of a control system at a special equilibrium point—the origin—is given.

THEOREM 5.1. *Suppose $\lambda = 0$ in system (2.4). Suppose (3.6) holds. If $\gamma_{zx_1} \neq 0$, then there exists C^1 state feedback which locally asymptotically stabilizes the system at the origin.*

Proof. Since the system can be transformed into its normal form (2.8), we only prove the theorem for systems in normal form. Use the feedback

$$u(z, x) = F_1 x_1 + F_2 x_2 + \cdots + F_{n-1} x_{n-1} + \alpha z + \beta z^2, \tag{5.1}$$

where $F = (F_1, F_2, \ldots, F_{n-1})$ stabilizes the controllable part; i.e.,

$$A_2 + B_2 F \tag{5.2}$$

is a Hurwitz matrix. Since F_1 is the constant term in the characteristic polynomial of the matrix (5.2), $F_1 \neq 0$. The center manifold of the closed-loop system is

$$x = \pi(z) = \begin{bmatrix} \pi_1(z) & \cdots & \pi_{n-1}(z) \end{bmatrix}^T \tag{5.3}$$

such that

$$\begin{bmatrix} \pi_2 & \pi_3 & \cdots & \pi_{n-1} & F\pi \end{bmatrix}^T + \begin{bmatrix} 0 & 0 & \cdots & 0 & \alpha z + \beta z^2 \end{bmatrix}^T + \tilde{f}^{[2]}(\pi_3, \ldots, \pi_{n-1})$$

$$= \frac{d\pi}{dz} \left(\sum_{i=1}^{n-1} \gamma_{x_i x_i} \pi_i^2 + \gamma_{z x_1} z \pi_1 + \gamma_{zz} z^2 \right) + O(z)^3. \tag{5.4}$$

Solving the equation for the linear part of π we get

$$\pi_1 = -\frac{\alpha}{F_1} z + \pi_1^{[2]}(z) + O(z)^3,$$

$$\pi_i(z) = O(z)^2 \qquad \text{for } i = 2, \ldots, n-1.$$

Substituting this result into (5.4), we get the equation for the quadratic part of $\pi(z)$:

$$\begin{bmatrix} \pi_2 \\ \pi_3 \\ \vdots \\ F_1 \pi_1^{[2]} + \sum_{i=2}^{n-1} F_i \pi_i \end{bmatrix} + \begin{bmatrix} 0 \\ 0 \\ \vdots \\ \beta z^2 \end{bmatrix} = \left(\frac{\gamma_{x_1 x_1} \alpha^2}{F_1^2} - \frac{\gamma_{z x_1} \alpha}{F_1} + \gamma_{zz} \right) z^2 \begin{bmatrix} -\frac{\alpha}{F_1} \\ 0 \\ \vdots \\ 0 \end{bmatrix} + O(z)^3.$$

Therefore, $\pi_i(z) = O(z)^3$ for $i = 3, \ldots, n-1$. Furthermore,

$$\begin{aligned}\pi_1(z) &= -\frac{\alpha}{F_1}z + \left(-\frac{\beta}{F_1} + \frac{\alpha F_2}{F_1^2}\left(\frac{\gamma_{x_1x_1}\alpha^2}{F_1^2} - \frac{\gamma_{zx_1}\alpha}{F_1} + \gamma_{zz}\right)\right)z^2 + O(z)^3,\\ \pi_2 &= -\frac{\alpha}{F_1}\left(\frac{\gamma_{x_1x_1}\alpha^2}{F_1^2} - \frac{\gamma_{zx_1}\alpha}{F_1} + \gamma_{zz}\right)z^2 + O(z)^3.\end{aligned} \tag{5.5}$$

We can choose α so that

$$\frac{\gamma_{x_1x_1}\alpha^2}{F_1^2} - \frac{\gamma_{zx_1}\alpha}{F_1} + \gamma_{zz} = 0. \tag{5.6}$$

In fact, if $\gamma_{zz} = 0$, we take $\alpha = 0$, if $\gamma_{zz} \neq 0$; the value of α is determined by

$$F_1 = \frac{\gamma_{zx_1} \pm \sqrt{\gamma_{zx_1}^2 - 4\gamma_{x_1x_1}\gamma_{zz}}}{2\gamma_{zz}}\alpha. \tag{5.7}$$

The sign "+" or "−" will be determined later. The condition $\det(Q) < 0$ implies $\gamma_{zx_1}^2 - 4\gamma_{x_1x_1}\gamma zz > 0$. Therefore, F_1 must be a real number. Substituting (5.6) into (5.5), we get

$$\begin{aligned}\pi_1(z) &= -\frac{\alpha}{F_1}z - \frac{\beta}{F_1}z^2 + O(z)^3,\\ \pi_i(z) &= O(z)^3 \qquad\qquad \text{for } i = 2, \ldots, n-1.\end{aligned}$$

Substituting this into the equation of z in (2.8), we get the reduced dynamic system of the closed-loop system on the center manifold

$$\dot{z} = -\beta\frac{\gamma_{zx_1}F_1 - 2\alpha\gamma_{x_1x_1}}{F_1^2}z^3 + ez^3 + O(z)^4 \tag{5.8}$$

where e is a constant depending on F_1, α, and the coefficients of z^3 in (2.8). However, it is independent of β. The value of β is determined by the following method. If $\gamma_{zz} = 0$, then $\alpha = 0$. The number $\gamma_{zx_1}F_1 - 2\alpha\gamma_{x_1x_1}$ is not zero because $\gamma_{zx_1} \neq 0$ is an assumption. By choosing β, we can make the coefficient of z^3 be negative. The dynamics are asymptotically stable. If $\gamma_{zz} \neq 0$, from (5.7)

$$\gamma_{zx_1}F_1 - 2\alpha\gamma_{x_1x_1} = \frac{\gamma_{zx_1}(\gamma_{zx_1} \pm \sqrt{\gamma_{zx_1}^2 - 4\gamma_{x_1x_1}\gamma_{zz}}) - 4\gamma_{x_1x_1}\gamma_{zz}}{2\gamma_{zz}}\alpha.$$

From (5.7) and the fact $F_1 \neq 0$, we know that $\alpha \neq 0$. Since $\gamma_{zx_1}^2 - 4\gamma_{x_1x_1}\gamma_{zz} > 0$, we can always choose "+" or "-" in this expression so that this number does not equal zero. Therefore, by a suitable choice of β, we can make the coefficient of z^3 less than zero. So, it is proved that there is feedback such that the reduced dynamic system on the center manifold is asymptotically stable. By the center manifold theorem, the closed-loop system is asymptotically stable. □

Remark. The proof, in fact, shows a method of designing stabilizing feedback for systems in normal form. It is given by

$$u(z, x) = Fx + \alpha z + \beta z^2,$$

where F stabilizes (A_2, B_2). The number α satisfies

$$\alpha = 0 \qquad \text{if } \gamma_{zz} = 0,$$

$$\alpha = \frac{2\gamma_{zz}F_1}{\gamma_{zx_1} \pm \sqrt{\gamma_{zx_1}^2 - 4\gamma_{x_1x_1}\gamma_{zz}}} \qquad \text{if } \gamma_{zz} \neq 0,$$

where the sign is chosen such that

$$\gamma_{zx_1} \pm \sqrt{\gamma_{zx_1}^2 - 4\gamma_{x_1x_1}\gamma_{zz}} \neq 0,$$

$$\gamma_{zx_1}(\gamma_{zx_1} \pm \sqrt{\gamma_{zx_1}^2 - 4\gamma_{x_1x_1}\gamma_{zz}}) - 4\gamma_{x_1x_1}\gamma_{zz} \neq 0.$$

The number β satisfies

$$\beta(\gamma_{zx_1}F_1 - 2\alpha\gamma_{x_1x_1}) > 0,$$

and the absolute value of β is sufficiently large.

6. Conclusion. Problems formulated from the bifurcation viewpoint concerning equilibrium sets, controllability, and stabilizability of control systems are introduced. Normal forms and invariants of control systems are employed in the analysis. The topology of the equilibrium set and the properties such as controllability and stabilizability of a control system point are proved to be closely related to the invariants. The local bifurcations of equilibrium sets are classified, and the set is linearly approximated by a parametrization. Typical diagrams of bifurcation equilibrium sets are shown by examples of systems in normal forms. Sufficient conditions given by invariants for controllability and stabilizability at the points in equilibrium sets are found.

In Part II, the same problems will be addressed for control systems with a single parameter. The equilibrium set is two dimensional. More complex bifurcations occur in this case.

Acknowledgment. The author would like to thank Professor Arthur J. Krener for his creative suggestions and comments.

BIFURCATION AND NORMAL FORM OF NONLINEAR CONTROL SYSTEMS, PART II*

WEI KANG†

Abstract. The normal forms and invariants of control systems with a parameter are found. Bifurcations of equilibrium sets are classified. The changes of properties such as controllability of the linearization or stabilizability near a bifurcation point of a control system are studied.

Key words. nonlinear systems, bifurcations, normal forms, invariants, linearly controllable, stabilizable

1. Introduction. In this paper, we continue the study of bifurcation problems formulated in Part I [10]. We focus on systems with a parameter. Comparing with the results in Part I, systems with a parameter have three types of normal forms instead of two. Another difference is that, in the presence of a parameter, the equilibrium sets are not curves. In fact, they are two-dimensional surfaces in the state-parameter space. In general, there always exists a curve on the equilibrium set such that the system is not linearly controllable at any point on it.

The following nonlinear system with parameter μ is considered:

$$\dot{\xi} = f(\xi, \mu) + g(\xi, \mu)v. \tag{1.1}$$

The variable $\xi \in \mathbb{R}^n$ is the state, $v \in \mathbb{R}$ is the input variable, and the parameter is $\mu \in \mathbb{R}$. The vector fields $f(\xi, \mu)$ and $g(\xi, \mu)$ are assumed to be C^k for some sufficiently large k. Our attention is focused on local bifurcation near the origin $(\xi, \mu) = (0, 0)$. Assume

$$f(0, 0) = 0, \quad g(0, 0) \neq 0.$$

Following Part I, the equilibrium set E is defined to be

$$E = \{(x, \mu) | \exists v_0 \text{ such that } f(x, \mu) + g(x, \mu)v_0 = 0\}. \tag{1.2}$$

The linearization of the system at the origin is (A, B)

$$A = \frac{\partial f}{\partial x}(0, 0), \quad B = g(0, 0).$$

If the system is linearly controllable at $\xi = 0$, $\mu = 0$, then the system is linearly controllable for all equilibrium points in E near $(x, \mu) = (0, 0)$. Therefore, Questions 1–3 formulated in Part I are interesting only if (1.1) is not linearly controllable at the origin. Similar to Part I, we always assume

Assumption.

$$\operatorname{rank}(\begin{bmatrix} B & AB & A^2B & \cdots & A^{n-1}B \end{bmatrix}) = n - 1. \tag{1.3}$$

To classify the equilibrium sets and their bifurcations, it is necessary to introduce normal forms and transformations. For systems with parameters, a transformation consists of a change of coordinates and feedback. Both can be parameter related. More specifically, a transformation is given by

$$\begin{aligned} x &= \phi(\xi,\mu),\\ u &= \alpha(\xi,\mu)+\beta(\xi,\mu)v \end{aligned} \tag{1.4}$$

in which $\frac{\partial\phi}{\partial x}(0,0)$ is nonsingular and $\beta(0,0)\neq 0$. If a transformation is applied to (1.1), denote the equilibrium set of the resulting system by $\bar{E}$. Then, in a neighborhood of $(\xi,\mu)=(0,0)$, a point (ξ,μ) is in E if and only if $(x,\mu)=(\phi(\xi,\mu),\mu)$ is in $\bar{E}$. Therefore, in the sense of diffeomorphism, the transformation (1.4) does not change the equilibrium set E (locally). Furthermore, the change of coordinates and feedback (1.4) does not change the properties of our interest such as controllability (of the linearization) or stabilizability [8].

Following the idea used in Part I, we simplify nonlinear control systems by the transformations of form (1.4). This will be done in section 2. In sections 3–5 the parametrization of equilibrium sets and the controllability at points in E are discussed for systems with different normal forms. In section 6 the problem of stabilizability is addressed for systems with a certain type of normal form. In this paper, the discussion is focused on systems with a control input. For systems without control, the classical bifurcation theory and some interesting applications can be found in [1], [2], [4], and [9].

2. Normal forms and quadratic invariants. The first step of finding normal forms is to simplify the linear part. Since the controllability index of (A,B) is $n-1$, there exists a linear change of coordinates and feedback independent of μ transforming the system (1.1) into

$$\begin{aligned} \dot{z} &= \lambda z+\gamma\mu+O(z,x,\mu,u)^2,\\ \dot{x} &= A_2x+\Gamma\mu+B_2u+O(z,x,\mu,u)^2, \end{aligned} \tag{2.1}$$

where $\Gamma=\begin{bmatrix}\gamma_1 & \gamma_2 & \cdots & \gamma_{n-1}\end{bmatrix}^T$, $x\in\mathbb{R}^{n-1}$, and $z\in\mathbb{R}$. The pair (A_2,B_2) is in Brunovsky form:

$$A_2=\begin{bmatrix} 0 & 1 & 0 & \cdots & 0\\ 0 & 0 & 1 & \cdots & 0\\ \vdots & \vdots & \vdots & \ddots & \vdots\\ 0 & 0 & 0 & \cdots & 1\\ 0 & 0 & 0 & \cdots & 0 \end{bmatrix}_{(n-1)\times(n-1)},\quad B_2=\begin{bmatrix} 0\\ 0\\ \vdots\\ 0\\ 1 \end{bmatrix}_{(n-1)\times 1}.$$

To further simplify the linearization of the system, consider another change of coordinates

$$\begin{aligned} \bar{x}_1 &= x_1,\\ \bar{x}_i &= x_i+\gamma_{i-1}\mu, \quad i=2,\dots,n,\\ \bar{u} &= u+\gamma_n\mu, \end{aligned} \tag{2.2}$$

which transforms system (2.1) into (2.3). For the reason of simplicity, we still use (z,x) and u to represent the state variables and control input for the new system:

$$\begin{aligned} \dot{z} &= \lambda z+\gamma\mu+O(z,x,\mu,u)^2,\\ \dot{x} &= A_2x+B_2u+O(z,x,\mu,u)^2. \end{aligned} \tag{2.3}$$

If $\lambda \neq 0$, the equation for z can be simplified by $\bar{z} = z + \frac{\gamma}{\lambda}\mu$. In the resulting system, the equation for $\bar{z}$ is

$$\dot{\bar{z}} = \lambda \bar{z} + O(\bar{z}, x, \mu, u)^2.$$

If $\lambda = 0$ and $\gamma \neq 0$, the change of coordinate $\bar{z} = \frac{1}{\gamma} z$ transforms the equation for z into

$$\dot{\bar{z}} = \mu + O(\bar{z}, x, \mu, u)^2.$$

The normal forms for the linear part of (1.1) are summarized in the following lemma.

LEMMA 2.1. *Given a system* (1.1) *satisfying assumption* (1.3)*, there exists a linear change of coordinates and feedback which transforms* (1.1) *into one of the following forms:*

$\lambda \neq 0$

$$\begin{aligned} \dot{z} &= \lambda z + f_1^{[2]}(z, x, \mu) + g_1^{[1]}(z, x, \mu)u + O(z, x, \mu, u)^3, \\ \dot{x} &= A_2 x + B_2 u + f_2^{[2]}(z, x, \mu) + g_2^{[1]}(z, x, \mu)u + O(z, x, \mu, u)^3; \end{aligned} \tag{2.4}$$

$\lambda = 0$*, Jordan form*

$$\begin{aligned} \dot{z} &= \mu + f_1^{[2]}(z, x, \mu) + g_1^{[1]}(z, x, \mu)u + O(z, x, \mu, u)^3, \\ \dot{x} &= A_2 x + B_2 u + f_2^{[2]}(z, x, \mu) + g_2^{[1]}(z, x, \mu)u + O(z, x, \mu, u)^3; \end{aligned} \tag{2.5}$$

$\lambda = 0$*, diagonal form*

$$\begin{aligned} \dot{z} &= f_1^{[2]}(z, x, \mu) + g_1^{[1]}(z, x, \mu)u + O(z, x, \mu, u)^3, \\ \dot{x} &= A_2 x + B_2 u + f_2^{[2]}(z, x, \mu) + g_2^{[1]}(z, x, \mu)u + O(z, x, \mu, u)^3. \end{aligned} \tag{2.6}$$

In the normal form, λ is an uncontrollable eigenvalue of the linearization at $(z, x, \mu) = (0, 0, 0)$. If $\lambda = 0$ and if μ is considered as a state variable with $\dot{\mu} = 0$, the matrix of uncontrollable dynamic system is a zero matrix or it can be simplified into a Jordan block. These two cases are shown in (2.5) and (2.6).

The following quadratic transformations are employed to simplify the quadratic part of a system into its normal form while leaving the linear part invariant:

$$\begin{aligned} \begin{bmatrix} \bar{z} & \bar{x} \end{bmatrix}^T &= \begin{bmatrix} z & x \end{bmatrix}^T + \phi^{[2]}(z, x, \mu), \\ \bar{u} &= u + \alpha^{[2]}(z, x, \mu) + \beta^{[1]}(z, x, \mu)u. \end{aligned} \tag{2.7}$$

The normal forms are given in the following theorem. The notation $\tilde{f}^{[2]}(x)$ in the theorem represents the extended controller form (see [10, equation (2.9)], [5], [7]).

THEOREM 2.2. *Consider a control system satisfying assumption* (1.3)*. Suppose that its linearization is in the form given by* (2.4)*,* (2.5)*, or* (2.6)*. Then there exists a quadratic change of coordinates and feedback* (2.7) *which transforms the system into one of the following normal forms.*

(i) *For* (2.4)*, the normal form is*

$$\begin{aligned}\dot{z} &= \lambda z + \sum_{i=1}^{n-1} \gamma_{x_i x_i} x_i^2 + \gamma_{z x_1} z x_1 + \gamma_{x_1 \mu} x_1 \mu + \gamma_{z\mu} z\mu + O(z, x, \mu, u)^3,\\ \dot{x} &= A_2 x + B_2 u + \tilde{f}^{[2]}(x) + O(z, x, \mu, u)^3.\end{aligned} \tag{2.8}$$

(ii) *For* (2.5) *the normal form is*

$$\begin{aligned}\dot{z} &= \mu + \sum_{i=1}^{n-1} \gamma_{x_i x_i} x_i^2 + \gamma_{z x_1} z x_1 + \gamma_{x_1 \mu} x_1 \mu + \gamma_{zz} z^2 + O(z, x, \mu, u)^3,\\ \dot{x} &= A_2 x + B_2 u + \tilde{f}^{[2]}(x) + O(z, x, \mu, u)^3.\end{aligned} \tag{2.9}$$

(iii) *For* (2.6)*, the normal form is*

$$\begin{aligned}\dot{z} &= \sum_{i=1}^{n-1} \gamma_{x_i x_i} x_i^2 + \gamma_{z x_1} z x_1 + \gamma_{x_1 \mu} x_1 \mu + \gamma_{z\mu} z\mu + \gamma_{zz} z^2 + \gamma_{\mu\mu}\mu^2 + O(z, x, \mu, u)^3,\\ \dot{x} &= A_2 x + B_2 u + \tilde{f}^{[2]}(x) + O(z, x, \mu, u)^3.\end{aligned} \tag{2.10}$$

Proof. The theorem shows three quadratic normal forms for systems with different linearizations. We prove them separately.

(i) Suppose the linearization has the same form as (2.4). We consider the following extended system in which μ is treated as a state variable:

$$\begin{aligned}\dot{z} &= \lambda z + f_1^{[2]}(z, x, \mu) + g_1^{[1]}(z, x, \mu)u + O(z, x, \mu, u)^3,\\ \dot{x} &= A_2 x + B_2 u + f_2^{[2]}(z, x, \mu) + g_2^{[1]}(z, x, \mu)u + O(z, x, \mu, u)^3,\\ \dot{\mu} &= 0.\end{aligned}$$

By the result in [6], there exists a quadratic transformation

$$\begin{aligned} z &= \bar{z} + \phi_1^{[2]}(\bar{z}, \bar{x}, \bar{\mu}), \quad x = \bar{x} + \phi_2^{[2]}(\bar{z}, \bar{x}, \bar{\mu}),\\ \mu &= \bar{\mu} + \phi_3^{[2]}(\bar{z}, \bar{x}, \bar{\mu}), \quad u = \bar{u} + \alpha^{[2]}(\bar{z}, \bar{x}, \bar{\mu}) + \beta(\bar{z}, \bar{x}, \bar{\mu})\bar{u}\end{aligned}$$

so that, under the new coordinates, the dynamics of $\bar{z}$ and $\bar{x}$ are in their quadratic normal forms given in [6], which are

$$\begin{aligned}\dot{\bar{z}} &= \lambda \bar{z} + \sum_{i=1}^{n-1} \gamma_{x_i x_i} \bar{x}_i^2 + \gamma_{z x_1} \bar{z}\bar{x}_1 + \gamma_{x_1 \mu} \bar{x}_1 \bar{\mu} + \gamma_{z\mu} \bar{z}\bar{\mu} + O(\bar{z}, \bar{x}, \bar{\mu}, \bar{u})^2,\\ \dot{\bar{x}} &= A\bar{x} + B\bar{u} + \tilde{f}^{[2]}(\bar{x}) + O(\bar{z}, \bar{x}, \bar{\mu}, \bar{u})^3.\end{aligned} \tag{2.11}$$

Since transformation (2.7) does not change the last variable μ, we substitute the relation

$$\mu = \bar{\mu} + \phi_3^{[2]}(\bar{z}, \bar{x}, \bar{\mu})$$

back into (2.11). It is obvious that this will not change the linear and quadratic parts in the dynamics of $\bar{z}$ and $\bar{x}$. Notice that the system (2.11) is in the same form as (2.8).

(ii) If a system has the same linearization as (2.5), the results in [6] do not provide a complete normal form for the system since the linearization of the uncontrollable part (including the dynamics of z and μ) is not diagonal. To simplify the proof by using results in [6], let's assume that $\mu = 0$. Then, system (2.5) is

$$\begin{aligned}\dot{z} &= f_1^{[2]}(z,x,0) + g_1^{[1]}(z,x,0)u + O(z,x,u)^3,\\ \dot{x} &= A_2x + B_2u + f_2^{[2]}(z,x,0) + g_2^{[1]}(z,x,0)u + O(z,x,u)^3.\end{aligned}$$

By a suitable transformation

$$\begin{aligned}&\bar{z} = z + \phi_1^{[2]}(z,x), \quad \bar{x} = x + \phi_2^{[2]}(z,x),\\ &\bar{u} = u + \alpha^{[2]}(z,x) + \beta^{[2]}(z,x)u,\end{aligned} \tag{2.12}$$

the system can be transformed into the following normal form given in [6]. To simplify the notation, we still use (z,x) instead of $(\bar{z},\bar{x})$ as the state variables:

$$\begin{aligned}\dot{z} &= \sum_{i=1}^{n-1}\gamma_{x_ix_i}x_i^2 + \gamma_{zx_1}zx_1 + \gamma_{zz}z^2 + O(z,x,u)^3,\\ \dot{x} &= A_2x + B_2u + \tilde{f}^{[2]}(x) + O(z,x,u)^3.\end{aligned}$$

So, transformation (2.12) transforms (2.5) into

$$\begin{aligned}\dot{z} &= \mu + \sum_{i=1}^{n-1}\gamma_{x_ix_i}x_i^2 + \gamma_{zx_1}zx_1 + \gamma_{zz}z^2 + \gamma_{z\mu}z\mu\\ &\quad + \sum_{i=1}^{n-1}b_{x_i\mu}x_i\mu + \gamma_{\mu\mu}\mu^2 + b_{\mu u}\mu u + O(z,x,\mu,u)^3,\\ \dot{x} &= A_2x + B_2u + \tilde{f}^{[2]}(x) + d_{z\mu}z\mu + \sum_{i=1}^{n-1}d_{x_i\mu}x_i\mu + d_{\mu\mu}\mu^2 + d_{\mu u}\mu u + O(z,x,\mu,u)^3,\end{aligned} \tag{2.13}$$

where $d_{z\mu}$, $d_{x_i\mu}$, $d_{\mu\mu}$, and $d_{\mu u}$ are constant vectors of dimension $n-1$. By a transformation $\bar{z} = z - b_{\mu u}\mu x_{n-1}$, $\bar{x} = x - d_{\mu u}\mu x_{n-1}$ the quadratic part μu in (2.13) can be cancelled. So, we focus on a system of the following form:

$$\begin{aligned}\dot{z} &= \mu + \sum_{i=1}^{n-1}\gamma_{x_ix_i}x_i^2 + \gamma_{zx_1}zx_1 + \gamma_{zz}z^2 + \gamma_{z\mu}z\mu + \sum_{i=1}^{n-1}b_{x_i\mu}x_i\mu + \gamma_{\mu\mu}\mu^2 + O(z,x,\mu,u)^3,\\ \dot{x} &= A_2x + B_2u + \tilde{f}^{[2]}(x) + d_{z\mu}z\mu + \sum_{i=1}^{n-1}d_{x_i\mu}x_i\mu + d_{\mu\mu}\mu^2 + O(z,x,\mu,u)^3.\end{aligned} \tag{2.14}$$

Let's consider a transformation

$$\bar{z} = z, \quad \bar{x} = x + \phi^{[2]}(z,x,\mu), \quad \bar{u} = u + \alpha^{[2]}(z,x,\mu) + \beta^{[1]}(z,x,\mu)u, \tag{2.15}$$

where $\phi^{[2]}(z,x,0) = 0$ and $\alpha^{[2]}(z,x,0) = 0$. To leave B_2 invariant, we also assume

$$\frac{\partial\phi_i^{[2]}}{\partial x_{n-1}} = 0 \tag{2.16}$$

for all $1 \le i \le n-2$, where $\phi_i^{[2]}$ is the ith component of $\phi^{[2]}$. By the separation principle in [6], this transformation will not change the quadratic part of the uncontrollable

dynamic system (the equation of z); it will not change the normal form $\tilde{f}^{[2]}$. Only the quadratic part related to μ in the controllable dynamic system is affected by this transformation. Denote by $f_\mu(z,x,\mu)$ the quadratic terms with μ in the dynamics of x in (2.14)

$$f_\mu(z,x,\mu) = d_{z\mu} z\mu + \sum_{i=1}^{n-1} d_{x_i\mu} x_i \mu + d_{\mu\mu}\mu^2. \tag{2.17}$$

Similarly, if the transformation (2.15) is applied to (2.14), the quadratic terms with μ in the resulting dynamics of $\bar{x}$ is denoted by $\bar{f}_\mu(z,x,\mu)$. The relation between f_μ and $\bar{f}_\mu$ is defined by the following homological equation from [6]:

$$\bar{f}_\mu + \Pi(\phi^{[2]}, \alpha^{[2]}) = f_\mu, \tag{2.18}$$

where Π is the linear operator

$$\Pi(\phi^{[2]}, \alpha^{[2]}) = \frac{\partial \phi^{[2]}}{\partial x} A_2 x + \frac{\partial \phi^{[2]}}{\partial z}\mu - A_2\phi^{[2]} - B_2\alpha^{[2]}.$$

Define a linear space W to be the space consisting of quadratic vectors f_μ in the form of (2.17). Define V to be a linear space consisting of the elements $(\phi^{[2]}, \alpha^{[2]})$ satisfying (2.16). Then Π is a linear map from V to W. The kernel of Π is

$$\ker(\Pi) = \left\{ (\phi^{[2]}, \alpha^{[2]}) \;\middle|\; \begin{array}{l} \phi_1^{[2]} = a_1 z\mu + a_2 x_1 \mu + a_3 \mu^2 \\ \\ \phi_i^{[2]} = \dfrac{\partial \phi_{i-1}^{[2]}}{\partial x} A_2 x + \dfrac{\partial \phi_{i-1}^{[2]}}{\partial z}\mu \;\text{ for }\; i = 1,\ldots,n-1 \\ \\ \alpha^{[2]} = \dfrac{\partial \phi_{n-1}^{[2]}}{\partial x} A_2 x + \dfrac{\partial \phi_{n-1}^{[2]}}{\partial z}\mu \end{array} \right\}.$$

Therefore, the dimension of $\ker(\Pi)$ is 3. The dimension of the image space under Π is $\dim(\Pi(V)) = \dim(V) - \dim(\ker(\Pi)) = n^2 - 1 = \dim(W)$. This implies that the map Π is onto. So, there exists a transformation given by $(\phi^{[2]}, \alpha^{[2]})$ in V which solves the homological equation (2.18) for $\bar{f}_\mu = 0$. Therefore, the vector field f_μ can be cancelled. By the homological equations of $g^{[1]}$ in [6] and condition (2.16), a suitable choice of $\beta(z,x,\mu)$ will avoid the quadratic terms involving u. Therefore, the system can be simplified into the following form without f_μ:

$$\begin{aligned} \dot{z} &= \mu + \sum_{i=1}^{n-1} \gamma_{x_i x_i} x_i^2 + \gamma_{z x_1} z x_1 + \gamma_{zz} z^2 + \gamma_{z\mu} z\mu + \sum_{i=1}^{n-1} b_{x_i\mu} x_i \mu + \gamma_{\mu\mu}\mu^2 + O(z,x,\mu,u)^3, \\ \dot{x} &= A_2 x + B_2 u + \tilde{f}^{[2]}(x) + O(z,x,\mu,u)^3. \end{aligned} \tag{2.19}$$

In the system, all quadratic parts are in normal forms except the terms with μ in the equation of z. This part can be simplified by

$$\bar{z} = z + \sum_{i=1}^{n-2} c_{x_i\mu} x_i \mu + c_{z\mu} z\mu + c_{\mu\mu}\mu^2 + c_{zz} z^2. \tag{2.20}$$

By the separation principle in [6], this transformation does not change the terms in the controllable part. The equation of z is transformed into

$$\begin{aligned}\dot{\tilde{z}} &= \mu + \sum_{i=1}^{n-1} \gamma_{x_i x_i} x_i^2 + \gamma_{z x_1} z x_1 + \gamma_{zz} z^2 + \gamma_{z\mu} z\mu + \sum_{i=1}^{n-1} b_{x_i\mu} x_i \mu + \gamma_{\mu\mu}\mu^2 \\ &+ \sum_{i=2}^{n-1} c_{x_{i-1}\mu} x_i \mu + c_{z\mu}\mu^2 + 2c_{zz} z\mu + O(z,x,\mu)^3.\end{aligned} \tag{2.21}$$

By choosing the transformation such that $b_{x_i\mu} = -c_{x_{i-1}\mu}$ for $2 \le i \le n-1$, $\gamma_{\mu\mu} = -c_{z\mu}$, and $\gamma_{z\mu} = -2c_{zz}$, the quadratic part of system (2.19) can be simplified into the normal form (2.9).

(iii) The argument similar to the proof of (i) can be applied to (iii). Given a system (2.6). If μ is considered as a state variable, the extended system is in the following form:

$$\begin{aligned}\dot{z} &= f_1^{[2]}(z,x,\mu) + g_1^{[1]}(z,x,\mu)u + O(z,x,\mu,u)^3, \\ \dot{x} &= A_2 x + B_2 u + f_2^{[2]}(z,x,\mu) + g_2^{[1]}(z,x,\mu)u + O(z,x,\mu,u)^3, \\ \dot{\mu} &= 0.\end{aligned}$$

From [6], this system can be simplified into a normal form

$$\begin{aligned}\dot{\bar{z}} &= \sum_{i=1}^{n-1} \gamma_{x_i x_i} \bar{x}_i^2 + \gamma_{z x_1} \bar{z}\bar{x}_1 + \gamma_{x_1\mu}\bar{x}_1\bar{\mu} + \gamma_{z\mu}\bar{z}\bar{\mu} + \gamma_{zz}\bar{z}^2 + \gamma_{\mu\mu}\bar{\mu}^2 + O(\bar{z},\bar{x},\bar{\mu},\bar{u})^3, \\ \dot{\bar{x}} &= A\bar{x} + B\bar{u} + \tilde{f}^{[2]}(\bar{x}) + O(\bar{z},\bar{x},\bar{\mu},\bar{u})^3.\end{aligned} \tag{2.22}$$

The quadratic transformation is

$$\begin{aligned}\bar{z} &= z + \phi_1^{[2]}(z,x,\mu), \quad \bar{x} = x + \phi_2^{[2]}(z,x,\mu), \\ \bar{\mu} &= \mu + \phi_3^{[2]}(z,x,\mu), \quad \bar{u} = u + \alpha^{[2]}(z,x,\mu) + \beta(z,x,\mu)u.\end{aligned}$$

Since the transformation for our purpose does not change μ, we substitute $\bar{\mu} = \mu + \phi_3^{[2]}(z,x,\mu)$ back into (2.22). It is easy to see that this will not change the linear and quadratic parts of the dynamics of z and x. Notice that the system (2.22) is in the same form as (2.10). □

In Part I, it is shown that the normal form of a system is completely determined by the invariants. The computation of invariants is straightforward. This implies that, given a control system, the normal form can be found without finding the change of coordinates. A similar result holds for systems with parameters, which is proved in the rest of the section. For the reason of simplicity, we assume that the linearization of the system is in the form of (2.4)–(2.6). The parameter μ is treated as a state variable such that $\dot{\mu} = 0$. In the following, the *extended system* (including the original system and $\dot{\mu} = 0$) is denoted by

$$\dot{x}_e = f_e(x_e) + g_e(x_e)u. \tag{2.23}$$

If a system is in one of the forms given by (2.4)–(2.6), then the extended system (2.23) has state variables

$$x_e = \begin{bmatrix} z & x & \mu \end{bmatrix}^T.$$

Denote by C_z, C_x, X_z, and X_μ the following row and column vectors in $\mathbb{R}^{n+1}$:

$$\begin{aligned} C_z &= \begin{bmatrix} 1 & 0 & 0 & \cdots 0 \end{bmatrix}, \quad C_x = \begin{bmatrix} 0 & 1 & 0 & \cdots & 0 \end{bmatrix}, \\ X_z &= \begin{bmatrix} 1 & 0 & 0 & \cdots 0 \end{bmatrix}^T, \quad X_\mu = \begin{bmatrix} 0 & 0 & \cdots & 0 & 1 \end{bmatrix}^T. \end{aligned} \tag{2.24}$$

The linearization of the extended system at $z = 0, x = 0, \mu = 0$ is denoted by (A_e, B_e),

$$A_e = \left.\frac{\partial f_e}{\partial x_e}\right|_{z=0,x=0,\mu=0}, \quad B_e = g_e(0).$$

DEFINITION 2.3. *Given a control system satisfying* (1.3)*. Suppose that its linearization is in the form of* (2.4)–(2.6)*. The quadratic invariants are defined to be*

$$\begin{aligned} a_{tr} &= \frac{1}{2}\, C_x A_e^{t-1}[ad_{f_e}^r(g_e), ad_{f_e}^{r-1}(g_e)]\Big|_{z=0,x=0,\mu=0}, \qquad \begin{matrix} 1 \le r \le n-3, \\ 1 \le t \le n-r-2, \end{matrix} \\ \gamma_{x_{n-r}x_{n-r}} &= \frac{1}{2}\, C_z[ad_{f_e}^r(g_e), ad_{f_e}^{r-1}(g_e)]\Big|_{z=0,x=0,\mu=0}, \quad 1 \le r \le n-1, \\ \gamma_{zx_1} &= (-1)^{n-1}\, C_z[X_z, ad_{f_e}^{n-1}(g_e)]\Big|_{z=0,x=0,\mu=0}, \\ \gamma_{x_1\mu} &= (-1)^{n-1}\, C_z[X_\mu, ad_{f_e}^{n-1}(g_e)]\Big|_{z=0,x=0,\mu=0}, \end{aligned} \tag{2.25}$$

and for (2.8)

$$\gamma_{z\mu} = C_z ad_{X_z} ad_{X_\mu}(f)\big|_{z=0,x=0,\mu=0}, \tag{2.26}$$

for (2.9)

$$\gamma_{zz} = \frac{1}{2} C_z ad_{X_z}^2(f)\Big|_{z=0,x=0,\mu=0}, \tag{2.27}$$

for (2.10)

$$\begin{aligned} \gamma_{z\mu} &= C_z ad_{X_z} ad_{X_\mu}(f)\big|_{z=0,x=0,\mu=0}, \\ \gamma_{zz} &= \frac{1}{2} C_z ad_{X_z}^2(f)\Big|_{z=0,x=0,\mu=0}, \\ \gamma_{\mu\mu} &= \frac{1}{2} C_z ad_{X_\mu}^2(f)\Big|_{z=0,x=0,\mu=0}. \end{aligned} \tag{2.28}$$

THEOREM 2.4. *Given a system satisfying* (1.3)*, suppose its linearization is one of* (2.4)–(2.6)*.*

(i) *Quadratic transformations defined by* (2.7) *do not change the values of the quadratic invariants.*

(ii) *The quadratic invariants of normal form* (2.8)–(2.10) *are the corresponding coefficients of the quadratic terms.*

Proof. (i) The quadratic invariants a_{tr}, $\gamma_{x_ix_i}$, γ_{zx_1}, and $\gamma_{x_1\mu}$ are defined in the same way as the invariants for systems without parameters because the parameters

in the system are treated as state variables. Following the same argument used in the proof of Theorem 2.1 in Part I, one can prove that a_{tr}, $\gamma_{x_i x_i}$, $\gamma_{z x_1}$, and $\gamma_{x_1 \mu}$ are invariant under the quadratic change of coordinates and feedback (2.7). For systems in the form of (2.4), $\gamma_{z\mu}$ is the coefficient of $z\mu$ in the uncontrollable dynamics, which is a resonant term (see, for instance, [3]). It cannot be changed by change of coordinates of the form

$$\bar{z} = z + \phi^{[2]}(z, \mu).$$

By the separation principle in [6], the coefficient of resonant term does not change under any quadratic transformation of the form (2.7). Similarly, one can prove that, for system (2.6), γ_{zz}, $\gamma_{z\mu}$, and $\gamma_{\mu\mu}$ are invariant under the quadratic transformations because they are the coefficients of resonant terms. If system (2.5) is under consideration, (2.21) shows that γ_{zz} is invariant under (2.20). By the separation principle in [6], transformations other than (2.20) do not change the coefficient γ_{zz}.

(ii) By the definition of invariants, it is obvious that $\gamma_{z\mu}, \gamma_{zz}$, and $\gamma_{\mu\mu}$ are the coefficients of $z\mu$, z^2, and μ^2, respectively. For the other invariants, we will prove the result for system (2.9). The other two cases are similar. Keep in mind that the state variables are in the order of z, x, μ for the extended system. The Lie brackets of f_e and g_e are

$$\begin{aligned} ad^r_{f_e}(g_e) = (-1)^r[\overbrace{0 \quad \cdots \quad 0 \quad 1}^{n-r} \quad 0 \quad \cdots \quad 0] \\ +(-1)^r[\overbrace{2\gamma_{x_{n-r}x_{n-r}}x_{n-r} \quad 2a_{1\,r}x_{n-r} \quad \cdots \quad 2a_{n-r-2\,r}x_{n-r}}^{n-r-1} \quad 0 \quad \cdots \quad 0] \\ +h_r(x_{n-r+1}, x_{n-r+2}, \ldots, x_{n-1}) + O(z, x, \mu)^2 \end{aligned}$$

for $1 \le r < n-2$. Furthermore,

$$\begin{aligned} ad^{n-2}_{f_e}(g_e) = (-1)^{n-2} \left(\begin{bmatrix} 0 & 1 & 0 & \cdots & 0 \end{bmatrix}^T + \begin{bmatrix} 2\gamma_{x_2x_2}x_2 & 0 & 0 & \cdots & 0 \end{bmatrix}^T \right) \\ +h_{n-2}(x_3, x_4, \ldots, x_{n-1}) + O(z, x, \mu)^2 \end{aligned}$$

and

$$\begin{aligned} ad^{n-1}_{f_e}(g_e) = (-1)^{n-1} \begin{bmatrix} 2\gamma_{x_1x_1}x_1 + \gamma_{zx_1}z + \gamma_{x_1\mu}\mu \\ 0 \\ \vdots \\ 0 \end{bmatrix} \\ +h_{n-1}(x_2, x_3, \ldots, x_{n-1}) + O(z, x, \mu)^2. \end{aligned}$$

Substituting these relations into the right side of (2.25), they are equal to the corresponding coefficients. □

Given a system satisfying assumption (1.3), the linear part of the system can be transformed into a system in one of the forms given by (2.4), (2.5), or (2.6). They have different bifurcation patterns which are addressed in the following sections.

3. Systems with $\lambda \neq 0$. In this section, we assume that the uncontrollable mode λ is not zero. By a linear change of coordinates, such systems can be transformed into (2.4). The main theorem in this section gives a parametrization of the equilibrium

set and the answer to Question 2 in Part I, namely, the controllability of the system at points in E.

THEOREM 3.1. *Consider a system of form* (2.4).

(i) *The equilibrium set E satisfies*

$$\begin{aligned} &x_1 = \nu, \\ &z = O(\nu,\mu)^2, \\ &x_i = O(\nu,\mu)^2, \quad 2 \le i \le n-1. \end{aligned} \tag{3.1}$$

(ii) *There exists a function $c(x_1,\mu)$ in the following form:*

$$c(x_1,\mu) = 2\gamma_{x_1x_1}x_1 + \gamma_{x_1\mu}\mu + O(x_1,\mu)^2 \tag{3.2}$$

such that the system is linearly controllable at $(z,x,\mu) \in E$ if and only if $c(x_1,\mu) \neq 0$.

Remark. The theorem implies that the equilibrium set is a two-dimensional manifold. At the origin, the manifold is tangent to the $x_1\mu$-space. For any fixed μ_0, the set of equilibrium points with $\mu = \mu_0$ is a smooth curve in the state space. Therefore, the equilibrium set does not have bifurcation. However, part (ii) of Theorem 3.1 shows that the controllability of the system changes as the equilibrium points are varied. In fact, if $\gamma_{x_1x_1}^2 + \gamma_{x_1\mu}^2 \neq 0$, the system is linearly controllable at all the equilibrium points in E except a one-dimensional submanifold. This submanifold is tangent to the subspace

$$2\gamma_{x_1x_1}x_1 + \gamma_{x_1\mu}\mu = 0$$

at the origin. If both $\gamma_{x_1x_1}$ and $\gamma_{x_1\mu}$ are zero, the controllability of the system depends on the higher degree terms.

Remark. If $\gamma_{x_1x_1} \neq 0$, then the submanifold $c(x_1,\mu) = 0$ is transversal to the set $E_0 = \{(x,0) \in E\}$. Therefore, the system is always linearly controllable at any equilibrium point in E_0 except the origin. This is actually the result shown in Theorem 4.1 in Part I.

Example. To show a typical example, we consider the following system in normal form:

$$\begin{aligned} \dot z &= -z + 5x_1^2 + x_2^2 + zx_1 + z\mu - 10x_1\mu, \\ \dot x_1 &= x_2, \\ \dot x_2 &= u. \end{aligned}$$

The equilibrium set is

$$x_2 = 0, \quad z = -\frac{5x_1^2 - 10x_1\mu}{-1 + x_1 + \mu}.$$

This manifold is tangent to $x_1\mu$-plane at the origin. In $zx_1\mu$-space, the graph of E is a saddle as shown in Figure 3.1. The curve on the surface E is the subset satisfying the condition $c(x_1,\mu) = 0$, where

$$c(x_1,\mu) = 10x_1 - \frac{5x_1^2 - 10x_1\mu}{-1 + x_1 + \mu} - 10\mu.$$

The system is not linearly controllable at the points on the curve.

Proof of Theorem 3.1. (i) Given any quadratic change of coordinates and feedback (2.7), under the new coordinates, the equations in (3.1) are equivalent to

$$\bar x_1 = \bar\nu, \quad \bar z = O(\bar\nu,\mu)^2, \quad x_i = O(\bar\nu,\mu)^2,$$

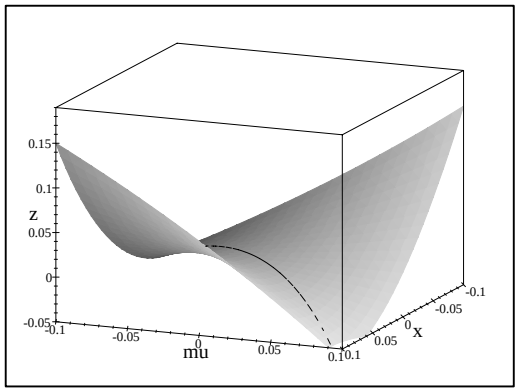

FIG. 3.1. *The equilibrium set in $zx_1\mu$-space.*

which have the same form as (3.1). Therefore, property (i) of Theorem 3.1 is invariant under quadratic transformations. To prove (i), it is enough to show the result for systems in the normal form. Consider system (2.8); it is obvious that a point in the equilibrium set satisfies

$$\begin{aligned} &x_i + O(z,x,\mu)^2 = 0, \quad 2 \le i \le n-1, \\ &\lambda z + O(z,x,\mu)^2 = 0. \end{aligned}$$

The solution of these equations for x_i, $i = 2, \ldots, n-1$ and z is in the form of (3.1).

(ii) Once again, we only prove the result for normal forms since the controllability and the linear part of $c(x_1,\mu)$ are invariant under quadratic transformations. Modulo higher degree terms, the matrix A and B in the linearization of (2.8) at any point $(z,x,\mu) \in E$ satisfies

$$A = \begin{bmatrix} \lambda & 0 \\ 0 & A_2 \end{bmatrix}$$

$$+ \begin{bmatrix} \gamma_{zx_1}x_1 + \gamma_{z\mu}\mu & 2\gamma_{x_1x_1}x_1 + \gamma_{zx_1}z + \gamma_{x_1\mu}\mu & 2\gamma_{x_2x_2}x_2 & 2\gamma_{x_3x_3}x_3 & \cdots & 2\gamma_{x_{n-1}x_{n-1}}x_{n-1} \\ 0 & 0 & 0 & 2a_{1\,n-3}x_3 & \cdots & 2a_{1\,1}x_{n-1} \\ \vdots & \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & 0 & \cdots & 2a_{n-3\,1}x_{n-1} \\ 0 & 0 & 0 & 0 & \cdots & 0 \\ 0 & 0 & 0 & 0 & \cdots & 0 \end{bmatrix},$$

$$B = \begin{bmatrix} 0 & 0 & \cdots & 1 \end{bmatrix}^T + O(z,x_1,\mu)^2.$$

From relation (3.1), the matrix A satisfies

$$A = \begin{bmatrix} \lambda & 0 \\ 0 & A_2 \end{bmatrix} + \begin{bmatrix} \gamma_{zx_1}x_1 + \gamma_{z\mu}\mu & 2\gamma_{x_1x_1}x_1 + \gamma_{x_1\mu}\mu & 0 \\ 0 & 0 & 0 \end{bmatrix}_{n\times n} + O(x_1,\mu)^2 \ .$$

Therefore, the controllability matrix at an equilibrium point is

$$\begin{bmatrix} B & AB & \cdots & A^{n-1}B \end{bmatrix} = \begin{bmatrix} 0 & 2\gamma_{x_1x_1}x_1 + \gamma_{x_1\mu}\mu \\ J & 0 \end{bmatrix} + O(x_1,\mu)^2,$$

where

$$J = \begin{bmatrix} 0 & 0 & \cdots & 1 \\ \vdots & \vdots & & \vdots \\ 0 & 1 & \cdots & 0 \\ 1 & 0 & \cdots & 0 \end{bmatrix}. \tag{3.3}$$

By suitable row and column operations, all the quadratic and higher degree terms can be cancelled except the element at the up right corner; the resulting matrix is

$$R = \begin{bmatrix} 0 & c(x_1, \mu) \\ J & 0 \end{bmatrix},$$

and $c(x_1, \mu)$ satisfies

$$c(x_1, \mu) = 2\gamma_{x_1 x_1} x_1 + \gamma_{x_1 \mu}\mu + O(x_1, \mu)^2.$$

It is obvious that the matrix R has full rank (i.e., the system is linearly controllable) if and only if $c(x_1, \mu) \neq 0$. This proves the second part of the theorem.

4. Systems with $\boldsymbol{\lambda = 0}$ and Jordan form in the uncontrollable dynamics. In this section, we consider system (2.5). In this case, the values of x_1 and z are used as the parameters of the equilibrium set E. Furthermore, since the transformation (2.7) does not change μ, all the quadratic terms in the parametric equation of μ can be found. The bifurcation addressed in the present section has a natural relation with the saddle node bifurcation of dynamic systems. Consider system (2.9) without cubic terms. Then $x = 0$ defines the zero dynamics of the system for output $y = x_1$. From the normal form (2.9), it is easy to show that its zero dynamics have a saddle node bifurcation at the origin.

THEOREM 4.1. *Given a system* (2.5)*, we have the following conditions.*

(i) *Its equilibrium set satisfies*

$$\begin{aligned} &x_1 = \nu_1, \\ &z = \nu_2, \\ &\mu = -\gamma_{x_1 x_1}\nu_1^2 - \gamma_{z x_1}\nu_1\nu_2 - \gamma_{zz}\nu_2^2 + O(\nu_1, \nu_2)^3, \\ &x_i = O(\nu_1, \nu_2)^2, \qquad\qquad 2 \leq i \leq n-1. \end{aligned} \tag{4.1}$$

(ii) *There exists a function $c(z, x_1)$ in the form*

$$c(z, x_1) = \gamma_{z x_1} z + 2\gamma_{x_1 x_1} x_1 + O(z, x_1)^2 \tag{4.2}$$

such that the system is linearly controllable at a point $(z, x, \mu) \in E$ if and only if $c(z, x_1) \neq 0$.

Remark. The projection of E to $zx_1\mu$-space is approximately a quadratic surface. It is a paraboloid or a saddle. In fact, if the matrix

$$Q_1 = \begin{bmatrix} \gamma_{x_1 x_1} & \dfrac{\gamma_{z x_1}}{2} \\ \dfrac{\gamma_{z x_1}}{2} & \gamma_{zz} \end{bmatrix} \tag{4.3}$$

is sign definite ($\det(Q_1) > 0$), E is approximately a paraboloid. If (4.3) is not sign definite but it has full rank ($\det(Q_1) < 0$), E is approximately a saddle. In any case, E has bifurcation near $\mu = 0$. More specifically, we define

$$E_{\mu_0} = \{(x, \mu) \in E | \mu = \mu_0\}. \tag{4.4}$$

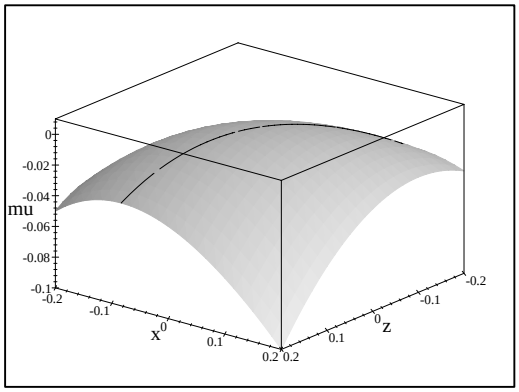

FIG. 4.1. *The equilibrium set in $zx_1\mu$-space.*

Then the topology of E_μ changes as μ passing through zero. If E is approximately a paraboloid, E_μ is empty for the values of μ on one side of zero, and it is a closed curve if μ is on the other side. If E is approximately a saddle, then E_μ is approximately two lines which meet at the origin for $\mu = 0$. It is a connected set. However, E_μ is approximately a hyperbola for $\mu \neq 0$ which is not a connected set. In the following, two examples are given to show the bifurcation diagrams of systems in normal form with $\det(Q_1) > 0$ and $\det(Q_1) < 0$.

Example. Consider the system

$$\begin{aligned} z &= \mu + x_1^2 + x_2^2 + zx_1 + x_1\mu + z^2, \\ \dot{x}_1 &= x_2, \\ \dot{x}_2 &= u. \end{aligned} \tag{4.5}$$

It is easy to check that $\det(Q_1) = 3/4$. Therefore, the graph of E is a paraboloid. In fact, the equilibrium set is

$$x_2 = 0, \quad \mu = -\frac{x_1^2 + zx_1 + z^2}{1 + x_1}.$$

The function $c(z, x_1)$ is

$$c(z, x_1) = 2x_1 + z - \frac{x_1^2 + zx_1 + z^2}{1 + x_1}.$$

The graph of E and the curve $c(z, x_1) = 0$ on E is shown in Figure 4.1. The system is linearly controllable at all points in E except the equilibria on the curve given by $c(z, x_1) = 0$.

From Figure 4.1, the bifurcation of E is obvious. If $\mu > 0$, the set E_μ is empty. If $\mu < 0$, the set E_μ is a closed curve around the origin.

Example. Consider the system

$$\begin{aligned} z &= \mu - x_1^2 + x_2^2 + zx_1 + x_1\mu + z^2, \\ \dot{x}_1 &= x_2, \\ \dot{x}_2 &= u. \end{aligned} \tag{4.6}$$

It is easy to check that $\det(Q_1) = -5/4$. Therefore, the graph of E is a saddle. In fact, the equilibrium set is

$$x_2 = 0, \quad \mu = -\frac{-x_1^2 + zx_1 + z^2}{1 + x_1}.$$

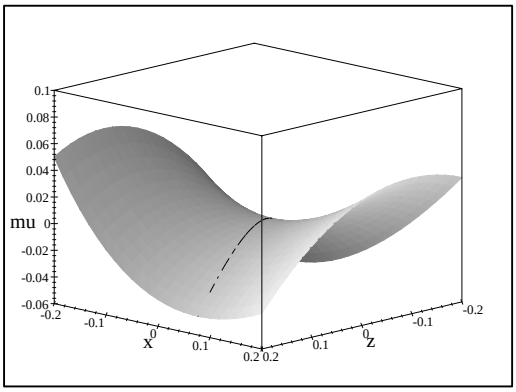

FIG. 4.2. *The equilibrium set in $zx_1\mu$-space.*

The function $c(z, x_1)$ is

$$c(z, x_1) = -2x_1 + z - \frac{-x_1^2 + zx_1 + z^2}{1 + x_1}.$$

The graph of E and the curve $c(z, x_1) = 0$ on E are shown in Figure 4.2. The system is linearly controllable at all points in E except the equilibria on the curve $c(z, x_1) = 0$.

The bifurcation of E is different from the previous example. In this case, E_μ consists of two lines through the origin when $\mu = 0$. If $\mu \neq 0$, the set E_μ is a hyperbola.

Proof of Theorem 4.1. (i) Modulo the higher degree terms in (4.1) $(O(\nu_1, \nu_2)^3$ in the equation of μ and $O(\nu_1, \mu_2)^2$ in the equations of x_i, $i = 2, \ldots, n-1)$, the functions are invariant under transformation (2.7). Therefore, we consider only a system in normal form, which is (2.9). Any point in the equilibrium set satisfies

$$u = O(x_1, \mu)^2, \quad x_i = O(x_1, \mu)^2, \quad 2 \leq i \leq n-1. \tag{4.7}$$

Substituting this relation into the equation

$$\mu + \sum_{i=1}^{n-1} \gamma_{x_i x_i} x_i^2 + \gamma_{z x_1} z x_1 + \gamma_{x_1 \mu} x_1 \mu + \gamma_{zz} z^2 + O(z, x, \mu, u)^3 = 0$$

we get

$$\mu + \gamma_{x_1 x_1} x_1 + \gamma_{z x_1} z x_1 + \gamma_{x_1 \mu} x_1 \mu + \gamma_{zz} z^2 + O(z, x_1, \mu)^3 = 0.$$

Define $x_1 = \nu_1$ and $z = \nu_2$. The equation has a unique solution for μ near $\mu = 0$, and its solution is in the form of (4.1).

(ii) Based on (4.1), the linearization of system (2.9) at a point in E is

$$A = \begin{bmatrix} \gamma_{z x_1} x_1 + 2\gamma_{zz} z & 2\gamma_{x_1 x_1} x_1 + \gamma_{z x_1} z & 0 & 0 & \cdots & 0 \\ 0 & 0 & 1 & 0 & \cdots & 0 \\ \vdots & \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & 0 & \cdots & 1 \\ 0 & 0 & 0 & 0 & \cdots & 0 \end{bmatrix} + O(z, x_1)^2, \tag{4.8}$$

$$B = \begin{bmatrix} 0 & 0 & \cdots & 1 \end{bmatrix}^T + O(z, x_1)^2.$$

The controllability matrix is

$$R = \begin{bmatrix} 0 & \gamma_{zx_1} z + 2\gamma_{x_1x_1} x_1 \\ J & 0 \end{bmatrix} + O(z, x_1)^2, \tag{4.9}$$

where J is a matrix defined in (3.3). By elementary matrix operations, the rank of the matrix equals the rank of a matrix in the following form:

$$\begin{bmatrix} 0 & c(z, x_1) \\ J & 0 \end{bmatrix},$$

where the function $c(z, x_1)$ is in the form of (4.2). Therefore, the system is linearly controllable if and only if $c(z, x_1) \neq 0$. □

5. Systems with $\lambda = 0$ and diagonal form in uncontrollable dynamics. Comparing with the previous section, the systems considered in this section have a fundamental difference. The linear part in the uncontrollable dynamic system is zero. To find a parametrization for the set E, the matrix of the quadratic part in the uncontrollable dynamics is very important. This matrix for normal form (2.10) is

$$Q = \begin{bmatrix} \gamma_{zz} & \frac{1}{2}\gamma_{zx_1} & \frac{1}{2}\gamma_{z\mu} \\ \frac{1}{2}\gamma_{zx_1} & \gamma_{x_1x_1} & \frac{1}{2}\gamma_{x_1\mu} \\ \frac{1}{2}\gamma_{z\mu} & \frac{1}{2}\gamma_{x_1\mu} & \gamma_{\mu\mu} \end{bmatrix}. \tag{5.1}$$

The eigenvalues of Q are denoted by d_1, d_2, d_3. Suppose T_1, T_2, T_3 are three column unit eigenvectors of Q associated with the eigenvalues d_1, d_2, d_3, respectively. In the parametrization of E, new variables w_1, w_2, w_3 are used. Their relation with the state variables and parameters are

$$\begin{bmatrix} w_1 & w_2 & w_3 \end{bmatrix}^T = \begin{bmatrix} T_1 & T_2 & T_3 \end{bmatrix}^T \begin{bmatrix} z \\ x_1 \\ \mu \end{bmatrix}. \tag{5.2}$$

THEOREM 5.1. *Given a system satisfying* (1.3)*, suppose its linearization is in the form of* (2.6)*.*

(i) *If Q is positive definite or negative definite, then $(z, x, \nu) = (0, 0, 0)$ is an isolated equilibrium point.*

(ii) *If Q is not sign definite and if it has full rank, then the equilibrium set satisfies*

$$\begin{aligned} w_3 &= \pm\sqrt{-\frac{d_1 w_1^2 + d_2 w_2^2}{d_3}} + O(w_1, w_2)^2, \\ x_i &= O(w_1, w_2)^2, \qquad\qquad 2 \leq i \leq n-1 \end{aligned} \tag{5.3}$$

where d_1 and d_2 represent the two eigenvalues with the same sign and w_i, $i = 1, 2, 3$, is defined by (5.2)*.*

(iii) *If the conditions in* (ii) *are satisfied, then there exists a function $c(z, x_1, \mu)$ in the following form:*

$$c(z, x_1, \mu) = \gamma_{zx_1} z + 2\gamma_{x_1x_1} x_1 + \gamma_{x_1\mu}\mu + O(z, x_1, \mu)^2 \tag{5.4}$$

such that the system is linearly controllable at a point $(z, x, \mu) \in E$ if and only if $c(z, x_1, \mu) \neq 0$.

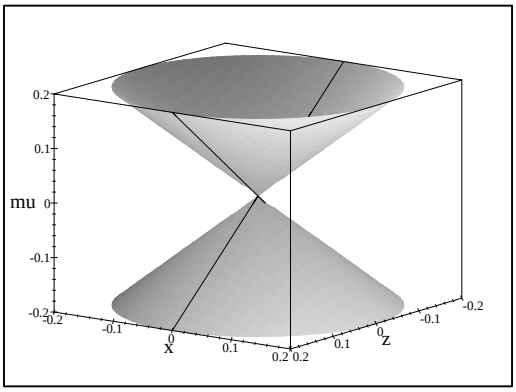

FIG. 5.1. *The equilibrium set in $zx_1\mu$-space.*

Remark. In case (ii), the graph of the equilibrium set in $zx\mu$-plane is approximated by a cone

$$d_1 w_1^2 + d_2 w_2^2 + d_3 w_3^2 = 0.$$

The center line of the cone is parallel to the eigenvector of d_3. For any fixed value of μ, the set of equilibrium points E_μ (defined in (4.4)) is approximately a conic curve. The shape of E_μ depends on the orientation of the cone in $zx_1\mu$-space. Furthermore, for small values of μ, the topology of E_μ at $\mu = 0$ is always different from that of E_μ at $\mu \neq 0$.

The surface $c(z, x_1, \mu) = 0$ is tangent to the plane $\gamma_{zx_1} z + 2\gamma_{x_1x_1} x_1 + \gamma_{x_1\mu}\mu = 0$ in $zx_1\mu$-space. In general, the intersection of such plane with the cone has a single point or it consists of two different lines. In the following, an example is shown in which the center line of the cone is μ-axis. The subset of E satisfying $c(z, x_1, \mu) = 0$ consists of two lines through the origin.

If a system in normal form (2.10) has no cubic and higher degree terms, then $x = 0$ defines its zero dynamics for the output $y = x_1$. Suppose that the eigenvectors of d_3 are not normal to $z\mu$-space, then the intersection between E and zx_1-plane consists of two lines when the bifurcation is a cone. This implies that the zero dynamics have a transcritical bifurcation.

Example. Consider the system

$$\begin{aligned} \dot{z} &= x_1^2 + x_2^2 + z^2 - \mu^2, \\ \dot{x}_1 &= x_2, \\ \dot{x}_2 &= u. \end{aligned}$$

The equilibrium set is

$$x_2 = 0, \quad x_1^2 + z^2 - \mu^2 = 0.$$

The function $c(z, x_1, \mu)$ is $2x_1$. In $zx_1\mu$-space, it is a cone shown in Figure 5.1. The two lines on the cone are the set $c(z, x_1, \mu) = 0$. The system is linearly controllable at all points in E except those on the two lines.

Proof of Theorem 5.1. (i) Consider the system (2.10). The points in equilibrium set satisfy equation (4.7). Substituting (4.7) into the equation

$$\sum_{i=1}^{n-1} \gamma_{x_i x_i} x_i^2 + \gamma_{zx_1} z x_1 + \gamma_{x_1\mu} x_1 \mu + \gamma_{z\mu} z\mu + \gamma_{zz} z^2 + \gamma_{\mu\mu}\mu^2 + O(z, x_1, \mu)^3 = 0$$

we get

$$(5.5)\quad \gamma_{x_1x_1}x_1^2+\gamma_{zx_1}zx_1+\gamma_{x_1\mu}x_1\mu+\gamma_{z\mu}z\mu+\gamma_{zz}z^2+\gamma_{\mu\mu}\mu^2+O(z,x_1,\mu)^3=0.$$

The matrix of the quadratic function in (5.5) is given by (5.1). Therefore, if the matrix Q is positive definite or negative definite, so is the function on the left side of (5.5). It has no nontrivial solution near $(z,x_1,\mu)=(0,0,0)$.

(ii) If the matrix Q in (5.1) is not sign definite, and if it has full rank, then the matrix has three nonzero eigenvalues d_1, d_2, and d_3. Furthermore, we can assume that $d_1d_1>0$. Then d_3 has different sign from d_1 and d_2. By a change of coordinates (5.2), equation (5.5) becomes

$$d_1w_1^2+d_2w_2^2+d_3w_3^2+O(w_1,w_2,w_3)^3=0,$$

solving the equation for w_3. The solution is in the form of (5.3).

(iii) Given an equilibrium point (z,x,μ) in E, keep in mind that x_i, $i=2,\dots,n-1$, has no linear terms of z,x_1,μ. Therefore, the linearization of the system at the point with respect to z,x is

$$A=\begin{bmatrix} \gamma_{zx_1}x_1+\gamma_{z\mu}\mu+2\gamma_{zz}z & 2\gamma_{x_1x_1}x_1+\gamma_{zx_1}z+\gamma_{x_1\mu}\mu & 0 & 0 & \cdots & 0\\ 0 & 0 & 1 & 0 & \cdots & 0\\ \vdots & \vdots & \vdots & \vdots & \ddots & \vdots\\ 0 & 0 & 0 & 0 & \cdots & 1\\ 0 & 0 & 0 & 0 & \cdots & 0 \end{bmatrix}+O(z,x_1,\mu)^2,$$

$$B=\begin{bmatrix} 0 & 0 & \cdots & 1 \end{bmatrix}^T+O(z,x_1,\mu)^2.$$

The controllability matrix is

$$\begin{bmatrix} 0 & 2\gamma_{x_1x_1}x_1+\gamma_{zx_1}z+\gamma_{x_1\mu}\mu\\ J & 0 \end{bmatrix}+O(z,x_1,\mu)^2$$

where J is defined by (3.3). Using elementary row and column operations, it can be proved that the matrix has the same rank as the following matrix R:

$$R=\begin{bmatrix} 0 & 2\gamma_{x_1x_1}x_1+\gamma_{zx_1}z+\gamma_{x_1\mu}\mu+O(z,x_1,\mu)^2\\ J & 0 \end{bmatrix}.$$

Define $c(z,x_1,\mu)$ to be the nonconstant entry

$$c(z,x_1,\mu)=2\gamma_{x_1x_1}x_1+\gamma_{zx_1}z+\gamma_{x_1\mu}\mu+O(z,x_1,\mu)^2.$$

In a neighborhood of the origin, the matrix R has full rank or, equivalently, the system is linearly controllable at the equilibrium point if and only if $c(z,x_1,\mu)\neq 0$. □

One conclusion from the results in sections 3–5 is that the topology and bifurcation of E has five different cases. This is summarized in Table 5.1.

6. Stabilizability. In this section, we prove a theorem on stabilizability of control systems around an uncontrollable equilibrium point. Given a system with controllability index $n-1$ at the origin, if the uncontrollable mode is positive (i.e., the case of $\lambda>0$), then the uncontrollable mode will be positive at all uncontrollable

TABLE 5.1
The classification of equilibrium sets.

Condition	Equilibrium set	Example
$\lambda \neq 0$	smooth 2-d manifold tangent to $x_1\mu$-plane	Figure 3.1
$\lambda = 0$, Jordan form $\det(Q_1) > 0$	paraboloid	Figure 4.1
$\lambda = 0$, Jordan form $\det(Q_1) < 0$	saddle	Figure 4.2
$\lambda = 0$, diagonal form Q is sign definite	single point	
$\lambda = 0$, diagonal form Q is indefinite, $\det(Q) \neq 0$	cone	Figure 5.1

equilibrium points near the origin. On the other hand, if $\lambda < 0$, the system is always stabilizable at all the equilibrium points near the origin. Therefore, the interesting case is $\lambda = 0$. In this section, we focus on the case in which the uncontrollable dynamics have Jordan form, i.e., the case of paraboloid or saddle bifurcations.

If one or both of the quadratic invariants $\gamma_{x_1x_1}$ and γ_{zx_1} are not zero, there is a curve $c(z, x_1) = 0$ in the equilibrium set E such that the system is not linearly controllable at all the points on the curve. In the following, we focus on the problem of feedback stabilization at the uncontrollable equilibrium, which is the set $E \cap \{c(z, x_1) = 0\}$. This set is denoted by $E_u = \{(z, x, \mu) \in E | c(z, x_1) = 0\}$.

THEOREM 6.1. *Consider a system* (2.5). *Suppose* $\det(Q_1) \neq 0$. *If* $\gamma_{x_1x_1}^2 + \gamma_{zx_1}^2 \neq 0$, *then the origin divides the curve* E_u *into two pieces. The system is stabilizable by* C^1 *state feedback on one piece and it is not stabilizable by any* C^1 *state feedback on the other piece. More specifically, the system is stabilizable around a point* (z, x, μ) *in* E_u *if* $\gamma_{zx_1}x_1 + 2\gamma_{zz}z < 0$, *and the system is not stabilizable at a point in* E_u *if* $\gamma_{zx_1}x_1 + 2\gamma_{zz}z > 0$.

Remark. The theorem shows that, in general, the property of stabilizability switches from stabilizable to unstabilizable or vice versa as equilibrium points in E_u pass through the origin. For instance, the system given in (4.5) satisfies $\gamma_{x_1x_1} = 1$, $\gamma_{zx_1} = 1$, and $\gamma_{zz} = 1$. The conditions in Theorem 6.1 are fulfilled. The stabilizable $(x_1 + 2z < 0)$ and unstabilizable $(x_1 + 2z > 0)$ equilibrium points in E_u are shown in Figure 6.1 by solid and dotted curves, respectively.

Proof of Theorem 6.1. It is sufficient to prove the theorem for the normal forms. Consider a system (2.9). Given an equilibrium point (z, x, μ) in E_u, the linearization of the system at the equilibrium point is given by (4.8). Since at least one of $\gamma_{x_1x_1}$ and γ_{zx_1} is not zero, we assume $\gamma_{x_1x_1} \neq 0$ (the proof for the case $\gamma_{zx_1} \neq 0$ is similar). From (4.2), the point (z, x, μ) in E_u satisfies

$$x_1 = -\frac{\gamma_{zx_1}}{2\gamma_{x_1x_1}} z + O(z)^2. \tag{6.1}$$

Substituting this relation into (4.8), we get the linearization of the system at the given equilibrium point:

$$A = \begin{bmatrix} -\dfrac{\gamma_{zx_1}^2}{2\gamma_{x_1x_1}} z + 2\gamma_{zz}z & 0 \\ 0 & A_2 \end{bmatrix} + O(z)^2, \quad B = \begin{bmatrix} 0 & 0 & \cdots & 1 \end{bmatrix}^T + O(z)^2. \tag{6.2}$$

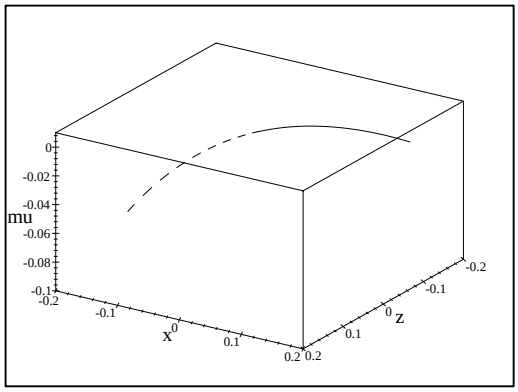

FIG. 6.1. *The set E_u. Dotted line: unstabilizable equilibrium points. Solid line: stabilizable equilibrium points.*

The controllability matrix is in the following form

$$R(z) = \begin{bmatrix} 0 & 0 \\ J & 0 \end{bmatrix} + O(z)^2.$$

In E_u, the rank of the matrix $R(z)$ is $n-1$. There is a vector valued function $C(z) = \begin{bmatrix} c_1(z) & \cdots & c_n(z) \end{bmatrix}$ such that $C(z)R(z) = 0$, $C(0) = [1, 0, \ldots, 0]$. It is easy to check that the function $C(z)$ has the form

$$C(z) = \begin{bmatrix} 1 & 0 & \cdots & 0 \end{bmatrix} + O(z). \tag{6.3}$$

By the linear control theory, the vector $C(z)$ is normal to the controllability subspace of the linear system (A, B). The uncontrollable mode of the linearization at a point in E_u is a number $\bar{\lambda}$ satisfying

$$C(z)A = \bar{\lambda}C(z). \tag{6.4}$$

From (6.2) and (6.3), relation (6.4) is equivalent to

$$-\frac{\gamma_{zx_1}^2}{2\gamma_{x_1x_1}}z + 2\gamma_{zz}z + O(z)^2 = \bar{\lambda}(1 + O(z)).$$

Therefore, the uncontrollable mode of the linearization at equilibrium point (z, x, μ) in E_u satisfies

$$\bar{\lambda} = \frac{4\gamma_{zz}\gamma_{x_1x_1} - \gamma_{zx_1}^2}{2\gamma_{x_1x_1}}z + O(z)^2. \tag{6.5}$$

Except for $z = 0$, this number is nonzero near the origin because $\det(Q_1) \neq 0$. The sign of the function changes as z passes through zero. From (6.1), on the curve E_u we have

$$\frac{4\gamma_{zz}\gamma_{x_1x_1} - \gamma_{zx_1}^2}{2\gamma_{x_1x_1}}z = \gamma_{zx_1}x_1 + 2\gamma_{zz}z + O(z).$$

This implies that, near the origin, the uncontrollable mode λ of the system at an equilibrium point in E_u has the same sign as $\gamma_{zx_1}x_1 + 2\gamma_{zz}z$. A nonlinear system

is stabilizable by C^1 feedback if the uncontrollable mode is less than zero, and it is not stabilizable by any C^1 state feedback if the uncontrollable mode is greater than zero. Therefore, the system is stabilizable if $\gamma_{zx_1}x_1 + 2\gamma_{zz}z < 0$ and the system is not stabilizable if $\gamma_{zx_1}x_1 + 2\gamma_{zz}z > 0$. Relation (6.5) implies that the property of stabilizability by C^1 feedback changes as z moving across zero. □

7. Conclusion. For control systems satisfying assumption (1.3), their equilibrium sets are classified under changes of coordinates and feedback. There are five different classes. They are summarized in Table 5.1. The equilibrium sets in different classes have either a different topology or a different bifurcation.

Another topic addressed in the paper is the relationship between quadratic invariants and controllability or stabilizability. In general, the uncontrollable equilibrium points form a one-dimensional curve. The tangent line of the curve is uniquely determined by quadratic invariants. Stabilizability at uncontrollable equilibrium points is discussed in section 6. If E is a paraboloid or a saddle, then it is proved that the stabilizability changes as an uncontrollable equilibrium point passes through the origin.

OPTIMAL RESIDENCE TIME CONTROL OF HAMILTONIAN SYSTEMS PERTURBED BY WHITE NOISE*

JAMES P. DUNYAK† AND MARK I. FREIDLIN‡

Abstract. Optimal control of perturbed Hamiltonian systems in $\Re^2$ is studied. Systems are considered with a control term scaling with the size of a small perturbing noise. The dynamics are shown to converge in a certain sense to a diffusion on a graph. Using the approach developed in [M. I. Freidlin and A. D. Wentzell, *Mem. Amer. Math. Soc.*, 109 (1994), pp. 1–82] and [M. I. Freidlin and A. D. Wentzell, *Ann. Probab.*, 21 (1993), pp. 2215–2245] for random perturbations of Hamiltonian systems, a convergence theorem is discussed. An optimal control theorem is then developed to maximize the expected exit time from a domain. This control is asymptotically robust for small noise. Several examples are provided.

1. Introduction.

Consider a Hamiltonian system in the plane

$$\begin{aligned} \dot{\tilde{X}}_t &= \overline{\nabla} H(\tilde{X}_t), \\ \tilde{X}_0 &= (\tilde{X}_0^1, \tilde{X}_0^2) = x \ \in \Re^2, \\ \overline{\nabla} H(x) &= \left[\frac{\partial H}{\partial x_2}(x), -\frac{\partial H}{\partial x_1}(x) \right]. \end{aligned} \tag{1}$$

Let $H(x) \to \infty$ as $|x| \to \infty$. The trajectories of this system describe a collection of oscillations which may be grouped in families based on the specific extrema of H they circle. For example, let $H(x)$ be shown in Figure 1(a) and the corresponding state-space trajectories be shown in Figure 1(b). The trajectories or oscillations in Figure 1(b) can be grouped into three families. The ∞-shaped curve Γ_4 is the separatrix, which goes through the Hamiltonian function's saddle point. Two families are inside the ∞-shaped curve Γ_4: the family circling O_1 (which includes the curve Γ_1) and the family circling O_3 (which includes the curve Γ_3). The third family of oscillations encircles the entire ∞-shaped curve Γ_4, including the points O_1, O_2, and O_3. The trajectory Γ_2 is in this family.

Of course, if there is no noise, the system will preserve the oscillations determined by the initial integral $H(x)$. Our interest is in the situation with a small perturbing noise and a similarly scaled control. Let the white noise $\sqrt{\epsilon}\dot{\tilde{W}}_t$ perturb the system, $0 < \epsilon \ll 1$,

$$\begin{aligned} \dot{\tilde{X}}_t^\epsilon &= \overline{\nabla} H(\tilde{X}_t^\epsilon) + \epsilon^{1/2} \dot{\tilde{W}}_t, \\ \tilde{X}_0^\epsilon &= x \ \in \Re^2. \end{aligned}$$

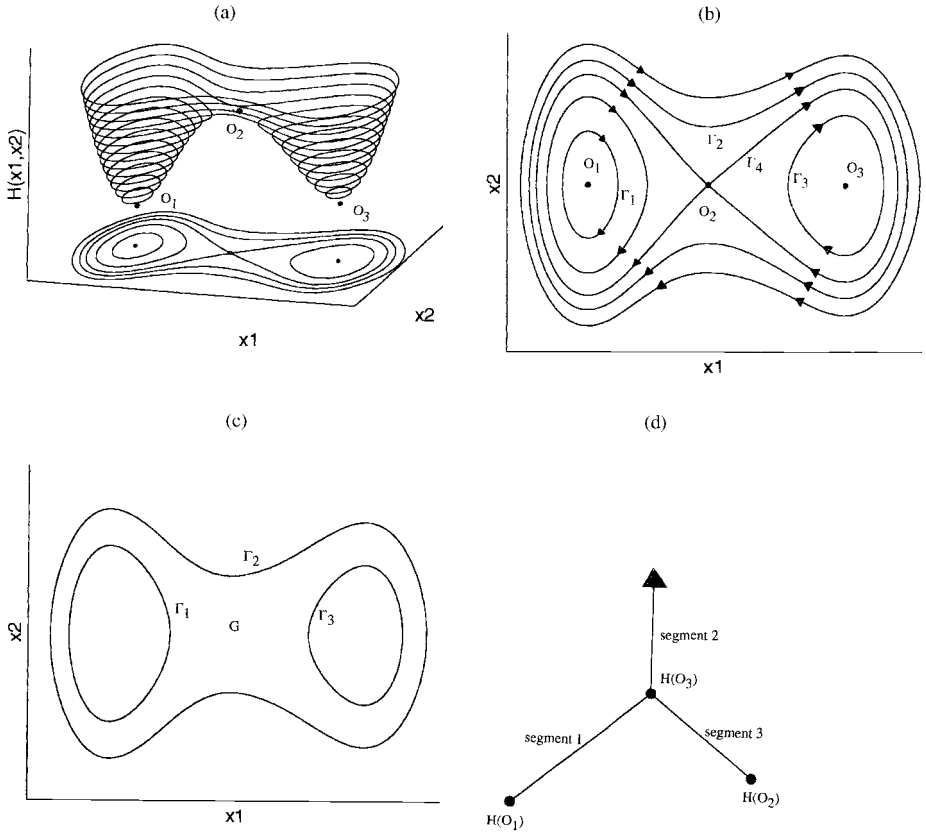

FIG. 1.

Then the perturbed trajectory will, with probability 1, sooner or later leave any bounded domain. Suppose we would like to preserve the oscillations of not very large and not very small amplitudes as long as possible. For example, a domain G is shown in Figure 1(c) bounded by the unperturbed system trajectories Γ_1, Γ_2, and Γ_3, and our goal is to keep the trajectory of the perturbed system inside G as long as possible. Suppose that to achieve this goal we can control the vector field in the dynamical system, and the size of the control is also scaled by ϵ:

$$\begin{aligned} \dot{\tilde{X}}_t^{\epsilon,c} &= \overline{\nabla} H(\tilde{X}_t^{\epsilon,c}) + \epsilon\, c(\tilde{X}_t^{\epsilon,c}) + \epsilon^{1/2}\dot{\tilde{W}}_t, \\ \tilde{X}_0^{\epsilon,c} &= x \ \in \Re^2. \end{aligned} \tag{2}$$

It can be shown that the exit time from the domain G is of order $\frac{1}{\epsilon}$. To make it of order 1 as $\epsilon \downarrow 0$ we rescale time $\frac{t}{\epsilon} \to t$. Then the equation for $X_t^{\epsilon,c} = \tilde{X}_{t/\epsilon}^{\epsilon,c}$ has the form

$$\begin{aligned} \dot{X}_t^{\epsilon,c} &= \frac{1}{\epsilon}\overline{\nabla} H(X_t^{\epsilon,c}) + c(X_t^{\epsilon,c}) + \dot{W}_t, \\ X_0^{\epsilon,c} &= x \ \in \Re^2. \end{aligned} \tag{3}$$

We assume that the vector field $c(x)$ is twice continuously differentiable (with uniformly bounded derivatives) everywhere except possibly at points located on a

finite number of trajectories of the nonperturbed system in equation (1). Krylov [13], among others, discusses stochastic differential equations with coefficients with simple discontinuities [14]. To bound the magnitude of the control, we allow only c such that $c^t(x)M(x)c(x) \leq K^2$ for some constant $K > 0$ and some matrix function $M(x)$ which is uniformly positive definite over G. $M(x)$ may be taken as symmetric since $c^t(x)M(x)c(x) = \frac{1}{2}c^t(x)(M(x)+M^t(x))c(x)$ for any matrix M. $M(x)$ is also assumed to be twice continuously differentiable with bounded derivatives. Such control vector fields we call permissible, and we denote the class of permissible fields by Π_K. This class Π_K is much narrower than is actually required but allows more direct application of the results in [1, 2]. The concluding section addresses this issue.

Let $\tau^{\epsilon,c}$ be the exit time from the domain G; $\tau^{\epsilon,c} = \min\{t : \ X_t^{\epsilon,c} \notin G\}$. Our goal is to make $E_x\tau^{\epsilon,c}$ as big as possible by choosing the control $c \in \Pi_K$. One can, of course, consider this problem for a fixed ϵ. If $c^{*,\epsilon} = c^{*,\epsilon}(x) \in \Pi_K$ is the optimal control and $V^{*,\epsilon}(x) = E_x\tau^{\epsilon,c^*}$, then one can write (for $M(x) = I$) the Bellman equation for $V^*(x)$:

$$\frac{1}{2}\Delta V^{*,\epsilon}(x) + \frac{1}{\epsilon}\overline{\nabla}H(x)\cdot\nabla V^{*,\epsilon}(x) + K|\nabla V^{*,\epsilon}(x)| = -1, \quad x \in G, \tag{4}$$

$$V^{*,\epsilon}(x)|_{\partial G} = 0.$$

Then $c^{*,\epsilon}(x) = \nabla V^{*,\epsilon}(x)$ and $V^{*,\epsilon}(x) = E_x\tau^{\epsilon,c^*} \geq E_x\tau^{\epsilon,c}$ for all $c \in \Pi_K$. Equation (4) requires the solution of a nonlinear boundary value problem in $\Re^2$ for each value of ϵ. We show in this paper how this problem may be replaced, for small ϵ, with an ordinary differential equation that is independent of ϵ. If $0 < \epsilon \ll 1$, one can give a more explicit answer which may be more useful in application. One can calculate a control $c^*(x) \in \Pi_k$ such that for any $c \in \Pi_K$,

$$E_x\tau^{\epsilon,c^*} \geq E_x\tau^{\epsilon,c}$$

for $x \in G$ and ϵ small enough. So the control c^* may be considered optimal in an asymptotic sense; c^* will outperform any other control if the noise is small enough.

We should comment first on the relative scaling of the noise and control. Of course, our theoretical result is a limit as $\epsilon \to 0$, but in applications we expect to have a fixed noise size (which implies a fixed ϵ). If this noise is "small," then the appropriately normalized exit time should be well approximated by the theoretical limit. This measure of "smallness" is in practice easy to recognize: the perturbed dynamical system should make many oscillations (very nearly following the deterministic unperturbed trajectories) before the noise causes much change in the value of the Hamiltonian $H(\tilde{X}_t^\epsilon)$. Thus, for short times, the Hamiltonian dynamics will clearly dominate the noise perturbations.

The control is also scaled by ϵ in equation (2). Again, in applications we anticipate a fixed (but "small") value of ϵ to be in effect. Scaling both noise and control together reflects the fact that they are both small and both approximately of the same order of magnitude. Example 1 below provides an example of how our optimum control performs for a fixed (but "small") size for the noise and control.

Of course, other relative scalings of the noise and control are possible and in some cases might be more appropriate. If the control is not small, then the underlying Hamiltonian dynamics are corrupted. These asymptotic control problems involving residence time and probability control have been considered before for non-Hamiltonian systems. Freidlin and Wentzell used large deviation theory to analyze

residence time control problems for non-Hamiltonian systems in [3, 4]. Results of this type were also discussed by Fleming and Souganidis in [5] and extended by Dupuis and Kushner [6] to minimizing escape probabilities in a special class of degenerate noise. Minimizing expected escape time or probability using large deviations for the linear, constant coefficient equation has been explored in detail by Meerkov, Runolfsson, and Kim in [7, 8, 9, 10, 11]. Kappos [12] also considered similar problems. Nonasymptotic stochastic control problems in $\Re^N$, allowing progressively measurable controls and more general performance measures, have been discussed in detail by Krylov [13] and in many other references. In general, difficult computations are involved in solving two-dimensional optimal stabilization problems using any of these methods, while the methods of this paper (applicable only in the Hamiltonian case) are quite implementable. The notable exception is in case of linear dynamics which is so effectively analyzed by Meerkov, Runolfsson, and Kim.

For Hamiltonian systems the exit from the domain is not a large deviation, and the large deviation approach is too rough for such problems. A graph Γ can be constructed that is homeomorphic to the set of connected components of the level sets of the Hamiltonian. The vertices of the graph correspond to the critical points of the Hamiltonian: exterior vertices correspond to extrema, interior vertices to the saddle points and their associated ∞-shaped trajectories. Interior points of the graph segments correspond to the periodic trajectories of the system. Our example in Figure 1 illustrates the map. Associated with the three trajectory families is the graph shown in Figure 1(d). The ∞-shaped separatrix Γ_4 is mapped to the joint in the center of the graph. The lower-left-hand segment corresponds to the family of trajectories encircling O_1, with the equilibrium O_1 mapping to the lower segment endpoint. Hence the curve Γ_1 maps to a point on segment 1. Similarly, the lower right segment in Figure 1(d) corresponds to oscillations circling O_3, with O_3 mapping to the lower segment endpoint. The curve Γ_3 maps to a point on segment 3. The oscillations circling the ∞- shaped curve Γ_4 map to the upper segment in the graph, so that Γ_2 maps to segment 2. Such a graph for description of the perturbed Hamiltonian system was introduced by Freidlin and Wentzell [1, 2], and we refer to this paper for a rigorous definition. Each point $x \in \Re^2$ with $H(x) = H$ belongs to a connected component $C_i(H)$ of the level set $\{x : \ H(x) = H\}$. Such a set can consist of one or several connected components. Let $Y(x) : \ x \to (i(x), H(x))$ be the mapping from $\Re^2$ into Γ. Then, for $x \in C_i(H)$, $Y(x)$ is the point of the graph Γ corresponding to $C_i(H)$.

As is shown in [1, 2], the stochastic process $Y(X_t^{\epsilon,0}) = Y_t^{\epsilon,0}$ in the case $c(x) = 0$ converges weakly to a diffusion process on Γ. Inside each edge the process is defined by averaging the diffusion in the plane along the periodic unperturbed Hamiltonian trajectories. At the vertices some gluing conditions should be added (see below). Let $\Gamma_G = Y(G)$ as shown, for example, in Figures 1(c) and 1(d). By a modification of the proof given in [1] we show here that if the drift $c(x)$ is added, as in equation (3), $Y_t^{\epsilon,c} = Y(X_t^{\epsilon,c})$ also converges weakly to a Markov process Y_t^c on the graph Γ. Then we can check that

$$\lim_{\epsilon \downarrow 0} E_x \tau^{\epsilon,c} = E_{Y(x)} \tau^c,$$

where τ^c is the exit time for Y_t^c from the set Γ_G. The function $E_{Y(x)}\tau^c = v(x)$ is the unique solution of a simple ordinary differential equation on Γ satisfying some natural boundary conditions and gluing conditions at the vertices. Using this fact, one can calculate explicitly the control c^* maximizing the $E_z\tau^c$, $z \in \Gamma_G$ in $c \in \Pi_K$. It turns out that in general $|c^*| = K$ everywhere, and c^* changes sign at a finite number of

points on the graph Γ. The number of these change points is less than the number of edges. A simple procedure to calculate these change points can be given in many cases. Then one can prove that the control

$$c^*(x) = K \ \ \text{sign}(v'(i(x), H(x))) \ \ M^{-1}(x)\nabla H(x)/(\nabla H^t(x) M^{-1}(x)\nabla H(x))^{1/2}$$

is asymptotically the best. Note, as expected, that this may be viewed as a "bang-bang" control law because the control is always saturated with $c^t Mc = K^2$. Here $v(i(x), H(x))$ is the solution to a differential equation on the graph discussed below. For each $c \in \Pi_K$ there is an ϵ_0 dependent on c with $E_x \tau^{\epsilon, c^*} \geq E_x \tau^{\epsilon, c}$ for any $\epsilon \leq \epsilon_0$.

2. The convergence theorem. Formulation of the control problem requires an appropriate convergence theorem. The theorem here is a modification of the convergence theorem in [1], allowing for the discontinuous drift term.

We use the following notation (see [1]):

I_i is the interior of a segment of the graph.

O_k is a vertex or joint on the graph.

D_i is the set of all points $x \in \Re^2$ such that $Y(x)$ belongs to the interior of segment I_i.

$C_k = \{x : \ Y(x) = O_k\}$.

$C_{ki} = C_k \bigcap \partial D_i$.

$C(H) = \{x : \ H(x) = H\}$ for H in the range of $H(x)$.

$C_i(H) = \{x \in D_i : \ H(x) = H\}$.

$D_i(H_1, H_2) = \{x \in D_i : \ H_1 < H(x) < H_2\}$.

$D_k(\pm\delta)$ is the connected component of $\{x : \ H(O_k) - \delta < x < H(O_k) + \delta\}$ containing C_k.

$C_{ki}(\delta) = \{x \in D_i : \ H(x) = H(O_k) \pm \delta\}$.

The time-scaled equation (3) is addressed in the theorem. Note that, for small ϵ, the trajectory of $X_t^{\epsilon, c}$ will circle many times before $H(X_t^{\epsilon, c})$ will change significantly. This leads to an averaging effect, which defines the limiting process inside the edges. The limiting process is a diffusion process on the graph Γ corresponding to the Hamiltonian.

This limiting diffusion will be described first. See [1, 2] for a technical description of processes on graphs. Associated with each point on each segment I_i on Γ there is a connected curve $C_i(H) \subset \Re^2$. This curve is a portion of the level set $\{x : \ H(x) = H\}$. With each segment I_i of the graph, associate a differential operator

$$L_i^c f(i, H) = \frac{1}{2} A_i^c(H) f''(i, H) + B_i^c(H) f'(i, H) \tag{5}$$

with

$$A_i^c(H) = \frac{\oint_{C_i(H)} \frac{|\nabla H(x)|^2}{|\overline{\nabla} H(x)|} dl}{\oint_{C_i(H)} \frac{1}{|\overline{\nabla} H(x)|} dl} \tag{6}$$

and

$$B_i^c(H) = \frac{\oint_{C_i(H)} \frac{\frac{1}{2}\Delta H(x) + \nabla H(x) \cdot c(x)}{|\overline{\nabla} H(x)|} dl}{\oint_{C_i(H)} \frac{1}{|\overline{\nabla} H(x)|} dl}. \tag{7}$$

Here $f'(i, \cdot)$ indicates the derivative with respect to the local coordinate H on the ith segment.

Associate with each graph joint a gluing condition

$$\sum_{i:I_i\sim O_k} (\pm\beta_{ki}) f'(i, H(x_k)) = 0. \tag{8}$$

The sign $\pm$ of the coefficients is given by $\pm\beta_{ki} \geq 0$ if $H \geq H(x_k)$ on I_i and $\pm\beta_{ki} \leq 0$ if $H \leq H(x_k)$ on I_i. These coefficients are computed as

$$\beta_{ki} = \int_{C_{ki}} |\nabla H(x)| dl$$

for curve C_{ki} corresponding to the portion of C_k in the inverse image of graph segment I_i. For example, in Figure 1 with the joint associated with the saddle point O_2 called joint 2, curve C_{21} is the left half of the ∞-shaped curve through O_2, curve C_{22} is the entire ∞-shaped curve, and curve C_{23} is the right half of the ∞-shaped curve.

The outer vertices must also be considered. If the integral

$$\int \exp\left[-\int \frac{2B_i^c(H)}{A_i^c(H)} dH\right] dH \tag{9}$$

diverges at the end $H(x_k)$, then the vertex is inaccessible. Noting that

$$|\nabla H(x)|^2 / |\overline{\nabla} H(x)| \;=\; |\nabla H(x)|$$

and the bound on the magnitude of $c(x)$, for $H \in I_i$,

$$\int \frac{2 \frac{\oint_{C_i(H)} \frac{\nabla H(x)\cdot c(x)}{|\overline{\nabla} H(x)|} dl}{\oint_{C_i(H)} \frac{1}{|\overline{\nabla} H(x)|} dl}}{A_i^c(H)} dH$$

is bounded. The article [1] establishes that the outer vertices for the uncontrolled system are inaccessible. As a result, the integral in (9) diverges, and the addition of control does not alter the accessibility of the outer vertices.

THEOREM 1. *Let the Hamiltonian $H(x)$, $x \in \Re^2$, be four times continuously differentiable; $H(x) \geq A_1|x|^2$, $|\nabla H(x)| \geq A_2|x|$, $\Delta H(x) \geq A_3$ for sufficiently large $|x|$, where A_1, A_2, A_3 are positive constants. Let $H(x)$ have a finite number of critical points x_1, x_2, ..., x_N at which the matrix of second derivatives $(\frac{\partial^2 H(x)}{\partial x^i \partial x^j})$ is nondegenerate. Also assume that each level curve, $C_k = \{x : Y(x) = Y(x_k)\}$, contains at most one critical point.*

Let $c(x)$, $x \in \Re^2$, meet two conditions: c is twice continuously differentiable (with uniformly bounded derivatives) except at points in a finite number of level sets of $H(x)$, and $|c(x)| \leq K$ for some positive constant K.

Let $(X_t^{\epsilon,c}, P_x^\epsilon)$ be the diffusion process on $\Re^2$ connected with problem (3)*, and define $Y_t^{\epsilon,c} = Y(X_t^{\epsilon,c})$ as the corresponding process on graph Γ. Let Y_t^c be the process on the graph corresponding to the differential operator on the graph Γ in problems* (5) *through* (8)*.*

Then the process $Y_t^{\epsilon,c}$ converges weakly to the Markov process Y_t^c.

The proof of Theorem 1 is essentially the same as the proof of Theorem 2.2 in [1], so the reader is directed to the reference for the proof. Note that, for a trajectory in the interior of a segment, $X_t^{\epsilon,c}$ rotates many times along the trajectories before

$H(X_t^{\epsilon,t})$ changes much. Consider Ito's equation for the value of the Hamiltonian. Since $\nabla H(X_t^{\epsilon,t}) \cdot \overline{\nabla} H(X_t^{\epsilon,t}) = 0$,

$$H(X_t^{\epsilon,t}) = H(X_t^{\epsilon,0}) + \int_0^t \nabla H(X_t^{\epsilon,s}) \cdot dW_s + \int_0^t \left(\frac{1}{2} \Delta H(X_t^{\epsilon,s}) + \nabla H(X_t^{\epsilon,t}) \cdot c(H(X_t^{\epsilon,s})) \right) ds. \tag{10}$$

The resulting averaging, in light of equation (10), will lead to the differential equation for the interior of the segment. This is proved rigorously for $c = 0$ in [1]; the proofs require little modification to handle the additional control term.

The joints provide more complications. The addition of the control does not change the gluing conditions. This may also be shown following the proof in [1] but noting that the proof uses a series of five lemmas, labeled 3.1 through 3.5. The last four require some modification in the method of proof. The new proofs follow by repeated application of the Girsanov–Cameron–Martin theorem relating the measure induced by X_t^ϵ and the uncontrolled trajectory Z_t^ϵ with

$$\dot{Z}_t^\epsilon = \frac{1}{\epsilon} \overline{\nabla} H(Z_t^\epsilon) + \dot{W}_t, \qquad Z_0^\epsilon = x, \tag{11}$$

and

$$\frac{d\mu_{Z_x^\epsilon}}{d\mu_{X_x^{\epsilon,c}}}(X_\cdot) = \exp\left\{ - \int_0^1 c(Z_t^\epsilon) \cdot dW_t - \frac{1}{2} \int_0^1 |c(Z_t^\epsilon)|^2 dt \right\}. \tag{12}$$

Results for Z_t^ϵ in equation (11) from [1] are then applied in the controlled case via equation (12).

COROLLARY 1. *Let the Hamiltonian and control $c(x)$ meet the conditions in Theorem* 1.

Let G_Γ be a closed and connected set on the graph Γ corresponding to the Hamiltonian $H(x)$, and let $G = Y^{-1}(G_\Gamma)$ be the corresponding inverse image in $\Re^2$. Assume G is a bounded set.

Then, for $x \in G$ with

$$\tau^{\epsilon,c} = \inf\{t : X_t^{\epsilon,c} \in \partial G\},$$

and

$$\tau^c = \inf\{t : Y_t^c \in \partial G_\Gamma\},$$

$$\lim_{\epsilon \to 0} E_x\{\tau^{\epsilon,c}\} = E_{Y(x)}\{\tau^c\}.$$

Proof. From Ito's formula,

$$H(X_t^{\epsilon,c}) = H(X_0^{\epsilon,c}) + \int_0^t \nabla H(X_s^{\epsilon,c}) \cdot dW_s + \int_0^t \left(\frac{1}{2} \Delta H(X_s^{\epsilon,c}) + \nabla H(X_s^{\epsilon,c}) \cdot c(X_s^{\epsilon,c}) \right) ds.$$

For a region U such that the closure of $Y(U)$ contains no vertices, standard results bound the exit time from U for all $\epsilon \in (0, 1]$ and $x \in U$ (see Theorem 4 of Chapter

2, [13]). Lemma 3.4 in [1] gives an upper bound for exit from a domain belonging to a neighborhood of a vertex. These are used to establish $E_x\{\tau^{\epsilon,c}\} < A < \infty$ for any $\epsilon \in (0,1]$, $x \in G$.

Now, from Theorem 1, for $T > 0$,

$$\lim_{\epsilon\to 0} E_x\left\{\tau^{\epsilon,c} \bigwedge T\right\} = E_x\left\{\tau^{c} \bigwedge T\right\}.$$

Also, using the Markov property through conditioning on $X_T^{\epsilon,c}$ and Chebyshev's inequality,

$$\begin{aligned} 0 \le E_x\{\tau^{\epsilon,c}\} - E_x\{\tau^{\epsilon,c} \bigwedge T\} &= E_x\{(\tau^{\epsilon,c} - \tau^{\epsilon,c} \bigwedge T)\, I_{\tau^{\epsilon,c}>T}\} \\ &\le A\, P_x\{\tau^{\epsilon,c} > T\} \\ &\le A^2/T. \end{aligned}$$

We see that

$$\lim_{T\to\infty} E_x\left\{\tau^{\epsilon,c} \bigwedge T\right\} = E_x\{\tau^{\epsilon,c}\}$$

uniformly in $\epsilon \in (0,1]$. Then immediately

$$\lim_{T\to\infty}\lim_{\epsilon\to 0} E_x\left\{\tau^{\epsilon,c} \bigwedge T\right\} = \lim_{\epsilon\to 0}\lim_{T\to\infty} E_x\left\{\tau^{\epsilon,c} \bigwedge T\right\}.$$

The corollary follows from Theorem 1 and the dominated convergence theorem. □

3. Solving the control problem. Theorem 1 provides the needed tool for solution of the control problem.

THEOREM 2. *Let G_Γ be a closed and connected set on the graph Γ corresponding to the Hamiltonian $H(x)$, and let $G = Y^{-1}(G_\Gamma)$ be the corresponding inverse image in $\Re^2$. Assume G is a bounded set.*

Let $H(x)$, $x \in \Re^2$, be four times continuously differentiable in G. Let $H(x)$ have a finite number of critical points $x_1, x_2, \ldots, x_N$ in G at which the matrix of the second derivatives is nondegenerate. Also assume that each level curve $C_k = \{x : Y(x) = Y(x_k)\}$ contains at most one critical point.

Let $v(i,y)$ be a solution, continuous and twice differentiable in the interior of the graph segments, of

$$\begin{aligned} &\frac{1}{2}A_i v''(i,y) + B_i v'(i,y) + KE_i|v'(i,y)| + 1 = 0, \qquad (i,y) \in G_\Gamma, \\ &\textstyle\sum_{i:I_i\sim O_k}(\pm\beta_{ki})v'(i,H(y_k)) \quad = 0 \quad \textit{for all interior vertices}, \\ &v(i,y) = 0 \quad \textit{on the boundary } \partial G_\Gamma \end{aligned} \tag{13}$$

with

$$A_i(H) = \frac{\oint_{C_i(H)} |\nabla H(x)| dl}{\oint_{C_i(H)} \frac{1}{|\overline{\nabla} H(x)|} dl}, \qquad B_i(H) = \frac{\oint_{C_i(H)} \frac{\frac{1}{2}\Delta H(x)}{|\overline{\nabla} H(x)|} dl}{\oint_{C_i(H)} \frac{1}{|\overline{\nabla} H(x)|} dl},$$

$$E_i(H) = \frac{\oint_{C_i(H)} \frac{(\nabla H^t(x) M^{-1}(x) \nabla H(x))^{1/2}}{|\overline{\nabla} H(x)|} dl}{\oint_{C_i(H)} \frac{1}{|\overline{\nabla} H(x)|} dl},$$

and

$$\beta_{ki} = \int_{C_{ki}} |\nabla H(x)| dl.$$

The sign $\pm$ *of the coefficients meet* $\pm\beta_{ki} \geq 0$ *if* $H \geq H(x_k)$ *on* I_i *and* $\pm\beta_{ki} \leq 0$ *if* $H \leq H(x_k)$ *on* I_i.

Define the optimal control $c^*(x)$ *by*

$$c^*(x) = K \ \ sign(v'(Y(x))) \ \ \frac{M^{-1}(x)\nabla H(x)}{(\nabla H^t(x) M^{-1}(x) \nabla H(x))^{1/2}} \tag{14}$$

and the set of permissible controls Π_K *as the set of functions* c *meeting two conditions:* c *is twice continuously differentiable (with uniformly bounded derivatives) in* G *except at points in a finite number of level sets of* $H(x)$*; and* $c^t(x)M(x)c(x) \leq K^2$ *for constant* $K > 0$*, with* $M(x)$ *twice continuously differentiable (with bounded derivatives),* $M(x)$ *uniformly positive definite on* $x \in G$*, and* $M(x)$ *assumed (without loss of generality) to be symmetric. Then, with*

$$\tau_x^{\epsilon,c} = \inf\{t : X_t^{\epsilon,c} \in \partial G\},$$

for each $c(x) \in \Pi_K$ *there exists an* ϵ_0 *(dependent on* c*) such that*

$$E\{\tau_x^{\epsilon,c}\} \leq E\{\tau_x^{\epsilon,c^*}\}$$

for all $\epsilon \leq \epsilon_0$*. The optimal control* c^* *is independent of initial conditions* x *in the interior of* G.

Comment. Note that all permissible control vector fields which are equal almost everywhere (in the Lebesgue sense) are considered equivalent.

Proof. The theorem follows easily from Theorem 1 and a representation of the solution to the diffusion equation on the graph as the expectation of a functional of the process on the graph. Consider the diffusion process on the graph governed by the operators (5) inside the edges and the gluing conditions (8) on the vertices. Let $\tau_y^{\epsilon,c}$ be the hitting time of the set G_Γ. Note that

$$u^c(i,y) = E\{\tau_y^c\} \tag{15}$$

is the solution of

$$\begin{gathered} L_i^c u^c(i,y) + 1 = 0, \qquad (i,y) \in G_\Gamma, \\ \textstyle\sum_{i:I_i \sim O_k} (\pm\beta_{ki}) u^{c\prime}(i, H(y_k)) = 0 \quad \text{for all interior vertices,} \\ u^c(i,y) = 0 \quad \text{on the boundary } \partial G_\Gamma \end{gathered} \tag{16}$$

(see [2]). Consider $\text{sign}(v'(i,x))$ as a fixed function and apply equations (13) and (16) to see that $u^{c^*}(i,x) = v(i,x)$. Let, for $c \in \Pi_K$,

$$e^c(i,y) = u^{c^*}(i,y) - u^c(i,y),$$

which is the solution to

$$L_i^c e^c(i,y)$$

$$+\left[K\frac{\oint_{C_i(y)}\frac{(\nabla H^t(x)M^{-1}(x)\nabla H(x))^{1/2}}{|\overline{\nabla}H(x)|}dl}{\oint_{C_i(y)}\frac{1}{|\overline{\nabla}H(x)|}dl}|v'(i,y)| - \frac{\oint_{C_i(y)}\frac{\nabla H(x)\cdot c(x)}{|\overline{\nabla}H(x)|}dl}{\oint_{C_i(y)}\frac{1}{|\overline{\nabla}H(x)|}dl}v'(i,y)\right]$$

$$= 0 \quad \text{for } (i,y)\in G_\Gamma,$$

$$\textstyle\sum_{i:I_i\sim O_k}(\pm\beta_{ki})e^c{}'(i,H(y_k)) = 0 \quad \text{for all interior vertices,}$$

$$e^c(i,y) = 0 \quad \text{on the boundary } \partial G_\Gamma.$$

Hence there is a functional integral representation for $e^c(i,y)$ with, for appropriate stochastic process (i_t, Z_t) on the graph,

$$e^c(i,y) = E_{i,y}\left\{\int_0^\tau\left[K\frac{\oint_{C_i(Z_t)}\frac{(\nabla H^t(x)M^{-1}(x)\nabla H(x))^{1/2}}{|\overline{\nabla}H(x)|}dl}{\oint_{C_i(Z_t)}\frac{1}{|\overline{\nabla}H(x)|}dl}|v'(i_t,Z_t)|\right.\right.$$

$$\left.\left. - \frac{\oint_{C_i(Z_t)}\frac{\nabla H(x)\cdot c(x)}{|\overline{\nabla}H(x)|}dl}{\oint_{C_i(Z_t)}\frac{1}{|\overline{\nabla}H(x)|}dl}v'(i_t,Z_t)\right]dt\right\}. \tag{17}$$

The requirement that the control vector satisfies $c^t(x)M(x)c(x)\le K^2$ establishes that $e^c(i,y)>0$ when $c\neq c^*$ (i.e., $c\neq c^*$ on a set of Lebesgue measure greater than zero). To see this, consider the problem of maximizing, for fixed x and $v'(i_t,Z_t)$,

$$\sup_{c(x):\, c^t(x)M(x)c(x)\le K^2} v'\nabla H(x)\cdot c(x). \tag{18}$$

Clearly, due to the linear nature of the optimization, the maximum will occur on the boundary. Using Lagrange multiplier λ, we maximize

$$v'\nabla H(x)\cdot c(x) + \lambda(c^t(x)M(x)c(x) - K^2).$$

Taking the gradient with respect to c and solving for c,

$$c(x) = -\left(\frac{2v'}{\lambda}M^{-1}(x)\nabla H(x)\right).$$

Differentiating with respect to λ yields the constraint and

$$\lambda = \pm\frac{2|v'|(\nabla H^t(x)M^{-1}(x)\nabla H(x))^{1/2}}{K}.$$

The sign is resolved by considering equation (18). Note that only the properties of $H(x)$ inside the set G are required to determine the process behavior until the exit from the set G. Corollary 1 then completes the proof. □

The following corollary follows immediately from Theorem 2 and shows that the optimal control c^* is asymptotically robust. Let τ^{c^*} be the exit time for the limit process $Y_t^{c^*}$ on the graph.

COROLLARY 2.

(1) *For any* $\epsilon_0>0$,

$$\inf_{\epsilon\in(0,\epsilon_0]} E_x[\tau^{\epsilon,c^*}] \le \sup_{c\in\Pi_K}\inf_{\epsilon\in(0,\epsilon_0]} E_x[\tau^{\epsilon,c}] \le E_x[\tau^{c^*}] \le \sup_{\epsilon\in(0,\epsilon_0]} E_x[\tau^{\epsilon,c^*}].$$

(2)

$$\lim_{\epsilon_0\downarrow 0}\sup_{c\in\Pi_K}\inf_{\epsilon\in(0,\epsilon_0]} E_x[\tau^{\epsilon,c}] = \lim_{\epsilon_0\downarrow 0} E_x[\tau^{\epsilon,c^*}] = E_x[\tau^{c^*}].$$

4. Comments on applying the control law. Several extensions of the results in Theorems 1 and 2 are available. An important generalization is the consideration of general conservation laws $H(x)$. Since the skew gradient $\overline{\nabla}H$ is orthogonal to the gradient ∇H, the unperturbed dynamics can always be written in terms of a scalar function $\beta(x)$ as

$$\dot{\tilde{X}}_t = \beta(\tilde{X}_t)\overline{\nabla}H(\tilde{X}_t),$$
$$\tilde{X}_0 = (\tilde{X}_0^1, \tilde{X}_0^2) = x \ \in \Re^2.$$

This equation is discussed in more detail in Borodin and Freidlin [15]. A controlled version of the perturbed dynamic system is then written as

$$\dot{\tilde{X}}_t^\epsilon = \beta(\tilde{X}_t^\epsilon)\overline{\nabla}H(\tilde{X}_t^\epsilon) + \epsilon c(\tilde{X}_t^\epsilon) + \epsilon^{1/2}\dot{\tilde{W}}_t,$$
$$\tilde{X}_0^\epsilon = x \ \in \Re^2.$$

As long as $\beta(x)$ is not equal to zero anywhere in G, then the results above need only small modification. The diffusions will again converge to diffusions on a graph, with the graph having the same structure as discussed above. A convergence result similar to Theorem 1 will hold for $Y_t^{\epsilon,c} = Y(X_t^{\epsilon,c})$, with $Y_t^{\epsilon,c} \to Y_t^c$. However, the operator coefficients will be determined differently. We will have a theorem of the following form, which is proved in the same way as Theorem 2.

THEOREM 3. *Let G_Γ be a closed and connected set on the graph Γ corresponding to the Hamiltonian $H(x)$, and let $G = Y^{-1}(G_\Gamma)$ be the corresponding inverse image in $\Re^2$. Assume G is a bounded set.*

Let $H(x)$, $x \in \Re^2$, be four times continuously differentiable in G. Let $H(x)$ have a finite number of critical points x_1, x_2, ..., x_N in G at which the matrix of second derivatives is nondegenerate. Also assume that each level curve $C_k = \{x : Y(x) = Y(x_k)\}$ contains at most one critical point. Finally, assume $\beta(x)$ is four times continuously differentiable and $\beta(x) \neq 0$ anywhere in G.

Let $v(i,y)$ be a solution, continuous and twice differentiable in the interior of the graph segments, of

$$\tfrac{1}{2}A_i v''(i,y) + B_i v'(i,y) + KE_i|v'(i,y)| + 1 = 0, \qquad (i,y) \in G_\Gamma,$$
$$\textstyle\sum_{i:I_i \sim O_k} (\pm\beta_{ki}) v'(i, H(y_k)) \quad = 0 \quad \textit{for all interior vertices},$$
$$v(i,y) = 0 \quad \textit{on the boundary } \partial G_\Gamma,$$

with

$$A_i(H) = \frac{\oint_{C_i(H)} \frac{|\nabla H(x)|^2}{|\beta(x)\overline{\nabla}H(x)|}dl}{\oint_{C_i(H)} \frac{1}{|\beta(x)\overline{\nabla}H(x)|}dl}, \qquad B_i(H) = \frac{\oint_{C_i(H)} \frac{\frac{1}{2}\Delta H(x)}{|\beta(x)\overline{\nabla}H(x)|}dl}{\oint_{C_i(H)} \frac{1}{|\beta(x)\overline{\nabla}H(x)|}dl},$$

$$E_i(H) = \frac{\oint_{C_i(H)} \frac{(\nabla H^t(x) M^{-1}(x) \nabla H(x))^{1/2}}{|\beta(x)\overline{\nabla}H(x)|}dl}{\oint_{C_i(H)} \frac{1}{|\beta(x)\overline{\nabla}H(x)|}dl},$$

and

$$\beta_{ki} = \int_{C_{ki}} |\beta(x)\nabla H(x)|dl.$$

The sign $\pm$ *of the coefficients meet* $\pm\beta_{ki} \geq 0$ *if* $H \geq H(x_k)$ *on* I_i *and* $\pm\beta_{ki} \leq 0$ *if* $H \leq H(x_k)$ *on* I_i.

Define the optimal control $c^*(x)$ *by*

$$c^*(x) = K \ \ sign(v'(Y(x))) \ \ \frac{M^{-1}(x)\nabla H(x)}{(\nabla H^t(x) M^{-1}(x) \nabla H(x))^{1/2}}$$

and the set of permissible controls Π_K *as the set of functions* c *meeting two conditions:* c *is twice continuously differentiable (with uniformly bounded derivatives) in* G *except at points in a finite number of level sets of* $H(x)$*; and* $c^t(x)M(x)c(x) \leq K^2$ *for constant* $K > 0$*, with* $M(x)$ *twice continuously differentiable (with bounded derivatives),* $M(x)$ *uniformly positive definite on* $x \in G$*, and* $M(x)$ *assumed (without loss of generality) to be symmetric. Then, with*

$$\tau_x^{\epsilon,c} = \inf\{t : X_t^{\epsilon,c} \in \partial G\},$$

for each $c(x) \in \Pi_K$ *there exists an* ϵ_0 *(dependent on* c*) such that*

$$E\{\tau_x^{\epsilon,c}\} \leq E\{\tau_x^{\epsilon,c^*}\}$$

for all $\epsilon \leq \epsilon_0$*. The optimal control* c^* *is independent of initial conditions* x *in the interior of* G.

Note that Corollary 2 will also apply, so the control will again be asymptotically robust. The formulation of this problem is more complex if $\beta(x) = 0$ somewhere in G. In this case, the structure of the resulting graph is changed.

Finally, we consider a problem of our most general form. Consider a more general noise model dependent on a nonsingular matrix σ. For scalar function β, let

$$\dot{\hat{X}}_t^\epsilon = \beta(\hat{X}_t^\epsilon)\overline{\nabla} H(\hat{X}_t^\epsilon) + \epsilon c(\hat{X}_t^\epsilon) + \epsilon^{1/2}\sigma\dot{\hat{W}}_t,$$
$$\hat{X}_0^\epsilon = x \ \in \Re^2.$$

By doing a simple transformation $\tilde{X}_t = \sigma^{-1}\hat{X}_t$, the equations become

$$\dot{\tilde{X}}_t^\epsilon = \beta(\sigma\tilde{X}_t^\epsilon)\sigma^{-1}\overline{\nabla} H(\sigma\tilde{X}_t^\epsilon) + \epsilon\sigma^{-1}c(\sigma\tilde{X}_t^\epsilon) + \epsilon^{1/2}\dot{\tilde{W}}_t,$$
$$\tilde{X}_0^\epsilon = x \ \in \Re^2.$$

Now the conservation law is $H(\sigma x)$. Defining $H_2(x) = H(\sigma x)$, the term $\beta(\sigma x)\sigma^{-1}\overline{\nabla} H(\sigma x)$ can be written as $\beta_2(x)\overline{\nabla} H_2(x)$ for some scalar function $\beta_2(x)$. In the same manner, define $c_2(x) = \sigma^{-1}c(\sigma x)$. The original domain $\hat{G}$ is transformed to $G_2 = \{x : \ \sigma x \in G\}$, and the original control limit matrix $\hat{M}$ is transformed to $M_2(x) = \sigma^t M(\sigma^{-1}x)\sigma$. Our optimization problem then becomes

$$\dot{\tilde{X}}_t^\epsilon = \beta_2(\tilde{X}_t^\epsilon)\overline{\nabla} H_2(\tilde{X}_t^\epsilon) + \epsilon c_2(\tilde{X}_t^\epsilon) + \epsilon^{1/2}\dot{\tilde{W}}_t,$$
$$\tilde{X}_0^\epsilon = x \ \in \Re^2$$

with region G_2 and control magnitude limit $c_2(x)^t M_2(x) c_2(x) \leq K^2$. Note in particular that if $\beta(x) \neq 0$ in G, then $\beta_2(x) \neq 0$ in G_2 so that Theorem 3 and then Corollary 2 can be applied.

Also note the special structure of the set G: the boundary ∂G is composed of level sets of the Hamiltonian H. This special structure is completely natural because

of the underlying Hamiltonian dynamics. If, for some $x \in G$, the unperturbed and uncontrolled solution $\tilde{X}_t$ with initial condition x leaves G, then no control $\epsilon c(\cdot)$ is able to prevent exit from G when ϵ is small. Thus for a more general domain $\tilde{G}$, we should decompose $\tilde{G} = G_1 \bigcup G_2$ with $G_1 = \{x : \ \tilde{X}_t \in G \ \forall t \geq 0 \text{ when } \tilde{X}_0 = x\}$ and $G_2 = \tilde{G} - G_1$. Then Theorem 2 is applied in G_1 and initial points in G_2 are not asymptotically stabilizable.

5. Examples. Several examples are given to illustrate application of the theorem. The first provides a simple numerical example to illustrate how the theory might be applied. The other examples discuss solving for the optimal control problem in a more general setting.

Example 1. Consider control of a simple linear oscillator perturbed by a small noise and controlled by a small control:

$$\begin{pmatrix} \dot{\tilde{X}}^c_{1\,t} \\ \dot{\tilde{X}}^c_{2\,t} \end{pmatrix} = \begin{pmatrix} \tilde{X}^c_{2\,t} \\ -\tilde{X}^c_{1\,t} \end{pmatrix} + 0.0001\ c(\tilde{X}^c_t) + 0.0001^{1/2}\dot{\tilde{W}}_t, \tag{19}$$
$$\tilde{X}^c_0 = x \ \in \Re^2.$$

Note that

$$\begin{pmatrix} \tilde{X}^c_{2\,t} \\ -\tilde{X}^c_{1\,t} \end{pmatrix} = \overline{\nabla} H(\tilde{X}^c_t)$$

for Hamiltonian function

$$H(x) = \frac{1}{2}(x_1^2 + x_2^2).$$

Here, clearly, is the situation we have discussed above with $\epsilon = 0.0001$. Choice of the constant K (in $c^t(x)M(x)c(x) \leq K^2$) will be used to constrain the precise size of the control with respect to the noise and Hamiltonian dynamics. In order to fit into the mathematical format above, we rescale time by $\frac{t}{0.0001} \to t$, with the resulting dynamics

$$\begin{pmatrix} \dot{X}^c_{1\,t} \\ \dot{X}^c_{2\,t} \end{pmatrix} = \frac{1}{0.0001}\begin{pmatrix} X^c_{2\,t} \\ -X^c_{1\,t} \end{pmatrix} + c(X^c_t) + \dot{W}_t, \tag{20}$$
$$X^c_0 = x \ \in \Re^2.$$

Our goal is to stabilize X^c_t so that $1 \leq H(X^c_t) \leq 2$ for as long as possible. We can see the geometry of the situation in Figure 2. The Hamiltonian and its level curves are shown in Figure 2(a) and 2(b). Our region G is shown in Figure 2(c), and G has boundaries $H(x) = 1$ and $H(x) = 2$. Figure 2(d) shows the segment of the graph corresponding to G. Note that the segment endpoints correspond to the trajectories $H(x) = 1$ and $H(x) = 2$.

We should first informally verify that application of our theory to this problem is reasonable: we should establish that X^0_t (note the control $c = 0$) generally makes a number of revolutions before the Hamiltonian $H(X^0_t)$ changes a great deal. Figure 3 shows a sample path for X^0_t and $H(X^0_t)$. Only a few sample paths need be examined to convince us that use of the theory is reasonable.

Now we can easily find the optimal control for various control size limits K ($c^t(x)M(x)c(x) \leq K^2$ with $M(x) = I$). For this example, we used $K = 2$ and

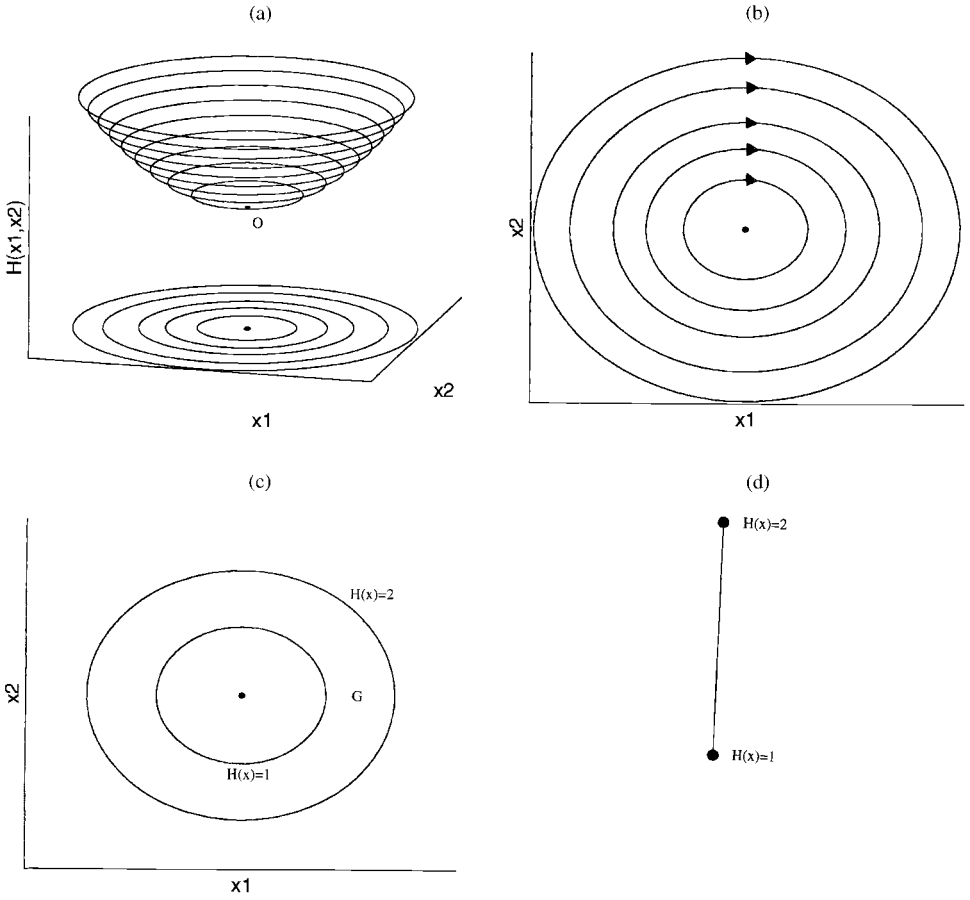

FIG. 2.

$K = 4$. The solution of the optimal control requires, from equation (13), the solution of

$$\begin{aligned} hv''(h) + v'(h) + \sqrt{2h}K|v'(h)| + 1 = 0, \quad h \in (1,2), \\ v(1) = v(2) = 0. \end{aligned} \tag{21}$$

Note that there is only one graph segment, so that the segment notation has been dropped. Then the control c is given according to equation (14). This problem was easily solved in MATLAB and required only a few minutes of coding and execution. The solution v also provides (for small ϵ and a specific K) the approximation

$$v(H(X_0^{\epsilon,c^*})) \approx E_x(\tau^{\epsilon,c^*})$$

as follows from equations (15) and (16). Note that solving equation (21) with $K = 0$ yields an estimate of the uncontrolled exit time. Figure 4 shows the theoretical limit (as $\epsilon \to 0$) of the mean exit times for no control, optimal control with $K = 2$, and optimal control with $K = 4$. These are, respectively, the solid, dashed, and dotted lines. The regions where v increases or decreases determine whether the control is along or opposed to the gradient ∇H, as seen in equation (14).

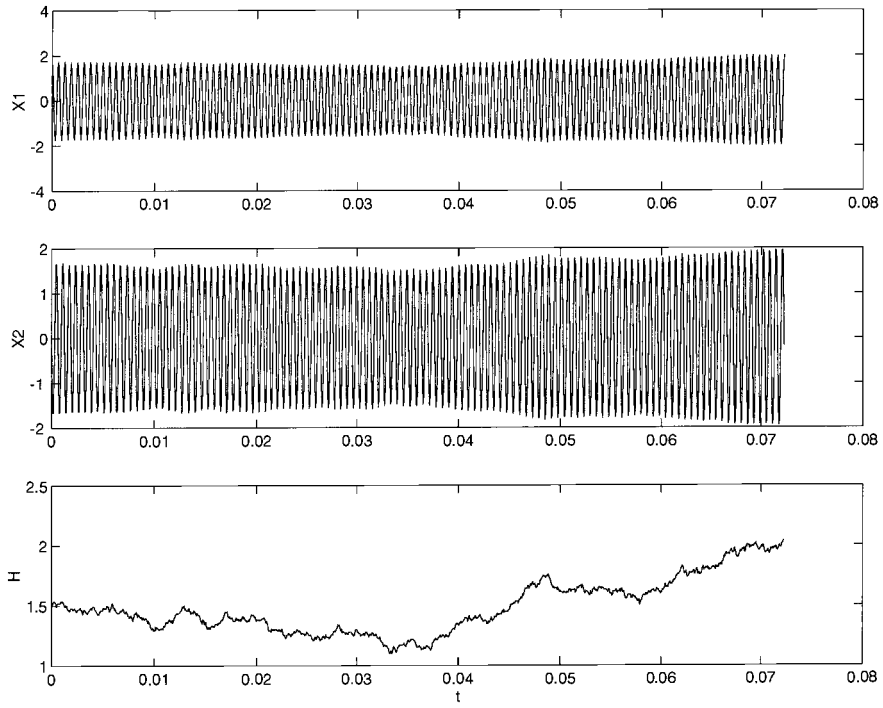

FIG. 3.

To test whether $\epsilon = 0.0001$ is indeed "small," Monte Carlo numerical simulations of equation (20) were also run in MATLAB. These computations turned out to be delicate: since the random trajectories generally circled hundreds or thousands of times before leaving $G = \{x : \ 1 \leq \frac{1}{2}(x_1^2 + x_2^2) \leq 2\}$, numerical errors in the integration scheme caused significant drift in $H(X_t^{c^*})$. This was counteracted by noticing that, since the Hamiltonian drifted slowly, equation (20) could be approximated as a linear equation over short time intervals. A state transition matrix was calculated and applied over each of these short time intervals. Using this viewpoint, 250 sample trajectories were calculated for each of the three controls and initial conditions corresponding to initial Hamiltonian values of 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 1.7, 1.8, and 1.9. The mean exit time over the 250 samples is plotted in Figure 4 as "o" for no control, "x" for optimal control with $K = 2$, and "+" for optimal control with $K = 4$.

Although there is some sampling error and probably still some error from the numerical integration scheme, the agreement in Figure 4 is good. The theoretical limit (as $\epsilon \to 0$) does predict the actual exit times for $\epsilon = 0.0001$, leading us to believe that the asymptotically optimal controls are good choices for controlling the exit time in equation (19).

Example 2. The second example is the simplest and most obvious. Consider the simple Hamiltonian function described in Figures 1(a) and 1(b), along with the corresponding graph in Figure 1(d). Let G be a set whose boundary is a level set of $H(x)$ and assume G contains all three extrema, O_1, O_2, and O_3. Let the matrix function $M(x) = I$ in the control constraint $c^t(x)M(x)c(x) \leq K^2$.

Theorem 2 may be easily applied to maximize the expected exit time from G. First note that the differential equation in (13) may be viewed as a first-order equation

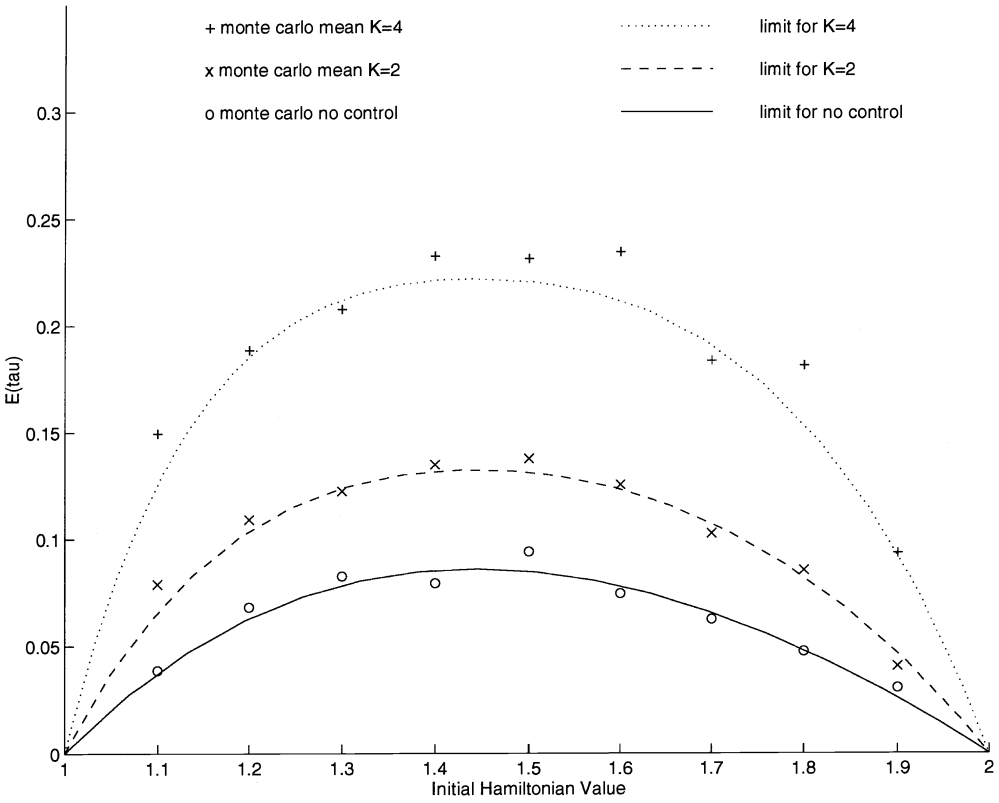

FIG. 4.

involving v' and its derivative v'', with no direct dependence on v. As long as v' is negative, the solution in the interior of a segment may be written as

$$
\begin{aligned}
v'(i,y) &= \exp\left\{\int_{y_0}^{y} -\frac{2}{A_i(\hat{y})}\left(B_i(\hat{y}) - KE_i(\hat{y})\right)d\hat{y}\right\} v'(i,y_0) \\
&+ \int_{y_0}^{y} -\frac{2}{A_i(\tilde{y})} \exp\left\{\int_{\tilde{y}}^{y} -\frac{2}{A_i(\hat{y})}\left(B_i(\hat{y}) - KE_i(\hat{y})\right)d\hat{y}\right\} d\tilde{y}.
\end{aligned} \tag{22}
$$

Consider the lower left segment of the graph in Figure 1(d). The inaccessibility condition in equation (9) establishes that $v'(1,y) < 0$ as y approaches the lower segment endpoint. Then, since $A_i(y) \geq 0$, $v'(1,y) < 0$ on the left segment. Similarly, $v'(3,y) < 0$ on the lower right segment. The boundary condition on the graph center node then requires that $v'(2,y) < 0$ for y at the center joint. Again applying (22) establishes $v'(3,y) < 0$ on the upper segment of the graph. Thus

$$c^*(x) = -K\ \nabla H(x)/|\nabla H(x)|$$

for Example 1. This result is expected; the control pushes away from the boundary of G along the gradient of $H(x)$.

Example 3. Let $H(x)$ have the general structure illustrated in Figures 1(a), 1(b), and 1(d). Let G be a set with the structure illustrated in Figure 1(c). The goal is to keep the dynamical system inside G; the system oscillations should not be too

far from the ∞-shaped curve passing through the saddle point O_2. Let the matrix function $M(x) = I$ in the control constraint $c^t(x)M(x)c(x) \le K^2$.

This problem is more complex, but a straightforward method may be constructed for its solution. For convenience, let $(1, y_1)$, $(2, y_2)$, and $(3, y_3)$ be the boundary of the image of G on the lower left graph segment, the upper graph segment, and the lower right graph segment, respectively. Note that in Theorem 2 the boundary conditions require $v(i, y_i) = 0$ for the three boundary points. Also use the notation y_n to indicate the value of y at the central node. Our problem requires six boundary and gluing conditions provided by

$$\begin{cases} v(1, y_1) = 0, \\ v(2, y_2) = 0, \\ v(3, y_3) = 0, \\ v(1, y_n) = v(2, y_n), \\ v(2, y_n) = v(3, y_n), \\ \beta_{12} v'(2, y_n) = \beta_{11} v'(1, y_n) + \beta_{13} v'(3, y_n) \end{cases}$$

with $\beta_{11} > 0$, $\beta_{12} > 0$, and $\beta_{13} > 0$.

Solution representations such as (22) show that the sign of v' can change sign at most once in the interior of an interval. Also, for Example 2, $v'(1, y_1) > 0$, $v'(2, y_2) < 0$, and $v'(3, y_3) > 0$ follow from the fact that $v(i, y) \ge 0$.

It is possible that $v'(1, y_n) = v'(2, y_n) = v'(3, y_n) = 0$. This can be tested immediately by using solution representations such as (22) to solve the resulting two-point boundary value problems using $v(i, x_i) = 0$ and $v'(i, y_n) = 0$. Each boundary value problem only requires solution of a linear algebraic equation. Continuity then requires $v(1, y_n) = v(2, y_n) = v(3, y_n)$. If this condition is met, then the optimal control is

$$c^*(x) = \begin{cases} K \frac{\nabla H(x)}{|\nabla H(x)|} & \text{for } x \in Y^{-1}(I_1), \\ -K \frac{\nabla H(x)}{|\nabla H(x)|} & \text{for } x \in Y^{-1}(I_2), \\ K \frac{\nabla H(x)}{|\nabla H(x)|} & \text{for } x \in Y^{-1}(I_3). \end{cases}$$

For the remainder of this example we consider the case when $v'(1, y_n) = v'(2, y_n) = v'(3, y_n) = 0$ does not hold. The node gluing condition then shows that $v'(i, y)$ must change sign on one or two of the graph segments. Changing sign on no segments or changing sign on all three segments leads to a violation of the joint gluing condition. The fact that at least one of the three segments does not change sign, and therefore is described by a linear differential equation, allows explicit solution without solving a nonlinear boundary value problem.

Now a method of solution may be constructed, based on solving for a single parameter via integration of one-dimensional differential equations. First solve the linear equation

$$L_i^{\hat{c}} u^{\hat{c}}(i, y) + 1 = 0, \qquad (i, y) \in G_\Gamma,$$

$$\sum_{i: I_i \sim O_k} (\pm \beta_{ki}) u^{\hat{c}\prime}(i, H(y_k)) = 0 \quad \text{for all interior vertices,}$$

$$u^{\hat{c}}(i, y) = 0 \quad \text{on the boundary } \partial G_\Gamma,$$

with

$$\hat{c}(x) = \begin{cases} K\frac{\nabla H(x)}{|\nabla H(x)|} & \text{for } x \in Y^{-1}(I_1), \\ -K\frac{\nabla H(x)}{|\nabla H(x)|} & \text{for } x \in Y^{-1}(I_2), \\ K\frac{\nabla H(x)}{|\nabla H(x)|} & \text{for } x \in Y^{-1}(I_3). \end{cases}$$

This corresponds to a control pushing toward the graph joint. The problem is easily solved by viewing $u^{\hat{c}'}(1, y_1)$, $u^{\hat{c}'}(2, y_2)$, and $u^{\hat{c}'}(3, y_3)$ as unknowns. Then three linear algebraic equations can be written for these unknowns. First define the state transition matrix for each segment:

$$\Phi_i^{\hat{c}'}(y, y_i) = \begin{bmatrix} -\frac{2}{A_i^{\hat{c}}(y)} B_i^{\hat{c}}(y) & 0 \\ 1 & 0 \end{bmatrix} \Phi(y, y_i), \qquad y \in I_i,$$

$$\Phi_i^{\hat{c}}(y_i, y_i) = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}.$$

Then

$$\begin{bmatrix} u^{\hat{c}'}(i, y) \\ u^{\hat{c}}(i, y) \end{bmatrix} = \Phi_i^{\hat{c}}(y, y_i) \begin{bmatrix} u^{\hat{c}'}(i, y_i) \\ 0 \end{bmatrix} - \int_{y_i}^{y} \Phi_i^{\hat{c}}(y, \hat{y}) \begin{bmatrix} \frac{2}{A_i^{\hat{c}}(\hat{y})} \\ 0 \end{bmatrix} d\hat{y}, \qquad y \in I_i. \tag{23}$$

Evaluating these three solutions at the joint y_n and applying the gluing and continuity conditions establishes three linear conditions in the three unknowns $u^{\hat{c}'}(1, y_1)$, $u^{\hat{c}'}(2, y_2)$, and $u^{\hat{c}'}(3, y_3)$. In the case that $u^{\hat{c}'}(1, y_n) = u^{\hat{c}'}(2, y_n) = u^{\hat{c}'}(3, y_n) = 0$, $\hat{c}$ is the optimal control. Due to the gluing conditions, at least one of the $u^{\hat{c}'}(i, y)$ does not change sign. For convenience, assume $u^{\hat{c}'}(3, y) > 0$ on I_3. Then, for the optimal control c^*, $u^{\hat{c}}(3, y) \leq u^{c^*}(3, y)$. This, together with

$$\begin{aligned} u^{\hat{c}'}(3, y) &= \exp\left\{ \int_{y_3}^{y} -\frac{2}{A_i^{\hat{c}}(\hat{y})} B_i^{\hat{c}}(\hat{y}) d\hat{y} \right\} u^{\hat{c}'}(3, y_3) \\ &\quad + \int_{y_3}^{y} -\frac{2}{A_i^{\hat{c}}(\tilde{y})} \exp\left\{ \int_{\tilde{y}}^{y} -\frac{2}{A_i^{\hat{c}}(\hat{y})} B_i^{\hat{c}}(\hat{y}) d\hat{y} \right\} d\tilde{y}, \end{aligned} \tag{24}$$

indicates that $u^{\hat{c}'}(3, y_3) \leq u^{c^*\prime}(3, y_3)$. We see then that $u^{c^*\prime}(3, y) = v'(3, y) > 0$ on segment I_3. This provides the key to solving the nonlinear control problem in equation (13).

The solution can now be described as solving a single equation for a single unknown α. For notational purposes, represent this nonlinear algebraic equation by

$$F(\alpha) = 0,$$

where evaluation of $F(\cdot)$ is best described by a procedure rather than an explicit formula. To calculate $F(\alpha)$, perform the following steps:

(1) Set $v'(1, y_1) = \alpha$.

(2) Use (13) and integrate the nonlinear equation along I_1 to the node. This results in boundary conditions at the node of $v(1, y_n)(\alpha) = v(2, y_n)(\alpha) = v(3, y_n)(\alpha)$ and $v'(1, y_n)(\alpha)$. The dependence on α is made explicit in the notation.

(3) Now solve the linear two-point boundary value problem along I_3. Because $v'(3,y) > 0$, $c^*(x) = \hat{c}(x)$ for $x \in Y^{-1}I_3$. Using the values $v(3,y_n)(\alpha)$ and $v(3,y_3) = 0$, the solution representation in equation (23) may be used to immediately calculate the resulting $v'(3,y_n)(\alpha)$.

(4) Continuity and gluing conditions in equation (13) immediately yield values for $v(2,y_n)(\alpha)$ and $v'(2,y_n)(\alpha)$. Use equation (13) on segment I_2 and integrate to finally find an endpoint value $v(2,y_2)(\alpha)$. The function $F(\alpha)$ may then be expressed by

$$F(\alpha) = v(2,y_2)(\alpha).$$

After a solution to $F(\alpha) = 0$ is found, the functions $v(i,y)$ are then calculated by setting $v'(1,y_1) = \alpha$ and integrating along the graph segments again. See the above four steps. The direction of optimal control is then along the gradient of $H(x)$, with direction determined by $sign(v'(i(x),H(x)))$ and magnitude equal to K.

This solution has an interesting interpretation. The unperturbed Hamiltonian oscillations at which

$$sign(v'(i(x),H(x)))$$

changes are in a sense the "safest" paths, and the control pushes the system trajectory toward these "most stable" solutions. If only one sign change of $v'(i,x)$ occurs on the graph in G_Γ, then all points in G are attracted to the resulting single most stable trajectory. If two sign changes of $v'(i,x)$ occur on the graph in G_Γ, then points in $x \in G$ are attracted to the "safe" path which is least risky to reach.

6. Conclusions. The results of this paper are easy to apply and have significant intuitive appeal: the optimal control is in the direction of the gradient of the Hamiltonian, with sign determined by solution of a simple boundary value problem on the corresponding graph. However, three important directions of expansion of these results are possible.

The admissible control class Π_K is not the broadest possible choice. A better choice would be all functionals $c_t = c(X_s^{\epsilon,c}, 0 \le s \le t)$ with $c^t(x)M(x)c(x) \le K^2$ and $c(\cdot)$ measurable with respect to the system trajectory up to time t. This appears possible, but it is complicated by the fact that the convergence occurs on the graph instead of in $\Re^2$. Many analytical tools have not yet been developed for processes on graphs. It is worth noting that for each fixed ϵ the optimal control given by equation (4) is in Π_K.

The noise process in our problem is two-dimensional white noise $\dot{W}_t$. These results can possibly be extended for a more general noise term of the form $\sigma(X_t^{\epsilon,c})\dot{W}_t$ (with spatial dependence in the noise field) for positive definite $\sigma(\cdot)$. Degenerate noise is much more problematic.

Finally, controls for perturbed Hamiltonian systems in $\Re^n$, with $n > 2$, are of course of great interest. Systems with more than one integral of motion could be considered; in this case, the random motion would occur not on a graph but on some higher-dimensional object. The geometry would be complicated, and the nonperturbed system trajectories would not in general provide the required averaging conditions. More can be said about a special case in $\Re^n$ in which averaging is accomplished by a second noise process. Consider, for example, a system such as

$$\dot{\tilde{X}}_t^{\epsilon,c} = f(\tilde{X}_t^{\epsilon,c}) + \zeta_t(\tilde{X}_t^{\epsilon,c}) + \epsilon\, c(\tilde{X}_t^{\epsilon,c}) + \epsilon^{1/2}\dot{\tilde{W}}_t,$$
$$\tilde{X}_0^{\epsilon,c} = x \ \in \Re^2.$$

Here ζ_t is a random process. As written here, ζ_t is smooth enough to allow stochastic integration, but a white noise process could also be used. We are interested in systems with an integral of motion $H(\cdot)$ for the uncontrolled and unperturbed system

$$\begin{aligned} \dot{\tilde{X}}_t &= f(\tilde{X}_t) + \zeta_t(\tilde{X}_t), \\ \tilde{X_0^{\epsilon,c}} &= x \ \in \Re^2, \end{aligned} \tag{25}$$

so

$$\begin{aligned} \nabla H(x) \cdot f(x) &= 0, \\ \nabla H(x) \cdot \zeta_t(x) &= 0. \end{aligned}$$

Conditions can be given for the noise process ζ_t so that the system in equation (25) is ergodic in the level sets of $H(\cdot)$. Then averaging will occur, and the approach used in this paper could be applied.

OUTPUT DEAD BEAT CONTROL FOR A CLASS OF PLANAR POLYNOMIAL SYSTEMS*

D. NEŠIĆ†, I. M. Y. MAREELS‡, G. BASTIN§, AND R. MAHONY†

Abstract. Output dead beat control for a class of nonlinear discrete time systems, which are described by a single input-output (I-O) polynomial difference equation, is considered. The class of systems considered is restricted to systems with a two-dimensional state space description. It is assumed that the highest degree with which the present input appears in the equation is odd. Necessary and sufficient conditions for the existence of output dead beat control and for the stability of the zero output constrained dynamics are presented. We also design a minimum time output dead beat control algorithm (feedback controller) which yields stable zero dynamics, whenever this is feasible. A number of interesting phenomena are discussed and illustrated with examples.

Key words. polynomial systems, dead beat, controllability

1. Introduction.

Linear dead beat control has received a great deal of attention in the past 30 years [16]. The discoveries in the area of linear dead beat control resulted in a better understanding of linear systems theory and a number of very successful applications. The fact that very often the dynamics of a plant cannot successfully be modeled using linear time invariant equations, provide motivation for considering nonlinear dead beat control. Dead beat control or controllability for special classes of nonlinear systems has been addressed by many authors [1, 7, 8, 9, 10, 12, 20, 21, 22]. Nevertheless, a wealth of open questions remain to be explored.

Polynomial I-O systems of the form $y_{k+1} = f(y_k, \ldots, y_{k-s}, u_{k-t}, \ldots, u_k)$ are often used [13, 14, 5] for system identification in black-box mode (see also [23, 24]). y, u, and k are, respectively, the output, input, and time index. The function f is a polynomial in all its arguments. This is an obvious generalization of linear ARMA models. Although a number of applications of I-O polynomial systems have been reported, e.g., [5, 14], their control properties are not well understood.

In this paper we consider a class of I-O polynomial systems of the following form:

$$y_{k+1} = f(y_k, u_{k-1}, u_k). \tag{1.1}$$

We assume throughout the paper that the highest exponent of the argument u_k in the polynomial f is an odd integer. An application of this class of systems can be found in [5] where a subsystem of a radiator and fan is identified in this form.

The control question that we are interested in is minimum time output dead beat regulation. In particular, we want to design a control law of the form

$$u_k = c(y_k, u_{k-1}) \tag{1.2}$$

such that $y_k = 0\ \forall k \geq t$ for some integer t and such that the constrained dynamics[1] defined by

$$\begin{aligned} 0 &= f(0, u_{k-1}, u_k), \\ u_k &= c(0, u_{k-1}) \end{aligned} \tag{1.3}$$

are stable in a sense to be specified later. The paper deals with two questions: output dead beat controllability and stability of constrained dynamics for (1.1).

Some pioneering work on controllability for a class of discrete time bilinear systems can be found in [11]. Papers [7, 8, 12] provide complete conditions for controllability for the same class of systems. Invariance of the control independent set was investigated in [11]. We show that a new notion of strongly invariant sets, first introduced in [20, 21], is crucial for output dead beat controllability of (1.1). We take a similar approach as in [20, 21], where dead beat controllability of scalar polynomial systems is considered. The output controllability result of this paper can be viewed as a generalization of some results on odd systems in [20, 21]. In the conference version [22] of this paper, we provided the output controllability test for (1.1). However, the design of a feasible dead beat controller and stability of constrained dynamics are analyzed in the sequel.

Output dead beat control of recursive nonlinear systems was investigated in [1, 3]. Existence of constrained dynamics together with a number of interesting phenomena were studied. The considered class of systems was, however, large and results are consequently weak. The notion of criterion of choice is introduced in the context of stability of constrained dynamics in [1, 3]. This notion is also important in our discussions. Stability of one-dimensional explicit constrained dynamics $u_k = f(u_{k-1})$ was investigated [2, 3]. Our paper extends these results to the case of implicitly defined polynomial dynamics (1.3) and we present necessary and sufficient conditions of the existence of a criterion of choice that leads to stable constrained dynamics. We point out that the stability of an interval that we consider was investigated in [3] and in [15], where this property is referred to as "permanence." In [15], global stability properties of a number of nonlinear explicit systems of the form $y_{k+1} = F(y_k, \ldots, y_{k-s})$ were investigated (see also [19] for continuous time results). We, however, consider the implicit difference equation in (1.3). We emphasize that the notion of constrained dynamics considered here differs from the concept of zero dynamics introduced in [17, 18]. Moreover, the notion of zero dynamics [17, 18] appears not to be sufficiently general to be applicable to the stabilizing dead beat control problem considered here.

This paper provides an explicit test for verifying the existence of an output dead beat control law which yields stable constrained dynamics for the system of the form (1.1). Furthermore, a constructive design method is provided to find any such feedback law. A purpose of this paper is to show the difficulties that one may face when tackling the output dead beat control problem for the simple class of I-O polynomial systems (1.1) and to present a number of interesting phenomena.

[1]The definition of stable zero output constrained dynamics that we analyze is more general than the usual definition of zero dynamics found in literature [17]. To make the distinction more obvious we refer to our definition as constrained dynamics and to the definition in [17] as zero dynamics.

The paper is organized as follows. In section 2 we present some notation, and in section 3 we define the problem and the class of systems that we consider. The question of the existence of dead beat control is addressed in section 4. Sections 5 and 6 are, dedicated to, respectively, the stability of constrained dynamics and a method to check the existence of a dead beat control law which yields stable constrained dynamics. The modified dead beat control law which zeros the output in minimum time and also yields stable constrained dynamics is then presented in section 7. In section 8, we present several examples which illustrate our methods. The summary and conclusion are given in the last section.

2. Mathematical preliminaries. We use the standard definitions of rings and fields [6]. We work over the field of real numbers which is denoted as $\Re$. $\Re^n$ is a set of all n-tuples of elements of $\Re$, where n is a nonnegative integer. The ring of polynomials in n variables over the real field $\Re$ is denoted as $\Re[x_1, x_2, \ldots, x_n]$. Let $f_1, f_2, \ldots, f_s$ be polynomials in $\Re[x_1, x_2, \ldots, x_n]$. Then we define

$$V(f_1, f_2, \ldots, f_s) = \{(a_1, a_2, \ldots, a_n) \in \Re^n : f_i(a_1, a_2, \ldots, a_n) = 0 \text{ for all } 1 \le i \le s\}.$$

We call $V(f_1, f_2, \ldots, f_s)$ the real algebraic set or real variety defined by $f_1, f_2, \ldots, f_s$. Since the defining polynomials of a real variety are often clear from the context, it is often denoted simply as V.

DEFINITION 2.1. *A real variety $V \subset \Re^n$ is* irreducible *if whenever V is written in the form $V = V_1 \cup V_2$, where V_1 and V_2 are real varieties, then either $V_1 = V$ or $V_2 = V$* [6, p. 196].

THEOREM 2.2 (see [6, p. 202]). *Let $V \subset \Re^n$ be a real variety. Then V can be written as a finite union of irreducible varieties $V = V_1 \cup V_2 \cup \cdots \cup V_m$ where each V_i is an irreducible variety.*

Let $f, g \in \Re[x_1, x_2, \ldots, x_n]$. $f|g$ means that g divides f; that is, there exists a polynomial $h \in \Re[x_1, x_2, \ldots, x_n]$ such that $f = hg$. $f \equiv g|h$ means that f is divisible by h modulo g; that is, given polynomials h and g, $deg(g) < deg(f)$ there exists a polynomial $h_1 \in \Re[x_1, x_2, \ldots, x_n]$ such that $f = h_1 h + g$. Also, $f \not| g$ and $f \equiv g \not| h$ denotes, respectively, that f is not divisible by g and f is not divisible by h modulo g.

We say that a variety $V \subset \Re^2$ has special form if

$$V = \left\{ (y, v) \in \Re^2 : y - \sum_{i=0}^{n-1} b_i v^i = 0,\ b_i \in \Re,\ i = 0, 1, \ldots, n-1 \right\}.$$

Varieties of special form are irreducible because they can be parametrized by polynomials [6, p. 197].

3. Definition of the system. We consider systems described by the following recursive I-O polynomial equation:

$$y_{k+1} = f(y_k, u_{k-1}, u_k), \tag{3.1}$$

where y_k is the output of the system at time k and u_k is the input to the system at time k. The function f is a polynomial, $f \in \Re[y, v, u]$. We assume that the highest exponent of u in $f(y, v, u)$ is an odd integer. A system (3.1) with this property is referred to as an *odd system*.

It is always possible to rewrite (3.1) in the following form:

$$y_{k+1} = g_n(y_k, u_{k-1})u_k^n + g_{n-1}(y_k, u_{k-1})u_k^{n-1} + \cdots + g_0(y_k, u_{k-1}), \tag{3.2}$$

where $g_n \not\equiv 0$ and n is an odd positive integer.

ASSUMPTION 1. *Constrained dynamics are defined as*

$$\forall v \in \Re, \quad \exists u \in \Re \text{ such that } f(0, v, u) = 0. \tag{3.3}$$

A sequence of controls is denoted as

$$\mathcal{U} = \{u_0, u_1, \ldots\}.$$

The truncation to a sequence of length $p+1$ is denoted as $\mathcal{U}_p = \{u_0, u_1, \ldots, u_p\}$. The composition of the function f in equation (3.1) under the action of a control sequence $\mathcal{U}_p$ which starts from $(y_0, u_{-1}) \in \Re^2$ is denoted as

$$f^{\mathcal{U}_p}(y_0, u_{-1}) = \underbrace{f(f(\ldots f(f}_{p \text{ times}}(y_0, u_{-1}, u_0), u_0, u_1), \ldots, u_{p-1}, u_p).$$

Obviously $y_{p+1} = f^{\mathcal{U}_p}(y_0, u_{-1})$ is the output at time $p+1$, given the starting point (y_0, u_{-1}) and the input $\mathcal{U}_p$.

We can introduce the state variables $x_1(k) = y_k$ and $x_2(k) = u_{k-1}$ and write accordingly the model in state space format. In the sequel, we refer to $(y_0, u_{-1}) \in \Re^2$ as an initial state although we work with the input output equation (3.1).

We are interested in output dead beat control in Definition 3.1.

DEFINITION 3.1. *The system* (3.1) *is output dead beat controllable if for every* $(y_0, u_{-1}) \in \Re^2$ *there is a sequence* $\mathcal{U} = \{u_0, u_1, \ldots\}$ *such that the output of the system* (3.1) *is driven to zero in finite time, that is,* $y_k = 0, \forall k \geq t$, *where* t *is a nonnegative integer.*

DEFINITION 3.2. *A feedback controller, given by* $u_k = c(y_k, u_{k-1})$, *is an output dead beat controller if there exists a positive integer* P *such that* $\forall (y_0, u_{-1}) \in \Re^2$ *and* $k \geq P$ *we have* $y_k = 0$, *where* $y_{k+1} = f(y_k, u_{k-1}, c(y_k, u_{k-1}))$.

Because of Assumption 1, we can split the dead beat control problem into two parts. Indeed, the control sequence $\mathcal{U}$ in Definition 3.1 may be split into two parts. $\mathcal{U}_t$ is the part of the sequence $\mathcal{U}$ that transfers the output to the origin and $\{u_{t+1}, \ldots\}$ the part which keeps the output at the origin. Section 4 is concerned with the existence of the sequence $\mathcal{U}_t$, which naturally leads to the construction of an (feedback) output dead beat controller. In section 5 we consider the properties of the obtained control laws, which settles the usefulness of the approach.

4. Output dead beat controllability of recursive polynomial systems. In this section, we consider when it is possible to transfer the output of the system (3.1) to the origin in finite time, starting from an arbitrary initial state $(y_0, u_{-1}) \in \Re^2$. The following definition is used in the sequel.

DEFINITION 4.1. *The one-step reachable set from an initial state* $(y_0, u_{-1}) \in \Re^2$ *is defined as*

$$V_r(y_0, u_{-1}) = \{(y, u) \in \Re^2 : y - f(y_0, u_{-1}, u) = 0\}.$$

We also define the projection of the one-step reachable set onto the first coordinate axis as

$$\Pi V_r(y_0, u_{-1}) = \{y \in \Re : \exists v \in \Re : (y, v) \in V_r(y_0, u_{-1})\}$$

and call it the set of one-step reachable outputs.

Observe that the one-step reachable set is a real variety and it has special form for any initial state in $\Re^2$. Moreover, since the systems is odd, the only states from

which it may not be possible to zero the output in one step belong to the real variety V_C defined by

$$V_C = \{(y, v) \in \Re^2 : g_n(y, v) = 0\}. \tag{4.1}$$

Notice that dim $V_C < 2$.

DEFINITION 4.2. *The variety V_C given by* (4.1) *is called the* critical variety.

DEFINITION 4.3. *The number of varieties of special form that are contained in V_C is denoted by N.*

Let V and W be varieties. We introduce the notation

$$V \xrightarrow{f} W \tag{4.2}$$

to denote that $V_r(y_0, u_{-1}) = W \ \forall (y_0, u_{-1}) \in V$. It should be emphasized that equation (4.2) means that the one-step reachable set from any initial state in V is *equal to W*.

DEFINITION 4.4. *A set $V_{I_j} \subseteq V_C$ is invariant if*

$$\forall (y, v) \in V_{I_j},\ V_r(y, v) \subseteq V_{I_j}. \tag{4.3}$$

The union of all invariant sets $V_I = \cup_j V_{I_j}$ is called the maximal invariant set.

DEFINITION 4.5. *A subset W_{I_j} of the variety V_C is strongly invariant if it is invariant and $\forall (y_0, u_{-1}) \in W_{I_j}$ there exists an integer $t \geq 0, t = t(y_0, u_{-1})$ and a sequence of controls $\mathcal{U}_t = \{u_0, u_1, \ldots, u_t\}$ which yields $(y_{t+1}, u_t) = (y_0, u_{-1})$, where $y_{t+1} = f^{\mathcal{U}_t}(y_0, u_{-1})$. The union of all strongly invariant sets $W_I = \cup_j W_{I_j}$ is called the maximal strongly invariant set.*

DEFINITION 4.6. *The number of varieties of special form that are contained in the maximal strongly invariant set W_I of V_C is denoted by L.*

The propositions below indicate some important properties of the maximal invariant and strongly invariant sets.

PROPOSITION 4.7. *The maximal strongly invariant set can be decomposed into finitely many strongly invariant subsets W_{I_j}, each of which can be decomposed into finitely many varieties of special form W_i:*

$$W_I = \underbrace{W_1 \cup \cdots \cup W_{L_1}}_{W_{I_1}} \cup \underbrace{W_{L_1+1} \cup \cdots \cup W_{L_1+L_2}}_{W_{I_2}} \cup \cdots \cup \underbrace{W_{L_1+\cdots+L_{p-1}+1} \cup \cdots \cup W_{L_1+\cdots+L_p}}_{W_{I_p}},$$

where $L_1 + L_2 + \cdots + L_p = L$. Therefore, the maximal strongly invariant set is itself a variety.

Sketch of the proof. We prove this proposition in four steps. Since $V_r(y_0, u_{-1})$ is of special form for any $(y_0, u_{-1}) \in V_C$, at least one variety of special form W_1 belongs to the maximal strongly invariant subset W_I. Then we can show that in order to have invariance one-step reachable sets from any initial state in W_1 must coincide; that is, $V_r(y_1, v_1) = V_r(y_2, v_2)\ \forall (y_1, v_1), (y_2, v_2) \in W_1$. Therefore, we show that one can write $V_r(y, v) = W_2\ \forall (y, v) \in W_1$, where W_2 is a variety of special form which is a subset of V_C. After this, we show that the union $W_1 \cup W_2 \cup \cdots \cup W_L$ is a subset of W_I. Finally, it is proved that the union $W_1 \cup W_2 \cup \cdots \cup W_L$ is equal to W_I, and the partition into smaller strongly invariant sets follows easily. For a more detailed proof see [22]. □

Proofs of the propositions below hinge on the proof of Proposition 4.7 (see [22]).

PROPOSITION 4.8. *Any invariant subset V_{I_j} of the critical variety V_C contains a strongly invariant subset W_{I_j}.*

PROPOSITION 4.9. *Any initial state that belongs to an invariant subset V_{I_j} of the critical variety V_C is transferred to a strongly invariant subset W_{I_j} (which is a subset of V_{I_j}) in finite time.*

PROPOSITION 4.10. *Any $(y_0, u_{-1}) \in V_C - V_I$ can be mapped to $\Re^2 - V_C$ in at most $N - L + 1$ time steps (see Definitions 4.3 and 4.6).*

COMMENT 1. An immediate consequence of Proposition 4.10 is that if $V_I = \emptyset$ any initial state in V_C can be mapped to $\Re^2 - V_C$ in at most $N + 1$ time steps and hence the output can be zeroed in at most $N + 2$ steps (see Definition 4.3).

PROPOSITION 4.11. *Consider the system (3.1). The critical variety V_C (4.1) contains a strongly invariant subset if and only if there exist polynomials $y - \sum_{i=0}^{n-1} b_i^p v^i$, $b_i^p \in \Re$, $p = 1, 2, \ldots, B$, $B \leq L \leq N$ such that*

$$g_n(y, v) | \left(y - \sum_{i=0}^{n-1} b_i^p v^i \right) \quad \forall p = 1, 2, \ldots, B,$$

$$g_i(y, v) \equiv b_i^{p+1} | \left(y - \sum_{i=0}^{n-1} b_i^p v^i \right) \quad \forall p = 1, 2, \ldots, B-1 \quad \forall i = 1, \ldots, n-1, \quad \textit{and}$$

$$g_i(y, v) \equiv b_i^1 | \left(y - \sum_{i=0}^{n-1} b_i^B v^i \right) \quad \forall i = 1, \ldots, n-1.$$

The above properties of invariant subsets of V_C, lead to necessary and sufficient conditions for output dead beat controllability for the class of odd systems (3.1).

THEOREM 4.12. *The odd system (3.1) is output dead beat controllable if and only if either the maximal invariant set $V_I = \emptyset$ or if $V_I \neq \emptyset$, then all irreducible components (varieties) $W_i, i = 1, 2, \ldots, L$ of the maximal strongly invariant set W_I intersect the line $y = 0$.*

Sketch of the proof. The whole state space can be partitioned as $W_I \cup (V_I - W_I) \cup (V_C - V_I) \cup (\Re^2 - V_C)$. Propositions 4.7, 4.8, 4.9, 4.10, together with the fact that any state in $V_C - V_I$ can be mapped to $\Re^2 - V_C$, give a characterization of all possible behaviors. □

COMMENT 2. It is easily verified that the conditions under which the critical variety V_C may contain invariant subsets (they are given in Proposition 4.11) are clearly not generic.

COMMENT 3. It is important to notice that Theorem 4.12 provides conditions for output controllability to the origin. If we want to check output controllability to some other point $y^* \neq 0$, then all irreducible components (varieties) W_i of the maximal strongly invariant set W_I should intersect the line $y = y^*$.

5. Stability of constrained dynamics. We examine in this section properties of the control law which keep the output of the system at zero after the output was zeroed. We extend Theorem 6.2 [3] to the class of polynomial implicitly defined systems. This theorem gives necessary and sufficient conditions for the global stability of an invariant interval for the class of explicit constrained dynamics defined by $u_k = g(u_{k-1})$ with g continuous. We consider implicitly defined polynomial systems. The equation that defines the behavior of the system is given below:

$$f(0, u_{k-1}, u_k) = 0. \tag{5.1}$$

It was noticed in [1] that the properties of the control law that keep the output at zero depend on the rule used to determine which particular solution from among the

possible alternatives u_k, satisfying (5.1), is used for any given u_{k-1}. This rule is referred to as a criterion of choice. If we have several control actions that satisfy the constraint (5.1) at our disposal, it is very important to apply "the most appropriate one."

In this section we define what we mean by stable constrained dynamics and find conditions which guarantee the existence of a "good" criterion of choice, i.e., one that leads to stable constrained dynamics. Now we give definitions for the concepts that we need in our developments.

DEFINITION 5.1. *A criterion of choice is a single valued function* $c : \Re \to \Re$ (*denoted also as* $u_k = c(u_{k-1})$) *such that*

$$f(0, v, c(v)) = 0 \quad \forall v \in \Re. \tag{5.2}$$

DEFINITION 5.2. *Consider a criterion of choice* c (*Definition* 5.1). *A bounded interval* $A \subset \Re$ *is invariant under mapping* c *if* $c(A) \subseteq A$.

DEFINITION 5.3. *Let* $A \subset \Re$ *be a bounded interval invariant under mapping* c. *Then*

1. A *is called stable if* $\forall E \subseteq \Re$, $A \subset E$, $\exists K(E) > 0$ *such that* $\forall u_{k-1} \in E$ *we have* $\sup_{u_{k-1} \in E} |c(u_{k-1})| \leq K(E) < \infty$;
2. A *is called attractive if* $\forall \Delta > 0$ $\forall u_{-1}$, $\exists T = T(\Delta, u_{-1})$ *such that* $\inf_{x \in A,} |x - u_k| < \Delta$ $\forall k > T$;
3. A *is called asymptotically stable if* 1 *and* 2 *hold.*

DEFINITION 5.4. *Implicitly defined constrained dynamics* (*equation* (5.1)) *are called stable if there exists a criterion of choice* c *such that there is a bounded interval* A *invariant under mapping* c *which is asymptotically stable.*

We emphasize that the present notion of stability is more general than allowed for in [17, 18], where only stability of equilibria is considered. Notice also that we consider a *global* stability property.

We now cite Theorem 6.2 from [3] which is used in the proof of the main result.

THEOREM 5.5 (see [3]). *Consider the map* $g : \mathbf{D} \to \mathbf{D}$, $\mathbf{D} \subset \Re$. *Let* $\mathcal{A} \stackrel{\triangle}{=} [a, b] \subset \Re$ *such that*

1. $\mathbf{D} \cap \mathcal{A}$ *is invariant under* g: $g(\mathbf{D} \cap \mathcal{A}) \subset \mathbf{D} \cap \mathcal{A}$;
2. $(\Re -]a, b[) \subset \mathbf{D}$;
3. g *is continuous on* $(\Re -]a, b[)$.

Then $\mathcal{A}$ *is globally attracting interval of the iterative map* $u(k+1) = g(u(k))$ *if and only if the following conditions hold:*

$$\begin{aligned}
&\forall x < a, && g(x) > x,\\
&\forall x > b, && g(x) < x,\\
&\forall x < a \ \text{ such that } \exists (x, z) \in G_R^{-1}, && g(x) < z,\\
&\forall x > b \ \text{ such that } \ \exists (x, z) \in G_L^{-1}, && g(x) > z.
\end{aligned} \tag{5.3}$$

The domain $\mathbf{D}$ represents the domain of definition of constrained dynamics. Other symbols used in the statement of Theorem 5.5 are given below:

$$\begin{aligned}
&G = \{(x, g(x)) : x \in \Re - [a, b]\}, \quad G_L = \{(x, g(x)) \in G : x < a\},\\
&G_R = \{(x, g(x)) \in G : x > b\}, \quad G_L^{-1} = \{(g(x), x) : (x, g(x)) \in G_L\},\\
&G_R^{-1} = \{(g(x), x) : (x, g(x)) \in G_R\}.
\end{aligned}$$

COMMENT 4. In our case the domain of definition of constrained dynamics is the whole real line; that is, $\mathbf{D} = \Re$. Therefore, condition 2 of Theorem 5.5 does not need to be verified.

Given $T \geq 0$ a real number, the following sets will be used in what follows:

$$S_1 = \{(v,u) \in \Re^2 : v < -T\}, \quad S_2 = \{(v,u) \in \Re^2 : v > T\}. \tag{5.4}$$

A very important feature of polynomial systems which is crucial for the stability of constrained dynamics is given in the theorem below.

THEOREM 5.6. *Consider the real variety V_z defined by*

$$V_z = \{(v,u) \in \Re^2 : f(0,v,u) = 0\}. \tag{5.5}$$

There exists $T \geq 0$ such that there are constant numbers n_1 and n_2 of continuous branches[2] *of variety V_z on sets S_1 and S_2 (5.4).*

Proof of Theorem 5.6. Sturm sequences can be used in order to check the exact number of distinct real roots of a univariate polynomial on any interval $[a,b]$, including $]-\infty,+\infty[$ [4]. We will regard u_{k-1} as a parameter, and for any fixed u_{k-1} we can find the number of distinct real roots u_k to (5.1). In other words, we can find the exact number of real roots to (5.1) on vertical lines $u_{k-1} = \text{const}$.

Consider the Sturm sequence of $f(0,v,u)$. It has the form

$$\begin{aligned} &A_n^0(v)u^n + \cdots + A_0^0(v), \\ &A_{n-1}^1(v)u^{n-1} + \cdots + A_0^1(v), \\ &\cdots \\ &A_0^n(v). \end{aligned} \tag{5.6}$$

The leading coefficient functions are rational functions in v. It turns out that for the number of real solutions u to (5.1) for a fixed value of the parameter v, only the leading coefficient functions are important. Actually, the signs of these functions determine the number of real roots, and since they are rational functions, we can find a set of the form $]-\infty,-D_1[\cup]D_1,+\infty[$ on which their signs do not change. The modified division algorithm which is used to determine the sequence (5.6) yields a special form of the leading coefficients in the Sturm sequence. Namely, the denominator of $A_{n-j+1}^{j+1}(v)$ has the same roots as the numerator of $A_{n-j}^j(v) \forall j > 1$. Also, $A_n^0 = g_n(0,v)$ and $A_{n-1}^1 = n\partial/\partial v[g_n(0,v)]$ are polynomials. Consequently, the set on which the $A_{n-j}^j(v)$ do not change signs can be determined considering the equations $A_{n-j}^j(v) = 0$ $\forall j = 0,\ldots,n$. We introduce the following set:

$$\mathcal{D}_1 = \{v \in \Re : A_{n-j}^j(v) = 0 \text{ for some } j = 0,\ldots,n\}. \tag{5.7}$$

Denote as D_1 the following number:

$$D_1 = \sup_{v \in \mathcal{D}_1} |v|. \tag{5.8}$$

It follows that on the set $]-\infty,-D_1[\cup]D_1,+\infty[$ all the leading coefficient functions do not change their signs. Therefore, there is a constant number of real roots u_k for every $u_{k-1} \in]-\infty,-D_1[$ and $u_{k-1} \in]D_1,+\infty[$ to (5.1). We can also say that there exists a constant number of continuous branches of V_z on sets $]-\infty,-D_1[\times\Re$ and $]D_1,+\infty[\times\Re$. This follows from the theorem on the continuity of real roots [4, p. 38]. Since $g_n(0,v) \neq 0$ ($g_n = A_n^0$) for $v \in]-\infty,-D_1[\cup]D_1,+\infty[$ and since there is a constant number of complex roots, all the conditions of the theorem are satisfied. □

[2]The term "branch of V_z" that we use corresponds to parts of irreducible varieties (curves) from which the variety V_z is composed [4, 6] that belong to sets S_1 and S_2.

COMMENT 5. Theorem 5.6 states that it is possible to find an interval $[-D_1, D_1]$ inside which all bifurcations of the variety V_z occur. Moreover, from the theorem on the continuity of roots [4, p. 38] we see that all intersections between branches of the variety V_z occur inside the same interval.

LEMMA 5.7. *A necessary condition for the existence of stable constrained dynamics is*

$$\sup_{|v|<K} \inf_{(v,u)\in V_z} |u| < +\infty \quad \forall K \in]0, +\infty[.$$

Proof of Lemma 5.7. Suppose that there exists a criterion of choice c which yields stable constrained dynamics. Suppose that there exists $v = u^*_{k-1}$ which belongs to the invariant interval such that all branches of the variety V_z have a vertical asymptote at $v = u^*_{k-1}$. In other words, the condition of Lemma 5.7 is not satisfied for any neighborhood of the origin that contains u^*_{k-1}. It is then obvious that the invariant interval must have one of the following forms: $]-\infty, +\infty[$, $[K, +\infty[$, or $]-\infty, K]$, and we have a contradiction since neither of these intervals is bounded. Suppose now that u^*_{k-1} does not belong to the invariant interval. In this case, constrained dynamics cannot be stable in the sense of Definition 5.4 because for u_{k-1} such that $u_{k-1} \to u^*_{k-1}$ we have that $|u_k| \to +\infty$, so we again obtain a contradiction. □

Now we can give definitions of maximal and minimal branches of the variety V_z.

DEFINITION 5.8. *Consider the variety V_z on sets S_1 and S_2. The maximal branch of V_z in S_2 is given by*

$$V_M^{S_2} = \{(v, u) : v \in]T, +\infty[,\ u = \max_{(v,y)\in(V_z\cap S_2),\ y<v} y\}.$$

The minimal branch of V_z in S_1 is such that

$$V_m^{S_1} = \{(v, u) : v \in]-\infty, -T[,\ u = \min_{(v,y)\in(V_z\cap S_1),\ y>v} y\}.$$

In other words, the maximal branch is the closest branch of V_z to the bisector $u = v$, which is below the bisector (on the set S_2). Notice that minimal and maximal branches are well-defined parts of irreducible varieties of V_z, following from the theorem on continuity of roots [4] and Bezout's theorem [6]. Bezout's theorem says that we can find a set $[-D_3, D_3] \times \Re$ inside which all intersections between the variety V_z and the bisector $u = v$ occur. Also notice that if there are no branches in S_2 that are below the bisector $u = v$, then by definition $V_M^{S_2} = \emptyset$.

COMMENT 6. Suppose that we can find a criterion of choice such that outside a bounded interval $[-T, T]$ all orbits are bounded, converge to the interval, and enter it in finite time from any given u_{-1}. Then it is easy to show that when Lemma 5.7 holds there exists an interval (perhaps larger than $[-T, T]$ but bounded) such that it is invariant and stable. Consequently, we will concentrate only on the existence of a bounded stable interval, and Lemma 5.7 guarantees that we can always have a criterion of choice for all $u_{-1} \in [-T, T]$ which renders the interval invariant.

Now we can state the main result.

THEOREM 5.9. *Implicitly defined constrained dynamics* (5.1) *are stable if and only if the mapping $u_k = g(u_{k-1})$ defined as*

$$u_k = \begin{cases} y & \text{such that } (u_{k-1}, y) \in V_m^{S_1} \text{ if } u_{k-1} < -T, \\ y & \text{such that } (u_{k-1}, y) \in V_M^{S_2} \text{ if } u_{k-1} > T, \\ y & \text{such that } (u_{k-1}, y) \in V_z \text{ if } u_{k-1} \in [-T, T] \text{ and} \\ & y \text{ has the smallest absolute value} \end{cases} \tag{5.9}$$

satisfies equations (5.3) *of Theorem* 5.5 *and Lemma* 5.7 *holds.*

Proof of Theorem 5.9. *Sufficiency.* Consider the criterion of choice (5.9). It is obvious that all the conditions of Theorem 5.5 are satisfied and this criterion yields stable constrained dynamics.

Necessity. We have to show only that the conditions (5.3) are necessary for stable constrained dynamics. We can find a set inside which all intersections between the variety V_z and the bisector $u = v$ occur and denote it as $[-D_3, D_3] \times \Re$. Moreover, we can find another set inside which all the intersections between V_z and $V_z^{-1} = \{(v, u) \in \Re^2 : f(0, u, v) = 0\}$ occur (modulo common components which may have infinitely many common points) and denote it as $[-D_2, D_2] \times \Re$. All the subsequent arguments are given for the sets S_1 and S_2 defined by the number $T = \max[D_1, D_2, D_3]$. Sets S_1 and S_2 (5.4) defined in this way obviously have the property that (modulo common components) there are no intersections between V_z and V_z^{-1} on the sets, there are no bifurcations of the variety V_z on the sets and, finally, minimal and maximal branches $V_m^{S_1}$ and $V_M^{S_2}$ are either parts of continuous curves or they are empty sets.

Suppose that the constrained dynamics are stable and that the first condition in (5.3) is not satisfied. Since $V_m^{S_1} = \emptyset$, all branches are below the bisector $u = v$ and as a consequence we have that $u_k \to -\infty$ as $k \to \infty$, $\forall u_{-1} \in]-\infty, -T]$. A similar situation happens when the second condition (5.3) is not satisfied and therefore the first two conditions in (5.3) are necessary to ensure stability of the constrained dynamics. In other words, a necessary condition for the stability of the implicitly defined constrained dynamics (5.1) is that $V_m^{S_1} \neq \emptyset$ and $V_M^{S_2} \neq \emptyset$.

Consider now what happens if the third condition in (5.3) is not satisfied. Since all branches of V_z in S_2 are above $V_M^{S_2}$, all their inverses will lay on the left-hand side (or below) of $(V_M^{S_2})^{-1}$. Thus, we suppose that no branch of V_z^{-1} satisfies the third condition in (5.3). Moreover, if we use pieces of branches of V_z to construct a piecewise continuous one-to-one function and use the modified Theorem 5.5 [3] we can see that no such function would satisfy the conditions of Theorem 5.5. Therefore, there does not exist a criterion of choice which yields stable constrained dynamics. The contradiction completes the proof. The last two conditions are symmetric and they are either both satisfied or not. □

6. An algebraic test for stability of constrained dynamics. We now present a method to check the conditions of Theorem 5.9. First, we provide a means of verifying the conditions of Lemma 5.7.

We write the function (5.1) as

$$f(0, v, u) = g_n(0, v)u^n + \cdots + g_0(0, v). \tag{6.1}$$

The only critical points that we have to check are the ones for which the leading coefficient $g_n(0, v)$ (6.1) vanishes [4, pp. 10, 39]. Therefore, the first step is to find all real solutions v to $g_n(0, v) = 0$. It is then necessary to check whether

$$f(0, v, u) = 0 \tag{6.2}$$

has real roots u for all critical values of v. We define the following sets:

$$\mathcal{A} = \{v : g_n(0, v) = 0\}, \tag{6.3}$$

$$\mathcal{B}(v) = \{u \in \Re : f(0, v, u) = 0\},\ v \in \mathcal{A}, \tag{6.4}$$

$$\mathcal{C} = \{(v, u) : v \in \mathcal{A},\ u \in \mathcal{B}(v)\}. \tag{6.5}$$

There must be at least one real root $u \in \mathcal{B}(v)\ \forall v \in \mathcal{A}$, otherwise Assumption 1 would not be satisfied. We can now use the implicit function theorem. For all pairs of

controls $(v,u) \in \mathcal{C}$ equation (5.1) holds. If for every $v \in \mathcal{A}$ there exists at least one $u \in \mathcal{B}(v)$ for which

$$\frac{\partial f}{\partial u} \mid_{(v,u)} \neq 0, \tag{6.6}$$

then the implicit function theorem guarantees the existence of a function $u = g(0,v)$, which is C^∞ since we deal with polynomials such that $f(0,v,g(0,v)) = 0$.

The implicit function theorem gives only sufficient conditions to check Lemma 5.7 but they are easy to check. If (6.6) does not hold, we may check whether Lemma 5.7 is satisfied. The easiest way to do this is to draw the variety V_z around every point (v,u) in $\mathcal{C}$ using Matlab (the set $\mathcal{C}$ contains finitely many points) and check whether there exists a branch of V_z which does not have a vertical asymptote at (v,u).

Before we give the classification of all possible situations we define bisectors and octants.

$$B_1 = \{(v,u) \in \Re^2 : v = u\}, \quad B_2 = \{(v,u) \in \Re^2 : -v = u\},$$

$$O_1 = \{(v,u) \in \Re^2 : v > 0,\ u > 0,\ u < v\}, \quad O_2 = \{(v,u) \in \Re^2 : v > 0,\ u > 0,\ u > v\},$$

$$O_3 = \{(v,u) \in \Re^2 : v < 0,\ u > 0,\ u > -v\}, \quad O_4 = \{(v,u) \in \Re^2 : v < 0,\ u > 0,\ u < -v\},$$

$$O_5 = \{(v,u) \in \Re^2 : v < 0,\ u < 0,\ u > v\}, \quad O_6 = \{(v,u) \in \Re^2 : v < 0,\ u < 0,\ u < v\},$$

$$O_7 = \{(v,u) \in \Re^2 : v > 0,\ u < 0,\ u < -v\}, \quad O_8 = \{(v,u) \in \Re^2 : v > 0,\ u < 0,\ u > -v\}.$$

We also use the notation A_1 and A_2 to denote, respectively, the line $v = 0$ and $u = 0$ in $\Re^2$.

A very important concept of the "inverse graph" of the variety V_z (5.5), which is given by

$$V_z^{-1} = \{(v,u) \in \Re^2 : f(0,u,v) = 0\} \tag{6.7}$$

is obtained by simply interchanging variables v and u in the defining polynomial. It is easy to check that if a point on a variety V_z is in the first octant O_1, the corresponding point on V_z^{-1} is in the second octant O_2 and vice versa. We use the following notation to summarize all possible situations:

$$O_2 \leftrightarrow O_1,\ O_3 \leftrightarrow O_8,\ O_4 \leftrightarrow O_7,\ O_5 \leftrightarrow O_6.$$

In some cases the position of branches $V_M^{S_2}$ and $V_m^{S_1}$ provide sufficient information to conclude on the stability of constrained dynamics since the conditions on the inverse graph are automatically satisfied. We summarize these trivial cases in the lemma below.

LEMMA 6.1.

1. *If one of the following conditions holds:*
   (a) $V_m^{S_1} \subset O_5$ *and* $V_M^{S_2} \subset O_1$,
   (b) $V_m^{S_1} \subset O_5$ *and* $V_M^{S_2} \subset O_8$,
   (c) $V_m^{S_1} \subset O_5$ *and* $V_M^{S_2} \subset O_7$,
   (d) $V_m^{S_1} \subset O_4$ *and* $V_M^{S_2} \subset O_1$,
   (e) $V_m^{S_1} \subset O_4$ *and* $V_M^{S_2} \subset O_8$,
   (f) $V_m^{S_1} \subset O_3$ *and* $V_M^{S_2} \subset O_1$,

then there exists a criterion of choice which yields stable constrained dynamics.

2. *If* $V_m^{S_1} \subset B_2$ *(*$V_M^{S_2} \subset B_2$*) then there exists a criterion of choice which yields stable constrained dynamics if and only if* $V_M^{S_2}$ *(*$V_m^{S_1}$*) belongs to the cone* $\{(v,u) \in \Re^2 : |v| < |u|\}$.
3. *If* $V_m^{S_1} \subset A_2$ *or* $V_M^{S_2} \subset A_2$*, the constrained dynamics are stable.*
4. *If* $V_m^{S_1} = \emptyset$ *or* $V_M^{S_2} = \emptyset$ *or* $V_m^{S_1} = \emptyset$ *and* $V_M^{S_2} = \emptyset$*, then the constrained dynamics are unstable.*
5. *If* $V_m^{S_1} \subset O_3$ *or* $V_M^{S_2} \subset O_7$ *or* $V_m^{S_1} \subset O_3$ *and* $V_M^{S_2} \subset O_7$*, then the constrained dynamics are unstable.*

It can easily be checked that the only remaining cases are

1. $V_m^{S_1} \subset O_3$ and $V_M^{S_2} \subset O_8$,
2. $V_m^{S_1} \subset O_4$ and $V_M^{S_2} \subset O_7$.

Only in these cases do we have to use "inverses" $(V_m^{S_1})^{-1}$ and $(V_M^{S_2})^{-1}$. Since we are dealing with polynomial systems, we can use the algebraic structure of these systems in order to obtain a "box" inside which all intersections between V_z and V_z^{-1} occur (modulo common components). We will use the theory of resultants to compute such a box. We denote $f_1 = f(0,v,u)$ and $f_2 = f(0,u,v)$.

Resultants procedure. First, we find the greatest common divisor of f_1 and f_2 which is denoted as $GCD(f_1,f_2) \in \Re[v,u]$. Then we compute "common components-free" polynomials:

$$f_1^{ccf} = \frac{f_1}{GCD(f_1,f_2)}, \quad f_2^{ccf} = \frac{f_2}{GCD(f_1,f_2)}. \tag{6.8}$$

Now, we can regard polynomials f_1^{ccf} and f_2^{ccf} as polynomials in v whose coefficients are polynomials in u. Now we can find the resultant of the two polynomials:

$$R(f_1^{ccf}, f_2^{ccf}) = \sum_{i=0}^{p} a_i u^i. \tag{6.9}$$

The resultant $R(f_1^{ccf}, f_2^{ccf})$ is a polynomial in u. We know that polynomials f_1^{ccf} and f_2^{ccf} have no common roots if $R(f_1^{ccf}, f_2^{ccf}) \neq 0$. We can find a number D_2 which is such that all absolute values of real roots of the resultant are less than D_2.

Second, we estimate the number D_2 using formulas for bounds on roots, e.g., $\hat{D}_2 = 1 + \sup_i |a_i|$ [4], where $a_i, i = 0,1,\ldots,p$, are coefficients of the resultant. Outside the box defined by $\{(v,u) \in \Re^2 : |v| \leq \hat{D}_2 \text{ and } |u| \leq \hat{D}_2\}$ the varieties V_z and V_z^{-1} have no intersections modulo common branches.

Third, we pick $\hat{u}$ such that $|\hat{u}| > |\hat{D}_2|$ and find sets of solutions:

$$\Sigma_1 = \{v \in \Re : f(0,v,\hat{u}) = 0\}, \quad \Sigma_2 = \{v \in \Re : f(0,\hat{u},v) = 0\}. \tag{6.10}$$

We can see that the sets Σ_1 and Σ_2 give a complete picture about the branches of varieties V_z and V_z^{-1} and therefore can be used to check whether constrained dynamics are stable for the two remaining cases. The criterion for the stability of constrained dynamics of the two last cases, which are not covered by Lemma 6.1, is given in the following lemma.

LEMMA 6.2. *If*

1. $V_m^{S_1} \subset O_3$ *and* $V_M^{S_2} \subset O_8$ *or*
2. $V_m^{S_1} \subset O_4$ *and* $V_M^{S_2} \subset O_7$,

then constrained dynamics are stable if there exist $\sigma_1 \in \Sigma_1$ *and* $\sigma_2 \in \Sigma_2$ *such that* $\sigma_1 < \sigma_2$. *In the first case sets* Σ_1 *and* Σ_2 (6.10) *are calculated using* $\hat{u} > \hat{T}$ *and in the second case* $\hat{u} < -\hat{T}$.

Proof of Lemma 6.2. It trivially follows from Theorem 5.9 and the procedure given above.

The method to check the existence of constrained dynamics consists of several steps:

1. Check the conditions of Lemma 5.7 as described before.
2. Form the Sturm sequence and find all leading coefficient functions. Using (5.8) and bounds on roots, determine the estimate $\hat{D}_1$.
3. Find the box inside which all intersections between the variety V_z and B_1, B_2, A_1, and A_2 occur. This is done in the following way. Find the following estimates:

   $$\hat{D}_3 = 1 + \max_i |n_i|,\ \hat{D}_4 = 1 + \max_i |m_i|,\ \hat{D}_5 = 1 + \max_i |k_i|,\ \hat{D}_6 = 1 + \max_i |l_i|,$$

   where $n_i,\ m_i,\ k_i,\ l_i \in \Re$ are, respectively, coefficients of polynomials $f(0, v, v)$, $f(0, v, -v)$, $f(0, 0, u)$, and $f(0, v, 0)$.
4. Find the estimate $\hat{T}$ of T using

   $$\hat{T} = \max(\hat{D}_1, \hat{D}_3, \hat{D}_4, \hat{D}_5, \hat{D}_6). \tag{6.11}$$

5. Pick any $v^* \in]-\infty, -\hat{T}[$ and compute all real roots of

   $$f(0, v^*, u) = 0. \tag{6.12}$$

   Pick any $v^{**} \in]\hat{T}, +\infty[$ and compute all real roots of

   $$f(0, v^{**}, u) = 0. \tag{6.13}$$

6. Determine to which octants do the pairs (v^*, real root to (6.12)) and (v^{**}, real root to (6.13)) belong and check whether Lemma 6.1 holds (remember that checking the position of a single point of the variety implies that the whole branch has the same position). If Lemma 6.1 is not satisfied, then proceed to the next step.
7. Compute $\hat{D}_2 = 1 + \max_i |f_i|$, where f_i are the coefficients of the resultant $R(f_1^{ccf}, f_2^{ccf})$; redefine $\hat{T} = \max(\hat{D}_1, \hat{D}_2, \hat{D}_3, \hat{D}_4, \hat{D}_5, \hat{D}_6)$; and apply the resultants procedure which is used to check conditions of Lemma 6.2.

7. Output dead beat control law with stable constrained dynamics. Propositions 4.7–4.11 can be used to design a dead beat controller (algorithm) as outlined in Figure 7.1. The obtained controller uses static feedback to compute the value of a control signal at any time instant k. The closed-loop system can be written in the form

$$\begin{aligned} y_{k+1} &= f(y_k, u_{k-1}, u_k), \\ u_k &= c(y_k, u_{k-1}). \end{aligned} \tag{7.1}$$

The control signal is obtained as a solution to a polynomial algebraic equation, and since there may be more than one solution, we need a criterion of choice to define the control law $c(y_k, u_{k-1})$. One criterion for the choice may be to apply the control signal that has the least absolute value. We may be able to shape the transient response

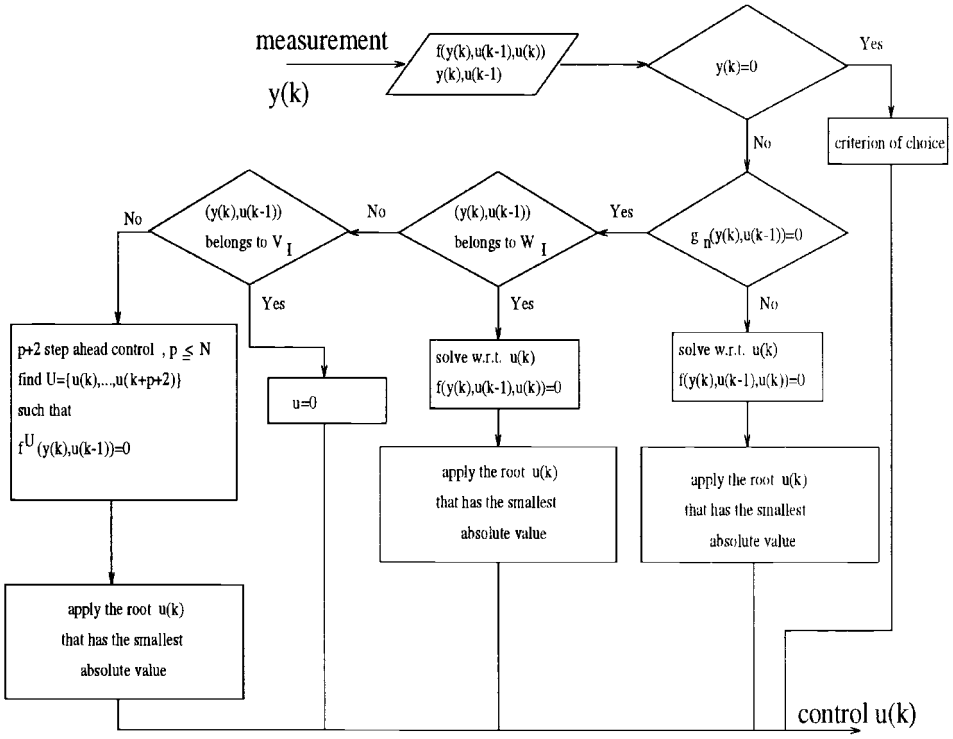

FIG. 7.1. *Output dead beat controller - algorithm.*

and keep the control signals as small as feasible, using a different criterion of choice. The question of which choice is not so critical if the output is not zero. Having zeroed the output, the criterion of choice becomes crucial for the stability of constrained dynamics and, consequently, for the stability of the closed loop system (7.1).

A criterion of choice which yields stable constrained dynamics is given by

$$u_k = \begin{cases} u \in V_m^{S_1} & \text{if } (v,u) \in S_1, \\ u \in V_M^{S_2} & \text{if } (v,u) \in S_2, \\ u \text{ s.t. it has minimum absolute value} & \text{if } v \in [-\hat{T}, \hat{T}]. \end{cases} \tag{7.2}$$

This choice does not guarantee the fastest convergence to the invariant interval, and other choices may be better in this sense than this control law. The tradeoff between the speed of convergence to the invariant interval and the shape of the transient response is a difficult problem in its own right, but very often it is possible to successfully tackle this problem on a case-by-case basis.

Notice that working with poor bounds on roots, such as the one that we have used, may yield an estimate $\hat{T}$ which is much larger than the minimal possible T, but the computations are simpler and faster to use when checking the existence of stable constrained dynamics. Computing exact roots, on the other hand, yields a smaller size of the invariant interval, which should be used when implementing the controller. Blocks in which we need to check whether $(y(k), u(k-1))$ belong to W_I or V_I are equivalent to testing whether a finite number of polynomials which define W_I and V_I are zero when evaluated at $(y(k), u(k-1))$.

8. Examples. The following example illustrates the concepts of invariant and strongly invariant subsets of the variety V_C.

EXAMPLE 1. Consider the system

$$y_{k+1} = (y_k - u_{k-1}^2 - 1)(y_k + u_{k-1}^2 + 1)[(y_k + 2)u_k^3 + u_k^2 + 1] + u_k^2 + 1. \tag{8.1}$$

Assumption 1 is satisfied. The critical variety V_C is defined by

$$V_C = \{(y, v) \in \Re^2 : (y - v^2 - 1)(y + v^2 + 1)(y + 2) = 0\}.$$

In this case we can verify that the only strongly invariant set is given by

$$W_I = \{(y, v) \in \Re^2 : (y - v^2 - 1) = 0\} \subset V_C.$$

We check the existence of strongly invariant sets via Proposition 4.11. There are three varieties of special form that are contained in V_C,

$$y - v^2 - 1, \quad y + v^2 + 1, \quad y + 2,$$

and we also have

$$g_0 = (y - v^2 - 1)(y + v^2 + 1) + 1; \quad g_1 = 0; \quad g_2 = (y - v^2 - 1)(y + v^2 + 1) + 1.$$

The only cycle of Proposition 4.11 is given by the divisions

$$g_0 \equiv 1 | (y - v^2 - 1), \quad g_1 \equiv 0 | (y - v^2 - 1), \quad g_2 \equiv 1 | (y - v^2 - 1),$$

which defines W_I. Since W_I does not intersect the line $y = 0$ according to Theorem 4.12 the system is not output dead beat controllable.

We have, therefore, $W_I \xrightarrow{f} W_I$, and t in Definition 4.5 can be chosen to be 1. From equation (8.1) it is clear that $\forall (y, v) \in V_1$, where $V_1 = \{(y, v) \in \Re^2 : (y + v^2 + 1) = 0\}$ (see Figure 8.1) we have $V_r(y, v) = W_I$. Therefore, any initial state in V_1 is transferred in one step to some point in W_I irrespective of the control that is applied. Thus, we can write

$$V_1 \xrightarrow{f} W_I \xrightarrow{f} W_I \xrightarrow{f} \dots.$$

Consider now initial states on the line $y_0 = -2$. The model of the system becomes

$$y_1 = [(-3 - u_{-1}^2)(-1 + u_{-1}^2) + 1](u_0^2 + 1).$$

Denote real solutions u_{-1} of the equations

$$[(-3 - u_{-1}^2)(-1 + u_{-1}^2) + 1] = -1,$$

$$[(-3 - u_{-1}^2)(-1 + u_{-1}^2) + 1] = 1$$

as a_i and b_i $(i = 1, 2)$, respectively. The set of one-step reachable states from $(-2, a_1)$ and $(-2, a_2)$, is V_1 and from $(-2, b_1)$ and $(-2, b_2)$ it is W_I. Notice also that $b_1 = 1$, $b_2 = -1$, and hence $(-2, b_1)$ and $(-2, b_2)$ belong to V_1. Therefore, we can write

$$(-2, a_i) \xrightarrow{f} V_1 \xrightarrow{f} W_I \xrightarrow{f} W_I \xrightarrow{f} \cdots, \ i = 1, 2.$$

The maximal invariant set V_I is

$$V_I = \{(y, v) \in \Re^2 : (y - v^2 - 1)(y + v^2 + 1) = 0\} \cup \{(-2, a_1), (-2, a_2)\}.$$

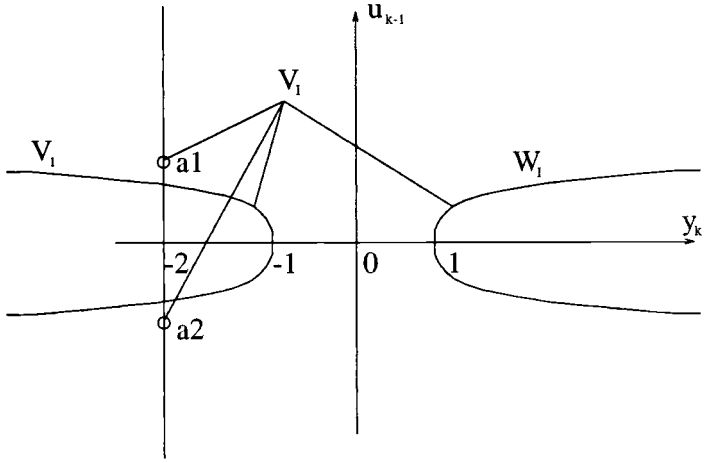

FIG. 8.1. *Invariant sets V_I and strongly invariant sets W_I (Example 1).*

Sets V_I and W_I are shown in Figure 8.1. The set $V_C - V_I$ is not invariant and there exists a control u_k which can map any initial state from it to $\Re^2 - V_C$ in one step. Observe that both V_I and W_I are real varieties, whereas $V_C - V_I$ is not. Also, initial states in V_1 are transferred to W_I in one step and the initial states $(-2, a_i),\ i = 1, 2$, are transferred to W_I in two steps.

The following example serves to illustrate why the present notion of stability of constrained dynamics is more appropriate in this context than the notion of zero dynamics introduced in [17, 18].

EXAMPLE 2. Consider the following system:

$$y_{k+1} = (u_k + 2u_{k-1} + y_k)(u_k - 0.5u_{k-1} - y_k).$$

We introduce the state variables $x_1(k) = y_k$ and $x_2(k) = u_{k-1}$ and write

$$\begin{aligned} x_1(k+1) &= (u_k + 2x_2(k) + x_1(k))(u_k - 0.5x_2(k) - x_1(k)), \\ x_2(k+1) &= u_k, \\ y(k) &= x_1(k). \end{aligned} \tag{8.2}$$

According to [17], the relative degree for system (8.3) is $d = 1$ and Assumption 1 in [17] holds. Two possible feedback laws can be used to transform the system into the form (2.6) in [17]:

$$u_k = \frac{-1.5x_2(k) + \sqrt{6.25x_2^2(k) + 10x_1(k)x_2(k) + 4x_1^2(k) + 4v(k)}}{2}, \tag{8.3}$$

$$u_k = \frac{-1.5x_2(k) - \sqrt{6.25x_2^2(k) + 10x_1(k)x_2(k) + 4x_1^2(k) + 4v(k)}}{2}, \tag{8.4}$$

where $v(k)$ is the new control input. If we use the control law (8.4), the corresponding zero dynamics are then defined as $x_2(k+1) = -2x_2(k)$ (with $x_1(k) = 0, v(k) = 0$) and are obviously not stable. If, on the other hand, we had chosen (8.3), we obtain $x_2(k+1) = 0.5x_2(k)$, which is obviously stable. In this case there are four different continuous feedback laws that transform the system into the form (2.6) in [17]. Three of them yield stable zero dynamics, and one yields unstable zero dynamics. Also, there

are infinitely many discontinuous control laws that keep the output at zero. Notice that all conditions in [17] are satisfied, and it appears that the stability of the zero dynamics depends on the choice of the feedback law. The criterion of choice that we use in the definition of stable constrained dynamics takes this phenomenon explicitly into account.

The following example illustrates the method for checking the existence of stable constrained dynamics.

EXAMPLE 3. Check the existence of stable constrained dynamics for the following system:

$$y_{k+1} = -2(1+y_k^2)u_k^5 - 2u_k^3 + 2u_k u_{k-1}(1+y_k^4) + 2u_k u_{k-1}^2 + u_{k-1}u_k^4 + u_{k-1}u_k^2 - u_{k-1}^2 - u_{k-1}^3 + y_k^3.$$

For $y_k = 0$ we have

$$-2u_k^5 - 2u_k^3 + 2u_k u_{k-1} + 2u_k u_{k-1}^2 + u_{k-1}u_k^4 + u_{k-1}u_k^2 - u_{k-1}^2 - u_{k-1}^3 = 0. \tag{8.5}$$

Therefore, the variety V_z is defined by

$$V_z = \{(v,u) \in \Re^2 : -2u^5 - 2u^3 + 2uv + 2uv^2 + vu^4 + vu^2 - v^2 - v^3 = 0\}.$$

We will follow the steps that are described in section 6 in order to check the existence of stable constrained dynamics.

Step 1. Since $g_5(0,v) = -2$, the conditions of Lemma 5.7 are satisfied.

Step 2. Using Maple[3], we obtain the following Sturm sequence:

$$\begin{aligned}
f_0 &= -2u^5 - 2u^3 + 2uv + 2uv^2 + vu^4 + vu^2 - v^2 - v^3,\\
f_1 &= -10u^4 - 6u^2 + 2v + 2v^2 + 4vu^3 + 2vu,\\
f_2 &= -\left(-\frac{4}{5} + \frac{2}{25}v^2\right)u^3 - \frac{12}{25}vu^2 - \left(\frac{41}{25}v^2 + \frac{8}{5}v\right)u + \frac{24}{25}(v^2+v^3),\\
f_3 &= -25\frac{(-24 + 7v^4 + 8v^3 - 80v - 82v^2)u^2}{(-10+v^2)^2} + 50\frac{v(-15v^2 + 4v^3 + 4v^4 - 16v - 4)u}{(-10+v^2)^2}\\
&\quad -50\frac{4v^3 + v^4 + v^5 + 4 + 4v + 4v^2}{(-10+v^2)^2},\\
f_4 &= -[8(12800v + 41680v^2 + 68240v^3 + 52516v^4 + 7268v^5 - 10960v^6\\
&\quad -3152v^7 + 449v^8 + 133v^9 + 8v^{10} + 4v^{11} + 1600)]/[25(-24 + 7v^4\\
&\quad +8v^3 - 80v - 82v^2)^2] + [v(161600v + 548160v^2 + 923680v^3\\
&\quad +727392v^4 + 113716v^5 - 142400v^6 - 41100v^7 + 4456v^8 + 1033v^9\\
&\quad +196v^{10} + 100v^{11} + 19200)u]/[25(-24 + 7v^4 + 8v^3 - 80v - 82v^2)^2],\\
f_5 &= [50(49v^{15} + 161v^{14} - 2148v^{13} - 8948v^{12} + 27908v^{11} + 175332v^{10}\\
&\quad +5760v^9 - 1338048v^8 - 2333952v^7 + 1619072v^6 + 10299904v^5 + 15313920v^4\\
&\quad +11967488v^3 + 5407744v^2 + 1351680v + 147456)v]/[(25v^5 + 24v^4\\
&\quad +728v^3 + 1360v^2 + 848v + 192)^2(-10+v^2)^2].
\end{aligned} \tag{8.6}$$

[3]Copyright ©1981–1992 by the University of Waterloo.

From the Sturm sequence we find the leading coefficient functions:

$$
\begin{aligned}
&-2,\ -10,\ -\left(-\frac{4}{5}+\frac{2}{25}v^2\right),\\
&-25\frac{(-24+7v^4+8v^3-80v-82v^2)}{(-10+v^2)^2},\\
&[v(161600v+548160v^2+923680v^3+727392v^4+113716v^5\\
&-142400v^6-41100v^7+4456v^8+1033v^9\\
&+196v^{10}+100v^{11}+19200)]/[25(-24+7v^4+8v^3-80v-82v^2)^2],\\
&[50(49v^{15}+161v^{14}-2148v^{13}-8948v^{12}+27908v^{11}+175332v^{10}\\
&+5760v^9-1338048v^8-2333952v^7+1619072v^6+10299904v^5+15313920v^4\\
&+11967488v^3+5407744v^2+1351680v+147456)v]/[(25v^5+24v^4\\
&+728v^3+1360v^2+848v+192)^2(-10+v^2)^2].
\end{aligned}
\tag{8.7}
$$

Using the formula for bounds on roots [4] we find that the highest coefficient functions do not change their signs for v belonging to intervals $]-\infty,-312529.98[$ and $]312529.98,+\infty[$. In other words, the estimate of D_1 is $\hat{D}_1 = 312529.98$.

Step 3. All intersections of the variety V_z with A_1, A_2, B_1, and B_2 lie in the interval $]-4,+4[$. It is easy to check that $\hat{D}_3 = 2,\ \hat{D}_4 = 4,\ \hat{D}_5 = 2$, and $\hat{D}_6 = 3$.

Step 4. Therefore, the estimates of sets S_1 and S_2 are defined using the number $\hat{T} = 312529.98$.

Step 5. We now substitute any number v from the interval $]-\infty,-312529.98[$ into (8.5) and find all real roots. We obtain the following set of points in $\Re^2$:

$$\{(-312530,u) : (-312530,+559.04293),(-312530,-559.04293),(-312530,-156265)\}.$$

Similarly, we obtain the set of roots

$$\{(312530,u) : (+312530,559.04383),(312530,-559.04383),(312530,156265)\}$$

when we substitute $v^{**} = 312530$ that belongs to the interval $]312529.98,+\infty[$ into (8.5). All these points represent branches and hence $V_m^{S_1} \subset O_5$ and $V_M^{S_2} \subset O_1$.

Step 6. We conclude that there exists stable constrained dynamics for this system since point 1.a of Lemma 6.1 is satisfied. We could work with better bounds on the roots in order to obtain better estimates for the intervals S_1 and S_2 or better still find the exact roots of the polynomials in the Sturm sequence. However, the proposed method is able to check the existence of the constrained dynamics quickly.

We have provided a constructive method to verify the existence of a criterion of choice leading to (*globally*) stable constrained dynamics. The method of [17, 18] appears not to be able to deal with this aspect in general, as the example shows. Indeed, the feedback law required in the method of [17, 18] for this example cannot be expressed in an explicit form (this requires an analytic solution for a fifth-degree polynomial equation).

9. Conclusion. We have presented necessary and sufficient conditions for output dead beat controllability for a class of discrete time systems described by a single I-O polynomial equation. The highest exponent of the current input is assumed to be an odd integer. The output controllability test amounts to checking whether a set of polynomial divisions is satisfied or not.

We obtained necessary and sufficient conditions for the existence of stable constrained dynamics defined by a scalar implicit equation. We assumed that the constrained dynamics exist for every u_{k-1}, but the defining polynomial $f(0, u_{k-1}, u_k)$ may be even. A dead beat controller that zeros the output of the system in minimum time and which yields stable constrained dynamics is derived.

It is important to say that all algorithms that we presented are computationally expensive and that the computational complexity for systems defined by polynomials of high total degree may be prohibitive. This is an intrinsic feature of polynomial systems and not a drawback of the particular methods that we used.

OPTIMAL CONTROL OF PROBLEMS GOVERNED BY ABSTRACT ELLIPTIC VARIATIONAL INEQUALITIES WITH STATE CONSTRAINTS*

MAÏTINE BERGOUNIOUX†

Abstract. In this paper we investigate optimal control problems governed by elliptic variational inequalities with additional state constraints. We present a relaxed formulation for the problem. With penalization methods and approximation techniques we give qualification conditions to get first-order optimality conditions.

Key words. state and control constrained optimal control problems, variational inequalities, optimality conditions

1. Introduction. In this paper we investigate optimal control problems governed by elliptic variational inequalities with additional state constraints. This topic has been widely studied by many authors. We mainly could mention Barbu [1, 2, 3], Friedman [11, 12], Mignot [13], Mignot and Puel [14], Tiba [15], and Bermudez and Saguez [8]. Most of these contributions (for example [1, 2, 3]) study the problem via the penalization of the state (in)equation. On the other hand Mignot and Puel [14] (for instance) give an equivalent formulation of the variational inequality via the associated Lagrange multiplier for the obstacle problem example. We have followed this point of view; our purpose is to set optimality conditions for such a problem that could easily be used from the numerical point of view. This paper is the generalization of the case of the obstacle problem that we have been studying in [5]. We deal here with quite abstract variational inequalities. Following our previous work, we first present a relaxed form of the original problem which can be considered as a good "approximation" of this problem. Then using both Moreau–Yosida approximation techniques and a penalization method we are able to set optimality conditions. We end the paper with the example of the obstacle problem.

2. Setting the problem. Let V and H be a pair of real Hilbert spaces such that V is a dense subset of H and $V \subset H \subset V'$ algebraically and topologically (V' denotes the dual of V). We suppose in addition that

$$\text{the injection } V \subset H \text{ is compact} \tag{2.1}$$

so that $H \subset V'$ is compact too. (For example, one may choose $V = H_o^1(\Omega)$ and $H = L^2(\Omega)$, where Ω is an open bounded "regular" subset of $\mathbb{R}^3$.) We denote $\langle\ ,\ \rangle$ the pairing between V and V', $(\ ,\ )_H$ the H-scalar product and $|\ |_V$ the norm of V. We call $\Lambda_V : V \to V'$ the canonical isomorphism. Let U be another Hilbert space (such that $U = U'$); we consider the variational inequality

$$Ay + \partial\Phi(y) \ni Bu + f, \tag{2.2}$$

where $A : V \to V'$ is a linear, continuous operator satisfying the coercivity condition

$$\exists \omega > 0 \ \forall v \in V \qquad \langle Av, v\rangle \geq \omega |v|_V^2; \tag{2.3}$$

$$\begin{gathered}\Phi \text{ is a convex, proper, lower semicontinuous (LSC) function} \\ \text{from } V \text{to } \mathbb{R} \cup \{+\infty\}.\end{gathered} \tag{2.4}$$

We denote

$$\text{dom } \Phi = \{\ y \in V \mid \Phi(y) < +\infty\ \}$$

the domain of Φ (which is convex and V-closed). We recall that the subdifferential $\partial\Phi(y_o)$ of Φ at $y_o \in V$ is

$$\partial\Phi(y_o) = \{\ z^* \in V' \mid \forall y \in V \quad \Phi(y) - \Phi(y_o) - \langle z^*, y - y_o\rangle \geq 0\}$$

and that dom $\Phi = \overline{\text{dom } \partial\Phi}$.

$f \in V'$ and

$$B \text{ is a linear, compact operator from } U \text{ to } V'. \tag{2.5}$$

Let us recall some general results about solutions of (2.2) (see [2, 3] for example).

THEOREM 2.1. (Barbu [2, p. 40]). *Under assumptions* (2.3)–(2.4) *and for all* $\psi \in V'$ *the variational inequality*

$$Ay + \partial\Phi(y) \ni \psi$$

has a unique solution $y(\psi) \in V$ *and the mapping* $\psi \mapsto y(\psi)$ *is Lipschitz from* V' *to* V.

COROLLARY 2.1. (Barbu [2, p. 63]). *With the assumptions of the previous theorem, for all* $u \in U$ *there exists a unique* $y(u) \in V$ *solution of* (2.2) *and the mapping* $u \mapsto y(u)$ *is weakly strongly continuous from* U *to* V.

In order to get some regularity results, we suppose from now on that

$$f \in H \text{ and } B \in \mathcal{L}(U, H), \tag{2.6}$$

so that (2.5) is fulfilled and we may use in addition the following result (Barbu [2, p. 42]): let us denote $A_H : H \to H$ the operator

$$A_H(y) = Ay \text{ for all } y \in D(A_H) = \{\ y \in V \mid Ay \in H\ \}. \tag{2.7}$$

This operator is maximal monotone in $H \times H$ and we have Theorem 2.2.

THEOREM 2.2. *Assume* (2.3) *and suppose in addition that there exists* $z \in H$ *and* $c \in \mathbb{R}$ *such that*

$$\forall y \in V, \forall \lambda > 0 \qquad \Phi((I + \lambda A_H)^{-1}(y + \lambda z)) \leq \Phi(y) + c\lambda. \tag{2.8}$$

Then for every $\psi \in H$ *the solution* $y(\psi)$ *of* $Ay + \partial\Phi(y) \ni \psi$ *belongs to* $D(A_H)$ *and*

$$|Ay(\psi)|_H \leq c(1 + |\psi|_H).$$

From now we suppose that (2.8) is ensured. This is the case for example for the obstacle problem given as an example in the last section of this paper, where $V = H_o^1(\Omega)$, $H = L^2(\Omega)$, and $D(A_H) = H^2(\Omega) \cap H_o^1(\Omega)$.

Applying this regularity result to our case we get that for all $u \in U$, $f + Bu \in H$ so that the solution of (2.2) y belongs to $D(A_H) \subset V$; that is, $Ay \in H$.

REMARK 2.1. *One could think that this regularity assumption is not really necessary. Indeed, it is not useful to prove the results of next section. Nevertheless, when we investigate penalized problems, then we shall need some "strong" convergence for the penalized solutions, that is with the compactness assumptions "weak" convergence in the pivot space H.*

Now, we investigate the following optimal control problem:

$$(\mathcal{P}) \qquad \begin{cases} \min \quad g(y) + h(u), \\ Ay + \partial\Phi(y) \ni Bu + f, \\ (y, u) \in K \times U_{ad}, \end{cases}$$

where the following hold.

• g is convex from H to $\mathbb{R}$, finite everywhere ($\mathrm{dom}(g) = H$) and continuous. This implies ([4, Proposition 1.9, p. 85]) that

$$\exists (a_g, c_g) \in H \times \mathbb{R} \quad \text{such that} \quad \forall y \in H \quad g(y) \geq (a_g, y)_H + c_g \tag{2.9}$$

(because g is LSC) and g is everywhere subdifferentiable.

• h is convex from U to $\mathbb{R}$, finite everywhere ($\mathrm{dom}(h) = U$), continuous, and coercive:

$$\lim_{|u|_U \to +\infty} \frac{h(u)}{|u|_U} = +\infty. \tag{2.10}$$

• U_{ad} (resp., K) is a closed, convex, nonempty subset of U (resp., V). We note that $y \in \mathrm{dom}\ \partial\Phi \subset \mathrm{dom}\ \Phi$ so that one may always suppose that

$$K \subset \ \mathrm{dom}\ \Phi. \tag{2.11}$$

REMARK 2.2. *From now, we always suppose that these assumptions are satisfied. They are not of course optimal. To get more information one can refer to Barbu* [3, p. 150].

We end this section with an existence result for $(\mathcal{P})$.

THEOREM 2.3. *Under assumptions* (2.3), (2.4), (2.9), (2.10), *problem* $(\mathcal{P})$ *has (at least) one optimal solution.*

Proof. The proof is quite similar to the one given in Barbu [3, p. 151]. The main difference is the addition of the state constraint $y \in K$, which does not modify the proof. □

3. "Relaxation" of the problem. We denote $\Phi^* : V' \to \mathbb{R}$ the conjugate function of Φ; it is also convex, proper, LSC and we know that (see [4, 10])

$$z \in \partial\Phi(y) \Leftrightarrow y \in \partial\Phi^*(z) \Leftrightarrow \Phi(y) + \Phi^*(z) = \langle y, z \rangle . \tag{3.1}$$

Because of the regularity result we always have $Bu + f - Ay \in H$, so that $z = Bu + f - Ay \in \partial\Phi(y) \cap H$ and (3.1) is equivalent to

$$z \in \partial\Phi(y) \Leftrightarrow y \in \partial\Phi^*(z) \Leftrightarrow \Phi(y) + \Phi^*(z) = (y, z)_H .$$

REMARK 3.1. *In addition such an element z belongs to* $\mathrm{dom}\ \partial\Phi^* \subset \mathrm{dom}\ \Phi^*$ *so that the condition "$z \in \mathrm{dom}\ \Phi^*$" is implicitly included in relation* (3.1).

Finally, problem $(\mathcal{P})$ is equivalent to

$$(\widetilde{\mathcal{P}}) \qquad \begin{cases} \min \quad g(y)+h(u), \\ Ay = Bu + f - z \in H, \\ \Phi(y) + \Phi^*(z) - (y,z)_H = 0, \\ y \in D(A_H) \cap K,\ (u,z) \in U_{ad} \times (\text{dom } \Phi^* \cap H)\,. \end{cases}$$

$w = (u,z)$ is now considered as a new control variable. Problem $(\widetilde{\mathcal{P}})$ is a state-constrained optimal control problem with a nonconvex (because of the bilinear term) constraint coupling the state y and the control w. This constraint is quite difficult to deal with. It is not convex and the equality constraint makes the interior of the feasible domain empty in a very strong sense. So as we have done in [5] for the particular case of the obstacle problem, we had rather study a "relaxed" problem. More precisely we consider

$$(\mathcal{P}_\alpha^R) \qquad \begin{cases} \min \quad g(y)+h(u), \\ Ay = Bu + f - z, \\ \Phi(y) + \Phi^*(z) - (y,z)_H \le \alpha, \\ y \in K,\ (u,z) \in U_{ad} \times B_R^*, \end{cases}$$

where $\alpha > 0,\ R > 0,\ B_R^* = B_H(0,R) \cap \text{dom } \Phi^*$, and $B_H(0,R)$ is the H-ball of radius R. B_R^* is convex and H-closed (since dom Φ^* is convex and V'-closed).

REMARK 3.2. *Let us comment on this "relaxed" form for problem $(\widetilde{\mathcal{P}})$. First we know that $\Phi(y) + \Phi^*(z) - (y,z)_H$ is always nonnegative. So*

$$\Phi(y) + \Phi^*(z) - (y,z)_H \le \alpha \tag{3.2}$$

is equivalent to $|\Phi(y) + \Phi^*(z) - (y,z)_H\,| \le \alpha$. This is the relaxed term: we have replaced the equality "$= 0$" with the inequality "$\le \alpha$," where α may be as small as wanted. This is quite realistic from the numerical point of view where equalities are indeed inequalities up to α.

On the other hand, if we do not add the constraint "$z \in B_H(0,R)$" the relaxed problem is not coercive and so in general it has no solution. Moreover, by virtue of assumptions (2.8) *and* (2.10) *the optimal solutions (y,u) and Ay remain in a bounded set of $H \times U$ and H and the constant R has to be chosen accordingly (that is large enough); in particular, R is greater than $|A\bar{y} - f - B\bar{u}|_H$ for any $(\bar{y},\bar{u})$ solution of $(\mathcal{P})$, so that the feasible domain of $(\mathcal{P}_\alpha^R)$ is nonempty.*

Anyway, this additional condition is not very restrictive. One could instead add a regularization term (as $|z|_H^2/R$) to the cost functional, which would have exactly the same effect. One may also add adapted penalization terms to this cost functional as $|y-\bar{y}|_V^2$ or $|z-\bar{z}|_H^2$.

From now we fix R so that we always omit the index R in the notations and $(\mathcal{P}_\alpha^R)$ becomes $(\mathcal{P}_\alpha)$.

THEOREM 3.1. *For every $\alpha > 0$, $(\mathcal{P}_\alpha)$ has at least one optimal solution denoted $(y_\alpha, u_\alpha, z_\alpha)$. Moreover, when $\alpha \to 0$, y_α strongly converges to $\bar{y}$ in V, u_α weakly converges to $\bar{u}$ in U, and z_α weakly converges to $\bar{z}$ in H where $(\bar{y},\bar{u})$ is a solution of $(\mathcal{P})$ and $\bar{z} = A\bar{y} - B\bar{u} - f \in H$.*

Proof. Let $\alpha > 0$; we have chosen R such that the feasible domain of $(\mathcal{P}_\alpha)$ is always nonempty. We first prove that $d_\alpha = \inf\ (\mathcal{P}_\alpha) \in \mathbb{R}$. The coercivity and continuity assumptions on A yield that A is an isomorphism from V to V'. Let

(y_n, u_n, z_n) be a minimizing sequence: $y_n = A^{-1}(Bu_n + f - z_n)$, $|z_n|_H \leq R$, $u_n \in U_{ad}$, $\Phi(y_n) + \Phi^*(z_n) - (y_n, z_n)_H \leq \alpha$, and $g(y_n) + h(u_n) \to d_\alpha$. Because of (2.9) we have

$$\begin{aligned} g(y_n) + h(u_n) &\geq \left(a_g, A^{-1}(Bu_n + f - z_n)\right)_H + h(u_n) + c_g \\ &\geq \left(a_g, A^{-1}Bu_n\right)_H + h(u_n) - \left(a_g, A^{-1}z_n\right)_H + c_g + \left(a_g, A^{-1}f\right)_H. \end{aligned}$$

As $|z_n|_H \leq R$, then $-\left(a_g, A^{-1}z_n\right)_H + c_g + \left(a_g, A^{-1}f\right)_H$ is bounded from below.

If $d_\alpha = -\infty$, then $\left(a_g, A^{-1}Bu_n\right)_H + h(u_n) \to -\infty$. If (u_n) were bounded in U, then (extracting a subsequence) u_n would be weakly convergent to some $\tilde{u}$ in U; as B is continuous Bu_n would be convergent to $B\tilde{u}$ weakly in H and strongly in V'. Therefore, $A^{-1}Bu_n$would be strongly convergent to $A^{-1}B\tilde{u}$ in V and $\left(a_g, A^{-1}Bu_n\right)_H \to \left(a_g, A^{-1}B\tilde{u}\right)_H$. Moreover h is LSC, so that $-\infty < h(\tilde{u}) \leq \lim_{n\to+\infty} \inf\, h(u_n)$, so we get a contradiction. This means that (u_n) is unbounded. Coercivity assumption (2.10) implies that

$$\lim_{n\to+\infty} \frac{h(u_n)}{|u_n|_U} = +\infty.$$

Moreover the Cauchy–Schwarz inequality shows that

$$\left| \frac{\left(a_g, A^{-1}Bu_n\right)_H}{|u_n|_U} \right| \leq c_o\ \frac{|u_n|_U}{|u_n|_U},$$

so

$$\lim_{n\to+\infty} \left(a_g, A^{-1}Bu_n\right)_H + h(u_n) = |u_n|_U \left[\frac{\left(a_g, A^{-1}Bu_n\right)_H}{|u_n|_U} + \frac{h(u_n)}{|u_n|_U} \right] = +\infty,$$

and we get a contradiction.

• As $|z_n|_H \leq R$ one may extract a subsequence (still denoted z_n) weakly convergent in H to $z_\alpha \in B_R^*$ (since B_R^* is weakly closed). As $d_\alpha > -\infty$, $h(u_n)$ is bounded, and by coercivity (u_n) is bounded in U; so (extracting a subsequence) u_n weakly converges to $u_\alpha \in U_{ad}$ (U_{ad} is weakly closed in U). The continuity of B yields that Bu_n converges to Bu_α weakly in H. So $Ay_n = Bu_n + f - z_n$ converges to $Bu_\alpha + f - z_\alpha$ weakly in H and strongly in V'. As A is an isomorphism from V to V', y_n converges to $y_\alpha = A^{-1}(Bu_\alpha + f - z_\alpha)$ strongly in V. Moreover $y_\alpha \in K$ since K is closed.

• Let us prove that $(y_\alpha, u_\alpha, z_\alpha)$ is feasible for $(\mathcal{P}_\alpha)$. It remains to show that $\Phi(y_\alpha) + \Phi^*(z_\alpha) - (y_\alpha, z_\alpha)_H \leq \alpha$. Φ and Φ^* are convex and LSC so they are weakly LSC and we have

$$\Phi(y_\alpha) + \Phi^*(z_\alpha) \leq \liminf_{n\to+\infty} \Phi(y_n) + \liminf_{n\to+\infty} \Phi^*(z_n) \leq \liminf_{n\to+\infty} \left[\Phi(y_n) + \Phi^*(z_n)\right].$$

Moreover the strong convergence of y_n to y_α in H and the weak convergence of z_n to z_α in H give

$$\lim_{n\to+\infty} (y_n, z_n)_H = (y_\alpha, z_\alpha)_H.$$

Finally

$$\Phi(y_\alpha) + \Phi^*(z_\alpha) - (y_\alpha, z_\alpha)_H \leq \liminf_{n\to+\infty} \left[\Phi(y_n) + \Phi^*(z_n) - (y_n, z_n)_H\right] \leq \alpha.$$

Therefore $(y_\alpha, u_\alpha, z_\alpha)$ is feasible for $(\mathcal{P}_\alpha)$ and $g(y_\alpha) + h(u_\alpha) \geq d_\alpha$. As g and h are LSC, we also have

$$g(y_\alpha) + h(u_\alpha) \leq \liminf_{n\to+\infty} g(y_n) + \liminf_{n\to+\infty} h(u_n) \leq \liminf_{n\to+\infty} [g(y_n) + h(u_n)] = d_\alpha.$$

Finally $g(y_\alpha) + h(u_\alpha) = d_\alpha$ and $(y_\alpha, u_\alpha, z_\alpha)$ is an optimal solution for $(\mathcal{P}_\alpha)$.

• It remains to prove the convergence of $(y_\alpha, u_\alpha, z_\alpha)$ to an optimal solution of $(\mathcal{P})$. Let (y_o, u_o, z_o) be an optimal solution of $(\mathcal{P})$ such that $z_o \in B_R^*$ (remember that we have chosen R to ensure the existence of such a solution). It is also a feasible triple for $(\mathcal{P}_\alpha)$ for any $\alpha > 0$. So

$$\forall \alpha > 0 \quad -\infty < d_\alpha = g(y_\alpha) + h(u_\alpha) \leq g(y_o) + h(u_o) = d_o.$$

So d_α is bounded from above in $\mathbb{R}$. If it were not bounded from below, then we could find a sequence $\alpha_n \to 0$ such that $d_{\alpha_n} \to -\infty$. The same proof as before shows that it is impossible. So $h(u_\alpha)$ is bounded (independently of α) and by coercivity (u_α) is bounded in U as well. Similarly (z_α) is bounded in H ($z_\alpha \in B_R^*$). Then one can show (as we have proved the existence of $(y_\alpha, u_\alpha, z_\alpha)$) that

$$y_\alpha \to \bar{y} \text{ strongly in } V,\ u_\alpha \rightharpoonup \bar{u} \text{ weakly in } U, \text{ and } z_\alpha \rightharpoonup \bar{z} \text{ weakly in } H,$$

where $(\bar{y}, \bar{u})$ is a solution of $(\mathcal{P})$ with $\bar{z} = A\bar{y} - B\bar{u} - f$ and that

$$\lim_{\alpha\to 0} [g(y_\alpha) + h(u_\alpha)] = g(\bar{y}) + h(\bar{u}). \qquad \square$$

4. Penalization of $(\mathcal{P}_\alpha)$.

4.1. The approximated-penalized problem. From now on, we fix also $\alpha > 0$ as small as we want and we shall omit the index α most of time. We are going to approximate and penalize the state equation of $(\mathcal{P}_\alpha)$ to get an approximated problem $(\mathcal{P}_\alpha^\varepsilon)$. Then we shall derive optimality conditions for this problem and set qualification conditions allowing us to pass to the limit with respect to ε. For $\varepsilon > 0$, we consider the following problem:

$$(\mathcal{P}_\alpha^\varepsilon) \qquad \begin{cases} \min J_\varepsilon(y, u, z), \\ (y, u, z) \in K \times U_{ad} \times B_R^*, \end{cases}$$

where

$$\begin{aligned} J_\varepsilon(y, u, z) = \quad & g_\varepsilon(y) + h_\varepsilon(u) \\ & + \frac{1}{2\varepsilon} |Ay - Bu - f + z|_{V'}^2 + \frac{1}{2\varepsilon} [\Phi_\varepsilon(y) + \Phi_\varepsilon^*(z) - (y, z)_H - \alpha]_+^2 \\ & + \frac{1}{2} |y - y_\alpha|_V^2 + \frac{1}{2} |u - u_\alpha|_U^2 + \frac{1}{2} |z - z_\alpha|_H^2. \end{aligned}$$

Here $g_+ = \max(0, g)$, and $g_\varepsilon,\ h_\varepsilon,\ \Phi_\varepsilon$, and Φ_ε^* are the Moreau–Yosida approximations of $g,\ h,\ \Phi$, and Φ^*.

First, we briefly recall some useful properties of the Moreau–Yosida approximation of convex functions. Let φ be a convex, proper, LSC function from $\mathcal{H}$ to $\mathbb{R} \cup \{+\infty\}$ where $\mathcal{H}$ is a Hilbert space (not necessarily identified with its dual). The Moreau–Yosida approximation of φ is defined by

$$\varphi_\varepsilon(x) = \inf \left\{ \frac{|x - y|_{\mathcal{H}}^2}{2\varepsilon} + \varphi(y), y \in \mathcal{H} \right\}$$

and we have the following properties [3, pp. 49–55] in Theorem 4.1.

THEOREM 4.1. *Let us call* $I_\varepsilon = (\Lambda_{\mathcal{H}} + \varepsilon D)^{-1}$ *the proximal mapping with* $D = \partial\varphi$, $\Lambda_{\mathcal{H}}$ *the canonical isomorphism from* $\mathcal{H}$ *to* $\mathcal{H}'$, *and* $D_\varepsilon = -\varepsilon^{-1}\Lambda_{\mathcal{H}}(I_\varepsilon - I)$.

i. I_ε *is single valued and nonexpansive.*

ii. $D_\varepsilon x \in \partial\varphi(I_\varepsilon x)$ *for all* $x \in \mathcal{H}$, *and for all* $x \in \mathrm{dom}(\partial\varphi)$, $\lim_{\varepsilon\to 0} D_\varepsilon x = D^o x \in \partial\varphi(x)$ *(strongly in* $\mathcal{H}'$*), where* $D^o(x)$ *is the element of minimal norm of* $\partial\varphi(x)$.

iii. *For all* $x \in \mathrm{dom}\ \varphi$, $I_\varepsilon x$ *converges strongly in* $\mathcal{H}$ *toward* x.

iv. *If* $\varepsilon_n \to 0$, $x_{\varepsilon_n} \to x_o$ *strongly in* $\mathcal{H}$, *and* $D_{\varepsilon_n} x_{\varepsilon_n} \rightharpoonup y_o$ *weakly in* $\mathcal{H}'$, *then* $y_o \in \partial\varphi(x_o)$.

v. φ_ε *is Fréchet differentiable and* $\varphi'_\varepsilon = D_\varepsilon$ *is Lipschitz (so that* φ_ε *is* $\mathcal{C}^1$*).*

vi. *For all* $x \in \mathcal{H}$ *and* $\varepsilon > 0$ $\varphi(I_\varepsilon x) \le \varphi_\varepsilon(x) \le \varphi(x)$.

Moreover, for all $x \in \mathcal{H}$, $\lim_{\varepsilon\to 0} \varphi_\varepsilon(x) = \varphi(x)$.

In addition, as we need sharper convergence results, we set some further assumptions about the function φ and we suppose that

$$\begin{aligned} &\forall (x_\varepsilon) \in \mathrm{dom}\ \varphi \text{ strongly convergent (in } \mathcal{H}\text{) to } x \in \mathrm{dom}\ \varphi \\ &\qquad \text{then } \varphi'_\varepsilon(x_\varepsilon) \text{ is bounded in } \mathcal{H}' \text{ (with respect to } \varepsilon). \end{aligned} \tag{4.1}$$

Then we have the following useful theorem

THEOREM 4.2. *For any convex, proper, LSC function* φ,

i. *if* x_ε *strongly converges to some* x *in* $\mathcal{H}$, *then* $\lim_{\varepsilon\to 0} I_\varepsilon x_\varepsilon = x$ *(strongly in* $\mathcal{H}$*);*

ii. *if* x_ε *weakly converges to some* $x \in \mathrm{dom}\ \partial\varphi$ *in* $\mathcal{H}$, *then* $\lim_{\varepsilon\to 0} \inf\ \varphi_\varepsilon(x_\varepsilon) \ge \varphi(x)$;

iii. *if* φ *satisfies condition* (4.1) *and if* $x_\varepsilon \in \mathrm{dom}\ \varphi$ *strongly converges to some* $x \in \mathrm{dom}\ \varphi$, *then* $\lim_{\varepsilon\to 0} \varphi_\varepsilon(x_\varepsilon) = \varphi(x)$ *and* $x \in \mathrm{dom}\ \partial\varphi$.

Proof. i and ii are direct consequences of Theorem 4.1. To prove iii, we use the relation (2.18) given in Barbu [3, p. 66]:

$$\forall z, y \in \mathcal{H}, \forall \varepsilon > 0, \quad \varphi_\varepsilon(y) - \varphi_\varepsilon(z) \le \langle \varphi'_\varepsilon(y), y - z\rangle_{\mathcal{H}',\mathcal{H}}$$

where $\langle\ ,\ \rangle_{\mathcal{H}',\mathcal{H}}$ denotes the pairing between $\mathcal{H}$ and $\mathcal{H}'$.

We use it first with $z = x_\varepsilon$ and $y = x$ and then with $y = x_\varepsilon$ and $y = x$; this gives

$$|\varphi_\varepsilon(x_\varepsilon) - \varphi_\varepsilon(x)| \le \max(|\varphi'_\varepsilon(x_\varepsilon)|_{\mathcal{H}'}, |\varphi'_\varepsilon(x)|_{\mathcal{H}'})|x - x_\varepsilon|_{\mathcal{H}}.$$

With Theorem 4.1 ii, assumption (4.1), and the strong convergence of x_ε to x, we get the strong convergence of $\varphi_\varepsilon(x_\varepsilon)$ to $\varphi_\varepsilon(x)$. We conclude with Theorem 4.1 vi. □

REMARK 4.1. *The above property is satisfied for any convex, proper, LSC function* φ *as soon as* $x \in \mathrm{int}(\mathrm{dom}\ \varphi)$ *since* $\partial\varphi(x)$ *is locally bounded in this case (see* [4, p. 60]*). Anyway, here it may happen that* $\mathrm{int}(\mathrm{dom}\ \varphi)$ *is empty and this result cannot be used.*

Now we make precise the hypotheses on functions Φ and Φ^*; from now we assume that

$$\Phi \text{ satisfies (4.1) with } \mathcal{H} = V \text{ and } \Phi^* \text{ satisfies (4.1) with } \mathcal{H} = V'\ . \tag{4.2}$$

This assumption is not so restrictive since it allows us to consider a wide class of convex functions; let us give some examples.

EXAMPLE 4.1. (*convex functions satisfying* (4.1)).

• Any continuous, convex function defined on the whole space V satisfies (4.1) since $\mathrm{int}(\mathrm{dom}\ \varphi) = V$ so that $\partial\varphi(x)$ is locally bounded for any x (we use also Theorem 4.2 i, Theorem 4.1 ii, and a result of Barbu and Precupanu [4, p. 60]).

• Any indicator function $\varphi = 1_C$ of a convex, closed, nonempty subset C of $\mathcal{H}$ satisfies (4.1) also; we recall that

$$1_C(y) = \begin{cases} 0 & \text{if } y \in C, \\ +\infty & \text{else,} \end{cases}$$

and $I_\varepsilon(x) = P_C(x)$ where P_C is the $\mathcal{H}$-projection on C. Then

$$\varphi_\varepsilon(x) = \frac{|x - P_C(x)|^2_{\mathcal{H}}}{2\varepsilon} \text{ and } \varphi'_\varepsilon(x) = \Lambda_{\mathcal{H}} \left(\frac{x - P_C(x)}{\varepsilon} \right).$$

If x_ε strongly converges to x in C =dom φ, then $\varphi'_\varepsilon(x_\varepsilon) = 0$ for all ε and so remains bounded in $\mathcal{H}'$.

EXAMPLE 4.2. (*convex functions satisfying* (4.2)).

• If Φ is the indicator function of a convex closed cone C of V, then $\Phi^* = 1_{C^*}$, where C^* is the polar cone of C in V'; so with Example 4.1 we see that (4.2) is ensured.

This case involves the obstacle problem or the Signorini problem.

• If $\Phi(x) = |x|_V$ is continuous and dom $(\Phi) = H$ then Φ^* is the indicator function of the unit ball of V'.

• $\Phi(x) = \frac{1}{p}|x|^p_V$ then $\Phi^*(x) = \frac{1}{p'}|x|^{p'}_{V'}$ where $p, p' \in]1, +\infty[$ are conjugate numbers (see Ekeland–Temam [10]). This leads to a *semilinear* state equation.

REMARK 4.2. *The approximation process concerns the functions g, h, Φ, and Φ^* which are not necessarily Fréchet differentiable and are replaced by their Moreau–Yosida approximations. This method provides $\mathcal{C}^1$ functions.*

We have also added two kinds of penalization terms: the state equation and the inequality (nonconvex) constraint are penalized in a standard way. The other terms are adapted penalization terms which ensure the strong convergence of the penalized solution toward the desired solution (when uniqueness does not hold).

First we have an existence and convergence result for $(\mathcal{P}^\varepsilon_\alpha)$.

THEOREM 4.3. *For all $\varepsilon > 0$, problem $(\mathcal{P}^\varepsilon_\alpha)$ has (at least) a solution $(y_\varepsilon, u_\varepsilon, z_\varepsilon)$. Moreover, when $\varepsilon \to 0$, $(y_\varepsilon, u_\varepsilon, z_\varepsilon) \to (y_\alpha, u_\alpha, z_\alpha)$ strongly in $V \times U \times H$.*

Proof. We first prove the existence of a solution for $(\mathcal{P}^\varepsilon_\alpha)$. We notice that $(y_\alpha, u_\alpha, z_\alpha)$ is a feasible triple for $(\mathcal{P}^\varepsilon_\alpha)$ so that the feasible domain of $(\mathcal{P}^\varepsilon_\alpha)$ is nonempty, and we may find a minimizing sequence $(y^n_\varepsilon, u^n_\varepsilon, z^n_\varepsilon)$ converging to $d_\varepsilon = \inf(\mathcal{P}^\varepsilon_\alpha)$. Setting $I_{\varepsilon,g} = (I_H + \varepsilon\partial g)^{-1}$ and $I_{\varepsilon,h} = (I_U + \varepsilon\partial h)^{-1}$ we get

$$J_\varepsilon(y, u, z) \geq g_\varepsilon(y) + h_\varepsilon(u) \geq g(I_{\varepsilon,g}(y)) + h(I_{\varepsilon,h}(u))$$

and

$$\inf_{V\times U\times H} J_\varepsilon(y, u, z) \geq \inf_{V\times U} g(I_{\varepsilon,g}(y)) + h(I_{\varepsilon,h}(u)) \geq \gamma > -\infty$$

because of the properties of g and h. So $d_\varepsilon \in \mathbb{R}$ and the end of the proof is standard (see Theorem 3.1).

Now we prove the convergence result. Since $(y_\alpha, u_\alpha, z_\alpha)$ is a feasible triple for $(\mathcal{P}^\varepsilon_\alpha)$ we have

$$d_\varepsilon = J_\varepsilon(y_\varepsilon, u_\varepsilon, z_\varepsilon) \leq g(y_\alpha) + h(u_\alpha) = d_\alpha. \tag{4.3}$$

We have just seen that d_ε is lower bounded (with respect to ε) so that y_ε, u_ε, and z_ε are bounded in V, U, and H. Extracting a subsequence, we get the weak convergence of $(y_\varepsilon, u_\varepsilon, z_\varepsilon)$ to $(\tilde{y}, \tilde{u}, \tilde{z})$ in $V \times U \times H$; in particular, this yields that $Ay_\varepsilon - Bu_\varepsilon - f + z_\varepsilon$ converges to $A\tilde{y} - B\tilde{u} - f + \tilde{z}$ weakly in V'.

Moreover $Ay_\varepsilon - Bu_\varepsilon - f + z_\varepsilon$ converges to zero strongly in V' so that $A\tilde{y} - B\tilde{u} - f + \tilde{z} = 0$. In addition, as U_{ad}, K and B^*_R are weakly closed we get $\tilde{u} \in U_{ad}$, $\tilde{y} \in K$, and $\tilde{z} \in B^*_R$. The injection of V in H is compact, so $y_\varepsilon \to \tilde{y}$ strongly in H; as $z_\varepsilon \rightharpoonup \tilde{z}$

weakly in H we get the convergence of $(y_\varepsilon, z_\varepsilon)_H$ to $(\tilde{y}, \tilde{z})_H$. Moreover Theorem 4.2 gives

$$\liminf_{\varepsilon\to 0} \ \Phi_\varepsilon(y_\varepsilon) \geq \Phi(\tilde{y}) \text{ and } \liminf_{\varepsilon\to 0} \Phi_\varepsilon^*(z_\varepsilon) \geq \Phi^*(\tilde{z}).$$

So we get

$$[\Phi(\tilde{y}) + \Phi^*(\tilde{z}) - (\tilde{y}, \tilde{z})_H - \alpha]_+ \leq \liminf_{\varepsilon\to 0}[\Phi_\varepsilon(y_\varepsilon) + \Phi_\varepsilon^*(z_\varepsilon) - (y_\varepsilon, z_\varepsilon)_H - \alpha]_+.$$

Since $\lim_{\varepsilon\to 0}[\Phi_\varepsilon(y_\varepsilon) + \Phi_\varepsilon^*(z_\varepsilon) - (y_\varepsilon, z_\varepsilon)_H - \alpha]_+^2 = 0$, this yields

$$[\Phi(\tilde{y}) + \Phi^*(\tilde{z}) - (\tilde{y}, \tilde{z})_H - \alpha]_+ = 0.$$

So $(\tilde{y}, \tilde{u}, \tilde{z})$ is feasible for $(\mathcal{P}_\alpha)$. Now relation (4.3) gives

$$g_\varepsilon(y_\varepsilon) + h_\varepsilon(u_\varepsilon) + \frac{1}{2}|y_\varepsilon - y_\alpha|_V^2 + \frac{1}{2}|u_\varepsilon - u_\alpha|_U^2 + \frac{1}{2}|z_\varepsilon - z_\alpha|_H^2 \leq g(y_\alpha) + h(u_\alpha).$$

Passing to the inf-limit in the above relation we get

$$g(\tilde{y}) + h(\tilde{u}) + \frac{1}{2}|\tilde{y} - y_\alpha|_V^2 + \frac{1}{2}|\tilde{u} - u_\alpha|_U^2 + \frac{1}{2}|\tilde{z} - z_\alpha|_H^2 \leq g(y_\alpha) + h(u_\alpha) \leq g(\tilde{y}) + h(\tilde{u}),$$

since $(\tilde{y}, \tilde{u}, \tilde{z})$ is feasible for $(\mathcal{P}_\alpha)$. So $\tilde{y} = y_\alpha$, $\tilde{u} = u_\alpha$ and $\tilde{z} = z_\alpha$. Furthermore $\lim_{\varepsilon\to 0} |y_\varepsilon - y_\alpha|_V = 0$, $\lim_{\varepsilon\to 0} |u_\varepsilon - u_\alpha|_U = 0$, and $\lim_{\varepsilon\to 0} |z_\varepsilon - z_\alpha|_H = 0$ and we get the strong convergence. □

COROLLARY 4.1. *There exists* $(y^*, z^*) \in \partial\Phi^*(z_\alpha) \times \partial\Phi(y_\alpha)$ *such that* $\Phi_\varepsilon'(y_\varepsilon) \rightharpoonup z^*$ *weakly in* V' *and* $\Phi_\varepsilon^{*'}(z_\varepsilon) \rightharpoonup y^*$ *weakly in* V *(and strongly in* H*). Moreover*

$$\lim_{\varepsilon\to 0} \langle \Phi_\varepsilon'(y_\varepsilon), y_\varepsilon\rangle = \langle z^*, y_\alpha\rangle \ \text{ and } \lim_{\varepsilon\to 0} \left(\Phi_\varepsilon^{*'}(z_\varepsilon), z_\varepsilon\right)_H = (y^*, z_\alpha)_H. \tag{4.4}$$

Proof. As $y_\varepsilon \in K \subset \mathrm{dom}(\Phi)$ strongly converges to y_α in V, we use assumption (4.2) to infer that $\Phi_\varepsilon'(y_\varepsilon)$ is bounded in V'. So we may extract a subsequence (denoted similarly) such that $\Phi_\varepsilon'(y_\varepsilon)$ weakly converges in V' to z^*. Theorem 4.1 iv implies that $z^* \in \partial\Phi(y_\alpha)$. Similarly, we may prove that $\Phi_\varepsilon^{*'}(z_\varepsilon) \rightharpoonup y^* \in \partial\Phi^*(z_\alpha)$ weakly in V and strongly in H, since z_ε strongly converges to z_α in V'. Relations (4.4) are obvious. □

4.2. Optimality conditions for $(\mathcal{P}_\alpha^\varepsilon)$. Now, we want to derive optimality conditions for $(\mathcal{P}_\alpha^\varepsilon)$. J_ε is $\mathcal{C}^1$ and the feasible domain of $(\mathcal{P}_\alpha^\varepsilon)$ is convex, so using convex variations we have

$$\forall (y, u, z) \in K \times U_{ad} \times B_R^*, \quad \nabla J_\varepsilon(y_\varepsilon, u_\varepsilon, z_\varepsilon)(y - y_\varepsilon, u - u_\varepsilon, z - z_\varepsilon) \geq 0. \tag{4.5}$$

This leads to the following penalized optimality system in Theorem 4.4.

THEOREM 4.4. *For all* $\varepsilon > 0$ *(small enough), there exist* $q_\varepsilon \in V$ *and* $\lambda_\varepsilon \in \mathbb{R}^+$ *such that*

$$\begin{array}{l} \forall y \in K \\ (g_\varepsilon'(y_\varepsilon), y - y_\varepsilon)_H + (y_\varepsilon - y_\alpha, y - y_\varepsilon)_V + \langle A^* q_\varepsilon + \lambda_\varepsilon[\Phi_\varepsilon'(y_\varepsilon) - z_\varepsilon], y - y_\varepsilon\rangle \geq 0, \end{array} \tag{4.6}$$

$$\forall u \in U_{ad} \quad (h_\varepsilon'(u_\varepsilon) - B^* q_\varepsilon + u_\varepsilon - u_\alpha, u - u_\varepsilon)_U \geq 0, \tag{4.7}$$

$$\forall z \in B_R^* \quad \Big(q_\varepsilon + \lambda_\varepsilon[\Phi_\varepsilon^{*'}(z_\varepsilon) - y_\varepsilon] + z_\varepsilon - z_\alpha, z - z_\varepsilon\Big)_H \geq 0, \tag{4.8}$$

where A^* and B^* are the adjoint operators of A and B.

Proof. Relation (4.5) may be decoupled to obtain

$$\forall y \in K, \quad \nabla_y J_\varepsilon(y_\varepsilon, u_\varepsilon, z_\varepsilon)(y - y_\varepsilon) \geq 0, \tag{4.9}$$

$$\forall u \in U_{ad}, \quad \nabla_u J_\varepsilon(y_\varepsilon, u_\varepsilon, z_\varepsilon)(u - u_\varepsilon) \geq 0, \tag{4.10}$$

$$\forall z \in B_R^*, \quad \nabla_z J_\varepsilon(y_\varepsilon, u_\varepsilon, z_\varepsilon)(z - z_\varepsilon) \geq 0. \tag{4.11}$$

Let us make precise these relations: setting $q_\varepsilon = \Lambda_V^{-1}(s_\varepsilon) \in V$ and

$$s_\varepsilon = \frac{Ay_\varepsilon - Bu_\varepsilon - f + z_\varepsilon}{\varepsilon} \in H \subset V', \ \lambda_\varepsilon = \frac{[\Phi_\varepsilon(y_\varepsilon) + \Phi_\varepsilon^*(z_\varepsilon) - (y_\varepsilon, z_\varepsilon)_H - \alpha]_+}{\varepsilon} \in \mathbb{R}^+ ,$$

relation (4.9) gives for all $y \in K$

$$\begin{aligned} &(g_\varepsilon'(y_\varepsilon), y - y_\varepsilon)_H + (y_\varepsilon - y_\alpha, y - y_\varepsilon)_V \\ +\ &\langle \lambda_\varepsilon[\Phi_\varepsilon'(y_\varepsilon) - z_\varepsilon], y - y_\varepsilon\rangle + \langle q_\varepsilon, A(y - y_\varepsilon)\rangle \geq 0; \end{aligned}$$

introducing the adjoint operator A^* of A we get (4.6). The other relations are obtained similarly. □

REMARK 4.3. *Equation* (4.8) *(and* (4.7) *as well) can be reformulated using the normal cone to B_R^*. Indeed, as B_R^* is convex this normal cone is characterized with*

$$N_{B_R^*}(z_\varepsilon) = \{\ \xi \in H \mid\ (\xi, z_\varepsilon - z)_H \geq 0 \quad \forall z \in B_R^*\ \}$$

(see for instance Clarke [9, p. 53]*), so that relation* (4.8) *is equivalent to*

$$-[q_\varepsilon + \lambda_\varepsilon(\Phi_\varepsilon^{*'}(z_\varepsilon) - y_\varepsilon)] \in z_\varepsilon - z_\alpha + N_{B_R^*}(z_\varepsilon). \tag{4.12}$$

5. Optimality conditions for ($\mathcal{P}_\alpha$). In order to pass to the limit (with respect to ε) in the previous relations we need further estimations on the multipliers q_ε and λ_ε.

5.1. Estimations of the penalized multipliers. Let $(y, u, z) \in K \times U_{ad} \times B_R^*$ and let us add relations (4.6)–(4.8). This gives

$$\begin{aligned} &(g_\varepsilon'(y_\varepsilon), y - y_\varepsilon)_H + (h_\varepsilon'(u_\varepsilon), u - u_\varepsilon)_U \\ +\ &(y_\varepsilon - y_\alpha, y - y_\varepsilon)_V + (u_\varepsilon - u_\alpha, u - u_\varepsilon)_U + (z_\varepsilon - z_\alpha, z - z_\varepsilon)_H \\ +\ &\langle q_\varepsilon, Ay - Bu + z - f - (Ay_\varepsilon - Bu_\varepsilon + z_\varepsilon - f)\rangle \\ +\ &\lambda_\varepsilon \Big[\langle \Phi_\varepsilon'(y_\varepsilon) - z_\varepsilon, y - y_\varepsilon\rangle + \Big(\Phi_\varepsilon^{*'}(z_\varepsilon) - y_\varepsilon, z - z_\varepsilon\Big)_H\Big] \geq 0\ . \end{aligned}$$

Using the definition of q_ε and that $\varepsilon\,\langle q_\varepsilon, \Lambda_V q_\varepsilon\rangle \geq 0$ we get

$$\begin{aligned} \langle -q_\varepsilon, Ay - Bu + z - f\rangle - \lambda_\varepsilon\Big[\langle \Phi_\varepsilon'(y_\varepsilon) - z_\varepsilon, y - y_\varepsilon\rangle + \Big(\Phi_\varepsilon^{*'}(z_\varepsilon) - y_\varepsilon, z - z_\varepsilon\Big)_H\Big] \\ \leq (g_\varepsilon'(y_\varepsilon), y - y_\varepsilon)_H + (h_\varepsilon'(u_\varepsilon), u - u_\varepsilon)_U \\ + (y_\varepsilon - y_\alpha, y - y_\varepsilon)_V + (u_\varepsilon - u_\alpha, u - u_\varepsilon)_U + (z_\varepsilon - z_\alpha, z - z_\varepsilon)_H\,. \end{aligned}$$

The right-hand-side term is bounded since $(y_\varepsilon, u_\varepsilon, z_\varepsilon) \to (y_\alpha, u_\alpha, z_\alpha)$ strongly in $V \times U \times H$, and $(g_\varepsilon'(y_\varepsilon), h_\varepsilon'(u_\varepsilon)) \rightharpoonup (y_\alpha^g, u_\alpha^h) \in \partial g(y_\alpha) \times \partial h(u_\alpha)$ weakly in $H \times U$ (because

of Theorem 4.2 iii and the continuity of g and h). The bounding constant σ depends only on (y, u, z). So we have, for all $\varepsilon > 0$ small enough,

$$-\lambda_\varepsilon \left[\langle \Phi_\varepsilon'(y_\varepsilon) - z_\varepsilon, y - y_\varepsilon \rangle + \left(\Phi_\varepsilon^{*'}(z_\varepsilon) - y_\varepsilon, z - z_\varepsilon \right)_H \right] - \langle q_\varepsilon, Ay - Bu + z - f \rangle \leq \sigma(y, u, z). \tag{5.1}$$

We first estimate the real number λ_ε. If the solution $(y_\alpha, u_\alpha, z_\alpha)$ is such that the nonconvex constraint is inactive, i.e.,

$$\Phi(y_\alpha) + \Phi^*(z_\alpha) - (y_\alpha, z_\alpha)_H - \alpha = G(y_\alpha, z_\alpha) < 0,$$

then convergence results yield

$$\exists \varepsilon_o > 0 \ \forall \varepsilon \leq \varepsilon_o, \ \Phi_\varepsilon(y_\varepsilon) + \Phi_\varepsilon^*(z_\varepsilon) - (y_\varepsilon, z_\varepsilon)_H - \alpha < 0$$

as well and $\lambda_\varepsilon = 0$; hence the limit $\lambda_\alpha = 0$.

Now, we investigate the case when the constraint is active; that is,

$$\Phi(y_\alpha) + \Phi^*(z_\alpha) - (y_\alpha, z_\alpha)_H - \alpha = G(y_\alpha, z_\alpha) = 0.$$

Let us assume the following condition (H_1):

$$\begin{gathered} \forall \alpha \text{ such that } G(y_\alpha, z_\alpha) = 0 \ \forall (y^*, z^*) \in \partial\Phi^*(z_\alpha) \times \partial\Phi(y_\alpha), \\ \exists (\tilde{y}, \tilde{u}, \tilde{z}) \in K \times U_{ad} \times B_R^* \text{ such that } A\tilde{y} = B\tilde{u} + f - \tilde{z}, \text{ and} \end{gathered} \tag{H_1}$$

$$[\Phi(y_\alpha) - \Phi(y^*) - \langle y_\alpha - y^*, \tilde{z} \rangle] + [\Phi^*(z_\alpha) - \Phi^*(z^*) - \langle z_\alpha - z^*, \tilde{y} \rangle] < 2\alpha. \tag{5.2}$$

REMARK 5.1. *Relation* (5.2) *is indeed equivalent to*

$$\langle y_\alpha - y^*, \tilde{z} - z_\alpha \rangle + \langle z_\alpha - z^*, \tilde{y} - y_\alpha \rangle > 0,$$

as we shall prove later. Moreover, in our case, $\langle y_\alpha - y^*, \tilde{z} \rangle = (y_\alpha - y^*, \tilde{z})_H$ *since* $\tilde{z} \in H$.

THEOREM 5.1. *Assume* (H_1)*; then* λ_ε *is bounded by a constant independent of* ε*, and we may extract a subsequence converging to* $\lambda_\alpha \in \mathbb{R}^+$.

Proof. If α is such that $G(y_\alpha, z_\alpha) < 0$, we have already seen that $\lambda_\alpha = 0$.

If $G(y_\alpha, z_\alpha) = 0$, we use (H_1). Let $(y^*, z^*) \in \partial\Phi^*(z_\alpha) \times \partial\Phi(y_\alpha) \subset V \times V'$ be given by Corollary 4.1. Let us apply relation (5.1) with the triple $(\tilde{y}, \tilde{u}, \tilde{z})$ given by (H_1). We get

$$\lambda_\varepsilon \left[\langle z_\varepsilon - \Phi_\varepsilon'(y_\varepsilon), \tilde{y} - y_\varepsilon \rangle + \left(y_\varepsilon - \Phi_\varepsilon^{*'}(z_\varepsilon), \tilde{z} - z_\varepsilon \right)_H \right] \leq \tilde{C} \tag{5.3}$$

and

$$\Phi(y_\alpha) - \Phi(y^*) - (y_\alpha - y^*, \tilde{z})_H + \Phi^*(z_\alpha) - \Phi^*(z^*) - \langle z_\alpha - z^*, \tilde{y} \rangle < 2\alpha.$$

As $y^* \in \partial\Phi^*(z_\alpha)$ and $z^* \in \partial\Phi(y_\alpha)$, we have $\Phi(y^*) + \Phi^*(z_\alpha) = (y^*, z_\alpha)_H$ and $\Phi^*(z^*) + \Phi(y_\alpha) = \langle z^*, y_\alpha \rangle$.

Moreover we are in the case where $\Phi(y_\alpha) + \Phi^*(z_\alpha) = (y_\alpha, z_\alpha)_H + \alpha$, so that (5.2) is equivalent to

$$\rho = (y_\alpha - y^*, \tilde{z} - z_\alpha)_H + \langle z_\alpha - z^*, \tilde{y} - y_\alpha \rangle > 0,$$

as mentioned in Remark 5.1.

Convergence results given in Theorem 4.3 and Corollary 4.1 imply that

$$\lim_{\varepsilon\to 0}\Big(y_\varepsilon-\Phi_\varepsilon^{*'}(z_\varepsilon),\tilde z-z_\varepsilon\Big)_H+\langle z_\varepsilon-\Phi_\varepsilon'(y_\varepsilon),\tilde y-y_\varepsilon\rangle=\rho>0.$$

So, there exists $\varepsilon_o>0$ such that for all $0<\varepsilon<\varepsilon_o$ we have

$$\Big(y_\varepsilon-\Phi_\varepsilon^{*'}(z_\varepsilon),\tilde z-z_\varepsilon\Big)_H+\langle z_\varepsilon-\Phi_\varepsilon'(y_\varepsilon),\tilde y-y_\varepsilon\rangle\geq\frac{\rho}{2}.$$

Then relation (5.3) gives

$$\forall\varepsilon<\varepsilon_o\qquad 0\leq\frac{\rho}{2}\lambda_\varepsilon\leq\tilde C.$$

So λ_ε is bounded and converges to some $\lambda_\alpha\in\mathbb{R}^+$ (extracting a subsequence). □

It remains to bound q_ε. Following [7] we assume the (qualification) condition (H_2):

$$(H_2)\qquad\begin{cases}\exists W \text{ separable Banach subspace such that}\\ W\subset V' \text{ continuously and densely,}\\ \exists\mathcal{M}\subset K\times U_{ad}\times B_R^* \text{ bounded in } V\times U\times H, \text{ such that}\\ 0\in \operatorname{Int}_W\mathcal{T}(\mathcal{M}) \text{ in } W\text{-topology,}\\ \text{where } \mathcal{T}(y,u,z)=Ay-Bu-f+z\ .\end{cases}$$

More precisely, $0\in\operatorname{Int}_W\mathcal{T}(\mathcal{M})$ means the existence of $\rho>0$ such that

$$\forall\xi\in W,\ \ |\xi|_W\leq 1,\ \exists(y_\xi,u_\xi,z_\xi)\in\mathcal{M}\ \text{ such that } Ay_\xi=Bu_\xi+f-z_\xi+\rho\xi.$$

THEOREM 5.2. *Assume (H_1) and (H_2); then q_ε is bounded in W', and one may extract a subsequence converging weak* to q_α in W'.*

Proof. Let $\rho>0$ be given by (H_2) and $\xi\in W$ such that $|\xi|_W\leq 1$. We use relation (5.1) with (y_ξ,u_ξ,z_ξ) and we get

$$\langle -q_\varepsilon,\rho\xi\rangle\leq C_1+C_2\lambda_\varepsilon,$$

where C_1 and C_2 are constants dependent only on (y_ξ,u_ξ,z_ξ). Assumption (H_1) provides a bound for λ_ε and $\mathcal{M}$ is bounded. So there exists a constant C (depending only on $\mathcal{M}$) such that

$$\forall\xi\in W,\ \ |\xi|_W\leq 1,\langle q_\varepsilon,\xi\rangle_{W',W}\leq C$$

(as $W\subset V'$ and $q_\varepsilon\in V$ then $q_\varepsilon\in W'$). Thus q_ε is bounded in W'. □

Now, we are able to pass to the limit in the penalized optimality system with respect to ε.

5.2. Optimality conditions for $(\mathcal{P}_\alpha)$.

THEOREM 5.3. *Let be $\alpha>0$ and assume (H_1) and (H_2); then there exists $(y_\alpha^g,u_\alpha^h,z_\alpha^*,y_\alpha^*)\in\partial g(y_\alpha)\times\partial h(u_\alpha)\times\partial\Phi(y_\alpha)\times\partial\Phi^*(z_\alpha)\subset H\times U\times V'\times V$ and $(q_\alpha,\lambda_\alpha)\in W'\times\mathbb{R}^+$ such that*

$$(5.4)\qquad\begin{array}{l}\forall y\in K \text{ such that } A(y-y_\alpha)\in W,\\ (y_\alpha^g,y-y_\alpha)_H+\langle q_\alpha,A(y-y_\alpha)\rangle_{W',W}+\lambda_\alpha\langle z_\alpha^*-z_\alpha,y-y_\alpha\rangle_{V',V}\geq 0\ ,\end{array}$$

$$(5.5)\qquad\begin{array}{l}\forall u\in U_{ad} \text{ such that } B(u-u_\alpha)\in W,\\ \big(u_\alpha^h,u-u_\alpha\big)_U-\langle q_\alpha,B(u-u_\alpha)\rangle_{W',W}\geq 0,\end{array}$$

$$\begin{aligned}&\forall z \in B_R^* \text{ such that } z - z_\alpha \in W,\\ &\langle q_\alpha, z - z_\alpha\rangle_{W',W} + \lambda_\alpha \left(y_\alpha^* - y_\alpha, z - z_\alpha\right)_H \geq 0,\end{aligned} \tag{5.6}$$

$$\lambda_\alpha \left[\Phi(y_\alpha) + \Phi^*(z_\alpha) - \left(y_\alpha, z_\alpha\right)_H - \alpha\right] = 0. \tag{5.7}$$

Proof. Let $y \in K$ be such that $A(y - y_\alpha) \in W,\ u \in U_{ad}$ such that $B(u - u_\alpha) \in W$ and $z \in B_R^*$ such that $z - z_\alpha \in W$. We use relations (4.6)–(4.8) with these test functions and add them to get

$$\begin{aligned}&\left(g_\varepsilon'(y_\varepsilon), y - y_\varepsilon\right)_H + \left(h_\varepsilon'(u_\varepsilon), u - u_\varepsilon\right)_U\\ &+\ \left(y_\varepsilon - y_\alpha, y - y_\varepsilon\right)_V + \left(u_\varepsilon - u_\alpha, u - u_\varepsilon\right)_U + \left(z_\varepsilon - z_\alpha, z - z_\varepsilon\right)_H\\ &+\ \langle q_\varepsilon, Ay - Bu + z - f - (Ay_\varepsilon - Bu_\varepsilon + z_\varepsilon - f)\rangle\\ &+\ \lambda_\varepsilon \left[\langle \Phi_\varepsilon'(y_\varepsilon) - z_\varepsilon, y - y_\varepsilon\rangle + \left(\Phi_\varepsilon^{*'}(z_\varepsilon) - y_\varepsilon, z - z_\varepsilon\right)_H\right] \geq 0;\end{aligned}$$

that is, as subsection 5.1,

$$\begin{aligned}&\left(g_\varepsilon'(y_\varepsilon), y - y_\varepsilon\right)_H + \left(h_\varepsilon'(u_\varepsilon), u - u_\varepsilon\right)_U\\ &+\ \left(u_\varepsilon - u_\alpha, u - u_\varepsilon\right)_U + \left(z_\varepsilon - z_\alpha, z - z_\varepsilon\right)_H\\ &+\ \langle q_\varepsilon, A(y - y_\alpha) - B(u - u_\alpha) + z - z_\alpha\rangle_{W',W}\\ &+\ \lambda_\varepsilon \left[\langle \Phi_\varepsilon'(y_\varepsilon) - z_\varepsilon, y - y_\varepsilon\rangle + \left(\Phi_\varepsilon^{*'}(z_\varepsilon) - y_\varepsilon, z - z_\varepsilon\right)_H\right] \geq 0.\end{aligned}$$

As g and h are continuous and finite everywhere, $(g_\varepsilon'(y_\varepsilon), h_\varepsilon'(u_\varepsilon))$ converges toward some $(y_\alpha^g, u_\alpha^h) \in \partial g(y_\alpha) \times \partial h(y_\alpha)$. Then we may pass to the limit in the above relation to infer

$$\begin{aligned}&\left(y_\alpha^g, y - y_\alpha\right)_H + \left(u_\alpha^h\right), u - u_\alpha\big)_U\\ &+\ \langle q_\alpha, A(y - y_\alpha) - B(u - u_\alpha) + z - z_\alpha\rangle_{W',W}\\ &+\ \lambda_\alpha \left[\langle z_\alpha^* - z_\alpha, y - y_\alpha\rangle + \left(y^*\alpha - y_\alpha, z - z_\alpha\right)_H\right] \geq 0\ .\end{aligned}$$

Taking in turn $y = y_\alpha,\ u = u_\alpha$, and $z = z_\alpha$ we obtain relations (5.4)–(5.6).

Finally if $\Phi(y_\alpha) + \Phi^*(z_\alpha) - \left(y_\alpha, z_\alpha\right)_H - \alpha < 0$ we have seen that $\lambda_\alpha = 0$. So relation (5.7) is satisfied. □

REMARK 5.2. *As we already mentioned in Remark* 4.3*, equation* (5.6) *is equivalent to*

$$-q_\alpha - \lambda_\alpha(y_\alpha^* - y_\alpha) \in N_{B_R^* \cap (z_\alpha + W)}(z_\alpha). \tag{5.8}$$

COROLLARY 5.1. *With assumptions of Theorem* 5.3*, there exist* $(y_\alpha^g, u_\alpha^h) \in \partial g(y_\alpha) \times \partial h(u_\alpha) \subset H \times U$ *and* $(q_\alpha, \lambda_\alpha) \in W' \times \mathbb{R}^+$ *such that*

$$\begin{aligned}&\forall y \in K \text{ s.t. } A(y - y_\alpha) \in W,\\ &\left(y_\alpha^g, y - y_\alpha\right)_H + \langle q_\alpha, A(y - y_\alpha)\rangle_{W',W}\\ &+\ \lambda_\alpha \left[\Phi(y) + \Phi^*(z_\alpha) - \left(y, z_\alpha\right)_H - \alpha\right] \geq 0\end{aligned} \tag{5.9}$$

$$\forall u \in U_{ad} \text{ s.t. } B(u - u_\alpha) \in W \qquad \left(u_\alpha^h, u - u_\alpha\right)_U - \langle q_\alpha, B(u - u_\alpha)\rangle_{W',W} \geq 0,$$

$$\begin{aligned}&\forall z \in B_R^* \text{ s.t. } z - z_\alpha \in W,\\ &\langle q_\alpha, z - z_\alpha\rangle_{W',W} + \lambda_\alpha \left[\Phi(y_\alpha) + \Phi^*(z) - \left(y_\alpha, z\right)_H - \alpha\right] \geq 0,\end{aligned} \tag{5.10}$$

$$\lambda_\alpha \left[\Phi(y_\alpha) + \Phi^*(z_\alpha) - \left(y_\alpha, z_\alpha\right)_H - \alpha\right] = 0.$$

Proof. Theorem 5.3 gives $(z_\alpha^*, y_\alpha^*) \in \partial\Phi(y_\alpha) \times \partial\Phi^*(z_\alpha) \subset V' \times V$ such that relations (5.4) and (5.6) are satisfied.

As $z_\alpha^* \in \partial\Phi(y_\alpha)$ we get, for all $y \in K$ such that $A(y - y_\alpha) \in W$,

$$\Phi(y) - \Phi(y_\alpha) \geq \langle z_\alpha^*, y - y_\alpha \rangle ,$$

so that relation (5.4) becomes

$$(y_\alpha^g, y - y_\alpha)_H + \langle q_\alpha, A(y - y_\alpha)\rangle_{W',W} + \lambda_\alpha \left[\Phi(y) - \Phi(y_\alpha) - (z_\alpha, y - y_\alpha)_H\right] \geq 0.$$

Using (5.7) we obtain relation (5.9). Similarly, we can show relation (5.10). ∎

COROLLARY 5.2. *With assumptions of the previous theorem and if g and h are Gâteaux differentiable, there exists $(q_\alpha, \lambda_\alpha) \in W' \times \mathbb{R}^+$ such that*

$$\begin{array}{l} \forall y \in K \ \textit{s.t.}\ A(y - y_\alpha) \in W, \\ (g'(y_\alpha), y - y_\alpha)_H + \langle q_\alpha, A(y - y_\alpha)\rangle_{W',W} + \lambda_\alpha \left[\Phi(y) + \Phi^*(z_\alpha) - (z_\alpha, y)_H - \alpha\right] \geq 0, \end{array}$$

$$\forall u \in U_{ad} \ \textit{s.t.}\ B(u - u_\alpha) \in W \qquad (h'(u_\alpha), u - u_\alpha)_U - \langle q_\alpha, B(u - u_\alpha)\rangle_{W',W} \geq 0,$$

$$\begin{array}{l} \forall z \in B_R^* \ \textit{s.t.}\ z - z_\alpha \in W, \\ \langle q_\alpha, z - z_\alpha\rangle_{W',W} + \lambda_\alpha \left[\Phi(y_\alpha) + \Phi^*(z) - (z, y_\alpha)_H - \alpha\right] \geq 0, \end{array}$$

$$\lambda_\alpha \left[\Phi(y_\alpha) + \Phi^*(z_\alpha) - (y_\alpha, z_\alpha)_H - \alpha\right] = 0.$$

REMARK 5.3. *The natural idea would now be to study the asymptotic behavior of the previous optimality system when $\alpha \to 0$. Unfortunately, we would have to set an "$(H1)$-like" assumption with $\alpha = 0$, to be able to pass to the limit in the α-optimality system. This is impossible since the interior of the feasible domain of $\mathcal{P}$ is empty because of the nonconvex equality constraint and an assumption like $(H1)$ with $\alpha = 0$ would never be ensured. However, as we have already mentioned, this relaxed approach is sufficient for numerical applications.*

6. Example of the obstacle problem. In this section we study an example where the variational inequality leads to an obstacle problem.

Let Ω be an open, bounded subset of $\mathbb{R}^n$ with a smooth boundary $\partial\Omega$. We consider a bilinear form $a(.,.)$ defined on $H_o^1(\Omega) \times H_o^1(\Omega)$ and A the continuous linear operator from $H_o^1(\Omega)$ to $H^{-1}(\Omega)$ associated with a such that

$$\left\{ \begin{array}{c} Ay = -\displaystyle\sum_{i,j=1}^{n} \partial_{x_i}(a_{ij}(x)\partial_{x_j} y) + a_0(x)y \ \text{ with} \\ a_{ij}, a_0 \in \mathcal{C}^2(\bar{\Omega}) \text{ for } i,j = 1,\ldots,n, \ \inf\ \{a_0(x) \mid x \in \bar{\Omega}\} > 0, \\ \displaystyle\sum_{ij=1}^{n} a_{ij}(x)\xi_i\xi_j \geq \delta \sum_{i=1}^{n} \xi_i^2 \forall x \in \bar{\Omega} \forall \xi \in \mathbb{R}^n, \delta > 0. \end{array} \right. \tag{6.1}$$

We shall denote $\|\ \|$, the $L^2(\Omega)$-norm, $(\ ,\ )$ the $L^2(\Omega)$-scalar product, and $\langle\ ,\ \rangle$ any duality product. We set

$$V = H_o^1(\Omega)\ ,\ H = L^2(\Omega)\ ,\ D_H(A) = H^2(\Omega) \cap H_o^1(\Omega)\ ,\ U = L^2(\Omega), \text{ and } B = Id_{L^2(\Omega)}.$$

Let us set also

$$K = V \text{ and } C^+ = \{y \mid y \in H_o^1(\Omega),\ y \geq 0 \text{ a.e. in } \Omega\}.$$

The convex function Φ is the indicator function I_+ of C^+ Then Φ^* is the indicator function I_- of the negative cone C^- of H^{-1}, and we have already mentioned that Φ and Φ^* satisfy condition (4.2). Then we get as a state equation

$$Ay = f + v - z \text{ in } \Omega, y = 0 \text{ on } \Gamma, \tag{6.2}$$

with $f,\ v$, and z belonging to $L^2(\Omega)$ (because of the regularity result mentioned in section 1). The constraint $z \in \partial\Phi(y)$ becomes

$$y \geq 0\ ,\ z \leq 0\ ,\ (y,z) = 0,$$

and the α-inequality constraint $\Phi(y) + \Phi^*(z) - (y,z) \leq \alpha$ gives:

$$y \geq 0\ ,\ z \leq 0\ ,\ (y,-z) \leq \alpha.$$

We set $\xi = -z$, so that the original control problem is defined as follows (see [5]):

$$\min\left\{J(y,v) = \frac{1}{2}\int_\Omega (y - z_d)^2\,dx + \frac{M}{2}\int_\Omega v^2\,dx\right\}, \tag{$\mathcal{P}$}$$

$$Ay = f + v + \xi \quad \text{in} \quad \Omega,\ y = 0 \quad \text{on} \quad \Gamma, \tag{6.3}$$

$$(y,v,\xi) \in \mathcal{D}, \tag{6.4}$$

where

$$\mathcal{D} = \{(y,v,\xi) \in H_o^1(\Omega) \times L^2(\Omega) \times L^2(\Omega) \mid v \in U_{ad},\ y \geq 0,\ \xi \geq 0, (y,\xi) = 0\}$$

and $z_d \in L^2(\Omega)$. The relaxed problem is

$$\min J(y,v), \tag{$\mathcal{P}^\alpha$}$$

$$Ay = v + \xi \quad \text{in} \quad \Omega,\ y \in H_o^1(\Omega), \tag{6.5}$$

$$(y,v,\xi) \in \mathcal{D}_\alpha^R, \tag{6.6}$$

where

$$\mathcal{D}_\alpha^R = \{(y,v,\xi) \in H_o^1(\Omega) \times L^2(\Omega) \times L^2(\Omega) \mid v \in U_{ad},\ y \geq 0,\ \xi \geq 0, \|\xi\| \leq R, (y,\xi) \leq \alpha\}.$$

The results of the previous section may be applied with $W = L^p(\Omega)$ and we get Theorem 6.1.

THEOREM 6.1. *Assume*

$$\begin{array}{c} \forall \alpha \text{ such that } \langle y_\alpha, \xi_\alpha\rangle = \alpha\ , \\ \exists(\tilde{y},\tilde{v},\tilde{\xi}) \in C^+ \times U_{ad} \times B_R^* \quad \text{such that} \\ A\tilde{y} = \tilde{v} + \tilde{\xi} \quad \text{and} \quad (\tilde{y},\xi_\alpha) + \left(y_\alpha,\tilde{\xi}\right) < 2\alpha \end{array} \tag{$\mathcal{H}_1$}$$

and

$$(\mathcal{H}_2)\qquad \begin{array}{c}\exists p\in[1,+\infty[,\ \exists\ \rho>0\quad \forall\ \chi\in L^p(\Omega),\ \|\chi\|_{L^p(\Omega)}\leq 1,\\ \exists(y_\chi,v_\chi,\xi_\chi)\ \textit{bounded in } C^+\times U_{ad}\times B_R^*\ \textit{(independently of } \chi)\\ \textit{such that } Ay_\chi=v_\chi+\xi_\chi+\rho\chi\quad \textit{in } \Omega,\end{array}$$

and let $(y_\alpha,v_\alpha,\xi_\alpha)$ *be a solution of* $(\mathcal{P}^\alpha)$*; then a Lagrange multiplier* $(q_\alpha,\lambda_\alpha)\in L^{p'}(\Omega)\times\mathbb{R}^+$ *exists such that*

$$\begin{array}{l}\forall y\in C^+\quad \textit{such that } A(y-y_\alpha)\in L^p(\Omega),\\ (y_\alpha-z_d,y-y_\alpha)+\langle q_\alpha,A(y-y_\alpha)\rangle+\lambda_\alpha\,(\xi_\alpha,y-y_\alpha)\geq 0\ ,\end{array}\tag{6.7}$$

$$\forall v\in U_{ad},\ v-v_\alpha\in L^p(\Omega),\quad \langle Mv_\alpha-q_\alpha,v-v_\alpha\rangle\ \geq 0,\tag{6.8}$$

$$\forall\xi\in B_R^*,\quad \xi-\xi_\alpha\in L^p(\Omega),\quad \langle\lambda_\alpha y_\alpha-q_\alpha,\xi-\xi_\alpha\rangle\ \geq 0,\tag{6.9}$$

$$\lambda_\alpha\,((y_\alpha,\xi_\alpha)-\alpha)=0.\tag{6.10}$$

For more details one can refer to [5]. We just mention that assumptions $(\mathcal{H}_1)$ and $(\mathcal{H}_2)$ are satisfied, for instance, if $U_{ad}=L^2(\Omega)$ or $U_{ad}=\{v\in L^2(\Omega)\mid v\geq\psi\geq 0$ a.e. in $\Omega\}$.

7. Conclusion. As already mentioned at the beginning of this paper, we have in mind the numerical aspects of the question: that is, why we have underlined that the "relaxed" problem $\mathcal{P}_\alpha$ is a good approximation of the original problem. Now, we think that the main tool for a good numerical approach for such problems is the (necessary) optimality conditions that we have obtained in Theorem 5.3. They allow us to interpret the optimal solution as the first argument of the saddle point of a linearized Lagrangian function, although the problem is not convex. We have developed this point of view and presented some algorithms in [6] for the case of the obstacle problem. The numerical behavior of these methods is quite nice.

On the other hand, though we have not tested methods using Yosida approximation, we believe that the use of penalization is not helpful for numerics. It seems to be too unstable (because of the suitable choice of the parameter ε), and we think it is only a theoretical tool.

ON THE ATTAINABLE SET FOR SCALAR NONLINEAR CONSERVATION LAWS WITH BOUNDARY CONTROL*

FABIO ANCONA† AND ANDREA MARSON‡

Abstract. We consider the initial value problem with boundary control for a scalar nonlinear conservation law

$$(*) \qquad u_t + [f(u)]_x = 0, \qquad u(0,x) = 0, \qquad u(\cdot,0) = \tilde{u} \in \mathcal{U},$$

on the domain $\Omega = \{(t,x) \in \mathbb{R}^2 : \ t \geq 0, \ x \geq 0\}$. Here $u = u(t,x)$ is the state variable, $\mathcal{U}$ is a set of bounded boundary data regarded as controls, and f is assumed to be strictly convex. We give a characterization of the set of attainable profiles at a fixed time $T > 0$ and at a fixed point $\bar{x} > 0$:

$$\begin{aligned} &\mathcal{A}(T,\mathcal{U}) = \{u(T,\cdot) : \ u \text{ is a solution of } (*)\}, \\ &\mathcal{A}(\bar{x},\mathcal{U}) = \{u(\cdot,\bar{x}) : \ u \text{ is a solution of } (*)\}, \end{aligned} \qquad \mathcal{U} = L^\infty(\mathbb{R}^+).$$

Moreover we prove that $\mathcal{A}(T,\mathcal{U})$ and $\mathcal{A}(\bar{x},\mathcal{U})$ are compact subsets of L^1 and $L^1{}_{loc}$, respectively, whenever $\mathcal{U}$ is a set of controls which pointwise satisfy closed convex constraints, together with some additional integral inequalities.

Key words. conservation laws, boundary control, attainable set

1. Introduction.

The paper is concerned with the initial boundary value problem for a scalar nonlinear conservation law in one space dimension:

$$u_t + [f(u)]_x = 0, \tag{1.1}$$

$$u(0,x) = 0, \qquad t,x \geq 0, \tag{1.2}$$

$$u(t,0) = \tilde{u}(t), \tag{1.3}$$

where $u = u(t,x)$ is the state variable, $\tilde{u}$ is a measurable bounded boundary data, and f is assumed to be a strictly convex function. Following [14] we shall consider only weak entropic solutions of (1.1)–(1.2) which satisfy the boundary condition (1.3) in a weak sense.

Here we study the system (1.1)–(1.3) from the point of view of control theory [8], regarding the boundary data $\tilde{u}$ as a control. Given a set $\mathcal{U} \subset L^\infty(\mathbb{R}^+)$ of admissible controls, we study the set of attainable profiles at a fixed time T

$$\mathcal{A}(T,\mathcal{U}) = \Big\{u(T,\cdot) : \ u \text{ is a solution to (1.1)–(1.3) with } \tilde{u} \in \mathcal{U}\Big\}.$$

We will give a precise characterization of the attainable set when $\mathcal{U} = L^\infty(\mathbb{R}^+)$ by using the theory of generalized characteristics developed by Dafermos [5]. Applications to calculus of variations and problems of optimization motivate the study of topological properties of $\mathcal{A}(T,\mathcal{U})$. Here closure and compactness of the attainable set will

be established in connection with classes of boundary controls which are measurable selections of a bounded multifunction with closed convex values and satisfy certain integral inequalities. In the proof of such results a key role will be played by the weak* compactness of the set of fluxes $\{f(\tilde{u}) : \ u \in \mathcal{U}\}$ of admissible boundary controls.

Results concerning the set of attainable profiles at a fixed point in space $\bar{x} > 0$,

$$\mathcal{A}(\bar{x}, \mathcal{U}) = \Big\{ u(\cdot, \bar{x}) : \ u \text{ is a solution to (1.1)–(1.3) with } \tilde{u} \in \mathcal{U} \Big\},$$

can be derived by similar arguments.

The compactness of the attainable sets allows us to prove the existence of solutions for a class of optimization problems, where the cost functional depends on the profiles of the solutions at some time T or at a fixed point $\bar{x}$. In section 5 we apply these results to a model of traffic flow where one wants to minimize the average time spent by cars travelling through a given stretch of highway. The controller acts by varying the density of cars entering the highway.

2. Preliminaries and statements of main results.

2.1. Formulation of the problem. On the domain $\Omega = \{(t, x) \in \mathbb{R}^2 : \ t \geq 0, \ x \geq 0\}$ consider the mixed initial boundary value hyperbolic problem

$$u_t + [f(u)]_x = 0, \tag{2.1}$$

$$u(0, x) = \bar{u}(x), \qquad t, x \geq 0, \tag{2.2}$$

$$u(t, 0) = \tilde{u}(t), \tag{2.3}$$

where $\tilde{u} \in L^\infty(\mathbb{R}^+)$, $\bar{u} \in L^\infty(\mathbb{R}^+) \cap L^1(\mathbb{R}^+)$, and $f : \mathbb{R} \to \mathbb{R}$ is a twice continuously differentiable strictly convex function. Denote $b(x) = (f')^{-1}(x)$ whenever $x \in \text{Range } (f')$ and $b(0) = -\infty$ if $0 \notin \text{Range } (f')$.

We recall that problems of this type do not possess classical solutions since discontinuities arise in finite time even if the initial and boundary data are smooth (see [4], [15]). Hence it is natural to consider weak solutions in the sense of distributions satisfying the usual *entropy conditions* [11], [13]

$$u(t, x-) \geq u(t, x+), \qquad t, x > 0. \tag{2.4}$$

As pointed out in [3], [6], and [14], in general the Dirichlet condition (2.3) may not be fulfilled pointwise a.e.; thus following [14] we require that an entropic solution u to (2.1)–(2.3) satisfies the above condition in a weaker sense which is motivated by the classical vanishing viscosity method (see [3], [14], and Definition 1). In [3] an entropic solution to (2.1)–(2.3) is obtained as the limit of solutions of suitable approximating parabolic problems, while in [14] Le Floch generalizes a result of Lax for the Cauchy problem for the scalar conservation law (see [12]), expressing a solution in terms of the pointwise minimum of a function $y \mapsto \Psi(t, x, y)$ for any $(t, x) \in \mathbb{R}^+ \times \mathbb{R}^+$ (see also Remark 2.1). Concerning uniqueness, in [14] an L^1-semigroup property in the class of piecewise regular solutions is established (see Remark 2.2).

As observed in [14], any solution of (2.1)–(2.3) with boundary data $\tilde{u}$ such that $f'(\tilde{u}(t)) < 0$ on a subset I of $\mathbb{R}^+$ of positive measure can be obtained with the boundary data

$$\tilde{u}'(t) = \begin{cases} b(0) & \text{if} \quad t \in I, \\ \tilde{u}(t) & \text{otherwise.} \end{cases}$$

Hence it is not restrictive to assume that the characteristics at the boundary are always entering the domain, i.e., $f'(\tilde{u}(t)) \geq 0$ for a.e. t: this hypothesis will be adopted in the rest of the paper. We recall here the definition of the solution to (2.1)–(2.3) as stated in [14].

DEFINITION 1. *A function $u \in L^1(\Omega;\mathbb{R})$ is a solution of (2.1)–(2.3) if*

(i) *it is a weak entropic solution of (2.1) in the interior of Ω;*

(ii) *there exists a set $\mathcal{E} \subset \mathbb{R}^+$ with zero measure such that*

$$\lim_{\substack{t\to 0^+ \\ t\notin\mathcal{E}}} \int_0^x u(t,\xi)\ d\xi = \int_0^x \bar{u}(\xi)\ d\xi, \qquad x \geq 0; \tag{2.5}$$

(iii) *the boundary condition is satisfied in the following weak sense: there exist a set $\mathcal{F} \subset \mathbb{R}^+$ with zero measure and two functions $\Upsilon : \mathbb{R}^+ \to \mathbb{R}$ and $\mu : \mathbb{R}^+ \to \{-1, 0, 1\}$ such that*

$$\lim_{\substack{x\to 0^+ \\ x\notin\mathcal{F}}} \int_0^t f(u(s,x))\ ds = \int_0^t \Upsilon(s)\ ds, \qquad t \geq 0, \tag{2.6}$$

$$\lim_{\substack{x\to 0^+ \\ x\notin\mathcal{F}}} sgn\ f'(u(t,x)) = \mu(t), \qquad a.e.\ t \geq 0, \tag{2.7}$$

and

$$\begin{cases} \Upsilon(t) = f(\tilde{u}(t)) & \text{if } \mu(t) \geq 0, \\ \Upsilon(t) \geq f(\tilde{u}(t)) & \text{if } \mu(t) = -1 \end{cases} \qquad a.e.\ t > 0. \tag{2.8}$$

Remark 2.1. In [14] Le Floch proves that under the above assumptions there exists a solution u to (2.1)–(2.3), having right and left limits in t and x at every point in the interior of Ω and such that for any fixed $t \geq 0$ $u(t,\cdot)$ has at most countably many discontinuities. Moreover it satisfies the bounds

(2.9)
$$\|u(\cdot,\cdot)\|_\infty \leq \max\left\{\|\bar{u}(\cdot)\|_\infty, \|\tilde{u}(\cdot)\|_\infty\right\},$$
$$\min\left\{f(u) :\ |u| \leq \|\tilde{u}\|_\infty, \|\bar{u}(\cdot)\|_\infty\right\} \leq\ \Upsilon(t)\ \leq \max\left\{\|f(\bar{u}(\cdot))\|_\infty,\ \|f(\tilde{u})(\cdot)\|_\infty\right\}$$

for a.e. $t > 0$. Such a solution admits the following explicit representation inside the domain:

$$u(t,x) = b\left(\frac{x - y(t,x)}{t}\right), \qquad t > 0, \quad x > 0, \tag{2.10}$$

where $y(t,x)$ denotes a point of minimum value for the function

$$y \mapsto \Psi_\Upsilon(t,x,y) = \begin{cases} \displaystyle\int_0^y \bar{u}(s)\ ds + t\ g\left(\frac{x-y}{t}\right) & \text{if } y \geq 0, \\ \displaystyle -\int_0^\tau \Upsilon(s)\ ds + (t-\tau)\ g\left(\frac{x}{t-\tau}\right) & \text{if } y \leq 0, \end{cases} \tag{2.11}$$

with g denoting the Legendre transform of a superlinear convex map $\tilde{f}$ which coincides with f on the closed ball $\{u \in \mathbb{R} :\ |u| \leq \|\tilde{u}\|_\infty\}$ and τ satisfying

$$\frac{x-y}{t} = \frac{x}{t-\tau}, \qquad y \leq 0.$$

Notice that in [11] it is shown that for any given $t \in [0,T]$ the function $y \mapsto \Psi_\Upsilon(t,x,y)$ attains its minimum at a single point for all but at most countably many $x > 0$. Furthermore the existence of the traces at $x = 0$ in the sense of (2.6)–(2.7) for the functions $f(u)$, sgn $f'(u)$ holds in general for any map u admitting a representation as in (2.10) with Ψ_Υ defined by (2.11) in connection with some L^∞ function Υ.

Remark 2.2. Regarding uniqueness in [14], the following L^1-semigroup property is established: if u and v are piecewise continuously differentiable solutions of (2.1)–(2.3) associated with initial and boundary data $\bar u$, $\tilde u$ and $\bar v$, $\tilde v$, respectively ($\tilde u$, $\tilde v \geq b(0)$), then

(2.12)
$$\int_0^{+\infty} |u(t,x) - v(t,x)|\, dx \leq \int_0^{+\infty} |\bar u(x) - \bar v(x)|\, dx + \int_0^t |f(\tilde u(s)) - f(\tilde v(s))|\, ds$$

holds for any $t > 0$. This property can be extended to all the solutions associated with an L^∞ boundary condition (for details see the Appendix), and hence any solution to (2.1)–(2.3) admits a representation of the form (2.10) for a.e. $(t,x) \in \text{int}\,\Omega$.

In this paper we are interested only in solution of (2.1)–(2.3) with null initial data $\bar u$. From now on we will adopt the semigroup notation $S_t\tilde u$ for the unique solution of (1.1)–(1.3) at time t. We shall be concerned with basic properties of the attainable sets for (1.1)–(1.2):

$$\mathcal{A}(T,\mathcal{U}) \doteq \{S_T\tilde u :\ \tilde u \in \mathcal{U}\}, \tag{2.13}$$

$$\mathcal{A}(\bar x,\mathcal{U}) \doteq \left\{S_{(\cdot)}\tilde u(\bar x) :\ \tilde u \in \mathcal{U}\right\}, \tag{2.14}$$

which consist of all profiles that can be attained at a fixed time $T > 0$ and at a fixed point $\bar x > 0$ by solutions of (1.1)–(1.2) with boundary data that varies inside a given class $\mathcal{U} \subseteq L^\infty$ of admissible boundary controls. In particular we give a characterization of

$$\mathcal{A}(T) \doteq \left\{S_T\bar u :\ \tilde u \in L^\infty(\mathbb{R}^+),\ \tilde u \geq b(0)\right\}, \tag{2.15}$$

$$\mathcal{A}(\bar x) \doteq \left\{S_{(\cdot)}\tilde u(\bar x) :\ \tilde u \in L^\infty(\mathbb{R}^+),\ \tilde u \geq b(0)\right\}, \tag{2.16}$$

and we establish the compactness of (2.13), (2.14) in connection with a special class of admissible boundary controls.

2.2. Statements of the main results. We present here the statements of the main results. Throughout the following,

$$D^-w(x) = \liminf_{h\to 0} \frac{w(x+h)-w(x)}{h}, \qquad D^+w(x) = \limsup_{h\to 0} \frac{w(x+h)-w(x)}{h}$$

will denote, respectively, the lower and upper Dini derivatives of a function w at x.

THEOREM 1. *In connection with problem* (1.1)–(1.2)*, for any fixed* $T > 0$, $\mathcal{A}(T)$ *is the set of all bounded functions* w *which satisfy the following conditions:*

$$w(x) \neq 0 \Longrightarrow f'(w(x)) \geq \frac{x}{T}, \tag{2.17}$$

$$w(x-) \neq 0 \quad \textit{and} \quad w(y) = 0\ \forall\ y > x \Longrightarrow f'(w(x-)) > \frac{x}{T}, \tag{2.18}$$

$$D^+w(x) \leq \frac{f'(w(x))}{xf''(w(x))} \tag{2.19}$$

for every $x > 0$.

Remark 2.3. By definition an element $\tilde{w} \in \mathcal{A}(T) \subseteq L^\infty(\mathbb{R}^+)$ is an equivalence class of essentially bounded measurable functions. Hence the above characterization must be interpreted in the sense that $\tilde{w} \in \mathcal{A}(T)$ iff there exists a representative w in the class $\tilde{w}$ satisfying (2.17)–(2.19).

Notice that if a bounded function w satisfies (2.17), then there exists $a > 0$ such that $w(x) = 0$ if $x \geq a$. Therefore, the boundedness of w together with (2.17), (2.19) imply that w has finite total increasing variation (and hence finite total variation as well) on subsets of $\mathbb{R}^+$ bounded away from the origin. Thus we may assume that w admits left limit in any point and (2.18) makes sense. Moreover from (2.19) it follows that $w(x-) > w(x+)$ at every point of discontinuity.

Remark 2.4. Having in mind the extension of the above result to attainable sets for classes of admissible boundary controls in $L^1(\mathbb{R}^+)$ (see [1]), it is useful to rewrite condition (2.19) in the following form:

$$w(y) \leq w(x) + \int_x^y \frac{f'(w(\xi))}{\xi f''(w(\xi))}\, d\xi \qquad \forall\ x, y > 0, \quad y \geq x, \tag{2.19$'$}$$

which is shown to be equivalent to (2.19) at the end of section 3.

THEOREM 2. *In connection with problem* (1.1)–(1.2)*, for any fixed* $\bar{x} > 0$*,* $\mathcal{A}(\bar{x})$ *is the set of all bounded functions* ρ *which satisfy the following conditions:*

$$\rho(t) \neq 0 \Longrightarrow f'(\rho(t)) \geq \frac{\bar{x}}{t}, \tag{2.20}$$

$$\rho(\tau+) \neq 0 \quad \textit{and} \quad \rho(t) = 0\ \forall\ t < \tau \Longrightarrow f'(\rho(\tau+)) > \frac{\bar{x}}{\tau}, \tag{2.21}$$

$$D^-\rho(t) \geq \frac{f'(\rho(t))}{tf''(\rho(t))} \tag{2.22}$$

for every $t > 0$.

The proof of Theorem 1 is given in section 3; the proof of Theorem 2 is entirely similar so it is omitted.

In order to achieve the closure of the attainable sets for (1.1)–(1.2) we need to restrict the class of admissible boundary controls by means of a suitable multifunction G.

THEOREM 3. *Let* $G : \mathbb{R}^+ \hookrightarrow [b(0), +\infty)$ *be a measurable uniformly bounded multifunction with convex closed values,* $q_i : \mathbb{R}^+ \times \mathbb{R} \to \mathbb{R}$*,* $i = 1, \ldots, N$*, measurable maps convex w.r.t. the second variable,* $g_i : \mathbb{R}^+ \to \mathbb{R}$*,* $i = 1, \ldots, N$*, measurable maps and let* J *be a possibly empty subset of* $\mathbb{R}^+$*. Denote*

$$\mathcal{U} = \Big\{ \tilde{u} \in L^\infty(\mathbb{R}^+) : \tilde{u}(t) \in G(t), \quad \textit{for a.e. } t, \\ \int_0^t q_i\big(s, f(\tilde{u}(s))\big)\, ds \leq g_i(t) \quad \forall\ t \in J,\ \forall\ i = 1, \ldots, N \Big\}. \tag{2.23}$$

Then $\mathcal{A}(T,\mathcal{U})$*,* $T > 0$*, and* $\mathcal{A}(\bar{x},\mathcal{U})$*,* $\bar{x} > 0$ *are compact subsets of* $L^1(\mathbb{R}^+)$ *and* ${L^1}_{loc}(\mathbb{R}^+)$*, respectively.*

The proof of Theorem 3 is given in section 4. (For references on the multifunction G see [2].)

Remark 2.5. The convexity assumption on the multifunction G cannot be relaxed in order to ensure the closure of the attainable set, as shown by the following example.

Example. Consider the problem (1.1)–(1.2) associated with the Burgers equation

$$u_t + \left(\frac{u^2}{2}\right)_x = 0, \tag{2.24}$$

and assume that the admissible boundary controls are all the measurable functions taking values in $\{0, 2\}$. We claim that the corresponding attainable set at time $T = 1$ is not closed in the topology of L^1. Indeed, define

$$\tilde{u}^\nu(t) = \begin{cases} 2 & \text{if} \quad \dfrac{k}{2^\nu} \le t \le \dfrac{k+1}{2^\nu} \quad k \text{ even}, \\ \\ 0 & \text{if} \quad \dfrac{k}{2^\nu} \le t \le \dfrac{k+1}{2^\nu} \quad k \text{ odd}, \end{cases} \qquad 0 \le k \le 2^\nu - 1. \tag{2.25}$$

Observe that $f(\tilde{u}^\nu)$ converges weakly in L^1 to $f(\tilde{u})$, with $\tilde{u}(t) \equiv \sqrt{2}$. Hence by the same arguments of section 4 it can be shown that $S_{(\cdot)}\tilde{u}^\nu(\cdot)$ converges in the L^1-norm to a solution of (2.24), (1.2), (1.3) with boundary data $\tilde{u}$: then

$$S_1\tilde{u}(x) = \begin{cases} \sqrt{2} & \text{if } 0 < x < \sqrt{2}/2, \\ 0 & \text{otherwise.} \end{cases} \tag{2.26}$$

It can be easily seen that such a profile cannot be obtained with a boundary data $\tilde{u}'$ which takes values in $\{0, 2\}$. Indeed, by tracing the backward generalized characteristics [5] and recalling (2.8), one gets

$$\tilde{u}'(t) = \sqrt{2} \quad \forall\, t \in [1/2, 1]. \tag{2.27}$$

Remark 2.6. The convexity assumption on the functions q_i cannot be relaxed too. Indeed, consider the Burgers equation (2.24) with admissible boundary data $\tilde{u}$ taking values in $[0, 2]$ and satisfying the inequality

$$\int_{1/2}^{1} \tilde{u}(s)\, ds \le \frac{1}{2}, \tag{2.28}$$

which is an integral constraint of the type given in (2.23) with

$$q(s, v) \doteq \begin{cases} 0 & \text{if} \quad 0 \le s < 1/2, \\ \operatorname{sgn}(v)\sqrt{2|v|} & \text{otherwise.} \end{cases}$$

Observe that the same sequence defined by (2.25) fulfills such a constraint. On the other hand, from (2.27) it follows that the profile in (2.26) cannot be attained by using any boundary control satisfying (2.28).

As stated in the introduction, the compactness of the attainable sets guarantees the existence of optimal controls for a class of minimization problems.

COROLLARY 1. *Let $F_1 : L^1(\mathbb{R}^+) \to \mathbb{R}$, $F_2 : L^1([0, \tau]) \to \mathbb{R}$, $\tau > 0$, be lower semicontinuous functionals and let $\mathcal{U}$ be defined as in* (2.23). *Then for every fixed $T, \bar{x} > 0$ the optimal control problems*

$$\min_{\tilde{u} \in \mathcal{U}} F_1\left(S_T\tilde{u}(\cdot)\right), \qquad \min_{\tilde{u} \in \mathcal{U}} F_2\left(S_{(\cdot)}\tilde{u}(\bar{x})\right)$$

admit a solution.

3. Proof of Theorem 1. The proof will be divided into two steps:

Step 1. Show that any element $S_T\tilde{u} \in L^\infty(\mathbb{R}^+)$ of the attainable set satisfies (2.17)–(2.19).

Step 2. Show that if $w \in \mathrm{BV}([\alpha, +\infty))\ \forall\ \alpha > 0$ is a bounded function satisfying (2.17)–(2.19), then there exists $\tilde{u} \in L^\infty([0,T])$, $\tilde{u} \geq b(0)$ such that $S_T\tilde{u} = w$.

3.1. Step 1. A technical result will be proved first.

LEMMA 3.1. *Let $w : \mathbb{R} \to \mathbb{R}$, $x > 0$, be a bounded right continuous function having right and left limits in any point. Then $\varphi : x \mapsto \frac{f'(w(x))}{x}$ is nonincreasing iff* (2.19) *holds.*

Proof. Observe that nonincreasing monotonicity of φ is equivalent to

$$D^+\varphi(x) \leq 0 \qquad \forall\ x > 0. \tag{3.1}$$

Suppose first that $x > 0$ is a point of continuity for w. Hence $f'' > 0$,

$$\begin{aligned} &\limsup_{h\to 0} \frac{\varphi(x+h) - \varphi(x)}{h} \\ &= \limsup_{h\to 0} \left[\frac{f'(w(x+h)) - f'(w(x))}{(w(x+h) - w(x))}\ \frac{w(x+h) - w(x)}{(x+h)h} - \frac{f'(w(x))}{x(x+h)} \right] \qquad (3.2) \\ &= \frac{f''(w(x))}{x} \limsup_{h\to 0} \frac{w(x+h) - w(x)}{h} - \frac{f'(w(x))}{x^2}, \end{aligned}$$

which shows that (3.1) and (2.19) are equivalent.

In the case when w is not continuous at x, assume (3.1) holds: then $w(x-) > w(x)$. Indeed, if it is false, then $f'(w(x-)) < f'(w(x))$ by convexity of f; hence there exists $y < x$ such that $\varphi(y) < \varphi(x)$ which contradicts the monotonicity assumption on φ. There follows that

$$D^+w(x) = \limsup_{h\to 0^+} \frac{w(x+h) - w(x)}{h};$$

thus (2.19) follows taking in (3.2) the lim sup as $h \to 0^+$. Conversely, if (2.19) holds then still $w(x-) > w(x)$. Since w and hence φ are right continuous it follows that $\varphi(x-) > \varphi(x)$, due to the monotonicity of f'. Thus it is sufficient to prove (3.1) for $h \to 0^+$. This follows immediately from (3.2) using the same arguments as before. □

Recalling Remark 2.1 we can choose a representative function w of $S_T\tilde{u}$ which is right continuous. Assume that $f'(w(x)) < x/T$ and let $\xi(\cdot)$ denote the maximal backward generalized characteristic through (T, x). Observe that $\xi(\cdot)$ is a genuine characteristic (see [5, Theorem 3.2]) and hence, by Theorem 3.3 in [5], $S_{(\cdot)}\tilde{u}(\xi(\cdot)) = v$ a.e. on $[0,T]$ for some constant v such that $\dot{\xi} = f'(v)$. Since Theorem 4.1 in [5] implies $v(0) = w(x)$, it follows that $\xi(t) = x + f'(w(x))(t-T)$ for all $t \in [0,T]$. Hence $\xi(0) = x - Tf'(w(x)) > 0$, which implies $w(x) = S_0\tilde{u}(\xi(0)) = 0$ thus proving (2.17).

Next, suppose that there exists $x > 0$ such that $f'(w(x-)) \leq x/T$. If $w(x-) = 0$ there's nothing to prove. Otherwise $f'(w(x-)) = x/T$. If $w(x+) = w(x-)$, again there's nothing to prove, otherwise, from arguments similar to the previous ones and since genuine characteristics do not intersect in the interior of Ω, it follows that $w(y) = 0\ \forall y > x$ and hence $w(x-) > 0$. Observe now that the values of the solution in the

interior of the funnel confined between minimal and maximal backward characteristics through (T,x) depend only on the values of the solution at $t=0$. Thus $S_t\tilde{u}(x)=0$ for any $0<t<T$ and $x>f'(w(x-))t$. There follows that the minimal characteristic is not genuine, which gives a contradiction, proving (2.18).

To prove (2.19) by Lemma 3.1 it is sufficient to show that the function $\varphi: x\mapsto f'(w(x))/x$ is nonincreasing. Let $0<x_1<x_2$ be given and trace the maximal backward characteristics $\xi_1(\cdot)$, $\xi_2(\cdot)$ through (T,x_1) and (T,x_2), respectively. By the same arguments as above they have the form

$$\xi_i(t)=x_i+f'(w(x_i))(t-T),\qquad i=1,2 \tag{3.3}$$

as long as they exist. Assume that $f'(w(x_1))<f'(w(x_2))$ (otherwise the result is obvious) and let $\tau\in\mathbb{R}$ be such that $\xi_1(\tau)=\xi_2(\tau)$ where, with an abuse of notation, $\xi_i(\cdot)$ denote the functions in (3.3) defined for all $t\in\mathbb{R}$. Since ξ_1 and ξ_2 are genuine characteristics and hence do not intersect in the interior of Ω (see [5]), we deduce that $\xi_i(\tau)\le 0$. Otherwise it should be $\tau<0$ which implies, by arguments as above, $f'(w(x_1))=f'(w(x_2))=f'(0)$. Therefore,

$$1+\frac{f'(w(x_1))}{x_1}(\tau-T)=\frac{\xi_1(\tau)}{x_1}\le\frac{\xi_2(\tau)}{x_2}=1+\frac{f'(w(x_2))}{x_2}(\tau-T)$$

showing $\varphi(x_1)\ge\varphi(x_2)$.

3.2. Step 2. Choose $w\in L^\infty(\mathbb{R}^+)$ satisfying (2.17)–(2.19). By Remark 2.3 we can assume that w is right continuous. Observe first that if $w\equiv 0$ then the boundary control

$$\tilde{u}\equiv\begin{cases}0 & \text{if}\quad f'(0)\ge 0,\\ b(0) & \text{if}\quad f'(0)<0\end{cases}$$

clearly produces the null solution. Next we prove the result in the case when w is made up of two constant states.

PROPOSITION 3.1. *Let $\omega,r>0$ be given with $f'(\omega)>r/T$. Then there exists $\tilde{u}\in L^\infty([0,T])$, $\tilde{u}\ge b(0)$, such that*

$$S_T\tilde{u}(x)=\begin{cases}\omega & \textit{if } x<r,\\ 0 & \textit{otherwise.}\end{cases} \tag{3.4}$$

Proof. If $c\doteq[f(\omega)-f(0)]/\omega\ge r/T$, set $t_1=T-r\,\omega/[f(\omega)-f(0)]\ge 0$. Then

$$\tilde{u}(t)=\begin{cases}\omega & \text{if}\quad t_1<t<T,\\ 0 & \text{if}\quad 0<t<t_1 \text{ and } f'(0)\ge 0,\\ b(0) & \text{if}\quad 0<t<t_1 \text{ and } f'(0)<0\end{cases}$$

produces the solution

$$S_t\tilde{u}(x)=\begin{cases}\omega & \text{if}\quad 0<x<r+\dfrac{f(\omega)-f(0)}{\omega}(t-T),\\ 0 & \text{otherwise}\end{cases}$$

which satisfy (3.4).

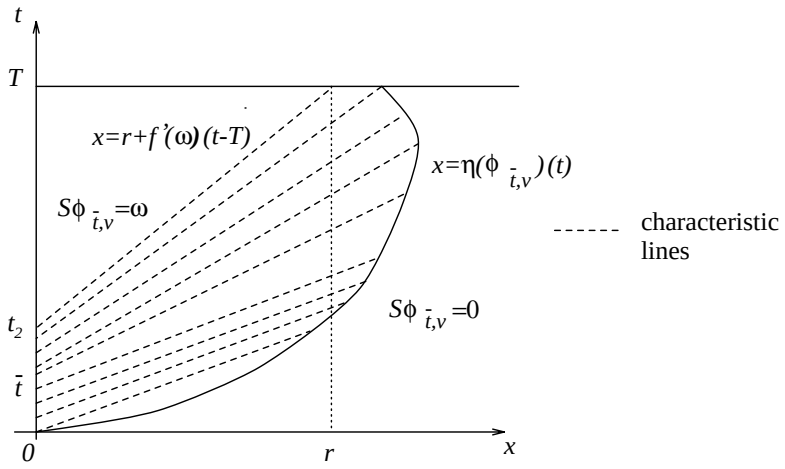

FIG. 1.

Now assume $c < r/T$ and call $t_2 = T - r/f'(\omega) > 0$. For any $\bar{t} \in [0, t_2)$ and $v \geq \omega$ define the function $\phi_{\bar{t},v} : [0,T] \to [\omega, +\infty)$ by setting

$$\phi_{\bar{t},v}(t) = \begin{cases} v & \text{if } 0 \leq t < \bar{t}, \\ b\left[f'(v) + \dfrac{t-\bar{t}}{t_2-\bar{t}}\,(f'(\omega) - f'(v))\right] & \text{if } \bar{t} \leq t < t_2, \\ \omega & \text{if } t \geq t_2. \end{cases} \tag{3.5}$$

If $v \geq \omega$ satisfies $f(v) > f(0)$, since $t \mapsto \phi_{\bar{t},v}(t)$ is decreasing on $[0, t_2]$ it can be easily seen that $S_{(\cdot)}\phi_{\bar{t},v}$ has a single shock curve $t \mapsto \eta(\phi_{\bar{t},v})(t)$ departing from the origin such that $S_t\phi_{\bar{t},v}(x) = 0$ for $x > \eta(\phi_{\bar{t},v})(t)$ as long as $\eta(\phi_{\bar{t},v})(\cdot)$ exists (see Figure 1).

We claim that there exist ω_0, $\omega_1 > \omega$ and $0 \leq \tau_0$, $\tau_1 < t_2$ such that $\eta(\phi_{\tau_0,\omega_0})(\cdot)$ and $\eta(\phi_{\tau_1,\omega_1})(\cdot)$ are defined on $[0,T]$ and

$$\eta(\phi_{\tau_0,\omega_0})(T) < r \leq \eta(\phi_{\tau_1,\omega_1})(T). \tag{3.6}$$

First we prove the existence of τ_1 and ω_1. To this end we show that there exist $v > \omega$ and $s \in (0,T)$ such that

$$\frac{f(v) - f(0)}{v}\; s > r + |c|(T - s), \tag{3.7}$$

$$0 < s - \frac{1}{f'(v)}\;\frac{f(v) - f(0)}{v}\; s < t_2. \tag{3.8}$$

Indeed, if $\lim_{v\to+\infty} f'(v) = +\infty$ then choose $s = t_2/2$ and $v > \omega$ satisfying (3.7). Otherwise, $f'(\omega) > r/T$ and hence

$$\frac{r}{T} < \lim_{v\to+\infty} f'(v) = \lim_{v\to+\infty} \frac{f(v) - f(0)}{v}, \tag{3.9}$$

there exists $\bar{v} > \omega$ such that $T\left[f(\bar{v}) - f(0)\right]/\bar{v} > r$. Then, using the continuity of the map

$$t \mapsto \frac{f(\bar{v}) - f(0)}{\bar{v}}\; t - r - |c|(T - t),$$

we find some $s \in (0,T)$ satisfying (3.7) with $v = \bar v$. But (3.9) and the convexity of f guarantee that there exists $v \geq \bar v$ satisfying (3.7)–(3.8) as well. Now set

$$\omega_1 = v, \qquad \tau_1 = s - \frac{1}{f'(v)}\ \frac{f(v)-f(0)}{v}\ s. \tag{3.10}$$

It follows that

$$\begin{aligned}\eta(\phi_{\tau_1,\omega_1})(T) &= \int_0^s \dot\eta(\phi_{\tau_1,\omega_1})(t)\ dt + \int_s^T \dot\eta(\phi_{\tau_1,\omega_1})(t)\ dt\\ &\geq \frac{f(\omega_1)-f(0)}{\omega_1}\ s + c(T-s)\\ &> r + (|c|+c)(T-s) \geq r.\end{aligned} \tag{3.11}$$

Now we set $\tau_0 = 0$ and prove the existence of ω_0. If $c > 0$, take $\omega_0 = \omega$. Otherwise set

$$\bar v = \sup\left\{v \geq \omega :\ S_T\phi_{0,v} \equiv 0\right\}. \tag{3.12}$$

By the previous analysis, $\bar v < +\infty$. Moreover, since the map $v \mapsto \phi_{0,v}$ is continuous from $[\omega, +\infty)$ into $L^\infty([0,T])$ w.r.t. the L^1-norm, from Remark 2.2 it follows that $S_T\phi_{0,\bar v} \equiv 0$. If $v > \bar v$, then $\eta(\phi_{0,v})(\cdot)$ is defined on $[0,T]$ and $\eta(\phi_{0,v})(T) > 0$. Indeed, if not, then there exists $\tau < T$ such that $\eta(\phi_{0,v})(\tau) = 0$. There follows that $S_\tau\phi_{0,v} \equiv 0$ and that $f(\phi_{0,v}(t)) \leq f(\phi_{0,v}(\tau)) < f(0)\ \ \forall t \geq \tau$. Hence $S_t\phi_{0,v} \equiv 0\ \ \forall t \geq \tau$, which contradicts (3.12). Moreover, if $0 < x < \eta(\phi_{0,v})(T)$, then $S_T\phi_{0,v}(x) \geq \omega$. In fact, due to (2.18), the minimal backward characteristic through $(T, \eta(\phi_{0,v})(T))$ reaches the t-axis in positive time. Since genuine characteristics do not intersect, all maximal backward characteristics through (T,x), $0 < x < \eta(\phi_{0,v})(T)$, intersect the t-axis. Since $\phi_{0,v}(t) \geq \omega$ for any $t \in [0,T]$, by arguments similar to the ones used in Step 1 we deduce that $S_T\phi_{0,v}(x) \geq \omega$. There exists $\delta > 0$ such that if $\bar v < v < \bar v + \delta$ then $\eta(\phi_{0,v})(T) < r$. Indeed assume by contradiction that there exists a decreasing sequence $(v_n)_{n\in\mathbb{N}}$ converging to $\bar v$ such that $\eta(\phi_{0,v_n})(T) \geq r\ \ \forall n$. Then

$$\|S_T\phi_{0,\bar v} - S_T\phi_{0,v_n}\|_{L^1} \geq \int_0^r |S_T\phi_{0,v_n}(x)|\ dx \geq \omega r,$$

which contradicts the continuity of the map $v \mapsto S_T\phi_{0,v}$, proving the existence of ω_0 with the required property. Consider now the continuous map $\phi : [0,1] \to L^\infty([0,T])$ defined by

$$\phi(\lambda) = \lambda\phi_{\tau_1,\omega_1} + (1-\lambda)\phi_{\tau_0,\omega_0}. \tag{3.13}$$

Set $\eta(\phi(\lambda))(T) = 0$ if $S_T\phi(\lambda) \equiv 0$. Then from the continuity of $\lambda \mapsto S_T\phi(\lambda)$, it follows that the map $\lambda \mapsto \eta(\phi(\lambda))(T)$ is continuous. Indeed, by the previous analysis, $S_T\phi(\lambda)(x) \geq \omega$ whenever $x < \eta(\phi(\lambda))(T)$. Hence

$$\begin{aligned}|\eta(\phi(\lambda_1))(T) - \eta(\phi(\lambda_2))(T)| &\leq \frac{1}{\omega}\left|\int_{\eta(\phi(\lambda_1))(T)}^{\eta(\phi(\lambda_2))(T)} |S_T\phi(\lambda_1)(x) - S_T\phi(\lambda_2)(x)|\ dx\right|\\ &\leq \frac{1}{\omega}\|S_T\phi(\lambda_1) - S_T\phi(\lambda_2)\|_{L^1},\end{aligned}$$

which approaches zero as $\lambda_1 - \lambda_2 \to 0$. It follows that there exists $\bar\lambda \in [0,1]$ such that $\eta(\phi(\bar\lambda))(T) = r$. We claim that $S_T\phi(\bar\lambda)$ satisfies (3.4). Indeed if $x < r$ let $t \mapsto \theta(t)$ be the maximal backward characteristic through (T,x). Then by (2.17) there exists $\tau \geq 0$ such that $\theta(\tau) = 0$. Actually $\tau \geq t_2$. If not, then

$$\dot\theta(t) = f'(S_T\phi(\bar\lambda)(x)) = \frac{x}{T-\tau} < \frac{r}{T-t_2} = f'(\omega),$$

which gives a contradiction since f' is increasing and $S_T\phi(\bar\lambda)(x) \geq \omega$. Thus $\tau \geq t_2$, from which it follows that $S_T\phi(\bar\lambda)(x) = \omega$. □

Throughout the following we denote by $\psi(\omega, r) \in L^\infty([0,T])$ a boundary control such that $S_T\psi(\omega,r)$ satisfies (3.4). In order to prove Step 2 in the general case we shall adopt the following procedure.

1. For every $x > 0$ we trace the lines θ_x^-, θ_x^+ through (T,x) with slope $f'(w(x-))$ and $f'(w(x+))$, respectively. These will be the minimal and maximal backward characteristics through (T,x) of the candidate solution. Due to (2.17), if $w(x) \neq 0$ they reach the t-axis in positive time. Assumption (2.19) guarantees that the lines $\{\theta_x^\pm : \ x > 0\}$ do not intersect each other in the interior of Ω.

2. Since a solution is constant along minimal and maximal backward characteristics [5], for every $t \in [0,T]$ for which there exists $x > 0$ such that $\theta_x^\pm(t) = 0$, we define $\tilde u(t) = w(x)$. The set of the remaining t is a disjoint union of open intervals. On any of such intervals $\tilde u$ is defined so as to produce a compression wave which generates a discontinuity at time T.

3. By using the fact that a solution is constant along genuine characteristics, we define a function $u : (0,T) \times \mathbb{R}^+ \to \mathbb{R}$, which is candidate, to be $S_{(\cdot)}\tilde u$ and we prove that u is a weak entropic solution of (1.1)–(1.2) in the interior of Ω.

4. We show that u satisfies the boundary condition related to the boundary control $\tilde u$ in the sense of Definition 1 (iii) and that $u(T-,\cdot) = w$.

1. For each $x > 0$ consider the lines

$$\theta_x^- : t \mapsto x + f'(w(x-))(t-T), \tag{3.14}$$

$$\theta_x^+ : t \mapsto x + f'(w(x))(t-T), \tag{3.15}$$

defined for $t \leq T$. By Remark 2.3 and convexity of f one has $\theta_x^-(t) \leq \theta_x^+(t) \ \ \forall\, t$. We claim that for any $0 < x < y$ the lines $\theta_x^\pm$ and $\theta_y^\pm$ do not intersect in the interior of Ω. By the previous argument it suffices to prove that $\theta_x^+(t) > \theta_y^-(t)$ in the interior of Ω. If $f'(w(x)) \geq f'(w(y-))$ the claim is obvious. Otherwise since $w(x) \neq w(y-)$, one of the two is nonzero. Hence due to (2.17) one of the two holds: $f'(w(x)) \geq x/T$ or $f'(w(y-)) \geq x/T$. Let $\tau < T$ be such that $\theta_x^+(\tau) = \theta_y^-(\tau) \doteq \xi$. Then $\tau \geq 0$ or $\xi \leq 0$. Actually $\xi \leq 0$. Indeed, let φ be as in Lemma 3.1. Then $\varphi(y-) \leq \varphi(x)$. Hence

$$\frac{\xi}{x} = 1 + \varphi(x)(\tau - T) \leq 1 + \varphi(y-)(\tau - T) = \frac{\xi}{y}$$

and since $x < y$ it follows that $\xi \leq 0$, which proves the claim.

2. Define

$$x_0 \doteq \inf\{x > 0 : \ w(y) = 0 \ \forall\ y \geq x\}. \tag{3.16}$$

To get a boundary control $\tilde u$ that produces a solution of (1.1)–(1.3) that attains w,

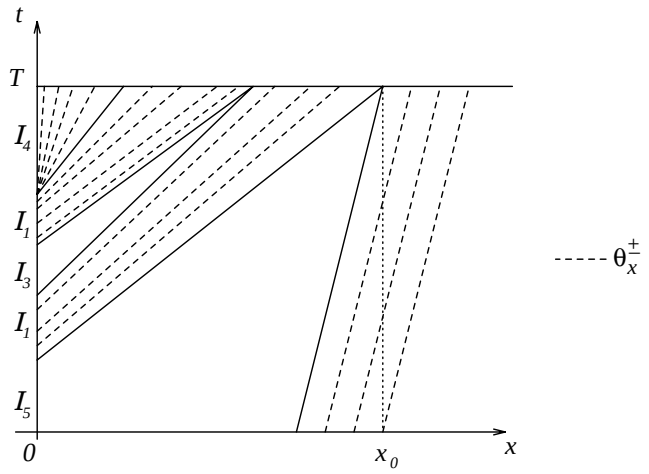

FIG. 2.

we consider the following partition of the interval $[0,T]$ (see Figure 2):

$$I_1 \doteq \left\{t\in[0,T]:\ \exists!\ x>0:\ \theta_x^-(t)=0 \text{ or } \theta_x^+(t)=0\right\}, \tag{3.17}$$

$$I_2 \doteq \left\{t\in[0,T]:\ \exists\ 0<x<y:\ \theta_x^+(t)=\theta_y^-(t)=0\right\}, \tag{3.18}$$

$$\begin{aligned} I_3 \doteq \Big\{t\in[0,T]:\ \ &\nexists\ x>0:\ \theta_x^-(t)=0 \text{ or } \theta_x^+(t)=0,\\ &\exists\ t'\in(0,t)\cap[I_1\cup I_2]\,,\ \exists\ t''\in(t,T)\cap[I_1\cup I_2]\,\Big\}, \end{aligned} \tag{3.19}$$

$$I_4 \doteq \left\{t\in[0,T]:\ \forall t'\geq t\ \ \nexists\ x>0:\ \theta_x^-(t')=0 \text{ or } \theta_x^+(t')=0\right\}, \tag{3.20}$$

$$I_5 \doteq \left\{t\in[0,T]:\ \forall t'\leq t\ \ \nexists\ x>0:\ \theta_x^-(t')=0 \text{ or } \theta_x^+(t')=0\right\}. \tag{3.21}$$

Here any of these sets could be empty. The above sets, whenever nonempty, satisfy the following properties:

(i) I_2 contains at most countably many points;

(ii) I_3 is the disjoint union of at most countably many open intervals $(\mathcal{I}_\nu)_{\nu\in\mathbb{N}}$ of the form

$$\mathcal{I}_\nu=(\tau_\nu^1,\tau_\nu^2),\qquad \theta^+_{x_\nu}(\tau_\nu^1)=\theta^-_{x_\nu}(\tau_\nu^2)=0\qquad \exists\ x_\nu>0, \tag{3.22}$$

where x_ν is a point of discontinuity for w.

(iii) I_4 is an interval of the form $I_4=(\tau^4,T]$ with $\tau^4\in I_1\cup I_2$.

(iv) I_5 is an interval of the form $I_5=[0,\tau^5)$ with $\theta^-_{x_0}(\tau^5)=0$.

To show (i) it is sufficient to observe that, since the lines $\{\theta_x^\pm\}_{x>0}$ do not intersect in the interior of Ω, for each $t\in I_2$ the set

$$J_t \doteq \left\{x>0:\ \theta_x^-(t)=0 \text{ or } \theta_x^+(t)=0\right\} \tag{3.23}$$

is an interval and $J_s\cap J_t=\emptyset$ for any $s,t\in I_2,\ s\neq t$.

Regarding (ii)–(iv), we first show that $I_3\cup I_4\cup I_5$ is open in $[0,T]$. Indeed, let $t\in I_3\cup I_4\cup I_5$ and assume by contradiction that $(t_\nu)_{\nu\in\mathbb{N}}\subseteq I_1\cup I_2$ is a sequence converging to t. Then there exists a sequence $(y_\nu)_{\nu\in\mathbb{N}}\subseteq\mathbb{R}^+$ such that $\theta^\pm_{y_\nu}(t_\nu)=0$. By eventually taking a subsequence, we shall assume $\theta^+_{y_\nu}(t_\nu)=0$, the other case being entirely similar. Since w is bounded, from (2.17) it follows that $(y_\nu)_{\nu\in\mathbb{N}}$ is bounded, so

it admits a converging subsequence which is still denoted by $(y_\nu)_{\nu\in\mathbb{N}}$. Call $\bar y$ its limit point. Again, up to a subsequence we can assume that $f'(w(y_\nu)) \to f'(w(\bar y))$. Then $0 = \theta^+_{y_\nu}(t_\nu) \to \theta^+_{\bar y}(t)$, which gives a contradiction. Observe now that $\inf I_4 \in I_1 \cup I_2$. Indeed, if $\inf I_4 = 0$, then it belongs to $I_1 \cup I_2$ by (2.17) since $w \not\equiv 0$. Otherwise, since $I_3 \cup I_4 \cup I_5$ is open, if $\inf I_4 \notin I_1 \cup I_2$, then there exists $t' < \inf I_4$ such that $(t', \inf I_4) \subseteq I_3 \cup I_4 \cup I_5$ which clearly gives a contradiction. Since by definition I_4 is an interval and $\sup I_4 = T$, this suffices to prove (iii).

Concerning (iv), in a similar way it can be proved that $\tau^5 = \sup I_5 \in I_1 \cup I_2$. Set

$$z \doteq \sup\left\{x > 0 :\ \theta^-_x(\tau^5) = 0 \text{ or } \theta^+_x(\tau^5) = 0\right\}. \tag{3.24}$$

Let $y > z$ and suppose that $w(y) \neq 0$. Then by (2.17) and (3.21), $\theta_y(\tau^5) = 0$, which contradicts (3.24). Thus it must be $z \geq x_0$. If $z > x_0$, then $0 = \theta^\pm_z(\tau^5) = z + f'(0)(\tau^5 - T)$. Hence there exists $y > z$ and $t \in (0, \tau^5)$ such that $\theta^\pm_y(t) = y + f'(0)(t - T) = 0$, which gives a contradiction by the definition of I_5. Thus $z = x_0$ and hence $\theta^-_{x_0}(\tau^5) = 0$ proving (iv).

Regarding (ii), since $\inf I_4, \sup I_5 \notin I_3$, I_3 is open; hence it is a disjoint union of at most countably many open intervals $\mathcal{I}_\nu = (\tau^1_\nu, \tau^2_\nu)$. Moreover $\tau^1_\nu, \tau^2_\nu \in I_1 \cup I_2$ since $I_3 \cup I_4 \cup I_5$ is open. Call

$$\begin{aligned} x^1_\nu &\doteq \inf\left\{x > 0 :\ \theta^-_x(\tau^1_\nu) = 0 \text{ or } \theta^+_x(\tau^1_\nu) = 0\right\}, \\ x^2_\nu &\doteq \sup\left\{x > 0 :\ \theta^-_x(\tau^2_\nu) = 0 \text{ or } \theta^+_x(\tau^2_\nu) = 0\right\}. \end{aligned}$$

Then $x^1_\nu = x^2_\nu \doteq x_\nu$. In fact $x^2_\nu \leq x^1_\nu$ since the lines $\{\theta^\pm_x\}_{x>0}$ do not intersect in the interior of Ω. If $x^2_\nu < x^1_\nu$, then choose $y \in (x^2_\nu, x^1_\nu)$. Then there exists $\tau \in (\tau^1_\nu, \tau^2_\nu)$ such that $\theta^\pm_y(\tau) = 0$, which is a contradiction. Since by (2.19) w satisfies (2.8), the conclusion of (ii) follows immediately.

Now we are ready to define the boundary data which produces the given profile:

$$\tilde u(t) = \begin{cases} w(x-) & \text{if} \quad t \in I_1,\ \theta^-_x(t) = 0, \\ w(x) & \text{if} \quad t \in I_1,\ \theta^+_x(t) = 0, \\ w\left((\sup J_t)-\right) & \text{if} \quad t \in I_2, \\ b\left(\dfrac{x_\nu}{T-t}\right) & \text{if} \quad t \in \mathcal{I}_\nu \subseteq I_3, \\ b(0) & \text{if} \quad t \in I_4, \\ \psi(w(x_0-), x_0)(t) & \text{if} \quad t \in I_5. \end{cases} \tag{3.25}$$

Notice that if $t \in \mathcal{I}_\nu \subseteq I_3$, then

$$f'(w(x_\nu)) < \frac{x_\nu}{T-t} < f'(w(x_\nu-)),$$

and hence $x_\nu/(T-t) \in \text{Range } f'$. Moreover, if $I_4 \neq \emptyset$, then $b(0) > -\infty$. Indeed, fix $\varepsilon > 0$. Then for any $x \in (0, \varepsilon(t - \tau^4))$ we have $0 < f'(w(x)) \leq \varepsilon$. In fact let $\xi > 0$ be such that $\theta^\pm_\xi(\tau^4) = 0$. If $f'(w(x)) > \varepsilon$, then there exists $\tau > \tau^4$ such that $\theta^\pm_\zeta(\tau) = 0$, thus contradicting (3.20). If $f'(w(x)) \leq 0$, then $\theta^\pm_\zeta$ and $\theta^\pm_\xi$ would intersect in the interior of Ω. Hence $\lim_{x\to 0^+} f'(w(x)) = 0$. Due to the boundedness of w, this implies $0 \in \text{Range } f'$. Thus (3.25) is well defined.

3. For each $s \in \mathcal{I}_\nu \subseteq I_3$ define the line

$$\theta_s : t \mapsto f'(\tilde u(s))(t - s) = \frac{x_\nu}{T-s}(t - s), \qquad s < t < T, \tag{3.26}$$

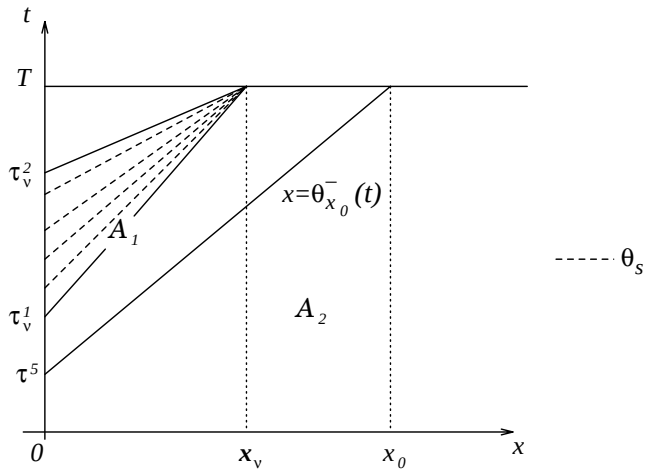

FIG. 3.

which is entirely contained in the open set $\left\{(t,x):\ s<t<T,\ \theta^-_{x_\nu}(t)<x<\theta^+_{x_\nu}(t)\right\}$. Observe that any of the θ_s cannot intersect one of the $\theta^\pm_x$ in the interior of Ω, otherwise $\theta^\pm_x$ would intersect $\theta^-_{x_\nu}$ or $\theta^+_{x_\nu}$ too. Denote (see Figure 3)

$$\begin{aligned}\mathcal{A}_1 &\doteq \left\{(\tau,\xi)\in \text{int }\Omega:\ \xi\le\theta^-_{x_0}(\tau)\right\},\\ \mathcal{A}_2 &\doteq \left\{(\tau,\xi)\in \text{int }\Omega:\ \xi>\theta^-_{x_0}(\tau))\right\}.\end{aligned}\tag{3.27}$$

We claim that for any $(\tau,\xi)\in\mathcal{A}_1$ there exists a unique line through (τ,ξ) belonging to the family $\Theta\doteq\{\theta^\pm_x:\ x>0\}\cup\{\theta_s:\ s\in I_3\}$. The uniqueness of such a line follows from the previous remark and from the fact that the lines of each family $\{\theta^\pm_x:\ x>0\}$ and $\{\theta_s:\ s\in I_3\}$ do not intersect in the interior of Ω. Regarding the existence observe that if $\xi\neq\theta^\pm_x(\tau)$ for any $x>0$, then there exists $s\in I_3$ such that $\theta_s(\tau)=\xi$. Indeed, the set

$$\mathcal{B}(\tau)\doteq\left\{0<x<\theta^-_{x_0}(\tau):\quad \nexists\ y>0:\ \theta^\pm_y(\tau)=x\right\}\tag{3.28}$$

is open. In fact, let $x\in\mathcal{B}(\tau)$ and assume by contradiction that there exists in $(0,\theta^-_{x_0}(\tau))$ a sequence $x_\nu=\theta^\pm_{y_\nu}(\tau),\ y_\nu>0$, converging to x. By eventually taking a subsequence, we shall assume that $x_\nu=\theta^+_{y_\nu}(\tau)$, the other case being entirely similar. Since w is bounded, from (2.17) it follows that $(y_\nu)_{\nu\in\mathbb{N}}$ is bounded. Therefore, there exists a subsequence, which we still denote by $(y_\nu)_{\nu\in\mathbb{N}}$, converging to some $\bar y>0$ and such that $f'(w(y_\nu))\to f'(w(\bar y))$. Then $\theta^+_{y_\nu}(\tau)\to\theta^+_{\bar y}(\tau)$ and hence $x=\theta^+_{\bar y}(\tau)$ which gives a contradiction.

Now, let (ξ_1,ξ_2) be the connected component of $\mathcal{B}(\tau)$ containing ξ. Then as above there exists $y>0$ such that $\theta^-_y(\tau)=\xi_1$ and $\theta^+_y(\tau)=\xi_2$. Let $t_1>t_2$ be such that $\theta^-_y(t_1)=\theta^+_y(t_2)=0$. Then clearly it must be $(t_2,t_1)=\mathcal{I}_\nu$, $y=x_\nu$, and

$$\frac{x_\nu-\xi}{T-\tau}=\frac{x_\nu}{T-s}=\dot\theta_s$$

for some $\nu\in\mathbb{N}$ and $s\in(t_2,t_1)$. Thus by (3.26) one has $\theta_s(\tau)=\xi$.

Consider now the function $u : (0,T) \times \mathbb{R}^+ \to \mathbb{R}$ defined by

$$u(\tau,\xi) = \begin{cases} w(x) & \text{if} \quad (\tau,\xi) \in \mathcal{A}_1,\ \theta_x^+(\tau) = \xi \quad \exists\ x > 0, \\ w(x-) & \text{if} \quad (\tau,\xi) \in \mathcal{A}_1,\ \theta_x^-(\tau) = \xi \quad \exists\ x > 0, \\ \tilde{u}(s) & \text{if} \quad (\tau,\xi) \in \mathcal{A}_1,\ \theta_s(\tau) = \xi \quad \exists\ s \in I_3, \\ S_\tau \psi(w(x_0-), x_0)(\xi) & \text{if} \quad (\tau,\xi) \in \mathcal{A}_2,\ w(x_0-) > 0, \\ 0 & \text{if} \quad (\tau,\xi) \in \mathcal{A}_2,\ w(x_0-) = 0. \end{cases} \tag{3.29}$$

We claim that, for every $(\tau,\xi) \in \mathcal{A}_1$, $u(\tau,\cdot)$ *is continuous on* $(0, \theta^-_{x_0}(\tau)]$ and $u(\cdot,\xi)$ *is continuous on* $[\tau, T)$. We only give the proof of the first property, the second one being derived in an entirely similar way. To this end we first show that $u(\tau,\cdot)$ satisfies the following properties on $(0, \theta^-_{x_0}(\tau)]$:

(a) if there exists $x > 0$ such that $\theta_x^-(\tau) = \xi$, then $u(\tau,\cdot)$ is left continuous at ξ;

(b) if there exists $x > 0$ such that $\theta_x^+(\tau) = \xi$, then $u(\tau,\cdot)$ is right continuous at ξ;

(c) if $\xi \in \mathcal{B}(\tau)$, then $u(\tau,\cdot)$ is continuous at ξ.

Observe first that if $\zeta \in \mathcal{B}(\tau)$, so that $\theta^-_{x_\nu}(\tau) < \zeta < \theta^+_{x_\nu}(\tau)$ for some $\nu \in \mathbb{N}$ and $\zeta = \theta_s(\tau)$ for some $s \in \mathcal{I}_\nu$, then

$$f'(w(x_\nu)) = \dot{\theta}^+_{x_\nu} = \frac{x_\nu}{T - \tau_\nu^1} < \frac{x_\nu}{T-s} < \frac{x_\nu}{T-\tau_\nu^2} = \dot{\theta}^-_{x_\nu} = f'(w(x_\nu-)).$$

Hence, since f' is strictly increasing,

$$w(x_\nu) < u(\tau,\zeta) < w(x_\nu-). \tag{3.30}$$

We now prove (a). Let $x, \xi > 0$ be such that $\theta_x^-(\tau) = \xi$. Then, by (3.29) $u(\tau,\xi) = w(x-)$. Fix $\varepsilon > 0$ and choose $\delta > 0$ such that

$$|w(y) - w(x-)| \le \varepsilon \qquad \forall y \in (x-\delta, x). \tag{3.31}$$

Let $\xi_\delta = \theta^+_{x-\delta}(\tau)$. By point 1, $\xi_\delta < \xi$. Then, for every $\zeta \in (\xi_\delta, \xi)$,

$$|u(\tau,\zeta) - u(\tau,\xi)| \le \varepsilon. \tag{3.32}$$

Indeed, using again point 1, if $\zeta = \theta_y^\pm(\tau)$ for some $y > 0$ then $y \in (x-\delta, x)$ and hence (3.32) follows from (3.31). Otherwise $\zeta \in \mathcal{B}(\tau)$ and (3.30) holds for some $x_\nu \in (x-\delta, x)$. Again (3.32) follows from (3.31).

The proof of (b) is entirely similar and (c) follows with an analogous argument by using the continuity of $\tilde{u}$ on I_3 instead of the existence of right and left limits of w.

Using (a), (b), and (c) we now derive the continuity of $u(\tau,\cdot)$ on $(0, \theta^-_{x_0}(\tau)]$. Indeed if $\xi = \theta_x^-(\tau) = \theta_x^+(\tau)$ for some $x > 0$ or $\xi \in \mathcal{B}(\tau)$ the conclusion is obvious. Otherwise, assume $\xi = \theta^-_{x_\nu}(\tau) < \theta^+_{x_\nu}(\tau)$ for some $\nu \in \mathbb{N}$. Since $\zeta \in \mathcal{B}(\tau)$ for any $\zeta \in (\xi, \theta^+_{x_\nu}(\tau))$ it follows

$$\lim_{\zeta \to \xi^+} u(\tau,\zeta) = \lim_{\zeta \to \xi^+} b\left(\frac{x_\nu - \zeta}{T-\tau}\right) = b\left(\frac{x_\nu - \xi}{T-\tau}\right) = b(f'(w(x_\nu-))) = u(\tau,\xi);$$

i.e., $u(\tau,\cdot)$ is right continuous at ξ, and hence continuous as well by (a). In a similar way it can be shown that if $\xi = \theta_x^+(\tau) > \theta_x^-(\tau)$, then $u(\tau,\cdot)$ is continuous at ξ.

In order to prove that u is a weak entropic solution of (1.1) in the region $\mathcal{A}_1$, we now show that u *is locally Lipschitz continuous*. As above we prove only that, for

every $\tau \in (0,T)$, $u(\tau,\cdot)$ is locally Lipschitz continuous on $(0,\theta^-_{x_0}(\tau))$. Observe first that, with the same arguments of Step 1, from the definition of u it follows

$$D^+_\xi u(\tau,\xi) \leq \frac{f'(u(\tau,\xi))}{\xi f''(u(\tau,\xi))}$$

for any $0<\xi<\theta^-_{x_0}(\tau)$. Hence, to derive the Lipschitz continuity of $u(\tau,\cdot)$ it suffices to show that locally there exists a constant $C_1 \leq 0$ such that

$$D^-_\xi u(\tau,\xi) \geq C_1 \qquad \forall\ \xi \in (0,\theta^-_{x_0}(\tau)). \tag{3.33}$$

If $D^-_\xi u(\tau,\xi) \geq 0$, there is nothing to prove. Otherwise let $\tau < T' < T$ be fixed. Since by construction

$$u(t,\xi + f'(u(\tau,\xi)))(t-\tau) = u(\tau,\xi) \qquad \forall\ t \in [\tau,T],\ (\tau,\xi) \in \mathcal{A}_1, \tag{3.34}$$

for every $\zeta \in (0,\theta^-_{x_0}(\tau))$ there exists a unique $z = z(\zeta) \in (0,\theta^-_{x_0}(T'))$ such that

$$\zeta = z + f'\left(u(T',z)\right)(\tau - T'), \qquad u(T',z) = u(\tau,\zeta).$$

Observe that

(3.35)

$$\begin{aligned} D^-_\xi u(\tau,\xi) &= \liminf_{z\to z(\xi)} \frac{u(T',z)-u(T',z(\xi))}{(z-z(\xi)) + [f'(u(T',z)) - f'(u(T',z(\xi)))]\,(\tau-T')} \\ &= \liminf_{z\to z(\xi)} \left(\frac{z-z(\xi)}{u(T',z)-u(T',z(\xi))} + \frac{f'(u(T',z)) - f'(u(T',z(\xi)))}{u(T',z)-u(T',z(\xi))}(\tau-T')\right)^{-1}. \end{aligned}$$

Choose a sequence $(z_\nu)_{\nu\in\mathbb{N}}$ converging to $z(\xi)$ such that

(3.36)

$$\begin{aligned} &D^-_\xi u(\tau,\xi) \\ &\quad = \lim_{\nu\to+\infty} \left(\frac{z_\nu - z(\xi)}{u(T',z_\nu)-u(T',z(\xi))} + \frac{f'(u(T',z_\nu)) - f'(u(T',z(\xi)))}{u(T',z_\nu)-u(T',z(\xi))}(\tau-T')\right)^{-1}. \end{aligned}$$

By the continuity of $u(T',\cdot)$,

$$\lim_{\nu\to+\infty} \frac{f'(u(T',z_\nu)) - f'(u(T',z(\xi)))}{u(T',z_\nu)-u(T',z(\xi))} = f''(u(T',z(\xi)))$$

and hence

$$\lim_{\nu\to+\infty} \frac{z_\nu - z(\xi)}{u(T',z_\nu)-u(T',z(\xi))}$$

does exist. Call ℓ its value. We observe that $\ell \leq 0$. In fact, assume by contradiction that $\ell > 0$. For ν sufficiently large

$$\frac{u(T',z_\nu)-u(T',z(\xi))}{z_\nu - z(\xi)} > 0. \tag{3.37}$$

Let $\xi_\nu = z_\nu + f'(u(T', z_\nu))(\tau - T')$. Hence $\xi_\nu \to \xi$ as $\nu \to +\infty$. Since f' is increasing, (3.34) and (3.37) imply

$$\frac{u(\tau, \xi_\nu) - u(\tau, \xi)}{\xi_\nu - \xi} = \frac{u(T', z_\nu) - u(T', z(\xi))}{\xi_\nu - \xi} > 0,$$

which contradicts the assumption on $D^-_\xi u(\tau, \xi)$. By (3.36)

$$D^-_\xi u(\tau, \xi) \geq \frac{1}{f''\left(u(T', z(\xi))\right)(\tau - T')},$$

proving (3.33).

Since u is locally Lipschitz continuous, then it is a.e. differentiable on $\mathcal{A}_1$ and by construction it satisfies $u_t + f'(u)u_x = 0$ a.e. Moreover by definition it is a weak entropic solution to (1.1) in $\mathcal{A}_2$. Now observe that, for any $t \in [0, T]$, $u(t, \theta^-_{x_0}(t)-) = w(x_0-)$ since $u(t, \cdot)$ is left continuous at $\theta^-_{x_0}(t)$. On the other hand, if $w(x_0-) > 0$ then one has $w(x_0-) = S_t\psi(w(x_0-), x_0)(\theta^-_{x_0}(t)-) = S_t\psi(w(x_0-), x_0)(\theta^-_{x_0}(t)+)$ since $\theta_{x_0^-}$ is a minimal backward characteristic of $S_{(\cdot)}\psi(w(x_0-), x_0)$. If $w(x_0-) = 0$ then $u(t, \theta^-_{x_0}(t)+) = 0$. Thus $u(t, \theta^-_{x_0}(t)-) = u(t, \theta^-_{x_0}(t)+)$ for any $t \in (0, T)$. It follows that u is a weak entropic solution to (1.1) in the interior of Ω. Furthermore it clearly fulfills (1.2) in the sense of (ii) in Definition 1.

4. We claim that for any $t \in I_1 \cup I_3 \cup I_4$,

$$\lim_{x \to 0^+} u(t, x) = \tilde{u}(t). \tag{3.38}$$

If $t \in I_1 \cup I_3$ (3.38) follows by using the same arguments at point 3. Let $t \in I_4$ and fix $\varepsilon > 0$. For any $x \in (0, \varepsilon(t - \tau^4))$ we have $0 < f'(u(t, x)) \leq \varepsilon$. Indeed fix $\xi > 0$ such that $\theta^\pm_\xi(\tau^4) = 0$. By construction $s \in I_3$ does not exist such that $\theta_s(t) = x$. Hence $x = \theta^\pm_\zeta(t)$ for some $\zeta > 0$ and $f'(u(t, x)) = f'(w(\zeta\pm))$. If $f'(u(t, x)) > \varepsilon$, then there exists $\tau > \tau^4$ such that $\theta^\pm_\zeta(\tau) = 0$, thus contradicting (3.20). If $f'(u(t, x)) \leq 0$, then $\theta^\pm_\zeta$ and $\theta^\pm_\xi$ would intersect in the interior of Ω. Hence $\lim_{x \to 0^+} f'(u(t, x)) = 0$, so that (3.38) holds. Moreover since $f'(\tilde{u}(t)) > 0$ for every $t \in I_1 \cup I_3$, it follows that

$$\lim_{x \to 0^+} \operatorname{sgn} f'(u(t, x)) = 1 \qquad \forall\, t \in I_1 \cup I_3 \cup I_4. \tag{3.39}$$

Thus if $t \in I_1 \cup I_3 \cup I_4$, then u satisfies the boundary condition related to $\tilde{u}$ in the sense of Definition 1. If $t \in I_5$ such a boundary condition is fulfilled by construction. Hence u solves (1.1)–(1.3) with $\tilde{u}$ as in (3.25). Now we show that

$$\lim_{t \to T^-} \int_0^{+\infty} |u(t, x) - w(x)|\ dx = 0. \tag{3.40}$$

Let $(t_\nu)_{\nu \in \mathbb{N}}$ be an arbitrary increasing sequence converging to T. Then

$$\int_0^{+\infty} |u(t_\nu, x) - w(x)|\ dx = \int_0^{x_0} |u(t_\nu, x) - w(x)|\ dx + \int_{x_0}^{+\infty} |u(t_\nu, x)|\ dx. \tag{3.41}$$

Let us estimate each term in the right-hand side of (3.41). Concerning the first term we show that

$$\lim_{\nu \to +\infty} u(t_\nu, x) = w(x) \qquad \forall\, x \in (0, x_0). \tag{3.42}$$

In fact, let $\varepsilon > 0$ be given and fix $\delta > 0$ such that $|w(y) - w(x)| \le \varepsilon$ whenever $x \le y < x + \delta$. Let $\tau < T$ be such that $\theta^-_{x+\delta}(\tau) = x$ (such a τ does exist since $f'(w(x)) \ge x/T$). We claim that if $t_\nu > \tau$ then $|u(t_\nu, x) - w(x)| \le \varepsilon$. Assume first $x \in \mathcal{B}(t_\nu)$. Then $\theta^-_{x_{k(\nu)}}(t_\nu) < x < \theta^+_{x_{k(\nu)}}(t_\nu)$ for some $k(\nu) \in \mathbb{N}$, with $x \le x_{k(\nu)} < x + \delta$ since $\theta^+_x, \theta^\pm_{x_{k(\nu)}}$, and $\theta^-_{x+\delta}$ do not intersect each other in the interior of Ω. Hence from the above remark and (3.30) it follows $|u(t_\nu, x) - w(x)| \le \varepsilon$. Suppose now that $x \notin \mathcal{B}(t_\nu)$. Then with arguments similar to the previous ones we get that $x = \theta^\pm_y(t_\nu)$ with $x \le y < x + \delta$ and $u(t_\nu, x) = w(y\pm)$. The conclusion follows easily.

Furthermore there exists $C_2 > 0$ such that $|u(t_\nu, x) - w(x)| \le C_2$ for any $x \in (0, x_0)$. Hence by the dominated convergence theorem we get

$$\lim_{\nu \to +\infty} \int_0^{x_0} |u(t_\nu, x) - w(x)| \, dx = 0. \tag{3.43}$$

Concerning the second term in the right-hand side of (3.41), observe first that if $w(x_0-) = 0$, then $f'(0) \ge x/T$, due to (2.17). Hence $u(t_\nu, x) = 0$ for any $x \ge x_0$ since $x_0 + f'(0)(t_\nu - T) \le x_0$. Otherwise, $t \mapsto S_t\psi(w(x_0-), x_0)$ is continuous as a map from $[0, T]$ into $L^1(\mathbb{R}^+)$ and $S_T\psi(w(x_0-), x_0)(y) = 0$ whenever $y \ge x_0$. By combining this with (3.41) and (3.43) and by the arbitrary choice of $(t_\nu)_{\nu \in \mathbb{N}}$, we obtain (3.40).

3.3. Proof of Remark 2.4. As in Remark 2.3 the boundedness of w together with (2.19′) imply that w has finite total increasing variation (and hence total increasing variation as well) on sets bounded away from the origin. Thus we can assume that w has left and right limits at every point and is right continuous. Moreover (2.19′) implies that $w(x-) \ge w(x)$. Next observe that (2.19′) holds iff the function

$$\gamma : x \mapsto w(x) - \int_c^x \frac{f'(w(\xi))}{\xi f''(w(\xi))} \, d\xi, \qquad c > 0, \tag{3.44}$$

is nonincreasing on $\mathbb{R}^+$ and hence iff

$$D^+\gamma(x) \le 0 \qquad \forall\ x > 0. \tag{3.45}$$

Now we show that

$$D^+\gamma(x) = D^+w(x) - \frac{f'(w(x))}{xf''(w(x))}. \tag{3.46}$$

If $x > 0$ is a point of continuity for w then

$$\begin{aligned} D^+\gamma(x) &= \limsup_{h \to 0} \left[\frac{w(x+h) - w(x)}{h} - \frac{1}{h} \int_x^{x+h} \frac{f'(w(\xi))}{\xi f''(w(\xi))} \, d\xi \right] \\ &= D^+w(x) - \frac{f'(w(x))}{xf''(w(x))}. \end{aligned}$$

Otherwise since w is right continuous and $w(x-) > w(x)$,

$$\limsup_{h \to 0^+} \left[\frac{w(x+h) - w(x)}{h} - \frac{1}{h} \int_x^{x+h} \frac{f'(w(\xi))}{\xi f''(w(\xi))} \, d\xi \right] = D^+w(x) - \frac{f'(w(x))}{xf''(w(x))},$$

$$\limsup_{h \to 0^-} \left[\frac{w(x+h) - w(x)}{h} - \frac{1}{h} \int_x^{x+h} \frac{f'(w(\xi))}{\xi f''(w(\xi))} \, d\xi \right] = -\infty,$$

which imply (3.46).

4. Proof of Theorem 3. We will give the proof of the statement concerning $\mathcal{A}(T,\mathcal{U})$, the one concerning $\mathcal{A}(\bar{x},\mathcal{U})$ being entirely similar. Let $(\tilde{u}_\nu)_{\nu\in\mathbb{N}} \subset \mathcal{U}$. Then, being G bounded, by (2.9) and (2.17) there exist $C, \alpha > 0$ such that

$$|S_t\tilde{u}_\nu(x)| \le \begin{cases} C & \text{if} \quad x < \alpha \\ 0 & \text{if} \quad x \ge \alpha \end{cases} \qquad \forall\, t \in [0,T] \quad \forall\, \nu \in \mathbb{N}. \tag{4.1}$$

Hence $(S_T\tilde{u}_\nu)_{\nu\in\mathbb{N}}$, $(S_{(\cdot)}\tilde{u}_\nu)_{\nu\in\mathbb{N}}$ are weak* relatively compact in $L^\infty(\mathbb{R}^+)$, $L^\infty(\Omega)$, respectively, so that we can assume

$$S_T\tilde{u}_\nu \overset{*}{\rightharpoonup} w \quad \text{in} \quad L^\infty(\mathbb{R}^+), \tag{4.2}$$

$$S_{(\cdot)}\tilde{u}_\nu \overset{*}{\rightharpoonup} u \quad \text{in} \quad L^\infty(\Omega), \tag{4.3}$$

for some functions $w \in L^\infty(\mathbb{R}^+)$, $u \in L^\infty(\Omega)$. We shall prove that $w \in \mathcal{A}(T,\mathcal{U})$ and that there exists a subsequence of $(S_T\tilde{u}_\nu)_{\nu\in\mathbb{N}}$ converging to w in $L^1(\mathbb{R}^+)$. By (4.1) and Remark 2.3 for every $a > 0$ there exists $C_a > 0$ such that

$$\mathrm{TV}\left\{S_t\tilde{u}_\nu; [a,+\infty)\right\} \le C_a \qquad \forall\, t \in [0,T] \quad \forall\, \nu. \tag{4.4}$$

Moreover there exists $L > 0$ such that if $0 < a' < a$, then

$$\int_a^{+\infty} |S_t\tilde{u}_\nu(x) - S_s\tilde{u}_\nu(x)|\ dx \le L|t-s|C_{a'} \qquad \forall\, t,s > 0 \quad \forall\, \nu. \tag{4.5}$$

By Helly's theorem for any fixed $a > 0$ there exists a subsequence $\left(S_t\tilde{u}_{\nu_j}\right)_{j\in\mathbb{N}}$ which converges to some function $v_a(t,\cdot)$ in $L^1{}_{loc}([a,+\infty))$ for every $t \in [0,T]$. But (4.3) implies that such a function must coincide with u and hence by using (4.1), for every $t \in [0,T]$, the original sequence $(S_t\tilde{u}_\nu)_{\nu\in\mathbb{N}}$ converges to $u(t,\cdot)$ in $L^1(\mathbb{R}^+)$. In particular, from the convergence of $(S_T\tilde{u}_\nu)_{\nu\in\mathbb{N}}$ to $u(T,\cdot)$ and (4.2) it follows that $u(T,\cdot) = w$. Thus to complete the proof it remains to show that u is a solution of (1.1)–(1.3) corresponding to a boundary data $\tilde{u} \in \mathcal{U}$.

By (4.1) and the regularity of f it can be assumed that, for every $t \in [0,T]$, the sequence $(f(S_t\tilde{u}_\nu))_{\nu\in\mathbb{N}}$ converges in $L^1(\mathbb{R}^+)$ to $f(u(t,\cdot))$. It follows that, for any nonnegative $\mathcal{C}^1$ function ϕ with compact support in $[0,T]\times(0,+\infty)$ and for any $k \in \mathbb{R}$, we obtain

$$\begin{aligned} &\iint \left\{|u-k|\,\phi_t + \big(f(u)-f(k)\big)\mathrm{sgn}\,(u-k)\phi_x\right\}\ dxdt \\ &\quad = \lim_{\nu\to+\infty} \iint \left\{|S_t\tilde{u}_\nu - k|\,\phi_t + \big(f(S_t\tilde{u}_\nu)-f(k)\big)\mathrm{sgn}\,(S_t\tilde{u}_\nu - k)\phi_x\right\}\ dxdt \\ &\quad \ge 0. \end{aligned} \tag{4.6}$$

Hence u is a weak entropic solution of (1.1)–(1.2) in the interior of Ω.

Next we show that the traces of the functions $f(u)$, sgn $f'(u)$ at $x = 0$ exist in the sense of (2.6)–(2.7). By Remark 2.1 it is sufficient to prove that u admits in the interior of Ω the representation (2.10). Let Υ_ν, $\nu \in \mathbb{N}$, be the traces of $f(S_{(\cdot)}\tilde{u}_\nu)$, $\nu \in \mathbb{N}$. By Remarks 2.1–2.2, for every given $t \in [0,T]$ and for any $\nu \in \mathbb{N}$, $S_t\tilde{u}_\nu(x) = b\left((x - y_\nu(t,x))/t\right)$ for a.e. $x > 0$ with $y_\nu(t,x)$ denoting the unique point where the function $y \mapsto \Psi_{\Upsilon_\nu}(t,x,y)$ defined by (2.11) attains its minimum. Since by (2.9) and (4.1) Υ_ν are uniformly bounded, there exists a subsequence still denoted

$(\Upsilon_\nu)_{\nu\in\mathbb{N}}$ which converges weak* in L^∞ to some function $\Upsilon \in L^\infty([0,T])$. Thus for every $(t,x) \in \text{int } \Omega$ the sequence of maps $(\Psi_{\Upsilon_\nu}(t,x,\cdot))_{\nu\in\mathbb{N}}$ converges uniformly to $\Psi_\Upsilon(t,x,\cdot)$ and hence for all $t \in [0,T]$ and for a.e. $x > 0$ the corresponding minimum points $y_\nu(t,x)$ being unique (see Remark 2.1) converge to the minimum point $y(t,x)$ of $\Psi_\Upsilon(t,x,\cdot)$ proving that u satisfies (2.10).

Observe now that $f(\tilde{u}_\nu)$ are uniformly bounded, and hence it can be assumed that

$$f(\tilde{u}_\nu) \overset{*}{\rightharpoonup} \Phi \quad \text{in} \quad L^\infty([0,T])$$

for some function $\Phi \in L^\infty([0,T])$. Since $f(\tilde{u}_\nu(t)) \in f(G(t))$ and by (2.8) $f(\tilde{u}_\nu(t)) \leq \Upsilon_\nu(t)$ for a.e. t, being f convex and G convex closed valued it follows that $\Phi(t) \in f(G(t))$ and $\Phi(t) \leq \Upsilon(t)$ for a.e. t. Hence there exists a measurable selection $\tilde{u}$ from G such that

$$\Phi(t) = f(\tilde{u}(t)), \quad f(\tilde{u}(t)) \in f(G(t)), \quad f(\tilde{u}(t)) \leq \Upsilon(t) \quad \text{for a.e. } t > 0.$$

Since, for any $t \in J$, on bounded subsets of L^∞ the functionals $y \mapsto \int_0^t q_i(s, y(s))\, ds$, $i = 1, \dots, N$, are sequentially lower semicontinuous w.r.t. weak convergence on L^1 (see Theorem 3 in [10]), it follows that $\tilde{u} \in \mathcal{U}$. Therefore, to prove that u fulfills (iii) in Definition 1, it remains to show that $\Upsilon(t) = f(\tilde{u}(t))$ whenever $\mu(t) \geq 0$, with μ denoting the trace of sgn $f'(u)$ at $x = 0$ as defined in (2.7). Assume that $\mu(t) = 0$. Then there exists $\delta > 0$ such that $f'(u(t,x)) = 0$ whenever $x \in (0,\delta) \setminus \mathcal{F}$, so that $\Upsilon(t) = f(b(0)) = f(\tilde{u}(t))$.

Now consider the set

$$\mathcal{P} \doteq \{t \in [0,T] : \ \mu(t) = 1\} \tag{4.7}$$

and assume that $\mathcal{P}$ has positive measure. Let μ_ν be the trace of sgn $f'(S_{(\cdot)}\tilde{u}_\nu)$ as defined in (2.7). We claim that

$$\liminf_{\nu\to+\infty} \mu_\nu(t) \geq 0 \qquad \text{for a.e. } t \in \mathcal{P}. \tag{4.8}$$

Indeed, suppose that (4.8) does not hold. Then there exists $\mathcal{P}' \subseteq \mathcal{P}$ with positive measure such that for every $t \in \mathcal{P}'$ there is a subsequence $(\mu_{\nu_k}(t))_{k\in\mathbb{N}}$ of $(\mu_\nu(t))_{\nu\in\mathbb{N}}$ such that $\mu_{\nu_k}(t) = -1$ for all k. This means that, for any such t, $f'(S_t\tilde{u}_{\nu_k}(x)) < 0$ for x sufficiently close to zero. Hence by (2.17), since genuine characteristics do not intersect in the interior of the domain, it follows that $S_t\tilde{u}_{\nu_k}(x) = 0$ for every $x > 0$ and hence $f'(0) < 0$. Fix $R > 0$ and define

$$\mathcal{R} \doteq \{(t,x) \in \mathcal{P}' \times [0,R] : \ f'(u(t,x)) > 0\}. \tag{4.9}$$

Clearly $meas(\mathcal{R}) > 0$. Let $0 < \varepsilon < meas(\mathcal{R})/2$. By Egoroff's theorem there exists $\mathcal{R}' \subset \mathcal{R}$ such that $meas(\mathcal{R} \setminus \mathcal{R}') < \varepsilon$ and $S_{(\cdot)}\tilde{u}_\nu$ converges uniformly to u on $\mathcal{R}'$. Therefore, if $(t,x) \in \mathcal{R}'$, for ν sufficiently large $S_t\tilde{u}_\nu(x) \geq b(0)$ which gives a contradiction since $f'(0) < 0$ implies $0 < b(0)$ by the convexity of f. Hence $\lim_{\nu\to\infty}(f(\tilde{u}_\nu)(t) - \Upsilon_\nu(t)) = 0$ for a.e. $t \in \mathcal{P}$. Since $f(\tilde{u}_\nu) \overset{*}{\rightharpoonup} f(\tilde{u})$ and $\Upsilon_\nu \overset{*}{\rightharpoonup} \Upsilon$ in L^∞, we get $f(\tilde{u})(t) = \Upsilon(t)$ for a.e. $t \in \mathcal{P}$.

5. An application. When modelling traffic phenomena in first approximation we find it is reasonable to treat a flow of traffic on a highway as a continuum with an observable density $u(t,x)$ equal to the number of cars per unit length and a flux

$f(t,x)$ equal to the number of cars crossing the point x per unit time. Making the assumption that at each point x the flux f is a function only of the density u at x leads to the conservation law (see [9])

$$u_t + [uv(u)]_x = 0, \tag{5.1}$$

where $v(u)$ represents the velocity of the cars as a function of their density. In practice one often takes $v(u) = a_1 \ln(a_2/u)$ for suitable constants a_1 and a_2. Consider the problem of minimizing the mean time which occurs in driving through a stretch of the highway between an entry at a point $x = 0$ and an exit at a point $x = \bar{x}$ by controlling the density $\tilde{u}(t)$ of cars entering the highway at time t equal to the value of u at the boundary $x = 0$. Suppose that at time $t = 0$ no cars are on the stretch of highway $[0, \bar{x}]$. Let $g(t)$ be the number of cars arriving at $x = 0$ per unit of time. We may assume that g is a continuous function with compact support. Let u_m be the maximum density, i.e., the value for which the cars are bumper to bumper. Then there are quite natural assumptions that can be made on the boundary data $\tilde{u}$:

(i) the net flux of cars entering the stretch of highway must be equal to the total number of cars arriving at the entry:

$$\int_0^{+\infty} \tilde{u}(s)v(\tilde{u}(s))\ ds = \int_0^{+\infty} g(s)\ ds; \tag{5.2}$$

(ii) at any time $t > 0$ the total number of cars which have entered the highway until that moment must be less than or equal to the total number of cars that have arrived at the entry in the same period of time:

$$\int_0^{t} \tilde{u}(s)v(\tilde{u}(s))\ ds \le \int_0^{t} g(s)\ ds; \tag{5.3}$$

(iii) the maximum number of cars entering the highway must be less than or equal to the maximum density of cars allowed on the highway:

$$\tilde{u}(t) \in [0, u_m]; \tag{5.4}$$

(iv) after a period of time sufficiently large no cars enter the highway:

$$\tilde{u}(t) = 0, \qquad t > \tau, \qquad \exists \tau > 0. \tag{5.5}$$

Then if $(t,x) \mapsto S_t\tilde{u}(x)$ denotes the solution to (5.1), (1.2), (1.3), we will be interested in minimizing the difference between the average incoming time of cars at $x = \bar{x}$ and at $x = 0$:

$$\left(\int_0^{+\infty} t\ S_t\tilde{u}(\bar{x})v\left(S_t\tilde{u}(\bar{x})\right)\ dt - \int_0^{+\infty} t\ g(t)\ dt\right)\left(\int_0^{+\infty} g(t)\ dt\right)^{-1}, \tag{5.6}$$

which clearly is equivalent to the minimization problem

$$\min_{\tilde{u}\in\mathcal{U}} \int_0^{+\infty} t\ S_t\tilde{u}(\bar{x})v\left(S_t\tilde{u}(\bar{x})\right)\ dt, \tag{5.7}$$

where the admissible set $\mathcal{U}$ consists of all L^∞ functions $\tilde{u}$ satisfying (5.2)–(5.5) for a.e. $t > 0$. Here we have a strictly concave flux $f(u) = uv(u)$. Since it is not restrictive to consider boundary data with characteristics entering the domain $\mathbb{R}^+ \times \mathbb{R}^+$, one can

assume that $\tilde{u} \in [0, b(0)] \subseteq [0, u_m]$ for a.e. $t > 0$ and for any admissible boundary data $\tilde{u}$. Moreover by the basic structure of a solution to (1.1)–(1.3), from (5.5) it follows that $S_t\tilde{u}(\bar{x}) = 0$ for a.e. $t > \tau + \bar{x}\ b(0)/f(b(0)) \doteq \tau'$. Therefore problem (5.7) can be restated

$$\min_{\tilde{u}\in\mathcal{U}} \int_0^{\tau'} t\ S_t\tilde{u}(\bar{x})\upsilon\big(S_t\tilde{u}(\bar{x})\big)\ dt, \tag{5.8}$$

where $\mathcal{U}$ is a set of the form (2.23), q being the identity map and G the multifunction

$$G(t) = \begin{cases} [0, b(0)] & \text{if} \quad t \le \tau', \\ \{0\} & \text{otherwise,} \end{cases}$$

with an additional constraint given by (5.2). Observe that the compactness of the attainable set $\mathcal{A}(\bar{x}, \mathcal{U})$ still holds in connection with such an admissible set of boundary controls as it follows from the proof of Theorem 3. Thus, since the map $u \mapsto \int_0^{\tau'} t\ u(t)\upsilon(u(t))\ dt$ is continuous as a functional from $\{\, u \in L^\infty([0,\tau']) :\ ||u||_\infty \le b(0)\,\}$ into $\mathbb{R}$ w.r.t. the L^1-norm, by Corollary 1 problem (5.8), admits a solution.

6. Appendix. Here we extend the L^1-contraction property (2.12) established in [14] for piecewise continuously differentiable solutions of the mixed initial boundary value problem (2.1)–(2.3) to the class of all solutions associated with every initial and boundary data in the domain

$$\mathcal{D} \doteq \big\{\, (\bar{u}, \tilde{u}) \in L^\infty(\mathbb{R}^+) \cap L^1(\mathbb{R}^+) \times L^\infty(\mathbb{R}^+) :\ \tilde{u}(t) \ge b(0) \quad \text{a.e.} \quad t \,\big\}.$$

In the following we denote $\mathcal{T}_t : L^\infty \to L^\infty,\ t > 0$, the translation operator, i.e., $\mathcal{T}_t\tilde{u}(s) \doteq \tilde{u}(t+s)\ \forall s > 0$.

THEOREM 4. *Let $f : \mathbb{R} \to \mathbb{R}$ be a continuously differentiable strictly convex function. Then there exists a continuous map $S : \mathbb{R}^+ \times \mathcal{D} \to L^\infty(\mathbb{R}^+)$ with the following properties:*

(i) $S_0(\bar{u}, \tilde{u}) = \bar{u},\ S_{s+t}(\bar{u}, \tilde{u}) = S_s\big(S_t(\bar{u}, \tilde{u}), \mathcal{T}_t\tilde{u}\big)\ \forall s, t > 0$;

(ii) $\|S_t(\bar{u}, \tilde{u}) - S_t(\bar{v}, \tilde{v})\|_{L^1(\mathbb{R}^+)} \le \|\bar{u} - \bar{v}\|_{L^1(\mathbb{R}^+)} + \|f(\tilde{u}) - f(\tilde{v})\|_{L^1([0,t])}\ \forall t > 0$;

(iii) *each trajectory $t \to S_t(\bar{u}, \tilde{u})$ yields the unique solution (in the sense of Definition 1) to the initial boundary value problem* (2.1)–(2.3).

Proof. For any given $R > 0$ consider the set

$$\mathcal{D}_R \doteq \big\{\, (\bar{u}, \tilde{u}) \in \mathcal{D} :\ \|\tilde{u}\|_\infty \le R \big\}$$

endowed with the product topology of $L^1(\mathbb{R}^+) \times {L^1}_{loc}(\mathbb{R}^+)$. Then to prove Theorem 4 it suffices to show that for any $R > 0$ there exists a continuous map $S : \mathbb{R}^+ \times \mathcal{D}_R \to L^\infty(\mathbb{R}^+)$ satisfying (i), (ii), (iii).

Let $\widehat{\mathcal{D}}_R$ be the set of couples $(\bar{u}, \tilde{u}) \in \mathcal{D}_R$ of piecewise constant functions (with finite number of discontinuities). Observe first that any solution of (2.1)–(2.3) associated with initial and boundary data in $\widehat{\mathcal{D}}_R$ is piecewise continuously differentiable. Then for every $(\bar{u}, \tilde{u}) \in \widehat{\mathcal{D}}_R$ let $\widehat{S}_t(\bar{u}, \tilde{u})$ be the value at time t of the solution to (2.1)–(2.3) which, by Remark 2.2, is unique, admits a representation of the form (2.10), and satisfies the L^1 contraction property (ii). Since $\widehat{\mathcal{D}}_R$ is a dense subset of $\mathcal{D}_R$ the continuous flow $\widehat{S} : \mathbb{R}^+ \times \widehat{\mathcal{D}}_R \to \mathcal{D}_R$ can be uniquely extended by continuity to a continuous map $S : \mathbb{R}^+ \times \mathcal{D}_R \to \mathcal{D}_R$ satisfying (ii) as well. Thus the proof will be

completed if we show that $t \to S_t(\bar{u}, \tilde{u})$ admits a representation of the form (2.10) for every $(\bar{u}, \tilde{u}) \in \mathcal{D}_R$.

Let $(\bar{u}_\nu)_{\nu\in\mathbb{N}}$, $(\tilde{u}_\nu)_{\nu\in\mathbb{N}}$, $(\bar{u}_\nu, \tilde{u}_\nu) \in \mathcal{D}_R$, be two sequences of piecewise constant functions such that

$$\bar{u}_\nu \to \bar{u} \quad \text{in} \quad L^1(\mathbb{R}^+), \tag{6.1}$$

$$f(\tilde{u}_\nu) \to f(\tilde{u}) \quad \text{in} \quad L^1{}_{loc}(\mathbb{R}^+). \tag{6.2}$$

Then by previous arguments, for every fixed $t > 0$, one has

$$S_t(\bar{u}_\nu, \tilde{u}_\nu)(x) = b\left(\frac{x - y_\nu(t,x)}{t}\right)$$

for a.e. $x > 0$, $y_\nu(t,x)$ denoting the unique minimum point for the function $y \mapsto \Psi_{\Upsilon_\nu}(t,x,y)$ defined by (2.11) in connection with the trace Υ_ν at $x = 0$ of $f\big(S_{(\cdot)}(\bar{u}_\nu, \tilde{u}_\nu)\big)$. Observe that by (2.9) Υ_ν are uniformly bounded. Thus there exists a subsequence still denoted $(\Upsilon_\nu)_{\nu\in\mathbb{N}}$ which converges weak* in L^∞ to some function $\Upsilon \in L^\infty(\mathbb{R}^+)$. Therefore, for every $x > 0$ the sequence of maps $(\Psi_{\Upsilon_\nu}(t,x,\cdot))_{\nu\in\mathbb{N}}$ converges uniformly to $\Psi_\Upsilon(t,x,\cdot)$. This implies that for a.e. $x > 0$ the corresponding minimum points $y_\nu(t,x)$ being unique (see Remark 2.1) converge to the minimum point $y(t,x)$ of $\Psi_\Upsilon(t,x,\cdot)$ and hence $\big(b\left((x - y_\nu(t,x))/t\right)\big)_{\nu\in\mathbb{N}}$ converges to $b\left((x - y(t,x))/t\right)$ for a.e. $x > 0$ proving that $S_t(\bar{u}, \tilde{u})$ satisfies (2.10). □

Acknowledgments. The authors would like to thank Prof. Alberto Bressan for suggesting the problem and for many helpful discussions.

INFINITE LINEAR PROGRAMMING AND MULTICHAIN MARKOV CONTROL PROCESSES IN UNCOUNTABLE SPACES*

ONÉSIMO HERNÁNDEZ-LERMA† AND JUAN GONZÁLEZ-HERNÁNDEZ‡

Abstract. In this paper we use infinite linear programming to study Markov control processes in Borel spaces and the average cost criterion in the "unichain" and "multichain" cases. Under appropriate assumptions we show that in both cases the associated linear programs are solvable and that there is no duality gap. Moreover, conditions are given for minimizing (respectively, maximizing) sequences for the primal (respectively, dual) programs to converge to optimal solutions.

Key words. (discrete-time) Markov control processes, average cost criterion, infinite linear programming, generalized Farkas theorem

1. Introduction.

In this paper we use infinite-dimensional linear programming to study discrete-time Markov control processes (MCPs) with Borel state and control spaces and the average cost (AC) criterion. Our results extend several recent works on MCPs in Borel [17, 18, 19] and countable [21, 25] spaces. Namely, we consider the so-called unichain and multichain cases and for each of them we show that the associated linear programs, both the primal and the dual, are *solvable* and that there is *no duality gap*. Furthermore, conditions are given for minimizing (respectively, maximizing) sequences for the primal (respectively, dual) programs to converge to optimal solutions.

Linear programming (LP) is a standard technique to study many different classes of control problems—see, e.g., [13, 19, 27, 28, 31] and their references. In particular, as shown in the historical remarks in [1, 4, 19, 23], LP has been used since the early 1960s to study MCPs, but except for just a few papers, all of the literature deals with *countable*—mainly *finite*—spaces. To our knowledge, this is the first paper dealing with *multichain* MCPs and *uncountable* spaces.

For *finite* state MCPs, the LP approach to the multichain case has been used for many years, beginning with Denardo and Fox [12] and further extended by several authors, including Hordijk and Kallenberg [20, 23]—see also [1, 4, 19] for additional references. Moreover, extending previous work of Kallenberg [23], Altman and Spieksma [2] have recently found an explicit relation between the measure ν in an optimal solution (μ, ν) for the corresponding linear program P (see (3.5) or (3.7)) and the so-called deviation matrix (see also [22]), but their analysis and the result itself heavily depend on the finiteness of the state space.

In the *countably infinite* case, the LP approach was initiated in an interesting recent paper by Hordijk and Lasserre [21], in which one can already appreciate the difficulties in going from the finite to the infinite-space situation. For instance, in

the latter case there seems to be nothing remotely close to the "deviation matrix" interpretation in [2] and there seems to be no direct way of getting the no-duality-gap condition, which is trivial in the finite-space case. More explicitly, one of the main technical difficulties in showing that our *infinite-dimensional* linear programs EP and P (see (3.3)–(3.4) and (3.5)–(3.6)) are consistent and solvable and that there is no duality gap requires verifying that some sets are *weakly closed* (see Theorems 5.1 and 5.6). Since typically this cannot be done by direct methods, we have to use "perturbations" of EP (see (4.4)–(4.6)) and P (see (4.13)) and "subconsistency" results (Theorem 5.5).

In addition to the LP approach, one could also use (in principle) recurrence-like conditions to study the multichain case. This has been done by Schäl [30] in the *countable*-space case under a Lyapunov condition and by Kurano [24] for *compact*-space MCPs under the Doeblin hypothesis. Both papers heavily rely of course on their respective assumptions, and extending their results to uncountable noncompact spaces poses a challenging problem.

The remainder of the paper is organized as follows. In section 2 we introduce the AC problems we shall be dealing with, and in section 3 we present the associated linear programs, which are called EP and P in the unichain and multichain cases, respectively, and their corresponding duals are called EP^* and P^*. In section 4, first we present two sets of hypotheses (Assumptions 4.1 and 4.2), and then we state our main results for EP (Theorems 4.5 and 4.6) and P (Theorems 4.9 and 4.10); their proofs are given in sections 6 and 7, respectively, whereas section 5 contains several technical preliminaries for the proofs. The latter include the *generalized Farkas theorem* of Craven and Koliha [11], which is used to give necessary and sufficient conditions for EP and P to be consistent. We conclude in section 8 with some general remarks.

2. Markov control processes and AC problems. MCPs have been discussed by many authors, so our review can be brief. Except for small changes, our notation generally follows Hernández-Lerma and Lasserre [17], which provides many related references. (See also [18], [19, Chapter 6].)

We consider an MCP $(X, A, \{A(x)|x \in X\}, Q, c)$ with state space X and control (or action) set A, both assumed to be Borel spaces with Borel σ-algebras $\mathcal{B}(X)$ and $\mathcal{B}(A)$, respectively. For every state $x \in X$, $A(x) \in \mathcal{B}(A)$ is the (nonempty) set of admissible control actions in x. We assume that the set

$$\mathbb{K} := \{(x, a)|x \in X,\ a \in A(x)\} \tag{2.1}$$

is a Borel subset of $X \times A$ and that it contains the graph of a measurable function from X to A. The transition law $Q(B|x, a)$, with B in $\mathcal{B}(X)$ and (x, a) in $\mathbb{K}$, is a stochastic kernel on A given $\mathbb{K}$, and the one-stage cost $c(x, a)$ is a *nonnegative* measurable function on $\mathbb{K}$.

Additional assumptions on the MCP are imposed in the following sections.

A *control policy* $\pi = \{\pi_0, \pi_1, \ldots\}$ is a sequence of stochastic kernels $\pi_t(\cdot|h_t)$ on A, given the previous history $h_t = (x_0, a_0, \ldots, x_{t-1}, a_{t-1}, x_t)$, satisfying the constraint

$$\pi_t(A(x_t)|h_t) = 1 \qquad \forall h_t,\ t = 0, 1, \ldots, \tag{2.2}$$

where x_n and a_n denote the state and control at time n. The set of all control policies is denoted by Π.

DEFINITION 2.1. (a) $\mathbb{F}$ *denotes the set of all measurable functions* $f : X \to A$ *such that* $f(x) \in A(x)$ *for all* X, *and* Φ *stands for the set of all stochastic kernels on* A, *given* X, *such that* $\varphi(A(x)|x) = 1$ *for all* $x \in X$.

(b) *A control policy* $\pi = \{\pi_t\}$ *is said to be a* randomized stationary *(or* relaxed*) policy—also known as a* Young measure *(see, e.g., Balder [5, 6])—if there exists* $\varphi \in \Phi$ *such that* $\pi_t(\cdot|h_t) = \varphi(\cdot|x_t)$ *for every history* h_t *and* $t = 0, 1, \ldots$.

(c) $\pi = \{\pi_t\}$ *is said to be a (deterministic or nonrandomized)* stationary policy *if there exists* $f \in \mathbb{F}$ *such that* $\pi_t(\cdot|h_t)$ *is concentrated at* $f(x_t)$ *for every* h_t *and* t.

We shall identify $\mathbb{F}$ (respectively, Φ) with the set of all stationary (respectively, randomized stationary) policies.

P_γ^π denotes the induced probability measure when using the policy π, given the initial distribution γ, and E_γ^π stands for the expectation operator with respect to P_γ^π. If γ is the unit mass at the initial state $x_0 = x$, we write P_γ^π and E_γ^π as P_x^π and E_x^π, respectively.

Remark 2.2. If $v(x, a)$ is a function on $\mathbb{K}$ and $\varphi \in \Phi$ is a randomized stationary policy, we write

$$v(x, \varphi) := \int_A v(x, a)\varphi(da|x), \quad x \in X.$$

In particular, for a stationary policy $f \in \mathbb{F}$, $v(x, f) := v(x, f(x))$.

AC problems. Let $J_n(\pi, \gamma)$ be the n-stage total expected cost when using the policy π, given the initial distribution γ; that is,

$$J_n(\pi, \gamma) := E_\gamma^\pi \left[\sum_{t=0}^{n-1} c(x_t, a_t) \right], \quad n = 1, 2, \ldots,$$

and $J_0(\cdot) \equiv 0$. The long-run expected AC is then defined as

$$J(\pi, \gamma) := \limsup_{n \to \infty} J_n(\pi, \gamma)/n, \tag{2.3}$$

and the *AC-value function* is

$$J^*(\gamma) := \inf_\pi J(\pi, \gamma), \quad \gamma \in \mathcal{P}(X), \tag{2.4}$$

where $\mathcal{P}(X)$ denotes the set of all probability measures on X. Then the so-called AC problem is to find a policy π^* such that

$$J(\pi^*, \gamma) = J^*(\gamma) \quad \text{for } \textit{all} \quad \gamma \in \mathcal{P}(X). \tag{2.5}$$

A policy π^* satisfying (2.5) is called *AC optimal*.

The usual *dynamic programming* approach to solve the AC problem is to find a *canonical triplet* (g, h, f^*), which consists of two real-valued functions g and h on X, and a stationary policy $f^* \in \mathbb{F}$, such that the pair (g, h) satisfies the *AC optimality equation* (2.6)–(2.7) below, and $f^*(x) \in A(x)$ attains the minimum in (2.6)–(2.7) for every $x \in X$, which (using the notation in Remark 2.2) yields (2.8)–(2.9): $\forall x \in X$,

$$g(x) = \inf_{a \in A(x)} \int_X g(y)Q(dy|x, a), \tag{2.6}$$

$$g(x) + h(x) = \inf_{a \in A(x)} \left[c(x, a) + \int_X h(y)Q(dy|x, a) \right], \tag{2.7}$$

$$g(x) = \int_X g(y)Q(dy|x, f^*), \quad \text{and} \tag{2.8}$$

$$g(x) + h(x) = c(x, f^*) + \int_X h(y)Q(dy|x, f^*). \tag{2.9}$$

Finally, if h is such that

$$\limsup_{n\to\infty} E_x^\pi[h(x_n)]/n = 0 \quad \text{for every } \pi \in \Pi \text{ and } x \in X, \tag{2.10}$$

then f^* is AC optimal and $g(\cdot)$ is the AC value function, i.e.,

$$J(f^*, x) = g(x) = J^*(x) \quad \forall x \in X, \tag{2.11}$$

and (2.5) is immediately obtained.

The LP formulation to the AC problem is closely related to (2.6)–(2.7), except that (2.5) is solved for every *fixed* initial distribution; i.e., given the initial distribution, say γ_0, we find π^* such that

$$J(\pi^*, \gamma_0) = J^*(\gamma_0) := \inf_\pi J(\pi, \gamma_0). \tag{2.12}$$

Another related problem is to find a *minimum pair* (π^0, γ^0), i.e., a policy π^0 and an initial distribution γ^0 such that

$$J(\pi^0, \gamma^0) = \inf_\gamma J^*(\gamma) =: \rho^*. \tag{2.13}$$

Of course, if the AC value function J^* is a *constant*, as in the so-called unichain case, using dynamic programming the idea would be to solve (2.6)–(2.9) with a *constant* function $g(\cdot)$, and then, under (2.10), we would obtain (2.11) with $g(\cdot) = J^*(\cdot) = \rho^*$.

The minimum pair problem is precisely the one solved in [17] and analyzed again here from a different viewpoint. We also study (2.12), which we call the γ_0-*AC problem* or AC problem in the *multichain* case (with initial distribution γ_0).

3. Associated linear programs. In this section we informally present the linear programs associated with the AC problems (2.12) and (2.13). The hypotheses under which they are well defined, together with our main results, are given in section 4.

As in [17] (see also [3], [18], or [19]), we first introduce the dual pairs $(M(\mathbb{K}), F(\mathbb{K}))$ and $(M(X), F(X))$ in Definition 3.1 below, where we use the functions

$$w(x, a) := 1 + c(x, a) \quad \text{and} \quad w_0(x) := \inf_{a\in A(x)} w(x, a). \tag{3.1}$$

Since (by assumption) c is nonnegative, we have

$$1 \le w_0(x) \le w(x, a) \qquad \forall (x, a) \in \mathbb{K}, \tag{3.2}$$

and—under Assumptions 4.1 or 4.2—w_0 is measurable.

DEFINITION 3.1. (a) $M(\mathbb{K})$ *denotes the normed vector space of finite signed measures* μ *on* $\mathbb{K}$ *with*

$$\|\mu\|_w := \int_{\mathbb{K}} w d|\mu| < \infty,$$

where $|\mu|$ stands for the total variation of μ, and $F(\mathbb{K})$ denotes the normed vector space of real-valued measurable functions u on $\mathbb{K}$ with

$$\|u\|_w := \sup_{(x,a)} |u(x,a)|/w(x,a) < \infty.$$

$(M(\mathbb{K}), F(\mathbb{K}))$ is a dual pair with respect to the bilinear form

$$\langle \mu, u \rangle := \int_K u d\mu, \quad \mu \in M(\mathbb{K}),\ u \in F(\mathbb{K}).$$

(b) *Similarly, replacing $\mathbb{K}$ and w by X and w_0, respectively, we get the dual pair $(M(X), F(X))$.*

We shall in fact consider several topologies on $M(\mathbb{K})$ (see Remark 5.3), but unless explicitly stated otherwise we shall always consider $M(\mathbb{K})$ to be endowed with the *weak topology* $\sigma(M(\mathbb{K}), F(\mathbb{K}))$. A similar remark holds for $M(X)$.

Notation. In any vector space, the "null" or "zero" vector will be denoted by "0". Thus $\mu(\cdot) = 0$ is the trivial measure and $u(\cdot) = 0$ is the null function. $M_+(\mathbb{K})$ denotes the convex cone of nonnegative measures in $M(\mathbb{K})$ and similarly for $M_+(X)$.

Now we introduce four linear operators (which will be *weakly continuous* under Assumptions 4.1 or 4.2—see Lemma 4.4):

$$L_0, L_1 : M(\mathbb{K}) \to M(X), \quad L : M(\mathbb{K}) \to \mathbb{R} \times M(X), \quad \text{and} \quad T : M(\mathbb{K})^2 \to M(X)^2,$$

defined, for every μ and ν in $M(\mathbb{K})$ and $B \in \mathcal{B}(X)$, as

$$\begin{aligned} &L_0\mu := \mu_1 := \text{marginal (or projection) of } \mu \text{ on } X, \\ &(L_1\mu)(B) := \mu_1(B) - \int_{\mathbb{K}} Q(B|x,a)\mu(d(x,a)), \\ &L\mu := (\langle \mu, 1\rangle, L_1\mu) \quad [\text{with} \quad \langle \mu, 1\rangle = \int_{\mathbb{K}} d\mu = \mu(\mathbb{K})], \end{aligned}$$

and

$$T(\mu, \nu) := (L_0\mu + L_1\nu, L_1\mu).$$

The corresponding adjoints

$$L_0^*, L_1^* : F(X) \to F(\mathbb{K}), L^* : \mathbb{R} \times F(X) \to F(\mathbb{K}), \text{ and } T^* : F(X)^2 \to F(\mathbb{K})^2$$

are given, for every g and h in $F(X)$, $\rho \in \mathbb{R}$, and $(x,a) \in \mathbb{K}$, by

$$\begin{aligned} &(L_0^* g)(x,a) := g(x), \\ &(L_1^* g)(x,a) := g(x) - \int_X g(y) Q(dy|x,a), \\ &L^*(\rho, g) := \rho + L_1^* g, \end{aligned}$$

and

$$T^*(g,h) := (L_0^* g + L_1^* h, L_1^* g).$$

With this notation, the *primal* linear program associated with the *minimum pair* problem (2.13) is (as in [17] or [19])

EP: minimize $\langle \mu, c \rangle$
(3.3) subject to $\mu \in M_+(\mathbb{K})$, $\langle \mu, 1\rangle = 1$, and $L_1\mu = 0$ (i.e., $L\mu = (1,0)$).

(See Remark 3.2(a).) The *dual* linear program is

$$\begin{aligned} &\boldsymbol{EP}^*\text{: maximize } \rho \ [= \langle (1,0),(\rho,h)\rangle] \\ &(3.4)\ \text{ subject to } L^*(\rho,h) \le c,\ (\rho,h) \in \mathbb{R} \times F(X). \end{aligned}$$

Similarly, for the γ_0 *AC problem* (2.12) the associated *primal* program is

$$\begin{aligned} &\boldsymbol{P}\text{: minimize } \langle \mu, c\rangle \ [= \langle (\mu,\nu),(c,0)\rangle] \\ &(3.5)\ \text{ subject to } T(\mu,\nu) = (\gamma_0, 0),\ (\mu,\nu) \in M_+(\mathbb{K})^2. \end{aligned}$$

The dual of P is

$$\begin{aligned} &\boldsymbol{P}^*\text{: maximize } \langle \gamma_0, g\rangle \ [= \langle (\gamma_0,0),(g,h)\rangle] \\ &(3.6)\ \text{ subject to } T^*(g,h) \le (c,0),\ (g,h) \in F(X)^2. \end{aligned}$$

Remark 3.2. (a) Vector equalities and inequalities are understood componentwise. For instance, (3.5) means that

$$L_0\mu + L_1\nu = \gamma_0 \quad \text{and} \quad L_1\mu = 0, \tag{3.7}$$

and (3.6) is the same as writing

$$L_0^* g + L_1^* h \le c \quad \text{and} \quad L_1^* g \le 0. \tag{3.8}$$

Incidentally, note that (3.8) (or (3.6)) can be "derived" from (2.6)–(2.7), in the sense that if (g,h) satisfies (2.6)–(2.7), then it satisfies (3.8). Thus, solving P^* is basically the same as finding the "maximal subsolution" of (2.6)–(2.7); see Lemma 7.1. This is interesting to note because, historically speaking, it is the way the "LP approach" to MCPs was born: trying to solve a dynamic programming equation rewriting it as a linear program.

(b) If (μ,ν) satisfies (3.5) (= (3.7))—in other words, if (μ,ν) is *feasible* for P—then μ is a *probability measure*. Of course, a similar remark holds if μ is feasible for EP—see (3.3).

(c) A function g in $F(X)$ will be identified with the function $(L_0^* g)(x,a) := g(x)$ in $F(\mathbb{K})$, in which case we can write $F(X) \subset F(\mathbb{K})$. This can be done because, by (3.2), $\|g\|_w \le \|g\|_{w_0} < \infty$ if g is in $F(X)$. Hence, we can also write $\langle \mu, g\rangle = \langle \mu_1, g\rangle$ for every $g \in F(X)$ and $\mu \in M(\mathbb{K})$, where $\mu_1 := L_0\mu$.

(d) The definition of the weight functions w and w_0 in (3.1) is useful because it automatically yields that c is in $F(\mathbb{K})$ and that (3.2) holds. However, it is important to keep in mind that to develop the LP approach we can take *any weight functions* w and w_0 as long as $c \in F(\mathbb{K})$ and (3.2) (together with Assumption 4.1(c)=4.2(d)) hold true. Similarly, Assumption 4.1(a) below can be replaced by the following statement: c is l.s.c. (lower semicontinuous) and the weight function w is inf-compact. This condition together with the requirement on w in Assumption 4.1(d) ensures, for instance, that the set of measures μ that satisfy (3.3) and $\int c d\mu < \infty$ is *tight* (cf. Assumption 5.1(c) in [17]).

4. Main results. In this section we present two different sets of assumptions, which are briefly discussed in Remark 4.3, and then we state our main results.

We shall use the following *notation*: If S is a metric space, we denote by $C_b(S)$ the Banach space of real-valued bounded continuous functions on S, endowed with

the supremum norm ($\|u\| := \sup_s |u(s)|$), and by $C_0(S)$ the subspace of continuous functions vanishing at infinity. If S is *compact*, then $C_b(S) = C_0(S)$.

The following assumption collects the hypotheses used in [17].

Assumption 4.1. (a) The one-stage cost function $c : \mathbb{K} \to \mathbb{R}_+$ ($\mathbb{R}_+ := [0, \infty)$) is *inf-compact*; i.e., for every real number r, the set $\{(x, a) \in \mathbb{K} | c(x, a) \leq r\}$ is compact.

(b) The transition law Q is *weakly continuous*; i.e., the function

$$\int_X v(y)Q(dy|\cdot) \text{ is in } C_b(\mathbb{K}) \text{ whenever } v \in C_b(X).$$

(c) $\int_X w_0(y)Q(dy|\cdot)$ is in $F(\mathbb{K})$; i.e., there is a constant C such that

$$\int_X w_0(y)Q(dy|x, a) \leq Cw(x, a) \quad \forall (x, a) \in \mathbb{K}.$$

(d) There is a policy π such that for every initial distribution γ, the average cost $J(\pi, \gamma) < \infty$, or, equivalently (by (3.1)),

$$\limsup_{n\to\infty} E^\pi_\gamma \left[\sum_{t=0}^{n-1} w(x_t, a_t)\right] /n < \infty.$$

Assumption 4.2. (a) X and $\mathbb{K}$ are locally compact separable metric spaces.

(b) The one-stage cost c is l.s.c.

(c) Q is weakly continuous (Assumption 4.1(b)) and, in addition, for every compact subset K of X, $Q(K|\cdot)$ vanishes at infinity; i.e., for every $\varepsilon > 0$ there is a compact set $K' = K'(\varepsilon, K)$ in $\mathbb{K}$ such that

$$Q(K|x, a) \leq \varepsilon \quad \forall (x, a) \notin K'.$$

(d) This is the same as Assumption 4.1(c).

Remark 4.3. (a) It is obvious that Assumptions 4.1 and 4.2 are not comparable. For instance, in Assumption 4.1 it is implicit that X and $\mathbb{K}$ are *Borel spaces* (see the second paragraph of section 2), which is a condition weaker than Assumption 4.2(a). But on the other hand, Assumption 4.1(a) is stronger than (i.e., it implies) Assumption 4.2(b). Similarly, Assumption 4.2(c) implies 4.1(b), but 4.1(d) is *not* required in Assumption 4.2.

(b) In most applications of MCPs, the spaces X and $\mathbb{K}$—and also the control set A—are "nice" subsets of Euclidean spaces, so Assumption 4.2(a) is not really too restrictive. A *sufficient condition* for it is that X and A are both locally compact separable metric spaces (which is a necessary and sufficient condition for $X \times A$ to be locally compact separable metric—see, e.g., Dieudonné [14, p. 75]) and that $\mathbb{K}$ is either open or closed in $X \times A$ [14, p. 66]. The main reason for requiring X and $\mathbb{K}$ as in Assumption 4.2(a) is explained in Remark 5.3.

(c) Assumption 4.2(c) on Q—as well as (4.10) below (see also the Remark following Theorem 4.5)—is related to conditions given by Benes [7] to ensure the existence of invariant distributions for Feller–Markov chains—observe that weak continuity of Q is a Feller-like condition. In our present context, Assumption 4.2(c) implies in particular that, as is easily shown,

$$\int_X u(y)Q(dy|\cdot) \quad \text{is in} \quad C_0(\mathbb{K}) \quad \text{if} \quad u \in C_0(X). \tag{4.1}$$

For a general (say, $\mathbb{R}^d$-valued) discrete-time system $x_{t+1} = F(x_t, a_t, \xi_t)$, $t = 0, 1, \ldots$, with independent and identically distributed disturbances ξ_t, Assumption 4.2(c) holds if, for every s, the function $F(x, a, s)$ is continuous in $(x, a) \in \mathbb{K}$ and, moreover, $F(x, a, s) \to \infty$ as $(x, a) \to \infty$. The general discrete-time system, in particular the additive-noise case in (d), below, includes many control models found in applications; see [4, 13, 16, 19].

(d) As an *example*, consider the additive-noise system

$$x_{t+1} = G(x_t, a_t) + \xi_t, \quad t = 0, 1, \ldots,$$

with state and control spaces $X = A = \mathbb{R}$ (so that $\mathbb{K} = \mathbb{R}^2$), where the disturbances ξ_t are independent and identically distributed random variables, independent of the initial state x_0. Moreover, the one-stage cost c is supposed to be a quadratic function, say $c(x, a) = \alpha x^2 + \beta a^2$ with positive α and β, and $G(x, a)$ is a given continuous function. In this case, Assumptions 4.1(a),(b) and 4.2(a),(b) are obviously satisfied, and conditions sufficient for Assumption 4.1(c),(d) are easily determined (see, for instance, [17]). Finally, the second part of Assumption 4.2(c) is also satisfied if, for instance, $|G(x, a)| \to \infty$ as $|(x, a)| \to \infty$. In other words, under the given conditions, Assumptions 4.1 and 4.2 both hold. Similar statements hold in the vector case.

(e) (See [3, p. 37] or [11, p. 984].) Let $(\mathcal{X}, \mathcal{Y})$ and $(\mathcal{Z}, \mathcal{W})$ be two dual pairs of vector spaces and $G : \mathcal{X} \to \mathcal{Z}$ a linear mapping with adjoint G^*. Then G is weakly continuous if and only if G^* maps $\mathcal{W}$ into $\mathcal{Y}$. For instance, by Remark 3.2(c), (3.2) implies that L_0^* maps $F(X)$ into $F(\mathbb{K})$ and, therefore, $L_0 : M(\mathbb{K}) \to M(X)$ is *weakly continuous*. Similarly, Assumption 4.1(c) (=4.2(d)) yields that, for all g in $F(X)$,

$$\left| \int g(y) Q(dy|x, a) \right| \le \|g\|_{w_0} \int w_0(y) Q(dy|x, a) \le \|g\|_{w_0} C w(x, a).$$

Hence, this assumption and (3.2) imply that L_1^* maps $F(X)$ into $F(\mathbb{K})$, so that $L_1 : M(\mathbb{K}) \to M(X)$ is *weakly continuous*. Combining these facts with the definitions of L and T (see section 3), we obtain part (a) in the following lemma.

LEMMA 4.4. (a) *Each of the operators L_0, L_1, L, and T is weakly continuous.*

(b) *L_0^* maps $C_b(X)$ into $C_b(\mathbb{K})$, and so does L_1^* if Q is weakly continuous* (*see Assumption* 4.1(b) *or* 4.2(c)).

Proof. Part (a) follows from Remark 4.3(e), and part (b) is obvious. □

Plainly, the dual programs EP^* and P^* are both consistent. For instance, for any constant k the pair $(\rho, h) := (0, k)$ and $(g, h) := (0, k)$ satisfy (3.4) and (3.6), respectively. In the remainder of this section, (i) we give necessary and sufficient conditions for the primal problems EP and P to be *consistent*; (ii) we show that for each of them there is *no duality gap*, i.e.,

$$\sup(EP^*) = \inf(EP) \qquad (= \rho^*; \quad \text{see (2.13)}), \tag{4.2}$$

and similarly for P; and, finally, (iii) we show that in each case there is *strong duality*, which means that EP and EP^* are both *solvable* and their optimal values satisfy

$$\max(EP^*) = \min(EP) \tag{4.3}$$

and similarly for P and P^*. (In writing (4.3) we follow the usual convention that "min" replaces "inf" for an attained infimum and similarly for "max" and "sup.") We shall first state the results for EP and then for P; the proofs are presented in sections 6 (for EP) and 7 (for P).

Main results for *EP*. Under Assumption 4.1, it is shown in [17] that EP is solvable and that it has no duality gap. Here, first we use Assumption 4.2 to obtain a *necessary and sufficient condition for EP to be consistent* (Theorem 4.5). To do this using a *generalized Farkas theorem* (Theorem 5.1) we would need to show that the set $L(M_+(\mathbb{K})) \subset \mathbb{R} \times M(X)$ is weakly closed. Since we are unable to prove this directly, we "perturbate" EP as follows.

Let v_0 be a strictly positive function in $C_0(X)$, and consider the linear operator $\mathcal{L} : M(\mathbb{K}) \times \mathbb{R}^2 \to M(X) \times \mathbb{R}^2$ with

$$\mathcal{L}(\mu, r_1, r_2) := (L_1\mu, \langle \mu, 1\rangle + r_1, \langle \mu, v_0\rangle - r_2). \tag{4.4}$$

The adjoint $\mathcal{L}^* : F(X) \times \mathbb{R}^2 \to F(\mathbb{K}) \times \mathbb{R}^2$ is given by

$$\mathcal{L}^*(h, \rho_1, \rho_2) = (L_1^* h + \rho_1 + \rho_2 v_0, \rho_1, -\rho_2). \tag{4.5}$$

Now note that EP *is consistent* (i.e., there is a measure μ satisfying (3.3)) *if and only if the linear equation*

$$\mathcal{L}(\mu, r_1, r_2) = (0, 1, \varepsilon) \text{ has a solution } (\mu, r_1, r_2) \text{ in } M_+(\mathbb{R}) \times \mathbb{R}^2_+ \tag{4.6}$$

for some $\varepsilon > 0$. This is obvious because if μ satisfies (3.3), then $(\mu, 0, 0)$ satisfies (4.6) with $\varepsilon := \langle \mu, v_0\rangle$; and, conversely, if (μ, r_1, r_2) satisfies (4.6), then $\langle \mu, v_0\rangle \geq \varepsilon$ implies $\langle \mu, 1\rangle > 0$ and, therefore, $\mu^* := \mu/\langle \mu, 1\rangle$ satisfies (3.3). We will show that (4.6) and the generalized Farkas theorem (see Theorem 5.1 below) yield part (a) in the following result.

THEOREM 4.5. *Suppose that Assumption* 4.2 *holds. Then*

(a) EP *is consistent (equivalently,* (4.6) *holds) if and only if*

$$L_1^* h + \rho_1 + \rho_2 v_0 \geq 0 \quad \text{with} \quad h \in F(X),\ \rho_1 \geq 0, \ \text{and}\ \rho_2 \leq 0 \tag{4.7}$$

implies

$$\rho_1 + \varepsilon\rho_2 \geq 0 \qquad \text{for some} \quad \varepsilon > 0. \tag{4.8}$$

(b) *Let* v_0 *and* w_0 *be as in* (4.4) *and* (3.1)*, respectively, and suppose there exists* $\varepsilon > 0$ *and a relaxed policy* φ *such that* $\forall x \in X$

$$\liminf_{n\to\infty} E_x^\varphi[w_0(x_n)]/n = 0 \quad \text{and} \tag{4.9}$$

$$\liminf_{n\to\infty} \sum_{t=0}^{n-1} E_x^\varphi[v_0(x_t)]/n \geq \varepsilon. \tag{4.10}$$

Then EP *is consistent.*

Remark. The hypotheses of Theorem 4.5(b) imply that the stochastic kernel $Q(\cdot|\cdot, \varphi)$ satisfies Benes's [7] condition (v) (hence, the equivalent conditions (i)–(iv)) for the existence of a nontrivial invariant measure. Indeed, suppose that $\varepsilon > 0$ is such that $\varepsilon \leq \|v_0\|$, and choose $0 < \varepsilon_0 < \varepsilon$. As $v_0(\cdot) > 0$ is in $C_0(X)$, there is a compact set K_0 such that $0 < v_0(x) \leq \varepsilon_0$ for all x not in K_0. Then (writing X as the union of K_0 and its complement) for all $t = 0, 1, \ldots$ and $x \in X$,

$$E_x^\varphi[v_0(x_t)] = \int_X v_0(y) Q^t(dy|x, \varphi) \leq (\|v_0\| - \varepsilon_0) Q^t(K_0|x, \varphi) + \varepsilon_0.$$

This implies, by (4.10),

$$\liminf_{n\to\infty} \frac{1}{n}\sum_{t=0}^{n-1} Q^t(K_0|x,\varphi) \geq (\varepsilon-\varepsilon_0)/(\|v_0\|-\varepsilon) > 0.$$

Finally, take Benes's measure μ as (for instance) the initial distribution γ_0 in (2.12) to obtain the condition (v) in [7].

In Theorem 4.6 we use the following definition. A sequence of measures μ^n in $M(\mathbb{K})$ is said to be a *minimizing sequence* for EP if each μ^n is feasible for EP (see (3.3)) and $\langle \mu^n, c\rangle \downarrow \inf(EP)$. Similarly (ρ_n, h_n) is a *maximizing sequence* for the dual EP^* if each (ρ_n, h_n) is feasible for EP^* and $\rho_n \uparrow \sup(EP^*)$. Of course, minimizing and maximizing sequences for P and P^*, respectively, are defined analogously.

THEOREM 4.6. *Suppose that either* (i) *Assumption* 4.1 *holds, or* (ii) *Assumptions* 4.2 *and* 4.1(a) *hold and EP is consistent with a finite value. Then the following hold.*

(a) *EP is solvable and there is no duality gap; i.e., there exists a feasible solution μ^* for EP such that*

$$\langle \mu^*, c\rangle = \min(EP) = \sup(EP^*) \quad (=\rho^*; \quad \textit{see } (2.13)). \tag{4.11}$$

(b) *If $\{\mu^n\}$ is a minimizing sequence for EP, then there exists a subsequence $\{j\}$ of $\{n\}$ such that μ^j converges in the weak topology $\sigma(M(\mathbb{K}), C_b(\mathbb{K}))$ (see Remark* 5.3(b)) *to an optimal solution for EP.*

(c) *If (ρ_n, h_n) is a maximizing sequence for EP^* with $\{h_n\}$ bounded in the w_0-weighted norm (i.e., there is a constant k such that $\|h_n\|_{w_0} \leq k\ \forall n$), then* (i) *$EP^*$ is solvable,* (ii) *strong duality holds* (*see* (4.3)), *and* (iii) *if μ^* is optimal for EP and $\mu_1^* = L_0\mu$ is its marginal on X, then the AC optimality equation* (2.6)–(2.7) *holds μ_1^*-almost everywhere (a.e.) with $g(\cdot) = \rho^*$; in fact, there is a function $h \in F(X)$ and a policy $f^* \in \mathbb{F}$ such that for μ_1^*-almost every $x \in X$:*

$$\begin{aligned} \rho^* + h(x) &= \min_{a\in A(x)} \left[c(x,a) + \int_X h(y) Q(dy|x,a) \right] \\ &= c(x,f^*) + \int_X h(y) Q(dy|x,f^*). \end{aligned} \tag{4.12}$$

We now turn our attention to the linear program P.

Main results for *P*. In analogy with EP, we use Theorem 5.1 to obtain a *necessary and sufficient condition for P to be consistent* (Theorem 4.9). And again, as with EP, instead of (3.5), we consider an *equivalent*, "perturbated" linear equation, (4.13), as follows.

Consider the linear mapping $\tau : M(\mathbb{K})^2 \times \mathbb{R} \to M(X)^2 \times \mathbb{R}$ defined by

$$\begin{aligned} \tau(\mu,\nu,r) &:= (L_0\mu + L_1\nu, L_1\mu, \langle \mu+\nu, w\rangle + r) \\ &= (T(\mu,\nu), \langle \mu+\nu, w\rangle + r). \end{aligned}$$

The adjoint $\tau^* : F(X)^2 \times \mathbb{R} \to F(\mathbb{K})^2 \times \mathbb{R}$ is given by

$$\begin{aligned} \tau^*(g,h,\rho) &:= (L_0^* g + L_1^* h + \rho w, L_1^* g + \rho w, \rho) \\ &= (T^*(g,h), 0) + \rho(w,w,1). \end{aligned}$$

Also consider the primal linear program, with $m \geq 1$ (see Remark 4.7),

$\boldsymbol{P}_m$: minimize $\langle \mu, c\rangle$ $[= \langle (\mu,\nu,r),\ (c,0,0)\rangle]$
(4.13) subject to $\tau(\mu,\nu,r) = (\gamma_0, 0, m)$, $(\mu,\nu,r) \in M_+(\mathbb{K})^2 \times \mathbb{R}_+$.

The corresponding dual is

$\boldsymbol{P}_m^*$: maximize $\langle \gamma_0, g\rangle + m\rho$ $[= \langle (\gamma_0, 0, m),\ (g,h,\rho)\rangle]$
subject to $\tau^*(g,h,\rho) \le (c,0,0)$, $(g,h,\rho) \in F(X)^2 \times \mathbb{R}$.

Remark 4.7. If (μ,ν,r) satisfies (4.13), then μ is a probability measure, which combined with (3.1), yields $m \ge 1$ since

$$m = \langle \mu + \nu, w\rangle + r \ge \langle \mu, w\rangle \ge \langle \mu, 1\rangle = 1.$$

The following proposition shows that P and P_m, as well as the duals P^* and P_m^*, are equivalent for all m s.l. (sufficiently large).

PROPOSITION 4.8. (a) *P is consistent if and only if P_m is consistent for m s.l.; moreover,* $\inf(P_m) \le \inf(P)$ *for all* $m \ge 1$.

(b) *If P_m is consistent ($m \ge 1$), then so is $P_{m'}$ and* $\inf(P_m) \ge \inf(P_{m'})$ $\forall m' \ge m$; *hence*

$$\inf(P) = \inf(P_m) \quad \textit{for all } m \textit{ s.l.} \tag{4.14}$$

(c) *If there is no duality gap for P_m, then there is no duality gap for P, and for all m s.l.:*

$$\inf(P) = \inf(P_m) = \sup(P_m^*) = \sup(P^*). \tag{4.15}$$

THEOREM 4.9. *Suppose that Assumption* 4.2 *holds. Then the following statements hold.*

(a) *P is consistent (equivalently, P_m is consistent for some $m \ge 1$) if and only if*

$$(g,h) \in F(X)^2,\quad L_0^*g + L_1^*h + \rho w \ge 0,\quad L_1^*g + \rho w \ge 0,\quad \textit{and}\ \ \rho \ge 0 \tag{4.16}$$

imply

$$\langle \gamma_0, g\rangle + \rho m \ge 0. \tag{4.17}$$

(b) *If P_m is consistent with a finite value, then it is solvable and there is no duality gap; hence (by* (4.15)*) for all m s.l., P is solvable and*

$$\min(P) = \min(P_m) = \sup(P_m^*) = \sup(P^*). \tag{4.18}$$

THEOREM 4.10. *Suppose that Assumptions* 4.2 *and* 4.1(d) *hold. Then*

(a) *P is solvable and there is no duality gap for it.*

(b) *Let (μ^n, ν^n) be a minimizing sequence for P and suppose that either* (i) *$\langle \mu^n + \nu^n, w\rangle$ is bounded, or* (ii) *Assumption* 4.1(a) *holds and $\langle \nu^n, w\rangle$ is bounded. Then there is subsequence $\{j\}$ of $\{n\}$ such that (μ^j, ν^j) converges to an optimal solution for P in the weak* topology $\sigma(M(\mathbb{K}), C_0(\mathbb{K}))$.*

(c) *Let (g^n, h^n) be a maximizing sequence for P^*. If the sequences g^n, h^n are bounded in the w_0-weighted norm (i.e., there is a constant k such that $\|g^n\|_{w_0}$, $\|h^n\|_{w_0} \le k$ $\forall n$), then* (i) *P^* is solvable. Hence,* (ii) *there is strong duality, i.e.,* $\min(P) = \max(P^*) = \langle \gamma_0, J^*\rangle$, *and* (iii) *an optimal solution (μ,ν) for P is such that*

- (2.6) *holds* ν_1*-a.e., and*
- (2.7) *holds* μ_1*-a.e.*

We conclude with the following interesting remark whose easy proof is left to the reader.

Remark 4.11. Under Assumptions 4.1 or 4.2, the set of optimal solutions for P is a weakly closed, convex, extremal subset of the set of feasible solutions for P—where *extremal* means that if (μ, ν) is optimal for P, if (μ^i, ν^i) is feasible $(i = 1, 2)$, and if

$$(\mu, \nu) = r(\mu^1, \nu^1) + (1 - r)(\mu^2, \nu^2) \quad \text{for} \quad 0 < r < 1,$$

then (μ^i, ν^i) is optimal for P $(i = 1, 2)$ (see [9]).

5. Technical preliminaries for the proofs. In this section we collect some facts used in the proofs of our main results.

If $(\mathcal{X}, \mathcal{Y})$ is a dual pair of vector spaces, we denote by $\sigma(\mathcal{X}, \mathcal{Y})$ the *weak topology* on $\mathcal{X}$ [3, 10, 15]. If $\mathcal{Y}$ is a Banach space and $\mathcal{X} = \mathcal{Y}^*$ the topological dual, then $\sigma(\mathcal{X}, \mathcal{Y})$ is called the *weak* topology* on $\mathcal{X}$.

Let $(\mathcal{X}, \mathcal{Y})$ be a dual pair, and S a convex cone in $\mathcal{X}$. Then the *dual cone* S^* is the set $\{y \in \mathcal{Y} | \langle x, y\rangle \geq 0 \ \forall x \in S\}$.

THEOREM 5.1 (generalized Farkas theorem [11, Theorem 2]). *Let* $(\mathcal{X}, \mathcal{Y})$ *and* $(\mathcal{Z}, \mathcal{W})$ *be two real dual pairs, let* S *be a convex cone in* $\mathcal{X}$*, and let* $G : \mathcal{X} \to \mathcal{Z}$ *be a weakly continuous linear map. If* $G(S)$ *is weakly closed, then the following are equivalent conditions on* $b \in \mathcal{Z}$ *(where* $G^* : \mathcal{W} \to \mathcal{Y}$ *denotes the* adjoint *of* G*):*

(a) *The equation* $Gx = b$ *has a solution* $x \in S$*.*

(b) $G^*w \in S^* \Rightarrow \langle b, w\rangle \geq 0$.

The following result is the *Alaoglu*, or *Banach–Alaoglu–Bourbaki theorem* (see [10, 15]), which is used in sections 6 and 7 in combination with Remark 5.3.

THEOREM 5.2. *Let* $\mathcal{X}$ *be a Banach space with topological dual* $\mathcal{X}^*$ *and let* U *be the closed unit sphere in* $\mathcal{X}^*$*. Then* U *is compact in the weak* topology* $\sigma(\mathcal{X}^*, \mathcal{X})$*. Moreover, if* $\mathcal{X}$ *is separable, then the weak* topology of* U *is metrizable.*

Remark 5.3. *(a)* Let us view $M(\mathbb{K})$ (see Definition 3.1) as the Banach space of finite signed measures on $\mathbb{K}$ endowed with the *total variation* norm $\|\cdot\|_{TV}$. Note that, by (3.1)–(3.2),

$$\|\mu\|_w = \int w d|\mu| \geq \|\mu\|_{TV},$$

so that $(M(\mathbb{K}), \|\cdot\|_w)$ is a subspace of $(M(\mathbb{K}), \|\cdot\|_{TV})$. On the other hand, with $\mathbb{K}$ as in Assumption 4.2(a), $(M(\mathbb{K}), \|\cdot\|_{TV})$ is the dual of the *separable* Banach space $C_0(\mathbb{K})$.

(b) We shall consider three topologies on $M(\mathbb{K})$: the *weak topology* $\sigma(M(\mathbb{K}), F(\mathbb{K}))$, the *weak topology* $\sigma(M(\mathbb{K}), C_b(\mathbb{K}))$, and the *weak* topology* $\sigma(M(\mathbb{K}), C_0(\mathbb{K}))$. However, as already noted in section 3, by "weak topology" we always mean $\sigma(M(\mathbb{K}), F(\mathbb{K}))$, unless explicitly stated otherwise.

(c) Under Assumption 4.2(a), if $\{\mu^j\}$ is a bounded sequence of measures on $\mathbb{K}$ that converges in the weak* topology, then also the sequence of marginals $L_0\mu^j = \mu_1^j$ on X converges in the weak* topology. That is, if

$$\text{(i)} \qquad \langle \mu^j, v\rangle \longrightarrow \langle \mu, v\rangle \qquad \forall v \in C_0(\mathbb{K}),$$

then

$$\text{(ii)} \qquad \langle \mu^j, u\rangle \longrightarrow \langle \mu, u\rangle \qquad \forall u \in C_0(X),$$

where in (ii) we have used Remark 3.2(c) to write $\langle \mu^j, u\rangle$ and $\langle \mu, u\rangle$ instead of $\langle \mu_1^j, u\rangle$ and $\langle \mu_1, u\rangle$, respectively. To prove (ii) first note that, under Assumption 4.2(a), $\mathbb{K}$ is σ-compact and, therefore, there exists an increasing sequence of compact sets $K_n \uparrow \mathbb{K}$. Moreover, by Urysohn's lemma [29, p. 39], for any given $\varepsilon > 0$ and all $n = 1, 2, \ldots$, there is a function α_n in $C_0(\mathbb{K})$ such that $0 \le \alpha_n \le 1$, with $\alpha_n = 1$ on K_n and $\alpha_n(x, a) = 0$ if the distance from (x, a) to K_n is $\ge \varepsilon$. Now, given u in $C_0(X)$, define $u_n(x, a) := u(x)\alpha_n(x, a)$ on $\mathbb{K}$. Then u_n is in $C_0(\mathbb{K})$, and for all (x, a) in $\mathbb{K}$,

$$|u_n(x, a)| \le |u(x)| \le \|u\| < \infty, \qquad \text{and} \qquad u_n(x, a) \to u(x) \qquad \text{as} \qquad n \to \infty.$$

Hence, by the bounded convergence theorem, for every fixed j,

$$\text{(iii)} \qquad \langle \mu^j, u_n\rangle \longrightarrow \langle \mu^j, u\rangle \qquad \text{and} \qquad \langle \mu, u_n\rangle \longrightarrow \langle \mu, u\rangle \qquad \text{as} \qquad n \to \infty.$$

On the other hand, for every fixed n, (i) yields

$$\text{(iv)} \qquad \langle \mu^j, u_n\rangle \longrightarrow \langle \mu, u_n\rangle \qquad \text{as} \qquad j \to \infty.$$

Finally, the desired conclusion (ii) follows from (iii), (iv), and the inequality

$$\begin{aligned} |\langle \mu^j, u\rangle - \langle \mu, u\rangle| \le\ & |\langle \mu^j, u\rangle - \langle \mu^j, u_n\rangle| \\ & + |\langle \mu^j, u_n\rangle - \langle \mu, u_n\rangle| + |\langle \mu, u_n\rangle - \langle \mu, u\rangle|. \end{aligned}$$

Linear programming. Let $(\mathcal{X}, \mathcal{Y})$, $(\mathcal{Z}, \mathcal{W})$, S, G, and b be as in Theorem 5.1, and consider the linear program, with $c \in \mathcal{Y}$,

$\boldsymbol{\mathcal{P}}$: minimize $\langle x, c\rangle$
(5.1) subject to $Gx = b$, $x \in S$.

The dual of $\mathcal{P}$ is

$\boldsymbol{\mathcal{P}}^*$: maximize $\langle b, w\rangle$
subject to $c - G^*w \in S^*, w \in \mathcal{W}$.

Weak duality. If x is feasible for $\mathcal{P}$ and w is feasible for $\mathcal{P}^*$, then $\langle b, w\rangle \le \langle x, c\rangle$; hence

$$\sup(\mathcal{P}^*) \le \inf(\mathcal{P}). \tag{5.2}$$

DEFINITION 5.4. (see [3, p. 40]). *Let H be the subset of $\mathcal{Z} \times \mathbb{R}$ defined as*

$$H := \{(Gx, \langle x, c\rangle + r) | x \in S, r \ge 0\}. \tag{5.3}$$

The program $\mathcal{P}$ is said to be subconsistent *if there is some $r \in \mathbb{R}$ with (b, r) in the weak closure* $\mathrm{cl}(H)$ *of H. If $\mathcal{P}$ is subconsistent, its* subvalue *is defined as the infimum of all $r \in \mathbb{R}$ for which (b, r) is in* $\mathrm{cl}(H)$. *(Thus, the subvalue is the infimum of r for which there is a net $\{x^\alpha\}$ in S with $Gx^\alpha \to b$ and $\langle x^\alpha, c\rangle \to r$.)*

THEOREM 5.5 (see [3, Theorem 3.3]). *$\mathcal{P}$ is subconsistent with a finite value r^* if and only if $\mathcal{P}^*$ is consistent with a finite value r^*.*

THEOREM 5.6 (see [3, Theorems 3.9, 3.22]). *If $\mathcal{P}$ is consistent with a finite value and H is weakly closed, then $\mathcal{P}$ is solvable and there is no duality gap for $\mathcal{P}$.*

6. Proof of the results for *EP*.

Proof of Theorem 4.5. (a) In this proof we use Theorem 5.1 with the following identifications (see (4.4)–(4.6))]:

$$(\mathcal{X},\mathcal{Y}) := (M(\mathbb{K})\times\mathbb{R}^2, F(\mathbb{K})\times\mathbb{R}^2),\ (\mathcal{Z},\mathcal{W}) := (M(X)\times\mathbb{R}^2, F(X)\times\mathbb{R}^2),$$

$$G := \mathcal{L},\quad S := M_+(\mathbb{K})\times\mathbb{R}^2_+,\quad b := (0,1,\varepsilon). \tag{6.1}$$

Then condition (a) in Theorem 5.1 is the same as (4.6), and condition (b) becomes

$$\mathcal{L}^*(h,\rho_1,\rho_2)\geq 0 \quad\Longrightarrow\quad \langle(0,1,\varepsilon),(h,\rho_1,\rho_2)\rangle\geq 0,$$

which is precisely that condition "(4.7) implies (4.8)." Hence, to prove Theorem 4.5(a) we only need to verify the hypotheses of Theorem 5.1; namely, we need to check that (in view of (6.1))

(i) $\mathcal{L}$ is weakly continuous, and

(ii) $\mathcal{L}(S)$ is weakly closed.

The requirement (i) follows from Lemma 4.4(a) and the definition of $\mathcal{L}$—see (4.4). Therefore, to complete the proof of Theorem 4.5(a) it only remains to prove (ii).

Proof of (ii). To prove that $\mathcal{L}(S)$ is weakly closed, let $(D,\leq)$ be a directed set, and let $\{(\mu^\alpha, r_1^\alpha, r_2^\alpha), \alpha\in D\}$ be a net in S such that $\mathcal{L}(\mu^\alpha, r_1^\alpha, r_2^\alpha)$ converges weakly to $(\nu,\rho_1,\rho_2)\in M(X)\times\mathbb{R}^2$; i.e. (by (4.4)),

$$\langle L_1\mu^\alpha, u\rangle \to \langle\nu, u\rangle \quad \forall u\in F(X), \tag{6.2}$$

$$\langle\mu^\alpha, 1\rangle + r_1^\alpha \to \rho_1, \quad \text{and} \tag{6.3}$$

$$\langle\mu^\alpha, v_0\rangle - r_2^\alpha \to \rho_2. \tag{6.4}$$

We wish to show that (ν,ρ_1,ρ_2) is in $\mathcal{L}(S)$; i.e., there exists (μ^0, r_1^0, r_2^0) in S such that

$$\text{(a)}\quad L_1\mu^0 = \nu,\ \text{(b)}\ \langle\mu^0,1\rangle + r_1^0 = \rho_1,\ \text{and (c)}\ \langle\mu^0, v_0\rangle - r_2^0 = \rho_2. \tag{6.5}$$

If $\rho_1 = 0$ in (6.3), then r_1^α and $\langle\mu^\alpha,1\rangle\to 0$, and it is easily verified that necessarily $\nu = 0$ and that (6.4) holds with $(\mu^0, r_1^0, r_2^0) = (0,0,-\rho_2)$. We shall now consider the case $\rho_1 > 0$.

Suppose that $\rho_1 > 0$. Then, by (6.3), there exists $\alpha_0\in D$ such that

$$0\leq\langle\mu^\alpha,1\rangle = \mu^\alpha(\mathbb{K})\leq 2\rho_1 \quad\forall\alpha\geq\alpha_0. \tag{6.6}$$

Hence, by Theorem 5.2 and Remark 5.3(a), there exists a measure μ^0 on $\mathbb{K}$ and a sequence $\{j\}$ in D such that $\mu^j\to\mu^0$ in the weak* topology $\sigma(M(\mathbb{K}), C_0(\mathbb{K}))$; i.e.,

$$\langle\mu^j, v\rangle\to\langle\mu^0, v\rangle \quad\forall v\in C_0(\mathbb{K}). \tag{6.7}$$

Moreover, μ^0 is in $M(\mathbb{K})$, since $0\leq\mu^0(\mathbb{K})\leq\liminf_j\mu^j(\mathbb{K})\leq 2\rho_1$ (see, e.g., [10, Proposition III.12]). Now, let u be an arbitrary function in $C_0(x)$. Then (6.7) and (4.1) yield, as $j\to\infty$,

$$\left\langle\mu^j, \int_X u(y)Q(dy|\cdot)\right\rangle \longrightarrow \left\langle\mu^0, \int_X u(y)Q(dy|\cdot)\right\rangle,$$

whereas (6.7) and Remark 5.3(c) yield

$$\langle \mu^j, u\rangle \longrightarrow \langle \mu^0, u\rangle.$$

Therefore, as $u \in C_0(X)$ was arbitrary, $L_1\mu^j$ converges to $L_1\mu^0$ in the weak* topology; i.e.,

$$\langle L_1\mu^j, u\rangle \longrightarrow \langle L_1\mu^0, u\rangle \qquad \forall u \in C_0(X). \tag{6.8}$$

By (6.2) and (6.8), we obtain $L_1\mu^0 = \nu$, which is condition (6.5)(a), and, finally, (b) and (c) in (6.5) hold with $r_1^0 := \rho_1 - \langle \mu^0, 1\rangle$ and $r_2^0 := \rho_2 - \langle \mu^0, v_0\rangle$. This proves (ii), which, as already noted, concludes the proof of Theorem 4.5(a).

(b) In view of part (a), to prove (b) it suffices to show that (4.7), together with (4.9) and (4.10), implies (4.8). So, let φ be as in (4.9) and let us rewrite (4.7) as

$$h(x) \geq \int h(y)Q(dy|x,a) - \rho_1 - \rho_2 v_0(x),\ h \in F(X),\ \rho_1 \geq 0,\ \rho_2 \leq 0. \tag{6.9}$$

Note that (4.9) obviously implies

$$\liminf_n E_x^\varphi[h(x_n)]/n = 0 \quad \forall h \in F(X),\ x \in X. \tag{6.10}$$

On the other hand, since (6.9) holds for all (x,a) in $\mathbb{K}$, integration with respect to $\varphi(\cdot|x)$ yields

$$h(x) \geq \int h(y)Q(dy|x,\varphi) - \rho_1 - \rho_2 v_0(x) \quad \forall x \in X,$$

which in turn (by iteration) implies, $\forall x \in X$ and $n = 1, 2, \ldots$,

$$h(x) \geq E_x^\varphi h(x_n) - n\rho_1 - \rho_2 \sum_{t=0}^{n-1} E_x^\varphi v_0(x_t);$$

i.e.,

$$h(x) + n\rho_1 + \rho_2 \sum_{t=0}^{n-1} E_x^\varphi v_0(x_t) \geq E_x^\varphi h(x_n).$$

Thus, multiplying by $1/n$ and taking lim inf as $n \to \infty$, (6.10) and (4.10) yield (4.8). Therefore, by part (a), EP is consistent. □

In the proof of Theorem 4.6 we shall use the following lemma in which (a) is a well-known result on disintegration of measures [32], and (b) is a result of Blackwell [8]—see also, e.g., [16, pp. 88, 97] or [19, Proposition D.8].

LEMMA 6.1. (a) *If μ is a finite measure on $\mathbb{K}$, then there exists a randomized stationary policy φ such that $\mu(d(x,a)) = \varphi(da|x)\mu_1(dx)$, where $\mu_1 = L_0\mu$ is the marginal of μ on X; i.e.,*

$$\mu(B \times C) = \int_B \varphi(C|x)\mu_1(dx) \quad \forall B \in \mathcal{B}(X),\ C \in \mathcal{B}(A). \tag{6.11}$$

(b) *If φ is a randomized stationary policy and $v : \mathbb{K} \to \mathbb{R}$ is a measurable function such that $v(\cdot,\varphi)$ (recall Remark 2.2) is a finite-valued function on X, then there exists a stationary policy $f \in \mathbb{F}$ satisfying*

$$v(x,\varphi) \geq v(x,f) \quad \forall x \in X.$$

Also note that if μ is feasible for EP and (ρ, h) is feasible for EP^*, then

$$\langle L_1\mu, h\rangle = 0 \quad \textit{and} \quad \langle L\mu, (\rho, h)\rangle = \rho. \tag{6.12}$$

Proof of Theorem 4.6. (a) This part is proved in [17] under condition (i), namely, Assumption 4.1, and in fact the proof works in exactly the same way under condition (ii).

(b) Let $\{\mu^n\}$ be a minimizing sequence for EP; that is, μ^n is feasible for EP, which (by (3.1)) means that

$$\text{(i)} \quad \langle \mu^n, 1\rangle = 1, \quad \text{and} \quad \text{(ii)} \quad L_1\mu^n = 0 \qquad \forall n, \tag{6.13}$$

and

$$\langle \mu^n, c\rangle \;\downarrow\; \min(EP). \tag{6.14}$$

In particular, (6.14) implies that for any given $\varepsilon > 0$ there exists $n(\varepsilon)$ such that

$$\min(EP) \le \langle \mu^n, c\rangle \le \min(EP) + \varepsilon \quad \forall n \ge n(\varepsilon).$$

The right-hand side inequality and Assumption 4.1(a) imply (see, for instance, [5, 6, 7, 17, 19]) the existence of a probability measure μ^* on $\mathbb{K}$ and a subsequence $\{j\}$ of $\{n\}$ such that μ^j converges to μ^* in the weak topology $\sigma(M(\mathbb{K}), C_b(\mathbb{K}))$; i.e.,

$$\langle \mu^j, v\rangle \to \langle \mu^*, v\rangle \quad \forall v \in C_b(\mathbb{K}). \tag{6.15}$$

Hence, as c is l.s.c.,

$$\langle \mu^*, c\rangle \le \liminf_j \langle \mu^j, c\rangle \le \min(EP) + \varepsilon.$$

As $\varepsilon > 0$ was arbitrary, the latter inequality shows that μ^* satisfies (4.11). Thus, to complete the proof of part (b) it only remains to show that μ^* is indeed feasible for EP (see (3.3)). But this, however, follows directly from (6.15) and (6.13)—in particular, note that Assumption 4.1(b), which is part of 4.2(c), implies that L_1^* maps $C_b(X)$ into $C_b(\mathbb{K})$ (see Lemma 4.4(b)) and, therefore, $\forall u \in C_b(X)$,

$$\langle L_1\mu^*, u\rangle = \langle \mu^*, L_1^*u\rangle = \lim_j \langle \mu^j, L_1^*u\rangle = \lim_j \langle L_1\mu^j, u\rangle = 0;$$

that is, $L_1\mu^* = 0$.

(c) Let (ρ_n, h_n) be a maximizing sequence for EP^*, i.e., (ρ_n, h_n) is feasible for EP^*, so that (by (3.4)) $\forall\ n = 1, 2, \ldots, (x, a) \in \mathbb{K}$,

$$\rho_n + h_n(x) \le c(x, a) + \int_X h_n(y)Q(dy|x, a), \tag{6.16}$$

and

$$\rho_n = \langle (1, 0), (\rho_n, h_n)\rangle \uparrow \sup(EP^*) = \rho^* \ \text{(by (4.11))}.$$

Define $h(x) := \limsup_n h_n(x)$, $x \in X$. Since, by hypotheses, $\|h_n\|_{w_0}$ is bounded, h is in $F(X)$ and, moreover, applying Fatou's lemma in (6.16) we see that

$$\rho^* + h(x) \le c(x, a) + \int h(y)Q(dy|x, a) \quad \forall (x, a) \in \mathbb{K}; \tag{6.17}$$

that is, (ρ^*, h) is feasible—hence *optimal* (as $\rho^* = \sup(EP^*)$)—for EP^*. This fact, combined with (4.11), yields *strong duality*: there exists an optimal solution μ^* for EP, and optimal solution (ρ^*, h) for EP^*, and $\langle \mu^*, c\rangle = \rho^*$. On the other hand, by (6.12),

$$\langle \mu^*, L^*(\rho^*, h)\rangle = \langle L\mu^*, (\rho^*, h)\rangle = \rho^*.$$

This yields

$$\langle \mu^*, c - L^*(\rho^*, h)\rangle = 0,$$

or, equivalently, writing $\mu^*(d(x,a)) = \varphi^*(da|x)\mu_1^*(dx)$ as in Lemma 6.1(a),

$$\begin{aligned} 0 &= \int \left[c(x,a) - L^*(\rho^*, h)(x,a)\right] \mu^*(d(x,a)) \\ &= \int \left[c(x,\varphi^*) - \rho^* - h(x) + \int h(y)Q(dy|x,\varphi^*)\right] \mu_1^*(dx). \end{aligned}$$

This equation and (6.17) yield, for μ_1^*-a.e. $x \in X$:

$$\begin{aligned} \rho^* + h(x) &= \min_{a\in A(x)} \left[c(x,a) + \int_X h(y)Q(dy|x,a)\right] \\ &= c(x,\varphi^*) + \int_X h(y)Q(dy|x,\varphi^*) \quad \text{(see (2.6)–(2.9))}. \end{aligned}$$

Finally, by Lemma 6.1(b), there is a stationary policy f^* such that

$$\rho^* + h(x) \geq c(x,f^*) + \int_X h(y)Q(dy|x,f^*)$$

for μ_1^*-a.e. $x \in X$, which combined with (6.17) yields (4.12). This completes the proof of Theorem 4.6. □

7. Proof of the results for *P*.

Proof of Proposition 4.8. (a) If (μ,ν) satisfies (3.5), then, in particular, $\langle \mu + \nu, w\rangle \leq m$ for some $1 \leq m < \infty$; hence (μ,ν,r) with $r := m - \langle \mu+\nu, w\rangle$ satisfies (4.13). Conversely, if (μ,ν,r) satisfies (4.13) for *any* $m \geq 1$, then obviously (μ,ν) satisfies (3.5). Moreover, the latter fact implies $\inf(P_m) \leq \inf(P)$ for all $m \geq 1$.

(b) If (μ,ν,r) is feasible for P_m and $m' \geq m$, then (μ,ν,r') with $r' := r + m' - m$ is feasible for $P_{m'}$, and, therefore, $\inf(P_m) \geq \inf(P_{m'})$. On the other hand, by part (a), if P is consistent then P_m is consistent for some $m \geq 1$ and, therefore, $P_{m'}$ is consistent for all $m' \geq m$. Combining this fact with part (a), there is some m s.l. such that

$$\inf(P) \geq \inf(P_m) \geq \inf(P_{m'}) \geq \inf(P) \quad \forall m' \geq m,$$

which yields (4.14).

(c) If (g,h) is feasible for P^* (i.e., (3.6) holds true), then (g,h,ρ) is feasible for P_m^* for all $\rho \leq 0$, and $\langle \gamma_0, g\rangle \geq \langle \gamma_0, g\rangle + m\rho$ $\forall m \geq 1$ and $\rho \leq 0$. Therefore,

$$\sup(P^*) \geq \sup(P_m^*). \tag{7.1}$$

Now suppose that there is no duality gap for P_m so that, by (4.14),

$$\inf(P) = \inf(P_m) = \sup(P_m^*). \tag{7.2}$$

If $\inf(P_m) = +\infty$, then (4.15) follows (by (7.1)). Now suppose that $\inf(P_m) < \infty$. Then if $\sup(P^*) > \sup(P_m^*)$, (7.1) and (7.2) yield $\sup(P^*) > \inf(P)$, which contradicts the weak duality property (see (5.2)). Hence $\sup(P^*) = \sup(P_m^*)$ and we obtain (4.15). □

Proof of Theorem 4.9. (a) The proof of this part is very similar to the proof of Theorem 4.5(a), so we only mention the main steps and leave the details to the reader.

As in the proof of Theorem 4.5(a), the idea is to use the *generalized Farkas theorem*, Theorem 5.1, for which we make the following identifications:

$$(\mathcal{X}, \mathcal{Y}) := (M(\mathbb{K})^2 \times \mathbb{R}, F(\mathbb{K})^2 \times \mathbb{R}),\ (\mathcal{Z}, \mathcal{W}) := (M(X)^2 \times \mathbb{R}, F(X)^2 \times \mathbb{R}),$$

$$S := M_+(\mathbb{K})^2 \times \mathbb{R}_+, \quad b := (\gamma_0, 0, m), \text{ and } G := \tau. \tag{7.3}$$

With this notation, part (a) in Theorem 5.1 turns out to be the same as (4.13), and part (b) becomes

$$\tau^*(g, h, \rho) \geq 0 \quad \Longrightarrow \quad \langle (\gamma_0, 0, m), (g, h, \rho) \rangle \geq 0,$$

which is the same as "(4.16) $\Longrightarrow$ (4.17)." Hence, Theorem 4.9(a) will be proved if we can show that (i) τ is weakly continuous, and (ii) $\tau(S)$ is weakly closed. Since (i) follows from Lemma 4.4(a), we only need to prove (ii). To do this, let $\{(\mu^\alpha, \nu^\alpha, r^\alpha), \alpha \in D\}$ be a net is S such that (recalling the notation (7.3))

$$\tau(\mu^\alpha, \nu^\alpha, r^\alpha) \to (\theta_1, \theta_2, \rho) \in \mathcal{Z} \text{ in the weak topology } \sigma(\mathcal{Z}, \mathcal{W}), \tag{7.4}$$

so we need to show that $(\theta_1, \theta_2, \rho)$ is in $\tau(S)$; in other words, there is (μ^0, ν^0, r^0) in S with

$$\tau(\mu^0, \nu^0, r^0) = (\theta_1, \theta_2, \rho). \tag{7.5}$$

This is done exactly, mutatis mutandis, as in (6.2)–(6.8).

(b) By Theorem 5.6 (see also (5.3)), we only need to show that (using notation (7.3)) the set

$$H := \{(\tau(\mu, \nu, r), \langle \mu, c \rangle + s) | (\mu, \nu, r) \in S,\ s \geq 0\}$$

is weakly closed in $\mathcal{Z} \times \mathbb{R} := M(\mathbb{K})^2 \times \mathbb{R}^2$; that is, if $(\mu^\alpha, \nu^\alpha, r^\alpha, s^\alpha)$ is a net in $S \times \mathbb{R}$ for which we have the weak convergence

$$(\tau(\mu^\alpha, \nu^\alpha, r^\alpha), \langle \mu^\alpha, c \rangle + s^\alpha) \to (\theta_1, \theta_2, \rho_1, \rho_2) \in \mathcal{Z} \times \mathbb{R},$$

then $(\theta_1, \theta_2, \rho_1, \rho_2)$ is in H. The latter means that

$$\tau(\mu^0, \nu^0, r^0) = (\theta_1, \theta_2, \rho_1) \text{ and } \langle \mu^0, c \rangle + s^0 = \rho_2$$

for some (μ^0, ν^0, r^0, s^0) in $S \times \mathbb{R}$. The first equality is obtained exactly as in (7.4)–(7.5), and the second holds with $s^0 := \rho_2 - \langle \mu^0, c \rangle$. □

In the proof of Theorem 4.10 we use the following lemma.

LEMMA 7.1. *If (g, h) is feasible for P^*, then $g(x) \leq J(\pi, x)$ for every initial state x and every policy π; hence $g(x) \leq J^*(x)$ $\forall x \in X$. Therefore, under Assumption* 4.1(d)*,*

$$\langle \gamma_0, g \rangle \leq \langle \gamma_0, J^* \rangle < \infty, \tag{7.6}$$

and so P^* is consistent with a finite value

$$\sup(P^*) \le \langle \gamma_0, J^* \rangle. \tag{7.7}$$

Proof. Standard calculations [4, 17, 18, 19] show that the second inequality in (3.6) (or (3.8)) implies

$$E_x^\pi g(x_n) \ge g(x),$$

and, similarly, the first inequality in (3.6) (or (3.8)) yields

$$\begin{aligned} J_n(\pi, x) + E_x^\pi h(x_n) &\ge h(x) + \sum_{t=0}^{n-1} E_x^\pi g(x_t) \\ &\ge h(x) + ng(x). \end{aligned}$$

Finally, since (2.10) holds for every policy π as in Assumption 4.1(d), we obtain $J(\pi, x) \ge g(x)$, which in turn yields the desired conclusion. □

Proof of Theorem 4.10. (a) Since P^* is consistent with a finite value $\sup(P^*)$ (Lemma 7.1), then (by (7.1)) so is P_m^* for every $m \ge 1$, with finite value

$$\sup(P_m^*) \le \sup(P^*) \le \langle \gamma_0, J^* \rangle. \tag{7.8}$$

Therefore (Theorem 5.5), P_m is subconsistent with subvalue $v = \sup(P_m^*)$. In other words (by Definition 5.4), there is a net $(\mu^\alpha, \nu^\alpha, r^\alpha)$ in S (see (7.3)) such that

$$\tau(\mu^\alpha, \nu^\alpha, r^\alpha) \to (\gamma_0, 0, m) \text{ weakly}, \tag{7.9}$$

and

$$\langle (\mu^\alpha, \nu^\alpha, r^\alpha), (c, 0, 0) \rangle = \langle \mu^\alpha, c \rangle \to v. \tag{7.10}$$

Moreover, (7.9) implies (see (7.4)–(7.5)) the existence of $(\mu^0, \nu^0, r^0) \in S$ such that

$$\tau(\mu^0, \nu^0, r^0) = (\gamma_0, 0, m),$$

whereas (7.10) yields $\langle \mu^0, c \rangle \le v$. This implies that (μ^0, ν^0) is feasible for P and

$$\begin{aligned} \langle \mu^0, c \rangle \le v = \sup(P_m^*) &\le \inf(P_m) \qquad \text{(by (5.2))} \\ = \inf(P) &\le \langle \mu^0, c \rangle \qquad \text{(by (4.14))}. \end{aligned} \tag{7.11}$$

Therefore, since equality holds throughout (7.11), (μ^0, ν^0) is an optimal solution for (P) and there is no duality gap for P_m, hence for P, by Proposition 4.8(c).

(b) Let (μ^n, ν^n) be a minimizing sequence for P and suppose that (i) holds; that is, $\langle \mu^n + \nu^n, w \rangle$ is bounded. Then, for every n, (μ^n, ν^n) satisfies (3.5), so that

$$L_0\mu^n + L_1\nu^n = \gamma_0,\ L_1\mu^n = 0, \quad \mu^n \text{ and } \nu^n \in M_+(\mathbb{K}), \tag{7.12}$$

and

$$\langle \mu^n, c \rangle = \langle (\mu^n, \nu^n), (c, 0) \rangle \downarrow \inf(P), \tag{7.13}$$

and

$$\langle \mu^n, 1 \rangle + \langle \nu^n, 1 \rangle \le \langle \mu^n + \nu^n, w \rangle \le k \tag{7.14}$$

for some constant k. By (7.14), Remark 5.3(a), and Theorem 5.2, there exist measures μ^*, ν^*, and a subsequence $\{j\}$ of $\{n\}$ such that

$$\mu^j \to \mu^* \text{ and } \nu^j \to \nu^* \text{ in the weak}^* \text{ topology } \sigma(M(\mathbb{K}), C_0(\mathbb{K})). \tag{7.15}$$

Therefore (as in (6.7)–(6.8)), (7.15), (7.14), and (7.12) yield that (μ^*, ν^*) is feasible for P, i.e.,

$$L_0\mu^* + L_1\nu^* = \gamma_0,\ L_1\mu^* = 0, \quad \mu^*, \nu^* \in M_+(\mathbb{K}),$$

whereas (7.13) and the fact that c is l.s.c. yield

$$\inf(P) = \lim_j \langle \mu^j, c\rangle \geq \langle \mu^*, c\rangle.$$

This completes the proof of (b), under condition (i), as $\langle \mu^*, c\rangle \geq \inf(P)$.

Let us now suppose (ii). Then (7.13) and Assumption 4.1(a) imply (as in (6.14)–(6.15)) the existence of a subsequence $\{i\}$ of $\{n\}$ and a probability measure μ^* in $M_+(\mathbb{K})$ such that $\mu^i \to \mu^*$ in the weak topology $\sigma(M(\mathbb{K}), C_b(\mathbb{K}))$—hence in the weak* topology $\sigma(M(\mathbb{K}), C_0(\mathbb{K}))$—and $\langle \mu^*, c\rangle = \inf(P)$. On the other hand, as $\langle \nu^i, w\rangle$ is bounded, there is a subsequence $\{j\}$ of $\{i\}$ and a measure ν^* such that (μ^j, ν^j) satisfies (7.15). Now (b) is concluded as in the previous paragraph.

(c) Let us first note the following obvious fact: *If* (g_1, h) *and* (g_2, h) *are two feasible solutions for* P^* (see (3.6) or (3.8)) *and* $g := \max(g_1, g_2)$, *then* (g, h) *is also feasible for* P.

Now let (g^n, h^n) be a maximizing sequence for P^*, with g^n and h^n bounded in the w_0-weighted norm; that is, for every $(x, a) \in \mathbb{K}$ and $n = 1, 2, \ldots$

$$g^n(x) + h^n(x) \leq c(x,a) + \int h^n(y) Q(dy|x,a), \tag{7.16}$$

$$g^n(x) \leq \int g^n(y) Q(dy|x,a), \tag{7.17}$$

$$\langle \gamma_0, g^n\rangle = \int g^n(x)\gamma_0(dx) \uparrow \sup(P^*), \tag{7.18}$$

and, for some $k \geq 0$,

$$|g^n(x)|,\ |h^n(x)| \leq k w_0(x). \tag{7.19}$$

By the remark in the previous paragraph (and recalling that $(0, N)$ is feasible for P^* for any constant N) we may assume that $\{g^n\}$ is a *nonnegative increasing* sequence in $F(X)$. Finally, define

$$g(\cdot) := \lim_n g^n(\cdot) \text{ and } h(\cdot) := \limsup_n h^n(\cdot), \tag{7.20}$$

and let $n \to \infty$ in (7.16) and (7.17). Then, by Fatou's lemma (which is indeed applicable, by (7.19) and Assumption 4.1(d)) and the monotone convergence theorem we obtain that (g, h) is feasible for P^* and $\langle \gamma_0, g\rangle = \sup(P^*)$; that is, (g, h) is an optimal solution for P^*. This proves (i), which combined with part (a) yields (ii).

To prove (iii) let (μ, ν) be an optimal solution for P and (g, h) an optimal solution for P^*. Then by strong duality

$$\langle (\mu, \nu), (c, 0)\rangle = \langle \mu, c\rangle = \langle \gamma_0, g\rangle.$$

On the other hand (for any (μ, ν) and (g, h) that are feasible for P and P^*, respectively),

$$\langle (\mu, \nu), T^*(g, h) \rangle = \langle T(\mu, \nu), (g, h) \rangle = \langle \gamma_0, g \rangle.$$

Hence

$$\langle (\mu, \nu), (c, 0) - T^*(g, h) \rangle = 0,$$

which is equivalent to

$$\int_{\mathbb{K}} (c - L_0^* g - L_1^* h) d\mu = \int_{\mathbb{K}} (L_1^* g) d\nu.$$

As the left-hand side is ≥ 0 and the right-hand side is ≤ 0 (see (3.6) or (3.8)), we obtain that each side equals 0; i.e.,

$$\int_{\mathbb{K}} \left[c(x, a) + \int_X h(y) Q(dy|x, a) - g(x) - h(x) \right] \mu(d(x, a)) = 0,$$

and

$$\int_{\mathbb{K}} \left[g(x) - \int_X g(y) Q(dy|x, a) \right] \nu(d(x, a)) = 0$$

Thus, disintegrating μ and ν as in Lemma 6.1(a) (see the proof of Theorem 4.6(c)), we conclude part (iii). □

8. Closing remarks. In the previous sections we have presented an LP approach to studying "unichain" and "multichain" AC problems for MCPs on uncountable spaces. Our results include necessary and sufficient conditions for the related linear programs to be consistent (Theorems 4.5 and 4.9) and conditions for solvability and strong duality (Theorems 4.6 and 4.10). There are, on the other hand, many questions that come to mind: (i) Why *LP* (why not one of the more standard approaches, such as dynamic programming or the "vanishing discount" approach)? (ii) Why do the assumptions look so "restrictive"? (iii) Can we actually compute a solution of the primal and/or the dual programs?

Concerning question (i) (and (iii)), at least for finite-state, finite-action MCPs, LP is the most widely used technique, and even in the countable-state case it has been proved to be very useful to study *constrained* and *adaptive* MCPs; see, for instance, [1] for an extensive list of related references. Hence, in the first place, it seems natural to try to extend the LP techniques to MCPs on more general spaces. But more importantly, *in the multichain uncountable-space case LP seems to be* (to the best of our knowledge) *the only "reasonable" approach*. Namely, all the other techniques (dynamic programming, "vanishing discount," etc.) assume, explicitly or implicitly, the *unichain* setting (see [4, 16, 19]); and even under very strong probabilistic-like hypotheses, *multichain* results are *not* ensured (see, for instance, [24]). These remarks are also related to question (ii): a comparison of our assumptions with those required by the other techniques would hardly yield that ours are more "restrictive." As to the nature of these assumptions, it should be noted that basically they are designed to obtain the "weak closedness" that makes applicable background results such as Theorems 5.1 and 5.6.

Finally, we have the computational question (iii), which is in fact a *common difficulty to all the known solution methods*. An approach we are currently investigating is based on the well-known fact that *in a Polish space S the class of probability measures with finite support is weakly dense in $\mathcal{P}(S)$*, that is, in the weak topology $\sigma(M(S), C_b(S))$. Now assume that X and A are both Polish spaces, and let D_X and D_A be countable dense sets in X and A, respectively. Next, consider MCPs of the form (X_n, A_n, Q_n, c), where X_n and A_n are suitably chosen *finite* subsets of D_X and D_A, respectively. And, finally, the idea is to exploit the denseness of D_X and D_A to show that, as $n \to \infty$, the values of the *finite* linear programs corresponding to (X_n, A_n, Q_n, c) converge (or at least give a good approximation) to the original linear programs EP or P in section 3. In view of Theorems 4.6(b), (c) and 4.10(b), (c), we expect to obtain that the finite programs will yield *monotone approximation schemes*, decreasing for EP and P, and increasing for the duals EP^* and P^*. More generally, from a computational viewpoint, it would be important to investigate whether some of the available approximation schemes for LP (see, for instance, [1, 27, 28]) can be extended to uncountable-state MCPs.

Acknowledgment. We would like to thank one of the anonymous reviewers for calling our attention to an embarrassing mistake in a previous statement of Lemma 4.4.

Note Added in Proof. The LP approximations mentioned in the last paragraph of section 8 have been recently developed in [33].

SPECTRAL APPROACH TO DUALITY IN NONCONVEX GLOBAL OPTIMIZATION*

ALEXEY S. MATVEEV†

Abstract. A nonconvex problem of constrained optimization is analyzed in terms of its ordinary Lagrangian function. New sufficient conditions are obtained for the duality gap to vanish. Among them, the main condition is that the objective and constraint functions be the sums of convex functionals and nonconvex quadratic forms with certain specific spectral properties. The proofs are related to extensions of the classic Toeplitz–Hausdorff theorem, which states that a continuous quadratic mapping $(y_1, y_2) = [\mathcal{B}_1(z), \mathcal{B}_2(z)]$ from a complex Hilbert space $H = \{z\}$ into $\mathbb{R}^2 = \{(y_1, y_2)\}$ transforms the unit sphere $|z| = 1$ into a convex set. The extensions deal with a quadratic mapping $[\mathcal{B}_1(z), \dots, \mathcal{B}_k(z)]$ from a real Hilbert space into $\mathbb{R}^k$ with k being arbitrary. Applications to linear-quadratic optimal control theory are considered.

1. Introduction and preliminaries.

In this paper we consider problems of global optimization whose abstract presentation is as follows:

$$\mathcal{F}(z) \to \inf \quad \text{subject to} \quad z \in Z \subset H, \quad \mathcal{G}(z) \leq 0. \tag{1.1}$$

Here Z is an affine subspace of a real linear space H, the functions $\mathcal{F} : H \to \mathbb{R}$ and $\mathcal{G} : H \to Y$ are given, and Y is a finite-dimensional real linear space. This space is assumed to be ordered with a convex cone $K_+ \subset Y = \{y\}, K_+ \ni 0$. Accordingly, the inequalities $y_1 \leq y_2$ and $y_2 \geq y_1$ signify the inclusion $y_2 - y_1 \in K_+$. The interior $\mathrm{int}K_+$ of the cone K_+ is supposed to be nonempty. An example of the constraint $\mathcal{G}(z) \leq 0$ under consideration is the system of scalar inequalities

$$\mathcal{G}_1(z) \leq 0, \dots, \mathcal{G}_k(z) \leq 0. \tag{1.2}$$

In this case, $Y = \mathbb{R}^k, \mathcal{G}(z) = \|\mathcal{G}_i(z)\|$, and $K_+ = \left\{y = \|y_i\| \in \mathbb{R}^k : y_1 \geq 0, \dots, y_k \geq 0\right\}$.

In what follows, our interest will be focused on the special case when, in (1.1),

$$\mathcal{F}(z) = B_{\mathcal{F}}(z, z) + \Phi_{\mathcal{F}}(z), \quad \mathcal{G}(z) = B_{\mathcal{G}}(z, z) + \Phi_{\mathcal{G}}(z). \tag{1.3}$$

Here $B_{\mathcal{F}} : H \times H \to \mathbb{R}, B_{\mathcal{G}} : H \times H \to Y$ are bilinear symmetric mappings and $\Phi_{\mathcal{F}} : H \to \mathbb{R}, \Phi_{\mathcal{G}} : H \to Y$ are convex mappings. We do not impose assumptions that imply positivity or convexity of the forms $B_{\mathcal{F}}(z, z)$ and $B_{\mathcal{G}}(z, z)$. So, in (1.1), the objective and constraint functions may be nonconvex. As is well known, this nonconvexity involves a series of troubles both in the analysis of the problem and in the computation of its global solution.

The purpose of this paper is to investigate the validity of the duality in the Arrow–Hurwicz sense [1], which makes use of the ordinary Lagrangian function

$$S(\tau^*, z) := \mathcal{F}(z) + \tau^* \mathcal{G}(z). \tag{1.4}$$

†Department of Mathematics and Mechanics, St. Petersburg University, Bybliotechnaya 2, Petrodvoretz, St. Petersburg, 198904, Russia (almat@niimm.spb.su).

(Here $\tau^* \in Y^*$ is a Lagrange multiplier.) So, throughout the paper, the term "method of duality" will denote the following specific rule (I)–(IV) to solve the problem (1.1).[1] Further the inequality $\tau^* \geq 0$ expresses that $\tau^* y \geq 0$ for all $y \geq 0$.

METHOD OF DUALITY

(I) *For any $\tau^* \geq 0$, solve the problem*

$$S(\tau^*, z) \to \inf \quad \textit{subject to} \quad z \in Z. \tag{1.5}$$

More exactly, it suffices to find only the value of the infimum

$$S_0(\tau^*) := \inf_{z \in Z} S(\tau^*, z). \tag{1.6}$$

(II) *Determine some solution τ_0^* of the dual problem*

$$S_0(\tau^*) \to \max \quad \textit{subject to} \quad \tau^* \geq 0, \tag{1.7}$$

where the maximum must be attained.

(III) *Find all solutions z of the problem* (1.5) *with $\tau^* = \tau_0^*$ and omit those not satisfying at least one of the following relations:*

$$\mathcal{G}(z) \leq 0, \qquad \tau_0^* \mathcal{G}(z) = 0. \tag{1.8}$$

The resultant set $\{z\}$ must coincide with the set of all solutions of the primal problem (1.1).

(IV) *Let $\inf\{\mathcal{F}(z) : z \in D\} > -\infty$, where $D := \{z \in Z : \mathcal{G}(z) \leq 0\}$ is the admissible domain in the problem* (1.1). *A sequence $\{z_n\} \subset Z$ is minimizing in this problem*

$$\mathcal{F}(z_n) \to \inf_{z \in D} \mathcal{F}(z) \quad \textit{as} \quad n \to \infty, \quad z_n \in D \quad \forall n \tag{1.9}$$

if and only if it is minimizing in the problem (1.5) *with $\tau^* := \tau_0^*$*

$$S(\tau_0^*, z_n) \to \inf_{z \in Z} S(\tau_0^*, z) \quad \textit{as} \quad n \to \infty \tag{1.10}$$

and

$$\mathcal{G}(z_n) \leq 0 \quad \forall n\,, \quad \tau_0^* \mathcal{G}(z_n) \to 0 \quad \textit{as} \quad n \to \infty. \tag{1.11}$$

The last item is of particular interest if the primal problem (1.1) has no solution and so the operations (I)–(III) result in the empty set.

In general, the method formulated fails to be correct and may produce a wrong result. Its validity is known to be equivalent to the *duality relation* [2, 13]

$$\inf_{\substack{z \in Z \\ \mathcal{G}(z) \leq 0}} \mathcal{F}(z) = \max_{\tau^* \geq 0} \inf_{z \in Z} S(\tau^*, z). \tag{1.12}$$

This relation is valid for convex problems (1.1) (i.e., if the functions $\mathcal{F}$ and $\mathcal{G}$ are convex) provided $\mathcal{G}(z_*) \in -\mathrm{int} K_+$ for some $z_* \in Z$ [1]. The same is true for specific variational problems and problems of optimal control that can be converted into

[1] The statement of this rule follows [11, 12].

convex ones by means of relaxation [3, Chapters IX, X]. Furthermore, there is known a number of other results on the validity of (1.12), which also utilize a specific nature of the problem under consideration ([4, 5] and others; see [6] for detailed survey).

On the whole, problems for which relation (1.12) is known to be true constitute a relatively small subclass in the class of all mathematical programming problems. In connection with this, a considerable number of generalized duality schemes has been developed. (See [7, 8, 9, 10] and many others. For an excellent survey of them, the reader may consult [6].) Proceeding from various ideas, these schemes replace some constructions in the duality method (I)–(IV) (such as the Lagrangian function, the dual problem, etc.) by generalized ones. However, there are applications where the use of the nongeneralized constructions is preferable and has the advantage of the considerable simplification of the method. Some examples of such applications were given in [11, 12, 13, 14]. A number of other examples will be considered in this paper. They deal with linear-quadratic optimal control problems whose statements differ from traditional ones by the presence of additional quadratic constraints.

In this paper we indicate a new class of problems to which the method (I)–(IV) is applicable. This class not only covers all convex problems but also includes an essential supplement in the region of nonconvex ones. In the description of this class, the main point is the decomposition (1.3) and certain assumptions on the spectral properties of the quadratic forms

$$\mathcal{B}_{\tau^*}(z) := B_{\mathcal{F}}(z,z) + \tau^* B_{\mathcal{G}}(z,z) \tag{1.13}$$

over the linear subspace $\mathfrak{M} := Z - z_0$ $(z_0 \in Z)$ that is a displacement of Z. To illustrate in outline what kind of properties is meant, here we adduce a particular, but suitable for immediate formulation, consequence of the results of this paper.

PROPOSITION 1.1. *In* (1.1) *let H be a real Hilbert space and the subspace Z be closed. Assume that the decomposition* (1.3) *is valid where the mappings $B_{\mathcal{F}}(\cdot,\cdot)$, $B_{\mathcal{G}}(\cdot,\cdot)$ are continuous with respect to the norm $|\cdot|_H$ of H and $\Phi_{\mathcal{F}}(\cdot), \Phi_{\mathcal{G}}(\cdot)$ are continuous with respect to the weak topology of the space H. Also let there exist an element $z_* \in Z$ such that $\mathcal{G}(z_*) \in -\mathrm{int}K_+$. Consider the bounded self-adjoint linear operator $A_{\tau^*} : \mathfrak{M} \to \mathfrak{M}$ that corresponds to the quadratic form* (1.13) $\mathcal{B}_{\tau^*}(z) = \langle A_{\tau^*} z, z\rangle$ $(\forall z \in \mathfrak{M})$. *(The symbol $\langle\cdot,\cdot\rangle$ denotes the inner product in H.)*

If for any $\tau^* \geq 0$ this operator either has no negative isolated eigenvalues of finite geometrical multiplicity at all or, at least, the minimal point of its spectrum is not such an eigenvalue, then relation (1.12) *is true and the method* (I)–(IV) *is valid.*

We recall that an eigenvalue is called *isolated* if some of its neighborhoods has no common points with the spectrum of the operator except for this eigenvalue. The *geometrical multiplicity* of an eigenvalue is merely the dimension of the space of all its eigenvectors.

Both this assertion and the further, more general, results of the paper cannot be applied to problems with a finite-dimensional subspace Z. Nevertheless these results have a series of useful applications to problems of optimal control of dynamical systems (see section 5). To deal with them, it is important that, under the assumptions of this paper, the Lagrangian function $S(\tau^*, z)$ proves to be convex on Z whenever $\tau^* \geq 0$ and $S_0(\tau^*) > -\infty$. This means that *the method of duality* (I)–(IV) *converts the nonconvex problem of global optimization* (1.1) *into two convex problems* (1.5) *and* (1.7).

Indeed, the function $S_0(\tau^*)$ is concave as the infimum (1.6) of the functions (1.4), which are linear in τ^*. So the dual problem (1.7) is convex. (More precisely, it becomes

convex by switching the sign in (1.7) $-S_0(\tau^*) \to \min,\ \ \tau^* \geq 0$.) In (1.7), one obviously can seek the maximum only on the convex domain $\mathcal{R} := \{\tau^* \geq 0 : S_0(\tau^*) > -\infty\}$. In doing so, one has to calculate the value $S_0(\tau^*)$ for $\tau^* \in \mathcal{R}$ by solution of the corresponding problem (1.5), which is also convex as it was remarked above.

The reduction of the primal problem (1.1) to two convex ones brings the possibility to solve it with the aid of the highly developed methods of convex programming. Furthermore, the resultant problems (1.5) and (1.7) are simpler than the original one (1.1) not only for their convexity. While the primal problem (1.1) is infinite dimensional and has a quite complicated admissible domain $D := \{z \in Z : \mathcal{G}(z) \leq 0\}$, the dual problem (1.7) is finite dimensional and the admissible domain Z in the problem (1.5) is quite simple. (It is an affine subspace.) Moreover, in many important applications, the problem (1.5) belongs to a thoroughly investigated class of problems and can be solved easily.

As an example, consider the stationary infinite-horizon linear-quadratic optimal control problem with quadratic inequality constraints. It presents some typical features of problems to be covered by the theory of this paper and is stated as follows:

$$\mathcal{G}_0 \to \min \quad \text{subject to} \tag{1.14}$$

$$\dot{x} = Ax + Bu, \quad x = x(t) \in \mathbb{R}^l, \quad u = u(t) \in \mathbb{R}^m, \quad 0 \leq t < \infty\ , \tag{1.15}$$

$$x(0) = a, \qquad |x(\cdot)| + |u(\cdot)| \in L_2\ , \tag{1.16}$$

$$\mathcal{G}_1 \leq 0, \ldots, \mathcal{G}_k \leq 0, \tag{1.17}$$

where

$$\mathcal{G}_i := \int_0^\infty g_i(x,u)dt - \gamma_i \qquad (i = 0, \ldots, k). \tag{1.18}$$

Here $g_i(x,u) = x^*G_ix + 2x^*Q_iu + u^*\Gamma_iu$ is a quadratic form, the asterisk stands for transposition, A, B, G_i, Q_i, Γ_i are constant matrices, and γ_i are given reals $\gamma_0 = 0$.

Omitting the constraints (1.17), we get the problem (1.14)–(1.16), which was thoroughly investigated in linear-quadratic optimal control theory ([15, 16, 17, 18] and others). This theory places at our disposal quite efficient methods of solution. They include simply verified criteria for the infimum $\mathcal{G}_0^{\inf}$ of the objective functional to be finite. If $\mathcal{G}_0^{\inf} > -\infty$, then solution of the problem ultimately looks like computation of $l \times l$ matrix P and $l \times m$ matrix r [15, 16, 17, 18]. Namely, $\mathcal{G}_0^{\inf} = a^*Pa$ and the optimal process is generated by the closed-loop controller $u = r^*x$ in the so-called regular case (see [19] for the definition). Otherwise, the matrix r is used to construct a minimizing sequence of admissible processes [19]. There are known quite simple and efficient methods to calculate the matrices P and r ([15, 16, 17, 18] and others).

As for the problem (1.14)–(1.18), the above theory did not directly deal with the constraints (1.17), which, however, are of interest for many applications. It was first discovered in [11] that the method (I)–(IV) not only is valid for the problem (1.14)–(1.18)[2] but also *permits us to harness classic linear-quadratic optimal control theory for solution of the problem with the constraints* (1.17).

[2]The same follows from Proposition 1.1; see section 5 for details.

Indeed, rewrite first the problem (1.14)–(1.18) in the form (1.1) with the constraints (1.2)

$$z = [x(\cdot), u(\cdot)], \quad H := L_2\left\{[0, +\infty) \to \mathbb{R}^l\right\} \times L_2\left\{[0, +\infty) \to \mathbb{R}^m\right\},$$

$Z := \{z \in Z : \text{(1.15) and (1.16) are true }\}$, $\mathcal{F} := \mathcal{G}_0$, and $\mathcal{G}_i$ is defined by (1.18). The point to note is that now (1.5) is an ordinary problem of linear-quadratic optimal control theory: *minimize*

$$S[\tau^*, x(\cdot), u(\cdot)] = \int_0^\infty g_\tau(x, u)dt - \gamma_\tau \tag{1.19}$$

subject to the constraints (1.15) *and* (1.16). Here $\tau^* = \tau = \|\tau_i\| \in \mathbb{R}^k$, the function $g_\tau := g_0 + \tau_1 g_1 + \cdots + \tau_k g_k$ is a quadratic form, and $\gamma_\tau := \tau_1\gamma_1 + \cdots + \tau_k\gamma_k$ is a constant. So the problem (1.5) can be solved easily by calculating the corresponding matrices P_τ and r_τ. Then the dual problem (1.7) takes the form $a^*P_\tau a - \gamma_\tau \to \max$. It remains to find its optimum τ^0 and either to generate the solution of the original problem (1.14)–(1.18) by the closed-loop controller $u = r^*_{\tau^0}x$ or to construct a minimizing sequence.

This example underscores the *advantage of the ordinary Lagrangian function* (1.4). This function inherits the quadratic and integral nature of the objective and constraint functionals, and it is for this reason that the effective methods of linear-quadratic optimal control theory can be drawn in solution.

Studies on the validity of the duality method are often related to revealing the convexity or some neighboring properties of the set

$$C_+ := \{\xi = (t, y) \in \mathfrak{Y} := \mathbb{R} \times Y : t \geq \mathcal{F}(z) \text{ and } y \geq \mathcal{G}(z) \text{ for some } z \in Z\}. \tag{1.20}$$

To illustrate their significance, assume that there exists a point $z_* \in Z$ for which $\mathcal{G}(z_*) \in -\mathrm{int}K_+$. Then relation (1.12) is valid if either (A) *the set* (1.20) *is convex* or (B) *its closure* $\overline{C_+}$ *is convex* [2, 13].

For the convex problem (1.1), assertion (A) is apparently true for the convexity of $\mathcal{F}$ and $\mathcal{G}$. There is another research trend, which proves the same assertion by reasons that may ultimately be boiled down to the so-called effect of Lyapunov [2, Chapter 2], [3, pp. 367–373], [20, p. 24]. This paper represents the third research trend, which does not appeal to the above reasons but utilizes the quadratic structure of the functionals under consideration. Its origins may be traced back to the following classic result [21, p. 166].

THEOREM 1.2 (Toeplitz–Hausdorff). *Let H be a complex Hilbert space and $\mathcal{G}_1, \mathcal{G}_2$ be continuous Hermitian forms on H.*

Then the image of the unit sphere $S := \{h \in H : |h| = 1\}$ under the mapping $\mathcal{G} := [\mathcal{G}_1, \mathcal{G}_2]$ is convex.

The following are basic known and quite general facts on the validity of the method (I)–(IV) that are based upon the quadratic structure of the functionals. This method is valid for the problem (1.1) with the constraints (1.2) if either (1) *H is a real linear space, $k = 1$, and $\mathcal{F}$, $\mathcal{G}_1$ are quadratic functionals*[3] [22] or (2) *H is a complex linear space, $k = 2$, and $\mathcal{F}$, $\mathcal{G}_1$, $\mathcal{G}_2$ are quadratic functionals* [23]. In (1) and (2), the number of constraints k cannot be increased because it would lead to the assertions,

[3] A functional $G : H \to \mathbb{R}$ is called *quadratic* if it can be written as the sum $G(h) = \mathcal{B}(h) + \mathrm{Re}l^*z + c$ where $B(h, h) \in \mathbb{R}$ is a quadratic (Hermitian in the case of a complex space H) form, $l^* \in H^*$ is a linear functional, and $c \in \mathbb{R}$.

which are wrong in general [23]. In [11, 14], the method (I)–(IV) was justified for the problem (1.14)–(1.18) with $\mathcal{G}_i$ being the sum of the integral (1.18) and a linear continuous functional on $L_2 \times L_2$. The backbone of the approach taken in [11, 14] was a result of [24] on the convexity of the set $\overline{\mathcal{G}(\mathfrak{M})} \subset R^k$. Here $\mathfrak{M}$ is the collection of all pairs $[x(\cdot),\ u(\cdot)]$ satisfying (1.15), (1.16) with $a := 0$ and $\mathcal{G} := [\mathcal{G}_1, \dots, \mathcal{G}_k]$ where $\mathcal{G}_i$ is defined by (1.18). In [11, 14], the method (I)–(IV) was also justified for certain specific abstract linear-quadratic problems with a finite [11] or infinite [14] number of inequality constraints. A generalization on the case when there also is a finite number of equality constraints was considered in [13]. Applications of the foregoing theory to stationary optimal control problems were considered in [11, 12, 13, 14].

All the results mentioned either impose very strong restrictions on the dimension of the space Y [22, 23] or appeal explicitly or implicitly to the periodicity or the stationarity of the problem [11, 12, 13, 14, 24]. This paper presents a more general approach and enlarges the class of problems to which the method (I)–(IV) is proven to be applicable. This approach does not appeal to the periodicity of the problem and it does not involve restrictions on $\dim Y$. Instead, this approach is actually related to new extensions of the founding Toeplitz–Hausdorff theorem. Since we do not need the explicit formulation of these extensions to prove our results, we state an example of such an extension here only to reveal the underlying ideas.

Let V be a linear space. A set $C \subset V$ is called *almost convex* if there exists a convex set $C_0 \subset V$ such that $C_0 \subset C \subset \overline{C_0}$.

THEOREM 1.3. *Let H be a real Hilbert space and $\mathcal{G}_1, \dots, \mathcal{G}_k$ be continuous quadratic forms on H. Given $\tau = \|\tau_i\| \in \mathbb{R}^k$, consider the quadratic form $\mathcal{G}_\tau(z) := \tau_1\mathcal{G}_1(z) + \dots + \tau_k\mathcal{G}_k(z) = \langle A_\tau z, z\rangle$, where A_τ is the corresponding self-adjoint bounded linear operator. Denote by $\sigma(A_\tau)$ its spectrum.*

If for any $\tau \in \mathbb{R}^k$ the extreme (i.e., the minimal and the maximal) points of the spectrum $\sigma(A_\tau)$ are not isolated eigenvalues of finite geometrical multiplicity, then the image of the unit sphere $S := \{z \in H : |z| = 1\}$ under the mapping $\mathcal{G}(z) := [\mathcal{G}_1(z), \dots, \mathcal{G}_k(z)]$ is almost convex.

The proof of this theorem will be given in section 3 below.[4]

The body of the paper is organized as follows. In section 2, we state our main results. They deal with the abstract problem (1.1). The proof of these results is given in section 4, which is prefaced with the study of vector-valued quadratic forms in section 3. The approach taken in this section develops some ideas and constructions from [27] as well as from [11, 13, 24]. Section 5 is devoted to applications of the general theory developed in the paper. We indicate there a series of infinite-horizon nonstationary and nonconvex optimal control problems to which the method (I)–(IV) is applicable. An example of its application is given in section 6.

Note in conclusion that, according to Lemma 1.1 of [13], results on the applicability of the method (I)–(IV) can be interpreted as criteria for equivalence of the following two conditions (A) and (B). (A) $\mathcal{F}(z) \geq 0$ *in the domain* $z \in Z$, $\mathcal{G}(z) \leq 0$. (B) *There exists a functional* $\tau^* \geq 0$ *such that* $S(\tau^*, z) \geq 0$ *for all* $z \in Z$, *where* $S(\tau^*, z)$ *is the Lagrangian function* (1.4). Called the *S-procedure*, the substitution (B) in place of (A) is used in the theory of stability [22], in the theory of H_∞-optimization, in the theory of robustness of uncertain systems [24], and also in some other branches

[4] In [25, 26], the reader may find a result that is close to another extension of the Toeplitz–Hausdorff theorem that also deals with an arbitrary number of forms but differs from Theorem 1.3 in assumptions.

of systems and control theory [28]. Thus, this paper indicates new cases when the S-procedure is applicable.

2. Statement of basic results. Given $y_1, y_2 \in Y$, the strict inequalities $y_1 < y_2$ and $y_2 > y_1$ denote the inclusion $y_2 - y_1 \in \mathrm{int}K_+$.

DEFINITION 2.1. *The problem* (1.1) *is called regular if there exists an element* $z_* \in Z$ *such that*

$$\mathcal{G}(z_*) < 0. \tag{2.1}$$

Given a topological space X, the *limit inferior* of a function $f : X \to \mathbb{R}$ at a point $x_0 \in X$ is defined as

$$\varliminf_{x \to x_0} f(x) := \liminf_{x \to x_0} f(x) := \sup_{V \in \mathcal{O}(x_0)} \inf_{x \in V} f(x). \tag{2.2}$$

Here $\mathcal{O}(x_0)$ is the collection of all neighborhoods of the point x_0. The following theorem offers a criterion for the method (I)–(IV) to be applicable.

THEOREM 2.2. *In* (1.1) *let* Z *be an affine subspace of a real locally convex topological linear space* H*, and let the finite-dimensional linear space* Y *be ordered with a convex cone* K_+*, which contains an interior point. Let also the functions* $\mathcal{F} : H \to \mathbb{R}$ *and* $\mathcal{G} : H \to Y$ *be given. Assume that*

(A) *the decomposition* (1.3) *is valid where* $B_{\mathcal{F}} : H \times H \to \mathbb{R}$ *and* $B_{\mathcal{G}} : H \times H \to Y$ *are bilinear symmetric mappings and the functions* $\Phi_{\mathcal{F}} : H \to \mathbb{R}, \Phi_{\mathcal{G}} : H \to Y$ *are continuous and convex on* Z*;*

(B) *given* $z \in Z$*, the linear operators* $B_{\mathcal{F}}(z, \cdot)$ *and* $B_{\mathcal{G}}(z, \cdot)$ *are continuous on the linear subspace* $\mathfrak{M} := Z - z_0 \quad (z_0 \in Z)$ *that is a displacement of* Z*;*

(C) *given* $\tau^* \in Y^*, \tau^* \geq 0$*, the quadratic form* (1.13) *has the following property:*

$$\mathcal{B}_{\tau^*}(h) < 0 \quad \textit{for some} \quad h \in \mathfrak{M} \Longrightarrow \varliminf_{\substack{h \to 0 \\ h \in \mathfrak{m}}} \mathcal{B}_{\tau^*}(h) < 0. \tag{2.3}$$

If, in addition, the problem (1.1) *is regular, then relation* (1.12) *is true and the method* (I)–(IV) *is valid. Furthermore, the Lagrangian function* (1.4) *is convex on* Z *and the quadratic form* (1.13) *is nonnegative on* $\mathfrak{M}$ *provided that* $\tau^* \geq 0$ *and the infimum* (1.6) *is finite.*

The proof of this theorem will be given in section 4 below.

It easily follows from (2.2) that $\varliminf_{x \to 0} f(x) = \varliminf_{x \to 0} f(\rho x)$ for any $\rho > 0$ and also that $\varliminf_{x \to 0} f(x) \leq 0$ provided $f(0) = 0$. Picking here $X := \mathfrak{M}, f(x) := \mathcal{B}_{\tau^*}(x)$, we get

$$\sigma_{\lim}(\tau^*) := \varliminf_{\substack{h \to 0 \\ h \in \mathfrak{m}}} \mathcal{B}_{\tau^*}(h) = \varliminf_{\substack{h \to 0 \\ h \in \mathfrak{m}}} \mathcal{B}_{\tau^*}(\rho h) = \rho^2 \sigma_{\lim}(\tau^*) \leq 0 \qquad \forall \rho > 0.$$

This implies that either $\sigma_{\lim}(\tau^*) = 0$ or $\sigma_{\lim}(\tau^*) = -\infty$. So the inequality $\sigma_{\lim}(\tau^*) < 0$ from (2.3) is equivalent to the equality $\sigma_{\lim}(\tau^*) = -\infty$.

The following two lemmas are useful to verify assumption (C) of Theorem 2.2.

LEMMA 2.3. *Any of the following assumptions* (C.1)–(C.3) *implies assumption* (C) *of Theorem* 2.2.

(C.1) *If* $\tau^* \in Y^*$, $\tau^* \geq 0$, $h \in \mathfrak{M}$*, and* $\mathcal{B}_{\tau^*}(h) < 0$*, then there exists a sequence* $\{h_n\}_{n=0}^{\infty} \subset \mathfrak{M}$ *such that*

$$h_n \to 0 \quad \textit{as} \quad n \to \infty, \quad \varliminf_{n \to \infty} \mathcal{B}_{\tau^*}(h_n) < 0. \tag{2.4}$$

(C.2) *For any* $\tau^* \in Y^*,\ \tau^* \geq 0$, *and* $h \in \mathfrak{M}$, *there exists a sequence* $\{h_n\}_{n=0}^{\infty} \subset \mathfrak{M}$ *such that*

$$h_n \to 0 \quad as \quad n \to \infty, \quad \liminf_{n\to\infty} \mathcal{B}_{\tau^*}(h_n) \leq \mathcal{B}_{\tau^*}(h). \tag{2.5}$$

(C.3) *There exists a sequence of mappings* $T_n : H \to H,\ n = 0, 1, \ldots$ *such that* $T_n\mathfrak{M} \subset \mathfrak{M}$ *for all* n *and*

$$B_{\mathcal{P}}(T_n h, T_n h) \to B_{\mathcal{P}}(h, h),\ T_n h \to 0 \ \ as \ \ n \to \infty \ \ (\forall h \in \mathfrak{M},\ \mathcal{P} := \mathcal{F}, \mathcal{G}). \tag{2.6}$$

Here $B_{\mathcal{F}}$ *and* $B_{\mathcal{G}}$ *are the quadratic summands in the decomposition* (1.3).

Proof. The proof comes from the chain of obvious implications (C.3) $\Rightarrow$ (C.2) $\Rightarrow$ (C.1) $\Rightarrow$ (C). □

In [11, 13, 14], the validity of the method (I)–(IV) was proved under assumptions, which included (C.3) with T_n being linear continuous operators.

In many applications, H is introduced to be a Hilbert space equipped with the corresponding weak topology. In this case, the limit inferior from (2.3) can be calculated explicitly. To do this, we recall some notions.

Let X be a real Hilbert space and $\mathcal{B} : X \to \mathbb{R}$ be a continuous quadratic form. A linear subspace $L \subset X$ is called $\mathcal{B}$-*negative* iff $\mathcal{B}(x) < 0$ whenever $x \in L$ and $x \neq 0$. The *(negative) index of inertia* $n_-[\mathcal{B}(\cdot)]$ of the form $\mathcal{B}(\cdot)$ is defined to be the least upper bound of $\dim L$ over all $\mathcal{B}$-negative linear subspaces $L \subset X$. Consider the self-adjoint continuous linear operator $A : X \to X$ that corresponds to the form $\mathcal{B}(x) = \langle Ax, x\rangle$. If its spectrum $\sigma(A)$ contains no negative points, then $n_-[\mathcal{B}(\cdot)] = 0$. If any point $\lambda \in \sigma(A) \cap (-\infty, 0)$ is an eigenvalue, then $n_-[\mathcal{B}(\cdot)] = \sum \deg\lambda$ where the sum is over $\lambda \in \sigma(A) \cap (-\infty, 0)$ and $\deg\lambda$ is the geometrical multiplicity of the eigenvalue λ. In general, $n_-[\mathcal{B}(\cdot)] = \dim \mathrm{Im} P\{(-\infty, 0)\}$, where $P(d\lambda)$ is the resolution of the identity for the operator A [29, p. 889].

LEMMA 2.4. *Let* X *be a real Hilbert space and* $\mathcal{B} : X \to \mathbb{R}$ *be a scalar quadratic form. Assume that the form* $\mathcal{B}$ *is continuous with respect to the norm of* X. *Then*

$$\sigma_{\lim} := \liminf_{x \rightharpoonup 0} \mathcal{B}(x) = \begin{cases} 0 & if \ \ n_-[\mathcal{B}(\cdot)] < \infty, \\ -\infty & if \ \ n_-[\mathcal{B}(\cdot)] = \infty. \end{cases} \tag{2.7}$$

Here the arrow $\rightharpoonup$ *denotes the convergence with respect to the weak topology.*

Proof. Since $\sigma_{\lim} = 0, -\infty$, it suffices to show that $\sigma_{\lim} = 0 \Leftrightarrow n_-[\mathcal{B}(\cdot)] < \infty$.

Let $\sigma_{\lim} = 0$. By (2.2), there exists a weak neighborhood V of the origin such that $c_-(V) := \inf_{x\in V} \mathcal{B}(x) > -\infty$. By the definition of the weak topology, we can pick linear functionals $m_1^*, \ldots, m_p^* \in X^*$ and a real $\epsilon > 0$ such that $V \supset \{x : |m_i^* x| < \epsilon,\ i = 1, \ldots, p\}$. Introducing the linear subspace $M := \{x : m_1^* x = 0, \ldots, m_p^* x = 0\}$, we have $M \subset V$ and, therefore, $\mathcal{B}(x) \geq c_-(V)$ for all $x \in M$. Here, putting $x := \rho x$ and letting $\rho \to \infty$ result in the inequality $\mathcal{B}(x) \geq 0$. Thus,

$$\boxed{m_1^* x = 0, \ldots, m_p^* x = 0} \Longrightarrow \mathcal{B}(x) \geq 0. \tag{2.8}$$

Show that $n_-[\mathcal{B}(\cdot)] \leq p$. Suppose to the contrary that $n_-[\mathcal{B}(\cdot)] \geq p + 1$. Then there exists a linear subspace $L \subset X$ such that $\dim L = p + 1$ and $\mathcal{B}(x) < 0$ whenever $x \in L$ and $x \neq 0$. Choose a basis of this subspace $e_1, \ldots, e_{p+1}$. The system of p linear algebraic equations

$$\sum_{i=1}^{p+1} \alpha_i \left(m_j^* e_i\right) = 0 \quad (\forall j = 1, \ldots, p)$$

has a nonzero solution $\alpha_1, \ldots, \alpha_{p+1}$. Then $x := \alpha_1 e_1 + \cdots + \alpha_{p+1} e_{p+1} \neq 0,\ x \in L$, and so $\mathcal{B}(x) < 0$ by the choice of L. But, on the other hand, $m_j^* x = 0$ for $j = 1, \ldots, p$ and, hence, $\mathcal{B}(x) \geq 0$ due to (2.8). This contradiction proves that $n_-[\mathcal{B}(\cdot)] \leq p < \infty$. Thus $\sigma_{\lim} = 0 \Rightarrow n_-[\mathcal{B}(\cdot)] < \infty$.

Conversely, let $n_-[\mathcal{B}(\cdot)] < \infty$. Consider the self-adjoint continuous linear operator $A : X \to X$ that corresponds to $\mathcal{B}$. Let $P(d\lambda)$ be its resolution of the identity [29, p. 889]. Denoting $P_- := P\{(-\infty, 0)\}$, we have $\dim \operatorname{Im} P_- = n_-[\mathcal{B}(\cdot)] < \infty$. From this it follows that P_- is a continuous operator from the space X endowed with the weak topology into the same space equipped with the norm topology. So the set $V := \{x : |P_- x| < 1\}$ is a weak neighborhood of the origin. Denote $-\lambda_- := \min_{\lambda \in \sigma(A)} \lambda$ and $-\lambda_-^0 := \min\{-\lambda_-,\ 0\}$, where $\sigma(A)$ is the spectrum of A. Given $x \in V$, we have [29, pp. 893, 899]

$$\mathcal{B}(x) = \int_{-\infty}^{+\infty} \lambda \ \ \langle P(d\lambda)x, x\rangle = \int_{(-\infty,0)} \lambda \ \ \langle P(d\lambda)x, x\rangle + \int_0^{\infty} \lambda \ \ \langle P(d\lambda)x, x\rangle$$

$$\geq \int_{\left[-\lambda_-^0, 0\right)} \lambda \ \ \langle P(d\lambda)x, x\rangle \geq -\lambda_-^0 \ \ \langle P_- x, x\rangle = -\lambda_-^0 \, |P_- x|^2 \geq -\lambda_-^0 > -\infty.$$

Passing to the infimum over $x \in V$ and taking into account equation (2.2), we get $\sigma_{\lim} := \liminf_{x \to 0} \mathcal{B}(x) \geq -\lambda_-$. Since $\sigma_{\lim} = 0, -\infty$, we have the equality desired: $\sigma_{\lim} = 0$. □

An immediate consequence of Lemma 2.4 is the following useful corollary.

COROLLARY 2.5. *Let the assumptions of Theorem* 2.2 *be fulfilled except for* (B), (C)*, and let H be a real Hilbert space endowed with the weak topology. Also let the mappings $B_{\mathcal{F}}(\cdot,\cdot), B_{\mathcal{G}}(\cdot,\cdot)$ be continuous with respect to the norm of H and let Z be closed. Then assumption* (B) *of Theorem* 2.2 *is satisfied, and assumption* (C) *of this theorem is equivalent to the following assertion.*

Given $\tau^* \in Y^*,\ \tau^* \geq 0$, the next implication takes place for the quadratic form (1.13)

$$n_-[\mathcal{B}_{\tau^*}|_{\mathfrak{m}}] \neq 0 \Longrightarrow n_-[\mathcal{B}_{\tau^*}|_{\mathfrak{m}}] = \infty. \tag{2.9}$$

In particular, if this assertion is valid, then the conclusion of Theorem 2.2 *is true.*

Proof. Since $\dim Y < \infty$ and the operators $B_{\mathcal{F}}(z,\cdot), B_{\mathcal{G}}(z,\cdot)$ are continuous with respect to the norm of H, they are also continuous with respect to the weak topology; i.e., assumption (B) of Theorem 2.2 is valid. Note that $n_-[\mathcal{B}_{\tau^*}|_{\mathfrak{m}}] \neq 0 \Leftrightarrow \mathcal{B}_{\tau^*}(h) < 0$ for some $h \in \mathfrak{M}$. So (2.9) implies (2.3) by (2.7). Thus, assumption (C) of Theorem 2.2 is true. □

Let the affine subspace Z be closed. Denote by $\sigma(A_{\tau^*})$ the spectrum of the bounded self-adjoint linear operator $A_{\tau^*} : \mathfrak{M} \to \mathfrak{M}$ that corresponds to the quadratic form (1.13) $\mathcal{B}_{\tau^*}(h) = \langle A_{\tau^*} h, h\rangle\ (\forall h \in \mathfrak{M})$. It is well known that the inequality $n_-[\mathcal{B}_{\tau^*}|_{\mathfrak{m}}] < \infty$ is true if and only if the negative part of the spectrum $\sigma(A_{\tau^*}) \cap (-\infty, 0)$ either is empty or consists of a finite number of eigenvalues each having finite geometrical multiplicity. Consequently, *the implication* (2.9) *means that the second case does not take place for any $\tau^* \geq 0$.* Thus, Proposition 1.1 readily follows from Corollary 2.5.

3. Upper limitrophe cones of quadratic forms. This section provides preliminary studies to be used further in the demonstration of Theorem 2.2.

Throughout the section, $\mathfrak{M}$ is a real locally convex linear topological space and Y is a real finite-dimensional linear space ordered with a nonempty convex cone $K_+ \subset Y$. Now we do not insist on its interior to be nonempty. A function $\mathcal{B} : \mathfrak{M} \to Y$ is called *(vector) quadratic form* iff it can be represented as follows $\mathcal{B}(h) = B(h,h)$ with $B(\cdot,\cdot)$ being a bilinear symmetric mapping $B : \mathfrak{M} \times \mathfrak{M} \to Y$. This mapping is determined uniquely by the simply verified formula $B(h_1,h_2) = 1/4\,[\mathcal{B}(h_1+h_2) - \mathcal{B}(h_1-h_2)]$. It shows that the continuity of the form $\mathcal{B}(\cdot)$ is equivalent to the continuity of the mapping $B(\cdot,\cdot)$.

The *upper image* of a set $V \subset \mathfrak{M}$ under a mapping $f : \mathfrak{M} \to Y$ is defined by $f(V)^+ := \{y \in Y : y \geq f(h) \text{ for some } h \in V\} = f(V) + K_+$. Let $\mathcal{B} : \mathfrak{M} \to Y$ be a quadratic form. Denote by $\mathcal{O}$ the collection of all neighborhoods $V \subset \mathfrak{M}$ of the origin. The set

$$\mathcal{K}^+(\mathcal{B}) := \bigcap_{V \in \mathcal{O}} \overline{\mathcal{B}(V)^+} \tag{3.1}$$

is called the *upper limitrophe cone* of the form $\mathcal{B}$. If $K_+ = \{0\}$, the adjective "upper" and the index $^+$ are dropped.

The usage of the term "cone" with respect to the set (3.1) is justified by the following lemma.

LEMMA 3.1. *Let $\mathcal{B} : \mathfrak{M} \to Y$ be a quadratic form.*

(a) *The set* (3.1) *is a cone; i.e., $\rho\mathcal{K}^+(\mathcal{B}) \subset \mathcal{K}^+(\mathcal{B})$ for all $\rho \geq 0$.*

(b) *The upper limitrophe cone* (3.1) *is closed and $K_+ \subset \mathcal{K}^+(\mathcal{B})$.*

(c) *If the form $\mathcal{B}$ is bounded on some neighborhood $V_0 \in \mathcal{O}$, then $\mathcal{K}^+(\mathcal{B}) = \overline{K_+}$.*

Proof. (a) Let $\rho > 0$. By (3.1), we have

$$\rho\mathcal{K}^+(\mathcal{B}) = \bigcap_{V \in \mathcal{O}} \rho\left[\overline{\mathcal{B}(V)^+}\right] = \bigcap_{V \in \mathcal{O}} \overline{\rho\mathcal{B}(V)^+} = \bigcap_{V \in \mathcal{O}} \overline{\rho\left[\mathcal{B}(V) + K_+\right]}$$

$$= \bigcap_{V \in \mathcal{O}} \overline{[\rho\mathcal{B}(V) + \rho K_+]} = \bigcap_{V \in \mathcal{O}} \overline{\mathcal{B}(\sqrt{\rho}V) + K_+} = \bigcap_{V \in \mathcal{O}} \overline{\mathcal{B}(\sqrt{\rho}V)^+}.$$

Here $\sqrt{\rho}V$ runs over $\mathcal{O}$ provided that V does so. This means that the last intersection coincides with (3.1) and $\rho\mathcal{K}^+(\mathcal{B}) = \mathcal{K}^+(\mathcal{B})$. If $\rho = 0$, then $\rho\mathcal{K}^+(\mathcal{B}) = \{0\} \subset \mathcal{K}^+(\mathcal{B})$.

(b) The proof is obvious.

c) Since (b) implies the inclusion $\overline{K_+} \subset \mathcal{K}^+(\mathcal{B})$, it remains to prove the opposite one, $\mathcal{K}^+(\mathcal{B}) \subset \overline{K_+}$. Let $y \in \mathcal{K}^+(\mathcal{B})$. Choose $\rho > 0, \epsilon > 0$. Since $\rho V_0 \in \mathcal{O}$, we have, by (3.1), $y \in \overline{\mathcal{B}\,(\rho V_0)^+}$ and so $y = \mathcal{B}(\rho h_{\rho,\epsilon}) + y^+_{\rho,\epsilon} + \delta y_{\rho,\epsilon}$ for some $h_{\rho,\epsilon} \in V_0, y^+_{\rho,\epsilon} \in K_+, |\delta y_{\rho,\epsilon}| < \epsilon$. Here $|\mathcal{B}\,(\rho h_{\rho,\epsilon})\,| \leq \rho^2 c$ with $c := \sup\{|\mathcal{B}(h)| : h \in V_0\}$ being finite by the assumption. Consequently, $\mathcal{B}\,(\rho h_{\rho,\epsilon}) \to 0, \delta y_{\rho,\epsilon} \to 0$ as $\rho \to +0, \epsilon \to +0$, and the above decomposition of y implies that $y^+_{\rho,\epsilon} \to y$ as $\rho \to +0, \epsilon \to +0$; i.e., $y \in \overline{K_+}$. □

The boundedness of the form $\mathcal{B}$ on some neighborhood V_0 follows from the continuity of $\mathcal{B}$. So, by Lemma 3.1(c), nontrivial upper limitrophe cones are associated with discontinuous forms only. A widespread situation to produce such a cone is the following: $\mathfrak{M}$ is a Hilbert space endowed with the weak topology, and the form $\mathcal{B}$ is continuous with respect to the strong topology of $\mathfrak{M}$ but is not continuous with respect to the weak one. In this case, the form $\mathcal{B}$ apparently has the following important property.

ASSUMPTION 3.1. *Consider the bilinear symmetric mapping $B : \mathfrak{M} \times \mathfrak{M} \to Y$ associated with the quadratic form $\mathcal{B}$. Given $h \in \mathfrak{M}$, the linear operator $B(h, \cdot) : \mathfrak{M} \to Y$ is continuous.*

The usefulness of the notion of upper limitrophe cone is predetermined in part by the following fact.

LEMMA 3.2. *Let Assumption* 3.1 *be fulfilled. Then the upper limitrophe cone* (3.1) *is convex. Furthermore,*

$$\overline{\mathcal{B}(V)^+} + \mathcal{K}^+(\mathcal{B}) \subset \overline{\mathcal{B}(V)^+} \tag{3.2}$$

for any convex neighborhood $V \subset \mathfrak{M}$ of the origin.

Proof. Note first that (3.2) ensures the convexity of the cone (3.1). Indeed, denote by $\mathcal{O}_{conv}$ the collection of all convex neighborhoods of the origin. Since the topology of $\mathfrak{M}$ is locally convex, one can obviously substitute $\mathcal{O}_{conv}$ for $\mathcal{O}$ in (3.1). Then (3.2) immediately results in the inclusion $\mathcal{K}^+(\mathcal{B}) + \mathcal{K}^+(\mathcal{B}) \subset \mathcal{K}^+(\mathcal{B})$ where $\mathcal{K}^+(\mathcal{B})$ is a cone by (a) of Lemma 3.1. This implies that the cone $\mathcal{K}^+(\mathcal{B})$ is convex [8, p. 14].

Thus, it suffices to prove (3.2). Let $V \in \mathcal{O}_{conv}$ and $y \in \overline{\mathcal{B}(V)^+} + \mathcal{K}^+(\mathcal{B}) = \overline{\mathcal{B}(V) + K_+} + \mathcal{K}^+(\mathcal{B})$. Choose $\epsilon > 0$ and $\kappa > 0$. Then $y = \mathcal{B}(z) + y^+ + y_0 + \delta y$ for some $z \in V, y^+ \in K_+, y_0 \in \mathcal{K}^+(\mathcal{B})$, and $|\delta y| < \epsilon$. By Assumption 3.1, the operator $B(z, \cdot)$ is continuous and so the set $V' := \{z' \in \kappa V : |B(z, z')| < \epsilon\}$ is a neighborhood of the origin. By (3.1), $y_0 \in \overline{\mathcal{B}(V')^+}$ and we have $y_0 = \mathcal{B}(z') + y_0^+ + \delta y_0$ where $z' \in V', y_0^+ \in K_+$, and $|\delta y_0| < \epsilon$. Hence

$$\begin{aligned} y &= \mathcal{B}(z) + y^+ + \delta y + y_0 = \mathcal{B}(z) + \mathcal{B}(z') + y^+ + y_0^+ + \delta y + \delta y_0 \\ &= \mathcal{B}(\underbrace{z + z'}_{z_{\epsilon,\kappa}}) + \underbrace{y^+ + y_0^+}_{y^+_{\epsilon,\kappa}} + \underbrace{\delta y - 2B(z, z') + \delta y_0}_{\delta y_{\epsilon,\kappa}}. \end{aligned} \tag{3.3}$$

Here $|\delta y_{\epsilon,\kappa}| \le |\delta y| + |\delta y_0| + 2|B(z, z')| \le 4\epsilon$. Let $\epsilon \to +0$. Then (3.3) means that $\mathcal{B}(z_{\epsilon,\kappa}) + y^+_{\epsilon,\kappa} \to y$ where $y^+_{\epsilon,\kappa} \in K_+$ and $z_{\epsilon,\kappa} = z + z' \in V + \kappa V = (1 + \kappa)V$. So $y \in \overline{\mathcal{B}\left[(1 + \kappa)V\right]^+} = (1 + \kappa)^2 \overline{\mathcal{B}(V)^+}$. Dividing by $(1 + \kappa)^2$ and letting $\kappa \to 0$, we get the inclusion $y \in \overline{\mathcal{B}(V)^+}$ where the vector $y \in \overline{\mathcal{B}(V)^+} + \mathcal{K}^+(\mathcal{B})$ is arbitrary. Thus, (3.2) is true. □

Given a normed space X and a set $Q \subset X$, the symbol ri$Q$ denotes the *relative interior* of the set Q, i.e., its interior in the affine hull aff$Q$ of the set Q.

The next lemma offers an important dual characterization of upper limitrophe cones.

LEMMA 3.3. *Let $\mathcal{B} : \mathfrak{M} \to Y$ be a quadratic form and Assumption* 3.1 *be fulfilled. Denote*

$$\mathcal{E}^*_+(\mathcal{B}) := \left\{\tau^* \in Y^* : \tau^* \ge 0 \ \text{ and } \ \inf_{h \in V} \tau^* \mathcal{B}(h) > -\infty \ \text{ for some } \ V \in \mathcal{O}\right\}, \tag{3.4}$$

where $\mathcal{O}$ is the collection of all neighborhoods of the origin. Then

$$\mathcal{K}^+(\mathcal{B}) = \left\{y \in Y : \tau^* y \ge 0 \ \text{ for all } \ \tau^* \in \mathcal{E}^*_+(\mathcal{B})\right\}, \tag{3.5}$$

where $\mathcal{K}^+(\mathcal{B})$ is the upper limitrophe cone (3.1).

Proof. If $y \in Y \Rightarrow y = 0$, the lemma is obvious. Let Y contain a nonzero vector. By Lemmas 3.1 and 3.2, $\mathcal{K}^+(\mathcal{B})$ is a closed convex cone. So the positive conjugate cone

$$\mathcal{P}^*(\mathcal{B}) := \left\{\tau^* \in Y^* : \tau^* y \ge 0 \ \text{ for all } \ y \in \mathcal{K}^+(\mathcal{B})\right\} \tag{3.6}$$

restores $\mathcal{K}^+(\mathcal{B})$ by the formula [8, p. 121]

$$\mathcal{K}^+(\mathcal{B}) = \{y \in Y : \tau^* y \geq 0 \ \text{ for all } \ \tau^* \in \mathcal{P}^*(\mathcal{B})\}.$$

Here the cone $\mathcal{P}^*(\mathcal{B})$ obviously can be replaced by any set $\mathcal{E}_+^* \subset Y^*$ such that $\overline{\mathcal{E}_+^*} = \mathcal{P}^*(\mathcal{B})$. Putting $\mathcal{E}_+^* := \mathcal{E}_+^*(\mathcal{B})$ entails (3.5) and so it suffices to prove the relation $\overline{\mathcal{E}_+^*(\mathcal{B})} = \mathcal{P}^*(\mathcal{B})$. Since $\mathcal{P}^*(\mathcal{B}) = \overline{\mathrm{ri}\,\mathcal{P}^*(\mathcal{B})}$ [8, p. 46], the equality desired results from the following inclusions to be demonstrated in the remainder of the proof:

$$\mathrm{ri}\mathcal{P}^*(\mathcal{B}) \subset \mathcal{E}_+^*(\mathcal{B}) \subset \mathcal{P}^*(\mathcal{B}). \tag{3.7}$$

We start with the second inclusion. Let $\tau^* \in \mathcal{E}_+^*(\mathcal{B})$. Then, by (3.4), $\tau^* \geq 0$ and $c(\tau^*, V) := \inf_{h \in V} \tau^* \mathcal{B}(h) > -\infty$ for some $V \in \mathcal{O}$. Choose $\epsilon > 0$ and consider $y \in \mathcal{B}(\epsilon V)^+$. It is clear that $y = \epsilon^2 \mathcal{B}(h) + y^+$ for some $h \in V$ and $y^+ \in K_+$. So

$$\tau^* y = \epsilon^2 \tau^* \mathcal{B}(h) + \tau^* y^+ \geq \epsilon^2 \tau^* \mathcal{B}(h) \geq \epsilon^2 \inf_{h' \in V} \tau^* \mathcal{B}(h') = \epsilon^2 c(\tau^*, V)$$

or finally $\tau^* y \geq \epsilon^2 c(\tau^*, V)$ for all $y \in \mathcal{B}(\epsilon V)^+$. By continuity, this inequality spreads on all $y \in \overline{\mathcal{B}(\epsilon V)^+}$ where $\overline{\mathcal{B}(\epsilon V)^+} \supset \mathcal{K}^+(\mathcal{B})$ due to (3.1). Letting $\epsilon \to +0$ and taking into account (3.6), we get the second inclusion in (3.7).

To demonstrate the first inclusion in (3.7), we first assume that *the cone* $\mathcal{K}^+(\mathcal{B})$ *includes no lines.* Then $\mathrm{aff}\mathcal{P}^*(\mathcal{B}) = Y^*$ [8, p. 126] and so $\mathrm{int}\mathcal{P}^*(\mathcal{B}) = \mathrm{ri}\mathcal{P}^*(\mathcal{B}) \neq \emptyset$. Let $\tau^* \in \mathrm{int}\mathcal{P}^*(\mathcal{B})$ and $\tau^* \neq 0$. There exists $\epsilon > 0$ such that $\delta\tau^* \in Y^*$ and $|\delta\tau^*| \leq \epsilon \Rightarrow \tau^* - \delta\tau^* \in \mathcal{P}^*(\mathcal{B})$. Given $y \in \mathcal{K}^+(\mathcal{B})$, by (3.6), we have $0 \leq (\tau^* - \delta\tau^*)\, y = \tau^* y - \delta\tau^* y$ and so $\tau^* y \geq \delta\tau^* y$. By passing to the maximum over $\delta\tau^* \in Y^*$ with $|\delta\tau^*| \leq \epsilon$, we get

$$\tau^* y \geq \epsilon |y| \qquad (\forall y \in \mathcal{K}^+(\mathcal{B})). \tag{3.8}$$

This and (b) of Lemma 3.1 ensure, in particular, that $\tau^* \geq 0$.

Assume that $\tau^* \overline{\in} \mathcal{E}_+^*(\mathcal{B})$. Given a convex neighborhood V of the origin, $c(\tau^*, V) = -\infty$ due to (3.4). So $\tau^* \mathcal{B}(h) \leq -\|\tau^*\|$ for some $h \in V$. Here $\tau^* \mathcal{B}(h) \geq -\|\tau^*\| |\mathcal{B}(h)|$. Hence $-\|\tau^*\| \geq -\|\tau^*\| |\mathcal{B}(h)|$ and so $|y'| \geq 1$ for $y' := \mathcal{B}(h)$. Putting $y := y'|y'|^{-1}$, we have $y = \mathcal{B}(|y'|^{-\frac{1}{2}} h) \in \overline{\mathcal{B}(V)^+}$, $|y| = 1$, and $\tau^* y = |y'|^{-1} \tau^* \mathcal{B}(h) \leq 0$. This means that the following compact set $C(V)$ is not empty

$$C(V) := \left\{ y \in Y : |y| = 1, \tau^* y \leq 0, y \in \overline{\mathcal{B}(V)^+} \right\}. \tag{3.9}$$

Given a finite number of neighborhoods of the origin $V_1, \ldots, V_N \in \mathcal{O}$, there exists a convex neighborhood $V_0 \in \mathcal{O}$ such that $V_0 \subset V_1 \cap \cdots \cap V_N$. It is easy to see that $C(V_0) \subset C(V_1) \cap \cdots \cap C(V_N)$ where $C(V_0) \neq \emptyset$ by the foregoing. Then, in accordance with the generalized principle of Cantor, $C_\infty := \bigcap_{V \in \mathcal{O}} C(V) \neq \emptyset$. Choose $y \in C_\infty$. By (3.9), $\tau^* y \leq 0, |y| = 1$, and $y \in \bigcap_{V \in \mathcal{O}} \overline{\mathcal{B}(V)^+} = \mathcal{K}^+(\mathcal{B})$. These relations apparently contradict (3.8).

So we are forced to reject the assumption $\tau^* \overline{\in} \mathcal{E}_+^*(\mathcal{B})$ and to recognize that $\tau^* \in \mathcal{E}_+^*(\mathcal{B})$ whenever $\tau^* \in \mathrm{ri}\mathcal{P}^*(\mathcal{B})$. Let us proceed to the case when *the cone* $\mathcal{K}^+(\mathcal{B})$ *includes lines.* Reduce this case to the previous one. To this end, consider the linear subspace $L := \mathcal{K}^+(\mathcal{B}) \cap [-\mathcal{K}^+(\mathcal{B})]$, the quotient space $\widehat{Y} := Y/L$, and the canonical projection $\pi : Y \to \widehat{Y}$. Let us order the space $\widehat{Y}$ with the cone $\widehat{K}_+ := \pi(K_+)$. The quadratic form $\widehat{\mathcal{B}}(\cdot) := \pi \circ \mathcal{B}$ obviously satisfies all the assumptions of Lemma 3.3. We are going to show first that

$$\pi^{-1} \mathcal{K}^+(\widehat{\mathcal{B}}) = \mathcal{K}^+(\mathcal{B}). \tag{3.10}$$

Indeed, let $V \in \mathcal{O}$. Note that

$$\widehat{\mathcal{B}}(V)^+ = \widehat{\mathcal{B}}(V) + \widehat{K}_+ = \pi\mathcal{B}(V) + \pi K_+ = \pi\left[\mathcal{B}(V) + K_+\right] = \pi\left[\mathcal{B}(V)^+\right]. \tag{3.11}$$

From this it follows that $\mathcal{B}(V)^+ \subset \pi^{-1}\widehat{\mathcal{B}}(V)^+ \subset \pi^{-1}\overline{\widehat{\mathcal{B}}(V)^+}$, where the set $\pi^{-1}\overline{\widehat{\mathcal{B}}(V)^+}$ is closed by the continuity of π. So $\pi^{-1}\overline{\widehat{\mathcal{B}}(V)^+} \supset \overline{\mathcal{B}(V)^+} \supset \mathcal{K}^+(\mathcal{B})$ and, by (3.1),

$$\pi^{-1}\mathcal{K}^+(\widehat{\mathcal{B}}) = \pi^{-1}\bigcap_{V\in\mathcal{O}}\overline{\widehat{\mathcal{B}}(V)^+} = \bigcap_{V\in\mathcal{O}}\pi^{-1}\overline{\widehat{\mathcal{B}}(V)^+} \supset \mathcal{K}^+(\mathcal{B}).$$

Conversely, given $V \in \mathcal{O}$, there exists a convex neighborhood $V_{aux} \in \mathcal{O}$ such that $V_{aux} \subset V$. By definition, $L \subset \mathcal{K}^+(\mathcal{B})$. So (3.2) implies the inclusion $\overline{\mathcal{B}(V_{aux})^+} + L \subset \overline{\mathcal{B}(V_{aux})^+}$. It is easy to see that $\overline{\mathcal{B}(V_{aux})^+} + L = \pi^{-1}\pi[\mathcal{B}(V_{aux})^+]$. Thus, $\overline{\mathcal{B}(V_{aux})^+} = \pi^{-1}[\pi(\overline{\mathcal{B}(V_{aux})^+})]$ and so $\pi^{-1}[\widehat{Y} \setminus \pi(\overline{\mathcal{B}(V_{aux})^+})] = Y \setminus \overline{\mathcal{B}(V_{aux})^+}$, i.e., $\widehat{Y} \setminus \pi[\mathcal{B}(V_{aux})^+] = \pi[Y \setminus \overline{\mathcal{B}(V_{aux})^+}]$. Here the set $Y \setminus \overline{\mathcal{B}(V_{aux})^+}$ is open, and so too is the image $\pi[Y \setminus \overline{\mathcal{B}(V_{aux})^+}]$ because the operator π transforms open sets into open ones [30, p. 20]. Consequently, the set $\pi[\overline{\mathcal{B}(V_{aux})^+}]$ is closed where, by (3.11), $\widehat{\mathcal{B}}(V_{aux})^+ = \pi[\mathcal{B}(V_{aux})^+] \subset \pi[\overline{\mathcal{B}(V_{aux})^+}]$. Therefore, $\overline{\widehat{\mathcal{B}}(V_{aux})^+} \subset \pi[\overline{\mathcal{B}(V_{aux})^+}]$. Furthermore, due to (3.1), $\overline{\widehat{\mathcal{B}}(V_{aux})^+} \supset \mathcal{K}^+(\widehat{\mathcal{B}})$. Hence $\pi^{-1}[\mathcal{K}^+(\widehat{\mathcal{B}})] \subset \overline{\mathcal{B}(V_{aux})^+} \subset \overline{\mathcal{B}(V)^+}$ for any $V \in \mathcal{O}$. Passing here to the intersection over all $V \in \mathcal{O}$ and taking into account (3.1), we get the inclusion desired: $\pi^{-1}[\mathcal{K}^+(\widehat{\mathcal{B}})] \subset \mathcal{K}^+(\mathcal{B})$. Thus, (3.10) is true.

The cone $\mathcal{K}^+(\widehat{\mathcal{B}})$ includes no lines $l \neq \{0\}$ because, otherwise, we would have, by (3.10), $\pi^{-1}(l) = -\pi^{-1}(l) \subset \pi^{-1}[\mathcal{K}^+(\widehat{\mathcal{B}})] = \mathcal{K}^+(\mathcal{B}), \pi^{-1}(l) \supset \pi^{-1}(0) = L \neq \pi^{-1}(l)$ that would contradict the definition $L = \mathcal{K}^+(\mathcal{B}) \cap [-\mathcal{K}^+(\mathcal{B})]$ of L. Thus, as it has been proven,

$$\mathrm{ri}\mathcal{P}^*(\widehat{\mathcal{B}}) = \mathrm{int}\mathcal{P}^*(\widehat{\mathcal{B}}) \subset \mathcal{E}^*_+(\widehat{\mathcal{B}}). \tag{3.12}$$

Formula (3.10) implies the following relationship between the positive conjugate cones (3.6) [8, p. 143] $\mathcal{P}^*(\mathcal{B}) = \overline{\pi^*\mathcal{P}^*(\widehat{\mathcal{B}})}$, where $\pi^* : \widehat{Y}^* \to Y^*$ is the adjoint operator. Since $\mathrm{Im}\pi = \widehat{Y}$, this operator maps isomorphically the space $\widehat{Y}^*$ onto $\mathrm{Im}\pi^*$. As a result, on the one hand, the image $\pi^*\mathcal{P}^*(\widehat{\mathcal{B}})$ of the closed set $\mathcal{P}^*(\widehat{\mathcal{B}})$ is also closed and we have $\mathcal{P}^*(\mathcal{B}) = \pi^*\mathcal{P}^*(\widehat{\mathcal{B}})$ and, on the other hand, $\mathrm{ri}\mathcal{P}^*(\mathcal{B}) = \pi^*\mathrm{int}\mathcal{P}^*(\widehat{\mathcal{B}})$.

To conclude the proof, consider $\tau^* \in \mathrm{ri}\mathcal{P}^*(\mathcal{B})$. The last equality means that $\tau^* = \pi^*\theta^*$ for some $\theta^* \in \mathrm{int}\mathcal{P}^*(\widehat{\mathcal{B}})$, i.e., $\tau^* = \theta^* \circ \pi$. By (3.12), $\theta^* \in \mathcal{E}^*_+(\widehat{\mathcal{B}})$ and (3.4) yields that $\theta^* \geq 0$ and $\widehat{c}(\theta^*, V) := \inf\{\theta^*\widehat{\mathcal{B}}(z) : z \in V\} > -\infty$ for some $V \in \mathcal{O}$. By definition, $\theta^* \geq 0 \Leftrightarrow \theta^*\widehat{y} \geq 0$ for all $\widehat{y} \in \widehat{K}_+ = \pi K_+ \Leftrightarrow \theta^* \circ \pi y \geq 0$ for all $y \in K_+ \Leftrightarrow \tau^* \geq 0$. In addition, $\widehat{c}(\theta^*, V) = \inf\{\theta^*\pi\mathcal{B}(z) : z \in V\} = \inf\{\tau^*\mathcal{B}(z) : z \in V\} > -\infty$ and, by (3.4), $\tau^* \in \mathcal{E}^*_+(\mathcal{B})$. Thus, $\tau^* \in \mathcal{E}^*_+(\mathcal{B})$ whenever $\tau^* \in \mathrm{ri}\mathcal{P}^*(\mathcal{B})$, and the first inclusion in (3.7) does hold. □

The following lemma characterizes the set (3.4) in terms of the limit inferior (2.2).

LEMMA 3.4. *Let $\mathcal{B} : \mathfrak{M} \to Y$ be a quadratic form. Then*

$$\mathcal{E}^*_+(\mathcal{B}) = \left\{\tau^* \in Y^* : \tau^* \geq 0 \quad \textit{and} \quad \liminf_{h\to 0}\tau^*\mathcal{B}(h) = 0\right\}. \tag{3.13}$$

Proof. Denote by $\mathcal{E}^*_{lim}$ the set on the right. By (2.2) and (3.4), $\mathcal{E}^*_{lim} \subset \mathcal{E}^*_+(\mathcal{B})$. Conversely, let $\tau^* \in \mathcal{E}^*_+(\mathcal{B})$. For each $V \in \mathcal{O}$, denote $I_-(V) := \inf\{\tau^*\mathcal{B}(h) : h \in V\}$.

By (3.4), $\tau^* \geq 0$ and $I_-(V_0) > -\infty$ for some $V_0 \in \mathcal{O}$. Given $\rho > 0$, we have $\rho V_0 \in \mathcal{O}$ and then, by (2.2),

$$l_- := \liminf_{h \to 0} \tau^* \mathcal{B}(h) \geq I_-(\rho V_0) = \inf_{h \in V_0} \tau^* \mathcal{B}(\rho h) = \rho^2 I_-(V_0).$$

By letting $\rho \to +0$, we get $l_- \geq 0$. Furthermore, $I_-(V) \leq \tau^* \mathcal{B}(0) = 0$ for any $V \in \mathcal{O}$ because $0 \in V$. Then equation (2.2) implies $l_- \leq 0$. Thus $l_- = 0, \tau^* \geq 0$ and so $\tau^* \in \mathcal{E}^*_{lim}$. □

We recall that the limitrophe cone $\mathcal{K}(\mathcal{B})$ is the upper limitrophe cone (3.1) corresponding to the trivial positive cone $K_+ = \{0\}$. In other words, $\mathcal{K}(\mathcal{B}) = \bigcap_{V \in \mathcal{O}} \overline{\mathcal{B}(V)}$ where $\mathcal{B}(V) := \{y : y = \mathcal{B}(h) \text{ for some } h \in V\}$ is the ordinary image and $\mathcal{O}$ is the collection of all neighborhoods of the origin.

LEMMA 3.5. *Let $\mathcal{B} : \mathfrak{M} \to Y$ be a quadratic form, Assumption* 3.1 *be fulfilled, and the cone $\mathcal{K}(\mathcal{B})$ does not contain vectors y such that $y \in -\overline{K_+}$ and $y \neq 0$. Then*

$$\mathcal{K}^+(\mathcal{B}) = \overline{\mathcal{K}(\mathcal{B}) + K_+}. \tag{3.14}$$

Proof. If $y \in Y \Rightarrow y = 0$, the lemma is obvious. Let Y contain a nonzero vector. Given $k \subset Y^*$, denote by k° the positive conjugate cone $k^\circ := \{y \in Y : \tau^* y \geq 0 \text{ for all } \tau^* \in k\}$ and put $K_+^* := \{\tau^* \in Y^* : \tau^* \geq 0\}$. We are going to show first that

$$\operatorname{ri} K_+^* \cap \operatorname{ri} \mathcal{E}^*(\mathcal{B}) \neq \emptyset, \tag{3.15}$$

where $\mathcal{E}^*(\mathcal{B})$ is the set (3.4) corresponding to the trivial positive cone $K_+ = \{0\}$, i.e.,

$$\mathcal{E}^*(\mathcal{B}) = \left\{ \tau^* \in Y^* : \inf_{h \in V} \tau^* \mathcal{B}(h) > -\infty \quad \text{for some} \quad V \in \mathcal{O} \right\}.$$

Suppose to the contrary that formula (3.15) violates $\operatorname{ri} K_+^* \cap \operatorname{ri} \mathcal{E}^*(\mathcal{B}) = \emptyset$. Here K_+^* and $\mathcal{E}^*(\mathcal{B})$ are obviously convex cones. Therefore, they are separable with a hyperplane; i.e., there exists a vector $y \in Y$ such that $y \neq 0, \tau^* y \geq 0$ for all $\tau^* \in \mathcal{E}^*(\mathcal{B})$, and $\tau^* y \leq 0$ for all $\tau^* \in K_+^*$. By Lemma 3.3, the second inequality yields that $y \in \mathcal{K}(\mathcal{B})$. In its turn, the third one means that $-y \in \left(K_+^*\right)^\circ$ where $\left(K_+^*\right)^\circ = \overline{K_+}$ [8, p. 125]. Thus, $y \in -\overline{K_+}$ and we have a contradiction to the assumption of the lemma. Therefore, (3.15) does hold.

By (3.15) and Corollary 16.4.2 [8, p. 146],

$$\left[K_+^* \cap \mathcal{E}^*(\mathcal{B})\right]^\circ = \overline{\left[\left(K_+^*\right)^\circ + (\mathcal{E}^*(\mathcal{B}))^\circ\right]}. \tag{3.16}$$

It is clear that $K_+^* \cap \mathcal{E}^*(\mathcal{B}) = \mathcal{E}^*_+(\mathcal{B})$, where the set $\mathcal{E}^*_+(\mathcal{B})$ is given by (3.4). Then (3.5) means that the left-hand side in (3.16) is equal to $\mathcal{K}^+(\mathcal{B})$ and $(\mathcal{E}^*(\mathcal{B}))^\circ = \mathcal{K}(\mathcal{B})$. Furthermore, $\left(K_+^*\right)^\circ = \overline{K_+}$ [8, p. 125]. So (3.16) takes the form $\mathcal{K}^+(\mathcal{B}) = \overline{\mathcal{K}(\mathcal{B}) + \overline{K_+}}$ where the inside closure sign can obviously be omitted. □

Note that, in general, formula (3.14) fails to be true.

As a principal tool in the justification of the method (I)–(IV), we shall use the following key result. To state it, we recall that a set $C \subset Y$ is called *almost convex* if there exists a convex set $C_0 \subset Y$ such that $C_0 \subset C \subset \overline{C_0}$. Thus, the set C is almost convex iff it differs from some convex set C_0 at most by boundary details.

THEOREM 3.6. *Let $\mathfrak{M}$ be a real locally convex linear topological space, and let Y be a real finite-dimensional linear space ordered with a nonempty convex cone $K_+ \subset Y$. Also let $\mathcal{B} : \mathfrak{M} \to Y$ be a quadratic form and Assumption* 3.1 *be fulfilled.*

Assume that, for any $\tau^* \in Y^*, \tau^* \geq 0$, the following implication takes place

$$\tau^*\mathcal{B}(h) < 0 \quad \textit{for some} \quad h \in \mathfrak{M} \Longrightarrow \liminf_{h\to 0} \tau^*\mathcal{B}(h) = -\infty. \tag{3.17}$$

Then the upper image $\mathcal{B}(\mathfrak{M})^+ = \{y \in Y : y \geq \mathcal{B}(h)$ for some $h \in \mathfrak{M}\}$ of the space $\mathfrak{M}$ is almost convex and its closure coincides with the upper limitrophe cone (3.1).

Moreover, given a neighborhood V of the origin, its upper image $\mathcal{B}(V)^+ := \{y \in Y : y \geq \mathcal{B}(h)$ for some $h \in V\}$ is almost convex and

$$\overline{\mathcal{B}(V)^+} = \overline{\mathcal{B}(\mathfrak{M})^+} = \mathcal{K}^+(\mathcal{B}), \tag{3.18}$$

$$\mathrm{ri}\mathcal{B}(V)^+ = \mathrm{ri}\mathcal{B}(\mathfrak{M})^+ = \mathrm{ri}\mathcal{K}^+(\mathcal{B}), \tag{3.19}$$

where $\mathcal{K}^+(\mathcal{B})$ is the upper limitrophe cone (3.1).

In the case of a Hilbert space $\mathfrak{M}$ equipped with the weak topology, the meaning of the implication (3.17) was discussed in section 2 (see Lemma 2.4 and the neighboring considerations).

We break up the proof of Theorem 3.6 into a string of three lemmas.

LEMMA 3.7. *Let the assumptions of Theorem* 3.6 *be valid. Then relations* (3.18) *are true for any $V \in \mathcal{O}$.*

Proof. The inclusions

$$\mathcal{K}^+(\mathcal{B}) \subset \overline{\mathcal{B}(V)^+} \subset \overline{\mathcal{B}(\mathfrak{M})^+} \tag{3.20}$$

result from (3.1). Given $\tau^* \in \mathcal{E}^*_+(\mathcal{B})$, it follows from (3.13) and (3.17) that $\tau^*\mathcal{B}(h) \geq 0$ for all $h \in \mathfrak{M}$ and $\tau^* y^+ \geq 0$ for all $y^+ \in K_+$. Summing up, we have $\tau^*\left[\mathcal{B}(h) + y^+\right] \geq 0$ for all $h \in \mathfrak{M}$ and $y^+ \in K_+$, i.e., $\tau^* y \geq 0$ for all $y \in \mathcal{B}(\mathfrak{M})^+, \tau^* \in \mathcal{E}^*_+(\mathcal{B})$. By Lemma 3.3, this implies that $y \in \mathcal{K}^+(\mathcal{B})$ whenever $y \in \mathcal{B}(\mathfrak{M})^+$. Thus, $\mathcal{B}(\mathfrak{M})^+ \subset \mathcal{K}^+(\mathcal{B})$ where the cone $\mathcal{K}^+(\mathcal{B})$ is closed by Lemma 3.1. So $\overline{\mathcal{B}(\mathfrak{M})^+} \subset \mathcal{K}^+(\mathcal{B})$ and, thanks to (3.20), we get $\overline{\mathcal{B}(\mathfrak{M})^+} = \mathcal{K}^+(\mathcal{B})$. Then the inclusions (3.20) come to relations (3.18). □

To prove (3.19), we need a topological technique, which is developed in the following lemma.

LEMMA 3.8. *Denote by $\mathcal{S}_r$ the standard $(r-1)$-dimensional simplex*

$$\mathcal{S}_r := \{\theta = \|\theta_i\| \in \mathbb{R}^r : \theta_i \geq 0 \quad \textit{for all } i, \quad \theta_1 + \cdots + \theta_r = 1\}.$$

Let a set $C \subset Y$ be given. Assume that

(i) *its closure $\overline{C}$ is convex,*

(ii) *given $r = 1, 2, \ldots$ and elements $y_1, \ldots, y_r \in C$, there exists an infinite sequence $f_1(\cdot), f_2(\cdot), \ldots$ of continuous functions $f_m : \mathcal{S}_r \to C$ such that*

$$f_m(\theta) \to y(\theta) := \sum_{i=1}^{r} \theta_i y_i \quad \textit{as} \quad m \to \infty \tag{3.21}$$

uniformly over $\theta = \|\theta_i\| \in \mathcal{S}_r$.

Then $\mathrm{ri}\,\overline{C} \subset C$.

Proof. It needs to be proven that $y_0 \in C$ whenever $y_0 \in \mathrm{ri}\overline{C}$. Without loss of generality, we can assume that $y_0 = 0$. Then $L := \mathrm{aff}C \ni 0$ is a linear subspace. Choose a real $\epsilon > 0$ such that $\boxed{y \in L, |y| \leq \epsilon} \Rightarrow y \in \mathrm{ri}\overline{C}$ and also choose a basis $y'_1, \ldots, y'_{r-1}$ of

L such that $|y'_1| = \cdots = |y'_{r-1}| = \epsilon/(r-1)$. The vectors $y'_1, \dots, y'_{r-1}$ obviously belong to $\mathrm{ri}\overline{C} \subset \overline{C}$, as does the vector $y'_r := -\left(y'_1 + \cdots + y'_{r-1}\right)$. Consequently, any vector y'_i can be approximated by an element $y_i \in C$. Choose so close approximations that the vectors $y_1, \dots, y_{r-1}$ constitute a basis of L and all the coefficients of the vector y_r with respect to this basis are strictly negative. Then the convex hull Q of the vectors $y_1, \dots, y_r$ is apparently a neighborhood of the origin in the subspace L. Denote by $\theta(y) = [\theta_1(y), \dots, \theta_r(y)] \in \mathcal{S}_r$ the row of the barycentric coordinates of a point $y \in Q$ with respect to the apices $y_1, \dots, y_r$, i.e., $y = \sum_{i=1}^r \theta_i(y) y_i, \theta_i(y) \geq 0$ for all i, and $\sum_{i=1}^r \theta_i(y) = 1$. Consider a sequence $f_1(\cdot), f_2(\cdot), \dots$ that corresponds to the elements $y_1, \dots, y_r \in C$ by Assumption (ii). Then introduce the continuous mappings

$$I_m(y) := y\left[\theta(y)\right] - f_m\left[\theta(y)\right] \in L, \quad y \in Q, \quad m = 1, 2, 3, \dots,$$

where $y(\theta)$ was defined in (3.21). Due to (3.21), the continuous function $I_m(\cdot)$ maps the compact convex neighborhood of the origin $Q \subset L$ into itself provided that the index m is sufficiently large. By the Brouwer's fixed-point theorem, this implies the existence of a fixed point $y_m = I_m(y_m) = y\left[\theta(y_m)\right] - f_m\left[\theta(y_m)\right] \in Q$. Since, by (3.21), $y\left[\theta(y)\right] = \sum_{i=1}^r \theta_i(y) y_i = y$ for all $y \in Q$, we have $y_m = y_m - f_m\left[\theta(y_m)\right]$. Hence $f_m\left[\theta(y_m)\right] = 0$, where $f_m(\theta) \in C$ for all θ by the assumptions of the lemma. Thus, $0 \in C$. □

To prove relations (3.19), we shall apply Lemma 3.8 to the set $C := \mathcal{B}(V)^+$. Then Assumption (i) of this lemma follows from Lemmas 3.2 and 3.7. So we need to demonstrate only Assumption (ii). This gap is filled by the following lemma.

LEMMA 3.9. *Let the assumptions of Theorem* 3.6 *be valid. Consider a continuous mapping $y : \mathcal{S}_r \to \mathcal{K}^+(\mathcal{B})$ where $\mathcal{K}^+(\mathcal{B})$ is the upper limitrophe cone* (3.1).

Given $\epsilon > 0$ and a neighborhood V of the origin, the function $y(\cdot)$ may be decomposed as follows:

$$y(\theta) = \mathcal{B}\left[z(\theta)\right] + y^+(\theta) + \Delta y(\theta) \qquad \forall \theta \in \mathcal{S}_r, \tag{3.22}$$

where $z : \mathcal{S}_r \to V, y^+ : \mathcal{S}_r :\to K_+, \Delta y : \mathcal{S}_r \to Y$ are continuous functions and $|\Delta y(\theta)| \leq \epsilon$ for all $\theta \in \mathcal{S}_r$.

Proof. Due to the compactness of the simplex $\mathcal{S}_r$, we can pick a real $\kappa > 0$ such that

$$\boxed{\theta', \theta'' \in \mathcal{S}_r, |\theta' - \theta''| < \kappa} \Rightarrow |y(\theta') - y(\theta'')| < \frac{\epsilon}{2}. \tag{3.23}$$

Choose a finite collection of nonempty open sets $O_1, \dots, O_{\mathfrak{n}} \subset \mathcal{S}_r$ such that $\mathcal{S}_r = O_1 \cup \cdots \cup O_{\mathfrak{n}}$ and $\sup_{\theta, \vartheta \in O_i} |\theta - \vartheta| < \kappa$. Given $\theta \in \mathcal{S}_r$ and $i = 1, \dots, \mathfrak{n}$, we put $\zeta_i(\theta) := \min_{\vartheta \in \mathcal{S}_r \setminus O_i} |\theta - \vartheta|$. Then $\zeta_i(\theta) > 0$ if $\theta \in O_i$ and $\zeta_i(\theta) = 0$ otherwise. Hence $\zeta(\theta) := \zeta_1(\theta) + \cdots + \zeta_{\mathfrak{n}}(\theta) > 0$ for all $\theta \in \mathcal{S}_r$. So the function $\rho_i(\theta) := \zeta(\theta)^{-1} \zeta_i(\theta)$ is well defined on $\theta \in \mathcal{S}_r$ and continuous. It is also easy to see that

$$\rho_1(\theta) + \cdots + \rho_{\mathfrak{n}}(\theta) = 1, \ \ \rho_i(\theta) \geq 0 \qquad \forall \theta \in \mathcal{S}_r, i = 1, \dots, \mathfrak{n}, \tag{3.24}$$

$$\mathrm{supp}\rho_i := \overline{\{\theta : \rho_i(\theta) \neq 0\}} \neq \emptyset, \ \max_{\theta', \theta'' \in \mathrm{supp}\rho_i} |\theta' - \theta''| < \kappa \quad \forall i = 1, \dots, \mathfrak{n}. \tag{3.25}$$

Choose an element $\theta^{(i)} \in \mathrm{supp}\rho_i$ for each $i = 1, \dots, \mathfrak{n}$, and also fix a convex neighborhood of the origin $V_{\mathrm{c}} \subset V$. Denote $\nu := \epsilon \left(2\mathfrak{n}^2\right)^{-1}$ and consider the bilinear symmetric mapping $B : \mathfrak{M} \times \mathfrak{M} \to Y$ associated with the form $\mathcal{B}(\cdot)$.

As a first step, we are going to choose vectors $x_1,\dots,x_{\mathfrak{n}}\in\mathfrak{M}, y_1^+,\dots,y_{\mathfrak{n}}^+$, and $\Delta y_1,\dots,\Delta y_{\mathfrak{n}}\in Y$ such that

$$y\left(\theta^{(i)}\right)=\mathcal{B}\left(x_i\right)+y_i^+ +\Delta y_i \qquad \forall i\,, \tag{3.26}$$

$$x_i\in\mathfrak{n}^{-1}V_{\mathrm{c}},\quad y_i^+\in K_+,\quad |\Delta y_i|<\nu \qquad \forall i\,, \tag{3.27}$$

$$|B\left(x_i,x_j\right)|<\nu \qquad \forall i\neq j\,. \tag{3.28}$$

Do this in a consecutive order. Namely, choose first x_1, y_1^+, Δy_1, then x_2, y_2^+, Δy_2, and so on. Denote $V_0:=\mathfrak{n}^{-1}V_{\mathrm{c}}$. Since $y\left(\theta^{(1)}\right)\in\mathcal{K}^+(\mathcal{B})$, we have by (3.1) $y\left(\theta^{(1)}\right)\in\overline{\mathcal{B}\left(V_0\right)^+}$ that apparently implies (3.26) and (3.27) for $i=1$ with appropriate $x_1, y_1^+, \Delta y_1$.

Consider $m=1,\dots,\mathfrak{n}-1$, and assume that the vectors $x_1,\dots,x_m, y_1^+,\dots,y_m^+$, $\Delta y_1,\dots,\Delta y_m$ have already been chosen. To construct $x_{m+1}, y_{m+1}^+, \Delta y_{m+1}$, note first that, by Assumption 3.1, the operator $B(x_i,\cdot):\mathfrak{M}\to Y$ is continuous for any $i\le m$. So the set $\widehat{V}:=\left\{h\in\mathfrak{n}^{-1}V_{\mathrm{c}}:|B\left(x_i,h\right)|<\nu \text{ for all } i=1,\dots,m\right\}$ is a convex neighborhood of the origin. This permits us to repeat the above considerations with respect to $V_0:=\widehat{V}, y\left(\theta^{(m+1)}\right)$. As a result, we conclude that (3.26) and (3.27) are true for $i=m+1$ with appropriate $x_{m+1}\in\widehat{V}, y_{m+1}^+$, and Δy_{m+1}. If $\max\{i,j\}\le m$, inequality (3.28) is valid by assumption. If $\max\{i,j\}=m+1$, it follows from the inclusion $x_{m+1}\in\widehat{V}$.

Thus, the requisite vectors $x_i, y_i^+, \Delta y_i$ do exist. Show that the functions

$$\begin{gathered} z(\theta):=\textstyle\sum_{i=1}^{\mathfrak{n}}\sqrt{\rho_i(\theta)}x_i,\ \ y^+(\theta):=\sum_{i=1}^{\mathfrak{n}}\rho_i(\theta)y_i^+,\\ \Delta y(\theta):=y(\theta)-\mathcal{B}\left[z(\theta)\right]-y^+(\theta)\end{gathered} \tag{3.29}$$

have all the properties desired. Indeed, it is clear that the decomposition (3.22) takes place and that the functions $z(\cdot)$ and $y^+(\cdot)$ are continuous, as is the function $\Delta y(\cdot)$ by the following concretization of the term $\mathcal{B}\left[z(\theta)\right]$ in its definition:

$$\mathcal{B}\left[z(\theta)\right]=B\left[z(\theta),z(\theta)\right]=\sum_{i=1}^{\mathfrak{n}}\rho_i(\theta)\mathcal{B}\left(x_i\right)+2\sum_{i<j}\sqrt{\rho_i(\theta)}\sqrt{\rho_j(\theta)}B\left(x_i,x_j\right).$$

Taking into account both this relation and (3.24), (3.26), (3.29), we get

$$|\Delta y(\theta)|=\left|y(\theta)-\mathcal{B}\left[z(\theta)\right]-y^+(\theta)\right|$$

$$=\left|\sum_{i=1}^{\mathfrak{n}}\rho_i(\theta)y(\theta)-\sum_{i=1}^{\mathfrak{n}}\rho_i(\theta)\mathcal{B}\left(x_i\right)-\sum_{i=1}^{\mathfrak{n}}\rho_i(\theta)y_i^+-2\sum_{i<j}\sqrt{\rho_i(\theta)}\sqrt{\rho_j(\theta)}B\left(x_i,x_j\right)\right|$$

$$\le\sum_{i=1}^{\mathfrak{n}}\rho_i(\theta)\underbrace{\left|y\left(\theta^{(i)}\right)-\mathcal{B}\left(x_i\right)-y_i^+\right|}_{=\Delta y_i}+\sum_{i=1}^{\mathfrak{n}}\rho_i(\theta)\left|y\left(\theta^{(i)}\right)-y(\theta)\right|$$

$$+2\sum_{i<j}\sqrt{\rho_i(\theta)}\sqrt{\rho_i(\theta)}\left|B\left(x_i,x_j\right)\right|.$$

Here $\theta^{(i)} \in \operatorname{supp}\rho_i$ by choice. So (3.25) implies that $\rho_i(\theta) \neq 0 \Rightarrow |\theta - \theta^i| < \kappa$ and, by (3.23), $|y(\theta^{(i)}) - y(\theta)| \leq \epsilon/2$. Consequently, $\rho_i(\theta)|y(\theta^{(i)}) - y(\theta)| \leq \rho_i(\theta)\epsilon/2$ for all $\theta \in \mathcal{S}_r$ where $\rho_i(\theta) \leq 1$ by (3.24). This and (3.26)–(3.28) permit us to continue the estimation

$$|\Delta y(\theta)| \leq \sum_{i=1}^{\mathfrak{n}} \rho_i(\theta)\nu + \frac{\epsilon}{2}\sum_{i=1}^{\mathfrak{n}} \rho_i(\theta) + 2\sum_{i<j} \nu = \frac{\epsilon}{2} + \mathfrak{n}^2\nu,$$

where $\nu = \epsilon\left(2\mathfrak{n}^2\right)^{-1}$ by choice. Thus, we get the inequality desired: $|\Delta y(\theta)| \leq \epsilon$. The inclusion $y^+(\theta) \in K_+$ results from (3.24), (3.27), and (3.29) because K_+ is a convex cone. Due to (3.24), $\rho_i(\theta) \leq 1$ and so (3.29) and the first inclusion in (3.27) yield that $z(\theta) \in V_{\mathrm{c}} \subset V$; i.e., the last property to be proved does take place. □

Now we are ready to prove Theorem 3.6. Relations (3.18) are true by Lemma 3.7. To prove (3.19), consider a neighborhood of the origin V and apply Lemma 3.8 to $C := \mathcal{B}(V)^+$. Lemma 3.8(i) follows from Lemmas 3.2 and 3.7. To prove assumption (ii), consider $y_1, \ldots, y_r \in C = \mathcal{B}(V)^+$. By (3.18), $y_1, \ldots, y_r \in \mathcal{K}^+(\mathcal{B})$ where $\mathcal{K}^+(\mathcal{B})$ is a convex cone by Lemma 3.2. So $y(\theta) := \theta_1 y_1 + \cdots + \theta_r y_r \in \mathcal{K}^+(\mathcal{B})$ for all $\theta = \|\theta_i\| \in \mathcal{S}_r$. Given a natural m, the application of Lemma 3.9 to the mapping $y(\cdot)$ and to the real $\epsilon := m^{-1}$ results in the corresponding continuous functions $z : \mathcal{S}_r \to V, y^+ : \mathcal{S}_r \to K_+$, and $\Delta y : \mathcal{S}_r \to Y$. It is clear that $f_m(\theta) := \mathcal{B}\left[z(\theta)\right] + y^+(\theta) \in \mathcal{B}(V)^+ = C$. Since $f_m(\theta) = y(\theta) - \Delta y_m(\theta)$, the function $f_m(\cdot)$ is continuous. From (3.22), we have $|y(\theta) - f_m(\theta)| = |\Delta y_m(\theta)| \leq \epsilon = m^{-1}$, which proves (3.21).

Thus, all the assumptions of Lemma 3.8 are valid. By this lemma, $\mathrm{ri}\mathcal{K}^+(\mathcal{B}) \subset \mathcal{B}(V)^+$, where, due to (3.18), $\mathcal{B}(V)^+ \subset \overline{\mathcal{B}(V)^+} = \mathcal{K}^+(\mathcal{B})$ and so $\mathrm{ri}\mathcal{B}(V)^+ = \mathrm{ri}\mathcal{K}^+(\mathcal{B})$. Here choosing $V := \mathfrak{M}$, we get (3.19).

Consider the convex set $C_0 := \mathrm{ri}\mathcal{K}^+(\mathcal{B})$. By (3.18) and (3.19), $C_0 = \mathrm{ri}\mathcal{B}(V)^+ \subset \mathcal{B}(V)^+ \subset \overline{\mathcal{B}(V)^+} = \mathcal{K}^+(\mathcal{B}) = \overline{C_0}$ or, in brief, $C_0 \subset \mathcal{B}(V)^+ \subset \overline{C_0}$. This means that the set $\mathcal{B}(V)^+$ is almost convex. So is the set $\mathcal{B}(\mathfrak{M})^+$ because $V := \mathfrak{M}$ is a particular case of a neighborhood of the origin. Thus, the proof of Theorem 3.6 is completed.

We conclude the section with the demonstration of Theorem 1.3 (see section 1).

LEMMA 3.10. *Let Y be a real linear finite-dimensional space and C_1, C_2 be almost convex sets.*

If $\mathrm{ri}\, C_1 \cap \mathrm{ri}\, C_2 \neq \emptyset$, then the intersection $C_1 \cap C_2$ is almost convex too.

Proof. By the definition of an almost convex set, there exist convex sets $C_1^0, C_2^0 \subset Y$ such that $C_i^0 \subset C_i \subset \overline{C_i^0}$ for $i = 1, 2$. These inclusions imply that, first, $C^0 := C_1^0 \cap C_2^0 \subset C_1 \cap C_2 \subset \overline{C_1^0} \cap \overline{C_2^0}$ with the set C^0 being convex and, second, $\mathrm{ri}C_i^0 \subset \mathrm{ri}C_i \subset \mathrm{ri}\overline{C_i^0}$, where $\mathrm{ri}C_i^0 = \mathrm{ri}\overline{C_i^0}$ [8, p. 46]. Therefore, $\mathrm{ri}C_i^0 = \mathrm{ri}C_i$ and we have $\mathrm{ri}C_1^0 \cap \mathrm{ri}C_2^0 \neq \emptyset$. From this it follows that $\overline{C^0} = \overline{C_1^0 \cap C_2^0} = \overline{C_1^0} \cap \overline{C_2^0}$ [8, p. 47]. Thus, $C^0 \subset C_1 \cap C_2 \subset \overline{C^0}$; i.e., the set $C_1 \cap C_2$ is almost convex. □

LEMMA 3.11. *Let H be a real Hilbert space and $\mathcal{G}_1, \ldots, \mathcal{G}_k$ be continuous scalar quadratic forms on H. Define the quadratic form $\mathcal{B} : H \to \mathbb{R}^{k+1}$ by $\mathcal{B}(z) := \left\{\mathcal{G}_1(z), \ldots, \mathcal{G}_k(z), |z|^2\right\}$, where $|z| = \sqrt{\langle z, z\rangle}$ is the norm in H.*

If the image $\mathcal{B}(H)$ of the space H is almost convex, then the image of the unit sphere $S := \{z \in H : |z| = 1\}$ under the mapping $\mathcal{G}(z) := [\mathcal{G}_1(z), \ldots, \mathcal{G}_k(z)]$ is almost convex too.

Proof. The function $J(y_1, \ldots, y_k) := (y_1, \ldots, y_k, 1)$ maps isomorphically $\mathbb{R}^k$ onto the affine subspace $C_2 := \left\{y = \|y_i\| \in \mathbb{R}^{k+1} : y_{k+1} = 1\right\} \subset \mathbb{R}^{k+1}$. Furthermore, it is easy to see that $J\left[\mathcal{G}(S)\right] = \mathcal{B}(H) \cap C_2$. So it suffices to prove that the intersection

$\mathcal{B}(H) \cap C_2$ is almost convex. By Lemma 3.10, this follows from the relation $\mathrm{ri}\mathcal{B}(H) \cap \mathrm{ri}C_2 \neq \emptyset$ to be demonstrated in the remainder of the proof.

Assume the opposite $\mathrm{ri}\mathcal{B}(H) \cap \mathrm{ri}C_2 = \emptyset$. By the definition of an almost convex set, there exists a convex set C such that $C \subset \mathcal{B}(H) \subset \overline{C}$. Then $\mathrm{ri}C \subset \mathrm{ri}\mathcal{B}(H) \subset \mathrm{ri}\overline{C}$ where $\mathrm{ri}\overline{C} = \mathrm{ri}C$ [8, p. 46]. So $\mathrm{ri}C = \mathrm{ri}\mathcal{B}(H)$ and we have $\mathrm{ri}C \cap \mathrm{ri}C_2 = \emptyset$ with both sets being convex. Consequently, they are separable with a hyperplane; i.e., there exists $\tau = \|\tau_i\| \in \mathbb{R}^{k+1}$ such that $\tau \neq 0$ and $\tau^* y' \geq \alpha \geq \tau^* y''$ for all $y' \in \mathrm{ri}C$, $y'' \in C_2$ where the asterisk stands for transposition. By continuity, these inequalities spread on all $y' \in \overline{\mathrm{ri}C} = \overline{C} \supset \mathcal{B}(H)$. Picking $y'' := (y_1, \ldots, y_k, 1)$ and letting successively $y_1 \to \pm\infty, \ldots, y_k \to \pm\infty$, we get $\tau_1 = 0, \ldots, \tau_k = 0$, $\alpha \geq \tau_{k+1} \neq 0$. Picking $y' := \mathcal{B}(z) \in \mathcal{B}(H)$, we get $\tau^* y' = \tau_{k+1}|z|^2 \geq \alpha \geq \tau_{k+1}$, $\tau_{k+1}(|z|^2 - 1) \geq 0$ for all $z \in H$. Hence $\tau_{k+1} = 0$, which contradicts the above inequality $\tau_{k+1} \neq 0$. Thus, we are forced to recognize that $\mathrm{ri}\mathcal{B}(H) \cap \mathrm{ri}C_2 \neq \emptyset$. □

Proof of Theorem 1.3. Define the quadratic form $\mathcal{B} : H \to Y := \mathbb{R}^{k+1}$ as in Lemma 3.11. We are going to apply Theorem 3.6. To this end, denote by $\mathfrak{M}$ the space H equipped with the weak topology and pick $K_+ := \{0\}$. Then Assumption 3.1 is clearly true. By Lemma 2.4, the implication (3.17) now takes the form

$$n_- \left[\tau^* \mathcal{B}(\cdot)\right] \neq 0 \Longrightarrow n_- \left[\tau^* \mathcal{B}(\cdot)\right] = +\infty, \tag{3.30}$$

where $\tau = \|\tau_i\| \in \mathbb{R}^{k+1}$, the asterisk stands for transposition, and $n_-(\cdot)$ is the (negative) index of inertia of the scalar quadratic form. Denoting $\widehat{\tau} := (\tau_1, \ldots, \tau_k) \in \mathbb{R}^k$, we obviously have $\tau^* \mathcal{B}(z) = \langle (A_{\widehat{\tau}} + \tau_{k+1} I)\, z, z \rangle$, where the operator $A_{\widehat{\tau}}$ was introduced in Theorem 1.3 and I is the identity operator on H. Consider the resolution of the identity $P(d\lambda)$ for the operator $A_{\widehat{\tau}}$. Then the last equality looks like the following [29, pp. 893, 899]:

$$\tau^* \mathcal{B}(z) = \int_{\lambda_-}^{\lambda_+} (\lambda + \tau_{k+1}) \quad \langle P(d\lambda) z, z \rangle\,. \tag{3.31}$$

Here $\lambda_- := \min\{\lambda : \lambda \in \sigma(A_{\widehat{\tau}})\}$ and $\lambda_+ := \max\{\lambda : \lambda \in \sigma(A_{\widehat{\tau}})\}$.

Let $n_- \left[\tau^* \mathcal{B}(\cdot)\right] \neq 0$. Then (3.31) implies that, on the one hand, $\lambda_- + \tau_{k+1} < 0$ and, on the other hand, $\boxed{z \in \mathrm{Im}P\left\{[\lambda_-, -\tau_{k+1})\right\},\ z \neq 0} \Rightarrow \tau^* \mathcal{B}(z) < 0$. So $n_- \left[\tau^* \mathcal{B}(\cdot)\right] \geq \mu := \dim \mathrm{Im}P\left\{[\lambda_-, -\tau_{k+1})\right\}$. Here λ_- is not an isolated eigenvalue of finite geometrical multiplicity by the assumptions of Theorem 1.3. So $\mu = \infty$ and (3.30) does hold.

Thus, the assumptions of Theorem 3.6 are valid. By this theorem, the image $\mathcal{B}(H)$ is almost convex. Then Lemma 3.11 completes the proof. □

4. Correctness of the method (I)–(IV). This section is devoted to the proof of Theorem 2.2. We recall first the following fact [2, 13, 14].

LEMMA 4.1. *Let, in* (1.1), *Z be a subset of a set H and $\mathcal{F} : H \to \mathbb{R}$, $\mathcal{G} : H \to Y$ be given functions. Assume that the finite-dimensional linear space Y is ordered with a convex cone $K_+ \subset Y$, which contains an interior point. Let also the problem* (1.1) *be regular (see Definition* 2.1*). Denote by D the admissible domain in this problem $D := \{z \in Z : \mathcal{G}(z) \leq 0\}$ and define the set C_+ by* (1.20).

If either $\inf_{z \in D} \mathcal{F}(z) = -\infty$ or the closure $\overline{C_+}$ of the set (1.20) *is convex, then relation* (1.12) *is true and the method of duality* (I)–(IV) *is valid.*

In the remainder of the section, the assumptions of Theorem 2.2 are assumed to be fulfilled. We shall consider the linear space $\mathfrak{Y} := \mathbb{R} \times Y$ and the mapping

$G(z) := [\mathcal{F}(z), \mathcal{G}(z)] \in \mathfrak{Y}$. The space $\mathfrak{Y}$ is assumed to be ordered with the convex cone $\mathfrak{K}_+ := \{\xi = (t, y) \in \mathfrak{Y} : t \geq 0, y \geq 0\}$. By (1.3), we obviously have

$$G(z) = \mathcal{B}(z) + \Phi(z), \tag{4.1}$$

where $\mathcal{B}(z) := B(z, z), B(z_1, z_2) := [B_{\mathcal{F}}(z_1, z_2), B_{\mathcal{G}}(z_1, z_2)]$, and $\Phi(z) := [\Phi_{\mathcal{F}}(z), \Phi_{\mathcal{G}}(z)]$. The functions $B(\cdot, \cdot)$ and $\Phi(\cdot)$ apparently have the same properties that the functions $B_{\mathcal{F}}, B_{\mathcal{G}}$ and, respectively, $\Phi_{\mathcal{F}}, \Phi_{\mathcal{G}}$ have by Assumptions (A) and (B) of Theorem 2.2. Here and throughout, $\mathfrak{M}$ denotes the linear subspace $\mathfrak{M} := Z - z_0 \quad (z_0 \in Z)$ that is a displacement of Z. It is endowed with the topology induced on $\mathfrak{M}$ by H.

To prove Theorem 2.2, it suffices to show that the closure of the set (1.20) is convex provided $\inf_{z \in D} \mathcal{F}(z) > -\infty$. We preface the study of this set with four technical lemmas. Further, the problem (1.1) is assumed to be regular.

LEMMA 4.2. *For the quadratic form* $\mathcal{B}|_{\mathfrak{m}}$, *define the set* $\mathcal{E}_+^* := \mathcal{E}_+^*(\mathcal{B}|_{\mathfrak{m}}) \subset \mathfrak{Y} = \mathbb{R} \times Y$ *in accordance with* (3.13).

If $\inf_{z \in D} \mathcal{F}(z) > -\infty$, *then there exists an element* $\overline{\tau}^* = (\tau_0, \tau^*) \in \mathcal{E}_+^*$ *with* $\tau_0 > 0$.

Proof. Suppose to the contrary that $\mathcal{E}_+^* \subset L^* := \{\overline{\tau}^* \in \mathfrak{Y}^* : \tau_0 = 0\}$. Let $\xi \in L := \{(t, y) \in \mathfrak{Y} : \ y = 0\}$. For any $\overline{\tau}^* \in \mathcal{E}_+^*$, we have $\overline{\tau}^* \in L^*$ and so $\overline{\tau}^* \xi = 0$. Then, by Lemma 3.3, $\xi \in \mathcal{K} := \mathcal{K}^+(\mathcal{B}|_{\mathfrak{m}})$, i.e., $L \subset \mathcal{K}$.

Consider the element $z_* \in Z$ from (2.1), and choose $\epsilon > 0$ such that $|\mathcal{G}(z_*) - y| < \epsilon \Rightarrow y < 0$. Denote by V the set of all $h \in \mathfrak{M}$ such that

$$\begin{array}{ll} |\Phi_{\mathcal{F}}(z_* + h) - \Phi_{\mathcal{F}}(z_*)| < 1, & |B_{\mathcal{F}}(z_*, \ h)| < 1, \\ |\Phi_{\mathcal{G}}(z_* + h) - \Phi_{\mathcal{G}}(z_*)| < \epsilon/4, & |B_{\mathcal{G}}(z_*, \ h)| < \epsilon/4. \end{array} \tag{4.2}$$

By Assumptions (A) and (B) of Theorem 2.2, the set $V \subset \mathfrak{M}$ is a neighborhood of the origin in the subspace $\mathfrak{M}$.

Given $\rho \in \mathbb{R}$, we have $(\rho, 0) \in L \subset \mathcal{K}^+(\mathcal{B}|_{\mathfrak{m}})$ and, by (3.1), $(\rho, 0) \in \overline{\mathcal{B}(V)^+}$. Hence, $(\rho, 0) = [B_{\mathcal{F}}(h, h), \ B_{\mathcal{G}}(h, h)] + (\rho^+, \ y^+) + (\Delta\rho, \ \Delta y)$ for some $h \in V, \ \rho^+ \geq 0, \ y^+ \geq 0, \ |\Delta\rho| < 1, \ |\Delta y| < \epsilon/4$. Letting $z := z_* + h \in Z$, we have by (1.3) and (4.2)

$$\left|\mathcal{G}(z) + y^+ - \mathcal{G}(z_*)\right|$$

$$= \left|B_{\mathcal{G}}(z_* + h, \ z_* + h) + \Phi_{\mathcal{G}}(z_* + h) + y^+ - B_{\mathcal{G}}(z_*, \ z_*) - \Phi_{\mathcal{G}}(z_*)\right|$$

$$\leq \Big| \underbrace{B_{\mathcal{G}}(h, h) + y^+}_{=-\Delta y} \Big| + 2\,|B_{\mathcal{G}}(z_*, \ h)| + |\Phi_{\mathcal{G}}(z_* + h) - \Phi_{\mathcal{G}}(z_*)| < \epsilon,$$

and, consequently, $\mathcal{G}(z) + y^+ < 0 \Rightarrow \mathcal{G}(z) \leq 0, \ z \in Z \Rightarrow z \in D$. Likewise,

$$\left|\mathcal{F}(z) - \rho + \rho^+ - \mathcal{F}(z_*)\right| \leq \Big| \underbrace{B_{\mathcal{F}}(h, h) - \rho + \rho^+}_{=-\Delta\rho} \Big| + 2\,|B_{\mathcal{F}}(z_*, \ h)|$$

$$+ |\Phi_{\mathcal{F}}(z_* + h) - \Phi_{\mathcal{F}}(z_*)| \leq 4.$$

Hence, $\mathcal{F}(z) \leq \rho + \mathcal{F}(z_*) + 4$, where $z \in D$. Thus, $f := \inf_{z \in D} \mathcal{F}(z) \leq \rho + \mathcal{F}(z_*) + 4$. By letting $\rho \to -\infty$, we get the contradiction to the assumption $f > -\infty$ of the lemma. This proves the lemma by contraposition. ∎

Given $Q \subset \mathfrak{Y}^*$, denote by kon$Q$ the minimal cone containing Q.

LEMMA 4.3. *Let $\mathcal{C} \subset \mathfrak{Y}^*$ be a convex set such that $\mathcal{E}_+^* \subset \overline{kon\ \mathcal{C}}$ and* ri$\mathcal{C} \cap \mathcal{E}_+^* \neq \emptyset$ *where the set $\mathcal{E}_+^*$ is defined in Lemma* 4.2.

Assume that, for any $\overline{\tau}^* \in \mathcal{C},\ \overline{\tau}^* \geq 0$, we have

$$\boxed{\overline{\tau}^*\mathcal{B}(h) < 0 \ \text{ for some } \ h \in \mathfrak{M}} \Longrightarrow \sigma\left(\overline{\tau}^*\right) := \liminf_{h \to 0, h \in \mathfrak{m}} \overline{\tau}^*\mathcal{B}(h) < 0. \tag{4.3}$$

Then this implication remains valid provided $\overline{\tau}^* \geq 0$ only.

Proof. $\boxed{\overline{\tau}^* \in \mathcal{C},\ \overline{\tau}^* \geq 0,\ \sigma\left(\overline{\tau}^*\right) = 0} \Rightarrow \boxed{\overline{\tau}^*\mathcal{B}(h) \geq 0 \quad \text{for all} \quad h \in \mathfrak{M}}$ due to (4.3). Furthermore, by (3.13), $\overline{\tau}^* \in \mathcal{E}_+^* \Leftrightarrow \boxed{\overline{\tau}^* \geq 0,\ \sigma\left(\overline{\tau}^*\right) = 0}$. Thus, $\mathcal{C} \cap \mathcal{E}_+^* \subset \mathcal{N}^* := \{\overline{\tau}^* \in \mathfrak{Y}^* : \overline{\tau}^*\xi \geq 0 \text{ for all } \xi \in \mathcal{B}(\mathfrak{M})\}$. Since $\mathcal{E}_+^*$ and $\mathcal{N}$ are cones, we have kon$\mathcal{C} \cap \mathcal{E}_+^* \subset \mathcal{N}^*$. Choose $\overline{\tau}_0^* \in$ ri$\mathcal{C} \cap \mathcal{E}_+^*$ and $\overline{\tau}^* \in \mathcal{E}_+^*$. Then $\overline{\tau}^* \in \overline{\text{kon}\mathcal{C}},\ \overline{\tau}_0^* \in$ ri$\mathcal{C} \subset$ ri(kon$\mathcal{C}$) $\Rightarrow \overline{\tau}_\epsilon^* := (1-\epsilon)\overline{\tau}^* + \epsilon\overline{\tau}_0^* \in$ kon$\mathcal{C}$ for any $\epsilon \in (0, 1]$ [8, p. 45], and, by (3.4), $\overline{\tau}^*,\ \overline{\tau}_0^* \in \mathcal{E}_+^* \Rightarrow \overline{\tau}_\epsilon^* \in \mathcal{E}_+^*$. In brief, $\overline{\tau}_\epsilon^* \in$ kon$\mathcal{C} \cap \mathcal{E}_+^* \subset \mathcal{N}^*$. Letting $\epsilon \to +0$, we get $\overline{\tau}^* \in \mathcal{N}^*$ where the element $\overline{\tau}^* \in \mathcal{E}_+^*$ is arbitrary. Thus, $\mathcal{E}_+^* \subset \mathcal{N}^*$.

Recalling (3.13) and the definition of the set $\mathcal{N}^*$, we can rewrite the last inclusion as follows $\boxed{\overline{\tau}^* \geq 0,\ \sigma\left(\overline{\tau}^*\right) = 0} \Rightarrow \boxed{\overline{\tau}^*\mathcal{B}(h) \geq 0 \text{ for all } h \in \mathfrak{M}}$ or, in other words, $\boxed{\overline{\tau}^*\mathcal{B}(h) < 0 \text{ for some } h \in \mathfrak{M}} \Rightarrow \sigma\left(\overline{\tau}^*\right) \neq 0$ provided $\overline{\tau}^* \geq 0$. To complete the proof, it suffices to recall that $\sigma\left(\overline{\tau}^*\right)$ can take only two values 0 and $-\infty$. □

LEMMA 4.4. *Let $\inf_{z \in D} \mathcal{F}(z) > -\infty$. Then the quadratic form $\mathcal{B}|_{\mathfrak{m}} : \mathfrak{M} \to \mathfrak{Y}$ satisfies the assumptions of Theorem* 3.6 *and, therefore,*

$$\overline{\mathcal{B}(\mathfrak{M})^+} = \mathcal{K}^+\left(\mathcal{B}|_{\mathfrak{m}}\right) \tag{4.4}$$

where the upper limitrophe cone $\mathcal{K}^+\left(\mathcal{B}|_{\mathfrak{m}}\right)$ is defined in accordance with (3.1).

Proof. Assumption 3.1 follows from assumption (B) of Theorem 2.2. Relation (4.4) is merely a part of (3.18). So it suffices to demonstrate only the implication (3.17). Now it takes the form (4.3) and has to be proven for any $\overline{\tau}^* \in \mathfrak{Y}^*,\ \overline{\tau}^* \geq 0$. To this end, we shall apply Lemma 4.3.

Denote $\mathcal{C} := \{\overline{\tau}^* = (\tau_0,\ \tau^*) \in \mathfrak{Y}^* = \mathbb{R} \times Y^* : \tau_0 = 1\}$ and define the set $\mathcal{E}_+^* = \mathcal{E}_+^*\left(\mathcal{B}|_{\mathfrak{m}}\right)$ in accordance with (3.13). Since kon $\mathcal{C} = \{\overline{\tau}^* : \tau_0 > 0\}$, we have $\overline{\text{kon}\ \mathcal{C}} = \{\overline{\tau}^* : \tau_0 \geq 0\}$ and, by (3.13), $\mathcal{E}_+^* \subset \overline{\text{kon}\ \mathcal{C}}$. By Lemma 4.2, there exists an element $\overline{\tau}^* = (\tau_0,\ \tau^*) \in \mathcal{E}_+^*$ with $\tau_0 > 0$. Then $\widetilde{\tau}^* := \tau_0^{-1}\overline{\tau}^* \in \mathcal{E}_+^*$ due to (3.13) and, obviously, $\widetilde{\tau}^* \in \mathcal{C}$ where $\mathcal{C} =$ ri$\mathcal{C}$. Thus, ri$\mathcal{C} \cap \mathcal{E}_+^* \neq \emptyset$. Given $\overline{\tau}^* = (1,\ \tau^*) \in \mathcal{C},\ \overline{\tau}^* \geq 0$, the implication (4.3) apparently has the form (2.3) and is thereby true. Then, by Lemma 4.3, the implication (4.3) is valid for all $\overline{\tau}^* \in \mathfrak{Y},\ \overline{\tau}^* \geq 0$. □

To state the next lemma, we recall that the space $\mathfrak{Y}$ is ordered with the cone $\mathfrak{K}_+ := \{\xi = (t, y) \in \mathfrak{Y} : t \geq 0,\ y \geq 0\}$.

LEMMA 4.5. *Let the vectors $z_1, z_2 \in Z, \delta z \in \mathfrak{M}, \xi^+, \Delta\xi \in \mathfrak{Y}$ and the reals $\theta_1 \in [0, 1], \epsilon > 0$ be given. Denote $\Delta z := z_2 - z_1$ and $\theta_2 := 1 - \theta_1$. Assume that*

$$\mathcal{B}(\Delta z) = \mathcal{B}(\delta z) + \xi^+ + \Delta\xi, \ \ \xi^+ \geq 0, \ \ |\Delta\xi| < \epsilon, \tag{4.5}$$

$$\delta z \in \mathfrak{M}, \ \ |B\left(z_1, \delta z\right)| < \epsilon, \ \ |B(\Delta z, \delta z)| < \epsilon, \tag{4.6}$$

$$\left|\Phi\left(\theta_1 z_1 + \theta_2 z_2 + \sqrt{\theta_1\theta_2}\delta z\right) - \Phi\left(\theta_1 z_1 + \theta_2 z_2\right)\right| < \epsilon. \tag{4.7}$$

Then the vector

$$z := \theta_1 z_1 + \theta_2 z_2 + \sqrt{\theta_1\theta_2}\delta z \tag{4.8}$$

belongs to Z. *Furthermore, there exists a vector* $\Delta \in \mathfrak{Y}$ *such that*

$$G(z) \le \theta_1 G(z_1) + \theta_2 G(z_2) + \Delta, \qquad |\Delta| < 6\epsilon. \tag{4.9}$$

Proof. Since Z is an affine subspace and $\mathfrak{M} = Z - Z$, we have

$$\boxed{\theta_1, \theta_2 \ge 0, \theta_1 + \theta_2 = 1, z_1, z_2 \in Z, \delta z \in \mathfrak{M}} \Rightarrow z \in Z.$$

In light of (4.1) and (4.8), it is straightforward to compute that

$$\begin{aligned} G(z) &= B\left(z_1 + \theta_2\Delta z + \sqrt{\theta_1\theta_2}\delta z\ ,\ z_1 + \theta_2\Delta z + \sqrt{\theta_1\theta_2}\delta z\right) + \Phi(z) \\ &= \mathcal{B}(z_1) + 2\theta_2 B(z_1, \Delta z) + \theta_2^2\mathcal{B}(\Delta z) + \theta_1\theta_2\mathcal{B}(\delta z) + \Phi(\theta_1 z_1 + \theta_2 z_2) \\ &+ \underbrace{2\sqrt{\theta_1\theta_2}B(z_1, \delta z) + 2\theta_1^{1/2}\theta_2^{3/2}B(\Delta z, \delta z) + \Phi(z) - \Phi(\theta_1 z_1 + \theta_2 z_2)}_{\Delta_1}. \end{aligned} \tag{4.10}$$

By (4.6)–(4.8) and the inequalities $0 \le \theta_1, \theta_2 \le 1$, we get

$$|\Delta_1| \le 2\sqrt{\theta_1\theta_2}\epsilon + 2\theta_1^{1/2}\theta_2^{3/2}\epsilon + \epsilon \le 5\epsilon. \tag{4.11}$$

Calculate $\mathcal{B}(\delta z)$ from (4.5) and put the result into (4.10)

$$G(z) = \underbrace{\mathcal{B}(z_1) + 2\theta_2 B(z_1, \Delta z) + \theta_2^2\mathcal{B}(\Delta z) + \theta_1\theta_2\mathcal{B}(\Delta z)}_{b}$$

$$-\theta_1\theta_2\left[\xi^+ + \Delta\xi\right] + \Phi(\theta_1 z_1 + \theta_2 z_2) + \Delta_1.$$

Here

$$b = (\theta_1 + \theta_2)\mathcal{B}(z_1) + 2\theta_2 B(z_1, \Delta z) + \theta_2(\theta_1 + \theta_2)\mathcal{B}(\Delta z)$$

$$= \theta_1\mathcal{B}(z_1) + \theta_2\left[\mathcal{B}(z_1) + 2B(z_1, \Delta z) + \mathcal{B}(\Delta z)\right] = \theta_1\mathcal{B}(z_1) + \theta_2\mathcal{B}\underbrace{(z_1 + \Delta z)}_{=z_2}.$$

Thus, we have

$$\begin{aligned} G(z) &= \theta_1\mathcal{B}(z_1) + \theta_2\mathcal{B}(z_2) + \Phi(\theta_1 z_1 + \theta_2 z_2) - \theta_1\theta_2\xi^+ \\ &+ \underbrace{\Delta_1 - \theta_1(1 - \theta_1)\Delta\xi}_{\Delta}. \end{aligned} \tag{4.12}$$

The third relation in (4.5) and (4.11) imply the second inequality in (4.9). By assumption (A) of Theorem 2.2, the function $\Phi = [\Phi_{\mathcal{F}}, \Phi_{\mathcal{G}}]$ is convex on Z, i.e., $\Phi(\theta_1 z_1 + \theta_2 z_2) \le \theta_1\Phi(z_1) + \theta_2\Phi(z_2)$. Recalling that $\xi^+ \ge 0$ by (4.5) and taking into account (4.1), we can continue (4.12) and complete the proof

$$G(z) \le \theta_1\mathcal{B}(z_1) + \theta_2\mathcal{B}(z_2) + \theta_1\Phi(z_1) + \theta_2\Phi(z_2) + \Delta$$

$$= \theta_1\left[\Phi(z_1) + \mathcal{B}(z_1)\right] + \theta_2\left[\Phi(z_2) + \mathcal{B}(z_2)\right] + \Delta = \theta_1 G(z_1) + \theta_2 G(z_2) + \Delta. \qquad \square$$

Now we are ready to study the set (1.20).

LEMMA 4.6. *Let* $\inf_{z\in D}\mathcal{F}(z) > -\infty$. *Define the set* C_+ *by* (1.20). *Then the closure* $\overline{C_+}$ *is convex.*

Proof. In terms of the mapping $G(z) := [\mathcal{F}(z), \mathcal{G}(z)] \in \mathfrak{Y} := \mathbb{R}\times Y$ and the cone $\mathfrak{K}_+ := \{\xi = (t,y) \in \mathfrak{Y} : t \geq 0, y \geq 0\}$, formula (1.20) takes the form $C_+ = G(Z) + \mathfrak{K}_+$ and implies that $C_+ + \mathfrak{K}_+ \subset C_+$, i.e., $C_+ + \xi^+ \subset C_+$ for any $\xi^+ \in \mathfrak{K}_+$. By passing to the closure, we get $\overline{C_+} + \xi^+ \subset \overline{C_+}$. In other words,

$$\overline{C_+} + \mathfrak{K}_+ \subset \overline{C_+}. \tag{4.13}$$

To prove the lemma, it suffices to demonstrate that

$$\theta_1 G(z_1) + \theta_2 G(z_2) \in \overline{C_+} \tag{4.14}$$

whenever $z_1, z_1 \in Z, \theta_1, \theta_2 \geq 0$, and $\theta_1 + \theta_2 = 1$. Indeed, (4.14) means that $\theta_1 G(Z) + \theta_2 G(Z) \subset \overline{C_+}$. Then, taking into account (4.13), we have

$$\theta_1 C_+ + \theta_2 C_+ = \theta_1 [G(Z) + \mathfrak{K}_+] + \theta_2 [G(Z) + \mathfrak{K}_+]$$

$$= [\theta_1 G(Z) + \theta_2 G(Z)] + [\theta_1 \mathfrak{K}_+ + \theta_2 \mathfrak{K}_+] \subset \overline{C_+} + \mathfrak{K}_+ \subset \overline{C_+}.$$

This immediately implies the inclusion $\overline{C_+} \supset \overline{\theta_1 C_+ + \theta_2 C_+}$, where clearly $\overline{\theta_1 C_+ + \theta_2 C_+} \supset \theta_1\overline{C_+} + \theta_2\overline{C_+}$. Thus $\theta_1\overline{C_+} + \theta_2\overline{C_+} \subset \overline{C_+}$ whenever $\theta_1, \theta_2 \geq 0$ and $\theta_1 + \theta_2 = 1$ that means the convexity of the set $\overline{C_+}$ and proves the lemma.

Turn to demonstration of (4.14). Let $z_1, z_2 \in Z, \theta_1, \theta_2 \geq 0$, and $\theta_1 + \theta_2 = 1$. Denote $\Delta z := z_2 - z_1 \in \mathfrak{M}$, and choose $\epsilon > 0$. Assumptions (A) and (B) of Theorem 2.2 yield that the set

$$\begin{aligned} V := \{h \in \mathfrak{M} : |B(z_1, h)| < \epsilon, |B(\Delta z, h)| < \epsilon, \\ |\Phi(\theta_1 z_1 + \theta_2 z_2 + h) - \Phi(\theta_1 z_1 + \theta_2 z_2)| < \epsilon\} \end{aligned} \tag{4.15}$$

is a neighborhood of the origin in $\mathfrak{M}$. Choose a convex neighborhood of the origin $V_{\mathrm{c}} \subset V$. Taking into account (4.4), we have $\mathcal{B}(\Delta z) \in \mathcal{B}(\mathfrak{M}) \subset \overline{\mathcal{B}(\mathfrak{M})^+} = \mathcal{K}^+(\mathcal{B}|_{\mathfrak{m}})$. By (3.1), this implies $\mathcal{B}(\Delta z) \in \overline{\mathcal{B}(V_{\mathrm{c}})^+}$. Consequently, there exist vectors $\delta z \in V_{\mathrm{c}}, \xi^+ \in \mathfrak{Y}$, and $\Delta\xi \in \mathfrak{Y}$ such that (4.5) is true. Since the set V_{c} is convex, $\rho\delta z \in V_{\mathrm{c}}$ for all $\rho \in [0,1]$ and, in particular, $\delta z, \sqrt{\theta_1\theta_2}\delta z \in V_{\mathrm{c}} \subset V$. Then, due to (4.15), we have (4.6) and (4.7). Thus, the assumptions of Lemma 4.5 are fulfilled.

By this lemma, the vector (4.8) belongs to Z and relations (4.9) are valid with an appropriate vector $\Delta \in \mathfrak{Y}$. By (1.20), the first relation in (4.9) means that $\theta_1 G(z_1) + \theta_2 G(z_2) + \Delta \in C_+$. Taking into account the second relation in (4.9) and letting $\epsilon \to +0$, we get (4.14). □

Proof of Theorem 2.2. By Lemma 4.1, formula (1.12) and the applicability of the method (I)–(IV) follow from Lemma 4.6.

It remains to prove the second assertion of Theorem 2.2. Namely, we have to show that the Lagrangian function (1.4) is convex on Z and the quadratic form (1.13) is nonnegative on $\mathfrak{M}$ whenever $\tau^* \geq 0$ and $S_0(\tau^*) := \inf_{z\in Z} S(\tau^*, z) > -\infty$.

Let $\tau^* \geq 0$ and $S_0(\tau^*) > -\infty$. Choose $z_0 \in Z$. Given $h \in \mathfrak{M}$, we have $z := z_0 + h \in Z$. Then, by (1.3), (1.4), and (1.13),

$$S_0(\tau^*) \leq S(\tau^*, z) = \mathcal{B}_{\tau^*}(z) + \underbrace{\Phi_{\mathcal{F}}(z) + \tau^*\Phi_{\mathcal{G}}(z)}_{\phi(z)}$$

$$= \mathcal{B}_{\tau^*}(z_0) + 2\underbrace{[B_{\mathcal{F}}(z_0, h) + \tau^* B_{\mathcal{G}}(z_0, h)]}_{b} + \mathcal{B}_{\tau^*}(h) + \phi(z_0 + h).$$

Let $h \to 0,\ h \in \mathfrak{M}$. Then $b \to 0$ by assumption (B) of Theorem 2.2 and $\phi(z_0 + h) \to \phi(z_0)$ due to assumption (A) of this theorem. Hence

$$-\infty < S_0(\tau^*) \le \mathcal{B}_{\tau^*}(z_0) + \phi(z_0) + \overbrace{\liminf_{h \to 0,\ h \in \mathfrak{m}} \mathcal{B}_{\tau^*}(h)}^{\sigma},$$

i.e., $\sigma > -\infty$. It was shown in section 2 that either $\sigma = 0$ or $\sigma = -\infty$. Therefore, $\sigma = 0$ and (2.3) implies that $\mathcal{B}_{\tau^*}(h) \ge 0$ for all $h \in \mathfrak{M}$; i.e., the quadratic form (1.13) is nonnegative on $\mathfrak{M}$. Then, as it is well known, this form is convex on Z, and so is the function $\phi(z)$ by assumption (A) of Theorem 2.2. As a result, the Lagrangian function $S(\tau^*, z) = \mathcal{B}_{\tau^*}(z) + \phi(z)$ is also convex on Z. □

5. Method of duality for nonconvex problems of optimal control with inequality constraints. In this section we apply Theorem 2.2 to indicate a number of nonconvex optimal control problems to which the method (I)–(IV) is applicable. It is only for definiteness that we shall confine our remarks to consideration of systems described by ordinary differential equations. Analogous examples can be given for other systems (discrete-time, distributed, and so on).

Consider the following problem of optimal control:

$$\mathcal{G}_0 \to \min \quad \text{subject to} \quad \mathcal{G}_1 \le 0, \dots, \mathcal{G}_k \le 0, \tag{5.1}$$

$$\dot{x} = A(t)x + B(t)u, \quad x = x(t) \in \mathbb{R}^l, \quad u = u(t) \in \mathbb{R}^m, \quad 0 \le t < \infty\,, \tag{5.2}$$

$$x(0) = a, \quad |x(\cdot)| + |u(\cdot)| \in L_2\,, \tag{5.3}$$

$$\mathcal{G}_i := \int_0^\infty g_i(t,x,u)\,dt + \int_0^\infty \phi_i(t,x,u)\,dt - \gamma_i \quad (i = 0, \dots, k)\,. \tag{5.4}$$

Here $x = x(t)$ is the state and $u = u(t)$ is the control, $A(t)$ and $B(t)$ are matrices of respective sizes $l \times l$ and $l \times m$, $g_i(t,x,u) = x^* G_i(t) x + 2x^* Q_i(t) u + u^* \Gamma_i(t) u$ is a quadratic form in x and u, the function $\phi_i(t,x,u)$ is assumed to be at least convex in $x,\ u$, and $\gamma_0, \dots, \gamma_k$ are given reals, $\gamma_0 = 0$. The matrix-valued functions $A(\cdot), B(\cdot), G_i(\cdot) = G_i(\cdot)^*, Q_i(\cdot), \Gamma_i(\cdot) = \Gamma_i(\cdot)^*$ are measurable, so are the functions $\phi_i(\cdot, x, u)$ for all x, u. Further we shall impose additional assumptions on $g_i(\cdot)$ and $\phi_i(\cdot)$ to ensure the convergence of the integrals in (5.4) for all $x(\cdot) \in L_2,\ u(\cdot) \in L_2$. The problem under consideration is a particular case of the abstract problem (1.1) with the constraints (1.2): now $H := L_2\left([0, +\infty) \to \mathbb{R}^l\right) \times L_2\left([0, +\infty) \to \mathbb{R}^m\right),\ Z := \{z = [x(\cdot),\ u(\cdot)] \in H : (5.2) \text{ and } (5.3) \text{ are true}\},\ \mathcal{F} := \mathcal{G}_0$, and $\mathcal{G}_1, \dots, \mathcal{G}_k$ are defined by (5.4).

It is worthy to note first that, in general, the method (I)–(IV) fails to be valid for the problem (5.1)–(5.4). (See the example in subsection 5.5 at the end of the section.) Nevertheless, we shall indicate a number of particular cases of this problem for which

($\mathfrak{A}$) *the method* (I)–(IV) *is valid and the duality relation* (1.12) *is true* and

($\mathfrak{B}$) *the Lagrangian function* (1.4) *is convex on the domain* Z *of all processes* $[x(\cdot), u(\cdot)]$ *that satisfy* (5.2) *and* (5.3) *whenever* $\tau^* \ge 0$ *and the infimum of the Lagrangian function on* Z *is finite.*

In each of these cases, the admissible domain and the objective function can be nonconvex due to the absence of assumptions on $g_i(t,x,u)$ that imply the convexity of the first summand in (5.4).

Interpreting Definition 2.1, we see that *the problem* (5.1)–(5.4) *is regular if and only if there exists a process* $[x(\cdot),\ u(\cdot)]$ *such that relations* (5.2) *and* (5.3) *are true and* $\mathcal{G}_1 < 0, \dots, \mathcal{G}_k < 0$ *with* $\mathcal{G}_i$ *being defined by* (5.4).

5.1. Stationary linear-quadratic problem.

LEMMA 5.1. *Let* $A(t) = A,\ B(t) = B,\ G_i(t) = G_i,\ Q_i(t) = Q_i,$ *and* $\Gamma_i(t) = \Gamma_i$ *be constant matrices. Assume that the pair* (A, B) *is stabilizable and* $\phi_i(t, x, u) = r_i(t)^* x + \rho_i(t)^* u$ *with* $|r_i(\cdot)| + |\rho_i(\cdot)| \in L_2$.

Then assertions $(\mathfrak{A})$ *and* $(\mathfrak{B})$ *are true provided that the problem* (5.1)–(5.4) *is regular.*

Proof. Rewrite the problem (5.1)–(5.4) in the form (1.1) as it was done above. Equip H with the weak topology. Given $z_i = [x_i(\cdot),\ u_i(\cdot)] \in H,\ i = 1, 2,\ z = [x(\cdot),\ u(\cdot)] \in H$, we put

$$B_i(z_1, z_2) := \int_0^{+\infty} \begin{bmatrix} x_1(t) \\ u_1(t) \end{bmatrix}^* \begin{pmatrix} G_i(t) & Q_i(t) \\ Q_i(t)^* & \Gamma_i(t) \end{pmatrix} \begin{bmatrix} x_2(t) \\ u_2(t) \end{bmatrix} dt\ , \tag{5.5}$$
$$B_{\mathcal{F}}(\cdot,\cdot) := B_0(\cdot,\cdot), \qquad B_{\mathcal{G}}(\cdot,\cdot) := [B_1(\cdot,\cdot), \dots, B_k(\cdot,\cdot)]\ ,$$

$$\Phi_i(z) := \int_0^{+\infty} \phi_i\left[t, x(t), u(t)\right]\ dt - \gamma_i\ , \tag{5.6}$$
$$\Phi_{\mathcal{F}}(\cdot) := \Phi_0(\cdot), \qquad \Phi_{\mathcal{G}}(\cdot) = [\Phi_1(\cdot), \dots, \Phi_k(\cdot)]\ .$$

Then the decomposition (1.3) is valid and the mappings $B_{\mathcal{F}}(\cdot,\cdot),\ B_{\mathcal{G}}(\cdot,\cdot),\ \Phi_{\mathcal{F}}(\cdot)$, and $\Phi_{\mathcal{G}}(\cdot)$ are evidently continuous with respect to the norm of H with $\Phi_{\mathcal{F}}(\cdot)$ and $\Phi_{\mathcal{G}}(\cdot)$ being linear in z. This clearly implies assumptions (A) and (B) of Theorem 2.2. Its assumption (C) follows from assumption (C.3) of Lemma 2.3 by this lemma. To prove (C.3), choose a sequence $\{t_n\},\ t_n > 0,\ t_n \to \infty$, and define the operator $T_n : H \to H$ to be the right shift $T_n[x(\cdot),\ u(\cdot)] := [\widehat{x}(\cdot),\ \widehat{u}(\cdot)],\ \widehat{x}(t) := x(t - t_n),\ \widehat{u}(t) := u(t - t_n)$ if $t \geq t_n$ and $\widehat{x}(t) := 0,\ \widehat{u}(t) := 0$ otherwise. Now the space $\mathfrak{M} := Z - Z$ is obviously described by relations (5.2) and (5.3) with $a = 0$. So it is very easy to see that, due to stationarity,

$$T_n \mathfrak{M} \subset \mathfrak{M},\ B_{\mathcal{P}}(T_n h,\ T_n h) = B_{\mathcal{P}}(h, h) \quad \forall n = 1, 2, \dots,\ \mathcal{P} := \mathcal{F}, \mathcal{G}, h \in \mathfrak{M}. \tag{5.7}$$

Given $z = [x(\cdot),\ u(\cdot)] \in \mathfrak{M},\ h = [y(\cdot),\ v(\cdot)] \in L_2 \times L_2$, we have

$$\begin{aligned} |\langle T_n z, h\rangle| &= \left| \int_{t_n}^{+\infty} y(t)^* x(t - t_n)\ dt + \int_{t_n}^{+\infty} v(t)^* u(t - t_n)\ dt \right| \\ &\leq \left(\int_{t_n}^{+\infty} |y(t)|^2 \right)^{1/2} \left(\int_0^{+\infty} |x(t)|^2 \right)^{1/2} + \left(\int_{t_n}^{+\infty} |v(t)|^2 \right)^{1/2} \left(\int_0^{+\infty} |u(t)|^2 \right)^{1/2} \end{aligned} \tag{5.8}$$

and, consequently, $T_n z \rightharpoonup 0$ with respect to the weak topology as $n \to \infty$. Invoking (5.7), we see that (2.6) is true. This completes the proof of assumption (C.3).

Thus, all the assumptions of Theorem 2.2 are fulfilled and, by this theorem, Lemma 5.1 is valid. □

Remark. Lemma 5.1 was first proved in [11]. Note also that this lemma readily follows from Proposition 1.1. Indeed, consider the self-adjoint operator $A_{\tau^*} : \mathfrak{M} \to \mathfrak{M}$ that corresponds to the form (1.13) $\mathcal{B}_{\tau^*}(h) = \langle A_{\tau^*} h, h\rangle,\ h \in \mathfrak{M}$, and denote by

λ_- the minimal point of its spectrum. Then $\mathcal{B}_-(h) := \mathcal{B}_{\tau^*}(h) - \lambda_- |h|_H^2 \geq 0$ for all $h \in \mathfrak{M}$. Assume that λ_- is an eigenvalue of A_{τ^*} and consider a corresponding eigenvector $h_0 \neq 0$. Then $\mathcal{B}_-(h_0) = 0$. By (5.7), the form (1.13) is invariant, $\mathcal{B}_{\tau^*}(T_n h) = \mathcal{B}_{\tau^*}(h)$, $h \in \mathfrak{M}$, and so evidently is the norm $|T_n h|_H = |h|_H$. From this it follows that $\mathcal{B}_-(T_n h_0) = \mathcal{B}_-(h_0) = 0$ where $T_n h_0 \in \mathfrak{M}$ and $\mathcal{B}_-(h) \geq 0$ for all $h \in \mathfrak{M}$. In other words, $T_n h_0 = \arg\min_{h \in \mathfrak{m}} \mathcal{B}_-(h)$. By applying the Fermat necessary conditions, we see that $h_n := T_n h_0$ is also an eigenvector $A_{\tau^*} h_n = \lambda_- h_n$. It remains to note that the linear hull of all the shifts $h_0, h_1, \ldots$ is an infinite-dimensional subspace provided $h_0 \neq 0$. Thus, even if λ_- is an eigenvalue, its geometrical multiplicity is infinite. So the assumptions of Proposition 1.1 are valid and we prove Lemma 5.1 once more.

In what follows, we shall denote the norm of the space L_q by $|\cdot|_q$.

5.2. Almost-periodic linear-quadratic problem with vanishing convex summands in the objective and constraint functions.

LEMMA 5.2. *Assume that*

(2.i) *the functions $A(\cdot), B(\cdot), G_i(\cdot), Q_i(\cdot)$, and $\Gamma_i(\cdot)$ are almost-periodic (more precisely, each of them has an almost-periodic extension on the real line);*

(2.ii) *the functions $\phi_i(t,x,u)$ are convex in x and u for almost all t and*

$$|\phi_i(t,x,u)| \leq \alpha_i(t)\left(|x|^2 + |u|^2\right) + \beta_i(t)\left(|x| + |u|\right) + \gamma_i(t), \tag{5.9}$$

where $\alpha_0(\cdot) \geq 0, \ldots, \alpha_k(\cdot) \geq 0$ are continuous functions of $t \in [0,\infty)$ such that $\alpha_i(t) \to 0$ as $t \to \infty$ and $\beta_i(\cdot) \in L_2, \gamma_i(\cdot) \in L_1, \beta_i(\cdot) \geq 0, \gamma_i(\cdot) \geq 0$ for all $i = 0, \ldots, k$;

(2.iii) *the system* (5.2) *is stabilizable. Namely, there exists a bounded continuous $m \times l$ matrix function $C(t), 0 \leq t < \infty$ such that the solution $x(\cdot)$ of the Cauchy problem*

$$\dot{x} = (A + BC)\, x + f(t), \quad 0 \leq t < \infty, \quad x(0) = 0, \tag{5.10}$$

belongs to $L_2\left[[0,\infty) \to \mathbb{R}^l\right]$ for any $f(\cdot) \in L_2\left[[0,\infty) \to \mathbb{R}^l\right]$ and

$$|x(\cdot)|_2 \leq c\, |f(\cdot)|_2 \tag{5.11}$$

where the constant c is independent of $f(\cdot)$.

Then assertions ($\mathfrak{A}$) *and* ($\mathfrak{B}$) *are true provided that the problem* (5.1)–(5.4) *is regular.*

Proof. We recall that any collection $\{p^\nu(\cdot)\}_{\nu \in \mathcal{A}}$ of seminorms on a linear space X generates a unique locally convex topology such that a set $V \subset X$ is a neighborhood of the origin iff $V \supset \{x \in X : p^{\nu_1}(x) < \epsilon_1, \ldots, p^{\nu_s}(x) < \epsilon_s\}$ for some $\nu_1, \ldots, \nu_s \in \mathcal{A}$, $\epsilon_1 > 0, \ldots, \epsilon_s > 0$, and $s = 1, 2, \ldots$. The convergence $x_n \to x$ with respect to this topology holds iff $p^\nu(x_n - x) \to 0$ as $n \to \infty$ for all $\nu \in \mathcal{A}$.

Rewrite the problem (5.1)–(5.4) in the form (1.1) just as it was done at the beginning of the section. Denote $\alpha(t) := \alpha_0(t) + \cdots + \alpha_k(t)$, $\beta(t) := \beta_0(t) + \cdots + \beta_k(t)$, and define the seminorm $p : H \to [0, +\infty)$ as

$$\begin{aligned} p(z) := &\left[\int_0^{+\infty} \alpha(t)\left(|x(t)|^2 + |u(t)|^2\right)\, dt\right]^{1/2} \\ &+ \int_0^{\infty} \beta(t)\left(|x(t)| + |u(t)|\right)\, dt. \end{aligned} \tag{5.12}$$

Equip the space H with the topology η that is generated by the collection of seminorms $p(\cdot), \{|\langle z,\cdot\rangle|\}_{z\in H}$ where $\langle\cdot,\cdot\rangle$ is the inner product in H. It is easy to see that

$$\begin{array}{c} h_n \xrightarrow{\eta} 0 \text{ as } n\to\infty \\ \Updownarrow \\ \boxed{h_n \rightharpoonup 0 \ \text{ with respect to the weak topology of } H} \text{ and } p(h_n)\to 0 \text{ as } n\to\infty. \end{array} \tag{5.13}$$

The decomposition (1.3) is clearly valid with the summands being defined by (5.5) and (5.6). Due to (5.6), (5.9), and (5.12), the convex functions $\Phi_{\mathcal{F}}(\cdot)$ and $\Phi_{\mathcal{G}}(\cdot)$ are bounded above on the η-open set $V := \{z\in H : p(z)<1\}$. From this it follows that these functions are η-continuous [3, p. 12], and so obviously are the operators $B_{\mathcal{F}}(z,\cdot)$ and $B_{\mathcal{G}}(z,\cdot)$ for any $z\in H$. This means that assumptions (A) and (B) of Theorem 2.2 are fulfilled.

To prove (C), it suffices to demonstrate assumption (C.2) of Lemma 2.3. To this end, consider a Lagrange multiplier $\tau^* = \tau = \|\tau_i\| \in \mathbb{R}^k,\ \tau\geq 0$. The corresponding form (1.13) clearly looks as follows:

$$\mathcal{B}_\tau(z) = \int_0^{+\infty} x^*G_\tau(t)x\,dt + 2\int_0^{+\infty} x^*Q_\tau(t)u\,dt + \int_0^{+\infty} u^*\Gamma_\tau(t)u\,dt, \tag{5.14}$$

where $z=[x(\cdot),u(\cdot)],\ x=x(t),\ u=u(t)$, and $P_\tau(\cdot) := P_0(\cdot)+\tau_1P_1(\cdot)+\cdots+\tau_kP_k(\cdot)$ for $P := G,Q,\Gamma$. For $P := G,Q,\Gamma$, the function $P_\tau(\cdot)$ is almost periodic [31, p. 10], and so is the function $\Xi(t) := [A(-t),B(-t),G_\tau(t),Q_\tau(t),\Gamma_\tau(t)]$ [31, p. 10]. Applying the Bohr definition of an almost-periodic function [31, p. 3] to $\Xi(\cdot)$, we conclude that there exists a sequence $\{t_n\}_{n=1}^\infty \subset (0,+\infty)$ such that $t_n\to\infty$ as $n\to\infty$ and

$$\Delta_n^P := \sup_{t\in\mathbb{R}} |P(t) - P(t+\sigma_P t_n)| \to 0 \quad \text{as} \quad n\to\infty \tag{5.15}$$

for any function $P(\cdot) := A(\cdot),B(\cdot),G_\tau(\cdot),Q_\tau(\cdot),\Gamma_\tau(\cdot)$, where $\sigma_P=-1$ for $P(\cdot) := A(\cdot),B(\cdot)$ and $\sigma_P := 1$ otherwise.

Let $h=[x(\cdot),u(\cdot)]\in\mathfrak{M}$ where $\mathfrak{M}$ is described by relations (5.2) and (5.3) with $a=0$. We have to construct a sequence $h_n=[x_n(\cdot),u_n(\cdot)]\in\mathfrak{M}, n=1,2,\ldots,$ such that (2.5) is true. Shift the process h to the right $\widehat{h}_n := [y_n(\cdot),v_n(\cdot)],\ y_n(t) := x(t-t_n),\ v_n(t) := u(t-t_n)$ if $t\geq t_n$ and $y_n(t):=0,\ v_n(t):=0$ otherwise. Then (5.2) implies that

$$\dot{y}_n = A(t)y_n + B(t)v_n + f_n(t), \quad 0\leq t<\infty, \quad y_n(0)=0,$$

where $f_n(t) := [A(t-t_n)-A(t)]\,y_n(t) + [B(t-t_n)-B(t)]\,v_n(t)$. Taking into account (5.15), we see that $|f_n(\cdot)|_2 \leq \Delta_n^A\,|y_n(\cdot)|_2 + \Delta_n^B\,|v_n(\cdot)|_2 = \Delta_n^A\,|x(\cdot)|_2 + \Delta_n^B\,|u(\cdot)|_2 \to 0$ as $n\to\infty$. Consider the solution $x(\cdot)=\Delta x_n(\cdot)$ of the Cauchy problem (5.10) with $f(\cdot) := -f_n(\cdot)$. Denoting $\Delta u_n(\cdot) := C(\cdot)\Delta x_n(\cdot),\ x_n(\cdot) := y_n(\cdot)+\Delta x_n(\cdot),\ u_n(\cdot) := v_n(\cdot)+\Delta u_n(\cdot)$, we see that, by (5.11),

$$|\Delta x_n(\cdot)|_2 + |\Delta u_n(\cdot)|_2 \to 0 \quad \text{as} \quad n\to\infty \tag{5.16}$$

and also that $x_n(0)=0,\ \dot{x}_n = \dot{y}_n + \Delta\dot{x}_n = [Ay_n+Bv_n+f_n] + [(A+BC)\Delta x_n - f_n]$ $= A(y_n+\Delta x_n) + B(v_n+C\Delta x_n) = Ax_n+Bu_n$, i.e., $h_n := [x_n(\cdot),u_n(\cdot)]\in\mathfrak{M}$.

Thus, a sequence $\{h_n\}\subset\mathfrak{M}$ is indicated. Put $z:=h_n$ in (5.14). Then the first summand in (5.14) looks as follows

$$\int_0^\infty [y_n(t)+\Delta x_n(t)]^* G(t)\,[y_n(t)+\Delta x_n(t)]\ dt$$

$$= \underbrace{\int_0^\infty y_n(t)^* G(t) y_n(t)\ dt}_{a_1} + \underbrace{2\int_0^\infty y_n(t)^* G(t)\Delta x_n(t)\ dt}_{a_2} + \underbrace{\int_0^\infty \Delta x_n(t)^* G(t)\Delta x_n(t)\ dt}_{a_3}.$$

Denoting $g := \sup_{t\in\mathbb{R}} |G(t)|$, we have by (5.16)

$$|a_2| \le 2g\,|y_n(\cdot)|_2\,|\Delta x_n(\cdot)|_2 = 2g\,|x(\cdot)|_2\,|\Delta x_n(\cdot)|_2 \to 0,\ \ |a_3| \le g\,|\Delta x_n(\cdot)|_2^2 \to 0 \text{ as } n\to\infty.$$

In the light of (5.15), we see that

$$\left|a_1 - \int_0^\infty x(t)^* G(t) x(t)\ dt\right| = \left|\int_{t_n}^\infty x\,(t-t_n)^*\,G(t)x\,(t-t_n)\ dt - \int_0^\infty x(t)^* G(t)x(t)\ dt\right|$$

$$= \left|\int_0^\infty x(t)^*\,[G\,(t+t_n) - G(t)]\,x(t)\ dt\right| \le \Delta_n^G |x(\cdot)|_2^2 \to 0 \ \text{ as } \ n\to\infty.$$

Thus, $a_1 \to \int x(t)^* G(t) x(t)\ dt$ as $n\to\infty$.

Considering the second and the third summands in (5.14) by analogy, we get the equality

$$\lim_{n\to\infty} \mathcal{B}_\tau\,(h_n) = \mathcal{B}_\tau(h),$$

which implies the second relation in (2.5). To complete the proof of (2.5), it remains to show that $h_n \xrightarrow{\eta} 0$ as $n\to\infty$. Since, in (5.13), the assertion framed follows from (5.8) and (5.16), we have to prove only the convergence $p\,(h_n)\to 0$ as $n\to\infty$, which evidently follows from (5.12) and the estimations

$$p\,(h_n) = p\,([y_n(\cdot),\ v_n(\cdot)] + [\Delta x_n(\cdot),\ \Delta u_n(\cdot)]) \le p\,[y_n(\cdot),\ v_n(\cdot)] + p\,[\Delta x_n(\cdot),\ \Delta u_n(\cdot)]\,,$$

$$p\,[y_n(\cdot),\ v_n(\cdot)] = \left(\int_{t_n}^\infty \alpha(t)\left(|x\,(t-t_n)|^2 + |u\,(t-t_n)|^2\right)\ dt\right)^{1/2}$$

$$+ \int_{t_n}^\infty \beta(t)\,(|x\,(t-t_n)| + |u\,(t-t_n)|)\ dt$$

$$\le \left[\ \sup_{t\ge t_n} \alpha(t)\right]^{1/2} \left(|x(\cdot)|_2^2 + |u(\cdot)|_2^2\right)^{1/2} + \left(\int_{t_n}^\infty |\beta(t)|^2\ dt\right)^{1/2} (|x(\cdot)|_2 + |u(\cdot)|_2)\,,$$

$$p\,[\Delta x_n(\cdot),\ \Delta u_n(\cdot)] \le \left[\ \sup_{t\ge t_n} \alpha(t)\right]^{1/2} \left(|\Delta x_n(\cdot)|_2^2 + |\Delta u_n(\cdot)|_2^2\right)^{1/2}$$

$$+ \left(\int_{t_n}^\infty |\beta(t)|^2\ dt\right)^{1/2} (|\Delta x_n(\cdot)|_2 + |\Delta u_n(\cdot)|_2)\,.$$

Here $\sup_{t\geq t_n}\alpha(t)\to 0$ and $\int_{t_n}^{\infty}|\beta(t)|^2\,dt\to 0$ as $n\to\infty$ by (2.ii). Thus, Assumption (C.2) of Lemma 2.3 is satisfied.

Thus, all the assumptions of Theorem 2.2 are fulfilled and, by this theorem, Lemma 5.2 is valid. □

In dealing with the previous examples, the point was the use of the right shifts of the process. The subsequent examples will present another technique. It leans upon the following frequency criterion for nonnegativity of an integral quadratic form on the subspace $\mathfrak{M}$ of all processes satisfying (5.2) and (5.3) with $a=0$.

LEMMA 5.3 (see [17]). *Let, in* (5.2), (5.4), $A(t)=A$, $B(t)=B$, $G_0(t)=G_0$, $Q_0(t)=Q_0$, $\Gamma_0(t)=\Gamma_0$ *be constant matrices and* $\phi_0(t,x,u)=0$, $\gamma_0=0$. *Also let the pair* A,B *be stabilizable. Denote by* $\mathbb{C}$ *the complex plane, and extend the function* $g(\cdot):=g_0(\cdot)$ *on* $\mathbb{C}^l\times\mathbb{C}^m$ *as Hermitian form, i.e.,* $g(x'+\imath x'',\,u'+\imath u'):=g(x',u')+g(x'',u'')$ *for all* $x',x''\in\mathbb{R}^l$, $u',u''\in\mathbb{R}^m$, *where* $\imath$ *is the imaginary unity. Define* $\mathcal{G}_0$ *by* (5.4), *and denote by* I *the unit* $l\times l$*-matrix.*

Then $\mathcal{G}_0\geq 0$ *for all processes* $x(\cdot),u(\cdot)$ *satisfying* (5.2) *and* (5.3) *with* $a=0$ *if and only if*

$$g(y,v)\geq 0 \text{ for all } y\in\mathbb{C}^l,\ v\in\mathbb{C}^m,\ \text{and } \omega\in\mathbb{R} \text{ such that } \imath\omega y=Ay+Bv. \tag{5.17}$$

5.3. Linear-quadratic problem with quadratic constraints. Stationary object and nonstationary quadratic forms.

LEMMA 5.4. *Assume* that

(3.i) $g_i(t,x,u)=g_i^0(x,u)+\Delta g_i(t,x,u)$, *where* $g_i^0(x,u)=x^*G_i^0x+2x^*Q_i^0u+u^*\Gamma_i^0u$ *and* $\Delta g_i(t,x,u)=x^*\Delta G_i(t)x+2x^*\Delta Q_i(t)u+u^*\Delta\Gamma_i(t)u$ *are quadratic forms in* x,u;

(3.ii) $\Delta g_i(t,x,u)\geq 0$ *for all* x,u *and almost all* $t\geq 0$;

(3.iii) $\Delta G_i(\cdot)\in L_\infty$, $\Delta Q_i(\cdot)\in L_\infty$, $\Delta\Gamma_i(\cdot)\in L_\infty$;

(3.iv) *given* $y\in\mathbb{R}^l$ *and* $v\in\mathbb{R}^m$, *we have*

$$\frac{1}{T}\int_0^T\Delta g_i(t,y,v)\,dt\to 0\quad as\quad T\to\infty; \tag{5.18}$$

(3.v) $A(t)=A$ *and* $B(t)=B$ *are constant matrices and the pair* (A,B) *is stabilizable;*

(3.vi) $\phi_i(t,x,u)=r_i(t)^*x+\rho_i(t)^*u$ *with* $|r_i(\cdot)|+|\rho_i(\cdot)|\in L_2$.

Then assertions $(\mathfrak{A})$ *and* $(\mathfrak{B})$ *are true provided that the problem* (5.1)–(5.4) *is regular.*

Proof. Rewrite the problem (5.1)–(5.4) in the form (1.1) just as it was done at the beginning of the section. Equip H with the weak topology and define the mappings $B_{\mathcal{F}}(\cdot)$, $B_{\mathcal{G}}(\cdot)$, $\Phi_{\mathcal{F}}(\cdot)$, $\Phi_{\mathcal{G}}(\cdot)$ by (5.5) and (5.6). Then the decomposition (1.3) is obviously valid and assumptions (A) and (B) of Theorem 2.2 are fulfilled. To prove (C), it suffices to demonstrate assumption (C.1) of Lemma 2.3. To this end, consider a Lagrange multiplier $\tau^*=\tau=\|\tau_i\|\in\mathbb{R}^k$, $\tau\geq 0$. The corresponding form (1.13) now clearly looks as follows:

$$\mathcal{B}_\tau(z):=\underbrace{\int_0^{+\infty}g_\tau^0\left[x(t),u(t)\right]\,dt}_{\mathcal{B}_\tau^0(z)}+\underbrace{\int_0^{+\infty}\Delta g_\tau\left[t,x(t),u(t)\right]\,dt}_{\Delta\mathcal{B}_\tau(z)}, \tag{5.19}$$

where $g_\tau^0(\cdot):=g_0^0(\cdot)+\tau_1g_1^0(\cdot)+\cdots+\tau_kg_k^0(\cdot)$ and $\Delta g_\tau(\cdot):=\Delta g_0(\cdot)+\tau_1\Delta g_1(\cdot)+\cdots+\tau_k\Delta g_k(\cdot)$. Assumptions (3.i)–(3.iv) apparently remain valid for $i:=\tau$.

Let $\mathcal{B}_\tau(h) < 0$ for some $h \in \mathfrak{M}$. Since $\Delta\mathcal{B}_\tau(h) \geq 0$ by (3.ii), we have $\mathcal{B}^0_\tau(h) < 0$. Thus, the quadratic form $\mathcal{B}^0_\tau(h)$ is not nonnegative on the subspace $\mathfrak{M}$ of all processes $[x(\cdot), u(\cdot)]$ satisfying (5.2) and (5.3) with $a = 0$. By Lemma 5.3,

$$g^0_\tau(y, v) < 0, \qquad \imath\omega = Ay + Bv \tag{5.20}$$

for some $y \in \mathbb{C}^l,\ v \in \mathbb{C}^m$, and $\omega \in \mathbb{R}$. Here $g^0_\tau(x, u)$ is extended on $\mathbb{C}^l \times \mathbb{C}^m$ as Hermitian form. Using the analogous extension of the form $\Delta g_\tau(t, x, u)$, we make the definition (5.19) of $\mathcal{B}_\tau(z)$ valid for processes $[x(\cdot), u(\cdot)]$ with complex-valued components $x(t) \in \mathbb{C}^l,\ u(t) \in \mathbb{C}^m$.

Since the pair (A, B) is stabilizable, there exists a real $l \times m$ matrix C such that the equation $\dot{x} = (A + BC^*)\, x$ is stable. Its solution $x(t),\ t \geq 0$ with $x(0) = a \in \mathbb{C}^l$ belongs to L_2. Denote $x(t|a) := x(t)$ if $t \geq 0$ and $x(t|a) := 0$ otherwise and put $u(\cdot|a) := C^* x(\cdot|a)$. Then we have

$$\dot{x}(t|a) = Ax(t|a) + Bu(t|a) \quad (\text{if } t \neq 0), \quad x(0 + 0|a) = a,$$

$$|x(\cdot|a)|_2 + |u(\cdot|a)|_2 \leq c_2|a| \qquad \forall a \in \mathbb{C}^l\ . \tag{5.21}$$

Now we are ready to construct a sequence of processes to ensure assumption (C.1) of Lemma 2.3. Namely, choose a sequence $\{t_n\} \subset (0, \infty),\ t_n \to \infty$, denote $\chi_n(t) := 1$ if $0 \leq t \leq t_n$ and $\chi_n(t) := 0$ otherwise, and put $z_n := [x_n(\cdot), u_n(\cdot)]$, where

$$\begin{aligned} x_n(t) :=\ & \underbrace{t_n^{-1/2} y\ e^{\imath\omega t}\chi_n(t)}_{x^0_n(t)} + \underbrace{t_n^{-1/2}\left\{x\,[|t| - y] + x\left[t - t_n|e^{\imath\omega t_n} y\right]\right\}}_{\Delta x_n(t)}, \\ u_n(t) :=\ & \underbrace{t_n^{-1/2} v\ e^{\imath\omega t}\chi_n(t)}_{u^0_n(t)} + \underbrace{t_n^{-1/2}\left\{u\,[|t| - y] + u\left[t - t_n|e^{\imath\omega t_n} y\right]\right\}}_{\Delta u_n(t)}. \end{aligned} \tag{5.22}$$

It is easy to see that $|x_n(\cdot)| + |u_n(\cdot)| \in L_2,\ \dot{x}_n = Ax_n + Bu_n$ for $t \geq 0, t \neq t_n$ and also that $x_n(0 + 0) = 0,\ x_n(t_n - 0) = x_n(t_n + 0)$. The last relation implies that the differential equation is valid for all $t \geq 0$. Therefore, separating the real $z^{(1)}_n$ and the imaginary $z^{(2)}_n$ parts of the process $z_n = z^{(1)}_n + \imath z^{(2)}_n$, we evidently have $z^{(1)}_n,\ z^{(2)}_n \in \mathfrak{M}$. (We recall that the subspace $\mathfrak{M}$ is described by relations (5.2) and (5.3) with $a = 0$.) By (5.19), $\mathcal{B}_\tau(z_n) = \mathcal{B}_\tau(z^{(1)}_n) + \mathcal{B}_\tau(z^{(2)}_n)$ and, consequently,

$$\liminf_{n\to\infty} \mathcal{B}_\tau(z_n) \geq \liminf_{n\to\infty} \mathcal{B}_\tau(z^{(1)}_n) + \liminf_{n\to\infty} \mathcal{B}_\tau(z^{(2)}_n)\,. \tag{5.23}$$

It is easy to see that $\left|x^0_n(\cdot)\right|_2 = |y|,\ \left|u^0_n(\cdot)\right|_2 = |v|$ and, by (5.21), $|\Delta x_n(\cdot)|_2 \leq 2t_n^{-1/2}c_2|y| \to 0,\ |\Delta u_n(\cdot)|_2 \leq 2t_n^{-1/2}c_2|y| \to 0$ as $n \to \infty$. Denoting $z^0_n := \left[x^0_n(\cdot), u^0_n(\cdot)\right]$ and $\Delta z_n := [\Delta x_n(\cdot), \Delta u_n(\cdot)]$, we have $\left|z^0_n\right|^2_H = |y|^2 + |v|^2,\ |\Delta z_n|_H \to 0$ as $n \to \infty$ and so

$$\left|\mathcal{B}_\tau(z_n) - \mathcal{B}_\tau\left(z^0_n\right)\right| \leq 2\left|B_\tau\left(\Delta z_n, z^0_n\right)\right| + \left|\mathcal{B}_\tau(\Delta z_n)\right|$$

$$\leq 2\,\|B_\tau\|\left|z^0_n\right|_H |\Delta z_n|_H + \|B_\tau\|\,|\Delta z_n|^2_H \to 0 \quad \text{as } n \to \infty.$$

This and the definition of $x^0_n(\cdot), u^0_n(\cdot)$ yield that

$$f := \lim_{n\to\infty} \mathcal{B}_\tau(z_n) = \lim_{n\to\infty} \mathcal{B}_\tau\left(z^0_n\right) = \lim_{n\to\infty} \left\{ t_n^{-1} \int_0^{t_n} g^0_\tau\left[e^{\imath\omega t}\ y,\ e^{\imath\omega t}\ v\right]\ dt \right.$$

$$\left. + t_n^{-1} \int_0^{t_n} \Delta g_\tau\left[e^{\imath\omega t}\ y,\ e^{\imath\omega t}\ v\right]\ dt \right\} = g^0_\tau(y, v) + \lim_{n\to\infty} t_n^{-1} \int_0^{t_n} \Delta g_\tau(t, y, v)\ dt.$$

Then, by (5.18) and (5.20), $f = g^0_\tau(y, v) < 0$. In light of (5.23), we see that $\liminf$ from (2.4) is negative at least for one of the two sequences $\{h_n\} := \{z^{(1)}_n\}$, $\{z^{(2)}_n\} \subset \mathfrak{M}$.

To complete the proof of assumption (C.1), it remains to show that $z^{(\nu)}_n \longrightarrow 0$ with respect to the weak topology of $L_2 \times L_2$ or, in other words, that $\langle z^{(\nu)}_n, \widetilde{z}\rangle \to 0$ as $n \to \infty$ for all $\widetilde{z} = [\widetilde{x}(\cdot),\ \widetilde{u}(\cdot)] \in L_2 \times L_2$. It is obvious that

$$|\langle z^{(\nu)}_n, \widetilde{z}\rangle| \le \underbrace{\int_0^\infty |x_n(t)|\,|\widetilde{x}(t)|\ dt}_{\alpha_n} + \underbrace{\int_0^\infty |u_n(t)|\,|\widetilde{u}(t)|\ dt}_{\beta_n},$$

$$\alpha_n \le \int_0^\infty |\Delta x_n(t)|\,|\widetilde{x}(t)|\ dt + \int_0^\infty \left|x^0_n(t)\right|\,|\widetilde{x}(t)|\ dt$$

$$\le |\Delta x_n(\cdot)|_2\,|\widetilde{x}(\cdot)|_2 + \int_0^T \left|x^0_n(t)\right|\,|\widetilde{x}(t)|\ dt + \int_T^\infty \left|x^0_n(t)\right|\,|\widetilde{x}(t)|\ dt$$

for any $T > 0$. Here $\left|x^0_n(t)\right| \le t_n^{-1/2}|y|$ for all $t \ge 0$ and $\left|x^0_n(\cdot)\right|_2 = |y|$. So we have

$$\alpha_n \le |\Delta x_n(\cdot)|_2\,|\widetilde{x}(\cdot)|_2 + t_n^{-1/2}|y| \int_0^T |\widetilde{x}(t)|\ dt + \left|x^0_n(\cdot)\right|_2 \left(\int_T^\infty |\widetilde{x}(t)|^2\ dt\right)^{1/2}$$

$$\le |\Delta x_n(\cdot)|_2\,|\widetilde{x}(\cdot)|_2 + \left(\frac{T}{t_n}\right)^{1/2} |y|\,|\widetilde{x}(\cdot)|_2 + |y| \left(\int_T^\infty |\widetilde{x}(t)|^2\ dt\right)^{1/2}.$$

Successively letting $n \to \infty$ and then $T \to \infty$, we see that $\alpha_n \to 0$ as $n \to \infty$. By analogy, $\beta_n \to 0$ as $n \to \infty$ that completes the proof of assumption (C.1).

Thus, all the assumptions of Theorem 2.2 are fulfilled and, by this theorem, Lemma 5.4 is valid. □

Remarks. 1. Lemma 5.4 remains valid if assumption (3.ii) is replaced by the following more general one.

(3.ii′) *For each* $\tau^* = \tau = \|\tau_i\| \in \mathbb{R}^k$, *denote* $g^0_\tau(\cdot) := g^0_0(\cdot) + \tau_1 g^0_1(\cdot) + \cdots + \tau_k g^0_k(\cdot)$, $\Delta g_\tau(\cdot) := \Delta g_0(\cdot) + \tau_1 \Delta g_1(\cdot) + \cdots + \tau_k \Delta g_k(\cdot)$. *Consider the collection* $\Theta = \{\tau\}$ *of all multipliers* $\tau \ge 0$ *for which the frequency criterion* (5.17) *is fulfilled with* $g := g^0_\tau$.

Given $\tau \in \Theta$, *we have* $\Delta g_\tau(t, x, u) \ge 0$ *for all* x, u *and almost all* $t \ge 0$.

Indeed, assumption (3.ii) was used only to demonstrate assumption (C.1) of Lemma 2.3; i.e., it was used to show that $\boxed{\tau \ge 0 \text{ and } \mathcal{B}_\tau(h) < 0} \Rightarrow f := \underline{\lim}_{n\to\infty} \mathcal{B}_\tau(h_n) < 0$ for the sequence $\{h_n\} \subset \mathfrak{M}$ constructed above. It has been actually demonstrated that $f < 0$ for any $\tau \overline{\in} \Theta$. So the role of (3.ii) was only to ensure the implication $\boxed{\tau \ge 0 \text{ and } \mathcal{B}_\tau(h) < 0} \Rightarrow \tau \overline{\in} \Theta$, which is clearly equivalent to the implication $\tau \in \Theta \Rightarrow \mathcal{B}_\tau(h) \ge 0$ $(\forall h \in \mathfrak{M})$ and now is still true. Indeed, if $\tau \in \Theta$ and $h \in \mathfrak{M}$, then $\mathcal{B}^0_\tau(h) \ge 0$ by Lemma 5.3 and $\Delta\mathcal{B}_\tau(h) \ge 0$ by (5.19) and (3.ii′). Therefore, $\mathcal{B}_\tau(h) \ge 0$.

2. The above considerations show that assumption (3.ii′) can be replaced by the still more general one: *given* $\tau \in \Theta$, *we have* $\mathcal{B}_\tau(h) \ge 0$ *for all* $h \in \mathfrak{M}$.

3. Shifting the functions (5.22) to the right by $s_n \ge 0$ and analyzing the above considerations, we see that assumption (3.iv) can be replaced by the following one.

(3.iv′) *Given* $y \in \mathbb{C}^l$ *and* $v \in \mathbb{C}^m$, *there exist infinite sequences of reals* $\{s_n\} \subset [0,\infty)$ and $\{t_n\} \subset (0,\infty)$ *such that* $t_n \to \infty$ *as* $n \to \infty$ *and*

$$t_n^{-1} \int_{s_n}^{s_n+t_n} \Delta g_i(t,y,v)\, dt \to 0 \quad \text{as} \quad n \to \infty \quad \text{for all} \quad i = 0,\dots,k.$$

5.4. Nonstationary linear-quadratic problem with coefficients, which become constant since some time instant. Consider the problem (5.1)–(5.4) and assume that

(4.i) *the matrix-valued functions* $A(\cdot)$, $B(\cdot)$, $G_i(\cdot)$, $Q_i(\cdot)$, *and* $\Gamma_i(\cdot)$ *are piecewise continuous. There exists a time instant* $t^0 \geq 0$ *such that they are constant in the domain* $t \geq t^0$, *i.e.,* $A(t) = A$, $B(t) = B$, $G_i(t) = G_i^0$, $Q_i(t) = Q_i^0$, *and* $\Gamma_i(t) = \Gamma_i^0$ *for all* $t \geq t^0$;

(4.ii) $\phi_i(t,x,u) = 0$ $(i = 0,\dots,k)$, *the pair* (A,B) *is stabilizable, and the system* $\dot{x} = A(t)x + B(t)u$, $0 \leq t \leq t^0$ *is controllable on any nontrivial subinterval* $[t_1,t_2] \subset \left[0,t^0\right]$; *i.e., given* $t_1,t_2 \in \left[0,t^0\right]$, $t_1 < t_2$, *and* $x_1,x_2 \in \mathbb{R}^l$, *there is a control* $u(\cdot)$, *which brings the system starting at time* t_1 *at* x_1 *to* x_2 *at time* t_2.[5]

To proceed further, we need some notation. Given a Lagrange multiplier $\tau = \|\tau_i\| \in \mathbb{R}^k$, the function $g_\tau(t,x,u) := g_0(t,x,u) + \sum_{i=1}^k \tau_i g_i(t,x,u) = x^*G_\tau(t)x + 2x^*Q_\tau(t)u + u^*\Gamma_\tau(t)u$ is independent of t in the domain $t \geq t^0$; i.e., $g_\tau(t,x,u) = g_\tau^0(x,u)$ for $t \geq t^0$.

(4.D) *Denote by* Θ *the collection of all Lagrange multipliers* $\tau = \|\tau_i\| \in \mathbb{R}^k$ *such that* $\Gamma_\tau(t) \geq 0$ *for* $t \geq 0$, *the frequency criterion* (5.17) *is fulfilled for* $g := g_\tau^0$, *and* $\tau_i \geq 0$ $(i = 1,\dots,k)$. *Introduce also the set* $\Theta^0 := \{\tau \in \Theta : \Gamma_\tau(t \pm 0) > 0$ *for all* $t \geq 0$ *and* (5.17) *is true for* $g(y,v) := g_\tau^0(y,v) - \delta\left(|y|^2 + |v|^2\right)$ *with some* $\delta > 0\}$.

Both the set Θ and the set Θ^0 can be empty. It is only to simplify the further formulations that we assume that

(4.iii) *Either* $\Theta = \emptyset$ *or* $\Theta^0 \neq \emptyset$ (*i.e.,* $\Theta \neq \emptyset \Rightarrow \Theta^0 \neq \emptyset$).

Let $\Theta^0 \neq \emptyset$, and consider $\tau \in \Theta^0$. By the Kalman–Yakubovich–Popov lemma [15, 16, 17, 18], there exist and are unique the real $l \times l$-matrix $P_\tau = P_\tau^*$ and the real $l \times m$ matrix r_τ such that

$$2x^*P_\tau\,(Ax + Bu) + g_\tau^0(x,u) = (u - r_\tau^*x)^*\,\Gamma_\tau^0\,(u - r_\tau^*x) \quad \forall x \in \mathbb{R}^l,\ u \in \mathbb{R}^m \tag{5.24}$$

and the system $\dot{x} = (A + Br_\tau^*)\,x$ is stable. There is known a number of efficient methods to calculate P_τ and r_τ [15, 16, 17, 18]. Introduce also the matrices

$$\begin{gathered}\mathcal{A}_\tau(t) := A(t) - B(t)\Gamma_\tau(t)^{-1}Q_\tau(t)^*, \qquad \mathcal{D}_\tau(t) := B(t)\Gamma_\tau(t)^{-1}B(t)^*\,, \\ \mathcal{C}_\tau(t) := G_\tau(t) - Q_\tau(t)\Gamma_\tau(t)^{-1}Q_\tau(t)^*\end{gathered} \tag{5.25}$$

and define $l \times l$ matrices $X(t)$ and $\Psi(t)$ as the solution of the Cauchy problem

$$\begin{array}{rcl} \dot{X}_\tau(t) &=& \mathcal{A}_\tau(t)X_\tau(t) + \mathcal{D}_\tau(t)\Psi_\tau(t), \\ \dot{\Psi}_\tau(t) &=& \mathcal{C}_\tau(t)X_\tau(t) - \mathcal{A}_\tau(t)^*\Psi_\tau(t), \end{array} \quad 0 \leq t \leq t^0, \tag{5.26}$$

$$X_\tau\left(t^0\right) = I, \qquad \Psi_\tau\left(t^0\right) = -P_\tau.$$

[5] See, for example, [20, pp. 92–96] about criteria for controllability.

The last assumption is the following.

(4.iv) *Given* $\tau \in \Theta^0$, *we have*

$$\det X_\tau(t) \neq 0 \qquad \left(\forall t \in \left(0, t^0\right]\right). \tag{5.27}$$

If $\Theta^0 = \emptyset$, this assumption is meant to be omitted.

In (5.27), the time instant t^0 can be chosen in various ways. However, the validity of (4.iv) is independent of this choice (see Lemma 5.6 below).

LEMMA 5.5. *Let the above assumptions* (4.i)–(4.iv) *hold. Then assertions* $(\mathfrak{A})$ *and* $(\mathfrak{B})$ *are true provided that the problem* (5.1)–(5.4) *is regular.*

We preface the proof of this lemma by two preliminary facts. To state them, we recall that $\mathfrak{M}$ is the collection of all processes $[x(\cdot), u(\cdot)]$ satisfying (5.2) and (5.3) with $a = 0$.

LEMMA 5.6. *Let assumptions* (4.i), (4.ii) *be fulfilled and a multiplier* $\tau \in \Theta^0$ *be given. Define the mapping* $\mathcal{B}_\tau : H \to \mathbb{R}$ *by* (5.14). *Then the relation*

$$\mathcal{B}_\tau(h) \geq 0 \qquad \forall h \in \mathfrak{M} \tag{5.28}$$

is true if and only if condition (5.27) *is fulfilled.*

Note that relation (5.28) does not use the time instant t^0. So the choice of this instant does not affect the validity of condition (5.27).

Proof of Lemma 5.6. (5.27) $\Rightarrow$ (5.28). Let $h = [x(\cdot), u(\cdot)] \in \mathfrak{M}$; i.e., let relations (5.2) and (5.3) be true with $a = 0$. By (5.5), we have

$$\mathcal{B}_\tau(h) = \int_0^{t^0} g_\tau\left[t, x(t), u(t)\right]\, dt + \int_{t^0}^{\infty} g_\tau^0\left[x(t), u(t)\right]\, dt. \tag{5.29}$$

Put $x := x(t)$ and $u := u(t)$ into (5.24) and recall that $\Gamma_\tau^0 \geq 0$ by the definition of the set $\Theta \supset \Theta^0 \ni \tau$. Then, for $t \geq t^0$, we get

$$\begin{aligned} &\frac{d}{dt}\left[x(t)^* P_\tau x(t)\right] + g_\tau^0\left[x(t), u(t)\right] \\ &= \left[u(t) - r_\tau^*(t)x(t)\right]^* \Gamma_\tau^0\left[u(t) - r_\tau^*(t)x(t)\right] \geq 0. \end{aligned} \tag{5.30}$$

Integrating over the interval $\left[t^0, \infty\right)$ results in the inequality

$$\int_{t^0}^{\infty} g_\tau^0\left[x(t), u(t)\right]\, dt \geq x\left(t^0\right)^* P_\tau x\left(t^0\right). \tag{5.31}$$

This permits us to establish a below bound of the quantity (5.29)

$$\mathcal{B}_\tau(h) \geq \mathcal{I} := \int_0^{t^0} g_\tau\left[t, x(t), u(t)\right]\, dt + x\left(t^0\right)^* P_\tau x\left(t^0\right). \tag{5.32}$$

Here

$$\dot{x}(t) = A(t)x(t) + B(t)u(t), \quad 0 \leq t \leq t^0, \quad x(0) = 0. \tag{5.33}$$

It remains to note that relation (5.27) is sufficient and necessary for nonnegativity of the functional $\mathcal{I} = \mathcal{I}\left[x(\cdot), u(\cdot)\right]$ from (5.32) over processes $\left[x(\cdot), u(\cdot)\right]$, $0 \leq t \leq t^0$ satisfying (5.33) [16, 32, 33].

(5.28) $\Rightarrow$ (5.27). By the above citation, it suffices to show that $\mathcal{I} \geq 0$ for any process $[x(\cdot), u(\cdot)]$, $0 \leq t \leq t^0$ satisfying (5.33). Consider such a process. For $t \geq t^0$, define $x(t)$ to be the solution of the Cauchy problem $\dot{x} = (A + Br_\tau^*)\, x,\ x\left(t^0 + 0\right) = x\left(t^0 - 0\right)$ and put $u(t) := r_\tau^* x(t)$ where r_τ^* is the matrix from (5.24). Since the system $\dot{x} = (A + Br_\tau^*)\, x$ is stable, relations (5.2) and (5.3) are true with $a = 0$, i.e., $h := [x(\cdot), u(\cdot)] \in \mathfrak{M}$. Put $x := x(t)$ and $u := u(t)$ into (5.24) and recall that $u(t) = r_\tau^* x(t)$ for $t \geq t^0$. Then we see that, in (5.30)–(5.32), the inequality sign can be replaced by the equality one. In particular, $\mathcal{I} = \mathcal{B}_\tau(h)$ by (5.32) where $\mathcal{B}_\tau(h) \geq 0$ due to (5.28). Thus, we have the inequality desired: $\mathcal{I} \geq 0$. □

In what follows, the symbol $\rightharpoonup$ will denote the convergence with respect to the weak topology of the space $H := L_2\left([0, +\infty) \to \mathbb{R}^l\right) \times L_2\left([0, +\infty) \to \mathbb{R}^m\right)$.

LEMMA 5.7. *Let assumptions* (4.i)–(4.iv) *be fulfilled and a multiplier* $\tau \in \mathbb{R}^k$ *be given. Define the mapping* $\mathcal{B}_\tau : H \to \mathbb{R}$ *by* (5.14) *and consider the set* Θ *from* (4.D).

If $\tau \overline{\in} \Theta$ *and* $\tau_i \geq 0$ *for all* $i = 1, \ldots, k$, *then*

$$f := \liminf_{h \rightharpoonup 0,\ h \in \mathfrak{m}} \mathcal{B}_\tau(h) < 0, \tag{5.34}$$

where lim inf *is with respect to the weak topology.*

Proof. By (4.D), either (1) $v^* \Gamma_\tau(\bar{t} + 0) v < 0$ for some $\bar{t} \geq 0$ and $v \in \mathbb{R}^m$ or (2) relations (5.20) are true for some $\omega \in \mathbb{R},\ y \in \mathbb{C}^l$, and $v \in \mathbb{C}^m$. Consider first the case (1). By (4.ii), there exists an $l \times m$ matrix C such that the equation $\dot{x} = (A + BC^*)\, x$ is stable. Denote by $x(\cdot|a)$ its solution with $x(0|a) = a$ and put $u(\cdot|a) := C^* x(\cdot|a)$. Then relations (5.21) are valid. Choose an instant t_* such that $t_* \geq t^0$ and $t_* \geq \bar{t} + 2$. Given $\epsilon \in (0, 1]$, we put $u_\epsilon(t) := \epsilon^{-1/2} v$ if $\bar{t} \leq t < \bar{t} + \epsilon$, $u_\epsilon(t) := -\epsilon^{-1/2} v$ if $\bar{t} + \epsilon \leq t < \bar{t} + 2\epsilon$, and $u_\epsilon(t) := 0$ if $0 \leq t < \bar{t}$ or $\bar{t} + 2\epsilon \leq t < t_*$. Consider the solution $x_\epsilon(\cdot)$ of the Cauchy problem $\dot{x}_\epsilon(t) = A(t) x_\epsilon(t) + B(t) u_\epsilon(t),\ 0 \leq t \leq t_*,\ x_\epsilon(0) = 0$. As is well known, $|x_\epsilon(\cdot)|_\infty \leq \mathcal{K} |u_\epsilon(\cdot)|_1$ and so

$$\max_{t \in [0, t_*]} |x_\epsilon(t)| \leq \mathcal{K} |u_\epsilon(\cdot)|_1 = \mathcal{K} \epsilon^{-1/2} |v| 2\epsilon \to +0 \ \text{ as } \ \epsilon \to +0. \tag{5.35}$$

Denote $a_\epsilon := x_\epsilon(t_*)$ and define $x_\epsilon(t)$, $u_\epsilon(t)$ for $t \geq t_*$ as follows: $x_\epsilon(t) := x(t - t_* | a_\epsilon)$, $u_\epsilon(t) := u(t - t_* | a_\epsilon)$. It is easy to see that $h_\epsilon := [x_\epsilon(\cdot), u_\epsilon(\cdot)] \in \mathfrak{M}$. By (5.35), $a_\epsilon \to 0$ as $\epsilon \to +0$ and so, due to (5.21) and (5.35), we have

$$|x_\epsilon(\cdot)|_2 \to 0,\ \int_{t_*}^{\infty} |u_\epsilon(t)|^2\ dt \to 0 \ \text{ as } \ \epsilon \to +0,\ \int_0^{t_*} |u_\epsilon(t)|^2\ dt = 2|v|^2. \tag{5.36}$$

Taking into account (5.14), we get

$$\begin{aligned} \mathcal{B}_\tau(h_\epsilon) \ = \ & \underbrace{\int_0^\infty x_\epsilon(t)^* G_\tau(t) x_\epsilon(t)\ dt}_{\delta_1} \ + \ 2 \underbrace{\int_0^\infty x_\epsilon(t)^* Q_\tau(t) u_\epsilon(t)\ dt}_{\delta_2} \\ & + \ \underbrace{\int_{t_*}^\infty u_\epsilon(t)^* \Gamma_\tau(t) u_\epsilon(t)\ dt}_{\delta_3} \ + \ \underbrace{\int_0^{t_*} u_\epsilon(t)^* \Gamma_\tau(t) u_\epsilon(t)\ dt}_{\delta_4}. \end{aligned}$$

Here $|\delta_1| \leq \sup_{t \geq 0} |G_\tau(t)|\, |x_\epsilon(\cdot)|_2^2 \to 0$ as $\epsilon \to +0$ by (5.36) and also $\delta_2 \to 0,\ \delta_3 \to 0$ as $\epsilon \to +0$ due to analogous reasons. Furthermore,

$$\delta_4 = \epsilon^{-1} \left[\int_{\bar{t}}^{\bar{t} + \epsilon} v^* \Gamma_\tau(t) v\ dt + \int_{\bar{t} + \epsilon}^{\bar{t} + 2\epsilon} (-v)^* \Gamma_\tau(t) (-v)\ dt \right] \to 2 v^* \Gamma_\tau(\bar{t} + 0) v \ \text{ as } \ \epsilon \to +0.$$

Thus,

$$\mathcal{B}_\tau\,(h_\epsilon) \to 2v^*\Gamma_\tau(\bar t+0)v<0 \ \text{ as } \ \epsilon\to+0. \tag{5.37}$$

To complete the proof, it remains to show that $h_\epsilon \rightharpoonup 0$ as $\epsilon\to+0$. For $\widetilde h = [\widetilde x(\cdot),\widetilde u(\cdot)]\in H$, we have

$$\Big\langle h_\epsilon,\widetilde h\Big\rangle = \underbrace{\int_0^\infty \widetilde x(t)^* x_\epsilon(t)\,dt}_{\Delta_1} + \underbrace{\int_{t_*}^\infty \widetilde u(t)^* u_\epsilon(t)\,dt}_{\Delta_2} + \underbrace{\int_0^{t_*} \widetilde u(t)^* u_\epsilon(t)\,dt}_{\Delta_3}.$$

Here $|\Delta_1|\le|\widetilde x(\cdot)|_2\,|x_\epsilon(\cdot)|_2\to 0$ as $\epsilon\to+0$ due to (5.36). Likewise, $\Delta_2\to 0$ as $\epsilon\to+0$ and

$$|\Delta_3|\le\int_{\bar t}^{\bar t+2\epsilon}|u_\epsilon(t)|\,|\widetilde u(t)|\;dt=\epsilon^{-1/2}|v|\int_{\bar t}^{\bar t+2\epsilon}|\widetilde u(t)|\;dt$$

$$\le\epsilon^{-1/2}|v|\left(\int_{\bar t}^{\bar t+2\epsilon}\;dt\right)^{1/2}\left(\int_{\bar t}^{\bar t+2\epsilon}|\widetilde u(t)|^2\;dt\right)^{1/2}=\sqrt{2}|v|\left(\int_{\bar t}^{\bar t+2\epsilon}|\widetilde u(t)|^2\;dt\right)^{1/2}\to 0$$

as $\epsilon\to+0$. Thus, $h_\epsilon\rightharpoonup 0$ as $\epsilon\to+0$ where $h_\epsilon\in\mathfrak{M}$ as it was shown above. Therefore, the quantity f in (5.34) does not exceed the limit $\lim_{\epsilon\to+0}\mathcal{B}_\tau\,(h_\epsilon)$, which is negative by (5.37). So relation (5.34) is true in case (1).

Consider case (2). It was shown in subsection 5.3 that there exists a sequence $h_n=[x_n(\cdot),u_n(\cdot)]\in\mathfrak{M},\ n=1,2,\dots$ such that $h_n\rightharpoonup 0$ as $n\to\infty,\ \dot x_n(t)=Ax_n(t)+Bu_n(t),\ 0\le t<\infty,\ x_n(0)=0$, and

$$\liminf_{n\to\infty}\underbrace{\int_0^\infty g_\tau^0\,[x_n(t),u_n(t)]\;dt}_{q_n}<0.$$

Shift the functions $x_n(\cdot)$ and $u_n(\cdot)$ to the right $\widetilde x_n(t):=x_n\big(t-t^0\big),\ \widetilde u_n(t):=u_n\big(t-t^0\big)$ if $t\ge t^0$ and $\widetilde x_n(t):=0,\ \widetilde u_n(t):=0$ otherwise. It is obvious that $\widetilde h_n:=[\widetilde x_n(\cdot),\widetilde u_n(\cdot)]\in\mathfrak{M},\ \widetilde h_n\rightharpoonup 0$ as $n\to\infty$ and, by (5.5), $\mathcal{B}_\tau(\widetilde h_n)=q_n$. It remains to note that the quantity f in (5.34) does not exceed $\liminf_{n\to\infty}\mathcal{B}_\tau(h_n)=\liminf_{n\to\infty}q_n<0$. □

Proof of Lemma 5.5. The reduction to the abstract problem (1.1) is performed just as it was done at the beginning of the section. Equip the space H with the weak topology. The verification of assumptions (A) and (B) of Theorem 2.2 is performed just as it was done in subsection 5.1. To prove (C), consider a multiplier $\tau=\|\tau_i\|\in\mathbb{R}^k$ with $\tau_i\ge 0$. We have to demonstrate relation (2.3), which is equivalent to the implication

$$f:=\liminf_{h\rightharpoonup 0,\ h\in\mathfrak{m}}\mathcal{B}_\tau(h)\ge 0\Rightarrow\mathcal{B}_\tau(h)\ge 0\quad\forall h\in\mathfrak{M}. \tag{5.38}$$

By Lemma 5.7, $f\ge 0\Rightarrow\tau\in\Theta$. So it suffices to show that

$$\tau\in\Theta\Rightarrow\mathcal{B}_\tau(h)\ge 0\quad(\forall h\in\mathfrak{M}). \tag{5.39}$$

For $\tau\in\Theta^0$, the conclusion from (5.39) is justified by Lemma 5.6.

Let $\tau\in\Theta$. By (4.iii), $\Theta^0\ne\emptyset$ and we can choose $\tau^0\in\Theta^0$. It easily follows from (4.D) that $\tau+\epsilon\tau^0\in\Theta^0$ for any $\epsilon>0$. So $\mathcal{B}_{\tau+\epsilon\tau^0}(h)\ge 0$ for all $h\in\mathfrak{M}$. By letting $\epsilon\to+0$, we get the conclusion from (5.39). Thus, (5.39) is true and all the assumptions of Theorem 2.2 are fulfilled. By this theorem, Lemma 5.5 is valid. □

5.5. Counterexample. In the conclusion of the section, we show that, in general, the method (I)–(IV) fails to be applicable to the problem (5.1)–(5.4). The following is the counterexample required

$$\mathcal{G}_0 := -\int_0^T \underbrace{2x_1x_2 + x_2^2 + x_1u}_{\mu}\, dt \to \min \quad \text{subject to} \tag{5.40}$$

$$\dot{x}_1 = x_2, \quad \dot{x}_2 = u, \quad 0 \le t < \infty, \quad x_1(0) = x_2(0) = 0, \quad |x_1(\cdot)| + |x_2(\cdot)| + |u(\cdot)| \in L_2, \tag{5.41}$$

$$\mathcal{G}_1 := 2\int_0^T \underbrace{x_2^2 + x_1u}_{\sigma}\, dt - 1 \le 0,\ \mathcal{G}_2 := -\int_0^T \underbrace{2x_2u + x_2^2 + x_1u}_{\eta}\, dt + 1 \le 0, \tag{5.42}$$

where the real $T > 0$ is fixed. We shall show that (1) *the problem* (5.40)–(5.42) *is regular and has a solution*, but (2) *the method* (I)–(IV) *fails to be applicable to this problem.*

To this end, note first that, by (5.41), $\sigma = d/dt\,(x_1x_2)$, $\eta = d/dt\,\big(x_2^2 + x_1x_2\big)$, and $\mu = d/dt\,\big(x_1^2 + x_1x_2\big)$. So the problem can be rewritten in terms of the state $y := [x_1(T), x_2(T)]$

$$f(y) := -y_1^2 - y_1y_2 \to \min \text{ subject to } y = \|y_i\| \in Z := \mathbb{R}^2, \quad g_1(y) := 2y_1y_2 \le 1, \quad g_2(y) := -y_2^2 - y_1y_2 \le -1. \tag{5.43}$$

(Relations (5.41) do not imply any restrictions on y due to controllability of the object $\dot{x}_1 = x_2,\ \dot{x}_2 = u$.) Consequently, it suffices to prove assertions (1) and (2) with respect to the problem (5.43).

(1) Since $g_1(0,2) = 0 < 1$ and $g_2(0,2) = -4 < -1$, the problem (5.43) is regular. It is straightforward to calculate that $f = -\frac{1}{2}g_1g_2/\left(g_2 + \frac{1}{2}g_1\right)$ for all y_1, y_2. To estimate the infimum of f in (5.43), consider the following chain of apparent implications, which starts with the inequalities $g_1 \le 1$ and $g_2 \le -1$ from (5.43)

$$\boxed{\begin{array}{c}\frac{2g_2}{g_2-1} \ge 1 \ge g_1,\\ g_2 - 1 < 0\end{array}} \Leftarrow \boxed{g_1 \le 1,\ g_2 \le -1} \Rightarrow \boxed{g_2 + 1/2g_1 < 0}$$
$$\Rightarrow \boxed{2g_2 \le (g_2 - 1)\, g_1} \Rightarrow \boxed{\begin{array}{c}2\,(g_2 + 1/2g_1)\\ \le g_1g_2\end{array}} \Rightarrow \boxed{\begin{array}{c}\frac{g_1g_2}{2\left(g_2+\frac{1}{2}g_1\right)}\\ = -f \le 1\end{array}}.$$

Thus, $f \ge -1$ for all points $y = (y_1,\ y_2)$ that satisfy the constraints from (5.43). Since $f\left(1/\sqrt{2},\ 1/\sqrt{2}\right) = -1$, $g_1\left(1/\sqrt{2},\ 1/\sqrt{2}\right) = 1$, and $g_2\left(1/\sqrt{2},\ 1/\sqrt{2}\right) = -1$, we see that the point $y_1 = 1/\sqrt{2},\ y_2 = 1/\sqrt{2}$ is a solution of the problem (5.43).

(2) Given a Lagrange multiplier $\tau = \|\tau_i\| \in \mathbb{R}^2$, the Lagrangian function $S(\tau, y_1, y_2) := f + \tau_1g_1 + \tau_2g_2 = -y_1^2 - y_1y_2 + 2\tau_1y_1y_2 - \tau_2\left(y_2^2 + y_1y_2\right) - \tau_1 + \tau_2$ is a quadratic form in y_1 with the negative main coefficient. So $\inf_{y\in\mathbb{R}^2} S\,(\tau, y_1, y_2) = -\infty$ and relation (1.12) fails to be true because its left-hand side is finite as it was shown above. Therefore, the method (I)–(IV) is valid neither for the problem (5.43) nor for (5.40)–(5.42). □

6. An example of application of the method (I)–(IV). Return to consideration of the problem (5.1)–(5.4) under the assumptions of subsection 5.4. The goal of this section is to illustrate in general outline the usefulness of the method (I)–(IV) for solution of linear-quadratic problems with quadratic constraints. To avoid consideration of details that are not directly related to this goal we shall impose additional simplifying assumptions on the problem. In what follows, we shall use the notations from (4.D), (5.24)–(5.26).

LEMMA 6.1. *Let assumptions* (4.i), (4.ii) *be fulfilled and* $\Theta^0 \neq \emptyset$. *Suppose that the problem* (5.1)–(5.4) *is regular and* $\det X_\tau(t) \neq 0$ *for all* $\tau \in \Theta^0$ *and* $t \in \left[0, t^0\right]$. *Denote* $R_\tau(t) := -\Psi_\tau(t) X_\tau(t)^{-1}$ $(t \in [0, t^0])$, *and assume that the problem*

$$b(\tau) := a^* R_\tau(0) a - \sum_{i=1}^{k} \tau_i \gamma_i \ \to \sup \quad \textit{subject to} \ \ \tau \in \Theta^0 \tag{6.1}$$

has a solution $\tau^0 \in \Theta^0$. (*Here* a *is the initial state from* (5.3).)

Then there exists and is unique the optimal process in the problem (5.1)–(5.4). *This process is generated by the closed-loop controller*

$$\begin{gathered} u = q_{\tau^0}(t)^* x, \\ \textit{where} \ \ q_\tau(t) := \overline{r}_\tau(t) \ \ \textit{for} \ \ 0 \leq t \leq t^0 \ \ \textit{and} \ \ q_\tau(t) := r_\tau \ \ \textit{for} \ \ t > t^0. \end{gathered} \tag{6.2}$$

Here r_τ *is the matrix from* (5.24) *and*

$$\overline{r}_\tau(t) := -\left[Q_\tau(t) + R_\tau(t) B(t)\right] \Gamma_\tau(t)^{-1}. \tag{6.3}$$

Remarks. 1. It readily follows from (5.26) and is also well known that the function $R_\tau(\cdot)$ is the solution of the matrix Riccati equation

$$\dot{R}_\tau(t) + R_\tau(t) A(t) + A(t)^* R_\tau(t) + G_\tau(t) = \overline{r}_\tau(t) \Gamma_\tau(t) \overline{r}_\tau(t)^*, \quad R_\tau\left(t^0\right) = P_\tau. \tag{6.4}$$

Here $\overline{r}_\tau(t)$ is supposed to be replaced by the right-hand side of (6.3) and P_τ is the matrix from (5.24).

2. In (6.1), the domain $\Theta^0 \subset \mathbb{R}^k$ is convex that easily follows from (4.D). It will be shown below that the function $b(\cdot)$ is concave. So the problem (6.1) can be solved by means of the methods of convex programming.

3. Consider the matrices P_τ and r_τ from (5.24) and put $R_\tau := P_\tau$, $\overline{r}_\tau(t) := r_\tau$ for $t \geq t^0$. Then relations (6.3) and (6.4) remain valid for $t \geq t^0$ [16, 17]. This implies that the choice of the time instant t^0 does not affect the coefficient (6.2).

4. It will be shown below that, in the case under consideration, (6.1) is in fact a concretized form of the dual problem (1.7). On the whole, Lemma 6.1 offers the following concretization of the method (I)–(IV).

(1) *Form the set* Θ^0 *in accordance with* (4.D).

(2) *Find a solution* $\tau^0 \in \Theta^0$ *of the problem* (6.1) *where the quantity* $a^* R_\tau(0) a$ *can be calculated as follows. Given* $\tau \in \Theta^0$, *determine the solution* $P_\tau = P_\tau^*$ *and* r_τ *of equations* (5.24) *such that the system* $\dot{x} = (A + B r_\tau^*)\, x$ *is stable,*[6] *and then find the solution* $R_\tau(\cdot)$ *of the Cauchy problem* (6.4).

(3) *Determine* $\overline{r}_\tau(\cdot)$ *by* (6.3). *The optimal process is generated by* (6.2).

Proof of Lemma 6.1. Since $\Theta^0 \neq \emptyset$ and $\det X_\tau(t) \neq 0$ for all $\tau \in \Theta^0$, $t \in \left[0, t^0\right]$, assumptions (4.iii) and (4.iv) are fulfilled. So, by Lemma 5.5, the method (I)–(IV)

[6] See, for example, [15, 16, 17, 18] for methods to calculate P_τ and r_τ.

is applicable and we can use it. In (1.4), now $S(\tau,z)=\mathcal{B}_\tau(z)-\sum_{i=1}^k\tau_i\gamma_i$ due to (1.3), (1.13), (4.ii), and (5.6). Given $\tau\overline{\in}\Theta,\tau\geq 0$, we have $\mathcal{B}_\tau(h)<0$ for some $h\in\mathfrak{M}$ by Lemma 5.7 and (2.2). So, choosing $z'\in Z$, we get $\inf_{z\in Z}S(\tau,z)+\sum_{i=1}^k\tau_i\gamma_i\leq\inf_{\rho\in\mathbb{R}}\mathcal{B}_\tau(z'+\rho h)=\inf_{\rho\in\mathbb{R}}\left[\rho^2\mathcal{B}_\tau(h)+2\rho B_\tau(h,z')+\mathcal{B}_\tau(z')\right]=-\infty$. This means that now the dual problem (1.7) takes the form

$$S_0(\tau)\to\max\ \text{ subject to }\ \tau\in\Theta. \tag{6.5}$$

Here the function $S_0(\tau)$ is concave as the infimum (1.6) of the functions (1.4), which are linear in τ. It easily follows from (4.D) that (1) the sets Θ and Θ^0 are convex; (2) $\mathrm{ri}\Theta^0\subset\Theta^0\subset\Theta=\overline{\Theta}$; and (3) $(1-\epsilon)\tau+\epsilon\tau^0\in\Theta^0$ for any $\epsilon\in(0,1)$, $\tau\in\Theta$, $\tau^0\in\Theta^0$, and so $\overline{\Theta^0}=\Theta$. From this it follows that [8, pp. 46, 55]

$$\max_{\tau\in\Theta}S_0(\tau)=\sup_{\tau\in\Theta^0}S_0(\tau). \tag{6.6}$$

We recall that now the subspace $Z=\{z=[x(\cdot),u(\cdot)]\}$ is described by (5.2) and (5.3). Let $\tau\in\Theta^0$ and $z\in Z$. Taking into account (5.2) and (6.3), (6.4), it is straightforward to compute that

$$\frac{d}{dt}\left[x(t)^*R_\tau(t)x(t)\right]+g_\tau\left[t,x,u\right]=\left[u-\overline{r}_\tau(t)^*x\right]^*\Gamma_\tau(t)\left[u-\overline{r}_\tau(t)^*x\right]$$

for $t\leq t^0$, where $x=x(t)$ and $u=u(t)$. Integrating both this equality and (5.30), we get by (5.29)

$$\begin{aligned}S(\tau,z)&=a^*R_\tau(0)a-\sum_{i=1}^k\tau_i\gamma_i\\&+\int_0^\infty\left[u(t)-q_\tau(t)^*x(t)\right]^*\Gamma_\tau(t)\left[u(t)-q_\tau(t)^*x(t)\right]\,dt,\end{aligned} \tag{6.7}$$

where $q_\tau(\cdot)$ is defined from (6.2). Since $\Gamma_\tau(t\pm 0)>0$ by the definition of the set $\Theta^0\ni\tau$, we have $S_0(\tau):=\inf_{z\in Z}S(\tau,z)=b(\tau)$ where $b(\tau)$ was defined in (6.1). This and (6.6) prove that the multiplier τ^0 from the statement of Lemma 6.1 is a solution for the dual problem (6.5). So we can use τ^0 in the items (III) and (IV) of the method (I)–(IV).

Show that the problem (5.1)–(5.4) has a solution. To this end, consider a minimizing sequence of processes $\{z_n\}_{n=1}^\infty$; i.e., $z_n=[x_n(\cdot),u_n(\cdot)]$ satisfies (5.2), (5.3) (with $x(\cdot):=x_n(\cdot)$, $u(\cdot):=u_n(\cdot)$) and

$$\mathcal{G}_i\left[z_n\right]\leq 0\ \ \forall\, i=1,\dots,k,\ n=1,2,\dots,\ \ \mathcal{G}_0\left[z_n\right]\to\inf_{z\in D}\mathcal{G}_0(z)\ \text{ as }\ n\to\infty, \tag{6.8}$$

where $\mathcal{G}_i$ is defined by (5.4). By the item (IV), $S(\tau^0,z_n)\to S_0(\tau^0)=a^*R_\tau(0)a-\sum_{i=1}^k\tau_i\gamma_i$ as $n\to\infty$. Then, due to (6.7), $\Delta u_n(\cdot):=u_n(\cdot)-q_{\tau^0}(t)^*x_n(\cdot)\to 0$ as $n\to\infty$ with respect to the L_2-norm. Put $x(\cdot):=x_n(\cdot)$ and $u(\cdot):=u_n(\cdot)=q_{\tau^0}(\cdot)^*x_n(\cdot)+\Delta u_n(\cdot)$ into (5.2)

$$\dot{x}_n(t)=\underbrace{\left[A(t)+B(t)q_{\tau^0}(t)^*\right]}_{S(t)}x_n(t)+B(t)\Delta u_n(t),\quad 0\leq t<\infty,\quad x_n(0)=a.$$

For $t\geq t_0$, the matrices $S(t)=S^0$ and $B(t)=B$ are constant due to (4.i) and (6.2). We recall also that the equation $\dot{x}=S^0x=(A+Br_{\tau^0}^*)x$ is stable by the

definition of the matrix r_{τ^0}. So $|x_n(\cdot)-x(\cdot)|_2 \to 0$ as $n \to \infty$ where $x(\cdot)$ is the solution of the Cauchy problem $\dot{x} = S(t)x(t)$, $0 \le t < \infty$, $x(0) = a$. Denoting $u(t) := q_{\tau^0}(t)^* x(t)$, we see that the pair $z_\infty := [x(\cdot), u(\cdot)]$ satisfies (5.2), (5.3) and $|u_n(\cdot) - u(\cdot)|_2 = |\Delta u_n(\cdot) + q_{\tau^0}(\cdot)^* [x_n(\cdot) - x(\cdot)]|_2 \to 0$ as $n \to \infty$. By (5.4), the functionals $\mathcal{G}_i$ are continuous with respect to the $L_2 \times L_2$ norm. So passing to the limit in (6.8), we get $\mathcal{G}_i[z_\infty] \le 0$ for $i = 1, \dots, k$ and $\mathcal{G}_0[z_\infty] = \inf_{z \in D} \mathcal{G}_0(z)$ where $z_\infty \in Z$. Thus, z_∞ is a solution of the problem (5.1)–(5.4).

Consider an optimal process $z^0 = \left[x^0(\cdot), u^0(\cdot)\right]$ in the problem (5.1)–(5.4). In correspondence with the item (III), $S(\tau^0, z^0) = \inf_{z \in Z} S(\tau^0, z) = a^* R_{\tau^0}(0) a - \sum_{i=1}^k \tau_i \gamma_i$ and so, by (6.7), $u^0(t) = q_{\tau^0}(t)^* x^0(t)$ for all $t \ge 0$. This implies that this process is generated by the controller (6.2) and is thereby unique. □

Example. Consider the following problem:

$$\text{minimize } \mathcal{G}_0 := \int_0^{+\infty} \left[u(t)^2 + \sigma x(t)^2\right] \, dt \text{ subject to} \tag{6.9}$$

$$\dot{x}(t) = u(t), \quad 0 \le t < \infty, \quad x(0) = a, \quad |x(\cdot)| + |u(\cdot)| \in L_2, \tag{6.10}$$

$$\mathcal{G}_1 := \int_T^{+\infty} u(t)^2 \, dt - \nu \int_T^{+\infty} x(t)^2 \, dt \le 0, \quad \mathcal{G}_2 := \int_0^T x(t)^2 \, dt \le \alpha, \tag{6.11}$$

where the reals $\sigma > 0, \nu > 0, \alpha > 0, T > 0$, and $a \in \mathbb{R}$ are given. This problem is to minimize the convex functional $\mathcal{G}_0$ on the domain $D := \{z = [x(\cdot), u(\cdot)] \in H := W_2^1(0, +\infty) \times L_2(0, +\infty) : (6.10) \text{ and } (6.11) \text{ are true}\}$, which is not convex. To prove this note first that the domain D is evidently closed with respect to the norm of H. So, were the domain D convex, it would be weakly closed [3, p. 4]. But it is not weakly closed. Indeed, consider a process $z = [x(\cdot), u(\cdot)] \in D' := \{z \in H : (6.10) \text{ is true and } \mathcal{G}_2 \le \alpha\}$. Given $n > 0$ and $\theta > T$, we put

$$\chi_n(t) := \begin{cases} n^{-1} & \text{for } 0 \le t < n, \\ -n^{-1} & \text{for } n \le t < 2n, \\ 0 & \text{otherwise,} \end{cases}$$

$$\Delta u_{n,\theta}(t) := \chi_n(t-\theta),$$
$$\Delta x_{n,\theta}(t) := \begin{cases} (t-\theta)\chi_n(t-\theta) & \text{for } t \le \theta + n, \\ (t-\theta-2n)\chi_n(t-\theta) & \text{for } \theta + n < t. \end{cases}$$

Denote by $\rightharpoonup$ the convergence with respect to the weak topology of H. By analogy with (5.8), we have $\Delta z_{n,\theta} := [\Delta x_{n,\theta}(\cdot), \Delta u_{n,\theta}(\cdot)] \rightharpoonup 0$ as $\theta \to \infty$ provided that the real n is fixed. It is clear that $z_{n,\theta} := z + \Delta z_{n,\theta} \in D'$ and

$$\begin{aligned} \mathcal{G}_1(z_{n,\theta}) &= \underbrace{\mathcal{G}_1(z) + 2n^{-1} - \nu\frac{2n}{3}}_{\Delta(n)} \\ &+ \underbrace{2\int_T^{+\infty} \left[u(t)\Delta u_{n,\theta}(t) - \nu x(t)\Delta x_{n,\theta}(t)\right] \, dt}_{\delta(n,\theta)}, \end{aligned} \tag{6.12}$$

where $\delta(n, \theta) \to 0$ as $\theta \to \infty$ because $\Delta z_{n,\theta} \rightharpoonup 0$ as $\theta \to \infty$. Choose $n^- > 0$ and $n^+ > 0$ such that $\Delta(n^-) < 0$ and $\Delta(n^+) > 0$. Then $\mathcal{G}_1\left(z_{n^-,\theta}\right) < 0$ and $\mathcal{G}_1\left(z_{n^+,\theta}\right) > 0$

provided that the real θ is sufficiently large. In other words, $z_{n^-,\theta} \in D$ and $z_{n^+,\theta} \in D' \setminus D$ where $z_{n,\theta} \rightharpoonup z \in D'$ as $\theta \to \infty$. Thus the set D and its complement $D' \setminus D$ are weakly dense in D'. This proves that the domain D is not weakly closed.

LEMMA 6.2. *There exists and is unique the optimal process in the problem* (6.9)–(6.11). *This process is generated by the closed-loop controller* $u = q(t)x$, *where the function* $q(t)$ *is determined as follows. Put*

$$p_0 := \begin{cases} \sqrt{\sigma} & \text{if } \nu > \sigma, \\ \frac{1}{2}\left(\sqrt{\nu} + \frac{\sigma}{\sqrt{\nu}}\right) & \text{otherwise,} \end{cases} \qquad r_0 := \begin{cases} -\sqrt{\sigma} & \text{if } \nu > \sigma, \\ -\sqrt{\nu} & \text{otherwise,} \end{cases} \tag{6.13}$$

$$\begin{aligned} \varphi(\lambda) &:= \lambda\left\{a^2\left[2p_0 + T\left(p_0^2 - \lambda^2\right)\right] - 2\alpha p_0^2\right\}\tanh^2(\lambda T) \\ &+ \left\{a^2\left(\lambda^2 + p_0^2\right) - 4\alpha\lambda^2 p_0\right\}\tanh(\lambda T) + a^2\lambda T\left(\lambda^2 - p_0^2\right) - 2\alpha\lambda^3. \end{aligned} \tag{6.14}$$

If $\varphi\left(\sqrt{\sigma}\right) \le 0$, *we put* $\lambda_0 := \sqrt{\sigma}$. *If* $\varphi\left(\sqrt{\sigma}\right) > 0$, *then the equation* $\varphi(\lambda) = 0$ *has a single root* λ_* *in the domain* $\lambda \ge \sqrt{\sigma}$ *and we put* $\lambda_0 := \lambda_*$. *The above coefficient* $q(\cdot)$ *is given by the formula*

$$r(t) := -\lambda_0 \frac{\lambda_0 \tanh\left[\lambda_0(T-t)\right] + p_0}{p_0 \tanh\left[\lambda_0(T-t)\right] + \lambda_0} \text{ if } 0 \le t \le T \text{ and } r(t) := r_0 \text{ otherwise.} \tag{6.15}$$

Proof. The problem (6.9)–(6.11) is a particular case of the problem (5.1)–(5.4): $l = m = 1,\ A(t) = 0,\ B(t) = 1,\ k = 2,\ \varphi_i(\cdot) = 0,\ g_0(t,x,u) = u^2 + \sigma x^2,\ g_1(t,x,u) = 0$ for $t \le T$ and $g_1(t,x,u) = u^2 - \nu x^2$ otherwise, $g_2(t,x,u) = x^2$ for $t \le T$ and $g_2(t,x,u) = 0$ otherwise, $\gamma_0 = \gamma_1 = 0,\ \gamma_2 = \alpha$. Furthermore, the problem (6.9)–(6.11) is regular, i.e., there exists a process $\overline{z} = [\overline{x}(\cdot), \overline{u}(\cdot)]$ such that (6.10) is true and $\mathcal{G}_1(\overline{z}) < 0,\ \mathcal{G}_2(\overline{z}) < \alpha$. Indeed, choose $\delta < \min\left\{T, 3\alpha/\left(a^2+1\right)\right\}, \theta > T$, and $n > \sqrt{3/\nu}$. Put $x_\delta(t) := a\left(1 - \delta^{-1}t\right),\ u_\delta(t) := -a\delta^{-1}$ for $0 \le t \le \delta$ and $x_\delta(t) := u_\delta(t) := 0$ for $t > \delta$ and pick $\overline{z} := [x_\delta(\cdot) + \Delta x_{n,\theta}(\cdot), u_\delta(\cdot) + \Delta u_{n,\theta}(\cdot)]$ where the process $[\Delta x_{n,\theta}(\cdot), \Delta u_{n,\theta}(\cdot)]$ was defined above. Then $\overline{z}$ apparently satisfies (6.10) and $\mathcal{G}_2(\overline{z}) = \int_0^T x_\delta^2\ dt = a^2\delta/3 < \alpha$. Putting $x(\cdot) := u(\cdot) := 0$ into (6.12) we get $\mathcal{G}_1(\overline{z}) = \mathcal{G}_1\left[\Delta x_{n,\theta}(\cdot), \Delta u_{n,\theta}(\cdot)\right] = 2n^{-1} - 2n\nu/3 < 0$.

The next step will be to apply Lemma 6.1. Its assumptions (4.i), (4.ii) are fulfilled with $t^0 := T$. Now $\tau = \|\tau_i\| \in \mathbb{R}^2$ and $g_\tau(t,x,u) := g_0(t,x,u) + \sum_{i=1}^2 \tau_i g_i(t,x,u) = u^2 + (\sigma + \tau_2)\,x^2$ for $t \le T$ and $g_\tau(t,x,u) = g_\tau^0(x,u) = (1+\tau_1)\,u^2 + (\sigma - \tau_1\nu)\,x^2$ for $t > T$. For $g(x,u) := g_\tau^0(x,u) - \delta\left(|x|^2 + |u|^2\right)$, the frequency criterion (5.17) takes the form $(1 + \tau_1 - \delta)\,|u|^2 + (\sigma - \tau_1\nu - \delta)\,|x|^2 \ge 0$ for all $\omega \in \mathbb{R}, x, u \in \mathbb{C}$ such that $\imath\omega x = u$ or, equivalently, $(1 + \tau_1 - \delta) + (\sigma - \tau_1\nu - \delta)\,\omega^{-2} \ge 0$ for all $\omega \ne 0$. So, by (4.D), we have $\Theta^0 = \left\{\tau = (\tau_1, \tau_2) : \tau_i \ge 0 \text{ and } \tau_1 < \sigma\nu^{-1}\right\}$. Thus the assumption $\Theta^0 \ne \emptyset$ is valid. Consider the problem (6.1) where the objective function is determined by (5.26) and (5.24). Let $\tau \in \Theta^0$. It is easy to verify that relations (5.24) $2P_\tau xu + (\tau_1 + 1)\,u^2 + (\sigma - \tau_1\nu)\,x^2 = (\tau_1 + 1)\,(u - r_\tau x)^2\ \ (\forall x, u)$ have the solution

$$P_\tau = \sqrt{(1+\tau_1)\,(\sigma - \nu\tau_1)} =: P_{\tau_1}, \qquad r_\tau = -\sqrt{(\sigma - \nu\tau_1)\,(1+\tau_1)^{-1}} \tag{6.16}$$

for which the equation $\dot{x} = (A + Br_\tau)\,x = r_\tau x$ is stable. The solution of the system (5.26) $\dot{X}_\tau = \Psi_\tau,\ \dot{\Psi}_\tau = (\sigma + \tau_2)\,X_\tau,\ 0 \le t \le T,\ X_\tau(T) = 1,\ \Psi_\tau = -P_\tau$ is given by

$$\begin{array}{lll} \Psi_\tau(t) = & -\lambda\sinh\left[\lambda(T-t)\right] & -P_\tau\cosh\left[\lambda(T-t)\right], \\ X_\tau(t) = & \cosh\left[\lambda(T-t)\right] & +\frac{P_\tau}{\lambda}\sinh\left[\lambda(T-t)\right], \end{array} \qquad \lambda := \sqrt{\sigma + \tau_2}, \tag{6.17}$$

and evidently satisfies the assumption $\det X_\tau(t) = X_\tau(t) \neq 0\ (\forall t \in [0,T])$ from Lemma 6.1. By (6.17), the problem (6.1) takes the form

$$b(\tau) = a^2\omega\left[P_{\tau_1}, \sqrt{\sigma+\tau_2}\,\right] - \alpha\tau_2 \to \sup \text{ subject to } \tau_2 \geq 0,\ 0 \leq \tau_1 < \sigma\nu^{-1}, \tag{6.18}$$

where $P_\tau = P_{\tau_1}$ is given by (6.16) and

$$\omega(p,\lambda) := \lambda\frac{p+\lambda\tanh(\lambda T)}{\lambda+p\tanh(\lambda T)}. \tag{6.19}$$

The function $\omega(p,\lambda)$ is strictly monotone with respect to p

$$\frac{\partial\omega}{\partial p}(p,\lambda) = \lambda^2\frac{1-\tanh^2(\lambda T)}{\left[\lambda+p\tanh(\lambda T)\right]^2} > 0.$$

So the problem (6.18) can be rewritten as follows:

$$w\left(\tau_2\right) := a^2\omega\left[p_0, \sqrt{\sigma+\tau_2}\,\right] - \alpha\tau_2 \to \sup \ \text{ subject to } \ \tau_2 \geq 0, \tag{6.20}$$

where $p_0 := \max\{P_{\tau_1} : 0 \leq \tau_1 < \sigma/\nu\}$. The maximum p_0 is achieved by $\tau_1 = \tau_1^0$ where $\tau_1^0 := 0$ if $\nu > \sigma$ and $\tau_1^0 := (2\nu)^{-1}(\sigma-\nu)$ otherwise.

By Remark 2 to Lemma 6.1, the function $b(\tau)$ is concave on Θ^0, and so evidently is the function $w\left(\tau_2\right)$ over $\tau_2 \geq 0$. It follows from (6.19) and (6.20) that $w\left(\tau_2\right) \to -\infty$ as $\tau_2 \to \infty$. So the problem (6.20) has a solution τ_2^0 and

$$\frac{dw}{d\tau_2}(0) \leq 0 \Rightarrow \tau_2^0 = 0, \qquad \frac{dw}{d\tau_2}(0) > 0 \Rightarrow \frac{dw}{d\tau_2}\left(\tau_2^0\right) = 0, \tag{6.21}$$

where the equation $\frac{dw}{d\tau_2}(\tau) = 0$ has no more than one solution. (Indeed, otherwise the set of all its roots is an interval and, therefore, the analytical function $\frac{dw}{d\tau_2}(\cdot)$ vanishes, i.e., $w(\cdot) =$ const that does not take place.) This implies that the problem (6.18) also has the solution $\tau^0 = \left(\tau_1^0, \tau_2^0\right) \in \Theta^0$. Thus all the assumptions of Lemma 6.1 are fulfilled.

By this lemma, the optimal process exists, is unique, and is generated by the closed-loop controller (6.2). Putting $\tau_1 := \tau_1^0$ into (6.16), we get (6.13). So, for $t \geq T$, the coefficient $q(\cdot) = q_{\tau^0}(\cdot)$ from (6.2) takes the form (6.15). Denote $\lambda := \sqrt{\sigma+\tau_2}$. The direct calculation shows that

$$\frac{dw}{d\tau_2}\left(\tau_2\right) = \frac{1}{2\lambda}\frac{\varphi(\lambda)}{\left[\lambda+p\tanh(\lambda T)\right]^2},$$

where $\varphi(\lambda)$ is defined by (6.14). This and (6.21) imply that the quantity $\lambda_0 := \sqrt{\sigma+\tau_2^0}$ is determined as it was indicated in the statement of the lemma. Putting $\tau := \tau^0$ into (6.3), we get $\overline{r}_{\tau^0}(t) = \Psi_{\tau^0}(t)X_{\tau^0}(t)^{-1}$ if $t \leq T$. So, taking into account (6.17), we get (6.15). □

GENERIC POLE ASSIGNMENT VIA DYNAMIC FEEDBACK*

SUSUMU ARIKI†

Abstract. An elementary proof of a sufficient condition for the generic pole placement problem based on a new elementary framework is given. This condition is the best at present and was proved by using algebraic geometry. The necessary condition is proved by considering a group action, which also suggests new treatment of the problem.

Key words. linear systems, output feedback pole placement

1. Introduction.

Let $S_{m,p,n}$ be the set of all strictly proper transfer functions of degree n with m inputs, p outputs. For $G(s) \in S_{m,p,n}$, we let $\chi(s)$ be the product of denominators of its Smith–MacMillan form. $\chi(s)$ is the characteristic polynomial of $G(s)$, and the degree of $\chi(s)$ is n. For a proper transfer function $K(s)$ of degree at most d with p inputs, m outputs, $G_{cl}(s) = (I_p - G(s)K(s))^{-1}G(s)$ is the transfer function of the closed-loop system. Its characteristic polynomial is denoted by $\chi_{cl}(s)$. Since $\chi_{cl}(s)$ determines the behavior of the closed-loop system, a basic design problem is to ask if we can control $\chi_{cl}(s)$. Design parameters are K, L, M, N such that $K(s) = M(sI_d - K)^{-1}L + N$. For almost all K, L, M, N, $\chi_{cl}(s)$ is a degree $n+d$ monic polynomial such that coefficients are polynomials with respect to design parameters. But for certain parameter values, cancellation may occur, and $\chi_{cl}(s)$ has less degree. Hence to keep everything continuous, it is better to control this polynomial, say $\chi'_{cl}(s)$, rather than $\chi_{cl}(s)$ itself. Ordinarily, this control problem is called the pole placement problem. For a precise description of $\chi'_{cl}(s)$, see Proposition 2.5 in the body of this paper.

We say that $G(s)$ is pole assignable by degree d compensators if for any polynomial of degree $n + d$ one can choose a $K(s)$ of degree at most d such that $\chi'_{cl}(s)$ coincides with the polynomial. (Both are assumed to be monic without loss of generality.) Since $G(s)$ is pole assignable by degree d compensators if and only if $G(s)^T$ is so, we can assume $p \leq m$.

The generic pole placement problem is to find the minimum d for almost all $G(s)$. (For a special $G(s)$, d may be smaller.)

To reach the goal, several authors study sufficient conditions. The best result among them, recently obtained by X. Wang and J. Rosenthal [8], is that $n < mp + d\max(m, p)$ is sufficient for generic pole placement. The method depends on a compactification of the moduli space of systems.

The purpose of this paper is to show that this result is a consequence of the following elementary fact.

Let X be a subset of a vector space V such that

(1) a neighborhood of the origin is contained in X;

(2) X is stable under multiplication by positive real numbers.

†Division of Mathematics, Tokyo University of Mercantile Marine, Etchujima 2-1-6, Koto-ku, Tokyo 135, Japan (ariki@ipc.tosho-u.ac.jp).

Then X coincides with V.

Hence we do not need algebraic geometry to reach the best result.

The necessary condition is $n \leq mp + d(m + p - 1)$, which is proved in [6] also by using algebraic geometry. But one can understand this fact by counting parameters as noticed by preceders. Another purpose of this paper is to prove this necessary condition along this idea. To verify the idea, we consider a group action here. It is because this new treatment suggests another approach to the pole placement problem.

(After submitting this paper, The author learned the work of X. Wang [7], [10], [11] and J. Leventides and N. Karcanias [12]. These treat the static feedback case. The latter is of special interest to the author, since the basic idea in the paper is very similar to his. But there are differences, and the results developed in this paper in order to work in dynamic feedback case are new.)

2. Preliminaries. We first review the theory of minimal bases. For the proof, we refer to [2], [4], [5]. They are interesting and not difficult to prove.

DEFINITION 2.1. *Let V be an r-dimensional subspace of $\mathbf{R}(s)^N$.*

A basis $\{g_1(s), \ldots, g_r(s)\}$ of V is called minimal if

(1) *$g_i(s)$'s have polynomial entries;*

(2) *the matrix $B(s) = (g_1(s), \ldots, g_r(s))$ is left invertible; i.e., there exists an $U(s) \in M(r, N, \mathbf{R}[s])$ such that $U(s)B(s) = I_r$;*

(3) *$\hat{B}(s) = B(s)\mathrm{diag}(s^{-\nu_1}, \ldots, s^{-\nu_r})$ is full rank at $s = \infty$, where ν_i is the highest degree of the entries in $g_i(s)$.*

ν_i is called the minimal index of $g_i(s)$. The following theorems are well known.

THEOREM 2.2. (1) *Minimal bases exist.*

(2) *The set of minimal indices is independent of the choice of a minimal basis.*

A minimal basis $B(s)$ is said to be in echelon form if $\nu_1 \geq \cdots \geq \nu_r$ and there exist different r row numbers γ_j $(1 \leq j \leq r)$ such that the following hold.

(1) γ_j increases on intervals $\{i | \nu_i = k\}$ for all k.

(2) The ith entry of the jth column has degree equal to or less than ν_j if $i < \gamma_j$, less than ν_j if $i > \gamma_j$. The γ_jth entry is a monic polynomial of degree ν_j.

(3) The γ_kth entry $(\nu_k \leq \nu_j)$ of the jth column has degree less than ν_k.

Note that if $\nu_k < \nu_j$, then it forces $k > j$, but if $\nu_k = \nu_j$, then $k > j$ and $k < j$ are both possible. It is obvious that there is a unique minimal basis in echelon form.

THEOREM 2.3. *Let (A, B) $(A \in M(n, n, \mathbf{R}), B \in M(n, m, \mathbf{R}))$ be controllable, i.e., $\mathbf{R}[A]\mathrm{Im}B = \mathbf{R}^n$. Then the set of minimal indices of* $\mathrm{Ker}\left(\begin{bmatrix} sI_n - A, & -B \end{bmatrix}\right)$ *coincides with the set of controlability indices as a multiset.*

THEOREM 2.4. (1) *Let $G(s)$ be a strictly proper transfer function of degree n with m inputs, p outputs. Then there exist $A \in M(n, n, \mathbf{R})$, $B \in M(n, m, \mathbf{R})$, $C \in M(p, n, \mathbf{R})$, such that*

(a) *$G(s) = C(sI_n - A)^{-1}B$,*

(b) *the characteristic polynomial $\chi(s)$ of $G(s)$ equals* $\det(sI_n - A)$,

(c) *(A, B) is controllable,*

(d) *(A, C) is observable.*

(2) *If $G(s)$ is of the form $G(s) = C(sI_n - A)^{-1}B$, then there exist $N_0(s) \in M(p, m, \mathbf{R}[s])$, $D_0(s) \in M(m, m, \mathbf{R}[s])$ such that*

(e) *the sum of highest degrees of columns in $D_0(s)$ is n,*

(f) *$\hat{D}_0(s)$ has full rank at $s = \infty$,*

(g) $\det(D_0(s)) = \det(sI_n - A)$,

(h) *$G(s) = N_0(s)D_0(s)^{-1}$.*

If (h) *holds and $G(s)$ is strictly proper, then*

(i) *all m minors of $B_0(s) = \begin{bmatrix} N_0(s) \\ D_0(s) \end{bmatrix}$ have degree equal to or less than n and the only m minor of degree n is* $\det(D_0(s))$.

(3) *If $B_0(s) \in M(m+p, m, \mathbf{R}[s])$ is such that* $\det(D_0(s))$ *is of degree n, other m minors with 1 row from $N_0(s)$, other $(m-1)$ rows from $D_0(s)$ have degrees less than n, then $G(s) = N_0(s)D_0(s)^{-1}$ is strictly proper.*

PROPOSITION 2.5. *Let $G(s)$ be a strictly proper transfer function of degree n with m inputs, p outputs. We take (A, B, C), $N_0(s)$, $D_0(s)$ as in Theorem* 2.4(1) *and* (2).

(1) *For $K(s) = M(sI_d - K)^{-1}L + N$, where $K \in M(d, d, \mathbf{R})$, $L \in M(d, p, \mathbf{R})$, $M \in M(m, d, \mathbf{R})$, $N \in M(m, p, \mathbf{R})$, we set*

$$\chi'_{cl}(s) = \det \left(\begin{bmatrix} I_p & 0 & N_0(s) & 0 \\ 0 & I_d & 0 & I_d \\ N & M & D_0(s) & 0 \\ L & K & 0 & sI_d \end{bmatrix} \right).$$

Then, $\chi_{cl}(s) = \chi'_{cl}(s)$ if and only if
$\left(\begin{bmatrix} A+BNC & BM \\ LC & K \end{bmatrix}, \begin{bmatrix} B \\ 0 \end{bmatrix} \right)$ *is controllable, and*
$\left(\begin{bmatrix} A+BNC & BM \\ LC & K \end{bmatrix}, \begin{bmatrix} C & 0 \end{bmatrix} \right)$ *is observable.*

(2) *All proper transfer functions of degree at most d with p inputs, m outputs may be described as $K(s) = M(sI_d - K)^{-1}L + N$.*

Proof. This can be proved in an elementary way, but here we appeal to the theory of elementary divisors.

We first note that the elementary divisors of the $\mathbf{C}[s]$-module

$$(G(s)\mathbf{C}[s]^m + \mathbf{C}[s]^p)/\mathbf{C}[s]^p$$

are nothing but denominators of the Smith–MacMillan form of $G(s)$. For a $\mathbf{C}[s]$-module A, we denote by $\chi(A)$ the product of the elementary divisors of A. Then if A is a submodule or a quotient module of B, $\chi(A)$ divides $\chi(B)$.

We also note that if we set

$$X(s) = \begin{bmatrix} sI_d - K^T & -M^T & 0 \\ L^T & N^T & I_p \\ 0 & D_0^T(s) & N_0^T(s) \end{bmatrix},$$

then $y = G_{cl}^T(s)r$ can be described as

$$X(s) \begin{bmatrix} z \\ y \\ -u \end{bmatrix} = \begin{bmatrix} 0 \\ -r \\ 0 \end{bmatrix}.$$

Hence we have

$$G_{cl}^T(s) = \begin{bmatrix} 0 & I_m & 0 \end{bmatrix} X(s)^{-1} \begin{bmatrix} 0 \\ -I_p \\ 0 \end{bmatrix}.$$

Therefore, $(G_{cl}^T(s)\mathbf{C}[s]^p + \mathbf{C}[s]^m)/\mathbf{C}[s]^m$ is a subquotient module of

$$(X(s)^{-1}\mathbf{C}[s]^{d+m+p} + \mathbf{C}[s]^{d+m+p})/\mathbf{C}[s]^{d+m+p},$$

and thus $\chi_{cl}(s)$ divides $\det(X(s))$. Since

$$\det\left(\begin{bmatrix} sI_d - K^T & -M^T & 0 \\ L^T & N^T & I_p \\ 0 & D_0^T(s) & N_0^T(s) \end{bmatrix}\right) = \pm\det\left(\begin{bmatrix} K^T & M^T & I_d & 0 \\ L^T & N^T & 0 & I_p \\ 0 & D_0^T(s) & 0 & N_0^T(s) \\ sI_d & 0 & I_d & 0 \end{bmatrix}\right),$$

we know that $\det(X(s))$ coincides with $\chi'_{cl}(s)$ up to sign. In particular, $\chi_{cl}(s)$ and $\chi'_{cl}(s)$ coincide if and only if the degree of $\chi_{cl}(s)$ is $n+d$.

To see when they coincide, we use the following description of $G_{cl}(s)$:

$$G_{cl}(s) = \begin{bmatrix} C & 0 \end{bmatrix} \begin{bmatrix} sI_n - A - BNC & -BM \\ -LC & sI_d - K \end{bmatrix}^{-1} \begin{bmatrix} B \\ 0 \end{bmatrix}.$$

Suppose that this triple for $G_{cl}(s)$ is either uncontrollable or unobservable; then $\chi_{cl}(s)$ has lower degree and never coincides with $\chi'_{cl}(s)$. On the other hand, they coincide if they are both controllable and observable. It has the same proof as Theorem 2.4(1). Hence we have (1). Equation (2) is a direct consequence of Theorem 2.4. □

By Proposition 2.5(1), we have that $\chi_{cl}(s) = \chi'_{cl}(s)$ for almost all K, L, M, N, and the coefficients of $\chi'_{cl}(s)$ are polynomials with respect to these design parameters if (A, B, C) is generic.

We say that $G(s)$ is pole assignable by compensators of degree d if all monic polynomials of degree $n+d$ can be expressed in the form $\chi'_{cl}(s)$ by compensators of degree at most d.

3. Pole placement map.

DEFINITION 3.1. *We denote by $S_{m,p,n}$ the set of strictly proper transfer functions of degree n with m inputs, p outputs. $S^{\le n}_{m,p} = \cup_{1\le k\le n} S_{m,p,k}$.*

For a partition ν of n into at most m parts, and a permutation γ of $\{1,\dots,m\}$ which increases on intervals $\{i|\nu_i = k\}$, we denote by $\Sigma^{\gamma,\nu}_{m,p}$ the set $\left\{B_0(s) = \left[\begin{smallmatrix} N_0(s) \\ D_0(s) \end{smallmatrix}\right]\right\}$ of elements satisfying

1. *$N_0(s) \in M(p, m, \mathbf{R}[s])$, and entries of the jth column have degree less than ν_j;*
2. *$D_0(s) \in M(m, m, \mathbf{R}[s])$, and the ith entry of the jth column have degrees equal to or less than ν_j if $i < \gamma_j$, less than ν_j if $i > \gamma_j$. The γ_jth entry is a monic polynomial of degree ν_j. Further, the γ_kth entry ($\nu_k \le \nu_j$) of the jth column must have degree less than ν_k.*

It is simply denoted $\Sigma^{\nu}_{m,p}$ if γ is the identity. We set $\Sigma^{\le n}_{m,p} = \cup_{|\nu|\le n} \Sigma^{\gamma,\nu}_{m,p}$.

Note that we do not assume that $B_0(s) \in \Sigma^{\gamma,\nu}_{m,p}$ is minimal. But the subset consisting of minimal ones is a dense open subset of $\Sigma^{\gamma,\nu}_{m,p}$.

For $B_0(s) \in \Sigma^{\le n}_{m,p}$, we set

$$N(s) = \begin{bmatrix} N_0(s) & 0 \\ 0 & I_d \end{bmatrix}, \quad D(s) = \begin{bmatrix} D_0(s) & 0 \\ 0 & sI_d \end{bmatrix}, \quad B(s) = \begin{bmatrix} N(s) \\ D(s) \end{bmatrix}.$$

We also set $G = GL(m+p+2d, \mathbf{R})$, and for $g \in G$, the product of g and $B(s)$ is partitioned as

$$gB(s) = \begin{bmatrix} N^{(g)}(s) \\ D^{(g)}(s) \end{bmatrix}.$$

LEMMA 3.2. *$p : \Sigma^{\leq n}_{m,p} \to S^{\leq n}_{m,p}$ defined by $p(B_0(s)) = N_0(s)D_0(s)^{-1}$ is well defined and onto. The subset consisting of minimal bases bijectively corresponds to $S_{m,p,n}$.*

Proof. By Theorem 2.4(3), $p(B_0(s))$ is strictly proper.

Since the characteristic polynomial of $G(s)$ divides $\det(D_0(s))$, its degree is equal to or less than n. Thus we have the well-definedness. For any $G(s)$, take $B_0(s)$ as in Theorem 2.4. Since $\hat{B}_0(s)$ has the form $\begin{bmatrix} G(s) \\ I_m \end{bmatrix} \hat{D}_0(s)$, we have that the highest degree of all entries in the jth column of $N_0(s)$ is smaller than that of $D_0(s)$. Then by multiplying $\hat{D}_0(\infty)^{-1}$ from the right, and after successive elementary column transformations if necessary, we have an element in $\Sigma^{\leq n}_{m,p}$ which maps to $G(s)$. The rest is an obvious consequence of the uniqueness of echelon form. □

Now we give the definition of a new type of a pole placement map, which allows us an elementary proof in an elementary framework.

DEFINITION 3.3. *For $B_0(s) \in \Sigma^{\leq n}_{m,p}$, we define the pole placement map*

$$\rho_{B_0} : G \times M(m+d, p+d, \mathbf{R}) \to \mathbf{R}[s]_{n+d}$$

by the following:

$$\rho_{B_0}(g, X) = \det(g)^{-1} \det \left(\begin{bmatrix} I_{p+d} & N^{(g)}(s) \\ X & D^{(g)}(s) \end{bmatrix} \right).$$

The following proposition is very useful. For the static case, this observation is due to R. W. Brocket and C. I. Byrnes [1]. But we note that their generalization of this technique does not allow us to use the differential map of the pole placement map. Our generalization is a key to the proof we will give in Theorem 4.3.

PROPOSITION 3.4. *Let $G(s) \in S_{m,p,n}$, and we take $B_0(s) \in \Sigma^{\leq n}_{m,p}$ as in Theorem 2.4. Then $G(s)$ is pole assignable by degree d compensators if and only if the pole placement map covers $\mathbf{R}[s]_{n+d} \setminus \mathbf{R}[s]_{n+d-1}$.*

Proof. Assume that $G(s)$ is pole assignable by degree d compensators. Then, by Proposition 2.5, the set

$$\left\{ \det \left(\begin{bmatrix} I_{p+d} & N(s) \\ X & D(s) \end{bmatrix} \right) | X \in M(m+d, p+d, \mathbf{R}) \right\}$$

coincides with the set of all monic polynomials of degree $n+d$. Since the image of the pole placement map is nothing but

$$\left\{ \det \left(\begin{bmatrix} K_1 & N(s) \\ K_2 & D(s) \end{bmatrix} \right) \middle| \begin{bmatrix} K_1 \\ K_2 \end{bmatrix} \text{is full rank} \right\},$$

we can conclude that ρ_{B_0} covers $\mathbf{R}[s]_{n+d} \setminus \mathbf{R}[s]_{n+d-1}$.

Conversely, we assume that ρ_{B_0} covers $\mathbf{R}[s]_{n+d} \setminus \mathbf{R}[s]_{n+d-1}$. Then any monic polynomial of degree $n+d$ is expressed as

$$\det \left(\begin{bmatrix} K_1 & N(s) \\ K_2 & D(s) \end{bmatrix} \right).$$

Laplace expansion tells us that it equals $\det(K_1)\det(D_0(s))+$ (a linear combination of other $m+d$ minors). Since $N(s)D(s)^{-1}$ is strictly proper, we have $\det(K_1) \neq 0$ by Theorem 2.4(2)(i). By putting $X = K_2 K_1^{-1}$, we know that the set of all monic

polynomials of degree $n+d$ coincides with

$$\left\{ \det\left(\begin{bmatrix} I_{p+d} & N(s) \\ X & D(s) \end{bmatrix} \right) \middle| X \in M(m+d, p+d, \mathbf{R}) \right\}.$$

Hence $G(s)$ is pole assignable by degree d compensators. □

4. Generic pole placement. We define a_n, b_n by $n = ma_n + b_n$ $(0 \leq b_n < m)$, and $\nu(n)$ by $\nu(n) = (a_n+1, \ldots, a_n+1, a_n, \ldots, a_n)$ (a_n+1 repeats b_n times).

Among $\Sigma_{m,p}^{\gamma,\nu}$'s, $\Sigma_{m,p}^{\nu(n)}$ is the unique set of the maximum dimension $n(m+p)$. (We know it by counting the number of coefficients.) Hence, to consider the generic pole placement problem, we can restrict ourselves to $p : \Sigma_{m,p}^{\nu(n)} \to S_{m,p}^{\leq n}$ by Lemma 3.2.

REMARK 4.1. *In fact, it is known that we can introduce a topology on $S_{m,p}^{\leq n}$ to make the image of the set of minimal bases in $\Sigma_{m,p}^{\nu(n)}$ the unique open cell* (see [6]).

The following lemma is the key idea to prove Theorem 4.3. Its proof depends on a quite elementary fact which we have explained in the introduction.

LEMMA 4.2. *Let $B_0(s)$ be an element in $\Sigma_{m,p}^{\leq n}$.*

(1) *If $\rho_{B_0}(g,-) : M(m+d, p+d, \mathbf{R}) \to \mathbf{R}[s]_{n+d}$ covers a neighborhood of the origin for some $g \in G$, then $p(B_0(s)) = G(s)$ is pole assignable by degree d compensators.*

(2) *If $\rho_{B_0}(g,-)$ maps 0 to 0, and its differential at $0 \in M(m+d, p+d, \mathbf{R})$ is surjective, then $\rho_{B_0}(g,-)$ covers a neighborhood of the origin.*

Proof. (1) Since the image of ρ_{B_0} is stable under multiplication by positive real numbers, the assumption ensures that ρ_{B_0} is surjective. Thus we have the pole assignability by Proposition 3.4. (2) is obvious. □

We now state the main theorem about generic pole assignability.

THEOREM 4.3. *If $d > \frac{n-mp}{max(m,p)}$, then $S_{m,p,n}$ is generic pole assignable by degree d compensators. More precisely, all elements in $p(U)$ are pole assignable by degree d compensators.*

Before we proceed to the proof, we briefly sketch the logical structure of the proof. We first define an open subset U of $\Sigma_{m,p}^{\nu(n)}$ and prove that U is dense. Next, we prove that all systems in U are pole assignable by degree d compensators. To define U, we first prepare notation.

DEFINITION 4.4. *For $h\begin{bmatrix} N(s) \\ D(s) \end{bmatrix} U(s)$ such that $h \in G$ and an invertible polynomial matrix $U(s)$, we write the first a_n+1 entries of the first column as*

$$\begin{bmatrix} B_1 \\ B_2 \end{bmatrix} \begin{bmatrix} 1 \\ s \\ \cdot \\ \cdot \\ s^{a_n} \end{bmatrix} \qquad \left(\begin{array}{l} B_1 \in M(a_n+1, a_n+1, \mathbf{R}), \\ B_2 \in M(m+p+2d-a_n-1, a_n+1, \mathbf{R}) \end{array} \right).$$

If $\det(B_1) \neq 0$, we define $g \in G$ by

$$g = \begin{bmatrix} B_1^{-1} & 0 \\ -B_2 B_1^{-1} & I_{m+p+2d-a_n-1} \end{bmatrix}.$$

If we compute $gh\begin{bmatrix}N(s)\\D(s)\end{bmatrix}U(s)$, *then we find that the first column has the entries in such a way that* 1 *to* s^{a_n} *in the ascending order in the first* a_n+1 *entries, and* 0*'s in the rest of entries.*

We also note that g *is determined by* $h\in G$ *and a polynomial matrix* $U(s)$.

Let U *be the open subset of* $\Sigma_{m,p}^{\nu(n)}$ *consisting of elements satisfying*

(1) $\det(B_1)\neq 0$ *for some* $h\begin{bmatrix}N(s)\\D(s)\end{bmatrix}U(s)$;

(2) *the set of* $m+d$ *minors which have one row from* $N^{(gh)}(s)$ *and other rows from* $D^{(gh)}(s)$ *span* $\mathbf{R}[s]_{n+d}$.

REMARK 4.5. *We form* $B(s)=\begin{bmatrix}N(s)\\D(s)\end{bmatrix}$ *from* $N_0(s)$ *and* $D_0(s)$ *as in the previous section.*

Note that U is dense if it is nonempty, since for each h, $U(s)$, the above set is defined as the complement of the set of zeros of a polynomial, and U is their union.

It is easy to see that U is nonempty. To find an element in U, we set, for example,

$$N_0(s)=\begin{bmatrix}0&\cdots&0&1\\0&\cdots&1&s^{\nu_m-p+1}\\\cdot&\cdots&\cdot&\cdot\\0&\cdots&1&s^{\nu_m-1}\end{bmatrix},D_0(s)=\begin{bmatrix}s^{\nu_1}&0&\cdots&0&0&0\\1&s^{\nu_2}&\cdots&0&0&0\\\cdot&\cdot&\cdots&\cdot&\cdot&\cdot\\0&0&\cdots&1&s^{\nu_{m-1}}&0\\0&0&\cdots&0&1&s^{\nu_m}\end{bmatrix}$$

for the most tight case $\nu_m=p+d-1$.

It turns out to be an element in U. To see it, it is enough to see the matrix transformation given below. We can treat the other case in the same way. (The constant feedback case is not the exception.)

We first move the mth column to the first column, the $(p+d+m)$th row to the $(p+d+1)$th row, and then the $(p+1)$th to the $(p+d)$th rows to the first d rows. $B(s)=\begin{bmatrix}N(s)\\D(s)\end{bmatrix}$ then becomes

$$\Rightarrow\begin{bmatrix}0&0&\cdots&0&1&0&\cdots&0\\0&0&\cdots&0&0&1&\cdots&0\\\cdot&\cdot&\cdots&\cdot&\cdot&\cdot&\cdots&\\0&0&\cdots&0&0&0&\cdots&1\\1&0&\cdots&0&0&0&\cdots&0\\s^{\nu_m-p+1}&0&\cdots&1&0&0&\cdots&0\\\cdot&\cdot&\cdots&\cdot&\cdot&\cdot&\cdots&\\s^{\nu_m-1}&0&\cdots&1&0&0&\cdots&0\\s^{\nu_m}&0&\cdots&1&0&0&\cdots&0\\0&s^{\nu_1}&\cdots&0&0&0&\cdots&0\\0&1&\cdots&0&0&0&\cdots&0\\\cdot&\cdot&\cdots&\cdot&\cdot&\cdot&\cdots&\\0&0&\cdots&s^{\nu_{m-1}}&0&0&\cdots&0\\0&0&\cdots&0&s&0&\cdots&0\\0&0&\cdots&0&0&s&\cdots&0\\\cdot&\cdot&\cdots&\cdot&\cdot&\cdot&\cdots&\\0&0&\cdots&0&0&0&\cdots&s\end{bmatrix}.$$

Next, we multiply each of the last d columns by a power of s and add in the first column. Then it is further transformed into

$$\Rightarrow \begin{bmatrix}
s^{d-1} & 0 & \cdots & 0 & 1 & 0 & \cdots & 0 \\
s^{d-2} & 0 & \cdots & 0 & 0 & 1 & \cdots & 0 \\
\cdot & \cdot & \cdots & \cdot & \cdot & \cdot & \cdots & \\
1 & 0 & \cdots & 0 & 0 & 0 & \cdots & 1 \\
1 & 0 & \cdots & 0 & 0 & 0 & \cdots & 0 \\
s^{\nu_m-p+1} & 0 & \cdots & 1 & 0 & 0 & \cdots & 0 \\
\cdot & \cdot & \cdots & \cdot & \cdot & \cdot & \cdots & \\
s^{\nu_m-1} & 0 & \cdots & 1 & 0 & 0 & \cdots & 0 \\
s^{\nu_m} & 0 & \cdots & 1 & 0 & 0 & \cdots & 0 \\
0 & s^{\nu_1} & \cdots & 0 & 0 & 0 & \cdots & 0 \\
0 & 1 & \cdots & 0 & 0 & 0 & \cdots & 0 \\
\cdot & \cdot & \cdots & \cdot & \cdot & \cdot & \cdots & \\
0 & 0 & \cdots & s^{\nu_{m-1}} & 0 & 0 & \cdots & 0 \\
s^{d} & 0 & \cdots & 0 & s & 0 & \cdots & 0 \\
s^{d-1} & 0 & \cdots & 0 & 0 & s & \cdots & 0 \\
\cdot & \cdot & \cdots & \cdot & \cdot & \cdot & \cdots & \\
s & 0 & \cdots & 0 & 0 & 0 & \cdots & s
\end{bmatrix}.$$

Now we eliminate the latter part of the first column entries by using elementary row transformations:

$$\Rightarrow \begin{bmatrix}
s^{d-1} & 0 & \cdots & 0 & 1 & 0 & \cdots & 0 \\
s^{d-2} & 0 & \cdots & 0 & 0 & 1 & \cdots & 0 \\
\cdot & \cdot & \cdots & \cdot & \cdot & \cdot & \cdots & \\
1 & 0 & \cdots & 0 & 0 & 0 & \cdots & 1 \\
1 & 0 & \cdots & 0 & 0 & 0 & \cdots & 0 \\
s^{\nu_m-p+1} & 0 & \cdots & 1 & 0 & 0 & \cdots & 0 \\
\cdot & \cdot & \cdots & \cdot & \cdot & \cdot & \cdots & \\
s^{\nu_m-1} & 0 & \cdots & 1 & 0 & 0 & \cdots & 0 \\
s^{\nu_m} & 0 & \cdots & 1 & 0 & 0 & \cdots & 0 \\
0 & s^{\nu_1} & \cdots & 0 & 0 & 0 & \cdots & 0 \\
0 & 1 & \cdots & 0 & 0 & 0 & \cdots & 0 \\
\cdot & \cdot & \cdots & \cdot & \cdot & \cdot & \cdots & \\
0 & 0 & \cdots & s^{\nu_{m-1}} & 0 & 0 & \cdots & 0 \\
0 & 0 & \cdots & -1 & s & 0 & \cdots & 0 \\
0 & 0 & \cdots & 0 & -1 & s & \cdots & 0 \\
\cdot & \cdot & \cdots & \cdot & \cdot & \cdot & \cdots & \\
0 & 0 & \cdots & 0 & 0 & 0 & \cdots -1 & s
\end{bmatrix}.$$

The next step is only to delete 1 in the first column by using the row just below it:

$$\Rightarrow \begin{bmatrix} s^{d-1} & 0 & \cdots & 0 & 1 & 0 & \cdots & 0 \\ s^{d-2} & 0 & \cdots & 0 & 0 & 1 & \cdots & 0 \\ \cdot & \cdot & \cdots & \cdot & \cdot & \cdot & \cdots & \\ s & 0 & \cdots & 0 & 0 & 0 & \cdots 1 & 0 \\ 0 & 0 & \cdots & 0 & 0 & 0 & \cdots & 1 \\ 1 & 0 & \cdots & 0 & 0 & 0 & \cdots & 0 \\ s^{\nu_m-p+1} & 0 & \cdots & 1 & 0 & 0 & \cdots & 0 \\ \cdot & \cdot & \cdots & \cdot & \cdot & \cdot & \cdots & \\ s^{\nu_m-1} & 0 & \cdots & 1 & 0 & 0 & \cdots & 0 \\ s^{\nu_m} & 0 & \cdots & 1 & 0 & 0 & \cdots & 0 \\ 0 & s^{\nu_1} & \cdots & 0 & 0 & 0 & \cdots & 0 \\ 0 & 1 & \cdots & 0 & 0 & 0 & \cdots & 0 \\ \cdot & \cdot & \cdots & \cdot & \cdot & \cdot & \cdots & \\ 0 & 0 & \cdots & s^{\nu_{m-1}} & 0 & 0 & \cdots & 0 \\ 0 & 0 & \cdots & -1 & s & 0 & \cdots & 0 \\ 0 & 0 & \cdots & 0 & -1 & s & \cdots & 0 \\ \cdot & \cdot & \cdots & \cdot & \cdot & \cdot & \cdots & \\ 0 & 0 & \cdots & 0 & 0 & 0 & \cdots -1 & s \end{bmatrix}.$$

It is now easy to check the condition (1), (2), since by rearranging rows of the above matrix we obtain the final form given below, and we have $B_1 = I$, $B_2 = 0$. We also remark here that $\nu_m = a_n$.

$$h \begin{bmatrix} N(s) \\ D(s) \end{bmatrix} U(s) = \begin{bmatrix} 1 & 0 & \cdots & \cdot & \cdot & \cdots & \cdot & \cdot \\ s & 0 & \cdots & \cdot & \cdot & \cdots & \cdot & \cdot \\ \cdot & \cdot & \cdots & \cdot & \cdot & \cdots & \cdot & \cdot \\ s^{\nu_m} & \cdot & \cdots & \cdot & \cdot & \cdots & \cdot & \cdot \\ 0 & s^{\nu_1} & \cdots & \cdot & \cdot & \cdots & \cdot & \cdot \\ 0 & 1 & \cdots & \cdot & \cdot & \cdots & \cdot & \cdot \\ \cdot & \cdot & \cdots & \cdot & \cdot & \cdots & \cdot & \cdot \\ 0 & \cdot & \cdots & s^{\nu_{m-1}} & 0 & \cdots & \cdot & \cdot \\ 0 & \cdot & \cdots & -1 & s & \cdots & \cdot & \cdot \\ 0 & \cdot & \cdots & 0 & -1 & \cdots & \cdot & \cdot \\ \cdot & \cdot & \cdots & \cdot & \cdot & \cdots & \cdot & \cdot \\ 0 & \cdot & \cdots & \cdot & \cdot & \cdots & -1 & s \\ 0 & \cdot & \cdots & \cdot & \cdot & \cdots & \cdot & 1 \end{bmatrix}.$$

Proof of the main theorem. As was explained in the introduction, we can assume $m \geq p$ without loss of generality. We consider the map ρ_{B_0} in Lemma 4.2. Take any element in U; we will show in the following that the corresponding transfer function has the pole assignability. Note that $\rho_{B_0}(gh, X)$ is a nonzero scalar multiple of

$$\det\left(\begin{bmatrix} I_{p+d} & N^{(gh)}(s) \\ X & D^{(gh)}(s) \end{bmatrix}\begin{bmatrix} I & 0 \\ 0 & U(s) \end{bmatrix}\right),$$

where g is as in the above definition. It is well defined by the condition (1).

Because of $d > \frac{n-mp}{m}$, we have $a_n < p + d$. Hence the first column of $D^{(gh)}(s)$ is zero vector and $\det(D^{(gh)}(s)) = 0$. In other words, the map $\rho_{B_0}(gh, -)$ maps $0 \in M(m + d, p + d, \mathbf{R})$ to the origin.

Since the image of its differential at $0 \in M(m + d, p + d, \mathbf{R})$ is spanned by $m + d$ minors which have one row from $N^{(gh)}(s)$, other rows from $D^{(gh)}(s)$, we know that the differential is surjective by the condition (2).

Therefore, $\rho_{B_0}(gh, -)$ covers a neighborhood of the origin of $\mathbf{R}[s]_{n+d}$, which means that any element in $p(U)$ is pole assignable by degree d compensators. Since we can find an element in U, U is dense, and we have the result.

5. Necessary condition for generic pole placement. The second application of Proposition 3.4 is the following result, which was known, and was "proved" naively by counting parameters [9]. We give a proof to this result along this idea. To verify the idea, we consider a group action. We think that this new treatment, i.e., the Lie group theoretic approach to the pole placement problem, fits well to the further study, since, in Lie group theory, orbit structures are considered over $\mathbf{R}$, compared with algebraic geometry which is mainly considered over $\mathbf{C}$. J. Rosenthal gave another proof using a different method [6]. The following proof is new, but we also remark that for the proof of this necessary condition we replace the general theorem from Lie group theory by an elementary ring theoretic argument, since the difference between $\mathbf{R}$ and $\mathbf{C}$ does not matter at this stage. The real advantage of this Lie group method remains for future research.

THEOREM 5.1. *If $G(s) \in S_{m,p,n}$ is pole assignable by degree d compensators, then $d \geq \frac{n-mp}{m+p-1}$.*

Proof. Let $\rho'_{B_0} : M(m+p+2d, p+d, \mathbf{R}) \to \mathbf{R}[s]_{n+d}$ be an extended pole assignment map given by

$$\rho'_{B_0}\left(\begin{bmatrix} K_1 \\ K_2 \end{bmatrix}\right) = \det\left(\begin{bmatrix} K_1 & N(s) \\ K_2 & D(s) \end{bmatrix}\right).$$

The image of the set of full rank matrices is the same as the image of ρ_{B_0}. ρ'_{B_0} naturally induces the algebra homomorphism

$$\mathbf{R}[a_0, \ldots, a_{n+d}] \to \mathbf{R}[x_{ij}],$$

where a_i's are the coefficients of polynomials in $\mathbf{R}[s]_{n+d}$, x_{ij}'s are matrix coordinates of $M(m+p+2d, p+d, \mathbf{R})$. Since $G(s)$ is pole assignable by degree d compensators, Proposition 3.4 tells us that it is injective.

Let H be the group consisting of the elements

$$h = \begin{bmatrix} h_1 & 0 & 0 \\ 0 & I_m & 0 \\ 0 & 0 & h_2 \end{bmatrix}$$

satisfying

$$h_1 \in GL(p+d, \mathbf{R}), \quad h_2 \in GL(d, \mathbf{R}), \quad \det(h_1) = \det(h_2).$$

We denote $\begin{bmatrix} I_p & 0 \\ 0 & h_2 \end{bmatrix}$, $\begin{bmatrix} I_m & 0 \\ 0 & h_2 \end{bmatrix}$ by $\phi_1(h_2)$, $\phi_2(h_2)$, respectively. H acts on $M(m+p+2d, p+d, \mathbf{R})$ by

$$h \cdot \begin{bmatrix} K_1 \\ K_2 \end{bmatrix} = \begin{bmatrix} \phi_1(h_2) K_1 h_1^{-1} \\ \phi_2(h_2) K_2 h_1^{-1} \end{bmatrix}.$$

We then have

$$\rho'_{B_0}\left(h\cdot\begin{bmatrix} K_1 \\ K_2 \end{bmatrix}\right) = \det\left(\begin{bmatrix} \phi_1(h_2)K_1h_1^{-1} & N(s) \\ \phi_2(h_2)K_2h_1^{-1} & D(s) \end{bmatrix}\right)$$

$$= \det\left(\begin{bmatrix} I_{p+d} & 0 \\ 0 & \phi_2(h_2) \end{bmatrix}\right)\det\left(\begin{bmatrix} \phi_1(h_2)K_1 & N(s) \\ K_2 & \phi_2(h_2)^{-1}D(s) \end{bmatrix}\right)$$

$$\times \det\left(\begin{bmatrix} h_1^{-1} & 0 \\ 0 & I_{m+d} \end{bmatrix}\right).$$

Since $D(s)$ commutes with $\phi_2(h_2)$, it equals

$$= \det(h_2)\det(h_1)^{-1}\det\left(\begin{bmatrix} \phi_1(h_2)K_1 & N(s) \\ K_2 & D(s)\phi_2(h_2)^{-1} \end{bmatrix}\right)$$

$$= \det\left(\begin{bmatrix} \phi_1(h_2)K_1 & N(s)\phi_2((h_2) \\ K_2 & D(s) \end{bmatrix}\right)\det\left(\begin{bmatrix} I_{p+d} & 0 \\ 0 & \phi_2(h_2)^{-1} \end{bmatrix}\right).$$

Similarly, we use $\phi_1(h_2)N(s) = N(s)\phi_2(h_2)$. Then,

$$= \det(h_1)^{-1}\det\left(\begin{bmatrix} \phi_1(h_2)K_1 & \phi_1(h_2)N(s) \\ K_2 & D(s) \end{bmatrix}\right) = \rho'_{B_0}\left(\begin{bmatrix} K_1 \\ K_2 \end{bmatrix}\right).$$

Hence we have that $\mathbf{R}[a_0,\ldots,a_{n+d}]$ is embedded in $\mathbf{R}[x_{ij}]^H$.

Take a Zariski open set U of $M(m+p+2d, p+d, \mathbf{R})$ consisting of elements $\begin{bmatrix} K_1 \\ K_2 \end{bmatrix}$ satisfying

(1) $\det(K_1) \neq 0$,

(2) $K_2 = \begin{bmatrix} N & M \\ L & K \end{bmatrix}$ such that K has d distinct eigenvalues, (K, L) controllable.

Then H acts on U freely. Now we consider an embedding $H \times U_0 \to U : (h, u) \mapsto h \cdot \begin{bmatrix} I_{p+d} \\ u \end{bmatrix}$, where U_0 is the set of $\begin{bmatrix} N & M \\ L & K \end{bmatrix}$ such that

(1) the last column of L is $\begin{bmatrix} 0 & \cdots & 1 \end{bmatrix}^T$,

(2) K is of the form

$$\begin{bmatrix} 0 & 1 & \cdots \\ \cdots & \cdots & \cdots \\ \cdots & \cdots & 1 \\ -k_1 & \ldots & -k_d \end{bmatrix},$$

which has distinct eigenvalues.

H acts on $H \times U_0$ by left multiplication, and the ring of H invariants is the polynomial ring in coordinates for U_0. By comparing the transcendental degrees of polynomial rings $\mathbf{C}[a_0,\ldots,a_{n+d}]$ and the coordinate ring of U_0, we can verify the dimension counting, which is

$$n + d + 1 \leq (m+p+2d)(p+d) - ((p+d)^2 + d^2 - 1) = mp + d(m+p) + 1,$$

which completes the proof. □

LOCAL EXACT BOUNDARY CONTROLLABILITY OF THE BOUSSINESQ EQUATION*

A. V. FURSIKOV† AND O. YU. IMANUVILOV‡

Abstract. We study the local exact boundary controllability problem for the Boussinesq equations that describe an incompressible fluid flow coupled to thermal dynamics. The result that we get in this paper is as follows: suppose that $\hat{y}(t,x)$ is a given solution of the Boussinesq equation where $t \in (0,T)$, $x \in \Omega$, Ω is a bounded domain with C^∞-boundary $\partial\Omega$. Let $y_0(x)$ be a given initial condition and $\|\hat{y}(0,\cdot) - y_0\| < \epsilon$ where $\epsilon = \epsilon(\hat{y})$ is small enough. Then there exists boundary control u such that the solution $y(t,x)$ of the Boussinesq equations satisfying

$$y|_{(0,T)\times\partial\Omega} = u, \qquad y|_{t=0} = y_0$$

coincides with $\hat{y}(t,x)$ at the instant T : $y(T,x) \equiv \hat{y}(T,x)$.

Key words. Boussinesq equation, local exact boundary controllability

Introduction. We study the local exact controllability problem for the Boussinesq equations that describe the incompressible fluid flow coupled to thermal dynamics. The control function is the Dirichlet boundary condition of the velocity and temperature vector field of fluid flow. More precisely, the investigated local exact controllability problem is as follows: suppose that

$$\partial_t y(t,x) + A(y) = f(t,x), \qquad t \in (0,T), \qquad x \in \Omega, \tag{0.1}$$

is a symbolic writing of the Boussinesq equations defined in a bounded domain $\Omega \subset \mathbf{R}^n$, $n = 2, 3$, where $y(t,x)$ is a velocity and temperature vector field, $f(t,x)$ is an external forces vector field, and $t \in (0,T)$ is a time. Assume that a solution $\hat{y}(t,x)$ of (0.1),

$$\partial_t \hat{y}(t,x) + A(\hat{y}) = f(t,x),$$

as well as an initial condition $y_0(x)$, are given and they satisfy the proximity condition

$$\|\hat{y}(0,\cdot) - y_0(\cdot)\| \le \epsilon, \tag{0.2}$$

where $\|\cdot\|$ is the norm of the corresponding initial conditions space and $\epsilon > 0$ is a sufficiently small magnitude. One has to find control u defined on the lateral surface $\Sigma = (0,T) \times \partial\Omega$ of the cylinder $(0,T) \times \Omega$:

$$y|_\Sigma = u \tag{0.3}$$

such that the solution $y(t,x)$ of (0.1), (0.3) supplied by the initial condition

$$y|_{t=0} = y_0 \tag{0.4}$$

coincides with the given solution $\hat{y}(t,x)$ at instant $t = T$:

$$y|_{t=T} = \hat{y}|_{t=T}. \tag{0.5}$$

One useful application of the local exact controllability property is as follows. Let $f(t,x) \equiv f(x)$ be independent on t and $\hat{y}(x)$ be a steady-state solution of (0.1) with zero boundary condition which, by definition, is a singular point in the phase space of the dynamical system generated by equation (0.1) supplied by zero boundary conditions. Suppose that this point $\hat{y}(x)$ is an unstable one. Then solvability of problem (0.1), (0.3), (0.5) implies that one can transfer an arbitrary point y_0 belonging to a small neighborhood of $\hat{y}$ to $\hat{y}$ via a solution of (0.1) by appropriate choice of boundary control. Hence, it is possible to suppress the rise of turbulence with the help of boundary control.

The interest in controllability problems for equations simulating a fluid flow was initiated by J.-L. Lions in [29], [30]. Different kinds of approximate controllability results for the Stokes system were obtained by J.-L. Lions in [29], [30], in A. Fursikov and O. Imanuvilov [18], [20], in J. I. Diaz and A. V. Fursikov [6], in J.-L. Lions and E. Zuazua [33]. A close problem was considered in C. Fabre and G. Lebeau [8]. Approximate controllability of the semilinear heat equation with nonlinearity satisfying the global Lipschitz condition was studied by C. Fabre, J.-P. Puel, and E. Zuazua [9], [10]. Approximate controllability for a system associated with Navier–Stokes equations but possessing the sublinear growth of its nonlinearity was proved by C. Fabre [7].

The solvability of (0.1), (0.3)–(0.5) was first proved in A. Fursikov and O. Imanuvilov [15] for the case when (0.1) is the Burgers equation. This problem was solved in the case of Navier–Stokes equations and $\hat{y} \equiv 0$ in A. Fursikov and O. Imanuvilov [16] when the dimension of the system $n = 2$ and in A. Fursikov [12] when $n = 3$. The case of Navier–Stokes equations and $\hat{y} \neq 0$ has been studied in A. Fursikov and O. Imanuvilov [17]. The results proved in this work as well as analogous results for the Navier–Stokes equations were announced in [19].

J.-M. Coron established exact controllability of the two-dimensional Euler equation in [3], [4] and approximate controllability of the two-dimensional Navier–Stokes equations in [5].

At last, exact controllability of a semilinear parabolic equation with coefficients depending on t and x and with nonlinearity satisfying the global Lipschitz condition was established by O. Imanuvilov [23]–[26]. A similar result was obtained by G. Lebeau and L. Robbiano [28] for the linear heat equation on manifolds. We are interested in the Boussinesq equations because the investigation of a fluid flow stability in the free convection problem is important in the theory of hydrodynamical stability (see D. Joseph [27]). Besides, as we think, the exact controllability result for Boussinesq equations should be useful for solution of certain reversibility problems in the theory of climate (see J.-L. Lions [29], [30]).

The first step of the controllability property proof is a reduction of the nonlinear problem (0.1), (0.3)–(0.5) to the solvability of the analogous problem for the linearization of (0.1). We do it with the help of one variant of the implicit function theorem. To establish solvability of the controllability problem we prove that the set of the data

for which the linear controllability problem has a solution is dense (section 3) and is closed (section 5) in the corresponding function space.

The main difficulties of the proof are connected with the pressure term in the Boussinesq equations. To overcome this difficulty we introduce some nonstandard functional spaces and construct in these spaces a decomposition of a vector field on solenoidal and potential components (section 4). This decomposition is based on the Carleman estimate for the Laplace operator (L. Hörmander [21], [22]) and for the heat equation (section 6). Note that in papers [12], [15], [16] mentioned above we also used Carleman estimates, but the method of proof of Carleman estimates which was applied in section 6 is more close to O. Imanuvilov [26] and A. Fursikov and O. Imanuvilov [17].

1. Statement of the problem and formulation of the main result. In a bounded domain $\Omega \subset \mathbf{R}^n$ ($n = 2$ or 3) with C^∞-boundary $\partial\Omega$ we consider the Boussinesq system

$$\partial_t v(t,x) - \Delta v + (v,\nabla)v + \theta(t,x)e_0 + \nabla p(t,x) = f(t,x), \tag{1.1}$$

$$\mathbf{div}\, v \equiv \sum_{j=1}^{n} \partial_{x_j} v_j = 0, \tag{1.2}$$

$$\partial_t \theta(t,x) - \Delta\theta + (v,\nabla\theta) + (v,e_0) = h(t,x), \tag{1.3}$$

$$v(t,x)|_{t=0} = v_0(x), \qquad \theta(t,x)|_{t=0} = \theta_0(x), \tag{1.4}$$

$$v|_\Sigma = u_v, \qquad \theta|_\Sigma = u_\theta. \tag{1.5}$$

Here $(t,x) \in Q = (0,T)\times\Omega$, $v(t,x) = (v_1(t,x),\dots,v_n(t,x))$ is the velocity of a fluid at point x and at instant t, $\theta(t,x)$ is the temperature of a fluid, ∇p is a pressure gradient, $f(t,x)$ is the density of external forces, $h(t,x)$ is the density of external heat sources, $e_0 \in \mathbf{R}^n$ is the vector of the gravity force direction, u_v, u_θ are Dirichlet boundary conditions (in our case, they are control functions), and v_0, θ_0 are initial conditions. Besides, $\Sigma = (0,T)\times\partial\Omega$, $\partial_t = \partial/\partial t$, $\partial_{x_j} = \partial/\partial_{x_j}$, Δ is the Laplace operator, $(v,\nabla)v = \sum v_j \partial_{x_j} v$, and $(v,\nabla\theta) = \sum_{j=1}^n v_j \partial_{x_j}\theta$.

We investigate the local exact controllability problem for Boussinesq equations. Its formulation is as follows. Suppose that $\hat v(t,x)$, $\hat p(t,x)$, $\hat\theta(t,x)$ is a given sufficiently smooth[1] solution of Boussinesq equations (1.1)–(1.3):

$$\partial_t \hat v(t,x) - \Delta\hat v + (\hat v,\nabla)\hat v + \hat\theta(t,x)e_0 + \nabla\hat p(t,x) = f(t,x),$$
$$\mathbf{div}\,\hat v = 0,$$
$$\partial_t\hat\theta(t,x) - \Delta\hat\theta(t,x) + (\hat v,\nabla\hat\theta) + (\hat v,e_0) = h(t,x),$$

and initial conditions $v_0(x)$, $\theta_0(x)$ are sufficiently close to $\hat v(0,x)$, $\hat\theta(0,x)$ with respect to an appropriate norm. One has to find boundary control (u_v,u_θ) defined on Σ such that the solution $(v(t,x),p(t,x),\theta(t,x))$ of boundary value problem (1.1)–(1.5) satisfies at instant $t = T$ the relations

$$v(T,x) \equiv \hat v(T,x), \qquad \theta(T,x) \equiv \hat\theta(T,x). \tag{1.6}$$

Let us introduce the functional spaces to set precisely the controllability problem and to formulate the main result. We use the Sobolev spaces $W_p^k(\Omega)$, $1 \le p < \infty$, k integer

[1] The precise smoothness conditions are formulated below.

not negative, possessing the norm

$$\|u\|_{W_p^k(\Omega)} = \left(\int_\Omega \sum_{|\alpha|\le k} \left| \frac{\partial^{|\alpha|} u(x)}{\partial x_1^{\alpha_1} \dots \partial x_n^{\alpha_n}} \right|^p \, dx \right)^{1/p},$$

where $\alpha = (\alpha_1, \dots, \alpha_n)$, $\mid \alpha \mid = \alpha_1 + \ldots + \alpha_n$. We also use the Sobolev spaces $W_2^\alpha(\Omega) = H^\alpha(\Omega)$ with an arbitrary real α. See their definition in J.-L. Lions and E. Magenes [32].

Define the functional space $V^k(\Omega)$ of solenoidal vector fields

$$V^k(\Omega) = \{v(x) \in (H^k(\Omega))^n : \mathbf{div}\, v(x) = 0\}. \tag{1.7}$$

We need the following spaces of functions defined in the cylinder Q:

$$W^{1,2(k)}(Q) = \{\theta(t,x) \in L_2(0,T; H^{k+2}(\Omega)) : \partial_t \theta \in L_2(0,T; H^k(\Omega))\}, \tag{1.8}$$

$$V^{1,2(k)}(Q) = \{v(t,x) \in (W^{1,2(k)}(Q))^n : \mathbf{div}\, v = 0\}. \tag{1.9}$$

The main result of this paper is as follows.

THEOREM 1.1. *Suppose that $f(t,x) \in (W^{1,2(2)}(Q))^n$, $h(t,x) \in W^{1,2(2)}(Q)$ are given data and $(\hat v(t,x), \hat p(t,x), \hat\theta(t,x)) \in V^{1,2(2)}(Q) \times L_2(0,T; H^3(\Omega)) \times W^{1,2(2)}(Q)$ is a solution of equations* (1.1)–(1.3)*, satisfying the property*

$$\int_{\Gamma_j} (\hat v(t,x), \nu(x))\, d\sigma = 0, \qquad j = 1, \dots, r, \qquad t \in [0,T), \tag{1.10}$$

where Γ_j are components of $\partial\Omega$: $\partial\Omega = \cup_{j=0}^r \Gamma_j$, $\Gamma_j \cap \Gamma_k = \{\emptyset\}$, if $j \ne k$, $\nu(x)$ is the vector field of outside normals to $\partial\Omega$. Suppose that $(v_0(x), \theta_0(x)) \in V^1(\Omega) \times H^1(\Omega)$ is a given initial datum satisfying conditions

$$\int_{\Gamma_j} (v_0(x), \nu(x))\, d\sigma = 0, \qquad j = 1, \dots, r, \tag{1.11}$$

which is close to $(\hat v(0,x), \hat\theta(0,x))$:

$$\|v_0 - \hat v(0,\cdot)\|^2_{V^1(\Omega)} + \|\theta_0 - \hat\theta(0,\cdot)\|^2_{H^1(\Omega)} < \epsilon, \tag{1.12}$$

where $0 < \epsilon \le \epsilon_0$ and ϵ_0 is of sufficiently small magnitude depending on $(\hat v, \hat\theta)$. Then there exists boundary control $(u_v, u_\theta) \in (L_2(\Sigma))^n \times L_2(\Sigma)$ such that there exists the solution $(v, p, \theta) \in V^{1,2(0)}(Q) \times L_2(0,T; H^1(\Omega)) \times W^{1,2(0)}(Q)$ of problem (1.1)–(1.5) *and this solution satisfies condition* (1.6)*. Moreover, there exist constants $\kappa > 0$, $c_1 > 0$ such that*

$$\|v(t,\cdot) - \hat v(t,\cdot)\|^2_{V^1(\Omega)} + \|\theta(t,\cdot) - \hat\theta(t,\cdot)\|^2_{H^1(\Omega)} \le c_1 e^{-\frac{\kappa}{(T-t)}} \qquad \text{as } t \to T. \tag{1.13}$$

In the remaining part of the paper we prove this theorem.

Remark 1.1. The condition $(\hat v, \hat p, \hat\theta) \in V^{1,2(2)}(Q) \times L_2(0,T; H^3(\Omega)) \times W^{1,2(2)}(Q)$ of Theorem 1.1 can be weakened. Namely, the assertion of Theorem 1.1 remains true if, instead of the assumptions mentioned above, we suppose that

$$\hat v(t,x) \in V^{1,2(1/2)}(Q) \cap (L_\infty(Q))^n, \qquad \hat\theta \in W^{1,2(1/2)}(Q). \tag{1.14}$$

In the case of assumption (1.14) we have to add to the proof of Theorem 1.1 with some more or less complicated applications of the Sobolev embedding theorem and also with one technical method mentioned below in Remark 5.1.

2. Reduction to a linear controllability problem.

2.1. Let us begin with a simple but useful remark. We will not specially construct the boundary control (v_u, θ_u). Instead, we will study the solvability of problem (1.1)–(1.4), (1.6), which does not contain boundary conditions (1.5). We will find a boundary control $(v_u,\, \theta_u)$ at the very end of the proof with the help of a restriction of the constructed solution (v, θ) at the boundary Σ.

We show now that one can reduce the controllability problem mentioned above to the case of bounded domain Ω with a connected boundary. Indeed, let Γ_0 be the external component of the boundary $\partial\Omega$. We denote by G the bounded domain with the boundary Γ_0. Evidently

$$G = \Omega \cup \cup_{j=1}^{r} (\Omega_j \cup \Gamma_j),$$

where Ω_j is the bounded domain with the boundary Γ_j. To reduce the proof of Theorem 1.1 to the case of domain G with connected boundary we have to continuously extend functions $(\hat{u}, \hat{p}, \hat{\theta}) \in V^{1,2(2)}(Q) \times L_2(0,T; W_2^3(\Omega)) \times W^{1,2(2)}(Q)$ up to $(\tilde{u}, \tilde{p}, \tilde{\theta}) \in V^{1,2(2)}(\hat{Q}) \times L_2(0,T; W_2^3(G)) \times W^{1,2(2)}(\hat{Q})$ where $\hat{Q} = (0,T) \times G$ and initial conditions $(v_0, \theta_0) \in V^1(\Omega) \times H^1(\Omega)$ up to $(\tilde{v}, \tilde{\theta}) \in V^1(G) \times H^1(G)$. After this extension we substitute $(\tilde{v}, \tilde{p}, \tilde{\theta})$ into (1.1), (1.3) and calculate the right side $(\tilde{f}, \tilde{h})$ of these equations. Naturally, $(\tilde{f}, \tilde{h})$ will be an extension of (f, h). When we prove Theorem 1.1 in the case of domain G, we will restrict the solution of the controllability problem at $\partial\Omega = \cup_{j=0}^{r} \Gamma_j$. Then the constructed function (v_u, θ_u) will be the control which solves the controllability problem in the case of domain Ω with disconnected boundary.

PROPOSITION 2.1. *For an arbitrary natural number l there exists the extension operator $L : L\theta(x)|_\Omega \equiv \theta(x)$ such that the maps*

$$L : H^k(\Omega) \to H^k(G)$$

are bounded for $k = 0, \dots, l$.

Although the proof of this proposition is well known we briefly revisit the construction of the extension, taking into account our future goals. After application of a partition of unity and rectification of the boundary, we obtain the extension problem for a function $u(x)$ defined in $\mathbf{R}^n_+ = \{x = (x_1, \dots, x_n), x_n > 0\}$ up to a function defined on $\mathbf{R}^n$. The extension operator L is now defined by the formula

$$Lu(x', x_n) = \begin{cases} u(x', x_n) & \text{when } x_n \geq 0, \\ \sum_{k=1}^{l} \lambda_k u(x', -x_n/k) & \text{when } x_n < 0, \end{cases}$$

where $\lambda_1, \dots, \lambda_n$ are the solutions of system

$$\sum_{k=1}^{l} \left(-\frac{1}{k}\right)^j \lambda_k = 1 \qquad (j = 0, 1, \dots, l-1).$$

This construction allows us to prove estimates declared in Proposition 2.1 (see V. Babich [2], L. Slobodetskii [37]). This construction and Proposition 2.1 imply the following.

PROPOSITION 2.2. *For an arbitrary natural k there exists a bounded extension operator*

$$L : W^{1,2(k)}(Q) \to W^{1,2(k)}(\hat{Q}), \qquad \hat{Q} = (0,T) \times G,$$
$$L : L_2(0,T; H^k(\Omega)) \to L_2(0,T; H^k(G)).$$

Let us consider functional spaces of solenoidal vector fields. We define the space

$$\hat{V}^k(\Omega) = \{v_0 \in V^k(\Omega) : v_0 \text{ satisfies (1.11)}\}.$$

Remark 2.1. Below we use the operator **rot**. Its definition in the three-dimensional case is well known. In the case when $\dim \Omega = 2$ we define the operator **rot** by formula

$$\mathbf{rot}\, u = \partial_{x_1} u_2 - \partial_{x_2} u_1.$$

PROPOSITION 2.3. (i) *For an arbitrary natural number k there exists the extension operator $\hat{L}$ such that the maps*

$$\hat{L} : \hat{V}^k(\Omega) \to V^k(G)$$

are bounded for $k = 0, 1, \dots, l$.

(ii) *For an arbitrary natural number k there exist bounded extension operators*

$$\hat{L} : V^{1,2(k)}(Q) \to V^{1,2(k)}(\hat{Q}), \qquad \hat{Q} = (0,T) \times G,$$
$$\hat{L} : L_2(0,T; V^k(\Omega)) \to L_2(0,T; V^k(G)).$$

Proof. Denote $H_\sigma = \{v \in V^0(\Omega) : (v,\nu)|_{\partial\Omega} = 0\}$, where (v,ν) is understood as an element belonging to $W^{-1/2}(\Omega)$ (see details in R. Temam [38]). For $u \in V^k(\Omega)$ we consider the boundary value problem

$$\mathbf{rot}\, v = u, \qquad x \in \Omega,$$
$$\mathbf{div}\, v = 0, \qquad x \in \Omega,$$
$$(v,\nu)|_{\partial\Omega} = 0.$$

There exists a solution $v \in V^k(\Omega) \cap H_\sigma$ of this problem, which satisfies the estimate

$$\|v\|_{V^{k+1}(\Omega)} \le c_1(\|u\|_{V^k(\Omega)} + \|v\|_{(L_2(\Omega))^n});$$

moreover, if we will take v from an orthogonal complement to $\operatorname{Ker} \mathbf{rot}\, V^1(\Omega)$ in the space H_σ, then

$$\|v\|_{(L_2(\Omega))^n} \le c_2 \|u\|_{(L_2(\Omega))^n}$$

(see R. Temam [38]). Hence, for such v we have the estimate

$$\|v\|_{V^{k+1}(\Omega)} \le c_3 \|u\|_{V^k(\Omega)}.$$

Now, for $u \in V^k(\Omega)$ we define the extension operator $\hat{L}$ by formula

$$\hat{L}u = \mathbf{rot}\, Lv,$$

where L is the extension operator from Proposition 2.1 and v is the solenoidal vector field constructed above by u. Evidently, the estimate for v written above and Propositions 2.1, 2.2 imply assertions (i) and (ii) of Proposition 2.3. □

2.2. Now we reduce the proof of Theorem 1.1 to the case of a linear controllability problem. Applying the well-known formula of vector analysis,

$$(v, \nabla)v = -v \times \mathbf{rot}\, v + \nabla(|v|^2/2),$$

where $\times$ is the operation of vector multiplication, we can rewrite equation (1.1) in the form

$$\partial_t v(t,x) - \Delta v - v \times \mathbf{rot}\, v + \theta(t,x) e_0 + \nabla p'(t,x) = f(t,x), \tag{2.1}$$

where $\nabla p' = \nabla(p + |v|^2/2)$. We write the solution (v, θ) in the form

$$v(t,x) = \hat{v}(t,x) + w(t,x), \qquad \theta(t,x) = \hat{\theta}(t,x) + \tau(t,x), \tag{2.2}$$

substitute (2.2) into equations (2.1), (1.2), (1.3), and subtract from them the same equations for $(\hat{v}, \hat{p}, \hat{\theta})$. As a result we get

$$\mathcal{N}(w,q,\tau) = \partial_t w(t,x) - \Delta w - \hat{v} \times \mathbf{rot}\, w - w \times \mathbf{rot}\, \hat{v} - w \times \mathbf{rot}\, w + \nabla q + \tau e_0 = 0, \tag{2.3}$$

$$\mathbf{div}\, w = 0, \tag{2.4}$$

$$\mathcal{H}(w,\tau) = \partial_t \tau(t,x) - \Delta \tau + (\hat{v}, \nabla\tau) + (w, \nabla\hat{\theta}) + (w, \nabla\tau) + (w, e_0) = 0, \tag{2.5}$$

where $\nabla q = \nabla p' - \nabla \hat{p}$. The functions w, τ satisfy the initial conditions:

$$w(0,x) = w_0(x), \qquad \tau(0,x) = \tau_0(x), \tag{2.6}$$

where $w_0(x) = v_0(x) - \hat{v}(0,x)$, $\tau_0(x) = \theta_0(x) - \hat{\theta}(0,x)$. Evidently we have reduced our problem to the construction of a solution $(w(t,x), \tau(t,x))$ of problem (2.3)–(2.6), which satisfies the equalities

$$w(T,x) = 0, \qquad \theta(T,x) = 0. \tag{2.7}$$

Remark 2.2. In the two-dimensional case we will rewrite the nonlinear term $(v, \nabla)v$ in the form

$$(v, \nabla)v = (-v_2\, \mathbf{rot}\, v, v_1\, \mathbf{rot}\, v) + \nabla(|v|^2/2)$$

and derive the analog of (2.3)–(2.7) in the same way as above. The obtained system differs from (2.3)–(2.7), but the proof of Theorem 1.1 will not differ from the proof given below for the three-dimensional case.

We will solve problem (2.3)–(2.7) with the help of the following variant of the implicit function theorem.

THEOREM (on a right inverse operator). *Suppose that X, Z are Banach spaces and*

$$\mathcal{A} : X \to Z \tag{2.8}$$

is a continuously differentiable map. We assume that for $x_0 \in X$, $z_0 \in Z$ the equality

$$\mathcal{A}(x_0) = z_0 \tag{2.9}$$

holds and the derivative $\mathcal{A}'(x_0) : X \to Z$ of the map $\mathcal{A}$ at x_0 is a surjective operator. Then there exists $\epsilon > 0$ such that for any $z \in Z$ which satisfies the condition

$$\|z - z_0\|_Z < \epsilon,$$

there exists a solution $x \in X$ of equation

$$\mathcal{A}(x) = z.$$

This theorem is a simple corollary of the generalization of the implicit function theorem which has been proved in V. Alekseev, V. Tikhomirov, and S. Fomin [1]. In our case X will be a space of triplets $x = (w, q, \tau)$,

$$\mathcal{A}(x) = (\mathcal{N}(w, q, \tau), \mathcal{H}(w, \tau), w|_{t=0}, \tau|_{t=0}), \tag{2.10}$$

and the collection of components in (2.10) defines the space Z. We note that (2.7) will be guaranteed by the insertion of special weights on the norm of X. We take $x_0 = (0, 0, 0)$, $z_0 = (0, 0, 0)$. Then equation (2.9) for operator (2.10), (2.3), (2.5) is fulfilled. Thus, the main condition that should be verified to apply the right inverse operator theorem is the assertion of solvability of the equation $\mathcal{A}'(0)x = z$ for any $z \in Z$. This equation in our case has the following form:

$$\mathcal{N}'(0)(v, p, \theta) = \partial_t v(t, x) - \Delta v - \hat{v} \times \mathbf{rot}\, v - v \times \mathbf{rot}\, \hat{v} + \theta e_0 + \nabla p = f, \tag{2.11}$$

$$\mathbf{div}\, v = 0, \tag{2.12}$$

$$\mathcal{H}'(0)(v, \theta) = \partial_t \theta(t, x) - \Delta\theta + (\hat{v}, \nabla\theta) + (v, \nabla\hat{\theta}) + (v, e_0) = h, \tag{2.13}$$

$$v|_{t=0} = v_0, \qquad \theta|_{t=0} = \theta_0, \tag{2.14}$$

$$v|_{t=T} = 0, \qquad \theta|_{t=T} = 0. \tag{2.15}$$

2.3. We now define the functional spaces X, Z corresponding to the problem (2.3)–(2.7). Let

$$\eta(t, x) \equiv \eta^s(t, x) = s(e^{2\hat{x}_1} - e^{x_1})/(T - t) \tag{2.16}$$

be the weight function where $s > 0$ is a parameter which will be chosen below, $\hat{x}_1 = \max_{x=(x_1 \dots x_n)\in\Omega} |x_1|$.

Denote

$$L_2(Q, \eta) \equiv L_2(Q, \eta^s) = \left\{ y(t, x) : \|y\|^2_{L_2(Q,\eta)} = \int_Q e^{2\eta^s} |y|^2 \, dx\, dt < \infty \right\}. \tag{2.17}$$

Below we will also use the space $L_2(Q, \beta)$ with different weights. We define the space $\mathbf{\Theta}(Q, \eta)$ of components $\theta(t, x)$ in (2.11)–(2.15):

$$\begin{aligned} \mathbf{\Theta}(Q, \eta) \equiv \mathbf{\Theta}(Q, \eta^s) = \Bigg\{ & \theta(t, x), (t, x) \in Q : \ \|\theta\|^2_{\mathbf{\Theta}(Q,\eta^s)} \equiv \|\partial_t\theta - \Delta\theta\|^2_{L_2(Q,\eta^s)} \\ & + \|(T - t)^{-3/2}\theta\|^2_{L_2(Q,\eta^s)} + \|(T - t)^{-1/2}|\nabla\theta|\|^2_{L_2(Q,\eta^s)} \\ & + \|(T - t)^{1/2}\partial_t\theta\|^2_{L_2(Q,\eta^s)} + \sum_{i,j=1}^{n} \|(T - t)^{1/2}\partial^2_{x_i x_j}\theta\|^2_{L_2(Q,\eta^s)} < \infty \Bigg\}. \end{aligned} \tag{2.18}$$

The space of right side components f in (2.11)–(2.15) is as follows:

$$\begin{aligned} F(Q, \eta) \equiv F(Q, \eta^s) = \{ & f \in (L_2(Q))^n : \ \exists \ f_1 \in (L_2(Q, \eta))^n, \\ & \exists \ f_2 \in L_2(0, T; H^1(\Omega)) \text{ such that } f = f_1 + \nabla f_2 \}. \end{aligned} \tag{2.19}$$

The norm of the space $F(Q, \eta)$ is defined by the relation

$$\|f\|_{F(Q,\eta^s)} = \inf_{\substack{f_1, \nabla f_2 \\ f = f_1 + \nabla f_2}} (\|f_1\|^2_{(L_2(Q,\eta^s))^n} + \|\nabla f_2\|^2_{(L_2(Q))^n})^{1/2}. \tag{2.20}$$

Remark 2.3. Note that $F(Q,\eta^s)$ is a Hilbert space. Indeed, since the functional $J(f_1,f_2)=(\|f_1\|^2_{(L_2(Q,\eta^s))^n}+\|\nabla f_2\|^2_{(L_2(Q))^n})^{1/2}$ is strictly convex, for an arbitrary $f\in F(Q,\eta^s)$ in the set of pairs $(f_1,\nabla f_2)\in L_2(0,T;H^1(\Omega))\times(L_2(Q,\eta))^n$ satisfying $f=f_1+\nabla f_2$ there exists the unique pair $(\hat f_1,\nabla\hat f_2)\in(L_2(Q,\eta^s))^n\times(L_2(Q))^n$ such that $\|f\|_{F(Q,\eta^s)}=J(\hat f_1,\hat f_2)$. Hence, the map $f=\hat f_1+\nabla\hat f_2\to(\hat f_1,\nabla\hat f_2)$ establishes isometric isomorphism between $F(Q,\eta^s)$ and $L_2(0,T;H^1(\Omega))\times L_2(Q,\eta^s)$, which implies that $F(Q,\eta^s)$ is a Hilbert space.

We define the space $\Xi(Q,\eta)$ of components v in (2.11)–(2.15) with the help of the equality

$$\Xi(Q,\eta)\equiv\Xi(Q,\eta^s)=\Bigg\{v(t,x):\ \ \mathbf{div}\,v=0,\quad \|v\|^2_{\Xi(Q,\eta^s)}$$

$$\equiv\|\partial_t v-\Delta v\|^2_{F(Q,\eta^s)}+\|(T-t)^{-1}v\|^2_{(L_2(Q,\eta^s))^n}+\|\nabla v\|^2_{(L_2(Q,\eta^s))^n}\tag{2.21}$$

$$+\|(T-t)\partial_t v\|^2_{(L_2(Q,\eta^s))^n}+\sum_{i,j=1}^n\|(T-t)\partial^2_{x_ix_j}v\|^2_{(L_2(Q,\eta^s))^n}<\infty\Bigg\}.$$

Now we can define the spaces X and Z in the case of problems (2.3)–(2.7) or (2.11)–(2.15):

$$X=X^s(Q)=\Xi(Q,\eta^s)\times L_2(0,T;H^1(\Omega))\times\mathbf{\Theta}(Q,\eta^s),\tag{2.22}$$

$$Z=Z^s(Q)=F(Q,\eta^s)\times L_2(Q,\eta^s)\times V^1(\Omega)\times H^1(\Omega).\tag{2.23}$$

Since the weight function $\eta^s(t,x)$ increases exponentially as $t\to T$, the functions $v\in\Xi(Q,\eta^s)$, $\theta\in\mathbf{\Theta}(Q,\eta^s)$ decrease exponentially as $t\to T$, and therefore equalities (2.15) are true.

2.4. Let us show that for an arbitrary parameter $s>0$, operator (2.8) and its derivative

$$\mathcal{A}'(0):X^s(Q)\to Z^s(Q)\tag{2.24}$$

are continuous, where $\mathcal{A}(x)$ is defined as in (2.10), (2.3), (2.5).

LEMMA 2.1. *Suppose that* $\hat v\in V^{1,2(2)}(Q)$, $\hat\theta\in W^{1,2(2)}(Q)$,

$$\mathcal{A}'(0)(v,p,\theta)=(\mathcal{N}'(0)(v,p,\theta),\mathcal{H}'(0)(v,\theta),v|_{t=0},\theta|_{t=0}),\tag{2.25}$$

where $\mathcal{N}'(0)$, $\mathcal{H}'(0)$ *are defined by* (2.11), (2.13). *Then, for* $s>0$, *the operator* (2.24) *is continuous.*

Proof. Since $n=\dim\Omega=2,3$, the embeddings $\Xi(Q,\eta)\subset V^{1,2(0)}(Q)$, $\mathbf{\Theta}(Q,\eta)\subset W^{1,2(0)}(Q)$ are continuous. Since the restriction operator $\gamma_0 y=y|_{t=0}$ acts continuously from $W^{1,2(0)}(Q)$ to $H^1(\Omega)$ and from $V^{1,2(0)}(Q)$ to $V^1(\Omega)$ (see [32]), the inequalities

$$\|\gamma_0 v\|_{V^1(\Omega)}\le c_4\|v\|_{\Xi(Q,\eta)},\qquad \|\gamma_0\theta\|_{H^1(\Omega)}\le c_5\|\theta\|_{\Theta(Q,\eta)}\tag{2.26}$$

hold. Let us prove that the operator

$$\mathcal{H}'(0):\Xi(Q,\eta)\times\mathbf{\Theta}(Q,\eta)\ \to L_2(Q,\eta)\tag{2.27}$$

defined in (2.13) is continuous. Since the embeddings

$$V^{1,2(2)}(Q) \subset C(0,T;C^1(\bar\Omega))^n, \qquad W^{1,2(2)}(Q) \subset C(0,T;C^1(\bar\Omega)) \tag{2.28}$$

are continuous for $n \le 3$, we obtain, taking into account (2.13), (2.17), (2.18),

$$\begin{aligned}\|\mathcal{H}'(0)(v,\theta)\|_{L_2(Q,\eta)} &\le \|\partial_t\theta - \Delta\theta\|_{L_2(Q,\eta)} + \|\hat v\|_{(C(\bar Q))^n}\|\nabla\theta\|_{(L_2(Q,\eta))^n}\\ &+ \|\nabla\hat\theta\|_{(C(\bar Q))^n}\|v\|_{(L_2(Q,\eta))^n} \le (1+\|\hat v\|_{V^{1,2(2)}(Q)})\|\theta\|_{\mathbf{\Theta}(Q,\eta)} + \|\nabla\hat\theta\|_{(C(\bar Q))^n}\|v\|_{\Xi(Q,\eta)}.\end{aligned} \tag{2.29}$$

The relations (2.11), (2.17)–(2.21) yield

$$\begin{aligned}\|\mathcal{N}'(0)(v,p,\theta)\|_{F(Q,\eta)} &\le \|\partial_t v - \Delta v - \hat v\times\mathbf{rot}\, v - v\times\mathbf{rot}\,\hat v + \theta e_0\|_{(L_2(Q,\eta))^n}\\ &+ \|\nabla p\|_{(L_2(Q))^n} \le \|\partial_t v + \Delta v\|_{(L_2(Q,\eta))^n} + \|\hat v\|_{C(0,T;(C^1(\bar\Omega))^n)}(\|v\|_{(L_2(Q,\eta))^n}\\ &+\||\nabla v|\|_{(L_2(Q,\eta))^n}) + c_6\|\theta\|_{L_2(Q,\eta)} + \|\nabla p\|_{(L_2(Q))^n}\\ &\le (1+\|\hat v\|_{V^{1,2(2)}(Q)})\|v\|_{\Xi(Q,\eta)} + c_7\|\theta\|_{\mathbf{\Theta}(Q,\eta)} + \|p\|_{L_2(0,T;H^1(\Omega))}.\end{aligned} \tag{2.30}$$

The inequalities (2.26), (2.29), (2.30) imply the desired assertion. □

LEMMA 2.2. *Suppose that $\hat v \in V^{1,2(2)}(Q)$, $\hat\theta \in W^{1,2(2)}(Q)$, and $\mathcal{A}$ is operator (2.10). Then for arbitrary $s > 0$ the operator*

$$\mathcal{A} : X^s(Q) \to Z^s(Q)$$

is continuous.

Proof. To prove this lemma we need only to complete the proof of Lemma 2.1 by the estimate of the terms $w\times\mathbf{rot}\, w$ and $(w,\nabla\tau)$. The Cauchy–Bunyakovskii inequality and the Sobolev embedding theorem yield:

$$\begin{aligned}\|e^\eta(w,\nabla\tau)\|_{L_2(Q)} &\le \int_0^T \|e^{\frac\eta2}w(t,\cdot)\|_{(L_4(\Omega))^n}\|e^{\frac\eta2}|\nabla\tau(t,\cdot)|\|_{L_4(\Omega)}\,dt\\ &\le c_8\int_0^T \|e^{\frac\eta2}w(t,\cdot)\|_{V^1(\Omega)}\|e^{\frac\eta2}\tau(t,\cdot)\|_{W_2^2(\Omega)}\,dt\\ &\le c_9\|e^{\frac\eta2}w\|_{C(0,T;V^1(\Omega))}\|e^{\frac\eta2}\tau\|_{L_2(0,T;W_2^2(\Omega))}\\ &\le c_{10}\|e^{\frac\eta2}w\|_{V^{1,2(0)}(Q)}\|e^{\frac\eta2}\tau\|_{L_2(0,T;W_2^2(\Omega))}.\end{aligned} \tag{2.31}$$

Taking into account (2.16), the evident inequality

$$(T-t)^{-k} \le c(k)e^{\frac\eta2},$$

and the definition of norms in the right side of (2.30), we get the upper bound:

$$\begin{aligned}\|e^{\frac\eta2}w\|_{V^{1,2(0)}(Q)}\|e^{\frac\eta2}\tau\|_{L_2(0,T;W_2^2(\Omega))} &\le c_{11}\Big(\|e^{\frac\eta2}(T-2)^{-2}w\|_{(L_2(Q))^n}\\ &+ \|e^{\frac\eta2}(T-t)^{-1}|\nabla w|\|_{(L_2(Q))^n} + \sum_{i,j=1}^n \|e^{\frac\eta2}\partial^2_{x_ix_j}w\|_{(L_2(Q))^n}\Big)\Bigg(\|e^{\frac\eta2}(T-t)^{-2}\tau\|_{L_2(Q)}\\ &+ \|e^{\frac\eta2}(T-t)^{-1}|\nabla\tau|\|_{L_2(Q)} + \sum_{i,j=1}^n \|e^{\frac\eta2}\partial^2_{x_ix_j}\tau\|_{L_2(Q)}\Bigg) \le c_{12}\|w\|_{\Xi(Q,\eta)}\|v\|_{\mathbf{\Theta}(Q,\eta)}.\end{aligned} \tag{2.32}$$

One can estimate the term $(w,\nabla)w$ analogously. □

Thus, in order to apply the right inverse operator theorem we have to prove surjectivity of the operator $\mathcal{A}'(0) : X^s(Q) \to Z^s(Q)$. To prove this assertion we will show that the image of this operator is dense in $Z^s(Q)$, and besides, it is a closed subset of $Z^s(Q)$ for s sufficiently large. These assertions imply that the image of $\mathcal{A}'(0)$ coincides with the whole space $Z^s(Q)$.

3. The solvability of the linear controllability problem for a dense set of data.

3.1. In order to solve the controllabilty problem for a dense set of data we need the Carleman estimate for elliptic and inverse parabolic equations.

We consider the Cauchy problem for the Laplace operator

$$\Delta z(x) = f(x), \qquad x \in \Omega, \qquad z|_{\partial\Omega} = \left.\frac{\partial z}{\partial \nu}\right|_{\partial\Omega} = 0, \tag{3.1}$$

where $\Omega \subset \mathbf{R}^n$ is a bounded domain with C^∞ boundary and $\partial/\partial\nu$ is the derivative along outside normal ν to $\partial\Omega$.

LEMMA 3.1. *Let $f(x) \in L_2(\Omega)$. There exists $s_0 > 0$ such that for any $s > s_0$ the solution $z(x) \in W_2^2(\Omega)$ of (3.1) satisfies the Carleman estimate:*

$$\int_\Omega \left(\frac{1}{s} \sum_{i,j=1}^n \left| \frac{\partial^2 z(x)}{\partial x_i \partial x_j} \right|^2 + s|\nabla z|^2 + s^3 z^2 \right) \exp(s e^{x_1})\, dx \le c_1 \int_\Omega f^2(x) \exp(s e^{x_1})\, dx, \tag{3.2}$$

where x_1 is the first component of $x = (x_1, \dots, x_n) \in \Omega$ and $c_1 > 0$ does not depend on s.

For the proof of Lemma 3.1 we refer to L. Hörmander [21], [22]. Note that estimate (3.2) can be obtained as a simple corollary of Lemma 3.2, which will be proved in section 6.

Let $\gamma(t)$ be a function satisfying the properties

$$\gamma(t) \in C^\infty(0,T), \qquad 0 < \gamma(t) \le 1 \,\forall\ t \in (0,T), \tag{3.3}$$

$$\gamma(t) = \begin{cases} t & \text{when } t \in (0, T_0), \\ T - t & \text{when } t \in (T - T_0, T), \end{cases} \quad T_0 = \min\left(\frac{T}{3}, \frac{1}{2}\right).$$

We define $\varphi(t,x)$, $\alpha(t,x)$ by relations

$$\varphi(t,x) = \frac{e^{x_1}}{\gamma(t)}, \qquad \alpha(t,x) = (e^{x_1} - e^{2\hat{x}_1})/\gamma(t), \tag{3.4}$$

$$\text{where } \hat{x}_1 = \max_{x=(x_1,\dots,x_n)\in\Omega} |x_1|.$$

COROLLARY 3.1. *Let $f(x) \in L_2(\Omega)$ and s be just the same as in Lemma 3.1. Then for any $t \in (0,T)$ the following estimate is true:*

$$\int_\Omega \left(\frac{\gamma(t)}{s} \sum_{i,j=1}^n \left| \frac{\partial^2 z(x)}{\partial x_i \partial x_j} \right|^2 + \frac{s}{\gamma(t)} |\nabla z|^2 + \frac{s^3}{\gamma(t)^3} |z|^2 \right) e^{s\varphi(t,x)}\, dx \le c_2 \int_\Omega f^2(x) e^{s\varphi(t,x)}\, dx. \tag{3.5}$$

Proof. We substitute $s = s_1(\gamma(t))^{-1}$ into (3.2) and obtain (3.5), where instead of s_1 we write s. In virtue of Lemma 3.1 estimate (3.5) is true when $s > s_0\gamma(t)$. Since $0 < \gamma(t) \le 1$ for $t \in (0,T)$, this inequality is also true when $s > s_0$. □

We consider the inverse heat equation

$$\partial_t z(t,x) + \Delta z = f(t,x), \qquad (t,x) \in Q, \tag{3.6}$$

with the boundary conditions

$$z|_\Sigma = 0, \qquad \left.\frac{\partial z}{\partial \nu}\right|_\Sigma = 0, \tag{3.7}$$

where, recall, $Q = (0,T) \times \Omega$, $\Sigma = (0,T) \times \partial\Omega$.

LEMMA 3.2. *There exists $s_0 > 0$ such that for any $s > s_0$ the solution $z(t,x)$ of* (3.6), (3.7) *satisfies the Carleman estimate:*

$$\int_Q \left((s\varphi)^{-1} \left(|\partial_t z|^2 + \sum_{i,j=1}^n |\partial^2_{x_i x_j} z(t,x)|^2 \right) + s\varphi \sum_{j=1}^n |\partial_{x_j} z|^2 + s^3\varphi^3 z^2 \right) e^{s\alpha(t,x)}\, dx\, dt \le c_3 \int_Q f^2(t,x) e^{s\alpha}\, dx\, dt, \tag{3.8}$$

where the functions $\varphi(t,x)$, $\alpha(t,x)$ are defined in (3.4) *and $c_3 > 0$ does not depend on s.*

We prove this lemma below, in section 6.

3.2. First, instead of problem (2.11)–(2.15), we consider an auxiliary problem. Let $\Omega_0 \subset \mathbf{R}^n$ be a bounded domain with C^∞-boundary $\partial\Omega_0$ which contains the closure $\bar\Omega$ of Ω : $\bar\Omega \subset \Omega_0$ and satisfies the condition $\sup_{x\in\Omega_0} |x_1| < 2 \sup_{x\in\Omega} |x_1|$. Therefore the function η from (2.16) is positive and the function α from (3.4) is negative. We denote

$$Q_0 = (0,T) \times \Omega_0, \quad \Sigma_0 = (0,T) \times \partial\Omega_0, \quad \omega = \Omega_0 \setminus \bar\Omega.$$

In Q_0 we consider the linearized Boussinesq equation with the distributed control concentrated in $(0,T) \times \omega$:

$$\begin{aligned} \acute{\mathcal{N}}'(w,p,\tau,u) &= \partial_t w(t,x) - \Delta w - \hat v \times \mathbf{rot} w + w \times \mathbf{rot}\hat v + \nabla p + \tau(t,x) e_0 + u'(t,x) \\ &= f(t,x), \end{aligned} \tag{3.9}$$

$$\mathbf{div}\, w = 0, \tag{3.10}$$

$$\hat{\mathcal{H}}'(w,\tau,u) = \partial_t \tau(t,x) - \Delta\tau + (w, \nabla\hat\theta) + (\hat v, \nabla\tau) + (w, e_0) + u_{n+1}(t,x) = h(t,x), \tag{3.11}$$

$$w(0,x) = w_0(x), \qquad \tau(0,x) = \tau_0(x), \tag{3.12}$$

$$w(T,x) = 0, \qquad \tau(T,x) = 0, \tag{3.13}$$

where $u(t,x) = (u'(t,x), u_{n+1}(t,x)) = (u_1, \dots, u_n, u_{n+1})$ is the distributed control concentrated in $Q_\omega = (0,T) \times \omega$: $\operatorname{supp} u \subset Q_\omega$. The functional space for data (f,h,w_0,τ_0) of problem (3.9)–(3.13) is as follows:

$$(f,h,w_0,\tau_0) \in \Phi^s(Q_0) = (L_2(Q_0,\eta^s))^n \times L_2(Q_0,\eta^s) \times V^1(\Omega_0) \times H^1(\Omega_0), \tag{3.14}$$

where $s > 0$ is an arbitrary fixed number. We define the functional space of solutions of problem (3.9)–(3.13) by the formula

$$(w, \nabla p, \tau, u) \in U^s(Q_0) \equiv \Xi(Q_0, \eta^s) \times L_2(Q_0, \eta^s) \times \mathbf{\Theta}(Q_0, \eta^s) \times (\hat{L}_2(Q_\omega, \eta^s))^{n+1}, \tag{3.15}$$

where $\hat{L}_2(Q_\omega, \eta^s)$ is the set of functions that belong to $L_2(Q_0, \eta^s)$ and equal zero on the set $Q_0 \setminus Q_\omega$; the constant s in (3.15) is just the same as in (3.14). We suppose that the functions $\hat{v}, \hat{\theta}$ in (3.9), (3.11) satisfy the condition

$$\hat{v} \in V^{1,2(1/2)}(Q_0), \qquad \hat{\theta} \in W^{1,2(1/2)}(Q_0). \tag{3.16}$$

As in Lemma 2.1 one can easily prove that the operator

$$\hat{\mathcal{A}}' : U^s(Q_0) \to \Phi^s(Q_0) \tag{3.17}$$

is continuous, where $\Phi^s(Q)$, $U^s(Q)$ are defined in (3.14), (3.15), and

$$\hat{\mathcal{A}}'(w, \nabla p, \tau, u) = (\hat{\mathcal{N}}'(w, \nabla p, \tau, u), \hat{\mathcal{H}}'(w, \tau, u), \gamma_0 w, \gamma_0 \tau) \tag{3.18}$$

with $\hat{\mathcal{N}}', \hat{\mathcal{H}}'$ defined in (3.9), (3.11).

LEMMA 3.3. *The image of operator* (3.17), (3.18) *is dense in the space* $\Phi^s(Q_0)$.

Proof. Suppose that the assertion of Lemma 3.3 is not true. Then there exists a nonzero collection $\phi \equiv (m(t,x), \zeta(t,x), z_0(x), \psi_0(x)) \in \Phi^s(Q_0)$ such that

$$(\mathcal{A}'(w, \nabla p, \tau, u), \phi)_{\Phi^s(Q_0)} = 0 \qquad \forall\ (w, \nabla p, \tau, u) \in U^s(Q_0). \tag{3.19}$$

We can rewrite equality (3.19) in the form

$$\begin{aligned} \int_{Q_0} &(\partial_t w(t,x) - \Delta w - \hat{v} \times \mathbf{rot}\, w - w \times \mathbf{rot}\, \hat{v} + \nabla p(t,x) + \tau(t,x) e_0 \\ &+ u'(t,x), m(t,x)) e^{2\eta^s(t,x)}\, dx\, dt + \int_{Q_0} (\partial_t \tau(t,x) - \Delta \tau + (w, \nabla \hat{\theta}) + (\hat{v}, \nabla \tau) \\ &+ (w, e_0) + u_{n+1}) \zeta(t,x) e^{2\eta^s}\, dx\, dt + (w(0,\cdot), z_0)_{V^1(\Omega_0)} + (\tau(0,\cdot), \psi_0)_{H^1(\Omega_0)} = 0. \end{aligned} \tag{3.20}$$

We set, in (3.20),

$$z(t,x) = m(t,x) e^{2\eta^s(t,x)}, \qquad \psi(t,x) = \zeta(t,x) e^{2\eta^s(t,x)}, \tag{3.21}$$

$\nabla p(t,x) \equiv 0$, $u(t,x) \equiv 0$, $w \in \Xi(Q_0, \eta) \cap (C_0^\infty(Q_0))^n$, and $\tau \in \mathbf{\Theta}(Q_0, \eta) \cap C_0^\infty(Q_0)$. Then integrating by parts in (3.20) yields the equations

$$\partial_t z + \Delta z = \mathbf{rot}\, (\hat{v} \times z) + z \times \mathbf{rot}\, \hat{v} + \psi(\nabla \hat{\theta} + e_0) + \nabla \tilde{p} \text{ in } Q_0, \tag{3.22}$$

$$\partial_t \psi + \Delta \psi = -\nabla(\psi \hat{v}) + (e_0, z) \qquad \text{in } Q_0. \tag{3.23}$$

If we set, in (3.20), $u \in (\hat{L}_2(Q_\omega, \eta))^{n+1}$, $\nabla p = 0$, $w = 0$, $\tau = 0$, we will obtain the equalities

$$z(t,x) \equiv 0, \qquad \psi(t,x) = 0, \qquad (t,x) \in Q_\omega = Q_0 \setminus Q. \tag{3.24}$$

In particular, (3.24) means that z and ψ equal zero in a neighborhood of $\Sigma_0 = (0,T) \times \partial\Omega_0$. After setting, in (3.20), $\nabla p \in (L_2(Q_0, \eta))^n$, $w = 0$, $\tau = 0$, $u = 0$, and taking into account (3.24), we get

$$\mathbf{div}\, z = 0 \text{ in } Q_0. \tag{3.25}$$

Equalities (3.22), (3.24) yield that

$$\nabla\tilde{p}(t,x)\equiv 0,\qquad (t,x)\in Q_\omega. \tag{3.26}$$

Applying to both parts of (3.22) the operator **div** and taking into account (3.25) and the formula $\mathbf{div}\,\mathbf{rot}\,y=0$, we obtain

$$-\Delta\tilde{p}=\mathbf{div}(z\times\mathbf{rot}\,\hat{v})+\mathbf{div}((\nabla\hat{\theta}+e_0)\psi). \tag{3.27}$$

Our main goal now is to deduce from relations (3.22)–(3.27) that $z\equiv 0$, $\psi\equiv 0$. We will make it with the help of Carleman estimates (3.5), (3.8). We can suppose that s_0 in Lemmas 3.1 and 3.2 are equal. Otherwise, we can replace them in both lemmas with their maximum.

Let

$$\sigma\geq\max(s,s_0), \tag{3.28}$$

where s is the constant from $\Phi^s(Q_0)$ in the formulation of Lemma 3.3. We take magnitude σ instead of s in (3.8) and apply estimate (3.8) to the equations (3.22), (3.23). Note that boundary conditions (3.7) are fulfilled in our case in virtue of (3.24). We have

$$\begin{aligned}\int_{Q_0}(\sigma\varphi|\nabla z|^2+(\sigma\varphi)^3|z|^2)e^{\sigma\alpha(t,x)}\,dx\,dt&\\ +\int_{Q_0}(\sigma\varphi|\nabla\psi|^2+(\sigma\varphi)^3|\psi|^2)e^{\sigma\alpha}\,dx\,dt&\\ \leq c_1\int_{Q_0}e^{\sigma\alpha}(|\hat{v}|^2|\nabla z|^2+|\nabla\hat{v}|^2|z|^2+|\psi|^2(1+|\nabla\hat{\theta}|^2)+|\nabla\tilde{p}|^2&\\ +|\psi|^2|\nabla\hat{v}|^2+|\nabla\psi|^2|\hat{v}|^2+|z|^2)\,dx\,dt.&\end{aligned} \tag{3.29}$$

We need estimate $\nabla\tilde{p}$ in the right side of (3.29). We do it by means of (3.27), (3.26). Note that $\tilde{p}$ is defined to within an arbitrary constant. We fix it by the condition

$$\tilde{p}(t,x)\equiv 0,\qquad (t,x)\in Q_\omega. \tag{3.30}$$

Taking into account (3.26), (3.30) we apply estimate (3.5) to (3.27). After multiplication (3.5) on $(\gamma(t)/\sigma)\exp(-e^{2\tilde{x}_1}/\gamma(t))$ scalarly in $L_2(\Omega)$ and integration with respect to t, we get

$$\begin{aligned}\int_{Q_0}|\nabla\tilde{p}|^2e^{\sigma\alpha}\,dx\,dt\leq c_5\int_{Q_0}\frac{\gamma(t)}{\sigma}(|\nabla z|^2|\nabla\hat{v}|^2+|z|^2|\nabla\mathbf{rot}\hat{v}|^2&\\ +|\nabla\psi|^2(1+|\hat{\theta}|^2)+|\psi|^2|\Delta\hat{\theta}|^2)e^{\sigma\alpha}\,dx\,dt&\\ \leq c_6(\|\hat{v}\|^2_{C(0,T;(C^1(\bar{\Omega}))^n)}+\|\hat{\theta}\|^2_{C(0,T;C^1(\bar{\Omega}))}+1)\int_{Q_0}\frac{\gamma(t)}{\sigma}(|\nabla z|^2+|\nabla\psi|^2)e^{\sigma\alpha}\,dx\,dt&\\ +c_7\left(\|\mathbf{rot}\,\hat{v}\|^2_{L_\infty(0,T;(W_4^1(\Omega_0))^n)}\int_0^T\left(\int_\Omega\left(e^{2\sigma\alpha}\left(\frac{\gamma(t)}{\sigma}\right)^2|z|^4\right)dx\right)^{1/2}dt\right.&\\ \left.+\|\Delta\hat{\theta}\|^2_{L_\infty(0,T;L_4(\Omega_0))}\int_0^T\left(\int_\Omega\left(\frac{\gamma(t)}{\sigma}\right)^2\psi^4e^{2\sigma\alpha}\,dx\right)^{1/2}dt\right).&\end{aligned} \tag{3.31}$$

Let us estimate the right side of (3.31) using the continuity of embeddings $W^{1,2(2)}(Q_0) \subset C(0,T;C^1(\bar{\Omega}_0))$, $W^{1,2(2)}(Q_0) \subset L_\infty(0,T;W_4^2(\Omega_0))$, and $H^1(\Omega_0) \subset L_4(\Omega_0)$ when $\dim \Omega_0 \le 3$, and taking into account that in virtue of (3.4)

$$|\partial_{x_j}(e^{\frac{\sigma\alpha}{2}} z)|^2 \le c_8(\sigma^2\varphi^2|z|^2 + |\nabla z|^2)e^{\sigma\alpha}.$$

As a result we obtain the inequality

$$\int_{Q_0} |\nabla \tilde{p}|^2 e^{\sigma\alpha}\,dx\,dt \le c_9(\|\hat{v}\|^2_{V^{1,2(2)}(Q_0)} + \|\hat{\theta}\|^2_{W^{1,2(2)}(Q_0)} + 1)\int_{Q_0}\left(\frac{\gamma(t)}{\sigma}(|\nabla z|^2 + |\nabla\psi|^2) + \frac{\sigma e^{2x_1}}{\gamma(t)}(|z|^2 + |\psi|^2)\right)e^{\sigma\alpha}\,dx\,dt. \tag{3.32}$$

The substitution of (3.32) into (3.29) and simple transformations give us the upper bound:

$$\begin{aligned}\int_{Q_0}\left(\frac{\sigma e^{x_1}}{\gamma(t)}(|\nabla z|^2 + |\nabla\psi|^2) + \frac{\sigma^3 e^{3x_1}}{\gamma(t)^3}(|z|^2 + |\psi|^2)\right)e^{\sigma\alpha}\,dx\,dt \\ \le c_{10}(\|\hat{v}\|^2_{V^{1,2(2)}(Q_0)} + \|\hat{\theta}\|^2_{W^{1,2(2)}(Q_0)} + 1)\int_{Q_0}\left(\left(\frac{\gamma(t)}{\sigma} + 1\right)(|\nabla z|^2 + |\nabla\psi|^2) \right. \\ \left. + \left(\frac{\sigma\ e^{2x_1}}{\gamma(t)} + 1\right)(|z|^2 + |\psi|^2)\right)e^{\sigma\alpha}\,dx\,dt.\end{aligned} \tag{3.33}$$

Note that (3.33) is true for arbitrary σ satisfying (3.28). We choose σ so large that estimates

$$\begin{aligned}\frac{\sigma e^{x_1}}{\gamma(t)} &> c_{10}(\|\hat{v}\|^2_{V^{1,2(2)}(Q_0)} + \|\hat{\theta}\|^2_{W^{1,2(2)}(Q_0)} + 1)\left(\frac{\gamma(t)}{\sigma} + 1\right), \\ \frac{\sigma^3 e^{3x_1}}{\gamma(t)^3} &> c_{10}(\|\hat{v}\|^2_{V^{1,2(2)}(Q_0)} + \|\hat{\theta}\|^2_{W^{1,2(2)}(Q_0)} + 1)\left(\frac{\sigma e^{2x_1}}{\gamma(t)} + 1\right)\end{aligned}$$

hold for all $(t,x) \in Q_0$. Then (3.33) yields that

$$z(t,x) \equiv 0, \qquad \psi(t,x) \equiv 0. \tag{3.34}$$

Substituting into (3.20) $\nabla p \equiv 0$, $u \equiv 0$, $w \in \Xi(Q_0,\eta)$, and $\tau \equiv 0$, and $\nabla p \equiv 0$, $u \equiv 0$, $w \equiv 0$, $\tau \in \boldsymbol{\Theta}(Q_0,\eta)$ yield the equalities

$$\begin{aligned}(w(0,\cdot), z_0)_{V^1(\Omega_0)} &= (w(0,\cdot), z(0,\cdot))_{L_2(\Omega_0)} = 0, \\ (\tau(0,\cdot), \psi_0)_{H^1(\Omega_0)} &= (\tau(0,\cdot), \psi(0,\cdot))_{L_2(\Omega_0)} = 0.\end{aligned}$$

Therefore

$$z_0 = 0, \qquad \psi_0 = 0. \tag{3.35}$$

Hence, by (3.21), (3.34), and (3.35), we have that $\phi \equiv (m(t,x), \zeta(t,x), z_0(x), \psi_0(x)) \equiv 0$. □

3.3. Now we can prove the main result of this section.

THEOREM 3.1. *Suppose that $\hat{v} \in V^{1,2(2)}(Q), \hat{\theta} \in W^{1,2(2)}(Q)$, the operator $\mathcal{A}'(0)$ is defined in* (2.25), (2.11), (2.13), *the spaces $X^s(Q), Z^s(Q)$ are defined in* (2.16)–(2.23),

and the parameter s of these spaces is an arbitrary positive number. Then the image of the operator

$$\mathcal{A}'(0) : X^s(Q) \to Z^s(Q)$$

is dense in the space $Z^s(Q)$.

Proof. Let Ω_0, Q_0 be the sets introduced in the beginning of section 3.2. By Propositions 2.2, 2.3 we extend the functions $\hat{v}(t,x), \hat{\theta}(t,x)$ continuously from $V^{1,2(2)}(Q)$ up to $V^{1,2(2)}(Q_0)$ and from $W^{1,2(2)}(Q)$ up to $W^{1,2(2)}(Q_0)$ correspondingly and denote these new functions also by $\hat{v}(t,x), \hat{\theta}(t,x)$. Comparing (3.9)–(3.12) and (2.11)–(2.14), we see that the restriction of operator (3.17), (3.18) on the cylinder Q coincides with the operator

$$\mathcal{A}'(0) : U^s(Q) \to \Phi^s(Q). \tag{3.36}$$

Here $\mathcal{A}'(0)$ is operator (2.25), and in contrast to (3.15),

$$U^s(Q) = \Xi(Q,\eta^s) \times L_2(Q,\eta^s) \times \mathbf{\Theta}(Q,\eta^s) \tag{3.37}$$

because the restriction of an arbitrary function from $\hat{L}_2(Q_\omega,\eta^s)$ to Q is identical to zero. Therefore, in virtue of Lemma 3.3, the image of operator (3.36), (2.25) is dense in $\Phi^s(Q)$. Let $(f,h,v_0,\theta_0) \in Z^s(Q)$ (see (2.23)) be an arbitrary element. Since $f \in F(Q,\eta^s)$ (see (2.19)) then $f = f_1 + \nabla f_2$ where $f_1 \in L_2(Q,\eta^s)$, $f_2 \in L_2(0,T;H^1(\Omega))$, and therefore $(f_1,h,v_0,\theta_0) \in \Phi^s(Q)$. By the density of the image of operator (3.36), for any $\epsilon > 0$ there exists $(f_1^\epsilon, h^\epsilon, v^\epsilon, \theta^\epsilon) \in \Phi^s(Q)$ possessing preimage $(v^\epsilon, p^\epsilon, \theta^\epsilon) \in U^s(Q)$,

$$\mathcal{A}'(0)(v^\epsilon, p^\epsilon, \theta^\epsilon) = (f_1^\epsilon, h^\epsilon, v_0^\epsilon, \theta_0^\epsilon), \tag{3.38}$$

and satisfying the inequality

$$\|(f_1 - f_1^\epsilon, h - h^\epsilon, v_0 - v_0^\epsilon, \theta_0 - \theta_0^\epsilon)\|_{\Phi^s(Q)} \le \epsilon. \tag{3.39}$$

By virtue of (2.11) and (3.38),

$$\mathcal{A}'(0)(v^\epsilon, p^\epsilon + f_2, \theta^\epsilon) = (f_1^\epsilon + \nabla f_2, h^\epsilon, v_0^\epsilon, \theta_0^\epsilon). \tag{3.40}$$

Since $f - (f_1^\epsilon + \nabla f_2) = f_1 - f_1^\epsilon$, then by (2.23), (2.20), (3.14), and (3.36) we have

$$\begin{aligned} \|(f - (f_1^\epsilon + \nabla f_2), h - h^\epsilon, v_0 - v_0^\epsilon, \theta_0 - \theta^\epsilon)\|_{Z^s(Q)} \\ \le \|(f - f_1^\epsilon, h - h^\epsilon, v_0 - v_0^\epsilon, \theta_0 - \theta_0^\epsilon)\|_{\Phi^s(Q)} < \epsilon. \end{aligned} \tag{3.41}$$

By (3.15), (2.22) the inclusion $(v^\epsilon, p^\epsilon, \theta^\epsilon) \in U^s(Q)$ involves the inclusion $(v^\epsilon, p^\epsilon + f_2, \theta^\epsilon) \in X^s(Q)$. Hence, by (3.40), $(v^\epsilon, p^\epsilon + f_2, \theta^\epsilon)$ is the preimage of $(f_1^\epsilon + \nabla f_2, h^\epsilon, v_0^\epsilon, \theta_0^\epsilon)$. This proves the theorem. □

Remark 3.1. The method of Lemma 3.3's proof, based on applying the Hahn–Banach theorem and using some uniqueness theorems, is well known (see J.-L. Lions [31]). The density of right-hand sides for which a solution of the corresponding boundary value problem exists was proved in A. Fursikov [13], [14] for certain situations different from those studied above.

4. On a decomposition of Weyl type. In this section we investigate the decomposition of the Weyl type,

$$y(t,x) = v(t,x) + \nabla q, \qquad (t,x) \in Q_0, \tag{4.1}$$

where $\mathbf{div}\, v = 0$ and $\nabla q = (\partial_{x_1} q, \dots, \partial_{x_n} q)$ is the gradient of a function. We do not impose any boundary conditions on v or ∇q but look for v belonging to the space $\Xi(Q_0, \eta)$ when $y \in (\Theta(Q_0, \eta))^n$. We do not look for natural uniqueness conditions for the decomposition (4.1) but need the following assumption to be fulfilled:

$$\text{if } \mathbf{div}\, y(0,x) \equiv 0, \text{ then } y(0,x) \equiv v(0,x). \tag{4.2}$$

To find decomposition (4.1) we consider the extremal problem

$$J(u) = \int_{Q_0} \frac{|u(t,x)|^2 e^{2\eta}}{(T-t)^4}\, dx\, dt \to \inf, \tag{4.3}$$

$$\Delta u(t,x) = \mathbf{div}\, y(t,x), \qquad (t,x) \in Q_0, \tag{4.4}$$

where $y(t,x) \in (\mathbf{\Theta}(Q_0, \eta))^n$ is a given function. If a solution $m(t,x)$ of problem (4.3), (4.4) exists, we will denote $v = y - \nabla m$. Then, by (4.4), the equality $\mathbf{div}\, v = 0$ will hold, and therefore decomposition (4.1) will be true.

LEMMA 4.1. *There exists s_0 such that for $y(t,x) \in (\mathbf{\Theta}(Q, \eta^s))^n$ where $s \geq s_0$, the problem* (4.3), (4.4) *has the unique solution $m(t,x) \in L_2(Q_0, \eta - 2\ln(T-t))$. This solution satisfies the estimates*

$$\int_{Q_0} \frac{|m(t,x)|^2}{(T-t)^4} e^{2\eta^s}\, dx\, dt \leq c_1 \int_{Q_0} \frac{|\mathbf{div}\, y|^2}{(T-t)} e^{2\eta^s}\, dx\, dt, \tag{4.5}$$

$$\int_{Q_0} |\partial_t m(t,x)|^2 e^{2\eta^s}\, dx\, dt \leq c_2 \|y\|^2_{\mathbf{\Theta}(Q_0, \eta^s)}. \tag{4.6}$$

Proof. Let s_0 be defined as in Lemma 3.1. We denote $Q_\epsilon = (0, T-\epsilon) \times \Omega_0$ and instead of (4.3), (4.4), consider the extremal problem

$$J_\epsilon(u) = \int_{Q_\epsilon} \frac{|u(t,x)|^2}{(T-t)^4} e^{2\eta}\, dx\, dt \to \inf, \tag{4.7}$$

$$\Delta u(t,x) = \mathbf{div}\, y(t,x), \qquad (t,x) \in Q_\epsilon. \tag{4.8}$$

The weight $e^{2\eta}(T-t)^{-4}$ is bounded above and below on Q_ϵ. Hence the space $U_\epsilon = \{u \in L_2(Q_\epsilon) : \Delta u \in L_2(Q_\epsilon)\}$ is natural for the problem (4.7), (4.8) and the set of its admissible elements is as follows:

$$A_\epsilon = \{u \in U_\epsilon : \Delta u = \mathbf{div}\, y\}.$$

As is well known, the limit $m_\epsilon \in A_\epsilon$ of a weakly converging subsequence of the minimizing sequence u_k: $J_\epsilon(u_k) \to \inf_{v \in A_\epsilon} J_\epsilon(v)$ is the solution of problem (4.7), (4.8). The uniqueness of m_ϵ follows from the functional J_ϵ strict-convexity. For $\epsilon_1 > \epsilon_2$, $m_{\epsilon_1}(t,x)$ coincides almost everywhere with the restriction of $m_{\epsilon_2}(t,x)$ on Q_{ϵ_1}. Indeed, if it is not so, then $J_{\epsilon_1}(m_{\epsilon_1}) < J_{\epsilon_1}(m_{\epsilon_2})$. But on this occasion, m_{ϵ_2} is not a solution because the function

$$\hat{m}(t,x) = \begin{cases} m_{\epsilon_1}(t,x), & (t,x) \in Q_{\epsilon_1}, \\ m_{\epsilon_2}(t,x), & (t,x) \in Q_{\epsilon_2} \backslash Q_{\epsilon_1} \end{cases}$$

satisfies (4.8) and inequality $J_{\epsilon_2}(\hat{m}) < J_{\epsilon_2}(m_{\epsilon_2})$ holds. That is why below we use the notation $m_\epsilon = m$. Since operator $\Delta : U_\epsilon \to L_2(Q_\epsilon)$ is surjective, we can apply to problem (4.7), (4.8) the Lagrange principle (see [1]). This principle asserts that there exists $p_\epsilon \in (L_2(Q_\epsilon))^n$ such that the Lagrange function

$$\mathcal{L}(u, p_\epsilon) \equiv \int_{Q_\epsilon} \left(\frac{1}{2} \frac{|u(t,x)|^2}{(T-t)^4} e^{2\eta} + (\Delta u - \mathbf{div}\, y) p_\epsilon(t,x) \right) dx\, dt$$

satisfies the equality $\partial_u \mathcal{L}(u, p_\epsilon)|_{u=m} = 0$; i.e., for any $h \in U_\epsilon$,

$$\int_{Q_\epsilon} \left(\frac{m(t,x)h(t,x)}{(T-t)^4} e^{2\eta} + \Delta h p_\epsilon(t,x) \right) dx\, dt = 0. \tag{4.9}$$

It follows from (4.9) that

$$\Delta p_\epsilon(t,x) + \frac{m(t,x)}{(T-t)^4} e^{2\eta} = 0 \text{ in } \Omega_0, \qquad p_\epsilon|_{\partial\Omega_0} = \left. \frac{\partial p_\epsilon}{\partial \nu} \right|_{\partial\Omega_0} = 0. \tag{4.10}$$

Relations (4.10) imply that p_ϵ does not depend on ϵ and therefore, below, we use the notation $p_\epsilon = p$. We apply to (4.10) Carleman estimate (3.2), substitute in this estimate $s = 2s_1(T-t)^{-1}$, multiply it on $(T-t)^4 \exp\{-2s_1 e^{2x_1}/(T-t)\}$, and integrate with respect to t. As a result we have the estimate

$$\int_{Q_\epsilon} (T-t) p^2 e^{-2\eta}\, dx\, dt \le c_3 \int_{Q_\epsilon} \frac{m^2}{(T-t)^4} e^{2\eta}\, dx\, dt, \tag{4.11}$$

where $c_3 > 0$ does not depend on ϵ. We substitute $u = m$ into (4.4), scale the obtained equation by p in $L_2(Q_\epsilon)$, integrate by parts, and apply (4.10). As a result we get

$$\begin{aligned} 0 = \int_{Q_\epsilon} (\Delta m - \mathbf{div}\, y) p\, dx\, dt &= \int_{Q_\epsilon} (m\Delta p - p\, \mathbf{div}\, y)\, dx\, dt \\ &= -\int_{Q_\epsilon} \left(\frac{m^2}{(T-t)^4} e^{2\eta} + p\, \mathbf{div}\, y \right) dx\, dt. \end{aligned}$$

This equality and (4.11) yield

$$\begin{aligned} \int_{Q_\epsilon} \frac{m^2}{(T-t)^4} e^{2\eta}\, dx\, dt &\le c_4 \left(\int_{Q_\epsilon} \frac{|\mathbf{div}\, y|^2}{(T-t)} e^{2\eta} dx dt \right)^{1/2} \left(\int_Q (T-t)|p|^2 e^{-2\eta}\, dx\, dt \right)^{1/2} \\ &\le c_5 \int_{Q_\epsilon} \frac{|\mathbf{div}\, y|^2}{(T-t)} e^{2\eta}\, dx\, dt + \frac{1}{2} \int_{Q_\epsilon} \frac{m^2}{(T-t)^4} e^{2\eta}\, dx\, dt, \end{aligned}$$

which gives us the upper bound

$$\int_{Q_\epsilon} \frac{m^2}{(T-t)^4} e^{2\eta}\, dx\, dt \le c_6 \int_{Q_\epsilon} \frac{|\mathbf{div}\, y|^2}{(T-t)} e^{2\eta}\, dx\, dt, \tag{4.12}$$

where c_6 does not depend on ϵ. Hence, we can pass to the limit in (4.12) as $\epsilon \to 0$ and obtain (4.5). Let $\hat{m}$ be the solution of problem (4.3), (4.4). Since m is the solution of (4.7), (4.8) we have

$$\int_{Q_\epsilon} \frac{m^2}{(T-t)^4} e^{2\eta}\, dx\, dt \le \int_{Q_\epsilon} \frac{\hat{m}^2}{(T-t)^4} e^{2\eta}\, dx\, dt \qquad \forall \epsilon > 0,$$

and therefore

$$\int_{Q_0} \frac{m^2}{(T-t)^4} e^{2\eta}\,dx\,dt = \int_{Q_0} \frac{\hat{m}^2}{(T-t)^4} e^{2\eta}\,dx\,dt.$$

This equation implies the equality $m = \hat{m}$ because the solution of problem (4.3), (4.4) is unique. Differentiation of the equations in (4.4), (4.10) with respect to t yields

$$\Delta \partial_t m = \mathbf{div}\,\partial_t y, \tag{4.13}$$

$$\Delta \partial_t p + (\partial_t m)\frac{e^{2\eta}}{(T-t)^4} + m\partial_t\left(\frac{e^{2\eta}}{(T-t)^4}\right) = 0. \tag{4.14}$$

Applying to (4.14) the Carleman estimate (3.2) in the same way as in (4.11) we obtain

$$\int_{Q_0} |\nabla \partial_t p|^2 (T-t)^7 e^{-2\eta}\,dx\,dt \le c_7 \int_{Q_0} (|\partial_t m|^2 + (T-t)^{-4}|m|^2) e^{2\eta}\,dx\,dt. \tag{4.15}$$

Scaling equation (4.13) by $\partial_t p$ in $L_2(Q_0)$, integration by parts, and application of (4.14) yield

$$\begin{aligned} 0 = \int_{Q_0} (T-t)^4 (\Delta \partial_t m - \mathbf{div}\partial_t y)\partial_t p\,dx\,dt = \int_{Q_0} (T-t)^4 (\partial_t m \Delta \partial_t p \\ -(\partial_t y, \nabla \partial_t p))\,dx\,dt = \int_{Q_0} \left(-|\partial_t m|^2 e^{2\eta} - \left((\partial_t m) m \partial_t \frac{e^{2\eta}}{(T-t)^4}\right)(T-t)^4 \right. \\ \left. - (T-t)^4 (\partial_t y, \nabla \partial_t p)\right) dx\,dt. \end{aligned}$$

This equality and (4.15) imply

$$\begin{aligned} \int_{Q_0} |\partial_t m|^2 e^{2\eta}\,dx\,dt \le c_8 \int_{Q_0} \left(|\partial_t m||m| \frac{e^{2\eta}}{(T-t)^2} \right. \\ \left. + e^{\eta}(T-t)^{1/2}|\partial_t y| e^{-\eta}(T-t)^{\frac{7}{2}} |\nabla \partial_t p|\right) dx\,dt \le \frac{1}{4}\int_{Q_0} |\partial_t m|^2 e^{2\eta}\,dx\,dt \\ + c_9 \int_{Q_0} \left(\frac{|m|^2}{(T-t)^4} e^{2\eta} + (T-t)|\partial_t y|^2 e^{2\eta}\right) dx\,dt. \end{aligned}$$

This inequality and (4.5) give (4.6). □

Let

$$\rho(x) \in C^\infty(\bar{\Omega}_0), \qquad \rho|_{\partial\Omega_0} = 0, \qquad \rho(x) > 0 \ \forall\ x \in \Omega_0.$$

Below, we use the following space:

$$\begin{aligned} M(Q_0,\eta) = \Bigg\{ f = (f_1,\dots,f_n) : \|f\|^2_{M(Q_0,\eta)} = \|(T-t)^{-1} f\|^2_{(L_2(Q_0,\eta^s))^n} \\ + \||\nabla f|\|^2_{(L_2(Q_0,\eta^s))^n} + \|(T-t)\partial_t f\|^2_{(L_2(Q_0,\eta^s))^n} \\ + \sum_{i,j=1}^n \|(T-t)\partial^2_{x_i x_j} f\|^2_{(L_2(Q_0,\eta^s))^n} < \infty \Bigg\}. \end{aligned} \tag{4.16}$$

LEMMA 4.2. *Let $m(t,x)$ be the solution of problem* (4.3), (4.4) *constructed in Lemma* 4.1. *Then*

$$\|\rho^3\nabla m\|^2_{M(Q_0,\eta)} \le c_{10}\|y\|^2_{(\mathbf{\Theta}(Q_0,\eta))^n}. \tag{4.17}$$

Proof. Set $\tilde m = m\rho$. Then (4.4), where $u = m$, implies the following equation for $\tilde m$:

$$\Delta\tilde m = m\Delta\rho + 2(\nabla\rho,\nabla m) + \rho\mathbf{div}\, y. \tag{4.18}$$

We multiply this equation by $-e^{2\eta}\tilde m(T-t)^{-2}$ scalarly in $L_2(Q_0)$, integrate by parts, and have as a result

$$\begin{aligned}\int_{Q_0}|\nabla\tilde m|^2e^{2\eta}(T-t)^{-2}\,dx\,dt &= \int_{Q_0}(T-t)^{-2}\left(\frac{1}{2}|\tilde m|^2\Delta e^{2\eta} - m^2\rho\Delta\rho e^{2\eta}\right.\\ &\left.+\frac{1}{2}m^2(\Delta\rho^2e^{2\eta} + (\nabla\rho^2,\nabla e^{2\eta})) - \rho^2me^{2\eta}\mathbf{div}\, y\right)dx\,dt\\ &\le c_{11}\int_{Q_0}\left(\frac{m^2}{(T-t)^4} + |\mathbf{div}\, y|^2\right)e^{2\eta}\,dx\,dt.\end{aligned}$$

This inequality, (4.5) and the definition (2.18) of the space $\mathbf{\Theta}(Q_0,\eta)$ imply:

$$\begin{aligned}\int_{Q_0}\frac{|\rho\nabla m|^2}{(T-t)^2}e^{2\eta}\,dx\,dt &\le c_{12}\int_{Q_0}\frac{|\nabla(\rho m)|^2}{(T-t)^2}e^{2\eta}\,dx\,dt\\ &+\int_{Q_0}\frac{m^2|\nabla\rho|^2}{(T-t)^2}e^{2\eta}\,dx\,dt \le c_{13}\|y\|^2_{(\mathbf{\Theta}(Q_0,\eta))^n}.\end{aligned} \tag{4.19}$$

Denote $m_0 = m\rho^2e^\eta$. Then we have, analogously to (4.18),

$$\Delta m_0 = g, \qquad m_0|_{\partial\Omega_0} = 0, \tag{4.20}$$

where $g = m\Delta(\rho^2e^\eta) + 2(\nabla(\rho^2e^\eta),\nabla m) + \rho^2e^\eta\mathbf{div}\, y$.

By (4.5), (4.19) we get

$$\|g\|_{L_2(Q)} \le c_{14}\|y\|_{(\mathbf{\Theta}(Q_0,\eta))^n}. \tag{4.21}$$

Applying to elliptic boundary value problem (4.20) the well-known estimate of its solution and taking into account (4.21) we obtain

$$\begin{aligned}\|m_0\|^2_{L_2(0,T;W_2^2(\Omega_0))} &= \|m\rho^2e^\eta\|^2_{L_2(0,T;W_2^2(\Omega_0))}\\ &\le c_{15}\|g\|^2_{L_2(Q_0)} \le c_{16}\|y\|^2_{\mathbf{\Theta}(Q_0,\eta)^n}.\end{aligned} \tag{4.22}$$

Since

$$\begin{aligned}|\partial^2_{x_ix_j}(\rho^2me^\eta)|^2 &\ge \frac{1}{2}|\partial_{x_i}(\rho^2\partial_{x_j}m)e^\eta|^2\\ &- c_{17}(|\rho^2(\partial_{x_j}m)\partial_{x_i}e^\eta|^2 + |(\partial_{x_i}m)\partial_{x_j}(\rho^2e^\eta)|^2 + |m\partial^2_{x_ix_j}(\rho^2e^\eta)|^2),\end{aligned}$$

then inequalities (4.22), (4.19), and (4.5) imply the estimate

$$\begin{aligned}\int_{Q_0}e^{2\eta}\sum_{j=1}^n|\partial_{x_j}(\rho^2\nabla m)|^2\,dx\,dt &\le c_{18}\int_{Q_0}\sum_{i,j=1}^n(|\partial^2_{x_ix_j}(\rho^2me^\eta)|^2\\ &+ |\rho^2(\partial_{x_j}m)\partial_{x_i}e^\eta|^2 + |(\partial_{x_i}m)\partial_{x_j}(\rho^2e^\eta)|^2 + |m\partial^2_{x_ix_j}(\rho^2e^\eta)|^2)\,dx\,dt\\ &\le c_{19}\|y\|^2_{(\mathbf{\Theta}(Q_0,\eta))^n}.\end{aligned} \tag{4.23}$$

Denote $m_i = \rho^3(\partial_{x_i} m)e^{\eta}(T-t)$. Then, by virtue of (4.4) with $u = m$,

$$\Delta m_i = g_i, \qquad m_i|_{\partial\Omega_0} = 0, \tag{4.24}$$

where

$$g_i = (\partial_{x_i} m)\Delta(\rho^3 e^{\eta}(T-t)) + 2(\nabla(\rho^3 e^{\eta}(T-t)), \partial_{x_i}\nabla m) + \rho^3 e^{\eta}(T-t)\partial_{x_i}\mathbf{div}\, y.$$

Apply an estimate of the solution of the Laplace equation to the solution m_i of problem (4.24). Then, as in (4.22), we get, with the help of inequalities (4.5), (4.19), (4.23),

$$\begin{aligned}\|\rho^3(\partial_{x_i} m)e^{\eta}(T-t)\|^2_{L_2(0,T;W_2^2(\Omega_0))} &\le c_{20}\Bigg(\|(\partial_{x_i} m)\Delta(\rho^3 e^{\eta}(T-t))\|^2_{L_2(Q_0)} \\ &+ \left\|\left(\frac{1}{\rho^2}\nabla(\rho^3 e^{\eta}(T-t)), (\partial_{x_i}(\rho^2\nabla m) - 2(\partial_{x_i}\rho)\rho\nabla m)\right)\right\|^2_{L_2(Q_0)} \\ &+ \|\rho^3 e^{\eta}(T-t)\partial_{x_i}\mathbf{div}\, y\|^2_{L_2(Q_0)}\Bigg) \le c_{21}\|y\|^2_{(\mathbf{\Theta}(Q_0,\eta))^n}.\end{aligned} \tag{4.25}$$

As in (4.22), inequalities (4.25) with $i = 1, \dots, n$, and estimates (4.23), (4.19), (4.5) imply:

$$\int_{Q_0} e^{2\eta}\sum_{k,l=1}^{n}|\partial^2_{x_k x_l}(\rho^3\nabla m)|^2(T-t)^2\,dx\,dt \le c_{22}\|y\|^2_{(\mathbf{\Theta}(Q_0,\eta))^n}. \tag{4.26}$$

By virtue of (4.13),

$$\Delta(\rho\partial_t m) = \partial_t m\Delta\rho + 2(\nabla\rho, \nabla\partial_t m) + \rho\,\mathbf{div}\partial_t y. \tag{4.27}$$

Scaling (4.27) by $-(\rho\partial_t m)e^{2\eta}(T-t)^2$ in $L_2(Q_0)$ and integrating by parts we have

$$\begin{aligned}\int_{Q_0}|\nabla(\rho\partial_t m)|^2(T-t)^2\,dx\,dt &= \int_{Q_0}\Bigg(\frac{1}{2}(\rho\partial_t m)^2\Delta e^{2\eta}(T-t)^2 - \rho(\partial_t m)^2\Delta\rho e^{2\eta}(T-t)^2 \\ &+\frac{1}{2}(T-t)^2(\partial_t m)^2\mathbf{div}(e^{\eta}\nabla\rho^2) - \rho^2\partial_t m(\mathbf{div}\,\partial_t y)e^{2\eta}(T-t)^2\Bigg)\,dx\,dt.\end{aligned}$$

This equality implies

$$\begin{aligned}\int_{Q_0}|\rho\nabla\partial_t m|^2(T-t)^2e^{2\eta}\,dx\,dt &\le c_{23}\int_{Q_0}|\partial_t m|^2(c_{24}|\nabla\rho|^2(T-t)^2 + \rho^2 \\ &+ |\rho\Delta\rho|(T-t)^2 + c_{25}(T-t)(|\nabla\rho^2| + (T-t)|\Delta\rho^2|))e^{2\eta}\,dx\,dt \\ &+ \int_{Q_0}[(\rho\nabla\partial_t m, \partial_t y)\rho e^{2\eta}(T-t)^2 + \partial_t m(\nabla(\rho^2 e^{2\eta}), \partial_t y)(T-t)^2]\,dx\,dt \\ &\le c_{26}\int_{Q_0}|\partial_t m|^2e^{2\eta}\,dx\,dt + \frac{1}{2}\int_{Q_0}|\rho\nabla\partial_t m|^2(T-t)^2e^{2\eta}\,dx\,dt \\ &+ c_{27}\int_{Q_0}e^{2\eta}|\partial_t y|^2(T-t)^2\,dx\,dt.\end{aligned} \tag{4.28}$$

After transferring the term with $\rho\nabla\partial_t m$ from the right side of (4.28) to the left side, we get, with the help of (4.6) and (2.18),

$$\int_{Q_0}|\rho\nabla\partial_t m|^2(T-t)^2e^{2\eta}\,dx\,dt \le c_{28}\|y\|^2_{(\mathbf{\Theta}(Q_0,\eta))^n}.$$

This equality and upper bounds (4.19), (4.23), (4.26) imply (4.17). □

We prove now the main result of this section.

THEOREM 4.1. *Let s satisfy the conditions of Lemma* 4.1. *Then an arbitrary vector field $y \in (\mathbf{\Theta}(Q_0, \eta^s))^n$ admits decomposition* (4.1), *where* $\mathbf{div}\, v(t,x) \equiv 0$ *and* $\rho^3 \nabla q \in M(Q_0, \eta^s)$, *and if $y(t,x)$ satisfies equality* $\mathbf{div}\, y(0,x) \equiv 0$, *then* $y(0,x) \equiv z(0,x)$.

Proof. We define the function $\varphi(t) \in C^\infty(0,T)$, such that $\varphi(t) \equiv 0$ when $t \in (0, T/4)$ and $\varphi(t) \equiv 1$ when $t \in [\frac{3}{4}T, T]$. Let $m(t,x)$ be the solution of problem (4.3), (4.4) constructed in Lemma 4.1. Since $y \in (\mathbf{\Theta}(Q_0, \eta))^n$, then for almost all $t \in (0,T)$ the function $\Delta m(t,\cdot) \in L_2(\Omega_0)$, and by virtue of (4.5), $m(t,\cdot) \in L_2(\Omega_0)$. Hence (see J.-L. Lions and E. Magenes [32]) the restriction $m(t,\cdot)|_{\partial\Omega}$ is well defined and belongs to $H^{-1/2}(\partial\Omega_0)$. We introduce the function $\zeta(t,x)$, defined on $(0,T) \times \partial\Omega_0$ by formula

$$\zeta(t,x) = \varphi(t) m(t,x), \qquad t \in (0,T),\ x \in \partial\Omega_0,$$

and consider the following Dirichlet problem:

$$\Delta q(t,x) = \mathbf{div}\, y(t,x), \qquad (t,x) \in Q_0, \tag{4.29}$$

$$q|_{(0,T)\times\partial\Omega_0} = \zeta. \tag{4.30}$$

The unique solution $q(t,x)$ of (4.29), (4.30) exists (see J.-L. Lions and E. Magenes [32]), and by virtue of the properties of $\zeta(t,x)$,

$$q(x,t) \equiv m(t,x) \qquad \forall\ (t,x) \in [3T/4, T] \times \Omega_0 \tag{4.31}$$

and

$$\forall t \in [0, T/4] \qquad \mathbf{div}\, y(t,x) \equiv 0 \qquad \text{implies} \qquad q(t,x) \equiv 0. \tag{4.32}$$

By virtue of (4.31) and (4.17) we have $\rho^3 \nabla q \in M(Q_0, \eta)$. Besides, (4.2) follows from (4.32). □

5. The proof of the main results.

5.1. First, we want to solve the exact controllability problem for linearized Boussinesq equations (2.11)–(2.15). To do it we apply the analogous controllability result for the parabolic equation which is formulated below. We consider the controllability problem for the heat equation

$$\partial_t \theta(t,x) - \Delta\theta(t,x) = h(t,x), \qquad (t,x) \in Q_0, \tag{5.1}$$

$$\theta|_{t=0} = \theta_0(x), \qquad \theta|_{t=T} = 0, \qquad x \in \Omega_0, \tag{5.2}$$

where the functions $h \in L_2(Q_0, \eta)$, $\theta_0 \in H^1(\Omega)$ are given . Many authors studied this controllability problem (see D. Russell [35], H. Fattorini [11], and T. Seidman [36]). But, taking into account the functional spaces where we look for a solution, the following result which can be extracted from A. Fursikov and O. Imanuvilov [15], [16], [26] is convenient for us.

THEOREM 5.1. *There exists a number s_1 such that for any $s > s_1$ and for arbitrary given $\theta_0 \in H^1(\Omega_0)$, $h \in L_2(Q_0, \eta^s)$ there exists the solution $\theta \in \mathbf{\Theta}(Q_0, \eta^s)$ of problem* (5.1), (5.2).

We consider also the controllability problem for the following parabolic system:

$$\partial_t y(t,x) - \Delta y - \hat{v} \times \mathbf{rot}\, y = f, \qquad (t,x) \in Q_0, \tag{5.3}$$

$$y|_{t=0} = y_0, \qquad y|_{t=T} = 0, \qquad x \in \Omega_0. \tag{5.4}$$

THEOREM 5.2. *Let $\hat{v}(t,x) \in V^{1,2(2)}(Q_0)$ be given. Then there exists a number s_2 such that for any $s > s_2$ and for arbitrary given data $y_0 \in (H^1(\Omega_0))^n$, $f \in (L_2(Q_0,\eta^s))^n$, a solution $y \in (\mathbf{\Theta}(Q_0,\eta^s))^n$ of problem* (5.3), (5.4) *exists.*

One can prove Theorem 5.2 absolutely by the same way as in A. Fursikov and O. Imanuvilov [15], [16], [26], [12]. Let us prove one abstract lemma.

LEMMA 5.1. *Suppose that X, Y are separable Hilbert spaces, a bounded linear operator $B : X \to Y$ is surjective, and $K : X \to Y$ is a linear compact operator. Then the image of the operator $B + K$ is closed in Y.*

Proof. For an arbitrary $\epsilon > 0$ there exists the operator K_ϵ that has finite-dimensional image and

$$\|K - K_\epsilon\| < \epsilon \tag{5.5}$$

(see [34]). The equality

$$B + K = B_\epsilon + K_\epsilon \qquad \text{where } B_\epsilon = B + (K - K_\epsilon)$$

is true. If in (5.5) ϵ is small enough, then the image of operator B_ϵ coincides with the whole Y. Thus, we reduce Lemma 5.1 to the case when operator $K : X \to Y$ has a finite-dimensional image.

We can suppose also that $\operatorname{Ker} B \cap \operatorname{Ker} K = 0$. Indeed, if it is not so we introduce the factor space $X_1 = X/(\operatorname{Ker} B \cap \operatorname{Ker} K)$, define operators B_1 and K_1 by formulas

$$B_1\tilde{x} = Bx, \qquad K_1\tilde{x} = Kx, \qquad \text{where} \qquad \tilde{x} = x + \operatorname{Ker} B \cap \operatorname{Ker} K,$$

and consider the problem on the closure of operators $B_1 + K_1 : X_1 \to Y$ image. Since operator K has a finite-dimensional image then there exists a finite linear independent system of vectors $e_1, \dots, e_k \in Y$ and a linear independent system of functionals $f_1, \dots, f_n$ defined and bounded on X such that

$$Kx = \sum_{j=1}^{k} f_j(x) e_j.$$

The linear independentness of $f_1, \dots, f_n$ implies that there exist such linear independent vectors $g_1, \dots, g_k \in X$ that $f_j(g_i) = \delta_{i,j}$, where $\delta_{i,j}$ is Kronecker symbol. Hence, the space X admits the decomposition

$$X = [g_1, \dots, g_k] + \operatorname{Ker} K$$

where $[g_1, \dots, g_k]$ is a linear span of $g_1, \dots, g_k$. Since $\operatorname{Ker} B \cap \operatorname{Ker} K = 0$, then $\dim \operatorname{Ker} B \le k$ and X admits the decomposition

$$X = S + \operatorname{Ker} B + \operatorname{Ker} K,$$

where S is a certain finite-dimensional space. Let B_2, K_2 be the restrictions at the space $S + \operatorname{Ker} K$ of the operators B and K, respectively. Since the operator

$$B : S + \operatorname{Ker} K \to Y$$

is an isomorphism, then by Fredholm theorem the image $B_2 + K_2$ is closed and has a finite codimension in Y. The coincidence $(B_2+K_2)(S+\operatorname{Ker} K) = (B+K)(S+\operatorname{Ker} K)$ implies the embedding

$$(B + K)(S + \operatorname{Ker} K) \subset (B + K)X.$$

Hence $(B+K)X = (B+K)(S+\mathrm{Ker}\ K)+S_1$, where S_1 is a certain finite-dimensional subspace of Y. Being a finite-dimensional space, the subspace S_1 is closed. Hence, $(B+K)$ is closed also. □

5.2. Now we prove the assertion on the closure of a set of data for which the controllability problem for the Boussinesq equations has a solution.

THEOREM 5.3. *Let $\hat{v}(t,x) \in V^{1,2(2)}(Q), \hat{\theta}(t,x) \in W^{1,2(2)}(Q)$. Then the set of data (f,h,v_0,θ_0) for which there exists a solution $(v,p,\theta) \in X^s(Q)$ of problem (2.11)–(2.15) is closed in the space $Z^s(Q)$ when the magnitude of parameter s is sufficiently large (spaces $X^s(Q), Z^s(Q)$ are defined in (2.22), (2.23)).*

Proof. To prove this theorem we intend to apply Lemma 5.1. We decompose the operator generated by problem (2.11)–(2.15) into the sum $B+K$, where B is the operator generated by the problem

$$\partial_t v(t,x) - \Delta v - \hat{v} \times \mathbf{rot}\, v + \nabla p = f(t,x), \qquad \mathbf{div}\, v = 0, \qquad v(0,x) = v_0(x), \tag{5.6}$$

$$\partial_t \theta(t,x) - \Delta\theta = h(t,x), \qquad \theta(0,x) = \theta_0(x), \tag{5.7}$$

$$v(T,x) \equiv 0, \qquad \theta(T,x) \equiv 0. \tag{5.8}$$

The operator K is defined by the formula

$$K(v,p,\theta) = (-v \times \mathbf{rot}\, \hat{v} + \theta e_0, (\hat{v}, \nabla\theta) + (v, \nabla\hat{\theta}) + (v, e_0), 0, 0). \tag{5.9}$$

The boundedness of the operator

$$B : X^s(Q) \to Z^s(Q) \tag{5.10}$$

is proved in Lemma 2.1. To prove that operator (5.10) is surjective we first, instead of (5.6), use more simple equations:

$$\partial_t y(t,x) - \Delta y - \hat{v} \times \mathbf{rot}\, y = f_1(t,x), \qquad y(0,x) = y_0(x). \tag{5.11}$$

Let Q_0, Ω_0 be the set introduced in the beginning of section 3.2. We continuously extend $\hat{v}(t,x)$ from $V^{1,2(2)}(Q)$ to $V^{1,2(2)}(Q_0)$ as well as $\hat{\theta}(t,x)$ from $W^{1,2(2)}(Q)$ to $W^{1,2(2)}(Q_0)$ using Propositions 2.2 and 2.3 and consider the problem (5.11), (5.7) on Q_0. Note that $y_0(x) \in V^1(\Omega_0)$ is an extension of $v_0 \in V^1(\Omega)$.

We choose a parameter s satisfying conditions of Theorems 4.1, 5.1, and 5.2 simultaneously. Then by virtue of these theorems for an arbitrary $(f_1,h,y_0,\theta_0) \in (L_2(Q_0,\eta^s))^n \times L_2(Q_0,\eta^s) \times V^1(\Omega_0) \times H^1(\Omega_0)$, there exists a solution $(y,\theta) \in (\mathbf{\Theta}(Q_0,\eta^s))^n \times \mathbf{\Theta}(Q_0,\eta^s)$ of problem (5.11), (5.7) defined on Q_0. With the help of Theorem 4.1 we decompose the component y of this solution as follows:

$$y(t,x) = v(t,x) + \nabla q, \tag{5.12}$$

where $\mathbf{div}\, v = 0$, $\rho^3 \nabla q \in M(Q_0,\eta^s)$. Here $M(Q_0,\eta)$ is space (4.16) and $y(0,x) = v(0,x) = y_0(x)$. We substitute (5.12) into (5.11) and verify that $v(t,x)$ satisfies the equation

$$\partial_t v(t,x) - \Delta v - \hat{v} \times \mathbf{rot}\, v + \nabla m = f_1(t,x),\ \mathbf{div}\, v = 0,\ v(0,x) = y_0(x), \tag{5.13}$$

$$m = (\partial_t q - \Delta q). \tag{5.14}$$

Now we can prove that operator (5.10) is surjective. Indeed, let $(f,h,v_0,\theta_0) \in Z^s(Q) = F(Q,\eta^s) \times L_2(Q,\eta^s) \times V^1(\Omega) \times H^1(\Omega)$. By the definition of the space $F(Q,\eta)$, the decomposition

$$f = f_1 + \nabla f_2, \qquad f_1 \in (L_2(Q,\eta^s))^n, \qquad f_2 \in L_2(0,T;H^1(\Omega))$$

holds. After extension of f_1, f_2, h from Q onto Q_0 and v_0, θ_0 from Ω onto Ω_0 we get, as was shown above, the function (v, m, θ), which satisfies (5.13), (5.7), (5.8). Evidently, if we define

$$p = m + f_2, \tag{5.15}$$

then (v, p, θ) will satisfy (5.6)–(5.8). After the restriction of (v, p, θ) at Q this triplet satisfies boundary value problem (5.6)–(5.8), which we consider on Q. We made an extension from Q to Q_0, and after that the restriction from Q_0 to Q, to have the equality (5.12) defined on Q with $\nabla q \in M(Q, \eta^s)$ (the restriction onto Q allows us to take off the multiplier ρ^3 including $\rho^3 \nabla q \in M(Q_0, \eta^s)$). Since $\nabla q \in M(Q, \eta^s)$, then by virtue of (5.14), (5.15), $p \in L_2(0, T; H^1(\Omega))$.

Equality (5.12) and inclusions $\nabla q \in M(Q, \eta), y \in (\boldsymbol{\Theta}(Q, \eta))^n$ imply that all terms in definition (2.21) of $\|\cdot\|^2_{\Xi(Q,\eta)}$ for v are finite, except perhaps the term $\|\partial_t v - \Delta v\|_{F(Q,\eta)}$. Let us show that this term is also finite. By virtue of (5.6), (5.15), (5.14)

$$\begin{aligned}\|\partial_t v - \Delta v\|_{F(Q,\eta)} &= \|f_1 + \hat{v} \times \mathbf{rot}\, v + \nabla f_2 - \nabla p\|_{F(Q,\eta)} \le \|f_1 + \hat{v} \times \mathbf{rot}\, v\|_{(L_2(Q,\eta))^n} \\ &+ \|\nabla f_2 - \nabla p\|_{(L_2(Q,\eta))^n} \le c_1(\|f_1\|_{(L_2(Q,\eta))^n} \\ &+ \|\hat{v}\|_{(C(\bar{Q}))^n} \||\nabla v|\|_{(L_2(Q,\eta))^n} + \||\nabla(\partial_t q - \Delta q)|\|_{(L_2(Q,\eta))^n}) < \infty.\end{aligned}$$

Hence, $v \in \Xi(Q, \eta)$, and therefore we have proved that operator (5.10) is surjective. We prove now that the operator

$$K : X^s(Q) \to Z^s(Q) \tag{5.16}$$

is compact, where K is as defined in (5.9). To prove this assertion one has to establish compactness of the operator

$$K_1 : X^s(Q) \to (L_2(Q, \eta))^n \times L_2(Q, \eta), \tag{5.17}$$

where

$$K_1(v, p, \theta) = (-v \times \mathbf{rot}\, \hat{v} + \theta e_0, (\hat{v}, \nabla\theta) + (v, \nabla\hat{\theta}) + (v, e_0)). \tag{5.18}$$

We have

$$\begin{aligned}&\int_{T-\delta}^{T} \int_\Omega e^{2\eta}(|v \times \mathbf{rot}\, \hat{v}|^2 + |(\hat{v}, \nabla\theta) + (v, \nabla\hat{\theta}) + (v, e_0)|^2)\, dx\, dt \qquad (5.19)\\ &\le c_2(\|\hat{v}\|^2_{C(0,T;(C^1(\bar{\Omega}))^n)} + \|\hat{\theta}\|^2_{C(0,T;C^1(\bar{\Omega}))} + 1) \int_{T-\delta}^{T} \int_\Omega e^{2\eta}(|v|^2 + |\theta|^2 + |\nabla\theta|^2)\, dx\, dt \\ &\le c_3(\|\hat{v}\|^2_{V^{1,2(2)}(Q)} + \|\hat{\theta}\|^2_{W^{1,2(2)}(Q)} + 1)\delta \int_{T-\delta}^{T} \int_\Omega e^{2\eta}((T-t)^{-2}(|v|^2 + |\theta|^2) \\ &+ (T-t)^{-1}|\nabla\theta|^2)\, dx\, dt \le c_4 c_3 \delta(\|\hat{v}\|^2_{V^{1,2(2)}(Q)} + \|\hat{\theta}\|^2_{W^{1,2(2)}(Q)})\end{aligned}$$

uniformly with respect to

$$(v, \theta) \in \Phi \equiv \{(v, \theta) : \|v\|^2_{\Xi(Q,\eta)} + \|\theta\|^2_{\boldsymbol{\Theta}(Q,\eta)} \le c_4\}.$$

Evidently, at $Q^\delta = (0, T - \delta) \times \Omega$ we have

$$\Xi(Q^\delta, \eta) = V^{1,2(0)}(Q^\delta), \qquad \boldsymbol{\Theta}(Q^\delta, \eta) = W^{1,2(0)}(Q^\delta), \qquad L_2(Q^\delta, \eta) = L_2(Q^\delta),$$

and by the Sobolev embedding theorem the operator

$$K : V^{1,2(0)}(Q^\delta) \times L_2(0,T;W_2^1(\Omega)) \times W^{1,2(0)}(Q^\delta) \to (L_2(Q^\delta))^{n+1} \times V^1(\Omega) \times H^1(\Omega)$$

is compact. This property of operator K and (5.19) prove the compactness of operator (5.17), (5.18). Hence, all assumptions of Lemma 5.1 are true and by this lemma we get assertion of Theorem 5.3. □

Now we can immediately prove Theorem 5.4.

THEOREM 5.4. *Let $\hat v \in V^{1,2(2)}(Q), \hat\theta \in W^{1,2(2)}(Q)$. Then for an arbitrary data $(f,h,v_0,\theta_0) \in Z^s(Q)$ there exists a solution $(v,p,\theta) \in X^s(Q)$ of problem* (2.11)–(2.15) *when the magnitude of parameter s is sufficiently large*[2].

Proof. By Theorem 3.1 the set of data $(f,h,v_0,\theta_0) \in Z^s(Q)$ for which problem (2.11)–(2.13) has a solution $(v,p,\theta) \in X^s(Q)$ is dense in $Z^s(Q)$, and by Theorem 5.3, it is closed. Hence, this set coincides with $Z^s(Q)$. □

Proof of Theorem 1.1. First we apply the right inverse operator theorem to problem (2.3)–(2.7). Let $\mathcal{A}$ be operator (2.10), (2.3), (2.5) and the spaces $X = X^s(Q)$, $Z = Z^s(Q)$ be defined in (2.22), (2.23), (2.17)–(2.21). Taking into account that $\mathcal{A}$ is a sum of linear and quadratic operators we can assert that continuous differentiability of operator (2.8) follows from Lemmas 2.1 and 2.2. Equality (2.9) is evident for $x_0 = 0$, $z_0 = 0$. At last, the assertion that operator

$$\mathcal{A}'(0) : X^s(Q) \to Z^s(Q)$$

is surjective has been proved in Theorem 5.4. So, all assumptions of the right inverse operator theorem are fulfilled and therefore there exists $\epsilon > 0$ such that for any initial data (w_0,τ_0) satisfying inequality

$$\|w_0\|^2_{V^1(\Omega)} + \|\tau_0\|^2_{H^1(\Omega)} \le \epsilon$$

and for zero right sides of equation (2.3), (2.5) the problem (2.3)–(2.7) possesses the solution $(v,q,\theta) \in \Xi(Q,\eta^s) \times L_2(0,T;H^1(\Omega)) \times \mathbf{\Theta}(Q,\eta^s)$. After returning from problem (2.3)–(2.7) to problem (1.1)–(1.4), (1.6) by change of variables (2.2) we get the assertion of Theorem 1.1. □

Remark 5.1. As we pointed out in Remark 1.1 the smoothness condition imposed on the given solution $(\hat v, \hat p, \hat\theta)$ in Theorem 1.1 can be replaced by the more weak condition (1.14). This change of condition would lead to the following complication of Theorem 5.3's proof, which we show below. We approximate functions $\hat v, \hat\theta$ by functions $\hat v_\epsilon \in V^{1,2(2)}(Q)$, $\hat\theta_\epsilon \in W^{1,2(2)}(Q)$:

$$\|\hat v - \hat v_\epsilon\|_{V^{1,2(1/2)}(Q)\cap(L_\infty(Q))^n} \le \epsilon, \qquad \|\hat\theta - \hat\theta_\epsilon\|_{W^{1,2(1/2)}(Q)\cap L_\infty(Q)} < \epsilon, \tag{5.20}$$

where ϵ is sufficiently small. We can write

$$B + K = B + R_\epsilon + K_\epsilon,$$

where

$$K_\epsilon(v,\theta) = (-v \times \mathbf{rot}\, \hat v_\epsilon + \theta e_0, (\hat v_\epsilon, \nabla\theta) + (v, \nabla\hat\theta_\epsilon) + (v, e_0), 0, 0),$$

$$R_\epsilon(v,\theta) = (-v \times \mathbf{rot}\, (\hat v - \hat v_\epsilon), (\hat v - \hat v_\epsilon, \nabla\theta) + (v, \nabla(\hat\theta - \hat\theta_\epsilon)), 0, 0).$$

By virtue of (5.20) the operator $R_\epsilon : X^s(Q) \to Z^s(Q)$ has a small norm, and therefore the operator $B + R_\epsilon : X^s(Q) \to Z^s(Q)$ is surjective. The compactness of operator $K_\epsilon : X^s(Q) \to Z^s(Q)$ has been proved in Theorem 5.3. Hence, by Lemma 5.1 the image of operator $B + R_\epsilon + K_\epsilon$ coincides with $Z^s(Q)$. □

[2]More precisely, s simultaneously satisfies the conditions of Theorems 4.1, 5.1, 5.2.

6. The proof of a Carleman estimate. In this section we prove Lemma 3.2.

Proof of Lemma 3.2. We make the change of variables

$$z(t,x) = e^{-s\alpha} w(t,x) \tag{6.1}$$

in (3.6), (3.7). As a result, by virtue of (6.1) we get

$$L_1 w(t,x) + L_2 w(t,x) = f_s(t,x), \qquad (t,x) \in Q, \tag{6.2}$$

$$w|_\Sigma = \left.\frac{\partial w}{\partial \nu}\right|_\Sigma = 0, \tag{6.3}$$

where

$$L_1 w = \Delta w + s^2\varphi^2 w - s(\partial_t \alpha) w, \tag{6.4}$$

$$L_2 w = \partial_t w - 2s\varphi \partial_{x_1} w, \tag{6.5}$$

$$f_s = e^{s\alpha} f + s\varphi w. \tag{6.6}$$

Besides, by virtue of (6.1) and by the properties of α we have

$$w|_{t=0} = w|_{t=T} = 0. \tag{6.7}$$

Equation (6.2) implies

$$\|L_1 w\|^2_{L_2(Q)} + \|L_2 w\|^2_{L_2(Q)} + 2(L_1 w, L_2 w)_{L_2(Q)} = \|f_s\|^2_{L_2(Q)}. \tag{6.8}$$

By virtue of (6.4), (6.5) we get

$$(L_1 w, L_2 w)_{L_2(Q)} = I_1 + I_2 + I_3, \tag{6.9}$$

where

$$I_1 = \int_Q (\Delta w + s^2\varphi^2 w - s(\partial_t\alpha) w)\partial_t w \, dx\, dt, \tag{6.10}$$

$$I_2 = -\int_Q \Delta w (2s\varphi \partial_{x_1} w)\, dx\, dt, \tag{6.11}$$

$$I_3 = -\int_Q (s^2\varphi^2 - s(\partial_t\alpha))(2s\varphi w \partial_{x_1} w)\, dx\, dt. \tag{6.12}$$

Let us transform I_1, I_2, I_3. Integration by parts in (6.10) with the help of (6.3), (6.7) yields

$$\begin{aligned} I_1 = \int_Q \left(-\frac{1}{2}\partial_t |\nabla w|^2 + \frac{1}{2}(s^2\varphi^2 - s(\partial_t\alpha))\partial_t |w|^2 \right) dx\, dt \\ = -\int_Q \left(s^2\varphi \partial_t \varphi - \frac{s}{2}\partial^2_{tt}\alpha \right) |w|^2 \, dx\, dt. \end{aligned} \tag{6.13}$$

Analogously, integration by parts with respect to x in (6.12) with help of (6.3) yields

$$\begin{aligned} I_3 = -\int_Q (s^2\varphi^2 - s\partial_t\alpha) s\varphi \partial_{x_1} w^2 \, dx\, dt = \int_Q (3s^3\varphi^3 w^2 \\ - s^2(\partial_t\varphi)\varphi w^2 - s^2(\partial_t\alpha)\varphi w^2)\, dx\, dt. \end{aligned} \tag{6.14}$$

Finally, let us estimate term (6.11). Integration by parts and (6.1) imply

$$I_2 = (\nabla w, \nabla(2s\varphi\partial_{x_1} w))_{(L_2(Q))^n} = \int_Q (2s\varphi(\partial_{x_1} w)^2 + s\varphi\partial_{x_1}|\nabla w|^2)\,dx\,dt = \int_Q (2s\varphi(\partial_{x_1} w)^2 - s\varphi|\nabla w|^2)\,dx\,dt. \tag{6.15}$$

We substitute (6.13), (6.14), (6.15) into (6.9), and after that substitute the obtained equality into (6.8). As a result we have

$$\|L_1 w\|^2_{L_2(Q)} + \|L_2 w\|^2_{L_2(Q)} + 2\int_Q (3s^3\varphi^3|w|^2 - s\varphi|\nabla w|^2 + (\partial_{x_1} w)^2 2s\varphi)\,dx\,dt = \|f_s\|^2_{L_2(Q)} + X_1, \tag{6.16}$$

where

$$X_1 = 2\int_Q \left(s^2\varphi\partial_t\varphi - \frac{s}{2}\partial^2_{tt}\alpha + s^2\varphi(\partial_t\varphi) + s^2\varphi(\partial_t\alpha)\right)|w|^2\,dx\,dt. \tag{6.17}$$

We get, with the help of a simple estimation of (6.6),

$$\|f_s\|^2_{L_2(\Omega)} \le 2\int_Q (e^{2s\alpha}|f|^2 + s^2\varphi^2|w|^2)\,dx. \tag{6.18}$$

Definition (3.4) of φ and α imply the inequalities

$$|\partial_t\varphi| \le c_1\varphi^2, \qquad |\partial_t\alpha| \le c_2\varphi^2, \qquad |\partial^2_{tt}\alpha| \le c_3\varphi^3, \tag{6.19}$$

where c_1, c_2, c_3 do not depend on s, t, x. The estimation of (6.17) with the help of (6.19) yields

$$|X_1| \le c_4\int_Q (1+s^2)\varphi^3|w|^2\,dx\,dt. \tag{6.20}$$

Scaling (6.2) by $s\varphi w$ in $L_2(Q)$ and taking into account (6.4) we get after integration by parts

$$\int_Q f_s s\varphi w\,dx\,dt = \int_Q (L_2 w)s\varphi w\,dx\,dt + \int_Q \left(s^3\varphi^3|w|^2 - s\varphi(\partial_t\alpha)|w|^2 - s\varphi|\nabla w|^2 + \frac{1}{2}s\Delta\varphi|w|^2\right)dx\,dt.$$

We can rewrite this equality in the form

$$\int_Q s\varphi|\nabla w|^2\,dx\,dt = \int_Q s^3\varphi^3|w|^2\,dx\,dt - X_2, \tag{6.21}$$

where

$$X_2 = \int_Q \left(f_s s\varphi w - (L_2 w)s\varphi w + s\varphi(\partial_t\alpha)|w|^2 - \frac{1}{2}s\varphi|w|^2\right)dx\,dt. \tag{6.22}$$

We estimate X_2, taking into account (6.18), (6.19):

$$|X_2| \le \frac{1}{4}\|L_2 w\|^2_{L_2(Q)} + c_5 \int_Q (e^{2s\alpha}|f|^2 + (s^2\varphi^2 + s^2\varphi^3 + s\varphi)|w|^2)\,dx\,dt. \tag{6.23}$$

The estimation of (6.16) by means of (6.20), (6.18) yields:

$$\|L_1 w\|^2_{L_2(Q)} + \|L_2 w\|^2_{L_2(Q)} + 2\int_Q (3s^3\varphi^3|w|^2 - s\varphi|\nabla w|^2)\,dx\,dt \le \int_Q e^{2s\alpha}|f|^2 dx dt + c_6 \int_Q ((1+s^2)\varphi^3 + s^2\varphi^2)|w|^2\,dx\,dt. \tag{6.24}$$

We express the terms $\int_Q s\varphi|\nabla w|^2\,dx\,dt$ in (6.24) by means of (6.21) and after that use estimate (6.23). As a result we get the upper bound

$$\|L_1 w\|^2_{L_2(Q)} + \|L_2 w\|^2_{L_2(Q)} + 2\int_Q 2s^3\varphi^3|w|^2\,dx\,dt \le \frac{1}{2}\|L_2 w\|^2_{L_2(Q)} + c_9 \int_Q (e^{2s\alpha}|f|^2 + s^2\varphi^3 w^2)\,dx\,dt. \tag{6.25}$$

By (6.25) there exists a parameter s_0 such that the following inequality holds:

$$\|L_1 w\|^2_{L_2(Q)} + \|L_2 w\|^2_{L_2(Q)} + \int_Q s^3\varphi^3|w|^2\,dx\,dt \le c_{10}\int_Q e^{2s\alpha}|f|^2\,dx\,dt \ \ \forall\ s \ge s_0, \tag{6.26}$$

where c_{10} does not depend on s. After the estimation of the right side of (6.21) with the help of (6.23), (6.26) we get

$$\int_Q s\varphi|\nabla w|^2\,dx\,dt \le c_{11}\int_Q e^{2s\alpha}|f|^2\,dx\,dt \ \ \forall\ s \ge s_0. \tag{6.27}$$

Multiplying (6.4) on $(s\varphi)^{-1/2}$ and estimating with the help of (6.26), (6.19) we get

$$\int_Q (s\varphi)^{-1}|\Delta w|^2\,dx\,dt \le c_{12}\int_Q ((s\varphi)^{-1}|L_1 w|^2 + s^3\varphi^3 w^2 + s(\varphi)^3 w^2)\,dx\,dt \le c_{13}\int_Q e^{2s\alpha}|f|^2\,dx\,dt \quad \forall\ s > s_0. \tag{6.28}$$

Analogously, multiplying (6.5) on $(s\varphi)^{-1/2}$, we obtain the following inequality by means of (6.26), (6.27):

$$\int_Q (s\varphi)^{-1}|\partial_t w|^2\,dx\,dt \le c_{14}\int_Q e^{2s\alpha}|f|^2\,dx\,dt \quad \forall\ s > s_0. \tag{6.29}$$

After substituting $w = e^{s\alpha}z$ into (6.26)–(6.29), we obtain (3.8). □

DISCRETIZED MAXIMUM LIKELIHOOD AND ALMOST OPTIMAL ADAPTIVE CONTROL OF ERGODIC MARKOV MODELS*

T. E. DUNCAN†, B. PASIK-DUNCAN†, AND L. STETTNER‡

Abstract. Three distinct controlled ergodic Markov models are considered here. The models are a discrete time controlled Markov process with complete observations, a controlled diffusion process with complete observations, and a discrete time controlled Markov process with partial observations. The partial observations for the third model have the special form of complete observations in a fixed recurrent set and noisy observations in its complement. For each of the models an almost self-optimizing adaptive control is given. These adaptive controls are constructed from a family of estimates that use a finite discretization of the parameter set and a finite family of almost optimal ergodic controls by a randomized certainty equivalence method. A continuity property of the information of a model for one parameter value with respect to another is used to establish this almost optimality property.

Key words. adaptive control, ergodic control, Markov processes, controlled Markov processes, almost optimal adaptive control

1. Introduction.

In many control problems the models are not completely described and there are perturbations or unmodeled dynamics that are described by noise so that the models are stochastic. If some distributions or parameters in the models are unknown then these control problems can be considered as problems of stochastic adaptive control. In this paper, three unknown ergodic Markov models are considered. The models are a discrete time controlled Markov process with complete observations, a controlled diffusion process with complete observations, and a discrete time controlled Markov process with partial observations. The discrete time Markov processes evolve in a compact state space, and the transition densities depend on an unknown parameter. The partial observations of the discrete time Markov process in the third model have the special form of complete observations in a fixed recurrent set and noisy observations in its complement. The controlled diffusion is described by a stochastic differential equation where the unknown parameter appears in the drift vector. The solution of the stochastic differential equation is given in the weak sense. Since there are some basic differences among these three models, it is convenient to treat them separately. Typically, the results that are given here are stated for each of the three models.

Since the true value of the parameter is unknown, it is estimated using the maximum likelihood procedure where the time differences between the successive updates of the estimates are sufficiently large so that an ergodic property of the information and the cost can be used. Since only almost self-optimality is desired, the maximum likelihood procedure is restricted to choosing from a finite set of possible values for

‡Institute of Mathematics, Sniadeckich 8, 00–950 Warsaw, Poland (stettner@impan.gov.pl).

the parameter that is a discretization of the possible parameter values. The adaptive strategy uses a randomized certainty equivalence control that chooses with probability almost 1 the control that is almost optimal for the current value of the estimates, and with small, positive probability each of the other almost optimal controls. This procedure is shown to give an almost self-optimizing adaptive control.

The adaptive control of ergodic Markov models has been considered elsewhere (e.g., [1, 2, 4, 6, 8, 9, 10, 13]). However, only here is the maximization of the likelihood function restricted to a finite, discretized set of the possible parameter values. The work of Agrawal [1] has motivated the use here of information and the randomized certainty equivalence adaptive control. A cost-biased maximum likelihood method introduced in [13] is used in [6, 8] for two of the models considered here. The methods used here relax some of the assumptions in [4, 6, 8]. For example, the global Lipschitz continuity of the drift vector with respect to the unknown parameter for the controlled diffusion model is replaced by only continuity, and the requirement that the law of large numbers for some martingales be uniform in the parameter, which necessitated some assumptions in [6, 8], is not required.

The three models that are considered here can be generalized in various ways. The discrete time Markov process can be modified to include the discrete time recursive model in [17]. The controlled diffusion model can be generalized by analogy to [7] to include processes that satisfy stochastic differential equations with delays. The partial observations structure used here can be modified to noisy observations everywhere if there is a sequence of random times such that the process at these times is a family of independent, identically distributed random variables.

The three models are specifically described as follows.

Model I—Discrete time controlled Markov process. A Markov process $(X_n,\, n \in \mathbb{N})$ evolves in a compact metric space E with the transition operator $P(x_n, \mathrm{d}y; v_n, \alpha^0)$ at time $n \in \mathbb{N}$, where $\alpha^0 \in \mathcal{A}$ is an unknown fixed parameter and $\mathcal{A}$ is a compact metric space, and the control v_n takes values in a compact metric space U and is adapted to $\sigma(X_0, \ldots, X_n)$. A generic parameter value $\alpha \in \mathcal{A}$ has a transition operator that is described by replacing α^0 by α above. The transition operators have continuous densities with respect to a fixed measure $\varphi(\,\cdot\,)$; that is, for each $B \in \mathcal{B}(E)$, the Borel σ-algebra on E, and each $\alpha \in \mathcal{A}$,

$$P(x, B; v, \alpha) = \int_B p(x, y, v, \alpha)\varphi(\mathrm{d}y), \tag{1}$$

where φ is a probability measure on E and $p : E \times E \times U \times \mathcal{A} \to \mathbb{R}_+$ is continuous. It is assumed that $p(x, y, v, \alpha) > 0$ for all $x, y \in E$, $v \in U$, and $\alpha \in \mathcal{A}$, and $\operatorname{supp}\varphi = E$. The control problem is to minimize the following ergodic cost functional:

$$I^1((v_n,\, n \in \mathbb{N})) = \limsup_{n\to\infty} \frac{1}{n} \sum_{i=0}^{n-1} c(X_i, v_i), \tag{2}$$

where $c : E \times U \to \mathbb{R}_+$ is a bounded, Borel measurable function. The family of controls $(v_n,\, n \in \mathbb{N})$ has the form $v_n = u(X_n)$, where $u \in \mathcal{U}$ and $\mathcal{U}$ is the family of Borel measurable functions from E to U.

Model II—Controlled diffusion process. Let $(X(t),\, t \in \mathbb{R}_+)$ be a controlled diffusion process that satisfies the following stochastic differential equation:

$$\begin{aligned} \mathrm{d}X(t) &= f(X(t))\mathrm{d}t + h(X(t), \alpha^0, v(t))\mathrm{d}t + \sigma(X(t))\mathrm{d}W(t), \\ X(0) &= x, \end{aligned} \tag{3}$$

where $X(t) \in \mathbb{R}^n$, $(W(t), t \geq 0)$ is a standard $\mathbb{R}^n$-valued Wiener process, $\alpha^0 \in \mathcal{A}$ is unknown and $\mathcal{A}$ is compact, $(v(t), t \geq 0)$ is adapted to $\sigma(X(s), s \leq t)$, and $v(t) \in U$, a compact set. The functions f and σ satisfy a global Lipschitz condition, $\sigma(x)\sigma^*(x) \geq cI > 0$ for all $x \in \mathbb{R}^n$, and $h : \mathbb{R}^n \times \mathcal{A} \times U \to \mathbb{R}^n$ is a bounded Borel measurable function and either $h(x, \cdot, v)$ is continuous uniformly in $v \in U$ and x from compact subsets of $\mathbb{R}^n$ or $h(x, \cdot, \cdot)$ is continuous for each $x \in \mathbb{R}^n$. The solution of the stochastic differential equation (3) is given in the weak sense by an absolutely continuous transformation of the measure of the strong solution of

$$\begin{aligned} \mathrm{d}Y(t) &= f(Y(t))\mathrm{d}t + \sigma(Y(t))\mathrm{d}W(t), \\ Y(0) &= x. \end{aligned} \tag{4}$$

The family of controls $(v(t), t \geq 0)$ has the form $v(t) = u(X(t))$, where $u \in \mathcal{U}$ and $\mathcal{U}$ is the family of Borel measurable functions from $\mathbb{R}^n$ into U. Let T_A be the first hitting time of $A \in \mathcal{B}(\mathbb{R}^n)$; that is,

$$T_A = \begin{cases} \inf\{s > 0 : X(s) \in A\}, \\ +\infty \qquad\qquad\qquad\qquad \text{if the above set is empty.} \end{cases}$$

Let Γ_1 and Γ_2 be two spheres in $\mathbb{R}^n$ with centers at 0 and radii $0 < r_1 < r_2$, respectively. Let τ be given as

$$\tau = T_{\Gamma_2} + T_{\Gamma_1} \circ \theta_{T_{\Gamma_2}}, \tag{5}$$

where $(\theta_t, t \geq 0)$ is the family of shift operators acting on $C(\mathbb{R}_+, \mathbb{R}^n)$. The random time τ is the first time that the process $(X(t), t \geq 0)$ hits Γ_1 after hitting Γ_2. It is assumed that

$$\sup_{\alpha \in \mathcal{A}} \sup_{u \in \mathcal{U}} \sup_{x \in \Gamma_1} E_x^{\alpha,u}[\tau^2] < \infty \tag{6}$$

and

$$E_x^{\alpha,u}[T_{\Gamma_1}] < \infty \tag{7}$$

for each $(x, \alpha, u) \in \mathbb{R}^n \times \mathcal{A} \times \mathcal{U}$, where $E_x^{\alpha,u}$ is the expectation with respect to a process $(X(t), t \geq 0)$ that satisfies (3) with α^0 replaced by α and $v(t) = u(X(t))$. The dependence of the solution of (3) on $\alpha \in \mathcal{A}$ and the control $(v(t), t \geq 0)$ is suppressed for notational convenience. However, it is shown explicitly when the expectations of functions of the solution are taken. The control problem is to minimize the ergodic cost functional

$$I^2((v(t), t \geq 0)) = \limsup_{t \to \infty} \frac{1}{t} \int_0^t c(X(s), v(s))\mathrm{d}s, \tag{8}$$

where $c : \mathbb{R}^n \times U \to \mathbb{R}_+$ is a bounded, Borel measurable function.

Model III—A partially observed discrete time controlled Markov process. A controlled Markov process $(X_n, n \in \mathbb{N})$ evolves in a compact subset E of R^d with the transition operator $P(x_n, \mathrm{d}y; v_n, \alpha^0)$ at time $n \in \mathbb{N}$, where $\alpha^0 \in \mathcal{A}$ is an unknown parameter, $\mathcal{A}$ is a compact metric space, and the control v_n takes values in a compact metric space U. A generic parameter value $\alpha \in \mathcal{A}$ has a transition operator

that is described by replacing α^0 by α above. The transition operators have densities with respect to Lebesgue measure; that is,

$$P(x, B; v, \alpha) = \int_B p(x, y, v, \alpha)\mathrm{d}y, \tag{9}$$

where $\alpha \in \mathcal{A}$, $B \in \mathcal{B}(E)$, and $p : E \times E \times U \times \mathcal{A} \to \mathbb{R}_+$ is continuous and $p > 0$ on $E \times E \times U \times \mathcal{A}$. The process $(X_n,\, n \in \mathbb{N})$ is completely observed in a nonempty compact subset $\Gamma \subset E$ and is partially observed in $E \setminus \Gamma$. The observation process $(Y_n,\, n \in \mathbb{N})$ is explicitly described as follows:

$$P(Y_i \in B | X_i, \mathcal{Y}_{i-1}) = 1_{B\cap\Gamma}(X_i) + 1_{\Gamma^{\mathrm{c}}}(X_i) \int_{B\cap\Gamma^{\mathrm{c}}} r(X_i, y)\mathrm{d}y, \tag{10}$$

where $B \in \mathcal{B}(E)$, $\mathcal{Y}_i = \sigma(Y_1, \ldots, Y_i)$, $\mathcal{Y}_0 = \{\emptyset, \Omega\}$, and $r : \Gamma^{\mathrm{c}} \times \Gamma^{\mathrm{c}} \to \mathbb{R}$ is Borel measurable such that $\int_{\Gamma^{\mathrm{c}}} r(x, y)\mathrm{d}y = 1$ for each $x \in \Gamma^{\mathrm{c}}$. A control v is a U-valued, $\mathcal{Y}_n$-adapted process. The control problem is to minimize the ergodic cost functional

$$I^3((v_n,\, n \in \mathbb{N})) = \limsup_{n\to\infty} \frac{1}{n} \sum_{i=0}^{n-1} c(X_i, v_i), \tag{11}$$

where $c \in C(E \times U)$. It is assumed that there is a nonempty compact set $\Gamma_1 \subset \Gamma$ such that for each probability law μ on X_0, control $u = (v_n,\, n \in \mathbb{N})$, and $\alpha \in \mathcal{A}$,

$$E_\mu^{\alpha,u}[T_{\Gamma_1}] < \infty \tag{12}$$

and

$$\sup_{x\in\Gamma_1} \sup_{u\in\mathcal{U}} E_x^{\alpha,u}[\tau^2] < \infty, \tag{13}$$

where T_{Γ_1} is the first hitting time of Γ_1, τ is the first hitting time of Γ_1 after hitting Γ^{c} ($\tau = T_{\Gamma^{\mathrm{c}}} + T_{\Gamma_1} \circ \theta_{T_{\Gamma^{\mathrm{c}}}}$), and $E_\mu^{\alpha,u}$ is the expectation for the process $(X_n,\, n \in \mathbb{N})$ with initial law μ, control u, and parameter $\alpha \in \mathcal{A}$. For a probability law μ for X_0 the measure-valued process $(\Pi_n^{\alpha^0},\, n \in \mathbb{N})$ is defined as follows:

$$\Pi_0^{\alpha^0}(B) = \mu(B), \tag{14}$$

$$\Pi_n^{\alpha^0}(B) = P_n(X_n \in B | \mathcal{Y}_n) \tag{15}$$

for each $B \in \mathcal{B}(E)$. This conditional measure process can be represented more explicitly using (10) (e.g., Lemma 1 of [18]) as follows:

$$\Pi_{n+1}^{\alpha^0}(B) = 1_{B\cap\Gamma}(Y_{n+1}) + 1_{\Gamma^{\mathrm{c}}}(Y_{n+1}) M(Y_{n+1}, \Pi_n^{\alpha^0}, v_n, \alpha^0)(B), \tag{16}$$

where

$$M(y, \nu, v, \alpha^0) = \frac{\displaystyle\int_{B\cap\Gamma^{\mathrm{c}}} r(z, y) p(\nu, z, v, \alpha^0)\mathrm{d}z}{\displaystyle\int_{\Gamma^{\mathrm{c}}} r(z, y) p(\nu, z, v, \alpha^0)\mathrm{d}z} \tag{17}$$

and

$$p(\nu, z, v, \alpha^0) = \int_E p(x, z, v, \alpha^0)\nu(\mathrm{d}x). \tag{18}$$

2. A finite family of almost optimal controls. For the adaptive control of Models I, II, and III a finite family of controls is constructed that includes at least one that is almost optimal for each parameter value $\alpha \in \mathcal{A}$.

To determine the almost optimal controls the averaged versions of the ergodic cost functionals (2), (8), (11) are used. These are denoted as follows:

$$J_\mu^{\alpha^0,1}((v_n,\, n\in\mathbb{N})) = \limsup_{n\to\infty} \frac{1}{n} E_\mu^{\alpha^0,v}\left[\sum_{i=0}^{n-1} c(X_i, v_i)\right], \tag{19}$$

$$J_\mu^{\alpha^0,2}((v(t),\, t\geq 0)) = \limsup_{t\to\infty} \frac{1}{t} E_\mu^{\alpha^0,v}\left[\int_0^t c(X(s), v(s))\mathrm{d}s\right], \tag{20}$$

$$J_\mu^{\alpha^0,3}((v_n,\, n\in\mathbb{N})) = \limsup_{n\to\infty} \frac{1}{n} E_\mu^{\alpha^0,v}\left[\sum_{i=0}^{n-1} c(X_i, v_i)\right], \tag{21}$$

where μ is the probability law for X_0 and $\alpha^0 \in \mathcal{A}$ is the true parameter value. The finite families of almost optimal controls for Models I, II, and III are constructed for the cost functionals $J_\mu^{\alpha^0,1}$, $J_\mu^{\alpha^0,2}$, and $J_\mu^{\alpha^0,3}$, respectively.

Model I. It is assumed that it suffices to consider controls of the form $v_n = u_n(X_n)$, where $u_n \in \mathcal{U} = B(E,U)$, the family of Borel measurable functions from E to U. Clearly, this restriction is satisfied if c is a continuous, bounded function because by (1) for $B \in \mathcal{B}(E)$, $x \in E$, $v \in U$, and $\alpha \in \mathcal{A}$,

$$P^{v,\alpha}(x,B) \geq \inf_{x,y\in E} \inf_{v\in U} \inf_{\alpha\in\mathcal{A}} p(x,y,v,\alpha)\varphi(B) \tag{22}$$

and

$$\inf_{x,y\in E} \inf_{v\in U} \inf_{\alpha\in\mathcal{A}} p(x,y,v,\alpha) > 0,$$

and (see Theorem 2.2 and Corollary 3.6 in Chap. 3 of [10]) for each $\alpha \in \mathcal{A}$, there is a $u_\alpha \in B(E,U)$ such that $J_\mu^{\alpha,1}(u_\alpha)$ is optimal.

For Model I there is a uniform ergodicity property and a finite family of almost optimal controls.

PROPOSITION 1. *For Model* I *with $\alpha \in \mathcal{A}$ and $u \in \mathcal{U}$ there is a probability measure π_u^α on $\mathcal{B}(E)$ such that*

$$\sup_{u\in\mathcal{U}} \sup_{\alpha\in\mathcal{A}} \sup_{x\in E} \|(P^{u,\alpha})^n(x,\cdot) - \pi_u^\alpha(\cdot)\|_{\mathrm{var}} \leq 2\gamma_0^{n-1} \tag{23}$$

where $\|\cdot\|_{\mathrm{var}}$ is the variation norm and

$$\gamma_0 = 1 - \inf_{x,y\in E} \inf_{v\in U} \inf_{\alpha\in\mathcal{A}} p(x,y,v,\alpha).$$

There is a constant K_1 such that for $\alpha, \beta \in \mathcal{A}$ and $u \in \mathcal{U}$

$$\|\pi_u^\alpha - \pi_u^\beta\|_{\mathrm{var}} \leq K_1 \sup_{x\in E} \|P^{u,\alpha}(x,\cdot) - P^{u,\beta}(x,\cdot)\|_{\mathrm{var}}. \tag{24}$$

Furthermore, given $\varepsilon > 0$ there is a finite family of controls $\mathcal{U}^1(\varepsilon) = \{u^1, \ldots, u^{r(\varepsilon)}\}$ such that for each $\alpha \in \mathcal{A}$ there is a $k \in \{1, \ldots, r(\varepsilon)\}$ and

$$J_\mu^{\alpha,1}(u^k(X(\cdot))) \leq \lambda_1(\alpha) + \varepsilon, \tag{25}$$

where

$$\lambda_1(\alpha) = \inf_{u\in\mathcal{U}} J_\mu^{\alpha,1}(u(X(\cdot))). \tag{26}$$

Proof. From (22) and (5.6) of [5], (23) is verified. The inequality (24) follows from the proof of Proposition 1 of [17]. The existence of a finite family $\mathcal{U}^1(\varepsilon)$ satisfying (25) follows from (24) and the proof of Lemma 2 of [17]. □

Model II. Let $(\tau_n,\ n\in\mathbb{N})$ be an increasing sequence of random times such that $\tau_1=\tau$ and $\tau_{n+1}=\tau_n\circ\theta_{\tau_n}$ for $n>1$. For a given control $u\in\mathcal{U}$ and parameter $\alpha^0\in\mathcal{A}$ there is a unique invariant measure $\eta_u^{\alpha^0}$ for the embedded Markov chain $(X_{\tau_n},\ n\in\mathbb{N})$ and $X_0\in\Gamma_1$ (e.g., [6]). Furthermore, there is a unique invariant measure $\pi_u^{\alpha^0}$ for the process $(X(t),\ t\ge 0)$ with $v(t)=u(X(t))$, and it has the form

$$\pi_u^{\alpha^0}(B) = \frac{\displaystyle\int_{\Gamma_1} E_x^{\alpha^0,u}\left[\int_0^\tau 1_B(X(s))\mathrm{d}s\right]\eta_u^{\alpha^0}(\mathrm{d}x)}{\displaystyle\int_{\Gamma_1} E_x^{\alpha^0,u}[\tau]\eta_u^{\alpha^0}(\mathrm{d}x)}. \tag{27}$$

For Model II there is an analogue of Proposition 1.

PROPOSITION 2. *For Model* II *there is* $\gamma_0\in(0,1)$ *such that*

$$\sup_{u\in\mathcal{U}}\sup_{\alpha\in\mathcal{A}}\sup_{x\in\Gamma_1}\sup_{B\in\mathcal{B}(\Gamma_1)} |P_x^{\alpha,u}(X(\tau_n)\in B)-\eta_u^\alpha(B)|\le\gamma_0^n, \tag{28}$$

where η_u^α *is the unique invariant measure for the embedded Markov chain. There is a constant* K_1 *such that for* $\alpha,\beta\in\mathcal{A}$ *and* $u\in\mathcal{U}$,

$$\|\eta_u^\alpha-\eta_u^\beta\|_{\mathrm{var}}\le K_1\sup_{x\in E}\sup_{B\in\mathcal{B}(\Gamma_1)}|P_x^{\alpha,u}(X(\tau)\in B)-P_x^{\beta,u}(X(\tau)\in B)|. \tag{29}$$

Furthermore, given $\varepsilon>0$ *there is a* $\delta>0$ *such that if* $\alpha,\beta\in\mathcal{A}$ *and* $\rho_{\mathcal{A}}(\alpha,\beta)<\delta$ *then*

$$\sup_{u\in\mathcal{U}}\sup_{x\in\Gamma_1}\sup_{B\in\mathcal{B}(\Gamma_1)}|P_x^{\alpha,u}(X(\tau)\in B)-P_x^{\beta,u}(X(\tau)\in B)|<\varepsilon \tag{30}$$

and

$$\sup_{u\in\mathcal{U}}\sup_{x\in\Gamma_1}\sup_{B\in\mathcal{B}(\Gamma_1)}\left|E_x^{\alpha,u}\left[\int_0^\tau 1_B(X(s))\mathrm{d}s\right]-E_x^{\beta,u}\left[\int_0^\tau 1_B(X(s))\mathrm{d}s\right]\right|<\varepsilon, \tag{31}$$

where $\rho_{\mathcal{A}}$ *is a metric on* $\mathcal{A}$ *compatible with its topology. Furthermore, given* $\varepsilon>0$, *there is a finite family of controls* $\mathcal{U}^2(\varepsilon)=\{u^1,\dots,u^{r(\varepsilon)}\}$ *such that for each* $\alpha\in\mathcal{A}$ *there is a* $k\in\{1,\dots,r(\varepsilon)\}$ *and*

$$J_\mu^{\alpha,2}(u^k(X(\cdot)))\le\lambda_2(\alpha)+\varepsilon, \tag{32}$$

where

$$\lambda_2(\alpha)=\inf_{u\in\mathcal{U}} J_\mu^{\alpha,2}(u(X(\cdot))). \tag{33}$$

Proof. By Proposition 2.2 of [6] and Theorem 4.1 of [3] the inequality (28) follows. Using the proof of Proposition 1 of [6], as in our Proposition 1, the inequality (29)

follows. The uniform continuity properties (30), (31) can be verified as for (10) and (19) of [6]. Since h is not assumed to be Lipschitz continuous with respect to $\alpha \in \mathcal{A}$, it is necessary to verify that the map

$$H : \Gamma_1 \times \mathcal{A} \to \mathbb{R} \tag{34}$$

given by

$$H(x,\alpha) = E_x\left[\int_0^t |\sigma^{-1}(Y(s))h(Y(s),\alpha,u(Y(s)))|^2 \mathrm{d}s\right] \tag{35}$$

is continuous uniformly in $u \in \mathcal{U}$, where E_x is the expectation for P_x that is the measure for the solution of (4), and

$$E_x\left[\int_0^t |\sigma^{-1}(Y(s))(h(Y(s),\alpha,u(Y(s))) - h(Y(s),\beta,u(Y(s))))|^2 \mathrm{d}s\right] \to 0$$

as $\rho_{\mathcal{A}}(\alpha,\beta) \to 0$ uniformly in $u \in U$. The proof of this last continuity is similar to the verification of the continuity of H, so only the verification of H is given. Since h is bounded, it is sufficient to verify the continuity of $\bar{H} : \Gamma_1 \times \mathcal{A} \to \mathbb{R}$ given by

$$\bar{H}(x,\alpha) = \int_{t_1}^t E_x|\sigma^{-1}(Y(s))h(Y(s),\alpha,u(Y(s)))|^2 \mathrm{d}s \tag{36}$$

for each $t_1 < t$ uniformly in $u \in U$. To verify this continuity note that the map $(s,x) \in (0,\infty) \times \mathbb{R}^d \mapsto P_x(Y(s) \in \cdot)$ is continuous in the variation norm topology. In fact, by Lemma 9.22 of [19], for $s_n \to s > 0$ and $x_n \to x$ the family of measures $(P_{x_n}(Y(s_n) \in \cdot),\, n \in \mathbb{N})$ is tight, so for any $\varepsilon > 0$ there is a compact set $K \subset \mathbb{R}^d$ such that

$$P_y(Y(s_n) \in K^{\mathrm{c}}) < \varepsilon$$

for all $y \in \{x, x_1, x_2, \ldots\}$. By Theorem 3.2.1 of [19] the measures $(P_\cdot(Y(s) \in \cdot),\, s > 0)$ have continuous densities. As $n \to \infty$ the following inequality is easily verified from the previous inequality:

$$\sup_{B \in \mathcal{B}(\mathbb{R}^d)} |P_{x_n}(Y(s_n) \in B) - P_x(Y(s) \in B)| \le 2\varepsilon + \int_K |p(s_n,x_n,y) - p(s,x,y)| \mathrm{d}y.$$

Thus the continuity in the variation norm of $P_\cdot(Y(s) \in \cdot)$ is verified. By this continuity and the continuity of $\alpha \mapsto h(y,\alpha,v)$ that is uniform in $v \in U$, the continuity of (36) and therefore (34) follows. Now only the verification of (32) remains. By (27), (29), (30), (31), given $\varepsilon > 0$, there is a $\delta > 0$ such that if $\alpha, \beta \in \mathcal{A}$ and $\rho_{\mathcal{A}}(\alpha,\beta) < \delta$, then

$$\sup_{u \in \mathcal{U}} \|\pi_u^\alpha - \pi_u^\beta\|_{\mathrm{var}} < \varepsilon.$$

So by Propositions 2.3 and 2.4 of [6] there is a finite family of controls $\mathcal{U}^2(\varepsilon)$ such that the inequality (32) is satisfied. □

Model III. Let $\tilde{\mathcal{U}}$ be a fixed compact subset of $C(\mathcal{P}(E),U)$ where $P(E)$ is the family of probability measures on E with the vague topology, and let $u(\alpha)$ be the control sequence such that $v_n = u(\Pi_n^\alpha)$. Define λ_3 as follows:

$$\lambda_3(\alpha) = \inf_{u \in \tilde{\mathcal{U}}} J_\mu^{\alpha,3}(u(\Pi_n^\alpha)) \tag{37}$$

and an increasing sequence of random times $(\tau_n,\, n \in \mathbb{N})$ as $\tau_1 = \tau$, $\tau_{n+1} = \tau_n + \tau \circ \theta_{\tau_n}$, where $(\theta_t,\, t \geq 0)$ is the family of shift operators acting on $C(\mathbb{R}_+, \mathbb{R}^d)$.

Some additional assumptions are made on Model III.

(A1) The function r given in (10) is continuous on $\Gamma^{\mathrm{c}} \times \Gamma^{\mathrm{c}}$ and bounded on $\Gamma^{\mathrm{c}}_\delta \times \Gamma^{\mathrm{c}}_\delta$ for some $\delta > 0$ where $\Gamma^{\mathrm{c}}_\delta = \{(y,z) \in \Gamma^{\mathrm{c}} \times \Gamma^{\mathrm{c}} : \rho_E(y,\Gamma) \geq \delta\} \cup \{(y,z) \in \Gamma^{\mathrm{c}} \times \Gamma^{\mathrm{c}} : \rho_E(y,z) \geq \delta\}$ and ρ_E is a metric on E that is compatible with its topology. If $(y_n,\, n \in \mathbb{N})$ is a sequence in Γ^{c} such that $y_n \to y \in \Gamma$ as $n \to \infty$, and for $\delta > 0$, $B(y,\delta) = \{z \in \Gamma^{\mathrm{c}} : \rho_E(z,y) \leq \delta\}$, then

$$\lim_{n\to\infty} \inf_{\alpha\in\mathcal{A}} \inf_{v\in\tilde{\mathcal{U}}} \inf_{x\in K} \int_{B(y,\delta)} r(z,y_n) P^{\alpha,v}(x,\mathrm{d}z) = \infty \tag{38}$$

for any compact subset $K \subset E$.

(A2) If $(z_n,\, n \in \mathbb{N})$ is a sequence in Γ^{c} that converges to z, then

$$\lim_{n\to\infty} R(z_n,\cdot) = R(z,\cdot),$$

where the topology is the vague convergence of measures and

$$R(z,A) = \begin{cases} \displaystyle\int_{A\cap\Gamma^{\mathrm{c}}} r(z,y)\mathrm{d}y & \text{for } z \in \Gamma^{\mathrm{c}}, \\ 1_A(z) & \text{for } z \in \Gamma \end{cases} \tag{39}$$

for $A \in \mathcal{B}(E)$.

Using (A1) and (A2) an analogue of Propositions 1 and 2 is given for Model III.

PROPOSITION 3. *For Model* III, *if* (A1) *and* (A2) *are satisfied, then there is a* $\gamma_0 \in (0,1)$ *and a measure* $\eta^\alpha_{u(\beta)}$ *on* Γ *such that*

$$\sup_{u\in\tilde{\mathcal{U}}} \sup_{\alpha,\beta\in\mathcal{A}} \sup_{x\in\Gamma} \sup_{B\in\mathcal{B}(\Gamma_1)} |P^{\alpha,u(\beta)}_x(X_{\tau_n} \in B) - \eta^\alpha_{u(\beta)}(B)| < \gamma_0^n. \tag{40}$$

Given $\varepsilon > 0$ *there is a finite family of controls* $\tilde{\mathcal{U}}(\varepsilon) = \{u^1,\dots,u^{r(\varepsilon)}\} \subset \tilde{\mathcal{U}}$ *and* $\delta_0 > 0$ *such that if* $\rho_{\mathcal{A}}(\alpha,\beta) < \delta_0$, *then*

$$\lambda_3(\beta) - \varepsilon \leq J^{\beta,3}_\mu(u^k(\Pi^\alpha_n)) \leq \lambda_3(\beta) + \varepsilon \tag{41}$$

for some $k \in \{1,\dots,r(\varepsilon)\}$.

Proof. The continuity and the positivity of the transition density p and (13) imply (40). Using the proof of Lemma 3 of [17], it follows that

$$J^{\beta,3}_\mu(u^k(\Pi^\alpha_n)) = \frac{\displaystyle\int_\Gamma E^{\beta,u(\alpha)}_x \left[\sum_{i=0}^{\tau-1} \int_E c(z,u(\Pi^\alpha_i))\Pi^\beta_i(\mathrm{d}z)\eta^\beta_{u(\alpha)}(\mathrm{d}x)\right]}{\displaystyle\int_\Gamma E^{\beta,u(\alpha)}_x[\tau]\eta^\beta_{u(\alpha)}(\mathrm{d}x)}.$$

By the proofs of Lemma 2 of [17] and Proposition 2.4 of [6], for the verification of (41) it suffices to show that given $\varepsilon > 0$, there is a $\delta > 0$ such that for $\alpha,\beta,\alpha_1,\beta_1 \in \mathcal{A}$, if $\rho_{\mathcal{A}}(\alpha,\alpha_1) < \delta$ and $\rho_{\mathcal{A}}(\beta,\beta_1) < \delta$ then

$$\sup_{u\in\tilde{\mathcal{U}}} |J^{\beta,3}_\mu(u(\Pi^\alpha_n)) - J^{\beta_1,3}_\mu(u(\Pi^{\alpha_1}_n))| < \varepsilon. \tag{42}$$

If the inequality (42) is not satisfied then there are sequences $(\alpha^m,\ m\in\mathbb{N})$, $(\alpha_1^m,\ m\in\mathbb{N})$ such that $\alpha^m\to\alpha$, $\alpha_1^m\to\alpha_1$, and $u_m(v)\to u(v)$ uniformly in $v\in\mathcal{P}(E)$ as $m\to\infty$ and

$$|J_\mu^{\alpha^m,3}(u_m(\Pi_n^{\alpha^m}))-J_\mu^{\alpha_1^m,3}(u_m(\Pi_n^{\alpha_1^m}))|\ge\varepsilon>0 \tag{43}$$

for all $m\in\mathbb{N}$. Using some continuity arguments in the proofs of Theorems 1 and 6 of [18], where the pair $(\alpha,v)\in\mathcal{A}\times U$ is considered as the control, it follows that

$$\lim_{m\to\infty}J_\mu^{\alpha^m,3}(u_m(\Pi_n^{\alpha^m}))=J_\mu^{\alpha,3}(u(\Pi_n^\alpha))$$

and

$$\lim_{m\to\infty}J_\mu^{\alpha_1^m,3}(u_m(\Pi_n^{\alpha_1^m}))=J_\mu^{\alpha,3}(u(\Pi_n^\alpha)),$$

which contradict the inequality (43). Thus (42) is satisfied and there is a finite family $\tilde{\mathcal{U}}(\varepsilon)$ of controls such that (41) is satisfied. □

Let $\tilde{\mathcal{A}}(\delta_0)=\{\alpha(1),\dots,\alpha(k(\delta_0))\}$ be distinguished points, one from each of a finite δ_0 net in $\mathcal{A}$. By Proposition 3, given $\varepsilon>0$, there is an $\tilde{\mathcal{A}}(\delta_0)$ from a δ_0 net of $\mathcal{A}$ such that the controls $(u^k(\Pi_n^\alpha),\ k\in\{1,\dots,r(\varepsilon)\}$ and $\alpha\in\tilde{\mathcal{A}}(\delta_0))$ form the family of ε optimal controls.

Remark. A finite family of controls for $\mathcal{U}^{(1)}(\varepsilon)$ can be obtained from a discretization of the Bellman equation (cf. [6] and Section 3.5 of [10]). A finite family of controls for $\mathcal{U}^{(2)}(\varepsilon)$ can be obtained using [14], and a finite family of controls for $\tilde{\mathcal{U}}(\varepsilon)$ can be obtained using [15].

3. The information for different parameters. Kullback and Leibler [11] have used a notion of information in statistics. For the adaptive control problems for the three models considered here the information is computed from the probability densities for different values of the unknown parameter. It is described in [16] as the information of one parameter value with respect to another. It is shown in [12] that it is naturally related to the notion of information in information theory. This quantity has a different form for each of the Markov models. It is denoted K^i, $i=1,2,3$, for the three models.

$$K_u^1(\alpha,\beta)=\int_E\int_E\ln\left(\frac{p(x,y,u(x),\beta)}{p(x,y,u(x),\alpha)}\right)p(x,y,u(x),\beta)\varphi(\mathrm{d}y)\pi_u^\beta(\mathrm{d}x), \tag{44}$$

where φ is given in (1), π is the invariant measure given in (23), $\alpha,\beta\in\mathcal{A}$, and $u\in\mathcal{U}$.

$$\begin{aligned}K_u^2(\alpha,\beta)&\\ &=\frac{1}{2}\int_{\Gamma_1}E_x^{\beta,u}\left[\int_0^\tau|\sigma^{-1}(X(s))(h(X(s),\alpha,u(X(s)))-h(X(s),\beta,u(X(s))))|^2\mathrm{d}s\right]\\ &\qquad\cdot\eta_u^\beta(\mathrm{d}x)\left(\int_{\Gamma_1}E_x^{\beta,u}[\tau]\eta_u^\beta(\mathrm{d}x)\right)^{-1},\end{aligned} \tag{45}$$

where η is the invariant measure for the embedded Markov chain given in (27), $\alpha,\beta\in\mathcal{A}$, and $u\in\mathcal{U}$.

$$K_u^3(\alpha,\beta,\gamma)=\int_\Gamma E_x^{\beta,u(\gamma)}\left[\sum_{i=0}^{\tau-1}\ln\left(\frac{F(\Pi_i^\beta,u(\Pi_i^\gamma),\beta)(Y_{i+1})}{F(\Pi_i^\alpha,u(\Pi_i^\gamma),\alpha)(Y_{i+1})}\right)\right]$$

$$\cdot\eta^{\beta}_{u(\gamma)}(\mathrm{d}x)\left(\int_{\Gamma} E_x^{\beta,u(\gamma)}[\tau]\eta^{\beta}_{u(\gamma)}(\mathrm{d}x)\right)^{-1}, \tag{46}$$

where η is given in (40), $\alpha,\beta,\gamma\in\mathcal{A}$, $u\in\tilde{\mathcal{U}}$, $u(\gamma)$ in (46) indicates that the control $u(\Pi_i^{\gamma})$ is used, and

$$\begin{aligned} F(\nu,v,\alpha)(y) &:= 1_{\Gamma}(y)p(\nu,y,v,\alpha) \\ &\quad + 1_{E\setminus\Gamma}(y)\int_{E\setminus\Gamma} r(z,y)p(\nu,z,v,\alpha)\mathrm{d}z. \end{aligned} \tag{47}$$

Now some important properties are verified for K^i, $i=1,2,3$.

PROPOSITION 4. *Consider Model* I *with the assumptions imposed on it. For each* $u\in\mathcal{U}$ *the map* $K^1_u:\mathcal{A}\times\mathcal{A}\to\mathbb{R}$ *is continuous. Furthermore, if* $K^1_u(\alpha,\beta)=0$, *then* $\pi^{\alpha}_u=\pi^{\beta}_u$.

Proof. Let $L:\mathcal{A}\times\mathcal{A}\times E\to\mathbb{R}$ be given by

$$L(\alpha,\beta,x)=\int_E \ln\left(\frac{p(x,y,u(x),\beta)}{p(x,y,u(x),\alpha)}\right)p(x,y,u(x),\beta)\varphi(\mathrm{d}y).$$

$L(\cdot,\cdot,x)$ is continuous and bounded uniformly in $x\in E$, so the continuity of K^1_u follows by (24).

For $x\in E$, Jensen's inequality implies that

$$\int_E \ln\left(\frac{p(x,y,u(x),\beta)}{p(x,y,u(x),\alpha)}\right)p(x,y,u(x),\beta)\varphi(\mathrm{d}y)\geq 0.$$

For each $B\in\mathcal{B}(E)$ it follows by the definition of invariant measures that

$$\pi^{\beta}_u(B)\geq \inf_{x,y\in E}\inf_{v\in U,\ \beta\in\mathcal{A}} p(x,y,v,\beta)\varphi(B).$$

If $K^1_u(\alpha,\beta)=0$, then

$$\int_E \ln\left(\frac{p(x,y,u(x),\beta)}{p(x,y,u(x),\alpha)}\right)p(x,y,u(x),\beta)\varphi(\mathrm{d}y)=0 \tag{48}$$

for (φ) almost all $x\in E$. Since $\ln(\cdot)$ is a strongly convex function it follows by Jensen's inequality that

$$p(x,y,u(x),\alpha)=p(x,y,u(x),\beta) \tag{49}$$

for (φ) almost all $x\in E$ and (φ) almost all $y\in E$. Thus for $B\in\mathcal{B}(E)$,

$$\begin{aligned} \pi^{\beta}_u(B) &= \int_E\int_B p(x,y,u(x),\beta)\varphi(\mathrm{d}y)\pi^{\beta}_u(\mathrm{d}x) \\ &= \int_E\int_B p(x,y,u(x),\alpha)\varphi(\mathrm{d}y)\pi^{\beta}_u(\mathrm{d}x) \\ &= \int_E P^{u,\alpha}(x,B)\pi^{\beta}_u(\mathrm{d}x). \end{aligned}$$

The last equality implies that π^{β}_u is an invariant measure for the transition operator $P^{\alpha,u}$. The uniqueness of the invariant measure for $P^{\alpha,u}$, which follows from (23), implies that $\pi^{\beta}_u=\pi^{\alpha}_u$. □

Now a result analogous to the above proposition is obtained for Model II.

PROPOSITION 5. *Consider Model* II *with the assumptions imposed on it. For each* $u \in \mathcal{U}$*, the map* $K_u^2 : \mathcal{A} \times \mathcal{A} \to \mathbb{R}$ *is continuous. Furthermore, if* $K_u^2(\alpha, \beta) = 0$*, then* $\pi_u^\alpha = \pi_u^\beta$.

Proof. The continuity of K_u^2 follows from (29), (30), (31) and the continuity of $h(x, \cdot, v)$. If $K_u^2(\alpha, \beta) = 0$, then by Lemma 3.4 of [6] it follows that

$$h(x, \alpha, u(x)) = h(x, \beta, u(x))$$

for all $x \in \mathbb{R}^n \setminus D$ where $\lambda(D) = 0$ and λ is an n-dimensional Lebesgue measure. Thus for (λ) almost all $x \in \mathbb{R}^n$, $t > 0$, and $B \in \mathcal{B}(\mathbb{R}^n)$,

$$P_x^{\alpha,u}(X(t) \in B) = P_x^{\beta,u}(X(t) \in B).$$

The uniqueness of the invariant measures, as in the proof of Proposition 4, implies that $\pi_u^\alpha = \pi_u^\beta$. □

For Model III an additional assumption is introduced:

$$\int_{E \setminus \Gamma} r(x, y)(p(\nu_1, x, v, \alpha) - p(\nu_2, x, v, \beta))\mathrm{d}x = 0 \tag{A5}$$

for almost all $y \in E \setminus \Gamma$ if and only if

$$p(\nu_1, x, v, \alpha) = p(\nu_2, x, v, \beta)$$

for almost all $x \in E \setminus \Gamma$.

Now an analogue of the previous two propositions is verified for Model III.

PROPOSITION 6. *If* (A1)–(A5) *are satisfied for Model* III*, then for each* $u \in \tilde{\mathcal{U}}$ *the map* $K_u^3 : \mathcal{A} \times \mathcal{A} \times \mathcal{A} \to \mathbb{R}$ *is continuous. Furthermore, if* $K_u^3(\alpha, \beta, \gamma) = 0$ *then the measures* $\Psi_{u(\gamma)}^\alpha$ *and* $\Psi_{u(\gamma)}^\beta$ *on the Borel* σ*-algebra of* $\mathcal{P}(E) \times \mathcal{P}(E)$ *coincide, where*

$$\Psi_{u(\gamma)}^\delta(B) = \frac{\displaystyle\int_\Gamma E_x^{\delta,u(\gamma)} \left[\sum_{i=0}^{\tau-1} 1_B(\Pi_i^\alpha, \Pi_i^\beta)\right] \eta_{u(\gamma)}^\delta(\mathrm{d}x)}{\displaystyle\int_\Gamma E_x^{\delta,u(\gamma)}[\tau]\eta_{u(\gamma)}^\delta(\mathrm{d}x)} \tag{50}$$

and $\delta = \alpha, \beta$ *and* $B \in \sigma(\mathcal{P}(E) \times \mathcal{P}(E))$.

Proof. The verification of the continuity of K_u^3 follows from the boundedness and continuity of $F(\cdot, \cdot, \cdot)(\cdot) : \mathcal{P}(E) \times U \times \mathcal{A} \times E \setminus \partial\Gamma \to \mathbb{R}$ (cf. Theorems 1 and 6 of [18]).

If $K_u^3(\alpha, \beta, \gamma) = 0$, then by the strict positivity of p it follows that

$$E_x^{\beta,u(\gamma)} \left[\sum_{i=0}^{\tau-1} \ln\left(\frac{F(\Pi_i^\beta, u(\Pi_i^\gamma), \beta)(Y_{i+1})}{F(\Pi_i^\alpha, u(\Pi_i^\gamma), \alpha)(Y_{i+1})}\right)\right] = 0$$

for almost all $x \in \Gamma$. The map $L : \Gamma \to \mathbb{R}$, where

$$L(x) = E_x^{\beta,u(\gamma)} \left[\sum_{i=0}^{\tau-1} \ln\left(\frac{F(\Pi_i^\beta, u(\Pi_i^\gamma), \beta)(Y_{i+1})}{F(\Pi_i^\alpha, u(\Pi_i^\gamma), \alpha)(Y_{i+1})}\right)\right]$$

is continuous for each $\beta \in \mathcal{A}$, and $u \in U$ (cf. Lemma 8 of [18]), so for all $x \in \Gamma$, $L(x) = 0$. Using (A5) and Lemma 4 of [8] it follows that

$$P_x^{\beta,u(\gamma)}(\Pi_i^\alpha = \Pi_i^\beta \text{ for } i \in \{0,\dots,\tau-1\}) = 1$$

for each $x \in \Gamma$. It follows from Corollary 2 of [8] that

$$E_x^{\beta,u(\gamma)}\left[\sum_{i=0}^{\tau-1} 1_B(\Pi_i^\beta, \Pi_i^\gamma)\right] = E_x^{\alpha,u(\gamma)}\left[\sum_{i=0}^{\tau-1} 1_B(\Pi_i^\beta, \Pi_i^\gamma)\right]$$

for each B in the Borel σ-algebra of $\mathcal{P}(E) \times \mathcal{P}(E)$, $x \in \Gamma_1$, and $\eta_{u(\gamma)}^\alpha = \eta_{u(\gamma)}^\beta$. Thus $\Psi_{u(\gamma)}^\alpha = \Psi_{u(\gamma)}^\beta$. □

4. Almost self-optimal adaptive strategies. For $\varepsilon > 0$ fixed, the controls are restricted to the finite families $\mathcal{U}^1(\varepsilon)$, $\mathcal{U}^2(\varepsilon)$, and $\tilde{\mathcal{U}}(\varepsilon)$ of ε optimal controls for Models I, II, and III, respectively. For $\varepsilon > 0$ there is a $\delta_0 > 0$ given in Proposition 3 and a δ_0 net of $\mathcal{A}$ with a distinguished point from each element of the net $\tilde{\mathcal{A}}(\delta_0) = \{\alpha(1),\dots,\alpha(k(\delta_0))\}$.

For a randomization of an adaptive control the following subsets of $\mathbb{R}$ are used. For $\varepsilon > 0$ let

$$\begin{aligned} S(\varepsilon) = \{&\beta^i(j) : i \in \mathbb{N},\ j \in \{1,2,\dots,r(\varepsilon)\} \text{ and for each } i \in \mathbb{N} \\ &\text{there is a } j_i \in \{1,\dots,r(\varepsilon)\} \text{ such that } \beta^i(j_i) = 1 - \varepsilon/\|c\| \\ &\text{and for } j \neq j_i,\ \beta^i(j) = \varepsilon/[(r(\varepsilon)-1)\|c\|]\} \end{aligned} \tag{51}$$

and

$$\begin{aligned} \tilde{S}(\varepsilon,\delta_0) = \{&\beta^i(j,k) : i \in \mathbb{N},\ j \in \{1,\dots,r(\varepsilon)\},\ k \in \{1,\dots,k(\delta_0)\}, \\ &\text{and for each } i \in \mathbb{N} \text{ there are } j_i \text{ and } k_i \text{ such that } \beta^i(j_i,k_i) = 1 - \varepsilon/\|c\| \\ &\text{and for } j \neq j_i \text{ or } k \neq k_i,\ \beta^i(j,k) = \varepsilon/[(r(\varepsilon)k(\delta_0)-1)\|c\|]\}, \end{aligned} \tag{52}$$

where $\|\cdot\|$ is the supremum norm.

The following result is a continuity property of the invariant measures for the three models and is naturally associated with Propositions 4, 5, and 6.

PROPOSITION 7. i) *Consider Model* I *with the assumptions imposed on it. For* $\varepsilon' > 0$ *there is a* $\delta > 0$ *such that if* $\{\tilde{\beta}^i(j)\} \subset S(\varepsilon)$, $\alpha, \beta \in \mathcal{A}$, $u^j \in \mathcal{U}^1(\varepsilon)$, *and*

$$\liminf_{n\to\infty} \frac{1}{n} \sum_{i=0}^{n-1} \left| \sum_{j=1}^{r(\varepsilon)} \tilde{\beta}^i(j) K_{u^j}^1(\alpha,\beta) \right| < \delta,$$

then

$$\sup_{u \in \mathcal{U}^1(\varepsilon)} \|\pi_u^\alpha - \pi_u^\beta\|_{\text{var}} < \varepsilon'.$$

ii) *Consider Model* II *with the assumptions imposed on it. For* $\varepsilon' > 0$ *there is a* $\delta > 0$ *such that if* $\{\tilde{\beta}^i(j)\} \subset S(\varepsilon)$, $\alpha, \beta \in \mathcal{A}$, $u^j \in \mathcal{U}^2(\varepsilon)$, *and*

$$\liminf_{n\to\infty} \frac{1}{n} \sum_{i=0}^{n-1} \left| \sum_{j=1}^{r(\varepsilon)} \tilde{\beta}^i(j) K_{u^j}^2(\alpha,\beta) \right| < \delta,$$

then

$$\sup_{u\in\mathcal{U}^2(\varepsilon)} \|\pi_u^\alpha - \pi_u^\beta\|_{\text{var}} < \varepsilon'.$$

iii) *Consider Model* III *with the assumptions* (A1)–(A5). *For* $\varepsilon' > 0$ *there is a* $\delta > 0$ *such that if* $\{\tilde{\beta}^i(j,k)\} \subset \tilde{S}(\varepsilon,\delta_0)$, $\alpha,\beta \in \mathcal{A}$, $u^j \in \tilde{\mathcal{U}}(\varepsilon)$, *and*

$$\liminf_{n\to\infty} \frac{1}{n} \sum_{i=0}^{n-1} \left| \sum_{j=1}^{r(\varepsilon)} \sum_{k=1}^{k(\delta_0)} \tilde{\beta}^i(j,k) K_{u^j}^3(\alpha,\beta,\alpha(k)) \right| < \delta,$$

then

$$\sup_{u\in\tilde{\mathcal{U}}(\varepsilon)} \sup_{\gamma\in\tilde{\mathcal{A}}(\delta_0)} \left| \int_{\mathcal{P}(E)\times\mathcal{P}(E)} \int_E c(z,u(\nu_2))\nu_1(\mathrm{d}z)\Psi_{u(\gamma)}^\alpha(\mathrm{d}\nu_1,\mathrm{d}\nu_2) \right.$$

$$\left. - \int_{\mathcal{P}(E)\times\mathcal{P}(E)} \int_E c(z,u(\nu_2))\nu_1(\mathrm{d}z)\Psi_{u(\gamma)}^\beta(\mathrm{d}\nu_1,\mathrm{d}\nu_2) \right| < \varepsilon'.$$

Proof. Only the verifications of i) and iii) are given because the verification of ii) is similar to that of i).

Verifying by contradiction, assume that i) is not true. Then there are sequences $(\alpha_m,\, m\in\mathbb{N})$ and $(\beta_m,\, m\in\mathbb{N})$ and $\{\tilde{\beta}^{i_m}(j)\} \subset S(\varepsilon)$ such that $\alpha_m \to \alpha$, $\beta_m \to \beta$ as $m\to\infty$,

$$\limsup_{m\to\infty} \liminf_{n\to\infty} \frac{1}{n} \sum_{i=0}^{n-1} \left| \sum_{j=1}^{r(\varepsilon)} \tilde{\beta}^{i_m}(j) K_{u^j}^1(\alpha_m,\beta_m) \right| = 0, \tag{53}$$

and

$$\sup_{u\in\mathcal{U}^1(\varepsilon)} \|\pi_u^{\alpha_m} - \pi_u^{\beta_m}\|_{\text{var}} > \varepsilon'. \tag{54}$$

By (53) and the definition of $S(\varepsilon)$, it follows that

$$\lim_{m\to\infty} K_{u^j}^1(\alpha_m,\beta_m) = 0$$

for each $j\in\{1,\dots,r(\varepsilon)\}$. Thus, by Proposition 4, $K_{u^j}^1(\alpha,\beta) = 0$ for $j\in\{1,\dots,r(\varepsilon)\}$ and $\pi_{u^j}^\alpha = \pi_{u^j}^\beta$ for $j\in\{1,\dots,r(\varepsilon)\}$. By (24) it follows that

$$\lim_{m\to\infty} \sup_{u\in\mathcal{U}^1(\varepsilon)} \|\pi_u^{\alpha_m} - \pi_u^\alpha\|_{\text{var}} = 0$$

and

$$\lim_{m\to\infty} \sup_{u\in\mathcal{U}^1(\varepsilon)} \|\pi_u^{\beta_m} - \pi_u^\beta\|_{\text{var}} = 0.$$

These last two equalities contradict (54). This contradiction verifies i).

Now assume that iii) is not satisfied. Then there are sequences $(\alpha_m,\, m \in \mathbb{N})$ and $(\beta_m,\, m \in \mathbb{N})$ and $\{\tilde{\beta}^{i_m}(j,k)\} \subset \tilde{S}(\varepsilon, \delta_0)$ such that $\alpha_m \to \alpha$, $\beta_m \to \beta$ as $m \to \infty$,

$$\limsup_{m\to\infty} \liminf_{n\to\infty} \frac{1}{n} \sum_{i=0}^{n-1} \left| \sum_{j=1}^{r(\varepsilon)} \sum_{k=1}^{k(\delta_0)} \tilde{\beta}^{i_m}(j,k) K^3_{u^j}(\alpha_m, \beta_m, \alpha(k)) \right| = 0 \tag{55}$$

and

$$\sup_{u\in\tilde{\mathcal{U}}(\varepsilon)} \left| \int_{\mathcal{P}(E)\times\mathcal{P}(E)} \int_E c(z, u(\nu_2)) \nu_1(\mathrm{d}z) \Psi^{\alpha_m}_{u(\gamma)}(\mathrm{d}\nu_1, \mathrm{d}\nu_2) \right.$$

$$\left. - \int_{\mathcal{P}(E)\times\mathcal{P}(E)} \int_E c(z, u(\nu_2)) \nu_1(\mathrm{d}z) \Psi^{\alpha}_{u(\gamma)}(\mathrm{d}\nu_1, \mathrm{d}\nu_2) \right| \geq \varepsilon'. \tag{56}$$

By (55) and the definition of $\tilde{S}(\varepsilon, \delta_0)$, it follows that

$$\lim_{m\to\infty} K^3_{u^j}(\alpha_m, \beta_m, \alpha(k)) = 0$$

for $j \in \{1, \ldots, r(\varepsilon)\}$ and $k \in \{1, \ldots, k(\delta_0)\}$. Thus, by Proposition 6, $K^3_{u^j}(\alpha, \beta, \alpha(k)) = 0$ for $j \in \{1, \ldots, r(\varepsilon)\}$, $k \in \{1, \ldots, k(\delta_0)\}$, and

$$\Psi^{\alpha}_{u(\gamma)} = \Psi^{\beta}_{u(\gamma)}$$

for $u \in \tilde{\mathcal{U}}(\varepsilon)$ and $\gamma \in \tilde{\mathcal{A}}(\delta_0)$. In the proof of Theorem 6 of [18] it is shown that

$$\lim_{m\to\infty} \Psi^{\alpha_m}_{u(\gamma)} = \Psi^{\alpha}_{u(\gamma)}$$

and

$$\lim_{m\to\infty} \Psi^{\beta_m}_{u(\gamma)} = \Psi^{\beta}_{u(\gamma)}$$

in the weak* topology of $\mathcal{P}(E) \times \mathcal{P}(E)$. By the continuity of c in the cost functional (11) there is a contradiction to (56). This contradiction verifies iii). □

Fix $\varepsilon > 0$. For Models I and II let $\varepsilon' = \varepsilon/\|c\|$, and for Model III let $\varepsilon' = \varepsilon$. Using this ε' by Proposition 7, there is a $\delta > 0$ such that i), ii), and iii) are satisfied for Models I, II, and III, respectively. There is a $\bar{\delta} > 0$ such that the following are satisfied.

i) For Model I and $\alpha, \beta \in \mathcal{A}$, if $\rho_{\mathcal{A}}(\alpha, \beta) < \bar{\delta}$, then for each $u \in \mathcal{U}^1(\varepsilon)$

$$|K^1_u(\alpha, \beta)| < \delta/3 \tag{57}$$

and

$$\|\pi^{\alpha}_u - \pi^{\beta}_u\|_{\mathrm{var}} \leq \frac{\varepsilon}{\|c\|}. \tag{58}$$

ii) For Model II and $\alpha, \beta \in \mathcal{A}$, if $\rho_{\mathcal{A}}(\alpha, \beta) < \bar{\delta}$, then for each $u \in \mathcal{U}^2(\varepsilon)$

$$|K^2_u(\alpha, \beta)| < \delta/3 \tag{59}$$

and

$$\|\pi_u^\alpha - \pi_u^\beta\|_{\text{var}} \le \frac{\varepsilon}{\|c\|}. \tag{60}$$

iii) For Model III and $\alpha, \beta \in \mathcal{A}$, if $\rho_{\mathcal{A}}(\alpha,\beta) < \bar{\delta}$, then for each $u \in \tilde{\mathcal{U}}(\varepsilon)$ and $\gamma \in \tilde{\mathcal{A}}(\delta_0)$

$$|K_u^3(\alpha,\beta,\gamma)| < \delta/3 \tag{61}$$

and

$$\left| \int_{\mathcal{P}(E)\times\mathcal{P}(E)} \int_E c(z,u(\nu_2))\nu_1(\mathrm{d}z)\Psi_{u(\gamma)}^{\alpha_m}(\mathrm{d}\nu_1,\mathrm{d}\nu_2) \right.$$

$$\left. - \int_{\mathcal{P}(E)\times\mathcal{P}(E)} \int_E c(z,u(\nu_2))\nu_1(\mathrm{d}z)\Psi_{u(\gamma)}^{\alpha}(\mathrm{d}\nu_1,\mathrm{d}\nu_2) \right| \le \varepsilon. \tag{62}$$

The existence of $\bar{\delta} > 0$ follows in i) from Proposition 4 and (24), in ii) from Proposition 5 and (27), (29), (30), (31), and in iii) from Proposition 6 and the continuity of the map $\Psi : \mathcal{A}\times\mathcal{A} \to \mathcal{P}(E)\times\mathcal{P}(E)$, which follows from the proof of Theorem 6 of [18].

For $\bar{\delta} > 0$ there is a finite covering of $\mathcal{A}$ by balls of radius $\bar{\delta}$ with centers at distinguished points that is denoted $\mathcal{A}(\bar{\delta})$. For $\varepsilon > 0$ and $\delta > 0$ given above, there is a positive integer N whose existence is justified subsequently such that

i) for Model I

$$\sup_{x\in E}\sup_{u\in\mathcal{U}^1(\varepsilon)}\sup_{\alpha\in\mathcal{A}(\bar{\delta})}\sup_{\beta\in\mathcal{A}} \left| \frac{1}{N}\sum_{i=1}^{N-1} E_x^{\beta,u}\left[\ln\left(\frac{p(X_i,X_{i+1},u(X_i),\beta)}{p(X_i,x_{i+1},u(X_i),\alpha)}\right)\right] - K_u^1(\alpha,\beta)\right| < \delta/3 \tag{63}$$

and

$$\sup_{x\in E}\sup_{u\in\mathcal{U}^1(\varepsilon)}\sup_{\beta\in\mathcal{A}} \left| \frac{1}{N}\sum_{i=1}^{N-1} E_x^{\beta,u}[c(X_i,u(X_i))] - \int_E c(z,u(z))\pi_u^\beta(\mathrm{d}z)\right| < \varepsilon; \tag{64}$$

ii) for Model II

$$\sup_{x\in\Gamma}\sup_{u\in\mathcal{U}^2(\varepsilon)}\sup_{\alpha\in\mathcal{A}(\bar{\delta})}\sup_{\beta\in\mathcal{A}} \left| E_x^{\beta,u}\left[\frac{1}{2}\int_0^{\tau_N} |\sigma^{-1}(X(s))(h(X(s),\alpha,u(X(s)))\right.\right.$$

$$\left.\left. - h(X(s),\beta,u(X(s))))|^2\mathrm{d}s\right](E_x^{\beta,u}[\tau_N])^{-1} - K_u^2(\alpha,\beta)\right| < \delta/3 \tag{65}$$

and

$$\sup_{x\in\Gamma_1}\sup_{u\in\mathcal{U}^2(\varepsilon)}\sup_{\beta\in A} \left| E_x^{\beta,u}\left[\int_0^{\tau_N} c(X(s),u(X(s)))]\mathrm{d}s\right.\right.$$

$$\left.\left. \cdot(E_x^{\beta,u}[\tau_N])^{-1} - \int_E c(z,u(z))\pi_u^\beta(\mathrm{d}z)\right| < \varepsilon; \tag{66}$$

iii) for Model III

$$\sup_{x\in\Gamma}\sup_{u\in\tilde{\mathcal{U}}(\varepsilon)}\sup_{\alpha\in\mathcal{A}(\bar{\delta})}\sup_{\gamma\in\tilde{\mathcal{A}}(\delta_0)}\sup_{\beta\in\mathcal{A}}\left|E_x^{\beta,u(\gamma)}\left[\sum_{i=0}^{\tau_N-1}\ln\left(\frac{F(\Pi_i^{\beta},u(\Pi_i^{\gamma}),\beta)(Y_{i+1})}{F(\Pi_i^{\alpha},u(\Pi_i^{\gamma}),\alpha)(Y_{i+1})}\right)\right]\right.$$

$$\left.\cdot(E_x^{\beta,u}[\tau_N])^{-1}-K_u^3(\alpha,\beta,\gamma)\right|<\delta/3 \tag{67}$$

and

$$\sup_{x\in\Gamma}\sup_{u\in\tilde{\mathcal{U}}(\varepsilon)}\sup_{\gamma\in\tilde{\mathcal{A}}(\delta_0)}\sup_{\beta\in\mathcal{A}}\left|E_x^{\beta,u(\gamma)}\left[\sum_{i=0}^{\tau_N-1}\int_E c(z,u(\Pi_i^{\alpha}))\Pi_i^{\beta}(\mathrm{d}z)\right](E_x^{\beta,U(\gamma)}[\tau_N])^{-1}\right.$$

$$\left.-\int_{\mathcal{P}(E)\times\mathcal{P}(E)}\int_E c(z,u(\nu_2))\nu_1(\mathrm{d}z)\Psi_{u(\gamma)}^{\beta}(\mathrm{d}\nu_1,\mathrm{d}\nu_2)\right|<\varepsilon, \tag{68}$$

where Ψ is given in (50).

The following three lemmas justify the existence of N in (63)–(68).

LEMMA 1. *For Model* I *let*

$$L=\sup_{x,y\in E}\sup_{v\in U}\sup_{\alpha,\beta\in\mathcal{A}}\left|\ln\frac{p(x,y,v,\beta)}{p(x,y,v,\alpha)}\right|.$$

Then for $N\geq 3L/(\delta(1-\gamma_0))$ *the inequality* (63) *is satisfied, and for* $N\geq\|c\|/(\varepsilon(1-\gamma_0))$ *the inequality* (64) *is satisfied where* γ_0 *is as given in Proposition* 1.

Proof. By (23) it follows that

$$\left|E_x^{\beta,u}\left[\ln\frac{p(X_i,X_{i+1},u(X_i),\beta)}{p(X_i,X_{i+1},u(X_i),\alpha)}\right]-K_u^1(\alpha,\beta)\right|$$

$$=\left|E_x^{\beta,u}\left[\int_E\ln\left(\frac{p(X_i,y,u(X_i),\beta)}{p(X_i,y,u(X_i),\alpha)}\right)p(X_i,y,u(X_i),\beta)\varphi(\mathrm{d}y)\right]-K_u^1(\alpha,\beta)\right|\leq L\gamma_0^{i-1}$$

for $x\in E$, $\alpha,\beta\in\mathcal{A}$, $u\in\mathcal{U}^1(\varepsilon)$, and $i\in\mathbb{N}$. Thus for $N\geq 3L/\delta(1-\gamma_0)$, the inequality (63) is satisfied. In a similar way by (23) it follows that the inequality (64) is satisfied for $N\geq\|c\|/\varepsilon(1-\gamma_0)$. □

LEMMA 2. *For Model* II *let*

$$L=\sup_{x\in\mathbb{R}^n}\sup_{\alpha\in\mathcal{A}}\sup_{v\in U}\|h(x,\alpha,v)^*\sigma^{-1}(x)\|,$$

$$M_1=\sup_{x\in\Gamma_1}\sup_{\alpha\in\mathcal{A}}\sup_{u\in\mathcal{U}}E_x^{\alpha,u}[\tau],$$

and

$$M_2=\inf_{x\in\Gamma_1}\inf_{\alpha\in\mathcal{A}}\inf_{u\in\mathcal{U}}E_x^{\alpha,u}[\tau].$$

For

$$N\geq\frac{12}{\delta}L^2M_1\frac{1}{M_2(1-\gamma_0)}\left(1+\frac{M_1}{M_2}\right),$$

the inequality (65) *is satisfied, and for*

$$N \geq \frac{1}{\varepsilon}\|c\| M_1 \frac{1}{M_2(1-\gamma_0)}\left(1+\frac{M_1}{M_2}\right),$$

where γ_0 *is given in Proposition* 2, *the inequality* (66) *is satisfied.*

Proof. By (28) it follows that

$$\left|\frac{1}{i}E_x^{\beta,u}\left[\int_0^{\tau_{i+1}} |\sigma^{-1}(X(s))(h(X(s),\alpha,u(X(s))) - h(X(s),\beta,u(X(s))))|^2 \mathrm{d}s\right]\right.$$

$$\left. - \int_{\Gamma_1} E_x^{\beta,u}\left[\int_0^{\tau} |\sigma^{-1}(X(s))(h(X(s),\alpha,u(X(s)) - h(X(s),\beta,u(X(s)))|^2 \mathrm{d}s\right]\eta_u^{\beta}(\mathrm{d}z)\right|$$

$$\leq \frac{1}{i}\sum_{j=0}^{i}\gamma_0^i 4L^2 M_1 = \frac{1}{i}\frac{1-\gamma_0^{i+1}}{1-\gamma_0}4L^2M_1$$

and

$$\left|\frac{1}{i}E_x^{\beta,u}[\tau_{i+1}] - \int_{\Gamma_1} E_z^{\beta,u}[\tau]\eta_u^{\beta}(\mathrm{d}z)\right| \leq \frac{1}{i}\frac{1-\gamma_0^{i+1}}{1-\gamma_0}M_1$$

for $x \in \Gamma_1$, $\beta \in \mathcal{A}$, and $u \in \mathcal{U}$.

Combining the above two inequalities, (65) is satisfied for N stated in the lemma.

In a similar way, (66) is verified. □

LEMMA 3. *For Model* III *let*

$$L_1 = \sup_{x,y\in E}\sup_{v\in U}\sup_{\alpha\in\mathcal{A}} p(x,y,v,\alpha),$$

$$L_2 = \inf_{x,y\in E}\inf_{v\in U}\inf_{\alpha\in\mathcal{A}} p(x,y,v,\alpha),$$

$$M_1 = \sup_{x\in\Gamma}\sup_{u\in\tilde{\mathcal{U}}(\varepsilon)}\sup_{\gamma\in\tilde{\mathcal{A}}(\delta_0)}\sup_{\beta\in\mathcal{A}} E_x^{\beta,u(\gamma)}[\tau],$$

and

$$M_2 = \inf_{x\in\Gamma}\inf_{u\in\tilde{\mathcal{U}}(\varepsilon)}\inf_{\gamma\in\tilde{\mathcal{A}}(\delta_0)}\inf_{\beta\in\mathcal{A}} E_x^{\beta,u(\gamma)}[\tau].$$

For

$$N \geq \frac{3}{\delta}\ln\left(\frac{L_1}{L_2}\right) M_1 \frac{1}{M_2(1-\gamma_0)}\left(1+\frac{M_1}{M_2}\right),$$

the inequality (67) *is satisfied, and for*

$$N \geq \frac{\|c\|}{\varepsilon} M_1 \frac{1}{(1-\gamma_0)M_2}\left(1+\frac{M_1}{M_2}\right),$$

the inequality (68) *is satisfied where* γ_0 *is given in Proposition* 3.

Proof. As in the verification of Lemma 2 it follows by (40) that

$$\left|\frac{1}{i}E_x^{\beta,u(\gamma)}\left[\sum_{j=0}^{\tau_{i+1}-1}\ln\frac{F(\Pi_j^\beta,u(\Pi_j^\gamma),\beta)(Y_{j+1})}{F(\Pi_j^\alpha,u(\Pi_j^\gamma),\alpha)(Y_{j+1})}\right]\right.$$

$$\left.-\int_\Gamma E_x^{\beta,u(\gamma)}\left[\sum_{j=0}^{\tau-1}\ln\frac{F(\Pi_j^\beta,u(\Pi_j^\gamma),\beta)(Y_{j+1})}{F(\Pi_j^\alpha,u(\Pi_j^\gamma),\alpha)(Y_{j+1})}\right]\cdot\eta_{u(\gamma)}^\beta(\mathrm{d}x)\right|\le\frac{1}{i}\frac{1-\gamma_0^{i+1}}{1-\gamma_0}\ln\left(\frac{L_1}{L_2}\right)M_1$$

and

$$\left|\frac{1}{i}E_x^{\beta,u(\gamma)}[\tau_{i+1}]-\int_\Gamma E_z^{\beta,u(\gamma)}[\tau]\eta_{u(\gamma)}^\beta(\mathrm{d}z)\right|\le\frac{1}{i}\frac{1-\gamma_0^{i+1}}{1-\gamma_0}M_1$$

for $x\in\Gamma$, $\beta\in\mathcal{A}$, $\gamma\in\tilde{\mathcal{A}}(\delta_0)$, $u\in\tilde{\mathcal{U}}(\varepsilon)$. These inequalities imply the inequalities for N for which (67) and (68) are satisfied. □

Now the construction of the almost self-optimal controls can be completed. Again, it is subdivided into the three models.

i) For Model I let $\hat{\alpha}_{jN}$ be a maximizer of

$$L_{jN}^1(\alpha)=\sum_{i=0}^{jN-1}\ln p(X_i,X_{i+1},v_i,\alpha) \tag{69}$$

over $\alpha\in\mathcal{A}(\bar{\delta})$, where v_i is the control at time i. The control v_i is a randomized certainty equivalence control. For $i\in\{jN:j\in\mathbb{N}\}$, choose the control $u_{jN}\in\mathcal{U}^1(\varepsilon)$ randomly among $(u^k,\,k=1,\dots,r(\varepsilon))$ as

$$P(u_{jN}=u^{k_0}|X(0),\dots,X(jN))=1-\frac{\varepsilon}{\|c\|}, \tag{70}$$

where u^{k_0} is the almost optimal control for $\alpha=\hat{\alpha}_{jN}$ in $\mathcal{U}^1(\varepsilon)$ and

$$P(u_{jN}=u^k|X(0),\dots,X(jN))=\frac{\varepsilon}{(r(\varepsilon)-1)\|c\|} \tag{71}$$

for $k=\{1,\dots,r(\varepsilon)\}\setminus\{k_0\}$. The control u_{jN} is also used at the times $jN+1,\dots,(j+1)N-1$; that is,

$$v_i=u_{jN}(X_i) \tag{72}$$

for $i=\{jN,\dots,(j+1)N-1\}$.

ii) For Model II, let $\hat{\alpha}(\tau_{jN})$ be a minimizer of

$$L^2(\tau_{jN})=\int_0^{\tau_{jN}}|\sigma^{-1}(X(s))(h(X(s),\alpha,v(s))-h(X(s),\alpha^0,v(s)))|^2\mathrm{d}s \tag{73}$$

over $\alpha\in\mathcal{A}(\delta)$. The control in $[\tau_{jN},\,\tau_{(j+1)N})$ is $u(\tau_{jN})\in U^2(\varepsilon)$, that is, a randomized certainty equivalence control such that

$$P(u(\tau_{jN})=u^{k_0}|X(s),\,0\le s\le\tau_{jN})=1-\frac{\varepsilon}{\|c\|} \tag{74}$$

and

$$P(u(\tau_{jN}) = u^k | X(s),\, 0 \le s \le \tau_{jN}) = \frac{\varepsilon}{(r(\varepsilon)-1)\|c\|} \tag{75}$$

for $k = \{1, \dots, r(\varepsilon)\} \setminus \{k_0\}$ and u^{k_0} is almost optimal for $\hat{\alpha}(\tau_{jN})$.

iii) For Model III let $\hat{\alpha}(\tau_{jN})$ be a maximizer of

$$L^3_{\tau_{jN}}(\alpha) = \sum_{i=0}^{\tau_{jN}-1} \ln F(\Pi^{\alpha}_i, v_i, \alpha)(Y_{i+1}) \tag{76}$$

over $\alpha \in \mathcal{A}(\bar{\delta})$. The controls $\hat{v}(\tau_{jN}), \hat{v}(\tau_{jN+1}), \dots, \hat{v}(\tau_{(j+1)N-1})$ are selected by a randomized certainty equivalence rule such that

$$P(\hat{v}(\tau_{jN}) = u^{k_0}(\Pi^{\alpha(l_0)}_{\tau_{jN}}), \dots, \hat{v}(\tau_{(j+1)N-1}) = u^{k_0}(\Pi^{\alpha(l_0)}_{\tau_{(j+1)N-1}}) | \mathcal{Y}(\tau_{jN})) = 1 - \frac{\varepsilon}{\|c\|} \tag{77}$$

and

$$\begin{aligned} P(\hat{v}(\tau_{jN}) &= u^k(\Pi^{\alpha(l)}_{\tau_{jN}}), \dots, \hat{v}(\tau_{(j+1)N-1}) = u^k(\Pi^{\alpha(l)}_{\tau_{(j+1)N-1}}) | \mathcal{Y}(\tau_{jN})) \\ &= \frac{\varepsilon}{(r(\varepsilon)k(\varepsilon)-1)\|c\|}, \end{aligned} \tag{78}$$

where $k \in \{1, \dots, r(\varepsilon)\} \setminus \{k_0\}$, $j \in \{1, \dots, \mathrm{card}(\tilde{\mathcal{A}}(\delta_{k_0}))\}$, and $u^{k_0}(\Pi^{\alpha(l_0)}_{\tau_{jN}})$ is almost optimal for $\hat{\alpha}(\tau_{jN})$.

Let $(\hat{v}_i,\, i \in \mathbb{N})$ or $(\hat{v}(s),\, s \ge 0)$ be the discrete or the continuous time randomized certainty equivalence control defined in i), ii), or iii) above. Let $(\bar{\beta}_i,\, i \in \mathbb{N})$, $(\bar{\beta}(s),\, s \ge 0)$, and $(\tilde{\beta}_i,\, i \in \mathbb{N})$ be processes with values in $\{1, \dots, r(\varepsilon)\}$ for the first two processes and in $\{(j,k) : j = 1, \dots, r(\varepsilon) \text{ and } k = 1, \dots, k(\delta_0)\}$ for the third process such that the first two processes correspond to the index of the control in $\mathcal{U}^i(\varepsilon)$, $i = 1, 2$, at each time and the third process (for Model III) is the index of the control function and the index of the element of $\tilde{\mathcal{A}}(\delta_0)$.

The following result is the almost self-optimality of the randomized certainty equivalence control for the three Models I, II, and III.

THEOREM 1. *Let $\varepsilon > 0$ be fixed. Let I^i be the pathwise cost functional for $i = 1, 2, 3$ given by* (2), (8), *and* (11), *respectively, for Models* I, II, *and* III, *respectively, and let $\lambda_i(\alpha^0)$ be the optimal cost for $i = 1, 2, 3$ for parameter α^0. Let $(\hat{v}_i,\, i \in \mathbb{N})$ and $(\hat{v}(s),\, s \ge 0)$ be the randomized certainty equivalence controls given above. For the Models* I, II, *and* III *the following inequalities are satisfied:*

$$\text{(i) } I^1((\hat{v}_n,\, n \in \mathbb{N})) \le \lambda_1(\alpha^0) + 6\varepsilon \quad a.s., \tag{79}$$

$$\text{(ii) } I^2((\hat{v}(s),\, s \ge 0)) \le \lambda_2(\alpha^0) + 6\varepsilon \quad a.s., \tag{80}$$

$$\text{(iii) } I^3((\hat{v}_n,\, n \in \mathbb{N})) \le \lambda_3(\alpha^0) + 6\varepsilon \quad a.s. \tag{81}$$

Proof. Initially consider Model I. By the definition of $\hat{\alpha}_{jN}$, it follows that

$$\sum_{i=0}^{jN-1} \ln \frac{p(X_i, X_{i+1}, \hat{v}_i, \hat{\alpha}_{jN})}{p(X_i, X_{i+1}, \hat{v}_i, \alpha^0)} \ge \sum_{i=0}^{jN-1} \ln \frac{p(X_i, X_{i+1}, \hat{v}_i, \bar{\alpha}^0)}{p(X_i, X_{i+1}, \hat{v}_i, \alpha^0)}, \tag{82}$$

where $\bar{\alpha}^0$ is an element in $\mathcal{A}(\bar{\delta})$ of minimum distance to α^0.

By the law of large numbers for martingales for $\alpha \in \mathcal{A}(\bar{\delta})$,

$$\lim_{n\to\infty} \frac{1}{n}\Bigg(\sum_{i=0}^{nN-1} \ln \frac{p(X_i, X_{i+1}, \hat{v}_i, \alpha)}{p(X_i, X_{i+1}, \hat{v}_i, \alpha^0)}$$

(83)
$$- \sum_{i=0}^{n-1} E^{\alpha^0}\Bigg[\sum_{j=iN}^{(i+1)N-1} \ln \frac{p(X_i, X_{i+1}, \hat{v}_i, \alpha)}{p(X_i, X_{i+1}, \hat{v}_i, \alpha^0)} \Bigg| X_0, \ldots, X_{iN}, \bar{\beta}_0, \ldots, \bar{\beta}_{iN} \Bigg] \Bigg) = 0 \quad \text{a.s.},$$

$$\lim_{n\to\infty} \frac{1}{n}\Bigg(\sum_{i=0}^{nN-1} c(X_i, \hat{v}_i)$$

$$(84) \qquad - \sum_{i=0}^{n-1} E^{\alpha^0}\Bigg[\sum_{j=iN}^{(i+1)N-1} c(X_j, \hat{v}_j) \Bigg| X_0, \ldots, X_{iN}, \bar{\beta}_0, \ldots, \bar{\beta}_{iN} \Bigg] \Bigg) = 0 \quad \text{a.s.},$$

$$(85) \qquad \limsup_{n\to\infty} \frac{1}{n} \sum_{i=0}^{n-1} \left(K^1_{u_{iN}}(\alpha, \alpha^0) - \sum_{j=1}^{r(\varepsilon)} \beta^i(j) K^1_{u^j}(\alpha, \alpha^0) \right) = 0 \quad \text{a.s.},$$

and

$$\limsup_{n\to\infty} \frac{1}{n} \sum_{i=0}^{n-1} J^{\hat{\alpha}_{iN},1}((u_{iN}(X_l),\, l \in \mathbb{N}))$$

$$(86) \qquad - \sum_{j=1}^{r(\varepsilon)} \beta^i(j) J^{\hat{\alpha}_{iN},1}((u^j(X_l),\, l \in \mathbb{N})) = 0 \quad \text{a.s.},$$

where $\beta^i(j) = P(\bar{\beta}_i = j | X_0, \ldots, X_{iN})$, and in the last equality the control functions u_{iN} and u^j are used and their costs are evaluated. Let $\mathcal{N}$ be a null set such that the above four equalities are satisfied on $\mathcal{N}^{\mathrm{c}}$. Let $F(\bar{\delta}) = \{\alpha \in \mathcal{A}(\bar{\delta}) : \text{there is an } \omega \in \Omega \backslash \mathcal{N}$ such that α is a frequent point of $(\hat{\alpha}_{jN}(\omega))\}$. In many subsequent expressions, the random variables are evaluated at some $\omega \in \Omega \setminus \mathcal{N}$ but this evaluation is suppressed for notational convenience. If $\alpha \in F(\bar{\delta})$ then for a corresponding $\omega \in \Omega \setminus \mathcal{N}$ it follows from (82), (83) that

$$(87) \qquad \limsup_{n\to\infty} \frac{1}{n} \sum_{i=0}^{n-1} E^{\alpha^0, u_{iN}}_{X_{iN}} \left[\sum_{j=iN}^{(i+1)N-1} \ln \frac{p(X_j, X_{j+1}, u_{iN}(X_j), \alpha^0)}{p(X_j, X_{j+1}, u_{iN}(X_j), \alpha)} \right]$$

$$\geq \limsup_{n\to\infty} \frac{1}{n} \sum_{i=0}^{n-1} E^{\alpha^0, u_{iN}}_{X_{iN}} \left[\sum_{j=iN}^{(i+1)N-1} \ln \frac{p(X_j, X_{j+1}, u_{iN}(X_j), \alpha^0)}{p(X_j, X_{j+1}, u_{iN}(X_j), \bar{\alpha})} \right]$$

for each $\bar{\alpha} \in \mathcal{A}(\bar{\delta})$. By (63) it follows that

$$\limsup_{n\to\infty} \frac{1}{n} \sum_{i=0}^{n-1} K^1_{u_{iN}}(\alpha, \alpha^0) + \frac{\delta}{3} \geq \limsup_{n\to\infty} \frac{1}{n} \sum_{i=0}^{n-1} K^1_{u_{iN}}(\bar{\alpha}, \alpha^0) - \frac{\delta}{3}. \tag{88}$$

Thus, by (57),

$$\limsup_{n\to\infty} \frac{1}{n} \sum_{i=0}^{n-1} K^1_{u_{iN}}(\alpha, \alpha^0) \geq -\delta, \tag{89}$$

and by (85),

$$\limsup_{n\to\infty} \frac{1}{n} \sum_{i=0}^{n-1} \sum_{j=1}^{r(\varepsilon)} \beta^i(j) K^1_{u^j}(\alpha, \alpha^0) \geq -\delta. \tag{90}$$

Therefore, by Proposition 7 with $\varepsilon^1 = \varepsilon/\|c\|$,

$$\sup_{u \in \mathcal{U}^1(\varepsilon)} \|\pi^{\alpha}_u - \pi^{\alpha^0}_u\|_{\text{var}} < \frac{\varepsilon}{\|c\|}. \tag{91}$$

By (84)

$$I^1((\hat{v}_n,\, n \in \mathbb{N})) = \limsup_{n\to\infty} \frac{1}{n} \sum_{i=0}^{n-1} E^{\alpha^0, u_{iN}}_{X_{iN}} \left[\sum_{j=iN}^{(i+1)N-1} c(X_j, u_{iN}(X_j)) \right] \quad \text{a.s.}, \tag{92}$$

so by (64),

$$I^1((\hat{v}_n,\, n \in \mathbb{N})) \leq \limsup_{n\to\infty} \frac{1}{n} \sum_{i=0}^{n-1} \int_E c(z, u_{iN}(z)) \pi^{\alpha^0}_{u_{iN}}(\mathrm{d}z) + \varepsilon \quad \text{a.s.} \tag{93}$$

For $\omega \in \Omega \setminus \mathcal{N}$ it follows from (93) that

$$I^1((\hat{v}_n,\, n \in \mathbb{N})) \leq \limsup_{n\to\infty} \frac{1}{n} \sum_{i=0}^{n-1} 1_{F(\bar{\delta})}(\hat{\alpha}_{iN}) \int_E c(z, u_{iN}(z)) \pi^{\alpha^0}_{u_{iN}}(\mathrm{d}z) + \varepsilon. \tag{94}$$

For $\alpha \in F(\bar{\delta})$, (91) is satisfied, so for $\omega \in \Omega \setminus \mathcal{N}$

$$I^1((\hat{v}_n,\, n \in \mathbb{N})) \leq \limsup_{n\to\infty} \frac{1}{n} \sum_{i=0}^{n-1} 1_{F(\bar{\delta})}(\hat{\alpha}_{iN}) \int_E c(z, u_{iN}(z)) \pi^{\hat{\alpha}_{iN}}_{u_{iN}}(\mathrm{d}z) + 2\varepsilon$$

$$= \limsup_{n\to\infty} \frac{1}{n} \sum_{i=0}^{n-1} J^{\hat{\alpha}_{iN},1}((u_{iN}(X_l),\, l \in \mathbb{N})) + 2\varepsilon. \tag{95}$$

For $\omega \in \Omega \setminus \mathcal{N}$ it follows by (86) that

$$I^1((\hat{v}_n,\, n \in \mathbb{N})) \leq \limsup_{n\to\infty} \frac{1}{n} \sum_{i=0}^{n-1} \sum_{j=1}^{r(\varepsilon)} \beta_i(j) J^{\hat{\alpha}_{iN},1}((u^j(X_l),\, l \in \mathbb{N})) + 2\varepsilon. \tag{96}$$

Using the definition of $\beta^i(j)$ and (25) it follows that for $\omega \in \Omega \setminus \mathcal{N}$

$$I^1((\hat{v}_n,\, n \in \mathbb{N})) \le \limsup_{n\to\infty} \frac{1}{n} \sum_{i=0}^{n-1} \left(1 - \frac{\varepsilon}{\|c\|}\right) \lambda_1(\hat{\alpha}_{iN}) + 3\varepsilon$$

$$\le \limsup_{n\to\infty} \frac{1}{n} \sum_{i=0}^{n-1} \lambda_1(\hat{\alpha}_{iN}) + 3\varepsilon \le \limsup_{n\to\infty} \frac{1}{n} \sum_{i=0}^{n-1} 1_{F(\bar{\delta})}(\hat{\alpha}_{iN}) \lambda_1(\hat{\alpha}_{iN}) + 3\varepsilon. \tag{97}$$

By (25) and (91) it follows that for $\alpha \in F(\bar{\delta})$

$$|\lambda_1(\alpha) - \lambda_1(\alpha^0)| \le 2\varepsilon + \sup_{u \in \mathcal{U}^1(\varepsilon)} \left| \int_E c(x, u(x)) (\pi_u^{\alpha}(\mathrm{d}x) - \pi_u^{\alpha^0}(\mathrm{d}x)) \right| \le 3\varepsilon. \tag{98}$$

Thus for $\omega \in \Omega \setminus \mathcal{N}$

$$I^1((\hat{v}_n,\, n \in \mathbb{N})) \le \limsup_{n\to\infty} \frac{1}{n} \sum_{i=0}^{n-1} 1_{F(\bar{\delta})}(\hat{\alpha}_{iN}) \lambda_1(\alpha^0) + 6\varepsilon = \lambda_1(\alpha^0) + 6\varepsilon.$$

The inequality (79) is verified.

Now consider Model III. By the construction of $\hat{\alpha}(\tau_{jN})$ it follows that

$$\sum_{i=0}^{\tau_{jN}-1} \ln \frac{F(\Pi_i^{\hat{\alpha}_{\tau_{jN}}}, \hat{v}_i, \hat{\alpha}_{\tau_{jN}})(Y_{i+1})}{F(\Pi_i^{\alpha^0}, \hat{v}_i, \alpha^0)(Y_{i+1})} \ge \sum_{i=0}^{\tau_{jN}-1} \ln \frac{F(\Pi_i^{\bar{\alpha}_i}, \hat{v}_i, \bar{\alpha}^0)(Y_{i+1})}{F(\Pi_i^{\alpha^0}, \hat{v}_i, \alpha^0)(Y_{i+1})}. \tag{99}$$

In analogy to (83)–(86), by the law of large numbers for martingales it follows that for $\alpha \in \mathcal{A}(\bar{\delta})$,

$$\lim_{n\to\infty} \frac{1}{n} \Bigg(\sum_{i=0}^{\tau_{nN}-1} \ln \frac{F(\Pi_i^{\bar{\alpha}_i}, \hat{v}_i, \alpha^0)(Y_{i+1})}{F(\Pi_i^{\alpha^0}, \hat{v}_i, \alpha)(Y_{i+1})}$$

$$- \sum_{i=0}^{\tau_{nN}-1} E^{\alpha^0} \Bigg[\sum_{j=\tau_{iN}}^{\tau_{(i+1)N}-1} \ln \frac{F(\Pi_i^{\bar{\alpha}_i}, \hat{v}_i, \alpha^0)(Y_{i+1})}{F(\Pi_i^{\alpha^0}, \hat{v}_i, \alpha)(Y_{i+1})} \Big| \mathcal{Y}(\tau_{iN}), \bar{\beta}_0, \ldots, \bar{\beta}_{\tau_{iN}} \Bigg] \Bigg) = 0 \qquad \text{a.s.}, \tag{100}$$

$$\lim_{n\to\infty} \frac{1}{n} \left(\tau_{nN} - \sum_{i=0}^{n-1} E^{\alpha^0} \left[\tau_{(i+1)N} - \tau_{iN} | \mathcal{Y}(\tau_{iN}), \bar{\beta}_0, \ldots, \bar{\beta}_{\tau_{iN}} \right] \right) = 0 \qquad \text{a.s.}, \tag{101}$$

$$\lim_{n\to\infty} \frac{1}{n} \Bigg(\sum_{i=0}^{\tau_{nN}} c(X_i, \hat{v}_i)$$

$$- \sum_{i=0}^{n-1} E^{\alpha^0} \Bigg[\sum_{j=\tau_{iN}}^{\tau_{(i+1)N}-1} \int_E c(z, \hat{v}_i) \Pi_i^{\alpha^0}(\mathrm{d}z) | \mathcal{Y}(\tau_{iN}), \bar{\beta}_0, \ldots, \bar{\beta}_{\tau_{iN}} \Bigg] \Bigg) = 0 \qquad \text{a.s.}, \tag{102}$$

(103)
$$\limsup_{n\to\infty}\frac{1}{n}\sum_{i=0}^{n-1}\left(K^3_{u_{\tau_{iN}}}(\alpha,\alpha^0,\tilde{\alpha}_{\tau_{iN}})-\sum_{j=1}^{r(\varepsilon)}\sum_{k=1}^{k(\delta_0)}\beta^i(j,k)K^3_{u^j}(\alpha,\alpha^0,\alpha(k))\right)=0 \qquad \text{a.s.},$$

$$\limsup_{n\to\infty}\frac{1}{n}\sum_{i=0}^{n-1}(J^{\hat{\alpha}_{\tau_{iN}},3}(u_{\tau_{iN}}(\Pi_l^{\tilde{\alpha}_{\tau_{iN}}}),\, l\in\mathbb{N}))$$

(104)
$$-\sum_{j=1}^{r(\varepsilon)}\sum_{k=1}^{k(\delta_0)}\beta^i(j,k)(J^{\hat{\alpha}_{\tau_{iN}},3}(u^j(\Pi_l^{\tilde{\alpha}_{\tau_{iN}}}),\, l\in\mathbb{N}))=0 \qquad \text{a.s.},$$

where $\tilde{\alpha}_{\tau_{iN}}$ is the element of $\tilde{\mathcal{A}}(\delta_0)$ chosen at time τ_{iN} in the construction of the control $\hat{v}_{\tau_{iN}}$,

$$\beta_i(j,k)=P(\tilde{\beta}_{\tau_{iN}}=(j,k)|\mathcal{Y}(\tau_{iN})),$$

and $J^{\alpha,3}$ is the evaluation of the average cost for $\alpha\in\mathcal{A}$. If $\alpha\in\mathcal{A}(\bar{\delta})$ for some $\omega\in\Omega\setminus\mathcal{N}$ is a frequent point of the estimation, then similar to (87)–(90), by (62), (67), (99) it follows that

$$\liminf_{n\to\infty}\frac{1}{n}\sum_{i=0}^{n-1}\sum_{j=1}^{r(\varepsilon)}\sum_{k=1}^{k(\delta_0)}\beta^i(j,k)K^3_{u^j}(\alpha,\alpha^0,\alpha(k))\geq-\delta,$$

so by Proposition 7

$$\sup_{u\in\tilde{\mathcal{U}}(\varepsilon)}\sup_{\beta\in\tilde{\mathcal{A}}(\delta_0)}\left|\int_{\mathcal{P}(E)\times\mathcal{P}(E)}\int_E c(z,u(\nu_2))\nu_1(\mathrm{d}z)\Psi^{\alpha}_{u(\beta)}(\mathrm{d}\nu_1,\mathrm{d}\nu_2)\right.$$

(105)
$$\left.-\int_{\mathcal{P}(E)\times\mathcal{P}(E)}\int_E c(z,u(\nu_2))\nu_1(\mathrm{d}z)\Psi^{\alpha^0}_{u(\beta)}(\mathrm{d}\nu_1,\mathrm{d}\nu_2)\right|<\varepsilon.$$

By (68), (101), (102) it follows that

$$J^{\alpha^0,3}((\hat{v}_n,\, n\in\mathbb{N}))$$

$$\leq\limsup_{n\to\infty}\frac{1}{n}\sum_{i=0}^{n-1}\int_{\mathcal{P}(E)\times\mathcal{P}(E)}\int_E c(z,u(\nu_2))\nu_1(\mathrm{d}z)\Psi^{\alpha^0}_{u_{\tau_{iN}}(\tilde{\alpha}_{\tau_{iN}})}(\mathrm{d}\nu_1,\mathrm{d}\nu_2)+\varepsilon.$$

Let $F(\bar{\delta})$ be the set given by $F(\bar{\delta})=\{\alpha\in\mathcal{A}(\bar{\delta}):$ there is an $\omega\in\Omega\setminus\mathcal{N}$ such that α is a frequent point of $\hat{\alpha}_{\tau_{iN}}(\omega)\}$. By (104), (105) it follows that

$$I^3((\hat{v}_n,\, n\in\mathbb{N}))\leq\limsup_{n\to\infty}\frac{1}{n}\sum_{i=0}^{n-1}1_{F(\delta)}(\hat{\alpha}_{\tau_{iN}})$$

$$\cdot\int_{\mathcal{P}(E)\times\mathcal{P}(E)}\int_E c(z,u(\nu_2))\nu_1(\mathrm{d}z)\Psi^{\hat{\alpha}_{\tau_{iN}}}_{u_{\tau_{iN}}(\tilde{\alpha}_{\tau_{iN}})}(\mathrm{d}\nu_1,\mathrm{d}\nu_2)+2\varepsilon,$$

so by (104)

$$I^3((\hat{v}_n,\, n \in \mathbb{N})) \le \limsup_{n\to\infty} \frac{1}{n} \sum_{i=0}^{n-1} \sum_{j=1}^{r(\varepsilon)} \sum_{k=1}^{k(\delta_0)} \beta^i(j,k)$$

$$\cdot J^{\hat{\alpha}_{\tau_{iN}},3}(u^j(\pi_l^{\alpha(k)}),\, l \in \mathbb{N}) + 2\varepsilon.$$

Similar to (97), it follows by (104) that

$$I^3((\hat{v}_n,\, n \in \mathbb{N})) \le \limsup_{n\to\infty} \frac{1}{n} \sum_{i=0}^{n-1} 1_{F(\bar{\delta})}(\hat{\alpha}_{\tau_{iN}}) \lambda_3(\hat{\alpha}_{\tau_{iN}}) + 3\varepsilon.$$

For $\alpha \in F(\bar{\delta})$ it follows from (41), (104) that

$$|\lambda_3(\alpha) - \lambda_3(\alpha^0)| \le 3\varepsilon$$

and

$$I^3((\hat{v}_n,\, n \in \mathbb{N})) \le \lambda_3(\alpha^0) + 6\varepsilon \quad \text{a.s.}$$

This verifies the inequality (81).

The verification of the inequality (80) for Model II is similar to the verification of (79) and (81), and is thereby omitted. □

5. Some other adaptive algorithms. The existence of a finite family of almost optimal controls that is shown in section 2 can be used in the construction of some other algorithms. Three such algorithms are i) maximum likelihood estimation with forcing, ii) cost watching with forcing, and iii) cost watching with randomization. The forcing algorithms (cf., e.g., [2]) are based on the forced use of all of the almost optimal controls successively at times $(T_n,\, n \in \mathbb{N})$ such that

$$\limsup_{n\to\infty} \frac{1}{n} \sum_{i=0}^{n-1} 1_{\{T_j,\, j\in\mathbb{N}\}}(i) = 0,$$

so that the forcing does not affect the value of the cost functional. The notion of cost watching is to compare the average costs incurred for each of the almost optimal controls. For cost watching during the nonforcing times, a control that has minimal average cost is used. For cost watching with randomization the control for which the current average cost is minimal is chosen with probability almost 1, and the other controls are chosen with small probability. It seems that the algorithms with forcing should converge slowly, but they have a simple construction. The algorithm given in section 4 is more complicated and requires some continuity properties of the invariant measures with respect to the information. A comparative analysis of the above algorithms requires further study.

DYNAMICS OF TIME-VARYING DISCRETE-TIME LINEAR SYSTEMS: SPECTRAL THEORY AND THE PROJECTED SYSTEM*

FABIAN WIRTH†

Abstract. We study structural properties of linear time-varying discrete-time systems. At first an associated system on projective space is introduced as a basic tool to understand the linear dynamics. We study controllability properties of this system and characterize in particular the control sets and their cores. Sufficient conditions for an upper bound on the number of control sets with nonempty interior are given. Furthermore, exponential growth rates of the linear system are studied. Using finite-time controllability properties in the cores of control sets the Floquet spectrum of the linear system may be described. In particular, the closure of the Floquet spectrum is contained in the Lyapunov spectrum.

Key words. time-varying, discrete-time, control sets, universal controls, projected system, Bohl exponents, Floquet exponents, Lyapunov exponents

1. Introduction.

In recent years spectral theory for time-varying linear systems has attracted renewed interest. While the foundations of the theory were laid by Floquet [25], Lyapunov [40], and Bohl [16] the introduction of the problems and considerations of control posed new questions to which different approaches have been proposed.

Here we present an approach to the spectral theory of families of discrete-time time-varying linear systems of the form

$$x(t+1) = A(u(t))x(t), \quad t \in \mathbb{N},$$

where the entries of A depend analytically on the time-varying parameter u, which takes values in a prescribed set. In order to gain insight into the dynamics of this system the system that is obtained by projecting on projective space is analyzed. This approach leads to two generalizations of objects well understood for time-invariant systems. The concept of eigenspace is extended to what is called a control set on projective space that is a set characterized by certain controllability properties. Eigenvalues find natural and well-understood generalizations in Floquet, Lyapunov, and Bohl exponents. We examine these different exponential growth rates and how control sets may be employed to characterize them.

Exponential stability is characterized by the Bohl exponent of a time-varying linear system [16]; see also [24]. Przyłuski and Rolewicz studied Bohl exponents (or generalized spectral radii, in their terminology) for discrete-time systems in [46], with further work appearing in [43]–[45]. On the other hand, Lyapunov exponents characterize exponential growth along trajectories. Properties of Lyapunov exponents were studied by Barabanov in [8]–[11], where sufficient conditions so that Lyapunov exponents characterize exponential stability for families of time-varying systems are shown. Berger and Wang [15], Lagarias and Wang [38], and Gurvits [27] study the

†Institut für Dynamische Systeme, Universität Bremen, D-28344 Bremen, Germany (fabian@math.uni-bremen.de)

joint and the generalized spectral radii given by a discrete inclusion (not to be confused with the notion of generalized spectral radius due to Przyłuski and Rolewicz). The works cited so far are concerned mainly with the largest exponents characterizing stability. In this article we are interested in the complete spectrum of exponential growth rates associated with the system. Also, we will briefly discuss the relation between the different notions appearing in the literature.

The basic idea of our approach is to study a system on projective space that can be constructed from the linear system by Bogolyubov's projection introduced by Has'minskii [28]. The study of this projection in connection with control theory has found numerous applications for continuous-time systems in the analysis of the Lyapunov spectrum. For deterministic systems, the work of Colonius and Kliemann [20], [21], [22] presents a full picture of what is known. In particular, the relation to exponential dichotomies and the dynamical spectrum as studied by Sacker and Sell [47] and Johnson, Palmer, and Sell [35] is analyzed in these references.

Interest in the complete spectrum of the linear system stems from diverse lines of research. One of these is the question of robust stability. Let $A(u_0)$ be a Hurwitz stable matrix (i.e., the spectrum of $A(u_0)$ consists of values with negative real part) and interpret U as a set determining the structure of possible perturbations to the time-invariant system given by $\dot{x} = A(u_0)x$. The problem of robust stability is to determine whether the perturbed system is exponentially stable under all possible perturbations $u : \mathbb{R} \to U$ that are, e.g., piecewise continuous; see Hinrichsen, Ilchmann, and Pritchard [29], [30] and Colonius and Kliemann [19]. The discrete-time problem has been treated by Wirth and Hinrichsen in [57], [55].

Interpreting u as a control term, knowledge about the set of exponential growth rates or Lyapunov exponents can be employed in the stabilization of such systems; see Colonius, Kliemann, and Krull [23] and Grüne [26].

If $u(t)$ is given a stochastic interpretation we are in the realm of stochastic systems. This problem was treated for continuous-time systems by Has'minskii [28], Arnold, Kliemann, and Oeljeklaus [6], Arnold and Kliemann [5], and Arnold and San Martin [7]. The discrete-time case was studied by Homblé in [32], [33] and Baxendale and Has'minskii [14], however, with the restriction that the discrete-time system is invertible.

In this article we wish to lay the foundation for the theory and treat some of the difficulties inherent in the discrete-time case. It is explained how the problem of noninvertibility can be partially overcome while retaining the possibility of obtaining a reasonable system on projective space. We study asymptotic properties of the projected system, show the existence of controls with universal properties, and examine the controllability structure of the projected system. This supplies the tools we need for an analysis of the different spectra.

We proceed as follows. Section 2 contains the problem statement along with the assumptions we make. In section 3 we study accessibility, transitivity, and regularity of discrete-time systems. Orbits and regular orbits are introduced and it is explained why forward accessibility can be characterized by the rank of a Jacobian. This has been noted by several other authors [41], [32]. What is particularly useful in the case of the projected system is that by Proposition 3.6 it is not necessary to check this in local coordinates on the projective space $\mathbb{P}^{n-1}_{\mathbb{K}}$.

In section 4 we exhibit some asymptotic properties of the system on projective space. The study of ω-limit sets follows the approach of Colonius and Kliemann [20] and is standard if the projections of linear systems on projective space are studied.

Using the regularity arguments from section 3 we obtain sufficient conditions for the generalized eigenspace of a transition matrix to project to a region of exact controllability.

In section 5 we state a result on universally regular controls and a controllability property that can be proved using the existence of universally regular controls. In spite of the activity in the study of accessibility of discrete-time systems, the existence of universal controls has only recently been investigated [54], [50]. In [49] Sontag shows the existence of universally regular (universal nonsingular, in his terminology) controls for analytic, strongly accessible continuous-time systems. Related, and at first glance more interesting, is the existence of universally distinguishing controls which has been studied by Sussmann [51] and Sontag and Wang [48]. It cannot be overemphasized, however, that without the existence of universally regular controls, the following results would lose a considerable amount of strength. The main result of this section is that forward accessibility on projective space implies that a whole linear subspace may be steered so as to simultaneously avoid a complementary linear subspace. An analogue of this statement (Proposition 5.3) has to our knowledge not been studied in continuous time.

A starting point in the study of nonlinear control systems are questions of controllability of a system. Unlike the linear case where controllability is a global property in the state space, nonlinear systems may possess several regions of controllability. An important conceptual tool is to study sets, where it is possible to steer arbitrarily close from any one point to any other. These are the so-called *control sets*, which are introduced in section 6.

Kliemann [37] studied properties of control sets of locally accessible systems on smooth manifolds in continuous time. For the projected system obtained in the continuous-time case, an upper bound on the number of control sets with nonvoid interior has been obtained in [20]. An improved version of this result has been given by Braga and San Martin [12], where smaller upper bounds than the dimension of the state space have been given depending on the group that is acting on projective space. In the discrete-time case control sets have been studied by Albertini and Sontag [3], [4], [2], who also introduced the concept of the core of a control set, which is a strictly discrete-time concept. Introducing a further assumption, we define regular cores which can be shown to enjoy the same properties one would expect for cores; in fact, for the class of systems studied in [3] the definitions of core and regular core coincide. We give an example of a system where the interior of a control set and its regular core do not coincide.

What is surprising is that in neither the continuous- nor the discrete-time case has an effort been undertaken to study control sets for *complex* systems, although it has been known for some time that even for real systems it is useful to study complex perturbations by the results of Hinrichsen and Pritchard [31].

A first observation for our system on projective space is that the generalized eigenspaces corresponding to universally regular controls project to the cores of appropriate control sets. Using this property we show in section 7 that under weak assumptions there exist a unique invariant control set and a unique open control set on projective space. These are maximal (resp., minimal) in the control order on the control sets. Here is the first time where the importance of the universally regular controls becomes clear, as their existence yields an easy proof for the existence of the maximal and minimal control sets. This is also the point where we have to depart from lines of proof available in the literature that are based on properties of Lie groups, if we do not want to restrict ourselves to the invertible case.

In section 8 further results on control sets with nonempty interior are presented. For these it is important what the minimal possible rank drop on a path connecting two admissible invertible matrices is. Depending on this singularity index, we show that the eigenspaces of universally regular controls corresponding to an eigenvalue whose modulus has index greater than the singularity index project to a control set uniquely determined by the index of the modulus. Control sets with this property are called main control sets. This leads to a sufficient condition in terms of the singularity index guaranteeing that there exist at most n control sets with nonempty interior, which are all main control sets. It is briefly explained in what sense control sets may be viewed as a generalization of generalized eigenspaces.

In section 9 we begin our discussion of spectral theory by introducing the different exponents we want to study. Our definition of Floquet and Lyapunov spectra follows Colonius and Kliemann [20], [22], with the exception that in these references the collection of the ith Floquet exponents is not introduced.

In section 10 the Floquet spectrum of the discrete-time system is analyzed. We study Floquet spectra corresponding to control sets with nonempty core. To each such control set an associated set of Floquet exponents is defined. The idea of the proof that the closure of such a set is an interval follows the continuous-time case. The key here is a finite-time controllability property in the cores of control sets. In section 11 we study Lyapunov and Bohl spectra and their relation to the Floquet spectrum. Using an idea already developed in [18] we show under which conditions it is possible to approximate Lyapunov exponents by periodic controls. Furthermore, it is shown that without any further assumptions the closure of a Floquet spectrum of a control set actually consists of Lyapunov exponents corresponding to trajectories that remain in that control set. This is the statement of Theorem 11.1 (ii). It follows that the closure of the Floquet spectrum is contained in the Lyapunov spectrum. It has been shown by Berger and Wang [15] that the joint and generalized spectral radii of a discrete inclusion given by a bounded set of matrices are equal. For our systems, this implies the equality of the suprema of Bohl, Floquet, and Lyapunov spectra. We show that the infima of Floquet and Lyapunov spectra coincide as well.

To indicate a further line of research let us point out that an extension to the theory of control sets is given by the so-called chain control sets, which have been introduced by Colonius and Kliemann [20], [22]. The idea is to consider not trajectories of the system but (ε, T)-chains to define chain-orbits and to use these to define chain control sets. For discrete-time systems, this has been studied by Albertini and Sontag in [4]. The extension of these concepts to the kind of systems we have studied will be an interesting direction for further research, since with chain control sets, it is possible to describe the Morse spectrum of the discrete-time system, which is an outer approximation of the set of Lyapunov exponents.

2. Problem statement. Let $\mathbb{K} = \mathbb{R}, \mathbb{C}$ and let $\tilde{U} \subset \mathbb{K}^m$ be open and connected. For an analytic map

$$A : \tilde{U} \to \mathbb{K}^{n\times n}\,, \tag{2.1}$$

we consider a family of time-varying linear systems of the form

$$x(t+1) = A(u(t))x(t)\,, \quad t \in \mathbb{N}, \tag{2.2}$$

$$x(0) = x_0 \quad \in \mathbb{K}^n, \tag{2.3}$$

where $u : \mathbb{N} \to U \subset \tilde{U}$. The set-up we have chosen contains in particular systems affine in u and positive systems as subclasses. Also, it naturally extends to periodic systems.

For $t \in \mathbb{N}$, U^t denotes the set of admissible finite control sequences $u = (u(0), \dots, u(t-1))$, while $U^{\mathbb{N}}$ is the set of infinite control sequences $u = (u(0), u(1), \dots)$. It will always be clear from the context whether u denotes an element of U, U^t, or $U^{\mathbb{N}}$.

For two finite control sequences $u_1 \in U^{t_1}$, $u_2 \in U^{t_2}$ we define the concatenation (u_1, u_2) to be the sequence in $U^{t_1+t_2}$ given by $(u_1, u_2) = (u_1(0), \dots, u_1(t_1 - 1), u_2(0), \dots, u_2(t_2 - 1))$. The k-times repeated concatenation of $u \in U^t$ is denoted by $(u)^k \in U^{tk}$. For infinite control sequences $u \in U^{\mathbb{N}}$ we consider for $t \in \mathbb{N}$, $u_{[0,t-1]} := (u(0), \dots, u(t-1)) \in U^t$, the "first part" of the control sequence u. The evolution operator generated by a control sequence $u \in U^{\mathbb{N}}$ is defined by

$$\Phi_u(s,s) = I\,, \quad \Phi_u(t+1,s) = A(u(t))\Phi_u(t,s)\,, \quad t \geq s \in \mathbb{N}\,. \tag{2.4}$$

With this notation, $\Phi_u(t,0)x_0$ is the solution of (2.2) corresponding to the initial value x_0 and the control u at time t.

We denote by U_{inv} the set $\{u \in U;\ \det A(u) \neq 0\}$, which is clearly the complement of a set defined by analytic equations in U. Thus U_{inv} is either ω-generic in U or empty, where we call a set ω-generic if its complement is contained in a proper analytic subset of $\tilde{U}$. The term generic will be used for sets whose complements are contained in closed subanalytic sets of dimension strictly less than the manifold considered. For details on the theory of analytic and subanalytic sets we refer the reader to [42], [36], and [52]. Below, we will have to make use of the existence of invertible matrices $A(u)$, so that we have to assume that $U_{inv} \neq \emptyset$.

The following general assumption will be made throughout the remainder of this article. Note, however, that the first one is just for convenience and without loss of generality.

ASSUMPTION 2.1. *Let $\mathbb{K} = \mathbb{R}, \mathbb{C}$ and consider system* (2.2)*. We assume that the map A in* (2.1) *and the sets $U \subset \tilde{U} \subset \mathbb{K}^m$ are such that*

(i) $0 \in U$,
(ii) *the set U_{inv} is ω-generic in U,*
(iii) $\operatorname{int} U$ *is connected,*
(iv) $U \subset \operatorname{cl} \operatorname{int} U \subset \tilde{U}$,
(v) U *is bounded.*

One tool for the study of Lyapunov exponents has been the projection onto the projective space, known as Bogolyubov's projection. It is based on the fact that in continuous time the angular component of the system may be decoupled from the radial and studied independently.

In our discrete-time system we do not exclude the possibility that the origin may be reached from nonzero states. If this is regarded from the point of view of stability or robust stability, it poses no problem, for once system (2.2) is at zero it remains there, as it is totally uncontrollable at zero. However, this means that system (2.2) as such may not be projected onto projective space. First the maximal subsystem that can be projected has to be identified.

To consider the discrete-time analogue of Bogolyubov's projection, we define for $x \in \mathbb{K}^n$

$$U(x) := \{u \in U; A(u)x \neq 0\}\,,$$

and with a slight abuse of notation the analogous sets for finite and infinite control sequences are denoted by $U^t(x)$ and $U^{\mathbb{N}}(x)$.

As $U_{inv} \subset U(x)$ and $U^t_{inv} := (U_{inv})^t \subset U^t(x)$ for all $x \in \mathbb{K}^n \backslash \{0\}$ it follows that for $x \neq 0$ the sets $U(x)$ and $U^t(x)$ are ω-generic in U (resp., U^t). Below, $\mathbb{P}^{n-1}_{\mathbb{K}}$ denotes the $(n-1)$-dimensional projective space, and for $W \subset \mathbb{K}^n$, $\mathbb{P}W$ denotes the natural projection of $W \backslash \{0\}$ onto the projective space $\mathbb{P}^{n-1}_{\mathbb{K}}$.

For $\xi \in \mathbb{P}^{n-1}_{\mathbb{K}}$ we define the admissible control values for ξ by

$$U(\xi) := U(x) \quad \text{iff } \xi = \mathbb{P}x\,,$$

and in an analogous fashion $U^t(\xi), U^{\mathbb{N}}(\xi)$. This is well defined, as $\operatorname{Ker} A(u)$ is a linear subspace. With this notation the projected system corresponding to our linear system (2.2) is given by

$$\xi(t+1) = \mathbb{P}A(u(t))\xi(t)\,, \quad t \in \mathbb{N}, \tag{2.5}$$

$$\xi(0) = \xi_0 \in \mathbb{P}^{n-1}_{\mathbb{K}}, \tag{2.6}$$

$$u \in U^{\mathbb{N}}(\xi_0). \tag{2.7}$$

We denote the solution of (2.5) corresponding to an initial value ξ_0 and a control sequence $u \in U^{\mathbb{N}}(\xi_0)$ by $\xi(\cdot; \xi_0, u)$. For a subset $V \subset \mathbb{P}^{n-1}_{\mathbb{K}}$, $t \in \mathbb{N}$, $u \in U^t$ the notation $\xi(t; V, u) := \{\xi(t; \eta, u); \eta \in V \text{ such that } u \in U^t(\eta)\}$ will be used.

3. Accessibility, transitivity, and regularity. Let us now study the projected system (2.5) from a control point of view. The variable "u" will be treated as if it were available for control of the system. A basic question in control theory is that of accessibility. We begin with the following basic definitions.

DEFINITION 3.1 (orbits). *Let $\mathbb{K} = \mathbb{R}, \mathbb{C}$. Consider system* (2.5). *The forward orbit of ξ at time t is defined as*

$$\mathcal{O}^+_t(\xi) := \{\eta \in \mathbb{P}^{n-1}_{\mathbb{K}}; \exists\, u \in U^t(\xi) \text{ with } \eta = \xi(t; \xi, u)\}\,.$$

The forward orbit of ξ is then defined by $\mathcal{O}^+(\xi) := \cup_{t \in \mathbb{N}} \mathcal{O}^+_t(\xi)$. The backward orbit of ξ at time t is given by

$$\mathcal{O}^-_t(\xi) := \{\eta \in \mathbb{P}^{n-1}_{\mathbb{K}}; \exists\, u \in U^t(\eta) \text{ with } \xi = \xi(t; \eta, u)\},$$

which leads to a definition of $\mathcal{O}^-(\xi)$ analogous to that of the positive forward orbit. Let

$$\mathcal{O}_0(\xi) := \{\xi\} \quad \mathcal{O}_{t+1}(\xi) := \bigcup_{\eta \in \mathcal{O}_t(\xi)} \mathcal{O}^+(\eta) \cup \mathcal{O}^-(\eta)\,, \quad t \in \mathbb{N}.$$

The orbit of ξ is then defined by

$$\mathcal{O}(\xi) = \bigcup_{t \in \mathbb{N}} \mathcal{O}_t(\xi). \tag{3.1}$$

DEFINITION 3.2 (accessibility). *The system* (2.5) *is called* forward accessible from ξ *if* $\operatorname{int} \mathcal{O}^+(\xi) \neq \emptyset$, backward accessible from ξ *if* $\operatorname{int} \mathcal{O}^-(\xi) \neq \emptyset$, and forward (*resp.,* backward) accessible *if it is forward* (*backward*) *accessible from all $\xi \in \mathbb{P}^{n-1}_{\mathbb{K}}$.*
System (2.5) *is called* transitive, *if* $\operatorname{int} \mathcal{O}(\xi) \neq \emptyset$ *for all $\xi \in \mathbb{P}^{n-1}_{\mathbb{K}}$.*

We note the following properties of the forward orbit.

LEMMA 3.3. *Let $\mathbb{K} = \mathbb{R}, \mathbb{C}$. Consider system* (2.5).

(i) *Let $\xi_1, \xi_2 \in \mathbb{P}^{n-1}_{\mathbb{K}}$. If $\xi_2 \in \operatorname{cl} \mathcal{O}^+(\xi_1)$, then $\operatorname{cl} \mathcal{O}^+(\xi_2) \subset \operatorname{cl} \mathcal{O}^+(\xi_1)$.*

(ii) *For all $t \in \mathbb{N}$, $\xi \in \mathbb{P}^{n-1}_{\mathbb{K}}$ it holds that $\operatorname{cl} \mathcal{O}^+_t(\xi)$ is connected.*

Proof. (i) follows from a simple continuity argument. In order to prove (ii) we proceed by induction over $t \in \mathbb{N}$. Let $t = 1$ and $0 \neq x \in \mathbb{K}^n$. For an analytic path $\gamma : [0,1] \to \operatorname{int} U$ with $A(\gamma(\tau))x \not\equiv 0$, we will show that $\operatorname{cl} \mathbb{P}\{A(\gamma(\tau))x; \tau \in [0,1]\}$ is pathwise connected. Assume that $A(\gamma(\tau_0))x = 0$ (there are at most finitely many such τ). Let $k \in \mathbb{N}$ be the smallest integer such that $\frac{d^k}{d\tau^k} A(\gamma(\tau))x|_{\tau=\tau_0} \neq 0$, and without loss of generality, assume that the first component of this vector is nonzero. In standard local coordinates around (1,0,...,0) we obtain a neighborhood of τ_0 where for $\tau \neq \tau_0$ it holds that

$$\mathbb{P}A(\gamma(\tau))x = \left(1, \frac{(A(\gamma(\tau))x)_2}{(A(\gamma(\tau))x)_1}, \cdots, \frac{(A(\gamma(\tau))x)_n}{(A(\gamma(\tau))x)_1}\right). \tag{3.2}$$

Using the rule of de l'Hospital we obtain that $\lim_{\tau \to \tau_0} \mathbb{P}A(\gamma(\tau))x$ exists, which shows our claim. As for every $u_1, u_2 \in \operatorname{int} U$ there exists a piecewise polynomial path connecting them, and using Assumption 2.1 (iv), we see that $\operatorname{cl} \mathcal{O}_1^+(\xi)$ is connected.

Assume now that $\operatorname{cl} \mathcal{O}_t^+(\xi)$ is connected. Then, for $u_0 \in U_{inv}$, it holds that $\mathbb{P}A(u_0) \operatorname{cl} \mathcal{O}_t^+(\xi)$ is connected as the continuous image of a connected set. Thus

$$\operatorname{cl} \mathcal{O}_{t+1}^+(\xi) = \operatorname{cl} \bigcup_{\eta \in \operatorname{cl} \mathcal{O}_t^+(\xi)} \operatorname{cl} \mathcal{O}_1^+(\eta)$$

is connected, as each of the sets in the union is connected and each of the sets intersects the connected set $\mathbb{P}A(u_0) \operatorname{cl} \mathcal{O}_t^+(\xi)$. □

It has been shown that forward accessibility is intimately related to the rank of a certain mapping in the case of smooth invertible systems [4]. To carry this result over to our case, let for every $t \in \mathbb{N}$

$$W_t := \left\{(\xi, u) \in \mathbb{P}_{\mathbb{K}}^{n-1} \times \operatorname{int} U^t; \quad u \in U^t(\xi)\right\} \tag{3.3}$$

and consider the map

$$F_t : W_t \to \mathbb{P}_{\mathbb{K}}^{n-1}, \quad F_t(\xi, u) := \xi(t; \xi, u). \tag{3.4}$$

For fixed $\xi \in \mathbb{P}_{\mathbb{K}}^{n-1}$ and $u_0 \in \operatorname{int} U^t(\xi)$ we consider the rank of the linearization of $F_t(\xi, \cdot) : U^t(\xi) \to \mathbb{P}_{\mathbb{K}}^{n-1}$ at $u_0 \in U^t \subset \mathbb{K}^{mt}$ with respect to $u = (u(0)_1, \ldots, u(0)_m, u(1)_1, \ldots, u(t-1)_1, \ldots, u(t-1)_m)$. We define the following shorthand notation:

$$\frac{\partial F_t}{\partial u}(\xi, u_0) = \left(\frac{\partial F_{t,i}}{\partial u(s)_j}(\xi, u_0)\right)_{i=1,\ldots,n-1; s=0,\ldots,t-1; j=1,\ldots,m},$$

where the $F_{t,i}$ are the ith components of the map $F_t(\xi, \cdot)$ with respect to some coordinate chart around $F_t(\xi, u_0)$. The important detail for us is the rank of this Jacobian which is denoted by

$$r(t; \xi, u_0) := \operatorname{rk} \frac{\partial F_t}{\partial u}(\xi, u_0). \tag{3.5}$$

DEFINITION 3.4 (regularity). *A pair* $(\xi, u) \in \mathbb{P}_{\mathbb{K}}^{n-1} \times \operatorname{int} U^t$ *is called* regular*, if* $u \in \operatorname{int} U^t(\xi)$ *and* $r(t; \xi, u) = n - 1$. *A control* $u \in \operatorname{int} U^t$ *is called* universally regular *if* (ξ, u) *is a regular pair for all* $\xi \in \mathbb{P}_{\mathbb{K}}^{n-1}$.

The following lemma summarizes some easy properties in connection with regularity.

LEMMA 3.5. *Let* $\mathbb{K} = \mathbb{R}, \mathbb{C}$, $u_0 \in \operatorname{int} U^t$, $v_0 \in \operatorname{int} U^s$. *For* $\xi_0 \in \mathbb{P}_{\mathbb{K}}^{n-1}$ *let* $F_{t+s}(\xi_0, (u_0, v_0))$ *be defined. Then*

(i) $r(t+s;\xi_0,(u_0,v_0)) \geq r(s;\xi(t;\xi_0,u_0),v_0)$;
(ii) *if* $v_0 \in \operatorname{int} U^s_{inv}$ *then* $r(t+s;\xi_0,(u_0,v_0)) \geq r(t;\xi_0,u_0)$.

Proof. Both assertions follow from an application of the chain rule. □

PROPOSITION 3.6. *Let* $\mathbb{K} = \mathbb{R}, \mathbb{C}$ *and consider system* (2.5). *For all* $x \in \mathbb{K}^n \backslash \{0\}, t \in \mathbb{N}, u \in \operatorname{int} U^t$, *the following statements are equivalent.*

(i) $(\mathbb{P}x, u)$ *is a regular pair.*
(ii) $\Phi_u(t,0)x \neq 0$ *and the following rank condition holds:*

$$\operatorname{rk} G_t(x,u) := \operatorname{rk} \left[\Phi_u(t,0)x \vdots \frac{\partial}{\partial u}\Phi_u(t,0)x \right] = n\,. \tag{3.6}$$

Proof. It is clear that $\Phi_u(t,0)x \neq 0$ is necessary for regularity. An application of the chain rule and a simple calculation in local coordinates yields the desired result. □

The preceding criterion will be frequently used, as it is easily handled in lower dimensions, where all our examples will be situated. Of course, if the dimension is high or the structure of the map A is complicated, this criterion is much too involved to yield a feasible procedure for checking whether a system is forward accessible.

DEFINITION 3.7 (regular orbit). *Let* $\mathbb{K} = \mathbb{R}, \mathbb{C}$ *and consider system* (2.5). *For* $\xi \in \mathbb{P}^{n-1}_{\mathbb{K}}$ *we define the* regular forward orbit *and* regular backward orbit *by*

$$\hat{\mathcal{O}}^+_t(\xi) := \{\eta;\ \exists u \in \operatorname{int} U^t(\xi)\ \textit{s.t.}\ (\xi,u)\ \textit{is regular and}\ \eta = \xi(t;\xi,u)\}\,, \tag{3.7}$$

$$\hat{\mathcal{O}}^-_t(\xi) := \{\eta;\ \exists u \in \operatorname{int} U^t(\eta)\ \textit{s.t.}\ (\eta,u)\ \textit{is regular and}\ \xi = \xi(t;\eta,u)\}. \tag{3.8}$$

The definitions of $\hat{\mathcal{O}}^+(\xi)$ *and* $\hat{\mathcal{O}}^-(x)$ *are then analogous to Definition* 3.1.

For subsets $V \subset \mathbb{P}^{n-1}_{\mathbb{K}}$ we will use the notations $\hat{\mathcal{O}}^+(V) := \bigcup_{\xi\in V} \hat{\mathcal{O}}^+(\xi)$, etc. The following results exhibit some properties of the regular forward orbits. Items (iii) and (v) are shown in [4] for analytic invertible systems, and similar arguments are applicable here.

LEMMA 3.8. *For* $\mathbb{K} = \mathbb{R}, \mathbb{C}$ *consider system* (2.5). *Let* $\xi \in \mathbb{P}^{n-1}_{\mathbb{K}}$; *then*

(i) $\hat{\mathcal{O}}^+_t(\xi)$ *is open in* $\mathbb{P}^{n-1}_{\mathbb{K}}$;
(ii) $\hat{\mathcal{O}}^-_t(\xi)$ *is open in* $\mathbb{P}^{n-1}_{\mathbb{K}}$;
(iii) $\operatorname{int} \mathcal{O}^+_t(\xi) \neq \emptyset$ *iff* $\hat{\mathcal{O}}^+_t(\xi) \neq \emptyset$;
(iv) *if, for* $t \in \mathbb{N}$, $\hat{\mathcal{O}}^+_t(\xi) \neq \emptyset$, *then* $\hat{\mathcal{O}}^+_s(\xi) \neq \emptyset$ *for all* $s \geq t$;
(v) $\operatorname{int} \mathcal{O}^+_t(\xi) \neq \emptyset \Rightarrow \operatorname{cl} \mathcal{O}^+_t(\xi) = \operatorname{cl} \hat{\mathcal{O}}^+_t(\xi)$.

In the case when ξ is a fixed point under a control u such that (ξ,u) is a regular pair, the following property is immediately obtained.

PROPOSITION 3.9. *Let* $\mathbb{K} = \mathbb{R}, \mathbb{C}$. *For* $\xi \in \mathbb{P}^{n-1}_{\mathbb{K}}$ *there exist* $u_\xi \in \operatorname{int} U^t, t \in \mathbb{N}$ *such that* (ξ, u_ξ) *is a regular pair and*

$$\xi = \xi(t;\xi,u_\xi) \tag{3.9}$$

iff there exists an open neighborhood V *of* ξ *such that* $V \subset \hat{\mathcal{O}}^+_t(\xi) \cap \hat{\mathcal{O}}^-_t(\xi)$.

Proof. "⇒": This follows as $\xi \in \hat{\mathcal{O}}^+_t(\xi) \cap \hat{\mathcal{O}}^-_t(\xi)$ and the fact that both $\hat{\mathcal{O}}^+_t(\xi)$ and $\hat{\mathcal{O}}^-_t(\xi)$ are open by Lemma 3.8. "⇐": This is obvious as $\xi \in \hat{\mathcal{O}}^+_t(\xi)$. □

Let us now extend this property to connected sets.

LEMMA 3.10. *Let $\mathbb{K} = \mathbb{R}, \mathbb{C}$. If $\Gamma \subset \mathbb{P}^{n-1}_{\mathbb{K}}$ is a connected set such that for every $\xi \in \Gamma$ the assumption of Proposition* 3.9 *holds for some $t(\xi) \in \mathbb{N}$, then there exists a connected open set V such that*

$$\Gamma \subset V \subset \bigcap_{\xi \in \Gamma} \hat{\mathcal{O}}^+(\xi) \cap \hat{\mathcal{O}}^-(\xi)\,. \tag{3.10}$$

Proof. Let $\xi \in \Gamma$ and consider the set $\hat{\mathcal{O}}^+(\xi) \cap \Gamma$, which is clearly open in Γ. Let $\eta \in \Gamma \cap \operatorname{cl} \hat{\mathcal{O}}^+(\xi)$. As $\eta \in \hat{\mathcal{O}}^-(\eta)$, which is open, it follows that $\hat{\mathcal{O}}^+(\xi) \cap \hat{\mathcal{O}}^-(\eta) \neq \emptyset$ and hence $\eta \in \hat{\mathcal{O}}^+(\xi)$. Thus $\hat{\mathcal{O}}^+(\xi) \cap \Gamma$ is open and closed in Γ and nonempty. As Γ is connected it follows that $\Gamma \subset \hat{\mathcal{O}}^+(\xi)$, and as $\xi \in \Gamma$ was arbitrary, it holds for all $\xi_1, \xi_2 \in \Gamma$ that $\xi_1 \in \hat{\mathcal{O}}^+(\xi_2)$ and thus $\hat{\mathcal{O}}^+(\xi_1) \subset \hat{\mathcal{O}}^+(\xi_2)$ by Lemma 3.5 (i). By symmetry, we obtain $\hat{\mathcal{O}}^+(\xi_1) = \hat{\mathcal{O}}^+(\xi_2)$. Furthermore, it follows for every $\eta \in \Gamma$ that $\Gamma \subset \hat{\mathcal{O}}^-(\eta)$, and again, for all $\xi_1, \xi_2 \in \Gamma$, it holds that $\hat{\mathcal{O}}^-(\xi_1) = \hat{\mathcal{O}}^-(\xi_2)$. As Γ is connected, we can thus choose V to be the connected component of $\hat{\mathcal{O}}^+(\xi) \cap \hat{\mathcal{O}}^-(\xi)$ containing Γ for some $\xi \in \Gamma$. ∎

4. Asymptotic properties on projective space. A first step in the study of the discrete-time system on projective space is the study of the ω-limit sets defined by constant matrices in Jordan block form, where we follow the argumentation from [20] and extend the arguments used there so that we may treat cases not considered in that reference. The following notation is used from now on.

Let $B \in \mathbb{K}^{n\times n}$. For an eigenvalue $\lambda \in \sigma(B) \cap \mathbb{K}$, $E(\lambda)$ denotes the eigenspace and $GE(\lambda)$ denotes the generalized eigenspace corresponding to λ. If $B \in \mathbb{R}^{n\times n}$ and $\lambda \in \sigma(B)$ is complex then $E(\lambda)$ denotes the real part of the sum of the eigenspaces corresponding to the eigenvalues $\lambda, \overline{\lambda}$. $GE(\lambda)$ denotes the appropriate generalized eigenspaces.

It will also be convenient to consider the set of absolute values of the eigenvalues defined by $|\sigma(B)| := \{|\lambda|\,;\, \lambda \in \sigma(B)\}$. For $1 \leq i \leq n$, let $r_i(B)$ be equal to the ith entry of the ordered sequence $|\lambda_1| \leq \cdots \leq |\lambda_n|$, where each element of the spectrum of B appears according to its algebraic multiplicity. For $r \in |\sigma(B)|$ we denote

$$E(r) = \bigoplus_{\substack{\lambda \in \sigma(B) \\ |\lambda| = r}} E(\lambda)\,, \quad GE(r) = \bigoplus_{\substack{\lambda \in \sigma(B) \\ |\lambda| = r}} GE(\lambda)\,. \tag{4.1}$$

Below, we will be concerned with eigenspaces of $\Phi_u(t,0)$ generated by some finite control sequence $u \in U^t$. To make the dependence on u explicit we write $E(\lambda, u), E(r, u)$, etc. The projection of generalized eigenspaces is particularly important if regularity arguments can be applied.

DEFINITION 4.1. *Let $\mathbb{K} = \mathbb{R}, \mathbb{C}$, $t \in \mathbb{N}$, $u \in U^t$, $r \in |\sigma(\Phi_u(t,0))|$. If $r > 0$, we call* $\mathbb{P}GE(r,u)$ regular *if u can be partitioned as $u = (u_1, u_2)$ with $u_1 \in U^{t_1}$, $u_2 \in \operatorname{int} U^{t_2}$, and $t = t_1 + t_2$, and it holds that*

$$(\xi, u_2) \text{ is a regular pair for every } \xi \in \mathbb{P}\Phi_{u_1}(t_1, 0) GE(r, u)\,. \tag{4.2}$$

DEFINITION 4.2 (limit sets). *Let $\mathbb{K} = \mathbb{R}, \mathbb{C}$, $u \in U^{\mathbb{N}}$, $\xi \in \mathbb{P}^{n-1}_{\mathbb{K}}$. The positive ω-limit set is defined by*

$$\omega^+(\xi, u) := \left\{ \eta \in \mathbb{P}^{n-1}_{\mathbb{K}}; \exists \{t_k\}_{k\in\mathbb{N}} \subset \mathbb{N}, \lim_{k\to\infty} t_k = \infty \text{ such that } \eta = \lim_{k\to\infty} \xi(t_k; \xi, u) \right\}\,. \tag{4.3}$$

The negative ω-limit set is defined by

$$\omega^-(\xi,u) := \Big\{ \eta \in \mathbb{P}^{n-1}_{\mathbb{K}}; \exists \{t_k\}_{k\in\mathbb{N}} \subset \mathbb{N}, \lim_{k\to\infty} t_k = \infty,\ \exists \{\eta_k\} \subset \mathbb{P}^{n-1}_{\mathbb{K}},$$

$$\xi = \xi(t_k;\eta_k,u) \text{ such that } \eta = \lim_{k\to\infty} \eta_k \Big\} \,. \tag{4.4}$$

For $t \in \mathbb{N}$, $u \in U^t$, $\xi \in \mathbb{P}^{n-1}_{\mathbb{K}}$, $\omega^+(\xi,u)$ (resp., $\omega^-(\xi,u)$) denotes the positive (resp., negative) ω-limit set that is obtained by applying the t-periodic continuation of u.

Note that with this definition we do not exclude the possibility that ω-limit sets may be empty, e.g., if $u \notin U^{\mathbb{N}}(\xi)$. For a discussion of the concept of ω-limit sets we refer the reader to [1, Chapter 1]. In the following lemma we collect some simple properties of limit sets pertinent to our problem. The proof is left to the reader.

LEMMA 4.3. *Let $\mathbb{K} = \mathbb{R}, \mathbb{C}$, $t \in \mathbb{N}, u \in U^t$, $\xi \in \mathbb{P}^{n-1}_{\mathbb{K}}$.*

(i) *$\omega^+(\xi,u)$, $\omega^-(\xi,u)$ are closed.*

(ii) *$\Phi_u(t,0)\omega^+(\xi,u) = \omega^+(\xi,u)$.*

(iii) *If $\xi = \mathbb{P}x = \mathbb{P}\sum_{j=1}^{l} x_j$ with $x_j \in GE(r_j,u)$ is the spectral decomposition of ξ and $r_1 < r_2 < \cdots < r_l$, then*

$$\omega^+(\xi,u) \subset \mathbb{P}GE(r_l)\,. \tag{4.5}$$

If $r_1 = 0$, then $\omega^-(\xi,u) = \emptyset$; otherwise

$$\omega^-(\xi,u) \subset \mathbb{P}GE(r_1)\,. \tag{4.6}$$

(iv) *If $r > 0$, then $\xi \in \mathbb{P}E(r,u) \Rightarrow \xi \in \omega^+(\xi,u) = \omega^-(\xi,u) \subset \mathbb{P}E(r,u)$.*

The following lemma states the fundamental asymptotic property of the projected system.

LEMMA 4.4. *Let $\mathbb{K} = \mathbb{R}, \mathbb{C}$.*

(i) *Let $J_n(\lambda)$ denote an $n \times n$ Jordan block to an eigenvalue $\lambda \in \mathbb{K}\backslash\{0\}$. Then for any $x \in \mathbb{K}^n\backslash\{0\}$*

$$\lim_{t\to\pm\infty} \mathbb{P}J_n(\lambda)^t x = \mathbb{P}[1,0,\ldots,0]'\,. \tag{4.7}$$

(ii) *Let $\mathbb{K} = \mathbb{R}$ and let $J_n(\lambda,\bar\lambda)$ denote a $2n \times 2n$ Jordan block to a complex pair of eigenvalues $\lambda, \bar\lambda$. Then, for any Riemannian metric d on $\mathbb{P}^{2n-1}_{\mathbb{R}}$ and any $x \in \mathbb{R}^{2n}\backslash\{0\}$, it holds that*

$$\lim_{t\to\pm\infty} d(\mathbb{P}J_n(\lambda,\bar\lambda)^t x, \mathbb{P}\mathrm{span}\{[1,0,\ldots,0]', [0,1,0,\ldots,0]'\}) = 0\,. \tag{4.8}$$

Proof.

(i) For $\lambda \in \mathbb{K}\backslash\{0\}$, $t > n$ it holds that

$$J_n(\lambda)^t = \begin{bmatrix} \lambda^t & t\lambda^{t-1} & \ldots & \ldots & \binom{t}{t-(n-1)}\lambda^{t-(n-1)} \\ 0 & \lambda^t & t\lambda^{t-1} & \ldots & \binom{t}{t-(n-2)}\lambda^{t-(n-2)} \\ 0 & 0 & \lambda^t & & \vdots \\ \vdots & & \ddots & \ddots & \vdots \\ 0 & & \ldots & 0 & \lambda^t \end{bmatrix}. \tag{4.9}$$

For $i > 1$ it follows immediately that

$$\lim_{t\to\infty} \left| \frac{(J_n(\lambda)^t e_j)_i}{(J_n(\lambda)^t e_j)_1} \right| = 0\,, \tag{4.10}$$

which proves the assertion in the limit $t \to +\infty$. The assertion for $t \to -\infty$ follows upon noting that $J_n(\lambda)^{-t}$ is similar to $J_n(\frac{1}{\lambda})^t$, where the vector e_1 is fixed under the similarity transformation.

(ii) The proof for the complex pair of eigenvalues follows the same pattern and is omitted. ∎

COROLLARY 4.5. *Let $\mathbb{K} = \mathbb{R}, \mathbb{C}$, $t \in \mathbb{N}$, $u \in U^t$. If for $r \in |\sigma(\Phi_u(t,0))|$, $r > 0$, the generalized eigenspace $\mathbb{P}GE(r,u)$ is regular, then there exists an open set V such that*

$$\mathbb{P}E(r,u) \subset V \subset \bigcap_{\xi\in\mathbb{P}E(r,u)} \hat{\mathcal{O}}^+(\xi) \cap \hat{\mathcal{O}}^-(\xi)\,. \tag{4.11}$$

Proof. Let $u = (u_1, u_2)$ be partitioned in accordance with Definition 4.1. If $\xi_0 \in \mathbb{P}E(r,u)$, then there exists a $\xi_2 \in \mathbb{P}\Phi_{u_1}(t_1,0)E(r,u)$ such that $\xi_0 = \xi(t_2;\xi_2,u_2)$ and (ξ_2,u_2) is regular. Furthermore it holds by Lemma 4.3 (iv) that $\xi_2 \in \mathbb{P}\Phi_{u_1}(t_1,0)\omega^+(\xi_0,u)$ and so $\mathcal{O}^+(\xi_0)\cap\hat{\mathcal{O}}^-(\xi_0) \neq \emptyset$ since the regular backward orbit is open by Lemma 3.8 (ii). Using Lemma 3.8 (v) it follows that $\xi_0 \in \hat{\mathcal{O}}^+(\xi_0)$.

As $\mathbb{P}E(r,u)$ is connected, the assertion follows from Lemma 3.10. ∎

COROLLARY 4.6. *Let $\mathbb{K} = \mathbb{R}, \mathbb{C}$, $t \in \mathbb{N}$, $u \in U^t$. If for $r \in |\sigma(\Phi_u(t,0))|$, $r > 0$, the generalized eigenspace $\mathbb{P}GE(r,u)$ is regular, then there exists an open set W such that*

$$\mathbb{P}GE(r,u) \subset W \subset \bigcap_{\xi\in\mathbb{P}GE(r,u)} \hat{\mathcal{O}}^+(\xi) \cap \hat{\mathcal{O}}^-(\xi)\,. \tag{4.12}$$

Proof. Let $u = (u_1, u_2)$ be partitioned in accordance with Definition 4.1 and $\xi \in \mathbb{P}GE(r,u)$. By Lemma 4.4 and Corollary 4.5 there exists $\eta \in \mathcal{O}^+(\xi) \cap \hat{\mathcal{O}}^-(\mathbb{P}E(r,u))$ and it follows that $\mathbb{P}E(r,u) \subset \hat{\mathcal{O}}^+(\xi)$. On the other hand, $\omega^-(\xi,u) \subset \mathbb{P}E(r,u)$ and so by Corollary 4.5 there exists an $\eta \in \hat{\mathcal{O}}^+(\mathbb{P}E(r,u))$ and a $k \in \mathbb{N}$ such that $\xi = \xi(kt;\eta,(u)^k)$. By regularity of the pair $(\xi((k-1)t+t_1;\eta,((u)^{k-1},u_1)),u_2)$ and using the fact that $\hat{\mathcal{O}}^-_{t_2}(\xi)$ is open, we see that $\eta \in \hat{\mathcal{O}}^-_{kt}(\xi)$. Hence $\mathbb{P}E(r,u) \subset \hat{\mathcal{O}}^-(\xi)$. It follows that $\xi \in \hat{\mathcal{O}}^+(\xi)$, and an application of Lemma 3.10 completes the proof. ∎

Now that we have seen that for generalized eigenspaces in projective space certain controllability properties hold if a regularity condition is satisfied, it is reasonable to ask whether we can, for certain controls, guarantee that this condition holds. This is discussed in the next section.

5. Universally regular controls. A crucial point in the development of the theory is the construction of universally regular controls and the proof of their genericity in U^t for t large enough. The following result is largely a restatement of results shown in [54] and [50].

PROPOSITION 5.1. *Let $\mathbb{K} = \mathbb{R}, \mathbb{C}$. For the projected system (2.5) the following statements are equivalent.*

(i) *System (2.5) is forward accessible.*

(ii) *There exist $t \in \mathbb{N}$, $u^* \in \operatorname{int} U^t$ such that u^* is universally regular.*

(iii) *There exists a $t^* \in \mathbb{N}$ such that for all $t > t^*$ the set of universally regular control sequences is generic in $\operatorname{int} U^t$.*

(iv) *There exists a* $t \in \mathbb{N}$, $u \in \operatorname{int} U^t$ *such that for every* $r \in |\sigma(\Phi_u(t,0))|$ *the generalized eigenspace* $\mathbb{P}GE(r,u)$ *is regular.*

Proof. The equivalence of (i), (ii), and (iii) follows from Corollaries 3.2 and 3.3 in [50]. For this, note in particular that by Proposition 3.6 the set of nonregular pairs in $\mathbb{P}^{n-1}_{\mathbb{K}} \times U^t$ is analytic. To complete the proof note that "(ii) $\Rightarrow$ (iv)" is obvious. For the converse direction let u be such that (iv) is satisfied. For any $\xi \in \mathbb{P}^{n-1}_{\mathbb{K}}$ Lemma 4.4 implies that $\omega^+(\xi,u) \subset \mathbb{P}E(r,u)$ for some $r \in |\sigma(\Phi_u(t,0))|$. Corollary 4.6 implies that $\hat{\mathcal{O}}^+(\xi) \neq \emptyset$, so (i) holds. ∎

The set of universally regular $u \in U^t$ will be denoted by U^t_{reg}, while t^* denotes the smallest $t \in \mathbb{N}$ such that $U^t_{reg} \neq \emptyset$. It follows from the results in [50] that if $\operatorname{int} \mathcal{O}^+_t(\xi) \neq \emptyset$ for all $\xi \in \mathbb{P}^{n-1}_{\mathbb{K}}$, then $t^* \leq tn$. Note that U^t_{reg} is open for all $t \in \mathbb{N}$.

Remark 5.2. Let us point out that we use the term *generic* for sets that are the complement of closed subanalytic sets of lower dimension in the real case or proper analytic subsets in the complex case. The reason that we work with analytically defined sets lies in the analytic dependence of A on u. In particular, we use in the proof of Proposition 8.1 that if the complement of a set Z is generic, then from every $x \in Z$ there exists a path that starts in $x \in Z$ and leaves Z immediately. This is due to the fact that subanalytic sets can be represented as a locally finite union of embedded analytic submanifolds; see [52].

PROPOSITION 5.3. *Let* $\mathbb{K} = \mathbb{R}, \mathbb{C}$. *Assume that* (2.5) *is forward accessible; then, for linear subspaces* $X, Y \subset \mathbb{K}^n$ *such that*

$$\dim X + \dim Y \leq n, \tag{5.1}$$

the set $\{u \in U^t_{reg}; \Phi_u(t,0)X \cap Y = \{0\}\}$ *is generic in* $\operatorname{int} U^t$ *for all* $t \geq t^*$.

Proof. For $X = \{0\}$ there is nothing to show, so assume $\dim X \geq 1$. Note that the set $\{(\xi,u) \in \mathbb{P}X \times \operatorname{int} U^t; u \notin U^t(\xi)$ or $[u \in U^t(\xi)$ and $\xi(t;\xi,u) \in \mathbb{P}Y]\}$ is analytic in $\mathbb{P}X \times \operatorname{int} U^t$. From Remmert's proper mapping theorem [36, Theorem 45.17] (resp., the definition of subanalytic sets [52, section 8]) it follows that the projection of this set given by

$$\{u \in \operatorname{int} U^t; \exists \xi \in \mathbb{P}X \text{ such that } [u \notin U^t(\xi) \text{ or } \xi(t;\xi,u) \in \mathbb{P}Y]\} \tag{5.2}$$

is analytic in $\operatorname{int} U^t$ for $\mathbb{K} = \mathbb{C}$ or subanalytic in $\operatorname{int} U^t$ for $\mathbb{K} = \mathbb{R}$. As the set is clearly closed and the intersection of two generic sets is generic, the assertion is thus proved in the real and the complex cases if the following statement is shown:

$$\begin{aligned} &\text{if } t \geq t^* \text{ and } u \in \operatorname{int} U^t, \text{ then in any open neighborhood of } u \\ &\qquad \text{there exists a } v \in U^t_{reg} \text{ such that } \Phi_v(t,0)X \cap Y = \{0\}. \end{aligned} \tag{5.3}$$

We prove (5.3) by induction over $\dim X$. Let $\dim X = 1$. Due to $u \in \operatorname{cl} U^t_{reg}$ it holds that $\xi(t;\xi,u) \in \operatorname{cl} \hat{\mathcal{O}}^+_t(\xi)$ for $\xi = \mathbb{P}X$, so (5.3) follows immediately. Assume that (5.3) is shown for $\dim X = k < n-1$ and let $X = \operatorname{span}\{x_1, \ldots, x_{k+1}\}$ for a linearly independent set of vectors $x_i \in \mathbb{K}^n$, $i = 1, \ldots, k+1$. Without loss of generality, let $Y \subset \operatorname{span}\{e_{k+2}, \ldots, e_n\}$. Denote $X' = \operatorname{span}\{x_1, \ldots, x_k\}$. Fix $u \in \operatorname{int} U^t$ and an open neighborhood $V \subset \operatorname{int} U^t$ of u. Thus there exists $v \in V \cap U^t_{reg}$ such that

$$\Phi_v(t,0)X' \cap \operatorname{span}\{e_{k+2}, \ldots, e_n\} = \{0\}. \tag{5.4}$$

Due to forward accessibility v may be chosen such that

$$\Phi_v(t,0)x_{k+1} \notin \operatorname{span}\{e_{k+2}, \ldots, e_n\}. \tag{5.5}$$

Let $W \subset V \cap U^t_{reg}$ be a neighborhood of v such that (5.4) and (5.5) are satisfied for all $v' \in W$. Let $P \in \mathbb{K}^{k+1\times n}$ be defined by

$$P = \begin{bmatrix} 1 & & 0 & 0 & \cdots & 0 \\ & \ddots & & \vdots & & \\ 0 & & 1 & 0 & \cdots & 0 \end{bmatrix}; \tag{5.6}$$

then

$$\mathrm{rk} P\Phi_v(t,0)[x_1 \vdots \cdots \vdots x_{k+1}] \geq k\,. \tag{5.7}$$

If the rank is equal to $k+1$, then indeed

$$\Phi_v(t,0)X \cap \mathrm{span}\{e_{k+2},\ldots,e_n\} = \{0\}\,. \tag{5.8}$$

Let $u' \in \mathbb{K}^{mt}$ and consider the mappings

$$h_i : (-\varepsilon,\varepsilon) \to \mathbb{K}^{k+1}, \tag{5.9}$$

$$h_i(\tau) = P\Phi_{v+\tau u'}(t,0)x_i \tag{5.10}$$

for $i = 1,\ldots,k+1$, where ε is small enough such that $v + \tau u' \in W$ for $|\tau| < \varepsilon$. We claim that there exist $u' \in \mathbb{K}^{mt}$ such that (5.8) holds for $\Phi_{v+\tau u'}(t,0)$ for some $|\tau| < \varepsilon$. Assume this is not the case. Then $h_{k+1}(\tau) \in \mathrm{span}\{h_i(\tau)\}_{i=1,\ldots,k}$ for all $|\tau| < \varepsilon$. Hence there exist continuously differentiable functions

$$\mu_i : (-\varepsilon,\varepsilon) \to \mathbb{K}, \quad i = 1,\ldots,k \tag{5.11}$$

such that

$$h_{k+1}(\tau) = \sum_{i=1}^{k} \mu_i(\tau)h_i(\tau), \tag{5.12}$$

where the differentiability follows from the differentiability of the h_i and the fact that the $h_i(\tau)$, $i = 1,\ldots,k$, are linearly independent. Hence, if we differentiate with respect to τ at $\tau = 0$,

$$h'_{k+1}(0) = \sum_{i=1}^{k} \mu'_i(0)h_i(0) + \mu_i(0)h'_i(0), \tag{5.13}$$

or equivalently, using the chain rule,

$$P\frac{\partial \Phi_v(t,0)x_{k+1}}{\partial u}\cdot u' = \sum_{i=1}^{k} \mu'_i(0)h_i(0) + \mu_i(0)P\frac{\partial \Phi_v(t,0)x_i}{\partial u}\cdot u'\,. \tag{5.14}$$

Let

$$B_i := P\frac{\partial \Phi_v(t,0)x_i}{\partial u} \in \mathbb{K}^{k+1\times mt} \tag{5.15}$$

be our shorthand notation; then we obtain that if u' is such that $B_i u' \in \mathrm{span}\{h_1(0), \ldots, h_k(0)\}$ for $i = 1,\ldots,k$ and $B_{k+1}u' \notin \mathrm{span}\{h_1(0),\ldots,h_k(0)\}$, then (5.14) cannot be solved and there exist τ arbitrarily small such that

$$\mathrm{rk} P\Phi_{u+\tau u'}(t,0)[x_1 \vdots \cdots \vdots x_{k+1}] = \mathrm{rk}\Phi_{u+\tau u'}(t,0)[x_1 \vdots \cdots \vdots x_{k+1}] = k+1 \tag{5.16}$$

and hence (5.3) holds.

Assume there is no u' satisfying these properties; i.e., for all $u \in \mathbb{K}^{mt}$ it holds that

$$B_i u \in \operatorname{span}\{h_1(0), \dots, h_k(0)\}, \quad i = 1, \dots, k \Rightarrow B_{k+1} u \in \operatorname{span}\{h_1(0), \dots, h_k(0)\}.$$

By (5.4) we obtain $\dim\{u \in \mathbb{K}^{mt};\, B_i u \in \operatorname{span}\{h_1(0), \dots, h_k(0)\}\} \geq mt - 1$ and thus

$$\dim\{u \in \mathbb{K}^{mt};\, B_i u \in \operatorname{span}\{h_1(0), \dots, h_k(0)\} \text{ for } i = 1, \dots, k\} \tag{5.17}$$

$$= \dim\{u \in \mathbb{K}^{mt};\, B_i u \in \operatorname{span}\{h_1(0), \dots, h_k(0)\} \text{ for } i = 1, \dots, k+1\} \tag{5.18}$$

$$\geq mt - k\,. \tag{5.19}$$

Hence, in suitable coordinates, the matrices B_i, $i = 1, \dots, k+1$, are of the form

$$\begin{array}{c} \\ k \\ \\ \\ 1 \end{array} \begin{array}{c} \begin{array}{cccccc} \multicolumn{3}{c}{mt-k} & & \multicolumn{2}{c}{k} \end{array} \\ \left[\begin{array}{ccccccc} * & \dots & * & & * & \dots & * \\ \vdots & & \vdots & & \vdots & & \vdots \\ * & \dots & * & & * & \dots & * \\ 0 & \dots & 0 & & * & \dots & * \end{array}\right] \end{array}, \tag{5.20}$$

and there are scalars $\nu_i \in \mathbb{K}$, $i = 1, \dots, k+1$, not all zero such that

$$\operatorname{Im} \sum_{i=1}^{k+1} \nu_i B_i \subseteq \operatorname{span}\{h_1(0), \dots, h_k(0)\}. \tag{5.21}$$

Now for the vector $\overline{x} = \sum_{i=1}^{k+1} \nu_i x_i \neq 0$ and with G_t as defined in (3.6) it follows that

$$\operatorname{rk} PG_t(\overline{x}, v) = \operatorname{rk} \left[\begin{array}{c:c} \sum_{i=1}^{k+1} \nu_i h_i(0) & \sum_{i=1}^{k+1} \nu_i B_i \end{array}\right] \leq k, \tag{5.22}$$

which contradicts the universal regularity of v by Proposition 3.6. ∎

In [34], [2], [4] accessibility and transitivity properties of analytic, invertible systems have been studied. In particular, Lie algebraic characterizations of these properties were obtained. It was also obtained that on compact manifolds, transitivity, forward, and backward accessibility are all equivalent. Since forward accessibility of system (2.5) implies the existence of a universally regular control, we can state the following proposition.

PROPOSITION 5.4. *Let $\mathbb{K} = \mathbb{R}, \mathbb{C}$. Assume system (2.5) is forward accessible. Then it is backward accessible and transitive. Furthermore, it holds for every $\xi \in \mathbb{P}^{n-1}_{\mathbb{K}}$ that $\hat{\mathcal{O}}^-(\xi) \neq \emptyset$.*

Proof. This is clear from the existence of a universally regular control. ∎

This proposition shows in particular that the criteria for accessibility developed in [34], [4] can be brought to use in our case, even though the full requirements of the theorems stated in these references are not met. This is due to the fact that system (2.5) is forward accessible iff there is an analytic invertible subsystem that is forward accessible. We call a system a subsystem if the map A is the same but the set of control values is restricted. Thus we could choose an open subset U' of

U_{inv} that is relatively compact in U_{inv}. For the system with control values in U' it is clear that its forward accessibility implies forward accessibility of the original system. But the converse is also true, as forward accessibility implies the generic existence of universally regular controls. This implies that there exists a universally regular control in $U'^{t^*}_{reg}$, where t^* is the constant of the original system.

The converse of the statement in Proposition 5.4 does not hold, as shown by the following example.

Example 5.5. Let $\mathbb{K} = \mathbb{R}, \mathbb{C}$ and $U = \mathbb{K}$. Define

$$A(u) := \begin{bmatrix} 1+2u & 0 \\ 0 & 1+u \end{bmatrix}.$$

Then the system

$$\xi(t+1) = \mathbb{P}A(u(t))\xi(t), \quad t \in \mathbb{N},$$

is clearly not forward accessible, as $\mathcal{O}^+(\mathbb{P}[1,0]') = \{\mathbb{P}[1,0]'\}$, $\mathcal{O}^+(\mathbb{P}[0,1]') = \{\mathbb{P}[0,1]'\}$. However, an open set can be steered to $\mathbb{P}[1,0]'$ by applying the constant control given by $\lambda = -1$ (resp., $\mathbb{P}[0,1]'$ and $\lambda = -\frac{1}{2}$). It is then easy to see that $\operatorname{int}\mathcal{O}_1^-(\xi) \neq \emptyset$ for all $\xi \in \mathbb{P}^1_{\mathbb{K}}$. So the system is backward accessible.

6. Control sets. Let us now give a precise meaning to the words "sets where it is possible to steer arbitrarily close from one point to another." Control sets are defined as maximal sets where a controllability property holds. Precontrol sets satisfy the same controllability properties without being maximal. We note that different control sets are disjoint, and that for every precontrol set there exists a unique control set containing it. Furthermore, for every point in a control set there exists a control sequence such that the corresponding trajectory stays in that control set for all times, and the closures of the forward orbits of two points contained in the same control set coincide.

DEFINITION 6.1 (control set). *Let* $\mathbb{K} = \mathbb{R}, \mathbb{C}$. *Consider system* (2.5). *A set* $\emptyset \neq D \subset \mathbb{P}^{n-1}_{\mathbb{K}}$ *is called a* precontrol set *if*

(i) $D \subset \operatorname{cl}\mathcal{O}^+(\xi), \quad \forall \xi \in D$;

(ii) *for every* $\xi \in D$ *there exists a* $u \in U^{\mathbb{N}}(\xi)$ *and an increasing sequence* $(t_k)_{k\in\mathbb{N}} \subset \mathbb{N}$ *such that* $\xi(t_k; \xi, u) \in D$ *for all* $k \in \mathbb{N}$.

A precontrol set D *is called a* control set *if, furthermore,*

(iii) D *is a maximal set with respect to inclusion satisfying* (i).

A control set C *is called an* invariant control set *if*

$$\operatorname{cl} C = \operatorname{cl}\mathcal{O}^+(\xi) \, \forall \xi \in C. \tag{6.1}$$

With this definition we obtain the following basic results.

PROPOSITION 6.2. *Let* $\mathbb{K} = \mathbb{R}, \mathbb{C}$ *and consider system* (2.5).

(i) *For two control sets* D_1, $D_2 \subset \mathbb{P}^{n-1}_{\mathbb{K}}$ *it holds that either* $D_1 = D_2$ *or* $D_1 \cap D_2 = \emptyset$.

(ii) *For every precontrol set* $D' \subset \mathbb{P}^{n-1}_{\mathbb{K}}$ *there exists a unique control set* D *such that* $D' \subset D$.

(iii) *If* $\xi_1, \xi_2 \in D$ *for some control set* $D \subset \mathbb{P}^{n-1}_{\mathbb{K}}$ *and for some* $u \in U^t$ *it holds that*

$$\xi_2 = \xi(t; \xi_1, u), \tag{6.2}$$

then

$$\xi(s;\xi_1,u)\in D \text{ for } s=0,\dots,t\,. \tag{6.3}$$

(iv) *For a control set D it holds that*

$$\operatorname{cl}\mathcal{O}^+(\xi_1)=\operatorname{cl}\mathcal{O}^+(\xi_2)\quad\forall\xi_1,\xi_2\in D\,. \tag{6.4}$$

(v) *Let D be a control set. For every $\xi\in D$ there exists a control $u\in U^{\mathbb{N}}(\xi)$ such that*

$$\xi(t;\xi,u)\in D\quad\forall t\in\mathbb{N}\,. \tag{6.5}$$

(vi) *Let D be a control set. For every $\xi\in D$ and every $T\in\mathbb{N}$ it holds that*

$$\operatorname{cl}\mathcal{O}^+(\xi)=\operatorname{cl}\bigcup_{t=T}^{\infty}\mathcal{O}_t^+(\xi)\,. \tag{6.6}$$

In the forward accessible case, invariant control sets enjoy further useful properties.

PROPOSITION 6.3. *Let $\mathbb{K}=\mathbb{R},\mathbb{C}$. Assume that* (2.5) *is forward accessible. A control set C is invariant iff it is closed and satisfies* $\operatorname{int}C\neq\emptyset$.

Proof. "⇒": If $C=\mathbb{P}^{n-1}_{\mathbb{K}}$ there is nothing to show. Assume that $\xi\in\operatorname{cl}C\setminus C$. This implies that $\xi\in\operatorname{cl}\mathcal{O}^+(\eta)$ for all $\eta\in C$. As $\xi\notin C$ it follows that $\mathcal{O}^+(\xi)\cap C=\emptyset$, for otherwise $C\subset\operatorname{cl}\mathcal{O}^+(\xi)$, and this would imply $\xi\in C$. By assumption, there exist $t\in\mathbb{N}$, $u\in U^t(\xi)$ such that $\xi(t;\xi,u)\in\operatorname{int}\mathcal{O}^+(\xi)$. By continuity, there exists a neighborhood V of ξ that is steered to $\operatorname{int}\mathcal{O}^+(\xi)$, and therefore there exists $\eta\in C$ such that $\mathcal{O}^+(\eta)\cap\operatorname{int}\mathcal{O}^+(\xi)\neq\emptyset$. But $\mathcal{O}^+(\eta)\subset\operatorname{cl}C$, a contradiction. Hence C is closed, and $C=\operatorname{cl}\mathcal{O}^+(\xi)$ for $\xi\in C$. As $\operatorname{int}\mathcal{O}^+(\xi)\neq\emptyset$ it follows that $\operatorname{int}C\neq\emptyset$.

"⇐": Let C be a closed control set with $\operatorname{int}C\neq\emptyset$. If $C=\mathbb{P}^{n-1}_{\mathbb{K}}$ there is nothing to show. Otherwise we have to show for every $\xi\in C$ that $\operatorname{cl}\mathcal{O}^+(\xi)\subset C$, or equivalently, as C is closed, $\mathcal{O}^+(\xi)\subset C$. For every $\eta\in C$ there exists $t\in\mathbb{N}$, $u\in U^t(\eta)$ such that $\xi(t;\eta,u)\in\operatorname{int}C$. By continuous dependence on the initial values there exists an open neighborhood $V(\eta)$ of η such that $\xi(t;V(\eta),u)\subset\operatorname{int}C$. Hence there exists an open set $V\supset C$ such that $\mathcal{O}^+(\xi)\cap\operatorname{int}C\neq\emptyset$ and therefore $C\subset\operatorname{cl}\mathcal{O}^+(\xi)$ for every $\xi\in V$.

Assume now that there exists a $\xi\in C$ and a $u\in U(\xi)$ such that $\xi(1;\xi,u)\notin C$. As $C\subset\operatorname{cl}\mathcal{O}^+(\xi)$ there exists an $\eta\in\mathcal{O}^+(\xi)\cap C$, and Proposition 6.2 (iii) guarantees that there exists a $v\in U(\xi)$ such that $\xi(1;\xi,v)\in C$. Now $\operatorname{cl}\mathcal{O}_1^+(\xi)\cap C\neq\emptyset$, but also $\operatorname{cl}\mathcal{O}_1^+(\xi)\not\subset C$. Since $\operatorname{cl}\mathcal{O}_1^+(\xi)$ is connected, it follows that there exists a $\zeta\in\mathcal{O}_1^+(\xi)\cap(V\setminus C)$. But then $\zeta\in\operatorname{cl}\mathcal{O}^+(\eta)$ for all $\eta\in C$ and $C\subset\operatorname{cl}\mathcal{O}^+(\zeta)$, and thus $\zeta\in C$, which is a contradiction. □

Cores of control sets, a strictly discrete-time concept, have been introduced in [4]. We give a definition of the core that differs slightly from the original definition in that we require a regularity condition to hold. So, to contrast it, it might be called the *regular core* of a control set. It should, however, be noted that for the systems studied in [4], core and regular core of a control set coincide.

DEFINITION 6.4 (regular core). *Let $\mathbb{K}=\mathbb{R},\mathbb{C}$. Let $D\subset\mathbb{P}^{n-1}_{\mathbb{K}}$ be a control set with* $\operatorname{int}D\neq\emptyset$. *The* (regular) core *of D is defined as*

$$\operatorname{core}(D):=\{\xi\in D;\hat{\mathcal{O}}^+(\xi)\cap D\neq\emptyset \text{ and } \hat{\mathcal{O}}^-(\xi)\cap D\neq\emptyset\}\,. \tag{6.7}$$

PROPOSITION 6.5. *Let $\mathbb{K} = \mathbb{R}, \mathbb{C}$ and consider system* (2.5). *It holds that $\xi \in \hat{\mathcal{O}}^+(\xi)$ iff there exists a control set D such that $\xi \in \operatorname{core}(D)$.*

Proof. "⇒": This follows from Proposition 3.9.

"⇐": Let $\eta \in \hat{\mathcal{O}}^-(\xi) \cap D$. By the implicit function theorem there exists a neighborhood V of η with $V \subset \hat{\mathcal{O}}^-(\xi)$. As $\eta \in D$ it follows that $V \cap \mathcal{O}^+(\xi) \neq \emptyset$. Therefore, $\hat{\mathcal{O}}^-(\xi) \cap \mathcal{O}^+(\xi) \neq \emptyset$, and so $\xi \in \hat{\mathcal{O}}^+(\xi)$. □

PROPOSITION 6.6. *Let $\mathbb{K} = \mathbb{R}, \mathbb{C}$ and consider system* (2.5). *Let $D \subset \mathbb{P}^{n-1}_{\mathbb{K}}$ be a control set with $\operatorname{int} D \neq \emptyset$. If system* (2.5) *is forward accessible from every $\xi \in D$, then*

(i) $\operatorname{core}(D)$ *is open in* $\mathbb{P}^{n-1}_{\mathbb{K}}$;

(ii) $\operatorname{cl}\operatorname{core}(D) = \operatorname{cl}\operatorname{int}(D) = \operatorname{cl} D$;

(iii) *if $\xi \in \operatorname{core}(D)$ then $\operatorname{core}(D) \subset \hat{\mathcal{O}}^+(\xi)$ and $D \subset \hat{\mathcal{O}}^-(\xi)$;*

(iv) *if $\xi \in \operatorname{core}(D)$, $t \in \mathbb{N}$, $u \in \operatorname{int} U^t_{inv}$, and $\xi(t;\xi,u) \in D$, then $\xi(s;\xi,u) \in \operatorname{core}(D)$ for $s = 0, \ldots, t$.*

Proof. (i) If $\xi \in \operatorname{core}(D)$, then by Proposition 6.5, $\xi \in \hat{\mathcal{O}}^+(\xi)$. Thus the assertion follows from Proposition 3.9, as there exists an open neighborhood V of ξ satisfying $V \subset \hat{\mathcal{O}}^+(\xi) \cap \hat{\mathcal{O}}^-(\xi)$. V is a precontrol set satisfying the rank condition in (6.7), and thus contained in $\operatorname{core}(D)$.

(ii) Clearly, $\operatorname{cl}\operatorname{core}(D) \subset \operatorname{cl}\operatorname{int} D \subset \operatorname{cl} D$. Let $\xi \in \operatorname{cl} D$ and V be any open neighborhood of ξ. Let $\eta \in \operatorname{int} D$. By Lemma 3.8 (v) and Proposition 6.2 (vi) we have $D \subset \operatorname{cl} \hat{\mathcal{O}}^+(\eta)$. Thus we may choose $\zeta \in D \cap V \cap \hat{\mathcal{O}}^+(\eta)$, and it follows that $\hat{\mathcal{O}}^-(\zeta) \cap \operatorname{int} D \neq \emptyset$. As $\zeta \in D$ we have as before that $\operatorname{int} D \subset D \subset \hat{\mathcal{O}}^+(\zeta)$ and so also $\hat{\mathcal{O}}^+(\zeta) \cap \operatorname{int} D \neq \emptyset$. Thus $\zeta \in \operatorname{core}(D) \cap V$.

(iii) If $\xi \in \operatorname{core}(D)$, then $\xi \in \operatorname{cl} \mathcal{O}^+(\eta)$ for every $\eta \in D$. By Proposition 3.9, $\xi \in \hat{\mathcal{O}}^-(\xi)$ and so $\mathcal{O}^+(\eta) \cap \hat{\mathcal{O}}^-(\xi) \neq \emptyset$, and hence $\eta \in \hat{\mathcal{O}}^-(\xi)$. This shows that $D \subset \hat{\mathcal{O}}^-(\xi)$. As $\xi \in \operatorname{core}(D)$ was arbitrary, this implies also that $\operatorname{core}(D) \subset \hat{\mathcal{O}}^+(\xi)$ for every $\xi \in \operatorname{core}(D)$.

(iv) This is clear as $D \subset \hat{\mathcal{O}}^-(\xi) \subset \hat{\mathcal{O}}^-(\xi(s;\xi,u))$ for $s = 0, \ldots, t$ by Lemma 3.5, and $\operatorname{core}(D) \subset \hat{\mathcal{O}}^+(\xi(t;\xi,u)) \subset \hat{\mathcal{O}}^+(\xi(s;\xi,u))$. □

From now on, control sets of the system on projective space are studied using the underlying linear structure which allows more precise statements. We begin by considering projected generalized eigenspaces that satisfy a regularity condition.

PROPOSITION 6.7. *Let $\mathbb{K} = \mathbb{R}, \mathbb{C}$, $t \in \mathbb{N}$, $u \in \operatorname{int} U^t$. Assume that for $r \in |\sigma(\Phi_u(t,0))|$, $r > 0$, the generalized eigenspace $\mathbb{P}GE(r,u)$ is regular. Then there exists a control set D such that*

$$\mathbb{P}GE(r,u) \subset \operatorname{core}(D)\,. \tag{6.8}$$

Proof. This follows from Corollary 4.6, and the fact that for every precontrol set, there is a control set containing it. □

PROPOSITION 6.8. *Let $\mathbb{K} = \mathbb{R}, \mathbb{C}$, $t \in \mathbb{N}$. Assume that $\gamma : [0,1] \to U^t$ is a continuous path with an associated continuous path $\gamma_2 : [0,1] \to \mathbb{R}$ such that for every $\tau \in [0,1]$*

$$0 \neq \gamma_2(\tau) \in \left|\sigma(\Phi_{\gamma(\tau)}(t,0))\right| \tag{6.9}$$

and $\mathbb{P}GE(\gamma_2(\tau), \gamma(\tau))$ is regular. Then there exists a connected open precontrol set D

contained in the core of a control set with

$$\bigcup_{\tau\in[0,1]} \mathbb{P}GE(\gamma_2(\tau),\gamma(\tau)) \subset D\,. \tag{6.10}$$

Proof. By Proposition 6.7, for every $\tau \in [0,1]$, there exists an open precontrol set $V(\tau) \supset \mathbb{P}GE(\gamma_2(\tau),\gamma(\tau))$ which we may assume without loss of generality to be connected and contained in the core of a control set. By the continuity properties of the eigenprojections (see [13, Chapter II.8]), for every $\tau \in [0,1]$ there exists an $\varepsilon(\tau) > 0$ such that $\mathbb{P}GE(\gamma_2(\tau'),\gamma(\tau')) \subset V(\tau)$ if $|\tau - \tau'| < \varepsilon(\tau)$. This shows that

$$D := \bigcup_{\tau\in[0,1]} V(\tau) \tag{6.11}$$

is connected and, by Lemma 3.10, is a precontrol set with the desired properties. □

For the system (2.5) the core of a control set corresponds to regular pairs (ξ, u), where ξ is an eigenvector of $\Phi_u(t,0)$ by Proposition 6.5. For a forward accessible system, even more is true. For any control set D with nonempty core we may find universally regular controls u that generate an eigenspace whose projection lies in any prescribed open subset of $\operatorname{core}(D)$.

PROPOSITION 6.9. *Let $\mathbb{K} = \mathbb{R}, \mathbb{C}$. Assume that system (2.5) is forward accessible. For every control set $D \subset \mathbb{P}^{n-1}_{\mathbb{K}}$ with $\operatorname{core}(D) \neq \emptyset$ and every open set $\emptyset \neq V \subset \operatorname{core}(D)$, there exist $t \in \mathbb{N}$, $u \in U^t_{reg}$ such that for some $r \in |\sigma(\Phi_u(t,0))|$*

$$\mathbb{P}E(r,u) \cap V \neq \emptyset\,, \text{ and } \mathbb{P}GE(r,u) \subset \operatorname{core}(D)\,. \tag{6.12}$$

Proof. Let $\xi \in V$. By Proposition 6.5, $\xi \in \hat{\mathcal{O}}^+(\xi)$, and we can choose $t \in \mathbb{N}$, $u \in \operatorname{int} U^t$ such that $r(t;\xi,u) = n-1$ and

$$\xi = \xi(t;\xi,u)\,. \tag{6.13}$$

Without loss of generality let $t > t^*$. Since the set of universally regular controls is generic in $\operatorname{int} U^t$, and by Proposition 6.5, we can choose $u_1 \in U^t_{reg}$ such that $\eta_1 := \xi(t;\xi,u_1) \in \hat{\mathcal{O}}^+_t(\xi) \cap \hat{\mathcal{O}}^-_t(\xi) \cap V$. Using the universal regularity of u_1 and applying the implicit function theorem it may be concluded that there exists an open neighborhood $V(\xi) \subset V$ such that for every $\eta \in V(\xi)$ there exists a universally regular $u(\eta) \in U^t_{reg}$ with $\eta_1 = \xi(t;\eta,u(\eta))$. Furthermore, as $\eta_1 \in \hat{\mathcal{O}}^-_t(\xi)$, we may choose $u_2 \in \operatorname{int} U^t_{inv}$ such that $\eta_2 := \xi(t;\eta_1,u_2) \in V(\xi)$. Hence

$$\eta_1 = \xi\left(2t;\eta_1,(u_2,u(\eta_2))\right), \tag{6.14}$$

and as $u_2 \in \operatorname{int} U^t_{inv}$ and $u(\eta_2) \in U^t_{reg}$, it follows by Lemma 3.5 that $(u_2,u(\eta_2))$ is universally regular. Now η_1 is the projection of an eigenvector of $\Phi_{(u_2,u(\eta_2))}(2t,0)$, which proves the first half of (6.12). To complete the proof note that by Proposition 6.7 there exists a control set $D_2 \supset \mathbb{P}GE(r,u)$. But then $D \cap D_2 \neq \emptyset$, and hence $D = D_2$ by Proposition 6.2 (i). □

It should be noted that elements of the cores of control sets need not be eigenvectors corresponding to eigenvalues for *universally regular* controls even though it holds that $\xi \in \hat{\mathcal{O}}^+(\xi) \Leftrightarrow \xi \in \operatorname{core}(D)$ for some control set D. This phenomenon will be exhibited in the following example. The small sidestep necessary in the proof of the previous Proposition 6.9 is thus explained.

Example 6.10. Let $\mathbb{K} = \mathbb{R}, \mathbb{C}$, and consider the map

$$A : \mathbb{K}^2 \to \mathbb{K}^{2\times 2}, \quad A(a,b) = \begin{bmatrix} 1 & a \\ b & 0 \end{bmatrix}. \tag{6.15}$$

Define $U := \{[a\,,\, b]' \in \mathbb{K}^2;\ |a| < 1,\ |b| < \frac{1}{4}\}$. The system (2.5) given with these data is forward accessible, which is most easily seen using the rank criterion of Proposition 3.6. Define

$$V := \left\{ [x_1, x_2]' \in \mathbb{K}^2; x_1 \neq 0,\ \frac{|x_2|}{|x_1|} < \frac{1}{2} \right\}. \tag{6.16}$$

It is easy to show that $\mathbb{P}V$ is an invariant subset of $\mathbb{P}^1_{\mathbb{K}}$. Also, for the point $\xi_0 := \mathbb{P}[1,0]' \in V$ and the control $u_0 = (0,0)$ it may be seen that $\xi_0 = \mathbb{P}A(u_0)\xi_0$ and (ξ_0, u_0) is a regular pair. Thus, by Proposition 6.5 there exists a control set D satisfying $\xi_0 \in \operatorname{core}(D)$, and by invariance of $\mathbb{P}V$ it holds that $D \subset \operatorname{cl}\mathbb{P}V$. (In fact, D is the unique invariant control set, but this will be shown later.) However, ξ_0 does not belong to the projection of a generalized eigenspace of a universally regular control. Note that there is no generalized eigenspace of dimension 2 corresponding to a universally regular control as otherwise $\mathbb{P}^1_{\mathbb{K}}$ would be contained in the core of a control set (by Proposition 6.7), which contradicts the invariance of V. It is easy to see that if $\det A(u) \neq 0$ and $\xi_0 = \mathbb{P}A(u)\eta_0$, then $\eta_0 = \mathbb{P}[0,1]' \notin \operatorname{cl}\mathbb{P}V$. As universal regularity implies invertibility it follows that if $\xi_0 = \xi(t;\xi_0,u)$ for some universally regular control u then $\xi(t-1;\xi_0,u) = \eta_0$, contradicting the invariance of $\mathbb{P}V$.

This difference between the projected eigenspaces of universally regular controls and the regions of complete controllability is unique for discrete systems and does not occur in continuous time. Compare [20, Proposition 3.8]. The reason appears to be the noninvertibility possible in discrete time.

PROPOSITION 6.11. *Let $\mathbb{K} = \mathbb{R}, \mathbb{C}$. Assume that system* (2.5) *is forward accessible. If $U = U_{inv}$, then*

$$\xi \in \operatorname{core}(D) \Leftrightarrow \exists t \in \mathbb{N},\ u \in U^t_{reg} \text{ such that } \xi = \xi(t;\xi,u), \tag{6.17}$$

where D is some control set.

Proof. "$\Leftarrow$" This is clear from Proposition 6.5.

"$\Rightarrow$" As $\xi \in \operatorname{core}(D)$ by Proposition 6.6 (iii) it follows that $\operatorname{core}(D) \subset \hat{\mathcal{O}}^+(\xi)$. Hence there exist $t \in \mathbb{N}$, $u \in U^t_{reg}$ such that $\xi(t;\xi,u) \in \operatorname{core}(D)$. As $\operatorname{core}(D) \subset \hat{\mathcal{O}}^-(\xi)$, there exist $s \in \mathbb{N}$, $v \in \operatorname{int} U^s = \operatorname{int} U^s_{inv}$ such that $\xi = \xi(t+s;\xi,(u,v))$. By Lemma 3.5, $(u,v) \in \operatorname{int} U^{t+s}$ is universally regular. □

A slight modification of Example 6.10 will show that there indeed exist cases where $\operatorname{core}(D) \neq \operatorname{int} D$ for control sets D.

Example 6.12. Let $\mathbb{K} = \mathbb{R}, \mathbb{C}$,

$$A : \mathbb{K}^2 \to \mathbb{K}^{2\times 2}, \quad A(a,b) = \begin{bmatrix} 1 & a^3 \\ b^3 & 0 \end{bmatrix}. \tag{6.18}$$

Let $U := \{[a\,,\, b]' \in \mathbb{K}^2;\ |a| < 1,\ |b| < (\frac{1}{4})^{\frac{1}{3}}\}$. Note that with this definition the system defined by (6.18) behaves no differently from the system in Example 6.10, in the sense that for every point ξ the forward and backward orbits of the two systems coincide, which is clear from the definitions of A and U. Hence there exists the same control set D as in Example 6.10. But still the point ξ_0 that was critical in

the previous example now does not even belong to the core of D. For this we show that $\hat{\mathcal{O}}^-(\mathbb{P}[1,0]') = \hat{\mathcal{O}}^-(\mathbb{P}[0,1]')$. Let $t \in \mathbb{N}$, $u = (u(0), \dots, u(t-1)) \in U^t$ with $u(t-1) = [a,0]'$, and $x \notin \operatorname{Ker} \Phi_u(t,0)$. Then $\xi(t; \mathbb{P}x, u) = \mathbb{P}[1,0]' = \xi_0$ but

$$G_t(x,u) = \left[\begin{array}{c|cc} * & 1 & a^3 \\ \vdots & & \\ 0 & 0 & 0 \end{array}\right] \cdot \frac{\partial \Phi_u(t-1,0)x}{\partial u} \begin{array}{cc} * & 0 \\ & \\ 0 & 0 \end{array}, \tag{6.19}$$

and hence $\operatorname{rk} G_t(x,u) = 1$ and $(\mathbb{P}x, u)$ is not a regular pair. If $b \neq 0$ and $\xi_0 = \mathbb{P}A(a,b)x$, it follows that $A(a,b)$ is invertible. As we have seen in Example 6.10, if $\det A(u) \neq 0$ then any trajectory going to the point ξ_0 must first go through $\eta_0 = \mathbb{P}[0,1]' \notin \operatorname{cl} \mathcal{O}^+(\xi)$ for all $\xi \in \mathbb{P}V$. So $\xi_0 \notin \hat{\mathcal{O}}^+(\xi_0)$ and hence $\xi_0 \in \operatorname{int} D \setminus \operatorname{core}(D)$.

It should also be noted that it cannot be concluded that the projection of an arbitrary eigenspace corresponding to any control is contained in the closure of a control set with nonempty interior. In fact, in the following example we show that any point of the projective space may be a precontrol set, but the control sets with nonempty interior do not cover the whole projective space. Note that the following example is given here, as it fits well in our discussion of control sets and generalized eigenspaces. We do, however, use a fact from the next section, namely, the existence of a unique open and a unique invariant control set.

Example 6.13. Let $\mathbb{K} = \mathbb{R}$,

$$A : \mathbb{R}^2 \to \mathbb{R}^{2\times 2}, \quad A(a,b) = \begin{bmatrix} 1 & ab \\ a & 1 \end{bmatrix}. \tag{6.20}$$

Define $U = \left\{[a,b]' \in \mathbb{R}^2;\, 0 \leq a \leq \frac{1}{2},\, 2 \leq b \leq 4\right\}$. Then, clearly, choosing $a = 0$ leads to a transition matrix for which every $\xi \in \mathbb{P}^1_{\mathbb{R}}$ is a fixed point. Furthermore, b may be chosen such that the rank condition (3.6) is satisfied. However, the controls for which this is possible are not in the interior of U, and hence the statements made until now do not infer that the system (2.5) is completely controllable on $\mathbb{P}^1_{\mathbb{R}}$. In fact, for the set

$$V := \{[x_1, x_2]' \in \mathbb{R}^2;\, 0 < x_2 < x_1\}, \tag{6.21}$$

$\mathbb{P}V$ is an invariant set of system (2.5), and thus the invariant control set satisfies $C \subset \operatorname{cl} \mathbb{P}V$. On the other hand, we have that the open control set satisfies

$$C^- \subset \mathbb{P}\{[x_1, x_2]' \in \mathbb{R}^2;\, x_1 x_2 \leq 0\}, \tag{6.22}$$

as for every $t \in \mathbb{N}$, $u \in \operatorname{int} U^t$ the matrix $\Phi_u(t,0)$ has only strictly positive entries. Thus, by the Perron–Frobenius theory for positive matrices, $\Phi_u(t,0)$ does not have two linearly independent nonnegative eigenvectors, and the eigenvalue corresponding to the nonnegative eigendirection has algebraic multiplicity 1 (see [39, Chapter 15.3, Theorem 1, and Exercise 11]). This implies that for any $u \in U^t_{reg}$ the evolution operator $\Phi_u(t,0)$ has an eigenvector $x = [x_1, x_2]'$ satisfying $x_1 x_2 \leq 0$ corresponding to an eigenvalue of algebraic multiplicity 1, while the eigenvector corresponding to the other eigenvalue of algebraic multiplicity 1 projects to $\mathbb{P}V$. As for every control set D with nonempty interior, there exists a universally regular control u such that $\mathbb{P}GE(r,u) \subset D$ for a suitable value r by Proposition 6.9, it follows that the set $\mathbb{P}\{[x_1, x_2]' \in \mathbb{R}^2;\ 0 < x_1 < x_2\}$ does not intersect a control set with nonempty interior, although every point in this set is a precontrol set.

7. The maximal and minimal control sets. It is now shown that there exist a unique invariant and a unique open control set. These two can be described in a particularly easy fashion: they are the intersection of the closures of forward orbits, respectively, in the interior of the intersection of closures of backward orbits. We call these control sets the maximal, respectively, minimal, control sets. This terminology is justified, as we may introduce a natural order on the set of all control sets on $\mathbb{P}^{n-1}_{\mathbb{K}}$, in which the maximal control set is the invariant one and the minimal is open.

THEOREM 7.1. *Let* $\mathbb{K} = \mathbb{R}, \mathbb{C}$. *Assume that system* (2.5) *is forward accessible. Then*

(i) *there exists a unique invariant control set* $C \subset \mathbb{P}^{n-1}_{\mathbb{K}}$, *given by*

$$C := \bigcap_{\xi \in \mathbb{P}^{n-1}_{\mathbb{K}}} \operatorname{cl} \mathcal{O}^+(\xi); \tag{7.1}$$

(ii) *there exists a unique open control set* $C^- \subset \mathbb{P}^{n-1}_{\mathbb{K}}$, *which satisfies*

$$\operatorname{cl} C^- = C^* := \bigcap_{\xi \in \mathbb{P}^{n-1}_{\mathbb{K}}} \operatorname{cl} \mathcal{O}^-(\xi)\,. \tag{7.2}$$

Moreover, it holds that $\operatorname{core}(C^-) = C^-$.

Proof. (i) To begin with, it has to be shown that C as defined by (7.1) is not empty. Let $u \in U^{t^*}_{reg}$ and $|\sigma(\Phi_u(t,0))| = \{r_1, \dots, r_\nu\}$ with $r_1 < \cdots < r_\nu$. By Proposition 6.7 there exists a control set D such that $\mathbb{P}GE(r_\nu, u) \subset \operatorname{core}(D)$. By Lemma 4.3 it holds for all $\xi \notin \mathbb{P} \bigoplus_{j=1}^{\nu-1} GE(r_j, u)$ that

$$\omega^+(\xi, u) \subset \mathbb{P}GE(r_\nu, u)\,. \tag{7.3}$$

Note that the set of ξ for which (7.3) holds is generic in $\mathbb{P}^{n-1}_{\mathbb{K}}$. By forward accessibility we may steer from any point into that generic set, as the interior of each forward orbit is open, and it follows that $\mathbb{P}GE(r_\nu, u) \cap \operatorname{cl} \mathcal{O}^+(\xi) \neq \emptyset$ for all $\xi \in \mathbb{P}^{n-1}_{\mathbb{K}}$. However, we know that $\mathbb{P}GE(r_\nu, u) \subset \operatorname{core}(D)$ so that $\mathcal{O}^+(\xi) \cap \operatorname{core}(D) \neq \emptyset$, and therefore $\operatorname{core}(D) \subset \mathcal{O}^+(\xi)$. In all, we have obtained that $\operatorname{core}(D) \subset C$. By the definition of C, it follows furthermore that $D = C$, for if $\xi \in C$, then $\operatorname{core}(D) \subset \operatorname{cl} \mathcal{O}^+(\xi)$, and also $\xi \in \operatorname{cl} \mathcal{O}^+(\eta)$ for all $\eta \in D$, so that $\xi \in D$. C is therefore a closed control set with nonempty interior and invariant by Proposition 6.3. As $C \subset \operatorname{cl} \mathcal{O}^+(\eta)$ for every $\eta \in \mathbb{P}^{n-1}_{\mathbb{K}}$, there can be no other invariant control set.

(ii) Let D be the control set with $\mathbb{P}GE(r_1, u) \subset \operatorname{core}(D)$. Recall that by Proposition 5.4, $\hat{\mathcal{O}}^-(\xi) \neq \emptyset$ for all $\xi \in \mathbb{P}^{n-1}_{\mathbb{K}}$. Hence for all $\xi \in \mathbb{P}^{n-1}_{\mathbb{K}}$, we may choose a control $v \in \operatorname{int} U^{t^*}$ and $\xi_2 \in \mathbb{P}^{n-1}_{\mathbb{K}}$ such that (ξ_2, v) is a regular pair, $\xi_2 \notin \mathbb{P} \bigoplus_{j=2}^{\nu} GE(r_j, u)$, and $\xi = \xi(t^*; \xi_2, v)$. By Lemma 4.3 (iii) it follows that $\omega^-(\xi_2, u) \subset \mathbb{P}GE(r_1, u)$. Thus there exists a $\xi_3 \in \operatorname{core}(D)$ such that $\xi_3 \in \hat{\mathcal{O}}^-(\xi)$. Since by Proposition 6.6 $\operatorname{core}(D) \subset \hat{\mathcal{O}}^-(\xi)$ for $\xi \in \operatorname{core}(D)$, it follows that $\operatorname{core}(D) \subset \hat{\mathcal{O}}^-(\xi)$ for all $\xi \in \mathbb{P}^{n-1}_{\mathbb{K}}$ and thus $\operatorname{core}(D) \subset C^*$.

In particular, for $\eta \in D$ it is obtained that $\operatorname{core}(D) \subset \hat{\mathcal{O}}^-(\eta)$ and thus $\eta \in \operatorname{core}(D)$. This implies that D is an open control set by Proposition 6.6 (i).

Finally, it has to be shown that $\operatorname{cl} D = C^*$. Let $\eta \in C^* \setminus \operatorname{cl} D$. As $\eta \in C^*$ it follows that $\eta \in \operatorname{cl} \mathcal{O}^-(\xi)$ for all $\xi \in D$. Hence, in every neighborhood of η there exists a ζ such that $D \subset \mathcal{O}^+(\zeta)$. On the other hand, $D \subset \hat{\mathcal{O}}^-(\zeta)$ and thus $\zeta \in D$, by

maximality. This, however, implies that $\eta \in \operatorname{cl} D$, a contradiction. Thus $\operatorname{cl} D = C^*$ and hence $C^- = D$ is the only open control set contained in C^*.

It remains to show that there is no other open control set in $\mathbb{P}^{n-1}_{\mathbb{K}}$. If D is a control set with $\operatorname{core}(D) \neq \emptyset$, then by Proposition 6.5 there exists $\xi \in \operatorname{core}(D)$, $t \in \mathbb{N}$, $u \in U^t$ such that (ξ, u) is regular and $\xi = \xi(t; \xi, u)$. By Proposition 6.9 we may assume that u is universally regular. Let $|\sigma(\Phi_u(t,0))| = \{r_1, \dots, r_\nu\}$, $r_1 < \dots < r_\nu$. Thus $\xi \in \mathbb{P}GE(r_i, u)$ for some $i > 1$, for otherwise $\xi \in C^-$, which may be seen using the previous arguments. Now for $\eta \in \mathbb{P}(GE(r_i,u) \oplus GE(r_1,u)) \backslash \mathbb{P}GE(r_1,u)$ it holds that $\omega^+(\eta, u) \subset \mathbb{P}GE(r_i, u)$ by Lemma 4.3 (iii). Thus $\partial D \cap \mathbb{P}(GE(r_i,u) \oplus GE(r_1,u)) \subset D$ and D is not open. □

COROLLARY 7.2. *Let $\mathbb{K} = \mathbb{R}, \mathbb{C}$. Assume that system (2.5) is forward accessible. If there exists exactly one control set D in $\mathbb{P}^{n-1}_{\mathbb{K}}$, then $D = \operatorname{core}(D) = \mathbb{P}^{n-1}_{\mathbb{K}}$.*

Proof. By Theorem 7.1 it follows that $D = C = C^- = \operatorname{core}(C^-)$. Thus D is open and closed and not empty, which shows that $D = \operatorname{core}(D) = \mathbb{P}^{n-1}_{\mathbb{K}}$. □

Using the fact that the invariant control set is closed, we may prove the following result on its connectedness.

PROPOSITION 7.3. *Let $\mathbb{K} = \mathbb{R}, \mathbb{C}$. Assume that (2.5) is forward accessible. Then the invariant control set C is connected.*

Proof. For each connected component Y of C and $u \in U_{inv}$ the image $\mathbb{P}A(u)Y$ is connected as the continuous image of a connected set. Since $\mathcal{O}^+_1(\xi)$ is also connected for all $\xi \in Y$ and $\operatorname{cl} \mathcal{O}^+_1(Y) \subset C$, it follows that there exists a connected component Y' of C such that $\operatorname{cl} \mathcal{O}^+_1(Y) \subset Y'$. Let $u \in U^{t^*}_{reg}$. For the connected component of C satisfying $\mathbb{P}GE(r_n, u) \subset Y$, which exists as $\mathbb{P}GE(r_n, u)$ is connected, it follows that $\mathcal{O}^+_{t^*}(Y) \subset Y$, but then $C = \operatorname{cl} \mathcal{O}^+(Y) \subset \bigcup_{s=1}^{t^*} \operatorname{cl} \mathcal{O}^+_s(Y) \subset C$, so that there are $k \leq t^*$ connected components of C. Hence we may assume that the connected components of C are ordered in such a way that

$$\operatorname{cl} \mathcal{O}^+_1(Y_i) \subset Y_{i+1}, \quad i = 1, \dots, k-1\,,$$

and

$$\operatorname{cl} \mathcal{O}^+_1(Y_k) \subset Y_1\,.$$

Let $v \in U^{kt^*+1}_{reg}$. Then, by universal regularity of v,

$$\mathbb{P}GE(r_n, v) \subset \operatorname{core}(C)\,,$$

and for every $i = 1, \dots, k$ it holds that

$$\xi \in Y_i \Rightarrow \xi(kt^* + 1; \xi, v) \in Y_{i \bmod k+1}\,.$$

But if $\xi \in \mathbb{P}GE(r_n, v)$ then clearly $\xi(kt^* + 1; \xi, v) \in \mathbb{P}GE(r_n, v)$ and $\mathbb{P}GE(r_n, v)$ is connected. So $i = i \bmod k + 1$ and thus $k = 1$. □

Remark 7.4. (i) The uniqueness of the invariant control set system (2.5) has been shown in [32] for the case in which all system matrices $A(u)$ are invertible. The proof relies, however, on a theorem in [7], where it has to be assumed that the group generated by $\{A(u); u \in U\}$ is a Lie group. We have shown that in our case these assumptions are not necessary.

(ii) From the proof of Theorem 7.1 it follows that for all $t \geq t^*$, $u \in U^t_{reg}$ we have

$$\mathbb{P}GE(r_1(\Phi_u(t,0)), u) \subset C^-\,, \tag{7.4}$$

$$\mathbb{P}GE(r_n(\Phi_u(t,0)), u) \subset C\,. \tag{7.5}$$

The last argument in the proof of Theorem 7.1 contains the fundamental idea on what order is in a sense natural on the set of control sets.

Let D_1, D_2 be control sets in $\mathbb{P}^{n-1}_{\mathbb{K}}$ for the system (2.5). We define

$$D_1 \leq D_2 :\Leftrightarrow \text{ there exist } \xi \in D_1,\ t \in \mathbb{N},\ u \in U^t \text{ such that } \xi(t;\xi,u) \in D_2\,. \tag{7.6}$$

A priori, this defines only a partial order on the control sets. What is, however, evident at this point is the following.

PROPOSITION 7.5. *Let $\mathbb{K} = \mathbb{R}, \mathbb{C}$. Assume that system* (2.5) *is forward accessible.*

(i) *C is the unique maximal control set with respect to the order "$\leq$" on the control sets.*

(ii) *C^- is the unique minimal control set with respect to the order "$\leq$" on the control sets.*

Proof. (i) is immediate from (7.1), while (ii) follows from (7.2). □

8. Main control sets. In this section we give sufficient conditions for which it is possible to recover exactly those results that are known in the continuous-time case. Namely, the number of control sets with nonvoid interior is bounded by n, the dimension of the state space; the control sets are completely ordered with respect to the order defined in the previous section; and to each control set an index may be assigned as the sum of the algebraic multiplicities of all the eigenvalues corresponding to a universally regular u, whose generalized eigenspace is projected into the core of that control set. Furthermore, in the complex or real invertible case, the control sets are connected.

We begin with the following definition. For every $t \in \mathbb{N}$, $u \in U^t$, we will from now on consider the set $\{r_1, \ldots, r_n\}$, where $r_i \in |\sigma(\Phi_u(t,0))|$, $r_1 \leq \cdots \leq r_n$, and each r_i occurs as often as the sum of the algebraic multiplicities of those $\lambda \in \sigma(\Phi_u(t,0))$ with $r_i = |\lambda|$. We define for $i = 1, \ldots, n$

$$Q_i(t) := \bigcup_{u \in U^t_{reg}} \mathbb{P}GE(r_i, u), \quad Q_i := \bigcup_{t=1}^{\infty} Q_i(t). \tag{8.1}$$

Furthermore, for a map $A : \tilde{U} \to \mathbb{R}^{n\times n}$, we introduce the following index, which is a measure of what sets of rank deficient matrices separate $A(\operatorname{int} U)$. Define the sets

$$U_i := \{u \in U;\, \dim \operatorname{Ker} A(u) \leq i\} \tag{8.2}$$

and the singularity index

$$\bar{i}(A,U) := \min\{i;\, \operatorname{int} U_i \text{ is pathwise connected}\}\,. \tag{8.3}$$

Note that all the sets U_i are generic in U, as $U_i \supset U_{inv} \neq \emptyset$. Moreover, $\mathbb{K} = \mathbb{C}$ implies that $\bar{i}(A,U) = 0$, as proper analytic subsets are nowhere separating in the complex case; see [36, Proposition 7.4]. The significance of the indices $i > \bar{i}(A,U)$ is explained in the following proposition.

PROPOSITION 8.1. *Let $\mathbb{K} = \mathbb{R}, \mathbb{C}$. Assume that* (2.5) *is forward accessible. If $i > \bar{i}(A,U)$ then Q_i is contained in a precontrol set.*

Proof. Let $u, v \in U^t_{reg}$, where we assume without loss of generality that the length of the sequences is the same and that $t \geq t^* + 1$. Denote $u = (u(0), u')$ and $v = (v(0), v')$ where $u(0), v(0) \in \operatorname{int} U_{inv}$ and $u', v' \in \operatorname{int} U^{t-1}_{inv}$. Let $\gamma_1 : [0,1] \to \operatorname{int} U$ be a continuous path connecting $u(0)$ and $v(0)$. γ_1 can be chosen piecewise analytic.

Hence we may assume there is a finite number of points τ_j, $j = 1, \dots, k$, such that $\det(A(\gamma_1(\tau_j))) = 0$. By definition we may assume that $\dim \operatorname{Ker} A(\gamma_1(\tau_j)) \leq \bar{i}(A, U)$ for $j = 1, \dots, k$. By Proposition 5.3, the set

$$Z := \left\{ u \in U_{reg}^{t-1};\, \Phi_u(t-1, 0) \operatorname{Im} A(\gamma_1(\tau_j)) \cap \operatorname{Ker} A(\gamma_1(\tau_j)) = \{0\} \text{ for } j = 1, \dots, k \right\} \tag{8.4}$$

is generic in $\operatorname{int} U^{t-1}$ since it is the finite intersection of generic sets. We may therefore choose a continuous path $\gamma_2 : [0, 1] \to \operatorname{int} U^{t-1}$ such that $\gamma_2(0) = u'$ and $\gamma_2(\tau) \in Z$ for all $\tau \in (0, 1]$. Let $\tilde{u}' := \gamma_2(1)$.

Now consider the path:

$$\gamma_3 : [0, 2] \to \operatorname{int} U^t, \tag{8.5}$$

$$\gamma_3(\tau) = \begin{cases} (u(0), \gamma_2(\tau)), & 0 \leq \tau \leq 1, \\ (\gamma_1(\tau - 1), \tilde{u}'), & 1 \leq \tau \leq 2. \end{cases} \tag{8.6}$$

For $0 \leq \tau \leq 1$, $\gamma_3(\tau)$ is universally regular as $\gamma_3(0) = u$ and $\gamma_2(\tau) \in U_{reg}^{t-1}$ for $\tau \in (0, 1]$. Furthermore, we obtain for $1 \leq \tau \leq 2$ and $i > \bar{i}(A, U)$ that $r_i(\Phi_{\gamma_3(\tau)}(t, 0)) > 0$. This is clear if $\det(A(\gamma_1(\tau - 1))) \neq 0$. For $\tau = 1 + \tau_j$, $j = 1, \dots, k$, we have that

$$\Phi_{\tilde{u}'}(t-1, 0) \operatorname{Im} A(\gamma_1(\tau_j)) \cap \operatorname{Ker} A(\gamma_1(\tau_j)) = \{0\},$$

and hence for the eigenvalue 0 of $\Phi_{\tilde{u}'}(t-1, 0) A(\gamma_1(\tau_j))$, algebraic and geometric multiplicity coincide.

In all we have constructed a continuous path from $u = (u(0), u')$ to $(v(0), \tilde{u}')$ such that $r_i > 0$ along this path if $i > \bar{i}(A, U)$ and furthermore $\tilde{u}' \in Z$ can be chosen arbitrarily close to u'. We wish to continue this procedure in an inductive manner. Assume that for some $0 < j < t - 1$ we have constructed a continuous path from u to $(v'(0), \dots, v'(j-1), v(j), w(j+1), \dots, w(t-1)) \in U_{reg}^t$, where $(v'(0), \dots, v'(j-1))$ is arbitrarily close to $(v(0), \dots, v(j-1))$ and $(w(j+1), \dots, w(t-1))$ is arbitrarily close to $(u(j+1), \dots, u(t-1))$. Furthermore, along this path the ith entry in the ordered spectrum is never 0 if $i > \bar{i}(A, U)$.

Since for all $w_1' \in U^{t-j-2}, w_2' \in U, w_3' \in U_{inv}^j$ the Jordan structures of

$$\Phi_{w_1'}(t-j-2, 0) A(w_2') \Phi_{w_3'}(j+1, 0)$$

and

$$\Phi_{w_3'}(j+1, 0) \Phi_{w_1'}(t-j-2, 0) A(w_2')$$

coincide by similarity, we may work as in the first part to construct a path with the desired properties from $(w(j+1), w(j+2), \dots, w(t-1), v'(0), \dots, v'(j-1), v(j))$ to $(v(j+1), \tilde{w})$, where $\tilde{w}$ may be chosen arbitrarily close to $(w(j+2), \dots, w(t-1), v'(0), \dots, v'(j-1), v(j))$. Note that this rearrangement does not destroy universal regularity by Lemma 3.5. By rearranging the sequence in the original order, we obtain the desired path in the jth step.

Continuing this procedure we obtain a continuous path γ_4 from u to $\tilde{v}$, where $\tilde{v}$ may be chosen arbitrarily close to v. As $v \in U_{reg}^t$, the path may be assumed to go from u to v.

By construction, $r_i(\Phi_{\gamma_4(\tau)}(t, 0)) > 0$ along this path if $i > \bar{i}(A, U)$. Now consider the continuous paths

$$\gamma_5, \gamma_6 : [0, 1] \to \operatorname{int} U^t, \tag{8.7}$$

$$\gamma_5(\tau) = (\gamma_4(\tau), u), \tag{8.8}$$

$$\gamma_6(\tau) = (\gamma_4(1 - \tau), v) \tag{8.9}$$

connecting (u,u) with (v,u) and (u,v) with (v,v), respectively. As u and v are universally regular, we have that for $i > \bar{i}(A,U)$ and all $\tau \in [0,1]$ the sets

$$\mathbb{P}GE(r_i(\tau), \gamma_5(\tau)),\ \mathbb{P}GE(r_i(\tau), \gamma_6(\tau)) \tag{8.10}$$

are regular. Hence each of the sets

$$\bigcup_{\tau\in[0,1]} \mathbb{P}GE(r_i(\tau), \gamma_5(\tau))\,, \tag{8.11}$$

$$\bigcup_{\tau\in[0,1]} \mathbb{P}GE(r_i(\tau), \gamma_6(\tau)) \tag{8.12}$$

is contained in an open precontrol set by Proposition 6.8. Furthermore, it holds that

$$\mathbb{P}GE(r_i, (v,u)) = \mathbb{P}\Phi_v(t,0)GE(r_i, (u,v))\,, \tag{8.13}$$

which is clear by the relation $\Phi_{(u,v)}(2t,0) = \Phi_v(t,0)\Phi_{(v,u)}(2t,0)\Phi_v(t,0)^{-1}$. By symmetry, we obtain furthermore that

$$\mathbb{P}GE(r_i, (u,v)) = \mathbb{P}\Phi_u(t,0)GE(r_i, (v,u)). \tag{8.14}$$

Thus it may be concluded that

$$\bigcup_{\tau\in[0,1]} \mathbb{P}GE(r_i(\tau), \gamma_5(\tau)) \cup \bigcup_{\tau\in[0,1]} \mathbb{P}GE(r_i(\tau), \gamma_6(\tau)) \tag{8.15}$$

is contained in a precontrol set. The proof is completed by fixing one universally regular control and noting that we may apply the procedure of this proof for a path to any other universally regular control. □

Remark 8.2. In the preceding theorem we did not make a statement about connectedness. In Example 6.12, in the case $\mathbb{K} = \mathbb{R}$, we have seen a system where indeed the core of the invariant control set C is not connected. On the other hand, we know by Proposition 6.9 and by the fact that Q_1 is contained in the open control set C^- that for every connected component W of core(C) it holds that $Q_2 \cap W \neq \emptyset$. Note that in this example the index $\bar{i}(A,U) = 1$ as $\mathrm{rk}A(u) \geq 1$ for all $u \in U$, and the controls $(\frac{1}{2}, -\varepsilon)$ $(\frac{1}{2}, \varepsilon)$ can only be connected through a point of the form $(a,0)$ which leads to a rank drop.

The following statement includes in particular the case of real invertible and complex systems.

PROPOSITION 8.3. *Let* $\mathbb{K} = \mathbb{R}, \mathbb{C}$. *Assume that* (2.5) *is forward accessible. If* $\bar{i}(A,U) = 0$, *then for each* $i = 1, \ldots, n$, *the set* Q_i *is contained in a connected component of* core(D) *for some control set* D.

Proof. Fix $u_1, u_2 \in U^t_{reg}$ (where again, without loss of generality, the length of the control sequences is the same) and let $\gamma : [0,1] \to \operatorname{int} U^t_{inv}$ be a continuous connecting path. Such a path exists as $\operatorname{int} U^t_{inv}$ is connected, but there may be $\tau \in [0,1]$ such that $\gamma(\tau)$ is not universally regular. Then the path

$$\gamma_2 : [0,2] \to \operatorname{int} U^{2t}, \tag{8.16}$$

$$\gamma_2(\tau) = \begin{cases} (u_1, \gamma(\tau)), & 0 \leq \tau \leq 1, \\ (\gamma(\tau - 1), u_2), & 1 \leq \tau \leq 2, \end{cases} \tag{8.17}$$

is a continuous path connecting (u_1, u_1) and (u_2, u_2) in $\operatorname{int} U^{2t}$. By Lemma 3.5, the invertibility of $A(\gamma(\tau))$ and the universal regularity of u_1, u_2, it follows furthermore

that $\gamma_2(\tau)$ is universally regular for all $\tau \in [0,2]$. The assertion now follows due to Proposition 6.8. □

THEOREM 8.4. *Let $\mathbb{K} = \mathbb{R}, \mathbb{C}$. Assume that (2.5) is forward accessible and that $\bar{i}(A,U) \leq 1$. Then the following statements hold.*

(i) *The number κ of control sets $D_1, \dots, D_\kappa$ with nonempty interior satisfies*

$$1 \leq \kappa \leq n\,. \tag{8.18}$$

(ii) *For every $t > 0$, $u \in U^t_{reg}$, $r \in |\sigma(\Phi_u(t,0))|$ there exists a control set D_i, $1 \leq i \leq \kappa$, such that*

$$\mathbb{P}GE(r,u) \subset \operatorname{core}(D_i)\,. \tag{8.19}$$

(iii) *The core of the control sets $D_1, \dots, D_\kappa$ consists of exactly those elements $\xi \in \mathbb{P}^{n-1}_{\mathbb{K}}$ which are eigenvectors to a nonzero eigenvalue of some $\Phi_u(t,0)$ where (ξ,u) is a regular pair. If $U = U_{inv}$ the control may be chosen to be universally regular.*

(iv) *For every $t > 0$, $u \in U^t$, $r \in |\sigma(\Phi_u(t,0))|$ there exists a $j \in \{1,\dots,\kappa\}$ with $\mathbb{P}GE(r,u) \cap \operatorname{cl} D_j \neq \emptyset$. Also, for every $t \in \mathbb{N}$, $u \in U^t$, and every $j = 1,\dots,\kappa$, there exists an $r \in |\sigma(\Phi_u(t,0))|$ with $\mathbb{P}GE(r,u) \cap \operatorname{cl} D_j \neq \emptyset$.*

Proof.

(i) Let D be a control set with $\operatorname{core}(D) \neq \emptyset$. By Proposition 6.9 there exists an $i \in \{1,\dots,n\}$ such that $Q_i \cap D \neq \emptyset$. If $i = 1$ then Q_i is contained in a control set by Remark 7.4 (ii). Using Proposition 8.1 it follows that $Q_i \subset D$. Thus the number of control sets with nonempty interior is bounded by n, the number of the sets Q_i.

(ii) This follows from Corollary 4.6 and (i).

(iii) This follows from Propositions 6.5 and 6.11.

(iv) The statement is clear for $u \in U^t_{reg}$. If $t < t^*$ choose l such that $lt \geq t^*$ and consider the control $(u)^l$. If $t \geq t^*$ and $u \notin U^t_{reg}$ by genericity of the universally regular controls, there exists a sequence $(u_k)_{k\in\mathbb{N}} \subset U^t_{reg}$ with $\lim_{k\to\infty} u_k = u$. Using again the continuity properties of the eigenprojections (Chapter II.8 in [13]) it follows that for $r_i \in |\sigma(\Phi_u(t,0))|$ it holds that $\mathbb{P}GE(r_i,u) \cap \operatorname{cl} Q_i \neq \emptyset$. This implies the assertion. □

It has been shown that under the assumption of the previous theorem for every $i \in \{1,\dots,n\}$, there exists a control set D such that $Q_i \subset D$. From now on, the following terminology is used.

DEFINITION 8.5 (main control set). *Let $\mathbb{K} = \mathbb{R}, \mathbb{C}$. Assume that (2.5) is forward accessible. A control set D is called* main control set *if for every index $1 \leq i \leq n$ it holds that*

$$Q_i \cap D \neq \emptyset \;\Rightarrow\; Q_i \subset D\,.$$

The result of the previous theorem may then be paraphrased by saying that in the case where $\bar{i}(A,U) \leq 1$, i.e., in particular, in the complex or real invertible case, the only control sets with nonempty core are main control sets. Let us now examine further properties of main control sets. Recall that $n(\lambda,u)$ denotes the dimension of the generalized eigenspace of the eigenvalue λ of $\Phi_u(t,0)$.

THEOREM 8.6. *Let $\mathbb{K} = \mathbb{R}, \mathbb{C}$. Assume that (2.5) is forward accessible. Then the following holds.*

(i) *If $\bar{i}(A,U) = 0$ then the core of every main control set is connected.*

(ii) *The main control sets are completely ordered with respect to the order "$\leq$."*

(iii) *For each main control set D the number*

$$m(D) = \sum_{\mathbb{P}GE(\lambda,u)\subset \mathrm{core}(D)} n(\lambda,u) \tag{8.20}$$

is independent of $u \in U^t_{reg}$ and $t \in \mathbb{N}$.

Proof.

(i) Let D be a main control set. For any open set $W \subset \mathrm{core}(D)$ there exists an i such that $W \cap Q_i \neq \emptyset$ by Proposition 6.9. As the sets Q_i are contained in connected components of the core by Proposition 8.3, it is sufficient to show the following. If there exists $i, j \in \{1, \dots, n\}$, $i \neq j$, such that $Q_i, Q_j \subset D$, then there exists a $1 \leq k \leq n$ such that $Q_k \subset D$, $Q_i \cap Q_k \neq \emptyset$, and $Q_j \cap Q_k \neq \emptyset$.

Let $\xi \in Q_i$, $\eta \in Q_j$. Hence there exist $t, s \in \mathbb{N}$, $u \in U^t_{reg}$, $v \in U^s_{reg}$ such that

$$\eta = \xi(t; \xi, u)\,, \tag{8.21}$$

$$\xi = \xi(s; \eta, v)\,. \tag{8.22}$$

(Indeed, if $\xi \in \mathbb{P}GE(r_i, u')$ for $u' \in U^{t'}_{reg}$ and $\xi = \xi(t'; \xi', u')$, then by the implicit function theorem there is an open neighborhood of ξ' that can be steered to ξ with universally regular controls. Into this neighborhood we can steer from η using an invertible control. A concatenation yields the desired control.)

Now $(v, u), (u, v) \in U^{t+s}_{reg}$. Furthermore, as $\sigma(\Phi_v(s, 0)\, \Phi_u(t, 0)) = \sigma(\Phi_u(t, 0)\, \Phi_v(s, 0))$ it follows that there exists a $\lambda \in \mathbb{C}^*$ such that

$$\xi \in \mathbb{P}GE(\lambda, (v, u)) \tag{8.23}$$

and

$$\eta \in \mathbb{P}GE(\lambda, (u, v))\,. \tag{8.24}$$

If $|\lambda| = r_k(\Phi_{(u,v)}(s + t, 0)) = r_k(\Phi_{(v,u)}(s + t, 0))$, it follows that $\xi, \eta \in Q_k$. Hence $Q_k \subset D_i$ and $Q_i \cup Q_j \cup Q_k$ is contained in a connected component of the core of D.

(ii) Let D_1, D_2 be two main control sets. Then there exists $Q_i \subset D_1$, $Q_j \subset D_2$. Let us assume that $i \leq j$. Then we claim that $D_1 \leq D_2$. Indeed, let $u \in U^{t^*}_{reg}$ and $\xi \in \mathbb{P}(GE(r_i, u) \oplus GE(r_j, u))$. As $r_i \leq r_j$ it follows that

$$\omega^+(\xi, u) \subset \begin{cases} \mathbb{P}GE(r_i, u) & \text{if } \xi \in \mathbb{P}GE(r_i, u), \\ \mathbb{P}GE(r_j, u) & \text{otherwise.} \end{cases} \tag{8.25}$$

As $\mathbb{P}GE(r_i, u) \subset \mathrm{core}(D_1)$ there exists $\eta \in D_1$ such that $\omega^+(\eta, u) \subset \mathrm{core}(D_2)$. This proves the assertion.

(iii) It is clear that

$$m(D) = \#\{1 \leq i \leq n;\, Q_i \subset D\}\,, \tag{8.26}$$

which is independent of $u \in U^t_{reg}$, $t \in \mathbb{N}$. □

As a result of Theorem 8.6 the following definition is straightforward.

DEFINITION 8.7 (index of a main control set). *Assume that* (2.5) *is forward accessible. For a main control set $D \subset \mathbb{P}^{n-1}_{\mathbb{K}}$ the number $m(D)$ is called the* index of the control set *D.*

It remains to analyze the case where $\bar{i}(A, U) > 1$. By the discussion up to this point it is clear that for $i = 1, n$ and $i > \bar{i}(A, U)$, there exists a main control set D_i

such that $Q_i \subset D_i$. For the remainder of the indices the question of whether there exists a unique control set with this property must for the moment be left unresolved.

To summarize, we have obtained the following picture of the control structure of the system on projective space. For a map A and a set of admissible controls U such that the system on $\mathbb{P}^{n-1}_{\mathbb{K}}$ is forward accessible and $\bar{i}(A,U) \leq 1$, there exists a sequence of indices $i_1, \ldots, i_\kappa$, with $\sum_{j=1}^{\kappa} i_j = n$.

To each index i_j there exists a control set D_j such that $m(D_j) = i_j$. More specifically, it is shown in [56] that if we write

$$\mu_j = \sum_{l=1}^{j} i_l$$

for $j = 1, \ldots, \kappa$, then

$$\bigcup_{i=\mu j-1+1}^{\mu_j} Q_i \subsetneqq \operatorname{core}(D_j),$$

where equality holds if $U = U_{inv}$. So the numbers from 1 to n are partitioned into κ noninterlacing subsequences which represent the indices i such that $Q_i \subset \operatorname{core}(D_j)$:

$$\underbrace{1, \ldots, \mu_1}_{D_1}, \underbrace{\mu_1 + 1, \ldots, \mu_2}_{D_2}, \underbrace{\mu_2 + 1, \ldots}_{\cdots\cdots}, \cdots, \underbrace{\ldots, \mu_{\kappa-1}}_{\cdots\cdots}, \underbrace{\mu_{\kappa-1} + 1, \ldots, n}_{D_\kappa}.$$

The order between the main control sets is simply reflected in the order of the subsequences. In case there are control sets with nonempty core that are not main control sets, this can be extended in a natural way by considering indices that do not correspond to main control sets but to control set clusters; see [53].

With this notation we may formulate the following invariance principle which also motivates the interpretation of control sets and their indices as an extension of eigenspaces and their dimension. For a proof, we refer to [53] or [56].

THEOREM 8.8. *Let $\mathbb{K} = \mathbb{R}, \mathbb{C}$ and assume that (2.5) is forward accessible. For $u \in U^{\mathbb{N}}$ define $d(u) := \max_{t \in \mathbb{N}} \dim \ker \Phi_u(t,0)$. Let $\mu_1, \ldots, \mu_\kappa$ be the indices for the control set structure as described above.*

(i) *For every main control set D_j with $\mu_{j-1} > d(u)$, there exists a linear subspace $X_j(u)$ satisfying*

$$\dim X_j(u) = m(D_j) = \mu_j - \mu_{j-1},$$

$$\text{for all } t \in \mathbb{N} \text{ it holds that } \mathbb{P}\Phi_u(t,0)X_j(u) \subset \operatorname{cl} D_j.$$

(ii) *If $d(u) > 0$ and a main control set D_j exists such that $\mu_{j-1} < d(u) < \mu_j$ then there exists a linear subspace $X_j(u)$ satisfying*

$$\dim X_j(u) = \mu_j - d(u),$$

$$\text{for all } t \in \mathbb{N} \text{ it holds that } \mathbb{P}\Phi_u(t,0)X_j(u) \subset \operatorname{cl} D_j.$$

9. Characteristic exponents. Up to now we have described the control structure of a system on projective space. With the insight that has been gained, let us now discuss properties of the set of characteristic exponents that may be deduced from our knowledge about the control sets.

For systems of the form (2.2) let $\lambda(x_0, u)$ denote the Lyapunov exponent corresponding to the initial value $(0, x_0) \in \mathbb{N}\times\mathbb{K}^n$ and the sequence $A(u(\cdot)) \in \ell^\infty(\mathbb{N}, \mathbb{K}^{n\times n})$ determined by $u \in U^{\mathbb{N}}$, i.e. the exponential growth rate of the corresponding solution:

$$\lambda(x_0, u) = \limsup_{t\to\infty} \frac{1}{t} \log \|\Phi_u(t, 0)x_0\|,$$

while $\beta(u)$ denotes the Bohl exponent determined by $u \in U^{\mathbb{N}}$:

$$\beta(u) = \limsup_{s,t-s\to\infty} \frac{1}{t-s} \log \|\Phi_u(t, s)\| .$$

Note that it is sufficient to study Lyapunov exponents corresponding to the initial time 0, as control sequences may be shifted; i.e., the Lyapunov exponent to the initial value (t, x_t) and the control sequence $u \in U^{\mathbb{N}}$ may be recaptured by studying the initial value $(0, x_t)$ and the control sequence $v \in U^{\mathbb{N}}$ defined by $v(s) = u(s + t)$. It is known that in general $\max_{x_0\neq 0} \lambda(x_0, u) \leq \beta(u)$ where strict inequality is possible; see [24].

Floquet exponents are the Lyapunov exponents corresponding to periodic sequences $u \in U^{\mathbb{N}}$. For $t \in \mathbb{N}$, $u \in U^t$ it is easy to see that the set of Floquet exponents determined by the t-periodic continuation of u is given by

$$\sigma_{Fl}(u) := \left\{ \frac{1}{t} \log r;\ r \in |\sigma(\Phi_u(t, 0))| \right\}, \tag{9.1}$$

where we continue to use the convention $\log 0 = -\infty$. For a system of the form (2.2) determined by the map A and the set of admissible controls U, the Lyapunov spectrum is defined as the union

$$\Sigma_{Ly}(A, U) := \{\lambda(x_0, u)\,;\, x_0 \in \mathbb{K}^n\backslash\{0\}, u \in U^{\mathbb{N}}\} . \tag{9.2}$$

The Floquet spectrum of (2.2) is defined by

$$\Sigma_{Fl}(A, U) := \bigcup_{t\geq 1, u\in U^t} \sigma_{Fl}(u). \tag{9.3}$$

Furthermore, we define

$$\Sigma_{Fl,i}(A, U) := \left\{ \frac{1}{t} \log r_i(\Phi_u(t, 0)); t \geq 1\,,\ u \in U^t \right\}. \tag{9.4}$$

Recall that $\mathbb{P}GE(r, u)$ is called *regular* if $u = (u_1, u_2)$ and (ξ, u_2) is a regular pair for all $\xi \in \mathbb{P}\Phi_{u_1}(t_1, 0)GE(r, u)$. For a control set D with nonempty core we define the Floquet spectrum of D to be

$$\Sigma_{Fl}(D) := \bigcup_{t\geq 1, u\in U^t} \left\{ \frac{1}{t} \log r;\ r \in |\sigma(\Phi_u(t, 0))|,\ \mathbb{P}GE(r, u) \subset \operatorname{core}(D) \right.$$

$$\left. \text{and } \mathbb{P}GE(r, u) \text{ is regular} \right\}. \tag{9.5}$$

Finally, we consider the Bohl spectrum of (2.2) defined as the set of all Bohl exponents the system can generate:

$$\Sigma_{Bo}(A, U) := \{\beta(u); u \in U^{\mathbb{N}}\} . \tag{9.6}$$

Let us begin by explaining how to obtain the Lyapunov exponent $\lambda(x_0, u)$ from the trajectory $\xi(\cdot; \mathbb{P}x_0, u)$ of the projected system. For $\xi \in \mathbb{P}^{n-1}_{\mathbb{K}}$, $u \in U(\xi)$ define

$$q(\xi, u) := \log \frac{\|A(u)x\|}{\|x\|}, \quad \text{where} \quad x \neq 0,\ \mathbb{P}x = \xi. \tag{9.7}$$

This is well defined, as multiplication of x with a nonzero scalar does not alter the value of $q(\xi, u)$. For $\xi \in \mathbb{P}^{n-1}_{\mathbb{K}}$, $t \in \mathbb{N}$, $u \in U^t(\xi)$ define

$$J(t; \xi, u) = \sum_{s=0}^{t-1} q(\xi(s; \xi, u), u(s)). \tag{9.8}$$

Then we obtain the following expression for Lyapunov exponents.

LEMMA 9.1. *Let $\mathbb{K} = \mathbb{R}, \mathbb{C}$. For $x_0 \in \mathbb{K}^n \setminus \{0\}$, $u \in U^{\mathbb{N}}$ it holds that*

$$\lambda(x_0, u) = \begin{cases} \limsup_{t\to\infty} \frac{1}{t} J(t; \mathbb{P}x_0, u) & \text{if} \quad u \in U^{\mathbb{N}}(x_0), \\ -\infty & \text{otherwise.} \end{cases} \tag{9.9}$$

Proof. This can be shown by a straightforward calculation. ∎

The previous lemma shows that we may speak of the Lyapunov exponent corresponding to $(\xi_0, u) \in \mathbb{P}^{n-1}_{\mathbb{K}} \times U^{\mathbb{N}}$, which we denote by $\lambda(\xi_0, u)$.

10. The Floquet spectrum. The Floquet spectrum is closely related to the structure of the control sets examined up to now. In order to explore this relationship we need a controllability property in the cores of control sets. Let $\mathbb{K} = \mathbb{R}, \mathbb{C}$, and consider system (2.5) on $\mathbb{P}^{n-1}_{\mathbb{K}}$. Consider the function

$$h : \mathbb{P}^{n-1}_{\mathbb{K}} \times \mathbb{P}^{n-1}_{\mathbb{K}} \to \mathbb{N} \cup \{\infty\}, \tag{10.1}$$

$$h(\xi, \eta) := \min\{t \in \mathbb{N};\ \text{there is a } u \in U^t \text{ such that } \xi(t; \xi, u) = \eta\},$$

where $\min \emptyset = \infty$.

The previous definition is the discrete-time analogue of the *first-time hitting map*, as defined, for instance, in [17], [18]. Since we treat noninvertible systems as well, it is important for us to obtain information not only on the time that elapses to steer from ξ to η, but also on the "cost" incurred in doing so. For the projected system (2.5) and the function q interpreted as a cost, $|q(\xi, u)|$ may be arbitrarily large if u is chosen such that $A(u)$ is almost singular. In analogy to the first-time hitting map, we define the *minimal absolute cost map* by

$$H : M \times M \to \mathbb{R}_+ \cup \{\infty\}, \tag{10.2}$$

$$H(\xi, \eta) := \inf\{\max_{1\le s\le t} |J(s; \xi, u)|; \quad t \in \mathbb{N};\ u \in U^t \text{ such that } \xi(t; \xi, u) = \eta\},$$

where $\inf \emptyset = \infty$. The essential point is that both these values may be simultaneously bounded if one tries to reach a compact subset of the core of a control set.

LEMMA 10.1. *Let $\mathbb{K} = \mathbb{R}, \mathbb{C}$ and assume that system (2.5) is forward accessible. Let $D \subset \mathbb{P}^{n-1}_{\mathbb{K}}$ be a control set. Assume there are two nonvoid compact sets K_1, K_2 with $K_1 \subset \mathcal{O}^-(D)$ and $K_2 \subset \operatorname{core}(D)$. Then the following statements hold.*

(i) *There are constants $\overline{h} \in \mathbb{N}, \overline{H} \in \mathbb{R}_+$ such that*

$$h(\xi, \eta) \le \overline{h} \ \text{ for all } \xi \in K_1,\ \eta \in K_2, \tag{10.3}$$

$$H(\xi, \eta) \le \overline{H} \ \text{ for all } \xi \in K_1,\ \eta \in K_2. \tag{10.4}$$

(ii) *If* $K_2 = \mathbb{P}GE(r,u)$ *for some* $t \in \mathbb{N}$, $u \in U^t_{reg}$, *and* $r \in |\sigma(\Phi_u(t,0))|$, *then* $\overline{h}$, $\overline{H}$ *may be chosen such that for all* $\xi \in K_1$, $\eta \in K_2$ *there exists* $v \in U^t_{reg}$ *with*

$$\eta = \xi(t;\xi,v), \tag{10.5}$$

$$t \le \overline{h}, \tag{10.6}$$

$$\max_{1\le s\le t} |J(s;\xi,v)| \le \overline{H}. \tag{10.7}$$

Proof. (i) Let $\xi \in K_1$, $\eta \in K_2$. Choose any point $\zeta \in \operatorname{core}(D) \cap \hat{\mathcal{O}}^+(\xi)$, which is possible by Lemma 3.8 (i) and Proposition 6.6 (iii). Thus there exist $u_1 \in \operatorname{int} U^{t_1}(\xi)$ such that $\zeta = \xi(t_1;\xi,u_1)$ and (ξ,u_1) is a regular pair. By the implicit function theorem there exist open neighborhoods V_1 of ξ, W_1 of u_1, and a continuous function $w : V_1 \to W_1$ such that $\zeta = \xi(t_1,\xi',w(\xi'))$ for every $\xi' \in V_1$. This shows that $h(\xi',\zeta) \le t_1$ for all $\xi' \in V_1$. Furthermore, by continuous dependence of $J(s;\xi',w(\xi'))$ on ξ', it may also be obtained that $H(\xi',\zeta) \le H_1$ for some suitable constant $H_1 \in \mathbb{R}$ and all $\xi' \in V_1$, where possibly V_1 has to be chosen to be smaller than the original choice.

On the other hand, there exist $t_2 \in \mathbb{N}$, $u_2 \in \operatorname{int} U^{t_2}(\zeta)$ such that $\eta = \xi(t_2;\zeta,u_2)$ and (ζ,u_2) is a regular pair. By regularity, for any open neighborhood W_2 of u_2, the set $\{\xi(t_2;\zeta,u');\ u' \in W_2\}$ contains an open neighborhood V_2 of η. Choosing W_2 small enough so that $\operatorname{cl} W_2 \subset \operatorname{int} U^{t_2}(\zeta)$ we see that $h(\zeta,\eta') \le t_2$ for all $\eta' \in V_2$ and also $H(\zeta,\eta') \le H_2$ for all $\eta' \in V_2$ and some suitable constant H_2.

In all we have obtained that

$$h(\xi',\eta') \le t_1 + t_2 \quad \text{for all} \quad \xi' \in V_1, \eta' \in V_2$$

and

$$H(\xi',\eta') \le H_1 + H_2 \quad \text{for all} \quad \xi' \in V_1, \eta' \in V_2.$$

The assertion now follows because we may choose a finite subcover of the open cover

$$\{V_1(\xi) \times V_2(\eta); \quad \xi \in K_1, \eta \in K_2\}$$

of the compact set $K_1 \times K_2$.

(ii) Let $\xi \in K_1$, $\eta \in K_2$. Choose ζ' such that $\xi(t;\zeta',u) = \eta$. As u is universally regular, there exists an open neighborhood V of ζ', $V \subset \operatorname{core}(D)$, such that for every $\zeta'' \in V$ there exists $u(\zeta'') \in U^t_{reg}$ with $\eta = \xi(t;\zeta'',u(\zeta''))$. As $\zeta' \in \operatorname{core}(D)$ there exists $t_1 \in \mathbb{N}$, $u_1 \in \operatorname{int} U^{t_1}_{inv}$ such that $\zeta := \xi(t_1;\xi,u_1) \in V$. Let $t_2 = t$, $u_2 = u(\zeta)$; then $\eta = \xi(t_1+t_2;\xi,(u_1,u_2))$, (u_1,u_2) is universally regular and we may proceed as in the proof of part (i) by genericity of $U^{t_1}_{inv}$ and $U^{t_2}_{reg}$. □

With this result in hand we may start to examine the structure of the set of Floquet exponents.

PROPOSITION 10.2. *Let* $\mathbb{K} = \mathbb{R}, \mathbb{C}$. *The set* $\Sigma_{Fl,i}(A,U)$ *is an interval.*

Proof. Consider the function

$$\begin{aligned} \lambda_{i,t} : \quad U^t &\to \mathbb{R} \cup \{-\infty\}, \\ u &\mapsto \frac{1}{t} \log r_i(\Phi_u(t,0)). \end{aligned}$$

By Chapter II.8 in [13], $\lambda_{i,t}$ is continuous and therefore $\lambda_{i,t}(U^t)$ is connected as the continuous image of a connected set, and thus an interval. Now

$$\Sigma_{Fl,i}(A,U) = \bigcup_{t=1}^{\infty} \lambda_{i,t}(U^t),$$

and furthermore, for $u \in U$ and all $t \geq 1$

$$\log |r_i(A(u))| \in \lambda_{i,t}(U^t),$$

as we may simply consider the sequence $(u)^t$. Thus the assertion follows. □

Thus, from the connectedness of the set of admissible controls, it is immediately obtained that the Floquet spectrum is the union of at most n intervals. However, a weak point of this statement is that it totally ignores the dynamics of the system. The interplay between Floquet spectrum and dynamical behavior is studied from now on.

PROPOSITION 10.3. *Let $\mathbb{K} = \mathbb{R}, \mathbb{C}$, and assume that (2.5) is forward accessible. For a control set D with $\operatorname{core}(D) \neq \emptyset$ the set $\operatorname{cl} \Sigma_{Fl}(D)$ is an interval.*

Proof. By Proposition 6.9 there exist $t \geq t^*$, $u_1 \in U^t_{reg}$, and $\lambda_1 \in \sigma(\Phi_{u_1}(t,0))$ such that $\mathbb{P}GE(\lambda_1, u_1) \subset \operatorname{core}(D)$. It is sufficient to show that for any $\lambda \in \Sigma_{Fl}(D)$ the Floquet exponents of D are dense in the interval determined by λ and $\frac{1}{t}\log|\lambda_1|$.

Let $t_2 \in \mathbb{N}$, $u_2 \in \operatorname{int} U^{t_2}$ be such that for some $\lambda_2 \in \sigma(\Phi_{u_2}(t_2,0))$ we have that $\mathbb{P}GE(\lambda_2, u_2) \subset \operatorname{core}(D)$ and the eigenspace is regular. Without loss of generality we may assume that $t = t_2$ and $|\lambda_1| \leq |\lambda_2|$.

By Lemma 10.1 there exist constants $\overline{h}$, $\overline{H}$ such that for any $\xi, \eta \in \mathbb{P}E(\lambda_1, u_1) \cup \mathbb{P}E(\lambda_2, u_2)$ it holds that

$$h(\xi, \eta) \leq \overline{h},$$

$$H(\xi, \eta) \leq \overline{H},$$

where furthermore the corresponding control steering from ξ to η may be chosen to be universally regular if $\eta \in \mathbb{P}E(\lambda_1, u_1)$. Choose $\xi_j \in \mathbb{P}E(\lambda_j, u_j)$, $j = 1, 2$. Clearly, it holds for $j = 1, 2$ that

$$\lambda(\xi_j, u_j) = \frac{1}{t}\log|\lambda_j|.$$

We wish to construct controls such that the corresponding Floquet exponents are dense in the interval $[\frac{1}{t}\log|\lambda_1|, \frac{1}{t}\log|\lambda_2|]$. To this end define the control $u_{k,l,m}$, $k, l, m \in \mathbb{N}$ by

$$u_{k,l,m} := ((u_1)^{mk}, v_{1,k,m}, (u_2)^{ml}, v_{2,m,l}),$$

where $s_{1,k,m}, s_{2,m,l} \leq \overline{h}$ and $v_{1,k,m} \in \operatorname{int} U^{s_{1,k,m}}$ is chosen such that

$$\xi(s_{1,k,m}; \xi(mkt; \xi_1, (u_1)^{mk}), v_{1,k,m}) = \xi_2,$$

and analogously, $\xi(s_{2,l,m}; \xi(mlt; \xi_2, (u_2)^{ml}), v_{2,l,m}) = \xi_1$ for a universally regular control $v_{2,l,m}$, which is possible by Lemma 10.1(ii). We obtain in all that $\xi_1 = \xi(m(k+l)t + s_{1,k,m} + s_{2,k,m}; \xi_1, u_{k,l,m})$. Thus, for some $r \in \mathbb{R}$, it holds that $\xi_1 \in \mathbb{P}GE(r, u_{k,l,m})$. This projected sum of generalized eigenspaces is regular by the universal regularity of $v_{2,l,m}$. The corresponding Floquet exponent is given by

$$\lambda(\xi_1, u_{k,l,m}) = \frac{J(mkt; \xi_1, (u_1)^{mk}) + J(mlt; \xi_2, (u_2)^{ml}) + H(k,l,m)}{m(k+l)t + h(k,l,m)},$$

where $h(k,l,m) \leq 2\overline{h}$ and $|H(k,l,m)| \leq 2\overline{H}$ for all $k, l, m \in \mathbb{N}$. Thus for $k, l \geq 1$ it may be seen that

$$\lim_{m\to\infty} \lambda(\xi_1, u_{k,l,m}) = \lim_{m\to\infty} \frac{1}{m(k+l)t}(J(mkt; \xi_1, (u_1)^{mk}) + J(mlt; \xi_2, (u_2)^{ml}))$$

$$= \frac{k\lambda(\xi_1, u_1) + l\lambda(\xi_2, u_2)}{k+l} \in \operatorname{cl} \Sigma_{Fl}(D).$$

Clearly, the set of points that may be obtained by choosing different $k, l \in \mathbb{N}$ is dense in $[\lambda(\xi_1, u_1), \lambda(\xi_2, u_2)]$. □

COROLLARY 10.4. *Assume that* (2.5) *is forward accessible.*

(i) *If* $\mathbb{K} = \mathbb{R}, \mathbb{C}$, *then for every control set* D *with* $\operatorname{core}(D) \neq \emptyset$ *it holds that*

$$\operatorname{cl} \Sigma_{Fl}(D) = \operatorname{cl} \bigcup_{t \in \mathbb{N}, u \in U^t_{reg}} \left\{ \frac{1}{t} \log |\lambda|;\ \lambda \in \sigma(\Phi_u(t,0)),\ \mathbb{P}GE(\lambda, u) \subset \operatorname{core}(D) \right\}. \tag{10.8}$$

(ii) *If* $\mathbb{K} = \mathbb{R}$, *then for every control set* D *with nonempty core,*

$$\operatorname{cl} \Sigma_{Fl}(D) = \operatorname{cl} \bigcup_{t \in \mathbb{N}, u \in U^t_{reg}} \left\{ \frac{1}{t} \log |\lambda| \in \Sigma_{Fl}(D);\ \lambda \in \sigma(\Phi_u(t,0)) \cap \mathbb{R} \right\}. \tag{10.9}$$

Proof.

(i) If for some $u \in U^t$ and $r \in |\sigma(\Phi_u(t,0))|$ it holds that $\mathbb{P}GE(r, u) \subset \operatorname{core}(D)$, then by the genericity of the universally regular controls and the continuity of the eigenvalues and eigenprojections we may choose universally regular controls whose eigenspaces project to the core of D and whose corresponding Floquet exponents approximate the Floquet exponent $\frac{1}{t} \log r$ arbitrarily close. This shows the assertion.

(ii) Since the intermediate values $\lambda(\xi_1, u_{k,l,m})$ constructed in the previous proof are in fact Floquet exponents corresponding to a real eigenvalue of $\Phi_{u_{k,l,m}}(m(k+l)t + s_{1,k,m} + s_{2,l,m}, 0)$, it follows that it is sufficient to consider real eigenvalues. Now we may argue as in part (i). □

THEOREM 10.5. *Let* $\mathbb{K} = \mathbb{R}, \mathbb{C}$ *and assume that* (2.5) *is forward accessible. Let* κ *be equal to the number of main control sets.*

(i) *For each main control set* D_j, $j = 1, \ldots, \kappa$, *the closed Floquet spectrum is an interval. We define*

$$\operatorname{cl} \Sigma_{FL}(D_j) =: [\alpha_j, \beta_j], \quad \alpha_j \leq \beta_j\,. \tag{10.10}$$

(ii) *If all control sets with nonempty interior are main control sets, then*

$$\operatorname{cl} \Sigma_{FL}(A, U) = \bigcup_{j=1}^{\kappa} [\alpha_j, \beta_j]\,. \tag{10.11}$$

(iii) *If there exist control sets with nonempty interior that are not main control sets, then there exists a constant* $\bar{\beta} \in \mathbb{R}$ *such that*

$$\operatorname{cl} \Sigma_{FL}(A, U) = \bigcup_{j=1}^{\kappa} [\alpha_j, \beta_j] \cup [-\infty, \bar{\beta}]\,. \tag{10.12}$$

(iv) *If for two main control sets,* $D_{j_1} < D_{j_2}$, *then*

$$\alpha_{j_1} \leq \alpha_{j_2}, \tag{10.13}$$

$$\beta_{j_1} \leq \beta_{j_2}. \tag{10.14}$$

(v) *For $j = 1, \dots, \kappa$ it holds that*

$$\#\operatorname{cl}\Sigma_{FL}(D_j) \setminus \Sigma_{FL}(D_j) \leq m(D_j) + 1\,. \tag{10.15}$$

Proof.

(i) This is clear by Proposition 10.3.

(ii) Let $t \in \mathbb{N}$, $u \in U^t$ and consider $\sigma_{Fl}(u)$. As the Floquet spectrum of u does not change if we consider $(u)^l$ for some $l \geq 1$, we may assume that $t \geq t^*$. Hence, we may choose a sequence $\{u_k\}_{k\in\mathbb{N}} \subset U^t_{reg}$ converging to u for k tending to infinity. By the continuity of the spectrum it follows that $\sigma_{Fl}(u) \subset \bigcup_{j=1}^{\kappa}[\alpha_j, \beta_j]$.

(iii) For a control set D with nonempty interior that is not a main control set it holds by Proposition 8.1 that $\inf \Sigma_{Fl}(D) = -\infty$. The assertion thus follows from Proposition 10.3 and the argumentation of (ii).

(iv) If for two main control sets, $D_{j_1} \leq D_{j_2}$, then $Q_i \subset D_{j_1}$ and $Q_j \subset D_{j_2}$ implies that $i < j$. Thus the assertion follows from the obvious inequalities $\inf \Sigma_{Fl,i}(A,U) \leq \inf \Sigma_{Fl,j}(A,U)$ and $\sup \Sigma_{Fl,i}(A,U) \leq \sup \Sigma_{Fl,j}(A,U)$ if $i < j$.

(v) Let $t \in \mathbb{N}$ and $u, v \in U^t_{reg}$. Consider a continuous path $\gamma : [0,1] \to \operatorname{int} U^t$ with $\gamma(0) = u$ and $\gamma(1) = v$. Now consider the control $(\gamma(\tau), u)$. For every $\tau \in [0,1]$ and every $i \in \{1, \dots, n\}$ it holds by the universal regularity of u that $r_i(\tau) := r_i(\Phi_{(\gamma(\tau),u)}(2t, 0)) > 0$ iff $\mathbb{P}GE(r_i(\tau), (\gamma(\tau), u))$ is regular. Thus it follows for every $i \in \{1, \dots, n\}$ that the interval $[r_i(\Phi_{(u,u)}(2t,0)), r_i(\Phi_{(v,u)}(2t,0))]$ is contained in $\Sigma_{Fl}(D)$ for some control set D by Proposition 6.8. Since the sets $\operatorname{int}\Sigma_{Fl,i}(A,U)$ are intervals and by $\operatorname{cl}\Sigma_{Fl}(D_j) = \bigcup_{Q_i \subset D_j} \operatorname{cl}\Sigma_{Fl,i}(A,U)$, it follows that the only points where the Floquet spectrum of a main control set and its closure may differ are the endpoints of the intervals $\Sigma_{Fl,i}(A,U)$. Of these there are at most $m(D_j) + 1$, which shows the assertion. □

It should be noted that the spectral intervals corresponding to different main control sets may overlap, i.e., that the statement $\alpha_i \leq \alpha_j$, $\beta_i \leq \beta_j$ in Theorem 10.5 in no way excludes the possibility that $\beta_i > \alpha_j$. In fact, it is even possible that $\alpha_i = \alpha_j$ and $\beta_i = \beta_j$ for $i \neq j$. To illustrate this phenomenon consider the following example.

Example 10.6. Let $\mathbb{K} = \mathbb{R}$. Define

$$A :\ \mathbb{R}^4 \longrightarrow \mathbb{R}^{2\times 2},$$

$$A(a,b,c,d) := \begin{bmatrix} a & b \\ c & d \end{bmatrix}.$$

Let $\mathbb{R}^n_{\geq 0}$ denote the set of vectors with nonnegative real entries. Define

$$U := \{[a\ b\ c\ d] \in \mathbb{R}^4_{\geq 0};\quad a + c \leq 1;\, b + d \leq 1\}.$$

Then $A(U)$ is exactly the set of nonnegative matrices in $\mathbb{R}^{2\times 2}$ with 1-norm less than or equal to 1. As the set of nonnegative vectors in $\mathbb{R}^2$ is invariant under $A(u)$ for any $u \in U$, i.e., $A(u)\mathbb{R}^2_{\geq 0} \subset \mathbb{R}^2_{\geq 0}$, it follows that the invariant control set $D_2 = C \subset \mathbb{P}\mathbb{R}^2_{\geq 0}$. Hence there also exists a minimal control set $D_1 = C^-$ and no other control set D with $\operatorname{core}(D) \neq \emptyset$.

Clearly, $\alpha_1 = \alpha_2 = -\infty$ as $0 \in A(U)$. Let us show also that $\beta_1 = \beta_2 = 0$. For any $t \geq 1$, $u \in U^t$, it holds that

$$r(\Phi_u(t,0)) \leq \|\Phi_u(t,0)\|_1 \leq \|A(u(t-1))\|_1 \cdot \ldots \cdot \|A(u(0))\|_1 \leq 1.$$

Hence $\beta_1, \beta_2 \leq \log 1 = 0$. On the other hand, $I \in A(U)$, and so $0 \in \operatorname{cl}\Sigma_{FL}(C)$, $0 \in \operatorname{cl}\Sigma_{FL}(C^-)$, and $\beta_1, \beta_2 \geq 0$.

In order to construct a two-dimensional example with identical spectral intervals and $U = U_{inv}$, it is sufficient to replace the set U of the previous example by $U' := \{u \in U;\ \det(A(u)) > 0\}$. If we require that $\operatorname{cl} A(U)$ consist of invertible matrices, then it is still possible to make upper or lower boundaries of spectral intervals equal, e.g., if the map A is replaced by $u \mapsto \exp(A(u))$. Note also that $\exp(A(U))$ consists of nonnegative matrices. Then, as in the preceding discussion, it is possible to obtain that for this modified example, $\beta_1 = \beta_2 = 1$. However, this comes with the price that $\alpha_1 = -1 \neq \alpha_2 = 0$. It is not known whether identical spectral intervals to different main control sets are possible if it is assumed that $\det(A(u)) \neq 0$ for all $u \in \operatorname{cl} U$.

11. The Lyapunov and Bohl spectrums. Let us now discuss how the results on the Floquet spectrum can be related to the other spectra of characteristic exponents. We begin by showing that the Lyapunov exponents corresponding to trajectories that evolve in a specific way in the core of control sets are contained in the closure of the associated Floquet interval. On the other hand, for every element of the closure of the Floquet interval of a control set there exists a control sequence that realizes this number as a Lyapunov exponent.

THEOREM 11.1. *Let $\mathbb{K} = \mathbb{R}, \mathbb{C}$, and assume that (2.5) is forward accessible.*

(i) *Let D be a control set, with $\operatorname{core}(D) \neq \emptyset$. Assume that $(\xi_0, u) \in \mathbb{P}^{n-1}_{\mathbb{K}} \times U^{\mathbb{N}}(\xi_0)$ are given with $\omega^+(\xi_0, u) \subset D$. If there exists a $t_0 \in \mathbb{N}$ with $\xi(t_0; \xi_0, u) \in \operatorname{core}(D)$, then $\lambda(\xi_0, u) \in \operatorname{cl}\Sigma_{Fl}(D)$.*

(ii) *Let D be a control set, with $\operatorname{core}(D) \neq \emptyset$. Then for every $\lambda \in \operatorname{cl}\Sigma_{Fl}(D)$ there exist $\xi_0 \in \operatorname{core}(D)$ and $u \in U^{\mathbb{N}}$ such that $\lambda = \lambda(\xi, u)$. In particular, it holds that*

$$\operatorname{cl}\Sigma_{Fl}(D) \subset \Sigma_{Ly}(A, U). \tag{11.1}$$

Proof. (i) Without loss of generality we may assume that $t_0 = 0$ as the Lyapunov exponents satisfy $\lambda(\xi_0, u) = \lambda(\xi(t_0; \xi_0, u), u(t_0 + \cdot))$ where $u(t_0 + \cdot) = (u(t_0), u(t_0 + 1), \ldots)$ is the shifted control. Let $\{t_k\}_{k\in\mathbb{N}} \subset \mathbb{N}$ be an increasing sequence such that

$$\lim_{k\to\infty} \frac{1}{t_k} J(t_k; \xi_0, u) = \lambda(\xi_0, u)\,. \tag{11.2}$$

Taking a subsequence we may assume that

$$\lim_{k\to\infty} \xi(t_k; \xi_0, u) =: \eta \in \omega^+(\xi_0, u) \subset D\,. \tag{11.3}$$

As $\xi_0 \in \operatorname{core}(D)$ it follows that $\eta \in \hat{\mathcal{O}}^-(\xi_0)$, and hence there is a $t \in \mathbb{N}$ and a neighborhood $V(\eta)$ such that $V(\eta) \subset \hat{\mathcal{O}}^-_t(\xi_0)$. For k large enough it holds that $\xi(t_k; \xi_0, u) \in V(\eta)$. By continuous dependence of $\xi(t_k; \xi_0, u)$ on u, the continuous dependence of $J(t_k; \xi_0, u)$ on u, and the genericity of $U^{t_k}_{reg}$, we may choose controls $u_k \in U^{t_k}_{reg}$ such that $\xi(t_k; \xi_0, u_k) \in V(\eta)$ for all k large enough and

$$\lim_{k\to\infty} \frac{1}{t_k} J(t_k; \xi_0, u_k) = \lambda(\xi_0, u)\,.$$

We can therefore find a control $v_k \in \operatorname{int} U^t$ such that $\xi_0 = \xi(t; \xi(t_k; \xi_0, u_k), v_k)$. The Floquet exponent corresponding to the control (u_k, v_k) and ξ_0 is given by

$$\begin{aligned} \lambda(\xi_0, (u_k, v_k)) &= \frac{1}{t_k + t} \left(J(t_k; \xi_0, u_k) + J(t; \xi(t_k; \xi_0, u_k), v_k)\right) \\ &= \lambda(\xi(t_k; \xi_0, u_k), (v_k, u_k)) \in \Sigma_{Fl}(D)\,, \end{aligned} \tag{11.4}$$

by the universal regularity of u_k. Letting $k \to \infty$ the assertion follows after noting that Lemma 10.1 guarantees that the v_k can be chosen so that $|J(t;\xi(t_k;\xi_0,u_k),v_k)|$ is bounded independently of k.

(ii) Let $\lambda^* \in \operatorname{cl}\Sigma_{Fl}(D)$. Let $u_k \in U^{t_k}_{reg}$, $k \in \mathbb{N}$, be a sequence of controls such that

$$\lim_{k\to\infty} \frac{1}{t_k} \log|\lambda_k| = \lambda^*, \tag{11.5}$$

where $\lambda_k \in \sigma(\Phi(t_k,u_k))$ and $\mathbb{P}E(\lambda_k,u_k) \subset \operatorname{core}(D)$. By Corollary 10.4 such a sequence exists and we may assume that $\lambda_k \in \mathbb{R}$ if $\mathbb{K} = \mathbb{R}$. For $k \in \mathbb{N}$ let $\xi_k \in \mathbb{P}E(\lambda_k,u_k)$. Therefore it holds for all $l,k \in \mathbb{N}$ that $\xi(lt_k;\xi_k,(u_k)^l) = \xi_k \in \operatorname{core}(D)$. For all $k \in \mathbb{N}$ there exists a control $v_k \in U^{s_k}$ such that $\xi_{k+1} = \xi(s_k;\xi_k,v_k)$. Let H_k be such that $|J(s;\xi_k,v_k)| < H_k$ for $0 \le s \le s_k$. We construct a control that generates the Lyapunov exponent λ^* as follows: choose $m_1 \in \mathbb{N}$ such that

$$\left|\left(\frac{m_1t_1}{m_1t_1+s_1+t_2}-1\right)\frac{1}{t_1}\log|\lambda_1|\right| < \frac{1}{8}, \tag{11.6}$$

$$\frac{H_1}{m_1t_1} < \frac{1}{8}, \tag{11.7}$$

$$\left|\frac{J(s;\xi_2,u_2)}{m_1t_1}\right| < \frac{1}{8}, \quad 0 \le s \le t_2. \tag{11.8}$$

Let $u_1^* := ((u_1)^{m_1},v_1) \in U^{T_1}$ and $T_1 := m_1t_1+s_1$. Using (11.6) and (11.7) it may be seen that for $0 \le s \le s_1$

$$\begin{aligned}&\left|\frac{1}{m_1t_1+s}J(m_1t_1+s;\xi_1,u_1^*) - \frac{1}{t_1}\log|\lambda_1|\right| \\ &\le \frac{1}{m_1t_1+s}|J(s;\xi_1,v_1)| + \left|\left(\frac{m_1t_1}{m_1t_1+s}-1\right)\frac{1}{t_1}\log|\lambda_1|\right| < \frac{1}{4}.\end{aligned} \tag{11.9}$$

Note also that by (11.8), we obtain as in (11.9) that for $0 \le s \le t_2$ and $v = (u_1^*,u_2)$,

$$\begin{aligned}&\left|\frac{1}{T_1+s}J(T_1+s;\xi_1,v) - \frac{1}{t_1}\log|\lambda_1|\right| \\ &\le \left|\frac{1}{T_1+s}J(m_1t_1;\xi_1,v) - \frac{1}{t_1}\log|\lambda_1|\right| + \frac{H_1}{T_1+s} + \left|\frac{1}{T_1+s}J(s;\xi_2,u_2)\right| < \frac{1}{2}.\end{aligned} \tag{11.10}$$

For $k > 1$ assume that we have constructed u_{k-1}^*, m_{k-1}, and T_{k-1} such that for $-s_{k-1} \le s \le t_k$ it holds that

$$\left|\frac{1}{(T_{k-1}+s)}J(T_{k-1}+s;\xi_1,(u_{k-1}^*,u_k)) - \frac{1}{t_{k-1}}\log|\lambda_{k-1}|\right| < 2^{-(k-1)}. \tag{11.11}$$

Choose $m_k \in \mathbb{N}$ such that

$$\left|\frac{1}{T_{k-1}+m_kt_k}J(T_{k-1};\xi_1,u_{k-1}^*)\right| < 2^{-(k+3)}, \tag{11.12}$$

$$\left|\left(\frac{m_kt_k}{T_{k-1}+m_kt_k+s_k+t_{k+1}}-1\right)\frac{1}{t_k}\log|\lambda_k|\right| < 2^{-(k+3)}, \tag{11.13}$$

$$\frac{H_k}{T_{k-1}+m_kt_k} < 2^{-(k+3)}, \tag{11.14}$$

$$\left|\frac{J(s;\xi_{k+1},u_{k+1})}{m_k t_k}\right| < 2^{-(k+2)}\,, \quad 0 \le s \le t_{k+1}. \tag{11.15}$$

Set $u_k^* := (u_{k-1}^*, (u_k)^{m_k}, v_k)$ and $T_k := T_{k-1} + m_k t_k + s_k$. For $T_{k-1} + m_k t_k \le t \le T_k$ we obtain with (11.12), (11.13), and (11.14) that

$$\begin{aligned}
&\left|\frac{1}{t}J(t;\xi_1,u_k^*) - \frac{1}{t_k}\log|\lambda_k|\right| \\
&\le \left|\frac{1}{t}J(T_{k-1};\xi_1,u_{k-1}^*)\right| + \left|\left(\frac{m_k t_k}{t} - 1\right)\frac{1}{t_k}\log|\lambda_k|\right| + \frac{1}{t}|J(t - T_{k-1} - m_k t_k;\xi_k,v_k)| \\
&< 2^{-(k+3)} + 2^{-(k+3)} + 2^{-(k+3)} < 2^{-(k+1)}\,.
\end{aligned}$$

Analogously to (11.10), it may be seen from (11.13) and (11.15) that for $0 \le s \le t_{k+1}$ and $v = (u_k^*, u_{k+1})$,

$$\left|\frac{1}{T_k + s}J(T_k + s;\xi_1,v) - \frac{1}{t_k}\log|\lambda_k|\right| < 2^{-k}\,. \tag{11.16}$$

For the control u^* that is recursively defined via $u^*_{[0,T_k]} = u_k^*$ we claim that

$$\lambda(\xi_1,u^*) = \lim_{k\to\infty}\frac{1}{t_k}\log|\lambda_k| = \lambda^*\,. \tag{11.17}$$

We have shown that for $k > 1$ and $T_{k-1} + m_k t_k \le t \le T_k + t_{k+1}$, it holds that

$$\left|\frac{1}{t}J(t;\xi_1,u^*) - \frac{1}{t_k}\log|\lambda_k|\right| < 2^{-k}.$$

Thus our claim follows if we can show that for $t = T_{k-1},\dots,T_{k-1} + (m_k - 1)t_k$ the following relation holds:

$$\left|\frac{1}{t}J(t;\xi_1,u_k^*) - \frac{1}{t_k}\log|\lambda_k|\right| \ge \left|\frac{1}{t + t_k}J(t + t_k;\xi_1,u_k^*) - \frac{1}{t_k}\log|\lambda_k|\right|\,, \tag{11.18}$$

because this means that the sequence behaves in a monotonic way, at least if viewed at every t_kth step. For $l = 0,\dots,m_k - 1$ and $t = T_{k-1} + l t_k$ this is clear by

$$\begin{aligned}
\left|\frac{1}{t}J(t;\xi_1,u_k^*) - \frac{1}{t_k}\log|\lambda_k|\right| &= \left|\frac{1}{t}(J(T_{k-1};\xi_1,u_k^*) + l\log|\lambda_k|) - \frac{1}{t_k}\log|\lambda_k|\right| \\
&= \frac{1}{t}\left|J(T_{k-1};\xi_1,u_k^*) - \frac{T_{k-1}}{t_k}\log|\lambda_k|\right|\,.
\end{aligned}$$

The other cases can be treated using the same argument, with the modification that the time from which periodicity is used is not T_{k-1} but $T_{k-1}+s$ for some $0 \le s \le t_k - 1$. This proves the assertion. □

A further question of interest, especially if stabilization and robust stability questions are considered, concerns the lower and upper bounds of the spectral sets that we have defined. For a general discrete inclusion given by a bounded set $\Sigma \subset \mathbb{K}^{n\times n}$ and

$$x(t+1) \in \{Ax(t)\,;\ A \in \Sigma\}\,, \quad t \in \mathbb{N}, \tag{11.19}$$

this has been studied in [8], [15], [38], [27]. In particular, the latter three references study the relation between the generalized spectral radius

$$\bar\rho(\Sigma) := \limsup_{t\to\infty}\bar\rho_t(\Sigma)^{1/t}\,,$$

where

$$\bar\rho_t(\Sigma) := \sup\{r(A_{t-1}\cdot\ldots\cdot A_0); A_s\in\Sigma, s=0,\ldots,t-1\},$$

and the joint spectral radius

$$\hat\rho(\Sigma) := \limsup_{t\to\infty}\hat\rho_t(\Sigma)^{1/t},$$

where

$$\hat\rho_t(\Sigma) := \sup\{\|A_{t-1}\cdot\ldots\cdot A_0\|; A_s\in\Sigma, s=0,\ldots,t-1\}.$$

Theorem IV in [15] states that for every bounded set Σ we have $\bar\rho(\Sigma)=\hat\rho(\Sigma)$. Although Berger and Wang restrict themselves to the real case, it is clear that they also prove the complex case, which may be seen via identification of $\mathbb{C}^{n\times n}$ with $\mathbb{R}^{2n\times 2n}$. Note that these definitions correspond to our definitions but for the fact that we have introduced the logarithm. Thus it is easy to see that

$$\log(\bar\rho(A(U))) = \sup\Sigma_{Fl}(A,U) \tag{11.20}$$

and

$$\log(\hat\rho(\Sigma)) = \limsup_{t\to\infty}\sup_{u\in U^{\mathbb{N}},\,\xi\in\mathbb{P}^{n-1}_{\mathbb{K}}}\frac{1}{t}J(t;\xi,u). \tag{11.21}$$

We therefore immediately obtain the following corollaries, where we do not have to make our usual forward accessibility assumption. In order to conform to our previously introduced notation we will still think of the discrete inclusion to be given by an analytic map A and a set U. Note, however, that if we drop Assumption 2.1, then any bounded set of matrices may be represented in this way.

COROLLARY 11.2. *Let $\mathbb{K}=\mathbb{R},\mathbb{C}$, and consider system* (2.2)*. Assume that $A(U)$ is bounded. Then*

$$\sup\Sigma_{Fl}(A,U)=\sup\Sigma_{Ly}(A,U)=\sup\Sigma_{Bo}(A,U)=\limsup_{t\to\infty}\sup_{u\in U^{\mathbb{N}},\,\xi\in\mathbb{P}^{n-1}_{\mathbb{K}}}\frac{1}{t}J(t;\xi,u).$$

Using this result we can also prove the following statements on the infima of the spectra.

PROPOSITION 11.3. *Let $\mathbb{K}=\mathbb{R},\mathbb{C}$, and consider system* (2.2)*. Assume that $A(U)$ is bounded. Then*

$$\inf\Sigma_{Fl}(A,U)=\inf\Sigma_{Ly}(A,U)=\liminf_{t\to\infty}\inf_{u\in U^{\mathbb{N}},\,\xi\in\mathbb{P}^{n-1}_{\mathbb{K}}}\frac{1}{t}J(t;\xi,u). \tag{11.22}$$

Proof. Obviously, it holds that

$$\inf\Sigma_{FL}(A,U)\geq\inf\Sigma_{Ly}(A,U)\geq\liminf_{t\to\infty}\inf_{u\in U^{\mathbb{N}},\,\xi\in\mathbb{P}^{n-1}_{\mathbb{K}}}\frac{1}{t}J(t;\xi,u).$$

If there exists a $u\in\operatorname{cl}U$ such that $\det(A(u))=0$ the claim is trivially true as both infima are given by $-\infty$. If this is not the case we may consider the time-reversed system

$$\begin{aligned} x(t+1) &= A(u(t))^{-1}x(t),\ t\in\mathbb{N},\\ x(0) &= x_0\in\mathbb{K}^n,\\ u(t) &\in U,\ t\in\mathbb{N}. \end{aligned} \tag{11.23}$$

Denote the Floquet spectrum of the time-reversed system by $\Sigma_{Fl}^{-}(A,U)$. It is immediate that $\sup \Sigma_{Fl}^{-}(A,U) = -\inf \Sigma_{Fl}(A,U)$. Note also that

$$\inf_{x\in\mathbb{K}^n,\|x\|=1} \log\|\Phi_u(t,0)x\| = -\sup_{x\in\mathbb{K}^n,\|x\|=1} \log\|\Phi_u(t,0)^{-1}x\|$$

and therefore

$$\liminf_{t\to\infty} \inf_{u\in U^{\mathbb{N}},\ \xi\in\mathbb{P}_{\mathbb{K}}^{n-1}} \frac{1}{t}J(t;\xi,u) = -\limsup_{t\to\infty} \sup_{u\in U^{\mathbb{N}},\xi\in\mathbb{P}_{\mathbb{K}}^{n-1}} \frac{1}{t}J^{-}(t;\xi,u),$$

where $J^{-}(t;\xi,u) = \log \frac{\|\Phi_u(t,0)^{-1}x\|}{\|x\|}$ for $\xi = \mathbb{P}x$. The assertion now follows by applying Corollary 11.2. □

Barabanov [9] proved that to each discrete inclusion given by a bounded set of matrices there exists a trajectory that realizes the maximal Lyapunov exponent. The following statement brings this in relation to the control structure of system (2.5).

PROPOSITION 11.4. *Let $\mathbb{K} = \mathbb{R},\mathbb{C}$, let Assumption 2.1 hold, and assume that (2.5) is forward accessible. Then*

(i) *there exist $u \in U^{\mathbb{N}}$, $\xi \in C$ such that $\lambda(\xi,u) = \beta(u) = \sup \Sigma_{Ly}(A,U)$;*

(ii) *there exist $v \in U^{\mathbb{N}}$, $\eta \in C^{-}$ such that $\lambda(\eta,v) = \inf \Sigma_{Ly}(A,U)$.*

Proof. (i) (resp., (ii)) follows from Corollary 11.2 (resp., Proposition 11.3, Remark 7.4(ii), and Theorem 11.1 (ii)). □

If the finiteness conjecture holds as discussed by Lagarias and Wang [38], then the previous result can be restated in terms of the Floquet spectrum; i.e., it would be possible to realize maximal and minimal Floquet exponents via some periodic control sequence u. This is the topic of ongoing research.

Let us also note that Gurvits [27] has shown that for discrete inclusions given by finitely many matrices, the indices $\inf \Sigma_{Fl,n}(A,U)$ and $\inf \Sigma_{Bo}(A,U)$ coincide. It remains to be investigated how this result may be carried over to our case.

Acknowledgment. The author wishes to express his thanks to F. Colonius, D. Hinrichsen, and W. Kliemann for a number of helpful discussions and remarks and an anonymous referee for supplying important references.

AN OPTIMAL CONTROL THEORY FOR DISCRETE EVENT SYSTEMS*

RAJA SENGUPTA† AND STÉPHANE LAFORTUNE‡

Abstract. In certain discrete event applications it may be desirable to find a particular controller, within the set of acceptable controllers, which optimizes some quantitative performance measure. In this paper we propose a theory of optimal control to meet such design requirements for deterministic systems. The discrete event system (DES) is modeled by a formal language. Event and cost functions are defined which induce costs on controlled system behavior. The event costs associated with the system behavior can be reduced, in general, only by increasing the control costs. Thus it is nontrivial to find the optimal amount of control to use, and the formulation captures the fundamental tradeoff motivating classical optimal control. Results on the existence of minimally restrictive optimal solutions are presented. Communication protocols are analyzed to motivate the formulation and demonstrate optimal controller synthesis. Algorithms for the computation of optimal controllers are developed for the special case of DES modeled by regular languages. It is shown that this framework generalizes some of the existing literature.

Key words. discrete event systems, optimal control, regular languages, dynamic programming

1. Introduction.

This paper presents a new framework for the optimal control of discrete event systems (DESs). The aim is to find methods to handle numerical performance measures in the DES controller design process.

The most influential paradigm for DES control is the supervisory control theory (SCT) suggested by Ramadge and Wonham [9, 8]. SCT makes certain system-theoretic assumptions which are appropriate for DES control problems. SCT as developed in [8] partitions all possible DES behavior into legal or illegal, and then addresses the problem of designing a DES controller that guarantees legal behavior. Here we enrich this view by accepting that some legal behaviors are better than others. For example, for a transaction submitted to a database management system (DBMS), all commit times below a certain threshold may be legal, but a smaller commit time is better. We propose numerical measures on the set of legal behaviors to capture such distinctions. The new problem, then, is to produce a controller that is not only legal but also "good" in the sense of the given numerical performance measures. We present our various findings collectively as a theory of *optimal control for discrete event systems.* It is our hope that this theory lays out the boundaries within which future work on the performance improvement or performance tuning of specific DESs can be attempted.

In the historical development of control theory, optimal control has been considered interesting only after the design and analysis of other control-theoretic concepts such as controllability, stabilizability, etc. have attained some degree of maturity.

These concepts are concerned with the design and analysis of controllers which are *feasible* or *tolerable* by some general specification. In the field of DESs there is a substantial body of literature on the design of controllers which will satisfy logical specifications. The theory of discrete event dynamical systems has evolved to a point where it is meaningful to study control methods that not only satisfy legality specifications but also improve quantitative measures of performance. Relevant published papers on the subject are Passino and Antsaklis [7], Kumar and Garg [6], and Sengupta and Lafortune [11, 12, 14, 13]. The work of Brave and Heymann [2] on the optimal attractor problem is also of interest.

Our view of the system, the controller, and their interaction is similar to SCT [8, 16] in the following manner. We view a DES as a system that usually operates with several concurrent processes. Each process may serve a different user or objective. A typical example is that of multiple transactions, reading and writing different records running concurrently on a database. In general, the concurrent processes have interdependencies, which suggest global level problems relating to correctness, consistency, fairness, etc. SCT conceives of an object called the supervisor that enforces correctness at the overall system level. We pose our problem in this setting of system and supervisor; i.e., we wish to design supervisors that are both correct and optimal. The supervisor acts by disabling events, where the events themselves are assumed to be generated *spontaneously, instantaneously,* and *asynchronously* by the DES itself. Since the demands and disturbances on DES are uncertain, the supervisor should be *minimally restrictive*; i.e., it should allow the DES maximum freedom in its response. It is not acceptable to prevent illegal behavior by preventing all behavior! The notion of a minimally restrictive supervisor guaranteeing a legality specification is formalized in [8] and computed in [16]. We adopt these assumptions on the role of the system and the supervisor. We will address the issue of minimally restrictive supervisors that improve quantitative performance measures.

We assume a formal language representation of a DES. The language is not necessarily regular. The behavior of a DES is constituted from events. The set of possible events is known as the *alphabet* (denoted Σ). In any given time line the DES executes a sequence of events. Each sequence is assumed to be of finite length and is a string in Σ^*, which represents the Kleene closure of Σ. The set of trajectories of the uncontrolled DES is represented by a set of strings, collectively referred to as the plant language (denoted $L \subseteq \Sigma^*$). The language is prefix-closed. This is a very general representation of a DES. Some strings in L are marked and these constitute a marked language $L_m \subseteq L$. A marked string represents a properly completed behavior, i.e., one that fulfills control objectives. We assume the plant is *nonblocking* ($L = \bar{L}_m$) [4]. Of course, many DESs would exhibit blocking behaviors without supervision. Nevertheless the nonblocking plant assumption is made because the synthesis of supervisors guaranteeing this property is well understood [8, 4]. Moreover, we require that any controlled DES must also be nonblocking; i.e., the supervisor must ensure that for any past there exists some future that accomplishes control objectives. Thus, we present our problem as one of finding the optimal nonblocking supervisor given a nonblocking plant. This innocuous requirement is actually extremely fundamental, since without it the optimal solution to many problems is to have the system do nothing at all!

All performance measures are modeled by two functions that we call event and control cost functions. In this paper we present one example to illustrate their use. The event cost is associated with the execution of an event by the plant and the control cost with the disabling of an event by the supervisor. These are the only

two types of actions in an SCT framework. The event and control costs are used to induce a cost on each string the system may generate. One part of this string cost is the sum of the event costs associated with the events in the string. It represents the energies and resources expended by the plant. The other part is the sum of the control costs associated with the various events disabled by the supervisor after each prefix of the string. It represents the energies and resources expended by the controller. The cost associated with a single string lying in two different controlled sublanguages may be different, since the supervisors will be different. The event and control costs are found to be naturally antagonistic as in classical optimal control. It will be shown that trying to reduce the event costs associated with a language by using control can raise the control costs. The overall cost of a string in the language, being the sum of the event and control costs, may increase. This could be undesirable, in which case we have an optimization problem.

It is reasonable to expect that the optimal and legal supervisor synthesis problems be related in the following manner. If a solution is optimal, then it should not allow any illegal traces. Such a view implies that any optimal sublanguage lies within the supremal controllable sublanguage of the legal language (assuming also that disabling uncontrollable events entail infinite cost). Since the synthesis of the supremal controllable sublanguage of a legal language is understood from [16], we will assume that our plant language L_m is legal. If it is not, our problem can be posed on the supremal controllable sublanguage of the legal language, i.e., $(L_m \cap H)^{\uparrow}$, where H is the legal language. $(L_m \cap H)^{\uparrow}$ can be computed as discussed in [16]. Thus the problem of synthesizing an optimal legal supervisor for a regular language DES can be solved as a two-step process. This paper provides the second step.

The prior literature is as follows. The work by Passino and Antsaklis [7] examines optimal control of DESs. Unlike the paradigm of SCT, this is a forced event model where the optimal controller drives the DES along the shortest path. The SCT notion of designing a controller that is robust under a variety of disturbances and user demands is lost in this work. Thus the representation of a supervisor that provides good quantitative performance in an uncertain environment requires a more general concept of optimality than that provided in [7]. Kumar and Garg [6] also study optimal control of DESs. Theirs is a state-based formulation for DESs modeled by finite state machines (FSMs). No intuition is provided into infinite state systems, though many DESs (e.g., queuing systems) are infinite state systems without control protocols or scheduling disciplines. We will study both finite and infinite state systems. However, the control assumptions in [6] are consistent with the generality of the supervisory control philosophy. The cost structure, which assumes payoff and control costs, is interesting. Payoff costs are associated with the set of reachable states, and the control costs, with the disabling of a transition in an FSM. Disabling costs and payoffs are incurred only once regardless of the number of times the state is visited. This is often restrictive, since in most DESs the cost is an explicit function of the dynamic behavior. We will also assume two cost functions, i.e., event costs and control costs, though we relate them to the dynamic behavior in a way that is more like classical optimal control. There are also a variety of interesting modeling and computational issues associated with the control cost function that are exposed in this paper.

The work of Brave and Heymann [2] on the optimal attractor problem is also relevant. They are concerned with the cost of keeping a DES within a given finite state set. Event traces taking the system outside this set are priced, and the supervisor disables events to return the DES to the designated state set as cheaply as possible.

However, unlike [6], disabling is free. As mentioned earlier, we see the control cost function as an important modeling tool that should not be ignored.

This paper presents results on the existence and computation of optimal controllers. In Sengupta and Lafortune [12] we studied a similar problem for DES modeled by finite vertex acyclic directed graphs. Here, the existence theory is developed for DES represented by any formal language defined over a countable alphabet. The computation theory is developed for DES represented by regular languages. Therefore the problem treated in [12] is a special case of the problem studied here.

Section 2 states the problem mathematically and presents examples to illustrate the formulation. Section 3 discusses the main existence and computational results. Proofs of the existence results are presented in section 4. Some additional concepts, required to prove the computational results, are introduced in section 5. The main computability theorems are proved in the same section. Section 6 is an investigation of polynomial-time controller synthesis for DES modeled by cyclic and acyclic FSMs. We present a controller synthesis algorithm together with a proof of correctness and complexity. An example is also included in the section to help the reader follow the different steps in the computation. Section 7 is a concluding comment. An index of notation is included as an appendix.

2. Mathematical formulation of the problem. To state the problem precisely it is necessary to define the plant, the supervisor, and the relationship between them mathematically. We also define the objective function and the set of feasible solutions.

As stated earlier, the uncontrolled system or plant is described by a language L and a marked language $L_m(L = \bar{L}_m)$, defined over an alphabet $\Sigma = \{\sigma_1, \sigma_2 \ldots\}$. The notation Σ^* represents the Kleene closure of Σ, and ε represents the empty string. The alphabet exhaustively represents the various events that can occur in the DES. It is assumed that $\Sigma = \Sigma_c \cup \Sigma_{uc}$ and $\Sigma_c \cap \Sigma_{uc} = \emptyset$; i.e., the alphabet is partitioned into controllable and uncontrollable events. For a language A and string $s \in \bar{A}$, we denote the *active set* at s in A by $\Sigma_A(s) = \{\sigma \in \Sigma : s\sigma \in \bar{A}\}$ and use $A/s = \{t \in \Sigma^* : st \in A\}$ to denote the set of continuations of s in A. A/s is called the suffix language of s in A. For two strings s and t the notation $s \leq t$ denotes that s is a prefix of t.

Our usage of the terms FSM and submachine of an FSM is as usual and is taken from [8] and [4], respectively. A FSM G is a 5-tuple $G = \langle \Sigma, Q, q_0, Q_m, \delta \rangle$, where Σ is the alphabet, Q is a finite set of states, $q_0 \in Q$ is the initial state, $Q_m \subseteq Q$ is a distinguished set of marked states, and $\delta : \Sigma \times Q \to Q$ is the transition function. We also use the extended transition function $\delta^* : \Sigma^* \times Q \to Q$, defined in the usual way by composing the transition function $\delta(.,.)$; i.e., $\delta^*(s, q)$ is defined if and only if there exists a sequence of transitions s in G starting at q. A FSM $A = \langle \Sigma_A, Q_A, q_{0A}, Q_{mA}, \delta_A \rangle$ is a submachine of G if $\Sigma_A \subseteq \Sigma, Q_A \subseteq Q, Q_{mA} \subseteq Q_m$, and wherever the transition function δ_A exists it is equal to the transition function $(\delta(.,.))$ of G.

A few norms and projection functions are used for mathematical convenience. For a string, the symbol $\|.\|$ denotes the length of the string, and for a language, $\|.\|$ denotes the number of equivalence classes. If L is regular, then $\|L\|$ is finite and known as the Myhill congruence index (refer to p. 65 of [5]) of L. It is assumed that $\|\varepsilon\| = 0$. Two projection functions denoted by p and P are defined on strings and languages, respectively. For a string s, $p_j(s)$ represents the prefix of length j. For any string, $p_0(.) = \varepsilon$. For a language A, $P_j(A) = \{s \in A : \|s\| = j\}$; i.e., it is the set of all strings of length j in A.

A supervisor is a disabling control law. We clarify our usage of the terms control law, controlled system, and controllability. The definitions are similar to those in section (iv) of Ramadge and Wonham [9]. A control law π is a map $\pi : \Sigma^* \longrightarrow 2^{\Sigma}$. It specifies the set of events allowed after a string. We use Π to denote the set of all control laws. π together with a string $s \in \bar{L}_m$ specifies a prefix-closed language in the following manner.

DEFINITION 2.1 (language specified by a control law). *For $s \in \bar{L}_m$ and $\pi \in \Pi$ define*

$$\mathcal{L}(\pi, s) = \{t = \sigma_0 \dots \sigma_{\|t\|-1} \in \Sigma^* : st \in \bar{L}_m, \sigma_i \in \pi(sp_i(t)), 0 \leq i \leq \|t\| - 1\},$$
$$\mathcal{L}_m(\pi, s) = \mathcal{L}(\pi, s) \cap L_m/s.$$

If $s = \varepsilon$, then we write $\mathcal{L}(\pi)$ or $\mathcal{L}_m(\pi)$.

Thus, for a control law π and plant L_m, the supervised system is $\mathcal{L}(\pi)$. Note that it is possible to have π, π' such that $\mathcal{L}(\pi, s) = \mathcal{L}(\pi', s)$. Obviously $\mathcal{L}(\pi, s) \subseteq \overline{L_m/s}$. $\mathcal{L}_m(.,.)$ denotes the marked language specified by the control law. The trajectories of a controlled DES should constitute some nonblocking sublanguage of L. The following definition is from [8]. For $A \subseteq L$, A is *nonblocking* iff $\overline{A \cap L_m} = A$. A control law π is *nonblocking* if for all $s \in \mathcal{L}(\pi), \mathcal{L}(\pi, s) = \overline{\mathcal{L}_m(\pi, s)}$. A nonblocking control law generates a nonblocking language. Let Π_{nb} denote the set of all nonblocking control laws.

We wish to construct the optimal nonblocking supervised system. The set of nonblocking control laws is equivalent to the set of L_m-closed sublanguages [8] of L_m in the sense of the following proposition. The proposition also states that the control laws can generate any prefix-closed sublanguage of L_m.

PROPOSITION 2.2. *For the control laws defined, the following are true. Let $t \in \bar{L}_m$.*

(i) $\forall A \subseteq \overline{L_m/t}, A$ *prefix-closed* $, \exists \pi$ *s.t.* $\mathcal{L}(\pi, t) = A$.
(ii) $\{\mathcal{L}_m(\pi, t) : \pi \in \Pi_{nb}\} = \{A \subseteq L_m/t : \bar{A} \cap L_m/t = A\}$.

The proofs are trivial and omitted. The condition $\bar{A} \cap L_m/t = A$ is the L_m-closure condition. It simply says that if a marked string is in A, then all marked prefixes of the string are also in A. This is not a serious restriction for reasons explained after defining the optimization problem. Our usage of controllability is standard and from [9].

A sublanguage $A \subseteq \bar{L}_m$ is controllable iff $\bar{A}\Sigma_{uc} \cap \bar{L}_m \subseteq \bar{A}$.

As expected, our definitions have the property that a sublanguage is controllable iff it can be specified by a control law that disables only controllable events. We next propose the numerical measures required in our framework. We start by defining two nonnegative real-valued functions

$$c_e : \Sigma \to \mathbb{R}^+ \cup \{0\},$$
$$c_c : \Sigma \to \mathbb{R}^+ \cup \{0, \infty\}$$

on the alphabet. They are known as the event and control cost functions, respectively. The event cost is incurred whenever the DES generates an event, and the control cost is incurred whenever the supervisor disables an event. Note that we do not allow infinite event costs. Infinite event costs are conceivably a good way of pricing illegal strings. However, for reasons explained in the introduction, it is assumed that L_m is a legal language. It is assumed that if $\sigma \in \Sigma_{uc}$ then $c_c(\sigma) = \infty$. Thus uncontrollable

events should not be disabled. We also denote the maximum and minimum values of these functions by $\bar{c}_e, \bar{c}_c$ and $\underline{c}_e, \underline{c}_c$, respectively. The event and control cost functions are used to induce a cost on the trajectories of a supervised system.

DEFINITION 2.3 (string cost function). *Let $t \in \bar{L}_m$ be a past behavior and π be a nonblocking control law. We define*

(i) *a one-stage cost function $\bar{c} : \bar{L}_m \times \Pi \times \Sigma \longrightarrow \mathbb{R}^+ \cup \{0, \infty\}$ for an event $\sigma \in \pi(t)$ to be*

$$\bar{c}(t, \pi(t), \sigma) = c_e(\sigma) + \sum_{e' \in \Sigma_{L_m}(t) - \pi(t)} c_c(e');$$

(ii) *string cost functions for a string $s = \sigma_0 \dots \sigma_{\|s\|-1} \in \mathcal{L}(\pi, t)$ to be*

$$c(t, \pi, s) = \sum_{j=0}^{j=\|s\|-1} \bar{c}(tp_j(s), \pi(tp_j(s)), \sigma_j) + \bar{c}(ts, \pi(ts), \phi),$$

where ϕ is a stopping event having zero event cost. We also define for any $s \in \mathcal{L}(\pi, t)$,

$$\hat{c}(t, \pi, s) = \sum_{j=0}^{j=\|s\|-1} \bar{c}(tp_j(s), \pi(tp_j(s)), \sigma_j);$$

i.e., the last term in $c(.,.,.)$ is left out.

Observe that the cost of a string is dependent upon the sublanguage in which it lies, or in other words, it is influenced by the control law. The first part of the one-stage cost function is an event cost. This part is independent of the control law or sublanguage. The second part is the sum of the control costs associated with all events that must be disabled after the string t is executed. This part is determined by the control law. Thus the cost of a trajectory or string in a supervised system is the sum of the event costs of the events in the string and the control costs of the control actions taken by the supervisor during that trajectory. The term $\bar{c}(ts, \pi(ts), \phi)$ accounts for the termination cost. If the system stops with behavior $ts \in L_m$, there is no event cost associated with the stopping but there may be control costs arising from $\pi(ts)$.

Two control laws can generate the same language. However, the costs remain unaffected in the sense of the following proposition. It is stated without proof.

PROPOSITION 2.4. *Let $t \in \bar{L}_m$ and $\pi, \pi' \in \Pi_{nb}$ be such that $\mathcal{L}(\pi, t) = \mathcal{L}(\pi', t) = A$. Then for all $s \in A$,*

$$c(t, \pi, s) = c(t, \pi', s).$$

Thus we can use the notation $c(t, A, .), A \subseteq \overline{L_m/t}$, with the understanding that A is generated by any one of the suitable control laws. The objective function is as follows.

DEFINITION 2.5 (objective function). *For a language $A \subseteq L_m/t, t \in \bar{L}_m$, the objective function is*

$$c_{\sup}(A, t) = \sup_{s \in A/t} c(t, A, s).$$

If the second argument in $c_{\sup}(.,.)$ is ε, it will be omitted and we write $c_{\sup}(A)$. This objective function costs a supervisor by the worst-case behavior it allows in the face of uncertain demands and disturbances. Therefore this formulation is consistent with the view that the supervisor will generate not one but any of a set of possible behaviors. This is also a weaker notion of optimality than an average or expected value criterion. However, since in DES control the supervisor is expected to interfere as little as possible, the notion of interfering only in the worst case is appropriate. Moreover, as our subsequent results show, this problem has useful and interesting features.

2.1. The optimal control problem. The most general class of nonblocking supervised systems possible is the set of systems represented by the nonblocking sublanguages of the plant language. This set is the feasible space for the optimization problem. Since $L = \bar{L}_m$, the set of nonblocking sublanguages of L is related to the sublanguages of L_m by

$$\{A \subseteq L : A = \bar{A}, \overline{A \cap L_m} = A\} = \{\bar{A}_m : A_m \subseteq L_m\}.$$

Thus a good description of the feasible space is the set of sublanguages of L_m.

The optimal control problem is to find a sublanguage A_{om} of L_m such that

$$c_{\sup}(A_{om}) \quad = \quad \min_{A_m \subseteq L_m} c_{\sup}(A_m) < \infty.$$

Such an A_{om} is an optimal sublanguage of L_m. The empty set is not admissible as a solution unless $L_m = \emptyset$. $\{\varepsilon\}$ is admissible as a solution if it is a nonblocking sublanguage of L_m. Note that the problem requires us to minimize over both the L_m-closed and non-L_m-closed sublanguages of L_m, whereas control laws as defined can only specify L_m-closed sublanguages of L_m (Proposition 2.2). Fortunately, the cost structure ensures that every non-L_m-closed language is contained in an L_m-closed language of equal cost. Due to this observation and Proposition 2.2 we get the following equivalence that we state as a proposition. Its proof is omitted.

PROPOSITION 2.6.

$$\min_{A_m \subseteq L_m} c_{\sup}(A_m) = \min_{\pi \in \Pi_{nb}} c_{\sup}(\mathcal{L}_m(\pi)).$$

Thus, equivalently, we can minimize over the set of nonblocking control laws.

We conclude this subsection with an example and a few remarks. First, though the event and control cost functions are defined on the alphabet, the case where they are state dependent is easily accommodated by expanding the alphabet. Second, since $\sigma \in \Sigma_{uc}$ implies $c_c(\sigma) = \infty$, we have the following proposition.

PROPOSITION 2.7. *Let $L \subseteq L_m$. If $c_{\sup}(L) < \infty$, then L is controllable.*

Consequently, any optimal language is controllable.

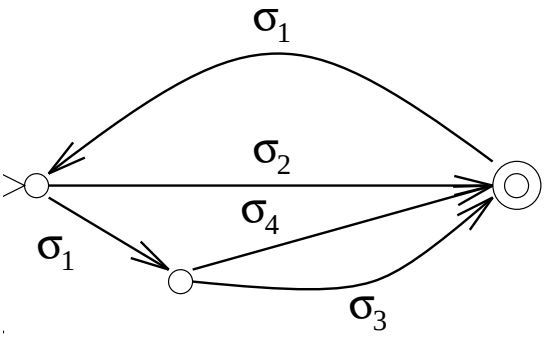
Example 2.1.1. This example illustrates the problem formulation. Let the plant language be

$$L_m = (\sigma_2 + \sigma_1(\sigma_3 + \sigma_4))(\sigma_1(\sigma_2 + \sigma_1(\sigma_3 + \sigma_4)))^*.$$

We assume all events are controllable and hence $\Sigma = \Sigma_c = \{\sigma_i : i = 1, 2, 3, 4\}$. A generator for this language and the cost functions defined on Σ are as shown in Figure 2.1.

Since $c_e(\sigma_1) > 0$ it is obvious that $c_{\sup}(L_m) = \infty$. Hence for any optimal solution the control law must set

$$\pi(\sigma_2) = \pi(\sigma_1\sigma_4) = \pi(\sigma_1\sigma_3) = \emptyset.$$



$$\begin{array}{llllll} c_e(\sigma_1) & = & 1, & c_c(\sigma_1) & = & 1 \\ c_e(\sigma_2) & = & 5, & c_c(\sigma_2) & = & 5 \\ c_e(\sigma_3) & = & 1, & c_c(\sigma_3) & = & 1 \\ c_e(\sigma_4) & = & 3, & c_c(\sigma_4) & = & 1 \end{array}$$

FIG. 2.1. *The plant.*

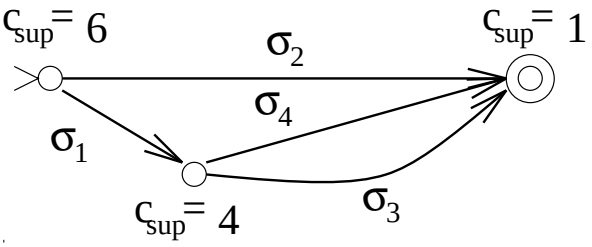


FIG. 2.2. *An optimal solution.*

Thus the optimal solution is contained in $A_m = \{\sigma_2, \sigma_1\sigma_4, \sigma_1\sigma_3\}$. The worst case of this language is set by σ_2. Since $\Sigma_{L_m}(\sigma_2) = \{\sigma_1\}$ and $\pi(\sigma_2) = \emptyset$, we obtain

$$c_{\sup}(A_m) = c(\varepsilon, A_m, \sigma_2) = c_e(\sigma_2) + c_c(\sigma_1) = 6.$$

It is easily shown by examining the six other marked sublanguages of A_m that A_m is actually optimal. It has minimum worst-case cost. The generator is as shown in Figure 2.2.

This optimization problem is also closely related to others in the literature. If the control costs are all zero, then for a language $A \subseteq L_m$, $c_{\sup}(A)$ is generated by the longest path, insofar as one exists. If all events are controllable, then a solution to the optimization problem is any shortest path in L_m. If uncontrollable events are allowed, but still no control costs, then we obtain a problem similar to the optimal attractor problem. The use of event and control costs is also standard in stochastic optimal control. Since L_m is a collection of strings of finite length defined over a countable alphabet, it is a countable set. An optimal sublanguage of L_m is like an optimal control for a Markov chain with a countable state space; i.e., the strings of the optimal language correspond to the set of state transition sequences of finite length having positive measure under the optimal control. However, this is a worst-case optimization (min-max) problem formulated on a deterministic system representation. The differences give this problem certain unique advantages and disadvantages with respect to the optimal control of Markov chains. We say more about this when presenting the specific results of this paper. For a detailed exposition the interested reader is referred to chapter 5 of [10].

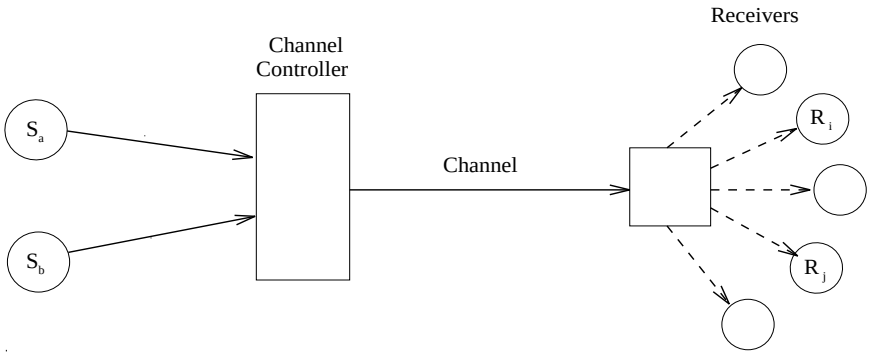

FIG. 2.3. *System configuration.*

We believe the event and control cost functions can be used in a variety of interesting ways. One use of the control costs is to represent the costs of impacting on an external environment which is not modeled. A large number of systems are embedded in very complex environments which cannot be modeled in detail. Control costs suffice as a crude way of recognizing the existence of this larger world. Event costs, on the other hand, represent physical resources such as time and energy that may be used by the plant to execute events. We present an example protocol design problem to motivate the modeling.

2.2. Example: Developing a protocol using delay priorities. Our objective is to provide tools for supervisor design. In this section we use the problem formulation to design supervisors for a channel in a communication network under three different design priorities. The example is similar to that of a CI (computer interconnect) bus connected to multiple nodes in a VAX cluster system (refer to [3]). For simplicity it is assumed that the channel has two users or senders connected to it. The task is to design a supervisor which arbitrates the channel allocation. We assume that the channel controller has complete knowledge of the demands of the senders but imprecise knowledge of conditions at the receiver end. It is also assumed that the channel controller has no control over events at the receiver end. Figure 2.3 illustrates the configuration.

The aim of the exercise is to show that if design priorities are specified by the cost functions, then the theory algorithmically develops the appropriate control laws. The system events are

t_i = sender i transmits on the channel,
y_i = sender i's transmission is positively acknowledged by the receiver,
n_i = sender i's transmission is negatively acknowledged by the receiver,

where $i \in \{a, b\}$. The set of all possible behaviors is generated by the FSM in Figure 2.4.

To complete the model we need to define the marked language. It is assumed that any behavior which gives both a and b at least one successful transmission is marked. Such a marking makes sense if both a and b have something to transmit. The new system model is as in Figure 2.5. Let L'_m denote the marked language generated by the FSM in Figure 2.5.

It is assumed that the channel controller can deny channel access to a sender. Thus the events t_a and t_b are controllable. Since receiver conditions are unknown

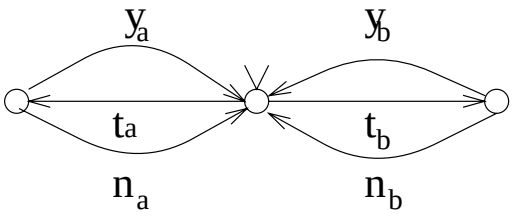

FIG. 2.4. *FSM generating all possible behaviors.*

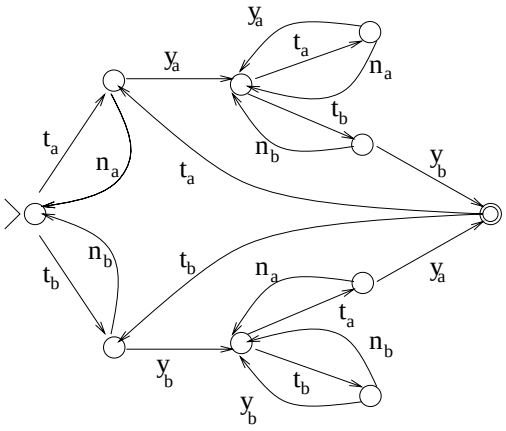

FIG. 2.5. *Plant FSM.*

the event t_i may be generally followed by either y_i or n_i. These events are assumed to be uncontrollable; i.e., $c_c(y_i) = c_c(n_i) = \infty, c_c(t_i) < \infty$. We also assume $c_e(y_i) = c_e(n_i) = 0$. Since transmission represents the use of channel time which is a network resource, it is assumed that $c_e(t_i) > 0$. It is also being assumed that all packet transmission times are the same, so that the same t_i and $c_e(t_i)$ are used for all packets.

From Figure 2.5, we see that $c_{\sup}(L'_m) = \infty$, and $c_{\sup}(L) = \infty$ for any $L \subseteq L'_m$. This is because successful transmission in finite time can only be guaranteed by disabling of uncontrollable events. Appropriately, this system has no solution under worst-case analysis. To allow the possibility of guaranteeing finite termination of transmission processes we introduce a *timeout* event and associate it with two modes of operation.

Assumption 1. If a sender accesses the channel three times in succession, then the third transmission attempt will be followed by a timeout.

Assumption 2. If a sender accesses the channel every alternate transmission, then the third transmission attempt will be followed by a timeout.

Observe that these two modes require the ordering and counting of transmissions. The alphabet is enriched to make this possible. The event t_i is superscripted as t_i^n to represent the transmission, by user i, of a packet which has already waited n transmission times in the network. This makes the alphabet Σ countably infinite. The new alphabet is more extensive than required by these two assumptions. However, the distinction between older and newer packets, introduced by the superscript n, allows us to reflect different design priorities. The timeout event represents the assumption that regardless of positive or negative acknowledgment, the job is dropped. We do not use a new event for the timeout but simply model it as a case of necessarily successful

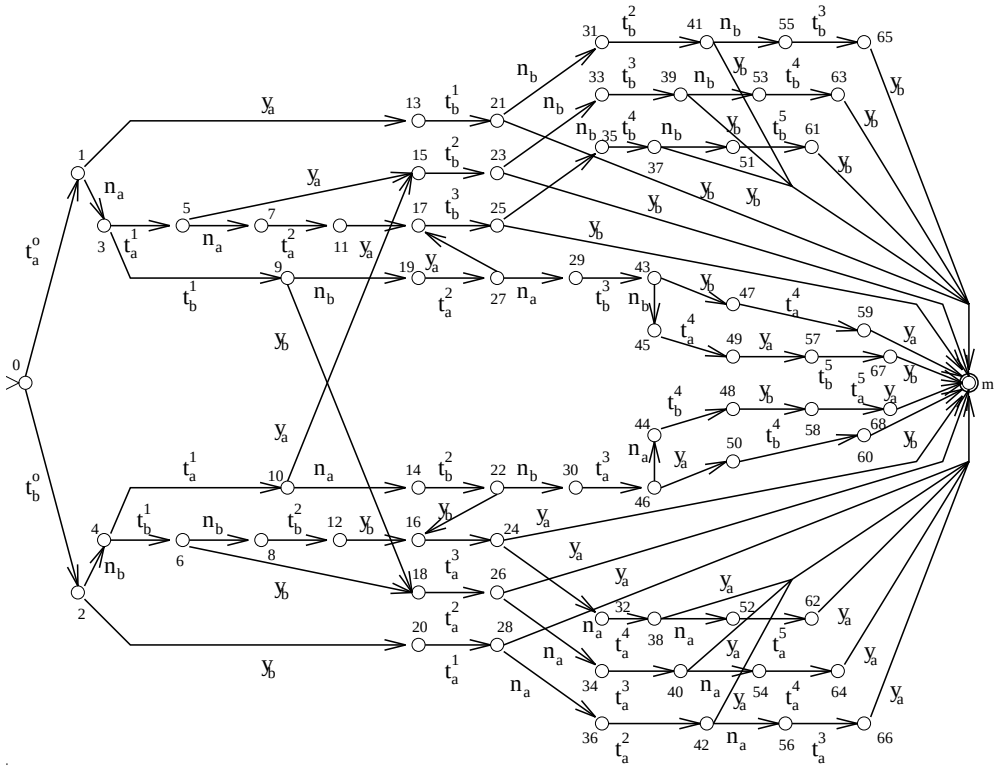

FIG. 2.6. *The FSM G_s.*

transmission. Thus a timeout state is one at which only a y_i is defined. There is no n_i.

The assumptions ensure that at least two modes of operation will terminate in a finite number of transmissions. This is not necessarily true of other modes. The FSM generating plant behavior under these two protocols is complex. Unlike the previous plant model there are now some states at which events y_i are possible but not the events n_i. These states are the timeout states. This model defines the plant. The machine will be denoted by G_m, and its generated marked language, will be denoted by L_m. It is a submachine of the superscripted version of the FSM in Figure 2.5. We will not say more about these complexities. Instead, we show a simpler way of approaching this problem, by means of the submachine of G_m, in Figure 2.6. The submachine is denoted by G_s and its generated language is L_s. We present a proof to show that all our optimization problems are reducible to equivalent problems on the FSM in Figure 2.6.

G_s is formed by disabling events in G_m. The required control actions are given in Table 2.1. Note that all the disabled events are controllable. Since all the sequences in G_s are of finite length and $c_c(t_i^n) < \infty$, G_s has finite worst-case cost. It actually generates only the fastest terminating sequences created by Assumptions 1 and 2, i.e., termination with three sequential transmissions and three alternating transmissions.

We make one more assumption. It is reasonable that controllers should clear everybody's transmission requests as fast as possible. To delay a particular user is plausible only if not doing so will hinder other more important users. The next assumption is one simple way to assure such behavior.

TABLE 2.1
Control law for the machine G_s.

State	Disabled events
7	t_b^2
13, 15, 17	t_a^0
19	t_b^2
29	t_a^3
31, 33, 35	t_a^1
45	t_b^4
51, 53, 55	t_a^2
57	t_a^0

State	Disabled events
8	t_a^2
16, 18, 20	t_b^0
14	t_a^2
30	t_b^3
32, 34, 36	t_b^1
44	t_a^4
52, 54, 56	t_b^2
58	t_b^0

Assumption 3. It is assumed that the cost $c_e(t_i) \equiv c_e$ and c_e is much greater than the control costs. More specifically,

$$c_e >> c_c(t_i), \quad \text{or in the case in which the events are denoted by } t_i^n,$$
$$c_e >> c_c(t_i^n), \quad 1 \leq n \leq 4.$$

Without this assumption, for decreasing control cost functions characterized by

$$c_c(t_i^n) > c_c(t_i^{n+1}),$$

the optimal solution may be such that the channel is unused and packets are kept waiting just because the control costs will reduce as the packets get older. The assumed high event cost will allow the examination of decreasing control cost functions without having them produce such strange solutions.

We formulate three optimal control problems (OCPs) with three types of cost structures.

OCP 1. $c_e(t_i^n) \equiv c_e$ and $c_c(t_i^n) \equiv c_c$. In other words the cost of delaying old or new packets is the same; i.e., all users, whether old or new, have equal priority.

OCP 2. $c_e(t_i^n) \equiv c_e$ and $c_c(t_i^n) = n^2, n \geq 0$. In other words the cost of delaying old packets is higher than that of delaying new packets; i.e., old users have higher priority than new users.

OCP 3. $c_e(t_i^n) \equiv c_e$ and $c_c(t_i^n) = \frac{1}{(n+1)^2}$. In other words the cost of delaying new packets is higher than that of delaying old packets; i.e., new users have higher priority than old users.

The analysis is structured into the following propositions.

PROPOSITION 2.8. *Any finite cost sublanguage of L_m must contain a string with at least six transmission events.*

Proof. It is assumed that both senders A and B have packets to transmit. Consequently a string is marked if and only if it represents successful transmission by both senders. By Assumptions 1 and 2 this can be guaranteed, without disabling uncontrollable events, only by three consecutive transmissions or by three alternating transmissions of each sender. The proposition follows. □

The following proposition establishes that our OCPs are reducible to an equivalent problem on the language generated by the FSM G_s shown in Figure 2.6.

PROPOSITION 2.9. *For all three cost functions the optimal solution is a sublanguage of L_s.*

Proof. Upon examination of Figure 2.6 and Table 2.1, we obtain that the worst-case control cost associated with a string in L_s is of the form

$$c_c(t_i^x) + c_c(t_j^y) + c_c(t_k^z) + c_c(t_l^w), \text{ with } i, j, k, l \in \{a, b\} \text{ and } 0 \leq x, y, z, w \leq 4.$$

Since by Assumption 3

$$c_e(t_i^n) = c_e > c_c(t_i^x) + c_c(t_j^y) + c_c(t_k^z) + c_c(t_l^w),$$

any sublanguage L of L_m containing a string with more than six transmission events in it, even if the string has zero control costs, will have $c_{\sup}(L) > c_{\sup}(L_s)$. Therefore, no optimal solution has more than six transmission events in any string belonging to it. This fact, together with Proposition 2.8, implies that the longest string in any optimal solution must have exactly six transmission events in it. Note that G_s represents the minimally restrictive system that is guaranteed to terminate with no more than six transmissions. Relaxing the control action at any state of G_s will force inclusion of strings of L_m containing more than six transmissions.

If G_s or L_s is the minimally restrictive controlled system guaranteeing termination in six transmission events, it follows that the optimal solution must be contained in L_s, since in the worst case it will have exactly six transmissions. □

The original problems are now equivalent to ones on a finite state system with a finite alphabet. The problem formulation is such that the optimal solution is a finitely terminating process. In practice, the protocol would reset to the initial state after reaching the marked state and repeat again.

Note that for all three OCPs $c_e(t_a^n) = c_e(t_b^n)$ and $c_c(t_a^n) = c_c(t_b^n)$. Thus the cost structure is symmetrical in a and b and so is the structure of the machine G_s. Hence, whatever cost analysis is done in one half of the graph is also true of the other half.

Solution to OCP 1. The worst-case cost in the L_s/t_a^0 half of G_s is obviously set by either

$$\begin{aligned} s &= t_a^0\ n_a\ t_a^1\ n_a\ t_a^2\ y_b\ t_b^3\ n_b\ t_b^4\ n_b\ t_b^5\ y_b \quad \text{or} \\ s' &= t_a^0\ n_a\ t_b^1\ n_b\ t_a^2\ n_a\ t_b^3\ n_b\ t_a^4\ y_a\ t_b^5\ y_b \end{aligned}$$

since these two strings involve both the largest number of transmission events and the largest number of control actions. The costs associated with the two strings are

$$\begin{aligned} c(s, L_s) &= c_e(t_a^0) + c_e(t_a^1) + c_c(t_b^2) + c_e(t_a^2) + c_c(t_a^0) + c_e(t_b^3) + c_c(t_a^1) \\ &\quad + c_e(t_b^4) + c_c(t_a^2) + c_e(t_b^5) \\ &= 6c_e + 4c_c \end{aligned}$$

and

$$\begin{aligned} c(s', L_s) &= c_e(t_a^0) + c_e(t_b^1) + c_c(t_b^2) + c_e(t_a^2) + c_c(t_a^3) + c_e(t_b^3) + c_c(t_b^4) \\ &\quad + c_e(t_a^4) + c_c(t_a^0) + c_e(t_b^5) \\ &= 6c_e + 4c_c. \end{aligned}$$

It is easily seen that the two worst-case paths in the L_s/t_b^0 half of G_s are similar and have exactly the same cost. Since any sublanguage of L_s must contain one of these four paths and they all have identical cost, it is clear that disabling any of these four paths can only increase the control costs, while leaving the event costs unchanged (refer to Theorem 3.4 in the following section). Since the cost of a string is the sum of event and control costs, the optimal solution is L_s or G_s itself.

Solution to OCP 2. Once again, the worst case in the L_s/t_a^0 half must be set by either s or s'. The associated costs are, however, different.

$$\begin{aligned} c(s, L_s) &= c_e(t_a^0) + c_e(t_a^1) + c_c(t_b^2) + c_e(t_a^2) + c_c(t_a^0) + c_e(t_b^3) + c_c(t_a^1) \\ &\quad + c_e(t_b^4) + c_c(t_a^2) + c_e(t_b^5) \\ &= 6c_e + 2^2 + 0^2 + 1^2 + 2^2 = 6c_e + 9 \end{aligned}$$

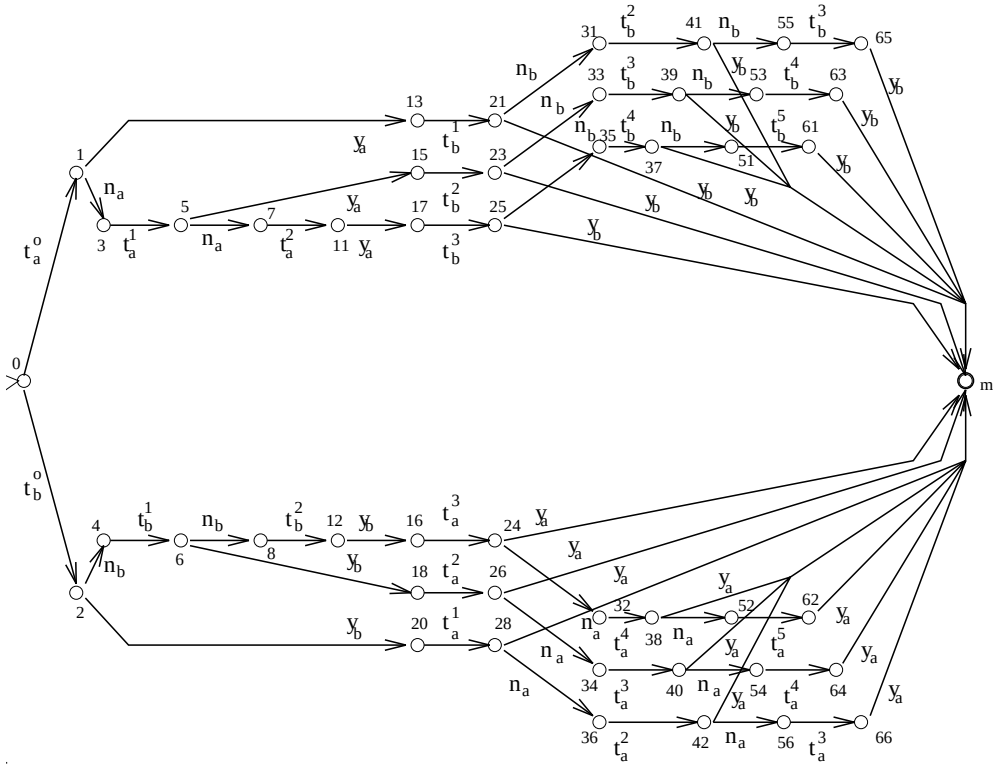

FIG. 2.7. *Solution to OCP* 2.

and

$$\begin{aligned} c(s', L_s) &= c_e(t_a^0) + c_e(t_b^1) + c_c(t_b^2) + c_e(t_a^2) + c_c(t_a^3) + c_e(t_b^3) + c_c(t_b^4) \\ &\quad + c_e(t_a^4) + c_c(t_a^0) + c_e(t_b^5) \\ &= 6c_e + 2^2 + 3^2 + 4^2 + 0^2 = 6c_e + 29. \end{aligned}$$

The analysis for the L_s/t_b^0 half is similar. By disabling the event t_b^1 after $t_a^0 n_a$ we remove the string s'. The worst-case cost is now $c_e + 9 + 1^2 = c_e + 10$. An identical cost will be obtained in the other half of G_s by disabling t_a^1 after $t_b^0 n_b$. The optimal solution is depicted in Figure 2.7. Obviously, the two control actions described above are in addition to those given in Table 2.1. The solution represents the forcing of sequential transmission.

Solution to OCP 3. Again, the worst case in the L_s/t_a^0 half must be set by either s or s'. The associated costs are different.

$$\begin{aligned} c(s, L_s) &= c_e(t_a^0) + c_e(t_a^1) + c_c(t_b^2) + c_e(t_a^2) + c_c(t_a^0) + c_e(t_b^3) + c_c(t_a^1) \\ &\quad + c_e(t_b^4) + c_c(t_a^2) + c_e(t_b^5) \\ &= 6c_e + \frac{1}{3^2} + \frac{1}{1^2} + \frac{1}{2^2} + \frac{1}{3^2} = 6c_e + 1.472 \end{aligned}$$

and

$$\begin{aligned} c(s', L_s) &= c_e(t_a^0) + c_e(t_b^1) + c_c(t_b^2) + c_e(t_a^2) + c_c(t_a^3) + c_e(t_b^3) + c_c(t_b^4) \\ &\quad + c_e(t_a^4) + c_c(t_a^0) + c_e(t_b^5) \\ &= 6c_e + \frac{1}{3^2} + \frac{1}{4^2} + \frac{1}{5^2} + \frac{1}{1^2} = 6c_e + 1.213. \end{aligned}$$

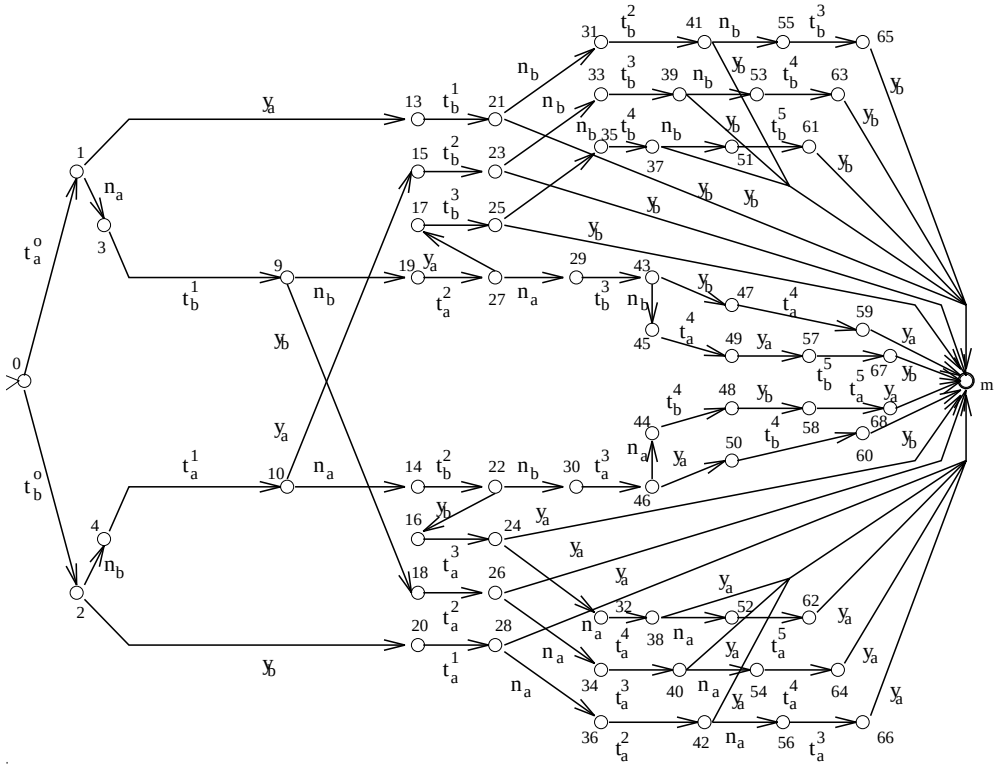

FIG. 2.8. *Solution to OCP* 3.

The analysis for the L_s/t_b^0 is similar. By disabling the event t_a^1 after $t_a^0 n_a$ we remove the string s. The worst-case cost is now $c_e + 1.213 + \frac{1}{2^2} = c_e + 1.463$. An identical cost will be obtained in the other half of G_s by disabling t_b^1 after $t_b^0 n_b$. The optimal solution is as depicted in Figure 2.8. Obviously, the two control actions described above are in addition to those given in Table 2.1. The solution represents the forcing of alternating transmission.

The clear connection between design priorities and the selected protocols can be seen if the results are summarized as follows.

OCP	**Cost assumption**	**Protocol**
1	Old and new users have same priority	Sequential or alternating protocol
2	Old users have higher priority	Force sequential protocol
3	New users have higher priority	Force alternating protocol

This example illustrates important features of our approach. The control cost of disabling a transmission event exists because of the obstruction of unmodeled sender activities; e.g., the sender may be executing programs which wait on the successful transmission of a packet. The event cost associated with spontaneously executing a transmission exists because it entails the use of channel time, which is a network resource. The control costs are used to represent the cost of impacting on an external environment which is not modeled. Event costs, on the other hand, represent physical resources such as time and energy that may be used by the plant to execute events.

We also note that, in this example, once design priorities are stated in the cost functions, then in all three cases there exist interesting and well-defined optimal solu-

tions. The optimal solutions are also minimally restrictive and satisfy the principle of dynamic programming; i.e., they have optimal substructure. The purpose of the subsequent results is to make these ideas clear and to characterize, in a general manner, problems for which we may expect these specific types of optimal solutions.

3. The principal results. For the convenience of the reader, we present all major results in this section. The section is divided into three subsections covering general existence results, the role of dynamic programming, and computational results, respectively. The proofs of the results in the first two subsections are covered in section 4. The proofs of the computational results are covered in sections 5 and 6. We present some general computational results and also investigate conditions under which optimal solutions are polynomially computable.

3.1. General existence results. The theorems in this section clarify conditions for the existence of optimal solutions and minimally restrictive optimal solutions. An optimal solution exists if the infimum of $c_{\sup}(.)$ over the sublanguages of L_m is finite and if it is realized by some sublanguage of L_m. In other words, the infimum must be a minimum that is a real number. The first existence theorem is stated for DES represented by a finite alphabet. It asserts that the existence of a sublanguage with bounded cost is sufficient for the existence of an optimum.

THEOREM 3.1. *Let $|\Sigma| < \infty$. An optimal sublanguage exists iff there exists some $A \subseteq L_m$ such that $c_{\sup}(A) < \infty$.*

The necessity of boundedness is trivial. For the sufficiency proof, it is immediate that the infimum exists. It remains to be argued that it is realized. Note that by Proposition 2.7 controllability is a necessary condition for a bounded cost sublanguage.

For the case of DES defined over a countable alphabet we present the following result.

THEOREM 3.2. *For all $s \in \bar{L}_m$ let $|\Sigma_{L_m}(s)| < \infty$. Let $c_e(.) > \delta > 0$. There exists an optimal sublanguage of L_m iff there exists $A \subseteq L_m$ such that $c_{\sup}(A) < \infty$.*

We assume that the event costs are greater than some positive number, however small. We also assume that the active event set after any string in $\bar{L}_m$ is finite. Under these assumptions we get a result similar to the first theorem. This theorem implies that optimal solutions to the problems in the example of section 2.2 exist. $\mathcal{L}(G_s)$ is a bounded cost sublanguage, and if we treat $t_i^n y_i$ and $t_i^n n_i$ as composite events with cost $c_e(t_i^n)$, then the conditions of the theorem are satisfied for all three control cost functions. The next theorem is stated for the case in which L_m is a regular language.

THEOREM 3.3. *Let L_m be a regular language. An optimal solution exists iff there exists $A_m \subseteq L_m, A_m$ regular, controllable, and having the following property for any $n \in \mathbb{N}$:*

$$\forall s = tu^*v \subseteq A_m, \quad \hat{c}(t, \bar{A}_m, u^n) = 0.$$

Intuitively the theorem says that optimal solutions exist when there are controllable sublanguages of L_m in which all cycles have zero-cost. Thus either cycles with positive cost must be broken in such a way that all the reachable broken prefixes can complete to marked states, or cycles with positive cost are altogether unreachable. Thus a system is not allowed to cycle around using resources (positive event cost) without finishing its task (completing to a marked string). The controllability condition ensures that the positive cost cycles can be broken using controllable events alone.

As a consequence of Theorem 3.3 all nonterminating behaviors of regular language DESs must be zero-cost. If the behavior of interest is itself a positive cost process,

e.g., steps involved in the manufacture of a part, then the formulation should be used to model only one cycle of the repetitive process which can then be optimized. A second step of optimization may then be to model the optimized single step-process as a repetitive zero-cost process and then use the formulation to optimize the deviation from this desired behavior, i.e., associate positive event costs on any events that disturb the process from its zero-cost trajectory. However, since such modeling approaches are domain-specific we will not discuss them further.

The next theorem characterizes the interaction of event and control costs.

THEOREM 3.4. *Let* $s \in A_m \subseteq B_m \subseteq L_m/t, t \in \bar{L}_m$. *Then* $c(t, A_m, s) \geq c(t, B_m, s)$.

The cost associated with a string lying in a nonincreasing sequence of languages is nondecreasing. Smaller languages entail more control and hence more control costs. As the language containing a string is made to shrink, the control cost associated with the string tends to rise. The event costs are independent of the language. The purpose of contracting a language is to remove strings with high event costs. Since this process is accompanied by rising control costs, we have an optimization problem. This tradeoff is similar to classical optimal control. Observe that the uncontrolled plant language has no control actions and no control costs. Its worst case is the longest path as obtained from the event costs. The use of control to disable this longest path may reduce the event cost, but only at the expense of additional control costs. The sum of event costs and control costs for the worst-case path in the new controlled system may be greater. This is the fundamental tradeoff that has made classical optimal control meaningful, and when captured as in section 2, it makes the same tradeoff interesting in the control of formal languages. This essence of optimal control is a powerful theoretical motivation for our formulation.

It can be established from Theorem 3.4 that the union of optimal solutions is optimal. As a language grows, the event costs associated with its strings do not change, but the control costs decrease. Therefore, the worst-case costs, in the union of two languages, cannot be worse than the worst of the two. Standard set-theoretic arguments lead to the existence of a unique supremal or minimally restrictive element in the class of optimal solutions. This is stated in the following theorem.

THEOREM 3.5. *If an optimal solution exists, then the unique supremal optimal solution exists.*

The supremal optimal sublanguage of L_m will be denoted by $L_o^{\uparrow}$. Note that $L_o^{\uparrow}$ should not be confused with the supremal controllable sublanguage ($L_m^{\uparrow}$) defined in [16] as a solution to the supervisory control problem defined under legality specifications. On the basis of this theorem we define an operator

$$\begin{aligned} \mathcal{L}_o^{\uparrow} &: \bar{L}_m \longrightarrow 2^{\Sigma^*}, \\ \mathcal{L}_o^{\uparrow}(s) &= \text{supremal optimal sublanguage of } L_m/s, \end{aligned}$$

if it exists. The operator is undefined otherwise. By the theorem, if an optimal solution exists in the post-language L_m/s, then the operator $\mathcal{L}_o^{\uparrow}(s)$ is well defined. Furthermore, from the definition of the Nerode equivalence relation[1] [5], if $s \equiv_{L_m} t$, where $\equiv_L$ represents the standard Nerode equivalence relation on a language $\bar{L}$, then $L_m/s = L_m/t$. This implies $\mathcal{L}_o^{\uparrow}(s) = \mathcal{L}_o^{\uparrow}(t)$. Hence it is meaningful to define

$$\mathcal{L}_o^{\uparrow} : \bar{L}_m/\equiv_{L_m} \longrightarrow 2^{\Sigma^*},$$

[1] $s, t \in L$ are Nerode equivalent iff $\{u : su \in L\} = \{v : tv \in L\}$.

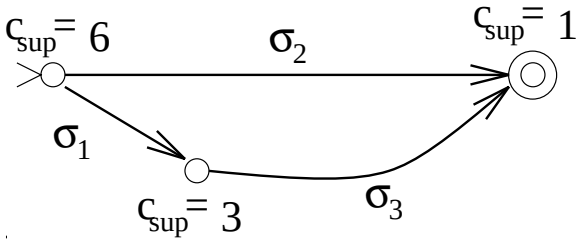

FIG. 3.1. *A DP-optimal solution.*

and accordingly, we will refer to $\mathcal{L}_o^{\uparrow}([s])$ or $\mathcal{L}_o^{\uparrow}([t])$ in the subsequent development, where $[s]$ and $[t]$ are the Nerode equivalence classes of s and t, respectively, and $\bar{L}_m/\equiv_{L_m}$ represents the set of Nerode equivalence classes of L_m. Note that $\mathcal{L}_o^{\uparrow}([\varepsilon]) = L_o^{\uparrow}$.

3.2. The principle of dynamic programming. There are interesting issues connected with the principle of dynamic programming in this problem of finding the worst-case optimal supervisor. The optimal solution to this problem is not unique. Moreover, all the optimal solutions do not structurally have optimal subsolutions (refer to [1]); i.e., they do not satisfy the principle of dynamic programming. This fact is later demonstrated by an example. Unlike the optimal control of Markov chains, the principle of dynamic programming is only a sufficient condition in this min-max problem. It is not necessary. However, we will prove that in the case of the finite alphabet, if optimal solutions exist, then solutions having optimal substructure also exist. We call this latter type a *DP-optimal* solution and define it as follows.

DEFINITION 3.6. *$A_{DO} \subseteq L_m$ is a DP-optimal solution iff it is optimal, and for all $s \in \bar{A}_{DO}$, A_{DO}/s is an optimal sublanguage of L_m/s.*

This type of optimal solution also has a unique physical significance. It guarantees the best possible future behavior, given that the system has already executed some prefix spontaneously in the past. Since this is a min-max problem, the post-languages of all optimal solutions do not have this property. It is shown later that if L_m is a regular language, then a computational specification of the supremal DP-optimal sublanguage can be derived in polynomial time by algorithms based on dynamic programming. Since we are unable to make the same claim for the supremal optimal solution, the DP-optimal solution is a crucial component of these investigations. We illustrate the distinctions by two examples.

Example 3.2.1. We illustrate the distinctions by referring back to Example 2.1.1. A_m and L_m are as previously defined. We see from Figure 2.2 that $\{\sigma_3, \sigma_4\}$ is not an optimal sublanguage of L_m/σ_1. Thus A_m does not have optimal substructure; i.e., it is optimal but not DP-optimal. We see from Figure 2.2 that $c_{\sup}(A_m/\sigma_1, \sigma_1) = 4$, whereas the optimal solution in the class L_m/σ_1 is $\{\sigma_3\}$ with $c_{\sup}(.) = 3$. We use this to construct a DP-optimal sublanguage of L_m. This language is $\{\sigma_2, \sigma_1\sigma_3\}$. A generator for this solution is shown in Figure 3.1.

Example 3.2.2. This example presents a DES with an infinite alphabet that has a supremal optimal solution but no DP-optimal solution. The plant state machine is as in Figure 3.2. The plant language is $L_m = \{b\} \cup \{a^i d_i : i \in \mathbb{N}\}$.

We assume $c_c(a) = c_c(b) = 100$ and $c_c(d_n) = 0$. The event costs are $c_e(a) = 0, c_e(b) = 1$, and $c_e(d_n) = \frac{1}{n}$. The supremal optimal sublanguage of this language is the language itself. However, in the post-language L_m/a, there is no optimal

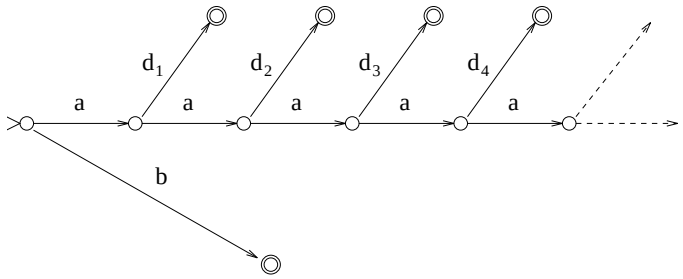

FIG. 3.2. *The plant.*

sublanguage. To see this consider the sequence of languages

$$L_0 = L_m/a, \qquad L_n = L_{n-1} - \{a^{n-1}d_n\}.$$

Then $\lim_{n\to\infty} c_{\sup}(L_n) = 0$, but there is no zero-cost nonblocking sublanguage in L_m/a. Consequently though an optimal sublanguage of L_m exists, no DP-optimal sublanguage exists.

The example reveals that the case of the infinite alphabet is complicated. However, for DES modeled by a finite alphabet, we are able to state the following theorem.

THEOREM 3.7. *Let $|\Sigma| < \infty$. If an optimal solution exists, then a DP-optimal solution exists, and furthermore the unique supremal DP-optimal solution, denoted by $L^{\uparrow}_{DO}$, exists.*

The union of DP-optimal solutions is also DP-optimal, and once again, a minimally restrictive DP-optimal solution exists. The theorem is proved by a construction detailed in section 4.2.

Our next theorem is a useful relation between the Nerode equivalence on the plant language and that on the supremal DP-optimal sublanguage.

THEOREM 3.8. *If $s, t \in L^{\uparrow}_{DO}$ and $s \equiv_{L_m} t$, then $s \equiv_{L^{\uparrow}_{DO}} t$.*

The theorem says that if two prefixes of the supremal DP-optimal sublanguage are Nerode equivalent in L_m, then they are also equivalent in $L^{\uparrow}_{DO}$.

Theorems 3.1, 3.2, 3.3, 3.5, and 3.7 constitute the existence theory. Theorems 3.1, 3.2, and 3.3 present existence conditions for different types of problems. Theorem 3.5 shows that minimally restrictive solutions are meaningful within this problem formulation and that they exist if the problem has any solution at all. Theorem 3.7 says that, for finite alphabet systems, if optimal solutions exist, then solutions having optimal substructure also exist, and there is such a unique minimally restrictive solution.

3.3. Computational results. We now discuss the main results on the computation of optimal solutions. It is possible to argue from Theorem 3.8 that if L_m is regular then $L^{\uparrow}_{DO}$ is also regular. This fact leads to the following computability theorem for DES modeled by regular languages.

THEOREM 3.9. *Let G be a FSM generating L_m and let an optimal sublanguage of L_m exist.*

(i) *There exists a unique submachine of G generating $L^{\uparrow}_{DO}$.*

(ii) *$L^{\uparrow}_{DO}$ is a regular language.*

$L^{\uparrow}_{DO}$ is exceptional in the fact that it is regular. Not all optimal solutions are necessarily regular. Theorem 3.9 tells us that in the finite set of trim submachines of G, there is a FSM generating $L^{\uparrow}_{DO}$. However, the theorem gives no way of identifying the

required submachine. In section 5 we show how to identify the FSM generating $L^{\uparrow}_{DO}$ by setting up an appropriate optimization problem on the set of trim submachines of G. It is shown that a specific type of solution to this new optimization problem generates $L^{\uparrow}_{DO}$. The time complexity is exponential in the number of states of G.

The results pertaining to polynomial-time complexity optimal controller synthesis are as follows. For DES modeled by cyclic FMSs we make additional assumptions. For DES modeled by acyclic FSMs no additional assumptions are required. For cyclic FSMs it is assumed that all event costs are positive and that the FSM has only one marked state; i.e., all strings in L_m are Nerode equivalent. The existence of a general polynomial algorithm for the acyclic case makes us suspect that it may be possible to relax the single marked state assumption for the cyclic case. However, this has not been proved. We discuss it further in section 6. We state the two main theorems.

THEOREM 3.10. *Let L_m be regular and such that all marked strings are equivalent in the sense of Nerode. Let all event costs be positive. If an optimal solution exists then, given a generator of L_m with n states, a generator for the supremal DP-optimal sublanguage is computable in time*

$$O(n^2|\Sigma|\log(|\Sigma|) + n^3|\Sigma|).$$

THEOREM 3.11. *Let the plant language L_m be generated by a trim acyclic FSM G having n states. A generator for the supremal DP-optimal solution is computable in time:*

$$O(n|\Sigma|\log(|\Sigma|)).$$

4. Proofs of the existence results. This section presents the proofs of theorems 3.1, 3.2, 3.3, 3.4, 3.5, 3.7, and 3.8. Theorems 3.9, 3.10, 3.11 require some additional concepts. They are proved in sections 5 and 6. Theorems are presented in this section in the order in which their proofs are developed. No earlier theorem uses a later theorem. The proof of Theorem 3.3 uses Theorem 3.8, and so Theorem 3.3 is proved last. All other theorems are proved in the order stated in section 3. We use the notation $\Pi_0(\pi(s)) = \Sigma_{L_m}(s) - \pi(s)$ to denote the set of active events disabled by the control law, i.e., events that determine the control cost.

4.1. Existence of optimal solutions. The following is the proof of the existence theorem for DES modeled by a finite alphabet.

THEOREM 3.1. *Let $|\Sigma| < \infty$. An optimal sublanguage exists iff there exists some $A \subseteq L_m$ such that $c_{\sup}(A) < \infty$.*

Proof. The necessity of the existence of a bounded cost sublanguage is trivial. We consider the sufficiency. The existence of $A_m \subseteq L_m$ such that $c_{\sup}(A_m) < \infty$ implies that the infimum in the optimal control problem exists. In particular, consider the set $X = \{A \subseteq L_m : c_{\sup}(A) \leq c_{\sup}(A_m)\}$. Then

$$\inf_{A \subseteq L_m} c_{\sup}(A) = \inf_{A \subseteq X} c_{\sup}(A) = x_0 < \infty,$$

where x_0 is a nonnegative real number. Pick a sequence $\langle A_n \rangle \subseteq X$ such that $\lim_{n\to\infty} c_{\sup}(A_n) = x_0$. We will establish that the elements of this sequence can take only finitely many values.

As a first step we show that for any $A \subseteq L_m, c_{\sup}(A) < c_{\sup}(A_m)$, there exists $u \in A$ such that $c(\varepsilon, A, u) = c_{\sup}(A)$. Consider a sequence $\langle u_k \rangle \subseteq A$ such that

$\lim_{k\to\infty} c(\varepsilon, A, u_k) = c_{\sup}(A)$. Now, by definition,

$$c(\varepsilon, A, u_k) = \sum_{j=0}^{j=\|u_k\|-1} \bar{c}(p_j(u_k), \pi_A(p_j(u_k)), \sigma_j^{(u_k)}) + \bar{c}(u_k, \pi_A(u_k), \phi),$$

where $u_k = \sigma_0^{(u_k)} \dots \sigma_{\|u_k\|-1}^{(u_k)}$. Since the alphabet is finite, $c_e(.)$ and $c_c(.)$ take only finitely many values, which implies that $\bar{c}(.,.,.)$ only takes values in some finite set Z. Define $\delta > 0$ such that $y \in Z$ implies that $y > \delta$ or $y = 0$. Pick M such that $M\delta \le c_{\sup}(A_m)$ but $(M+1)\delta > c_{\sup}(A_m)$. Then, in any u_k, there are not more than M events with positive one-stage costs. Thus $c(\varepsilon, A, u_k)$ takes one of $|Z|^M + 1$ possible values for all k. Since this is a finite set there exists u_k such that $c(\varepsilon, A, u_k) = c_{\sup}(A)$.

By the above property we can construct a sequence $\langle u_n \rangle, u_n \in A_n, c(\varepsilon, A_n, u_n) = c_{\sup}(A_n)$ such that $\lim_{n\to\infty} c(\varepsilon, A_n, u_n) = x_0$. But $c(\varepsilon, A_n, u_n)$ takes only values in a finite set of cardinality $|Z|^M + 1$, which implies that there exists n such that $c(\varepsilon, A_n, u_n) = c_{\sup}(A_n) = x_0$. Then A_n is an optimal sublanguage. □

The following is the proof of the existence theorem for the countable alphabet. It uses the condition $c_e(.) > \delta > 0$ to establish an equivalent finite alphabet problem. The theorem is then immediate.

THEOREM 3.2. *For all $s \in \bar{L}_m$ let $|\Sigma_{L_m}(s)| < \infty$. Let $c_e(.) > \delta > 0$. There exists an optimal sublanguage of L_m iff there exists $A_m \subseteq L_m$ such that $c_{\sup}(A_m) < \infty$.*

Proof. Let A_m be as in the hypothesis of the theorem. The necessity of the existence of a bounded cost language is trivial. We consider the sufficiency. Once again, pick $M > 0$ such that $M\delta \le c_{\sup}(A_m)$ but $(M+1)\delta > c_{\sup}(A_m)$. Then for any $A \subseteq L_m$ and $u \in A$ with $c_{\sup}(A) < c_{\sup}(A_m)$, there are at most M events in u. Consider $X = \{s \in L_m : \|s\| \le M\}$. Then

$$c_{\sup}(A) \le c_{\sup}(A_m) \Longrightarrow A \subseteq X.$$

Let $|\Sigma_{L_m}(u)|$ be finite for all $u \in \bar{L}_m$. Then $|X|$ is finite, which implies

$$\inf_{A\subseteq L_m} c_{\sup}(A) = \inf_{A\subseteq X} c_{\sup}(A) = \min_{A\subseteq X} c_{\sup}(A)$$

since $|X|$ is finite. Thus the minimum in the set X is an optimal sublanguage. □

The following is the proof of the monotonicity of the cost functions.

THEOREM 3.4. *Let $s \in A_m \subseteq B_m \subseteq L_m/t, t \in \bar{L}_m$. Then $c(t, A_m, s) \ge c(t, B_m, s)$.*

Proof. Let $s = \sigma_0 \dots \sigma_{\|s\|-1}$. By Definition 2.3

$$c(t, A_m, s) = \sum_{j=0}^{j=\|s\|-1} c_e(\sigma_j) + \sum_{j=0}^{j=\|s\|-1} \sum_{\sigma\in\Pi_0(\pi_{A_m}(p_j(s)))} c_c(\sigma) + \bar{c}(ts, \pi_{A_m}(ts), \phi).$$

But

$$\begin{array}{rrcl}
 & A_m & \subseteq & B_m \\
\Longrightarrow & \pi_{A_m}(tp_j(s)) & \subseteq & \pi_{B_m}(tp_j(s)) \\
\Longrightarrow & \Pi_0(\pi_{B_m}(p_j(s))) & \subseteq & \Pi_0(\pi_{A_m}(p_j(s))) \\
\Longrightarrow & \displaystyle\sum_{\sigma\in\Pi_0(\pi_{B_m}(tp_j(s)))} c_c(\sigma) & \le & \displaystyle\sum_{\sigma\in\Pi_0(\pi_{A_m}(tp_j(s)))} c_c(\sigma) \\
\Longrightarrow & c(t, B_m, s) & \le & c(t, A_m, s). \quad \square
\end{array}$$

The next proof establishes the existence of a unique minimally restrictive optimal solution.

THEOREM 3.5. *If an optimal solution exists, then the unique supremal optimal solution exists.*

Proof. Let L_o and L'_o be two optimal sublanguages of $L_m/t, t \in \bar{L}_m$. By Theorem 3.4, for any $s \in L_o$,

$$c(t, L_o \cup L'_o, s) \leq c(t, L_o, s).$$

Since the same argument applies for $s \in L'_o$ we have that

$$c_{\sup}(L_o \cup L'_o, t) \leq c_{\sup}(L_o, t) = c_{\sup}(L'_o, t).$$

Thus $L_o \cup L'_o$ is optimal, or in general, the union of optimal solutions is optimal. Hence

$$L_o^{\uparrow} = \bigcup_{\substack{L_o \subseteq L_m/t \\ L_o \text{ optimal}}} L_o$$

is the unique supremal optimal solution. □

4.2. Existence of the supremal DP-optimal solution. We prove the existence of the supremal DP-optimal solution by construction. The symbol "$\circ$" will denote the concatenation of a string with a language. If s is a string and A is a language, then

$$s \circ A = \{su : u \in A\}.$$

Consider the following nonincreasing sequence of sets having the supremal optimal solution as its first element.

$$\begin{aligned} & K_0 = L_o^{\uparrow}, \\ & K_n = A_n \cup B_n, \\ \text{where} \quad & A_n = \left(\bigcup_{\omega \in P_n(\bar{K}_{n-1})} \omega \circ \mathcal{L}_o^{\uparrow}([\omega]) \right), \\ & B_n = B_{n-1} \cup (P_n(A_n) \cap L_m), \\ \text{and} \quad & B_0 = \begin{cases} \{\varepsilon\} \text{ if } \varepsilon \in L_m, \\ \emptyset \text{ otherwise.} \end{cases} \end{aligned}$$

The two sets A_n and B_n contain the strings of K_n which are of length greater than n and less than n, respectively. The strings of length n are contained in both sets. It is easily shown that K_n is a sublanguage of L_m.

The intuition of the construction is easily seen from the definition of a DP-optimal solution. The nth step of the construction replaces all post-languages of prefixes of length n with supremal optimal sublanguages. It will be shown that for all $s \in \bar{K}_n, \|s\| \leq n$, K_n/s is an optimal sublanguage. K_n is in a sense "*$(n-DP)$-optimal*" and the limit may be expected to be DP-optimal. The supremality will come from the use of the supremal optimal sublanguage at each step.

We first establish that

$$K = \bigcap_{j=0}^{j=\infty} K_j$$

is nonempty whenever the supremal optimal solution (K_0) exists. The proof proceeds by showing that in the supremal optimal solution (K_0), among the strings realizing the worst-case behavior, there exists at least one whose costs cannot be reduced by optimizing at successive prefixes as is done in the construction of the sequence K_n. Intuitively, this must be the the case, because if the costs of all strings in $\mathcal{L}_o^{\uparrow}(L_m) = K_0$ could be reduced, then the supremal optimal solution would not be optimal. Lemma 4.3 (ii) proves the existence of such a string and (iii) establishes that it survives in all the K_n. Once we have established that K is nonempty, we prove that it is supremal DP-optimal. This is done by arguing that the jth element of the sequence $\langle K_n \rangle$ is such that for any $s \in \bar{K}_j$ with $\|s\| \leq j$, the language K_j/s is optimal. This is the precise meaning of the sense of ($j-$DP)-optimal. The relevant result is Lemma 4.5. Thereafter, we prove that K is supremal DP-optimal by establishing that any DP-optimal sublanguage is contained by it.

The proof is broken into five lemmas. Lemmas 4.1 and 4.2 establish certain properties of our definitions and the construction $\langle K_n \rangle$. Lemmas 4.3 and 4.5 are as described above. Lemma 4.4 is essentially a convergence result establishing that the prefix-closures of K_n converge to the prefix-closure of K. We start with Lemma 4.1, which states two simple properties of our definitions. It is stated without proof.

LEMMA 4.1.

(i) $\forall n \in \mathbb{N}, P_n(A \cup B) = P_n(A) \cup P_n(B)$.

(ii) *For all* $s \in \bar{A}_m, \sigma \in \Pi_0(\pi_{A_m}(s))$ *iff* $s\sigma \in P_{\|s\|+1}(\bar{L}_m) - P_{\|s\|+1}(\bar{A}_m)$.

The next lemma states some properties of the sequence $\langle K_n \rangle$. The first part states that the set B_n is made of strings with length not greater than n. The second part states that the sequence is a nested one. The third part says that the prefixes of length less than n of K_n remain in the prefix-closure of all subsequent languages of the sequence.

LEMMA 4.2.

(i) $\forall n \in \mathbb{N}, s \in B_n \Rightarrow \|s\| \leq n$.

(ii) $\forall n \in \mathbb{N}, P_n(\bar{K}_n) = P_n(\bar{K}_{n-1})$.

(iii) $\forall n \in \mathbb{N}, K_n \subseteq K_{n-1} \subseteq L_m$.

(iv) $\forall j, n, n'$ *where* $j \leq n \leq n'$, $P_j(\bar{K}_n) = P_j(\bar{K}_{n'})$.

Proof.

(i) By definition, $B_0 = \{\varepsilon\}$ or $\emptyset$. If $B_0 = \emptyset$, then $\|s\| \leq 0$ trivially. If $B_0 = \{\varepsilon\}$, then $\|\varepsilon\| = 0$ by definition. Hence B_0 satisfies the hypothesis. Let the result be true for $n-1$. By definition, $B_n = (P_n(A_n) \cap L_m) \cup B_{n-1}$. If $s \in B_{n-1}$, then by assumption, $\|s\| \leq n-1$. If $s \in P_n(A_n) \cap L_m$ then $\|s\| = n$. The result follows.

(ii)

$$
\begin{array}{rcll}
P_n(\bar{K}_n) & = & P_n(\overline{A_n \cup B_n}) & \\
& = & P_n(\bar{A}_n \cup \bar{B}_n) & \\
& = & P_n(\bar{A}_n) \cup P_n(\bar{B}_n) & \text{[by (i)]} \\
& = & P_n(\bar{A}_n) \cup P_n(\bar{B}_{n-1}) \cup P_n(\overline{P_n(A_n) \cap L_m}) & \text{[by (i)]} \\
& = & P_n(\bar{A}_n) \cup (P_n(A_n) \cap L_m) & \text{[by (i), } P_n(B_{n-1}) = \emptyset\text{]} \\
& = & P_n(\bar{A}_n) & [P_n(A_n) \subseteq P_n(\bar{A}_n)] \\
& = & P_n(\bar{K}_{n-1}) & \text{[by definition of } K_n\text{]}.
\end{array}
$$

(iii) We first establish that $A_n \subseteq A_{n-1}$.

Let $s = p_{n-1}(s)\sigma_n t \in A_n$. Then, by definition of A_n, $t \in \mathcal{L}_o^{\uparrow}([p_n(s)])$ and $p_n(s) = p_{n-1}(s)\sigma_n \in P_n(\bar{K}_{n-1})$, which implies $p_{n-1}(s)\sigma_n \in \bar{K}_{n-1}$, $p_{n-1}(s)\sigma_n \in$

$\bar{A}_{n-1}$ (by (1)), and $\sigma_n \in \overline{\mathcal{L}_o^{\uparrow}([p_{n-1}(s)])}$. Thus

$$c_{\sup}(\mathcal{L}_o^{\uparrow}([p_{n-1}(s)])) \geq c_e(\sigma_n) + \sum_{\sigma \in \Pi_0\left(\pi_{\mathcal{L}_o^{\uparrow}([p_{n-1}(s)])}(\varepsilon)\right)} c_c(\sigma) + c_{\sup}(\mathcal{L}_o^{\uparrow}([p_{n-1}(s)])/\sigma_n)$$

$$\geq c_e(\sigma_n) + \sum_{\sigma \in \Pi_0\left(\pi_{\mathcal{L}_o^{\uparrow}([p_{n-1}(s)])}(\varepsilon)\right)} c_c(\sigma) + c_{\sup}(\mathcal{L}_o^{\uparrow}([p_n(s)]))$$

by the optimality of $\mathcal{L}_o^{\uparrow}([p_n(s)])$. Since $\mathcal{L}_o^{\uparrow}([p_{n-1}(s)])$ is supremal optimal, this implies that $\sigma_n \circ \mathcal{L}_o^{\uparrow}([p_n(s)]) \subseteq \mathcal{L}_o^{\uparrow}([p_{n-1}(s)])$. Thus

$$s = p_{n-1}(s)\sigma_n t \in p_{n-1}(s)\sigma_n \mathcal{L}_o^{\uparrow}([p_n(s)]) \subseteq p_{n-1}(s) \circ \mathcal{L}_o^{\uparrow}([p_{n-1}(s)]) \subseteq A_{n-1},$$

since $p_{n-1}(s) \in P_{n-1}(\bar{A}_{n-1})$. This proves $A_n \subseteq A_{n-1}$.

The inclusion $K_n \subseteq K_{n-1}$ is now easy. Let $s \in K_n = A_n \cup (P_n(A_n) \cap L_m) \cup B_{n-1} = A_n \cup B_{n-1}$. If $s \in A_n$, then $s \in A_{n-1} \subseteq K_{n-1}$. If $s \in B_{n-1}$ then $s \in K_{n-1}$ by definition. The inclusion $K_n \subseteq L_m$ follows from $K_0 \subseteq L_m$ and an inductive application of $K_n \subseteq K_{n-1}$.

(iv) By part (iii)

$$K_{n+1} \subseteq K_n \Rightarrow \bar{K}_{n+1} \subseteq \bar{K}_n \Rightarrow P_j(\bar{K}_{n+1}) \subseteq P_j(\bar{K}_n).$$

Let $s \in P_j(\bar{K}_n), j \leq n$. Then $\|s\| = j$ and $\exists s'$ such that $ss' \in K_n$. The argument may be considered in two cases.

Case 1. $ss' \in B_n$. By definition of B_{n+1}, $ss' \in B_{n+1}$, which implies $s \in P_j(\bar{K}_{n+1})$.

Case 2. $ss' \notin B_n$. Then $ss' \in A_n$, but $ss' \notin P_n(A_n)$. Hence $p_{n+1}(ss')$ exists, which implies $p_{n+1}(ss') \in P_{n+1}(\bar{K}_n) = P_{n+1}(\bar{K}_{n+1})$. Since $j \leq n$ and $\|s\| = j$, we get $s \in P_j(\bar{K}_{n+1})$. By induction, $s \in P_j(\bar{K}_{n'})$ for all $n' \geq n$. □

We prove next that K is nonempty in three steps. First we state the simple property that if a string is not in the supremal optimal sublanguage, then any language containing that string is nonoptimal. Next we show that there exists a string in K_0 that realizes the supremum, and the post-languages corresponding to all prefixes of this string are optimal. Finally, it is established that this particular string must be contained in K.

LEMMA 4.3.

(i) *Let $s \in L_m/u$ and $s \notin \mathcal{L}_o^{\uparrow}(L_m/u)$. Then, for any $L \subseteq L_m/u$ and $s \in L$, we have*

$$c_{\sup}(L) > c_{\sup}(\mathcal{L}_o^{\uparrow}(L_m/u)).$$

(ii) *There exists $s \in K_0 = \mathcal{L}_o^{\uparrow}(L_m)$ such that $K_0/p_i(s)$ is optimal for all $i, 0 \leq i \leq \|s\|$.*

(iii) *Let there exist s as in part* (ii). *Then $s \in K$.*

Proof.

(i) Let the hypotheses be true and $c_{\sup}(L) \leq c_{\sup}(\mathcal{L}_o^{\uparrow}(L_m/u))$. Then L is optimal. This implies $s \in L \subseteq \mathcal{L}_o^{\uparrow}(L_m/u)$, which contradicts the hypothesis. The result follows.

(ii) Suppose that for all $s \in K_0$ there exists i such that $c_{\sup}(K_0/p_i(s), p_i(s)) > c_{\sup}(\mathcal{L}_o^{\uparrow}(L_m/p_i(s)), p_i(s))$. Let $i(s)$ denote the smallest such i for s. If $s \leq t$ then $i(s) = i(t)$. Note that $K_0 = \mathcal{L}_o^{\uparrow}(L_m)$. Define

$$L = \bigcup_{t \in \overline{\mathcal{L}_o^{\uparrow}(L_m)}} p_{i(t)}(t) \circ \mathcal{L}_o^{\uparrow}(L_m/p_{i(t)}(t)).$$

Let $u \in L$. Then there exists $s \in K_0$, such that $u = p_{i(s)}(s)v$. Then we have

$$\begin{aligned} c(\varepsilon, L, u) &= c(\varepsilon, L, p_{i(s)}(s)v) \\ &\leq \bar{c}(\varepsilon, L, p_{i(s)}(s)) + c_{\sup}(L/p_{i(s)}(s), p_{i(s)}(s)) \\ &= \bar{c}(\varepsilon, L, p_{i(s)}(s)) + c_{\sup}(\mathcal{L}_o^{\uparrow}(L_m/p_{i(s)}(s)), p_{i(s)}(s)) \\ &< \bar{c}(\varepsilon, L, p_{i(s)}(s)) + c_{\sup}(K_0/p_{i(s)}(s), p_{i(s)}(s)). \end{aligned}$$

Next we claim that for all j, such that $0 \leq j \leq i(s) - 1$,

$$p_j(s)\sigma \in \bar{K}_0 \Leftrightarrow p_j(s)\sigma \in \bar{L}.$$

The case $p_j(s)\sigma = p_{j+1}(s)$ is trivial. The following argument is for the case $p_j(s)\sigma \neq p_{j+1}(s)$. Let $p_j(s)\sigma \in \bar{K}_0$. Then there exists $w = p_j(s)\sigma v \in K_0$ and $i(w)$ such that $K_0/p_{i(w)}(w)$ is not optimal. By definition of $i(s)$, $i(w) > j$. This is true since $i(w) \leq j$ implies that $i(w) < i(s)$, which contradicts the definition of $i(s)$ as the smallest such i for the string s. Thus $p_{i(w)}(w) \circ \mathcal{L}_o^{\uparrow}(L_m/p_{i(w)}(w)) \subseteq L$, which implies $p_j(s)\sigma \in \bar{L}$. For the reverse inclusion assume $p_j(s)\sigma \in \bar{L}$. Then there exists v such that $p_j(s)\sigma v \in L$, and there exists $w \in K_0$ such that $p_{i(w)}(w) \in \bar{K}_0$ and $p_j(s)\sigma v \in p_{i(w)}(w) \circ \mathcal{L}_o^{\uparrow}(L_m/p_{i(w)}(w))$. By definition of $i(s)$, $i(w) > j$, which implies $p_j(s)\sigma \in \bar{K}_0$. This proves the claim. The claim implies $\bar{c}(\varepsilon, L, p_{i(s)}(s)) = \bar{c}(\varepsilon, K_0, p_{i(s)}(s))$, from which

$$c(\varepsilon, L, u) < \bar{c}(\varepsilon, K_0, p_{i(s)}(s)) + c_{\sup}(K_0/p_{i(s)}(s), p_{i(s)}(s)) \leq c_{\sup}(K_0)$$

for all $u \in L$. Next we use the finiteness of the alphabet to show that there exists $u \in L$ such that $c_{\sup}(L) = c(\varepsilon, L, u)$. Define a sequence $\langle u_n \rangle$ in L such that

$$\lim_{n \to \infty} c(\varepsilon, L, u_n) = c_{\sup}(L).$$

Since the alphabet, which is the domain of definition of c_e, and c_c, is finite, the range of these functions is also finite. This, together with the fact that $c_{\sup}(L) < \infty$, implies that $c(\varepsilon, L, .)$ can take only finitely many values. Thus there exists $N \in \mathbb{N}$ such that $c(\varepsilon, L, u_n) = c_{\sup}(L)$ for $n \geq N$. Hence,

$$c_{\sup}(L) = c(u_n, L) < c_{\sup}(K_0),$$

which contradicts the optimality of K_0. The result follows.

(iii) Let $s \notin k$. Get the smallest n such that $s \notin K_n$. Then $s \in K_{n-1}$, which implies that $p_n(s) \in \bar{K}_n$, by definition of K_n. Let $s = p_n(s)v_n$. Then $v_n \notin \bar{K}_n/p_n(s)$, and by definition of K_n, $v_n \notin \mathcal{L}_o^{\uparrow}(L_m/p_n(s))$. But $v_n \in L_m/p_n(s)$ and $v_n \in K_0/p_n(s) \subseteq L_m/p_n(s)$. By part (i)

$$c_{\sup}(K_0/p_n(s), p_n(s)) > c_{\sup}(\mathcal{L}_o^{\uparrow}(L_m/p_n(s)), p_n(s)).$$

This contradicts the hypothesis on s. Hence $s \in K_n$ for all n, implying $s \in K$. ∎

Observe that part (ii) of the lemma says that the hypothesis of part (iii) is not vacuous. The two parts taken together then establish that K is nonempty. The next lemma states that the sequence K_n develops K incrementally.

LEMMA 4.4. $\forall j \leq n \in \mathbb{N}, P_j(\bar{K}) = P_j(\bar{K}_n)$.

Proof. We prove $\bar{K} = \cap_{n=0}^{n=\infty} \bar{K}_n$. The inclusion $\bar{K} \subseteq \cap_{n=0}^{n=\infty} \bar{K}_n$ is obvious.

Let $s \in \cap_{n=0}^{n=\infty} \bar{K}_n$. Then for all n there exists v_n such that $sv_n \in \bar{K}_n$. In particular, consider $K_{\|s\|}/s = \mathcal{L}_o^{\uparrow}([s])$. We use Lemma 4.3 with K_0 replaced by $\mathcal{L}_o^{\uparrow}([s]) = H_0$ and

L_m replaced by L_m/s. Denote the analogous sequence by $\langle H_n \rangle$. It is easy to show that $H = K/s$. Then by Lemma 4.3, there exists $v \in H = K/s$. This implies $sv \in K$ and hence $s \in \bar{K}$. This proves the reverse inclusion.

Now by the above and Lemma 4.2 (iv),

$$P_j(\bar{K}) = \bigcap_{n=0}^{n=\infty} P_j(\bar{K}_n) = P_j(\bar{K}_i)$$

for any $i \geq j$. The result follows. □

The next lemma states that the worst-case costs associated with the post-language of a prefix s do not change after $\|s\|$ iterations, and moreover, that the post-language becomes and remains optimal.

LEMMA 4.5.

(i) $\forall s \in K_j, c_{\sup}(K_j/s, s) = c_{\sup}(K_i/s, s) = c_{\sup}(\mathcal{L}_o^{\uparrow}([s])), j \geq i \geq \|s\|$.

(ii) $\forall s \in \bar{K}, c_{\sup}(K/s, s) = c_{\sup}(K_j/s, s) = c_{\sup}(\mathcal{L}_o^{\uparrow}([s])), j \geq \|s\|$.

Proof.

Claim 4.5.1. $\forall s \in \bar{K}_i, \|s\| \leq i \leq j, 0 \leq k \leq \|s\|$,

$$\Pi_0(\pi_{K_i}(p_k(s))) = \Pi_0(\pi_{K_j}(p_k(s))).$$

Proof. First consider the case $k < i \leq j$.

$$\begin{array}{rrcll} & \sigma & \in & \Pi_0(\pi_{K_i}(p_k(s))) & \\ \Leftrightarrow & p_k(s)\sigma & \in & P_{k+1}(\bar{L}_m) - P_{k+1}(\bar{K}_i) & \text{[Lemma 4.1 (ii)]} \\ \Leftrightarrow & p_k(s)\sigma & \in & P_{k+1}(\bar{L}_m) - P_{k+1}(\bar{K}_j) & \text{[Lemma 4.2 (iv)]} \\ \Leftrightarrow & \sigma & \in & \Pi_0(\pi_{K_j}(p_k(s))) & \text{[Lemma 4.1 (ii)].} \end{array}$$

Next consider the case $k = i < j$.

$$\begin{array}{rrcll} & \sigma & \in & \Pi_0(\pi_{K_i}(p_i(s))) & \\ \Leftrightarrow & p_i(s)\sigma & \in & P_{i+1}(\bar{L}_m) - P_{i+1}(\bar{K}_i) & \text{[Lemma 4.1 (ii)]} \\ \Leftrightarrow & p_i(s)\sigma & \in & P_{i+1}(\bar{L}_m) - P_{i+1}(\bar{K}_{i+1}) & \text{[Lemma 4.2 (ii)]} \\ \Leftrightarrow & p_i(s)\sigma & \in & P_{i+1}(\bar{L}_m) - P_{i+1}(\bar{K}_j) & \text{[Lemma 4.2 (iv)]} \\ \Leftrightarrow & \sigma & \in & \Pi_0(\pi_{K_j}(p_i(s))) & \text{[Lemma 4.1 (ii)].} \end{array}$$

The case $k = i, j = i$ is trivial. □

Next we show that $c_{\sup}(K_{i+1}/s, s) \leq c_{\sup}(K_i/s, s)$ for all $s \in \bar{K}_i, i \geq \|s\|$.

$$\begin{aligned} c_{\sup}(K_{i+1}/s, s) &= c_{\sup}((A_{i+1} \cup B_{i+1})/s, s) \\ &= c_{\sup}((A_{i+1} \cup (P_{i+1}(A_{i+1}) \cap L_m) \cup B_i)/s, s) \\ &= c_{\sup}((A_{i+1} \cup B_i)/s, s) \\ &= c_{\sup}(A_{i+1}/s \cup B_i/s, s) \\ &= c_{\sup}((\cup_{\omega \in P_{i+1}(\bar{K}_i)} \omega \circ \mathcal{L}_o^{\uparrow}([\omega]))/s \cup B_i/s, s). \end{aligned}$$

If $u \in B_i/s$ then $c(s, K_{i+1}/s, u) = c(s, K_i/s, u)$ by the following argument:

$$u \in B_i/s \Rightarrow su \in B_i \Rightarrow \|su\| \leq i \quad \text{[Lemma 4.2 (i)]},$$

from which by Claim 4.5.1,

$$\Pi_0(\pi_{K_i}(p_k(su))) = \Pi_0(\pi_{K_{i+1}}(p_k(su))).$$

From the definition of the cost of a string in a language it is now evident that

$$\begin{array}{rrcl} & c(\varepsilon, K_{i+1}, su) & = & c(\varepsilon, K_i, su) \\ \Rightarrow & c(s, K_{i+1}/s, u) & = & c(s, K_i/s, u) \\ \Rightarrow & c(s, K_{i+1}/s, u) & \leq & c_{\sup}(K_i/s, s). \end{array}$$

This takes care of the case $u \in B_i/s$. The other possible case is $u \in A_{i+1}/s$ with $u = t\omega$ and $st \in P_{i+1}(\bar{K}_i)$. Let $t = \sigma_0 \ldots \sigma_{\|t\|-1}$. Observe that $\hat{c}(s, K_i/s, t) = \hat{c}(s, K_{i+1}/s, t)$ since

$$\begin{array}{rcl} \hat{c}(s, K_i/s, t) & = & \displaystyle\sum_{l=0}^{l=\|t\|-1} c_e(\sigma_l) + \sum_{k=\|s\|}^{k=\|st\|-1} \sum_{\sigma \in \Pi_0(\pi_{K_i}(p_k(st)))} c_c(\sigma) \\ & = & \displaystyle\sum_{l=0}^{l=\|t\|-1} c_e(\sigma_l) + \sum_{k=\|s\|}^{k=\|st\|-1} \sum_{\sigma \in \Pi_0(\pi_{K_{i+1}}(p_k(st)))} c_c(\sigma) \quad \text{[Claim 4.5.1]} \\ & = & \hat{c}(s, K_{i+1}/s, t), \end{array}$$

where Claim 4.5.1 is used with $p_{\|st\|-1}(st)$ substituted for s, $\|st\| - 1$ substituted for i, $\|st\|$ substituted for j, and k such that $\|s\| \leq k \leq \|st\| - 1$. Equipped with this observation on the nature of $\hat{c}(.,.,.)$, the following argument is made.

$$\begin{array}{rcl} c(s, K_{i+1}/s, u) & = & c(s, K_{i+1}/s, t\omega) \\ & = & \hat{c}(s, K_{i+1}/s, t) + c(st, K_{i+1}/st, \omega) \\ & = & \hat{c}(s, K_i/s, t) + c(st, K_{i+1}/st, \omega) \\ & \leq & \hat{c}(s, K_i/s, t) + c_{\sup}(K_{i+1}/st, st) \\ & = & \hat{c}(s, K_i/s, t) + c_{\sup}(\mathcal{L}_o^{\uparrow}([st]), st) \\ & \leq & \hat{c}(s, K_i/s, t) + c_{\sup}(K_i/st, st) \\ & \leq & c_{\sup}(K_i/s, s). \end{array}$$

Since u is arbitrary we obtain from the two cases that $c_{\sup}(K_{i+1}/s, s) \leq c_{\sup}(K_i/s, s)$. By induction, it follows that $\forall j \geq i \geq \|s\|$,

$$c_{\sup}(K_j/s, s) \leq c_{\sup}(K_i/s, s).$$

In particular, if $i = \|s\|$, then

$$c_{\sup}(K_j/s, s) \leq c_{\sup}(K_{\|s\|}/s, s) = c_{\sup}(\mathcal{L}_o^{\uparrow}([s]), s)$$

by definition of K_i. Now the optimality of $\mathcal{L}_o^{\uparrow}([s])$ gives $c_{\sup}(K_j/s, s) = c_{\sup}(\mathcal{L}_o^{\uparrow}([s]), s)$. Thus part (i) is proved.

The proof of part (ii) is similar. We begin with an analogous claim.

Claim 4.5.2. $\forall s \in \bar{K}, \|s\| \leq j, 0 \leq k \leq \|s\|$,

$$\Pi_0(\pi_K(p_k(s))) = \Pi_0(\pi_{K_j}(p_k(s))).$$

Proof. Consider first the case $k < \|s\|$.

$$\begin{array}{rrcll} & \sigma & \in & \Pi_0(\pi_K(p_k(s))) & \\ \Leftrightarrow & p_k(s)\sigma & \in & P_{k+1}(\bar{L}_m) - P_{k+1}(\bar{K}) & \text{[Lemma 4.1 (ii)]} \\ \Leftrightarrow & p_k(s)\sigma & \in & P_{k+1}(\bar{L}_m) - P_{k+1}(\bar{K}_j) & \text{[Lemma 4.4]} \\ \Leftrightarrow & \sigma & \in & \Pi_0(\pi_{K_j}(p_k(s))) & \text{[Lemma 4.1 (ii)].} \end{array}$$

For the case $k = \|s\|$,

$$\begin{array}{rrcll} & \sigma & \in & \Pi_0(\pi_K(s)) & \\ \Leftrightarrow & s\sigma & \in & P_{\|s\|+1}(\bar{L}_m) - P_{\|s\|+1}(\bar{K}) & \text{[Lemma 4.1 (ii)]} \\ \Leftrightarrow & s\sigma & \in & P_{\|s\|+1}(\bar{L}_m) - P_{\|s\|+1}(\bar{K}_{\|s\|+1}) & \text{[Lemma 4.4]} \\ \Leftrightarrow & s\sigma & \in & P_{\|s\|+1}(\bar{L}_m) - P_{\|s\|+1}(\bar{K}_{\|s\|}) & \text{[Lemma 4.2 (ii)]} \\ \Leftrightarrow & \sigma & \in & \Pi_0(\pi_{K_{\|s\|}}(p_{\|s\|}(s))) & \text{[Lemma 4.1 (ii)]} \\ \Leftrightarrow & \sigma & \in & \Pi_0(\pi_{K_j}(s)) & \text{[Claim 4.5.1].} \quad \square \end{array}$$

This claim is used to prove part (ii). Let $t = \sigma_0 \dots \sigma_{\|t\|-1}$. By definition,

$$\begin{array}{rcll} c(s, K/s, t) & = & \displaystyle\sum_{k=0}^{k=\|t\|-1} c_e(\sigma_k) + \sum_{k=\|s\|}^{k=\|st\|} \sum_{\sigma \in \Pi_0(\pi_K(p_k(st)))} c_c(\sigma) & \\ & = & \displaystyle\sum_{k=0}^{k=\|t\|-1} c_e(\sigma_k) + \sum_{k=\|s\|}^{k=\|st\|} \sum_{\sigma \in \Pi_0(\pi_{K_{\|st\|}}(p_k(st)))} c_c(\sigma) & \text{[Claim 4.5.2]} \\ & = & c(s, K_{\|st\|}/s, t) & \\ & \leq & c_{\sup}(K_{\|st\|}/s, s) & \\ & = & c_{\sup}(K_j/s, s), \quad j \geq \|s\| & \text{[part (i)]} \\ & = & c_{\sup}(\mathcal{L}_o^{\uparrow}([s]), s). & \end{array}$$

Thus $c_{\sup}(K/s, s) \leq c_{\sup}(K_j/s, s), j \geq \|s\|$, and by the optimality of $\mathcal{L}_o^{\uparrow}([s])$

$$c_{\sup}(K/s, s) = c_{\sup}(K_j/s, s) = c_{\sup}(\mathcal{L}_o^{\uparrow}([s]), s)$$

for all $j \geq \|s\|$. $\square$

We now have all properties of the sequence $\langle K_n \rangle$ necessary to prove existence of the supremal DP-optimal solution.

THEOREM 3.7. *Let $|\Sigma| < \infty$. If an optimal solution exists, then a DP-optimal solution exists, and furthermore, the unique supremal DP-optimal solution, denoted by $L_{DO}^{\uparrow}$, exists.*

Proof. We claim that K is the supremal DP-optimal solution. Note first that by Lemma 4.1 (iii), K is a sublanguage of L_m. By Lemma 4.3, K is nonempty. The DP-optimality of K is immediate from Lemma 4.5 (ii) since for all $s \in \bar{K}$

$$c_{\sup}(K/s, s) = c_{\sup}(\mathcal{L}_o^{\uparrow}([s]), s),$$

which is the definition of a DP-optimal sublanguage of L_m.

The supremality of K is established as follows. Let A_{DO} be any DP-optimal sublanguage of L_m and $s = \sigma_0 \dots \sigma_{\|s\|-1} \in A_{DO} \subseteq L_o^{\uparrow}$. Since $L_o^{\uparrow}(= K_0)$ exists, we get $\varepsilon \in \bar{K}_0$, whence $\varepsilon \in P_0(\bar{K}_0)$. This is the base case for an inductive argument. Assume $p_j(s) \in P_j(\bar{K}_j)$. Since $A_{DO}/p_j(s)$ is optimal and $K_j/p_j(s) = \mathcal{L}_o^{\uparrow}([p_j(s)])$ it implies that

$$\begin{array}{rrcll} & A_{DO}/p_j(s) & \subseteq & K_j/p_j(s) & \\ \Rightarrow & \sigma_j & \in & \overline{A_{DO}/p_j(s)} \subseteq \overline{K_j/p_j(s)} & \\ \Rightarrow & p_{j+1}(s) & \in & \bar{K}_j & \\ \Rightarrow & p_{j+1}(s) & \in & P_{j+1}(\bar{K}_j) = P_{j+1}(\bar{K}_{j+1}) & \text{[by Lemma 4.2 (ii)].} \end{array}$$

Thus, by induction, $p_{\|s\|}(s) = s \in P_{\|s\|}(\bar{K}_{\|s\|})$. Since $s \in L_m$ and $\mathcal{L}_o^{\uparrow}([s])$ exists, we get $\varepsilon \in \mathcal{L}_o^{\uparrow}([s])$. This implies $s \in A_{\|s\|}$ and so

$$s \in P_{\|s\|}(A_{\|s\|}) \cap L_m \subseteq B_{\|s\|} \subseteq K.$$

Since s was arbitrary we have $A_{DO} \subseteq K$. Thus K contains all DP-optimal solutions, and being itself DP-optimal, it is the unique supremal DP-optimal solution. □

The next theorem proves that if two strings are Nerode equivalent in the plant language, they are Nerode equivalent in the supremal DP-optimal sublanguage.

THEOREM 3.8. *If $s, t \in L^{\uparrow}_{DO}$ and $s \equiv_{L_m} t$ then $s \equiv_{L^{\uparrow}_{DO}} t$.*

Proof. For $s \in \bar{L}_m$ let $\mathcal{L}^{\uparrow}_{DO}(s)$ represent the supremal DP-optimal sublanguage in the post-language L_m/s if it exists. Since $s, t \in L^{\uparrow}_{DO}$ and it is supremal DP-optimal we have

$$L^{\uparrow}_{DO}/s = \mathcal{L}^{\uparrow}_{DO}(s),$$
$$L^{\uparrow}_{DO}/t = \mathcal{L}^{\uparrow}_{DO}(t)$$

because by definition of DP-optimality the post-languages are DP-optimal, and it is easily shown that if the post-languages are not supremal, then $L^{\uparrow}_{DO}$ is not supremal either. But $s \equiv_{L_m} t$ implies that $L_m/s = L_m/t$. This, together with the uniqueness of the supremal DP-optimal sublanguage, gives

$$\mathcal{L}^{\uparrow}_{DO}(s) = \mathcal{L}^{\uparrow}_{DO}(t) \Rightarrow L^{\uparrow}_{DO}/s = L^{\uparrow}_{DO}/t \Rightarrow s \equiv_{L^{\uparrow}_{DO}} t. \qquad \square$$

The last theorem in this section is the existence theorem for DESs represented by regular languages. The theorem uses the existence of the unique supremal DP-optimal sublanguage, Theorems 3.8 and 3.1.

THEOREM 3.3. *Let L_m be a regular language. An optimal solution exists iff there exists $A_m \subseteq L_m, A_m$ regular, controllable, and having the following property for any $n \in \mathbb{N}$:*

$$\forall s = tu^*v \subseteq A_m, \quad \hat{c}(t, \bar{A}_m, u^n) = 0.$$

Proof. If an optimal solution exists, then $L^{\uparrow}_{DO}$ exists. By Theorem 3.8, $\|L^{\uparrow}_{DO}\| \leq \|L_m\|$. This implies that $L^{\uparrow}_{DO}$ is regular. By Proposition 2.7, $L^{\uparrow}_{DO}$ is also controllable. For $tu^*v \subseteq L^{\uparrow}_{DO}, \hat{c}(t, L^{\uparrow}_{DO}, u^n) \geq n\hat{c}(t, L^{\uparrow}_{DO}, u)$, which implies $c_{\sup}(L^{\uparrow}_{DO}) \geq n\hat{c}(t, L^{\uparrow}_{DO}, u)$. Then necessarily, $\hat{c}(t, L^{\uparrow}_{DO}, u) = 0$. This establishes that the given conditions are necessary for the existence of an optimal solution.

The sufficiency is argued as follows. Let A_m be as in the hypothesis of the theorem. Let $s = \sigma^s_0 \ldots \sigma^s_{\|s\|-1} \in A_m$. The condition on $\hat{c}(.,.,.)$ implies the following. For $i \leq j$,

$$p_i(s) \sim_{A_m} p_j(s) \Longrightarrow \hat{c}(p_i(s), \pi_{A_m}, \sigma^s_i \ldots \sigma^s_{j-1}) = 0.$$

Thus,

$$\bar{c}(p_k(s), \pi_{A_m}(p_k(s)), \sigma^s_k) > 0 \Longrightarrow [p_k(s)\sigma^s_k]_{A_m} \neq [p_i(s)]_{A_m}$$

for all $i \leq k$. Since L_m is a regular language $|\{k : [p_k(s)\sigma^s_k]_{A_m} \neq [p_i(s)]_{A_m}, i \leq k\}| \leq \|A_m\|$. Thus

$$\begin{array}{rrcl} & c(\varepsilon, A_m, s) & \leq & \|A_m\|(\bar{c}_e + |\Sigma|\bar{c}_c) \\ \Longrightarrow & c_{\sup}(A_m) & \leq & \|A_m\|(\bar{c}_e + |\Sigma|\bar{c}_c). \end{array}$$

Thus $A_m \subseteq L_m$ is a bounded cost sublanguage defined over a finite alphabet. The existence of an optimal sublanguage is immediate from Theorem 3.1. □

All the existence results stated in section 3 are now proven.

5. Computability. We have developed the existence theory and some of the structural properties of optimal supervisors for DESs represented by any formal language consisting of strings of finite length. This section is concerned with the additional developments possible for DESs represented by regular languages only; i.e., we are able to develop controller synthesis algorithms having polynomial complexity. The algorithms involve several complex manipulations of FSMs and are unfortunately more complicated than the algorithms synthesizing legal supervisors. Accordingly, we have tried to be careful and rigorous in arguing the correctness and complexity of our synthesis algorithms. Intuitive explanations, showing similarities with shortest path algorithms for finite vertex-directed graphs, are provided. However, this controller synthesis problem computes an optimal submachine of a FSM or, in graph-theoretic terms, an optimal subgraph of a directed graph. It requires additional stages of processing not seen in the shortest path problem.

In general, there are infinitely many sublanguages of L_m, and therefore, infinitely many candidate solutions. It is assumed in the subsequent development that an optimal sublanguage, i.e., one that realizes the infimum, exists. We show how to synthesize a FSM generating the supremal DP-optimal sublanguage ($L_{DO}^{\uparrow}$). This is done in two steps. First it is shown that a FSM generating the supremal DP-optimal solution is contained within the set of submachines of any FSM (G) generating the plant language. This is Theorem 3.9. While this theorem characterizes a finite set within which the solution may be found, it gives no way of identifying the submachine of interest. We solve this problem by setting up an appropriate optimization problem on the set of submachines of G. The submachine of interest is an optimal solution to this problem. Thus, a FSM generating an optimal sublanguage can at least be found by evaluating the objective function for every submachine of G and then finding one that realizes the minimum. This is the import of Theorem 5.3.

The following additional notation is used in this section. We define for any FSM A and $q \in Q_A$,

$$\begin{aligned} \mathcal{T}(A) &= \{(\sigma, q, q') : \sigma \in \Sigma, q \in Q_A, \delta_A(\sigma, q) = q'\}, \\ \mathcal{T}(A, q) &= \{(\sigma, q, q') : \sigma \in \Sigma, \delta_A(\sigma, q) = q'\}. \end{aligned}$$

These two functions represent the transitions in the machine A and the transitions defined at each state of A, respectively. $\Sigma_A(q)$ will denote the active event set at state q of machine A. The projection functions π_1, π_2, π_3 are used to represent the first, second, and third components of the 3-tuple (σ, q, q'), respectively. Recall the definition of a submachine of a FSM from section 2. It is immediate that $\mathcal{T}(A) \subseteq \mathcal{T}(G)$. The statement "$A \subseteq G$" denotes that A is a submachine of G. We also say A is a submachine of G at q whenever $q_{0A} = q \in Q$ and $A \subseteq G$.

We are particularly interested in *trim* [8] submachines of G. Trim submachines of G at q_0 generate nonblocking sublanguages of L_m. If G is accessible with respect to q_0 and co-accessible with respect to Q_m then it is *trim*. The notation $\mathcal{M}(G, q) = \{A \subseteq G : A \text{ trim}, q_{0A} = q\}$ represents the set of trim submachines of G at q. The set $\mathcal{M}(G, q)$ has a maximal element, in the sense that all other elements of $\mathcal{M}(G, q)$ are submachines of the maximal element. The maximal element is denoted by $M(G, q)$. The language generated by an FSM A is denoted by $\mathcal{L}(A)$, and the marked language, by $\mathcal{L}_m(A)$. If A is trim then $\mathcal{L}(A) = \overline{\mathcal{L}_m(A)}$. We reserve the symbol G for a trim generator of L_m. Since L_m is nonblocking,

$$\overline{\mathcal{L}_m(G)} = \bar{L}_m = L = \mathcal{L}(G).$$

The following general property of regular languages gives us an important implication of Theorem 3.8. Its proof is omitted. The interested reader is referred to [10].

LEMMA 5.1. *Let $A_m \subseteq L_m$ have the property,*

$$((s, t \in \bar{A}_m) \wedge (s \equiv_{L_m} t)) \Rightarrow s \equiv_{A_m} t.$$

Let $G = \langle \Sigma, Q, q_o, Q_m, \delta \rangle$ be an FSM generating L_m. Then there exists a submachine of G that generates A_m.

It is evident from Theorem 3.8 that $L^{\uparrow}_{DO}$ and L_m satisfy the preconditions of Lemma 5.1. We can now prove Theorem 3.9.

THEOREM 3.9. *Let G be an FSM generating L_m and let an optimal sublanguage of L_m exist.*

(i) *There exists a unique submachine of G generating $L^{\uparrow}_{DO}$.*

(ii) *$L^{\uparrow}_{DO}$ is a regular language.*

Proof. By Theorem 3.7, $L^{\uparrow}_{DO}$ exists. Part (i) follows from Theorem 3.8 and Lemma 5.1. The uniqueness property follows from the determinism of G. (ii) is immediate from (i). □

To identify the required submachine we define a new optimization problem on the set of trim submachines of G as follows.

For all $q \in Q, A_o \in \mathcal{M}(G, q)$ is an optimal submachine if

$$c^g_{\sup}(A_o) = \min_{A \in \mathcal{M}(G,q)} c^g_{\sup}(A) < \infty.$$

The notation $c^g_{\sup}(A)$ represents the worst-case behavior that is possible in submachine A. Its mathematical definition is

$$c^g_{\sup}(A) = \sup_{s \in \mathcal{L}_m(A)} c^g(q_{0A}, A, s),$$

where $c^g(q_{0A}, A, s)$ is the cost of a string s, which starts at q_{0A} and is generated by A. For any submachine A and state $q \in Q_A$ and string $s = \sigma^s_0 \sigma^s_1 \ldots \sigma^s_{\|s\|-1}$, such that $\delta^*_A(s, q)$ exists, the mathematical definition of $c^g(.,.,.)$ is

$$\begin{aligned} c^g(q, A, s) &= \sum_{j=0}^{j=\|s\|-1} c_e(\sigma^s_j) + \sum_{j=0}^{j=\|s\|} \sum_{e' \in \mathcal{T}(G, \delta^*(p_j(s), q)) - \mathcal{T}(A, \delta^*_A(p_j(s), q))} c_c(e') \\ &= \sum_{j=0}^{j=\|s\|-1} \bar{c}^g(\delta^*_A(p_j(s), q), A, \sigma^s_j) + \bar{c}^g(\delta^*_A(s, q), A, \phi), \end{aligned}$$

where $\bar{c}^g(.,.,.)$ is a one-stage cost function. The lower limit of the control cost summation represents the set of transitions in G that are disabled in A. The one-stage cost function is defined for any submachine A, state $q' \in Q_A$, and $\sigma \in \Sigma_A(q')$ by

$$\bar{c}^g(q', A, \sigma) = c_e(\sigma) + \sum_{\tau \in \mathcal{T}(G, q') - \mathcal{T}(A, q')} c_c(\pi_1(\tau)).$$

Note that ϕ is a dummy symbol having zero event cost. The term containing ϕ has only control costs associated with the end of the string. We also define, for mathematical convenience, the function

$$\hat{c^g}(q, A, s) = \sum_{j=0}^{j=\|s\|-1} \bar{c}^g(\delta^*_A(p_j(s), q), A, \sigma^s_j),$$

with the last term of $c^g(.,.,.)$ missing.

Note the similarity of $c^g(.,.,.)$ with the function $c(.,.,.)$ denoting the cost of a string occurring in a sublanguage of L_m. The cost of a transition σ generated by A at state q', $(\bar{c}^g(q', A, \sigma))$, is the event cost of the transition plus the control cost of all events disabled at state q' in submachine A. The event cost of a transition is independent of the submachine. This is not true of the control cost. A transition in a smaller submachine may have more control costs associated with it than the same transition in a bigger submachine. This is because smaller submachines imply more disabling actions. The following result, similar to Theorem 3.4, is useful. Its proof is omitted.

LEMMA 5.2. *Let $A \subseteq B \subseteq G$. Then for all $s \in \Sigma^*$ and $q \in Q_A$ such that $\delta_A^*(s, q)$ is defined, we have*

$$\bar{c}^g(q, A, s) \geq \bar{c}^g(q, B, s),$$
$$c^g(q, M(A, q), s) \geq c^g(q, M(B, q), s) \quad \text{if } \delta_A^*(s, q) \in Q_{mA}.$$

The new optimization problem on FSMs has been set up to get the following equalities. If $s \in \mathcal{L}_m(A)$ and t is such that $\delta^*(t, q_0) = q_{0A}$, then $c^g(q_{0A}, A, s) = c(t, \mathcal{L}_m(A), s)$. Obviously, then, for any submachine A of G,

$$c^g_{\sup}(A) = c_{\sup}(\mathcal{L}_m(A)). \tag{5.1}$$

This is the desired relationship between the objective function of our new FSM optimization problem and the original language optimization problem. This relationship does not in itself imply that an optimal solution to the FSM problem generates an optimal solution to the language problem. The complication is due to the fact that in general most sublanguages of L_m are not generated by submachines of G. However, Theorem 3.9 together with the above equality are enough to establish the equivalence of the FSM and the language optimization problems. To state the theorem we require one more concept. This is the definition of a DP-optimal submachine. It is analogous to the definition of a DP-optimal sublanguage.

A submachine $A_{DO} \in \mathcal{M}(G, q)$ is DP-optimal iff it is optimal and for all $q' \in Q_{A_{DO}}, M(A_{DO}, q')$ is an optimal submachine in $\mathcal{M}(G, q')$.

Note that the statement "A is an optimal submachine of G" will imply $q_{0A} = q_0$ unless stated otherwise. If a particular DP-optimal FSM includes all other DP-optimal FSMs as submachines of itself, then we call it the *maximal DP-optimal submachine.* The following theorem asserts the existence of a unique maximal DP-optimal submachine of G and that it generates the supremal DP-optimal sublanguage of L_m. The theorem concludes our investigation of computability since the maximal DP-optimal submachine can be found by exhaustively searching the finite set of trim submachines of G. Recall that the notation $\mathcal{L}^{\uparrow}_{DO}(.)$ represents the supremal DP-optimal sublanguage of the language (.).

THEOREM 5.3. *Assume that an optimal sublanguage of L_m exists. Then an optimal submachine of G exists, and the unique maximal DP-optimal submachine $(G^{\uparrow}_{DO})$ of G also exists. Moreover, $\mathcal{L}_m(G^{\uparrow}_{DO}) = \mathcal{L}^{\uparrow}_{DO}(\mathcal{L}_m(G))$; i.e., the maximal DP-optimal submachine generates the supremal DP-optimal sublanguage of $\mathcal{L}_m(G)$.*

Proof. Since an optimal sublanguage exists, by Theorem 3.7, $L^{\uparrow}_{DO}$ exists and $c_{\sup}(L^{\uparrow}_{DO}) < \infty$. From this, by (5.1), Theorem 3.9, and the finiteness of the set of submachines of G, an optimal submachine of G exists. By Theorem 3.9 there exists a submachine of G that generates $L^{\uparrow}_{DO}$. Let this FSM be denoted by $G^{\uparrow}_{DO} \subseteq G$. We show that $G^{\uparrow}_{DO}$ is the maximal DP-optimal submachine of G.

Claim 5.3.1. $G^{\uparrow}_{DO}$ is a DP-optimal submachine of G.

Proof. Let there exist $A_q \in \mathcal{M}(G,q), q \in Q_{G^{\uparrow}_{DO}}$, such that

$$c^g_{\sup}(A_q) < c^g_{\sup}(M(G^{\uparrow}_{DO},q)).$$

Pick some s such that $\delta^*_{G^{\uparrow}_{DO}}(s,q_0) = q$. By (5.1)

$$c_{\sup}(\mathcal{L}_m(A_q),s) < c_{\sup}(\mathcal{L}_m(M(G^{\uparrow}_{DO},q)),s) = c_{\sup}(L^{\uparrow}_{DO}/s,s).$$

This contradicts the DP-optimality of $L^{\uparrow}_{DO}$. Thus $M(G^{\uparrow}_{DO},q)$ is optimal. Since q is arbitrary, $G^{\uparrow}_{DO}$ is a DP-optimal submachine of G. □

Claim 5.3.2. Let A be a DP-optimal submachine of G. Then $\mathcal{L}_m(A)$ is a DP-optimal sublanguage of $\mathcal{L}_m(G)$; i.e., for all $s \in \overline{\mathcal{L}_m(A)}, \mathcal{L}_m(A)/s$ is optimal.

Proof. Pick any $s \in \overline{\mathcal{L}_m(A)}$ such that $\delta^*_A(s,q_0) = q$. $M(A,q)$ is a DP-optimal submachine in $\mathcal{M}(G,q)$. Thus, by (5.1), $c^g_{\sup}(M(A,q)) = c_{\sup}(\mathcal{L}_m(A)/s,s) < \infty$. This implies that an optimal solution exists in $\mathcal{L}_m(G)/s$. By Theorem 3.9 there exists a submachine in the set $\mathcal{M}(G,q)$ which generates $\mathcal{L}^{\uparrow}_{DO}(\mathcal{L}_m(G)/s)$. Let this submachine be represented by $A^{\uparrow}_{DOq}$. By Claim 5.3.1, $A^{\uparrow}_{DOq}$ is a DP-optimal submachine of $M(G,q)$. $M(A,q)$ is DP-optimal by hypothesis, which gives

$$c_{\sup}(\mathcal{L}_m(A)/s,s) = c^g_{\sup}(M(A,q)) = c^g_{\sup}(A^{\uparrow}_{DOq}) = c_{\sup}(\mathcal{L}^{\uparrow}_{DO}(\mathcal{L}_m(G)/s),s).$$

Thus $\mathcal{L}_m(A)/s$ is optimal in $\mathcal{L}_m(G)/s$. Since s was any string in $\overline{\mathcal{L}_m(A)}$, $\mathcal{L}_m(A)$ is a DP-optimal sublanguage. □

Claim 5.3.3. A maximal DP-optimal submachine of G exists. It is $G^{\uparrow}_{DO}$.

Proof. Let A be a DP-optimal submachine of G. Pick any $s \in \mathcal{L}_m(A)$. By Claim 5.3.2, $\mathcal{L}_m(A)$ is DP-optimal. It must be a sublanguage of $\mathcal{L}^{\uparrow}_{DO}(\mathcal{L}_m(G))$, which by hypothesis is generated by $G^{\uparrow}_{DO}$. Hence $s \in \mathcal{L}_m(G^{\uparrow}_{DO})$. Thus $\mathcal{L}_m(A) \subseteq \mathcal{L}_m(G^{\uparrow}_{DO})$, and since both are submachines of the deterministic machine G, we obtain $A \subseteq G^{\uparrow}_{DO}$. Thus $G^{\uparrow}_{DO}$ is the maximal DP-optimal submachine of G. □

The proof of the theorem is immediate from Claim 5.3.3. □

The maximal DP-optimal submachine of a machine G at q will be denoted by $M^o_D(G,q)$. Theorem 5.3 establishes that if an optimal sublanguage exists, then the maximal DP-optimal solution to the FSM problem will generate the supremal DP-optimal solution to the language problem. Observe that the only assumptions made are that the plant language is regular and the costs are nonnegative. We have been unable to prove this method for other optimal solutions. It is easy to show from Theorem 5.3 and (5.1) that any optimal FSM of G will generate an optimal sublanguage of $\mathcal{L}_m(G)$. It is the converse that is not obvious. In particular, we do not know whether the supremal optimal sublanguage is generated by an optimal submachine of G or, for that matter, by any FSM at all.

On the basis of Theorem 5.3 the computational complexity is exponential. However, we will make some additional assumptions in order to address the issue of polynomial computability in section 6.

6. Polynomial computation of optimal solutions. In this section we investigate the polynomial computability of optimal solutions. Additional assumptions are required to establish the results in this section. We treat languages modeled by cyclic and acyclic FSMs separately. This is because the computational complexities

in the two cases, and also the required assumptions, are significantly different. The synthesis algorithms together with proofs of correctness and complexity are stated for cyclic systems. Acyclic systems are easier to deal with than cyclic systems. They are discussed informally.

6.1. DP-optimal solutions: The cyclic case. As stated before, two additional assumptions are required for polynomial computability. They are

(i) $\forall \sigma \in \Sigma, c_e(\sigma) > 0$,
(ii) $|Q_m| = 1$.

In other words all event costs are positive, and there is only one marked state in G. This implies that all strings of $\mathcal{L}_m(G)$ are equivalent since they go to the same state. Note that this is not necessarily true of $\mathcal{L}(G)$.

We are relatively comfortable with the first assumption since it appears likely that in practice the execution of any event will entail the use of some system resource and accordingly some positive cost. Of course, from a theoretical standpoint, this cost is allowed to be any arbitrarily small positive number. The critical property realized by this assumption is that though plant FSMs may contain cycles, the optimal submachines must be acyclic. In a way we have a type of decyclization problem on a finite vertex digraph. Unfortunately the general decyclization problem is intractable. Here we exploit properties of the cost structure to do this in polynomial time.

The second assumption seems more severe. Note that connecting multiple marked states to a hypothetical marked state does not work. If the algorithm given below is started at this hypothetical marked state, it is easy to construct cases for which the algorithm will be incorrect. We explain this further after presenting the algorithm. For acyclic FSMs the single marked state assumption is not required, which might suggest the existence of a polynomial-time algorithm in the general case. However, based on our investigations of the multiple marked state case, we conjecture that any algorithm accommodating multiple marked states will be of higher complexity than the algorithm presented here.

An intuitive explanation of the algorithm follows this formal statement. It is basically a DP-algorithm that recurses backwards state by state. At each state it solves a "local" optimization problem. We formalize this local object as a one-step submachine. It is any FSM comprised of a state in $q \in Q$ and some of the transitions defined out of it, i.e., any subset of $\mathcal{T}(G, q)$. Any state of Q_m is allowed to be a one-step submachine by itself.

DEFINITION 6.1. *A is a one-step submachine of G at q if*

$$A = \langle \Sigma, Q_A, q_{0A}, Q_{mA}, \delta_A \rangle$$

satisfies

(i) $q_{0A} = q$,
(ii) $\mathcal{T}(A) \subseteq \mathcal{T}(G, q)$,
(iii) $\mathcal{T}(A) = \emptyset \Rightarrow q_{0A} \in Q_m$,
(iv) $Q_A = \{q' \in Q : \exists \tau \in \mathcal{T}(A), (\pi_3(\tau) = q')\} \cup \{q\}$,
(v) $Q_{mA} = Q_m \cap Q_A$.

Note that A is not generally trim. The transitions of A are some subset of those defined out of q in G. Condition (iii) says that only in the case $q \in Q_m$ is the trivial submachine

$$\langle \Sigma, \{q\}, q, \{q\}, \delta|_{\Sigma \times \emptyset} \rangle$$

a valid one-step submachine of G at q. We denote the set of all one-step submachines of G at q by $\mathcal{M}_1(G,q)$. This set also has a maximal element in the sense of containing all other elements as submachines. It is denoted by $M_1(G,q)$.

The Algorithm. All new notation adopted in this section is defined below for easy reference. The states of the plant FSM are assumed to be stored in a data structure having pointers to parent states and children states. Note that $|Q| = n$. Complexity will be stated in terms of n and $|\Sigma|$.

(i) SL = solved list of states (also sometimes called the closed list).

(ii) $\mathcal{T}_{opt}(q)$ = the set of transitions of $M_1(M_D^o(G,q),q)$, the maximal one-step submachine of $M_D^o(G,q)$ rooted at q.

(iii) $CL = \{(q, c_{\sup}(M_D^o(G,q))) : q \in Q_G\}$. This is the cost list maintained by the algorithm for the recursive computation of the cost associated with a particular submachine.

The variables CL^{temp} and $\mathcal{T}_{opt}^{temp}(.)$ are also used for temporary storage of the same quantities.

(iv) C = set of states to be processed in the current iteration.

(v) $P_f(C) = \{q \in Q : \exists \tau \in \mathcal{T}(G), (\pi_2(\tau) = q) \wedge (\pi_3(\tau) \in C)\}$.

(vi) $S_f(C) = \{q \in Q : \exists \tau \in \mathcal{T}(G), (\pi_3(\tau) = q) \wedge (\pi_2(\tau) \in C)\}$.

In other words $P_f(C)$ is the set of parent states of set C, and $S_f(C)$, the set of children of states of C. A function denoted by $c_{\max}(E)$, where E is some set of transitions of a one-step submachine, will be used in the algorithm. This is appropriate since each step of the algorithm only computes some one-step object and assumes that the rest has been correctly computed in prior iterations. The function represents worst-case cost.

For the convenience of modularity we present the algorithm as a main program and two subprograms referred to as Optimize and One-Step Optimize, respectively. The main program primarily orders the backward recursive search and updates C and SL based on data provided by the subprogram Optimize. The optimization at each state is described in the subprogram Optimize, which in turn calls the subprogram One-Step Optimize.

The Main Program.

(i) Input: $\Sigma, Q, q_o, q_m, \delta, c_e, c_c$.

(ii) Initialize: $C = \{q_m\}, SL = \emptyset, CL = \emptyset, CL^{temp} = \emptyset$. If there exists $\sigma \in \Sigma_{uc}$ and $q \in Q$ such that $(\sigma, q_m, q) \in \mathcal{T}(G)$, then STOP since no optimal solution exists. Otherwise set

$$\hat{E_0}(q_m) = E_0(q_m) = \emptyset.$$

(iii) Optimize: Call subprogram Optimize with argument C.

(iv) Compute

$$A = \{q_d \in C : c_{\max}(\mathcal{T}_{opt}^{temp}(q_d)) = \min_{q \in C} c_{\max}(\mathcal{T}_{opt}^{temp}(q))\}.$$

(Note: $c_{\max}(.)$ is computed in the subprogram One-Step Optimize.)

(v)

$$\begin{aligned} \forall q \in A \quad \mathcal{T}_{opt}(q) &= \mathcal{T}_{opt}^{temp}(q), \\ CL &\rightarrow CL \cup \{(q, c_{\max}(\mathcal{T}_{opt}(q))\}, \\ SL &\rightarrow SL \cup A, \\ CL^{temp} &= \emptyset. \end{aligned}$$

(vi) Termination condition: Is $q_o \in SL$? If yes then STOP. Otherwise continue.

(vii) Computation of the states to be optimized in the next iteration: Compute the following.

$$\begin{array}{rrcl} & P_f(SL) & & \\ & A & = & P_f(SL) - SL, \\ \forall q \in A, & \hat{E}_0(q) & = & \{\tau \in \mathcal{T}(G,q) : \pi_3(\tau) \notin SL\}, \\ & E_0(q) & = & \mathcal{T}(G,q) - \hat{E}_0(q), \\ & B & = & \{q \in A : \exists \tau \in \hat{E}_0(q), \pi_1(\tau) \in \Sigma_{uc}\}, \\ & C & = & A - B. \end{array}$$

If $C = \emptyset$, then STOP since no optimal solution exists.

(viii) GOTO (iii).

Complexity: Steps (i) and (viii) are independent of n. Step (ii) is linear in $|\Sigma|$. Steps (iv), (v), and (vi) are linear in n. Step (vii) is $O(n^2|\Sigma|)$. This is explained in Remark 6.1.1 made after the statement of this algorithm. Let the complexity of (iii) be $O(x)$. Because of step (viii) the complexity of the main program is $O(n(x+n^2|\Sigma|))$.

Optimize.

(i) Input: $C, \{\hat{E}_0(q) : q \in C\}, \{E_0(q) : q \in C\}$.

(ii) Pick any $q_d \in C$.

(iii) Update C: $C = C - \{q_d\}$.

(iv) If $E_0(q_d) \neq \emptyset$ order $E_0(q_d)$ such that

$$i < j \Rightarrow c_e(\pi_1(\tau_i)) + c^g_{\sup}(M^o_D(G, q_i)) \leq c_e(\pi_1(\tau_j)) + c^g_{\sup}(M^o_D(G, q_j)),$$

where $\pi_3(\tau_k) = q_k$ for $k = i, j$.

(v) If $E_0(q_d) = \emptyset$ then set $c_{\max}(E_0(q_d)) = \sum_{\tau \in \mathcal{T}(G,q_d)} c_c(\pi_1(\tau))$. Else set

$$c_{\max}(E_0(q_d)) = c_e(\pi_1(\tau_n)) + c^g_{\sup}(M^o_D(G, \pi_3(\tau_n))) + \sum_{\tau \in \hat{E}_0(q_d)} c_c(\pi_1(\tau)).$$

(vi) Call subprogram One-Step Optimize.

(vii) Termination condition: Is $C = \emptyset$? If yes then return to the main program. Otherwise GOTO (iii).

Complexity: Steps (i), (ii), (iii), (v), and (vii) are independent of n. Step (iv) is $O(|\Sigma| \log(|\Sigma|))$. Let the complexity of (vi) or One-Step Optimize be $O(y)$. Then since $|C|$ is $O(n)$, the complexity of Optimize is $O(n(|\Sigma| \log(|\Sigma|) + y))$.

One-Step Optimize. We use the notation $c_{\max}(E)$ where $E = \{\tau_1, \ldots, \tau_j\}$ to denote the following calculation:

$$c_{\max}(E) = c_e(\pi_1(\tau_j)) + c^g_{\sup}(M^o_D(G, \pi_3(\tau_j))) + \sum_{i=j+1}^{i=n} c_c(\pi_1(\tau_i)) + \sum_{\tau \in \hat{E}_0(q_d)} c_c(\pi_1(\tau)),$$

where $\hat{E}_0(.)$ is precalculated in the main program.

(i) Input: $q_d, E_0(q_d), \hat{E}_0(q_d), c_{\max}(E_0)$.

(ii) Initialize: $E = E_0(q_d)$, $E' = E_0(q_d)$, $CMAX = c_{\max}(E_0(q_d)), \mathcal{T}^{temp}_{opt}(q_d) = \emptyset$.

If $E' = \emptyset$ then goto (iv).

Note that the elements of E' are always kept in the same order as $E_0(q_d)$.

(iii) Compute $E' \leftarrow E' - \{\tau_i : i = \max_{\tau_j \in E'} j\}$. If $E' \neq \emptyset$ then set

$$c_{\max}(E') = c_e(\pi_1(\tau_{i-1})) + c^g_{\sup}(M^o_D(G, \pi_3(\tau_{i-1}))) + \sum_{k=i}^{k=n} c_c(\pi_1(\tau_k)) + \sum_{\tau \in \hat{E_0}(q_d)} c_c(\pi_1(\tau)).$$

(iv) Termination condition: Is $E' = \emptyset$?
If yes, then set

$$\mathcal{T}^{temp}_{opt}(q_d) \leftarrow \mathcal{T}^{temp}_{opt}(q_d) \cup E,$$
$$CL^{temp} \leftarrow CL^{temp} \cup \{(q_d, c_{\max}(E))\}$$

and return to Optimize. Otherwise continue.

(v) Recursion condition: Is $c_{\max}(E') < CMAX$? If not then GOTO (iii). If yes, then continue.

(vi) Set $E = E', CMAX = c_{\max}(E')$.

(vii) GOTO (iii).

Complexity: All steps here are independent of n. Since E_0 is of order $O(|\Sigma|)$ the complexity of One-Step Optimize is $O(|\Sigma|)$.

Remark 6.1.1. The following pieces of pseudocode compute step (vii) of the main program.

```
Nextiter (A)
        q = first (A)
        trantest (q, T(G,q), A)
        C ← C ∪ {q}
        Nextiter (A − {q})
trantest (q, T(G,q), A)
        τ = first (T(G,q))
        if π3(τ) ∉ SL then
                if π1(τ) ∈ Σuc
                   then Nextiter (A − {q})
                else Ê0(q) ← Ê0(q) ∪ {τ}
                     trantest (q, T(G,q) − {τ}, A)
        else E0(q) ← E0(q) ∪ {τ}
             trantest (q, T(G,q) − {τ}, A)
```

The function Nextiter (.) computes the vertices to be optimized in the next iteration. It stores the new list in C. The function first (.) returns the first element of a set. It is assumed that the set is structured as a linked list. The function trantest (.) checks transitions for the conditions stated in (vii) and computes $E_0(.)$ and $\hat{E}_0(.)$. The function trantest (.) may recurse at most $|\Sigma|$ levels, and at each level the greatest number of computations is $|SL|$. Thus trantest (.) is of order $O(n|\Sigma|)$. Nextiter (.) recurses at most $|A|$ times. Since the cardinality of A is $O(n)$ the overall complexity of *Nextiter (.)* is $O(n^2|\Sigma|)$. Note that the computation of A itself is $O(n^2)$ and that of $P_f(SL)$ is $O(n)$. Hence the dominant term is $O(n^2|\Sigma|)$.

The overall complexity of the algorithm can now be calculated as follows. Since $O(y) = O(|\Sigma|)$ the complexity of Optimize is

$$O(x) = O(n(|\Sigma| + |\Sigma| \log(|\Sigma|))) = O(n|\Sigma| + n|\Sigma| \log(|\Sigma|)) = O(n|\Sigma| \log(|\Sigma|)).$$

The complexity of the main program is obtained by substituting for x. This gives

$$O(n(n|\Sigma| \log(|\Sigma|) + n^2|\Sigma|)) = O(n^2|\Sigma| \log(|\Sigma|) + n^3|\Sigma|).$$

In general the alphabet is expected to be small. In such cases the complexity is $O(n^3)$. The complexity is set by the computation of the set C in the main program. The updating of SL creates the $O(n^2|\Sigma|\log(|\Sigma|))$ term in the expression. Without the ordering of $E_0(.)$ this step would have become exponential.

It is important to note that the algorithm as stated will generally produce a submachine that is not trim. In particular, it will have states not accessible from q_0. However, the trimming of a submachine is a standard problem, and consequently we shall not dwell on it any more.

We draw attention to the connection between the acyclic nature of the optimal solution and the stopping criteria in (ii) and (vi) of the main program. Since there are no cycles and only one marked state, if there is an uncontrollable transition defined out of q_m, then it must execute a path returning to q_m. This is because the optimal solution is also trim. This path is a cycle and we have a contradiction which is resolved by concluding that the optimal solution does not exist. If the condition in (vi) fails to evaluate, then once again the acyclic nature of the optimal solution guarantees that the set C in (vii) will be nonempty (refer to the proof of Theorem 6.7 presented later in this section).

The algorithm bears some procedural similarity to a backward recursive shortest path algorithm. The shortest path algorithm will start at the terminal state and place it on the solved list (SL). At each step it will develop the set of parents of SL (denoted by $P_f(SL)$). From this set the algorithm identifies the next state to be added to SL. This identification is $O(n)$, and since the identification process is repeated each time a state is added to SL, the overall complexity is $O(n^2)$.

Our algorithm also starts at the terminal state (q_m) and places it in SL. At each step it develops $P_f(SL)$ (main program, (vii); complexity $O(n^2|\Sigma|)$) and identifies the next state to be added to SL (main program, (iv)). Unlike the path algorithm the complexity of the identification process is $O(n|\Sigma|\log(|\Sigma|))$. Since the process is repeated each time a state is added to SL the overall complexity is $O(n^2|\Sigma|\log(|\Sigma|) + n^3|\Sigma|)$.

The next state to be added to SL is determined as follows. Develop the set C and pick some $q \in C$. In general, q has transitions leading to children which are not in SL. Disable all such transitions and consider the one-step FSM constituted of the remaining transitions (main program, (vii)). This is the set $E_0(q)$. Sort these transitions (Optimize, (iv)) as required by Theorem 6.8 and construct the sequence of submachines $\langle M'_j \rangle$. This sort is $O(|\Sigma|\log(|\Sigma|))$. Next find the minimum cost M_j (One-Step Optimize). Let it be denoted by M_q. M_q must be found for each $q \in C$. The states realizing $\min_{q \in C} c^g_{\sup}(M_q)$ may be added to SL (main program, (iv), (v)) with the corresponding $\mathcal{T}_{\mathcal{T}}(q)$ representing $M_1(M^o_D(G, q), q)$ (main program, (v)). This completes one iteration of of the algorithm. It continues until $q_0 \in A$ (main program, (vi)). For a clearer understanding of the working of the algorithm, refer to the example presented in section 6.

Before passing to the proofs of correctness we give a brief explanation of why the introduction of a hypothetical marked state does not work. The correctness of the algorithm, as will be proven in the subsequent results, rests upon the nonexistence of cycles in the optimal solution and the property that the point at which the algorithm starts is the one and only one point at which all strings terminate in the optimal solution. No string that reaches this state ever goes anywhere again. The hypothetical marked state would not have this property, since if two marked states are connected to it a behavior might reach one marked state and hence the hypothetical state, but then continue onto the other marked state and hence to the hypothetical marked state

again. Thus, to make the algorithm correct, the hypothetical marked state should only be identified with those marked states which in the optimal solution have no transitions going out of them. How does one find this subset of Q_m? Exhaustive examination of all subsets of Q_m is exponential in the cardinality of Q_m. It is obvious that new properties of the structure must be discovered and exploited to isolate this subset.

It now remains to prove correctness. Since the algorithm computes by incrementally constructing bigger submachines out of smaller submachines, we define an algebraic operation called *merge* that combines FSMs.

DEFINITION 6.2 (merge operation). *Let A, B be FSMs and $q_{0C} \in Q_A \cup Q_B$ be some state. Then*

$$\begin{array}{rcccl} A \oplus B & = & C & = & \langle \Sigma_C, Q_C, q_{0C}, Q_{mC}, \delta_C \rangle, \\ & & \Sigma_C & = & \Sigma_A \cup \Sigma_B, \\ & & Q_C & = & Q_A \cup Q_B, \\ & & Q_{mC} & = & Q_{mA} \cup Q_{mB}, \\ & & \delta_C(\sigma, q) & = & \begin{cases} \delta_A(\sigma, q) \text{ if it exists,} \\ \delta_B(\sigma, q) \text{ if it exists,} \\ \text{undefined otherwise.} \end{cases} \end{array}$$

Observe that the merge is defined not just by A and B but also by the state q_{oC}. The merge of A and B produces a machine C whose transitions are the union of the transitions of A and B. It is apparent from this definition that the merge of two trim FSMs is not necessarily a trim FSM. It is also true that the transition function is not necessarily well defined. Fortunately, the next lemma allows us to avoid these pitfalls in this specific problem. Its proof is straightforward.

LEMMA 6.3. *Let $A, B \subseteq G$. Then the transition function for $C = A \oplus B$ in Definition 6.2 is well defined. Moreover, if $q_{0A} \in Q_B$ and A, B are trim, then*

$$C = \langle \Sigma_C, Q_C, q_{0B}, Q_{mC}, \delta_C \rangle$$

is a trim submachine of G.

The requirement that A, B be submachines of G ensures that if $\delta_A(\sigma, q)$ exists and $\delta_B(\sigma, q)$ exists, then $\delta_A(\sigma, q) = \delta_B(\sigma, q)$.

For all $A, B \in \mathcal{M}(G, q)$ this lemma implies that $A \oplus B \in \mathcal{M}(G, q)$, whence $\mathcal{M}(G, q)$ has a maximal element in the sense that all others in the set are submachines of it. This maximal trim submachine of G at q will be denoted by $M(G, q)$. Similarly, for all $A, B \in \mathcal{M}_1(G, q)$ it can be shown that $A \oplus B \in \mathcal{M}_1(G, q)$, and consequently, there exists a maximal element $M_1(G, q)$. Obviously $\mathcal{T}(M_1(G, q)) = \mathcal{T}(G, q)$. In the subsequent development it is implicitly assumed that all FSMs are trim unless mentioned otherwise.

The following theorem establishes that the merge operation also preserves DP-optimality.

THEOREM 6.4. *Let A be a DP-optimal submachine in the set $\mathcal{M}(G, q_{0A})$ and B be DP-optimal in $\mathcal{M}(G, q_{0B})$. Furthermore, let $q_{0B} \in Q_A$. Then $A \oplus B$ is DP-optimal in $\mathcal{M}(G, q_{0A})$.*

Proof. Observe that by Lemma 6.3 $A \oplus B$ is a trim submachine of G. It lies in the set $\mathcal{M}(G, q_{0A})$. Let $s \in \Sigma^*$ be such that $\delta^*_{A \oplus B}(s, q)$ exists for some $q \in Q_A \cup Q_B$. Assume $q \in Q_A$. The case $q \in Q_B$ is identical. By the definition of "$\oplus$" there exists a decomposition of s such that $s = u_1 \dots u_n$, where for all i, $1 \leq i \leq n$, $\delta^*_{A \oplus B}(u_1 \dots u_i, q) = q_i, \{q_1, \dots q_{n-1}\} \subseteq Q_A \cap Q_B$ and $\delta^*_{A \oplus B}(u_i, q_{i-1}) =$

$\delta_A^*(u_i, q_{i-1})$ or $\delta_B^*(u_i, q_{i-1})$. Note that $q_0 = q$. From Lemma 5.2, if $\delta_A^*(u_i, q_{i-1})$ exists then $\hat{c^g}(q_{i-1}, A \oplus B, u_i) \leq \hat{c^g}(q_{i-1}, A, u_i)$. The case when $\delta_B^*(u_i, q_{i-1})$ exists is similar. We also note that for all $q_i,\ 1 \leq i \leq n-1$,

$$c^g_{\sup}(M(A, q_i)) = c^g_{\sup}(M(B, q_i)).$$

This follows from the DP-optimality of A and B. The rest of the proof proceeds by induction. Let

$$c^g(u_{i+1} \dots u_n, M(A \oplus B, q_i)) \leq c^g_{\sup}(M(A, q_i)) = c^g_{\sup}(M(B, q_i)).$$

Consider a case with $\delta_B^*(u_i, q_{i-1})$ defined. The case with $\delta_A^*(u_i, q_{i-1})$ defined is identical.

$$\begin{array}{lll} & c^g(u_i \dots u_n, M(A \oplus B, q_{i-1})) & \\ = & \hat{c^g}(q_{i-1}, A \oplus B, u_i) + c^g(u_{i+1} \dots u_n, M(A \oplus B, q_i)) & \text{[by definition of } c^g(.)] \\ \leq & \hat{c^g}(q_{i-1}, B, u_i) + c^g_{\sup}(M(B, q_i)) & \text{[Theorem 5.2]} \\ \leq & c^g_{\sup}(M(B, q_{i-1})) & [u_i \circ \mathcal{L}_m(M(B, q_i)) \subseteq \mathcal{L}_m(M(B, q_{i-1}))] \\ = & c^g_{\sup}(M(A, q_{i-1})) & \end{array}$$

The base case is argued as follows. Assume $\delta_A^*(u_n, q_{n-1})$ exists. The case where $\delta_B^*(u_n, q_{n-1})$ exists is similar. By Theorem 5.2,

$$c^g(u_n, M(A \oplus B, q_{n-1})) \leq c^g(u_n, M(A, q_{n-1})) \leq c^g_{\sup}(M(A, q_{n-1})).$$

By induction

$$c^g(s, M(A \oplus B, q)) = c^g(u_1 \dots u_n, M(A \oplus B, q)) \leq c^g_{\sup}(M(A, q)).$$

Since s was arbitrary we obtain $c^g_{\sup}(M(A \oplus B, q)) \leq c^g_{\sup}(M(A, q))$, whence $M(A \oplus B, q)$ is optimal. Since q was arbitrary and the case $q \in Q_B$ can be argued similarly, we conclude that $A \oplus B$ is DP-optimal. □

We are now ready to establish correctness. The first theorem establishes the relevance of the DP-equation.

THEOREM 6.5.

$$c^g_{\sup}(M^o_D(G, q_d)) = \min_{A' \in \mathcal{M}_1(G, q_d)} \left[\max_{\tau \in \mathcal{T}(A')} [\bar{c}^g(q_d, A', \pi_1(\tau)) + c^g_{\sup}(M^o_D(G, \pi_3(\tau)))] \right],$$
$$M^o_D(G, q_d) = M' \oplus \left(\oplus_{\tau \in \mathcal{T}(M')} M^o_D(G, \pi_3(\tau)) \right),$$

where M' is the maximal minimizing A' above.

Proof. The first equation is an application of the principle of dynamic programming. The second equation is a consequence of the maximality of $M^o_D(G, q)$ and Theorem 6.4. □

Thus a maximal DP-optimal solution is constituted of other maximal DP-optimal solutions. If the other maximal DP-optimal solutions are known, then it is only necessary to find the largest minimizing A' in the DP-equation. While this is a substantial simplification, observe that there are $O(2^{|\Sigma|})$ candidate one-step submachines. In view of the large number of times this equation is solved, exhaustive examination is computationally prohibitive. Consequently, we have sought methods to solve the equation in polynomial time. We will prove that this can be done in $O(|\Sigma| \log(|\Sigma|))$ computations.

Some new notation is adopted for convenience. $SL(i)$ denotes the value of the set SL in the ith iteration of the algorithm. For each $q \in P_f(SL) - SL$ let $B_1(q, SL)$ represent the maximal one-step submachine of G rooted at q with all transitions disabled other than those leading into SL. Define

$$B(q_d, SL) = B_1(q_d, SL) \oplus \left(\oplus_{\tau \in \mathcal{T}(B_1(q_d, SL))} M_D^o(G, \pi_3(\tau))\right).$$

The next result establishes that in each iteration of the algorithm there exists a parent state q of $SL(i)$ for which the DP-optimal solution exists. The lemma also says that the solution will be a submachine of $B(q, SL)$. Lemmas 6.7 and 6.8 show how to find one or more such q. The three lemmas together show that if an optimal solution exists, then SL will keep growing until q_0 is one of the q's.

LEMMA 6.6. *If an optimal sumachine of G exists and $q_0 \notin SL(i)$, then there exists $q \in P_f(SL(i)) - SL(i)$ such that $M_D^o(G, q) \in \mathcal{M}(B(q, SL(i)), q)$.*

Proof.

Claim 6.6.1. Let $q \notin SL(i)$. Then for all $s \in \Sigma^*$ such that $\delta^*(s, q)$ is defined, there exists

$$q' \in P_f(SL(i)) - SL(i) \text{ and } t, u \in \Sigma^*$$

such that $s = tu$ and $\delta^*(t, q) = q'$.

Proof. From the description of the algorithm (main program, (v)), we have $SL(i) \subseteq SL(i+1)$. The proof is immediate from $q_m \in SL(i)$, the co-accessibility of G with respect to q_m and $q \notin SL(i)$. □

Claim 6.6.2. If an optimal submachine of G exists and $q_0 \notin SL(i)$, then there exists $q \in (P_f(SL(i)) - SL(i))$ such that $M_D^o(G, q)$ exists.

Proof. Pick any $s \in \mathcal{L}_m(M_D^o(G, q_0))$. Since $\mathcal{L}_m(M_D^o(G, q_0)) \subseteq \mathcal{L}_m(G)$, Claim 6.6.1 implies that there exists $q \in P_f(SL(i)) - SL(i), tu \in \Sigma^*$ such that $s = tu$ and $q = \delta^*(t, q_0)$. Thus q is a state of $M_D^o(G, q_0)$, which implies that an optimal submachine exists at q. Hence $M_D^o(G, q)$ exists for at least one $q \in P_f(SL(i)) - SL(i)$. □

Let $P'_f(SL(i)) = \{q \in P_f(SL(i)) - SL(i) : M_D^o(G, q) \text{ exists}\}$. By the prior claim, $P'_f(SL(i)) \neq \emptyset$. We now prove the lemma by contradiction.

For all $q \in P'_f(SL(i))$ let $M_D^o(G, q) \notin \mathcal{M}(B(q, SL(i)), q)$. Then, by Theorem 6.5,

$$M_1(M_D^o(G, q), q) \notin \mathcal{M}_1(B(q, SL(i)), q),$$

which implies that there exists $\tau \in \mathcal{T}(M_D^o(G, q), q), \pi_3(\tau) \notin SL(i)$. Pick such a τ. By Claim 6.6.1 there exists $q'' \in P_f(SL(i)) - SL(i)$ and $u \in \Sigma^*$ such that $\delta^*(\pi_1(\tau)u, q) = q''$ and $\pi_1(\tau)u \in \mathcal{L}(M_D^o(G, q))$.

Define $R(q) = \{q' \in P_f(SL(i)) - SL(i) : \exists s \in \mathcal{L}(M_D^o(G, q)), \delta^*(s, q) = q', q \neq q'\}$. Obviously $q'' \in R(q)$ and $R(q) \neq \emptyset$ for all $q \in P'_f(SL(i))$. Consider the following inductive construction.

(i) Base step: Pick any $q \in P'_f(SL(i))$. Set $q_1 = q$.

(ii) Induction step: $q_{j+1} = q, q \in R(q_j)$.

Since $R(q) \neq \emptyset, q_{j+1}$ always exists and the construction never terminates. Since no cycles are possible in an optimal solution,

$$\begin{array}{rrcl} & q_1, \ldots q_j, q_{j+1} & \notin & R(q_{j+1}) \\ \Rightarrow & 0 < |R(q_{j+1})| & \leq & |P'_f(SL(i))| - (j+1) \\ \Rightarrow & j+1 & \leq & |P'_f(SL(i))| \end{array}$$

for all j. By the finiteness of $P'_f(SL(i))$ this is a contradiction. Thus the lemma is proved. □

The next lemma indicates how q as in the prior lemma can be found. From the construction of $B(q, SL(i))$ and the fact that $M_D^o(G, q')$ exists for all $q' \in SL(i)$, it is evident that if $M_D^o(G, q) \in \mathcal{M}(B(q, SL(i)), q)$ then $c^g_{\sup}(B(q, SL(i))) < \infty$. By Theorem 5.3 the maximal DP-optimal submachine $\hat{M}_D^o(G, q)$ of $B(q, SL(i))$ also exists. These entities, well defined by this argument, are referred to in the next lemma.

LEMMA 6.7. *For all $q \in P_f(SL(i)) - SL(i)$ such that $c^g_{\sup}(B(q, SL(i))) < \infty$, let $\hat{M}_D^o(G, q)$ be the maximal DP-optimal submachine in the set $\mathcal{M}(B(q, SL(i)), q)$. In particular, let $q_d \in P_f(SL(i)) - SL(i)$ be such that*

$$c^g_{\sup}(\hat{M}_D^o(G, q_d)) = \min_{\substack{q \in P_f(SL(i)) - SL(i) \\ c^g_{\sup}(B(q, SL(i))) < \infty}} c^g_{\sup}(\hat{M}_D^o(G, q)).$$

Then $M_D^o(G, q_d) = \hat{M}_D^o(G, q_d)$.

Proof. Let $c^g_{\sup}(M_D^o(G, q_d)) < c^g_{\sup}(\hat{M}_D^o(G, q_d))$. Then

$$M_D^o(G, q_d) \notin \mathcal{M}(B(q_d, SL(i)), q_d).$$

Set $q_1 = q_d$. We define an inductive construction with this as the base case.

Inductive step: Let $q_j \in P_f(SL(i)) - SL(i), M_D^o(G, q_j) \notin \mathcal{M}(B(q_j, SL(i)), q_j)$, and

$$c^g_{\sup}(M_D^o(G, q_1)) > \cdots > c^g_{\sup}(M_D^o(G, q_j)).$$

We will now show the construction of q_{j+1} having all the same attributes as q_j. Since $M_D^o(G, q_j) \notin \mathcal{M}(B(q_j, SL(i)), q_j)$, by Theorem 6.5 there exists $\tau \in \mathcal{T}(M_D^o(G, q_j))$ such that $\pi_3(\tau) \notin SL(i)$. By Claim 6.6.1 there exists $q'' \in P_f(SL(i)) - SL(i), uv \in \Sigma^*$ such that

$$\pi_1(\tau)uv \in \mathcal{L}_m(M_D^o(G, q_j)) \wedge \delta^*(\pi_1(\tau)u, q_j) = q''.$$

Assume q'' is such that $M_D^o(G, q'') \in \mathcal{M}(B(q'', SL(i)), q'')$. By the above properties of q'',

$$\begin{array}{rcll} c^g_{\sup}(M_D^o(G, q_j)) & > & c^g_{\sup}(M_D^o(G, q'')) & [\delta^*(\pi_1(\tau)u, q) = q'', \pi_1(\tau)u \in \mathcal{L}(M_D^o(G, q_j))] \\ & = & c^g_{\sup}(\hat{M}_D^o(G, q'')) & [M_D^o(G, q'') \in \mathcal{M}(B(q, SL(i)), q)] \\ & \geq & c^g_{\sup}(\hat{M}_D^o(G, q_d)) & [\text{hypothesis of theorem}] \\ & > & c^g_{\sup}(M_D^o(G, q_d)) & [\text{by assumption}] \\ & = & c^g_{\sup}(M_D^o(G, q_1)) & [\text{base case } q_d = q_1] \\ & > & c^g_{\sup}(M_D^o(G, q_j)) & [\text{induction hypothesis}], \end{array}$$

which is absurd. Thus $M_D^o(G, q'') \notin \mathcal{M}(B(q'', SL(i)), q'')$. Moreover

$$c^g_{\sup}(M_D^o(G, q'')) < c^g_{\sup}(M_D^o(G, q_j)) < \cdots < c^g_{\sup}(M_D^o(G, q_1)).$$

Set $q_{j+1} = q''$. The state q_{j+1} has all the properties of q_j. Observe that the positivity of the event cost function has been explicitly used in the above argument.

This is obviously a nonterminating construction. From the uniqueness of the maximal DP-optimal solution (Theorem 5.3 and the strict inequality on the cost $M_D^o(G, q_j)$) we have that no two members of the sequence $\langle q_j \rangle_{j=1}^{j=\infty}$ are equal. But for any given j,

$$\{q_1, \ldots, q_j\} \subseteq P_f(SL(i)) - SL(i).$$

Since the set $P_f(SL(i)) - SL(i)$ has finite cardinality, this is a contradiction. The lemma is immediate. □

The next lemma shows how the one-step submachine of $\hat{M}_D^o(G,q)$ may be constructed efficiently, i.e., $O(|\Sigma|\log(|\Sigma|))$, though in general there could be $2^{|\Sigma|}$ candidate solutions.

LEMMA 6.8. *Let $q_d \in Q$ be such that $M_D^o(G,q_d)$ exists. Consider the following construction. Let*

$$\hat{Q} = \{q \in Q : (\exists \tau \in \mathcal{T}(G,q_d), \pi_3(\tau) = q) \wedge (M_D^o(G,q) \text{ exists})\} = \{q_1, \ldots, q_{|\hat{Q}|}\}.$$

For all i such that $1 \leq i \leq |\hat{Q}|$ let

$$M_i = M_i' \oplus \left(\oplus_{j=1}^{j=i} M_D^o(G,q_j)\right),$$
$$\text{where } \mathcal{T}(M_i') = \{\tau_1, \ldots, \tau_i\} \subseteq \mathcal{T}(G,q_d), \tau_i = (\sigma_i, q_d, q_i), \quad \text{and}$$
$$c_e(\pi_1(\tau_i)) + c_{\sup}^g(M_D^o(G,q_i)) \leq c_e(\pi_1(\tau_{i+1})) + c_{\sup}^g(M_D^o(G,q_{i+1})).$$

Then $M_D^o(G,q_d) \in \{M_i : 1 \leq i \leq |\hat{Q}|\}$.

Proof. For each q_i define the one-step submachine

$$A_i = \langle \Sigma, \{q_d, q_i\}, q_d, q_m, \delta_{A_i} \rangle,$$
$$\delta_{A_i}(\sigma_i, q_d) = q_i.$$

We assume that δ_{A_i} is undefined for all other states and events. Since A_i has only one transition and $M_D^o(G,q_i)$ is trim, $A_i \oplus M_D^o(G,q_i)$ is a trim submachine of G at q_d. Furthermore

$$M_i = \oplus_{j=1}^{j=i}(A_j \oplus M_D^o(G,q_j)),$$

whence by Lemma 6.3, M_i is trim for all i. We prove that for all $j \leq i$,

$$A_i \oplus M_D^o(G,q_i) \subseteq M_D^o(G,q_d) \Rightarrow A_j \oplus M_D^o(G,q_j) \subseteq M_D^o(G,q_d).$$

The latter inclusion is equivalent to the statement

$$M_D^o(G,q_d) \oplus A = M_D^o(G,q_d),$$

where $A = A_j \oplus M_D^o(G,q_j)$. The following argument proves this statement.

We use the notation $\mathcal{Q}_f(.)$ to represent the set of states of the machine $(.)$. We first show that $M(A,q)$ is optimal for all $q \in \mathcal{Q}_f(A), q \neq q_d$. By definition of "$\oplus$" $\mathcal{Q}_f(M_D^o(G,q_d) \oplus A) = \mathcal{Q}_f(M_D^o(G,q_d)) \cup Q_A$. Consider the case $q \in \mathcal{Q}_f(M_D^o(G,q_d))$. Let

$$X = \mathcal{Q}_f(M(M_D^o(G,q_d),q)) \cap \mathcal{Q}_f(M_D^o(G,q_j)).$$

Then we obtain the following decomposition of $M_D^o(G,q_d)$.

$$\begin{aligned} M(M_D^o(G,q_d) \oplus A, q) &= M(M_D^o(G,q_d),q) \oplus (\oplus_{q' \in X} M(M_D^o(G,q_j),q')) \\ &= M_D^o(G,q) \oplus (\oplus_{q' \in X} M_D^o(G,q')) \qquad \text{[Theorem 5.3]} \\ &= M_D^o(G,q) \qquad \text{[Theorem 6.4].} \end{aligned}$$

The case $q \in \mathcal{Q}_f(M_D^o(G,q_j))$ can be treated similarly by interchanging $M_D^o(G,q_d)$ and $M_D^o(G,q_j)$ in the preceeding argument. Thus for all $q \neq q_d$, $M(M_D^o(G,q_d) \oplus A, q)$

is optimal. We now prove the case $q = q_d$ by splitting the argument into two cases. Consider any $s \in \mathcal{L}_m(M_D^o(G, q_d) \oplus A)$. The first case covers all s such that the first event of s lies in $M_D^o(G, q_d)$, whereas the second case covers all s such that the first event lies in A.

Case 1. $s = \sigma_j u$.

$$\begin{aligned}
c^g(s, M_D^o(G, q_d) \oplus A) &= \bar{c}^g(q_d, M_D^o(G, q_d) \oplus A, \sigma_j) + c^g(q_j, M(M_D^o(G, q_d) \oplus A, u)) \\
&= c_e(\sigma_j) + \textstyle\sum_{\tau \in \mathcal{T}(G,q_d) - (\mathcal{T}(M_D^o(G,q_d),q_d) \cup \mathcal{T}(A,q_d))} c_c(\pi_1(\tau)) \\
&\quad + c^g(q_j, M_D^o(G, q_j), u) \\
&\leq c_e(\sigma_j) + \textstyle\sum_{\tau \in \mathcal{T}(G,q_d) - \mathcal{T}(M_D^o(G,q_d),q_d)} c_c(\pi_1(\tau)) \\
&\quad + c^g_{\sup}(M_D^o(G, q_j)) \\
&\leq c_e(\sigma_i) + \textstyle\sum_{\tau \in \mathcal{T}(G,q_d) - \mathcal{T}(M_D^o(G,q_d),q_d)} c_c(\pi_1(\tau)) \\
&\quad + c^g_{\sup}(M_D^o(G, q_i)) \\
&= \bar{c}^g(q_d, M_D^o(G, q_d), \sigma_i) + c^g_{\sup}(M_D^o(G, q_i)) \\
&= \bar{c}^g(q_d, M_D^o(G, q_d), \sigma_i) + c^g_{\sup}(M(M_D^o(G, q_d) q_i)) \\
&\leq c^g_{\sup}(M_D^o(G, q_d)).
\end{aligned}$$

Note that the second-to-last inequality follows from the ordering hypothesis.

Case 2. $s = \sigma_k u,\ \sigma_k \neq \sigma_j$.

$$\begin{aligned}
c^g(s, M_D^o(G, q_d) \oplus A) &= \bar{c}^g(q_d, M_D^o(G, q_d) \oplus A, \sigma_k) + c^g(q_k, M(M_D^o(G, q_d) \oplus A, u)) \\
&= c_e(\sigma_k) + \textstyle\sum_{\tau \in \mathcal{T}(G,q_d) - (\mathcal{T}(M_D^o(G,q_d),q_d) \cup \mathcal{T}(A,q_d))} c_c(\pi_1(\tau)) \\
&\quad + c^g(q_k, M_D^o(G, q_k), u) \\
&\leq c_e(\sigma_k) + \textstyle\sum_{\tau \in \mathcal{T}(G,q_d) - \mathcal{T}(M_D^o(G,q_d),q_d)} c_c(\pi_1(\tau)) \\
&\quad + c^g_{\sup}(M_D^o(G, q_k)) \\
&= \bar{c}^g(q_d, M_D^o(G, q_d), \sigma_k) + c^g_{\sup}(M_D^o(G, q_k)) \\
&= \bar{c}^g(q_d, M_D^o(G, q_d), \sigma_k) + c^g_{\sup}(M(M_D^o(G, q_d) q_k)) \\
&\leq c^g_{\sup}(M_D^o(G, q_d)).
\end{aligned}$$

Observe that in Case 2 we have the following advantage:

$$\sigma_k \circ M_D^o(G, q_k) \subseteq M_D^o(G, q_d).$$

The same cannot be said of j in Case 1. The extra steps in Case 1 take us from j to i, the i being equivalent to k in Case 2.

Thus for all $s \in \mathcal{L}_m(M_D^o(G, q_d) \oplus A)$ we have

$$c^g(q_d, M_D^o(G, q_d) \oplus A, s) \leq c^g_{\sup}(M_D^o(G, q_d)),$$

and consequently, $c^g_{\sup}(M_D^o(G, q_d) \oplus A) \leq c^g_{\sup}(M_D^o(G, q_d))$. Thus $M_D^o(G, q_d) \oplus A$ is optimal. Since we have already shown that for all $q \neq q_d$

$$M(M_D^o(G, q_d) \oplus A, q) = M_D^o(G, q),$$

it follows that $M_D^o(G, q_d) \oplus A$ is DP-optimal. Since the maximal DP-optimal solution is unique this implies

$$M_D^o(G, q_d) \oplus A \subseteq M_D^o(G, q_d).$$

The reverse inclusion being obvious, we conclude that

$$M_D^o(G, q_d) \oplus A = M_D^o(G, q_d) \Rightarrow A_j \oplus M_D^o(G, q_j) \subseteq M_D^o(G, q_d).$$

The lemma is immediate. □

The correctness proof is a simple argument based on these results.

THEOREM 6.9. *The algorithm is correct. It computes the maximal DP-optimal FSM* $M_D^o(G, q_0)$ *with worst-case complexity*

$$O(n^2|\Sigma|\log(|\Sigma|) + n^3|\Sigma|).$$

Proof. We prove correctness inductively. As a base case we show that $\mathcal{T}_{opt}(q_m)$ is computed correctly. From step (ii) of the main program, $C = \{q_m\}$. Since $c_e(.) > 0$ there are no cycles in any optimal solution. Also, there exists only one marked state. These two facts taken together imply that if there exists $(\sigma, q_m, q) \in \mathcal{T}(M_D^o(G, q_0))$ such that $\sigma \in \Sigma_{uc}$, then all controllable trim submachines (submachines constructed by disabling only controllable events) must contain some cycle passing through q_m. All optimal submachines, if they exist, must lie within the class of controllable submachines, and consequently, no optimal solution exists. Thus the testing condition in step (ii) is correct. If an optimal solution exists, then, q_m being the only marked state, $M_D^o(G, q_m)$ must exist and $\mathcal{T}(M_D^o(G, q_m)) = \emptyset$. Note that $\mathcal{T}_{opt}^{temp}(q_m) = \emptyset$ by step (iv) of One-Step Optimize. In step (v) of the main program, $A = \{q_m\}$ and consequently $\mathcal{T}_{opt}(q_m) = \emptyset$, as theoretically expected. Thus the computation for q_m is correct.

Assume that for all $q \in SL$, $\mathcal{T}_{opt}(q), c_{\max}(\mathcal{T}_{opt}(q))$, and consequently $M_D^o(G, q)$ and $c_{\max}(M_D^o(G, q))$ are known correctly. By the DP-equation (Theorem 6.5), for any $q_d \in P_f(SL) - SL$, it is only necessary to find the maximal $A_1 \in \mathcal{M}_1(G, q_d)$ which solves the DP-equation.

Statement (vi) of the main program tests the hypothesis of Lemma 6.6. If the program does not terminate here and an optimal solution exists, then the hypothesis of Lemma 6.6 is satisfied and it guarantees that $C \neq \emptyset$, since otherwise there will not exist any $B(q, SL)$, $q \in P_f(SL) - SL$ with finite cost, and consequently no $M_D^o(G, q) \subseteq B(q, SL)$. Thus C in the main program is the set of all $q \in P_f(SL) - SL$ for which $c_{\sup}^g(B(q, SL))$ is finite. Next, by Lemma 6.7 it is necessary to construct $M_1(\hat{M}_D^o(G, q))$ for each $q \in C$, and by Lemma 6.8 this can be done by sorting and ordering the transitions of $B_1(q, SL)$. The required sorting and ordering is done in step (iv) of Optimize, and the minimum of the ordered set is computed in One-Step Optimize, which returns the transitions of $M_1(\hat{M}_D^o(G, q))$ in $\mathcal{T}_{opt}^{temp}(q)$ and its cost in $CMAX$. The minimization required in the hypothesis of Lemma 6.7 is done in step (iv) of the main program. Consequently, by Lemma 6.7, $\mathcal{T}_{opt}(q)$ in step (v) correctly represents the transitions of $M_1(M_D^o(G, q))$ and $c_{\max}(\mathcal{T}_{opt}(q)) = c_{\sup}^g(M_D^o(G, q))$. Thus $\mathcal{T}_{opt}(q)$ solves the DP-equation. This proves the correctness of the algorithm.

The complexity is immediate from remarks made during the statement of the algorithm and from Remark 6.1.1. □

Theorem 3.10 summarizes the computational theory for cyclic systems. It is an aggregation of Theorems 5.3 and 6.9.

THEOREM 3.10. *Let* L_m *be regular and such that all marked strings are equivalent in the sense of Nerode. Let all event costs be positive. If an optimal solution exists, then, given a generator of* L_m *with* n *states, a generator for the supremal DP-optimal sublanguage is computable in time*

$$O(n^2|\Sigma|\log(|\Sigma|) + n^3|\Sigma|).$$

This concludes the examination of cyclic FSMs.

6.2. DP-optimal solutions: The acyclic case. In the subsequent development the plant FSM (G) is assumed to be acyclic. The notation used is as defined in

the prior subsection. The positivity assumption on the event costs and that on the marked states are relaxed. Thus we return to the premise that the cost functions are nonnegative and G is co-accessible with respect to the set Q_m. Observe that since $c_e(.)$ is always finite, the existence issues are trivial for the following reasons. The FSM is acyclic and there exists a path of maximum length. All event costs being finite this implies $c^g_{\sup}(M(G,q)) < \infty$ for all $q \in Q$. The set of possible submachines (sublanguages) is also finite. Thus optimal solutions always exist at all states of G. The complexity result is as follows.

THEOREM 3.11. *Let the plant language L_m be generated by a trim acyclic FSM G having n states. A generator for the supremal DP-optimal solution is computable in*

$$O(n|\Sigma|\log(|\Sigma|)).$$

The proof is similar to the cyclic case. We discuss it informally. Since the FSM G is acyclic it is possible to order the states of G so that any state in the sequence is connected only to states to the right of it. This can be done by a topological sort (refer to Leiserson, Cormen, and Rivest [15, section 23.4, p. 485]). This sort is of complexity

$$O(n + |\mathcal{T}(G)|) = O(n + n|\Sigma|) = O(n|\Sigma|).$$

The rightmost states in this order are the marked states of zero outdegree, since they are connected to nothing at all. The backward recursive algorithm will start at these states. Note that since G is nonblocking there always exists at lease one marked state having zero outdegree. The controller synthesis algorithm should proceed on the sequence of states from right to left, starting with the marked states of zero outdegree. For each state it must compute the maximal DP-optimal submachine at that state, using the maximal DP-optimal submachines at states to the right of it. This can be done by sorting the edges of the maximal one-step submachine rooted at the state, as in step (iv) of Optimize. This is of complexity $O(|\Sigma|\log(|\Sigma|))$. The maximal DP-optimal submachine is then computed by One-Step Optimize exactly as in the cyclic case. Since there are n states in the sequence, the overall time complexity is $O(n|\Sigma|\log(|\Sigma|))$. The leftmost state in the sequence will always be the initial state if G is trim. The algorithm will terminate when it reaches the initial state.

6.3. Examples. The following example is constructed to illustrate the essential features of the algorithm stated in section 6.1. The plant model and costs are as in Figure 6.1 and Table 6.1, respectively.

For each run of the algorithm we present the values of the variables

$$C, \mathcal{T}^{temp}_{opt}(.), c_{\max}(\mathcal{T}^{temp}_{opt}(.)), A, \mathcal{T}_{opt}(.), CL, SL.$$

The working of Optimize and One-Step Optimize is detailed only in the fourth iteration or Run 4 of the algorithm. These routines, being simpler for the other iterations, are omitted. The algorithm is initialized with $C = \{m\}$. The six figures given next (Figures 6.2–6.7) represent the submachines computed by the six consecutive runs required to find the optimal solution.

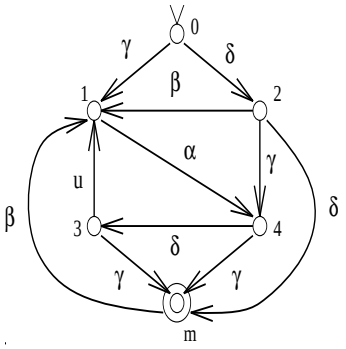

FIG. 6.1. *The plant machine G.*

TABLE 6.1
Costs and controllability of G.

Event	$c_e(.)$	$c_c(.)$	Remarks
α	0.5	2	Controllable

γ	1	2	Controllable
δ	1	2	Controllable
u	1	∞	Uncontrollable

FIG. 6.2. *Run* 1.

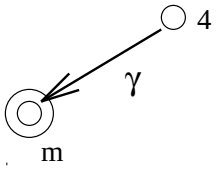

FIG. 6.3. *Run* 2.

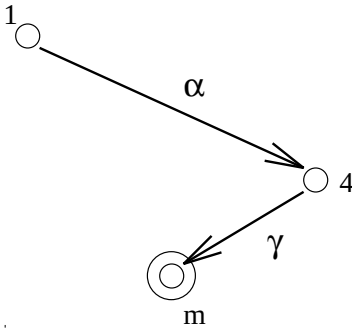

FIG. 6.4. *Run* 3.

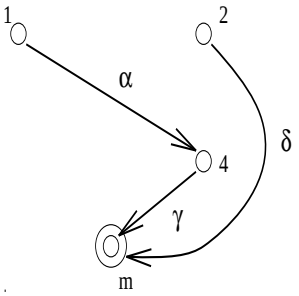

FIG. 6.5. *Run* 4.

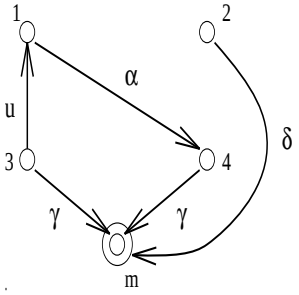

FIG. 6.6. *Run* 5.

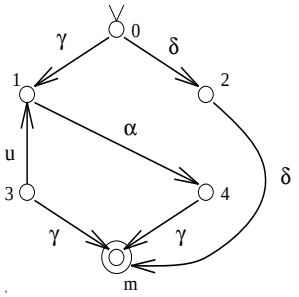

FIG. 6.7. *Run* 6.

Run 1:

$$\begin{aligned}
\mathcal{T}_{opt}^{temp}(m) &= \emptyset, \\
c_{\max}(\mathcal{T}_{opt}^{temp}(m)) &= 1, \\
\mathcal{T}_{opt}(m) &= \emptyset, \\
c_{\max}(\mathcal{T}_{opt}(m)) &= 1, \\
CL &= \{(m,1)\}, \\
SL &= \{m\}, \\
C &= \{2,4\}.
\end{aligned}$$

Note that $1 \notin C$ since u is uncontrollable and 1 is not in SL (refer to step (vii) of the main program).

Run 2:

$$\begin{aligned}
\mathcal{T}_{opt}^{temp}(2) &= \{(\delta, 2, m)\},\\
c_{\max}(\mathcal{T}_{opt}^{temp}(2)) &= 5,\\
\mathcal{T}_{opt}^{temp}(4) &= \{(\gamma, 4, m)\},\\
c_{\max}(\mathcal{T}_{opt}^{temp}(4)) &= 4,\\
\mathcal{T}_{opt}(4) &= \{(\gamma, 4, m)\},\\
c_{\max}(\mathcal{T}_{opt}(4)) &= 4,\\
CL &= \{(m, 1)(4, 4)\},\\
SL &= \{m, 4\},\\
C &= \{1, 2\}.
\end{aligned}$$

Note that the figure is drawn by using the data in the array $[\mathcal{T}_{opt}(m)\ \mathcal{T}_{opt}(4)]$.

Run 3:

$$\begin{aligned}
\mathcal{T}_{opt}^{temp}(1) &= \{(\alpha, 1, 4)\},\\
c_{\max}(\mathcal{T}_{opt}^{temp}(1)) &= 4.5,\\
\mathcal{T}_{opt}^{temp}(2) &= \{(\delta, 2, m)\},\\
c_{\max}(\mathcal{T}_{opt}^{temp}(2)) &= 5,\\
\mathcal{T}_{opt}(1) &= \{(\alpha, 1, 4)\},\\
c_{\max}(\mathcal{T}_{opt}(1)) &= 4.5,\\
CL &= \{(m, 1)(4, 4)(1, 4.5)\},\\
SL &= \{m, 4, 1\},\\
C &= \{0, 2, 3\}.
\end{aligned}$$

Run 4:

$$\begin{aligned}
\mathcal{T}_{opt}^{temp}(0) &= \{(\gamma, 0, 1)\},\\
c_{\max}(\mathcal{T}_{opt}^{temp}(0)) &= 7.5,\\
\mathcal{T}_{opt}^{temp}(2) &= \{(\delta, 2, m)\}\text{(refer to computations below)},\\
c_{\max}(\mathcal{T}_{opt}^{temp}(2)) &= 5,\\
\mathcal{T}_{opt}^{temp}(3) &= \{(u, 3, 1), (\gamma, 3, m)\},\\
c_{\max}(\mathcal{T}_{opt}^{temp}(3)) &= 5.5,\\
\mathcal{T}_{opt}(2) &= \{(\delta, 2, m)\},\\
c_{\max}(\mathcal{T}_{opt}(2)) &= 5,\\
CL &= \{(m, 1)(4, 4)(1, 4.5)(2, 5)\},\\
SL &= \{m, 4, 1, 2\},\\
C &= \{0, 3\}.
\end{aligned}$$

The working of Optimize and One-Step Optimize in the computation of $\mathcal{T}_{opt}^{temp}(2)$ is as follows. Observe that $E_0(2) = \{(\beta, 2, 1), (\gamma, 2, 4), (\delta, 2, m)\}$. When $q_d = 2$ in Optimize the set is reordered by step (iv) to $E_0(2) = \{(\delta, 2, m), (\gamma, 2, 4), (\beta, 2, 1)\}$. The required data is obtained from CL in Run 2, e.g., $c_{\sup}^{g}(M_D^o(G, 1)) = 4.5$. The event costs are of course known a priori. Finally, $c_{\max}(E_0(2)) = 5.5$. In One-Step Optimize the sequence of computation is

(i)

$$\begin{aligned}
E' &= \{(\delta, 2, m), (\gamma, 2, 4), (\beta, 2, 1)\},\\
c_{\max}(E') &= 5.5,\\
CMAX &= 5.5.
\end{aligned}$$

(ii)

$$\begin{aligned} E' &= \{(\delta, 2, m), (\gamma, 2, 4)\}, \\ c_{\max}(E') &= 6, \\ CMAX &= 5.5. \end{aligned}$$

(iii)

$$\begin{aligned} E' &= \{(\delta, 2, m)\}, \\ c_{\max}(E') &= 5, \\ CMAX &= 5. \end{aligned}$$

Thus, finally, we obtain $E = \{(\delta, 2, m)\}$ and $\mathcal{T}_{opt}^{temp}(2), c_{\max}(\mathcal{T}_{opt}^{temp}(2))$ as already stated.

Run 5:

$$\begin{aligned} \mathcal{T}_{opt}^{temp}(0) &= \{(\gamma, 0, 1)(\delta, 0, 2)\}, \\ c_{\max}(\mathcal{T}_{opt}^{temp}(0)) &= 6, \\ \mathcal{T}_{opt}^{temp}(3) &= \{(u, 3, 1), (\gamma, 3, m)\}, \\ c_{\max}(\mathcal{T}_{opt}^{temp}(3)) &= 5.5, \\ \mathcal{T}_{opt}(3) &= \{(u, 3, 1), (\gamma, 3, m)\}, \\ c_{\max}(\mathcal{T}_{opt}(3)) &= 5.5, \\ CL &= \{(m, 1)(4, 4)(1, 4.5)(2, 5)(3, 5.5)\}, \\ SL &= \{m, 4, 1, 2, 3\}, \\ C &= \{0\}. \end{aligned}$$

Run 6:

$$\begin{aligned} \mathcal{T}_{opt}^{temp}(0) &= \{(\gamma, 0, 1)(\delta, 0, 2)\}, \\ c_{\max}(\mathcal{T}_{opt}^{temp}(0)) &= 6, \\ \mathcal{T}_{opt}(0) &= \{(\gamma, 0, 1), (\delta, 0, 2)\}, \\ c_{\max}(\mathcal{T}_{opt}(0)) &= 6, \\ CL &= \{(m, 1)(4, 4)(1, 4.5)(2, 5)(3, 5.5)(0, 6)\}, \\ SL &= \{m, 4, 1, 2, 3, 0\}. \end{aligned}$$

The information used to construct Figure 6.7 is in the array $[\mathcal{T}_{opt}(.)]$. Observe that this FSM is not trim. It can now be trimmed by standard methods to obtain the trim maximal DP-optimal submachine depicted in Figure 6.8.

7. Conclusion. In this paper we have introduced numerical performance measures in supervisory control theory. The DES is represented by a formal language, and the measures are represented by event and control cost functions. The two costs are associated with the generation of events by the DES and the disabling of events by the supervisor, respectively. Using these quantitative measures, we have examined the problem of minimizing the worst-case behavior of a DES. DESs operate in uncertain environments and it is desirable that a DES supervisor deal with uncertainty in a minimally restrictive manner. Thus computing a DES supervisor is more than computing a trajectory. This gives some interesting and unique features to the problem of defining and computing an optimal supervisor. We have presented an example in section 2, to motivate an interesting use of the cost function and DES models. Another example may be found in [10].

The investigation in this paper shows us that optimal supervisory control is related to two important domains. One is the area of path problems on a directed graph and

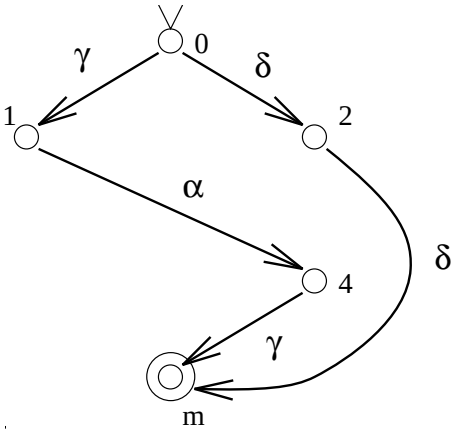

FIG. 6.8. *Trim maximal DP-optimal submachine of G.*

the other is the optimization of Markov decision processes. For further details on the latter, we refer to [10]. If there are no control costs, then an optimal supervisor is one that disables everything other than the shortest path, and a minimally restrictive supervisor would be one that allows all shortest paths. At the other end of the spectrum we have the class of optimization problems on Markov chain models. In stochastic control it is assumed that the system is uncertain, though one has stochastic information about the uncertainty. The system may execute any of a set of transition sequences, and control consists of altering the probability distribution on the set of future behaviors. Like our formulation, this involves control costs. The concept of disabling used in SCT can be viewed as altering the probability distribution so as to reduce the probabilities associated with some events to zero. The modeling and control assumptions are remarkably similar.

The principle of dynamic programming plays an important role. An interesting feature of the worst-case problem, which it shares with other min-max problems, is that all optimal solutions do not necessarily solve a DP-equation, though if optimal solutions exist, the DP-equations also have solutions. These solutions represent the DP-optimal solutions. Moreover, in this class of solutions there exists a minimally restrictive DP-optimal solution. The minimally restrictive DP-optimal solution guarantees the best possible future regardless of the past.

Theorems 3.1–3.7 constitute the existence theory. Theorem 3.1 deals with DES defined over a finite alphabet and asserts that the existence of a bounded-cost supervisor is sufficient for the existence of an optimal supervisor. Theorem 3.2 asserts the same for DES defined over a countable alphabet, but assumes positive event costs and a finite active event set. Theorem 3.3 covers specifically the case of DES modeled by regular languages. Theorems 3.5 and 3.7 deal with the existence of specific types of optimal solutions, when it is already known that an optimal solution exists. The two types of solutions are the supremal optimal solution and the supremal DP-optimal solution, respectively.

Aside from the interesting property that the supremal DP-optimal solution always guarantees the best possible worst-case behavior for a particular past in a minimally restrictive manner, it also has a suboptimal structure that we are able to exploit to develop two polynomially computable algorithms. The first is for DES modeled by FSMs having cycles, and the second is for DES modeled by acyclic FSMs. The implications of this suboptimal substructure are developed in section 5. Theorem 3.8

implies that the number of Nerode equivalence classes of the supremal DP-optimal sublanguage is no more than that of the plant language. Moreover, Theorem 3.9 says that any deterministic FSM generating the plant language has a submachine generating the supremal DP-optimal sublanguage. The next step is to find the relevant submachine. This is accomplished by formulating an equivalent (in the sense of equation (5.1)) optimization problem on the set of submachines of G (generator of the plant language). Then Theorem 5.3 establishes that the required submachine is the unique maximal DP-optimal submachine of G.

The polynomial-time algorithms presented in section 6 involve a few stages of processing. They are backward recursive dynamic programming algorithms. We summarize the acyclic case first. The algorithm starts at the set of terminal marked states and recurses backwards. For each state a DP-equation has to be solved over the set of subsets of the set of child states (Theorem 6.5). This is more complex than computing a shortest path or supremal controllable sublanguage, which require search operations only over the set of child states. Although the set of subsets of a state is not polynomially related to the alphabet, it is possible to use certain structural properties of the DP-optimal solution to sort the set of child states (Lemma 6.8). Using this sorted set the DP-equation can be solved with linear complexity. All these operations collectively result in an overall complexity of $O(n|\Sigma|\log(|\Sigma|))$ (Theorem 3.11).

For DES modeled by FSMs having cycles, the additional complication lies in the ordering of the vertices for the backward recursion. In the acyclic case this ordering is straightforward and obtained by starting at the set of terminal marked vertices. The DP-equation can be solved at all parents of this set, and the new set of solved vertices obtained. Once again, the entire set of parent states can be computed, the DP-equation can be solved at all of them, and the solved state list can be augmented as before. This process can be repeated until the initial state is seen. However, if the plant model has cycles in it, then the DP-equation cannot necessarily be correctly solved for all parent states of the set of solved states. Once again, a structural property of the supremal DP-optimal solution, i.e., that it is acyclic (hence the assumption that event costs are positive), can be used to extract a subset of the parent states for which the DP-equation can be solved correctly (Lemmas 6.6 and 6.7). This limited set of states can be added to the solved list and the new process repeated until the initial state is encountered. This additional processing of the set of parent states increases the complexity and makes the overall complexity rise to $O(n^2|\Sigma|\log(|\Sigma|) + n^3|\Sigma|)$ (Theorems 6.9 and 3.10). We have included an example, for the cyclic case, to help the reader understand the different stages in the algorithms.

The controller synthesis process involves several complex manipulations of FSMs. Accordingly, we have been mathematically rigorous in ascertaining the correctness of the algorithms. To the best of our knowledge the different stages of processing are unavoidable. It is desirable that an efficient controller synthesis algorithm be developed for cyclic DES having multiple marked states.

Appendix. List of notation.

$\|.\|$	=	Myhill congruence index of a language or the length of a string,
$\equiv_{L_m}$	=	the Nerode equivalence relation on the language $\bar{L}_m$,
$[.]$	=	Nerode equivalence class of a string,
$\bar{L}_m/\equiv_{L_m}$	=	set of equivalence classes of the language $\bar{L}_m$ defined by the Nerode equivalence relation.
ε	=	empty event,

$\delta_A(.,.)$ = transition function of machine A,
$\delta_A^*(.,.)$ = extension of δ_A to strings,
σ_j = jth event in the alphabet,
Π = set of control laws,
Π_{nb} = set of nonblocking control laws,
$\Pi_0(.)$ = set of active events disabled by the control law after a particular string,
$\pi(.)$ = control law defined on a language,
π_{A_m} = control law generating sublanguage A_m,
Σ = plant alphabet or event set,
Σ_c = set of controllable events,
Σ_{uc} = set of uncontrollable events,
$\Sigma_A(q)$ = active event set at state q in machine A,
$\Sigma_L(s)$ = active event set after string s in language L,
Σ^* = Kleene star closure of Σ.

$c_c(.)$ = control cost,
$c_e(.)$ = event cost,
$c(.,.)$ = cost of a string in a language,
$\hat{c}(.,.,.)$ = cost of a string less control costs after the last event,
$\bar{c}(.,.,.)$ = one-stage cost of an event in a language,
$c_{\sup}(.)$ = worst-case cost of a language,
$c^g(.,.,.)$ = cost of a string in a FSM,
$\bar{c}^g(.,.)$ = one-stage cost of an event in a FSM,
$c^g_{\sup}(.)$ = worst-case cost of a FSM,
$p_j(.)$ = prefix of length j of a string,
q_0 = initial state of FSM G,
q_{0A} = initial state of submachine A,
$\bar{s}$ = set of prefixes of the string s,
u^* = $\{u^n : n \in \mathbb{N}\}$.

G = plant FSM,
$G^{\uparrow}_{DO}$ = maximal DP-optimal submachine of G,
L = language,
$\bar{L}$ = prefix closure of L,
L_m/s = post-language of $s \in \bar{L}_m = \{t \in \Sigma^* : st \in L_m\}$,
$L^{\uparrow}_o$ = supremal optimal sublanguage,
$L^{\uparrow}_{DO}$ = supremal DP-optimal sublanguage,
L_m = the plant language,
$M(A,q)$ = the maximal trim submachine of A at $q \in Q_A$,
$M_1(A,q)$ = the maximal one-step submachine of A at $q \in Q_A$,
$M^o_D(G,q)$ = maximal DP-optimal submachine of G at q,
$P_f(q)$ = set of parent states of state q,
$P_j(.)$ = set of strings of length j in a language,
Q_A = set of states of FSM A,
Q_{mA} = set of marked states of submachine A,
$S_f(q)$ = set of children states of state q.

$\mathcal{L}_o^{\uparrow}([s])$ = supremal optimal solution in L_m/s,
$\mathcal{L}_{DO}^{\uparrow}([s])$ = supremal DP-optimal solution in L_m/s,
$\mathcal{M}(A,q)$ = set of trim submachines of A at $q \in Q_A$,
$\mathcal{M}_1(A,q)$ = set of one-step submachines of G at $q \in Q_A$,
$\mathbb{R}^+$ = positive reals (excluding zero).

Acknowledgment. We thank the reviewers for their useful comments.

CLASSES OF NONLINEAR PARTIALLY OBSERVABLE STOCHASTIC OPTIMAL CONTROL PROBLEMS WITH EXPLICIT OPTIMAL CONTROL LAWS*

CHARALAMBOS D. CHARALAMBOUS† AND ROBERT J. ELLIOTT‡

Abstract. This paper introduces certain nonlinear partially observable stochastic optimal control problems which are equivalent to completely observable control problems with finite-dimensional state space. In some cases the optimal control laws are analogous to linear-exponential-quadratic-Gaussian and linear-quadratic-Gaussian tracking problems. The problems discussed allow nonlinearities to enter the unobservable dynamics as gradients of potential functions. The methodology is based on explicit solutions of a modified Duncan–Mortensen–Zakai equation.

Key words. stochastic control, risk-sensitive, nonlinear filtering, sector-bounded nonlinearities, exact optimal controls

1. Introduction.

An important concept associated with closed loop control laws for noisily observed linear systems is the so-called "*separation principle*." This principle allows one to solve an estimation problem first, and then solve a completely observable control problem whose state is the estimate (observer state). For linear-quadratic-Gaussian (LQG) tracking problems the observer dynamics are given by the conditional mean and error covariance equations (see [1, 2]); for linear-exponential-quadratic-Gaussian (LEQG) tracking problems the observer dynamics are given by a variant of the conditional mean and error covariance equations (see [2, 3, 4, 5, 6]). Thus, the problem of optimally controlling the dynamics of the plant is equivalent, for both the LQG and the LEQG regulator problems, to a standard completely observable optimal control problem with a new state which is either the conditional mean or a variant of the conditional mean, respectively.

However, when the dynamics or observations are nonlinear in the unobservable state, the optimal control laws are infinite dimensional and, consequently, the classical separation principle discussed above does not apply. In this paper we identify classes of partially observed optimal control problems which are equivalent to completely observed control problems having a finite-dimensional state space. This allows us to apply the separation principle, as in LEQG/LQG problems. We then state sufficient conditions that enable us to compute the optimal control laws explicitly. Further, we describe techniques which compute suboptimal control laws in closed form.

Our results are also applicable in evaluating Feynman–Kac integrals for partially observable systems, such as the ones arising in risk-sensitive filtering. In addition, from the duality between estimation and control problems, explicit solution of the es-

timation problem translates into explicit solution of completely observable, stochastic optimal control problems (see [7]).

The classes of problems which we shall treat involve an $\Re^n$-valued unobservable state process $x(\cdot)$ given by the stochastic differential equation

$$dx(t) = f(t, x(t))dt + B(t, u(t, y))dt + G(t)dw(t), \qquad x(0) \in \Re^n, \quad 0 \le t \le T. \tag{1.1}$$

This is observed through an $\Re^d$-valued process $y(\cdot)$, which satisfies the stochastic differential equation

$$dy(t) = h(t, x(t))dt + N(t)^{\frac{1}{2}} db(t), \qquad y(0) = 0 \in \Re^d. \tag{1.2}$$

$y(\cdot)$ is called the observation process. Here, $w(\cdot), b(\cdot)$ are, respectively, $\Re^n$- and $\Re^d$-valued independent Wiener processes, independent of the random variable $x(0)$, $u(\cdot)$ is the control process, and $T \in \Re$ is fixed and finite. The cost function to be minimized over the controls u (which are nonanticipating functionals of the observations y) is of the general form

$$\begin{aligned} J_G^\theta(u(\cdot)) = E^u \Big\{ \int_0^T \ell_2(t, x(t), u(t, y)) \exp\theta \Big(\int_0^t \ell_1(s, x(s), u(s, y))ds \Big) dt \\ + \varphi_2(T, x(T)) \exp\theta \Big(\int_0^T \ell_1(t, x(t), u(t, y))dt + \varphi_1(T, x(T)) \Big) \Big\}, \quad \theta > 0. \end{aligned} \tag{1.3}$$

Here $\ell_i, \varphi_i, i = 1, 2$ are real-valued functions and E^u denotes expectation with respect to a certain probability measure P^u. The precise assumptions on the coefficients of (1.1)–(1.3) are stated under Assumptions 2.1. This cost criterion appears to be quite general, as it includes both the integral and the exponential-of-integral cost criteria: the integral cost criterion can be found by considering

$$J_I^0(u(\cdot)) \doteq \left\{ J_G^\theta(u(\cdot)); \quad \theta = 0 \right\}, \tag{1.4}$$

while the exponential-of-integral cost criterion can be found as

$$J_{EI}^\theta(u(\cdot)) \doteq \left\{ J_G^\theta(u(\cdot)); \quad \ell_2 = 0, \varphi_2 = 1 \right\}. \tag{1.5}$$

The approach is based on an "information state" formulation which recasts the problem as a completely observable control problem with an infinite-dimensional state space, and control laws which are functionals of this quantity. The information state associated with the usual integral cost criterion is the unnormalized conditional distribution; this satisfies the Duncan–Mortensen–Zakai (DMZ) equation (see [8]). The information state for the exponential-of-integral cost criterion is a modified version of the unnormalized conditional distribution; this satisfies a variant of the DMZ equation [3, 4, 5, 9]. To distinguish between the two we refer to the former as the information state and to the latter as the Feynman–Kac information state.

The results obtained in this paper are extensions of recent related work pursued independently by Charalambous, Naidu, and Moore [9], Bensoussan and Elliott [10], and Charalambous [6].

In section 2, we state the main assumptions, identify an "information state," and present an equivalent formulation of the partially observable problem (1.1)–(1.3), which, although completely observable, has an infinite-dimensional state space.

In section 3, we restrict the coefficients in the unobservable dynamics, observations, and cost (see (1.1)–(1.3)) to forms (for simplicity we often write x_t instead of $x(t)$, etc.)

$$f(t, x, u) = F_t x + g(t, x) + f_t + B_t u, \quad h(t, x) = H_t x + h_t, \quad \ell_2 = 0, \tag{1.6}$$

$$2\ell_1(t,x,u) = Q_t x.x + R_t x.x + 2m_t x + 2n_t u + \tilde{\ell}_1(t,x,u), \qquad 2\varphi_1(T,x) = Q_T x.x + 2m_T x. \tag{1.7}$$

Here the notation "$\alpha.\beta \doteq \alpha'\beta$" is used throughout the paper, where $(\cdot)'$ denotes the transpose of a matrix. We show that if

$$g(t,x) = G_t G_t' \frac{\partial}{\partial x}\phi(x), \tag{1.8}$$

$$\tilde{\ell}_1(t,x,u) = \tfrac{1}{\theta}\left\{|G_t^{-1}(F_t x + f_t + B_t u + g(t,x))|^2 - |G_t^{-1}(F_t x + f_t + B_t u)|^2 + Tr(D_x g(t,x))\right\}, \tag{1.9}$$

then the sufficient statistics are similar to those of an LEQG tracking problem and, consequently, the optimal control laws are finite-dimensional. Moreover, if in addition

$$\varphi_2(T,x) = \exp(-\phi(x)), \tag{1.10}$$

then the optimal control law is precisely that of the LEQG tracking problem.

When $\tilde{\ell}_1(t,x,u) \equiv \tilde{\ell}_1(x,u) = \frac{1}{\theta}V(x,u)$, which is a quadratic function of x and u and (without loss of generality) $G_t = I_n$ (an identity matrix), using $g(x) = D_x\phi(x)$, then (1.9) is reduced to the controlled Riccati equation

$$Tr\left(\frac{\partial}{\partial x}g(x)\right) + |g(x)|^2 + 2(Fx + f + Bu).g(x) = V(x,u). \tag{1.11}$$

Solutions of (1.11) yield finite-dimensional controllers. Notice that, when $\tilde{\ell}_1(t,x,u) \equiv \tilde{\ell}_1(x,u) = \frac{2}{\theta}(Fx+f+Bu).g(x) + \frac{1}{\theta}\tilde{V}(x)$, where $\tilde{V}(\cdot)$ is a quadratic function of x, then (1.9) reduces to the Riccati equation

$$Tr\left(\frac{\partial}{\partial x}g(x)\right) + |g(x)|^2 = \tilde{V}(x), \tag{1.12}$$

encountered in identifying finite-dimensional solutions of the DMZ equation by Benes in [11].

In section 3.1.1, we also show that if $\varphi_2 = 1$ and the nonlinear drift terms $g(\cdot)$ satisfy sector criteria (see A14), then suboptimal linear feedback control laws are found by employing simple upper and lower bounds on the terminal cost. Finite-dimensional sufficient statistics are found when the coefficients in the observations have the form $h(t,x) = \frac{1}{2}x.\tilde{H}_t x + H_t x + h_t$. Analogous results for stochastic control problems with cost (1.4) are derived in section 4. In section 5, we discuss the use of dynamic programming to formally derive verification theorems for nonlinear stochastic control problems which emerge from solving the above Riccati equations.

The optimal solutions of two examples that emerge from the developments of this paper are now presented.

Example 1.1. Consider the stochastic optimal control analog of Benes's filter (see [11]):

$$dx_t = \tanh(x_t)dt + u(t,y)dt + dw_t, \qquad x(0) = 0 \in \Re,$$
$$dy_t = x_t dt + db_t, \qquad y(0) = 0 \in \Re.$$

The objective is to determine the optimal control law u^* that minimizes the cost function

$$J^\theta(u(\cdot)) = E^u\left\{\exp\tfrac{\theta}{2}\left(\int_0^T\left[Qx_t^2 + Ru(t,y)^2\right]dt + Q_T x_T^2\right)\right.$$
$$\left.\times\exp\left(\int_0^T u(t,y)\tanh(x_t)dt\right)\times\tfrac{1}{\cosh(x_T)}\right\},$$

where $Q_T, Q \geq 0, R > 0$.

Example 1.2. Consider a stochastic optimal control problem with cubic nonlinearity in the unobservable dynamics:

$$dx_t = -\alpha x_t^{2p+1}dt + u(t,y)dt + dw_t, \qquad x(0) = 0 \in \Re, \qquad \alpha > 0, \quad p = 1,3,5,\ldots,$$
$$dy_t = x_t dt + db_t, \qquad y(0) = 0 \in \Re.$$

The objective is to determine the optimal control law u^* that minimizes the cost function

$$J^\theta(u(\cdot)) = E^u\left\{\exp\tfrac{\theta}{2}\left(\int_0^T\left[Qx_t^2 + Ru(t,y)^2\right]dt + Q_T x_T^2\right)\right.$$
$$\times\exp\left(\int_0^T\tfrac{1}{2}\left[|-\alpha x_t^{2p+1} + u(t,y)|^2 - u(t,y)^2 + \tfrac{\partial}{\partial x}(-\alpha x_t^{2p+1})\right]dt\right.$$
$$\left.\left.+\tfrac{\alpha}{2p+2}x_T^{2p+2}\right)\right\},$$

where $Q_T, Q \geq 0, R > 0$. Completing the squares in x and u ensures that the integrand in the exponent is bounded below.

The solution of Example 1.1 is an application of Theorem 5.1; the solution of Example 1.2 is an application of Theorem 3.4 (using (1.8)–(1.10)). The optimal control law and optimal sensitivity parameter for the above two problems are identical and are:

$$u^*(t) = -R^{-1}\Sigma_t r_t = -R^{-1}(1-\theta S_t P_t)^{-1}S_t r_t,$$

$$\theta^* = \sup\left\{\theta; \quad P_t \geq 0,\ S_t \geq 0,\ (1-\theta P_t S_t) > 0 \quad \forall t \in [0,T]\right\}.$$

Here $\Sigma(\cdot), S(\cdot)$ are the solutions of the Riccati differential equations:

$$\dot\Sigma_t + 2\theta P_t Q - \Sigma(R^{-1} - \theta P_t^2)\Sigma_t = 0, \qquad \Sigma_T = (1-\theta Q_T P_T)^{-1}Q_T,$$
$$\dot S_t - S_t(R^{-1} - \theta)S_t + Q = 0, \qquad S_T = Q_T, \tag{1.13}$$

and $r(\cdot), P(\cdot)$ are solutions of the observer dynamics:

$$dr_t = \theta P_t Q r_t dt + u^*(t,r)dt + P_t(dy_t - r_t dt), \qquad r(0) = 0,$$
$$\dot P = -P_t(1-\theta Q)P_t + 1, \qquad P(0) = 0.$$

Setting $R = Q = 1, Q_T = 0$, one can verify that the control Riccati differential equations and observer dynamics correspond to the following $\mathcal{H}^\infty$, or robust, control problem:

$$\dot x_t = u(t,y) + w_t, \qquad x(0) = 0 \in \Re,$$
$$y_t = x_t + b_t, \qquad y(0) = 0 \in \Re,$$
$$J_{\mathcal{H}^\infty}(u^*(\cdot)) = \inf_u \sup_{(w,b)} \int_0^T \frac{1}{2}\left[x_t^2 + u(t,y)^2 - \frac{1}{\theta}\left(w_t^2 + b_t^2\right)\right]dt,$$

where $w(\cdot), b(\cdot) \in L^2([0,T];\Re)$. In addition, from [12, pp. 131–132], we know that, for $\theta > 1$, there exist unique solutions

$$P_t = \frac{\tan((\sqrt{\theta-1})t)}{\sqrt{\theta-1}}, \qquad S_t = \frac{\tan(\sqrt{\theta-1}(T-t))}{\sqrt{\theta-1}},$$

provided $\theta < \frac{4T^2+\pi^2}{4T^2}$. Also, for $T = \frac{\pi}{2}$ the optimal risk-sensitive parameter θ^* is $\theta^* \approx 1.3763$. Therefore, for $1 < \theta < 1.3763$ the optimal control law $u^*(\cdot)$ exists for a family of optimal controllers. An important observation concerning the exact solution of Examples 1.1 and 1.2 is the linearity of the observer dynamics, despite the nonlinearity of the unobservable dynamics. This feature of the observer is also present in the Benes's filter in [11].

2. Problem formulation.

2.1. Dynamics. We start with a reference probability space $(\Omega, \mathcal{A}, P)$ with a complete filtration $\{\mathcal{F}_t; t \in [0,T]\}$, two $\{\mathcal{F}_t; t \in [0,T]\}$-adapted Wiener processes $\{w(t); t \in [0,T]\}$, $\{b(t); t \in [0,T]\}$, and an $\mathcal{F}_0$-measurable random variable $x(0)$ such that:

$$w : [0,T] \times \Omega \to \Re^n \quad \text{is a standard Wiener process independent of } b(\cdot),$$

$$b : [0,T] \times \Omega \to \Re^d \quad \text{is a standard Wiener process independent of } w(\cdot),$$

$$x(0) : \Omega \to \Re^n \quad \text{is a random variable independent of } w(\cdot), b(\cdot).$$

Further, suppose an observation process $y(\cdot)$ is given by

$$dy(t) = N(t)^{\frac{1}{2}} db(t), \qquad y(0) = 0 \in \Re^d. \tag{2.14}$$

The assumptions concerning (1.1)–(1.3) are now given; some of these assumptions will be weakened at a later stage depending on the nature of the optimization problem under consideration.

ASSUMPTION 2.1. *$|\cdot|^2$ denotes the Euclidean norm and $\mathcal{L}(V_1; V_2)$ denotes the space of linear transformations of a vector space V_1 into a vector space V_2.*

A1. *$\mathcal{U}$ is a nonempty subset of $\Re^m$.*

A2. *$f : [0,T] \times \Re^n \to \Re^n$ is continuous in t, continuous differentiable in x, and*

$$|f(t,x) - f(t,z)| \le K|x-z|, \qquad |f(t,x)| \le K(1+|x|). \tag{2.15}$$

A3. *$B : [0,T] \times \mathcal{U} \to \Re^n$ is Borel measurable, continuous in t, and*

$$|B(t,u)| \le K(1+|u|).$$

A4. *$h : [0,T] \times \Re^n \to \Re^d$ is continuous in t, once continuously differentiable in t, twice continuously differentiable in x, and*

$$|h(t,x)| \le K(1+|x|). \tag{2.16}$$

A5. *$N : [0,T] \to \mathcal{L}(\Re^d; \Re^d)$, $N = N^{\frac{1}{2}} N^{\frac{1}{2}\prime}$, $\exists\, \beta_1 > 0$ such that $N \ge \beta_1 I_d$.*

A6. *$G : [0,T] \to \mathcal{L}(\Re^n; \Re^n)$, $\exists\, \beta_2 > 0$ such that $G \ge \beta_2 I_n$.*

A7. *$\ell_i : [0,T] \times \Re^n \times \mathcal{U} \to \Re$, $\varphi_i : [0,T] \times \Re^n \to \Re, i = 1,2$ are Borel measurable, continuous in t, and*

$$|\ell_i(t,x,u)| \le K(1+|x|+|u|)^{l_i}, \quad |\varphi_i(t,x)| \le K(1+|x|)^{k_i}, \quad i = 1,2, \tag{2.17}$$

where l_i, k_i are positive constants.

A8. *The distribution* $\Pi_0(\cdot)$ *of* $x(0)$ *has a density* $q_0^\theta(\cdot)$ *in the space*

$$\mathcal{M}_k \doteq \left\{ p \in L^1(\Re^n); \quad ||p||_k \doteq \int_{\Re^n} (1+|x|^k)|p(x)|dx < \infty \right\} \quad \textit{for all } k \geq 1.$$

A9. N, G *are continuous in* t.

We write $\{\mathcal{F}_t^y; t \in [0,T]\}$ for the complete filtration generated by the observation σ-algebras $\sigma\{y(s); 0 \leq s \leq t \leq T\}$, and we denote by E^u (resp., $E, \hat{E}^u$), the expectation with respect to measure P^u (resp., $P, \hat{P}^u$).

DEFINITION 2.2. *Denote by* $L_y^2\left([0,T];\Re^k\right)$ *the set of square integrable stochastic processes adapted to* $\{\mathcal{F}_t^y, t \in [0,T]\}$ *with values in* $\Re^k$. *The set of admissible controls denoted by* $\hat{\mathcal{U}}$ *is defined by*

$$\hat{\mathcal{U}} \doteq \left\{ u(\cdot) \in L_y^2([0,T];\Re^k); \quad u(t,y) \in \mathcal{U}, \textit{ a.e. } t \, P\text{—a.s.} \right\}.$$

For the system $(\Omega, \mathcal{A}, P; \mathcal{F}_t)$ and for $u \in \hat{\mathcal{U}}$, consider the diffusion process $x(\cdot)$ satisfying the Ito equation

$$dx(t) = f(t,x(t))dt + B(t,u(t,y))dt + G(t)dw(t), \qquad x(0) \in \Re^n. \tag{2.18}$$

Under Assumptions 2.1 we have $B(\cdot, u(\cdot,y)) \in L_y^2([0,T];\Re^n)$, and there exists a unique solution $x(\cdot) \in L^2(\Omega, \mathcal{F}_t, P; C([0,T];\Re^n))$ of (2.18). For $u \in \hat{\mathcal{U}}$ define the $\{\mathcal{F}_t; t \in [0,T]\}$-adapted process $\Lambda^u(\cdot)$ by

$$\Lambda^u(t) \doteq \exp\left\{ \int_0^t h(s,x(s)).N(s)^{-1}dy(s) - \frac{1}{2}\int_0^t h(s,x(s)).N(s)^{-1}h(s,x(s))ds \right\}.$$

For $u \in \hat{\mathcal{U}}$, in view of Assumptions 2.1 we deduce that there exists some $\delta > 0$ such that $\sup_{t\in[0,T]} E\left\{\exp\left(\delta \int_0^t |N(s)^{-\frac{1}{2}}h(s,x(s))|^2 ds\right)\right\} < \infty$, and thus we have $E[\Lambda^u(t)] = 1$ (as in [13, Theorems 4.7, 6.1]). Therefore, for $u \in \hat{\mathcal{U}}$ a new measure P^u can be defined through the Radon–Nikodým derivative

$$\frac{dP^u}{dP}|_{\mathcal{F}_T} \doteq \Lambda^u(T).$$

Then, Girsanov's theorem states that P^u is a probability measure on $(\Omega, \mathcal{A}; \mathcal{F}_t)$ and that if the stochastic processes $w^u(\cdot), b^u(\cdot)$ are defined by

$$dw^u(t) \doteq dw(t), \qquad db^u(t) \doteq db(t) - N(t)^{-\frac{1}{2}}h(t,x(t))dt,$$

then $b^u(\cdot), w^u(\cdot)$ are independent standard Wiener processes on $(\Omega, \mathcal{A}, P^u; \mathcal{F}_t)$. Furthermore, for each $u \in \hat{\mathcal{U}}$, under P^u, $(x(\cdot), y(\cdot))$ is a unique weak solution of

$$dx(t) = f(t,x(t))dt + B(t,u(t,y))dt + G(t)dw^u(t), \qquad x(0) \in \Re^n, \tag{2.19}$$

$$dy(t) = h(t,x(t))dt + N(t)^{\frac{1}{2}}db^u(t), \qquad y(0) = 0 \in \Re^d. \tag{2.20}$$

Now let $w(\cdot) \equiv w^u(\cdot), b(\cdot) \equiv b^u(\cdot)$; then (2.19), (2.20) correspond, respectively, to the stochastic equations (1.1), (1.2).

2.2. Cost criterion. The problem consists of controlling the evolution of the state process $\{x(t); t \in [0,T]\}$ using the control process $\{u(t,y); t \in [0,T]\}$, which is a function of the data $\{y(t); t \in [0,T]\}$. The objective is to find an optimal control, denoted by u^*, such that

$$J_G^\theta(u^*(\cdot)) = \inf_{u \in \hat{\mathcal{U}}} J_G^\theta(u(\cdot)), \tag{2.21}$$

where $J_G^\theta(u(\cdot))$ is given by (1.3). Under the reference probability measure P, (2.21) has the equivalent representation

$$\begin{aligned} J_G^\theta(u(\cdot)) = E\Big\{ & \Lambda^u(T) \int_0^T \ell_2(t,x(t),u(t,y)) \exp\theta\left(\int_0^t \ell_1(s,x(s),u(s,y))ds\right) dt \\ & + \Lambda^u(T)\varphi_2(T,x(T)) \exp\theta\left(\int_0^T \ell_1(t,x(t),u(t,y))dt + \varphi_1(T,x(T))\right)\Big\}. \end{aligned} \tag{2.22}$$

2.3. Feynman–Kac information state. In this section we shall introduce the Feynman–Kac information state associated with the stochastic control problem (2.19)–(2.21) (or equivalently, (1.1)–(1.3)).

For each $u \in \hat{\mathcal{U}}$ and $\phi \in C_b^2(\Re^n)$ consider the (backward) differential operator

$$A\phi \doteq \frac{1}{2} Tr\left(GG' \frac{\partial^2}{\partial x^2}\phi\right) + (f+B).\frac{\partial}{\partial x}\phi = \frac{1}{2} Tr\left(GG' D_x^2 \phi\right) + (f+B).D_x\phi,$$

whose formal adjoint is denoted by A^*. Write

$$\chi_t^{u,\theta} = \exp\left\{\theta \int_0^t \ell_1(s,x(s),u(s))ds\right\}, \qquad (\alpha,\beta) = \int_{\Re^n} \alpha(z)\beta(z)dz.$$

A consequence of the above formulation and Assumptions 2.1 is the following theorem.

THEOREM 2.3. *Suppose Assumptions* 2.1 *hold with* $k_1 = 2$, $l_1 = 0$, *and* $\mathcal{U}$ *in* $A1$ *is replaced by a compact subset of* $\Re^m$. *For some* $0 < \theta \le \theta^*$ *there exists an* $\mathcal{F}_t^y$*-measurable positive function* $q^\theta(x,t) \equiv q^\theta(x,\{y(s); 0 \le s \le t\},t)$ *satisfying the Feynman–Kac stochastic evolution equation*

$$\begin{aligned} dq^\theta(x,t) &= \left(A(t)^* + \theta\ell_1(t,x,u(t))\right) q^\theta(x,t)dt + h(t,x)q^\theta(x,t).N(t)^{-1}dy(t), \\ q^\theta(x,0) &= q_0^\theta(x), \end{aligned} \tag{2.23}$$

P*—a.s. for any* $u \in \hat{\mathcal{U}}$, *which is unique among the functions with exponential growth condition in the space variable.*

For any bounded continuous function $\varphi : \Re^n \to \Re$ *with compact support we have*

$$\rho_t^\theta(\varphi) \doteq E^u\left[\varphi(x(t))\chi_t^{u,\theta} | \mathcal{F}_t^y\right] = \int_{\Re^n} \rho^\theta(z,t)\varphi(z)dz = \frac{\int_{\Re^n} q^\theta(z,t)\varphi(z)dz}{\int_{\Re^n} q^\theta(z,t)dz}, \tag{2.24}$$

where

$$\begin{aligned} d\rho^\theta(x,t) &= \left(A(t)^* + \theta\ell_1(t,x,u(t))\right)\rho^\theta(x,t)dt - \theta\rho_t^\theta(\ell_1)\rho^\theta(x,t)dt \\ &\quad + [h(t,x) - \rho_t^\theta(h)].N(t)^{-1}d\hat{b}^u(t), \quad d\hat{b}^u(t) \doteq dy(t) - \rho_t^\theta(h)dt, \\ \rho_t^\theta(x,0) &= q_0^\theta(x), \end{aligned} \tag{2.25}$$

P^u*—a.s. for any* $u \in \hat{\mathcal{U}}$.

Furthermore, for $u \in \hat{\mathcal{U}}$, the total cost given in section 2.2 has the equivalent representation

$$J_G^\theta(u(\cdot)) = E\left\{\int_0^T \left(\ell_2(t,\cdot,u(t)), q^\theta(t)\right) dt + \left(\varphi_2 \exp\theta(\varphi_1), q^\theta(T)\right)\right\}. \tag{2.26}$$

When $l_1 = 2$, similar results hold for sufficiently small values of $\theta > 0$, that ensure $\theta\ell_1(t,x,u) - \frac{1}{2}|h(t,x)|^2 < 0\ \forall (t,x,u) \in [0,T] \times \Re^n \times \mathcal{U}$.

Proof. The evolution of the Feynman–Kac information state is established in [4] (and in [9, 5] when the signal and observation noises are correlated). When $\theta = 0$ this theorem is derived in [14], by first establishing existence and uniqueness results for (2.23) indirectly, using results from parabolic PDEs (see [15]). Following the derivation in [14], for a fixed sample path of the observation process $y(\cdot,\omega) \in C([0,T];\Re^d)$ and, consequently, a fixed sample path of the control process, we introduce the gauge transformation:

$$\hat{q}_t^\theta = \exp(-h(t,x).N_t^{-1}y_t)q_t^\theta, \qquad 0 \le t \le T. \tag{2.27}$$

Using (2.23) (see also [4, 16]), we see that $\hat{q}_t^\theta$ satisfies the following robust, or pathwise, version of the Feynman–Kac information state equation:

$$\frac{\partial}{\partial t}\hat{q}_t^\theta = \hat{A}(t)^*\hat{q}_t^\theta + e(t,x,y_t)\hat{q}_t^\theta, \qquad \hat{q}^\theta(x,0) = q^\theta(x,0). \tag{2.28}$$

Here

$$\hat{A} = A - D_x.GD_x(h.N^{-1}y_t), \tag{2.29}$$

and

$$e(\cdot,x,y_t) = \frac{1}{2}|G'D_x(h.N^{-1}y_t)|^2 - N^{-1}y_t.\left(\frac{\partial}{\partial t}h + Ah\right) - \frac{1}{2}|N^{-\frac{1}{2}}h|^2 + \theta\ell_1. \tag{2.30}$$

This is a parabolic PDE with $y(\cdot,\omega) \in C([0,T];\Re^d)$ entering parametrically through the coefficients. It has a bounded diffusion term, a linear growth drift term, and a quadratic growth potential term (because $l_1 = 0$). Therefore, for sufficiently small θ, there exists a unique positive fundamental solution $\hat{\Gamma}(x,t;z,s), 0 \le s \le t \le T$ (see [15, Theorem 4.5]) of (2.28) satisfying $|D_x^m\hat{\Gamma}(x,t;z,s)| < c(t-s)^{-(r+|m|)/2}\exp[-\mu\frac{|x-z|^2}{t-s}]$, $0 \le |m| \le 2$. Here c, μ are constants depending on $y(\cdot,\omega)$. Then, (2.28) has the classical solution $\hat{q}^\theta(\cdot) \in C_{x,t}^{2,1}(\Re^n \times [0,T])$ given by

$$\hat{q}^\theta(x,t) = \int_{\Re^n} \hat{\Gamma}(x,t;z,0)q^\theta(z,0)dz, \tag{2.31}$$

which is unique among the class of functions bounded above by $\alpha_1 \exp\left(-\alpha_2|x|^2\right), \alpha_1 > 0, \alpha_2 > 0$. Since the gauge transformation (2.27) is invertible, one easily verifies that $q_t^\theta = \exp(h(t,x).N_t^{-1}y_t)\hat{q}_t^\theta$ solves (2.23) P—a.s. The results translate directly into corresponding results for $q^\theta(\cdot)$, as claimed.

If we now set $\rho^\theta(x,t) = q^\theta(x,t)(\int_{\Re^n} q^\theta(x,t)dx)^{-1}$ and apply the Ito differential rule, (2.25) follows.

The derivation of (2.24) is established by introducing the adjoint backward version of (2.28) and following the derivation in [14], which treats the case $\theta = 0$. Moreover,

by Assumptions 2.1, with $l_1 = 0$, for $y(\cdot,\omega) \in C([0,T];\Re^d)$, we have

$$\begin{aligned} &\rho_t^\theta \in \mathcal{M}_k, \quad A(t)^*\rho_t^\theta \in \mathcal{M}_{k-1}, \quad \left[\ell_1 - \theta\rho_t^\theta(\ell_1)\right]\rho_t^\theta \in \mathcal{M}_k, \\ &\left[h - \rho_t^\theta(h)\right].N^{-1}\left[dy_t - \rho_t^\theta(h)dt\right]\rho_t^\theta \in \mathcal{M}_{k-1} \end{aligned} \tag{2.32}$$

for all $0 < t \le T$. This allows us to establish (2.24) for functions $\varphi(\cdot)$ which are continuous and satisfy the growth condition $|\varphi(T,x)| \le \exp\beta(|x|^2), \beta > 0$. Consequently, for sufficiently small $\theta > 0$, (2.26) is established. □

From Theorem 2.3 we formally deduce, setting $\theta = 0$, the evolution equation for the information state known as the DMZ equation:

$$\begin{aligned} dq^0(x,t) &= A(t)^*q^0(x,t)dt \\ &+h(t,x)q^0(x,t).N(t)^{-1}dy(t), \quad q^0(x,0) = q_0^0(x) = q_0^\theta(x). \end{aligned} \tag{2.33}$$

The new stochastic control problem derived in Theorem 2.3, although fully observable, has an infinite-dimensional state $q^\theta(\cdot)$, because the process $q^\theta(\cdot)$ is determined by the PDE (2.23). If we are able to describe the state process $q^\theta(\cdot)$ by finite-dimensional parameters, then we might be able to convert the infinite-dimensional control problem of Theorem 2.3 to a standard, finite-dimensional control problem. This is done by seeking an explicit solution of the equation governing the information state and its Feynman–Kac version in terms of the solutions of a finite number of ordinary differential equations which form finite-dimensional sufficient statistics for the estimation problem. If these statistics are also sufficient for the control problem, then by carrying out the integration of inner product terms $(\cdot,\cdot)$ present in (2.26) (whenever possible), we recover a cost function which is expressed in terms of the sufficient statistics. Unfortunately, one cannot in general expect the state space of the Feynman–Kac information state to evolve on a finite-dimensional manifold unless some restrictions on the vector fields $f(t,\cdot,u), h(t,\cdot)$ are imposed.

3. Finite-dimensional Feynman–Kac information states.

3.1. Nonlinear dynamics linear sensor problem. First consider the following family of nonlinear control systems.

Control system (Σ_G^1). Suppose Assumptions 2.1 hold with $l_1 = 2, k_1 = 2$. Suppose the dynamics, observations, and cost criterion are given by:

$$dx_t = (F_tx_t + g_t(x) + f_t)\,dt + B_tu(t,y)dt + G_tdw_t, \qquad x(0) \in \Re^n, \tag{3.34}$$

$$dy_t = (H_tx + h_t)\,dt + N_t^{\frac{1}{2}}db_t, \qquad y(0) = 0 \in \Re^d, \tag{3.35}$$

$$\begin{aligned} J^\theta_{\Sigma_G^1}(u(\cdot)) = E^u\Big\{&\varphi_2(T,x_T)\exp\tfrac{\theta}{2}\Big(\int_0^T[Q_tx_t.x_t + R_tu_t.u_t \\ &+ 2m_tx_t + 2n_tu_t + \tilde{\ell}_1(t,x_t,u_t)]dt + (Q_Tx_T.x_T + 2m_Tx_T)\Big)\Big\}. \end{aligned} \tag{3.36}$$

Further, suppose the following additional assumptions hold.

A10. The nonlinear drift term is the gradient of some potential function; that is,

$$g(t,x) = G_tG_t'D_x\phi(x), \qquad \phi \in C_x^2(\Re^n), \tag{3.37}$$

where $\phi(\cdot)$ has at most quadratic growth in the space variable.

A11. The nonlinear function $\tilde{\ell}_1(\cdot)$ is related to the nonlinear drift term by

$$\begin{aligned}\tilde{\ell}_1(t,x,u) &= \tfrac{1}{\theta}\left\{2(F_tx+f_t+B_tu).(G_tG_t')^{-1}g(t,x)\right.\\ &\qquad \left.+\, g(t,x).(G_tG_t')^{-1}g(t,x)+Tr(D_xg(t,x))\right\}\\ &= \tfrac{1}{\theta}\left\{|G_t^{-1}\left(F_tx+f_t+B_tu+g(t,x)\right)|^2\right.\\ &\qquad \left.-\,|G_t^{-1}\left(F_tx+f_t+B_tu\right)|^2+Tr\left(D_xg(t,x)\right)\right\}.\end{aligned} \tag{3.38}$$

A12. The density of random variable $x(0)$ is

$$q_0^\theta(x)=\exp(\phi(x))\times\tilde{q}_0^\theta(x),\qquad \tilde{q}_0^\theta(x)=\frac{\exp(-P_0^{-1}(x-\xi).(x-\xi))}{(2\pi)^{\frac{n}{2}}|P_0|^{\frac{1}{2}}}, \tag{3.39}$$

where $P_0=P_0'\geq 0$.

A13. $Q_t=Q_t'\geq 0,\quad R_t=R_t'>0\,\forall t\in[0,T]$.

Remark 3.1. Suppose $m_t=0, n_t=0, f_t=0\ \forall t\in[0,T]$. From A11 it is easily verified that when $Tr(D_xg(x,t))\geq 0\ \forall(t,x)\in[0,T]\times\Re^n$, there exist matrices $Q_t\geq 0, R_t>0, t\in[0,T]$, such that the integrand in the exponential of (3.36) is nonnegative $\forall(t,x,u)\in[0,T]\times\Re^n\times\mathcal{U}$.

For $u\in\hat{\mathcal{U}}$ the Feynman–Kac information state equation associated with system Σ_G^1 is

$$\begin{aligned}dq_t^\theta &= \tfrac{1}{2}Tr\left(G_tG_t'D_x^2q_t^\theta\right)dt-D_x.\left(q_t^\theta\left(F_tx+g_t(x)+f_t+B_tu\right)\right)dt\\ &\quad+\tfrac{\theta}{2}\left(Q_tx.x+R_tu.u+2m_tx+2n_tu+\tilde{\ell}_1(t,x,u)\right)q_t^\theta dt\\ &\quad+\left(H_tx+h_t\right).q_t^\theta N_t^{-1}dy_t,\qquad q^\theta(x,0)=q_0^\theta(x).\end{aligned} \tag{3.40}$$

We now show that (3.40) is, after a gauge transformation, equivalent to the Feynman–Kac information state of a LEQG tracking problem.

Introduce the gauge transformation

$$\tilde{q}_t^\theta=\exp(-\phi(x))q_t^\theta. \tag{3.41}$$

Using (3.40) and A10–A12 we derive the following stochastic PDE for $\tilde{q}^\theta(\cdot)$:

$$\begin{aligned}d\tilde{q}_t^\theta &= \tfrac{1}{2}Tr\left(G_tG_t'D_x^2\tilde{q}_t^\theta\right)dt-D_x.\left(\tilde{q}_t^\theta\left(F_tx+f_t+B_tu\right)\right)dt\\ &\quad+\tfrac{\theta}{2}\left(Q_tx.x+R_tu.u+2m_tx+2n_tu\right)\tilde{q}_t^\theta\\ &\quad+\left(H_tx+h_t\right).\tilde{q}_t^\theta N_t^{-1}dy_t,\qquad \tilde{q}^\theta(x,0)=\tilde{q}_0^\theta(x).\end{aligned} \tag{3.42}$$

Now, (3.42) is the Feynman–Kac information state equation corresponding to the LEQG tracking problem specified by (3.51)–(3.53) (see [3, 5]). Moreover, the solution of (3.42) corresponding to setting $\theta=0$, and denoted by $\tilde{q}^0(\cdot)$, is the solution of the DMZ equation corresponding to the LQG tracking problem. As the coefficients of (3.42) are continuous in t, we can infer that there exists a unique solution of (3.42) among the class of Gaussian density functions [5, 6]. Using the invertibility of the Gauge transformation (3.41) and the quadratic growth assumption on $\phi(\cdot)$, the existence and uniqueness results for $\tilde{q}^\theta(\cdot)$ translate directly into corresponding results for $q^\theta(\cdot)$ satisfying (3.40).

From the solution of (3.42) and the gauge transformation (3.41) we have the following lemma.

LEMMA 3.2. *Suppose there exists a* $0 < \theta \leq \theta^*$ *such that* $H_t' N_t^{-1} H_t - \theta Q_t \geq 0 \; \forall t \in [0,T]$. *The solution of* (3.40) *is given by*

$$q^\theta(x,t) = \exp(\phi(x)) \times \frac{\exp\left(-\frac{1}{2} P_t^{-1}(x-r_t).(x-r_t)\right)}{(2\pi)^{\frac{n}{2}} |P_t|^{\frac{1}{2}}} \times \exp(c_t + \lambda_t). \tag{3.43}$$

Here $P = P' : [0,T] \to \mathcal{L}(\Re^n; \Re^n)$ *is the solution of the Riccati equation*

$$\dot{P}_t = F_t P_t + P_t F_t' - P_t \left(H_t' N_t^{-1} H_t - \theta Q_t\right) P_t + G_t G_t', \quad P(0) = P_0, \tag{3.44}$$

and $r : [0,T] \times \Omega \to \Re^n$ *is the observer state satisfying*

$$\begin{aligned} dr_t = {} & (F_t + \theta P_t Q_t)\, r_t dt + f_t dt + B_t u(t,y) dt \\ & + \theta P_t m_t' dt + P_t H_t' N_t^{-1} (dy_t - H_t r_t dt - h_t dt), \quad r(0) = \xi. \end{aligned} \tag{3.45}$$

Moreover, $c : [0,T] \times \Omega \to \Re, \lambda : [0,T] \times \Omega \to \Re$ *are given by*

$$c_t = \int_0^t (H_s r_s + h_s).N_s^{-1} dy_s - \frac{1}{2} \int_0^t |N_s^{-\frac{1}{2}} (H_s r_s + h_s)|^2 ds, \tag{3.46}$$

$$\begin{aligned} \lambda_t = {} & \tfrac{\theta}{2} \textstyle\int_0^t [Q_s r_s.r_s + R_s u(s,y).u(s,y) + 2 m_s r_s \\ & + 2 n_s u(s,y) + Tr(P_s Q_s)]\, ds. \end{aligned} \tag{3.47}$$

Proof. This follows from the explicit solution of (3.42) (see, for example, [3, 5]) and the gauge transformation (3.41); it is also a special case of the results derived in Theorem 3.7. □

Rewriting the total cost (3.36) of system Σ_G^1 using (2.26) (by setting $\ell_2 = 0$) and then substituting (3.43), the resulting total cost is

$$\begin{aligned} J^\theta_{\Sigma_G^1}(u(\cdot)) &= E\left\{ \textstyle\int_{\Re^n} \varphi_2(T,x) \times \exp\left(\phi(z) + \frac{\theta}{2}(Q_T z.z + 2 m_T z)\right) \right. \\ &\qquad \left. \times \frac{1}{(2\pi)^{\frac{n}{2}} |P_T|^{\frac{1}{2}}} \exp\left(-\tfrac{1}{2} P_T^{-1}(z-r_T).(z-r_T)\right) dz \; \times \exp(c_T + \lambda_T) \right\} \\ &= \hat{E}^u \left\{ \textstyle\int_{\Re^n} \varphi_2(T,x) \times \exp\left(\phi(z) + \frac{\theta}{2}(Q_T z.z + 2 m_T z)\right) \right. \\ &\qquad \left. \times \frac{1}{(2\pi)^{\frac{n}{2}} |P_T|^{\frac{1}{2}}} \exp\left(-\tfrac{1}{2} P_T^{-1}(z-r_T).(z-r_T)\right) dz \; \times \exp(\lambda_T) \right\}. \end{aligned} \tag{3.48}$$

In the second equality the expectation is with respect to measure $\hat{P}^u$ and is established as follows. Define $\hat{\Lambda}_t^u \doteq \exp(c_t)$. Since $(Hr_t + h_t)$ is a Gaussian random variable for $0 < \theta \leq \theta^*$ we have $E[\hat{\Lambda}_t^u] = 1 \; \forall t \in [0,T]$. Therefore, for $u \in \hat{\mathcal{U}}$ we define a new measure $\hat{P}^u$ through the Radon–Nikodým derivative $\frac{d\hat{P}^u}{dP}|_{\mathcal{F}_T^y} \doteq \hat{\Lambda}_T^u$. (Note that this is different from that defined in section 2.1 because for each $t \in [0,T]$, $\hat{\Lambda}_t^u$ is now an $\mathcal{F}_t^y$-measurable random variable.) By Girsanov's theorem $\hat{P}^u$ is a probability measure on $(\Omega, \mathcal{A}; \mathcal{F}_t^y)$ and the second equality in (3.48) is established. If we define $d\hat{b}_t^u \doteq dy_t - (Hr_t + h_t)dt$, then $\hat{b}^u(\cdot)$ is a Wiener process corresponding to the innovations process with correlation $N(\cdot)$ on $(\Omega, \mathcal{A}, \hat{P}^u; \mathcal{F}_t^y)$. Consequently, the observer state $r(\cdot)$ satisfies, under measure $\hat{P}^u$, the following equation:

$$\begin{aligned} dr_t = {} & (F_t + \theta P_t Q_t)\, r_t dt + f_t dt + B_t u(t,y) dt \\ & + \theta P_t m_t' dt + P_t H_t' N_t^{-1} d\hat{b}_t^u, \quad r(0) = \xi, \quad d\hat{b}_t^u \doteq dy_t - (Hr_t + h_t)dt. \end{aligned} \tag{3.49}$$

Clearly, the optimal stochastic control problem associated with the family of control systems Σ_G^1 is equivalent to the standard, completely observable, stochastic optimal control problem of minimizing (3.48) subject to the observer state satisfying the linear stochastic differential equation (3.49).

We have thus established the following recipe for constructing partially observable stochastic optimal control problems equivalent to LEQG optimal control problems.

THEOREM 3.3. *Consider the family of control system Σ_G^1, and assume*

$$\varphi_2(T,x) = \exp(-\phi(x)). \tag{3.50}$$

Then the optimal control law corresponding to Σ_G^1 is precisely given by the optimal control law of the following LEQG tracking problem:

$$J_{EQ}^{\theta}(u^*(\cdot)) = \min_{u\in\hat{\mathcal{U}}} E^u \left\{ \exp\tfrac{\theta}{2}\left(\int_0^T [Q_t x_t.x_t + R_t u(t,y).u(t,y) + 2m_t x_t + 2n_t u(t,y)]\,dt + (Q_T x_T.x_T + 2m_T x_T)\right)\right\}, \tag{3.51}$$

subject to

$$dx_t = (F_t x_t + f_t)dt + B_t u(t,y)dt + G_t dw_t, \qquad x(0)\in\Re^n, \tag{3.52}$$

$$dy_t = (H_t x_t + h_t)dt + N_t^{\frac{1}{2}}\,db_t, \qquad y(0) = 0 \in \Re^d. \tag{3.53}$$

Here $x(0)$ is a Gaussian random variable with density $\tilde{q}_0^{\theta}$ given in A12.

Proof. The proof follows from the above construction. The solution of (3.51)–(3.53) is derived in [3] using the method of completing the squares, in [6], using dynamic programming, and in [5], using a maximum principle; it is also given in section 5.1. □

3.1.1. Nonlinear systems Σ_G^1 with sector-bounded nonlinearities. Consider now the family of nonlinear systems Σ_G^1 with $\varphi_2(T,x) = 1$. In this case the corresponding terminal cost of (3.48), which results from carrying out the integration against the space variable, is not an exponential-of-quadratic function of the observer state r, because $\phi(\cdot)$ is generally a nonquadratic function of x. Consequently, the optimal control minimizing (3.48) with $\varphi_2(T,x) = 1$ subject to (3.49) cannot be computed explicitly, as in Theorem 3.3. However, when such a situation arises one can derive suboptimal control laws for the important class of nonlinear drift terms known as sector-bounded nonlinearities (see [17, Chapter 5]). These are sometimes known as first and third quadrant nonlinearities. This family of control systems is defined by Σ_G^1 and the following assumption.

A14. Suppose $\varphi_2(T,x) = 1$, $\phi(x) = \sum_{j=1}^{\ell}\int_0^{y_j}\tilde{g}_j(\sigma)d\sigma$, $y_j = C_j x$, $C_j \in (\Re^n)'$, $1\le j\le \ell$, where the $\{\tilde{g}\}_{j=1}^{\ell}$ satisfy the "sector criterion"

$$k_j^-|y_j|^2 \le \tilde{g}_j(C_j x)C_j x \le k_j^+|y_j|^2, \quad 0\le k_j^-\le k_j^+,\ 1\le j\le \ell. \tag{3.54}$$

(Condition (3.54) ensures that the graph of $y_j \to \tilde{g}_j(y_j)$ lies in the first and third quadrants.)

Note that for the class of systems Σ_G^1 which satisfy A14, the martingale problem is well posed, and therefore (3.34) has a unique weak solution (see [18, Theorem 10.2.2, p. 255]). Moreover, by A10 and A14 we have

$$g(t,x) = \sum_{j=1}^{\ell} G_t G_t' C_j' \tilde{g}_j(y_j), \qquad \frac{1}{2}\sum_{j=1}^{\ell} k_j^-|y_j|^2 \le \phi(x) \le \frac{1}{2}\sum_{j=1}^{\ell} k_j^+|y_j|^2. \tag{3.55}$$

Substituting (3.55) into (3.48), the upper and lower bounds of $\phi(\cdot)$ translate into the following upper and lower bounds for $J^{\theta}_{\Sigma^1_G}(u(\cdot))$, respectively:

$$J^{\theta,-}_{\Sigma^1_G}(u^-(\cdot)) \leq J^{\theta}_{\Sigma^1_G}(u(\cdot)) \leq J^{\theta,+}_{\Sigma^1_G}(u^+(\cdot)), \tag{3.56}$$

where

$$\begin{aligned} J^{\theta,-}_{\Sigma^1_G}(u^-(\cdot)) = \hat{E}^u \Bigg\{ & \int_{\Re^n} \exp\left(\tfrac{\theta}{2}\left[Q^{\theta,-}_T z.z + 2m_T z\right]\right) \\ & \times \tfrac{1}{(2\pi)^{\frac{n}{2}}|P_T|^{\frac{1}{2}}} \exp\left(-\tfrac{1}{2}|P_T^{-\frac{1}{2}}(z-r_T)|^2\right) dz \times \exp\left(\lambda_T\right) \Bigg\}, \end{aligned} \tag{3.57}$$

$$\begin{aligned} J^{\theta,+}_{\Sigma^1_G}(u^+(\cdot)) = \hat{E}^u \Bigg\{ & \int_{\Re^n} \exp\left(\tfrac{\theta}{2}\left[Q^{\theta,+}_T + 2m_T z\right]\right) \\ & \times \tfrac{1}{(2\pi)^{\frac{n}{2}}|P_T|^{\frac{1}{2}}} \exp\left(-\tfrac{1}{2}|P_T^{-\frac{1}{2}}(z-r_T)|^2\right) dz \times \exp\left(\lambda_T\right) \Bigg\}. \end{aligned} \tag{3.58}$$

Also

$$Q^{\theta,-}_T \doteq Q_T + \frac{1}{\theta}\sum_{j=1}^{\ell} k_j^- C_j' C_j \quad \text{and} \quad Q^{\theta,+}_T \doteq Q_T + \frac{1}{\theta}\sum_{j=1}^{\ell} k_j^+ C_j' C_j,$$

where $P(\cdot), r(\cdot)$ are solutions of (3.44), (3.49), respectively, and $\lambda(\cdot)$ is given by (3.47). Moreover, the optimal control laws $u^{-,*}(\cdot), u^{+,*}(\cdot)$ resulting from minimizing (3.57), (3.58), respectively, subject to (3.49), are linear feedback, reminiscent of the optimal control law of the LEQG tracking problem of Theorem 3.3. Hence, the optimal cost of the family of control systems Σ^1_G satisfying A14 is bounded from above and from below by the optimal cost of an LEQG tracking problem.

3.1.2. Nonlinear systems Σ^1_G with polynomial nonlinearities. We now wish to relax the linear growth assumption on the nonlinear drift term $g(\cdot)$ associated with the family of nonlinear control systems Σ^1_G, to consider the situation when the nonlinear drift terms are polynomial functions of the unobservable state as described by the next assumption.

A15. $n = d = m = 1, G_t = 1\ \forall t \in [0,T], k_1 = 2p$, and the nonlinear drift term $g(\cdot)$ is a polynomial of odd degree and stable; that is,

$$g(t,x) = D_x\phi(x) = \sum_{j=1}^{2p-1} F_j x^j, \qquad F_{2p-1} < 0, \quad p \geq 2. \tag{3.59}$$

Notice that the growth condition (2.17) is now specified by substituting (3.59) into (3.38). Conditions on existence and uniqueness of solutions for the robust version of the DMZ equation, (2.33), having strongly unbounded coefficients (i.e., greater than polynomial growth in x), are derived in [19], and include as a special case the situation when the drift, diffusion, and signal terms in (1.1), (1.2) have polynomial growth (see [19, section III, Example 1, pp. 207–210]). Following [19], we first note that the class of state processes $x(\cdot)$ associated with system Σ^1_G and satisfying A15 does not explode in finite time because they satisfy Khas'minskii's test of nonexplosion (see [18]). Second, from [19, section III] we deduce that for each $y(\cdot,\omega) \in C([0,T];\Re^d)$ and for some $\theta > 0$, the robust version of the Feynman–Kac equation of systems Σ^1_G satisfying A15 has a unique positive solution among those having exponential growth

$\alpha_1 \exp(-\alpha_2|x|^{2p}), \alpha_1 > 0, \alpha_2 > 0$, because the dominant part of $q^\theta(x,0)$, as $|x| \to \infty$, in the exponent is $F_{2p-1}\frac{|x|^{2p}}{2p}$. Alternatively, we can establish existence and uniqueness of solutions of the Feynman–Kac information state equation corresponding to system Σ_G^1 and A15, by invoking the gauge transformation (3.41) given by

$$q_t^\theta = \exp\left(\sum_{j=1}^{2p-1}\int_0^x F_j\sigma^j\, d\sigma\right)\tilde{q}_t^\theta, \tag{3.60}$$

where $\tilde{q}^\theta(\cdot)$ is the unique Gaussian density function satisfying (3.42), and $q^\theta(\cdot)$ is the information state of system Σ_G^1 and A15. As $|x| \to \infty$, its dominant part in the exponent is $F_{2p-1}\frac{|x|^{2p}}{2p}$. Thus, we establish for each $y(\cdot,\omega) \in C([0,T];\Re^d)$ the existence and uniqueness results stated above.

THEOREM 3.4. *Suppose there exists a* $0 < \theta \le \theta^*$ *such that* $H_tN_tH_t' - \theta Q_t \ge 0\ \forall t \in [0,T]$. *The Feynman–Kac information state corresponding to system* Σ_G^1 *and A15 is*

$$\begin{aligned} q^\theta(x,t) &= \exp\left(\textstyle\sum_{j=1}^{2p-1}\int_0^x F_j\sigma^j\, d\sigma\right) \\ &\quad \times \tfrac{1}{(2\pi)^{\frac{1}{2}}|P_t|^{\frac{1}{2}}}\exp\left(-\tfrac{1}{2}|P_t^{-\frac{1}{2}}(x-r_t)|^2\right) \times \exp\left(c_t+\lambda_t\right), \end{aligned} \tag{3.61}$$

where P, r, c, λ *are given in Lemma* 3.2.

Moreover, suppose

$$\varphi_2(t,x) = \exp\left(-\sum_{j=1}^{2p-1}\int_0^x F_j\sigma^j\, d\sigma\right). \tag{3.62}$$

Then the optimal control law corresponding to system Σ_G^1 *and* A15 *is given by the optimal control law of the LEQG tracking problem* (3.51)–(3.53).

Proof. This follows from the above construction, Lemma 3.2, and Theorem 3.3. □

Example 1.2 presented in the introduction is an application of Theorem 3.4.

Remark 3.5. In many practical applications one is usually interested in minimizing exponential-of-quadratic integral cost functions of the form (3.51). Such cost functions can be incorporated into our earlier framework by requiring $\tilde{\ell}_1(\cdot)$ to be quadratic in x, u. For example, suppose

$$\tilde{\ell}_1(t,x,u) = \frac{1}{\theta}\left(\tilde{V}(t,x) + \tilde{R}_tu.u + 2\tilde{n}u\right), \quad \tilde{V}(t,x) \doteq \Lambda_tx.x + 2x.\sigma_t + \delta_t, \tag{3.63}$$

where $\Lambda = \Lambda' : [0,T] \to \mathcal{L}(\Re^n;\Re^n), \sigma : [0,T] \to \Re^n, \delta : [0,T] \to \Re, \tilde{R} = \tilde{R}' : [0,T] \to \mathcal{L}(\Re^m;\Re^m), \tilde{n} : [0,T] \to (\Re^m)'$. In this case, the potential functions $\phi(\cdot)$ related to $g(\cdot)$ by A10 should be smooth classical solutions of the PDE (obtained from (3.38)), namely,

$$\begin{aligned} &\tfrac{1}{2}Tr\left(G_tG_t'D_x^2\phi(x)\right) + \tfrac{1}{2}D_x\phi(x).G_tG_t'D_x\phi(x) + \left(F_tx + f_t + B_tu\right).D_x\phi(x) \\ &\qquad = \tfrac{1}{2}\left(\tilde{V}(t,x) + \tilde{R}_tu.u + 2\tilde{n}_tu\right). \end{aligned} \tag{3.64}$$

If (3.63) takes the form $\tilde{\ell}_1(t,x,u) = \frac{2}{\theta}\left(F_tx + f_t + B_tu\right).(G_tG_t')^{-1}g(x) + \frac{1}{\theta}\tilde{V}(t,x)$ and we set $\tilde{R} = 0, \tilde{n} = 0$, then (3.64) is reduced to the well-known Riccati equation

$$Tr\left(D_xg(x)\right) + |G_t^{-1}g(x)|^2 = \tilde{V}(t,x),$$

first introduced in [20] for evaluating Feynman–Kac-type Wiener integrals, and in [11] for identifying finite-dimensional nonlinear filtering examples.

3.2. Nonlinear dynamics quadratic sensor problem. Now consider the generalized family of nonlinear control systems described by allowing the observations to be quadratic functions of the unobservable state.

Control system (Σ_G^2). Suppose Assumptions 2.1 hold with $l_1 = 4, k_1 = 2$, and $\mathcal{U}$ in A1 replaced by a compact subset of $\Re^m$. A4 is replaced by a quadratic growth condition, and the dynamics, observations, and cost criterion are given by

$$dx_t = (F_t x_t + g_t(x) + f_t)\,dt + B(t, u(t,y))dt + G_t dw_t, \qquad x(0) \in \Re^n, \tag{3.65}$$

$$dy_t = \left(\frac{1}{2} x_t' \tilde{H}_t x_t + H_t x_t + h_t\right) dt + N_t^{\frac{1}{2}} db_t, \qquad y(0) = 0 \in \Re, \tag{3.66}$$

$$J^{\theta}_{\Sigma_G^2} \doteq J^{\theta}_G(u(\cdot)) = (1.3). \tag{3.67}$$

Furthermore, suppose the following additional assumptions hold.

A16. $g(t,x) = G_t G_t D_x \phi(x,t)$, $\phi(\cdot) \in C^{2,1}_{x,t}(\Re^n \times [0,T])$, $\phi(\cdot)$ has at most quadratic growth in the space variable uniformly in t, $Fx + g(t,x)$ is stable, and the initial density of $x(0)$ is $q^{\theta}(x,0) = \exp(\phi(x,t)) \times \tilde{q}^{\theta}(x,0)$, where $\tilde{q}^{\theta}(\cdot)$ is a Gaussian density function (see A12).

A17. $2\ell_1(t,x,u) = \tilde{Q}(t,u)x.x + \tilde{R}(t,u)u.u + 2\tilde{m}(t,u)x + 2\tilde{n}(t,u)u + \tilde{\ell}_1(t,x,u)$.

A18. $\tilde{Q} : [0,T] \times \mathcal{U} \to \mathcal{L}(\Re^n; \Re^n), \tilde{R} : [0,T] \times \mathcal{U} \to \mathcal{L}(\Re^m; \Re^m), \tilde{m} : [0,T] \times \mathcal{U} \to (\Re^n)', \tilde{n} : [0,T] \times \mathcal{U} \to (\Re^m)', \tilde{\ell}_1 : [0,T] \times \Re^n \times \mathcal{U} \to \Re, \tilde{Q} = \tilde{Q}' \geq 0, \tilde{R} = \tilde{R}' > 0$.

Whenever $\tilde{H} = 0$ we assume $y : [0,T] \times \Omega \to \Re^d$.

A derivation of the sufficient statistics associated with system Σ_G^2, when $g = 0$, is given in [9], using the Fisk–Stratonovich version of the Feynman–Kac information state equation.

First, we point out that by the stability of $Fx + g(t,x)$ and the quadratic growth of $h(\cdot)$ (as in [19], at least for $n = 1$) we deduce that for each $y \in C([0,T]; \Re)$, and for some $\theta > 0$, there exists a unique solution of the robust version of the Feynman–Kac information state equation of system Σ_G^2, among the class of functions bounded above by $\alpha_1 \exp(-\alpha_2 |x|^2), \alpha_1 > 0, \alpha_2 > 0$.

Remark 3.6. Notice that for $\tilde{H} \neq 0$, the observation process associated with system Σ_G^2 is defined by $y : [0,T] \times \Omega \to \Re$ (i.e., is a real-valued function), although we believe that one can generalize the results of this section to multidimensional observations of the form

$$dy_t = \left(\frac{1}{2}\tilde{H}_t(x)x + H_t x_t + h_t\right) dt + N_t^{\frac{1}{2}} db_t,$$

where

$$\tilde{H}_t(x) = \sum_{i=1}^n x_i H_t^i, H^i : [0,T] \to \mathcal{L}(\Re^n; \Re^d), H : [0,T] \to \mathcal{L}(\Re^n; \Re^d), h : [0,T] \to \Re^d.$$

For $u \in \hat{\mathcal{U}}$ the Feynman–Kac information state equation associated with control system Σ_G^2 is given by

$$\begin{aligned} dq_t^{\theta} &= \tfrac{1}{2} Tr\left(G_t G_t' D_x^2 q_t^{\theta}\right) dt - \tfrac{\partial}{\partial x}\left(q_t^{\theta}\left(F_t x + g_t(x) + f_t + B(t,u)\right)\right) dt \\ &\quad + \tfrac{\theta}{2}\left(\tilde{Q}_t(u)x.x + \tilde{R}_t(u)u.u + 2\tilde{m}_t(u)x + 2\tilde{n}_t(u)u + \tilde{\ell}_1(t,x,u)\right) q_t^{\theta} dt \\ &\quad + q_t^{\theta}\left(\tfrac{1}{2} x' \tilde{H}_t x + H_t x + h_t\right) . N_t^{-1} dy_t \doteq RHS, \qquad q^{\theta}(x,0) = q_0^{\theta}(x). \end{aligned} \tag{3.68}$$

We derive solutions of (3.68) through an alternative technique, by seeking a solution of the form

$$q^\theta(x,t) = \exp\left(\phi(x,t) - \frac{1}{2}\tilde{P}_t x.x + \tilde{r}_t.x + \tilde{\rho}_t\right). \tag{3.69}$$

Here we suppose

$$\tilde{P} : [0,T]\times\Omega \to \mathcal{L}(\Re^n;\Re^n), \quad \tilde{P} = \tilde{P}', \quad \tilde{r} : [0,T]\times\Omega \to \Re^n, \quad \tilde{\rho} : [0,T]\times\Omega \to \Re,$$

and the random processes $\tilde{P}(\cdot), \tilde{r}(\cdot), \tilde{\rho}(\cdot)$ satisfy the following stochastic differential equations:

$$d\tilde{r}_t = k_t dt + H_t' N_t^{-1} dy_t, \quad k : [0,T]\times\Omega \to \Re^n, \tag{3.70}$$

$$d\tilde{P}_t = Z_t dt - \tilde{H}_t' N_t^{-1} dy_t, \quad Z : [0,T]\times\Omega \to \mathcal{L}(\Re^n;\Re^n), \tag{3.71}$$

$$d\tilde{\rho}_t = \mu_t dt + h_t' N_t^{-1} dy_t, \quad \mu : [0,T]\times\Omega \to \Re. \tag{3.72}$$

From (3.69) we have

$$D_x q_t^\theta = \left(D_x\phi_t - \tilde{P}_t x + \tilde{r}_t\right) q_t^\theta, \quad Tr\left(D_x^2 q_t^\theta\right) = |D_x\phi_t - \tilde{P}_t x + \tilde{r}|^2 q_t^\theta + Tr\left(D_x^2\phi_t - \tilde{P}_t\right) q_t^\theta.$$

Since $q^\theta(x,t) \equiv q^\theta(x,\tilde{r},\tilde{P},\tilde{\rho},t)$, an application of the Ito differential rule yields

$$\begin{aligned} dq_t^\theta = \Big\{ & \tfrac{\partial\phi_t}{\partial t}dt + x.\left(k_t dt + H_t.N_t^{-1}dy_t\right) + \left(\mu_t dt + h_t.N_t^{-1}dy_t\right) \\ & - \tfrac{1}{2}x.\left(Z_t dt - \tilde{H}_t.N_t^{-1}dy_t\right)x + \tfrac{1}{2}\left(H_t x.N_t^{-1}H_t x + h_t.N_t^{-1}h_t\right. \\ & \left. + \tfrac{1}{4}\tilde{H}_t x.xN_t^{-1}x'\tilde{H}_t x + \ 2H_t x.N_t^{-1}h_t + H_t x.N_t^{-1}x'\tilde{H}_t x + x'\tilde{H}_t x.N_t^{-1}h_t\right) dt\Big\} q_t^\theta. \end{aligned}$$

From (3.68) we have

$$\begin{aligned} RHS = \Big\{ & \Big[\tfrac{1}{2}|G_t'(D_x\phi_t - \tilde{P}_t x + \tilde{r}_t)|^2 \\ & + \tfrac{1}{2}\left(G_t G_t'\left(D_x^2\phi_t - \tilde{P}_t\right)\right) - B(t,u).\left(D_x\phi_t - \tilde{P}_t x + \tilde{r}_t\right) \\ & - Tr(F_t) - Tr(D_x g_t(x)) - (g_t(x) + F_t x + f_t).\left(D_x\phi_t - \tilde{P}x + \tilde{r}_t\right) \\ & + \tfrac{\theta}{2}\left(\tilde{Q}_t(u)x.x + \tilde{R}_t(u)u.u + 2\tilde{m}_t(u)x + 2\tilde{n}_t(u)u + \tilde{\ell}_1(t,x,u)\right) \\ & - \ B(t,u).\left(D_x\phi_t - \tilde{P}_t x + \tilde{r}_t\right)\Big] dt + \left(\tfrac{1}{2}x'\tilde{H}_t x + H_t x + h_t\right).N_t^{-1}dy_t\Big\} q_t^\theta. \end{aligned}$$

Equating dq_t^θ to RHS, the stochastic integral terms cancel; therefore, we deduce the following equation for $\phi(\cdot)$:

$$\begin{aligned} & \tfrac{\partial\phi_t}{\partial t} - \tfrac{1}{2}x.Z_t x + x.k_t + \mu_t + \tfrac{1}{2}|N_t^{-\frac{1}{2}}\left(\tfrac{1}{2}x.\tilde{H}_t x + Hx + h_t\right)|^2 \\ & - \tfrac{1}{2}|G_t'(D_x\phi_t - \tilde{P}_t x + \tilde{r}_t)|^2 - \tfrac{Tr}{2}\left(G_t G_t'\left(D_x^2\phi_t - \tilde{P}_t\right)\right) \\ & + (g_t(x) + F_t x + f_t).\left(D_x\phi_t - \tilde{P}_t x + \tilde{r}_t\right) + Tr(D_x g_t(x)) + Tr(F_t) \\ & - \tfrac{\theta}{2}\left(\tilde{Q}_t(u)x.x + \tilde{R}_t(u)u.u + 2\tilde{m}_t(u)x + 2\tilde{n}_t(u)u\right) \\ & - \tfrac{\theta}{2}\tilde{\ell}_1(t,x,u) + B(t,u).\left(D_x\phi_t - \tilde{P}_t x + \tilde{r}_t\right) = 0. \end{aligned}$$

Now isolate the coefficients of powers of x^2, x^1, x^0, respectively, as follows:

$$x.\left(-\tfrac{1}{2}Z_t - \tfrac{1}{2}\tilde{P}_t G_t G_t' \tilde{P}_t - F_t'\tilde{P}_t - \tfrac{\theta}{2}\tilde{Q}_t(u)\right)x,$$

$$\begin{aligned} &x.\Big(k_t + \tilde{P}_t G_t G_t' D_x\phi_t + \tilde{P}_t G_t G_t'\tilde{r}_t - \tilde{P}_t g_t(x) \\ &\quad + F_t'\tilde{r}_t - \tilde{P}_t f_t - \tilde{P}_t B(t,u) - \theta\tilde{m}_t'(u)\Big), \end{aligned} \tag{3.73}$$

$$\begin{aligned} &\mu_t - \tfrac{1}{2}\tilde{r}_t' G_t G_t' - D_x\phi_t.G_t G_t'\tilde{r}_t + \tfrac{1}{2}Tr\left(G_t G_t'\tilde{P}_t\right) + g_t(x).\tilde{r}_t \\ &\quad + f_t.\tilde{r}_t - \tfrac{\theta}{2}\tilde{R}_t(u)u.u - \theta\tilde{n}_t(u)u + B(t,u).\tilde{r}_t. \end{aligned}$$

Since $g(t,x) = G_t G_t' D_x\phi_t$, we have $D_x(g_t(x)) = G_t G_t' D_x^2\phi_t$, $g_t(x).D_x\phi_t = G_t G_t' \times D_x\phi_t.D_x\ \phi_t$. Therefore, the coefficients of powers of x^2, x^1, x^0 are independent of $g(\cdot), D_x\phi(\cdot)$.

Now introduce the matrix-valued, vector-valued, and scalar-valued functions $\gamma(\cdot)$, $\alpha(\cdot), \beta(\cdot)$ as follows:

$$\gamma_t \doteq -\frac{1}{2}Z_t - \frac{1}{2}\tilde{P}_t G_t G_t'\tilde{P}_t - F_t'\tilde{P}_t - \frac{\theta}{2}\tilde{Q}_t(u), \tag{3.74}$$

$$\alpha_t \doteq k_t + \tilde{P}_t G_t G_t'\tilde{r}_t + F_t'\tilde{r}_t - \theta\tilde{m}_t'(u) - \tilde{P}_t B(t,u) - \tilde{P}_t f_t, \tag{3.75}$$

$$\begin{aligned} \beta_t \doteq{}& \mu_t - \tfrac{1}{2}\tilde{r}_t' G_t G_t'\tilde{r}_t + \tfrac{1}{2}Tr\left(G_t G_t'\tilde{P}_t\right) - \tfrac{\theta}{2}\tilde{R}_t(u)u.u - \theta\tilde{n}_t(u)u \\ &+ B(t,u).\tilde{r}_t + f_t.\tilde{r}_t. \end{aligned} \tag{3.76}$$

Using (3.74)–(3.76) in the equation for $\phi(\cdot)$ we see

$$\begin{aligned} &\tfrac{\partial\phi_t}{\partial t} + \tfrac{1}{2}Tr\left(G_t G_t' D_x^2\phi_t\right) + \tfrac{1}{2}D_x\phi_t.G_t G_t' D_x\phi_t + F_t x.D_x\phi_t + \tfrac{1}{2}|N_t^{-\frac{1}{2}}(\tfrac{1}{2}x'\tilde{H}_t x + Hx + h_t)|^2 \\ &\quad = -Tr(F_t) + x.\left(-\alpha_t\right) + \tfrac{1}{2}x.\left(-2\gamma_t\right)x - \beta_t + \tfrac{\theta}{2}\tilde{\ell}_1(t,x,u) - B(t,u).D_x\phi_t. \end{aligned}$$

Rearranging the terms of this equation and setting

$$\Lambda_t = -2\gamma_t - H_t' N_t^{-1} H_t - \tilde{H}_t' N_t^{-1} h_t, \quad \Lambda_t = \Lambda_t', \tag{3.77}$$

$$\sigma_t = -\alpha_t - H_t' N_t^{-1} h_t, \tag{3.78}$$

$$\delta_t = -\beta_t - \frac{1}{2}h_t' N_t^{-1} h_t - Tr(F_t), \tag{3.79}$$

we have

$$\begin{aligned} &\tfrac{\partial\phi_t}{\partial t} + \tfrac{Tr}{2}\left(G_t G_t' D_x^2\phi_t\right) + \tfrac{1}{2}D_x\phi_t.G_t G_t' D_x\phi_t + \left(F_t x + f_t\right).D_x\phi_t = \tfrac{1}{2}x.\Lambda_t x + x.\sigma_t + \delta_t \\ &\quad + \tfrac{\theta}{2}\tilde{\ell}_1(t,x,u) - B(t,u).D_x\phi_t - \tfrac{1}{2}|N_t^{-\frac{1}{2}}\tfrac{1}{2}x'\tilde{H}_t x|^2 - \tfrac{1}{2}x'\tilde{H}_t x N_t^{-1} H_t x. \end{aligned}$$

Using (3.74)–(3.76) and (3.77)–(3.79), the equations satisfied by the functions $\tilde{P}(\cdot)$, $\tilde{r}(\cdot), \tilde{\rho}(\cdot)$ are given by (see (3.70)–(3.72))

$$
\begin{aligned}
d\tilde{P}_t + \left(\tilde{P}_t F_t + F_t'\tilde{P}_t + |G_t\tilde{P}_t|^2\right)dt &= \left(\Lambda_t + H_t' N_t^{-1} H_t\right)dt \\
&\quad + \tilde{H}_t' N_t^{-1} h_t dt - \theta\tilde{Q}_t(u)dt - \tilde{H}_t' N_t^{-1} dy_t, \\
d\tilde{r}_t + \left(F_t' + \tilde{P}_t G_t G_t'\right)\tilde{r}_t dt - \tilde{P}_t f_t dt + \sigma_t dt - \tilde{P}_t B(t,u)dt + H_t' N_t^{-1} h_t dt & \\
-\theta\tilde{m}_t'(u)dt = H_t' N_t^{-1} dy_t, & \\
d\tilde{\rho}_t + \left(-\tfrac{1}{2}|G_t'\tilde{r}_t|^2 + \delta_t + \tfrac{1}{2}|N_t^{-\frac{1}{2}} h_t|^2 + \tfrac{1}{2}Tr\left(G_t G_t'\tilde{P}_t + 2F_t\right)\right)dt + B(t,u).\tilde{r}_t dt & \\
+ f_t.\tilde{r}_t - \tfrac{\theta}{2}\left(\tilde{r}_t.\tilde{Q}_t(u)\tilde{r}_t + \tilde{R}_t(u)u.u + 2\tilde{n}_t(u)u\right)dt = h_t' N_t^{-1} dy_t. &
\end{aligned}
$$

Hence, we obtain the following theorem.

THEOREM 3.7. *Consider system Σ_G^2 and suppose for $u \in \hat{\mathcal{U}}$ there exist functions $\phi \in C_{x,t}^{2,1}(\Re^n \times [0,T])$, which are independent of the paths of y, which satisfy the PDE*

$$
\begin{aligned}
&\tfrac{\partial\phi_t}{\partial t} + \tfrac{1}{2}Tr\left(G_t G_t' D_x^2\phi_t\right) + \tfrac{1}{2}D_x\phi_t.G_t G_t' D_x\phi + \left(F_t x + f_t\right).D_x\phi_t = \tfrac{1}{2}x.\Lambda_t x + x.\sigma_t + \delta_t \\
&\quad + \left(\tfrac{\theta}{2}\tilde{\ell}_1(t,x,u) - B(t,u).D_x\phi_t - \tfrac{1}{2}|\tfrac{1}{2}N_t^{-\frac{1}{2}} x'\tilde{H}_t x|^2 - \tfrac{1}{2}x'\tilde{H}x.N_t^{-1}H_t x\right).
\end{aligned}
\tag{3.80}
$$

Here the function $\tilde{\ell}_1(\cdot)$ is free to be chosen so that (3.80) *yields explicit solutions. Then, a Feynman–Kac information state corresponding to system Σ_G^2 and satisfying* (3.68) *is given by*

$$
q^\theta(x,t) = \exp\left(\phi(x,t) + \tilde{c}_t + \tilde{\lambda}_t + \lambda_t\right) \times \frac{\exp\left(-\tfrac{1}{2}P_t^{-1}(x - r_t).(x - r_t)\right)}{(2\pi)^{\frac{n}{2}}|P_t|^{\frac{1}{2}}},
\tag{3.81}
$$

where

$$
r : [0,T]\times\Omega \to \Re^n, \quad P = P' : [0,T]\times\Omega \to \mathcal{L}(\Re^n;\Re^n), \quad \tilde{c}, \tilde{\lambda}, \lambda : [0,T]\times\Omega \to \Re
$$

are given by the following equations:

$$
\begin{aligned}
dr_t &= \left\{F_t - P_t\left(\tilde{H}_t' N_t^{-1} h_t - \theta\tilde{Q}_t(u) + \Lambda_t\right)\right\} r_t dt + \left(f_t - P_t\sigma_t + B(t,u)\right)dt \\
&\quad + \left(P_t\tilde{H}_t' N_t^{-1} P_t H_t' + \theta P_t\tilde{m}_t'(u)\right)dt + P_t H_t' N_t^{-1}\left(dy_t - H_t r_t dt - h_t dt\right) \\
&\quad + P_t\tilde{H}_t' N_t^{-1}\left(r_t dy_t - P_t\tilde{H}_t r_t dt\right), \quad r(0) = \xi,
\end{aligned}
\tag{3.82}
$$

$$
\begin{aligned}
dP_t &= \left\{F_t P_t + P_t F_t' - P_t\left(H_t' N_t^{-1} H_t + \tilde{H}_t' N_t^{-1} h_t + \Lambda_t - \theta\tilde{Q}_t(u)\right)P_t\right\}dt \\
&\quad + \left(P_t\tilde{H}_t' P_t N_t^{-1}\tilde{H}_t P_t + G_t G_t'\right)dt + P_t\tilde{H}_t' N_t^{-1} P_t dy_t, \qquad P(0) = P_0,
\end{aligned}
\tag{3.83}
$$

$$
\begin{aligned}
\lambda_t &= \tfrac{\theta}{2}\int_0^t \left\{[\tilde{Q}_s(u) - \tfrac{\Lambda_s}{\theta}]r_s.r_s + Tr\left(P_s[\tilde{Q}_s(u) - \tfrac{\Lambda_s}{\theta}]\right)\right\}ds \\
&\quad + \tfrac{\theta}{2}\int_0^t \left(\tilde{R}_s(u)u_s.u_s + 2r_s.[\tilde{m}_s(u)' - \tfrac{\sigma_s}{\theta}] + 2[\tilde{n}_s(u)u_s - \tfrac{\delta_s}{\theta}]\right)ds,
\end{aligned}
\tag{3.84}
$$

$$
\begin{aligned}
\tilde{\lambda}_t &= \tfrac{1}{2}\int_0^t \left\{|\tfrac{1}{2}N_s^{-\frac{1}{2}} r_s'\tilde{H}_s r_s|^2 + r_s'\tilde{H}_s r_s.N_s^{-1}H_s r_s + r_s.(-3\tilde{H}_s' N_s^{-1} P_s\tilde{H}_s)r_s\right. \\
&\quad \left. + r_s.\tilde{H}_s' P_s N_s^{-1} H_s'\right\}ds + \tfrac{1}{2}\int_0^t Tr\left\{-P_s\tilde{H}_s' N_s^{-1} h_s + P_s\tilde{H}_s' N_s^{-1} P_s\tilde{H}_s\right. \\
&\quad \left. - \tfrac{1}{2}\tilde{H}_s' N_s^{-1}\tilde{H}_s\right\}ds + \tfrac{1}{2}\int_0^t Tr\left(P_s\tilde{H}_s' N_s^{-1}\right)dy_s, \\
\tilde{c}_t &= \int_0^t \left(H_s r_s + h_s + \tfrac{1}{2}r_s'\tilde{H}_s r_s\right).N_s^{-1} dy_s \\
&\quad - \tfrac{1}{2}\int_0^t |N_s^{-\frac{1}{2}}\left(H_s r_s + h_s + \tfrac{1}{2}r_s'\tilde{H}_s r_s\right)|^2 ds.
\end{aligned}
$$

The above results will be valid whenever there exists a $0 < \theta \leq \theta^*$ *such that*

$$H_t' N_t^{-1} H_t + \tilde{H}_t' N_t^{-1} h_t + \Lambda_t - \theta \tilde{Q}_t(u) \geq 0 \quad \forall (t,u) \in [0,T] \times \mathcal{U}.$$

Proof. Define the functions $P(\cdot), r(\cdot), \rho(\cdot)$ by

$$P_t \doteq \tilde{P}_t^{-1}, \quad r_t \doteq \tilde{P}_t^{-1} \tilde{r}_t, \quad \rho_t = -2\tilde{\rho}_t,$$

and seek a representation of $q^\theta(\cdot)$ in the form

$$q^\theta(x,t) = \exp\left(\phi(x,t) - \frac{1}{2} P_t^{-1}(x - r_t).(x - r_t) + \tilde{\mu}_t \right), \qquad \tilde{\mu}_t = \frac{1}{2} P_t^{-1} r_t . r_t - \frac{1}{2} \rho_t.$$

To this end define

$$\begin{aligned} \tilde{c}_t \doteq & \int_0^t \left(H_s r_s + h_s + \tfrac{1}{2} r_s' \tilde{H}_s r_s \right) . N_s^{-1} dy_s \\ & - \tfrac{1}{2} \int_0^t | N_s^{-\frac{1}{2}} \left(H_s r_s + h_s + \tfrac{1}{2} r_s' \tilde{H}_s r_s \right) |^2 ds. \end{aligned} \tag{3.85}$$

An application of the Ito differential rule yields (3.82), (3.83), and

$$\begin{aligned} d\tilde{\mu}_t = & \, d\tilde{c}_t + \tfrac{1}{2} \left(\theta \tilde{Q}_t(u) - \Lambda_t \right) r_t . r_t dt \\ & + \left(-r_t . \sigma_t - \delta_t + \tfrac{1}{2} | N_t^{-\frac{1}{2}} r_t' \tilde{H}_t r_t |^2 + \tfrac{1}{2} r_t' \tilde{H}_t r_t . N_t^{-1} H_t r_t \right) dt \\ & + \Big(-\tfrac{3}{2} r_t' \tilde{H}_t' N_t^{-1} P_t \tilde{H}_t r_t + \tfrac{1}{2} \tilde{H}_t r_t . P_t N_t^{-1} H_t' + \tfrac{1}{2} H_t P_t N_t^{-1} H_t' \\ & \quad - \tfrac{1}{2} Tr \left(2F_t + G_t' P_t^{-1} G_t \right) \Big) dt + \tfrac{\theta}{2} \left(\tilde{R}_t(u) u . u + 2 \tilde{m}_t(u) r_t + 2 \tilde{n}_t(u) u \right) dt, \\ \tilde{\mu}(0) = & \, \tfrac{1}{2} P(0)^{-1} r(0) . r(0) - \tfrac{1}{2} \rho(0). \end{aligned}$$

Writing (3.83) in the form

$$\begin{aligned} dP_t = & \left\{ F_t + P_t F_t' P_t^{-1} + P_t \tilde{H}_t' N_t^{-1} P_t \tilde{H}_t + G_t G_t' P_t^{-1} \right. \\ & \left. - P_t \left(H_t' N_t^{-1} H_t + \tilde{H}_t' N_t^{-1} h_t + \Lambda_t - \theta \tilde{Q}_t(u) \right) \right\} P_t dt + \left(P_t \tilde{H}_t' N_t^{-1} \right) P_t dy_t, \end{aligned}$$

we deduce

$$\begin{aligned} d(\log |P_t| = & \, Tr \left(F_t + P_t F_t' P_t^{-1} + P_t \tilde{H}_t' N_t^{-1} P_t \tilde{H}_t + G_t G_t' P_t^{-1} \right) dt + Tr \left(P_t \tilde{H}_t N_t^{-1} \right) dy_t \\ & + Tr \{ -P_t \left(H' N_t^{-1} H_t + \tilde{H}_t' N_t^{-1} h_t + \Lambda_t - \theta \tilde{Q}_t(u) \right) - \tfrac{1}{2} \tilde{H}_t' N_t^{-1} \tilde{H}_t \} dt. \end{aligned}$$

Hence,

$$\begin{aligned} & Tr \left(2F_t + G_t G_t' P_t^{-1} \right) = d \left(\log |P_t| \right) + Tr(-P_t \tilde{H}_t' P_t N_t^{-1} \tilde{H}_t + \tfrac{1}{2} \tilde{H}_t' N_t^{-1} \tilde{H}_t) dt \\ & + Tr \left\{ P_t \left(H_t' N_t^{-1} H_t + \tilde{H}_t' N_t^{-1} h_t + \Lambda_t - \theta \tilde{Q}_t(u) \right) \right\} dt - Tr \left(P_t \tilde{H}_t' N_t^{-1} \right) dy_t. \end{aligned}$$

If we set

$$\rho(0) = r(0)' P(0)^{-1} r(0) + \log[(2\pi)^n |P(0)|],$$

and then substitute into the equation of $\tilde{\mu}(\cdot)$ we have

$$\begin{aligned}
d\tilde{\mu}_t = {} & d\tilde{c}_t + \tfrac{1}{2} r_t . \left(\tilde{H}_t' P_t N_t^{-1} H_t' - 2\sigma_t \right) dt + \tfrac{\theta}{2} \left(\tilde{R}_t(u) u.u + \tilde{m}_t(u) r_t + 2\tilde{n}_t(u) u \right) dt \\
& + \tfrac{1}{2} r_t \left(\theta \tilde{Q}_t(u) - \Lambda_t - 3\tilde{H}_t' N_t^{-1} P_t \tilde{H}_t \right) . r_t dt \\
& + \tfrac{1}{2} \left(|\tfrac{1}{2} N_t^{-\frac{1}{2}} r_t' \tilde{H}_t r_t|^2 + r_t' \tilde{H}_t r_t . N_t^{-1} H_t r_t \right) dt \\
& + \tfrac{1}{2} Tr \left\{ P_t \left(\theta \tilde{Q}_t(u) - \Lambda_t - \tilde{H}_t' N_t^{-1} h_t \right) + P \tilde{H}_t' N_t^{-1} P_t \tilde{H}_t - \tfrac{1}{2} \tilde{H}_t' N_t^{-1} \tilde{H}_t \right\} dt \\
& + \tfrac{1}{2} Tr \left(P_t \tilde{H}_t' N_t^{-1} \right) dy_t - \delta_t dt - \tfrac{1}{2} d \left(\log \left\{ (2\pi)^n |P_t| \right\} \right), \\
\tilde{\mu}(0) = {} & \log \left\{ (2\pi)^n |P(0)| \right\}^{-\frac{1}{2}} .
\end{aligned}$$

This yields the desired results. □

Remark 3.8. Theorem 3.7 implies that whenever (3.80) admits an explicit solution, $q^\theta(\cdot)$ is described by finite-dimensional parameters. If we set $\phi(\cdot) = 0$, $\Lambda(\cdot) = 0, \sigma(\cdot) = 0, \delta(\cdot) = 0$, $\tilde{H}(\cdot) = 0$, we recover the solution of the Feynman–Kac information state equation corresponding to the LEQG tracking problem given in [3, 5, 6], while if, in addition, we set $\theta = 0$, we recover the conditional density of the LQG tracking problem.

3.2.1. Examples of nonlinear drift terms for Σ_G^2. In this section we present specific examples of nonlinear systems Σ_G^2 that admit explicit solutions of (3.80) and so, finite-dimensional representations of the information state $q^\theta(\cdot)$, for various nonlinear drift terms $g(\cdot)$.

We first turn (3.80) into a linear second-order PDE by introducing the transformation

$$W(x,t) = \exp \phi(x,t).$$

The equation governing $W_t \equiv W(x,t)$ is given by

$$\begin{aligned}
\tfrac{\partial W_t}{\partial t} + \tfrac{Tr}{2} \left(G_t G_t' D_x^2 W_t \right) + \left(F_t x + f_t + B(t,u) \right) . D_x W_t = {} & W_t \left\{ \tfrac{1}{2} x . \Lambda_t x + x . \sigma_t + \delta_t \right\} \\
& + W_t \{ \tfrac{\theta}{2} \tilde{\ell}_1(t,x,u) - \tfrac{1}{2} |\tfrac{1}{2} N_t^{-\frac{1}{2}} x' \tilde{H}_t x|^2 - \tfrac{1}{2} x' \tilde{H}_t x . N_t^{-1} H_t x \}.
\end{aligned} \tag{3.86}$$

Thus, we seek solutions of (3.86). We shall present two alternative methods for solving this equation, each leading to different classes of nonlinear control systems Σ_G^2. In the first method, we choose the function $\tilde{\ell}_1(\cdot)$ to cancel the control-dependent term $B(t,u).D_x W(\cdot)$. This implies that the function $g(\cdot)$ entering the unobservable dynamics is independent of the control $u(\cdot)$. In the second method, we allow $g(\cdot)$ to depend on the control parameter $u(\cdot)$ and hence on the paths of $y(\cdot)$. It is important to note that, from the family of nonlinear systems Σ_G^2, the class of Benes-type [11] nonlinearities emerges from the first method but not the second method. This observation will be made precise through examples. Moreover, the second method might yield finite-dimensional states which are not sufficient for the control, in the sense that the information state depends on the control directly, not indirectly through the finite-dimensional sufficient statistics.

THEOREM 3.9 (uncontrolled classes). *Suppose $u \in \hat{\mathcal{U}}$ and there exists $0 < \theta \leq \theta^*$ such that*

$$H_t' N_t^{-1} H_t + \tilde{H}_t' N_t^{-1} h_t + \Lambda_t - \theta \tilde{Q}_t(u) \geq 0 \qquad \forall (t,u) \in [0,T] \times \mathcal{U}.$$

Define

$$\Gamma_2(t,x) \doteq \frac{1}{2} \Delta_t x . x + x . \zeta_t + \eta_t,$$

where $\Delta(\cdot), \zeta_t(\cdot), \eta(\cdot)$ *are deterministic functions shortly to be made precise, and set*

$$\tilde{\ell}_1(t,x,u) = \frac{2}{\theta}\left\{ B(t,u).D_x\phi(x,t) + \frac{1}{2}\left(\left| \frac{1}{2} N_t^{-\frac{1}{2}} x' \tilde{H}_t x \right|^2 + x'\tilde{H}_t x.N_t^{-1} H_t x \right) \right\}.$$

The Feynman–Kac information state $q^\theta(\cdot)$ *given in Theorem* 3.7 *is a density function, at least for the following two classes of nonlinear drift terms* $\phi(\cdot), (g(\cdot) = GG'D_x\phi(\cdot))$.

Class 1 *(rational nonlinearities). Suppose* $\Gamma_2(t,x) > 0\ \forall (t,x) \in [0,T] \times \Re^n$. *A solution of* (3.80) *is*

$$\phi_{R_2}(x,t) = \log W_1(x,t), \qquad W_1(x,t) = \Gamma_2(x,t),$$

which implies that the nonlinear drift term $g(\cdot)$ *should be of the form*

$$g_t(x) = G_t G_t' D_x \phi_{R_2}(x,t) = \frac{G_t G_t'}{\frac{1}{2}\Delta_t x.x + x.\zeta_t + \eta_t} \left(\Delta_t x + \zeta_t \right).$$

Here

$$\begin{aligned}
&\dot{\Delta}_t + F_t'\Delta_t + \Delta_t F_t = \delta_t \Delta_t,\\
&\dot{\zeta}_t + F_t'\zeta_t + \Delta_t f_t = \delta_t \zeta_t,\\
&\dot{\eta}_t + \frac{1}{2} Tr\left(G_t G_t' \Delta_t \right) + f_t.\zeta_t = \delta_t \eta_t,\\
&\Lambda_t = 0, \quad \sigma_t = 0, \quad \delta_t = \textit{arbitrary}.
\end{aligned}$$

Moreover, if $\Delta_t > 0, \eta_t - \frac{1}{2}\zeta_t.\Delta_t^{-1}\zeta_t > 0\ \forall t \in [0,T]$, *then* $\Gamma_2(t,x) > 0\ \forall (t,x) \in [0,T] \times \Re^n$, *and the nonlinear drift term* $g(t,x)$ *is nonsingular* $\forall (t,x) \in [0,T] \times \Re^n$.

Class 2 *(exponential nonlinearities). A solution of* (3.80) *is*

$$\phi_{E_2}(x,t) = \log W_2(x,t), \qquad W_2(x,t) = \gamma_t^1 \exp\left(\Gamma_2(x,t)\right) + \gamma_t^2 \exp\left(-\Gamma_2(x,t)\right).$$

This implies that the nonlinear drift term $g(\cdot)$ *should be of the form*

$$g_t(x) = G_t G_t' D_x \phi_{E_2}(x,t) = \frac{\gamma_t^1 \exp\left(\Gamma_2(x,t)\right) - \gamma_t^2 \exp\left(-\Gamma_2(x,t)\right)}{\gamma_t^1 \exp\left(\Gamma_2(x,t)\right) + \gamma_t^2 \exp\left(-\Gamma_2(x,t)\right)} G_t G_t' \left(\Delta_t x + \zeta_t \right),$$

where

$$\begin{aligned}
&\dot{\Delta}_t + F_t'\Delta_t + \Delta_t F_t = 0,\\
&\dot{\zeta}_t + F_t'\zeta_t + \Delta_t f_t = 0,\\
&\dot{\eta}_t + \frac{1}{2} Tr\left(G_t G_t' \Delta_t \right) + f_t.\zeta_t = \frac{1}{2}\frac{d}{dt}\left(\log \frac{\gamma_t^1}{\gamma_t^2} \right),\\
&\Lambda_t = \Delta_t G_t G_t' \Delta_t, \quad \sigma_t = \Delta_t G_t G_t' \zeta_t,\\
&\delta_t = \frac{1}{2}\zeta_t' G_t G_t' \zeta_t + \frac{1}{2}\frac{d}{dt}\left(\log \gamma_t^1 \gamma_t^2 \right).
\end{aligned}$$

Class 3 (*combination of classes* 1 *and* 2). *We can take* $\phi(x,t)$ *to be linear combinations of the logarithm of solutions* $W_1(x,t), W_2(x,t)$.

Proof. Follow the derivation given in [2], or substitute the solutions into the evolution equation of $W(\cdot)$ or $\phi(\cdot)$. The last class follows from the linearity of (3.86). ∎

Example 3.10 (rational nonlinearities). Here, we wish to construct specific examples of nonlinear drift terms $g(\cdot)$ using the results of Theorem 3.9 stated under Class 1.

Case 1. Suppose that F, G, f, Γ_2 are independent of time and $F = \frac{\alpha}{2} I_n, \alpha \in \Re$. The nonlinear drift term is

$$g(x) = \frac{GG'}{\frac{1}{2}\Delta x.x + x.\zeta + \eta}(\Delta x + \zeta),$$

where Δ is arbitrary, $\delta = \alpha, \zeta = \frac{2}{\alpha}\Delta f, \eta = \frac{1}{2\alpha} Tr(GG'\Delta) + f.\frac{2}{\alpha^2}\Delta f$. Moreover, $g(x)$ is nonsingular $\forall x \in \Re^n$ provided $\Delta > 0$ and $\alpha > 0$.

Case 2. Suppose F, G, Γ_2 are independent of time and $F = \frac{\alpha}{2} I_n, \alpha \in \Re, f = 0$. The nonlinear drift term is

$$g(x) = \frac{GG'}{\frac{1}{2}\Delta x.x + \eta}\Delta x,$$

where Δ is arbitrary, $\delta = \alpha, \zeta = 0, \eta = \frac{1}{2\alpha} Tr(GG'\Delta)$. Clearly, in this case $g(x)$ is nonsingular $\forall x \in \Re^n$ provided $\Delta > 0$ and $\alpha > 0$.

Case 3. Suppose $F_t = 0, f = 0$. The nonlinear drift term is

$$g(t, x) = \frac{G_t G_t'}{\frac{1}{2}\Delta_t x.x + \eta_t}\Delta_t x,$$

where $\dot{\Delta}_t = \delta_t \Delta_t$, $\zeta_t = 0, \dot{\eta}_t + \frac{1}{2} Tr(G_t G_t' \Delta_t) = \delta_t \eta_t$, $\delta(\cdot)$ is arbitrary. Moreover, $g(t, x)$ is nonsingular $\forall (t, x) \in [0, T] \times \Re^n$ provided $\Delta_t > 0$ and $\eta_t > 0\ \forall t \in [0, T]$.

The functions $\Delta(\cdot), \zeta(\cdot), \eta(\cdot), \Lambda(\cdot), \sigma(\cdot), \delta(\cdot)$ are measurable functions of t. Thus they do not depend on the control $u \in \hat{\mathcal{U}}$, and hence on the paths of $y(\cdot)$. However, an important disadvantage of the results of Theorem 3.9 is the presence of the term $\frac{2}{\theta} B(t, u).D_x \phi_t$ as part of $\tilde{\ell}_1(t, x, u)$. We can overcome this disadvantage by allowing the functions $\phi(\cdot)$, and thus $g(\cdot)$, to be pathwise-dependent on the observations $y(\cdot)$ through the control $u(t, y)$. This modification leads to the additional classes of nonlinear control systems presented in the next theorem.

THEOREM 3.11 (controlled classes). *Suppose $u \in \hat{\mathcal{U}}$ and there exists a $\theta \leq \theta^*$ such that*

$$H_t' N_t^{-1} H_t + \tilde{H}_t' N_t^{-1} h_t + \Lambda_t - \theta \tilde{Q}_t(u) \geq 0 \qquad \forall (t, u) \in [0, T] \times \mathcal{U}.$$

Define

$$\Gamma_2^u(t, x) \doteq \frac{1}{2}\Delta_t x.x + x.\zeta_t^u + \eta_t^u,$$

where $\Delta(\cdot), \zeta_t^u(\cdot), \eta^u(\cdot)$ will be made precise shortly. Set

$$\tilde{\ell}_1(t, x, u) = \frac{2}{\theta}\left\{\frac{1}{2}\left(\left|\frac{1}{2} N_t^{-\frac{1}{2}} x' \tilde{H}_t x\right|^2 + x' \tilde{H}_t x.N_t^{-1} H_t x\right)\right\}.$$

Suppose (3.80) *has a Borel measurable solution $\phi^u : \Re^n \times \mathcal{U} \times [0, T] \to \Re$. The Feynman–Kac information state $q^\theta(\cdot)$ given in Theorem* 3.7 *is a density function at least for the following two classes of control-dependent, nonlinear drift terms $\phi^u(\cdot)$ $(g^u(\cdot) = GG' D_x \phi^u(\cdot))$.*

Class 1 *(rational nonlinearities). Suppose* $\Gamma_2^u(t,x) > 0 \; \forall (t,x,u) \in [0,T] \times \Re^n \times \mathcal{U}$. *A control-dependent solution of* (3.80) *is*

$$\phi_{R_2}^u(x,t) = \log W_1^u(x,t), \qquad W_1^u(x,t) = \Gamma_2^u(x,t).$$

This implies that the nonlinear drift term $g(\cdot)$ *should be of the form*

$$g_t^u(x) = G_t G_t' D_x \phi_{R_2}^u(x,t) = \frac{G_t G_t'}{\frac{1}{2}\Delta_t x.x + x.\zeta_t^u + \eta_t^u} \left(\Delta_t x + \zeta_t^u\right),$$

where

$$\begin{aligned}
&\dot{\Delta}_t + F_t'\Delta_t + \Delta_t F_t = \delta_t \Delta_t,\\
&\dot{\zeta}_t^u + F_t'\zeta_t^u + \Delta_t f_t + \Delta_t B(t,u) = \delta_t \zeta_t^u,\\
&\dot{\eta}_t^u + \frac{1}{2} Tr\left(G_t G_t' \Delta_t\right) + f_t.\zeta_t^u + B(t,u).\zeta_t^u = \delta_t \eta_t^u,\\
&\Lambda_t = 0, \quad \sigma_t = 0, \quad \delta_t = \textit{arbitrary}.
\end{aligned}$$

The functions $\zeta^u(\cdot) \equiv \zeta(\cdot,u), \eta^u(\cdot) \equiv \eta(\cdot,u)$ *are measurable in* t, *and the function* $\phi_{R_2}^u(\cdot) \equiv \phi(\cdot,u,\cdot)$ *is pathwise-dependent on the observations* $y(\cdot)$ *through the control* $u(t,y)$.

Moreover, if $\Delta_t > 0, \eta_t^u - \frac{1}{2}\zeta_t^u.\Delta_t^{-1}\zeta_t^u > 0 \; \forall (t,u) \in [0,T] \times \mathcal{U}$, *then* $\Gamma_2^u(t,x) > 0 \; \forall (t,x,u) \in [0,T] \times \Re^n \times \mathcal{U}$, *and the nonlinear drift term* $g^u(t,x)$ *is nonsingular* $\forall (t,x,u) \in [0,T] \times \Re^n \times \mathcal{U}$.

Class 2 *(exponential nonlinearities). A control-dependent solution of* (3.80) *is*

$$\phi_{E_2}^u(x,t) = \log W_2^u(x,t), \qquad W_2^u(x,t) = \gamma_t^1 \exp\left(\Gamma^u(x,t)\right) + \gamma_t^2 \exp\left(-\Gamma_2^u(x,t)\right),$$

which implies that the nonlinear drift term $g(\cdot)$ *should be of the form*

$$g_t^u(x) = G_t G_t' D_x \phi_{E_2}^u(x,t) = \frac{\gamma_t^1 \exp\left(\Gamma_2^u(x,t)\right) - \gamma_t^2 \exp\left(-\Gamma_2^u(x,t)\right)}{\gamma_t^1 \exp\left(\Gamma_2^u(x,t)\right) + \gamma_t^2 \exp\left(-\Gamma_2^u(x,t)\right)} G_t G_t' \left(\Delta_t x + \zeta_t^u\right),$$

where

$$\begin{aligned}
&\dot{\Delta}_t + F_t'\Delta_t + \Delta_t F_t = 0,\\
&\dot{\zeta}_t^u + F_t'\zeta_t^u + \Delta_t f_t + \Delta_t B(t,u) = 0,\\
&\dot{\eta}_t^u + \frac{1}{2} Tr\left(G_t G_t' \Delta_t\right) + f_t.\zeta_t^u + B(t,u).\zeta_t^u = \frac{1}{2}\frac{d}{dt}\left(\log \frac{\gamma_t^1}{\gamma_t^2}\right),\\
&\Lambda_t = \Delta_t G_t G_t' \Delta_t, \quad \sigma_t^u = \Delta_t G_t G_t' \zeta_t^u,\\
&\delta_t^u = \frac{1}{2}\zeta_t^u.G_t G_t' \zeta_t^u + \frac{1}{2}\frac{d}{dt}\left(\log \gamma_t^1 \gamma_t^2\right).
\end{aligned}$$

The functions $\zeta^u(\cdot) \equiv \zeta(\cdot,u), \eta^u(\cdot) \equiv \eta(\cdot,u), \delta^u(\cdot) \equiv \delta(\cdot,u), \sigma^u(\cdot) \equiv \sigma(\cdot,u)$ *are measurable in* t, *the nonlinear function* $\phi_{E_2}^u(\cdot) \equiv \phi(\cdot,u,\cdot)$ *is pathwise dependent on the observations* $y(\cdot)$ *through the control* $u(t,y)$.

Proof. Follow the derivation given in [2], or substitute the solutions into the evolution equation for $W(\cdot)$ or $\phi(\cdot)$ to verify the results. □

We now demonstrate through specific examples that whether the function $\phi(\cdot)$ is chosen to depend on the control u or not, leads to different classes of nonlinear control problems.

Example 3.12. Suppose we are interested in the control analog of nonlinear dynamical systems with Benes-type [11] nonlinearities, namely:

$$dx_t = \tanh(x_t)dt + u(t,y)dt + dw_t, \qquad x(0) \in \Re, \tag{3.87}$$

$$dy_t = x_t dt + db_t, \qquad y(0) = 0 \in \Re. \tag{3.88}$$

This is a special case of the nonlinear control systems defined by the class Σ_G^2 (i.e., $F = H = \tilde{H} = f = h = 0, G = 1, B(t,u) = u$). When $u = 0$, the above model is shown in [11] to yield finite-dimensional filters. Here, we wish to determine whether the results of Theorems 3.9, 3.11, stated under Class 2, yield explicit solutions of the Feynman–Kac information state equation for the above control system. This will be possible if the results of Theorems 3.9, 3.11, stated under Class 2, can be specialized to the particular form $\Gamma_2(t,x) = x$, $\Gamma^u(t,x) = x$, respectively. That is, we require $\Delta_t = 0, \zeta_t = 1, \eta_t = 0$. If we set $\gamma_1 = \gamma_2 = 1, \Delta(0) = 0, \eta(0) = 0, \zeta(0) = 1$ in the results of Theorem 3.9, stated under Class 2 we deduce

$$\zeta_t = 1, \quad \Delta_t = 0, \quad \eta_t = 0, \qquad \Lambda_t = 0, \quad \sigma_t = 0, \quad \delta_t = \frac{1}{2}.$$

Hence,

$$g_t(x) = \frac{\exp(x) - \exp(-x)}{\exp(x) + \exp(-x)} = \tanh(x).$$

This implies that the Feynman–Kac information state equation associated with the above system admits an explicit solution when $\tilde{\ell}_1 = \frac{2}{\theta} u(t,y) \tan h(x)$ (see Theorem 3.9). On the other hand, one could show that the results of Theorem 3.11, stated under Class 2, do not admit an explicit solution for this Feynman–Kac information state equation because, although we could have $\Delta_t = 0, \zeta_t = 1$, we also have $\dot{\eta}_t + u(t,u) = 0$. This would never yield the desired solution $\eta_t = 0$ (and hence $\Gamma^u(t,x) = x$), unless $u(t,y) = 0$.

Example 3.13. Suppose we are interested in the following scalar problem:

$$dx_t = \frac{\Delta_t x_t + \zeta_t}{\frac{1}{2}\Delta_t x_t^2 + \zeta_t x_t + \eta_t} dt + u(t,y)dt + dw_t, \qquad x(0) \in \Re, \tag{3.89}$$

$$dy_t = x_t dt + db_t, \qquad y(0) = 0 \in \Re. \tag{3.90}$$

Setting $F_t = H_t = \tilde{H}_t = f_t = h_t = 0, G_t = 1, B(t,u) = u$ in the results of Theorem 3.9 stated under Class 1, we deduce

$$\dot{\Delta}_t = \delta_t \Delta_t, \quad \dot{\zeta}_t = \delta_t \zeta_t, \quad \dot{\eta}_t + \frac{\Delta_t}{2} = \delta_t \eta_t.$$

By choosing $\delta_t = \delta =$constant, we have

$$\Delta_t = \Delta(0)\exp(\delta t), \quad \zeta_t = \zeta(0)\exp(\delta t), \quad \eta_t = \eta(0)\exp(\delta t) - \frac{1}{2}\Delta(0)\exp(\delta t)t.$$

Therefore, when $\tilde{\ell}_1(t,x,u) = \frac{2}{\theta} u(t,y) \frac{\Delta_t x + \zeta_t}{\Delta_t x^2 + \zeta_t x + \eta_t}$ the Feynman–Kac information state is finite-dimensional and the nonlinear drift term in (3.89) is nonsingular provided $\Delta(0) > 0$ and $\eta(0) - \frac{1}{2}\Delta(0)t - \frac{1}{2}\frac{\zeta(0)^2}{\Delta(0)} > 0$. On the other hand, it is easy to show that

the results of Theorem 3.11, stated under Class 1, do not admit systems of this form because

$$\dot{\Delta}_t = \delta_t \Delta_t, \quad \dot{\zeta}_t^u + \Delta_t u(t,y) = \delta_t \zeta_t^u, \quad \dot{\eta}_t^u + \frac{\Delta_t}{2} + u(t,y)\zeta_t^u = \delta_t \eta_t^u.$$

Thus, $\zeta(\cdot), \eta(\cdot)$ in (3.89) are functionals of u.

Remark 3.14. The last two examples seem to suggest that the results of Theorem 3.9 are better suited for modeling nonlinearities entering the dynamics of the unobservable states. On the other hand, a disadvantage is the presence of the term $\frac{2}{\theta} B(t,u).D_x\phi(x,t)$ as part of $\tilde{\ell}_1(t,x,u)$. This is not present in the results of Theorem 3.11.

3.2.2. Representation of cost function. We shall now convert the family of nonlinear control systems Σ_G^2, which were originally infinite dimensional (see Theorem 2.3), to standard, finite-dimensional, completely observable stochastic control problems. By Theorem 3.7, we know that if a solution of (3.80) exists such that $q^\theta(\cdot)$ is a density function, then the total cost function (2.26) can be expressed in terms of the functions $\phi(\cdot)$ (or $\phi^u(\cdot)$), $P(\cdot), r(\cdot)$, and the differential observation process $dy(\cdot)$. (We shall distinguish between $\phi(\cdot)$ and $\phi^u(\cdot)$ only when referring to specific examples.) To this end we define

$$\breve{\ell}_2(t,x,P,u) \doteq \int_{\Re^n} \ell_2(t,z,u) \frac{\exp\left(\phi(z,t) - \frac{1}{2}P_t^{-1}(z-x).(z-x)\right)}{(2\pi)^{\frac{n}{2}}} dz,$$

$$\breve{\varphi}_2(x,P,u) \doteq \int_{\Re^n} \varphi_2(T,z) \exp\left(\theta\varphi_1(T,z)\right) \frac{\exp\left(\phi(z,T) - \frac{1}{2}P_T^{-1}(z-x).(z-x)\right)}{(2\pi)^{\frac{n}{2}}} dz.$$

Clearly, by incorporating the results of Theorem 3.7, the infinite-dimensional, stochastic control problem given under Theorem 2.3, is now equivalent to a completely observable finite-dimensional stochastic control problem with cost function given by

$$\begin{aligned} J^\theta_{\Sigma_G^2}(u(\cdot)) = E\Bigg\{ & \int_0^T \frac{1}{|P_t|^{\frac{1}{2}}} \breve{\ell}_2(t,r_t,P_t,u) \exp\left(\tilde{c}_t + \tilde{\lambda}_t + \lambda_t\right) dt \\ & + \frac{1}{|P_T|^{\frac{1}{2}}} \breve{\varphi}_2(r_T,P_T) \exp\left(\tilde{c}_T + \tilde{\lambda}_T + \lambda_T\right) \Bigg\}. \end{aligned} \tag{3.91}$$

The functions $\tilde{c}(\cdot), \tilde{\lambda}(\cdot), \lambda(\cdot)$ are defined in Theorem 3.7 and the evolutions of $r(\cdot), P(\cdot)$ are given by (3.82), (3.83), respectively.

4. Finite-dimensional information states.

4.1. Nonlinear dynamics linear sensor problem. Unfortunately, if we consider the quadratic sensor problem the information state equation (2.33) will not evolve on a finite-dimensional manifold. This is not surprising because the Feynman–Kac information state equation contains the additional term $\tilde{\ell}_1$ which has been chosen in Theorems 3.7 and 3.9 in such a way as to cancel nonlinearities in x of specific type. On the other hand, if we set $\tilde{H} = 0$ in the definition of the control system Σ_G^2, we obtain from the results of section 3.2 a finite-dimensional representation for $q^0(\cdot)$. These results are summarized in the next theorem.

Control system (Σ_I^u). Suppose Assumptions 2.1 hold, with $\mathcal{U}$ in A1 replaced by a compact subset of $\Re^m$, and the dynamics and observations are given by

$$\begin{aligned} dx_t &= (F_t x_t + f_t + g(t,x,u(t,y)))\, dt \\ &\quad + B(t,u(t,y))dt + G_t dw_t, \qquad x(0) \in \Re^n, \end{aligned} \tag{4.92}$$

$$dy_t = (H_t x_t + h_t)\, dt + N_t^{\frac{1}{2}} db_t, \qquad y(0) = 0 \in \Re^d, \tag{4.93}$$

$$J^0_{\Sigma_I^u}(u(\cdot)) \doteq J^0_I(u(\cdot)) = (1.4). \tag{4.94}$$

Here $g^u \equiv g : [0,T] \times \Re^n \times \mathcal{U} \to \Re^n$ is Borel measurable, and A10 and A12 hold with $g \to g^u, \phi(x) \to \phi(t,x,u), \tilde{q}_0^\theta(x) \to \tilde{q}_0^0(x)$.

For $u \in \hat{\mathcal{U}}$ the information state associated with the control system Σ_I^u evolves according to the equation

$$dq_t^0 = \tfrac{1}{2} Tr\left(G_t G_t' D_x^2 q_t^0\right) dt - \tfrac{\partial}{\partial x}\left(q_t^0 \left(F_t x + g_t(x,u)\right)\right) dt + \left(H_t x + h_t\right).q_t^0 N_t^{-1} dy_t,$$
$$q^0(x,0) = q_0^\theta(x).$$

The next theorem is a direct consequence of Theorems 3.7 and 3.9. The results corresponding to uncontrolled diffusion processes (i.e., $B = 0$) were first derived in [21].

THEOREM 4.1. *Consider the control system Σ_I^u, suppose $H_t' N_t^{-1} H_t + \Lambda_t^u \geq 0$ $\forall (t,u) \in [0,T] \times \mathcal{U}$, and for $u \in \hat{\mathcal{U}}$, there exist functions $\phi^u \in C^{2,1}_{x,t}(\Re^n \times [0,T])$ satisfying the partial differential equation*

$$\begin{aligned} &\tfrac{\partial \phi_t^u}{\partial t} + \tfrac{1}{2} Tr\left(G_t G_t' D_x^2 \phi_t^u\right) + \tfrac{1}{2} D_x \phi_t^u . G_t G_t' D_x \phi_t^u \\ &+ \left(F_t x + f_t + B(t,u)\right).D_x \phi_t^u = \tfrac{1}{2} x \Lambda_t^u . x + x.\sigma_t^u + \delta_t^u. \end{aligned} \tag{4.95}$$

Here $\Lambda^u(\cdot), \sigma^u(\cdot), \delta^u(\cdot)$ are free to be chosen so that (4.95) *yields explicit solutions. Then*

$$q^0(x,t) = \exp\left(\phi^u(x,t)\right) \frac{\exp\left(-\frac{1}{2} P_t^{-1}(x - r_t).(x - r_t)\right)}{(2\pi)^{\frac{n}{2}} |P_t|^{\frac{1}{2}}} \exp\left(c_t + \mu_t\right).$$

The cost function is

$$J^0_{\Sigma_I^u}(u(\cdot)) = E\left\{ \int_0^T (\ell_2(t,\cdot,u_t), q_t^0) dt + (\varphi_2(T,\cdot), q_T^0) \right\}. \tag{4.96}$$

Here $P(\cdot), r(\cdot), \mu(\cdot), c(\cdot)$ satisfy the following equations:

$$\begin{aligned} dr_t &= \left(F_t - P_t \Lambda_t^u\right) r_t dt + f_t dt - P_t \sigma_t^u dt \\ &\quad + B(t,u) dt + P_t H_t' N_t^{-1} \left(dy_t - H_t r_t dt - h_t dt\right), \quad r(0) = \xi, \\ \dot{P}_t &= F_t P_t + P_t F_t' - P_t \left(H_t' N_t^{-1} H_t + \Lambda_t^u\right) P_t + G_t G_t', \quad P(0) = P_0, \\ d\mu_t &= -\frac{1}{2}\left(r_t.\Lambda_t^u r_t + 2 r_t.\sigma_t^u + 2\delta_t^u + Tr(P_t \Lambda_t^u)\right) dt, \quad \mu(0) = 0, \\ dc_t &= \left(H_t r_t + h_t\right).N_t^{-1} dy_t - \frac{1}{2} |N_t^{-\frac{1}{2}} \left(H_t r_t + h_t\right)|^2 dt, \quad c(0) = 0. \end{aligned}$$

In addition, the information state $q^0(\cdot)$ can be written explicitly for the classes of nonlinear functions $\phi^u(\cdot)$ given in Theorem 3.11.

Proof. The first part of the theorem follows by setting $\theta = 0$ and $\tilde{H} = 0$ in the results of Theorem 3.7. The second part of the theorem follows from Theorem 3.11. ∎

5. Examples of optimal and suboptimal controls for Σ_G^2 with $\tilde{H} = 0$. Note that, when the Feynman–Kac information state is expressed in terms of a finite number of quantities, as in Theorem 3.7, under an appropriate hypothesis one could employ dynamic programming arguments as in [4, 6] to derive a Hamilton–Jacobi (HJ) equation satisfied by the optimal cost-to-go, and then establish a verification theorem. Consequently, in this case, if the optimal control laws exist, they are finite-dimensional.

In the next two theorems we present sufficient conditions for identifying nonlinear partially observable stochastic control problems with $\tilde{H} = 0$, which have exact optimal control laws, reminiscent of LEQG/LQG tracking problems.

THEOREM 5.1. *Suppose Assumptions* 2.1 *hold. Consider the problem of finding a control law $u^* \in \hat{\mathcal{U}}$ minimizing the total cost function*

$$J^\theta(u(\cdot)) = E^u \Big\{ \varphi_2(T, x_T) \exp \tfrac{\theta}{2} \Big(\int_0^T [Q_t x_t . x_t + R_t u(t,y).u(t,y) + 2m_t x_t + 2n_t u(t,y) + \tilde{\ell}_1(t, x_t, u(t,y)]dt + [Q_T x_T . x_T + 2m_T x_T] \Big) \Big\}. \tag{5.97}$$

Here

$$Q = Q' : [0,T] \to \mathcal{L}(\Re^n; \Re^n), \quad R = R' : [0,T] \to \mathcal{L}(\Re^m; \Re^m),$$
$$m : [0,T] \to (\Re^n)', \quad n : [0,T] \to (\Re^m)', \quad Q \geq 0, \quad R > 0,$$

and x, y are subject to dynamics:

$$dx_t = (F_t x_t + g(t, x_t) + f_t)\, dt + B_t u(t,y) dt + G_t dw_t, \quad x(0) \in \Re^n, \tag{5.98}$$

$$dy_t = (H_t x_t + h_t)\, dt + N_t^{\frac{1}{2}} db_t, \quad y(0) = 0 \in \Re^d. \tag{5.99}$$

I. *Suppose the following conditions hold.*

1. *The function $\tilde{\ell}_1(\cdot)$ is defined by*

$$\tilde{\ell}_1(t,x,u) \doteq \frac{2}{\theta} B_t u(t,y).D_x \phi(x,t) + \hat{\ell}_1(t,x,u), \tag{5.100}$$

where $\hat{\ell}_1(\cdot)$ is chosen so that there exists some solution of (3.80) *with $\tilde{H} = 0$.*

2. *The function $\varphi_2(\cdot)$ is defined by*

$$\varphi_2(T,x) \doteq \exp(-\phi(x,T)). \tag{5.101}$$

3. *$\Lambda(\cdot), \sigma(\cdot)$ are functions of t and $\delta(\cdot)$ is either a function of t or $\delta(t,\cdot)$ is a linear function of u.*

Then the optimal control $u^* \in \hat{\mathcal{U}}$ is linear, feedback, as in the LEQG tracking problem.

II. *If conditions* I1, I3 *hold and*

$$\frac{1}{2}\left(\tilde{Q}_T^- x.x + 2\tilde{m}_T^- x + \tilde{\rho}_T^-\right) \leq \phi(x,T) \leq \frac{1}{2}\left(\tilde{Q}_T^+ x.x + 2\tilde{m}_T^+ x + \tilde{\rho}_T^+\right), \quad \varphi 2 = 1, \tag{5.102}$$

where $\tilde{Q}_T^- = \tilde{Q}_T^{-,\prime}, \tilde{Q}_T^+ = \tilde{Q}_T^{+,\prime}$, then the optimal total cost $J(u^*(\cdot))$ is bounded above and below by that of the LEQG tracking problem.

If the term $\frac{2}{\theta} B_t u(t,y).D_x\phi(x,t)$ is removed from (5.100) *one must allow $g(\cdot)$ to be pathwise-dependent on the observations, thus generalizing* (5.98).

Proof. I. From Theorem 3.7, we know that if there exists a function $\phi \in C^{2,1}_{x,t}(\Re^n \times [0,T])$ satisfying (3.80) with $\tilde{H} = 0$, and if we choose the function $\tilde{\ell}_1(\cdot)$ according to condition I1, then the Feynman–Kac information state equation associated with control problem (5.97)–(5.99) is given by

$$q^\theta(x,t) = \exp(\phi(x,t) + c_t + \lambda_t) \times \frac{\exp\left(-\frac{1}{2}P_t^{-1}(x-r_t).(x-r_t)\right)}{(2\pi)^{\frac{n}{2}}|P_t|^{\frac{1}{2}}}\hat{\Lambda}^u_{0,T},$$

where $r(\cdot), P(\cdot)$ satisfy the equations

$$\begin{aligned} dr_t = {} & (F_t - P_t(\Lambda_t - \theta Q_t))\, r_t dt + f_t dt + B_t u(t,y) dt + \theta P_t m_t' dt - P_t \sigma_t dt \\ & + P_t H_t' N_t^{-1}(dy_t - H_t dt - h_t dt), \quad r(0) = \xi, \end{aligned} \tag{5.103}$$

$$\dot{P}_t = F_t P_t + P_t F_t' - P_t(H_t' N_t^{-1} H_t + \Lambda_t - \theta Q_t)P_t + G_t G_t', \quad P(0) = P_0. \tag{5.104}$$

$\hat{\Lambda}^u(\cdot)$ is defined earlier, and $\lambda(\cdot)$ is given by the equation

$$\begin{aligned} \lambda_t = {} & \exp\tfrac{\theta}{2}\left(\int_0^T \left(r_s[Q_s - \tfrac{\Lambda_s}{\theta}].r_s + R_s u(s,y).u(s,y) + Tr\left(P_s[Q_s - \tfrac{\Lambda_s}{\theta}]\right)\right) ds\right) \\ & \times \exp\left(\tfrac{\theta}{2}\int_0^T \left(2r_s.[m_s' - \tfrac{\sigma_s}{\theta}] + 2[n_s u(s,y) - \tfrac{\delta_s}{\theta}]\right) ds\right). \end{aligned} \tag{5.105}$$

If φ_2 is defined according to condition I2 and $I : [0,T] \to \Re$, from Theorem 2.3, we know that the cost function (5.97) admits the representation

$$\begin{aligned} J^\theta(u(\cdot)) = I_{0,T} E\Big\{ & \exp\tfrac{\theta}{2}\left(\int_0^T \left(r_s[Q_s - \tfrac{\Lambda_s}{\theta}].r_s + R_s u(s,y).u(s,y) + Tr\left(P_s[Q_s - \tfrac{\Lambda_s}{\theta}]\right)\right) ds\right) \\ & \times \exp\left(\tfrac{\theta}{2}\int_0^T \left(2r_s.[m_s' - \tfrac{\sigma_s}{\theta}] + 2[n_s u(s,y) - \tfrac{\delta_s}{\theta}]\right) ds\right) \\ & \times \exp\tfrac{\theta}{2}\left(\hat{\varphi}_2(T, r_T)\right) \times \hat{\Lambda}^u_{0,T}\Big\}. \end{aligned} \tag{5.106}$$

Here the function $\hat{\varphi}_2(\cdot)$ is quadratic in r. If condition I3 holds as well, then $\Lambda(\cdot), \sigma(\cdot)$ are deterministic functions of t, and either $\delta(\cdot) : [0,T] \to \Re$ or $\delta(t,\cdot)$ is a linear function of u. Hence, the problem of minimizing (5.97) over $u \in \hat{\mathcal{U}}$, subject to dynamics (5.98), (5.99), is equivalent to the problem of minimizing (5.106) over $u \in \hat{\mathcal{U}}$, subject to dynamics (5.103), (5.104). However, the latter problem is equivalent to a completely observable LEQG tracking problem. Therefore, the optimal control is linear, feedback, and of separated form $u^*(t) = u(t,r)$ (see [3, 6]).

II. This follows by substituting (5.102) into (5.106).

A similar derivation holds when the function $\phi(\cdot)$ is pathwise-dependent on the observation y. This then implies that the term $\frac{2}{\theta}B_t u(t,y).D_x\phi^u(x,t)$ is not present in $\tilde{\ell}_1(\cdot)$. Moreover, it is possible to relax the third condition, allowing σ to be a linear function of u and δ to be a quadratic function of u. □

THEOREM 5.2. *Suppose the assumptions corresponding to the family of systems Σ_I^u hold with $\mathcal{U}$ as defined in* A1. *Consider the problem of finding a control law $u^* \in \hat{\mathcal{U}}$ minimizing the total cost function*

$$\begin{aligned} J^0(u(\cdot)) = {} & \tfrac{1}{2}E^u\Big\{\int_0^T \hat{\ell}_2(t, x_t, u(t,y)) \times (Q_t x_t.x_t + R_t u(t,y).u(t,y) \\ & + 2m_t x_t + 2n_t u(t,y))\, dt + \hat{\varphi}_2^u(T, x_T) \times (Q_T x_T.x_T + 2m_T x_T)\Big\}, \end{aligned} \tag{5.107}$$

where Q, R, m, n are specified in Theorem 5.1, *subject to dynamics and observations given by*

$$dx_t = (F_t x_t + g^u(t, x_t) + f_t)\, dt + B_t u(t, y) dt + G_t dw_t, \quad x(0) \in \Re^n, \tag{5.108}$$

$$dy_t = (H_t x_t + h_t)\, dt + N_t^{\frac{1}{2}} db_t, \quad y(0) = 0 \in \Re^d. \tag{5.109}$$

I. *Suppose the following conditions hold.*

1. *There exists some solution $\phi^u(\cdot)$ of* (4.95).
2. *The functions $\hat{\ell}_2, \hat{\varphi}_2^u(\cdot)$ are defined by*

$$\hat{\ell}_2(t, x, u) \doteq \exp(-\phi^u(x, t)), \qquad \hat{\varphi}_2^u(T, x) \doteq \exp(-\phi^u(x, T)). \tag{5.110}$$

3. *$\Lambda^u(\cdot) = 0, \sigma^u(\cdot) = 0$, and $\delta^u(\cdot) = \delta(\cdot)$ is a function of t.*

Then the optimal control $u^* \in \hat{\mathcal{U}}$ is linear, feedback, as in the LQG tracking problem.

Proof. From Theorem 4.1, we know that, if there exists a function $\phi^u \in C_{x,t}^{2,1}(\Re^n \times [0, T])$, satisfying (4.95), and we set $g^u = GG' D_x \phi^u \mathrm{c}$, then the information state equation associated with control problem (5.107)–(5.109) is given by

$$q^0(x, t) = \exp(\phi^u(x, t) + \lambda_t) \times \frac{\exp\left(-\frac{1}{2} P_t^{-1}(x - r_t).(x - r_t)\right)}{(2\pi)^{\frac{n}{2}} |P_t|^{\frac{1}{2}}} \hat{\Lambda}_{0,t}^u.$$

Here $r(\cdot), P(\cdot)$ satisfy the equations

$$\begin{aligned} dr_t = {} & (F_t - P_t \Lambda_t^u)\, r_t dt + f_t dt + B_t u(t, y) dt - P_t \sigma_t^u dt \\ & + P_t H_t' N_t^{-1} (dy_t - H_t dt - h_t dt), \quad r(0) = \xi, \end{aligned} \tag{5.111}$$

$$\dot{P}_t = F_t P_t + P_t F_t' - P_t (H_t' N_t^{-1} H_t + \Lambda_t^u) P_t + G_t G_t', \quad P(0) = P_0. \tag{5.112}$$

$\hat{\Lambda}^u(\cdot)$ is the exponential martingale defined earlier, and $\lambda(\cdot)$ is given by the equation

$$\lambda_t = \exp \frac{1}{2} \left\{ - \int_0^t \left(r_s[\Lambda_s^u].r_s + Tr\left(P_s[\Lambda_s^u]\right) + 2 r_s.[\sigma_s^u] + 2[\delta_s^u] \right) ds \right\}. \tag{5.113}$$

If conditions I1–I3 of the theorem are satisfied, from Theorem 4.1, we know that the cost function (5.107) is represented by

$$\begin{aligned} J^0(u(\cdot)) = E \Big\{ & \tfrac{1}{2} \Big(\textstyle\int_0^T \left(Q_t r_t.r_t + R_t u(t, y).u(t, y) + 2 r_t.m_t' + 2 n_t u(t, y) \right) dt \\ & + \left(Q_T r_T.r_T + 2 r_T.m_T' \right) + \textstyle\int_0^T Tr\left(P_t Q_t\right) dt + Tr\left(P_T Q_T\right) \Big) \hat{\Lambda}_{0,T}^u \Big\} \\ & \times \exp(-\textstyle\int_0^T \delta_t dt). \end{aligned} \tag{5.114}$$

Hence, the problem of minimizing (5.107) over $u \in \hat{\mathcal{U}}$, subject to dynamics (5.108), (5.109), is equivalent to the problem of minimizing (5.114) over $u \in \hat{\mathcal{U}}$ subject to dynamics (5.111), (5.112). However, the latter problem is equivalent to a completely observable LQG tracking problem. Therefore, the optimal control is linear, feedback, and of separated form $u^*(t) = u(t, r)$. □

In the next two subsections we shall present specific examples of general nonlinear partially observable control problems that yield linear observer dynamics and linear feedback optimal control laws.

5.1. Nonlinear dynamics exponential-of-integral cost. Control system $(\Sigma_{E_i}, i = 1, 2)$. We specialize (5.97)–(5.99) of Theorem 5.1 to the following case. The dynamics and observations are given by

$$dx_t = (F_t x_t + g_i(t, x_t) + f_t)\, dt + B_t u(t, y)dt + G_t dw_t, \qquad x(0) \in \Re^n, \qquad i = 1, 2,$$
$$dy_t = (H_t x_t + h_t)\, dt + N_t^{\frac{1}{2}} db_t, \qquad y(0) = 0 \in \Re^d.$$

Here

$$\Gamma_2^i(t, x) = \frac{1}{2}\Delta_t^i x.x + x.\zeta_t^i + \eta_t^i, \quad i = 1, 2,$$

$$g_1(t, x) \doteq G_t G_t' \frac{D_x \Gamma_2^1(t, x)}{\Gamma_2^1(t, x)} = \frac{G_t G_t'}{\frac{1}{2}\Delta_t^1 x.x + x.\zeta_t^1 + \eta_t^1} \left(\Delta_t^1 x + \zeta_t^1\right),$$
$$g_2(t, x) \doteq \frac{\gamma_t^1 \exp(\Gamma_2^2(t, x)) - \gamma_t^2 \exp(-\Gamma_2^2(t, x))}{\gamma_t^1 \exp(\Gamma_2^2(t, x)) + \gamma_t^2 \exp(-\Gamma_2^2(t, x))} G_t G_t' D_x \Gamma_2^2(t, x).$$

The functions $\Delta^i, \zeta^i, \eta^i, i = 1, 2$, satisfy the equations stated in Theorem 3.9 under Classes 1, 2, respectively. Define

$$\ell_Q^i(t, x, u) \doteq Q_t x.x + R_t u.u + 2m_t x + 2n_t u + \tilde{\ell}_1^i(t, x, u), \qquad i = 1, 2,$$

where

$$\tilde{\ell}_1^i(t, x, u) = \frac{2}{\theta} B_t u.\, (G_t G_t')^{-1} g_i(t, x), \qquad i = 1, 2.$$

For $i = 1, 2$ we wish to minimize over $u \in \hat{\mathcal{U}}$ the cost function

$$J_{\Sigma_{E_i}}^{\theta}(u(\cdot)) = E^u \left\{ \varphi_2^i(T, x_T) \exp \frac{\theta}{2} \left(\int_0^T \ell_Q^i(t, x_t, u_t)dt + (Q_T x_T.x_T + 2m_T x_T) \right) \right\},$$

where

$$\varphi_2^1(T, x) \doteq \frac{1}{\Gamma_2^1(t, x)} = \frac{1}{\Delta_t^1 x.x + x.\zeta_t^1 + \eta_t^1}, \tag{5.115}$$
$$\varphi_2^2(T, x) = \left\{ \gamma_T^1 \exp(\Gamma_2^2(t, x)) + \gamma_T^2 \exp(-\Gamma_2^2(t, x)) \right\}^{-1}.$$

In order to determine explicitly the optimal feedback control law corresponding to the control problem associated with systems $\Sigma_{E_i}, i = 1, 2$, we shall need the following equations.

Observer dynamics.

$$dr_t^i = \left\{ F_t - P_t^i \left(\Lambda_t^i - \theta Q_t \right) \right\} r_t^i dt + \left(f_t - P_t^i \sigma_t^i \right) dt + B_t u(t, y)dt \tag{5.116}$$
$$+\theta P_t^i m_t' dt + P_t^i H_t' N_t^{-1} d\hat{b}_t^u, \quad r^i(0) = \xi, \quad \hat{b}_i^u \equiv \text{Wiener process}, \quad i = 1, 2,$$

$$\dot{P}_t^i = F_t P_t^i + P_t^i F_t' - P_t^i \left(H_t' N_t^{-1} H_t - \theta[Q_t - \tfrac{\Lambda_t^i}{\theta}] \right) P_t^i \tag{5.117}$$
$$+ G_t G_t',\ P^i(0) = P_0, \quad i = 1, 2.$$

Control gains.

$$\begin{aligned}
&\dot{\Sigma}_t^i + \Sigma_t^i \left(F_t + \theta P_t^i [Q_t - \tfrac{\Lambda_t^i}{\theta}]\right) + \left(F_t' + \theta [Q_t - \tfrac{\Lambda_t^i}{\theta}] P_t^i\right) \Sigma_t^i + [Q_t - \tfrac{\Lambda_t^i}{\theta}] \\
&\quad - \Sigma_t^i \left\{B_t R_t^{-1} B_t' - \theta P_t^i H_t' N_t^{-1} H_t P_t^i\right\} \Sigma_t^i = 0, \quad i = 1,2, \qquad (5.118) \\
&\Sigma_T^i = \tfrac{1}{2} \left\{ \left(I - \theta Q_T P_T^i\right)^{-1} Q_T + Q_T \left(I - \theta P_T^i Q_T\right)^{-1} \right\}, \quad i = 1,2. \\
&\dot{k}_t^i + k_t^i \left(F_t + \theta P_t^i H_t' N_t^{-1} H_t P_t^i \Sigma_t^i + \theta P_t^i [Q_t - \tfrac{\Lambda_t^i}{\theta}] - B_t R_t^{-1} B_t' \Sigma_t^i\right) \\
&\quad + [m_t - \tfrac{\sigma_t^{i,*}}{\theta}] + \left(f_t' + \theta [m_t - \tfrac{\sigma_t^i}{\theta}] P_t^i - n_t R_t^{-1} B_t'\right) \Sigma_t^i = 0, \quad i = 1,2, \qquad (5.119) \\
&k_T^i = m_T \left(I - \theta P_T^i Q_T\right)^{-1}, \quad i = 1,2. \\
&\dot{\rho}_t^i + Tr\left(P_t^i H_t' N_t^{-1} H_t P_t^i \Sigma_t^i\right) + \theta k_t^i P_t^i H_t' N_t^{-1} H_t P_t^i k_t^{i,\prime} \\
&\quad + 2k_t^i \left(f_t + \theta P_t^i [m_t - \tfrac{\sigma_t^{i,\prime}}{\theta}]\right) - |R_t^{-\frac{1}{2}} \left(B_t' k_t^{i,\prime} + n_t'\right)|^2 = 0, \quad i = 1,2, \qquad (5.120) \\
&\rho_T^i = 0, \quad i = 1,2. \\
&I_{0,T}^i = \tfrac{1}{|I - \theta P_T^i Q_T|^{\frac{1}{2}}} \exp\left\{ \tfrac{\theta^2}{2} n_T \left(I - \theta P_T^i Q_T\right)^{-1} P_T^i n_T' \right. \\
&\quad \left. + \tfrac{\theta}{2} \int_0^T \left(Tr(P_t^i [Q_t - \tfrac{\Lambda_t^i}{\theta}]) - \tfrac{\delta_t^i}{\theta}\right) dt \right\}, \quad i = 1,2. \qquad (5.121)
\end{aligned}$$

Introduce the Riccati differential equation

$$\begin{aligned}
&\dot{S}_t^i + F_t' S_t^i + S_t^i F_t - S_t^i \left(B_t R_t^1 B_t' - \theta G_t G_t\right) S_t^i \\
&\quad + [Q_t - \tfrac{\Lambda_t^i}{\theta}] = 0, \quad S_T^i = Q_T, i = 1,2. \qquad (5.122)
\end{aligned}$$

Denote by $\tilde{\rho}(AB)$ the spectral radius of AB (where A, B are matrix-valued functions), and define

$$\theta^* \doteq \sup \left\{ \theta;\ P_t^i \geq 0, S_t^i \geq 0\ \forall t \in [0,T],\ \tilde{\rho}(P_t^i S_t^i) < \frac{1}{\theta}\ \forall t \in [0,T] \right\}. \qquad (5.123)$$

Whenever the functions $\Lambda^i(\cdot), \sigma^i(\cdot), \delta^i(\cdot)$ are set to zero, the above equations are identical to the equations associated with determining the optimal control for LEQG tracking problems specified by (3.51)–(3.53) (see [3, 6]).

COROLLARY 5.3 (exact optimal control laws). *Suppose $0 < \theta \leq \theta^*$. The optimal control law corresponding to control system $\Sigma_{E_i}, i = 1,2$, is given by*

$$u^{i,*}(t) = -R_t^{-1} B_t' \left(\Sigma_t^i r_t^i + k_t^{i,\prime}\right) - R_t^{-1} n_t', \quad i = 1,2,$$

where $r^i(\cdot) \equiv r^{i,u^*}(\cdot), P^i(\cdot)$ are given by (5.116), (5.117), *respectively, for $i = 1,2$. Furthermore, the optimal total cost associated with system $\Sigma_{E_i}, i = 1,2$, is given by*

$$J_{\Sigma_{E_i}}^{\theta}(u^{i,*}(\cdot)) = I_{0,T}^i \times \exp \frac{\theta}{2} \left(\Sigma^i(0) r^i(0).r^i(0) + 2k^i(0) r^i(0) + \rho^i(0)\right), \quad i = 1,2,$$

respectively.

Proof. This is a special case of Theorem 5.1. □

Remark 5.4. Proceeding along the lines of the derivation of Corollary 5.3, we could derive the analog of this corollary for the classes of nonlinear control systems identified in Theorem 3.11 under Class 1.

Next, we introduce an example with an explicit optimal control law.

Example 5.5 (control problem with rational polynomial nonlinearities). Suppose we are interested in the stochastic optimal control problem emerging from Example 3.10, Case 2 by setting $\Delta = 2, \alpha = 2$, $\eta = \frac{1}{2}$. Namely,

$$\begin{aligned} dx_t &= x_t dt + \frac{2x_t}{x_t^2 + \frac{1}{2}} dt + u(t,y)dt + dw_t, \qquad x(0) = 0 \in \Re, \\ dy_t &= x_t dt + db_t, \qquad y(0) = 0 \in \Re. \end{aligned} \tag{5.124}$$

The objective is to find the optimal control law $u \in \hat{\mathcal{U}}$ that minimizes the cost function

$$\begin{aligned} J^\theta(u(\cdot)) = E^u \Big\{ &\exp \tfrac{\theta}{2} \left(\int_0^T \left[Qx_t^2 + Ru(t,y)^2 \right] dt + Q_T x_T^2 \right) \\ &\times \exp \left(\int_0^T \left[u(t,y) \tfrac{2x_t}{x_t^2 + \frac{1}{2}} \right] dt + \ln(x_T^2 + \tfrac{1}{2})^{-1} \right) \Big\}. \end{aligned}$$

From Corollary 5.3 we deduce that the optimal control law is given by $u^*(t) = -R^{-1}, \Sigma_t r_t = -R^{-1} \left(1 - \theta S_t P_t\right) S_t r_t$, where $\Sigma(\cdot), S(\cdot), r(\cdot)$ satisfy appropriate equations.

5.2. Nonlinear dynamics integral cost. Control system ($\Sigma_{I_1}^u$). Suppose the dynamics and observations are those given under control system Σ_{E_1} defined by

$$\Sigma_{I_1}^u \doteq \left\{ \Sigma_{E_1}; g_1(t,x) \to g_1(t,x,u) \equiv g^u(t,x), \zeta_t^1 \to \zeta_t^u, \eta_t^1 \to \eta_t^u \right\},$$

and the objective is to minimize over $u \in \hat{\mathcal{U}}$ the cost function

$$\begin{aligned} J_{\Sigma_{I_1}^u}(u(\cdot)) = \tfrac{1}{2} E^u \Big\{ &\tfrac{Q_T x_T . x_T + m_T x_T}{\frac{1}{2}\Delta_T x_T . x_T + \zeta_T^u . x_T + \eta_T^u} \\ &+ \int_0^T \left(\tfrac{Q_t x_t . x_t + R_t u_t . u_t + 2 m_t x_t + 2 n_t u_t}{\frac{1}{2}\Delta_t x_t . x_t + \zeta_t^u . x_t + \eta_t^u} \right) dt \Big\}. \end{aligned}$$

As in section 5.1 we shall show, by using the results of section 4, that the control problem associated with $\Sigma_{I_1}^u$ yields an explicit optimal feedback control law. To this end we introduce the following equations:

$$\dot{\Sigma}_t + \Sigma_t F_t + F_t' \Sigma_t - \Sigma_t B_t R_t^{-1} B_t' \Sigma_t + Q_t = 0, \quad \Sigma_T = Q_T, \tag{5.125}$$

$$\dot{k}_t + k_t \left(F_t - B_t R_t^{-1} B_t' \Sigma_t \right) + m_t + \left(f_t' - n_t R_t^{-1} B_t' \right) \Sigma_t = 0, \quad k_T = m_T, \tag{5.126}$$

$$\dot{\rho}_t + Tr \left(P_t H_t' N_t^{-1} H_t P_t \Sigma_t \right) + 2 k_t f_t - |R_t^{-\frac{1}{2}} \left(B_t' k_t' + n_t' \right)|^2 = 0, \quad \rho_T = 0. \tag{5.127}$$

COROLLARY 5.6 (exact optimal control laws). *The optimal control law corresponding to system $\Sigma_{I_1}^u$ is given by*

$$u^*(t) = -R_t^{-1} B_t' \left(\Sigma_t r_t + k_t' \right) - R_t^{-1} n_t'.$$

Here $\Sigma(\cdot), k(\cdot)$ are given by (5.125), (5.126), *respectively, and $r(\cdot) \equiv r^{u^*}(\cdot)$ is given by*

$$dr_t = F_t r_t dt + f_t dt + B_t u^*(t) dt + P H_t' N_t^{-1} d\hat{b}_t, \qquad r(0) = \xi, \qquad \hat{b}_t \doteq \textit{Wiener process.}$$

Proof. This is a special case of Theorem 5.2. ∎

5.3. Nonlinear dynamics exponential-of-quadratic cost. Now, specialize the cost function (3.91) (i.e., (2.26)) to that corresponding to an exponential-of-integral cost by consider the following family of control systems.

Control system (Σ_{EQ}). Consider the dynamics and observations given by

$$\begin{aligned} dx_t &= (F_t x_t + g(t,x_t) + f_t)\,dt + B_t u(t,y)dt + G_t dw_t, \qquad x(0) \in \Re^n, \\ dy_t &= (H_t x_t + h_t)\,dt + N_t^{\frac{1}{2}} db_t, \qquad y(0) = 0 \in \Re^d. \end{aligned} \tag{5.128}$$

Here

$$g(t,x) = \frac{\gamma_t^1 \exp(\Gamma_2(t,x_t)) - \gamma_t^2 \exp(-\Gamma_2(t,x_t))}{\gamma_t^1 \exp(\Gamma_2(t,x_t)) + \gamma_t^2 \exp(-\Gamma_2(t,x_t))} G_t G_t' (\Delta_t x_t + \zeta_t),$$

$$\Gamma_2(t,x) \doteq \frac{1}{2}\Delta_t x.x + x.\zeta_t + \eta_t,$$

and $\Delta(\cdot), \zeta(\cdot), \eta(\cdot)$ satisfy the equations of Theorem 3.9 under Class 2.

The cost function to be minimized over $u \in \hat{\mathcal{U}}$ is

$$J^\theta_{\Sigma_{EQ}}(u(\cdot)) = E^u \Big\{ \exp\tfrac{\theta}{2} \Big(\int_0^T \Big[Q_s x_s.x_s + R_s u_s.u_s + 2m_s x_s + 2n_s u_s + \tilde{\ell}_1(s,x_s,u_s) \Big] ds + (Q_T x_T.x_T + 2m_T x_T) \Big) \Big\}, \qquad \tilde{\ell}_1(t,x,u) = B(t,u).(G_t' G_t)^{-1} g(t,x),$$

and $Q_t = Q_t' \geq 0, R_t = R_t' > 0$.

Define

$$\begin{aligned} \tilde{\varphi}_1^{EQ}(x,T) \doteq \int_{\Re^n} &\big\{ \gamma_T^1 \exp\big(\tfrac{1}{2}\Delta_T z.z + z.\zeta_T + \eta_T\big) + \gamma_T^2 \exp\big(-\tfrac{1}{2}\Delta_T z.z - z.\zeta_T - \eta_T\big) \big\} \\ &\times \exp\tfrac{\theta}{2}(Q_T z.z + 2m_T z) \times \tfrac{1}{(2\pi)^{\frac{n}{2}} |P_T|^{\frac{1}{2}}} \exp\big(-\tfrac{1}{2} P_T^{-1}(z-x).(z-x)\big)\, dz. \end{aligned} \tag{5.129}$$

As before, we know that the partially observable stochastic control problem Σ_{EQ} is equivalent to the following finite-dimensional, completely observable control problem.

Cost function. Minimize over $u \in \hat{\mathcal{U}}$ the cost function

$$\begin{aligned} J^\theta_{\Sigma_{EQ}}(u(\cdot)) = \hat{E}^u \Big\{ &\tilde{\varphi}_1^{EQ}(r_T,T) \times \exp\Big(\tfrac{\theta}{2} \int_0^T Tr\big(P_s[Q_s - \tfrac{\Lambda_s}{\theta}]\big)\, ds \Big) \\ &\times \exp\Big(\tfrac{\theta}{2} \int_0^T \big(r_s[Q_s - \tfrac{\Lambda_s}{\theta}].r_s + R_s u(s,y).u(s,y) \big)\, ds \Big) \\ &\times \exp\Big(\tfrac{\theta}{2} \int_0^T \big(2r_s.[m_s' - \tfrac{\sigma_s}{\theta}] + 2[n_s u(s,y) - \tfrac{\delta_s}{\theta}] \big)\, ds \Big) \Big\} \end{aligned}$$

subject to the following dynamics.

Observer dynamics.

$$\begin{aligned} dr_t = &\{F_t - P_t(\Lambda_t - \theta Q_t)\} r_t dt + (f_t - P_t \sigma_t)\, dt \\ &+ B_t u(t,y)dt + \theta P_t m_t' dt + P_t H_t' N_t^{-1} d\hat{b}_t^u, \quad r(0) = \xi, \end{aligned} \tag{5.130}$$

$$\begin{aligned} \dot{P}_t = &F_t P_t + P_t F_t' - P_t \big(H_t' N_t^{-1} H_t + \Lambda_t - \theta Q_t \big) P_t \\ &+ G_t G_t', \quad P(0) = P_0. \end{aligned} \tag{5.131}$$

Define

$$Q_T^+ \doteq Q_T + \frac{1}{\theta}\Delta_T, \qquad m_T^+ \doteq m_T + \frac{1}{\theta}\zeta_T, \tag{5.132}$$

$$Q_T^- \doteq Q_T - \frac{1}{\theta}\Delta_T, \qquad m_T^- \doteq m_T - \frac{1}{\theta}\zeta_T, \tag{5.133}$$

$$\tilde{\Sigma}_T^+ \doteq \left(I - \theta P_T Q_T^+\right)^{-1}, \quad \tilde{\Sigma}_T^- \doteq \left(I - \theta P_T Q_T^-\right)^{-1}. \tag{5.134}$$

Use the normalization property of Gaussian densities to deduce

$$\begin{aligned}\tilde{\varphi}_1^{EQ}(x,T) = \hat{\gamma}_T^+ \times \exp\tfrac{\theta}{2}\left(\tilde{\Sigma}_T^+ x.\left(Q_T^+ x + 2m_T^{+,\prime}\right)\right) \\ + \hat{\gamma}_T^- \times \exp\tfrac{\theta}{2}\left(\tilde{\Sigma}_T^- x.\left(Q_T^- x + 2m_T^{-,\prime}\right)\right),\end{aligned} \tag{5.135}$$

where

$$\begin{aligned}\hat{\gamma}_T^+ &= \gamma_T^1 |\tilde{\Sigma}_T^+|^{\frac{1}{2}} \exp\frac{\theta^2}{2}\left(m_T^+ \tilde{\Sigma}_T^+ P_T m_T^{+,\prime} + \eta_T\right), \\ \hat{\gamma}_T^- &= \gamma_T^2 |\tilde{\Sigma}_T^-|^{\frac{1}{2}} \exp\frac{\theta^2}{2}\left(m_T^- \tilde{\Sigma}_T^- P_T m_T^{-,\prime} - \eta_T\right).\end{aligned}$$

Denoting the optimal cost-to-go corresponding to the total cost $J^{\theta}_{\Sigma_{EQ}}(u(\cdot))$ by $S_{EQ}(\cdot)$ and defining

$$I_{t,T}^{EQ} \doteq \exp\frac{\theta}{2}\left\{\int_t^T Tr\left(P_s\left[Q_s - \frac{\Lambda_s}{\theta}\right]\right) ds\right\}$$

for each $u \in \hat{\mathcal{U}}$, the cost-to-go is now given as follows.

Exponential-of-integral cost-to-go.

$$\begin{aligned}S_{EQ}(r,t) = \tfrac{1}{I_{t,T}^{EQ}} \inf_{u\in\hat{\mathcal{U}}} \hat{E}^u \left\{\tilde{\varphi}_1^{EQ}(r_T,T) \times \exp\tfrac{\theta}{2}\left(\int_t^T r_s[Q_s - \tfrac{\Lambda_s}{\theta}].r_s ds\right)\right. \\ \left. \times \exp\tfrac{\theta}{2}\left(\int_t^T \left(R_s u_s.u_s + 2r_s.[m_s - \tfrac{\sigma_s}{\theta}] + 2[n_s u_s - \tfrac{\delta_s}{\theta}]\right) ds\right) |\mathcal{F}_{0,t}^y\right\}\end{aligned} \tag{5.136}$$

subject to observer dynamics given as follows.

Observer dynamics.

$$\begin{aligned}dr_t = \left\{F_t - P_t\left(\Lambda_t - \theta Q_t\right)\right\} r_t dt + \left(f_t - P_t\sigma_t\right) dt \\ + B_t u(t,y) dt + \theta P_t m_t' dt + P_t H_t' N_t^{-1} d\hat{b}_t^u, \quad r(0) = \xi.\end{aligned} \tag{5.137}$$

Formally, the function $S_{EQ}(\cdot)$ satisfies the second-order HJ equations

$$\begin{aligned}\tfrac{\partial}{\partial t} S_{EQ}(r,t) + \tilde{A}^{\theta}(t) S_{EQ}(r,t) \\ + \tfrac{\theta}{2}\left\{r[Q - \tfrac{\Lambda}{\theta}].r + 2r.[m' - \tfrac{\sigma}{\theta}] - 2\tfrac{\delta_s}{\theta}\right\} S_{EQ}(r,t) \\ + \mathcal{H}^{\theta}(r, D_r S_{EQ}(r,t), D_r S_{EQ}(r,t)) = 0, \qquad \Re^n \times [0,T),\end{aligned} \tag{5.138}$$

with terminal condition

$$\begin{aligned}S_{EQ}(r,T) = \tilde{\varphi}_1^{EQ}(r,T) = \hat{\gamma}_T^+ \times \exp\tfrac{\theta}{2}\left(\tilde{\Sigma}_T^+ r.\left(Q_T^+ r + 2m_T^{+,\prime}\right)\right) \\ + \hat{\gamma}_T^- \times \exp\tfrac{\theta}{2}\left(\tilde{\Sigma}_T^- r.\left(Q_T^- r + 2m_T^{-,\prime}\right)\right).\end{aligned} \tag{5.139}$$

Here

$$\tilde{F}_t \doteq F_t - P_t\left(\Lambda_t - \theta Q_t\right), \qquad \tilde{\alpha}_t \doteq P_t H_t' N_t^{-1} H_t P_t,$$

and for $\Phi \in C_x^2(\Re^n)$

$$\tilde{A}^\theta(t)\Phi(x) = \frac{1}{2}Tr\left(\tilde{\alpha}_t D_x^2\Phi(x)\right) + \left(\tilde{F}_t x + \theta P_t m_t' + f_t - P_t\sigma_t\right).D_x\Phi(x),$$
$$\mathcal{H}^\theta(x,p,s) = \inf_{u\in\Re^m}\left\{p.Bu + \frac{\theta}{2}\left(Ru.u + 2nu\right)s\right\}.$$

Hence, the total optimal cost corresponding to control system Σ_{EQ} is obtained from

$$J^\theta_{\Sigma_{EQ}}(u^*(\cdot)) = \inf_{u\in\hat{\mathcal{U}}} J^\theta_{\Sigma_{EQ}}(u(\cdot)) = I^{EQ}_{0,T}S_{EQ}(r(0),0). \tag{5.140}$$

If the terminal condition $S_{EQ}(T,r)$ is an exponential-of-quadratic function of r, the above HJ equations can be solved explicitly to yield optimal controls which are of linear feedback form. Several attempts to solve explicitly the HJ equation (5.138), (5.139) have been unsuccessful. For this reason we shall seek suboptimal control laws.

COROLLARY 5.7. *Consider the HJ equation* (5.138), (5.139) *corresponding to the control system* Σ_{EQ}*, and suppose*

$$\begin{gathered} m = 0, \quad \eta = 0, \quad \zeta = 0, \quad \Delta_T \geq 0, \\ Q_T - \tfrac{1}{\theta}\Delta_T \geq 0, \quad I - \theta P_T(Q_T + \tfrac{1}{\theta}\Delta_T) > 0, \quad \theta > 0. \end{gathered} \tag{5.141}$$

Denoting by $S_{EQ^-}, S_{EQ}, S_{EQ^+}$ *the solutions of* (5.138) *corresponding to the terminal cost functions* $\tilde{\varphi}_1^{EQ^+}, \tilde{\varphi}_1^{EQ}, \tilde{\varphi}_1^{EQ^-}$*, respectively, defined by*

$$\tilde{\varphi}_1^{EQ^+}(x,P_T) \doteq \left(\hat{\gamma}_T^+ + \hat{\gamma}_T^-\right) \times \exp\frac{\theta}{2}\left(x.\tilde{\Sigma}_T^+ Q_T^+ x\right), \tag{5.142}$$

$$\tilde{\varphi}_1^{EQ}(x,P_T) \doteq \hat{\gamma}_T^+ \times \exp\frac{\theta}{2}\left(x.\tilde{\Sigma}_T^+ Q_T^+ x\right) + \hat{\gamma}_T^- \times \exp\frac{\theta}{2}\left(x.\tilde{\Sigma}_T^- Q_T^- x\right), \tag{5.143}$$

$$\tilde{\varphi}_1^{EQ^-}(x,P_T) \doteq \left(\hat{\gamma}_T^+ + \hat{\gamma}_T^-\right) \times \exp\frac{\theta}{2}\left(x.\tilde{\Sigma}_T^- Q_T^- x\right), \tag{5.144}$$

where

$$\hat{\gamma}_T^+ = \gamma_T^1|\tilde{\Sigma}_T^+|^{\frac{1}{2}}, \qquad \hat{\gamma}_T^- = \gamma_T^2|\tilde{\Sigma}_T^-|^{\frac{1}{2}},$$

we have the following bounds:

$$S_{EQ^-}(r,t) \leq S_{EQ}(r,t) \leq S_{EQ^+}(r,t) \qquad \forall (r,t) \in \Re^n \times [0,T]. \tag{5.145}$$

Furthermore,

$$I^{EQ}_{0,T}S_{EQ^-}(r(0),0) \leq J^\theta_{\Sigma_{EQ}}(u^*(\cdot)) \leq I^{EQ}_{0,T}S_{EQ^+}(r(0),0), \tag{5.146}$$

and the suboptimal control laws obtained by solving the HJ equations associated with S_{EQ^-}, S_{EQ^+} *are similar to that of the LEQG tracking problem.*

Proof. This is a direct consequence of Theorem 5.1, part II, which is obtained as follows: from (5.135) and (5.141) we deduce (5.143). Using (5.132)–(5.135) and (5.141) we deduce

$$\begin{gathered} Q_T^+ \geq Q_T^-, \qquad \tilde{\Sigma}_T^+ \geq \tilde{\Sigma}_T^-, \\ \tilde{\varphi}_1^{EQ^-}(r,T) \leq \tilde{\varphi}_1^{EQ}(r,T) = S_{EQ}(r,T) \leq \tilde{\varphi}_1^{EQ_2^+}(r,T). \end{gathered} \tag{5.147}$$

From the theory of dominating solutions of PDEs we derive (5.145). Consequently, we establish (5.146). ∎

Remark 5.8. Lower and upper bounds, such as the ones derived above, can be derived for other nonlinear drift terms $g(\cdot)$ which admit finite-dimensional solutions of the Feynman–Kac information state equation.

6. Conclusion. In general, nonlinear partially observable stochastic optimal control problems have an infinite-dimensional state space. In this paper we have presented an approach for treating systems with nonlinearities which enter the unobservable dynamics as gradients of potential functions, and the observations as quadratic functions, of the unobservable state. When the observations are linear in the unobservable state, sufficient conditions are given to compute optimal control laws explicitly, along the lines of LEQG/LQG tracking problems.

When the cost function is either quadratic or an exponential-of-quadratic function of x and u, we have shown that finite-dimensional sufficient statistics are available, provided the nonlinearities entering the unobservable dynamics are gradients of potential functions and satisfy a generalized version of the Riccati equation. In addition, suboptimal linear feedback control laws are derived for nonlinearities satisfying "sector criteria."

Acknowledgments. The work of this paper arose from the authors' discussion concerning related work pursued independently, at the 33rd IEEE Conference on Decision and Control (1994). The anonymous referees and the associate editor, Professor S. Shreve, have provided several suggestions which improved both the presentation and the technical content of this manuscript.

A FREE BOUNDARY PROBLEM IN $\mathbb{R}^d$ WITH BOTH SMOOTH AND NONSMOOTH FIT*

J. R. DORROH† AND GUILLERMO FERREYRA†

Abstract. A deterministic infinite-horizon singular control problem with unbounded control set is solved completely. The methods used here are those of dynamic programming and viscosity solutions. The novelty is that the value function is convex, C^1 along a piece of the free boundary and not C^1 along another piece of it.

Key words. singular control, viscosity solution, Bellman equation, smooth fit

1. Introduction. We consider the following optimal control problem. Let $d \geq 2$ and let A_d be the space of antisymmetric $d \times d$ matrices a endowed with the norm $|a| = \sqrt{\frac{1}{2}\text{trace}(aa')}$, where a' denotes the transpose of a. The system to be controlled is the bilinear system

$$\dot{x} = a(t)x, \qquad x(0) = x \in \mathbb{R}^d, \tag{1.1}$$

where the control $a(\cdot) \in \mathcal{A}_d$, the space of measurable functions of time valued in A_d. The cost function is defined by

$$v^a(x) = \int_0^\infty e^{-t} \left[\langle x(t), b\rangle + |a(t)|\right] dt, \tag{1.2}$$

where $b \in \mathbb{R}^d \setminus \{0\}$ is fixed throughout and $\langle \cdot, \cdot \rangle$ is the inner product in $\mathbb{R}^d$, and the value function is

$$v(x) = \inf\{v^a(x) \colon a(\cdot) \in \mathcal{A}_d\}. \tag{1.3}$$

We show that v is a convex, Lipschitz viscosity solution of the *free boundary problem*

$$\max(u(x) - \langle b, x\rangle, \lambda(x, \nabla u(x)) - 1) = 0, \qquad x \in \mathbb{R}^d, \tag{1.4}$$

where $\langle \cdot, \cdot \rangle$ denotes the euclidean inner product on $\mathbb{R}^d$ and

$$\lambda(x, p) = |x|\,|p| \sin\theta, \tag{1.5}$$

with θ the angle between x and p. We shall see that the free boundary—the hypersurface where both terms in (1.4) equal zero—consists of two $(d-1)$-dimensional manifolds F_0 and F_1. The manifold F_0 is part of the cylinder in $\mathbb{R}^d$ with axis through b and defining equation

$$\lambda(x, b) = 1. \tag{1.6}$$

*Received by the editors April 3, 1996; accepted for publication (in revised form) January 8, 1997. http://www.siam.org/journals/sicon/36-2/30144.html

†Department of Mathematics, Louisiana State University, Baton Rouge, LA 70808 (dorroh@math.lsu.edu, ferreyra@math.lsu.edu).

The manifold F_1 is harder to describe; that is done in section 3. The value function is C^1 along F_0 but it is not C^1 along F_1. Besides this, the value function is not C^1 along a ray L in the direction of b; see Figure 2. We will also show that the optimal control is either zero or impulsive. In this problem optimal impulsive controls have delicate behavior. In fact, in the region J where the optimal control is impulsive, the optimal trajectories jump along integral curves of (1.1) determined by the feedback control

$$\mathbf{a}(x(t)) = x(t) \wedge \nabla v(x(t)).$$

These control functions turn out to be constant along the trajectories they determine. When we let $x(0)$ vary in J, the optimal impulsive trajectories end up along all of F_0, the only part of the free boundary along which the value function is C^1. The methods used in this paper are those of dynamic programming and viscosity solutions of the Bellman equation. These methods were also used in [8]. The remarkable difference between the behavior of the value function along the free boundary in [8] and that presented here is the existence in our case (1.1)–(1.4) of the piece of the free boundary F_1 along which the value function is not C^1. Moreover, our value function is convex. All stochastic singular control problems with a convex value function found in the literature (see [11, p. 332]) possess the additional property that the value function is C^2 (smooth fit property) along the free boundary. We conjecture that stochastic versions of our problem can provide examples of stochastic singular control problems with a convex value function and nonsmooth fit. Other work dealing with the question of smooth fit can be found in [1], [5], [6], [9], [10], [15], [16], and [17]. The problem (1.1)–(1.4) is somewhat related to the euclidean elastica problem (cf. [13]) if one remembers that the Frenet–Serret formulas for curves in $\mathbb{R}^3$ are a bilinear system with an antisymmetric matrix, as is (1.1) (cf. [2, p. 303]). In such a case, the control system (1.1) describes general smooth curves in $\mathbb{R}^3$ with the matrix $a(t)$ controlling the curvature and the torsion of the curve. The elastica problem is finite horizon with $b = 0$.

2. Derivation of the Bellman equation. If $\xi \in \mathbb{R}^d$, then $|\xi|$ denotes its euclidean length, if $a \in A_d$, then $|a|^2 = \frac{1}{2}\text{trace}(aa') = \sum_{i<j} a_{ij}^2$, and if $a(\cdot) \in \mathcal{A}_d$, then $||a(\cdot)|| = \text{ess sup}\{|a(t)|\colon t \geq 0\}$.

If ξ, η are two vectors in $\mathbb{R}^d \setminus \{0\}$, then the angle between them is given by $\theta = \cos^{-1}(\langle \xi/|\xi|, \eta/|\eta| \rangle) \in [0, \pi]$.

The wedge product $\xi \wedge \eta$ is the antisymmetric $n \times n$ matrix defined by

$$\xi \wedge \eta = \xi\eta' - \eta\xi',$$

and we have

$$\begin{aligned} |\xi \wedge \eta|^2 &= \frac{1}{2}\text{trace}((\xi \wedge \eta)(\xi \wedge \eta)') \\ &= \sum_{i<j} (\xi_i\eta_j - \xi_j\eta_i)^2. \end{aligned}$$

An easy computation shows that $|\xi \wedge \eta|^2 + |\langle \xi, \eta \rangle|^2 = |\xi|^2|\eta|^2$ and hence $|\xi \wedge \eta| = |\xi|\,|\eta| \sin\theta = \lambda(\xi, \eta)$, where θ is the angle between ξ and η.

For $\epsilon > 0$ set

$$v_\epsilon(x) = \inf\{v^a(x)\colon\ \epsilon||a(\cdot)|| \leq 1, a(\cdot) \in \mathcal{A}_d\}.$$

Then an easy approximation argument shows that

$$v(x) = \inf_{\epsilon>0} v_\epsilon(x). \tag{2.1}$$

LEMMA 1. *$v_\epsilon \to v$ uniformly on compact subsets of $\mathbb{R}^d$ as $\epsilon \downarrow 0$ and v, v_ϵ are convex and Lipschitz on $\mathbb{R}^d$ with Lipschitz constant $|b|$ for all $\epsilon > 0$. Moreover, $v(x)$ and $v_\epsilon(x)$ are bounded above by $\langle b, x\rangle$ and below by $-|b|\,|x|$.*

Proof. Let $\Phi(t,s)$ denote the fundamental solution of (1.1) corresponding to a given control $a(\cdot)$. Since $(d/dt)|x(t)|^2 = 2\langle x(t), a(t)x(t)\rangle = 0$, we have $|x(t)| = |x|$, which yields $||\Phi(t,0)|| = 1$ (operator norm). Since

$$\nabla v^a(x) = \int_0^\infty e^{-t}\Phi'(t,0)b\,dt,$$

it follows that $|\nabla v^a(x)| \le |b|$. Since v and v_ϵ are infima of v^a, they are Lipschitz with constant $|b|$.

Let $a(\cdot)$ be a bounded control and suppose $x_\epsilon \to x$. Then

$$v^a(x) = \limsup_{\epsilon\downarrow 0} v^a(x_\epsilon) \ge \limsup_{\epsilon\downarrow 0} v_\epsilon(x_\epsilon),$$

and so $v(x) \ge \limsup_{\epsilon\downarrow 0} v_\epsilon(x_\epsilon)$. By (2.1) we have

$$\liminf_{\epsilon\downarrow 0} v_\epsilon(x_\epsilon) \ge \liminf_{\epsilon\downarrow 0} v(x_\epsilon) \ge v(x).$$

This establishes continuous convergence. Then the local uniform convergence follows; see [4, p. 268]. The last part follows from the fact that $v^0(x) = \langle b, x\rangle$ for all x and from $v(0) = 0$.

Finally, to prove that v is convex, let $\alpha \in [0,1]$ and let $x^\alpha = (1-\alpha)x^0 + \alpha x^1$ be a convex combination of initial states for (1.1). Let $\epsilon > 0$ and let $a_i(\cdot)$ be controls satisfying $v^{a_i}(x^i) \le v(x^i) + \epsilon, i = 0, 1$. Let $a_\alpha = (1-\alpha)a_0 + \alpha a_1$. Then the corresponding solutions of (1.1) satisfy $x^\alpha(t) = (1-\alpha)x^0(t) + \alpha x^1(t)$, and the convexity of (1.2) implies

$$\begin{aligned} v(x^\alpha) &\le v^{a_\alpha}(x^\alpha) \le (1-\alpha)v^{a_0}(x^0) + \alpha v^{a_1}(x^1) \\ &\le (1-\alpha)v(x^0) + \alpha v(x^1) + \epsilon. \end{aligned}$$

Since ϵ was arbitrary, this proves that v is convex. □

We now derive the Bellman equation satisfied by v_ϵ. For the concept of "viscosity solution," see [3].

LEMMA 2. *For all $\epsilon > 0$, v_ϵ is a viscosity solution of*

$$\frac{1}{\epsilon}H(x, \nabla v_\epsilon) + v_\epsilon - \langle x, b\rangle = 0, \qquad x \in \mathbb{R}^d, \tag{2.2}$$

where

$$\begin{aligned} H(x,p) &= \sup\{-\langle ax, p\rangle - |a| \colon\ |a| \le 1, a \in A_d\} \\ &= (|p \wedge x| - 1)^+ = (\lambda(x,p) - 1)^+. \end{aligned} \tag{2.3}$$

Proof. We start with the dynamic programming principle [11], which states that for each $T > 0$

$$v_\epsilon(x) = \inf\left\{\int_0^T e^{-t}[\langle x(t), b\rangle + |a(t)|]dt + e^{-T}v_\epsilon(x(T))\right\}, \tag{2.4}$$

where the infimum is over all controls $a(\cdot) \in \mathcal{A}_d$ satisfying $\epsilon||a(\cdot)|| \le 1$.

Now suppose $\phi \in C^1(\mathbb{R}^d)$ and $x \in \mathbb{R}^d$ with $\phi(x) = v_\epsilon(x)$ and $v_\epsilon - \phi \leq 0$ near x. Then (2.4) yields for all constant $a \in A_d$ satisfying $\epsilon|a| \leq 1$,

$$\phi(x) \leq \int_0^T e^{-t} \left[\langle x(t), b\rangle + |a|\right] dt + e^{-T}\phi(x(T)),$$

which implies by the chain rule and the fundamental theorem of calculus

$$0 \leq \frac{1}{T}\int_0^T e^{-t} \left[\langle x(t), b\rangle + |a| - \phi(x(t)) + \langle \nabla\phi(x(t)), ax(t)\rangle\right] dt;$$

letting $T \downarrow 0$ and taking the supremum over a we obtain

$$\frac{1}{\epsilon}H(x, \nabla\phi(x)) + \phi(x) - \langle b, x\rangle \leq 0.$$

On the other hand, suppose x and $\phi \in C^1(\mathbb{R}^d)$ are such that $\phi(x) = v_\epsilon(x)$ and $v_\epsilon - \phi \geq 0$ near x. Since

$$\sup_{\epsilon||a||\leq 1} \left(\sup_{0\leq t\leq T} |x(t) - x|\right) \to 0 \qquad \text{as } T \downarrow 0, \tag{2.5}$$

(2.4) implies, for $T > 0$ sufficiently small,

$$0 \geq \inf_{\epsilon||a||\leq 1} \left\{\frac{1}{T}\int_0^T e^{-t} \left[\langle x(t), b\rangle + |a(t)| - \phi(x(t)) + \langle \nabla\phi(x(t)), a(t)x(t)\rangle\right] dt\right\}.$$

Now (2.5) allows us to pass to the limit $T \downarrow 0$ and obtain

$$\frac{1}{\epsilon}H(x, \nabla\phi(x)) + \phi(x) - \langle b, x\rangle \geq 0.$$

The maximization in (2.3) is carried out as follows. Let

$$f(a) = -\langle ax, p\rangle - |a| = \sum_{i<j} a_{ij}(x_i p_j - x_j p_i) - |a|.$$

Then by the Cauchy–Schwarz inequality

$$f(a) \leq |a|(|x \wedge p| - 1).$$

Therefore, if $|x \wedge p| \leq 1$, we have $\max f(a) = 0$, attained (not uniquely) at $a = 0$. If $|x \wedge p| > 1$, then $\max f(a) = |x \wedge p| - 1$, attained (uniquely) when

$$a_{ij} = \frac{x_i p_j - x_j p_i}{|x \wedge p|}. \qquad \square$$

THEOREM 1. *v is a Lipschitz viscosity solution of* (1.4).

Proof. Lemma 1 states that v is Lipschitz. Let $x \in \mathbb{R}^d$ and $\phi \in C^1$ be such that $v - \phi$ has a local maximum at x. Then [3, Theorem 1.1, Lemma 1.1] there exists $x_\epsilon \to x$ such that $v_\epsilon - \phi$ has a local maximum at x_ϵ. This implies, by (2.2),

$$\frac{1}{\epsilon}H(x_\epsilon, \nabla\phi(x_\epsilon)) + v_\epsilon(x_\epsilon) - \langle x_\epsilon, b\rangle \leq 0.$$

Since $H \geq 0$ we obtain $v_\epsilon(x_\epsilon) - \langle x_\epsilon, b\rangle \leq 0$; letting $\epsilon \downarrow 0$ yields $v(x) - \langle x, b\rangle \leq 0$. Also multiplying by ϵ and sending $\epsilon \downarrow 0$ yields $H(x, \nabla\phi(x)) \leq 0$. By Lemma 2, we obtain $\lambda(x, \nabla\phi(x)) - 1 \leq 0$. Thus v is a subsolution of (1.4).

Let x and $\phi \in C^1$ be such that $v - \phi$ has a local minimum at x. Choose [3] $x_\epsilon \to x$ such that $v_\epsilon - \phi$ has a local minimum at x_ϵ. Then by (2.2)

$$\frac{1}{\epsilon} H(x_\epsilon, \nabla\phi(x_\epsilon)) + v_\epsilon(x_\epsilon) - \langle x_\epsilon, b\rangle \geq 0.$$

Now if $v(x) - \langle x, b\rangle \geq 0$ then v is a supersolution of (1.4). If not, then it follows that $H(x_\epsilon, \nabla\phi(x_\epsilon)) > 0$, which by Lemma 2 implies $\lambda(x_\epsilon, \nabla\phi(x_\epsilon)) - 1 > 0$, which yields in the limit $\lambda(x, \nabla\phi(x)) - 1 \geq 0$. Thus v is a supersolution of (1.4). □

3. Solution of the free boundary problem. In this section we explicitly construct a candidate value function U that is Lipschitz on $\mathbb{R}^d$ and that solves (1.4) in the classical sense except for lower-dimensional submanifolds of $\mathbb{R}^d$. To gain some intuition on the construction of U, note that from (1.2) we can deduce that if a nonzero control $a(\cdot)$ is optimal along a piece of a trajectory of (1.1), then the inner product $\langle x(\cdot), b\rangle$ must not increase along $x(\cdot)$ and, in the regions where $a = 0$ is optimal, $\langle x(\cdot), b\rangle$ should not be too large. The construction of U is divided into three steps.

Step 1. Let D be the closed region bounded by the half of the cylinder (1.6) in the direction of $-b$:

$$D = \{x \in \mathbb{R}^d \colon \langle x, b\rangle \leq 0, \lambda(x, b) \leq 1\},$$

and let F_0 be the part of the boundary of D where $\lambda(x, b) = 1$. Then F_0 is a half-cylinder. Define

$$U(x) = \langle x, b\rangle, \qquad x \in D. \tag{3.1}$$

Then U is a classical solution of (1.4) in the interior of D. Up to this point there is no justification for the requirement $\langle x, b\rangle \leq 0$ that we put in the definition of D. In fact, below, we will define $U(x) = \langle x, b\rangle$ in a region strictly larger than D.

Step 2. We try to define U outside of D using the method of characteristics [12, Ch. 1, section 7], [7, section 35.1]. The problem is to solve $\lambda(x, \nabla u) = 1$ with boundary condition $u(x) = \langle x, b\rangle$ on F_0.

Since $\lambda \in C^\infty((\mathbb{R}^d \setminus \{0\}) \times (\mathbb{R}^d \setminus \{0\}))$, the flow α_t of the Hamiltonian vector field

$$\begin{aligned} X_\lambda &= \langle \nabla_p \lambda, \nabla_x\rangle - \langle \nabla_x \lambda, \nabla_p\rangle \\ &= \frac{\langle |x|^2 p - \langle x, p\rangle x, \nabla_x\rangle - \langle |p|^2 x - \langle x, p\rangle p, \nabla_p\rangle}{|x \wedge p|} \end{aligned}$$

is well defined.

Let $x_0 \in F_0$, let $\frac{\pi}{2} \leq \theta < \pi$ be the angle between x_0 and b, and let $\Gamma(x_0)$ denote the Hamiltonian trajectory segment $\Gamma(x_0) = \{\alpha_t(x_0, b) : 0 \leq t < \theta\}$. These are curves in phase (x, p)-space whose projections $\Gamma_1(x_0)$ onto position x-space are drawn in Figure 1.

Although the Hamiltonian trajectory segments, being integral curves of the C^∞ vector field X_λ, cannot intersect, their projections onto x-space, the characteristics, can and do in fact intersect. As we shall see below, the locus of points of intersections of the closures of the projections of $\Gamma(x_0)$ is a ray in the direction of b.

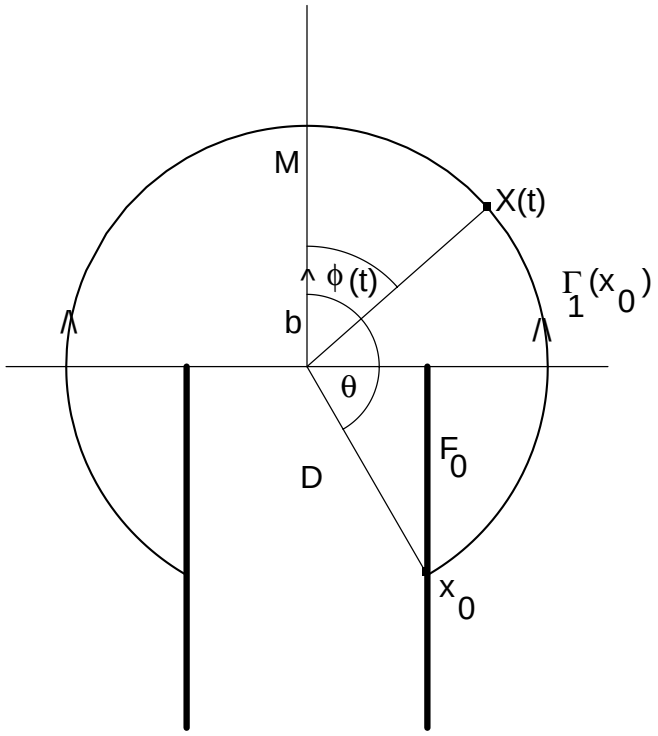

FIG. 1.

Recall that the *Poisson bracket* of λ and $\beta = \beta(x,p)$,

$$\{\lambda,\beta\} = X_\lambda(\beta) = \langle \nabla_p\lambda, \nabla_x\beta\rangle - \langle \nabla_x\lambda, \nabla_p\beta\rangle,$$

vanishes if and only if the function β is a constant of the motion; see [7, section 34.2]. In particular, λ is a constant of the motion and hence $\lambda(x,p) = |x \wedge p| = 1$ on $\Gamma(x_0)$ for all $x_0 \in F_0$. Other constants of the motion are $\langle x,p\rangle$, $|x|$, $|p|$, and each entry $(x_ip_j - x_jp_i)$ of the matrix $x \wedge p$. Thus, $\Gamma_1(x_0)$ is contained on the sphere with center at the origin and radius $|x_0|$.

Next, determine $\Gamma(x_0)$ explicitly for $x_0 \in F_0$. The trajectory $(X(t),P(t)) = \alpha_t(x_0,b)$ starting from (x_0,b) satisfies

$$\begin{aligned} \dot{x}(t) &= -Ax(t) + Bp(t), \qquad x(0) = x_0, \\ \dot{p}(t) &= -Cx(t) + Ap(t), \qquad p(0) = \nabla u(x_0) = b, \end{aligned}$$

where $A = \langle x(t), p(t)\rangle$, $B = |x(t)|^2$, and $C = |p(t)|^2$ are constants.

Then

$$\begin{aligned} X(t) &= (\cos t - A\sin t)\, x_0 + B(\sin t)\, b, \\ P(t) &= -C(\sin t)\, x_0 + (\cos t + A\sin t)\, b. \end{aligned} \tag{3.2}$$

Note that $X(\cdot)$ stays in the plane determined by the vectors b and x_0. Now take the inner product of the first of the pair (3.2) with b and divide throughout by $|X(t)|\,|b|$. Let $\phi(t)$ denote the angle between $X(t)$ and b. Using $|x_0 \wedge b| = 1$ and $\sin\theta = \frac{|x_0 \wedge b|}{|x_0|\,|b|}$

we obtain

$$\begin{aligned}\cos\phi(t) &= \frac{\langle X(t),b\rangle}{|X(t)|\,|b|} = \frac{\cos t\langle x_0,b\rangle + \sin t(-A\langle x_0,b\rangle + B\langle b,b\rangle)}{|x_0|\,|b|}\\ &= \cos t\frac{\langle x_0,b\rangle}{|x_0|\,|b|} + \sin t\frac{(-|\langle x_0,b\rangle|^2 + |x_0|^2\,|b|^2)}{|x_0|\,|b|}\\ &= \cos t\,\cos\theta + \sin t\frac{|x_0\wedge b|^2}{|x_0|\,|b|} = \cos t\,\cos\theta + \sin t\,\sin\theta\\ &= \cos(\theta - t).\end{aligned}$$

Hence $\phi(t) = \theta - t, 0 \le t < \theta$. Thus, space trajectories intersect when $\phi(t) = 0$ or along a ray in the direction of b. Finally, by the method of characteristics, the solution $\hat{U}$ of $\lambda(x,\nabla u) = 1$ satisfies

$$\frac{d}{dt}\hat{U}(X(t)) = \langle \nabla_p\lambda(X(t),P(t)),P(t)\rangle = \lambda^2(X(t),P(t)) = 1.$$

Here we use $\hat{U}$, because to define U, we intend to restrict the domain further. Since $U(x_0) = \langle x_0,b\rangle$ then

$$\hat{U}(X(t)) = t + \langle x_0,b\rangle, \qquad 0 \le t < \theta. \tag{3.3}$$

To express $\hat{U}$ in terms of $X(t)$ note that since $x_0 \in F_0$ then $\theta = \pi - \sin^{-1}(\frac{1}{|b|\,|X(t)|})$, and $|b|^2|X(t)|^2\cos^2(\theta) = |b|^2|X(t)|^2(1-\sin^2(\theta)) = |b|^2|X(t)|^2 - 1$. Therefore, writing x instead of $X(t)$ and ϕ instead of $\phi(t)$

$$\begin{aligned}\hat{U}(x) &= \theta - \phi + |b|\,|x|\cos\theta\\ &= \pi - \sin^{-1}\left(\frac{1}{|b|\,|x|}\right) - \phi - \sqrt{|b|^2|x|^2 - 1}.\end{aligned}$$

Step 3. There is an additional $(d-1)$-dimensional switching manifold F_1 defined by

$$F_1 = \{x \in \mathbb{R}^d : \hat{U}(x) = \langle x,b\rangle \ge 0\}.$$

To analyze F_1, let

$$\begin{aligned}S(r,\phi) &= \hat{U}(x) - \langle x,b\rangle\\ &= \pi - \sin^{-1}\left(\frac{1}{|b|r}\right) - \phi - \sqrt{|b|^2r^2 - 1} - |b|r\cos\phi,\end{aligned} \tag{3.4}$$

where $r = |x|$. Then F_1 is defined implicitly by $S(r,\phi) = 0, 0 \le \phi \le \frac{\pi}{2}$. Now, $S(r,\phi) \ge \pi - \sin^{-1}(\frac{1}{|b|r}) - \phi$ and $r \le \frac{1}{|b|\sin\phi}$ on F_1. Moreover, for $0 \le \phi < \frac{\pi}{2}$ we have $\frac{dr}{d\phi} = -\frac{S_\phi}{S_r}$, where

$$\begin{aligned}S_\phi &= -1 + |b|r\sin\phi \le 0,\\ S_r &= r^{-1}(-\sqrt{|b|^2r^2 - 1} - |b|r\cos\phi).\end{aligned} \tag{3.5}$$

It follows from (3.4), (3.5), and elementary calculations that $S(r,\phi) = 0$ has a unique solution $r = R(\phi), 0 \le \phi \le \frac{\pi}{2}$, that $\frac{1}{|b|} \le R(\phi) \le \frac{1}{|b|\sin\phi}$, and that $R'(\phi) < 0$ on $[0,\frac{\pi}{2})$ so that $R(\cdot)$ is strictly decreasing on $[0,\frac{\pi}{2}]$. Now define the closed regions

$$E = \{x \in \mathbb{R}^d\colon \langle x,b\rangle \ge 0, |x| \le R(\phi)\}, \qquad N = D \cup E, \qquad J = \mathbb{R}^d \setminus \text{interior}(N)$$

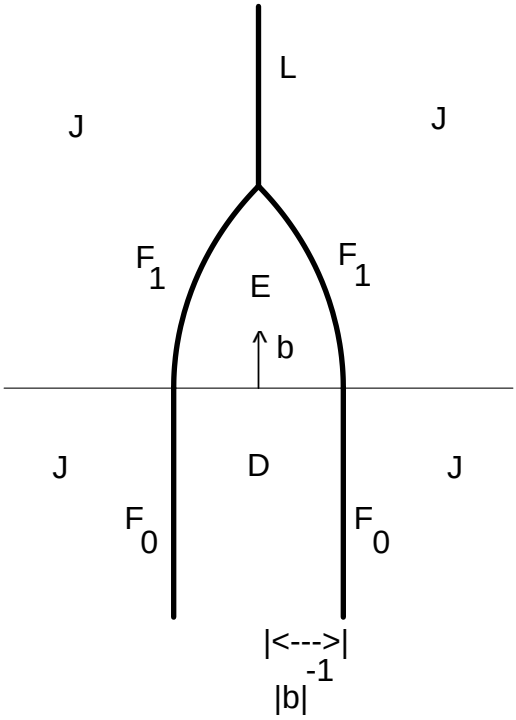

FIG. 2.

and let

$$U(x) = \langle x, b\rangle, \qquad x \in N,$$
$$U(x) = \hat{U}(x), \qquad x \in J. \tag{3.6}$$

Finally, let $L = \{rb/|b| : r \in [r_0, \infty)\}$, with $r_0 = R(0)$, be the ray where the projections Γ_1 intersect. See Figure 2.

Then we have proved the following theorem.

THEOREM 2. *There is a Lipschitz function U on $\mathbb{R}^d$ such that*
(1) *U is $C^{1,1}$ on $\mathbb{R}^d \setminus (F_1 \cup L)$,*
(2) *U is C^∞ on $\mathbb{R}^d \setminus (F_0 \cup F_1 \cup L)$,*
(3) *$\lambda(x, \nabla U) < 1$ in the interior of N,*
(4) *$\lambda(x, \nabla U) = 1$ on the complement of $N \cup L$,*
(5) *$U(x) < \langle x, b\rangle$ on the complement of N,*
(6) *$U(x) = \langle x, b\rangle$ on N;*
in particular, U is a classical solution of (1.4) *on $\mathbb{R}^d \setminus (F_1 \cup L)$.*

4. Equality of U and v.

THEOREM 3. *$U = v$ on $\mathbb{R}^d$.*

Proof. We first show that $v(x) \geq U(x)$ for all $x \in \mathbb{R}^d$. To this end, it is enough to establish $v^a(x) \geq U(x)$ for all bounded controls $a(\cdot)$.

Let $a(\cdot)$ be an arbitrary bounded control and let $x(\cdot)$ denote the solution trajectory of (1.1) starting from x. Since $U(\cdot)$ is Lipschitz and $x(\cdot)$ is absolutely continuous, then

$t \to e^{-t}U(x(t))$ equals the integral of its derivative, and hence

$$e^{-T}U(x(T)) = U(x) + \int_0^T e^{-t}\left(-U(x(t)) + \frac{d}{dt}U(x(t))\right)\,dt \tag{4.1}$$

for all $T > 0$. Let E_0 denote the set of all t such that $x(t) \notin (F_1 \cup L)$, and let E_1 denote the set of all t such that $x(t) \in (F_1 \cup L)$. We have

$$\frac{d}{dt}U(x(t)) = \langle \nabla U(x(t)), a(t)x(t)\rangle$$

almost everywhere (a.e.) for $t \in E_0$, and we will show that $(d/dt)U(x(t)) = 0$ a.e. for $t \in E_1$.

Let E_2 denote the set of all $t \in E_1$ such that $U(x(\cdot))$ is differentiable at t. Since $U(x(\cdot))$ is absolutely continuous, then $E_1 \setminus E_2$ has measure 0. Since each orbit of (1.1) is contained in a sphere centered at the origin (see the proof of Lemma 1), then no orbit intersects both L and $F_1 \setminus L$. ($L \cap F_1$ consists of a single point.)

If the orbit intersects L, then it intersects it in a single point, so that $U(x(\cdot))$ is constant on E_2, and thus has derivative 0 at any $t \in E_2$ that is an accumulation point of E_2. If E_2 has positive measure, then E_2 is uncountable, and by [14, section 23.III, p. 251], all but countably many points of E_2 are condensation points of E_2, and thus accumulation points of E_2.

If the orbit intersects F_1, then for all $t \in E_2$, we have $x(t) \in F_1$, so that

$$U(x(t)) = \langle x(t), b\rangle = |b|\,|x(t)|\cos\phi(t).$$

Since $S(|x(t)|, \phi(t)) = 0$ and $|x(t)|$ is a constant, then $\phi(t)$ is also a constant. This follows since $S(r, \phi) = 0$ defines r as a strictly decreasing function of ϕ on $[0, \frac{\pi}{2}]$, as observed in the proof of Theorem 1 (between (3.5) and (3.6)). Therefore, $U(x(\cdot))$ is constant on E_2, so that $(d/dt)U(x(t)) = 0$ for any $t \in E_2$ that is an accumulation point of E_2. Again, if E_2 has positive measure, then E_2 is uncountable, and all but countably many points of E_2 are accumulation points of E_2.

We know that $-U(x(\cdot)) + [U(x(\cdot))]' \in L^\infty[0, \infty)$, so letting $T \to \infty$ in (4.1), we get

$$0 = U(x) + \int_0^\infty e^{-t}\left(-U(x(t)) + \frac{d}{dt}U(x(t))\right)\,dt.$$

Combining this with (1.2), we get

$$v^a(x) = U(x) + \int_0^\infty e^{-t}\left(\langle x(t), b\rangle - U(x(t)) + \frac{d}{dt}U(x(t)) + |a(t)|\right)\,dt. \tag{4.2}$$

Since $\langle x, b\rangle - U(x) \geq 0$ and $(d/dt)U(x(t)) = 0$ a.e. on E_1, then the integrand in (4.2) is nonnegative a.e. on E_1. On E_0 we have

$$\frac{d}{dt}U(x(t)) + |a(t)| = \langle \nabla U(x(t)), a(t)x(t)\rangle + |a(t)|$$

a.e., and this is nonnegative since by Lemma 2

$$\begin{aligned}
&-\langle \nabla U(x), ax\rangle - |a| = |a|\left(-\left\langle \nabla U(x), \frac{a}{|a|}x\right\rangle - 1\right)\\
&\leq |a|\sup\{-\langle \nabla U(x), ax\rangle - |a|\colon\ |a| \leq 1, a \in A_d\}\\
&= |a|(\lambda(x, \nabla U(x)) - 1)^+ = 0.
\end{aligned}$$

Thus $v^a \geq U$ and $v \geq U$ on $\mathbb{R}^d$.

Next, we show $v \le U$ on $\mathbb{R}^d$. Since $v^0(x) = \langle b, x\rangle$, we have $v = U$ on N. Since L has no interior and since both v and U are Lipschitz, it remains to prove that they are equal on the complement of $N \cup L$. For x in the complement of $N \cup L$ define

$$\mathbf{a}(x) = x \wedge \nabla U(x) = x\,\nabla U(x)' - \nabla U(x)\,x'$$

and check that

$$\begin{aligned}\mathbf{a}(x)x &= (x\,\nabla U(x)')x - (\nabla U(x)\,x')x = \langle x, \nabla U(x)\rangle x - |x|^2 \nabla U(x)\\ &= -\nabla_p \lambda(x, \nabla U(x)).\end{aligned} \tag{4.3}$$

Here we have used (4) of Theorem 2.

Fix x in the complement of $N \cup L$ and let $x_1(t)$, $t \ge 0$, be the integral curve of the vector field $\mathbf{a}(x)x$ starting at x at time zero. Setting $p_1(t) = \nabla U(x_1(t))$, differentiating $\lambda(x, \nabla U(x)) = 1$, and using (4.3) shows

$$\begin{aligned}\dot{x}_1 &= -\nabla_p \lambda(x_1, p_1),\\ \dot{p}_1 &= +\nabla_x \lambda(x_1, p_1).\end{aligned}$$

Thus $(x_1(t), p_1(t))$ is the integral curve of $-X_\lambda$ through $(x, \nabla U(x))$ at $t = 0$ and through (x_0, b), with $x_0 \in F_0$, at some time $t = T$. Hence,

$$(x_1(s), p_1(s)) = \alpha_{T-s}(x_0, b) = (X(T-s), P(T-s)),$$

where $(X(t), P(t))$ is as in (3.2). Now define a sequence of controls $a_\epsilon(\cdot)$ satisfying $\lim_{\epsilon \downarrow 0} v^{a_\epsilon}(x) = U(x)$. Set $a_1(s) = \mathbf{a}(x_1(s))$, $0 \le s < T$, $a_1(s) = 0$, $s \ge T$. It follows that the unique solution of (1.1) corresponding to $a_1(\cdot)$ equals $x_1(t)$, if $0 \le t \le T$, and equals x_0 if $t \ge T$. But we need to spend no time in the complement of N. Accordingly, we define

$$a_\epsilon(t) = \frac{1}{\epsilon} a_1\left(\frac{t}{\epsilon}\right), \qquad t \ge 0. \tag{4.4}$$

Let $x_\epsilon(\cdot)$ and $v^{a_\epsilon}(x)$ be the corresponding trajectory and cost. From (4.2) we obtain

$$v^{a_\epsilon}(x) = U(x) + \int_0^{\epsilon T} e^{-t}[\langle x_\epsilon(t), b\rangle - U(x_\epsilon(t))]dt.$$

Here we have used that (3.3) and (4.3) imply $\langle \nabla U(x_1), a_1\, x_1\rangle = -\lambda^2(x_1, \nabla U(x_1)) = -1 = -|a_1|$ and (3.6). Finally, replacing $x_\epsilon(t) = x_1(t/\epsilon)$ and changing variables, we obtain $v(x) \le \lim_{\epsilon \downarrow 0} v^{a_\epsilon}(x) = U(x)$. □

POSITIVE LINEAR OBSERVERS FOR LINEAR COMPARTMENTAL SYSTEMS*

J. M. VAN DEN HOF†

Abstract. Linear compartmental systems are mathematical systems that are frequently used in biology and mathematics. The inputs, states, and outputs of such systems are positive, because they denote amounts or concentrations of material. For linear dynamic systems the observer problem has been solved. The purpose of the observer problem is to determine a linear observer such that the state can be approximated. The difference between the state and its estimate should converge to zero. The interpretation in terms of a physical system requires that an estimate of the state be positive, like the state itself. In this paper conditions on the system matrices are presented that guarantee that there exists a positive linear observer such that both the error converges to zero and the estimate is positive.

Key words. compartmental systems, positive linear observers, asymptotic stability

1. Introduction.

The purpose of this paper is to derive positive linear observers for linear compartmental systems.

Compartmental systems are mathematical systems that are frequently used in biology and mathematics. In addition, a subclass of the class of chemical processes can be modeled as compartmental systems. A compartmental system consists of several compartments with more or less homogeneous amounts of material. The compartments interact by processes of transportation and diffusion. The dynamics of a compartmental system are derived from mass balance considerations.

In this paper linear compartmental systems consisting of inputs, states, and outputs will be studied. The outputs of these systems are not the real outputs, i.e., material leaving the system, but the observations of the amount or concentrations of material, for example, in one or more compartments. The inputs, states, and outputs are positive, so these systems are called positive linear systems in system theory. As in linear system theory, the purpose is to determine a linear observer such that the state x can be approximated by $\widehat{x}$. The error, $\widehat{x}(t) - x(t)$, should converge to zero. For positive linear systems, the observer provides an approximation of the positive state. Therefore, the observer should be chosen in such a way that the approximation of the state, $\widehat{x}(t)$, is positive, like the state, $x(t)$, itself.

For linear systems the observer problem has been solved by Luenberger [11]. See also [10]. As far as we know, there is no literature on positive observers for positive linear systems, in which the positivity of $\widehat{x}(t)$ is taken into account. It turns out that the existence of a positive linear observer satisfying the above conditions depends largely on the structure of the system matrices, i.e., the zero/nonzero pattern. Some relation can be found in the work of Sontag [13, 14].

The outline of the paper is as follows. In section 2 the problem is posed. In section 3 continuous-time linear compartmental systems are considered, and in section 4 the discrete-time case is treated. Concluding remarks are made in section 5.

*Received by the editors July 8, 1996; accepted for publication (in revised form) January 13, 1997. http://www.siam.org/journals/sicon/36-2/30611.html

2. Problem formulation. In this section some notation is introduced and the problem is posed.

The set $R_+ = [0, +\infty)$ is called the set of the *positive real numbers*. Let $Z_+ = \{1, 2, \ldots\}$ denote the set of positive integers, $Z_n = \{1, \ldots, n\}$, and $\boldsymbol{N} = \{0, 1, 2, \ldots\}$. Denote by R_+^n the set of n-tuples of the positive real numbers. The set $R_+^{n\times m}$ will be called the set of *positive matrices* of size n by m. Note that R_+^n is not a vector space because it does not admit an inverse with respect to addition. For matrices $A, B \in R^{n\times m}$, we will write $A \geq B$ if $a_{ij} \geq b_{ij}$ for all $i \in Z_n$, $j \in Z_m$, and $A > B$ if $A \geq B$ and $A \neq B$. A matrix $A \in R^{n\times n}$ is said to be a *Metzler matrix* if all its off-diagonal elements are in R_+; see [9]. Metzler matrices can be characterized as follows.

PROPOSITION 2.1. *A matrix $A \in R^{n\times n}$ is a Metzler matrix if and only if there exists an $\alpha \in R_+$ such that $(A + \alpha I) \in R_+^{n\times n}$.*

DEFINITION 2.2. *Consider a continuous-time linear dynamic system*

$$\begin{aligned} \dot{x}(t) &= Ax(t) + Bu(t), \quad x(t_0) = x_0, \\ y(t) &= Cx(t) + Du(t), \end{aligned} \tag{2.1}$$

with $x(t) \in X \subset R^n$, $u(t) \in U \subset R^m$, $y(t) \in Y \subset R^k$, $t \in T = [t_0, \infty)$. Equation (2.1) *is said to represent a* (continuous-time) positive linear system *if for all $x_0 \in R_+^n$ and for all $u(t) \in R_+^m$, $t \in T$, we have $x(t) \in R_+^n$ and $y(t) \in R_+^k$ for $t \in T$; in other words, $X = R_+^n$, $U = R_+^m$, and $Y = R_+^k$.*

The following proposition provides a characterization of continuous-time positive linear systems.

PROPOSITION 2.3. *A continuous-time linear dynamic system of the form* (2.1) *is a positive linear system if and only if*

$$B \in R_+^{n\times m}, \quad C \in R_+^{k\times n}, \quad D \in R_+^{k\times m}, \quad \text{and} \quad A \text{ is a Metzler matrix.}$$

Proof. Suppose first $u(t) = 0$ for all $t \in T$. For $i \in Z_n$, $x_i(t) \geq 0$ if and only if $\dot{x}_i \geq 0$ whenever $x_i = 0$ and $x_j \geq 0$ for all $j \neq i$. This is equivalent to $a_{ij} \geq 0$ for all $j \neq i$. Moreover, $y(t) = Cx(t) \geq 0$ for $x(t) \geq 0$ if and only if $C \in R_+^{k\times n}$. Now suppose $u(t) \neq 0$. For $i \in Z_n$, $x_i(t) \geq 0$ if and only if $\dot{x}_i \geq 0$ whenever $x_j = 0$ for all $j \in Z_n$. This is equivalent to $b_{ir} \geq 0$ for $r \in Z_m$. Furthermore, if $x(t) = 0$, then $y(t) = Du(t) \geq 0$ if and only if $D \in R_+^{k\times m}$. □

For discrete time, the definition of a positive linear system is presented below.

DEFINITION 2.4. *Consider a discrete-time linear dynamic system*

$$\begin{aligned} x(t+1) &= Ax(t) + Bu(t), \quad x(0) = x_0, \\ y(t) &= Cx(t) + Du(t), \end{aligned} \tag{2.2}$$

with $x \in X \subset R^n$, $u \in U \subset R^m$, $y \in Y \subset R^k$, $t \in T = \boldsymbol{N}$. Equation (2.2) *is said to represent a* (discrete-time) positive linear system *if for all $x_0 \in R_+^n$ and for all $u(t) \in R_+^m$, $t \in T$, we have $x(t) \in R_+^n$ and $y(t) \in R_+^k$ for $t \in T$; in other words, $X = R_+^n$, $U = R_+^m$, and $Y = R_+^k$.*

A characterization of discrete-time positive linear systems is as follows.

PROPOSITION 2.5. *A discrete-time linear system of the form* (2.2) *is a positive linear system if and only if*

$$A \in R_+^{n\times n}, \quad B \in R_+^{n\times m}, \quad C \in R_+^{k\times n}, \quad D \in R_+^{k\times m}.$$

The positive linear observer problem is as follows. A positive linear observer for a positive linear system is a positive linear system described by the equations

$$\dot{\widehat{x}}(t) = H\widehat{x}(t) + Ky(t) + Eu(t), \quad \widehat{x}(t_0) = \widehat{x}_0,$$
$$\widehat{x}(t+1) = H\widehat{x}(t) + Ky(t) + Eu(t), \quad \widehat{x}(t_0) = \widehat{x}_0,$$

for the continuous-time case and the discrete-time case, respectively, which yields an estimate $\widehat{x}(t)$ of the state $x(t)$ at time $t \in T$ of system (2.1), (2.2), respectively. As in linear system theory, the observer has to satisfy the following two conditions:

1. $\widehat{x}(t_0) = x(t_0)$ implies $\widehat{x}(t) = x(t)$ for all $t \geq t_0$ and for all input functions $u(t)$, $t \geq t_0$;
2. $\widehat{x}(t)$ should converge to $x(t)$ for $t \to \infty$, for all input functions $u(t)$, $t \geq t_0$.

For linear systems the problem of finding an observer satisfying 1 and 2 has been completely solved [11]. The solution is

$$\dot{\widehat{x}}(t) = (A - KC)\widehat{x}(t) + Ky(t) + Bu(t),$$
$$\widehat{x}(t+1) = (A - KC)\widehat{x}(t) + Ky(t) + Bu(t),$$

respectively, with $K \in R^{n\times k}$ such that $A - KC$ is *asymptotically stable*; i.e., for the continuous-time case, $\sigma(A - KC) \subseteq \{\lambda \in C \mid \mathrm{Re}(\lambda) < 0\}$, and for the discrete-time case, $\sigma(A - KC) \subseteq \{\lambda \in C \mid |\lambda| < 1\}$. Here $\sigma(A)$ denotes the spectrum of A. The necessary and sufficient conditions for the existence of a matrix $K \in R^{n\times k}$ such that $A - KC$ is asymptotically stable depend on the matrices A and C; i.e., the pair (A, C) should be detectable. Equivalent conditions for detectability can be found in, for example, [3, pp. 259 and 293], respectively. The interpretation in terms of a physical system requires that an estimate $\widehat{x}(t)$ be, like $x(t)$, positive. So a positive linear observer for a positive linear system should also satisfy the following condition:

3. $\widehat{x}(t) \in R^n_+$, for all $t \geq t_0$, if $\widehat{x}(t_0) \in R^n_+$, $y(t) \in R^k_+$, and $u(t) \in R^m_+$ for all $t \geq t_0$.

This third condition is satisfied if and only if $K \in R^{n\times k}_+$ and, for the continuous-time case, $A - KC$ is a Metzler matrix, or for the discrete-time case, $A - KC \in R^{n\times n}_+$. This follows from Propositions 2.3 and 2.5, respectively. Now detectability of (A, C) defined in [3] cannot be used, because then it may be possible that $K \notin R^{n\times k}_+$. Of course, detectability is a necessary condition but is not sufficient. Therefore, new necessary and sufficient conditions on A and C have to be found. The problem considered in this paper is stated below.

Problem 2.6.

Continuous time. Formulate necessary and sufficient conditions on a Metzler matrix $A \in R^{n\times n}$ and a positive matrix $C \in R^{k\times n}_+$ such that there exists a $K \in R^{n\times k}_+$, $K \neq 0$, with

1. $A - KC$ a Metzler matrix;
2. $\sigma(A - KC) \subseteq \{\lambda \in C \mid \mathrm{Re}(\lambda) < 0\}$.

Discrete time. Formulate necessary and sufficient conditions on positive matrices $A \in R^{n\times n}_+$ and $C \in R^{k\times n}_+$ such that there exists a $K \in R^{n\times k}_+$, $K \neq 0$, with

1. $A - KC \in R^{n\times n}_+$;
2. $\sigma(A - KC) \subseteq \{\lambda \in C \mid |\lambda| < 1\}$.

These problems will be solved for linear compartmental systems, which form a subclass of positive linear systems.

3. Continuous time. In this section conditions for the existence of a positive linear observer for continuous-time linear compartmental systems will be derived. First results from the theory on compartmental systems will be presented.

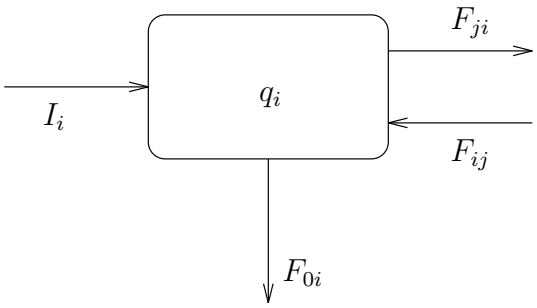

FIG. 3.1. *One compartment with possible flows.*

3.1. Continuous-time compartmental systems. A compartmental system is a system consisting of a finite number of subsystems, which are called compartments. Each compartment is kinetically homogeneous; i.e., any material entering the compartment is instantaneously mixed with the material of the compartment. Compartmental systems are dominated by the law of conservation of mass. They also form natural models for other areas of applications that are subject to conservation laws.

Consider an n-compartmental system. The behavior of the ith compartment can be represented as in Figure 3.1. In this figure, q_i denotes the amount of material considered in compartment i. The arrows represent the flows into and out of the compartment. $I_i \geq 0$ is the flow into compartment i from outside the system, called the *inflow*. $F_{ij} \geq 0$ and $F_{ji} \geq 0$ represent the flow from compartment j into compartment i and the flow from compartment i into compartment j, respectively. Finally, $F_{0i} \geq 0$ is the *outflow* to the environment from compartment i. The mass balance equations for every compartment can be written as

$$\dot{q}_i = \sum_{j \neq i} (-F_{ji} + F_{ij}) + I_i - F_{0i}. \tag{3.1}$$

In this paper the flows F_{ij} will be assumed to be linearly dependent on q_j:

$$F_{ij} = f_{ij} q_j, \quad i = 0, \ldots, n, \quad j = 1, \ldots, n, \quad i \neq j,$$

in which f_{ij} are called the *fractional transfer coefficients*. In general, f_{ij} are functions of q and time t. If f_{ij} is independent of q, the system is a linear system. In this paper it is assumed that f_{ij} is also independent of the time t; i.e., the system is a time-invariant linear system. Using this, (3.1) can be written as

$$\dot{q} = Fq + I,$$

where $q = \begin{pmatrix} q_1 & \cdots & q_n \end{pmatrix}^T \in R_+^n$, $F = (f_{ij}) \in R^{n \times n}$, with $f_{ii} = -(f_{0i} + \sum_{j \neq i} f_{ji})$ and f_{ij} constant for $i \neq j$, and I denotes the inflow from outside the system. Since $q_i \geq 0$ and $I_i \geq 0$, this system is easily seen to be a positive linear system, if the *output* is taken as

$$y = Cq, \quad y \in R^k, \quad C \in R_+^{k \times n},$$

where y denotes the vector of the observations. Note that the output is *not* the outflow of the compartmental system. The outflow, which is sometimes also called *excretion*, represents the flow of material leaving the system. The outputs of an experiment are

measurements and usually differ from the material outflows. On the other hand, the terms *inflow* and *input* can be used interchangeably.

Another property of compartmental systems is that the total flow out of a compartment over any time interval cannot be larger than the amount that was initially present plus the amount that flowed into the compartment during that interval. Together with the constraints on positive linear systems, this comes down to

$$1. \qquad f_{ij} \geq 0 \quad \text{for all } i,j \in Z_n, \quad i \neq j,$$

$$2. \qquad -f_{jj} \geq \sum_{i=1, i\neq j}^{n} f_{ij} \geq 0 \quad \text{for all } j \in Z_n.$$

A matrix F satisfying conditions 1 and 2 above is said to be a *compartmental matrix*. There is an extensive amount of literature on compartmental systems. See, for example, [1, 7, 8, 9]. Condition 2 states that all column sums of F are less than or equal to zero.

Below some properties of compartmental matrices from the literature will be discussed that are needed in this paper. References are [5, 6, 9, 15].

DEFINITION 3.1. *A matrix $A \in R^{n\times n}$ is said to be* reducible *if there exists a permutation matrix $P \in R^{n\times n}$ such that*

$$PAP^T = \begin{pmatrix} U & 0 \\ Q & R \end{pmatrix},$$

with U and R square matrices. A is said to be irreducible *if A is not reducible.*

Let $F \in R^{n\times n}$ be a compartmental matrix. Then it follows from [2, Theorem 6.4.6] that $\sigma(F) \subseteq \{\lambda \in C \mid \mathrm{Re}(\lambda) < 0 \text{ or } \lambda = 0\}$. Since a system $\dot{x} = Fx$ is asymptotically stable if and only if $\sigma(F) \subseteq \{\lambda \in C \mid \mathrm{Re}(\lambda) < 0\}$, a compartmental matrix is asymptotically stable if and only if $0 \notin \sigma(F)$. In the rest of this subsection compartmental matrices with zero eigenvalues are characterized.

PROPOSITION 3.2 (adapted from [15, Theorem III]). *Let $F \in R^{n\times n}$ be an irreducible compartmental matrix. Then $0 \in \sigma(F)$ if and only if $\sum_{i=1}^{n} f_{ij} = 0$ for all $j \in Z_n$*

DEFINITION 3.3. *Consider an n-compartmental system. A* trap *is a compartment or a set of compartments from which there are no transfers or flows to the environment nor to compartments that are not in that set. A trap is said to be* simple *if it does not strictly contain a trap.*

In the physical literature traps are usually referred to as *sinks*.

Let S be a linear compartmental system consisting of the compartments C_1, $C_2, \ldots, C_n$ and let q_j be the amount of material in C_j. Let $T \subseteq S$ be a subsystem of S. Renumbering the compartments, assume T consists of the compartments $C_m, C_{m+1}, \ldots, C_n$, for $m \leq n$. Let $F \in R^{n\times n}$ be the compartmental matrix corresponding to S, consistent with this renumbering. Then T is a trap if and only if

$$(3.2) \quad f_{ij} = 0 \quad \text{for all } (i,j) \text{ such that } j = m, m+1, \ldots, n, \quad i = 0, 1, \ldots, m-1.$$

The following two theorems are due to Fife [5].

THEOREM 3.4. *S contains a trap if and only if one of the following conditions holds:*

1. *for all $j \in Z_n$*

$$\sum_{i=1}^{n} f_{ij} = 0;$$

2. *there exists a permutation matrix* $P \in R^{n\times n}$ *such that*

$$PFP^T = \begin{pmatrix} U & 0 \\ Q & R \end{pmatrix},$$

with U, R *square matrices and the sum of entries of every column of* R *is zero.*

THEOREM 3.5. *S contains a trap if and only if $0 \in \sigma(F)$.*

In response to Fife [5], Foster and Jacquez [6] derived the following result. See also Theorems 1 and 2 together with their proofs in [9].

THEOREM 3.6. *Let S be a compartmental system with system matrix F.*

1. *Zero is an eigenvalue of F of multiplicity $m \in Z_+$ if and only if S contains m simple traps.*

2. *Assume zero is an eigenvalue of F of multiplicity $m \in Z_+$. Then there exists a partition of S into a disjoint union of subsystems*

$$S = S_1 \cup S_2 \cup \cdots \cup S_p$$

such that S_i receives no input from $S_{i+1}, \ldots, S_p$, $i = 1, \ldots, p-1$, and $S_{p-m+1}, \ldots, S_p$ are traps. Relative to this partition the system matrix is given by

$$PFP^T = \widetilde{F} = \begin{pmatrix} F_{11} & 0 & 0 & 0 & \cdots & 0 \\ \vdots & \ddots & 0 & & & \\ F_{p-m,1} & & F_{p-m,p-m} & 0 & & \\ F_{p-m+1,1} & & F_{p-m+1,p-m} & F_{p-m+1,p-m+1} & & \\ \vdots & & \vdots & 0 & \ddots & 0 \\ F_{p1} & \cdots & F_{p,p-m} & 0 & 0 & F_{pp} \end{pmatrix},$$

where F_{ii} is irreducible for all $i \in Z_p$ and zero is an eigenvalue of F_{ii} of multiplicity 1 for $i = p-m+1, \ldots, p$, and the sum of entries of every column of F_{ii}, $i = p-m+1, \ldots, p$, is zero.

An additional consequence of this theorem is that if zero is an eigenvalue of a compartmental matrix of (algebraic) multiplicity m, the geometric multiplicity is also m, so there are always m independent eigenvalues for the eigenvalue zero.

3.2. Positive linear observers. In this subsection conditions for the existence of a positive linear observer for continuous-time linear compartmental systems will be derived. Consider a compartmental matrix $F \in R^{n\times n}$. If $F \in R^{n\times n}$ is a compartmental matrix and $K \in R_+^{n\times k}$, $C \in R_+^{k\times n}$ are such that $F - KC$ is a Metzler matrix, then $F - KC$ is also a compartmental matrix, since condition 1 in section 3.1 is satisfied because $F - KC$ is a Metzler matrix and condition 2 becomes

$$\sum_{i=1}^{n} (F - KC)_{ij} = \sum_{i=1}^{n} f_{ij} - (KC)_{ij} \leq \sum_{i=1}^{n} f_{ij} \leq 0.$$

Therefore, for the special class of compartmental matrices, the problem to be solved is the following.

Problem 3.7. Formulate necessary and sufficient conditions on a compartmental matrix $F \in R^{n\times n}$ and a positive matrix $C \in R_+^{k\times n}$ such that there exists a $K \in R_+^{n\times k}$, $K \neq 0$, with

1. $F - KC$ a compartmental matrix;
2. $\sigma(F - KC) \subseteq \{\lambda \in C \mid \mathrm{Re}(\lambda) < 0\}$.

To solve this problem, the notions of positive modifiability and positive detectability will be defined.

DEFINITION 3.8. *Let $F \in R^{n\times n}$ be a compartmental matrix and $C \in R_+^{k\times n}$. The matrix pair (F, C) is said to be* positively modifiable *if there exists a $K \in R_+^{n\times k}$ such that $KC \neq 0$ and $F-KC$ is a compartmental matrix. This implies that $\sigma(F-KC) \subseteq \{\lambda \in C \mid \mathrm{Re}(\lambda) < 0 \text{ or } \lambda = 0\}$. (F, C) is said to be* positively detectable *if there exists a $K \in R_+^{n\times k}$ such that $KC \neq 0$ and $F-KC$ is an asymptotically stable compartmental matrix. This implies that $\sigma(F-KC) \subseteq \{\lambda \in C \mid \mathrm{Re}(\lambda) < 0\}$.*

Note that solving Problem 3.7 is equivalent to checking positive detectability. To solve Problem 3.7, positive modifiability will be used, for which the following characterization can be given.

PROPOSITION 3.9. *Let $F \in R^{n\times n}$ be a compartmental matrix and $C \in R_+^{k\times n}$. The matrix pair (F, C) is positively modifiable if and only if there exists an $i \in Z_n$ and an $r \in Z_k$ such that the rth row in C is nonzero and*

$$\{\text{for all } j \neq i \text{ with } c_{rj} \neq 0, \text{ also } f_{ij} \neq 0\}. \tag{3.3}$$

Remark 3.10. In terms of compartments, Proposition 3.9 can be interpreted as follows: an output can be seen as a strictly positive linear combination of one or more compartments. These compartments contribute to this output. For positive modifiability there should exist an output such that all the compartments contributing to this output have a direct flow to one and the same compartment. A compartmental system with system matrix F can be represented by a unique directed graph; see, for example, [4] or [8, Chapter 3]. Every compartment is represented by a vertex and there is a directed arc from x_i to x_j if and only if $f_{ji} > 0$. If compartment i contributes to output j, i.e., $c_{ji} \neq 0$, this will be represented by a dashed arc. The claim in Proposition 3.9 is equivalent to saying that the graph of F should contain a subgraph of the form given in Figure 3.2(a) if the considered output has one contributing compartment or, for example, Figure 3.2(b) if the considered output has three contributing compartments.

Proof. ($\Rightarrow$) Assume (F, C) is positively modifiable, so a $K \in R_+^{n\times k}$ can be found such that $KC \neq 0$ and $F - KC$ is a compartmental matrix. $KC \in R_+^{n\times n}$, since $K \in R_+^{n\times k}$ and $C \in R_+^{k\times n}$. Therefore there exist $i, s \in Z_n$ such that $0 < (KC)_{is} = \sum_{t=1}^{k} k_{it}c_{ts}$. Hence there exists an $r \in Z_k$ such that $k_{ir}c_{rs} > 0$, which implies $k_{ir} > 0$ and $c_{rs} > 0$. From this it follows that the rth row in C is nonzero. Next, the following holds for $j \in Z_n$, $j \neq i$, since $F - KC$ is a compartmental matrix,

$$0 \leq (F - KC)_{ij} = f_{ij} - \sum_{t=1}^{k} k_{it}c_{tj}. \tag{3.4}$$

Suppose $c_{rj} \neq 0$; i.e., $c_{rj} > 0$. Since $k_{ir} > 0$, this implies $\sum_{t=1}^{k} k_{it}c_{tj} \geq k_{ir}c_{rj} > 0$. Then it follows from (3.4) that $f_{ij} > 0$. So there exist $i \in Z_n$, $r \in Z_k$ such that row r in C is nonzero and for all $j \neq i$ with $c_{rj} \neq 0$, also, $f_{ij} \neq 0$.

($\Leftarrow$) Assume there exist $i \in Z_n$, $r \in Z_k$ such that row r in C is nonzero, and for all $j \neq i$ with $c_{rj} \neq 0$, $f_{ij} \neq 0$ also. Since row r in C is nonzero and $C \in R_+^{k\times n}$, there exists either an $s \in Z_n \setminus \{i\}$ such that $c_{rs} > 0$, or $c_{rs} = 0$ for all $s \in Z_n \setminus \{i\}$ and $c_{ri} > 0$. Assume first that there exists an $s \in Z_n \setminus \{i\}$ such that $c_{rs} > 0$. By assumption, this implies $f_{is} > 0$, and in general, for all $v \in Z_n \setminus \{i\}$, $c_{rv} > 0$ implies $f_{iv} > 0$. Now take

$$0 < k_{ir} < \min_{v\in Z_n\setminus\{i\}, c_{rv}>0} \frac{f_{iv}}{c_{rv}}$$

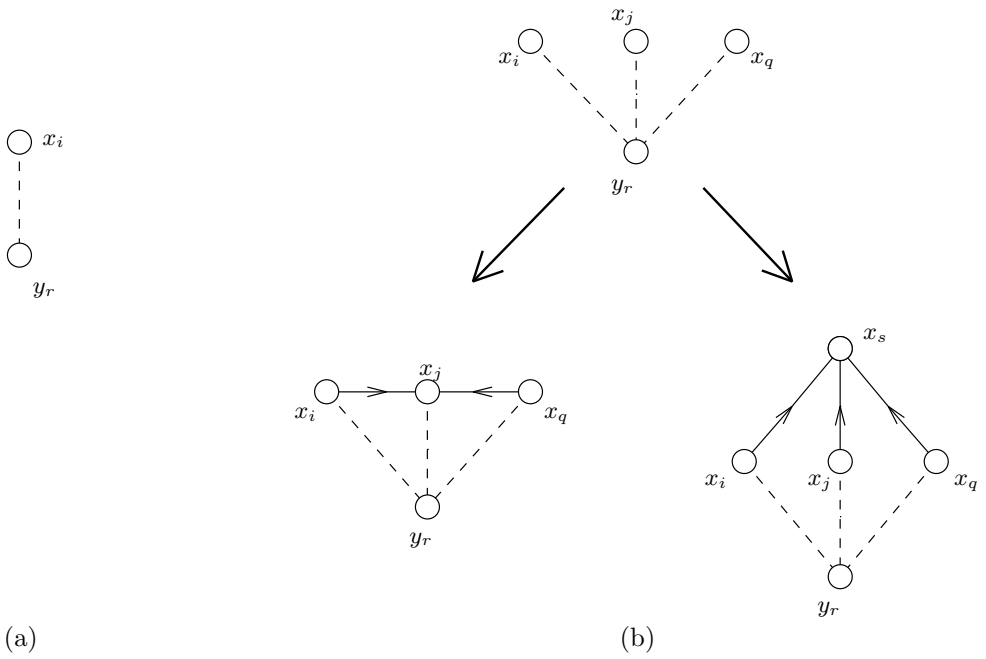

FIG. 3.2. *Subgraphs.*

and all other entries of K equal to zero. Then $K \in R_+^{n\times k}$ and

$$(F-KC)_{iw} = f_{iw} - k_{ir}c_{rw} = \begin{cases} f_{iw} - k_{ir}c_{rw} \in (0, f_{iw}), & \text{if } c_{rw} > 0, \quad w \neq i, \\ f_{iw} \geq 0, & \text{if } c_{rw} = 0, \quad w \neq i; \end{cases}$$

$$(F-KC)_{hw} = f_{hw} \geq 0 \quad \text{for } h \neq i, \quad w \neq h;$$

$$(F-KC)_{ii} = f_{ii} - k_{ir}c_{ri} \leq f_{ii} \leq -\sum_{q=1,q\neq i}^{n} f_{qi} \leq -\sum_{q=1,q\neq i}^{n} (F-KC)_{qi};$$

$$\begin{aligned}(F-KC)_{hh} = f_{hh} &\leq -\sum_{q=1,q\neq h}^{n} f_{qh} \leq -(f_{ih} - k_{ir}c_{rh}) - \sum_{q=1,q\neq h,q\neq i} f_{qh} \\ &= -\sum_{q=1,q\neq h} (F-KC)_{qh} \quad \text{for } h \neq i.\end{aligned}$$

It follows that K given above satisfies $KC \neq 0$, and $F - KC$ satisfies the conditions for a compartmental matrix.

Now assume $c_{rs} = 0$ for all $s \in Z_n \setminus \{i\}$ and $c_{ri} > 0$. Take $k_{ir} > 0$, any positive constant, and all other entries of K equal to zero. Then $K \in R_+^{n\times k}$,

$$(F-KC)_{hw} = f_{hw} \geq 0 \quad \text{for } h \in Z_n, \quad w \neq h;$$

$$(F-KC)_{hh} = f_{hh} \leq -\sum_{q=1,q\neq h}^{n} f_{qh} = -\sum_{q=1,q\neq h} (F-KC)_{qh} \quad \text{for } h \neq i;$$

$$(F-KC)_{ii} = f_{ii} - k_{ir}c_{ri} < f_{ii} \leq -\sum_{q=1,q\neq i}^{n} f_{qi} \leq -\sum_{q=1,q\neq i}^{n} (F-KC)_{qi}.$$

Again it follows that K given above satisfies $KC \neq 0$, and $F - KC$ satisfies the conditions for a compartmental matrix. □

A matrix $K \in R_+^{n\times k}$ such that $KC \neq 0$ and $F - KC$ is a compartmental matrix can be found by the following algorithm.

ALGORITHM 3.11. *Consider $F \in R^{n\times n}$, $C \in R_+^{k\times n}$. Define the sets*

$$R_c = \{(i,r) \in Z_n \times Z_k \mid \text{ row } r \text{ of } C \text{ is nonzero and (3.3) holds for } (i,r)\}$$

and

$$T_{(i,r)} = \{j \in Z_n \setminus \{i\} \mid c_{rj} \neq 0\}.$$

Form the matrix $K \in R_+^{n\times k}$ as follows.

1. *For every pair $(i,r) \in R_c$ with $T_{(i,r)} \neq \emptyset$, take*

$$0 \leq k_{ir} < \min_{j\in T_{(i,r)}} \frac{f_{ij}}{c_{rj}}.$$

2. *For every pair $(i,r) \notin R_c$ with $T_{(i,r)} \neq \emptyset$, take $k_{ir} = 0$.*
3. *For every pair $(i,r) \in Z_n \times Z_k$ with $T_{(i,r)} = \emptyset$, take any positive constant $k_{ir} \geq 0$.*

Of course, for KC to be nonzero, at least one k_{ir}, for a pair $(i,r) \in R_c$, should be strictly positive. It follows from Proposition 3.9 that the set R_c is nonempty if and only if the pair (F,C) is positively modifiable, and if this is the case, K can be chosen in such a way that $KC \neq 0$.

Before presenting the main theorem of this section, the following proposition is stated.

PROPOSITION 3.12. *Let $F \in R^{n\times n}$ be an irreducible compartmental matrix. Assume $C \in R_+^{k\times n}$ and $K \in R_+^{n\times k}$ are such that $KC \neq 0$ and $F-KC$ is a compartmental matrix. Then $F - KC$ is asymptotically stable.*

Proof. Let

$$K = \begin{pmatrix} K_1 \\ \vdots \\ K_n \end{pmatrix}, \quad \text{with } K_i \in R_+^{1\times k}, \quad C = \begin{pmatrix} C_1 & \cdots & C_n \end{pmatrix}, \quad \text{with } C_i \in R_+^{k\times 1}.$$

From $K \in R_+^{n\times k}$ and $C \in R_+^{k\times n}$ it follows that $(F - KC)_{rs} \leq f_{rs}$ for all $r,s \in Z_n$.

First, assume $F - KC$ is irreducible. Since $KC \neq 0$, there exist $i,j \in Z_n$ such that $(KC)_{ij} > 0$, or equivalently, $(F - KC)_{ij} < f_{ij}$. It follows that

$$\sum_{q=1}^{n} (F - KC)_{qj} < \sum_{q=1}^{n} f_{qj} \leq 0.$$

With Proposition 3.2 this implies that zero is not an eigenvalue of $F-KC$, so $F-KC$ is asymptotically stable.

Now, assume $F - KC$ is reducible. Suppose zero is an eigenvalue of $F - KC$. Without loss of generality it may be assumed that

$$F - KC = \begin{pmatrix} U & 0 \\ Q & R \end{pmatrix},$$

where $U \in R^{r\times r}$, with $1 \leq r < n$, $R \in R^{(n-r)\times(n-r)}$, and the sum of entries of every column of R is zero (see Theorem 3.4). For all $j = 1,\ldots,n-r$,

$$\sum_{i=1}^{n-r} R_{ij} = \sum_{i=1}^{n} (F - KC)_{i,r+j} = \sum_{i=1}^{n} (f_{i,r+j} - K_i C_{r+j}).$$

Since F is irreducible, there exists a $t \in Z_r$ such that $f_{t,r+j} > 0$, and because $f_{t,r+j} - K_t C_{r+j} = (F - KC)_{t,r+j} = 0$, $K_t C_{r+j} = f_{t,r+j} > 0$. This implies

$$\sum_{i=1}^{n-r} R_{ij} = \sum_{i=1}^{n} (f_{i,r+j} - K_i C_{r+j}) < \sum_{i=1}^{n} f_{i,r+j} \leq 0.$$

This contradicts the requirements on R. It follows that zero is not an eigenvalue of $F - KC$, so $F - KC$ is asymptotically stable. ∎

From Proposition 3.12 it follows that for an irreducible compartmental matrix $F \in R^{n\times n}$ and a positive matrix $C \in R_+^{k\times n}$, positive modifiability of (F, C) is equivalent to positive detectability of (F, C).

Consider a linear compartmental system S. Assume S contains $m \geq 0$ traps. If $m \geq 1$, then S can be partitioned as in Theorem 3.6, with system matrix

$$F = \begin{pmatrix} F_{11} & 0 & 0 & 0 & \cdots & 0 \\ \vdots & \ddots & 0 & & & \\ F_{p-m,1} & & F_{p-m,p-m} & 0 & & \\ F_{p-m+1,1} & & F_{p-m+1,p-m} & F_{p-m+1,p-m+1} & & \\ \vdots & & \vdots & 0 & \ddots & 0 \\ F_{p1} & \cdots & F_{p,p-m} & 0 & 0 & F_{pp} \end{pmatrix} \in R^{n\times n}, \tag{3.5}$$

in which F_{ii} is irreducible for all $i \in Z_p$ and the sum of entries of every column of the square matrices $F_{p-m+1,p-m+1}, \ldots, F_{pp}$ equals zero. Note that

1. $0 \notin \sigma(F_{ii})$ for $i = 1, \ldots, p - m$;
2. $0 \in \sigma(F_{ii})$ with multiplicity 1 for $i = p - m + 1, \ldots, p$.

Consider $C \in R_+^{k\times n}$, $K \in R_+^{n\times k}$, and decompose them to conform to the partition in (3.5):

$$C = \begin{pmatrix} C_1 & \cdots & C_p \end{pmatrix}, \quad K = \begin{pmatrix} K_1 \\ \vdots \\ K_p \end{pmatrix}. \tag{3.6}$$

Now the main theorem of this subsection can be stated. It solves Problem 3.7.

THEOREM 3.13. *Consider a linear compartmental system S, as defined above, with $m \geq 0$ traps.*

1. *If $m = 0$, then $F - KC$ is asymptotically stable for all $K \in R_+^{n\times k}$ with $F - KC$ a compartmental matrix. Moreover, (F, C) is positively detectable if and only if (F, C) is positively modifiable.*

2. *For $m \geq 1$, let F, K, and C be partitioned as in* (3.5) *and* (3.6). *(F, C) is positively detectable if and only if (F_{ii}, C_i) is positively modifiable for all $i = p - m + 1, \ldots, p$.*

Proof. 1. Since S contains no traps, it follows from Theorem 3.5 that $0 \notin \sigma(F)$, so F itself is asymptotically stable. Let $K \in R_+^{n\times k}$ be such that $F - KC$ is a compartmental matrix. Suppose $0 \in \sigma(F - KC)$. Because $0 \notin \sigma(F)$, $KC \neq 0$ and with Theorem 3.4 it follows that either

$$\sum_{q=1}^{n} (F - KC)_{qj} = 0 \quad \text{for all } j \in Z_n \tag{3.7}$$

or there exists a permutation matrix $P \in R^{n\times n}$ such that

$$P(F - KC)P^T = \begin{pmatrix} U & 0 \\ Q & R \end{pmatrix}$$

where $U \in R^{r\times r}$, with $1 \le r < n$, and $R \in R^{(n-r)\times(n-r)}$, with

$$\sum_{q=1}^{n-r} R_{qj} = 0 \quad \text{for all } j = 1,\dots,n-r. \tag{3.8}$$

Since there exist $s,t \in Z_n$ such that $(KC)_{st} > 0$, the equation

$$\sum_{q=1}^{n}(F-KC)_{qt} < \sum_{q=1}^{n} F_{qt} \le 0$$

contradicts (3.7). For the other possibility, assume without loss of generality that $P = I$. Since F contains no traps, the last $n-r$ columns of $F-KC$ cannot be identical to the last $n-r$ columns of F, so there exist $s \in Z_n$ and $t \in Z_{n-r}$ such that $(F-KC)_{s,r+t} < F_{s,r+t}$, from which it follows that

$$\sum_{q=1}^{n-r} R_{qt} = \sum_{q=1}^{n}(F-KC)_{q,r+t} < \sum_{q=1}^{n} F_{q,r+t} \le 0,$$

which contradicts (3.8). It follows that $0 \notin \sigma(F-KC)$ for all $K \in R_+^{n\times k}$ such that $F-KC$ is a compartmental matrix. By the definition of positive modifiability and positive detectability, the second statement in 1 follows.

2. The blocks of $F-KC$ are $F_{ij}-K_iC_j$, for $i,j \in Z_p$. Consider $F_{ii}-K_iC_i$ for $i = p-m+1,\dots,p$. There exists a positive matrix K_i such that $K_iC_i \neq 0$ and $F_{ii}-K_iC_i$ is a compartmental matrix if and only if (F_{ii},C_i) is positively modifiable, by definition.

($\Leftarrow$) Assume (F_{ii},C_i) is positively modifiable for all $i = p-m+1,\dots,p$. Let $i \in \{p-m+1,\dots,p\}$. Since F_{ii} is irreducible, it follows from Proposition 3.12 that if (F_{ii},C_i) is positively modifiable, i.e., $K_iC_i \neq 0$ and $F_{ii}-K_iC_i$ is a compartmental matrix for some positive matrix K_i, then $0 \notin \sigma(F_{ii}-K_iC_i)$. For $j \in \{1,\dots,p-m\}$, $0 \notin \sigma(F_{jj})$, which implies by 1 above that $0 \notin \sigma(F_{jj}-K_jC_j)$ for all positive matrices K_j such that $F_{jj}-K_jC_j$ are compartmental matrices. Hence $0 \notin \sigma(F-KC)$, and it follows that (F,C) is positively detectable.

($\Rightarrow$) Assume (F,C) is positively detectable; i.e., there exists a $K \in R_+^{n\times k}$ such that $KC \neq 0$, $F-KC$ is a compartmental matrix, and $0 \notin \sigma(F-KC)$. Then $0 \notin \sigma(F_{ii}-K_iC_i)$ for all $i \in Z_p$. In particular, $0 \notin \sigma(F_{ii}-K_iC_i)$ for $i = p-m+1,\dots,p$. But $0 \in \sigma(F_{ii})$, which implies $F_{ii}-K_iC_i \neq F_{ii}$; i.e., $K_iC_i \neq 0$. Since $F_{ii}-K_iC_i$ is also a compartmental matrix, it follows that (F_{ii},C_i) is positively modifiable for $i = p-m+1,\dots,p$. □

To construct a positive linear observer, the following algorithm can be used.

ALGORITHM 3.14. *Consider a linear compartmental system S, with system matrix $F \in R^{n\times n}$ and $C \in R_+^{k\times n}$. Assume S contains $m \ge 0$ traps.*

1. *Write F and C in the forms* (3.5) *and* (3.6), *and decompose a matrix $K \in R_+^{n\times k}$ accordingly.*

2. *With Proposition* 3.9 *check positive modifiability of (F_{ii},C_i) for every $i = p-m+1,\dots,p$.*

3. *Execute Algorithm* 3.11 *for every pair (F_{ii},C_i), $i = 1,\dots,p$.*

4. *If (F_{ii},C_i) is positively modifiable for every $i = p-m+1,\dots,p$, step* 3 *provides a positive linear observer. Otherwise (F,C) is not positively detectable.*

Note that in step 3 it is not necessary to have $K_iC_i \neq 0$ for $i = 1,\dots,p-m$, whereas it is necessary for $i = p-m+1,\dots,p$.

To illustrate the theory, this section will be concluded with an example.

Example 3.15. Consider a continuous-time compartmental system with matrices

$$F = \begin{pmatrix} -2 & 0 \\ 1 & 0 \end{pmatrix}, \quad C = \begin{pmatrix} 0 & 1 \end{pmatrix}.$$

The second compartment turns out to be a trap, and F has the form (3.5), with $m = 1$ and $p = 2$. Since $(F_{22}, C_2) = (0, 1)$ satisfies the conditions stated in Proposition 3.9, (F_{22}, C_2) is positively modifiable. Hence with Theorem 3.13, (F, C) is positively detectable, so there exist $k_1, k_2 \in R_+$ such that

$$F - KC = \begin{pmatrix} -2 & -k_1 \\ 1 & -k_2 \end{pmatrix}$$

is an asymptotically stable compartmental matrix. Indeed, this can be achieved by choosing $k_1 = 0$ and $k_2 > 0$. Note that the eigenvalues of $F - KC$ cannot be arbitrarily located in the complex plane, because of the necessary condition $k_1 = 0$. One eigenvalue, -2, cannot be moved. The other eigenvalue can be placed, but only on the real negative axis. The larger k_2, the deeper this latter eigenvalue is placed in the left-half complex plane, but this makes the observer very sensitive to possible observation noise. The problem of choosing a suitable k_2 has not been solved yet. Because of the restriction $k_1 = 0$, the theory for linear optimal observers, as described in, for example, [10], cannot be used.

4. Discrete time. In this section conditions for the existence of a positive linear observer for discrete-time linear compartmental systems will be derived. Most of the results are closely related to the continuous-time case. Again, first, some theory on compartmental systems will be presented.

4.1. Discrete-time compartmental systems. In this subsection discrete-time compartmental systems will be considered. For that purpose it is assumed that transfer of material occurs at discrete times $t_1, t_2, \ldots$, or a continuous-time system is sampled at discrete times, in which case the state at time t_k has been changed into the state at time t_{k+1}. What happens in between will not be considered explicitly. Therefore, this can also be seen as if a transfer has occurred at time t_{k+1}. The discrete times will be assumed to be equally spaced to obtain a time-invariant system. Let this space be the unit time, so $t_{k+1} = t_k + 1$.

Let $q_i(t)$ be the amount of material in the ith compartment at time t. The amount transferred from the jth to the ith compartment between time t and time $t + 1$ is $G_{ij}(t)$. This transferred material will be assumed to be linearly dependent on q_j; i.e., $G_{ij}(t) = g_{ij} q_j(t)$. The state at time $t + 1$ will be given by

$$q_i(t+1) = \sum_{j \neq i} g_{ij} q_j(t) + I_i(t) + g_{ii} q_i(t),$$

where $g_{ii} q_i(t)$ is the amount of material that was in compartment i at time t and is still (or again) in compartment i at time $t + 1$. This amount $g_{ii} q_i(t)$ is equal to $q_i(t)$ minus the amount that left compartment j:

$$g_{ii} q_i(t) = q_i(t) - g_{oi} q_i(t) - \sum_{j=1, j \neq i}^{n} g_{ji} q_i(t) = \left(1 - g_{oi} - \sum_{j=1, j \neq i}^{n} g_{ji} \right) q_i(t).$$

Hence define

$$g_{ii} = 1 - g_{oi} - \sum_{j=1, j\neq i}^{n} g_{ji}.$$

The total outflow of a compartment at time $t+1$ cannot be larger than the amount that was present at time t if the inflow from outside is assumed to be zero. Together with the constraints on positive linear systems (in discrete time), this comes down to

1. $g_{ij} \geq 0$ for all $i, j \in Z_n$;
2. $\sum_{i=1}^{n} g_{ij} \leq 1$ for all $j \in Z_n$.

A matrix G satisfying conditions 1 and 2 above is said to be a *compartmental matrix* (in the discrete-time case). Condition 2 states that all column sums of $G = (g_{ij}) \in R_+^{n\times n}$ are less than or equal to one.

Below properties of compartmental matrices in discrete time will be discussed, analogous to the continuous-time case. In the rest of this subsection, G refers to a discrete-time compartmental matrix, whereas F refers to a continuous-time compartmental matrix.

Let $G \in R_+^{n\times n}$ be a compartmental matrix. Then $\sigma(G) \subseteq \{\lambda \in C \mid |\lambda| \leq 1\}$, since the sum of entries of every column of G is less than or equal to one; see [12, Section 6.2] or [2, Chapter 2]. Because a system $x(t+1) = Gx(t)$ is asymptotically stable if and only if $\sigma(G) \subseteq \{\lambda \in C \mid |\lambda| < 1\}$, it follows from the Perron–Frobenius theorem (see [12]) that a compartmental system is asymptotically stable if and only if the spectral radius $\rho(G) \neq 1$, which is equivalent to $1 \notin \sigma(G)$. Analogously to the continuous-time case, compartmental matrices having spectral radius one are characterized.

PROPOSITION 4.1. *Let $G \in R_+^{n\times n}$ be an irreducible compartmental matrix. Then $\rho(G) = 1$ if and only if $\sum_{i=1}^{n} g_{ij} = 1$ for all $j \in Z_n$.*

Proof. This follows from [2, Theorem 2.2.35]. ∎

A trap in an n-compartmental system is defined in the same way as for continuous-time systems; see Definition 3.3. As in the continuous-time case, let $C_1, C_2, \ldots, C_n$ be the compartments of a linear compartmental system S. After renumbering, let $T \subseteq S$ consist of the compartments $C_m, C_{m+1}, \ldots, C_n$, for $m \leq n$. Then T is a trap if and only if

$$g_{ij} = 0 \quad \text{for all } (i,j) \text{ such that } j = m, m+1, \ldots, n, \quad i = 0, 1, \ldots, m-1, \tag{4.1}$$

where $G = (g_{ij}) \in R_+^{n\times n}$ is the compartmental matrix corresponding to S. Consider $F = G - I$. Since

1. $f_{ij} = g_{ij} \geq 0, \quad \text{for } i, j \in Z_n, \quad i \neq j;$
2. $\sum_{j=1}^{n} f_{ji} = g_{ii} - 1 + \sum_{j=1, j\neq i}^{n} g_{ji} = \sum_{j=1}^{n} g_{ji} - 1 \leq 0.$

The matrix F is a continuous-time compartmental matrix. Assume F is the system matrix for a continuous-time compartmental system S_F and let $T_F \subseteq S_F$ consist of the last $n - m + 1$ compartments $\widetilde{C}_m, \ldots, \widetilde{C}_n$.

PROPOSITION 4.2. *Consider $T \subseteq S$ and $T_F \subseteq S_F$ defined above. Then T is a (simple) trap if and only if T_F is a (simple) trap.*

Proof. T is a trap if and only if (4.1) holds, which is equivalent to

$$\text{(4.2)} \quad \begin{cases} g_{ij} = 0 \quad \text{for all } (i,j) \text{ such that } j = m, m+1, \ldots, n, \quad i = 1, 2, \ldots, m-1, \\ \text{and} \\ g_{jj} = 1 - \sum_{i=1, i \neq j}^{n} g_{ij} \quad \text{for all } j = m, m+1, \ldots, n, \end{cases}$$

since $g_{0j} = 0$. Because $f_{ij} = g_{ij}$ for $i \neq j$ and $f_{jj} = g_{jj} - 1$, (4.2) is equivalent to

$$\begin{cases} f_{ij} = 0 \quad \text{for all } (i,j) \text{ such that } j = m, m+1, \ldots, n, \quad i = 1, 2, \ldots, m-1, \\ \text{and} \\ f_{jj} = -\sum_{i=1, i \neq j}^{n} f_{ij} \quad \text{for all } j = m, m+1, \ldots, n, \end{cases}$$

which is, because $f_{0j} = -\sum_{i=1}^{n} f_{ij}$, equivalent to (3.2); i.e., T_F is a trap. In the same way it can be proved that T is a simple trap if and only if T_F is a simple trap. ∎

Using Proposition 4.2, the following theorems, analogous to Theorems 3.4, 3.5, and 3.6, can be proved.

THEOREM 4.3. *S contains a trap if and only if one of the following conditions holds.*

1. *For all $j \in Z_n$*

$$\sum_{i=1}^{n} g_{ij} = 1;$$

2. *There exists a permutation matrix $P \in R^{n \times n}$ such that*

$$PGP^T = \begin{pmatrix} U_1 & 0 \\ Q_1 & R_1 \end{pmatrix},$$

with U_1, R_1 square matrices and the sum of entries of every column of R_1 being one.

Proof. Since

$$\sum_{i=1}^{n} f_{ij} = \left(\sum_{i=1}^{n} g_{ij} \right) - 1 \quad \text{and}$$

$$PFP^T = P(G - I)P^T = PGP^T - I = \begin{pmatrix} U_1 - I & 0 \\ Q_1 & R_1 - I \end{pmatrix} =: \begin{pmatrix} U & 0 \\ Q & R \end{pmatrix},$$

in which the sum of entries of every column of $R = R_1 - I$ is equal to the sum of entries of every column of R_1 minus one, it follows that the conditions stated in the theorem are equivalent to the conditions stated in Theorem 3.4. The theorem now follows using Proposition 4.2. ∎

THEOREM 4.4. *S contains a trap if and only if $1 \in \sigma(G)$.*

Proof. The following statements are equivalent: (i) $0 \in \sigma(F)$; (ii) $\det(F) = 0$; (iii) $\det(G - I) = 0$; (iv) $1 \in \sigma(G)$; and (v) $\rho(G) = 1$. The last equivalence relation follows from the Perron–Frobenius theorem. With Proposition 4.2, the theorem is proved. ∎

THEOREM 4.5. *Let S be a compartmental system with system matrix G.*

1. *One is an eigenvalue of G of multiplicity $m \in Z_+$ if and only if S contains m simple traps.*

2. *Assume one is an eigenvalue of G of multiplicity $m \in Z_+$. Then there exists a partition of S into a disjoint union of subsystems*

$$S = S_1 \cup S_2 \cup \cdots \cup S_p$$

such that S_i receives no input from $S_{i+1}, \ldots, S_p$, $i = 1, \ldots, p-1$, and $S_{p-m+1}, \ldots, S_p$ are traps. Relative to this partition the system matrix is given by

$$PGP^T = \widetilde{G} = \begin{pmatrix} G_{11} & 0 & 0 & 0 & \cdots & 0 \\ \vdots & \ddots & 0 & & & \\ G_{p-m,1} & & G_{p-m,p-m} & 0 & & \\ G_{p-m+1,1} & & G_{p-m+1,p-m} & G_{p-m+1,p-m+1} & & \\ \vdots & & \vdots & 0 & \ddots & 0 \\ G_{p1} & \cdots & G_{p,p-m} & 0 & 0 & G_{pp} \end{pmatrix},$$

where G_{ii} is irreducible for all $i \in Z_p$ and one is an eigenvalue of G_{ii} of multiplicity one for $i = p-m+1, \ldots, p$, and the sum of entries of every column of G_{ii}, $i = p-m+1, \ldots, p$, is one.

Proof. 1. The following statements are equivalent:

(i) one is an eigenvalue of G of multiplicity $m \in Z_+$;

(ii) $\det(G - \lambda I) = (\lambda - 1)^m p(\lambda)$ with $p(1) \neq 0$;

(iii) $\det(F - \lambda I) = \lambda^m p_1(\lambda)$ with $p_1(0) = p(1) \neq 0$;

(iv) zero is an eigenvalue of F of multiplicity $m \in Z_+$.

The equivalence between the second and third statements follows from $\det(F - \lambda I) = \det(G - I - \lambda I) = \det(G - (\lambda + 1)I) = ((\lambda + 1) - 1)^m p(\lambda + 1) = \lambda^m p_1(\lambda)$ with $p_1(\lambda) = p(\lambda + 1)$. Now statement 1 follows from Proposition 4.2 and statement 1 of Theorem 3.6.

2. Consider the following statements.

a. one is an eigenvalue of G of multiplicity $m \in Z_+$;

b. zero is an eigenvalue of F of multiplicity $m \in Z_+$;

c. statement 2 in Theorem 3.6;

d. statement 2 in Theorem 4.5.

From 1 it follows that a $\Leftrightarrow$ b, and Theorem 3.6 provides b $\Rightarrow$ c. Noting that $PGP^T = PFP^T + I$, $G_{ij} = F_{ij}$ for $i \neq j$, and $G_{ii} = F_{ii} + I$, where the sum of entries of every column of G_{ii} is equal to the sum of entries of every column of F_{ii} plus 1; the implication c $\Rightarrow$ d follows from the statements of the proof of part 1 for $m = 1$. This completes the proof of part 2. ∎

4.2. Positive linear observers. In this subsection conditions for the existence of a positive linear observer for discrete-time linear compartmental systems will be derived. Consider a compartmental matrix $G \in R^{n \times n}$. If $G \in R_+^{n \times n}$ is a compartmental matrix and $K \in R_+^{n \times k}$, $C \in R_+^{k \times n}$ are such that $G - KC \in R_+^{n \times n}$, then $G - KC$ is also a compartmental matrix, since condition 1 in section 4.1 is satisfied because $G - KC \in R_+^{n \times n}$ and condition 2 becomes

$$\sum_{i=1}^{n} (G - KC)_{ij} = \sum_{i=1}^{n} g_{ij} - (KC)_{ij} \leq \sum_{i=1}^{n} g_{ij} \leq 1.$$

The problem for the special class of compartmental matrices is stated below.

Problem 4.6. Formulate necessary and sufficient conditions on a compartmental matrix $G \in R_+^{n \times n}$ and a positive matrix $C \in R_+^{k \times n}$ such that there exists a $K \in R_+^{n \times k}$, $K \neq 0$, with

1. $G - KC \in R_+^{n \times n}$ being a compartmental matrix;

2. $\sigma(G - KC) \subseteq \{\lambda \in C \mid |\lambda| < 1\}$.

Note that 2 is equivalent to $\rho(G - KC) < 1$, under the assumption that 1 holds.

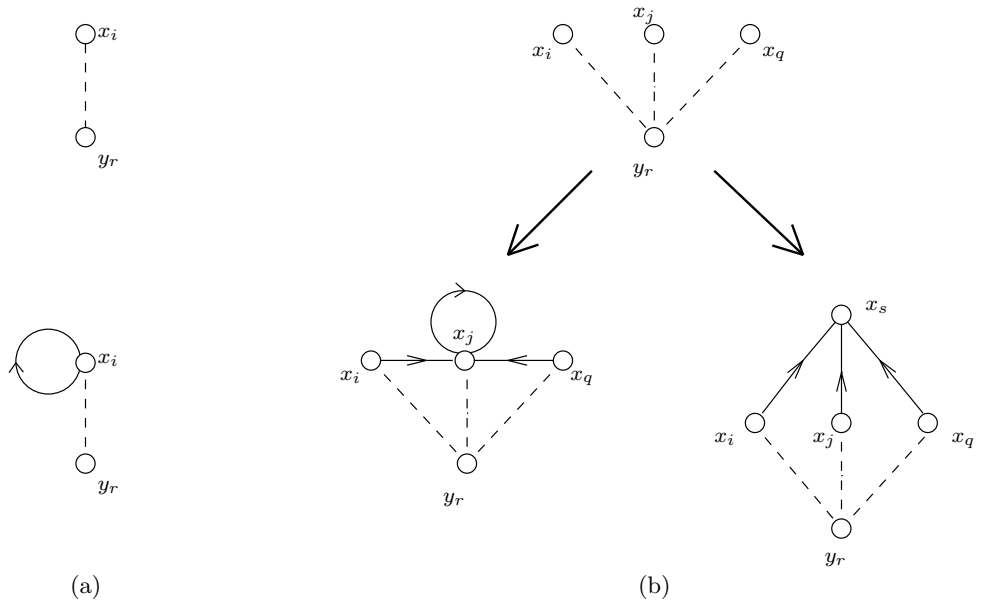

FIG. 4.1. *Subgraphs.*

The notions of positive modifiability and positive detectability are defined analogously to the continuous-time case.

DEFINITION 4.7. *Let $G \in R_+^{n\times n}$ be a compartmental matrix and $C \in R_+^{k\times n}$. The matrix pair (G, C) is said to be* positively modifiable *if there exists a $K \in R_+^{n\times k}$ such that $KC \neq 0$ and $G-KC$ is a compartmental matrix. This implies that $\sigma(G-KC) \subseteq \{\lambda \in C \mid |\lambda| \leq 1\}$. The matrix pair (G, C) is said to be* positively detectable *if there exists a $K \in R_+^{n\times k}$ such that $KC \neq 0$ and $G - KC$ is an asymptotically stable compartmental matrix. This implies that $\sigma(G - KC) \subseteq \{\lambda \in C \mid |\lambda| < 1\}$.*

For the discrete-time case, the condition for positive modifiability is somewhat different, because the diagonal elements of G also play a role.

PROPOSITION 4.8. *Let $G \in R_+^{n\times n}$ be a compartmental matrix and $C \in R_+^{k\times n}$. (G, C) is positively modifiable if and only if there exists an $i \in Z_n$ and an $r \in Z_p$ such that the rth row in C is nonzero and*

$$\{\textit{for all } j \in Z_n \textit{ with } c_{rj} > 0, \textit{ also } g_{ij} > 0\}. \tag{4.3}$$

Remark 4.9. The interpretation of Proposition 4.8 is that for positive modifiability there should exist an output such that all the compartments contributing to this output have a direct flow to one and the same compartment. Note that in contrast to the continuous-time case, if this last mentioned compartment is a compartment that contributes to the output, also is "flow" to itself needed. This means that some of the material in this compartment is still in this compartment one time step ahead. Defining a graph for system matrix G as in Remark 3.10, then the condition in Proposition 4.8 says that the graph of G should contain a subgraph of the form shown in Figure 4.1. In this case, "flow" to itself is represented by a loop, which occurs if $g_{ii} > 0$.

Proof. ($\Rightarrow$) Assume (G, C) is positively modifiable, so a $K \in R_+^{n\times k}$ can be found, such that $KC \neq 0$ and $G - KC$ is a compartmental matrix. $KC \in R_+^{n\times n}$, since

$K \in R_+^{n\times k}$ and $C \in R_+^{k\times n}$. Therefore, there exist $i, s \in Z_n$ such that $0 < (KC)_{is} = \sum_{t=1}^{k} k_{it}c_{ts}$. Hence there exists an $r \in Z_k$ such that $k_{ir}c_{rs} > 0$, which implies $k_{ir} > 0$ and $c_{rs} > 0$. From this it follows that the rth row in C is nonzero. Next,

$$0 \le (G - KC)_{ij} = g_{ij} - \sum_{t=1}^{k} k_{it}c_{tj} \tag{4.4}$$

holds for all $j \in Z_n$, since $G-KC$ is a compartmental matrix. Suppose $c_{rj} > 0$. Since $k_{ir} > 0$, this implies $\sum_{t=1}^{k} k_{it}c_{tj} \ge k_{ir}c_{rj} > 0$. From (4.4) it follows that $g_{ij} > 0$. So there exist $i \in Z_n$, $r \in Z_k$ such that row r in C is nonzero, and for all $j \in Z_n$ with $c_{rj} > 0$, $g_{ij} > 0$ also.

($\Leftarrow$) Assume there exist $i \in Z_n$, $r \in Z_k$ such that row r in C is nonzero, and for all $j \in Z_n$ with $c_{rj} > 0$, $g_{ij} > 0$ also. Since row r in C is nonzero, there exists an $s \in Z_n$ such that $c_{rs} > 0$. This implies $g_{is} > 0$, and in general, for all $v \in Z_n$, $c_{rv} > 0$ implies $g_{iv} > 0$. Now take

$$0 < k_{ir} < \min_{v\in Z_n, c_{rv}>0} \frac{g_{iv}}{c_{rv}}$$

and all other entries of K equal to zero. Then $K \in R_+^{n\times k}$ and

$$(G - KC)_{iw} = g_{iw} - k_{ir}c_{rw} = \begin{cases} g_{iw} - k_{ir}c_{rw} \in (0, g_{iw}) & \text{if } c_{rw} > 0, \\ g_{iw} \ge 0 & \text{if } c_{rw} = 0; \end{cases}$$
$$(G - KC)_{hw} = g_{hw} \ge 0 \quad \text{for } h \ne i.$$

It follows that K given above satisfies $KC \ne 0$, and $G - KC$ satisfies the conditions for a compartmental matrix. □

A matrix $K \in R_+^{n\times k}$ such that $KC \ne 0$ and $G - KC$ is a compartmental matrix can be found by the following algorithm.

ALGORITHM 4.10. *Consider $G \in R_+^{n\times n}$, $C \in R_+^{k\times n}$. Define the sets*

$$R_d = \{(i, r) \in Z_n \times Z_k \mid \text{ row } r \text{ of } C \text{ is nonzero and (4.3) holds for } (i, r)\}$$

and

$$D_{(i,r)} = \{j \in Z_n \mid c_{rj} \ne 0\}.$$

Form the matrix $K \in R_+^{n\times k}$ as follows.

1. *For every pair $(i, r) \in R_d$, take*

$$0 \le k_{ir} < \min_{j\in D_{(i,r)}} \frac{g_{ij}}{c_{rj}}.$$

2. *For every pair $(i, r) \notin R_d$, take $k_{ir} = 0$.*

Of course, for KC to be nonzero, at least one k_{ir}, for a pair $(i, r) \in R_d$, should be strictly positive. It follows from Proposition 4.8 that the set R_d is nonempty if and only if the pair (G, C) is positively modifiable, and if this is the case, K can be chosen in such a way that $KC \ne 0$. Analogous to the continuous-time case, the following results can be stated.

PROPOSITION 4.11. *Let $G \in R_+^{n\times n}$ be an irreducible compartmental matrix. Assume $C \in R_+^{k\times n}$ and $K \in R_+^{n\times k}$ are such that $KC \ne 0$ and $G-KC$ is a compartmental matrix. Then $G - KC$ is asymptotically stable.*

Consider a linear compartmental system S. Assume S contains $m \geq 0$ traps. If $m \geq 1$, then S can be partitioned as in Theorem 4.5, with system matrix

$$G = \begin{pmatrix} G_{11} & 0 & 0 & 0 & \cdots & 0 \\ \vdots & \ddots & 0 & & & \\ G_{p-m,1} & & G_{p-m,p-m} & 0 & & \\ G_{p-m+1,1} & & G_{p-m+1,p-m} & G_{p-m+1,p-m+1} & & \\ \vdots & & \vdots & 0 & \ddots & 0 \\ G_{p1} & \cdots & G_{p,p-m} & 0 & 0 & G_{pp} \end{pmatrix} \in R_+^{n\times n}, \tag{4.5}$$

in which G_{ii} is irreducible for all $i \in Z_p$ and the sum of entries of every column of the square matrices $G_{p-m+1,p-m+1}, \ldots, G_{pp}$ equals one. Note that

1. $1 \notin \sigma(G_{ii})$ for $i = 1, \ldots, p-m$;
2. $1 \in \sigma(G_{ii})$ with multiplicity 1 for $i = p-m+1, \ldots, p$.

Consider $C \in R_+^{k\times n}$, $K \in R_+^{n\times k}$, and decompose them to conform to the partition in (4.5):

$$C = \begin{pmatrix} C_1 & \cdots & C_p \end{pmatrix}, \quad K = \begin{pmatrix} K_1 \\ \vdots \\ K_p \end{pmatrix}. \tag{4.6}$$

The main theorem of this subsection, solving Problem 4.6, is stated below.

THEOREM 4.12. *Consider a linear compartmental system S, as defined above, with $m \geq 0$ traps.*

1. *If $m = 0$, then $G - KC$ is asymptotically stable for all $K \in R_+^{n\times k}$ with $G - KC$ a compartmental matrix. Moreover, (G, C) is positively detectable if and only if (G, C) is positively modifiable.*

2. *For $m \geq 1$, let G, K, and C be partitioned as in (4.5) and (4.6). (G, C) is positively detectable if and only if (G_{ii}, C_i) is positively modifiable for all $i = p-m+1, \ldots, p$.*

Proofs of Proposition 4.11 *and Theorem* 4.12. These proofs are analogous to the proofs of Proposition 3.12 and Theorem 3.13, using Proposition 4.1, Theorem 4.3, and Theorem 4.4, respectively, instead of Proposition 3.2, Theorem 3.4, and Theorem 3.5, respectively, and changing F into G and the appropriate zeros into ones. Details are left for the reader. □

To construct a positive linear observer, the following algorithm can be used.

ALGORITHM 4.13. *Consider a linear compartmental system S, with system matrix $G \in R_+^{n\times n}$ and $C \in R_+^{k\times n}$. Assume S contains $m \geq 0$ traps.*

1. *Write G and C in the forms* (4.5) *and* (4.6), *and decompose a matrix $K \in R_+^{n\times k}$ accordingly.*

2. *With Proposition* 4.8 *check positive modifiability of (G_{ii}, C_i) for every $i = p-m+1, \ldots, p$.*

3. *Execute Algorithm* 4.10 *for every pair (G_{ii}, C_i), $i = 1, \ldots, p$.*

4. *If (G_{ii}, C_i) is positively modifiable for every $i = p-m+1, \ldots, p$, step* 3 *provides a positive linear observer. Otherwise (G, C) is not positively detectable.*

Note that in step 3 it is not necessary to have $K_i C_i \neq 0$ for $i = 1, \ldots, p-m$, whereas it is necessary for $i = p-m+1, \ldots, p$.

5. Concluding remarks. Positive linear observers for linear compartmental systems have been considered. Conditions on the system matrices A and C have been

derived for the existence of positive linear observers, i.e., linear observers that provide positive estimates of the state in case the estimate of the initial state and the input is positive. As has been shown in the example in section 3.2, the problem of finding an *optimal* positive linear observer is also worthwhile to be studied. By an *optimal* positive linear observer we mean on the one hand one with a "large" gain K, but on the other hand one that is not too sensitive to possible observation noise. This problem remains to be investigated.

In linear system theory, the dual of the observer problem is the stabilization problem by linear state feedback; see, for example, [3, 10]. Of course, duals of the results in this chapter can be derived. But these results will have no physical meaning since a stabilization problem by linear state feedback would be to design for a positive linear system

$$\dot{x}(t) = Ax(t) + Bu(t)$$

a positive linear control law

$$u(t) = Fx(t) + v(t),$$

with $v(t) \in R_+^m$ a new input, such that the closed loop system

$$\dot{x}(t) = (A + BF)x(t) + Bv(t)$$

is asymptotically stable. For physical reasons, this control law should produce a positive input u, given positive state x and positive input v, so $F \in R_+^{m \times n}$. Therefore $A + BF \geq A$, whereas $A - KC \leq A$. So new results for this problem have to be found, and they are definitely *not* dual to the results in this chapter.

EXISTENCE OF MARKOV CONTROLS AND CHARACTERIZATION OF OPTIMAL MARKOV CONTROLS*

THOMAS G. KURTZ† AND RICHARD H. STOCKBRIDGE‡

Abstract. Given a solution of a controlled martingale problem it is shown under general conditions that there exists a solution having Markov controls which has the same cost as the original solution. This result is then used to show that the original stochastic control problem is equivalent to a linear program over a space of measures under a variety of optimality criteria. Existence and characterization of optimal Markov controls then follows. An extension of Echeverria's theorem characterizing stationary distributions for (uncontrolled) Markov processes is obtained as a corollary. In particular, this extension covers diffusion processes with discontinuous drift and diffusion coefficients.

Key words. Markov controls, optimal controls, martingale problems, stationary processes, linear programming, occupation measures

1. Introduction and formulation.

We consider processes whose dynamics are specified through a controlled martingale problem for their generator, that is, by the requirement that

$$f(X(t)) - \int_0^t Af(X(s), u(s))\, ds \tag{1.1}$$

be a martingale for every f in the domain of the generator A. In this expression X is the state process and u is a process which "controls" X. (A detailed formulation of the dynamics is given later in this section.) The controller usually compares control processes by observing their associated "costs" according to a prescribed criterion. In this paper we consider infinite-horizon discounted and long-term average costs, finite-horizon costs, and first passage or first exit costs.

The controller may use any nonanticipating process to control the state. The restriction on the control process is implicit in the martingale requirements; however, it is easy to check that any solution of the controlled martingale problem corresponds to a solution with the same state process and a (relaxed) control adapted to the filtration generated by the state process. Controls may be based on the full history of the state and control processes or they may depend only on the present value of the state. The latter control processes are referred to as Markov or feedback controls.

There are usually two desires which the controller would like to fulfill. The first and most important is to choose the control so as to obtain the minimum cost possible; however, from a practical point of view, the controller would also like to have as simple a control as possible.

In this paper, we show that it is possible to fulfill both desires simultaneously, at least in one sense, by showing the existence of optimal Markov controls. Furthermore, we develop a method for determining an optimal Markov control.

The question of existence of optimal Markov controls has been studied in [4, 8, 12]. Each paper considers controlled diffusion processes and gives conditions under which existence of optimal Markov controls is assured. The approach of the last two papers is to apply the Krylov selection theorem to obtain a Markov solution to the martingale problem and thus a Markov control. This approach gives existence of an optimal Markov control but does not characterize the control.

The method we use to determine an optimal control is to reformulate the original control problem as a linear program over a collection of measures. This approach has a long history starting with Manne [15] and has been widely applied in a discrete setting (see, for example, [5, 6, 16, 20]). The extension to continuous time processes having continuous state and control processes was given in [19]. However, the optimal controls obtained in [19] were only shown to be progressively measurable and only applied to long-term average control problems. Fleming and Vermes [10] use a similar reformulation in terms of occupation measures. They use convex analysis techniques to show that the solution is given by the upper envelope of the smooth subsolutions of the Hamilton–Jacobi–Bellman equation.

This paper has two main components. The first considers existence of Markov controls for solutions of the controlled martingale problem for the generator A. These existence results typically take two forms. One form starts with a given solution to the martingale problem and establishes existence of another solution having a Markov control whose cost matches the cost of the given solution. The other form begins with an identity in which a measure (or measures) annihilates the generator (or generators) of the process(es) and constructs a solution having a Markov control. The second component develops the LP reformulations of the various control problems.

The organization of this paper is as follows. We give the formulation of the dynamics of the controlled process in section 1.1. Existence of stationary solutions having a Markov control and such that the one-dimensional distributions are prescribed is shown for any prescribed distribution satisfying a stationarity condition (2.1) in section 2. Section 3 extends Echeverria's theorem (see [9, Theorem 4.9.17]) to operators whose ranges include discontinuous functions and considers the forward equation. In section 4, we show that for any solution of the controlled martingale problem there exists another solution having a (time-inhomogeneous) Markov control which has the same one-dimensional state and control distributions as the given solution. Since the long-term average, discounted and finite-horizon cost criteria depend only on the one-dimensional distributions, this result implies that the new solution has the same expected cost for these criteria. The distribution of the Markov control corresponds to the projection of the given control onto the σ-algebra generated by the current state. A corresponding result is also obtained for the first exit criterion. Section 5 provides existence of a solution with a *time-homogeneous* Markov control which matches the costs of a given solution, though the one-dimensional distributions may no longer be the same as the given solution. Finally, in section 6 we determine the equivalent LP formulations of the control problems for each of the cost criteria.

The existence results in section 4 are similar in nature to an observation by Dvoretsky [7] for discrete processes which says that any sequence of random variables has the same one-dimensional distributions as a Markov chain. More recently, for a diffusion having adapted drift and diffusion coefficients, Krylov [13] shows existence of drift

and diffusion coefficients which are functions of the state such that the two diffusions have the same Green measure (see Corollary 5.4 of section 5.1). Gyöngy [11] shows existence of state- and time-dependent coefficients such that the one-dimensional distributions of the diffusions are the same (see Corollary 4.3 of section 4). For controlled diffusions in which the control only affects the drift coefficient, Borkar [3] establishes a similar existence of Markov controls such that the one-dimensional distributions of the diffusions agree. The results in sections 4 and 5 generalize [3, 11, 13].

Following the completion of the first draft of this paper, the authors became aware of work of Bhatt and Borkar [2] that has substantial overlap with the results of this paper. Both papers are based on extensions of Echeverria's theorem to controlled processes given in [18, 19]. Bhatt and Borkar work in the context of complete, separable, metric state spaces and compact control spaces while we treat locally compact (not necessarily compact), separable, metric state and control spaces. Their paper contains analogues of our Theorems 2.2 and 4.1, although the method of proof used in Theorem 2.2 is substantially different. They study the discounted criterion with a fixed discount rate, whereas section 5.1 of our paper allows the discount rate to be state- and control-dependent. This dependence is used to extend Krylov's result on the Green measures. Their characterization of the finite-horizon problem does not include terminal costs since they work with test functions which vanish at the terminal time. Our results (sections 4.2 and 6.3) allow terminal costs. The results on the first-passage criterion (sections 4.1 and 5.2) and the forward equation for Markov processes (section 3) appear only in this paper.

1.1. Formulation. In this paper, we only consider *relaxed* solutions for the martingale problem, so we begin by stating the definition of a relaxed solution.

For a measurable space S, we define $\widehat{C}(S)$ to be the space of continuous functions on S which vanish at ∞, $\overline{C}(S)$ to be the space of bounded, continuous functions on S, $\mathcal{M}(S)$ to be the space of finite Borel measures on S, and $\mathcal{P}(S)$ to be the space of probability measures on S.

Let the state space E and control space U be locally compact, complete, separable metric spaces and let $E^\Delta = E \cup \{\Delta\}$ be the one-point compactification of E. Let $A : \mathcal{D}(A) \subset \widehat{C}(E) \to C(E \times U)$ and $\nu \in \mathcal{P}(E)$. Then an $E \times \mathcal{P}(U)$-valued process (X, Λ) is a relaxed solution of the controlled martingale problem for (A, ν) if there exists a filtration $\{\mathcal{F}_t\}$ such that (X, Λ) is $\{\mathcal{F}_t\}$-progressive, X has initial distribution ν, and for every $f \in \mathcal{D}(A)$,

$$f(X(t)) - \int_0^t \int_U Af(X(s), u)\, \Lambda_s(du)\, ds \tag{1.2}$$

an $\{\mathcal{F}_t\}$-martingale.

We assume that the generator A satisfies the following conditions, which are sufficient to guarantee existence of solutions (at least in E^Δ) to the controlled martingale problem for each $\nu \in \mathcal{P}(E)$:

(i) $\mathcal{D}(A)$ is dense in $\widehat{C}(E)$,

(ii) for each $f \in \mathcal{D}(A)$ and $u \in U$, $Af(\cdot, u) \in \widehat{C}(E)$,

(iii) for each $f \in \mathcal{D}(A)$ and compact $K \subset U$, $\limsup_{x \to \Delta} \sup_{u \in K} |Af(x, u)| = 0$, and

(iv) for each $u \in U$, $A_u f = Af(\cdot, u)$ satisfies the positive maximum principle.

The fundamental existence result (Theorem 2.2) requires the additional condition that

(v) $\mathcal{D}(A)$ is an algebra.

For compactness purposes we also assume that

(vi) there exists $\psi \in C(U)$, $\psi > 0$, such that for each $f \in \mathcal{D}(A)$ there exist constants a_f and b_f satisfying

$$|Af(x,u)| \leq a_f + b_f\psi(u). \tag{1.3}$$

Integrability assumptions of two types will be placed on ψ; the particular assumption will be specified in each theorem. An additional assumption (6.1) relating the cost function c with ψ is imposed in the LP reformulation section.

The results of this paper can be extended to a nonlocally compact state space E as in [1, 2]. We treat the locally compact case for simplicity of exposition.

This paper considers the infinite-horizon discounted cost, the long-term average cost, the finite-horizon cost, and the first passage or first exit cost associated with solutions of the controlled martingale problem. There are two forms to the LP reformulations of each control problem which are based on the existence results contained in sections 4 and 5, respectively. The results in section 4 allow the running cost and terminal or exit cost functions to be time-dependent and lead to LP reformulations in which time is a component. When there is no time-dependence in the cost criteria aside from (possibly) discounting, the LP reformulations are simpler and use the existence of time-homogeneous Markov controls established in section 5.

With this in mind, let $c \in M(E \times U)$ and $g \in M(E)$ be bounded below. ($M(E)$ will denote the Borel measureable functions on E.) The four standard criteria are

- the discounted cost

$$E\left[\int_0^\infty e^{-\alpha t}\int_U c(X(t),u)\Lambda_t(du)\,dt\right]; \tag{1.4}$$

- the finite-horizon cost

$$E\left[\int_0^T \int_U c(X(t),u)\Lambda_t(du)\,dt + g(X(T))\right]; \tag{1.5}$$

- the long-term average cost

$$\limsup_{t\to\infty} E\left[t^{-1}\int_0^t \int_U c(X(s),u)\Lambda_s(du)\,ds\right]; \tag{1.6}$$

- the first passage cost

$$E\left[\int_0^\tau \int_U c(X(s),u)\,\Lambda_s(du)\,ds + g(X(\tau))\right], \tag{1.7}$$

where $E_0 \subset E$ is an open set and $\tau = \inf\{t \geq 0 : X(t) \in E_0^c\}$.

The criteria (1.4), (1.5), and (1.7) are adjusted appropriately when c and g are time-dependent. In addition, for the first passage cost we allow $E_0 \subset \mathbb{R}^+ \times E$ and $\tau = \inf\{t \geq 0 : (t, X(t)) \in E_0^c\}$. We also consider discount rates that depend on the state and control.

2. Stationary solution to the controlled martingale problem. The objective of this section is to establish the existence of a particular form of stationary solution for the controlled martingale problem for a generator A.

Suppose μ is a probability measure on $E \times U$ which satisfies

$$\int_{E\times U} Af(x,u)\,\mu(dx\times du) = 0 \qquad \forall f \in \mathcal{D}(A)\ . \tag{2.1}$$

Denote the state marginal by $\mu_0 = \mu(\cdot \times U)$ and let η be the regular conditional distribution of u given x; that is, η satisfies

$$\mu(\Gamma_1 \times \Gamma_2) = \int_{\Gamma_1} \eta(x,\Gamma_2)\,\mu_0(dx) \quad \forall \Gamma_1 \in \mathcal{B}(E), \quad \Gamma_2 \in \mathcal{B}(U)\ . \tag{2.2}$$

If X is a stationary process with $X(0)$ having distribution μ_0, the pair $(X, \eta(X,\cdot))$ is stationary and the one-dimensional distributions satisfy

$$E[I_{\Gamma_1}(X(t))\,\eta(X(t),\Gamma_2)] = \mu(\Gamma_1\times\Gamma_2), \quad t \geq 0.$$

We show that there exists a stationary process X such that the $E\times\mathcal{P}(U)$-valued process $(X,\eta(X,\cdot))$ is a stationary relaxed solution of the controlled martingale problem for (A,μ_0). The following lemma is essential to this result.

LEMMA 2.1. *Let X_n, X be processes in $D_E[0,\infty)$ with $X_n \Rightarrow X$, and let $D_X = \{t : P\{X(t) \neq X(t-)\} > 0\}$. Suppose, for each $t \geq 0$, that $X_n(t)$ and $X(t)$ have a common distribution $\nu_t \in \mathcal{P}(E)$. Let g be Borel measurable on $[0,\infty)\times E$ and satisfy*

$$\int_0^t \int_E |g(s,x)|\nu_s(dx)ds < \infty$$

for each $t > 0$. Then

$$\int_0^{[n\cdot]/n} g(s,X_n(s))\,ds \Rightarrow \int_0^{\cdot} g(s,X(s))\,ds \tag{2.3}$$

and, in particular, for each $m \geq 1, 0 \leq t_1 \leq \cdots \leq t_m < t_{m+1}$, $t_i \notin D_X$, and $h_1,\ldots,h_m \in \overline{C}(E)$,

$$\begin{aligned}\lim_{n\to\infty} E\left[\int_{[nt_m]/n}^{[nt_{m+1}]/n} g(s,X_n(s))\,ds \prod_{i=1}^m h_i(X_n(t_i))\right]\\ = E\left[\int_{t_m}^{t_{m+1}} g(s,X(s))\,ds \prod_{i=1}^m h_i(X(t_i))\right].\end{aligned} \tag{2.4}$$

Proof. For each $\epsilon > 0$, there exists $g_\epsilon \in \overline{C}([0,\infty)\times E)$ satisfying $\int_0^\infty e^{-t}\int_E |g(s,x) - g_\epsilon(s,x)|\,\nu_s(dx)ds < \epsilon$. Then

$$\begin{aligned}&\left|E\left[\int_{[nt_m]/n}^{[nt_{m+1}]/n} \{g(s,X_n(s)) - g_\epsilon(s,X_n(s))\}\,ds \prod_{i=1}^m h_i(X_n(t_i))\right]\right|\\ \leq\ & \prod_{i=1}^m ||h_i|| E\left[\int_{[nt_m]/n}^{[nt_{m+1}]/n} |g(s,X_n(s)) - g_\epsilon(s,X_n(s))|\,ds\right]\\ \leq\ & \prod_{i=1}^m ||h_i||(t_{m+1}-t_m+1)e^{t_{m+1}}\epsilon.\end{aligned}$$

Similarly,

$$\left| E\left[\int_{t_m}^{t_{m+1}} \{g(s,X(s)) - g_\epsilon(s,X(s))\}\, ds \prod_{i=1}^m h_i(X(t_i)) \right] \right| \le \prod_{i=1}^m ||h_i|| (t_{m+1} - t_m + 1) e^{t_{m+1}} \epsilon.$$

The result now follows since the convergence in (2.4) is immediate with g replaced by g_ϵ. The proof of (2.3) is obtained in a similar manner. □

THEOREM 2.2. *Suppose that E, U, A, and ψ are as in section* 1.1. *Suppose $\mu \in \mathcal{P}(E \times U)$ satisfies* (2.1). *Let η satisfy* (2.2). *Assume that ψ satisfies*

$$\int \psi(u)\, \mu(dx \times du) < \infty. \tag{2.5}$$

Then there exists a stationary process X such that $(X, \eta(X,\cdot))$ is a stationary relaxed solution of the controlled martingale problem for (A, μ_0).

Remark 2.3. It will be clear from the proof that there always exists a modification of X with sample paths in $D_{E^\Delta}[0,\infty)$ (where E^Δ is the one-point compactification of E), but our assumptions do not imply that the process will have sample paths in $D_E[0,\infty)$. For example, let $Af = (1+x^4)(f''(x) + f'(x))$. It is easy to check that $\mu(dx) = c(1+x^4)^{-1}dx$ satisfies $\int_{\mathrm{R}} Af(x)\mu(dx) = 0$, but the corresponding process will repeatedly "go out" at $+\infty$ and "come back in" at $-\infty$.

For clarity of exposition, we break the proof into two parts. The main part of the proof is given in the next theorem, which differs from the more general result in that the range of the generator A consists of *bounded* continuous functions. The second part of the proof consists of applying the theorem to bounded generators which approximate A and showing relative compactness of the solutions.

THEOREM 2.4 (cf. [2, Theorem 2.1 and Corollary 2.1]). *Suppose that E, U are as in section* 1.1. *Let $A : \mathcal{D}(A) \subset \widehat{C}(E) \to \overline{C}(E \times U)$ satisfy conditions* (i)–(v). *Suppose $\mu \in \mathcal{P}(E \times U)$ satisfies* (2.1). *Let η satisfy* (2.2). *Then there exists a stationary process X such that $(X, \eta(X,\cdot))$ is a stationary relaxed solution of the controlled martingale problem for (A, μ_0).*

Proof. As in [18, Theorem 4.1], we may assume E is compact and $A1 = 0$, where 1 denotes the constant function 1, by using E^Δ and extending A to the space $C(E^\Delta)$, if necessary. For $n = 1, 2, 3, \ldots$, define the Yosida approximations A_n by $A_n g = n[(I - n^{-1}A)^{-1} - I]g$ for $g \in \mathcal{R}(I - n^{-1}A)$ and note that for $f \in \mathcal{D}(A)$ and $g = (I - n^{-1}A)f$, $A_n g = Af$.

Let M be the linear subspace of functions of the form

$$\begin{aligned} F(x_1,x_2,u_1,u_2) = &\sum_{i=1}^m \left\{ h_i(x_1) \left[(I - n^{-1}A) f_i(x_2,u_1) + g_i(x_2,u_2) - g_i(x_2,u_1) \right] \right\} \\ &+ h_0(x_2,u_1,u_2), \end{aligned} \tag{2.6}$$

where $h_1, \ldots, h_m \in \overline{C}(E)$, $h_0 \in \overline{C}(E \times U \times U)$, $f_1, \ldots, f_m \in \mathcal{D}(A)$, and $g_1, \ldots, g_m \in \overline{C}(E \times U)$. Define the linear functional Ψ on M by

(2.7)
$$\begin{aligned}\Psi F &= \int_{E\times U}\int_U \sum_{i=1}^m \{h_i(x_2)[f_i(x_2)+g_i(x_2,u_2)-g_i(x_2,u_1)]\}\,\eta(x_2,du_2)\,\mu(dx_2\times du_1)\\ &\quad+\int_{E\times U}\int_U h_0(x_2,u_1,u_2)\,\eta(x_2,du_2)\,\mu(dx_2\times du_1)\\ &=\int_{E\times U}\int_U\left[\sum_{i=1}^m h_i(x_2)f_i(x_2)+h_0(x_2,u_1,u_2)\right]\eta(x_2,du_2)\,\mu(dx_2\times du_1),\end{aligned}$$

in which the second representation follows from the fact that

$$\int_{E\times U}\int_U h(x_2)[g(x_2,u_2)-g(x_2,u_1)]\eta(x_2,du_2)\,\mu(dx_2\times du_1)=0 \tag{2.8}$$

(write $\mu(dx_2\times du_1)=\eta(x_2,du_1)\mu_0(dx_2)$). Also define the linear operator Π: $\mathrm{B}(E\times E\times U\times U)\to\mathrm{B}(E\times E\times U)$ by

$$\Pi F(x_1,x_2,u_1)=\int_U F(x_1,x_2,u_1,u_2)\,\eta(x_2,du_2) \tag{2.9}$$

and the functional p on $\mathrm{B}(E\times E\times U\times U)$ by

$$p(F)=\int_{E\times U}\sup_{x_1}|\Pi F(x_1,x_2,u_1)|\mu(dx_2\times du_1). \tag{2.10}$$

Observe that $\Pi(\Pi F)=\Pi F$, so

$$p(F-\Pi F)=0. \tag{2.11}$$

In order to simplify notation, define the operator B on $\overline{C}(E\times U)$ by

$$Bg(x_2,u_1)=\int_U[g(x_2,u_2)-g(x_2,u_1)]\,\eta(x_2,du_2). \tag{2.12}$$

First, we claim $|\Psi F|\le p(F)$. To see this, fix $F\in M$. Fix $\alpha_i\ge||(I-n^{-1}A)f_i+Bg_i||\vee||f_i||, i=1,\dots,m$, and let ϕ be a polynomial on $\mathbb{R}^m$ which is convex on $\prod_{i=1}^m[-\alpha_i,\alpha_i]$. By the convexity of ϕ and [18, Lemma 3.5],

$$\begin{aligned}&\phi((I-n^{-1}A)f_1+Bg_1,\dots,(I-n^{-1}A)f_m+Bg_m)\\ &\quad\ge\phi(f_1,\dots,f_m)-n^{-1}\nabla\phi(f_1,\dots,f_m)\cdot(Af_1,\dots,Af_m)\\ &\qquad+\nabla\phi(f_1,\dots,f_m)\cdot(Bg_1,\dots,Bg_m)\\ &\quad\ge\phi(f_1,\dots,f_m)-n^{-1}A\phi(f_1,\dots,f_m)+\nabla\phi(f_1,\dots,f_m)\cdot(Bg_1,\dots,Bg_m).\end{aligned}$$

In light of (2.1) and (2.8), integration with respect to μ yields

$$\int\phi((I-n^{-1}A)f_1+Bg_1,\dots,(I-n^{-1}A)f_m+Bg_m)\,d\mu\ge\int\phi(f_1,\dots,f_m)\,d\mu, \tag{2.13}$$

and this inequality can be extended to arbitrary convex functions. Consider, in particular, the convex function $\phi(r_1, \dots, r_m) = \sup_{x_1} \sum_{i=1}^m h_i(x_1) r_i$. It follows that

$$\begin{aligned}
\Psi F &\le \int_{E\times U} \left\{ \sup_{x_1} \sum_{i=1}^m h_i(x_1) f_i(x_2) + \int_U h_0(x_2, u_1, u_2)\, \eta(x_2, du_2) \right\} \mu(dx_2 \times du_1) \\
&= \int_{E\times U} \left\{ \phi(f_1, \dots, f_m)(x_2) + \int_U h_0(x_2, u_1, u_2)\, \eta(x_2, du_2) \right\} \mu(dx_2 \times du_1) \\
&\le \int_{E\times U} \big\{ \phi((I - n^{-1}A) f_1 + Bg_1, \dots, (I - n^{-1}A) f_m + Bg_m)(x_2, u_1) \\
&\qquad\qquad + \int_U h_0(x_2, u_1, u_2)\, \eta(x_2, du_2) \Big\} \mu(dx_2 \times du_1) \\
&= \int_{E\times U} \sup_{x_1} \Pi F(x_1, x_2, u_1)\, \mu(dx_2 \times du_1) \\
&\le p(F).
\end{aligned}$$

Also, $-\Psi F = \Psi(-F) \le p(-F) = p(F)$, so $|\Psi F| \le p(F)$.

Since $\Psi 1 = 1$, observe that for $F \ge 0$,

$$||F|| - \Psi F = \Psi(||F|| - F) \le ||\, ||F|| - F|| \le ||F||,$$

so $\Psi F \ge 0$. As a result, we can apply the Hahn–Banach theorem (cf. [17, p. 187]) to extend Ψ to the entire space $\overline{C}(E \times E \times U \times U)$, still satisfying $|\Psi F| \le p(F)$, and the extension of the Riesz representation theorem in [1, Theorem 2.3] to conclude that there exists a measure $\nu \in \mathcal{P}(E \times E \times U \times U)$ such that

$$\Psi F = \int_{E\times E\times U\times U} F(x_1, x_2, u_1, u_2)\, \nu(dx_1 \times dx_2 \times du_1 \times du_2). \tag{2.14}$$

By considering functions F of particular forms, we observe some of the consequences of this representation of Ψ. First, for F of the form $F(x_1, x_2, u_1, u_2) = h(x_1)(I - n^{-1}A)1(x_2, u_1)$, with 1 being the constant function, it is clear that $\nu(\cdot \times E \times U \times U) = \mu_0(\cdot)$. Second, consider F of the form $F(x_1, x_2, u_1, u_2) = h(x_1)(I - n^{-1}A) f(x_2, u_1)$. Letting $\nu(dx_1 \times dx_2 \times du_1 \times du_2) = \tilde{\eta}(x_1, dx_2 \times du_1 \times du_2)\mu_0(dx_1)$, we have

$$\begin{aligned}
&\int_E h(x_1) f(x_1)\, \mu_0(dx_1) \\
&\qquad = \Psi F \\
&\qquad = \int_{E\times E\times U\times U} h(x_1)(I - n^{-1}A) f(x_2, u_1)\, \nu(dx_1 \times dx_2 \times du_1 \times du_2) \\
&\qquad = \int_E h(x_1) \left[\int_{E\times U} (I - n^{-1}A) f(x_2, u_1)\, \tilde{\eta}(x_1, dx_2 \times du_1 \times U) \right] \mu_0(dx_1),
\end{aligned}$$

and thus letting $\widehat{\eta}(x_1, dx_2 \times du_1) = \tilde{\eta}(x_1, dx_2 \times du_1 \times U)$, it follows that

$$\int_{E\times U} (I - n^{-1}A) f(x_2, u_1) \widehat{\eta}(x_1, dx_2 \times du_1) = f(x_1) \quad \text{a.e. } \mu_0(dx_1). \tag{2.15}$$

Third, observe that $\Psi F = \Psi(\Pi F)$ by (2.11). With $F(x_1, x_2, u_1, u_2) = f(x_1, x_2, u_1) g(u_2)$ and writing $\nu(dx_1 \times dx_2 \times du_1 \times du_2) = \bar{\eta}(x_1, x_2, u_1, du_2)\bar{\nu}(dx_1 \times dx_2 \times du_1)$, we thus

have

$$\begin{aligned}\int_{E\times E\times U} f(x_1,x_2,u_1)\left[\int_U g(u_2)\,\bar\eta(x_1,x_2,u_1,du_2)\right]\bar\nu(dx_1\times dx_2\times du_1)\\ &= \Psi F\\ &= \Psi(\Pi F)\\ &= \int_{E\times E\times U} f(x_1,x_2,u_1)\left[\int_U g(u_2)\eta(x_2,du_2)\right]\bar\nu(dx_1\times dx_2\times du_1).\end{aligned}$$

Therefore

$$\begin{aligned}\nu(dx_1\times dx_2\times du_1\times du_2) &= \eta(x_2,du_2)\bar\nu(dx_1\times dx_2\times du_1)\\ &= \eta(x_2,du_2)\widehat\eta(x_1,dx_2\times du_1)\mu_0(dx_1).\end{aligned}$$

Furthermore, using $F(x_1,x_2,u_1,u_2)=h(x_1)[g(x_2,u_2)-g(x_2,u_1)]$, it follows that

$$\begin{aligned}0 &= \Psi F\\ &= \int_E h(x_1)\left[\int_{E\times U}\int_U \{g(x_2,u_2)-g(x_2,u_1)\}\eta(x_2,du_2)\widehat\eta(x_1,dx_2\times du_1)\right]\mu_0(dx_1)\end{aligned}$$

and so

$$\int_{E\times U}\int_U \{g(x_2,u_2)-g(x_2,u_1)\}\eta(x_2,du_2)\widehat\eta(x_1,dx_2\times du_1)=0 \quad \text{a.e. } \mu_0(dx_1). \tag{2.16}$$

Let $\{(X_k,u_k)\colon k=1,2,\dots\}$ be a Markov chain on $E\times U$ having initial distribution μ and transition function $\widehat\eta$. A straightforward computation shows that the Markov chain is stationary, and by (2.15) and (2.16), for each $f\in\mathcal{D}(A)$ and $g\in\overline{C}(E\times U)$,

$$[(I-n^{-1}A)f](X_k,u_k)-\sum_{i=0}^{k-1} n^{-1}A_n[(I-n^{-1}A)f](X_i,u_i)$$

and

$$\sum_{i=0}^{k} Bg(X_i,u_i)$$

are martingales with respect to the filtration $\mathcal{F}_k=\sigma((X_i,u_i)\colon 0\le i\le k)$.

Define $X_n(\cdot)=X_{[n\cdot]}$, $u_n(\cdot)=u_{[n\cdot]}$, and $\mathcal{F}_t^n=\sigma((X_n(s),u_n(s))\colon 0\le s\le t)$. It immediately follows (recall $A_n(I-n^{-1}A)f=Af$) that

$$[(I-n^{-1}A)f](X_n(t),u_n(t))-\int_0^{[nt]/n} Af(X_n(s),u_n(s))\,ds \tag{2.17}$$

and

$$\int_0^{[nt]/n} Bg(X_n(s),u_n(s))\,ds \tag{2.18}$$

are $\mathcal{F}_t^n$-martingales.

Define the measure-valued random variable Γ_n by

$$\Gamma_n([0,t]\times G) = \int_0^{[nt]/n} I_G(u_n(s))\,ds.$$

Let $\mathcal{L}(U)$ be the space of measures ξ on $[0,\infty)\times U$ such that $\xi([0,t]\times U)<\infty$ for each $t>0$. We take the topology on $\mathcal{L}(U)$ such that $\xi_n\to\xi$ if and only if

$$\int f\,d\xi_n \to \int f\,d\xi$$

for every $f\in \overline{C}([0,\infty)\times U)$ with $\operatorname{supp}(f)\subset[0,t_f]\times U$ for some $t_f<\infty$. Relative compactness of $\{\Gamma_n\}$ follows from the fact that

$$E[\Gamma_n([0,t]\times U)]\le t,$$

and for each $\epsilon>0$, there exists a compact set $K\subset U$ such that

$$E[\Gamma_n([0,t]\times K^c)] = \frac{[nt]}{n}\mu(E\times K^c)\le \epsilon t.$$

See [14, Corollary 1.2]. It follows that (X_n,Γ_n) is relatively compact in $D_E[0,\infty)\times\mathcal{L}(U)$. Along any convergent subsequence with limit point (X,Γ), by [14, Lemma 1.5]

$$\int_{[0,\cdot]\times U} g(X_n(s),u)\Gamma_n(ds\times du) \Rightarrow \int_{[0,\cdot]\times U} g(X(s),u)\Gamma(ds\times du),$$

and as in the proof of [14, Theorem 2.1], there exists a filtration $\{\mathcal{G}_t\}$ such that

$$f(X(t)) - \int_0^t\int_U Af(X(s),u)\,\Gamma(ds\times du) \tag{2.19}$$

is a $\{\mathcal{G}_t\}$-martingale for each $f\in\mathcal{D}(A)$. Since X_n is stationary for time shifts that are multiples of n^{-1}, it follows that X is a stationary process.

Since (2.18) is a martingale, for $h_1,\dots,h_j\in\overline{C}(E), g\in\overline{C}(E\times U)$, and $0\le t_1\le\cdots\le t_j<t_{j+1}$,

$$\begin{aligned}E\left[\int_{[nt_j]/n}^{[nt_{j+1}]/n}\int_U g(X_n(s),u)\,\eta(X_n(s),du)\,ds\prod_{i=1}^j h_i(X_n(t_i))\right]\\ = E\left[\int_{[nt_j]/n}^{[nt_{j+1}]/n}\int_U g(X_n(s),u_n(s))\,\Gamma_n(ds\times du)\prod_{i=1}^j h_i(X_n(t_i))\right].\end{aligned}$$

By the weak convergence of (X_n,Γ_n) to (X,Γ) and Lemma 2.1, letting $n\to\infty$, we obtain

$$\begin{aligned}E\left[\int_{t_j}^{t_{j+1}}\int_U g(X(s),u)\,\eta(X(s),du)\,ds\prod_{i=1}^j h_i(X(t_i))\right]\\ = E\left[\int_{t_j}^{t_{j+1}}\int_U g(X(s),u)\,\Gamma(ds\times du)\prod_{i=1}^j h_i(X(t_i))\right].\end{aligned}$$

In particular, this implies, by taking $g = Af$, that

$$f(X(t)) - \int_0^t \int_U Af(X(s),u)\,\eta(X(s),du)\,ds$$

is an $\{\mathcal{F}_t^X\}$-martingale. □

Proof of Theorem 2.2. For each $n \geq 1$, let $\psi_n = 2^{-n}(2^n \vee \psi)$, $k_n(x) = \int \psi_n(u)\,\eta(x,du)$, and $c_n = \int k_n(x)\,\mu_0(dx) = \int \psi_n(u)\,\mu(dx \times du)$. Observe that $\psi_n \geq 1$ for all n and as $n \to \infty$, $\psi_n(u) \to 1$, $c_n \searrow 1$, and $k_n \searrow 1$. Define the operators A_n on $\mathcal{D}(A)$ by

$$A_n f(x,u) = Af(x,u)/\psi_n(u),$$

and note that $A_n : \mathcal{D}(A) \to \overline{C}(E \times U)$. Also for each n, define the measure $\mu_n \in \mathcal{P}(E \times U)$ by

$$\mu_n(\Gamma) = c_n^{-1} \int_\Gamma \psi_n(u)\mu(dx \times du) \quad \forall \Gamma \in \mathcal{B}(E \times U).$$

Observe that the state marginal of μ_n has density $\frac{k_n(x)}{c_n}$ with respect to μ:

$$\mu_n^0(dx) = \frac{k_n(x)}{c_n}\,\mu_0(dx),$$

and the conditional distribution of u given x under μ_n is given by

$$\eta_n(x,du) = \frac{\psi_n(u)}{k_n(x)}\eta(x,du).$$

The pairs (A_n, μ_n) satisfy the conditions of Theorem 2.4, so there exist stationary processes $\{X_n\}$ such that $(X_n, \eta_n(X_n,\cdot))$ is a solution of the controlled martingale problem for (A_n, μ_n^0).

The relative compactness of $\{X_n\}$ is established by applying [9, Theorem 3.9.1] and [18, Theorem 4.5] exactly as in [18, Theorem 4.7]. Let X be a weak limit of X_n, and without loss of generality, assume the entire sequence converges.

By a monotone class argument, for each $f \in \mathcal{D}(A)$,

$$f(X(t)) - \int_0^t \int_U Af(X(s),u)\,\eta(X(s),du)\,ds$$

is an $\{\mathcal{F}_t^X\}$-martingale if and only if

$$E\left[\left(f(X(t_{m+1})) - f(X(t_m)) - \int_{t_m}^{t_{m+1}} \int_U Af(X(s),u)\,\eta(X(s),du)\,ds\right)\prod_{i=1}^m h_i(X(t_i))\right] = 0 \tag{2.20}$$

for each $m \geq 1$ and $0 \leq t_1 \leq \cdots \leq t_m < t_{m+1}$ and $h_1, \ldots, h_m \in \overline{C}(E)$.

Note that condition (2.21) is satisfied with A_n, η_n, and X_n replacing A, η, and X since $(X_n, \eta_n(X_n,\cdot))$ is a solution of the controlled martingale problem for A_n.

Fix $f \in \mathcal{D}(A)$, $t_1, \ldots, t_{m+1} \in \{t \geq 0 : P(X(t) = X(t-)) = 1\}$, and $h_1, \ldots, h_m \in \overline{C}(E)$. Since $X_n \Rightarrow X$ as $n \to \infty$,

$$E\left[(f(X_n(t_{m+1})) - f(X_n(t_m)))\prod_{i=1}^m h_i(X_n(t_i))\right]$$
$$\to E\left[(f(X(t_{m+1})) - f(X(t_m)))\prod_{i=1}^m h_i(X(t_i))\right].$$

Lemma 2.1 does not apply directly to the integral terms since the distributions of $X_n(t)$ and $X(t)$ are not the same. However, a similar argument can be used by approximating $\int_U Af(x,u)\,\eta(x,du)$ by a continuous function in $\mathcal{L}^1(\mu_0)$ and using the facts that $X_n(t)$ has distribution $\mu_n^0(dx) = k_n(x)/c_n\mu_0(dx)$ and $k_n \searrow 1$ as $n \to \infty$. Therefore, (2.20) is established for $t_1, \ldots, t_{m+1} \in \{t \geq 0 : P(X(t) = X(t-)) = 1\}$. The result is extended to all $t_1, \ldots, t_{m+1}$ by the right continuity of X. Thus

$$f(X(t)) - \int_0^t \int_U Af(X(s),u)\,\eta(X(s),du)\,ds$$

is an $\{\mathcal{F}_t^X\}$-martingale. □

3. Stationary solutions and the forward equation for Markov processes. Theorem 2.2 extends Echeverria's theorem (cf. [9, Theorem 4.9.17]) to include control in the dynamics. This theorem can in turn be used to extend the result in the uncontrolled setting to operators with range in $M(E)$, the (not necessarily bounded) measurable functions on E; that is, we relax both the boundedness and the continuity assumptions of the previous results.

THEOREM 3.1. *Let E be locally compact and separable. Let $\widehat{A} : \mathcal{D}(\widehat{A}) \subset \widehat{C}(E) \to M(E)$, let $\mathcal{D}(\widehat{A})$ be an algebra, and let $\widehat{\mu} \in \mathcal{P}(E)$ satisfy*

$$\int_E \widehat{A}f(x)\,\widehat{\mu}(dx) = 0 \qquad \forall f \in \mathcal{D}(\widehat{A}). \tag{3.1}$$

Suppose that there exists a locally compact, separable, metric space U, an operator $A : \mathcal{D}(A) \equiv \mathcal{D}(\widehat{A}) \subset \widehat{C}(E) \to C(E \times U)$ satisfying conditions (i)–(iv)*, a transition function η from E to U such that*

$$\widehat{A}f(x) = \int_U Af(x,u)\,\eta(x,du) \qquad \forall f \in \mathcal{D}(\widehat{A}),$$

and a $\psi \in C(U)$ satisfying condition (vi) *and*

$$\int_{E\times U} \psi(u)\,\eta(x,du)\widehat{\mu}(dx) < \infty.$$

Then there exists a stationary solution X of the (uncontrolled) martingale problem for $(\widehat{A}, \widehat{\mu})$.

Proof. This theorem follows immediately from Theorem 2.2, defining $\mu \in \mathcal{P}(E \times U)$ by $\mu(dx \times du) = \eta(x,du)\widehat{\mu}(dx)$. □

Theorem 3.1 immediately gives a generalization of Proposition 4.9.19 of [9] regarding solutions of the forward equation

$$\int_E f\,d\nu_t = \int_E f\,d\nu_0 + \int_0^t \int_E \widehat{A}f\,d\nu_s\,ds\,, \quad f \in \mathcal{D}(\widehat{A}), \tag{3.2}$$

for a $\mathcal{P}(E)$-valued function ν. The proof of the next corollary uses the argument of Theorem 4.1 in the next section.

COROLLARY 3.2. *Let $\widehat{A} : \mathcal{D}(\widehat{A}) \subset \widehat{C}(E) \to M(E)$, A, and ψ be as in Theorem* 3.1*, and let ν satisfy* (3.2) *and*

$$\int_0^\infty e^{-\lambda s} \int_{E\times U} \psi(u)\, \eta(x, du)\nu_s(dx)ds < \infty \tag{3.3}$$

for all sufficiently large $\lambda > 0$. Then there exists a solution X of the martingale problem for $(\widehat{A}, \nu_0)$ such that $X(t)$ has distribution ν_t. If uniqueness holds for the martingale problem for $(\widehat{A}, \nu_0)$, then uniqueness holds for (3.2) *among solutions satisfying the integrability condition* (3.3).

Proof. Existence of the process X follows by the proof of Theorem 4.1 when the measure $\pi \in \mathcal{P}(\mathbb{R}^+ \times E \times U)$ is defined to satisfy

$$\int_{\mathbb{R}^+\times E\times U} h(s, x, u)\pi(ds \times dx \times du) = \alpha \int_0^\infty e^{-\alpha s} \int_E \int_U h(s, x, u)\eta(x, du)\nu_s(dx)ds$$

for $h \in \overline{C}(\mathbb{R}^+ \times E \times U)$. The proof of uniqueness is identical to that of Proposition 4.9.19 of [9]. □

Example 3.3 (linear combinations of generators). Suppose

$$\widehat{A}f(x) = \sum_{k=1}^m \beta_k(x)A_k f(x),$$

in which each A_k satisfies conditions (i)–(v), $A_1, \ldots, A_m$ have a common domain, and the coefficients β_k are only assumed to be nonnegative and measurable. Suppose $\widehat{\mu}$ satisfies (3.1) and

$$\int_E \sum_k \beta_k(x)\widehat{\mu}(dx) < \infty.$$

Then there exists a stationary solution of the martingale problem for $(\widehat{A}, \widehat{\mu})$. To see that Theorem 3.1 applies, take $U = [0, \infty)^m$, $Af(x, u) = \sum_{k=1}^m u_k A_k f(x)$, $\eta(x, du) = \prod_{k=1}^m \delta_{\{\beta_k(x)\}}(du_k)$, and $\psi(u) = \sum_{k=1}^m |u_k|$. Similarly, if $\{\nu_t\}$ satisfies (3.2) and

$$\int_0^\infty e^{-\lambda s} \int_E \sum_k \beta_k(x)\nu_s(dx)ds < \infty$$

for all sufficiently large λ, then by Corollary 3.2 there exists a solution X of the martingale problem for $\widehat{A}$ such that ν_t is the distribution of $X(t)$.

Example 3.4 (diffusion operators with discontinuous coefficients). Consider the diffusion generator on $\mathbb{R}^d$,

$$\widehat{A}f(x) = \frac{1}{2}\sum_{i,j=1}^d a_{ij}(x)\frac{\partial^2}{\partial x_i \partial x_j}f(x) + \sum_{i=1}^d b_i(x)\frac{\partial}{\partial x_i}f(x)$$

with domain $\mathcal{D}(\widehat{A}) = C_c^2(\mathbb{R}^d)$, in which the coefficients are only assumed to be measurable. Suppose that $\widehat{\mu} \in \mathcal{P}(E)$ satisfies

$$\int_E \widehat{A}f(x)\, \widehat{\mu}(dx) = 0 \qquad \forall f \in \mathcal{D}(\widehat{A}) \tag{3.4}$$

and

$$\int [\|a(x)\| + |b(x)|]\, \widehat{\mu}(dx) < \infty,$$

where $a(x) = ((a_{ij}(x)))$ and $b(x) = (b_1(x), \ldots, b_d(x))$.

Let $U = \mathbb{M}_+^{d\times d} \times \mathbb{R}^d$, where $\mathbb{M}_+^{d\times d}$ denotes the space of nonnegative definite $d \times d$ matrices, and, with $u = (u^1, u^2)$, define

$$Af(x,u) = \frac{1}{2}\sum_{i,j=1}^{d} u^1_{ij} \frac{\partial^2}{\partial x_i \partial x_j} f(x) + \sum_{i=1}^{d} u^2_i \frac{\partial}{\partial x_i} f(x)\ ,$$

$\eta(x, du) = \delta_{\{a(x)\}}(du^1)\delta_{\{b(x)\}}(du^2)$, and $\psi(u) = \|u^1\| + |u^2|$. Then Theorem 3.1 gives the existence of a stationary solution of the martingale problem for $(\widehat{A}, \widehat{\mu})$. Similarly, if there exists a solution of (3.2) satisfying

$$\int_0^\infty e^{-\lambda s} \int [\|a(x)\| + |b(x)|]\, \nu_s(dx)ds < \infty$$

for all sufficiently large $\lambda > 0$, then there exists a solution X of the martingale problem for $\widehat{A}$ such that for each $t \geq 0$, ν_t is the distribution of $X(t)$.

Example 3.5 (jump processes). Let E be locally compact and

$$\widehat{A}f(x) = \lambda(x) \int_E (f(y) - f(x))\gamma(x, dy),$$

where λ is a nonnegative measurable function on E and γ is a transition function on E. Suppose that $\widehat{\mu} \in \mathcal{P}(E)$ satisfies (3.1) and $\int_E \lambda(x)\widehat{\mu}(dx) < \infty$. Let E^Δ denote the one-point compactification of E and $U = [0, \infty) \times \mathcal{P}(E^\Delta)$. Define

$$Af(x,u) = u_1 \int (f(y) - f(x))u_2(dy)\ ,$$

$\psi(u) = u_1$, and $\eta(x, du) = \delta_{\{\lambda(x)\}}(du_1)\delta_{\{\gamma(x,\cdot)\}}(du_2)$. Then Theorem 3.1 gives the existence of a stationary solution of the martingale problem for $(\widehat{A}, \widehat{\mu})$. Similarly, if there exists a solution of (3.2) satisfying

$$\int_0^\infty e^{-\lambda s}\lambda(x)\, \nu_s(dx)ds < \infty$$

for all sufficiently large $\lambda > 0$, then there exists a solution X of the martingale problem for $\widehat{A}$ such that for each $t \geq 0$, ν_t is the distribution of $X(t)$.

4. Feedback controls. We now use Theorem 2.2 to show that for each solution (X, Λ) of the controlled martingale problem for A there is a process Y and a transition function $\eta(s, y, du)$, $(s, y) \in [0, \infty) \times E$, such that $\{(Y(s), \eta(s, Y(s), \cdot)) : s \geq 0\}$ is a solution of the controlled martingale problem for A and for each $s \geq 0$, $(Y(s), \eta(s, Y(s), \cdot))$ has the same distribution as $(X(s), E[\Lambda_s|X(s)])$. To obtain the desired process, we introduce a time-space generator $\tilde{A}$, identify a stationary distribution for $\tilde{A}$, and apply Theorem 2.2 to obtain a (stationary) solution of the martingale problem for $\tilde{A}$. An absolutely continuous change of measure produces the desired solution of the controlled martingale problem for A.

THEOREM 4.1 (cf. [2, Theorem 2.4]). *Suppose E, U, A, and ψ satisfy the conditions of section* 1.1. *Let (X, Λ) be a relaxed solution of the controlled martingale problem for (A, ν_0), and suppose there exists $\alpha > 0$ such that*

$$\int_0^\infty e^{-\alpha t} E\left[\int_U \psi(u)\Lambda_t(du)\right] dt < \infty. \tag{4.1}$$

Then there exists a process Y and a transition function η from $[0,\infty) \times E$ to U such that $\{(Y(s), \eta(s, Y(s), \cdot)) : s \geq 0\}$ is a relaxed solution of the controlled martingale problem for (A, ν_0) and for each $t \geq 0$, the distribution of $(Y(t), \eta(t, Y(t), \cdot))$ on $E \times \mathcal{P}(U)$ is the same as $(X(t), E[\Lambda_t(\cdot)|X(t)])$.

Proof. Define the time-space generator

$$\tilde{A}(\gamma f)(s,x,u) = \gamma(s)Af(x,u) + \gamma'(s)f(x) + \alpha\left[\gamma(0)\int_E f(y)\nu_0(dy) - \gamma(s)f(x)\right] \tag{4.2}$$

for $f \in \mathcal{D}(A)$ and $\gamma \in \widehat{C}^1(\mathbb{R}^+)$ and observe that $\tilde{A}$ satisfies conditions (i)–(iv).

Define the measure $\pi \in \mathcal{P}(\mathbb{R}^+ \times E \times U)$ by

$$\int_{\mathbb{R}^+\times E\times U} h(s,x,u)\pi(ds \times dx \times du) = \alpha \int_0^\infty e^{-\alpha s} E\left[\int_U h(s, X(s), u)\Lambda_s(du)\right] ds \tag{4.3}$$

for $h \in \overline{C}(\mathbb{R}^+ \times E \times U)$. The following computation verifies that π is a stationary distribution for $\tilde{A}$. Let $f \in \mathcal{D}(A)$ and $\gamma \in \widehat{C}^1(\mathbb{R}^+)$. Then

$$\begin{aligned}
&\int_{\mathbb{R}^+\times E\times U} \tilde{A}(\gamma f)(s,x,u)\,\pi(ds \times dx \times du) \\
&\quad = \alpha\int_0^\infty \gamma(s)e^{-\alpha s}E\left[\int_U Af(X(s),u)\Lambda_s(du)\right] ds + \alpha\int_0^\infty \gamma'(s)e^{-\alpha s}E[f(X(s))]\,ds \\
&\qquad + \alpha^2\int_0^\infty e^{-\alpha s}\,ds\gamma(0)E[f(X(0))] - \alpha^2\int_0^\infty \gamma(s)e^{-\alpha s}E[f(X(s))]\,ds \\
&\quad = \alpha\int_0^\infty \gamma(s)e^{-\alpha s}E\left[\int_U Af(X(s),u)\Lambda_s(du)\right] ds \\
&\qquad + \alpha E\left[\int_0^\infty \frac{d}{ds}(\gamma(s)e^{-\alpha s})f(X(s))\,ds\right] + \alpha\gamma(0)E[f(X(0))] \\
&\quad = \alpha\int_0^\infty \gamma(s)e^{-\alpha s}E\left[\int_U Af(X(s),u)\Lambda_s(du)\right] ds + E\left[\alpha\gamma(s)e^{-\alpha s}f(X(s))\,|_{s=0}^{s=\infty}\right] \\
&\qquad - \alpha\int_0^\infty \gamma(s)e^{-\alpha s}E\left[\int_U Af(X(s),u)\,\Lambda_s(du)\right] ds + \alpha\gamma(0)E[f(X(0))] \\
&\quad = 0.
\end{aligned}$$

Let $\eta(s,x,du)$ denote the regular conditional distribution of u given (s,x) such that

$$\pi(\Gamma_1\times\Gamma_2)=\int_{\Gamma_1}\eta(s,x,\Gamma_2)\,\pi(ds\times dx\times U)\qquad\forall\Gamma_1\in\mathcal{B}(\mathbb{R}^+\times E),\Gamma_2\in\mathcal{B}(U).$$

Since π is a stationary distribution for $\tilde{A}$ and the definition of π together with (4.1) implies (2.5) is satisfied, Theorem 2.2 gives the existence of a stationary time-space process $\{(S(t),Z(t)):t\geq 0\}$ and a filtration $\mathcal{G}_t$ such that $\{(S(t),Z(t),\eta(S(t),Z(t),\cdot)):t\geq 0\}$ is a relaxed solution of the controlled martingale problem for $\tilde{A}$ with distribution π.

Before constructing the desired process Y, we investigate the stationary time process S more carefully. For simplicity, assume that the state space E is compact and $A1=0$; otherwise compactify E as in Theorem 2.2. Then, by choosing $f=1$, we see that

$$\gamma(S(t))-\int_0^t\left(\gamma'(S(r))+\alpha[\gamma(0)-\gamma(S(r))]\right)dr \tag{4.4}$$

is an $\{\mathcal{F}_t^{S,Z}\}$-martingale for every $\gamma\in\widehat{C}^1(\mathbb{R}^+)$. By [9, Theorem 4.4.1], uniqueness holds for the martingale problem (4.4). Now define a process $\tilde{S}$ as follows. Let $\Delta_1,\Delta_2,\Delta_3,\ldots$ be a sequence of independent exponential random variables with parameter α and let $\tilde{S}(0)$ also be an exponential random variable with parameter α which is independent of $\{\Delta_n\}$. Let

$$\tilde{S}(t)=\begin{cases}\tilde{S}(0)+t, & 0\leq t<\Delta_1,\\ \\ t-\Delta_n, & \Delta_n\leq t<\Delta_{n+1}.\end{cases}$$

$\tilde{S}$ is a stationary solution of (4.4) and thus the process S has been identified. Note that we may assume that (S,Z) is defined for all $t\in(-\infty,\infty)$.

Now let $\tau_1=\inf\{t>0:S(t)=0\}$ and, for $k\geq 1$, $\tau_{k+1}=\inf\{t>\tau_k:S(t)=0\}$. Also define $\tau_{-1}=\sup\{t\leq 0:S(t)=0\}$. Define the process Y by $Y(t)=Z(\tau_1+t)$, $t\geq 0$, and the filtration $\mathcal{F}_t=\mathcal{G}_{\tau_1+t}$. Again, for simplicity, compactify the time dimension by taking the one-point compactification $[0,\infty]$ and extend the generator (4.2) by linearity, where for the constant function 1,

$$\tilde{A}(1f)(s,x,u)=Af(x,u)+\alpha\left[\int_E f(y)\nu_0(dy)-f(x)\right]. \tag{4.5}$$

An application of the optional sampling theorem (cf. [9, Theorem 2.2.13]) shows that (with $\gamma=1$)

$$f(Y(t))-\int_0^t\int_U\left[Af(Y(r),u)+\alpha\left(\int_E f(y)\nu_0(dy)-f(Y(r))\right)\right],\\ \eta(S(\tau_1+r),Y(r),du)\,dr$$

is an $\{\mathcal{F}_t\}$-martingale under P.

Define

$$L(t)=[\alpha(\tau_1-\tau_{-1})]^{-1}e^{\alpha t}I_{[0,\tau_2-\tau_1)}(t)$$

and observe that L is an $\{\mathcal{F}_t\}$-martingale with $E[L(t)] = 1$. Let $\widehat{P}$ be a new probability having Radon–Nikodým derivative $L(t)$ on $\mathcal{F}_t$ with respect to the original probability P. Denote expectation with respect to $\widehat{P}$ by $E^{\widehat{P}}[\cdot]$.

Remark 4.2. The Radon–Nikodým derivative $L(t)$ includes the term $[\alpha(\tau_1 - \tau_{-1})]^{-1}$ because we have been unable to show that the $\{\tau_k\}$ are regeneration times for (S, Z). (They are for S alone.) In fact, in general there will be stationary solutions of the controlled martingale problem for $\tilde{A}$ for which the $\{\tau_k\}$ are not regeneration times. When the $\{\tau_k\}$ are regeneration times for (S, Z), the independence between cycles implies

$$E^{\widehat{P}}\left[\int_0^\infty e^{-\alpha t}\int_U h(t, Y(t), u)\,\eta(t, Y(t), du)\,dt\right]$$
$$= E\left[\int_{\tau_1}^{\tau_2}\int_U h(S(t), Z(t), u)\,\eta(S(t), Z(t), du)\,dt\right]$$

and the following argument can be considerably simplified.

We claim that $\{(Y(t), \eta(t, Y(t), \cdot)), t \geq 0\}$ under $\widehat{P}$ is the desired solution. We will first show that this process is a solution to the original martingale problem for A.

A straightforward calculation shows that for $f \in \mathcal{D}(A)$,

$$\lim_{h\searrow 0} h^{-1}E\left[[\alpha(\tau_1 - \tau_{-1})]^{-1}\left\{e^{\alpha(t+h)}I_{[0,\tau_2-\tau_1)}(t+h)f(Y(t+h))\right.\right.$$
$$\left.\left. - e^{\alpha t}I_{[0,\tau_2-\tau_1)}(t)f(Y(t))\right\}|\mathcal{F}_t\right]$$
$$= [\alpha(\tau_1 - \tau_{-1})]^{-1}e^{\alpha t}I_{[0,\tau_2-\tau_1)}(t)\int_U Af(Y(t), u)\,\eta(t, Y(t), du),$$

which implies that

$$[\alpha(\tau_1 - \tau_{-1})]^{-1}e^{\alpha t}I_{[0,\tau_2-\tau_1)}(t)f(Y(t))$$
$$- \int_0^t [\alpha(\tau_1 - \tau_{-1})]^{-1}e^{\alpha s}I_{[0,\tau_2-\tau_1)}(s)\int_U Af(Y(s), u)\,\eta(s, Y(s), du)\,ds$$

is an $\{\mathcal{F}_t\}$-martingale under P. In particular,

$$0 = E\left[[\alpha(\tau_1 - \tau_{-1})]^{-1}\left\{e^{\alpha t_{n+1}}I_{[0,\tau_2-\tau_1)}(t_{n+1})f(Y(t_{n+1})) - e^{\alpha t_n}I_{[0,\tau_2-\tau_1)}(t_n)f(Y(t_n))\right.\right.$$
$$\left.\left. - \int_{t_n}^{t_{n+1}} e^{\alpha s}I_{[0,\tau_2-\tau_1)}(s)\int_U Af(Y(s), u)\,\eta(s, Y(s), du)\,ds\right\}\prod_{i=1}^n h_i(Y(t_i))\right]$$

$$= E\left[[\alpha(\tau_1-\tau_{-1})]^{-1}\left\{e^{\alpha t_{n+1}}I_{[0,\tau_2-\tau_1)}(t_{n+1})f(Y(t_{n+1}))\right.\right.$$
$$- E[e^{\alpha t_{n+1}}I_{[0,\tau_2-\tau_1)}(t_{n+1})|\mathcal{F}_{t_n}]f(Y(t_n))$$
$$- \int_{t_n}^{t_{n+1}} E[e^{\alpha t_{n+1}}I_{[0,\tau_2-\tau_1)}(t_{n+1})|\mathcal{F}_s]$$
$$\left.\left.\times\int_U Af(Y(s),u)\,\eta(s,Y(s),du)\,ds\right\}\prod_{i=1}^n h_i(Y(t_i))\right]$$

$$= E^{\widehat{P}}\left[\left\{f(Y(t_{n+1}))-f(Y(t_n))\right.\right.$$
$$\left.\left.-\int_{t_n}^{t_{n+1}}\int_U Af(Y(s),u)\eta(s,Y(s),du)\,ds\right\}\prod_{i=1}^n h_i(Y(t_i))\right]$$

for each $n\geq 1$, $0\leq t_1\leq\cdots\leq t_n<t_{n+1}$, and $h_1,\ldots,h_n\in\overline{C}(E)$. It follows that

$$f(Y(t))-f(Y(0))-\int_0^t\int_U Af(Y(s),u)\eta(s,Y(s),du)ds$$

is an $\{\mathcal{F}_t^Y\}$-martingale under $\widehat{P}$.

We now derive the one-dimensional distributions of this solution. First, for each $h\in\overline{C}(\mathbb{R}^+\times E\times U)$,

$$E^{\widehat{P}}\left[\alpha\int_0^T e^{-\alpha t}\int_U h(t,Y(t),u)\,\eta(t,Y(t),du)\,dt\right]$$
$$= E\left[[\alpha(\tau_1-\tau_{-1})]^{-1}\alpha e^{\alpha T}I_{[0,\tau_2-\tau_1)}(T)\int_0^T e^{-\alpha t}\int_U h(t,Y(t),u)\,\eta(t,Y(t),du)\,dt\right]$$
$$= E\left[\int_0^T(\tau_1-\tau_{-1})^{-1}E[e^{\alpha T}I_{[0,\tau_2-\tau_1)}(T)|\mathcal{F}_t]e^{-\alpha t}\int_U h(t,Y(t),u)\,\eta(t,Y(t),du)\,dt\right]$$
$$= E\left[(\tau_1-\tau_{-1})^{-1}\int_{\tau_1}^{\tau_2\wedge(\tau_1+T)}\int_U h(S(t),Z(t),u)\,\eta(S(t),Z(t),du)\,dt\right],$$

and letting $T\to\infty$ yields

$$E^{\widehat{P}}\left[\alpha\int_0^\infty e^{-\alpha t}\int_U h(t,Y(t),u)\,\eta(t,Y(t),du)\,dt\right]$$
$$= E\left[(\tau_1-\tau_{-1})^{-1}\int_{\tau_1}^{\tau_2}\int_U h(S(t),Z(t),u)\,\eta(S(t),Z(t),du)\,dt\right]. \tag{4.6}$$

Now, for $t\geq 0$, define $\tau_{-1}^t=\sup\{r\leq t: S(r)=0\}$, $\tau_1^t=\inf\{r>t: S(r)=0\}$, and $\tau_2^t=\inf\{r>\tau_1^t: S(r)=0\}$. Note that $\tau_i^0=\tau_i$ for $i=-1,1$. Observe that

$$(\tau_1^t - \tau_{-1}^t)^{-1} \int_{\tau_1^t}^{\tau_2^t} \int_U h(S(r), Z(r), u)\, \eta(S(r), Z(r), du)\, dr$$

is stationary in t and that for $t \in [\tau_k, \tau_{k+1})$,

$$(\tau_1^t - \tau_{-1}^t)^{-1} \int_{\tau_1^t}^{\tau_2^t} \int_U h(S(r), Z(r), u)\, \eta(S(r), Z(r), du)\, dr$$

$$= (\tau_{k+1} - \tau_k)^{-1} \int_{\tau_{k+1}}^{\tau_{k+2}} \int_U h(S(r), Z(r), u)\, \eta(S(r), Z(r), du)\, dr.$$

Let $N(t)$ denote the number of jumps in the interval $[0, t]$. Then, by stationarity (letting $\tau_0 = \tau_{-1}$),

$$E\left[(\tau_1 - \tau_{-1})^{-1} \int_{\tau_1}^{\tau_2} \int_U h(S(r), Z(r), u)\, \eta(S(r), Z(r), du)\, dr\right]$$

$$= E\left[T^{-1} \int_0^T (\tau_1^t - \tau_{-1}^t)^{-1} \int_{\tau_1^t}^{\tau_2^t} \int_U h(S(r), Z(r), u)\, \eta(S(r), Z(r), du)\, dr\, dt\right]$$

$$= T^{-1} E\left[\sum_{k=1}^{N(T)+1} \frac{T \wedge \tau_k - \tau_{k-1} \vee 0}{\tau_k - \tau_{k-1}} \times \left(\int_{\tau_k}^{\tau_{k+1}} \int_U h(S(r), Z(r), u)\, \eta(S(r), Z(r), du)\, dr\right)\right]$$

$$= T^{-1} E\left[\int_0^T \int_U h(S(r), Z(r), u)\, \eta(S(r), Z(r), du)\, dr\right]$$

$$- T^{-1} E\left[\int_0^{\tau_1 \wedge T} \left(1 - \frac{T \wedge \tau_1}{\tau_1 - \tau_{-1}}\right) \int_U h(S(r), Z(r), u)\, \eta(S(r), Z(r), du)\, dr\right]$$

$$+ T^{-1} E\left[I_{\{N(T)=1\}} \frac{\tau_1}{\tau_1 - \tau_{-1}} \int_T^{\tau_2} \int_U h(S(r), Z(r), u)\, \eta(S(r), Z(r), du)\, dr\right]$$

$$+ T^{-1} E\left[I_{\{N(T)>1\}} \int_T^{\tau_{N(T)+1}} \int_U h(S(r), Z(r), u)\, \eta(S(r), Z(r), du)\, dr\right]$$

$$+ T^{-1} E\left[I_{\{N(T)>0\}} \frac{T - \tau_{N(T)}}{\tau_{N(T)+1} - \tau_{N(T)}} \times \int_{\tau_{N(T)+1}}^{\tau_{N(T)+2}} \int_U h(S(r), Z(r), u)\, \eta(S(r), Z(r), du)\, dr\right].$$

The first term equals $\int h(s, x, u)\, \pi(ds \times dx \times du)$ and the other terms converge to 0

as $T \to \infty$. Thus

$$E\left[(\tau_1 - \tau_{-1})^{-1} \int_{\tau_1}^{\tau_2} \int_U h(S(r), Z(r), u)\, \eta(S(r), Z(r), du)\, dr\right]$$

$$= \int h(s, x, u)\pi(ds \times dx \times du) \tag{4.7}$$

$$= \alpha \int_0^\infty e^{-\alpha s} E\left[\int_U h(s, X(s), u)\, \Lambda_s(du)\right] ds.$$

Combining (4.6) and (4.7) yields

$$E^{\widehat{P}}\left[\alpha \int_0^\infty e^{-\alpha t} \int_U h(t, Y(t), u)\, \eta(t, Y(t), du)\, dt\right]$$

$$= E\left[\alpha \int_0^\infty e^{-\alpha t} \int_U h(t, X(t), u)\, \Lambda_t(du)\, dt\right]. \tag{4.8}$$

Let $\{h_n\} \subset \overline{C}(E)$ be a countable collection which is separating (cf. [9, p. 112]). Taking $h(t, x, u)$ in (4.8) to be of the form $\gamma(t)h_n(x)$, we see that

$$E^{\widehat{P}}[h_n(Y(t))] = E[h_n(X(t))] \quad \text{a.e. } t.$$

Since $\{h_n\}$ is separating, it follows that $Y(t) \stackrel{d}{=} X(t)$, a.e. t, and by right continuity we have

$$Y(t) \stackrel{d}{=} X(t) \quad \forall\ t. \tag{4.9}$$

More generally, modifying $\eta(t, x, du)$ at a set of t of measure zero if necessary, we have that for $h \in \overline{C}(E)$ and $g \in \overline{C}(U)$

$$E^{\widehat{P}}\left[h(Y(t)) \int_U g(u)\, \eta(t, Y(t), du)\right] = E\left[h(X(t)) \int_U g(u)\, \Lambda_t(du)\right] \quad \forall\ t.$$

The relation (4.9) then implies

$$E\left[h(X(t)) \int_U g(u)\, \eta(t, X(t), du)\right] = E\left[h(X(t)) \int_U g(u)\, \Lambda_t(du)\right]$$

for each $h \in \overline{C}(E)$ and $g \in \overline{C}(U)$. Since this is true for each bounded, continuous h, it follows that

$$E\left[\int_U g(u)\Lambda_t(du)|X(t)\right] = \int_U g(u)\eta(t, X(t), du) \quad \text{a.s.}$$

for each bounded continuous g, and hence that the distributions of $\eta(t, Y(t), \cdot)$ and $E[\Lambda_t(\cdot)|X(t)]$ as random measures are the same and also

$$(Y(t), \eta(t, Y(t), \cdot)) \stackrel{d}{=} (X(t), E[\Lambda_t(\cdot)|X(t)]) \quad \forall\ t. \qquad \square \tag{4.10}$$

Theorem 4.1 gives the existence of a relaxed control η which is Markovian in the sense that it only depends on the current state $Y(t)$ and time t and does not depend on

the history of the process. Moreover, (4.10) implies that these solutions have the same cost under any criterion which only depends on the one-dimensional distributions. In particular, this holds for the discounted criterion (1.4), for the finite-horizon criterion (1.5), and for the long-term average criterion (1.6).

The following corollary relaxes the boundedness and uniform ellipticity assumptions in the result of Gyöngy [11].

COROLLARY 4.3. *Suppose that W is an $\mathbb{R}^d$-valued $\{\mathcal{F}_t\}$-Brownian motion; $\widehat{\sigma}$ and $\widehat{b}$ are measurable, $\{\mathcal{F}_t\}$-adapted processes taking values in $\mathbb{M}^{d\times d}$ and $\mathbb{R}^d$, respectively; and $X(0)$ is $\mathbb{R}^d$-valued and $\mathcal{F}_0$-measurable. Let*

$$X(t) = X(0) + \int_0^t \widehat{\sigma}(s)dW(s) + \int_0^t \widehat{b}(s)ds.$$

Then there exist measurable functions $\sigma : [0,\infty)\times\mathbb{R}^d \to \mathbb{M}^{d\times d}$ and $b : \mathbb{R}^d \to \mathbb{R}^d$, an $\mathbb{R}^d$-valued Brownian motion $\tilde{W}$, and a process Y satisfying

$$Y(t) = Y(0) + \int_0^t \sigma(s, Y(s))d\tilde{W}(s) + \int_0^t b(s, Y(s))ds$$

such that for each $t \geq 0$, the distributions of $(X(t), E[\widehat{b}(t)|X(t)], E[\widehat{\sigma}(t)\widehat{\sigma}^T(t)|X(t)])$ and $(Y(t), b(t, Y(t)), \sigma(t, Y(t))\sigma^T(t, Y(t)))$ are the same.

Proof. Let the control space $U = \mathbb{M}_+^{d\times d} \times \mathbb{R}^d$, where $\mathbb{M}_+^{d\times d}$ denotes the space of nonnegative definite $d\times d$ matrices, and, with $u = (u^1, u^2)$, define the time-space generator

$$A(\gamma f)(t,x,u) = \gamma(t)\left(\frac{1}{2}\sum_{i,j=1}^d u^1_{ij} f_{x_i x_j}(x) + \sum_{i=1}^d u^2_i f_{x_i}(x)\right) + \gamma'(t)f(x),$$

where $\gamma \in C_c^1(\mathbb{R}^+)$ and $f \in \mathcal{D}(\widehat{A})$.

Let $\widehat{a}(t) = \widehat{\sigma}(t)\widehat{\sigma}(t)^T$ and $\Lambda_t(du) = \delta_{\{\widehat{a}(t)\}}(du^1)\delta_{\{\widehat{b}(t)\}}(du^2)$. Then (X,Λ) determines a solution to the controlled martingale problem for A. Taking $\psi(u) = ||u^1|| + |u^2|$, the conditions of Theorem 4.1 are satisfied and an application of the theorem gives the existence of a process Y and measurable functions a and b. Let σ be the symmetric square root of a (which will exist even in the degenerate case). Existence of $\tilde{W}$ follows by [9, Theorem 5.3.3], and the result follows. □

4.1. First passage problems. We now turn our attention to the issue of existence of Markov controls for exit problems. In this section, we seek to minimize (1.7), in which c and g are time-dependent and $E_0 \subset \mathbb{R}^+ \times E$, over all solutions (X,Λ) of the controlled martingale problem such that $X(0)$ has distribution ν_0 and where, to avoid degeneracies, we assume $\nu_0\{x : (0,x) \in E_0\} = 1$.

The key to this existence result is the characterization of the occupation measures similar to that given by (2.1). We consider pairs of measures $\mu_0 \in \mathcal{M}(E_0\times U)$ ($\mathcal{M}(E_0\times U)$, the Radon measures on $E_0\times U$) and $\mu_1 \in \mathcal{P}(E_0^c)$, such that

$$\mu_0(E_0\times U) < \infty. \tag{4.11}$$

The condition corresponding to (2.1) is

$$\int_{E_0\times U} [\gamma(s)Af(x,u) + \gamma'(s)f(x)]\,\mu_0(ds\times dx\times du) + \gamma(0)\int f\,d\nu_0 - \int_{E_0^c}\gamma(s)f(x)\,\mu_1(ds\times dx) = 0 \tag{4.12}$$

for all $\gamma \in \widehat{C}^1(\mathbb{R}^+)$ and $f \in \mathcal{D}(A)$.

To motivate this condition on the measures μ_0 and μ_1, consider a process (X, Λ) as above and assume $E[\tau] < \infty$. Then, under appropriate conditions,

$$E\left[\gamma(\tau)f(X(\tau)) - \gamma(0)f(X(0)) \right.$$

$$\left. - \int_0^\tau \int_U [\gamma(s)Af(X(s),u) + \gamma'(s)f(X(s))]\,\Lambda_s(du)\,ds\right] = 0.$$

Let μ_0 be given by

$$\mu_0(B) = E\left[\int_0^\tau \int_U I_B(s, X(s), u)\Lambda_s(du)ds\right],$$

and let μ_1 be the joint distribution of the exit time and exit location $(\tau, X(\tau))$. Then (4.12) is satisfied.

The following lemma will be needed to establish properties of solutions to the controlled martingale problem. Its proof is delayed to the appendix (section 7).

LEMMA 4.4. *Let Q be a nonnegative, $\{\mathcal{F}_t\}$-adapted, cadlag process, let V_1 and V_2 be bounded, nonnegative, measurable, $\{\mathcal{F}_t\}$-adapted processes, and suppose that*

$$g(Q(t)) - \int_0^t (V_1(s)g'(Q(s)) + V_2(s)(g(0) - g(Q(s))))\,ds$$

is an $\{\mathcal{F}_t\}$-martingale for every C^1 function g with g and g' bounded. Let τ be a stopping time, and define $\sigma_0^\tau = \inf\{t > \tau : Q(t) > 0\}$ and $\sigma_1^\tau = \inf\{t > \sigma_0^\tau : Q(t) = 0\}$. Then, for $\tau \le t < \sigma_1^\tau$, $Q(t) - Q(\tau) = \int_\tau^t V_1(s)ds$, and if $\sigma_1^\tau < \infty$ a.s.,

$$P\left\{\int_{\sigma_0^\tau}^{\sigma_1^\tau} V_2(s)\,ds > x \middle| \mathcal{F}_{\sigma_0^\tau}\right\} = e^{-x}, \qquad x \ge 0.$$

The next result demonstrates existence of solutions corresponding to measures μ_0 and μ_1 which satisfy (4.11) and (4.12).

THEOREM 4.5. *Suppose that E, U, A, and ψ satisfy the conditions of section* 1.1 *and that $E_0 \subset \mathbb{R}^+ \times E$ is open. Let μ_0 and μ_1 satisfy* (4.11) *and* (4.12) *and setting $\mu_0^*(\Gamma) = \mu_0(\Gamma \times U)$, $\Gamma \in \mathcal{B}(E_0)$, let η be the transition function satisfying*

$$\mu_0(\Gamma_0 \times \Gamma_1) = \int_{\Gamma_0} \eta(s, x, \Gamma_1)\mu_0^*(ds \times dx).$$

Suppose

$$\int \psi(u)\mu_0(ds \times dx \times du) < \infty. \tag{4.13}$$

Then there exists a process Y with initial distribution ν_0 adapted to a filtration $\{\mathcal{F}_t\}$ and an $\{\mathcal{F}_t\}$-stopping time $\tilde{\tau}$ such that

$$f(Y(t \wedge \tilde{\tau})) - \int_0^{t\wedge\tilde{\tau}} \int_U Af(Y(s), u)\,\eta(s, Y(s), du)\,ds$$

is an $\{\mathcal{F}_t\}$*-martingale for each* $f \in \mathcal{D}(A)$ *and*

$$\begin{aligned} &\text{(i)} \quad P((\tilde{\tau}, Y(\tilde{\tau})) \in E_0^c) = 1 \\ &\textit{and} \\ &\text{(ii)} \quad \{t : (t, Y(t)) \in E_0^c, t < \tilde{\tau}\} \textit{ has Lebesgue measure } 0. \end{aligned} \tag{4.14}$$

Moreover, for each $\Gamma_1 \in \mathcal{B}(E_0 \times U)$,

$$E\left[\int_0^{\tilde{\tau}} \int_U I_{\Gamma_1}(s, Y(s), u)\, \eta(s, Y(s), du)\, ds\right] = \mu_0(\Gamma_1),$$

and for each $\Gamma_2 \in \mathcal{B}(E_0^c)$

$$E[I_{\Gamma_2}(\tilde{\tau}, Y(\tilde{\tau}))] = \mu_1(\Gamma_2).$$

Remark 4.6. Y can be extended to a solution of the controlled martingale problem for A for all $t \geq 0$, with sample paths in $D_{E^\Delta}[0, \infty)$. (See [9, Lemma 4.5.16].)

The hypotheses of the theorem do not rule out the possibility that $\tilde{\tau} > \sigma = \inf\{t : (t, Y(t)) \in E_0^c\}$. However, for many processes one can show that $\inf\{t : (t, Y(t)) \in E_0^c\} = \inf\{t : (t, Y(t)) \in (\overline{E}_0)^c\}$ a.s., which, by (4.14), implies $\tilde{\tau} = \sigma$ a.s.

Proof. The structure of this proof is very similar to that of Theorem 4.1 in that we augment the space, define both a new generator $\overline{A}$ and a corresponding stationary distribution $\overline{\mu}$, invoke Theorem 2.2 to obtain a stationary process, and use the optional sampling theorem in conjunction with an absolutely continuous change of measures to obtain the result. The specifics, however, are substantially different, and we therefore provide complete details.

First we augment the state space with extra time dimensions and augment the control space with a $\{0, 1\}$ component. Thus the state space is $\mathbb{R}^+ \times \mathbb{R}^+ \times E$ and the control space is $U \times \{0, 1\}$. Define the generator $\overline{A}$ by

$$\begin{aligned} \overline{A}(\beta\gamma f)(r, s, x, u, v) &= v\beta(r)[\gamma(s)Af(x, u) + \gamma'(s)f(x)] \\ &\quad + (1 - v)\left[\beta(0)\gamma(0)\int f\, d\nu_0 - \beta(r)\gamma(s)f(x) + \beta'(r)\gamma(s)f(x)\right] \end{aligned}$$

for $\beta, \gamma \in \widehat{C}^1(\mathbb{R}^+)$ and $f \in \mathcal{D}(A)$. It will be shown that the "s" component measures the time the process specified by generator A runs, whereas the "r" component measures the (mean 1) exponential time before all state components are reset. The control "v" determines whether the process governed by A runs or the jump process runs and will be restricted by the stationary measure so that $v = 1$ when $(s, x) \in E_0$ and $v = 0$ when $(s, x) \in E_0^c$.

Let u^* be a fixed point of U and let $K = \mu_0(E_0 \times U) + 1$. Define the measure $\overline{\mu} \in \mathcal{P}(\mathbb{R}^+ \times \mathbb{R}^+ \times E \times U \times \{0, 1\})$ by

$$\begin{aligned} &\int h(r, s, x, u, v)\, \overline{\mu}(dr \times ds \times dx \times du \times dv) \\ &\qquad = K^{-1}\left(\int_{E_0 \times U} h(0, s, x, u, 1)\, \mu_0(ds \times dx \times du)\right. \\ &\qquad\quad \left. + \int_0^\infty \int_{E_0^c} e^{-r} h(r, s, x, u^*, 0)\, \mu_1(ds \times dx)\, dr\right) \end{aligned}$$

for each bounded, continuous h. Observe that the conditional distribution of (u,v) given (r,s,x) under $\overline{\mu}$ is

$$\overline{\eta}(r,s,x,du\times dv)=\begin{cases}\eta(s,x,du)\delta_{\{1\}}(dv), & (s,x)\in E_0,\\ \delta_{\{u^*\}}(du)\delta_{\{0\}}(dv), & (s,x)\in E_0^c.\end{cases} \tag{4.15}$$

Note that we can determine the value of v by observing whether $(s,x)\in E_0$ or E_0^c, so we define $v(s,x)=I_{E_0}(s,x)$. In particular, v is an ordinary feedback control, and we therefore slightly abuse notation and write $\overline{\eta}(r,s,x,du)$ in the sequel. Note also that $I_{E_0}(s,x)=I_{\{0\}}(r)$ a.e. $\bar{\mu}$.

A straightforward computation shows that (4.12) implies that $(\overline{A},\overline{\mu})$ satisfies the stationarity condition (2.1). The conditions of Theorem 2.2 on the state and control spaces and the generator are also satisfied, which therefore implies existence of a stationary $\mathbb{R}^+\times\mathbb{R}^+\times E$-valued process (R,S,X) (which we may assume defined for all $t\in\mathbb{R}$) such that

$$\begin{aligned}&\beta(R(t))\gamma(S(t))f(X(t))\\ &-\int_0^t\int_U \overline{A}(\beta\gamma f)(R(s),S(s),X(s),u,v(S(s),X(s)))\,\overline{\eta}(R(s),S(s),X(s),du)\,ds\end{aligned} \tag{4.16}$$

is an $\{\mathcal{F}_t^{R,S,X}\}$-martingale for all $\beta,\gamma\in\widehat{C}^1(\mathbb{R}^+)$ and $f\in\mathcal{D}(A)$. In addition, we have that $v(S(s),X(s))=I_{E_0}(S(s),X(s))=I_{\{0\}}(R(s))$ a.s. for each $s\geq 0$.

For each $t\geq 0$, define the following random variables (cf. Theorem 4.1): $\sigma_{-1}^t=\sup\{r<t: S(r)=0,R(r)=0\}$, $\sigma_1^t=\inf\{r\geq t: S(r)=0,R(r)=0\}$, $\tau_1^t=\inf\{t>\sigma_1^t: R(t)>0\}$, and $\sigma_2^t=\inf\{r>\sigma_1^t: R(r)=0\}$. For $s\in[\sigma_1^t,\tau_1^t)$, by definition, $R(s)=0$ and by Lemma 4.4 $S(s)=\int_{\sigma_1^t}^s I_{\{0\}}(R(r))dr=(s-\sigma_1^t)$. For $s\in[\tau_1^t,\sigma_2^t)$, by Lemma 4.4, $R(s)=\int_{\tau_1^t}^s I_{(0,\infty)}(R(r))dr=s-\tau_1^t$ a.s. and conditional on $\mathcal{F}_{\tau_1^t}$, $\sigma_2^t-\tau_1^t$ is exponentially distributed with mean 1, and again by Lemma 4.4, $S(s)=S(\tau_1^t)+\int_{\tau_1^t}^s I_{\{0\}}(R(r))dr=S(\tau_1^t)=\tau_1^t-\sigma_1^t$. Starting with $g(r+s)=e^{-\alpha(r+s)}$ and approximating more general g by linear combinations of these exponentials, we see that

$$g(S(t)+R(t))-\int_0^t\left(g'(S(r)+R(r))+(1-v(S(r),X(r)))(g(0)-g(S(r)+R(r)))\right)dr$$

is a martingale for C^1 functions with g and g' bounded. Letting $\tilde{\sigma}_2^t=\inf\{s>\tau_1^t: S(s)+R(s)=0\}$, Lemma 4.4 implies

$$\begin{aligned}P\left\{\int_{\tau_1^t}^{\sigma_2^t}(1-v(S(r),X(r)))dr>x\Big|\mathcal{F}_{\tau_1^t}^{R,S,X}\right\}&=e^{-x}\\ &=P\left\{\int_{\tau_1^t}^{\tilde{\sigma}_2^t}(1-v(S(r),X(r)))dr>x\Big|\mathcal{F}_{\tau_1^t}^{R,S,X}\right\},\end{aligned}$$

and since $\sigma_2^t\leq\tilde{\sigma}_2^t$, we must have $\sigma_2^t=\tilde{\sigma}_2^t$ a.s. In particular, $S(\sigma_2^t)=0$ a.s. Finally, defining $Z(u)=(R(\tau_1^t+u),S(\tau_1^t+u),X(\tau_1^t+u))$ for $u\leq\sigma_2^t-\tau_1^t$, we can extend Z to be a solution of the martingale problem for

$$Cg(r,s,x)=\int g(0,0,y)\nu_0(dy)-g(r,s,x)+\frac{\partial}{\partial r}g(r,s,x).$$

Since any solution of this martingale problem has the property that the final component is constant except for jumps that occur when the first two components jump to zero, it follows that $X(u) = X(\tau_1^t)$ for $\tau_1^t \le u < \sigma_2^t$.

Let h be a fixed, bounded, continuous function, and define

$$H_\epsilon(r) = \int_U e^{-\epsilon(R(r)+S(r))} h(R(r), S(r), X(r), u, v(S(r), X(r))\, \overline{\eta}(R(r), S(r), X(r), du)).$$

Then, as a process in t,

$$(\sigma_1^t - \sigma_{-1}^t)^{-1} \int_{\sigma_1^t}^{\sigma_2^t} H_\epsilon(r)\, dr \tag{4.17}$$

is stationary, and for each t and $s \in [\sigma_{-1}^t, \sigma_1^t)$,

$$(\sigma_1^s - \sigma_{-1}^s)^{-1} \int_{\sigma_1^s}^{\sigma_2^s} H_\epsilon(r)\, dr = (\sigma_1^t - \sigma_{-1}^t)^{-1} \int_{\sigma_1^t}^{\sigma_2^t} H_\epsilon(r)\, dr.$$

These expressions are set equal to 0 whenever $\sigma_{-1}^t = -\infty$ or $\sigma_1^t = +\infty$.

Using stationarity,

$$E\left[(\sigma_1^t - \sigma_{-1}^t)^{-1} \int_{\sigma_1^t}^{\sigma_2^t} H_\epsilon(r)\, dr\right] = T^{-1} \int_0^T E\left[(\sigma_1^t - \sigma_{-1}^t)^{-1} \int_{\sigma_1^t}^{\sigma_2^t} H_\epsilon(r) dr\right] dt, \tag{4.18}$$

in which both sides may be infinite due to the $(\sigma_1^t - \sigma_{-1}^t)^{-1}$ term. The following argument, in fact, shows both terms are finite and identifies their common value.

Let $N(T)$ denote the number of jumps of the process (R, S, X) in the interval $[0, T]$, let $\{\sigma_k : k = 1, \dots, N(T)\}$ denote these jump times, and let $\sigma_{N(T)+1}$ and σ_{-1} ($= \sigma_0$ in the summation) denote the first jump time after time T and the last jump time before time 0, respectively. Then the right-hand side of (4.18) equals

$$\begin{aligned}
&T^{-1} E\left[\sum_{k=1}^{N(T)+1} \frac{T \wedge \sigma_k - \sigma_{k-1} \vee 0}{\sigma_k - \sigma_{k-1}} \int_{\sigma_{k+1}}^{\sigma_{k+2}} H_\epsilon(r)\, dr\right] \\
&\quad = T^{-1} E\left[\int_0^T H_\epsilon(r)\, dr\right] \\
&\qquad - T^{-1} E\left[\int_0^{\sigma_1 \wedge T} \left(1 - \frac{T \wedge \sigma_1}{\sigma_1 - \sigma_{-1}}\right) H_\epsilon(r)\, dr\right] \\
&\qquad + T^{-1} E\left[I_{\{N(T)=1\}} \frac{\sigma_1}{\sigma_1 - \sigma_{-1}} \int_T^{\sigma_2} H_\epsilon(r)\, dr\right] \\
&\qquad + T^{-1} E\left[I_{\{N(T)>1\}} \int_T^{\sigma_{N(T)+1}} H_\epsilon(r)\, dr\right] \\
&\qquad + T^{-1} E\left[I_{\{N(T)>0\}} \frac{T - \sigma_{N(T)}}{\sigma_{N(T)+1} - \sigma_{N(T)}} \int_{\sigma_{N(T)+1}}^{\sigma_{N(T)+2}} H_\epsilon(r)\, dr\right].
\end{aligned}$$

Observe that the first term is

$$\int e^{-\epsilon(r+s)}h(r,s,x,u,v)\,\overline{\mu}(dr\times ds\times dx\times du\times dv) \tag{4.19}$$

and the last four terms are bounded above by $4||h||/(\epsilon T)$. Thus all terms are finite, implying that the terms in (4.18) are finite, and moreover, as $T\to\infty$, these converge to (4.19).

Letting $\epsilon\to 0$ gives, for each bounded, continuous h (and hence for each bounded, measurable h),

$$\begin{aligned}&E\left[(\sigma_1^t-\sigma_{-1}^t)^{-1}\int_{\sigma_1^t}^{\sigma_2^t}\int_U h(R(r),S(r),X(r),u,v(S(r),X(r)))\,\overline{\eta}(R(r),S(r),X(r),du)dr\right]\\ &\qquad=\int h(r,s,x,u,v)\,\overline{\mu}(dr\times ds\times dx\times du\times dv).\end{aligned} \tag{4.20}$$

Then, considering $h(r,s,x,u,v)=I_{\{0\}}(v)$ in (4.20) yields

$$\begin{aligned}K^{-1} &= E[(\sigma_1^t-\sigma_{-1}^t)^{-1}(\sigma_2^t-\tau_1^t)]\\ &= E[(\sigma_1^t-\sigma_{-1}^t)^{-1}],\end{aligned}$$

in which the last equality follows from the fact that, conditional on $\mathcal{F}^{R,S,X}_{\tau_1^t}$, $\sigma_2^t-\tau_1^t$ is exponentially distributed with mean 1.

Now define the process Y by $Y(t)=X(\sigma_1^0+t)$, $\tilde{R}(t)=R(\sigma_1^0+t)$, $\tilde{S}(t)=S(\sigma_1^0+t)$, and the filtration $\{\mathcal{F}_t\}=\{\mathcal{F}^{R,S,X}_{\sigma_1^0+t}\}$. Let $\tilde{\tau}=\inf\{t\ge 0:\tilde{R}(t)>0\}$ and $\sigma=\inf\{t>\tilde{\tau}:\tilde{R}(t)=0\}$, and note that $Y(t)=Y(\tilde{\tau})$ for $\tilde{\tau}\le t<\sigma$. Observe that both σ_1 and σ_{-1} are $\mathcal{F}_0$-measurable. Define a new probability measure $\widehat{P}$ to have Radon–Nikodým derivative $K(\sigma_1-\sigma_{-1})^{-1}$. It then follows from (4.20) that

$$\begin{aligned}&E^{\widehat{P}}\left[\int_0^{\sigma}\int_U h(\tilde{R}(r),\tilde{S}(r),Y(r),u,v(\tilde{S}(r),Y(r)))\,\overline{\eta}(\tilde{R}(r),\tilde{S}(r),Y(r),du)dr\right]\\ &\qquad=\int h(r,s,x,u,v)\,\overline{\mu}(dr\times ds\times dx\times du\times dv)/E[(\sigma_1-\sigma_{-1})^{-1}]\\ &\qquad=\int h(0,s,x,u,1)\mu_0(ds\times dx\times du)\\ &\qquad\quad+\int_0^{\infty}\int e^{-r}h(r,s,x,u^*,0)\mu_1(ds\times dx)dr.\end{aligned} \tag{4.21}$$

Considering $h(r,s,x,u,v)=I_0(r)I_{E_0^c}(s,x)$ and $h(r,s,x,u,v)=I_{(0,\infty)}(r)I_{E_0}(s,x)$ in (4.22) indicates that $(\tilde{S},Y,\tilde{\tau})$ satisfy (4.14).

The optional sampling theorem implies that under $\widehat{P}$,

$$f(Y(t\wedge\tilde{\tau}))-\int_0^{t\wedge\tilde{\tau}}\int_U Af(Y(s),u)\,\eta(s,Y(s),du)\,ds$$

is a martingale with respect to the filtration $\{\mathcal{F}_t\}$.

For $\Gamma_1 \in \mathcal{B}(E_0^c)$ and $h(r,s,x,u,v) = I_{\Gamma_1}(s,x)$, (4.22) implies

$$\begin{aligned}\mu_1(\Gamma_1) &= E\left[\int_{\tilde\tau}^{\sigma} I_{\Gamma_1}(\tilde S(r), Y(r))\,dr\right]\\ &= E[I_{\Gamma_1}(\tilde\tau, Y(\tilde\tau))(\sigma-\tilde\tau)]\\ &= E[I_{\Gamma_1}(\tilde\tau, Y(\tilde\tau))],\end{aligned}$$

where the last equality follows from the fact that $\sigma - \tilde\tau$ is a mean 1 exponential time conditional on $\mathcal{F}_{\tilde\tau}$. Similarly, for $\Gamma_2 \in \mathcal{B}(E_0 \times U)$ and $h(r,s,x,u,v) = I_{\Gamma_2}(s,x,u)$, (4.21) implies

$$E\left[\int_0^{\tilde\tau}\int_U I_{\Gamma_2}(s,Y(s),u)\eta(s,Y(s),du)ds\right] = \mu_0(\Gamma_2). \qquad \square$$

COROLLARY 4.7. *Suppose E, U, A, and ψ satisfy the conditions of section* 1.1, *and $E_0 \subset \mathbb{R}^+ \times E$ is open. Let (X,Λ) be a solution of the controlled martingale problem for A such that $\tau = \inf\{t \ge 0 : (t, X(t)) \in E_0^c\}$ has finite expectation. Suppose*

$$E\left[\int_0^{\tau}\int_U \psi(u)\Lambda_s(du)ds\right] < \infty. \tag{4.22}$$

Then there exists a process Y adapted to a filtration $\{\mathcal{F}_t\}$, a transition function η from $\mathbb{R}^+ \times E$ into U, and an $\{\mathcal{F}_t\}$-stopping time $\tilde\tau$ satisfying (4.14) *such that for $f \in \mathcal{D}(A)$*

$$f(Y(t\wedge\tilde\tau)) - \int_0^{t\wedge\tilde\tau}\int_U Af(Y(s),u)\,\eta(s,Y(s),du)\,ds \tag{4.23}$$

is a martingale with respect to $\{\mathcal{F}_t\}$, and for each $t \ge 0$, $(t\wedge\tilde\tau, Y(t\wedge\tilde\tau), \eta(t\wedge\tilde\tau, Y(t\wedge\tilde\tau),\cdot))$ has the same distribution as $(t\wedge\tau, X(t\wedge\tau), E[\Lambda_{t\wedge\tau}(\cdot)|X(t\wedge\tau)])$.

Proof. Define $\mu_0 \in \mathcal{M}(E_0 \times U)$ by

$$\mu_0(\Gamma) = E\left[\int_0^{\tau}\int_U I_\Gamma(s,X(s),u)\,\Lambda_s(du)\,ds\right] \qquad \forall \Gamma \in \mathcal{B}(E_0\times U),$$

and $\mu_1 \in \mathcal{P}(E_0^c)$ by

$$\mu_1(\Gamma) = E[I_\Gamma(\tau, X(\tau))].$$

The pair (μ_0,μ_1) satisfies (4.12). Theorem 4.5 then implies the existence of a process Y, a transition function η, and random variable $\tilde\tau$ satisfying (4.14) such that (4.23) is a martingale. The fact that

$$(t\wedge\tilde\tau, Y(t\wedge\tilde\tau), \eta(t\wedge\tilde\tau, Y(t\wedge\tilde\tau),\cdot)) \stackrel{d}{=} (t\wedge\tau, X(t\wedge\tau), E[\Lambda_{t\wedge\tau}(\cdot)|X(t\wedge\tau)]) \tag{4.24}$$

follows by essentially the same argument as in Theorem 4.1. $\square$

4.2. Finite-horizon problems. Control problems over a finite horizon can be formulated as first exit problems, and thus the results of the previous section can be applied to finite-horizon problems.

A minor change in the time-space generator of the process from $\gamma(s)Af(x,u) + \gamma'(s)f(x)$ to $\gamma(s)Af(x,u) - \gamma'(s)f(x)$ augments a time component to the original state

component, which decreases linearly at rate 1. Taking $E_0 = (0,T] \times E$, the results of the previous section show that the time-dependence of the feedback control can be taken to only depend on the time remaining. Observe also that the process will exit as soon as it hits the boundary $\{0\} \times E$, so the conclusions are stronger.

The first result establishes existence of a solution for each pair of measures (μ_0, μ_1) which satisfy condition (4.25) given below.

THEOREM 4.8. *Suppose E, U, A, and ψ satisfy the conditions of section* 1.1. *Let $E_0 = (0,T] \times E$ and $\mu_0 \in \mathcal{M}(E_0 \times U)$ and $\mu_1 \in \mathcal{P}(E)$ satisfy*

$$\int_{(0,T]\times E\times U} [\gamma(s)Af(x,u) - \gamma'(s)f(x)]\,\mu_0(ds \times dx \times du) + \gamma(T)\int_E f\,d\nu_0 - \gamma(0)\int_E f(x)\,\mu_1(dx) = 0 \qquad \forall \gamma \in \widehat{C}^1(\mathbb{R}^+), f \in \mathcal{D}(A)\ . \tag{4.25}$$

Let η be the regular conditional distribution of u given (s,x). Suppose ψ satisfies (4.13). *Then there exists a process Y with initial distribution ν_0 such that*

$$\gamma(T-(t\wedge T))f(Y(t\wedge T)) - \int_0^{t\wedge T}\int_U [\gamma(T-s)Af(Y(s),u) - \gamma'(T-s)f(Y(s))]\,\eta(T-s,Y(s),du)\,ds$$

is a martingale with respect to a filtration $\{\mathcal{F}_t\}$. Moreover, for each $\Gamma_1 \in \mathcal{B}(E_0 \times U)$,

$$E\left[\int_0^T \int_U I_{\Gamma_1}(T-s,Y(s),u)\,\eta(T-s,Y(s),du)\,ds\right] = \mu_0(\Gamma_1),$$

and for each $\Gamma_2 \in \mathcal{B}(E)$,

$$E[I_{\Gamma_2}(Y(T))] = \mu_1(\Gamma_2).$$

The next result essentially states that for any given solution (X,Λ) of the finite-horizon problem there exists a process Y and feedback control η whose one-dimensional distributions match the given solution.

COROLLARY 4.9. *Suppose E, U, A, and ψ satisfy the conditions of section* 1.1. *Let (X,Λ) be a solution of the controlled martingale problem for A. Suppose*

$$E\left[\int_0^T \int_U \psi(u)\,\Lambda_s(du)\,ds\right] < \infty.$$

Then there exists a process Y, a transition function η from $(0,T] \times E$ into U such that

$$\gamma(T-(t\wedge T))f(Y(t\wedge T)) - \int_0^{t\wedge T}\int_U [\gamma(T-s)Af(Y(s),u) - \gamma'(T-s)f(Y(s))]\,\eta(T-s,Y(s),du)\,ds$$

is a martingale with respect to a filtration $\{\mathcal{F}_t\}$ and

$$(Y(t), \eta(T-t,Y(t),\cdot)) \stackrel{d}{=} (X(t), E[\Lambda_t|X(t)]) \qquad \forall\ 0 \le t \le T.$$

5. Time-homogeneous Markov controls. When the state space E does not contain any time component, the existence result in Theorem 2.2 indicates that, under the long-term average criterion, to each solution there corresponds a solution having a time-homogeneous Markov control with the same cost. Theorems 4.1 and 4.5 of the previous section require augmenting the state space with a time component, and thus the Markov controls obtained are time-dependent. In fact, time-dependence is necessary in order for (4.10) and (4.24) to hold.

A dynamic programming argument, however, indicates that there should exist optimal controls for the discounted and first exit criteria which are stationary (not time-dependent). The next theorems show that it is possible to have a solution $(Y, \eta(Y,\cdot))$ in which η is a stationary Markov control and for which the discounted or first exit cost matches the corresponding cost of a given solution (X, Λ).

5.1. Discounted problems. We begin by considering the discounted criterion more carefully and allow the discount rate to be a function of the state and control.

THEOREM 5.1. *Suppose that E, U, A, and ψ satisfy conditions* (i)–(vi) *of section* 1.1. *Let (X,Λ) be a relaxed solution of the controlled martingale problem for (A,ν_0), let α be a nonnegative, bounded, and continuous function on $E\times U$, and suppose that*

$$E\left[\int_0^\infty e^{-\int_0^t\int_U \alpha(X(s),u)\Lambda_s(du)ds}\int_U(1+\psi(u))\Lambda_s(du)dt\right]<\infty\,.$$

Then there exists a process Y and a transition function η from E to U such that $(Y,\eta(Y,\cdot))$ is a relaxed solution of the controlled martingale problem for (A,ν_0) and

$$\begin{aligned}&E\left[\int_0^\infty e^{-\int_0^t\int_U \alpha(Y(s),u)\eta(Y(s),du)ds}\int_U c(Y(t),u)\,\eta(Y(t),du)\,dt\right]\\&\quad=E\left[\int_0^\infty e^{-\int_0^t\int_U \alpha(X(s),u)\Lambda_s(du)ds}\int_U c(X(t),u)\,\Lambda_t(du)\,dt\right]\end{aligned}$$

for every $c\in M(E\times U)$ that is bounded below (in the sense that if one side is infinite so is the other).

Remark 5.2. Note that Y and η will, in general, depend on α.

Proof. The proof is very similar to the proof of Theorem 4.1. We therefore only identify the differences. We take the state space to be $\{-1,1\}\times E$ and define the generator

$$A^\alpha(\gamma f)(\theta,x,u)=\gamma(\theta)Af(x,u)+\alpha(x,u)\left[\gamma(-\theta)\int_E f(y)\nu_0(dy)-\gamma(\theta)f(x)\right],\tag{5.1}$$

where $f\in\mathcal{D}(A)$ and $\gamma\in \mathrm{B}(\{-1,1\})$. Let $\Gamma_X(t)=\int_0^t\int_U\alpha(X(s),u)\Lambda_s(du)ds$. Define the measure $\pi\in\mathcal{P}(\{-1,1\}\times E\times U)$ by

$$\begin{aligned}&\int_{\{-1,1\}\times E\times U}h(\theta,x,u)\,\pi(d\theta\times dx\times du)\\&\quad=\frac{E\left[\int_0^\infty e^{-\Gamma_X(s)}\left(\int_U h(-1,X(s),u)\,\Lambda_s(du)+\int_U h(1,X(s),u)\,\Lambda_s(du)\right)ds\right]}{2E\left[\int_0^\infty e^{-\Gamma_X(s)}ds\right]}\end{aligned}\tag{5.2}$$

for $h \in \overline{C}(\{-1,1\} \times E \times U)$. The fact that π is a stationary measure for A^α follows from the fact that

$$e^{-\Gamma_X(t)} f(X(t)) - f(X(0)) - \int_0^t e^{-\Gamma_X(s)} \int_U (Af(X(s),u) - \alpha(X(s),u) f(X(s))) \, \Lambda_s(du) ds$$

is a martingale which, taking expectations and letting $t \to \infty$, implies

$$E\left[\int_0^\infty e^{-\Gamma_X(s)} \int_U \left(Af(X(s),u) + \alpha(X(s),u) \left[\int f \, d\nu_0 - f(X(s)) \right] \right) \Lambda_s(du) ds \right] = 0.$$

Observe that π can be written as

$$\begin{aligned} \pi(d\theta \times dx \times du) &= \frac{1}{2}(\delta_{\{-1\}}(d\theta) + \delta_{\{1\}}(d\theta)) \widehat{\pi}(dx \times du) \\ &= \frac{1}{2}(\delta_{\{-1\}}(d\theta) + \delta_{\{1\}}(d\theta)) \pi_0(dx) \eta(x, du) \, , \end{aligned}$$

where $\widehat{\pi}$ and π_0 denote the marginals of π on $E \times U$ and E, respectively, and η does not depend on θ. Theorem 2.2 therefore gives the existence of a stationary process (Θ, Z) with marginal distribution $\frac{1}{2}(\delta_{\{-1\}}(d\theta) + \delta_{\{1\}}(d\theta))\pi_0(dx)$ such that $(\Theta, Z, \eta(Z, du))$ is a solution of the controlled martingale problem for A^α.

Let $\tau_1 = \inf\{t > 0 : \Theta(t) \neq \Theta(0)\}$, $\tau_{-1} = \sup\{t < 0 : \Theta(t) \neq \Theta(0)\}$, and $\tau_{k+1} = \inf\{t > \tau_k : \Theta(t) \neq \Theta(\tau_k)\}$. As in the proof of Theorem 4.1, define $Y(t) = Z(\tau_1 + t)$. It is no longer the case that the τ_k are the jump times of a Markov chain; however, taking $C = E[(\tau_1 - \tau_{-1})^{-1}]$,

$$L(t) = [C(\tau_1 - \tau_{-1})]^{-1} e^{\int_0^t \int_U \alpha(Y(s),u)\eta(Y(s),du)ds} I_{[0,\tau_2 - \tau_1)}(t)$$

is still a mean 1 martingale. (Note that C is finite by the boundedness of α.) The remainder of the proof is the same as before, with (4.8) replaced by

$$\begin{aligned} &E^{\widehat{P}}\left[\int_0^\infty e^{-\int_0^t \int_U \alpha(Y(s),u)\eta(Y(s),du)ds} \int_U c(Y(t),u) \, \eta(Y(t),du) \, dt\right] \\ &\quad = E\left[\int_0^\infty e^{-\Gamma_X(t)} \int_U c(X(t),u) \, \Lambda_t(du) \, dt\right], \end{aligned}$$

which gives the desired result. □

The following result is a consequence of the construction in the proof of Theorem 5.1 and will be used in our discussion of the linear programing approach to the solution of optimal discounted control problems.

COROLLARY 5.3. *Suppose that E, U, A, and ψ satisfy conditions* (i)–(vi) *of section* 1.1. *Suppose that $\widehat{\pi} \in \mathcal{P}(E \times U)$ satisfies*

$$\int_{E \times U} \left[Af(x,u) + \alpha(x,u) \left(\int f(y)\nu_0(dy) - f(x) \right) \right] \widehat{\pi}(dx \times du) = 0 \quad \forall f \in \mathcal{D}(A)$$

and

$$\int \psi(u) \, \widehat{\pi}(dx \times du) < \infty.$$

Let η satisfy $\widehat{\pi}(dx \times du) = \widehat{\pi}_0(dx)\eta(x, du)$. Then there exists a process Y such that $(Y, \eta(Y, \cdot))$ is a relaxed solution of the controlled martingale problem for (A, ν_0) and

$$\frac{E\left[\int_0^\infty e^{-\int_0^t \int_U \alpha(Y(s),u)\eta(Y(s),du)ds} \int_U c(Y(t),u)\,\eta(Y(t),du)\,dt\right]}{E\left[\int_0^\infty e^{-\int_0^t \int_U \alpha(Y(s),u)\eta(Y(s),du)ds}\,dt\right]} \tag{5.3}$$

$$= \int_{E\times U} c(x,u)\widehat{\pi}(dx \times du)$$

for every $c \in B(E \times U)$ and for every nonnegative $c \in M(E \times U)$ (in the sense that if one side is infinite so is the other).

Proof. Define $\pi(d\theta \times dx \times du) = \frac{1}{2}(\delta_{\{-1\}}(d\theta) + \delta_{\{1\}}(d\theta))\widehat{\pi}(dx \times du)$. Then π is a stationary distribution for A^α given by (5.1), and the construction in the proof of Theorem 5.1 gives the desired process. □

Since the discount rate is allowed to be state and control dependent, Theorem 5.1 implies an extension of Theorem 1 of Krylov [13] in which it is shown that to each diffusion $\xi(t)$ having nonanticipating drift and diffusion coefficients and nonanticipating killing rate $\gamma(t)$, there exists a diffusion $x(t)$ having drift and diffusion coefficients and a killing rate g which are all functions of the state alone such that they have the same Green measure: for each $\Gamma \in \mathcal{B}(\mathbb{R}^d)$,

$$\begin{aligned}\mu(\Gamma) &= E\left[\int_0^\infty I_\Gamma(\xi(t))e^{-\int_0^t \gamma(s)\,ds}\,dt\right] \\ &= E\left[\int_0^\infty I_\Gamma(x(t))e^{-\int_0^t g(x(s))\,ds}\,dt\right].\end{aligned}$$

Theorem 1 of [13] requires a uniform ellipticity assumption on the diffusion ξ which the following corollary relaxes.

COROLLARY 5.4. *Suppose that W is an $\mathbb{R}^d$-valued, $\{\mathcal{F}_t\}$-Brownian motion; $\widehat{\sigma}$ and $\widehat{b}$ are measurable, $\{\mathcal{F}_t\}$-adapted processes taking values in $\mathbb{M}^{d\times d}$ and $\mathbb{R}^d$, respectively; $X(0)$ is $\mathbb{R}^d$-valued and $\mathcal{F}_0$-measurable; and γ is a nonnegative, bounded, $\{\mathcal{F}_t\}$-adapted process such that*

$$E\left[\int_0^\infty e^{-\int_0^t \gamma(s)ds}(1 + \|\widehat{\sigma}(t)\widehat{\sigma}^T(t)\| + |\widehat{b}(t)| + \gamma(t))dt\right] < \infty.$$

Let

$$X(t) = X(0) + \int_0^t \widehat{\sigma}(s)dW(s) + \int_0^t \widehat{b}(s)ds.$$

Then there exist measurable functions $\sigma : \mathbb{R}^d \to \mathbb{M}^{d\times d}$, $b : \mathbb{R}^d \to \mathbb{R}^d$, and $g : \mathbb{R}^d \to [0, \infty)$, an $\mathbb{R}^d$-valued Brownian motion $\tilde{W}$, and a process Y satisfying

$$Y(t) = Y(0) + \int_0^t \sigma(Y(s))d\tilde{W}(s) + \int_0^t b(Y(s))ds$$

such that for each $\Gamma \in \mathcal{B}(\mathbb{R}^d)$

$$E\left[\int_0^\infty I_\Gamma(X(t))e^{-\int_0^t \gamma(s)ds}dt\right] = E\left[\int_0^\infty I_\Gamma(Y(t))e^{-\int_0^t g(Y(s))ds}dt\right].$$

Proof. Let $E = \mathbb{R}^d$ and $U = \mathbb{M}_+^{d\times d} \times \mathbb{R}^d \times \mathbb{R}$. Define the generator for $f \in C_c^2(\mathbb{R}^d)$ (and $u = (u^1, u^2, u^3)$) by

$$Af(x,u) = \frac{1}{2}\sum_{i,j=1}^{d} u_{ij}^1 f_{x_i x_j}(x) + \sum_{i=1}^{d} u_i^2 f_{x_i}(x)$$

and let $\alpha(x,u) = u^3$ and $\psi(u) = ||u^1|| + |u^2| + |u^3|$. Letting $\widehat{a}(t) = \widehat{\sigma}(t)\widehat{\sigma}(t)^T$ and $\Lambda_t(du) = \delta_{\{\widehat{a}(t)\}}(du^1)\delta_{\{\widehat{b}(t)\}}(du^2)\delta_{\{\gamma(t)\}}(du^3)$, (X,Λ) is a solution of the controlled martingale problem for A. Using the cost function $c(x,u) = I_\Gamma(x)$, Theorem 5.1 yields the result where

$$a(x) = \int_U u^1 \eta(x,du), \qquad b(x) = \int_U u^2 \eta(x,du), \qquad g(x) = \int_U \alpha(x,u)\eta(x,du),$$

σ is the symmetric square root of a (which exists even in the degenerate case), and $\tilde{W}$ is obtained from [9, Theorem 5.3.3]. □

5.2. First passage problems. The previous formulation of the exit problem includes time as a component of the state of the process and allows the running cost c and exit cost g to depend on the time component. The result naturally has time-dependence in the Markov control.

We now consider cost structures *in which the only time-dependence is through discounting at a rate* $\alpha \geq 0$ that can depend on the state and the control. We show existence of solutions with a time-homogeneous Markov control. In this model, the cost is defined using the state process up to the time it leaves an open region $\tilde{E}_0 \subset E$ rather than the time-state process leaving an open region $E_0 \subset \mathbb{R}^+ \times E$.

THEOREM 5.5. *Suppose E, U, A, and ψ satisfy conditions* (i)–(vi) *of section* 1.1. *Let $\tilde{E}_0 \subset E$ be open. Let (X,Λ) be a solution of the controlled martingale problem for A, let α be a nonnegative, bounded, and continuous function on $E \times U$, define $\tau = \inf\{t \geq 0 : X(t) \in \tilde{E}_0^c\}$, and assume that*

$$E\left[\int_0^\tau e^{-\int_0^t \int_U \alpha(X(s),u)\Lambda_s(du)ds}\left(1 + \int_U \psi(u)\Lambda_t(du)\right)dt\right] < \infty.$$

Then there exists a process Y adapted to a filtration $\{\mathcal{F}_t\}$, a transition function η from E into U, and an $\{\mathcal{F}_t\}$-stopping time $\tilde{\tau}$ such that

$$f(Y(t\wedge\tilde{\tau})) - \int_0^{t\wedge\tilde{\tau}} \int_U Af(Y(s),u)\,\eta(Y(s),du)\,ds$$

is an $\{\mathcal{F}_t\}$-martingale for all $f \in \mathcal{D}(A)$, $P\{Y(\tilde{\tau}) \notin \tilde{E}_0^c, \tilde{\tau} < \infty\} = 0$, the Lebesgue measure of $\{t : Y(t) \in \tilde{E}_0^c, t < \tilde{\tau}\}$ is zero a.s., and, setting

$$\Gamma_Y(t) = \int_0^t \int_U \alpha(Y(s),u)\eta(Y(s),du)ds$$

and

$$\Gamma_X(t) = \int_0^t \int_U \alpha(X(s),u)\Lambda_s(du)ds,$$

$$E\left[\int_0^{\tilde\tau}\int_U e^{-\Gamma_Y(s)}c(Y(s),u)\,\eta(Y(s),du)\,ds + e^{-\Gamma_Y(\tilde\tau)}g(Y(\tilde\tau))\right]$$

$$= E\left[\int_0^{\tau}\int_U e^{-\Gamma_X(s)}c(X(s),u)\,\Lambda_s(du)\,ds + e^{-\Gamma_X(\tau)}g(X(\tau))\right] \tag{5.4}$$

for every $c \in M(E\times U)$ and $g \in M(E)$ that are bounded below (cf. Theorem 5.1*).*

Proof. Augment the state with a nonnegative component to form a new state space $\mathbb{R}^+ \times E$. Add a new point u^* to U giving $\overline{U} = U \cup \{u^*\}$ and augment the control space with a $\{0,1\}$ component to form a new control space $\overline{U}\times\{0,1\}$. Define $c(x,u^*) = 0$, $\alpha(x,u^*) = 1$ and $\psi(u^*) = 1$. Define the generator $\overline{A}$ by

$$\overline{A}(\gamma f)(s,x,u,v) = v\gamma(s)Af(x,u) + (1-v)\gamma'(s)f(x)$$

for all $f \in \mathcal{D}(A)$ and $\gamma \in \widehat{C}^1(\mathbb{R}^+)$.

Define

$$(\overline{S}(t),\overline{X}(t)) = (t - t\wedge\tau, X(t\wedge\tau))$$

and the relaxed control on $\overline{U}\times\{0,1\}$,

$$\overline{\Lambda}_t(du\times dv) = [\Lambda_t(du)\times\delta_{\{1\}}(dv)]\cdot I_{[0,\tau)}(t) + [\delta_{\{u^*\}}(du)\times\delta_{\{0\}}(dv)]\cdot I_{[\tau,\infty)}(t).$$

Then $(\overline{S},\overline{X},\overline{\Lambda})$ is a relaxed solution to the controlled martingale problem for $\overline{A}$ with $\overline{S}(0) = 0$ and $\overline{X}(0)$ having distribution ν_0, where ν_0 is the initial distribution of X. Let $\overline{\nu}_0 = \delta_{\{0\}}\times\nu_0$. As in the proof of Theorem 4.5, we can define $v(x) = I_{\tilde E_0}(x)$, and we will have $v(\overline{X}(t)) = I_{\{0\}}(\overline{S}(t))$ a.s.

Observe that with

$$\overline{c}(x,u,v) = \begin{cases} c(x,u) & \text{for} \quad x\in\tilde E_0, u\in\overline{U},\\ \alpha(x,u)g(x) & \text{for} \quad x\in\tilde E_0^c, u\in\overline{U},\end{cases}$$

the infinite-horizon discounted cost of $(\overline{S},\overline{X},\overline{\Lambda})$ satisfies

$$E\left[\int_0^\infty\int_{\overline{U}\times\{0,1\}} e^{-\int_0^t\int_{\overline{U}\times\{0,1\}}\alpha(\overline{X}(s),u)\overline{\Lambda}_s(du\times dv)ds}\overline{c}(\overline{X}(t),u,v)\overline{\Lambda}_t(du\times dv)\,dt\right]$$

$$= E\left[\int_0^\tau\int_U e^{-\int_0^t\int_U\alpha(X(s),u)\Lambda_s(du)}c(X(s),u)\Lambda_s(du)\,ds\right.$$

$$\left. +\ e^{-\int_0^\tau\int_U\alpha(X(s),u)\Lambda_s(du)}g(X(\tau))\right].$$

By Theorem 5.1, there exists a process (S,Y) and a transition function η from $\mathbb{R}^+\times E$ to $\overline{U}$ such that $(S,Y,\eta(S,Y,\cdot))$ is a relaxed solution of the controlled martingale problem for $(\overline{A},\overline{\nu}_0)$ and

$$E\left[\int_0^\infty\int_{\overline{U}} e^{-\Gamma_{\bar X}(t)}h(\overline{S}(t),\overline{X}(t),u,v)\,\overline{\Lambda}_t(du\times dv)\,dt\right]$$

$$= E\left[\int_0^\infty\int_{\overline{U}} e^{-\Gamma_Y(t)}h(S(t),Y(t),u,v(Y(t)))\eta(S(t),Y(t),du)\,dt\right] \tag{5.5}$$

for every measurable function h which is bounded below. In particular, taking $h(s,y,u,v) = |I_{\{0\}}(s) - v|$, we see that $I_{\{0\}}(S(t)) = v(Y(t))$ a.s.

Define $\tilde{\tau} = \inf\{r > 0 : S(r) > 0\}$ and $\sigma = \inf\{t > \tilde{\tau} : S(t) \leq 0\}$. Then for $f \in \mathcal{D}(A)$ and $\gamma \in \widehat{C}^1(\mathbb{R}^+)$,

(5.6)
$$\gamma(S((\tilde{\tau}+t)\wedge\sigma))f(Y((\tilde{\tau}+t)\wedge\sigma)) - \gamma(S(\tilde{\tau}))f(Y(\tilde{\tau})) - \int_{\tilde{\tau}}^{(\tilde{\tau}+t)\wedge\sigma} \gamma'(S(s))f(Y(s))ds$$

(taking (5.6) to be zero if $\tilde{\tau} = \infty$) is an $\{\mathcal{F}^{S,Y}_{\tilde{\tau}+t}\}$-martingale, and it follows from uniqueness for the martingale problem for $B\gamma f(s,x) = \gamma'(s)f(x)$ that $S(\tilde{\tau}+t) \equiv t$ and $Y(\tilde{\tau}+t) \equiv Y(\tilde{\tau})$, when $\tilde{\tau} < \infty$. In particular, if h does not depend on s, (5.5) becomes

$$E\left[\int_0^\tau \int_U e^{-\Gamma_X(t)}h(X(t),u,1)\,\Lambda_t(du)\,dt + e^{-\Gamma_X(\tau)}h(X(\tau),u^*,0)\right]$$
$$= E\left[\int_0^{\tilde{\tau}} \int_U e^{-\Gamma_Y(t)}h(Y(t),u,1)\eta(0,Y(t),du)\,dt + e^{-\Gamma_Y(\tilde{\tau})}h(Y(\tilde{\tau}),u^*,0)\right]$$

and (5.4) follows. □

COROLLARY 5.6. *Suppose that E, U, A, and ψ satisfy conditions* (i)–(vi) *of section* 1.1 *and that $\tilde{E}_0 \subset E$ is open. Let $E_0 = \mathbb{R}^+ \times \tilde{E}_0$. $$=\int_{\tilde{E}_0\times U}c(x,u)\,\mu_0(dx\times du)+\int_{\tilde{E}_0^c}g(x)\mu_1(dx)$$

for every $c\in M(E\times U)$ *and* $g\in M(E)$ *that are bounded below (cf. Theorem* 5.1*).*

Proof. Consider the generator $\tilde{A}$ for a process in $[0,\infty)\times E$ with control space $U\times\{0,1\}$ defined by

$$\tilde{A}(\zeta f)(s,x,u,v)=v\zeta(s)Af(x,u)+(1-v)\zeta'(s)f(x)+(1-v)\left(\zeta(0)\int f\,d\nu_0-\zeta(s)f(x)\right),$$

and for some fixed $u^*\in U$, define $\pi\in\mathcal{P}([0,\infty)\times E\times U\times\{0,1\})$ by

$$\pi(ds\times dx\times du\times dv)=C(\delta_{\{0\}}(ds)\delta_{\{1\}}(dv)\mu_0(dx\times du)+e^{-s}ds\delta_{\{0\}}(dv)\delta_{\{u^*\}}(du)\mu_1(dx))\,,$$

where C is a constant normalizing π to be a probability measure. Then π is a stationary measure for $\tilde{A}$, and defining $\alpha(s,x,u,v)=(1-v)$, we see that the conditions of Corollary 5.3 are satisfied with A replaced by

$$A_0(\zeta f)(s,x,u,v)=v\zeta(s)Af(x,u)+(1-v)\zeta'(s)f(x).$$

Consequently, noting that

$$\eta_0(s,x,du\times dv)=I_{\{0\}}(s)\eta(x,du)\delta_{\{1\}}(dv)+I_{(0,\infty)}(s)\delta_{\{0\}}(dv)\delta_{\{u^*\}}(du),$$

there exists a process (S,Y) such that $((S,Y),\eta_0(S,Y,\cdot))$ is a relaxed solution of the controlled martingale problem for $(A_0,\nu_0\times\delta_{\{0\}})$. Using the cost function $c(s,x,u,v)=c(x,u)v+g(x)(1-v)$, (5.3) implies

$$\frac{E\left[\int_0^\infty e^{-\int_0^t I_{(0,\infty)}(S(s))ds}\left(\int_U c(Y(t),u)I_{\{0\}}(S(t))\eta(Y(t),du)+g(Y(t))I_{(0,\infty)}(S(t))\right)dt\right]}{E\left[\int_0^\infty e^{-\int_0^t I_{(0,\infty)}(S(s))ds}\,dt\right]}$$
$$=C\left(\int_{\tilde{E}_0\times U}c(x,u)\mu_0(dx\times du)+\int_{\tilde{E}_0^c}g(x)\mu_1(dx)\right).$$

Finally, since for any solution of the martingale problem for A_0, $S(t)>0$ implies that $S(r)>0$ for all $r>t$, if we define $\tilde{\tau}=\inf\{t:S(t)>0\}$, we have the desired result. □

6. LP reformulations. In this section we reformulate the original control problems as linear programs over appropriate spaces of measures. The importance of these reformulations is that they provide a way to *characterize* an optimal Markov control. Compute the measure(s) μ, $\widehat{\pi}$, π, or μ_0 and μ_1 satisfying the appropriate constraints which minimizes the cost criterion. The relaxed control is then the conditional distribution η on the control space U given the state.

Throughout this section we assume that E, U, A, and ψ satisfy the conditions of section 1.1. In addition, we assume that there are constants a and b such that

$$\psi(u) \le a + bc(x,u) \quad \text{or} \quad \psi(u) \le a + bc(s,x,u) \tag{6.1}$$

and

$$\{(x,u) : c(x,u) \le a\} \quad \text{or} \quad \{(s,x,u) : c(s,x,u) \le a\} \quad \text{is compact for each } a > 0. \tag{6.2}$$

6.1. Long-term average problems. The LP reformulation is especially straightforward for long-term average control problems provided the minimization is over all solutions of the controlled martingale problem for A without any restrictions on the initial distribution.

THEOREM 6.1. *Suppose that E, U, A, and ψ satisfy conditions* (i)–(vi) *of section* 1.1. *Let $c : E \times U \to \mathbb{R}$ be lower semicontinuous, bounded below, and satisfy* (6.1) *and* (6.2). *Then the long-term average control problem of minimizing* (1.6) *over all solutions of the controlled martingale problem for A is equivalent to the LP of minimizing*

$$\int_{E\times U} c(x,u)\,\mu(dx \times du) \tag{6.3}$$

over all distributions $\mu \in \mathcal{P}(E \times U)$ satisfying

$$\int_{E\times U} Af(x,u)\,\mu(dx \times du) = 0 \qquad \forall f \in \mathcal{D}(A). \tag{6.4}$$

Remark 6.2. This result is a combination of Theorems 3.2 and 3.3 in [19]. However, the result stated here is stronger in that the proof of the equivalence uses the existence of a solution with Markov controls given in Theorem 2.2 in place of Theorem 4.1 in [18].

Proof. Let (X, Λ) be a solution of the controlled martingale problem for A, and define

$$\mu_t(\Gamma_1 \times \Gamma_2) = E\left[t^{-1}\int_0^t \int_U I_{\Gamma_1\times\Gamma_2}(X(s),u)\Lambda_s(du)ds\right].$$

If (1.6) is finite, then the conditions on c imply that $\{\mu_t\}$ is relatively compact. The lower semicontinuity of c implies that for any limit point μ of $\{\mu_t\}$, $\int c d\mu$ is smaller than (1.6). Furthermore, $\int Af d\mu = 0$ for all $f \in \mathcal{D}(A)$. It follows that the minimum cost for the LP is a lower bound for (1.6) for all solutions of the controlled martingale problem.

The conditions on c imply that if there exists at least one μ satisfying (6.4) for which (6.3) is finite, then there exists a solution μ^* for the LP. But by Theorem 2.2 there exists a stationary solution of the controlled martingale problem with marginals given by μ^*, and hence with long-run average cost given by $\int c\,d\mu^*$, that is, the minimal value of the LP. □

6.2. Discounted problems. We first reformulate the control problem in which the *only* time-dependence is through discounting.

THEOREM 6.3. *Suppose that E, U, A, and ψ satisfy conditions* (i)–(vi) *of section* 1.1. *Let c be a measurable function which is bounded below, and which satisfies* (6.1) *and* (6.2). *Then, for each $\alpha > 0$, the discounted control problem of minimizing* (1.4) *over all solutions of the controlled martingale problem for (A, ν_0) is equivalent to the linear programming problem of minimizing*

$$\alpha^{-1} \int_{E\times U} c(x,u)\widehat{\pi}(dx \times du) \tag{6.5}$$

over all distributions $\widehat{\pi} \in \mathcal{P}(E \times U)$ satisfying

$$\int_{E\times U} A^{\alpha} f(x,u)\widehat{\pi}(dx \times du) = 0 \quad \forall f \in \mathcal{D}(A), \tag{6.6}$$

where

$$A^{\alpha} f(x,u) = Af(x,u) + \alpha \left[\int f(y)\nu_0(dy) - f(x) \right].$$

Proof. Let (X, Λ) be a solution of the controlled martingale problem for A, and define $\widehat{\pi}$ by

$$\int_{E\times U} h(x,u)\widehat{\pi}(dx \times du) = \alpha \int_0^{\infty} e^{-\alpha s} E\left[\int_U h(X(s),u)\Lambda_s(du) \right] ds.$$

If the α-discounted cost is finite, that is,

$$E\left[\int_0^{\infty} e^{-\alpha s} \int_U c(X(s),u)\, \Lambda_s(du)\, ds \right] < \infty,$$

then by (6.1), (4.1) holds, and as in the proof of Theorem 5.1, $\widehat{\pi}$ satisfies (6.6). Moreover, the definition of $\widehat{\pi}$ implies that the α-discounted cost satisfies

$$E\left[\int_0^{\infty} e^{-\alpha s} \int_U c(X(s),u)\, \Lambda_s(du)\, ds \right] = \alpha^{-1} \int_{E\times U} c(x,u)\widehat{\pi}(dx \times du)\ .$$

Conversely, if $\widehat{\pi}$ satisfies (6.6) and (6.5) is finite, then by (6.1), the conditions of Corollary 5.3 are satisfied and hence there exists a solution $(Y, \eta(Y,\cdot))$ of the controlled martingale problem for the original generator A whose α-discounted cost is also given by (6.5). □

When the running cost function is allowed to be time-dependent, the existence result in Theorem 4.1 can be used in the preceding argument in place of Theorem 5.1, resulting in a different LP formulation. The resulting Markov control is now time-dependent. This observation is summarized in the next theorem. It is interesting to note that both LP formulations are equivalent to the discounted problem when c does not depend on time, and thus the two LPs have the same value.

THEOREM 6.4. *Suppose that E, U, A, and ψ satisfy conditions* (i)–(vi) *of section* 1.1. *Let c be a measurable function which is bounded below and satisfies* (6.1) *and* (6.2). *Then the discounted control problem of minimizing* (1.4) *over all solutions of*

the controlled martingale problem for (A, ν_0) is equivalent to the linear programming problem of minimizing

$$\alpha^{-1} \int_{E\times U} c(s,x,u)\pi(ds \times dx \times du)$$

over all distributions $\pi \in \mathcal{P}(\mathbb{R}^+ \times E \times U)$ satisfying

$$\int_{E\times U} \tilde{A}(\gamma f)(s,x,u)\, \pi(ds \times dx \times du) = 0 \qquad \forall f \in \mathcal{D}(A)\ , \gamma \in \widehat{C}^1(\mathbb{R}^+),$$

where $\tilde{A}$ is defined by

$$\tilde{A}(\gamma f)(s,x,u) = \gamma(s)Af(x,u) + \gamma'(s)f(x) + \alpha\left[\gamma(0)\int f(y)\nu_0(dy) - \gamma(s)f(x)\right].$$

6.3. Finite-horizon problems. Since the optimal control depends on the time remaining, the equivalent LP formulation for a finite-horizon control problem is the same regardless of whether or not the running cost c is time-dependent.

THEOREM 6.5. *Suppose that E, U, A, and ψ satisfy conditions* (i)–(vi) *of section* 1.1. *Let c and g be measurable functions which are bounded below and suppose c satisfies* (6.1) *and* (6.2). *Then the finite-horizon control problem of minimizing* (1.5) *over all solutions of the controlled martingale problem for (A, ν_0) is equivalent to the linear programming problem of minimizing*

$$\int c(s,x,u)\, \mu_0(ds \times dx \times du) + \int g(x)\, \mu_1(dx)$$

over all measures $\mu_0 \in \mathcal{M}((0,T] \times E \times U)$ and $\mu_1 \in \mathcal{P}(E)$ satisfying

$$\int \overline{A}(\gamma f)(s,x,u)\, \mu_0(ds \times dx \times du) + \int \overline{B}(\gamma f)(x)\, \mu_1(dx) = 0$$
$$\forall\, f \in \mathcal{D}(A)\ , \gamma \in \widehat{C}^1(\mathbb{R}^+),$$

where $\overline{A}$ is defined by

$$\overline{A}(\gamma f)(s,x,u) = \gamma(s)Af(x,u) - \gamma'(s)f(x)$$

and $\overline{B}$ is

$$\overline{B}(\gamma f)(x) = \gamma(T)\int f(y)\, \nu_0(dy) - \gamma(0)f(x).$$

Proof. The proof is essentially the same as for Theorem 6.3 but uses Theorem 4.8 and Corollary 4.9 in place of Theorem 5.1 and Corollary 5.3. □

6.4. First passage problems. We consider three slightly different cases for the first passage criterion and develop equivalent LP formulations. We first consider the general case in which the running cost c and exit cost g are time-dependent.

THEOREM 6.6. *Suppose that E, U, A, and ψ satisfy conditions* (i)–(vi) *of section* 1.1. *Let c and g be measurable functions which are bounded below and suppose c*

satisfies (6.1) *and* (6.2). *Then the first passage control problem of minimizing* (1.7) *over all solutions of the controlled martingale problem for* (A, ν_0) *is equivalent to the linear programming problem of minimizing*

$$\int_{E_0} c(s,x,u)\,\mu_0(ds \times dx \times du) + \int_{E_0^c} g(s,x)\mu_1(ds \times dx)$$

over all measures $\mu_0 \in \mathcal{M}(E_0 \times U)$ *and* $\mu_1 \in P(E_0^c)$ *satisfying*

$$\int \widehat{A}(\gamma f)(s,x,u)\,\mu_0(ds \times dx \times du) + \int \widehat{B}(\gamma f)(s,x)\,\mu_1(ds \times dx) = 0$$

$$\forall\, f \in \mathcal{D}(A)\ , \gamma \in \widehat{C}^1(\mathbb{R}^+),$$

where $\widehat{A}$ *is defined by*

$$\widehat{A}(\gamma f)(s,x,u) = \gamma(s)Af(x,u) + \gamma'(s)f(x)$$

and $\widehat{B}$ *is*

$$\widehat{B}(\gamma f)(s,x) = \gamma(0)\int f(y)\,\nu_0(dy) - \gamma(s)f(x).$$

Proof. The proof is essentially the same as for Theorem 6.3 but uses Theorem 4.5 and Corollary 4.7 in place of Theorem 5.1 and Corollary 5.3. □

We now consider the special case in which the only time-dependence is through discounting at a rate $\alpha > 0$; i.e., $c(s,x,u) = e^{-\alpha s}\tilde{c}(x,u)$ and $g(s,x) = e^{-\alpha s}\tilde{g}(x)$.

THEOREM 6.7. *Let* c *and* g *be measurable functions which are bounded below and suppose* c *satisfies* (6.1) *and* (6.2). *Then the first passage control problem of minimizing* (1.7) *over all solutions of the controlled martingale problem for* (A, ν_0) *is equivalent to the linear programming problem of minimizing*

$$\int_{E_0} e^{-\alpha s}c(x,u)\,\mu_0(ds \times dx \times du) + \int_{E_0^c} e^{-\alpha s}g(x)\mu_1(ds \times dx)$$

over all measures $\mu_0 \in \mathcal{M}(E_0 \times U)$ *and* $\mu_1 \in P(E_0^c)$ *satisfying*

$$\int \widehat{A}(\gamma f)(s,x,u)\,\mu_0(ds \times dx \times du) + \int \widehat{B}(\gamma f)(s,x)\,\mu_1(ds \times dx) = 0$$

$$\forall\, f \in \mathcal{D}(A)\ , \gamma \in \widehat{C}^1(\mathbb{R}^+),$$

where $\widehat{A}$ *is defined by*

$$\widehat{A}(\gamma f)(s,x,u) = \gamma(s)Af(x,u) + \gamma'(s)f(x)$$

and $\widehat{B}$ *is*

$$\widehat{B}(\gamma f)(s,x) = \gamma(0)\int f(y)\,\nu_0(dy) - \gamma(s)f(x).$$

Proof. The proof is essentially the same as for Theorem 6.3 but uses Theorem 5.5 and Corollary 5.6 in place of Theorem 5.1 and Corollary 5.3. □

Note that, in general, the optimal control η^* obtained from Theorem 6.6 will be time-dependent, whereas that from Theorem 6.7 will be time-homogeneous.

Finally, we consider the undiscounted criterion in which the running cost and exit cost functions do not depend on the time.

THEOREM 6.8. *Let c and g be measurable functions which are bounded below and suppose c satisfies* (6.1) *and* (6.2). *Then the first passage control problem of minimizing* (1.7) *over all solutions of the controlled martingale problem for (A, ν_0) is equivalent to the linear programming problem of minimizing*

$$\int_{\tilde{E}_0} c(x,u)\,\mu_0(dx \times du) + \int_{\tilde{E}_0^c} g(x)\mu_1(dx)$$

over all measures $\mu_0 \in \mathcal{M}(\tilde{E}_0 \times U)$ and $\mu_1 \in P(\tilde{E}_0^c)$ satisfying

$$\int_{\tilde{E}_0 \times U} Af(x,u)\mu_0(dx \times du) + \int_{\tilde{E}_0^c} Bf(x)\mu_1(dx) = 0, \quad f \in \mathcal{D}(A),$$

where B is defined by

$$Bf(x) = \int f(y)\,\nu_0(dy) - f(x).$$

Proof. The proof is essentially the same as for Theorem 6.3 but uses Theorem 5.5 and Corollary 5.7 in place of Theorem 5.1 and Corollary 5.3. □

7. Appendix. The proof of Lemma 4.4 relies on the following result.

LEMMA 7.1. *Let $S(t)$ be a nonnegative, real-valued, cadlag stochastic process adapted to a filtration $\{\mathcal{F}_t\}$ and let ν be a random measure on $(0,\infty)\times(0,\infty)$ adapted to $\{\mathcal{F}_t\}$ in the sense that $\nu((0,t]\times A)$ is $\mathcal{F}_t$-measurable for each $A \in \mathcal{B}((0,\infty))$ and each $t \geq 0$. Suppose that for each continuously differentiable γ with γ and γ' bounded*

$$M_\gamma(t) = \gamma(S(t)) - \int_0^t \gamma'(S(u))du - \int_{(0,t]\times(0,\infty)} (\gamma(0) - \gamma(s))\nu(du \times ds) \tag{7.1}$$

is an $\{\mathcal{F}_t\}$-local martingale and that there exists a sequence of stopping times with $\alpha_n \to \infty$ a.s. such that for each $t > 0$,

$$E[\nu((0, t\wedge\alpha_n]\times(0,\infty))] < \infty. \tag{7.2}$$

Then, except for a discrete set of time points at which S jumps to zero, S increases linearly at rate 1. *Defining $\mathcal{Z} = \{u \geq 0 : S(u) = 0\}$ and letting $N(t)$ be the cardinality of $\mathcal{Z} \cap [0,t]$, $N(t)$ is a counting process such that*

$$N(t) - \nu((0,t]\times(0,\infty)) \tag{7.3}$$

is an $\{\mathcal{F}_t\}$-local martingale.

Proof. Note that if we define

$$S_n(t) = \begin{cases} S(t), & t < \alpha_n, \\ S(\alpha_n) + t - \alpha_n, & t \geq \alpha_n, \end{cases}$$

and

$$\nu_n((0,t]\times(a,b]) = \nu((0, t\wedge\alpha_n]\times(a,b])$$

and replace (S,ν) in the statement of the lemma by (S_n,ν_n), then M_γ will be a martingale (rather than a local martingale), and if the conclusion of the lemma holds for (S_n,ν_n) for all n, then the conclusion of the lemma holds for (S,N). With that observation, we assume that M_γ is a martingale and that $E[\nu((0,t]\times(0,\infty))]<\infty$. Under these assumptions, we will show that (7.3) is a martingale.

We approximate the set $\mathcal{Z}$ using the following level crossing times. Let $0<\delta<\epsilon$ and define $\tau_0^{\delta,\epsilon}=0$:

$$\begin{aligned}\sigma_1^{\delta,\epsilon}&=\inf\{t>0:S(t)>\epsilon\},\\ \tau_k^{\delta,\epsilon}&=\inf\{t>\sigma_k^{\delta,\epsilon}:S(t)\le\delta\},\\ \sigma_{k+1}^{\delta,\epsilon}&=\inf\{t>\tau_k^{\delta,\epsilon}:S(t)>\epsilon\},\end{aligned}$$

and $\Gamma_t=\cup_{k=1}^\infty(t\wedge\sigma_k^{\delta,\epsilon},t\wedge\tau_k^{\delta,\epsilon}]$. Note that

$$Z\cap[0,t]\subset[0,\sigma_1^{\delta,\epsilon})\cup\cup_{k=1}^\infty[t\wedge\tau_k^{\delta,\epsilon},t\wedge\sigma_{k+1}^{\delta,\epsilon})\ .$$

Let $\gamma\ge0$ with $\gamma(s)=0$ for $s\le\epsilon$ and $\gamma(s)>0$ for $s>\epsilon$. Then for $k\ge1$, the optional sampling theorem implies

$$\begin{aligned}0&=E[M_\gamma(t\wedge\sigma_{k+1}^{\delta,\epsilon})-M_\gamma(t\wedge\tau_k^{\delta,\epsilon})]\\ &=E\left[\gamma(S(t\wedge\sigma_{k+1}^{\delta,\epsilon}))+\int_{(t\wedge\tau_k^{\delta,\epsilon},t\wedge\sigma_{k+1}^{\delta,\epsilon}]\times(0,\infty)}\gamma(s)\nu(du\times ds)\right].\end{aligned}\tag{7.4}$$

Since $\gamma(s)>0$ on (ϵ,∞), it follows that

$$\nu((\tau_k^{\delta,\epsilon},\sigma_{k+1}^{\delta,\epsilon}]\times(\epsilon,\infty))=0\tag{7.5}$$

a.s. for each $k\ge1$ such that $\tau_k^{\delta,\epsilon}<\infty$, and $S(\sigma_k^{\delta,\epsilon})=\epsilon$ for each $k\ge2$ such that $\sigma_k^{\delta,\epsilon}<\infty$.

Now let γ satisfy $\gamma(0)=1$, $0\le\gamma(s)<1, s>0$, and $\gamma(s)=0, s\ge\delta$. Then, since $M(t\wedge\tau_k^{\delta,\epsilon})-M(t\wedge\sigma_k^{\delta,\epsilon})$ is a martingale for each k by the optional sampling theorem, (7.2) and the monotone convergence theorem imply that

$$\begin{aligned}\sum_{k=1}^\infty(M(t\wedge\tau_k^{\delta,\epsilon})-M(t\wedge\sigma_k^{\delta,\epsilon}))&=\sum_{\tau_k^{\delta,\epsilon}\le t}\gamma(S(\tau_k^{\delta,\epsilon}))-\gamma(0)\nu(\Gamma_t\times(0,\infty))\\ &\quad+\int_{\Gamma_t\times(0,\delta)}\gamma(s)\nu(du\times ds)\end{aligned}\tag{7.6}$$

is a martingale. It follows that

$$\gamma(0)E[\nu(\Gamma_t\times(0,\infty))]=E\left[\sum_{\tau_k^{\delta,\epsilon}\le t}\gamma(S(\tau_k^{\delta,\epsilon}))+\int_{\Gamma_t\times(0,\delta)}\gamma(s)\nu(du\times ds)\right].\tag{7.7}$$

Since the left side of (7.7) depends on γ only through $\gamma(0)$, which we fix as 1, and both terms on the right side are monotone increasing in γ, it follows that $\nu(\Gamma_t\times(0,\delta))=0$ a.s. and that $S(\tau_k^{\delta,\epsilon})=0$ for each $k\ge1$ such that $\tau_k^{\delta,\epsilon}<\infty$ (otherwise changing γ would change the value of the right side). Since δ and ϵ are arbitrary, it in turn

follows that S is monotone increasing except for jumps to 0. Since $\gamma(0) = 1$, $N^\epsilon(t) = \sum_{\tau_k^{\delta,\epsilon} \le t} \gamma(S(\tau_k^{\delta,\epsilon}))$ (which does not depend on δ) simply counts the number of jumps of S from above ϵ to 0. The martingale in (7.10) can be written

$$N^\epsilon(t) - \nu(\Gamma_t \times [0,\infty)),$$

keeping in mind that Γ_t does depend on ϵ. Since

$$E[N^\epsilon(t)] = E[\nu(\Gamma_t \times [0,\infty))] \le E[\nu((0,t] \times [0,\infty))] < \infty,$$

$N(t) = \lim_{\epsilon \to 0} N^\epsilon(t)$ exists, and letting $\delta, \epsilon \to 0$, (7.5) implies that (7.6) converges to

$$N(t) - \nu((0,t] \times (0,\infty)), \tag{7.8}$$

which, consequently, is a martingale. Note that if we show that S is strictly increasing except for the jumps to zero we will have that $N(t)$ is the cardinality of $\mathcal{Z} \cap [0,t]$.

Now let $\tau_x^r = \inf\{t > r : S(t) \ge x\}$ and assume that $\gamma \ge 0$ and $\gamma(z) = 0$ for $z \le x$ and $\gamma(z) > 0$ for $z > x$. Then

$$E[I_{\{S(r)<x\}}\gamma(S(\tau_x^r \wedge t))] = -E\left[I_{\{S(r)<x\}} \int_{(r,\tau_x^r \wedge t] \times (0,\infty)} \gamma(z)\nu(du \times dz)\right], \tag{7.9}$$

and it follows that both sides must be zero so that $S(\tau_x^r) = x$, if $S(r) < x$ and $\tau_x^r < \infty$. Note that this conclusion implies that S has no upward jumps and hence is continuous except for jumps to zero. Consequently,

$$\gamma(S(t)) - \int_0^t (\gamma(0) - \gamma(S(u-)))dN(u)$$

is continuous. The fact that (7.8) is a martingale implies that

$$\int_0^t (\gamma(0) - \gamma(S(u-)))dN(u) - \int_{(0,t]\times(0,\infty)} (\gamma(0) - \gamma(S(u-)))\nu(du \times ds) \tag{7.10}$$

is a martingale, and adding (7.10) to (7.1), we see that

$$\begin{aligned} \gamma(S(t)) - \int_0^t \gamma'(S(u))du - \int (\gamma(0) - \gamma(S(u-)))dN(u) \\ + \int_{(0,t]\times(0,\infty)} (\gamma(s) - \gamma(S(u-)))\nu(du \times ds) \end{aligned} \tag{7.11}$$

is a martingale. Equation (7.9) also implies that $\nu((r, \tau_x^r] \times (x,\infty)) = 0$, and hence for $0 = r_0 < r_1 < \cdots$ and $0 = x_0 < x_1 < \cdots$, we have

$$\sum_{i,j} I_{(S(r_i-),\infty)}(x_j)\nu((r_i, \tau_{x_j}^{r_i} \wedge r_{i+1}] \times (x_j, x_{j+1}]) = 0.$$

Letting $\max_i(r_{i+1} - r_i) \to 0$ and observing that if $x_j > S(u-)$, then $\tau_{x_j}^r > u$,

$$\liminf \sum_i I_{(S(r_i-),\infty)}(x_j) I_{(r_i, \tau_{x_j}^{r_i} \wedge r_{i+1}]}(u) \ge I_{(S(u-),\infty)}(x_j),$$

and hence

$$\sum_j \int_{(0,\infty)} I_{(S(u-),\infty)}(x_j)\nu(du \times (x_j, x_{j+1}]) = 0.$$

Now letting $\max_j(x_{j+1} - x_j) \to 0$, we have

$$\lim \sum_j I_{(S(u-),\infty)}(x_j) I_{(x_j,x_{j+1}]}(s) = I_{(S(u-),\infty)}(s),$$

and hence

$$\int_{(0,\infty)\times(0,\infty)} I_{(S(u-),\infty)}(s)\nu(du \times ds) = 0. \tag{7.12}$$

Let $\tau_r = \inf\{t > r : S(t) = 0\}$, and let $\gamma(0) = 1$, $\gamma(x) < 1$ for $0 < x < a$ and $\gamma(x) = 1$ for $x \geq a$. Then

$$E\left[I_{\{S(r)\geq a\}} \int_{(r,\tau_r\wedge t]\times(0,\infty)} (1-\gamma(s))\nu(du \times ds)\right] = E[I_{\{S(r)\geq a\}}(M_\gamma(\tau_r \wedge t) - M_\gamma(r))] = 0,$$

and it follows that

$$I_{\{S(r)\geq a\}}\nu((r, \tau_r] \times (0, a)) = 0 \qquad \text{a.s.} \tag{7.13}$$

Since a is arbitrary, it follows that (7.13) holds for all rational a a.s. and hence, by taking limits, for all a a.s. Consequently, approximating as in the proof of (7.12), (7.13) implies

$$\int_{(0,\infty)\times(0,\infty)} I_{(0,S(u-))}(s)\nu(du \times ds) = 0 \tag{7.14}$$

and (7.12) and (7.14) imply that the support of ν is contained in $\{(u, S(u-)) : u > 0\}$, and hence the last term in (7.11) is zero. But that observation implies that (7.11) is a continuous martingale and hence is constant. Taking $\gamma(s) = s$ gives

$$S(t) - S(0) + \int_0^t S(u-)dN(u) = t,$$

and it follows that S increases linearly at rate 1 except for jumps to zero. □

Proof of Lemma 4.4. For $\lambda > 0$, let $Z(t) = e^{\lambda t}Q(t)$. Then for g in C^1 with g and g' bounded,

$$g(Z(t)) - \int_0^t \left((V_1(s)e^{\lambda s} + \lambda Z(s))g'(Z(s)) + V_2(s)(g(0) - g(Z(s)))\right) ds$$

is an $\{\mathcal{F}_t\}$-local martingale. For simplicity, assume that $\int_0^\infty V_1(u)du = \infty$ a.s. (If not, we can modify Q so that the integral is infinite and the conclusions of the lemma for the modified process imply the conclusions for the original.) Let $\zeta(t) = \inf\{r > \tau : \int_\tau^r (V_1(u)e^{\lambda s} + \lambda Z(s))\, du > t\}$, $\tilde{Z}(t) = Z \circ \zeta(t)$, and

$$\nu((0,t] \times (0,a]) = \int_\tau^{\zeta(t)} V_2(u) I_{(0,a]}(Z(u))du = \int_{\sigma_0^\tau}^{\zeta(t)} V_2(u) I_{(0,a]}(Z(u))du.$$

Then, by the optional sampling theorem,

$$g(\tilde{Z}(t)) - \int_0^t g'(\tilde{Z}(s))\,ds - \int_{(0,t]\times(0,\infty)} (g(0)-g(s))\nu(du\times ds) \tag{7.15}$$

is an $\{\mathcal{F}_{\zeta(t)}\}$-local martingale. By Lemma 7.1, $\tilde{Z}$ increases linearly at rate one except for jumps to zero. Consequently, for $\zeta(t) < \sigma_1^\tau$

$$Z(\zeta(t)) - Z(\zeta(0)) = \tilde{Z}(t) - \tilde{Z}(0) = t = \int_\tau^{\zeta(t)} (V_1(u)e^{\lambda s} + \lambda Z(s))\,du\,,$$

where the first equality is the definition of $\tilde{Z}$, the second is the consequence of Lemma 7.1, and the third is the definition of $\zeta(t)$. Note that if $Z(\tau) > 0$, then $\zeta(0) = \tau$, and if $Z(\tau) = 0$, then $Z(\zeta(0)) = 0$. In either case, since λ is arbitrary, it follows that $Q(t) - Q(\tau) = \int_\tau^t V_1(u)du$ for $\tau \le t < \sigma_1^\tau$ and that $\zeta(0) = \sigma_0^\tau$.

Now assume that $\sigma_1^\tau < \infty$ a.s. Let N be the counting process of jumps to zero by $\tilde{Z}$, and let

$$\Lambda(t) = \int_{\zeta(0)}^{\zeta(t)} V_2(s) I_{(0,\infty)}(Z(s))ds.$$

Then, again by Lemma 7.1,

$$N(t) - \Lambda(t) \tag{7.16}$$

is an $\{\mathcal{F}_{\zeta(t)}\}$-local martingale, and since ζ is continuous on any interval on which $\tilde{Z}$ is positive, Λ is continuous. Let τ_1 be the time of the first jump of N. Then $\zeta(\tau_1) = \sigma_1^\tau$. Note that

$$\Lambda(\tau_1) = \int_{\zeta(0)}^{\zeta(\tau_1)} V_2(s) I_{(0,\infty)}(Z(s))ds = \int_{\sigma_0^\tau}^{\sigma_1^\tau} V_2(s)ds.$$

Let $\eta(x) = \inf\{u : \Lambda(u) > x\}$, and for bounded positive f, define

$$L_f(t) = f(N(t)) \exp\left\{ - \int_0^t \frac{f(N(s)+1) - f(N(s))}{f(N(s))} d\Lambda(s) \right\}.$$

Then, by Itô's formula,

$$L_f(t) = f(0) + \int_0^t L_f(s-)d(N(s) - \Lambda(s)),$$

and hence L_f is a local martingale. In particular, it follows that

$$\begin{aligned} 1 &= E[L_f(\tau_1 \wedge \eta(x))|\mathcal{F}_{\zeta(0)}] \\ &= E[f(1)I_{\{\tau_1 < \eta(x)\}} e^{-\frac{f(1)-f(0)}{f(0)}\Lambda(\tau_1)\wedge x} |\mathcal{F}_{\zeta(0)}] + E[f(0)I_{\{\tau_1 \ge \eta(x)\}} e^x |\mathcal{F}_{\zeta(0)}]. \end{aligned}$$

Letting $f(0) = 1$ and then taking a limit as $f(1) \to 0$, we have

$$P\{\Lambda(\tau_1) \ge x|\mathcal{F}_{\sigma_0^\tau}\} = P\{\Lambda(\tau_1) \ge x|\mathcal{F}_{\zeta(0)}\} = P\{\tau_1 \ge \eta(x)\} = e^{-x}. \qquad \square$$

A CONSTRUCTION OF RATIONAL WAVELETS AND FRAMES IN HARDY–SOBOLEV SPACES WITH APPLICATIONS TO SYSTEM MODELING*

NICHOLAS F. DUDLEY WARD† AND JONATHAN R. PARTINGTON†

Abstract. Using the Daubechies wavelet theory we establish rational wavelet decompositions of the Hardy–Sobolev classes on the half-plane. The decay of wavelet coefficients is analyzed and error bounds for approximation are given. We give applications to the modeling of linear systems and to the model reduction of infinite-dimensional systems.

Key words. wavelets, frames, atomic decompositions, matching pursuits, infinite-dimensional systems, Hardy–Sobolev spaces

1. Introduction.

1.1. Notation and conventions.

$\mathbb{C}_+ = \{s = x + iy : x > 0\}$ right half-plane,
$\mathbb{I} = \{iy : y \in \mathbb{R}\}$ imaginary axis.

For f belonging to $L^2(\mathbb{R})$ the Fourier transform $\hat{f}$ is defined using the following convention:

$$\hat{f}(\xi) = \int_{-\infty}^{\infty} f(t)e^{-i\xi t}dt.$$

For g belonging to $L^2((0,\infty))$ we write $G = (\mathcal{L}g)(s)$ for the Laplace transform of g:

$$G(s) = (\mathcal{L}g)(s) = \int_0^{\infty} g(t)e^{-st}dt.$$

$H^2(\mathbb{C}_+)$ denotes the Hardy space of functions $F(s)$ analytic in the right half-plane and such that

$$\|F\|_2 = \sup_{x>0} \int_{\infty}^{\infty} |F(x+iy)|^2 dy < \infty.$$

By the Paley–Wiener theorem every $F(s)$ belonging to $H^2(\mathbb{C}_+)$ is the Laplace transform of some $f(t) \in L^2((0,\infty))$ such that $\|F\|_2 = (2\pi)^{1/2}\|f\|_2$. Upper-case letters will be used to denote the Laplace transform of the corresponding lower-case letter, e.g., $\Psi(s) = (\mathcal{L}\psi)(s)$. (For further details of Hardy spaces defined on a half-plane see [28] or [36].)

Lettered results, e.g., Theorem A, will denote a known result in the literature. Numbered results will be proved.

1.2. General background. The approximation and identification of transfer functions of stable linear time-invariant infinite-dimensional systems by those of finite-dimensional systems is an important part of modern systems theory, and there are two norms which are most commonly considered. The H^∞ norm has found applications in robust control [20], whereas the H^2 norm is the basis of linear quadratic Gaussian control. However, it is widely regarded as desirable to be able to consider both H^2 and H^∞ criteria simultaneously: see, for example, the articles of Foias, Frazho, and Tannenbaum [19] and Bernstein and Haddad [5]. One approach to this is by means of Hardy–Sobolev classes.

Hardy–Sobolev classes for the disc were considered in [15] and [2]. For the upper half-plane the Hardy–Sobolev class $H^{2,m}$, $m \in \mathbb{R}$, is defined as follows: let $H^{2,m}$, $m \in \mathbb{R}$, be the class of functions $F(s)$ analytic in the right half-plane such that $F(s) = (\mathcal{L}f)(s)$ and

$$\|F\|_{2,m} = \left(\int_0^\infty |f(t)|^2 (1+t)^{2m} dt \right)^{1/2} < \infty. \tag{1.1}$$

If $m = 0$, $H^{2,0}$ corresponds to the classical Hardy space H^2 for the half-plane, and if m is a positive integer, $F(s)$ belonging to $H^{2,m}$ is equivalent to the first m derivatives of $F(s)$ belonging to H^2. An equivalent norm can then be defined on $H^{2,m}$ by the formula

$$\|F\|_{2,m}^2 = \|F\|_2^2 + \|F'\|_2^2 + \cdots + \|F^m\|_2^2.$$

In this investigation we shall be concerned mainly with the range $|m| \leq 1$. The range $m > 1/2$ is of particular interest since for $F(s)$ belonging to $H^{2,m}$ we have $\|F\|_\infty \leq C_m \|F\|_{2,m}$, where C_m is a constant, and so approximation in the Hardy–Sobolev norm gives simultaneous approximations in both the uniform and the L^2 norms. Indeed, we can say more: since we obtain, using the Cauchy–Schwarz inequality,

$$\begin{aligned} \|f\|_{L^1} &= \int_0^\infty |f(t)|\, dt \\ &\leq \|f(t)(1+t)\|_{L^2} \|1/(1+t)\|_{L^2} \\ &= \|F\|_{2,1}, \end{aligned}$$

we obtain simultaneous approximation in the L^1 norm as well, itself important in bounded input, bounded output (BIBO) stable control theory (cf. [10]).

The approach to approximation that we shall take will involve the theory of wavelets, and we now outline this.

1.3. Wavelet classes for H^2. We give a definition of wavelet which is perhaps somewhat more geometric than is normal, and which includes the more usual analytic definition and is appropriate for both the disc and half-plane. By a lattice $\mathcal{L}$ we mean a discrete set of points in the right half-plane which is both sufficiently dense and separated with respect to the pseudohyperbolic metric: there exists $0 < \delta_1 \leq \delta_2 < 1$ such that the union of balls $B(S, \delta_2)$, $S \in \mathcal{L}$, covers $\mathbb{C}_+$ (i.e., δ_2 dense) and S, $T \in \mathcal{L}, S \neq T \Longrightarrow \rho(S,T) > \delta_1$ (i.e., δ_1 separated), where

$$\rho(S,T) = \left| \frac{S-T}{S+\overline{T}} \right|.$$

(See [42] for details.)

In effect, to say that a set is separated in the above sense amounts to the fact that the ratio of the distance between neighboring points in the right half-plane to the distance from the imaginary axis is approximately constant. In this paper we are interested in lattices of the following form:

$$\mathcal{L} = \left\{ S_{j,k} : S_{j,k} = \frac{1}{2^j} + i\frac{k}{2^j} b_0; j, k \in \mathbb{Z} \right\},$$

where b_0 is some fixed positive constant. Clearly, $\mathcal{L}$ is separated and $C_1 \operatorname{dist}(S_{j,k}, \mathbb{I}) \leq \operatorname{dist}(S_{j,k}, S_{j',k'}) \leq C_2 \operatorname{dist}(S_{j,k}, \mathbb{I})$. Associated with a given lattice $\mathcal{L}$ will be a wavelet class $\mathcal{W} = \{F_W : W \in \mathcal{L}\}$. Notice that any point in $\mathcal{L}$ can be transformed onto another by a dilation followed by a translation. We construct $\mathcal{W}$ so that each F_W is obtained from some fixed *mother wavelet* $\Psi(y) \in H^2$ in a similar fashion. Thus $\mathcal{W}$ actually consists of the system of functions $\Psi_{j,k}(y) = 2^{j/2}\Psi(2^j y - kb_0)$ where we have normalized them in L^2.

In this investigation we are interested in wavelet classes for H^2 with mother wavelets of the form $\Psi(y) = (1 + iy)^p$, where p is a fixed positive integer. Suppose that $W = X + iY = 2^{-j} + ikb_0 2^{-j} \in \mathcal{L}$. Then the corresponding function $\Psi_{j,k}$ can be written

$$\begin{aligned} \Psi_W(y) &= \frac{X^{-1/2}}{(1 + i(y - Y)/X)^p} \\ &= \frac{X^{p-1/2}}{((X - iY) + iy)^p} \\ &= \frac{X^{p-1/2}}{(iy + \overline{W})^p}. \end{aligned}$$

For $p = 1$ Ψ_W is just the normalized Cauchy kernel with pole at $-\overline{W}$, and for $p = 2$ Ψ_W is the Bergman kernel evaluated on the imaginary axis. From the practical point of view the usefulness of the wavelet classes just given is based on the observation that one has a system of rational functions whose poles cluster on the left of the imaginary axis. Much of the present investigation centers about the general problem of obtaining decompositions by using wavelets as elementary building blocks in a sense which will be made precise below.

Using a fundamental result of Daubechies we obtain decompositions of H^2 where the mother wavelets consist of powers of the Cauchy kernel for the right half-plane. Consider for a moment the space $H^{2,1}$ of the disc. It is easy to see that $f(z) = \sum_{n=0}^{\infty} a_n z^n \in H^{2,1}$ is equivalent to $\|f\|_{2,1}^2 = \sum_{n=0}^{\infty}(1 + n^2)|a_n|^2 < \infty$. That is, one can determine whether a function $f(z)$ in H^2 also has L^2 bounded derivative by examining decay of the Taylor coefficients $a_n = \langle f, z^n \rangle$. We obtain similar conditions for $H^{2,1}(\mathbb{C}_+)$ where the building blocks are replaced by a nonorthogonal system of rational wavelets. We also consider in section 6 the half-plane algebra $A(\mathbb{C}_+)$ for the right half-plane and use a result of Hayman and Lyons to show that suitable sets of Cauchy kernels are fundamental for $A(\mathbb{C}_+)$. In section 7 we consider error estimates, and in section 8 we deduce algorithms which may be applied to the model reduction of a system.

The following results will be established.

THEOREM 1.1. *Let $\Psi(y) = (1 + iy)^{-3}$, let $\Psi_{j,k}(y) = 2^{j/2}\Psi(2^j y - b_0 k)$ where $j, k \in \mathbb{Z}$, $b_0 > 0$, and let $\langle \cdot, \cdot \rangle$ be the usual L^2-inner product.*

If $b_0 > 0$ is sufficiently small, then for each m with $-1 \leq m \leq 1$ there exist positive constants A_m and B_m such that for $F(s) \in H^{2,m}$ the wavelet coefficients

$\langle F, \Psi_{j,k}\rangle$ satisfy the following pair of inequalities:

$$A_m\|F\|_{2,m}^2 \le \sum_{j,k} |\langle F, \Psi_{j,k}\rangle|^2 (1+2^j)^{2m} \le B_m\|F\|_{2,m}^2. \tag{1.2}$$

Our next result is an atomic decomposition of $H^{2,m}$. Let $\ell^2((1+2^{2j})^m)$ denote the weighted ℓ^2-space

$$\ell^2((1+2^j)^{2m}) = \left\{\boldsymbol{\lambda} = (\lambda_{j,k}) : \|\boldsymbol{\lambda}\|_{2,m}^2 = \sum |\lambda_{j,k}|^2 (1+2^j)^{2m} < \infty\right\}.$$

A sequence $\Psi_{j,k}$ in $H^{2,m}$ will be called a *set of atoms (with respect to* $\ell^2((1+2^j)^{2m})$*)* for $H^{2,m}$ if the mapping $S : \ell^2((1+2^j)^{2m}) \to H^{2,m}$ defined by

$$S : \boldsymbol{\lambda} \mapsto \sum_{j,k} \lambda_{j,k}\Psi_{j,k}$$

is a surjection. Let $\Psi_{j,k} = 2^{j/2}\Psi(2^j y - b_0 k)$ where $\Psi(t) = (1+iy)^{-3}$.

THEOREM 1.2. *The system $(\Psi_{j,k})$, $j,k \in \mathbb{Z}$, is a set of atoms for $H^{2,m}$ for sufficiently small b_0 in the sense defined above. Furthermore, for each F belonging to $H^{2,m}$ we have the inequalities*

$$\frac{1}{B_{-m}}\|F\|_{2,m}^2 \le \inf\left\{\|(\lambda_{j,k})\|_{2,m}^2 : F = \sum_{j,k}\lambda_{j,k}\Psi_{j,k}\right\} \le \frac{1}{A_{-m}}\|F\|_{2,m}^2. \tag{1.3}$$

THEOREM 1.3. *Let T be the operator defined on $H^{2,m}$, where $m = 1$ or $m = -1$ by the formula*

$$TF = \sum \langle F, \Psi_{j,k}\rangle \Psi_{j,k}, \quad F \in H^{2,m}.$$

Then, for sufficiently small b_0, T is a bounded map $H^{2,m} \to H^{2,m}$. Furthermore, T is a surjection and invertible.

Finally, we have the following frame decomposition of $H^{2,m}$ for both $m = 1$ and $m = -1$.

COROLLARY 1.4. *Every $F \in H^{2,m}$, $m = \pm 1$, has the wavelet series representation*

$$F = TT^{-1}F = \sum_{j,k} \left\langle T^{-1}F, \Psi_{j,k}\right\rangle \Psi_{j,k}.$$

We shall prove Theorem 1.1 for the cases $m = \pm 1$ in section 3, and for the general case at the end of section 5. Theorems 1.2 and 1.3 will be proved in sections 4 and 5, respectively. We also obtain estimates for the various constants for a range of b_0 which appear in the given results by means of computer, and for these we refer to the tables.

2. Frames and wavelet decompositions of H^2.

2.1. Brief exposition of the theory of frames. Frames were introduced by Duffin and Schaeffer in [17] in the context of nonharmonic Fourier series, and give a technique for expanding vectors in a Hilbert space by means of systems of non-orthogonal vectors.

We give below a brief exposition of the theory of frames. For further details and fuller proofs we refer to [17], [13], and [34]. Let H be a Hilbert space with inner

product $\langle \cdot, \cdot \rangle$. A system (ϕ_j) of vectors in H will be called a *frame* for H if there exist positive constants A and B so that the following pair of inequalities obtain:

$$A\|f\|^2 \leq \sum_j |\langle f, \phi_j \rangle|^2 \leq B\|f\|^2, \quad f \in H. \tag{2.1}$$

We define the operator T on H by means of the formula

$$Tf = \sum_j \langle f, \phi_j \rangle \phi_j, \quad f \in H.$$

From (2.1) it follows that T is a positive operator on H such that $\langle Tf, f \rangle \geq A\|f\|^2$. Next one can establish that T is a surjection and is invertible by means of the following piggyback closed range theorem.

LEMMA A. *If U is a positive operator on H such that $\langle Uf, f \rangle \geq \alpha\|f\|^2$ for all $f \in H$ then U is invertible on H and its inverse U^{-1} satisfies $\|U^{-1}\| \leq 1/\alpha$.*

Proof. We first note that range(U) is a closed subspace of H. Let f_n be a Cauchy sequence in range(U). Then $f_n = U(g_n)$, and by hypothesis,

$$\|g_n - g_m\|^2 \leq \alpha^{-1} \langle U(g_n - g_m), g_n - g_m \rangle \leq \alpha^{-1} \|U(g_n - g_m)\| \cdot \|g_n - g_m\|.$$

Thus g_n is also a Cauchy sequence in H with limit g. It follows from the continuity of U that U has closed range.

Next we show that range(U) is dense in H: if $g \in H$ is such that $\langle Uf, g \rangle = 0$ for all $f \in H$, it follows in particular that $\langle Ug, g \rangle = 0$. We have $\alpha\|g\|^2 \leq \langle Ug, g \rangle$, and hence we deduce that $g = 0$. Hence, by the first part, range$(U) = H$.

Finally, since any $f \in H$ can be written as $f = Ug$ we may define $U^{-1}f = g$ and

$$\alpha\|U^{-1}f\|^2 \leq \langle UU^{-1}f, U^{-1}f \rangle = \langle f, U^{-1}f \rangle \leq \|f\| \cdot \|U^{-1}f\|,$$

whence $\|U^{-1}f\| \leq \alpha^{-1}\|f\|$. This completes the proof. □

In fact, one can show using (2.1) that $I - 2(A + B)^{-1}T$ is a contraction and so compute T^{-1} by a Neumann series: suppose that $f \in H$, and define a *residual vector* $R(f)$ by the equation

$$R(f) = f - \frac{2}{A + B} \sum_j \langle f, \phi_j \rangle \phi_j.$$

Then $-\frac{B-A}{B+A} I \leq R \leq \frac{B-A}{B+A} I$, and so, since R is symmetric, $\|R\| \leq \frac{B-A}{B+A}$. If B is close to A we obtain a good reconstruction of f. Otherwise we can write down an algorithm, viz., a Neumann series for the reconstruction of f with exponential convergence. (See [13] for details.)

Since T^{-1} is symmetric it follows that $\langle T^{-1}f, \phi_j \rangle = \langle f, T^{-1}\phi_j \rangle$ and so $f \in H$ has the expansions

$$f = TT^{-1}f = \sum \langle T^{-1}f, \phi_j \rangle \phi_j = \sum \langle f, T^{-1}\phi_j \rangle \phi_j.$$

The system defined by $\tilde{\phi}_j = T^{-1}\phi_j$ is called the *dual frame* associated with ϕ_j. It can also be shown that $\tilde{\phi}_j$ is itself a frame.

2.2. Fundamental theorem of Daubechies. Given a function $\Psi \in L^2(\mathbb{R})$, and $a_0 > 1$ and $b_0 > 0$, we define the system of functions

$$\Psi_{j,k}(t) = {a_0}^{j/2}\Psi(a_0^j t - kb_0), \quad j,k \in \mathbb{Z}. \tag{2.2}$$

We ask for conditions on Ψ and b_0 such that the system given by (2.2) is a frame for $L^2(\mathbb{R})$. That is, there exist positive constants A, B such that

$$A\|f\|_2^2 \le \sum_{j,k} |\langle f, \Psi_{j,k}\rangle|^2 \le B\|f\|_2^2, \quad f \in L^2(\mathbb{R}).$$

Daubechies [12], [13], proves the following fundamental result.

THEOREM B. *Suppose that $\Psi \in L^2(\mathbb{R})$ and $a_0 > 1$ are such that*

$$\inf_{1\le|\xi|\le a_0} \sum_{-\infty}^{\infty} |\hat\Psi(a_0^j\xi)|^2 > 0,$$

$$\sup_{1\le|\xi|\le a_0} \sum_{-\infty}^{\infty} |\hat\Psi(a_0^j\xi)|^2 < \infty,$$

and if $\beta(s) = \sup_{1\le|\xi|\le a_0} \sum |\hat\Psi(a_0^j\xi)||\hat\Psi(a_0^j\xi+s)|$ decays at least as fast as $(1+|s|)^{-(1+\epsilon)}$ with $\epsilon > 0$, then there exists a $\tilde b_0 > 0$ such that the $\Psi_{j,k}$ constitute a frame for all $b_0 < \tilde b_0$. For such b_0 the following equalities are frame bounds for the $\Psi_{j,k}$:

$$A = \frac{2\pi}{b_0}\left\{\inf_{1\le|\xi|\le a_0} \sum_{-\infty}^{\infty} |\hat\Psi(a_0^j\xi)|^2 - \sum_{\substack{k=-\infty\\k\ne0}}^{\infty} \left[\beta\left(\frac{2\pi}{b_0}k\right)\beta\left(\frac{-2\pi}{b_0}k\right)\right]^{1/2}\right\},$$

$$B = \frac{2\pi}{b_0}\left\{\sup_{1\le|\xi|\le a_0} \sum_{-\infty}^{\infty} |\hat\Psi(a_0^j\xi)|^2 + \sum_{\substack{k=-\infty\\k\ne0}}^{\infty} \left[\beta\left(\frac{2\pi}{b_0}k\right)\beta\left(\frac{-2\pi}{b_0}k\right)\right]^{1/2}\right\}.$$

Since the Fourier transforms of H^2 functions of the lower half-plane are functions in $L^2(\mathbb{R})$ supported on the positive real axis, we may apply Theorem B to $H^2(\mathbb{P})$ where $\mathbb{P} = \{x + iy : y < 0\}$. By rotating, we see that Theorem B is applicable to establishing frames for $H^2(\mathbb{C}_+)$. In particular, it is routine to check that the estimates given in the hypotheses of Theorem B are satisfied by mother wavelets of the form $\Psi(y) = (1 + iy)^{-p}$ where p is a positive integer not less than 2 (since $\Psi(y)$ is the Laplace transform of $\psi(t) = t^{p-1}e^{-t}/(p-1)!$, $t > 0$).

In the main we will be interested in the system $\Psi_{j,k}(y) = 2^{j/2}\Psi(2^j y - b_0 k)$ where Ψ is the mother wavelet $\Psi(y) = (1+iy)^{-3}$. However, in order to establish our results, we also consider some auxiliary systems of wavelets—in particular, ones generated by $\Phi(y) = (1 + iy)^{-2}$. With $a_0 = 2$ and a given mother wavelet Ψ, one can then easily establish by means of a computer a range of b_0 for which the corresponding system $\Psi_{j,k}(y)$ is a frame for H^2. See Tables 2.1 and 2.2 for the wavelets $\Psi(y) = (1 + iy)^{-3}$ and $\Phi(y) = (1 + iy)^{-2}$.

3. Proof of Theorem 1.1 for $m = \pm 1$.

3	0.118	1.392	11.777

3.1. Proof of Theorem 1.1: $m = 1$. The proof of Theorem 1.1 for $m = 1$ follows from the considerations of the previous section. Since $\Psi_{j,k}(y)$ is a frame for H^2 it follows that for F belonging to H^2,

$$A_\Psi \|F\|_2^2 \le \sum_{j,k} |\langle F, \Psi_{j,k}\rangle|^2 \le B_\Psi \|F\|_2^2. \tag{3.1}$$

If, in addition, F' also belongs to H^2 (so that $F \in H^{2,1}$) then since $\Phi_{j,k}(y)$ with $\Phi(y) = 2(1+iy)^{-2}$ is also a frame for H^2 we have

$$A_\Phi \|F'\|_2^2 \le \sum_{j,k} |\langle F', \Phi_{j,k}\rangle|^2 \le B_\Phi \|F'\|_2^2. \tag{3.2}$$

Up to a constant, Ψ is attained from Φ by differentiation with respect to y. Therefore we may integrate by parts and obtain

$$\begin{aligned}\langle F', \Phi_{j,k}\rangle &= \int_{-\infty}^{\infty} F'(it)\overline{\Phi}_{j,k}(t)dt \\ &= 2^j \int_{-\infty}^{\infty} F(it)\overline{\Psi}_{j,k}(t)dt \\ &= 2^j \langle F, \Psi_{j,k}\rangle .\end{aligned}$$

Therefore, (3.2) may be replaced by

$$A_\phi \|F'\|_2^2 \le \sum_{j,k} |\langle F, \Psi_{j,k}\rangle|^2 2^{2j} \le B_\phi \|F'\|_2^2. \tag{3.3}$$

Adding (3.1) and (3.3) and noting that

$$\frac{1}{2}(1+x)^2 \le (1+x^2) \le (1+x)^2,$$

we obtain the conclusion of Theorem 1.1 with $A_1 = 1/4 \min\{A_\Psi, A_\phi\}$ and $B_1 = \max\{B_\Psi, B_\phi\}$.

Remark. One could prove Theorem 1.1 directly using the same technique as the proof of Theorem 3.1 below. However, the proof given has the merit of being elementary, although it will not give the best estimates for A_1 and B_1.

3.2. Proof of Theorem 1.1: $m = -1$. We wish to establish the existence of positive constants A_{-1} and B_{-1} such that for $G = \mathcal{L}g$ belonging to $H^{2,-1}$, the following inequalities obtain:

$$A_{-1}\|G\|_{2,-1}^2 \le \sum_{j,k} |\langle G, \Psi_{j,k}\rangle|^2 (1+2^j)^{-2m} \le B_{-1}\|G\|_{2,-1}^2.$$

Since $G = \mathcal{L}(g) \in H^{2,-1}$ it follows that $\tilde{g}(t) = g(t)(1+t)^{-1} \in L^2((0,\infty))$. If $\Phi_{j,k} = \mathcal{L}(\phi_{j,k})$ is a frame for H^2 there exist constants A_ϕ, B_ϕ such that

$$A_\phi\|\tilde{g}\|_2^2 \le \sum_{j,k} |\langle \tilde{g}, \phi_{j,k}\rangle|^2 \le B_\phi\|\tilde{g}\|_2^2,$$

i.e.,

$$A_\phi\|g\|_{2,-1}^2 \le \sum_{j,k} |\langle \tilde{g}, \phi_{j,k}\rangle|^2 \le B_\phi\|g\|_{2,-1}^2.$$

Now

$$\langle \tilde{g}, \phi_{j,k}\rangle = \left\langle g, (1+t)^{-1}\phi_{j,k}\right\rangle.$$

We would like to choose a frame $\Phi_{j,k}$ for H^2 so that

$$\phi_{j,k} = (1+t)(1+2^j)^{-1}\psi_{j,k},$$

where Ψ is the mother wavelet $\Psi(y) = \mathcal{L}(t^2e^{-t}/2) = (1+iy)^{-3}$, $\Psi_{j,k} = 2^{j/2}\Psi(2^j y - b_0 k)$, and $\Psi_{j,k} = \mathcal{L}(2^{-j/2}(2^{-j}t)^2 e^{-2^{-j}(t-ib_0k)})$.

Our next result is an analogue of Theorem B.

THEOREM 3.1. *Suppose that $\Psi(y) \in H^2(\mathbb{C}_+)$ and that $\Psi_{j,k}(y) = 2^{j/2}\Psi(2^j y - kb_0)$, $j,k \in \mathbb{Z}$. Define the system $\Phi_{j,k}$ by $\phi_{j,k}(t) = (1+t)(1+2^j)^{-1}\psi_{j,k}(t)$. Suppose further that*

$$\inf_{0<t<\infty}(1+t)^2\sum_{-\infty}^{\infty}(1+2^j)^{-2}|\psi(2^{-j}t)|^2 > 0,$$

$$\sup_{0<t<\infty}(1+t)^2\sum_{-\infty}^{\infty}(1+2^j)^{-2}|\psi(2^{-j}t)|^2 < \infty,$$

and if $\gamma(s) = \sup_{0<t<\infty}(1+t)^2\sum(1+2^j)^{-2}|\psi(2^{-j}t)||\psi(2^{-j}t+s)|$ decays at least as fast as $(1+|s|)^{-(1+\epsilon)}$ with $\epsilon > 0$, then there exists a $\tilde{b}_0 > 0$ such that the $\Phi_{j,k}$ constitute a frame for H^2 for all $b_0 < \tilde{b}_0$. For such b_0 the following equalities are frame bounds for the $\Phi_{j,k}$:

$$A_{-1} = \frac{2\pi}{b_0}\left\{\inf_{0<t<\infty}(1+t)^2\sum_{-\infty}^{\infty}(1+2^j)^{-2}|\psi(2^{-j}t)|^2 - \sum_{\substack{k=-\infty\\k\neq 0}}^{\infty}\left[\gamma\left(\frac{2\pi}{b_0}k\right)\gamma\left(\frac{-2\pi}{b_0}k\right)\right]^{1/2}\right\},$$

$$B_{-1} = \frac{2\pi}{b_0}\left\{\sup_{0<t<\infty}(1+t)^2\sum_{-\infty}^{\infty}(1+2^j)^{-2}|\psi(2^{-j}t)|^2 + \sum_{\substack{k=-\infty\\k\neq 0}}^{\infty}\left[\gamma\left(\frac{2\pi}{b_0}k\right)\gamma\left(\frac{-2\pi}{b_0}k\right)\right]^{1/2}\right\}.$$

Suppose that $G = \mathcal{L}g \in H^2$. We proceed to analyze $\sum_{j,k} |\langle g, \phi_{j,k}\rangle|^2$ using the method of Daubechies:

$$\begin{aligned}
\sum_{j,k} |\langle g, \phi_{j,k}\rangle|^2 &= \sum_{j,k} \int_0^\infty g(t)\overline{\phi_{j,k}}(t)dt \int_0^\infty \overline{g}(t')\phi_{j,k}(t')dt' \\
&= \sum_{j,k} (1+2^j)^{-2} \int_0^\infty g(t)(1+t)\overline{\psi_{j,k}}(t)dt \\
&\qquad \times \int_0^\infty \overline{g}(t')(1+t')\psi_{j,k}(t')dt' \\
&= \sum_{j,k} (1+2^j)^{-2} 2^{-j} \int_0^\infty g(t)(1+t)\overline{\psi}(2^{-j}t)e^{-i2^{-j}b_0kt}dt \\
&\qquad \times \int_0^\infty \overline{g}(t')(1+t')\psi(2^{-j}t')e^{i2^{-j}b_0kt'}dt' \\
&= \frac{2\pi}{b_0} \sum_{j,k} (1+2^j)^{-2} \int_0^\infty \int_0^\infty g(t)\overline{g}(t')(1+t)\overline{\psi}(2^{-j}t)(1+t')\psi(2^{-j}t') \\
&\qquad \times \delta(t'-t-2\pi k 2^j b_0^{-1})\,dt\,dt' \\
&= \frac{2\pi}{b_0} \sum_{j,k} (1+2^j)^{-2} \int_0^\infty g(t)\overline{g}(t-2\pi 2^j b_0^{-1}k)(1+t)\overline{\psi}(2^{-j}t) \\
&\qquad \times (1+t-2\pi k 2^j b_0^{-1})\psi(2^{-j}t-2\pi k b_0^{-1})dt \\
&= \frac{2\pi}{b_0} \sum_{j} (1+2^j)^{-2} \int_0^\infty |g(t)|^2(1+t)^2|\psi(2^{-j}t)|^2dt + \mathrm{rest}(g),
\end{aligned}$$

where in the fourth line we have used the Poisson summation formula $\sum_{l\in\mathbb{Z}} \exp(ilax) = 2\pi a^{-1}\sum_{k\in\mathbb{Z}} \delta(x - 2\pi k a^{-1})$. This is justified by supposing first that g is smooth and has compact support and then proceeding by a standard density argument. If

$$\begin{aligned}
m &= \inf_{0<t<\infty} (1+t)^2 \sum_{-\infty}^{\infty} (1+2^j)^{-2}|\psi(2^{-j}t)|^2, \\
M &= \sup_{0<t<\infty} (1+t)^2 \sum_{-\infty}^{\infty} (1+2^j)^{-2}|\psi(2^{-j}t)|^2
\end{aligned}$$

we have

$$m\|g\|_2^2 \le \sum_j (1+2^j)^{-2} \int_0^\infty |g(t)|^2(1+t)^2|\psi(2^{-j}t)|^2dt \le M\|g\|_2^2. \tag{3.4}$$

3.3. Analysis of rest(g). We have

$$\begin{aligned}
\mathrm{rest}(g) = \frac{2\pi}{b_0} \sum_j \sum_{k\neq 0} (1+2^j)^{-2} \int_0^\infty g(t)\overline{g}(t-2\pi k 2^j b_0^{-1})(1+t)\overline{\psi}(2^{-j}t) \\
\times(1+t-2\pi k 2^j b_0^{-1})\psi(2^{-j}t-2\pi k b_0^{-1})dt.
\end{aligned}$$

TABLE 3.1
Estimates of A_{-1} and B_{-1} in Theorem 1.1.

b_0	A_{-1}	B_{-1}
0.25	13.699	65.524
0.5	6.797	32.814
1.0	0.775	19.031
1.1	−0.324	18.330

By the Cauchy–Schwarz inequality for integrals we have

$$|\operatorname{rest}(g)| \le \frac{2\pi}{b_0}\sum_j\sum_{k\neq 0}(1+2^j)^{-2}\left\{\int_0^\infty |g(t)|^2(1+t)^2|\psi(2^{-j}t)||\psi(2^{-j}t-2\pi kb_0^{-1})|dt\right\}^{1/2}$$
$$\times\left\{\int_0^\infty |g(t-2\pi k2^jb_0^{-1})|^2(1+t-2\pi k2^jb_0^{-1})^2|\psi(2^{-j}t)||\psi(2^{-j}t-2\pi kb_0^{-1})|dt\right\}^{1/2}.$$

We make the substitution $t-2\pi k2^jb_0^{-1}\mapsto t$ in the second integral and deduce that

$$|\operatorname{rest}(g)| \le \frac{2\pi}{b_0}\sum_j\sum_{k\neq 0}(1+2^j)^{-2}\left\{\int_0^\infty |g(t)|^2(1+t)^2|\psi(2^{-j}t)||\psi(2^{-j}t-2\pi kb_0^{-1})|dt\right\}^{1/2}$$
$$\times\left\{\int_0^\infty |g(t)|^2(1+t)^2|\psi(2^{-j}t)||\psi(2^{-j}t+2\pi kb_0^{-1})|dt\right\}^{1/2}.$$

Next we apply the Cauchy–Schwarz inequality for sums to the sum indexed by j and obtain

$$|\operatorname{rest}(g)| \le \frac{2\pi}{b_0}\sum_{k\neq 0}\left\{\sum_j(1+2^j)^{-2}\int_0^\infty |g(t)|^2(1+t)^2|\psi(2^{-j}t)||\psi(2^{-j}t-2\pi kb_0^{-1})|dt\right\}^{1/2}$$
$$\times\left\{\sum_j(1+2^j)^{-2}\int_0^\infty |g(t)|^2(1+t)^2|\psi(2^{-j}t)||\psi(2^{-j}t+2\pi kb_0^{-1})|dt\right\}^{1/2}.$$

Therefore, if we write

$$\gamma(s)=\sup_{0<t<\infty}(1+t)^2\sum_j(1+2^j)^{-2}|\psi(2^{-j}t)||\psi(2^{-j}t+s)|,$$

we obtain

$$|\operatorname{rest}(g)| \le \frac{2\pi}{b_0}\sum_{\substack{k=-\infty\\k\neq 0}}^{\infty}\left[\gamma\left(\frac{2\pi}{b_0}k\right)\gamma\left(\frac{-2\pi}{b_0}k\right)\right]^{1/2}. \tag{3.5}$$

Combining (3.4) with (3.5), we obtain the conclusion of Theorem 3.1.

We apply Theorem 3.1 to the considerations above with $\Psi(y)=(1+iy)^{-3}$. Since $\psi(t)=2^{-1}t^2e^{-t}$ it is easy to see that the hypotheses of the theorem are satisfied. We refer to Table 3.1 for estimates of frame bounds for different b_0. This completes the proof of Theorem 1.1 in the case $m=-1$.

4. Proof of Theorem 1.2. Although $H^{2,m}$ is a Hilbert space and so, by the Riesz–Fréchet theorem, is its own dual, we identify $(H^{2,m})^*$ with $H^{2,-m}$ by means of the following pairing:

$$\langle F, G\rangle = \int F\overline{G}, \quad F \in H^{2,m}, \quad G \in H^{2,-m}.$$

In fact, the map $M_{(1+t)^{2m}} : H^{2,m} \to H^{2,-m}$, $F(s) \mapsto (\mathcal{L}f(t)(1+t)^{2m})(s)$ is an isometric isomorphism. (For further details, see [21].) Note also that $|\langle F, G\rangle| \le \|F\|_{2,m}\|G\|_{2,-m}$ and that $\sup\{|\langle F, G\rangle| : \|G\|_{2,-m} = 1\} = \|F\|_{2,m}$.

4.1. Atomic decompositions of $H^{2,m}$. A useful tool for establishing atomic decompositions for a Banach space is Banach's closed range theorem, which we state below for the convenience of the reader. We refer to the articles of Bonsall [6], [7] (see also [14]) and the references contained therein for further information.

For a subset E of a normed space X let $E^\perp = \{\phi \in X^* : \phi(x) = 0 \quad \text{for} \quad x \in X\}$; for a subset F of X^* let $F_\perp = \{x \in X : \phi(x) = 0 \quad \text{for} \quad \phi \in X^*\}$.

THEOREM C (Banach's closed range theorem). *Let T be a bounded linear mapping of a Banach space X into a Banach space Y.*

(i) *If T^*Y^* is closed in X^*, then TX is closed in Y and $TX = (\ker T^*)_\perp$.*

(ii) *If TX is closed in Y, then T^*Y^* is closed in X^* and $T^*Y^* = (\ker T)^\perp$.*
